We have analyzed baroreceptor inputs onto single nucleus tractus solitarius (NTS) neurons (n=71) which responded with short (<5 ms) and consistent (<±0.5 ms) latency evoked action potentials to ipsilateral aortic nerve stimulation (3-15 V, 0.1 ms, 1 Hz) in anesthetized, paralyzed, artificially ventilated rats. The vast majority of these neurons (61/71) also received a synaptic input following ipsilateral vagus nerve stimulation. Ten of these neurons were analyzed for cardiac phase-related and tracheal pressure-related activity, interspike interval distribution, power spectra of action potential times, and activity during induced pressor responses (phenylephrine, 0.5-3.0 mg i.v.). It was found that 9/10 neurons showed clear peaks in their R-wave triggered histograms (PRWTHs), while 4/6 showed clear peaks in their tracheal pressure triggered histograms. Furthermore, 3/9 neurons revealed novel peaks in their PRWTHs during elevated arterial pressures which were not present at resting pressures. These results suggest that individual baroreceptors, once they reach threshold, may directly shape cardiac phase-related activity in NTS neurons at the first stage of afferent signal processing. These results also imply that at least some NTS neurons are active in controlling both cardiovascular and respiratory function, as indicated by pulmonary afferent influence on barosensitive NTS neuronal activity patterns.

IMPORTANCE OF THE VENTROLATERAL MEDULLA FOR THE CENTRAL CARDIOVASCULAR EFFECTS OF ENDOTHELIN. R. Mosqueda-Garcia*, K. Yates, M. Appalsamy, T. Inagami. Departments of Medicine and Biochemistry, Vanderbilt University, Nashville, TN 37232.

Intracisternal administration of endothelin 1 (ET-1) evokes a hypotensive and bradycardic phase that is followed by hypertension. With increasing doses there is a subsequent impairment of respiratory function that results in cardio-respiratory collapse and death. In the present studies we investigated whether the effects of intracisternal ET-1 are mediated by neuronal cell groups within the ventrolateral medulla oblongata. An intracisternal catheter was placed in urethane anesthetized rats for ET-1 administration. The animals were placed in groups that received bilateral microinjections of saline (group 1, 60 nl, n=4) or the ET-receptor antagonist, BQ-123 (2 pmol/per site, group 2, n=4) in both the rostral (RVLM) and caudal (CVLM) ventrolateral medulla. Two other groups of rats received microinjections of BQ-123 in either the RVLM (group 3, n=6) or into the CVLM (group 4, n=4).

In group 1, the intracisternal administration of ET-1 (20 pmol) decreased mean BP from 90±7 to 71±5 mmHg and HR from 373±14 to 335±23 bpm within 5 min. This phase was followed by sustained hypertension (+50±15 mmHg) and bradycardia. Mortality was 25%, 75% and 100% at 5, 10, and 15 min after ET-1 injection. In group 2, pretreatment with BQ-123 completely inhibited the hypotensive phase and reduced by 83% the subsequent rise in BP evoked by ET. Importantly, cardio-respiratory arrest was prevented in all the animals in this group. In group 3, the initial ET-1-hypotensive phase was left intact, the hypertensive period was attenuated by 39%, with an overall mortality of 67%. Bilateral microinjection of BQ-123 into the CVLM did not prevent the hypertensive phase and cardiorespiratory arrest was present in 75% of the animals in this group. These results suggest that the ventrolateral medulla is an important site for the mediation of effects of circulating CSF-ET. (Supported in part by the Smokeless Tobacco Research Council)

EXCITATION OF SYMPATHOEXCITATORY RETICULOSPINAL NEURONS OF ROSTRAL MEDULLA BY HYPOXIA OR CYANIDE IS DIRECT AND NOT MEDIATED BY ACTIVATION OF NITRIC OXIDE SYNTHASE OR PROTEIN KINASE C NOR BY GLUTAMATE. M.-K. Sun* and D.J. Reis. Div. of Neurobiol., Cornell Univ. Med. Coll., New York, NY 10021.

In rats, sympathoexcitatory reticulospinal neurons of the rostral ventrolateral medulla (RVL) are rapidly and reversibly excited by hypoxia and by locally applied cyanide *in vivo* and *in vitro* (Sun *et al.*, *Am. J. Physiol.* 262:R182-R189, 1992; Sun and Reis, *Soc. Neurosci. Abstr.* 18:1269, 1992), resulting from a rapid activation of membrane calcium channel conductance. We investigated whether excitation of these RVL neurons by hypoxia or cyanide could be due to a rapid activation of nitric oxide synthase (NOS), protein kinase C (PKC), and/or release of L-glutamate via a calcium-independent mechanism. *In vivo*, in anesthetized chemo-denervated rats, the rapid increase in sympathetic nerve activity (by 120%) elicited by hypoxia (PaO₂: 27 mmHg) was not attenuated by intracisternal administration of the specific NOS inhibitor N^G-nitro-L-arginine (NO₂-Arg, 2 μmol), the broad spectrum excitatory amino acid receptor antagonist kynurenatate (2 μmol), or 1-(5-isoquinolinesulphonyl)-2-methyl-piperazine (H-7, 1 μmol), a specific inhibitor of protein kinase C. *In vitro*, cyanide (300 μM, 40 s) applied to RVL pacemaker neurons recorded in slices under voltage-clamp (V_h=-70 mV) and in the presence of tetrodotoxin (10 μM) evoked a rapid inward current (peak: 0.5-0.6 nA), which was not attenuated by NO₂-Arg (500 μM), kynurenatate (500 μM), or H-7 (100 μM). We conclude (a) the rapid excitation of RVL sympathoexcitatory neurons by hypoxia or cyanide cannot be attributed to generation of nitric oxide, activation of PKC, or release of excitatory amino acids; (b) hypoxia excites RVL sympathoexcitatory neurons directly and non-synaptically; (c) sympathoexcitatory neurons of RVL may be central oxygen detectors.

KYNURENATE ATTENUATES VAGUS NERVE (VN) AND CAROTID SINUS NERVE (CSN) EVOKED DISCHARGE IN NTS NEURONS. S.W. Mifflin and W. Zhang. Spon: R.D. Huffman*. Dept. of Pharmacology, University of Texas Health Science Center, San Antonio, TX. 78284

Microinjection studies have shown that excitatory amino acid receptors (EAAs) within NTS play an important role in arterial baro- and chemo-reflexes. To examine the role of EAAs at the single cell level, the effects of iontophoretic application of kynurenatate (KYN) on VN and CSN evoked discharge of NTS neurons were examined in pentobarbital anesthetized rats. Barrels of a multi-barrelled pipette were filled with: KYN (100mM, pH 8.1); xanthurenatate (XAN, 100mM, pH 8.1); glutamate (20mM, pH 8.6), substance P (1.5 mM, pH 4.5); 4M NaCl (current balancing); 2% Chicago Sky Blue for marking recording sites. A single electrode, filled with 2M NaCl and used for extracellular recording of VN (n=7) or CSN (n=5) evoked discharge, was positioned so that its tip extended 20-30μm beyond the tip of the multi-barrelled electrode and glued in place. Discharge evoked by 25 stimuli was compared under control conditions, during iontophoresis of either KYN or XAN, and following cessation of iontophoresis. Application of KYN with currents of 30-75nA attenuated VN and CSN evoked discharge (45±7 spikes/25 stimuli during control periods vs. 13±3 spikes/25 stimuli during KYN iontophoresis; p<.01) while XAN had no effect. The percent reduction of VN and CSN evoked discharge during KYN iontophoresis was the same whether the input was monosynaptic (82±9; n = 2 CSN, 1 VN) or polysynaptic (67±8; n = 3 CSN, 6 VN) (p>.2). KYN ejection currents >100nA were associated with local anesthetic effects. The results suggest EAAs play a role in VN and CSN excitation of NTS neurons at the level of both first order and higher order neurons. (Supported by HL-41894)

EFFECT OF PHARMACOLOGIC INDUCED BLOOD PRESSURE CHANGES ON CAT ROSTRAL VENTRAL MEDULLARY SURFACE ACTIVITY ASSESSED WITH HIGH TEMPORAL RESOLUTION OPTICAL IMAGING. R.M. Harper*, D.M. Rector, X.W. Dong and D. Gozal. Dept. of Anatomy & Cell Biology, UCLA Sch. of Med.; Childrens Hosp., USC Sch. of Med., Los Angeles, CA.

The rostral ventral medullary surface (RVMS) plays a significant role in cardiovascular regulation. We examined temporal properties of activity in RVMS regions at high sampling rates to determine patterns associated with pharmacologic manipulation of blood pressure. The VMS was surgically exposed in 5 adult anesthetized, spontaneously breathing cats. A 3.2 mm coherent optical fiber bundle, attached to a charge-coupled device (CCD) camera, was positioned over the RVMS. Neural tissue was illuminated with 660 nm light-emitting diodes, and images were digitized at 60 fields/sec before, and during intravenous injections of phenylephrine (5, 10, 15 and 20 μg/kg). Significant bradypnea and increases in blood pressure (BP) followed all injections except after 5 μg/kg, where only a mild increase in BP was noted. Spectral analysis of the overall reflectance changes revealed consistent decreases in spectral power within the 8-13 Hz range at all phenylephrine doses except with 5 μg/kg, where no effect on spectral peaks was observed. Since increases in 8-13 Hz spectral power accompany ventilatory stimulation, we speculate that phenylephrine induces significant decreases in activity of respiratory neuronal pools within the RVMS.

Impairment of Baroreceptor Reflexes Following Kaicnic Acid Lesions of the Lateral Tegmental Field M.E. Clement* and R.B. McCall. Cardiovascular Diseases Research, The Upjohn Company, Kalamazoo, MI 49001. The lateral tegmental field (LTF) has been proposed as a site for the generation of basal sympathetic nerve activity. Although LTF contains both baroreflex modulated sympathoexcitatory and sympathoinhibitory neurons, there is little evidence to suggest that the LTF is an important relay in the baroreflex arc. We examined the effects of kaicnic acid lesions of the LTF on baroreceptor function in the anesthetized cat. Baroreflex function was determined by evaluating the reflex sympathoinhibition during pressor responses, the temporal locking of sympathetic slow waves to the cardiac cycle and the power spectra of sympathetic slow waves. We found that kaicnic acid lesions of the LTF mimicked baroreceptor denervation in that it abolished the baroreceptor-mediated inhibition of sympathetic nerve activity in response to increased blood pressure. Baroreceptor denervation has also been demonstrated to temporally uncouple sympathetic slow waves and the cardiac cycle. Following kaicnic acid microinjection, sympathetic activity was no longer temporally related to the cardiac cycle. We used power spectral analysis routines to determine the frequency components contained within sympathetic nerve activity. As previously shown with baroreceptor denervation, the power spectra of sympathetic activity shifted to higher frequencies following LTF lesioning. In conclusion, our data indicates that the LTF is an integral part of the baroreflex and lesions of this area produce an impairment of the baroreceptor effects on sympathetic activity.

PARTIAL COHERENCE ANALYSIS REVEALS SELECTIVE RELATIONSHIPS AMONG THE 10-HZ RHYTHMIC DISCHARGES OF DIFFERENT SYMPATHETIC NERVES. G.L. Gebber*, S. Zhong, Y. Patel, and S.M. Barman. Dept. Pharmacol. & Toxicol., Michigan State Univ., East Lansing, MI 48824.

The 10-Hz rhythms in the discharges of postganglionic sympathetic nerves with different targets are strongly correlated as evidenced by coherence values near one. In the current study on baroreceptor-denervated, decerebrate cats, partial coherence analysis was used to determine whether the 10-Hz rhythmic discharges of the cardiac (C), lumbar (L), renal (R), and vertebral (V) sympathetic nerves are differentially related. This analytical technique mathematically removes the portion of the ordinary coherence between two signals attributable to a third signal. Specifically, the coherence functions relating the 10-Hz discharges of two sympathetic nerves were compared before and after removal of the influences of the central sources of the activity of a third nerve (as reflected by its discharges). We observed nonuniform changes in coherence at 10 Hz for different nerve pairs after partialization. For example, removal of R discharges sometimes eliminated the coherence at 10-Hz for C and L discharges with minimal effect on the coherence for C and V discharges. We also found cases when the coherence value relating the 10-Hz discharges of two nerves (e.g., C and V) was reduced to a greater extent after removal of the influences of R discharges than L discharges. Importantly, the pattern of differential relationships could change within and between experiments. The results might be explained by 1) differential gating of the outputs of a single 10-Hz generator to its targets, 2) differential crosstalk among central circuits receiving inputs from the same generator, or 3) differential coupling of multiple 10-Hz oscillators. (Supported by NIH grants HL-13187 and HL-33266.)

CHRONIC CAFFEINE TREATMENT ATTENUATE THE CARDIOVASCULAR EFFECTS OF ADENOSINE IN RAT BRAINSTEM. H.C. Lin, C.S. Tung, and C.J. Tseng. Dept. of Pharmacology and Physiology, National Defense Medical Center, Taipei, Taiwan, R.O.C.

We reported previously that microinjection of adenosine into the nucleus tractus solitarius (NTS) decreased mean blood pressure (MBP) and heart rate (HR) in normotensive rats through the putative adenosine receptors. The purpose of this study is to investigate the effect of chronic caffeine treatment on the cardiovascular effects of adenosine in the NTS. Male Sprague-Dawley rats were pretreated with either caffeine-containing water (0.1%) or water for different period of time. Microinjection (60 nl) of adenosine in the NTS produced a dose-related decrease in HR and MBP in water pretreated rats. However, a gradual attenuation of the hypotensive and bradycardic effects of adenosine were noted as the caffeine pretreatment maintained for more than 3 days. After one week of caffeine treatment, the cardiovascular effects of adenosine in the NTS were completely abolished. These effects recovered completely after the rats were abstained from the caffeine-containing water for more than one week. We concluded that the cardiovascular effects of adenosine in the NTS were attenuated by the pretreatment of caffeine, which might be due to a development of tolerance to caffeine in rats.

MEDULLARY LATERAL TEGMENTAL FIELD NEURONS PLAY A PERMISSIVE ROLE IN GOVERNING THE 10-HZ RHYTHM IN SYMPATHETIC NERVE DISCHARGE. S.M. Barman* and G.L. Gebber. Dept. Pharmacol. & Toxicol., Michigan State Univ., East Lansing, MI 48824.

Recordings from sympathetic nerves in decerebrate cats show a variable mixture of 10-Hz and 2- to 6-Hz discharges. Although medullary lateral tegmental field (LTF) neurons are considered to be a source of the 2- to 6-Hz oscillation in sympathetic nerve discharge (SND), their role in the control of the 10-Hz rhythm has not been critically evaluated. This issue served as the focus of the current study. In the first series of experiments, spike-triggered averaging of inferior cardiac SND was used in an attempt to identify LTF neurons with activity correlated to the 10-Hz rhythm in SND. The discharges of only one of 120 LTF neurons studied were correlated to this component of SND. In two of these experiments, we were able to identify neurons (4 of 17) in nucleus raphe pallidus with activity correlated to the 10-Hz rhythm in SND. In experiments in which a 2- to 6-Hz oscillation was prominent, we identified LTF neurons (17 of 79) with activity correlated to this component of SND. These data indicate that LTF neurons neither receive input from nor are components of the 10-Hz rhythm generator. In a second series of experiments, muscimol (1 nmol in 100 nl) was microinjected slowly (10-20 s) into each of four LTF sites on both sides of the medulla. Chemical inactivation of the LTF with muscimol either eliminated the 10-Hz rhythm or reduced the power and peak frequency in this band of SND in five of six cats. Partial recovery of the 10-Hz rhythm occurred within 90 min after completing the injections. These data support the view that LTF neurons have a permissive role in governing the 10-Hz rhythm in SND, likely by acting on elements of the rhythm generator located elsewhere. NITRIC OXIDE SYNTHASE IN RAT SYMPATHETIC PREGANGLIONIC NEURONS: AN IMMUNOHISTOCHEMICAL AND ELECTROPHYSIOLOGICAL STUDY. N. J. Dun*, S. Y. Wu, S. L. Dun and U. Förstermann. Dept. of Anatomy, Medical College of Ohio, Toledo, OH 43614 and Abbott Laboratories, Abbott Park, IL 60064.

The presence of nitric oxide synthase-immunoreactivity (NOS-IR) was detected in the rat spinal cord using an antibody against rat cerebellar NOS. NOS-IR was found to be concentrated in rat sympathetic preganglionic neurons (SPNs) but not in ventral horn motoneurons. NOS-IR was also detected in neurons of the dorsal horn, particularly laminae I and II and around the central canal. To evaluate a possible role of NO in SPNs, whole-cell patch clamp recordings were made from these neurons in transverse (500 μ m) thoracolumbar spinal cord slices removed from immature (12-16 day) rats. Superfusion of L-arginine (L-Arg; 0.1-0.5 mM), the precursor of NO, reversibly increased the inward current induced by NMDA and AMPA applied to the SPNs by pressure. This effect was stereospecific, as D-Arg in comparable concentrations was ineffective. Superfusion of N⁶-Methyl-L-arginine (NMA; 100 μ M), a potent inhibitor of NOS, slightly decreased the NMDA- and AMPA-induced currents. Pretreatment of the spinal cord slices with NMA nullified the potentiating effect of subsequent application of L-Arg. Superfusing the slices with 8-bromo-cGMP and 3-isobutyl-1-methylxanthine increased the NMDA/AMPA-induced currents in a reversible manner. In addition, L-Arg reversibly increased the outward current induced by pressure application of glycine. Our results show that agents that stimulate NO formation increase the responses induced by NMDA/AMPA and glycine in rat SPNs, and agents that inhibit NO formation exert the opposite effect. As cGMP mimics these effects, the intracellular mechanism may involve phosphorylation of membrane proteins by cGMP-dependent protein kinase.

LEARNING AND MEMORY: SYSTEMS AND FUNCTIONS VIII

447.1

REGIONAL CEREBRAL BLOOD FLOW CHANGES DURING CLASSICAL EYEBLINK CONDITIONING IN MAN. T.A. Zeffiro*, T. Blaxton, J. Gabrieli, S.Y. Bookheimer, M. Carrillo, E. Binion, J. Disterhoff, and W. Theodore. MNB and ERB, NINDS, National Institutes of Health, Bethesda, MD; Stanford University, Palo Alto, CA; Northwestern University, Chicago, IL.

Classical conditioning studies of the rabbit nictitating membrane reflex have implicated the cerebellum and hippocampus as putative sites for the storage or formation of the association between the unconditioned and conditioned stimuli. In this study we explored the neuroanatomical localization of this type of learning.

rCBF changes were recorded with positron emission tomography in 15 subjects using bolus injection of H₂¹⁵O in 3 conditions: (1) central fixation, (2) uncorrelated tone and airpuff (pseudoconditioning), and (3) correlated 400 msec tone and 150 msec airpuff (short-delay conditioning). Trials were administered in 2 blocks of pseudoconditioning and 4 blocks of conditioning, with each block lasting 2 minutes. Scans were spatially standardized to a common coordinate system. Planned comparisons made between the task and control conditions yielding statistical parametric maps of rCBF change.

Contrasting conditioning and pseudoconditioning blocks revealed conditioning-related rCBF changes including: (1) increases in ipsilateral cerebellar nuclei, ipsilateral hippocampus, contralateral putamen and bilateral prefrontal cortex ($p < .01$); and (2) decreases in ipsilateral cerebellar cortex ($p < .01$).

These results support a role for the cerebellum and hippocampus in associative learning as suggested by previous animal studies. The prefrontal cortex and putamen may play a more prominent role in short-delay eyeblink conditioning in man.

447.2

NEUROPHYSIOLOGICAL SUBSTRATES OF HUMAN MEMORY IMPAIRMENTS: ALTERED REGIONAL CEREBRAL GLUCOSE UTILIZATION IN ALCOHOLIC KORSAKOFF'S SYNDROME AND ALZHEIMER'S DISEASE, AS MEASURED BY POSITRON EMISSION TOMOGRAPHY (PET). K.A. Paller*, B.C. Richardson, A.P. Shimamura, Q. Plaisant, B.R. Reed, and W.L. Jagust. Center for Functional Imaging, Lawrence Berkeley Laboratory (MS 55-121), Berkeley, CA 94720, and Department of Neurology, University of California, Davis.

Although structural neuroimaging indicates that Korsakoff's syndrome is associated with damage to the medial thalamus and the mammillary bodies, additional brain areas (such as the hippocampus) may also be dysfunctional and thus responsible for the amnesic symptoms in these patients. We investigated this possibility by measuring regional cerebral metabolic rates for glucose using the radiotracer [¹⁸F]-fluorodeoxyglucose and PET imaging with high spatial resolution (2.6 mm in-plane, FWHM). Comparisons were made between patients with Korsakoff's Syndrome, alcoholic control subjects, nonalcoholic control subjects, and patients with Alzheimer's Disease. The procedure included a continuous recognition test as a behavioral challenge during the radiotracer uptake period, and performance measures were obtained assessing recognition (as a function of retention delay) as well as stem-completion priming. Dissociations between recognition and priming were found, replicating prior studies. PET results showed that Alzheimer's disease was associated with abnormally low metabolic rates in temporal and parietal neocortical areas, whereas Korsakoff's syndrome was associated with a more widespread decline in function in both neocortical and subcortical regions. Further, there was no evidence that hippocampal metabolism was disproportionately affected in Korsakoff's syndrome.

447.3

FUNCTIONAL NEUROANATOMY OF VERBAL MEMORY AS REVEALED BY WORD LIST RECALL DURING PET SCANNING. J.T. Becker*, M.A. Mintun, D. Diehl, S.T. DeKosky, J. Dobkin, Depts. of Psychiatry & Radiology, University of Pittsburgh Medical Center, Pittsburgh, PA.

Data obtained from normal individuals using functional neuroimaging provides the opportunity for testing existing neuropsychological models. In the present study, 12 healthy, young individuals performed word recall tasks while undergoing $H_2^{15}O_2$ Positron Emission Tomography (PET) scanning.

When the subjects repeated lists of words exceeding their memory span, areas activated included the dorso-lateral prefrontal cortex (Areas 9&10) and the anterior cingulate cortex. No activation was seen in the temporal lobes in addition to that observed during word repetition. By contrast, when comparing 1-word or 3-word repetition to resting state, cortical areas of activation included the superior temporal cortex and the mesial temporal regions in the vicinity of the hippocampus.

These within-subject analyses are consistent with those between-subject studies reported by Grasby and colleagues and suggest that mesial temporal activation occurs during any memory task, even when those brain regions are not critical for the performance of the task. Further, the pattern of activation and of free recall performance suggests that the prefrontal activation is secondary to current concepts of normal memory functions, and to the brain structures which support them.

447.5

INTACT CONCEPTUAL PRIMING BUT IMPAIRED CUED RECALL IN PATIENTS WITH FRONTAL LOBE LESIONS. E. B. Gershberg* and A. P. Shimamura. Dept. of Psychology, University of California, Berkeley, CA 94720.

Studies of patients with damage to dorsolateral prefrontal cortex have revealed deficits in free recall and use of organizational strategies but normal recognition memory and perceptual priming. The present study examined performance of frontal patients on implicit tests of conceptual priming and explicit tests of cued recall and free recall. In Experiment 1, 7 frontal patients and 12 controls studied a 15-word, categorized list (5 exemplars from each of 3 categories). They were then given an implicit test in which they were asked to produce 8 exemplars for each of 6 categories (3 studied and 3 new). Priming occurs when the production of studied exemplars is greater than the baseline guessing rate for new categories. After a break, subjects studied a new categorized list and then were given an explicit test using category names as cues for recall. Frontal patients showed normal priming on the implicit test but showed impaired performance on the explicit test. Baseline guessing rate, however, was lower for patients than for controls. Experiment 2 was conducted to address this problem by using an easier test task involving free association. Six frontal patients and 12 controls studied lists made up of 3 clusters of 5 words linked to a common associate (e.g., circus, hunter, tamer, mane, king). The procedures were identical to those of Experiment 1 except that the test cues consisted of 6 single words, 3 of which were associates of studied words (e.g., lion). For the implicit test, subjects were asked to produce 8 words related to each cue word, and for the explicit test, they were told to use the cue words to help them recall list words related to the cues. Frontal patients again showed normal priming, this time with a normal baseline. The cued recall impairment was also replicated. Taken with previous findings, these results suggest that frontal patients are impaired on tests which tap the encoding of list organization, as do explicit tests of category- and associate-cued recall, but normal on tests which tap primarily the conceptual processing of individual list items, as do implicit tests of category and associate generation. INTACT CONCEPTUAL TRANSFER ON AN IMPLICIT PERCEPTUAL TASK IN GLOBAL AMNESIA AND ALZHEIMER'S DISEASE. D.A. Grosse*, J.D.E. Gabrieli, S.L. Reminger, L.A. Monti, J.A. Weiner and B.S. Wilson. Rush Medical College, Chicago, IL, 60612 and Dept. of Psychology, Stanford University, Stanford, CA, 94305.

A profound explicit memory deficit is a defining feature of global amnesia (GA) and of Alzheimer's disease (AD). In contrast, GA and AD patients have shown intact implicit memory on a number of perceptual repetition priming tasks, such as the perceptual identification (PI) of briefly presented words. Normal PI priming is thought to be primarily perceptual (data-driven) since study-phase reading yields greater priming than study-phase generating of the unseen word. PI priming that is evident after study-phase generation can be considered conceptual transfer in a perceptual task. PI priming in memory-disordered patients has been examined only after perceptual encoding. It is unknown whether these patients would show intact conceptual transfer on this perceptual task. Our subjects were 16 patients with mild AD, 16 normal elderly controls (NC), and 5 patients with GA. For perceptual encoding, subjects saw and read single words aloud. For conceptual encoding, subjects generated a word when given a short definition and the first letter of the word. For the implicit PI test, subjects identified briefly presented and masked words, and priming was measured as the advantage in identifying repeated vs. baseline words. For the explicit yes/no recognition task, subjects made recognition judgments about singly presented studied and unstudied words. The NC subjects were more accurate in their recognition judgments for generated than for read words, and were more accurate in both conditions than the two patient groups. Both GA and AD patients showed intact PI priming magnitudes for the perceptual and conceptual encoding conditions. All subjects performed best for words read, second best for words generated, and least well for baseline (new) words. The patients' intact priming in the conceptual generate condition indicates that they had intact conceptual transfer occur on an implicit perceptual task. These results suggest that the same memory system retains both perceptual and conceptual information on a perceptually-driven task, and that this neural system probably does not include structures damaged in GA and early AD. Supported by the Alzheimer's Association, grant # IIRG-92-063.

447.4

DOUBLE DISSOCIATION OF SPATIAL AND OBJECT WORKING MEMORY IN NORMAL HUMANS USING PET. J. Jonides*, E.E. Smith, R. Koeppe, S. Minoshima, and E. Awh. Department of Psychology (Jonides, Smith, and Awh) and Department of Nuclear Medicine (Koeppe and Minoshima), University of Michigan, Ann Arbor, MI 48109.

Behavioral experiments on brain-injured humans as well as electrophysiological experiments on monkeys suggest that working memory for spatial and object information may be mediated by different processing pathways. The present experiments show that the processes of spatial and object working memory can be doubly dissociated using PET in normal humans.

Subjects were given one of two tasks while PET measurements were taken. In a spatial task, visual targets were presented at three locations, and after a 3-sec delay subjects were given a probe and had to indicate whether it appeared at one of the previously occupied locations. In an object task, two target objects were presented, and after a 3-sec delay subjects had to indicate whether a probe object was identical to one of the previously presented targets. The spatial task engaged processes of right hemisphere occipital, parietal, prefrontal and premotor areas while the object task engaged processes of left hemisphere temporal, parietal, prefrontal, and cingulate areas. These results identify different pathways for the two working memory tasks. One difference is in the hemisphere predominantly responsible for processing in the two tasks. Another difference is that the spatial task recruits processes of a dorsal processing system while the object task recruits processes of a ventral system. Yet another difference is in the locus of processes presumably involved in retention of the respective stimuli in prefrontal cortex.

447.6

AMNESIC PATIENTS SHOW NORMAL PRIMING AND A NORMAL DEPTH-OF-PROCESSING EFFECT IN A CONCEPTUALLY DRIVEN IMPLICIT MEMORY TASK. M.M. Keane*, J.D.E. Gabrieli, L.A. Monti, J.M. Cantor, and J.S. Noland. Memory Disorders Research Center, Boston University School of Medicine and DVAMC, Boston, MA 02130; and Rush Alzheimer's Disease Center, Chicago, IL 60612.

Although patients with global amnesia show impaired performance on recall and recognition memory tests (explicit measures of memory), they can show intact performance on repetition priming tasks (implicit measures of memory), which measure the influence of prior exposure to test stimuli on subsequent performance. Some investigators have argued that implicit/explicit memory tasks typically confound data-driven/conceptually driven processes, and have suggested that the latter distinction may provide a better account of spared and impaired memory function in amnesia. By this view, data-driven processes (invoked in tasks that require analysis of surface features of stimuli) are spared in amnesia, and conceptually driven processes (invoked in tasks that require analysis of stimulus meaning) are impaired in amnesia. We evaluated these competing theories by comparing the performance of 13 amnesic patients (AMN) and 16 control subjects (CS) on a conceptually driven, implicit memory task: category exemplar production. In a study phase, subjects answered questions that induced deep ("Natural or man-made?") or shallow ("Uppercase or lowercase letters?") processing of category exemplars (e.g., "mango"). In the test phase, subjects generated examples of given categories (e.g., "fruit"). The measure of priming was the degree to which subjects were biased above baseline to generate exemplars from the study list. The results showed that priming was 1) equivalent in the AMN and CS groups; 2) greater following deep than shallow processing; and 3) similarly affected in both groups by the depth-of-processing manipulation. Amnesic patients were impaired in an explicit measure of category exemplar cued recall. Like prior findings, these results demonstrate that memory processes spared in amnesia can support normal performance on conceptually driven memory tasks, provided that those tasks do not depend upon deliberate reference to a prior study episode. Supported by NINDS grant NS 26985 and grant IIRG-92-063 from the Alzheimer Association.

447.8

RECOGNITION MEMORY IN PARKINSON'S DISEASE AND ALZHEIMER'S DISEASE: EVIDENCE FOR INTACT FLUENCY. G.I. Stebbins*, J.D.E. Gabrieli, D.A. Grosse, J.A. Weiner, C.G. Goetz, Dept. of Neurological Sciences, Rush Medical College, Chicago, IL 60612

Two components to explicit memory have been proposed: recollection (controlled/conscious processes) and fluency (automatic/unconscious processes). Little is known about the neural bases for these putatively separable explicit memory processes. We examined the status of fluency in patients with known damage to limbic and neocortical structures (Alzheimer's disease (AD)) and to the basal ganglia (Parkinson's disease (PD)). 16 mildly demented AD patients with 16 matched control subjects (NC), and 16 non-demented PD patients with 10 matched NC participated in the study. Jacoby's Fame Judgement task was employed to assess fluency. Subjects first read aloud a list of 20 moderately famous and 20 non-famous names. Subjects next viewed a list of 80 mixed old and new famous and non-famous names and were asked to judge whether or not a name was famous. Fluency was measured by the probability of calling an old name famous minus the probability of calling a new name famous. Subjects next read a new list of 40 famous and non-famous names, and then made yes/no recognition judgements on a list of those names combined with 40 foils. PDs showed similar recognition memory to their NCs, while ADs were significantly impaired in comparison to their NCs. Fluency was comparable across all groups. These findings suggest that: 1) despite impaired recognition memory in AD, fluency is intact in comparison to age and education matched NCs; 2) automatic, fluent memory is not impaired by either the limbic or the neocortical damage found in AD, nor by damage to the basal ganglia found in PD. Supported by the Office of Naval Research and the Illinois Department of Public Health.

TEXT-SPECIFIC IMPLICIT MEMORY IN PATIENTS WITH ALZHEIMER'S DISEASE AND GLOBAL AMNESIA: EVIDENCE FOR IMPLICIT MEMORY FOR NEW ASSOCIATIONS. L. A. Monti*, J. D. E. Gabrieli, R. S. Wilson, N. J. Cohen, S. L. Reminger, C. Vaidya, and A. Ortony. Rush Alzheimer's Disease Center, Chicago, IL 60612.

Patients with Alzheimer's disease (AD) and global amnesia are impaired on tests of explicit memory (recall and recognition), but intact on some implicit memory tasks. Most of these implicit tasks involve the processing of individual words or pictures and, therefore, do not permit the construction of new associations between items. Two experiments were designed to investigate whether memory-impaired patients can implicitly learn and retain new associations between words. In the first, ten mildly demented AD patients and ten age-matched normal control (NC) subjects read two passages three times, as quickly as possible, and answered recognition memory questions after the third reading of each passage. The AD patients had poor explicit memory for the passages, as evidenced by impaired recognition memory performance, but had intact implicit memory for the passages, as evidenced by normal decreases in the times for successive readings. The baseline reading times for AD patients and NC subjects were comparable. Even though one third of the words were shared by both passages, there was no cross-passage facilitation, indicating that the rereading effect was a text-specific rather than a word-level effect. In a second experiment, amnesic patients read: (1) a normal passage three times, (2) a randomized version of a passage three times, and (3) three different random versions of a passage. Results showed significant priming except in the last of these conditions. These findings suggest that the rereading effect is mediated by rereading words in their original contexts, in which new between-word associations are learned, rather than by individual word repetition or general reading skills. Supported by grants from the NIA #F32-AG05568-01A1 and the Alzheimer's Association #1RG-92-063.

DEFICITS IN WORKING MEMORY APPEAR EARLY IN HUNTINGTON'S DISEASE. A. W. Deckel*. Division of Neuropsychology, Dept. of Psychiatry, UCONN Medical School, Farmington, CT 06030.

Huntington's Disease (HD) is an autosomal dominant, slowly progressive neurodegenerative disorder that leads to impaired motor functioning and results in a progressive dementia. Although memory deficits are a frequent finding, deficits in so-called "working memory" have not been systematically evaluated early in the course of the disease.

Three groups of patients, including those with "early" HD, detoxifying substance abusers, and normal controls were asked to memorize a 12 square "grid" filled either with visual designs (visual-spatial) or 3 letter words (verbal-spatial). After assessing immediate recall, they were given 4 "learning" trials during which they were asked to learn the "order" of the designs/words in space, and then were assessed for their immediate and delayed "post-learning" memory. They were also given a task which required them to place in temporal "order" a story they were read.

HD patients had difficulty in learning the "template" during the learning trials, regardless if the trial employed a word or design. Even patients who were "early" in the course of the disease and generally appeared intact cognitively demonstrated difficulty with the task. HD patients also had impaired delayed recall of the grid compared to controls. Similarly, their ability to "order" a story was impaired.

These results suggest that working memory is impaired early in the course of HD, possibly because of the contribution of frontal-lobe dysfunctioning or, alternatively, because of disturbances in the ability of the basal ganglia to "integrate" frontal lobe functioning.

ANATOMIC AND COGNITIVE SUBGROUPS AFTER ACoA ANEURYSM. L.M. Grattan¹, P.J. Eslinger², D. Rigamonti², S.M. August¹, & A. Depati². Depts. of Neurology¹ & Neurosurgery², Univ. of MD Med. Sch. Baltimore, MD 21201 & ³Penn State Univ. College of Med., Hershey, PA 17033.

Based upon the study of a consecutive series of anterior communicating artery aneurysm (ACoA) patients we reported considerable heterogeneity in the nature of their memory disturbance and lesion sites. This investigation examines in detail patterns of memory disorders and their neuroanatomic correlates after rupture and surgical correction of ACoA aneurysms. We report the neuroanatomic and cognitive findings in a series of 8 patients studied during acute recovery. Lesion data were obtained from CT/MRI studies and intraoperative reports. Standard and experimental cognitive measures examined specific components of learning and memory. These included measures of attention, learning levels, rate of forgetting, subjective organization, spatial and temporal judgment and serial position effect. Findings indicated 5 distinct neuroanatomic subgroups: 1) isolated involvement of the basal forebrain, 2) involvement of basal forebrain together with the vascular territory of the recurrent artery of Heubner (raH), 3) involvement of the basal forebrain with raH and mesial frontal cortex, 4) involvement of the basal forebrain with mesial frontal cortex and 5) involvement of the basal forebrain, raH and lateral frontal cortex. Each subgroup presented with a different pattern of performance on standard and experimental measures of learning and memory. It is conceivable, that like its counterpart in neuroanatomy, patterns of memory impairment after ACoA aneurysm may reflect disruption of different components of memory.

CONTRIBUTION OF THE STRIATUM AND CEREBELLUM IN VISUOMOTOR SKILL LEARNING. J. Doyon*, R. Laforce, Jr., D. Gaudreau, M. Castonguay, P.J. Bédard, J.P. Bouchard, & J. Roy. Centre de Recherche en Neurobiologie, Faculté de Médecine, Université Laval, Québec, Canada, G1J 1Z4.

There is now considerable evidence from both animal (e.g., Wang et al., 1990; McDonald & White, 1993) and human studies (e.g., Heindel et al., 1989) indicating that the implicit learning of a variety of skills may depend upon the integrity of a complex cortico-striatal neural pathway. Some investigators have recently shown, however, that the cerebellum may also play a role in motor and non-motor skill learning. The goal of the present study was thus to investigate further the contribution of these structures in the incremental learning of a visuomotor skill. The performance of patients with idiopathic Parkinson's Disease (PD) or with a circumscribed lesion of the cerebellum (Ce), was compared to that of matched normal-control subjects (NC) on an adapted version of the Repeated Sequence Test (Nissen & Bullemer, 1987). This test consist of a choice reaction-time task in which the stimuli follows a set sequence of ten items that repeats itself 10 times in a block of trials. Subjects received 4 blocks of trials on each of the six training days, which took place once a week over a period of 6 weeks. Following the last experimental block of trials on Day 6, subjects were required to respond to a short questionnaire and to complete two blocks of trials in a self-generated sequence task in order to evaluate their declarative knowledge of the sequence and to examine directly the possible dissociation between the two memory systems. The results demonstrate that both PD and Ce patients were impaired on the learning of the repeated sequence over training trials, whereas their performance did not differ from that of the NC subjects on the declarative memory tests. Our findings suggest that the incremental learning of a visuomotor skill (but not declarative memory) may depend, along with the complex cortico-striatal system, upon a parallel cortico-cerebellar circuit.

HIPPOCAMPAL SPECIFIC ATROPHY IS ASSOCIATED WITH DELAYED SECONDARY MEMORY IMPAIRMENT IN NORMAL HUMAN AGING. J. Golomb, A. Kluger, M.J. de Leon, A. Comvit, H. Rusinek, A.E. George, S. de Santi, S.H. Ferris*. New York Univ. Sch. of Med. New York, NY 10016.

The hippocampal formation (HF) is an important mediator of declarative secondary memory; atrophy of this structure has been described in Alzheimer's disease and other amnesic disorders. HF dysfunction may also explain milder secondary memory deficits seen in normal aging. We used magnetic resonance imaging (MRI) to test the hypothesis that in normal human aging, after controlling for generalized cortical atrophy, volume reductions of the HF but not of the superior temporal gyrus (ST) are specifically associated with relatively impaired delayed secondary memory performance.

54 healthy elderly persons (ages 55-87, \bar{x} = 69.0 \pm 7.9) participating in a study of normal aging were consecutively selected on the basis of a Global Deterioration Scale score \leq 2 and a Mini Mental State Exam score \geq 28. Subjects were administered tests of primary memory (digit span), and tests of secondary memory with immediate and delayed recall components (paragraph, paired associate, list recall; facial recognition). Separate composite scores for the immediate and delayed components were created by combining, with equal weighting, the subtests of each category. The WAIS vocabulary subtest was used as a control measure for language and intelligence. Coronal T1 weighted MRI scans were used to derive head size normalized measurements of the HF, ST and extraventricular CSF (to estimate generalized cerebral atrophy).

After partialling out the effects of age, sex, WAIS vocabulary and generalized cerebral atrophy, normalized HF size was found to correlate significantly with delayed secondary memory performance ($r = .32$, $p < .05$), but not with immediate secondary memory or primary memory. Parallel analyses revealed no significant partial correlations for normalized ST size.

Our results suggest that HF size may be an anatomically specific correlate of delayed secondary memory function in normal human aging.

DISTINCTIVE FORMS OF PARTIAL RETROGRADE AMNESIA. P.J. Eslinger¹, L.M. Grattan² & A. Easton¹. Depts. of Neurology, ¹Penn State Univ. Coll. of Med., Hershey, PA 17033, & ²Univ. of Maryland Med. Sch., Baltimore, MD 21201.

In contrast to extensive retrograde amnesia (RA), partial forms of RA can elucidate component characteristics of memory disorder associated with select neural lesions. We describe 2 cases (EK, DR) of partial RA from asymmetric temporal lobe lesions after herpes encephalitis. Despite impaired scores on standardized RA measures, experimental probes indicated contrasting findings in the subjects. EK could not name famous faces from the past, nor complete famous name stems, or spontaneously match names and faces. On forced choice testing, her selection of famous names was barely above chance level but selection of famous faces and temporal ordering of faces were normal. These findings contrast sharply with DR who demonstrated normal name completion and name selection. However, DR was poor in famous face selection compared to name selection and when presented facial stimuli compared to name stimuli in name-face matching tasks. These cases show striking lesion localization differences with EK's lesion predominantly in the left medial (amygdala, hippocampus, parahippocampal gyrus) and lateral temporal regions, while DR's lesion was predominantly in the right homotopic areas. The findings indicate dissociated forms of partial RA with distinct left and right temporal cortex contributions to RA.

SCIATIC NERVE AXOTOMY INCREASES EXPRESSION OF BETA-ACTIN mRNA. L.M. Lund, C.H. Block and I.G. McQuarrie*. Neural Regen. Ctr., VA Med. Ctr., Cleveland, OH 44106.

During development, mRNAs for neuronal actin and tubulin are made in high quantities. After axons connect to appropriate targets, these mRNAs are downregulated. We are interested in axonal regeneration in the peripheral nervous system as a recapitulation of development. We looked at changes in mRNA levels for beta-actin, a protein which (with tubulin) is upregulated after axotomy. Bilateral sciatic nerve crush (or sham) was done at the level of the hip joint. Using an appropriate riboprobe, in combination with Northern blot analysis of mRNA extracted from spinal motor neurons, we found that beta-actin mRNA increases 3-5 fold at Day 4 postaxotomy (PA), whereas, levels are approximately normal at 28 hours and below control at Day 14. Transcription factors are known to be regulators of mRNA synthesis. We are interested in determining which transcription factors are responsive to axotomy. To study this, we used Northern blot analysis with riboprobes of several candidate factors. The Jun family is promising, and we found that Jun D expression is induced 3-fold by 28 hours PA, remains elevated at Day 4 PA, and returns to normal by Day 14.

STABILIZED MICROTUBULES ARE ENRICHED IN THE PROXIMAL REGION OF AXONAL NEURITES DURING EARLY OUTGROWTH IN NB2a/d1 NEUROBLASTOMA. TB Shea*, PA Paskevich, SL Vincent and ML Beermann. McLean Hospital, Harvard Medical School, Belmont MA

Acetylation and detyrosination of α -tubulin are correlated with microtubule (MT) stabilization. We examined the appearance and distribution of stabilized MTs during early (day 1-7) dbcAMP-mediated axonal neurite outgrowth in NB2a/d1 cells with antibodies specific for acetylated (acet), detyrosinated (detyr), tyrosinated (tyr), or all forms (total) of α -tubulin. Day 1 neurites contained tyr MTs along their length, but detyr MTs extended only into the proximal neurite region. Acet MTs were not visible at day 1, suggesting that this modification is delayed relative to detyrosination. We quantitated the relative distribution of stabilized MTs in day 3 and day 7 neurites as follows. The neurite shaft of 50-100 cells in multiple fields was divided into approximate halves according to the phase-contrast image. Neurites were scored according to the relative intensity of immunoreactivity in the proximal (P) versus the distal (D) neurite half. The majority of day 3 and 7 neurites displayed roughly equivalent total and tyr MT reactivity in both P and D halves; the remaining percentages for each antibody were equally distributed between neurites displaying more staining in the P or D halves. By contrast, the majority of day 3 and 7 neurites displayed more intense acet and detyr reactivity in the P neurite half, with the remainder of neurites displaying roughly equivalent staining in P and D. Differential distribution of acet MTs was highlighted in one or more longitudinally-oriented planes of focus obtained in a Z-series during confocal microscopic analyses, suggesting that acet MTs may also be differentially distributed through the neurite shaft radius. That the distribution of acet and detyr MTs differs from the total MT distribution indicates that these modified MTs represent a small percentage of total axonal MTs. This small subset of selectively stabilized MTs may reflect the existence of an older or more slowly transported MT population within the P half of the developing neurite.

EXPRESSION OF MICROTUBULE-ASSOCIATED PROTEIN, MAP-1A, IN DORSAL ROOT GANGLIA (DRG). R.K. Yip*, L. Boyne, and I. Fischer. Dept. of Anatomy and Neurobiology, Medical College of Pennsylvania, 3200 Henry Ave., Philadelphia, PA 19129.

MAP-1A is a microtubule-associated protein expressed late in development of the nervous system. This protein has been proposed to play a role in the stabilization of the adult neuronal cytoskeleton, but no primary neuronal cultures had been available to study its expression. We prepared specific antibodies against purified MAP-1A and examined the distribution of the protein in DRGs in vivo and in purified neuronal cultures. The staining of MAP-1A in the DRGs was present in cell bodies and axons. However, not all the neurons stained to the same degree. Cultured DRG neurons from neonates did not exhibit MAP-1A staining. In contrast, the MAP-1A antibodies intensely stained the cell bodies of cultured adult DRG neurons, while the neurites stained mostly in their proximal regions. Our results demonstrate that adult DRG cultures can provide a unique neuronal system to study the expression and role of MAP-1A. Supported by NIH NS24707 and NS24725.

THE MOLECULAR GENETICS OF NEURONAL GROWTH: CHARACTERIZATION OF THE $T\alpha 1$ α -TUBULIN PROMOTER IN TRANSGENIC MICE. A. Gloster*, A. Speelman, J. Toma, E. Chan, and F.D. Miller. Dept. Anatomy. & Cell Biol., University of Alberta, Edmonton, Alberta, T6G 2H7.

The $T\alpha 1$ α -tubulin gene is one member of the α -tubulin multigene family that is regulated as a function of neuronal growth in both developing and mature mammalian neurons. We have generated transgenic mice carrying a fusion gene comprised of 1100 nucleotides of the upstream, putative $T\alpha 1$ promoter region linked to a nuclear β -galactosidase reporter gene. At embryonic days 14 and 16, a developmental period when expression of the endogenous gene is maximal, the transgene is expressed in the nervous system of 5 out of 8 founder lines, with expression varying independently of copy number. Although expression in one of these lines is only partial, expression in the remaining three occurs throughout the embryonic nervous system, in a pattern that is indistinguishable from that of the endogenous gene. Developmentally, expression of the transgene appears early during embryogenesis and appears to be coincident with neurogenesis. Expression of the transgene remains high during neuronal morphogenesis, at birth, and is subsequently downregulated following neural maturation, as indicated both by X-gal staining and by Western blot analysis. At all timepoints the transgene is specific to the nervous system. Thus, the sequences responsible for coupling gene expression to neuronal growth exist within this promoter region. We are currently analyzing the expression of this transgene in specific neuronal populations during development and following injury in mature neurons.

MANGANESE-INDUCED NEURITE OUTGROWTH IS ACCOMPANIED BY ELEVATED LEVELS OF MAP1B. J.M. Aletta*, M. Pacheco, J. Roth and K. Larsen. Dept. Pharmacol. SUNY@Buffalo School of Medicine, Buffalo, N.Y.

Manganese chloride (Mn^{2+}) stimulates neurite outgrowth from a variant line of PC12 cells (Lin et al., *J. Neurosci. Res.* 34: 546-561, 1993). Mn^{2+} -treatment also induces peripherin and GAP-43 in these cells. The present study focuses on the microtubule-associated protein, MAP1B based upon its putative role in neurite initiation. We have examined the effects of Mn^{2+} (100 μM in RPMI+1%serum) on its steady state protein level and on its phosphorylation (P). Additional experiments using the wild type PC12 (WT) cells treated with Mn^{2+} were also carried out. Results from the variant line indicate that MAP1B levels rise as early as 12h after treatment. After 2d of treatment, MAP1B measured by western blot is elevated 4-fold (± 0.8 SEM, n=4) relative to total cellular protein. Metabolic radiolabeling of MAP1B with ^{32}P -orthophosphate followed by gel scanning densitometry showed that phosphate incorporation at this time is elevated 1.7-fold (± 0.1 , n=7). These results imply that a significant proportion of the elevated amount of MAP1B is not phosphorylated. In WT cells treated with NGF, process outgrowth is accompanied by increases in both the amount of MAP1B and its P. When treated with Mn^{2+} , WT cells flatten, but do not extend neurites of significant length ($<20\mu m$). Mn^{2+} induction of peripherin levels is also absent in WT. Regeneration of neurites from WT, however, can be stimulated transiently by 100 μM Mn^{2+} (38 \pm 3.6% of the NGF response @12-20h n=6). Mn^{2+} can also potentiate the NGF response in WT as shown previously for the variant line, but these limited neurotogenic effects of Mn^{2+} are not accompanied by changes in P of MAP1B. We conclude that large increases in the P of MAP1B are not necessary for initiation of neurite formation. Variant PC12 cell lines that exhibit different phenotypes regarding neurogenesis should facilitate further inquiry into the mechanisms of nerve process formation.

HIGH IMMUNOREACTIVITY FOR A PHOSPHORYLATED MAP1B ISOFORM CORRELATES WITH ADULT CNS AREAS THAT RETAIN CAPACITY FOR STRUCTURAL PLASTICITY. E. Nothias*, I. Fischer¹, P. Vernier and J.-D. Vincent. Inst. A. Fessard, CNRS, 91198 Gif/Yvette, France; ¹Dept. Anat. and Neurobiol., Med. College of PA, Philadelphia, PA 19129.

Microtubule-associated proteins (MAPs) are major structural components of the neuronal cytoskeleton and their expression is regulated during brain development. MAP1B is highly expressed in newborn rat brain and decrease dramatically in adult brain, particularly its phosphorylated isoforms. The present study was undertaken to determine whether MAP1B is specifically expressed in areas of adult rat brain which undergo morphological reorganization under particular physiological and experimental conditions. High immunostaining, using a monoclonal antibody 1B-P that recognizes only the phosphorylated isoform of MAP1B, was observed in restricted areas such as hypothalamic system, olfactory nuclei as well as other regions that also retain the expression of embryonic neural cell adhesion molecule (PSA-NCAM). At the cellular level, immunostaining of phosphorylated MAP1B was localized only in axons and not in perikarya. In contrast, immunostaining of total MAP1B, revealed by antibodies that recognize all its isoforms, was more widespread and not as restricted. MAP1B mRNA was also ubiquitous, present in most of the neurons. Since MAP1B, in particular its phosphorylated isoforms, is present predominantly in growing axons, our observations support the hypothesis of its involvement in morphological plasticity in adult CNS.

448.7

Expression and distribution of phosphorylated MAP1B in growing axons of cultured hippocampal neurons. L. Boyne, E. Paige, J. Deitch*, I. Fischer, Dept. of Anatomy and Neurobiology, Medical College of Pennsylvania, Philadelphia, PA 19129

Microtubule associated protein, MAP1B, is a major structural component of growing axons. It is expressed at high levels early in development including a phosphorylated isoform. In previous studies (Mol. Cell. Neurosci. 2:39, 1991) we have shown that in cultured primary hippocampal neurons MAP1B is sorted into growing axons and is concentrated in the distal tip of axons. In the present study a specific monoclonal antibody, 1B-P, against phosphorylated MAP1B was used to study the distribution of the phosphorylated isoform in hippocampal cultures compared to total MAP1B. During the early stages of minor process extension (1 day in culture) phosphorylated MAP1B was colocalized with total MAP1B and MAP2 in cell bodies and processes, but 1B-P labeled the growth cones more extensively. When neurons acquired axonal and dendritic polarity (2-4 days in culture), MAP2 was segregated to the dendrites, whereas MAP1B was concentrated in the axons. However, phosphorylated MAP1B became gradually restricted only to axons, and was not present in dendrites and cell bodies. By the end of the first week in culture, levels of phosphorylated MAP1B decreased, but that of total MAP1B decreased only after 3 weeks. Treatment of the hippocampal cultures with MAP1B antisense oligonucleotides resulted in a significant decrease in neurite outgrowth. These results suggest that MAP1B plays a role in axonal development and that it is phosphorylated in the growing axons. Supported by NIH grants NS24725 and T32NS07287.

A SPATIAL GRADIENT OF TAU PROTEIN PHOSPHORYLATION IN NASCENT AXONS. J.W. Mandell*, D.L. Benson and G.A. Banker, Dept. of Neuroscience, University of Virginia School of Medicine, Charlottesville, VA 22908.

Tau, a major microtubule-associated protein, has been implicated as a critical molecule for axonogenesis (Caceres and Kosik, 1990; Nature, 343:461). Because the ability of tau to promote microtubule assembly is regulated by phosphorylation, we have measured tau phosphorylation at the subcellular level in cultured rat hippocampal neurons undergoing axonogenesis. Semi-quantitative analysis of tau phosphorylation was achieved by fluorescence ratio measurements on cells double-labeled with a combination of two anti-tau antibodies: tau-1, a monoclonal antibody recognizing a tau epitope only in its dephosphorylated state, and 7A5, a polyclonal antibody recognizing amino terminal epitopes on tau independent of phosphorylation state. Measurements on neurons cultured for 24 hr revealed three consistent findings: 1) the distribution of total tau protein was relatively unpolarized; it was found not only in axons but also in somata and minor processes (dendrite precursors). 2) the distribution of dephospho-tau was markedly polarized to the nascent axon. 3) the polarized axonal distribution of dephospho-tau was not discontinuous but took the form of a spatial gradient: the ratio of dephospho-tau to total tau increased smoothly in a proximo-distal fashion. Minor processes, whether from cells with axons or without, lacked a detectable phosphorylation gradient. Enzymatic dephosphorylation of fixed cells with alkaline phosphatase dramatically increased the tau-1 signal in all cellular compartments without affecting 7A5 immunofluorescence. The magnitude of the alkaline phosphatase effect was greater in somata and minor processes than in axons, consistent with the presence of more highly phosphorylated tau in these compartments. The generation of subcellular phosphorylation gradients may be an early step in neuronal polarization. Current studies are aimed at understanding the genesis of the tau phosphorylation gradient and the relationship between axonal growth and local control of tau phosphorylation. Supported by grants NS17112, NS07199, NS09491, MH10301.

448.11

THE LOCALIZATION OF CALCINEURIN IN CULTURED NEURONS AND THE FUNCTIONAL CONSEQUENCES OF ITS INHIBITION. A. Ferreira, R.L. Kincaid and K.S. Kosik*, Harvard Med. Sch. Boston, MA 02115 and NIAAA, Bethesda, MD 20852.

In vitro studies have shown that calcineurin (CN), a Ca^{2+} /calmodulin dependent protein phosphatase highly enriched in neurons, is involved in the dephosphorylation of tau, MAP-2 and tubulin among other substrates. Here we show that CN is localized at the growing tip of neuritic processes in cultured cerebellar macroneurons. This localization depends upon intact actin filaments and microtubules. These observations suggest that CN is well positioned to mediate the interaction among different cytoskeletal elements during neurite outgrowth. To test this hypothesis, E15 cerebellar macroneurons were treated with the CN inhibitors, cyclosporin A and the autoinhibitory peptide C, for 24 hrs. The results show that: 1) although treated cells normally extend minor neurites they failed to elongate one as an axon; 2) tau proteins no longer remain attached to microtubules; 3) there is a lack of immunoreactivity for Tau-1, an antibody directed to a tau dephosphorylated epitope, both by immunocytochemistry and immunoblot analyses; 4) acetylated microtubules are present in a single neurite, suggesting that microtubule stabilization, an early step in polarity acquisition has taken place. Taken collectively, these results suggest that CN may be involved in axonal elongation by regulating the state of phosphorylation of tau proteins. This phosphorylation event may regulate tau binding to microtubules and the rapid elongation phase of neurite outgrowth.

448.8

THE LOCALIZATION OF PHOSPHORYLATED CYTOSKELETAL ELEMENTS DURING THE ESTABLISHMENT OF POLARITY BY CULTURED HIPPOCAMPAL NEURONS. D.L. Benson*, F.H. Watkins, J. W. Mandell, and G. Banker, Department of Neuroscience, University of Virginia School of Medicine, Charlottesville, Virginia 22908

The differential distribution of phosphorylated and non-phosphorylated neurofilaments is commonly used as a marker of neuronal polarity. SMI31, an antibody directed against a phosphorylated epitope of neurofilament H, is commonly used as a marker for axons. We investigated the development and distribution of SMI31 immunoreactivity in hippocampal cultures. Western blots revealed that at E18 (when hippocampal neurons are taken for culture) virtually all SMI31 immunoreactivity was concentrated in a band that comigrated with MAP1B rather than neurofilament H, confirming an earlier report by Fischer and Romano-Clarke (J. Neurochem. 55:328, 1990). When the blots were treated with alkaline phosphatase, all immunoreactivity for SMI31 was eliminated. In the first few hours after plating hippocampal neurons, SMI31 immunostaining was faint and uniformly distributed throughout neuronal cell somata and minor processes. When a single process exceeded the others in length, becoming the axon, SMI31 immunoreactivity became concentrated in that process. By 3 days, SMI31 immunoreactivity was entirely confined to axonal processes. Within the axon, immunostaining was distributed in a gradient which became more intense distally. SMI31 immunoreactivity was frequently excluded from the most proximal portion of the axon. We conclude that early in culture, the majority of SMI31 immunoreactivity represents MAP1B. The phosphorylated form of MAP1B can stabilize microtubules and is thought to play a role in neurite outgrowth by PC12 cells. In hippocampal neurons, as in cortical neurons (Mansfield et al., J. Neurocytol. 21:1007, 1991), MAP1B may contribute to the selective outgrowth of the axon that is an early event in the establishment of neuronal polarity. Supported by NIH grant NS23094, NS09491 and postdoctoral fellowships MH10301 and NS09491.

PHOSPHORYLATION OF HUMAN TAU PROTEIN. S. Green, E. M. Clark, R. Carlsen*, and R. Vulliet, Dept. of Veterinary Pharmacol. and Tox., Dept. of Human Physiol., Univ. of Calif., Davis, CA 95616

Human tau protein was observed to be multiply phosphorylated when expressed in SF-9 cells. Infection of SF-9 cells with tau containing baculovirus resulted in the multiple bands of tau protein. Exposure of the infected cells with okadaic acid, a phosphatase inhibitor, decreased the rate of migration of tau protein when analysed by SDS PAGE. Treatment of the BCV expressed-tau with either alkaline phosphatase or hydrofluoric acid increased the rate of tau migration. This rate of migration was identical rate to tau protein that was expressed in *E. Coli*. Using ^{32}P -labelled inorganic phosphate to label tau *in situ*, the rate of migration of the tau protein was inversely related to its degree of phosphorylation. Tryptic analysis of the phosphorylation sites revealed the presence of sites in addition to those known to be phosphorylated by the proline-directed protein kinase (cyclin A/p34 kinase).

DEVELOPMENTAL EXPRESSION OF A NOVEL SET OF MICROTUBULE-ASSOCIATED PROTEINS DURING CELL DIFFERENTIATION IN THE RAT BRAIN. T.A. Comery*, N. Hawrylak, T.L. Karr and W.T. Greenough, Depts. of Psych., Biochem., Cell and Structural Biol., Neuroscience Program, and Beckman Institute, Univ. of Illinois, Urbana, IL 61801.

We have been investigating immunoreactivity to three novel proteins identified in *Drosophila* that co-purify with the microtubule fraction (Alcantara et al., Soc. Neur. Abst., 1992; Srinivasan et al., Soc. Neur. Abst., 1992). Immunoblot analysis indicates that these proteins are developmentally regulated in the rat cerebellum (see adjacent poster). Here we describe the spatiotemporal patterns of expression of immunoreactivity to the three antibodies (termed FLAT-MAPs 1, 2 and 3) on postnatal days 1, 5, 7, 10, 14, 21 and 35.

Expression of immunoreactivity to all three antibodies within the cerebellum displays no consistent pattern prior to P7. Expression of FLAT-MAPs 1 and 3 is diffuse throughout the cerebellar cortex at P5 with punctate labeling of Purkinje cell somata and dendrites at P7 and P10. Diffuse labeling in molecular, Purkinje cell and granule cell layers diminishes gradually following P10. FLAT-MAP2 is consistently observed in parallel fibres at P7 but not at earlier or later developmental ages. All three cerebellar cortical layers express diffuse FLAT-MAP2 labeling prior to P7, with expression declining to background levels at later developmental ages. Similar developmental regulation of the expression of these proteins is observed in other brain regions. The expression of these proteins corresponds to periods of process extension, cell differentiation and synapse formation. Supported by MH40631 and NSF BNS 88 21219.

CHARACTERIZATION OF THREE NOVEL MICROTUBULE-ASSOCIATED PROTEINS EXPRESSED IN *DROSOPHILA MELANOGASTER* EMBRYOS AND RAT BRAIN. S. Srinivasan, C.O. Doge* and T.L. Karr. Dept. of Biochem., and Cell & Structural Biology, Beckman Institute, Univ. of Illinois, Urbana, IL 61801

Microtubule-Associated Proteins (MAPs) are a group of heterogeneous proteins that co-purify with tubulin during microtubule purification. The functional roles of MAPs in the cell are poorly understood. We are interested in using the *Drosophila* embryo to characterize neural MAPs. We have used purified MAP fractions from 16 hour *Drosophila* embryos as antigens and obtained three monoclonal antibodies of which two recognize proteins expressed in the *Drosophila* ventral nerve cord. These three antibodies recognize proteins in rat brain and hence we have named these cross reactive antibodies ELY-rAT or FLAT-MAPs. Two dimensional immunoblots with microtubule proteins from 6 and 16 hour *Drosophila* embryos with FLAT-MAPs 1,2 & 3 indicate that these proteins are expressed in different isoforms during embryonic development. Western blots with cerebellar cell extracts obtained from rats at postnatal days 1,5,7,10,14,21,35 & 90 indicate that FLAT-MAPs 1,2, & 3 increase and subsequently decrease during development of the rat cerebellum. Furthermore, all three FLAT-MAPs are present in the purified (Microtubule Proteins) MTP fraction from rat brain. Immunoblots with FLAT-MAPs 1,2, & 3 were performed on *Drosophila* MTP taken through four cycles of assembly and disassembly. FLAT-MAPs 2 & 3 were determined to be Quantitative MAPs or Q-MAPs since the ratio of MAP/tubulin remains constant through successive assembly/disassembly cycles.

DYNAMICS OF PHOSPHORYLATION AND ASSEMBLY OF THE HIGH MOLECULAR WEIGHT NEUROFILAMENT PROTEIN IN MOUSE CNS

I. Fischer, M.L. Beermann, R.A. Nixon, M.A. Edwards* and T.B. Shea
McLean Hospital, Shriver Center, Harvard Med. School, Med. Coll. Penn.

Phosphorylation of the high molecular weight neurofilament subunit (NF-H) results in multiple isoforms that migrate on SDS-gels at approximately 200kDa (Hphos). Hphos was detectable in immunoblots of cytoskeletal fractions at embryonic day 17 (E17), increased from postnatal day 14 (P14)-P60, and remained high from P60-P120. A transient appearance of Hphos was detected in the Triton-soluble fraction from P14-60 by 3 different antisera directed against Hphos and a monoclonal antibody (SMI-31) directed against phosphorylated NF-H and NF-M epitopes. Certain polyclonal antisera demonstrated that over 50% of the H-200 was Triton-soluble between P14-60. However, soluble Hphos was not reactive with RT97 or SMI-34, although cytoskeletal Hphos was strongly reactive with these antibodies, indicating that certain phosphorylation events are only characteristic of cytoskeletal Hphos. Alkaline phosphatase treatment diminished Triton-soluble Hphos immunoreactivity. Unlike NF-H, NF-M and NF-L were at all times present only in the cytoskeletal fraction.

Retinas and proximal axons of adult mouse retinal ganglion cells contain Triton-soluble Hphos as determined by immunocytochemical and immunoblot analyses with SMI-31 and polyclonal anti-Hphos antibodies. Pulse-chase radiolabeling analyses followed by immunoprecipitation demonstrated that a percentage of newly-synthesized NF-H subunits were converted to Hphos forms within retinas before they were axonally transported and incorporated into Triton-insoluble structures. These findings raise the possibility that NF-H assembly behavior may differ from that of NF-M and NF-L during postnatal development, and that the interaction of NF-H with neurofilaments may be more dynamic than is generally recognized.

A PHOSPHORYLATION-DEPENDENT EPITOPE OF THE NEUROFILAMENT PROTEIN NF-M EVOKED IN CHICK SENSORY AXONS BY SECOND MESSENGERS AND TURNING. M. Szente and L. Landmesser*, Dept. of Physiology & Neurobiology, University of Connecticut, Storrs, CT 06269-3042.

In vivo, Mab 5E10 recognizes a phosphorylation dependent epitope of NF-M that is expressed by chick lumbar sensory and motor axons during initial outgrowth beginning at specific points where subsets of growth cones diverge to grow toward their own targets, apparently upon detection of target-derived guidance cues. In explant cultures of E6-7 day DRG neurons two types of 5E10 expression were evoked. First, a variety of external stimuli including depolarization, calcium ionophore and phorbol ester treatment caused a transient increase in expression of 5E10 that returned after several hours to the low background level characteristic of DRG neurons. Expression was reduced below background by treatments that inhibit PKC, such as long term-TPA, staurosporine, and sphingosine. Second, a much more intense and stable expression was evoked in the growth cones and distal neurites of cells as they encountered a boundary, and expression was maintained in that portion of the neurite that turned and continued to grow along the boundary. Associated with this was a cytoskeletal rearrangement in which more of the 5E10 antigen was incorporated into the triton-insoluble cytoskeleton, and in which neurites became more resistant to agents that cause axon retraction, including those that depolymerize microtubules. Axons treated with staurosporine did not increase 5E10 expression at the boundary and did not turn. It is suggested that 5E10 expression and/or some associated cytoskeletal rearrangement is part of a mechanism by which growth cones respond to certain extrinsic guidance cues and alter their trajectories.

ANALYSIS OF mRNA AND PROTEIN DISTRIBUTION OF THE MICROTUBULE-ASSOCIATED PROTEIN TAU DURING NEURONAL DIFFERENTIATION. E. LoPresti*, Y. Wang, R.P. Zinkowski and L.I. Binder. Dept. of Cell Biology, Univ. of Alabama at Birmingham, Birmingham, Alabama 35294-0005.

The microtubule associated protein tau is concentrated in the axons of neurons. However, tau proteins are also found in the somatodendritic compartment as well. Recently, our laboratory reported the presence of nuclear tau in cultured human cells concomitant with the expression of a novel 2 Kb tau transcript (Wang et al. J. Cell Biol. 121:257-267, 1993). We have utilized fluorescence microscopy to analyze tau protein distribution by immunofluorescence and tau mRNA distribution by Fluorescence In Situ Hybridization (FISH) during differentiation of the human neuroblastoma cell line SHSY5Y induced by aphidicolin and nerve growth factor. Immunostaining of undifferentiated SHSY5Y cells with the Tau-1 antibody demonstrated the expression of both nuclear and cytoplasmic tau. Detection of tau mRNA by FISH using a labeled 3-repeat tau cDNA revealed that the majority of tau message displayed perinuclear localization. In differentiated SHSY5Y we observed reduced nuclear tau immunostaining coupled with a dramatic increase in tau immunostaining along numerous neuronal processes. As well, FISH revealed a redistribution of tau mRNA during differentiation. Tau mRNA appeared to be distributed uniformly throughout the cell body and many of the processes formed during differentiation exhibited patches of fluorescence suggesting that pools of the message are targeted to specific regions of neurites. As expected, some extensions did not have any staining, suggesting that they represent axon-like neurites. Currently, we are attempting to identify tau mRNA positive extensions as dendritic- or axon-like neurites by differential immunostaining and FISH. We are also attempting to correlate the changes in nuclear versus cytoplasmic tau immunostaining with alternative targeting of tau mRNA in undifferentiated versus differentiated cells. NEUROFILAMENT PROTEINS AS MARKERS FOR NEURITE MATURATION IN DISSOCIATED EMBRYONIC SPINAL CORD CULTURES OF *XENOPUS LAEVIS*. W. Lin* and B.G. Szaro. Dept. of Biol. Sci., SUNY-Albany, Albany, NY 12222.

Dissociated embryonic spinal cord cultures of *X. laevis* have been used to study channel activities, membrane properties, synaptogenesis and tubulin dynamics of developing neurons. A major question in any dissociated culture system is how closely it matches what happens *in situ*. During development, newly differentiated neurons express neurofilament (NF) proteins in a progression indicative of axonal maturation. We used a panel of NF antibodies, previously characterized on developing spinal cord neurons *in situ*, to assess neurite development in *Xenopus* cultures started at stage 22. These antibodies react with two low molecular weight neurofilament proteins (NF-L and *Xenopus* neuronal intermediate filament protein (XNIF)), non-phosphorylated NF-M and NF-H, and two distinct phosphorylated epitopes of NF-M. As determined by immunofluorescence, both XNIF and non-phosphorylated NF-M began to appear in neurites within the first 3 hours. Gradually over the next two days, NF-M in neuritic processes became progressively more phosphorylated, and NF-L was also expressed. These early events followed a similar timecourse in culture as *in situ*. However, few cultured neurons survived long enough to have mature axons expressing NF-H. On the third day of culture, less than 10% of surviving neurons expressed NF-H. Nevertheless for the first two days in culture, neurites closely resembled axons differentiating *in situ*. NIH R29-NS30682.

CYTOSKELETAL MECHANISMS AND SUBSTRATE INTERACTIONS THAT INITIATE NEURITE OUTGROWTH. C.L. Smith*. Lab. of Neural Control, NINDS, NIH, Bethesda, MD 20892.

Neurite formation by chick peripheral ganglion neurons grown *in vitro* involves invasion of filopodia by cytoplasm from the perinuclear region. In cultures grown on polyornithine, invasion can be initiated by contact of the tip of a filopodium with a large polyornithine-coated polystyrene bead. After the tip of the filopodium attaches to the bead, the filopodium detaches from the substrate and straightens, suggesting that it is under tension. Cytoplasm begins to invade the filopodium just as it begins to straighten or shortly thereafter. Concurrently, the entire cell body moves toward the base of the filopodium. For this sequence of events to occur, the bead must be attached to the substrate and, if it detaches, the cytoplasm retracts back into the cell body. A model of the cytoskeletal interactions that produce these movements is proposed, based on the observation that filopodia retrogradely transport small beads that attach to their surfaces and the hypothesis that the beads move because they are coupled to actin filaments that are pulled retrogradely by molecular motors (Sheetz, et al., Cell 61: 231, 1990). The present model suggests that when a large, immobile bead becomes coupled to actin filaments, the retrograde movement of the filaments is impeded. The stress produced by the molecular motors pulling actin filaments toward the cell body straightens the filopodium, causing it to detach from the substrate. The same motors might pull perinuclear cytoplasm into the filopodium. The prediction that actin filaments in filopodia cease moving retrogradely when they become distally anchored is currently being tested by monitoring the movements of small beads on the surfaces of filopodia while their tips attach to large beads.

TIME SERIES ANALYSIS OF GROWTH CONE MOTILITY AND SIMULATED MICROTUBULE DYNAMICS. D.J. Odde* and H.M. Buechner. Department of Chemical and Biochemical Engineering, Rutgers University, Piscataway, NJ 08855.

Cytoskeletal dynamics are an important feature of neurite outgrowth. An outstanding problem is the relationship between microtubule assembly and growth cone motility. Here we apply time series analysis to provide an objective and quantitative framework for characterizing the net displacements of rat superior cervical ganglion (SCG) growth cones and simulated microtubules. Microtubule length life histories were simulated assuming constant growth and shrinkage rates coupled with random selection of growth and shrinkage times from gamma probability distributions, a formulation based on the dynamic instability model of microtubules. A basic parameter set was chosen, 10 $\mu\text{m}/\text{min}$ growth and shrinkage rates and 60 sec mean growth and shrinkage times, and then varied over several orders of magnitude. Net microtubule displacements were calculated over discrete time intervals and characterized using the power spectrum as well as the autocorrelation and partial autocorrelation functions. Simulated microtubules showed significant autocorrelation and periodicity depending on the sampling rate and the dynamic parameters. The time series analysis was sensitive to variations in the growth and shrinkage time probability distributions and the mean time spent in one phase relative to the other but not to the growth and shrinkage rates. Since growing axons contain parallel arrays of microtubules, we simulated and characterized noninteracting microtubule populations. The time series behavior was not significantly different than that for a single microtubule with the same parameter set. For comparison, we characterized experimental measurements of rat SCG growth cone centroid displacements in the directions parallel and perpendicular to the axon. Five growth cones had uncorrelated, nonperiodic displacements while 1 was correlated and periodic. Our results indicate that growth cones and simulated microtubules possess a variety of potential dynamic behaviors, in keeping with the complex and highly adaptable nature of the nerve growth cone.

Cytoskeletal changes and retarded neurite outgrowth accompany the inhibition of AChE in non-cholinergic neurons. J.L. Dupree and J.W. Bigbee. Dept. of Anatomy, Med. Coll. Va., Richmond, VA 23298

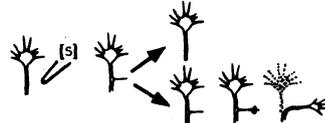

While various non-cholinergic roles for AChE have been suggested, a consistent finding is its transient expression during neurite outgrowth. Our previous results have shown that pharmacological inhibition of AChE retards neurite outgrowth from non-cholinergic dorsal root ganglion neurons (DRGN) grown on collagen. In the same system, neurite outgrowth and AChE activity co-vary with the permissiveness of the extracellular matrix (Gupta and Bigbee, J. Neurosci. Res., 31:454, 1992). In the present study, dissociated DRGN from E15 rat embryos were grown on Type I collagen or the reconstituted basal lamina, Matrigel™ in the presence of BW 284c51 (BW), a specific AChE inhibitor, at 10^{-4}M to 10^{-7}M . After 14 days, morphometric analyses of outgrowth and electron microscopy were performed while additional cultures were allowed to recover from the BW treatment. BW treatment resulted in a dose dependent reduction in outgrowth on both substrata with more pronounced inhibition on the less permissive collagen. Analysis of cell number revealed no difference in cell survival between groups and removal of BW resulted in normal recovery of outgrowth. Interestingly, the cell bodies of BW-treated neurons contained large spiraling masses of 8-10 nm filaments which resembled Pick's bodies or inclusions seen in ganglioneuromas and were often associated with large Golgi bodies. These data suggest that AChE may play a role in axonal outgrowth and that the induction of cytoskeletal accumulations may provide a model for reversible neuropathies.

IN VITRO INDUCTION OF BACKBRANCHES: IMPLICATIONS FOR AN ALTERNATE MECHANISM OF TARGET LOCATION. C.V. Williams*, R.W. Davenport, P. Dou, S.B. Kater. Anatomy and Neurobiology, Colorado State University, Ft. Collins, CO 80523.

Backbranches may play a critical role in the formation of neuronal connections during development. One model suggests that filopodial-like outgrowths can be induced along the neurite shaft in response to

environmental stimuli [S]. If appropriate cues are detected, the outgrowth could be maintained, transformed to a backbranch and possibly become the primary axon.

We have begun to study the hypothesis that filopodial-like outgrowths can become neurites, which eventually form synaptic connections. We have studied the *in vitro* induction of backbranches in response to locally applied stimuli known to induce growth cone filopodia in cultured *Helisoma* neurons. Outgrowths can be consistently induced along relatively smooth neurites in response to a locally applied electric field (>90%, n>50). These outgrowths rapidly elongate toward the electric field source, often reaching lengths of 30-40 μm . These dimensions are comparable to those of induced filopodia. Also like filopodia, induced outgrowths orient toward the cathode side of the field. This phenomenon is a developmentally constrained process, since these outgrowths can not be induced along neurites of neurons at stable state. This is the first *in vitro* evidence demonstrating the initial steps in the induction of backbranches and supports the first step in the proposed model.

IN SITU HYBRIDIZATION REVEALS CHANGING DISTRIBUTION OF LAMININ EXPRESSION DURING NEURONAL DEVELOPMENT AND AFTER INJURY IN THE LEECH CNS. A.E. Luebke*, I.M. Dickerson, and K.J. Muller. Dept. of Physiol. & Biophysics and GRECC, Univ. of Miami Med Sch, Miami, FL 33101

A laminin-like molecule extracted from the leech nerve cord promotes neurite outgrowth *in vitro* (Masuda-Nakagawa *et al.*, 1988). Laminin-like immunoreactivity, which in the adult CNS is confined to the perineurial sheath, reappears within the CNS after injury. Yet, the source of laminin is not known. To determine which cells in the leech CNS are synthesizing laminin, a probe was generated for leech laminin by degenerate PCR based on conserved regions of vertebrate and *Drosophila* B2-laminins.

Messenger RNA was isolated from juvenile leeches, reverse-transcribed, and subjected to PCR. The resulting probe was 1.3 kb in length, and showed striking sequence homology to other laminins. A digoxigenin-labeled riboprobe was synthesized using RNA polymerase and visualized using an alkaline phosphatase-conjugated antibody.

In 10-14 day embryos, laminin is expressed in cells throughout the perineurial sheath and in the vicinity of axon-bundles. In embryos older than 17 days and adults, laminin expression is confined to the perineurial sheath despite probe access deeper within the ganglia and connectives. If a crush is made to the connectives in either 17 day old embryos or adults, laminin expression markedly increases within the nerve cord, matching published increases in appearance of laminin immunoreactivity. Preliminary results indicate that microglia can synthesize laminin at the crush site. (Supported by NIH and AHA grants).

DIFFERENTIATION OF DROSOPHILA PHOTORECEPTOR CELLS IN PRIMARY CULTURES. Chinglu Li* and I.A. Meinertzhagen. Life Sciences Centre, Dalhousie University, Halifax, Nova Scotia, Canada B3H 4J1.

In order to procure synaptogenesis and explore possible trophic interactions in *Drosophila melanogaster* between cultures of photoreceptor and optic lobe cells we have developed a primary culture system and optimized the conditions for co-culturing the two cell types. Eye imaginal disc fragments and optic lobe cells from wild-type 3-hr white pupae were cultured in several media using supplements of fetal bovine serum (FBS). Eye discs were more exacting in their culture requirements than optic lobe cells. While optic lobe cells survive and differentiate well in nearly all conditions tested, the best survival of, and neurite outgrowth from, eye disc cultures was obtained with MM3 medium supplemented with 2% FBS or from 27% Liebovitz L-15 medium with 5% FBS. Greater FBS concentrations delayed neurite outgrowth, while with lower FBS concentrations both survival and neurite outgrowth were poorer. Both eye disc fragments and optic lobe cells underwent mitoses in both culture conditions; optic lobe BrdU incorporations were most frequent after 2 hrs *in vitro*, declining about 50% by 10hrs, mirroring development *in vivo*. Vigorous neurite outgrowth was observed from both cultured cell types. Ommatidial clusters recognizable in some eye disc fragments persisted during the culture period. By 4d *in vitro*, a transparent cornea-like sheet covered some eye disc fragments. Both optic lobe and eye disc fragment cells were immunoreactive to anti-HRP, an insect neuronal marker. In addition, eye disc cultures were immunoreactive to photoreceptor-specific monoclonal antibodies 22C10 and 24B10. We also examined histamine immunoreactivity, which is found in the mature photoreceptor. Cultured eye disc fragments and their neurites were histamine-immunoreactive, and double staining revealed that histamine positive fibers were also immunoreactive to 24B10. Absence of histamine immunoreactivity in some 24B10 positive cells could reflect earlier onset of immunoreactivity to 24B10 than histamine.

DYNAMIC ANALYSIS OF ACTIN FILAMENTS IN GROWTH CONES. C.S. Cohan* and P. Torrealba. Depts. of Anatomical Sciences and Biophysics, SUNY at Buffalo, Buffalo, N.Y. 14214.

The motility of growth cones is closely associated with their morphological properties. For example, stimuli that inhibit growth cone movements cause a loss of filopodia and retraction of the lamellipodium. The morphological properties of growth cones are derived from their cytoskeleton, which consists of microtubules and actin filaments. The distribution of these components differs such that microtubules are restricted to the central mound whereas actin filaments are present throughout the lamellipodium as a meshwork and as bundles in filopodia. The focus of this work was to determine whether changes in growth cone motility and structure result from changes in the organization of actin filaments.

Actin filaments in growth cones were directly visualized using a fluorescent precursor, g-Actin. Neurons of the pond snail *Helisoma* were pressure injected with rhodamine-labeled g-Actin. Pictures were acquired using a CCD camera at exposures of 400 msec.

Three to four hr after injection of g-Actin into cell bodies, actin filaments were brightly stained in filopodia as well as actin filament meshwork in the lamellipodium could be visualized. Dynamic movements of actin filaments were studied in isolated neurons by time-lapse images acquired at 1-2 min intervals. These movies demonstrated the retrograde movement of actin filaments in both the lamellipodial meshwork and filopodial bundles. Application of KCl, as reported previously, caused retraction of the lamellipodium and loss of filopodia. Actin filaments were still visible in these growth cones, and actin bundles extended through filopodia that lengthened as growth cone retraction ensued. These experiments make it possible to correlate changes in actin filaments with alterations in growth cone function.

DIFFERENCES IN REGENERATIVE GROWTH FROM CRA YFISH TONIC AND PHASIC MOTOR AXONS. K. Egid* & G.A. Lnenicka Dept. of Biol. Sci., State Univ. of New York, Albany, New York 12222

Terminals of tonically and phasically active motoneurons of crayfish have characteristic differences in physiology and morphology (Lnenicka, N.Y. Aca. Sci. 627: 197-211, 1991). To examine the development of these differences, we used an explant of the crayfish abdominal nerve cord in which tonic and phasic axons grow from separate branches of the third roots onto a polylysine substrate. The *in vitro* axonal growth differed between tonic and phasic neurons. The rate of neurite outgrowth from phasic axons ($X=1.72$ mm/day) was significantly greater than for tonic axons ($X=0.36$ mm/day). Neuritic arbors of the phasic axons had a denser appearance due to the fact that they produced twice as many branches within the same area as did tonic axons (67.4 vs 33.4). Growth cones of phasic axons were larger than those of tonic axons. Our results suggest that some of the morphological differences between the tonic and phasic motor terminals are related to differences in the growth programs of the motoneurons. For identified motoneurons, we are further quantifying the relationship between the neurite branching pattern and diameter observed *in vitro* and the morphology of motor terminals examined *in situ*. In addition, we are investigating the role of impulse activity in these differences in axonal growth. (Supported by NSF grant IBN-9121757)

449.7

THE DEVELOPMENT OF THE PERIPHERAL TERMINAL FIELDS OF AP AND DORSAL T NEURONS DEPENDS ON PIONEER DORSAL P NEURONS W.B. Gan, L.R. Woloszyn* and E.B. Macagno Dept. of Biological Sciences, Columbia University, New York, N.Y. 10027

Pioneer neurons are necessary for the initial outgrowth of late-developing neurons in some systems. This study investigates their function in the formation of the terminal fields of some late-developing neurons in the leech *Hirudo medicinalis*. The dorsal pressure-sensitive neurons (PD) are among the first neurons to send axons along the dorsal-posterior nerve towards the dorsal body wall. By staining with two different fluorescent dyes (DiI and DiO), the peripheral branches of the AP and TD neurons are found to follow precisely the processes of the PD cells, up to their fourth-order branches. Four to five days after killing the PD cell at embryonic day 8, the AP and TD cells showed significantly reduced axonal outgrowth and dramatically abnormal branching patterns in the dorsal body wall. This result suggests that the PD cell is a pioneer neuron that is critical in promoting axonal outgrowth of the AP and TD neurons, and in guiding the normal formation of their terminal fields. Interestingly, the PD cells have large numbers of filopodia along their axons and at their growth cones, most of which disappear gradually, whereas the AP and TD cells have few or no filopodia. Currently, we are investigating the function of these filopodia in pathfinding by these neurons.

CILIARY NEUROTROPHIC FACTOR INDUCES NEURITE OUTGROWTH IN CULTURED HELISOMA NEURONS.

D.-B. Wang, A. G. M. Bulloch* and K. Lukowiak. Dept. Med. Physiol. and Neurosci. Res. Group, Univ. of Calgary, Calgary, Alberta, Canada T2N 4N1

The response of identified neurons from the fresh water snail, *Helisoma trivolvis*, to different neurotrophic conditions was investigated *in vitro*. Individually isolated motoneurons or interneurons from adult *Helisoma* central nervous system were cultured in defined medium (DM), DM supplemented with recombinant rat ciliary neurotrophic factor (CNTF), or brain-conditioned medium (CM). These neurons did not exhibit significant neurite outgrowth in DM alone. However, the cells showed extensive neurite outgrowth after two to three days in either CM or CNTF-supplemented DM. This observation, together with previous experiments on the related mollusc *Lymnaea* (Bullock et al., Soc. Neurosci. Abstr, 1992), supports that CNTF-like factors may exist in more than one mollusc species. This result also indicates that the effect of CNTF on neurite outgrowth is not mediated indirectly via non-neuronal cells or other factors but directly on the neurons themselves, suggesting the existence of CNTF receptors on these cells. Supported by MRC (Canada).

CYPROHEPTADINE BLOCKS 5-HT INHIBITION OF LESION-INDUCED SPROUTING IN THE SNAIL CNS. M. W. Baker* & R. P. Croll. Dept. of Physiol. & Biophys., Dalhousie Univ. Halifax N.S. Canada.

We have previously documented (Baker & Croll, Soc. Neurosci. Abstr, 18) that, following a cut to the cerebral-buccal connective in the snail *Achatina fulica*, serotonin content in the ipsilateral buccal ganglia is depleted as a result of distal degeneration of fibers from the ipsilateral, serotonergic, metacerebral giant (MCG) cell. Dye-injections, electrophysiological measures and HPLC quantification all suggest that the uninjured, contralateral MCG normally sprouts into the denervated buccal ganglion, but this sprouting can be suppressed by injections of 5-HT (every second day) following the lesion. These findings suggest that neuritic sprouting by the MCG in the buccal ganglia may normally be tonically inhibited by the serotonergic innervation of that ganglion.

In this report we use selected serotonergic antagonists to investigate the receptor(s) involved in this inhibition. Intracellular recordings from the MCG soma reveal that focally applied 5-HT results in a slow depolarization, which is characterized by an increase in R_m and which reverses near E_{K^+} , suggesting that one action of 5-HT may be a decreased gK^+ -dependent depolarization. This depolarization is effectively blocked *in vitro* by the vertebrate 5-HT₂ blocker cyproheptadine (CYP). CYP (0.5 mg in saline) when administered 1 hour prior to injection of 5-HT (0.5 mg in saline every second day) also blocks the inhibitory influence of 5-HT on MCG sprouting following the lesion; sprouting by the uninjured MCG 4 weeks following the lesion is within the range expected of untreated lesioned animals and lesioned animals treated by CYP alone.

These results provide *in vivo* evidence that a neurotransmitter can exert receptor-mediated influences upon neuronal outgrowth and provide a model system in which to examine how 5-HT might govern normal innervation in an intact nervous system.

APLYSIA HEMOLYMPH ENHANCES NEURITE OUTGROWTH FROM IDENTIFIED HELIX NEURONS IN CELL CULTURE.

Santarelli L., Ghirardi M., Casadio A., Montarolo P.G. Dept. of Human Anatomy & Physiology, C.so Raffaello 30 - 10125 Torino. Italy (Spon: ENA)

Isolated cells grown in culture provide an excellent system for examining synapse formation and plasticity. We have obtained a robust growth of identified neurons from the cerebral ganglion of *Helix Pomatia* in dissociated cell culture. The two large cerebral neurons C1 and C3 from small adult animals were isolated by enzymatic and mechanical dissociation and plated onto polylysine-coated dishes that contained either conditioned medium or that were pretreated with *Aplysia* hemolymph. The conditioned medium was obtained by exposing *Helix* cerebral and circumoesophageal ganglia in L15, adjusted to the osmolarity to the *Helix* hemolymph, for 72 hrs. The *Aplysia* hemolymph was added to cover the bottom of the polylysine-treated dishes and left for at least 24 hrs, being removed just before the cells were added.

We have compared the growth effect of the two conditioning factors by measuring neurite elongation and the extent of branching. We have found that: 1) with both conditioning factors cells isolated with their axons remain essentially polar, whereas cells without their original axons sprout numerous processes from their cell bodies. 2) The *Aplysia* hemolymph remarkably enhances the extent and rate of linear neurite outgrowth and the degree of branching. Hemolymph also decreases the diameter of the outgrowing neurite fascicle. Intracellular recording made in *Helix* saline showed that the resting and action potentials of cultured cells were comparable to those of cells *in vivo*.

449.10

NEURITE OUTGROWTH MAY BE INHIBITED BY A RETROGRADELY TRANSPORTED FACTOR IN A HELISOMA NEURON. P. J. Kruk* and A. G. M. Bulloch. Department of Medical Physiology and Neuroscience Research Group, University of Calgary, Calgary, Alberta, Canada, T2N 4N1.

This report continues our study of the mysterious failure of axonal regeneration that can occur in buccal neuron 4 (B4) of the mollusc *Helisoma trivolvis*. This neuron has two axons which innervate the two salivary glands. Both axons can regenerate; however, the ipsilateral axon fails to regenerate when axotomized close to the soma if the contralateral axon is left intact (*J. Neurosci. Res.* 31: 401-412, 1992). This failure occurs both *in vivo* and in organ culture. To test the possible involvement of target-derived factors in this phenomenon, we attempted to block retrograde axonal transport in the intact contralateral axon by local exposure of its distal segment to the antimitotic drug colchicine. Two series of experiments were performed on cultured buccal ganglia with the salivary glands attached. First, the effectiveness of 1 μ M colchicine to block retrograde transport in neuron B4 was demonstrated using Fluoro Ruby. Second, contralateral block of transport after proximal ipsilateral axotomy resulted in an increased success of axonal regeneration of the ipsilateral axon (blind assessment, $p < 0.05$, Mann-Whitney test). This result suggests that the failure of regeneration may be attributed to a factor transported retrogradely from the terminals of the intact contralateral axon. Supported by M.R.C. (Canada) and Alberta Heritage Foundation for Medical Research.

FIRST INGROWTH OF RETINAL AXONS IN THE RHESUS MONKEY EMBRYO. C.H. Meissirel* and L.M. Chalupa. Dept of Psychology and the Center for Neuroscience, University of California, Davis, CA 95616.

In the developing rhesus monkey, the retinal decussation pattern is highly specified at early stages unlike other mammals (Chalupa and Lia, 1991). Thus, this species may provide a unique model to understand the cellular interactions that play a role in sorting out crossed and uncrossed retinal axons at the chiasm. In order to examine the first ingrowth of retinal axons in the monkey we implanted pairs of embryonic retinae in fixed specimen using two carboxyanide dyes DiI and DiA. After brains were stored at 37°C for 5 to 11 weeks, 100-200 µm thick sections were cut with a vibratome and labelled retinal axons were examined using conventional and confocal microscopy. Five fetal rhesus monkey ranging in age from embryonic (E) days 30 to E50 (gestation 165 ± 2 days) have been studied.

Optic axons reach the presumptive chiasm by E35-36. Only a few fibers are just crossing the midline at that age, with the great majority of the retinal axons taking an ipsilateral route. Crossed fibers are intermingled with uncrossed axons before turning abruptly toward the midline. At this age, some cells in the vicinity of the developing chiasmatic region were also labelled, suggesting that closed contacts are formed between ingrowing axons and midline cells. By E40 and E42 numerous labelled axons are located within the chiasm and the most advanced crossed fibers have reached the optic tract. At this stage, there is a clear partial segregation of the crossed and the more numerous uncrossed retinal fibers. Uncrossed axons are mainly located in the deep part of the tract, whereas crossed axons are more superficially placed. By E50 the vicinity of the visual targets is reached.

These results indicate that the leading retinal projections are initially uncrossed in the optic tract of the monkey. Thus, it appears that binocular interactions do not play a role in the choice made by axons when they first enter the optic tract.

PROTEOGLYCAN EXPRESSION BY TECTAL MIDLINE GLIA IN RELATION TO THE GROWTH OF RETINOTECTAL AND INTERTECTAL AXONS IN DEVELOPING HAMSTERS. Sonal Jhaveri*, Dept. Brain & Cognitive Sci., M.I.T., Cambridge, MA 02139.

Glial cells along the tectal midline form a barrier for developing retinal axons and contribute to maintaining the laterality of the retinotectal projection (Wu et al., SN Abstr., 1990). Chondroitin sulfate Proteoglycan (CSPG), deposited along the tectal midline in postnatal animals, may provide a molecular substrate for this barrier function (Wu et al., 1991; Snow et al., 1990). Yet, intertectally projecting axons succeed in crossing through this same glial boundary. Using immunohistochemistry, the developmental expression of CSPG is compared with the times of retinotectal axon ingrowth and of intertectal axon crossing.

CSPG is first detected rostrally along the midbrain raphe around E14, when retinal axons are just beginning to enter the tectum. As retinal axons extend into the caudal tectum, the expression of CSPG proceeds from rostral to caudal along the midline. Some intertectal axons (visualized with TuJ1, an antibody to neuron-specific B-Tubulin, courtesy A. Frankfurter) have crossed the tectal midline by E14, prior to the expression of CSPG along the raphe glia. However, increasing numbers of axons continue to be recruited across the midline over the next few days.

Thus, the early axons projecting across the tectal midline may provide a substrate for later-growing intertectal fibers. Alternatively, retinotectal and intertectal axons may be differentially responsive to CSPG.

MEROSIN IS FOUND WITHIN THE PATHWAY OF AVIAN RETINAL PROJECTIONS DURING DEVELOPMENT. N. Morissette* and S. Carbonetto. Center for Research in Neuroscience, Montreal General Hospital Research Institute and McGill University, Montreal (Quebec) CANADA H3G 1A4.

The developmental regulation of integrins in avian retinal ganglion cells (RGCs) correlates temporally with the growth of these cells to their targets in the tectum. Merosin, an A-chain laminin isoform, is a potent ligand for integrin-mediated neurite outgrowth by embryonic chick retinal ganglion cells *in vitro* (Cohen et al. (1991) *J. Cell Science* 15, 1-7). In the present study, we provide evidence that merosin is present during development of avian RGC projection pathways.

During the formation of chick retinal projections (embryonic days 7 to 12), merosin immunoreactivity was detected within the optic nerves and chiasm, and within the retinal ganglion cell and nerve fiber layers where ganglion cell bodies and axons are located respectively. In addition, merosin expression was detected along the optic tracts and along the outer surface of the optic lobes. Within the optic tectum, merosin-positive tracts were found associated with the tectobulbar fibers that converge at the base of the tectum to form the tectobulbar tract. The distribution of merosin in the chick retina and along the optic pathway suggests that it serves as a ligand for integrin-mediated outgrowth of RGCs to the tectum.

CHANGES IN THE ORGANIZATION OF GLIAL PROCESSES AND OPTIC AXONS IN THE DEVELOPING CHIASMATIC REGION OF THE FERRET. B.E. Reese*, T.M. Maynard, D.R. Hocking and S.F. Geller. Neuroscience Research Institute and Department of Psychology, University of California at Santa Barbara

The present study has compared the optic fiber reorderings of the chiasmatic region to changing features in the developing glial environment. Three groups of fetuses, sampled at three day intervals beginning on E-24, were used: 1) immunocytochemistry was used to study the distribution of glial processes containing the intermediate filament proteins, vimentin and glial fibrillary acidic protein (GFAP); 2) crystals of DiI were used to label the optic axons as they course through the chiasmatic region, or to label the processes of the radial glial cells; and 3) thin sections of the chiasmatic region were examined with the electron microscope.

Optic axons have invaded the developing chiasmatic region on E-24, with few fibers reaching the optic tract. Vimentin staining is weak within the optic stalk, while staining within the ventral diencephalon is intense and primarily radial. At all later ages, the pattern of vimentin-staining is distinct within the stalk, chiasmatic region, and optic tracts. The stalk continues to be characterized by weakly immunoreactive processes of varying orientation; the chiasmatic region is composed of primarily radial processes that course in a concave direction at the lateral margins; and the optic tract contains both radial as well as parallel vimentin-positive processes, the latter being particularly dense at the deep border of the tract. Those latter processes arise from radial glial cells, as they can be labeled from the ventricular surface. GFAP-positive processes, by contrast, are not observed until E-36, being restricted to the chiasmatic midline, oriented mainly in the radial axis.

The change in the distribution of vimentin-immunoreactive processes between the stalk and chiasmatic region is coincident with the onset of the chronotropic reordering of optic axons, although the distribution of growth cones occupies a greater proportion of the depth of the chiasmatic midline than in the tract. Hence, the chronotropic reordering is established only gradually as fibers traverse the chiasmatic region. The change in the organization of vimentin processes between the chiasmatic midline and the tract is coincident with the sudden segregation of dorsal from ventral optic axons that occurs in this region. The spatial distribution of GFAP-positive profiles is coincident with the locus where temporal optic axons become directed ipsilaterally. However, at least at the stages when GFAP is expressed, optic axons arriving at the chiasmatic midline all take a crossed course.

TWO CHONDROITIN SULFATE PROTEOGLYCAN EXPRESSED DURING CHICK EMBRYO VISUAL SYSTEM DEVELOPMENT. C. Ring*, W. Halfter, and V. Lemmon. Dept. of Neurobiology, Univ. of Pittsburgh, 15261.

Chondroitin sulfate proteoglycans (CSPGs) purified from cartilage have been shown to be inhibitory to neurite outgrowth *in vitro*. Based on these findings, it has been hypothesized that CSPGs function as barrier molecules to neurite outgrowth *in vivo*. We wanted to examine if CSPGs derived from embryonic tissues would have similar effects. We have isolated two monoclonal antibodies (mAbs), 2B9 and 9BA12, which recognize two CSPGs that are developmentally expressed in the chick embryo. The 2B9 mAb recognizes a 1000 kD CSPG with a core protein of approximately 270 kD. Its staining pattern in polyacrylamide gels under reducing conditions, its appearance in rotary shadowed preparations, and its developmental expression in chondrogenic tissues and the vitreous body, suggest that it is a collagen type IX PG. Neurite outgrowth assays reveal that the 2B9 antigen is not a favorable substrate for retinal axon outgrowth alone, however, substrate mixtures of the 2B9 antigen with retinal basal lamina extract, support axonal outgrowth. Neurites growing on these substrates appear fasciculated, with numerous side branches along their lengths.

The 9BA12 mAb recognizes an as yet unidentified CSPG expressed in the retinal optic fiber layer and brain during early embryonic development. The brain-derived 9BA12 antigen does not support retinal fiber outgrowth alone, but is supportive in combination with basal lamina extract. In contrast to the 2B9 antigen, retinal fibers in these cultures appear longer, less fasciculated, and have fewer side branches, indicating that the brain-derived 9BA12 antigen is more supportive for neurite outgrowth than the 2B9 antigen. Our study demonstrates the existence of two species of CSPGs in the developing chick visual system. Their neurite outgrowth supporting activity in combination with basal lamina proteins in *in vitro* culture systems would seem to contradict the hypothesis that chondroitin sulfate proteoglycans are a class of molecules which are inhibitory to neurite outgrowth.

DEAFFERENTED TARGET REGIONS REEXPRESS SPECIFIC GUIDANCE INFORMATION FOR REGENERATING RETINAL AXONS. A. Wizenmann*, E. Bonhoeffer*, S. Klostermann* and M. Bähr*. *Neurologische Universitätsklinik, Hoppe-Seyler-Str. 3, and +Max-Planck-Institut für Entwicklungsbiologie, Spemannstr. 35/I, W-7400 Tübingen

During CNS development a topographic projection of ganglion cells from the retina to the superior colliculus is established. In higher vertebrates, putative guidance molecules for retinal axons seem to be expressed only during the time when the retino-collicular projection is being formed.

We have used the stripe assay to compare the growth of rat and chick retinal axons on membranes from (a) normal adult (control, not deafferented) and (b) deafferented adult rat SC. Deafferentation was achieved by cutting the contralateral optic nerve about 2 weeks before preparation of the SC membranes. Our results show that putative guidance molecules, which are not detectable in the normal adult SC, are reexpressed after optic nerve transection in adult rats. Guidance of both, nasal and temporal retinal axons could be observed *in vitro* as indicated by a preferential growth of retinal axons on membranes from appropriate target regions of the deafferented SC. Furthermore, we found that regenerating retinal axons of adult rats were able to elongate on these membrane preparations and also showed a clear preference for membranes from their appropriate target region.

These findings show that target specific guidance information is reexpressed after deafferentation of the SC *in vivo* and that regenerating adult retinal axons respond to such guidance cues. These results support the hope that topographically ordered projections could possibly be reestablished after lesions in the adult mammalian CNS.

MAPPING CUES THAT DETERMINE THE LAMINA-SPECIFIC BEHAVIOR OF RETINAL AXONS IN CHICK OPTIC TECTUM
M. Yamagata and J.R. Sanes*, Dept. Anatomy and Neurobiology, Washington University Sch. Med., St. Louis, MO 63110.

Retinal axons enter the chick optic tectum through a superficial lamina, the *stratum opticum* (SO); they then extend branches into distinct deeper laminae, arborize, and form synapses (1). To identify cues that guide these behaviors, we developed an organotypic culture system in which a 200 μ m-thick transverse slice of tectum is mounted on a supporting membrane and overlaid by a retinal explant large enough to have direct access to all tectal laminae. When E7 retinal explants were combined with E13-16 tectal slices, retinal axons grew selectively along the SO. Some axons sent branches into the retinal receptive laminae; few extended beyond these laminae. Similar patterns of outgrowth were observed on tecta from embryos that had been enucleated at E3, suggesting that retinal axons were recognizing tectal cues, not merely previously-arriving retinal axons. To test whether these cues are specific for retinal axons, or generally permissive for growth, we prepared cultures in which E6 tectal explants (2) confronted tectal slices. Tectobulbar axons that emerged from the explants did not choose to grow into the SO, but instead grew into the deep laminae that they normally traverse *in vivo*. When tectal slices were methanol-fixed before retinal explants were added, the retinal axons still grew along the SO and branched into retinal target laminae, suggesting that non-diffusible cues guide these behaviors. The experimental accessibility of this culture system may facilitate the cellular localization and molecular identification of these cues. (Refs: 1. Mey & Thanos (1992) *J. Hirnforsch.* 33:673; 2. REGENERATION OF RETINOTECTAL FIBERS IN THE PRESENCE OR ABSENCE OF IPSILATERALLY PROJECTING OPTIC FIBERS IN THE LEOPARD FROG. B.C. Weber and E.R. Gruberg*. Biology Dept., Temple University, Philadelphia, PA 19122.

We previously showed that after midsagittal sectioning of the optic chiasm most retinotectal fibers regenerate to the ipsilateral tectal lobe. These frogs recover vision, but respond to prey and looming stimuli as if a stimulus was not in its actual position but at the symmetrical location in the contralateral field. Are regenerating retinotectal fibers misdirected by mechanical disruption or by cues in the optic chiasm? We made selective cuts in the region of the chiasm: After extracranial, bilateral sectioning of the optic nerves, animals recover with accurate responses. After intracranial, bilateral sectioning of the optic nerves animals respond to the actual stimulus position approximately 80% of the time and to mirror image position 20% of the time (80%A:20%M). After transverse sectioning of the chiasm animals respond with a ratio 80%A:20%M. When transverse and midsagittal cuts are produced together, animals respond with a ratio of 60%A:40%M. After paired, symmetrical, parasagittal cuts of the lateral chiasm, animals respond quite differently from each other (range - 0%A:100M to 70%A:30%M). After unilateral lesion to the optic tract individual animals either show normal behavior (100%A:0%M) or mirror image behavior (0%A:100%M). Using HRP and DiI histochemistry we find that in normal animals ipsilateral projecting fibers have trajectories restricted to the lateral part of the chiasm. Our results suggest that if ipsilaterally projecting optic fibers are spared when retinotectal fibers are cut, mirror image responses are likely. Mechanical disruption plays an additional role in misdirecting regenerating fibers. Supported by NIH EY04366.

THE EARLY DEVELOPMENT OF DESCENDING TECTAL PROJECTIONS IN CHICK. I.T. Shepherd and J.S.H. Taylor. SPON: Brain Research Association Dept. Human Anatomy, University of Oxford, OX1 3QX, UK

The development of two descending projections from the chick tectum has been studied. An initial cohort of axons arises between stages 14-16 and grows dorso-ventrally to the ventral margin of the tectum, where they turn 90° to form a caudally directed tract. This tract descends into the hindbrain past the region of the trigeminal nerve and is assumed to be the tectobulbar tract. A second population of axons emerges at stage 17, initially in the rostral part of the tectum, which also grows dorso-ventrally. These axons fail to turn at the tectal margin, continuing to the ventral midline where the axons decussate and turn caudal, joining the contralateral ventro lateral tract (VLT). These form the tectospinal projection.

Embryos which had either the rostral or caudal tectum ablated at stage 12 and allowed to develop to stage 16/17, show that rostral tectobulbar axons are not dependent on caudal tectal axons for guidance into the hindbrain. It appears that the guidance cues are within the undifferentiated neuroepithelium.

Immunocytochemistry, using an antibody to chondroitin sulphate (CS), shows an increase in staining which delineates the border at which the tectobulbar axons turn caudally. The CS staining at later stages also delineates the VLT. To test whether CS is inhibitory for tectal axons, dissociated cells from E6 tecta have been grown on laminin substrate (100 μ g/ml) dotted with spots of CS. Axon outgrowth is inhibited on the CS spots, an effect that can be reversed by treatment with Chondroitinase ABC. Interestingly on low concentrations of substrate laminin (10 μ g/ml) CS forms a poor yet permissive substrate for tectal axon growth.

To investigate adhesion molecules which might be involved in the guidance of the tectospinal axons, an immunocytochemical study has been carried out. An antibody to chick TAG-1 (a gift from J. Dodd) has been found not to stain the tectobulbar axons, but does stain later developing axons. The expression is along the whole length of these axons and does not show a down regulation at the ventral midline.

HEPARIN BLOCKS TARGET RECOGNITION IN THE DEVELOPING VISUAL SYSTEM OF XENOPUS. S. McFarlane*, A. Walz and C.E. Holt, Dept. of Biology, Univ. of California San Diego, La Jolla, CA 92093-0322.

The axons of developing retinal ganglion cells (RGC) navigate along a defined route and, on reaching the optic tectum, they stop and begin to arborize. Target recognition is mediated by specific interactions between the axon tips and the surfaces of their local environment. Since growth factors and their receptors are expressed in specific regions of the developing brain, we have begun to investigate the possibility that these molecules play a role in recognition events, using heparin and other reagents known to block the action of growth factors.

Exposed brain preparations were used to bath apply reagents to the developing optic tract during the period when RGCs axons grow from the base of the optic tract to the tectum (stages 33/34 to 40), and axons were visualized with HRP at stage 40. Heparin (0.1 mg/ml) had little effect on the trajectories of axons in the optic tract, but had striking effects on retinotectal targeting. Axons typically ignored the tectum, scouting around its edges, and continued to grow beyond it. Rostrally, axons frequently crossed over the dorsal midline, while ventrally, axons extended into the medulla and the spinal cord. Axons that entered the tectum either grew back out, dived deep into the neuroepithelium, or continued on caudally and did not appear to arborize. To test for specificity of action, compounds which act similarly to heparin were also used. Pentosan polysulfate (0.1 mg/ml) showed similar effects to heparin, interfering with normal target recognition, whereas suramin (0.03 mg/ml) retarded growth. Immunohistochemistry showed that basic fibroblast growth factor (bFGF), a heparin-binding growth factor, and heparan sulfate, a heparin-like glycosaminoglycan, appear to colocalize in the developing optic tract. Since heparan sulfate is required for the function of bFGF, it is possible that the effects of heparin and pentosan polysulfate reflect their binding to bFGF. These results show that heparin blocks target recognition without interfering with axonal extension or guidance and suggest that heparin-binding growth factors may be involved in target recognition.

ALTERNATE PROJECTION PATHWAYS FOR XENOPUS RETINAL FIBERS AFTER TECTAL ABLATION.

K.M. MacLeod, S. Cohen-Cory, V. Goss, and S.E. Fraser*, Division of Biology, California Institute of Technology, Pasadena, CA 91125.

We have investigated the possible guidance cues for retinal ganglion cell (RGC) axons as they project to the optic tectum during development. After disruption of their local target environment we observed the paths taken by fluorescently labelled fibers over several successive days *in vivo*. Ablations of the left tectum or the adjacent diencephalon were performed on stage 37-45 *Xenopus laevis* embryos, and RGC axons were labelled by pressure injection of contralateral temporal or nasal retina with DiI. The live embryos were viewed by video microscopy over a 24-72 hour period. In embryos in which the diencephalon only or diencephalon and rostral tectum were removed, a significant number of both temporal and nasal axons showed a tendency to reverse direction after passing the optic chiasm but before reaching the tectum and course toward the ipsilateral side, in most cases reaching and arborizing in the ipsilateral tectum. Other path fates included passing the chiasm and continuing down the contralateral optic nerve toward the eye or projecting rostrally into the forebrain. If the diencephalon were left intact but rostral tectum removed, the axons stalled and remained at the diencephalic-tectal border. Often multiple axons in a single embryo displayed two or more path choices. If only the caudal portion of the tectum were removed, most axons projected contralaterally, but one or two nasal axons projected ipsilaterally. These results suggest that both local cues and longer ranged interactions are important for the guidance of optic axons and formation of a normal retinotectal projection.

INTERSTITIAL BRANCHING OF CORTICAL AXONS RELATED TO THE LOCAL ENVIRONMENT OF THEIR PATHWAY. M. Bastmeyer*, M.M. Daston, H. Posselt, D.D.M. O'Leary., The Salk Institute, La Jolla, CA 92037.

Previous studies have shown that the corticospinal projection is established by interstitial axonal budding from corticospinal axons. Corticospinal axons growing in the cerebral peduncle, pass by a major target, the basilar pons, and collateral branches arise from the axon shaft well behind the advancing growth cone. Evidence suggests that a diffusible chemoattractant, released by the pons, acts at a distance to promote the formation of collaterals and to direct their growth. On the other hand, specialized glia and extracellular matrix (ECM) molecules have been implicated in directing axon growth in other brain areas. The goal of this study is to determine whether the spatiotemporal patterning of cellular or molecular components in the cerebral peduncle correlates with the initiation and/or direction of axon collateral growth.

We have performed an immunohistochemical analysis of rat cerebral peduncles in the region overlying the basilar pons. The distribution of glia, dendrites, and ECM components was examined over the time that collaterals form. We have found that glial processes (identified by RC-1 and anti-GFAP) surround, but do not invade the cerebral peduncle at sites where interstitial branching occurs. We also found that the spatiotemporal distribution of cytotactin and CSPG does not correlate with branch formation. However, dendritic processes (identified by anti-MAP-2) are present in the cerebral peduncle and are oriented parallel to the direction of collateral elongation.

Our findings show that radial glia are not involved in the initiation and directed growth of interstitial branches, but the MAP-2 stain suggests that, in addition to the chemoattractant, dendrites may participate in this process. An ultrastructural study to confirm these results is in progress.

DESCENDING BRAINSTEM-SPINAL AXONS MAKE CORRECT ROSTRO-CAUDAL POLARITY CHOICES IN CULTURE. S.Liu* and R.H. Nordlander, Depts. of Oral Biol., Anat., Ohio State Univ., Columbus OH 43210

Many brainstem neurons normally innervate targets in the spinal cord. To investigate whether their axons recognize polarity cues along the rostrocaudal neural axis, brainstem and spinal cord explants from Xenopus larvae (st 40-45) were cocultured up to 7 days in collagen matrices. Outgrowth from brainstem explants toward cord segments of differing axial orientations were compared. Pairs of segments were placed at about 40° to, but at opposite sides of the brainstem axis and at a distance of 300-400 μm from the brainstem.

If presented with equidistant cord segments of opposite orientations, most neurites extended toward the segment whose rostral end faced the brainstem. Dil introduced in these segments marked axons and cells of the raphe and reticular formation, both of which normally send axons into the spinal cord. If both cord segments have the same orientation, equal numbers of neurites go to each segment, with more fibers entering the segments if rostral ends face the brainstem. If presented with the choice of one or several rostrally oriented pieces, a dose effect is exhibited. Our results suggest that descending brainstem axons can recognize and respond to polarity cues inherent in the spinal cord and perhaps diffusing from it.

Decrease of astrocytes during development of rat cortex affects the projection of thalamic axons to cortex. M.F. Barbe* and P. Levitt, Dept. of Physical Therapy, Temple Univ., Philadelphia, PA 19140 and Dept. of Anatomy and Neurobiology, Med. Coll. of Pennsylvania, Philadelphia, PA 19129.

Developing thalamic axons projecting to the cortex may wait in the subplate with the most significant growth occurring postnatally. Gliogenesis begins late prenatally and extends into the postnatal animal. In order to investigate whether astrocytes play a role in the ingrowth and collateralization of thalamic axons into the cortex, we injected an antimetabolic agent, methylazoxymethano acetate (MAM), into pregnant rat dams to specifically destroy glial precursors. One injection of either 20 or 25 mg/kg body weight was made into dams on E19, E20 or E21. The brains were collected on postnatal (P) day 7, midsagittally sectioned and Dil inserted into midthalamus. 12 weeks later, the brains were sectioned and the Dil-labeled axons examined in the internal and external capsules, subplate and cortical plate. Brains of siblings were cut on a cryostat and immunostained with anti-glial fibrillary acidic protein (GFAP). The thalamocortical axons of pups that had received 20 mg/kg MAM at E19 appeared similar to controls, showing substantial growth into the cortex. Most of the labeled thalamocortical axons of pups injected with 20 mg/kg MAM at E20 did not extend past the lateral border of the internal capsule, suggesting a retraction of axons. Brains of pups that received 20mg/kg MAM on E21 had a few axons that were present in the external capsule, but the numbers extending into the cortex were significantly decreased from control rats or those injected at E19. The number of GFAP-immunoreactive astrocytes present in P7 brains was greatly reduced in pups injected with MAM on E20 or E21 when compared to controls or those injected on E19. Brains of pups injected with 25 mg/kg MAM appeared to have undergone reactive gliosis. Dil-labeled thalamic axons in brains of sibling pups of these latter groups stopped abruptly at the border between the internal and external capsule, with pronounced endings that appeared growth-cone-like. The data indicate that astrocytes are important for regulating thalamic ingrowth into the cortical plate during development. (Supported by Temple Univ. and NIMH Grant MH45507).

MATURATIONAL CHANGES IN MEMBRANE ASSOCIATED MOLECULES IN THE CORTICAL PLATE MAY CONTROL DEVELOPMENT OF THALAMOCORTICAL AND INTRACORTICAL CONNECTIONS. R. Tuttle*, B.L. Schlaggar, and D.D.M. O'Leary, The Salk Institute, La Jolla, CA 92037.

Thalamocortical afferents (TCAs), the first to grow into the neocortex, follow an intracortical path that is centered on the subplate layer and avoids the overlying cortical plate (CP). TCAs reach occipital (visual) cortex on E17 and extend into the CP around E19. This pattern of growth may be controlled, in part, by the CP, which may initially be too immature to attract or permit the ingrowth of TCAs.

To study this, explants of rat CNS were placed onto a substrate composed of alternating stripes of E18 vs. P0 or E19 vs. P1 rat CP membranes dissected from the occipital neocortex. E18 lateral geniculate (LG) neurites displayed a clear preference for the neonatal CP membranes. E18 cortical neurites also grew well on CP membranes and preferred neonatal CP. However, these CP membranes were generally a poor substrate for neurite growth from explants of E18 retina and P7 cerebellum, neither of which project to cortex.

These findings suggest that membrane associated molecules in CP undergo maturation-dependent changes that thalamocortical axons are responsive to and, therefore, might promote their invasion into the CP. The behavior of the cortical neurites suggests that these molecules may also regulate the onset of the development of intracortical connections.

GROWTH PROMOTING MOLECULES IN THE DEVELOPING CORTEX GUIDE THALAMIC AXONS. M. Hübener*, M. Götz, and J. Bolz, Friedrich-Miescher-Labor der Max-Planck-Gesellschaft, 7400 Tübingen, Germany.

Thalamic axons do not grow into an embryonic cortex, but they do grow into an early postnatal rat cortex. We have previously shown that substrate bound molecules in the cortex control thalamic fiber ingrowth (Götz et al., Development 116, 507, 1992). Here we present evidence that growth promoting molecules in the postnatal cortex, rather than growth inhibiting molecules in the embryonic cortex, are responsible for this behavior. Time-lapse video-microscopy revealed that thalamic fibers grow slower and collapse more often on embryonic day 16 (E16) than on postnatal day 7 (P7) cortical membranes. On a laminin substrate growth-rate and frequency of growth-cone collapses were about equal as on E16 membranes, indicating that the differences in growth behavior on both membrane substrates are due to growth promoting factors present on P7 cortical membranes. Heat-inactivation of embryonic cortical membranes at different temperatures never enhanced their growth promoting properties. Moreover, when thalamic fibers were given a choice between heat-inactivated E16 membranes and P7 membranes in a stripe-assay, the fibers always preferred P7 membranes, again giving no indication of inhibitory molecules on E16 membranes. Most fibers encountering a border between E16 and P7 cortical membranes either stopped their growth or changed their direction of growth. The majority of the fibers that performed turns upon reaching a border did so without a growth-cone collapse, also arguing against inhibitory molecules on E16 membranes. During development *in vivo* thalamic fibers are always confined to regions which can be stained intensely with the lectin peanut agglutinin (PNA; Götz et al., Development 116, 507, 1992). In the membrane stripe-assay addition of PNA to the culture medium significantly decreased the preference of thalamic fibers for the P7 membranes. Taken together these results suggest that during cortical development thalamic axons are guided by the differential distribution of growth promoting, PNA-binding molecules.

3-D CONFOCAL MICROSCOPIC STUDY ON THE EARLY DEVELOPMENT OF THALAMOCORTICAL PROJECTIONS IN THE RAT

Zoltán Molnár¹, Richard Adams² and Colin Blakemore^{1,2} University Laboratory of Physiology¹ and MRC Research Centre in Brain and Behaviour², Parks Road, Oxford OX1 3PT, UK.

We are interested in the topography and interrelationship of descending axons from the cortical subplate and the early thalamocortical projection. A confocal microscope (Leica) was used to image fibres revealed with carbocyanine dyes (DiI, Dil) placed into different parts of the thalamus and cortex in fixed tissue from rat embryos aged E14 to E21. Sections were counter-stained with the chromatin stain, acridine orange. To obtain high-resolution reconstructions of the entire fibre pathways we used both serial sections and fine optical sections to construct 3-D datasets. Discrete placement of small crystals into putative sensory thalamic nuclei appeared to label thalamic axons alone and did not back-label cells in the cortex. Neighbouring thalamocortical axons show three distinct patterns of organization in different parts of the pathway. Adjacent axons remain parallel and closely associated throughout the internal capsule. Upon entering the striatum the tight, homogeneous bundle breaks up and the fibres reorganize into small fascicles. While the gross topography of the projection is maintained there is some crossing of axons between neighbouring fascicles. At the lateral edge of the striatum the fibres defasciculate and individual axons course towards the cortex along parallel paths in the white matter. Between E14 and 15, early corticothalamic and thalamocortical axons labelled with different dyes placed in corresponding regions of cortex and thalamus are intimately intermingled and share the same fascicles in the region of the striatum.

3D-reconstruction of the entire fibre pathway was performed after multiple restricted dye placements into the cortex at E16 to E19 (labelling both thalamic and subplate axons). This showed that contiguity of ascending and descending axons and gross topographic order were maintained at all points along the pathway.

CORTICAL GROWTH CONE BEHAVIORS IN EXPLANT CO-CULTURES REFLECT PERMISSIVE OR INHIBITORY TARGET CUES. M. Merline*, R.Z. Kuang, K. Kalil, Neuroscience Training Program and Dept. of Anatomy, University of Wisconsin, Madison, WI 53706.

During development *in vivo* corticospinal axons are highly specific in their innervation of spinal targets. Similarly, *in vitro*, cortical axons invade spinal targets but are repelled from cerebellar explants, as shown by Dil labeling of fixed co-cultures (Kuang et al. Soc. Neurosci. Abs. 1992). In order to characterize growth cone behaviors that mediate target selection by growing cortical axons, we carried out video microscopy on living cortical explants co-cultured with either spinal cord or cerebellum. Explants of P0-P1 hamster sensorimotor cortex were co-cultured in collagen gels with explants of P0-P1 cervical spinal cord or cerebellum. After 1-2 days video microscopy was carried out under phase optics. Control cortical growth cones growing in the collagen gel in the absence of target tissue were only occasionally interrupted in their forward advance by collapse of the growth cone lamellipodium and contraction of the motile tip into a static tapered or club shaped ending. Collapsing behaviors by control growth cones were most often temporary, and growth cones rapidly resumed forward extension. In co-cultures with cerebellar targets, cortical growth cones contacting cerebellar explants showed rapid and dramatic collapsing behaviors, and often went through repeated cycles of collapse and withdrawal. In contrast, cortical growth cones contacting spinal cord targets extended smoothly into the explants. They sometimes paused or slightly retracted but did not go through large withdrawals or repeated collapsing behaviors. These results show that contact mediated growth cone interactions with target cells form the basis for appropriate target selection by cortical axons. Growth cone collapse and withdrawal inhibit axon extension into inappropriate targets whereas growth cones entering appropriate targets rarely show inhibitory behaviors. ANALYSIS OF PARALLEL FIBER ELONGATION IN THE WILD TYPE AND MUTANT MOUSE CEREBELLUM. M.W. Vogel*, J. Soha, J. Prittie, and J.E. Crandall. MPRC, Baltimore, MD 21228., Dept. of Surgery, Yale Medical School, New Haven, CT 06511, and Shriver Center, Waltham, MA 02254.

Granule cell parallel fibers extend for long distances in the cerebellum in an ordered parallel array. While parallel fibers begin to grow soon after granule cells start to differentiate in the external granule cell layer, little is known about the regulation of their development. We have begun an investigation of parallel fiber growth in wild type, *lurcher*, and *staggerer* mice using DiI labeling in fixed cerebellar tissue.

Wild type and mutant mice (P2 to P41) were killed by cardiac perfusion with 4% phosphate buffered paraformaldehyde. A DiI coated micropipette was inserted into the vermis of the fixed cerebella (pyramid or declive). After incubation in fixative for 24 hours to 1 week in the dark (RT or 37° C), the cerebella were sectioned coronally on a vibratome, and the sections analyzed with an epifluorescence microscope.

In whole mounts of wild type cerebella, the DiI micropipette labels a thin band of fibers stretching across the vermis. In coronal sections, DiI labeled parallel fibers and granule cells extend on either side of the injection site. Surprisingly, the apparent maximum length of parallel fibers did not increase greatly from P3 to P41. This is consistent with the hypothesis that parallel fibers attain their maximum length before granule cells migrate into the inner granule cell layer. Despite Purkinje and granule cell loss in *+Lc*, parallel fibers appear to reach normal lengths in *+Lc* pups. We are in the process of examining parallel fiber labeling in *staggerer* pups and verifying DiI parallel fiber labeling by examining the ultrastructure of photoconverted DiI labeled fibers.

AXON PATHFINDING IN INITIAL TRACT FORMATION IN THE EMBRYONIC MOUSE MIDBRAIN. GS Mastick and SS Easter, Jr.*, Dept. of Biology, Univ. of Michigan, Ann Arbor, MI 48109-1048.

The embryonic mouse CNS has a stereotyped pattern of axon outgrowth starting on embryonic day 8.75 (E8.75) as revealed by labelling of fixed embryos with an antibody to neuron-specific class III β -tubulin (Easter, *et al.*, J. Neurosci. 13:285-299). The first axons arise from near the dorsal midline of the mesencephalon, course caudally as a loose group, and turn laterally around the cerebellar plate, to form a tight, longitudinal tract (dtmesV) (*ibid*).

More detailed examination of small groups of axons near the mesencephalon/metencephalon border (E9.25) revealed pathfinding errors, suggesting a reduced precision in guidance cues at this point. At E10.0, local injections of DiI into the wall of the rostral mesencephalon labelled the caudal projections of dtmesV axons and a second ventrally-projecting population of axons, superficial to dtmesV. They projected across the ventral midline just caudal to the oculomotor nerve.

As a first step toward examining growth cone dynamics of the initial CNS axons *in situ*, embryos were cultured *in vitro* from E8.75 to E9.5. Both anti- β -tubulin and DiI labelling demonstrated that these cultured embryos had normal timing and pattern of early axon pathfinding.

NEW EVIDENCE FOR A CORRELATION BETWEEN THE EARLY NEURONAL ORGANIZATION AND THE PATTERN OF AXONAL TRACTS. M.-C. Bélanger, F. Auclair, N. Valdés, L. Bertrand and R. Marchand. Centre de Recherche en Neurobiologie, Hôp. de l'Enfant-Jésus, 1401, 18e rue, Québec (Qc), Canada, G1J 1Z4.

The primitive columnar organization of early generated neurons predicts the pattern of several longitudinal axonal tracts (Bélanger *et al.* '93). To improve our knowledge of the correlation that appears to exist between the position of early neurons and the pattern of axonal bundles, one or two injections of bromodeoxyuridine (BrdU, 60 μ g/g) were made to gestating rats between days 11.5 and 12.5 in order to visualize early generated neurons that will appear as *unlabeled* for BrdU. One to three days later, fixed embryos originating from these litters received crystals of carbocyanines along different points of the columns of early generated neurons as in the chiasmatic ridge, the prospective accessory olfactory bulb and the amygdaloid complex among other sites which are known to contain populations of early generated neurons. Fluorescent bundles of axons and cell bodies were photographed from cryostat sections which were then processed for anti-BrdU immunostaining. Comparison of both labeling patterns confirmed that axons travel along columns of unlabeled neurons. These axons represent recognizable axonal tracts of the adult brain like the medial forebrain bundle, the accessory olfactory tract and the mesencephalic root of the trigeminal nerve for example. These results support the hypothesis that the primitive organization of early neurons might be involved in the elaboration of a terrain favorable to axonal growth. AXON GUIDANCE MECHANISMS AND PATHWAYS V

451.1

INFLUENCE OF CHONDROITIN SULFATE ON RETINAL AXON GROWTH IN VITRO. B.D. McAdams and S.C. McLoon*. Dept. of Cell Biology & Neuroanatomy, Univ. of Minnesota, Minneapolis, MN 55455.

An inhibitory or impedance effect on neurite extension has been attributed to chondroitin sulfate-bearing proteoglycans. These proteoglycans have been suggested to be components of barriers to axon growth during development. However, chondroitin sulfate immunoreactivity has previously been observed in the developing retinofugal pathway of chick. Furthermore, the distribution of immunoreactivity suggests that chondroitin sulfate is produced by retinal ganglion cells or adjacent cells. The present study utilized immunocytochemistry to determine whether neurites from chick retinal explants are immunoreactive for chondroitin sulfate and to examine their behavior in the presence of chondroitin sulfate. Chondroitin sulfate immunoreactivity was observed in association with retinal neurites grown on laminin. The immunoreactivity was present both along the neurite, on the growth cone, and immediately adjacent to some neurites and explants. Therefore, the chondroitin sulfate immunoreactivity observed *in vivo* may be of retinal ganglion cell origin. To determine the effect of chondroitin sulfate on neurite extension, retinal neurites were grown on vitreous or with chondroitin sulfate-supplemented medium. Retinal explants extended neurites in intact or cryostat-sectioned chondroitin sulfate-containing embryonic chick vitreous. When medium supplemented with chondroitin sulfate was added to cultured retinal explants, growth cones transiently collapsed and new filopodia extended from the neurites and growth cones within minutes. These results suggest that, while chondroitin sulfate may influence growth cone behavior, it does not prevent growth cone extension. (Supported by EY05371.)

EXPRESSION OF MUTANT β 1 INTEGRIN AND N-CADHERIN IN THE DEVELOPING RETINA. A. Lilienbaum, R. H. Riehl, A. A. Reszka, A. E. Horwitz and C. E. Holt*. Dept. of Biology, UC San Diego, La Jolla, CA 92093-0322.

Integrins and N-cadherin are substrate and cell adhesion molecules that act synergistically to promote neurite outgrowth from retinal cells *in vitro*. These molecules are expressed in the optic pathway of *Xenopus laevis* embryos at a time when retinal ganglion cells (RGCs) are sending their axons to the tectum. To determine the role that these molecules play in axonal growth and guidance *in vivo* we have expressed mutant forms of β 1 integrin and N-cadherin in embryonic retinal cells with the aim of blocking their function in developing RGCs.

cDNAs were introduced into the retina by multiple focal injections of lipofectin/cDNA made directly into the proliferative neuroepithelium of the eye primordium. We used a *myc*-tagged dominant-negative form of *Xenopus* N-cadherin with a large extracellular deletion and three different chicken β 1 integrin mutants (cytoplasmic deletions and amino acid substitutions) with severely reduced adhesion plaque-forming activity. A non-functional N-cadherin mutant and luciferase were used as controls. Transfected cells expressing mutant N-cadherin and β 1 integrin proteins were detected immunohistochemically using *c-myc* and chicken specific antibodies respectively. Transfections were done at stage 19-20 and strongly expressing cells were assayed 48 hours later at stages 40 and 41. Entire transfected RGCs were visualized from soma to axon tip in 50 μ m DAB stained vibratome sections.

Retinal cells expressing high levels of mutant N-cadherin or β 1 integrin exhibited normal patterns of laminar migration and were present in all layers of the differentiated retina in numerous cell types. The number of processes (dendrites and axons) that β 1 integrin and N-cadherin expressing RGCs elaborated, however, was significantly reduced from those transfected with the luciferase reporter (13-50% vs 80%). RGC axons expressing mutant adhesion molecules followed the correct pathway and terminated in the tectum. These results suggest that loss of or reduced adhesion molecule function interferes with the initiation and/or the rate of axonogenesis in RGCs *in vivo* but not with axonal guidance. Supported by NIH #NS23780, PEW Scholars Award, March of Dimes and CNRS.

AXONIN I IS SELECTIVELY EXPRESSED IN DEVELOPING PRIMARY AFFERENT PATHWAYS IN THE AVIAN BRAIN. Y.P.L. Yip¹, L. Felder¹, C.D. Balaban¹, W. Halfter and J.W. Yip. Departments of Neurobiology and Otolaryngology¹, University of Pittsburgh, Pittsburgh, PA 15261

Axonin I (Ax-I), the avian homolog of TAG-1, is a membrane adhesion molecule that may facilitate axon fasciculation and neurite growth. Our previous studies demonstrated that Ax-1 is expressed selectively in cutaneous and visceral sensory afferents and in the retinorecatal pathway during axon outgrowth. This study examines the time course and regional distribution of Ax-1 expression in developing brain. Immunocytochemical staining with a specific monoclonal antibody (1A12) shows that Ax-1 is expressed by primary visual, auditory, somatosensory and visceral sensory pathways. Immunoreactive axons are observed on E4 and could be traced to the dorsal funiculi, trigeminal root and spinal trigeminal tract, retino-pretectal, retino-thalamic and accessory optic visual pathways, olfactory nerve, vestibular and cochlear nuclear afferent pathways and the tractus solitarius. However, expression is absent in the mesencephalic trigeminal tract and nucleus, components of a proprioceptive primary afferent pathway. A striking down-regulation of Ax-1 immunoreactivity is observed in the optic tectum and vestibular and cochlear nerves by E8. By day 19, weak expression remains only in the dorsal funiculi. This study confirms that non-proprioceptive somatic and visceral sensory primary afferents selectively express Ax-1 during development. This suggests that Ax-1 plays an essential role in the development of primary sensory pathways.

L-14, AN ENDOGENOUSLY SYNTHESIZED LECTIN OF THE RAT OLFACTORY SYSTEM: IS IT A BIFUNCTIONAL PROTEIN INVOLVED IN AXON GUIDANCE? N.K. Mahanthappa^{*}, D.N.W. Cooper, S.H. Barondes and G.A. Schwarting. Dept. of Biomed. Sci., The Shriver Center, Waltham, MA 02254; Dept. of Psychiatry, UCSF, San Francisco, CA 94143; and the Prgrm. in Neurosci., Harvard Med. Sch., Boston, MA 02115.

L-14, a divalent lectin found in a variety of vertebrate tissues, shows specific binding to terminally lactosaminylated glycans and poly-lactosamine. The protein is expressed at high levels in a subset of rat dorsal root ganglion neurons where it is co-expressed with a lactosamine-immunoreactive epitope and thus thought to potentially mediate specific adhesive interactions (Regan et al., *PNAS* (1986) 83:2248). In the rat olfactory system, we have demonstrated that L-14 is expressed at high levels in the olfactory nerve, and co-localizes with two ligands: a lactosaminylated glycolipid on the surface of nascent axons, and a laminin-related protein in the extracellular matrix. Both ligands bind L-14 in a carbohydrate-dependent manner. We have thus hypothesized that L-14 may crosslink the axonal surface to the extracellular matrix and thus play a role in the guidance of olfactory axons to the olfactory bulb.

In vitro we have found that L-14 appears to promote two distinct adhesive interactions among primary olfactory neurons. The first occurs at high L-14 concentrations (~10mM), is carbohydrate-dependent, and promotes intercellular adhesion. The second interaction occurs at low L-14 concentrations (~10µM), is carbohydrate-independent, and promotes substrate adhesion. Neither interaction is inhibited by RGDS peptides or anti-integrin antibodies. We are presently investigating whether a novel, high affinity, carbohydrate-independent, L-14 binding site (similar to that reported on fibroblasts by Wells and Mallucci, *Cell* (1991) 64:91) is present on olfactory neurons. We are also performing in situ hybridization studies to determine the site of L-14 synthesis in the olfactory system.

MOLECULAR CLONING OF NEUROLIN AND ITS EXPRESSION IN GOLDFISH AND EMBRYONIC ZEBRAFISH CNS. U. Laessing^{*}, S. Giordano, F. Lottspeich⁺ and C.A.O. Stuermer. Faculty of Biology, University of Konstanz, and ⁺MPI Biochemie, München, Germany

Neurolin, a ~90kd cell surface glycoprotein is found on all retinal ganglion cells (RGC) and axons in the goldfish embryo but is restricted to new RGC axons in adults and re-expressed on all regenerating RGC axons following optic nerve transection (Paschke et al., 1992).

We report here a 500 bp cDNA coding for the C-terminus of Neurolin which was obtained using PCR and specific primers determined from amino acid sequencing of the purified protein. There is a striking homology between the predicted amino acid sequence of Neurolin and DM-Grasp protein (Burns et al., 1991) extending 60 amino acids from the carboxy terminus. This similarity, however, is not extended throughout the entire PCR fragment and the overall amino acid homology is about 50%. A cDNA library from regenerating goldfish retina is now being screened for a full length Neurolin clone to determine if Neurolin is the fish homolog to DM-Grasp or a related protein.

In addition, two new monoclonal antibodies against purified Neurolin were used to examine Neurolin expression in zebrafish embryos. Staining in whole mounts was on retinal axons, spinal cord neurons, DRGs and in the hindbrain of 2 day old embryos.

Neurolin expression in the developing and regenerating CNS and its homology to DM-Grasp indicate that Neurolin may be important for the formation of CNS fiber tracts in fish.

451.4

Differential Effects of Glycosaminoglycans on Neurite Extension on L1 and Laminin Substrates. Chang-Lin Dou^{*} and Joel M. Levine. Department of Neurobiology and Behavior, SUNY at Stony Brook, Stony Brook, NY 11794

The glycosaminoglycans (GAGs) keratan-sulfate (KS) and chondroitin-sulfate (CS) are thought to be negative regulators of axon growth (Exp.Neurol.,109:111). This hypothesis remains controversial since 1) soluble GAGs may promote neurite growth (Development,114:17) and 2) some proteoglycans inhibit neurite extension after treatment with GAG hydrolases (J.Neurosci.,11:822). To examine the role of GAGs as modulators of neurite growth, we tested the ability of these negatively charged carbohydrates to inhibit neurite extension on L1 and laminin substrates.

Tissue culture surfaces were coated with poly-L-lysine followed by either L1 or laminin alone (both at 2µg/ml), or a mixture of laminin (or L1) and various amounts of CS or KS. Cerebellar granule neurons were isolated from postnatal day 5 and 6 rats, seeded onto the surfaces in media supplemented with bFGF, and after 24hr, the extent of cell attachment and neurite outgrowth was quantitated. The neurons attached equally well to all substrates tested. On laminin alone, 50% of the cells extended neurites and the mean neurite length was 85µ. When laminin was mixed with KS (10-1000µg/ml), only 25% of the cells grew neurites and the mean neurite length was 50µ (40% inhibition). CS inhibited neurite growth on laminin in a dose-dependent manner, reaching a maximum of 45% inhibition at 50µg/ml or higher concentrations. On L1 surfaces, 42% of the cells extended neurites with a mean length of 98µ. KS (10-1000µg/ml) did not inhibit neurite growth on L1 coated surfaces and 1mg/ml of CS was needed to achieve a 50% inhibition of neurite growth. Digestion of CS with chondroitinase ABC reversed its inhibition completely on both laminin and L1 substrates.

These results suggest that CS and KS may not exert strong negative influences over axonal elongation in the developing cerebellum and other CNS regions where L1 is abundant. GAGs may play a role in modulating the growth of axons of the PNS which extend through an environment rich in laminin.

451.6

EXPRESSION OF E587 ANTIGEN IN EMBRYONIC ZEBRAFISH CNS AND IN VITRO FUNCTIONAL ANALYSIS. S. Giordano^{*}, M. Bastmeyer, A.Y. Loos and C.A.O. Stuermer. Faculty of Biology, University of Konstanz, Germany

The E587 antigen (Ag), which was previously identified as a likely cell adhesion molecule in the goldfish visual system, is associated with growing retinal axons in embryos and regenerating retinal axons in adults but is absent from mature axons (Vielmetter et al., 1991).

The expression of E587 Ag in zebrafish embryos was examined using new mono- and polyclonal antibodies (Ab) against the purified protein. Staining was observed on retinal ganglion cell axons in the retina, optic nerve/tract and in the tectum of two day old embryos. Staining was also present in the spinal cord.

To determine if E587 Ag can influence the behavior of growing axons, growth cones from goldfish retinal explants were observed advancing on polylysine stripes. In this assay 80% of growth cones fasciculate. In the presence of E587 monoclonal Ab, however, only 60% of growth cones fasciculate. In addition the increase in velocity growth cones exhibit when in fascicles, as compared to growth on polylysine, was abolished by this Ab.

In vitro growth cones also show a preference for growth on goldfish oligodendrocytes, which express E587 Ag (Bastmeyer et al., 1993). In contrast, in media containing E587 Ab, there is a significant reduction in the number of contacts growth cones have with oligodendrocytes and they appear to lose their preference for these cells.

These results demonstrate that E587 Ag contributes to axon fasciculation and axon-glial cell interactions in vitro and suggest this may be a function for this molecule in vivo. This view is strengthened by the expression of E587 Ag on outgrowing axons in development and its re-expression during retinal axonal regeneration.

451.8

CLONING AND CHARACTERIZATION OF A ZEBRAFISH cDNA SIMILAR TO CHICK DM-GRASP, A NEURAL CELL SURFACE PROTEIN IN THE IMMUNOGLOBULIN SUPERFAMILY. J.P. Kanki^{*} and J.Y. Kuwada, Dept. of Biology, University of Michigan, Ann Arbor, MI 48109.

A number of neural cell surface molecules have been characterized that localize to restricted subsets of axons and are members of the immunoglobulin superfamily of cell adhesion molecules. These molecules are likely to be involved in axon guidance during early neural development. One such molecule that has been characterized in the chick is DM-GRASP, also known as SC1 or BEN. We have recently cloned and begun to characterize a zebrafish cDNA that is similar to DM-GRASP. 6x10⁵ zebrafish clones were screened with a 1.6kb restriction enzyme fragment of the Chick DM-GRASP cDNA (Burns, et al. 1991). One of these clones contains a 2.1kb insert which shares 54.6% identity with the nucleotide sequence of Chick DM-GRASP (Pearson and Lipman, 1988). Northern analysis indicates that this zebrafish transcript is expressed during the period of early axonogenesis. This clone contains a single open reading frame of 610 amino acids which shares 35.1% identity as well as structural homology with the Chick DM-GRASP protein. A portion of the Zebrafish DM-GRASP coding region was inserted into the pGEX-KN vector (Hakes and Dixon, 1992) and over-expressed in *E. Coli*. This fusion protein was purified and injected into rabbits for the production of antisera. Initial immunohistological results indicate that the Zebrafish DM-GRASP protein is expressed on the axons of a subset of neurons during early zebrafish development. These results indicate that we have cloned either the zebrafish homolog of DM-GRASP, or a very closely related member in the immunoglobulin superfamily. (Supported by NIH)

451.9

Purified Chick DM-GRASP Supports Neurite Extension From A Subpopulation Of Neurons In Vitro A.P. DeBernardo and S. Chang*

Department of Neuroscience, U. of Penn., Philadelphia, PA 19104
DM-GRASP (DM) is an integral membrane glycoprotein expressed on a restricted set of axons in the developing chick nervous system. Currently, three lines of evidence suggest that DM may be involved in axonal pathfinding: (1) Its expression pattern is temporally dynamic and roughly coincides with axonogenesis. (2) Antibodies to DM can block the extension of sympathetic neurites on sympathetic axons. (3) Purified DM can support the extension of dorsal root ganglion (DRG) neurites. We have extended these findings by demonstrating that purified DM supports neurite extension in a distinct subpopulation of neurons. This subpopulation is defined by DM expression. Both DRG and spinal motor neurons (SMN) express DM *in vivo*. Dissociated and explant cultures of DRG and SMN extend neurites on laminin, G4/L1, and DM substrates that are significantly longer than on a control BSA substrate. Preincubation of substrates with 100 ug/ml monoclonal antibody against DM blocks extension on DM, but does not affect extension on other substrates. In contrast, retinal ganglion cells do not express DM. Dissociated or explant cultures of retina do not extend neurites on DM that are longer than on BSA. Retinal neurons are able to extend neurites on laminin or G4/L1 under the same culture conditions. This data suggests that purified DM selectively supports neurite extension from DM bearing subclasses of neurons. The selective fasciculation model of pathfinding predicts that particular axonal tracts support axonal extension from subclasses of neurons. Known substrate molecules support extension from a wide variety of neurons. The finding that DM can selectively support neurite extension suggests it may be involved in selective fasciculation.

451.11

CLONING AND ANALYSIS OF DEVELOPMENTAL EXPRESSION PATTERN OF L1 AND TENASCIN HOMOLOGUES IN ZEBRAFISH.

E. Tongiorgi*, R.R. Bernhardt and M. Schachner

Neurobiology, ETH-Hönggerberg, 8039 Zürich, Switzerland
Zebrafish homologues of chicken tenascin and mouse L1 have been isolated from a 33-36h embryonic zebrafish cDNA library. Their expression patterns during embryonic development have been analysed by *in situ* hybridisation.

High levels of tenascin message are expressed in the hypochord, a single row of cells located ventral to the notochord from 16h, the earliest stage tested. At 16h, tenascin-specific message is detectable also in somites. The signal is strongest in the rostral half of each somite and restricted to cells occupying medial positions in the central third of each somite, including muscle pioneers. From 18h, in more mature somites, the message is present over the entire width of the somitic anterior-posterior axis and transiently over a larger region along the dorso-ventral axis. At 19h, tenascin positive cells are detectable in dorsal regions of the trunk. The time of appearance, position and shape suggest that they are neural crest cells. Onset of L1 expression appears correlated with axonogenesis. At 18h, groups of neurons with early axonogenesis such as the early clusters of brain neurons, hindbrain neurons and head sensory ganglia are conspicuously L1 positive. Nucleus PC neurons with later axonogenesis are first positive at 21h. In the spinal cord the first L1 positive cells are the Rohon-Beard cells. Other spinal neurons are labelled slightly later. In the eye retinal ganglion cells (RGC) also start to be L1 positive by the time of their axonogenesis (about 36h). During post-larval development L1 expression in the RGC layer becomes restricted to the retinal margin. In general higher levels of L1 message are seen during embryonic development than at early post-larval and adult stages.

STUDIES OF S-LAMININ FUNCTION *IN VITRO* AND *IN VIVO*.

B.E. Porter, P.G. Noakes*, M. Gautam#, J.P. Merlie# and J.R. Sanes.

Departments of Anatomy and Neurobiology, and of Molecular Biology and Pharmacology#, Washington University School of Medicine, St. Louis, MO 63110

Axons preferentially reinnervate original synaptic sites on muscle fibers. We are testing the idea that s-laminin, a laminin-like chain concentrated in the basal lamina of the neuromuscular junction, is one of the molecules that influences motor axons at synaptic sites. S-laminin fusion proteins contain a binding site, LRE, to which motoneuron-like cells from chick ciliary ganglion (CG) or a spinal-cord derived cell line (NSC-34) selectively adhere (CSHSQB 55:419, 1990). Although adhesive, these proteins do not promote neurite outgrowth. We now show that s-laminin fusion proteins inhibit neurite outgrowth from both CG and NSC-34 cells. Fusion proteins with LRE mutated to QRE or LRA do not inhibit outgrowth. Outgrowth is not inhibited from PC12 or sensory cells, which do not adhere to LRE. These results suggest that LRE might serve as a stop signal for motor axons, an idea we tested with patterned substrates. CG cells growing on laminin stop at borders of s-laminin-LRE but cross borders onto s-laminin-QRE. We are now determining if growth cones differentiate into nerve terminals at s-laminin-LRE borders. In addition, we will assess the function of s-laminin *in vivo* using a gene knockout approach in embryonic stem (ES) cells. We have isolated s-laminin genomic clones, constructed targeting vectors, and generated ES cells with an inactivated s-laminin gene. We are currently injecting these cells into blastocysts to eventually generate s-laminin-null mutants. These two approaches will test the role of s-laminin in the formation and stabilization of neuromuscular synapses. (Support: NIH and MDA).

GROWTH CONES OF COMMISSURAL AXONS IN THE ZEBRAFISH SPINAL CORD CHANGE THEIR SUBSTRATE AT THE VENTRAL MIDLINE. R.R. Bernhardt*, E. Tongiorgi, and M. Schachner. Neurobiology, ETH-Hönggerberg, 8093 Zürich, Switzerland.

Commissural (Co) axons initially extend ventrally from dorsally located cell bodies. After crossing the ventral (ve) midline they grow dorsally to ultimately extend anteriorly in a dorsal longitudinal pathway. Why do Co growth cones first extend to, but then away from, the ve midline? A switch in the adhesive properties might be triggered when the axon passes the ve midline. EM analysis of labeled Co growth cones has now revealed morphological evidence consistent with such a switch. Growth cones which have arrived in the ventrolateral cord, but not yet crossed the ve midline, have many filopodia which make extensive contacts with neuroepithelial cells, and possibly with ventral neurons, but show very little apposition to the basement membrane (BM). In striking contrast, growth cones which occupy equivalent positions after having crossed the ve midline have few filopodia and show extensive contact with the BM. We are now exploring molecular mechanisms which may underlie this change. Candidates are recognition molecules at the cellular surface and in the extracellular matrix. One among them is L1, the spatially and temporally regulated expression of which has been implicated in influencing Co axonal pathfinding in mammals. *In situ* hybridisation demonstrates that Co neurons in zebrafish express an L1 homologue. The regulation of L1 expression by Co neurons is currently under investigation.

451.12

HNK-1 AND TENASCIN DISTRIBUTION IN THE DEVELOPING NEUROMUSCULAR SYSTEM OF *XENOPUS*. T. Somasekhar and R.H. Nordlander*. Depts. Oral Biol. and Anat., Ohio State Univ., Columbus, OH 43210.

The antibody HNK-1 marks developing neurons in *Xenopus*, including outgrowing motor axons (Devel. Br. Res., 50:147-153, '89). HNK-1 recognizes an epitope common to many cell adhesion molecules, including tenascin (TN). Both the HNK-1 antigen and TN are involved in neurodevelopment. This study examines staining patterns of HNK-1 and anti-TN at developing myotomes of *Xenopus* in order to: 1) compare their distributions, and 2) determine whether TN may account for HNK-1-immunoreactivity (HNK1-IR) at the developing myotomal neuromuscular junction.

HNK1-IR occurs on the surfaces of all peripheral axons in a graded rostrocaudal pattern. HNK-1 labeling also outlines the presynaptic nerve terminals at the intermyotomal furrows, the sites of myotendinous and neuromuscular junctions. On muscle, HNK1-IR is restricted to synaptic sites, first labeling the motor axon and later the postsynaptic membrane. TN-IR also appears at the furrows in a graded pattern. It precedes the arrival of motor axons. Unlike HNK1-IR, TN-IR is not closely associated with axons and neuromuscular junctions. These mutually exclusive distributions suggest that TN does not carry the HNK-1 epitope during innervation and maturation of the axial musculature in *Xenopus*.

452.1

DEVELOPMENTAL EXPRESSION OF NEURONAL NICOTINIC RECEPTOR SUBUNITS IN THE CENTRAL NERVOUS SYSTEM. R. Krauss*, K.M. Rosen and G.D. Fischbach. Department of Neurobiology, Harvard Medical School, Boston, MA 02115. Neuronal Nicotinic Acetylcholine Receptor (NnAChR) subunits belong to a family of closely related genes. They display discrete (sometimes overlapping) patterns of gene expression in CNS. The NnAChRs are multimers containing a mixture of α and β subunits which determine their physiological and pharmacological properties. The $\alpha 7$ subunit forms channels highly permeable to Calcium and may participate in regulatory processes including synaptogenesis. The steady-state expression of the $\alpha 7$ NnAChR subunit mRNA was studied by Northern blots in different regions of rat CNS and compared to the expression of $\alpha 3$ and $\alpha 4$. Total RNA samples were analyzed at E19, P0, P3, P6, P9, P12, P18 and P21. In most regions the $\alpha 7$ mRNA is low around birth and then increases. In the cerebral cortex (Cx) $\alpha 7$ increases at P3, then maintains steady levels until P21. This pattern is also followed by $\alpha 3$ and $\alpha 4$. In the Hippocampus (Hip), $\alpha 7$ increases at P6 and, as in Cx, is maintained at steady levels until P21. Similarly to Cx this increase at P3 is followed by $\alpha 3$ and $\alpha 4$ but, as a difference $\alpha 3$ declines after 3 days. In the Brainstem (Bs) $\alpha 7$ appears at P3, remains constant through P12, then undergo a transient decrease at P15. The same pattern is followed by $\alpha 4$, but $\alpha 3$, which is similar from E19 to P12, declines after P15. In the Diencephalon $\alpha 7$ has two transient peaks, one at P3 and a later one at P9-P12. By contrast, $\alpha 4$ increases at P9 and this level is subsequently maintained at steady levels until P21, whereas $\alpha 3$ maintains constant levels throughout development. A different situation occurs in the Cerebellum (Cb) where $\alpha 7$ has an increase at birth, then declines and increases again at P9 to be maintained steady through P21. By contrast $\alpha 3$ is present at late embryonic stages (E19-P0) then decreases sharply at P3 and finally disappears. It is concluded that the expression of the $\alpha 7$ subunit is regulated differently in different brain regions. Moreover, in some areas (i.e. Cx, Hip, Bs) $\alpha 7$ is regulated coordinately with one or more α subunits, whereas in others (i.e. Di, Cb) the regulation of $\alpha 7$, $\alpha 3$ and $\alpha 4$ is independent from each other.

452.3

SYNTHESIS OF HISTAMINE IN DEVELOPING RAT BRAIN. A. Vanhala, A. Yamatodani and P. Panula*. Dept. Anatomy, Univ. Helsinki, 00170 Helsinki, Finland, Dept. Molec. Physiol. Chem., Osaka Univ., Osaka, Japan and Dept. Biology, Abo Akademi University, Biocity, 20520 Turku, Finland. High histamine (HA) concentration is found in embryonal rat brain in transiently HA-ir neurons. We detected low HA concentrations in prosencephalon/telencephalon, mesencephalon/diencephalon, and pons/medulla on day E12 using HPLC fluorometry. A clear increase in all areas occurred on day E13, and by day E18 the concentration declined in all areas. The only HA-ir neuron population during that period was in the developing raphe area. In this area, a subpopulation of cells were immunoreactive for both serotonin and HA. A specific antiserum against histidine decarboxylase (HDC) revealed immunoreactivity in these cells. After day E18, these cells were still intensely immunoreactive for serotonin but no HA-ir was detected. Oligonucleotide probes complementary to rat HDC detected a small population of cells in the raphe area on day E16. The results suggest that histamine is synthesized in developing rat brain in a subpopulation of developing raphe neurons, which sends projections to other areas.

INCREASED GALANIN AND VASOACTIVE INTESTINAL PEPTIDE MESSENGER RNA EXPRESSION IN SYMPATHETIC NEURONS OF THE ADULT RAT SUPERIOR CERVICAL GANGLION AFTER AXOTOMY. R.P. Mohney*, R.E. Siegel, and R.E. Zigmond. Department of Neurosciences, Case Western Reserve University, School of Medicine, Cleveland, OH 44106.

In the sympathetic nervous system, galanin-like immunoreactivity (IR) is absent in neurons of the adult rat superior cervical ganglion (SCG; Schreiber et al., preceding abstract) and vasoactive intestinal peptide (VIP)-IR is present at a low level (Hokfelt et al., Neurosci., 1977). Immunoreactivity for both neuropeptides increases *in vivo* after postganglionic axotomy of sympathetic neurons, as measured by immunohistochemistry and radioimmunoassay (Schreiber et al., preceding abstract; Hyatt-Sachs et al., J. Neurosci., 1993).

We have examined changes in messenger RNA for galanin and VIP by *in situ* hybridization using radiolabeled oligonucleotide probes. The level of galanin mRNA in the SCG increased after 48 hr in culture, and this increase is seen in neurons throughout the SCG. *In vivo* axotomy of both postganglionic trunks of the SCG, the internal and external carotid nerves (ICN, ECN), resulted in an increase in galanin mRNA qualitatively similar to that seen in culture. The number of neurons containing detectable galanin mRNA after axotomy was higher than the number containing detectable galanin-IR. Lesioning the ICN resulted in an increase in neuronal cell bodies expressing galanin mRNA located primarily in the rostral half of the SCG. Conversely, cutting the ECN produced an increase in galanin mRNA in neurons residing primarily in the caudal portion of the SCG. Decentralization of the SCG, produced by lesioning the cervical sympathetic trunk, increased galanin mRNA expression in a small population of neurons near the caudal end of the SCG. These data are consistent with the hypothesis that galanin mRNA increases predominantly, if not solely, in neurons that have been axotomized. *In vivo* and *in vitro* experiments produced similar increases in VIP mRNA, but a smaller population of neurons was affected than in the case of galanin mRNA. No evidence for an increase in either peptide in non-neuronal cells in the SCG was obtained.

452.2

MAINTENANCE OF PHENOTYPE OF MATURE SWEAT GLAND NEURONS AFTER DISRUPTION OF CONTACT WITH TARGET. S. Harulano and S.C. Landis*. Dept. of Neurosci., CWRU, Cleveland OH 44106.

Downregulation of noradrenergic properties in and acquisition of the mature cholinergic and peptidergic phenotype by rat sweat gland neurons depends on interaction with their target. It is not clear, however, whether maintenance of the neurotransmitter phenotype of the mature sweat gland neurons requires continued interaction with the target. To examine this question we identified sweat gland neurons in the lower lumbar sympathetic ganglia of adult rats by retrograde labeling from hind footpads with fast blue, and then analyzed their neurotransmitter properties at various times after axotomy. Sweat gland neurons constitute a minor population of sympathetic neurons. They either have faint or no tyrosine hydroxylase immunoreactivity (TH-IR), lack neuropeptide Y immunoreactivity (NPY-IR) and contain vasoactive intestinal peptide immunoreactivity (VIP-IR). When retrogradely labeled neurons were examined in sham-operated animals, 81.8±9.1% had faint or no TH-IR, 84.6±11.9% were negative for NPY-IR, and 81.3±8.3% were positive for VIP-IR. The expression of TH-IR, NPY-IR and VIP-IR within retrogradely labeled neurons did not change significantly after axotomy. Fourteen days after surgery, 89.5±4.7% of retrogradely labeled neurons on the axotomized side had faint or no TH-IR, 86±0% were negative for NPY-IR, and 86±0% were positive for VIP-IR. The continued absence of TH-IR after axotomy suggests that axotomy does not alter the neurotransmitter phenotype induced in sweat gland neurons by interactions with their target tissue during development. Further, our results provide evidence that maintenance of the transmitter phenotype of mature sweat gland neurons does not require continued contact with the target.

452.4

REGULATION OF GALANIN EXPRESSION IN THE ADULT SUPERIOR CERVICAL GANGLION (SCG) AFTER AXOTOMY. R.C. Schreiber*, T.A. Bennett, H. Hyatt-Sachs, and R.E. Zigmond. Department of Neurosciences, Case Western Reserve University, School of Medicine, Cleveland, OH 44106.

Postganglionic axotomy of sympathetic neurons results in an increased expression of substance P and vasoactive intestinal peptide-like immunoreactivity (IR) and their mRNAs (Hyatt-Sachs et al., J. Neurosci., 1993; Rao et al., J. Neurobiol., 1993). Another neuropeptide, galanin, has been shown to increase after axotomy of sensory neurons (Hokfelt et al., Neurosci Lett, 1987) and cranial motor neurons (Saika et al., Brain Res, 1989; Moore, J Comp Neurol, 1989).

We have examined the regulation of galanin-IR in the rat SCG after cutting the cervical sympathetic trunk (CST), internal and external carotid nerves (ICN, ECN), and after explant culture. Forty-eight hours after cutting the ICN and ECN or placing the SCG in culture, galanin-IR increased 238- and 438-fold, respectively, as measured by radioimmunoassay (RIA). Immunohistochemical analysis indicated galanin labeled neurons and fibers distributed throughout the SCG. When only the ECN was cut, a 127-fold increase in galanin-IR resulted, and the immunostained neurons were highly concentrated in the caudal portion of the ganglion. Cutting the ICN also resulted in a 127-fold increase in galanin-IR and galanin labeling of neurons and fibers in the rostral portion of the SCG. Lastly, cutting the CST resulted in only a 2.6-fold increase in galanin-IR and a few immunostained neurons near the caudal pole of the SCG. Based on previous retrograde labeling studies (Bowers & Zigmond, J Comp Neurol, 1979) this distribution pattern is consistent with the view that changes in galanin-IR occur primarily, if not solely, in axotomized neurons. The content of galanin mRNA was shown to increase by Northern blot analysis after the ECN and ICN are transected, after explantation and, to a much smaller extent, after the CST was cut. Thus, these data, together with previous studies, indicate that galanin expression increases in sensory, motor, and sympathetic neurons after peripheral nerve transection.

452.6

REGULATION OF GALANIN IN AXOTOMIZED SYMPATHETIC NEURONS IN THE MIDDLE AND INFERIOR CERVICAL GANGLIA. A. M. Shadiack*, S. A. Vaccariello, and R. E. Zigmond. Dept. of Neurosciences, Case Western Reserve Univ, School of Med, Cleveland, OH 44106.

Sympathetic neurons in the rat superior cervical ganglion (SCG) respond to axotomy by increasing levels of certain neuropeptides. Our laboratory has previously shown that vasoactive intestinal peptide and galanin increase 22-fold and 238-fold, respectively, 48 hrs after axotomy.

These observations raised certain questions: 1) Is this a phenomenon restricted to the SCG or do other sympathetic neurons in other ganglia respond similarly? 2) Since axotomy is performed within millimeters of the SCG, is local tissue damage the trigger of this response? 3) Is the peptide regulation occurring in the same neurons that are being axotomized? In order to answer these questions we turned to the middle and inferior cervical ganglia (MICG) which is caudal to the SCG in the sympathetic chain and contains a population of neurons which project rostrally through the cervical sympathetic trunk (CST) (Bowers & Zigmond, Neurosci 1981).

Animals were anesthetized and their CST transected nearly 2 cm away from the MICG so as to leave the ganglion undisturbed. The number of neurons exhibiting galanin-immunoreactivity (IR) increased by 7 days after surgery. We then applied the retrograde label fast blue to the transected CST which resulted in the labeling of a modest portion of the total neurons in the MICG. This tissue was then examined for galanin-IR by immunohistochemistry. Galanin-positive cells followed a similar distribution to the axotomized cells with approximately 75% of the immunostained neurons containing fast blue. As controls, sham-operated animals showed very few galanin-positive cells and, in retrograde labeling experiments, the contralateral MICG showed only a handful of fast blue labeled cells.

452.7

ALTERATION IN ENKEPHALIN EXPRESSION BY SYMPATHETIC NEURONS FOLLOWING INTERRUPTION OF TARGET CONTACT. S. Tyrrell and S. C. Landis. Dept. of Neurosci., Case Western Reserve Univ., Cleveland, OH 44106.

Sympathetic neurons are plastic with respect to their transmitter phenotype. The factors which regulate this plasticity *in vivo* are poorly defined. Previous studies have implicated target tissues in the development of neuropeptide phenotypes. We examined the effect of target contact on enkephalin (Enk) expression by disrupting interactions between the superior cervical ganglion (SCG) and its targets with one dose of the neurotoxin, 6-hydroxydopamine (6-OHDA) on postnatal day (P)1. During normal development, leucine (L)-Enk and methionine (M)-Enk immunoreactive (-IR) SCG neurons were first detected by immunocytochemistry (ICC) on P2. The number of Enk-IR cells and the concentration of Enk-IR assayed by radioimmunoassay (RIA) increased during the first 2 postnatal weeks but decreased dramatically after 3 weeks. *In situ* hybridization studies with a probe complementary to proenkephalin mRNA showed that the percentage of cells with grain densities above background increased until P21. In addition, the mean density of grains over neurons increased until P14 while after P21 neither the proportion of cells with grain densities above background nor the mean grain density changed. Two days after treatment of neonates with 6-OHDA, the density of tyrosine hydroxylase (TH)-IR fibers within the submandibular gland, a target of SCG Enk-IR neurons, was dramatically reduced but by P14 the density of TH-IR fibers was equivalent to that in control animals. Enk-IR detected by ICC and RIA was substantially reduced in the SCG of 6-OHDA treated rats until after P21, while NPY-IR assayed with ICC was unchanged. Moreover, *in situ* hybridization studies showed decreased proenkephalin mRNA in adult SCG. These data indicate that expression of Enk during development and in the adult is altered by neonatal 6-OHDA treatment which disrupts neuron-target interactions. Since we were unable to detect any peak in Enk-IR, and less proenkephalin mRNA was detected in the adult, we conclude that the normal increase in Enk expression was not just delayed, but prevented.

452.9

DEVELOPMENT OF NEUROPEPTIDES AND NADPH-DIAPHORASE IN THE ENTERO-PANCREATIC INNERVATION OF THE RAT. T. Tharakan, A. Kirchgessner, L. V. Baxi, T. Rothman* and M. D. Gershon. Columbia Univ. P&S New York, NY 10032

Pancreatic ganglia are formed by neural crest-derived precursors that migrate first to the bowel and then to the pancreas. These cells are innervated by enteric neurons, which evoke amylase and insulin secretion. Most of the neuropeptides found in the bowel are also present in the pancreas. In addition, the enzyme NADPH-diaphorase (d) is located in a subset of enteric and pancreatic neurons, where it is coexpressed with neuropeptide Y (NPY), vasoactive intestinal peptide (VIP) gastrin releasing peptide (GRP) and galanin (GAL). The expression of neuropeptides and NADPH-d was studied in the fetal and neonatal rat gut and pancreas (E12-P28) *in situ* and in organotypic cultures of pancreatic rudiments and foregut. Neural markers included the immunoreactivities of GAP-43 and NC-1 (which is expressed by crest-derived cells). Neurotransmitter-related markers included dopamine β -hydroxylase (DBH), NPY, VIP, GAL, GRP. At day E12, NC-1 and GAP-43-immunoreactive cells were found in the primordial stomach. These cells were also DBH-immunoreactive. Cells that expressed these markers were visualized in the pancreas one day later, on day E13, along with NPY, which appeared to be present in endocrine cells. Pancreatic NPY-immunoreactive neurons were detected by day E18. GRP immunoreactivity (IR) was first detected in the stomach at day E18 and in the pancreas by birth. VIP-IR could not be detected in the bowel until day E20 and not in the pancreas until birth. GAL-IR appeared in the gut at day E18 and in the pancreas at E20. NADPH-d activity was first found in neurons in the presumptive stomach on day E13. Scattered neurons that expressed NADPH-d activity were visualized in the pancreas on day E14. NADPH-d activity was found in neurons in pancreatic rudiments explanted on day E13; therefore, pancreatic neural precursors must have been present in the pancreatic rudiments when they were explanted. These observations support the idea that pancreatic ganglia develop from transiently catecholaminergic precursors that migrate to the pancreas from the fetal foregut. DEVELOPMENT OF THE DOPAMINE TRANSPORTER (COCAINE BINDING SITE) IN THE RAT MIDBRAIN: AUTORADIOGRAPHY WITH [³H]WIN 35,428. C. L. Coulter, H. K. Happe, L. C. Murrin*. Dept. of Neurology, Creighton Univ. Sch. Med., Omaha NE 68131 and Dept. of Pharmacology, Univ. Neb. Med. Sch., Omaha, NE 68198.

Information on the development of dopaminergic mesencephalic nuclear groups is important in understanding the growth of the mesolimbic and nigrostriatal systems. Radioligands that bind to the dopamine transporter (cocaine binding site) allow visualization of these dopaminergic neurons and their projections. We used [³H]WIN 35,428 to study the developmental distribution of the dopamine transporter in rat midbrain from birth to adult. Rat brain was sectioned at 16 μ and thaw-mounted onto subbed slides. Sections were incubated in 10 mM sodium phosphate buffer, 0.32 M sucrose, 120 mM NaCl, pH 7.4 at 4°C for 120 min, then rinsed 2 x 2 min in ice-cold buffer. Sections were apposed to Hyperfilm for 90 days (adult rats) to 180 days (day 0 rats). Quantitative analysis of autoradiograms showed early maturation of dopamine transporter sites in substantia nigra and ventral tegmental area. Substantia nigra, zona compacta reached adult levels of binding by day 5, as did the posterior portion of the substantia nigra reticulata. The more anterior portion of the substantia nigra reticulata reached adult levels by day 10. In adults there was a caudal (higher) to rostral (lower) gradient of binding in the substantia nigra reticulata that was not appreciable at earlier ages. The ventral tegmental area appeared to develop rapidly since binding to transporter peaked at day 5 and regressed to adult levels by day 15. The subthalamic nucleus showed moderately low levels of binding until day 10, then steadily increasing binding through days 15 and 21. Normative data on development of the dopamine transporter will allow investigation of the effects of perinatal insults from anoxia, toxins (drugs), or infection on the dopaminergic system. Supported by NS 23975.

BEHAVIORAL EFFECTS OF PRENATAL EXPOSURE TO AN ALPHA-1 AGONIST AND ANTAGONIST. W. Briner*, B. Miller, and E. Martin. Dept. of Psychology, Univ. of Nebraska at Kearney, Kearney, NE 68849.

It has been suggested that many of the traditional neurotransmitters may modulate neuronal development. For instance, 5-HT has been shown to exert a trophic effect on embryonic CNS neurons and norepinephrine (NE) innervation is required for normal development of the cerebellum. We have examined the role of the α -1 receptor in early neural development by administering the α -1 agonist phenylephrine (PH) and the α -1 antagonist terazosin (TZ) to rats during early gestation. Female rats were given injections of PH (20.5mg/kg), TZ (171.1mg/kg), injected with saline from days 6-10 of gestation, or left untreated. After birth the pups were examined for the emergence of developmentally significant behaviors. Pups that received the α -1 agonist PH were delayed in the emergence of the surface righting reflex, but advanced for walking. In open-field testing these animals engaged in more rearing behavior than did the other groups. The α -1 antagonist (TZ) group did not differ significantly from the controls. These findings reinforce the concept that the NE system is involved in cerebellar development, but the α -1 receptor may not modulate development in the same direction or manner for all behavioral systems.

452.10

INNERVATION OF POSTNATAL RAT HEART BY NEUROPEPTIDE Y (NPY)- AND TYROSINE HYDROXYLASE (TH)- IMMUNOREACTIVE (IR) NERVES. C. Nyquist-Battie*, S. Sands, P. Cochran and B.M. Chronwall. School of Biological Sciences, University of Missouri - Kansas City, Kansas City, MO 64108

Postnatal development of cardiac NPY-IR nerves was documented and compared to that of TH-IR nerves to determine if these two putative co-localized markers of cardiac sympathetic nerves exhibited the same temporal and spatial developmental pattern. On postnatal day (PN) 2, the NPY-IR sympathetic trunk was easily recognized as it entered the heart. Intense NPY-IR nerve plexuses were present in nodal areas at birth but their density declined with age. Additionally, in newborn hearts individual NPY-IR fibers were present in the myocardium of the atrial septum, being quite noticeable at the atrio-ventricular junction. In all areas, the epicardium contained a NPY-IR nerve plexus on PN2. A rapid NPY-IR innervation of the myocardium occurred between PN2 and PN21 with atrial innervation preceding ventricular innervation. Perivascular innervation was present before myocyte innervation in most instances. The density of NPY-IR fibers in ventricular myocardium decreased between the third postnatal week and adulthood. TH-IR innervation developed similarly to that of NPY, confirming the localization of NPY in sympathetic fibers and suggesting a co-regulation of NPY and TH expression in developing cardiac sympathetic nerves.

452.12

FETAL MOTOR BEHAVIOR AND THE DOPAMINE SYSTEM: EFFECTS OF CENTRAL ADMINISTRATION OF D1 RECEPTOR AGONIST AND ANTAGONIST. E. S. Petrov, E. I. Varlinskaya. Institute for Experimental Medicine, Russian Academy of Medical Sciences, St. Petersburg.; S. R. Robinson, and W. P. Smotherman*. Laboratory of Perinatal Neuroethology, Center for Developmental Psychobiology, Binghamton University, Binghamton, NY 13902-6000.

Intraperitoneal (IP) administration of D1 receptor agonists and antagonists has been shown to produce behavioral effects in rats during the prenatal and early postnatal periods. Understanding the functional role of developing dopaminergic systems may be advanced by central administration of agonist and antagonist drugs and *in vivo* measurement of fetal motor behavior. The D1 agonist SKF-38393 and antagonist SCH-23390 were administered to rat fetuses on E21 by intracerebral (IC) or intrahemispheric (IH) injection. Both routes of agonist administration resulted in increased motor activity. IC injection of SKF-38393 in various dosages (0.2-10.0 μ g) elicited a pronounced increase in movements of the head, limbs and body trunk, which comprise the main categories of movement during spontaneous activity. IC injection of the D1 antagonist did not change overall activity in the dosage range of 5.0-20.0 μ g, but fetuses treated with SCH-23390 showed an increase in specific behavioral categories seldom observed during spontaneous activity (facial wiping, mouthing and licking movements), and a decrease in common movement categories (head, forelimb and rearlimb). Unilateral IH injection resulted in similar changes in fetal behavior, suggesting that the right and left hemispheres of the fetal brain are sensitive to D1 receptor manipulation. Differences in behavioral effects of left and right IH injections suggest lateral asymmetry in sensitivity to a D1 agonist, but only in females. These data confirm that central dopamine systems play an important role in the regulation of motor behavior during the prenatal period.

DEVELOPMENT OF SEROTONIN CONTENT AND
TURNOVER AFTER NEONATAL 5,7-
DIHYDROXYTRYPTAMINE TREATMENT IN RATS.

M. Mercugliano*, H.Q. Nguyen, S. Djali, and I. Lucki. Children's Seashore House and Departments of Pediatrics, Pharmacology, and Psychiatry, University of Pennsylvania, Philadelphia, PA. 19104.

The neurochemical effects of treatment with the serotonin (5-HT) neurotoxin, 5,7-dihydroxytryptamine (5,7-DHT) were examined by HPLC 4, 8, and 12 weeks after neonatal i.c.v. administration (100 µg free base). Region-specific patterns in the development of 5-HT and 5-hydroxyindoleacetic acid (5-HIAA) content were found in control rats. In the hippocampus, 5-HT was unchanged while 5-HIAA increased from 4 to 12 weeks. In the striatum, 5-HT increased while 5-HIAA was unchanged. In the cortex, both 5-HT and 5-HIAA increased. In treated rats, 5-HT was reduced by 82-94% without evidence of recovery or further decrease in these regions from 4 to 12 weeks. 5-HIAA was also significantly reduced, but declined further from 4 to 12 weeks. The ratio of 5-HIAA to 5-HT (turnover) differed in each region. In the cortex it was consistently decreased, in the striatum it was transiently increased, and in the hippocampus, it declined from 4 to 12 weeks. In the brainstem, 5-HT and 5-HIAA content were similar to controls until 12 weeks when both were significantly decreased. Normal 5-HT turnover was maintained. These results indicate differences between the forebrain and brainstem response to neonatal 5,7-DHT treatment, as well as differences between individual forebrain regions in subsequent 5-HT turnover. Supported by USPHS grants MH 36262, HD 26979 and K08 NS01594-01.

DEVELOPMENTAL REGULATION OF OCTOPAMINE
BIOSYNTHESIS IN THE CNS OF *MANDUCA SEXTA*.
H.K. Lehman*, C. Murguic, and J.G. Hildebrand. ARL Div. of
Neurobiology, Univ. of Arizona, Tucson, AZ 85721.

Octopamine is a widespread neurotransmitter in *M. sexta*, and the enzyme tyramine β-hydroxylase (TBH) is essential for the biosynthesis of octopamine. To study the developmental regulation of the octopaminergic phenotype, we have analysed the biochemical and morphological development of octopaminergic neurons in the insect nervous system.

In *M. sexta*, two octopaminergic neurons in each abdominal ganglion develop during embryogenesis. TBH activity remains unchanged in each ganglion from early to mid stages of adult development, but in later stages (beginning at pupal day 10), TBH activity increases 6-fold specifically in the terminal abdominal ganglion (TAG). The rise in TBH activity is coincident with the appearance of putative octopaminergic neurons in the TAG. A copper histochemical technique was used to visualize TBH containing cells during metamorphosis; 4 neurons appear in the male and 3 in the female. In addition, increased TBH levels are temporally correlated with changes in steroid hormone levels during development. The transformation from a larva to an adult is controlled by three pulses of ecdysteroids during metamorphosis: a small commitment peak, a prepupal peak, and a large pupal peak. Results of ligation experiments indicate that the largest pulse of 20-hydroxyecdysone (20-HE), the pupal peak, is required for normal development of TBH. Infusions of 20-HE to mimic the pupal peak are being used to confirm that the steroid is necessary and sufficient for the development of TBH in the TAG. [Supported by NSF IBN-92309780 (HKL.)]

Birmingham B67 7JX, UK.

With the use of foetal neural tissue as donor tissue for transplantation in the treatment of Parkinson's disease, it has become necessary to expand our understanding of the functional development of dopaminergic (DA) neurones in the brain. In this study we have investigated the development of DA function by measuring cyclic AMP accumulation in the presence of DA and the selective partial D1 receptor agonist SKF38393 in the ventral mesencephalon which contains the substantia nigra and the striatum of 17 to 20 week old human foetal brain. cAMP accumulation was measured in cross-chopped slices by a prelabelling assay using 3H-adenine in the presence of the phosphodiesterase inhibitor rolipram.

In the ventral mesencephalon, cyclic AMP production was increased by DA and to a lesser extent by SKF38393. In the striatum however, no increase was observed with DA receptor activation. The direct adenylyl cyclase activator forskolin increased cyclic AMP levels in both brain areas. These results indicate the presence of the functional enzyme in both the ventral mesencephalon and in the striatum. A functional link between the DA receptor and the second messenger system appears only to be established in the ventral mesencephalon at this stage of development, indicating that the functional linkage of the DA receptors in the striatum occurs at a later stage.

SEROTONIN-IMMUNOREACTIVE NEURONS DEVELOP IN
CULTURES OF THE EMBRYONIC CHICK HYPOTHALAMUS.
A.M. Gabaldon, V.A. Roe, Y.M. Bellis, A.Y. Gonzales and J.A.
Wallace*. Dept. of Anatomy, Univ. of New Mexico Sch. of
Med., Albuquerque, NM 87131.

We have reported previously on the presence of tryptophan hydroxylase (TPOH) immunoreactive neurons in the hypothalamus of the chick embryo near hatching (SON Abs. 18:1471,'92). However, while TPOH is the first enzyme in the synthesis of serotonin (5-HT), no 5-HT immunoreactive cells are found in hypothalamic regions where TPOH+ neurons occur. To investigate whether hypothalamic TPOH+ cells have the potential to synthesize 5-HT during development, primary cultures of the embryonic hypothalamus were examined for the presence of 5-HT-containing neurons. Dissociated cells from the diencephalon of chick embryos at 8 days of incubation were plated on collagen-coated Petri dishes and grown for 5-7 days. Cultures grown in media (DMEM-F12) containing either 10% horse serum or 10% Serum Plus (Hazelton) produced numerous, intensely stained 5-HT immunoreactive neurons. The occurrence of these cells may indicate plasticity in the ability of TPOH+ neurons to synthesize 5-HT, or the induction of a novel population of 5-HT synthesizing or accumulating cells. Supported by grants DHHS GM08222 and RR08139.

452.16

EFFECTS OF SEROTONIN (5HT) ON SOMATOSENSORY CORTEX OF
NEONATAL RATS *IN VITRO*. M.-Y. Shi*, R.D. Mooney, C.A. Bennett-
Clarke, and R.W. Rhoades. Medical College of Ohio, Toledo OH 43699.

Recent data from our lab indicate that 5HT_{1B} receptors in S1 cortex are found on terminals of thalamocortical afferents during the first two postnatal weeks. We have examined the function of these receptors by intracellular and whole-cell recording using brain slices cut obliquely in order to preserve the thalamocortical projection. A stimulating electrode was placed in ventrobasal thalamus. To date we have tested 29 cells in S1 in animals 7-12 days of age. Using bath application, 5HT invariably reduced the amplitude of evoked EPSPs but also produced changes in membrane resistance and resting potential. To evaluate the role of the 5HT_{1B} receptors, we have used selective 5HT_{1B} agonists, TFMP and CGS12066B, and have also applied 5HT after pretreatment of slices with ligands selective for 5HT_{1A} and 5HT₂ receptors. In 90% (n=10) of cells tested with 5HT_{1B} agonists, the evoked EPSPs were reduced by at least 50% in amplitude without any corresponding change in membrane potential. In the presence of 5HT₂ antagonist ketanserin plus 5HT_{1A} agonist 8-OH-DPAT, 5HT produced no additional change in membrane potential but reduced EPSP amplitude by >50% for all 7 cells tested. After pretreatment with less selective antagonists, methiothepin, cyproheptidine and spiperone, 5HT in each case (n=6) reduced EPSP amplitude and either hyperpolarized or depolarized the neurons according to whether 5HT₂ or 5HT_{1A} receptors were antagonized, respectively. In summary, 5HT produces a number of effects upon S1 cortical neurons consistent with the presence of several subtypes of 5HT receptors. Moreover, the 5HT_{1B} receptor appears to mediate presynaptic inhibition of thalamocortical transmission in neonates.

NEUROTRANSMITTER STIMULATION OF G PROTEIN GTPASE
ACTIVITY IN DEVELOPING CHICK HEART. R.S. Aronstam* and T.L.
Craazzo, Guthrie Research Institute, Sayre, PA 18840 and Dept. Cellular
Biology & Anatomy, Medical College of Georgia, Augusta, GA 30912.

The ability of muscarinic and β-adrenergic agonists to activate the G protein cycle during development of chick heart was determined by monitoring agonist stimulation of G protein GTPase activity. GTPase activity was determined by the method of Cassel and Selinger. The reaction was carried out for 10 min at 37°C, and then quenched by the addition of 5% activated charcoal in 20 mM phosphoric acid (pH 2.5). Low K_M GTPase activity was calculated by subtracting activity measured in the presence of 100 µM GTP. Acetylcholine stimulated low K_M GTPase activity by up to 120% (incubation day 12) with an EC50 of 1 µM. This stimulation was completely blocked by atropine with an IC50 of 100 nM. Isoproterenol stimulated GTPase activity by 40% with an EC50 of 3 µM; this stimulation was blocked by propranolol. Basal GTPase activity measured in the absence of receptor agonist increased steadily from incubation day 4 to incubation day 17 (from 8.8 to 17.6 pmol/mg protein/min). The amount of activity stimulated by both acetylcholine and isoproterenol was constant from incubation day 4 to incubation day 12, then rose 25% by day 17. G protein activation as indicated by fractional stimulation of basal activity declined steadily throughout development until day 12, after which it remained constant. These findings are consistent with the presence of G protein-coupled muscarinic and β-adrenergic receptors early in the development of chick heart, prior to sympathetic and parasympathetic innervation. MORPHOLOGY AND CALCIUM CURRENT IN PC12D CELLS AFTER TREATMENT OF DOPAMINE(DA)-DEPLETED STRIATAL TISSUE EXTRACT. H. Hida, K. Nakajima, T. Hashitani, A. Fukuda, Robert E. Petroski², M. Inase¹ and H. Nishino. Dept. Physiol., Nagoya City Univ. Med. Sch., Nagoya, 467. ¹Natl Inst. Physiol. Sci., Okazaki, 444, Japan. ²Robert Wood Johnson Med. Sch., Piscataway, NJ 08854.

Development in morphology and Ca-current in PC12D cells were investigated after treatment of tissue extract from DA-depleted striatum. In Wistar rat, 6-OHDA was microinjected in the substantia nigra(SN) unilaterally to make chemical lesions in the nigrostriatal DAergic pathway. Two weeks after the lesion, DA-depleted striata were dissected out from rats that exhibited significant amphetamine-induced rotations. These DA-depleted striatal and intact striatal tissues were homogenized with leupeptin and mercaptoethanol, centrifuged (35000 rpm, 1h) and the supernatant was collected. PC12D cells were plated on poly-L-lysine or collagen coated dishes with 2% horse serum and 1% fetal calf serum. Extracts were added to the culture every three days. The DA-depleted striatal extract promoted neurite outgrowth in PC12D cells in concentration dependent manner. The effect was stronger than the intact striatal extracts. The extract induced a rather straight neurite extension with fewer arborizations compared to the treatment of NGF. Under whole cell patch clamp, with standard bath solution containing TTX and cesium-containing pipette bigger long-lasting inward current were observed in cells treated with DA-depleted striatal extract than in control cells. Data suggest the increase in Ca current may partly be the basis of differentiation of PC12D cells after treatment of DA-depleted striatal tissue extract.

453.3

CHARACTERIZATION OF THE ACUTE SYNAPTIC EFFECTS OF THE NEUROTROPHINS NT-3 AND BDNF. A.M. Lohof*, N.Y. Ip⁺, and M.-m. Poo, Department of Biological Sciences, Columbia University, New York, NY 10027 and ⁺Regeneron Pharmaceuticals, Tarrytown, NY 10591

We have previously shown that acute exposure to either neurotrophin-3 (NT-3) or brain-derived neurotrophic factor (BDNF) can produce rapid potentiation of the spontaneous and impulse-evoked synaptic activity at developing *Xenopus* neuromuscular junctions in culture; similar treatment with nerve growth factor (NGF) has no effect. The effect of NT-3 or BDNF on the frequency of spontaneous synaptic currents (SSCs) appears to reflect an increase in the frequency of spontaneous acetylcholine (ACh) secretion rather than an increase in post-synaptic ACh receptor sensitivity. Neither the mean SSC amplitude nor the distribution of SSC amplitudes changed following application of the neurotrophins. Further characterization of the synaptic potentiation produced by NT-3 indicates that the continuous presence of the factor is required; the frequency of SSCs returns to control levels after NT-3 is removed from the recording bath, whether the time of exposure to NT-3 is 15 min or 1 hr. This result suggests that exposure to the neurotrophin does not produce a lasting modulation of the synapse. Rather a rapid and reversible alteration in the secretion mechanism probably produces the change in SSC frequency. Finally, the effect of NT-3 appears to be mediated by Trk receptors, since pretreatment of cultures with 200 nM K252a prevented any change in SSC frequency when NT-3 was applied. Pretreatment with K252b, which does not inhibit Trk receptors at this concentration, did not prevent the NT-3 effect. Together, our results suggest that neurotrophins may play a role in regulating the function of developing synapses.

REGULATION OF VOLTAGE-GATED ION CHANNELS BY NEUROTROPHIC FACTORS IN NEURAL CELL LINES. S. S. Lesser and D. C. Lo*. Department of Neurobiology, Box 3209, Duke University Medical Center, Durham NC 27710.

Although the development and maintenance of neuronal excitability is thought to be strongly influenced by neurotrophic factors, their regulation of ion channel and neurotransmitter receptor expression remains largely uncharacterized. We have conducted a preliminary study of the regulation of voltage-gated sodium, potassium, and calcium channel expression by neurotrophic factors in "neural" cells such as the human neuroblastoma line SK-N-SH, the parent line of SH-SY5Y cells. Because the SK-N-SH cell line has been used extensively in signal transduction studies of neurotrophic factors and also as a model for neuronal differentiation, it is particularly attractive for examining neurotrophic control over the development of excitability.

We found that NGF treatment caused an increase in sodium channel expression (2-fold in peak current; N=40), potassium channel expression (2-fold; N=8) and calcium channel expression (5-fold; N=52) as measured by whole-cell, perforated-patch, and single-channel recording. Induction was seen within 2-3 days after NGF addition, but became most pronounced by 5-6 days of treatment. Although it has previously been shown that SK-N-SH cells and SH-SY5Y cells respond to CNTF by increased *c-fos* expression, CNTF addition did not significantly alter sodium or calcium channel expression either alone (N=20) or in combination with NGF (N=18). Similarly, BDNF addition had no effect on sodium or calcium channel induction in SK-N-SH cells (N=17), even though BDNF has been shown to induce *c-fos* in SH-SY5Y cells. Differentiation by TPA (20 nM), led to an increase in sodium and calcium channel expression smaller than that induced by NGF (N=14), while retinoic acid (10 μ M) affected neither sodium nor calcium channel expression (N=13). These and other experiments demonstrate that neural cell lines will provide a good system for the study of neurotrophic regulation of neuronal excitability through a combined use of molecular, imaging, and electrophysiological approaches.

IN VITRO DEVELOPMENT OF IMMORTALIZED MURINE HIPPOCAMPAL PROGENITOR CELLS. R. Rozental^{1,2}, M.F. Mehler^{2,3}, M. Morales², A.F. Andrade-Rozental^{1,2}, J.A. Kessler^{2,3} and D.C. Spray². ¹Institute of Biophysics "Carlos Chagas Filho", UFRJ, 21941, Brazil; and Departments of ²Neuroscience and ³Neurology, A. Einstein College of Medicine, Bronx, New York, 10461, USA.

We examined the temporal interrelationship among gap junctions, voltage- and ligand-gated responses during neuronal maturation. In immortalized murine embryonic hippocampal progenitor cells (Mehler et al., *Nature*, 1993), *in vitro* differentiation was induced by either interleukin (IL)-7 alone or concurrently with TGF α and bFGF and evaluated under patch clamp, dye-coupling and Ca²⁺ imaging techniques. Electrotonic coupling between untreated neuroblasts was observed within 24 hours of plating in serum-free media. However, as neuroblasts differentiated into neurons both the junctional conductance and the extent of dye coupling progressively decreased. Voltage-dependent inward currents, that in time became TTX-sensitive, were observed under whole-cell patch clamp technique within two to six days of neuroblast treatment with cytokines. At this stage, however, these cells did not respond to glutamate and glycine ($\leq 100 \mu$ M) or to acetylcholine ($\leq 300 \mu$ M) (outside-out patch configuration). Contrary to expectation, the neuronal steady-state [Ca²⁺]_i did not change during ontogeny. Together, these findings indicate that certain cytokines may be involved in the development of excitability in neurons. Furthermore, the onset of voltage-dependent responses and the disappearance of intercellular coupling in these hippocampal cells seem to precede the expression of chemosensitivity to a variety of neurotransmitters.

453.4

SODIUM CURRENT PROPERTIES OF POSTNATAL RAT CHROMAFFIN CELLS EXPOSED TO NGF IN VITRO GRADUALLY RESEMBLE THOSE OF DIFFERENTIATED RAT SYMPATHETIC NEURONS. Islas-Suárez L., Gómez-Chavarrín M., Verdugo-Díaz J., Méndez M., Drucker-Colín R., and Hernández-Cruz A*. Instituto de Fisiología Celular, UNAM; A.P. 04510, México city, México.

Postnatal adrenal chromaffin cells undergo neuron-like morphologic differentiation in response to NGF. An increased excitability has been documented in their neoplastic correlate (PC12 cells), were NGF markedly increases sodium current (I_{Na}) density. Although PC12 cell differentiation is widely used as a model for the development and maturation of cells from the simpatoadrenal lineage, it fails to reproduce some key observations. For instance, peak current potential, voltage dependence of activation and inactivation, and reversal potential of I_{Na} differ markedly between chromaffin cells and mature sympathetic neurons, however, the properties of I_{Na} in PC12 cells remain unchanged after NGF treatment. This work describes changes both in the current density and in the functional properties of I_{Na} during the NGF-induced neuronal differentiation of postnatal chromaffin cells. Rat chromaffin cells from postnatal day 7 were grown either in control media (DMEM, 10% FCS and antibiotics) or control media supplemented with 50-100 ng/ml NGF for periods up to 18 days. Freshly dissociated chromaffin cells and sympathetic SCG neurons from 18 day old rats were also used for comparison. Whole-cell patch-clamp experiments were conducted at different stages of differentiation. (Pipette solution (mM): CsCl 110, HEPES 10, EGTA 11, MgCl₂ 1, pH 7.3; External solution (mM): NaCl 120, Hepes 10, MgCl₂ 2, KCl 2.8, CaCl₂ 1.8, pH 7.4). As a result of NGF treatment for 18 days, cell capacitance increased from 6.5 to 24 pF reflecting soma growth and neurite extension. At the same time, the average peak I_{Na} increased from 240 to 3000 pA, and the current density from 52 to 142 μ A/cm². This compares with an average of 170 μ A/cm² for mature sympathetic neurons. The peak current potential, half-activation, half-inactivation and reversal potential of I_{Na} in mature chromaffin cells were, respectively, +10, -10.9, -37.6 and +60 mV. In contrast, mature sympathetic neurons had -15, -35, -43 and +30. In cultured chromaffin cells these values started at +9, -9.7, -41.4, and +60 on day 0 and reached -2, -25.4, -43.6 and +43 after 18 days of NGF treatment. Thus, during NGF-induced neuronal differentiation, the properties of I_{Na} which are characteristic of the chromaffin phenotype change to resemble those of the sympathetic phenotype. Current investigation is aimed to find out if complete transformation requires more prolonged NGF treatment or if a limit to the complete transdifferentiation exists. NGF INCREASES VOLTAGE-DEPENDENT SODIUM CURRENT IN PANCREATIC β -CELLS. T. Rosenbaum, D. Sánchez-Herrera, R. Vidal-Tamayo, M.C. Sánchez-Soto, M. Hiriart*. Inst. Fisiología Celular Dept. Bioenergética, UNAM, México D.F., 04510, MEXICO.

We have previously shown the induction of neurite outgrowth by NGF in pancreatic β -cells (Soc. Neurosci., 1992, Abst. 542.4). Following the study of the phenotypical NGF-induced changes in pancreatic β -cells, we have also assessed the cytoskeleton role in neurite outgrowth, and found that 92 % of the neurites are positive to tubulin (IF), suggesting that the β -cell cytoskeleton is actively participating in the process of neurogenization.

On the other hand, it has also been observed in other cell types that respond to NGF, like PC12 cell-line, that neurogenization is accompanied by changes in membrane electrical properties, which include a significant increase in sodium channel density. Normal pancreatic β -cells have voltage-dependent sodium channels which are important for membrane depolarization. In this study, the effect of 2.5S NGF on voltage-dependent sodium current of isolated β -cells was investigated. Islet cells were cultured for one week in the presence of 2.5S NGF (50 ng/ml), and inward ionic currents were recorded with a WCR variant of the patch clamp technique. The results indicate that NGF induced a 43% increase in macroscopic TTX-sensitive Na current with respect to control cells, from -37.89 \pm 4.5 pA to -54.09 \pm 5.3 pA (n=32 for each one, p<0.05). Our data suggest that one of the mechanisms of action of NGF on pancreatic β -cells is similar to that observed in other systems that respond to this factor with an increase in sodium channels expression.

A SENSITIVE AND QUANTITATIVE BIOASSAY FOR NEUROTROPHINS USING SERUM-FREE MEDIUM.

S.A. Scott, X. Tian and K.A. Critcher. Department of Neurosurgery, University of Cincinnati School of Medicine, Cincinnati OH 45267.

Assays employing embryonic chick sympathetic and dorsal root ganglia are routinely used to demonstrate the biological activity of NGF and related neurotrophins. These assays vary in sensitivity for several reasons, notably the type of dissection (explants versus dissociated cells) and the components of the tissue culture medium. When measuring neurotrophin-like bioactivity in tissue extracts, the ability to reliably measure very low levels (i.e., less than 10 pg/ml) is often necessary. We have developed a quantitative and serum-free bioassay for such purposes, using explants from sympathetic and dorsal root ganglia of E9 chick embryos. Medium consisted of Ham's F12 supplemented with selenium, putrescine, progesterone, human transferrin, and antibiotics, along with recombinant human proteins NGF (Genentech), BDNF or NT-3 (both from Amgen) ranging in final concentration from less than 1 pg/ml to over 100 ng/ml. Cultures were grown overnight in polyornithine-treated petri dishes and subsequently fixed and stained with silver nitrate. Neurite outgrowth was assessed using both image analytic and semiquantitative approaches.

The sympathetic ganglion assay consistently detected NGF in the range of 1-3 pg/ml, considerably below the limit of detection reported in previous studies. NT-3 was detectable below 10 pg/ml. BDNF was ineffective in the sympathetic assay but did stimulate neurite growth from sensory ganglia (as did both NGF and NT-3) at concentrations as low as 10 pg/ml. Areal measurements of neurite outgrowth alone correlated very highly with NGF levels up to 200 pg/ml. At higher concentrations, the density of neurites continued to increase whereas areal outgrowth (i.e., neurite length) did not. The maximally effective concentration of NGF was ~ 500 pg/ml, in accordance with a previous report (Greene, 1974), suggesting that biologically relevant levels of NGF are detected with this assay.

STRUCTURE/ACTIVITY RELATIONSHIPS OF NGF/BDNF CHIMERIC PROTEINS. D. Dawbarn*, S.M. Colebrook, R. Feeney, S.H. MacGowan, S.J. Allen and M. Ashcroft. Molecular Neurobiology Group, Dept. Med. (Care of the Elderly), Bristol Univ., Bristol, BS2 8HW.

We have identified four regions of variability between the otherwise highly homologous protein sequences of the human neurotrophins (NGF, BDNF, NT-3 & NT-5). PCR homologue mutagenesis was used to generate a series of mutant genes, each encoding the human NGF gene with one or more of these four variable domains replaced with the equivalent domain from BDNF. The chimeric mutant proteins were expressed in Sf21 cells using the baculovirus system and production quantified using a two site ELISA. The neurotrophic biological activity of the mutants was assessed using a PC12 cell neurite outgrowth assay for NGF and a chick nodose ganglia assay for BDNF. The receptor binding and phosphorylation ability of each mutant was studied using p140trkA and p145trkB receptors expressed in COS-7 cells. These studies have identified regions within the neurotrophins that are required for activation of specific trk receptors.

NEUROTROPHIC ACTIVITY OF RAT HIPPOCAMPAL MOSSY FIBER SYNAPTOSOMAL FRACTIONS

Ph. Taupin*, Y. Ben-Ari, M.P. Roisin and G. Barbini. INSERM U29, 123 Bd Port-Royal, 75014 Paris, France.

In the hippocampus, the axons of the dentate granule cells, the Mossy Fibers, project to CA3 pyramidal neurons.

We have developed a procedure for the isolation from Wistar adult rat hippocampal Mossy Fiber synaptosomes on 3-steps Percoll gradients from the post-nuclear pellet. The PII and PIII fractions are enriched in zinc, in dynorphin and in typical Mossy Fiber synaptosomes (EM). All these features are absent in synaptosomes prepared from neonatally irradiated hippocampus to destroy the granule cells and Mossy Fibers (Ph. Taupin et al., submitted 1993).

We now report that Mossy Fiber synaptosomal fractions promote mitotic reinitiation on 3T3 fibroblasts and neurite outgrowth on PC12 cells. These activities are heat-inactivated, trypsin-sensitive and retained with molecular weight cut off device of 10 kDa (centricon). These results suggest that Mossy Fiber endings contain proteic factor(s) exhibiting neurotrophic activities. These factor(s) may be acting as paracrine or autocrine factors; the modification of expression of these factor(s) might be involved in Mossy Fiber sprouting. The granule cells synthesize a variety of trophic factors including NGF, BDNF, NT3, FGF. We are now pursuing the characterization of this factor(s) and testing these fractions on primary cultures of hippocampal neurons. (supported by INSERM and Servier)

HIGH-LEVEL PRODUCTION AND CHARACTERIZATION OF RECOMBINANT BRAIN-DERIVED NEUROTROPHIC FACTOR AND NEUROTROPHIN-3 EXPRESSED IN INSECT CELLS. D. M. Lang, S. L. Meyer, M. E. Forbes, E. Knight, Jr., J. D. Hirsch, S. P. Trusko, J. C. Kauer*, and R. W. Scott. Cephalon, Inc., West Chester, PA 19380.

Bioactive brain-derived neurotrophic factor (BDNF) and neurotrophin-3 (NT-3) were produced at high levels using the baculovirus expression system and purified to homogeneity using ion-exchange and reversed-phase chromatography. Yields of purified neurotrophin-3 (300-500 µg/L) were similar to levels reported for baculovirus-expressed nerve growth factor (NGF), whereas initial yields of BDNF were significantly lower (20-50 µg/L). Improved production of BDNF (150-200 µg/L) was achieved by expressing BDNF from a chimeric preproNGF/mature BDNF construct using the *Trichoplusia ni* insect cell line, Tn-5B1-4. Examination of the distribution of BDNF protein from both the chimeric preproBDNF and the chimeric preproNGF/mature BDNF viruses in Sf-21 and Tn-5B1-4 infected cells suggests a specific deficiency in the Tn-5B1-4 cells in processing the nonchimeric precursor. In addition, the vast majority of the BDNF protein at was intracellular and insoluble. Reversed-phase HPLC separated both the BDNF and NT-3 into two species, having similar bioactivity and identical N-terminal amino acid sequences. SDS-PAGE analysis under non-reducing conditions revealed that one HPLC species is the neurotrophin monomer and the other species is the dimer. Bioactivity was characterized *in vitro* on primary neuronal cultures from the CNS and PNS.

SYNERGISTIC TROPHIC ACTIONS REVEALED BY NGF/BDNF CHIMERIC MOLECULES. I.B. Black*, W.J. Friedman, H. Persson¹, and C.F. Ibáñez¹ Department of Neuroscience and Cell Biology, UMDNJ-Robert Wood Johnson Medical School, 675 Hoes Lane, Piscataway, N.J. 08854, USA, and ¹Lab of Molecular Neurobiology, Karolinska Institute, Box 60400, S-10401 Stockholm, Sweden

Members of the neurotrophin family of trophic factors act on specific neuronal populations to influence survival and/or function. We have previously shown that different neurotrophins have distinct influences on basal forebrain cholinergic neurons: NGF increased ChAT activity but had no effect on cholinergic cell survival, while BDNF, NT-3 and NT-4 all increased survival.

We have now employed a purified chimeric trophic molecule combining active domains of NGF and BDNF (Ibáñez et al., EMBO J. 10, 2105-2110, 1991) to examine the combined effects of the two trophic activities. We compared the influence of this chimera on substantia nigra (SN) dopaminergic (DA) neurons (which are influenced by BDNF but not NGF) with the basal forebrain (BF) cholinergic neurons (which are differentially influenced by the two factors). In pure neuronal cultures from the SN, the chimera reproduced the effects of purified BDNF, eliciting an approximate 15% increase in DA neurons. In contrast, in BF neuronal cultures the chimera was 100x more potent than BDNF in promoting cholinergic cell survival. Identical results were obtained when NGF and BDNF were added together to the cultures. These data suggest that although NGF itself does not influence cholinergic cell survival, this factor may potentiate the survival effects of BDNF in the BF. PROTO-ONCOGENE JUN-B AS A TARGET FOR ACTIVIN ACTION IN NEURONAL CELLS Makoto Hashimoto, V.J. Roberts* and W.W. Vale, Clayton Foundation Laboratories for Peptide Biology, The Salk Institute for Biological Studies, La Jolla, CA 92037

Activins are implicated in the regulation of growth, development and differentiation of a variety of biological systems; for example, they are involved in the control of pituitary hormone secretion, neuronal cell survival, retrograde regulation of somatostatin expression in ciliary ganglion cells and the induction of embryonic mesoderm. We have sought to identify immediate early genes whose altered expression may provide a common nuclear event which mediates a myriad of activin-regulated phenotypic changes in neuronal and other cell types. We utilized PC12 pheochromocytoma cells, in which activin was found to suppress cell proliferation and reduce tyrosine hydroxylase expression, but did not cause neurite formation. We analyzed the expression of mRNAs for the proto-oncogenes junB, c-jun, and c-fos at various times following activin stimulation. Activin treatment selectively increased expression of junB mRNA within 1hr, whereas neither c-jun nor c-fos mRNA were observed in treated or untreated cells. The transient induction of junB expression was transcription-dependent and protein synthesis-independent. Similar results were obtained using human K562 myelogenous leukemia cells, indicating that JunB induction may be a common step in the activin signal transduction pathway in a diverse set of tissues, including the central nervous system.

A NOVEL NEURITE-PROMOTING FACTOR FROM HUMAN T-CELL HYBRIDOMA: IDENTIFICATION AS EOSINOPHIL MAJOR BASIC PROTEIN PRECURSOR WITH CHONDROITIN SULFATE GLYCOSAMINOGLYCAN. Y. Arakawa*, K. Isahara, Y. Shikata and S. Tachibana. Tsukuba Res. Labs., Eisai Co., Tsukuba 300-26, Japan.

There are extensive reports on crosstalk between nervous systems and immune systems as exemplified by cytokines and neurotrophic factors. Here we found neurite-promoting activity (NPF act) in serum-free medium conditioned by human T-cell hybridoma (C-108) using serum-free culture of fetal rat septal neurons. NPF act was purified by batchwise and gradient elutions on DEAE-Sepharose columns and by gel-filtration chromatography on Sepharose CL-4B. Since the factor, designated as CII, contains many free cysteine residues, it was reduced and carboxymethylated for the stabilization of the activity (designated as CII-CM). Both CII and CII-CM showed potent NPF act on septal neurons with half-maximal activity at 130ng/ml and 71ng/ml, respectively. A broad band of CII-CM on SDS-PAGE at 88-110 kDa, shifted to 35kDa after chondroitinase ABC digestion (CII-CM core), and after further digestion with glycopeptidase A to 32kDa, indicating that CII-CM has glycosaminoglycans and N-oligosaccharides. CII-CM core still showed a significant activity (1/6 of CII-CM), suggesting that the core protein plays a key role in NPF act. The amino acid and sequence analysis revealed that the protein part of CII is identical to eosinophil major basic protein precursor. Secretion of NPF act from an immune cell line suggests the involvement of immune cells in the regeneration of CNS after damage.

STABLE TRANSFECTION OF C6 ASTROCYTOMA CELLS WITH BASIC FIBROBLAST GROWTH FACTOR SENSE AND ANTISENSE cDNA. G. J. Redekop and C. C. G. Naus. Departments of Anatomy and Clinical Neurological Sciences, The University of Western Ontario, London, Canada, N6A 5C1.

Peptide growth factors play a major role in the control of cell division and differentiation. Aberrant autocrine control by such growth factors is postulated as a mechanism by which disordered regulation of cell proliferation may occur. We have used the C6 astrocytoma cell line as a model to study the role of basic fibroblast growth factor (bFGF) in tumor growth. C6 cells produce bFGF messenger RNA and at least two bFGF protein species, with molecular weights of 18 and 22.5 kDa. In addition, they have high affinity FGF receptors through which exogenous bFGF acts as a mitogen, confirming its function as an autocrine growth factor. To further investigate the role of bFGF we have transfected C6 cells with bFGF cDNA in both the sense and antisense orientation using a stably incorporated plasmid vector (pLTR/gpt). Clones with high mRNA expression of the sense construct exhibit increased rates of proliferation in cell culture when compared to the parent cell line and show increased levels of intracellular and extracellular bFGF by immunocytochemistry. Clones with high expression of the antisense construct show a diminished rate of proliferation in culture and reduced levels of immunologically detectable bFGF. These C6 bFGF transfectants will be useful for further *in vivo* and *in vitro* study of the role of bFGF in tumor growth. Supported by the Medical Research Council of Canada and the Brain Research Fund.

NEONATAL OLIGODENDROCYTES EXPRESS NEU AND RESPOND TO NEU DIFFERENTIATION FACTOR

S. Stuy, T. Neuberger, A. Welcher*, N. Liu, R. Koski, D. Wen, and G.H. De Vries. Dept. of Biochem. & Biophysics, MCV/VCU, Richmond, VA 23298-0614 Amgen, Thousand Oaks, CA 91320

Neu differentiation factor (NDF) is a glycoprotein with a molecular weight of 44 kDa which is believed to be a ligand for Neu-receptor. Addition of either of the two isoforms of NDF- (α or β) to primary neonatal oligodendroglia (OLG) had no effect on OLG proliferation as measured by ^3H -thymidine uptake. However, pretreatment of OLG with either NDF- α or NDF- β for 3 days followed by the addition of basic fibroblast growth factor (bFGF) caused a decrease in the mitogenic response of OLG relative to non-pretreated OLG. Pretreatment of OLG with NDF- α followed by the addition of axolemma enriched fraction (AEF) had no effect on AEF mitogenicity, whereas pretreatment with NDF- β followed by the addition of AEF resulted in an increase of OLG proliferation. Addition of anti-NDF antibodies to AEF resulted in a decrease in ^3H -thymidine uptake relative to AEF treated OLG. OLG showed a strong positive immunoreactivity to both the intracellular and extracellular domain of the Neu-receptor. We conclude that under these conditions neither NDF isoform by itself acts as a mitogen for OLG, AEF contains NDF-related molecules that potentiate the AEF mitogenicity for the OLG and that neonatal OLG express Neu-receptors. 453.14

REVERSAL BY NGF OF CYTOSTATIC DRUG-INDUCED REDUCTION OF NEURITE OUTGROWTH IN RAT DORSAL ROOT GANGLIA IN VITRO. P.N.M. Konings*, W.K. Makkink, H.L.A. Philipsen, P.R. Bär*, G.S.F. Ruijt. Organon International BV, PO 20, 5340 BH Oss, The Netherlands, ¹Dept. Neurology, Univ. Utrecht, Heidelberglaan 100, 3584 CX Utrecht, The Netherlands.

Cytostatic drugs, e.g. cisplatin, vincristine, and taxol, damage the sensory neurones present in dorsal root ganglia (DRG). We, therefore, use intact DRG from rats (E15) *in vitro* as a model to study the neuropathy caused by cytostatic agents and the potential neuroprotective effect of nerve growth factor (NGF). Neuritegenesis from DRG was measured with an image analysis system. Several doses of cytostatic drugs were tested on intact DRG (1 DRG/well, n=10 per dose) in the presence of 3 ng NGF/mL and Ara-C (10^{-6} M). Relative neurite outgrowth in intact DRG in culture was reduced dose-dependently a) by vincristine starting at a dose of 400 pg/mL for 2 days (-33% as compared to control; P<0.001, Student's t-test); b) by taxol 10 ng/mL (-60%; P<0.001), and c) by cisplatin 4 $\mu\text{g/mL}$ (-56%, P<0.001). Cisplatin also prevented the migration of fibroblasts/glia cells from the intact DRG into the well in contrast to control, vincristine, or taxol. To evaluate the neuroprotective potential of NGF in this *in vitro* cytostatic neuropathy model, we incubated intact DRG with cytostatic agents in combination with increasing amounts of NGF. The neurite outgrowth from DRG treated with vincristine (400 pg/mL) + NGF (6 ng/mL) for 2 days was significantly higher, (+72%) than vincristine alone (400 pg/mL; P<0.01). The neurite outgrowth from DRG treated with taxol (10 ng/mL) + NGF (6 ng/mL) for 2 days was significantly higher (+49%) than taxol alone (10 ng/mL; P<0.01). Neuritegenesis from DRG treated with cisplatin (4 $\mu\text{g/mL}$) + NGF (6 ng/mL) for 2 days was not significantly higher (+14%) than cisplatin alone (4 $\mu\text{g/mL}$). NGF, therefore, has a clear neuroprotective effect in vincristine- and taxol- induced neuropathy as demonstrated in this *in vitro* model.

453.16

NEU DIFFERENTIATION FACTOR ISOFORMS HAVE DIFFERENTIAL EFFECTS ON SCHWANN CELL PROLIFERATION AND DIFFERENTIATION. T.J. Neuberger*, A. Welcher, N. Liu, R. Koski, D. Wen, and G.H. De Vries Dept of Biochemistry, Med. Coll. Va., Richmond Va. and Amgen Inc. Thousand Oaks Ca.

Neu-differentiation factor (NDF) is a 44kD polypeptide which exists in an alpha (NDF- α) and beta (NDF- β) form. While the addition of NDF- α had no effect on Schwann cell (Sc) proliferation, addition of NDF- β resulted in a dose dependent increase in proliferation. Pretreatment of primary Schwann cells (Sc) with NDF- α resulted in a diminished mitogenic response when the Sc were subsequently challenged with a number of known Sc mitogens including fibroblast growth factor (FGF), transforming growth factor β (TGF β) and the axolemma enriched fraction (AEF). In contrast, simultaneous addition of NDF- α to either FGF, TGF β or AEF had no effect on the mitogen induced Sc proliferation. Western blotting of AEF using an anti-NDF antisera demonstrated a major 25kD band and a minor 44kD band. Pre-incubation of the AEF with this same antisera resulted in enhanced Sc proliferation. NDF- β , when added with AEF, had a synergistic effect on Sc proliferation while NDF- β plus FGF was additive. In contrast, the response Sc to NDF- β was diminished by the addition of TGF β . While treatment with NDF- α had no effect on the normal morphology of the Sc, addition of NDF- β resulted in a dramatic alteration in morphology. Within 24 hours, cell aggregates composed of 5-10 Sc with short processes and thick cell bodies dissociated into individual Sc with long processes and thin cell bodies. We conclude that AEF contains a NDF related molecule (probably the NDF- α form) and that NDF- β and NDF- α have opposite effects on the proliferation of cultured Sc. NDF- α inhibits proliferation while NDF- β acts like a potent mitogen (Supported by NS10821, NS15408, Neurotech and Amgen).

CNTF MODIFIES THE RESPONSE OF CULTURED OLIGODENDROCYTES TO GLUTAMATE AND TNF. Y. Lev-Ram*, I. C. Louis*, R.Y. Tsien* and M.H. Ellisman* Depts. Pharmacology¹; Biology²; Pharmacology & Chemistry and Howard Hughes Medical Institute³; Neurosciences⁴; University of California San Diego, La Jolla, CA 92093

Developing oligodendrocytes undergo spontaneous death *in vitro* and *in vivo*, unless sufficient amounts of trophic factors are available. We found that ciliary neurotrophic factor (CNTF), a cytokine produced by astrocytes in the CNS, promotes the survival and maturation of cultured oligodendrocytes. CNTF also protects oligodendrocytes from tumor necrosis factor (TNF α) and glutamate cytotoxicity. To investigate the protective effect of CNTF we studied the response of cultured oligodendrocytes to glutamate and TNF α by monitoring their intracellular calcium levels ($[\text{Ca}^{++}]_i$). The fractional change in fluorescence was determined using the non-ratiometric calcium indicator fluo3 and quantitative measurements were made using fur2. Both dyes were loaded into the cells via their AM-esters. Cells were treated with CNTF for 3 and 4 days, after which their responses to glutamate and TNF α were tested. Control cells responded to glutamate with a large and prolonged increase in $[\text{Ca}^{++}]_i$; $[\text{Ca}^{++}]_i$ levels declined to baseline levels within 10 minutes following removal of glutamate. Repetitive application of glutamate, after recovery, induced similar transients. Challenging CNTF treated cells with glutamate resulted in more rapid transients and faster recovery. However, subsequent exposures, after the first glutamate challenge, did not yield $[\text{Ca}^{++}]_i$ transients. $[\text{Ca}^{++}]_i$ transients in response to TNF α were detected in some CNTF treated cells whereas in control conditions most of the cells had a large and fast recovering $[\text{Ca}^{++}]_i$ transient (60-120 sec.). In addition, the CNTF-treated cells differed from the control cells in their response to thapsigargin, with control cells exhibiting a large sustained $[\text{Ca}^{++}]_i$ increase and CNTF treated cells responding with a $[\text{Ca}^{++}]_i$ transient. These findings suggest that the ability of CNTF to modify changes in $[\text{Ca}^{++}]_i$ responses of cells to injurious signals may underlie its survival-promoting activity.

NERVE GROWTH FACTOR EFFECTS ON PRIMARY GLIAL CULTURES. L.A. Hutton, C.P. Turner & J.R. Perez-Polo. Dept. of HBC&G, Univ. of Tx. Med. Branch, Galveston, TX 77555.

Cultures of rat pup cortical type I astrocytes respond to NGF treatment by increasing levels of p75 mRNA (J.Neurosc.Res.32:375-383,1992). They also express trkA and trkB mRNAs which encode the NGF and BDNF receptors. Both p75 and trkA are involved in high affinity NGF binding and in the biological response to NGF. Since primary cultures of type I astrocytes express p75 and trkA, we examined the effects of NGF on primary astrocytes. GFAP+ cells assumed a fibrous morphology when cultured for five days in serum free medium with 50ng/ml NGF. In control cultures GFAP+ cells remained polygonal after 5 days of serum deprivation. NGF had no effect on the morphology of GFAP+ cells in the presence of fetal calf serum. ¹²⁵I-NGF was used to measure NGF internalization in purified astrocyte cultures. Pretreatment with 50ng/ml NGF for 72h prior to labeling with ¹²⁵I-NGF decreased the amount of internalized ¹²⁵I-NGF compared to untreated cultures. Together these data support the notion that astrocytes respond to NGF treatment *in vitro*. Publication No.8A supported by USPHS grant PO1 AG10514 awarded by the National Institute on Aging and a grant from the American Paralysis Association.

BDNF INCREASES GFAP+ PROCESS-BEARING CELLS IN A SUBPOPULATION OF ASTROCYTES. L.M. Buono, L.S. Aibel, I.B. Black and C.F. Dreyfus*. Dept. Neuroscience & Cell Biology, Robert Wood Johnson Medical School, UMDNJ, Piscataway, NJ 08854 and Cook College, Rutgers University, New Brunswick, NJ 08903.

Previous studies from our laboratory suggested that neurotrophins may affect glial function. For example, the p75 neurotrophin receptor, as well as low-affinity binding sites for NGF were localized to non-neuronal cells in mixed neuron-glial cultures derived from embryonic day 17 rat basal forebrain (bf). Moreover, NGF (1µg/ml) elicited a 9-fold increase in the number of glial fibrillary acidic protein (GFAP+) cells (Yokoyama et al., 1991). GFAP is a marker for astrocytes. In the present study we investigated the putative role of related neurotrophins.

Cultures of enriched bf astrocytes were established from postnatal day 1 rats and found to contain > 90% GFAP+ cells. To determine whether neurotrophins influence these populations, cultures were stained for the receptor, trk, using a pan-trk antibody, as well as for trkB and p75 receptors. Both trk and trkB were localized to a subpopulation of astrocytes. Similarly, p75 was co-localized to a GFAP+ subpopulation, suggesting that astrocytes are responsive to neurotrophins. Cultures were treated with NGF, BDNF, NT-3 or NT-4 produced by cos cells transfected with appropriate plasmids. (Cos cell medium was generously provided by W. Friedman.) BDNF significantly increased GFAP+ process-bearing cells. Concomitantly, GFAP negative cells decreased. Other neurotrophins did not elicit these effects. Our observations suggest that BDNF elicits differentiation of a subpopulation of astrocytes, possibly working through the trkB and/or p75 receptors.

RECOMBINANT CNTF ENHANCES ADRENAL MEDULLA CELL SURVIVAL *IN VITRO* M.A. Tokiwa* and L.C. Doering, Division of Anatomy, McMaster University, Hamilton, Ontario, Canada, L8N 3Z5.

Previous experiments showed the long term survival of adrenal medulla (AM) cells when transplanted into the rat peripheral nerve environment (Doering and Tokiwa, 1991; Brain Res. 551:267). We are currently assessing the effects of recombinant trophic factors and non-neuronal cells (fibroblasts, Schwann cells) from peripheral nerve on AM cell survival in culture.

Recombinant rat ciliary neurotrophic factor (rr CNTF), supplied by Genentech, was tested on enriched neonatal AM cell cultures at concentrations of 25-500 ng/ml in serum-free media. Viable chromaffin cells were quantitated after 4 days *in vitro* by tyrosine hydroxylase (TH) immunohistochemistry. The addition of CNTF to the cultures enhanced AM cell survival (p<0.001 for 500 ng/ml).

AM cells were also co-cultured with neonatal rat peripheral nerve fibroblast monolayers. Increased survival of TH-positive cells occurred when co-cultured with the fibroblasts (p<0.001 compared to controls). Experiments are in progress to determine if Schwann cells can similarly elevate the survival of chromaffin cells.

The results indicate that recombinant growth factors in addition to NGF, as well as non-neuronal cells of the peripheral nerve (fibroblasts) can support the survival of chromaffin cells *in vitro*. (Supported by The Parkinson Foundation of Canada)

A PERIPHERAL NERVE-DERIVED NEUROTROPHIC FACTOR. G.M. Villegas*, Y.R. Olivares, A.T. Haustein, J.C. Bournat and R. Villegas. Instituto Internacional de Estudios Avanzados (IDEA), Apartado 17606, Caracas 1015-A, Venezuela.

A new factor was found in a conditioned medium (CM) prepared with adult rat sciatic nerves cultured in DMEM containing fetal bovine and horse sera during nine days. This factor caused (1) sympathetic-like neuron differentiation of PC12 cells, and (2) survival and neurite outgrowth of the cells of dorsal root (DRG) and ciliary ganglia (CG) of eight-day old chicken embryos (E8). The effect on the E8 ganglia was identical to those described for the Neuronal Growth Factor (NGF) on the DRG and the Ciliary Neurotrophic Factor (CNTF) on the CG. The PC12 differentiation caused by the CM was similar to that produced by the NGF. The changes caused by the CM were not inhibited by antibodies against NGF, b-Fibroblast Growth Factor, laminin and fibronectin. No morphological changes of the PC12 cells were produced by CNTF. Trypsin (0.2 mg/ml) abolished the CM effect. Heating at 95°C, 20 min, decreased by 50% the CM activity with complete inhibition after 1 h. The CM effect on the levels of Na⁺ channel type II mRNA of PC12 cells was similar to that of NGF. MC ultrafiltration followed by gel exclusion chromatography (Sephadex G100 & Sephacryl S300) produced an active fraction enriched in a 65-75 kD peptide observed by SDS-PAGE electrophoresis.

Supported by grants S1-1485 (G.M.V.) and S1-2180 (R.V.), CONICIT, Venezuela; and donations from the Vollmer Research Fund of CEC-Caracas, and Prof. Betty G. Uzman.

PHENOTYPIC RESPONSES OF SCHWANN CELLS TO NEUREGULIN (GLIAL GROWTH FACTOR) TREATMENT O. Bermingham-McDonogh, S. Scherer, C. Nolan, R. Toms, C. Kirk, D. Gwynne* and M. Marchionni. Cambridge NeuroScience, Cambridge MA 02139 and *Department of Neurology, University of Pennsylvania, Philadelphia, PA 19104.

Proliferation of Schwann cells appears to be an important step in nerve regeneration following injury. Glial Growth Factor (GGF), a mitogen for Schwann cells has been recently cloned and found to be a member of a large superfamily including the heregulins and ARIA, which are all likely to be alternative spliced products of the same gene. With the availability of recombinant GGF material we have undertaken a study of the changes in gene expression after GGF treatment. We will present data showing levels of expression of growth factor genes and their receptors, and also differentiation markers such as myelin genes.

453.24

NERVE GROWTH FACTOR CONVERTS GH-3 CELLS INTO LACTOTROPH-LIKE CELLS. E. Borroni, S. Sigala*, C. Missale and P.F. Spano. Div. of Pharmacology Dept. of Biomed. Sci. and Biotech, University of Brescia, Italy.

Nerve growth factor (NGF) promotes the growth and differentiation of sensory and sympathetic cells and of cells of the immune system. In the present study we first report that NGF dictates the differentiation of a cell line of endocrine origin. An established cell line (GH-3), which differs from pituitary lactotrophs in the production of both prolactin (PRL) and growth hormone (GH) and in the lack of D-2 receptors for dopamine (DA) was employed. GH-3 cells possess both the gp75 and the gp140trk components of the NGF receptor as shown by both Western and immunofluorescence experiments. Following exposure to NGF, GH-3 cells markedly decreased their proliferation rate. This effect was maximal 3 days after beginning of treatment and was maintained during the following days of exposure. This was paralleled by a change in the hormone production. The PRL secretion was indeed increased 6 fold, while that of GH was remarkably inhibited. GH-3 cells also re-expressed the lactotroph-specific D-2 receptor protein in response to NGF, as evidenced with the D-2 receptor ligand N-(p-aminophenyl)spiperone coupled to fluorescein. An intense fluorescence was in fact evident in NGF-treated cells, but not in untreated cultures. The pharmacological characterization of the receptor labelled with [¹²⁵I]iodosulpride was consistent with its D-2 nature. The expressed D-2 receptors were functionally active in inhibiting PRL secretion. GH-3 cells thus respond to NGF by acquiring a phenotype similar to that of pituitary lactotrophs.

RESPONSIVENESS OF MOTOR NEURONS TO NEUROTROPHIC FACTORS BECOMES RESTRICTED IN THE ADULT Young W. Kwon¹, Qiao Yan², and Mark E. Gurney¹. ¹Dept. of Cell, Molecular and Structural Biology, Northwestern Univ., 303 E. Chicago Ave., Chicago, IL, 60611 and ²Neurobiology Program, Amgen Inc., Amgen Center, Thousand Oaks, CA. 91320.

Local administration of ciliary neurotrophic factor (CNTF) causes sprouting by healthy, undamaged, adult motor neurons. As a corollary to that study, we addressed the three following issues. One, can CNTF cause motor neuron sprouting after systemic administration? Two, are the sprouts induced by CNTF qualitatively similar to those caused by muscle paralysis? Three, can any other neurotrophic factors, to which motor neurons respond either in culture or during development *in vivo*, induce sprouting by adult motor neurons? We found that high dose injections of CNTF at 0.4 mg/kg/day and 1.2 mg/kg/day for 7 days acted systemically to cause sprouting from 33±4% (SEM) and 27±6% respectively of the terminals examined. The sprouts induced by CNTF, from either systemic or local injections, differed little in type or quality from the sprouts caused by muscle paralysis following injection of botulinum toxin. Muscle paralysis did, however, induce more terminal sprouts per endplate (1.32±0.12 vs. 1.13±0.05) as well as more nodal sprouts (10±1.2 vs. 3.3±0.5 per 100 preterminal axons). Finally, none of the other neurotrophic factors that we tested were able to cause sprouting by adult motor neurons. Leukemia inhibitory factor (LIF), oncostatin M (OSM), acidic and basic fibroblast growth factors (aFGF, bFGF), insulin-like growth factor type 1 (IGF1) and type 2 (IGF2), brain-derived neurotrophic factor (BDNF), neurotrophin-3 (NT-3), and nerve growth factor (NGF) all failed to induce sprouting by healthy, undamaged, adult motor neurons. Since CNTF is the only factor that induces sprouting by adult motor neurons, our results imply that responsiveness of motor neurons to neurotrophic factors becomes restricted in the adult.

IS THERE A SENSITIVE PERIOD FOR THE EFFECT OF CILIARY NEUROTROPHIC FACTOR ON NEUROMUSCULAR SYNAPSE ELIMINATION? A.W. English^{*} and G. Schwartz. Dept. of Anatomy and Cell Biology, Emory Univ. Sch. of Med., Atlanta, GA 30322

Daily intramuscular injections of ciliary neurotrophic factor (CNTF) for one week in neonatal rats results in a retention of multiple innervation of muscle fibers. However, these animals gain weight less rapidly than their untreated litter mates. To examine whether this systemic effect influenced the outcome of neuromuscular synapse elimination, we made single injections of recombinant rat CNTF into the lateral gastrocnemius (LG) muscle and then assayed the amount of multiple innervation present during the second postnatal week using intracellular recording. For animals injected at postnatal age 2 days (P2), a dose-dependent retention of multiple innervation was found. At 100 µg/kg, we observed a transient but significant increase in the amount of multiple innervation. At higher doses, we found a more sustained elevation, nearly doubling the normal amount. In animals injected at age P6, LG contained the normal amount of multiply innervated fibers at all doses examined. In animals injected at P0 or as E18 fetuses, we found nearly three the times normal proportion of multiply innervated fibers as late as P14. Normal weight gain was unaffected by these treatments in any animals, suggesting that CNTF-induced retention of multiple innervation was not due to an effect on normal postnatal growth. These results suggest that a sensitive period does exist during which developing neuromuscular synapses are susceptible to treatment with CNTF. Supported by Regeneron Pharmaceuticals, Inc., the BRSG of Emory University, and NS20545 from the USPHS.

NEUROTROPHIC FACTORS RESCUE MOUSE MOTONEURONS FROM NATURALLY OCCURRING AND AXOTOMY-INDUCED CELL DEATH. L. Li, R. W. Oppenheim, M. Lei and L. J. Houenou Dept. of Neurobiology & Anatomy, Bowman Gray Sch. of Med., Wake Forest Univ., Winston-Salem, NC 27157.

We have examined the ability of different neurotrophic agents to prevent naturally occurring and axotomy-induced cell death in the developing mouse spinal cord. In utero treatment with 1µg BDNF or CNTF on embryonic day 14 (E14) rescued 50-60% motoneurons (MNs) from naturally occurring cell death when examined on E18. Although in utero treatment with NGF did not affect MN survival, it rescued the sensory neurons in dorsal root ganglia. After postnatal unilateral section of the sciatic nerve, most MN loss occurs in the fourth lumbar segment (L4). Axotomy-induced cell death occurred after surgery performed on or before postnatal day 5 (P5). In contrast, no significant cell loss was found when axotomy was performed after P10. Axotomy on P5 resulted in a 41% loss of MNs in L4 on P12. Implantation of gelfoam (2mm³) presoaked with neurotrophic factors in the lesion site significantly rescued axotomized MNs. CNTF rescued 20-30% of MNs whereas BDNF and NT-3 rescued virtually all axotomized MNs. In summary, the *in utero* studies reported here are the first to demonstrate an effect of neurotrophic agents on naturally occurring MN death in mammals *in vivo*. The data from the postnatal studies support previous investigations in showing that CNTF, BDNF and NT-3 can rescue mammalian MNs from injury-induced cell death. Supported by NIH, MDA and IRIP.

454.2

NEUROTROPHIC FACTORS RESET THE TIMING OF PROGRAMMED SYNAPSE ELIMINATION IN NEONATAL MUSCLES ME Gurney^{*} and YW Kwon Dept. Cell, Molec. Struct. Biol., Northwestern Univ. Med. Schl. Chicago IL 60611

Neonatal muscle fibers are innervated by multiple motor axons at a single endplate. Elimination of excess synaptic inputs occurs after birth and is due in part to competition between motor inputs for maintenance of the synaptic contact. Although it has been proposed that motor inputs may compete for a neurotrophic factor that is in limiting supply, we find no evidence for that hypothesis. Instead, the related factors, leukemia inhibitory factor (LIF), ciliary neurotrophic factor (CNTF) and oncostatin M (OSM), delay synapse elimination in neonatal mouse muscles without affecting the rate of the underlying process that is driving withdrawal of synapses. This occurs independently of the effects of such factors upon neuronal survival. The effect of LIF was dose- and time-dependent. Maximum delay of synapse elimination in the mouse tensor fascia latae muscle was obtained with 100-500 ng LIF injected per day. A maximum delay of synapse elimination of 5 days was obtained with LIF exposure beginning at 3 days after birth. Acidic and basic fibroblast growth factors had no effect.

454.4

CILIARY NEUROTROPHIC FACTOR DELAYS SYNAPSE ELIMINATION IN THE RAT LEVATOR ANI MUSCLE. C. L. Jordan^{*}. Dept. Psych., Univ. California, Berkeley, CA 94720.

During developmental synapse elimination, synapses may compete for target-supplied trophic substances. Because exogenous ciliary neurotrophic factor (CNTF) prevents the normal loss of synapses during synapse elimination in the rat gastrocnemius muscle (English & Schwartz, Soc. Neurosci. Abs. 18: 618), CNTF may be the object of competition. I have extended these findings to the rat levator ani (LA) muscle in which synapse elimination is regulated by gonadal androgens.

Gonadally intact male rat pups received daily sc perineal injections of human recombinant CNTF [a gift of Regeneron (0.5 or 1.0 µg/g BW)] or vehicle during the normal period (14-28 day) of synapse elimination in the LA. At 28 days, LA muscles were stained with tetranitroblue tetrazolium and the number of stained motor axons contacting individual muscle fibers counted. The percentage of multiply innervated fibers was much higher in CNTF-treated than in vehicle-treated LA muscles.

DOSE	CNTF	VEHICLE
HIGH	81 ± 2%	24 ± 6% (fibers multiply innervated)
LOW	68 ± 3%	25 ± 1%

Thus, androgen may prevent synapse elimination in the LA muscle by increasing the amount of CNTF available to nerve terminals. Supported by HD15021 and IBN-9210229.

OVEREXPRESSION OF NGF IN SKIN OF TRANSGENIC MICE CAUSES HYPERTROPHY OF THE SENSORY AND SYMPATHETIC NERVOUS SYSTEM. K.M. Albers^{*}, D.E. Wright, K.B. Seroogy, H. Traurig, and B.M. Davis. Departments of Pathology^{*} and Anatomy & Neurobiology, University of Kentucky Sch. of Med., Lexington KY, 40536.

Previously we described alterations in the sensory nervous system of transgenic mice expressing a fusion gene that contained the mouse NGF cDNA linked to the keratin 14 (K14) gene promoter. The K14 promoter is expressed in the epidermis at ca. E14 during the period of naturally occurring neuronal death. K14-NGF mice exhibited overexpression of NGF mRNA in the skin and consequently a hypertrophy of the sensory ganglia and peripheral sensory nerves. We now report on the effect of NGF overexpression on the sympathetic nervous system and extend our observations on the sensory nervous system. Calcitonin gene related peptide (CGRP) immunoreactivity and tyrosine hydroxylase (TH) immunoreactivity was used as a marker of sensory and sympathetic processes, respectively. A major increase in both CGRP and TH immunoreactive positive fibers was detected in K14-NGF skin. Moreover, an increase in the number of CGRP positive neurons was observed in the trigeminal ganglion. Cell counts of transgenic trigeminal ganglia were two-fold higher than control values. This increase is consistent with the number of cells lost through naturally occurring cell death. In comparison, an increase in the number of cells in the superior cervical ganglion was several fold greater than control values suggesting that increased mitosis occurred as well as blockade of cell death. This difference may reflect the dependence of sympathetic neuron survival on NGF throughout life versus sensory neuron dependence on NGF that occurs during a brief developmental period. Supported by AR40873 to KMA and NS 31826 to BMD.

CHANGES IN SENSORY THRESHOLDS IN TRANSGENIC MICE EXPRESSING NGF SENSE AND ANTISENSE mRNA. B.M. Davis¹, G.R. Lewin¹, L.M. Mendel¹, M. Jones², and K.M. Albers². Depts. of Anatomy & Neurobiology¹ and Pathology², Univ. of Kentucky Sch. of Med., Lexington, KY, 40536; Dept. of Neurobiology & Behavior¹, SUNY at Stony Brook, Stony Brook, NY 11794.

Previous experiments have demonstrated that chronic or acute injections of NGF or anti-NGF antisera can effect nociceptive responses in rats. To examine the role of NGF in sensory perception we have created two lines of transgenic mice that overexpress NGF and two lines that express antisense NGF mRNA in the skin. Both sense and antisense mRNA expression is driven by the keratin 14 (K14) promoter that is expressed in skin at ca. E14. These mice provide noninvasive models in which either an increased level of NGF peptide is produced by a target of NGF dependent sensory neurons (the NGF sense mice) or a decreased level of NGF peptide is produced (the antisense mice). In mice expressing increased amounts of K14-NGF sense mRNA, a dramatic increase in the size of the trigeminal ganglion was observed whereas mice expressing the K14-NGF antisense mRNA showed no discernable change in trigeminal size. These results likely reflect the temporal overlap of expression of the K14 promoter with the period of naturally occurring cell death that begins at ca. E15. In K14-NGF sense mice elevation of NGF levels blocks cell death. Production of antisense NGF may not increase cell death since no significant atrophy of the trigeminal occurred. Analysis of the threshold for mechanical stimulation using Von Frey hairs indicates that mechanical thresholds are decreased 80% in K14-NGF sense mice (compared to controls) whereas in K14-NGF antisense mice an increase of 144% occurred. Supported by AR40873 to KMA and NS31826 to BMD.

CHARACTERIZATION OF THE DORSAL ROOT AFFERENT PROJECTION TO SPINAL CORD IN THE *trkB* "KNOCKOUT" MOUSE. ¹J. Silos-Santiago, ¹L. Zhang, ¹W.D. Snider, ²R. Klein, ²M. Barbacid, ²R.J. Smeyne. ¹Dept. Neurology, Washington Univ., Med. Sch., St. Louis, MO. ²Dept. Molecular Biology, Bristol-Myers Squibb Pharmaceutical Research Institute, Princeton, NJ.

An ideal tool to address the function of neurotrophin receptors is the analysis of mice carrying targeted deletions of the gene(s) encoding these proteins. Recently, using homologous recombination in ES cells, a mouse carrying a "knockout" of the *trkB* gene, *trkB*^{TK(-/-)}, was generated. This animal demonstrated a loss of 40-60% of the neurons in the dorsal root and trigeminal ganglia, and cranial and spinal motor pools. To characterize the populations of DRG cells lost, we compared the dorsal root afferent projection to the spinal cord of P0 wild-type and *trkB*^{TK(-/-)} mice. In the *trkB*^{TK(-/-)} mice, no gross abnormalities in the laminar architecture of the spinal cord were detected. The most clearcut finding was normal-appearing Ia afferents projecting to the motor pool and branching to Clarke's column. In the dorsal horn, we observed some fibers characteristic of hair follicle afferents entering medially, projecting to lamina IV, turning upwards and terminating in lamina III. This suggests that some members of this class of low-threshold mechanoreceptors (LTMs) are present. Laminae I and II also contained large number of fibers. Although the distribution of spinal cord afferents appears normal, the overall reduction of DRG neurons in the *trkB*^{TK(-/-)} suggests that some classes of these cells may not have a full complement of fibers. It is also possible that some classes of LTMs or fine cutaneous afferents are eliminated. We conclude that at least some DRG neurons innervating muscle-spindles and hair follicles can differentiate, extend axons to appropriate targets and survive without expressing *trkB*. Whether these neurons do not require BDNF or NT4/5 during normal development or whether compensatory mechanisms occur in the *trkB*^{TK(-/-)} mice remains to be determined.

GENDER AND REGIONAL DIFFERENCES IN [³H]GBR 12935 BINDING IN THE BRAINS OF TRANSGENIC MICE.

R. Goldberg, L. Hilakivi-Clarke, A. Hitri, S.I. Deuschle. Psychiatry Dept. Georgetown University, Lombardi Cancer Res.Ctr., NIDA Research/Psychiatry Serv., DVA Med. Ctr. Washington DC.20422. Recently, transforming growth factor alpha (TGF2_{alpha}) mRNA, protein and receptors in rodent brain have been demonstrated; however, TGF2_{alpha}'s role has not been elucidated. Transgenic CD-1 mice overexpressing TGF2_{alpha} exhibit gender specific alterations in locomotor activity and aggressive behavior. Furthermore, TGF2_{alpha} is known to stimulate dopamine (DA) uptake in the rat fetal dopaminergic neurons. The present study examined [³H]GBR 12935 labeled DA transporter alterations in the male and female transgenic TGF2_{alpha} mice. The results indicate a 26% decrease in [³H]GBR 12935 binding in the cerebellum of both male and female TGF2_{alpha} mice, compared to normal control mice. In the frontal cortex, while there are no gender differences in the control mice, the gender differences are clearly present in TGF2_{alpha} mice: [³H]GBR 12935 binding in the frontal cortex of the male TGF2_{alpha} mice is 31% (p<0.05) lower than in TGF2_{alpha} female mice. The data suggest regional differences in TGF2_{alpha} modulation of [³H]GBR 12935 binding and are consistent with the role of TGF2_{alpha} in DA uptake and dopaminergic transmission.

PERTURBATION OF CARDIAC DEVELOPMENT BY INCREASED EXPRESSION OF NGF IN TRANSGENIC MICE. A. Hassankhani¹, C.A. Altart² and H.J. Federoff. Departments of Neuroscience and Medicine, Albert Einstein Coll. of Med. Bronx, N.Y. 10461, and ¹Regeneron Pharm., Tarrytown, N.Y. 10591.

We have previously reported the production and analysis of transgenic mice that over express a nerve growth factor (NGF) mini-gene driven by the cardiac specific α -myosin heavy chain (α -MHC) promoter (Hassankhani *et al.*, *Soc. Neurosci. Abstr.*, Vol. 18, part 2, p. 1289, 1992). In these mice the α -MHC promoter turns-on the expression of the NGF transgene in the heart as early as E13.5 and expression persists throughout the animal's life. Transgenic mice develop cardiomegaly, which is produced by two components: an increase in ventricular myocardial mass and a hyperplasia of presumptive neural crest derivatives within the base of the heart, particularly in the atrial appendages. Our data suggest that over-expression of NGF leads to increased survival of the innervating cardiac sympathetic neurons, thus creating a hyperinnervated heart. To determine the mechanisms that could induce ventricular growth we have begun to examine the role of adrenergic neurotransmission in this process, since catecholamines have been implicated in the development of myocardial hypertrophy. Immunohistochemical analysis for the catecholamine biosynthetic enzyme tyrosine hydroxylase reveals abundant expression within nerve fibers and ectopic neural crest cells. Increased nerve fiber bundle density was also demonstrated by immunolabeling with an antibody against neurofilament M, which identifies neuritic processes. Measurements of catecholamines and their metabolites were made by HPLC and the data indicate that transgenic heart has significant elevation of norepinephrine (NE), dopamine and several catecholamine metabolites. Catecholamine measurements were performed at several developmental time points. We have observed a 30-fold increase in the NE content in one week old transgenic atria and ventricles compared with non-transgenic mice. This difference is less marked at later developmental times, including adults. Similarly, NE content was elevated 7-fold in the atrial appendage of transgenic mice at one week of age. Whereas, in the atrial appendages of adult transgenic mice only 2.7 fold increase in NE content was observed. These data suggest either that the transgenic heart is innervated prematurely or that the increased catecholamines derive from the ectopic cells found largely within the atrial appendages. Supported by PHS grant HD27226.

454.10

FGF, BDNF, AND NT3 GENE EXPRESSION DIRECTED TO NORADRENERGIC CELLS IN TRANSGENIC MICE. Stephen Skirboll, Bridgid Stirling, Phyllis Harbor, Mark Bothwell. Dept of Physiol. & Biophysics, Univ of Washington, Seattle, WA 98195.

To further discern the role of various neurotrophic factors in the development of specific neuronal systems, we are examining the gene expression of basic fibroblast growth factor (FGF), brain-derived neurotrophic factor (BDNF) and neurotrophin-3 (NT3) directed to noradrenergic cells in transgenic mice using the 5' flanking region from the human dopamine-beta-hydroxylase (DBH) gene. A number of mouse lines have been generated which stably carry the DBH-FGF, DBH-BDNF and DBH-NT3 gene constructs. Expression of the transgene was characterized by *in situ* hybridization using a probe to a mouse protamine-1 DNA tag included in each construct. Initial studies demonstrated expression of the DBH-FGF transgene in adrenal chromaffin cells, the enteric nervous system, and in the locus coeruleus and other brainstem nuclei. Preliminary studies show similar expression patterns for DBH-BDNF and DBH-NT3. Other possible sites of expression are being examined. A variety of phenotypic abnormalities have been observed in these transgenic mice. The possible role of transgene expression in generation of these phenotypes is under investigation. This work was supported by NIH grant NS30305 and a grant from the Research Foundation of the American Association of Neurological Surgeons.

TARGET TISSUE REGULATION OF p65 (SYNAPTO-TAGMIN) IN SYMPATHETIC GANGLIA IN VITRO K.F. Greif*, H. Fahl, D. Frederick, F. Kim and S. Yang. Dept. of Biology, Bryn Mawr College, Bryn Mawr, PA 19010.

The expression of the synaptic vesicle protein, p65 (synapto-tagmin), in rat superior cervical ganglion (SCG) can be influenced by anterograde transsynaptic factors both in vivo and in vitro. Axotomy of the SCG in vivo reduces the levels of p65, but the factors responsible for this reduction cannot be determined directly. The present study investigates whether interactions with target tissues contribute to the regulation of expression p65 in vitro. SCGs from 2-day old rats were grown in explant culture in defined medium (Linderman and Greif, 1990), either in isolation or co-cultured with explants of either salivary gland or skin. Protein levels were determined by RIA. p65 levels significantly increased after seven days co-culture with salivary gland, a normal target of SCG neurons. Co-culture with skin, a non-target tissue, did not significantly increase p65 levels. Histological analysis confirmed that target tissues survived in the defined medium. To rule out the possibility that the salivary gland effect was due to elevated levels of NGF, SCGs were cultured alone with a ten-fold excess of NGF added to basal medium. Levels of p65 were not altered in cultures grown in elevated NGF.

These results indicate that interactions with target tissue play a significant role in regulation of expression of p65 in sympathetic neurons. Further experiments are required to determine the biochemical nature of the factor produced by salivary gland.

BDNF SUPPORTS NEURITE OUTGROWTH FROM OCULOMOTOR NEURONS IN VITRO AND IS RETROGRADELY TRANSPORTED IN VIVO. Y. Kinoshita*, M. Bothwell, and C.S. von Bartheld. Department of Physiology & Biophysics (SJ-40), University of Washington, Seattle, WA 98195.

BDNF supports the survival of many populations of motoneurons *in vivo*. We have tested if BDNF promotes neurite outgrowth of oculomotor nucleus explants *in vitro*. To identify the oculomotor nucleus, the fluorescent tracer DiI was injected pericircularly in 11-13 day-old chick embryos *in ovo*. Following retrograde transport of the dye for 16-20 hours, the labeled motor nucleus was identified in brain slices, dissected and explanted in Matrigel. Neurite outgrowth was considerably enhanced with treatment of BDNF (4 ng/ml) for 5-14 days when compared with controls. To determine if BDNF is retrogradely transported from the eye muscles *in vivo*, radio-iodinated BDNF was injected pericircularly and/or intraocularly in 14-day old chick embryos *in ovo*. The animals were sacrificed after 16-18 hours, and sections through the oculomotor nucleus were processed for autoradiography. Following exposure for 5 weeks, radioactive BDNF was apparent in many oculomotor neurons and in particular in the Edinger Westphal component of the oculomotor complex. These findings show that BDNF supports not only the survival but also neurite outgrowth from oculomotor neurons *in vitro* and that BDNF is retrogradely transported by developing oculomotor neurons *in vivo*.

Supported by NIH grants HD 29177 and NS 30305.

NORADRENERGIC NEURONS IN LOCUS COERULEUS: EFFECTS OF NEUROTROPHINS IN VITRO AND IDENTIFICATION OF TARGETS IN VIVO. M. Bothwell¹, Y. Kinoshita¹, A. Schober¹, S. Borson^{1,2}, and C.S. von Bartheld¹. Departments of ¹Physiology & Biophysics (SJ-40) and ²Psychiatry (RP-10), University of Washington, Seattle, WA 98195.

Noradrenergic neurons of the locus coeruleus express the low-affinity neurotrophin receptor (p75) in chicken (von Bartheld and Bothwell 1992, *J. Comp. Neurol.* 320:479-500). To determine which of the neurotrophins may support the noradrenergic subpopulation, coeruleus neurons from 18-20 day-old chick embryos were treated in primary culture with NGF, BDNF or NT-3 (7 days, 1 ng/ml), and noradrenergic neurons were immunolabeled with an antibody against dopamine-beta-hydroxylase (EugeneTech). NT-3 supported the survival of noradrenergic neurons two-threefold when compared with controls or treatment with NGF or BDNF. To identify targets of developing noradrenergic coeruleus neurons, the tracer DiI was injected into various regions of the brain in E15-19 chick embryos *in vivo*, and frozen sections through the brain were subsequently processed with an antibody against the p75 neurotrophin receptor (gift of Dr. H. Tanaka, Kumamoto University). Following injections of DiI into the telencephalon, about 800 neurons were retrogradely labeled in the locus coeruleus proper and up to 240 in the nucleus subcoeruleus. Some of these neurons could be double-labeled with the p75 antibody. We are currently testing if NT-3 is retrogradely transported to the noradrenergic subpopulation in the locus coeruleus. Supported by NIH grants HD 29177, NS 30305, and a grant from the German Science Foundation.

COMPARISON OF THE BIOLOGICAL ACTIVITY OF OTOCYST-DERIVED FACTOR TO NEUROTROPHINS AND FGF. L.M. Bianchi* and C.S. Cohan. Dept. of Anatomical Sciences, SUNY at Buffalo, Buffalo, NY 14214

The developing inner ear (otocyst) releases a survival and neurite-promoting factor that influences the associated statoacoustic ganglia (SAG). This unidentified factor is released during the early stages of auditory and vestibular development, at the period preceding target cell innervation (E4-E6 in the chick).

We have found that the ODF is both heat and trypsin sensitive, suggesting that ODF has proteinaceous properties. Previous work from this lab demonstrated that the activity of the ODF was not mimicked by NGF, BDNF or CNTF. Further comparisons of ODF to identified growth factors revealed that NT-3, aFGF and bFGF also failed to mimic the activity of the ODF. In cultures of dissociated E5 SAG neurons, ODF promoted both neuronal survival and outgrowth. However, in the presence of NT-3, aFGF or bFGF, the amount of SAG survival and outgrowth was similar to controls cultured in the absence of any growth factor. Furthermore, combinations of the various identified growth factors did not increase SAG survival or outgrowth above control levels. These results indicate that none of the growth factors tested, alone or in combination, produced effects that were similar to ODF. Thus, ODF may represent an untested factor or combination of growth factors, or a unique target-derived factor.

RETROGRADE AND ANTEROGRADE TRANSPORT OF NEUROTROPHINS FROM THE EYE TO THE BRAIN IN CHICK EMBRYOS. C.S. von Bartheld, L.C. Scheecterson*, and M. Bothwell. Department of Physiology & Biophysics (SJ-40), University of Washington, Seattle, WA 98195.

BDNF and NT-3 are expressed in the retina and in the tectum of chick embryos, with substantial levels of BDNF expression by presumptive retinorecipient tectal neurons. Previous studies have shown that BDNF supports the survival of retinal ganglion cells, and that BDNF and NT-3 support the survival of neurons in the isthmo-optic nucleus (ION) in chick embryos. Increased levels of NGF, however, enhance developmental cell death in the ION (von Bartheld et al., 1992, *Soc. Neurosci. Abstr.* 18:1291). Negative effects of NGF may be due to inhibition of BDNF or NT-3 binding to the 75 kD (low-affinity) neurotrophin receptor (p75), thereby blocking retrograde signaling. To test this hypothesis, radio-iodinated BDNF or NT-3 was co-injected into the eye of 14-day old chick embryos with an excess of cold NGF, with cytochrome C, or with antibodies against the p75 receptor. BDNF and NT-3 alone or in combination with cytochrome C were transported heavily to the ION within 8-20 hours. When cold NGF or antibodies against p75 were co-injected, retrograde transport of BDNF was substantially reduced. Transport of I-125 NGF was not observed in the midbrain. Radioactive BDNF and NT-3 were also transported anterogradely, apparently by retinal ganglion cells, to the layer of afferent retinal fibers in the contralateral optic tectum. These results provide first direct evidence that neurons can transport neurotrophins in the anterograde direction. Supported by NIH grants HD 29177, NS 30305, and a grant from the Muscular Dystrophy Association.

NGF, BDNF AND NT-3 PLAY UNIQUE ROLES IN THE PATTERNING OF INNERVATION OF THE INNER EAR. H. Staecker, W. Liu, V. Galinovic-Schwartz, P. Lefebvre, G. Moonen, T.R. Van De Water*. Lab of Developmental Otolibology, Albert Einstein College of Medicine, Bronx, N.Y., 10461.

Development and innervation of the sensory epithelia of the inner ear have been shown to depend on a number of factors that include epithelial mesenchymal interactions, the presence of specific substrate molecules as well as the action of numerous soluble and bound growth factors. Among the most important of these is the Nerve Growth Factor (NGF) family of neurotrophins which include NGF, Brain Derived Neurotrophic Factor (BDNF) and Neurotrophin-3 (NT-3). To evaluate their significance in the developing inner ear, we have specifically and individually downregulated the production of NGF, BDNF and NT-3 in organotypic E 10.5 day otocyst-cochleovestibular ganglion cultures using antisense oligonucleotides directed against these three neurotrophins. After three days *in vitro*, cultures were double stained with anti 66 Kd neurofilament (FITC label) and anti laminin (TRITC label) and subsequently analyzed with confocal microscopy to evaluate neuronal morphology. In these organotypic cultures of the developing inner ear, downregulation of BDNF results in neuronal degeneration, downregulation of NGF causes inhibition of neuritogenesis, whereas downregulation of NT-3 results in a loss of targeting of the neurites to the otic epithelium. Furthermore using *in situ* reverse transcription PCR (IS RT-PCR) we have shown that not only BDNF and NT-3 but also NGF are actively produced in the neuroepithelial tissues of the developing inner ear.

BASIC FGF AFFECTS DEVELOPMENT OF CHICK EMBRYO ACOUSTICO-VESTIBULAR NEURONS IN VITRO. D.K. Morast*, X. Zhou, A. Brennan and C. Balg. Anatomy Dept., Univ. CT Health Ctr., Farmington, CT 06092.

Effects of basic fibroblast growth factor (bFGF) on presumptive auditory and vestibular neurons from the medulla were studied in primary cell cultures. The part of the rhombic lip that forms nuc. magnocellularis (homologue of the mammalian anteroventral cochlear nucleus) was explanted from White Leghorn embryos at Hamburger-Hamilton stage 28, when precursors of the magnocellularis bushy cells migrate and begin to differentiate *in situ*. *In vitro* the neuroblasts migrate onto 2-D substrates of purified collagen and differentiate in Ham's F12 base with L-glutamine and defined additives (ITS+, Collaborative). Half of the cultures were supplemented with fetal bovine serum (Nuseron IV, Collaborative); the others, with human recombinant bFGF (UBI), either 10 ng/ml (replaced daily) or 250 ng/ml (replaced every other day) for 5-7 days. Neuroblast migration and neurite outgrowth were measured and averaged for 154 cultures. Compared to serum, bFGF at either concentration produced a 20-fold increase in the area covered by migration and neurite outgrowth during the first 3 days. Migration began sooner in bFGF but was surpassed in serum after the 2nd day. Longer neurites grew in bFGF but usually degenerated after 4-5 days; their growth in serum continued for several weeks. Differentiation of neuronal morphology, including axons and dendrites, began within 2-3 days in bFGF but required at least 5-7 days in serum. Preliminary histochemical observations with an antibody to bFGF receptor (UBI) demonstrated immunopositive patches on many young neurons in the stage 28 medulla. The findings suggest that bFGF stimulates early migration and initial differentiation of neuroblasts in the cochlear nucleus. bFGF may accelerate cell death by overstimulating neuroblasts, but no doubt other factors are needed to sustain them. Supported by NIH grant NS29613.

BIOLOGICAL EFFECTS OF NEUROTROPHINS ON DEVELOPING DRG CELLS IN VIVO. L. Zhang, L. Kutka, D. Privette, R. Oppenheim and W.D. Snider. Dept. Neurology, Washington Univ. Sch. of Med. St. Louis, MO 63110. ²Dept. Neurobiol & Anat. Wake Forest Univ. Bowman Gray Med. Sch. Winston-Salem, NC 27157

It is unknown whether newly described neurotrophins exert the same spectrum of biological effects on their responsive neurons as the prototypical factor NGF. The dorsal root ganglion (DRG) is a favorable population of neurons in which to address this question. In order to determine the effects of neurotrophins on DRG development, we have administered mouse NGF and human recombinant BDNF and NT3 to rat embryos *in utero* and chick embryos *in ovo* and assessed neuronal survival, neuronal size and axon growth in spinal cord. Chicks were studied at E10 after injections on E6-E9. Rats were studied at E16 (after injections on E14,15) and E19 (after injections on E15, E17). As expected, NGF had dramatic effects on all parameters studied. DRGs were markedly larger than in controls, size-frequency histograms were shifted strikingly toward larger soma areas and growth and collateral branching of certain classes of dorsal root axons in the spinal cord were enhanced. BDNF had a substantial effect on cell survival and a slight effect on cell size in chick, but, surprisingly, NT3 influenced neither of these parameters. In contrast to the marked effects of NGF on dorsal root axon growth and branching, neither BDNF nor NT3 induced clearcut changes in the shape or laminar distribution of dorsal root axons in gray matter. In fact, NT3 consistently delayed collateral axon branching in gray matter at early developmental stages. Whether BDNF and NT3 have more subtle effects on parameters such as number of axon collaterals or growth cones is currently under investigation.

We conclude that NGF induces a spectrum of effects on DRG cells *in vivo* with striking influences on cell size and axon growth. In contrast, influences of BDNF and NT3 were more subtle, and we were unable to demonstrate major effects on the dorsal root projection to the spinal cord in chick or rat. Whether this represents lack of efficacy of human recombinant factors in these systems, a greater responsiveness to these factors at developmental stages earlier than those studied here, or differences in the way that different DRG cell types respond to neurotrophins *in vivo* remains to be determined.

VISUAL FORM DEPRIVATION INDUCES MYOPIA IN THE INFANT RABBIT, WHICH IS REDUCED BY MUSCARINIC ANTAGONISTS APPLIED DIRECTLY TO THE SCLERA. R.W. BEUERMANN, S.J. CHEW. LSU EYE CENTER, NEW ORLEANS, LA 70112, THE ROCKEFELLER UNIVERSITY, NEW YORK, NY 10021

MYOPIA IS A REFRACTIVE ERROR DUE TO EXCESS ELONGATION OF THE EYE. RETINAL NEUROTRANSMITTERS ARE KEY TO THE MODULATION OF ACTIVE SCLERAL GROWTH. ACETYLCHOLINE (ACh) IS IMPLICATED BY THE ATROPINE INHIBITION OF MYOPIA IN CHILDREN AND FORM-DEPRIVATION MYOPIA IN TREE SHREWS AND CHICKS. WE FOUND THAT MUSCARINIC ANTAGONISTS REDUCE PROLIFERATION OF HUMAN NEONATAL SCLERAL FIBROBLASTS IN CULTURE. THIS STUDY WAS PERFORMED TO TEST ITS EFFECTS IN VIVO IN A NEW MAMMALIAN MODEL OF MYOPIA. WE APPLIED 2-MM FILTER PAPER DISKS SOAKED WITH 0.1M NAOH FOR 5SEC TO THE APICAL CORNEAS OF 15 INFANT NZW RABBITS. IN 5 OF THESE, THE OPACIFIED EYE ALSO RECEIVED TWICE-WEEKLY RETROBULAR INJECTIONS OF ATROPINE 1MM. THIS ROUTE OF ADMINISTRATION MAXIMIZED THE SCLERAL DRUG DOSE. FORM DEPRIVATION CAUSED BY OPACIFIED CORNEAS INDUCED A 0.5MM EXCESS GLOBE ELONGATION AT 2 WEEKS, AND 1.4MM BY 4 WEEKS. ATROPINE-TREATED EYES DID NOT SHOW SIGNIFICANT DIFFERENCES IN LENGTH, AS ASSESSED BY ULTRASONOGRAPHY, FROM CONTROLS. AXIAL LENGTHS AT 2 WEEKS WERE 1MM LESS THAN UNTREATED FORM-DEPRIVED EYES. WE SUGGEST THAT MUSCARINIC ANTAGONISTS CAN ACT DIRECTLY ON THE SCLERA TO CONTROL FIBROBLAST PROLIFERATION AND COLLAGEN SYNTHESIS.

NEURAL INFLUENCE ON MUSCLE DYSTROPHIN: PROTEIN LOCALISATION AND GENE EXPRESSION.

G. Poiana, R. Pierantoni and C. Perrone-Capano. *Dept. Cell Biol. & Development, Rome Univ. "La Sapienza", Italy; ²Dept. Hum. Physiol. & Integr. Biol., Naples Univ., Italy; Dept. Gen. Environm. Physiol., Naples Univ., Italy and Internl. Inst. Genetics Biophys., CNR, Naples, Italy;

We have studied the influence exerted by neurons and embryo extracts on the localization of dystrophin in cultured muscle cells, on its distribution in the subsynaptic area and on dystrophin gene transcription. Immunofluorescence staining shows that dystrophin is expressed at a very low level in 1-day old myoblasts from chick embryo pectoral muscles and in 4-day old myotubes cultured in the absence of extracts. Dystrophin immunopositivity is increased in myotubes co-cultured with chick embryo ciliary ganglion neurons, and it is very high in all myotubes in cultures supplemented with embryo extracts.

A quantitative RT-PCR assay was used to evaluate the expression of dystrophin mRNA in myotubes cultured in the different conditions described above. Preliminary data strongly suggest that dystrophin is up-regulated in myotubes cultured with brain extracts; when cocultured with ciliary ganglion neurons, there was also an increase of dystrophin mRNA, but to a lesser extent. Such findings suggest the presence of a factor in embryo extracts (whole embryo or brain extracts) that specifically increases the production of dystrophin in cultured myotubes, also independently from the presence of neurons in the culture.

Experiments aimed at the detection and quantitation of neuronal dystrophin are in progress in order to examine the transcriptional regulation of the neuronal molecule.

INTERLEUKIN-7 IS A NEURONAL GROWTH FACTOR. M. D. Michaelson, H. Xu, M. F. Mehler and J. A. Kessler. Departments of Neurology and Neuroscience, Albert Einstein College of Medicine, Bronx, NY 10461.

Numerous parallels exist between mechanisms regulating development of the hematopoietic and neuropoietic systems, including the importance of various cytokines in each. In this study, we have found that IL-7 is present *in vivo* in adult and developing murine brain, and that it has neurotrophic actions *in vitro*. Studies using reverse transcription-polymerase chain reaction (RT-PCR) confirm the presence of IL-7 mRNA in adult whole brain, and in specific regions including cerebellum and striatum; further, IL-7 may be enriched in neonatal brain relative to adult brain. Embryonic neurons from selective regions including cortex, hippocampus, striatum, and hypothalamus respond *in vitro* to IL-7 treatment in a dose-dependent manner with significantly enhanced survival and increased neurite outgrowth. These lines of evidence point to a role for IL-7 as a neuronal growth factor. Similarly, experimental evidence *in vivo* and *in vitro* suggests a developmental role for IL-5. In contrast, by RT-PCR analysis, the IL-12 p35 subunit is present in adult but not in developing brain. Characterization of the spatial and temporal expression profiles of these and other non-traditional neural growth factors will advance our understanding of neurogenesis.

INDICATIONS THAT MATERNAL VIP REGULATES PRENATAL GROWTH AND DEVELOPMENT. J.M. Hill, S.K. McCune, J. Keimowitz and D.E. Brenneman. Lab. of Dev. Neurobiol., NICHD, NIH, Bethesda, MD 20892; Dept. of Neonatol., Children's Natl. Med. Ctr., George Washington Univ., Washington, DC 20010.

VIP has neurotrophic properties (PNAS 83:1159,1986; Nature 343:564,1990) and influences neurobehavioral development (Peptides 12:87,1991). It has recently been shown that VIP has a dramatic effect on *in vitro* embryonic growth and that this growth-enhancing action occurs through VIP receptors localized to the CNS (Nature 362:155,1993). Additional recent work has shown that while VIP receptors are abundant during both pre- and postnatal development, and express changing patterns of distribution related to ontogenic events, the mRNA for VIP is not expressed prenatally in the CNS. This data suggests that extraembryonic VIP may bind to prenatal VIP receptors and regulate fetal development. *In situ* hybridization revealed no mRNA for VIP in placenta suggesting that maternal serum may be a potential source of ligand. The present study examined maternal serum daily (E9-E21) for levels of VIP and somatostatin. VIP concentrations exhibited oscillatory changes ranging from 20-280 pg/ml. *In vitro* experiments indicated that VIP concentrations in the upper range were maximally efficacious in increasing survival of spinal cord neurons. Somatostatin measurements from the same serum samples showed no significant change. In addition, the pattern of VIP degradation also changed throughout pregnancy. Intravenous injection of radiolabeled VIP into pregnant rats revealed that radiolabeled material reached the fetal brain and that at least some co-eluted on FPLC with intact VIP. Given the potent neurotrophic properties of VIP and its demonstrated effects on fetal growth, these data suggest that maternal VIP plays a role in the regulation of prenatal growth and development.

MULTIPLE COLONY-STIMULATING FACTORS (CSFs) DIFFERENTIALLY REGULATE CNS GROWTH AND DEVELOPMENT. H. Xu, M. F. Mehler and J. A. Kessler. Depts. of Neurology and Neuroscience, Albert Einstein College of Medicine, Bronx, NY 10461.

Converging lines of evidence suggest that neurogenesis and hematopoiesis may be mediated by a series of growth factors common to both systems. Four CSFs, granulocyte-macrophage (GM-CSF), multifunctional (IL3), granulocyte (G-CSF) and macrophage (CSF I), are known to regulate early, intermediate and later stages of hematopoiesis. To examine the potential CNS developmental role for these functionally diverse cytokines, we established primary dissociated cultures of five rat embryonic brain regions in serum-free media at different densities to preferentially assess growth factor effects on neuronal survival and differentiation. In hippocampus and hypothalamus, GM-CSF, G-CSF and IL3 exhibited dose-dependent, but qualitatively distinct enhancement of neurite outgrowth, terminal branching and cellular survival. Further, in striatum and cerebellum, IL3 showed, respectively, additional short and intermediate-term effects on process outgrowth and survival. By contrast, in cortex or hypothalamus, CSF I demonstrated significant and dose-dependent potentiation of process-outgrowth, branching and cellular survival. Cytokine effects were apparent by 24 hrs of treatment, peaked by 48-60 hrs and showed phenotypic specificity. These observations establish a differential regional and cellular developmental role for the four known hematopoietic CSFs in CNS growth and differentiation.

INCREASED TRANSFORMING GROWTH FACTOR- β 1 (TGF β -1) mRNA IN THE BRINDLED MOUSE (MO^{Dr}) BRAIN IS REVERSED BY COPPER
C. Peterson, T.E. Morgan, J. Valverde and N. Nichols Dept. Gerontology, University of Southern California, Los Angeles, CA 90089

The Brindled mouse (MO^{Dr}) is a murine model of the X-linked inherited disorder Menkes disease which is characterized by a defect in copper transport. Major neuropathological changes include severe neuronal loss, swollen mitochondria, decreased microtubules and cytoskeletal inclusions. Astrocytic alterations accompany neuronal degeneration in the MO^{Dr} brain. Between post-natal days 12 and 15 there is a progressive increase in GFAP immunoreactivity that is preceded by an increase in GFAP mRNA. In lesion models of neurodegeneration, alterations in GFAP mRNA are preceded by an elevation in the cytokine, transforming growth factor beta-1 (TGF β -1) mRNA; therefore, we studied TGF β -1 in the MO^{Dr} brain.

An increase in TGF β -1 mRNA is detected by northern blot hybridization by post-natal day 12 in the striatum, hippocampus, cortex and midbrain of MO^{Dr} male mice. No increases in TGF β -1 mRNA were observed in normal male or heterozygous female littermates. A developmental time course using *in situ* hybridization indicates that the increase in TGF β -1 mRNA appears between postnatal days 10-12. *In situ* hybridization localizes this increase in TGF β -1 mRNA to areas where there are changes in astrocytes and microglia. Systemic treatment of MO^{Dr} mice with copper on days 7 and 10 prevents the increases in brain TGF β -1 mRNA and decreases the neuropathological alterations. Although the alterations in TGF β -1 mRNA may be an indirect effect of the copper transport defect, the results of these studies will help determine the role that cytokines play in developmental neurodegeneration. Supported by AG07855 and AG05589.

NEUROTROPHIC FACTORS: BIOLOGICAL EFFECTS VIII

455.1

NEUROTROPHIN-LIKE ACTIVITY IN SCIATIC NERVE AFTER TRANSECTION LESION: THE EFFECTS OF ELECTROMAGNETIC FIELDS. BF Sisk-en*, FM Longo, I Walker, S Hamilton, JF Hyde and R Stach. Center for Biomed Engr & Dept Anat & Neurobiol., Univ. Kentucky, Lexington, KY 40506; Dept. of Neurology, UC San Francisco, CA 94143; Div. Orthop. Surg., Univ. of Kentucky, Lexington, KY 40506; Dir Res, Univ. Mich-Flint, Flint, MI 48502

We are using pulsed electromagnetic fields (PEMF) to stimulate nerve regeneration (Sisk-en et al, 1989). To understand the underlying mechanisms of this stimulation, we are investigating the role of neurotrophic activity of lesioned nerves. Twelve rats subjected to transection lesions were separated equally into control and treated groups. Control animals were restrained for 4 hours/day and treated animals were restrained and exposed to low levels of PEMF (amplitude 3 gauss, rep rate 2 Hz). Two days post-transection 5 mm lengths taken of unoperated nerve, and of proximal and distal segments of transected nerves were frozen. Neurotrophin-like activity was determined in nerve extracts using a neurite growth assay of dissociated chick dorsal root ganglia neurons. Preliminary findings indicate that neurotrophin-like activity in lesioned stumps was 5-10 fold higher than in unoperated nerve segments. In the distal stumps of the operated nerves there was 79% more activity than in the proximal stumps ($p=0.001$). There was no significant difference between untreated animals and animals treated with PEMF in unoperated nerves, proximal stumps or distal stumps, nor any PEMF effects on ratios of proximal vs distal activities. Although neurotrophin-like activity may play a role in the mechanism of PEMF stimulation of nerve regeneration, we find no compelling evidence that this role is primary. CNTF-like activity is also being investigated. Supported by NIH NS 29621-02, Orthop. Res. Educ. Found., NIH AG 09873, United Cerebral Palsy and the V.A.

FUNCTIONAL AND HISTOLOGICAL EFFECTS OF LOCALLY APPLIED EXTRACELLULAR MATRIX WITH AND WITHOUT bFGF FOLLOWING SPINAL CORD TRANSECTION. B.B. Walters*, E.S. Bachman, A.E. Houston. Div. of Neurosurgery, Univ. of North Carolina at Chapel Hill, NC 27599-7060.

23 Sprague-Dawley rats underwent an open midthoracic procedure under methoxyflurane anesthesia within 36 hours of birth. 5 had laminectomies alone (LAMI), 4 had intradural transection and one segment myelotomy (TRANS), 7 had myelotomies with implantation of approx. 7 μ l of Matrigel (ECM), and 7 had implants containing approx. 5 μ g of bFGF. The animals were evaluated in blinded fashion by a subset of the combined behavioral score of Wrathall (*Exp. Neurol.* 88: 123, 1985) 3 times weekly for 6 weeks. The LAMI animals performed significantly better than all other groups at all times. For weeks 1-3, the other animals performed similarly to each other. During weeks 4-6, ECM and bFGF performed the same and were significantly better than TRANS. At 6 weeks, spinal cord tissues spanning the injury sites were harvested, serially sectioned, processed with solochrome-Van Gieson stain, and in blinded fashion semiquantitatively examined by true color image processing to evaluate relative areas of myelin and scar. Preliminary analysis reveals LAMI had mean spinal cord areas of 3.71 mm² & mean myelin staining of 83% of that area; for all other groups these values were significantly lower. Mean areas and myelin % of the tissue defined as "cord" were 1.03 mm² and 52% for TRANS, 0.77 mm² and 36% for bFGF, and 0.59 mm² and 33% for ECM. The myelin % is significantly higher for TRANS than bFGF or ECM. Though the areas of scar within the "cord" tissue did not differ among TRANS, ECM, and bFGF, the mean total harvested scar areas were significantly higher with bFGF (0.18 mm²) than with TRANS (0.11 mm²) or ECM (0.10 mm²). Other quantitative comparisons and correlations will be presented.

455.2

EFFECT OF BASIC FIBROBLAST GROWTH FACTOR (bFGF) ON RETROGRADE DEGENERATION IN THE DORSAL LATERAL GENICULATE NUCLEUS (LGN). S. Agarwala* and R.E. Kalil. Center for Neuroscience and Dept. of Ophthalmology, Univ. of Wisconsin, Madison, WI 53706

In most mammals, a lesion of visual cortex leads to the retrograde degeneration of neurons in the LGN. In many species, the rate and magnitude of retrograde degeneration in the LGN is variable, being influenced, for example, by age at the time of the cortical lesion or the extent of the cortical damage. Recently, it has been demonstrated in several regions of the mammalian CNS that certain neurotrophic factors also may influence the time course and/or severity of neuronal degeneration. We have studied the effect of one of these factors, bFGF, on the retrograde degeneration of LGN neurons after a lesion of visual cortex. A unilateral lesion of visual cortex was made by subpial suction in 7 adult (250-300g) rats. Three rats (RVC) received only a lesion of visual cortex, while 4 rats (RVCF) were given 5 injections (0.5 μ l) of bFGF (0.25mg/ml in saline or 2% rat serum) directly into visual cortex 2 days prior to making the lesion. In addition, a gelatin sponge soaked in an identical solution of bFGF was placed on the surface of the lesion in the injected animals. After 1 week, the animals were perfused with 4% paraformaldehyde, and serial sections through the brain in the frontal plane were stained with cresyl violet. Material from 3 normal adult rats also was available.

The total number of neurons in each LGN ipsilateral to the cortical lesion was estimated by counting samples of neurons with a 100x objective, and correcting the sample counts for the measured volume of the nucleus. Similar estimates of neuron number were made in the normal rats. After 1 week, the approximate number of neurons surviving in RVC rats is 36% of normal and it is 46% of normal in RVCF rats. Thus bFGF appears to promote about a 28% improvement in LGN neuron survival after a lesion of visual cortex. This suggests that bFGF may be an effective neuroprotectant in the LGN, especially if long-term neuroprotection can be shown.

SOLUBLE FACTORS FROM SKELETAL MUSCLE PROMOTE SURVIVAL OF NEURONS IN SENSORY GANGLIA AFTER AXOTOMY. W.H.A. Yu*, R.M.W. Chau and F. Ren. Dept. of Cell Biol. and Anat. Sci., City Univ. of New York Medical School, New York, NY 10031 and Dept. of Anat., Univ. of Hong Kong, Hong Kong.

Using the protein band-fishing by cells method, two protein bands migrated at 35kd and 22kd on Phast gel electrophoresis from extracts of the peroneal muscles of young rats were identified to contain soluble factors which enhanced neurite outgrowth and promoted the survival of anterior horn motoneurons *in vitro*. Putative neurotrophic factors in 35kd and 22kd protein bands were named as MNTF1 and MNTF2, respectively. Application of minced Phast gel containing MNTF1 and MNTF2 to stumps of transected facial and sciatic nerves also promoted the survival of axotomized motoneurons *in vivo*. In this study, the efficacy of MNTF1 and MNTF2 was tested on the survival of sensory neurons after their peripheral processes were cut in order to further characterize MNTF1 and MNTF2. The infraorbital and sciatic nerves of 10-day-old rats were transected unilaterally under hypothermia. MNTF1 and MNTF2 in Phast gel minced to small pieces were placed between transected nerve stumps. At 2 weeks postaxotomy, rats were perfused intracardially with formaldehyde fixative. The trigeminal ganglia (TG) and dorsal root ganglia (DRG) from L_{4,5} were excised bilaterally and embedded in Paraplast. Neuronal cell numbers in TG (excluding the mandibular portion of the ganglia) and DRG were counted in serial sections stained with cresyl violet to determine the percentage survival. Results indicated that about 50% of the ganglion cells were lost from axotomy. Treatment with either MNTF1 or MNTF2 significantly attenuated neuronal cell loss in TG and DRG, suggesting that MNTF1 and MNTF2 can also protect sensory neurons from axotomy-induced cell death.

EFFECTS OF CILIARY NEUROTROPHIC FACTOR ON AXOTOMY-INDUCED DEATH IN RETROGRADELY-LABELLED SCIATIC MOTONEURONS IN NEONATAL RATS. R. Vejsada, Y. Sagot and A.C. Kato, Division Clinical Neurophysiology & Dept. Pharmacology, CMU, Univ. Geneva, Geneva, Switzerland

Death of motoneurons after nerve lesion in immature animals provides a means to study effects of neurotrophic factors on neuronal degeneration. We have developed a quantitative method for examining short and long-term survival of axotomized sciatic motoneurons in neonatal rats in presence or absence of exogenous ciliary neurotrophic factor (CNTF). Under cold anaesthesia, the sciatic nerve was cut either on postnatal day 3 (P3) or 7 (P7). Direct detection and quantitation of the lesioned motoneurons was obtained by their retrograde labelling by fluorescent dye (FluoroGold, FG), applied in a small sealed tube on the central nerve stump. Either CNTF or bovine serum albumin (BSA) was simultaneously added to the tube.

After 1 or 2-week survival, the sectioned spinal cords were examined for fluorescent motoneurons. In rats that had been operated on P3, only 100-200 motoneurons survived in the controls, whereas significantly more motoneurons (700-800) were still present in rats treated with CNTF after 1 week. However, following 2 weeks of survival, the number of surviving motoneurons in control and experimental animals was the same. As in BSA-treated control rats, the FG label appeared in cell debris and in abundant microglia. Similar results were obtained in rats operated on P7; since degeneration rates were significantly lower in the control animals, differences were less important. These findings suggest that rescuing immature axotomized motoneurons from degeneration may require repeated application of neurotrophic factor. (CNTF was generously provided by Regeneron)

BDNF PREVENTS ATROPHY OF RAT RUBROSPINAL NEURONS AFTER AXOTOMY. W. Tetzlaff, N.R. Kobayashi and A.M. Bedard Dept. of Physiology, University of Ottawa, Ottawa, Ontario, Canada, K1H 8M5

Rat rubrospinal neurons undergo massive atrophy between day 7 and 14 after axotomy at the cervical level of the spinal cord (C3). This atrophy is accompanied by a drop in total tubulin and actin mRNA expression (Tetzlaff et al., J. Neurosci. 11:2528, 1991). We have previously demonstrated the presence of trkB and p75^{NGFR} mRNA in normal and axotomized rubrospinal neurons (Soc. Neurosci. Abstr. Vol.18:1294, 1992). This provided the rationale to test whether BDNF, the presumed ligand at trkB receptors, could prevent this neuronal atrophy and sustain regeneration associated gene expression. BDNF was applied at doses of 125 or 500 ng/ μ l/h via an osmotic minipump (Alzet) between days 7 and 14 after axotomy. In those experiments with BDNF infusion less than 1 mm away (n=3) from the red nucleus a full prevention of neuronal atrophy was observed, i.e. mean soma area was 97.2% of contralateral, compared to 54.6% in saline controls. The effect was only partial with greater infusion needle to red nucleus distances. Axotomized BDNF treated neurons were chromatolytic and expressed high levels of GAP43 mRNA. A detailed analysis of regeneration associated gene expression is currently under way. To the best of our knowledge, this is the first demonstration of a response to neurotrophic factors in rubrospinal neurons. (BDNF was a generous gift of REGENERON PHARMACEUTICALS Inc.. Supported by MRC, Canada and Rotary International).

EFFECT OF NEUROTROPHIN-4 ADMINISTRATION ON THE SURVIVAL OF AXOTOMIZED RETINAL GANGLION CELLS IN ADULT RATS. D.B. Clarke, Y.-C. Wang, G.M. Bray, M. Raaminsky, and A.J. Aguayo. McGill University Centre for Research in Neuroscience, Montreal General Hospital Research Institute, 1650 Cedar Avenue, Montréal, Québec, H3G 1A4.

To determine the survival effect of neurotrophin-4 (NT-4) on axotomized retinal ganglion cells (RGCs), the RGC densities were measured in adult rats after intraorbital optic nerve (ON) cut and a concurrent single intravitreal 5 μ l injection of NT-4 (0.6 μ g/ μ l; Regeneron Pharmaceuticals Inc.) in 0.1M phosphate buffered saline (PBS). Two groups of animals with cut ONs were used as controls: one group had an injection of the vehicle (5 μ l of PBS) and the other had no further treatment.

Single injection of NT-4 posteriorly through the sclera and retina prevented the loss of more than one quarter of the RGCs by maintaining a normal RGC population at one week. In the NT-4 injected group, 99% of RGCs survived after 7 days, compared with 52% (p<0.01) after ON cut alone and 72% (p<0.01) after injection of PBS. At 10 days, 62% of RGCs survived after NT-4 injection, compared with 21% after ON cut (p<0.01) and 22% after injection of PBS (p<0.01). At 14 days, the RGC survival effect of NT-4 was almost completely dissipated. The increased survival of RGCs caused by injection of vehicle without NT-4 was more pronounced with anterior injections into the vitreous chamber through the cornea-sclera junction than with posterior injections through the sclera and retina.

The single intravitreal administration of NT-4 has a potent, though short-lived, survival effect on axotomized RGCs. The RGC survival effect of control injections may be due to synthesis within the eye of trophic factors stimulated by ocular injury.

DEATH OF AVIAN MOTOR AND SENSORY NEURONS AFTER AXOTOMY AND THEIR RESCUE BY NEUROTROPHIC AGENTS. A.C. Lo, R.W. Oppenheim and L.J. Houenou. Dept. of Neurobiology & Anatomy, Bowman Gray Sch. of Med., Wake Forest Univ., Winston-Salem, NC 27157.

In neonatal mammals axonal injury (axotomy) results in a substantial loss of motor and sensory neurons. Furthermore treatment with exogenous neurotrophic agents can promote the survival of axotomized rat motoneurons (MNs). The present study was aimed at determining the time-course of motor and sensory neuron death following sciatic nerve axotomy in the chick. In addition, we have examined whether neurotrophic agents, including the neurotrophins and CNTF, can promote the survival of axotomized avian neurons. Results indicate that chick MNs are vulnerable to axotomy up to embryonic day (E) 12, whereas injury-induced sensory neuron death occurred up to E14. Four days after axotomy on E12, 43% of the motor neurons died whereas 62% of the sensory neurons were lost. Treatment of axotomized embryos with NGF rescues significant numbers of both motor (21%) and sensory (22%) neurons from cell death. Daily administration of CNTF completely prevents axotomized MNs from dying and significantly increased DRG neurons survival by 30%. Because of the ineffectiveness of NGF on normal MN death, these data suggest that injured avian MNs may aberrantly express NGF receptors. Alternatively, NGF may affect MN indirectly via the rescue of DRG cells. The effects of other members of the neurotrophin family will also be discussed. Supported by MDA, IRIP, and Synergen, Inc.

NEUROTROPHIN-4 (NT-4) SUPPORTS THE SURVIVAL OF RETINAL GANGLION CELLS AND NEURITE OUTGROWTH FROM ADULT RAT RETINAL EXPLANTS *IN VITRO*. A. Cohen, J. Beer*, G.M. Bray and A.J. Aguayo. Centre for Research in Neuroscience, McGill University and Montréal General Hospital Research Institute, 1650 Cedar Avenue, Montréal, Québec H3G 1A4, Canada.

NT-4, a novel member of the neurotrophin family, has been reported to induce neurite outgrowth from chick dorsal root ganglia explants with almost no effect on sympathetic or nodose ganglia. In this study we compared the effects of NT-4, brain derived neurotrophic factor (BDNF) (both provided by Regeneron Pharmaceuticals Inc.), nerve growth factor (NGF), ciliary neurotrophic factor (CNTF) and basic fibroblast growth factor (bFGF) on retinal ganglion cell (RGC) survival and neurite outgrowth from adult rat retinal explants *in vitro*. The responses to NT-4 were dose dependent. Maximal neurite outgrowth was observed with 5 ng/ml and the half-maximal effect was about 0.5 ng/ml. This NT-4 dose-response was similar to that obtained with BDNF. NT-4 and BDNF also supported the survival of Fluorogold[®] prelabeled RGCs in the retinal explants. In contrast, we did not observe significant effects of NGF, CNTF and bFGF in these culture conditions. These results demonstrate that among the neurotrophic factors tested, NT-4 and BDNF are the most effective in promoting RGC survival and neurite outgrowth. Combination of saturating concentrations of NT-4 and BDNF did not further augment neurite outgrowth suggesting that NT-4 and BDNF share the same signaling pathway.

455.10

STRENGTHENING OF FUNCTIONAL CONNECTIVITY IN THE SPINAL CORD AS A RESULT OF NGF-DEPENDENT SPROUTING OF UNDAAMAGED PERIPHERAL NERVES. B.A. Urschel, K. Mearow, and J. Diamond. Dept. of Biomedical Sciences, McMaster University, Hamilton, Ontario L8N3Z5.

Using induction of the immediate early gene c-fos as a marker of functional connectivity, we have recently demonstrated that collateral sprouting of undamaged peripheral nociceptive axons results in a concomitant increase in the number of c-fos immunoreactive cells in the dorsal horn of the spinal cord. This strengthening of functional connectivity within the cord was not observed if the peripheral sprouting was prevented with daily systemic injections of antibodies to Nerve Growth Factor (NGF). We have undertaken several morphological approaches in order to determine if the increase in the number of c-fos positive cells can be explained by intraspinal sprouting and synaptogenesis, or whether other mechanisms of increasing synaptic effectiveness are involved. Counts of both myelinated and unmyelinated axons in the dorsal roots above and below the root corresponding to the peripheral nerve of interest revealed no difference between chronically and acutely isolated sides; thus if intraspinal sprouting is occurring it is not a result of degeneration of the central processes of the adjacent cut peripheral nerves vacating sites within the spinal cord. Currently, tracing and immunocytochemical approaches are being used to look for morphological evidence of intraspinal sprouting. We expect to present the results at the meeting. We also hope to report the results of associated PCR studies examining NGF, BDNF, Neurotrophin-3, trk, trkB, and p75^{NGFR} expression in the dorsal horn of the affected spinal cords.

SPATIAL DISTRIBUTION OF NGF MAY DEFINE REGIONS TO BE INNERVATED BY NGF-SENSITIVE FIBERS J.M. Conner* and S. Varon Department of Biology, University of California San Diego, La Jolla, CA 92093

Cholinergic deafferentation of the hippocampal formation stimulates fibers from the superior cervical ganglion to innervate this CNS territory. The distribution of sympathetic fibers in the denervated hippocampal formation differs from the preexisting pattern of cholinergic terminals and is restricted primarily to the mossy fiber pathway. While NGF has been suggested to play a role in this sprouting response, the extent to which it is involved and the mechanism by which it may act remain to be elucidated. In the present investigation, correlations were made between the distribution of NGF immunoreactivity (NGF-ir) and the pattern of sympathetic ingrowth into the cholinergically deafferented hippocampal formation of adult rats. Following a fimbria fornix transection, superior cervical ganglia were dissected from neonatal rats and transplanted into the lesion cavity. Following a 16 or 30 day survival interval, sympathetic fibers from the ganglia had innervated the mossy fiber region as reported. This distribution of fibers correlated well with the distribution of NGF-ir seen in adjacent sections. If, at the time of the ganglion transplantation, the animal also received an entorhinal cortex lesion ipsilateral to the transplant, an additional band of NGF-ir appeared in the outer molecular layer of the dentate gyrus. The appearance of this new "patch" of NGF-ir was accompanied by new sprouting of sympathetic fibers into this region. These results support the hypothesis that NGF is involved in the sprouting response of sympathetic fibers following cholinergic deafferentation of the hippocampal formation and further suggests that a topographical distribution of NGF may define the region to be innervated by NGF-sensitive sympathetic fibers. RECOMBINANT HUMAN IGF-I, Des (1-3)IGF-I and R³ IGF-I ENHANCE FUNCTIONAL RECOVERY FROM SCIATIC CRUSH IN MICE. Cathy Steffler, David B. Stong, Erva Yu, Kathy Callison, Malini Dasgupta, Jeffry L. Vaught and Patricia C. Contreras*, Cephalon Inc., West Chester, PA 19380.

The purpose of this study was to compare the ability of recombinant human IGF-I (rhIGF-I) to that of des (1-3)IGF-I and R³ IGF-I, two analogs of IGF-I with reduced affinity for IGF binding proteins, to enhance functional recovery from sciatic nerve crushes. After both sciatic nerves were crushed, mice were injected sc. daily with 0.1 or 1 mg/kg of rhIGF-I, des (1-3)IGF-I or R³ IGF-I or vehicle until Day 14 post crush. Initially after both sciatic nerves were crushed, mice lost the ability to grip an inverted wire screen with their hindpaws and parameters of gait, toe spread, internal toe spread and angle between hindfeet, were adversely affected, but the mice slowly regained control of their hindfeet over the next 14 days. However, when mice were dosed with rhIGF-I (0.1 and 1 mg/kg), des (1-3)IGF-I (1 mg/kg) and R³IGF-I (0.1 and 1 mg/kg), gripping ability returned back to control levels faster than that of vehicle-treated mice. The different parameters of gait consistently returned back to control levels sooner than that of vehicle-treated mice when animals were treated with rhIGF-I (0.1 and 1 mg/kg) or R³IGF-I (1 mg/kg). In contrast, des(1-3)IGF-I only returned toe spread values back to control sooner than that of vehicle-treated mice. The reason that R³IGF-I and des(1-3)IGF-I were less potent/effective may be due to the finding that rhIGF-I has a longer t_{1/2} in plasma than des(1-3)IGF-I or R³IGF-I.

TROPIC AND TROPIC INFLUENCE OF EXOGENOUS NT-3 AND BDNF AFTER NEONATAL SPINAL CORD LESIONS. P. Diener-Ostfield, P.S. DiStefano, M.M. McAtee, and B.S. Bregman, Dept. of Anatomy and Cell Biology, Georgetown University School of Medicine, Washington, DC 20007, and Regeneron Pharmaceuticals, Inc., Tarrytown, NY 10591.

Immature central and peripheral neurons are dependent upon target derived trophic support for survival. Axotomy at birth results in massive retrograde cell loss of the injured neurons. After spinal cord lesion at birth, transplants of fetal spinal cord tissue permanently rescue immature axotomized brainstem-spinal neurons and permit regrowth of their axons into and through the transplant. Nontarget transplants (cortex, CX, hippocampus, HC) rescue these neurons and support axonal growth only transiently. Dorsal root neurons survive central axotomy and maintain axonal projections in both target and nontarget transplants. The current series of experiments tested the capacity of different combinations of neurotrophic support and fetal striatal transplants (which lack a trophic influence) to rescue immature axotomized brainstem-spinal and dorsal root neurons and support regrowth of their axons. Neurotrophic factors (NT-3, BDNF) or fetal striatal transplants with or without exogenous NT-3 or BDNF were inserted directly into the lesion site created by a thoracic spinal cord hemisection in 3 day old rat pups. Neuronal survival and axonal elongation were examined at one and four weeks after injury. NT-3, BDNF and striatal transplants rescue neurons in the red nucleus and locus coeruleus. Unlike fetal HC or CX, however, striatal transplants fail to support the growth of brainstem-spinal or dorsal root axons at either survival period. This suggests that the requirements of immature axotomized neurons for survival differ from their requirements for axonal elongation and that a substrate, per se, is insufficient for axonal elongation. Exogenous NT-3 or BDNF combined with striatal transplants, however, elicited regeneration of a subpopulation of dorsal root but not brainstem-spinal axons. This observation suggests that there may be pathway specificity in the trophic influences of particular neurotrophic factors. Other guidance cues unique to fetal spinal cord tissue also may be required for regeneration of brainstem-spinal axons. Supported by NIH NS 19259 and RCDA NS01356 to BSB. Purified NT-3, BDNF provided by Amgen/Regeneron.

DURATION OF NERVE GROWTH FACTOR-INDUCED CEREBROVASCULAR SPROUTING. L.G. Isaacson*¹, F. Simpson¹, and K.A. Crutcher², ¹Dept Zoology, Miami University, Oxford, OH 45056; ²Dept Neurosurgery, University of Cincinnati College of Medicine, Cincinnati, OH 45267.

We have previously shown that intraventricular infusion of nerve growth factor (NGF) into the adult rat brain elicits sprouting from mature cerebrovascular axons associated with the intradural internal carotid artery (ICA). A 3-fold increase in the total number of perivascular axons was found at the ultrastructural level (Isaacson et al. 1990). Recently we determined that the majority of the sprouted axons are sympathetic in origin (Isaacson et al. 1992) and concluded that mature cerebrovascular innervation can be modulated by NGF infusion. We carried out the present study to determine how long the sprouted axons persist following the two week infusion period. The animals received a 2-week intracerebroventricular infusion of either NGF or cytochrome C. Following the infusion period, two groups of rats (NGF; n=3 and VEH; n=3) were sacrificed immediately for electron microscopy. Other rats were reanesthetized and the pump tubing was clipped to halt the flow of pump infusate. Following either a 1 week (NGF-1; n=4; VEH-1; n=4) or 3 week (NGF-3; n=4; VEH-3; n=4) survival, these animals were sacrificed. The total number of perivascular axons associated with the ICA was determined at the ultrastructural level. Similar to previous reports, NGF elicited a 3-fold increase in the number of perivascular axons (x=1771) when compared with the VEH rats (x=607). One week after NGF infusion was halted (NGF-1), the number of axons (x=977) was significantly higher than that observed in NGF-3 (x=575) and all control groups (VEH-1=560; VEH-3=647) but significantly less than NGF rats (x=1771). The number of perivascular axons in NGF-3 rats (x=575) was comparable to that observed in control animals. The results of this study indicate that, even though NGF can elicit sprouting of perivascular axons in the adult, continued infusion of NGF is necessary to maintain the axonal sprouts.

RECOMBINANT HUMAN INSULIN-LIKE GROWTH FACTOR-I (rhIGF-I) PREVENTS DEVELOPMENT OF VINCRISTINE-INDUCED NEUROPATHY IN MICE. Patricia C. Contreras, Cathy Steffler, Shelley Dennis, Joseph C. Arezzo, Michael E. Lewis, Stuart C. Apfel, John A. Kessler, John A. Gruner* and Jeffry L. Vaught, Cephalon, Inc., West Chester, PA 19380.

One of the major dose-limiting side-effects of vincristine is induction of a severe peripheral neuropathy. To assess whether rhIGF-I, which supports the survival of motoneurons and dorsal root ganglionic neurons *in vitro* and enhances neuronal sprouting *in vivo*, could prevent the development of a vincristine-induced neuropathy *in vivo*, mice were treated twice a week with 2 mg/kg of vincristine administered ip for 8 weeks. Mice were also treated concurrently with rhIGF-I (1 or 0.3 mg/kg) or vehicle administered sc. daily for the duration of the study. Vincristine treatment decreased body weight, affected several parameters of gait, reduced ability to grip an incline plane and decreased the response to a noxious stimulus. Vincristine also increased latency and reduced the amplitude of the compound action potential of the caudal nerve and decreased the amplitude of muscle contraction in response to stimulation of the tibial nerve. All of the effects of vincristine, except decreased amplitude of the action potential of the caudal nerve, were prevented by co-treating mice with 1 mg/kg of rhIGF-I. The effect of rhIGF-I was dose-dependent as 0.3 mg/kg of rhIGF-I was not as efficacious as 1 mg/kg of rhIGF-I. These results suggest that rhIGF-I may be useful clinically in preventing the vincristine-induced peripheral neuropathy.

RETINOECTAL REGENERATION: bFGF EFFECTS IN CO-CULTURE PREPARATIONS PARALLEL *IN VIVO* RESULTS. G.E. Schneider* & D.E. Chen, Dept. Brain & Cognitive Sciences, M.I.T., Cambridge, MA

We have shown that retinofugal axons will reinnervate the superior colliculus (SC) of the Syrian hamster with transection of the brachium of the SC on postnatal day 3 (P3) or earlier (So et al., 1980). The regrowth fails after transections on P4, but a gelfoam implant soaked in basic fibroblast growth factor (bFGF) extends the period of regeneration well beyond P3 (Carman & Schneider, submitted). Now we are obtaining comparable results with an organotypic co-culture system in which retinal explants from postnatal hamsters are placed adjacent to the superficial gray layer of living slices of SC, at sites of pial disruption. After 5 days, the co-cultures are fixed in paraformaldehyde and outgrowth of axons is assessed by placing crystals of Dil in the retina. With source and target tissue taken from pups of the same age, retinal axons extend into the tectum in cultures from P0 animals (N=3), but not from P1-P5 animals (N=18). Since axons take 2-3 days to reach and penetrate an SC slice, the age of the tissue in the P0 cases when axons penetrate the tectum is 2-3 days. However, adding bFGF (30 ng/ml) to cultures of tissue taken from P5 animals results in a dramatic increase in retinal axon growth and penetration of the superficial midbrain (N=3).

In heterochronic co-cultures, very limited axonal growth from P19 and adult retinae occurred into E13 SC (see Chen et al., this vol.). However, with bFGF added to similar cultures, large numbers of axons succeeded in interconnecting retina and tectum.

The co-culture model should facilitate the specification of optimal conditions for induction of regenerative growth, as well as spur progress towards understanding the mechanisms of growth-promoting and inhibiting molecular factors. (Support: NIH grants EY00126, EY05504, EY02621; bFGF provided by Creative Biomolecules of Hopkinton, Mass.)

CORRESPONDENCE BETWEEN HRP-LABELLED OLIVOCEREBELLAR FIBERS AND L7/PCP2+ PURKINJE CELLS IN TRANSGENIC MICE DURING EMBRYOGENESIS. M.A. Paradise[§], R.J. Smeyne[†], J.D. Oberdick[‡], J.I. Morgan^Ω and L.M. Eisenman[§]. [§]Dept. of Anatomy and Molec. Biology, Thos. Jefferson Univ., Philadelphia, PA; [†]Dept. of Molec. Biology, Pharm. Res. Inst., Bristol Myers-Squibb, Princeton, NJ; [‡]Dept. of Anatomy and Neurobiology, Ohio State Univ., Columbus, OH; ^ΩRoche Inst. of Molec. Biology, Nutley, NJ.

There is great interest in determining the factors responsible for afferent organization in the mammalian cerebellum. Purkinje cells (PC) have been suggested to perform this function as they express biochemical heterogeneities during embryonic development in the rat. By using an *in vitro* perfusion system, it is possible to selectively label groups of olivocerebellar (OC) fibers to determine how their termination zones relate to biochemically-defined groups of PC. The transgenic mice used carry a β-gal reporter gene linked to an L7/PCP2 promoter. In the cerebellum L7/PCP2 is expressed exclusively in PC and is upregulated heterogeneously during embryonic development. OC fibers labelled after horseradish peroxidase (HRP) application to the caudal medial accessory olive at E17 terminate primarily among L7/PCP2+ PC located in parasagittal bands in the medial cerebellum. In addition, the boundaries between HRP-labelled and -unlabelled areas appear to correspond to those between L7/PCP2+ and L7/PCP2- PC clusters in many areas. However, not all HRP-labelled fibers are colocalized with L7/PCP2+ cells, questioning the nature of the relationship between L7/PCP2 expression and OC fiber organization.

NITRIC OXIDE SYNTHASE EXPRESSION REVEALS COMPARTMENTS OF CEREBELLAR GRANULE CELLS AND SUGGESTS A ROLE FOR MOSSY FIBERS IN THEIR DEVELOPMENT Karl Schilling^{*} & Stephan L. Baader

Dept. Anatomy & Cell Biology, University of Ulm, D-89069 Ulm, Germany

Nitric oxide (NO) is a pluripotent molecule involved in multiple functions, including neurotransmission. It has been theorized that NO signalling also affects neural development. To address this issue experimentally, we investigated the developmental expression of nitric oxide synthase (NOS) in the murine cerebellum and correlated it to the well established developmental history of the cerebellar cortex. NOS was visualized by NADPH-diaphorase histochemistry. Cerebellar granule cells (GC) expressed NOS only after reaching the internal GC layer. Initially, the nascent internal GC layer stained uniformly for NADPH-diaphorase throughout the cerebellum. Following invasion by mossy fibers, a pattern of differential NOS expression by GCs emerged, such that clusters of heavily stained GCs became separated by areas of unstained GCs. Analysis of cultured GCs indicated that initial induction of NOS is independent of mossy fiber signals and that the level of NOS expression becomes sensitive to electrical activity once GCs establish functional synapses. These findings show that GC precursors are endowed with an intrinsic program which regulates NOS induction and which is executed independently of correct positional cues. The data also suggest that synaptic activity of mossy fibers plays an important role for development of GC compartments. These compartments are defined by differential expression of NOS and may contribute to the functional organization of the cerebellar cortex. Supported by BMFT grant 0316915A.

EFFECTS OF PRE- AND POSTNATAL SEROTONIN DEPLETION UPON THE ORGANIZATION OF THALAMOCORTICAL AFFERENTS IN THE RAT'S PRIMARY SOMATOSENSORY CORTEX. C.A. Bennett-Clarke^{*}, N.L. Chiaia, M.J. Leslie and R.D. Lane. Dept. of Anatomy, Medical College of Ohio, Toledo, OH 43699

A previous study (Blue, M.E. et al., *Cerebral Cortex*, 1991;1:380-389) has shown that depletion of serotonin (5-HT) from the developing somatosensory cortex in rats by means of systemic injection of *p*-chloroamphetamine delays, but does not prevent, the formation of a vibrissae-related pattern by thalamocortical afferent axons. This interesting study was limited by the facts that the extent of the 5-HT depletion was not quantified and appeared modest and that all depletions were carried out after birth, an age at which the vibrissae-related pattern can already be discerned. We employed single subcutaneous injections of 5,7-dihydroxytryptamine (5,7-DHT) on either embryonic day (E-) 16 or the day of birth (P-0) to deplete cortical 5-HT and evaluated the organization of thalamocortical afferents on P-5 through P-8. In most of the animals used for the assessment of thalamocortical organization, the amount of 5-HT in one hemisphere was measured with high pressure liquid chromatography. Anatomical and biochemical results from experimental animals were compared with those from age-matched normal animals. Injection of 5,7-DHT on E-16 resulted in an 89% reduction in cortical 5-HT; injections on P-0 produced an average reduction of 91%. Neither pre- nor postnatal depletion of 5-HT resulted in a significant alteration in the vibrissae-related pattern of thalamocortical afferents within the primary somatosensory cortex.

IDENTIFICATION OF A cDNA ENCODING A PUTATIVE TRANSCRIPTIONAL REGULATOR OF L7-EXPRESSION IN PURKINJE CELLS. C. Kürschner and J.I. Morgan^{*}. Roche Institute of Molecular Biology, Roche Research Center, Nutley, NJ.

The Purkinje cell-specific gene, L7, is expressed in mouse cerebellum in a dynamic temporal and spatial pattern that resembles segmental gene expression in developing invertebrates, such as *Drosophila*. To identify transcription factors that regulate L7 expression, a mouse cerebellum cDNA library was generated, that allows for functional screening in yeast strains carrying an L7 promoter-lacZ fusion reporter construct. With this approach, we isolated a cDNA clone that codes for a protein ("LZCP" for leucine zipper containing protein) with a "leucine zipper" motif and a "basic region", the putative DNA binding domain of the protein. We assume that LZCP, like other proteins of this type, is a transcription factor. The target DNA sequence of LZCP in the L7 promoter was identified using gel shift assays and transient expression activation assays in yeast. The effects on the map of L7 expression of mutating this site is analysed in transgenic mice carrying a mutant L7 promoter-lacZ fusion construct as a transgene.

MOLECULAR DISTINCTIONS BETWEEN THALAMIC NUCLEI DURING DEVELOPMENT: DIFFERENTIAL EXPRESSION OF KERATAN SULFATE PROTEOGLYCANS. B. Miller^{*}, A.M. Sheppard and A.L. Pearman. Depts. of Cell Biol. and Neurology, Washington Univ. Sch. of Med., St. Louis, MO 63110.

Thalamic nuclei are distinct in their connectivity and function, but the molecular signals that act during development to determine these distinctions are not known. Components of the peri- and extracellular matrix, including proteoglycans, have important roles in development, particularly in cell migration, axonal elongation, and response to growth factors. We have analyzed the distribution of keratan sulfate proteoglycans (KSPGs) in the developing thalamus of the rat (E16-P14) by immunohistochemistry with a monoclonal antibody (5D4, generously provided by B. Caterson) to the glycosaminoglycan side chains. We find three striking distinctions between developing thalamic nuclei in the expression of KSPGs.

i) Nuclear groups differ appreciably in their level of immunolabeling. For example, lateral nuclei (L, LP, LGd) are intensely immunolabeled throughout the period of expression while anterior nuclei (AV, AM) label less intensely. ii) Selected nuclei (e.g. LGv, AD) within groups express no detectable KSPGs while their neighbors (LGd, AV) are strongly immunolabeled. iii) Expression patterns within a nuclear group are temporally distinct; both VbM and VbI have intense immunolabeling at E18, but a rapid decline in labeling begins in VbM several days before a similar decline occurs in VbI. Immunolabeling in all nuclei is developmentally regulated, beginning at E16-18 and declining in the first or second postnatal week. Thalamic axons express KSPGs as they leave the thalamus and enter the internal capsule. Thus neurons of the thalamus express KSPGs in developmentally regulated, differential patterns that respect the boundaries of thalamic nuclei. Expression along their axons suggests that these distinctions may be involved in processes that determine connectivity such as pathfinding, fasciculation, and target selection.

Delayed barrel boundary development in the somatosensory cortex of thyroxine-deficient rodents. E.D. Laywell, J.A. Brodkey, L. Van Middlesworth, J. Evans, T. F. O'Brien^{*}, and D. A. Steindler. Depts. Anat. & Neurobiol., Neurosurg., and Physiol., Univ. of Tenn., Memphis, TN 38163

Previous studies have shown that transient cellular (astrocyte) and molecular (e.g. tenascin) boundaries surround individual cortical whisker barrels during the first week of postnatal development. Boundaries are most distinct on postnatal day 6 (P6), and they persist until the second to third postnatal week. Boundary expression is associated with a so-called critical period during which manipulations of the periphery (i.e. vibrissae lesions) lead to changes in central cytoarchitecture. We describe here a 1 week delay in whisker barrel boundary appearance in the pups of female rats and mice maintained during pregnancy and weaning on an iodine-free diet supplemented with propylthiouracil (PTU) to interfere with thyroxine synthesis. PTU pups fail to show barrel boundaries until P13, using conventional barrel-boundary labeling methods. This delay does not seem to be due to a general retarded development of the whisker-barrel pathway, since normal boundaries are present at apparently normal developmental times in the brainstem trigeminal complex of PTU pups. Studies are underway to correlate this altered boundary molecule expression with the development of thalamocortical afferent projections, and to establish that this delay in boundary development corresponds to a lengthened critical period. The lengthened development of cortical barrel boundaries provides a useful model for studies of barrel development because of the protraction of the normally short period of postnatal barrel maturation. Cellular and molecular mechanisms behind PTU effects on cortical barrel maturation may reflect a crucial interaction between thyroid hormone and neural cells involved in normal CNS circuit construction and plasticity. Support - NIH, NS 20856.

AXONAL TRANSPORT BLOCKADE MIMICS EFFECTS OF NEONATAL INFRAORBITAL NERVE TRANSECTION UPON VIBRISSEAE-RELATED PATTERNS. N.L. Chiaia¹, R.S. Crissman, C.A. Bennett-Clarke and R.W. Rhoades. Dept. of Anatomy, Medical College of Ohio, Toledo, OH 43699

Uninterrupted connections with the periphery are necessary for the normal development and maintenance of central somatotopic patterns. This has been shown to be true for the representation of the mystacial vibrissae in the trigeminal (V) system, but additional studies have demonstrated that neither NGF deprivation nor neuronal activity blockade disrupts vibrissae-related patterns. To determine if a peripheral factor was necessary for the maintenance of vibrissae-related patterns, we applied ELVAX chips impregnated with colchicine to the infraorbital nerve (ION) at birth (P-0) and killed animals between P-4 and P-7. In brainstems stained for cytochrome oxidase, there was a complete loss of the dense patches corresponding to the mystacial vibrissae follicles ipsilateral to the colchicine implants. Labelling of thalamocortical afferents with Di-I or staining of cortices with an antibody directed against serotonin demonstrated a pattern with five rows, but no individual patches. This pattern is also observed after neonatal ION transection. Retrograde labelling of V ganglion cells after Di-I injection into the face in fixed tissue and direct examination of treated nerves demonstrated that the colchicine-impregnated ELVAX did not sever the ION. However, the number of myelinated fibers in the nerve was reduced. None of the effects reported above were observed in animals that received blank ELVAX implants. These results suggest that a peripheral factor other than NGF may be necessary for the maintenance of central vibrissae-related patterns.

FETAL INFRAORBITAL NERVE TRANSECTION INCREASES THE AREA DEVOTED TO THE PRIMARY SOMATOSENSORY CORTICAL REPRESENTATION OF THE LOWER JAW. S.E. Fish¹.

H.P. Killackey, N.L. Chiaia, C.A. Bennett-Clarke, and R.W. Rhoades. Dept. of Anatomy, Medical College of Ohio, Toledo, OH 43699, Dept. of Psychobiology, University of California, Irvine, CA 92717 and Dept. of Anatomy, Marshall University Medical School, Huntington WV 25704

Nerve lesions at different stages of development were used to determine the role of the periphery in the establishment of cortical territories devoted to representations of different portions of the body surface. Transection of the infraorbital nerve (ION), the trigeminal branch that supplies the whisker pad, in fetal (embryonic day 15 through embryonic day 18), but not newborn, rats resulted in a significant reduction in the area within the primary somatosensory cortex devoted to the representation of the mystacial vibrissae as demonstrated by staining the cortex with an antibody to serotonin or labelling of thalamocortical afferents with Di-I. Such lesions in fetal, but not neonatal, rats also resulted in significant increases in the cortical area devoted to the representation of the lower lip and jaw. There was a significant positive correlation between the reduction in the vibrissae representation and the expansion of that of the lower jaw. Damage to the ION in either neonatal or fetal rats failed to significantly increase the amount of cortex devoted to the representation of the forepaw. These results indicate that the primary afferent innervation of the periphery does influence the cortical areas devoted to representations of different parts of the body surface and that the representation of one region can expand significantly when that of another body part is reduced. AREA-SPECIFIC REGULATION OF THE GABA_A RECEPTOR $\alpha 1$ -SUBUNIT IN DEVELOPING RAT NEOCORTEX DEPRIVED OF AFFERENT INNERVATION. L.Paysan¹, A.Kossl², R.Thanos², J.M.Fritschy¹, H.Mohler¹ and J.Bolz^{2*}, ¹Institut für Pharmakologie der Universität Zürich, Switzerland; ²Friedrich-Miescher Labor der Max-Planck Gesellschaft, Tübingen, Germany.

The mechanisms underlying the specification of functionally and architectonically distinct cortical areas during development are not known. Using an antisense specific for the $\alpha 1$ -subunit of the GABA_A-receptor, we found that immunohistochemical staining for this antigen delineates the primary visual (V1) and somatosensory (Sm1) cortex during early postnatal development. Already at the day of birth (P0), staining for the $\alpha 1$ -subunit revealed a band restricted to the lower cortical plate and immature layer 4 in V1 and Sm1. This pattern was very prominent at P2 and clearly demarcated these areas from adjacent cortical regions during the first postnatal week. Later in development, staining was gradually detected in all neocortical layers and areas. Since at birth thalamic fibers have not yet reached layer 4, these observations suggest that the boundaries of Sm1 and V1 are already defined at this early age outside the zone of thalamic afferents. To further analyze whether this area-specific distribution of the $\alpha 1$ -subunit is regulated by intrinsic cortical mechanisms or by the ingrowth of thalamic axons, the emergence of this pattern was examined *in vivo* after lesions of the thalamus performed at P0, and *in vitro* using slice cultures prepared from rats between embryonic days 18-20. The results of both types of experiments indicated that the regional specificity of $\alpha 1$ -subunit staining in neocortex was preserved in the absence of afferent innervation. Thus, our results suggest that cortical parcellation is induced prenatally, and that factors intrinsic to the maturing cortex are involved in the specification of cortical areas.

RETENTION OF VIBRISSEAE-RELATED PRIMARY AFFERENT PATTERNS AFTER NEONATAL ION TRANSECTION IN THE RAT. F.A. White^{*}, C.A. Bennett-Clarke, N.L. Chiaia, R.S. Crissman and R.W. Rhoades. Dept. of Anatomy, Medical College of Ohio, Toledo, OH 43699

Immunocytochemistry for galanin (GAL) and anterograde labelling with Di-I were used to evaluate trigeminal (V) brainstem organization in rats that sustained perinatal damage to either the infraorbital nerve (ION) or individual vibrissae follicles. After nerve damage on the day of birth (P-0), dense GAL-immunoreactivity appeared throughout the V brainstem complex and had a patchy distribution similar to that of vibrissae-related V primary afferents in normal rats. Damage to a row of vibrissae follicles or a single follicle at birth produced a single row or patch of GAL-immunoreactive terminals in the ipsilateral V brainstem complex. This immunoreactivity was apparent by P-3 and disappeared at some time after P-14. Upregulation of GAL immunoreactivity occurred in rats that sustained ION damage as late as P-21. Experiments in which nerve damage was followed by destruction of the V ganglion demonstrated that the GAL-immunoreactivity was in primary afferent axons. The combination of immunocytochemistry and electron microscopy showed further that many myelinated primary afferent fibers in the nerve-damaged animals were GAL-immunoreactive. Placement of Di-I in the V ganglion of neonatally nerve damaged rats demonstrated that labelled primary afferent axons filled central ION territory and that their terminal distribution, while less dense than normal, was patchy. These results indicate that the V ganglion cells that survive neonatal peripheral axotomy retain somatotopically organized projections to the V brainstem complex for at least a limited postnatal period. Supported by NS 28888, DE 07734, and DE 08971

REORGANIZATION OF PRIMARY AFFERENT PROJECTIONS TO THE GRACILE NUCLEUS AFTER FETAL HINDLIMB REMOVAL IN RAT. H.P. Killackey^{*}, N.L. Chiaia, B.F. Hoeflinger and R.W. Rhoades. Dept. of Anatomy, Medical College of Ohio, Toledo, OH 43699 and Dept. of Psychobiology, University of California, Irvine, CA 92717

Previous experiments from our laboratories have shown that sciatic nerve afferents invade the cuneate nucleus when the forelimb is removed prior to birth. Since hindlimb-related primary afferents are among the last to arrive in the dorsal column nuclei, we asked, in the present experiment, whether earlier arriving axons from the forelimb exhibited the same plasticity. The central projections of the axons comprising the brachial plexus were traced in normal adult rats and in animals that sustained removal of the hindlimb on embryonic day 16 using a combination of WGA-HRP, cholera toxin-conjugated HRP, and free HRP. Tracing in normal rats revealed no brachial plexus afferents in the gracile nucleus. Labelled axons were present throughout the cuneate and external cuneate nuclei, and a number of labelled fibers were also visible in the lateral portion of the trigeminal brainstem complex primarily in subnucleus interpolaris. In adult rats that sustained fetal hindlimb removal, labelled brachial plexus axons were present in all of the above-described targets and they could also be seen in the gracile nucleus. The latter labelling consisted of small bundles of axons and isolated fibers whose terminations were mainly restricted to the peripheral portions of the nucleus. This labelling was visible in each (N=8) of the experimental animals. The present results thus demonstrate that forelimb- as well as hindlimb-related primary afferents can alter their central projections as a result of prenatal primary afferent lesions.

THY-1 IMMUNOREACTIVITY DISTINGUISHES PATCHES FROM MATRIX IN THE EARLY POSTNATAL STRIATUM OF RAT.

C.W. Shults^{*}, VA Med. Ctr. and Dept. of Neurosci., Univ. of Cal., San Diego, San Diego CA 92161

The cell adhesion molecule Thy-1 emerges in specific regions of neurons at certain stages in development and appears to be involved in inhibition of neurite outgrowth and stabilization of synapses. Coronal sections from rat embryos and pups were immunolabelled for both Thy-1 and tyrosine hydroxylase (TH). At P0, patches of increased density of TH-immunoreactive (TH-IR) axons were noted in the striatum. At this age, we also noted patches of increased amounts of Thy-1-immunoreactive (Thy-1-IR) material, which coincided with the patches of dense dopaminergic axons. Patches of increased density of Thy-1-IR material were noted on P2 and P3, but by P5 the distribution of Thy-1-IR material was homogeneous throughout the developing striatum. Patches of dense dopaminergic axons were still noted at P9. The most parsimonious explanation for our finding is that after neurons destined to be incorporated in the patch compartment complete their initial extension of axons to the midbrain, during the late prenatal period, production of Thy-1 and deposition in the developing dendrites is increased. During this period, the neurons in the later developing matrix, which only begin to extend axons to the SN during the early postnatal period, have relatively less Thy-1-IR material. As neurons in the matrix compartment complete the initial elongation of axons to the SN, they begin to accumulate Thy-1, and the patch and matrix compartments are no longer distinctive because of differing amounts of Thy-1 on neurons in each compartment. Thy-1 may serve as a signal to suppress further outgrowth from dopaminergic neurites and stabilize developing synapses with the striatal neurons.

The Development of Striatal Compartments by 5-Bromo-deoxyUridine Immunocytochemistry. D. D. SONG* AND R. E. HARLAN. Department of Anatomy and Neuroscience Training Program, Tulane University School of Medicine, New Orleans, LA, 70112.

To study birthdates and migration patterns of striatal patch and matrix cells, 5-Bromo-deoxyUridine (BrdU) was injected into pregnant rats at embryonic days 14 (E14) or E19, respectively. Immunocytochemistry for BrdU was performed on coronal cryostat sections through the forebrain at 2hrs post-injection and E16, E19, and postnatal day 0 (P0). At E14 2hrs post-injection, strongly labelled cells could be identified throughout the striatal neuroepithelium, in both ventricular (VZ) and subventricular zones (SVZ). By E16, strongly BrdU labelled cells were only found in more differentiated portions of the neostriatal anlage. Only weakly labelled cells were found in the VZ and SVZ, indicating dilution of BrdU in mitotically active cells. By E19, cells labelled at E14 were distinctly congregated along the ventrolateral border of the CPU. Other E19 embryos injected 2hrs previously with BrdU, had strongly labelled cells throughout the VZ and SVZ of the CPU and nucleus accumbens (Acb). Very few labelled cells were present in the more differentiated CPU. By P0, a dense narrow ventrolateral accumulation of E14-labelled BrdU cells was present along the external capsule. Some labelled cells were dispersed medially in the CPU with clumps or patches of labelled cells being found in the middle of the CPU just caudal to and at the level of the posterior limb of the anterior commissure. Double labelling for the patch marker Substance P (SP) resulted in correspondence of SP and E14-BrdU patches and subcallosal streak. Despite the presence of SP patches, progressively fewer E14-labelled BrdU cells were found at more rostral levels. In contrast, E19-labelled BrdU cells at P0 were quite numerous rostrally, spreading out ventrolaterally into the CPU and Acb. Thus, early developing patch neurons appear to be initially aggregated in the ventrolateral CPU and are dispersed dorsomedially into patches as later matrix neurons migrate around them ventrolaterally. Neurons remaining in the ventrolateral CPU spread out along the external capsule to form the subcallosal streak of the patch compartment. Supported by DA05523 (DDS) and NS24148 (REH).

A THREE-DIMENSIONAL RECONSTRUCTION OF THE HUMAN HYPOTHALAMUS J.K. Young and G.B. Stanton, Dept. Anatomy, Howard Univ. Washington, D.C. 20059.

Our previous 3-dimensional reconstruction (3-DR) of the rat hypothalamus (Young and Stanton, Brain Res. Bull. 26:279, 1991) revealed an organization of nuclei into 3 major clusters. This clustering may relate to the presence of 3 hypothalamic anlagen in the embryo and to a restriction of marker proteins to specific regions of the hypothalamus during development (Stainier, et al., Dev. Biol. 147:22, 1991; Mathis, et al., Embo. J. 11:2551, 1992). To see if a similar clustering was present in the human hypothalamus, and to examine volumetric homologies of human nuclei with those of the rat, a 3-DR of the hypothalamus from a male cadaver was prepared. Hypothalamic nuclei from serial, Nissl-stained, frozen sections were projected onto paper, traced and digitized with a graphics tablet.

The 3-DR showed a clustering of human hypothalamic nuclei into 3 anterior-posterior groups. With reference to the well-defined rat and human supraoptic nuclei, the suprachiasmatic, supramammillary and lateral mammillary nuclei were proportionately 10-fold smaller in the human than in the rat. Human and rat anterior nuclei were proportionately equal in size; middle hypothalamic nuclei were proportionately 4-5 fold larger in the rat, and medial- and tubero-mammillary nuclei of the posterior cluster were proportionately larger in the human.

EARLY HISTOGENESIS OF THE CENTRAL MOTOR COMPONENTS OF THE FACIAL NERVE IN THE RAT EMBRYO. F. AUCLAIR, N. VALDES, R. MARCHAND*. Centre de recherche en Neurobiologie, Univ. Laval (Hôpital de l'Enfant-Jésus), Québec, Canada, G1J 1Z4.

The primary goal of this study was to describe the early histogenesis of the motor components of the facial nerve within the hindbrain. Specific labeling of one or the other motor component of the nerve could be achieved by precise dye deposition at peripheral sites. The injections included the main branchiomeric trunk of the facial nerve, the chorda tympani or the greater petrosal nerve. Dil crystals were used on fixed embryos of 13, 14 and 15 gestational days of age (E13, E14, E15). On E13, branchiomeric motoneurons were distributed in a longitudinal column lying close to the midline. They migrated first caudally and then ventrolaterally on E14 and E15. Most of them had reached their "adult" ventrolateral position in the tegmentum by E15. At the same stages of development, visceral motoneurons could also be labeled. On E13, they extended laterally from the medial branchiomeric group to the region of the sulcus limitans, and longitudinally, from a region slightly more caudal than the level of exit of the motor nerve to the level of the caudal end of the medial branchiomeric group. On E14, they continued to slide more laterally and on E15, most of them were lying in the prospective parvocellular reticular formation. Another group of laterally situated visceral motoneurons appeared more rostrally, extending from the level of the exit point of the motor nerve to a level slightly more rostral. It contained less neurons than the first visceral group. Branchiomeric and visceral central components of the facial nerve could further be distinguished by the course of their axons. Branchiomeric axons coursed first rostrally and then turned laterally to exit the hindbrain. Visceral axons coursed first laterally and then turned rostrally to exit the hindbrain. These results describe the evolution in time of the relative position of the branchiomeric and visceral motor components of the facial nerve in a mammalian embryo and suggest that both types of motoneurons are generated in a region close to the midline. Supported by MRC of Canada and FRSQ.

DEVELOPMENTAL PLASTICITY IN THE HABENULO-INTERPEDUNCULAR SYSTEM CORRELATES WITH HETEROGENEOUS EXPRESSION OF GAP-43, TENASCIN, HNK-1 AND CHONDROITIN SULFATE PROTEOGLYCAN

Carol A. Murphy and Marion Murray*. Dept. of Anatomy and Neurobiology, Medical College of PA, 3200 Henry Ave., Philadelphia, PA 19129

The medial habenular nuclei (MH) project to discrete subnuclei of the interpeduncular nucleus (IPN) via the fasciculus retroflexus (FR). Substance P (SP) neurons in the dorsal MH innervate the lateral subnuclei of the IPN, while cholinergic cells in the ventral MH project to the central and intermediate subnuclei. SP innervation of the IPN is present at birth and retains plasticity in the adult, whereas cholinergic innervation is not seen until the second postnatal week, and does not show plasticity after this age. The developmental expression of two extracellular matrix molecules, tenascin and chondroitin sulfate proteoglycan (CSPG), of GAP-43, a molecule associated with axonal growth cones, and of HNK-1, an epitope common to a number of cell adhesion and matrix molecules, were evaluated in the habenulo-IPN system of neonatal and adult rats. At P0, CSPG-IR clearly delimited the subnuclei of the IPN, consistent with CSPG's putative role in the formation of boundaries. At P7, CSPG and HNK-1 were expressed almost exclusively in the central subnucleus, coinciding with the onset of the period of cholinergic innervation. In contrast, tenascin was uniformly present in the IPN at P7 and P14, but confined to the SP target subnuclei in adults. GAP-43 was selectively expressed in the lateral subnuclei at P0 and in adults. Within the MH, HNK-1 was present in cells in the ventral region while GAP-43 was selectively expressed by cells in the dorsal region. The differential expression of tenascin and CSPG in the IPN suggests glial heterogeneity among adjacent subnuclei. The non-overlapping patterns of HNK-1 and GAP-43 expression in both MH and IPN suggest differences in molecular expression by cholinergic and SP neurons, respectively. We conclude that these developmental changes in the molecular expression contribute to the differential plasticity of the two systems.

EXPRESSION PATTERN AND DEVELOPMENTAL CONTROL OF TOPAP: A GRADIENT MOLECULE IN THE CHICK RETINOTECTAL SYSTEM.

J.M. Savitt, D. Trisler*, C. Cargile and D.C. Hilt. Depts. of Biochemistry, Human Genetics and Neurology, Univ. of Maryland Sch. of Med., Baltimore, MD 21201. Laboratory of Biochemical Genetics, NHLBI, NIH, Bethesda, MD 20892.

TOPAP is a 40 kD protein expressed in a position-specific, continuously graded, fashion in the chick retina and tectum. Antibody binding studies and immunocytochemical staining have shown that TOPAP is preferentially expressed in the more posterior region of the retina and in the more anterior region of the optic tectum. This pattern of expression mirrors that of the retinotectal projections themselves, thus it is possible that TOPAP plays a role in the generation of position-specific neuronal connections. In an attempt to learn more about the structure, function and expression of this protein, a cDNA clone encoding TOPAP was isolated from a posterior quadrant chick retina library. Analysis of the 3.2kb cloned sequence demonstrated a near full length cDNA with an open reading frame coding for 359 amino acids. The translated sequence showed limited similarity to known protein-coding regions found in the SWISS-PROT database. Nucleic acid probes as well as polyclonal antibodies have been generated and used to demonstrate the expression pattern of the TOPAP protein and mRNA on positional, temporal, tissue-specific and subcellular levels. Initial studies have shown that the graded expression of TOPAP is present at the mRNA level and that the protein and mRNA are up-regulated late in embryonic development. The mRNA and protein are differentially expressed in various tissues with the highest expression seen in heart and retina. Finally, biochemical characterization of native and cloned protein, coupled with immunocytochemical staining of primary retinal cells and transfected cells have implied a complex subcellular localization pattern including the presence of TOPAP in membranes.

EFFECTS OF NEONATAL ION DAMAGE UPON THE DISTRIBUTION OF GALANIN RECEPTORS IN THE RAT'S TRIGEMINAL BRAINSTEM COMPLEX. M.J. Leslie*, C.A. Bennett-Clarke and N.L. Chiaia. Dept. of Anatomy, Medical College of Ohio, Toledo, OH 43699

We have recently demonstrated a marked and transient up-regulation of galanin (GAL)-immunoreactive axons in trigeminal (V) nucleus principalis (PrV) and all of the V spinal subnuclei after perinatal damage to the infraorbital nerve (ION). In this study, radioligand binding with [¹²⁵I]-GAL was used to determine how this marked up-regulation in GAL immunoreactivity affected the distribution of receptors for this peptide. Receptor binding experiments were carried out in normal rats and in animals that sustained ION damage during the first week of life. In normal adult and perinatal rats, GAL receptors in PrV, subnucleus interpolaris, and the magnocellular portion of subnucleus caudalis form a pattern which is the negative image of vibrissae-related primary afferent terminations. In rats killed 7 days after neonatal ION transection (an age at which there is a clear up-regulation in damaged V primary afferents), there is a dramatic reduction in the density of GAL receptors ipsilateral to the lesion. The decrease occurs in all V subnuclei. In rats killed at longer (> 60 day) intervals after neonatal ION damage when the up-regulation of GAL immunoreactivity is no longer present, the density of GAL receptors in the V brainstem complex ipsilateral to the lesion is much closer to normal, but the vibrissae-related pattern can no longer be discerned. These results thus indicate that the dramatic and transient lesion-induced increase in GAL immunoreactivity in the V brainstem complex is associated with a marked and equally transient down-regulation of receptors for this peptide. PATTERNS OF *GOTCH* mRNA EXPRESSION IN DEVELOPING GOLDFISH. S.A. Sullivan, B.L. Largent & P.A. Raymond*. Department of Anatomy & Cell Biology, University of Michigan, Ann Arbor, MI 48109-0616.

Using digoxigenin-labeled RNA probes derived from *Gotch*, a goldfish *Notch* homologue cloned previously, we have characterized *Gotch* mRNA expression patterns in the developing goldfish via whole embryo *in situ* hybridization. Some embryos were subsequently frozen and cryosectioned. Robust expression of *Gotch* message was seen as early as the embryonic shield stage [st. 15, Kajishima *Jap. J. Ichthyol.* 1960] in the presumptive neural keel and associated structures. Expression remained primarily specific to the CNS through hatching [st. 25], at which time hybridization signals decreased markedly. At all stages *Gotch* expression was localized to regions of cell proliferation and differentiation (e.g. periventricular layer in the brain and spinal cord, peripheral germinal zone in the retina), in accord with its postulated role as an enabler of cell fate decisions in *Drosophila*.

DISTRIBUTION OF NICOTINIC ACETYLCHOLINE RECEPTOR ALPHA3 SUBUNIT mRNA IN DEVELOPING RAT BRAIN. T.A. Austin* and J.L. Fuchs. Dept. of Biological Sciences, University of North Texas, Denton TX 76203.

The regional distribution of nAChR alpha3 subunit mRNA was examined in rat brains from embryonic day 16 through adult. Cryostat sections were hybridized with [³⁵S]mRNA, and film autoradiographs were prepared. Most brain regions that express high levels of alpha3 mRNA in adults were also prominently labeled in prenatal or early postnatal development. These brain regions typically showed a peak of intense labeling during postnatal weeks 1 or 2, with a subsequent decline to adulthood. The time of peak labeling varied across brain regions. Labeling in the habenula and retina was strong as early as E16. Regions that were prominently labeled in adult and also in perinatal brains included the pineal, certain thalamic nuclei, substantia nigra pars compacta, and patches in the caudate-putamen.

In neocortex, dense labeling distinguished layer IV beginning in area 17 on postnatal day 2 (P2). Labeling in layer IV reached a peak around P14 before declining, but remained prominent in layer IV of all areas of adult neocortex, especially visual cortex.

The hippocampal formation was somewhat unusual in being well labeled only in immature brains. Levels in str. pyramidale of CA3-CA4 were moderate in neonates, highest around P4, and then declined in subsequent weeks. Labeling in the dentate str. granulare was moderately low beginning on P4 and peaked around P6-14 before declining to low levels in adults.

These results suggest that neurons that express high levels of alpha3 nAChR mRNA generally acquire this identity early in ontogeny. Transiently high levels of receptor mRNA in immature brain regions might serve to stabilize or increase the effectiveness of developing synapses.

Supported by NIMH MH41865. We thank J. Patrick for the cDNA.

CONSTRUCTION OF RETROVIRAL COEXPRESSION VECTORS TO INVESTIGATE MOLECULAR MECHANISMS OF CNS DEVELOPMENT. E.A. Grove¹*, H. Moreau², V. Calaora², G. Rougon² and J. Price¹. ¹N.I.M.R., London, U.K., and ²Universite d'Aix-Marseille, France.

Investigation of the molecular mechanisms of CNS development is hampered by the limited means of altering the expression of specific genes in the mammalian embryo. We have constructed several retroviral coexpression vectors that will allow us to alter the expression of selected neurotrophins and cell surface molecules in embryonic cells, and to mark the cells so that their fate can be followed. These vectors, based on murine MuLV vectors provided by J. Majors (Washington University School of Medicine, St. Louis), carry the gene of interest (or an antisense or mutated form), followed by the picornavirus internal ribosome entry site (IRES), followed in turn by the marker gene *lacZ*. Expression of both genes is thus driven by the endogenous retroviral promoter in the LTR. We have found that a high proportion of COS-7 or C6 cells transfected with constructs of this form express both genes. A construct containing the gene for alkaline phosphatase in the first position will allow us to quantify coexpression. We are testing the levels of gene expression in infected cells by functional assays *in vitro*. Effects of altered gene function on normal cerebral and cerebellar cortical development will be determined by following the fate of cells marked by infecting germinal layer cells in the rat CNS.

457.2

ONTOGENY OF CORTICOTROPIN RELEASING HORMONE GENE EXPRESSION IN THE RAT INFERIOR OLIVE. D. Chang, M.C. Citron and T.Z. Baram. Dept. Neurology Univ. Southern Calif.; Div. Neurology, Childrens Hosp. Los Angeles, Los Angeles, CA 90027.

Corticotropin releasing hormone (CRH) has been shown to be a neurotransmitter in the inferior olive (IO) of both the rat and the human. CRH excites neurons in a variety of neuronal circuits. We have demonstrated age-specific potency and rapidity of the convulsant effects of CRH in the neonatal/infant rat.

We analyzed IO of 25 rats by semi-quantitative *in situ* hybridization histochemistry using an S³⁵-labelled deoxy-oligonucleotide probe directed against CRH-messenger RNA. We determined the onset and anatomic distribution of CRH-mRNA in rats aged 1,2,3,5,7,10, 14 and 18 days in comparison with adults. CRH-mRNA was first detectable on postnatal day 2, most prominently in the principal and medial accessory subnuclei. CRH-mRNA abundance in IO increased with age, in contradistinction with the ontogenic course of CRH gene expression in the paraventricular nucleus. We conclude that the CRH neurons in IO may be functional during the first postnatal days.

A NOVEL RECEPTOR-TYPE PROTEIN TYROSINE PHOSPHATASE EXPRESSED DURING NEUROGENESIS OF OLFACTORY NEURONS. B.L. Largent*, K.J. Martell, J.E. Dixon and K.M. Walton. Biol. Chem. and Anat. & Cell Biol., Univ. of Michigan, Ann Arbor MI 48109-0616.

Tyrosine phosphorylation is a principal mechanism for regulating biological processes. Protein-tyrosine phosphatases (PTPs) have emerged as an important component in the regulation of tyrosine phosphorylation. We postulated that the olfactory system, with its capacity of neural regeneration, might express specific PTPs serving a regulatory role in regenerative processes such as neural proliferation or axon extension. To identify both known and novel PTPs expressed in olfactory epithelium, we amplified putative PTP sequences by PCR using degenerate oligomers which hybridize to highly conserved sequences in PTPs. The amplified products were cloned and analyzed by DNA sequencing. Fourteen unique clones were identified: 8 clones were previously reported PTPs (or the rat homolog); and 6 clones represented novel PTPs. The RNA expression pattern of these novel clones was predominantly neural. For one clone, PTP NE3, we have determined the full length cDNA sequence which predicts a transmembrane protein with extracellular domains of Ig and FN III-like repeats and two cytoplasmic phosphatase domains. PTP NE3 appears neural specific with highest expression in the olfactory epithelium and the brain hippocampal formation. *In situ* hybridization demonstrates PTP NE3 expression by neural precursors and sensory neurons of the olfactory epithelium. The predicted transmembrane structure with extracellular adhesion motifs suggests a role in axon extension and/or neural soma migration.

A DEVELOPMENTALLY REGULATED NGF-INDUCED GENE, VGF, IS REGULATED BY ELECTRICAL ACTIVITY IN THE RAT VISUAL SYSTEM. A. Lombardo, F. Cremisi, S. Rabacchi, T. Pizzorusso, M.C. Cenni, G. Barsacchi, L. Maffei, R. Possenti*. Scuola Normale Superiore, Pisa; Universita' di Pisa, Sez. Biologia Cellulare e Sviluppo, Pisa; Istituto di Neurofisiologia CNR, Pisa; Istituto di Neurobiologia CNR, Roma; ITALY.

In the pre-natal and post-natal rat brain we studied the expression of VGF, a gene previously found to be induced by NGF and whose protein is released following depolarization in PC12 cells. RNase protection, *in situ* hybridization and immunohistochemical techniques have been performed. Both the mRNA and the protein are particularly abundant in the developing thalamic nuclei that project to primary sensory cortical areas, appearing respectively at embryonal day 16 and 18. Strong immunoreactivity (but no hybridization signal) has also been found at the cortical subplate, presumably reflecting the presence of the protein in axonal terminals of thalamic neurons. The peak distribution of VGF mRNA in the dorsal geniculate nucleus is reached during the second postnatal week, followed by a gradual decline of expression.

Interestingly, the blockade of afferent electrical activity by intraocular injection of tetrodotoxin strongly reduces the level of VGF mRNA in the dorsal geniculate nucleus. The temporal correlation between the arrival of retinal fibers and the first expression of VGF suggests that retinal afferents switch on this gene either by afferent electrical activity or by anterograde factors. VGF spatio-temporal expression and regulation by electrical activity point to a role of this protein in the process of synaptogenesis and/or synaptic stabilization in the developing geniculocortical connections and introduces the possibility that this factor is involved in the communication processes between pre- and post-synaptic partners.

IDENTIFICATION OF NUCLEAR PROTEINS THAT ARE DEVELOPMENTALLY REGULATED IN EMBRYONIC RAT BRAIN. E.R. Thormodsson[§], L. Redmond and S. Hockfield. Section of Neurobiology, Yale University Sch. of Med., New Haven, CT 06510 and §Dept. of Anatomy, University of Iceland, Med. Sch., 101 Reykjavik, Iceland.

To identify nuclear proteins that might play a role in the acquisition of neuronal phenotype, 2D-PAGE was used to analyze proteins differentially expressed over the course of embryonic rat brain development. Metabolically labeled rat brain nuclear proteins from embryonic day 14 (E14) were compared to proteins from embryonic day 19-20 (E19-20). Over this period, the rat brain develops from a collection of relatively homogeneous precursor cells into a complex structure containing many different classes of neurons.

Analysis of 2D-PAGE fluorograms, using a computerized gel scanner, permitted the identification of 11 proteins that show increases in their rate of synthesis between E14 and E19-20. Twenty proteins that consistently appear at E19-20 are not detectable on fluorograms of E14 nuclear proteins, even after long exposures, and thus may be considered to appear *de novo*. Fifty-eight proteins show consistent down-regulation between E14 and E19-20, and of these, 19 were not detectable on fluorograms of E19-20 nuclear proteins. The electrophoretic properties of many of these proteins suggest that they are previously unreported, developmentally-regulated nuclear proteins. Comparisons of gels of brain nuclear protein to gels of liver nuclear proteins indicate that several of these proteins may be enriched in brain relative to non-neural tissues. Some of the developmentally regulated, brain enriched nuclear proteins identified here may play a role in regulating the expression of neural genes important for cellular differentiation in the mammalian CNS. [Supported by NS22807.]

A TYROSINE PHOSPHATASE EXPRESSED IN DEVELOPING AND ADULT RAT BRAIN. L.M. Boulanger^{*1}, G. Apicelli¹, P. Kim¹, G. Matthews¹, P.J. Lombroso², and J.R. Naegele^{1,2}.

¹Department of Biology, Wesleyan University,

Middletown, CT 06459, and ²Child Study Center, Yale University School of Medicine, New Haven, CT 06473.

Protein phosphorylation is one of the key mechanisms underlying neuronal growth, proliferation, and function. We have investigated the patterns of protein and mRNA expression of a tyrosine phosphatase designated STEP (Lombroso et al, 1993) in developing and adult rat brain. Monoclonal antibodies against an 18 amino acid sequence from the non-phosphatase domain recognized several forms of STEP on Western blots, including a cytosolic triplet of 46, 37, and 33 kDa and a membrane band of about 65 kDa. The membrane band appeared by birth, preceding the cytosolic bands, and both forms were present at adult-like levels by postnatal day 15 (PND 15). In striatum, STEP immunoreactivity shifted from small clusters of cells and neuropil to a continuous pattern between PND 0 and PND 15. STEP protein and/or mRNA was also detected in the retina, olfactory bulb, septum, hippocampus, choroid plexus, cerebellum, brainstem, and cerebral cortex, including the cortical subplate. Comparison of tyrosine hydroxylase, DARPP, and STEP immunoreactivity demonstrated that most of these cells are also dopaminergic, suggesting STEP is localized to a functionally distinct neuronal subset.

CORTEXIN mRNA EXPRESSION IN FETAL AND POSTNATAL RODENT BRAIN. P.M. Coulter II, C.F. Landry, J.E. Margulies, A.T. Campagnoni^{*}, and J.B. Watson. Mental Retardation Research Center, Department of Psychiatry and Biobehavioral Sciences, UCLA School of Medicine, Los Angeles, CA 90024.

Cortexin is a novel, brain-specific protein of 82 residues that was first identified as a cDNA clone of cortex-enriched mRNA in rat brain by subtractive hybridization (Watson et al, 1992, Brain Dysfunct. 5:94-105; P.M. Coulter II et al, 1993, J. Neurochem., in press). The amino acid sequence of rat cortexin and its mouse homologue are nearly identical (98% similarity) and both contain a putative single-membrane-spanning region in the middle of each sequence. Northern blot analysis shows that cortexin mRNA is brain-specific, cortex-enriched, and present at significant levels in fetal rodent brain with peak expression occurring in postnatal brain. *In situ* hybridization with ³⁵S-labeled probes detects cortexin mRNA mostly in pyramidal neurons of neocortex laminae II and VI, CA1, CA3, CA4 of hippocampus, and piriform cortex, and in granule cells of dentate gyrus of adult brain. There is little or no expression in midbrain, hindbrain, or white matter regions. Digoxigenin-labeled probes visualized cortexin mRNA in cortical neurons of E14-E18 fetal mouse brain. We postulate that cortexin may play a unique signalling role for neurons in both the developing and adult cerebral cortex. Supported by NIH grant HD 25831(A.T.C., J.B.W.).

457.8

STRUCTURE, EXPRESSION, AND FUNCTION OF A NOVEL RECEPTOR PROTEIN-TYROSINE KINASE, TYRO-3. Martin J. Gore^{1,2}, Cary Lai³, Paul Shilling², and Greg Lemke^{*1}. ¹Molecular Neurobiology Laboratory, The Salk Institute, ²UCSD Department of Neurosciences, and ³Department of Neuropharmacology, The Scripps Research Institute, La Jolla, CA 92037.

We have previously described the isolation and characterization of cDNA clones encoding a series of novel protein-tyrosine kinases (PTKs) including the neural Tyro-3 [Neuron 6 691-704]. The deduced amino acid sequence of Tyro-3 suggests a transmembrane receptor PTK with an extracellular region similar to neural adhesion molecules such as N-CAM, L1, TAG-1, and fasciclin II. We have now studied Tyro-3 expression in the embryonic and adult CNS. We have also generated fibroblast cell lines that stably express this neural receptor, in order to (a) assess its functional properties, and (b) identify its ligand. We have in addition isolated Tyro-3 genomic clones, which are currently being adapted for use in elucidating the developmental role of Tyro-3 *in vivo*.

457.10

MOLECULAR CHARACTERIZATION OF A DEVELOPMENTALLY REGULATED PROTEIN FROM THE EMBRYONIC RAT CORTEX.

J.E. Minturn^{*}, H.J.L. Fryer, and S.Hockfield. Section of Neurobiology, Yale Univ. School of Medicine, New Haven, CT 06510

Using 2-dimensional PAGE we previously identified a 64 kD protein (protein 310) that is abundant in the embryonic rat cerebral cortex and is down regulated postnatally (J.Neurosci.9:4304). Microsequencing of gel-purified protein identified 5 peptides that show no significant homology to previously characterized proteins. Polyclonal antisera raised to 2 synthetic peptide fragments demonstrate that protein 310 is expressed by early post-mitotic neurons and is down-regulated during the second post-natal week.

Degenerate oligonucleotide primers to these two peptide sequences were used to amplify cDNA from post-natal day 5 rat neocortex. PCR products were subcloned and sequenced. The predicted amino acid sequence of one of the products contains protein 310 peptide sequence that extends into the clone beyond the primer region. Developmental northern analysis demonstrates a 4.8 kb mRNA species in rat cortex that is down regulated in the second post-natal week, and is absent from both liver and kidney. *In situ* hybridization at embryonic day 16 reveals that the mRNA is present throughout the developing brain and spinal cord as well as in the dorsal root ganglia. The message is especially abundant in the developing cortical plate and is far less abundant in the ventricular and intermediate zones, consistent with expression by post-mitotic neurons.

BESTFIT analysis of the translated clone reveals modest homology (20% identity, 44% similarity) to the C. elegans protein unc-33 which has been suggested to be important in axonal outgrowth and guidance in the developing nematode. Further sequence information may provide additional indications of the function of protein 310. (Supported by NS22807 and the Howard Hughes Medical Institute).

457.12

ONTOGENY AND EFFECT OF ACTIVITY ON PREPROTACHYKININ mRNA AND SUBSTANCE P IN THE CHICK: EXPRESSION IN NOTOCHORD, FLOOR PLATE AND SPINAL CORD NEURONS. L.K. Garner^{*}, B.M. Mendelson², K.L. Cox, and B.M. Davis. Dept. of Anatomy and Neurobiology, Univ. of Kentucky Med. Cntr., Lexington KY 40536; Dept. of Anatomy², Univ. of Arkansas Med. Sch., Little Rock, AR 72205.

Activity is included in a list of possible epigenetic factors that alter gene expression during development. For these studies, ontogeny of preprotachykinin (PPT) mRNA was determined in chick spinal cord during normal development and in embryos treated with d-tubocurarine during embryonic days 5-13. A chick specific PPT cRNA probe was used, for *in situ* hybridization along with immunocytochemistry for the substance P (SP) peptide. Both PPT mRNA and the SP-like immunoreactivity (SPLI) can be detected in the developing embryo as early as stage 23 (E4) in the notochord and presumptive dorsal and ventral horns. At stage 28 (E6) PPT mRNA is expressed in developing ventral floor plate and PPT mRNA and SPLI are found in cells in the dorsal and ventral horns of the spinal cord. By stage 37, cells in the ventral floor plate no longer express PPT mRNA, however, motoneurons in the ventral horn and cells in the dorsal horn are positive for PPT mRNA and SPLI. At stage 39 (E14), the adult pattern is seen for the PPT mRNA localized in the dorsal horn, intermediate lamina and ventral horn motoneurons. Following blockade of activity using dTc, a downregulation of the mRNA was seen in areas of the dorsal horn and intermediate lamina. Ventral horn motoneurons appear to be unaffected. Supported by AA-09205 to BMM.

457.13

LOCALIZATION OF HUMAN D₃ RECEPTOR mRNA IN MIDGESTATIONAL HUMAN FETAL CORTEX BY *IN SITU* HYBRIDIZATION. A.S. Unis* and D.M. Dorsa. Dept. of Psychiatry and Behavioral Sciences, Univ. of Washington, Seattle, WA 98195.

Although [³H]-YM09151-2 specific binding is distributed in a stratified fashion in the cortical plate and subplate regions of midgestational human forebrain (Unis, 1993), it does not discriminate D₂-like receptor subtypes. In order to determine whether some component of this D₂-like radioligand binding might be due to D₃ receptors expressed in human fetal cortex at the twentieth gestational week, we performed *in situ* hybridization using ³⁵S-labeled cRNA probe transcribed from the human D₃ receptor cDNA (Sokolov et al., 1992).

³⁵S-labeled D₃ riboprobe hybridized in a discrete distribution corresponding to the cortical plate and the ventricular zone in sections obtained from the parietal-occipital cortex. Hybridization signal was likewise detected in human caudate control sections. These data suggest that a component of [³H]-YM09151-2 specific binding, which is localized to the subplate zone at this gestational age, may be to the D₃ receptor. The distribution of hybridization signal suggests that these sites are produced by cells in the cortical plate and the ventricular zone. Further characterization of these D₃ mRNA-expressing cells is in progress using emulsion-dipped sections, counter-stained for histological identification.

EMERGENCE OF 13 GABA_A RECEPTOR SUBUNIT AND GAD TRANSCRIPTS IN EMBRYONIC RAT SPINAL CORD. R. Somogyi*, W. Ma, V. Smallwood and J.L. Barker. Laboratory of Neurophysiology, NIH, Bethesda, MD 20892

Inter-cellular communication by chemical messengers plays a critical role in the concerted differentiation of phenotypes during development. A simple chemical messenger, γ -aminobutyric acid (GABA), and its synthesizing enzyme, glutamic acid decarboxylase (GAD), have been found in the spinal cord at embryonic day 13 (E13) and persisted into adulthood. To elucidate the role of GABA during cord development, we determined when and where the receptors for this amino acid are expressed. We analyzed the expression of mRNA for 13 subunits (α 1-6, β 1-3, γ 1-3, δ) of the GABA_A receptor. Using the most sensitive method for the detection of mRNA, PCR (polymerase chain reaction), we clearly identified transcripts for the α 1, α 2, α 3, α 5, β 3 and γ 3 subunits at E12, while α 4, β 1 and δ subunits were just above the limit of detectability. At E13, the γ 2 subunit appeared, followed by the emergence of the β 2 and γ 1 subunits at E17. From E12 to P0, the full complement of subunit transcripts emerged and steadily increased in signal intensity, except for the α 6 subunit, which could never be detected in spinal cord, and the δ subunit, which fluctuated around the limit of sensitivity. From P0 to adult, a general decrease of expression intensities was found. Using *in situ* hybridization for the same GABA_A receptor subunits, we found that expression begins at E12-13 in motoneurons and continues to emerge along a ventral-dorsal gradient into other regions of neurogenesis to reach maximum abundance at P0. A region- and subunit-specific depletion of transcripts occurs during the transition from P0 to adult. Although PCR enabled us to identify several subunit transcripts before they were detectable by *in situ* hybridization, the results obtained using both methods were in general agreement.

VOLTAGE-GATED CA²⁺ CHANNELS AND DTBHQ-SENSITIVITY ARE UPREGULATED PRIOR TO THE ONSET OF SPONTANEOUS CA²⁺ SPIKING AND NEURITE OUTGROWTH. E. C. Olson* and X. Gu. Department of Biology, UCSD, La Jolla, CA 92093.

Calcium influx through voltage-gated calcium channels (VOCs) regulates aspects of differentiation including neurotransmitter expression and K⁺-channel modulation in *Xenopus* spinal neurons. Agents such as Ni²⁺, which block VOCs and alter differentiation, eliminate a specific class of spontaneous transient [Ca²⁺]_i elevations in these neurons, termed spikes. Furthermore DTBHQ, which depletes intracellular calcium stores, reduces the amplitude of elicited spikes and suppresses neurotransmitter expression. In this study the developmental appearance of spikes has been investigated with respect to the appearance of VOCs and DTBHQ-sensitivity.

The appearance of spikes was examined in neural plate cultures on laminin polylysine from 2-7 hr, this period encompasses neural tube formation *in vivo*. Spontaneous spike-like elevations of [Ca²⁺]_i-induced fluo-3 fluorescence are first observed at 4-5 hr in neurons with processes (mean incidence 7/hr; n=5). Depolarization with KCl increases fluorescence in all of these cells. Prior to process extension, most spontaneous elevations of [Ca²⁺]_i are substantially slower. The percentage of morphologically undifferentiated cells which respond to KCl depolarization increases from 3-7 hr in culture: 11% of cells (n=9) respond at 2-3 hr, 75% (n=4) by 6 hr. These observations imply that upregulation of functional VOCs occurs during this period, prior to neurite outgrowth. The KCl response is an effective predictor of cells that will morphologically differentiate as neurons. Sensitivity to DTBHQ precedes the response to KCl (n=6) in differentiating neurons, implying that changes in [Ca²⁺]_i homeostasis also occur in this period prior to neurite outgrowth. Supported by the NSF (ECO) and the NIH (XG, NCS).

DEVELOPMENTAL REGULATION OF NITRIC OXIDE SYNTHASE IN THE CHICK RETINA. R. Paes-de-Carvalho, J.L.M. do Nascimento and M.H. de Faria. Dep. Neurobiologia, Univ. Fed. Fluminense, Niterói, RJ, Brazil. NADPH-diaphorase histochemistry, reported to label Nitric oxide synthase (NOS) positive cells, reveals the presence of groups of neurons synthesizing the intercellular messenger Nitric oxide in the CNS. Here we show the presence of NOS and its regulation by Ca²⁺ in the developing chick retina. Homogenates from retinas at several developmental stages were incubated at 37°C in 50mM Tris Ph 8.1 containing 1mM β -NADPH and 0.5mM Nitro Blue Tetrazolium and the absorbance was measured at 585nm to detect NADPH-diaphorase activity. L-N^G-Nitro-Arginine (L-NARG) and L-N^G-Monomethyl-Arginine (NMMA), inhibitors of NOS, blocked 40 to 60% of NADPH-diaphorase activity at all ages studied. Ca²⁺ ions were able to stimulate enzyme activity by 30% and 60% in homogenates of E8 and E14 retinas, respectively. However, Ca²⁺ dependence could no longer be demonstrated in post-hatching retinas. Inhibition curves for L-NARG indicated the presence of two distinct NOS, one stimulated by Ca²⁺, present only in embryonic stages of development and inhibited by low concentrations of L-NARG and another independent on Ca²⁺ ions and inhibited by high concentrations of L-NARG. The results indicate the existence of different populations of NOS in the chick retina that could be differentially regulated during development. (Supported by CNPq and PROPP/UFF).

P19 MOUSE EC CELLS PROVIDE MODEL FOR NEURONAL REGULATION OF *Ache* GENE EXPRESSION. B.A. COLEMAN* AND P. TAYLOR. Dept. of Pharmacology, UCSD School of Med., La Jolla, CA 92093.

Acetylcholinesterase (*Ache*) has commonly been used as a marker for terminal differentiation of neurons and has been proposed to play a role in development of the vertebrate nervous system. Mouse P19 embryonic carcinoma cells are uncommitted, pluripotent cells which can be induced to terminally differentiate along the neuroectodermal lineage. Neurons, glia and astrocytes develop after aggregates, previously cultured with retinoic acid (RA), are plated onto tissue culture dishes. Neuronal cultures up to 90% purity can be obtained by treatment with mitotic inhibitors. We have begun using this cell line to examine the developmental and tissue-specific transcriptional regulation of *Ache*. *Ache* activity is not expressed in undifferentiated cells but can be detected within 24 hr of plating neuronally-induced cultures and increases to approximately 20 nmols/min/mg protein. This correlates with the increase in cells exhibiting neuronal morphology. Histochemical and immunohistochemical results indicate that *Ache* activity is associated with neuron-like cells containing processes, but not with flattened, glia-like cells. The presence of *Ache* mRNA, as detected by message protection, parallels expression of the enzyme. Splicing of the *Ache* mRNA appears consistent with that observed in mouse brain. The 5' flanking region (3 kb) of *Ache* was linked to the luciferase gene for transient transfection assays. Levels of the reporter gene rose 3.5-fold in neuronally-induced cultures over that observed in untreated controls suggesting that this upstream region of the *Ache* gene contains elements capable of enhancing transcription in neuronal cultures and that increased transcription occurs after neuronal differentiation. Thus the P19 cell line appears to provide a suitable model for further studies of *Ache* gene regulation during neuronal development. (Supported by USPHS GM18360 and 24437)

SPONTANEOUS CA²⁺ SPIKES AND WAVES IN EMBRYONIC *XENOPUS* SPINAL NEURONS *IN VITRO* AND *IN VIVO*. X. Gu* and N. C. Spitzer. Department of Biology & Center for Molecular Genetics, UCSD, La Jolla CA 92093.

Calcium plays an important role in the normal differentiation of embryonic amphibian spinal neurons during an early period of development. Previous studies showed that cultured neurons exhibit spontaneous rapid Ca²⁺ spikes and slow Ca²⁺ waves during this Ca²⁺-sensitive period. We have now extended the study over much of this period by semi-continuous, confocal imaging of [Ca²⁺]_i-induced fluo-3 fluorescence at 10 second intervals for 5 hours (7-12 hr *in vitro*). We find that 88% of neurons exhibit spontaneous elevations of [Ca²⁺]_i in culture (n=25). Among them, 17 show spikes and 19 show waves. Interestingly, most spikes (104 of 177) occur during the first 2 hours, while waves are relatively uniformly distributed throughout this period. The incidence of waves is higher in growth cones (8-9/hr) than in the cell body (1-2/hr), although their temporal distribution is similar.

Spontaneous spikes and waves are also observed in neurons in the intact embryonic spinal cord. At early neural tube stages (corresponding to 2-6 hr *in vitro*), 50% of cells in spinal cord exhibit spikes, at a frequency of 10/hr. The incidence and frequency of spiking decline to 20% and 2/hr at tailbud stages (9-15 hr *in vitro*). The appearance of synchronously active cells characterizes the spinal cord at these later stages, when the neurons are electrically coupled. Groups of 2-4 cells in a field of 100 generate synchronous spikes repeatedly, 2-5 times. Remarkably, these cells are not always contiguous, consistent with neurite extension that begins at these stages. The mechanisms by which these calcium elevations encode these aspects of differentiation remain to be elucidated.

Supported by NIH NS15918.

IN VIVO CONFOCAL MICROSCOPY OF NERVE STRUCTURES IN THE HUMAN CORNEA. B.R. MASTERS*, A.A. THAER, Institute for Medical Vision Aid, Bahnhofstrasse 19a, 6330 Wetzlar, Germany; Uniformed Services University of the Health Sciences, Department of Anatomy and Cell Biology, 4301 Jones Bridge Road, Bethesda, MD 20814.

The cornea richly supplied with sensory nerves and is unique in that its innervation can be noninvasively imaged in the living human eye without staining. A new scanning slit in vivo confocal microscope was developed for imaging the living human eye. The light source is a halogen lamp. Two sets of adjustable confocal slits provide the optical sectioning capability. A double sided mirror provides both scanning and descanning. An intensified video camera detects the images. The optical sections are 1-2 microns thick. No frame averaging or digital image enhancement is required. The studies we described in this paper were made with a Leitz 50X, NA 1.0 water immersion objective. Other studies which required a larger field of view used a Leitz 25X, NA 0.6, water immersion objective. The confocal microscope operated in the back scattered light mode produced single video frames of corneal nerves. The nerves in the anterior stroma penetrate Bowman's membrane and form a plexus under the basal epithelium. The deep fiber bundles in the stroma and the subepithelial fibers are imaged with high contrast without any staining. We observed long nerve fibers, beaded fibers and nerves bridged by short branches. The ability to noninvasively image the innervation in the anterior cornea of the live human eye provides a new approach to monitor in real-time changes in pattern and structure. This work was supported by a grant from NIH, National Eye Institute, EY-06958 (BRM). The authors acknowledge the cooperation from The Institute for Medical Vision Aid, and Helmut Hund GmbH.

AN EASY METHOD FOR ULTRASTRUCTURAL ANALYSIS OF IDENTIFIED GROWING NEURONS WITH THE HELP OF THE CONFOCAL LASER SCANNING MICROSCOPE. H.A. Vischer* and M. Dürrenberger. Dept. Pharmacology and Interdepartmental Electronmicroscopy Facility, Biocenter, Univ. of Basel, 4056 Basel, Switzerland.

A problem in ultrastructural analysis of identified neurons is to localize them with exact precision in the tissue block used for thin sectioning. We have labeled with Dil fibers growing in an immature mammalian spinal cord. After labeling with Dil for 2 days at room temperature, the cord was cut on a vibratome into 100µm thick horizontal sections. After investigation under rhodamine fluorescence, sections exhibiting labeled neurons were soaked in 0.03 % DAB and photoconverted under the same illumination for 1 hour. Sections were placed into folding grids, dehydrated, infiltrated and embedded in Quetol 651 (Pelco Inc.) which allowed immunocytochemistry on thin sections. After trimming, the Quetol blocks were fixed in block holders and mounted on an inverted confocal laser scanning microscope (CLSM; Tracor Odyssey). The block was optically sliced at 1µm intervals with a 40x (NA=0.75) Zeiss Planapo lens in fluorescent light mode (FITC). The 3D position of the labeled fibers, relative to the block surface, could thus be determined with an accuracy of ±0.5µm. With imaging techniques, it was possible to localize not only the exact position of the growth cones of the Dil labeled fibers but also the light microscopic 3D distribution of their axons before sectioning for electron microscopy.

CHARACTERIZATION AND LOCALIZATION OF ORBICULARIS OCULI MOTONEURONS FROM 3D RECONSTRUCTIONS. B.F. Lofthus¹ and T.H. Brown^{2,3}. Program in Neuroscience¹ and Depts. of Psychology², and Cellular & Molecular Physiology³, Yale Univ., New Haven, CT 06520

The rat eye blink reflex is useful for neurophysiological studies of associative learning and adaptive gain control (Donegan et al, *Neuro. Abstr.* 18, 146.6. In the present study, we determined the number, location and morphological characteristics of the motoneurons that produce the downward force generating the eye blink. These neurons, which innervate the orbicularis oculi (oo) muscle, are located in the facial motor nucleus (FMN).

Until now, studies of the motoneuron pool innervating a particular facial muscle have typically involved HRP or one of its conjugates in thin sections that have been previously dehydrated. Tissue shrinkage and incorrect cell counts are two common problems with this technique. Our method of retrograde labeling from the oo muscle, combined with confocal microscopy and 3D reconstruction of thick tissue, eliminates these problems. *In vivo* injections of tetramethylrhodamine were made into the oo muscle. Fixed tissue containing the FMN was transversely sliced at 200 µm and optically sectioned using a laser scanning confocal microscope. Cells were then reconstructed using the Voxal View 3D reconstruction system.

Statistical analysis of the number of oo motoneurons revealed a mean (±SE) = 21 ± 1 cells per animal per FMN. The oo motoneurons span 1,400 µm rostrocaudally and form a cap around the posterior edge of the FMN. Soma sizes ranged from 450 - 1,487 µm², with larger cells being distributed more rostrally and smaller cells more caudally. In addition to providing quantitative data on dendritic length, width, and arborization, the 3D reconstruction system allowed visualization of novel cell-to-cell interactions. Supported by NIH (THB), NSF(BFL) and CTAN.

458.2

3-D VISUALIZATION AND MORPHOMETRICS OF MYELIN IN INTACT NERVE SEGMENTS OF NORMAL AND TREMBLER MUTANT MICE BY CONFOCAL MICROSCOPY. B. Kosaras*, M. Tang and R.L. Sidman. Division of Neurogenetics, New England Regional Primate Research Center, Harvard Medical School, Southborough, MA 01772-9102.

We have examined segments of whole nerve many mm in length by confocal microscopy. Intact segments of one-year-old wild-type (+/+) and trembler (Tr/+) mouse nerve from lumbar root levels to the plantaris nerve in the foot were fixed in single or mixed aldehydes, washed in buffer, and dehydrated in 50%, 70%, 90%, and 100% DMSO. Nerves were stained for 0.5 hr at room temperature by immersion in 0.01% Dil (Molecular Probes, Eugene, OR) in DMSO, rinsed in 1-2 changes of DMSO, and then were embedded in glycol methacrylate at 4° C. The transparent blocks were oriented on microscope slides with gum and examined with a Sarastro laser scanning confocal microscope (Molecular Dynamics, Sunnyvale, CA). Nerves were viewed transversely and longitudinally, but were optically clearer in transverse view. The red fluorescent stain was intense and selective for myelin. With 20X-60X oil immersion objectives, optical sections of the full transverse face or of selected fascicles were collected at 0.3 or 0.5 µm intervals for depths >100 µm into the plastic block. By alternate confocal scanning and thick sectioning, the length of nerve that can be imaged is limited only by available computer memory. Morphometric measurements in 2-D and 3-D were made with VoxalView software (Vital Images, Fairfield, IA) on a Silicon Graphics (Mountain View, CA) Indigo computer. Myelin occupied 63-83% of the nerve volume at the various +/+ nerve levels, with the highest value in the dorsal L3 root, but occupied only 2-3% of the nerve volume in Tr/+, except in the dorsal root, where the value was 8%. Myelin concentration was 2.5-4.2% of normal at all levels in Tr/+ except for 9.6% in the L3 dorsal root. In the +/+ controls, myelin was continuous along a given axon except at the nodes of Ranvier, as expected, but in Tr/+ the segments of myelin appeared at random; almost no nodes were identified—confirming the Schwann cell as the site of Tr gene action. (Supported by NIH grant NS20820.)

MEASUREMENTS OF PHRENIC MOTONEURON SOMAL VOLUMES USING LASER SCANNING CONFOCAL MICROSCOPY: COMPARISONS WITH ESTIMATES USING THE CAVALIERI PRINCIPLE AND THE NUCLEATOR. Y.S. Prakash*, K.G. Smithson and G.C. Sieck. Departments of Anesthesiology, Physiology and Biophysics, Mayo Clinic and Foundation, Rochester, MN 55905

In neuromorphometry, spatial information about neural elements is obtained essentially from two-dimensional (2D) images while the objects themselves are three-dimensional (3D). Until recently, parameters (e.g., cell volume) have been estimated from 2D images using stereological techniques which require assumptions about the size, shape and orientation of the 3D object. This approach can lead to considerable errors in estimating parameters of interest since neuronal shape or orientation can deviate significantly from these assumptions. Recently two new unbiased methods which make no shape assumptions, the Cavalieri principle (Gundersen, H.J. et al. *J. Microsc.* 147:229, 1987), and the nucleator (Gundersen, H.J. *J. Microsc.* 151:3, 1988) have been introduced to estimate cell volume. Alternatively it is possible to make direct measurements of cell volume using confocal microscopy (Prakash, Y.S. et al. *Soc. Neurosci. Abstr.* 18:966, 1992). In the present study these three volume estimation methods were compared: 1) confocal microscopy, 2) nucleator, and 3) Cavalieri principle. Optical sections of forty-nine rhodamine-labeled phrenic motoneurons were obtained by confocal microscopy; here neuronal volumes were determined by voxel counting. Nucleator and Cavalieri methods were simulated by computer manipulation of these optical sections. Individual motoneuron volumes were similar for confocal and Cavalieri methods, but were significantly different from volumes estimated by the nucleator. Furthermore, the distributions of neuronal volumes showed a similar relationship. These results suggest that the nucleator was not an accurate method for determining individual cell volume, or the distribution of cell volumes, for phrenic motoneurons. Estimates obtained by both "direct" confocal measurements and by the Cavalieri method were in good agreement suggesting that less stringent optical sectioning parameters may suffice for cell volume measurements when using confocal microscopy. CONFOCAL "GRID-MAPPED" FREEZE FRACTURE OF PREFELECTED NEURONS IN SPINAL CORD AND BRAIN

J. E. Rash*, L. R. Whalen, P. B. Guthrie, M. Morita, R. K. Dillman, T. Yasumura and D. Fay-Guthrie. Dept. of Anatomy and Neurobiology, Colorado State University, Fort Collins, CO 80523

Interpretation of freeze-fracture images from complex nervous tissues is subject to many uncertainties, including those introduced by tissue dissection, sample orientation during freezing, the near random nature of the fracture plane, and fragmentation of replicas during cleaning. We have developed the "grid-mapped" freeze-fracture technique to address many of these limitations. Histological slices were mapped in three-dimensions by confocal microscopy, allowing selected neurons to be cleaved using the precision microtome (±0.5 µm) in a JEOL JFD-9000 freeze-fracture machine. After replication, each frozen sample was stabilized in a Lexan film on a gold "Finder" grid. To confirm the location of the fracture plane, samples were thawed and re-mapped by confocal microscopy. A second carbon film applied before removal of the Lexan support film yielded unfragmented, undisplaced replicas as large as 2 x 2 mm. Spinal cord neurons linked by gap junctions were mapped to Rexed Laminae VI, VII, VIII, and IX (motor neurons and interneurons). Similarly, histological stains applied after freeze fracturing allowed us to identify replicated neurons in the hippocampus and suprachiasmatic nucleus. The "grid-mapped" freeze-fracture technique provides for unambiguous identification and mapping of replicated neurons and their major neuritic processes, and is allowing us to develop criteria for identifying neuronal subtypes based on a growing "library" of IMP markers.

Supported by NIH Grant # NS-39503.

MAPPING OF THE HUMAN BRAIN. THE SINGLE CELL LEVEL, EMPLOYING LUCIFER YELLOJO MICROINJECTION, IMMUNOHISTOCHEMISTRY, AND CONFOCAL LASER SCANNING MICROSCOPY. P.V. Belichenko and A. Dahlström*. Brain Res. Inst., Russian Acad. Med. Sci., Moscow, Russia; and Inst. Neurobiol., Dept. of Anat. and Cell Biol., Univ. of Göteborg, Medicinaregatan 5, S-413 90 Göteborg, Sweden.

Modern neuroscience is looking for technologies suitable for mapping of the human brain. Neurons in the CNS integrate more than 95% of the information from other neurons on their dendrites and alterations in the dendritic receptive capacity may play a crucial role in some neuropathological conditions. A complete picture of single neurons, with dendrites and axons, the fundamental functional units of organization, must be included in brain mapping. Our strategy for contributing to the "Mapping of the Human Brain" uses intracellular injections of Lucifer Yellow (LY), neurotransmitter immunohistochemistry and confocal laser scanning microscopy (CLSM). Under microscopic control, LY was injected into a great number of single neurons and glial cells in 200µm thick vibratome serial sections from brain specimens removed during neurosurgery. We successfully combined LY injections with immunohistochemistry, using a variety of antisera, e.g. anti-synapsin I, anti-P38, anti-MAO, anti-β-adrenoceptor, etc. Using CLSM, the fluorescence microscope pictures of single cells and neurotransmitter distribution are stored in file format and transferred to a computer, where 3-D structures of the injected cells are created. With this approach we have started to collect a confocal 3-D image library. This approach was tested for frontal, temporal, parietal, and occipital cortices, and of hippocampus in normal and pathology human brains. The clinical application has been the study of neuronal dysplasia in cortical areas of epileptic patients.

THE LIVING AND THE DEAD: INTERACTIVE VISUALIZATION OF NERVE CELLS

B.J. Burbach¹, R.S. Avila¹, L.M. Sobierajski², A.E. Kaufman², and P.R. Adams¹
¹Howard Hughes Medical Institute and ²Dept. Computer Science, SUNY at Stony Brook, Stony Brook, NY 11794-5230

The electrical properties of neurons are strongly influenced by geometric factors such as membrane capacity, channel localization and diffusion pathways. Laser scanning confocal fluorescence microscopy together with volume rendering are powerful techniques for exploring and quantifying these aspects of three dimensional morphology. We have investigated a variety of preparations including tracer-injected neurons in fixed brain slices (e.g., hippocampus, LGN), immunofluorescently labeled cells (e.g., PC 12), and live vitally stained bullfrog sympathetic ganglion cells in culture. Particular attention was paid to optical aberrations, calibration, sampling and thresholding. A volume visualization system, VolVis, was developed and utilized to reconstruct, visualize, and measure serial optical sections. The VolVis system provides the ability to load multiple volumetric and geometric data sets, navigate in real time through a reduced resolution polygonal representation of the data sets, render the scene using several projection algorithms, and perform volume and surface area measurements. Rendering capabilities include a fast ray casting algorithm called PARC (Polygon Assisted Ray Casting) and a volumetric ray tracer, both of which can render a scene with volumetric surfaces or transparency and may perform parallel or perspective projections. The position of the view is interactively manipulated using the navigation component. The VolVis system is running on Silicon Graphics workstations using X/Motif/GL, Sun workstations using X/OpenLook, and Hewlett-Packard workstations using X/Motif/Starbase. VolVis is available free of charge to educational and research institutions. Contact R. Avila at avila@cs.sunysb.edu.

THREE-DIMENSIONAL MORPHOLOGICAL ANALYSIS OF MOSSY-FIBER SYNAPSES IN RAT HIPPOCAMPAL BRAIN SLICES. T.-P. Yu¹ and T.H. Brown^{1,2} Depts. of Psych.¹ and Cell. and Mol. Physiol.², Yale University, New Haven, CT 06520.

The hippocampal mossy-fiber (mf) synapse is attractive for studies of neurophysiology and use-dependent plasticity because of its large size and electrotonic proximity to the soma. We previously reported (Yu and Brown, *Soc. Neurosci. Abstr.* 18, 1992) the visualization and identification of presynaptic mf boutons (expansions) using confocal laser scanning microscopy (CLSM) applied to living brain slices. Here we perform a morphological analysis of the boutons using a volume rendering system.

The methods used for visualization of living mf synaptic expansions were as described previously (*op. cit.*). Living rat brain slices were sectioned at 400 - 450 µm, the mf boutons were stained with diI or diA, and the labelled boutons were then imaged using CLSM. The rendering system enabled three-dimensional (3D) visualization of the boutons at different angles and permitted analysis of area and volume.

The mf boutons were highly variable with respect to both size and shape. In most cases, they were irregular oval structures, occasionally having rough surfaces. About 70% of the boutons were bipolar, being more or less fusiform enlargements on the axis of the mf axon. Sometimes we could see thin protuberances emanating from the expansion. The volumes of the boutons varied from 25 to 510 µm³ [mean (±SE) = 161 ± 23 µm³]. The 3D surface areas ranged from 32 to 416 µm² [mean (±SE) = 174 ± 18 µm²].

Unexpectedly, the analysis suggested a linear relationship between mf volume and 3D surface area, suggesting that as the volume increases there is a change in the shape or an increase in the surface irregularity. We are currently examining these possibilities. Supported by NIMH and CTAN.

EVIDENCE AGAINST PERSISTENT NUCLEAR/CYTOSOLIC CALCIUM GRADIENTS IN BULLFROG SYMPATHETIC NEURONS. DM O'Malley*, SP Yu, BJ Burbach, & PR Adams. Dept of Neurobiology & Behavior and Howard Hughes Medical Institute, SUNY, Stony Brook, NY, 11794.

Cultured neurons were loaded with the calcium indicator fluo 3 via a whole-cell patch electrode and imaged using the Biorad MRC 600 Laser Scanning Confocal Microscope. Cells were held at -70 mV and depolarized to 0 mV for 5 to 200 msec to activate calcium currents. The influx of calcium was visualized in images acquired at 200 msec intervals. A ring of calcium influx was evident under the plasma membrane immediately after the pulse. The calcium then diffused through the cytoplasm and into the nucleus. The absolute fluorescence increase was largest in the nucleus. However, after correcting for autofluorescence, the relative increase in nuclear fluorescence was roughly equal to that in a region of cytoplasm the same distance from the plasma membrane as the nucleus. The relative fluorescence change in these regions was much smaller than the maximal early increase seen under the plasma membrane. Rapid imaging with 2-msec line-scans revealed calcium transients entering the nucleus within 10-20 msec after arriving at the nuclear envelope.

Although the nuclear envelope appeared freely permeable to calcium transients, the fluorescence of fluo 3 in the nucleus was about 2.3-fold brighter than in the cytoplasm. To evaluate whether the increased nuclear fluorescence was due to a persistent nuclear/cytosolic calcium gradient, a calibration curve was generated by patching onto cells with pipettes containing different levels of free calcium and 10 mM BAPTA. Using confocal volumes, independent calibration curves were made for the nucleus and cytoplasm. The nucleus was 2- to 2.5-fold brighter than the cytosol at all calcium levels. Perfusion of the patch pipette with different concentrations of calcium or manganese allowed generation of complete calibration curves in individual cells. These calibrations argue against persistent calcium gradients and suggest that nuclear fluorescence exceeds cytoplasmic fluorescence because of the exclusion of fluo 3 by cytoplasmic organelles. [DMO supported by NIH Fellowship NS09113-02].

ULTRASTRUCTURAL DISTRIBUTION OF CAM KINASE II ISOFORM mRNAs IN RAT HIPPOCAMPUS: ELECTRON MICROSCOPIC IN SITU HYBRIDIZATION USING THICK CRYOSECTIONS. M.E. Martone, J. A. Pollock¹, Y. Zhang and M. H. Ellisman*. Microscopy and Imaging Resource, Univ. Calif., San Diego, 92093-0608, ¹Biology Dept., Carnegie Mellon University, Pittsburgh, PA.

We investigated the ultrastructural distribution of mRNA for Ca²⁺ calmodulin-dependent protein kinase II (CAMKII) isoforms in the rat hippocampus using an EM in situ hybridization protocol utilizing thick cryosections viewed with intermediate high voltage electron microscopy (IVEM). IVEM offers several advantages over standard electron microscopy for EM in situ hybridization. Thicker sections survive the harsh pretreatments necessary to render the mRNAs accessible better than do thin sections and also include greater numbers of target mRNA molecules per section. Semi-thick and thick (0.5-1µm) ultracyrosections were obtained from the rat hippocampus and collected on gold EM grids. Grids were floated in 0.1N HCl followed by 2XSSC, rapid heating to 70°, 4% paraformaldehyde, dehydration-rehydration in either ethanol or glycerol with PBS rinses between steps. Grids were incubated overnight at 37° with biotin- or digoxigenin- labeled probes which included a 600 bp cDNA generated from a restriction fragment of CAMKII (provided by Dr. P. Kelly, Univ. Texas, Houston) and synthetic oligonucleotides specific for either the alpha or beta CAMKII isoforms (Burgin et al. *J. Neurosci.* 1990, 10, 1788). Following a series of high stringency washes, labeled probes were detected using silver intensified 1nm colloidal gold. Various controls were included to test probe and method specificity. Sections embedded in LR White were viewed at 400 keV using a JEOL 4000EX IVEM.

Labeling for both alpha and beta isoforms was localized to granule and pyramidal cell bodies. Labeling for beta extended into proximal pyramidal cell dendrites but abruptly stopped between 5-10 µm from the cell body. In contrast, labeling for alpha was followed up to 30 µm into apical dendrites where it gradually diminished. These results confirm and extend light microscopic observations of Burgin et al. (1990) and suggest that the use of semi-thick cryosections provides a sensitive method for EM level detection of mRNAs.

459.2

ANATOMICAL CHARACTERIZATION OF ZEBRAFISH RETINAL ANTIGENS WITH ALKALINE PHOSPHATASE-MEDIATED METHODS USING A NEW FLUOROGENIC SUBSTRATE tK.D. Larison, Jr., BreMiller, tV. Paragas, tV. Singer, tJ.J. Naleway and tR.P. Haugland. tMolecular Probes, Inc., Eugene, OR 97402; ‡Institute of Neuroscience, University of Oregon, Eugene, OR 97403.

Molecular Probes' researchers have synthesized a new alkaline phosphatase substrate, 2-(2'-phosphoryloxyphenyl)-4(3H)-quinazolinone, which we used with standard immunohistochemical techniques to characterize monoclonal antibodies against fish retina (FRet monoclonals). The tissue was first probed with a FRet antibody, followed by sequential application of biotinylated goat anti-mouse, streptavidin, biotinylated alkaline phosphatase, and then finally the substrate. With the methods we have developed, we were able to localize FRets that bind to pigment epithelial cells (FRet 45), to double-cone cells (FRet 43), to nuclear membranes of a subset of retinal cells (FRet 34), to retinal synaptic layers (FRets 8 and 19) and to cell surfaces just scleral to the outer limiting membrane (FRet 6). The substrate's pattern of staining for each of these antibodies was identical to that seen with HRP/DAB (horseradish peroxidase-diaminobenzidine) methods. The advantage of this newly developed method over standard HRP/DAB techniques is that it can be used in conjunction with any number of fluorescent probes, including fluorophore-conjugated immunoreagents, to facilitate multicolor labeling. The substrate produces an extremely bright and photostable fluorescent precipitate (excitation, ~360-420 nm; fluorescence, ~500-540 nm). We have also used the substrate for Western blotting to further characterize these antibodies. Supported by NIH grant R43GM48306-01 to R.P. Haugland.

VISUALIZATION OF ASPARTATE AND GLUTAMATE DISTRIBUTIONS IN HIPPOCAMPUS USING UNIQUE NEW NETWELL REACTION TRAY SYSTEM. W. K. Newell, M. W. Fleck, and G. Barrionuevo*. Departments of Behavioral Neuroscience and Psychiatry; University of Pittsburgh, Pittsburgh, PA 15260.

We evaluated the utility of a new disposable reaction tray system for use in immunohistochemical and serial staining of sliced tissues. A new Netwell reaction tray system (Costar) was tested which allows for pre treatment of live tissue slices by superfusion followed by immediate fixation and reaction in disposable trays. Compared with the custom-built apparatus used in previous experiments, the disposable Netwell reaction tray system reduced experimental time and damage artifact while significantly increasing slice yield.

Rat hippocampal slices (100 μ m thick) were obtained by Vibratome slicing following rapid cardiac perfusion with oxygenated sucrose solution. Slices were incubated in the reaction trays by superfusion of oxygenated artificial CSF of varying ionic compositions. Superfusion source was then changed to medium containing cacodylate and sodium metabisulfite for 10 min, and then to the same medium containing glutaraldehyde. Slices were separated into two groups and reacted with antibodies raised in rabbit against the glutaraldehyde fixation products of either ASP or GLU (Chemicon). Slices were then incubated with a secondary anti-rabbit antibody raised in goat (Vecto). Antigens were revealed with ABC-DAB reactions.

Only weak staining was observed in the three principal cell-body regions, CA1, CA3, and dentate gyrus. Diffuse ASP-like immunoreactivity was apparent in all dendritic regions but especially in area CA1 and dentate. Diffuse GLU-like immunoreactivity was equally robust in all dendritic regions. A thin dense band in the middle third of the dentate molecular layer showed both ASP-like and GLU-like immunoreactivities. In CA3, a thin GLU-like immunoreactive band was observed in stratum lucidum. These results support a neurotransmitter role for GLU and ASP in hippocampus. Supported by NS26288 and an NIMH predoctoral fellowship.

A QUANTITATIVE ANALYSIS OF THE RELATIONSHIP BETWEEN NEURON COUNTS AND OPTICAL DENSITY OF NADPH-DIAPHORASE HISTOCHEMISTRY IN THE RAT STRIATUM. H. Kuo*, J. Hengemihle, W. DeLoriers, S. Grant, and D. K. Ingram. GRC, NIA, NIH, Baltimore, MD 21224 and Dept. of Psychology, Univ. of Delaware, Newark, DE 19716.

NADPH diaphorase histochemistry is a useful technique for examining select neuronal populations in both experimental studies and in human neuropathology and also provides a simple method to localize nitric oxide synthase in the CNS (Hope, *PNAS*, 88:2811, 1991). However, no established method exists for detecting quantitative changes of NADPH diaphorase histochemistry under different experimental conditions. To develop a quantitative procedure, we investigated the correlation between the number of NADPH diaphorase positive cells and the optical density of NADPH diaphorase histochemistry in the rat striatum. Fourteen male F-344 rats (3 mo old) were used. Brains were sectioned parasagittally into 30 μ m serial sections on a cryostat. NADPH diaphorase histochemistry (Vincent, *Neuroscience*, 46:755, 1992) was performed at a series of different incubation times (0.5-8 hr). The calibrated optical density of the whole striatum at a specific plan (lateral 2.5 mm) was measured using automated densitometry (RAS system, Amersham) and the number of positive cells per unit in this plan was counted by hand. Our results showed that during the reaction, the cell body was stained first and then the major processes and neuropil. Up to 5 hr incubation, an increase in incubation time increased the optical density of NADPH diaphorase staining. In contrast, the number of NADPH diaphorase positive cells counted was relatively consistent across incubation times. Therefore, little correlation existed between the optical density and cell number. This results indicate that when using NADPH diaphorase histochemistry, the number of NADPH positive neurons is independent of the optical density of the staining, and these two parameters should be considered and treated separately when conducting quantitative analysis related to an experimental treatment.

459.7

NON-ISOTOPIC *IN SITU* HYBRIDIZATION IN BRAIN WHOLEMOUNTS OF THE SEA LAMPREY *PETROMYZON MARINUS*. G.P. Swain* and M.E. Selzer. Dept. of Neurology & David Mahoney Institute of Neuroscience, Univ. of PA, Phila., PA 19104.

Non-isotopic *in situ* hybridization (NISH) using a variety of colorimetric reporter molecules is rapidly replacing autoradiographic techniques because of its more rapid processing time, safety and improved localization of signal. Until now NISH has been limited largely to sectioned material or cultured cells. We have developed a hybridization protocol using digoxigenin-labeled cRNA probes suitable for whole mount *in situ* preparations of the lamprey CNS. The ability to do NISH in wholemounts permits the rapid examination of large sample sizes and thus facilitates investigations of gene expression during CNS development (e.g., metamorphosis) and regeneration. These preparations can then be compared to wholemounts labeled by other methods such as retrograde transport of HRP, immunohistochemistry, etc. The technique is illustrated in this poster using probes transcribed from lamprey neurofilament (NF 180) cDNA. Neurofilament mRNA is expressed in most of the cranial nerve nuclei and in the reticulospinal cells in the larval and adult lamprey. Expression of NF180 in the cells of the oculomotor and trochlear nuclei begins upon metamorphosis (i.e., coincidental with the functional development of the eyes). The ability to do NISH in wholemount brain, even in adult specimens, is an additional advantage of the lamprey as an experimental model for vertebrate neurobiology. (Supported by grant #NS 14837)

NEURAL ANTIGEN DETECTION IS NOT IMPAIRED BY DECALCIFICATION. D.B. Henken* & J.R. Martin, NIH, NINDS, LEMP, Bethesda, MD, USA, 20892.

Decalcification using EDTA (ethylenediaminetetraacetic acid) has been used by pathologists to examine bone and neural tissues encased by it. Whether the decalcification process reduces the sensitivity of antigen detection in neural tissues has not been addressed. Here, in dissected sensory ganglia and undissected, decalcified preparations that include spinal ganglia and spinal cord, quantitative and semiquantitative comparisons are made of numbers and staining intensities of neurons immunocytochemically labeled with antibodies that include the neuropeptides, substance P (SP) and calcitonin gene-related peptide (CGRP) as well as two other neural markers, neuron specific enolase (NSE) and glial fibrillary acidic protein (GFAP). Adult female BALB/c mice (n=9) were cardiac perfused with 10% formalin. The vertebral columns of 5 mice were removed and decalcified. The sensory ganglia from the remaining 4 mice were dissected. All tissues were embedded in paraffin, sectioned (7 μ m), and processed for immunocytochemical detection of the appropriate antigen. In undissected decalcified tissues, the immunoreactivities of these neural antigens were compared with those in dissected sensory ganglia. Decalcification does not reduce either the numbers or staining intensities of antigen-positive neural cells. Tissues are well preserved and complex anatomical relationships are maintained.

459.6

ENHANCED IMMEDIATE EARLY GENE EXPRESSION WITH BIOTIN AMPLIFICATION. K.A. BERGHORN, K.D. RYAN*, and G.E. HOFFMAN. Departments of Neurobiology, and Cell Biology and Physiology, University of Pittsburgh, Pittsburgh, PA, 15261.

Identification of activated neurons using c-Fos and/or Fos related antigens (FRAs) is an important technique with which to study functional pathways following a specific stimulus. Expression of Fos, revealed by immunoreactivity, has been used extensively in this laboratory to study the regulation of several autonomic and neuroendocrine systems. Increased sensitivity and enhancement of Fos immunocytochemical localization would be of great benefit. Recently, Adams (J Histochem Cytochem 40:1457-1463, 1992) described a biotin amplification procedure (BAP) which increased sensitivity in histochemical stains. Through modification of his protocol, we applied BAP for enhancement of ABC "elite" immunoperoxidase and developed a BAP procedure for immunofluorescent staining of immediate early gene proteins. Using BAP, Fos and FRA staining with immunoperoxidase protocol was enhanced variably over the "elite" ABC peroxidase protocol. Antibody titers could be reduced 2-15X, depending on the antibody. For certain N-terminal-directed Fos antisera, BAP increased background staining. However, in general Fos and FRA staining intensity was increased and sensitivity improved. The greatest advantage came with immunofluorescence staining. There, BAP markedly increased the signal to noise ratio, reduced background staining and permitted decreases in titers. In total, the application of BAP to localization has the promise of aiding the scientist in detecting these immediate early gene projects. Supported by NIH HD 07481 and NS 28730.

SEMI-AUTOMATIC IMAGE ANALYSIS FOR *IN SITU* HYBRIDIZATION EXPERIMENTS. F. T. Banfro¹, C. L. Thouron¹, L. R. Lucas², R. E. Harlan¹, and R. R. Mize¹. ¹Dept. of Anatomy and the Neuroscience Center, Louisiana State Univ. Med. Ctr. and ²Dept. of Anatomy and Neuroscience Training Program, Tulane University Med. School, New Orleans, LA 70112.

We have developed a procedure for semi-automatic computer-based image analysis of *in situ* hybridization experiments. The procedure is designed to count autoradiographic grains over cells, to measure the number of cells and their size, and to calculate the grain density per cell. The procedure is used with a Joyce-Loebl MD image analyzer running a specially written macro task list. In order to distinguish autoradiographic grains from thionin stained neurons, the task list makes two passes, one to recognize cells, the other to recognize grains. In the first pass, a green filter is used to enhance the cells. A parabola spatial filter and a heighten contrast gray level operator are applied to enhance cell contour. We then set the grey level threshold so that cells are captured in binary memory. Separation and size filters are applied to separate apposed cells and eliminate artifacts. The size and number of cells are then measured. A second pass is used to extract the grains. A blue wratten filter is used to mask the thionin stained cells. Non-linear density and Laplacian filters are applied to enhance grain edges. The grains are then thresholded and separation and size filters applied to extract the grains and store them in a second binary memory. Boolean operators are applied to both binary images in order to selectively count the grains overlying each cell. Grain density is then computed using the cell size and grain measurements. The procedure has been used to quantify levels of mRNA expression in the rat caudate putamen. Comparison of manual and automatic grain counts revealed a high correlation between the two methods, although the computer slightly underestimated the counts obtained manually. Advantages of the procedure include speed and the ability to accurately separate grains from cells. Supported by EY-02973, RR-02800 (RRM) and, NS 24148, DA06194 (REH).

FLUORESCIN AS A LABEL FOR NON-RADIOACTIVE IN SITU HYBRIDIZATION IMAGING TECHNIQUES. I. Durrant*, S. Brunning, P. Chadwick and M. Cunningham.

Amersham International R&D Lab., Amersham, Bucks, HP7 9LL, UK.

The current studies were performed to investigate the properties of fluorescein as a label for in situ hybridization probes. This label should not have any endogenous background and high affinity antibody was available. Fluorescein labelled nucleotides have been incorporated into RNA, DNA and oligonucleotide probes. The efficiency of probe labelling is checked in a rapid fluorescence-based assay. Hybridizations, in a new buffer system, can be performed in only 4 hours and the entire process can be completed in 1 working day, with results available the following morning. The probes have been tested on a variety of systems, including the detection of messenger RNA for peptide hormones, including POMC in rat pituitary. Signal is high, resolution is high and background is low.

A NOVEL METHOD TO RELATE OPTICAL DENSITY OF PKC-ISOFORM ANTIBODY STAINING OF HIPPOCAMPAL SECTIONS TO KNOWN PKC EPITOPE CONCENTRATIONS USING AVIDIN-BIOTIN-PEROXIDASE (ABP) IMMUNOHISTOCHEMISTRY ON NITROCELLULOSE FILM SLIDES. M. Rossi, L. deToledo-Morrell, F. Morrell. Dept. Neurol. Sci., Rush Med. Coll., Chgo, IL 60612.

An innovative technique is introduced to quantify protein kinase C (PKC) epitope-antibody binding in brain tissue sections using ABP immunohistochemistry against known concentrations of purified PKC proteins or peptides of interest. A nitrocellulose (NC) film formulation was developed by Grace Bio-Oncology, Inc. After some modification to the formulation, exceptional histocoherent transfers of unfixed frozen 10 μ m thick brain sections were achieved. To prepare calibrated standards, a dilution series for immunodot staining was performed using known quantities of purified PKC- α and γ proteins, as well as synthetic peptide sequences of PKC- α , β I, β I/ β II, and γ . All epitopes effectively adhered to the NC film coated glass microscope slides. Double gelatinized glass slides did not significantly bind the proteins or peptides. In addition, using quantitative image analysis, antibody staining of brain sections with serial dilutions of all antibodies were compared on glass and NC film slides. The latter slides showed staining of PKC isoforms with densitometric anatomical resolution superior to that of gelatinized glass slides. Application of this immunohistochemical method where anatomic specificity is preserved will greatly augment the ability to quantify PKC-mediated changes implicated in neural plasticity.

SIMULTANEOUS ANTEROGRADE LABELING OF DIFFERENT AFFERENT PATHWAYS USING BIOTINYLATED DEXTRAN AMINE AND CHOLERA TOXIN SUBUNIT B. J.M. Alisky* and D.L. Tolbert. Dept. of Anat. and Neurobiol. and Surgery (Neurosurg.) St. Louis Univ., St. Louis MO 63104.

To orthogradely label two cerebellar afferent pathways in the same animal, biotinylated dextran amine (BDA) and cholera toxin subunit B (CTb) were pressure injected into the brainstem or spinal cord of rats. Survival periods varied from 1 to 3 weeks. Sections of cerebellum were mounted onto slides and reacted first for BDA and then for CTb. BDA label was visualized as a black reaction product using cobalt-enhanced diaminobenzidine as the substrate for an avidin-biotinylated peroxidase reaction. CTb was visualized as a brown reaction product by using diaminobenzidine without cobalt in an immunoperoxidase reaction. Terminals labeled by these two tracers could always be differentiated based on their color under brightfield illumination. Cobalt-intensified BDA mossy fiber terminals were always dark black to purple, whereas CTb labeled terminals were always reddish-brown. Under darkfield illumination CTb labeled mossy fiber terminals appeared bright orange while BDA mossy fiber terminals were barely visible or not seen at all. BDA and CTb labeled mossy fiber terminals also differed in their degree of resolution of labeling terminal morphology. BDA labeled terminals were Golgi-like in appearance and preterminal axons were usually labeled. CTb labeled mossy fiber terminals had a granular appearance and preterminal axons were generally not labeled. Controls showed that the sensitivity of BDA and CTb was unaffected by their combined use. BDA and CTb should have a wide range of applications for double anterograde labeling studies. (Supported by NIH grant NS20227)

VISUALIZATION OF ACTIVITY-DEPENDENT EXPRESSION AND DISTRIBUTION OF M₁ MUSCARINIC ACH RECEPTORS IN LIVING VISUAL CORTEX NEURONAL CULTURES. Y.Wang*, O.Gu, F.Mao¹, R.P.Haugland¹ and M.S.Cynader. Dept. of Ophthalmology, Univ. of British Columbia, Vancouver, B.C. Canada V5Z 3N9 and ¹Molecular Probes Inc., Eugene, OR 97402.

We have employed the fluorescently labeled muscarinic M₁ receptor selective antagonist BODIPY-pirenzepine to study the activity-dependent distribution and expression of muscarinic M₁ ACh receptors (M₁AChRs) in cultured neurons derived from rat visual cortex. Binding of BODIPY-pirenzepine retained the specificity of pirenzepine for M₁ receptors, with a similar K_d and displacement profile. Using confocal microscopy, the receptors were predominantly localized to cell bodies early in development in the culture environment. After two weeks in culture, the receptors were labeled not only in cell bodies but also in neuritic processes, especially on the initial segments. Chronic membrane depolarization with 40 mM potassium chloride caused a dramatic increase in M₁ receptor expression in these cultured neurons. Conversely chronic blockade of neural activity with 0.1 μ M TTX decreased expression of the receptors. Receptor expression increased after cells were treated chronically with 50 nM pirenzepine, whereas it decreased after exposure to 10 μ M carbachol. The results demonstrate for the first time the precise location of muscarinic receptors in living cultured neurons and also illustrate activity-dependent expression of M₁ receptors. The results also show that both chronic membrane depolarization and application of antagonists can up-regulate receptor expression, whereas blocking bioelectrical activity and applying agonist down-regulate receptor expression in living cells.

A SIMPLE METHOD TO IMPROVE THE RELIABILITY OF IONTO-PHORETIC ADMINISTRATION OF TRACER SUBSTANCES. D. Yu* and F.J. Gordon. Dept. of Pharmacology, Emory Univ. School of Medicine, Atlanta, GA 30322.

While conducting experiments using iontophoretic application of wheat germ agglutinin conjugated to horseradish peroxidase (WGA-HRP) we encountered many instances where WGA-HRP was not deposited into brain tissue. Microscopic examination indicated that extracellular fluid, drawn into the pipette tip by capillary action, may have diluted the tracer and reduced the concentration of WGA-HRP available for iontophoretic deposition. Coating the lumen of the capillary tube with silicone to reduce its surface tension, reduced the incidence of failures from 40% to 0%. The lumen of glass capillary tubes (WPI Kwik-fil, 1.2 mm o.d.) was coated with silicone (Sigmacote) by slowly drawing the fluid into the tube and expelling it 3 times. After drying, pipettes were pulled and tips cut back to 20-30 μ m o.d. Silicone treated and untreated pipettes were filled with 2% WGA-HRP (Vector or Sigma). In 10 rats, iontophoretic depositions (5 μ A anodal current, 5 sec on/5 sec off for 10 min) were made using silicone coated and uncoated pipettes positioned in the basal ganglia. 24 hr later, HRP was developed with TMB-tungstate. For uncoated pipettes, injection size was highly variable and in 4 of 10 cases the injection site could not be detected. Using silicone-treated pipettes, injections were invariably larger, more consistent in size, no failures were observed and the number of retrogradely labelled cells in the substantia nigra was increased. Similar results were found with Fluorogold. These results indicate that coating the lumen of glass micropipettes with silicone can significantly improve the reliability of iontophoretic deposition. Supported by grants NIH-HL36907 and Amer.Heart Assoc. to F.J.G.

EMBRYONIC TRACT TRACING WITH 3 K DEXTRAN AMINES. B. Fritsch*, D.H. Nichols and M.A. Christensen. Creighton Univ., Dept. Biomed. Sci., Omaha, NE 68104.

Higher molecular weight dextran amines have been used successfully in studies of neuronal morphogenesis. The use of smaller 3K dextran amines gives excellent results where long survival times are a problem due to their rapid rate of spread; up to 2 mm/hr. at room temperature. 3 K Dextran amines spread bi-directionally over identical distances whether or not microtubules have been disrupted using colchicine or nocodazole. Diffusion thus appears the most likely mechanism of spread; at least over short distances. 3 K Dextran amines diffuse little in the extracellular space thus allowing detailed examination near injection sites as well as the specific analysis of outgrowing fibers after focal applications. Applications of a few seconds will fill cut or damaged neuronal processes enough to allow Golgi-like fillings at several millimeters distance. Dextran amines can be combined with other techniques such as immunolocalization or histochemistry to allow both detailed topographical analysis of gene expression and the morphogenesis of neurons potentially affected by those genes. Biotinylated dextrans can be used to obtain permanent records for the detailed analysis of whole mounted embryonic brains. Supported by the NIH.

CULTURED NEURONAL CELLS FLUORESCENCE WHEN INCUBATED WITH 2-ME-HARMALINIUM OR DIHYDROISOQUINOLINIUM COMPOUNDS. E.J. Neafsey* and M.A. Collins. Departments of Cell Biology, Neurobiology & Anatomy and Molecular and Cellular Biochemistry, Loyola University Medical Center, Maywood, IL 60153.

Primary cultures of fetal (E14) rat mesencephalon were prepared using trituration and enzymatic digestion. After washing and resuspension, a trypan blue viability count was done, and cells were then plated at a density of 7.5×10^5 cells/well in Costar 6 well poly-D-lysine coated plates in DMEM F12 N2-supplemented (Bottenstein) medium. No serum was used. Fluoro-deoxyuridine was added as an anti-mitotic. Cultures were incubated at 37 degrees in 5% CO₂ for 7 days, and the medium was changed every other day. On day 7 either the beta-carboline 2-methyl-harmalinium iodide (2MeHL) or the 2-carboxymethyl-6,7-dihydroxy-3,4-dihydroisoquinolinium (DIQ) product of dopamine and glyoxylic acid was added to individual wells so that their final concentration was 200 μ M (2MeHL) or 300 μ M (DIQ); the two compounds were synthesized as part of our laboratory's investigation of various putative endogenous neurotoxins. After incubation for 30 minutes (and subsequent replacement of the brightly fluorescent DIQ medium with Hanks buffer), the cells were observed using both phase contrast and epi-fluorescence illumination (50 W Hg) on an Leica DMIL inverted fluorescence microscope using filter cube A2 (BP270-380, BP410-580) or D (BP355-425, LP460). Most cell bodies were fluorescent when viewed with either filter cube; some were very bright while others were barely visible. DIQ also caused many of the fine neurites to fluoresce brightly, suggesting it may be useful in visualizing detailed neuronal cell morphology in culture. (Supported by NIH grant NS 23891; thanks to Dr. Mary Druse-Manteuffel and Ms. Roberta Gillespie for providing the cell cultures.)

TRANSFERRIN AND FERRITIN IMMUNOHISTOCHEMISTRY AND IRON STAINING IN NORMAL AND HYPOTRANSFERRINEMIC (HP) MICE. T.K. Dickinson* and J.R. Connor. Dept of Neurosci & Anatomy, PSU Sch of Med, Hershey, PA 17033.

The importance of iron regulation in the brain is rapidly evolving as knowledge of the effects and extent of oxidative damage in the brain become better appreciated. In this study, the cellular distribution of transferrin (Tf; iron mobilization protein), ferritin (Frt; iron sequestration) and iron was determined in normal (adult CD1) and Hp mice. Normally, iron is found predominantly in oligodendrocytes. Tf is also found throughout the mouse brain mainly in oligodendrocytes. Ferritin immunostaining in the mouse was found in predominantly microglial. Astrocytic immunostaining was also observed particularly in white matter tracts. Neuronal staining was observed in select subcortical nuclei most prominently in the nucleus accumbens. Similar to the iron staining, tanycytes also label for ferritin. The Hp mice were investigated because these animals have a mutation in the Tf gene. The resulting phenotype has <1% of the normal circulating plasma level of Tf. The animals require weekly i.p. injections of Tf for survival. The overall pattern of staining for iron, Tf and Frt in the Hp mouse brain was similar to normal animals, although the number of Tf-positive cells was greatly reduced. The normal cellular distribution of iron and the iron regulatory proteins in Hp mice suggests that the exogenously introduced Tf enters the brain from the plasma (carrying iron) and enters appropriate cell types. Alternatively, these data may indicate that endogenous brain Tf is not critical for iron transport to cells in the brain. These observations are critical to the understanding of iron transport within the brain.

CARBACHOL INDUCTION OF *c-fos* mRNA IN OLIGODENDROCYTES IS MEDIATED BY PROTEIN KINASE C (PKC)

Almazan, G. * and Cohen, R. I.

McGill Univ. Dept. of Pharmacology, Montreal, PQ H3G 1Y6

We have previously reported that in oligodendrocytes carbachol stimulated phosphoinositide hydrolysis (mobilization of [Ca²⁺]_i) and attenuated b-adrenergic stimulated cyclic AMP formation via M1 and M2 type muscarinic receptors, respectively. We postulated that stimulation of the M1 type muscarinic receptor, which results in the formation of DAG (and IP₃) can lead to the activation of PKC. Furthermore, Bhat has recently demonstrated that TPA, a potent activator of PKC, induces *c-fos* mRNA levels in oligodendrocytes (Bhat, N. R. J. *Neurosci. Res.* 32, 340-349 1992). Therefore, in line with our previous hypothesis, we investigated the effect of carbachol on the expression of *c-fos* mRNA in oligodendrocytes.

Using Northern blot analysis we determined that carbachol (100 μ M) caused a maximal *c-fos* induction 30-60' after addition. This was blocked by a 5 minute pretreatment with 10 μ M atropine, the non-selective muscarinic antagonist. In addition, the induction was concentration dependent (10 - 1000 μ M), and correlated well with our previous PI hydrolysis results. The induction with carbachol was also blocked with the PKC inhibitor H7 (30 μ M). Our results suggest that neuronal cholinergic signals affect the expression of *c-fos* in oligodendrocyte cell culture through the activation of PKC. (Supported by the MRC of Canada).

EFFECT OF SODIUM BUTYRATE ON ACYLTRANSFERASE ACTIVITIES OF A CLONAL OLIGODENDROCYTE CELL LINE, CB-II. S. H. Sun*, Y. W. Chen, K. C. Chen, and A. C. Chang, Neurosciences Institute, National Yang Ming Medical College, Taipei, Taiwan, R. O. C.

Sodium butyrate was supplemented in the culture medium of CB-II, a clonal oligodendrocyte cell line, for 48 hrs, a 40% increase in the [³H]-arachidonic acid incorporation into phosphatidylcholine (PC) and a concomitant 75% decrease in phosphatidylethanolamine (PE) was observed. Only a slight, 2%, increase in PC was observed when the cells were labeled with [¹⁴C]-myristic acid. In this study we examine the effect of sodium butyrate on the activities of [³H]-arachidonic acid-lysophospholipid acyltransferases directly by an *in vitro* assay system. In the absence of sodium butyrate and exogenous lysophospholipids, [³H]-arachidonic acid incorporated into all major phospholipids in 10 min. PC was maximally labeled, and phosphatidylserine (PS) minimally labeled. Phosphatidylinositol (PI), phosphatidylethanolamine (PE) and plasmalogen phosphatidylethanolamine (PLPE) were also labeled effectively. Additional sodium butyrate in the incubation system significantly stimulated the activities of acyltransferases and an increase in the labelling of PC was observed. In the presence of exogenous lysophosphatidylcholine (LPC), lysophosphatidylinositol (LPI), and lysophosphatidylethanolamine (LPE), increased the radioactivities of PC, PI, and PE respectively. Additional sodium butyrate with exogenous LPC, LPI, and LPE, resulted in a further 70%, 60% and 160% increases in the labelling of PC, PI, and PE respectively. We conclude that the mechanism for sodium butyrate to induce morphological transformation and alter membrane-phospholipid metabolism is partially due to stimulating the activities of acyltransferases in CB-II.

DETECTION OF NOVEL RNA SEQUENCES HOMOLOGOUS TO THE PROTEOLIPID PROTEIN GENE. N.L. Nadon* and E.U. Bagriacik. Biology Dept., University of Tulsa, Tulsa OK 74104.

The proteolipid proteins are the most abundant proteins in CNS myelin. There are currently two known products of the PLP gene produced through alternative splicing in exon 3. PLP, the predominant form in adult myelin has 276 amino acids, while DM20 lacks 35 internal amino acids but is otherwise identical to PLP. We have evidence for up to three new RNAs with homology to PLP. Preliminary experiments utilized Reverse Transcriptase Polymerase Chain Reaction (RT-PCR) to amplify the region from exon 3 to exon 4 from the PLP gene transcripts, using very stringent annealing temperatures (65°C). In addition to bands corresponding to DM20 and PLP mRNAs, three extra bands were observed. These extra bands are observed in RT-PCR from mouse, rat and dog brain RNA. The new bands are not observed in E16 mouse brain, when DM20 but not PLP is expressed, but are detected by P1 when PLP has been turned on. Two of the RT-PCR derived cDNA fragments have been cloned, and sequence analysis will determine if they are new isoforms of PLP produced through alternative splicing or products of a gene closely related to the PLP gene. MYELINATION BY CELLS FROM THE CG-4 GLIAL CELL LINE FOLLOWING TRANSPLANTATION INTO THE MYELIN DEFICIENT RAT SPINAL CORD. D.R. Archer, U. Tontsch, M. DuBois-Dalq and I.D. Duncan. School of Veterinary Medicine, University of Wisconsin, Madison, WI 53706 and # NINDS, NIH, Bethesda, MD 20892.

Cells from the bipotential rat glial cell line CG-4 are capable of differentiating into oligodendrocytes or type II astrocytes (Louis et al. J. Neurosci. Res. 1992 31 193). In this study we examined the ability of these bipotential cells to myelinate axons of the myelin deficient rat spinal cord *in vivo*. CG4 cells were kept proliferating with conditioned medium from the B104 neuroblastoma cell line. The CG4 cells were collected and concentrated to 25,000 cells/ μ l. At least 85% of the cells were A2B5 positive by immunolabelling, indicative of the O2-A phenotype. Two microliters of the cells were injected into the T13/L1 region of myelin deficient rats. Thirteen days later the rats were euthanized by perfusion fixation, the spinal cords removed and tissue at the transplantation site examined by light and electron microscopy. In each of 12 animals, cells with the appearance of normal oligodendrocytes formed patches of myelination in the dorsal columns of the transplant recipients. These results show that cells from a glial cell line are capable of myelination *in vivo* and that they represent a continued source of cells for experimentation and possible use in future therapies for demyelinating diseases. (Supported by NS23124 and The Myelin Project)

REQUIREMENT OF POLYSIALIC-ACID FOR THE MIGRATION OF THE O-2A GLIAL PROGENITOR CELL IN VITRO. C. Wang, G. Rougon and J. Z. Kiss. Department of Morphology, University of Geneva Medical School, Geneva, Switzerland, ¹Laboratoire de Génétique et Physiologie du Développement, Marseille, France

While the capacity of O-2A oligodendrocyte progenitors to migrate in cell culture and during *in vivo* myelin formation is well documented, little is known about factors that regulate the motility of these cells. Here, we report on an *in vitro* model that allowed us to evaluate the contribution of α 2-8 linked polysialic acid (PSA) to O-2A cell motility. Using explant cultures of newborn rat neurohypophysis, we observed that individual glial fibrillary acidic protein (GFAP) positive cells rapidly disperse from the explants, and that cells of the O-2A lineage predominate in the migratory cell pool. A monoclonal antibody, which recognizes the α 2-8 linked PSA characteristic of the embryonic form of NCAM, revealed immunoreactivity on the surface of O-2A progenitor cells, whereas mature oligodendrocytes, type 2, type 1 astrocytes as well as flat GFAP negative cells were negative. Treatment of the explants with endoneuraminidase purified from phage K1, that specifically removes PSA from the surface of the cell, resulted in a complete blockade of the dispersion of O-2A lineage population from the explant. The effects of the enzymatic treatment were both selective and reversible: migration of GFAP negative flat cells or type 1 astrocytes that are PSA negative was not influenced, and upon removal of the enzyme, cells of the O-2A lineage were readily detectable in the migrating population. These results provide direct evidence that α 2-8 linked PSA contribute to the motility of O-2A, glial progenitor cells.

DEVELOPMENTAL MODULATION OF GLUTAMATE TOXICITY IN OLIGODENDROGLIA IN CULTURE. A. Oka, I.W. Lin, P.A. Rosenberg and J.L. Volpe. Children's Hospital and Harvard Medical School, Boston, MA 02115.

We have reported marked cytotoxicity of glutamate (GLU) to cultured rat oligodendroglia (OL) (J. Neurosci. 1993, 13:1441-1453). We now have addressed the developmental characteristics of this toxicity and the mechanisms of any such developmental vulnerability. We compared the effect of GLU on cells at day 3 after plating, consisting mainly of immature OL, with the effects on day 6 and day 9 cells, which are more mature (as judged by immunocytochemical criteria). EC₅₀'s for 24-hour exposures to GLU for day 3, 6, and 9 OL were 0.3 \pm 0.1mM, 2.7 \pm 1.6mM, and 7.0 \pm 0.4mM respectively. We next evaluated the mechanisms for this striking developmental vulnerability. Because we have shown previously that GLU-induced toxicity is mediated by GLU uptake and subsequent glutathione (GSH) depletion, we measured the reduction rates of GSH at different stages of OL development. Maximal reduction rate of GSH was observed at day 3, when OL were maximally vulnerable to GLU toxicity. Moreover, buthionine sulfoximine, an inhibitor of GSH synthesis, resulted in toxicity only at day 3 but not at days 6 or 9, suggesting that GSH is the critical antioxidative mechanism in immature OL only and that other antioxidative mechanisms develop during maturation. This notion was supported further by showing that GLU leads to accumulation of H₂O₂, visualized by 2'7'-dichlorofluorescein diacetate, presumably because the GSH depletion inhibits the GSH peroxidase (GSH-Px) reaction. In order to define the requirement for GSH further, we studied the development of GSH-Px and catalase (CAT), both scavengers of H₂O₂. While GSH-Px activity, if anything, decreased over the first nine days in culture, CAT activity increased from 24 μ mole H₂O₂/mg protein/minute at day 3 to 18 μ mole H₂O₂/mg protein/minute at day 6. In addition, 3mM 3-amino-1,2,4-triazole (AT), which inhibited catalase activity by 87 \pm 3%, enhanced GLU toxicity at day 9 (EC₅₀ = 3.9 \pm 0.5mM N=4). There was no effect of AT on GLU toxicity at day 3. These results suggest that the development of catalase activity may, in part, underlie the emergence of resistance to glutamate toxicity in OL in culture. (Supported by grants from the NIH and United Cerebral Palsy Foundation.)

EFFICIENT GENE TRANSFER INTO RAT AND DOG OLIGODENDROCYTES IN CULTURE. Z. Guo, S.S. Jiaot, L. Cheng, N.S. Yang, I.D. Duncan, J.A. Wolff. Dept. of Medical Science, SVM; Dept. of Pediatrics†, Waisman Center, Univ. of Wisconsin; Agracetus, Inc. §, Madison, WI 53706

In order to determine the optimal method of foreign gene transfer into primary cultures of oligodendrocytes, particle bombardment (Accell Gene Gun), cationic liposome-mediated transfection (Lipofectin, BRL), calcium phosphate precipitation, and retroviral infection were tried. Post-natal rat and dog brain tissue were mechanically and enzymatically dissociated. Highly enriched oligodendrocytes (>95% pure) were obtained by sequential immuno-panning with the O1 antibody. The most efficient expression of the β -galactosidase reporter gene was obtained with particle bombardment. Two days after bombardment with pCMVLacZ, 20% of the rat oligodendrocytes expressed β -galactosidase. 10% of the rat cells were positive after lipofection with pCMVLacZ. Less than 0.1% β -galactosidase-positive cells were observed after exposure of the rat cells to FGF (known to stimulate mitosis in these oligodendrocytes) and an amphotropic β -galactosidase retroviral vector (LTR-BGAL-SV40 prom.-NEO-LTR; titre > 10⁶/ml). Approximately 2% of the rat cells were positive after exposure of the rat cells to calcium phosphate precipitates of pCMVLacZ for four hours, but many of the cells died. Using the luciferase reporter gene, the highest expression was observed also with particle bombardment. Relatively large amounts of luciferase activity (~ 30 X 10⁶ total L.U.) was obtained after pCMVLux was bombarded into rat and dog oligodendrocytes. These levels were approximately 4- and 100-fold greater than that with the Lipofectin and calcium phosphate methods, respectively. Particle bombardment enabled similarly high levels of expression with hGH reporter gene. In conclusion, the ability to efficiently express foreign genes in primary cultures of oligodendrocytes will be useful for studies of oligodendrocyte function, promoter analysis and gene therapy. (Supported by NS23124)

MYELIN BASIC PROTEIN MRNA APPEARS NOT TO TRANSLOCATE IN SHARK OLIGODENDROCYTES. Robert M. Gould, NYS Inst. for Basic Res., Staten Island, N.Y. 10314

Sharks are the most primitive vertebrates that have a myelinated nervous system. Their sheaths, like those in mammals, contain two major proteins, myelin basic protein (MBP) and protein zero (P₀). CRNA probes, ³⁵S- and digoxigenin-labeled, localize mRNAs to MBP and P₀ to oligodendrocytes in sections of the spinal cords and medulla of adults and myelinating embryos. Both mRNAs were concentrated to the perinuclear regions of myelinating oligodendrocytes. This result is expected for P₀, since it requires posttranslational processing in perinuclear Golgi and because mRNAs for its mammalian counterpart, proteolipid protein is similarly localized to the perinuclear oligodendrocyte cytoplasm. In contrast, mammalian MBP mRNAs which are used in long oligodendrocyte processes, *in situ* hybridization studies have demonstrated a more diffuse distribution of its mRNA in tissue sections (Trapp et al, 1987). In the shark, MBP mRNA colocalizes with P₀ mRNA. These results indicate that MBP mRNA is not translocated to oligodendrocyte processes during shark CNS myelination and, hence, mRNA translocation is an event which appears at an evolutionary stage between sharks and mammals. (Supported by grant NS-13980).

MIGRATION AND DIFFERENTIATION OF TRANSPLANTED OLIGODENDROCYTE LINEAGE, VISUALIZED BY TRANSGENIC MARKER. V. L. Friedrich Jr., D.S. Rickman and R.A. Lazzarini. Brookdale Center for Molecular Biology, Mount Sinai Medical Center, New York, NY 10029.

Migration of transplanted oligodendrocytes or their progenitors into host CNS has been demonstrated in recipients experimentally or genetically dysmyelinated; however, the behavior of the oligodendrocyte lineage when transplanted into normal CNS remains largely unknown. To approach this problem, we have transplanted CNS bearing the MbetaP transgenic marker. This transgene, which encodes *E. coli* beta-galactosidase under control of a promoter/enhancer fragment from the gene for myelin basic protein, is expressed strongly and specifically in oligodendrocytes. Histochemical (X-gal), and immunostaining mark oligodendrocyte cell bodies and processes as well as myelin internodes.

Tissue pieces and dispersed cell suspensions transplanted from subependymal plate and olfactory bulb of perinatal MbetaP transgenic mice into brains of perinatal nontransgenic hosts yielded X-gal positive, myelin-bearing oligodendrocytes distributed over territories up to 4 mm across. Preparations placed in cerebral cortex yielded labeled cells in surrounding cortex and subcortical white matter but not in adjacent caudoputamen. Preparations placed in caudoputamen or thalamus myelinated deeper structures but yielded little myelination within subcortical white matter or cerebral cortex. These data suggest that migration of oligodendrocytes or their progenitors may be guided or restricted by mechanisms yet to be defined.

PROGRESSIVE DEMYELINATION IN THE TWITCHER SPINAL CORD. M.TANIKE AND K.SUZUKI* Department of Pathology, University of North Carolina, Chapel Hill, NC27599-7525

The twitcher (tw/tw) is an authentic murine model of human metabolic demyelinating disease, globoid cell leukodystrophy. We investigated the time course and distribution of demyelinating lesions in the spinal cord with LFB-PAS stain or immunohistochemistry using antibodies against MBP, MAG (s- and l-) and CNPase. Paraffin sections of tw/tw and age-matched controls were examined at 5-45 PND. At 5 PND, only l-MAG and MBP were expressed in the ventral columns and the fasciculus cuneatus. At 15 PND, immunostaining was dense throughout the white matter except for the corticospinal tract, where cauda-rostral gradient of myelination was observed. The myelin markers were expressed in the following order: l-MAG, MBP, CNPase and then s-MAG. There were no differences in the pattern and density of immunostaining between tw/tw and controls up to 15 PND. Around 20 PND, PAS(+) macrophages and demyelinated patches were first recognized in the ventral column of tw/tw. Generally aggregation of PAS(+) cells were coincided with the demyelinated lesions. MBP(-) lesions were discrete while MAG(-) or CNPase(-) lesions were more diffuse. Demyelination appeared to start in the ventral column, become the most extensive in the lateral column after 25 PND, and seems to be more prominent in the cervical and thoracic level than in the lumbar level. The results of this study suggest 1)early myelination is normal in tw/tw; 2)demyelination progresses in an orderly pattern in tw/tw. (Supported in part by U.S.P.H.S Grants NS24453, HD-03110 and ES-01104.)

EN SHEATHMENT AND EARLY MYELINATION OF RAT SPINAL AND CALLOSAL FIBERS. C. Bjartmar*, C. Hildebrand and K. Loider. Dept of Cell Biology, Faculty of Health Sciences, S-581 85 Linköping, Sweden.

Ensheathment and initial myelination of prospective large spinal cord (SC) ventral funicular axons and prospective small corpus callosum (CC) axons in rat, was examined by qualitative electron microscopy at different ages and serial section analysis of individual glial units at two specific developmental stages. The results show that ensheathment commences 19 days after conception in the SC and 12 days postnatally (P 12) in the CC. Multipolar SC and CC oligodendrocytes provide axons with uncompacted cytoplasmic sheaths through slender processes with various lengths. Other axons (not counted) were contacted but not ensheathed by oligodendroglial processes. The average number of axons ensheathed by each cell was 7 in the SC and 13 in the CC. The mean diameter of ensheathed axons was 0.72 μ m in the SC and 0.35 μ m in the CC. Myelin sheaths (4-8 lamellae) appear at birth and at P 17 in the SC and CC respectively. The mean number of myelinated axons per oligodendrocyte was 3 in the SC and 15 in the CC. The mean diameter of myelinated axons was 1.04 μ m in the SC and 0.54 μ m in the CC. The average midnuclear-midaxonal distance increased 1.4 times in the SC between ensheathment and myelination, while it remained unchanged in the CC. Our results suggest that ensheathing spinal oligodendrocytes contact fewer axons than ensheathing cerebral cells do and that this difference increases with time. It seems that ensheathing spinal oligodendrocytes reduce the number of axonal contacts when they shift from cytoplasmic ensheathment to formation of compact myelin.

TRANSFORMING GROWTH FACTORS- β 1 AND - β 2 SLIGHTLY INHIBIT SCHWANN CELL PROLIFERATION IN NEURON/SCHWANN CELL CO-CULTURES. V. Guenard* and P.M. Wood. The Miami Project & Depart. Neurol. Surg., Univ. Miami School Med., Miami, FL.

Transforming growth factor- β 1 and - β 2 (TGF- β 1, - β 2) are mitogens for Schwann cells (SCs) in culture. However, SCs are always associated with neurons in vivo. In this study, the influence of TGF- β 1 and - β 2 on neuron-induced SC proliferation and myelination was evaluated. Cultures of purified embryonic rat dorsal root ganglion (DRG) neurons were seeded with sciatic nerve-derived SCs. To assess proliferation, serum-free medium supplemented with TGF- β 1 or - β 2 (0-10.0 ng/ml) were tested on SC, DRG/SC or CCL-64 mink lung (Mv1Lu) cells. After 48 hours, the cultures were exposed to [3 H]-thymidine (0.5 μ Ci/ml) and proliferation assessed by autoradiography. As previously observed, TGF- β 1 enhanced the proliferation of isolated SCs in a dose-dependent fashion. In contrast, both TGF- β 1 and - β 2 slightly inhibited SC proliferation on DRG neurites in a dose-dependent fashion. TGF- β 1 and - β 2 affected Mv1Lu cells as expected, by inhibiting their proliferation. The influence of both TGF- β 1 and - β 2 was partially inhibited by their respective specific antibodies (0.1-10.0 μ g/ml). For the myelination assay, the cultures were maintained in serum-free feed containing laminin and TGF- β 1 or - β 2 (0-10.0 ng/ml). In a single experiment carried to date, neither TGF- β 1 nor - β 2 show a significant effect on myelination. This study demonstrates that TGF- β 1 and - β 2 are slight inhibitors of SC proliferation on DRG neurites and do not either promote or inhibit myelination. Our data suggest that the response of SCs to TGF- β depends on whether neurons are present or not. Although TGF- β does not seem to induce either SC proliferation or myelination, TGF- β could function by partially controlling the arrest of SC proliferation, a necessary step for SC differentiation. TGF- β could also stimulate SC division in response to injury when axonal contact is lost. Supported by NIH grant NS28059, NMSS grant RG 2210-A-2 and The Miami Project.

TRACER-COUPPLING REVEALS THREE CLASSES OF OLIGODENDROCYTE IN RABBIT RETINA. E.C.G.M. Hampson, S.R. Robinson and D.I. Vanev*. Vision, Touch and Hearing Research Centre, The University of Queensland, Australia 4072.

Oligodendrocytes myelinate CNS axons and form gap junctions with astrocytes, suggesting communicative and/or metabolic support roles. We examined the morphology and gap junction permeability of oligodendrocytes injected with the biotinylated tracers, biocytin (373 Da) and Neurobiotin (286 Da). Rabbit retinae were incubated for 20 min in Ames medium with the fluorescent dye Hoechst 38317, to label the morphologically distinct nuclei of astrocytes and oligodendrocytes. Individual cells near the edge of the medullary rays were injected (+0.5 nA, 1-2 min) with tracers under direct microscopic control. Oligodendrocytes were identified by their characteristic morphology (Butt & Ransom, *Glia* 2: 470-475, 1989) and the absence of immunoreactivity for anti-GFAP, which selectively labels astrocytes. We distinguished three morphological classes of oligodendrocyte. "Standard" oligodendrocytes comprised 38% of the injected population and have processes which run parallel to axons in the nerve fibre layer (NFL). "Radial" oligodendrocytes (16%) have dendrites that radiate in all directions within the NFL; they terminate in spines and varicosities. "Bilaminar" oligodendrocytes (46%) have dendrites extending parallel to axons in the NFL, and a second arbor of radial processes in the inner plexiform layer. Radial and bilaminar cells rarely tracer-coupled, whereas 50% of the standard cells were coupled to about 30 nearby oligodendrocytes and astrocytes. Thus, small molecules can pass from standard to radial and bilaminar oligodendrocytes, but not back the other way. These findings suggest that these morphologically distinct classes are also functionally distinct. Supported by ARC & NHMRC.

DISRUPTION OF FAST AXONAL TRANSPORT IN VIVO LEADS TO ALTERATIONS IN SCHWANN CELL GENE EXPRESSION. W. Wu, J.G. Toma, H. Chan, R.S. Smith, and F.D. Miller* Dept. Anat & Cell Biol., University of Alberta.

Following nerve injury, Schwann cells distal to the site of injury downregulate genes associated with myelination. We hypothesized that at least some of these alterations were due to the loss of ongoing homeostatic signals that were transduced as a function of fast axonal transport. To directly address this hypothesis, we selectively blocked fast axonal transport *in vivo* by locally-cooling the sciatic nerve to 5-8° C (a cold block). Immunocytochemistry, light and electron microscopy show that macrophages do not invade the cold-blocked nerve, and that the nerve distal to the cold block shows no signs of Wallerian degeneration, with maintenance of normal axon and myelin profiles. Thus, any effects of the cold block treatment are not likely due to nerve injury, inflammatory responses, or loss of physical contact between axons and Schwann cells. To determine whether this treatment affected nonneuronal cells, we examined expression of the major myelin protein P₀ and p75 NGF receptor, both of which are regulated as a function of Schwann cell:axon contact. Levels of p75 NGF receptor mRNA and protein were unaffected by the cold block. In contrast, levels of P₀ mRNA were decreased in the distal nerve in a fashion similar to that observed following axotomy. These data suggest that P₀ and p75 NGF receptor are regulated as a function of two different aspects of Schwann cell:axon communication, one of which involves maintenance of normal fast axonal transport. Furthermore, these data demonstrate that at least some of the axotomy-induced alterations in the peripheral nerve are not due to either macrophage infiltration or Wallerian degeneration, but to disruption of ongoing homeostatic mechanisms.

PURIFICATION OF P₀ AND ITS INTRACELLULAR COOH-TERMINAL DOMAIN. Y. Ding, S. L. Yates*, K. R. Brunden. Univ. Miss. Med. Ctr., Jackson, MS 39216 and Gliotech, Inc., Cleveland, OH 44122

P₀, the major protein of peripheral myelin, has been proposed to play a role in myelin membrane apposition. Little is known about the role of the cytoplasmic domain of P₀ in the formation of the myelin major dense line. We have developed procedures for the rapid purification of P₀ and subsequent isolation of a proteolytic fragment comprising the intracellular domain of this protein. Rat sciatic nerve endoneuria were homogenized in PBS and centrifuged at 160,000 x g. The resulting membrane pellet was homogenized in PBS containing 3% Triton X-100, and the detergent-solubilized proteins were applied to a cellulose phosphate column. The loosely bound proteins were eluted with PBS containing Triton X-100, and P₀ was subsequently removed with buffer containing Triton X-100 and 0.6 M NaCl. Since the intracellular portion of P₀ has only one tryptophan, cleavage at the carboxyl side of this residue with iodosobenzoic acid should give rise to a fragment containing the COOH-terminal 65 amino acids (C-fragment) of the 69 residue cytoplasmic domain. P₀ was cleaved with iodosobenzoic acid in 4 M guanidine-HCl/80% acetic acid at room temperature for 36 to 48 hour. The cleavage reaction was terminated by adding dithioerythritol, and the digest was dialyzed against 2 M NaCl. The dialysate was passed through SM-2 resin to remove residual detergent, and the detergent-depleted sample was dialyzed against PBS and subsequently applied to a DE 52 column. The C-fragment was specifically eluted from the column using a step NaCl gradient. The availability of a peptide comprising the intracellular domain of P₀ will expedite studies aimed at elucidating the role of P₀ in the formation of the myelin major dense line. (NS27587)

THE PROLIFERATION OF SCHWANN CELLS BY MBP-RELATED PEPTIDES IS ENHANCED BY FORSKOLIN AND b-FGF

S.F. Tzeno¹, G.E. Deibler², G.R. Leichnetz^{3*}, and G.H. De Vries¹. ¹Dept. of Biochem., MCV, Richmond, VA 23298-0614. ²NIH, Building 36, Room 1A-05, Bethesda, MD 20892. ³Dept. of Anat., MCV, Richmond, VA 23298-0709.

Macrophages treated with myelin enriched fraction (MEF) produced a conditioned media (MEF-Macro CM) which has been shown to be mitogenic for Schwann cells (SCs) (PNAS, 85, 1701, 1988). Myelin basic protein (MBP) incorporated into liposomes also stimulated SC proliferation *in vitro* (BBRC, 164, 883, 1989). MBP alone (3µM) was not mitogenic for quiescent SCs. Forskolin (1µM) or bFGF (1ng/ml) was a weak mitogen for SCs. Simultaneous addition of forskolin or b-FGF with MBP markedly increased the mitogenicity of MBP for SCs. In contrast to MEF, the mitogenic effect of MBP was not decreased by the addition of NH₄Cl indicating that the response of SCs to MBP did not require lysosomal processing. Forskolin also potentiated the mitogenic effect of MBP fragment 1-88 and 89-169. Relative to MBP 1-88, MBP 89-169 was a weaker SC mitogen and required a longer time to stimulate SC proliferation. Stimulation of SCs with MBP peptide 1-36 or 1-42 yielded a dose-dependent increase in SC proliferation. Peptide 37-88 or 43-88 was not mitogenic for SCs. Addition of MBP or Macro-MEF CM with varying concentrations of bFGF to SC demonstrated a marked increase in the mitogenicity. The increase in mitogenicity was maximal at 0.1ng/ml b-FGF. Therefore, we postulate that elevated intracellular cAMP in SCs can modulate the subsequent mitogenic response to MBP-related peptides. b-FGF was able to synergistically increase the mitogenic effect of MBP or Macro-MEF CM. One mitogenic region of MBP is contained in the initial 42 residues. b-FGF or forskolin may play a critical role in up-regulating the receptor for MBP. (Supported by NS15408)

SCHWANN CELLS IN CONTACT WITH NEURONS MAINTAIN AN ATP-MEDIATED CALCIUM RESPONSE. S.A. Lyons¹, P. Morell^{1*} and K.D. McCarthy². Biochemistry and Biophysics¹ and Pharmacology² Depts. University of North Carolina at Chapel Hill, NC 27599

Unique exchanges of information occur between Schwann cells (SC) and axons that affect the development, maintenance and repair of the peripheral nervous system. We were interested in examining neurotransmitter-activated calcium signaling systems of SC during development. We demonstrated previously that 80-90% of freshly-isolated neonatal rat sciatic nerve SC responded to 10µM ATP with an increase in [Ca²⁺]_i. The ATP-induced calcium response appeared to be mediated by purinergic P₂Y receptors. The ATP calcium response disappeared with time *in vitro* but could be recovered by growing SC in medium containing cyclic AMP analogs (i.e., dibutyryl-cAMP and 8Br-cAMP) and 1% fetal bovine serum. Immunostaining results indicated that these SC (S100β⁺) had differentiated toward the myelinating phenotype (P₀⁺, 192IgG (NGFR)⁻, O1⁺). These results suggested that cAMP analogs were necessary for the reappearance of SC sensitivity to ATP in culture and the development of SC stage-specific markers. Neuronal contact has also been reported to upregulate the same SC markers. Together, these findings led us to hypothesize that contact with neurons would upregulate SC calcium responsiveness to P₂Y purinergic stimulation. To test the hypothesis, SC were introduced into cultures of purified neurons prepared from rat E15 DRG. Results of these experiments indicated that SC recovered the ability to respond to ATP with increases in [Ca²⁺]_i when in direct contact with neurons. In addition, there was no ATP response in cocultured SC not in contact with neurites. SC were tested for ATP responses after 6d in the presence of neurons and again after 35d when myelin was present. These data suggested that contact with neurons (which may raise cAMP levels) was necessary for the expression of the ATP-mediated calcium response. Further studies will address the question of what population(s) of SC are responding to ATP (myelinating, non-myelinating or both). NS11615

SEROTONIN RECEPTORS ON CULTURED SCHWANN CELLS. E. Yoder¹, V. Lev-Ram¹, and M. H. Ellisman. San Diego Microscopy and Imaging Resource, Departments of Neurosciences and ¹Pharmacology, University of California, San Diego, La Jolla, CA, 92093-0608.

[Ca²⁺]_i transients were measured on primary cultures of rat Schwann cells loaded with the calcium indicator dye fluo-3 introduced via its AM ester. We have previously reported that some cells transiently increase their [Ca²⁺]_i in response to cholinergic agonists, and that these transients were antagonized by curare [Yoder *et al.*, NS Abstr. pg. 1489, 1992]. We now report that a subpopulation of cells respond to pharmacological manipulation in manners consistent with the expression of 5-HT_{1C} or 5-HT₂ receptors. 5-HT elicited a dose-dependent transient increase in [Ca²⁺]_i in many cells. Transients were induced by exposure to concentrations of 5-HT as low as 10nM. A few of these responding cells began oscillating when exposed to a minimal dose of 1µM 5-HT. The 5-HT-induced transients, which occurred in the absence of [Ca²⁺]_o (with 0.5 mM EGTA), were blocked by ketanserin. The calcium source of transients occurring in 0 [Ca²⁺]_o is likely to be from IP₃-sensitive intracellular calcium stores, since thapsigargin, but not caffeine, increased [Ca²⁺]_i and prevented further 5-HT-induced [Ca²⁺]_i transients. Current studies attempt to correlate the cells' stage of differentiation with expression of the 5-HT-induced [Ca²⁺]_i transients.

PMP22 MODULATES GROWTH OF SCHWANN CELLS.

G. Zoidl, C. Schmalenbach, D. D'Urso and H.-W. Müller*. Molecular Neurobiology Lab., Dept. of Neurology, University of Düsseldorf, FRG.

The peripheral myelin protein PMP22 has recently been cloned. The expression pattern of PMP22 during development, nerve regeneration and in adult tissues follows that of known myelin proteins like Po and MBP. Mutations within the PMP22 coding region in mice (*trembler, tremblerJ*) or chromosomal rearrangements in man (*Charcot-Marie-Tooth Typ1a, HNPP*) affect myelination in PNS. Sequence homologies to the growth-arrest-specific gene gas3 suggest potential growth regulatory functions for PMP22. In order to study the function(s) of PMP22 in myelination and/or Schwann cell growth we established recombinant Schwann cells with altered PMP22 expression by retroviral mediated gene transfer. A set of vectors with partial PMP22 cDNA sequences in both sense or antisense orientation under control of an internal CMV promoter were constructed. Cell culture supernatants collected from high titer Psi2 producer cell lines were used to infect secondary Schwann cell cultures. Selected G418-resistant cells were characterized for either constitutive overexpression or depletion of PMP22 mRNA and protein expression. Schwann cell proliferation is significantly reduced when PMP22 expression is increased. Conversely when PMP22 is expressed at lower than normal levels the proliferation rate of the recombinant Schwann cells is slightly increased. Our results show that recombinant Schwann cell lines with the described alteration in PMP22 expression are a useful tool to elucidate the mechanisms by which PMP22 can modulate cell growth. Using the same cells in an *in vitro* myelinating cell culture system will allow us to investigate the role of PMP22 in myelination of peripheral axons. (Supported by BMFT and F. Thyssen-Stiftung)

CLONING AND EXPRESSION OF BASIC HELIX-LOOP-HELIX PROTEINS FROM THE MAMMALIAN CENTRAL NERVOUS SYSTEM. A. Bartholomä, A. Pühlhofer, M. Rossner, M. Schwab, M. Klugmann, and K.-A. Nave*. Center for Molecular Biology (ZMBH), University of Heidelberg, D-6900 Heidelberg, Germany.

Transcription factors, structurally related by the helix-loop-helix (HLH) domain and a basic DNA binding site, determine cell lineage and differentiation of drosophila proneural stem cells. The finding of mammalian homologues for the drosophila genes *achaete-scute*, *hairy*, and *enhancer-of-split* suggests that bHLH proteins are also involved in vertebrate neural determination. To identify bHLH proteins regulating the later stages of neuronal and glial development in mammals, we have used highly degenerate primers to PCR amplify novel bHLH sequences from adult brain cDNA. One such clone encodes NEX, a brain-specific bHLH protein that is highly abundant in adult hippocampal pyramidal neurons and throughout the neocortex. In the embryo, NEX expression is restricted to postmitotic neurons which have migrated out of the ventricular zone and form the cortical plate. NEX expression peaks at the time of maximal synaptogenesis in the first postnatal week. Another novel protein identified in this screen is encoded by a mRNA that is most abundant in the CNS and gradually increases throughout brain development, peaking in the adult. A shorter isoform of its transcript is specifically expressed in glial cells of the O-2A lineage. Finally, we screened a λgt11 expression library to clone the bHLH protein that binds to the single E-box target sequence footprinted in the promoter of the PLP gene. Sequence analysis suggests that it may be the rat homologue of TFE3, a bHLH-leucine zipper protein also expressed in cells of the immune system. (Supported by the BMFT #0316000A)

KINESIN mRNA IS PRESENT IN THE SQUID GIANT AXON. A.E. Gioio*, J.T. Chun, J. Panza, M. Crispino, C. Perrone Capano, A. Giuditta and E.B. Kaplan. Dept. Psychiatry, Univ. Pittsburgh School of Medicine, Pittsburgh, PA 15213 and Dept. Gen. Physiology, Univ. Naples, Naples, Italy.

Previously, we reported that the squid giant axon contains a heterogeneous population of mRNAs and polyribosomes (Giuditta *et al.* 1991 *J. Neurosci. Res.* 28:18). Two of these mRNAs have been characterized and encode β-actin and β-tubulin (Kaplan *et al.* 1992 *Mol. Cell. Neurosci.* 3:133). To further characterize the axonal mRNA population, an axonal cDNA library was screened using a squid kinesin clone as a probe. The sequence analysis of several positive clones manifested >98% sequence identity to squid heavy chain kinesin (Kosik *et al.* 1990 *J. Biol. Chem.* 265:3278). Results of *in situ* hybridization histochemistry using [³⁵S]labeled riboprobes established the axonal location of kinesin mRNA. To explore the biological significance of this finding, polysomes were isolated from the giant axon, and kinesin sequences amplified from the RNA using PCR methodology. The results of this experiment clearly demonstrate the presence of kinesin RNA sequences in the polyribosome fraction. Taken together, these findings demonstrate that kinesin mRNA is present in the squid giant axon, and raises the possibility that key elements of the axonal transport system are locally synthesized in the squid giant axon.

461.3

HIPPOCAMPAL EXPRESSION AND ALTERNATIVE SPLICING OF HZF-2, A NOVEL MEMBER OF THE THYROID HORMONE RECEPTOR FAMILY. G.A. Jamieson Jr. and S. Peña de Ortiz* Toxicology Program, Department of Environmental Health, University of Cincinnati College of Medicine, Cincinnati, Ohio 45267-0056.

Signal-transcription coupling is hypothesized to be a major mechanism governing long-term hippocampal responses to stimulation or injury. In the current study, our goal was to isolate rat hippocampal cDNAs which encode novel members of the superfamily of ligand-dependent transcription factors. Our cloning strategy took advantage of the high degree of homology which exists between the zinc finger regions of these nuclear receptors. This approach resulted in the isolation of twelve cDNA clones encoding the DNA binding domain of nuclear hormone receptors, including two novel isolates, HZF-2 and HZF-3. Full length HZF-2 and HZF-3 cDNA clones were isolated from a rat hippocampal library. Sequence analysis revealed HZF-2 to be highly homologous to EAR-1, an ERB-A related orphan receptor. The DNA binding domain of HZF-2 is 90% homologous to that of EAR-1. Reverse transcription-PCR (RT-PCR) analysis was used to study the brain distribution of HZF-2 and determined HZF-2 to be preferentially expressed in the rat hippocampus (hippocampus >> cerebellum >>> cortex). Interestingly, we obtained several clones for HZF-2, varying in size from 2.0 to 1.0 kb, suggesting this gene may be alternatively spliced. Northern blot analyses support this hypothesis. RT-PCR is being used to further examine the expression of multiple HZF-2 isoforms in the brain. *In situ* hybridization analysis will complement these studies and enhance our understanding of the spatial distribution of HZF-2 isoforms. These experiments will assist our assignment of potential functional roles to HZF-2 mediated regulation of gene expression in the hippocampus. Supported by ONR N00014-90-J-1898, NIMH Minority Fellowship, Ford Foundation Minority Dissertation Fellowship.

MOLECULAR CHARACTERIZATION OF NeuN, A NOVEL NEURONAL NUCLEAR PROTEIN. D.L. Somers, M.J. Ghosh and C.R. Buck*. Dept. of Cell Biology and Anatomy, Medical Univ. of SC, Charleston SC 29425.

NeuN is a nuclear protein, identified with monoclonal antibody (MAB) A60, that is specifically expressed by vertebrate neurons. The expression of the protein is developmentally regulated, appearing in most mouse neurons immediately following withdrawal from the cell cycle and maintained thereafter. Biochemical analysis of NeuN indicates that it is a soluble nuclear phosphoprotein capable of binding to DNA in a specific manner that is similar to that of known transcription factors. In order to obtain a full length cDNA clone which will allow direct assessment of the functional role of this protein, MAb A60 was used to isolate a cDNA clone from a gt11 expression library. This initial cDNA (1Kb) has been sequenced, confirmed with independent clones from different libraries, and represents about 2/3 of a 1.6Kb mRNA identified by RNA blot analysis. An open reading frame has been identified, but the 5' end of the NeuN cDNA has been refractory to characterization. Genomic Southern blot analysis indicates that this protein is encoded by a single copy gene. Analysis of a mouse NeuN genomic clone and overlapping but divergent cDNA clones indicates that the epitope-encoding sequence may be but one of multiple 5' splicing alternatives. One splice alternative contains two exons not present in our original cDNA. Alternative splicing of NeuN is consistent with immunoblot analysis of mouse brain nuclear proteins indicating three immunoreactive species of 46 to 48Kd, and with primer extension studies suggesting multiple 5' ends for this mRNA. To confirm the authenticity of the putative NeuN cDNA sequence to date, *in situ* hybridization was performed on adult rat brain tissue sections using an antisense oligonucleotide probe that will hybridize to at least two splice alternatives. Film autoradiograms revealed hybridization of this probe over most of the same brain regions identified immunohistochemically with MAb A60. Comparison of the sequence for both splicing alternatives to the sequence databases revealed no significant homologies, supporting the suggestion that NeuN is a novel neuronal nuclear protein. Supported by NIH NS31011 and MUSC 22040CR25.

MOLECULAR CLONING OF AN ORPHAN RECEPTOR cDNA FROM OVINE PITUITARY GLAND. M. I. Masana*, R.C. Brown, M.E. Gurney and M.L. Dubocovich. Depts. Pharmacol. and Cell.Mol.Biol., Northwestern Univ. Med. Sch. Chicago, IL 60611

Using degenerate primers designed for the polymerase chain reaction (PCR) based on homologies in the II and VII transmembrane domains between the members of the G-protein receptor (GPR) gene family (Cell 65:175, 1991), we successfully cloned a novel cDNA receptor sequence from the ovine pituitary gland. Template cDNA was obtained by reverse transcription of mRNA from the pituitary stalk (PS) in a block of tissue containing also portions of median eminence and pituitary pars nervosa / pars distalis. The cDNA clone (S856) has a single open reading frame which when translated has a pattern of repeating hydrophobic domain that resemble the membrane spanning domains of GPR sequences and is 56 % homologous over its length to another orphan sequence from human endothelial cells named endothelial differentiation gene: edg-1 (J.Biol.Chem. 265:9308, 1990). Using a random primed ³²P-DNA probe of S856 we screened a size-selected cDNA ovine pars tuberalis library prepared in the plasmid expression vector pCDNA1 and cloned a sequence of 2500 bp that contains the S856 sequence (edg-2). By Northern analysis of poly(A)⁺mRNA we found that a transcript of 1.7 kb was present in the ovine PS, pituitary pars nervosa / distalis, retina and cerebral blood vessels. In addition, cDNAs from these tissues and hypothalamus were amplified by PCR using internal oligonucleotide primers and a product of the expected size (415 bp) was observed. Edg1 and edg-2 appears to be distinct genes which may encode protein products that bind the same ligand. Supported by NIH grants: MH42922 (MLD), T32-NS07140 (RCB) and a Glaxo grant

SOMATIC DNA CHANGES IN IMMORTALIZED NEURAL CELL LINES. A.L. Barth¹, M.E. Lim¹, B.H. Morimoto^{1*}, E.W. Hodf¹, E.M. Eyes², M.R. Rosner², B.H. Wainer², and H. Sakano¹. ¹Dept. Mol. and Cell Biol., Univ. of Calif. - Berkeley, Berkeley, CA 94720 and ²Dept. Pharm.-Phys., Univ. of Chicago, Chicago, IL 60637.

Transgenic mice were made carrying a recombination reporter gene consisting of recombination signal sequences from immunoglobulin genes flanking lacZ, where inversion of the transgene through recombination can activate lacZ transcription. LacZ expression was detected in lymphoid tissues as well as discrete regions of the brain, and DNA rearrangement was verified by PCR amplification of the recombination breakpoints. Stable transfection of immortalized CNS cell lines with the same recombination substrate showed activation of the reporter gene and the presence of PCR-amplifiable recombination breakpoints. A transfected glial line showed a significantly lower percentage of β-gal positive cells. In both the transgenic and tissue culture systems, the neural-specific recombination event appears different from V(D)J-type recombination in its site-specificity. In addition, RAG-1 expression in at least one transfected neural line showing reporter gene activation was undetectable by northern and RT-PCR, suggesting that RAG-1 is not required for this type of DNA rearrangement. Detection of a recombination activity in neural cell lines allows their use as a tool to analyze the specificity and regulation of this reaction.

CHARACTERIZATION OF HUMAN BRAIN SEPIAPTERIN REDUCTASE (SR) cDNA. R.A. Levine^{1,2,4}, P.Z. Anastasiadis¹, S. K. Demetriou¹, J.C. and States³. ¹William T. Gossett Neurology Labs of Henry Ford Hospital, ²Cellular and Clinical Neurobiology Pgm, Dept. of Psychiatry, Wayne State University (WSU), ³Center for Molecular Biology, WSU, Detroit, MI, and ⁴Veterans Administration, Allen Park, MI.

Sepiapterin reductase (SR) catalyzes the final reaction in the synthesis of tetrahydrobiopterin (BH₄), the cofactor for tyrosine and tryptophan hydroxylases in dopamine and serotonin synthesis. Cloning of human SR gene will allow the study of altered genetic expression of BH₄ biosynthetic enzymes in neuropsychiatric illnesses caused by altered biogenic amine metabolism. We have recently cloned the cDNA encoding human brain SR (1630 bp) and compared this with the rat liver (1157 bp) and human liver (833 bp) cDNAs. The open reading frames of human brain and liver cDNAs are identical. Human brain SR cDNA contains 260 bp of 5' upstream untranslated region (compared with 22 bp in human liver) and 569 bp of 3' downstream untranslated region (compared with 25 bp in human liver). There are several potential regulatory elements in 5' untranslated region of the human brain cDNA; there is a 78% nucleotide homology and 68% amino acid homology with rat liver SR cDNA. Northern blot analysis of rat and human liver RNA demonstrated that there was weak cross-hybridization of rat and human SR cDNA with mRNA from the opposite species. Human brain SR mRNA was slightly larger than rat SR mRNA. Current studies are focused on comparing human brain and liver mRNA, measuring SR mRNA in neurological diseased postmortem human tissue, and isolating the human SR gene.

461.8

Cloning and molecular characterization of the mouse astrocyte glycogen synthase

G. Pellegrini, C. Rossier, S. de Rham, P.J. Magistretti and J.-L. Martin*. Institut de Physiologie, Université de Lausanne, Switzerland

In the brain, glycogen is predominantly localized in astrocytes, although its presence has been detected in certain large neurons, in ependymal and choroid plexus cells. Glycogen is synthesized by the enzyme glycogen synthase (GlyS) from UDP-glucose. Out of the different isozymes, only the muscle and the liver forms of GlyS have been cloned. We have isolated and characterized from a mouse astrocyte λZapII cDNA library, a cDNA clone encoding the mouse cerebral cortical astrocyte GlyS. The 3.5 kb clone isolated contains an open reading frame of 2214 bp encoding a protein of 738 amino acids. The predicted molecular weight of the astrocyte GlyS (83.6 kDa) corresponds to that of the enzyme purified by HPLC from canine brain (88 kDa) (Inoue et al., 1988). The coding region of the mouse astrocyte GlyS cDNA shares 87% and 86% identity with the nucleotide sequences of the human muscle and the rabbit muscle GlyS cDNAs respectively. At the amino acid level the identity is even more striking with 95.5% and 96.6%. GlyS activity is regulated by phosphorylation. Out of the nine phosphorylation sites identified *in vivo* for the rabbit muscle GlyS, all are conserved in the mouse astrocyte GlyS. The cellular distribution of the GlyS mRNA studied by Northern blotting shows the presence of a single transcript of 4 kb both in astrocytes and neurons.

We are currently examining by *in situ* hybridization the regional distribution of the astrocyte GlyS mRNA in the mouse brain. Inoue, N. et al. (1988) J. Neurochem. 50 (2), 400-405.

461.9

CLONING AND EXPRESSION OF RAT ASTROGLIAL INDUCIBLE NITRIC OXIDE SYNTHASE. **E. Galea***, **D.J. Reis**, and **D.L. Feinstein**, Division of Neurobiol., Dept of Neurol. and Neurosci., Cornell University Medical College, New York, NY 10021.

Rat cortical astrocytes in primary cultures express a nitric oxide synthase (aNOS) that is reminiscent of the macrophage enzyme in its biochemical characteristics and inducibility by cytokines and bacterial endotoxin (LPS).

To determine the sequence of the aNOS mRNA, a cDNA library was prepared from astrocytes exposed to LPS for 5 hours, and one million plaques were screened at low stringency (42 °C, 2xSSC) with a fragment of the mouse macrophage NOS cDNA that spanned the two NADPH binding sites. The longest clone isolated and sequenced contained a 2.0 kb-insert corresponding to the carboxyl terminus of the NOS protein, as well as the entire 3' untranslated region. Additional DNA sequence was obtained with polymerase chain reaction (PCR) amplification of upstream regions using degenerate primers directed against highly conserved areas amongst all NOS proteins. The combined DNA sequences reveal that at the coding region the rat aNOS mRNA is 92% identical to the NOS mRNA expressed in mouse macrophages, while the identity between untranslated regions is 81%. The deduced amino acid sequence shows 93% identity between the NOS's from rat astrocytes and mouse macrophages, 70% of the substitutions being conservative.

A quantitative PCR assay has been developed to evaluate expression of aNOS mRNA *in vivo* and *in vitro*, using primers that flank a 400-bp segment at the end of the translated region. A PCR product of the expected size was detected in cultured astrocytes and in the rat C6 glioma cell line after a 4-hour exposure to LPS and LPS and interferon- γ , respectively, while no product was obtained in untreated cells. This assay is being used to analyze the regulation of aNOS mRNA expression by cytokines and neurotransmitters in brain samples.

461.11

Characterization of M6 and Identification of a PLP/DM2 gene family

Y. Yan*, **C. Lagenaar**, and **V. Narayanan**, Departments of Neurobiology and Pediatrics, University of Pittsburgh, Pittsburgh, PA 15261

M6 is a membrane glycoprotein which is expressed on central neurons and certain polarized epithelia from early developmental stage. Antibodies against M6 interfere with cerebellar neurite outgrowth *in vitro*. Two closely related cDNAs, M6a and M6b, were obtained by expression cloning, both of which showed high homology to the major CNS myelin protein PLP/DM20. Although M6 clones and PLP/DM20 share many molecular characteristics, *in situ* hybridization revealed nonoverlapping distributions of their mRNAs in mouse CNS, in agreement with previous results that M6 is expressed on neurons in CNS while PLP/DM20 is present on oligodendrocytes.

Preliminary functional studies of M6 protein showed that M6 antibody affected cerebellar neurite outgrowth when the cells were grown on polylysine and laminin but had less effect on those grown on L1. Antisense oligodeoxynucleotide, supposedly inhibits M6 expression, significantly decreased neuron survival in culture.

The identification of a gene family including neuronal specific M6 and glial specific PLP/DM20 in CNS and the importance of M6 for cell survival revealed by cell culture studies suggest a broader functional role for these molecules than myelination.

461.13

HUMAN OMP GENE: CLONING AND *IN SITU* LOCALIZATION.

O. Buiakova¹, **N.S. Rama Krishna²**, **H. Baumeister¹**, **M.L. Getchell³**, **T.V. Getchell^{2,3}**, and **F.L. Margolis¹**, ¹Roche Inst. of Molecular Biol., Nutley, NJ 07110; ²Dept. of Physiol. & Biophys., ³Div. Otolaryngol. Dept. of Surgery, Univ. of Kentucky College of Medicine, Lexington, KY 40503.

We have cloned the genes for olfactory marker protein (OMP) from human, mouse and rat to study conserved sequences that may be associated with gene regulation and the encoding of functional protein domains. OMP is expressed primarily in mature olfactory receptor neurons. The coding regions from the three species were highly conserved. The 162 amino acid OMP protein differs by 3 amino acids in rat vs. mouse and by 17 amino acids in rat vs. human. Almost all the substitutions are conserved. Nucleotide identity was very high in the 5' untranslated region of rat and mouse genes. In human, the first 400 bp upstream to the ATG codon had 75% identity to the rat and mouse, whereas further upstream, the identity was 50%. The 5'-upstream promoter regions of the OMP genes had highly conserved Olf-1 binding motifs (Kudrycki et al., Mol. Cell. Biol., May, 1993). Olf-1 may regulate OMP expression. Another potential regulatory motif, UBE, was identified in rat, mouse and human OMP genes. Olf-1-binding sites and UBEs from the human and mouse genes bound proteins from rat olfactory epithelium, and were competed by the corresponding rat sequences. Initial data indicates UBE contains NF-1 binding activity. Expression was studied in human olfactory epithelium with *in situ* hybridization using human OMP cRNA probes. Hybridization signal was localized specifically in olfactory receptor neurons, but not in other cell types in olfactory or respiratory mucosae. *In situ* localization of OMP mRNA was congruent with the immunocytochemical localization of the protein in human olfactory receptor neurons. Supported by NIH grants DC-00159 (TVG) and DC-001715 (MLG).

461.10

SUBTRACTION CLONING OF CEREBELLAR GENES.

Vinodh Narayanan, M.D.*, Departments of Pediatrics and Neurology, The University of Pittsburgh, Pittsburgh, PA.

The granule cells of the cerebellum arise from the external germinal layer (EGL), a structure that persists into the postnatal period. Cells from the pre-migratory zone of the EGL migrate along the surface of Bergmann glial processes to the internal granule cell layer. We have undertaken a molecular biologic approach to isolate genes expressed in differentiated granule cells, and those activated during granule cell differentiation and migration.

Following Altman, et al, we used focal, low-dose X-irradiation of newborn rat pups to ablate the granule cells. Within these agranular cerebella, the Purkinje cells occupied several layers and were mis-oriented. We then extracted mRNA from normal P12 rats (CTRL) and irradiated P12 rats (RADS), constructed directional cDNA libraries in λ ZAP II (Stratagene Inc.), and used these to generate a subtracted cDNA library (CTRL minus RADS). We have screened this library for clones absent from the RADS mRNA, and have identified differentially expressed clones, by Northern blot analysis. The spatial distribution of the corresponding mRNAs are being analyzed by *in situ* hybridization. This approach will allow us to study gene expression during neuronal differentiation.

461.12

TRANSGENIC ANALYSIS OF THE OMP PROMOTER. **E. Walters, M. Grillo***, **K. Kudrycki**, **C. Bocchiaro**, **A. Phillips**, **F.L. Margolis**. Roche Institute of Molecular Biology, Nutley, N.J., 07110, USA.

This laboratory previously reported the presence of putative novel transcriptional regulatory sequences in the 5' flanking region of the olfactory marker protein (OMP) gene. We proposed that an olfactory-specific transacting factor, designated Olf-1 (Kudrycki et al., Molec. Cell. Biol., May, 1993), binds to two upstream sites of the OMP gene. The role of the Olf-1 binding sites in olfactory-specific gene expression was analyzed by studying the expression of E.coli Lac-Z placed under the control of differently truncated regions of the rat OMP promoter. Lac-Z expression in olfactory tissue of transgenic mice was analyzed biochemically and histochemically. Immunoenzymatic assays using CPRG as a substrate for β -galactosidase generally revealed substantial activity in olfactory tissue from mice carrying a construct with 0.3 kb upstream. In contrast, less activity was measured in olfactory tissue of mice carrying a larger construct (0.8 kb upstream). X-gal staining of olfactory tissue reflected the results of the biochemical assays. X-gal-positive olfactory neurons of mice carrying either construct were apically localized throughout the neuroepithelium. In one line carrying the shorter construct, intensely stained olfactory neurons occurred as clusters primarily in the caudal region of the epithelium. These neurons spanned the entire thickness of the neuroepithelium and correlated with robust staining of some glomeruli in the bulb. Lac-Z expression observed in some regions of the CNS suggests that additional sequences in the OMP gene participate in regulating olfactory neuron-specific gene expression. Overall, these data reveal that as little as 0.3 kb upstream of the OMP translational start site (harboring a single Olf-1 binding motif) is sufficient for expression of OMP and imply the presence of silencer elements in this gene.

CLONING AND CHARACTERIZATION OF A NOVEL SYNAPTOTAGMIN-RELATED GENE.

B. S. Hilbush* and **J. I. Morgan**. Dept. of Neurosciences, Roche Institute of Molecular Biology, Roche Research Center, Nutley, NJ 07110.

The discovery of several families of proteins thought to be involved in synaptic vesicle exocytosis has provided the first step in elucidating the molecular events underlying neurotransmitter release. One important family of these molecules is the synaptotagmins, synaptic vesicle proteins which possess properties of a Ca²⁺ sensor and may serve as key regulatory elements in vesicle fusion. Biochemical and molecular genetic approaches were used previously to identify two family members, synaptotagmin I and II. We used a PCR-based strategy to isolate additional family members from the mouse central nervous system. Using this approach, we have cloned a novel synaptotagmin-related gene that contains significant homology to both synaptotagmins. The homology amongst all of these members is greatest in the internal repeats of the C2 domain, a region found in the Ca²⁺/phospholipid regulatory region of protein kinase C. Northern blot analysis with a probe specific for the new member reveals a single 4.5 kb transcript whose expression is restricted to neural tissues. The identification of a third member of the synaptotagmin family suggests that multiple Ca²⁺-sensitive components of the fusion machinery may be required for regulated exocytosis.

ISOLATION AND CHARACTERIZATION OF NEUROTRANSMITTER TRANSPORTER-HOMOLOGOUS cDNA CLONES IN *DROSOPHILA*. W. S. Neckameyer*. Dept. of Pharmacological & Physiological Science, St. Louis University School of Medicine, St. Louis MO 63104.

A *Drosophila melanogaster* adult head cDNA library was screened with an oligomer whose sequence was derived from a highly conserved region of the norepinephrine and γ -aminobutyric acid transporters, and which was used to isolate a dopamine transporter in rat (Shimada *et al.*, Science 254: 576-578, 1991).

Of the three clones initially isolated, a partial sequence of one cDNA clone was found to span 50 amino acid residues encompassing the proposed first and second transmembrane domains. This sequence was remarkably well conserved in *Drosophila*, and therefore this cDNA clone was used in a second screen of the same library. Several cDNA clones have now been isolated, which fall into two major classes by Southern analysis of *Drosophila* genomic DNA. A detailed characterization of these cDNAs encoding putative neurotransmitter transporters will be presented.

DIFFERENTIAL RNA SPLICING OF CR16, A NOVEL GENE EXPRESSED IN HIPPOCAMPAL NEURONS. J.N. Masters*, W.H. Ashman and S.L. Cotman. Department of Cell Biology, Neurobiology and Anatomy and the Ohio State Biotechnology Center, The Ohio State Univ., Columbus, OH 43210

CR16 is a novel gene expressed in subsets of neurons in the brain including hippocampal pyramidal cells CA1-CA3 and the dentate gyrus granule cells. RNA blots identify CR16 as a 3.9 kb mRNA which is reduced 50% in abundance by adrenalectomy (ADX) and elevated 3-4 fold in ADX rats by high levels of exogenous corticosterone (CORT) treatment. Both aldosterone and low levels of CORT raise CR16 to intact endogenous levels in ADX rats suggesting that the gene is regulated primarily by the mineralocorticoid receptor. To further characterize the CR16 gene, we have isolated overlapping cDNA clones from a hippocampal library which span 4.5 kb. No significant homologies to the CR16 DNA sequence were found in GenBank, protein databases or the Procite database indicating that CR16 represents a novel gene. However, the DNA sequence identifies 2 classes of cDNA clones which differ by the inclusion of 102 nt in the carboxyterminal region of the presumed coding region. Six cDNA clones were isolated which span this region and two contain the 102 nt insert while the four others do not. Genomic clones confirm that this difference is due to differential RNA splicing. We have subcloned the differentially spliced exon and are currently using *in situ* hybridization to determine whether this splicing event is specifically regulated in brain areas expressing CR16 and whether steroid treatment affects the relative expression of these sub-types. PROMOTER ACTIVITIES AND UNUSUAL SPLICING PATTERNS ASSOCIATED WITH THE GABRB3 GENE.

E.F. Kirkness* The Institute for Genomic Research, 932 Clopper Road, Gaithersburg, MD 20878.

Transcription of the GABA_A receptor $\beta 3$ subunit gene (GABRB3) involves the use of alternative exons 1 (exon 1 or 1a) that encode distinct signal sequences (J. Biol. Chem. 268, 4420-4428). The predominant $\beta 3$ subunit mRNA species in human brain contains exon 1 sequence and is transcribed from a promoter termed P1. Deletion analysis of CAT-constructs has identified strong P1 promoter activity within a 90bp element of the gene. A region of this element that binds nuclear factors was found to adopt a single-stranded conformation when supercoiled. The binding specificity of nuclear factors has been examined by gel retardation assays. Point mutations that affect binding have been incorporated into CAT-constructs and shown to modulate promoter activity in transfected cells.

A RACE analysis of $\beta 3$ subunit transcripts has uncovered another alternatively spliced exon that can replace exons 1 or 1a. The DNA sequence of this exon is very highly conserved between species. Primary transcripts that contain the novel sequence can be spliced into at least two forms. In addition to the expected linear RNA, an unusual circular transcript appears to result from the splicing of a downstream exon to the 5' end of the transcript. This unusual splicing pattern may play a novel role in post-transcriptional regulation of $\beta 3$ subunit expression.

ALTERNATIVE SPLICING OF A HUMAN AMYLOID PRECURSOR PROTEIN MINI-GENE CONSTRUCT IN MOUSE P19 EMBRYONAL CARCINOMA CELLS. D. Willoughby*, S. A. Johnson, and C. E. Finch. Andrus Gerontology Center and Department of Biological Sciences, University of Southern California, Los Angeles, CA 90089

β -amyloid is a 42-43 amino acid peptide which is deposited extracellularly in the brains of Alzheimer's disease patients and to a lesser extent in the brains of normal elderly persons. β -amyloid is a proteolytic fragment of the carboxy-terminal region of the amyloid precursor protein (APP). Unprocessed APP contains 695, 751, or 770 amino acids. These alternative forms of APP are generated by variable inclusion of exon 7 and exon 8 in the mRNA. Exon 7 encodes a 57 amino acid Kunitz protease inhibitor domain (KPI), while exon 8 encodes a 19 amino acid motif with similarity to OX2, a neuron and thymocyte cell surface marker. We and others have found that the ratio of KPI-containing/KPI-lacking-mRNAs is increased in the cortex and hippocampus of Alzheimer's disease patients.

Several groups have shown that APP-695-mRNA, which lacks the KPI exon, is selectively up-regulated during retinoic acid-induced neuronal differentiation of P19 cells. We transfected differentiated P19 cells with a human APP mini-gene splicing construct. The KPI exon was spliced out of most construct-derived-mRNAs in these cells. In contrast, the KPI exon was spliced into most construct derived mRNAs in rat C6 glioma and human U87 astrocytoma. Similarly, in mouse Neuro-2A neuroblastoma and human SK-N-SH neuroblastoma the KPI-exon was contained in most mRNAs derived from the splicing construct. The differences in splicing between P19 cells and other cell lines will be exploited in order to identify cis-acting RNA sequence elements involved in cell type specific alternative processing of the APP pre-mRNA. DW was supported by TG-AG00037-13; this work was supported by AG7909 to C. E. F.

ALTERNATIVE SPLICING OF AN SH2 DOMAIN CONTAINING PROTEIN TYROSINE PHOSPHATASE THAT IS ENRICHED IN THE BRAIN. L. Mei* and R. L. Huganir. Department of Neuroscience, Howard Hughes Medical Institute, The Johns Hopkins University School of Medicine, Baltimore, MD 21205.

Recent studies demonstrating a high level of expression of protein tyrosine kinases in the central nervous system suggest that tyrosine phosphorylation may be involved in neuronal function. Moreover, abundant expression of protein tyrosine kinases at synapses, both presynaptically and postsynaptically, suggests that tyrosine phosphorylation may be involved in the modulation of synaptic transmission. We are interested in identifying protein tyrosine phosphatases that are important in the regulation of synaptic transmission. We recently isolated cDNAs that encode a protein tyrosine phosphatase with two src homology 2 (SH2) domains from a rat brain cDNA library. Since SH2 domains directly bind to specific phosphotyrosyl proteins, the SH2 domain in a tyrosine phosphatase is believed to play a role in targeting or anchoring the substrates to be dephosphorylated or forming complexes with functionally related proteins. The deduced sequence of this phosphatase shows a high percentage of identity at amino acid level to rat SH-PTP2. However, this phosphatase appears to be a novel form of SH-PTP2 generated by alternative splicing of the same or related gene. Northern blot analysis revealed its high-level expression in the brain, intermediate-level expression in the lung, skeletal muscle and heart, low level expression in the kidney, intestine and liver. Studies are under way to characterize the substrate specificities and tissue distributions of the alternatively spliced forms of the protein tyrosine phosphatase.

461.20

ALTERNATIVE RNA SPLICING OF THE MOUSE GLUR2 GENE *IN VIVO*. J. A. Izzo*, C. A. Sherman and J. W. Kusiak. Molecular Neurobiology Unit, GRC, NIA, NIH, Baltimore, MD 21224

Mutually exclusive splicing of the Flop and Flip exons of the glutamate receptor subunit gene GLUR-2, generates functionally distinct protein isoforms. To investigate which sequences are involved in regulating Flop and Flip splicing, we constructed a minigene (MG) containing the Flip and Flop genomic region. We have examined the expression of the endogenous GLUR2 gene and our MG construct in several cell lines by RT-PCR. HeLa cells do not express endogenous GLUR2 mRNA, however RNA from the minigene is spliced accurately with a strong preference for the Flop exon. Splicing together of the flanking constitutive exons is also seen. Undifferentiated PC-12 cells transfected with the minigene express both Flip and Flop containing RNAs in a pattern which mimics the splicing choice of the endogenous gene.

A deletion analysis was conducted to identify important cis-acting sequences. Deletion of a long polypyrimidine tract between Flop and Flip (Δ CT) did not qualitatively change the splicing pattern compared to MG. A 165 bp deletion from -47 to -212 upstream of the Flip 3' acceptor site (Δ EF) also did not change the splicing pattern. Extending the Δ EF deletion to -25 upstream of Flip altered the recognition of the Flop exon donor site. Based on these results, we conclude that our MG minigene construct has the necessary sequences for correct splicing. Deletion of a consensus branch point sequence 31 nt upstream of the Flip exon changes the pattern of splicing suggesting that this sequence is critical for correct recognition of the Flop exon donor site. These results suggest that recognition of the Flop 5' donor site and branchpoint site does not occur independently but is tightly linked.

462.1

EFFECTOR DOMAIN OF Rab3 REGULATES NEUROTRANSMITTER RELEASE IN *APLYSIA* SYNAPTOSOMES. Y. Hu, R. Baston, B.-K. Kaang*, and E.R. Kandel, Center for Neurobiology & Behavior, Columbia University College of Physicians & Surgeons, HHMI, New York, NY 10032.

We have cloned Rab3 cDNA from the central nervous system of *Aplysia* and studied its role in neurotransmitter release from presynaptic terminals. Rab3 is a small GTP-binding protein associated with synaptic vesicles. It is thought to be involved in targeting synaptic vesicles to the active zone and in regulating the fusion of the vesicles with the plasma membrane at release sites. Rab3 is in turn activated by a GTPase activating protein (GAP), which regulates the GTPase activity of Rab3 by interacting with its effector domain. Since the GTP-bound form of Rab3 is active, inhibiting its GTPase activity by blocking GAP with a peptide encoding the Rab3 effector domain might keep Rab3 persistently active and thereby enhance neurotransmitter release.

To test this possibility we have introduced into *Aplysia* synaptosomes the effector domain of Rab3 and studied its effect on neurotransmitter release and on the GTPase activity of Rab3. We found that the effector domain of Rab3 inhibited the GTPase activity of the Rab3 protein and enhanced neurotransmitter release from synaptosomes. We propose that the Rab3 effector domain may compete with the Rab3 protein for the binding of a Rab3-specific GAP in the synaptosome, thereby decreasing the GTPase activity of Rab3 and increasing the concentration of the GTP-bound form of Rab3. Thus, our results suggest that the Rab3 protein is involved in the regulation of neurotransmitter release at the nerve terminal and that the activity of RAB3 depends on its GTPase activity.

RECORDINGS FROM CALYX NERVE TERMINALS AND POSTSYNAPTIC NEURONS IN CHICK COCHLEAR NUCLEUS.

S. Sivaramakrishnan* and G. Laurent. Division of Biology, California Institute of Technology, Pasadena, CA 91125.

We have developed a preparation to study synaptic transmission in the vertebrate CNS. The synapse is that formed by VIIIth nerve afferents on nucleus magnocellularis (NM) neurons in the chick brainstem. Confocal images of Dil-filled afferents show one or two calyx-type nerve terminals impinging on the soma of NM neurons. 250-300 μ m thick brain slices and whole-cell patch-clamp recordings are used to characterize pre- and postsynaptic conductances and postsynaptic currents (PSCs) evoked by stimulation of VIIIth nerve afferents. In NM cells under voltage-clamp conditions, depolarizing steps evoke Na and K currents. The K current activates rapidly and shows no inactivation during 600 ms long voltage steps. It is partially blocked by high concentrations of TEA and 4-AP. Under similar conditions, presynaptic calyces also show inward Na and outward K currents. The K current has two components of decay and is completely blocked by TEA and 4-AP. Calcium currents recorded in the presynaptic calyx in the presence of Na and K channel blockers activate at -55 mV (from a holding potential of -70 mV), reach a peak amplitude of 500-800 pA at +40 mV and slowly inactivate during 500 ms long voltage steps. EPSCs recorded in NM cells by stimulation of VIIIth nerve afferents are 3-5 nA in amplitude at a holding potential of -70 mV and peak currents are reached in about 0.4 ms. Preliminary results indicate that these EPSCs are greatly reduced by omega-conotoxin GVIA.

MODULATION OF GNRH-INDUCED CALCIUM OSCILLATIONS IN PITUITARY GONADOTROPHS. A. Tse*, F.W. Tse and B. Hille. Dept. Physiol. & Biophys., U. of Washington, Seattle, WA 98195.

In identified gonadotropes of male rat, gonadotropin-releasing hormone (GnRH) stimulates a rhythmic release of Ca^{2+} from an IP_3 -sensitive store, which in turn induces an oscillatory apamin-sensitive $I_{K(Ca)}$ (Tse & Hille, Science 255:462) and bursts of exocytosis (Tse et al., Science 260:82). Since GnRH also activates PKC, we examine the effect of phorbol esters by simultaneously measuring $[Ca^{2+}]_i$ and $I_{K(Ca)}$. Application of PMA (100 nM) has little effect on the basal $[Ca^{2+}]_i$ ($n = 3$). PMA or PDBu, but not the inactive 4 α -PDD ($n = 6$), reduces the frequency of oscillations by $48 \pm 3\%$ and increases peak $I_{K(Ca)}$ by $108 \pm 18\%$ (mean \pm S.E.; $n = 46$). However, despite the enhancement of peak $I_{K(Ca)}$, the amplitude of $[Ca^{2+}]_i$ oscillations is not typically increased ($n = 15$). Both the slowing of oscillations and the $I_{K(Ca)}$ enhancement can be mimicked by 1,2-dioctanoyl-sn-glycerol (50-200 μ M; $n = 8$), and they can be induced during oscillations that have been initiated irreversibly by GnRH in cells loaded with 100 μ M GTP- γ -S ($n = 15$). In contrast, in cells loaded with 10 or 20 μ M IP_3 , phorbol esters enhance $I_{K(Ca)}$ but have no significant effect on the frequency of oscillations ($n = 11$). Therefore, the slowing of $[Ca^{2+}]_i$ oscillations by phorbol ester probably involves PKC modulation of steps after G-protein activation but before IP_3 generation. Our results also suggest that phorbol esters can enhance $I_{K(Ca)}$ independently of changes in $[Ca^{2+}]_i$. Thus, caution must be taken when $I_{K(Ca)}$ is used to monitor changes in $[Ca^{2+}]_i$. (Supported by AR-17803, HD-12629 and the Mellon, McKnight and W. M. Keck Foundations.)

PRESYNAPTIC LOCUS FOR SLOW DEVELOPING POTENTIATION IN THE CEREBRAL GANGLION OF *APLYSIA*. M.V. Storozhuk and S.M. Fredman*, A.A. Bogomolez Institute of Physiology, Kiev, Ukraine and Dept. of Physiology, Meharry Medical College, Nashville, TN 37208.

The A-B neuron synapse in the cerebral ganglion of *Aplysia* exhibits a novel form of enhanced synaptic transmission, slow developing potentiation (SDP). Brief stimulation of single A neurons (4, 500 msec duration trains of 35 msec pulses @ 20 Hz) causes a long-lasting (~25 min) increase in EPSP amplitudes in B neurons. Previous results suggested that SDP is due in part to the activation of PKC and increases in presynaptic Ca^{2+} . The possibility of a postsynaptic component to SDP was not eliminated. To test this, SDP was induced while recording either pre- or postsynaptic neurons using two electrode voltage clamp. During SDP, the amplitude of EPSCs in voltage clamped postsynaptic B neurons increased in phase with EPSPs in a second simultaneously recorded B neuron. There was a significant correlation ($n = 70$, $r = 0.81$, $p < 0.001$) between EPSC and EPSP amplitudes. With the membrane potential of B neurons clamped between -45 and -60 mV there was no change in holding current during SDP. This eliminates postsynaptic membrane currents and changes in membrane resistance contributing to SDP. Additionally, the reversal potential of baseline and potentiated EPSCs was the same -10 to 0 mV. In contrast, the induction of SDP in presynaptic A neurons clamped at -50 mV and stepped to 0 mV, resulted in an increase in total inward current and a decrease in outward current. The ionic basis for these changes is presently being studied. Taken together, the results indicate that SDP has a presynaptic locus and is presumably due to increases in transmitter release by A neurons.

MODULATION OF ACTION POTENTIAL PROPAGATION THROUGH EMBRYONIC DORSAL ROOT GANGLION CELLS BY REPETITIVE STIMULATION.

CHR. LÜSCHER*, R. QUADRONI*, J. STREIT & H.-R. LÜSCHER. DEPT. OF PHYSIOLOGY, UNIVERSITY OF BERN, & INSTITUTE OF THEORETICAL PHYSICS, ETH-ZÜRICH, SWITZERLAND

A: Impulse conduction in axons is not simply a transmissive process but has integrative functions. The dorsal root ganglion (DRG) of the embryonic rat put into culture forms a monolayer and is thus accessible to conventional microelectrode technique, which allows testing the above hypothesis. We have chosen a dual approach by correlating experimental electrophysiological data from the culture with results obtained from a compartmental computer model. **B:** When a train of stimuli at frequencies of 5-20 Hz is applied to the central or peripheral branch of the axon of a DRG cell the following phenomena can be recorded in the soma: during the first twenty to fifty stimuli action potential (AP) invasion of the soma is reliable, but there is an increase in the latency from time of stimulation to the onset of the AP, a decrease of the upstroke velocity, a decrease of the afterhyperpolarization amplitude and a disappearance of the "calcium-shoulder". For the next stimuli AP invasion intermittently fails, leaving an electrotonic residue (ER) of one discrete amplitude level in bipolar cells and ERs with two discrete amplitude levels in unipolar cells. The smaller ER reflects conduction failure at the branch point and the larger ER conduction failure at the entrance of the axon into the soma. **C:** Our experiments suggest that conduction may fail at sites of subtle impedance mismatch when periaxonal potassium accumulation and Ca-induced Ca channel inactivation occur. A compartmental computer model based on voltage clamp data from the literature reproduced the majority of the experimental findings. (SNF 31-27553.89 to H.-R.L.)

CALCIUM HOMEOSTASIS IN PITUITARY GONADOTROPHS

F.W.Tse*, A. Tse and B. Hille. Dept. Physiol. & Biophys., U. of Washington, Seattle, WA 98195.

Using whole-cell voltage-clamp and indo-1 fluorometry, we examine cytoplasmic Ca^{2+} dynamics in male rat gonadotropes identified by the reverse hemolytic plaque assay. During depolarizing voltage steps (< 1s) to potentials between -40 and +20 mV, Ca^{2+} entries estimated from the integral of I_{Ca} closely parallel the peak amplitude of $[Ca^{2+}]_i$ rises. For a comparable Ca^{2+} entry, the $[Ca^{2+}]_i$ rise is attenuated 5.4-fold when the total concentration of Ca^{2+} buffers (indo-1 and BAPTA) loaded into cells via the whole-cell pipette is increased from 25 μ M to 500 μ M. Comparison of depolarization-induced $[Ca^{2+}]_i$ rises and Ca^{2+} entries with different pipette Ca^{2+} buffer concentrations suggests that, in the absence of any pipette Ca^{2+} buffers, the essentially non-diffusible endogenous Ca^{2+} buffers would immediately bind ~99% of the Ca^{2+} entering the cytoplasm. With 25 μ M pipette Ca^{2+} buffer, depolarization-induced $[Ca^{2+}]_i$ rises decay with a 2-s time constant. Inhibition of intracellular Ca^{2+} -ATPases by thapsigargin, cycloplazonic acid or 2,5-di-(tert-butyl)-1,4-benzohydroquinone (BHQ) results in a slow increase of $[Ca^{2+}]_i$. BHQ (10 μ M) also slows the decay of depolarization-induced $[Ca^{2+}]_i$ rises by ~3 fold, implicating intracellular Ca^{2+} -ATPases in the slow removal of cytoplasmic Ca^{2+} . These inhibitors do not block the release of intracellular Ca^{2+} induced by gonadotropin-releasing hormone (GnRH), but transform GnRH-induced $[Ca^{2+}]_i$ oscillations into a single, slow monophasic decay. (Supported by AR-17803, HD-12629, and the Mellon, McKnight and W. M. Keck Foundations.)

REGULATION OF INTRACELLULAR CALCIUM IN ISOLATED SECRETORY NERVE ENDINGS OF THE NEUROHYPOPHYSIS. E.L. Stuenkel* Department of Physiology, Univ. of Michigan, Ann Arbor, MI 48109-0622

Stimulated release of chemical messengers from nerve endings is initiated by a rise in intracellular calcium concentration ($[Ca^{2+}]_i$). The amplitude and duration of impulse evoked Ca^{2+} transients are determined by properties of Ca^{2+} influx and mobilization as well as by intracellular buffering, sequestration and efflux. To characterize these properties $[Ca^{2+}]_i$ and calcium currents were simultaneously measured under whole-cell voltage clamp at isolated secretory nerve endings of the rat neurohypophysis. The peak amplitude of $[Ca^{2+}]_i$ was found to closely parallel calcium currents evoked by depolarizing voltage commands. These results suggest that neither voltage nor Ca^{2+} -induced Ca^{2+} release significantly affect depolarization evoked $[Ca^{2+}]_i$ transients. This is supported by a lack of effect of ryanodine and caffeine on elevated K^+ -induced $[Ca^{2+}]_i$ transients. Voltage steps to +10 mV (h.p. -90 mV) led to a rapid equilibration of $[Ca^{2+}]_i$ (< 100 ms) at 10 mM $[Ca^{2+}]_o$. Recovery of $[Ca^{2+}]_i$ to prestimulation levels was gradual (15 - 30 sec) even for brief depolarizations. The rate of $[Ca^{2+}]_i$ recovery was uninfluenced by return to holding potentials over the range of -90 to -50 mV following the step depolarization. The kinetic difference between rapid $[Ca^{2+}]_i$ equilibration and slow recovery allowed estimation of the endogenous Ca^{2+} binding capacity of the nerve endings (method, Neher and Augustine, 1992). The endogenous binding capacity ($167 \pm 11, X \pm SEM$) remained stable over a period of 5 min following initiation of whole cell recording, suggesting the endogenous Ca^{2+} buffer is of low mobility.

CALCIUM-DEPENDENT EXOCYTOSIS IN INDIVIDUAL SYNAPTIC TERMINALS OF A CNS INTERNEURON. Henrique von Gersdorff and Gary Matthews*. Dept. of Neurobiology, SUNY, Stony Brook, NY 11794.

Exocytosis was studied in giant synaptic terminals of goldfish retinal bipolar neurons, using combined patch-clamp, fura-2, and capacitance measurements. Dynamics of capacitance changes elicited by Ca influx through Ca channels were described previously (von Gersdorff & Matthews, *Biophys. J.*, 64, A319). With light Ca -buffering (0.5 mM BAPTA), the capacitance jump elicited by a single 250-ms depolarizing pulse averaged 83 ± 20 fF (mean \pm s.e.m., $N=11$); with stronger buffering (10 mM BAPTA), the response to a single pulse was abolished (-9 ± 7 fF; $N=15$). After 15 repetitive pulses at 1/sec, the change in capacitance for 10 mM BAPTA (145 ± 54 fF) was little different from 0.5 mM BAPTA (190 ± 31 fF). Thus, BAPTA retarded but did not prevent the increase in capacitance. To examine the Ca -dependence of exocytosis, terminals were dialyzed with solutions containing $[Ca]$ strongly buffered at 1.4 μM (which is similar to the average $[Ca]$ reached during sustained activation of Ca current) or 52 μM (see Fig.). With 1.4 μM Ca , no change in capacitance was seen (16 ± 69 fF; $N=12$). With 52 μM Ca , capacitance increased following break-in (242 ± 83 fF; $N=7$). This suggests that $[Ca]$ achieved locally during release evoked by Ca current is much higher than the bulk $[Ca]$ measured by fura-2 in the whole terminal. Fig. Capacitance of isolated terminals measured with lock-in amplifier following break-in (at arrows).

A MINIATURE SYNAPTIC CURRENT IS GENERATED BY A GROUP OF PERIODIC EXOCYTOTIC BURSTS. B.R. Maple* and S.M. Wu, Cullen Eye Institute, Baylor College of Medicine, Houston, TX 77030

Off-center bipolar cells of the salamander retina display spontaneous miniature excitatory postsynaptic currents (MEPSCs), thought to be generated by the vesicular release of glutamate from photoreceptors. These events vary tremendously in amplitude and time course, suggesting that the MEPSCs represent a multivesicular release process. We have performed a two-dimensional analysis which reveals a MEPSC subunit structure.

Bipolar cells in retinal slices were voltage-clamped with patch electrodes, and MEPSCs were observed under conditions where presynaptic calcium influx was suppressed. Bandpass filtered MEPSCs were fit to a filtered difference of exponentials to yield an estimated amplitude and integrated charge for each unfiltered event. A duration (defined as the charge/amplitude ratio) was calculated for each MEPSC, and the events were plotted as a density in a charge vs. duration plane. These plots exhibited a complex structure, with periodicities along both the charge and duration axes.

This structure was consistent with a model in which exocytosis occurs as a series of bursts with an interburst interval of about 1.2 msec. In this model the number of vesicles released in the first burst was governed by an exponentially decaying probability density. The number of vesicles released in subsequent bursts was governed by binomial statistics, where the probability of release increased as a function of the number of vesicles released in the previous burst. A further prediction of the model was that the effects of synchronously released vesicles do not sum linearly, but instead display positive cooperativity.

Visual inspection of the MEPSCs showed a tendency for slight inflections in the MEPSC waveforms to occur periodically at the same interval predicted by the model. Thus, it appears that the basic unit of transmitter release from photoreceptors does not correspond to a single glutamate vesicle, but rather to a group of vesicles released in a series of exocytotic bursts. The rate of MEPSC decay, then, does not primarily reflect either channel kinetics or the rate of glutamate uptake, but rather the time course of vesicle mobilization during a synaptic release event.

462.10

FACILITATION AT CRAYFISH NEUROMUSCULAR JUNCTIONS IN THE PRESENCE OF A CALCIUM IONOPHORE. U. Musser and S.J. Velez*, Department of Biological Sciences, Dartmouth College, Hanover, N. H. 03755.

We examined the facilitation characteristics of synapses made by neurons innervating the superficial flexor muscles of the crayfish *Procambarus clarkii* while changing the calcium concentration of the Ringers bathing the preparation, in the presence and absence of the calcium ionophore A23187. The nerve was stimulated at 1 Hz and 10 Hz while the junction potentials generated (JP's) were recorded with intracellular microelectrodes impaling the muscle fibers. With the microelectrode in the same muscle fiber, the Ringers solution was changed several times to ones containing 30%, 70%, 100%, 117% and 200% normal calcium concentrations. JP's recorded at 1 Hz were compared to those recorded at 10 Hz and facilitation ratios were calculated (JP at 10 Hz/JP at 1 Hz). These synapses facilitated through all these external calcium changes. Upon addition of a 15 μM solution of the calcium ionophore A23187 in the different calcium Ringers, the amount of facilitation was reduced at the lower calcium concentrations and disappeared in the 200% calcium Ringers, i.e. the JP's generated at 10 Hz were smaller than those generated at 1 Hz. Upon removal of the ionophore, the terminals again facilitated. It appears that too much calcium entry into these terminals affects the mechanism of facilitation.

EFFECT OF REPETITIVE STIMULATION ON MINIATURE END-PLATE POTENTIAL FREQUENCY UNDER CONDITIONS OF DEPRESSION OF EVOKED RELEASE. M.A. Sosa* and J.E. Zengel. Depts. of Neurosci. & Neurosurg., U. of Fla. Coll. of Med. and DVA Med. Ctr., Gainesville FL 32610.

Repetitive stimulation of the frog neuromuscular junction under conditions of normal or high levels of release results in a depression of endplate potential (EPP) amplitude that has traditionally been attributed to a depletion of available transmitter. The purpose of this study was to determine whether transmitter release in the form of miniature EPPs (MEPPs) is also affected by depression.

MEPPs were recorded from frog sartorius neuromuscular junctions in 3.6 mM Ca Ringer using standard intracellular recording techniques. Muscle action potentials were blocked by 5 μM μ -conotoxin. Nerves were conditioned with trains of 200-4800 impulses (20 imp/sec).

We found that whereas the conditioning stimulation resulted in the expected depression of EPP amplitude, the frequency of MEPPs was dramatically increased. The increase in MEPP frequency following conditioning stimulation could be described by four components with time constants of decay similar to those reported for the components of increased release observed under low quantal conditions when depression is absent.

Our results support the idea that the mechanisms that produce the components of increased release can be present simultaneously with those that produce depression of release. They are not consistent, however, with the hypothesis that depression results from a depletion of available quanta, unless one assumes that evoked release (EPPs) and asynchronous release (MEPPs) arise from different pools of quanta.

ON THE SIMULTANEOUS MEASUREMENTS OF CALCIUM CURRENTS AND ACETYLCHOLINE RELEASE FROM MOTOR NERVE ENDINGS. Redman, R.S.* and Silinsky, E.M. Dept. Pharmacology, Northwestern U. Med. Schl., Chicago, IL 60611.

A number of laboratories have been successful in recording Ca currents from motor nerve endings by perineural or 'loose patch' methods. Such measurements are generally made in normal Ca solutions in the presence of high concentrations of the K channel blockers 3,4, diaminopyridine (DAP) and tetraethylammonium (TEA), conditions that cause a rapid depletion of acetylcholine (ACh) quanta. Simultaneous measurements of Ca currents and stable levels of ACh release are thus not possible in such solutions, an unfortunate feature that precludes studies in which effects of an exogenous agent on ACh release may be compared simultaneously to its effect on Ca currents. We have found that Ringer containing 0.9 mM Ca, 10 mM Mg, 100 μ M DAP and low TEA concentrations (250 μ M) produced sufficient blockade of the Ca activated-K current to allow unobscured measurements of Ca currents and to minimize depletion of ACh release. In this solution, increases or decreases in extracellular Ca produce parallel effects on both the perineural Ca currents and end-plate potentials (EPPs) measured simultaneously. By making simultaneous measurements of presynaptic currents and EPPs in this solution, we have been able to differentiate between agents that affect ACh release by an action on presynaptic ion channels (e.g., increases in release with difluoro-methylornithine or NaF; decreases in release by Co) from those that affect release by other means (decreases in release by adenosine in the frog). (Supported by NIH grants NS12782 and NS30795)

CHOLINE CHLORIDE CAN INCREASE TRANSMITTER RELEASE AT THE NEUROMUSCULAR JUNCTION OF THE RAT. D. F. Wilson* Zoology Dept. Miami Univ., Oxford, OH, USA 45056.

The presynaptic effect of exogenously applied choline chloride on transmitter release in the rat diaphragm was examined by testing the effects of 0.5 and 0.75 mM choline chloride on evoked transmitter release. Intracellular recording techniques were used to monitor end-plate potentials (EPPs) and miniature end-plate potentials (MEPPs) in the isolated cut-muscle rat diaphragm-phrenic nerve preparation. Quantal release in the presence and absence of choline chloride was examined. In the presence of 0.5 mM choline chloride, no significant changes were observed. In the presence of 0.75 mM choline chloride however the initial output of quantal release was increased by 36% and the MEPP amplitudes were depressed by 42%. It is suggested that the enhancing effect of choline on transmitter release is due to its ability to block nicotinic receptors on the nerve terminal that serves a negative feedback role (Supported by NIH grant NS-27260).

PROTON IONOPHORES DELAY ONSET OF BOTULINUM PARALYSIS IN ISOLATED MOUSE SKELETAL MUSCLE. R. E. Sheridan* Neurotoxicology Branch, Pathophysiology Division, USAMRICD, APG, MD 21010-5425.

Botulinum and tetanus toxins are thought to enter cells through endocytotic vesicles where acidification is required for release of these toxins into the cytoplasm. The role of vesicular acidification in the development of botulinum intoxication was studied in the isolated mouse phrenic nerve/diaphragm muscle preparation. Isolated hemidiaphragms were incubated at 4°C for 1 hr with or without botulinum toxin. The muscles were then washed with oxygenated Tyrode's solution and transferred to 36°C baths that contained the test drugs. The phrenic nerves were stimulated and the resulting twitches were measured isometrically. Two ionophores, nigericin and monensin, that increase membrane permeability to H⁺ and K⁺ or H⁺, Na⁺ and K⁺ respectively, block vesicle acidification by acting as H⁺ shunts to neutralize pH gradients across vesicular membranes. Both drugs were inherently toxic at concentrations greater than 1 μ M, resulting in loss of nerve-elicited contractions. For nigericin at 1 μ M, electrical recordings at MEPP amplitude showed a decrease in MEPP frequency without any change in MEPP amplitude or muscle membrane potential. There was no apparent effect of either ionophore on contractions due to direct electrical stimulation of the muscles. Concentrations of monensin and nigericin \leq 10 nM showed no inherent toxicity over a 4-6 hr period. Either monensin or nigericin treatment (40 nM) of botulinum type A or B (10¹⁰ to 10⁹ M)-exposed diaphragms delayed paralysis 2- to 3-fold compared to muscles in botulinum alone. This delay was roughly equivalent to a 10-fold reduction in the effective concentration of botulinum toxin. Treatment with 1-3 nM nigericin did not significantly delay onset of botulinum type B paralysis. Neutralization of endocytotic vesicles was thus able to slow the onset and reduce the effective concentration for multiple botulinum toxin serotypes.

OPTICAL MEASUREMENTS OF PRESYNAPTIC CALCIUM DYNAMICS IN FROG TECTUM. M. B. Feller, K. R. Delaney* & D. W. Tank. Biological Computation Research Dept., AT&T Bell Laboratories, Murray Hill, NJ 07974.

Visually guided prey-catching in the frog displays a form of behavioral facilitation that decays on a time scale of 1-10 seconds. The biophysical basis of this effect may be short term synaptic enhancement caused by rapid buildup and slow decay of residual calcium in presynaptic terminals. As a first step in testing this hypothesis, we have used optical imaging techniques and the calcium indicator fura-2 to measure the kinetics of presynaptic calcium ion concentration in optic nerve fibers in the optic tectum of *Rana pipiens*.

Membrane permeable fura-2AM was bath applied to the optic tectum *in vivo* and to isolated brains. Following labeling, a transient decrease in 380 nm excited fluorescence was observed in response to optic nerve shocks. The transient had a rapid onset (20 msec) and decayed to pre-stimulus levels on a time scale of a few seconds, significantly longer than the decay of extracellular field potentials. Several features of this fluorescence signal suggest that the change corresponds to transient increases in residual calcium in unmyelinated optic nerve fibers. First, bath-applied glutamate antagonists reversibly eliminated post-synaptic components from the field potential but did not affect the measured calcium transients, implying the origin of the signal is pre-synaptic. Second, when the stimulation intensity is lowered so that only the myelinated fibers are activated, the calcium response to the optic nerve shock disappears. Finally, the staining of fura-2 in the tectum is strongest in the outer layers, which is the region which corresponds to the termination zone of the unmyelinated fibers. We have also demonstrated temporal summation of the presynaptic calcium changes during 10-50 Hz stimulus trains.

In summary, we have measured changes in presynaptic calcium in frog optic tectum *in vivo*. Our results suggest that the decay times of presynaptic residual calcium are on the same time scale as the decay of behavioral short term memory effects in frog visually-guided prey catching.

462.16

SIMULTANEOUS BARIUM-INDUCED CATECHOLAMINE QUANTAL RELEASE AND FURA-2 RESPONSE AT SINGLE BOVINE CHROMAFFIN CELLS. J. M. Finnegan, J. A. Jankowski, T. J. Schroeder, and R. M. Wightman* Dept. of Chemistry, Univ. of North Carolina, Chapel Hill, NC 27599-3290.

Simultaneous measurement of quantal release of catecholamines and intracellular divalent-ion concentration with fura-2 allows the stimulus-secretion coupling at the bovine adrenal chromaffin cell to be probed at the single-cell level. The quantal release of catecholamine is monitored by placing a carbon-fiber microelectrode adjacent to a single cell. Oxidation of released catecholamines by the electrode results in electrochemical current spikes which are due to exocytosis from individual vesicles.

The high conductance of barium through voltage gated Ca²⁺ channels allows Ba²⁺ to substitute for Ca²⁺ in many intracellular processes, including binding to the divalent-cation probe fura-2. Barium is a potent secretagogue capable of evoking exocytosis with or without extracellular calcium. The intracellular divalent-cation concentration remains at a high plateau for greater than 10 min. with Ba²⁺, while K⁺ depolarizations give a transient response returning [Ca²⁺]_i to basal levels in less than 40 s. The detected catecholamine packets resulting from Ba²⁺-induced release are taller, more frequent, and longer lasting than those due to high K⁺ depolarizations at the same cell. However, spikes induced by high K⁺ applied after Ba²⁺ show characteristics much like those from Ba²⁺ itself. The data indicate that Ba²⁺ causes a measurable alteration of the intravesicular cocktail even after the Ba²⁺-induced release has subsided.

ROLE OF N- AND NON-N-TYPE CALCIUM CHANNELS IN TRANSMISSION AT CORTICOSTRIATAL SYNAPSES. D.M. Lovinger*, A. Merritt and D. Reyes. Dept. Molecular Physiology and Biophysics, Vanderbilt Med. School, Nashville, TN 37232-0615.

N-type Ca²⁺ channels are thought to participate in excitation/secretion coupling at presynaptic terminals. However, there is little evidence implicating N channels in transmission in the CNS. We have examined the action of the selective N channel blocker ω -conotoxin GVIA (CgTx) on excitatory synaptic transmission at corticostriatal synapses in rat brain slices. During field potential recording, application of 1 μ M CgTx depressed the amplitude of the stimulus-evoked, synaptically-driven population spike (PS) by 49 \pm 5% (n=27). Depression was irreversible after extensive washing and higher CgTx concentrations did not produce additional depression. The PS produced by direct activation of neurons due to stimulus current was not affected by CgTx. During whole-cell recording, application of 1 μ M CgTx irreversibly depressed EPSP amplitude by 52 \pm 6% (n=17). CgTx induced inconsistent changes in postsynaptic neuron excitability which did not correlate with synaptic depression. Pretreatment with CgTx did not alter synaptic depression induced by 50 μ M 1S,3R-ACPD (% decrease in PS amplitude in 6 untreated slices=61 \pm 5 in ACPD compared to 63 \pm 7 after CgTx, n=7). CgTx pretreatment also did not prevent potentiation of transmission by the phorbol ester PDBu (% increase in PS amplitude=33 \pm 7 in 8 untreated slices and 55 \pm 25 in 5 CgTx-treated slices). Similar results were observed during whole-cell recording. N- and non-N-type Ca²⁺ channels appear to be involved in transmission at corticostriatal synapses; perhaps in glutamate release. Alterations in transmission by presynaptic receptor or protein kinase C activation do not appear to require N channels. Supported by NS 30470.

GABA_B RECEPTORS INHIBIT CULTURED DORSAL ROOT GANGLION NEURONE CALCIUM CURRENTS VIA G_o: EVIDENCE FROM ANTISENSE OLIGONUCLEOTIDE STUDIES. A.C. Dolphin,* V. Campbell and N. Berrow. Dept. of Pharmacology, Royal Free Hospital School of Medicine, Rowland Hill Street, London, NW3 2PF, UK.

Calcium channel currents (I_{Ca}) were recorded in cultured dorsal root ganglion neurones (DRGs), 24-32 h after microinjection with 20-mer phosphorothioate antisense oligonucleotides complementary either to a G_{α_o} or a G_{α_i} unique sequence, or with a nonsense sequence. The ability of the GABA_B agonist (-)-baclofen (50 μM) to inhibit I_{Ca} was examined. The maximum peak current was inhibited by 35.2 ± 4.0% (n=11) in control noninjected cells, and by 38.1 ± 2.6% (n=11) and 34.8 ± 4.2% (n=5) in nonsense and G_{α_i} oligonucleotide injected cells. Following G_{α_o} oligonucleotide injection, the inhibition of I_{Ca} by (-)-baclofen was significantly reduced (p < 0.05) to 21.0 ± 3.3% (n=19). Confocal immunocytochemical localisation of G_{α_o} showed prominent staining at the plasma membrane in control DRGs, and this was also present in G_{α_o} and nonsense oligonucleotide injected cells. The G_{α_o} staining at the plasma membrane was much reduced in G_{α_o} oligonucleotide injected cells. In contrast, confocal immunocytochemical localisation of G_{α_i} showed immunostaining in the membrane and cytoplasm of control, G_{α_o} and nonsense injected DRGs, whereas this was greatly depleted in G_{α_i} oligonucleotide injected cells. These results indicate that the GABA_B receptor couples to voltage sensitive calcium channels via the G protein G_o and not G_i, and that antisense oligonucleotides can be used to deplete G proteins in DRGs. Supported by Wellcome Trust.

INTERACTION BETWEEN ENKEPHALIN AND NEFIRACETAM (DM-9384), A NOOTROPIC AGENT, OBSERVED IN CALCIUM CHANNEL CURRENTS AND cAMP IN NG108-15 CELLS. M. Yoshii¹, Y. L. Murashima¹, S. Watabe^{2*}, T. Shiotani² and M. Tanaka². ¹Dept. of Neurophysiol., Tokyo Inst. of Psychiatry, Tokyo 156 and ²Tokyo R & D Center, Daiichi Pharmaceu. Co. Ltd, Tokyo 134, Japan.

We have previously reported that the nootropic agent, nefiracetam (DM-9384), activates cAMP-dependent processes, resulting in a facilitation of long-lasting (or type II) Ca channel currents in NG108-15 cells (Yoshii et al., Soc. Neurosci. Abstr. 18, 435, 1992). The nefiracetam action reverses an inhibitory effect of Leu-enkephalin on the Ca channels (Watabe et al., Soc. Neurosci. Abstr. 18, 434, 1992). In the present study, we have investigated whether cAMP mediates the interaction between opioid and nootropic by measuring the intracellular level of cAMP (enzymatic method) as well as by recording Ca channel currents (whole cell clamp). When Leu-enkephalin (50 nM) was applied, cAMP levels were enhanced markedly (more than 10-fold) within 5-10 min whereas type II currents were reduced. The opioid-induced increase in cAMP was further enhanced by nefiracetam (1 μM) in an additive manner. Under such conditions, Ca channel currents were recovered from inhibition and even potentiated. The results suggest that cAMP does not mediate the interaction between opioid and nootropic appearing in Ca channel currents. It is also suggested that cAMP-sensitive Ca channels may not be influenced by a group of cAMP enhanced by opioids.

ACTIVATION OF METABOTROPIC GLUTAMATE RECEPTORS INHIBITS SPONTANEOUS OSCILLATIONS OF CYTOSOLIC Ca²⁺ IN CULTURED RAT CORTICAL NEURONS. Kenneth A. Stauderman* and Rebecca A. McKinney. Marion Merrell Dow Research Institute, 2110 E. Galbraith Rd., Cincinnati, OH 45215.

Primary cultures of rat cortical neurons develop spontaneous, synchronized, oscillations of cytosolic Ca²⁺ concentration ([Ca²⁺]_i) that depend on glutamatergic neurotransmission (Kuroda et al., Neurosci. Lett. 135: 255-258, 1992), making them a convenient model to study endogenous synaptic activity. Using fura-2 loaded cells, we found that activation of metabotropic glutamate receptors (mGluRs) with (1S,3R)-1-aminocyclopentane-1,3-dicarboxylic acid (*trans*-ACPD) inhibited spontaneous oscillations of [Ca²⁺]_i in a dose-dependent manner. Low concentrations of *trans*-ACPD (1-20 μM) inhibited the frequency of oscillations without altering amplitude, whereas higher concentrations (> 20 μM) obliterated the oscillations. The effects of 20 μM *trans*-ACPD were not blocked by 300 μM L-AP3, and were often observed without accompanying increases of [Ca²⁺]_i, suggesting that mGluR1 and mGluR5 subtypes may not be involved. Also, L-AP4 was not as effective as *trans*-ACPD at decreasing oscillation frequency, making mGluR4 activation unlikely. We are characterizing in more detail the effects of mGluR activation and the nature of the spontaneous oscillations of [Ca²⁺]_i.

SEROTONIN INHIBITS HIGH-THRESHOLD Ca²⁺ CURRENT IN AMYGDALA PYRAMIDAL NEURONS. Reese S. Scroggs* and Robert C. Foehring Dept. of Anat. and Neurobiol., Univ. of Tennessee, Memphis, TN 38163

The amygdala plays an important role in emotion, motivation, learning, and memory, yet little is known about ion currents and their modulation in amygdala neurons. In this study, high-threshold Ca²⁺ currents were recorded from freshly dissociated amygdala pyramidal neurons using the whole-cell patch-clamp technique. Neurons harvested from the several nuclei in the amygdala were grouped together. In neurons held at -90mV, Ca²⁺ current peaked around -10mV and averaged 1.5nA ± 0.32 SEM. 5μM nifedipine (nifed) inhibited 30% ± 4.1 SEM of peak current, while 5μM Bay K 8646 increased peak current by 55% ± 2.4 SEM. 1μM ω-conotoxin GVIA (ω-CgTx) inhibited 30.4% ± 5.6 SEM of peak current. Thus, both L- and N-type Ca²⁺ channels are important for Ca²⁺ entry in amygdala neurons. 40% ± 6.9 SEM of the current was not blocked by the combination of 5μM nifedipine and 1μM ω-CgTx. About 1/3 of the nifed/ω-CgTx resistant current was blocked by 100nM ω-agatoxin IVA, indicating that these cells also express P-type Ca²⁺ channels. In some neurons, part of the nifed/ω-CgTx resistant Ca²⁺ entry appeared to result from T-type Ca²⁺ channel activity, similar to a report by Kaneda and Akaike, (1989). However, a significant portion of Ca²⁺ entry occurred via uncharacterized Ca²⁺ channels.

2μM serotonin (5HT) was observed to block 25% ± 2.8 SEM of high-threshold Ca²⁺ current in neurons held at -90mV. The effect of 5HT was nearly completely occluded by pretreatment with 1μM ω-CgTx, indicating that most of 5HT's effect was on N-type Ca²⁺ channels. 5HT did not affect the slow component of the tail current in neurons treated with 5μM Bay K 8644, indicating that 5HT receptors were not coupled to L-type Ca²⁺ channels. Supported by NINDS grant# NS27180 to RCF

463.4

INVOLVEMENT OF GLUTAMATE RECEPTORS IN LONG-TERM INDUCTION OF Ca²⁺ CURRENTS IN HIPPOCAMPAL NEURONS. D.E. Garcia¹, P.N. Velázquez², A. Cavalié³ and H.D. Lux¹. Dept. of ¹Physiology and ²Histology, Fac de Medicina, UNAM. AP 70250, CP 04510, México and ³Dept of Neurophysiology, MPI für Psychiatrie, Am Klopferspitz 18A, W-8033 Martinsried, FRG.

Voltage-gated Ca²⁺ channels are associated with functional adaptive changes in neurons. We report that periodic exposure of cultured hippocampal neurons to glutamate or potassium depolarization, increased currents from high voltage-activated calcium channels after a latency of a couple of days. This enhancement was not due to change in membrane capacitance but instead indicated that newly functional channels were present in the membrane. The gating was not changed and, therefore, it was presumably due to an increase in channel density. The intracellular calcium transient (Ca_i) was assessed by Fura-2. In the case of glutamate, Ca_i fell to zero during prolonged exposure whereas in the potassium depolarization it overlapped the application. AP5 partially suppressed Ca_i yet the current response was completely blocked suggesting a possible involvement of the glutamate receptors. These observations point out the importance of calcium channels for synaptic transmission in the nervous system.

463.6

STIMULATION OF m4 MUSCARINIC RECEPTOR SUBTYPE ENHANCES AN L-TYPE CALCIUM CONDUCTANCE IN AIT20 CELLS. K.E. Pemberton* and S.V.P. Jones. Molecular Neuropharmacology, Department of Psychiatry, University of Vermont College of Medicine, Burlington, VT 05405.

The effects of activation of the m4 muscarinic receptor subtype on calcium conductances were studied in the AIT20 cell line, using the whole cell patch clamp technique. AIT20 cells have been previously shown to express only the m4 receptor subtype. Calcium currents were recorded in extracellular solutions containing (mM) NaCl 155, MgCl₂ 1, BaCl₂ 5, Hepes 10, Glucose 20. Patch pipettes (5-7 MΩ) contained (mM) NMGCl 100, MgCl₂ 4, EGTA 10, Hepes 10, ATP 4, creatine phosphate 5, creatine kinase 50 units/ml. Current voltage (I-V) relationships were constructed from the currents measured at the end of 100-500 ms steps from -90 to 50 mV in 10 mV increments from a holding potential of -90 mV. The I-V relationship indicated that the calcium current activated around -30 mV and peaked around -10 mV. Application of BayK8644 (7 μM) dramatically increased the current amplitude and addition of 2-300 μM nifedipine inhibited the current. This is indicative of an L-type calcium conductance. Application of 50 μM acetylcholine (ACh) from a pressure ejection pipette reversibly increased the amplitude of the calcium current 16 ± 3% (n=8). This effect was abolished by pirenzepine (1-3 μM). The ACh-induced increase in calcium current was inhibited in the presence of nifedipine. Preincubation of the AIT20 cells in Pertussis toxin (PTX) overnight also inhibited the ACh effect. It is therefore concluded that stimulation of the m4 muscarinic receptor leads to an enhancement of L-type calcium channel activity mediated by a PTX sensitive G-protein.

Muscarinic-Cholinergic Stimulated Increases in Cytosolic Calcium in SH-SY5Y Human Neuroblastoma have Two Components. by Vincent J. Andaloro and Fulton T. Crews*. Dept. of Pharmacology and Center for Neurobiology of Aging, University of Florida, 32610.

SHSY-5Y cells were loaded with FURA-II to measure intracellular free calcium ($[Ca^{2+}]_i$) responses. Stimulation by carbachol (CCh), a cholinergic agonist, results in a rapid and transient peak increase in cytosolic calcium which decays within two minutes to a sustained plateau level above baseline. Pretreatment with atropine blocks both peak and plateau responses, whereas treatment during the plateau phase rapidly returns $[Ca^{2+}]_i$ to basal levels indicating that both peak and plateau responses require continuous carbachol stimulation. Dose response curves indicate that the ED50 values for peak and plateau are different: 17 ± 4 mM and 0.8 ± 0.2 mM CCh for peak and plateau, respectively. Decreasing extracellular calcium to low levels or the addition of Ni^{2+} or Mn^{2+} , calcium channel antagonists, abolish the plateau suggesting that the peak primarily represents the release of intracellular calcium stores whereas the plateau requires extracellular calcium. Nifedipine did not change either response. Carbachol dose response, time course, and atropine-antagonism experiments measuring inositol polyphosphate formation are consistent with these second messengers mediating one or both of the $[Ca^{2+}]_i$ responses. Pretreatment with CCh results in a rapid loss of the peak $[Ca^{2+}]_i$ response within 1 hour which after 24 hours decreases 94% from control. In contrast, the plateau decrease is only 34% after 24 hrs. These data support the hypothesis that the peak and plateau phases are indeed distinct phenomena, and may even have different physiological roles. (Supported by AG10485 and T32 AG00196).

463.9

MODULATION OF HIGH THRESHOLD CALCIUM CURRENTS BY NOREPINEPHRINE IN ACUTELY ISOLATED RAT SENSORIMOTOR CORTICAL NEURONS. Foehring, R. C.* and Lorenzon, N. M., Dept. of Anatomy and Neurobiology, Univ. of Tenn., Memphis, TN 38163.

We used whole cell recordings of acutely isolated neocortical pyramidal cells to study modulation of Ca^{2+} currents by norepinephrine (NE). NE decreased high-threshold Ca^{2+} currents in a dose-dependent manner. 500 nM NE blocked $12 \pm 5\%$ of the whole cell current and 2 μ M NE blocked $42 \pm 20\%$ of the current. This effect was rapid (onset within a few s, maximum within 30 s), repeatable and fully reversible. NE reduced Ca^{2+} currents at all ages examined (P1-adult). In adults, ω -conotoxin blocked $37 \pm 17\%$ of the current and greatly reduced the amount of current blocked by NE, suggesting that the effect is at least partly exerted upon N-type channels. NE had no effect on the large, slow tail currents induced by BayK-8644, suggesting that L-type channels were not involved under these recording conditions (Ba^{2+} as charge carrier, NMG internal, 10 mM EGTA in pipette to chelate Ca^{2+}).

Specific agonists (isoproterenol, clonidine, phenylephrine) and antagonists (timolol, yohimbine, prazosin) were used to determine the adrenergic receptor subtype involved. These data suggest the involvement of B and α -2 receptors. The effects of NE or isoproterenol were not reduced by prepulses to very positive potentials (+120 mV). In conclusion, NE reduces high-threshold Ca^{2+} currents in neocortical pyramidal cells by multiple mechanisms, involving different receptors, channel types and signalling pathways. Supported by NINDS grant NS27180pk (R.C.F.) and an NIMH predoctoral fellowship (N.M.L.)

NOREPINEPHRINE MODULATION OF CALCIUM CURRENT RECORDED IN THE CELL-ATTACHED PATCH CONFIGURATION. Keith S. Elmstie*, Paul J. Kammermeier & Stephen W. Jones. Depts. of Physiology & Biophysics and Neuroscience, Case Western Reserve University, Cleveland, OH 44106.

Norepinephrine (NE) inhibits ~50% of N-type calcium current when recorded in the whole-cell patch configuration. This inhibition is voltage-dependent since it can be reversed by strong depolarization (facilitation). However, Delcour & Tsien (*Science* 259: 980, 1993) found little, if any, voltage-dependence of NE modulation of N-channels recorded in the cell-attached patch configuration. We recorded from cell-attached patches containing many channels (macropatches) to determine if voltage-dependent modulation could be observed.

Nine of 15 patches recorded with 100 μ M NE in the pipet showed the facilitation expected from modulation (Fig.). For the 9 responsive patches, the postpulse/prepulse ratio ranged from 1.2-1.6 at peak current, compared to 0.9-1.1 in unresponsive patches. The range for control patches (n=6) was 0.9-1.1. Desensitization may explain the absence of observed modulation in unresponsive patches. Alternatively, it is possible that N-channels in some patches are not coupled to adrenergic receptors.

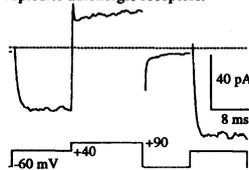

Fig. The trace is an average of 4 runs. The pipet solution contained (mM) 90 $BaCl_2$, 10 TEA-Cl, 10 NMG-HEPES & 100 μ M NE.

INHIBITION BY NORADRENALINE AND NPY OF CALCIUM CURRENTS EVOKED BY ACTION POTENTIAL WAVE FORMS IN RAT SYMPATHETIC NEURONS P.T. Toth* and R.J. Miller. Dept. of Pharmacol. and Physiol. Sciences, Univ. of Chicago, Chicago, IL 60637

Which Ca^{2+} channels are activated during physiological stimuli and how are these regulated by neurotransmitters? In order to answer these questions we studied the inhibition of calcium currents by noradrenaline (NA, 10 μ M) NPY (300nM) and ω -conotoxin GVIA (ω -CgTx, 5 μ M) evoked by action potential wave forms (APW) and regular square wave forms (SW) in neonatal rat sympathetic neurones within 12-36 hours after isolation. Action potentials were recorded in the current clamp mode of whole cell patch-clamp from sympathetic neurones, and the pre-recorded action potential wave form was played back to another sympathetic neuron in a sweep, where a 40 ms square wave depolarization to +10 mV from the same holding potential followed the action potential wave form. The magnitude of APW evoked calcium current was 1.55 times higher than the maximum current evoked by SW (n=24). NA inhibited the APW evoked and the SW evoked calcium currents by 53% and 47% respectively (n=11). NPY inhibition was 40% (APW) and 35% (SW) (n=6). ω -CgTx inhibited the APW evoked and the SW evoked calcium currents by 79% and 70% respectively (n=11). Application of 300 nM nifedipine inhibited the residual calcium current seen after ω -CgTx inhibition by a further 30% (n=5). In another series of experiments the action potential wave form was applied 4 and 8 times (40 and 77 Hz action potential train simulation) in one sweep and the inhibition produced by NA and NPY on the APW evoked calcium currents were compared. Increasing the APW numbers in a sweep gave no relief of the calcium current inhibition by NA and NPY. These results imply that the strength of the presynaptic inhibition produced by NA and NPY at high frequency stimulation would not be decreased. Supported by Fogarty International Fellowship to PTT.

POSTNATAL DEVELOPMENT OF HIGH THRESHOLD CALCIUM CURRENTS IN ACUTELY ISOLATED RAT SENSORIMOTOR CORTICAL NEURONS. Lorenzon, N. M.* and Foehring, R. C. Dept. of Anatomy and Neurobiology, Univ. of Tenn., Memphis, TN 38163.

We studied the postnatal development of voltage-gated calcium currents in acutely isolated rat sensorimotor cortical neurons (P0-adult). In adult cortical neurons, high-voltage activated currents were observed in all cells (average peak current amplitude, 890 ± 378 pA; recording conditions: 5 mM Ba^{2+} as charge carrier, NMG internal with 10 mM EGTA). At a given age, we saw considerable variability in the relative proportions of the various current components. The dihydropyridine antagonist, nifedipine (2-10 μ M) blocked $31 \pm 13\%$ of the high threshold current, and ω -conotoxin (1-2 μ M) blocked $37 \pm 17\%$. The dihydropyridine agonist, BayK 8644 increased the peak current by $14 \pm 13\%$, and produced large slow tail currents. ω -agatoxin reduced the peak current by about 20%. There was a current component that was resistant to all three blockers.

Calcium current density increased during the first postnatal week reaching adult levels at about the second postnatal week. At postnatal days 2-4, high threshold calcium currents were small in amplitude (172 ± 85 pA), and were composed of a small nifedipine-sensitive component ($6 \pm 6\%$), a larger conotoxin-sensitive component ($29 \pm 34\%$), and was dominated by a nifedipine- and conotoxin-resistant component. The relative proportions of these three components to the high threshold current reach adult values at approximately 1 week of age. Supported by NINDS grant NS27180 (R.C.F.) and an NIMH predoctoral fellowship (N.M.L.).

DOPAMINE MODULATES SINGLE CHANNEL PROPERTIES OF L-TYPE CALCIUM CHANNELS IN WHITE BASS CONE HORIZONTAL CELLS. C. Pfeiffer-Linn* and E.M. Lasater. Dep't. Ophthalmology, Univ. of Utah, Salt Lake City, UT.

White bass cone horizontal cells contain a voltage-activated calcium current which resembles a sustained L-type current. Recently, using whole cell patch clamp techniques, we have found that dopamine enhanced this L-type current through the D1 type receptor via the cAMP second messenger system (Pfeiffer-Linn and Lasater, J. Gen. Physiol., In Press). Here, we report the effect of dopamine on the single channel properties of the L-type calcium channel using outside-out excised patches obtained from isolated cultured white bass cone horizontal cells. Under pharmacological conditions favoring the sole expression of L-type calcium currents, dopamine significantly effected channel open and close times. Distributions for both the open and close times were best fit with 2 exponentials. Dopamine significantly increased the mean open times by 38% for τ_1 and by 35% for τ_2 from control conditions. As a result, calcium conductance through channels increased by an average of 138%. Dopamine also increased the frequency of channel openings by an average of 225% from control. Similar results were obtained using specific D1 receptor agonists and a cAMP activator. We conclude that dopamine potentiates the activity of L-type calcium channels in bass cone horizontal cells by increasing the amplitude of calcium current through individual channels and by altering the kinetics of the ion channel to favor the open state.

EFFECTS OF NERVE GROWTH FACTOR (NGF) ON ACUTE ETHANOL INHIBITION OF CALCIUM (Ca^{2+}) CURRENTS INVOLVE MULTIPLE PROCESSES IN PC12 CELLS. D. Mullikin-Kilpatrick* and S. N. Treisman. Department of Pharmacology, University of Massachusetts Medical Center, Worcester, MA. 01655.

Differentiation with NGF requires a period of days before many of the morphological and intracellular changes associated with this treatment occur. NGF treatment (50ng/ml for 7-10 days) of PC12 cells caused a decrease in acute ethanol (25 mM) inhibition of high voltage-activated Ca^{2+} channels from ~45% in undifferentiated (UND) cells to ~17% in treated cells. We examined the time-course of this reduction in ethanol sensitivity, using whole-cell patch clamp techniques. The decrease in sensitivity occurred in two phases. Inhibition of currents in cells treated with NGF for 15 min was comparable to inhibition in UND cells, but fell to ~26% of UND values after a 2 hr exposure to NGF. This spike of insensitivity to ethanol was followed by a return to values indistinguishable from UND values after a 5 hr exposure to NGF. Further exposure (10-240 hrs) led to a second phase which was characterized by a steady decline in inhibition to ~37% of UND values. Ca^{2+} channel sensitivity to ethanol returned to UND cell levels after removal of NGF. We also examined the ability of dbcAMP to affect ethanol inhibition. A 2 hr exposure to 0.5mM dbcAMP caused a sharp drop in inhibition, similar to the transient effect seen after NGF treatment. However, the second phase of reduced sensitivity seen with NGF treatment was absent. These results suggest that the effects of NGF on acute ethanol inhibition of Ca^{2+} currents involve multiple processes with varying time courses. Supported by NIH grant AA05542

EPIDERMAL GROWTH FACTOR (EGF) STIMULATES THE FUNCTIONAL EXPRESSION OF HIGH-THRESHOLD CALCIUM CHANNELS IN CLONAL PITUITARY CELLS. U. Meza, A. Navarrete, A. Marin and G. Cota*. Dept. of Neurosciences, Cinvestav, Mexico, DF 07000.

Chronic treatment of GH_3 cells and related rat pituitary cell lines with EGF stimulates prolactin synthesis. We investigate here whether EGF regulates the functional activity of voltage-dependent Ca channels. GH_3 cells were cultured for 5-6 days under standard conditions or in the presence of 5 nM EGF. Patch-clamp experiments were then carried out to record whole-cell Ca^{2+} currents (5 mM external Ca^{2+} ; HP -80 mV). Peak current at +20 mV was -95 ± 12 pA in control cells (mean \pm SE, n=20) and -208 ± 19 pA in EGF-treated cells (n=18). Cell capacitance was 11.2 ± 0.7 and 13.7 ± 0.6 pF, respectively. Analysis of tail Ca^{2+} currents revealed a selective increase in the activity of high-threshold Ca channels in the EGF-treated cells, with no significant change in channel closing kinetics. Such an effect was long-lasting, and gradually decreased following EGF withdrawal; full recovery took 3-5 days. Regulation of Ca channel expression by growth factors may be a general mechanism for producing long-term changes in the secretory behavior of endocrine cells.

PREFERENTIAL INHIBITION OF ONE KINETIC COMPONENT OF L-TYPE CALCIUM CHANNEL CURRENT BY TRH IN GH_3 CELLS. D.M. Fagg* and E.S. Levitan. Depts. of Behavioral Neuroscience and Pharmacology, Univ. of Pittsburgh, Pittsburgh, PA 15260.

Thyrotropin releasing hormone (TRH) inhibits L-type calcium channels in GH_3 cells. To test the voltage dependence of this inhibition, whole cell patch clamp barium tail currents were measured under conditions which isolated L-current. Following a 10 ms depolarization to a maximally activating potential (+50 mV), the tail current measured at -40 mV decayed with a time constant of ~150 μ s. Application of the dihydropyridine agonist BAY K 8644 (1 μ M) shifted the activation curve to the left by 15 mV and slowed the tail current decay. The BAY K 8644 modified tails measured at -40 mV were fit by two exponentials with time constants of $1.79 \pm .29$ ms and 7.86 ± 1.56 ms (n = 10). TRH (1 μ M) reduced the amplitude of the tail currents by ~25% in a voltage-independent manner both in the presence and absence of BAY K 8644. TRH-inhibited tail currents had altered decay kinetics from controls. Specifically, TRH preferentially reduced the amplitude of the slow component of the decay (by 53%, p = .001), while only slightly reducing the fast component (by 20%, p = .04). The time constants of the tails were not altered by TRH. Preliminary evidence indicates that the two components of the tail may be differentially sensitive to BAY K 8644. One possible conclusion is that two subtypes of L-channels are expressed in GH_3 cells with different sensitivities to TRH and dihydropyridines.

NGF MAY DIRECTLY ACTIVATE VOLTAGE INDEPENDENT CALCIUM CHANNELS IN PC12 CELLS. S.A. Scott* and J.A. Strong. Dept. of Biol. Sci., Purdue University., W. Lafayette, IN 47907.

Voltage independent calcium channels have been described in a variety of cell types. This broad class of Ca channels includes channels that are regulated by either extracellular or intracellular ligands. We reported that PC12 cells contain two novel voltage independent Ca channels that are usually inactive in cell-attached patches which could be activated by patch excision or incubation with pertussis toxin¹. The question still remains as to what the physiological regulator(s) of these Ca channels are. PC12 cells differentiate when incubated with nerve growth factor (NGF), changing from a proliferating secretory cell to a "sympathetic neuron". Among the many effects of NGF on PC12 cells are very rapid morphological changes which do not require protein synthesis and long term effects such as neurite outgrowth which do require protein synthesis. One of the early effects of NGF is a rapid, transient influx of Ca which occurs at least in part through voltage independent pathways^{2,3}. These rapid Ca changes have been measured using Ca sensitive fluorescent dyes and ⁴⁵Ca influx across the plasma membrane. The single channel basis for this Ca influx is still unknown. Using single channel recording techniques we find that two voltage independent Ca channels are active in cell-attached membrane patches when NGF (50-100 ng/ml) is included in the recording pipette (10 of 17 patches p<.1 when compared to 14 control patches). These two NGF-activated channels share several characteristics with the PTX- and excitation activated channels: they have the same conductances (3-5 and 16 pS in 20mM Ca), long open times, and lack of voltage dependence. In contrast, when NGF was added to the bath solution no channel activity was seen in cell-attached patches (n=3), suggesting the NGF effect is membrane delimited. These two channels may be subject to both positive and negative regulation, through multiple converging pathways. ¹ Soc. Neurosci. Abstr 18:1270. ² A.P. Alonso et al., FEBS Lett 208: 48-51. ³ A. 463.16

NEURAL REGULATION OF Ca CHANNEL EXPRESSION IN PITUITARY MELANOTROPES OF NEONATAL RATS. J.C. Gomora*, A. Navarrete, A. Marin and G. Cota. Dept. of Physiology, Biophysics and Neurosciences, Cinvestav, Mexico, DF 07000.

The dopaminergic innervation of the intermediate lobe (IL) of the rat pituitary is first detected on postnatal day 3, and is well developed 9 days later (Gary and Chronwall, *Int. J. Devl. Neurosci.* 10:131, 1992). Here, we show a clear reduction on the activity of high-threshold Ca channels in the endocrine cells of the IL (melanotropes) concomitant with the onset of innervation. IL cell cultures were obtained from 2- or 12-day-old rats (PN2 and PN12 cells, respectively). Whole-cell Ca^{2+} currents were recorded from single melanotropes after 5-22 h in culture by using the patch-clamp technique. In the presence of 10 mM external Ca^{2+} , peak Ca^{2+} current at +20 mV (HP -80 mV) was -80 ± 9 pA in PN2 cells (mean \pm SE, n=16) and -31 ± 5 pA (n=14) in PN12 cells. Cell capacitance was close to 4 ± 3 pF in both cell groups. The high-threshold Ca current was 2.3-fold larger in PN2 cells than in PN12 cells, as determined from tail current measurements. The results suggest that Ca channel expression in melanotropes is drastically inhibited following innervation.

SUBCELLULAR LOCALIZATION OF NITRIC OXIDE SYNTHASE AND MODULATION OF CALCIUM CHANNELS BY NITRIC OXIDE IN ROD PHOTORECEPTORS. D.E. Kurenyy*, L.L. Moroz* and S. Barnes*. Neuroscience Research Group, University of Calgary, Alberta, Canada T2N 4N1 and Department of Physiology, Byelorussian State University, Minsk, Belarus.

Two subcellular compartments in the outer retina of tiger salamander were identified as likely sites of nitric oxide (NO) production using NADPH-diaphorase histochemistry and NO synthase immunocytochemistry. One, within the photoreceptors, is the ellipsoid region of both rods and cones, the other, surrounding the photoreceptor cell bodies, is confined to the most distal region of Müller (glial) cells. This pattern of staining suggests a role for NO in photoreceptor function, possibly via intra- or trans-cellular modulation of inner segment ion channels.

The actions of NO on the barium conducting L-type Ca channel of rods were investigated via superfusion of NO-generator S-nitrosocysteine (SNC) using the nystatin perforated patch technique. First applications of fresh NO-containing solutions increased barium current by shifting the Ca channel activation curve on the voltage axis. SNC (100-200 μ M) shifted activation by -4.1 ± 0.8 mV (n=6, SE) (e.g. in the negative direction). Second and third applications of SNC produced shifts of -0.7 ± 0.4 mV and -0.3 ± 0.4 mV, respectively. No change in leak current at the holding potential of -60 mV occurred in barium-containing saline. Degassed solutions were used as controls and had no statistically significant effects (shift of $+0.3 \pm 0.6$ mV). As adjustments in Ca channel activation translate into significant changes in synaptic output, NO could act to alter transmission from photoreceptors. We thank T. Dawson and S. Snyder for antibodies against rat cerebellar NO synthase. Supported by the Medical Research Council and the Alberta Heritage Foundation for Medical Research.

NITRIC OXIDE MODULATES Ca^{2+} CURRENTS OF SUPERIOR CERVICAL GANGLION NEURONS. Chu Chen* and Geoffrey G. Schofield. Department of Physiology, Tulane University School of Medicine, New Orleans, LA 70112.

Increased evidence suggests that nitric oxide (NO) is a central and peripheral neuronal messenger or a new class of neurotransmitter. Recent experiments show that NO is involved in modulation of norepinephrine (NE) release, but the results are quite controversial. It has been reported that NO inhibits NE release from sympathetic nerve terminals, whereas others show that NO synthesis inhibitors decrease the release of NE. We observed recently that NO donors enhance the amplitude of neuronal Ca^{2+} currents which could underly enhanced exocytotic release of NE. In the present study we investigated possible mechanism(s) of NO induced enhancement of Ca^{2+} channel currents in rat sympathetic neurons using the whole-cell patch-clamp technique. 500 μ M of the nitric oxide donors, sodium nitroprusside (SNP) and S-nitroso-N-acetylpenicillamine (SNAP) increased Ca^{2+} current amplitudes by either extracellular or intracellular application. Intracellular application of 1 mM cGMP or 100 μ M M & B 22948 (a cGMP phosphodiesterase inhibitor) also enhanced the amplitude of Ca^{2+} currents. 100 μ M methylene blue decreased the SNP (500 μ M) induced enhancement of Ca^{2+} currents. In addition, SNP and SNAP, as well as cGMP prevented NE-induced inhibition of Ca^{2+} currents and reduced NE-induced facilitation of Ca^{2+} current amplitude produced by a depolarizing conditioning pulse. The results suggest that NO may facilitate the release of NE from the sympathetic neurons and that NO induces enhancement of Ca^{2+} currents via stimulation of cGMP formation. COMPLEMENTARY DNA CLONING OF A CYCLIC NUCLEOTIDE ACTIVATED CATION CHANNEL FROM CHICK BRAIN AND HEART. Leslie C. Timpe* and Katherine A. Logee, Cardiovascular Research Institute, Box 0572, UCSF, San Francisco, California 94143.

Ion channels that select for cations and that are activated by membrane hyperpolarization have been identified in vertebrate photoreceptors, in various central neurons, and in cardiac pacemaker tissue. The cardiac channel is activated directly by cAMP (DiFrancesco and Tortora, Nature 351:145). Sensory transduction channels of vertebrate photoreceptors and olfactory epithelia are also activated by cyclic nucleotides and are cation-selective. We designed degenerate primers for the polymerase chain reaction (PCR) from the sensory transduction channel amino acid sequences, and used them in PCR reactions with cow, Xenopus tadpole and chick heart cDNA as template, in an attempt to clone complementary DNA for a hyperpolarization-activated channel. The PCR reactions yielded 800 base pair products that are approximately 80% identical to the sensory transduction channels in predicted amino acid sequence. Regions of identity include part of a cyclic nucleotide binding domain; there is also limited sequence similarity to a potential pore-lining sequence in Shaker K^+ channels. Northern blots of chick brain, heart, limb and liver A^+ RNA demonstrate a signal of 3.5 to 4 kb in each organ. The PCR fragments are being used for in situ hybridization to identify the tissues that express the message, and for screening cDNA libraries.

CALCIUM-ACTIVATED CHLORIDE CURRENTS ELICITED BY FLASH PHOTOLYSIS OF DM-NITROPHEN IN CULTURED RAT SENSORY NEURONES. K.P.M. Currie* and R.H. Scott. Dept. of Physiology, St. George's Hosp. Med. Sch., London SW17 0RE, UK.

We have previously reported that a subpopulation of cultured dorsal root ganglion neurones possess a Ca^{2+} -activated chloride current ($I_{Cl(Ca)}$) which can be activated by release of Ca^{2+} from intracellular stores or by Ca^{2+} influx through voltage-gated Ca^{2+} currents (I_{Ca}). Here we further characterise $I_{Cl(Ca)}$ and report its activation by photorelease of Ca^{2+} from DM-Nitrophen (DM). Cells were voltage clamped using the whole cell recording technique with CsCl based patch pipette solution containing 4mM DM and 2mM Ca^{2+} . Flash photolysis elicited transient inward currents (mean peak amplitude of -417 ± 83 pA ($n=34$)) only in those cells which possessed an inward tail current following I_{Ca} . Flash responses could also be obtained during the decay of the tail currents but were never larger than the peak amplitude of the tail current itself. The flash responses were identified as $I_{Cl(Ca)}$ using the chloride channel blocker niflumic acid (10 μ M) which inhibited the current by $69 \pm 3\%$ ($n=5$) and by extracellular anion substitution. Our results suggest that under these conditions, at least at negative holding potentials, $I_{Cl(Ca)}$ decay is due to deactivation rather than inactivation, but at depolarised holding potentials only comparatively small flash induced outward currents were ever seen (even at +90mV) suggesting inward rectification of the flash induced current.

HYPOTONIC STRESS INDUCES A Ca^{2+} INDEPENDENT INWARD CURRENT IN HSG-PA CELLS. S. Fatherazi*, K. Izutsu, R. Wellner & C. Belton, Oral Biology, Univ. of Washington, Seattle, WA 98195, & Toxicology Div., USAMRIID, Ft. Detrick, Frederick, MD 21701.

The whole cell patch-clamp technique was used to characterize the inward current activated by hypotonic stress in HSG-PA cells. Cells were perfused with a medium containing (mM): 140 N-methyl-D-glucamine (NMG) Cl, 2 $CaCl_2$, 5 KCl, 1 $MgCl_2$, pH=7.4, and dialyzed with (mM): 135 CsCl, 2 NaATP, 2 $MgCl_2$, 0.1 EGTA, 0.2 GTP, pH=7.4. Cell conductance changes were monitored using a holding potential of -39 mV and 100 msec pulses to 0 mV, the equilibrium potential for Cl ion and -90 mV, the equilibrium potential for K ions. I-V curves were generated using a staircase of 10-20 mV voltage steps of 10 msec duration. Replacement of internal K^+ with Cs^+ and external Na^+ with NMG $^+$ minimized the K^+ and nonspecific cationic currents. Then, exposing cells to 20% to 50% hypotonic solutions induced an inward current. This current reversed at $+3 \pm 1$ mV ($n=5$) and shifted towards more positive membrane potential when Cl^- was replaced with the less permeable gluconate ion (45 ± 5 mV, $n=5$ versus expected reversal potential of +64 mV). Although exposure of Fura-2 loaded cells to 30% hypotonic solutions caused a 3-5 fold increase in intracellular Ca^{2+} concentration, 5-10 mM BAPTA in the pipette did not block the activated current ($n=7$). Application of 50 μ M SITS (4-acetamido-isothiocyanostilbene-2,2'-disulphonic acid), a Cl^- channel blocker, rapidly and reversibly decreased this current by $92.5 \pm 2.5\%$ ($n=4$). These results suggest that hypotonic stress activates a Ca^{2+} independent inward Cl current in HSG-PA cells. Supported by NIDR grant DE09812.

Neurokinin-3 receptors coupled to a chloride conductance in guinea pig myenteric neurons. P. P. Bertrand, J. J. Galligan. Dept. Pharmacol./Toxicol. Michigan State University, E. Lansing, MI 48824.

In the myenteric plexus, substance P (SP), acting at neurokinin-3 (NK-3) receptors, is a putative mediator of the slow excitatory post-synaptic current (sEPSC). The sEPSC is due to inactivation of resting calcium-activated potassium conductance ($G_{K(Ca)}$) and activation of a non-potassium (non- G_K) inward current associated with a conductance increase. SP and the SP analog senktide (a NK-3 selective agonist) mimic the sEPSC. The purpose of this study was to characterize the conductances coupled to NK-3 receptor activation. Conventional single electrode voltage clamp techniques were used to record membrane currents from single AH-cells. The non- G_K was evident in approx. 25% of neurons and reversed at -8 ± 2 mV with a 2M KCl recording electrode. The non- G_K was unmasked by forskolin, which selectively inhibits $G_{K(Ca)}$. Niflumic acid (NFA) (3-300 μ M), a non-specific chloride channel blocker, inhibited the senktide-activated non- G_K (EC_{50} 30 μ M). In addition, NFA (30-300 μ M) caused an increase in $G_{K(Ca)}$ (rev. -94mV) that was sensitive to calcium channel blockade and available for senktide-dependent closure. Chloride replacement with isethionate, gluconate or glucose (both Na^+ and Cl^- replacement) first attenuated, then blocked the non- G_K . Replacement of NaCl with choline-Cl had no effect. Pressure applied gamma-aminobutyrate (GABA) (1mM) produced a large chloride conductance (G_{Cl}) that was partially blocked by NFA in a use-dependent fashion and was transiently increased, then decreased by chloride replacement. In summary, these data suggest that NK-3 activation inhibits $G_{K(Ca)}$ and activates G_{Cl} . NFA blocked the increase in G_{Cl} caused by both senktide and GABA. In addition, NFA opened a population of $G_{K(Ca)}$ that was similar to potassium channels closed by NK-3 activation. (Supported by DK 40210)

SECRETION-ASSOCIATED MODULATION OF CHLORIDE CHANNELS PRESENT IN SECRETORY VESICLES.

H. Tamir*, J. Piscopo, K.P. Liu, M. Adlersberg, E.A. Nunez, and M.D. Gershon, Phillips Electronic, Mahwah, NJ; NY State Psych. Inst. and Dept. of Anat. and Cell Biol. Columbia University, New York, NY.

Parafollicular (PF) cells of the thyroid gland are paraneurons; they are derived from the neural crest and extend neurites when exposed to NGF. PF cells exhibit properties, such as biosynthesis and secretion of 5-HT, that are also manifested by serotonergic neurons. 5-HT is stored in secretory vesicles together with a nerve-specific serotonin binding protein. PF cells secrete 5-HT in response to stimulation by thyroid stimulating hormone (TSH) or \uparrow $[Ca^{2+}]_i$. The interior pH in most of the secretory vesicles of unstimulated cells is near neutral; however, the vesicles acidify prior to exocytosis when the cells are treated with a secretagogue. It has been proposed that this acidification is due to the ATP-driven translocation H^+ into vesicles, which is made possible by the secretagogue-evoked opening of Cl^- channels in the vesicular membrane. This channel opening would permit Cl^- to enter the vesicles and dissipate the membrane potential that would otherwise be generated by the movement of H^+ and prevent further H^+ transport. This hypothesis was tested. We now demonstrate that antibodies raised against a 62 kDa Cl^- channel, purified from renal epithelium, specifically react with a 62 kDa protein in ghosts prepared from isolated secretory vesicles of PF cells. X-ray microanalysis, carried out with an electron microscope, revealed that treatment of isolated PF cells with the secretagogues, TSH or \uparrow $[Ca^{2+}]_i$ causes the relative concentration of Cl^- (the Cl^- /sulfur ratio) within secretory vesicles to increase 8-10-fold. The possibility the vesicular Cl^- channel could be gated by phosphorylation was evaluated. Isolated vesicles were found to exhibit endogenous kinase activity and these kinases phosphorylate the Cl^- channel in the presence of ^{32}P -ATP. These observations confirm that a Cl^- channel is present in the membranes of the secretory vesicles of PF cells and directly demonstrate that secretion is preceded by the movement of Cl^- into the vesicles. It is suggested that secretion-acidification coupling in the 5-HT-storing vesicles of PF cells is mediated by phosphorylation of the vesicular Cl^- channels. This study was supported by grants MH 37575, DK19743, and NS12969.

PURIFICATION OF PHOTOAFFINITY LABELED AVERMECTIN BINDING PROTEINS FROM *CAENORHABDITIS ELEGANS* AND *DROSOPHILA MELANOGASTER*. S.P. Rohrer*, E. Birzin, E. Hayes, E. Jacobson and J. Schaeffer, Department of Cellular Biochemistry and Physiology, Merck Research Laboratories, Rahway, NJ 07065

The avermectins are a family of macrocyclic lactones isolated as natural fermentation products from the bacterium *Streptomyces avermitilis* and characterized by their potent anthelmintic and insecticidal properties. This class of compounds displays a high degree of selectivity for invertebrate tissues and while they are known to cause an increase in membrane permeability to chloride ions, the precise mechanism by which they exert their paralytic effects in insects and nematodes has yet to be elucidated. Avermectin binding proteins from the free living nematode, *Caenorhabditis elegans* and from the fruit fly, *Drosophila melanogaster* were identified by photoaffinity labeling with a radioactive azido-avermectin analog. Affinity labeled proteins from both *C. elegans* and *Drosophila* were partially purified under denaturing conditions on Sephacryl S-300 gel filtration columns. The second step in the purification scheme involved the use of a monoclonal antibody against avermectin B_{1a} as an immunofluorescence reagent. ^{125}I -Azido-AVM labeled proteins from *C. elegans* as well as the affinity labeled *Drosophila* protein were immunoprecipitated by the anti-AVM MAb coupled covalently to Sepharose beads. 45 pmol of the *Drosophila* AVM binding protein were purified using this approach.

VOLUME-SENSITIVE ANION CHANNELS MEDIATE SWELLING-ACTIVATED INOSITOL AND TAURINE EFFLUX FROM C6 GLIOMA CELLS. K. Strange* and P. S. Jackson, Div. of Nephrology, Dept. of Medicine, and Dept. of Neurosurgery, Children's Hospital, Harvard Medical School, Boston, MA 02115.

C6 glioma cells, like brain cells *in vivo*, accumulate volume regulatory organic osmolytes such as inositol and taurine in response to chronic hypertonic stress. Upon return to isotonic conditions, the cells minimize osmotic swelling by rapid activation of volume-sensitive transport pathways that mediate the efflux of these solutes. The inositol efflux pathway is a Na^+ -independent, passive, unsaturable transport system that is blocked 80-100% by a number of anion transport inhibitors, certain lipoxigenase inhibitors and various polyunsaturated fatty acids. The taurine efflux pathway has characteristics that are identical to those of the inositol efflux mechanism including kinetics of activation and inactivation, osmotic sensitivity, pharmacological sensitivity and inhibition by certain Na^+ and Cl^- substitutes. These results suggest strongly that volume-sensitive inositol and taurine efflux are mediated by a common transport mechanism. The inhibition of the transport pathway by anion transport blockers and unsaturated fatty acids suggests indirectly that efflux of these solutes may be mediated by an anion channel. We tested this hypothesis by performing whole cell patch clamp measurements with symmetrical CsCl solutions. Under hypertonic conditions, C6 cells had an extremely small membrane conductance (< 0.02 nS/pF). Following cell swelling induced by return to isotonic medium, however, a large anion conductance (1.5-2 nS/pF) was activated rapidly. This conductance was outwardly rectified, selective for Cl^- and was inhibited 80-100% by blockers of swelling-activated inositol and taurine efflux. The relative taurine permeability (i.e., $P_{taurine}/P_{Cl}$) of the conductance was 0.2. We conclude that a volume-sensitive anion channel mediates that the efflux of structurally diverse organic osmolytes such as taurine and inositol from the cell. (Supported by NIH grants NS30591 and DK45628, and the American Heart Association).

ACETYLCHOLINE RECEPTORS: MUSCARINIC SUBTYPES

465.1

m5 MUSCARINIC RECEPTORS: AUTORADIOGRAPHIC LOCALIZATION IN RAT AND HUMAN BRAIN. M.T. Vilaró, J.M. Palacios* and G. Mengod*. 1) Dpt. Neurochemistry, CID/CNIC, 2) Laboratorios Almirall. Barcelona. Spain.

Five genes (m1-m5) encoding muscarinic acetylcholine receptors have been cloned and their mRNAs detected in brain. However, only 4 subtypes (M_1 - M_4) have been described pharmacologically. We have combined *in situ* hybridization histochemistry and *in vitro* receptor autoradiography to study the possible existence of m5 receptor proteins in brain. m5 mRNA had a restricted distribution in rat brain. Most notably, it was present in hippocampus, substantia nigra compacta (SNc), ventral tegmental area, lateral habenula (LH), hypothalamic nuclei, and parabrachial nucleus. In previous autoradiographic studies with 3H -4-DAMP, a reported M_1/M_3 selective antagonist, we observed rather high densities of labelled sites in rat SNC. On the other hand, 3H -4-DAMP has high affinities for m1 and m3 cloned receptors but also for m4 and m5 receptors. Thus, it is possible that 3H -4-DAMP sites in SNC correspond to m5 receptors. We studied the pharmacological properties of 3H -4-DAMP sites in SNC and LH in comparison with sites in regions enriched in M_1 , M_3 and M_4 receptors. The compound AQ-RA 741 was used since it has much lower affinities for cloned m5 receptors than for the other 4 subtypes. Brain sections were incubated with 3H -4-DAMP and increasing concentrations of AQ-RA 741. The compound had much lower affinity for 3H -4-DAMP sites in SNC and LH than for sites in M_1 -, M_3 - and M_4 -rich regions, thus suggesting the presence in rat brain of muscarinic receptor proteins encoded by the m5 gene and with pharmacological properties resembling those of cloned m5 receptors. Therefore, the pharmacological classification of muscarinic receptors can tentatively be expanded to include M_5 receptors. Data from similar experiments in human brain will also be presented. (Part of this work was done at Sandoz Pharma, Basel, Switzerland)

465.2

m1-m5 MUSCARINIC RECEPTOR DISTRIBUTION AND QUANTIFICATION IN RAT CNS BY RT-PCR AND HPLC. J. Wei, A. Milici and J.J. Buccafusco*, Department of Pharmacology and Toxicology, Medical College of Georgia, and the DVAMC, Augusta, GA 30912.

Five muscarinic receptor (MR) (m1-m5) genes have been cloned which encode distinct MR subtypes. Because of their structural homology and pharmacological similarity, ligand binding probes currently available do not clearly distinguish among the subtypes. To obtain a clear distribution within the CNS of molecularly-defined MR subtypes, 7 brain regions were examined for the expression of the respective mRNAs. The most sensitive method for detecting mRNA is through amplification of the respective cDNAs. Brain regions were obtained from male Wistar rats and total RNA was isolated using the RNazol kit. Next, the extracted RNA was extensively treated with RNase-free DNase to remove any residual genomic DNA. $1\mu g$ total RNA was reverse transcribed using random primers and reverse transcriptase. The resulting cDNA was amplified using a thermal cycler for 33 cycles at 95°C for 1 min and 62°C for 1 min. The PCR-amplified products were analyzed by gel electrophoresis (1.8% agarose gel containing ethidium bromide) and were visualized with fluorescent illumination. PCR-amplified samples were also injected directly onto an HPLC anion exchange column and quantitated by UV detection. At least 4 of the 5 MR subtypes were found in each brain region examined. The m1 subtype was most abundant in cortex and gradually declined in content caudally to the spinal cord. The m2 subtype was most abundant in thalamus and pons-medulla. The m4 subtype was found in greatest amount in the striatum while m3 and m5 were expressed consistently throughout the CNS. Supported by a grant from the DVAMC.

465.3

PREDICTION OF THE THREE-DIMENSIONAL STRUCTURE OF MUSCARINIC ACETYLCHOLINE RECEPTORS BASED ON STUDIES WITH CHIMERIC m2/m5 RECEPTORS. Z. Pittel and J. Wess². Natl. Inst. of Diabetes and Digestive and Kidney Diseases, Lab. of Bioorganic Chemistry, Bethesda, MD 20892.

Current three-dimensional models of G protein-coupled receptors are based primarily on high-resolution structural data obtained with bacteriorhodopsin, an integral membrane protein whose molecular structure is characterized by the presence of seven α -helical transmembrane domains (TM I-VII). However, since bacteriorhodopsin does not couple to G proteins and shows very little sequence homology with G protein-linked receptors, the general usefulness of such models remains uncertain.

To gain more direct insight into the three-dimensional structure of muscarinic acetylcholine receptors, we have analyzed the pharmacological properties of a series of hybrid human m2/m5 muscarinic receptors. We found that several of the chimeric constructs studied were unable to bind significant amounts of the radioligand [³H]NMS (drastic reduction in B_{max}), following their transient expression in COS-7 cells. A common structural feature of these constructs was that TM I was derived from the m5 receptor, whereas TM VII originated from the m2 receptor. When the N-terminal portion (including TM I) of these hybrid receptors was replaced with m2 receptor sequence, the resulting chimeric receptors were expressed at high levels (as determined by [³H]NMS saturation binding) and displayed ligand binding properties similar to the two wild type receptors. These data strongly suggest that the molecular architecture of muscarinic receptors (and, most likely, other G protein-coupled receptors) resembles that of bacteriorhodopsin in that the seven TM helices are arranged in a ring-like fashion such that TM I lies directly adjacent to TM VII.

CHOLINERGIC AND GABAergic NEURONS IN THE RAT MEDIAL SEPTUM EXPRESS MUSCARINIC ACETYLCHOLINE RECEPTORS (mAChRs). E.A. Van der Zee¹, T. Matsuyama and P.G.M. Luiten. Dept. of Animal Physiology, University of Groningen, P.O.Box 14, 9750 AA Haren, The Netherlands.

The interaction of the GABAergic and cholinergic systems in the medial septum is crucial for hippocampal functioning, particularly in relation to the generation of theta rhythms. In the present study we determined whether cholinergic and GABAergic neurons of the medial septum express mAChRs employing the monoclonal antibody M35 raised against purified mAChR-protein. Alternating cryosections of 6 young adult male Wistar rats were immunoprocessed for mAChRs, ChAT, or histochemically stained for AChE. Immunofluorescence doublelabeling was performed for mAChRs and the GABA synthesizing enzyme GAD employing FITC and Phycoerythrin-conjugated antisera, respectively. Numerous medial septal neurons were positively stained for mAChRs, GAD, ChAT and AChE. Adjacent alternating sections revealed that the cholinergic cells express mAChRs. Additionally, GAD-positive cells were found to be mAChR-positive. Quantitative immunocytochemistry showed that approximately half of all mAChR-positive neurons (52.3%; 1115 out of 2132 neurons) belonged to the GABAergic cell group. Most single-labeled mAChR-positive neurons were located in the lateral regions of the medial septum. Conversely, nearly all GAD-positive neurons were immunostained for mAChRs (98.6%; 1296 out of 1314 neurons). In general, the GABAergic, muscarinic cholinergic neurons were intensely stained for mAChRs, whereas the non-GABAergic, muscarinic cholinergic neurons revealed only weak to moderate levels of mAChR immunoreactivity. The current data show that both GABAergic and cholinergic medial septum neurons express mAChRs, adding anatomical evidence for cholinergic neurotransmission upon both groups of cells.

FUNCTIONAL EXPRESSION OF THE RAT M5 MUSCARINIC ACETYLCHOLINE RECEPTOR (mAChR) IN FISH CELLS. C.-F. Liao^{1*}, Y. G. Lee¹, L.-G. Chen², C.-M. Kuo² and J.-L. Wu¹ Institute of Zoology¹, Academia Sinica Taipei, Taiwan 11529, R.O.C; Institute of Fisheries Science², National Taiwan University, Taipei, Taiwan 10764, R.O.C.

The purpose of this study was to test whether the rat mAChR can interact with a fish G protein. The gene encoding the rat mAChR subtype M5 was subcloned into the expression vector p91023(B). By utilizing calcium phosphate-mediated transfection, the recombinant M5 DNA construct was co-transfected with a *neo* gene selection marker into the mAChR-negative chinook salmon embryo CHSE-214 cells. Stable transformants were selected with G418 and tested for acquisition of mAChRs by following appearance of specific binding sites for the muscarinic ligand [³H]-methyl-scopolamine. Two transfected cell lines, CHSEM5-1 and -2, stably expressing typical mAChRs were obtained. Stimulation of the M5 receptor with carbachol results in time- and dose-dependent increase in phosphoinositide hydrolysis in the CHSEM5 cells. The results suggest that mammalian mAChRs can functionally couple to fish G proteins.

465.4

DIFFERENTIAL LOSS OF STRIATAL MUSCARINIC AND DOPAMINE RECEPTOR SUBTYPES AND THEIR mRNAs FOLLOWING SPECIFIC LESION OF DOPAMINE OR CHOLINERGIC NEURONS. Z. Zang¹ and Jan Creese. Center for Molecular & Behavioral Neuroscience, Rutgers, The State University of New Jersey, Newark, NJ 07102 USA.

Quantitative solution hybridization/RNase protection assays (SHRPA) were developed to examine the effects of 6-OHDA lesion of the nigrostriatal dopaminergic pathway or AF64A lesion of striatal cholinergic neurons on the levels of rat striatal muscarinic receptor subtype (m1-m4) and D₂ receptor mRNAs. Muscarinic or dopamine (D₁ and D₂) receptor binding was also determined. Three weeks following 6-OHDA lesion, there was a 19% reduction in striatal muscarinic receptor [³H]QNB binding sites. SHRPA showed that D₂ receptor mRNA was increased (+30%) by the lesion. None of the muscarinic receptor mRNAs were altered. Three weeks after intrastriatal AF64A injection non-M₁ receptor binding sites were decreased by 19%, m2 and m4 receptor mRNAs were reduced by -26% and -36% respectively and the striatal D₂ receptor mRNA was also reduced by -27%. However, AF64A lesion did not alter M₁ receptors, m1 or m3 mRNA or D₁ receptor levels. These results suggest that (1) presynaptic muscarinic receptors are found on dopamine neuron terminals, (2) D₂ receptors and a sub-population of muscarinic receptors (m2 and m4) are expressed by striatal cholinergic neurons and (3) D₁, m1 and m3 receptors are expressed by non-cholinergic striatal neurons.

465.6

MUSCARINIC RECEPTOR SUBTYPES IN RAT COCHLEAR NUCLEUS. Kejian Chen¹, Glen E. Green², Hardress J. Waller^{2*}, Dennis G. Drescher², Donald A. Godfrey¹, Depts. of Otolaryngology¹ and Neurological Surgery², Medical College of Ohio, Toledo, OH 43699; and Depts. of Otolaryngology and Biochemistry², Wayne State University, School of Medicine, Detroit, MI 48201.

Acetylcholine is a neurotransmitter in centrifugal pathways to the cochlea and cochlear nucleus. The cholinergic receptor type was previously found with pharmacological methods in brain stem slice preparations to be predominantly muscarinic in dorsal cochlear nucleus. Cholinergic effects on spontaneous activities of rat dorsal cochlear nucleus neurons were not mediated primarily by M₁, M₂ or M₃ subtypes of muscarinic receptors. Selective drugs are not available for M₄ or M₅ subtypes.

The polymerase chain reaction (PCR) method was used to analyze the expression of muscarinic receptor genes in cochlear nucleus. Total RNA was extracted with guanidine thiocyanate from the cochlear nuclei of 20-60 day old, male and female Sprague Dawley rats, and treated with DNase. Messenger RNA was isolated with oligo-dT cellulose and reverse-transcribed with oligo-dT₁₂₋₁₈ primer and RNase H-free reverse transcriptase. The resulting cDNA was amplified by PCR. The reverse-transcription step was omitted in each control group. Specific PCR primers corresponded to published nucleotide sequences for rat mAChRs m₁-m₅. Our preliminary data suggest that the muscarinic acetylcholine receptor subtypes expressed in the rat cochlear nucleus are predominantly m₄ and m₅, which is in agreement with the electrophysiological results.

BINDING OF [³H]- (R)-QUINCLIDINYL BENZILATE ([³H]- (R)-QNB) AND PIRENZEPINE TO PIGEON BRAIN MEMBRANES. E.C. Kohler^{2*}, #W.S. Messer, Jr. and V.P. Bingman. Dept. of Psychology, Bowling Green State Univ., Bowling Green, OH 43403 and #Dept. of Medicinal & Biological Chemistry, College of Pharmacy, University of Toledo, Toledo, OH 43606.

There is evidence suggesting the existence of at least five subtypes of muscarinic acetylcholine receptors (mAChRs). Furthermore, there has been autoradiographic demonstration of heterogeneous distribution of mAChR subtypes in the mammalian brain. The data from other studies (Tietje et al., J. Biol. Chem. 265:2828, '90; J. Biol. Chem. 266:17382, '91) suggests that there may also be more than one type of mAChR in the avian brain. Here we examine the possibility of multiple mAChRs by investigating the binding of [³H]- (R)-QNB and the ability of the M₁ receptor antagonist pirenzepine (PZ) to reduce the binding of [³H]- (R)-QNB in membranes from pigeon brain. An excess of atropine was used to assess non-specific binding in each assay. Saturation curves for [³H]- (R)-QNB indicated a B_{max} of 0.296 pmoles/mg protein and an apparent dissociation constant (K_d) of 39.7 pM. An Eadie-Hofstee analysis suggested biphasic binding of PZ to the receptors in the membrane preparation. There appeared to be a small proportion of receptors (<15%) that bind PZ with very high affinity, with a majority of the receptors having a lower affinity. Current investigations include examination of the distribution of putative mAChR subtypes in the pigeon brain. These data will be useful in determining some of the specific roles of the cholinergic system in studies of avian behavior. This work was supported in part by NS 01493.

465.9

THE BLOCKADE OF M-1 MUSCARINIC RECEPTORS IN THE SUBTHALAMIC NUCLEUS ABOLISHES MUSCULAR RIGIDITY IN RESERPINIZED (PARKINSONIAN) RATS. G. Flores, S. Hernández, A. Sierra, J.-L. Góngora-Alfaro, M. Rosales and J. Aceves. Dept. of Physiology, Biophysics and Neurosciences. CINVESTAV-IPN. Apartado Postal 14-740. 07000 México, D.F., México.

Here we have tested the possibility that the action of anticholinergic drugs in Parkinson's disease could be mediated by blocking the excitatory cholinergic action in the subthalamic nucleus. The experiments were done in unanesthetized rats in which a cannula was chronically positioned just in the border of the subthalamic nucleus. After 5-6 days of the positioning of the cannula, reserpine (5 mg/Kg i.p.) was injected. After 2 h of the injection the locomotor activity was measured for 1 h and then, the spontaneous EMG activity of the ipsilateral gastrocnemius-soleus muscle was continuously recorded. All reserpined rats (n=5) presented a drastic reduction in locomotor activity and all presented spontaneous EMG activity (none normal rat presented EMG activity in the same recording conditions). The injection of the selective antagonist of M-1 muscarinic receptors pirenzepine (1 µg/0.25 µl) into the subthalamic nucleus practically abolished (produced more than 90% fall) the EMG activity (the injection of the same volume of saline did not modified the EMG activity). These results suggest that by blocking the activation of M-1 muscarinic receptors in the subthalamic nucleus anticholinergic drugs control muscular rigidity (judged by the appearance of EMG) in experimental parkinsonism.

DIETARY LIPID MODULATION OF LOW Km GTPase ACTIVITY IN STRIATA OF MATURE F344 RATS. J.F. Kelly,* S.A. Erat, J.A. Joseph, R.P. Mason and G.S. Roth. GRC/NIA/NIH, Baltimore, MD 21224 and U of Conn Health Sciences Ctr, Farmington, Conn.

To investigate the effects of dietary lipid modulation on muscarinic-cholinergic receptor-G protein linked signal transduction in the striatum, we fed 12 mo (mature) male F344 rats purified diets containing 5% soybean oil (Ctrl), 4.5% cholesterol (Hichol), 7.5% coconut oil/2.5% soybean oil (Hisatf) and 0.5% soybean oil (Lofat) for one month. Animals were sacrificed by decapitation and striata frozen and stored at -80 C. Low Km GTPase activity stimulated by oxotremorine (O) 10^{-5} M and carbachol (C) 10^{-3} M was measured using crude striatal membrane incubated with 32 P GTP. For O, all groups differed from Ctrl (Duncans tests $p < .05$). For C, Hichol and Lofat showed significant decreases from Ctrl (Duncans tests $p < .05$). Preliminary analysis of small angle X-ray diffraction of cortical synaptosomes from Lofat animals showed a decrease in membrane width, suggesting both structural and functional effects of dietary lipid modulation in mature F344 rats.

ACETYLCHOLINE RECEPTORS: NICOTINIC RECEPTOR EXPRESSION

466.1

Neural Crest Cells Express mRNA Encoding Neuronal Nicotinic Acetylcholine Receptor Subunits. Marthe J. Howard* and Michael D. Gershon. Department of Anatomy/Cell Biology, Columbia University, New York, NY 10032.

The neural crest gives rise to neurons that express a variety of different neurotransmitters and neurotransmitter receptors. The kinds of neuron that differentiate in tissue culture are dependent upon the growth medium. A subset of sensory and enteric neurons and all sympathetic and parasympathetic neurons express neuronal nicotinic acetylcholine receptors (nAChRs) *in vivo*. The factors in the embryonic environment that induce the expression of these receptors or regulate the subunit composition are unknown. The current studies were undertaken to examine the expression of nAChRs on quail neural crest cells developing in culture and to examine the coordinate expression of AChR α and β subunits. Catecholaminergic and cholinergic neurons develop under the growth conditions used. The polymerase chain reaction (PCR) was used to assess the time of expression of mRNA encoding nAChR subunits; PCR primers were designed from the published sequence of the chicken nAChR subunits. mRNA encoding the $\alpha 3$ subunit of the nAChR was present as early as two days in culture while the mRNA encoding the $\beta 4$ subunit was not detected until the cells had been in culture for 4 days. Northern blot analysis of RNA isolated from neural crest cells grown in culture for 8 or 10 days, using a cDNA probe for the $\alpha 3$ subunit, showed 2.0 kb and 3.5 kb mRNA bands; the 2.0 kb mRNA is not present at 8 days in culture but was detectable by 10 days. Cloning and sequencing of $\alpha 3$ PCR products demonstrated that the quail sequence is 94% homologous at the nucleotide level and 100% homologous at the amino acid level to the chicken sequence. Expression of mRNA encoding *c-jun* did not correlate with the expression of nAChR subunits, but did coincide with the appearance of dopamine- β -hydroxylase, a marker relevant to the noradrenergic phenotype. The data suggest that AChR subunit expression is regulated early in neural crest cell development.

POSTNATAL EXPRESSION OF $\alpha 4$ AND $\beta 2$ SUBUNITS OF THE NEURONAL ACETYLCHOLINE NICOTINIC RECEPTORS IN THE RAT BRAIN. M. Cimino, P. Marini, S. Colombo, F. Cattabeni, N. Brunello*, D. Fomasari and F. Clementi. Inst. of Pharmacol. Univ. of Urbino 61029 Urbino, Dept. of Pharmaceutical Sci. Univ. of Modena, Inst. of Pharmacol. Sci. and CNR Center of Cytopharmacol. Univ. of Milan, Milan, Italy.

Molecular cloning of neuronal acetylcholine receptors (nAChRs) brought to the identification and anatomical localization of mRNAs for several α and β subunits which can generate many subtypes of nAChRs with diverse functional and pharmacological properties. The nAChR formed by the $\alpha 4\beta 2$ subunits is the major brain ACh receptor with high affinity for 3H-L-nicotine. In this study we report the ontogenetic regulation of $\alpha 4$ and $\beta 2$ mRNAs in selected areas of the rat brain using *in situ* hybridization. Brains at 1,7,14, 28,56 and 90 postnatal days (PN) were sectioned and hybridized with 35S-labeled riboprobes. At birth high levels of transcripts were already detected although an uneven distribution of $\alpha 4$ and $\beta 2$ mRNAs was observed. Quantitative analysis revealed that there was a different rate at which the two messages developed in the brain regions. In the hippocampus, a differential ontogenetic expression of the two subunits was observed. Their expression remained unchanged from birth to adulthood in the Ammon's horn, whereas in the dentate gyrus an age-related increase was shown. In the thalamus, the medial, lateral and ventral nuclei showed a decrease of the $\beta 2$ signal from birth to PN14 which, then, rise again to reach its plateau at PN56. A similar pattern was observed in the medial habenula for both probes. In contrast, the expression of $\alpha 4$ showed only a modest increase in the medial and lateral nuclei from birth to PN14. The pattern of distribution for $\alpha 4$ and $\beta 2$, in the thalamic nuclei, was compared with that of the high affinity nicotine binding sites. It is concluded that the expression of both $\beta 2$ and $\alpha 4$ is differentially regulated during brain maturation and that, at least in the thalamus, it doesn't coincide with the development of the 3H-L-nicotine binding sites.

REGULATION OF NICOTINIC ACETYLCHOLINE RECEPTOR TRANSCRIPT LEVELS IN CHICK CILIARY GANGLION NEURONS *IN SITU*. M. Schwartz Levey*, C. Brumwell and M.H. Jacob. Worcester Foundation for Experimental Biology, Shrewsbury, MA 01545.

Nicotinic acetylcholine receptors (AChRs) mediate chemical synaptic transmission in the chick ciliary ganglion (CG) and synaptic AChRs in the CG are composed of $\alpha 3$, $\alpha 5$ and $\beta 4$ subunits. To gain insights into the events that influence the formation, maintenance and function of synapses in the CG, we have been examining the role of cell-cell interactions in regulating $\alpha 3$, $\alpha 5$ and $\beta 4$ subunit mRNA levels. We have previously established that the disruption of afferent inputs or efferent connections in the CG of newly hatched chicks results in a 3- to 4-fold decline in $\alpha 3$ mRNA levels. We have now examined $\alpha 5$ and $\beta 4$ mRNA levels in denervated and axotomized CGs of posthatch chicks using RT-PCR with mutated AChR cRNA internal standards.

Alpha5 and $\beta 4$ subunit mRNA levels are decreased 3- to 4-fold in denervated ganglia as compared to contralateral control innervated ganglia after 9 days. Five days after axotomy, $\alpha 5$ and $\beta 4$ mRNA levels are also reduced 3- to 4-fold relative to contralateral control ganglion values. Further, $\alpha 3$ and $\beta 4$ mRNA levels are decreased 1.5- to 2-fold in embryonic CG neurons that have developed in the absence of these cell-cell interactions following surgical removal of the preganglionic nucleus or the target tissues in the eye prior to synapse formation. These results demonstrate that presynaptic inputs and retrograde signals from the target tissue induce increases in and maintain AChR $\alpha 3$, $\alpha 5$ and $\beta 4$ subunit mRNA levels in CG neurons *in situ*.

THE EFFECT OF CHOLINERGIC DEAFFERENTATION ON HIPPOCAMPAL NEURON RESPONSIVENESS TO NICOTINE. C.J. Frazier* and G.M. Rose. Neuroscience Training Program, UCHSC, and Medical Research, VAMC, Denver, CO 80220

Hippocampal CA1 pyramidal neurons demonstrate an increased responsiveness to nicotine in aged rats (Engstrom et al., *Neurobiol. Aging*, in press). In the periphery, such a change occurs following deafferentation. We therefore decided to test the hypothesis that the loss of cholinergic input to the hippocampus would result in an increase in sensitivity to nicotine. Electrolytic lesions of the medial septal area were made in young male Fischer 344 rats. Approximately thirty days later, the animals were anesthetized with pentobarbital and nicotine was locally applied to electrophysiologically identified CA1 pyramidal neurons using pressure microinjection. Neurons recorded from rats with septal lesions required significantly lower doses of nicotine than control animals to demonstrate a similar excitation. This result supports the hypothesis that an age-related loss of cholinergic input could mediate the observed increase in CA1 pyramidal neuron sensitivity to locally applied nicotine. Interestingly, the lesion-induced increase in sensitivity to nicotine was not as great as that previously observed in the aged population. Based on the assumption that the cholinergic denervation was greater in the lesioned than in the aged rats, these results suggest that some factor other than (or in addition to) simple deafferentation must be involved in the age-related increase in nicotine sensitivity. One possibility is an age-related change in nicotinic receptor subunit composition, leading to differences in receptor conductance.

466.5

NERVE GROWTH FACTOR INCREASES THE TRANSCRIPTIONAL ACTIVITY OF THE NEURONAL NICOTINIC ACETYLCHOLINE RECEPTOR $\beta 4$ SUBUNIT PROMOTER IN PC12 CELLS. M. Hu^{1,2} and P.D. Gardner¹. ¹Institute of Biotechnology, University of Texas Health Science Center, San Antonio, TX 78245 and ²Program in Biochemistry, Dartmouth Medical School, Hanover, NH 03755.

Neuronal nicotinic acetylcholine receptors (nAChR) play a critical role in synaptic transmission in the nervous system. However, little information is available concerning the molecular mechanisms regulating expression of nAChR. We have begun studying the transcriptional regulation of the nAChR genes during neuronal differentiation using nerve growth factor (NGF) treatment of the rat PC12 cell line as a model system. PC12 cells respond to NGF treatment with a broad spectrum of changes and the conversion to a sympathetic neuron-like phenotype. Included in this spectrum is an increase in the number of nAChR on the cell surface and increases in the steady state levels of mRNA encoding the $\alpha 3$, $\alpha 5$, $\alpha 7$, $\beta 2$ and $\beta 4$ subunits. We investigated the possibility that these increases are a consequence of increased transcription of the receptor genes, focussing on the $\beta 4$ subunit gene. We isolated a 2.3-Kb 5'-flanking region of the $\beta 4$ gene and localized the $\beta 4$ transcription initiation site within this region. We demonstrated that this 2.3-Kb fragment is capable of activating transcription of a reporter gene in transfected neuronal cell lines. The transcriptional activity of this fragment is up-regulated approximately 5-fold following treatment of PC12 cells with NGF. These results are consistent with the observed increase of endogenous $\beta 4$ mRNA levels in PC12 cells upon NGF treatment.

CALCIUM-DEPENDENT REGULATION OF NICOTINIC ACETYLCHOLINE RECEPTOR GENE EXPRESSION. D. W. Walke and Daniel Goldman.* Dept. of Biol. Chem., Mental Health Res. Inst., Univ. of Michigan, Ann Arbor, MI 48105.

We have previously shown that raising intracellular levels of cAMP will reverse the effects of muscle depolarization on nAChR gene expression (Chahine et al., JBC 268:2893; 1993). In addition, we have found that raising intracellular levels of calcium will decrease the level of nAChR gene expression found in inactive muscle (Soc. for Neurosci. abstract #189.1 p 436, 1992). Therefore, both cAMP and calcium may be mediating the activity-dependent expression of nAChRs in rat skeletal muscle. We now report that the sequences of the nAChR δ -subunit and ϵ -subunit promoters that mediate calcium regulation map to regions within 102 and 108 nucleotides, respectively, upstream of the start site of transcription. Interestingly these same regions contain sequences conferring activity-dependent regulation on the δ -subunit gene (Chahine et al., Development 115:213; 1992) and synapse-specific expression of the ϵ -subunit gene (Dulcert et al., PNAS 90:3043; 1993). Internal deletions and site-directed mutagenesis have further localized the calcium-dependent regulatory element in the δ -subunit promoter to a small region containing a MyoD binding site consensus sequence.

COOPERATIVITY BETWEEN CYCLIC AMP- AND C-KINASE-DEPENDENT PROCESSES IN THE REGULATION OF NICOTINIC ACETYLCHOLINE RECEPTOR EXPRESSION AND FUNCTION. Ronald J. Lukas* and Merouane Bencherif. Div. Neurobiol., Barrow Neurological Inst., 350 West Thomas Road, Phoenix, Arizona 85013, USA.

We previously have reported that nAChR expression and function in TE671/RD cells can be modulated through stimuli involving transcriptional, translational and/or posttranslational mechanisms (Bencherif and Lukas, Mol. Cell. Neuro., 2: 52-65, 1991; J. Neurochem. in press). Here we report that activation of protein kinase C (PKC) with PMA or mezerein produces (i) immediate enhanced desensitization of nAChR function, (ii) delayed down-regulation of surface nAChR (hours), and (iii) a later increase in total but not surface nAChR numbers (days). By contrast, activation of cAMP-dependent signaling (see Bencherif and Lukas, this volume) enhances recruitment of nAChR from intracellular to cell surface pools. Synchronous activation of PKC and cAMP-dependent pathways produces (i) immediate enhanced desensitization of nAChR function and (ii) an *early* increase in total receptor number (200% at 1 day) followed by (iii) a marked increase in cell surface receptor (400% at 2 days). These data and Northern blot analyses suggest that PKC effects are mediated via both transcriptional and posttranslational mechanisms whereas cAMP effects are limited to changes in posttranslational processing of intracellular nAChR and/or nAChR subunits.

466.6

NGF INCREASES ACh RECEPTOR GENE EXPRESSION AND CURRENT DENSITY IN WILD TYPE AND PROTEIN KINASE A-DEFICIENT PC12 CELLS. L.P. Henderson, M.J. Gdovin, C.L. Liu, P.D. Gardner* and R.A. Maug. Depts of Physiology and Biochemistry, Dartmouth Medical School, Hanover, NH 03755.

Neuronal nicotinic acetylcholine receptors (nAChR) play a key role in synaptic transmission and information transfer in the nervous system. In order to investigate the molecular mechanisms that govern the expression of nAChR and determine their functional properties, we have investigated the nerve growth factor (NGF)-mediated regulation of nAChR expression in rat pheochromocytoma (PC12) cells and protein kinase A (PKA)-deficient PC12 cells (123.7 cells; Ginty et al. J. Biol. Chem. 266:15325). Northern blot analysis of total RNA detected mRNAs encoding the $\alpha 3$, $\alpha 5$, $\alpha 7$, $\beta 2$, and $\beta 4$ subunits in PC12 and 123.7 cells. In contrast, mRNAs encoding the $\alpha 2$, $\alpha 4$, $\alpha 6$ and $\beta 3$ subunits were not detected. NGF treatment increased the steady state levels of the $\alpha 3$, $\alpha 5$, $\alpha 7$, $\beta 2$, and $\beta 4$ subunit mRNAs by 2- to 3-fold in both cell types. The NGF-dependent increases in the steady state levels of nAChR mRNAs were correlated with a 2.5-fold increase in the occurrence of ACh-induced single channel activity in excised outside-out patches. Nearly all ACh-induced events in both untreated and NGF-treated PC12 and 123.7 cells could be attributed to a single class, which had a slope conductance of -46 pS and an average burst duration of -14 ms at -80 mV. In both PC12 and 123.7 cells, ACh-induced macroscopic current density (at -80 mV) was also increased -2.7 -fold by NGF treatment, from -16 pA/pF to -44 pA/pF. There were no significant differences between the kinetic properties of the macroscopic currents elicited in PC12 cells and 123.7 cells, as indicated by the time-to-peak current (~ 100 ms), time constants of the fast and slow components of the current decay (-0.35 and 5 sec) and the relative contribution of the fast component to the total macroscopic current decay ($\sim 75\%$). The results indicate that the NGF-dependent increase in ACh sensitivity in PC12 cells is correlated with increased expression of specific nAChR subunit mRNAs and that a deficiency in PKA activity does not alter the constitutive expression, NGF-stimulated expression or functional properties of nAChRs in these cells. Supported by NIH NS28668 (LPH), NS30243 (PDC), NS28767 (RAM), AHEI, ALSA (LPH), Alfred P. Sloan Foundation (RAM).

466.8

EFFECTS OF DIBUTYRYL CYCLIC AMP OR FORSKOLIN ON MUSCLE- OR GANGLIA-TYPE NICOTINIC RECEPTOR FUNCTION ARE CYCLIC AMP INDEPENDENT. Merouane Bencherif* and Ronald J. Lukas. Division of Neurobiology, Barrow Neurological Institute, 350 West Thomas Road, Phoenix, Arizona 85013, USA.

Dibutyryl cyclic AMP (dbcAMP) and forskolin (FSK) have been widely used as pharmacological tools to implicate cyclic AMP (cAMP)-dependent mechanisms in cellular events. Our studies on muscle- or ganglia-type nicotinic receptor (nAChR) regulation now suggest that effects of dbcAMP or FSK on nAChR expression are unrelated to their putative mimicry of cAMP-dependent signaling. dbcAMP-stimulated downregulation of surface and total nAChR numbers takes hours to develop, reverses with a $T_{1/2}$ of days, is transcriptionally-based, but reflects effects of sodium butyrate alone. At concentrations commonly used to activate adenylyl cyclase (between 5 and 50 μ M), FSK acts acutely (within seconds) to non-competitively antagonize nAChR function and to *inhibit* agonist-induced desensitization of nAChR without affecting nAChR numbers. By contrast, studies with 8-(4-chlorophenylthio)-cAMP and modulators of adenylyl cyclase indicate that activation of cAMP-dependent pathways has no effect on agonist-stimulated receptor function and no effect on total nAChR numbers, but induces a 40% increase in cell surface nAChR within 1 day of drug treatment. These results indicate that effects of dbcAMP or FSK are independent of those due to cAMP and are consistent with cAMP-dependent recruitment of intracellular nAChR to the cell surface.

PROTEIN KINASE A MODULATES NICOTINIC RECEPTOR mRNAs IN PC 12 CELLS. TC Madhok*, HS Beyer and BM Sharp. Endocrine-Neuroscience Research Lab., Minneapolis Medical Research Foundation and Dept. of Medicine, Hennepin County Medical Center and University of Minnesota, Minneapolis, MN 55404

To delineate mechanisms regulating the expression of neuronal nicotinic cholinergic receptors (nChRs), we studied cAMP-dependent second messenger systems. We reported previously that specific 3 H-nicotine binding was upregulated (up to 4-fold) on PC 12 cells grown in dibutyryl-cAMP, in a dose- and time-dependent manner, for 7 d. On the basis of the following observations that: 1) forskolin (10-100 μ M) + isobutyl-methylxanthine (IBMX, 1.0 mM) enhanced 3 H-nicotine binding 2-3-fold at 7 d, whereas forskolin and IBMX alone had no effect, and 2) 3 H-nicotine binding to PC 12 cell mutants (A126.1B2 and A123.7), which do not have cAMP-responsive protein kinase A (PKA) Types I and II, were unaffected by dbcAMP, we suggest that protein kinase A plays a role in regulating expression of nChRs. To gain insight into mechanism(s), the effect of dbcAMP (0.1 mM) on nChR mRNA levels was studied. Northern gels showed that $\alpha 3$ -, $\alpha 5$ -, $\beta 2$ - and $\beta 4$ -mRNAs were present, whereas $\alpha 4$ -, $\alpha 6$ -, and $\beta 3$ -transcripts were not detected. Northern gels also showed that the $\alpha 3$ -, $\alpha 5$ -, and $\beta 4$ -mRNAs were markedly decreased by dbcAMP at 4 hours. However, $\beta 2$ -mRNA increased at 4 h, and then returned to baseline by 24 h. These studies indicate that PKA is involved in the regulation of nChRs. These studies also suggest that enhanced 3 H-nicotine binding may not involve synthesis of new receptor subunit proteins. (Supported by DA04446 and 03977).

CEREBROCORTICAL NEUROTOXICITY AND CHRONIC MEMORY IMPAIRMENT INDUCED BY MK-801 IN THE MOUSE. G. Brosnan-Watters, D. F. Wozniak*, M. McEwen, J. W. Olney, Washington University, St. Louis, MO 63110.

Behavioral and histologic experiments were conducted to study the neurotoxic effects of MK-801 in male mice. A modified version of a hole board food search task was used with a repeated measures design and a massed trials protocol to evaluate the acute effects of a low dose of MK-801 (n=10; 0.05 mg/kg) and then the more chronic effects of a high dose of MK-801 (n=8; 10 mg/kg). The 0.05 mg/kg dose (ip) of MK-801 impaired acquisition on one version of the hole board task (learning which hole was baited in a row of 4) relative to saline performance levels but the same dose did not impair acquisition on another version of the task (4-corner stimulus configuration). Mice were then injected (ip) with the 10 mg/kg dose of MK-801 and tested 2 weeks later on the row configuration and 6 weeks later on the 4-corner version of the task. Relative to their earlier saline performances, they were significantly impaired on both the row and 4-corner configurations. Histologic studies were conducted on separate mice to determine if MK-801 produces the same pathomorphological side effects in mouse cerebrocortical neurons that are produced in the rat (cytoplasmic vacuole formation and dissolution of mitochondria in pyramidal neurons from layers III and IV of the posterior cingulate/retrosplenial (PC/RS) cortices). Mice were injected (sc) with either 0.5 or 1.0 mg/kg MK-801 and sacrificed 4 hr later. Brains were embedded in plastic, thin-sectioned and stained with methylene blue/azure II and examined by light microscopy. Fifty percent (3/6) of the mice dosed with 0.5 mg/kg MK-801 showed evidence of vacuoles in the PC/RS cortical area while 100% (6/6) of the mice treated with 1.0 mg/kg had vacuoles. Thus, in mice, a low dose of MK-801 causes transient memory impairment and higher doses cause acute injury of PC/RS neurons and chronic memory impairment. N-METHYL-D-ASPARTATE (NMDA) ACUTELY INCREASES PROENKEPHALIN mRNA IN THE RAT STRIATUM. R.M. Beckstead, Dept. Cell Biol. & Anat., Med. Univ. of South Carolina, Charleston, SC 29425.

The influence of NMDA receptor activation on proenkephalin (PPE) mRNA levels was examined acutely in the rat striatum and compared to protachykinin (PPT) and α -tubulin mRNA. NMDA (dissolved in 2 μ l artificial CSF) was injected into the lateral ventricle at one of 3 doses (1, 10, 25 nmol; 6 rats per dose group). So that any processing effects were common within an experiment, a vehicle injected control group was prepared along with each dose group. Eight hours after the injection, the rats were perfused and processed for *in situ* hybridization with a [³⁵S]dATP end-labeled oligonucleotide probe followed by quantitative film autoradiography. PPE was increased in a dose-dependent manner compared to controls, reaching 140% of control level at the highest dose of NMDA. There was no significant change at any dose in the level of PPT or α -tubulin mRNA suggesting that the response was not uniform across striatal neurons nor an unspecific generalized augmentation of transcription. The increase in PPE was completely blocked by pretreatment with the competitive NMDA antagonist CGP 37849 injected systemically (12 mg/kg; ip) 20 minutes prior to the NMDA infusion. The data are consistent with a specific acute effect on PPE regulation by excitatory amino acid transmission mediated by the NMDA receptor. The direction and magnitude of change is consistent with earlier results in which acute depression of PPE was observed after treatment with NMDA antagonists. The data provide further support for the notion that the NMDA receptor mediates a rapid-onset, excitatory amino acid-stimulated up-regulation of met-enkephalin biosynthesis.

Supported by NIH (NINDS) grant NS24971.

POLYAMINE NMDA ANTAGONISTS RELATED TO IFENPRODIL REDUCE NMDA-INDUCED, NO-DEPENDENT cGMP SYNTHESIS, INTRACELLULAR CALCIUM LEVELS AND CYTOTOXICITY.

P.M. Beart*, A. Schousboe and A. Frandsen, PharmaBiotec Research Center, Royal Danish School of Pharmacy, DK-2100 Copenhagen, Denmark.

Actions of ifenprodil and related aminoalcohols (e.g. tibaloxine), which are polyamine NMDA antagonists (Beart et al., Mol. Neuropharmac. 2: 11, 1992), were investigated in cultured cortical neurones to characterize their NMDA-mediated cytoprotective potential. Mouse cerebral cortical neurones were cultured in the presence of cytosine arabinoside for 7-8 days before assessment of NMDA-mediated functions. NMDA (100 μ M)-stimulated production of cGMP was blocked by TCP (1 μ M) and N^ω-nitro-L-arginine (100 μ M). All aminoalcohols dose-dependently inhibited the NO-dependent synthesis of cGMP; ifenprodil (IC₅₀ 150 nM) exhibited higher potency than its benzothiazine (IC₅₀ 625 nM) and thiochromane (IC₅₀ 6 μ M) analogues. Ifenprodil and analogues also displayed a similar range of potencies as blockers of the NMDA (300 μ M)-induced increase in [Ca²⁺]_i in mouse cortical neurones; blockade produced by the polyamine NMDA antagonists was complete and dose-dependent. Leakage of lactate dehydrogenase activity from the cultures after exposure to NMDA (100 μ M, 4h) was used as an index of neuronal death; all aminoalcohols reduced NMDA-induced cytotoxicity with ifenprodil giving almost complete protection at 10 μ M. Polyamine NMDA antagonists possess potential as cytoprotective agents in ischaemic events - the aforementioned ifenprodil analogues are lipophilic, unlike ifenprodil, and are suitable for systemic administration.

Supported by Danish State Biotechnology Program and NHMRC (Australia).

DIFFERENTIAL EFFECTS OF ANTAGONISTS AT THE STRYCHNINE-INSENSITIVE GLYCINE RECEPTOR ON ANTICONVULSANT AND ANXIOLYTIC TESTS. T.C. McCloskey, H.S. White, B.M. Baron, Y. Senyah, A.L. Stone, B.W. Siegel*, B.L. Harrison, F. Salituro, M.G. Palfreyman, and J.H. Kehne, Marion Merrell Dow Research Institute, 2110 E. Galbraith Rd., Cincinnati OH 45215.

The anticonvulsant and anxiolytic potential of antagonists at various sites associated with the NMDA glutamate receptor complex has been demonstrated preclinically, though the relationship between these two activities is not clear. The present study evaluated the anticonvulsant and anxiolytic activities of compounds derived from indole-2-carboxylic acid or quinoline-2-carboxylic acid and containing either an aromatic or a carboxylate-bearing substituent (*J. Med. Chem.* 35: 1835, 1992; *J. Med. Chem.* 33: 3130, 1990; *Bioorg. Med. Chem. Lett.* 1: 455, 1991). Examples of compounds were found which have anxiolytic effects in the rat pup separation-induced vocalization (SIV; Kehne et al., *Eur. J. Pharmacol.*, 193: 283, 1991) model and apparent lack of motoric side-effects as measured with the "tune on an inclined plane" (TIP) test, relative to competitive NMDA antagonists or ion-channel blockers. Anticonvulsant activity was measured using audiogenic seizure-susceptible DBA/2J mice. Surprisingly, differential effects were seen in that glycine antagonists which were potent anxiolytics tended to have weak anticonvulsant activity, and vice versa. Motoric disruption was better correlated with anticonvulsant than with anxiolytic activity. Anticonvulsant potency of "selective" anxiolytics was not demonstrable upon direct i.c.v. injection, suggesting that simple CNS bioavailability did not explain these differential functional effects. These results might be explained by activity on regionally-specific glycine receptor subtypes, though biochemical characterization to date has failed to reveal apparent differences between the compounds.

POLYAMINES AND NMDA RECEPTORS IN ELECTRO CONVULSIVE SHOCK INDUCED EPILEPTIC SEIZURES.

Z. Iqbal*, F. Siddiqui, C. Lu and H. Koenig, VA Lakeside Medical Center and Northwestern University Medical School & Institute for Neuroscience, Chicago, IL 60611.

We have previously shown that electroconvulsive shock (ECS)- and methionine sulfoximine (MSO)-induced epileptic seizures in rat and mouse are associated with an activation of polyamine (PA) synthesis regulating enzyme ornithine decarboxylase (ODC). We now report that the changes in ODC and PA levels associated with ECS-induced epileptic seizures are linked to N-Methyl-D-Aspartate (NMDA) receptor activation. A single ECS (120 V/1 second) caused a significant (>25%) increase in rat cerebral ODC activity and PA levels within 15 seconds. Pretreatment of animals with PA synthesis inhibitors α -difluoromethylornithine (500 mg/kg) and methyl glyoxal bis guanylhydrazone (200 mg/kg) blocked the increases in ODC and PA levels and also prevented the seizures. Furthermore, the ECS-induced increases in cerebral ODC and PA levels associated with epileptic seizures were effectively suppressed when the animals were administered with NMDA receptor antagonist, MK-801. A sharp (<15 seconds) and transient (lasting for 1-2 minutes) increase in ODC and PA levels support the hypothesis that NMDA receptor activation associated epileptic seizures require post translational activation of existing ODC leading to increases in PA levels.

NMDA RECEPTOR-DEPENDENT INCREASE IN CYCLIC AMP INDUCED BY HIGH FREQUENCY ELECTRICAL STIMULATION IN THE DENTATE GYRUS OF RAT HIPPOCAMPAL SLICE. M.J. Bonner* and J.M. Sarvey, Department of Pharmacology, Uniformed Services University of the Health Sciences, Bethesda, MD 20814.

Cyclic AMP (cAMP) levels were induced by a high frequency train (HFT; 100Hz, 2 sec) to the perforant path in the dentate gyrus *in vitro* in hippocampal slices. As previously demonstrated in this lab, the parameters used for the HFT are sufficient to produce long-term potentiation, a form of synaptic plasticity. After HFT the dentate gyrus was cut from the rest of the hippocampal slice, cAMP levels in the dentate were then determined by a protein binding assay. Levels of cAMP were determined at intervals (n=8 rats /interval) during a 1 to 60 min post-HFT time period. Initially post-HFT cAMP levels were greatly increased to 246% of the basal level at the 1 min interval and declined to 147% at the 30 min interval. The NMDA-receptor antagonist CPP, present before and during the HFT, significantly suppressed post-HFT cAMP levels to approx 50% of no-CPP HFT stimulated levels. The suppression of cAMP levels by the presence of CPP (0.1, 1.0, 10.0 μ M) was concentration dependent. The presence of 10.0 μ M CPP immediately after HFT also resulted in suppression of cAMP levels. Excitatory amino acid receptor antagonists AP3 (100 μ M) and CNQX (10 μ M) did not significantly reduce the levels of cAMP induced by HFT stimulation. These results suggest that stimulation of cAMP by HFT involves a NMDA CPP-sensitive receptor.

N-ACETYLSPARTYLGLUTAMATE INHIBITS CYCLIC GMP FORMATION IN CEREBELLAR GRANULE CELLS. J. H. Neale* and B. Wroblewska. Department of Biology, Georgetown University, Washington D.C. 20057.

N-acetylspartylglutamate (NAAG) is a dipeptide present in the brain in very high concentrations. NAAG has been shown to activate NMDA receptors, including homomeric NMDAR1 receptor, with low potency as compared to glutamate. We have reported previously that NAAG inhibits cAMP formation in the cerebellar granule cells, through the activation of metabotropic mGluR receptor(s). These data indicate that NAAG is a candidate for an endogenous agonist at central glutamate receptors. The aim of the present study was to evaluate the role of NAAG in the second messenger responses to glutamatergic stimulation in cultured cerebellar granule neurons. We found that NAAG does not affect phosphatidylinositol hydrolysis, calcium fluxes, or cGMP formation. However, NAAG inhibits the elevation of cGMP levels which are stimulated by kainate, NMDA, or glutamate. The mechanism of this inhibition is unknown, but NAAG has no effect on nitric oxide synthase activity, nor does it inhibit the direct response of these cells to nitric oxide which activates guanylate cyclase and increases formation of cGMP. NAAG also does not affect directly soluble or particulate guanylate cyclase activity. The release of arachidonic acid which is a stimulator of cGMP formation in granule cells is not affected by NAAG. Inhibition of cGMP formation is specific for NAAG, and not mimicked by N-acetylaspartate or glutamate, indicating that NAAG peptidase is not involved. The inhibitory action of NAAG is not prevented by glutamatergic antagonists of NMDA receptor, MK-801 or Mg^{2+} , but is blocked by non-NMDA antagonist, CNQX.

SEVERAL IRON LIGANDS, 1,10-PHENANTHROLINE AND 2,2-DIPYRIDYL, AUGMENT THE N-METHYL-D-ASPARTATE-INDUCED RELEASE OF GLUTAMATE AND ELEVATION OF INTRACELLULAR CALCIUM ($[Ca^{2+}]_i$) IN NEURONAL CULTURE. S. Oh* and P. P. McCaslin. Dept. Pharmacol. & Toxicol., Univ. Mississippi Med. Ctr., Jackson, MS 39216.

These studies were designed to examine the effect of the iron ligands, 1,10-phenanthroline and 2,2-dipyridyl, on glutamate neurotransmission. The N-methyl-D-aspartate (NMDA) receptor has several modulatory sites, and it is possible that the receptor is a metalloprotein containing Fe_2S_2 at or near the active site. The glutamate receptor agonists, NMDA and kainic acid, result in the elevation of $[Ca^{2+}]_i$ when measured by fura-2 fluorometry in cerebellar granule neurons. The NMDA- but not the kainate-induced elevation of $[Ca^{2+}]_i$ was potentiated by 1,10-phenanthroline and 2,2-dipyridyl. Similarly results were found for the excitatory amino acid-induced release of glutamate from granule cells. Neither 1,10-phenanthroline or 2,2-dipyridyl had effects on basal levels of glutamate release or $[Ca^{2+}]_i$. The elevation of cyclic GMP is also correlated with elevations of $[Ca^{2+}]_i$; however, 1,10-phenanthroline was without effect on the NMDA- or kainate-induced elevation of cyclic GMP levels. 2,2-Dipyridyl was less potent than 1,10-phenanthroline on the above effects. These observations suggest that a metallic center or a metallic-like center may be an important regulatory site on the NMDA receptor. Supported by NIDA grant DA 64843.

MODIFICATION OF NMDA-EVOKED NEUROTRANSMITTER RELEASE IN THE CEREBRAL CORTEX BY HIGH D-GLUCOSE LEVELS COMPATIBLE WITH HYPEROSMOLAR DIABETIC COMA. M. Göthert*, K. Fink and V. Schmitz. Inst. Pharmacol. Toxicol., Univ. Bonn, Reuterstr. 2b, 5300 Bonn 1, Germany.

The aims of the present study were to investigate whether high D-glucose (GLUC) modifies the $[^3H]$ neurotransmitter ($[^3H]NT$) release evoked by NMDA receptor stimulation and whether this property is shared by other hexoses, NaCl and dimethylsulfoxide (DMSO) at equimolar concentrations. Rat brain cortical slices preincubated with $[^3H]GABA$ and $[^3H]$ norepinephrine ($[^3H]NE$) were superfused with Krebs' solution which under control conditions, contained 11 mM GLUC; stimulation was carried out by addition of NMDA (300 μM , unless stated otherwise) for 2 min. Elevation of GLUC by 60 or 100 mM increased the NMDA-evoked $[^3H]GABA$ overflow (which could be inhibited by competitive and noncompetitive NMDA receptor antagonists), but decreased the NMDA-evoked $[^3H]NE$ overflow. The inhibitory effect on $[^3H]NE$ overflow also occurred in the presence of L-glucose, D-fructose, D-galactose, NaCl and sorbitol, but not of the easily membrane-permeable DMSO, at equimolar concentrations. When complete concentration-response curves for NMDA were determined, GLUC caused a depression of the maximum response. A decrease in pH from 7.4 to 7.0 did not affect the degree of GLUC-induced inhibition of $[^3H]NE$ overflow. The inhibitory effect of 60 mM GLUC was significantly reduced by CGP 35348 (p-(3-aminopropyl)-p-diethoxymethyl-phosphonic acid), a GABA_A receptor antagonist. In conclusion, NMDA receptors mediate a stimulation of $[^3H]NT$ release not only from noradrenergic nerve terminals but also from GABAergic interneurons in the cerebral cortex. GLUC modifies the NMDA-evoked $[^3H]NT$ release in the same manner as the K^+ -evoked release (previous findings; Fink and Göthert, Brain Res., in press). The osmotic gradient extra- versus intracellular plays a crucial role in the mechanism(s) underlying the changes of $[^3H]NT$ release. The inhibition of $[^3H]NE$ release appears to be partially mediated by an increased stimulation of inhibitory GABA_A receptors, which, in turn, is the consequence of the increased GABA release. The changes in NT release probably play a role in the pathogenesis of hyperosmolar diabetic coma.

POTENTIATION OF NMDA-STIMULATED NITRIC OXIDE SYNTHASE ACTIVITY BY DIBUTYRYL cAMP AND FORSKOLIN. N.J. Toms and P.J. Roberts*. Dept. of Pharmacology, Sch. of Med. Sci., Univ. of Bristol, Bristol, U.K.

In the rat cerebellum, the synthesis of nitric oxide (NO) is coupled to activation of Ca^{2+} -gated NMDA receptors. This occurs primarily within the granule cells and involves the constitutive Ca^{2+} /CaM-dependent enzyme, nitric oxide synthase (NOS). Since glutamate stimulates cyclic AMP (cAMP) formation in cerebellum, possibly by release of other transmitters such as adenosine, we have investigated the ability of forskolin and dibutyl cAMP to influence NO formation. Exposure of cerebellar slices from 10 day-old rats to NMDA, resulted in robust, dose-dependent increases in NO formation (assayed by conversion of L- $[^3H]$ arginine to L- $[^3H]$ citrulline.) Addition of either dibutyl cAMP (1mM) or forskolin (60 μM) produced a marked potentiation (203 and 209% over basal) of the response to a submaximal concentration (10 μM) of NMDA. These substances both showed negligible direct effects on cAMP formation in the absence of NMDA. Dibutyl cAMP produced a parallel leftwards shift in the NMDA response curve, without affecting the maximal response and the enhancement was fully antagonised by inclusion of the competitive NMDA antagonist, D-APV (50 μM)

These results indicate that a cAMP-dependent process may regulate NMDA receptor/NO coupling in the developing rat cerebellum, probably by direct phosphorylation of the receptor. NJT is an SERC Research Student.

Na^+/Ca^{2+} EXCHANGER REGULATES GLUTAMATE-INDUCED Ca^{2+} RESPONSE IN ASTROCYTES. W. T. Kim and A. H. Cornell-Bell*. Dept. of Cell Biology, Yale Univ. Sch. of Med., New Haven, CT 06510.

We have previously demonstrated that Ca^{2+} flux through the plasma membrane is necessary for sustained oscillations and waves in mammalian astrocytes. Several lines of evidence suggest that Na^+ flux is necessary as well. The Na^+/Ca^{2+} exchanger, as a major mediator of both these fluxes, may play a key role in modulating Ca^{2+} oscillations and waves. We used time-lapse confocal laser microscopy and Fluo-3 to monitor $[Ca^{2+}]_i$ changes after application of 100 μM glutamate. While being superfused with zero- Na^+ saline, astrocytes exposed to glutamate showed a significant decrease (p<.01, N=30) in the frequency of oscillations in comparison to Ca^{2+} responses in normal saline. This decrease in oscillation frequency was also seen in a dose-dependent manner when astrocytes were treated with Benzamil (1 μM -1 mM), an amiloride inhibitor of the Na^+/Ca^{2+} exchanger. With 500 μM Benzamil, the oscillation frequency decreased from 6.6 \pm 0.6/min to 2.0 \pm 0.8/min. Furthermore, no intercellular Ca^{2+} waves were seen. The initial Ca^{2+} peak was unaffected by either zero- $[Na^+]_{out}$ or Benzamil treatments suggesting that the mechanism of release from intracellular stores is independent of oscillation and wave generation. Ionic regulation of the astrocyte through the Na^+/Ca^{2+} exchanger is critical in setting the frequency of Ca^{2+} oscillations and intercellular waves.

467.12

GLUTAMATE RECEPTOR AGONISTS INCREASE INTRACELLULAR CALCIUM AND REGULATE GENE EXPRESSION IN OLIGODENDROCYTE PROGENITORS. V. Gallo*, J. L. Curtis, F. Vaccarino, P. W. Wright and J.T. Russell. Lab. Cell. Mol. Neurophysiol., NICHD, NIH, Bethesda, MD and Yale Child Study Ctr. Yale University, New Haven, CT.

Fura-2 fluorescence measurements performed in a glial progenitor cell line (CG-4) showed that glutamate receptor agonists caused a rapid increase in intracellular Ca^{2+} . Application of kainate, glutamate and quisqualate to both bipolar LB1⁺ progenitors and multipolar O4⁺ oligodendrocytes increased intracellular Ca^{2+} . In progenitor cells, maximal responses to kainate and glutamate were observed after 4 days *in vitro* and were inhibited by CNQX. The kainate-induced Ca^{2+} increase was blocked in the absence of extracellular Ca^{2+} . Addition of nimodipine (10 μM) or Cd^{2+} (100 μM) reduced kainate responses by 75% (n=17) and 57% (n=37), respectively. A rapid and transient elevation of mRNA levels for the primary response gene *zif/268* was observed after the addition of glutamate receptor agonists to CG-4 cells. Under similar conditions, *c-fos* and *c-jun* mRNA levels were unchanged. Induction of *zif/268* by kainate was time-dependent, reaching a 5-fold stimulation after 1 hour and returning to basal levels within 4 hours. Depolarization of CG-4 cells with 40 mM K^+ did not cause any increase in *zif/268* mRNA levels. Our results indicate that excitatory amino acids can induce Ca^{2+} influx in immature glia through voltage-dependent channels and through Ca^{2+} -permeable kainate-activated channels. Activation of these channels selectively regulates the expression of the primary response gene *zif/268*.

467.13

EXCITATORY AMINO ACIDS INHIBIT MEMBRANE-BOUND GUANYLATE CYCLASE IN CEREBELLAR NEURONS. B. Wroblewska¹, J.H. Neale¹ and J.T. Wroblewski². ¹Department of Biology and ²Fidia-Georgetown Institute for the Neurosciences, Georgetown University, Washington D.C. 20007.

In primary cultures of cerebellar granule cells excitatory amino acids induce a large accumulation of cGMP by stimulating the nitric oxide-dependent soluble guanylate cyclase. In addition, a smaller accumulation of cGMP is also observed in these cells after application of atrial natriuretic peptide (ANP) which, together with related peptides, is known to activate a family of cell surface receptors expressing the activity of membrane-bound guanylate cyclase. In granule cells ANP potently ($EC_{50} = 70$ nM) stimulated cGMP accumulation. This effect did not require the presence of extracellular calcium, and was not inhibited by the NO synthase inhibitor nitroarginine. However, the stimulatory effect of ANP was inhibited, in a non-competitive manner, by the excitatory amino acid receptor agonist quisqualate. The inhibition induced by quisqualate was independent of the presence of the phosphodiesterase inhibitor IBMX. It was, however eliminated by the absence of extracellular calcium and by the ionotropic glutamate receptor antagonist 6-cyano-7-nitroquinoxaline-2,3-dione. A similar inhibitory effect on ANP-induced cGMP accumulation was produced by other agonists of ionotropic glutamate receptors, glutamate, kainate, α -amino-3-hydroxy-5-methyl-4-isoxazolepropionic acid and *N*-methyl-D-aspartate (NMDA), when their actions were tested in the presence of nitroarginine, used to inhibit the stimulation of the soluble guanylate cyclase. In contrast, the agonists of metabotropic glutamate receptors *trans*-1-aminocyclopentane-1,3-dicarboxylic acid and *N*-acetylglutamate were inactive. The inhibitory effect of glutamate was partially reduced by the presence of NMDA receptor antagonists Mg^{2+} and MK-801, indicating the involvement of both NMDA and non-NMDA ionotropic glutamate receptors. Our results suggest that alterations of intracellular ionic homeostasis induced by the activation of ionotropic glutamate receptors may play a role in the control of ANP-induced cGMP formation.

INHIBITION OF POTASSIUM-INDUCED HIPPOCAMPAL RELEASE OF GLUTAMATE AND ASPARTATE BY L-CPPENE IN FREELY MOVING RATS. B.S. Meldrum^{*}, M.H. Millan and A.G. Chapman. Department of Neurology, Institute of Psychiatry, De Crespigny Park, London, UK.

CPPene (3-(2-carboxypiperazin-4-yl)-1-propenyl-1-phosphonic acid) is a potent competitive NMDA antagonist with anticonvulsant activity, where the D-enantiomer is 10-20 fold more potent than the L-enantiomer both as an antagonist and as an anticonvulsant (Aebischer et al. (1989) *Helv. Chim. Acta*, 72, 1043-1051; Patel et al. (1990) *Epi. Res.* 7, 3-10).

L-CPPene, on the other hand, is 10 fold more active than D-CPPene in inhibiting K^+ -induced release of glutamate (GLU) and aspartate (ASP) in awake rats. When rats implanted with microdialysis probes in the dorsal hippocampus were subjected to high K^+ stimuli (100 mM through probe, 2x 10 min stimuli, 40 min apart) there were rapid 300-500% increases in the dialysate concentrations of ASP, GLU, GABA and TAU in response to both stimuli. The S2/S1 values (ratios between the second and first K^+ -responses) were 0.7-0.9 for all the amino acids in the control groups. L-CPPene (25-250 μ M in perfusate during second K^+ -stimulus) selectively inhibited ASP and GLU release (S2/S1 = 0.2-0.3) without affecting GABA and TAU release.

467.17

EFFECT OF MAGNESIUM ON OPEN-CHANNEL BLOCKADE OF NMDA RECEPTORS BY 9-AMINOACRIDINES. M.E. Nelson¹, J.G. Montes¹, and E.X. Albuquerque^{1,2*}. ¹Dept. Pharmacol. Exp. Ther., Univ. Maryland Sch. Med., Baltimore, MD, USA 21201; ²Lab. Mol. Pharmacol., IBCCF, UFRJ, Brazil 21944.

Bis-9-aminoacridines have been found to be potent blockers of NMDA-activated single-channel currents in outside-out patches from cultured rat hippocampal neurons (*Neurosci. Soc. Abs.*, 18:1510, 1992). The concentration and voltage dependence of the blockade led us to propose an open-channel blocking mechanism to describe the effect. However, analysis of the forward blocking rate constants for 1,2-propylene-bis-9,9'-aminoacridine (1,2-PAA) and 1,4-n-butylene-bis-9,9'-aminoacridine (1,4-BAA), as well as the mono-9-aminoacridine, 9-amino-1,2,3,4-tetrahydroacridine (THA), suggested that a model for open-channel blockade was inappropriate because plots of reciprocal channel open time (τ_{open}^{-1}) versus acridine concentration were not linear, but hyperbolic. This finding was surprising as previous whole-cell studies of NMDA-activated currents in these neurons were consistent with an open-channel blocking mechanism for THA (*Neurosci. Soc. Abs.*, 15:1166, 1989). It was possible that the 3- μ M Mg^{2+} present in our "nominally Mg^{2+} -free" solutions might have altered the interaction of the acridines with NMDA-activated channels. Therefore, additional single-channel experiments were performed with the acridines in Mg^{2+} -free solutions (<0.5 μ M, by spectrophotometry). The results are consistent with a model of open-channel blockade for describing the interactions of the 9-aminoacridines with the NMDA receptor as evidenced by the linear relationship between (τ_{open}^{-1})⁻¹ and acridine concentration between -40 and -100 mV and at concentrations up to 10 μ M for 1,2-PAA or 1,4-BAA, and up to 50 μ M for THA. At -80 mV, τ_{open} was reduced by more than 85% compared to controls at these drug concentrations. These data suggest that the kinetics of interactions of 9-aminoacridines with the ion-channel of the NMDA receptor are significantly altered by the presence of low micromolar concentrations of Mg^{2+} . Supp.: USPHS Grants NS25296, ES05730.

Stimulation of *c-fos* expression by VIP in cortical neurons is mediated by glutamate

J.-L. Martin, S. de Rham, D. Gasser and P.J. Magistretti*. Institut de Physiologie, Université de Lausanne, Lausanne, Switzerland

The regulation of *c-fos* expression by VIP was examined in primary cultures of astrocytes or neurons originating from the mouse cerebral cortex. In primary cultures of cortical neurons, VIP increases cAMP levels and stimulates *c-fos* expression. Interestingly however, VIP stimulation is completely blocked by MK-801, a non-competitive NMDA receptor antagonist, but not by CNQX or AP3, which are antagonists of respectively AMPA/kainate and metabotropic receptors. *c-fos* expression stimulated by glutamate also shares the same pharmacology. These results suggest an involvement of glutamate in the stimulation of *c-fos* expression evoked by VIP in primary cultures of cortical neurons.

In cultured astrocytes, VIP also stimulates *c-fos* expression in a concentration-dependent manner with an EC_{50} of 1 nM. VIP stimulation of *c-fos* expression is detectable after 30 min, reaching a maximal value after 4 hours and returning to control values within 9 hours. A comparable profile is also observed, although less pronounced, when VIP is applied as a 10 minute pulse. Noradrenaline (NA) also stimulates *c-fos* expression with a 9.7-fold stimulation already observed at 100 nM. When added together VIP and NA exhibit additive effects on *c-fos* expression, thus suggesting different pathways of activation. Potent activators of either protein kinase A, i.e. dBcAMP, or protein kinase C, i.e. PdBu or mezerein also stimulate *c-fos* expression in primary cultures of astrocytes. When added together dBcAMP and PdBu exhibit additive effects.

467.16

D-2-AMINO-5-PHOSPHONOVALEATE BLOCKS INDUCTION OF LONG-TERM DEPRESSION OF THE NMDA RECEPTOR-MEDIATED SYNAPTIC COMPONENT IN RAT HIPPOCAMPUS. P.W. Gean^{*}, J.H. Lin, and C.C. Huang. Dept. of Pharmacology, College of Medicine, National Cheng-Kung University, Tainan, Taiwan, R.O.C.

An in vitro slice preparation of rat hippocampus was used to study the long-term modifications of pharmacologically isolated *N*-methyl-D-aspartate (NMDA) receptor-mediated excitatory postsynaptic potential (EPSP_{NMDA}). Intracellular recordings were made from CA1 pyramidal cells in the presence of 6-cyano-7-nitroquinoxaline-2,3-dione (CNQX, 10 μ M) and picrotoxin (50 μ M) which block non-NMDA and GABA_A receptors respectively. Pairing of low-frequency EPSP_{NMDA} with postsynaptic depolarization induced a long-term depression (LTD) of EPSP_{NMDA}. The maximal reduction of EPSP_{NMDA} amplitude amounted to 81.3% of the control 1 min after the pairing. When low-frequency synaptic stimulation was paired with strong postsynaptic depolarization, a long-term potentiation (LTP) of EPSP_{NMDA} could be induced. The LTD of EPSP_{NMDA} was blocked by D-APV. In normal medium, the EPSP_{NMDA} remained depressed (45.2 \pm 6.5% of control, n=14) 20 min following the pairing. In the presence of D-APV, the EPSP_{NMDA} returned to control level (101 \pm 10.9%, n=6) at 20 min after the pairing. These results suggest that the induction of EPSP_{NMDA} LTD requires an increase in postsynaptic Ca^{2+} likely, at least in part, due to synaptic activation of NMDA receptors during concomitant postsynaptic depolarization.

GABAergic action on identified cholinergic neurones of the nucleus basalis in guinea-pig brain slices. A. Pegna, A. Khateb, P. Fort*, B.E. Jones^o and M. Mühlenthaler *Dept. of Physiology, CMU, 1211 Geneva 4, Switzerland and ^oMontreal Neurological Inst., McGill University, Canada H3A 2B4*

Cholinergic neurones within the nucleus basalis are surrounded by GABAergic neurones which may in part provide an innervation to the cholinergic cells as local interneurons. Our goal was thus to determine the action of GABA on identified cholinergic cells, whose properties we have described in the guinea-pig brain. Employing intracellular recordings we found that such neurones were depolarized by GABA which was administered by superfusion in the bath. This effect did not appear to be due to the activation of GABAB receptors since baclofen had no effect. In contrast the effect was strongly mimicked by muscimol, a GABA selective agonist and blocked by bicuculline, a GABA antagonist. It appeared that the effect of muscimol was postsynaptic since it persisted in presence of a high $Mg^{2+}/low Ca^{2+}$ solution, which interferes with synaptic transmission. The depolarizing effect of muscimol was accompanied by a drop in membrane resistance and an inhibition of firing in cells which were spontaneously active in control conditions. These results suggest that GABA depolarizes but nonetheless inhibits cholinergic basalis neurons through a mechanism that remains to be elucidated. This action would prevent both the tonic and burst modes of firing by the cholinergic neurones. (Swiss NSF, Canadian MRC, Fondation Fyssen and Lyonnaise des Banques).

CONDITIONS NECESSARY FOR GABA_A RECEPTOR-MEDIATED EXCITATION ARE DIFFERENT IN ADULT CA1 VS DENTATE GYRUS NEURONS K.J. Staley* *Neurology Dept, University of Colorado Health Sciences Center, Denver, CO 80262*

GABA_A receptor-mediated excitation has been reported under various experimental conditions in most types of hippocampal neurons. If excitation = action potential generation, then GABA_A receptor-mediated excitation can occur only if 1) the chloride reversal potential (E_{Cl}) is less than action potential (AP) threshold and 2) the resting membrane potential (RMP) is large enough to prevent inactivation of the voltage-dependent Na conductances which underlie the AP.

In dentate gyrus granule cells (DGGC), whole-cell recordings with 131-139 mM KCl electrodes revealed a steady state RMP of -74 mV, an E_{Cl} of 0 mV, and an AP threshold of -55 mV (n=17). Thus in DGGC, chloride loading is sufficient to produce GABA_A receptor-mediated excitation.

In CA1 pyramidal cells, whole-cell recordings with 131 mM KCl electrodes revealed a slow decline of the RMP from -65 to -30 mV, while E_{Cl} reached a steady state of only -22 mV; AP threshold was -55 mV (n=10). Inactivation of Na conductances together with the small driving force (8 mV) for GABA_A receptor-mediated postsynaptic potentials prevented GABA_A receptor-mediated excitation unless the RMP was increased with current injection. Blockade of cation-Cl cotransport with furosemide only enhanced the depolarization of the RMP.

These findings indicate that a large pathway for conductive Cl efflux is present in CA1 neurons but not DGGC. In addition to Cl loading, blocking (or counteracting) this Cl conductance is necessary to produce GABA_A receptor-mediated excitation in adult CA1 pyramidal cells. Supported by NIH NS15173.

A PHOTOREACTIVE DERIVATIVE OF 5,7-DICHLOROKYNURENIC ACID THAT DISPLACES [³H] MUSCIMOL BINDING IN MEMBRANE ASSAYS A.C. Nichols* and K.L. Yielding. *Department of Pharmacology, University of Texas Medical Branch, Galveston, Tx.*

4-Methylamino-5,7-dichloroquinoline-2-acyl azide, a derivative of the glycine antagonist 5,7-dichlorokynurenic acid, was synthesized for testing as a photoaffinity probe for the glycine site. The compound had very low affinity for the glycine receptor (IC_{50} approx. 1mM), but was found to compete for [³H]-muscimol binding in synaptosomal membrane preparations with an IC_{50} of about 30 μ M. Gel electrophoresis of synaptosomal membrane fragments photolabeled with a [¹⁴C] derivative of the probe had radiolabeled protein which migrated between 80 and 49.5 kDalton standards. Such photosensitive probes may provide a useful means of identifying specific sub-sets of neurotransmitter sites.

GABA EVOKED WHOLE CELL AND SINGLE-CHANNEL CURRENTS ARE MODULATED BY INTRACELLULAR FREE CALCIUM IN CULTURED CEREBELLAR GRANULE CELLS. M.Martina*, G.Klicic, and E.Cherubini. *Biophysics Lab, SISSA, Via Beirut 4, 34013 Trieste, Italy.*

The patch clamp technique was used to study the effects of intracellular free calcium [Ca_i] on GABA_A evoked whole cell and single channel currents of cultured cerebellar granule cells. Changes in [Ca_i] were obtained by varying the extracellular calcium concentration [Ca_o], in the presence of the calcium ionophore A23187 (2 μ M). The relationship between [Ca_i] and [Ca_o] in the presence (or in the absence) of A23187 was assessed using fluorimetric measurements from Fura 2 AM loaded cells. In a bathing solution containing 10, 100 and 1000 μ M calcium, the [Ca_i] was 200, 230 and 230 nM without A23187 and 220, 350 and 1400 nM in the presence of A23187 respectively. In whole cell experiments (symmetrical chloride concentration) in calcium free solution at a holding potential of -50 mV bath application of GABA (0.5 μ M for 40-60 s) induced inward currents (14 ± 2 pA) that did not desensitize. The currents were reduced to 7 ± 2 pA in 2 mM [Ca_o]. Single channel currents activated by 0.5 μ M GABA were also recorded in outside-out configuration. In calcium free medium the open probability was 0.134 ± 0.01 . When [Ca_i] was raised to 800 μ M the open probability decreased to 0.003 ± 0.002 and no change in single channel conductance or mean open time was observed. It is concluded that [Ca_i] plays an important role in modulating GABA activated whole cell or single channel currents probably by changing the affinity of the amino acid for the GABA_A receptor.

ABILITY OF GABAergic IPSPs TO REDUCE THE EFFICACY OF GLUTAMATE-EVOKED POSTSYNAPTIC POTENTIALS IN DENDRITES OF HIPPOCAMPAL CA1 PYRAMIDAL CELLS IN VITRO. D.D. Samulack*, and J.-C. Lacaille. *Centre de recherche en sciences neurologiques et Département de physiologie, Université de Montréal, Montréal, QC, Canada H3C 3J7.*

Populations of inhibitory interneurons which display differences in regional distribution of terminals and that utilize different GABA postsynaptic mechanisms, may show variation in their postsynaptic inhibitory effectiveness. The ability of inhibitory postsynaptic potentials (IPSPs), evoked by microapplication of glutamate (500 μ M) in *stratum (str.) pyramidale* (PYR glut-IPSP), or in *str. lacunosum-moleculare* (L-M glut-IPSP), to depress depolarizing postsynaptic potentials (DPs) evoked by glutamate microapplication in the dendrites (mid-radiatum), was studied through collision of these IPSPs with the DPs recorded intracellularly from CA1 pyramidal cells in slices (450 μ m thickness) of the rat hippocampus (125-250 g, male, Sprague-Dawley). Preliminary data showed that PYR glut-IPSPs (GABA_A-mediated; Samulack and Lacaille, *Hippocampus*, 1993) (n=4) were more effective than L-M glut-IPSPs (GABA_B-mediated; Williams and Lacaille, *Synapse*, 1992) (n=4) in reducing the amplitude of DPs evoked in apical dendrites of the recorded pyramidal cells (28.4% versus 14.8% reduction, respectively, with peak-to-peak collision, measured at the apparent equilibrium potential for the IPSP). The ability of the IPSP, to reduce the amplitude of the DP, decremented as the onset of the DP was delayed with respect to the peak of the IPSP. It seems, therefore, that currents from PYR glut-IPSPs (GABA_A) which are likely generated by interneurons of the feedback inhibitory loop (e.g. basket cells, vertical cells, etc..) appear more effective than those of L-M glut-IPSPs (GABA_B) produced by feedforward inhibitory interneurons (stellate cells) in shunting excitatory inputs to the apical dendrites of pyramidal cells.

ACTIONS OF NICOTINIC ANTAGONISTS AT THE GABA_A RECEPTOR.

V.E. Wotring* and K.-W. Yoon, *Department of Pharmacological and Physiological Science and Division of Neurosurgery, Saint Louis University School of Medicine, St. Louis, MO 63104.*

It has previously been noted that d-tubocurarine can act as an antagonist at the GABA_A receptor as well as at the nicotinic acetylcholine receptor. (Labeda et al., *J. Neurophys.* 48:3, 1982) We pursued the possibility that other nicotinic antagonists might behave similarly.

Measurements of GABA evoked currents were made using the whole cell patch clamp technique. Recordings were made from rat hippocampal cells grown in culture for 7 to 16 days. Drug applications were made with a U-tube. 30 μ M d-tubocurarine reduces GABA current evoked with 10 μ M GABA by 52% (n=6). 50 μ M trimethaphan reduces the GABA current by 35% (n=5). These blockades were reversible, dose-dependent, and independent of the holding potential. Dihydro- β -erythroidine (100 μ M) has no effect on the GABA current (n=7), nor do mM concentrations of open channel blockers at the nicotinic receptor, hexamethonium (n=6) and mecamlamine (n=6). Furthermore, we attempted to elucidate the mechanisms of GABA_A receptor blockades caused by d-tubocurarine and trimethaphan.

EFFECTS OF GABA_A RECEPTOR ACTIVATION ON CYCLE ALTERNATION IN THE MOTOR RHYTHM OF MOUSE SPINAL CORD, IN VITRO. I.D. Oliver, P. Hernandez* and M.H. Droge. Biology Dept., Texas Woman's Univ., Denton, TX 76204, *Biology Dept., Abilene Christian Univ., Abilene, TX 79601.

The mouse spinal cord-hindlimb (SCHL) preparation exhibits locomotor-like rhythm in gastrocnemius (G) and tibialis anterior (TA) muscle activity (Hernandez et al., Exp. Brain Res. 1991). However, the rhythm typically lacks cycle alternation. The objective of the present study was to determine if GABA_A receptor activation can produce motor rhythm with cycle alternation in the mouse spinal cord, in vitro.

The GABA_A agonist muscimol (5-20 μM) and antagonist bicuculline (5-20 μM) were bath applied to SCHL explants as well as to isolated spinal cords prepared from 1-5 day old Balb/C mice. Recordings of G and TA muscle activity or bilateral ventral root activity were obtained, depending on the preparation. In cases where little spontaneous activity was observed, muscimol typically increased motor activity and could evoke rhythmic EMG or ENG sequences. The muscimol-evoked rhythm included cycle periods ranging from 0.3 to 1.6 s as well as some episodes of cycle alternation. In cases where NMDA (10-15 μM) was applied to evoke motor rhythm, subsequent application of NMDA + muscimol increased the incidence of cycle alternation. However muscimol did not evoke prolonged sequences of cycle alternation. Nevertheless, these data suggest that GABA_A receptor activation contributes to the reciprocal antagonism involved in coordinating motor rhythm

GABA_A RECEPTOR FUNCTION IS MODULATED BY AGENTS WHICH AFFECT MICROTUBULE ASSEMBLY. V.J. Whatley, S.J. Mihic and R.A. Harris*. Dept. Pharmacology, Univ. Colo. Sch. Med. and Denver VAMC, Denver, CO 80262.

Cytoskeleton-associated clustering of the nicotinic acetylcholine receptor (nACh-R) has been shown to modulate its function, by a mechanism believed to involve microtubules. Since the GABA_A receptor shares significant sequence homology with the n-ACh-R, we questioned whether it would also be affected by clustering. Microtubule-affecting agents were tested for their effects on GABA_A receptor function, by measuring muscimol-stimulated ³⁶Cl⁻ uptake into mouse cerebral cortical microsacs. Colchicine (1-100 μM) decreased muscimol-stimulated uptake at 34°C, but had no effect at 0°C, where microtubules have already depolymerized. Microsacs treated with colchicine (1-100 μM) for only 3 sec displayed the same inhibition of uptake as membranes treated for 30 min. The inactive analog of colchicine, β-lumicolchicine (1 μM) potentiated muscimol-stimulated uptake at 34°C and 0°C. In *Xenopus* oocytes expressing α₁β₂γ_{2s} GABA receptor constructs, colchicine (1-100 μM) inhibited, while β-lumicolchicine (1-100 μM) potentiated, GABA-induced currents. Taxol (1 μM), an agent promoting microtubule assembly, potentiated muscimol-stimulated chloride uptake. These data suggest that agents which affect microtubule assembly or disassembly can modulate GABA_A receptor function, possibly by a mechanism involving receptor clustering. Supported by the VA and NIH/NIAAA.

ROLE OF GABA (γ-AMINOBUTYRIC ACID) IN ANOXIC-INDUCED ION CHANGES IN THE HIPPOCAMPUS. G.V. Obrocea* and M.E. Morris. Dept. of Pharmacology, University of Ottawa, Ottawa, Canada K1H 8M5.

To determine the role of the inhibitory neurotransmitter, γ-aminobutyric acid (GABA), in the generation of ionic responses of the brain to anoxia, ion-selective microelectrodes were used to measure changes in extracellular [Na⁺], [K⁺] and [Cl⁻] in stratum pyramidale (SP) and stratum radiatum (SR) in CA1 guinea pig hippocampal slices. GABA (5 mM perfusion for 5 min) induced increases (↑) in [K⁺]_o and [Cl⁻]_o and a decrease (↓) in [Na⁺]_o in SP; in contrast in SR there was an ↑ in [K⁺]_o and a ↓ in both [Na⁺]_o and [Cl⁻]_o. Replacement of O₂ by N₂ for 5 min produced identical changes of the same/greater magnitude. [K⁺]_o ↑s evoked in SR by GABA (0.7 mM) and N₂ (3.2 mM) were greater than in SP (0.5 and 2.0 mM, respectively); [Na⁺]_o ↓s (-23.5 mM with GABA and -32.8 mM with N₂) in SR were also significantly greater than in SP (-17.0 and -25.2 mM). GABA and N₂ evoked [Cl⁻]_o ↑s of +21.3 and +25.1 mM in the SP, and ↓s of -14.8 and -33.8 in the SR. Bicuculline (BMI 100 μM) reversibly blocked or attenuated all ion changes evoked by both GABA and N₂. In SP BMI depressed ↑s in [K⁺]_o/[Cl⁻]_o with GABA by 90% and with N₂ by 50-60%. In SR K⁺ accumulation during GABA was abolished and with anoxia was attenuated by 70%; ↓s in Cl⁻ were depressed by >50%. [Na⁺]_o changes in SP and SR were affected to a lesser extent, being blocked by only 20-30%. The observed similarity of changes supports the hypothesis of a GABA-mediated contribution to the changes in extracellular ion levels which are induced by anoxia.

INTRACELLULAR CYCLIC GMP MODULATES GABA_A RECEPTOR FUNCTION. D. J. Bradshaw* and M. A. Simmons, Marshall University School of Medicine, Dept. of Pharmacology, Huntington, WV 25755-9310.

Previous research from our lab suggested that GTP is capable of modulating GABA_A receptor (GABA_AR) activity in the absence of exogenous ATP. The aim of this study is to determine what mechanism endogenous GTP might employ to enhance GABA_AR function. In all experiments bullfrog dorsal root ganglion cells were voltage-clamped at -70 mV, and the GABA evoked Cl⁻ current recorded in the presence of tetrodotoxin and cesium (to inhibit Na⁺ and K⁺ currents, respectively). GABA (100 μM) was applied via superfusion for 5 seconds at 5 minute intervals for 30 minutes postimpalement. We found previously that when the recording electrode contains no ATP or GTP, the 6th responses to GABA decrease to a mean ± s.e.m. of 33 ± 7% (n=5) of the initial response. Modulation by G-protein activation, and cGMP generation were both examined as plausible processes. Intracellular application of 100 μM AlCl₃, 10 mM NaF (or KF), and 100 μM GDP did not provide protection against rundown. This suggests direct modulation by a G-protein is unlikely. Intracellular application of varying concentrations of cGMP (500 μM, 0.5 μM, and 0.5 nM) presented 6th responses of 147 ± 18% (n=2), 125 ± 24% (n=3), and 100% (n=1 at 5th response), respectively. The mean initial responses for each cGMP concentration were -10.8 ± 2.0 nA (n=3), -1.9 ± 0.3 nA (n=4), and -0.5 ± 0.1 nA (n=4), respectively. Extracellular application of 20 μM 8-Br-cGMP provided a 6th response of 150 ± 77% (n=3). These preliminary results suggest that an increase in cytosolic cGMP can positively modulate the GABA_AR in the absence of exogenous ATP.

INFLUENCE OF PHOSPHORYLATION EFFECTORS ON GABA_A RECEPTOR FUNCTION AND DESENSITIZATION T.M. DeLorey*, M. Gorday, R. Tyndale, and R.W. Olsen Department of Pharmacology and Brain Research Institute, UCLA School of Medicine, Los Angeles CA 90024

The GABA_A receptor is a macromolecular complex, composed of multiple subunits (α, β, γ, δ). Each subunit contains four membrane spanning regions with a large intracellular loop connecting transmembrane regions 3 and 4. Consensus sequences for phosphorylation by various kinases are located within this loop. Based on the structural homology shared between the nACh receptor and the GABA_A receptor, it has been suggested that phosphorylation may modulate GABA_A receptor desensitization. It has been demonstrated by muscimol-stimulated ³⁶Cl⁻ flux, in rat whole brain microsacs, that drugs such as the adenylyl cyclase activator forskolin and the cAMP analog CPTcAMP, drugs which influence the cAMP dependent protein kinase (PKA) pathway, inhibit muscimol-stimulated ³⁶Cl⁻ flux to varying degrees (Leidenheimer et al. Mol. Pharm. 38, 823-28, 1990). We have further demonstrated a regional variability in CPTcAMP influence on muscimol-stimulated ³⁶Cl⁻ flux. Chloride flux in the thalamus, inferior colliculus and hippocampus is inhibited by 60% with 1.5 mM CPTcAMP while flux in the caudate putamen and olfactory tubercle is inhibited by 100%. Both the caudate putamen and olfactory tubercle are enriched in the GABA_A receptor β₃ subunit mRNA. The β₃ subunit contains a consensus sequence for PKA phosphorylation. We have further demonstrated using recombinant expression of α₁β₃γ_{2s} in *Xenopus* oocytes that IBMX, a phosphodiesterase inhibitor, in combination with forskolin leads to an overall reduction in peak height of GABA-mediated chloride conductance. This effect requires the presence of forskolin but was dependent on the dose of IBMX. Furthermore, the forskolin-IBMX combination appears to decrease the overall rate of desensitization. These data suggest that PKA-mediated phosphorylation may influence desensitization of the GABA_A receptor, probably via the β₃ subunit. (Supported by NS 28772)

GABA-A RECEPTOR REGULATION BY A CHLORIDE-DEPENDENT KINASE AND A SODIUM-DEPENDENT PHOSPHATASE. R.A. Lanius*, B.A. Pasqualotto & C.A. Shaw, Depts. of Neuroscience, Ophthalmology & Physiology, c/o Dept. of Anatomy, University of British Columbia, Vancouver, B.C., V6T 1Z3, Canada.

We have recently reported that agonist (muscimol) and depolarizing stimulation (veratridine) require kinase or phosphatase activity to regulate GABA-A receptors (³H]-SF 95531) in slices of adult rat cortex (Pasqualotto et al., *NeuroReport* 4(4), 447-450, 1993). Muscimol and veratridine both lead to changes in ionic concentrations inside the affected neurons: Muscimol activates Cl⁻ currents through GABA-A receptors; veratridine blocks Na⁺ channel inactivation thus leading to increased intracellular Na⁺ concentrations. Based on these data, we predicted that Cl⁻ and Na⁺ serve as triggers for kinase(s) and phosphatase(s) involved in the regulation of the GABA-A receptor. The effects of Cl⁻ and Na⁺ were examined alone and in the presence of protein kinase A (PKA) or alkaline phosphatase (AP). The results showed a decrease in binding after incubation with Cl⁻ alone; this decrease was further enhanced in the presence of PKA. Both effects could be blocked by a PKA inhibiting peptide. Conversely, an increase in binding was observed after incubation with Na⁺ alone; this increase was further enhanced in the presence of AP. In both cases these increases could be blocked by sodium-ortho-vanadate. These results suggest that Cl⁻ and Na⁺ may trigger kinase(s) and phosphatase(s) involved in GABA-A receptor regulation.

PROTEIN KINASE C MODULATES ETHANOL ENHANCEMENT OF SYNAPTIC GABA_A CURRENT IN RAT HIPPOCAMPAL CA1 NEURONS. J.L. Weiner*, L. Zhang, and P.L. Carlen. Playfair Neurosci. Unit, Addiction Research Foundation, Toronto Hosp. Res. Inst., Univ. of Toronto, Dept. of Pharmacol., Canada M5T 2S8.

We have previously demonstrated that clinically relevant concentrations of ethanol and benzodiazepines enhance pharmacologically isolated GABA_A IPSCs recorded in rat hippocampal CA1 neurons in brain slices. Using the whole-cell patch-clamp recording technique, we investigated protein kinase C (PKC) modulation of the sensitivity of synaptic GABA_A currents to ethanol and diazepam.

Pretreatment of slices with selective inhibitors of PKC blocked ethanol (20 mM) enhancement of IPSCs but did not depress the effects of diazepam (100 nM). In addition, removing ATP from the recording solution or replacing it with AMP-PNP, a non hydrolyzable ATP analog, reduced ethanol-mediated enhancement of GABA_A IPSCs but did not depress the action of diazepam. Furthermore, inclusion of 400 μM GDP-βS in the recording solution also occluded ethanol potentiation of IPSCs. Surprisingly, incubating slices in activators of PKC (3 μM PDBu or 1 μM PMA for 15-60 min.) also significantly reduced ethanol enhancement of IPSCs but did not reduce the potentiation induced by diazepam. Incubation of slices in the inactive phorbol, 4-α PDBu (3 μM) did not interfere with ethanol enhancement of IPSCs.

These results demonstrate, as previously shown for recombinant GABA_A receptors recorded in *Xenopus* oocytes (Wafford and Whiting, *FEBS LET.*, 313: 113-117, 1992), that the sensitivity of GABA_A receptors mediating inhibitory synaptic transmission in the mammalian CNS may be modulated by PKC. The mechanisms underlying this modulation are currently under investigation. (Supported by the Medical Research Council of Canada)

EFFECTS OF GLUTAMATE AND CALCIUM ON GABA-INDUCED CHLORIDE FLUX. Tory A. Masonis and Michael P. McCarthy*. CABM/Pharmacology, UMDNJ-RWJMS, Piscataway, NJ, 08854.

Chloride flux through the γ-aminobutyric acid_A receptor (GABA_A receptor) is modulated by a wide number of effectors. We have studied the effects of excitatory amino acids on chloride influx in rat brain membranes using the ³⁶Cl⁻ influx assay of Harris and Allan¹. Earlier workers found that glutamate enhanced GABA-induced ³⁶Cl⁻ influx in mouse synapto-neurosomes, but did not induce influx in the absence of GABA². We have found that, in the absence of calcium, 100 mM glutamate moderately inhibited GABA-induced ³⁶Cl⁻ influx, but also produced significant influx alone. Aspartate (100 μM) also induced significant ³⁶Cl⁻ influx in the absence of GABA. Glutamate- and aspartate-induced ³⁶Cl⁻ influx was blocked by picrotoxin. However, in the presence of calcium (1 mM), glutamate alone did not induce ³⁶Cl⁻ influx, in agreement with earlier studies². Glutamate may be acting as a partial agonist (in the absence of calcium), as it also inhibited [³H]muscimol binding approximately 50%.

ELECTROPHYSIOLOGICAL EVIDENCE FOR TWO TYPES OF ZOLPIDEM-BINDING RECEPTORS BASED UPON THE ABILITY OF ETHANOL TO ENHANCE GABA-INDUCED INHIBITION. H.E. Criswell*, G.R. Breese, and A.L. Morrow. U.N.C. Sch. of Med., Chapel Hill NC 27599.

For some time it has been believed that ethanol produces some of its behavioral effects by an action on the GABA_A receptor complex. The specific subunits incorporated into the GABA_A receptors determine their pharmacological properties. Recent electrophysiological studies have shown that ethanol enhances GABA-induced inhibition of some but not all neurons, suggesting that only a subset of the GABA_A isoreceptors are sensitive to ethanol. The localization of ethanol sensitive neurons to brain areas with high levels of zolpidem binding suggested that ethanol acts on a GABA_A isoreceptor which binds zolpidem. We tested this hypothesis by examining the effect of iontophoretically applied ethanol and zolpidem on GABA-induced inhibition in several brain areas. Neurons which responded to ethanol also responded to zolpidem enhancement of GABA-induced inhibition. However, some neurons responded to zolpidem which were unresponsive to ethanol's enhancement of GABA-induced inhibition. These data indicate heterogeneity of GABA_A receptors sensitive to zolpidem and provide further evidence for the selectivity of ethanol's action on GABA_A receptors. This heterogeneity may be due to the presence of differing GABA_A isoreceptors sensitive to zolpidem or differences in post-translational processing of the receptors. ALCOHOL-HEIGHTENED AGGRESSION MICE SHOW REDUCED GABA_A-BENZODIAZEPINE RECEPTOR BINDING IN VIVO. K.A. Miczek*, E.M. Weerts¹, M. Wiadro¹, H. Barros¹, J.M. Koff², L.G. Miller² Tufts Univ., Dept. of Psychology¹, Medford, MA 02155 and Dept. of Pharmacology and Experimental Therapeutics², Boston, MA 02111, USA

Recent analysis of individual differences in alcohol's effects on aggression have identified subgroups of mice and rats that show qualitatively different effects. While some individuals show alcohol-heightened aggression (AHA), others show only alcohol-suppressed aggression (ASA) or no reliable effects (ANA) in the same low to moderate dose ranges and on repeated occasions. Alcohol-heightened aggressive behavior is antagonized by benzodiazepine receptor antagonists. Do AHA and ASA mice show different binding at the GABA_A-benzodiazepine receptor? Male, CFW mice were pair-housed with females for at least 21 days and screened for reliable attack behavior in 5 minute resident-intruder tests. Animals that attacked naive intruder males over four separate test days were administered distilled water or 1.0 g/kg alcohol in alternating sequence so that each animal received alcohol twice. There were no differences in baseline levels of locomotion, aggression, attack latency, body weight gain or reproductive success in AHA, ASA and ANA mice. AHA mice had lower [³H]Ro 15-1788 in vivo binding in cortex when compared to ANA mice. [³H]Flunitrazepam binding in vitro revealed no significant differences between groups. These data indicate that lower binding at the GABA_A-benzodiazepine receptor in cortex may be linked to alcohol's pro-aggressive effects in some individuals.

GABA_A RECEPTORS IN CELL LINES.

R.F. Tyndale*, A.J. Tobin, R.W. Olsen and T.G. Hales. Depts. of Biology, Pharmacology & Anesthesiology, UCLA, LA, CA 90024.

We have investigated the GABA_A receptor composition using subunit specific oligo-primers and RT-PCR in 14 cell lines (B35, B65, B103, B104, RINm5F, Rat1, PC12, C6, C17, C27, βTC3, NB41A3, AtT-20 & HIT). Thirteen GABA_A receptor subunits have been cloned from mammalian tissue; α1-6, β1-3, γ1-3 and δ. This multiplicity of subunits provides a basis for the diverse pharmacology of the GABA_A receptor. Attempts to understand the regulation and pharmacology of individual subunits and of the hetero-oligomeric receptor combinations have been impeded by a lack of access to pure populations of cells expressing GABA_A receptor subunits. Permanent cell lines provide such a source.

Each of the receptor subunit mRNAs has been identified in at least one cell line and each cell line contained at least one GABA_A subunit mRNA. However, in 6 cell lines examined using the patch-clamp technique, only the RINm5F cell line contained functional GABA_A receptors (Hales et al., this meeting). We are currently investigating, using transfection and knockout strategies, the subunit requirements for functional channels in these cells.

In conclusion, these cell lines transcribe GABA_A receptor subunits and therefore provide a tissue source for regulation and pharmacological studies. (Supported by MRC of Canada (RFT), NS22256 (AJT), NS28772 (RWO)).

CHLORIDE CHANNELS ACTIVATED BY GABA IN HIPPOCAMPAL SLICES AND IN SF9 CELLS INFECTED WITH RECOMBINANT VIRUSES. B. Birnir, A. Everitt, A.C. Field*, M.L. Tierney, S.M. Howitt, G.B. Cox and P.W. Gage. John Curtin School of Medical Research, Australian National University, Canberra ACT 2601, Australia.

We have recorded single channel chloride currents activated by GABA in the dentate gyrus of rat hippocampal brain slices for comparison with events in cells expressing known subunits of the GABA_A receptor. The brain was immersed in artificial cerebrospinal fluid and 400 μm thick slices, cut with a standard vibrating microslicer, were incubated for an hour at 35 °C. The slices were then kept at room temperature for the remainder of the day and patched using the "blind" patch clamp method. No enzymes were applied. The single channel current-voltage relation showed outward rectification in cell-attached and inside-out patches. Subconductance states were present and were more numerous at depolarized than at hyperpolarized potentials. Conductance states up to 65 pS were observed at 80 mV. We have also expressed the α1, β1 and γ2S subunits of the GABA_A receptor in the SF9-baculovirus expression system. The formation of functional channels was found to be dependent on subunit composition. Properties of reconstituted receptors are being compared with native GABA_A receptor.

5-HT₃ RECEPTOR ANTAGONISTS AND GABA_A RECEPTORS: A FUNCTIONAL STUDY. R.L. Klein, E. Sanna, S.J. McQuilkin, J.M. Sikela*, P.J. Whiting and R.A. Harris. Dept. of Pharmacol., Univ. of Colorado & Denver VAMC, Denver, CO 80262, and Merck, Sharp & Dohme Res. Lab., Essex, U.K.

5-HT₃ receptor antagonists and drugs acting on GABA_A receptors share the property to modulate anxiety and to alter some behavioral effects of ethanol. Based on these similarities, we tested the ability of different 5-HT₃ receptor antagonists to affect GABA-gated Cl⁻ currents recorded in *Xenopus* oocytes injected with human GABA_A receptor subunit cDNAs. In oocytes expressing α1β1γ2S receptors MDL 72222 and LY 278584 inhibited GABA-gated currents, while zacopride was ineffective. ICS 205-930 induced a biphasic effect. At lower concentrations (0.1-5 μM), it potentiated, in a dose-dependent manner, GABA responses (44%, at 2.5 μM), whereas higher concentrations (50-100 μM) produced about 50% inhibition. Ro15-1788 (1 μM) antagonized the ICS 205-930-induced increase of GABA-gated currents. Similarly, when oocytes were injected with α1β1 (but not the γ2S) subunit cDNAs, the stimulatory effect of ICS 205-930 could no longer be observed, suggesting that ICS 205-930 might interact with the benzodiazepine site. Consistent with these results is the finding that ICS 205-930 displaced ³H-flunitrazepam binding in mouse cortical membranes and HEK 293 cells transfected with α1β1γ2S subunit cDNAs, with Ki values of about 1 μM. MDL 72222 and LY 278584 displaced this binding with Ki values around 20 μM. On the contrary, the inhibitory action on GABA-gated currents induced by higher concentrations (25-100 μM) of ICS 205-930 was not prevented by Ro15-1788. These results indicate that ICS 205-930 and other 5-HT₃ receptor antagonists modify GABAergic function, an effect that may be important for some of the actions of these drugs.

469.2

RINm5F: A PANCREATIC CELL LINE WITH FUNCTIONAL GABA_A RECEPTORS. T.G. Hales*, R.W. Olsen, A.J. Tobin and R.F. Tyndale. Depts. Anesthesiology, Pharmacology and Biology, UCLA, LA, CA 90024.

We have used the patch-clamp technique to characterize GABA_A receptors expressed by an insulin-secreting cell line (RINm5F). γ-Aminobutyric acid type A (GABA_A) receptors are expressed throughout the mammalian nervous system. The receptor is also found in peripheral tissues e.g. the adrenal medulla and the islets of Langerhans. Despite the abundance of GABA_A receptors *in vivo* and in primary cultured cells there has only been one report of a cell line expressing functional GABA_A receptors (Hales et al., Mol. Pharm. 42: 197, 1992). The occurrence of 13 GABA_A receptor subunits has been investigated by RT-PCR in this cell line and 12 others (Tyndale et al., this meeting).

Whole-cell GABA-evoked currents were recorded using the patch-clamp technique. RINm5F cells were voltage-clamped at -60 mV with CsCl and NaCl based internal and external solutions. GABA (100 μM) was applied transiently by pressure ejection (1.4 x 10⁵ Pa for 0.01-1 s).

GABA activated inward currents in all cells tested (n=40). With a Cl⁻ reversal potential of 0 mV, GABA-evoked currents reversed at 1.3 ± 4.9 mV (± sem, n=4). GABA-activated currents were abolished (n=4) by bicuculline methiodide (10 μM) and potentiated by pentobarbital (100 μM) to 317 ± 89% of control amplitude (n=6). GABA-evoked currents were unaffected (n=4) by diazepam (10 μM) and were inhibited by 55 ± 10% (n=4) by Zn²⁺ (10 μM), in accordance with the RINm5F cell GABA_A receptors lacking γ subunits.

RINm5F cells are the second cell line demonstrated to have functional GABA_A receptors. We are now investigating the subunits required for functional receptors in cell lines using antisense and transfection paradigms.

PROTEIN KINASE C INCREASES RECOMBINANT α1β1γ2L GABA_A RECEPTOR CURRENTS EXPRESSED IN L929 CELLS. Y.-F. Lin¹, M.D. Browning² and R.L. Macdonald^{1,2}. Depts. of Physiology¹ and Neurology², Univ. of Michigan, Ann Arbor, MI 48109, and Dept. of Pharmacology³, Univ. of Colorado, Denver, CO 80262.

During whole-cell recording from mouse fibroblast L929 cells which were transiently transfected with recombinant α1β1γ2L GABA_A receptor subunit cDNAs, intracellular dialysis with intrapipette solutions containing catalytically active protein kinase C (c-PKC, 1-2 μM) enhanced the GABA_A receptor currents and reduced the rate of current run-down during repetitive GABA (10 μM) application. Addition of PKC-inhibitory peptide (PKC-I, 4 μM) to the c-PKC resulted in GABA responses which were similar to those of control cells. Peak and normalized peak GABA-evoked currents ran down faster over 12 minutes in both control cells (1124 ± 231 to 532 ± 135 pA, 100% to 58 ± 7%, mean ± SEM, n = 14) and c-PKC- plus PKC-I-treated cells (1075 ± 282 to 395 ± 120 pA, 100% to 57 ± 16%, n = 6), than those of c-PKC-treated cells (1287 ± 240 to 1012 ± 187 pA, 100% to 86 ± 7%, n = 20). Consecutive recordings from individual cells with a pipette containing control internal solution alone followed by another pipette containing c-PKC in addition to the control internal solution further confirmed that PKC increased GABA-evoked whole-cell currents. These data suggest that the function of GABA_A receptors is enhanced by PKC, most likely by direct PKC phosphorylation of the GABA_A receptors, or indirectly through phosphorylation of other intracellular components. Data from single-channel recordings are under analysis.

Supported by a Markey Foundation grant to R.L.M.

INTERACTIONS BETWEEN Zn AND THE GABA_A RECEPTOR/IONOPHORE COMPLEX EXPRESSED IN XENOPUS OOCYTES. D. A. Gurley*, V. Stirling, C. Harnett, P.C. Ross, G. White, Neurogen Corp., Branford, CT 06405.

Benzodiazepine insensitive αβ subunit combinations are affected in a non-competitive manner by Zn (Draughn et al. Neuron 5:1990). αβγ combinations are insensitive to Zn and are sensitive to benzodiazepines (Ibid). However, in benzodiazepine sensitive cultured neurons Zn produces a non-competitive block of GABA current. This block is not altered by benzodiazepines (Celentano et al. Mol. Pharm. 40:1991), suggesting that Zn can act independently of the γ subunit. In addition, Zn reduces synaptic responses in cultured neurons (Mayer and Vyklicky, J. Physiol. 415:1989), but not in brain slices (Xie and Smart, Nature 349:1991). The lack of effect in brain slices could result from high GABA concentrations at the synapse overcoming the block by Zn in a competitive manner.

Xenopus oocytes were injected with poly-A mRNA coding for different GABA_A subunits or with poly-A selected cortical message with and without anti-sense to γ1, γ2, and γ3 mRNA. Zn decreased current amplitude evoked by 10 μM GABA for cortical mRNA (IC50=9±1 μM, n=5), cortical+anti-sense mRNA (IC50=7±1 μM, n=4), and α1β1γ2 mRNA (IC50=1±1 μM, n=5). This interaction appeared competitive because the maximum amplitude of GABA current and the Hill coefficients were not altered (p>0.2). The shift in EC50 (log μM GABA) was larger in cortical and cortical+anti-sense cells than in α1β1γ2 cells (0.17±0.02 (n=6) and 0.22±0.03 (n=5) vs 0.09±0.03 (n=5), respectively, p=0.1). For α1β2 subunits, interactions were non-competitive. 40 μM Zn inhibited saturated GABA (1mM) responses by 50±5% (n=4). Anti-sense+ cortical mRNA and α1β2δ injected cells were insensitive to benzodiazepines. Other cells were sensitive.

In summary, reduction of GABA current by Zn can appear competitive. Blocking γ expression in the presence of cortical mRNA does not alter sensitivity to Zn. δ in combination with α1β2 subunits does not mimic the γ2 subunit in terms of Zn pharmacology. We conclude that Zn is not a reliable probe for identifying the γ subunit. More than one factor contributes to inhibition of the GABA_A complex by Zn and to the nature of the inhibition.

469.7

PROPOFOL MODULATES GABA_A RECEPTORS WITH AND WITHOUT $\gamma 2$ SUBUNITS. E.P. Greenblatt, A.R. Brooks-Kayal, D.B. Pritchett, N.L. Harrison, M.V. Jones, T.G. Hales. Depts Anesth, Pediat, Pharmacol & Neurol Univ Penn, PA 19104, Dept Anesth & Crit Care & Dept Pharmacol & Physic Sci, Univ Chicago, IL 60637 & Dept Anesthesiol, UCLA, CA 90024.

The anesthetic propofol potentiates GABA responses and directly activates GABA_A receptors. Some GABA_A receptor properties are subunit specific; we have compared GABA and propofol modulation of $\alpha 2\beta 1$ and $\alpha 2\beta 1\gamma 2$ combinations.

The calcium phosphate method was used to transfect 293 cells with pCIS2 plasmids containing $\alpha 2$, $\beta 1$ and $\gamma 2$ GABA_A receptor subunit cDNAs. Patch-clamp recordings at -60 mV, with CsCl and NaCl based internal and external solutions, were made 48-74 hr after transfection. GABA and propofol (PROP) were applied by pressure (28 kPa for 0.1-80 s) from low (-5 M Ω) resistance pipettes.

PROP (100 μ M) activated currents in cells with $\alpha 2$, $\beta 1$ (n=12) and $\alpha 2$, $\beta 1$, $\gamma 2$ (n=13) cDNAs. Zn²⁺ (5 μ M) inhibited PROP-activated currents in cells transfected with $\alpha 2$, $\beta 1$ cDNAs by 74% (n=2). 50 μ M and 100 μ M Zn²⁺ reduced PROP-evoked currents in cells with $\alpha 2$, $\beta 1$, $\gamma 2$ cDNAs by 18 \pm 7% (\pm sem, n=4) and 66% (n=2). To abolish a contribution of $\alpha 2\beta 1$ receptors in cells with $\alpha 2$, $\beta 1$, $\gamma 2$ cDNAs, we included Zn²⁺ (100 μ M) in the external solution. Single-cell dose-response curves of current activation by GABA and PROP gave EC₅₀ values of 9.4 and 8.3 μ M for cells with $\alpha 2$, $\beta 1$ cDNAs and 16.6 and 17.9 μ M for cells with $\alpha 2$, $\beta 1$, $\gamma 2$ cDNAs. In these cells peak current amplitudes evoked by PROP were 42% ($\alpha 2\beta 1$) and 200% ($\alpha 2\beta 1\gamma 2$) of those evoked by GABA, suggesting that the efficacy of PROP relative to GABA may be influenced by the $\gamma 2$ subunit. Dose-response curves of potentiation by PROP of GABA (3 μ M)-evoked currents had EC₅₀ values of 2.5 μ M ($\alpha 2\beta 1$) and 4.8 μ M ($\alpha 2\beta 1\gamma 2$). Propofol enhances GABA responses and activates GABA_A receptors in cells with or without the $\gamma 2$ subunit.

CLONING AND TISSUE SPECIFIC FUNCTIONAL CHARACTERIZATION OF THE RAT DBI PROMOTER. M. Kolmer¹, L. Pani², P. Longone², E. Costa² and H. Alho^{1*}. ¹Dept. of Biomed. Sci., University of Tampere, 33101 Tampere, Finland, ²Fidia Georgetown Institute for Neurosciences, University of Georgetown, Washington DC 20007, USA.

Diazepam binding inhibitor (DBI) is a 10 kDa polypeptide with diverse biological actions. This protein regulates mitochondrial steroidogenesis, glucose-induced insulin secretion, metabolism of acyl-CoA esters and GABA action on GABA_A receptors. Three positive clones were isolated from a rat genomic library. One of the clones contained DBI genomic DNA fragment, encompassing 4 kb of the 5' untranslated region, the first two exons and part of the second intron of the DBI gene. Two other overlapping clones contained one of the DBI processed pseudogenes. Several transcription initiation sites were detected using RNase protection and primer extension assays. Different tissues exhibited clear differences in the efficiencies of transcription site usage. Transient expression experiments, with DNA fragments of different length from the 5' untranslated region of the DBI gene showed that basal promoter activity requires -146 bp of the proximal DBI sequence, while full activation is achieved with 423 bp of the 5' untranslated region. DNaseI footprint experiments with liver nuclear proteins demonstrated three protected region between nucleotides -387 to -333; -295 to -271 and -139 to -176 from the ATG. The most proximal region (-139 to -176) in gel shift assays binds several general transcription factors (Sp1 and Ap1) as well nuclear restricted proteins which may be related to specific regulatory pterns in different tissues. The DBI gene possesses some features of a housekeeping gene but also includes a regulation depending on the function that it subserves in different cell types.

GABA ρ 1 RECEPTOR: MUTAGENESIS OF BASIC EXTRACELLULAR RESIDUES. T. Kusama, C.E. Spivak*, J.B. Wang, and G. Uhl. Mol. Neurobiol. Br., ARC/NIDA & Depts. Neurol. & Nsci., JHUSM, Box 5180, Baltimore, MD 21224.

The GABA ρ 1 subunit, enriched in retina, can function as a homooligomeric GABA-gated chloride channel. ρ 1 may recognize GABA_A agonists in conformations different from those in which they are recognized by other GABA_A receptors. We sought sites corresponding to these pharmacological differences between the ρ 1 and $\alpha 1$ subunits by constructing 18 mutations in basic, putative extracellular ρ 1 residues and testing expression in voltage-clamped *Xenopus* oocytes.

Mutations in residue 141H diminished the affinity of GABA or abolished GABA responses. Four mutations increased affinity by up to 3-fold. Mutants displayed Hill coefficients as low as 1.24 and as high as 3.9 (wildtype ρ 1 n_H = 2.26). No mutant enhanced the characteristically low ρ 1 responses to THIP; each mutant receptor retained ρ 1-like agonist selectivity. These results support significant roles for basic, extracellular residues of this GABA receptor in agonist recognition and in the subunit-subunit interactions thought to mediate cooperativity.

ALCOHOL MODULATION OF GABA-INDUCED CHLORIDE CURRENTS IN TRANSFECTED HUMAN KIDNEY CELLS. W. Marszalec¹, Y. Kurata¹, B.J. Hamilton², D.B. Carter² and T. Narahashi^{1*}. ¹Dept of Pharmacol., Northwestern Univ. Med. Sch., Chicago, IL 60611 and ²CNS Diseases Research, The Upjohn Company, Kalamazoo, MI 49001.

The modulation of GABA-induced Cl⁻ currents by ethanol and octanol was studied in A293 cells expressing either the $\alpha 1\beta 2\gamma 2$ s or $\alpha 6\beta 2\gamma 2$ s GABA_A receptor subunit combination. GABA evoked currents in $\alpha 1\beta 2\gamma 2$ s and $\alpha 6\beta 2\gamma 2$ s cells with ED₅₀s of 9.1 and 1.7 μ M, respectively. Co-applications of 100 μ M octanol increased the current amplitude in both combinations, shifting the dose-response curve to the left. Although ethanol (3 to 100 mM) did not increase the currents of either subunit combination, it significantly decreased the current desensitization time constant in $\alpha 6\beta 2\gamma 2$ s, but not $\alpha 1\beta 2\gamma 2$ s. Ethanol perfusion (100 mM, 1-10 min) decreased the average desensitization time constant from 7.9 to 4.3 sec in $\alpha 6\beta 2\gamma 2$ s. Octanol perfusion, however, decreased the desensitization rates of both receptor combinations. Thus, ethanol has a differential effect on the desensitization rates of $\alpha 6\beta 2\gamma 2$ s and $\alpha 1\beta 2\gamma 2$ s GABA_A without increasing the current amplitude in either combination. Supported by NIH grant AA07836.

GABA RECEPTORS: FUNCTION—BENZODIAZEPINES

470.1

A COMPARISON OF GABA_A RECEPTOR FUNCTION AND SUBUNIT DISTRIBUTION IN THE CEREBRAL CORTEX AND HYPOTHALAMUS. Ingelfield, J.R.^{1*}, Sieghart, W.³, and Kellogg, C.K.² Depts. of Neurobiology and Anatomy¹ and Psychology², Univ. of Rochester, New York, 14642 and ³Biochem. Psychiatry, University Clinic for Psychiatry, Vienna, Austria.

Allosteric interactions between binding sites on the GABA_A receptor complex are thought to implicate functional changes in the complex. Of current interest is the determination of subunit compositions that mediate specific receptor functions. We compared subunit distribution, by immunoreactivity to specific antipeptides, and function, measuring chloride (Cl⁻) facilitation of clonazepam-displaceable [³H]-flunitrazepam (Flu; 1 nM) binding, between the cerebral cortex and hypothalamus (HYPO) in the rat. The $\alpha 1$ subunit was of the highest density in both regions and prevalent throughout both regions. However, the $\alpha 2$ and $\beta 2/\beta 3$ subunits, while of intermediate density in cortex, were of low density (or absent) in the HYPO. This difference in subunit distribution between regions corresponded to the functional reactivity of the GABA_A receptor. Flu binding in the cortex was facilitated by increasing concentrations (12.5-500 mM) of Cl⁻, and this facilitation was potentiated following 15 min. of restraint. In the HYPO, Flu binding was not responsive to increasing [Cl⁻] in either the basal or restraint-stress conditions. As a result, there were no stressor-induced changes in Flu binding. Analysis of other subunits and functional indices of the complex are underway. The data indicate that the GABA_A receptor differs in composition between the two regions, thereby yielding receptors with different functional properties. Supported by Grant No. DA 07080.

470.2

REGIONAL EXPRESSION OF GABA_A SUBUNIT mRNA MEASURED IN SITU AFTER CHRONIC FLURAZEPAM (FZP) TREATMENT. E.I. Tietz*, X. Weng, H.C. Rosenberg and T.H. Chiu, Department of Pharmacology, Medical College of Ohio, Toledo, OH 43699

Chronic flurazepam (FZP) treatment results in BZ tolerance, GABA_A agonist subsensitivity and a reduction in GABA_A-mediated IPSP amplitude in CA1 region of *in vitro* hippocampus. Regulation of GABA_A receptor subunits may be associated with reduced GABA-mediated inhibition in hippocampus of FZP-treated rats. Expression of $\alpha 1$ and $\alpha 2$ subunit mRNAs were measured *in situ* in brain sections (10 μ M) from 1 week FZP-treated (100 mg/kg X 3 days; 150 mg/kg X 4 days, p.o. in 0.2% saccharin) and control rats (6 rats/group) 2 days after the end of treatment. Post-fixed, dehydrated and defatted sections, handled in parallel, were hybridized (42°C, 4XSSC, 50% formamide, 100 mM DTT) with 45-base $\alpha 1$ (342-356) or $\alpha 2$ (355-369) oligoprobes, 3'-tailed with [³⁵S]dATP. Sections were washed (2XSSC @ 22°C to 0.5XSSC @ 55°C), dehydrated and dipped in NTB2 emulsion. Grains/1000 μ m² were counted over cresyl violet-stained neurons in hippocampal regions CA1, CA3, CA4 and dentate gyrus, from digitized, microscopic (500x) images. For $\alpha 1$, grains were also measured in frontoparietal cortex and dorsolateral and ventromedial substantia nigra pars reticulata. Expression of $\alpha 1$ was significantly reduced 30% (CON:50.2 \pm 3.5; FZP:34.3 \pm 3.9) only in CA1 region of hippocampus (p<.01). Expression of $\alpha 2$, which is primarily localized to hippocampus, was not changed. The discretely localized decrease in $\alpha 1$ mRNA expression in CA1 region may explain the inability to detect changes in hippocampus previously and may contribute to GABA inhibitory dysfunction in CA1 region. The lack of change in $\alpha 1$ expression in some areas, i.e. cortex, may reflect limited sampling. Additional subunits and brain regions are under study. Supported by NIDA grant RO1-DA04075 and RSDA K02-DA00180 to EIT.

470.3

TRANSCRIPTIONAL REGULATION OF GABA_A RECEPTOR ALPHA-1 SUBUNIT GENE EXPRESSION. L. Kang*, D. Linquist, T.B. Kinane, L. Ercolani and L.G. Miller. Dept. of Pharmacology and Experimental Therapeutics, Tufts University, Sch. of Med., Boston, MA 02111, Renal Unit, Massachusetts General Hospital, Boston, MA 02114.

We have previously demonstrated that murine GABA_A receptor alpha-1 and gamma-2 subunit mRNA levels are regulated by chronic administration of benzodiazepine *in vivo* (Kang & Miller, Br. J. Pharmacol. 1990, 103, p1285). To determine the molecular basis for this regulation, we screened a human genomic library to obtain DNA segments encoding the alpha-1 subunit gene. These DNA segments were then fused to a firefly luciferase reporter gene and transfected into primary cultures of chick cortical neurons to determine if they contained the 5' regulatory region of this gene. A strong orientation specific firefly luciferase activity was detected in these segments indicating they contained the gene promoter. Successive deletions indicated the minimal promoter to be encoded by a 50 nucleotide segment that lacked a TATAA sequence. Following chronic benzodiazepine treatment of chick neurons, the transcriptional activity of the gene was repressed in a dose dependent manner. We are currently determining the protein factors that act in "trans" which are required for the coordinated regulation of this gene.

470.5

CHRONIC ALPRAZOLAM ADMINISTRATION DECREASES GABA_A RECEPTOR ALPHA1 mRNA.

G.A. Prithcard*, B. Laurijssens and L.G. Miller. Department of Pharmacology and Experimental Therapeutics, Tufts University School of Medicine, Boston, MA 02111.

Chronic benzodiazepine administration is known to be associated with the functional downregulation of the GABA_A/Benzodiazepine receptor complex. The receptor downregulation is responsible for the tolerance and dependence associated with chronic benzodiazepine administration. Previously we have demonstrated in an mouse model of chronic benzodiazepine administration that receptor downregulation, as indicated by behavioral and biochemical, data occurs between days four and seven. However, Northern analysis indicate that the time period for mRNA downregulation is not observed until day 14 of benzodiazepine administration. The present study utilized chronic administration of alprazolam (2 mg/kg) or vehicle for 1, 7, 14 and 28 days. *In Situ* hybridization histochemistry was utilized to quantitate mRNA levels with the cerebral cortex (layers II-IV, V and VI) and within the hippocampus (CA1 and CA3) and dentate gyrus. No effect of alprazolam was observed at days 1 and 7 of alprazolam administration, but at days 14 Alpha1 mRNA levels were significantly reduced in all levels of the cerebral cortex and within CA1 and the dentate gyrus but not CA3. Decreased levels of mRNA were also observed at day 28 of Alprazolam administration but to a lesser degree compared to day 14. These data indicate that chronic benzodiazepine administration significantly attenuates mRNA levels within various regions of the CNS and show regional and temporal specificity.

470.7

LABELLING OF DIAZEPAM-INSENSITIVE BENZODIAZEPINE RECEPTORS WITH A NOVEL SELECTIVE RADIOLIGAND. G. Wong¹, Z.-Q. Gu^{1,2}, B. de Costa², D. Matecka², L. Fossom¹, K. Rice², P. Skolnick¹. Laboratories of ¹Neuroscience and ²Medicinal Chemistry, NIDDK, NIH, Bethesda, MD 20892.

A diazepam-insensitive (DI) benzodiazepine receptor (BzR) subtype has been described in cerebellar tissues from a range of species including humans, rats, mice, cows, and pigeons. This subtype is distinguished by high affinity binding of the putative ethanol antagonist Ro15-4513, and some other imidazobenzodiazepines, pyrazoloquinolines, and β -carbolines, but not diazepam, flunitrazepam, or other 1,4-benzodiazepines. Molecular biology and expression studies have determined that the DI binding site can be reconstituted with $\alpha 6$ or $\alpha 4$, $\beta 2$, and $\gamma 2$ subunits. Novel 8-substituted imidazo[1,5-a][1,4]benzodiazepine esters were recently synthesized and evaluated for their affinities at DI. Among these compounds, tert-butyl 8-chloro-5,6-dihydro-5-methyl-6-oxo-4H-imidazo[1,5-a][1,4]benzodiazepine 3-carboxylate (ZG-63) was tritiated, and radioligand binding studies were performed in adult rat cerebellar and cortical tissues. Saturation analyses of [³H]ZG-63 binding to cerebellar and cortical DI receptors revealed K_d values of 2.6 \pm 0.2 nM and 8.5 \pm 4.3 nM respectively, and B_{max} values of 609 \pm 66 and 224 \pm 93 fmol/mg protein, respectively. The high affinity and selectivity of this ligand for DI suggests this compound will be useful for elucidating the function(s) of this benzodiazepine receptor subtype.

470.4

SUBTYPE SPECIFIC CHANGES IN BENZODIAZEPINE NUMBER FOLLOWING SUBACUTE EXPOSURE TO ALPRAZOLAM. R.J. Primus, J. Yu, M. Lee and D.W. Gallager*. Neurogen Corp., 35 N.E. Industrial Rd., Branford, CT 06405.

We have previously reported significant decreases in $\alpha 1$ and $\gamma 2$ subunit mRNA levels of the GABA/BZD receptor complex in cortical membranes from rats continuously exposed to the BZD agonist diazepam (DZ). While these changes accompany behavioral signs of tolerance and physical dependence, surprisingly no change in ³H-Flunitrazepam (Flu) or ³H-RO151788 binding site density or affinity have been observed. Such discrepancies may suggest that the decrease in mRNA levels reflect receptor subtype-specific effects or that mRNA levels may not accurately reflect receptor protein. In the present study, we have examined the effects of alprazolam (ALP) using a short exposure course (3 days) of high p.o. doses (100 mg/kg, b.i.d.) on ³H-Zolpidem binding. This treatment schedule was sufficient to produce both tolerance to the bicuculline seizure threshold elevating effects of ALP and physical dependence as demonstrated by precipitated withdrawal after BZD antagonist administration in ALP-treated rats. Zolpidem has previously been shown to be selective for the Type I BZD receptor, binding to $\alpha 1$ -containing constructs expressed in mammalian cells. A significant decrease in B_{max} , but not K_D , for ³H-Zolpidem binding was measured in cortical membranes from rats treated chronically with ALP as compared to membranes from vehicle-treated rats. While a decrease in GABA enhancement of ³H-Flu binding has previously been shown in cortical membranes from chronic DZ-treated rats, no change in GABA enhancement of ³H-Zolpidem binding was observed in cortical membranes from chronic ALP-treated rats. Results will be presented to demonstrate whether differences in chronic ALP and chronic DZ treatments reflect agonist- or receptor subtype-specific changes in the GABA/BZD receptor complex.

470.6

CHARACTERIZATION OF A NOVEL BENZODIAZEPINE RECEPTOR IN THE RAT SPINAL CORD USING [³H]Ro15-1788 AND [³H]Ro15-4513. P.A. Maguire*, M.F. Davies and G.H. Loew. Molecular Research Institute, Palo Alto, CA 94304.

We have recently detected a relatively low affinity binding site for [³H]Ro15-1788 in the rat spinal cord that was insensitive to the imidazopyridine, alpidem (65 μ M). We have begun to characterize this site by competitive binding of BDZR and nonBDZR ligands using both [³H]Ro15-1788 and [³H]Ro15-4513 at 0°C in the presence of 65 μ M alpidem. Nonspecific binding was determined in the presence of 100 μ M Ro15-1788 or Ro15-4513, respectively. The BDZR ligands Ro15-1788, Ro15-4513, diazepam, clonazepam, chlordiazepoxide, triazolam, alprazolam and brotizolam were used in competitive binding assays against [³H]Ro15-4513. The rank order of affinity of these ligands was: Ro15-4513 (IC_{50} = 4 nM; nH = 1.1) > brotizolam (IC_{50} = 14 nM; nH = 0.8) > Ro15-1788 (IC_{50} = 20 nM; nH = 1.0) > triazolam (IC_{50} = 26 nM; nH = 0.5) > alprazolam (IC_{50} = 88 nM; nH = 0.8) > clonazepam (IC_{50} = 141 nM; nH = 0.7) > diazepam (IC_{50} = 208 nM; nH = 0.6) > chlordiazepoxide (IC_{50} > 10,000 nM). This rank order confirmed that found in preliminary studies using [³H]Ro15-1788. Several additional ligands (zolpidem, prazepam, Ro5-4864 and PK11195) were unable to displace specific [³H]Ro15-1788 binding from the alpidem-insensitive site at concentrations of up to 10 μ M. It is clear that this BDZ binding site is not the peripheral BDZ receptor that is present in the spinal cord. However, it is equally clear from the receptor binding characteristics of BDZR ligands that this site is unlike any cloned receptor so far reported. Supported by NIDA Grant DA 06304.

FAST MONOSYNAPTIC INHIBITION IS REDUCED IN CA1 REGION OF HIPPOCAMPUS AFTER CHRONIC FLURAZEPAM TREATMENT. Xu Zeng*, X.H. Xie and E.I. Tietz, Department of Pharmacology, Medical College of Ohio, Toledo, OH 43699

Chronic flurazepam (FZP) treatment reduces GABA-mediated feedforward and recurrent inhibition in CA1 region of hippocampus and decreases GABA_A-mediated IPSP amplitude. The role of inhibitory interneurons in mediating reduced GABA inhibition in FZP-treated rats was assessed indirectly by activation of monosynaptic inhibition in *in vitro* hippocampal slices from rats made tolerant to FZP (100 mg/kg X 3 days; 150 mg/kg X 4 days in 0.02% saccharin). Slices (400 μ M) were cut from rats sacrificed 2 days after treatment, when residual BZs are not detected in hippocampus. CA1 pyramidal cells were recorded intracellularly with glass microelectrodes (3M KAc, 60-80 M Ω , 33°C). Resting membrane potential was not different between groups and was adjusted to -60 mV for all cells during subsequent PSP measurements. As reported previously for cells recorded at 22°C, fast IPSPs elicited with just-subthreshold Schaffer collateral stimulation were significantly reduced (CON: 6.8 \pm 0.6; FZP: 2.2 \pm 0.3, $p < .01$). Pure monosynaptic IPSPs were activated in stratum radiatum <0.5 mm from the recording electrode in the presence of the excitatory amino acid receptor antagonists APV (50 μ M) and DNQX (10 μ M). Slow monosynaptic IPSPs were selectively depressed by addition of the GABA_A receptor antagonist CGP (25 μ M). The fIPSP was decreased during superfusion with APV and DNQX (CON: 6.7 \pm 0.9 mV; FZP: 3.7 \pm 0.7 mV $p < .01$) and with CGP (CON: 6.4 \pm 1.2; FZP: 3.4 \pm 0.8 mV $p < .05$). Reduction of interneuron firing rate may not be related to decreased GABA-mediated inhibition in hippocampus after chronic BZ treatment. Supported by NIDA grant RO1-DA04075 and RSDA K02-DA00180 to E.I.T.

470.9

³H]ZOLPIDEM BINDING TO DIAZEPAM AND MIDAZOLAM TOLERANT RAT BRAIN BENZODIAZEPINE RECEPTORS. Y. Wu, T.H. Chiu and H.C. Rosenberg*. Dept. of Pharmacology, Medical College of Ohio, Toledo, Ohio 43699.

Treatment of rats with flurazepam causes tolerance to several benzodiazepines (BZs) and can decrease the Bmax of [³H]flunitrazepam (FNP) binding in cerebral cortex (CT) and hippocampus (HP), but not in cerebellum (CB). Binding assays using [³H]zolpidem (Zol), a selective agonist for BZ₁ receptors, revealed an even greater down-regulation in all areas, including in CB. Since treatment with diazepam (DZP) or midazolam (MDZ) also produced tolerance, it was hypothesized that down-regulation of BZ₁ receptors might also be produced during chronic treatment with these BZs. [³H]Zol binding was studied in DZP and MDZ treated rat brain. Male, Sprague-Dawley rats were treated 3 wk with DZP released from s.c. silastic reservoirs, or MDZ (40 mg/kg/day) in drinking water, and then sacrificed immediately after stopping treatment. Results of [³H]Zol binding to homogenates from CT, CB and HP were analyzed by Scatchard analysis. In DZP tolerant rats, no change in Kd or Bmax of [³H]Zol binding was found in any of these three regions. No change in [³H]Zol binding was found in CB of MDZ tolerant rat brain. These results suggest that tolerance in DZP-treated rats is not mediated by down-regulation of BZ₁ receptors, and that tolerance in MDZ-treated rats is not mediated by down-regulation of BZ₂ receptors in CB. Studies of [³H]Zol binding to CT and HP of MDZ tolerant rat brain are under way. Supported by R01-DA02194

MODULATION OF MUSCIMOL STIMULATED ³⁶CHLORIDE INFLUX INTO BRAIN MEMBRANE VESICLES BY ANTICONVULSANT AND ANTISPASTIC TRIAZOLES. J.A. Miller*, D.L. Braun and P.A. Chmielewski, Marion Merrell Dow Research Institute, Cincinnati, OH, 45215.

Two classes of novel triazoles have previously been identified as either potent broad spectrum anticonvulsants or selective in protecting against strychnine seizures and hyperreflexia, a model of spasticity. Neither class of compound displaces the binding of [³H]muscimol, [³H]flunitrazepam or [³⁵S]TBPS to the GABA_A receptor. We examined the effects of the anticonvulsant triazoles, MDL 27,266 and MDL 27,192 and the antispastic triazole MDL 27,531 on muscimol stimulated ³⁶Cl⁻ influx into brain membrane vesicles. Vesicles were prepared from rat brain by the method of Harris and Allan (Science 228: 1108, 1985).

MDL 27,531 (100 nM) enhanced muscimol stimulated ³⁶Cl⁻ influx into cerebellar but not cortical membranes. This effect was attenuated by the benzodiazepine antagonist flumazenil (10 μM). MDL 27,266 had no effect on either cortical or cerebellar muscimol stimulated ³⁶Cl⁻ influx but inhibited influx in the presence of flumazenil (10 μM) in cerebellar membranes. MDL 27,192 (10 - 10000 nM) had no effect on ³⁶Cl⁻ influx in cortical and cerebellar tissue. These data (and see Ogden and Rogers, Soc. Neurosci. Abstr., 1993) suggest that MDL 27,531 and MDL 27,266 selectively interact with some GABA_A receptor subtypes in a novel manner.

470.13

THE EFFICACY OF IMIDAZENIL ON ISONIAZID-INDUCED DOWNREGULATION OF GABAERGIC TRANSMISSION. M. Serra*, C.A. Ghiani, C. Motzo, P. Giusti and G. Biggio. Depts. Experimental Biology and Pharmacology, Universities of Cagliari and Padua, Italy.

In rats and mice, the effect of the imidazobenzodiazepine imidazenil (IMZ), a new ligand for benzodiazepine (BZ) receptor possessing anxiolytic and anticonvulsant properties, was evaluated on the function of central γ-aminobutyric acid (GABA)_A receptor complex, both "in vitro" and "in vivo". IMZ displaced [³H]flumazenil binding with a IC₅₀ of 0.9 nM showing that this compound binds with high affinity to BZ receptors. Added "in vitro" to mouse cortical membrane preparation, IMZ like the antagonist flumazenil, failed to modify [³H]muscimol binding, muscimol-stimulated ³⁶Cl⁻ uptake and [³⁵S]butylbicyclophosphorothionate ([³⁵S]TBPS) binding. After i.p. injection to mice IMZ failed to change [³⁵S]TBPS binding measured "ex vivo" in cortical unwashed membrane preparations. On the contrary, the i.p. administration of lorazepam (LZ) and abecarnil (AB) induced in 30 min a marked reduction of [³⁵S]TBPS binding in the same tissue preparation. In contrast to the effect in control animals, IMZ reduced in a dose-dependent manner the increase of [³⁵S]TBPS binding elicited by isoniazid (200 mg/kg s.c.), an effect mimicked by LZ and AB while bretazenil (BTZ) failed to do it. Moreover, IMZ at very low dose (0.05 mg/kg i.p.) delayed the onset of convulsions and death elicited by isoniazid and reduced significantly the number of mice presenting seizures. Thus, IMZ showed an efficacy much greater than BTZ and lower than LZ and AB. On the other hand, IMZ had a potency almost similar to AB. Accordingly, IMZ showed also a great potency in antagonizing the convulsion induced by pentylenetetrazole (PZ). In fact, at the dose of 0.8 mg/kg p.o. it antagonized the 50% of convulsions induced by 70 mg/kg (i.p.) of PZ while LZ and BTZ had the same effect at higher doses (3.8 and 2.4 mg/kg, respectively). Finally, IMZ antagonized completely the increase of [³⁵S]TBPS binding induced by both foot shock and exposure to carbon dioxide. The results demonstrate that the efficacy of IMZ on GABA_A receptor function is greatly enhanced when the GABAergic transmission is reduced. This unique property of IMZ may give to this drug an efficacious anticonvulsant and anxiolytic action with a reduced incidence of unwanted side effects.

470.10

COMPARISON OF THE ANTICONVULSANT ACTION OF THE BENZODIAZEPINES NNC 13-8119 AND DIAZEPAM: TOLERANCE AND CROSS-TOLERANCE STUDIES IN MICE. H.C. Jackson*. (SPON: Brain Research Association). Novo Nordisk A/S, Måløv, DK-2760, Denmark.

NNC 13-8119 (3-(5-cyclopropyl-1,2,4-oxadiazol-3-yl)-5,6-dihydro-5-methyl-6-oxo-4H-imidazo(1,5-a)(1,4) benzodiazepine) is a more potent anticonvulsant than diazepam in mice (ED50 values against clonic seizures induced by pentylenetetrazol (PTZ, 160 mg/kg s.c.) are 0.2 and 1.3 mg/kg i.p., respectively). It also produces less motor impairment than diazepam (ED50 rotarod >10 c.f. 1.3 mg/kg i.p.). This study investigates whether tolerance develops to the anticonvulsant action of NNC 13-8119 and also whether cross-tolerance occurs between NNC 13-8119 and diazepam. Male NMRI mice (20g; n=10) were treated twice a day for 3 days with NNC 13-8119 (1 or 3 mg/kg i.p.) or diazepam (10 mg/kg i.p.). On day 4 animals were given the same drug treatment (or the other benzodiazepine) and 30 min later clonic seizure thresholds were determined following i.v. infusion of PTZ (15 mg/ml; 12 ml/h). Control groups were given vehicle for 3 days and drug on day 4 or vehicle throughout. Clonic seizure thresholds of mice treated acutely with the benzodiazepine agonists were over 3 times higher than those of the vehicle-treated controls. Tolerance did not occur to the anticonvulsant effects of either dose of NNC 13-8119 in this model. However, the increase in seizure threshold of animals given chronic diazepam was reduced by 63% c.f. the acute group. The effects of NNC 13-8119 were significantly reduced (70%, 1 mg/kg; 59%, 3 mg/kg) in mice given chronic diazepam. In contrast the anticonvulsant effects of diazepam (10 mg/kg) were not altered by chronic NNC 13-8119 (1 mg/kg) and only slightly reduced (25%) by chronic NNC 13-8119 (3 mg/kg). These results suggest interesting differences between the effects of NNC 13-8119 and diazepam that warrant further investigation.

470.12

GABA-ACTIVATED CHLORIDE CURRENTS FROM CULTURED RAT NEURONS ARE SELECTIVELY MODULATED BY ANTICONVULSANT AND ANTISPASTIC TRIAZOLE COMPOUNDS. C.J. ROGERS* AND A.M. OGDEN, Marion Merrell Dow Research Institute, Cincinnati, OH 45215.

Two classes of triazole-derived compounds have been identified previously, one a broad spectrum anticonvulsant, the other an antispastic selective for protection against strychnine-induced seizures and hyperreflexia. These compounds did not displace binding of [³H]muscimol, [³H]flunitrazepam or [³⁵S]TBPS to the GABA_A receptor. We sought to determine whether the anticonvulsants MDL 27266 and MDL 27192 as well as the antispastic selective compound MDL 27531 modulate GABA-activated chloride currents. GABA-activated chloride currents are modulated via allosteric receptor interactions.

Single channel recordings were obtained from cultured rat hippocampal- or spinal cord motor-neurons in response to the pressure application of the neurotransmitter gamma aminobutyric acid (GABA 2uM) alone or GABA(2 uM) plus either MDL 27531(100nM), 27266(100nM) or 27192(100nM).

Each of these compounds increased total pooled GABA-activated chloride current. MDL 27531, the antispastic compound increased GABA-activated chloride current in spinal cord motoneurons but did not increase chloride current in hippocampal pyramidal neurons suggesting a GABA_A subtype selective effect. MDL 27266 produced a small enhancement of total chloride current in hippocampal pyramidal neurons while MDL 27192 greatly enhanced total chloride current. These data indicate (and see Miller et al., Soc. Neurosci. Abstr., 1993) that MDL 27531, 27266 and 27192 modulate GABA_A receptor chloride currents in a receptor subtype specific manner.

470.14

ZINC MODULATION OF GABA_A RECEPTOR FUNCTION IN BRAIN MICROSACS. M. Li, T.H. Chiu* and H.C. Rosenberg. Dept. of Pharmacology, Med. College of Ohio, Toledo, OH 43699.

Previous studies suggested that zinc inhibited the effect of GABA at GABA_A receptors. Most of the evidence was obtained from electrophysiological experiments in cultured cells. In the present study, we examined zinc modulation of GABA_A receptor function using GABA-stimulated ³⁶Cl⁻ influx in rat brain microsacs. ZnCl₂ (1-100 μM) did not affect basal Cl⁻ influx, but inhibited the 30 μM GABA-stimulated Cl⁻ influx in a dose dependent fashion. Zinc (30 μM) inhibition could be partially, but not completely, surmounted by increasing the GABA concentration (e.g., 55.0% inhibition at 5 μM GABA, 17.6% inhibition at 500 μM GABA). Zinc produced differing degrees of inhibition in different brain regions. The order of sensitivity to inhibition of 30 μM GABA-stimulated Cl⁻ flux was hippocampus (48.3%) > cerebral cortex (34.9%) > cerebellum (18.8%). These regional differences may reflect the structural heterogeneity of GABA_A receptors among brain areas. In the presence of zinc, the percent enhancement of GABA-stimulated Cl⁻ influx produced by diazepam was increased, showing that zinc did not interfere with the ability of benzodiazepine (BZ) to enhance GABA-stimulated Cl⁻ flux. This suggests that GABA_A receptors possessing BZ sites may be less susceptible to zinc inhibition. Studies are in progress to determine if zinc modulation of GABA function may be a useful tool in studying BZ tolerance. (Supported grant R01-DA02194)

470.15

Effects of propofol and midazolam on GABA_A receptor-mediated responses in rat hippocampal neurons *in vitro* and pars reticulata neurons *in vivo*. R.F. Cox*, D.G. Lang, and C.M. Wang. Burroughs Wellcome Co., Research Triangle Park, NC 27709.

Propofol and midazolam are induction agents whose effects have been associated with activation of the GABA_A-chloride channel complex. We characterized the mechanisms of propofol and midazolam effects on this complex in cultured hippocampal neurons *in vitro* and on firing rates of substantia nigra pars reticulata (SNR) neurons *in vivo*.

Propofol potentiated GABA-induced chloride currents in a dose-dependent manner in hippocampal neurons with an EC₅₀ of 41 μM. Propofol alone activated a current that showed ionic selectivity for chloride like the current activated by GABA. The potency of propofol was one-tenth that of GABA. The GABA-mimetic action of propofol was not affected by diazepam or flumazenil. Both propofol- and GABA-induced currents were inhibited by bicuculline and picrotoxin. Midazolam, inactive alone, potentiated GABA with an EC₅₀ of 3.8 μM, an effect blocked by flumazenil and picrotoxin. Neither propofol or midazolam affected glycine-induced chloride currents.

Propofol (0.3-5 mg/kg, iv) inhibited SNR firing rates in a dose-dependent manner with an ID₅₀ of 1 mg/kg. This action was partially blocked by bicuculline (5-10 mg/kg iv) and reversed by picrotoxin (4-8 mg/kg iv), but was unaffected by flumazenil (1 mg/kg iv). Low doses of propofol potentiated inhibitions of SNR firing rate induced by iontophoretically applied GABA. Midazolam alone inhibited SNR firing with an ID₅₀ of 50 μg/kg, an effect which could be reversed by flumazenil. Like propofol, midazolam enhanced the activity of GABA applied by iontophoresis.

These results indicate that propofol has a direct GABA-mimetic effect and also potentiates GABA at the GABA_A-chloride channel. The activity of midazolam is dependent upon endogenous or applied GABA.

470.17

FUNCTIONAL AND PHARMACOLOGICAL PROPERTIES OF GABA_A RECEPTORS IN ACUTELY DISSOCIATED RAT CEREBELLAR PURKINJE CELLS. P. Avenet*, V. Itier, P. Granger, B. Biton, B. Scatton, and H. Depoortere. Dept. of Biology, Synthelabo Recherche (L.E.R.S.), 31 Ave. P.V-Couturier, 92220 Bagneux, France.

The distinct pharmacological properties (affinity and efficacy) of the omega (BZ) site agonists zolpidem, diazepam and zopiclone has been used to identify the subtype(s) of GABA_A receptors present in native Purkinje cells. Cerebellar Purkinje cells were isolated from 7-11 day-old rat cerebella using a trypsin/mechanical dissociation protocol and GABA-induced currents studied using the whole cell configuration of the patch-clamp technique. All Purkinje cells responded to GABA and GABA-induced currents could be recorded for more than an hour without sign of run-down when the standard CsCl ATP containing pipette solution was used. With a -20 mV holding voltage, the current induced by 1 μM GABA averaged 107 ± 14 pA (n=29). Desensitization was slow (time constant > 60 sec) for GABA concentrations below 10 μM. The GABA concentration dependence reached saturation at 30 μM GABA with an EC₅₀ value of 2.9 μM and a Hill coefficient of 1.8. Zolpidem, diazepam and zopiclone potentiated the GABA (1 μM)-induced current with EC₅₀ values of 94, 50 and 22 nM and potentiation factors (at 1 μM) of 2.48, 1.91 and 2.16, respectively. These results are similar to those previously obtained with α₁β₂γ₂ recombinant receptors transfected in 293 kidney cells (Avenet et al. 1992, Neurosci. abstr. 18:402) and taken together indicate the expression, in native Purkinje cells, of this GABA_A receptor subtype, the exclusive presence of which was previously suggested by *in situ* hybridization experiments.

REGIONAL VARIATIONS OF Zn-SENSITIVITY OF GABA_A RECEPTORS IN RAT BRAIN. M. Gordey, I. Spigelman, T. DeLorey and R.W. Olsen*. Department of Pharmacology, School of Medicine, University of California, Los Angeles, CA 90024.

Zn²⁺ known to play an essential role in neuronal excitability, inhibits GABA_A receptor function in rat brain *in vitro* and the effect varies with brain region. Zn²⁺ is widespread throughout the brain, concentrated highly in hippocampal mossy fibers, cortex and cerebellum, but is absent in other nontelencephalic regions. Recombinant GABA_A receptors lacking γ-subunits are susceptible to Zn²⁺ inhibition. We have found that ZnCl₂ (100 μM) decreases muscimol (50 μM)-stimulated ³⁶Cl⁻ efflux in slices of rat thalamus and hippocampus, with similar sensitivity in DG and CA1 regions. Inferior colliculus and cerebellum appear to be insensitive to Zn²⁺. By contrast, in microsome assays, muscimol (10 μM)-stimulated ³⁶Cl⁻ flux was inhibited by Zn²⁺ in all four regions: hippocampus (72±4%), cerebellum (58±4%), thalamus (45±3%), inferior colliculus (54±7%). According to previous observations, Zn²⁺-sensitive receptors are devoid of benzodiazepine stimulatory effects. Our experiments with simultaneous application of diazepam (10 μM) and ZnCl₂ (100 μM) during 5 sec incubation of μsacs with ³⁶Cl⁻ and muscimol (10 μM) appear to show the possible existence of a GABA_A receptor subtype that is sensitive to both Zn²⁺ and benzodiazepines.

CHRONIC NEUROSTEROID TREATMENT PRODUCE UNCOUPLING OF THE GABA-BENZODIAZEPINE RECEPTOR COMPLEX IN MAMMALIAN CORTICAL NEURONS. Maharaj K. Ticku* and Rong Yu. University of Texas Health Science Center, San Antonio, TX 78284-7764.

The effect of chronic 5α-pregnane-3α-ol-20-one (neurosteroid 5α3α) treatment was investigated on the binding of [³H]flunitrazepam and its coupling to various sites associated with the GABA_A receptors in cultured cortical neurons. Chronic treatment with neurosteroid 5α3α did not alter the basal [³H]flunitrazepam binding to the intact neurons. However, 5α3α treatment produced a decrease in the E_{MAX} value of GABA enhancement (determined with 500 μM GABA) on [³H]flunitrazepam binding from 118% (control cells) to 85% and 31% after 5α3α treatment (2 μM for 3 and 5 days, respectively); to 106%, 91%, 105%, 85% and 31% (5α3α 5 days with concentrations of 0.1, 0.2, 0.5, 1 and 2 μM). Studies of enhancement of [³H]flunitrazepam binding by various modulators showed that the EC₅₀ value of GABA, pentobarbital sodium and 5α3α were unaltered, however, their E_{MAX} value decreased. The E_{MAX} value of GABA decreased from 120% to 27%; while the EC₅₀ (12 μM v/s 9 μM) value was not altered after chronic treatment (5α3α; 2 μM for 5 days). The E_{MAX} value of pentobarbital sodium decreased from 155% to 40%; while the EC₅₀ was not altered (210 μM v/s 160 μM). The E_{MAX} of 5α3α decreased from 60% to 0. The results indicate that chronic neurosteroid treatment produces a functional uncoupling of allosteric sites of GABA receptor complex in the mammalian cortical neurons. This uncoupling appears to be heterologous in nature. The molecular basis of the uncoupling phenomenon is under investigation. (Supported by NIH-NINDS grant # NS-15339)

GABA RECEPTORS: FUNCTION—GABA_B, GABA_C

471.1

The GABA_B Receptor Agonist Baclofen and Antagonist CGP-35348 Modulate Synaptically-Evoked Responses in the Rat Dentate Gyrus, *In-Vivo*. F.H. Brucato¹, W.A. Wilson^{1,3*}, H.S. Swartzwelder^{2,3} Duke Univ. Depts. of Medicine¹, Psychiatry², and VA Med Center³ Durham NC 27705

There is now much evidence from hippocampal slices that GABA_B receptors inhibit single and paired-pulse evoked responses in the hippocampus/dentate gyrus network. However, few *in-vivo* studies have demonstrated the role of GABA_B receptors in modulating synaptic responses. We have previously shown that the GABA_B receptor antagonist, CGP-35348, attenuates paired-pulse disinhibition in this network *in-vivo*, in the absence of any significant effect on baseline population spikes (PS) or pEPSPs.

We report here that the GABA_B agonist baclofen significantly effects synaptically evoked responses in the dentate gyrus *in-vivo*. Extracellular recordings were made in the dentate gyrus of urethane anesthetized rats following stimulation of the angular bundle. At a dose of 10mg/kg, baclofen produced a significant enhancement of single pEPSP durations. In addition, baclofen attenuated paired pulse (150 ms) disinhibition of pEPSP durations. Paired pulse disinhibition of PS amplitude was also reversed by baclofen when paired pulses were presented at 150 ms interstimulus intervals. Baclofen also reversed recurrent inhibition at 25ms interstimulus intervals. CGP-35348 reduced this effect of baclofen on recurrent inhibition in addition to reversing baclofen's enhancement of a single pEPSP duration. We conclude that GABA_B receptor activation produces mixed inhibitory and disinhibitory effects in the dentate gyrus *in-vivo*, and that these effects are prominent at interstimulus intervals which mimic endogenous theta activity.

BACLOFEN INHIBITS GLUTAMATE-MEDIATED EXCITATORY POSTSYNAPTIC CURRENTS IN RAT SUPRACHIASMATIC NEURONS *IN VITRO* Z.-G. Jiang* and R.A. North. Vollum Institute, Oregon Health Sciences University, Portland, OR 97201.

Membrane currents were recorded with whole-cell patch clamp methods from cells in horizontal slices (500 μm) of brain with optic nerves attached. Single stimuli to the optic nerve evoked inward synaptic currents (EPSC, 5 - 120 pA at -60 mV) in almost all cells. Focal stimulation of the slice surface evoked a combined EPSC and outward synaptic current (IPSC). Spontaneous EPSCs and IPSCs persisted in tetrodotoxin; they were up to 60 pA and occurred at 0.2 to 60 Hz. Evoked and spontaneous EPSCs were blocked by CNQX (10 μM); evoked and spontaneous IPSCs were blocked by bicuculline (30 μM). Baclofen (1 μM) reduced the amplitude of the evoked EPSC by 20 - 60 % and reduced the frequency of spontaneous EPSCs by 15 - 55%; these effects were blocked by 2-hydroxysaclofen. Baclofen did not change the amplitude of spontaneous EPSCs, and did not affect evoked or spontaneous IPSCs. It is concluded that activation of GABA_B receptors inhibits the release of excitatory amino acids at synapses within the suprachiasmatic nucleus.

471.3

ACTIVATION OF GABA_B RECEPTORS INDUCES A TRANSLOCATION OF PROTEIN KINASE C IN NEONATAL RAT HIPPOCAMPAL SLICES. M.P. Roisin, E. Tremblay and Y. Ben-Ari, U29, 123 Bd Port-Royal, 75014 Paris, France.

Protein phosphorylation constitutes an important mechanism in the transduction of extracellular signals that modulate neuronal processes. GABA receptors which mediate most of the inhibitory drive in the adult CNS play an important role in the early postnatal life (Cherubini et al. *TINS* 14, 515-519, 1991). We now report that GABA acting on GABA_B receptors induces in neonatal but not in adult hippocampus a translocation of protein kinase C (PKC).

PKC activity was determined in cytosolic and membrane fractions, using a PKC enzyme assay kit (Amersham). Application of GABA (300 μM) caused a rapid increase in PKC activity in the membrane fraction (by 30-50%) and a decrease in the cytosol (by 30-50%). These effects of GABA 1) were neither blocked by the GABA_A antagonist bicuculline (10 μM) and not mimicked by the GABA_A agonist isoguvacine (10-100 μM); 2) were reproduced with the GABA_B agonist baclofen (30 μM), an effect prevented by the GABA_B antagonist saclofen (200 μM); 3) were not observed with slices from adult rats, even with 3 mM GABA. Using antibodies of various PKC isoforms present in the neonatal hippocampus (α, β, ε, ζ), we found that PKCα, PKCβ and to a less extent PKCε but not PKCδ are increased in the membrane fraction after GABA_B receptor stimulation.

These results suggest that GABA acting on G-protein-linked GABA receptors modulates the activation of some PKC isoforms in the developing neonatal rat hippocampus.

471.5

PHARMACOLOGICALLY DISTINCT RELEASE-MODULATING GABA_B AUTORECEPTORS IN RAT BRAIN CORTEX AND SPINAL CORD. G. Bonanno, G. Bozzo Costa, F. Donadini, A. Fassio and M. Raiteri. Istituto di Farmacologia e Farmacognosia, Viale Cembrano 4 - 16148 Genova (Italy).

GABA receptors inhibiting [³H]GABA release have been characterized pharmacologically using rat brain cortex and spinal cord synaptosomes depolarized in superfusion with 9 mM KCl. Exogenous GABA concentration-dependently inhibited the release of [³H]GABA both in cortex and spinal cord (EC₅₀: 1.23 and 1.01 μM, respectively). The effect of GABA was not mimicked by muscimol nor it was antagonized by bicuculline and picrotoxin. Similarly to GABA behaved the GABA_B receptor agonist 3-aminopropylphosphonous acid (EC₅₀: 0.095 μM, cortex, and 0.075 μM, spinal cord). (-)-baclofen was equipotent to GABA in the cortex (EC₅₀: 1.37 μM) whereas it was almost inactive in the spinal cord (EC₅₀: 425 μM). (+)-baclofen was extremely weak in both brain areas. Phaclofen antagonized the effect of GABA in the cortex (IC₅₀: 47.9 μM) but not in the spinal cord (IC₅₀: > 1000 μM). Opposite results were obtained with another GABA_B receptor antagonist, CGP 35348, which antagonized GABA in the spinal cord (IC₅₀: 1.07 μM) but was inactive in the cortex (IC₅₀: > 300 μM). It can be concluded that pharmacologically distinct GABA autoreceptors exist in the central nervous system of the same animal species. The present results, compared to those obtained previously (Bonanno and Raiteri, *J. Pharmacol. Exp. Ther.* 262, 114-118, 1992), suggest the existence of at least four pharmacological subtypes of the GABA_B receptor. Supported by Italian MURST and CNR.

471.7

GABA_B RECEPTOR-MEDIATED REGULATION OF PERIVENTRICULAR-HYPOPHYSIAL DOPAMINERGIC NEURONAL ACTIVITY AND THE SECRETION OF α-MELANOCYTE STIMULATING HORMONE. J.L. Goudreau*, E.J. Wagner, K.E. Moore, and K.J. Lookingland, Department of Pharmacology and Toxicology, Michigan State University, East Lansing, MI 48824

Periventricular-hypophysial dopaminergic (PHDA) neurons tonically inhibit the secretion of α-melanocyte stimulating hormone (αMSH) from the intermediate lobe (IL) of the pituitary. The purpose of the present study was to examine GABA_B receptor-mediated regulation of PHDA neuronal activity and the secretion of αMSH in the male rat. To this end, the effects of the GABA_B agonist baclofen, and antagonist 2-hydroxysaclofen on PHDA neuronal activity and αMSH secretion were characterized. PHDA neuronal activity was estimated by measuring the concentrations of 3,4-dihydroxyphenylacetic acid (DOPAC) in the terminals of these neurons in the IL of the pituitary. Intraperitoneal administration of baclofen produced a dose- and time-related decrease in IL DOPAC concentrations and a corresponding increase in plasma αMSH concentrations. Intracerebroventricular administration of the GABA_B antagonist 2-hydroxysaclofen did not alter basal IL DOPAC concentrations or plasma αMSH concentrations *per se* indicating that GABA does not tonically inhibit PHDA neuronal activity or αMSH secretion via GABA_B receptors. 2-Hydroxysaclofen, however, did block the baclofen-induced decrease in IL DOPAC concentrations and increase in plasma αMSH concentrations. These results indicate that GABA_B receptor activation inhibits PHDA neuronal activity and thereby increases the secretion of αMSH. (Supported by NIH grant, NS 15911)

PAIRED-PULSE DEPRESSION OF IPSCs IN RAT HIPPOCAMPAL PYRAMIDAL CELLS. T.A. Pitler* & B.E. Alger, Dept. of Physiol., Univ. of MD Sch. Med., Baltimore, MD 21201.

Paired-pulse stimulation results in depression of the second evoked GABAergic IPSC in hippocampal neurons (PPD), an effect believed to involve inhibition of transmitter release by a presynaptic GABA_B autoreceptor. Previous work, using pharmacological methods, has not determined whether or not pre- and post-synaptic GABA_B mechanisms are the same, and indeed, in some cases, PPD may result from "synaptic fatigue," independent of GABA_B receptors. Using whole-cell voltage clamp in thick, rat hippocampal slices, we studied PPD of evoked monosynaptic IPSCs. Low-intensity stimulation produced little PPD, while higher intensities increased PPD, in apparent agreement with the "fatigue" hypothesis. However, while alterations of extracellular [Ca²⁺] and [Mg²⁺] changed the extent of synaptic fatigue, they did not affect PPD. Moreover, the specific GABA_B antagonist CGP 35348 completely blocked PPD; thus, in our hands, PPD is mediated by GABA_B receptors.

To determine if the GABA_B mechanism of PPD was the same as that responsible for the postsynaptic GABA_B response, we tested Ba²⁺, pertussis toxin and phorbol esters and confirmed previous reports that each of these virtually abolishes postsynaptic GABA_B responses. In contrast, in the identical cells, neither Ba²⁺ nor phorbol esters had any effect on PPD, and pertussis toxin only partly reduced it. These data provide the first clear distinction between physiologically activated post- and pre-synaptic GABA_B receptors.

GABA_B RECEPTOR-MEDIATED REGULATION OF TUBEROINFUNDIBULAR DOPAMINERGIC NEURONS IN THE MALE RAT. E.J. Wagner*, J.L. Goudreau, K.E. Moore and K.J. Lookingland. Dept. of Pharm. & Tox., Michigan State Univ., E. Lansing, MI 48824.

Dopamine released from the terminals of tuberoinfundibular dopaminergic (TIDA) neurons in the median eminence inhibits the secretion of prolactin from the anterior pituitary. The purpose of the present study was to examine the effects of GABA_B receptor activation and blockade on the activity of TIDA neurons in the male rat, and to correlate changes in the activity of these neurons with alterations in plasma levels of prolactin. The activity of TIDA neurons was estimated by measuring the concentration of the dopamine metabolite 3,4-dihydroxyphenylacetic acid (DOPAC) in the median eminence. Plasma concentrations of prolactin were determined by double antibody radioimmunoassay. Intraperitoneal administration of the GABA_B receptor agonist baclofen decreased DOPAC concentrations in the median eminence, and increased plasma concentrations of prolactin, in a dose- and time-dependent manner. Intracerebroventricular administration of the GABA_B receptor antagonist 2-hydroxysaclofen had no effect on TIDA neurons *per se*, but did block the baclofen-induced decrease in DOPAC concentrations in the median eminence. These results reveal a lack of GABA_B receptor-mediated tonic inhibition of TIDA neurons, but activation of these receptors following the administration of the GABA_B agonist baclofen inhibits these neurons and thereby increases the secretion of prolactin. (Supported by NIH Grant MH 42802.)

A NOVEL GABA-INDUCED CURRENT IN SUBSTANTIA GELATINOSA NEURONS. M. Yoshimura, Y. Yajiri, K. Morita* and S. Nishi, Dept. of Physiology, Kurume Univ. Sch. of Med., Kurume, 830 Japan.

Substantia gelatinosa (SG) neurons have been thought to play a critical role in modulation of nociceptive transmission in the spinal cord. Intracellular recordings revealed in a subset of SG neurons that the GABA induced-response is partially insensitive to bicuculline and phaclofen. To study the property of this bicuculline and phaclofen insensitive fraction, blind patch clamp recordings were made from SG neurons in the transverse spinal cord slice of the adult rat. Bath applied GABA (100-500 μM) produced an outward current consisted of an initial peak and a slowly decaying plateau. The peak current was depressed by bicuculline (10-20 μM), but the plateau current was hardly affected. GABA_B receptor antagonist, phaclofen (500 μM) also had no obvious effect on the plateau current. Both the peak and plateau currents were reversed in polarity near the Cl⁻ equilibrium potential. It appears, therefore, that the plateau current is similar to the recently reported GABA_C receptor-mediated current. The GABA_C receptor analog, *trans*-4-aminocrotonic acid (CACA; 0.5-1 mM) was, in fact, found to produce in SG neurons a response similar to the GABA response. The CACA-induced current was, however, completely abolished by bicuculline (20 μM). These findings provide evidence that SG neurons may express a novel GABA receptor which is not likely to be identical to GABA_C receptor found recently in a visual pathway and that the receptor might be involved in modulation of nociceptive transmission in the spinal dorsal horn.

CRUSTACEAN THORACIC NEURONS IN CULTURE SHOW GABA RESPONSES WITH GABA_C PHARMACOLOGY. C. Jackel, W. D. Krenz and F. Nagy. LNPC, Univ. Bordeaux I and CNRS, 33120 Arcachon, France.

Two main classes of γ -aminobutyric acid receptors (GABA_A and GABA_B) have been described in central nervous system of vertebrates. In invertebrates, most GABA receptors are "non-A" and "non-B". Here, we describe in crustacean neurons a GABA response with characteristics similar to the novel GABA_C pharmacology described in the vertebrate retina (Feigenspan et al., 1993, *Nature* 361:159-161; Qian and Dowling, 1993, *Nature* 367: 162-164).

Neurons were dissociated from thoracic ganglia of *Homarus gammarus*, and cultured for 3-4 days. GABA was applied by pressure ejection and whole-cell currents were recorded with patch pipettes. Under voltage-clamp conditions, GABA evoked inward current at potentials more negative than -49 mV, together with an increase in membrane conductance. Reversal potentials determined with various intracellular chloride concentrations corresponded nicely to the chloride equilibrium potential. 70% of the GABA current was blocked by picrotoxin (50 μ M). These data indicate that the GABA response is mediated by Cl⁻ channels. The effects of GABA were mimicked by the GABA_A agonists muscimol and isoguvacine with a potency gradient of muscimol > GABA > isoguvacine, but were totally insensitive to the GABA_A antagonists bicuculline and SR95531. Diazepam (1 μ M) and phenobarbital (100 μ M) had no effect on the GABA response, which was also insensitive to GABA_B receptor agonists (baclofen, 3-APA) and antagonists (phaclofen). Finally we tried cis-4-aminocrotic acid (CACA), a folded analogue of GABA that is diagnostic for a novel GABA_C receptor (Drew et al., 1984, *Neurosci. Lett.* 52:317-321). As in the vertebrate retina, it evoked membrane currents mediated by Cl⁻ channels as exemplified by the reversal potential value and picrotoxin sensitivity. Furthermore it was insensitive to bicuculline and baclofen. In conclusion, GABA receptors of thoracic ganglia neurons in *Homarus* and GABA_C receptors in vertebrates have similar pharmacological profiles.

Evidence of GABAergic Neurons and GABA Receptors in *Limulus* CNS. R.F. Newkirk, M.A. Blackshear, C. Lawrence, and B. Washington. Department of Biological Sciences, Tennessee State University, Nashville, TN 37209-1561.

Recently, emphasis has been focused on GABA as an inhibitory transmitter in both vertebrates and invertebrates. Most of the invertebrate work has been concentrated on Crustaceans' peripheral motor neurons and large neurons of the abdominal muscle receptor organs of lobsters and crayfish. In *Limulus*, GABA has been shown to inhibit the rhythmic activity of the isolated heart and cardiac ganglion (Burgess and Kuffler, 1957; Van Burg & Corning, 1971) and to inhibit dorsal nerve activity and neurons in central ganglia (Walker & Robert, 1982; Washington et al., 1990). Also, Benson (1989) has identified a novel GABA receptor in *Limulus* heart. This study demonstrates the presence of GABA immunoreactive neurons in the post esophageal ganglia of *Limulus*. This distribution is consistent with axonal outputs in the 6th, 7th, and 8th dorsal nerves which give rise to nerves innervating the heart. Additionally, our results provide evidence of [³H] GABA binding sites and endogenous GABA levels in these ganglia. These results support the contention that GABA serves as a neurotransmitter in *Limulus* and strongly suggests that the function is mediated through the 7th and 8th dorsal nerves. (NIH 506 GM08092 and 5612 RR03033.)

GABA RECEPTORS: DEVELOPMENT

472.1

GABA RECEPTOR-COUPLED Cl⁻ CHANNELS EXHIBIT HETEROGENEOUS ELECTRICAL PROPERTIES IN EARLY EMBRYONIC NEUROEPITHELIAL CELLS. R. Serafini*, W. Ma, K. Tang, and J.L. Barker. Lab. Neurophysiology, NINDS, NIH, Bethesda MD 20892.

In situ hybridization histochemistry of embryonic (E) rat spinal cord probed for 13 GABA_A receptor subunit mRNAs has shown that only $\alpha_4\beta_1\gamma_1$ subunit mRNAs can be detected in the ventricular zone (vz) over E13-17. We have isolated vz cells at E13 from the dorsal cervical spinal cord and studied the electrical properties of GABA receptor-coupled Cl⁻ channels by perforated-patch whole-cell recording. Dose-response curves showed that 1) 5-10 μ M was the minimal effective dose, 2) 200 μ M evoked the maximum effects, 3) E.C.₅₀ was 33 μ M and 4) the Hill coefficient was 1.3. Fluctuation analysis of currents evoked by 10 μ M GABA led to estimated preferred conductances of 7-8 pS (n=2), 12-15 pS (n=3), 18-19 pS (n=2) and 27-28 pS (n=2). Single channel level of activity directly recorded in whole cell yielded conductances of 23-25 pS (n=8) and 28 pS (n=1). Neither 100 μ M bicuculline nor 100 μ M picrotoxin, nor 100 μ M zinc completely blocked these channels while 1 μ M 5 β pregnane-20-one was ineffective. Benzodiazepine drugs modulated GABA-activated channels in each cell tested. The results indicate that E cells in the vz of the rat spinal cord exhibit heterogeneous electrical properties, which may reflect co-expressions of $\alpha_4\beta_1\gamma_1$ subunit combinations.

ACCUMULATION OF SPLICE VARIANTS OF GABA_A RECEPTOR β 2 AND β 4 SUBUNIT mRNAs DURING MATURATION OF CORTICAL NEURONS IN VITRO. B.J. Baumgartner and E.M. Barnes, Jr.* Dept. of Biochemistry, Baylor Col. of Med., Houston, TX 77030.

The isolation and sequencing of the chicken GABA_A receptor β 2 and β 4 subunit cDNAs revealed that two transcripts are produced by alternate splicing of the primary transcripts (splice variants differing by 51 and 12 nucleotides, respectively, for β 2 and β 4) from each of two β subunit genes (M. Darlson, personal commun., and Bateson et al., (1991) *J. Neurosci.* 56:1432, respectively). We have used quantitative RT-PCR to measure the relative levels of the β 2 and β 4 subunit transcripts in embryonic chick cortical neurons from days 2-8 in vitro. Previous experiments have shown that the level of GABA_A ligand binding increases 4-fold during this period. The efficiency of amplification (R) was found to be equal for cDNAs of transcripts from the β 2 and β 4 genes (R = 0.81 \pm 0.01). The extent of amplification was constant up to 27 cycles for 50 ng total RNA. Therefore, the amount of PCR product after 25 cycles was used to determine the relative levels of the β subunit mRNAs. In neurons 2 days in vitro, PCR products from cDNAs of the smaller splice variants for the two β subunit genes were more predominant (β 2L = 8.0 \pm 2.7, β 2S = 63 \pm 20, β 4L = 98 \pm 20, β 4S = 122 \pm 29; fmol PCR product; n = 4). By day 6, the amount of the products from the β 2L transcript increased 3.3 fold and the β 2S products increased 2.5 fold (to 27 \pm 2.9 and 155 \pm 13 fmol, respectively). In contrast, products of the transcripts of the β 4 subunit genes only increased 40 to 50% by 6 days (β 4L = 141 \pm 13, β 4S = 179 \pm 22). In general, the relative ratio of the large/small variants of β 4 is much greater than β 2 (ca., 0.8 for β 4L/ β 4S and 0.15 for β 2L/ β 2S). During the in vitro maturation period, the large/small ratio for the β 2 variants increased from 0.13 to 0.22, while the corresponding ratio for the β 4 variants remained essentially unchanged.

NEURONS DERIVED FROM EMBRYONAL CARCINOMA (P19) CELLS EXPRESS MULTIPLE GABA_A RECEPTOR SUBUNITS AND FULLY FUNCTIONAL GABA_A RECEPTORS J. Reynolds*, A. Prasad and G. Paterno. Faculty of Medicine, Memorial University, St. John's, NF, Canada A1B 3V6.

Embryonal carcinoma (EC) cells have frequently been used as a model system to investigate events involved in embryonic development and cellular differentiation. The EC cell line P19 was induced to differentiate into neurons and glia by exposure to 0.5 μ M all-trans retinoic acid for 5 days. At 7 days after retinoic acid treatment, neurons derived from P19 cells were examined for (i) GABA immunoreactivity, (ii) GABA_A receptor-activated Cl⁻ currents (I_{GABA}), (iii) modulation of I_{GABA} by flurazepam, (iv) expression of GABA_A receptor subunit mRNA, (v) expression of neurofilament mRNA. I_{GABA} and modulation of I_{GABA} by the hypnotic benzodiazepine flurazepam were determined using whole-cell voltage-clamp recording. Messenger RNA for GABA_A receptor subunits and for neurofilament were detected after reverse transcriptase PCR amplification.

P19 EC cells were found to constitutively express some, but not all, GABA_A receptor subunits. Seven days after retinoic acid treatment, all GABA_A receptor subunits examined could be detected. Of particular interest, both γ 2L and γ 2S mRNA were expressed in differentiated P19 cells, but only γ 2L mRNA was detected in undifferentiated cells. A large proportion of the neuronal cells also contained GABA immunoreactivity. I_{GABA} in differentiated P19 cells had an EC₅₀ value of 12 μ M, and a Hill slope of 1.3. I_{GABA} in differentiated P19 cells was strongly potentiated by flurazepam (1 μ M). Including cAMP (2 mM) in the recording pipette resulted in a slowly developing inhibition of I_{GABA}. Thus, P19 EC cells provide the advantages of a stable cell line which express fully functional GABA_A receptors.

ONTOGENY OF THE MODULATORY EFFECTS OF ANXIOLYTIC DRUGS ON TYPE I AND TYPE II GABA_A RECEPTORS IN THE CEREBRAL CORTEX OF THE RAT.

M.G. Corda*, D. Lecca, R. Loi and O. Giorgi.

Department of Toxicology, University of Cagliari, Italy.

The ontogeny of GABA_A receptors was studied by measuring ³⁵S-t-butylbicyclophosphorothionate (³⁵S-TBPS) and ³H-Flunitrazepam (³H-FNT) binding in the cerebral cortex of the rat at intervals (1-90 days) after birth. The density of ³⁵S-TBPS binding sites increased approximately 4-fold from day 1 to day 15 after birth and progressively decreased thereafter (-30 % by postnatal day 45, when it returned to the adult value). The postnatal changes in the density of ³H-FNT binding sites had a very similar time course. In addition, competition binding studies using ³H-FNT and ligands with preferential affinity for type I sites (Zolpidem, 2-Oxoquazepam and CI 218 872) showed a very low density of these sites at birth (< 10 %) followed by a rapid increase during the postnatal development (60 % of type I sites in adult rats). Although the allosteric modulation of ³⁵S-TBPS binding by GABAergic drugs was already detectable at birth, the IC₅₀ for GABA was 3-fold larger in 1 day old rats as compared to adult counterparts. Moreover, a rightward shift was observed in the concentration-response curves for the inhibitory effects of type I selective ligands on ³⁵S-TBPS binding in newborn versus adult rats.

472.5

TRANSIENT EXPRESSION OF A NOVEL TYPE OF GABA RESPONSE IN HIPPOCAMPAL NEURONS DURING DEVELOPMENT. F.G.Strata and E.Cherubini. Biophysic Lab., Sissa, via Beirut 2-4, 34013 Trieste, Italy.

Intracellular recordings were performed with 3M KCl filled microelectrodes on hippocampal CA3 neurons in slices obtained from neonatal (P0-P9) rats. As already reported (Cherubini et al., TINS, 515-519, 14, 1991) GABA (0.1-0.5 mM) elicited a dose-dependent depolarization from -65±5 mV, associated with a conductance increase. This effect was mimicked by the GABA_A agonist isoguvacine (10µM) but not by the GABA_A agonist baclofen (30µM), which at same potential induced a hyperpolarization. Bicuculline (50µM) partially reduced the effects of GABA but it abolished the response to isoguvacine, without affecting baclofen induced hyperpolarization. In the presence of bicuculline, the fractional conductance increase (R/R'-1) induced by GABA (300 and 500 µM) was respectively 1.16±0.29 and 1.76±0.34 (mean ± s.e.m., n=22). The bicuculline-insensitive GABA response was Cl⁻ dependent, as E_{rev} changed at different [Cl⁻]_o concentrations (isethionate substitution). The bicuculline-insensitive GABA-response was blocked in an uncompetitive manner by picrotoxin (30-100µM) and was mimicked by the GABA analogue *cis*-4-aminocrotonic acid (CACA; 1mM). The same concentration of CACA had no effect on adult CA3 neurons. The GABA response was enhanced in the presence of a low Na⁺ medium (choline substitution) or nipecotic acid (1mM). The bicuculline-insensitive GABA response seems to be mediated by activation of a novel type of GABA receptor, termed as GABA_C, and recently described in retinal horizontal and bipolar cells.

472.7

EXPRESSION OF GABA_A RECEPTOR mRNAs IN CULTURED CEREBELLAR GRANULE NEURONS IS DEPENDENT ON DEVELOPMENTAL SIGNALS. K. Behringer and R.E. Siegel. Dept. of Pharmacology, Case Western Reserve University, Cleveland, OH 44106.

GABA_A receptor subunit mRNA expression in the CNS is developmentally regulated in a region-specific manner. We demonstrated previously that the mRNAs encoding $\alpha 1$, $\beta 2$, and $\gamma 2$ subunits in the rat cerebellum rise several fold during the second postnatal week. A similar developmental pattern for the $\beta 2$ and $\gamma 2$ subunit mRNAs is found in cultured cerebellar granule neurons prepared at P10. In contrast, the mRNAs remain constant in cultures prepared at E19, a relatively immature stage of cerebellar development. These studies suggest that subunit mRNA expression is not intrinsic to the neurons but may be regulated by cues received during cerebellar maturation. To determine the developmental stage at which subunit mRNA expression is initiated, cultures of rat cerebellar granule neurons were prepared at 2-day intervals from P2 through P8, and the relative levels of the $\alpha 1$, $\beta 2$, and $\gamma 2$ subunit mRNAs were assessed over time in culture by PCR. In cultures prepared at P2, P4, and P6, the subunit mRNAs were present at constant levels throughout the 14-day culture period. In contrast, in cultures prepared at P8, the $\beta 2$ and $\gamma 2$ subunit mRNAs rose approximately 7-fold between 2 and 7 days in culture in a pattern similar to that observed in P10 cultures. These findings suggest that the program of GABA_A receptor subunit mRNA expression has been initiated by P8, a time at which extensive cell migration from the external germinal layer to the internal granule cell layer has begun. The exact point along the differentiation pathway at which receptor gene expression is triggered and the nature of the regulatory cues remain unknown.

472.9

PEPTIDES FROM RED ALGAE AND CYANOBACTERIA THAT INDUCE METAMORPHOSIS OF MARINE INVERTEBRATE LARVAE ARE LIGANDS FOR MURINE GABA RECEPTORS. H.G. Trapido-Rosenthal¹ and A.N.C. Morse². ¹Bermuda Biological Station for Research, St. George's GE01, Bermuda, and ²Marine Biotechnology Center and Marine Science Institute, University of California, Santa Barbara, California 93106.

The effectiveness of a new class of small peptides as novel ligands for pharmacologically distinct GABA receptors from both invertebrate and vertebrate organisms has been investigated. Larvae of the gastropod mollusc *Haliothis rufescens* are induced to settle from the plankton and begin metamorphosis specifically in response to this class of compound, initially identified and biochemically characterized from the crustose coralline red alga, *Lithothamnium californicum* (Corallinaceae). Although only peptides from members of this algal family are ecologically significant in the recruitment process, metamorphosis can be mimicked experimentally by GABA and a number of GABA analogs, as well as by peptides of the same class isolated from foliose red algae (Rhodophyta), and cyanobacteria (Cyanophyta). The peptide isolated from *Lithothamnium* competes for the binding of the radiolabeled GABA analog baclofen at the metamorphosis-mediating chemoreceptor of abalone larvae. In addition, this peptide competes for specific binding of radio-labeled muscimol at GABA_A receptors from murine brain, as do peptides of the same class isolated from other algal and bacterial sources. These latter neural binding sites have a higher affinity for the algal and bacterial peptide ligands than they do for GABA itself. These peptides thus appear to comprise an interesting class of GABA-mimetic compounds that may be of pharmacological significance.

GABA_A RECEPTOR-MEDIATED, Cl⁻-DEPENDENT POTENTIAL CHANGES AND Ca²⁺ RESPONSES IN CHICK EMBRYONIC TELENCEPHALIC CELLS CHANGE WITH TIME IN CULTURE. K. Torimitsu¹, A. Kawana¹ and J.L. Barker². ¹NTT Basic Research Labs., Musashino-shi, Tokyo 186, Japan., ²Lab. of Neurophysiology, NINDS, NIH, Bethesda, MD 20892, USA.

GABA and the GABA_A agonist muscimol induce depolarizing responses of acutely dissociated embryonic chick telencephalic cells studied using voltage-sensitive dyes and flow cytometry. However, the ionic mechanism of the depolarization is not known. Here we report transient intracellular calcium (Ca²⁺) and chloride ion (Cl⁻) changes caused by GABA in cultured chick embryonic telencephalic cells, which were studied using the fluorescent Cl⁻ indicator MQAE and the fluorescent Ca²⁺ indicator Fura 2. Cells were dissociated from embryonic day 6 and grown in a MEM-based, serum-containing medium, then stained with MQAE and Fura 2. Transient Cl⁻ and Ca²⁺ responses were recorded after adding 10µM GABA or muscimol, which depended on the number of days in culture. At early times in culture (<7 days), there were transient increases in Ca²⁺ and decreases in Cl⁻. Thus, net Cl⁻ efflux occurred at a time when neurons could be depolarized by muscimol, suggesting that depolarizing responses could be due to Cl⁻ efflux. The Ca²⁺ increase was only observed at a time when neurons exhibited depolarizing GABA_A-type responses to muscimol. Since the Ca²⁺ responses were inhibited by T-type Ca²⁺ channel blockers (ethosuximide, Ni, amiloride), the transient Ca²⁺ increase induced by muscimol could be explained by Ca²⁺ influx through voltage-gated Ca²⁺ channels, which would be activated by depolarization due to Cl⁻ efflux. Some cells expressed Ca²⁺ signals in response to muscimol that were insensitive to these Ca²⁺ channel blockers. After 7 days in culture, muscimol decreased Ca²⁺ and increased Cl⁻, indicating that GABA_A receptor functions had changed *in vitro* as they do *in vivo* and suggesting that changes in Cl⁻ and Ca²⁺ are interdependent.

CHRONIC EXPOSURE OF CHICK EMBRYOS TO GABA_A AGONISTS IN OVO DOWN-REGULATES CEREBELLAR GABA_A RECEPTORS. P.A. Calkin^{*} and E.M. Barnes, Jr. Dept. of Biochemistry, Baylor Col. of Med., Houston, TX 77030.

Chick embryos with an undeveloped blood brain barrier were used to examine the down regulation of GABA_A receptors *in vivo*. Eggs containing 8-day embryos were windowed and the GABA_A agonist isoguvacine (5 mmol) was applied to the vascularized chorioallantoic membrane. The isoguvacine treatment was repeated on days 11, 14 and 17, and the embryos were sacrificed on day 18. Washed cerebellar membranes from isoguvacine-treated 18-day (stage 42) embryos showed a reduction of 30.2 ± 6.4 % in clonazepam-displacable binding of [³H]flunitrazepam (5 nM final concentration) compared to vehicle-treated or unwinded controls. Reductions of lower magnitude were observed in the level of [³H]flunitrazepam binding to membranes from the cerebral cortex and optic lobes. The reduction in cerebellar membranes was dose-dependent, allowing a value for the half-maximum reduction in [³H]flunitrazepam binding to be estimated at 8 µM isoguvacine. Binding of the GABA_A channel ligand [³⁵S]-t-butylbicyclophosphorothionate (TBPS, 10 nM) was measured in the presence of R5135 (1 µM) to eliminate interference by agonist carry-over. The standard isoguvacine treatment produced a 43.6 ± 7.6 % reduction in the specific binding of [³⁵S]TBPS to cerebellar membranes compared to controls. However, this treatment produced no change in total embryonic, whole brain, or cerebellar wet weights, or in the specific binding of [³H]-N-methylscopolamine to muscarinic acetylcholine receptors on cerebellar membranes. Saturation binding studies with [³H]flunitrazepam revealed that isoguvacine exposure reduced the B_{max} value by 27.5 ± 7.3 % or 31.7 ± 6.9% compared to vehicle-treated or unwinded embryos, respectively. The results indicate that chronic treatment *in ovo* with a GABA_A agonist produces a down-regulation of GABA_A/benzodiazepine receptors in the cerebellum of chick embryos.

IMMUNOCYTOCHEMICAL LOCALIZATION OF CORTICOTROPIN-RELEASING FACTOR IN THE HUMAN BRAINSTEM. V. Arango*, P.M. Rice, R.W. Smith, M.C. Austin and J.J. Mann. Laboratories of Neuropharmacology, University of Pittsburgh, Pittsburgh, PA 15213.

Corticotropin-releasing factor (CRF) plays an important role in the stress response. We showed by immunocytochemistry and *in situ* hybridization (Austin *et al.*, 1992) that the locus coeruleus (LC) of the human receives a dense CRF innervation, suggesting a CRF modulatory role on the LC. In this study we mapped the location of CRF-immunoreactive (CRF-IR) cells and fibers in the human midbrain and pons, relative to tyrosine hydroxylase (TH-IR) and serotonergic (PH8) immunoreactivity.

Human brainstems (n=3) were blocked to include the midbrain and upper pons, sectioned (50 μ m) coronally and processed for immunocytochemistry (every 500 μ m) using CRF antisera, preadsorbed with melanin. We plotted the outline of each section and the location of CRF-IR cells and fibers.

A dense population of CRF-IR cells appears anterior to the pedunculopontine tegmental nucleus (PPTg) in a continuous column that first corresponds to the PPTg and extends medially towards the dorsolateral medial longitudinal fasciculus. CRF-IR neurons are also seen ventromedial to, and within the LC, on neurons devoid of TH-IR. The CRF-IR column of cells remains in that position throughout the caudal extent of the pontine tegmentum. CRF-IR neurons correspond to distinct cell groups as seen with Nissl. The serotonergic nuclei (dorsal raphe, caudal linear and median raphe) receive a strong CRF innervation. The paramedian raphe, which contains PH8-IR fibers, also has dense CRF fibers. The dorsal tegmental n, which is devoid of PH8-IR, exhibits strong CRF-IR throughout its rostrocaudal extent, mostly in fibers. The strong CRF innervation of serotonergic nuclei provides evidence for a neuromodulatory role of this peptide on the serotonergic system. Similarly, this CRF system may represent the basis for neuromodulation by CRF of noradrenergic neurons in the LC. (Supported by MH40210, MH46745 and AA09004)

INTERLEUKIN-1 β -LIKE IMMUNOREACTIVITY IN CSF IN NORMAL, ALZHEIMER'S DISEASE AND OTHER NEUROLOGICAL DISORDERS: METHODOLOGICAL CONSIDERATIONS. S.N. Nair, S. Wahhab, D. Kapkov, J.C. Lehmann*, Hahnemann University School of Medicine, Philadelphia PA

The role of cytokines in neurodegenerative disorders of the central nervous system has become a topic of intense investigation. The interest in cytokines and CNS neurodegenerative disorders stems partly from analogies between Alzheimer's disease (AD) and the acute phase response. Therefore we set out to measure IL-1 β levels in CSF of AD patients, with a view to explaining disparate results obtained in various laboratories, using two commercially available EIAs, one commercially available RIA, and Western blotting with yet another antibody. CSF was used from 10 patients with Alzheimer's disease, 9 patients with acute relapsing multiple sclerosis in exacerbation, and 10 control subjects, obtained from the National Neurological Research Specimen Bank (Los Angeles, CA).

No EIA assay reliably detected IL-1 β -like immunoreactivity, and one commercially available IL-1 β antibody failed as well to detect IL-1 β -like immunoreactivity. The Advanced Magnetics (Boston MA) RIA successfully detected IL-1 β -like immunoreactivity, and the polyclonal antibody moreover successfully detected IL-1 β -like immunoreactivity at 14 kDa in Western blots. This study shows that detection of IL-1 β in CSF is probably disrupted by an endogenous substance, and that post-mortem CSF samples are not acceptable for valid IL-1 β determination.

DIFFERENTIAL DISTRIBUTION OF NEUROTENSIN-IMMUNOREACTIVE NEURONS IN THE FOREBRAIN OF SHR AND WKY RATS. R.S. Canbeyli, L. Skaredoff & B.G. Yongue*, Dept. of Developmental Psychobiology, New York State Psychiatric Institute, New York, NY 10032.

Neurotensin (NT) and Neuropeptide Y (NPY), implicated in cardiovascular and fluid/electrolyte regulation, were measured immunohistochemically in spontaneously hypertensive rats (SHR) and normotensive Wistar-Kyoto rats (WKY). To minimize variability, aged-matched SHR and WKY (♂, 5-10 mo) were perfused in pairs and alternate 50-micron sections were marked and processed together for immunohistochemical staining for NPY or NT.

Preliminary work indicates that there is a slightly increased density of NPY terminal staining in the hypothalamic paraventricular nucleus of SHRs compared to WKYs (9/11 pairs). No NPY-immunoreactive perikarya were observed subcortically in the two strains. There were significantly ($p < 0.01$) more NT-immunoreactive neurons in the central nucleus of the amygdala (CeA) in SHR ($3.5 \pm .4$; mean \pm sem, per CeA) than in the WKY ($1.2 \pm .3$) with no strain difference (8 pairs) in the density of NT immunostaining. There were very few immunoreactive cells in the rostral CeA; most were observed mid rostrocaudally. SHRs also had significantly ($p < 0.01$) more NT-cells ($1.7 \pm .2$) than WKYs ($0.4 \pm .1$) in the rostral bed nucleus of the stria terminalis (BST). These results do not indicate general differential staining between strains, and may point to specific functional differences since SHRs and WKYs had similar numbers of NT-immunoreactive neurons in the medial amygdala and the intraamygdaloid division of BST, the only other structures in which clusters of immunoreactive perikarya were observed. A study is under way to determine distribution of NT messenger RNA expression in the two strains. (MH00803 & MH45951)

PREPROTACHYKININ B [NEUROKININ B (NKB)] IMMUNOREACTIVE (IR) NEURONAL PROCESSES IN HUMAN BRAIN. D. Mileusnic,¹ D.J. Magnuson,² S.A. Lorens¹ and J.M. Lee.^{1,2} Departments of Pharmacology¹ and Pathology,² Loyola University Chicago Medical Center (Bldg. 135), Maywood IL 60153.

NKB is a mammalian tachykinin which is predominantly localized in the CNS. The distribution of NKB-like IR and NKB mRNA positive perikarya and fibers in the rat CNS have been described using immunohistochemical and *in situ* hybridization techniques (*J. Comp. Neurol.* 317:341, 1992). Ligand-binding studies [using [³H]eledoisin; in: Henry, J.L. *et al. Substance P and Neurokinins*. Springer-Verlag:NY, 1987, pp. 363-365] and Northern blot analyses (*FEBS Lett.* 299:90, 1992) have documented the presence of NKB receptors (NK3) in both the rat and human brain. Although the functional role(s) of CNS NK3 receptor mediated events have yet to be firmly established, the available evidence suggests that NKB modulates midbrain raphe serotonergic neurons involved in the regulation of behavioral arousal (*J. Pharmacol. Exp. Ther.* 251:388, 1989; *Brain Res.* 517:11, 1990). In order to visualize NKB-like IR perikarya and fibers in the human brain, we employed rabbit polyclonal antibodies (AB) directed against NKB(1-10) and against amino acids 50-79 of preprotachykinin B [peptide 2 (P2); generously provided by Dr. J. Krause, Washington Univ., St. Louis] using the avidin-biotin (ABC; Vector) technique with nickel intensification. Control procedures included both the omission of the primary AB and the preincubation of the AB with NKB(1-10) or P2 (10 μ M, 24 h at 4°C). We have observed P2 IR neurons and/or fibers in several human CNS regions (including the mesencephalic raphe, the granular layer of the cerebellum, the hippocampus, and the entorhinal, cingulate and frontal cortices). The NKB-like perikarya and fibers appear to have a distribution similar to that found in the rat brain. The human NKB neuronal processes also exhibit morphological properties similar to those discerned in the rat CNS: punctated or evenly stained perikarya and dendrites, as well as branched beaded axons. Pursuant to these observations, we are conducting a comparative neuroanatomical analysis of NKB systems in the mammalian CNS.

LOCALIZATION OF ANGIOTENSINOGEN mRNA IN RAT BRAIN *IN SITU* HYBRIDIZATION. B. Kimura, L. Shen, V. Cook* and M.I. Phillips. Dept. of Physiology, University of Florida, Gainesville, FL 32610.

The renin-angiotensin system (RAS) in the brain is involved in cardiovascular control and fluid volume homeostasis. All components of the system have been identified in the brain, but angiotensinogen mRNA has been localized in glial cells and not in neurons. We have studied the distribution of angiotensinogen mRNA in the rat brain using *in situ* hybridization. The results show high concentration of mRNA in the paraventricular nucleus (PVN) which is mainly neuronal and in other areas involved in cardiovascular control such as nucleus tractus solitarius (NTS), organum vasculosum of the lamina terminalis (OVLT) and supraoptic nucleus (SON). There was also high amounts of angiotensinogen mRNA in areas with different functions, including the inferior olive (IO), the periventricular nucleus (PeVN) and the suprachiasmatic nucleus (SCN). The signal for angiotensinogen mRNA was localized to a few nuclei in the brainstem, however in the hypothalamic region the distribution was both in nuclei and diffusely spread in the preoptic area, the anterior hypothalamic and thalamic area and the amygdaloid nuclei. The distribution and density we found corresponds well with the distribution of angiotensinogen found with immunohistochemistry and indirect radioimmunoassay (Naruse *et al.*, 1985). This study also corroborates and refines a previously published preliminary study by Younge *et al.* 1991. Our results indicate that both neurons and glia contain angiotensinogen mRNA because there were neuronal nuclei with strong signals and more diffuse areas which contain glial cells. The results could also explain why the highest levels of angiotensin II in the brain are in the brainstem and hypothalamus since both contain considerable angiotensinogen mRNA compared to other regions.

473.6

GALANIN IMMUNOREACTIVITY AND BINDING SITES IN THE NUCLEUS TRACTUS SOLITARIUS OF THE CAT. B.E. Maley*, C. Colson, J.P. McGillis and J.F. Hyde. Dept. of Anatomy & Neurobiology and Dept. of Microbiology and Immunology, Univ. of Kentucky Med. Ctr., Lexington, KY 40536

Galanin is a 29 amino acid polypeptide isolated from the intestine. It has a wide spread distribution throughout the central nervous system where it has a variety of functional roles. Galanin has been localized in the nucleus tractus solitarius (NTS), suggesting it plays a role in the regulation of autonomic function. It was the purpose of this study to investigate the distribution of galanin in the various subdivisions of the feline NTS.

Cats were perfused either with phosphate buffered 4% paraformaldehyde (immunocytochemistry) or buffered 0.1% paraformaldehyde (receptor binding). Sections for galanin immunocytochemistry were immunostained with the peroxidase, anti-peroxidase method, while galanin binding sites were labeled with [¹²⁵I]galanin.

The NTS had a dense plexus of galanin-like immunoreactive fibers throughout its rostral to caudal length. The majority of immunostaining was localized to the medial, dorsal, commissural and interstitial subdivisions. Lesser amounts were present in the parvicellular, ventrolateral and intermediate subdivisions. Galanin binding sites had a similar distribution throughout the various subdivisions of the nucleus.

Results of the present investigation provide a morphological basis for galanin's role in the regulation of autonomic functions, since it is localized in areas of the NTS involved in control of respiration and cardiovascular function. The presence of galanin binding sites indicates that it may be acting as a neuromodulator at synaptic junctions.

DISTRIBUTION AND mRNA EXPRESSION OF A NOVEL NEURON-SPECIFIC 14 kDa PROTEIN. S. Nakajo¹, S. Shioda², Y. Nakai² and K. Nakaya². Showa Univ., Schs. of Pharmaceut. Sci. and Med.¹, Shinagawa-ku, Tokyo 142, Japan.

A neuron-specific protein with a molecular mass of 14 kDa, phosphoprotein 14 (PNP 14) is phosphorylated by EGF receptor and pp60^{v-src} on tyrosine residue(s) and by CaM-kinase II on a serine residue *in vitro*. Here we show the distribution and mRNA expression of PNP 14 in rat brain. PNP 14 immunoreactivity was observed in the nerve fibers and their terminals distributed in the brain including telencephalon, diencephalon, cerebellum, and cerebrum. In the cerebellum, PNP 14 immunoreactive fibers were numerous distributed in the molecular layer and in lesser amounts in the granular layer. In the cerebrum, the immunoreactivities were observed throughout the cerebral cortex and their terminals were found to be in contact with the pyramidal cells in the layer V. *In situ* hybridization revealed that PNP 14 mRNA was expressed particularly rich in granular layer of the cerebellum, in the hippocampus, and in the pyriform cortex of the cerebrum. These results suggest that PNP 14 might play an important role in the terminus of neuronal cells, and its function may be modulated by the protein phosphorylation reaction.

NEUROACTIVE PEPTIDES EXIST IN THE MIDBRAIN DOPAMINERGIC NEURONS THAT CONTAIN CALBINDIN-D_{28k}. C.-L. Liang and D.C. German*. Dept. of Psychiatry, UT Southwestern Medical Center, Dallas, TX 75235-9070.

Calbindin-D_{28k} (CaBP) is a 28 kDa calcium-binding protein that is found within the cell bodies, dendrites and axons of specific nerve cells, and it binds micromolar concentrations of intracellular calcium. CaBP has been found within a subpopulation of midbrain dopaminergic (DA) neurons in several species, including man (e.g., Gerfen et al., 1985; German et al., 1992). The neuroactive peptides, cholecystokinin (CCK) and neurotensin (NT), have also been colocalized within a subpopulation of midbrain DA neurons (e.g., Hokfelt et al., 1980). The purpose of the present study was to determine whether CaBP is colocalized within the midbrain DA neurons that contain the peptides. Double and triple-labeling immunocytochemical staining techniques were used in the rat. Virtually all of the cells that contained CCK also contained CaBP, and most of the cells that contained NT also contained CaBP; such cells were found in the ventral tegmental area, substantia nigra pars compacta (dorsal region), and substantia nigra pars lateralis. CaBP may play a role in the co-release of neuroactive peptides, with dopamine, from the midbrain DA neurons.

437.11

NITRIC OXIDE SYNTHASE IMMUNOREACTIVITY AND NADPH-DIAPHORASE LOCALIZATION IN MONKEY CEREBRAL CORTEX. T. Hashikawa*, M. G. Leggio, R. Hattori and Y. Yui. Lab. for Neural Systems, F.R.P., RIKEN, Wako 351-01, Japan, Exp. Neurology Lab., Catholic University, Rome, Italy, and Dept. of Internal Medicine, Kyoto University Hospital, Kyoto 606, Japan.

Neurons that contain the enzyme involved in NO synthesis, nitric oxide synthase (NOS), have proven readily identifiable in the central nervous system because of the apparent identity of NOS with nicotinamide adenine dinucleotide phosphate diaphorase (NADPH-d), an enzyme that can be revealed by a histochemical stain. However, there has been no systematic study of these neurons in the primate cerebral cortex. Moreover, although it seems likely that NADPH and NOS will invariably be colocalized in neurons, this has not been the subject of a detailed study. The present work was aimed at studying systematically the pattern of NOS immunoreactive and NADPH-d histochemical staining in the cerebral cortex of Japanese macaques. NADPH-d and NOS positive cells presented a similar uniform distribution in all cortical areas although significant differences were found in the pattern of distribution of fiber plexuses. Plexuses of fine beaded fibers were clearly identifiable with NADPH-d staining while only isolated fibers of similar type could be found in the NOS immunoreactive sections. In all areas there was a dense plexus in layer I composed of fibers mainly oriented parallel to the pial surface. Labeled fibers were also always present in layer VI and the underlying white matter. Other plexuses tended to vary from area to area. For instance, a relatively dense plexus of irregularly oriented fibers in layer II and the adjacent part of layer III was seen in many areas while a prominent layer IV plexus was evident almost exclusively in area 17. The present results indicate that NOS, as revealed immunohistochemically, and NADPH-d, as revealed histochemically, characterize the same population of cortical neurons in monkeys, and provide evidence of areal specificity in the distribution of NADPH-d containing fibers in the primate cortex.

437.8

CALRETININ-CONTAINING PATHWAYS IN THE CENTRAL NERVOUS SYSTEM OF THE RAT. P. Krzywkowski, M.C. Senut, D.M. Jacobowitz and Y. Lamour*, INSERM U161, Paris, France, and Lab. Clinical Science, NIMH, NIH, Bethesda, USA.

The pattern of projection of central neurons containing the calcium-binding protein calretinin might provide clues as to the function of this protein. In order to identify the calretinin-containing pathways, immunohistochemical techniques using a well characterized polyclonal antibody were combined with the retrograde transport of a WGA-apoHRP-colloidal gold complex injected in various brain regions in the adult male rat. Double-labelled neurons were consistently found in the paraventricular nucleus of the thalamus, hilus of the dentate gyrus and lateral hypothalamus (medial septal injections), paraventricular nucleus of the thalamus, lateral hypothalamus (diagonal band injections), lateral mammillary nucleus (antero-dorsal nucleus of the thalamus injections), septo-fimbrial nucleus, nucleus triangularis, nucleus reticularis thalami, nucleus reuniens, anterior amygdaloid nucleus (habenula and medio-dorsal thalamic nucleus injections), substantia nigra, ventral tegmental area (caudate and globus pallidus injections), medial habenula (interpeduncular injections) zona incerta, ventral tegmental area (cortical injections). In contrast no double-labelling was found in other populations of calretinin-positive neurons. For instance no double labelling was observed in the cerebral cortex after thalamic, cortical or striatal injections. Our results demonstrate that subpopulations of calretinin-positive neurons in the central nervous system are projection neurons. Projections arising from the substantia nigra-ventral tegmental area complex, the lateral mammillary nucleus, caudal septum, medial habenula, zona incerta and several thalamic nuclei seem especially rich in calretinin.

437.10

LOCALIZATION OF ACIDIC FIBROBLAST GROWTH FACTOR mRNA IN THE MOUSE BRAIN. A.E. Kresse*, A.J. Bean, and T. Hokfelt. Department of Histology and Neurobiology, Karolinska Institute, Stockholm 104 01, Sweden.

The anatomical localization of acidic fibroblast growth factor (aFGF) mRNA in the adult male mouse brain was examined *in situ* histochemically using a radiolabelled 51-mer synthetic oligonucleotide probe. Consistent with recently published immunocytochemical data (Fallon et al., *Growth Factors* 6: 139-157, 1992), it could be shown that aFGF is expressed in several defined functional systems of the brain, e.g. the auditory (superior olive, cochlear, lateral lemniscal and trapezoid nuclei) and vestibular (vestibular nuclei) systems, somatosensory (spinal and mesencephalic trigeminal nuclei, cuneate nucleus) systems as well as autonomic-related structures (hypothalamus, laterodorsal tegmental nucleus, locus coeruleus, raphe nuclei, dorsal motor nucleus of the vagus). Unlike the reported distribution of aFGF peptide, the highest levels of aFGF mRNA were found in large somatomotor (nucleus of the oculomotor nerve and hypoglossal nucleus, ventral spinal cord) and visceromotor neurons (motor nucleus of the trigeminal nerve, facial and ambiguous nuclei). On the other hand, the reported immunocytochemical data as well as an *in situ* histochemical study concerning the aFGF mRNA expression in the young adult rat brain (Wilcox and Unnerstall, *Neuron* 6: 397-409, 1991) also revealed some other systems (pyramidal neurons of the neocortex, dentate granule cells of the hippocampus, external and internal granule cell layer and mitral cell layer of the olfactory bulb, striatum), where no aFGF mRNA was detectable in the present study in mouse. This might be due to methodical conditions (immunocytochemistry versus *in situ* hybridization), and species (rat versus mouse) and age (young adult versus adult) differences.

Though there is evidence for aFGF as a mitogen for a wide variety of cultured cells, its physiological significance is still unknown. However, its defined expression in several brain areas suggests that it may have an important neurotrophic or neuromodulatory function within these systems.

A NOVEL METHOD FOR THE COLOCALIZATION OF mRNA AND PROTEIN IN MAMMALIAN BRAIN. N.B. Hastings, D.S. Albeck, and B.S. McEwen*. Laboratory of Neuroendocrinology, The Rockefeller University, New York, NY, 10021.

In situ hybridization histochemistry (ISHH) studies have demonstrated that corticosteroids can negatively regulate levels of arginine vasopressin (AVP) mRNA in the rat paraventricular nucleus (PVN). Double immunocytochemical (ICC) studies have indicated that type II glucocorticoid receptors (GR) are colocalized with AVP in the PVN. However, there is no technique readily used to simultaneously demonstrate colocalization and regulation. We have developed a method for the cellular colocalization of AVP mRNA with GR-ir using quantitative *in situ* hybridization histochemistry (ISHH) and immunocytochemistry (ICC). This methodology employs low salt ISHH washes that are stringent enough to destabilize non-specific RNA-DNA duplexes but wash temperatures low enough to spare antigenicity. Using this method, we have confirmed the presence of AVP mRNA in GR positive cells within the rat PVN. Control experiments indicate that labeling of mRNA and protein is specific and quantifiable. We believe that such a methodology, in conjunction with appropriate hormonal manipulations, may be readily used to identify sites of steroid hormone action and quantify changes in the mRNA of target genes.

474.3

COEXISTENCE OF CORTICOTROPIN-RELEASING HORMONE (CRH) AND GABA IMMUNOREACTIVITY IN LAMINA I OF THE FELINE CORTEX.

Y. Tizabi*, P.J. Gatti and V. J. Massari. Dept. Pharmacology, Coll. Med. Howard Univ. Washington, D.C. 20059.

It is well known that CRH is localized in the hypothalamus, where it serves to regulate the pituitary-adrenal axis. However, CRH immunoreactive cells are also distributed in many other areas of the brain. Previously (Neurosci. Abst. 17:969, 1991), we have reported the existence of CRH containing cells in lamina I of the feline cerebral cortex. Since this lamina also contains numerous GABAergic cells, we sought to determine whether CRH and GABA are colocalized in this lamina. Frozen 10-20µm thick sections from colchicized cats were processed by an indirect immunofluorescence method. Double labeled cells containing CRH and GABA, as well as single labeled cells containing either CRH or GABA, were detected in lamina I of the cortical areas examined. The number of single labeled GABA cells was much higher than the number of cells containing CRH. Double labeled CRH-GABA immunoreactive cells were seen more frequently than cells containing CRH alone. The physiological significance of these observations in the control of cortical function remain to be elucidated. Supported in part by grants from the American Heart Association / N.C.A.

474.5

CHOLECYSTOKININ (CCK) MESSENGER RNA (mRNA) IS EXPRESSED IN CORTICO-THALAMIC PROJECTION NEURONS: *IN SITU* HYBRIDIZATION COMBINED WITH RETROGRADE TRACING WITH RHODAMINE LATEX MICROSPHERES (RLM).

V.V. Senatorov*, V. Trudeau, B. Hu. Loeb Research Institute, Ottawa Civic Hospital, Ottawa, Ontario, Canada, K1Y 4E9.

Neocortical neurons reportedly contain a high density CCK mRNAs. Using combined retrograde tracing and *in situ* hybridization we now report that a large subpopulation of cortical CCK neurons send their axon projections to the thalamus.

Anaesthetized Long-Evans rats received a stereotaxic injection of RLM (0.03-0.20 µL) into the left ventrolateral (VL) thalamic nucleus and/or the medial geniculate body (MGB). After 7 days animals were anaesthetized and sacrificed by transcardial perfusion with 4% paraformaldehyde. Coronal sections (6-20 µm) were cut with cryostat and mounted on slides. The 24-base oligonucleotide probe complementary to the 3' coding region of the rat precholecystokinin mRNA was labelled with Fluorescein-dUTP or Digoxigenin-dUTP for direct or indirect (immunofluorohistochemistry) hybridization, respectively.

High levels of CCK transcripts were revealed in selected brain regions including the neocortex. CCK-hybridized perikarya were found in all cortical layers with moderate labelling in layers V-VI. Signals using control probe (oxytocin) were absent. A dense population of corticothalamic neurons was retrogradely labelled by RLM in the superficial/deep layer V and layer VI of the parietal-temporal cortices [Paxinos & Watson, 1986]. Co-localizations of CCK mRNAs and RLM were found in most corticothalamic neurons in the superficial layer V and in 65-80% of the cells located within deep layer V and layer VI. The present study suggests that CCK can be used as a neuromodulator in corticothalamic pathways. Supported by Parkinson Foundation of Canada, Ontario Mental Health Foundation and MRC of Canada.

ELECTRONMICROSCOPIC IMMUNOCYTOCHEMISTRY STUDY ON THE NEUROPEPTIDES IN THE HYPOTHALAMUS OF THE CAT J.J. Kim*. Dept. of Anat., Chosun Univ., Kwang-joo, Korea 501-759.

This study was carried out to investigate the morphology and distribution of the neuropeptide-immunoreactivities in the hypothalamus of the cat.

The neuropeptide-immunoreactivities were identified in the hypothalamus immunocytochemically with antisera raised against somatostatin (SOM), corticotropin releasing factor (CRF), Neuropeptide-Y (NPY), Vasopressin (VP) and Oxytocin (OT).

Generally most SOM, CRF, NPY, VP and OT-neurons were found in the anterior periventricular, arcuate, paraventricular and supraoptic nuclei in the hypothalamus. Neuropeptides neurons were round, oval, spindle in shape, and the diameters of the were SOM, CRF and NPY neurons were 20-25 µm, but VP and OT neurons were 30-40µm in the cat, respectively.

Under the electronmicroscopic observations, the rough endoplasmic reticulum, mitochondria, Golgi apparatus and microtubules were all neuropeptide-immunoreactivity neurons. Also afferent axo-dendritic, axo-axonal and axo-somatic synapses were appeared symmetrically and asymmetrically.

474.4

LOSS OF CCK mRNA IN DORSOLATERAL THALAMUS AFTER CORTICAL LESIONS. M.K.Panni*, U.Capoor†, M.V. Sofroniew and M.A.N. Rattray†. Department of Anatomy, University of Cambridge, Cambridge CB2 3DY, U.K. and †Division of Biochemistry, UMDS, Guy's Hospital, London SE1 9RT, U.K.

Traumatic or stroke-like injuries of the cerebral cortex result in the retrograde degeneration of thalamic relay neurons that project to the damaged area. The basis for the extreme sensitivity of relay neurons to axotomy and the mechanisms involved in the degenerative process are not well understood. We have analysed the effects of cortical lesions on several messenger RNA's which are expressed at high levels in neurons of the thalamus and cerebral cortex, including a mRNA encoding a neuropeptide, cholecystokinin (CCK), and a growth associated protein, GAP-43. Under full anesthesia, male Wistar rats were given unilateral suction lesions of the fronto-parietal region of the cerebral cortex. After 24 hours, 2 weeks and 4 weeks survival, the animals were killed, their brains removed, rapidly frozen and sectioned. Antisense oligonucleotides were end-labelled with ³⁵S-dATP and used for *in situ* hybridisation. Film autoradiography revealed that after cortical lesions, CCK mRNA levels were markedly reduced in the dorsolateral thalamus at 2 and 4 weeks, but not at 24 hours. In contrast GAP-43 mRNA levels were relatively unchanged. Analysis of Nissl stained sections revealed that the decline in CCK mRNA was accompanied by the appearance of degenerating cell bodies. These results suggest that CCK mRNA levels are a sensitive marker for neurodegeneration and that GAP-43 is made by non-neuronal cells during retrograde degeneration. (Supported by MRC, UK).

NEUROPEPTIDE EXPRESSION IN TARGET SPECIFIC NEURONS IN THE RAT SUPERIOR CERVICAL GANGLION. A.F. Elshaar* and L.L. Wright. Dept. Anatomy/Neurobiology, BUMS, Boston, MA 02118.

This study was to compare the pattern of neuropeptide Y-like immunoreactivity (NPY-li) and dynorphin A-like immunoreactivity (DYN-A) in adult and developing rat sympathetic superior cervical ganglion (SCG) neurons projecting to purely vascular targets, and those projecting to "mixed" vascular and glandular targets. Adult and postnatal day 5 (P5), P15, P25 male rats were used. The retrograde tracer Fluorogold (FG) was injected into the temporalis muscle or frontal cortex to label SCG neurons projecting to a "purely vascular" target, and into the submandibular gland, to label neurons projecting to a "mixed" end organ. Immunofluorescence was utilized to compare the relative proportions of each population of SCG neurons that contained NPY-li or DYN-A-li.

Analysis of the results showed that nearly all (98.7%) of temporalis projecting neurons contain NPY, most (80.2%) of cerebral blood vessels projecting neurons contain NPY, and few (6.8%) of submandibular projecting neurons contain NPY. In contrast, few (7.8%) and (8.6%) of the temporalis and cerebral blood vessel projecting neurons contain DYN-A, respectively, and most (94%) of submandibular projecting neurons contain DYN. The results were similar at P5, P15, and P25, in that most of the SCG neurons projecting to the cerebral blood vessels and temporalis muscle contained NPY-li but few contained DYN. In addition, significantly fewer of those projecting to the submandibular gland contained NPY-li but most contained DYN. From these data, we conclude that the population of neurons projecting to these target organs are chemically coded by their target tissues because they differ significantly in the percentage of neurons displaying NPY-li or DYN-li in adult. This pattern is present after the fifth postnatal day of development. This work has been supported by a B.U. GSRA to AFE.

SUBSTANCE P (SP) FIBERS OVERLAP CALBINDIN (Cb) CONTAINING NEURONS IN THE RAT SPINAL CORD. G. Battaglia*, C. Colacitti, C. Lizier, A. Princivalle. Neurological Institute "C. Besta", Milano, Italy. A selective anatomical relationship between substance P immunoreactive fibers and Calbindin immunoreactive perikarya was recently demonstrated in the rat thalamus (Battaglia et al., '92). The same methodological approach was employed in the present work to study the distribution of SP and Cb immunoreactivities (SP-ir and Cb-ir) in the rat spinal cord. The distribution of Cb-ir perikarya is similar at different spinal cord levels. Small Cb-ir neurons are densely concentrated in the superficial layers of the dorsal horn. A few large fusiform neurons are evident in lamina I, with proximal dendrites parallel oriented to the white matter border. Large multipolar Cb-ir neurons are evident in the lateral part of lamina V, and in the lateral spinal nucleus. In the ventral horn, large Cb-ir neurons are sparsely distributed in lamina VII and VIII. Small darkly stained Cb-ir neurons, with long proximal dendrites, are located around the groups of motoneurons in lamina IX. Pale stained neurons are present in the intermediolateral cell column (IML). The distribution of SP-ir fibers is very similar to that of Cb-ir perikarya along the extent of the cord, particularly in the superficial laminae of the dorsal horn, in lateral lamina V, and in lamina VIII. The soma and the proximal dendrites of lamina VIII neurons are frequently contacted by SP-ir puncta. SP-ir fibers are moreover concentrated over Cb-ir perikarya in the IML. The present data demonstrate that a selective anatomical relationship between SP-ir fibers and Cb-ir perikarya exists not only in the thalamus, but also in a subpopulation of spinal neurons.

474.9

PROJECTIONS OF HYPOTHALAMIC NEUROPEPTIDE FF-IR NEURONS TO LIMBIC AREAS IN THE RAT BRAIN. A.A. Aarnisalo, L. Kivipelto* and P. Panula. Dept. Anatomy, University of Helsinki, 00170 Helsinki, Dept. Neurosurgery, Univ. Helsinki, and Dept. Biology, Åbo Akademi University, Biocity, 20520 Turku, Finland.

Neuropeptide FF (NPFF), a morphine-modulating neuropeptide, occurs in a prominent group of neurons between the dorsomedial and ventromedial hypothalamic nucleus. One projection of this cell group extends to the solitary tract nucleus, but other projections are unknown. Phaseolus vulgaris-leucoagglutinin (PHA-L) was injected iontophoretically between the dorsomedial and ventromedial nucleus of five rats. After 8-15 days, the rats were perfused with paraformaldehyde and the brains were processed for double immunofluorescence to visualize PHA-L and NPFF. Both markers were seen in the same fibers in the ventral and intermediate part of the lateral septal nucleus, in the medial amygdaloid nucleus and amygdalohippocampal area. No double-stained fibers were seen in the posterior pituitary. The results suggest that NPFF may function in the limbic system, where it is involved in connections between the limbic system and hypothalamus.

474.11

DISTRIBUTION OF PROENKEPHALIN mRNA EXPRESSING CELLS IN THE AVIAN RETINA. M. Molnar, G. Casini, N.C. Brecha and P. Bagnoli*. Dept. of Physiol. & Biochem., Pisa Univ., Italy 56127 and Dept. of Anat. & Cell Biol. Med., UCLA School of Medicine, Los Angeles, CA U.S.A.

Immunohistochemical studies provide evidences for the existence of enkephalin-like substances in the vertebrate retina. Using in situ hybridization technique, we examined the pattern of distribution of proenkephalin (PPE) mRNA containing cells in the retina of pigeons and chickens. Retinal sections, either perpendicular or parallel to the vitreal surface, were hybridized with a riboprobe synthesized from a 600 bp PPE cDNA. PPE mRNA was localized to numerous cells in both chicken and pigeon retinas. The hybridization signal was higher in the chicken although its pattern of distribution was comparable in the two species. A prominent population of PPE mRNA expressing cells was present in the amacrine region of the inner nuclear layer through the entire retina although its density was lower in the peripheral region. The above findings are in agreement with prior immunohistochemical studies and suggest a possible involvement of enkephalin peptides in the processing of the visual information.

474.8

EFFECTS OF INTRACEREBROVENTRICULAR ADMINISTRATION OF BOMBESIN ON LOCAL CEREBRAL GLUCOSE UTILIZATION IN THE RAT. F. Wang, Z. Merali and P. Ramm. Dept. of Biol. Sci., Brock Univ., St. Catharines, ON, Canada, L2S 3A1.

2-[¹⁴C]deoxyglucose (2DG) was used to show regional cerebral functional activity (LCGU) in the rat brain after intracerebroventricular administration of bombesin (BN) (vehicle, 0.1 µg, 0.5 µg). At each dose condition, rats were run freely moving or restrained to determine whether alterations in cerebral function were the direct result of BN influences upon tissue, or were the result of BN-induced motor stereotypy (grooming). The anteroventral thalamic nucleus, ventrolateral part (AVVL), exhibited increased rates of metabolism ($p < 0.01$) under both restraint conditions. Elsewhere in anterior thalamus, we observed increased metabolic rates in some regions in freely moving animals ($p < 0.05$), but not in restrained animals. These effects were observed under both BN dose conditions. In sum, we observed a marked and highly localized alteration in cerebral metabolism within parts of the anterior thalamus. We failed to observe significant alterations in metabolism in any other of the 150 brain regions analyzed. These results suggest that BN exerts major effects on function in some components of anterior thalamus, and that in AVVL, at least, those effects do not reflect the emission of stereotyped motor behaviors. Rather, they reflect a direct influence of BN upon thalamic functioning.

PEPTIDERGIC INNERVATION OF THE RAT CORNEA. M.A. Jones, C.F. Marfurt and S.F. Echtenkamp*. Northwest Center for Medical Education, Indiana University School of Medicine, Gary, IN 46408

The innervation patterns and densities of peptidergic nerve fiber populations within the rat cornea were determined by using an avidin-biotin immunohistochemical procedure and primary antisera directed against the neuropeptides calcitonin gene-related peptide (CGRP), substance P (SP), galanin (GAL), neuropeptide Y (NPY), met-enkephalin (ENK), vasoactive intestinal polypeptide (VIP), somatostatin (SOM), and cholecystokinin (CCK). Immunohistochemical processing was performed on 40 µm thick sections cut tangential to the corneal surface. The distributions of peptidergic fiber populations within each corneal section were plotted onto line drawings using a camera lucida. CGRP-, SP-, and GAL-immunoreactive (-IR) nerve fiber populations were found in abundance within the corneal limbus and cornea proper. NPY-, ENK-, and VIP-IR fibers were less numerous; however, moderate numbers of axons were found in the limbus and small numbers of fibers were consistently observed in the cornea proper. CCK- and SOM-IR corneal nerves were not seen in the present study. The origins of these peptidergic fiber populations were determined by selective ocular denervations. Transection of the ophthalmomaxillary nerve and/or extirpation of the superior cervical ganglion (SCG) revealed that all corneal CGRP- and SP-IR nerves, and most GAL-IR nerves, were sensory. Most VIP- and ENK-IR nerves, and occasional GAL-IR nerves survived the combined sensory and sympathetic denervations and were presumed to be parasympathetic. Following extirpation of the SCG, a small number of NPY-IR fibers were seen only in the limbus; however, after combined sensory and sympathetic denervations many NPY-IR fibers were observed in both the limbus and cornea proper, suggesting upregulation of NPY by parasympathetic nerves. WGA-HRP retrograde tracing experiments demonstrated that a few cells in the ciliary (but not the pterygopalatine) ganglion project to the cornea or corneoscleral limbus. In conclusion, these studies have demonstrated a complex peptidergic innervation of the rat cornea that includes a previously unrecognized parasympathetic contribution from the ciliary ganglion. (PHS EY05717 to C.F.M.)

IMMUNOHISTOCHEMICAL EVIDENCE FOR THE RELEASE OF GABA VIA HYDROLYSIS OF NEURONAL HOMOCAROSINE (GABA-HIS). M.C. Jackson, J.M. Hardman, J.F. Lenney. Depts. of Pharmacology and Pathology, John A. Burns School of Medicine, University of Hawaii, Honolulu, HI 96816

Polyclonal antibodies to GABA-his and human serum carnosinase (HSC) were used to localize immunoreactivity in the cerebellum and other human brain regions. GABA-his was abundant in the cytoplasm of Purkinje cells, whereas HSC was localized in axons entering the folium in the medullary (M) layer, traversing the granule cell (GC) layer and terminating at the interface between the GC and M layers in the vicinity of the Purkinje cells. In other brain regions, HSC and GABA-his were also present in synaptically connected neuronal pathways or were co-localized in the same neuron. For example, HSC and GABA-his were both present in the retina, (rods and cones, ganglionic neurons) and the optic nerve.

Cerebellar and cortical homogenates contained a proteinase-sensitive, heat stable 1.25KD HSC inhibitor. Non-competitive inhibitory activity was abolished by pre-incubation of HSC with 0.8mM Cd²⁺.

These results support the hypothesis that a glutamic acid decarboxylase-independent pathway exists for the release of GABA at synaptic terminals via the hydrolysis of GABA-his by HSC and that the release may be regulated by a peptide inhibitor.

475.1

PROBING THE OPIOID RECEPTOR COMPLEX WITH (+)-TRANS-SUPERFIT: RESOLUTION OF TWO δ_{CX} BINDING SITES. X.Y. Cha¹, H. Xu¹, K.C. Rice^{2*}, C.-H. Kim², and R.B. Rothman¹. ¹NIDA, ARC, NIH, Baltimore, MD 21224 and ²LMC, NIDDK, NIH.

Previous studies support the existence of two δ receptor subtypes called δ_{CX} and δ_{NCX} for δ receptors which are and are not associated with the μ - δ opioid receptor complex. The δ_{CX} site is optimally assayed with [³H]DADL (10 mM TRIS-HCl, pH 7.4, 100 mM NaCl, 3 mM MnCl₂, 2 μ M GTP and 5 mM 2-mercaptoethanol) using membranes depleted of δ_{NCX} sites by pretreatment with the δ_{NCX} -selective acylating agent, (+)-trans-SUPERFIT. The present study examined the effect of a wide range of morphine (MOR) concentrations (0, 12.5, 25, 50, 100, 400, 800 nM) or DPDPE (0, 2, 20, 150, 1000 nM) on the K_d and B_{max} of the δ_{CX} binding sites. The data resolved two binding sites: a δ_{CX1} site where MOR is a potent noncompetitive inhibitor, and a δ_{CX2} site where MOR was a weak competitive inhibitor. In contrast, DPDPE was a weak competitive inhibitor at the δ_{CX1} site, and a potent competitive inhibitor at the δ_{CX2} site. Ligand-selectivity analysis indicated that MOR and DAMGO were relatively selective for the δ_{CX1} site, and DPDPE, DPLPE, DELT-II and [pCl]DPDPE had high affinity and selectivity for the δ_{CX2} site. Studies in progress will address the possibility that these the two δ_{CX} binding sites are two states of a single receptor and also explore the relationship between the δ_{CX2} site and the δ_{NCX} binding sites. Viewed collectively, these studies provide further evidence for heterogeneity of the opioid δ receptor.

475.3

ETONITAZENE PRODUCES POTENT, SUPRASPINALY-MEDIATED ANTINOCICEPTION IN NORMAL AND IN OPIOID- μ_1 DEFICIENT (CXBK) MICE. Charlene D. Connelly, Rebecca P. Martinez, James J. Schupsky and Robert B. Raffa*. Drug Discovery, The R.W. Johnson Pharmaceutical Research Institute, Spring House, PA 19477-0776.

It has recently been reported (Moolten *et al.*, *Life Sci/Pharmacol. Letts.* 52, PL-199-203, 1993) that etonitazene displays selective affinity for opioid μ receptor types. Using specific radioligand binding protocols, these authors demonstrated K_i values (nM) for etonitazene of 0.00042 at μ_1 sites, 0.41 at μ_2 sites, 423.0 at δ sites, 900.0 at κ sites and > 1 μ M at σ sites. These findings make etonitazene one of the most μ -selective compounds. Additionally, the approximately 10-fold greater potency of etonitazene than morphine at the μ_2 site suggests that it might be a valuable pharmacologic tool to investigate the possibility of μ_2 -mediated antinociception. The purpose of the present study was twofold: first, to determine if high *in vitro* affinity would be translated into high *in vivo* antinociceptive potency and, second, to determine if etonitazene could produce antinociception through μ_2 receptors. Male, albino mice (Crl:CD-1[®]), 18-24 g, or CXBK mice were administered etonitazene by *icv* (intracerebroventricular) injection and then antinociception was assessed 15 min later using a standard tail-flick test or 55°C tail-immersion test. Antinociception was quantified by converting tail-withdrawal latency to a percent of the maximum possible effect (%MPE). In the albino mice, etonitazene produced dose-related antinociception in both the tail-flick and tail-immersion tests. Etonitazene-induced antinociception was blocked by naloxone (demonstrating an opioid mechanism) and by β -FNA (demonstrating involvement of μ receptors), but not by ICI-174,864 or naltrindole (demonstrating the lack of involvement of δ receptors). Identical results were obtained in the μ_1 -deficient CXBK mice. These findings demonstrate that etonitazene produces potent, supraspinally-mediated antinociception, possibly through opioid μ_2 receptors.

475.5

SYNTHESIS AND PHARMACOLOGICAL CHARACTERIZATION OF SUBSTITUTED OCTAHYDRONAPHTHOQUINOLIZINES, A NEW CLASS OF LIGANDS FOR THE SIGMA RECEPTOR/BINDING SITE. D.I. Schuster, B. Cai, M. Cornibise, G. Stoupakis and R. B. Murphy, Department of Chemistry and Center for Neural Science, New York University, Washington Square, New York, NY 10003.

We have recently described a method for synthesis of members of a new tetracyclic ring system, the octahydronaphthoquinolizines (OHNQs). (1) These compounds are analogs of 3-PPP and related tricyclic compounds which have high affinity for the sigma receptor/binding site (SRBS). The OHNQs are of particular interest in the elucidation of structure-activity correlations for the SRBS because they exist as eight stereoisomers, comprising four sets of enantiomers. We have now prepared additional members of this family with methoxy, hydroxy, fluoro, chloro and bromo substituents at three different positions on the aromatic ring. Using radioligand binding assays, we find that certain members of this group, particularly those with *trans,trans* ring fusions, have good affinity for the SRBS but are inactive toward dopamine D2 receptors. Some stereoisomers have no demonstrable activity at either of these receptor sites. Several of the sigma-active compounds have been additionally screened for activity at 40 other receptor sites under the NovaScreen program. Of these, activity was found only at the 5-HT2 receptor. Thus, the OHNQs appear to represent a new class of compounds with selective affinity for the SRBS. (Supported by NYU Research Challenge and Technology Transfer Funds)

475.2

DIFFERENTIAL BINDING OF OPIOID PEPTIDES AND OTHER DRUGS TO TWO SUBTYPES OF THE OPIOID δ_{NCX} BINDING SITE IN MOUSE BRAIN. H. Xu^{1*}, J.S. Partilla¹, B.R. de Costa², S.N. Calderon², K.C. Rice² and R.B. Rothman¹. ¹NIDA Addiction Research Center, PO Box 5180, Baltimore MD 21224. ²LMC, NIDDK, NIH, Bethesda, MD 20892.

A variety of data support the hypothesis of a μ - δ opioid receptor complex. This model postulates two classes of δ binding sites: a δ binding site not associated with the opioid receptor complex, termed the δ_{NCX} site, and a δ site associated with the receptor complex, termed the δ_{CX} site. A major purpose of this study was to clarify the relationship between the δ_{NCX} binding sites and the δ_1 and δ_2 receptors. Mouse brain membranes were depleted of μ sites by pretreatment with the site directed acylating agent, BIT, and the δ_{NCX} binding sites were labeled with [³H]DADL. Binding surface and ligand-selectivity analysis resolved two binding sites termed δ_{NCX-1} and δ_{NCX-2} which were not two states of a single receptor. Other studies suggested that neither δ_{NCX} binding site had the characteristics expected of the δ_2 receptor, and that the δ_{NCX-1} site, but not the δ_{NCX-2} site, was synonymous with the δ_1 receptor. The racemic non-peptide δ agonist, BW373U86, had high affinity and selectivity for the δ_{NCX-2} site, suggesting that this site may be a novel δ receptor which mediates some of the effects of BW373U86. Ligand-selectivity studies of resolved enantiomers of BW373U86 are now underway. These data provide additional evidence for heterogeneity of the opioid δ receptor.

475.4

MOLECULAR MODELING OF SIGMA RECEPTOR LIGANDS: DERIVATION OF A MODEL FOR THE BINDING SITE BASED ON CONFORMATIONAL CONSIDERATIONS. B. Cai*, R. B. Murphy and D. I. Schuster, Department of Chemistry and Center for Neural Science, New York University, Washington Square, New York, NY 10003.

The sigma receptor/binding site (SRBS) has attracted considerable interest due to its ability to bind with significant affinity to a variety of psychoactive compounds, including opiates of the benzomorphan type and compounds which show neuroleptic activity and little affinity for dopamine D2 receptor sites. The structural variety of potent SRBS ligands is very great, including haloperidol and other butyrophenones, disubstituted guanidines, phenylpiperidines, 1,2-diaminocyclohexanes, and a new class of tetracyclic ligands recently synthesized in our laboratory, the octahydronaphthoquinolizines. Earlier studies indicated a wide degree of tolerance by the SRBS for stereochemical and topographical demands of the ligands. The present study involved the search for low energy conformation of the major classes of sigma ligands using quenched molecular dynamics (MD) simulations. Structures were constructed using x-ray crystal coordinates or with the aid of the BUILDER module in INSIGHT II. MD simulations were performed using DISCOVER, version 2.9, running on a Silicon Graphics IRIS Crimson Eitan workstation. Integrations used a leap-frog algorithm with a time step of 1.0 femtosecond at constant temperature. The calculations suggest there are two different pharmacophores for the SRBS, or alternatively two sites which may or may not be coupled allosterically. These will be described in detail. 475.6

A STRUCTURE-AFFINITY STUDY OF SIGMA-1 RECEPTOR BINDING. S. Y. Ablordepey[†], J. B. Fischer^{†*}, K. J. Burke Howie[‡], J. A. Dunn[‡], R.A. Glennon[†]. [†]Medical College of VA/VCU, Richmond, VA 23298; [‡]Cambridge Neuroscience, Cambridge, MA 02139.

We have previously characterized sigma subtype binding and demonstrated support for at least 2 sigma receptor binding sites (sigma-1 and sigma-2) in guinea pig brain membranes (*Soc. Neurosci. Abstr.* 1992, 18, 455). To understand the topographical requirements of sigma-1 binding sites, a structure-affinity study of sigma-1 ligand binding was undertaken. Based on these studies, we now report that binding of ligands at sigma-1 sites has considerable similarities to overall sigma binding. For example, increasing the alkyl spacer between the phenyl and N atom of phenylalkyl substituted phenethylamines from 3 to 5 increases binding affinity (K_i = 11 nM, 2.6 nM, and 0.17 nM, respectively), but affinity appears to drop off beyond a pentyl chain. Using 48 sigma-1 ligands (K_i = 0.2 to 4000 nM), a 3D QSAR study was performed using CoMFA. The binding model provides a very high correlation between observed and predicted affinities (r = 0.96, n=48, s = 0.31). To test the predictive validity, the model was used to predict the binding affinities of a newly synthesized series of 17 compounds with widely diverse structures. A plot of predicted versus observed affinities showed a high correlation (r = 0.76, n = 17; r = 0.95, n = 65, s = 0.40). The CoMFA steric contour map also suggests that sigma-1 sites may be quite tolerant of steric bulk.

475.7

IDENTIFICATION OF POTENT AND SELECTIVE SIGMA LIGANDS: DESIGN, SYNTHESIS AND STRUCTURE-ACTIVITY RELATIONSHIP OF PD 128298 REGIOISOMERS. H. Teclé, Y. Pei, J. C. Jaen*, W. H. Moos, L. D. Wise, Y. Shih, T. A. Pugsley, and T. G. Heffner. Parke-Davis Pharmaceutical Research Division of Warner-Lambert Company, 2800 Plymouth Road, Ann Arbor, Michigan 48105

PD 128298 exhibits high affinity ($IC_{50} = 1.55$ nM) and selectivity for the sigma binding sites. It is at least 500 fold selective for sigma binding sites versus various other neurotransmitter receptors. Nevertheless, PD 128298 has appreciable affinity for muscarinic receptors. Consequently, biological results could not unequivocally be attributed to the interaction of PD 128298 with sigma receptors. Structural modification of PD 128298 led to the synthesis of sigma ligands **1** and **2**, analogs of PD 128298 devoid of affinity for muscarinic receptors. Ligands **1** and **2** are regioisomers of PD 128298. These sigma ligands are as potent and selective as PD 128298 in receptor binding assays and possess negligible affinity for the muscarinic receptor.

475.9

THE EFFECTS OF CHRONIC SPINAL ADMINISTRATION OF SELECTIVE OPIOID ANTAGONISTS. B. J. Keck*, J. L. Stafinsky and T. Crisp. Department of Pharmacology, N. E. Ohio Universities College of Medicine, Rootstown, OH, 44272.

Male Sprague-Dawley rats were chronically treated with selective opioid receptor antagonists for 7 days to determine if supersensitivity developed (i.e., enhanced analgesia) following spinal opioid agonist administration. The tail-flick measure was used to determine sensitivity to thermal nociceptive stimuli. Each rat was implanted with an indwelling intrathecal (i.t.) cannula which was later connected to a subcutaneously implanted Alzet osmotic minipump (model 2001). The minipumps continuously delivered the mu antagonist CTOP or the delta antagonist naltrindole (NTI) for 7 days. Following a 24 hour washout period, rats were tested for supersensitivity after receiving an i.t. bolus dose (ED_{50}) of either DAMPGO or DPDPE (i.e. the mu agonist DAMPGO was administered to the chronically treated CTOP rats or the delta agonist DPDPE was administered to the chronically treated NTI rats). Findings revealed that chronic spinal treatment with selective opioid antagonists did not induce supersensitive responses to selective opioid agonists on the tail-flick measure of thermal analgesia.

475.11

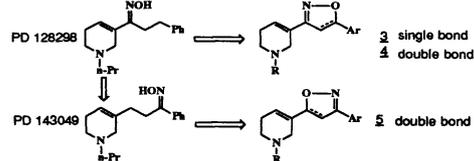

STRUCTURAL DETERMINANTS OF THE 5-HT AND NE UPTAKE INHIBITING ACTIVITY OF OPIOID AGONISTS AND ANTAGONISTS. E. E. Codd* and B. P. Shank. CNS Research, Drug Discovery Research, The R. W. Johnson Pharmaceutical Research Institute, Welsh and McKean Roads, Spring House, PA 19477-0776

Compounds that inhibit the neuronal uptake of norepinephrine and/or serotonin are analgesic in some preclinical pain models and are used clinically in the treatment of certain chronic pain conditions. These compounds also enhance opiate-induced analgesia in an additive or synergistic manner. The results of the present study show that some opioids, in addition to binding to opioid receptors, also inhibit the uptake of norepinephrine and/or serotonin. Structure-activity analysis revealed that phenanthrene opioids that have an oxygen bridge between C4 and C5, such as morphine and naloxone, did not block norepinephrine or serotonin uptake, whereas phenanthrene opioids without the oxygen bridge, such as levorphanol and levomethorphan, did inhibit uptake, as did non-phenanthrene opioids, such as d-propoxyphene and methadone. Thus a clear structure-activity relationship underlies the presence of this additional activity in opioidergics. Since uptake inhibiting activity contributes to the analgesic effect of at least some opioids (such as tramadol), the demonstration of a structure-activity relationship underlying the presence or absence of the activity advances understanding of the analgesic activity of opioid drugs.

475.8

IDENTIFICATION OF POTENT AND SELECTIVE SIGMA LIGANDS: DESIGN, SYNTHESIS AND STRUCTURE-ACTIVITY RELATIONSHIP OF TETRAHYDROPYRIDINYL-ISOXAZOLINES AND -ISOXAZOLES AS CYCLIC ANALOGS OF PD 128298 AND ITS REGIOISOMERS. Yazhong Pei, Haile Teclé, Walter H. Moos, Lawrence D. Wise, Hyacinth Akunne, Thomas A. Pugsley, David A. Downs* and Thomas G. Heffner. Parke-Davis Pharmaceutical Research Division of Warner-Lambert Company, 2800 Plymouth Road, Ann Arbor, Michigan 48105

Tetrahydropyridinylisoxazoline **3** and tetrahydropyridinylisoxazoles **4** and **5** are potent and selective sigma ligands. Many of these ligands exhibit subnanomolar affinity for sigma binding sites. Structure-activity relationship work culminated in the synthesis of PD 144418 (**5**, R=n-propyl and Ar=4-methylphenyl). PD 144418 is a selective sigma ligand. It is at least 1500 fold selective for sigma binding sites labeled with $[^3H]$ -(+)-3PPP ($IC_{50} = 0.067$ nM) when compared with its affinity in other receptor/second messenger assays.

475.10

NERVE GROWTH FACTOR RAPIDLY PROLONGS THE ACTION POTENTIAL OF MATURE SENSORY NEURONS IN CULTURE AND THIS EFFECT REQUIRES ACTIVATION OF EXCITATORY G_s-COUPLED KAPPA OPIOID RECEPTORS ON THESE CELLS. K.-F. Shen and S.M. Crain* Dept. of Neuroscience, Albert Einstein Coll. Med., Bronx, N.Y. 10461

NGF (pM-nM) rapidly prolongs the Ca^{2+} component of the action potential duration (APD) of mouse dorsal-root ganglion (DRG) neurons in long-term organotypic culture. NGF-induced APD prolongation is blocked by pretreatment of the DRG neurons with: 1) monoclonal antibodies to rodent NGF receptors; 2) the opioid receptor antagonist, naloxone and the specific kappa opioid antagonist, nor-binaltorphimine (but not by specific mu and delta opioid antagonists); or 3) cholera toxin. The results suggest that NGF stimulates the release of opioids from DRG neurons and that prolongation occurs secondarily by activation of excitatory G_s-coupled kappa opioid receptors on these same or nearby cells. Extremely low (fM-nM) concentrations of exogenous opioid agonists can elicit similar excitatory effects on these neurons (S&C, Br. Res. '89, '90, '92). These studies suggest that excitatory opioid receptor functions may mediate some types of rapid NGF-induced physiologic effects, e.g. hyperalgesia. (Supported by DA-02031 to SMC.)

476.1

EFFECT OF CHRONIC I.C.V. INFUSION OF ANTI-DYNORPHIN IgG ON OPIOID MU AND DELTA RECEPTORS IN RAT BRAIN: AN AUTORADIOGRAPHIC STUDY. C.B. Goodman¹, M.H. Baumann¹, I.S. Partilla¹, J.L. Cadet¹, K.F.A. Soliman^{2*} and R.B. Rothman¹. ¹CPS, NIDA, ARC, Baltimore, MD 21224, ²Florida A&M University, College of Pharmacy and Pharmaceutical Sciences, Tallahassee, FL 32307.

Several endogenous peptides are known to exhibit anti-opioid activity, including dynorphin, which is an endogenous ligand for the kappa opioid receptor. Preliminary binding studies showed that chronic i.c.v. infusion of anti-Dynorphin A antiserum decreased the Bmax of mu opioid receptors to 68% of control, and that infusion of 1 µg/µl control rabbit IgG did not alter mu receptor binding. The purpose of this study was to determine the effect of chronic i.c.v. infusion of anti-dynorphin A IgG or anti-dynorphin(1-8)-IgG on mu and delta opioid binding sites using the technique of *in vitro* autoradiography. ALZET 2002 osmotic minipumps (0.5 µl/hr for 13 days) were filled with saline, anti-dynorphin A IgG (1 µg/3.75 µl 0.9% NaCl) or anti-dynorphin(1-8) IgG (1 µg/3.75 µl 0.9% NaCl). The solutions were infused via i.c.v. cannula placed in the left lateral ventricle and attached to the osmotic minipumps. The rats were sacrificed on day #13 of the infusion, and prepared for *in vitro* autoradiography. Regional brain sections (20 µm in diameter) at the level of N. Accumbens, Substantia nigra, Thalamus, Hippocampus, and Periaqueductal Gray will be used to assess treatment effects on mu receptors labeled by [125I]DAMGO and delta receptors labeled by [125I]Deltorphin-I. These data will provide pertinent information as to the possible modulatory role of endogenous dynorphin on mu and delta opioid receptors in rat brain.

476.3

REGULATION OF OPIOID RECEPTOR EXPRESSION IN STRIATUM AND VENTRAL MESENCEPHALON DISSOCIATED CELL CULTURES. J.A.M. Smith, S.E. Loughlin*, and F.M. Leslie, Depts. of Pharmacology, Anatomy and Neurobiology, College of Medicine, University of California, Irvine, CA 92717.

Recently, we have demonstrated that *in vivo* striatal opioid receptor expression is under transsynaptic regulation by dopaminergic innervation from the substantia nigra (Smith et al., Neuroscience, in press). To further investigate the factors controlling opioid receptor expression, both individual and combined dissociated cell culture models of striatum and ventral mesencephalon were established. Striata and ventral mesencephali were dissected from rat brains at embryonic days 17 and 15, respectively. Cells were enzymatically and mechanically dissociated and plated in serum-containing media at a concentration of 1.3×10^6 cells/ml. For coculture conditions, equal volumes of striatal and ventral mesencephalic cell suspensions were mixed such that the final plating concentration was 1.3×10^6 cells/ml. At 8 days *in vitro* (DIV), in whole cell preparations of striatal cultures, [³H]diprenorphine bound to a single site with $K_d = 0.35$ nM. Pharmacological studies indicated that this site was naloxone-sensitive, but exhibited low or negligible affinity for kappa or delta agonists. Naloxone-sensitive [³H]diprenorphine binding sites were detected also in ventral mesencephalic cultures. In cocultures of striatum and ventral mesencephalon there was an approximately 3 fold increase in the level of opioid binding sites, as compared to the sum of that in the two individual cultures. This potentiation was apparent at 4 DIV but was most dramatic at 8 and 12 DIV. The pharmacology of the additional sites and the cell type(s) upon which they are expressed have yet to be determined. [³H] Dopamine uptake was not potentiated in the cocultures suggesting that dopaminergic neuronal number/function had not been modulated under these coculture conditions. The precise mechanisms underlying the increase in opioid binding site expression in striatum/ventral mesencephalon cocultures are currently under investigation.

THE EFFECT OF CHRONIC FOOD RESTRICTION ON MU OPIOID RECEPTORS IN THE RAT: A QUANTITATIVE AUTORADIOGRAPHIC STUDY. T.D. Wolinsky*, K. Carr, J.M. Hiller, and E.J. Simon Dept. of Psychiatry, NYU School of Medicine, New York, NY 10016

We have previously shown that chronic food restriction produces opioid facilitation of lateral hypothalamic self-stimulation (*Brain Res* 607: 141-148, 1993). Recently, this effect has been attributed, in part, to mu opioid activity (see Carr et al., this meeting). While binding to opioid receptors has been shown to be modified by food deprivation, the receptor type(s) and brain regions involved in this phenomenon have yet to be defined. We are therefore using quantitative receptor autoradiography to address this issue. Brains from rats that had been on either an *ad lib* or a restricted diet (10 grams per day for 14 days) were sectioned from the level of the prefrontal cortex to the posterior hypothalamus and processed using standard autoradiographic methods. [³H]-DAGO (4 nM) was used to identify mu receptors. Areas analyzed included the cingulate cortex, caudate, nucleus accumbens, bed nucleus of the stria terminalis, ventral pallidum, various regions of the hypothalamus and the habenular complex. Most regions were examined at at least three rostrocaudal levels.

Of the areas sampled thus far, only the habenula appears to be affected by chronic food restriction - with a 17 - 25% decrease in mu opioid binding. The effect on mu binding in other brain regions, as well as on kappa opioid binding is currently being investigated. Supported by NIDA Grant DA-03956 (K.C) and NRSA DA-05441 (T.W.)

476.2

BIOCHEMICAL CHARACTERIZATION OF κ_1 OPIATE BINDING SITES IN R1.1 THYMOMA CELLS G.P. Brown*, K.M. Standifer, and G.W. Pasternak. The Cotzias Laboratory of Neuro-Oncology, Memorial Sloan-Kettering Cancer Center and Depts. of Neurology/Neuroscience and Pharmacology, Cornell University Medical College, NY NY 10021.

κ_1 opiate binding sites have been demonstrated in the mouse thymoma cell line R1.1 (Bidlack et al., *EJP* 227:257, 1992). Binding studies have indicated a single site. The potency of U50,488H (K_i 0.45 ± 0.06 nM) and poor affinity for DAMGO (K_i > 700 nM) and DSLET (K_i > 4 µM) strongly imply a κ_1 classification. We have confirmed the presence of opioid binding sites in this cell line in standard binding assays. Like the prior studies, we find evidence suggesting a single site with a selectivity profile consistent with κ_1 receptors. These sites bind an [¹²⁵I]-opioid affinity ligand synthesized in our laboratory with high affinity (K_D 1 nM). UV irradiation covalently attaches the ligand to the binding site. CHAPS solubilized, photoaffinity labeled R1.1 membranes run over an FPLC Mono-Q anion exchange column reveal a single peak of specific [¹²⁵I]-affinity labelled receptor in the R1.1 cell line which corresponds to a κ_1 opioid receptor.

476.4

EFFECT OF ESTROGEN ON μ -OPIOID RECEPTOR G-PROTEIN COUPLING IN GUINEA-PIG MADIOBASAL HYPOTHALAMUS (MBH). G. Zhang*, T.F. Murray¹ and M.J. Kelly. College of Pharmacy, Oregon State Univ., Corvallis¹ and Dep. of Physiology, Oregon Health Sci. Univ., Portland, OR 97201.

Previous findings have shown that estrogen decreases the potency of μ -agonist Tyr-D-Ala-Gly-MePhe-Gly-ol (DAMGO) mediated hyperpolarization of MBH neurons (Kelly et al., *J. Neurosci.*, 12:2745,1992). The aim of the present study was to explore the effect of estrogen on μ -opioid receptor/G-protein coupling in MBH. MBH were obtained from ovariectomized females treated with oil (n=8) or 17 β -estradiol benzoate (25 µg, s.c., n=8) 24 hr prior to sacrifice. The total membrane particulate fraction was subjected to NaCl (120 mM) + GTP (100 µM) + EDTA pre-incubation conditions prior to use. μ -Opioid receptor competition binding was performed using [³H]diprenorphine as an opioid antagonist radioligand and DAMGO as a competitor in a 50 mM Tris buffer containing 6 mM Mg⁺⁺ either with or without Gpp(NH)p (50 µM). Since we found that μ , δ and κ subtypes all exist in MBH, selective agonists were included in assays to block δ and κ receptors. In control animals, most of the μ receptors were in the high affinity state with an IC_{50} value of 12.0 nM (95%CI:8.8-16.5), and this population of receptors was completely shifted to an intermediate affinity state with an IC_{50} of 56.7 nM (38.0-84.6) by Gpp(NH)p. Similar populations and Gpp(NH)p effects were observed in estrogen-treated animals with IC_{50} and IC_{50} values of 8.9 nM (7.0-11.2) and 40.2 nM (32.9-57.1). Therefore, it appears that under the assay conditions employed estrogen does not attenuate the regulatory action of guanine nucleotide on opioid μ binding (supported by DA05158).

MU, KAPPA, AND DELTA OPIOID RECEPTOR DISTRIBUTION IN THE SONGBIRD HIPPOCAMPUS. P. Deviche* and C.C. Gullledge. Inst. Arctic Biology, Univ. Alaska Fairbanks, Fairbanks, AK 99775.

Previous research has found that the chick and pigeon hippocampal complex (hippocampus: Hp; parahippocampus: AHP) contains regionally located opioid peptide-like immunoreactivity and receptors, but no information on this subject is available for songbirds. We used *in vitro* autoradiography to localize μ , κ and δ opioid receptors in the Hp complex of an adult male songbird (dark-eyed junco, *Junco hyemalis*). Tritiated DAMGO, EKC, and pCl-DPDPE were used to label μ , κ and δ receptors, respectively. Specific binding was measured in the AHP and in the dorsolateral (D), dorso-medial, and ventral Hp divisions. Data show that the AHP contains a high density of all three receptor types. Low κ and high μ receptor densities are found in all Hp regions. Finally, δ receptors are more abundant in the D than in other Hp regions. Thus, each receptor type has a unique neuroanatomical distribution, which differs from that seen in other species. These data suggest that the avian Hp complex is a site where opioids exert physiological, possibly species-specific effects. Supported by NSF Award BNS-9121258.

CHARACTERIZATION AND LOCALIZATION OF DELTA OPIOID BINDING SITES IN THE BOVINE PINEAL. P.S. Pazdalski, W.P. Battisi and V. J. Aloyo*. Dept. of Pharmacology and Anatomy and Neurobiology, Medical College of PA, Philadelphia, PA

Opioid binding sites in the crude membrane fraction of bovine pineal were characterized using the highly selective delta opioid agonist, ^3H -[D-Pen², pCl-Phe⁴, D-Pen⁵]enkephalin (DPDP(CL)E). Pineal membranes possess a single class of high affinity binding sites for this delta ligand ($K_d = 260$ pM). The specific opioid antagonist, naloxone, dose dependently inhibited ^3H -DPDP(CL)E binding confirming that this ligand is indeed binding to opioid receptors. The delta selective ligands deltorphin and [D-Pen², D-Pen⁵]enkephalin(DPDP)E were much more potent than the μ selective compounds dermorphin and [D-Ala², MePhe⁴, Gly⁵-ol]enkephalin (DAMGO) in inhibiting ^3H -DPDP(CL)E binding. These results demonstrate that in bovine pineal membranes, DPDP(CL)E binds to delta opioid sites. Autoradiographic studies showed that ^3H -DPDP(CL)E binding is uniformly distributed over the bovine pineal. Thus, ^3H -DPDP(CL)E binding is a general characteristic of all pinealocytes. This wide spread distribution of delta opioid receptors supports the hypothesis that endogenous opioid peptides modulate pineal function. Supported by MH16841.

HIGH AFFINITY BINDING OF (+)[^3H]-3-(3-HYDROXYPHENYL)-N-(1-PROPYL)PIPERIDINE ((+)-3-PPP) TO DOPAMINE RECEPTORS IN RAT AND BOVINE STRIATA. A.G. Hohmann*, S.L. Patrick, J. Park, and J.M. Walker. Schrier Research Laboratory, Department of Psychology, Brown University, Providence, RI 02912.

Studies of the anatomical and biochemical pharmacology of (+)[^3H]-3-(3-hydroxyphenyl)-N-(1-propyl)piperidine ((+)-3-PPP) have led to the hypothesis that the effects of this ligand are mediated predominantly by binding to sigma receptors. Nonetheless, *in vivo* evidence suggests a role for (+)-3-PPP as a dopamine autoreceptor agonist, despite findings that it only weakly displaces several dopaminergic ligands from their receptors *in vitro*. The present study was undertaken to directly examine whether (+)[^3H]-3-PPP binds to dopamine receptors in membranes from striatum, a structure that exhibits a much greater density of dopamine compared to sigma receptors. Rat and bovine striata were rapidly dissected, homogenized with a polytron and centrifuged at 1000 X g for 10 min. Following centrifugation of the supernatant at 31,000 X g for 15 minutes, the pellet was resuspended in the 10 mM Tris HCl pH 7.4 for binding studies. All assays were performed under sigma receptor binding conditions in the presence of 10 μM 1,3-di-o-tolylguanidine (DTG) to block binding to sigma sites. Nonspecific binding was determined in the presence of 10 μM apomorphine. Scatchard analyses in rat striata revealed a $K_d = 21.0 \pm 6$ and a $B_{\text{max}} = 144.7 \pm 20.7$ for three assays performed in triplicate. Competition curves performed in both rat and bovine revealed a rank order of potency consistent with binding to dopamine D₂ receptors: quinirole was more potent than apomorphine, which was more potent than SCH23390 in inhibiting (+)[^3H]-3-PPP binding. Although the selectivity of (+)-3-PPP for D₂ receptors remains to be determined, the high potency of quinirole ($\text{IC}_{50} = 5.2$ nM in rat striatum) in inhibiting (+)-3-PPP binding is consistent with actions of this sigma ligand at dopamine autoreceptors. (Supported by PHS DA04988 and MH48869).

POSITIVE SELECTION OF LEUKOCYTES EXPRESSING THE KAPPA OPIOID RECEPTOR. D.M.P. Lawrence* and J.M. Bidlack, Dept. of Pharmacology, University of Rochester Medical Center, Rochester, NY 14642.

The R1.1 mouse thymoma cell line expresses a high affinity κ opioid receptor that is negatively coupled to adenylyl cyclase through a pertussis toxin-sensitive G_i protein. To purify cells of the immune system that express opioid receptors, we have developed a method for magnetic separation using an affinity ligand for opioid receptors, 14 β -(bromoacetamido)-7,8-dihydro-N(cyclopropylmethyl)-normorphinone (N-CPM-H₂BAMO). This compound bound with high affinity to the κ receptor on R1.1 cell membranes, as demonstrated by the IC_{50} value of 1.5 nM against the binding of 1 nM [^3H]U69,593. Under sterile conditions, N-CPM-H₂BAMO was covalently attached to iron oxide beads coated with sulfhydryl groups, forming a thioacetamido linkage. Using a bead to cell ratio of 5:1, the N-CPM-H₂BAMO-coupled beads were incubated with either R1.1 cells or a similar T-cell line that does not express opioid receptors. Optimal results were obtained with an incubation time of 30 min at 4°, using RPMI 1640 media with 15% bovine serum albumin to minimize nonspecific binding. After separation with a magnet, 70% of the R1.1 cells were associated with the magnetic beads, while less than 5% of cells from a T-cell line not expressing opioid binding sites bound to the beads. The beads were removed from the selected cells by incubation in media at 37° for 24 hr. We are currently attempting to positively select for cells of the mouse immune system which express the κ opioid receptor, in order to determine the phenotype of those cells as well as to identify the effector functions associated with leukocytic opioid receptors. 476.8

CHARACTERIZATION OF [^3H]4-PHENYL-1-(4-PHENYLBUTYL)-PIPERIDINE BINDING IN RAT BRAIN. K. Hashimoto* and E.D. London†. †Addiction Res. Ctr., NIDA, NIH, Balto., MD 21224; §Dept. Radiology, The Johns Hopkins Med. Inst., Balto., MD 21205; ¶Dept. Pharmacol. & Exper. Ther., Univ. of Maryland Sch. Med., Balto., MD 21201.

4-Phenyl-1-(4-phenylbutyl)piperidine (4-PPBP) is a novel ligand for σ receptors, and has a higher affinity for binding sites labeled with tritiated di-o-tolylguanidine (DTG) than haloperidol (Glennon et al., *J. Med. Chem.* 34: 3360-3365, 1991). We have reported that 4-PPBP is the most potent drug tested in competition assays with [^3H]ifenprodil binding to a subtype of σ receptors (Hashimoto and London, *Eur. J. Pharmacol.* in press, 1993). Ifenprodil, a noncompetitive antagonist of NMDA receptors, has been shown to be cytoprotective in animal models of focal ischemia. Therefore, 4-PPBP also may be active in animal models of brain ischemia. The present study was undertaken to examine specific binding of [^3H]4-PPBP in rat brain membranes. Binding of [^3H]4-PPBP (49.8 Ci/mmol) was examined in 50 mM Tris-HCl buffer (pH 7.4) at 25°C. Nonspecific binding was estimated in the presence of 10 μM haloperidol. [^3H]4-PPBP bound with high affinity to two populations of sites (high affinity $K_d = 79.5$ pM, $B_{\text{max}} = 999$ fmol/mg protein; low affinity $K_d = 5.98$ nM, $B_{\text{max}} = 1826$ fmol/mg protein). The rank order of affinities from competition experiments was: 4-PPBP > haloperidol > ifenprodil > SL 82.0715 > amiodarone > flunaridine > (+)-pentazocine > BMY 14802 > (-)-butaclamol > (-)-pentazocine > DTG > (+)-3-PPP > (-)-3-PPP > rimcazole > (+)-SKF 10,047 > (+)-butaclamol > (-)-SKF 10,047. The regional distribution of [^3H]4-PPBP binding in brain was as follows: medulla oblongata > midbrain > hypothalamus > cortex > cerebellum > hippocampus > striatum. Thus, [^3H]4-PPBP labels haloperidol-sensitive, binding sites, with a regional distribution that is unlike that of σ receptors. As a number of σ receptor ligands interact with these sites, [^3H]4-PPBP may label a novel subtype of σ receptors in rat brain.

14 β -(THIOGLYCOLAMIDO)-7,8-DIHYDRO-N(CYCLOPROPYLMETHYL)-NORMORPHINONE LABELS KAPPA OPIOID RECEPTORS IN THE MOUSE THYMOMA CELL LINE. Q. Jiang* and J.M. Bidlack, Dept. of Pharmacology, Univ. of Rochester, Rochester, NY 14642.

The mouse thymoma cell line R1.1 expresses a brain-type κ opioid receptor with a sulfhydryl group at or near the κ opioid binding site. The present study was directed at labeling the κ opioid receptor in R1.1 cell membranes using the sulfhydryl-containing affinity ligand, 14 β -(thioglycolamido)-7,8-dihydro-N(cyclopropylmethyl)-normorphinone (N-CPM-TAMO). The affinity of N-CPM-TAMO for κ opioid receptors on R1.1 cell membranes was compared to guinea-pig brain membranes. Incubating R1.1 cell or guinea-pig brain membranes with N-CPM-TAMO, followed by extensive washing, produced a concentration-dependent inhibition of the binding of the κ -selective ligand [^3H]U69,593. The concentration of N-CPM-TAMO that resulted in a 50% inhibition of 1 nM [^3H]U69,593 binding was 104 ± 14 and 162 ± 4 nM in R1.1 cell and guinea-pig brain membranes, respectively. The κ opioid ligand, U50,488 but not μ or δ opioids protected the binding site from N-CPM-TAMO alkylation. Incubating membranes with 100 nM N-CPM-TAMO significantly decreased the B_{max} values from 62.2 ± 1.7 to 7.9 ± 3.7 in R1.1 cell and from 62.2 ± 1.7 to 16.8 ± 2.7 fmol/mg of protein in guinea-pig brain membranes, without changing the K_d value for [^3H]U69,593. The wash-resistant inhibition of [^3H]U69,593 binding by N-CPM-TAMO was partially reversed by the addition of the disulfide-bond reducing reagent dithiothreitol. Thus, these results indicate that N-CPM-TAMO irreversibly bound to the κ opioid binding sites in R1.1 cell membranes, as well as in guinea-pig brain membranes, by forming a disulfide bond between the κ binding site and the affinity ligand. (Supported by grant DA04355)

ALKYLATION OF KAPPA OPIOID RECEPTORS ON THE R1.1 THYMOMA CELL LINE BY β -CHLORNALTREXAMINE: EVIDENCE FOR SPARE RECEPTORS. D.B. Joseph* and J.M. Bidlack, Dept. of Pharmacology, Univ. of Rochester, Rochester, NY 14642.

The κ opioid receptor expressed by the murine thymoma cell line R1.1 is coupled through a G_i-protein to adenylyl cyclase. Evidence for downregulation of this receptor was obtained from binding studies, which showed that the B_{max} value for the κ -selective ligand [^3H]U69,593 was reduced in membranes from R1.1 cells cultured for 24 hr with the κ agonist U50,488. Since receptor downregulation is usually accompanied by receptor desensitization, studies were performed to determine if κ -opioid inhibition of forskolin-activated adenylyl cyclase activity was attenuated following chronic exposure of R1.1 cells to U50,488. R1.1 cells were exposed to 100 nM U50,488 for 24 hr, a treatment which produced a 50% reduction of the B_{max} value for [^3H]U69,593. Surprisingly, inhibition of adenylyl cyclase activity by U50,488 was unchanged in membranes from 24 hr-treated cells, compared to control membranes from 15 min-treated cells. To determine if spare receptors were involved in the preservation of the κ -agonist response following downregulation of κ receptors, membranes from 24 hr-treated R1.1 cells were exposed to 50 μM of the irreversible opioid antagonist β -chlornaltrexamine (β -CNA), followed by extensive washing. A complete loss of [^3H]U69,593 binding and of U50,488 inhibition of cAMP production was observed in β -CNA treated membranes, whereas treatment with the reversible antagonist naltrexone had minimal effect on these parameters. The results provide evidence for the presence of spare κ opioid receptors on the R1.1 cell line, which appear to maintain the functional response following receptor downregulation. A NEW ASSAY FOR μ_1 BINDING IN CALF THALAMIC MEMBRANES USING A NOVEL, HIGHLY SELECTIVE DELTA LIGAND. L.M. Visconti, K.M. Standifer, P. Schiller, G.W. Pasternak*. The Cotzias Laboratory of Neuro-Oncology, Memorial Sloan-Kettering Cancer Center, New York, NY 10021 and Lab. of Chemical Biology and Peptide Research, Institut de Recherches Cliniques de Montreal, Canada H2W 1R7

Previously, we reported a selective μ_1 binding assay. At low concentrations ^3H -DADL labels predominantly μ_1 and delta receptors. The assay depends upon the selective blockade of the delta sites, leaving μ_1 binding. Bovine thalamus contains very low concentrations of delta binding sites, enabling DPDPE to lower delta binding to less than 10% of total binding without interfering appreciably with μ_1 binding. However, the assay is not valid in tissues with higher densities of delta receptors since it is not possible to adequately compete delta binding without also interfering with μ_1 binding due to the limited delta/ μ_1 selectivity of DPDPE. TIPP[ψ] (H-Tyr-Tic- ψ -[CH₂NH]Phe-Phe-COOH) is a highly selective delta ligand. In standard binding assays, it competes delta binding with a K_i of approximately 0.2 nM while its K_i values against μ_1 , μ_2 , κ_1 and κ_3 sites are $> 1 \mu\text{M}$, leaving TIPP[ψ] with a delta/ μ_1 selectivity of $> 5,000$, compared to only 25 with DPDPE. We have utilized this highly selective delta ligand to develop a μ_1 binding assay in bovine thalamus which is applicable to other tissues as well.

476.15

δ OPIOID RECEPTOR BINDING IN THREE HUMAN NEUROBLASTOMA CELL LINES. A.M. Babey*, J. Cheng, L. Visconti, K.M. Standifer, J.L. Biedler, and G.W. Pasternak. Cotzias Laboratory of Neuro-Oncology and Laboratory of Cellular & Biochemical Genetics, Memorial Sloan-Kettering Cancer Center and Depts. of Neuroscience and Pharmacology, Cornell University, New York, NY 10021

Advances in the characterization of opioid receptor subtypes have been markedly enhanced by the use of cultured cell lines. Recent progress in the application of molecular biology techniques to the study of opioid receptors has led to the cloning of the murine δ receptor. We would like to report that three human neuroblastoma cell lines, CHP-212, CHP-234 and SMS-KAN, express δ opioid receptor binding. Analysis of total opioid receptor binding, determined using the non-selective ligand ^3H -diprenorphine, revealed K_D values of 0.35 nM, 0.42 nM and 0.52 nM respectively and B_{max} values of 54 fmol/mg, 93 fmol/mg and 120 fmol/mg respectively, compared to δ binding in SH-SY5Y of 26.2 fmol/mg. The δ -selective ligand DPDPE competed well against ^3H -diprenorphine, with K_i values of 3.5 nM, 1.6 nM and 2 nM respectively. Attempts to identify μ , κ_1 and κ_3 binding using selective binding assays (^3H -DAMGO: μ ; ^3H -U69,593: κ_1 ; ^3H -NalBzOH: κ_3) and competition studies against ^3H -diprenorphine failed to demonstrate the presence of μ , κ_1 or κ_3 receptor subtypes.

476.14

κ_3 OPIOID RECEPTORS ARE PRESENT IN SH-SY5Y NEUROBLASTOMA CELLS. Jie Cheng*, Kelly M. Standifer, J.L. Biedler, and Gavril W. Pasternak. Cotzias Lab of Neuro-Oncology and Laboratory of Cellular & Biochemical Genetics, Memorial Sloan-Kettering Cancer Center and Depts. of Neuroscience and Pharmacology, Cornell Univ. Medical College, New York, NY 10021.

The human neuroblastoma cell line, SH-SY5Y, has high levels of both μ and δ opioid receptors. However, the combined B_{max} values for μ and δ receptors constitute only about 60% of the B_{max} of the nonselective antagonist ^3H -diprenorphine. We now report that this remaining 40% of ^3H -diprenorphine binding corresponds to κ_3 receptors. The identity of the κ_3 sites was confirmed by competition studies. The poor affinity of DPDPE and U50,488H at the κ_3 site indicates that the binding was neither δ nor κ_1 . The μ selective ligands DAMGO, morphine and fentanyl compete μ binding 4- to 10-fold more potently than κ_3 binding. In undifferentiated SH-SY5Y cell membranes, the ratio of μ : δ : κ_3 receptor subtypes is 3:3:4. Differentiation with retinoic acid for six days increases the binding of all classes. The levels of μ and δ binding doubled, while κ_3 binding increased 3-fold. All three receptor classes inhibit the accumulation of cAMP. Thus, SH-SY5Y cells contain a binding site with the binding specificity expected of κ_3 receptors. This site is upregulated to a larger degree than either μ or δ sites in the differentiated state, and is functionally active.

476.16

EXPRESSION OF κ_3 AND μ BINDING SITES IN *BUFO MARINUS* (GIANT TOAD) AND *CARASSIUS AURATUS* (GOLDFISH) BRAIN. A.L. Brooks, K.M. Standifer, G.R. Ciszewska*, J. Cheng, and G.W. Pasternak. The Cotzias Laboratory of Neuro-Oncology, Memorial Sloan-Kettering Cancer Center, New York, NY 10021.

Opiate receptor expression in phylogenetically different species has played an important role in the study of opioid receptor pharmacology. Previously it has been reported that *Bufo marinus* brains express a variety of opioid receptor subtypes. We now report that *Bufo marinus* and *Carassius auratus* brains express predominantly κ and some μ opioid binding. Total opioid binding measured with the non-selective ligand ^3H -diprenorphine reveals a B_{max} of 21.7 ± 1.37 fmol/mg protein and a K_D of 0.17 ± 0.03 nM in *Bufo marinus* and a B_{max} of 18.8 ± 0.41 fmol/mg protein and a K_D of 0.47 ± 0.18 nM in *Carassius auratus*. Binding of ^3H -DAMGO (μ) and ^3H -NalBzOH (κ_3) accounted for all of the binding observed with ^3H -diprenorphine. No specific binding of ^3H -U69,593 (κ_1), or ^3H -DPDPE (δ) was seen. In both species, ^3H -NalBzOH binding accounts for 90% of total binding with ^3H -DAMGO binding representing 10%. Competition studies confirm that ^3H -DAMGO is labelling a μ site. The selectivity of ^3H -NalBzOH is similar to previously reported κ_3 site. However, affinity labelled toad binding sites elute differently from a Mono-Q column than κ_3 sites in rat, mouse, or human tissue. While the κ binding in toad and goldfish appear to fall within a κ_3 classification, further studies are being conducted in order to more accurately define these sites.

OPIOIDS: ANATOMY AND PHYSIOLOGY II

477.1

OPIOID ACTIONS ON RAT CINGULATE CORTEX NEURONS E. Tanaka* and R. A. North. Vollum Institute, Oregon Health Sciences University, Portland, OR 07201.

Intracellular recordings were made from layer V pyramidal neurons of rat anterior cingulate cortex in vitro; biocytin labelling was used to identify cell types. [^3H]enkephalin (ME; 30 nM - 30 μM) reversibly inhibited both fast EPSPs and bicuculline-sensitive IPSPs; half-maximal concentration was about 800 nM and 60 nM, respectively. These actions of ME were mimicked by DPDPE but not by DAMGO; they were blocked by naltrindole but not by CTOP. ME did not change the amplitudes of depolarizations evoked by glutamate or hyperpolarizations evoked by muscimol. Fifty percent of pyramidal cells were hyperpolarized by ME (through δ -receptors) and 70% hyperpolarized by ME (through μ -receptors). It is concluded that activation of δ opioid receptors hyperpolarizes some pyramidal neurons in the prefrontal cortex, and also inhibits presynaptically the release of excitatory amino acids and GABA at synapses onto pyramidal neurons. Activation of μ opioid receptors hyperpolarizes nonpyramidal neurons but does not have the presynaptic inhibitory effects.

477.2

MODIFICATION OF MEDIAL PREFRONTAL CORTICAL NEURONAL FIRING IN RESPONSE TO MORPHINE ADMINISTRATION J. L. Giacchino* and S. J. Henriksen. Dept. of Neuropsychology, The Scripps Research Institute, La Jolla, CA 92037.

Studies of the medial prefrontal cortex (mPFC) and its connectivity to the nucleus accumbens suggest the importance of this area in reinforcement and drug-related behaviors in the rat. Compared to data on the effect of psychostimulants, less is understood regarding the mPFC contribution to the opiate reinforcement pathway. To address this issue, electrophysiological characterization of mPFC neurons was performed in twenty-five halothane-anesthetized rats. Morphine (2.5 mg/kg sq and naloxone (5.0 mg/kg sq) were administered after establishment of a 10 min stable baseline firing rate. Response to sq saline injection was also evaluated. In addition to evaluation of change in firing rate, the response to stimulation of the nucleus accumbens was investigated. Neurons encountered in the mPFC typically fired in bursts, with a baseline mean firing rate range of from 1 to 11 pulses/sec. Response to saline and/or drug was calculated as percent of mean baseline firing rate; data was collected over successive five minute epochs following injection. At 15 min post-morphine, there was a significant decrease in mPFC firing rate compared to that of the control period ($p < 0.01$); the response was more marked at 20 min ($p < 0.001$) with 14 of 24 rats having a significant decrease in firing rate at the end of this period. Naloxone appeared to reverse this change, at the end of 25 min, with 13 of 17 rats showing no significant difference in % mean firing rate from baseline. There was not a significant change in firing rate following saline injection. Only four mPFC neurons were found to be driven by stimulation of the nucleus accumbens, one of these cells was not spontaneously active. A relative inhibitory period (200-400 msec) followed stimulation of the nucleus accumbens; this inhibition was not altered by morphine. Preliminary data employing iontophoretic application of DAMGO suggest that mPFC firing rate is decreased by this selective μ agonist. (Supported by ARC grant #AA06420)

DOSE DEPENDENT EFFECTS OF SYSTEMIC MIRFENTANIL, SUFENTANIL, AND MORPHINE ON ANTINOCICEPTION AND CO₂ RESPONSE FUNCTION IN THE DOG. I. Isackson, MS Wallace, TL Yaksh. Dept. of Anesthesiology, Univ. of Calif. at San Diego, San Diego, CA 92093.

Several opioids were administered intravenously (IV) to compare analgesic effects with levels of depression of the CO₂ response. Dogs were prepared with chronic tracheostomies and trained to stand in restraint. Analgesia was measured with skin twitch (SkT) (latency in seconds between placement of a 1cm² probe, heated to 60±0.5°C, and SkT). CO₂ response was measured with a rebreathing study (rebreathing a CO₂ mixture and measuring end-tidal CO₂ and minute ventilation). It was found that IV Morphine (M)(0.02-2.0 mg/kg), Sufentanil (S)(0.03-3.3 ug/kg), and Mirfentanil (Mi)(0.01-3.0 ug/kg) would induce dose dependent increases in SkT response latency and a reduction in the slope of the Ve/CO₂ response curve. The relative potency for increasing SkT response latency was: S>Mi>M, while depression of respiration ordering was: S>M>Mi. Comparison of the slopes of the regression lines (plotting peak respiratory depression versus analgesia) for each agent revealed the ordering to be M>S>Mi, with Mi significantly different from M. Calculation of the ratio of the slopes of the dose response curves (Slope skin twitch/Slope CO₂ response) revealed the ratios to be M 1.1±0.2, S 1.5±0.1, Mi 2.0±0.3. These data suggest that for a given degree of antinociception, there is a smaller decrement in respiratory function for Mi as compared to M and S. The analgesic and respiratory effects of all the drugs were antagonized by IV naloxone, excepting the respiratory effects of Mi. Sponsored by Anaquest and NIH GM45458 (MW).

477.5

DIFFERENTIAL SUPPRESSION OF HIGH AFFINITY CHOLINE UPTAKE BETWEEN THE CORTEX AND AMYGDALA WITH μ , δ and κ OPIOID AGONIST INJECTIONS IN THE VENTRAL PALLIDUM. T.C. Napier*, F. Rehman and L.K. Gorman. Dept Pharmacol, Loyola Univ Chicago, Sch Med, Maywood, IL 60153; and Dept Psychol, Johns Hopkins Univ, Baltimore, MD 21218.

Cholinergic neurons that project to the frontal cortex (fCTX) and amygdala (AMG) are located in the ventral pallidum region of the basal forebrain (VP). Enkephalin- and dynorphin-like immunoreactivity and μ , δ and κ opioid receptor subtypes are located in the VP, and opioid terminals synapse onto VP cholinergic neurons. Microiontophoresis of DAMGO (μ), DPDPE (δ) and U50488H (κ) decrease VP neuronal firing, but many cells are sensitive to only one agonist (Mitrovic and Napier, this meeting). This suggests that VP neurons are differentially regulated by the various opioid receptors. Since VP cholinergic neurons projecting to the cortex are distinct from those projecting to the amygdala, the present study investigated whether these two systems exhibit dissimilar sensitivities to the opioid agonists. Changes in hemicholinium (HC-3) binding, a marker for high affinity choline uptake, was measured in fCTX, AMG, hippocampus and striatal tissue homogenates as an indicator for cholinergic neuronal function. Intra-VP microinjection of opioids were performed in rats previously implanted with guide cannulae, and the cholinergic terminal regions were dissected 30 min post treatment. DAMGO injected in doses known to induce locomotor behaviors (i.e., 33pmoles or 1.0nmole per VP) did not alter HC-3 binding; however, larger doses (33nmoles) decreased fCTX and AMG HC-3 binding by 33% and 39%, respectively. In contrast, DPDPE (10nmoles) and U50488H (33nmoles) decreased only AMG HC-3 binding (46% and 42%, respectively). None of the treatments affected hippocampal or striatal HC-3 binding. These results suggest that particular opioid receptor subtypes may be able to specifically regulate fCTX and AMG cholinergic projections. These data will be discussed in terms of behavioral and electrophysiological functions of VP opioids. Work supported by DA05255 to TCN.

DIRECT EXCITATORY OPIATE ACTION MEDIATED BY POSTSYNAPTIC DEPOLARIZATION ON RAT MEDIAL VESTIBULAR NEURONS. Y. Lin* and D.O. Carpenter. Wadsworth Labs, NYS Dept. Health and School of Public Health, Albany, NY 12201.

Opiates increase firing of rat medial vestibular nucleus (MVN) neurons (*Ann. NY Acad. Sci.* 656: 668, 1992). We have attempted to determine the mechanism of these excitatory opiate actions by extracellular recording of neuronal activity with ionophoretic application of opiate agonists and bath application of antagonists. The spontaneous pacemaker activity of approximately 30% of MVN neurons, scattered throughout the nucleus, was increased by ionophoretic application of either morphine or enkephalin, implicating the presence of both μ and δ receptors. The excitatory responses to both were blocked by the opiate receptor antagonist naloxone. Most previous reports of direct opiate excitation have proven to be due to disinhibition. This is not the case here, since the excitatory opiate response was sustained when GABA receptors were blocked by bicuculline. Even in neurons whose spontaneous firing was almost totally depressed by adenosine, the opiate-induced depolarization was still evident. Perfusion of a 0.1 mM calcium/6.3 mM magnesium solution blocks synaptic transmission, but did not block the excitatory responses to both opiates. This result indicates that the excitation is neither due to disinhibition or a presynaptic opiate action. We conclude that medial vestibular neurons have postsynaptic opiate receptors which mediate a direct depolarization and excitation. Supported by the Aaron Diamond Foundation.

477.4

THE ROLE OF μ , δ and κ OPIOID RECEPTORS IN VENTRAL PALLIDAL NEURONAL ACTIVITY. I. Mitrovic* and T.C. Napier. Dept. of Pharmacology, Loyola University Chicago, Stritch School of Medicine, Maywood, IL 60153.

Enkephalin- and dynorphin-like immunoreactivity and μ , δ and κ opioid receptor subtypes are located in the ventral pallidum region of the basal forebrain (VP). Previous work in our laboratory demonstrated that (1) systemically administered, or (2) iontophoretically applied morphine alters firing rate of single neurons recorded in the VP, and (3) electrical stimulation of the nucleus accumbens, a source of VP enkephalineric inputs, elicits responses that are modified by VP morphine and naloxone iontophoresis. Since these agents do not discriminate among opioid receptor subtypes, an evaluation of subtype-specific agonists was needed to provide a clearer profile of opioid physiology within the VP. Using chloral hydrate anesthetized rats, the present study characterized VP neuronal responses to microiontophoretic applications of DAMGO (μ ; 10mM), DPDPE (δ ; 10mM) and U50488H (κ ; 200mM) to ascertain whether a differential sensitivity occurs. Approximately 57% of the 137 spontaneously firing neurons tested demonstrated a rate change to DAMGO, 38% of 105 were sensitive to U50488H, and 35% of 49 to DPDPE. Rate suppression was observed in 80-97% of the responding neurons. The extent of opioid-induced decreases was correlated with increases in the agonist ejection current, indicative of a "dose"-response relationship. Iontophoresis of CTOP, a μ antagonist (4mM), attenuated DAMGO-induced rate changes and nor-binaltorphimine, a κ antagonist (4mM), attenuated responses to U50488H. Intravenous injections of naloxone (0.1-1mg/kg) blocked DAMGO, but not U50488H. All three agonists were tested on 37 neurons and 70% of the opioid sensitive cells responded to one agonist only. These studies demonstrate, at the level of the single neuron, the functional consequences of activating specific opioid receptor subtypes, and suggest that many VP neurons may receive either dynorphin- or enkephalin-containing inputs, but not both. DIFFERENTIAL NATURE OF DYNORPHIN ACTIONS ON CALCIUM- AND SODIUM-DEPENDENT ACTION POTENTIALS IN CA3 PYRAMIDAL NEURONS OF THE GUINEA PIG HIPPOCAMPUS. Z.J. Aguirre, N.A. Moy, M.R. Luna, M. Huerta* and M.F. Pacheco. Centro Universitario de Investigaciones Biomédicas, Universidad de Colima, Colima, Col. México.

The goal of the present study was to investigate the actions of dynorphin A 1-17 (DYN) on calcium- and sodium-dependent action potentials (APs) in hippocampal CA3 pyramidal cells. Transverse slices from hippocampus of adult guinea pigs were continuously perfused with artificial cerebrospinal fluid (ACF), and intracellular recordings with glass microelectrodes (30-18 M Ω , CsCl 2 M) were performed by means of a switched current-clamp amplifier. Bath-applied DYN (10-100 nM) gradually reduced the amplitude of sodium-dependent APs, elicited by depolarizing pulses (500 msec), and increased the stimulus strength necessary for initiation of the AP; attaining maximum effects 15 to 30 min after the beginning of the peptide application. These actions followed a concentration-response pattern; fully recovered after 30 to 80 min wash; were mimicked by dynorphin A 2-13; and were not prevented by naloxone 1 μ M. Whereas the actions of DYN (10-100 nM) on calcium-dependent APs (recorded in ACF containing 1 μ M TTX) affected the same parameters than for sodium-activated APs; such actions were naloxone-sensitive; and were not replicated by dynorphin A 2-13. These results are indicative that DYN exerts a potent modulation of the membrane excitability on CA3 pyramidal cells of the hippocampus, acting by mechanisms similar to the local anesthetic drugs on TTX-sensitive sodium-dependent APs, and inhibiting cadmium-sensitive calcium-dependent APs. Furthermore, DYN actions on calcium-dependent APs are mediated throughout opioid receptors; whereas the effects of this peptide on sodium-dependent APs are of nonopioid nature. DYNORPHIN ACTIONS ON NMDA-ACTIVATED CURRENTS IN TRIGEMINAL NEURONS -- A SINGLE CHANNEL ANALYSIS. L. Chen* and L.-Y.M. Huang^{1,2} Marine Biomedical Institute¹ and Department of Physiology and Biophysics² The University of Texas Medical Branch, Galveston, Texas, 77555-0843.

Tissue injury or repetitive stimulation of small diameter primary afferent fibers triggers expansion of receptive fields and/or prolonged depolarization of nociceptive neurons in the spinal and medullary dorsal horns. This hypersensitivity of dorsal horn neurons requires the activation of N-methyl-D-aspartate (NMDA) receptors. The expression of dynorphin peptides increases many fold following peripheral injury. Application of dynorphin directly onto the surface of the spinal cord can cause enlargement of receptive fields. These observations have led to the suggestion that dynorphin plays a key role in neuronal plasticity in the nociceptive system. We have studied the effects of dynorphin on NMDA responses in trigeminal neurons (*Neurosci. Abst.* 18:1502, 1992). Unlike μ -opioid receptor agonist DAGO which causes a sustained increase in NMDA-activated currents (Neuron, 7:319-326, 1991), dynorphin was found to reduce NMDA responses. To further understand the mechanism of actions of dynorphin, we now examine the effect of dynorphin on single NMDA channels. The experiments were performed on trigeminal neurons acutely isolated from 9-15 day old rats. The single NMDA-receptor channel currents were measured from outside-out patches using the patch clamp recording technique. In the 14 patches we studied, dynorphin caused a 3-4 fold reduction in the frequency of the channel opening, but had no effect on single channel conductance, or the mean open time of the channel. A detailed kinetic analysis of the dynorphin blockade of NMDA-receptor channels will be presented. Supported by NIH grants NS30045, NS11255 and NS23061.

KAPPA1 OPIOID RECEPTORS ARE EXPRESSED ON PERFORANT PATH TERMINALS IN GUINEA PIG HIPPOCAMPUS. M.L. Simmons*, C.T. Drake, G.W. Terman^Y and C. Chavkin. Depts. of Pharmacology and Anesthesiology^Y, Univ. of Wash., Seattle, WA 98195.

Kappa1 opioid receptors are thought to decrease granule cell excitation by decreasing glutamate release from perforant path terminals. Two additional points support the conclusion that kappa1 receptors are on the presynaptic glutamatergic terminals. First, paired pulse facilitation (PPF) of granule cell population spikes was examined, since manipulations that decrease glutamate release cause an increase in the PPF ratio. The stimulus intensity which produced a half maximal amplitude of the first spike (S1/2) was used, and paired pulses were delivered 20 msec apart. In the presence of 10 μ M bicuculline, the kappa1 agonist U69593 (100 nM) caused a 52% decrease in the amplitude of the first spike. After readjustment of the stimulus intensity to the new S1/2, the PPF ratio was increased 27%, from 1.81 ± 0.11 to 2.30 ± 0.16 ($p < 0.05$, $n=7$). The effect was reversible with washout of U69593 or addition of the kappa antagonist norbinaltorphimine (NorBNI, 100 nM). Second, electrolytic lesions of perforant path cell bodies in the entorhinal cortex resulted in a significant decrease in specific [³H]U69593 binding in the ipsilateral hippocampus compared to the unlesioned side. These results suggest that kappa1 receptors are located on the perforant path terminals, and decrease excitatory transmission by presynaptic inhibition of glutamate release. Supported by NIH grant DA 04123 and a Merck Predoctoral Fellowship.

ENDOGENOUS DYNORPHIN BLOCKS INDUCTION OF LTP IN THE GUINEA PIG HIPPOCAMPAL DENTATE GYRUS G.W. Terman^{1,2}, ML Simmons¹, and C. Chavkin¹. Departments of Pharmacology¹ and Anesthesiology², University of Washington, Seattle, WA 98195.

We have recently reported that in the dentate gyrus both exogenous kappa opioids and endogenous dynorphin released by hilar electrical stimulation of granule cell axons can inhibit excitatory neurotransmission and long-term potentiation (LTP) at the perforant path/granule cell synapse. The present studies investigated whether the LTP inhibitory effects of dynorphin were primarily due to effects on LTP induction, maintenance or expression. Stimulating electrodes were placed in both the hilus and the perforant path of hippocampal slices and a recording electrode was placed in the granule cell layer. Long term potentiation was defined as the % increase from baseline population response seen 30 min after stimulation of the perforant path (PPHFS) with a 20 ms train of 100 Hz 300 μ A 0.3 μ s pulses given 3 times at 10 sec intervals. LTP seen in control slices (38%, $n=6$) could be blocked by 6, 1 sec 50 Hz trains of 300 μ A 0.3 μ s pulses given at 10 sec intervals to the hilus immediately before PPHFS (0.2%, $n=6$). This inhibition was blocked by 100 nM of the kappa1 opioid receptor antagonist, norbinaltorphimine (30%, $n=6$) and if the hilar stimulation was given immediately after, instead of immediately before, PPHFS (31%, $n=6$). Thus kappa opioids inhibit LTP primarily by interfering with mechanisms of induction - probably via presynaptic inhibition of glutamate release. DPLPE, a delta selective opiate agonist, also inhibited excitatory neurotransmission but failed to block LTP ($n=6$). Supported by DA04123 and the Foundation for Anesthesia Education and Research with a grant from Abbott Laboratories.

CHRONIC TREATMENT WITH MORPHINE IS ASSOCIATED WITH NON-SPECIFIC REDUCTIONS IN RESPONSIVENESS OF NUCLEUS TRACTUS SOLITARIUS NEURONS (nTS) IN VITRO. C.J. Malanga, W.W. Fleming, C.R. Craig* and D.A. Taylor. Dept. Pharmacol. and Toxicol., WVU Hlth. Sci. Ctr., P.O. Box 9223, Morgantown, WV 26506-9223.

Chronic treatment with morphine leads to the development of nonspecific subsensitivity in guinea-pig myenteric S neurons. To determine whether a similar nonspecific reduction in responsiveness occurs in a guinea-pig CNS preparation, the effect of chronic treatment with morphine on the sensitivity of nTS neurons to pharmacologically unrelated inhibitory agonists was studied using extracellular recording techniques to record spontaneous neuronal activity in an *in vitro* brainstem slice preparation. Muscimol (MUS), morphine (MOR) and 2-chloroadenosine (CAD) were applied by superfusion and changes in frequency of firing compared using interspike interval histogram analysis. Concentration-response curves were generated and EC20 or EC50 values determined by interpolation. MOR and CAD produced both excitation and inhibition of nTS neurons; furthermore, neither MOR nor CAD achieved greater than 60% inhibition of neuronal activity. MUS consistently produced inhibitions with near maximal (100%) responses. In preparations obtained from animals chronically treated with morphine, the responsiveness of nTS neurons to MOR was reduced approximately 2.5 fold at the level of the EC20 compared to naive controls. Similarly, the responsiveness to CAD was also reduced by 5.2 fold at the EC20. Neither of these reductions were statistically significant. However, the geometric mean EC50 for MUS was significantly reduced 5.2 fold in neurons from animals chronically treated with morphine. These data suggest that 1) the *in vitro* guinea-pig nTS preparation can serve as a model CNS system for the study of opioid tolerance, and 2) that the development of opioid tolerance in the nTS is nonspecific among pharmacologically dissimilar agonists and, therefore, appears similar to tolerance in the myenteric plexus. DYNORPHIN LOCALIZATION AND EFFECTS IN GUINEA PIG DENTATE GYRUS MOLECULAR LAYER CT Drake¹, GW Terman^{1,2}, DD Kunkel³, TA Milner⁴, PA Schwartzkroin³ and C Chavkin¹. Depts of ¹Pharmacol., ²Anesthesiol., ³Neurosurg., Univ. of Washington, Seattle WA 98195 and ⁴Dept of Neurol. & Neurosci., Cornell Univ. Medical College, New York, NY 10021.

In the guinea pig hippocampal slice preparation, endogenous dynorphin release stimulated by antidromic activation of dentate granule cells significantly depressed the extracellularly recorded population spike amplitude within 30 seconds of dynorphin release. These effects were completely blocked by 1 μ M naloxone or 100 nM norbinaltorphimine, suggesting that the response was mediated by kappa1 opioid receptors. The rapid onset of effect indicated that dynorphin may have been released from a local source within the dentate molecular layer. Thus the distribution of dynorphin A(1-8) and dynorphin B(1-13) immunoreactivity (dyn-LI) in this region was examined with light and electron microscopy. In sections corresponding to those used for physiological studies, light microscopy revealed light dyn-LI distributed in a few scattered processes. Electron microscopic analysis revealed that dyn-LI was localized over dense-core vesicles in axons and spiny dendrites throughout the molecular layer. Significantly more molecular layer dyn-LI dense-core vesicles were observed in dendrites than in axons (74% vs 26% of 178). These results suggest that the granule cell dendrites may be a source of the endogenous dynorphin which acts to regulate excitatory perforant path inputs to the hippocampus, thus counteracting excitation-induced phenomena such as long-term potentiation. Supported by DA04123, GM07604, NS18895, DA08259.

EXOGENOUSLY APPLIED AND ENDOGENOUSLY RELEASED OPIOIDS DECREASE SPONTANEOUS INHIBITORY CURRENTS IN GRANULE CELLS OF THE RAT DENTATE GYRUS. S.B. Bausch and C. Chavkin*. Dept. of Pharmacology, University of Washington, Seattle, WA. 98195.

Pharmacological studies have shown that exogenous application of opioids regulate excitability in the rat dentate gyrus. Moreover, Bramham, et al. (1991) and Xie and Lewis (1991) have shown that endogenous opioids regulate LTP induction in this same region; however, the mechanism of the endogenous opioid effect is not known. To further define opioid actions on excitability, we investigated the effects of exogenous application of the μ and δ agonists DAMGO and DPDPE, as well as the effects of endogenously released opioids on spontaneous synaptic activity in dentate granule cells using the whole-cell voltage clamp technique. Bath application of DAMGO or DPDPE reduced bicuculline-sensitive sIPSCs, but did not change the input conductance of dentate granule cells. The reduction in sIPSCs could be reversed by the opioid antagonist naloxone. High frequency stimulation, using a paradigm previously shown to release endogenous opioids from the perforant path also decreased sIPSCs. The mechanism mediating the reduction in sIPSCs following high frequency stimulation is still under investigation. Thus, exogenously applied, and possibly endogenously released opioids acted to modulate the activity of GABAergic neurons as shown by a decrease in amplitude and frequency of sIPSCs. Supported by DA04123 and GM07750.

CHOLECYSTOKININ (CCK) INHIBITS MORPHINE-INDUCED EXCITATION OF PYRAMIDAL NEURONS IN THE CA1 REGION OF THE RAT HIPPOCAMPAL SLICE. Karen K. Miller* and Carl R. Lupica. Dept. of Pharmacology, Univ. Colorado Health Sciences Center, Denver, Colorado 80262

Opioids have an excitatory effect on pyramidal neurons in the hippocampus, due to the inhibition of GABA release from interneurons. This opioid-induced excitation of CA1 pyramidal cells is manifest using extracellular recording as an increase in population spike amplitudes. Opioid effects in other areas of the CNS, such as the spinal cord, have been shown to be inhibited by the neuropeptide cholecystokinin (CCK) (Faris et al., *Science*, 219:310-312, 1983). CCK is also found in high levels in the hippocampus, and several studies have reported conflicting effects of CCK in this brain region (MacVicar et al., *Brain Research*, 406:130-135, 1987; Jaffe et al., *Brain Research*, 415:197-203, 1987), but none have examined the interaction between CCK and opioids. In the present study, we tested the hypothesis that, as in the spinal cord, CCK could antagonize the actions of morphine in the CA1 region of the hippocampus. Dose dependent increases in population spike amplitudes were observed during bath application of morphine (1-500 μ M). The sulfated form of the CCK octapeptide (CCK-8s) (1 μ M) significantly blocked the population spike increases seen at all concentrations of morphine, through a non-competitive interaction. The antagonism of the morphine-induced excitation could be reversed upon washout of CCK-8s, or by co-administration of CCK-8s and the CCK_B receptor antagonist PD-135,158 (1.5 μ M). Neither PD-135,158 nor CCK-8s significantly affected baseline population spikes, in contrast to previous reports that CCK-8s directly affects extracellular hippocampal responses. The results of this study demonstrate that CCK-8s antagonizes the effects of morphine in the hippocampus through actions at a CCK_B receptor and suggest that CCK may function as an endogenous opiate antagonist in the brain as well as in the spinal cord. Supported by NIDA grant DA 07725 (C.R.L.).

MU AND DELTA OPIOID MODULATION OF EXCITATION AND MINIATURE GABA-MEDIATED IPSCs IN THE CA1 REGION OF THE RAT HIPPOCAMPUS. Carl R. Lupica*, and Karen K. Miller, Dept. Pharmacology, Univ. Colorado Sch. Med., Denver, CO, 80262.

Opioid peptides indirectly increase the excitability of hippocampal CA1 pyramidal cells through the inhibition of GABA release from interneurons. However, examination of μ or δ receptor selective enkephalin actions has revealed that while both receptors increased pyramidal neuron excitability (i.e. population spikes and EPSPs), GABA-mediated IPSPs evoked by moderate intensity stimulation of stratum radiatum were decreased only by μ agonists. In addition, both μ and δ opioid receptor activation significantly reduced spontaneous, action potential-dependent IPSPs (Lupica and Dunwiddie, *Synapse*, 8:237, 1991; Lupica et al., *Brain Research*, 593:226, 1992). One hypothesis to account for these differences is that μ agonists modulate interneuron GABA release directly by a nerve terminal action, while δ agonists inhibit GABA release indirectly via hyperpolarization of the interneuron soma (by activating a K^+ channel). This hypothesis was tested by examining the effects of the enkephalin agonists DAGO (μ) and DPDPE (δ) on population spikes during application of the K^+ channel blocker BaCl, and by examining the actions of these peptides on miniature, TTX-insensitive spontaneous inhibitory postsynaptic currents (mIPSCs), recorded from pyramidal neurons. The dose-dependent increase of population spikes caused by DPDPE ($EC_{50} = 6nM$) was blocked by pretreatment with BaCl (500 μ M), while the effect of DAGO ($EC_{50} = 43nM$) was unaltered. In contrast to the differential effect of BaCl on μ - and δ -mediated population spike increases, both DAGO and DPDPE reduced the mIPSC frequency (55% and 57% of control, respectively) without affecting mIPSC amplitude distributions. These results suggest that both μ and δ agonists can act directly at interneuron nerve terminals to decrease GABA release, and that δ , but not μ , receptors utilize a BaCl-sensitive mechanism to increase excitability in CA1. Supported by NIDA grant DA 07725 (C.R.L.).

SPINAL ANTINOCICEPTION INDUCED BY THE SELECTIVE μ -OPIOID AGONIST TYR-D-ARG²-PHE-SAR (TAPS)

J. H. Millison, S. Vonhof* and A-L. Sirén, Dept. of Neurology, Uniformed Services University of the Health Sciences, Bethesda, MD 20814.

Our previous studies have suggested that Tyr-D-Arg²-Phe-Sar (TAPS), is a full μ_1 -opioid agonist whereas it may act as a partial μ_2 -opioid agonist. Intracerebroventricular (ICV) administration of TAPS at picomole doses induced respiratory stimulation, analgesia and catalepsy which were blocked by the μ_1 -antagonist, naloxonazine (NAZ) (Paakkari P., et al., *J. Pharm. Exp. Ther.*, in press). In the present study the antinociceptive and cataleptic properties of TAPS were examined after intrathecal (I.T.) administration in male Sprague-Dawley rats (275g-350g, n=31). An I.T. catheter (PE-10) was inserted into the lumbar subarachnoid space and a catheter was implanted into the right jugular vein 48 h prior to the experiment. Antinociception was measured by the radiant heat tail-flick latency method. TAPS (10, 20, 30 and 100 pmol/10 μ l, I.T.) produced dose-dependent antinociception. The maximum antinociception after each dose was reached within 30 min. After the 100 pmol dose, the antinociceptive effect was observed for 3 h after administration. The calculated ED_{50} for the I.T. antinociception was 20 pmol (95% confidence limits of: 16-25 pmol). TAPS, I.T. did not produce catalepsy. The antinociception induced by TAPS (30 pmol, I.T.) was inhibited by naloxone (5 mg/kg, i.v.) whereas NAZ (10 mg/kg, i.v., 24 h before TAPS) did not block this effect. The data suggest that, in contrast to its supraspinal (ICV) effects, the antinociceptive effect of TAPS in the spinal cord does not involve activation of μ_1 -opioid receptors.

QX-314 BLOCKS THE POTASSIUM COMPONENT OF THE OPIOID-INDUCED OUTWARD CURRENT AND SPARES THE CATIONIC COMPONENT IN LOCUS COERULEUS (LC) NEURONS

M. Alreja* and G.K. Aghajanian, Depts. of Psychiatry and Pharmacology, Yale University School of Medicine, New Haven, CT 06508.

We recently reported that opiates hyperpolarize LC neurons by simultaneously opening K^+ channels and closing a resting Na^+ -dependent cationic conductance, resulting in a reversal potential more negative than E_K . The K^+ component is partially blocked by external Ba^{2+} , and the cationic component is abolished by Na^+ substitution in the perfusate. We have now tested the effect of QX-314, which blocks G-protein-gated K^+ channels (Andrade, 1991), on the opiate response in LC neurons.

The effect of bath-applied met-enkephalin (200 μ M) was studied in rat LC neurons under voltage clamp using intracellular electrodes filled with 2M KCl alone or with 50 mM QX-314. In cells impaled with QX-314 electrodes, the enkephalin-induced outward current was reduced and parallel or divergent *i-v* curves were obtained in the -60 to -120 mV range, suggesting lack of a significant K^+ component. Furthermore, the QX-314-resistant current was virtually abolished following 80% substitution of Na^+ in the perfusate with TRIS, suggesting that the opiate current in QX-314 loaded cells is dependent almost entirely on external Na^+ . Consistent with the presence of a cationic component, we have also found that the opiate current in LC neurons reverses not only in the hyperpolarizing but also in the depolarizing direction (\sim -20 mV).

We conclude that QX-314 blocks K^+ channels but spares the cationic component of the opiate current in LC neurons.

HIGH-DOSE NARCOTICS CAUSE SEIZURES AND LIMBIC BRAIN DAMAGE IN VENTILATED RATS. WA Kofke*, RH Garman, R Garman, M Rose, Depts. of Anes/CCM & Path, Univ. of Pitt., Pittsburgh, PA

High dose alfentanil (A), in rats causes hypermetabolism seizure, and limbic system (LS) damage. We determined if A, sufentanil (S), and fentanyl (F), are neurotoxic. **Methods:** After animal Use Committee approval fed male SD rats, 300-450 gm, were anesthetized with halothane (halo) in O_2/N_2O 30/70, intubated and ventilated. After arterial/venous cannulation halo was stopped with O_2/N_2O 30/70 continued. Pancuronium was given. Temp was 38°C. At 60 m of no halo, opioid (with O_2/N_2 30/70) infusion was started. There were 2 opioid dosage groups (Hi, Lo) and 4 opioid drug groups (control (C), A, S, F). Half of the hi and all of the lo rats received hexamethonium (hex) iv 20 mg/kg then 40-120 mg/kg/hr. Opioid was infused for 2 h followed by extubation & then overnight in a cage. Each rat 18 h later underwent *in vivo* cerebral perfusion fixation followed by examination for pathology injury and grading from 0 (normal) to 4. **Results:** MAP was lower in hex-treated rats (145±3 vs 107±2 p < .0001). No C's sustained LS damage. LS lesions occurred in 4 A, 5 F, and 6 S treated rats. Hi dose opioid was associated with LS damage (p = .009). **Discussion:** All 3 clinically used fentanyl congeners cause LS damage in rats.

OPIOIDS: ANATOMY AND PHYSIOLOGY III

478.1

PREJUNCTIONAL INHIBITION OF VAGAL HEART RATE RESPONSE BY MET-ENKEPHALIN-ARG-PHE (MEAP). B.A. Barron*, Z. Mateo, J.F. Gaugl, J.L. Caffrey, Dept of Physiology, Texas College of Osteopathic Medicine, Ft Worth, TX 76107.

We have identified proenkephalin-immunoreactive fragments in canine myocardium with an antibody directed against the C-terminal MEAP of proenkephalin. Ventricular MEAP-activity (104 fmol/mg protein) is 30 X greater than met-enkephalin (ME, 3.8 fmol/mg protein) and is 5 X higher than in atria (17.6 fmol/mg protein). Histochemical analysis of the heart with this MEAP antibody reveals immunoreactivity concentrated around the intercalated discs. Dogs were pretreated with atenolol (81 adrenergic blocker) and the right vagus was stimulated (0.5-4 Hz) producing a 10-50 bpm decrease in heart rate. Infusion of MEAP (30-3000 pmol/kg/min) reduced the vagal response by 60%. The ED_{50} for MEAP (300 pmol/kg/min) corresponds to an EC_{50} of approximately 3 nM. The ED_{50} for ME was 3 X higher (900 pmol/min/kg). Both enkephalin effects were prevented by the opioid antagonist diprenorphine (100 μ g/kg). The experiments were repeated with the infusion of methacholine (muscarinic agonist) to examine the possibility that MEAP exerted its effect postjunctionally at the SA node. MEAP did not inhibit the decrease in heart rate caused by methacholine infusion. These data suggest that local enkephalins inhibit vagal stimulation at either cardiac parasympathetic ganglia sites or presynaptically in the SA node by inhibiting ACh release.

MICROINJECTION OF NANOGRAM AMOUNTS OF MORPHINE INTO THE CAUDAL SUBRETROFACIAL AREA (CSRFA) OF THE VENTROLATERAL MEDULLA CAUSES APNEA. S.M. Magee, R.A. Gillis and A.M. Taveira-DaSilva*, Departments of Medicine and Pharmacology, Georgetown University, Washington, DC., 20007.

Opioids produce respiratory depression because of an interaction with receptors located in the region of the ventrolateral medulla (*J. Clin. Invest.* 72:1209, 1983). However, the precise location of this site(s) has not been determined. A novel potential site of action for the respiratory depressant effects of opioids is a recently described area in the cat's medulla oblongata where bilateral microinjection of a non-specific universal excitatory amino acid antagonist causes apnea (*J. Pharmacol. Exp. Ther.* 259:1388, 1991). Amino acid transmission at this site, named caudal subretrofacial area (CSRFA), is required for breathing to occur. The purpose of this research was to determine whether bilateral microinjection of nanogram amounts of morphine into the CSRFA caused respiratory depression. Morphine (4, 50 and 100 ng/40 μ l) microinjected bilaterally into the CSRFA (7.6 mm caudal to foramen cecum; 4 mm lateral to midline; 1.5 mm below surface) of 17 chloralose-anesthetized cats while monitoring minute ventilation, tidal volume (V_t), respiratory rate (f), end-tidal CO_2 ($FECO_2$), heart rate and blood pressure, produced apnea and a disordered breathing pattern in 16 animals. Apnea was observed 20 ± 6 minutes after administration of the 100 ng dose and this effect was preceded by a significant decrease in V_t (-13 ± 1 ml $P < 0.05$) and an increase in $FECO_2$ ($+1.3 \pm 0.2\%$, $P < 0.05$) and f ($+16 \pm 3$ breaths/min, $P < 0.05$). A significant decrease in V_t was also observed after the 4 ng (-15 ± 5 ml, $P < 0.05$) and the 50 ng (-9 ± 2 ml, $P < 0.095$) doses of morphine. We conclude that the CSRFA is an important site of action for the respiratory depressant effects of opioids.

478.3

INHIBITION OF β -ENDORPHIN-1-31-INDUCED HYPOTENSION BY GLYCYL-L-GLUTAMINE. C.B. Unal, M.D. Owen-Kumer and W.R. Millington. Division of Molecular Biology & Biochemistry, and Department of Anesthesiology, University of Missouri-Kansas City, MO 64108.

β -endorphin-1-31 is post-translationally processed to β -endorphin-1-27 and glycyl-L-glutamine (Gly-L-Gln; β -endorphin-30-31) in the pituitary and certain brain regions, including brainstem nuclei involved in cardiovascular homeostasis. Like β -endorphin-1-31, β -endorphin-1-27 lowers blood pressure and heart rate when centrally injected, but the cardiovascular effects of Gly-L-Gln have not been investigated. The present study was undertaken to determine whether Gly-L-Gln modulates β -endorphin-1-31 induced hypotension and bradycardia.

β -endorphin-1-31 was administered intracerebroventricularly to pentobarbital anesthetized rats followed 15 min thereafter by either saline or Gly-L-Gln; mean arterial pressure (MAP) and heart rate were measured through a carotid artery catheter. β -endorphin-1-31 (0.5 nmol/10 μ l) lowered MAP (42.3 ± 6.2 mm Hg) and heart rate (154.0 ± 13.7 beats/min) within 60 min. Gly-L-Gln (0.3, 0.6, 1.0, and 10.0 nmol) inhibited β -endorphin-1-31-induced hypotension, but not bradycardia, in a dose dependent manner; 1.0 and 10.0 nmol completely blocked the response. Co-injection of equimolar amounts of L-glycine and L-glutamine produced no effect indicating that Gly-L-Gln's inhibitory activity was not due to hydrolysis. α -N-acetyl-Gly-L-Gln also inhibited β -endorphin-1-31-induced hypotension but Gly-D-Gln was ineffective, suggesting that the response was stereospecific. Gly-L-Gln injection alone at doses as high as 100 nmol produced no hemodynamic variation from baseline. Receptor binding studies demonstrated that Gly-L-Gln did not displace [3 H]naloxone binding to rat brain homogenates at concentrations of up to 10 μ M. These data indicate that the effects of Gly-L-Gln are not mediated by either glycine or opioid receptors but suggest that Gly-L-Gln acts through a stereospecific binding site to inhibit the central hypotensive effects of β -endorphin-1-31. Supported by USAMRDC DAMD17-90-Z-0022

NEUROTENSIN (NT) RELEASE FROM THE PERIAQUEDUCTAL GRAY (PAG) AND PREOPTIC ANTERIOR HYPOTHALAMUS (POAH) OF THE RAT: EFFECTS OF THE SELECTIVE μ AND κ OPIOID RECEPTOR AGONISTS. L. Xin*, E. B. Geller and M. W. Adler. Dept. of Pharmacology, Temple University School of Medicine, Philadelphia, PA 19140

It has been presumed that there is a functional interaction between opioids and some neuropeptides in their effects on body temperature (Tb) or antinociception. We have reported that opioid receptor agonists decreased substance P release from the PAG caused by noxious cold. In the present study, we investigated the effects of selective opioid agonists on the release of neurotensin (NT) from different brain regions. Artificial cerebrospinal fluid was microdialyzed through a probe located in the PAG or POAH of S-D rats for 3 hours. Samples were collected every 20 min. NT-like immunoreactivity in the samples was measured by RIA. After a 60-min baseline collection period, the selective μ opioid receptor agonist PL017 (1.2 μ g), κ receptor agonist dynorphin (Dyn, 5 μ g), KCl (150 mM) or vehicle was microinjected into the regions where microdialysis probes were located. In the PAG, NT release was increased by 120% and 150% over baseline after PL017 and Dyn injection, respectively. In the POAH, NT release was increased by 210% and 120% above baseline after PL017 and Dyn injection, respectively. KCl produced a NT increase of 260% and 406% in the POAH and PAG, respectively. Microdialysis of NT (3 μ g/ μ l) into the PAG for 1 hour produced 65% maximum possible analgesia in the cold water tail-flick test, which was not antagonized by the pretreatment of naloxone. There was no significant change in Tb. However, NT microdialyzed into POAH induced hyperthermia (Δ Tb: -1.44 ± 0.12 °C). These data indicate that the activation of opioid receptors within the POAH or PAG can increase NT release in these areas and that NT is involved in the effects of opioids on analgesia and Tb regulation. ESTROGEN'S RAPID MODULATION OF μ -OPIOID POTENCY IN GUINEA PIG HYPOTHALAMIC ARCULATE NEURONS. A.H. Lagrange, O.K. Rönnekleiv, J.A. Resko* and M.J. Kelly. Department of Physiology, Oregon Health Sci. Univ., Portland, OR 97201-3098.

As a regulator of the hypothalamic-pituitary-gonadal axis, β -endorphin neurons are a site of 17β -estradiol (E_2) feedback action. We used intracellular electrophysiologic recording in *in vitro* hypothalamic slices taken from ovariectomized guinea pigs to show the direct and unusually rapid actions of E_2 to alter the response to μ -opioids. Cumulative dose-response curves (D/R) were made by measuring the hyperpolarization in response to increasing concentrations of the μ -opioid selective agonist, DAMGO. After washout of DAMGO and superfusion with 100nM E_2 for 20 minutes, a second DAMGO D/R was done. The EC_{50} shifted from 64 ± 4 nM (n=30) before E_2 to 239 ± 9 nM after E_2 (n=13, p<0.001). E_2 had no effect on the maximal hyperpolarization, RMP, τ , or the resting voltage/current relationships of these cells. There was also no change in the size of the DAMGO-induced conductance increase or the reversal potential of the current (-92mV). This E_2 effect is not homologous desensitization to DAMGO, as it is seen following E_2 in cells that have not been exposed to DAMGO previously. 17α -estradiol did not alter DAMGO potency (n=3), including a cell that subsequently responded to 17β - E_2 . In contrast, 10 μ M forskolin did decrease the potency of DAMGO, with an EC_{50} of 138nM \pm 13 (n=3). A subset of the E_2 -responsive cells were histochemically double-labelled as β -endorphin neurons (n=3). Estrogen's effects on the potency of β -endorphin autoreceptors could have profound consequences for the opioidergic modulation of forebrain function as well as the reproductive axis. HYPOTHERMIC EFFECT OF HIGH-DOSE CENTRALLY ADMINISTERED μ -OPIOID AGONISTS: SENSITIVITY TO NALOXONE. D. Mondock, J.U. Adams*, E.B. Geller and M.W. Adler. Department of Pharmacology, Temple University School of Medicine, Philadelphia, PA 19140.

Centrally administered μ -opioid agonists, at analgesic doses, induce dose-related increases in core body (rectal) temperature (Tb) in rats. However, with 10-fold greater doses of the highly selective μ agonists, [D-Ala², NMe-Phe⁴, Gly⁵-ol]enkephalin (DAMGO) and [NMePhe³, D-Pro⁴]morphine (PL017), hypothermia is the primary result. For example, with 6.25 μ g icv DAMGO, Tb decreased by 1.19 (\pm 0.58) °C. 45 min post-injection and returned to baseline within 2 hr. The same dose of PL017 induced a 0.56 (\pm 0.25) °C decrease in Tb at 30 min, then a 0.44 (\pm 0.38) °C increase above baseline Tb at 90 min. Is the hypothermic effect of these high doses mediated by opioid receptors, or are nonspecific or compensatory mechanisms involved? To test for opioid specificity, the competitive opioid antagonist naloxone (NLX; 10 mg/kg, sc) was injected at various intervals after agonist injection. At t=+15 min, NLX antagonized the hypothermia induced by 6.25 μ g icv DAMGO. At t=+30 or +45 min, NLX failed to reverse the decrease in Tb. These data suggest that the effects of DAMGO were initially mediated by opioid receptors, but then a post-receptor cascade of events occurred which was not sensitive to NLX. Unlike the effects of DAMGO, at t=+15 or +30 min, NLX increased the magnitude and duration of the hyperthermia induced by 6.25 μ g icv PL017. This might suggest that NLX was selectively blocking the hyperthermic component of the change in Tb, resulting in a hyperthermia which was not opioid-receptor mediated. It is not clear why NLX appeared to interact differently with the doses of DAMGO and PL017 tested. It is possible that these were not equi-effective doses and the interaction with NLX is a dose-dependent effect. Alternatively, the two agonists may differ in terms of 1) time course of opioid receptor occupation, or 2) nonspecific (non-opioid) effects. NIDA Grants T32 DA07327, DA00376.

ENDOCRINE RESPONSE TO MU AND DELTA SPECIFIC OPIOID AGONISTS IN NEONATAL RATS. C. Kuhn*, P. Little, F. Porreca and R. Francis. Dep't of Pharmacology, Duke Medical Center, Durham, NC 27710.

Opiates are reported to stimulate prolactin (PRL) and corticosterone (CS) secretion in rats through actions on mu opiate receptors, while stimulation of GH is reported to reflect actions on both mu and delta receptors. However, previous studies have employed mu and delta agonists with poor selectivity for mu and delta receptors and no ability to differentiate between the newly described delta receptor subtypes. The purpose of the present study was to test the hypothesis that both mu and delta receptors contribute to control of anterior pituitary hormone secretion. Neonatal (day 10) rats were injected icv with saline, or various doses of the mu-selective agonist DAMGO, the delta-1 selective agonist DPDPE or the delta-2 selective agonist deltorphin, killed 20 minutes later, and serum hormone levels determined by RIA. As expected, DAMGO stimulated secretion of GH, PRL and CS. DPDPE stimulated only CS, while deltorphin significantly increased CS and PRL. Neither delta agonist increased GH. Similar results with GH were obtained in 20-day old pups. These results suggest that the delta receptor subtypes have a significant and specific role in endocrine regulation, although not in control of GH secretion. These findings further suggest that the delta-2 receptor may be the predominant delta receptor involved in endocrine regulation. Supported by DA02739.

CELLULAR MECHANISMS OF OPIATE TOLERANCE IN HYPOTHALAMIC ARCULATE (ARC) NEURONS. M.J. Kelly*, A.H. Lagrange, G. Zhang, S.A. MacMillan and O.K. Rönnekleiv. Dept. Physiology, Oregon Health Sciences U., Portland, OR 97201.

The effects of the μ -opioid agonist Tyr-D-Ala-Gly-MePhe-Gly-ol (DAMGO) on ARC neurons was compared in hypothalamic slices prepared from ovariectomized guinea pigs (GPs) implanted with placebo or morphine (morph) pellets (10 x 75 mg) for one week. DAMGO caused a decrease in R_{in} and an outward current which reversed at $\approx E_{K^+}$ and exhibited inward rectification ($I_{K^+,ir}$). Membrane hyperpolarization in response to increasing concentrations of DAMGO was determined. Chronic morphine caused a rightward shift in the DAMGO dose-response curve: $EC_{50} = 185.9 \pm 21.9$ nM (N=9) in morph GPs versus $EC_{50} = 64.0 \pm 4.4$ nM (N=30) in controls. The maximum hyperpolarization (V_{max}) induced by DAMGO in morph GPs was 72% of the V_{max} of controls (9.2 ± 1.5 mV vs. 12.7 ± 0.9 mV). Since μ -opioid and GABA_B receptors are coupled to $I_{K^+,ir}$ in ARC neurons, the response to the GABA_B agonist baclofen was also studied. Baclofen was occluded in ARC neurons from control GPs ($V_{max} = 12.6 \pm 1.3$ mV). However, the V_{max} for DAMGO was 50% of the V_{max} for baclofen in cells (N=4) from morph GPs. Therefore, chronic morphine decreases the number of functional μ -opioid receptors in ARC neurons possibly through a down regulation of μ -opioid receptors. (supported by DA05158)

KAPPA AGONIST BRL 52656 INHIBITS OSMOTICALLY-STIMULATED VASOPRESSIN SECRETION PREFERENTIALLY AT HYPOTHALAMIC SITES. NF Rossi* and DP Brooks, Wayne State U. Detroit, MI 48201 and SmithKline Beecham, King of Prussia, PA 19406.

Kappa opioid agonists provoke water diuresis. Besides inhibition of vasopressin (AVP) renal antidiuretic activity, kappa agonists that cross the blood brain barrier antagonize AVP secretion *in vivo*. We hypothesize the BRL 52656 [S(-)-2-(2-(1-pyrrolidinylmethyl)-1-(4-(trifluoromethyl)phenylacetyl) piperidine hydrochloride)] inhibits osmotically-induced AVP secretion by acting on hypothalamic (HT) opiate receptors. Explants of the rat hypothalamo-neurohypophysial system (HNS) were placed into compartmentalized static cultures with Ham F12 nutrient mixture, such that the only communication between the HT and the neurohypophysis (NH) was the infundibular stalk. A rise in HT medium osmolality of 15 mosmol/kg water with NaCl increased AVP release by 507 ± 139 %/HNS/h ($n=6$, $p < 0.02$). Increasing NH osmolality effected no change in AVP secretion. Osmotically-induced AVP secretion was significantly inhibited by $0.1 \mu\text{M}$ BRL 52656 at the HT site 87 ± 30 %/HNS/h ($n=7$, $p < 0.01$) and was suppressed by the agonist at NH sites 183 ± 49 %/HNS/h ($n=4$, $p = 0.10$). However, $0.01 \mu\text{M}$ BRL 52656 antagonized hormone release only at HT sites: HT 199 ± 36 %/HNS/h ($n=4$, $p < 0.05$); NH 488 ± 49 %/HNS/h ($n=4$, $p = 0.93$). The average rise in osmolality was 314 ± 1 to 329 ± 1 mosmol/kg water. Leaking between compartments was less than 1 %. These data are consistent with BRL 52656 inhibiting osmotically stimulated AVP secretion at both HT and NH opiate receptor sites, but that the HT mechanism is more sensitive to the kappa agonist by at least one order of magnitude.

478.11

OPIOIDS ENHANCE AND INHIBIT STIMULATED cAMP FORMATION. L. Wang and A.R. Gintzler*, Dept. of Biochemistry, SUNY Health Science Center at Brooklyn, N.Y. 11203 Electrically stimulated release of methionine-enkephalin from the myenteric plexus is regulated by a bimodal, opiate receptor-coupled mechanism. Low concentrations of opioid enhance release whereas higher concentrations inhibit the magnitude of evoked release. Indirect, pharmacological analysis suggested, but did not unequivocally establish, the involvement of the adenylyl cyclase/cAMP second messenger system in this bimodal regulatory mechanism. Accordingly, experiments were undertaken to directly ascertain the effect of opioids on stimulated cAMP accumulation in the myenteric plexus. The results demonstrate that a mu opiate receptor agonist, sufentanil, can regulate, in a bimodal fashion, the activity of adenylyl cyclase. The direction of the opioid modulation of this enzyme depends on the concentration employed. Low doses of opioid (10^{-10} M) enhance whereas higher concentrations (10^{-8} M) inhibit the magnitude of cAMP that is formed in response to electrical stimulation. Thus, opioid agonists can regulate, in a bimodal fashion, the accumulation of cAMP in the myenteric plexus. The parallel between these observations and those obtained for the opioid regulation of stimulated enkephalin release strongly suggest a causal relationship between opioid regulated cAMP levels and opioid regulated release of enkephalin. Thus, adenylyl cyclase is one biochemical substrate for the bimodal opiate receptor-coupled regulatory mechanism governing the stimulated release of enkephalin.

CONCOMITANT ACTIVATION OF MULTIPLE SPINAL ANALGESIC MECHANISMS DURING GESTATION. M.E. Dawson-Basoa* and A.R. Gintzler, Dept. of Biochemistry, SUNY Health Science Center at Brooklyn, NY, USA 11203.

Pain thresholds increase during pregnancy and parturition in both laboratory animals and humans. Previous studies in this laboratory have demonstrated that this analgesia is mediated, at least in part, by a spinal dynorphin/kappa opioid system. Intrathecal (i.t.) application of the kappa-selective antagonist, nor-binaltorphimine, significantly reduces nociceptive thresholds on gestational day 20, as does the i.t. administration of antibodies specific for dynorphin (1-17). In the current study, the first evidence is provided that multiple spinal analgesic mechanisms are responsible for the opioid-mediated analgesia of pregnancy. The involvement of additional types of opiate receptor in the analgesia of pregnancy was investigated using the delta-specific antagonist naltrindole (NTI). I.t. administration of NTI significantly reduces the threshold for responsiveness to aversive stimuli on day 20 of pregnancy. Maximum reduction in pain thresholds is observed twelve minutes after injection. In non-pregnant, ovariectomized rats i.t. NTI has no effect on analgesic thresholds. The activation of a spinal delta analgesic receptor during gestation is consistent with previous reports from this lab of a modest, but significant increase in spinal cord content of both met-enkephalin, and its precursor during this period.

SIGMA RECEPTOR ROLE IN MALE FERTILITY. X.-Z. Wu*, J.F. Siegel, M. Rich, B. Mellinger and L. Kushner, Department of Urology, Long Island Jewish Medical Center, New Hyde Park, NY 11041.

The sigma-1 (σ_1) receptor is highly dense in all male reproductive organs. Scatchard analysis of [^3H](+)-N-allylnormetazocine (NAMN) binding to membranes revealed a single class of binding sites in adult rat epididymis ($K_d=66$ nM, $B_{max}=930$ fmol/mg protein) at a density 3-fold that of rat brain. The rank order of potency of drugs at this site was haloperidol > 1,3-di(2-tolyl)guanidine (DTG) > (+)-NAMN > (+)-3-(3-hydroxyphenyl)-N-(1-propyl)piperidine > progesterone > (-)-NAMN, with no significant binding of phencyclidine, opioid, adrenergic, or cholinergic receptor ligands to this site. Thus, this site is pharmacologically similar to the neuronal σ_1 receptor. Sigma receptors were present in the prostate ($K_d=42$ nM, $B_{max}=560$ fmol/mg protein), seminal vesicle ($K_d=41$ nM, $B_{max}=510$ fmol/mg) and testis ($K_d=47$ nM, $B_{max}=640$ fmol/mg).

DTG (8 mg/kg/d), haloperidol (2.5 mg/kg/d), (+)- or (-)-NAMN (10 mg/kg/d), or vehicle was injected IP to male Sprague-Dawley rats (450 g) for 8 d, after which caudal epididymal sperm were analyzed by computer-assisted semen analysis. DTG or haloperidol treatment caused a 50% ($p < 0.001$) decrease in sperm concentration. A 10% decrease in motility with haloperidol and a 28% ($p < 0.01$) decrease in motility with DTG treatment occurred. Neither (+)- nor (-)-NAMN resulted in differences from vehicle in either fertility parameter.

Epididymides from these rats were analyzed for specific binding of [^3H](+)-NAMN. Scatchard analysis revealed that DTG and haloperidol treatment resulted in 90-100% downregulation of σ receptors. No change in σ receptor density or affinity was detected in the epididymides from (+)- or (-)-NAMN-treated animals. A correlation ($r=0.93$) between receptor downregulation and reduction of sperm count was demonstrated. This suggests that the σ receptor has a role in male fertility. (Supported by the Weingrow Family Foundation.)

ENHANCED PRODYNORPHIN PROCESSING DURING GESTATION. V.M. Medina*, M.E. Dawson-Basoa and A.R. Gintzler, Dept. of Biochemistry, SUNY Health Science Center at Brooklyn, N.Y. 11203

Behavioral and pharmacological experiments have demonstrated that during late gestation and parturition there is a significant activation of a maternal spinal cord dynorphin/ κ opioid analgesic system. Consistent with these results, spinal levels of dynorphin (1-17 and 1-8) are elevated during the same periods of the gestational process, an effect restricted to the lumbar region of the spinal cord. In the present study, these observations of dynorphin modulation during pregnancy have been extended to include analyses of the spinal cord content of prodynorphin. The tryptic generation of leucine-enkephalin-arg was used as an indicator of dynorphin precursor content. The latter was quantified by RIA using an antibody specific for this hexapeptide. It is now demonstrated that late pregnancy is associated with a significant modulation of dynorphin precursor content; a marked decrease (50%) in the spinal cord content of prodynorphin occurs across all spinal regions. The amount of dynorphin represented by the decline in precursor content is about 3x greater in the lumbar cord than in cervical or thoracic areas. The decline in precursor content in the lumbar cord is about 10x greater than is the combined increase in content of dynorphin (1-17 and 1-8). The difference between the decrease in precursor content and the increase in dynorphin peptides suggests markedly enhanced release of this opioid peptide(s) in the spinal cord during the gestational period.

479.1

DUAL MECHANISMS FOR THE RELEASE OF 3H-NE BY CLENBUTEROL. K. D. Murugaiah, M. R. Glover, J. D. Steketee* and J. M. O'Donnell. Dept. of Pharmacology, Louisiana State University Medical School, Shreveport, LA 71130-3932.

The effect of clenbuterol (CLEN), a beta-2 adrenergic receptor agonist on 3H-NE release from brain slices was investigated. Tissue slices were incubated with 3H-NE for 30 min and 3H overflow determined during electrical stimulation (3 Hz, 20 mA, 2 ms, 2 min) at 20 (S1) and 65 (S2) min. Superfusion of slices from the cortex (CTX), hypothalamus (HYPO), or hippocampus (HPC) with CLEN (10 - 100 μ M) for 15 min increased both basal and electrically induced overflow of 3H-NE in a concentration-dependent manner. 3H-NE efflux was increased to 185% (CTX), 186% (HYPO) and 155% (HPC) of control by 30 μ M CLEN. CLEN-induced increases in 3H efflux were still evident in calcium-free medium. By contrast, electrically stimulated release of 3H-NE was not observed in the absence of calcium. Repeated administration of CLEN (1 mg/kg for 10 or 21 days or 10 mg/kg for 14 days) did not alter the effect of CLEN on basal release of 3H-NE despite a marked decrease in the density of beta-2 adrenergic receptors. However, the beta adrenergic receptor antagonists propranolol (0.5 μ M) and ICI 118,551 (0.1 - 10 μ M) partially antagonized CLEN-induced 3H-NE release. These findings suggest that CLEN may increase 3H-NE release via dual mechanisms: a) an amphetamine-like effect independent of synaptic transmission; and b) a beta adrenergic receptor-mediated facilitatory effect on stimulated release similar to that reported previously for isoproterenol. (Supported by USPHS Grant MH40694.)

CYTOCHROME P-450 MEDIATED CATECHOLAMINE RELEASE FROM ADRENAL CHROMAFFIN CELLS T.L. Thompson* and R.L. Moss. Dept. of Physiology, Univ. of Texas Southwestern Med. Ctr., Dallas, TX 75235

Hormones which stimulate catecholamine (CA) release from chromaffin cells liberate arachidonic acid (AA) from the plasma membrane. A number of studies have shown that inhibition of AA liberation prevents stimulated CA release while direct application of AA can stimulate CA release from these cells. However, inhibition of AA metabolism attenuates secretagogue-stimulated CA release from chromaffin cells suggesting that a metabolite of arachidonic acid and not AA itself is responsible for the observed response. The metabolism of AA proceeds by cyclooxygenase and non-cyclooxygenase (lipoxygenase and cyto. P-450 monooxygenase) mediated pathways.

We have examined the role of cyto. P-450 mediated AA metabolism on stimulated CA release from resuspended cultured adrenal chromaffin cells using an *in vitro* voltammetric technique. CA release was measured in response to 2mM acetylcholine. Chromaffin cells were treated with cyto. P-450 inhibitors, piperonyl butoxide (PB) or YYB (a structural analogue of AA) for at least 15 min prior to stimulation. PB pretreatment produced a dose dependent decrease in stimulated CA release. 1.5 μ M PB was sufficient to cause a 94% inhibition of ACH stimulated release. Preliminary data suggest that YYB is also a potent inhibitor of release; 1.15 μ M YYB resulted in a 63% reduction in CA release. The ability of 5,6-epoxyeicosatrienoic acid (5,6-EET), a synthetic product of AA metabolism formed by the activity of cyto. P-450, to overcome PB induced inhibition of CA release was examined. 5,6-EET (40-1.0 μ M) triggered a rapid, transient and massive release of a CA-like substance from the chromaffin cells in the presence or absence of PB. These data suggest that cyto. P-450 mediated oxidation of AA may play a vital role in secretagogue stimulated CA release from chromaffin cells. Supported by NIH grant MH47418.

479.5

RELEASE OF HIPPOCAMPAL NOREPINEPHRINE IN VITRO FOLLOWING ISOLATION-REARING IN THE RAT A.J. Fuford and C.A. Marsden (SPON: Brain Research Association) Department of Physiology and Pharmacology, Medical School, Queen's Medical Centre, Nottingham, NG7 2UH, U.K.

The changes in dopaminergic and serotonergic function following isolation from weaning are well documented. We have recently shown that α_2 adrenoceptor function is also affected (Fuford *et al* (1993) Br. J. Pharmacol., 103: 281P. Isolation at weaning induced an enhancement in presynaptic α_2 function and an elevation in hippocampal α_2 receptor number. In the present study we have examined the effect of isolation from weaning on the release of norepinephrine (NE) in hippocampal slices *in vitro*. At four weeks postweaning differentially reared male, Lister hooded rats were killed and the hippocampi removed and halved to provide paired control and test tissues. Tissue slices were prepared and incubated in Krebs at 37°C in a shaking water bath for 5 min prior to administration of either elevated K⁺ solution (30mM), idazoxan (10 μ M) or clonidine (10 μ M). After a further 20 min incubation, samples were centrifuged and the supernatants retained for the measurement of NE content by HPLC-ED. In addition the Ca²⁺ dependency of the release was investigated. The basal release of hippocampal NE tended to be lower in isolated compared to group-reared rats, although this did not reach significance. In both groups the release was Ca²⁺ dependent and potentiated by elevated K⁺. Idazoxan significantly increased NE release in isolated but not group-reared rats. Similarly, the reduction in release produced by clonidine was only significant in tissue from the isolation-reared animals. Preincubation of idazoxan blocked the reduction in release of NE induced by clonidine confirming α_2 receptor involvement. These results provide neurochemical evidence of a change in presynaptic α_2 adrenoceptor function following isolation-rearing in the rat. The significance of these changes remains to be determined.

479.2

INHIBITORY EFFECTS OF ETHAVERINE ON CATECHOLAMINE SECRETION AND [Ca²⁺]_i RISE IN DEPOLARIZED PC12 CELLS. Kyong-Tai Kim and Byung-Chang Suh. Dept. of Life Science, Pohang Institute of Science and Technology, Pohang, Kyong Buk, 790-600 Korea.

Ethaverine, a derivative of papaverine, is used as a vasodilator and antispasmodic drug because of its inhibitory effects in arterial and cardiac muscle membrane Ca²⁺ channels. We have investigated the effects of ethaverine on neuronal cell line-PC12 cells depolarized by high K⁺ treatment. Therapeutic concentration (1 μ M) of ethaverine treatment with 70 mM K⁺ decreases catecholamine secretion to 40%. Inhibitory mode of ethaverine shows that its inhibition of secretion is dose-dependent and EC₅₀ is about 2 μ M. To study its inhibitory action mechanism on secretion, we examined intracellular Ca²⁺ level. Ethaverine pretreatment decreased the depolarized long-lasting phase with the concentration-dependent mode but still induced an initial phase of Ca²⁺ profile. General L-type Ca²⁺ channel blockers nifedipine, a dihydropyridine, and verapamil, a phenylalkylamine also inhibited high K⁺-induced persistent phase of [Ca²⁺]_i rise. In contrast ω -conotoxin, N-type voltage-gated Ca²⁺ channel antagonist, pretreatment inhibited the initial phase but had no effects on the persistent phase. Ethaverine treatment at persistent phase decreased to the basal Ca²⁺ level like the action of L-type Ca²⁺ channel blockers, nifedipine and verapamil, and did not affect the initial phase of internal Ca²⁺ transient. We have concluded that treatment of ethaverine to PC12 cells resulted in reduction of catecholamine secretion through the blocking of L-type voltage-sensitive Ca²⁺ channel.

INTRACEREBRAL MICRODIALYSIS IN THE HUMAN CEREBRAL CORTEX: ON-LINE MEASUREMENT OF NORADRENALINE DURING ANESTHESIA AND WAKEFULNESS.

Z.L. Rossetti, G. Nurchi, M. Corradu, and G. L. Gessa. Dept. of Neuroscience, Univ. of Cagliari and Neurosurgery Unit, Ospedale "Brotzu", Cagliari, Italy.

The changes in the extracellular concentrations of noradrenaline in the human cerebral cortex were investigated using *in vivo* microdialysis. Patients undergoing neurosurgery for tumor asportation, subarachnoid hemorrhage or severe head injuries, underwent implantation of a concentric dialysis probe into the parieto-occipital cortex. The probe was perfused for periods ranging from 6 to 24 h with sterile artificial CSF at a flow rate of 2 μ l/min. Dialysates were analyzed for noradrenaline (NA) by HPLC-EC in 15 or 20 min samples. Neurochemical measurements were matched in time with the level of anesthesia and with systolic blood pressure. Following probe implantation, a relatively rapid decay in extracellular NA levels was observed. Perfusate NA concentrations progressively decreased and reached stable levels (0.6 \pm 0.12 pg/sample, mean \pm S.E.M.) within 2 h following the implantation of the probe. Omission of Ca²⁺ from the perfusion medium reduced NA output to undetectable levels, indicating the neuronal origin of the measured endogenous amine. During surgery, the changes in extracellular NA concentrations were temporally correlated with the levels of anesthesia. In the awakening phase, NA perfusate levels raised by about six-fold. These results provide the first direct biochemical evidence *in vivo* that in humans the waking state is associated with activation of the noradrenergic system. Thus microdialysis in neurosurgical patients could be valuable in detecting regional changes in brain activity and may open new fields of clinical research.

HVA AND MHPG: CORRELATIONS BETWEEN SALIVARY AND PLASMA LEVELS. Ren-Kui Yang, Rachel Yehuda, Donna D. Holland, Robert A. Levengood and Peter J. Knoff. Department of Psychiatry, Mount Sinai School of Medicine, NY 10029 and Department of Veterans Affairs, Bronx, NY 10468.

Plasma levels of 3-methoxy-4-hydroxyphenylglycol (MHPG) and homovanillic acid (HVA) are frequently measured as indicators of brain noradrenergic and dopaminergic activity, respectively. We now find that salivary levels of MHPG and HVA correlate significantly with plasma levels of these catecholamine metabolites.

Method: Salivary samples were obtained from volunteer subjects between 08:00 and 16:00 hours using Salivette (Sarstedt) collection tubes. Blood was collected concurrently into heparinized vacutainers by venipuncture. Saliva and plasma samples were stored at -20°C until assayed for MHPG and HVA by HPLC with electrochemical detection.

Results: Salivary HVA concentration correlated significantly with plasma HVA concentration (0.4231, n=25, P<0.0351). The saliva:plasma ratio for HVA was always less than 1 (0.53 \pm 0.14). Similarly, salivary MHPG concentration correlated significantly with plasma MHPG concentration (r=0.7154, n=23, P<0.0001). However, the saliva:plasma ratio for MHPG was always greater than 1 (1.52 \pm 0.23). Enzyme hydrolysis revealed that MHPG in plasma is both free (about 30%) and also conjugated with sulfate and glucuronide in roughly equal proportions but that it exists entirely free in saliva. Saliva did not hydrolyse glucuronide or sulfate conjugates and furthermore did not inhibit the actions of glucuronidase or sulfatase enzymes.

Conclusions: Significant correlations of salivary HVA and MHPG with plasma concentrations of these catecholamine metabolites suggests that salivary measurement may be of utility in situations where blood samples cannot be readily obtained.

DETERMINATION OF NOMIFENSINE AND DOPAMINE IN DIALYSATE USING GC/MS. T.L. Townsend and W.H. Church. Dept. of Chemistry, East Carolina Univ., Greenville, NC 27858.

A GC/MS method is presented which allows for the simultaneous determination of striatal levels of dopamine (DA) and nomifensine (NOMI) in rats. Dialysate samples were collected every 30 minutes before and after i.p. injection of NOMI (10 mg/kg) using a microdialysis probe and then derivitized using TFE and TFAA. Samples were then injected onto a capillary GC column and individual components detected by quadrupole GC in SIM mode. DA increased in the first sample following drug injection. NOMI was detected in this sample also. Extracellular DA levels were elevated for the next 2 hours and then slowly decreased towards pre-drug levels. NOMI was detected in the dialysate for up to 4 hours following injection. Optimization studies of derivative stability, signal-to-noise enhancement, and dialysate collection methods are presented.

GRAPHITE FIBER ELECTROCHEMICAL PROBE CONSTRUCTED WITH FUSED SILICA TUBING¹. C. Ksir* and G.A. Gerhardt², Department of Psychology and Neuroscience Program, University of Wyoming, Laramie, WY 82071.

Graphite fiber working electrodes are commonly used for in-vivo electrochemical recording of dopamine and other neurotransmitters and/or metabolites. A fabrication technique is described that employs no electrode puller or other specialized equipment.

A 30 μ m graphite fiber is passed through a 7 mm length of fused silica tubing (40 μ m i.d., 150 μ m o.d.) which is then inserted into a 1 cm length of fused silica tubing (200 μ m i.d., 300 μ m o.d.). 3 mm of the smaller tubing is left exposed. Epoxy is used to seal the two connections.

The open end of the larger tubing is packed with graphepoxy. A 36-ga copper wire is inserted into the graphepoxy to make a connection to the graphite fiber. The tip of the exposed graphite fiber is cut back so that approximately 100 μ m is exposed as the working surface.

After applying 6 coats of Nafion, these electrodes were calibrated for dopamine recording. The electrodes showed selectivities of 1500 or more for dopamine relative to ascorbate, with oxidation/reduction current ratios of 0.40-0.50. Signal-to-noise during calibration indicates sensitivities of approximately 0.02 μ M. Fused-silica electrodes have been used to record the clearance from rat striatum of dopamine microinjected from a pipette positioned 300 μ m from the recording electrode tip.

A SIMPLE AND FLEXIBLE VERTICAL PROBE FOR BRAIN MICRODIALYSIS. E. Carboni.* Dept. Of Toxicology, University of Cagliari 09126 Cagliari Italy.

The construction, the implantation and the properties of a new vertical probe for microdialysis are described. A Hospal dialysis fiber closed at one end and covered with epoxy glue over its entire surface, except for 2.5 mm at its end was implanted in the dorsal caudate without any rigid connection with the skull in order to reduce brain damage. The fiber was perfused through a silica fused capillary tubing with Ringer. The dialysate was analysed for dopamine with an HPLC coupled with an electrochemical detector. A fiber as described above, implanted in the dorso-lateral caudate recovered 113 ± 12 fmoles (n=8) of dopamine in 20 μ l of perfusate (1 μ l/min). Basal dopamine output 24 h after the implant was calcium dependent and stimulated by the dopamine receptor blocker haloperidol. Histological analysis of a frontal section of caudate slice implanted with a probe, revealed minor damage along the fiber track. The technique described has several advantages, including simplicity, high recovery, and favorable histology.

SEROTONIN RECEPTORS: MOLECULAR BIOLOGY II

480.1

MOLECULAR CLONING AND CHARACTERIZATION OF A RAT BRAIN cDNA ENCODING A 5-HT5B RECEPTOR. M.M. Voigt¹, E. Parker², C. Mable², D. Grisel², H. Nowak², E. Yocca², P. Seeburg³ and W. Wisden³. ¹Dept. Pharmacol., Univ. Coll., Dublin, Ireland. ²Bristol-Myers Squibb Co., Wallingford, CT 06492. ³Center for Mol. Biol., Univ. Heidelberg, Heidelberg, FRG.

A gene encoding a novel serotonin (5-HT) receptor, termed 5-HT5B, was cloned from a rat forebrain cDNA library. The 5-HT5B receptor is moderately homologous to other cloned 5-HT receptors. The radiolabelled agonist [³H]5-carboxamidotryptamine (5-CT) bound to two affinity states of the 5-HT5B receptor in COS1 cell membranes ($K_{DH}=0.8$ nM, $K_{DL}=31$ nM). The proportion of receptors in the high affinity state was reduced by the inclusion of guanine nucleotides in the binding assay, suggesting that the receptor couples to a G-protein in COS1 cell membranes. However, this receptor does not appear to alter either cAMP accumulation or phosphoinositide turnover in a variety of fibroblast cell lines. Several serotonergic ligands displayed affinity for the 5-HT5B receptor, with the following rank order potency: 5-CT > LSD > 5-HT > methysergide=methiothepin=8-OH-DPAT > cyproheptadine > sumatriptan. Ketanserin, pindolol, yohimbine, spiperone, mesulergine and zacopride were inactive. In the rat brain, 5-HT5B gene expression occurs predominantly in the medial habenulae and hippocampal CA1 cells, with considerably lower levels detected in the entorhinal cortex and dorsal raphe. The ontogenic profile of this gene shows that low to undetectable levels are expressed prior to birth, with post-natal expression peaking in the adult. Based on its primary structure, pharmacological profile and signal transduction mechanism, the 5-HT5B receptor appears to be a member of a new family of G-protein coupled serotonin receptors.

⁴Circadian Neurobiology Group, Armstrong Laboratory, Brooks AFB, Texas 78235.

A polymerase chain reaction (PCR)-based strategy was used to identify a gene (REC20) encoding a novel G-protein-coupled serotonin receptor. REC20, encoding a putative 435 amino acid protein, exhibits greatest identity within the transmembrane domains to the 5-HT-dro1 receptor (54%). Transient expression of REC20 in CosM6 cells results in high affinity [¹²⁵I]-LSD binding which is antagonized by a variety of serotonin ligands including the 5-HT_{1A} agonist 8-OH-DPAT and the 5-HT_{1C/2} antagonist ritanserin. In addition, these cells accumulate cAMP in response to 5-HT agonists with the same rank order of potency as their binding affinity vs. [¹²⁵I]-LSD. Northern blot hybridization detects two mRNA transcripts (3 and 4.2 kb) predominantly in the hypothalamus and thalamus. *In situ* hybridization studies indicate specific expression in CA3 of the hippocampus, several cortical layers, as well as thalamic and hypothalamic nuclei. We have also shown that the circadian phase of spontaneous neuronal activity in the rat suprachiasmatic nucleus advances in response to serotonin ligands with a pharmacological profile consistent with that of REC20. The pharmacology and tissue distribution of REC20 do not correlate with the known properties of the putative 5-HT₄ receptor, therefore we have provisionally identified it as the 5-HT₇ receptor.

480.3

CLONING OF A NOVEL HUMAN SEROTONIN RECEPTOR, 5-HT₇, FUNCTIONALLY COUPLED TO ADENYLATE CYCLASE ACTIVATION. J.A. Bard, J.M. Zgombick, N. Adham, P.J.J. Vaysse, T.A. Branchek*, and R.L. Weinshank. Synaptic Pharmaceutical Corp., Paramus, NJ 07652.

Primary amino acid sequence and signal transduction data are now published for 5-HT₇-like receptors, 5-HT₁ receptors and 5-HT₂ receptors, which couple to inhibition of adenylate cyclase, phosphoinositide hydrolysis and ligand-gated ion channel/Ca²⁺ mobility, respectively. We report here the cloning of a human 5-HT receptor, distinct from 5-HT₁ (and from the recently cloned 5-HT₂ receptor), that couples to the stimulation of adenylate cyclase activity, which we propose to name 5-HT₇. This receptor was identified by low homology screening with transmembrane probes from the *Drosophila* serotonin receptor gene, 5-HT_{2Dro1}. This intron-containing gene exhibits greatest homology in the transmembrane regions with 5-HT_{2Dro1} (57%) and 39-53% with other serotonin receptor subfamilies. The pharmacological binding profile obtained with membranes derived from transiently transfected Cos-7 cells showed high affinity, saturable [³H] 5-HT binding (K_d=8.5±0.8 nM; B_{max}=6.6±0.8 pmol/mg protein) with the rank order of binding potency: 5-CT > methiothepin > metergoline > 5-HT > 8-OH DPAT > sumatriptan > ketanserin > zacopride. Functional responses of 5-HT₇ indicated coupling to stimulation of adenylate cyclase: both 5-HT and 5-CT elicited a 20-fold increase in cAMP release over basal levels. The mRNA encoding the 5-HT₇ receptor, analyzed by reverse transcriptase-polymerase chain amplification, is expressed in human brain and a variety of human peripheral tissues. The divergent amino acid sequences of the 5-HT₁ and 5-HT₂ receptors, combined with their pharmacologic divergence from the 5-HT₇ receptor, indicates an unusual complexity in the structures of adenylate cyclase stimulatory 5-HT receptors.

480.5

CHARACTERIZATION AND LOCALIZATION OF mRNA FOR A NOVEL SEROTONIN (5-HT) RECEPTOR POSITIVELY COUPLED TO ADENYLATE CYCLASE IN GUINEA PIG BRAIN. L.B. Jakeman*, D.W. Bonhaus, J.S. Ramsey, E.H.F. Wong, H.Chan, C. Bach, R.M. Eelen, and A.P. Tsou. Inst. Pharmacology and Bio-Organic Chemistry, Syntex Discovery Research, Palo Alto, CA 94304.

Using homology cloning with a human 5-HT_{1A} receptor probe, a novel cDNA was isolated from a guinea pig hippocampal library. The sequence contains an open reading frame of 1338 base pairs encoding a 466 amino acid protein with 7 hydrophobic sequences representing putative transmembrane domains. Homology mapping to known receptors showed closest resemblance to 5-HT_{2Dro1} (46%). Transient expression in COS-7 cells revealed specific, high affinity binding to [³H] 5-HT. The binding was displaced by 5-CT>5-HT>methiothepin>8-OH-DPAT>spiperone>ketanserin. Functional expression in CHO-K1 cells showed positive coupling to an adenylate cyclase, with a rank order of potency for agonists of 5-CT>5-HT>5-MeOT>DP>5-CT>8-OH-DPAT. Spiperone and methiothepin antagonized the response to 5-HT in a competitive manner (K_i = 56 nM and 36 nM), whereas pindolol was inactive. This pharmacological profile does not correspond to that of previously described 5-HT receptors including 5-HT₁, 5-HT₂ or 5-HT₆. *In situ* hybridization using a cRNA probe directed against the coding region of the gene revealed mRNA in guinea pig hippocampus (DG>CA3>CA2>>CA1), periventricular thalamus and superficial cortex (layers 2-3). These results demonstrate the isolation of a unique receptor with high affinity for 5-HT, which is found in cortical and limbic brain areas that receive serotonergic projections. Further studies are underway to determine the relationship between this receptor and other operationally defined 5-HT receptors.

480.7

CLONING AND EXPRESSION OF THE OPOSSUM KIDNEY (OK) CELL LINE 5-HT_{1B} SEROTONERGIC RECEPTOR. D.R. Cerutis*, L.J. Iversen and D.B. Bylund. Dept. of Pharmacol., Univ. Neb. Coll. Med., Omaha, Nebraska 68198-6260.

Previous studies from our laboratory have demonstrated the presence of the 5-HT_{1B} receptor in the OK cell line, an established renal proximal tubule epithelial cell line. Using primers directed at the first and sixth transmembrane domains of the 5-HT_{1B} receptor for reverse-transcriptase PCR (RT-PCR) on OK cell cDNA, we obtained a 780 bp product having > 94% similarity with the corresponding region of the rat and mouse 5-HT_{1B} receptors. 5' and 3' RACE (Rapid Amplification of cDNA Ends) clones were obtained using internal sequence information from this 780 bp clone and adapter primers (BRL). (Cerutis *et al.*, FASEB J. 7(4):A694, 1993). The 5' and 3' RACE clones were sequenced and were shown to contain sequence from the 780 bp clone as well as approximately 250 bp of 5' noncoding region upstream from the start codon and the stop codon with 3' untranslated ~ 200 bp sequence. In order to acquire a full-length 5-HT_{1B} receptor cDNA clone, we performed PCR on OK cell cDNA using oligonucleotide primers for the receptor's N and C-terminus designed from the 5' and 3' RACE clones. The product obtained was cloned into pRC/CMV (Invitrogen) for sequencing and expression. The OK cell 5-HT_{1B} receptor is 80.1% identical and 12.8% similar to the mouse and human 5-HT_{1B} receptors at the amino acid level. Transient transfection of this cDNA (OKc1) into COS-1 cells gave high affinity binding of [³H]5-HT and saturation studies using [¹²⁵I]iodocyanopindolol bound a single saturable site with a K_d of 0.20 nM. Inhibitions were performed with the following drugs: 5-HT, cyanopindolol, methiothepin, RU24969, sumatriptan, methylsergide, isoproterenol, and 8-OH-DPAT. These all yielded K_i values consistent with 5-HT_{1B} pharmacology. (Supported by NIMH grant MH47354).

480.4

PHARMACOLOGICAL PROPERTIES AND LOCALIZATION OF A NOVEL CLONED RAT SEROTONIN RECEPTOR (5HT₇)

M. Ruat, E. Traiffort, J.M. Arrang, R. Leurs, G. Diaz, A. Enjalbat*, J. Tardivel-Lacombe and J.C. Schwartz. U.109 de l'INSERM, Centre Paul Broca, 75014 PARIS.

We have isolated a cDNA encoding a novel serotonin (5-HT) receptor, termed 5HT₇. This 448 amino acid protein displayed limited homology with previous cloned 5-HT receptors belonging to the superfamily of G-protein coupled receptors except (38%) with a *Drosophila* Dro1 5-HT receptor (Witz *et al.*, 1990). The 5HT₇ receptor is characterized by the presence of an unusual hydrophobic domain located at its long N-terminal end, and by at least two introns in its coding sequence, located at the end of the third hydrophobic domain and in its C-terminal end. Stable expression of the 5HT₇ receptor led to the appearance of high affinity [³H]5-HT binding sites (K_d=1nM) on membranes of transfected CHO cells. The pharmacological profile of the 5HT₇ receptor was clearly distinct from that of any other serotonergic receptor as indicated by K_i's of a series of serotonergic agents: 5-HT (EC₅₀=1nM), lysergic acid diethylamide (LSD, EC₅₀=10nM) and several serotonergic agonists potentially stimulated cAMP accumulation in transfected CHO cells. Northern blot analysis of a variety of rat tissues revealed two mRNAs of 3.9 and 3.1kb. These transcripts were highly expressed in hypothalamus, brainstem and hippocampus whereas the signal was the lowest in stomach and ileum. Detailed *in situ* hybridization with a cRNA probe revealed a highly heterogeneous distribution of transcripts in rat brain, where the highest levels were found in the retrosplenial cortex, hippocampus, tenia tecta, posterior hypothalamus, amygdaloid complex, thalamus, and pontine nuclei. The 5HT₇ receptor seems to be mainly associated with limbic structures, suggesting its potential role in control of functions such as learning, mood or neuroendocrine regulations.

480.6

ORGANIZATION OF THE MURINE 5-HT_{3A} RECEPTOR GENE AND INVESTIGATION OF ITS SPLICE VARIANTS. P. Werner, Y. Humbert, F. Boess, J. Reid, K. Jones*, E. Kavashima. Glaxo Institute for Molecular Biology, Geneva, Switzerland

The 5-HT₃ receptor has recently been cloned (Maricq *et al.*, Science, 254: 432, 1991) and shown to be a member of the ligand-gated ion channel superfamily. We have isolated from an NG108-15 cDNA library a molecular variant (5-HT_{3AS}) of the original cDNA (5-HT_{3AL}), which is missing 18 base pairs. This variant lacks a casein kinase II phosphorylation site in the second cytoplasmic loop that is predicted for 5-HT_{3AL}. Electrophysiological measurements in HEK-293 cells transfected with 5-HT_{3AS} show a rapidly desensitizing response to 5-HT (EC₅₀ = 1.8μM) that is reversibly blocked by ICS205-930 (IC₅₀ = 0.3nM). These properties are similar to those previously observed for 5-HT_{3AL}. To investigate further the physiological roles of the two variants we studied their relative abundance in a variety of tissues. In NG108-15 cells approximately 80% of the 5-HT_{3A} mRNAs code for 5-HT_{3AS}. We have also looked for and found 5-HT_{3AS} mRNA in areas of the mouse nervous system that are known to have 5-HT₃ receptors, such as cortex, hippocampus and superior cervical ganglion. We are currently quantifying the ratio of the two forms in these tissues, and preliminary results show that the predominant form is 5-HT_{3AS}. The isolation of a mouse genomic λ phage clone, which spans the entire 5-HT_{3A} receptor gene, allowed us to sequence the boundaries between coding exons and the respective introns. This analysis suggests that 5-HT_{3AS} and 5-HT_{3AL} mRNAs are generated by an alternative use of 3' splice sites.

480.8

TRANSCRIPTION OF A HUMAN SEROTONIN 5-HT_{1D} PSEUDOGENE. S.P. Nawoschik, J.A. Bard, L.A. Borden*, T.A. Branchek and R.L. Weinshank. Synaptic Pharmaceutical Corp., Paramus, NJ 07652.

Molecular biological tools have permitted cloning and expression of a number of serotonergic receptor genes and demonstrated the presence of an array of genes within this G protein-coupled receptor gene family. Recently, two subtypes of 5-HT_{1D}, 5-HT_{1Da}, and 5-HT_{1Db}, have been cloned and shown to display similar pharmacological profiles; the human 5-HT_{1Da} corresponds to gene RDC4 in the dog. To search for related serotonin clones, the canine RDC4 clone was used as a probe to screen a human genomic library. One genomic DNA clone exhibited greatest homology to the 5-HT_{1Da}, exhibiting 76% identity (over 1088 nts.) to 5-HT_{1Da} and only 67% identity to 5-HT_{1Db}. Several structural features of this DNA sequence, including multiple in-frame termination codons and insertion of 45 bp contiguous to an *Alu* repetitive element in the third extracellular loop (between transmembrane domains VI and VII), suggest that this gene is not translationally active and, is therefore, a pseudogene (ψ5-HT_{1Da}). Confirmation of the existence of this pseudogene in the human genome was obtained by human genomic Southern blot analysis and genomic PCR cloning and sequencing. mRNA expression of both the 5-HT_{1Da} gene, as well as the pseudogene in human peripheral tissue, by reverse transcriptase-polymerase chain amplification (RT-PCR), demonstrated that the pseudogene is transcribed and has a similar tissue distribution as the 5-HT_{1Da} receptor. This serotonergic pseudogene most likely arose from a gene duplication or transposition event. Use of molecular tools may lead to the discovery of other G protein-coupled pseudogenes and may provide insight into the genetic variation and evolutionary diversity that has occurred at this multi-gene superfamily.

480.9

A SINGLE POINT MUTATION INCREASES THE AFFINITY OF SEROTONIN 5-HT_{1D}, 5-HT_{1D}, 5-HT_{1E} AND 5-HT_{1F} RECEPTORS FOR β -ADRENERGIC ANTAGONISTS. N. Adham*, J.A. Tamm, J.A. Salon, R.L. Weinsbank, and T.A. Branchek. Synaptic Pharmaceutical Corp., Paramus, NJ 07652.

The serotonin 5-HT_{1A} and 5-HT_{1B} receptors bind certain β -adrenergic antagonists, such as propranolol and pindolol, with high affinity. This pharmacological convergence between adrenergic and serotonin receptors can be attributed to conservation of a key asparagine (N) residue in the seventh transmembrane domain of receptors that bind β -antagonists with high affinity. Other 5-HT₁ receptors display very low affinity for these ligands and have either a threonine (T; 5-HT_{1D}, 5-HT_{1E} and 5-HT_{1F}) or an alanine (A; 5-HT_{1B}) residue in the homologous position. Replacement of this T in 5-HT_{1D} with N, increases its ability to bind β -adrenergic antagonists (Oksenberg et al., 1992). To evaluate the generality of these observations, we have used site-directed mutagenesis to replace the T or A in 5-HT_{1D}, 5-HT_{1E} and 5-HT_{1F} receptors with the corresponding N. Radioligand binding studies were performed by using [³H]-5-HT and [¹²⁵I]-iodocyanopindolol on transient transfectants in COS 7. Using [³H]-5-HT, we found that the affinities of all the mutant receptors for propranolol and pindolol, but not 5-HT, were significantly increased by 100-10,000 fold, the 5-HT_{1D} receptor showing the highest and the 5-HT_{1E} receptor displaying the lowest affinity. All mutant receptors bound [¹²⁵I]-iodocyanopindolol with high affinity [K_d values in nM: 0.029, 5-HT_{1D}; 0.10, 5-HT_{1E}; 0.52, 5-HT_{1F}; 0.42, 5-HT_{1B}]. Wild-type receptors failed to show any specific binding. Therefore, the presence of this key asparagine residue confers binding for β -antagonists even in serotonin receptors which differ substantially in molecular structure.

480.11

THE ALA/SER²⁴² SPECIES VARIATION RESULTS IN SPECIES SELECTIVITY WITH CERTAIN SUBSTITUTED ERGOLINES AND TRYPTAMINES FOR 5-HT₂ RECEPTORS. M.P. Johnson¹, D.B. Wainwright, V.L. Lucaites, J.D. Kursar, L. Mercurio, R.J. Loncharich Jr., M. Baez and D.L. Nelson. Lilly Research Laboratories, Eli Lilly and Company, Indianapolis, IN 46285; ¹Current address: Marion Merrell Dow Research Institute, CNS Research, Cincinnati, OH, 45215.

Previously it had been reported (Nelson et al., *J. Pharmacol. Exper. Ther.*, In press, Johnson et al., *Euro. J. Pharmacol.*, In press) that N(1) alkyl substitution alters the species selectivity of selected substituted ergolines and tryptamines at 5-HT₂ receptors. With the ser²⁴² containing human 5-HT₂ receptor N(1) unsubstituted ergolines and tryptamines have a higher affinity, while with the ala²⁴² containing rat 5-HT₂ receptor the N(1) alkyl substituted analogs have a higher affinity. Using mutagenesis of the rat 5-HT₂ receptor the importance of the ala/ser²⁴² species variation was examined. All mutations were confirmed by sequencing, showed no decrease in affinity for [¹²⁵I]DOI or [³H]ketanserin, and stimulated PI hydrolysis. The mutant A242S (ala²⁴² mutated to ser) showed an increase in affinity for the N(1) unsubstituted analogs and a decrease in affinity for the N(1) alkyl analogs as compared to the wild type rat receptor clone. The affinities of the test compounds for the A242S mutant and the human cloned 5-HT₂ receptor were very similar. The mutant A242T (ala²⁴² mutated to thr) resulted in a higher affinity for the N(1) unsubstituted ergolines, similar to what was seen with A242S, and a substantial decrease in affinity for the N(1) alkyl ergolines, significantly lower than seen with any other form of the 5-HT₂ receptor examined. The mutant A242V, resulted in no change in affinity for the N(1) isopropyl ergolines but significantly decreased the affinity of N(1) unsubstituted ergolines versus the wild type receptor. The results suggest that this position is in close contact with the some of 5-HT₂ ligands and that a H-bond occurs between the N(1) position on some indole containing ligands and the ser²⁴² of the human 5-HT₂ receptor. Preliminary data with two other mutants of the rat 5-HT₂ receptor (S207A and S239A) will also be presented.

480.13

Site-specific mutagenesis demonstrates that Arginine 195 in TMD 4 is a critical determinant for agonist affinities at the 5-HT_{1C} and 5-HT₂ receptors. S. Leonhardt*, K. Herrick-Davis, B.D. Wilcox, B.J. Hoffman@, and M. Teitler Dept. of Pharmacology (S.L., K.H.D., M.T.) and Dept. of Medicine, Albany Medical College, Albany, NY 12208; @ Laboratory of Cell Biology, NIMH, Bethesda, MD 20892

5-HT₂ and 5-HT_{1C} receptors appear to be closely related, displaying a similar pharmacological profile, the same second messenger system (PI metabolism) and a high degree of sequence homology. However, there are striking differences in the interactions of serotonin with the 5-HT_{1C} and 5-HT₂ receptors. 5HT binds with a 22-fold higher affinity to radiolabeled 5-HT_{1C} receptors than to radiolabeled 5-HT₂ receptors; 5HT_{1C} receptors can be directly radiolabeled with ³H-5HT while 5HT₂ receptors cannot. 5HT is 12-fold more potent in 5HT_{1C}-mediated stimulation of PI metabolism than in 5HT₂-mediated stimulation of PI metabolism. In order to explore the molecular basis for the higher affinity and potency of 5HT at the 5HT_{1C} receptor, we investigated the role of arginine 195 (at the postulated interface of trans-membrane domain IV and the second extracellular loop) in the interaction of 5HT with the 5HT_{1C} receptor. This residue is present in all mammalian 5HT receptor sub-types displaying high affinity for 5HT; in the 5HT₂ receptor a glutamine is substituted at this position. We report that mutating ARG 195 of the 5-HT_{1C} receptor to the corresponding residue of the 5-HT₂ receptor (GLN 195) decreases the affinity of 5HT for the mutated receptor by 8-fold, and for the agonist DOI by two-fold. Antagonist affinities were not affected by the mutation. This specific receptor domain has previously not been implicated in 5HT binding to the 5-HT₂ receptor family. The effect of this mutation on 5HT potency in second messenger studies is being investigated. (Supported by MH40716 (M.T.))

480.10

PROBING THE SIGNAL TRANSDUCTION DOMAINS OF SEROTONIN 5-HT₂ RECEPTORS BY MUTAGENESIS. Y. Shu*, D. Pritchett, Children's Seashore House; Depts. of Ped. and Pharm., University of Pennsylvania; Phila., PA 19104

Serotonin 5HT₂ receptors are members of the G-protein coupled receptor family. Mutant or chimeric receptor studies with adrenergic and muscarinic receptors suggest that the third intracellular loop plays a role in signal transduction. To identify consensus sequences and pinpoint the specific amino acids necessary for signal transduction in 5HT₂ receptors, we used polymerase chain reaction to create a restriction site cassette flanking the third intracellular loop, and replaced the third loop with oligonucleotides to create deletion mutants. These mutant receptors were expressed in human embryonic kidney 293 cells, and screened with ketanserin binding assay, phosphoinositol hydrolysis assay, and aequorin expression assay. Aequorin expression assay is a method to measure intracellular calcium increase, based on bioluminescent aequorin expressed in 293 cells. A mutant deleting 49 amino acids from the center of the loop and leaving 7 amino acids on the N-terminal and 9 amino acids on the C-terminal can be expressed and has significant ketanserin binding and intracellular calcium increase upon serotonin treatment. All of the remaining amino acids in the loop can be deleted or non-conservatively substituted without destroying coupling to phosphoinositol hydrolysis. Three amino acids in the C-terminal appear to be required for receptor assembly as assayed by binding of ketanserin. No consensus sequence or specific amino acids have been identified through these intensive deletion studies to be absolutely necessary for signal transduction of 5HT₂ receptor. The lack of required amino acids in the third intracellular loop is consistent with the lack of a consensus amino acid sequence among other receptors coupled to phosphoinositol hydrolysis. Both of these observations call into questioning models which require protein-protein contact between the receptor and G-proteins in this area. Experiments demonstrating changes in coupling specificity due to changes in the third loop sequence are not inconsistent with models in which there are no direct contacts between G-proteins and the third intracellular loop of the receptor.

Site-Directed Mutagenesis of the 5-HT₂ Receptor: Identification of Amino Acids Involved in Ligand Binding and Receptor Activation by Agonists and Antagonists. Cheng-Dian Wang and Jean C. Shih*. Dept. of Mol. Pharm. and Tox., Sch. of Pharmacy, Univ. of Southern California, 1985 Zonal Avenue, Los Angeles, CA 90033

The 5-HT₂ receptor belongs to the G protein-coupled seven transmembrane domain receptor family. Stimulation of 5-HT₂ receptor by serotonin or other agonists activates phosphoinositide(PI) formation. The amino acids involved in the ligand binding domain and PI coupling of 5-HT₂ receptor were studied by site-directed mutagenesis. Mutants were assayed in stably transfected NIH3T3 cells by radioligand binding using [³H]ketanserin as the 5-HT₂ receptor specific ligand. Binding constants and the displacement profile of agonists and antagonists were compared to wild type receptor. The response to agonists stimulated PI turnover for each mutant and wild type 5-HT₂ receptor were also determined. Our results indicated Asp120 is involved in G protein-coupling whereas Asp155 is involved in ligand binding for 5-HT₂ receptor. Additional site-directed mutations were performed for aromatic amino acids(tryptophan, tyrosine and phenylalanine) and proline. The role of these residues in ligand binding and PI coupling to 5-HT₂ receptor will be discussed.(Supported by Merit Award R01 MH37020, R37 MH39085 and Research Scientist Award K05 MH00796, from the National Institute of Mental Health and Welin Professorship).

A RECOMBINANT HERPES SIMPLEX TYPE 1 VIRUS EXPRESSING ANTISENSE 5-HT₂ RECEPTORS. William W.-G. Jia¹, Leone Gatzke¹, Xiaoning Wu¹, Yihong Wang², Frank Tufano¹ and Max Cynader². ¹Department of Microbiology and Immunology, ²Department of Ophthalmology, University of British Columbia, Vancouver, B.C. Canada

Herpes simplex type-1 virus (HSV-1) possesses a great potential as a vector to transfer and stably express genes in neurons as it can efficiently infect neurons and establish latency, in which the viral DNA persists without causing detectable cytopathic effects in host cells. In the present study, a recombinant HSV-1 virus vTKSR2(-) was constructed by homologous recombination. The viral genome contains an antisense rat 5-HT₂ receptor sequence and a poly A addition sites driven by the CMV major immediate early promoter. Since it was inserted in the coding region of the viral thymidine kinase gene, the virus is replication defective in postmitotic cells. The insertion was confirmed by restriction enzyme digestion, PCR and southern blots. The generation of antisense transcripts in infected Green monkey kidney cells by 5 to 20h PI was detected by RNase protection assay. The TKSR2(-) virus was also used to infect primarily cultured cerebral cortical cells at MOI=1 and the expression of 5-HT₂ receptors in these cells was measured by binding of [³H]ketanserin, a 5-HT_{1C/2} antagonist. Specific binding to the cells infected with vTKSR2(-) was reduced by 66% at 16 hours postinfection compared to the control cells infected with the parental virus. The results show that foreign gene(s) can be carried by a HSV-1 virus and can be efficiently expressed in the nervous system. The TKSR2-2 recombinant virus may be useful for functional studies of 5-HT₂ receptors in development and plasticity of CNS by "knocking out" expression of the receptors in neurons in a relatively permanent manner.

481.1

PHARMACOLOGICAL CHARACTERIZATION OF A SEROTONIN RECEPTOR FROM MOLLUSCAN EMBRYOS. T.J. Diefenbach*, N.K. Koehncke, K.J. Christopher, C. Neumann and J.I. Goldberg. Dept. of Zoology, U. of Alberta, Edmonton, AB, Canada T6G 2E9.

Vertebrate serotonin (5-HT) receptors show broad diversity in tissue distribution, signal-transduction coupling, pharmacology and molecular structure. However, little is known about molluscan 5-HT receptors. *Helisoma trivolvis* embryos display a cilia-driven rotational behavior that is regulated by endogenous 5-HT. In this study, the receptors which mediate the cilio-excitatory action of 5-HT were pharmacologically characterized. Time-lapse video microscopy was used to quantify the effects of 5-HT agonists and antagonists using two assays: whole-embryo rotation rate and cilia beat frequency of isolated ciliated cells. In rotation experiments, 5-carboxamidotryptamine and methysergide had effective agonist activity in dose ranges similar to that of 5-HT (1-100 μ M). In contrast, 8-hydroxy-DPAT displayed agonist activity of lower potency and effectiveness. Several compounds displayed antagonist activity in the 1-100 μ M dose range, including mianserin, spiperone, ritanserin, 1-(1-naphthyl)piperazine and propranolol. α -methyl 5-HT had mixed agonist-antagonist activity. Metoclopramide and MDL-72222, antagonists of vertebrate 5-HT₃ receptors, displayed neither agonist nor antagonist activity. In experiments on isolated cells, the dose-dependency of the 5-HT stimulation of cilia beat frequency, and the effective antagonism by mianserin, were similar to those observed in the whole-embryo experiments. These results implicate the presence of a novel 5-HT receptor on ciliated cells of *Helisoma* embryos that share some pharmacological characteristics with the 5-HT₁ and 5-HT₂ vertebrate receptor families.

This research was supported by NSERC Canada.

DO NOVEL [³H]5-CT BINDING SITES IN RAT HABENULA REPRESENT 5-HT_{5A} OR 5-HT_{5B} RECEPTORS?

L.G. Iben*, H.P. Nowak, C.D. Mahle, and F.D. Yocca, CNS Drug Discovery, Bristol-Myers Squibb Co., Wallingford, CT 06492.

Novel 5-HT₅ receptors have been cloned from mouse (5-HT_{5A} and 5B; Matthes et al., *Mol. Pharmacol.*, 1993) and rat (5-HT_{5B}; Wisden et al., submitted) brain. [³H]5-carboxamidotryptamine ([³H]5-CT) displays high affinity for these receptors. *In situ* hybridization discretely localizes detectable levels of message for these receptors in the medial and lateral habenula for both species. Due to this specific localization, we sought to determine if these receptors could be identified in native tissue. To this end, we used saturation analysis and competition studies, while selectively masking 5-HT 1A, 1B, 1C, and 1D binding sites, to identify the [³H]5-CT sensitive binding sites present in these tissues. Saturation analysis of [³H]5-CT in rat habenula indicates the presence of two binding sites, both of which appear to be Gpp(NH)p insensitive. Competition studies performed using [³H]5-CT (1nM) reveal the following rank order potency: 5CT > 5-HT > dihydroergotamine > LSD > methiothepin > sumatriptan > 8-OH-DPAT > cyproheptadine. These data indicate the presence of two distinct [³H]5-CT sensitive binding sites in rat habenula. While the high affinity site may represent a 5-HT₅ "like" receptor, the low affinity site may represent a potentially novel [³H]5-CT sensitive receptor.

481.5

THE SELECTIVE 5-HT_{1A} RECEPTOR AGONIST (R)-8-OH-DPAT EXERTS A PREFERENTIAL STIMULATORY ACTION ON THE MESOCORTICAL DOPAMINE (DA) SYSTEM. L. Arborelius*, G.G. Nomikos, U. Hacksell and T.H. Svensson. Dept. of Pharmacology, Karolinska Institutet, Box 60400, S-10401 Stockholm, Sweden.

In the present study we have examined the effects of (R)-8-OH-DPAT on the neuronal activity of midbrain DA cells using extracellular single cell recording in anesthetized rats. (R)-8-OH-DPAT in low doses (2-32 μ g/kg i.v.) caused an increase in the firing rate of DA neurons in the ventral tegmental area (VTA), an effect that was more pronounced in the parabrachial pigmented nucleus (PBP) than in the paranigral nucleus (PN), two major subdivisions of the VTA. In contrast, (R)-8-OH-DPAT in this dose range did not affect the firing rate of DA neurons in the substantia nigra (SN). We have also used *in vivo* microdialysis in freely moving animals to study the effects of (R)-8-OH-DPAT on extracellular concentrations of DA, DOPAC and HVA in three dopaminergic terminal areas; the prefrontal cortex (PFC), which is predominantly innervated by DA neurons in the PBP; the nucleus accumbens (NAC), which receives DA projections from both the PBP and PN; and the dorsal striatum (STR), which is mainly innervated by DA neurons in the SN. (R)-8-OH-DPAT (25 μ g/kg s.c.) significantly increased DA concentrations in the PFC to approximately 140% and DOPAC and HVA to 120% of basal values, but had only minor effect on DA, DOPAC and HVA concentrations in the NAC or in the STR. These data support a preferential, stimulatory action of low doses of (R)-8-OH-DPAT on the mesocortical DA system. Since 5-HT_{1A} receptor agonists may possess antidepressant activity and depression seems associated with dysfunction of the PFC, our finding that (R)-8-OH-DPAT preferentially increases DA release in the PFC is of considerable interest.

CHARACTERIZATION OF THE INTERACTION OF (R) AND (S) RS-56812 AT 5-HT₃ RECEPTORS IN VITRO AND IN VIVO. E.H.F. Wong*, D.W. Bonhaus, E. Leung, K.H. Lee and R.M. Eglen. Institute of Pharmacology, Syntex Discovery Research, Palo Alto, CA 94304, USA.

5-HT₃ receptor antagonists have been reported to have a multitude of pharmacological effects in behavioral models for emesis, anxiolysis, cognition and psychosis actions (Costall et al., 1991). The availability of potent and selective antagonists for this receptor should help to establish mechanism(s) involved in conferring the above actions. The enantiomers of RS-56812 3-(1-azabicyclo[2.2.2]octan-3-yl) aminocarbonylcarbonyl-1-methylindole hydrochloride exhibit high affinities for the 5-HT₃ receptor (pK_i vs [³H]quipazine for (R) and (S) isomers were 9.3 \pm 0.1 and 7.8 \pm 0.1, respectively), and weak affinity at 30 other receptor binding assays (pK_i < 6.0). In the guinea-pig ileum functional assay for 5-HT₃ receptors, (S) RS 56812 was inactive as an agonist up to 100 mM, while (R) RS-56812 acted as a partial agonist (pEC₅₀: 6.3; intrinsic activity: 0.45). Both the (R) and (S) isomers of RS 56812 induced the von Bezold-Jarisch reflex with EC₅₀ of 1 and 100 mg/kg (i.v.), respectively. Evidence of partial agonism was indicated by a maximum response which was only 50% of that observed with 2-methyl-5-HT. Indeed, the bradycardia elicited by 2-methyl-5-HT was inhibited by (R) and (S) RS-56812 (IC₅₀ of 7.4 and 553 mg/kg, i.v., respectively). These *in vitro* and *in vivo* studies indicated that (R) and (S) RS 56812 were potent and selective 5-HT₃ receptor partial agonists. These compounds will facilitate investigation into the neurochemical basis of the behavioral effects of 5-HT₃ receptor antagonists.

481.4

DETERMINATION OF THE 5-HYDROXYTRYPTAMINE (5HT) RECEPTOR SUBTYPES MEDIATING THE EFFECTS OF 5HT ON FOS-LIKE IMMUNOREACTIVITY IN THE PARAVENTRICULAR NUCLEUS OF THE HYPOTHALAMUS. S. Bovoletto, C. Rouillard, J. Gervais, and D. Richard*. Department of Physiology, Faculty of Medicine, Laval University, Québec G1K-7P4, CANADA.

This study was carried out to determine the 5-hydroxytryptamine (5HT) receptor subtypes mediating the stimulating effects of 5HT on the expression of the primary response gene *c-fos* in the paraventricular nucleus (PVN) of the hypothalamus. In a first series of experiments PVN FOS-like immunoreactivity (FLI) was measured in *d,l*-fenfluramine-treated rats that were concomitantly injected with either i) the 5-HT-1.2 receptor antagonist methysergide (5 mg/kg), ii) the 5HT-1B receptor (-)-propranolol (3mg/kg), or iii) the 5HT-1C,2 receptor antagonist ritanserin (2 mg/kg). In a second series of animals, PVN FLI was determined in rats which were treated with i) the 5HT-1a receptor 8-OH-DPAT (2.5 mg/kg), ii) the 5HT-1b receptor CGS-12066B (10 mg/kg), iii) the 5HT-1C,2 receptor DOI (2.5 mg/kg), or iv) the 5HT-3 receptor 1-phenylbiguanide (5 mg/kg). Sixty minutes following the injections, rats were perfused via an intracardially inserted cannula with a 4% paraformaldehyde solution. FLI was measured in 40 μ m-thick slices using the peroxidase-avidin-biotin complex method. Methysergide prevented the marked increase in PVN FLI induced by the serotonin indirect agonist *d,l*-fenfluramine whereas both propranolol and ritanserin blunted the effect of *d,l*-fenfluramine without completely preventing it. DOI and 8-OH-DPAT led to a noticeable increase in FLI in PVN whereas CGS-12066B and 1-phenylbiguanide had no effect. The present results provide evidence for the involvement of 5HT-1A and 1C,2 receptor in the stimulating effects of 5HT in the expression of the early response gene *c-fos* in PVN.

PHARMACOLOGICAL CHARACTERIZATION OF LY293284, A SELECTIVE AND POTENT 5-HT_{1A} AGONIST. M.M. Foreman*, R.W. Fuller, D.L. Nelson, K. Rasmussen, D.T. Wong, D.O. Calligaro, C.J. Paget, M.E. Flaugh, R.N. Booher, J.E. Barrett¹ and L. Zhang². Lilly Res Labs, Eli Lilly Corp Ctr, Indianapolis, IN, 46285; ¹CNS Res Dept, Lederle Labs, American Cyanamid Co, Pearl River, NY, 10965; ²Dept of Psychiatry, Uniformed Serv Univ Hlth Sci, Bethesda, MD, 20814.

LY293284, (-)-4R-6-acetyl-4-(di-n-propylamino)1,3,4,5 tetrahydrobenz[c,d]indole, is a rigid tryptamine derivative with an acetyl group serving as a protophilic substitution for the hydroxyl in serotonin. In ligand displacement assays, LY293284 had a K_i of 0.13 nM for the 5-HT_{1A} receptor but no significant affinity for other monoaminergic receptors. In rats, LY293284 reduced hypothalamic 5-HIAA levels at 3 μ g/kg sc, increased serum corticosterone levels at 30 μ g/kg sc, reduced body temperature at 3 μ g/kg sc, induced lower lip retraction and flat posture at 10 μ g/kg sc, reduced ejaculatory latency at 10 ng/kg sc and suppressed firing rate of raphe neurons with an ED₅₀ of 8.5 ng/kg iv. LY293284 increased punished responding in pigeons at 3 μ g/kg im and decreased immobility time in the rat forced swim test at 30 μ g/kg sc, which are indices of potential anxiolytic and antidepressant activity, respectively. LY293284 is a novel selective 5-HT_{1A} receptor agonist that is 10-100 X more potent than 8-OH-DPAT in these tests.

[1-125]trans-8-OH-PIPAT: A NEW 5-HT_{1A} RECEPTOR LIGAND. H.F. Kung*, M.P. Kung and Z.P. Zhuang. Departments of Radiology and Pharmacology, University of Pennsylvania, Philadelphia, PA 19104

In order to prepare tracers with higher specific activity for *in vitro* and *in vivo* evaluation of 5-HT_{1A} receptor subtype, we have prepared a new iodinated ligand, (R,S)trans-8-hydroxy-2-(N-n-propyl-N-3'-iodo-2'-propenyl)aminotetralin (trans-8-OH-PIPAT), to supplant the currently used tracer [H-3]8-OH-DPAT. Binding studies with rat hippocampal membrane preparations showed that the iodinated compound exhibited a K_i value of 0.92 nM against (R,S)[H-3]8-OH-DPAT. Radiolabeled racemic [1-125]trans-8-OH-PIPAT was prepared from the corresponding tri-n-butyltin precursor via an iododestannylation reaction with sodium [1-125]iodide and hydrogen peroxide as the oxidant (purity >98%, sp. act. 2,000 Ci/mole). Saturation studies in the hippocampal homogenates revealed that [1-125]trans-8-OH-PIPAT bound to a single population of high affinity site with a K_d of 0.38 ± 0.03 nM. The B_{max} value (310 ± 20 fmol/mg of protein) was comparable to those measured by (R,S)[H-3]8-OH-DPAT under the same assay conditions. Competition binding experiments clearly indicated that the ligand displayed the 5-HT_{1A} receptor binding profile. The rank order of potency was: (R,S)trans-8-OH-PIPAT > (R,S)8-OH-DPAT > WB4101 > 5-HT > (R,S)trans-7-OH-PIPAT > (R,S)7-OH-DPAT > (R,S)propranolol > spiperone >> ketanserin >> dopamine > atropine. Recently, the racemic radioiodinated ligand was successfully separated into two isomers by high pressure liquid chromatography using a chiral column (retention time 19 and 24 min, respectively). The optically resolved ligand may prove to be more potent than the racemic mixture. This new iodinated ligand is an excellent probe for the investigation and characterization of 5-HT_{1A} receptors due to its high specific activity, high binding affinity and low nonspecific binding. Acknowledgement: Support from PHS (NS-24538 and MH-48125).

DISPLACEMENT OF 5-HYDROXYTRYPTAMINE BINDING IN THE SPINAL CORD BY SELECTIVE 5-HT RECEPTOR LIGANDS: AN AUTORADIOGRAPHIC ANALYSIS. L.M. Pabols* and S.D. Dawson R.S. Dow Neurological Sciences Institute, Portland, OR 97209.

Previous investigators have reported that high affinity (5-HT₁) 5-HT binding to spinal cord is not fully displaceable by any combination of known specific 5-HT receptor ligands. This study was undertaken to re-examine this question using a 5-HT uptake blocker, as well as selective 5-HT₁ agonists and antagonists. Quantitative receptor binding autoradiographic methods (Pabols et al., *Neurosci. Lett.*, 142:111, 1992) were used to evaluate displacement of 2 nM [³H]5-HT binding to individual rat spinal cord laminae. Blockers included 8-OH-DPAT, TFMP, mesulergine (MES), zimelidine (ZIM), and unlabelled 5-HT. Unlabelled 5-HT displaced an average of 82% of total binding, while a combination of DPAT, TFMP, and MES displaced an average of 70%. Displacement was not increased by the addition of ZIM (500 nM). A low concentration (100 nM) of ZIM alone failed to displace binding. Thus, the amount of unidentified 5-HT₁ binding is less for these data than reported previously, but some binding is still not accounted for. Differences were observed in the laminar pattern of displacement caused by the individual ligands, suggesting that 5-HT_{1A} and 1B sites predominate in the dorsal horn, and 1A and 1C sites in the ventral horn. (Support: NIH: NS19523)

481.11

IMMUNOLocalIZATION OF 5-HT_{1A} RECEPTORS IN THE NERVOUS SYSTEM OF THE BOWEL AND PANCREAS. A.L. Kirchgessner*, M.-T. Liu, J.R. Raymond and M.D. Gershon. Dept. of Anat. & Cell Biol., Columbia University, New York, NY 10032.

5-HT_{1A} receptors have been demonstrated in the guinea pig bowel by electrophysiological techniques and specific binding of [³H]-5-HT_{1A} agonists has been observed, both in the enteric plexuses and in the ganglionated plexus of the rat pancreas. mRNA encoding the 5-HT_{1A} receptor has also been detected in enteric neurons by *in situ* hybridization. Immunocytochemistry was employed to determine which neurons of the gut and pancreas express 5-HT_{1A} receptors. Antibodies generated against a peptide found in the third intracellular loop of the human 5-HT_{1A} receptor were utilized. 5-HT_{1A} receptor immunoreactivity was found on the surfaces of a subset of neurons in both the submucosal and myenteric plexuses in all regions of the rat and guinea pig bowel and in the guinea pig gall bladder. Immunolabeling was blocked by the peptide used to generate the antibody, but not by a control peptide. 5-HT-immunoreactive (ir) axons were found in close proximity to sites of 5-HT_{1A} immunoreactivity. Calbindin (CBP)-ir neurons (Dogiel type II cells) of the guinea pig myenteric plexus expressed 5-HT_{1A} immunoreactivity. Dogiel type I myenteric neurons that did not contain CBP immunoreactivity were also 5-HT_{1A}-ir. 5-HT_{1A}-ir myenteric neurons became doubly labeled following injections of the retrograde tracer, FluoroGold into the submucosal plexus. These injections also caused 5-HT_{1A}-ir neurons in distant submucosal ganglia to become doubly labeled. In the pancreas, 5-HT_{1A} immunoreactivity was observed on nerves, islet cells and exocrine ducts. These observations suggest that 5-HT_{1A} receptors are present on Dogiel type II myenteric neurons, which are known to be innervated by serotonergic neurons, and on submucosal interneurons. Pancreatic 5-HT_{1A} receptors may be located on the targets of serotonergic enteropancreatic axons. The abundance of 5-HT_{1A} receptor immunoreactivity on nerves of the gut and pancreas suggests that drugs designed to interact with these receptors may have visceral actions. PHARMACOLOGICAL CHARACTERIZATION OF A NOVEL [³H]DPAT BINDING SITE IN THE DORSAL RAPHE NUCLEUS. R.G. Johnson*, C.M. Severin and R. A. Rabin. Dept. of Pharmacology, SUNY BUFFALO, Buffalo, NY 14214.

This study was undertaken to characterize the properties of the [³H]DPAT binding site in the dorsal raphe nucleus (DRN). In DRN membranes, [³H]DPAT bound to a single homogeneous population of binding sites (Hill coef. -1) with a K_D of 16 nM. Unlike other 5HT receptor subtypes, the inclusion of magnesium decreased specific [³H]DPAT binding, while GTP had no effect. Similar magnesium and GTP effects were obtained in the DRN with [³H]5HT, indicating that these effects are not ligand specific. Of the various adrenergic, dopaminergic, and serotonergic ligands tested, only serotonin, spiperone, methiothepin, fluoxetine and citalopram showed appreciable affinity for the [³H]DPAT binding site in the DRN (K_i values 100-500 nM). However, the pharmacological profile of this binding site does not correspond to a current serotonergic receptor subtype or to the serotonergic transporter. Thus the present study describes a high affinity [³H]DPAT binding site in the DRN whose properties are not consistent with any currently recognized serotonin receptor subtype.

481.10

IDENTIFICATION OF mRNA ENCODING 5-HT RECEPTORS IN THE ENTERIC NERVOUS SYSTEM (ENS) E. Fiorica-Howells and M.D. Gershon. Dept. Anat. & Cell Biol., Columbia Univ. Coll. of P & S. New York, NY 10032

5-HT plays roles in the initiation of peristaltic reflexes and in neurotransmission in the ENS. Responses of the gut to 5-HT are difficult to analyze because subtypes of 5-HT receptor are present that have not yet been fully characterized. Pharmacological data suggest that the small intestine contains the 5-HT_{1A}, 1P, 2, 3, 4 and an additional receptor positively coupled to cAMP; all, except the 5-HT₃, are coupled to G proteins and thus are members of the 7-transmembrane domain receptor family. The current experiments were carried out to identify the 7-transmembrane domain 5-HT receptors expressed in the ENS of the guinea pig and rat small intestine. The polymerase chain reaction (PCR) was used. The PCR strategy takes advantage of the fact that highly conserved regions are present within the transmembrane domains of these receptors. Three different sets of degenerate primers were designed based on sequences found in the 3rd and 6th transmembrane domains. One set had maximum homology to the 5-HT_{1A}, 1B, and 1D receptors, the second with the 5-HT₂, 2F and 1C receptors, and the third with the 5-HT_{1E} receptor. The PCR reaction was carried out with total RNA or with poly A⁺ RNA from mucosa-free rat small intestine or from longitudinal muscle + myenteric plexus dissected from guinea pig ileum. As a positive control, RNA from the brain of each species was also studied using the same oligonucleotides. Many products of the expected size (400-650 bp) were obtained. Electrophoretic patterns of the products were tissue- and species-specific. PCR products were subcloned (pT7Blue plasmid) and sequenced. Several 7-transmembrane domain receptors were identified. These include the 5-HT_{2F} receptor, which was found in the rat small intestine, a receptor in guinea pig ileum that is 90% homologous to the human 5-HT₂ receptor, and a receptor in guinea pig brain that is 85% homologous to the human 5-HT_{1C} receptor. Each of these was obtained with 5-HT₂ receptor-based primers. This is the first report of a small intestinal 5-HT_{2F} receptor and of a 5-HT₂-related receptor in the guinea pig ileum. Finally, a substance P receptor was detected in the guinea pig ileum, using 5-HT_{1A}-related primers. It is concluded that PCR will enable enteric 7-transmembrane 5-HT receptors to be identified and cloned. Supported by NIH grants NS07062, NS12969 and NS 22637.

BIOCHEMICAL HETEROGENEITY OF [³H]8-OH-DPAT BINDING TO CNS 5HT_{1A} RECEPTORS: STUDIES USING THIOL REACTIVES.

E.K. Nénonéné*, F. Radja and T.A. Reader. Centre de recherche en sciences neurologiques, Université de Montréal (Québec) CANADA.

The heterogeneity of 5HT_{1A} receptors was investigated biochemically in rat cerebral cortex (Ctx) and hippocampus (Hip), by using L-dithiothreitol (L-DTT) to reduce disulfide bridges, or N-ethylmaleimide (NEM) to alkylate free sulfhydryls. L-DTT caused significant decreases of 2nM [³H]8-OH-DPAT binding in a dose-dependent manner. The inhibition curves for L-DTT were monophasic, with half maximal effects (IC₅₀) at 0.89 ± 0.12 and 0.27 ± 0.08 mM, for Ctx and Hip, respectively. These changes were fully reversible after one wash and could be prevented by previous occupancy of receptor sites by the ligand. The effect of NEM was also a dose-dependent inhibition of [³H]8-OH-DPAT binding but, contrary to L-DTT, the changes were irreversible and the curves biphasic. In Ctx the inhibition of binding by NEM showed a high-affinity IC₅₀ of 18.8 ± 4.5 μM, and a low-affinity IC₅₀ of 8.7 ± 2.9 mM. For Hip the IC₅₀ values were of 18.7 ± 1.95 μM and 14.4 ± 3.4 mM, respectively. After a 200 μM treatment with NEM, differences in spared [³H]8-OH-DPAT binding sites could be documented by autoradiography for several regions; the decreases in binding were greater in the CA1 region (32%) than in the Dentate gyrus (18.5%) or in the septum or Raphe nuclei (15%). These results show the role of disulfide and sulfhydryl groups in the primary ligand recognition site in Ctx and Hip and provide further evidence on 5HT_{1A} receptor heterogeneity. [Supported by the Savoy Found., the FRSQ and the MRC].

RECEPTOR RESERVE FOR 5-HT_{1A} RECEPTOR-MEDIATED INCREASE IN SERUM CORTICOSTERONE (CORT) IN THE RAT. K. Bohmaker* and E. Meller. Dept. of Psychiatry, NYU Medical Center, New York, NY 10016.

5-HT_{1A} receptor stimulation elicits increases in plasma CORT, ACTH, prolactin and growth hormone. These effects appear to be mediated by postsynaptic receptors in the hypothalamus which display high sensitivity to 8-OH-DPAT, and desensitization produces a large rightward shift in the dose-response curve for elevation of serum CORT (Kelder & Ross, 1992), suggesting the presence of a large receptor reserve (RR). The extent of RR was directly determined by the method of partial irreversible receptor inactivation. In control rats, 8-OH-DPAT maximally elevated serum CORT about 10-fold (ED₅₀ = 65 µg/kg). After treatment with the receptor inactivating agent N-ethoxycarbonyl-2-ethoxy-1,2-dihydroquinoline (EEDQ) (6 mg/kg), the dose-response curve for 8-OH-DPAT was shifted 4.3-fold to the right (ED₅₀ = 282 µg/kg) and the maximal response was reduced (to 7.5-fold increase). Analysis of the data yielded a hyperbolic receptor occupancy vs. response curve; half-maximal response occurred at 5.5% receptor occupancy. A RR of 75-80% was apparent. Since serum CORT is also regulated by 5-HT_{1A} and D2 receptors, and these receptors are also inactivated by EEDQ, the specificity of 5-HT_{1A} receptor mediation by 8-OH-DPAT was assessed. The attenuated response to 0.3 mg/kg 8-OH-DPAT in EEDQ-treated rats was almost completely prevented by pretreatment with the 5-HT_{1A} receptor antagonist pindolol (30 mg/kg) but was not affected by pretreatment with a drug cocktail (drug, mg/kg) to prevent inactivation of D1/D2 (cis-flupenthixol, 2), α₁ (prazosin, 5), α₂ (idazoxan, 1.25) and 5-HT₂ receptors (ketanserin, 10). Studies assessing the 5-HT_{1A} RR for other neuroendocrine hormones are in progress.

481.15

DISTRIBUTION OF 5-HT_{1B} AND 5-HT_{1D} SEROTONIN RECEPTOR mRNA IN THE RAT BRAIN. J.F. Neumaier*, D.M. Dorsa and M.W. Hamblin. GRECC, SVAMC, and the Department of Psychiatry and Behavioral Sciences, University of Washington, Seattle, WA 98108.

While the 5-HT_{1B} and 5-HT_{1D} (5-HT_{1Dβ} and 5-HT_{1Dα}) serotonin receptors serve as presynaptic terminal autoreceptors for serotonin, postsynaptic functions of these receptors have also been suggested. To determine the location of cells expressing these genes in the rat brain, we have undertaken a detailed mapping of these two closely related receptors.

A "cocktail" of three oligonucleotides complementary to different portions of either the 5-HT_{1B} or 5-HT_{1D} serotonin receptor mRNAs were end-labeled by the TDT reaction using ³³P-dATP. Standard *in situ* hybridization techniques were used on both coronal and sagittal rat brain sections. Hybridization of the probes to the tissue sections was detected using either film or emulsion dipped slides analyzed microscopically.

Hybridization signal for 5-HT_{1B} receptor mRNA expression was detected in a number of brain regions, most notably the hippocampal CA1 field, the striatum, nucleus accumbens, ventral tegmental area, purkinje layer of the cerebellum, dorsal raphe, and central gray. There was less prominent hybridization in a number of other regions, especially in nuclei of the thalamus and hypothalamus.

Hybridization signal for 5-HT_{1D} receptor mRNA expression was more scarce. It was prominent in the olfactory bulbs, major cell body layers of the hippocampal formation, dorsal raphe, central gray, and the granular layer of the cerebellum. It was also expressed in several other discrete brain regions at lower levels.

These overlapping, but distinct, distributions for the 5-HT_{1B} and 5-HT_{1D} receptors have physiological implications for understanding the roles of these receptors and the adaptation of the serotonergic system to pharmacologic challenges.

481.17

ONTOGENETIC DEVELOPMENT OF 5-HT_{1D} RECEPTORS IN HUMAN BRAIN: AN AUTORADIOGRAPHIC ANALYSIS. E. Pazos*, E. del Olmo, C. del Arco, A. Diaz, G. Mengod, J. Pascual and J.M. Palacios. ¹Dept. Physiol. Pharmacol., Univ. Cantabria, Santander; ²Dept. Neurochem., Cent. Invest. Des., CSIC, Barcelona; ³Res. Inst. Almirall Lab., Barcelona, Spain.

The pattern of ontogenetic development of brain 5-HT_{1D} receptors in the human brain was studied by autoradiography in tissue from 11 fetal and newborn cases (gestational ages between 25 and 40 weeks) and 4 infants. ¹²⁵I-GTI was used as a ligand. At gestational ages under the 32nd week, the density of these receptors was low in general terms though the substantia nigra and the basal ganglia already exhibited relevant densities of specific binding. In newborns, 5-HT_{1D} receptors were present at high or very high densities in the globus pallidus (lateral and medial parts), substantia nigra and visual cortex. Lower but still important levels of ¹²⁵I-GTI specific binding were on the caudate and putamen and, at a lesser degree, over the frontal cortex. This distribution is in good correlation with that previously reported in the adult. A progressive increase in the amount of these receptors was observed during the postnatal period, reaching adult levels at the first decade of life. These results demonstrate the existence of a clear delay in the ontogenetic appearance of 5-HT_{1D} receptors in the human, when compared to that found for 5-HT_{1A} receptors (Supported by DGICYT, Ministry of Education, PM88-0170)

[³H]-SEROTONIN BINDING TO 5-HT_{1D} RECEPTORS IN THE FERRET CORTEX. N.T. Brammer, C. Ennis and M.C.W. Minchin*.

Biomedical Research Dept. Wyeth Research (U.K.) Ltd. Taplow, Maidenhead, SL6 0PH England.

5-HT_{1D} binding sites have been reported in a number of non-rodent species (Bruinvels et al, 1992). This study was performed in order to investigate if the ferret could be used as an alternative small laboratory animal to guinea-pig in which to study 5-HT_{1D} receptors. Under conditions where the binding of [³H]-serotonin to 5-HT_{1A}, 5-HT_{1C} and 5-HT₂ sites was blocked with 8-OH-DPAT (100 nM) and mesulergine (100 nM) a single binding site (K_D = 7.4±0.5 nM; B_{max} = 138±5 fmoles/mg protein was observed in ferret cortical membranes.

In competition studies serotonin displaced [³H]-serotonin in a monophasic manner whereas biphasic curves were obtained with 5-CT, sumatriptan and CGS 12066B, all with a high affinity component in the nM range. Idazoxan, prazosin and R,S-zacopride did not compete with the radioligand for this binding site.

In order to discriminate between 5-HT_{1D} and possible 5-HT_{1B} binding sites competition curves were constructed using known 5-HT_{1B} ligands and compared to the binding profile in species previously shown to possess 5-HT_{1D} sites (pig, Beer et al, 1992) or 5-HT_{1B} sites (rat, Hoyer et al, 1985). The compounds (-)propranolol, (±)pindolol and CP93,129 produced monophasic competition curves for the pig and ferret (IC₅₀ values = 2318, 4355 and 6166 nM for the pig; 2197, 2344 and 4755 nM for the ferret). However, in the rat a biphasic curve was obtained for all three compounds with an IC₅₀ for the high affinity site = 6.47, 6.87 and 12.87 nM respectively, for the three compounds examined.

481.16

IN SITU HYBRIDIZATION EVIDENCE OF THE SYNTHESIS OF 5-HT_{1B} RECEPTORS IN CENTRAL SEROTONINERGIC NEURONS. E. Doucet, M.B. Emerit, M. Pohl, S. ElMestikawy, J. Adrien, B. Berger*, M. Hamon. INSERM U288, CHU Pitié Salpêtrière, 91 Bd de l'Hôpital, 75013 PARIS, FRANCE.

The regional distribution of the mRNA encoding the serotonin 5HT_{1B} receptor was studied in the rat brain by *in situ* hybridization histochemistry and Northern blot analysis. A 200 bp probe, corresponding to a highly selective portion of the third intracellular loop of the rat 5HT_{1B} receptor, was used. In most brain structures a single ~5kb message was found by Northern analyses. However, two additional bands (~2.5 and 4kb) were detected in the striatum. The rank order of 5HT_{1B} mRNA abundance was as follows: striatum > septum = substantia nigra = colliculi = hypothalamus > hippocampus = cerebellum = brainstem > dorsal horn of the spinal cord > cerebral cortex > ventral horn of the spinal cord > olfactory tubercle. This general pattern of distribution was confirmed by *in situ* hybridization, but with a higher degree of resolution. In particular the 5HT_{1B} mRNA was visualized in the layer IV of cerebral cortex, the Purkinje and molecular cell layers of the cerebellum, the pyramidal neurons in the CA1 area of the hippocampus and the dorsal raphe nucleus, (DRN). *In situ* hybridization was also performed in nomifensine (10mg/Kg i.p.) pretreated rats whose 5HT neurons were extensively and selectively lesioned by the microinjection of 5,7-dihydroxytryptamine (5,7-DHT, 8µg/1µl) directly in the antero-ventral vicinity of anterior raphe nuclei three weeks before sacrifice. In 5,7-DHT-lesioned rats, 5HT_{1B} mRNA was present in the same areas as in control rats, except in the DRN where it was no longer detected. These data provided the first demonstration of the synthesis of 5HT_{1B} receptor within DRN 5HT neurons, as expected of their presynaptic autoreceptor function at the level of serotonergic terminals.

MOLECULAR AND PHARMACOLOGICAL CHARACTERIZATION OF HUMAN 5-HT RECEPTOR SUBTYPES. N. Stam*, P. Vanderheyden, Th. de Boer, C. Van Alebeek, J. Klomp and W. Olijve. Scientific Development Group, Organon Int. B.V., P.O. Box 20, 5340 BH Oss, The Netherlands.

Pharmacological and molecular studies have revealed the existence of multiple receptor subtypes for the neurotransmitter serotonin (5-HT) both in the central and peripheral nervous system. These subtypes are divided into four major pharmacological classes (5-HT₁-like to 5-HT₄-like, based on their pharmacological and functional characteristics. Molecular cloning and expression of the distinct receptor subtypes in Swiss 3T3 cells allows a detailed pharmacological and functional characterization of the individual receptor subtypes.

The coding sequences for the 5-HT_{1A}, the 5-HT_{1Dβ}, the 5-HT_{1C}, and the 5HT₂ receptor subtypes were obtained by screening genomic and cDNA libraries with probes corresponding to transmembrane regions, under low stringency conditions. Cells transfected with the 5-HT_{1A} receptor displayed a single high affinity site for the agonists [³H]-OH-DPAT and [³H]-5-HT (K_d = 0.7 and 2 nM, respectively). Exposure of these cells to 5-HT resulted in a dose dependent inhibition of forskolin-stimulated cAMP levels. The 5-HT₂ transfectants expressed a single high affinity binding site for the antagonist [³H]-ketanserin (K_d = 1.7 nM) and showed a pharmacological profile very similar to that of the rat 5-HT₂ receptor in frontal cortex. High affinity binding sites were found in cells expressing the human 5-HT_{1C} receptor for [³H]-mesulergine (K_d = 3 nM) and [³H]-5-HT (K_d = 5 nM). Whereas the 5-HT_{1A} and 5-HT_{1Dβ} receptors were negatively coupled to adenylate cyclase, both the 5-HT₂ and 5-HT_{1C} receptor subtypes were functionally linked with phospho-lipase C. These data, together with data on the genomic organization of these receptors indicate that the 5-HT_{1C} receptor subtype belongs to the subclass of 5-HT₂-like receptors, rather than being a member of the 5-HT₁-like receptor subclass.

481.19

DIFFERENTIAL DOSE-DEPENDENT INACTIVATION OF BRAIN SEROTONIN RECOGNITION SITES BY EEDQ: LACK OF INACTIVATION OF THE 5-HT TRANSPORTER. W. Pinto, D. Guran, A.G. Karczmar* and G. Battaglia. Department of Pharmacology and Neuroscience Program, Loyola University of Chicago, Stritch School of Medicine, Maywood, IL 60153.

In vivo, EEDQ (N-ethoxycarbonyl-2-ethoxy-1,2-dihydroquinoline) can inactivate several brain monoamine receptors by affecting the ligand recognition site. Following irreversible inactivation by EEDQ, receptor recovery can be monitored and the data used to determine receptor turnover parameters (i.e. receptor production and degradation rate constants). The present study investigates the feasibility of using EEDQ as a tool to inactivate various brain 5-HT recognition sites. Adult male Sprague-Dawley rats were given a single s.c. injection of vehicle (1:1 EtOH/H₂O) or EEDQ (1, 3, 6 and 10 mg/kg) and sacrificed 4 hours post-injection. Brain regions were dissected and frozen until assay. Saturation studies of 5-HT uptake sites (³H-paroxetine), 5-HT_{1A} (³H-DPAT), 5-HT_{1B} (¹²⁵I-CYP), 5-HT₂ (³H-ketanserin) and 5-HT_{2/1C} (¹²⁵I-DO) receptors were carried out in cortical homogenates. EEDQ dose-dependently reduced the B_{max} of each of the receptors (76-89%) but was without effect on the 5-HT transporter recognition site, even at the highest dose. The K_D of 5-HT_{1A} receptors was increased, but only at the higher doses of EEDQ. There were no significant effects of any dose of EEDQ on the affinity of the 5-HT_{1B}, 5-HT₂ or 5-HT_{2/1C} receptors. The present data indicate a differential dose-dependent inactivation of 5-HT recognition sites by EEDQ with the following rank order of sensitivity: 5-HT_{1A} > 5-HT₂ ≈ 5-HT_{2/1C} > 5-HT_{1B} >>> 5-HT uptake sites. These findings demonstrate: (1) EEDQ can differentially inactivate 5-HT receptor subtypes and therefore can be a useful tool to study 5-HT receptor turnover kinetics and (2) EEDQ does not inactivate the ligand recognition site of the 5-HT transporter. RECEPTORIAL PROFILES OF ATYPICAL ANTIPSYCHOTICS AT CLONED, HUMAN DOPAMINE D₂ AND D₃ RECEPTORS AND AT RAT D₂ AND 5-HT_{1C/2} RECEPTORS IN VITRO/EX VIVO. V. Audinot*, H. Canton, V. Jacques, L. Verrièle and M.J. Millan. I.D.R.S., 7 rue Ampère, 92800 Puteaux - France.

Whereas the typical neuroleptic, haloperidol, interacts primarily with dopamine D₂ receptors, the atypical antipsychotic, clozapine, also displays marked affinity for 5-HT_{1C/2} receptors. As the novel antipsychotics, risperidone, sertindole, amperozide and ocapiridone possess an atypical profile in preclinical studies, we evaluated their actions at 5-HT_{1C/2} and D₂ receptors in the rat *ex vivo*. The tracers were: D₂ ([³H]-spiperone, striatum); 5-HT_{1C} ([³H]-mesulergine, choroid plexus) and 5-HT₂ ([³H]-ketanserin, cortex). In view of the putative relevance of D₂ receptors to schizophrenia, we also examined actions at cloned, human D₂ and D₃ receptors: ([³H]-iodosulpride, transfected CHO cells). Results are given as pK_i (*in vitro*) and % displacement (*ex vivo*) c.f. vehicle (= 0%) at the dose specified in mg/kg, s.c.. Drugs were given 60 min pre-specific.

DRUG	DOSE (ex vivo)	5-HT _{1C} pK _i /%	5-HT ₂ pK _i /%	D ₂ pK _i /%	D ₂ (h) pK _i	D ₃ (h) pK _i
HALOPERIDOL	(2.5)	5.2/0	7.1/34	8.7/69	9.2	8.5
CLOZAPINE	(10.0)	8.1/62	7.6/78	6.6/18	7.1	6.6
RISPERIDONE	(2.5)	7.5/10	9.2/79	8.3/7	8.5	8.0
OCAPIRIDONE	(0.63)	7.7/0	8.9/70	9.0/23	9.2	8.6
SERTINDOLE	(2.5)	9.0/85	8.8/81	8.3/14	8.6	8.1
AMPEROZIDE	(40.0)	5.7/0	7.1/49	6.1/14	6.2	6.2

As compared to their actions at D₂ receptors, all antipsychotics except haloperidol exerted pronounced actions at 5-HT₂ or 5-HT_{1C/2} receptors. However, no ligand showed preferential activity at D₃ versus D₂ receptors. These data suggest that actions at 5-HT_{1C/2} receptors may contribute to the distinctive profiles of atypical antipsychotics.

SEROTONIN: NEUROTOXINS, BEHAVIOR AND PHYSIOLOGY

482.1

EVIDENCE FOR SEROTONIN NEUROTOXICITY IN RECREATIONAL MDMA ("ECSTASY") USERS: A CONTROLLED STUDY. U.D. McCann*, A. Ridenour, Y. Shaham, and G.A. Ricaurte. Department of Neurology, Johns Hopkins Medical Institutions, Baltimore, Maryland 21224

3,4-Methylenedioxyamphetamine (MDMA), an increasingly popular recreational drug, is known to damage brain serotonin neurons in animals, including nonhuman primates. Whether MDMA is neurotoxic in humans has not been established. Twenty-nine MDMA users and 24 controls were admitted to a controlled inpatient setting for measurement of biological and behavioral indexes of serotonin function. Outcome measures, obtained after at least two weeks of drug abstinence, included concentrations of monoamine metabolites in cerebrospinal fluid (CSF), prolactin responses to L-tryptophan, nociceptive responses to ischemic pain, and personality characteristics in which serotonin has been implicated (i.e., impulsivity and aggression). MDMA subjects had lower levels of 5-hydroxyindoleacetic acid (5-HIAA, the major metabolite of serotonin) in CSF than controls (p=0.008). Although not different from controls in their prolactin response to L-tryptophan, MDMA users had lower tolerance to ischemic pain (p=0.05) and lower scores on assaultiveness (p=0.04) and indirect hostility (p=0.02) personality scales. These results suggest that serotonin neurotoxicity is a potential complication of recreational MDMA use. Further studies of MDMA-exposed individuals could help elucidate the role of serotonin in normal brain function as well as in neuropsychiatric disease states. [Supported by DA05938 and MO1RR02719]

482.3

RELATION OF BRAIN LEVELS OF DEXFENFLURAMINE (DFEN) TO DEPLETION OF SEROTONERGIC (5HT) MARKERS AFTER CHRONIC TREATMENT IN GENETICALLY OBESE MICE. N.E. Rowland*. Psychology, Univ. of Florida, Gainesville FL 32611-2065.

DFEN, and its metabolite dexnorfenfluramine (DNOR), produce long-lasting depletions of brain 5HT markers in animals. The relationship between brain concentrations of DFEN or DNOR and 5HT during chronic administration is unknown. Mice were used because, like humans, they metabolize DFEN to DNOR slowly. Obese (ob/ob) and lean mice were given a 2 wk regimen of DFEN (0, 6 or 24 mg/kg/day via SC-impanted minipump) and were killed either on the last day of infusion, or 3 or 14 days thereafter. Hemibrain and plasma samples were assayed for DFEN and DNOR. The other hemibrain was assayed for [³H]-paroxetine binding, an index of 5HT uptake capacity. Mice treated with 24, but not 6 mg/kg/day had 40% depletions of paroxetine binding at all 3 survival times. Brain concentrations of DFEN and DNOR increased about 6-fold with the 4-fold increase in dose. Concentrations of less than about 10⁻⁵M were not associated with loss of 5HT uptake sites. Dose-dependency of DFEN and DNOR action on 5HT cells will be discussed. [Supported by I.R.I. SERVIER. DFEN was assayed by D.B. Campbell (Servier UK)].

482.2

REORGANIZATION OF ASCENDING 5-HT PROJECTIONS AFTER MDMA INJURY. G.A. Ricaurte*, C.A. Fischer, G. Hatzidimitriou, J.L. Katz. Department of Neurology, Johns Hopkins Medical Institutions, Baltimore, MD 21224.

3,4-Methylenedioxyamphetamine (MDMA), a synthetic amphetamine analog with abuse potential, induces a chemical axotomy of central 5-HT neurons in experimental animals and, possibly, humans. Presently there is a lack of consensus regarding the fate of 5-HT neurons following MDMA injury. In rodents, there is evidence that 5-HT projections recover, but the extent and duration of the recovery remain uncertain; in nonhuman primates, the data indicate that some 5-HT projections recover (e.g., those to hypothalamus), while others do not (e.g., those to dorsal neocortex). To further study 5-HT axonal recovery after MDMA injury, we have examined ascending 5-HT projections in rats and squirrel monkeys treated with MDMA 1-2 years previously. Neurochemical and quantitative autoradiographic studies indicate that in most MDMA-treated rats, ascending 5-HT axons recover and reinnervate their targets in a pattern approaching that observed in controls. In some MDMA-treated rodents (approximately 25%), 5-HT axonal recovery does not take place, at least not in brain regions that are: a) initially very severely affected by MDMA, b) distant from the rostral raphe nuclei and/or c) far removed from a main 5-HT axon bundle (e.g., MFB). Interestingly, in these same animals, brain regions that originally sustain less severe MDMA injury, are closer to the rostral raphe nuclei and/or in proximity to the MFB recover substantially, often excessively. Such brain regions include the hypothalamus, amygdala, olfactory tubercle and septum. In the MDMA-treated primate, this pattern of persistent denervation in some brain regions with hyperinnervation of others is the rule rather than the exception. These results, which are reminiscent of previous findings with 5,7-DHT, indicate that in some rodents and in most nonhuman primates MDMA injury leads to a lasting reorganization of ascending 5-HT projections. [Supported by DA05707]

482.4

NMDA- AND AMPA- GLUTAMATE RECEPTORS AND 5-HT DEPLETION INDUCED BY REPEATED ADMINISTRATION OF HIGH DOSES OF DEXFENFLURAMINE IN RAT BRAIN. A.M. Gardier*, C. Rocher and C. Jacquot. Dept. Pharmacol. Fac. Pharmacie, Chateau-Malabry 92290, France.

Dexfenfluramine (d-fen) is an indirect serotonergic agonist which releases serotonin (5-HT) and blocks the neurotransmitter reuptake. The reason why repeated administration of high doses of d-fen reduces brain 5-HT is still unclear. We recently shown that autoreceptors located at nerve terminals are involved in this phenomenon (Gardier et al., *Brain Res.*, 588: 67-74, 1992) but heteroreceptors may also. Since a glutamate receptor-mediated control of brain 5-HT release has been described (Whitton et al., *J. Neurochem.*, 58: 1573-75, 1992), we tested the effects of two antagonists of either NMDA or AMPA type of excitatory amino acid receptors (dizocilpine=MK-801: 0.5, 1, 2.5 mg/kg i.p. or 2,3-dihydroxy-6-sulfamoyl-benzo(F)quinoxaline=NBQX: 3, 10, 30 mg/kg i.p., respectively) on d-fen-induced depletion of brain 5-HT. 5-HT and DA metabolites were studied after treatment with d-fen (5 injections of 1.3, 2.5, 5 & 10 mg/kg i.p., at 2 h intervals) in conjunction with 2 injections of MK-801, or NBQX administered 15 min. before and 3 h after the first d-fen injection. 3 days post-treatment, d-fen dose-dependently reduced 5-HT levels (by between 40 and 70% depending on the region examined). 2.5 mg/kg MK-801 alone decreased striatal HVA (-36%) and hypothalamic DOPAC (-21%) levels, while 10 mg/kg NBQX alone did alter DA metabolism but increased hypothalamic 5-HT levels (+43%). MK-801+d-fen did not change the d-fen-induced 5-HT depletions in all brain areas studied. At the highest dose, NBQX enhanced hypothalamic depletion of 5-HT induced by 10 mg/kg d-fen. Thus, central effects of NBQX, a selective antagonist at AMPA receptors, need to be confirmed in view of recent data showing that probenecid, by inhibiting the transport of NBQX out of brain tissue, may prolong its central effects (Taylor and Vartanian, *Eur.J.Pharmacol.*, 213:151-153, 1992).

482.5

SHORT TERM MDMA AND METHAMPHETAMINE ADMINISTRATION IN RATS FAILS TO REDUCE NEUROENDOCRINE RESPONSES TO A 5-HT RELEASER. G. Battaglia, F. Tung, L.D. Van de Kar and D. Guran, Department of Pharmacology, Loyola University of Chicago, Maywood, IL 60153.

Short term administration of MDMA (3,4-methylenedioxymethamphetamine) or methamphetamine (METH) produces neurotoxic effects on brain serotonin (5-HT) axons and terminals. We hypothesized that functional changes in 5-HT mediated plasma hormone responses to a 5-HT releaser, such as p-chloroamphetamine (PCA), may provide a peripheral marker of central 5-HT neurotoxicity. Male Sprague-Dawley rats (175-200 g) were administered saline (1ml/kg), MDMA (20 mg/kg equiv. as free base) or METH (20 mg/kg) s.c. b.i.d. for four days. Two weeks post-treatment, rats from each group were administered saline or PCA (8 mg/kg, i.p.) and sacrificed 1 hour later. MDMA markedly reduced 5-HT uptake sites in cortex (-61%), hippocampus (-52%), striatum (-56%), midbrain (-59%) & hypothalamus (-64%), confirming the loss of 5-HT axons and terminals. In contrast, METH significantly decreased 5-HT uptake sites in cortex, hippocampus and midbrain, but not in hypothalamus or striatum. Functional alterations in 5-HT systems were determined by changes in the stimulation of plasma hormones by PCA. Neither MDMA nor METH attenuated the PCA stimulation of plasma ACTH, renin or prolactin. The corticosterone response to PCA was increased (+42%) by METH. There were no apparent compensatory changes in 5-HT receptors, as cortical 5-HT_{1A}, 5-HT_{1B} or 5-HT₂ receptors were unchanged. These data indicate that plasma hormone responses to a 5-HT releaser may not provide an index for gross central neurotoxicity. The lack of reductions in all neuroendocrine responses following PCA suggests that (1) 5-HT projections to hypothalamic nuclei mediating these responses are unaffected or (2) that the remaining 5-HT terminals are sufficient to produce a maximal response. (Supported by Loyola University Potts Foundation and MH 45812).

482.7

DIFFERENTIAL REGULATION OF 5-HT_{1A}-MEDIATED

RESPONSES. P.A. Scott*, J. Chou, & A. Frazer. Dept. of Psychiat, Univ. of Pa. Sch. of Med. and Vet. Affairs Med. Ctr., Phila., PA 19104.

In the rat, 5-HT_{1A} receptor activation causes hypothermia and the 5-HT syndrome (flat body posture, forepaw treading, side-to-side body movement, and resting tremor). Of these latter symptoms, forepaw treading in rats pretreated with reserpine seems most directly linked to activation of 5-HT_{1A} receptors. We have previously reported the effects of three structurally dissimilar types of 5-HT_{1A} agonists on these two responses (Soc. Neurosci. Abstr., 18: 1383, 1992). The three agonists (the tetralin derivative, 8-hydroxy-2-(di-n-propylamino)tetralin (8-OH-DPAT); the substituted azapirone gepirone; and the methoxy-chroman derivative (+) S-20499) all induced comparable degrees of hypothermia, albeit with different potencies (8-OH-DPAT > gepirone > (+) S-20499). By contrast, only 8-OH-DPAT induced the 5-HT syndrome. We now report that (+) S-20499 is unable to either induce or antagonize the forepaw treading caused by either 8-OH-DPAT or 5-methoxy-N,N-dimethyltryptamine (5-MeODMT) in reserpine pretreated rats (1.0 mg/kg s.c.; 18-24 hrs prior to experiment). Treatment with either 8-OH-DPAT (4.0 mg/kg) or 5-MeODMT (5.0 mg/kg) induced high levels of forepaw treading, whereas treatment with either gepirone (10 mg/kg) or (+) S-20499 (at doses up to 75 mg/kg) did not. These doses of gepirone and (+) S-20499 are about 5-10 fold higher than their respective EC₅₀ doses in causing hypothermia. Pretreatment with gepirone (5-10 mg/kg) attenuated the forepaw treading induced by either 8-OH-DPAT or 5-MeODMT. By contrast, pretreatment with (+) S-20499 (75 mg/kg) did not attenuate the forepaw treading induced by these drugs. The inability of (+) S-20499 to either induce or antagonize forepaw treading is unlikely to be due to its inability to penetrate into brain (calculated partition coefficient: log p > 2). One possible explanation for the actions of (+) S-20499 is that there are subtypes of the 5-HT_{1A} receptor that differentially mediate hypothermia and the 5-HT syndrome and that (+) S-20499 is capable of discriminating between these putative subtypes. (Supported by Research Funds from the VA, USPHS Grant MH48125, and IRI Servier).

482.9

PHARMACOLOGICAL DIFFERENCES BETWEEN 5-HT_{1A}-INDUCED DEFENSIVENESS AND INHIBITION OF VOMITING IN CATS. J.B. Lucot*, Dept. Pharmacol., Wright State Univ. Dayton, OH 45435.

5-HT_{1A} agonists exert a broad-spectrum antiemetic effect. Individual agonists differ in the doses that elicit defensiveness compared with those which suppress vomiting; e.g. buspirone elicits defensiveness at doses that suppress motion sickness while flesinoxan and DPAT elicit defensiveness at doses higher than those which suppress motion sickness. The defensive behavior elicited by flesinoxan and DPAT is blocked by NAN-190, whereas it was more effective at reversing the antiemetic effect of flesinoxan than of DPAT. (-)Propranolol was less effective at reducing defensive behavior. LY 285271, which is a selective, high affinity full agonist on standard measures of 5-HT_{1A} receptor function, was remarkably weak at suppressing motion sickness but elicited very strong defensive behavior. It also did not reverse the antiemetic effect of flesinoxan or DPAT suggesting that it bound weakly to the antiemetic site. The 5-HT_{1A} sites which elicit defensive behavior are pharmacologically different from those which are antiemetic.

482.6

REGIONAL CNS MONOAMINE METABOLISM AND SEROTONIN (5HT) IMMUNOREACTIVE (IR) NEURONS IN MALE F344 RATS EXPOSED TO REPEATED HIGH DOSES OF (+)FENFLURAMINE (d-FEN): EFFECTS OF PRETREATMENT WITH THE MONOAMINE OXIDASE INHIBITOR (MAOI) TRANYLCYPROMINE (TCP). M. George, J.M. Lee* and S.A. Lorens. Departments of Pharmacology and Pathology, Loyola University Chicago Medical Center (Bldg. 135), Maywood IL 60153.

Immunohistochemical (IHC) studies which have examined the effects of d-FEN, a 5HT releaser and reuptake inhibitor, on 5HT IR neuronal processes have employed a MAOI in order to increase the concentration of the antigen (5HT) to microscopically detectable levels, particularly in axons and terminals. Our objective was to document the effects of a MAOI on the regional CNS concentrations of 5HT, norepinephrine (NE) and dopamine (DA), and their metabolites, in vehicle (VEH) and d-FEN treated rats. We thus assayed by HPLC the concentrations of these monoamines and their metabolites 2 weeks after d-FEN (12 mg/kg, s.c., b.i.d. x 4 consecutive days) or VEH (1.0 ml/kg, s.c., b.i.d. x 4 days) treatment, and 2.0 h after TCP (10.0 mg/kg, i.p.) or saline (SAL, 1.0 ml/kg, i.p.) administration. Although d-FEN reduced regional CNS 5HT and 5HIAA concentrations, pretreatment of the d-FEN rats with TCP resulted in substantial elevations in 5HT content with concomitant decreases in 5HIAA levels. Similarly, the MAOI also increased the concentrations of both NE and DA while reducing the levels of their metabolites. These data indicate that rats treated with repeated high doses of d-FEN are quite capable of synthesizing 5HT. This view is supported by our 5HT IHC results which showed regionally distinct enhanced 5HT IR in both the d-FEN and VEH rats. These findings may explain why other laboratories have reported aberrant and/or reduced 5-HT IR after d-FEN in certain brain areas. Our results clearly suggest that although daily high doses of d-FEN can produce significant reductions in CNS 5HT and 5HIAA concentrations, consistent with its mechanism of action, it does not produce neurotoxicity.

482.8

EFFECT OF 5-HT_{1A} AGONISTS ON THE LOCOMOTOR ACTIVITY OF GUINEA PIGS. J.L. Evenden*, Department of Behavioural Pharmacology, Astra Arcus AB, Södertälje, S-151 85, Sweden.

The prototypical 5-HT_{1A} agonist, 8-OH-DPAT, generally reduces the locomotor activity of naive rats and mice. However, species specific differences have been seen in the effects of this drug on other aspects of behaviour e.g. the 5-HT syndrome (rats vs mice), or body temperature (rats vs guinea pigs). The present study was conducted to examine the effects of 8-OH-DPAT on locomotor activity (LA) in the guinea pig in an 80 by 80 cm open field, and to compare the effects of this drug with other 5-HT_{1A} agonists. In this species, doses of 1.0 to 10.0 mg/kg of the drug increased LA to a level of about 5 times that seen in control. Similar effects were seen with 5-MeODMT (1.0 - 10.0 mg/kg) and flesinoxan (3.0 and 10.0 mg/kg). Buspirone (10.0-100.0 mg/kg) also marginally increased LA, whereas ipsapirone (up to 30 mg/kg) had no significant effect. Dopamine D2 receptor blockade using the selective antagonist, raclopride (0.1 - 3.0 mg/kg) neither increased nor decreased LA. The increase in LA induced by 1.0 mg/kg 8-OH-DPAT was attenuated by ipsapirone (30 mg/kg) and raclopride (3.0 mg/kg) but was, if anything, enhanced by pretreatment with the beta-blocker and 5-HT_{1A} antagonist (-) alprenolol (15 mg/kg). However, the most notable blockade was obtained with the relatively selective 5-HT_{1A} antagonist (-)-UH-301, which reduced LA to control levels. These results suggest that hyperactivity is a major component of the 5-HT syndrome mediated by 5-HT_{1A} receptors in the guinea pig. This hyperactivity is only seen after administration of relatively full agonist, and is only weakly detectable after partial agonists, which may themselves antagonise the effects of 8-OH-DPAT. The relatively low levels of locomotor activity shown by guinea pigs in this test may underlie these effects of the drugs, since 8-OH-DPAT can increase activity in rats which have been habituated to the apparatus (Evenden and Ångeby-Möller, 1990)

QUIPAZINE-KETANSERIN DRUG DISCRIMINATION PROVIDES A BEHAVIORAL BASELINE SENSITIVE TO CHANGES IN SEROTONIN-2 RECEPTOR ACTIVITY. R.L. Smith*, E. Sanders-Bush and R.J. Barrett. Dept. of Pharmacology, Vanderbilt University and V.A. Medical Center, Nashville, TN 37232.

The present study was conducted to determine first, whether animals could be trained to discriminate a serotonin-2 (5HT₂) agonist from a 5HT₂ antagonist, and second, the usefulness of this model for studying adaptive changes in the 5HT₂ receptor system and for characterizing novel serotonin compounds. Rats were trained to discriminate quipazine (QUIP) (0.5 mg/kg) from ketanserin (KET) (1.0 mg/kg) on a VI-20 schedule of reinforcement. Training doses were adjusted so that when the animals were tested on saline 48 h after the last acquisition session, they made 42% of their responses on the QUIP lever. Following acquisition, a QUIP-KET dose-response function was found to be orderly and reproducible. Additional 5HT₂ agonists (DOI and MK 212) and antagonists (pizotifen and cyproheptadine) were tested for generalization and found to substitute for QUIP and KET, respectively. A single large dose of QUIP (20 mg/kg) produced a rebound KET-like effect 20 h following administration; however, a single large dose of KET (10 mg/kg) did not produce a rebound QUIP-like effect. Additional novel serotonin compounds are presently being tested against this unique behavioral baseline. (Supported by USPHS Grant MH34007 and Fellowship DA05413)

ROLE OF SEROTONERGIC RECEPTORS IN SPINAL CONTROL OF MICTURITION IN CAT. M.J. Espey*, H.-J. Du, J.W. Downie. Departments of Pharmacology and Urology, Dalhousie Univ., Halifax, NS. B3H 4H7

Our previous study implicated spinal serotonin (5HT) as an inhibitory neurotransmitter in the spinal control of micturition (Espey et al. 1992 EJP 221:167). The present studies were performed to investigate the site and receptor subtypes involved in the spinal action of 5HT. In chloralose-anesthetized cats, an action on the afferent limb of the micturition reflex was studied by recording, with a tungsten microelectrode, ascending multiple or single unit activity in the thoracic spinal cord in response to pelvic nerve stimulation. In 3/7 animals intrathecal 5HT (0.3-6µmol) diminished the total number of spikes elicited by pelvic nerve stimulation. In 4/7 animals 5HT was ineffective. Methysergide (60nmol), a 5HT_{1/2} receptor antagonist, increased ascending activity to 165% of control. 5HT₃ antagonists MDL72222, ICS 205 930 and zatosetron increased pelvic nerve-evoked ascending activity. In addition, the 5HT₃ antagonists decreased reflex discharge on the pudendal motor nerve in response to pelvic nerve stimulation. These data suggest that endogenous serotonin may suppress ascending signals from the bladder at the sacral spinal cord through 5HT₃ and 5HT_{1/2} receptors. As well, serotonin may have an excitatory role, through 5HT₃ receptors, in the pelvic-pudendal reflex pathway. (Supported by MRC)

SEROTONIN AND HPA AXIS REGULATION IN CONGENITALLY LEARNED HELPLESSNESS. E. Edwards* and S.Y. Nguven. Dept. Pharmacology & Toxicology, University of Maryland at Baltimore, MD 21201

Congenitally learned helpless rats (cLH) and non learned-helpless rats (cNLH) can be differentiated by a dysfunctional HPA axis and an abnormal hippocampal serotonin (5-HT) system. These experiments examine whether 5-HT has a regulatory role in the stress activation of the HPA axis by comparing the plasma levels of adrenocorticotropic hormone (ACTH) and corticosterone (CORT) following a 30 min, 0.8mA footshock exposure in intact cLH and cNLH rats as well as in rats from either strains subjected to 5,7-dihydroxytryptamine (5,7-DHT) lesions of the fornix-fimbria region. The degeneration of hippocampal serotonergic neurons one week after the injection of 5,7-DHT (5 µg in 400 nl of 0.025% ascorbic saline; 15° angle from the vertical line, coordinates in mm: P 6.7, L 1.0, V 4.5 to bregma) was associated with a significant decrease in ³H-serotonin uptake (-70%) in cLH and cNLH rats. Footshock exposure resulted in significant increases in ACTH levels in intact, 5,7-DHT and sham-lesioned cLH rats (6-23 fold (+)). Similarly, ACTH levels were significantly elevated in cNLH rats under the same conditions (4-17 fold (+)). Since both cLH and cNLH sham-lesioned rats exhibited ACTH increases comparable to that of 5,7-DHT treated rats, the ACTH rise may be due to an additive effect of surgery and shock exposure. In addition, CORT plasma levels measured in the same rats were similarly elevated in cLH and cNLH rats under all three conditions. There was no differential effect in the stress response of either cLH or cNLH rats treated with 5,7-DHT.

These results do not support a regulatory role for 5-HT in stress activation of the HPA axis response of cLH rats.

SEROTONIN-DEGRADATIVE PATHWAYS IN THE TOAD BRAIN AND HUMAN PSYCHIATRIC DISORDERS. Naokuni Takeda*, Dept. of Biotechnology, COSMO Research Institute, Saito, Saimama, 340-01, Japan

Bufotenin (5-hydroxy-N,N-dimethyl tryptamine; BUTN) is a hallucinogen with psychotropic effects. High levels of BUTN and its precursor, N-methyl-5-hydroxytryptamine (N-MET) are shown for the first time to occur and to accumulate in the brain during the degradation of serotonin in the central nervous system of the toad, Bufo bufo japonica. These compounds are concentrated in the hindbrain which includes the cerebellum and medulla oblongata. BUTN can also be detected in blood and urine specimens from the toad. In humans, autism is in some respect related to schizophrenia that appears to be a functional disease of the brain. BUTN can be detected in urine specimens from infant autistic patients. Analysis by three-dimensional HPLC suggests that the presence and levels of BUTN may be important markers for the diagnosis of autism. Therefore, it appears that some aspects of the central nervous system of Bufo may provide useful pharmacological clues to the etiology of human psychiatric diseases, such as autism, that are known to be linked to the methylation of serotonin.

CENTRAL 5-HT_{1A} RECEPTORS MODULATE THE BRADYCARDIA CAUSED BY THE "DIVING RESPONSE" IN ANAESTHETIZED RABBITS. A.G. Ramage*, M.P. Gilbey¹, J.G.P. Pires² & H.A. Futuro-Neto², Departments of Pharmacology & ¹Physiology, Royal Free Medical School, London, NW3, 2PF, U.K. & ²Departamento de Ciencias Fisiologicas, Universidade do Espirito Santo, Vitoria, Brazil.

Stimulation of receptors in the nasal cavity with smoke excites cardiac vagal motoneurons (CVM's), raising BP and producing an apnoea. This apnoea then excites chemoreceptors causing a potentiation of this reflex excitation of CVM's. This combined effect is known as the "diving response". Drugs that act on 5-HT_{1A} receptors may modify this bradycardia as this receptor type affects the excitability of CVM's and modulates central respiratory drive.

In urethane anaesthetized, spontaneous breathing and atenolol (1mg/kg) pretreated rabbits recordings were made of BP, HR, renal nerve activity (RNA) and the duration of the apnoea. Cigarette smoke (10-30ml) was administered through the trachea to the upper airways. Test drugs (n=5-6) were given i.c. 8-OH-DPAT (50µg/kg) decreased while buspirone (200 µg/kg) potentiated the smoke induced bradycardia by -57 ± 12 and +37 ± 12 bpm (P<0.05), respectively. 8-OH-DPAT also decreased the pressor effect by -15 ± 2 mmHg while buspirone potentiated the apnoea by 4 ± 2 s. 8-OH-DPAT tended to decrease the apnoea but this was not significant (ANOVA; least significant difference). Saline i.c. and i.v. 8-OH-DPAT had little effect on the changes caused by smoke. The increase in RNA was also unaffected by these drugs.

These data show that 5-HT_{1A} receptors play an important role in the central pathways involved in the "diving response".

482.14

COMPARISON OF 8-OH-DPAT AND CHLORDIAZEPOXIDE ON PUNISHED RESPONDING AND CONDITIONED EMOTIONAL RESPONSE. A.R. Allen* and I. Lucki. Departments of Pharmacology and Psychiatry, University of Pennsylvania, Philadelphia, PA 19104.

Anti-anxiety drugs with activity at 5-HT_{1A} receptors lack consistent effects on most animal models of anxiety, in particular punished responding. The conditioned emotional response (CER) may offer an alternative procedure for evaluating the effects of 5-HT_{1A} ligands on models of anxiety. In the present experiments, effects of the 5-HT_{1A} agonist 8-OH-DPAT and several 5-HT_{1A} partial agonists were compared to those of chlordiazepoxide (CDP) on the CER and punished operant responding in rats (N=8 per group). Both procedures included a suppressed and an unsuppressed schedule component. As expected, CDP increased previously suppressed responding in the punishment paradigm. On the CER, CDP increased the ratio of suppressed to unsuppressed responding (suppression ratio). 8-OH-DPAT did not share CDP's rate-increasing effect on punished responding, but did increase the suppression ratio. On the CER, 8-OH-DPAT also increased the suppression ratio. The effects of the 5-HT_{1A} partial agonists on suppression ratio varied across drugs. These results suggest that changes in the relative sensitivity to shock-induced suppression, rather than changes in response rate of individual components, may provide a more valid measure of anxiolytic activity of serotonergic drugs. Supported by USPHS grants MH 14654 and MH 36262.

NITRIC OXIDE IN MOLLUSCS: LOCALIZATION AND PUTATIVE ROLE. K. Lukowiak, L. Moroz, M. Gruhn, J. Jacklet, I. Roger, A.G.M. Bulloch and N.I. Syed Neuroscience and Respiratory Research Groups, University of Calgary, Alberta, Canada T2N 4N1 and ²Department of Biological Sciences, SUNY, Albany, NY 12222.

NADPH-diaphorase (NADPH-d) histochemical staining is used to identify mammalian neurons containing nitric oxide synthase, which catalyzes the production of nitric oxide, a putative retrograde signalling molecule. To determine if nitric oxide might be used in neuronal signalling in molluscs, we performed NADPH-d histochemistry on central and peripheral neural tissues of *Aplysia californica*, *Bulla* sp., *Phylaplysia* sp., *Lymnaea stagnalis* and *Helisoma trivolvis*. In all of the species investigated, intense NADPH-d positive staining was observed in both peripheral and central structures. Staining was intense in some specific tracts, synaptic glomeruli (including the optic tracts lateral terminus), esophagus, gills, eyes and neuropil of cerebral, pedal and pleural ganglia of *Aplysia*. In addition, individual neuronal fibers, telodendria in the neuropil and individual cell somata located within the cerebral and other ganglia of *Aplysia* were also found to be NADPH-d positive. A similar pattern of staining was observed in *Phylaplysia*, whereas in *Bulla* only a few weakly stained cells were found in the central ganglia. In both *Lymnaea* and *Helisoma*, staining was predominantly confined to peripheral tissues such as salivary gland, esophagus, osphradium and pneumostome area. Furthermore, individual clusters of neurons that showed positive staining were also found in buccal, cerebral, pedal, pleural, parietal and visceral ganglia of these fresh water snails. The distribution of NADPH-d positive cells within the peripheral and central tissues suggests that nitric oxide (or a related substance) may be involved in neuronal signalling at molluscan synapses.

483.3

DISTRIBUTION OF PUTATIVE NITRIC OXIDE PRODUCING NEURONS IN PERIOESOPHAGEAL GANGLIA OF *Helix aspersa*. Sánchez-Alvarez M., León-Olea M., Talavera E., Pellicer F., Sánchez-Islas E., Alvarez-Leefmans FJ*, Martínez-Lorenzana G. División de Neurociencias, Instituto Mexicano de Psiquiatría, Av. México-Xochimilco 101, CP 14370, México, D.F.

Nitric oxide (NO) is a highly reactive molecule which participates in functions such as maintenance of blood pressure, muscle relaxation and neurotransmission. NO has been found in chicken, crab and toad tissues. Since *Helix* neurons are used as model systems in neurobiological research, we thought it interesting to look for the presence of NO. Perioesophageal ganglia of snails, *Helix aspersa* were used. After dissection, the ganglia (n=5) were fixed in 4% paraformaldehyde in 0.1 M sodium phosphate buffer (pH 7.4, 4°C), and cryoprotected in 15% sucrose during 3 h. Tissue sections (10 µm) were collected in chromoallumin gelatinized slides. The reaction to detect the NADPH-diaphorase was as described by Vincent and Kimura (Neurosci. 46: 775, 1992). The results show a positive reaction in small cells (7.5 µm in diameter) from the lateral part of pro-cerebrum. The mesocerebrum shows a few positive cells (between 27 µm and 50 µm major diameter). We also found positive fibers scattered in the neuropile of pro- and post-cerebra, and in the cerebral commissure, as well as in the neuropile of the suboesophageal ganglia.

The data suggest the presence of NO containing neurons in the nervous system of snails. Additional studies will be required to establish the role of this molecule.

483.5

ARE NITRIC OXIDE AND FREE RADICALS OF OXYGEN INTERCELLULAR MESSENGERS IN THE MOLLUSCAN CNS?

W. Winlow*, J.-H. Park and L.L. Moroz. Department of Physiology, University of Leeds, Leeds LS2 9NQ, UK.

Putative nitric oxide (NO)-containing neurones and NO synthase have been demonstrated in *Lymnaea stagnalis* and are predominantly localised in the buccal ganglia and pneumostome area, suggesting a regulatory role for NO in the feeding and respiratory programmes. On the other hand, NO and NO synthase itself are also involved in generation of the active radicals of oxygen. Thus, both NO and oxygen radicals could be intercellular messengers. To test this hypothesis we have investigated the effects of NO-generating substances and agents generating active forms of oxygen on the respiratory and feeding networks using semi-intact preparations consisting of the CNS, pneumostome and buccal mass. Up to four microelectrodes and 2 channels of optical recording of effector movements have been used simultaneously. We found that generation of NO, O₂⁻ and ·OH both activated buccal and pneumostome movements and modulated the activity of neurones of the respiratory and feeding networks, including their central pattern generators. However, NO and oxygen radicals activated distinct, separate and specific motor patterns of both the pneumostome/mantle area and the buccal mass. We suggest that both NO and active radicals of oxygen may be involved as messengers in intercellular communications.

Supported by the Royal Society (London) and ESF (Strasbourg).

483.2

DISTRIBUTION OF PUTATIVE NITRIC OXIDE IN THE BRAIN OF CRAY FISH *Cambarellus montezumae* USING NADPH-DIAPHORASE HISTOCHEMISTRY. Martínez-Lorenzana G., Talavera E., Sánchez-Alvarez M., Sánchez-Islas E., Sitges M.* and Pellicer F. División de Neurociencias, Instituto Mexicano de Psiquiatría, Av. México-Xochimilco 101, CP 14370, México, D.F.

Recent studies have shown that nitric oxide (NO) functions as a neurotransmitter or neuromessenger in the central and peripheral nervous systems. The presence of NO in tissues of lower species is scarce. Thus, in this work the localization of NO producing cells in brain ganglia of the crayfish *Cambarellus montezumae* was determined. The ganglia of five freshwater crayfish were dissected and fixed for 2 h in 4% paraformaldehyde in 0.1 M phosphate buffer (pH 7.2, 4°C), placed in a sucrose solution (15%) for 24 h at 4°C. The brains were cut into 20 µm thick sections and submitted to the NADPH-diaphorase reaction (Vincent and Kimura, Neurosci. 46:755, 1992). Positive fibers were localized in the olfactory and the accessory lobes, as well as, fibers along the deutocerebral commissure. A group of positive cells was mainly localized in the dorso-lateral region (Somata II). Its presence in the nervous system of this organism suggests an early evolutionary origin.

This work was partially supported by CONACyT grants MLO 1183-N9203 and FP N9111.

483.4

NITRIC OXIDE SIGNALLING IN INVERTEBRATE NERVOUS SYSTEMS M.R. Elphick, I.C. Green* and M. O'Shea*. Sussex Centre for Neuroscience and *Biochemistry Lab, Sch. of Biol. Sci., Sussex Univ., BN1 9QG, U.K.

Nitric oxide (NO) is a novel neuronal signalling molecule that exerts numerous physiological effects in mammals by causing an elevation of cyclic GMP in target cells. We have demonstrated that the nervous system of the locust *Schistocerca gregaria* contains the two key enzymes necessary for NO signalling: a NO synthase (NOS) and a NO-activated guanylyl cyclase. Since NO is synthesized in mammalian cells from L-arginine, and citrulline is a by-product, we assayed NOS activity in extracts of locust cerebral ganglia by monitoring conversion of [¹⁴C]arginine to [¹⁴C]citrulline. Locust neural NOS has similar properties to mammalian neural NOS; it is a NADPH requiring enzyme that generates citrulline from L-arginine upon activation by Ca²⁺/calmodulin and it is inhibited by the N^ω-Nitro and N^ω-Methyl analogs of L-arginine. A guanylyl cyclase is the likely target of NO in the insect nervous system, as in mammals, since exposure of locust cerebral ganglia to the NO donors 3-morpholinodimethylamine (0.5mM), 5-nitroso-N-acetylpenicillamine (0.5mM) and hydroxylamine (1mM) causes a four to eight fold elevation of cyclic GMP, but not cyclic AMP. We are using immunocytochemistry and NADPH diaphorase histochemistry to localize the sources and targets of NO in the nervous systems of *Schistocerca* and the snail *Lymnaea stagnalis*. Some of the neurons that appear to utilize the NO-cyclic GMP signalling pathway have been identified previously according to their transmitter content or physiological function. We are examining the role of NO in identified invertebrate neurons and exploring interactions between the NO-cyclic GMP pathway and other signalling systems. (Supported by S.E.R.C. grant GR/G52524 to M.O.)

484.1

NEUROTENSIN-INDUCED FACILITATION OF 3H DOPAMINE RELEASE IN PRIMARY CULTURES OF MESENCEPHALIC CELLS: EFFECT OF CALCIUM CHANNEL BLOCKERS **A. Brouard¹, D. Pelaprat¹, M. Vial¹, A.-M. Lhiaubet¹, Y. Masuo² and W. Rostene¹.** ¹U 339 INSERM, Hôpital Saint-Antoine, 75012 Paris, France. ²Takeda Chemical Industries, Tsukuba-shi, Ibaraki-ken, Japan 300-42.

It was previously suggested that neurotensin (NT) increased dopamine (DA) release from mesencephalic DAergic neurons by opening voltage-sensitive Ca²⁺ channels. In the present work, this hypothesis was tested on primary cultures of rat mesencephalic cells. The potentiation by NT (10⁻⁷M) of K⁺-evoked ³H DA release was abolished in the absence of extracellular Ca²⁺ and strongly diminished (-60%) by the non-selective Ca²⁺ channel blocker cadmium (3x10⁻⁴M). However, NT effect was always observed in the presence of amiloride (10⁻⁴M), omega-conotoxin (10⁻⁷M) or nifedipine (5x10⁻⁷M), respective blockers of T-, N- or L-type Ca²⁺ channels. Taken together, these results suggest that Ca²⁺ entry is indeed necessary for the NT-induced increase in ³H DA release, but that the NT effect was not due to the opening of N-, L- or T-type Ca²⁺ channels by the peptide. Since NT was also previously shown to mobilize Ca²⁺ from intracellular pools, our results may further indicate that this process is unable to trigger DA release by itself and needs the simultaneous rise in intracellular Ca²⁺ through the Ca²⁺ entry induced by the potassium depolarization.

484.3

EFFECTS OF DOPAMINE (DA) AGONISTS ON THE RELEASE OF NEUROPEPTIDE Y (NPY)-IMMUNOREACTIVITY FROM THE NUCLEUS ACCUMBENS AND STRIATUM OF RAT BRAIN. **G.H. Cao and T.C. Westfall***. Dept. Pharmacol. Physiol. Sci., Saint Louis Univ. Sch. of Med., St. Louis, MO 63104

The caudate nucleus, putamen and nucleus accumbens contain a high density of NPY-immunoreactive cells. Moreover, DA axons are frequently found in close apposition to NPY neurons (Hendry, Biol. of NPY; Humana Press 65, 1993). Striatal injections of NPY has been shown to result in an increase in DA turnover (Beal et al., Neurosci Lett 71:118, 1986), while amphetamine administration has been observed to decrease NPY release (Tatsuoka et al., Brain Res 411:200, 1987). The purpose of the present study was to further investigate dopaminergic regulation of NPY release in the striatum and nucleus accumbens. Animals were sacrificed by decapitation and brains rapidly removed and placed (ventral side up) in a chilled rat brain matrix which allowed for reproducible sectioning of rat brains into 1 mm coronal slices. Dissects of the nucleus accumbens and striatum were removed from 1 mm brain slices and the release of NPY-immunoreactivity measured by radioimmunoassay (RIA). Basal release of NPY-IR could be measured in 10 min fractions and stimulation with a high K⁺ buffer (40 mM) produced a 100-150% increase in NPY release. Apomorphine, a nonspecific dopamine agonist, produced a concentration dependent (10⁻⁶-10⁻⁸M) attenuation of K⁺-evoked NPY release in both regions. In contrast neither the D₁ selective agonist SKF 38393 nor the D₂ selective agonist quinperole, when administered separately, altered the basal or K⁺ stimulated NPY release when examined at concentrations up to 10⁻⁴M. These results suggest that separate stimulation of either D₁ or D₂ dopamine receptors is not sufficient to alter NPY release from the striatum or nucleus accumbens. Stimulation of more than one receptor subtype may be necessary to influence NPY release in these brain regions. Supported by HL26319 and HL35202.

484.5

EFFECT OF DOPAMINERGIC DRUGS ON THE RELEASE OF SOMATOSTATIN IN THE RAT STRIATUM. **J.M. Radke, C. Spyrali and K. Themos***. Lab of Pharmacology, Dept. of Basic Sciences, Sch. of Medicine, Univ. of Crete, Heraklion, Crete, Greece

The neuropeptide somatostatin is found throughout the central nervous system where it is believed to act as a neurotransmitter. At present, its function in the brain and the mechanisms via which it interacts with other neurotransmitter systems remain unclear. In the rat striatum, somatostatin is contained within a specific population of interneurons. Pharmacological and behavioural studies have provided evidence suggesting a dopamine-somatostatin interaction. To provide a better understanding of how dopamine terminals in the striatum interact with the somatostatin containing interneurons, the effect of dopaminergic agonists and antagonists on the in vivo release of somatostatin was examined using intracerebral microdialysis in combination with a somatostatin radioimmunoassay. Using a trans-cerebral designed probe, basal levels of 10-15 femtomoles of somatostatin were measured per 20 µl sample (40 min). Previous studies in our laboratory have established that the levels of somatostatin, collected under these conditions, were increased by depolarization and found to be calcium dependent. Initial studies examined the effects of various doses of apomorphine (0.00; 0.05; 0.1; 0.5; 1.0 mg/kg s.c.) on somatostatin release in the unanaesthetized rat. Under these conditions, all doses of apomorphine were found to have no significant effect on the release of somatostatin in the rat striatum. To examine the effect of apomorphine more directly, we infused apomorphine directly into the striatum via the microdialysis probe (10⁻⁴M; 10⁻⁵M). As with the systemic administration, the infusion of apomorphine did not statistically alter the release of somatostatin. Furthermore, infusions of either the D₁ dopamine antagonist SCH 23390 (10⁻⁴M; 10⁻⁵M) or the D₂ antagonist sulpiride (10⁻⁴M; 10⁻⁵M) failed to show changes in the release of somatostatin. The results from this in vivo study fail to support a direct interaction of the dopamine-somatostatin systems. We suggest that an intermediate neurotransmitter system may be responsible for mediating the dopamine-somatostatin interactions reported by other investigators. Studies are currently underway in our laboratory to ascertain this hypothesis.

484.2

THERAPEUTIC LITHIUM LEVELS ALTER RAT BRAIN REGIONAL NEUROPEPTIDE CONCENTRATIONS. **Garth Bissette*, Dan Griff, Michelle Melisko and Rita Clement.** Department of Psychiatry, Duke University Medical Center, Durham, NC 27710.

We investigated whether a 3-week period of lithium (Li⁺) treatment would alter concentrations of the neuropeptides corticotropin-releasing factor (CRF), somatostatin release inhibiting factor (SRIF), somatostatin, thyrotropin releasing hormone (TRH) and neurotensin (NT) in various brain regions of laboratory rats. These peptides are altered in diseases where Li⁺ is therapeutic. Groups of ten adult, male, Sprague-Dawley rats (225g) were given standard rat chow or a custom rat chow diet with Li⁺ (Teldad, Madison, WI). This treatment resulted in average Li⁺ levels of 0.8 mEq/liter/g protein in cerebellum samples of the Li⁺ treated rats and this compares favorably to the lower human therapeutic dose range. Brains were dissected into 16 discrete regions and acid extracted for neuropeptide quantification by radioimmunoassay. CRF, TRH and NT were elevated in the lithium treated group in all of the regions where significant alterations were noted with the exception of a TRH decrease in the amygdala. Conversely, SRIF was decreased in the Li⁺ group in all of the regions where significant changes were detected except for an increase in the hippocampus. TRH was significantly altered in the most brain regions (five), CRF and NT was significantly changed in 3 regions and somatostatin was significantly altered in 2 regions. CRF concentrations in the septal/diagonal band region was the most profoundly increased (p<0.0009, t-test) by Li⁺ treatment. An increase in peptide concentration can reflect increased release and synthesis or can be produced by decreased release relative to controls. These two completely different mechanisms cannot be discriminated without measurement of messenger RNA levels and/or receptor number and affinity. Supported by NIMH grant MH48975 to Garth Bissette.

484.4

MODULATION OF DOPAMINE (DA) RELEASE BY THE CO-TRANSMITTER, NEUROPEPTIDE Y (NPY) IN PC-12 CELLS. **X. Chen* and T.C. Westfall.** Dept. Pharmacol. Physiol. Sci., Saint Louis Univ. Sch. of Med., St. Louis, MO 63104

We have previously shown that the NPY-Y₂ agonist, NPY13-36, inhibits the evoked release of dopamine (DA) in nerve growth factor (NGF) treated PC12 cells (Soc. Neurosci. Abs. 17:189, 1991). NPY13-36 also attenuated the K⁺-evoked increase in intracellular calcium by decreasing the influx of extracellular calcium (Soc. Neurosci. Abs. 18:989, 1992). In the present study, we have further examined the concept that DA and NPY act as co-transmitters in PC12 cells and the mechanisms underlying the modulatory effect of NPY on DA release. PC12 cells were treated with NGF for 5-7 days and DA measured by HPLC-EC detection and NPY by RIA. Simultaneous basal release of both DA and NPY was observed with a significant increase in both following application of high K⁺ or nicotine (NIC). NPY13-36 significantly attenuated both K⁺ and NIC-evoked DA release. Nifedipine also attenuated the evoked release of DA in a concentration dependent manner. In the presence of maximum concentrations of nifedipine, NPY13-36 did not produce further inhibition of DA release while inhibitory effects of NPY13-36 and ω-conotoxin on DA release were additive. These results are consistent with NPY13-36 and nifedipine acting through a common pathway (inhibition of L-type Ca²⁺ channels). The inhibitory effect of NPY13-36 on the evoked release of DA was not altered by K⁺-channel blockers (4-aminopyridine or TEA) suggesting that the effect was not through Ca²⁺-activated K⁺ channels. NPY13-36 induced inhibition of DA release was abolished by pertussis toxin pretreatment (PTX) suggesting the involvement of an inhibitory G-protein. Our results are consistent with a co-transmitter role for DA and NPY in NGF-treated PC-12 cells and that Y₂ receptor mediated inhibition of DA release acts by inhibition of L-type Ca²⁺ channels via a PTX-sensitive G protein. Supported by HL26319, HL35202 and NS07254.

CHOLINE ACETYLTRANSFERASE ACTIVITY AND MUSCARINIC RECEPTOR SUBTYPES IN ADULT SOMATOSTATIN TRANSGENIC MICE. **R.Quirion¹, LAubert¹, E.Moyse², S.Krantic², M.L.Oster-Granite³ and S.L.Kinsman⁴.** ¹Douglas Hospital Res. Ctr/McGill Univ. Dept. Psychiatry and Neurology & Neurosurgery, Montreal, Quebec, Canada; ²Laboratoire de Physiologie Neurosensorielle, Lyon, France; ³Dept. Anatomy, UC Riverside, CA and ⁴Kennedy Krieger Inst. & Dept. Neurology, Johns Hopkins Medical Institute Baltimore, MD 21205.

In Alzheimer's disease, decrements of various cholinergic markers and somatostatin (SRIF)-immunoreactivity are among the most consistent neurochemical findings. However, it appears that SRIF is not colocalized with acetylcholine, at least in cortical and hippocampal areas. On the other hand, we have shown that SRIF can modulate the release of acetylcholine in the rat hippocampus (Araujo et al., *J.Neurochem.*, 55, 1546-1555, 1990). In order to investigate further the potential interaction between SRIF and cholinergic innervations, we studied one line of somatostatin transgenic mice [*Tgm Smt 13*] which carry extra copies of the mouse preprosomatostatin gene. Choline acetyltransferase (ChAT) activity, and quantitative *in vitro* receptor autoradiography of muscarinic M₁ ([³H]pirenzepine, 15 nM) and M₂ ([³H]AF-DX 384 2 nM) binding sites were determined. In transgenic (n=4) as compared to control (n=5) mice, no changes in cortical ChAT activity were detected. Similarly, the density of muscarinic M₁ binding sites was not altered in any brain regions of the transgenic animals. In contrast, a significant decrease in M₂ binding was quantified in the cerebellum (but not in the cortex or in the hippocampus) of the transgenic mice. This decrease in M₂ cerebellar sites may be inversely related to the marked increase in SRIF binding observed in this structure in transgenic animals (Moyse et al., this meeting). Supported by MH46529, K08 NS01455-01S1 and MRCC.

484.7

BRAIN SOMATOSTATIN RECEPTOR SUB-TYPES IN ADULT SOMATOSTATIN TRANSGENIC MICE. E. Mousse¹, S. Krantic², R. Quirion³, M.L. Oster-Granite⁴, S.L. Kinsman⁵, ¹Labo. Physio. Neurosensorielle, Lyon, France; ²Ecole Normale Sup., Lyon, France; ³Douglas Hospital Res. Ctr./McGill Univ., MtL, Qc, Canada; ⁴Dpt. of Anatomy, UC Riverside, CA; ⁵Kennedy Krieger Inst. & Dpt. Neurology, Johns Hopkins Univ., Baltimore, MD.

Somatostatin (SRIF) is one of the most abundant neuropeptides of the brain. Its purported biological effects are numerous and include the modulation of the release of various neuroendocrine hormones, and the stimulation of learning behaviors. In order to investigate further the role of SRIF in the nervous system, transgenic mice carrying extra copies of the mouse preprosomatostatin gene were developed. Here we investigate one line of these transgenic mice (TginSmst13) for the quantitative radioautographic distribution of SRIF receptor sub-types. SRIF binding sites were labelled on frozen 20 µm-thick brain sections using 0.2 nM (¹²⁵I)Tyr⁰-D-Trp⁸-SRIF₁₄ in the absence (SRIF receptors 1, 2, and 3) or in the presence (R₁ and R₃) of 1 µM SMS-201995, and quantified by computerized film densitometry. In the control mice (n=5), the regional distribution of SRIF receptor sub-types differed from that seen in the rat and human brain by the absence of the R₂ sub-type in the cerebral cortex, and an overall lower density of labelling in the CA1 sub-field of the hippocampus. In the transgenic animal (n=5), specific (¹²⁵I)Tyr⁰-D-Trp⁸-SRIF₁₄ binding was significantly lower (17 to 53%) than in control animals in 22 areas including the anterior olfactory nucleus, the lateral septum, various diencephalic nuclei and the nucleus tractus solitarius. In contrast, specific SRIF binding was increased in the cerebellum (40 fold over control), frontal and cingulate cortices and in the claustrum. No significant alterations were detected in more than 60 other structures. These results demonstrate that SRIF receptors can be endogenously regulated by an over-expression of SRIF. Interestingly, the pattern of regulation is highly region-specific suggesting complex modulation. This work was supported by MH46529 and K08 NS01455-0181, and by CNRS.

SEROTONIN-INDUCED HISTAMINE RELEASE FROM CORTICAL SYNAPTOSOMES MEASURED BY IN VITRO SUPERFUSION.

L. Tuomisto¹, H. Kosunen and K.S.M. Laitinen. Dept of Pharmacol & Toxicol, Univ of Kuopio, SF-70211 Kuopio, Finland.

Histamine (HA), serotonin (5-HT) and noradrenaline (NA) are all proposed to participate e.g. in the control of sleep-wakefulness, but their exact roles and interrelationships are far from clear. HA has been reported to inhibit 5-HT release from rat cortical slices through pre-synaptic H₃-heteroreceptors. On the other hand, there are facilitatory 5-HT receptors in the CNS, as evidenced by increased NA release from rabbit hippocampus. We studied whether 5-HT also influences histamine release. Rat cortical synaptosomes were purified using a Ficoll-gradient. Synaptosomes (4 mg of protein) were loaded in 300 µl chambers and superfused with artificial CSF (250 µl/min). After a 30 min stabilization period, 3 min samples of superfusate were collected. The synaptosomes were stimulated with 5-HT (1-300 µM) for 3 min. HA was analyzed by HPLC. The basal release of HA was 50-300 fmol/3min. 5-HT induced a dose related increase in HA release up to several pmol/3min. The release was Ca²⁺-dependent. The results suggest that there are facilitatory 5-HT receptors on cortical HA-ergic terminals. Together with other data this may imply reciprocal interactions between the HA- and 5-HT-ergic systems.

SEROTONIN-INDUCED HISTAMINE RELEASE IN THE RAT HYPOTHALAMUS MEASURED BY IN VIVO MICRODIALYSIS. K.S.M. Laitinen¹, J.T. Laitinen and L. Tuomisto. Departments of Pharmacol & Toxicol and Physiology, Univ of Kuopio, 70211 Kuopio, Finland.

Histamine (HA) is a putative neurotransmitter in the mammalian brain and is assumed to modulate e.g. arousal and the sleep-wake cycle. In the rat hypothalamus, HA content is highest in the suprachiasmatic nucleus (SCN). One of the main inputs to the SCN is the serotonergic projection from the midbrain raphe cells. Hypothalamic serotonin (5-HT) is also thought to be involved in the regulation of biological rhythms. We used *in vivo* microdialysis to study the effects of 5-HT on hypothalamic HA release. Rats were anesthetized and a microdialysis probe was implanted into the anterior hypothalamus (aimed at the SCN). The probe was perfused with aCSF (2 µl/min) and samples were collected every 30 min. After 3-4 basal samples, 5-HT (10 or 100 µM) was delivered via the probe for 1 h. The dialysate HA concentration was analyzed by HPLC with fluorescence detection. Basal HA level was 104 ± 5 fmol/30 min. 5-HT infusion (10 and 100 µM) increased HA release up to 170 and 330 %, respectively, reaching maximal effect at 1 h. Methysergide (10 mg/kg i.p.), a nonselective 5-HT_{1c/2} blocker, completely antagonized the response elicited with 10 µM 5-HT. Methysergide alone also decreased basal HA release by 20 %. These data suggest that 5-HT has a tonic stimulatory effect on the histaminergic terminals in the rat the hypothalamus.

ACTIVATION OF SEROTONIN₃ RECEPTORS ENHANCES THE ELECTRICALLY-EVOKED RELEASE OF [3H]NOREPINEPHRINE IN RAT LIMBIC STRUCTURES. R. Mongeau¹, C. de Montigny and P. Blier. Neurobiological Psychiatry Unit, McGill University, Montréal, Québec, Canada.

The ability of serotonin (5-HT) agonists to modulate the electrically-evoked (3 Hz, 20 mA, 2 min) release of [3H]norepinephrine (NE) was tested on preloaded slices of the rat brain. The 5-HT₃ agonist 2-methyl-5-HT enhanced the electrically-evoked release of [3H]NE in the hippocampus, hypothalamus and frontal cortex. The enhancing effect of 2-methyl-5-HT was blocked by the 5-HT₃ antagonist ondansetron. Elevated levels of endogenous 5-HT, achieved through selective reuptake blockade with paroxetine, as well as the addition of exogenous 5-HT in the medium, also enhanced [3H]NE release. Furthermore, the effect of paroxetine was blocked by nanomolar concentrations of the 5-HT₃ antagonists ondansetron, ICS-205,930 and (S)-zacopride. The possibility that the enhancing effect of 2-methyl-5-HT could have been due to an antagonism of α₂-autoreceptors on NE terminals was ruled out by the unaltered effectiveness of the α₂-adrenergic agonist UK-14,304 to attenuate [3H]NE release in the presence of 2-methyl-5-HT. Moreover, the activation of α₂-autoreceptors by endogenous NE reduced the effect of 5-HT₃ receptors activation. Indeed, there was an increase in the ability of 2-methyl-5-HT and of paroxetine to enhance the release of [3H]NE in absence of α₂-autoreceptors activation, achieved in pseudo-one-pulse experiments (4 pulses, 100 Hz, 20 mA). The selective 5-HT_{1A} and 5-HT_{1B} agonists 8-OH-DPAT and CP-93,129, respectively, as well as the non-selective 5-HT₁ agonist 5-carboxyamidotryptamine, were devoid of effect on the release of [3H]NE. Lesioning 5-HT fibers with the neurotoxin 5,7-dihydroxytryptamine did not alter the action of 2-methyl-5-HT on [3H]NE release, indicating that this effect is not attributable to an action of this 5-HT₃ agonist on 5-HT terminals.

A METHOD FOR THE SIMULTANEOUS ASSAY OF NOREPINEPHRINE, DOPAMINE, SEROTONIN AND THEIR METABOLITES IN RAT HYPOTHALAMIC MICRODIALYSATES. Kenneth W. Perry and Ray W. Fuller¹, Lilly Research Laboratories, Eli Lilly and Company, Lilly Corporate Center, Indianapolis, IN 46285.

Measuring both norepinephrine (NE) and serotonin (5HT) in microdialysates presents a challenging chromatography problem because in order to obtain adequate resolution of NE from the large void volume peak the retention time for 5HT is increased so much that the peak becomes very broad and difficult to quantitate. As a result of this problem, NE and 5HT values are rarely reported in the same experiment. We have devised one way to solve that problem and measure the metabolites as well. A ten-port HPLC valve with 5 and 20 µl sample loops was used to inject samples from the on-line dialysis system onto two separate HPLC columns. The columns were Spherisorb ODS2 3µ 2x150 mm, both housed in a column oven at 40°C. The 5 µl injection went onto the column with a mobile phase of 75 mM potassium acetate, 0.5 mM EDTA, pH 5.1, at a flow rate of 0.23 ml/min which was optimal for separation of the metabolites (DHPG, DOPAC, MHPG, 5HIAA and HVA). The 20 µl injection went onto the column with a mobile phase which resolved NE, DA and 5HT: 75 mM potassium acetate, 0.5 mM EDTA, 1.4 mM sodium octanesulfonic acid and 8% methanol, pH 4.9. The mobile phase for the amine column was delivered with a flow programmable pump at an initial flow rate of 0.2 ml/min increasing to 0.3 ml/min at 5 min then decreasing back to 0.2 ml/min at 26 min with a total run time of 30 min. Flow programming was used to elute the 5HT within a 25 min time period. The electrochemical detector (EG&G, Model 400) used for the metabolite column was set on a potential of 500 mV at a sensitivity of 5 nA/V, while a separate detector for the amine column was set at a potential of 400 mV and a sensitivity of 0.2 nA/V. This method has been useful in measuring the effects of uptake inhibitors on concentrations of NE, DA and 5HT, along with their metabolites, in dialysate samples from rat hypothalamus.

THE EFFECTS OF CP-93129, A SELECTIVE 5-HT_{1B} AGONIST, ON DOPAMINE RELEASE: MICRODIALYSIS STUDIES IN VIVO. Camille S. Suchowski, Michael J. Keegan and Matthew P. Galloway¹. Cellular & Clinical Neurobiology, Wayne State Univ Sch Med, Detroit, MI 48207 USA

Using microdialysis, the facilitation of dopamine (DA) release was monitored in response to the co-perfusion of a selective 5-HT_{1B} receptor agonist CP-93129 (3-(1,2,5,6-tetrahydropyrid-4-yl)pyrrolo[3,2-b]pyrid-5-one) into the anterior striatum of chloral hydrate anesthetized rats. Changes in extraneuronal DA levels were also assessed after systemic administration of either CP-93129 or m-CPP(1-(m-chlorophenyl)piperazine. Perfusion of CP-93129 facilitated DA release in a dose dependent manner. For example, local perfusion of either 0.4 nmol or 4.0 nmol CP-93129 increased extraneuronal levels of DA to 219±33% and 567±101% of control respectively (n=6). Systemic administration of 1mg/kg (i.v.) m-CPP caused a 7-fold increase in extraneuronal levels of DA whereas systemic application CP-93129 did not alter the extraneuronal levels of DA. Using striatal brain slices, *in vitro*, CP-93129 (1-30µM) did not increase extracellular DA levels, suggesting that CP-93129 is not an amphetamine-like substrate for the DA transporter. The results suggest that serotonergic innervation of the anterior striatum may exert a facilitatory influence on DA release. Further, the 5-HT_{1B} selectivity of CP-93129 and its facilitatory influence on DA release suggest that 5-HT_{1B} receptors may be involved in the control of DA release. Supported by DA-04120 and Michigan Dept. of Mental Health.

MK-801-INDUCED STIMULATION OF STRIATAL DOPAMINE RELEASE: ANALYSIS OF POSSIBLE MECHANISMS. *D.W. Miller** and *E.D. Abercrombie*. Center for Molecular and Behavioral Neuroscience, Rutgers University, Newark, NJ 07102.

A number of studies have shown that glutamate and dopamine (DA) interactions are important in regulating the behavioral outputs of the basal ganglia. We have observed that systemic administration of the non-competitive NMDA antagonist MK-801 significantly increases extracellular DA in striatum, measured with *in vivo* microdialysis in awake rats. At a dose of 0.2 mg/kg (n=7) a 53% increase in extracellular DA is produced by MK-801 and at 0.5 mg/kg (n=7) a 60% increase is observed. The present experiments are an attempt to analyze possible substrates for this interaction. The increase in extracellular DA produced by systemic MK-801 was impulse-dependent, i.e., blocked by striatal infusion of TTX (10 μ M or 1 μ M). These data indicate that the substrate for MK-801-induced increases in striatal DA release is at least in part located within the striatum and that this interaction may be mediated indirectly via antagonism of NMDA receptors on striatal neurons that tonically inhibit striatal DA. Consistent with these suggestions, we have found, in preliminary experiments, that pulse infusions of NMDA (1 mM, 20 min; n=3) into striatum produce a 30% decrease in striatal DA levels. The ability for MK-801 to block this effect of NMDA is currently being tested. The typically reported NMDA-induced increases in striatal DA were only observed with prolonged infusion of 10 mM NMDA. The present data, as well as biochemical and electrophysiological data from other laboratories, suggest a working model to explain NMDA-mediated regulation of striatal DA release in which NMDA receptors activate the GABAergic striatonigral pathway which is, in turn, inhibitory to nigral DA afferents to striatum. EFFECTS OF SIGMA LIGANDS ON THE EXTRACELLULAR CONCENTRATION OF DOPAMINE (DA) IN THE STRIATUM OF THE RAT. *Gary A. Gudelsky**, Department of Psychiatry, Case Western Reserve University, Cleveland, OH 44106

Sigma ligands have been reported to increase the activity of striatal tyrosine hydroxylase *in vitro* and increase striatal DOPAC concentrations in post mortem tissue from rats. In the present study the effects of benzomorphan and non-benzomorphan type sigma ligands on the extracellular concentrations of DA in the striatum of rats were determined using *in vivo* microdialysis. Extracellular concentrations of DA in the striatum were increased approximately 40% for 120-150 min following the administration of (+)-N-allyl-normetazocine (NANM) (10 and 20 mg/kg, sc). This effect appeared to be stereoselective for NANM, since (-)-NANM (20 mg/kg, sc) did not significantly alter DA concentrations in dialysis samples of the striatum. (+)-Pentazocine (15 and 30 mg/kg, sc) also evoked a 40% increase in the extracellular concentration of DA. In contrast, (+)-3-hydroxyphenyl-N-(1-propyl-piperidine) ((+)-3-PPP) (20 mg/kg, sc) reduced DA concentrations by 75%. Di-tolylguanidine (1 mg/kg, ip) did not alter striatal DA efflux. These results are consistent with the view that benzomorphan type sigma ligands can enhance the release of DA from terminals of nigrostriatal neurons.

CORTICO-STRIATAL REGULATION IN THE RHESUS MONKEY: AN *IN VIVO* NEUROCHEMICAL ASSESSMENT OF DOPAMINE AND GLUTAMATE INTERACTION. *B.S. Kolachana**, *R.C. Saunders*, *D.B. Weinberger*. CBDB/NIMH Neuroscience Center at St. Elizabeths, Washington, DC 20032

Prefrontal and sub-cortical DA terminal field interdependence has been demonstrated in rodents (Loulaf et al., *Neuroscience* 29:45-56, 1989). Previously we demonstrated this phenomenon in the rhesus monkey with dopamine (DA) agonists (amphetamine or cocaine) infused into the prefrontal cortex (Pfc) which resulted in reduced caudate DA levels as measured by *in vivo* microdialysis (Kolachana et al., *Soc. Neurosci. Abst.* 1992). The present study examines further the local Pfc neurochemical events involved in the regulation of the cortico-striatal pathway. Tetrodotoxin (TTX) was infused into the Pfc to block a broad spectrum of impulse dependent neuronal activity. Kynurenic acid (KYN), an antagonist of excitatory amino acid receptor subtypes, was infused into Pfc to determine the effects of blocking local glutamatergic transmission on glutamate (GLU) levels in the caudate. During dialysis, rhesus monkeys were anesthetized using isoflurane gas and microdialysis probes positioned into the medial bank of sulcus principalis of Pfc and head of the caudate nucleus with the aid of previously implanted guide holders. Artificial cerebrospinal fluid (pH 7.4) supplemented with ascorbate was continuously infused at 1 μ l/min flow rate. Dialysate (25 μ l) was collected every 25 mins and analyzed for DA and GLU using HPLC-ED. Samples were collected and baseline determined from the Pfc and caudate during the 3.5 hrs after probe implantation and before a 50 min infusion of TTX (10ng/ μ l) or KYN (100ng/ μ l) into the Pfc. In contrast to previously reported reductions in caudate DA levels seen after DA agonist or glutamate infusions into Pfc, TTX infusion greatly increased DA levels in the caudate (200-500%). KYN infusion, while reducing cortical GLU by 90%, increased caudate GLU levels by 300%. These data implicate complex interactions of excitatory and inhibitory events in Pfc, possibly involving local inhibitory circuit neurons in cortical regulation of striatal DA levels.

SECOND MESSENGERS: NITRIC OXIDE AND CALCIUM

485.1

CEREBELLAR NEURON AND ASTROCYTE CULTURES EXPRESS BOTH THE CONSTITUTIVE AND THE INDUCIBLE NITRIC OXIDE SYNTHASES. *D. Minc-Golomb** and *J.P. Schwartz*. Clinical Neuroscience Branch, NINDS, NIH, Bethesda, MD 20892

Nitric oxide (NO) has been identified as an important neuromodulator, as well as implicated in mediating neurotoxicity. NO is produced through the conversion of arginine to citrulline by two different forms of NO synthase (NOS): a constitutive form (cNOS) which generates NO tonically, and an inducible enzyme (iNOS), which mediates primarily toxic effects and requires gene transcription. The present study was designed to examine the expression of brain cNOS in neurons and astrocytes in culture. Since the granule cell layer in the cerebellum is the richest in cNOS in the brain, cultured cerebellar granule cells (CGC) were chosen as a model for this study. Furthermore, because of the potential role of iNOS in neurotoxicity, we wished to determine whether these neurons could be stimulated to produce iNOS by cytokines, which increase in the brain following various insults. Transcription of the genes encoding the two different forms of NOS was examined by RNA-specific reverse transcription followed by polymerase chain reaction (RS-PCR), and by fluorescent *in situ* hybridization. NOS enzymatic activity was assessed by the conversion of labeled arginine to citrulline. We show that CGC and type I astrocytes in culture transcribe the gene encoding brain cNOS, and in addition, can be stimulated by lipopolysaccharide (LPS) and interferon- γ (IFN- γ) to transcribe the gene encoding iNOS. The iNOS transcripts were not detected in untreated cultures. Both mRNAs are translated into active enzymes. Either LPS or IFN- γ alone increased the activity to a lesser extent than their combination. The demonstration that one type of neuron, the CGC, is capable of expressing two forms of NOS (cNOS and iNOS) raises the possibility that iNOS plays a role in neuronal damage following activation of brain microglia and production of cytokines such as interferon.

FURTHER CHARACTERIZATION OF NITRIC OXIDE SYNTHASE (NOS) ACTIVITY IN RAT FRONTAL CORTEX. *S. Alaqarsamy**, *G. Lonart* and *K. M. Johnson*. The Department of Pharmacology and Toxicology, The University of Texas Medical Branch, Galveston, TX 77555-1031.

We have previously shown that activation of classical N-methyl-D-aspartate (NMDA) receptors, 50mM K⁺ and calcium ionophores can stimulate NOS activity in the frontal cortex. We now show that the K⁺ response is blocked by 10 μ M N^o-nitro-L-arginine, calcium free buffer, 100 μ M Cd²⁺, 10mM Mg²⁺ and 10mM Co²⁺. This suggests that the response to 50mM K⁺ is due to calcium influx through voltage-dependent calcium channels. Pharmacological characterization of the specific calcium channel is inconclusive; however, 200 μ M Ni²⁺, 10 μ M nifedipine or 100nM ω -conotoxin do not block the K⁺ response. These data suggest that the voltage-dependent calcium channel involved in the K⁺ response is not the T, L or N-type. The suspected channel is the newly described P-type channel.

Although NMDA can stimulate NOS activity there is no response observed with 300 μ M kainate or 30 μ M α -amino-3-hydroxy-5-methylisoxazole-4-propionate (AMPA). In addition, 300 μ M glutamate stimulates NOS and this response is blocked by 3 μ M phencyclidine and 1.2mM Mg²⁺.

Further characterization of NOS activity has shown that the NMDA response can be blocked by 1mM carbamyl chloride and 30 μ M dopamine. The pharmacology of these interactions is yet unknown; however, future experiments will address these topics. Supported by DA-02073.

CHARACTERISATION OF RAT PINEAL NITRIC OXIDE SYNTHASE. N.C. Schaad*, D.C. Klein and P.E. Schulz. Div. of Clinical Psychopharmacology, Dept of Psychiatry of the University of Geneva, 1225 Chêne-Bourg, Switzerland

The rat pineal gland respond to norepinephrine (NE) with a 100-fold increase in cGMP formation. Neither the function nor the molecular mechanism controlling its formation are fully understood. It is known however that the NO generator sodium nitroprussiate stimulates guanylate cyclase activity in pineal membrane and cytosolic preparations, and cGMP formation in intact pineal tissue. Accordingly, it appears that NO might be involved in the NE stimulation of pineal cGMP formation. To pursue this, we have determined if the pineal gland contains the enzyme which generates NO from arginine, NO synthase (NOS). A modification of a published method was used (PNAS, 86:9030-33). Pineal NOS activity was about 40 % of that in the cerebellum, 30 % higher than in the hippocampus and 80 % higher than in the cerebral cortex. Enzyme activity was cytosolic (95 % of total activity), Ca⁺⁺-dependent (EC₅₀=140 nM), and inhibited by trifluoperazine. These results indicate that a constitutive, Ca⁺⁺/calmodulin-dependent form of NOS is present in the rat pineal gland. Pineal [Ca⁺⁺]_i is regulated via an α₁-adrenergic mechanism, which points to the probability that NE activation of the pineal gland elevates NOS activity through elevation of [Ca⁺⁺]_i and the resulting increase in [NO]; plays a role in the stimulation of cGMP formation.

Developmental studies indicate that NOS activity is present before the cGMP response to NE treatment is first detected and circadian studies indicate that it does not change significantly on a 24-hour basis in the adult.

METALLOPORPHYRINS INHIBIT NITRIC OXIDE-INDUCED ACTIVATION OF SOLUBLE GUANYLYL CYCLASE *IN VIVO*. D. Luo and S.R. Vincent. Dept. of Psychiatry, The University of British Columbia, Vancouver, B.C. Canada

We previously showed using *in vivo* microdialysis, that activation of nitric oxide synthase results in a large increase in extracellular cGMP levels in the rat cerebellar cortex. We now use this technique to examine the direct activation of guanylyl cyclase by local application of sodium nitroprusside. Rats were implanted with a transverse microdialysis probe in the cerebellar cortex, and the probe was perfused two days later at 5 μl/min. Samples were collected every 20 min and assayed for cGMP by radioimmunoassay. Inclusion of sodium nitroprusside in the dialysate produced a dose-dependent increase in extracellular cGMP, with a 1600% increase at the ED₅₀ of 25 μM. Perfusion with a calcium-free solution, or inclusion of N^G-nitro-L-arginine, both of which completely prevent the cGMP increases in response to activation of endogenous nitric oxide formation, had no effect on nitroprusside-induced increases in extracellular cGMP. Thus the nitric oxide-dependent increase in extracellular cGMP is calcium-independent.

It has been known for many years that certain metalloporphyrins which act as competitive substrates for heme in the heme oxygenase reaction, can also directly inhibit soluble guanylyl cyclase, and prevent its activation by nitric oxide. In this study, inclusion of Zn-protoporphyrin-IX (10 μM) in the perfusate attenuated the nitroprusside-induced increase in cGMP. Inclusion of Sn-protoporphyrin-IX also produced a dose-dependent inhibition of basal extracellular cGMP, and attenuation of the nitroprusside-induced increase in cGMP. These results indicate that metalloporphyrins can inhibit soluble guanylyl cyclase *in vivo*, and prevent the activation of this enzyme by nitric oxide. This agrees with *in vitro* results suggesting that metalloporphyrins with high affinity for soluble guanylyl cyclase can displace the heme, required for nitric oxide-induced enzyme activation.

485.7

ACTIVATION OF STRIATAL NMDA RECEPTORS *IN VIVO* INCREASES HYDROXYL FREE RADICAL OUTPUT THROUGH A NITRIC OXIDE SYNTHASE-DEPENDENT MECHANISM. Byron Hammer¹, Davis Parker^{1,2} and James Bennett^{1,3,4,*} Departments of (1) Neurology, (2) Pediatrics, (3) Psychiatric Medicine and (4) Pharmacology, University of Virginia School of Medicine, Charlottesville, VA 22908.

NMDA receptor activation participates in excitotoxic neuronal death in acute paradigms (hypoxia-ischemia, hypoglycemia, status epilepticus) and may contribute to neuronal loss in chronic neurodegenerative diseases. NMDA receptor-mediated Ca²⁺ influx can activate nitric oxide synthase (NOS) through Ca²⁺-calmodulin and protein kinase C, and resulting NO⁻ could be converted to destructive OH⁻ radical. We have used brain dialysis of dorsolateral striatum in awake rats to monitor OH⁻ production before and after NMDA receptor stimulation by perfusion with Mg²⁺-free csf containing 5 mM salicylic acid (SA), an OH⁻ trap. Efflux of the SA derivatives (2,3- and 2,5-dihydroxybenzoic acid, DHB) was quantitated by HPLC-EC.

After 2-3 hours of stable baseline output of DHB's, the dialysis solution was changed to one containing 10 mM NMDA, yielding an average 4-fold increase in dialysate [DHB's]. The increased DHB output after NMDA infusion was reduced to baseline by 10 mM nitro-L-arginine, not altered by 10 mM L-arginine, and blocked by adding 100 μM MK801 before NMDA.

Our results demonstrate that local NMDA receptor activation in striatum increases production of destructive OH⁻ by a mechanism sensitive to nitro-L-arginine, suggesting that NOS activity is necessary for this process. (Supported by NIH NS30024).

EFFECTS OF PROTAMINE, HISTONE AND MYELIN BASIC PROTEIN ON NEURONAL NITRIC OXIDE SYNTHASE. J. Hu*, J. Fridlund and E.E. El-Fakahany. Division of Neuroscience Research in Psychiatry, Uni. of Minnesota Medical School, Minneapolis, MN 55455.

Activation of neuronal nitric oxide synthase (NOS) converts L-arginine into L-citrulline and releases nitric oxide. To examine whether endogenous proteins whose amino acid sequences are rich in arginine affect the activity of NOS, we studied the effects of protamine, histone and myelin basic protein (MBP) on conversion of [³H]L-arginine into [³H]L-citrulline by NOS and on formation of cyclic GMP. In cytosolic preparations of rat cerebellum, protamine, histone and MBP all inhibited the formation of [³H]L-citrulline in a concentration-dependent manner, with IC₅₀ values of 12 μg/ml, 8 μM and 42 μg/ml, respectively. These proteins also stimulated the synthesis of cyclic GMP in neuroblastoma N1E-115 cells (EC₅₀ values were 20 μg/ml, 7 μM and 396 μg/ml for protamine, histone and MBP, respectively). The stimulation of cyclic GMP formation by the basic proteins was blocked by N-nitro-L-arginine (but not by N-nitro-D-arginine) and hemoglobin, indicating an activation of the NOS/cyclic GMP pathway by these proteins. Moreover, equalizing extracellular and intracellular Ca²⁺ concentrations by EGTA abolished the effects of the proteins on cyclic GMP formation. Our results suggest that the endogenous basic proteins might be involved in the regulation of neuronal NOS activity.

PROTEIN TARGETS FOR ENDOGENOUS AND NITRIC OXIDE-DEPENDENT ADP-RIBOSYLATION IN NEURONAL TISSUE. A. Surin*, R. Rauli and J.T. Wroblewski. Fidia-Georgetown Institute for the Neurosciences, Georgetown University School of Medicine, Washington D.C. 20007.

In cerebellar granule neurons the activation of glutamate receptors leads to the activation of nitric oxide synthase and release of nitric oxide (NO). In addition to enhancing guanylate cyclase activity, NO may influence the ADP-ribosylation of intracellular proteins. In this study we compared the effects of NO on the endogenous ADP-ribosylation of proteins in homogenates obtained from adult rat brain and from primary cultures of cerebellar neurons and astrocytes. The incubation of rat brain homogenates with [³²P]NAD in ADP-ribosylating conditions caused the appearance of multiple radiolabelled proteins as visualized by autoradiograms of SDS-PAGE gels. In contrast, homogenates from cerebellar neurons exhibit a major radiolabelled band in the range of 36-39 kDa. In homogenates from cerebellar astrocytes we observed the appearance of three major bands with M_r of 37, 41 and 47 kDa. Incubations in the presence of sodium nitroprusside (SNP), a NO releasing agent, caused a strong increase in the ADP-ribosylation of the single protein band observed in neurons, but enhanced only ADP-ribosylation of the 37 kDa protein in cerebellar astrocytes. In view of the known ability of NO to enhance ADP-ribosylation of glyceraldehyde-3-phosphate dehydrogenase (GAPDH) we investigated the effects of SNP on ADP-ribosylation of glutamate dehydrogenase (GDH) and alcohol dehydrogenase (ADH). Similarly to GAPDH, the ADP-ribosylation of ADH was enhanced by SNP, although to a lesser extent. The ADP-ribosylation of GDH enhanced by GTP and ADP, the allosteric regulators of this enzyme but, in contrast to GAPDH and ADH, SNP decreased these effects. The comparison of SDS-PAGE and isoelectrofocusing gels of neuronal homogenates and purified dehydrogenases indicates that the band of SNP-dependent ADP-ribosylated protein in neurons contains proteins corresponding to GAPDH, ADH, and an unidentified protein. Our results indicate that neuronal and glial cells contain different protein targets undergoing ADP-ribosylation. As shown in the case of ADH and GDH the ADP-ribosylation may be positively and negatively regulated by nitric oxide.

485.8

NITRIC OXIDE TREATMENT OF TYPE I ADENYLYL CYCLASE CAUSES A REVERSIBLE LOSS OF CALCIUM/CALMODULIN SENSITIVITY VIA CYSTEINE OXIDATION. R.J. Duhe, A. H. Dittman, E. C. Villacres*, E.J. Choi & D. R. Storm. Dept. Pharmacology, Univ. of Washington, Seattle, WA 98195

Type I adenylyl cyclase (ACI), overexpressed in Sf9 cell membranes via the baculoviral expression vector system (BEVS), was treated with reagents which selectively modify cysteine residues. N-ethylmaleimide treatment resulted in a rapid loss of all catalytic activity. Treatment with limiting amounts of o-iodosobenzoate (IBZ), which oxidizes vicinal sulfhydryls to disulfides, resulted in the complete loss of ACI stimulation by calcium/calmodulin (Ca⁺⁺/CaM), but not by forskolin. Ca⁺⁺/CaM stimulation was restored by treatment with dithiothreitol (DTT), which reduces disulfides to free thiols.

Nitric oxide (NO) treatment resulted in a complete and DTT-reversible loss of calcium/calmodulin stimulation without significant impairment of either basal catalytic rates or forskolin stimulation of catalysis. NO also removed the calcium/calmodulin sensitivity of adenylyl cyclase activity in rat hippocampal membranes in a DTT-reversible process. These results implicate a novel role for NO in neuronal signal transduction.

NITRIC OXIDE GENERATORS CAN INDUCE BOTH SHORT- AND LONG-TERM CHANGES IN THE ACTIVITY OF RAT STRIATAL DOPAMINE TRANSPORTER. G. Lonart* and K.M. Johnson. Dept. of Pharmacol. and Toxicol. Univ. of Texas Med. Branch, Galveston, TX 77555.

We have recently observed that nitric oxide (NO) generator-induced dopamine (DA) release from striatal slices was reduced by nomifensine. Since this indicated a role for reverse DA transport, we tested the action of S-nitroso-L-cysteine (Cys-NO), a NO generator, on the DA transport by measuring the uptake of [³H]DA into crude striatal synaptosomes. Five min treatment with Cys-NO (0.01-3 mM) concentration-dependently inhibited [³H]DA uptake (complete inhibition at 3 mM, IC₅₀ ≈ 500 μM). Hemoglobin (300 μM) antagonized the Cys-NO effects. The major component (79%) of the effect of 3 mM Cys-NO was wash-resistant and long-lasting (> 20 min). The inhibition by 1 mM Cys-NO (78%) was completely reversible. Scatchard analysis of the [³H]DA uptake revealed that Cys-NO reduced the capacity of the DA transporter. Cys-NO had no significant effect on [³H]mazindol binding of the striatal membrane preparation. Collectively, these data suggest that NO regulates DA transport and that the site of action is not identical with the DA recognition site of the DA transporter. Supported by DA-02073.

SOMATOSTATIN INHIBITS TRANSMITTER RELEASE VIA NITRIC OXIDE AND cGMP-DEPENDENT KINASE IN CHOROID NERVE TERMINALS. D.B. Gray*, V. Scranton, and G. Pilar. Dept. of Physiology & Neurobiology, University of Connecticut, Storrs, CT 06269.

In hatchling chicks 50 nM somatostatin (SOM) inhibits 80 - 100% of Ca dependent, K-evoked ³H-ACh release from ciliary ganglion nerve terminals in the excised choroid coat. This inhibition of transmitter release is thought to occur by modulation of N-type Ca channels (Gray et al., 1989, J. Neurosci., 9:1683). Incubation of choroid tissue with 10 μM 8-bromo-cGMP inhibits K-evoked ACh release by 83 ± 16%, mimicking the effect of SOM. Preincubation with 83-bromoguanosine 3',5'-monophosphorothioate, Rp isomer (BioLog), a specific inhibitor of cGMP-dependent kinase (PKG), has no significant effect on basal or control evoked ACh release. However, evoked release from choroids treated with the PKG inhibitor is no longer sensitive to SOM, suggesting that activation of PKG is involved in SOM induced inhibition of ACh release. Increased cGMP levels may be stimulated by production of nitric oxide (NO). Inhibitors of NO synthase such as nitroarginine or nitro-arginine mono-methyl ester (L-NMMA) reverse SOM-induced inhibition of ACh release while inactive enantiomers such as D-NMMA do not. Incubation of choroids with sodium nitroprusside, a NO producing compound, also inhibits ACh release. This data suggests that activation of the SOM receptor activates a series of intermediates including NO, cGMP, and PKG resulting in a decrease of both calcium influx into the nerve terminal and subsequent transmitter release. Supported by NSF #IBN-9213204 and NIH NS 10338.

PHARMACOLOGIC MODULATION OF REFILLING INTRACELLULAR CA²⁺ STORES IN NEURONAL CELLS. T. M. Lo* and S. A. Thayer. Dept. of Pharmacology, Univ. of Minnesota, Minneapolis, MN 55455.

At least 3 intracellular stores of Ca²⁺ are present in NG108-15 cells. Caffeine (10 mM) and Bradykinin (BK, 30 nM) mobilize Ca²⁺ from the ryanodine- and 1,4,5-inositol trisphosphate (IP₃)-sensitive pools, respectively. These stores are distinct. The caffeine and BK releasable stores are subsets of a larger pool released by the ATPase inhibitors cyclopiazonic acid (CPA, 30 μM) and thapsigargin (TG, 10 nM). The effects of CPA on intracellular stores were reversible. In the absence of extracellular Ca²⁺, depleting the stores with CPA prevented Ca²⁺ mobilization by BK or TG. Depletion of intracellular Ca²⁺ stores by CPA did not evoke Ba²⁺ or Ca²⁺ influx, indicating that capacitative Ca²⁺ entry does not occur in these cells. However, refilling the store did require extracellular Ca²⁺ and the Ca²⁺ influx required for refilling could be inhibited pharmacologically. Refilling of the BK-sensitive store was blocked completely by SKF96365 (20 μM) and econazole (10 μM). Multiple pharmacologic targets are present along the route by which Ca²⁺ re-enters the IP₃-sensitive store in neuronal cells.

MODULATION OF BASAL AND STIMULATED DOPAMINE RELEASE BY NITRIC OXIDE. P. Sun*, A. Kanthasamy, and G.E. Isom. Dept. of Pharmacol. & Toxicol., Sch. of Pharm. & Pharmacol. Sci., Purdue Univ., West Lafayette, IN 47907

Previous investigations suggest the involvement of nitric oxide (NO) in the regulation of neurotransmitter release. This study characterized the effect of NO generating compounds on basal and potassium stimulated dopamine (DA) release in PC12 cells. The levels of DA released and DA remaining in cells were quantitated by HPLC-EC after 10 min of incubation. Although 5 mM isosorbide dinitrate (ISDN) increased DA release to 142.4% of basal levels, 1 mM and 5 mM ISDN attenuated KCl (56 mM) evoked release to 76.5% and 50.4%, respectively. In control studies, isosorbide, chemically similar to ISDN but lacking NO generating capacity, produced no effect on K⁺ stimulated release. Also, s-nitrosol-acetyl-penicillamine, another NO donor, produced inhibition of K⁺ evoked release. In additional studies, 5 mM ISDN potentiated DA secretion initiated by both the Ca ionophore A23187 and the Ca slow channel agonist Bay K 8644. 8-Br-cGMP, a phosphodiesterase resistant cGMP analogue, did not mimic ISDN on either K⁺ or A23187 induced secretion. To study the mechanism underlying NO's action, cytosolic free calcium levels ([Ca²⁺]_i) were measured; ISDN blocked the K⁺ stimulated increase of [Ca²⁺]_i by 48.7%. These results suggest NO modulates DA release through a cGMP independent mechanism by affecting Ca mobilization during depolarization and/or possibly Ca²⁺ mediated exocytosis. (Supported by NIH Grant ESO4140)

485.12

A Modified, Sensitive Dual Label Assay for Nitric Oxide Synthase (NOS). Maria-Isabel Loza-Garcia¹, and Saul Maayani^{2*}. Depts. of Pharmacology¹, University of Santiago, 15706 Santiago de Compostela, Spain (MILG) and Anesthesiology², Mount Sinai Medical Center, CUNY, NY, NY 10029.

Production of nitric oxide (NO) by constitutive or inducible cytosolic NOS has been described in a variety of tissues. NOS activity is assayed by measuring conversion of [³H]-arginine (Arg) to [³H]-citrulline (Cit) which is isolated with ion-exchange chromatography. Current protocols do not correct for recovery of [³H]-Cit from the columns. In addition, the commercially available [³H]-Arg has 2-5% of "[³H]-Cit-like" material(s) and these contaminants increase up to 10% within two months. We have developed simple modifications which increase the sensitivity of the NOS assay. Stock [³H]-Arg is purified at 4°C by applying 50 μCi of [³H]-Arg to a 0.1 ml resin bed (AG-50X4, sodium form; Bio-Rad). The [³H]-Cit-like materials are removed by washing the resin with 1500 μl H₂O and the purified [³H]-Arg is eluted with 800 μl 0.01 N NaOH, into 28 μl of 1 M citric acid (final pH = 5-6; stability = 3 days). To protect the [³H]-Arg during purification, all solutions contain 5% ethanol. The purification procedure reduces [³H]-Cit-like materials present in stock solutions to 0.04-0.06% with a yield of 60-80%. To measure NOS activity, cytosolic fractions (40,000 x g x 10 min) from whole brain (rat or guinea pig) are prepared in 0.3 M sucrose, 20 mM HEPES and 1 mM DTT [pH=7.2]. The final incubation mixture (500 μl, pH=7.2) contains 0.1 mM NADPH, 20 mM HEPES, 1 mM EDTA, 60 mM sucrose, 0.02 mM DTT, 0.2 mM CaCl₂ and 0.6 mg cytosol protein. The assay (10-30 min, 37°C) is initiated by the addition of 50-150,000 dpm of [³H]-Arg and is terminated by addition of citric acid/EGTA to create pH=4.0. [¹⁴C]-Cit (3000-5000 dpm in 10 mM Cit) is added (to monitor recovery) and each sample is transferred to a 1 ml bed of AG-50 x 4 (sodium form). The Cit is eluted with 2 ml of H₂O and counted in a scintillation counter (dual labeled dpm). (USPHS GM 34852; MH 48125).

2',3' DIDEOXYCYTIDINE ALTERS CALCIUM BUFFERING IN CULTURED RAT DORSAL ROOT GANGLION NEURONS. J.L. Werth* and S.A. Thayer. Department of Pharmacology, University of Minnesota Medical School, Minneapolis, MN 55455.

Depolarization of cultured rat DRG neurons with 50 mM K⁺ elicits [Ca²⁺]_i transients with a prominent plateau phase that is due to mitochondrial Ca²⁺ sequestration. In cell culture 2',3' dideoxycytidine (ddC) increases lactic acid synthesis and decreases levels of mitochondrial DNA. We tested the possibility that mitochondrial Ca²⁺ buffering can be altered by chronic treatment with ddC. [Ca²⁺]_i transients were measured in single DRG neurons grown in primary culture with Indo-1 based dual emission microfluorimetry. Cultures were treated with 1 μM ddC and challenged with 50 mM K⁺ following 2, 4, 6, and 8 days of drug treatment. Following 4 days of ddC treatment [Ca²⁺]_i transients were shorter in duration (278 ± 59 s, mean ± SEM, N=12) compared to untreated cells (559 ± 101 s, N=7, p < .05). This trend was also apparent after 6 days of ddC treatment, [Ca²⁺]_i transients were shorter in treated cells (246 ± 47 s, N=10) compared to control cells (455 ± 88 s, N=10, p < .05). Changes in mitochondrial Ca²⁺ buffering may underlie the peripheral neuropathy produced by ddC. Furthermore, ddC promises to be a useful tool for studying the role of mitochondria in neuronal function.

INTRACELLULAR CALCIUM WAVES INDUCED IN ADULT MAMMALIAN NEURONS BY CAFFEINE. M.N. Rand*, S.G. Waxman, and J.D. Kocsis, Dept. Neurology, Yale School of Medicine, New Haven, CT 06510; and VAMC, West Haven, CT 06516.

Calcium participates in a variety of intracellular second-messenger pathways, including gene expression following injury. Caffeine is thought to release calcium from intracellular stores by increasing the sensitivity of the ryanodine receptor to cytosolic free calcium. Single waves of intracellular calcium were induced in dissociated adult rat DRG neurons and studied in real time with confocal microscopy and the calcium indicator dye, fluo-3. Brief application of caffeine (20 mM) to the edge of a neuron via micropipette resulted in the propagation of a calcium wave with an average velocity of $68 \mu\text{m s}^{-1}$. Waves began ~400 ms after focal application of caffeine; during this latent period we frequently observed a reduction of the fluorescence signal within the area of caffeine stimulation. In some neurons, a slight decrease in calcium-induced fluorescence preceded the wave as it moved through the cell, suggesting a reduction in cytosolic free calcium at the leading edge of the wave. The magnitude of the calcium signal was relatively constant as it moved through the cytoplasm. Calcium signals moved through the nucleus concurrent with those in the cytoplasm; neurons were visualized with elevated calcium signals partially filling the nucleus and parallel with those in the cytoplasm. Calcium signals were high upon entering the nucleus (several-fold greater than cytoplasmic signals) and decreased their velocity to ~ $20 \mu\text{m s}^{-1}$ within the nucleus. Nucleolar signals exceeded those of the nucleus. Calcium waves could be induced in neurons bathed in calcium-free solution, and could be induced in the same cell many times. These observations indicate that focal application of caffeine can trigger calcium waves generated by calcium-induced calcium release, and provide useful insights into mechanisms of calcium signal propagation in mammalian neurons.

REGULATION OF INTRACELLULAR CALCIUM IN CULTURED RAT DORSAL ROOT GANGLION NEURONS BY CALCIUM-RELEASING AGENTS AND NEUROTRANSMITTERS. B.N. Christensen and M.D. Christensen*, Dept. Physiology & Biophysics and Dept. Int. Medicine, Univ. Tx. Med. Br., Galveston, TX 77555.

Dorsal root ganglion cells 1 - 4 days in culture were loaded with Fura-2am for measuring $[\text{Ca}^{2+}]_i$. The calcium releasing agent caffeine (10 mM) was pressure ejected onto individual cells and the change in fluorescence (340/380 nm) ratio measured. Caffeine produced a rapid increase in $[\text{Ca}^{2+}]_i$ that reached a peak within 2-3 sec. Ten second applications of caffeine produced a peak $[\text{Ca}^{2+}]_i$ response that decreased to a plateau and remained elevated for the duration of the application. In some cells, reduction of $[\text{Na}^+]_o$ (to 8 mM) markedly slowed the recovery from the caffeine-induced Ca^{2+} release suggesting that the $\text{Na}^+/\text{Ca}^{2+}$ exchanger was important for clearing Ca^{2+} from the cytoplasm.

The glutamate metabotropic agonist (\pm)-1-aminocyclopentane-trans-1,3-dicarboxylic acid (ACPD) also was an effective releasing agent. Responses to ACPD were generally considerably longer e.g. a 10 sec application produced more than a 200 sec increase in $[\text{Ca}^{2+}]_i$. Supported by grant NS-29640.

INTRACELLULAR AND INTERCELLULAR CALCIUM SIGNALING IN NEURONS AND GLIAL CELLS IN PRIMARY CULTURE A.C. Charles* Dept. of Neurology, UCLA School of Medicine, Los Angeles CA 90024

Neurons and glial cells in primary mouse cortical cultures showed distinct patterns of Ca^{2+} signaling as observed with fluorescence video imaging and fura-2. Neurons, identified with rhodamine-conjugated tetanus toxin fragment, showed spontaneous Ca^{2+} spikes with a periodicity of 0.5-10 sec. These Ca^{2+} spikes were most often asynchronous in individual neurons, although synchronous Ca^{2+} spikes in groups of 3-5 neurons were commonly observed. Ca^{2+} spikes in neurons had a rapid rise time (33 - 100 ms) and involved the entire cell simultaneously. Spontaneous neuronal Ca^{2+} spikes were abolished by 1 μM TTX. Glial cells also showed spontaneous Ca^{2+} spikes, but the periodicity was greater (5 - 60 sec) and the rise time was greater (0.5-3 sec) than those of neuronal Ca^{2+} spikes. TTX did not inhibit glial Ca^{2+} spikes. Glial Ca^{2+} spikes began in one part of the cell and propagated as a wave throughout the cell. In some cultures, spontaneous intercellular Ca^{2+} waves were observed in glial cells. These intercellular Ca^{2+} waves appeared to originate from sites of contact with neurons. Mechanical stimulation of a single neuron induced an increase in $[\text{Ca}^{2+}]_i$ in the stimulated neuron and some neighboring neurons, and frequently initiated an intercellular Ca^{2+} wave in surrounding glial cells. Mechanical stimulation of a single glial cell initiated an intercellular Ca^{2+} wave in neighboring glial cells, as well as a transient increase in $[\text{Ca}^{2+}]_i$ in some nearby neurons. These results suggest distinct mechanisms for intracellular and intercellular calcium signaling in neurons and glial cells, and provide evidence for direct communication between neurons and glia.

TRANSFECTED PARVALBUMIN ALTERS CALCIUM HOMEOSTASIS IN A CELL LINE. B.K. Mueller, P. Kabos, T. Neumann, B. Belhage, S.B. Kater* Anatomy and Neurobiology, Colorado State University, Ft. Collins, CO 80523.

Maintenance of calcium homeostasis is crucial for neurons. Indirect evidence supports a protective role of some EF-hand calcium-binding proteins against calcium induced neurotoxicity. Little is known about how these proteins influence cytosolic calcium levels. After cloning the parvalbumin gene into an expression vector, teratocarcinoma cells (PCC 7) were transfected. Transfected and untransfected cells were loaded with the calcium indicator Fura-2 and were exposed, in the same dish, to low concentrations of the calcium ionophore A23187. Calcium imaging technology and a computerized microscope stage enabled nearly simultaneous measurements of intracellular calcium. Before addition of A23187 both cell types showed no significant differences in rest calcium levels. However, 20 nM A23187 rapidly induced a very high increase of intracellular calcium in all the untransfected cells. In contrast, the majority of transfected cells showed only a modest, slow increase. A minority of transfected cells had similar calcium rises. One hour later these transfected cells had reduced their internal calcium levels much more efficiently than their untransfected neighbors. These results support the hypothesis that parvalbumin is able to contribute a powerful, stabilizing influence to calcium homeostasis.

CHANGES IN CALCIUM MOBILIZATION AND PHOSPHATIDYLINOSITOL TURNOVER BY AGENTS THAT ELEVATE CYCLIC AMP IN HUMAN NEUROBLASTOMA SK-N-SH CELLS. P.-S. Liu, H.-Y. Tu and L.-S. Kao* Department of Microbiology, Soochow University; Institute of Biomedical Sciences, Academia Sinica, Taipei, Taiwan, R. O. C.

The effects of cyclic AMP-elevating agents on changes in cytosolic calcium concentration ($[\text{Ca}^{2+}]_i$) and phosphatidylinositol (PI) turnover induced by the activation of muscarinic receptors was studied in human neuroblastoma SK-N-SH cells. The carbachol-induced $[\text{Ca}^{2+}]_i$ rise was enhanced by forskolin or IBMX but was inhibited by caffeine if agents were added to the cells 30 sec before the addition of carbachol. The inhibitory effect of caffeine increased as caffeine concentration was increased. However, when the cells received longer pretreatment (30 min) with forskolin, IBMX, or caffeine, all three agents inhibited the carbachol-induced $[\text{Ca}^{2+}]_i$ transient rise and PI turnover. Caffeine caused the greater inhibition. It appears that forskolin and IBMX which elevate cytosolic cAMP concentration, exert a biphasic effect on $[\text{Ca}^{2+}]_i$ change. Carbachol-induced $[\text{Ca}^{2+}]_i$ change and PI turnover might be inhibited upstream from phospholipase C, while they be enhanced through a pathway downstream from IP_3 generation. Caffeine, in addition to its effect on cAMP, may inhibit the carbachol-induced $[\text{Ca}^{2+}]_i$ rise through the depletion of some internal Ca^{2+} pools. DYNAMIC REGULATION OF IP_3 -DEPENDENT CALCIUM RELEASE BY EXTRAVESICULAR CALCIUM. E. A. Finch^{1,3} and S. M. Goldin^{2,3}. ¹Program in Neuroscience and ²Biol. Chem. Dept., Harvard Med. Sch. Boston, MA; ³Cambridge Neuroscience, Inc., Cambridge, MA.

We have used a rapid superfusion system to study the regulation and kinetics of IP_3 -dependent ^{45}Ca release from brain microsomal vesicles. We previously reported that elevation of extravesicular $[\text{Ca}]$ rapidly potentiates and more slowly inactivates IP_3 -induced ^{45}Ca release (Finch et al., *Science* 252, 1991) and that ATP further potentiates this Ca release. This suggests that the IP_3 receptor may mediate IP_3 -dependent Ca -induced Ca release (CICR), similar to CICR mediated by the ryanodine receptor. Further investigation of the dynamic regulation of this Ca release supports this hypothesis.

The subsecond time resolution of our superfusion system and the ability to clamp extravesicular $[\text{Ca}]$ with 5 mM EGTA or BAPTA permit pre-steady state measurements that result in temporal separation of the rapid activation and slow inactivation of IP_3 -mediated ^{45}Ca release by Ca . Under these conditions, a biphasic $[\text{Ca}]$ dependence with a maximum release rate at 3 - 10 μM Ca is observed. At steady state $[\text{Ca}]$, release rate was also biphasically dependent on $[\text{Ca}]$, with a maximum at 300 - 500 nM, reflecting the combined effects of both activation and inactivation by Ca .

The ability of the superfusion system to effectively clamp the $[\text{Ca}]$ during ^{45}Ca release prevented feedback regulation of the IP_3 receptor by released Ca . Under these conditions, exposure of the preparation to step changes in $[\text{Ca}]$ in the continued presence of IP_3 rapidly modulated the rate of ^{45}Ca release, such that a rapid enhancement of the release rate was elicited by a step increase in $[\text{Ca}]$ from 100 nM - 1 μM to 10 μM and an immediate decrease in release rate resulted from a step decrease in $[\text{Ca}]$ from 10 μM to 100 nM - 1 μM . These data demonstrate that the rate of IP_3 -mediated Ca release rapidly responds to changes in extravesicular $[\text{Ca}]$. Superfusion with buffers with decreased Ca buffering capacity (<1 mM EGTA or BAPTA), which resulted in changes in extravesicular $[\text{Ca}]$ during ^{45}Ca release, directly illustrated that feedback regulation by released Ca altered the kinetics of ^{45}Ca mobilization by IP_3 , further supporting the hypothesis that localized changes in cytosolic $[\text{Ca}]$ in the vicinity of the receptor dynamically regulate IP_3 -dependent Ca release.

DOPAMINERGIC PARTICIPATION IN TRIADIMEFON-INDUCED HYPERACTIVITY. R.C. MacPhail^{1,3}, J.D. Farmer¹, T.-H. Chu² and Q.D. Walker⁴. ¹Neurotoxicology Division, U.S. EPA, Research Triangle Park, NC 27711, ²North Carolina School of Science and Mathematics, Durham, NC 27705, ³Department of Psychology and Curriculum in Neurobiology and ⁴Curriculum in Toxicology, The University of North Carolina, Chapel Hill, NC 27514.

Recent data indicate that triadimefon (a triazole fungicide) produces many behavioral effects, including hyperactivity, that resemble those produced by psychomotor stimulants. Since stimulant-induced hyperactivity is largely mediated by CNS dopamine receptors, this experiment determined the effect of dopamine-receptor blockade on triadimefon-induced hyperactivity. Thirty-six adult male Long-Evans rats were tested for four days during 30-min sessions in a photocell activity device. Before the fifth session, rats were divided into six groups (N=6/group) and received either: vehicle then vehicle or 100 mg/kg triadimefon, 15 µg/kg SCH23390 (a selective D₁ receptor blocker) then vehicle or 100 mg/kg triadimefon; or 0.1 mg/kg remoxipride (a selective D₂ receptor blocker) then vehicle or 100 mg/kg triadimefon. Treatments were given s.c. (1 ml/kg) 60 min and 30 min pre-session. Triadimefon increased motor activity, SCH23390 decreased activity and remoxipride had no effect on activity. Both blocking agents partially attenuated triadimefon-induced hyperactivity. A second experiment used a smaller dose of SCH23390 (5 µg/kg) and a larger dose of remoxipride (0.3 mg/kg). SCH23390 decreased activity, remoxipride slightly decreased activity and triadimefon increased activity. Compared to the first experiment, SCH23390 produced less attenuation, and remoxipride produced greater attenuation, of triadimefon-induced hyperactivity. In all instances, the attenuation of triadimefon-induced hyperactivity was greater than that predicted by effect additivity. These results indicate that triadimefon-induced hyperactivity requires dopamine-receptor activation.

AMPHETAMINE, COCAINE, AND DIZOCILPINE ENHANCE PERFORMANCE ON A LEVER-RELEASE, CONDITIONED AVOIDANCE RESPONSE TASK. J.M. White¹, J.C. Christensen, K.M. Marley, G.S. Flory, and G.V. Rebec. Prog. Neural Science, Dept. Psychology, Indiana University, Bloomington, IN 47405.

A lever-release version of the conditioned avoidance response (CAR) task in rats is extremely sensitive to changes in forebrain dopamine transmission. In fact, CAR performance is impaired by relatively low doses of dopamine antagonists (White et al., *Pharmacol. Biochem. Behav.*, 41:29-35, 1991), whereas apomorphine, a direct dopamine agonist, exerts the opposite effect (Wilcox and Spirduso, *Psychopharmacology*, 95:276-279, 1988). In the present study, we extended this line of research to amphetamine and cocaine, well-known psychomotor stimulants that facilitate dopamine transmission. We also assessed CAR performance in response to dizocilpine (MK-801), a behavioral stimulant that acts as a noncompetitive NMDA antagonist. Adult, male, Sprague-Dawley rats (n=32) were trained to make a lever-release response within 500 msec after the onset of an auditory cue (85 dB) in order to avoid shock (0.6 mA). All subjects, trained to avoid at least 70% of signalled shocks on two consecutive sessions, received 60 trials prior to drug injection followed by 60 post-drug trials. Amphetamine (0.1 and 0.25 mg/kg), cocaine (7.5 and 15.0 mg/kg), and dizocilpine (0.01 and 0.05 mg/kg) enhanced CAR performance relative to vehicle treatment. Thus, all doses both increased percent avoidance and decreased avoidance latency without altering the latency of the escape response. These results suggest that indirect dopamine agonists as well as NMDA antagonists facilitate CAR performance.

INTRANIGRAL INJECTIONS OF SCH 23390 INHIBIT AMPHETAMINE AND SKF82958-INDUCED ROTATIONAL BEHAVIOR. David M. Yurek¹ and Susan B. Hipkens. Univ. of Kentucky College of Med., Div. of Neurosurgery and Dept. of Anatomy & Neurobiology, Lexington, Kentucky 40536.

Rats were given unilateral 6-hydroxydopamine lesions of the nigrostriatal pathway and permanent indwelling cannula were surgically implanted into the non-lesioned side of the brain; cannula were used for direct injections of dopamine antagonists into the pars reticulata region of the non-lesioned substantia nigra. The selective D₁ receptor antagonist, SCH 23390, was injected intranigraly at various concentrations [3.0, 1.5, 1.0, 0.6, or 0.3 mM] just prior to an intraperitoneal injection of amphetamine. SCH 23390 dose-dependently inhibited amphetamine-induced rotational behavior with the highest doses completely blocking rotational behavior in some animals. An intranigral injection of the selective D₂ receptor antagonist, (-) sulpiride (1.0 mM), did not produce a significant reduction in amphetamine-induced rotational behavior whereas an equivalent molar concentration of SCH 23390 (1.0 mM) produced a significant 62% reduction in amphetamine-induced rotational behavior. A concentration of SCH 23390 that produced a 50% reduction in rotational behavior when injected directly into the substantia nigra was unable to produce a significant reduction in rotational behavior when injected directly into the striatum. The effects of intranigral injections of SCH 23390 on apomorphine-induced rotational behavior were directly opposite to that observed for amphetamine-induced rotational behavior; contralateral rotational behavior increased relative to baseline measures.

SCH 23390 injected into the lesioned substantia nigra completely blocked rotational behavior induced with a subcutaneous injection of SKF 82958 [0.0075 mg/kg] whereas rotational behavior induced with quinpirole [0.2 mg/kg, s.c.] was not affected by even the highest doses of SCH 23390 pretreatment. These data support the hypothesis that dopamine release in the midbrain may act as a neuromodulator of motor behavior, and that D₁ receptors play a functional role in this process. Supported by Univ. of Kentucky Med. Col. Research Fund and USPHS NS 29994.

486.2

CHARACTERIZATION OF THE STIMULUS PROPERTIES OF THE FULL D₁ AGONIST SKF 82958. C.L. Zuch, S.C. Johnson, B. Weiss* and D.A. Cory-Slechta. Department of Environmental Medicine, University of Rochester School of Medicine and Dentistry, Rochester, NY 14642.

Previous studies of D₁ receptor-mediated function have concluded that D₁ receptors may play a less significant role in drug abuse than D₂ receptors. These conclusions were based on studies using the partial D₁ agonist SKF 38393. However, more recent studies indicate that unlike SKF 38393, the full D₁ agonist SKF 82958 readily crosses the blood-brain barrier and is self-administered by rodents. Since the stimulus properties of drugs are important to their reinforcing properties, this study sought to determine whether SKF 82958 could serve as a discriminative stimulus. Rats were trained in a standard two-lever food-reinforced operant drug discrimination paradigm to discriminate 0.05 mg/kg SKF 82958 from saline with responding reinforced on an FR10 schedule. Acquisition of the discrimination was defined as 77% accuracy in 8 of 10 consecutive sessions. Generalization testing to other doses of SKF 82958, saline and the training dose followed acquisition. The average time taken to reach criterion was 44 sessions (s.e.m.=1.78). SKF 82958 engendered dose-dependent increases in drug lever responding, with an ED₅₀ value of 0.041 mg/kg. Response rates in the presence of 0.025 mg/kg SKF 82958 were increased relative to saline response rates whereas at 0.031 mg/kg SKF 82958 and higher, response rates were decreased in comparison to saline. These data thus demonstrate that the selective D₁ agonist SKF 82958 has discriminative stimulus properties. ES05017, ES05903.

486.4

APAMIN SELECTIVELY ATTENUATES THE PRESYNAPTIC BEHAVIORAL EFFECTS OF THE DOPAMINE D₂ AGONIST QUINPIROLE IN SQUIRREL MONKEYS. S. Rosenzweig-Lipson* and J.E. Barrett. CNS Department, Lederle Laboratories, American Cyanamid Company, Pearl River, NY 10965

The present study investigated the ability of apamin, a selective potassium channel blocker, to modify the pre- and postsynaptic behavioral effects of the dopamine D₂ receptor agonist quinpirole in squirrel monkeys. The duration of immobility and/or unusual postures indicative of catalepsy (presynaptic) or the duration of scratching (postsynaptic) were scored during 5 minute observation periods. Saline or incremental doses of quinpirole were administered 10 minutes prior to each observation period. Administration of saline did not increase the durations of catalepsy (2-16% of the observational period) or scratching (0-1% of the observational period) in individual monkeys. Low doses of quinpirole (0.003 - 0.03 mg/kg) dose-dependently increased the duration of catalepsy to approximately 18 - 84% of the observational period in individual monkeys. Higher doses of quinpirole (0.1 - 0.3 mg/kg) did not increase the duration of catalepsy, rather these doses increased the duration of scratching to approximately 30 - 80% of the observational period in individual monkeys. Pretreatment with apamin (0.003 - 0.03 mg/kg) 1 hr prior to the first observation period attenuated the effects of quinpirole (0.01 - 0.03 mg/kg) on catalepsy, with cataleptic postures maintained for 3 - 50% of the observational periods in individual monkeys. In contrast, pretreatment with apamin had little effect on the scratching produced by quinpirole (0.1 - 0.3 mg/kg) with scratching occurring for 60 - 80% of the observational periods in individual monkeys. The present results suggest that potassium channel blockade can differentially modify the pre- and postsynaptic behavioral effects of dopamine D₂ agonists in monkeys.

INVOLVEMENT OF GLUTAMATE AND GABA IN TURNING BEHAVIOR CAUSED BY MICROINJECTIONS INTO THE DORSAL STRIATUM OF RATS. I.D. Smith¹, K. Mitha and R.J. Beninger. Department of Psychology, Queen's University, Kingston, Canada.

Among the afferent systems projecting to the dorsal striatum are glutamatergic (GLU) inputs from the cortex, dopaminergic (DA) projections from the substantia nigra, and GABAergic input from local circuits within the basal ganglia. An imbalance in striatal DA transmission causes a directional bias in the rat. We have shown previously that activation of striatal NMDA or kainic acid (KA) receptors with sub-toxic agonist microinjections also causes rotation. Several experiments were carried out to further characterize the involvement of AMPA and GABA_A receptors in circling behavior.

Male Wistar rats received 0.5µl drug injections into the dorsal striatum (A-0.3, L3.0, V4.5) and turning activity over 20 minutes was measured in an automated rotometer chamber. Injections of 200µM (21.3ng) KA induced significant contralateral turning and was blocked by co-injection of 7.9mM (20µg) of the DA antagonist *cis*-flupenthixol (*c*-flu). AMPA injections (50, 200, 400µM (4.7, 18.6, 37.2ng)) caused dose-dependent contralateral rotation and the effect of the highest dose was reversed by *c*-flu and by co-injection of 200µM (23.2ng) CNQX. The GABA_A antagonist bicuculline (50, 200, 500µM (11.6, 46.2, 115.5ng)) also caused contralateral turning, whereas injections of the GABA_A agonist muscimol (50, 200, 500µM (4.9, 19.5, 48.8ng)) had no significant effect.

These results show that blocking GABA_A receptors and activating non-NMDA glutamate receptors causes contralateral rotation. The KA and AMPA effects seem to depend on intact DA neurotransmission, and may operate through increasing local DA levels. The bicuculline effect may involve a similar mechanism and may also increase striatal output unit discharge through direct postsynaptic disinhibition. (Supported by NSERC)

DEVELOPMENT AND REVERSAL OF SENSITIZATION TO AMPHETAMINE ANOREXIA: ROLE OF TEMPORAL, BEHAVIORAL AND PHARMACOLOGICAL VARIABLES. D.L. Wolgin*. Department of Psychology, Florida Atlantic University, Boca Raton, FL 33431.

Rats given 35 injections of either amphetamine (2.5 mg/kg; Group A) or saline (Group S) at 3-d intervals developed sensitization to the anorexic effect of the drug, as assessed by shifts to the left in dose-response (DR) functions conducted before and after the chronic treatment. Group A, but not Group S, also displayed sensitization of stereotypy. These results suggest that sensitization of anorexia developed as a result of the passage of time and/or the stress of repeated injections between the DR determinations. Subgroups from each group were then given daily injections of amphetamine (2 mg/kg) either before or after access to milk for 4 wk. Other subgroups were given injections of saline as a control. On a final DR determination, the control groups showed no further changes in milk intake. Groups given the drug after milk showed a loss of sensitization (DR 3 = DR 1), whereas groups given the drug before milk developed tolerance (DR 3 > DR 1). These results demonstrate that, unlike tolerance, the reversal of sensitization does not require access to milk while in the drugged state.

EVIDENCE OF ALTERED SENSITIVITY OF OPIATE RECEPTORS AFTER SEIZURES KINDLED BY PICROTOXIN. J. Thomas* & W.L. Nores, Dept. of Psychology, Univ. of New Orleans, New Orleans, LA 70148.

The possibility that the development of increased sensitivity to picrotoxin-induced focal seizures as a result of previous seizure episodes was related to changes in the function of endogenous opiate mechanisms was investigated. Adult male rats were injected with saline or a convulsant dose of picrotoxin (3 mg/kg, SC). The latency to and number of focal seizure episodes was scored. This procedure was repeated twice at one week intervals for a total of three seizure induction days. Five months after the third seizure testing day, the saline and picrotoxin-treated rats were pretreated with morphine (.5 mg/kg, IP) and tailflick latencies were measured. The results showed that rats given the repeated picrotoxin treatment showed a greater incidence of focal seizures on Day 3 of testing relative to Day 1. Mean tailflick latencies after morphine were longer in the picrotoxin-treated rats than in the saline-treated controls. The results of the study suggest that alterations in the sensitivity of opiate mechanisms occur during the kindling of seizures with picrotoxin.

486.11

NALORPHINE AS A STIMULUS IN DRUG DISCRIMINATION LEARNING. S.T. Smurthwaite* and A.L. Riley. Psychopharmacology Laboratory, The American University, Washington, D.C. 20016.

Utilizing the drug discrimination procedure, nalorphine has been reported to substitute for both mu and kappa agonists, as well as the mu antagonist naloxone. Given that the training drug has been reported to be an important factor in generalization patterns, in the present study animals were trained to discriminate nalorphine from distilled water. In subsequent tests for generalization, the mu agonist morphine substituted for the nalorphine stimulus in a dose-dependent manner, while the kappa agonist U50,488 and the mu antagonists naloxone and naltrexone failed to do so, suggesting that discriminative control was mediated by its agonist activity at the mu receptor. Although it remains unclear what specific mechanism underlies the different generalization patterns when different compounds are used as the training drug, it is clear that training drug is important in determining the generalization patterns with the opiate antagonists.

486.8

POSSIBLE ROLE OF A DA RECEPTOR RESERVE IN PREWEANLING RATS C.A. Bolanos and S.A. McDougall*. Dept. of Psychology, California State University, San Bernardino, CA 92407.

Evidence consistent with the presence of both a D1 and a D2 receptor reserve has been found using the preweanling rat, as 17-day-old rats treated with EEDQ (an irreversible DA antagonist) showed normal increases in behavior after challenge with the DA agonists NPA or quinpirole. To assess the receptor reserve idea, we treated 17-day-old pups with EEDQ and flupentixol (a reversible DA antagonist) and then challenged them with NPA. If a receptor reserve hypothesis is correct, pups receiving EEDQ should be more sensitive to the effects of a reversible antagonist than pups not receiving EEDQ. The 16-day-old pups were injected with EEDQ (7.5 mg/kg) after DA receptors were either unprotected or protected using sulpiride and SCH 23390. Flupentixol (0.1 or 0.2 mg/kg) was then administered to the pups 24 hrs after EEDQ. Locomotor activity and stereotyped sniffing were then measured during a 20 min testing session. NPA-induced sniffing was blocked in a dose-dependent fashion by flupentixol. Importantly, EEDQ did not differentially affect flupentixol's ability to block sniffing. Locomotor activity was also enhanced by NPA, but EEDQ and flupentixol did not combine to maximally antagonize this behavior. Therefore, these results suggest that the presence of a receptor reserve cannot explain EEDQ's inability to disrupt the agonist-induced responding of preweanling rat pups.

486.10

THE TEMPORAL ANALYSIS OF THE GENERALIZATION FUNCTION WITHIN THE CONDITIONED TASTE AVERSION BASELINE OF DRUG DISCRIMINATION LEARNING. A.L. Riley*, C.L. Wetherington, and B.X. Sobel. Psychopharmacology laboratory, The American University, Washington, DC 20016

Although the generalization gradient in drug discrimination learning is often described as being quantal in nature (Mathis and Emmett-Oglesby J. Neurosci. Methods 31:23-33, 1991), we have recently reported that within the taste aversion baseline of drug discrimination learning this function is more graded, i.e., individual subjects display intermediate drug control at intermediate doses of the training drug (Riley et al. Beh. Pharm. 2:323-334, 1992). In the present experiment, within-session licking patterns were observed for rats acquiring naloxone or pentobarbital discriminations within the taste aversion baseline. Although every individual subject displayed a graded dose-response function in subsequent assessments with varying doses of the training drug, i.e., consumption was intermediate at intermediate doses of the training drug, these intermediate levels of consumption actually reflected differences in onset and offset of drug action. Specifically, consumption was generally at control levels within the first five minutes of the 20-min session, followed by complete suppression and then rapid recovery to control levels near session termination. The averaging of these quantal effects (presumably reflecting drug onset and offset) appears to mediate the graded dose-response function with naloxone and pentobarbital within this baseline of drug discrimination learning.

EVIDENCE FOR CROSS-TOLERANCE TO THE LOW EFFICACY AGONIST, NALBUPHINE, IN PIGEONS DISCRIMINATING AMONG TWO DOSES OF MORPHINE AND SALINE. S.A. Vanecek* and A.M. Young. Dept. of Psych., Wayne State University, Detroit, MI 48202.

Cumulative doses of nalbuphine (NB) were evaluated in pigeons trained to discriminate among 1.8 mg/kg (low dose) and 10 mg/kg (high dose) morphine (MS) and saline (SAL) under fixed-ratio 30 schedules for food reinforcement. At the lowest dose tested, 0.1 mg/kg, NB evoked SAL key responding. Higher doses (0.32-32 mg/kg) evoked low dose key responding, but did not engender high dose key responding prior to rate-suppressing doses. Suspending training and administering 56 mg/kg MS, b.i.d., a treatment that confers tolerance to MS itself, or 10 mg/kg MS, b.i.d., a treatment that does not confer tolerance to MS, produced cross-tolerance to the MS-like effects of NB and markedly increased the rate-decreasing potency of NB. In MS-treated birds, NB evoked only SAL key responding, and the doses required to suppress rates decreased 30- to 100-fold. An acute dose of 0.32 mg/kg NB during treatment with 10 mg/kg MS, b.i.d., or 1.0 mg/kg NB during treatment with 56 mg/kg MS, b.i.d., increased the doses of MS required to evoke either low dose or high dose key responding. In the absence of repeated treatment, these acute NB doses either evoked low dose key responding themselves or decreased the doses of MS required to evoke low dose key responding, and also increased the doses of MS required to evoke high dose key responding. These findings are consistent with the hypothesis that NB functions as a partial agonist at mu opioid receptors, and that it is less efficacious than MS. (Supported by DA03796 and K02 DA00132)

LONG-TERM EFFECTS OF d-FENFLURAMINE AND d-norFENFLURAMINE ON SEROTONIN AND 5-HIAA IN THE RAT HIPPOCAMPUS. M. Puig de Parada, M.A. Parada and B.G. Hoebel*. Dept. of Psychology, Princeton University, Princeton, NJ 08544 and School of Medicine, Universidad de Los Andes, Mérida, Venezuela.

This study compared chronic effects of a three week regimen of daily ip injections of saline, d-fenfluramine (d-FEN) (10mg/Kg/day) and d-norfenfluramine (d-norFEN) (5mg/Kg/day) on extracellular serotonin (5-HT) and (5-HIAA) in the rat hippocampus. Microdialysis was performed in the same awake animals during the first and last day of ip treatment, and two and four weeks after treatment ended. The first drug injection increased 5-HT (272% with d-FEN and 715% with d-norFEN). Only d-FEN decreased 5-HIAA. The last day of treatment basal 5-HT was normal. Basal 5-HIAA decreased to 41% of the first-day baseline with d-FEN and to 31% with d-nor-FEN. The last drug injection no longer released 5-HT. Two weeks after treatment basal 5-HT was still at or above the day-1 baseline. 5-HIAA was normal in the saline group and still depressed in the d-FEN group (57%) and specially the d-norFEN group (35%). A month after the treatment, 5-HT was still at the original baseline and 5-HIAA was low in all groups. High potassium (KCl, 65mM) infused at the end of the experiment released 5-HT in the control animals, but not in the d-FEN or d-norFEN groups. The results suggest that d-norFEN might account for the long term effects of d-FEN in rats.

THE EFFECT OF ALPHA₂-ADRENOCEPTOR AGONISTS AND ANTAGONISTS ON THE STIMULUS PROPERTIES OF LSD. D. Marona-Lewicka*, R. Oberlander, D.E. Nichols Depts. of Medicinal Chemistry and Pharmacognosy, and Pharmacology and Toxicology School of Pharmacy and Pharmacal Sciences, Purdue University, West Lafayette, IN 47907

Substantial evidence suggests that the discriminative stimulus effect of LSD is mediated by actions at postsynaptic 5-HT receptors. However, in rats trained to discriminate LSD from saline complete generalization is reported with the alpha₂-adrenoceptor antagonist, yohimbine, and partial substitution with the alpha₂-agonist, clonidine. Rats were trained to discriminate LSD tartrate (0.08 mg/kg) from saline in a food-reinforced two lever procedure with FR=50. Partial generalization of the LSD stimulus was observed with clonidine (0.01-0.08 mg/kg) or yohimbine (1.0-3.0 mg/kg) 57% and 80%, respectively. Failure to achieve complete substitution of clonidine or yohimbine may be explained by the inability of subjects to complete the test session (high % of disruptions produced by moderate doses of clonidine and higher doses of yohimbine). Neither clonidine nor yohimbine were able to block the LSD cue. When clonidine (0.04mg/kg) or yohimbine (2 mg/kg) and various doses of LSD were given together, the LSD dose response curve was shifted significantly to the left. It is possible that serotonergic properties of yohimbine (e.g. nanomolar affinity at the 5-HT_{1A} receptor), may be responsible for the potentiation of LSD. The role of alpha₂ adrenoceptors in the stimulus effect of LSD was further examined using more specific alpha₂ antagonists, idazoxan and RS-26026-197.

ANTIDEPRESSANT-LIKE EFFECTS OF CENTRALLY ADMINISTERED ISOPROTERENOL. J.M. O'Donnell*, S. Frith and J. Wilkins. Dept. of Pharmacology, LSU Medical School, Shreveport, LA 71130.

Isoproterenol (1-30 µg, i.c.v.) reduced response rate and increased reinforcement rate of rats under a DRL 72-sec schedule. Propranolol (1 mg/kg, i.p.) antagonized this effect of isoproterenol. After propranolol administration, doses of isoproterenol up to 100 µg failed to affect DRL behavior. By contrast, following vehicle administration, doses of isoproterenol of 10 and 30 µg reduced response rate and increased reinforcement rate. The beta-1 selective antagonist betaxolol and the beta-2 selective antagonist ICI 118,551 antagonized, in a dose-dependent manner, the ability of 30 µg isoproterenol to alter DRL behavior. These antagonists exhibited similar potency suggesting that the effects of isoproterenol were mediated by both beta-1 and beta-2 adrenergic receptors. In order to further examine the role of the beta adrenergic receptor subtypes, the effects of i.c.v. administration of isoproterenol were determined in rats treated repeatedly with the centrally acting beta-2 adrenergic agonist clenbuterol in order to reduce the responsiveness of beta-2 adrenergic receptors. Following this treatment, isoproterenol still produced antidepressant-like effects on DRL behavior; there was, however, a tendency for slightly diminished responsiveness to isoproterenol in clenbuterol-treated rats compared to vehicle-treated rats. The present results indicate that stimulation of central beta adrenergic receptors by isoproterenol alters DRL behavior in a manner similar to that observed after administration of proven antidepressant drugs. This behavioral action of isoproterenol appears to be a consequence of stimulation of both beta-1 and beta-2 adrenergic receptors. (Supported by USPHS Grant MH40694.)

d-FENFLURAMINE REQUIRES CALCIUM TO INCREASE EXTRACELLULAR SEROTONIN IN VIVO. M.A. Parada*, M. Puig de Parada and B.G. Hoebel. Dept. of Psychology, Princeton University, Princeton, NJ 08544 and School of Medicine, Universidad de Los Andes, Mérida, Venezuela.

It is known that d-Fenfluramine (d-FEN) releases 5-HT from an intravesicular pool while d-norfenfluramine (d-norFEN) releases mainly cytosolic 5-HT. d-FEN is a weak base and it could release intravesicular serotonin by a disruption of the pH gradient across the vesicle membrane (weak base mechanism) as ammonium chloride does, or it could promote an exocytotic mechanism by allowing calcium entry into the terminals. Reverse microdialysis was used to infuse drugs into the hippocampus of freely moving rats. Ammonium chloride (100mM) and d-FEN (1 mM) increased extracellular 5-HT in the same proportion (800%) when administered separately, and their effects were additive when administered together in the same infusion (2569%). Verapamil (1 mM) in calcium-free Ringer perfusate prior to the infusion of either 1 mM d-FEN, 1 mM d-norFEN or 100 mM ammonium chloride prevented the full increase in 5-HT by d-FEN (725% vs 2198%) but not ammonium chloride (525% vs 607%) or d-norFEN (1226% vs 1589%). EGTA with calcium-free Ringer also prevented the increase in 5-HT induced by d-FEN (635% vs 2929%). Tetrodotoxin (10µM) did not modify d-FEN release of 5-HT (1364% vs 1661%). These results suggest that d-FEN applied locally requires calcium to trigger the exocytotic process in 5-HT terminals in vivo.

DISCRIMINATION OF ELECTRICAL STIMULATION (ES) OF THE DORSAL RAPHE NUCLEUS (DRN), GENERALIZATION TO THE 5-HT₂ AGONIST DOI AND CORRELATION WITH CHANGES IN 5-HT LEVELS IN FOREBRAIN BY MICRODIALYSIS. D.J. Mokler*, B. Whitten, A. Gully, S. Field and M. Dixon. Dept. Pharmacol., Univ. New England, Biddeford ME 04005.

Sprague-Dawley rats were trained to discriminate ES of the DRN (200µA, 100µsec, 20Hz) by associating the ES with saccharin consumption made aversive by LiCl injection after the session. The discrimination was learned within 6 training sessions. Lowering the ES current to 50-150 µA resulted in non-stimulation levels of saccharin consumption. The 5-HT₂ agonist DOI (.5-1 mg/kg) generalized to ES of the DRN; i.e., animals reduced saccharin consumption following DOI. In order to evaluate the neurochemical changes in 5-HT release following ES of the DRN, the dorsal hippocampus was sampled by microdialysis in awake animals. Absolute levels of 5-HT in dialysate were 23.8 ± 4.2 femtomoles/20µl (mean ± s.e.m.). ES (200µA) produced a decrease in 5-HT levels in the hippocampus to below levels of detectability (> 0.5 femtomoles/20µl), which was maximal 20-60 min after ES. DOI (1 mg/kg) also decreased 5-HT levels in the hippocampus to the same extent. This was maximal 60-120 min after ES. These studies suggest that the behavioral generalization between ES of the DRN and DOI is due to a decrease in 5-HT release in forebrain areas. This may be the result of inactivation of 5-HT neurons of the DRN caused by activation of somatic autoreceptors or through long-loop feedback mechanisms. (Supported by NIDA grant 07316.)

486.18

SEROTONIN UPTAKE INHIBITOR-INDUCED MOTOR BEHAVIORS-A POSSIBLE MODEL FOR SCREENING ANTIDEPRESSANTS? C.L. Pinter, J.J. Rutter and S.B. Auerbach*. Nelson Biol. Lab., Rutgers Univ., Piscataway, NJ 08855.

Several behaviors were consistently observed in rats shortly after the administration of 5-HT reuptake inhibitors. We hypothesized that these behaviors - flat body posture (FBP), hindlimb abduction/flexion (HAF), and abdominal contraction (AC) - could be quantified and therefore serve as a screening test for other 5-HT uptake inhibitors. In the first set of experiments, duration of FBP, HAF and AC was recorded for 30 minutes following peripheral administration of reuptake inhibitors selective for 5-HT (fluoxetine; FLU & sertraline; SER), NE (desipramine; DMI & maprotiline; MAP), DA (nomifensine; NOM), or the nonselective NE/5-HT uptake inhibitor (imipramine; IMI). Additional observations were made on rats receiving an MAOI (pargyline; PAR) or the 5-HT releaser fenfluramine (FEN). While all the compounds but NOM produced significant FBP, only the selective 5-HT and NE inhibitors produced significant HAF and AC. In a second group of rats, pretreatment with the 5-HT synthesis inhibitor PCPA (100 mg/kg/day x 3 days) was used to test the hypothesis that decreased whole brain levels of 5-HT should attenuate expression of behaviors in response to FLU but not MAP. PCPA pretreatment decreased brain 5-HT levels by 90%. Compared to non-PCPA treated rats, those receiving FLU following PCPA exhibited significantly less FBP and more HAF, while those rats receiving MAP showed no change in behavior. Future investigations will examine the effects of MAP and FLU on extracellular NE and 5-HT via microdialysis. Supported by a grant from NSF.

3 β 5 α PREGNANOLONE IS NOT AN INACTIVE ANESTHETIC STEROID. C. Bukusoglu and N.R. Krieger.

Department of Anesthesia, Brigham and Women's Hospital, Boston, MA 02115.

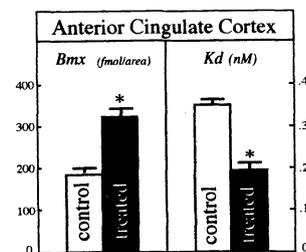

3 β 5 α -pregnanolone (3 β) has been studied for more than 50 years and is widely supposed to be an inactive anesthetic steroid. Here we re-evaluate the activity of this steroid. Following i.v. injection of 3 β (12 mg/kg, cremophore/ saline) the times to LRR (tLRR) were 9, 6 and 2 min with 0.0, 0.5 and 1.1 g/kg ethanol respectively. Ethanol alone demonstrated less than 10% LRR. Thus 3 β could be supposed to have intrinsic anesthetic activity, or to be a precursor for an active metabolite or both. To demonstrate whether or not 3 α has intrinsic activity, we co-injected 3 β with subthreshold doses of 3 α 5 α pregnanolone (3 α). 3 β (24 mg/kg) was co-injected with 3 α (0.75 mg/kg) in the presence of ethanol (1.1 g/kg). tLRR values were reduced to 12 \pm 2 sec (mean \pm SEM, n=3). This time is too short to permit metabolite formation. Therefore, 3 β itself must have intrinsic anesthetic potency. 3 β was estimated to have 1/40th the potency of 3 α .

RECEPTOR MODULATION, UP- AND DOWN-REGULATION III

487.1

EFFECT OF SERTRALINE TREATMENT ON BENZODIAZEPINE RECEPTORS IN THE RAT BRAIN. L. Giardino, M. Zanni, A. Velardo, L. Calzà*, Center of Pathophysiol. of the Nervous System, Hesperia Hospital, 41100 Modena, Italy.

The antidepressant drug sertraline also exhibits anxiolytic properties. In this study we investigated the effect of 8, 15 and 30 days sertraline treatment (10 mg/kg day, ip) on 3 H-flunitrazepam (3 H-FLU) binding sites in the rat brain by means of quantitative receptor autoradiography. After 8 days an increase of 3 H-FLU receptor density is found in the olfactory tubercle. This effect is reversed at 15 and 30 days. At 15 days, an increase is observed in the anterior cingulate cortex. This increase is still present after 30 days. At the same time, we also found an increase of 3 H-FLU in the frontoparietal motor cortex and in the septal nuclei. The Scatchard plots obtained from the saturation experiments indicate that this

increase of the receptor density is due to an increase of both the receptor number and affinity (see figure). All the other investigated areas are unaffected by the sertraline treatment. The benzodiazepine receptor modification described after the chronic block of 5-HT reuptake could be involved in the anxiolytic effects observed during sertraline treatment.

487.3

PARASYMPATHETIC DENERVATION SUPERSENSITIVITY TO MUSCARINIC AND PURINERGIC AGONISTS IN SINGLE PAROTID ACINAR CELLS. L. Tenneti* and B.R. Talamo, Neuroscience Labs, Tufts Med. Sch., Boston, MA.

Parotid acinar cells are innervated by both sympathetic and parasympathetic nerves and thus serve as a useful model to study neuronal modulation of target cell sensitivity and synaptic impulse trafficking. Although selective modulation of secretory response has been described in denervated animals, the mechanism of supersensitivity at the cellular level is largely unknown. Previously we observed that parotid cell responses to the muscarinic agonist carbachol and to extracellular ATP (P₂ receptors) are sensitized after parasympathetic denervation but that the muscarinic receptor number was not altered. Fluorescence ratio imaging was used to examine cytosolic Ca²⁺ (Ca_i) responses in single acinar cells prepared from control and parasympathetically denervated glands. In control preparations concentration response curves for carbachol and ATP showed that the threshold for activation varied in individual cells, indicating the presence of subsets of acinar cells with different sensitivities. Acinar cells prepared from denervated glands were sensitized to both agonists: the proportion of cells responding at low concentrations of agonists was 2-3 fold higher compared to control cells. A range of cell sizes was observed in both control and denervated cells. Following denervation there were more small cells and these cells tended to be more sensitive to agonist stimulation. Thus the lower cell volume in denervated cells which retain their full complement of receptors might in part explain the increased Ca_i response at very low concentrations of agonists. Supported by NS28556.

487.2

PARADOXICAL UP-REGULATION OF MUSCARINIC RECEPTORS BY AGONISTS IN NCB-20 CELLS. S. Gucker* and D.-M. Chuang, Biological Psychiatry Branch, National Institute of Mental Health, Bethesda, MD 20892.

Carbachol treatment (1mM, 24 h) of NCB-20 cells induces down-regulation (to 58 \pm 2% of control level) of muscarinic receptors coupled to adenylate cyclase inhibition and stimulation of phosphoinositide turnover. 1 mM Oxotremorine-M and 0.1 mM McN-A-343, M₁-type agonists, induce down-regulation similar to carbachol (56 \pm 11% and 71 \pm 2%, respectively, of control, after 24 h). However, this classical agonist-induced down-regulation is not shared by all agonists. 1 mM Bethanechol treatment induces no down-regulation (92 \pm 1%) after 24 h. Surprisingly, pilocarpine and oxotremorine induce up-regulation of [3 H]QNB binding to cell membrane homogenates from chronically treated NCB-20 cells. 1 mM pilocarpine or 1 mM oxotremorine induce 164 \pm 14% or 157 \pm 13%, respectively, of control binding after 24 h. Scatchard analysis of [3 H]QNB binding reveals K_d values of 48 \pm 7, 63 \pm 7, and 42 \pm 10 pM for control, carbachol, and pilocarpine treated cell membranes, respectively, but B_{max} values of 76 \pm 4, 40 \pm 18, and 119 \pm 16 fmol/mg protein. The effect of pilocarpine is blocked by atropine, indicating that the paradoxical up-regulation is not due to any antagonistic or partial agonist property of pilocarpine. Current studies seek to determine the specific receptor and mRNA subtypes involved in this phenomenon.

487.4

EFFECT OF LATE INSULIN TREATMENT INITIATED AFTER THE ESTABLISHMENT OF THE DIABETIC STATE ON RAT BLADDER DOME MUSCARINIC RECEPTORS. J. Latifpour*, Y. Fukumoto, M. Yoshida and B. M. Weiss, Yale Univ. Sch. of Med., New Haven, CT 06510.

To determine whether diabetes- and diuresis-induced alterations in muscarinic receptors in rat bladder dome are reversible, we administered insulin (started 8 weeks after the onset of diabetes) or removed sucrose from drinking water (begun 8 weeks after the onset of diuresis). Five groups of rats were maintained for 16 weeks: 1) STZ-induced diabetic (65 mg/kg i.v.); 2) insulin-treated diabetic, 5-8 U/day s.c.; 3) sucrose-fed, 5% sucrose in drinking water throughout 16 weeks; 4) sucrose-removed, sucrose withdrawn from drinking water after 8 weeks; 5) age-matched controls. Saturation binding experiments with [3 H] quinuclidinyl benzilate showed an increase in the density of muscarinic receptors in bladder dome of diabetic and sucrose-fed rats compared with age-match controls. Removing the 5% sucrose from the drinking water of diuretic rats reversed the increased water intake and urine output and the upregulation of the muscarinic receptors. Late insulin treatment partially corrected the bladder enlargement, polydipsia, polyuria and the muscarinic receptor upregulation in the diabetic rat. Pharmacological evaluation indicated that the induction of diabetes did not affect muscarinic subtype specificity but did result in an alteration in muscarinic receptor-G protein coupling in rat bladder dome (Supported in part by NIH grants DK 38311 and DK 42530).

487.5

GABA_A RECEPTOR MODULATION BY PROTEIN KINASE-A (PKA) AND β -SUBUNIT EXPRESSION IN CEREBELLAR PURKINJE CELLS. J.E. Cheun, E.V. Grigorenko and H.H. Yeh*, Dept. Physiology & Pharmacology, Bowman Gray School of Medicine, Wake Forest University, Winston-Salem, NC 27157.

Norepinephrine (NE) potentiates GABA-evoked current (I_{GABA}) in Purkinje cells acutely dissociated from the rat cerebellum. We have previously communicated preliminary data suggesting that this effect could be mimicked by components of the adenylate cyclase system, including PKA, and have postulated that this system participates in transducing the cross-talk between the β -adrenergic and the GABA_A receptors. Here, we present new evidence that PKA is an intermediary in this transduction cascade. In addition, we used reverse transcription and polymerase chain reaction to profile in single Purkinje cells messages for the GABA_A receptor β -subunits, one of which ($\beta 3$) is a likely target for phosphorylation by PKA.

Catalytic subunit of PKA, introduced into acutely-dissociated Purkinje cells during whole-cell recording, potentiated I_{GABA} in a time-dependent manner. This effect was blocked by PKA inhibitor. Similarly, Rp-cAMP and the regulatory subunit of PKA blocked the NE-induced potentiation of I_{GABA} . In inside-out patches, PKA plus ATP increased GABA-evoked single channel activity by increasing the probability of channel opening. Under conditions that favor phosphorylation, closed time distribution shifted towards shorter durations, leaving unitary conductance level and open time distribution unaltered. Profiling GABA_A receptor β -subunit mRNAs in individual Purkinje cells from which patch clamp data had been obtained revealed consistently messages for the $\beta 1$ and $\beta 3$ subunits but that for the $\beta 2$ subunit was variable. In contrast, granule cells appear to express the $\beta 2$ message exclusively.

Overall, electrophysiology combined with profiling of gene expression in single neurons is a promising approach for revealing the structural/functional bases underlying the modulation of the native GABA_A receptor.

THE PHOSPHOLIPASE A₂ INHIBITOR BROMOPHENACYL BROMIDE PREVENTS THE DEPOLARIZATION-INDUCED INCREASE IN ³H-AMPA BINDING IN RAT SYNAPTONEUROSOMES. J. Bernard*, A. Lahsaini, M. Baudry and G. Massicotte. Département de Chimie-Biologie, Université du Québec à Trois-Rivières, C.P.500, Québec, Canada, G9A 5H7.

The expression of long-term potentiation (LTP) in area CA1 of hippocampus has been proposed to result from an increased sensitivity of the AMPA receptors. We previously demonstrated that potassium (KCl)-induced depolarization of synaptoneuromes prepared from rat telencephalon increased ³H-Amino-3-Hydroxy-5-Methylisoxazole-4-Propionate (³H-AMPA) binding to the AMPA receptor. In the present study, we established optimal conditions to produce depolarization-induced increase in ³H-AMPA binding in rat synaptoneuromes and evaluated the effects of various inhibitors of calcium dependent enzymes on the regulation of AMPA receptors. The effect of depolarization on ³H-AMPA binding was sensitive to temperature, as the increase in binding was present at both room (25°C) and physiological (37°C) temperatures but absent at 0°C. In addition, the effect was time- and calcium-dependent, with a maximal increase after 10-15 min in a physiological medium containing 0.5 mM calcium chloride. Treatment of intact synaptoneuromes with the phospholipase A₂ (PLA₂) inhibitor, bromophenacyl bromide (BPB), produced a marked and dose-dependent reduction in KCl-induced enhancement in ³H-AMPA binding. BPB had no significant effect on the ³H-TTP accumulation in intact synaptoneuromes, an index of membrane depolarization. In contrast, inhibitors of calcium-dependent kinases and proteases had no significant effect on the KCl-induced increase in ³H-AMPA binding. Since activation of phospholipases has been reported to play a critical role in the formation of LTP the results strengthen the hypothesis that phospholipase-induced modification of AMPA receptor properties is an important component of synaptic plasticity. This work was supported by NSERC Canada.

EFFECT OF 15-HYDROPEROXYEICOSATETRAENOIC ACID (15-HPETE) ON PHOSPHOINOSITIDE (PID) TURNOVER IN SYNAPTONEUROSOMES (SN). M. M. Zaleska* and D. F. Wilson. Dept. of Biochem. and Biophys., Univ. of Pennsylvania School of Medicine, Philadelphia, PA 19104.

We have studied the interaction of lipoxygenase metabolite of arachidonic acid (AA) with agonist-evoked PID turnover in rat brain SN. When SN are prelabeled for 60 min with [³H]myo-inositol and incubation is continued in its presence, inositol phosphates (IP) accumulate linearly for up to 90 min with 1 mM glutamate (Glu), 100 μ M quisqualate (Q) or 100 μ M norepinephrine (NE). Accumulation of IP evoked by Glu and Q but not NE was significantly inhibited by 25 μ M 15-HPETE. Concomitantly, the incorporation of [³H]myo-inositol into PID was inhibited by 69% by 15-HPETE. Glu alone significantly inhibited the labeling of PID, while simultaneous presence of Glu and 15-HPETE resulted in 80% inhibition. Separation of individual lipids by HPTLC revealed that synthesis of [³H]phosphatidylinositol (PI) and [³H]PI monophosphate (PIP) was decreased by 60% and 50% by 25 μ M 15-HPETE. Concurrent presence of Glu resulted in 77% and 50% inhibition of labeling of PI and PIP pools, respectively. The synthesis of [³H]inositol lipids was not significantly affected by 100 μ M NE. In order to separate the effects of 15-HPETE on PID hydrolysis from those on inositol lipid resynthesis, prelabeled SN were washed extensively before their exposure to agents. In such SN 25 μ M 15-HPETE alone stimulated IP formation and did not inhibit agonist-evoked IP accumulation. Carbamylcholine-induced IP generation was not affected by 15-HPETE. It is suggested that AA oxygenation products may modulate the functional expression of excitatory amino acid metabotropic receptors by selectively reducing the availability of their lipid substrates. DEPOLARIZATION UPREGULATES GABA_A RECEPTOR NUMBER IN LIVING HIPPOCAMPAL SLICES. H. Tabuteau, N. de Lanerolle*, and M. Brines. Neurosurgery and Neuroendocrinology, Yale Medical School, New Haven, CT 06510

GABA is a predominant inhibitory neurotransmitter of the hippocampus. Regulation of the GABA_A receptor in living preparations was studied to determine how depolarization affects the GABA_A receptor and to delineate the ion dependency of this regulation. GABA_A receptors were labeled using the antagonist [³H]SR95531. Slices depolarized with K⁺, veratridine, veratridine/glutamate (vera/glut) and ouabain produced average increases in binding of 72%, 113%, 127%, and 215% respectively. The approximate doubling of receptor number demonstrates a large reserve of GABA_A receptors in the hippocampus. The response to vera/glut was accentuated in Ca⁺⁺-free medium (a tripling of binding), suggesting that Ca⁺⁺ plays an inhibitory role. Depolarization with Na⁺-free, 140mM K⁺ medium resulted in an approximate doubling of receptor number. Thus upregulation is not Na⁺-dependent. Ocreotide, a stable somatostatin analog, and 6-cyclohexyl adenosine (CHA), a selective adenosine A1 agonist, blunted the vera/glut response (25% and 30% decrease in upregulation respectively). Ocreotide and CHA also blunted the upregulatory response to 140mM extracellular K⁺. Thus, ocreotide does not decrease upregulation by hyperpolarizing the cell. Furthermore, this suggests that both ocreotide and CHA inhibit an increase in GABA_A receptor number by decreasing intracellular cAMP levels. Disruption of the cell membrane through freezing and thawing resulted in substantial radioligand binding but a lack of upregulation.

These data suggest that membrane potential determines GABA_A receptor number. Although depolarization appears necessary for an increase in receptor number, ocreotide and CHA do not inhibit up-regulation by changing membrane potential. No major extracellular ion is essential for upregulation. However, calcium, which has been implicated in excitotoxicity, inhibits upregulation.

SELECTIVE ALTERATIONS IN [125I]IGF I AND [125I]IGF II SITES IN THE RAT HIPPOCAMPAL FORMATION FOLLOWING SYSTEMIC INJECTION OF KAIDIC ACID. L. Srivastava*, S. Kar, D. Seto and R. Ouirion. Douglas Hosp. Res. Ctr. Dept. of Pharmacol. & Ther. & Psychiatry, McGill Univ., Montreal, CANADA H4H 1R3.

The insulin-like growth factors I and II (IGF I and IGF II) are similar in their structure with overlapping biological functions. These peptides are localized in distinct brain regions and their functions are mediated by IGF I and IGF II receptors. Both receptors are discretely distributed in various brain areas including the hippocampal formation. Functionally, IGFs are considered to play an important role in normal functions of the brain and also in response to pharmacological and surgical lesions. Following systemic injection of kainic acid (KA) to the adult rat (12 mg/kg; i.p.), the possible alterations in [125I]IGF I and [125I]IGF II binding sites, together with changes in neuronal and glial populations, were evaluated in the hippocampal formation at different time-periods (12h, 1, 2, 4 and 12 days). In the normal hippocampus, [125I]IGF I sites are concentrated primarily in the dentate gyrus (DG) and in the CA2-CA3 sub-fields whereas [125I]IGF II binding sites are discretely localized in the pyramidal layer and in the granular layer of the DG. Administration of KA, as indexed by GFAP immunostaining, induced proliferation of reactive astrocytes in all sub-fields of the hippocampal formation during 1-12 days periods. Severe neuronal damage followed by loss of neurons were evident particularly in the CA1-CA2 sub-fields during 4-12 days after injection. [125I]IGF I binding sites at early stages (12h- 2day) following KA injection were found to be decreased in CA1-CA3 sub-fields whereas in later periods (4-12 days) a marked increase was noted particularly in CA1-CA2 sub-fields. As for [125I]IGF II binding sites, a marked depletion was noted in the pyramidal layer of CA1-CA3 sub-fields at all time periods studied. Granular layer of the DG however, did not exhibit any alteration in the density of IGF II binding sites. Thus, it appears that IGFs I and II receptors in the hippocampal formation are differentially affected following peripheral KA injection and the observed responses which coincide temporally with glial proliferation and/or neuronal degeneration possibly reflect the involvement of IGFs in kainic acid induced plasticity in this model. AGING DECREASES THE DENSITY AND MODIFIES THE RESPONSIVENESS OF NICOTINE RECEPTORS IN RAT STRIATUM. Z.J. Yu, Y. N. Hsu and L. Wecker*. Department of Pharmacology, University of South Florida College of Medicine, Tampa, Florida 33612.

The effects of aging on the density and function of nicotine binding sites were studied in striata from male F-344 x BN rats 4 months, 14 months and 24 months of age. Rats received injections (s.c.) of saline or nicotine bitartrate (1.76 mg/kg) twice daily for 10 days. The affinity (K_d) and density (B_{max}) of nicotine receptors were determined by measures of [³H]cytisine binding to membranes and Rosenthal-Scatchard analyses; function was ascertained by measures of the ability of 10 μ M nicotine and 25 mM KCl to release [³H]DA from superfused striatal synaptonemes. Nicotine binding site density decreased by 20% and 30% in striata from rats aged 14 months and 24 months, respectively, as compared to tissue from 4 month-old rats; affinity was unaltered. Despite this decreased receptor density, the ability of 10 μ M nicotine to release [³H]DA from striata from rats aged 14 and 24 months increased by 100% relative to the response obtained in tissue from 4 month-old rats; release in response to 25 mM KCl was unaltered. The chronic administration of nicotine increased the density of nicotine binding sites by 30% in all age groups. In striata from 4 month old rats, this increased receptor density was accompanied by a 100% increased nicotine-induced release of [³H]DA. In contrast, nicotine-induced [³H]DA release from striata from 14- and 24-month old rats did not exhibit an enhanced response. Results indicate that normal aging is associated with a decreased density of nicotine binding sites in striatum, but an increased ability of nicotine to release [³H]DA. In addition, although the up regulation of binding site density is not compromised in aged rats, there is a decrease in the ability of nicotine to release [³H]DA. DIFFERENTIAL CHANGES IN D-2, D-3 AND D-4 DOPAMINE RECEPTOR mRNA LEVELS DURING AGING. A. Valerio, M. Belloni, C. Tinti, M. Memo, P.E. Spano*, Institute of Pharmacology, Department of Biomedical Sciences and Biotechnologies, University of Brescia, 25124 Brescia, Italy

One of the basic feature of aging brain is the decline of the postsynaptic decoding of dopamine signal. Particularly, several authors have reported age-related reductions of dopamine D-2 receptor number and function in various areas of rodent and primate brain. The reduction in dopamine D-2 receptors is associated with a fall by 30-40% in the dopamine content during aging. This is an intriguing finding since various experimental models have demonstrated that decreases in presynaptic input are followed by the induction of supersensitive receptors. Interpretation of these results is also hampered by the new knowledge in the dopamine receptor field. To date, dopamine receptors can be classified into two main families (D-1 and D-2), each of them including several variants. The D-2 like family comprises D-2 short, D-2 long, D-3 and D-4 dopamine receptor.

Reverse Transcriptase Polymerase Chain Reaction (RT-PCR) technique was used to determine the steady-state levels of the mRNA encoding the different dopamine receptors in various brain areas of 6, 12, 18 and 24 month rats.

We found a progressive, age-dependent reduction in the mRNA levels of D-2 short and D-2 long dopamine receptor isoforms in corpus striatum, substantia nigra and frontal cortex. On the contrary, D-2 short and D-2 long receptor mRNA levels were unchanged in hippocampus while they increased in pituitary. D-3 receptor mRNA levels were reduced in olfactory tubercle and unchanged in striatum. D-4 receptor mRNA levels were unmodified in pituitary gland.

These data suggest that the mechanisms responsible for regulating the pattern of expression of the various dopamine receptor isoforms is differentially affected by aging.

DIFFERENTIATION OF NG-108 NEUROBLASTOMA CELLS VIA SERUM STARVATION OR DIMETHYL SULFOXIDE (DMSO) TREATMENT YIELDS MARKED DIFFERENCES IN ANGIOTENSIN II RECEPTOR EXPRESSION. K.J.N. Seidman*, J.H. Barsuk, R.F. Johnson, and J.A. Weyhenmeyer, Neuroscience Program, University of Illinois, Urbana, IL 61820.

Neuroblastoma cells can be differentiated by various methods, including serum starvation and dimethyl sulfoxide (DMSO) treatment. Differentiation of NG-108 cells under conditions of serum starvation results in extensive neurite extension that is not seen following DMSO treatment. Recently, angiotensin (ANG) receptor expression in NG-108 cells has been reported to be dramatically upregulated following differentiation with 1.5% DMSO and low serum (0.5%) (Bryson, S.E., *et al.*, *Eur. J. Pharm.* 225:119). In the present study we investigated whether serum starvation or DMSO/low serum, which give rise to very different culture morphologies, differentially influenced ANG receptor expression in NG-108 cells.

K_D values for all treatment conditions were not significantly different (0.64 ± 0.12 nM). Prior to treatment, the B_{max} for undifferentiated cells was 26.8 ± 9.29 fmol/mg. Treatment for 3 days with DMSO/low serum or serum starvation yielded B_{max} values of 212 fmol/mg and 24.1 ± 8.9 fmol/mg, respectively ($p < 0.005$), while treatment for 4 days yielded B_{max} values of 607 ± 139 fmol/mg and 50.33 ± 4.91 fmol/mg, respectively ($p < 0.001$). Serum starved cells never showed the dramatic increase in ANG receptor expression (after serum starvation for 7 and 14 days B_{max} values were 98.67 ± 13.5 fmol/mg and 108 fmol/mg, respectively). Previous studies indicate that most of the ANG receptor upregulation observed in DMSO treated NG-108 cells is accounted for by AT_2 receptor upregulation (Bryson, *et al.*), and we are currently investigating individual receptor subtype expression in DMSO treated and serum starved cells.

Clearly, the differentiation paradigm significantly influences ANG receptor expression. Whether these agents alter the synthesis of ANG receptors at the transcriptional, translational, or post-translational levels is under investigation.

EFFECT OF OROSENSORY DEPRIVATION ON NEUROPEPTIDE Y RECEPTOR POPULATION. M. C. Lee*, J. Grant, C. Clark, P. Mannon, T. N. Pappas, Departments of Surgery and Medicine, Duke Univ. Sch. of Med., Durham, NC 27710.

Centrally administered neuropeptide Y (NPY) is a known potent orexigenic, which produces a robust feeding behavior in satiated rats. Studies have demonstrated that NPY peptide levels in the paraventricular nucleus (PVN) fluctuate with different oral diets (eg. food-deprivation, hyperphagia). The purpose of our study was to examine whether orosensory deprivation alters NPY receptor levels in the rat brain. Fisher 344 rats were randomized to receive total parenteral nutrition (TPN) or saline as control. Half of the saline-infused rats were allowed to feed on standard rat chow to maintain their weights (sal-fed), and the other half was food-deprived (sal-dep). The third group of rats was orosensory-deprived, but they were given calories intravenously (tpn-dep). After 72 hours of continuous infusion, the rats were sacrificed and their brains were removed for NPY receptor autoradiographic studies. The NPY receptor population was measured by densitometry in four brain regions and is expressed in nCi/mg (* $p < 0.05$; ** $p < 0.005$).

	paraventricular		olfactory	
	nucleus	thalamus	dentate gyrus	cortex
SAL-DEP	1.51±0.15	1.55±0.10	0.25±0.10	1.91±0.25
SAL-FED	1.40±0.20	1.60±0.13	0.41±0.13	2.15±0.33
TPN-DEP	2.29±0.19**	2.06±0.13*	1.01±0.13**	3.07±0.29*

NPY receptor density was significantly increased in TPN-infused rats compared to saline controls in the brain regions examined. We conclude 1) NPY receptor population is increased in these particular brain areas after 72 hours of orosensory deprivation accompanied by intravenous caloric infusion, and 2) orosensory deprivation without intravenous calories does not produce a significant change in NPY receptor number, perhaps due to diminished protein availability from increased catabolism. This data suggests that the absence of an oral diet with intravenous feeding results in an increase in NPY receptor number in the rat brain. This is consistent with the hypothesis that orosensory deprivation without concomitant weight loss may lead to decreased NPY peptide levels, resulting in an initial compensatory upregulation of NPY receptors in the rat brain.

DEVELOPMENTAL EXPRESSION OF THE A_1 ADENOSINE RECEPTOR AND G_i PROTEINS IN RAT CEREBRAL CORTEX. M. Wilson, T.W. Gettys, C.J. Moody*, V. Ramkumar, Dept. of Pharmacology, SIU School of Medicine, Springfield, IL 62794

Functions mediated via the A_1 adenosine receptor (A_1AR) are inhibited by caffeine, a methylxanthine and the active ingredient in common beverages such as coffee and cola. Methylxanthines can regulate the expression of both the A_1AR and its associated G_i proteins transducing protein, and can therefore alter their expression in the fetus and newborn during pregnancy and early postnatal development. Understanding how the A_1AR and G_i proteins are regulated during normal postnatal development is essential before the effects of methylxanthines could be explored. In this study, the developmental expression of the A_1AR and the G_i protein (α and β subunits) in rat cerebral cortical plasma membranes were characterized using an A_1AR antagonist radioligand ($[^3H]DPCPX$). A_1AR increased from 76 ± 15 fmol/mg protein in 7 d old rats to 210 ± 48 , 339 ± 42 and 348 ± 42 fmol/mg protein 17 d, 3 months and 19 months postnatally without changes in receptor affinity (K_D values ranging from 0.48 to 0.51 nM). No change in the A_1AR/G_i protein interaction was observed during development, as determined from computer modeling of R-PIA (agonist) competition curves. Western blotting for the $G_{\alpha i}$ and β subunits indicate significant increases in the expression of these proteins during development. Levels of α_{i1} , α_{i2} , α_{i3} and β subunits increased 5.2, 3.2, 7.6 and 7.3 fold, respectively, from postnatal day 7 to 3 months. Interestingly, high levels of transcripts encoding these $G_{\alpha i}$ subunits could be detected on postnatal day 7. These data suggest that the A_1AR and its associated G proteins are coordinately regulated during development in order to maintain efficient functional coupling during postnatal development.

EFFECT OF THE NEUROTENSIN RECEPTOR ANTAGONIST SR48692 ON THE EXPRESSION OF NEUROTENSIN AND NEUROTENSIN RECEPTOR mRNA IN RAT BRAIN.

C. Bolden-Watson*, M. Watson and E. Richelson, Dept. of Psychiatry and Psychology, and Pharmacology, Mayo Clinic Jacksonville, Jacksonville, FL 32224.

We examined the effect of chronic (two weeks) treatment with the selective, nonpeptide neurotensin receptor antagonist, SR48692 (Gully *et al.*, *PNAS*, 90:65, 1993), on neurotensin (NT) and neurotensin receptor mRNA expression by *in situ* hybridization histochemistry. Quantitative optical density analysis showed SR48692 increased NTR mRNA levels in the substantia nigra/ventral tegmental area over that seen in control tissue. In contrast, the same treatment did not affect the expression of NT mRNA in rat brain. These results are similar to the effects observed in our previous study with haloperidol in rats. Two week treatment with haloperidol resulted in an increase in the expression of NTR mRNA but not NT mRNA. Others have shown acute treatment with haloperidol dramatically increases the expression of NT mRNA in rat brain. We are currently investigating the acute effects of SR48692 on NT and NTR mRNA expression. [Support: Mayo Foundation and U.S.P.H.S. grants MH10104 (C.B.) and MH27692 (E.R.); SR48692, batch no. 9200VI, from Sanofi Recherche].

HYPOTHALAMIC ESTROGEN RECEPTOR mRNA IN NORMAL AND NEONATALLY ANDROGENIZED FEMALE AND CASTRATED MALE RATS. L. Givon*, D.L. Hurley and A.A. Gerall, Depts. of Psychology and Cell and Molecular Biology, Tulane University, New Orleans, LA 70118.

Perinatal androgen exposure renders the female rat anovulatory and non-receptive, while early castration enables the male rat to manifest female sexual behaviors. These reproductive processes are mediated by the estrogen receptor (ER). Basal levels of ER mRNA in selected brain sites were higher in female than male rats and decreased by exogenous estrogen (Laubert *et al.*, 1991; Simerly & Young, 1991).

The present study investigated the effects of adult estrogen on ER mRNA in female rats injected sc on day 4 with either 1.25 mg testosterone propionate (TP), 50 μ g TP or sesame oil, and male rats castrated at 6 hr, day 5 or day 34. The females were ovariectomized postpubertally. When 5 mo. old, half of the rats were injected with 9.9 μ g estradiol benzoate (EB) and the remainder with sesame oil, and 18 hr later all were anesthetized and their brains frozen at -100°C . *In situ* hybridization (Simerly & Young, 1991) was performed on 25 μ m thick coronal brain sections using ^{35}S -labeled 850 nt antisense probe (provided by R. Simerly, ORPRC) to detect ER mRNA. Relative hybridization intensities were quantified from x-ray films in the anteroventral periventricular nucleus (AVPV), medial preoptic area (MPOA), arcuate nucleus and ventromedial nucleus (VMN).

Lordosis quotients for the 1.25 mg TP, 50 μ g TP and control females were 0%, 85% and 100%, respectively; and for the 34 day, 5 day and 6 hr castrated males were 0%, 37% and 80%, respectively. In females, neonatal androgen decreased basal levels of ER mRNA in the AVPV and VMN. Adult EB injection decreased ER mRNA in the AVPV and MPOA. Analysis of data from males is in progress. REGULATION OF RETINAL PRESYNAPTIC EP₃-RECEPTORS BY ENDOGENOUS PROSTAGLANDINS. Al-Zadjali, K. and Ohia, S.E.; Dept. of Pharmaceutical Sciences, Creighton University, Omaha, Nebraska

We have previously shown that exogenous prostaglandins (PG) inhibit dopamine (DA) release from the rabbit retina via an effect presynaptic EP₃ receptors. (Al-zadjali et al. Invest. Ophthalm. Vis. Sci. 34:1047, 1993). Since there is evidence that endogenously generated PGs may regulate neurotransmitter release, the present study investigated the effects of intramurally produced PGs on the responsiveness of presynaptic EP₃-receptors to exogenous agonists. Neural retinas from albino rabbits were incubated in oxygenated Krebs solution containing 0.15 μM [³H]DA at 37°C for 20 mins and then pre-prepared for superfusion studies. Release of [³H]DA was elicited by electrical field stimulation applied at 55 (S₁) and 91 (S₂) mins. after onset of superfusion. Application of the cyclo-oxygenase inhibitor, flurbiprofen (FBF, 3 μM) (24 mins. before S₂), had no effect on basal or evoked [³H]DA overflow. Inhibition caused by PGE₂ (3 nM) was increased from 31.9 ± 6.0% (n = 6) to 36.4 ± 3.2% (n = 4) in the presence of FBF (3 μM) (P = 0.6) We conclude that endogenously produced PGs are not involved in basal or evoked [³H]DA release in the retina nor do they alter the responsiveness of presynaptic EP₃-receptors to exogenous agonists. (Supported by PMA Foundation)

INDUCTION OF OLFACTORY RECEPTOR SENSITIVITY IN MICE. H.-W. Wang, C. J. Wysocki and G. H. Gold*. Monell Chemical Senses Center, 3500 Market Street, Philadelphia, PA 19104.

Exposure to androstenone can induce sensitivity to that odorant in humans with specific anosmia to androstenone (Wysocki et al., 1989). Recordings of the olfactory receptor potential (EOG) were used to determine if induction can occur at the receptor cell level in mice. Androstenone-insensitive (NZB/B1NJ) and -sensitive (CBA/J) strains were chosen as animal models for androstenone-insensitive and -sensitive individuals, respectively, based on their behavior in conditioned aversion assays. In NZB/B1NJ mice, 2-4 weeks of 16 hr daily exposure to androstenone caused up to a 3.6-fold increase in the EOG response amplitude to androstenone, but did not significantly affect responses to isoamyl acetate. However, in CBA/J mice androstenone exposure had no effect on response amplitudes to either odorant. Similar induction of iso-valeric acid sensitivity was demonstrated in an iso-valeric acid-insensitive strain (C57BL/6J). Thus, induction of olfactory sensitivity in mice: 1) occurs at least in part at the receptor cell level, 2) occurs only in strains that initially have low sensitivity to the exposure odorant, and 3) increases sensitivity specifically for that odorant. In view of the odorant specificity of induction, it may reflect increased expression of olfactory receptor proteins with a high affinity for the exposure odorant. If so, olfactory induction may constitute a novel form of stimulus-regulated gene expression.

HYPOTHALAMIC-PITUITARY-ADRENAL AXIS REGULATION: POMC AND STEROID RECEPTOR STUDIES

488.1

THE CELLULAR REGULATION OF POMC: THE ROLE OF *c-fos* AND *c-jun*. B.B. Ruzicka* and H. Akil, Mnt Hlth Res Inst, University of Michigan, Ann Arbor, Michigan, 48109-0720.

In this study, a murine anterior pituitary cell line (AtT20) was used as the model system to examine the role of the immediate-early genes (IEGs), *c-fos* and *c-jun*, in the cellular regulation of pro-opiomelanocortin (POMC). AtT20 cells were plated in DMEM+10% FCS and grown until ~60% confluent. Subsequently, the medium was replaced with DMEM+2.5% FCS and the cells were incubated for a further overnight period. The cells were then exposed to corticotropin releasing factor (CRF, 10nM) or interleukin-1β (IL1β, 0.5nM) for various times (5min-48h) and analyzed for levels of β-lipotropin (βLPH) and β-endorphin (βE) secretion and content and POMC, *c-fos* and *c-jun* mRNA. Both CRH and IL1β modulated βLPH and βE secretion and content in a time-dependent manner. CRH only weakly stimulated βLPH secretion, but enhanced βE release in a biphasic fashion: peak responses, reflecting 4- and 2-fold increases in βE release occurred at 30min and 8h of CRH exposure, respectively. Generally, the CRH-evoked changes in peptide secretion were inversely related to the CRH-elicited changes in peptide content. In contrast, IL1β preferentially stimulated βLPH, rather than βE secretion: the peak response, reflecting a 2-fold increase in βLPH release, occurred after 24h of IL1β exposure. IL1β had little effect on peptide content. CRH and IL1β produced no apparent change in POMC mRNA, but, at 1h, maximally elevated POMC heteronuclear RNA by 20% and 30%, respectively. Following a 1h exposure, CRH and IL1β also maximally increased *c-fos* mRNA by 6- and 3-fold, respectively. Additionally, a 1h exposure to IL1β, but not CRH, maximally elevated *c-jun* mRNA by 70%. These data show that CRH and IL1β differentially modulate POMC peptide secretion, content and IEG expression in AtT20 cells. Experiments conducted with antisense *c-fos* and *c-jun* DNA should provide more conclusive data regarding the role that these IEGs play in the cellular regulation of POMC. Supported by NIMH grant PO1MH42251. B.B.R. is the recipient of a Medical Research Council of Canada post-doctoral fellowship.

INTRAOCULAR TETRODOTOXIN (TTX) REDUCES 2-[¹²⁵I]-Iodomelatonin BINDING IN SELECTED VISUAL AREAS OF THE CHICK BRAIN.

M.L. Dubocovich*, S. Jacob*, F.S.-P. Yao*, D.N. Krause*, Depts. Pharmacol., Med. Sch., *Northwestern Univ., Chicago, IL 60611 and †Univ. of Calif., Irvine, 92717.

Unilateral transection of the chick optic nerve (ON) significantly decreases specific 2-[¹²⁵I]-iodomelatonin binding to ML-1 melatonin receptor sites in many, but not all, of the target brain retinorecipient areas and throughout the tectofugal visual pathway, i.e., optic tectum (OT), thalamic nucleus rotundus (ROT), and telencephalic ectostriatum (E) (Krause, Siuciak, Dubocovich, 1993). To determine whether these changes were the result of blockade of electrical activity in the ON, chicks (3 weeks old) were injected every 3 days with 6 ug TTX in one eye and saline/vehicle in the other eye. Chicks were sacrificed after a period of 7 days, during which the pupillary reflex remained suppressed in the experimental eye. Brain sections were processed for quantitative receptor autoradiography using 90 pM 2-[¹²⁵I]-iodomelatonin. Specific binding was defined using 1uM melatonin. Because the majority of the ON fibers cross in the chiasm, the areas ipsilateral to the TTX-injected eye served as a control. Inhibition of retinal electrical activity by TTX for 7 days significantly reduced specific 2-[¹²⁵I]-iodomelatonin binding in the contralateral OT (61 ± 3% of ipsilateral OT), the ROT (40 ± 1%), the isthmi nuclei (67 ± 2%) which also receive tectal projections, and the E (67 ± 5%). In contrast, TTX treatment had no effect on binding in the ON or primary retinorecipient areas, i.e., the ventrolateral geniculate nucleus and tectal gray, where ON transection dramatically reduced binding. The latter findings may reflect nerve degeneration resulting in loss of axonal presynaptic melatonin receptors, while the results with TTX suggest that expression of melatonin receptors in the tectofugal pathway and other tectal projections is influenced by the visual input to these pathways. REGULATION OF PITUITARY GLAND PRO-OPIMELANOCORTIN IN HYPERTENSIVE AND HYPERACTIVE RATS. K.M. Braas*, E.D. Hendley and V. May. Depts. of Anatomy & Neurobiology and Molecular Physiology & Biophysics, Univ. of Vermont College of Medicine, Burlington, VT 05405.

Pro-opiomelanocortin (POMC) levels are changed in pituitary glands from spontaneously hypertensive rats (SHR) compared to normotensive Wistar Kyoto (WKY) animals. Previously, to determine whether altered POMC expression was associated with the hypertensive or hyperactive trait of the SHR, we examined peptide levels in two genetically related strains: WKHT is only hypertensive while WKHA is only hyperactive. Decreased anterior pituitary gland POMC peptide content was associated with the hypertensive trait, while increased intermediate pituitary gland levels of POMC peptides were associated with the hyperactive trait. We have further examined the cellular basis for these tissue-specific changes in POMC expression. Anterior pituitary corticotrope POMC mRNA levels, determined by Northern blot analysis, were decreased 55% in SHR and WKHT rats compared to WKY rats. Immunocytochemically stained corticotrope cell numbers were decreased 40 to 45% in SHR and WKHT tissues. Using *in situ* hybridization, the number of cells expressing POMC mRNA was decreased approximately 40% in the hypertensive SHR and WKHT rat strains, suggesting that the decreased POMC expression results primarily from decreased corticotrope cell number. Intermediate pituitary melanotrope POMC mRNA levels were increased approximately 300% only in the hyperactive SHR and WKHA strains. Morphological studies indicate that the increased intermediate pituitary POMC expression in the hyperactive rats may be the result of increased melanotrope number. Additional studies are required to determine whether there are changes in corticotrope or melanotrope responsiveness to secretagogues in the hypertensive and hyperactive rat strains. REGULATION OF CYTOSOLIC CALCIUM IN FURA-2-LOADED CULTURES OF ANTERIOR PITUITARY CORTICOTROPE CELLS (AtT-20/D16v). J.F. Fiekers, Dept. Anatomy & Neurobiology, Univ. Vermont College of Medicine, Burlington, VT 05405.

Agonist-induced changes in $\{Ca^{2+}\}_i$ in neuroendocrine cells depend on either extracellular Ca^{2+} entry or release of Ca^{2+} from internal stores (Fiekers, et al., Soc. Neurosci. Abstr., 1992). The present experiments examined the mechanisms of $\{Ca^{2+}\}_i$ regulation in single cells from cultures of anterior pituitary (AtT-20/D16v) cells. $\{Ca^{2+}\}_i$ was monitored in individual corticotropes by dual excitation microspectrofluorometry using fura-2. Elevated $\{K\}_o$ produced an increase in $\{Ca^{2+}\}_i$ which rapidly reached a peak and declined to resting levels following exposure. The response was abolished by either extracellular Co^{2+} (2mM) or antagonists of L-type voltage-gated Ca^{2+} channels but was unaffected by TTX. The amplitude, but not the duration, was significantly increased with elevated $\{Ca^{2+}\}_o$. Exposure of the cells to potassium cyanide produced a slow elevation of $\{Ca^{2+}\}_i$ which was independent of $\{Ca^{2+}\}_o$. 40% of the cells responded with an increase in $\{Ca^{2+}\}_i$ in response to 10 mM caffeine. Caffeine responses decreased with subsequent exposure even when primed by a previous K-depolarization. These results suggest that Ca^{2+} entry through voltage-gated Ca^{2+} channels is an important pathway for regulating $\{Ca^{2+}\}_i$, and that cyanide- and caffeine-sensitive intracellular stores are potential sites for Ca^{2+} release and sequestration in these corticotropes.

NUCLEAR VS. CYTOPLASMIC GLUCOCORTICOID RECEPTOR IMMUNOREACTIVITY IN HIPPOCAMPUS OF ADRENAL-ECTOMIZED AND INTACT RATS: DIFFERENT PROFILES WITH TWO DIFFERENT ANTIBODIES. R.L. Spencer*, A.H. Miller and B.S. McEwen, Lab. of Neuroendo., Rockefeller Univ., and Dept. Psychiatry, Mt. Sinai Sch. of Med., New York, NY.

A widely accepted, although not fully supported, model of glucocorticoid receptor (GR) function asserts that the unoccupied form of the receptor resides in the cytoplasm, whereas the hormone activated form of the receptor translocates to the nucleus. It may be possible to use the relative pattern of nuclear vs. cytoplasmic GR immunostaining present during different hormone conditions to assess the differential occupation/activation of GR by glucocorticoids. We have examined the patterns of hippocampal GR immunostaining (Vector Labs ABC kit) present in adrenal-intact and 3 d ADX male Sprague-Dawley rats. Two GR reactive antibodies were compared (GR#57 and BUGR2, Affinity Bioreagents). Interestingly, the two antibodies gave a different profile of immunostaining, with GR#57 exhibiting mostly nuclear immunostaining in the adrenal-intact rat and mostly cytoplasmic staining in the ADX rat. On the other hand, with this duration of ADX, BUGR2 exhibited predominantly nuclear immunostaining in both cases, although the immunostaining was stronger in the intact rats. This suggests that antibodies recognizing different epitopes of GR may differentially bind to the receptor depending, not only on the activation state of the receptor, but also on the nuclear vs. cytoplasmic location of the receptor. This prospect is being further explored with western blots and immunocytochemistry of cells treated with different hormone conditions in vitro. (Supported by MH47674 and the McArthur Foundation)

LOCALIZATION OF THE MINERALOCORTICOID RECEPTOR mRNA 5' SPLICE VARIANTS IN THE DEVELOPING HIPPOCAMPUS. D.M. Vázquez, S.P. Kwak, J.F. López, S.J. Watson and H. Akil, Mental Health Research Institute and Department of Pediatrics, University of Michigan, Ann Arbor, MI 48109-0720.

Our laboratory has previously reported an MR cDNA clone from rat hippocampus (HC) which shares a high degree of homology with the kidney MR rat clone throughout the coding and 3' untranslated region (Patel et al. 1992). However, these two clones differ significantly at the 5' untranslated region (5' UT). These clones have been named alpha 5' UT (kidney cDNA clone) and beta 5' UT (HC cDNA clone). Subsequent studies have shown that these 5' UT regions are located on separate exons of a single gene and give rise to two mRNAs that encode the same protein. Both alpha and beta MR mRNA forms are found in the adult HC and have a distinct regional distribution (Kwak et al. 1993). We were interested in investigating the presence of these distinct MR mRNA forms in the developing rat HC. In situ hybridization with specific alpha and beta cRNA probes was performed in the HC of post natal day (PND) 10, 18, 28, 35 and 60 (adult) animals. We found that alpha is highly expressed in the CA2 subfield compared to other regions. This high expression is more evident in the PND 10 animal. The beta form is evenly expressed over all pyramidal cell subfields. A higher level of beta is evident over the granular cells of the dentate gyrus in all ages, except in PND 10. Our results, therefore, show that the alpha and beta 5' UT forms achieve an adult pattern of distribution in the HC after PND 10. This coincides with the emergence of the developing animal from the Stress Hypo-Responsive Period (SHRP). Supported by NIMH MH09720 and MH422251.

EFFECTS OF HEAVY METAL DIVALENT CATIONS ON TRANSCRIPTION OF PROOPOMELANOCORTIN IN AtT-20 CELLS. B.A. Ashton, N. Levin* and J.L. Roberts, Dr. Arthur M. Fishberg Research Center for Neurobiology, Mount Sinai Medical Center, New York, NY 10029.

Corticotropin releasing hormone (CRH) induces a rise in the intracellular concentrations of cAMP and Ca^{2+} , followed by an increased rate of proopiomelanocortin (POMC) transcription. In preliminary studies, this stimulation was abolished by lowering the intracellular concentration of Ca^{2+} . Further lowering of intracellular Ca^{2+} led to a decrease in the basal transcription rate of POMC, suggesting that the two Ca^{2+} -dependent processes may be differentially regulated (Lorang and Roberts, submitted). Additional studies indicated that POMC transcription was also inhibited by Cd^{2+} and Co^{2+} through a mechanism that does not involve blockade of Ca^{2+} channels. The purpose of the current work is to characterize the mechanism by which Ca^{2+} ion modulates the basal level of transcription of the POMC gene in pituitary, using the AtT-20/D16-16 mouse corticotroph cell line as a model system. We have used RNase protection assays of POMC primary transcript as an indirect measure of the effects of divalent cations on POMC transcription rates, utilizing a probe that spans exon 2 of the mouse POMC gene, extending into introns A and B. Cells were incubated for one hour in serum-free media prior to addition of varying concentrations of ions (chloride salts). Incubation with Zn^{2+} or Cd^{2+} caused a dose-dependent decrease in the level of primary transcript (IC_{50} = 60 and 50 μ M, respectively), with a greater than 90% decrease at 500 μ M. Co^{2+} was less potent, leading to a 25% reduction in primary transcript levels at 500 μ M, the highest concentration tested. The reduction of POMC primary transcript levels following incubation with selected divalent cations suggests that the transcriptional complex has been inhibited.

NGFI-A AND GLUCOCORTICOID RECEPTOR mRNA EXPRESSION IS INDUCED IN THE HIPPOCAMPUS AFTER ENVIRONMENTAL ENRICHMENT IN ADULT RATS. T. Olsson, A.K. Mohammed¹, K.L. French, and J.R. Seckl* Dept Med, West Gen Hosp, Edinburgh Univ and ¹Dept Ger, Huddinge Hosp, Stockholm.

Neonatal manipulations that permanently increase hippocampal glucocorticoid receptor (GR) expression prevent age-related cognitive deficits. In adult rats we recently found that chronic environmental enrichment increases hippocampal nerve growth factor (NGF) concentrations and also improves cognitive performance. We have now evaluated hippocampal GR and mineralocorticoid receptor (MR) gene expression in response to environmental manipulation. We also studied a possible mediator of changes in GR expression, the NGF-induced immediate early gene-transcription factor NGFI-A (zif268, krox24). Adult male Sprague-Dawley rats were housed in enriched or isolated environments for 30 days. Expression of mRNAs encoding GR, MR and NGFI-A was determined by *in situ* hybridization. The enriched environment was associated with significantly greater GR mRNA expression in pyramidal neurons of CA1 (28% rise), CA2 (76%) and CA4 (44%) but GR gene expression was not altered in other hippocampal subfields, including the dentate gyrus, or in parietal cortex neurons. MR mRNA expression was unchanged. There was a 55% increase in NGFI-A gene expression in the CA2 region ($p < 0.01$) with non-significant increases in CA1 and CA4 regions. Thus, environmental enrichment increases GR gene expression in specific hippocampal subfields in adult rats. These effects may be mediated through NGF induction of transcription factors, including NGFI-A.

ONTOGENY OF FORSKOLIN-STIMULATED CYCLIC AMP (cAMP)-DEPENDENT PROTEIN KINASE, AND OF DEXAMETHASONE SUPPRESSION OF FORSKOLIN-STIMULATED cAMP PRODUCTION IN RAT ANTERIOR HYPOTHALAMUS. S.-I. Yi and T.Z. Baram, Division of Neurology, Childrens Hospital Los Angeles and University of Southern California, Los Angeles, CA 90027.

An major regulatory mechanisms of corticotropin releasing hormone (CRH) synthesis in the adult hypothalamic paraventricular nucleus (PVN) is a negative feedback via local glucocorticoid (GC) receptors. The cAMP-cAMP-dependent protein kinase (cA-PK)/second messenger cascade has been shown to participate in signal transduction of GC modulation of CRH gene expression. This GC-induced pathway, leading to suppression of the CRH gene promoter may not be operative in the neonatal rat, since we have previously shown that CRH gene expression was not regulated by GC before the 9th postnatal day, despite the presence of GC receptors in the PVN. This study was performed to examine whether GC altered cAMP accumulation and cA-PK activity in the anterior hypothalamus of neonatal and adult rats.

We found that forskolin (10 μ M) increased cAMP production 10-fold in the adult rat and 3 to 6-fold in 3 to 13 day-old neonatal rats. Dexamethasone inhibited forskolin-stimulated cAMP accumulation in the anterior hypothalamus of adult rats. The suppression of forskolin-induced cAMP production by dexamethasone was considerably reduced in the anterior hypothalamus of 9 - 13 day-old rats, and was negligible in 3 - 4 day-old rats. A stimulatory effect of forskolin (10 μ M) on cA-PK activity was seen in adult and 12 - 18 day-old rats, but not 4 - 11 day-old neonatal rats. These results indicate that "uncoupling" of GC receptors with cAMP-cA-PK second messenger cascade, a crucial element of the signal transduction pathway between GC and the CRH promoter, may underlie the lack of down regulation of CRH synthesis by GC in the neonatal rat PVN.

GLUCOCORTICOID RECEPTOR mRNA ONTOGENY IN THE FETAL AND POSTNATAL RAT BRAIN. T.Z. Baram, S.-J. Yi and J.N. Masters, Div. Neurology, Childrens Hospital Los Angeles; Dept. Neurology University of Southern California, Los Angeles, CA 90007 and Biotechnology Center, Ohio State University, Columbus OH 43210.

Glucocorticoid receptor (GR) localization has been well studied in postnatal rat brain. However, the ontogeny of GR distribution in fetal brain has not been reported. This study focuses on the distribution of GR-mRNA in the fetal and postnatal rat, with emphasis on hypothalamic and limbic structures. Time pregnant rats (day 0 defined by sperm-positive smear), were decapitated at 8:30-9:30 am on fetal days 14 (F14), F16, F17, F18, F19 and postnatal days 1, 5, 7 and 12. Fetuses were decapitated and heads quick-frozen. For postnatal rats, brains were removed from skulls, then frozen on dry-ice. Cryostat sections (20 μ) were subjected to *in situ* hybridization (ISH), using a cRNA probe directed to the GR-mRNA. GR-mRNA was detectable in the fornices as early as F14. By F16, GR gene expression was evident in the hypothalamic paraventricular nucleus (PVN). During late gestation (F17-F19), GR-mRNA was detectable also in thalamus, ventromedial hypothalamus amygdala and discrete cortical regions. Subsequent to birth, GR-mRNA was clearly localized to the CA1 hippocampal field, piriform cortex and dorsal endopiriform nucleus, and specific amygdaloid nuclei; the suprachiasmatic hypothalamic nucleus contained GR-mRNA as well. Semiquantitative analysis revealed much higher GR-mRNA abundance in the piriform cortex and PVN than in most other structures. In PVN, GR-mRNA is detectable prior to the onset of CRH gene expression (F17), which may suggest a role for GR in neuronal differentiation. REGULATORY CHANGES IN CORTICOSTEROID RECEPTOR AND ACTH SECRETAGOGUE mRNA EXPRESSION WITH CHRONIC STRESS. C.M. Meyers*, D.H. Adams and J.P. Herman, Dept. of Anatomy and Neurobiology, University of Kentucky Medical Center, Lexington, KY 40536-0084.

Chronic stress affects stress-hormone secretion by the hypothalamic-pituitary-adrenal (HPA) axis in a long term fashion. Stress may exert these HPA actions via modulation of brain corticosteroid receptors. The present studies were designed to assess the effects of chronic stress on GR and MR mRNA in discrete hippocampal subfields and ACTH secretagogue biosynthesis in stress-integrative neurons of the paraventricular nucleus (PVN). Groups of rats were chronically stressed using variable stressor paradigms (bi-daily exposure to cold, warm water swim, cold water swim, crowding, vibration, isolation). Control rats were handled bidaily. Adrenal weight and basal corticosterone secretion were significantly increased in the chronically stressed animals, verifying the efficacy of the stress procedure. Semi-quantitative *in situ* hybridization histochemistry was used to assess regulatory changes in PVN and hippocampus. In response to chronic stress, GR mRNA was significantly down regulated in the dentate gyrus (DG) and the frontoparietal cortex. No change was seen in CA3 or ventral subiculum (VSub). MR mRNA was significantly down regulated in CA1, DG, and VSub. There was a marginal decrease in CA3, but no significant change was noticed in CA2 or frontoparietal cortex. CRH mRNA was upregulated in the PVN in chronically stressed animals (50% increase). Thus, chronic stress exerts an increase in ACTH secretagogue biosynthesis and a subfield-specific down-regulation of hippocampal corticosteroid receptor expression. The relationship between these stress-induced changes in corticosteroid receptor mRNA and HPA function remains to be determined. (Supported by MH49698)

EFFECTS OF AGING ON CORTICOSTEROID RECEPTOR, CRH AND AVP mRNA EXPRESSION IN HPA REGULATORY CIRCUITS. D.H. Adams, M.I. Morano, H. Akil, J.D. Porter* and J.P. Herman, Dept. of Anatomy and Neurobiology, Univ. of Kentucky, Lexington, KY 40536, and Mental Health Research Inst., Univ. of Michigan, Ann Arbor, MI 48109.

Aging has deleterious effects on regulation of the hypothalamo-pituitary-adrenocortical (HPA) stress response and on hippocampal corticosteroid receptor expression. The documented connection between the hippocampus and HPA regulation mandates careful correlation of age-related changes in hippocampal corticosteroid receptor regulation and expression of ACTH secretagogues. To approach this problem, the present studies used semi-quantitative *in situ* hybridization analysis to assess regulation of mRNAs encoding the mineralocorticoid receptor (MR), glucocorticoid receptor (GR), corticotropin releasing hormone (CRH) and arginine vasopressin (AVP) in HPA regulatory circuits of 26 mo. old (aged) and 9 mo. old (control) Fisher 344 rats. As previously documented, aged rats showed prolonged plasma corticosterone increases following acute restraint. CRH mRNA was significantly increased in the medial parvocellular paraventricular nucleus of aged rats (30%), whereas AVP mRNA was unchanged. In hippocampus, GR mRNA was significantly reduced only in the ventral subiculum, whereas MR mRNA was reduced in subfield CA3 and in the dentate gyrus. No other subfields were affected, nor was MR or GR mRNA in frontoparietal cortex. Results indicate an up-regulation of the HPA axis which is specific for the CRH component of this system, and down-regulation of corticosteroid receptor mRNA expression only in discrete hippocampal regions. The relationship between changes in corticosteroid receptor mRNA changes and age-related hippocampal/hypothalamic cell death is under determination. (Supported by MH49698 and MH42251).

RAPID GLUCOCORTICOID EFFECTS ON CALPAINS IN RABBIT HIPPOCAMPUS. K. Ostwald* and J.O. Karlsson, Institute of Neurobiology, Medicinaregatan 5, S-413 90 Göteborg, Sweden.

Ten pairs of adult New Zealand White rabbits were given a single, intramuscular injection of betamethasone (0.3 mg/kg) or saline, and were sacrificed at various intervals between 20 min. and 86 h. after the injection. The soluble and particulate fractions from the hippocampi were assayed for calpain activity. The soluble fraction was also assayed for calpastatin activity, and subjected to hydrophobic interaction chromatography. All fractions were assayed for calpain activity and immunoreactivity (ELISA), and the total amount eluted was compared with the control animal. Major peaks were further subjected to anion exchange HPLC, revealing no changes in chromatographic behavior after glucocorticoid treatment. Just 20 min. after the injection, calpain activity in the soluble fraction was reduced to 80 % of control, but increased to 126 % in the particulate fraction, gradually returning to control levels after 4 h. The level of μ -calpain immunoreactivity decreased to 46 % of control after 20 min., and returned to control level after 80 min. The level of m-calpain immunoreactivity decreased at first to 80 % of control, increased to 150 % after 80 min., and returned to control level after 4 h. These results indicate that glucocorticoids have a rapid effect on the calcium-activated proteases in the hippocampus.

488.12

RAPID DOWN-REGULATION OF MINERALOCORTICOID RECEPTOR HETERONUCLEAR (hn) RNA BY ACUTE STRESS. J.P. Herman*, P.D. Patel and S.J. Watson, Dept. of Anatomy and Neurobiology, Univ. of Kentucky, Lexington, KY 40536-0084, and Mental Health Research Institute, Univ. of Michigan, Ann Arbor, MI 48109-0720.

The hippocampal mineralocorticoid receptor (MR) serves to interpret circulating levels of glucocorticoids into appropriate neuronal responses. In recent years, this receptor has been implicated in tonic regulation of hypothalamo-pituitary-adrenocortical stress (HPA) axis and in regulation of neuroendocrine stress responses. The present studies utilized an *in situ* hybridization paradigm to assess regulation of the MR gene by stressful stimuli. *In situ* hybridization experiments were performed using cRNA probes complementary to a coding-region intron of the rat MR gene, or to the 3' coding region-untranslated domain of rat MR mRNA. In normal rats, the distribution of MR hnRNA overlapped that of MR mRNA completely. MR hnRNA was confined to the cell nucleus, and was easily detectable, suggesting either a high ongoing MR transcription rate or a stable MR splicing intermediate in the nucleus. For stress experiments, rats were placed in restraint cages and sacrificed 30 m, 1 h or 2 h later, with unstressed rats serving as controls. MR hnRNA was significantly decreased by some 50% in all hippocampal subfields following 1 h or 2 h of stress; in contrast, no changes in MR mRNA were observed during this period, suggesting a lag between transcription and changes in the cytoplasmic message pool. These results suggest a rapid decrease in MR gene transcription following stress; whether this decrease is associated with changes in circulating glucocorticoids is presently being determined. In all, the results indicate that stress can induce changes in corticosteroid receptor production and thereby, the manner in which hippocampal cells process steroid-related information. (Supported by MH49698 and MH42251).

INFLUENCE OF DOPAMINE ON BRAIN CORTICOSTEROID RECEPTORS AND CORTICOSTERONE SECRETION. P. Casolini¹, M. Kabaj², P.V. Piazza², F. Rouge-Pont², L. Angelucci¹, H. Simon², M. LeMoal² and S. Maccari². ¹Institute of Pharmacology II, University of Rome "La Sapienza" P.le A. Moro 5, 00185 Rome, Italy ²INSERM U259 Rue Camille St Saëns 33077 Bordeaux, France.

Central type I and type II corticosteroid receptors play a major role on corticosterone secretion. There is also evidence for a direct neural control of these receptors. We have previously shown that both noradrenaline and serotonin regulate brain corticosteroid receptors. However, the role of dopamine (DA) on these receptors is as yet unknown. In order to investigate the influence of DA we tested: i) the effects of 6-OHDA lesion of the ventral tegmental area on corticosteroid receptors in the dorsal striatum, ventral striatum and hippocampus, and on basal and restraint stress-induced corticosterone secretion; ii) the effect of intraperitoneal injection of D₁ (SKF38393) and D₂ (LY171555) DA agonists on corticosteroid receptors in the hippocampus and ventral striatum. Three weeks after the DA lesion was observed: i) an increase in type II receptor affinity in the ventral striatum but no effects in the dorsal striatum or hippocampus; ii) a reduction in basal and stress-induced corticosterone secretion after DA lesion; iii) a decrease in type II receptor affinity in the hippocampus after D₁ agonist treatment but no differences in binding in the ventral striatum after injection of DA agonists. These studies suggest that i) DA is involved in the regulation of brain corticosteroid receptors and that it affects receptor affinity rather than number; ii) D₁ receptor could be responsible for DA regulation; iii) DA may have a stimulatory influence on the HPA axis. In conclusion, these results shed light on mechanisms linking the DA and the HPA axis. (Supported by INSERM).

50% CORTICOSTERONE PELLET TREATMENT DOES NOT AFFECT GLUCOCORTICOID FAST FEEDBACK. E.A. Young*, K. Fried and E. Ho, Mental Health Research Institute, University of Michigan, Ann Arbor, MI 48109.

Our previous studies have demonstrated that implantation of 50% corticosterone pellets raised the morning plasma levels of corticosterone to 4-5µg/dl and resulted in inhibition of evening corticosterone secretion. Implantation of these pellets was associated with a decrease in thymus weight, adrenal atrophy and a decrease in anterior pituitary proopiomelanocortin mRNA (ACTH pro-hormone). However, anterior pituitary ACTH content was normal. No changes were found in brain glucocorticoid receptors. To test whether this small increase in baseline corticosterone secretion would affect in vivo feedback, animals were subjected to 30 minutes of restraint stress and blood was sampled by tail nicks for measurement of plasma ACTH and corticosterone. Each rat was tested on 4 occasions, twice at baseline before corticosterone treatment and twice following implantation of corticosterone pellets. In each test session half the rats received saline and half the rats received a cortisol injection before the onset of the restraint stress. There was no difference in the plasma ACTH response at 5 or 30 minutes before and after the implantation of corticosterone pellets. Injection with cortisol significantly decreased the plasma ACTH response to restraint stress both before and after corticosterone pellet treatment. These data suggest that 50% corticosterone pellet treatment is able to inhibit circadian induced ACTH secretion but not stress-induced ACTH secretion. In addition, they suggest that glucocorticoid fast feedback is not affected by this low dose corticosterone treatment.

SPLANCHNICECTOMY ALTERS DIURNAL SENSITIVITY TO ACTH AND ABOLISHES DIURNAL RHYTHMICITY IN CORTICOSTERONE SECRETION IN AWAKE RATS. M.S. Jasper* and W.C. Engeland, Dept. of Surgery/Dept. of Neurobiology, RI Hospital/Brown Univ., Providence, RI, U.S. 02903

An ultradian rhythm in adrenal secretion of corticosterone (CORT) has been described in awake rats using intra-adrenal microdialysis. To determine the role of splanchnic neural activity in diurnal changes in the CORT rhythm, CORT secretion was studied in intact (CTRL) and splanchnicectomized (SPLNX) rats during the inactive (AM) and active phases (PM) of the rat's circadian cycle. Experiments conducted between 1000 h and 0110 h, 5 days after surgery, consisted of continuous collection of dialysate at 10 min intervals. Discrete pulse detection revealed that the inter-pulse interval (IPI) was greater in the AM than in the PM in CTRL animals, but not in SPLNX animals. Power spectral analysis results supported this finding. CORT pulse amplitude was greater during the PM in both CTRL and SPLNX animals. Total integrated secretion was diurnally modulated in CTRL animals, whereas SPLNX animals secreted equal amounts of CORT during the AM and PM. To test whether neural modulation of pulsatile secretion during the AM was due to a direct effect of the splanchnic nerve on adrenal sensitivity to ACTH, rats treated with dexamethasone to suppress endogenous secretion of ACTH were repeatedly administered constant pulses of ACTH. Both CTRL and SPLNX rats were tested at 2 or 5 days after surgery. The results showed that adrenal sensitivity to ACTH was markedly reduced in CTRL animals compared to SPLNX animals at 5 days, but not at 2 days after surgery. This finding is consistent with the reduction in pulsatile secretion in CTRL animals during the AM, 5 days after surgery, which was abolished by SPLNX, suggesting that splanchnic neural activity provides inhibitory input to the adrenal cortex during the AM. The increased AM IPI observed in the CTRL group may result in part from a relatively insensitive adrenal cortex that responds to fewer of the endogenous ACTH pulses presented to it. The absence of AM neural inhibition of sensitivity to ACTH, 2 days after surgery, suggests that surgical stress obscures this splanchnic neural effect. Supported in part by NIH grant DK38951.

THE PREOPTIC AREA AS A SITE OF STEROIDAL REGULATION OF STRESS-RELATED HYPOTHALAMIC-PITUITARY-ADRENAL ACTIVITY. V. Viau* & M.J. Meaney, Developmental Neuroendocrinology Laboratory, Douglas Hospital Research Centre, Depts. of Psychiatry and Neurology/Neurosurgery, McGill Univ., Montreal H4H 1R3, Canada

Previous studies in our laboratory have indicated that male rats secreting high plasma testosterone (T) levels show reduced ACTH responses to stress. Furthermore, gonadectomized males replaced with elevated T levels show an increase in glucocorticoid receptor density only in the preoptic area (POA). These studies suggest a possible role for the POA in mediating glucocorticoid feedback inhibition of the HPA axis, which is perhaps regulated by T. This is consistent with previous electrophysiological studies implicating a role for the POA in regulating the HPA axis (Saphier and Feldman, 1986). To further examine the role of the POA on HPA activity, we examined the ACTH response to restraint in animals receiving either B (corticosterone) or T implants in the POA for 1 week prior to testing.

Animals with B or T implants in the POA showed significantly ($P < 0.05$) lower peak ACTH responses to 10 min of restraint compared to animals receiving cholesterol (CHOL) implants (539 ± 82 , 656 ± 75 , and 896 ± 89 pg/ml, respectively). B and T implanted animals also showed significantly ($P < 0.01$) lower ACTH levels up to 30 min following stress as indicated by area under curve analysis (211 ± 19 , 263 ± 17 , and 373 ± 28 pg/ml/min, respectively). No differences were found in pre-stress basal levels of ACTH. POA steroid implants did not affect median eminence CRH content, however, AVP content was significantly ($P < 0.01$) reduced in animals receiving B compared to T and CHOL implants ($CRH = 14 \pm 3$, 16 ± 1 , and 18 ± 2 pg/µg, respectively; $AVP = 47 \pm 5$, 62 ± 7 , and 80 ± 6 pg/µg, respectively). These studies suggest that B and T inhibition of the HPA response to stress occurs at the level of POA, effects which may be related to the regulation of AVP synthesis. Thus, the POA appears to represent an important site within the brain mediating B and T regulation of the HPA axis.

GLUCOCORTICOID RECEPTOR ACTIVATION DOES NOT ALTER SYNAPTIC POTENTIALS IN AREA CA1 OF RAT HIPPOCAMPAL SLICES. S. Birnstiel, T. List and S.G. Beck, Dept. Pharmacol., Loyola Univ. Med. Ctr., Maywood, IL 60153.

Stressful stimuli increase corticosterone (CT) production by the hypothalamic-pituitary-adrenal (HPA) axis. One site of the feedback regulation of the HPA axis is the hippocampal CA1 subfield, which contains high densities of both mineralocorticoid (MR) and glucocorticoid (GR) receptors. Basal plasma CT levels occupy MR receptors; high concentrations of CT also activate the GR, which is implicated in the feedback control of the HPA. To investigate if the feedback control by CT is due to an action on fast amino acid mediated synaptic transmission in area CA1, intracellular recordings of excitatory and inhibitory synaptic potentials were obtained from the CA1 pyramidal cell layer of transversal hippocampal slices. Male Sprague-Dawley rats (75-190 g at the beginning of treatment) were adrenalectomized (ADX) 14 days prior to recording. A second ADX group was chronically treated with a corticosterone pellet (12.5 mg) to mimic basal CT plasma levels. Perfusion with high concentrations of CT (100 nM for 30 min) did not change synaptic potentials in any group up to 60 min later, nor did it alter passive or active cell properties. These results argue against the hypothesis that HPA feedback control is mediated by an effect on amino acid transmission via GR receptors in area CA1 of the hippocampus. However, chronic treatment with CT seemed to prevent rundown of synaptic potentials over a 90 min recording period. A possible mediation of feedback control by other neurotransmitter systems is under current investigation. Supported by USPHS NS28512 and MH 00880.

STRESS-INDUCED INCREASES IN ADRENAL SENSITIVITY TO ACTH ARE MEDIATED IN PART BY SPLANCHNIC NEURAL ACTIVITY. W.C. Engeland and J.T. Walworth, Dept. of Surg., Univ. of Minn., Mpls, MN 55455.

Sympathetic neural input to the adrenal gland has been proposed as an extra-ACTH mechanism for the control of adrenal corticosteroid secretion during stress. To determine if splanchnic neural activity affects stress-induced adrenal responses by changing adrenal sensitivity to ACTH, adrenal sensitivity was tested *in vitro* after thoracic splanchnic nerve section (SPLNX). Rats ($n=6$ /group) underwent unilateral SPLNX and at 6 days were killed in the AM by decapitation (non-stress) or after 5 min of continuous restraint (stress). Additional groups received dexamethasone (DEX) 2 h prior to stress to assess the role of ACTH in adrenal responses. Trunk blood was collected and plasma was assayed for ACTH and corticosterone by RIA; SPLNX and intact (CTRL) adrenals were removed, decapsulated and cortical cells from single adrenals were isolated with collagenase prior to *in vitro* testing with ACTH. Restraint stress resulted in increases in plasma ACTH and corticosterone, which were blocked by DEX treatment. Dose-dependent increases in corticosterone release were observed for all adrenals after *in vitro* exposure to ACTH. Stress increased *in vitro* adrenal sensitivity (CTRL: stress vs non-stress; $p < 0.05$) and responses to low doses of ACTH were reduced by SPLNX (CTRL-stress vs SPLNX-stress; $p < 0.05$). Following blockade of ACTH secretion by DEX, both stress-induced increases in adrenal sensitivity (CTRL/DEX: stress vs non-stress; $p < 0.05$), and reduced responses observed after SPLNX (CTRL/DEX-stress vs SPLNX/DEX-stress; $p < 0.05$) persisted. These data show that restraint stress induces a rapid increase in adrenal sensitivity to ACTH and that SPLNX reduces the response in the presence and absence of endogenous ACTH. These findings suggest that splanchnic neural activity augments adrenal sensitivity to ACTH and represents an extra-ACTH mechanism for augmenting stress-induced increases in adrenocortical secretion.

HIGH-FAT FEEDING IMPAIRS BOTH BASAL AND STRESS-INDUCED HYPOTHALAMIC-PITUITARY-ADRENAL (HPA) RESPONSIVENESS. B.M. Tannenbaum*, D. Francis, G.S. Tannenbaum, D.N. Brindley, M.F. Dallman and M.J. Meaney, Dept. Neurol/Neurosurg., McGill Univ., Montreal, Canada, H3A 2B4; Dept. Biochem., Univ. of Alberta, Edmonton, Canada, T6G 2C2; Dept. Physiol., UCSF, San Francisco, CA, 94143.

Rats fed a high fat diet develop insulin resistance which could lead to elevated levels of circulating corticosterone (B). The present study was undertaken to determine whether dietary fat-induced increases in B, in turn, cause further alterations in the regulatory components of the HPA axis. Adult, male rats were maintained on a high fat (23%) or control (3%) diet for 1-3 weeks. Six hour plasma B profiles obtained from undisturbed, free moving rats revealed marked elevations in a.m. basal B levels as early as 7 days after fat diet onset compared to controls. In a second study, plasma B and ACTH levels were examined before, during and following a 20 min. restraint stress after 1, 9 or 12 weeks exposure to either the high fat or control diet. At 20, 60 and 120 minutes post-stress, all groups of rats fed the high fat diet had significantly elevated B and ACTH levels and showed a significant resistance to insulin compared to normal fed controls. To assess the mechanism, we examined glucocorticoid negative feedback in high fat and control animals. The inhibition of basal ACTH levels by B was comparable in the two groups, providing little evidence for changes in negative feedback sensitivity in the high fat fed animals. Moreover, no differences in resting-state median eminence content of CRH or AVP were found in response to high fat feeding. Finally, animals maintained on the high fat diet for 3 weeks and exposed to chronic, intermittent cold stress during this period showed evidence of an enhanced HPA response to a novel stressor (restraint) compared to normal fed controls. Taken together, these results suggest that high-fat intake acts as a background form of chronic stress, elevating a.m. basal B levels and enhancing HPA responses to stress. This latter effect may be associated with an augmented dietary fat-induced increased sensitivity to the neural signals associated with stress. (Supported by the MacArthur Foundation)

CORTICOTROPIN RELEASING FACTOR mRNA EXPRESSION IN THE FETAL SHEEP BRAIN: REGIONAL CHANGES AFTER MATERNAL RU486 TREATMENT. C.J. Keiger*, J.P. Figueroa^{1,2}, G. Brewer³, MS Thomas⁴ and J.C. Rose^{1,2}. Departments of Phys/Pharm¹, Ob/Gyn², Micro/Immuno³, and Comparative Med⁴. Bowman Gray School of Medicine of WFU, Winston-Salem, NC 27157.

Mifepristone (RU486), an antiprogesterone and antigluco-corticoid, is used to induce labor in early and late pregnancy. The fetal effects of maternal administration of RU486 are presently unknown. The aim of this study was to determine the effect of maternal RU486 on CRF mRNA expression in regions of the fetal brain associated with neuroendocrine and stress responses. Eight pregnant sheep (127-137 days gestation, term ~ 145 days) received either 100 mg RU486 or vehicle (i.p.) on two consecutive days. Fetal brain tissue was collected on day 3. CRF mRNA was quantified in the fetal hypothalamus (HYPO), hippocampus and amygdala (HA), frontal cortex (FC), and brainstem (BS) using a RNase protection assay with a sheep antisense probe. CRF mRNA is expressed as fg per μ g total RNA (Table, mean \pm SEM). Data were analyzed by ANOVA and two-sample tests.

GROUP	HYPO	HA	FC	BS
Vehicle	8.0 \pm 1.7	3.2 \pm 1.1	27.6 \pm 4.8	8.9 \pm 1.4
RU486	12.6 \pm 6.2	18.6 \pm 3.8	28.1 \pm 11.3	24.0 \pm 6.2

Maternal RU486 significantly increased fetal CRF mRNA expression in the HA and BS ($P < 0.01$). In the vehicle group, CRF mRNA levels were greater in the FC than in the other regions ($p < 0.001$). Combined neural and endocrine responses resulting from fetal hypoxia and somatosensory stimulation caused by RU486 induced uterine activity may be responsible for the observed changes in CRF mRNA. These differences in fetal CRF gene expression in response to maternal RU486 may reflect different interactions of intracellular messengers and transcription factors in various brain regions. Although unlikely, we cannot rule out direct fetal effects of RU486. Supported by grants HD 11210 and HD 25175.

CHRONIC DEXAMETHASONE TREATMENT ALTERS ARACHIDONIC ACID-STIMULATED PRODUCTION OF *EX VIVO* PROSTAGLANDIN E₂ PRODUCTION IN SELECTED BRAIN REGIONS. T.M. Rampy*, F.A. Fitzpatrick and G.M. Rose. Dept. of Pharmacology and Neuroscience Training Program, UCHSC, and Medical Research, VAMC, Denver, CO 80220

Prostaglandins (PG) are an important class of neuromodulators. In many peripheral tissues, corticosteroids suppress the production of PGs. However, little is known about the effects of steroids upon PGs in the CNS. Thus, we examined the effect of chronic dexamethasone phosphate (DEX) treatment on prostaglandin E₂ (PGE₂) synthesis in several brain regions. Male Sprague Dawley rats received daily injections of DEX (30 mg/kg, i.p.) for two weeks. After sacrifice, levels of basal and arachidonic acid-stimulated *ex vivo* PGE₂ production were determined using quantitative enzyme immunoassays. In work to this point, we have found that chronic DEX pretreatment did not alter basal levels of PGE₂ in any brain region examined. By contrast, arachidonic acid-stimulated PGE₂ synthesis was reduced by DEX in hippocampus and prefrontal cortex, but not cerebellum. These results indicate that corticosteroids can modulate CNS prostaglandin production. The pattern of results suggest that this is accomplished through inhibition of cyclooxygenase (COX) enzymes, perhaps the recently described, steroid-suppressible, COX-2. Our observations may provide an explanation for the behavioral abnormalities sometimes observed with chronic steroid treatment (i.e. the clinical Steroid Psychosis syndrome).

EFFECTS OF ADRENAL STEROIDS AND REPEATED STRESS ON DYNORPHIN MRNA EXPRESSION AND KAINATE RECEPTOR BINDING IN THE HIPPOCAMPUS. Y. Watanabe*, N.G. Weiland and B.S. McEwen. Lab. of Neuroendocrinology, The Rockefeller Univ. New York, NY 10021.

Adrenal steroids and repeated stress cause atrophy of apical dendrites of CA3 neurons, and they also act in dentate gyrus neurons to regulate long-term potentiation. In the former actions, excitatory amino acid transmission via mossy fiber may have an important role. At mossy fiber terminals, dynorphin (DYN) and glutamate autoregulate their own release. In this study, we investigated the effects of adrenal steroids and repeated stress on DYN mRNA expression in dentate gyrus and kainate receptors in the hippocampus, by *in situ* hybridization and receptor binding autoradiography, respectively. ADX decreased DYN mRNA levels (25.8%) and corticosterone (CORT) replacement restored it, in agreement with other reports. In addition, CORT treatment of intact rats (40mg/kg, 21d) elevated DYN mRNA levels (31.7%). Kainate receptors in stratum radiatum, which may be associated with mossy fiber terminals, are decreased after ADX (18.6%) and restored by CORT replacement. However, CORT treatment of intact rats failed to elevate kainate receptor binding above control levels. Neither 3h/d nor 6h/d restraint stress for 21 days affected DYN mRNA levels, and 3h/day restraint stress for 14d did not alter kainate receptor binding in the hippocampus. Since hippocampal pyramidal neurons and dentate gyrus granule neurons contain both type I and type II adrenal steroid receptors, the role of both receptor types in DYN mRNA expression and kainate receptor binding are being explored. CORTICOSTERONE EFFECTS ON CRH mRNA IN PARVOCELLULAR PVN AND THE CENTRAL NUCLEUS OF THE AMYGDALA. S. Makino, P.W. Gold, and J. Schulkin*. Clinical Neuroendocrinology Branch, National Institute of Mental Health, NIH, Bethesda, MD 20892.

The central administration of corticotropin releasing hormone (CRH) to the rat facilitates pathways subserving arousal and cautious avoidance and inhibits pathways subserving vegetative functions such as feeding, growth, and reproduction. It has been hypothesized that the principal role of glucocorticoid secretion during stress is to counter-regulate the major effectors of the stress response, including CRH. This has been previously shown for paraventricular nucleus (PVN) CRH, which is likely to mediate the inhibition of vegetative functions, but not for extrahypothalamic CRH, which is thought to be more influential in promoting arousal. We report here a study of effects of low (1 mg/kg/day) and high doses (5mg/rat/day) of corticosterone (CORT) on CRH mRNA levels in the PVN and central nucleus (medial-caudal region) of the amygdala (CEA). We found that low and high doses of CORT given for 2, 4, 8 and 14 days significantly diminished CRH mRNA levels in PVN at all time points; however, high dose CORT increased CRH mRNA expression in CEA at 4 and 8 days. These data suggest that glucocorticoid secretion during stress may restrain the impact of CRH on inhibiting vegetative functions, while enhancing the arousal producing effects of extrahypothalamic CRH.

GLUCOCORTICOID ACT VIA TYPE II RECEPTORS TO REGULATE VASOPRESSIN mRNA IN THE PVN. D. Albeck*, N. Hastings and B. McEwen. Lab. of Neuroendo., Rockefeller University, NY NY 10021.

Adrenal steroids mediate neuropeptide synthesis by acting via intracellular receptors. Two types of glucocorticoid receptors are expressed in the paraventricular nucleus (PVN): type I (MR) and type II (GR). GR receptors predominate in the PVN, and in the PVN of adrenalectomized (ADX) rats the GR agonist dexamethasone is more potent than MR agonists in restoring vasopressin immuno-reactivity to baseline level (J. NSci., 7: 1093-1106, 1987). Vasopressin mRNA also increases after ADX and dexamethasone reverses this increase (PNAS, USA, 83: 1145-1149, 1986). Using *in situ* hybridization we have examined the effect of several adrenal steroid agonists in preventing the ADX induced increase in vasopressin mRNA within the parvocellular PVN. ADX rats showed an increase in vasopressin mRNA ($p < 0.002$, $n=4$). Physiological ($n=4$) and supra physiological ($n=4$) doses of corticosterone prevented the ADX induced increase in vasopressin mRNA, as did the selective GR agonist RU28362 ($n=4$). The selective MR agonist aldosterone ($n=5$) did not prevent the increase. These results indicate that adrenal steroids regulate vasopressin mRNA in the PVN through GR receptors. Currently we are examining steroid mediated regulation of vasopressin synthesis in extra hypothalamic nuclei. [Grant support: 1 F32 MH10232-01A1 (D.A.) and MH 41256 (B.Mc.)]

CHROMAFFIN AND ADRENOCORTICAL CELL INTERACTIONS *in vivo* and *in vitro*. M.A. Holzwarth*. Department of Physiology and Neuroscience Program, University of Illinois, Urbana-Champaign IL 61801.

Recent studies show that adrenocortical cell secretion is modulated by adrenal medullary cells and hence, indirectly by splanchnic nerve activity. We have shown that a network of VIP-containing nerve fibers in the glomerulosa of the rat adrenal originates from a subpopulation of medullary cells and that adrenocortical cells are responsive to VIP (Ann NY Acad Sci 512:449). We are currently using the frog adrenal as a model to study the chromaffin cell modulation of adrenocortical secretion because chromaffin and adrenocortical cells are interspersed in the frog. We show that like in the mammal, frog chromaffin cells express catecholamines, VIP, leu-enkephalin and substance P and networks of catecholaminergic and substance P containing nerve fibers are distributed throughout the adrenal. Chromaffin cells extend processes which appear to contact both cortical and other chromaffin cells. Steroidogenesis is stimulated by VIP, carbachol, norepinephrine and is comparable to ACTH, AII and forskolin as measured *in vitro*. To facilitate the investigation of chromaffin-cortical cell interaction, we have established primary cell cultures of frog adrenal cells. Growth and long term survival in our cultures are optimal using Pronectin-F plus laminin as a substrate and 55% L-15 medium supplemented with insulin, transferrin, ascorbate and α -tocopherol. NGF (50 ng/ml) and bFGF (10 ng/ml) enhance the neurite extension by chromaffin cells; these fine processes project to cortical and other chromaffin cells. The cultured chromaffin cells retain their expression of catecholamines and neuropeptides for several weeks. The cortical cells continue to proliferate and secrete both aldosterone and corticosterone. These co-cultures provide a useful model to study chromaffin-cortical cell interactions.

THE EFFECTS OF CORTICOSTERONE ON BRAIN AMINE OVERFLOW IN THE AWAKE AND FREELY MOVING RAT. D.N. Thomas*, R.M. Post and A. Pert. Biological Psychiatry Branch, NIMH, Bldg. 10, Rm 3N212, Bethesda, MD 20892

There is evidence to suggest important modulatory control of brain amine function by corticosteroids. The perikaryal regions of all three major brain amine systems, for example, contain surprisingly high concentrations of glucocorticoid receptors. Furthermore, corticosterone and dexamethasone have both been found to alter brain amine metabolism and turnover. The purpose of these studies was to evaluate the effects of corticosterone on brain amine function in the awake freely moving rat using *in vivo* microdialysis. Male Sprague Dawley rats were implanted with guide cannulae into the frontal cortex (Fcx), striatum (Str) and the nucleus accumbens (Nac). Following recovery from surgery a dialysis probe was introduced into one of the structures on the day of the experiment. After stabilization of the baseline, corticosterone was administered (5mg/kg, s.c) and the extracellular levels of the monoamine was monitored for a further 2hrs. Basal extracellular DA in the Str, Nac and Fcx were 11.6 ± 0.3 , 2.2 ± 0.2 and 1.1 ± 0.04 pg/sample (n=3-5) respectively. Following corticosterone, extracellular DA in the Fcx and the Nac decreased by 45% and 38% respectively, whilst there was no change in the Str DA. Basal extracellular 5-HT in the Fcx, Nac and Str were 6.4 ± 0.7 , 0.77 ± 0.05 and 0.5 ± 0.06 pg/sample (n=3-5) respectively. Upon administration of corticosterone, 5-HT decreased in a manner similar to DA in the Fcx with a 68% decrease relative to the baseline, whilst in the Nac and Str no effects were observed. Preliminary studies suggest that corticosterone applied focally to the ventral tegmental area produces effects on Nac DA consistent with those seen following systemic injections. Studies are underway to more clearly define the effects of corticosterone on the noradrenergic and serotonergic systems.

TYPE II GLUCOCORTICOID RECEPTOR MEDIATED REGULATION OF HYPOTHALAMIC NPY EXPRESSION. P. Ponsalle* and J.D. White. Dept. Neurobiology and Behavior, SUNY Stony Brook, Stony Brook, NY 11794

Neuropeptide Y (NPY) is the most potent orexigenic agent known and hypothalamic NPY synthesis and secretion is modulated by peripheral metabolic status. Food deprivation (FD) increases hypothalamic NPY mRNA content 2.5 fold over fed controls, and glucocorticoids are required for this response. The present studies sought to determine if the effect of glucocorticoids on hypothalamic NPY gene expression is mediated via the type I and/or type II glucocorticoid receptor. Animals underwent adrenalectomy (Adx), or not. All Adx animals received the type II agonist RU28362 (25µg/kg/d) via Alzet minipumps, implanted at the time of surgery. 24 hr later, food was removed from half of the AdxRU and Con groups; 72 hr later all animals were sacrificed. Nuclease protection analyses revealed that hypothalamic NPY mRNA content in the AdxRU-FD group was increased 3.5 fold over fed controls. Preliminary studies with aldosterone replacement suggest that type I receptor stimulation only partially restores increased hypothalamic NPY gene expression observed in intact FD animals. These findings suggest that increased hypothalamic NPY gene expression with FD occurs primarily via the type II receptor, but that there may be more than one pathway through which glucocorticoids modulate NPY expression.

489.11

CYCLIC-AMP-DEPENDENT STEROIDOGENESIS OCCURS IN RAT BRAIN VIA ACTIVATION OF THE MITOCHONDRIAL DBI RECEPTOR (MDR). M.L. Barbaccia*, G. Roscetti, M. Trabucchi, C. Ambrosio§ and M. Massotti§. Dept. of Exp. Medicine, Univ. of Roma "Tor Vergata" and § Lab. of Pharmacology, Istituto Superiore di Sanita', Roma-Italy.

In brain, glial cells are endowed with the enzymatic machinery that synthesizes steroids from cholesterol (P.N.A.S. 84,8215,1987). MDR, so-called for its ability to bind the endogenous peptide DBI together with other selective "peripheral benzodiazepine" ligands, appears to mediate the cyclic-AMP-dependent and the ACTH-induced steroidogenesis in adrenocortical and Leydig cells (J.B.C. 266(6),3682,1991). We have observed that minces (300x300 µm) prepared from adult rat brain cortex are a suitable model to study the process of brain steroidogenesis. A 30 min exposure of brain cortical minces to forskolin (6-50µM) or cyclic-AMP (0.2-1.0 mM) elicited a significant increase in pregnenolone(PRE) production (+50% and +30%, respectively). The forskolin-stimulated PRE synthesis was abolished by incubating the tissue with the isoquinoline-carboxamide Pk 11195, a selective antagonist at the MDR. Moreover in minces of intact or adrenalectomized/orchiectomized rats pretreated with the protein synthesis inhibitor cycloheximide the levels of PRE and some of its metabolites were significantly decreased. These results show that, also in brain, steroidogenesis is a protein synthesis-dependent process which can be rapidly activated, in a cyclic-AMP and MDR-dependent manner, and suggest that some PRE derivatives produced in brain may participate in the physiological modulation of fast synaptic transmission.

BEHAVIORAL CHARACTERIZATION OF A TRANSGENIC MOUSE MODEL OF IMPAIRED TYPE II GLUCOCORTICOID RECEPTOR FUNCTION. S. Beaulieu*, I. Rousse, A. Gratton, N. Barden¹ and J. Rochford. Department of Psychiatry, McGill University, Montreal, and Department of Physiology¹, Laval University, Quebec.

A transgenic mouse model of impaired type II glucocorticoid receptor function has been developed recently (Pepin et al., Nature, 355, 1992; 725-728). The locomotor activity of transgenic mice (1st generation: C57BxC3H = B6C3F1, subsequent generations: B6C3F1XB6C3F1) and control non-transgenic mice (B6C3F1) were compared. Locomotor activity was recorded in chambers equipped with photoelectric cells. The activity was recorded in both dark and light phases of the circadian cycle in different groups of transgenic and control mice. Results indicate that the transgenic animals are more active than the controls in the first 30 min of testing during the light phase. However, no difference could be observed between the groups during the dark phase of the circadian cycle. These results parallel endocrine data indicating that during the dark phase period, the corticosterone and ACTH plasma levels of control mice reach similar high values to those observed in transgenic animals. However, when injected i.p. with d-amphetamine (1 mg/kg) during the dark phase period, the transgenic animals demonstrated a greater level of locomotor activity than the controls. In parallel, the transgenic mice demonstrate a decreased immobility time in the Porsolt swim test compared to controls. These results may provide some insight into the behavioral sequelae resulting from alterations in glucocorticoid receptor function. (Supported by the FRSQ and the MRC)

GLUCOCORTICOID INHIBIT D₁ BUT NOT D₂ RECEPTOR MEDIATED ANF PRODUCTION IN HYPOTHALAMIC NEURONS. A.T. Lim, D. Lee, W. Huang, Z. Yang, D. Copolov and J. Boublik*. Cell Biology Unit, Mental Health Res. Inst., Melbourne, 3052 and *Baker Medical Res. Inst., Melbourne, 3004, AUSTRALIA.

Recent evidence suggests that dopamine (DA) modulates the function of hypothalamic atrial natriuretic factor (ANF) neurons in a bimodal manner acting directly through D₂ and D₁ receptors which have very different affinity for DA (Lee, D., et al. submitted). Employing well characterised radioimmunoassay and colorimetric Northern blot analysis with synthetic oligonucleotide probes complementary to pro-ANF mRNA (Huang W et al. 1992 *Endocrinology* 131, 1562), we have examined the effect of glucocorticoids on DA-stimulated ANF neurons in long term primary cultures of neonatal rat hypothalamic cells. Although dexamethasone (DM) alone did not affect basal secretion of immunoreactive (ir)ANF, it reduced D₁ agonist, (SKF38393)-induced irANF secretion to half (P<0.001). This effect of DM was both time-dependent and dose-related with an EC₅₀ of 0.1 nM; it was blocked by 100 nM of RU38486 (P<0.05), a glucocorticoid receptor antagonist, but not by 100nM RU28318, a mineralocorticoid receptor antagonist. In addition, the effect of DM was mimicked by corticosterone (EC₅₀ 10nM), but not by progesterone. The increased expression of pro-ANF mRNA signal induced by D₁ agonists in culture was also suppressed by DM in a similar manner. In contrast to the D₁ receptor effect, DM failed to modulate ANF production and secretion induced by D₂ agonist, quinpirole. Consistent with this finding, whereas DM abolished the D₁ receptor mediated stimulation of irANF release induced by high doses (10⁻⁶ and 10⁻⁸M) of DA, it had no detectable effect on modulating D₂ receptor mediated changes produced by low concentrations of DA (10⁻⁹ and 10⁻⁸M). We thus conclude that in monolayer cultures of rat hypothalamic neurons, glucocorticoids selectively abolish D₁ but not D₂ receptor mediated stimulation of irANF secretion and proANF mRNA expression.

PROGESTERONE RECEPTOR MEDIATED EFFECTS OF 5β-REDUCED STEROIDS. T. Trapp, R. Rupprecht, K. Damm, J.M.H.M. Reul, and F. Holsboer*. Max-Planck-Institute of Psychiatry, Clinical Institute, Department of Neuroendocrinology, Munich.

5β-metabolites of progesterone modulate neuronal excitability by modifying membrane permeability. However, genomic effects of these steroids have not yet been demonstrated. We characterized the molecular effects of 5β-pregnane-3,20-dione (5β-DHP) mediated by the chicken (cPR_β) and human (hPR_β) progesterone receptor (PR). In transient transfection studies employing the human neuroblastoma cell line SK-N-MC and the mouse mammary tumor virus promoter fused to the luciferase gene as a reporter system, 5β-DHP potently induced gene expression via both cPR_β and hPR_β. The cPR_β responded to 5β-DHP in the low nanomolar range, whereas concentrations in the upper nanomolar range were required to activate the hPR_β. As shown by gel shift analysis, DNA-binding of the cPR_β was induced by 5β-DHP in a progestin-like fashion. 5β-DHP bound to the cPR_β reconstituted in COS-1 cells with a K_d value of 1.1 nM and to the hPR_β with a K_d value of 35 nM. Thus, 5β-reduced metabolites of progesterone may modulate neuronal function via both membrane and genomic mechanisms.

ESTROGEN MODULATION OF mRNA FOR TWO FORMS OF GLUTAMIC ACID DECARBOXYLASE (GAD) IN RAT BRAIN.

M.M. McCarthy*, L.C. Kaufman, P.J. Brooks, D.W. Pfaff and S. Schwartz-Giblin. Rockefeller University, New York, NY 10021

Two genes coding for separate forms of GAD (GAD65 and GAD67) have been identified (*Neuron* 7; 1991). Numerous studies indicate that mRNA levels for GAD67 are readily modifiable whereas GAD65 mRNA levels remain stable. We investigated the hormonal modulation of the two forms of GAD. Brains were harvested from ovariectomized rats treated with estradiol benzoate (EB; 10µg/day; 2 days prior) or vehicle. Specific DNA probes for GAD65 or GAD67 were ³²P radiolabeled using amplified primer extension. Results of *in situ* hybridization were analyzed for magnocellular preoptic area (McPOA), zona incerta (ZI), dorsal medial hypothalamus (DMH), midbrain central gray (MCG) and several regions of the hippocampus. In most of these brain areas, Kolmogorov-Smirnov analysis indicated GAD65 mRNA levels were less than GAD67, regardless of endocrine condition. Levels of GAD65 were reduced by EB-treatment vs veh in granule cell layer (p<.001) and hilus (p<.01) of dentate gyrus and pyramidal cell layers of CA1 and CA2 (p<.05) in hippocampus. EB also reduced GAD65 in ZI and DMH (p<.01). An exception was McPOA where GAD65 increased and GAD67 decreased with EB-treatment. In MCG, K-S analysis showed no differences in GAD mRNA levels/cell, but the proportion of cells expressing detectable levels of GAD65 or GAD67 was greater in EB-treated rats (X²; p<.001). The DMH was notable in that GAD65 was greater than GAD67 in veh-treated rats but EB treatment decreased GAD65 while simultaneously increasing GAD67 (ANOVA). In summary, EB acts to reduce GAD67 in the forebrain but increases it in the hypothalamus and midbrain, which is consistent with previous observations of regional effects of GABA neurotransmission on EB-dependent lordosis.

A SEX DIFFERENCE IN THE EFFECT OF 5α-DIHYDROTESTOSTERONE (DHT) ON OCCUPIED ESTROGEN RECEPTOR BINDING IN SPECIFIC RAT BRAIN NUCLEI. T.J. Brown*, G. Adler, and N.J. MacLusky. Div. of Reprod. Sci., Department of OB/GYN, The Toronto Hospital, Toronto, ON, Canada

Androgens are known to oppose the actions of estrogen on a number of neuroendocrine functions in the rat. Although earlier attempts to relate these antagonistic actions of androgens with a possible down-regulation of neural estrogen receptors have been unsuccessful, we have used an *in vitro* autoradiographic assay combined with an ¹²⁵I-labeled estrogen receptor ligand to compare the effect of DHT on occupied estrogen receptor binding in the male and female rat brain. Gonadectomized/adrenalectomized rats were divided into 2 groups per sex. All animals received daily estradiol benzoate injections (EB:40 µg/kg BW) for 4 days. Animals in the treatment group received DHT (2.5 mg/250 g BW) every 12 hr for 4 days while animals in the control group received vehicle injections. Animals were killed 4 hr after the final EB/DHT injection and their brains were frozen on dry ice. Frozen sections (20 µm) from the preoptic - hypothalamic areas were incubated at 37 C for 2 hr with 2.5 nM [¹²⁵I]ME₂. Sections were washed at 4 C to remove unbound radioligand, dried, and placed against Amersham Hyperfilm for 24 hours. Resulting images were analyzed by computer-assisted densitometry. High levels of estrogen binding were observed in the periventricular and medial preoptic area (PVP and mPO), bed nucleus of the stria terminalis, arcuate nucleus, ventromedial nucleus (VMN), and cortical and medial amygdala. As previously reported, higher levels of estrogen binding were present in the PVP, mPO, and VMN of the female than of the male. In the female, DHT treatment reduced estrogen binding in the PVP and VMN by 30 and 38% respectively, whereas in the male no significant regional effects were observed. These results demonstrate that androgens can inhibit estrogen binding in regions of the female brain implicated in the control of gonadotropin secretion and sexual behavior. Supported by the MRC Canada.

ALLOPREGNANOLONE MIMICS THE ACTION OF PROGESTERONE ON GLUTAMATE DECARBOXYLASE GENE EXPRESSION IN THE HIPPOCAMPUS. N.G. Weiland*, M. Orchinik, P.J. Brooks, B.S. McEwen. Rockefeller Univ., New York, NY 10021.

Progesterone (P) inhibits the activity of glutamate decarboxylase (GAD), the rate limiting enzyme for the synthesis of GABA (Endocrinology 131:2697, 1992). P may act at the classical intracellular receptor (PR) or through one of its metabolites such as allopregnanolone (A; 3α-hydroxy-5α-pregnan-20-one) which interacts with the GABA_A receptor rather than the PR. Because many of the effects of estrogen on the hippocampus are confined to the CA1 and estrogen induces PR in this region, we hypothesized that P is acting at the PR. However, if A treatment mimics P's action, then the P-induced suppression of GAD mRNA may be indirect and mediated by a metabolite-induced activation of the GABA_A receptor. Adult female rats were ovariectomized for 1 wk, then adrenalectomized, and 2 days later injected with 3 mg/kg P, A, or oil (O) and killed 5 hr later. The brains were processed for *in situ* hybridization using specific DNA probes for GAD65 labeled with ³²P using amplified primer extension. Treatment with either progesterone or allopregnanolone decreased the levels of mRNA for GAD65 compared to vehicle-treated controls (P, 29.2 ± 1.4; A, 30.7 ± 1.3; O, 36.0 ± 2.0 specific gray levels). The steroid-induced suppression of GAD65 was limited to the CA1 region of the hippocampus. Interestingly, the action of A paralleled the action of P indicating that the actions of these steroids may not be exclusively through the PR.

EFFECTS OF ESTRADIOL (E₂) AND PROGESTERONE (P₄) ON EXPRESSION OF mRNAs ENCODING GABA_A RECEPTOR SUBUNITS. S.L. Petersen*, A. Reeves¹, M. Keller¹, E. Gardner¹, L.C. Mahan² and S. McCrone¹. Dept. of Anatomy and Neurobiology, Univ. Missouri, Columbia, MO 65212¹; Lab of Neurochemistry, NINDS, Bethesda 20892².

E₂ and P₄ alter GABA_A receptor binding in the CNS and GABA receptors play an important role in the control of sexual behavior and gonadotropin release. In the present study we examined the effect of E₂ and P₄ on levels of mRNAs encoding several GABA_A receptor subunits in regions involved in the control of these functions and in the hippocampus. We implanted 16 one-week ovariectomized (OVX) rats with E₂ or oil capsules. On Day 2, we injected 8 E₂-treated rats with P₄ and 4 h later, collected and froze their brains. We hybridized cryosections from regions containing the organum vasculosum of the lamina terminalis (OVLT) and rostral preoptic area (rPOA), hippocampus, and ventral medial nucleus (VMN) to ³⁵S-tailed 48-base oligodeoxynucleotide probes specific for β₂, β₃- or γ₂-subunit mRNAs. We found that in the region of the OVLT/rPOA neither E₂ nor P₄ altered levels of β₃-subunit and, although E₂ had no effect on levels of β₂-subunit mRNA, combined E₂ and P₄ decreased these levels. E₂ increased levels of the γ₂-subunit mRNA and P₄ reversed this effect in the OVLT/rPOA. We found no hormone-induced changes in levels of β₂-subunit mRNA in the dentate gyrus or CA1 region of the hippocampus, but in the VMN, E₂ increased these levels and P₄ had no effect. Our findings show that E₂ and P₄ have differential, neuroanatomically-specific effects on the levels of mRNAs encoding β₂, β₃- and γ₂-subunits of GABA_A receptors.

HORMONAL INFLUENCE ON THE DEVELOPMENT OF GENDER-SPECIFIC SOCIAL INTERACTION IN FEMALE RATS. B.A. Etzel* and C.K. Kellogg. Dept. of Psychology, Univ. of Rochester, Rochester, NY 14627.

Social interaction (SI) behavior is both age and gender specific. Adult male rats typically spend less time interacting with a stranger of the same sex in a neutral environment that is unfamiliar to both rats than they do in an environment that is familiar to both rats. On the other hand, adult females and prepubertal males (28 days old) make no such distinction between the two types of environment. Both pubertal males and females (35 days old), however, display environment-specific SI. We have also shown that males require testosterone (T) during puberty, but not during adulthood, for the emergence of adult-typical SI behavior.

The purpose of this study was to determine why females lose environment-related SI over adolescence. Three questions were addressed: (1) do adult females require ovarian hormones for maintenance of female-typical SI, (2) does SI in females change over adolescence due to increasing levels of ovarian hormones or because of the lack of T, and (3) will neonatal exposure to T masculinize adult female SI? Results indicate (1) ovariectomy at 60 days did not lead to environment-specific SI in females tested 4 weeks later, although it did increase SI overall, (2) exposure of intact females to testosterone propionate (TP) via implanted silastic capsules over days 28-60 also increased overall SI without inducing environment-specific SI at 60 days, and (3) neonatal exposure to TP by injection within 5 hours of birth and again 24 hours later did not alter SI in gonadally intact 60-day-old females in any way. Thus, the hormonal milieu during puberty and adulthood, but not at birth, may be critical for the emergence of gender-typical SI. Supported by grant no. DA07080.

CENTRAL PATTERN GENERATION IN *IN VITRO* BRAINSTEM-SPINAL CORD PREPARATIONS OF NEONATAL RATS. A. Tarasiuk, Z. Siddiqi and A.L. Sica. Albert Einstein Coll. Med., Long Island Jewish Med. Ctr., Departments of Medicine (Pulmonary Div.) and Pediatrics, New Hyde Park, NY 11042.

Synchronization of inspiratory (I) discharges has been attributed to modulating inputs from a central pattern generator (CPG) and is signalled by the presence of correlated frequencies in coherence spectra. Although I activities have been recorded from different motoneuron pools in *in vitro* preparations, there is no information regarding the presence of CPG modulation. Thus, in 0-3 d old pups (n=14), extracellular recordings (bandpass 1 Hz to 10 kHz) of spontaneous I activity were obtained from different pairs of nerve roots in normal Ringer's solution (27°C) and in an acidified (pH 6.8-7.0) solution which is known to augment respiratory activity. Power spectral analyses were carried out on low pass filtered (400 Hz) signals sampled at 1024 Hz; auto-power spectra (APS) were constructed from I and from expiratory (E) activities. I-triggered APS of cranial nerve roots (n11, n12) and spinal ventral roots (C1, C4, C5, T2) had prominent peaks in a low frequency band (2-6 Hz) during control conditions; such peaks were not found in E-triggered APS. The 2-6 Hz peaks were highly correlated as indicated by values of magnitude ranging from 0.28-0.98 in coherence spectra. Acidic stimulation produced increases in peak amplitudes, but no increases of coherence or shifts beyond the 2-6 Hz band. In summary, we have found evidence of CPG modulation originating in the brain stem and distributed to a number of I motoneuron pools. Furthermore, the finding of correlated frequencies in a relatively low frequency band may be important for identifying neurons involved in the generation of central I activity.

INCREASED AUGMENTING AND LATE INSPIRATORY MEDULLARY NEURONAL ACTIVITY DURING REM SLEEP IN THE ADULT CAT. J. Orem* and R.H. Trotter. Physiology Department, Texas Tech Univ. Hlth. Sci. Cntr. Sch. of Med., Lubbock, TX 79430.

Breathing is variable; obstructive apneas may be prolonged; and central apneas can occur in REM sleep. The cause of these respiratory effects, whether due to changes in respiratory drive or nonrespiratory mechanisms, is unknown. One study suggests that central respiratory drive might be decreased in REM sleep (Kubin et al., *Brain Res.*, 592:91, 1992), but another study gives mixed results (*J. Appl. Physiol.* 48:54, 1980). Augmenting inspiratory (I-aug), and possibly late inspiratory (I-late) medullary cells are predominantly premotor cells whose activities may be representative of central respiratory drive. We studied 15 I-aug and 12 I-late neurons during normal wakefulness (W), NREM and REM sleep in adult cats. All I-aug cells had high η^2 -valued activity (>0.8) (*J. Neurophysiol.* 50:1098, 1983) and were more active in REM sleep than in W and, with one exception, than in NREM sleep. REM rates averaged 174% of W rates and 165% of NREM rates. For I-late cells ($\eta^2 = 0.6-0.9$), REM rates averaged 216% of W rates and 423% of NREM rates, confirming an earlier study (*Brain Res.* 458:224., 1988). These results suggest that central respiratory drive increases in REM sleep. Supported by grant Hb21257.

INSPIRATORY SHORTENING ELICITED BY ARACHIDONIC ACID REQUIRES GABA_A-MEDIATED NEUROTRANSMISSION IN CATS. D.R. Karius*, K.M. Krause and W.R. Revelette. Dept. of Physiology, Univ. of Kentucky, Lexington KY 40536

Delivery of arachidonic acid (AA) into the arterial circulation (in close proximity to the phrenic artery) elicits a shortening of inspiratory duration (T_I) in the cat. While it is believed that diaphragmatic afferents are responsible for this response, the neural pathways are unknown. This study tested the hypothesis that GABA_A-receptor mediated neurotransmission is required in the production of this response. Adult cats were anesthetized with pentothal (50 mg/kg, i.p. initially, supplemented i.v. as required). Inspiratory activities of the costal and crural diaphragm were recorded with EMG electrodes. In order to limit input from afferent fibers not arising from the diaphragm, the vagus nerves and brachial plexi were cut. The spinal cord was transected at C₇ and caudal segments destroyed. Arachidonic acid (6 - 10 mg in 100 mM NaHCO₃, total volume: 1 ml; n = 6) injected through a catheter positioned in the thoracic aorta shortened T_I by 21 ± 8.0% (mean ± S.D.). The GABA_A-receptor antagonist bicuculline (0.1 mg/kg) was given intravenously at least 25 minutes after the injection. Five minutes after bicuculline delivery, AA injected into the artery did not elicit a shortening of T_I in any animal ($\Delta T_I = +21 \pm 21\%$). In most cases (4 of 6 experiments), the inspiratory duration was prolonged by stimulation with AA. Arachidonic acid injections were repeated at 30 - 40 minutes intervals thereafter. One to two hours after bicuculline delivery, AA injected into the artery again elicited some degree of inspiratory shortening in all animals tested (average $\Delta T_I = -13 \pm 3.3\%$; n = 5). These results indicate that the inspiratory shortening elicited by AA injected into the arterial circulation requires GABA_A-receptor mediated neurotransmission. (Supported by NIH PO1 40369)

EFFECTS ON BREATHING OF EXCITATORY AMINO ACID (EAA) ANTAGONISTS IN DEVELOPING OPOSSUMS. J.P. Farber* and A.M. Hutson. Dept. of Physiol., Univ. Okla. HSC, Okla. City, OK, USA.

Medullary respiratory neurons in spontaneously breathing thiobarbiturate-anesthetized immature opossums (*Didelphis virginiana*) can be excited by kainic acid (KA) or n-methyl-D-aspartate (NMDA), but do EAAs play a role in setting breathing pattern during early development? To test this possibility, the above preparation was studied from 3-14 postnatal weeks of age. The ventral medulla was exposed from just ahead of C1 to the trapezoid body. Dura was removed typically from midline to 2/3 the distance to the left lateral margin of the medulla. Drugs were administered by droplet on the ventral surface of the medulla because of close proximity to regions presumably affecting cardiopulmonary functions. Raw diaphragm EMG and the moving average of the EMG (IEMG) were recorded; these values were used to obtain peak IEMG, T_I , and T_{tot} . Effects developed over 5-7 min. Except for the oldest animals, the NMDA antagonist, MK801 (1 or 5 mg/ml) significantly reduced respiratory output (peak IEMG/ T_{tot}), most typically with an increase in T_{tot} . T_I was not consistently affected. The oldest animals showed a fall in peak IEMG, typically coupled to decreased T_{tot} . Responses to the KA antagonist, CNQX (0.1 or 0.5 mg/ml), were less consistent, although peak IEMG/ T_{tot} was significantly reduced on average. Apnea rarely occurred with either drug. Since the opossum requires about 8-9 weeks to achieve the gross maturation of a newborn cat or rabbit, it appears that endogenous excitatory amino acid systems, accessible from the ventral medullary surface, participate in the expression of breathing pattern at relatively early stages of development. (Supported by HL37318 from NIH).

SUPERIOR LARYNGEAL NERVE AFFERENT INPUTS TO THE DORSAL RESPIRATORY GROUP INVOLVE NON-NMDA RECEPTORS. D.F. Speck* and D.R. Karius. Dept. of Physiology, Univ. of KY, Lexington KY 40536

Single shock stimulation of the superior laryngeal nerve (SLN) in cats elicits a transient excitation of the contralateral phrenic nerve activity which does not alter inspiratory timing. This excitation is believed to be the result of a monosynaptic activation of dorsal respiratory group (DRG) neurons (*Brain Res.* 135:231-254, 1977). In a previous study, it was noted that injection of excitatory amino acid (EAA) antagonists near the DRG consistently led to a slow decrease in the amplitude of the short-latency excitation (*J.A.P.* 1993. *In Press*). This study tested the hypothesis that the short-latency excitation produced by SLN stimulation in the cat is mediated by neurotransmission at non-NMDA EAA receptors within the DRG. Adult cats were anesthetized (sodium thiopental, 50 mg/kg i.p.), decerebrated, paralyzed, artificially ventilated and vagotomized. Inspiratory motor output was recorded from the phrenic nerve and one or both SLN were cut and placed on bipolar stimulating electrodes. After recording the control responses to SLN stimulation, injection of the non-NMDA antagonist NBQX (the kind gift of Novo-Nordisk; 1 mM; 100 - 460 nl) into the ipsilateral DRG led to a significant (F(2,8) = 98.5) decrease in the amplitude (measured from peri-stimulus-triggered histograms, 40 - 50 cycles) of the short-latency excitation of the phrenic nerve discharge 10 and 30 minutes after antagonism. Injection of the NMDA receptor antagonist AP5 into the DRG (n = 1) or injection of NBQX outside the DRG (n = 1) had no effect on the amplitude of the excitation. We conclude that non-NMDA receptors within the DRG are involved in the production of the short-latency excitation elicited by SLN stimulation in cats. (Supported by NIH PO1 40369)

RESPIRATORY NEURONS IN VENTROLATERAL MEDULLA OF NEONATAL RATS HAVE PACEMAKER-LIKE PROPERTIES IN LOW Ca⁺⁺ SOLUTION *IN VITRO*. S.M. Johnson*, J.C. Smith, & J.L. Feldman. Systems Neurobiology Laboratory, Dept. of Physiological Science, UCLA, Los Angeles, CA, 90024-1527

Respiratory neurons with voltage-dependent pacemaker-like properties are located in the pre-Bötzinger Complex (preBötC) of ventrolateral medulla (Smith et al., *Science* 254:726, '91). We tested whether preBötC neurons still exhibit oscillatory bursting following synaptic blockade in low Ca⁺⁺ solution. Medullary slices (650 μ m thick) from neonatal rats (0-4 days old) were prepared (*ibid.*). Control solution was (mM): 128 NaCl, 9-11 KCl, 1.5 CaCl₂, 1.0 MgSO₄, 21 NaHCO₃, 0.5 NaH₂PO₄, and 30 glucose (gassed with 95% O₂-5% CO₂ at 27°C). Low Ca⁺⁺ solution was identical except for: 120 NaCl, 0.2 CaCl₂, 4.0 MgCl₂. Inspiratory rhythm was recorded with suction electrodes on the hypoglossal (nerve XII) roots.

In low Ca⁺⁺ solution, we recorded extracellularly from 38 bursting cells [burst duration/frequency = 0.80±1.0 s / 0.38±0.27 Hz (mean ± SD)]. After switching to control solution, the respiratory rhythm was activated and these cells were identified as: I-cells (n=27, discharge coincident with nerve XII output), E-cells (2, discharge tonic except during nerve XII output), or tonic cells (9, discharge tonic). From a separate group of 11 I-cells, 7 E-cells, and 2 tonic cells that were initially identified in control solution, only 3 I-cells exhibited bursting in low Ca⁺⁺ solution. We conclude that there are subpopulations of I-, E- and tonic cells that have intrinsic bursting properties under conditions of synaptic blockade. The relatively large fraction of I-cells with these properties supports the hypothesis that pacemaker properties may play a key role in respiratory rhythmogenesis. Supported by NIH Grants HL02204, HL40959 and HL08524.

490.7

ROLE OF EXCITATORY AMINO ACID (EAA) RECEPTORS IN RESPIRATORY RHYTHM GENERATION AND DRIVE TRANSMISSION *IN VITRO*. G.D. Funk*, J.C. Smith, & J.L. Feldman. Systems Neurobiology Laboratory, Department of Physiological Science, UCLA, Los Angeles, CA, 90024-1527.

Medullary slices from neonatal rat containing the pre-Bötzing Complex (pre-BötC) generate inspiratory (I) oscillations in cranial nerves IX and XII (Smith *et al.*, *Science*, 254:726, '91). To determine the role of EAAs in rhythmogenesis and drive transmission, antagonists of NMDA (MK-801, 100 μ M) and non-NMDA receptors (CNQX, 20 μ M) were injected into the pre-BötC and rostral ventral respiratory group (rVRG). MK-801 had no effect. Injections of CNQX produced dose-dependent decreases in: i) I amplitude and frequency (f). Amplitude reductions were produced following injections in rVRG and pre-BötC. Perturbations in f only occurred following injections into a limited region of pre-BötC. We tested the effects of local application of CNQX, MK-801 and AP-4 on I-modulated synaptic inputs to XII motoneurons (XII MNs). CNQX (50 μ M) reduced synaptic currents by >95%, MK-801 (1.0 mM) had little effect, and AP-4 (1.0 mM) produced a 25% reduction. Local application of NMDA and non-NMDA (Quis, AMPA, Kain) agonists to synaptically isolated XII MNs (1.0 μ M TTX) induced large inward currents. We also examined the role EAA receptor desensitization in I drive transmission to XII MNs by blocking desensitization with locally applied cyclothiazide (50-250 μ M). I currents increased 10-15%. Results indicate that: i) rhythm generation in the *in vitro* neonatal rat medullary slice is dependent on endogenously released EAAs acting at non-NMDA receptors within a specific region of the pre-BötC; ii) EAA transmission within rVRG is involved in transmission of I drive to motor or premotoneurons; iii) XII MNs possess NMDA and non-NMDA (AMPA and Kain) receptors, but an EAA-like substance acting primarily at non-NMDA receptors mediates transmission of I drive to XII MNs; iv) minimal desensitization of glutamate receptors occurs during I-mediated glutamate release at the XII MN. Supported by NIH Grants HL40959 & HL02204 and Parker B. Francis Foundation.

EFFECT OF ACETAZOLAMIDE ON CO₂ CHEMOSENSITIVITY OF CULTURED MEDULLARY NEURONS. A.A. Martin and J.A. Neubauer*. Department of Medicine, UMDNJ-Robert Wood Johnson Medical School, New Brunswick, NJ.

To determine whether inhibition of carbonic anhydrase alters the CO₂ chemosensitivity of dissociated medullary neurons, CO₂ sensitivity was characterized in neurons (4-6 days *in vitro*) before and during exposure to 10⁻⁶ M acetazolamide. Dissociated cell cultures were prepared from ventral medulla of neonatal rats (0-1 day old) and grown in defined medium. Membrane potential was monitored in spontaneously active cells using the nystatin perforated patch technique. pH was transiently decreased from 7.4 to 7.1 (τ on = 20 sec; τ off = 30 sec) by varying the PCO₂ of bicarbonate buffer solutions. In 12 cells mean membrane potential was -53.4 mV (SE 1.3) and mean firing frequency was 3.09 Hz (SE 0.38). Five cells decreased firing frequency and 5 did not change when exposed to high PCO₂. In 2 of 12 cells, acidosis produced a transient large depolarization, a partial repolarization and a smaller secondary depolarization and increase in firing frequency (+3.5 Hz) which decayed more slowly (τ = 70 s) than the initial transient. In the depressed cells acetazolamide delayed recovery of firing rate after acidosis. However, in the excited cells, acetazolamide was associated with a faster decay of the small sustained depolarization while the initial large transient was unaffected. We conclude that acetazolamide affects the CO₂ sensitivity of cells which respond to CO₂ and that in cells that are excited, carbonic anhydrase is important for a sustained membrane response to CO₂-induced acidosis. Support: HL07467, HL16022 and AHA-NJ.

490.11

MEDULLARY RESPIRATORY NEURONS RESPONSE TO CEREBELLAR STIMULATION. Fadi Xu and Donald T. Frazier*. Dept. Physiology, University of Kentucky, Lexington, Ky. 40536.

Our previous reports suggest that the cerebellum modulates the ventilatory response to mechanical and chemical loading. Our hypothesis is that activation of cerebellar pathways can modulate both the pattern and timing of brainstem pre-motor inspiratory and expiratory neurons. Adult cats were anesthetized with pentothal, paralyzed and ventilated. Stereotaxic coordinates were used to position a bipolar stimulating electrode into the rostral fastigial nucleus (rFN) and recording tungsten micro-electrodes within the medullary respiratory groups (DRG, VRG, NA, NRA). Stimuli (150 μ A) were applied between 5 and 200 Hz at different phases in the cycle. The results show that 1) <10Hz delivered during expiration did not alter expiratory neuronal activity, however, >20Hz led to termination of the expiratory burst and an earlier onset of the next inspiration (phrenic neurogram) which was enhanced in both duration and amplitude; 2) <10 Hz delivered at beginning of inspiration did not affect inspiratory neuronal behavior, but 20-100 Hz produced prolongation of inspiratory duration and enhancement of peak JPN; 3) reversing the function of stimulating and recording electrodes failed to demonstrate antidromic activation in the rFN. We conclude that the cerebellum is capable of modifying both the pattern and timing of the respiratory output at the brainstem level utilizing polysynaptic pathways. (NIH P01 40369).

490.8

RETROTRAPEZOID NUCLEUS (RTN) GLUTAMATE INJECTIONS: LONG-TERM STIMULATION OF PHRENIC ACTIVITY. Eugene E. Nattie* and Aihua Li. Department of Physiology, Dartmouth Medical School, Lebanon, N.H., 03756-0001

In chloralose-urethane anesthetized, paralyzed, vagotomized, glomectomized, and servo-ventilated cats, we injected glutamate (10 nM; 10 mM, 100 mM, and 1M) unilaterally over 60 sec into the RTN. Seven 10 mM injections had no consistent effects. Ten 100 mM injections increased the integrated phrenic amplitude from a baseline average of 31 +/- 2 (SEM) % of maximum to a peak response of 50 +/- 3 % of maximum over a time period of 45.6 +/- 8.6 min. This response was significantly attenuated by prior injection of kynurenic acid. Seven 1 M injections decreased phrenic amplitude from 29 +/- 3 % to 20 +/- 5 % of maximum. Comparison of glutamate (10 nM; 100 mM) injected over 60 sec vs 30 msec showed that the prolonged increase in the integrated phrenic amplitude was present only with the more prolonged injection. On average the mean firing rate of 5 RTN single units increased significantly at 5 min following the 60 sec injection. One of these units had a prolonged increase in firing rate over 40 min and two others were increased for 10 and 15 min. Following the 30 msec injection, integrated phrenic amplitude and RTN single unit firing rate were increased for the first two breaths and at 5 min (less than after the more prolonged injection). With three 1 M injections the RTN unit activity was silenced. We conclude that glutamate injected into the RTN at a dose which avoids depolarisation block can produce a prolonged stimulation of phrenic activity associated with an increase in RTN single unit firing rate which is also prolonged in some cases. (Supported by HL 28066).

EFFECTS OF ETHANOL ON HYPOGLOSSAL DISCHARGE IN THE NEONATAL RAT BRAINSTEM-SPINAL CORD PREPARATION. S. Iscoe*, E. DiPasquale, G. Hilaire, and R. Monteau. Biologie des Rythmes et du Développement, URA CNRS 0205, Faculté des Sciences et Techniques St.-Jérôme, BP 332, 13397 Marseille cedex 13, France.

Hypoglossal and other cranial motoneurons are more susceptible than phrenic motoneurons to certain agents. We hypothesized that alcohol, previously shown to depress hypoglossal, but not phrenic, activity in adult anesthetized cats, would exert the same effect in the neonatal rat brainstem-spinal cord preparation. We added ethanol in concentrations between 1 and 12 mM (approximately 0.005 to 0.06 vol%) to the superfusate of these preparations from 1 to 3 day old rat pups. After 5 and 10 min, ethanol at all concentrations did not affect burst frequency or amplitude of cervical (phrenic) activity. In contrast, after 5 min, ethanol (6 mM, n=6; and 12 mM, n=4) significantly (P < 0.05) reduced peak integrated hypoglossal activity by 50 and 38%, respectively. After 10 min, all concentrations of ethanol reduced hypoglossal activity (-71% at 12 mM). Ethanol (6 and 12 mM) eventually abolished hypo-glossal activity which did not recover 30 min after removal of ethanol from the superfusate. If the ethanol-induced depression of hypoglossal motoneuron activity is characteristic of that of other cranial motoneurons, and higher structures, this preparation may be a useful model of Fetal Alcohol Syndrome. (Supported by CNRS and the Medical Research Council of Canada)

REGULATION OF NEUROTRANSMITTER RELEASE BY GABA AND TRH WITHIN THE PHRENIC MOTOR NUCLEUS OF NEONATAL RATS. Y. Sun*, P.G. Wagner, and M.S. Dekin. Pulmonary Div., Dept. of Medicine, UMDNJ-Robert Wood Johnson Sch. of Medicine, New Brunswick, NJ 08903.

Presynaptic inhibition mediated by GABA_A receptors is insensitive to blockade by Ba⁺⁺ ions (Lambert *et al.*, 1991). We have described a Ba⁺⁺ insensitive outward rectifying K⁺ conductance (g_{Ba}) in bulbospinal respiratory neurons which is activated via GABA_A receptors and inhibited by thyrotropin-releasing hormone (TRH; see Dekin *et al.*, this volume). The Ba⁺⁺-insensitivity and outward rectifying properties of g_{Ba} are consistent with a role in presynaptic inhibition. Because of this, we tested the hypothesis that GABA and TRH act in a reciprocal manner to regulate neurotransmitter release. All experiments employed spinal cord slices from neonatal rats and whole cell recordings from phrenic motoneurons. The Ringer solution contained 500 μ M BaCl₂ to suppress Ba⁺⁺-sensitive conductances coupled to GABA_A and TRH, high Ca⁺⁺-Mg⁺⁺ to block polysynaptic pathways, and 10 μ M bicuculline to inhibit Cl⁻ mediated IPSP's. Monosynaptic EPSP's were elicited by stimulation of bulbospinal axons in either the lateral or ventral funiculus and could be blocked by the excitatory amino acid antagonist CNQX (HBC complex; 200 μ M). Bath application of the GABA_A agonist, (+)baclofen (100 μ M), caused a significant depression of the EPSP amplitude measured at -80 mV (p < 0.01). Similar application of TRH (1 μ M) resulted in a significant enhancement of the EPSP amplitude (p < 0.01). Measurement of the V-I relationship using small current injections into the postsynaptic cell showed that neither drug treatment affected input resistance. We also observed that (+)baclofen and TRH could each antagonize the others action on EPSP amplitude in a reversible manner. These data provide direct evidence that GABA and TRH act antagonistically on a common presynaptic conductance(s) to regulate transmitter release from respiratory bulbospinal neurons. (Supported by NIH Grants HL40369 and HL02314)

THYROTROPIN-RELEASING HORMONE (TRH) INHIBITS OUTWARD RECTIFYING GABA_A ACTIVATED K⁺ CHANNELS VIA A PROTEIN KINASE C DEPENDENT PATHWAY. *M.S. Dekin*, Y. Sun, and P.G. Wagner*, Pulmonary Div., Dept. of Medicine, UMDNJ-Robert Wood Johnson School of Medicine, New Brunswick, New Jersey, 08903.

The GABA_A receptor agonist, (±)baclofen, activates a Ba⁺⁺-insensitive outward rectifying K⁺ conductance (g_B) in labeled respiratory bulbospinal neurons cultured from neonatal rats (Wagner and Dekin, *J. Neurophysiol.*, 69:286, 1993). It has also been demonstrated that g_B is inhibited by TRH (Dekin and Wagner, *Neurosci. Abstr.*, 18:488, 1992). In this study we examined the mechanism(s) by which TRH acted on g_B. All recordings employed the patch clamp technique in the cell-attached configuration. During bath application of 100 μM (±)baclofen alone, g_B exhibited bursts of repeated channel openings separated by short quiescent periods. Mean channel open time (τ_o) was described by a single time constant. Closed times for g_B exhibited two time constants; a fast component (τ_{CF}) for channel closings within a burst of activity and a slow component (τ_{CS}) which reflected the interburst interval. In the presence of TRH, the open time probability for g_B was decreased (>30% in control vs. <10% in TRH) and τ_{CS} was lengthened. τ_o and τ_{CF} were not altered. These effects of TRH on g_B were identical to those produced by 8-bromo-cAMP (see Wagner *et al.*, accompanying abstract). To determine if TRH increased cAMP levels we applied Rp-cAMP, a competitive inhibitor of cAMP-dependent protein kinases. In the presence of Rp-cAMP (1 μM in the pipette), inhibition of g_B by TRH was prevented. Exposure to the protein kinase C (PKC) inhibitor, H-7 (100 μM in the bath), had a similar protective effect. These data suggest that TRH stimulated PKC to increase cAMP levels which then caused phosphorylation of g_B channels via a cAMP-dependent protein kinase. (Supported by NIH Grants HL40369 and HL02314)

INTERSPECIES AND AGE-RELATED MORPHOLOGIC DIFFERENCES OF VENTRAL MEDULLARY STRUCTURES INVOLVED IN CHEMOSENSITIVE CARDIORESPIRATORY CONTROL. *C. Ovid Trough*, Y. Pan, R. Douglas, L.M. Sexcius, R.M. Millis*. Department of Physiology & Biophysics, Howard University, College of Medicine, Washington, D.C. 20059

Microscopic examination of the cat and rat caudal ventral medullary surface revealed age-related and interspecies differences. (1) *Age-related differences*: In both cats and rats, the marginal glia of newborns was smoother and synaptic vesicles more numerous at the ventral surface than in adults. (2) *Interspecies similarities*: Chemosensitive neurons were found to lie lateral to the medullary pyramids and ventral to the inferior olives in both adult rats and cats. Three types of chemosensitive neurons were identified. Type I in the marginal glia; Type II within the neuropil below the marginal glia; and Type III at the walls of blood vessels (neurovascular elements) traversing the chemosensitive zones from pia mater. The marginal glia was found to be thicker and a greater number of synapses were identified in the chemosensitive area than in other areas of the ventral medulla. (3) *Interspecies Differences*: Differences between adult cat and rat structures were found in localization of chemosensitive neurons relative to the hypoglossal nerve rootlets. The chemosensitive neurons in the rat were located lateral and in the cat medial to the exit of the hypoglossal rootlets from the brainstem. Three distinct zones having chemosensitive neurons were demarcated in the cat, while in the rat the chemosensitive neurons were found to lie in two areas. It is concluded that age-related interspecies and morphologic differences might be indicative of physiologic variations in cardiorespiratory control at the ventral medullary surface. DORSOLATERAL PONS MODULATES RESPIRATORY RESPONSE TO UPPER AIRWAY STIMULATION. *T.E. Dick* and J.S. Jodkowski*. Dept. of Med., Case Western Reserve Univ., Cleveland, OH 44106.

We hypothesized that parabrachial nuclei modulate the reflex motor response to upper airway stimulation. In barbiturate anesthetized rats, electrical stimulation (2-1 mA, 1ms, 1 pulse/ breath) of the nasal mucosa induced a short-latency (7-8 ms) and transient (4-33 ms) inhibition in diaphragmatic EMG in spontaneously breathing rats (n=6) or in phrenic ENG in paralyzed, vagotomized, ventilated rats (n=6). Conditioning electrical stimuli (Pulse: 1ms, 2-100μA, 100Hz, train duration: 50 ms) were delivered to the parabrachial area with a tungsten unipolar electrode positioned stereotaxically. The averaged (n=50) motor responses to nasal stimulation alone were compared to those that were preceded (5-200ms) by conditioning stimuli to the pons. Stimuli were delivered in the same phase of inspiration. In all experiments, the evoked inhibition of motor activity diminished after conditioning stimuli. This decrease in the evoked response was time dependent but lasted 100 ms. Conditioning did not occur after lesioning the site. In three rats, the electrode was replaced with a glass micropipette and L-glutamate (70-200 nl, 10 mM) was injected in the same area. The nasal-evoked inhibition in phrenic ENG was diminished after these injections for a period up to 20 min. D-glutamate (200 nl, 10 mM) injections were ineffective (n=2). Analogous experiments with electrical stimulation in decerebrate cats (n=3) produced similar results. We interpret these data to indicate that neurons in the dorsolateral pons modulate the response of respiratory muscles to upper airway stimuli. (Supported by HL-42400.)

CYCLIC ADENOSINE MONOPHOSPHATE (cAMP) INHIBITS GABA_A ACTIVATED OUTWARD RECTIFYING K⁺ CHANNELS IN CULTURED BULBOSPINAL NEURONS OF THE NEONATAL RAT. *P.G. Wagner*, Y. Sun, and M.S. Dekin*, Pulmonary Div., Dept. of Medicine, UMDNJ-Robert Wood Johnson School of Medicine, New Brunswick, NJ 08903.

The GABA_A receptor agonist (±)baclofen activates a Ba⁺⁺-insensitive outward rectifying K⁺ conductance (g_B) in labeled bulbospinal respiratory neurons of neonatal rats (Wagner and Dekin, *J. Neurophysiol.*, 69:286, 1993). The biophysical properties of g_B are similar to those of the S-type K⁺ conductance (g_S) found in invertebrates. In this report, we further characterized g_B by studying the effects of second messengers known to control g_S. Specifically, we tested the hypothesis that phosphorylation of g_B via a cAMP dependent protein kinase inhibits channel activity. All recordings were made using the patch clamp technique in the cell-attached configuration. (±)Baclofen (100 μM) and 8-Bromo-cAMP (1-5 mM) were applied via the bath. During exposure to (±)baclofen alone, g_B channels displayed bursts of activity with a high open time probability (>30%). Within a burst, the mean channel lifetime (τ_o) was described by a single time constant. Closed times for g_B were fit with both fast (τ_{CF}) and slow (τ_{CS}) time constants; τ_{CF} corresponded to rapid closings within a burst while τ_{CS} corresponded to silent periods between bursts of channel activity. During exposure to 8-bromo-cAMP the open time probability decreased (<10%) and τ_{CS} was lengthened. Neither τ_o nor τ_{CF} were affected. 1 μM Rp-cAMP, a competitive inhibitor of cAMP-dependent protein kinases, prevented inhibition of g_B. These data establish cAMP mediated phosphorylation of g_B (or an associated protein) as a regulator of this channel in vertebrates and indicates that such phosphorylation inhibits bursts of channel openings without altering the kinetics of channel activity within a burst. (Supported by NIH Grants HL40369 and HL02314)

CONCURRENT CHANGES IN VENTRAL RESPIRATORY GROUP (VRG) NEURON DISCHARGE PATTERNS DURING FICTIVE COUGH. *R. Shannon*, K.F. Morris and B.G. Lindsey*. Physiol. & Biophys., Col. Med., Univ. South Fla., Tampa, FL 33612

VRG premotor inspiratory and expiratory neurons that provide descending drive during eupnea are also active during cough (Soc. Neurosci. Abst. 18:124, 1992). Experiments were conducted to test the hypothesis that medullary neurons implicated in generating and shaping the eupneic pattern of breathing also produce the cough motor pattern. Decerebrate, thoracotomized, paralyzed, phrenic-triggered ventilated cats (n=6) were used. Up to 15 neurons were recorded simultaneously in the rostral and caudal VRG with arrays of microelectrodes. Caudal VRG bulbospinal neurons were identified by antidromic stimulation. Single neuron activity and phrenic and lumbar efferent neurograms were monitored during fictive cough produced by mechanical stimulation of the intra-tracheobronchial tree. Virtually all "types" of previously identified respiratory-related discharge patterns were observed. Comparison of neurons with firing rate changes during eupnea and cough showed that: 1) there were concurrent alterations in patterns in both the rostral and caudal VRG, 2) some neurons with similar discharge patterns during eupnea, responded differently during cough, 3) most neuronal types responded as predicted by cough model network simulations. The results support the aforementioned hypothesis. (Supported by USF Research and Creative Scholarship Grant)

THE CHARACTERISTICS OF NEURONAL ACTIVITY THAT MEDIATED THE PONTILE OFF-SWITCHING MECHANISM. *M.-L. Fung* and W.M. St. John*. Department of Physiology, Dartmouth Medical School, Lebanon, NH 03756.

Pontile off-switching is an essential component of the neurogenesis of eupnea. We studied the topographical organization of the rostral pons and found that neural inspiratory duration increases dramatically after small chemical lesions were placed in an extreme rostralateral region. We believed that neuronal activities in the region are involved in off-switching of ventilatory activity. The purpose of this study was to characterize these neuronal activities. We recorded the unit activity extracellularly in decerebrate, cerebellectomized, paralyzed and vagotomized cats. Phrenic nerve activity was taken as the index for defining the respiratory cycle. The activities of thirty-three neurons were characterized during hyperoxic normocapnia. All had activities spanning through the respiratory cycle. The level of respiratory modulation was quantified by the h² value (Orem and Dick, 1983). Units had h² values ranging from 0.67 to 0.02, and about one third (12/33) had h² values above 0.2. Most units had peak activities either during late inspiration (I) or early expiration (E). Progressive hypoxic was induced by inhalation of carbon monoxide (1%) during the recording of 15 neuronal activities, and the activities of all declined and ceased during hypoxia. Units with low h² value had peak activities temporally related to the I-E transition when the unit resumed activity during the recovery from hypoxia. The hypercapnic responses of eight units were evaluated by step increases of the inhaled carbon dioxide level. The h² values of all of the units increased and some of the units increased the discharge rate during hypercapnia. Injections of high magnesium solution (6.3 mM, 10 nl) decreased the unit activities. In contrast, glutamate (5 mM) increased the unit activities. We concluded that (1) the late I and post I activities in the rostralateral region are involved in the pontile off-switching mechanism; (2) the neuronal activities in the rostral pons that are required for the termination of inspiration are depressed during hypoxia; (3) chemical transmission is important for the functional properties of the rostral pons. ALZ-50 IMMUNOSTAINS MAINLY PRIMARY SENSORY FIBERS IN THE RAT SPINAL CORD. P. Liberini*, P. Piccardo, W. Ma, A.C. Cuello and A. Ribeiro-da-Silva. Dept. of Pharmacology & Therapeutics, McGill University, Montréal, Québec, Canada H3G 1Y6.

The monoclonal antibody (mAb) Alz-50 has been proposed as a marker for cellular pathological changes in Alzheimer's disease. However, it has been reported that this mAb also reacts with specific epitopes located in discrete hypothalamic regions in normal individuals. Furthermore, intense Alz-50 immunoreactivity (IR) has been recently described in the hypothalamus and spinal cord of rat and monkey. In the present study, we analyzed the distribution pattern of Alz-50-IR in the rat spinal cord. Male Wistar rats, 300-350 g in weight, were anesthetized with Equithesin and perfused through the ascending aorta with an aldehyde mixture. Cross-sections for all levels of the spinal cord were processed for light microscopic immunocytochemistry. The ultrastructural study was carried out at cervical levels only. Using light microscopy, immunostained fibers and varicosities were detected mainly in laminae I-II, although some immunostaining could be detected in deeper laminae. At the ultrastructural level, immunostained axonal varicosities could be detected in lamina I and outer 2/3 of lamina II. The varicosities appeared either scalloped or dome-shaped and contained numerous agranular synaptic vesicles and a few dense-core vesicles. Most varicosities were presynaptic to dendrites. A few immunostained dendrites were also observed, but glial cells were never immunostained. Some ultrathin sections were processed for postembedding immunogold detection of CGRP-IR and GABA-IR. Most of the varicosities which were immunoreactive for Alz-50 co-localized CGRP-IR. In contrast, GABA-IR was never co-localized with Alz-50-IR. These results indicate that, in the superficial dorsal horn, the epitope recognized by the Alz-50 antibody is located mainly, but not exclusively, in primary sensory fibers. A COMPARISON OF CELL TYPES IN FETAL AND POSTNATAL SPINAL CORD PRIMARY CULTURES. L. Kehl*, G. Poliac and G. Wilcox. Program in Neuroscience and Dept. of Pharmacology, University of Minnesota, Minneapolis, Minnesota, U.S.A.

Studies underway in this laboratory have focused on the electrophysiological examination of a subset of postnatal spinal cord neurons. However, neurons in these cultures are not easily distinguishable on the basis of morphology or electrophysiology. Indeed, electrophysiological studies in other laboratories have attested to the "neuronal-like" excitability of certain glial cell subtypes in rat spinal cord. Therefore, the purpose of these studies was to characterize a cross-section of fetal and postnatal spinal cord cell types maintained in primary culture using electrophysiological, pharmacological and immunohistochemical techniques.

Primary cultures of spinal cord tissue were obtained from fetal or 14-15 day old Sprague Dawley rats in the following manner. Spinal cords were removed, treated with enzymes, mechanically dissociated, plated onto laminin-coated coverslips and co-cultured with cortical glial monolayers. These were incubated at 37°C (10% CO₂) in MEM with 10% fetal bovine serum. Patch clamp studies using the amphotericin B perforated patch technique were performed between 1 and 30 days after plating. Drugs were administered in close proximity to the cell being studied (100-150 µm) using a U-tube. Immunostaining was performed using antibodies to neuronal proteins (neuron-specific beta tubulin and MAP2) and glial proteins (GFAP and OX-1).

In the postnatal cultures, immunostaining with neuronal markers labeled predominantly bipolar cells. However, postnatal cells with varying morphologies demonstrated action potential-like responses when depolarized from rest (-48mV to -83mV). PERIODIC AND APERIODIC ACTIVITY IN ISOLATED MAMMALIAN SPINAL CORD: POINCARÉ MAPS.

A.J. Dekhuijzen* and J. Bagust. Dept. Physiology and Pharmacology, University of Southampton, Southampton SO9 3TU, England, U.K.

The description of neural activity by traces from the oscilloscope does not necessarily represent the long term behavior of the neurons. Methods using interspike interval (ISI) histograms were compared to an analysis with Poincaré maps. The Poincaré maps showed the time preceding a spike against the time following the spike. Controls and several experimental interventions, 4-aminopyridine (2 µM) and modulation of temperature were applied to study the neural output of dorsal roots in the isolated spinal cord of the rat and hamster. ISI histograms showed unimodal, bimodal and trimodal distributions, depending on the experimental intervention. Poincaré maps revealed interburst intervals, ISIs within bursts of activity, the extent of periodic or aperiodic activity obtained, and were useful to study the effect of using a specific drug. Using maps, continuous firing of action potentials (periodic activity), higher order periodic patterns and aperiodic behavior were shown in the results. Artificial signals revealed distinct patterns in the Poincaré maps. Thus, Poincaré maps disclosed more about the inherent properties of the neural activity in the recorded data, as compared to ISI histograms alone.

OPTICAL RECORDING OF DORSAL ROOT STIMULUS-INDUCED RESPONSES IN RAT SPINAL CORD SLICES STAINED WITH A VOLTAGE-SENSITIVE DYE. K. Murase*, H. Yamada, M. Tanifuji and P.D. Ryu. Dept. Information Science, Fukui University, 3-9-1 Bunkyo, Fukui 910, Japan.

A high-resolution optical recording of neuronal activities was performed in spinal cord slices, and mechanism of sensory signal transmission was investigated. Transverse and sagittal slices of the rat spinal cord with attached dorsal rootlets were stained with a voltage-sensitive dye NK-3630 (Nippon Kankoshikiso), and the light absorption was measured by an 128x128-pixel image sensor (SD1001, Fuji Film Microdevices) at every 0.6msec. Single dorsal root stimuli evoked optical response consisted of at least two phases, fast and slow components: The fast excitation lasting for several milli seconds occurred predominantly at the laminae II-III. It was followed by the slower excitation lasting for up to .5sec occurring most intensely at the laminae I-II and less at deeper laminae. Both components are of neuronal origin since no optical response was recorded when TTX was added in the perfusate. The former component probably resulted from the afferent fiber activation and the latter from the following postsynaptic events, because a calcium-free perfusate eliminated only the latter. A bath application of CNQX (5-20µM), a selective antagonist of non-NMDA-type excitatory amino acid receptors, eliminated almost completely the presumable postsynaptic component. In contrast, APV (30-50µM), a selective antagonist of NMDA-type excitatory amino acid receptors, abolished only a part of the postsynaptic component, the long-lasting part, while the initial part within 10-30msec was unchanged. A substance P receptor antagonist, spantide (10-50µM), reduced the long-lasting part as well. Adding suramin or α,β-methylene ATP, the antagonist and agonist of ATP receptors, in the perfusate did not alter the spatio-temporal pattern of the response. Supported by grants from Jpn Min. Edu.

Classification of Cellular Properties of Spinal Dorsal Horn Neurons.

M.C. Jiang*, C.L. Cleland and G.F. Gebhart. Department of Pharmacology, University of Iowa, Iowa City, IA 52242

Cellular properties can generate endogenous neural activity and play a role in modifying synaptic input. In order to study the contributions of cellular properties to the processing of nociceptive and non-nociceptive synaptic input to spinal cord neurons, we have first identified and characterized the expression of cellular properties in spinal dorsal horn neurons.

Intracellular recordings were obtained from spinal dorsal horn neurons in the L6-S1 spinal segments of intact, pentobarbital anesthetized adult rats. To stabilize neural recordings, a platform was placed under the spinal cord and a pneumothorax was performed to reduce movements caused by arterial pulsation and respiration. These manipulations allowed us to maintain stable recordings for up to 2 hours. Natural stimulation was applied to identify the receptive fields of the neurons. Cellular properties were tested by intracellular current injection.

Dorsal horn neurons could be divided into two groups: one group (n=9) had predominantly single-component afterhyperpolarizations (AHPs) and the other group (n=34) had multiple-component AHPs. The duration and magnitude of AHPs varied between neurons. Neurons with single-component AHPs tended to have longer duration action potentials. Regarding spike frequency adaptation (SFA), nine neurons had fast SFA, five slow SFA, and eight no SFA at all. We also observed oscillations in five neurons. In one neuron, the existence and frequency of oscillation were voltage dependent, suggesting that the oscillations arose from endogenous mechanisms. In ten neurons, post inhibitory rebound was observed. Currently, we are investigating the relationship between these cellular properties and natural input.

491.6

CLASSIFICATION OF THE RAT SPINAL CORD DORSAL HORN NEURONS BY CLUSTER ANALYSIS. J.W. Leem*, W.D. Willis and J.M. Chung. Marine Biomed. Inst., Depts. of Anat. & Neurosci. and of Physiol. & Biophys., Univ. Texas Med. Br., Galveston, TX 77555.

The aim of this study was to classify dorsal horn neurons in the rat spinal cord with the use of a previously defined natural stimulus set that activates differentially different kinds of modality-specific cutaneous afferents in the rat foot.

The mean discharge rates of 89 sampled units evoked by 6 different stimuli applied to the skin of the foot were measured in anesthetized rats. The data set was subjected to hierarchical cluster analysis.

Five clusters were defined by cluster analysis. Two clusters included units receiving inputs only from low-threshold mechanoreceptors (LTMs) and those only from mechanical nociceptors. Three clusters contained units receiving inputs from LTMs as well as from nociceptors, which could be categorized conventionally as a "wide dynamic range" (WDR) class: a) units receiving greater inputs from mechano-heat nociceptors than from LTMs; b) units having strong inputs from both mechanical nociceptors and LTMs; and c) units with weak inputs from mechanical nociceptors and LTMs.

The results suggest that WDR cells in the rat spinal cord dorsal horn can be divided further into several functional groups. (Supported by NIH grants NS21266, NS11255 and NS09743 and a grant from Bristol-Myers Squibb Co.)

491.7

MODULATION OF SENSORY INPUT IN SUPERFICIAL AND DEEP LAMINAE OF THE RAT DORSAL HORN. P. Bernardi, J.G. Valschanoff, R.J. Weinberg and A. Rustioni. Dept. Cell Biology & Anatomy, UNC, Chapel Hill, NC 27599.

Immunocytochemical investigation of excitatory amino acids in terminals of primary afferents in the spinal cord of rats suggests that glutamate may be released by all terminals in superficial (I and II) and deep (III and IV) laminae of the dorsal horn, whereas aspartate may be co-released by terminals in superficial laminae only.

In the present work we investigated whether modulation of sensory input to the dorsal horn may differ in superficial versus deep laminae. Anterograde tracer was injected into the sciatic nerve to identify primary afferent terminals (WGA-HRP to label superficial laminae, CTB-HRP to label deeper laminae). The tracers were revealed with TMB/tungstate histochemistry. Nitric oxide synthase (NOS) was visualized using preembedding immunocytochemistry. Thin sections were further stained using post-embedding immunocytochemistry for GABA or glycine.

In superficial laminae, about 15% of type I primary afferent terminals received synaptic contacts from GABA-positive terminals. A larger percentage of type II terminals (about 30%) received synaptic contacts from GABA-positive terminals. Terminals of type I but not of type II were presynaptic to vesicle-containing GABA-positive profiles, mostly identifiable as dendrites. In deep laminae, about 15% of primary afferent terminals received synaptic contacts from GABA-positive terminals. Primary afferent terminals in these laminae were not presynaptic to vesicle-containing profiles. Glycine-positive terminals (also enriched in GABA) contacted only type II primary afferent terminals in superficial laminae. Glycine-positive terminals in deep laminae did not establish synaptic contacts on primary afferent terminals. Dendrites contacted by primary afferents in superficial laminae could be NOS-positive, whereas those in deep laminae were often glycine-positive.

491.9

GABA IMMUNOREACTIVITY IS CO-LOCALIZED WITH ENKEPHALIN OR ChAT IMMUNOREACTIVITIES IN THE DORSAL HORN OF THE RAT SPINAL CORD. AN ULTRASTRUCTURAL DOUBLE-LABELING STUDY A. Ribeiro-da-Silva*, M. Ballak and A. C. Cuervo. Dept. of Pharmacology & Therapeutics, McGill University, Montréal, Québec, Canada H3G 1Y6.

In previous studies, we demonstrated the occurrence of choline acetyltransferase (ChAT) immunoreactive (IR) (J. Comp. Neurol. 295: 370-384, 1990) and enkephalin (ENK)-IR varicosities (J. Neurosci. 11: 1068-1080, 1991) which were presynaptic to primary sensory fibers in the superficial dorsal horn of the rat spinal cord. As GABA-IR profiles are also known to be presynaptic to primary sensory fibers in the spinal cord, we decided to investigate the possibility of a co-localization of the above neurochemicals. Adult male Wistar rats were anesthetized with Equithesin and fixed by vascular perfusion with an aldehyde mixture. Transverse sections of the cervical spinal cord were processed for either ENK or ChAT ultrastructural preembedding immunocytochemistry using monoclonal antibodies. GABA-IR sites were demonstrated using a postembedding immunogold protocol. For the simultaneous demonstration of ChAT- and ENK-IR sites, a combination of radioimmunocytochemistry and enzyme-based immunocytochemistry was used. Most of the ChAT-IR profiles were also GABA-IR. Some ENK-IR boutons co-localized GABA immunoreactivity. In synaptic glomeruli, GABA/ChAT co-localization was detected in boutons presynaptic to the central varicosities. Although less frequent, GABA/ENK co-localization was also found in some boutons which were presynaptic to the glomerular central varicosities. Interestingly, the radioautographic pre-embedding study did not reveal any ENK/ChAT co-localization. These results indicate that GABA participates in the presynaptic modulation of primary sensory information through at least two independent neuronal systems, one co-localizing ENK and the other co-localizing ChAT.

NITRIC OXIDE SYNTHASE-CONTAINING NEURONS IN THE DORSAL ROOT GANGLION ARE SUSCEPTIBLE TO CAPSAICIN-INDUCED EXCITOTOXICITY. K. Ren*, E.H. Franklin and M.A. Ruda. Neurobiology and Anesthesiology Branch, NIDR, NIH, Bethesda, MD 20892.

Reduced nicotinamide adenine dinucleotide phosphate-diaphorase (NADPH-d) activity has been localized to spinal sensory ganglia and may be used as a marker for nitric oxide synthase. To study the involvement of NADPH-d/nitric oxide synthase in functions of primary sensory neurons, NADPH-d activity in spinal lumbar dorsal root ganglia (DRG) was examined in neonatally capsaicin-treated (CAP), (50 mg/kg, s.c.) or vehicle-treated rats seven days after sciatic nerve cut using a standard enzyme histochemical technique. In vehicle-treated rats, 7.4% (167/2271) of L5 DRG neurons exhibited intense NADPH-d activity. Among the labeled neurons, 83.8% had cross-sectional areas less than 1000 μm^2 (small) and 16.2% were between 1000 and 2000 μm^2 (medium). In CAP-treated rats, the number of NADPH-d positive neurons, mainly small-sized, was significantly reduced to 2.2% (43/1935, χ^2 , $p < 0.0001$). Following sciatic transection, NADPH-d positive neurons in ipsilateral L5 DRG were markedly increased to 14.1% (285/2026, χ^2 , $p < 0.0001$). CAP-treated rats showed no significant induction of NADPH-d activity after peripheral axotomy. These results suggest that a large number of primary sensory neurons exhibiting NADPH-d activity are CAP-sensitive neurons. Nitric oxide synthase appears to be primarily involved in the functional activity of small-sized DRG neurons, many of which are nociceptive.

WIND UP MEDIATED BY L-TYPE CALCIUM CHANNELS IN TURTLE DORSAL HORN NEURONS.

R.E. Russo & J. Hounsgaard* Department of Medical Physiology, University of Copenhagen, DK-2100, Denmark.

Wind up of the response to repeated synaptic activation of dorsal horn neurons is an elementary type of plasticity in the spinal cord. We have found wind up in deep dorsal horn neurons in an in vitro preparation of the turtle spinal cord. The number of spikes elicited by ipsilateral dorsal root stimulation (0.5-1 Hz) increased over the first few stimuli, and a prolonged afterdischarge was observed when stimulation was terminated. A slow depolarization and an increase in background synaptic noise was evident when cells were hyperpolarized, but the duration of the response was longer at depolarized membrane potentials. In some cells it was also possible to elicit wind up with depolarizing current pulses. This phenomenon was due to the activation of a plateau potential that accumulated between pulses. The accumulation of the plateau potential decreased and eventually disappeared as the cell was hyperpolarized.

APV (100 μM) reduced the overall response to dorsal root stimulation but, it was still possible to elicit wind up of the response. The intracellularly-induced wind up was not affected by APV. Nifedipine (10-50 μM) reduced the plateau potential as well as both types of wind up. Therefore, we propose that a plateau potential mediated by the L-type Ca channel is involved in wind up generation.

UNMASKING OF A NOVEL LONG-LASTING SLOW IPSP IN RAT SUBSTANTIA GELATINOSA NEURONS FOLLOWING BLOCKADE OF GLYCINE AND GABA RECEPTORS. Y. Yajiri, H. Baba, M. Yoshimura* and S. Nishi. Dept. Physiol., Kurume Univ. Sch. Med., Kurume, 830 Japan.

Intracellular recordings were made from substantia gelatinosa (SG, lamina II) neurons in tissue slices of the adult rat spinal cord. A dorsal root was retained attached to the slice preparation. Stimulation of primary afferent A δ fibers evoked in 40% of SG neurons glycinergic and/or GABAergic IPSPs with a duration less than 500 ms. After blocking these IPSPs by strychnine and bicuculline, an additional slow IPSP with an exceptionally long time course, lasting 30-120 s following a single stimulus, appeared. The new IPSP, hereafter, may be referred to as the long-lasting slow IPSP (l. s. IPSP). Stimulation of A δ fibers alone could generate the l. s. IPSP of full size. The l. s. IPSP was associated with a decrease in input resistance and reversed in polarity near the potassium equilibrium potential. The l. s. IPSP was abolished by CNQX but not by catecholaminergic, serotonergic or cholinergic antagonists. Several peptides which are reported to be contained in spinal interneurons have been tested, but they showed no appreciable effects on SG neurons, except for somatostatin. Somatostatin produced in SG neurons a slow hyperpolarizing response that was electrophysiologically analogous to the l. s. IPSP. These observations suggest that glycinergic and GABAergic interneurons normally suppress a subset of interneurons or their terminals which liberate the transmitter responsible for production of the l. s. IPSP. The transmitter in question might possibly be somatostatin, but this remains to be investigated further.

A BIOASSAY FOR NITRIC OXIDE RELEASE FROM SPINAL CORD IN RATS. J.C. Eisenach*, P. Li, C. Tong. Dept. of Anesthesia, Wake Forest University Medical Center, Winston-Salem, NC 27157-1009.

The purpose of this study was to determine if NMDA caused nitric oxide release in spinal cord, as measured by a vascular bioassay system. Rat aortic rings were denuded of endothelium and mounted on transducers for tension recording with a polygraph. Perfusion of spinal cord with NMDA caused concentration-dependent relaxation of the detector aortic rings, while this agent applied to the aortic rings themselves had no effects. Preincubation of spinal cord with different NOS inhibitors and methylene blue attenuated NMDA's effects. Pretreatment with the specific NMDA receptor antagonist, MK-801 blocked NMDA induced aortic rings dilation. These results demonstrate the release of a vasodilating substance from spinal cord during incubation with NMDA acting on NMDA receptors. This substance is likely nitric oxide because (1) this dilation response could be blocked by NOS inhibitors and methylene blue; (2) prostaglandin production was blocked by indomethacin; (3) applying these agents alone had no effect on the aortic rings' tension. Further studies will determine more definitively whether this substance is nitric oxide and examine factors which increase or decrease nitric oxide release from the spinal cord.

Supported in part by grant GM35523 from the NIH.

BIPHASIC EFFECTS OF ENFLURANE ON DORSAL HORN NEURONS. T. Yanagidani, K. Ota, A. Hinds, S. Cannan, Y. Yamamori*, J.G. Collins. Dept. of Anesthesiology, Yale Univ. Sch. of Med., New Haven, CT 06510

The purpose of this study is to examine the effects of enflurane (E) on responses of spinal dorsal horn neurons to low intensity stimulation of their peripheral receptive fields (RFs).

This protocol was approved by the Yale Animal Care and Use Committee. Following isolation of single neurons in intact, awake, drug-free cats, RF area sensitive to light touch was mapped and the most sensitive area was stimulated by brushing, pinching and heating to define baseline responses. The short acting i.v. anesthetic propofol was then used to induce anesthesia, the trachea was intubated and lungs were ventilated with 2.1% E in O₂. RF areas and responses to stimuli were again evaluated at 5, 30, 45 and 60 minutes after induction of anesthesia. Paired t test was used for analysis.

Ten low-threshold neurons and one wide dynamic range neuron have been studied to date. 60 minutes after induction, E significantly reduced the mean RF size to 76% of control. In spite of reducing RF sizes E significantly increased the mean neuronal response of those same neurons to RF brushing to 177% of control. The increased sensitivity to low-intensity stimulation in the remaining RF area was also evident in a reduction in von Frey thresholds.

As we have observed with other anesthetics (pentobarbital, halothane, nitrous oxide, propofol, dexmedetomidine) E reduces the low-threshold RF area of spinal dorsal horn neurons. Unlike those other drugs, however, it increases the response of the neurons to low-intensity stimulation in the remaining RF area. These results point to significant impact of anesthetics on low-threshold sensory processing in the spinal dorsal horn and may help to explain the cortical hyperexcitability seen during E anesthesia.

EFFECTS OF NITROUS OXIDE ON SPINAL DORSAL HORN NEURONAL RESPONSES TO LOW-INTENSITY RECEPTIVE FIELD STIMULATION IN CATS. J.G. Collins*, K. Ota, T. Yanagidani, A. Hinds, S. Cannan. Dept. of Anesthesiology, Yale Univ. Sch. of Med., New Haven, CT 06510.

Our laboratory is pursuing a better understanding of the effects of anesthetics on spinal sensory processing. Nitrous oxide (N₂O) is an important anesthetic agent but, because of low potency, is used in combination with other drugs. The purpose of this study is to examine the effects of N₂O on spinal dorsal horn neurons in the presence of halothane or enflurane.

This protocol was approved by the Yale Animal Care and Use Committee. The effects of halothane or enflurane on neuronal receptive field (RF) size and response to RF brushing, pinching and heating were first determined. We then added 70% nitrous oxide to the anesthetic mixture, allowed for a 15 minute period of equilibration, and re-evaluated neuronal responses. 15 neurons (4 enflurane, 2.1%, 11 halothane, 1.3%) have been studied to date.

In the presence of halothane anesthesia, 70% N₂O produced a 50% reduction in RF size from the baseline halothane level. Halothane had already reduced the mean RF area by 40% from the intact, awake, drug-free preparation. N₂O may produce less of a reduction in RF size in the presence of enflurane. None of the four RFs studied to date were reduced by greater than 20%.

The presence of nitrous oxide appears to contribute to the depressant effects of enflurane and halothane on spinal dorsal horn neuronal responses to low-threshold receptive field stimulation. It appears that most anesthetics depress such responses at the level of the spinal cord.

HALOTHANE REDUCES SPINAL DORSAL HORN NEURONAL RESPONSE TO LOW-THRESHOLD RECEPTIVE FIELD STIMULATION K. Ota, T. Yanagidani, A. Hinds, S. Cannan, K. Kishikawa*, J.G. Collins. Dept. of Anesthesiology, Yale Univ. Sch. of Med., New Haven, CT 06510.

The purpose of this study is to evaluate the effects of halothane (H) on the response of spinal dorsal horn neurons to low-intensity receptive field (RF) stimulation.

This protocol was approved by the Yale Animal Care and Use Committee. Following isolation of single neurons in intact, awake, drug-free cats, RF areas sensitive to light touch were mapped and the most sensitive area was stimulated by brushing, pinching and heating to define baseline responses. The short acting i.v. anesthetic propofol was then used to induce anesthesia, the trachea was intubated and lungs were ventilated with 1.3% H in O₂. RF areas and responses to stimuli were again evaluated at 5, 30, 45 and 60 minutes after induction of anesthesia. Paired t test was used for analysis.

To date 15 low-threshold (LT) neurons have been studied. 60 minutes after induction, a time when propofol effects are known to have dissipated, H significantly reduced the mean RF size to 59% of control. Neuronal responses to both static and dynamic low-threshold RF stimulation were also significantly reduced. Rapidly adapting LT neurons seemed to be less sensitive to the a reduction in RF size than slowly adapting neurons.

This study demonstrates the ability of H to reduce spinal dorsal horn neuron responses to low-intensity stimulation. As proposed by de Jong and Wagman,¹ these effects at the level of the spinal cord could contribute to anesthetic induced loss of sensation.

SPINOTHALAMIC AND SPINOMESEPHALIC NEURONS WITH COLLATERALS TO THE MEDULLARY RETICULAR FORMATION IN THE SUPERFICIAL DORSAL HORN (SDH) OF THE RAT LUMBAR SPINAL CORD. T.N. Bice and J.A. Beal*. Department of Cellular Biology and Anatomy, Louisiana State University Medical Center, Shreveport, LA 71130.

Neurons in the SDH of the rat spinal cord have been shown to project to the medullary reticular formation and are thought to be involved in the relay of nociception to pain modulatory and autonomic centers, as well as to the cerebellum. It is not known, however, what percentage of these neurons project beyond the reticular formation to more rostral nociceptive relay centers. To make this determination, two fluorescent retrograde axonal tracers, Fluoro-Gold (FG) and True Blue (TB), were injected stereotaxically into specific CNS centers. TB was delivered into the right dorsal, lateral, and ventrolateral reticular nuclei, and FG was delivered into the dorsal thalamus (medial and lateral) and midbrain (cuneiform nucleus, parabrachial nucleus, and periaqueductal gray). After 14 days, animals were anesthetized and intracardially perfused with 4.0% paraformaldehyde. Spinal cord segment L1 was serially sectioned in the transverse plane and examined under the fluorescence microscope. Results showed that some SDH nerve cells were labelled with FG alone, but the majority were double labelled, i.e., labelled with both FG and TB. No SDH neurons were labelled with TB alone. Results indicate that 100% of the input to the medullary reticular formation from the SDH is comprised of collaterals of spinomesencephalic or spinothalamic neurons.

NEURAL CODING EFFICACIES OF SPIKE GENERATING CELLS IN LIMULUS EYES: COMPARISON WITH PHOTORECEPTOR CELL RESULTS. Zixi Cheng and Gerald S. Wasserman*. Sensory Coding Laboratory, Department of Psychological Sciences, Purdue University, West Lafayette, IN 47907-1364

Biological signals found in nerve cells exhibit complex temporal characteristics and are very different in shape from the stimuli that evoke them. Two current neural coding theories address these phenomena: Multiple Meaning Theory holds that these patterns make statements about combinations of stimulus properties. More specifically, the Task Dependence Hypothesis suggests that different properties (i.e., neural codes) of identical neural responses might mediate different behavioral tasks. (Both theories reviewed in Wasserman, G. S., *Biological Signals*, 1992, 1, 117-142.)

We have characterized neural responses intracellularly recorded from single spike generating cells in *Limulus* lateral eyes across a wide range of light adaptation states and stimulus intensities. Six candidate codes were measured and their efficacies were calculated using Signal Detection Theory (TSD) as an objective index. The results show that: A) Both adaptation state and intensity affect efficacy. B) The efficacies of these neural codes are significantly different and can be arranged in the order: Area \geq Peak \geq Mean \geq Slope \geq Duration-End = Duration-Drop. C) As light adaptation reduces detection sensitivity, it increases discrimination acuity as characterized by TSD.

Though these results are similar to our previously reported findings in *Limulus* photoreceptors (Cheng, Z. and Wasserman, G. S., *Soc. Neurosci. Abstr.*, 1991, 17, 298), they are not identical. We found: A) All efficacies tend to reduce between neural levels. B) The reduction is code dependent; the Peak, in particular, is affected less than the Area. C) The code which transmits best between cells therefore appears to differ from the code which has the highest efficacy within a cell.

492.2

INCREASE IN THE LIGHT RESPONSE OF LATERAL EYE PHOTORECEPTORS IN LIMULUS PRODUCED BY TWO ENANTIOMERS OF OCTOPAMINE. George H. Renninger*, Biophysics Group, Physics Dept., Univ. of Guelph, Ontario N1G 2W1.

Octopamine (OCT) is synthesized in the eyes of the horseshoe crab, *Limulus polyphemus*. It is stored in the terminals of efferent nerve fibers originating in the central nervous system, and released when the fibers are depolarized. Activation of these fibers by a central circadian clock produces changes in the compound lateral eye, among which is an increased responsiveness of the photoreceptor cells to light. OCT applied to a preparation of the lateral eye *in vitro* partially mimics the effects of efferent activity on the light response (review: Battelle, 1991).

Commercially available OCT is a racemic mixture of the enantiomers D(-) OCT and L(+) OCT. Application of D(-) and L(+) OCT separately to the *in vitro* preparation reveals that the concentration of D(-) OCT producing a half maximal effect is about two orders of magnitude lower than that of L(+) OCT. Thus the effects of OCT on photoreceptor response show stereospecificity for the D(-) enantiomer of OCT, which is the naturally occurring form.

The steady-state light response generally begins to increase within 5 - 10 min after application of D(-) OCT, reaching a steady level within 0.5 - 0.8 h. The increase is difficult to reverse, requiring more than 1 hr when reversal occurs. These observations suggest that OCT produces relatively stable changes in photoreceptor response, which perhaps require other factors to reverse *in vivo*.

NEURAL CODING IN THE *LIMULUS* VISUAL SYSTEM: COMPUTATIONAL AND ELECTROPHYSIOLOGICAL STUDIES
E.D. Herzog*, F.A. Dodge, and R.B. Barlow, Jr.
Institute for Sensory Research, Syracuse University, Syracuse, NY 13244

What is the neural code that underlies visual behavior? We address this question by recording from and modeling responses of the optic nerve of *Limulus*.

We record retinal responses to behaviorally significant scenes (Powers, et al., 1991, *Vis. Neurosci.* 7: 179-89) in order to determine the threshold and suprathreshold neural codes for objects of different contrast and size. We record from 1-3 optic fibers while the animal moves in the Atlantic Ocean and also in an "indoor ocean." Field experiments include parameters that are difficult to simulate in the lab. In both the lab and the field, modulation of the optic nerve activity is determined by 1) the animal's velocity relative to the object, 2) the object's size and contrast and 3) the properties of the retinal network.

We simulate modulation of the optic nerve activity by first computing how the optics of an ommatidium transform the visual scene and second how neural elements of the retina transform this information into a neural code. We have tested a variety of candidates for the neural code and find that several correlate well with the animals' behavior.

A highly simplified model of the retinal array of receptors suggests that the ensemble activity of only a few adjacent receptors may be sufficient to detect objects of interest to the animal.

INOSITOL TRISPHOSPHATE RELEASE FROM THE MEMBRANE IN THE PHOTORESPONSE OF THE HERMISSINDA TYPE B PHOTORECEPTOR CELL. M. Sakakibara¹, T. Kouchi², H. Inoue² and T. Yoshioka^{2*}
¹ Department of Biological Science and Technology, School of High Technology for Human Welfare, Tokai University, Numazu, 410-03,
² Department of Molecular Neurobiology, School of Human Sciences, Waseda University, Tokorozawa, 359, Japan

Despite a considerable number of studies, elucidation of the phototransduction mechanism in invertebrates remains out of reach. The major reason for this is the difficulty of identifying the second messengers involved. The present idea stems from two contradictory results: (i) phosphatidylinositol 4,5-bisphosphate (PIP₂) specific phospholipase C (PLC) is necessary, (ii) but inositol trisphosphate (IP₃), the hydrolyzed product of PIP₂, is not necessary for the generation of photoreceptor potential. By introducing the idea that the invertebrate photoreceptor may be triggered by perturbation of the membrane field change by the hydrolysis of PIP₂, we are able to explain a variety of properties of the photoreceptor. Although the PIP₂ content is very low, the effect of IP₃ release from the membrane on the membrane field around the Na⁺-selective channel underlying the photoreceptor should be quite large, since IP₃ has 5 negative charges in the physiological pH range. We hypothesized that the photoreceptor is triggered by the conformational change of the Na⁺-selective channel induced by IP₃ release. If this were the case, inhibition of PIP₂ specific PLC by screening of the negative charges of PIP₂ by positively charged compounds should suppress the photoreceptor. In order to test this idea we injected substances with high positive charges into Hermissinda type B photoreceptor cell, and observed an effect on the photoreceptor. Various kinds of negative charge chelator for PIP₂ produced reversible block of the photoreceptor, while injection of IP₃, cAMP or cGMP had no significant effect.

THE EYE SPECIFIC GENE *inaD* ENCODES A NOVEL POLYPEPTIDE WHICH IS INVOLVED IN DEACTIVATION AND LIGHT ADAPTATION IN *DROSOPHILA* PHOTORECEPTORS.

Barbara Niemeyer¹, Bih-Hwa Shieh² and Charles Zuker^{1*}. ¹Howard Hughes Medical Institute and Departments of Biology and Neuroscience, University of California at San Diego, La Jolla, CA 92093, ²Department of Pharmacology, Vanderbilt University, TN.

Although the initial events leading to activation of the phototransduction cascade are fairly well understood in the invertebrate photoreceptor, less is known about the mechanisms of deactivation and adaptation. The *inaD* gene was isolated by a subtractive hybridization scheme designed to identify genes preferentially expressed in the *Drosophila* eye. *inaD* flies show an abnormal electroretinogram phenotype, suggesting that *inaD* is involved in visual transduction. We further characterized the electrophysiology of *inaD* mutant photoreceptors using whole cell patch-clamp recordings, and found that the deactivation of the light response was dramatically slower in *inaD* flies when compared with wildtype.

The deactivation defect suggests that the *inaD* gene product is an important player in the regulation of the photoreceptor response. Indeed, when we generated transgenic flies that overexpress the wildtype copy of *inaD* under the control of a heatshock promoter in a wildtype background, the deactivation processes become faster.

Finally, we also constructed flies that express the mutant copy of *inaD* in a wildtype background and found that the deactivation kinetics were slower than wildtype, suggesting that *inaD* has an antimorphic effect.

492.4

PROTEIN KINASE C ACTIVATES TRANSIENT MEMBRANE SHEDDING AND SCREENING PIGMENT MOVEMENT IN THE *LIMULUS* LATERAL EYE.
R.N. Jinks, J.N. Licameli, E.J. Wladis, and S.C. Chamberlain*, Bioengineering & Neuroscience & Inst. for Sensory Research, Syracuse University, Syracuse, NY 13244.

Phorbol ester activation of protein kinase C (PKC) has been shown to induce rhabdomeral disorganization and assembly in dark-adapted photoreceptors of the moth *Manduca sexta* (*ARVO Abstracts*, 33/4: 239). Our detailed understanding of the nature of daily rhabdom shedding and its control in *Limulus* makes it an ideal system to examine possible roles of the 1,2 diacylglycerol/PKC second messenger cascade in mediating transient membrane shedding.

Animals maintained under natural lighting were placed in a light proof tank at sundown. After 12 h, one lateral eye of each animal was subretinally injected with phorbol ester (PE) or DL-erythro-dihydro-sphingosine, a semi-specific PKC inhibitor, while the other eye served as a control. Eyes treated with PE (and their controls) were fixed in the dark 30 min after injection. Sphingosine treated eyes (and their controls) were fixed after 30 min of post-injection light exposure.

Membrane whorls typical of daily shedding were present in abundance in the rhabdomeral arrays of the ommatidia of eyes treated with the PE, phorbol 12,13-diacetate (150 - 1500 μM), in *Limulus* Ringers. Untreated control eyes in these animals did not shed. Negative controls using the inactive ester, 4α-phorbol, did not shed. The PKC inhibitor, sphingosine (100 μM in DMSO), appears to block light-driven shedding. Screening pigment granules, which have been shown to migrate rapidly into the rhabdomeral segment at light onset were found there in PE treated photoreceptors. These data suggest that phorbol esters mimic light onset by triggering transient membrane shedding and the movement of screening pigment granules through the activation of a diacylglycerol/PKC second messenger cascade. THRESHOLD MEASUREMENTS IN A PHOTORECEPTOR.

E.P. Hornstein and T.E. Cohn*. Group in Vision Science, University of California, Berkeley, CA 94720.

The estimate of threshold in a neural system is a common measure of its performance. In psychophysics, threshold measurements are based on the ability of an observer to just detect the stimulus presented (via verbal communication or pressing a button). In neurophysiology, the quantification of threshold is not so clear, since there is spontaneous activity (noise) and variability of response associated with neurons. The purpose of this study is to explore a procedure whereby the effects of variability of response and randomness in the absence of a stimulus are explicitly accounted for in the efficient determination of threshold.

We have adapted a two alternative forced choice staircase procedure (Relkin & Pelli, *J. Acoust. Soc. Am.* 82:1679, 1987) to measure threshold in the dark-adapted locust (*Schistocerca gregaria*) photoreceptor. The stimulus used was a green current controlled LED. The time integral of the cell's intracellularly recorded membrane potential was computed, taking account of the latency and duration of response in each of the two intervals. The two integrals were compared and a decision was made by computer as to which interval the stimulus was presented in. Concurrently, a human decision based on the membrane potential was also made. In a given run, staircase rules were based on either computer or human decisions. There are instances in each type of staircase where computer decisions are correct and human decisions are incorrect, and vice versa. Thresholds using human decisions are more than 50% lower. Therefore, if likelihood ratios were to be adopted for both decision rules, an optimized joint decision rule could be produced. This should lead to an improved computer receiver for the photoreceptor response, and thus, to better threshold estimates. Supported by NIH EY07607.

492.8

THE *trp* MUTATION INHIBITS WHILE THE *inaC* MUTATION ENHANCES LIGHT-INDUCED Ca²⁺ INFLUX INTO *DROSOPHILA* PHOTORECEPTORS.

A. Peretz^{1,2}, C. Sandler², K. Kirschfeld², R.C. Hardie³, E. Suss-Toby¹, S. Barash¹ and B. Minke¹. Physiology, Hebrew Univ.-Hadassah Med. Sch., Jerusalem 91010, Israel; MPI für Biologische Kybernetik, D-7400, Tübingen, Germany²; Zoology, Cambridge Univ., Cambridge, UK³.

The *trp* and eye-PKC (*inaC*) mutations in *Drosophila* both inhibit light adaptation and result in response inactivation. The *trp* gene encodes a light-activated Ca channel. We have shown using whole cell recordings that *inaC* has a functional light-activated *trp* channels. Light-induced Ca²⁺ influx can be monitored using extracellular Ca selective microelectrodes. Compared to wild type the Ca²⁺ influx is enhanced in *inaC* but largely blocked in *trp* or the double mutant *trp;inaC*. The large light-induced Ca²⁺ influx observed in *inaC* is associated with a Ca-dependent inactivation of the *trp* channels.

The fact that light adaptation is nearly absent in *inaC*, in spite of high intracellular Ca²⁺ level indicates that in the absence of protein kinase C (PKC) the well known coupling between increased cytosolic Ca²⁺ and light-adaptation is disrupted.

492.9

CIRCADIAN EFFERENT INPUT TO *LIMULUS* RETINA STIMULATES THE PHOSPHORYLATION OF A PROTEIN SIMILAR TO THE *NINAC* GENE PRODUCTS OF *DROSOPHILA*. W. C. Smith, B. Eschweiler, A.W. Andrews, R.M. Greenberg and B.A. Battelle*. Whitney Lab. and Dept. of Neuroscience, Univ. of Florida, St. Augustine, FL. 32086

Circadian efferent input to *Limulus* eyes increases retinal sensitivity and responsiveness to light at night and primes photoreceptors for photo-mechanical movements, including membrane shedding. Efferent input also stimulates the phosphorylation of a visual system-specific 122 kD protein (pp122) via a cAMP-dependent mechanism. Here we report that pp122 is similar to the *ninaC* proteins of *Drosophila*.

Degenerate oligonucleotides, designed from peptide sequences of gel purified pp122, were used in PCR to obtain a product that was then used to screen a cDNA library from *Limulus* lateral eye. A full length cDNA sequence encoding pp122 was isolated. Its deduced amino acid sequence has 52% total similarity (38% identity) with the *ninaC* proteins from *Drosophila*, and like the *ninaC* gene products, pp122 has a kinase domain and a myosin heavy chain domain. Northern analysis and PCR studies suggest that there is one *ninaC*-like gene product in *Limulus* - in *Drosophila* there are two - and the *Limulus* protein is smaller than the *Drosophila ninaC* proteins. Numerous potential A-kinase phosphorylation sites are distributed throughout the length of pp122. Preliminary CNBr cleavage studies suggest the protein can be phosphorylated at multiple sites including more than one site in the myosin domain. Based on analogy with *Drosophila* we propose that *Limulus* pp122 is involved in the circadian changes in structure and function of the rhabdomere. RETINA: CHOROID, PIGMENT EPITHELIUM, AND PHOTORECEPTORS

493.1

11-CIS- AND ALL-TRANS-RETINYL ESTER HYDROLASE ACTIVITIES IN THE RETINAL PIGMENT EPITHELIUM OF THE EYE. E.P. Rodriguez, A.T.C. Tsif, N.L. Mata, S. Ziar, and J. Bustamante. Division of Life Sciences, The University of Texas at San Antonio, San Antonio, Texas 78249.

Preliminary investigation of 11-*cis*- and all-*trans*-retinyl ester hydrolase (REH) activities in bovine retinal pigment epithelium (RPE) microsomes suggests that the two hydrolytic activities may be distinct from each other (Mata et al., 1992, *J. Biol. Chem.* 267: 9794). In order to further explore the possibility of distinct hydrolytic sites for the two retinyl ester isomers, we have conducted studies using inhibitors of serine and thiol hydrolases. Specifically, we have employed inhibitors which modify catalytic sites containing cysteine residues (*N*-ethylmaleimide, NEM and phenylmethylsulfonyl fluoride, PMSF), serine residues (PMSF), and histidine residues (*N*-tosyl-L-phenylalanine chloromethyl ketone, TPCK). Effects of these inhibitors on 11-*cis*- and all-*trans*-REH activities in RPE microsomes were determined by monitoring product formation with increasing protein concentrations in the absence and presence (0.25 mM and 0.50 mM) of inhibitor. Hydrolysis of all-*trans*-retinyl palmitate was significantly inhibited (60 - 70%) by NEM, PMSF, and TPCK while hydrolysis of 11-*cis*-retinyl palmitate was inhibited by PMSF (50%) and TPCK (40%) only. Inhibition of 11-*cis*-REH by NEM was less than 15% at the highest inhibitor concentration (p.50 mM). These observations suggest that 11-*cis*- and all-*trans*-REH do not utilize the same amino acid residues for catalytic activity. Thus, based upon differential inhibitions, our results support the hypothesis of distinct 11-*cis*- and all-*trans*-REH activities in bovine RPE microsomes. Supported by grants from the NIH and the San Antonio Area Foundation.

PROTEASES ACTIVITY IN MICROVESSELS OF RETINA, CHOROID, CILIARY BODY AND IRIS OF RAT EYE. A. Mitro, L.E. De Bault and R.E. Nordquist. University of Oklahoma Health Sciences Center and Dean McGee Eye Institute, Oklahoma City, OK 73104.

There is evidence which suggests that various types of brain microvessels have distinct compliments of membrane-bound proteases, which cleave peptide bonds and may have a major role in the activation, deactivation and/or modulation of blood-borne neurohormones. However, the precise functions of these proteases is not yet well understood. The present study was undertaken to determine the presence and localization of glutamyl aminopeptidase (EAP), microsomal alanyl aminopeptidase (mAAP), dipeptidyl peptidase IV (DPP-IV), and gamma-glutamyl transpeptidase (γ -GTP) in rat eye. Cryostat sections of the adult rat eye were stained histochemically for EAP, mAAP, DPP-IV and γ -GTP according to the methods of Lajda et al. (1979). Vessels of the retina were strongly positive for EAP and mAAP, but weak to negative for γ -GTP. Retinal vessels were negative for DPP-IV. In the case of choroid, ciliary body, and iris, positive reactions were observed for EAP, mAAP, and DPP-IV, while γ -GTP was negative. These results suggest that blood-borne peptide hormones or other substances may be affected by EAP, mAAP, and DPP-IV, but not by γ -GTP in choroid, ciliary body, and iris. The absence of DPP-IV in retinal vessels suggests a functional role of retinal endothelium that differs from the role of vascular endothelium of the above mentioned eye structures. Supported by NIH grant NS18775 and an unrestricted grant from Research to Prevent Blindness, Inc.

THE EFFECTS OF DIFFUSIBLE FACTORS FROM ADULT HUMAN RETINAL PIGMENT EPITHELIAL CELLS ON PHOTORECEPTORS AND MULLER CELLS IN VITRO. H.J. Sheedlo, A. Davis, C.D. Jaynes and J.E. Turner*. Department of Anatomy and Cell Biology and North Texas Eye Research Institute, Texas College of Osteopathic Medicine, Fort Worth, TX.

Rat RPE-cell diffusible factors promote photoreceptor survival and Muller cell proliferation (Sheedlo et al., 1992). This study was undertaken to determine if primary, passaged and immortalized adult human RPE secrete factors which cause a similar cell response. RPE cells were isolated from adult humans, cultured and passaged. Rat photoreceptors and Muller cells were separately isolated from retinas of day 2 rats and cultured in media conditioned by human RPE (CM). The number of opsin-stained photoreceptors and carbonic anhydrase-stained Muller cells were counted after 3 days *in vitro*. RPE-CM from a 32 year-old human promoted the survival of 10,780 \pm 278 photoreceptors, which was equivalent to the maximal response in cultures in CM of neonatal rat RPE-CM (11,429 \pm 3035). In contrast, 1,572 \pm 161 cells were counted in 74 year-old human RPE-CM cultures, but CM of first- and second-passaged RPE of a 81 year-old human effected the survival of 11,131 \pm 1829 and 15,823 \pm 438 cells, respectively. CM of immortalized adult human RPE cells caused the survival of Muller cells, which died when grown in a defined medium. This study showed that factors of adult human RPE affected photoreceptor survival and Muller cell proliferation. Specifically, old RPE cells could be upregulated in culture to release such factors, which may mimic their glial cell activities in retinal pathologies such as proliferative vitreoretinopathy. Supported by NIH grant EY 04337.

TOPOGRAPHICAL SEPARATION OF COLOUR SPECIFIC CONES IN THE RABBIT RETINA. B. Juliusson^{1,2}, A. Bergström¹, P. Röhlich³, B. Ehinger^{1*}, T. van Veen², A. Szé^{2,3}. ¹Dept of Ophthalmology, Univ. of Lund, Sweden; ²Dept of Zoology, Univ. of Göteborg, Sweden. ³Lab. of Electron Microscopy, Semmelweis Univ. of Medicine, Budapest, Hungary.

Recently, a marked heterogeneity of the mouse retinal cone cell distribution has been reported (Szé et al., *J. Comp. Neurol.* 325:327,1992). The presence of complementary cone fields in the mouse retina was considered as a unique feature of the mouse, since not even close relatives of this species (wood mouse, rat, gerbil, hamster) shows this special cone pattern. Mapping the distribution of the colour specific cones in the rabbit retina, we found a narrow crescent-shaped area with an unusually high number of shortwave-sensitive cones (S-cones) and what appeared to be a total lack of middlewave-sensitive cones (M-cones), thus resembling the S-field of the mouse retina. Although the extension of this peculiar cone field (tentatively called blue-streak) was considerably smaller than the S-field of the mouse retina, its position was similar to that, since it also occupied the lowermost part of the retina.

For the identification of the two different cone types, we used the monoclonal antibodies COS-1 and OS-2, specific for middlewave and shortwave sensitive visual pigments, respectively. Immunofluorescent staining was performed on whole mounts of adult rabbit retinas.

The majority of the retinal surface, including the visual streak, exhibited a dominance of M-cones over S-cones with a ratio of about 10:1. It was only the lower 5% of the total retinal area (blue-streak) that showed a complete lack of M-cones and a high frequency of S-cones.

The functional implications of this finding is as yet unknown, however, it can be assumed that the blue streak is designed for an enhanced perception of predators approaching from above.

Supported by grants from the Swedish Medical Research and the Swedish Natural Sciences Councils (projects #14X-2321 and #4642-130), the RP Foundation Fighting Blindness, the T and R Söderberg Foundation and the Riksbankens Jubileumsfond.

493.5

SPECTRAL SENSITIVITY OF RETINAL CONES IN THE GOLDFISH (*CARASSIUS AURATUS*): Adrian G. Palacios* & Timothy H. Goldsmith, Department of Biology, Yale University, New Haven, USA.

Spectral sensitivities of individual goldfish cones were investigated by drawing the outer segments into pipette electrodes and measuring the membrane photocurrents. The amplitude of the cone response as a function of intensity is represented better by a Michaelis-Menten than an exponential function. The maximal photocurrent observed in these experiments was 20 pA. We find four classes of cones with maximal sensitivity at 368 (near UV), 458, 535 and 616 nm. The spectral sensitivity functions are fit better by a porphyropsin than a rhodopsin template, but the long wavelength limbs of the sensitivity curves descend more gradually with wavelength than predicted by the function of Mooij and van den Berg (1983), an analytical treatment that attempts to describe sensitivity of porphyropsin-containing receptors at wavelengths where absorbance is too low to measure by microspectrophotometry.

493.7

LOCALIZATION AND MODULATORY ACTIONS OF ZINC IN VERTEBRATE RETINA S.M. Wu*, X. Qiao, X.L. Yang, and J.L. Noebels, Cullen Eye Institute, Division of Neuroscience and Department of Neurology, Baylor College of Medicine, Houston, TX 77030.

Vertebrate photoreceptors are thought to use glutamate as their neurotransmitter and a number of glutamatergic neurons in the nervous system contain zinc (Zn^{+2}) in their presynaptic vesicles. We therefore studied the localization and the actions of Zn^{+2} in the larval tiger salamander retina. By using the Neo-Timm staining method which allows selective visualization of Zn^{+2} associated with synaptic vesicles, we observed heavy staining in the basal regions of cell bodies of both rods and cones. Little staining was observed elsewhere in the retina. At EM level, zinc-positive particles were located in synaptic vesicle-rich regions of the photoreceptor terminals. Application of 5-50 μM Zn^{+2} hyperpolarized the horizontal cells (HCs) and suppressed their light responses, an action similar to that exerted by application of Co^{+2} , which blocks presynaptic calcium channels. 5 μM Zn^{+2} partially, and 50 μM Zn^{+2} completely, blocked the depolarizing action of GABA, which was mediated by GABA_A receptors. In contrast, application of Zn^{+2} (up to 100 μM) exerted no effect on the depolarizing action of glutamate. We have demonstrated that endogenous zinc is present in photoreceptors. The staining distribution pattern suggests that it is associated with synaptic vesicles. If Zn^{+2} is released from the photoreceptors, it may regulate the presynaptic release of glutamate, and may be involved in regulating the HC response kinetics by modulating GABA_A receptors.

PCR SEQUENCE OF LARVAL AND ADULT OPSIN PROTEINS IN WINTER FLOUNDER. B. L. Evans*, T. L. Kasten, M. Nadal-Vicens, and R. D. Fernald, Stanford University, Stanford CA 94305-2130.

At metamorphosis, the winter flounder retina undergoes an extensive structural transformation (Evans and Fernald, 1993) and the wavelength of peak absorbance also changes for the photoreceptors (Evans et al., 1993). Larval retinas have one photoreceptor type, a cone, arranged in a hexagonal array with its spectral absorbance peak at 519 nm ("green"). After metamorphosis, the retina has rods, single and double cones. The three adult cone-types are arranged in a square array differing from one another in peak spectral absorbance (single cone = 457 nm; double cone members = 531 nm, 547 nm). All three cone absorbances are also unique from that of the premetamorphic cone. Using PCR, we have isolated and sequenced regions of the photoreceptor opsin genes presumed responsible for determining the wavelength of peak absorbance. The adult flounder retinal tissue yielded DNA sequences with high homology to blue and red absorbing cone opsins and to the rhodopsin found in adult rods. Using a similar approach, we obtained two putative cone opsin sequences for winter flounder larvae. The larval opsin partial sequences have high homology to the red and blue opsins found in the adult retina. Metamorphosis transforms existing cone photoreceptors from the single larval phenotype into three postmetamorphic phenotypes. Since the larval opsin sequences differ from those of the adult, such a process requires an exquisitely coordinated change in opsin gene expression across the retina. COMPONENTS OF THE PHOTOTRANSDUCTION CASCADE IN CONES AND ROD-LIKE CELLS OF THE GROUND SQUIRREL RETINA. M. von Schantz, A. Szél, T. van Veen and D.B. Farber*, Jules Stein Eye Institute, UCLA School of Medicine, Los Angeles, CA 90024, and Dept. of Zoology, University of Göteborg, S-413 90 Göteborg, Sweden.

We have studied the expression and distribution of phototransduction gene products in the cone-dominant retina of the ground squirrel *Spermophilus tridecemlineatus*. mRNA expression was studied with Northern blot hybridization, and the distribution of the gene products was investigated with immunocytochemistry.

Northern blot hybridization showed messages for the $\beta 1$ - and $\beta 3$ -subunits of transducin, and for arrestin, recoverin, and IRBP (interphotoreceptor retinoid-binding protein), but was negative for opsin, $\alpha 1$ -transducin, and the γ -subunit of cGMP phosphodiesterase. The rod-like cells were immunopositive for opsin and blue opsin. All photoreceptor elements were positive for the α - and $\beta 3$ -subunits of transducin, the γ -subunit of rod phosphodiesterase, and IRBP, while no cells were labelled by antibodies against the rod α - and β -subunits of phosphodiesterase or the rod cGMP-gated cation channel. Rod-like cells and blue cones were stained by antibodies against $\beta 1$ -transducin, arrestin, and phosducin.

Our results indicate that blue cones and rods share a similar or identical phosphorylation-dependent signal quenching mechanism involving arrestin and phosducin. We also present evidence for new cone-like traits in the biochemical make-up of the rod-like cells, further emphasizing their deviation from the classical duplicity theory.

OPSIN PHYLOGENY AND EVOLUTION: A MODEL FOR BLUE SHIFTS IN WAVELENGTH REGULATION. B.S.W. Chang^{1*}, K.A. Crandall², J.P. Carulli¹ and D.L. Hartl¹. ¹Harvard University, Biological Labs, 16 Divinity Ave., Cambridge, MA 02138; ²Washington University, Biology Dept., St. Louis, MO 63130.

Shifts in absorption maxima of opsins are thought to be a result of interactions between amino acid side chains extending into the opsin binding pocket, and the protonated Schiff base (SBH⁺) chromophore. We used a comparative approach to identify residues important in opsin wavelength regulation. Opsin sequences were obtained from the literature, and aligned according to current understanding of the structural and functional domains of the molecule. Several methods of phylogenetic analysis were used to construct an opsin tree. Amino acid substitutions were traced along the branches of the opsin tree, using evidence from structural and functional studies of opsins (and other receptors with seven helical transmembrane domains) to identify residues likely to reside within the chromophore-binding pocket. Functionally convergent, nonconservative amino acid substitutions in independently evolved opsins with similar shifts in spectral properties were especially of interest. The results of this comparative analysis are summarized in a model for blue shifts of opsin absorption spectra. This model may explain some of the diversity of short wavelength opsins apparent in both vertebrates and invertebrates.

A QUANTITATIVE ACCOUNT OF THE ROLE OF Ca^{2+} IN LIGHT ADAPTATION OF ROD PHOTORECEPTORS. Y. Koutalos¹, K. Nakatani^{2*}, and K.-W. Yau^{1,3}. Dept. of Neuroscience, Johns Hopkins Univ. Sch. of Med.¹, Howard Hughes Med. Inst.³, Baltimore, MD 21205, USA and Inst. of Biological Sciences, Univ. of Tsukuba², Tsukuba, Ibaraki 305, JAPAN.

cGMP, the intracellular messenger that mediates phototransduction, is synthesized from GTP by a guanylate cyclase and is hydrolyzed to 5'-GMP by a light-sensitive phosphodiesterase. Both enzymes have been shown to be Ca^{2+} -sensitive, a property found to be important for the adaptation of photoreceptors to background light. We have used a truncated rod outer segment preparation from the tiger salamander to study these enzymes under conditions close to the physiological situation. The distal portion of a rod outer segment was drawn into a suction pipette to allow recording of membrane current, while its proximal portion was removed by truncation to allow internal dialysis. In this way the cGMP-gated channels of the outer segment membrane can be used to monitor the cGMP concentration. The truncated outer segment can then be used to study the *in situ* activities of the cGMP-metabolizing enzymes. Our preliminary results indicate, for the guanylate cyclase, an inhibition by Ca^{2+} with a $K_{1/2}$ of 100 nM and a Hill coefficient of 1.5; for the steady-state phosphodiesterase activity elicited by steps of light, the stimulation by Ca^{2+} shows a $K_{1/2}$ of 410 nM and a Hill coefficient of 1.0. On the basis of these measurements the steady-state step response-intensity relation of the intact rod can be predicted. The predicted relation is in close agreement with experimental data from intact cells.

RETINAL DEGENERATION IN THE MOTOR NEURON DISEASE MUTANT (*Mnd*) MOUSE. D.L. Price and C.A. Pardo*. The Johns Hopkins Sch. of Med., Balto., MD 21205

The *Mnd* mutant mouse was described originally as an animal model for motor neuron disease. Recently, we and others have demonstrated that *Mnd* mice show widespread neuronal and nonneuronal accumulation of lipofuscin-like material and retinal degeneration. The time course of degenerative changes in the retina in *Mnd* mice was studied by immunocytochemical and electron microscopic techniques. Retinal degeneration was detected as early as two months of age, with loss of the outer segment of photoreceptors and cytoplasmic accumulation of autofluorescent lipofuscin-like material in photoreceptor and ganglion cell bodies. By the age of four months, extensive degeneration of the outer and inner segments of photoreceptors, as well as reductions in the number of nuclei in the outer nuclear layer (ONL), was observed. At this age, a decrease in the ONL thickness and synapsis was demonstrated with antisynaptophysin and anti-MAP-2 antibodies. By six months, the photoreceptor, ONL, and outer plexiform layers had degenerated completely, with decreases in the thickness and cell density of inner nuclear, inner plexiform, and ganglion cell layers. Ultrastructurally, lipofuscin-like material was characterized by granular, multilamellar, fingerprint, and curvilinear profiles surrounded by a limiting membrane. Immunocytochemical and Western blot analyses demonstrated abnormal accumulation of subunit *c* of mitochondrial ATP synthase in *Mnd* as compared with wild-type mice. The neuropathological changes, accumulation of subunit *c*, and retinal degeneration suggest that the *Mnd* mouse is a form of neuronal ceroid lipofuscinosis (NCL) and demonstrated that, rather than a model for motor neuron disease, the *Mnd* mouse is a suitable model to study NCL or Batten's disease.

ABNORMALITIES IN CIRCADIAN RHYTHM OF DOPAMINE METABOLISM IN DYSTROPHIC RETINAS OF MUTANT *RDS* MICE. L. Nir¹ and P.M. Luvone² Dept. of Pathol., Univ. of Texas Health Sci. Ctr., San Antonio, TX¹, and Dept. Pharmacol., Emory Univ. Sch. of Med., Atlanta, GA².

Retinitis pigmentosa (RP) is a neurodegenerative disease, manifested by progressive loss of photoreceptors and blindness. Recent molecular genetics analysis revealed a mutation in *peripherin/rds* gene in retinal degeneration slow (*rds*) mice and subsequently in humans with RP. In mice the mutation is noted by the absence of normal light sensitive outer segments. In prior studies of *rds* retinas we discovered loss of the diurnal rhythm in arrestin gene expression. This observation led us to study dopamine (DA), which was reported to affect diurnal rhythms in the retina. DA metabolism was studied in BALB/c and *rds* mice at various stages of retinal degeneration. Levels of catecholamines were determined by HPLC-EC. Steady state DA levels were essentially the same in light and dark adapted retinas of BALB/c and *rds* mice. Levels of DA metabolite, DOPAC, increased significantly in illuminated retinas of BALB/c but not *rds* mice, indicating limited release and degradation of DA in the mutant. DA synthesis, as estimated by accumulation of DOPA following inhibition of DOPA decarboxylase, was markedly higher in BALB/c than in *rds* retinas. Rate of DA turnover, as calculated in 1 month old mice treated with α MPT, was 8 fold lower in the *rds* retina in comparison to BALB/c. Thus, although DA synthesis is limited in the *rds* retina, relatively high steady state levels are maintained as a result of a concomitant low turnover rate. In conclusion, the relatively high level of DA which is maintained in the *rds* retina might not be available to exert its effect on retinal functions.

493.15

CHARACTERIZATION OF L, M, AND S CONE PEDICLES IN PRIMATE FOVEA Pooneh Esfahani¹, Stan Schein^{2*}, Karl Klug¹, Yoshihiko Tsukamoto², and Peter Sterling² Dept of Psychology, UCLA¹, Los Angeles, CA; Hyogo Coll Med², Hyogo, Japan; Dept of Neuroscience, Univ of Pennsylvania³, Phila, PA

To determine characteristics of cone pedicles that might distinguish L, M and S types, we reconstructed 40 contiguous, complete pedicles in a small patch of foveal retina from electron micrographs of serial thin sections. We measured the volume of each pedicle and characterized its synaptic ribbons. Based on the pedicle's connections to bipolar cells (Klug et al.1992; Calkins et al. 1992), we identified 17 putative L cone pedicles, 6 putative M cone pedicles, and 4 S cone pedicles. The remaining 13 pedicles were non-S. The results were as follows:

- Pedicle volumes increased from 480 to 640 microns eccentricity. S pedicles were among the smallest at any eccentricity, but five non-S pedicles were similarly small. The volumes of L and M pedicles were indistinguishable.
- All four S pedicles had 22 ribbons. The non-S pedicles had 16-21. L pedicles, with 16-20 ribbons and M pedicles, with 18-20 ribbons, were similar.
- Synaptic ribbons are flat rectangles characterized by a range of docking lengths (0.1 to 1.3 μ m) and constant heights of approximately 0.3 μ m.
- Total docking length of ribbon in each pedicle increased with eccentricity and ranged from 8 to 14 μ m. L, M, and S pedicles did not differ in this regard.
- The average ribbon lengths in S pedicles were among the smallest, but the average ribbon length in five other pedicles was similarly small.

Only the number of ribbons distinguished S from non-S pedicles, and that measure might fail with a larger sample. None of the measurements distinguish L from M cone pedicles. Connections with bipolar cells remain the only feature that distinguishes cone types. Supported by NIH grant EY06096

Basic PGF mRNA Expression during Retinal Development in Normal and *rd* C57BL/6J Mice H. Gao, S.E. Basinger* and J.G. Hollyfield, Cullen Eye Institute and Division of Neuroscience, Baylor College of Medicine, Houston TX 77030 We reported previously that bFGF immunoreactivity was localized to the outer retina and more bFGF was detected in *rd* than in the normal mouse retina at certain developmental stages. To examine bFGF gene expression and compare bFGF mRNA levels in normal and *rd* retinas, *in situ* hybridization and ribonuclease protection assay (RPA) were performed using radiolabeled riboprobes synthesized by *in vitro* transcription from a cDNA segment (480 bp) coding for the mouse bFGF open reading frame. Both methods demonstrated that bFGF mRNA expression could be detected in earlier stages and at higher levels in *rd* than in normal retinas. bFGF mRNA expression was not detected in normal retina by *in situ* hybridization until postnatal day 10 (P10), when the hybridization signal was first detectable in the photoreceptor inner segments (IS). In *rd* P10, however, strong signals were detected in the IS in the central retina. At P12, much higher level of bFGF mRNA expression could be detected in the IS in *rd* than in normal retina. At P15, the *rd* residual photoreceptors express high levels of bFGF mRNA, especially near the ora serrata area. In adult retinas, *rd* demonstrated much stronger mRNA signals in more INL cells than the normal retina. Some cells in the INL and GCL could also be labeled with the probe in the normal and *rd* retinas. Intense hybridization signals were detected in astrocytes localized in the optic disc area during development. When RPA was employed for quantitative studies, bFGF mRNA could be detected from P6 *rd* neural retina, but not from P6 normal retina. At P10, up to 5 fold more bFGF mRNA was present in *rd* as compared to normal retinas. Normal adult retina contains more bFGF mRNA than P10 retina using RPA. These results suggest that (1) bFGF mRNA expression is up-regulated during retinal development. (2) Photoreceptor degeneration in the *rd* retina is accompanied by elevated levels of bFGF mRNA expression in the photoreceptors. (3) Astrocytes in the optic disc area express high levels of bFGF mRNA during development. Supported by NEI Grant 02363, the Retina Research Foundation and RP Foundation.

Is a Circadian Rhythm Expressed in the Structural Organization of the Outer Plexiform Layer in the Japanese Quail?

M.E. Kelly and R.B. Barlow, Jr.*
Institute for Sensory Research, Syracuse Univ., Syracuse, NY 13244

The Japanese quail retina exhibits a circadian rhythm in cone and pigment granule movement at the light microscopic level.¹ Cones contract and pigment disperses during the day while at night cones elongate and pigment recedes. Are circadian changes limited to the most distal, light sensitive cells of the retina? Can the clock modulate structural changes at the initial site of visual transmission - the photoreceptor-bipolar synapse?

In an attempt to answer this question, we discovered a two-tiered arrangement of photoreceptor terminals. Cone pedicles and rod spherules are found in both tiers. Cone pedicles contain traditional triad synapses which appear to be influenced by environmental lighting conditions. Specifically, the ribbon per pedicle ratio decreases with prolonged darkness (about 30 hrs).

Circadian changes in retinal structure are not unique in birds. Circadian retinomotor movements of cones and retinal pigment epithelium granules have been detected in fish as well as rhythms in ribbon and horizontal cell spinule formation.^{2,3}

CORRELATED LIGHT AND ELECTRON MICROSCOPY OF OPSIN-IMMUNOREACTIVE NEURONS IN LIZARD BASAL BRAIN. M.S. Grace*, V. Alones, M. Menaker, R.G. Foster. Dept. of Biology, Univ. of Virginia, Charlottesville, VA 22903.

Photoreceptors mediating circadian responses to light are distinct from retinal rods and cones. In non-mammalian vertebrates, these cells are extra-ocular, since removal of eyes does not prevent light input to the circadian system. Opsin immunoreactivity (IR) and retinoid identification suggest that photoreceptors exist in the basal brain of iguanids (Foster et al., *J. Comp. Physiol. A* 172:33-45, 1993). We investigated the ultrastructure of these putative photoreceptors using combined light and electron microscopic (EM) immunocytochemistry. *Iguana iguana* and *Anolis carolinensis* were perfused, and their brains sectioned at 50 μ m. Free-floating sections were immunostained with anti-cone opsin CERN 874, and HRP/DAB. Sections were plastic embedded and viewed by light microscopy (LM). Immunostaining in brain was observed only among pinealocytes and CSF-contacting ependymal neurons of the basal portion of the lateral ventricles. Sections containing IR CSF-contacting neurons were excised, thin-sectioned, and viewed by transmission EM. Individual IR cells observed by LM were readily identified by EM. These cells are flask-shaped, with a single dendrite and an axon emanating from opposite sides of the soma. The dendritic process contains an axoneme, ends in a bulbous terminal protruding into the lateral ventricle, and receives synaptic input. Opsin-IR CSF-contacting neurons contain many 110-190nm diameter vesicles in the perinuclear region, dendrite, and bulbous terminal. These vesicles may be analogous to "lipochondria" or "photic vesicles" of extra-ocular photoreceptors in gastropod mollusks. Opsin IR may be concentrated within these vesicles, and is diffusely distributed throughout the bulbous terminal. Together, these results suggest that opsin-IR CSF-contacting neurons may be photoreceptors. Support: NIH 5R29MH49837 (RGF); NSF PCM8409010 (MM)

NADPH-diaphorase positive neurons and fibers in the ciliary ganglion and choroid of the pigeon. M.E.C. Fitzgerald* and A. Reiner. Dept. of Anatomy & Neurobiology, Univ. of TN, Memphis, TN.

Choroidal blood flow (CBF) in the avian eye is under vasodilatory cholinergic control by the ciliary ganglion (CG). Since nitric oxide has been implicated in many vascular beds as a vasodilator, we sought to determine if the neurons in the ciliary ganglion contained the necessary enzyme to produce nitric oxide by using NADPH-diaphorase histochemistry. Pigeons were transcardially perfused with a paraformaldehyde fixative, the eyes were removed with the ciliary ganglion intact, rinsed in buffer, cryoprotected in a sucrose-buffer solution, sectioned at 20µm in a cryostat and mounted on slides. The slide-mounted sections were stored in the freezer and later processed for diaphorase activity.

Within the ciliary ganglion, both choroidal and ciliary neurons stained positively for NADPH-diaphorase. The presynaptic endings on the choroidal neurons appeared negative for NADPH-diaphorase; however, some diaphorase positive structures appeared to be cap-like endings, which were presynaptic to weakly labelled ciliary neurons. Within the choroid numerous diaphorase positive nerve fibers were observed around blood vessels. Additional diaphorase positive cells were observed within the extracellular space of the choroid and within the walls of choroidal blood vessels. Bundles of diaphorase positive ciliary nerves were also observed within the choroid and in the ciliary body, where individual fibers were observed to extend into the ciliary processes. The existence of NADPH-diaphorase positive neurons within the ciliary ganglion helps clarify the dramatic choroidal vasodilation we have observed in pigeons with activation of input to the ciliary ganglion.

POLARIZATION SENSITIVITY IN SINGLE UNITS OF THE RAINBOW TROUT (*ONCORHYNCHUS MYKISS*) VISUAL SYSTEM. D. I. Coughlin and C. W. Hawryshyn* Dept. of Biol., Univ. of Victoria, Victoria, B.C. V8W 2Y2 Canada

Polarization sensitivity (PS) has previously been demonstrated in multi-unit responses from the optic nerve of rainbow trout (Parkyn and Hawryshyn, '93, J. Comp. Phys. A). Discrimination of the *e*-vector of a polarized light stimulus in rainbow trout requires the presence of the UV cone mechanism, and UV sensitivity in rainbow trout is found primarily in the torus semicircularis (TS), a sub-tectal midbrain region. This study investigated polarization sensitivity in single units from the trout TS, by isolating individual cone mechanisms with chromatic adaptation and by examining polarization opponency in the most common color-coded units of the trout TS. Under a UV cone mechanism isolating background, single units always gave an ON response and showed PS with a sensitivity peak for stimuli with vertical (0° and 180°) *e*-vector. Under middle (M) and/or long (L) isolating backgrounds, single units gave either ON responses or OFF responses. The ON response units generally showed no PS, while the OFF response units were polarization sensitive with a sensitivity peak for stimuli with a horizontal (90°) *e*-vector. Examination of PS in biphasic color-coded units, which have opponency between an ON response from the UV mechanism and OFF responses from both the M and L mechanisms, showed PS consistent with the responses of isolated cone mechanisms. Thus, biphasic units discriminate the *e*-vector of polarized light stimuli and permit polarized light vision by rainbow trout. Alternatively, other types of color-coded TS single units did not code polarized light information and were polarization insensitive. Supported by an NSF-NATO PDF to DJC and an NSERC operating grant to CWH.

493.19

CHARACTERIZATION OF POLARIZED-LIGHT SENSITIVITY FROM THE OPTIC NERVE OF THE RAINBOW TROUT (*ONCORHYNCHUS MYKISS*). D. C. Parkyn* and C. W. Hawryshyn. Dept. of Biol., Univ. of Victoria, Victoria, B.C. V8W 2Y2 Canada.

We investigated the optic-nerve ganglion responses underlying polarization sensitivity (P.S.) in rainbow trout, using a compound action potential recording technique. Chromatic adaptation allowed us to characterize two orthogonally-oriented classes of polarization sensitive cones and one polarization-insensitive cone type. Adapted Ultraviolet (UV)-sensitive cones were found to respond with peak sensitivity to vertically (0/180°) polarized light or *e*-vector, whereas isolated middle and long wavelength-sensitive cone mechanisms responded maximally to horizontal (90°) *e*-vector. Short wavelength-sensitive cones (as well as rods) were found to be insensitive to the plane of polarization. *E*-vector adaptation, a technique analogous to chromatic adaptation can be used to reduce the relative sensitivity of one *e*-vector sensitive mechanism to its orthogonal mechanism. Differential sensitivity to various orientations of *e*-vector was greater following chromatic adaptation than following *e*-vector adaptation. The presence of UV light is necessary for orientation of trout under a downwelling plane-polarized light field (Hawryshyn et al. '90, J. Comp. Physiol.). We present evidence that P.S. is mediated by the comparison of the responses from the vertically- and horizontally-sensitive mechanisms in the UV region of the spectrum in a manner analogous to colour vision. Supported by a NSERC operating grant and Dept. of Fisheries and Oceans subvention grant to CWH as well as grants from the University of Victoria.

TRANSNEURONAL BIOCYTIN DELINEATES SPECIES DIFFERENCES IN A BRAINSTEM VOCAL-ACOUSTIC CIRCUIT IN SOUND PRODUCING FISH. A. H. Bass*, M. A. Marchaterre and R. Baker. Neurobiology and Behavior, Cornell Univ., Ithaca, N.Y. 14853; Physiology and Biophysics, NYU Medical Center, New York, N.Y. 10016.

The closely-related toadfish and midshipman generate vocalizations with species-typical temporal and spectral properties by the simultaneous contraction of sonic swimbladder muscles. Intracellular staining and recording in both species show that each muscle is innervated ipsilaterally by motoneurons in a brainstem sonic motor nucleus (SMN). Individual pacemaker neurons (PMNs) lie lateral to sonic motoneurons, innervate them bilaterally, and establish their fundamental discharge frequency. Transneuronal biocytin transport has now identified species-typical pacemaker circuitries. In both species, labelling of the sonic nerve ipsilaterally resulted in biocytin-filled neurons bilaterally within and lateral to the SMN; the lateral neurons overlapped the location of previously-identified PMNs. In toadfish, the PMNs formed a dense network along the entire length of the SMN, while in midshipman they were clustered rostral to the SMN. PMN neurites branched extensively across the midline, either ventral (toadfish) or rostral (midshipman) to the SMN. In both species, PMN neurites joined a lateral fiber bundle containing axons that terminated in the statoacoustic area of the medulla, including the efferent neurons that innervate the sacculus, the largest division of the inner ear which is considered the major acoustic end organ. The lateral pathway is likely a part of the vocal circuitry that provides temporal information to acoustic afferent and efferent nuclei. Species diversity in pacemaker/command circuitry may underlie species-typical vocal signalling and acoustic recognition. Support from NSF and NIH.

CHAT-IMMUNOREACTIVE COCHLEAR EFFERENT NEURONS IN THE CHICK BRAINSTEM. R.A. Code* and C.E. Carr. Dept. of Zoology, Univ. of Maryland, College Park, MD 20742-4415.

We have studied cholinergic neurons in the chick auditory brainstem using an antiserum to choline acetyl transferase (ChAT), the biosynthetic enzyme for acetylcholine (Code and Carr, '93, ARO abstr. 16: 125). ChAT-immunoreactive (ChAT-I) neurons were found in a ventrolateral and a dorsomedial cell group. The ventrolateral group is a rostrocaudally directed column of cells which surround the superior olive (SO), are ventromedial to the ventral facial nucleus (VIIv), and are lateral to the nucleus pontis lateralis (PL) as far rostrally as the nucleus subceruleus ventralis. Cells in the dorsomedial group were found in the pontine reticular formation medial to the dorsal facial nucleus and lateral to the abducens nerve root.

Because cochlear efferents in the pigeon stain for acetylcholinesterase and efferent terminals in the chick cochlea are morphologically similar to those in the pigeon, we wished to determine which cholinergic neurons in the brainstem project to the chick cochlea. A double-labeling technique was used combining ChAT-I and the retrograde transport of biotinylated dextran amine (BDA) from the inner ear. About 61% of cochlear efferent neurons are located contralateral to the injected cochlea and 39% are ipsilateral. Double-labeled cells were found bilaterally in both the ventrolateral and dorsomedial cell groups, with the exception of large ChAT-I cells dorsal to the SO which do not appear to project to the cochlea. ChAT-I cells that project to the cochlea were classified into three morphological groups: multipolar, elongate and round-to-oval. Both the ventrolateral and dorsomedial cell groups appear to have a mixture of these different cell types. The average somal area of double-labeled cells was 246 mm². Only about 70% of the cochlear efferent neurons, however, are cholinergic.

The ChAT antiserum was kindly provided by Dr. Miles Epstein, University of Wisconsin, Madison. This work was supported by NIDCD grants R03 DC01867 to R.A.C. and DC00436 to C.E.C.

ENHANCED C-FOS GENE EXPRESSION IN THE COCHLEAR NUCLEUS BY SOUND STIMULATION IN CONJUNCTION WITH AN EPINEPHRINE ANALOG. D.E. Hillman*, S. Chen, R. Winicki, R. Giacchi and J. Cousins Dept. Otolaryngology and Physiol./Biophys. NYU Med. Ctr., New York, NY 10016

The proto-oncogene *c-fos* is rapidly and transiently expressed in response to increased neuronal activity following various types of experimental stimulations. In this study, *c-fos* was used as a marker for physiological activity and a test for drug responses. Dipivefrin, an epinephrine analog that crosses the blood-brain barrier, was injected intraperitoneally. The animals were exposed immediately to unfamiliar complex sound (UCS) for two hours at 40-90 dB. Five groups of rats (naive, dipivefrin, UCS, UCS+dipivefrin, and UCS+various dosage of 0.1% dipivefrin ranging from 0.25 mg/kg to 3 mg/kg) were analyzed for *c-fos* gene expression in the cochlear-nucleus complex. The results of quantitative analysis revealed that the number of *c-fos* neurons: 1) increased by 2-fold above basal levels as a result of dipivefrin, 2) increased by 5-fold following UCS as compared to the naive group, 3) was enhanced by dipivefrin to 35% above the UCS group, and 4) followed a linear response dependent on the dosage of dipivefrin. *C-fos* is believed to synthesize proteins that are involved with plasticity and learning. This drug enhances the activation of *c-fos*, and may facilitate learning. Supported by USPHS NS-13742 and AG-09480.

DIVERSE INPUTS TO MULTIPOLAR CELLS AND SMALL CELLS THAT RECEIVE MEDIAL OLIVOCOCHLEAR (MOC) SYNAPSES. T.E. Benson*¹ and M.C. Brown^{2,3,4}. ¹Dept. Biomedical Engineering, Boston University, Boston, MA 02215; ²Depts. Cellular and Molecular Physiology and ³Otology and Laryngology, Harvard Medical School, Boston, MA; ⁴Eaton-Peabody Lab., Mass. Eye and Ear Infirmary, Boston, MA 02114.

Via branches to granule cell regions of the cochlear nucleus, MOC fibers synapse with large dendrites from a class of multipolar cells and with varicose dendrites from "small" cells (Benson and Brown 1990, *J.Comp.Neurol.* 295: 52). What other inputs might these target dendrites receive? To begin answering this question MOC branches labeled by HRP injection in the spiral ganglion were studied by serial electron microscopy to identify labeled terminals, to reconstruct unlabeled target dendrites, and to identify other unlabeled terminals synapsing upon the targets.

The following terminal types were observed to form synapses in 3 mice (134 synapses/10 dendrites): labeled MOC (16%); unlabeled with small round vesicles (44%); unlabeled with large round vesicles (18%); unlabeled with pleomorphic vesicles (16%); unlabeled degenerating terminals (6%). Terminals with small round vesicles may represent additional unlabeled MOC input. Terminals with large round vesicles may be type I primary afferents. Terminals with pleomorphic vesicles suggest an inhibitory input. Judging by their similarity with HRP-labeled type II terminals and the known projection of type II axons into this region, degenerating terminals may be from type II primary afferents severed by the labeling pipette.

These data suggest that MOC targets in the cochlear nucleus may also be driven by auditory nerve input. Furthermore, functional linkage of MOC fibers and type II fibers may be multiple if they both share target dendrites in the cochlear nucleus and contact outer hair cells in the cochlea.

GLYCINE-ERGIC NEURONS IN THE AUDITORY BRAINSTEM OF THE CHICKEN. D.W.F. Schwarz*, I.E. Schwarz and B. Westerberg. Div. Otolaryng. & Dept. Physiol., U.B.C., Vancouver, B.C., Canada.

Retrograde transport of [³H]-glycine was used in an attempt to identify glycine-ergic projection neurons in the auditory brainstem of the chicken. Glycine uptake was enhanced in the central nucleus of the inferior colliculus. Injections there led to retrogradely labeled cells on the ipsilateral side in the ventral nucleus of the lateral lemniscus, in the peripheral region of the oliva superior and in a newly identified nucleus of the trapezoid body. [³H]-glycine also labeled the projection from the inferior colliculus to the thalamic nucleus ovoidalis on both sides as well as the commissural projection to the contralateral inferior colliculus. Injections of [³H]-glycine into the oliva superior led to ipsilateral retrograde labeling in the nucleus of the trapezoid body, a minority of cells in the nucleus angularis, and, surprisingly, the nucleus laminaris. Anterograde label was found in n. magnocellularis ipsilaterally and the contralateral intermediate nucleus of the lateral lemniscus and inferior colliculus.

FOS IS INDUCED BY ACOUSTIC STIMULATION IN LIMITED CELL POPULATIONS. J.C. Adams* Dept. of Otolaryngology, Mass. Eye & Ear Infirmary, Boston, MA 02114.

Unilateral tone bursts at moderate sound levels were used to induce the expression of Fos in auditory brainstem nuclei in urethane anesthetized cats. The numbers of labeled cells and the strength of their labeling was directly related to the stimulus intensity. Using an Oncogene Sciences antibody, bands of labeled cells were found in the ventral and dorsal cochlear nuclei, in the ipsilateral lateral superior olive, and in the contralateral inferior colliculus. The band of labeled cells in the colliculus continued across nuclear subdivisions from the central nucleus to the dorsal surface. Scattered positive cells were also present in periolivary regions. Counter-staining the immunostained sections for Nissl substance showed that in every region except the lateral nucleus of the trapezoid body, small cells were predominantly labeled. Preliminary results with double immunostaining for Fos and for nerve terminals indicate that in the ventral cochlear nucleus the predominant, if not the exclusive, non-granule cell class that expresses Fos is type 1 stellate cells. This finding indicates that Fos expression can be used as a powerful tool for mapping these cells' locations and for studying their physiology.

Another Fos antibody (UBI) showed similar results only in the cochlear nucleus. An antibody to the product of zif 268 showed similar results in the cochlear nucleus and superior olive. Both these antibodies showed high numbers of positive cells in the colliculus even without sound induction.

GFAP-POSITIVE PROCESSES ARE PARALLEL TO THE TONOTOPIC AXIS IN THE DORSAL COCHLEAR NUCLEUS OF THE PERINATAL HAMSTER. G. Riggs* and L. Schweitzer Dept. of Anatomical Sciences and Neurobiology, Univ. of Louisville School of Medicine, Louisville, KY 40292.

The most salient feature of maturation of the dorsal cochlear nucleus (DCN) is the development of its laminar organization. The laminae are oriented parallel to the surface of the DCN and parallel to the underlying strial fibers. Cells sort into these laminae, axonal inputs distribute within the DCN obeying laminar borders, and developmental markers such as peanut agglutinin are organized with respect to the laminae. In contrast, the tonotopic axis of the nucleus is radial to the brainstem and is, therefore, orthogonal to the laminar axis. In the hamster, during the first postnatal week, cochlear fibers course under the nucleus and, beginning on PND 3, they begin to turn abruptly to grow into the nucleus. Their growth is oriented at right angles to the laminar axis. These radially-directed axons set up the tonotopic map of the nucleus.

With a polyclonal antibody to glial fibrillary acidic protein (GFAP), we have recently demonstrated that the organization of GFAP-positive processes is radial as well. The radial organization is especially visible perinatally, begins to disappear by about PND 4 and gives way to a more disorganized distribution of GFAP-positive processes, typical of the astrocytic label seen in much older animals. GFAP is the first marker we have studied that is distributed with respect to the tonotopic rather than the laminar organization in the nucleus. The radial pattern of GFAP-positive processes is observed at a time during which it could guide axonal ingrowth and early neuronal migration patterns.

GABAergic AND GLYCINEergic PROJECTIONS OF THE AUDITORY MIDBRAIN. K.A. Hutson, K.K. Glendinning, B.N. Baker and R.B. Masterton*. Dept. of Psychology, Florida State Univ., Tallahassee, FL 32306.

Glycine is the major inhibitory transmitter within the auditory hindbrain and, via ascending pathways to the IC, accounts for one source of inhibition at midbrain levels. However, our recent evidence has shown that the chief inhibitory transmitter in the ascending system changes abruptly at the DNLL and IC from glycine to GABA.

Antibodies directed against glycine label fibers and puncta but not cell bodies within the IC and DNLL, while antibodies against GABA label cells throughout the IC and DNLL as well as fibers and puncta. Further, injection of [³H]-glycine into the IC retrogradely labels many cells within the hindbrain but no labeled cells in the contra IC while its injection into MG does not retrogradely label cells in either the ipsi or contra IC. In sharp contrast, injection of [³H]-GABA into the IC retrogradely labels many cells in the contra IC and both DNLLs while its injection into MG vividly labels many cells in the ipsi and some cells in the contra IC.

Thus, the IC may be the last structure along the ascending auditory pathway where glycinergic inhibition directly participates in shaping neuronal responses. At the IC and above, it is Golgi Type I as well as Type II GABAergic neurons that assume the major inhibitory role. Supported by NIH Grant DC00197.

EVIDENCE THAT CERTAIN COCHLEAR NUCLEUS EFFERENTS MAY USE AN EXCITATORY AMINO ACID TRANSMITTER. S.K. Suneja, C.G. Benson, J. Gross and S.J. Potashner*, Department of Anatomy, University Connecticut Health Center, Farmington, CT, 06030.

This study attempts to determine if certain projections ascending from the guinea pig cochlear nucleus could be glutamatergic or aspartatergic. In anesthetized animals, one cochlear nucleus was ablated with multiple radio frequency lesions, using tungsten electrodes. Four days later, the brain stem was excised and cut transversely into 500 μm sections from which samples of the lateral (LSO) and medial superior olive (MSO), medial nucleus of the trapezoid body (MNTB), and ventral nucleus of the lateral lemniscus (VNLL) were punched or microdissected. Tissue samples were incubated with ^3H -D-aspartate before the electrically evoked release of radioactivity was assessed in a superfusion system (Suneja *et al.*, Neurosci. Abs. 18: 1036, 1992). Unilateral cochlear nucleus ablation depressed ^3H -D-aspartate release in the ipsilateral LSO and MSO as well as in the contralateral MSO, MNTB, and VNLL. A small deficit in release also appeared in the contralateral LSO. These findings suggest that the projections ascending from the cochlear nucleus to the LSO, MSO, MNTB and VNLL may use glutamate or aspartate as a transmitter. (Supported by DC00199 from NIH-NIDCD)

TRANSPORT OF EXTRACELLULARLY INJECTED BIOCYTIN AND NEUROBIOTIN IN SUPERIOR OLIVARY TISSUE SLICES. N. Kuwabara* and J.M. Zook, Dept. of Biol. Sci. and OUCOM, Ohio University, Athens, OH 45701.

Previously, we have used *in vitro* intracellular labeling to show extensive interconnections between several major and periolivary cell groups within the mammalian superior olivary complex. Of particular interest were the extensive projections from the medial nucleus of the trapezoid body (MNTB) to the medial superior olive (MSO), as well as the projections from both the MNTB and the MSO to the superior paraolivary nucleus (SPN). In an attempt to establish the extent and distribution of these projections, we made extracellular, focal injections of Biocytin and/or Neurobiotin within the boundaries of individual nuclei of the superior olivary complex in an *in vitro* gerbil brainstem slice preparation.

Iontophoretic or pressure injections of Biocytin or Neurobiotin were made within the MNTB, the MSO, or both cell groups. At the injection site, cell bodies, dendrites and axons were stained in near-Golgi fashion. After MNTB injection, collateral axons and numerous terminal boutons were labeled within the lateral superior olive (LSO), the MSO and the SPN. Projections were more randomly distributed in the SPN than in the LSO. In the LSO, projections were organized in somewhat columnar fashion. After MSO injection, axon terminals were found in the SPN. Preliminary results indicate that the projection from the MNTB to the SPN is larger than the projection from the MSO to the SPN. We are combining local anterograde labeling with retrograde pre-labeling of cells to study relationships between labeled axons and identified post-synaptic cell populations. NEURONS WITH INTRINSIC AXONAL TERMINATIONS IN THE GERBIL'S LATERAL LEMNISCUS. G. P. Tuck, J. M. Zook* and N. Kuwabara, Dept. of Biological Sciences and OUCOM, Ohio University, Athens, OH 45701.

The cell groups of the lateral lemniscus have often been viewed as simple relays of ascending auditory information from the cochlear nuclei and the superior olives to the inferior colliculi. We have begun to intracellularly label lemniscal neurons in a Gerbil brain slice preparation in order to reveal the detailed morphology and interconnections of lemniscal cells.

Our main finding is that all three lemniscal nuclei contain cells with intrinsic axonal terminations. In the dorsal, intermediate and ventral lemniscal nuclei, cells were found with single axons that branched immediately upon leaving the soma. One branch commonly could be traced out of the lateral lemniscus. The other axon branch terminated locally forming small *en passant* and terminal boutons. The results indicate that the nuclei of the lateral lemniscus can not be thought of as simple relays of ascending information. Rather, the local terminations indicate communication between various cells within the lemniscal nuclei and indicate a clear potential for modification or elaboration of information at this level.

Three-Dimensional (3D) Analysis of the Medial Superior Olive (MSO). S. Schreiner, D. L. Oliver*, and T. Ju, Dept. of Anatomy, Univ. of Connecticut Health Center, Farmington, CT 06030-3405.

In the present experiment, we attempt to clarify the relationship between the anatomy of the MSO and its ability to code interaural time differences. We have constructed 3D images of the major nuclei within the superior olivary complex (SOC) and labeled axons which project from the cochlear nucleus to the MSO. Biotin-labelled dextran was injected into the anteroventral cochlear nucleus (CN) in two cats. After ten days, the brain was fixed in formaldehyde, frozen, and cut into either 60, 100, or 150 μm -thick sections. The tissue sections underwent ABC histochemistry and were stained with neutral red. Drawings of the nuclei within the SOC and of the labeled axons projecting from the CN were made with a camera lucida at $\times 25$. Outlines of the SOC nuclei for each section were digitized and edited on an IBM-PC. Then, the data was transferred to a Silicon Graphics computer (310-4DGTX). Custom programs were used to connect the individual sections and display the model.

The reconstructions show the MSO to be a thin, oblong plane, running rostral-caudally, with slight lateral curvatures at both ends. The low-frequency, dorsal part of MSO is long, while the high-frequency, ventral MSO is short. Axons terminate in horizontal bands that may be related to the bandwidth of MSO cells. The symmetry of the projections and the fine structure of the axons as they terminate may reveal mechanisms related to coding for interaural time differences.

GABA AND GLYCINE IMMUNOREACTIVITIES DEFINE PRINCIPAL SUBDIVISIONS OF THE CAT LATERAL LEMNISCAL NUCLEI.

R.L. Saint Marie*, Neuroanatomy Department, House Ear Institute, Los Angeles, CA 90057.

The lateral lemniscal nuclei (NLL) are a major source of ascending projections to the auditory midbrain, second only to the cochlear nuclei in the size of their projections. Traditionally, the NLL have been divided into 3 subdivisions, dorsal (DNLL), intermediate (INLL), and ventral (VNLL), based on differences in cytoarchitecture, response type, and afferent and efferent connections. Although much has been reported about the transmitters of DNLL and VNLL, little is known about INLL. In the present study, immunoreactivities for the transmitters, GABA and glycine, are used to differentiate between the 3 subdivisions of the NLL. DNLL contains mostly large ($\geq 28 \mu\text{m}$, ave diam) and medium-sized (18-27 μm) neurons that are GABA-immunoreactive (GABA⁺) and not glycine⁺. Most of the principal neurons in VNLL are medium-sized and either glycine⁺, GABA⁺, or both. With few exceptions, however, principal neurons in INLL are medium-sized and neither glycine⁺ nor GABA⁺, but are completely encircled by glycine⁺ boutons. The latter is consistent with reports that INLL receives up to 50% of its projections from VNLL and the medial nucleus of the trapezoid body, both of which contain mostly glycine⁺ neurons. Glycine⁺ perisomatic boutons are much less prevalent in DNLL and VNLL, as are GABA⁺ perisomatic boutons in all 3 subdivisions. As defined, the boundaries between the subdivisions are clear and distinct. These observations suggest that neurons in INLL are strongly inhibited by contralaterally driven monaural inputs and, unlike neurons in DNLL and VNLL, probably do not provide inhibitory projections to the auditory midbrain. Supported by NIH grant DC00726.

SUBCELLULAR LOCALIZATION OF THE Kv3.1 POTASSIUM CHANNEL PROTEIN IN THE RAT AUDITORY BRAINSTEM. I.M. Permy*, E. Maloni², P. Eager², J.K. Kaczmarek¹ and J.R. Schwartz², ¹Dept. of Pharmacology or ²Dept. of Surgery/Otolaryngology and Section of Neurobiology, Yale School of Medicine, New Haven, CT 06510.

A polyclonal antibody specific for the Shaw-like Kv3.1 α (Kv4) potassium channel was generated by immunizing rabbits with a synthetic peptide corresponding to the last 15 C-terminal amino acids. Using this antibody, we have demonstrated that the Kv3.1 channel protein is highly enriched in the nuclei of the auditory brain stem where it is found both outlining the cell somata and in the neuropil. We now describe the precise subcellular distribution of this K⁺ channel in the rat auditory system using electron microscopic immunohistochemistry.

A nonhomogeneous distribution of HRP reaction product was observed. As expected, much of the label was seen associated with the cytoplasmic face of the neuronal surface membrane. However, significant patches of reaction product were seen associated with lamellae of ER and sometimes with cisterns of Golgi suggesting that there may be a high turnover rate for the Kv3.1 α protein. Patches of reaction product were also observed in the cell nuclei of some neurons showing cell membrane staining, especially in bushy cells of the VCN. The significance of this finding is not known.

Reaction product associated with cell membranes was most often observed on cell somata, dendritic processes and spines. However, we also observed staining inside presynaptic terminals including the calyces of the end bulbs of Held and sometimes of axonal fibers especially in the molecular layer of DCN. The cell surface labeling was usually found in patches on either side of both pre- and postsynaptic specializations. These results suggest that the Kv3.1 α protein may be preferentially localized near synaptic sites of auditory neurons and may play a role in shaping the fast synaptic transmission seen in auditory pathways.

494.15

COMPARISON OF CALRETININ, PARVALBUMIN AND CALBINDIN STAINING IN AUDITORY NUCLEI OF THE MUSTACHED BAT. M.L. Zettel*, M. Gordon, and W.E. O'Neill. Dept. of Physiology and Prog. in Neuroscience, Univ. of Rochester Sch. of Medicine and Dentistry, Rochester, NY 14642.

There has been much interest in the role of calcium binding proteins as possible intraneuronal calcium buffers. In the auditory system of the echolocating mustached bat such a buffering system could be critical for the response to rapid temporal events. Cross-reactivity among various calcium binding proteins has been questioned. We have examined the staining of antibodies to calretinin (cr) and parvalbumin (pv) and compared it to previously reported calbindin D-28k (cabp) staining.

The cochlear nucleus and the inferior colliculus had similar staining patterns using all three antibodies. Cells of the medial nucleus of the trapezoid body were very darkly stained for cabp and pv, but only some cells were cr+. Calyceal endings were seen with all antibodies. The cells of the lateral superior olive were cabp- and cr-, but were strongly pv+. The medial superior olive contained only a few cabp+ marginal cells, while cr stained all but the most central cells, and pv stained cells throughout. The ventral (columnar) division of the ventral nucleus of the lateral lemniscus (LL) had darkly stained pv+ and cabp+ cells with fine bouton endings. However, only some cells were cr+ and large calyceal endings were prominent. Only cabp stained the granular cap in the intermediate nucleus of LL. The dorsal nucleus of LL was cabp-, partly cr+, and strongly pv+. The medial geniculate was strongly cabp+ and mildly cr+, whereas the supragenulate was negative for both, but strongly pv+. The dorsal division of MGB was especially immunopositive for both cabp and cr, but was pv-. (Supported by NIDCD DC0267)

ACETYLCHOLINESTERASE STAINING IN THE AUDITORY BRAINSTEM OF A SYMMETRICALLY EARED OWL. J.A. Mazer* and M. Konishi, Division of Biology, Caltech, Pasadena, CA 91125

Electrophysiological studies of the symmetrically eared great horned owl, *Bubo virginianus*, have shown that cells in the external nucleus of the inferior colliculus (ICx) have auditory receptive fields restricted in azimuth but not in elevation. This is in contrast to the asymmetrically eared barn owl, *Tyto alba*, which uses ear asymmetry to convert elevation into interaural intensity differences. In the barn owl ICx cells have receptive fields restricted in both azimuth and elevation.

Acetylcholinesterase (AChE) histochemistry in the barn owl has been shown to distinguish two parallel pathways in the brainstem: nuclei that process intensity are AChE positive, while those processing time or azimuthal cues are AChE negative.

Despite the lack of asymmetry, AChE staining in the great horned owl is qualitatively similar to that seen in the barn owl. Both fibers and cell bodies in N. angularis, a cochlear nucleus (CN) primarily involved in encoding intensity information, stain strongly for AChE. In n. magnocellularis (NM), a monoaural CN in the time pathway, fibers show no staining and cell bodies stain only weakly. In n. laminaris, which receives bilateral input from NM, neither fibers nor cell bodies stain for AChE. At the level of the lemniscal nuclei, the posterior portion of n. ventralis lemnisci lateralis (VLVp), part of the intensity pathway, stains for AChE, while the anterior portion (VLVa), part of the time pathway, does not.

At the level of the inferior colliculus (IC), the medial and lateral shells of the central nucleus of IC (ICc) and ICx, those subdivisions which in the barn owl process intensity information, are AChE positive in the great horned owl, while the core region of ICc, which in the barn owl processes only temporal cues, is AChE negative.

Though it is not yet clear how intensity information is used by the great horned owl, it appears that there are two histochemically distinct auditory pathways in the brainstem which are anatomically similar to the two parallel pathways seen both physiologically and histochemically in the brainstem of the barn owl.

SENSORIMOTOR CORTEX: FUNCTIONAL STIMULATION, MODELS, AND BEHAVIOR

495.1

MOTOR CORTEX RESPONSIVENESS TO TRANSCRANIAL MAGNETIC STIMULATION FOLLOWING PERFORMANCE OF A FATIGUING MOTOR TASK

W.B. McKay*, S. Tuel, A.M. Sherwood, M.R. Dimitrijevic
Div. of Restorative Neurology and Human Neurobiology, Baylor College of Medicine, Houston, TX 77030

It is well established that volitional activation of a muscle lowers its threshold for elicitation of a motor evoked potential (MEP) by transcranial magnetic stimulation (TMS) of the motor cortex. However, the effects on MEPs recorded following the performance of a fatiguing exercise are not known. We recorded MEPs through surface EMG electrodes placed over both quadriceps, hamstring, anterior tibial and triceps surae muscles. MEPs were elicited by a 14 cm. diameter coil placed over the scalp vertex before and after the performance of maximal voluntary isometric contraction of one anterior tibial muscle until the force generated decreased to less than 50% of its initial value. To monitor neuromuscular excitability of the exercised anterior tibial muscle, we recorded supramaximal M-waves elicited by electrical peroneal nerve stimulation. In all 5 subjects, MEPs recorded from the exercised muscle dropped to well below pre-exercise control values while the M-wave remained unchanged or increased. MEPs from non-exercised muscles, particularly the contralateral quadriceps and hamstring, showed marked amplitude increases following the isometric dorsiflexion exercise period. These changes in the non-exercised muscle MEPs were short lasting (<1 min.) while the post-exercise depression of the MEP in the exercised anterior tibial muscle lasted from 3 minutes to more than 30 minutes. These results suggest that central and peripheral mechanisms used to generate movement (force) can be studied separately using TMS and peripheral nerve stimulation with appropriate motor task conditioning.

495.3

LARYNGEAL MUSCLE RESPONSES TO TRANSCRANIAL MAGNETIC STIMULATION. C.L. Ludlow*, A. Pascual-Leone, C. Cozens-Hoffman, T. Yamashita and M. Hallett. Voice and Speech Section, VSLLB, NIDCD and Human Motor Control Section, MNB, NINDS, NIH, Bethesda, MD 20892.

Our purpose was to map the right and left cranial regions producing laryngeal muscle responses to transcranial magnetic stimulation in normal right handed adults. A figure 8 coil was used to map all the scalp positions over each hemisphere from which contralateral and ipsilateral muscle responses were obtained in bipolar hooked wire recordings of the thyroarytenoid and cricothyroid laryngeal muscles. Surface recordings of the abductor pollicis brevis (APB) were also used to determine muscle responses. All responses were identified visually and the total area under the curve was computed after subtracting resting activity for the same duration. In contrast with APB for which only contralateral responses were obtained similarly in each hemisphere, both contralateral and ipsilateral laryngeal muscle responses were obtained in most subjects. The ipsilateral and contralateral responses had similar latencies, between 10 and 20 ms. Responses to peripheral stimulation on the neck had earlier latencies and were infrequent using this stimulator. In some subjects, the map of the laryngeal muscles in the left hemisphere extended beyond the margins of representation of the APB. The results suggest variability in the degree of bilateral representation of the laryngeal muscles in each hemisphere in humans, with some subjects having larger regions of representation in the left than in the right hemisphere.

495.2

VARIABILITY OF SINGLE MOTOR UNIT RESPONSES TO TRANSCRANIAL MAGNETIC STIMULATION. J. Qiao and B. Brouwer* Department of Rehabilitation Therapy, Queen's University, Kingston, ON, Canada K7L 3N6.

The intrasubject and population variabilities of responses evoked in tibialis anterior (TA), medial gastrocnemius (MG) and soleus (SOL) motoneurons (MNs) by transcranial magnetic stimulation were examined in 33 normal subjects. A total of 3-7 low threshold motor units were identified and recorded from each subject from a given muscle. The magnitudes of the postsynaptic potentials (PSP) produced in spinal motoneurons were estimated from the changes in firing probability of voluntarily activated single motor units. Short latency facilitations were observed in 54/56 TA MNs, 23/65 MG MNs and 27/66 SOL MNs. The mean estimated PSP amplitude was approximately 3 times greater in TA MNs than that observed in MG or SOL MNs ($p < .001$). Short latency inhibitions were found in 1/56 TA MNs, 4/65 MG MNs, and 2/66 SOL MNs. The remaining motor units (a total of 76 from all muscles) showed no short latency responses, but 87% of these demonstrated longer latency effects. The variability in amplitudes of the short latency effects was high for a given species of MN (coefficients of variation, CV, ranging from 70% (TA) to 208% (MG)). Intrasubject amplitude variability reflected that of the population. TA MNs responded consistently within a given subject (mean CV = 46%) whereas variances were significantly higher for MG (mean CV = 166%; $p < .001$) and SOL (mean CV = 172%; $p < .01$). Variability in the direction of the response (i.e. facilitation, inhibition or no response) contributed strongly to both intrasubject and population variances in response amplitude in MG and SOL MNs. These findings provide insight as to the probability of evoking a response of a given direction and relative amplitude in a specific MN pool. Similarly varied corticospinal effects are exhibited in other primates.

This project was funded by the Botterell Foundation of Queen's University.

495.4

THE EFFECT OF VOLUNTARY CONTRACTION ON CORTICO-CORTICAL INHIBITION IN THE CORTICAL MOTOR AREAS OF MAN. M. Ridding, J. Taylor and J.C. Rothwell*. MRC Human Movement and Balance Unit, Institute of Neurology, Queen Square, London WC1N 3BG, UK.

A single transcranial magnetic stimulus applied on the scalp over the motor area of cortex can evoke EMG responses in contralateral muscles of conscious subjects. If this stimulus is preceded by a smaller conditioning stimulus, the response can be dramatically suppressed if the interval between the stimuli (ISI) is 6ms or less. In an initial set of experiments on 4 subjects we found that the threshold for this effect was $28 \pm 3\%$ (s.e.) less than the intensity needed to produce a response in active muscle. Since conditioning stimuli of this intensity produce no effects on either spinal H-reflexes or responses evoked during activity in the same muscle by low intensity anodal electric stimulation of the motor area, we presume that the effects on the test response occur through cortical mechanisms. In the main set of experiments on 6 subjects, the intensity of the conditioning stimulus was set at 5-10% below threshold for producing an EMG response in active muscle, and the time course of its effect on a subsequent test shock was examined either when the subjects were completely relaxed, or when they made a minimal tonic contraction of the first dorsal interosseous muscle. In order to produce responses of equal size in the two conditions, the intensity of the test shock was slightly larger when subjects were at rest than when they were active. When relaxed, test responses were suppressed by an average of $55 \pm 11\%$ when the ISI was 2, 3 or 4ms. At an ISI of 10 and 15ms the responses were facilitated to $125 \pm 16\%$ of their control value. When subjects activated their muscle, the responses were inhibited by only $21 \pm 12\%$ (paired t-test with relaxed condition, $P < 0.01$) and there was no obvious excitatory phase at 10 and 15ms ($78 \pm 5\%$ ($P < 0.005$)). These results suggest that cortical circuits which mediate inhibition at rest are suppressed during voluntary activity of the target muscle.

495.5

INHIBITION AND EXCITATION OF THENAR MUSCLES TO TRANSCRANIAL MAGNETIC STIMULATION DURING VOLUNTARY CONTRACTION IN CERVICAL SPINAL CORD INJURY PATIENTS. P.H. Ellaway*, N.J. Davey and D.W. Maskill. Dept. of Physiology, Charing Cross and Westminster Medical School, LONDON W6 8RF, UK

Electromyographic responses of thenar muscles to transcranial magnetic stimulation (TMS) of the motor cortex were recorded in patients with incomplete lesions of the spinal cord at the cervical level. During weak voluntary contraction we measured the threshold and latency for excitation, and for inhibition in the absence of preceding excitation, in response to TMS. As in normal man (Davey et al. 1992 J. Physiol. 446:447P) the inhibition had a lower threshold than excitation. On average, threshold (percentage maximum stimulator output) for inhibition in patients (44 ± 6 , mean \pm S.D., $n=6$) was greater than in control subjects (26 ± 3.5 , $n=6$). Threshold for excitation was also greater in patients (58 ± 13.5 , $n=8$) than in controls (33 ± 6 , $n=6$). In all patients, the latency of inhibition was longer ($40-66.5$ ms, $n=6$) than in controls ($28.5-34.5$ ms, $n=6$). However, the latency for excitation in patients ($22-45$ ms, $n=8$) was greater than for controls ($23-28$ ms, $n=6$) in only 3 cases. Since the thenar muscles were active under voluntary drive it is likely that the differences seen in spinal injury reflect changes at the level of the motor cortex. We thank patients and staff at the National Spinal Injuries Centre, Stoke Mandeville, UK.

495.7

THE RELATIVE TIMING OF MOTOR EVOKED RESPONSES (MEPS) TO TRANSCRANIAL MAGNETIC STIMULATION (TMS) IN CONTRALATERAL AND IPSILATERAL HUMAN MUSCLES. E. M. Wassermann*, A. Pascual-Leone and M. Hallett. Human Motor Control Section, National Institute of Neurological Disorders and Stroke, NIH, Bethesda, MD 20892

TMS can produce MEPS in voluntarily activated ipsilateral, as well as contralateral, muscles. It is not known how the ipsilateral MEPS are conducted or whether the same pathways serve proximal and distal ipsilateral muscles.

In 2 normal subjects, we stimulated the optimal scalp positions for producing MEPS in the ipsilateral and contralateral first dorsal interosseous (FDI) and deltoid muscles during activation of the ipsilateral muscles and made 10 trial averages of MEPS.

Responses in the contralateral muscles were always earlier. The difference in latency between the ipsilateral and contralateral MEPS in the FDI was 6.5 ms in subject 1, and 4.5 ms in subject 2. In the deltoid, the latency difference was 3.5ms in subject 1 and 0 ms in subject 2.

Contralateral MEPS in all muscles are thought to be conducted by fast axons in the corticospinal tract. Ipsilateral MEPS in distal and proximal muscles appear to be conducted by different pathways. The pathway for proximal muscles may be recruited faster by TMS or contain faster-conducting axons or fewer synapses.

495.9

MOTOR CONTROL AND GAIT PERFORMANCE IN CHRONIC INCOMPLETE SPINAL CORD INJURED PERSONS.

S.F.T. Tang, M.M. Dimitrijevic, S.M. Tuel, M.R. Dimitrijevic. Div. of Restorative Neurology, Baylor College of Med., Houston, TX. 77030
Neurocontrol of movement following spinal cord injury (SCI) is often spared, but few studies have investigated the chronic incomplete SCI patient. Brain motor control assessment, a multi-channel surface electromyography (SEMG) recording that through a series of volitional and reflex events provides a profile that describes characteristics of neurocontrol. The relationship of these neurocontrol characteristics to clinical function is as yet incompletely described. This study retrospectively evaluated the relationship between neurocontrol patterns in the supine position and ambulation ability. The records of 15 neurologically healthy (9 male; 6 female) and 36 incomplete SCI persons (27 male; 9 female) (C2-T10) were used. SEMG was recorded from both quadriceps, hamstrings, anterior tibialis and triceps surae muscles and displayed on a stripchart for analysis. Patterns of activity recorded in the supine position during volitional, unilateral, multi-joint (hip and knee flexion and extension) movement attempts were characterized, divided into 7 groups, and compared to the subjects' ambulatory capabilities (independent, cane, crutches, walker or nonambulatory). The neurocontrol patterns recorded in the supine position correlated well with the SCI subjects ambulatory capabilities. Marked decreases in motor unit output and/or loss of motor organization were found in the nonambulatory group. Coactivation of proximal muscles, poor timing of muscle activity, and radiation of activity into contralateral muscles were also noted in subjects who required a walker or crutches. To a lesser degree, abnormal motor patterns were also noted in subjects who ambulated with a cane or independently.

495.6

MOTOR EFFECTS OF FRONTAL AND CINGULATE STIMULATION IN HUMANS. F. Richer*, M. Robert, G. Bouvier, J.M. St-Hilaire. Dept. Neurologie, Hôpital Notre-Dame, Montreal, Que. Canada, H2L-4M1.

Motor phenomena were evoked by stimulation of frontal and cingulate regions in epileptic patients undergoing a presurgical investigation with chronic intracerebral electrodes. An incremental sequence of bipolar stimulation trains was delivered at each of 327 sites in 96 patients through horizontal multicontact electrodes while monitoring stimulus afterdischarge propagation at frontal and temporal sites. Stimulation of medial regions evoked movements more frequently than lateral stimulation. In the supplementary motor area, the phenomena evoked included contralateral head and/or eye deviations, and contralateral or bilateral arm movements. In the anterior cingulate, evoked phenomena included movements of the mouth, of the eyelids, and of the ipsilateral arm, whereas in the posterior cingulate, stimulation evoked bilateral movements of the legs or arms. In lateral premotor cortex, stimulation dorsal to the inferior frontal gyrus evoked movements of the contralateral hand or mouth. The results agree with evidence from non-human primates of multiple motor areas in frontal and cingulate cortex.

CUTANEOUS AFFERENT CONDITIONING OF MEPS FOLLOWING TRANSCRANIAL MAGNETIC STIMULATION OF MOTOR CORTEX. D.L. Wolfe and K.C. Hayes, Neuroscience Prog., U. of Western Ontario, London, Ont., Canada, N6A 5C2.

Conditioning of motor evoked potentials (MEPs) by a preceding afferent stimulation has previously been shown to be helpful in detection of corticospinal input compromised by spinal injury. In the present investigation we electrically stimulated the sural nerve (20 ms train - 500 Hz - 0.1 ms pulse width) of normal human subjects at 5 x sensory threshold and at varying time intervals prior to cortical stimulation. The purpose was to determine if stimulation of a purely cutaneous nerve in the lower limb resulted in a pattern of MEP modulation in the ipsilateral tibialis anterior similar to that seen with conditioning a nerve with both proprioceptive and cutaneous fibers. Condition-test (C-T) intervals from 0 to 150 ms were employed randomly and compared to control unconditioned MEPS. Two separate phases of MEP facilitation were evident at C-T:20-30 ms and C-T:60-140 ms. The time course of the later facilitation was similar to that we have previously reported following conditioning of the medial plantar nerve (combined cutaneous and proprioceptive). This result suggests that in the lower limb stimulation of cutaneous (and/or nociceptive) afferents per se results in MEP amplitude modulation. These observations contrast with earlier reports that cutaneous afferent stimulation does not facilitate MEPS evoked in the upper limb and may reflect a differential organization of afferent inputs between the upper and lower limbs in man.

UNCOUPLING OF SPATIAL CHARACTERISTICS IN CALLOSOTOMY PATIENTS DURING A BIMANUAL TASK. J.C. Ellassen¹, E.A. Franz², R.B. Ivry², A.P. Shimamura² and M.S. Gazzaniga¹. ¹Center for Neuroscience, University of California, Davis, CA 95616 and ²Department of Psychology, University of California, Berkeley, CA 94720.

Studies of normal subjects have revealed spatial and temporal coupling between the limbs in bimanual tasks. The present study examined the possibility that spatial coupling (both movement amplitude and direction) results from communication between the two cortical hemispheres via the corpus callosum. Two split brain patients and two normals were tested on a bimanual drawing task. Subjects were seated in front of a video monitor and fixated a center point. Stimuli were presented 3 degrees or more from fixation, unilaterally or bilaterally, for 150 ms to assure lateralization in the callosotomy patients. The basic stimulus was a three segment figure equivalent to three sides of a rectangle opening up, down, right, or left. Subjects were instructed to draw the stimuli at a preferred pace without visual feedback. Subjects were videotaped (60 Hz) and data were recorded analog on two drawing tablets (78Hz). For bilateral presentation subjects were instructed to begin drawing with the two limbs simultaneously. Qualitative and quantitative analyses indicated that normal subjects exhibited greater accommodation of amplitude and direction between the two limbs than the patients. Displacement profiles of normals revealed larger temporal pauses between segments of the movements, which is taken as evidence of a strategy to overcome bimanual spatial coupling effects. One callosotomy patient exhibited no such pausing strategy while the other did on some trials. These results suggest that the spatial characteristics of amplitude and direction are coupled via the corpus callosum. Supported by NIH/NINDS P01 NS17778-11 and the McDonnell-Pew Foundation.

PREDICTING SYNAPTIC WEIGHT PATTERNS FROM SENSORIMOTOR COORDINATE TRANSFORMATIONS RELATED TO POPULATION CODING OF MOVEMENT DIRECTION IN MOTOR CORTEX. Gyöngyi Gaál* and John P. Donoghue, Dept of Neuroscience, Brown University, Providence, RI 02912

We compared four population coding algorithms to reconstruct stimuli in neural coordinate systems defined by preferred response vectors of neurons (such as receptive field profiles for sensory areas or preferred directions for motor areas, Gaál, Neural Networks, 1993a; J Theor Biol, 1993b). One such algorithm was designed by Georgopoulos et al. (1988, J Neurosci). Another was derived from the tensor network theory (Pellionisz & Llinas, 1979, Neurosci). A third was inspired by an iterative network using feedforward-feedback connections (Daugman 1988, IEEE Trans ASSP) for image compression and reconstruction. We tested also a fourth algorithm, a non-vectorial, non-linear mapping to estimate movement direction from responses of simulated neurons (Gaál 1993b). We show that each algorithm, although equally plausible in computer simulations, provide different predictions for the functional architecture of the coding network. In the temporal domain, the population coding algorithms are capable not only of stimulus reconstruction but also of short-term prediction. Georgopoulos et al. (1993, Science) reported experimental results that are consistent with our predictions regarding the neural implementation of their population code to estimate the direction of arm movement from responses of directionally tuned motor cortical neurons. They found that the angle between preferred directions of pairs of neurons and the synaptic strength of their interconnections are negatively correlated. In contrast, the synaptic weight patterns found by Fetz (1992, Brain Behav Sci) for neurons nearer to motor output might seem to be counterintuitive: neurons with similar response properties can also inhibit one another, while neurons with dissimilar responses can excite each other. We will show how such connection patterns might be interpreted in terms of sensorimotor transformations as the Jacobian matrix of transformations between different coordinate systems. We will also demonstrate that cells with nonlinear responses (e.g. complex cells in visual cortex) might calculate invariants that are independent of coordinate systems. Supported by Grant NS 25074

A NETWORK MODEL OF DIRECTION TUNING AND MENTAL ROTATION. S. J. Lee* and D. Zipser, Department of Cognitive Science, UC San Diego, La Jolla, CA 92093

Many neurons in the arm region of monkey primary motor cortex are tuned to the 3D direction of reaching. The tuning of these neurons is sensitive to the location of the starting point for a reaching movement, but the population vector calculated over all tuned neurons always indicates the direction of motion. Most interestingly, if the animal has been trained to reach in a direction rotated from that of a visual target, the direction of the population vector rapidly rotates from the target direction to the actual movement direction (Georgopoulos et al, Science, 243:234-236, 1989). To account for starting position dependent direction tuning, we assume that M1 receives ongoing afferent information about both current and target hand position, and continuously computes a transformation to the motion direction that will bring the hand to the target. To account for the observations about mental rotation we hypothesize that the motor cortex initially gets afferent location information from the visual target, and then gets afferent information about the location of the rotated target from some other brain area that has learned to associate visual with rotated targets. Under our assumptions, the observed rotation of the population vector then comes from the inherent dynamics of M1 provided with two successive target locations, one from vision and one internally generated from associative memory. To test the consistency of these assumptions, a computational model of M1 was generated by training a fully recurrent neural network to continuously track a moving target. Network inputs consisted of current and target hand positions, encoded as two sets of arm joint angles. Network output indicates the direction required to bring the hand to the target. Since the network was recurrent and the training task continuous, the model of M1 developed its own internal dynamics. When tested on simulations of physiological experiments, the hidden unit and population vector behavior matched the starting position dependent, 3D directional tuning of cortical neurons and their population vectors. In simulated mental rotation experiments in which the visual and rotated target positions were successively presented to the model, the population vector rotated with dynamics similar to those observed experimentally.

DIFFERENT REACHING BEHAVIOR IN RATS WITH MOTOR AND SOMATOSENSORY CORTEX LESIONS. M. Saling,* T. Sitarova, M. R. Dimitrijevic. Inst. Norm. Pathol. Physiol., Bratislava, Slovakia, Restorative Neurology and Human Neurobiology, Baylor College of Medicine, Houston, TX.

Selective lesions of sensorimotor cortex in rats result in specific impairment of reaching task. The aim of presented work was to analyze the effect of discrete cortical lesions on reaching behavior in different reaching task. Reaching for food pellet into the tube and through the grid was studied in the rats with bilateral motor - MCL (AP 0.5-3mm, L 1.5-3.5mm) and somatosensory - SCL (AP -1-1mm, L 3-4.5mm) cortex lesions over a prolonged recovery period. Continuous recording of movement based on magnetic induction was used to monitor reaching. The success of reaching was quantified. Reaching attempts (mainly into the tube) in rats with MCL were accompanied by "copying" movements of non-reaching forepaw. With recovery the "copying" movements were less expressed in reaching into the tube and disappeared in reaching through the grid. Permanent significant decrease of successfulness in rats with MCL was observed only in reaching into the tube. In rats with SCL the modulation of ongoing reaching execution by information about grasping pellet were lost. Loss of tactile information related to the grasping was substituted by "anticipatory reaching behavior". The successfulness of reaching was persistently decreased in both reaching tasks. The results showed that the lesions resulted in different behavioral reactions.

MODELING PERISPIKE FEATURES IN SPIKE TRIGGERED AVERAGES OF RECTIFIED EMG ACTIVITY. B. I. McKiernan* and P. D. Cheney. Dept. of Physiology and Smith Mental Retardation Research Center, Univ. of Kansas Med. Ctr., Kansas City, KS 66160.

Spike triggered averaging (STA) of rectified EMG activity has proven to be an effective means of identifying cortical and red nucleus neurons that are synaptically coupled to motoneurons (Cheney et al., Prog. Brain Res. 87: 213, 1991). Most STAs have one prominent peak corresponding to a transient period of postspike facilitation (PSF). In addition to the primary peak, STAs often exhibit additional secondary features that straddle the primary peak. One such feature is a trough, or period of low average EMG activity, that precedes and follows the primary PSF peak. The purpose of this study was to investigate the factors contributing to the production of troughs in STAs. A computer controlled premotor cell spike was used to evoke a discharge in one of many motor units contributing to the EMG record. The model enabled manipulation of several parameters including: 1) the probability that a premotor cell spike would evoke a discharge in a motoneuron, 2) the repetitive firing characteristics of the premotor cells, 3) the number of motor units in the EMG recording, 4) the fraction of recorded motor units coupled to the premotor cell, 5) the repetitive firing characteristics of the motor units, and 6) background noise levels. Repetitive firing characteristics of the premotor cells were quantified by computing autocorrelograms and interspike interval histograms. Results from the model show that the troughs straddling PSF peaks in spike triggered averages of EMG activity are linked to troughs in the autocorrelogram of the trigger cell which result from the cell's refractory period. In conclusion, a simple model is presented that exhibits many of the features evident in spike triggered averages of EMG activity. Supported by NIH grant NS25646.

A LESION IN PRIMARY MOTOR CORTEX CAUSES WRIST MOVEMENTS TO BE MISDIRECTED. D. S. Hoffman* and P. L. Strick, Research Service, VAMC and Depts. of Neurosurgery and Physiology, SUNY-HSC, Syracuse, NY 13210.

We removed the contralateral arm area of primary motor cortex (M1) in a primate trained to make rapid wrist movements in 8-16 different directions. Prior to the lesion, the animal's movements were smooth and nearly straight in all directions. Five months after the lesion, the monkey's wrist movements remained markedly slowed, more curved and more variable than prelesion movements. Most remarkably, the monkey "tacked" to reach some targets; that is, movements to these targets were made using a zig-zag trajectory with 1-2 sharp changes in direction. Thus, in the absence of M1, it appears that some directions of wrist movement are inaccessible to the animal. EMG recordings using intramuscular electrodes showed that alternating agonist and antagonist bursts were not present in single forearm muscles after the lesion. The absence of these bursts is the likely cause of the decrease in movement velocity. The spatial patterning of agonist muscle activity also was markedly altered. Wrist muscles were more narrowly tuned after the lesion, and movements in each direction were performed by activating fewer muscles. We conclude that M1 contributes to the broad tuning of muscles and thereby provides fine control of movement direction by grading muscle synergies. Supported by VA Medical Research Service.

ROLE OF THE VENTROLATERAL ORBITAL CORTEX IN SPATIAL LEARNING IN THE RAT. J. V. Corwin*, M. Fussinger, R. C. Meyer, V. R. King, and R. L. Reep. Depts. of Psychology, Northern Illinois University, DeKalb, IL 60115; and Univ. of Wisconsin, Madison, WI 53706; and Dept. of Physiol. Sciences, Univ. of Florida, Gainesville, FL 32610.

Our previous research has indicated that the posterior parietal (PPC), medial agranular (AGM), and ventrolateral orbital (VLO) cortices form part of an interconnected cortical network for spatial orientation. Unilateral destruction of each of these areas produces severe multimodal neglect. In learning tasks bilateral destruction of the PPC or AGM produces dissociable deficits for allocentric and egocentric spatial learning respectively. However, the role of the VLO in spatial learning has not been directly examined. Therefore, the present studies directly examined the effects of bilateral VLO destruction on performance in allocentric and egocentric spatial tasks.

The effects of bilateral VLO destruction were examined in two spatial contexts, a cheese board task (allocentric, n=23) in which a food reward is kept in a constant location relative to extramaze cues and in an adjacent-arm maze (egocentric, n=23) in which the location of a food reward varies depending on the subjects' location in space. Three surgical groups were examined in each task: a Sham group, a VLO group, and a group which experienced equivalent destruction of the laterally adjacent lateral orbital cortex (LO) which has a different pattern of connectivity than the VLO.

The results indicated that the VLO operates were significantly impaired in the acquisition of the cheese board (allocentric) task relative to both the Sham and LO groups. In the adjacent-arm (egocentric) maze the VLO group was not impaired relative to the Sham group, and was superior to the LO group. The LO and Sham groups did not differ in either task. The results suggest that the VLO is involved in allocentric spatial processing and support the contention that the PPC, AGM, and the VLO form part of the cortical circuitry for the processing of space in rodents.

- MAGNETIC SOURCE IMAGING FOR PRESURGICAL LOCALIZATION OF FUNCTIONAL CORTEX • CC.**
Gallen*, B.J. Schwartz, H. Tung, B. Copeland. The Scripps Research Institute, La Jolla, CA 92037.
- Five patients with mass lesions near eloquent cortex were measured with Magnetic Source Imaging (MSI) preoperatively, and results were compared with intraoperative electrocorticography (ECoG). A Magnes™ 37-channel Biomagnetometer recorded evoked somatosensory fields, with functional localizations overlaid on MR slices. Localizations were depicted on the surface of a 3D reconstruction of the brain based on MR, complete with vascular landmarks derived from MR angiography. Accuracy of MSI was assessed against ECoG results: discrepancy was typically within several mm. MSI has potential utility in planning and facilitating intraoperative procedures, and may in some cases help in the selection of craniotomy and surgical approach.

ANALYSIS OF MOTOR AND PREMOTOR REGIONS IN HUMANS STUDIED ACROSS MULTIPLE PET EXPERIMENTS.
H. Van Mier*, M. Corbetta, J.A. Fiez, F.M. Miezin, R.L. Buckner, M.E. Raichle and S.E. Petersen. Washington University, School of Medicine, Box 8111, St. Louis, MO 63110.

PET activation studies produce large amounts of information that might be beneficial beyond the original intentions of a single experiment. To examine the consistency of active regions across different conditions and subject groups, an analysis of activation foci was performed using eight groups of subjects (three keypress groups, and five verbal response groups) in 36 conditions (19 keypress and 17 verbal). Foci of activation along the central sulcus and in adjacent areas of frontal cortex were identified using a computer search algorithm and statistical screens. Extending from the medial surface to the operculum, several clusters were identified: 1) along the central sulcus that probably represent primary motor cortex (M1); 2) along the midline surface of the frontal cortex consistent with supplementary motor area (SMA); 3) anterior to M1 consistent with a localization to premotor regions; and 4) along the frontal operculum that is possibly in areas 44/45. In primary motor cortex, SMA, and premotor cortex, the localizations of the verbal and keypress activations were statistically distinguishable from each other consistent with somatotopic representation. While significant, the somatotopic organization was less straightforward in the opercular region, and appears to form more than one representation. These results show, that despite reports of significant intersubject variability in human cortical anatomy, central tendencies are strong enough to do analyses across subject groups and tasks. Such analyses are useful for guiding more targeted within-subjects experimental designs.

MAGNETIC FIELDS IN THE CEREBRAL CORTEX ASSOCIATED WITH VISUALLY INITIATED FINGER MOVEMENTS IN HUMAN SUBJECTS.
A. Nambu¹*, R. Matsuzaki¹, H. Gemba² and K. Sasaki¹. ¹Dept. of Integrative Physiology, National Institute for Physiological Sciences, Okazaki 444, Japan and ²Dept. of Integrative Brain Science, Fac. of Medicine, Kyoto Univ., Kyoto 606, Japan

Magnetic and electric fields were recorded simultaneously over the scalp by using a 37-channel first-order SQUID gradiometer system (BTi, CA) while subjects performed flexion of a unilateral index finger in reaction to visual cue stimuli. Two components of magnetic field change were observed over the contralateral scalp to the index finger. The first component which reversed its polarity between the medial and lateral parts of the scalp preceded the onset of movements. This component reached the peak amplitude of 100-200 fT immediately prior to EMG onset. The second component which reversed its polarity in the direction opposite to the first one followed the onset of movements. The estimated current dipole of the first component was directed anteriorly around the central sulcus. This implies the existence of intracellular current flow directed from the surface to the depth of the anterior bank of the central sulcus. This component appears to represent the activation of the hand area of the motor cortex through the cerebello-thalamo-cortical pathway as reported in monkeys (Sasaki, Gemba and Mizuno, Exp. Brain Res., 1982, 46: 29-36). The estimated current dipole of the second component was in the opposite direction and located slightly posterior and lateral to that of the first component, representing the activation of the somatosensory cortex. When the subjects performed unilateral toe movements in reaction to visual cue stimuli, current dipoles were estimated at the midline, which suggests the activation of the foot areas of the motor and somatosensory cortices respectively.

HUMAN FRONTAL MOTOR CORTICAL AREAS RELATED TO MOTOR PERFORMANCE AND MENTAL IMAGERY USING MAGNETIC RESONANCE IMAGING. IN **Sanes***, CE. Stern, JR. Baker, KK. Kwong, JP. Donoghue, BR. Rosen Department of Neuroscience, Brown University, Providence, RI 02912 and MGH-NMR Center and Harvard Medical School, Charlestown, MA 02129.

Previous studies in humans indicated that imagery of sequential movements uniquely activated non-primary cortical motor fields. By contrast, studies in monkeys indicated that mental rotation before performance of simple movements activated neurons in primary motor cortex. We hypothesized that human non-primary and primary motor cortical fields are distinguishable during actual or imagined simple, repetitive movements by physiological activation patterns obtained by functional magnetic resonance imaging (fMRI).

Normal humans rested, performed index finger movements in a square-like form, or imagined performing the finger movements, each for 1 min and with the eyes closed. In other experiments, subjects fixated a spot and rested or performed or imagined performing index finger movements. High-speed, echo-planar fMRI techniques measured the paramagnetic state of deoxyhemoglobin every 3 sec during each behavioral condition across 14-20 brain slices (7 mm thick) roughly aligned with the plane of the central sulcus.

Several brain areas contralateral and ipsilateral to the moving finger showed enhanced activation during selective periods of the motor task. At the level of the central sulcus, regions contralateral to the moved finger exhibited enhanced activation during motor performance. These regions were consistent with the primary motor, premotor, and cingulate cortex. More rostral extensions of sites in the premotor and cingulate cortex active only during motor performance showed enhanced activation during both actual and imagined motor performance. As yet, no frontal sites have been identified that exhibit enhanced activation only during motor imagery.

These data suggest that premotor and cingulate motor areas have a greater role in higher order processing related to motor actions compared to the primary motor cortex. However, there may be segregation of function within non-primary motor areas. (Support: AG10634, McDonnell-Pew Foundation, MH50054, NS25074.)

AN MRI STUDY OF THE SUPERIOR TEMPORAL SURFACE IN MONOZYGOTIC TWINS DISCORDANT FOR SCHIZOPHRENIA AND IN HEALTHY TWINS. K. Vlodar*, J.J. Kulynych, D. W. Jones, E. F. Torrey and D. R. Weinberger. Clinical Brain Disorders Branch, IRP, NIMH, Neuroscience Center at St. Elizabeths, Washington, DC 20032

The superior surface of the temporal lobe consists of language related areas, including the transverse temporal gyrus of Heschl (HG) and the planum temporale (PT). The PT commonly exhibits asymmetry, the left side being larger than the right. Recent MRI studies of the PT reported the loss of this asymmetry in schizophrenia (Rossi et al., 1990). Moreover, Crow proposed that "schizophrenia is a disorder of the genetic mechanism to control the development of cerebral asymmetry" (Crow et al., 1989). We conducted an MRI study of the PT and HG of 8 pairs of right handed monozygotic (MZ) twins discordant for schizophrenia and of 10 healthy right handed MZ twin pairs. Using sagittal volume MRI (1.5 mm contiguous slices) we created 3-dimensional surface renderings of the supratemporal plane. The HG and PT area measurements were made on these renderings. 3-way ANOVA using diagnosis (healthy vs. unaffected vs. affected) and gender (male vs. female) as between group factors and side (right vs. left) as a repeated measure showed no significant main effects of the between factors and a significant diagnosis by gender by side interaction ($p < 0.03$). Post hoc tests revealed no significant pairwise comparisons. In a separate analysis of the healthy twin pairs by 2-way ANOVA (gender as between factor and side as repeated measure) a significant gender by side interaction ($p < 0.03$) was found. Post hoc comparison demonstrated a trend in the males ($p < 0.07$) towards PT asymmetry, the left side being larger than the right, and no such tendency in the females ($p > 0.98$). Similar ANOVAs indicated no significant effects of group or side and no interactions in any comparison of the HG areas. Our measurements of the supratemporal structures do not support theories linking schizophrenia to genetically determined asymmetries.

A SPATIAL FILTERING MODEL FOR COMPARISON OF THE FORWARD AND INVERSE PROBLEMS FOR THE ELECTROENCEPHALOGRAPH AND THE MAGNETOENCEPHALOGRAPH.
J. P. Wikswo, Jr.*, R. S. Wijesinghe and L. A. Bradshaw. Living State Physics Group, Vanderbilt University, Nashville, TN 37235.

Current sources in the brain produce magnetic and electric fields. Using a volume conductor model based upon a spatial filtering technique, we simulate measurement of the electroencephalogram (EEG) and the magnetoencephalogram (MEG) by calculating the electric and magnetic fields produced by current sources in the cortex. We examine the effects of skull and scalp geometry and conductivity on the EEG and the MEG. Spatial filters allow easy visualization of the effects of volume conduction on the signals. The inverse calculations then give an estimate of the original current source distribution from the EEG and the MEG, and we can consider the effects of noisy signals on current source estimation. By inward-continuing the fields, we can examine the effects of noise, source depth and spatial separation of measurements on imaging and localizing resolution.

We find that the inverse filter functions act as high-pass amplifiers and lead to instabilities at high spatial frequencies. Windowing the functions can reduce the instability, but may also reduce spatial resolution and signal-to-noise ratio. We can easily visualize the sensitivity of the spatial filters to errors in the choice of parameters by comparing them with actual spatial filters.

NARROW-BAND OSCILLATORY ACTIVITY IN THE HUMAN MOTOR SYSTEM. R. Kristeva, B. Feige, S. Makeig¹ and T. Elbert Inst. Exp. Audiology, Kardinal von Galen Ring 10, 4400-Münster, Germany; 1 - Naval Health Research Center, San Diego, CA 92186, USA; SPON: European Brain and Behaviour Society

Changes in spectral power associated with a motor task requiring a high level of sensorimotor integration (SMI) were investigated by analyzing spontaneous neuromagnetic activity during motor preparation (WAIT), SMI, and control conditions in four healthy, right-handed subjects. In the SMI condition, subjects attempted to rapidly identify four different plastic figures by touch. Periods in which subjects were waiting for instruction to begin SMI (WAIT) were compared with periods of task performance (SMI). As a cross-check, 'eyes closed' and 'eyes open' conditions with no manual task were also recorded.

Neuromagnetic fields were observed over the left sensorimotor cortex using a 37-channel first-order gradiometer. A total of 60 to 100 artefact-free periods (3-10 s length) per subject were analyzed in each condition.

Results showed a narrow-band rhythm at about 19 Hz which was prominent during the WAIT state in all four subjects, but was absent during SMI and no-task conditions. This rhythm thus appears to be a "motor preparation rhythm" of the brain.

During SMI only, high-frequency activity at 28-30 Hz occurred in one of the four subjects, suggesting that narrow-band gamma activity may accompany SMI in humans, but is not obligatory for coding of information in the human motor system.

REGIONAL CEREBRAL BLOOD FLOW CHANGES DURING CONDITIONAL MOTOR LEARNING IN THE HUMAN MOTOR CORTEX. A.R. Mitz*, S.P. Wise and T.A. Zeffiro. Lab. Neurophysiol., NIMH, Poolesville, MD and Medical Neurology Branch, NINDS, NIH, Bethesda, MD.

Neurons in the dorsal premotor area (PMd) of monkeys significantly change their task-related activity during conditional motor learning (Mitz et al. *J. Neurosci.* 11:1855;1991). In this study, we measured regional cerebral blood flow (rCBF) with positron emission tomography while 8 normal human subjects learned a conditional motor task. We used bolus injections of H_2O^{15} , and each subject was scanned in 3 task conditions: (1) a movement control task, (2) a conditional motor task (CMT), and (3) a sensory control task. In task 1, the subjects moved a joystick in 1 of 4 directions as instructed by an arrow, which pointed in the correct movement direction. In task 2, the CMT, the subjects learned by trial and error which 1 of the same 4 movements was instructed by a colored geometric form (e.g., a red circle). Feedback was provided at the end of each trial: a green spot indicated correct performance. In task 3, the subjects were instructed simply to view the same stimuli. Scans were obtained every 10 min for a total of 40 min during the CMT. All subjects performed at >75% correct by the first CMT scan, but averaged only ~25% correct (chance level) during the last scan. After stereotaxic normalization, statistical parametric maps were generated by making planned comparisons of task and control conditions. Whereas movement-related rCBF increases (task 1 vs. 3 and task 2 vs. 3) were seen in the primary motor cortex (M1) and anterior cerebellum, the strongest learning-related increases (task 2 vs. 1) were observed in PMd and in one or more cingulate motor areas (CMA) ventral to the supplementary motor cortex. In both PMd and CMA, these learning-related rCBF increases were inversely correlated with task performance. These results further support PMd's role in the mediation of conditional motor behavior and suggest an important role for CMA, as well.

EEG-BASED BRAIN-COMPUTER INTERFACE: ON-LINE METHODS FOR IMPROVING FREQUENCY RESOLUTION. D.J. McFarland*, L. McCane, T. Lefkowitz, and J.R. Wolpaw. Wadsworth Labs, NYSDOH/SUNY, Albany, NY 12201.

Individuals can learn to control the amplitude of 8-12 Hz mu rhythm activity in the EEG recorded over sensorimotor cortex and use it to move a cursor to a target on a video screen (Electroenceph clin Neurophysiol 78:252-259, 1991). Up to the present, mu rhythm amplitude has been assessed by Fourier analysis of successive time segments, which necessitates a trade-off between resolution in frequency and resolution in time.

In order to improve accuracy and rapidity of cursor control, we are exploring methods for improving frequency resolution while maintaining a close temporal relationship between EEG activity and cursor movement. Better frequency resolution is needed to distinguish between mu rhythm components, and good time resolution is needed to minimize delay between mu rhythm amplitude and cursor movement.

One method for improving frequency resolution without corresponding increase in delay is to apply Fourier analysis to overlapping, rather than successive, time segments. To date, we have implemented this method in 6 subjects. For example, analysis of half-second segments at 8 Hz provides 2 Hz frequency resolution and 8 cursor movements/sec. We are also implementing an autoregressive frequency analysis algorithm. In combination with greater topographic resolution, these methods should support improved two-dimensional cursor control.

ANALYSIS OF MOTOR FUNCTION BY MEG, fMRI AND TMS.

J.D. Lewine*¹, J.A. Sanders¹, J.S. George², B.S. Astur¹ and W.W. Orison¹. ¹MSI Facility, VAMC, 2100 Ridgecrest Drive, SE, Albuquerque, NM 87108; ²Mail Stop M715, Los Alamos National Laboratory, Los Alamos, NM 87545.

The ability to noninvasively map human motor cortex could be of particular utility in preoperative planning of neurosurgical interventions in patients with tumors or vascular malformations in the vicinity of the central sulcus. Several different biomagnetic techniques offer promise in this regard. These techniques include magnetoencephalography (MEG) which is capable of measuring the weak neuromagnetic signals generated by current flow within pyramidal cells of motor cortex; functional magnetic resonance imaging (fMRI) which is capable of measuring activity-induced changes in the hemodynamics and blood oxygenation of motor cortex; and transcranial magnetic stimulation (TMS) which is capable of activating motor cortex via the application of a strong magnetic pulse which generates eddy currents within the brain. Because each technique is based upon a different physiological mechanism, their combined use provides a richer picture of cortical organization than is attainable when each is used in isolation. The cortical substrates of hand movements were examined in one subject using each technique. As expected, dipole sources for the motor evoked magnetic field localized to the pre-central gyrus as identified by structural magnetic resonance imaging methods. Movement induced changes in fMRI hemodynamics which co-localized with these dipole sources to within 1 cm. Movement of the hand was evoked most effectively by placing the center of a butterfly TMS coil at a position where the line passing through the center of the head and the center of the coil passed within 1 cm of the regions identified by MEG and fMRI. The techniques appear to cross-validate each other with respect to localization abilities.

496.10

ACTIVATION OF CORTICAL MOTOR AREAS: AN INDIVIDUAL PET ANALYSIS. Uwe Knorr, Gottfried Schlaug, Harald Hefter*, Yanxiang Huang, Hans Herzog, Helmuth Steinmetz, Rüdiger J. Seitz. Dept. of Neurology, University of Düsseldorf and Institute of Medicine, Jülich, Germany.

The inter-individual variability of cerebral anatomy impairs the capability of identification and localization of regional cerebral blood flow (rCBF) changes in activation studies with positron emission tomography (PET). Additionally, the individual task performance will influence the rCBF changes also. To estimate those two aspects of anatomo-functional variability we studied simple and complex finger movements. In 12 blindfolded, right-handed subjects the rCBF was measured with [^{15}O -butanol] and the SCX PC4095/15WB camera during the execution of simple and complex finger, and right hand movements in comparison to a control condition. The movements were paced at low and high rates (between 0.8 and 3.0 Hz) internally, as well as externally. PaCO₂ corrected values of the rCBF were used. After spatial alignment and integrated display of PET and high resolution magnetic resonance (MR) images, task specific rCBF increases were identified using the individual response identification algorithm. Results were compared to inter-subject averaged images using pixel-by-pixel t-map analysis. At high movement rates task-specific rCBF increases were consistently observed in the contralateral primary sensorimotor cortex. Activations in premotor, supplementary motor areas and subcortical regions had an individual distribution reflecting the inter-individual anatomo-functional variability in task performance. The individual activation patterns are strong evidence for functional heterogeneity among different subjects.

ANTEROGRADE TRANSNEURONAL SPREAD OF HERPES SIMPLEX VIRUS FROM THE MURINE TOOTH PULP TO TWO CORTICAL AREAS ASSOCIATED WITH JAW MOVEMENT. E. M. Barnett¹, G. D. Evans², M. D. Cassell¹, and S. Perlman¹. ¹Neuroscience Program, ²College of Dentistry, University of Iowa College of Medicine, Iowa City, IA 52242.

Transneuronal spread of herpes simplex virus type 1 (HSV-1) into and throughout the brain was examined following inoculation into the murine tooth pulp. Openings were made into the pulp of left mandibular incisors of Balb/c mice. The pulp was partially removed, approximately 3×10^5 PFU of HSV-1 strain H129 was placed into the opening using a micropipette, and the tooth was sealed. Animals were sacrificed 5-9 days post-inoculation (p.i.) and *in situ* hybridization for HSV-1 nucleic acid was performed using a [³⁵S]-labeled anti-sense RNA probe. The H129 strain of HSV-1 has previously been reported to spread anterogradely.

Within several days p.i. ipsilateral perioral, lingual, and eye lesions were noted, suggesting spread within the semilunar ganglion following infection of the inferior alveolar nerve. Virus first appeared at 4-5 days p.i. in the dorsomedial spinal nucleus of the trigeminal nerve, and the lateral nucleus of the solitary tract, consistent with entry via the mandibular division only. Over the next several days virus spread to infect the subcortical efferents of these two structures, such as the ventral posterior medial thalamus, lateral parabrachial nucleus, paraventricular hypothalamus, and central extended amygdala. As early as 6 days p.i., virus was detected in laminae II/III and V of ipsilateral agranular insular cortex and lamina IV of contralateral cortex corresponding to the primary jaw motor area. These two cortical areas have been shown to produce rhythmical jaw movements upon electrical stimulation. The pattern of spread was generally consistent with anterograde spread of virus. Thus, the pathways defined by viral spread are consistent with sensory input from the trigeminal mandibular division into motor areas controlling jaw movement.

SUPPLEMENTARY MOTOR AREA (SMA) INPUT TO THE CERVICAL CORD. R.P. Dum^{*} and P.L. Strick. VA Research Service, VAMC and Depts. Neurosurgery & Physiology, SUNY Health Science Ctr., Syracuse, NY 13210.

In prior studies we demonstrated that a substantial number of corticospinal neurons originate in the SMA. In this experiment, we used anterograde transport of WGA-HRP in macaques to examine the pattern of terminations of efferents from the 'arm' area of the SMA within the cervical spinal cord. For comparison, we also examined the pattern of terminations from the primary motor cortex (M1). SMA efferents terminated densely in 4 regions of the gray matter of the cervical cord: a lateral portion of the intermediate zone (laminae V-VII), a medial portion of the intermediate zone (laminae VI-VII at the base of the dorsal columns), a ventromedial portion of the intermediate zone (laminae VII-VIII) and a dorsolateral part of the motor nuclei (lamina IX). Terminations in motor nuclei were primarily found in regions of lower cervical segments (C7-T1) known to contain motoneurons that innervate muscles of the fingers and wrist. M1 efferents terminated densely in the same regions of the cervical cord as efferents from the SMA. The terminations of M1 generally were more dense and more extensive than those from the SMA. M1 terminations extended further into the base of the dorsal horn (lamina V) and included a larger portion of lamina IX. In summary, terminations from the SMA and M1 are focused on largely the same regions of the cervical cord. Each cortical area has terminations that appear to directly innervate motoneurons, particularly those innervating hand muscles. These results further support the concept that corticospinal efferents from the SMA and M1 represent parallel channels for motor output. Contrary to some previous hypotheses, the SMA has the potential to directly control hand movements independent of M1. Support: VA Rehab. R&D and USPHS 24328 (PLS).

DIFFERENTIAL SPINAL PROJECTIONS OF SUBREGIONS WITHIN THE FORELIMB AREA OF CAT MOTOR CORTEX. J.H. Martin¹, C. Ghez. Columbia Univ., Ctr for Neurobiology and Behavior, NY, NY 10032

Two subregions have been identified within the forelimb area of the cat motor cortex that are located rostral and caudal to the cruciate sulcus. Reversible inactivation of portions of the subregions in which the distal joints are represented produces different effects on performance of a prehension task (Exp Brain Res 1993). Within the rostral subregion, inactivation produces both deficits in the control of locally represented joints as well as more generalized deficits in aiming and adapting trajectories. Inactivation of the adjacent caudal subregion does not impair prehension *per se*. We now examine if these subregions have differential projections to the contralateral cervical spinal gray matter using anterograde transport of WGA-HRP.

Consistent with their common somatotopy, both subregions projected more densely to the cervical enlargement than to the upper cervical segments. However, there were striking differences in the dorsoventral pattern of projections of the two subregions to the spinal gray matter. Injections in the rostral subregion produced dense labeling of terminals in the intermediate zone. This was the case both at upper cervical segments, where the C3-C4 propriospinal neurons are located, and in the cervical enlargements, where other populations of premotor neurons are found. Injections in the caudal subregion preferentially labeled the deeper laminae of the dorsal horn, where mechanoreceptive afferent fiber terminals and ascending projection neurons are located.

The present findings suggest that the functions of the rostral subregion are expressed through projections to premotor neurons at both upper and lower cervical levels. The projection of the caudal subregion to portions of the cord that process somatic sensory inputs suggests that it may play a role in motor tasks in which such inputs are critical.

497.2

ORIGIN, SOMATOTOPY AND DENSITY OF THE CORTICOSPINAL PROJECTIONS FROM THE MOTOR AREAS OF THE MESIAL WALL OF THE HEMISPHERE IN THE MACAQUE MONKEY.

M. Matelli, G. Luppino, R. Camarda, G.P. Basso and G. Rizzolatti ^{*}(SPON: European Brain and Behavior Society) Istituto di Fisiologia Umana Università di Parma Via Gramsci 14 I-43100 Parma Italy.

Recent microstimulation experiments showed that on the mesial cortical surface of the macaque monkey there are four nonprimary motor areas (Luppino et al. J. Comp. Neurol. 311:463-482,1991). Two of them occupy the mesial sector of area 6: F3 (SMA-proper) and F6 (pre-SMA). The other two areas are located in the dorsal part of cingulate area 24: area 24d and area 24c.

In the present experiments we matched the site of origin, the somatotopy and the density of the corticospinal (CS) projections from the mesial wall of the hemisphere with the location and the somatotopy of the four above mentioned motor areas. Neural tracers (HRP and DY) were injected at various levels in the spinal cord of two macaque monkeys and their retrograde transport plotted. The results showed that all the mesial motor areas have CS projections, although with marked differences in their somatotopy and density. The two caudal areas, F3 and 24d, have segregated projections to both cervical and lumbar levels. In F3 the density of CS neurons is slightly less than that of F1 (area 4) (243 vs. 273 cells/sq. mm) and higher than that of area 24d (223 cells/sq. mm). The two rostral areas, F6 and 24c, project mainly to the cervical level. The CS projections from F6 are scanty and limited to a small sector of it. In the agranular cingulate motor areas 24d and 24c the density of CS neurons is similar and markedly differs from that of the unexcitable granular area 23c (123 cells/sq. mm). These data are in good agreement with the parcellation of mesial agranular frontal and cingulate areas proposed in our previous electrophysiological studies.

PREFRONTOPONTINE PROJECTIONS IN THE RHESUS MONKEY. Jeremy D. Schmahmann^{*}, and Deepak N. Pandya. Massachusetts General Hospital, Boston, MA, and E.N.R.M. Veterans Hospital, Bedford, MA, 01730.

The prefrontal connections to the basis pontis have been incompletely studied and a detailed understanding of their organization is not available. We injected tritiated amino acids into subregions of the lateral, medial, and ventral prefrontal cortices in 18 Rhesus monkeys and studied the projections to the pons using the technique of autoradiography. The dorsal lateral convexity and the medial prefrontal cortex provided the majority of the pontine efferents, whereas the ventral lateral convexity and the orbitofrontal cortex provided sparse, or no, pontine terminations. Projections from the lateral prefrontal convexity were derived from dorsal area 46, areas 8B, 9, and 10; and those from the medial prefrontal cortex originated from areas 9 and 32. A minor projection was noted from ventral area 46. Our studies to date have not revealed pontine projections from areas 11, 12, and 14 in the orbitofrontal region. The projections from areas 8B, dorsal area 46, and area 9 were distributed throughout the rostrocaudal extent of the pons. The projections from area 10, medial area 9, area 32, and ventral area 46 occupied the rostral one-third to one-half of the pons. The distribution of terminal label favored the medial, paramedian, and dorsomedial pontine nuclei, with some label present also in the nucleus reticularis tegmenti pontis, and medial aspects of the ventral and peduncular nuclei. More medial prefrontal cases resulted in label at the most medial pontine regions, whereas following lateral prefrontal injections the pontine terminations shifted away from the midline. The existence and organization of these differential prefrontopontine projections, including those from area 10 at the frontal pole, are consistent with the notion that the cerebellum has access to higher order information from the cerebral hemispheres (Schmahmann and Pandya, '87; Leiner et al., '88; Schmahmann, '91). (Supported in part by NIH grant 16841 and the ENRM VA Hospital, Bedford, MA 01730).

497.6

PALLIDOTHALAMOCORTICAL PATHWAY IN THE RAT: A LIGHT & ELECTRON MICROSCOPIC ANALYSIS. S.T. Sakai^{*} & K. Bruce. Dept. of Anatomy, Michigan State University, East Lansing, MI 48824.

Pallidothalamic input to the supplementary motor area is thought to provide an important link in motor control pathways in primates. Our purpose was to determine if the medial agranular cortex (AGm) which is thought to contain the supplementary motor area in the rat also receives the pallidothalamocortical pathway. A double-labeling paradigm was employed whereby pressure injections of the retrograde tracer, Cholera toxin subunit B (CTB) were made into AGm combined with iontophoretic injections of the anterograde tracer, *Phaseolus vulgaris leucoagglutinin* (PHA-L) made into the entopeduncular nucleus (EP) (homologue of the primate globus pallidus). Vibratome sections were reacted using a sequential immunohistochemical protocol. The greatest coincidence of both CTB labeled cells and PHA-L labeled pallidothalamic fibers was observed in the anterolateral portion of the ventral anterolateral nucleus (VAL). Both labels were also observed in the ventral medial nucleus (VM). Electron microscopic analysis of serial sections of VAL revealed numerous PHA-L labeled terminals as well as CTB retrogradely labeled cell bodies and large dendrites. The PHA-L labeled boutons were generally large with numerous mitochondria and attached to the postsynaptic elements by synaptic junctions as well as several puncta adhaerentia. Synapses were observed onto CTB labeled somata as well as onto labeled and unlabeled dendrites. These results demonstrate for the first time the pallidothalamocortical pathway by way of VAL to the AGm in the rat. This pathway may provide an anatomical substrate for the motor control functions ascribed to the AGm in the rat. (Supported by the College of Human Medicine BRSG).

THALAMIC CONNECTIONS OF THE DORSAL AND VENTRAL PREMOTOR AREAS IN OWL MONKEYS. I. Stepniewska, T.M. Preuss, and J.H. Kaas. Dept. of Psychology, Vanderbilt University, Nashville, TN 37240.

In owl monkeys, as in macaques, the lateral premotor cortex includes two separate dorsal (PMD) and ventral (PMV) areas (Stepniewska et al. 1993, *J. Comp. Neurol.*, 330:238-271). In this study, we investigated the thalamic projections to PMD and PMV, with injections of fluorescent dyes (Diamidino Yellow, Fluoro-Ruby, Fast Blue) and WGA-HRP. Microstimulation was used to localize injection sites in the forelimb representations of PMD and PMV in 6 adult owl monkeys (*Aotus trivirgatus*). Perfused brains were sectioned in the coronal plane, and alternate series of sections were stained for Nissl, acetylcholinesterase, and cytochrome oxidase to locate the borders of thalamic nuclei.

Both PMD and PMV are strongly interconnected with the nuclei of the ventrolateral complex and with the mediadorsal (MD) and intralaminar nuclei; the major connections of both areas were similar. Labeling in the ventrolateral complex was concentrated in the medial (VLx) and anterior (VLa) subnuclei, with only a few cells labeled in the dorsal (VLd) and posterior (VLp) subnuclei. Labeling in MD was concentrated in the most lateral and posterior parts of the nucleus. Within the VL complex and MD, labeling after PMV injections was concentrated ventrally, while PMD injections labeled more dorsal territories. Other connections of premotor cortex were with the ventral anterior (VA) and ventromedial (VM) nuclei. Our results suggest that PMD and PMV both receive inputs from the cerebellum (e.g., through VLx) and basal ganglia (e.g., through VLa). [Supported by NS 164445 and JSMF 90-35]

497.9

CORTICO-CORTICAL PROJECTIONS BETWEEN PRIMARY AND SECONDARY SOMATOSENSORY AREAS OF RATS: BACKWARD PROJECTIONS LABEL LAYER I MOST HEAVILY. Barbara Clancy and Larry J. Caulier*, GR41, Cognition and Neuroscience Program, University of Texas at Dallas, Richardson, TX 75083-0688.

Projections between somatosensory areas of rats were labeled by multiple injections of fluorescent retrograde (Fast Blue or Diamidino Yellow) and anterograde tracers (rhodamine-labeled Dextran 10kMW, lysine-fixable; Molecular Probes). Overlapping or contralateral injections of these retrograde AND anterograde tracers (R&A) were employed to demonstrate the reciprocity of these connections and to analyze the topographical relationships between these reciprocally interconnected areas. All tracers were injected by air pressure (General Valves). Small R&A injections (<0.5 mm diameter centered in layer IV) into the dorsal vibrissal somatosensory area (SI) retrogradely labeled cells in all layers at two sites in the lateral parietal area, including SII (Par II) and the lateral agranular insular cortex. In both of these retrogradely labeled areas, anterogradely labeled fibers from SI were found which terminated throughout all layers in register with the retrogradely labeled cells. Similar R&A injections into the lateral parietal area (SII) retrogradely labeled cells in layers III and V of SI. Anterogradely labeled "backward" fibers from SII traveled medially through layer VI to the site in SI where retrogradely labeled cells were found. These backward fibers terminated most heavily in layer I, less heavily in layer II, with thick terminal branches in layers III and V, and only thick fibers passing through layer IV. Many of the backward fibers that reached layer I extended horizontally within layer I for at least 1 mm. We conclude that reciprocal projections interconnect common neuronal populations and the backward limb extends horizontally to spread this process to adjacent populations in surrounding representations of SI.

497.11

DIFFERENCES IN THE IPSILATERAL CORTICAL INPUTS TO SUPERIOR AND INFERIOR REGIONS OF THE POSTARCULATE PREMOTOR AREA: A QUANTITATIVE STUDY OF RETROGRADELY LABELED NEURONS IN MACACA FASCICULARIS. S. Ghosh*, Dept. of Physiology & Pharmacology, University of Queensland, St. Lucia, Qld 4072, Australia

In order to investigate cortical inputs to the Postarcuate Premotor Area (PMA) Wheatgerm Agglutinin conjugated with Horseradish Peroxidase (WGA-HRP) was injected into the forelimb region of PMA (identified by cortical stimulation) in 2 adult macaques: 0.3 μ L of a 5% solution behind the superior limb of the arcuate sulcus (AS) in one animal (M2) and 0.3 μ L of a 10% solution behind the inferior limb of the arcuate sulcus (AI) in the other animal (M3). Every fourth serial section (50 μ m) was stained by Tetramethyl Benzidine and all labeled cells counted. Nearly 30,000 neurons were counted in the ipsilateral cortex of M2 and 75,000 neurons counted similarly in M3. The study reveals profuse connections within the posterior bank and posterior lip of AS or AI, but very few connections between AS and AI. Both areas are well connected with area 4 and areas 5 and 7. However, projections from SMA and SII are numerically greater to the inferior than to the superior part of PMA.

497.8

IPSILATERAL CORTICAL CONNECTIONS OF THE DORSAL AND VENTRAL PREMOTOR AREAS IN OWL MONKEYS. T.M. Preuss, I. Stepniewska, and J.H. Kaas. Dept. of Psychology, Vanderbilt Univ., Nashville, TN 37240.

In owl monkeys (*Aotus trivirgatus*), we have identified separate dorsal and ventral premotor areas (PMD, PMV) based on responsiveness to microstimulation and architectonics (Stepniewska et al. 1993, *J. Comp. Neurol.*, 330:238-271). In the present study, we made tracer injections in the forelimb representations of PMD and PMV, identified using microstimulation. Injections were made in 6 animals (3 for PMD, 2 for PMV, and 1 with separate injections of both PMD and PMV), using Diamidino Yellow, Fast Blue, Fluoro-Ruby, and WGA-HRP. After sacrifice, the distribution of labeling (primarily retrograde) was examined in sections cut coronally or flattened and cut tangential to the cortical surface.

PMD and PMV receive projections from multiple somatic sensory and motor areas; some areas project predominantly either to PMD or PMV, and some project to both. PMD and PMV differ principally in their somatosensory connections, PMD receiving input mainly from the parietal convexity (presumptive area 5), whereas PMV receives projections from multiple areas along the frontoparietal operculum, including S2, the parietal ventral area (PV), and the "parietal rostral" area (PR). Areas which project to both PMD and PMV include the primary motor area (M1); dorsal and ventral segments of the supplementary motor area (SMAd, SMAv); cingulate cortex; a region of posterior parietal cortex that is probably homologous to macaque area 7b; and a region in the lateral sulcus caudal to S2. [Supported by NS 164445 and JSMF 90-35].

497.10

GRAY MATTER TRAJECTORY OF CORTICOCORTICAL AXONS IN RATS: PATHWAYS FOR DIRECTED ATTENTION R.L. Reep*, I.L. Vandeveld and J.V. Corwin, Department of Physiological Sciences, University of Florida, Gainesville, FL 32610; and Dept. of Psychology, Northern Illinois University.

In rats, the medial agranular (AGm), ventrolateral orbital (VLO) and posterior parietal (PPC) cortical areas each play a role in directed attention and spatial orientation, and are highly interconnected. In anterograde tracing studies using Fluoro-Ruby, we have discovered that a large proportion of the axons linking these areas travel in the deep gray matter rather than in the underlying white matter. These axons are oriented rostrocaudally, and travel predominantly in layer VI, extending rostrally and caudally from the injection site to their cortical targets, where they ramify and terminate in more superficial layers. Axons directed subcortically are grouped as a compact bundle in the deep white matter which can be followed to terminal fields in the striatum, thalamus and brainstem.

In preliminary behavioral studies, we have found deficits in directed attention after knife cuts which interrupt these axons without causing appreciable cortical damage.

These findings suggest the hypothesis that directed attention behavior in rats may be mediated in large measure by corticocortical connections among AGm, VLO and PPC.

497.12

IDENTIFICATION OF A TRANSITIONAL (CINGULATE) FIELD IN THE CAUDAL PART OF THE HUMAN MEDIAL FRONTAL LOBE: A CYTOARCHITECTONIC STUDY. R. Morris*, T. Paus, M. Petrides and D.N. Pandya, Montreal Neurological Institute, McGill University, Montreal, Que, Canada and Edith Nurse Rogers Memorial Veterans Hospital, Bedford, MA, USA.

The architecture of the caudal portion of the medial surface of the frontal lobe was reexamined to establish whether there is a transitional field between the preisocortex of the cingulate gyrus and the dorsally located isocortical areas 4 and 6. Proceeding in a ventrodorsal direction, we observed gradual but stepwise changes in cellular organization characterized by an increase in overall cortical thickness and in the supragranular layers relative to the infragranular layers. A transitional field, sharing features of both the preisocortex below it and the isocortex above it was observed. Along the rostrocaudal axis, this field represents a caudal extension of the classically defined area 32. The cytoarchitecture of this field resemble the cortex found in the fundus of the monkey cingulate sulcus at corresponding rostrocaudal levels. Its position is consistent with the location of rCBF changes related to the control of manual responses obtained in our previous PET study (Paus et al. *J. Neurophysiol.*, 70 (2), 1993).

497.13

A CYTOARCHITECTONIC INVESTIGATION OF THE HUMAN PREFRONTAL CORTEX. Chiavaras M, Petrides M, Pandya DN* Edith Nourse Rogers Memorial Veterans Hospital, Bedford, MA, USA and Montreal Neurological Institute, McGill University, Montreal, Canada.

A cytoarchitectonic analysis of the human prefrontal cortex shows that its architectonic areas can be arranged into four major groups according to their laminar features. The first group consists of areas 24, 25, 32 and the caudal orbitofrontal region and is characterized by the absence of a granular layer IV, a cell sparse layer III, and prominent infragranular layers V and VI. The second group includes medial areas 9 and 8B and orbital areas 13, 11, and 14 (Brodmann's areas 11 and 12). These areas have an incipient layer IV, medium pyramidal cells in layer III, and decreased infragranular cell density. The third group is comprised of areas 10, 46, and 47/12 and is characterized by a better developed layer IV, increased size of layer III pyramidal cells, and equal cell density in both the infra- and supragranular layers. The last group consists of lateral areas 9, 9/46, 8A, and 45. These areas have a densely packed layer IV, large layer III pyramidal cells, and prominent supragranular layers.

According to progressive laminar differentiation, these prefrontal cortical groups can be arranged into two parallel trends. The *mediodorsal* trend begins in areas 24, 32, and 25, extends to medial areas 8B, 9, and dorsal area 10, passes to dorsolateral areas 10 and 46 and finally to dorsal areas 9, 9/46 and 8A. The *basoventral* trend extends from orbital preoccipital areas 13, 14, and 11, progresses through areas 47/12, ventral areas 10 and 46 and finally reaches area 45 and ventral areas 9/46 and 8A.

The organization of cortical areas into two trends with sequential laminar differentiation may provide a framework for better understanding clinical disorders and frontal lobe functioning. (Supported by NIH grant 16841)

497.15

CEREBELLAR AND PALLIDAL INPUTS, VIA THE THALAMUS, TO THE PRIMARY (M1) AND SUPPLEMENTARY (SMA) MOTOR CORTICAL AREAS: EVIDENCE FROM MULTIPLE NEUROANATOMICAL TRACING IN MONKEYS. E.M. Rouiller*, F. Liang, A. Babalian, V. Moret and M. Wiesendanger. Institute of Physiology, University of Fribourg, CH-1700 Fribourg, Switzerland.

In order to clarify whether or not the primary motor cortex (M1) and the supplementary motor cortex (SMA) are each addressed, via the motor thalamus, by cerebellar and basal ganglia outflows, the goal of the present study was to compare directly, in the same animal, the thalamic territories that: a) project to M1 and SMA, b) receive cerebellar-nuclear (CN) and pallidal (GP) afferents. The 4 territories were mapped in 3 monkeys by means of 2 retrograde tracers for M1 and SMA injections and of 2 anterograde tracers for CN and GP injections. All injections were conducted under electrophysiological control. Injections in M1 and SMA-proper were restricted to the hand/arm representation. The anterogradely and retrogradely labeled thalamic territories all formed a number of highly complex patches that were usually not confined to one cytoarchitectonically defined thalamic nucleus. The overlap of clusters of labeled terminals and perikarya was evaluated morphometrically (area measurements) at regular intervals along the anteroposterior extent of the motor thalamus. Confirming previous studies, the thalamic territories fed by CN and GP afferents rarely overlapped. The new finding is, however, that the territories projecting to M1 and to SMA included thalamic islands receiving CN- as well as GP-projections. These data support the previous conclusion (based on transsynaptic labeling) that SMA receives not only pallidal but also transthalamic CN inputs (Wiesendanger and Wiesendanger, 1985, Exp. Brain Res. 59, 105-117). Reciprocally, M1 receives not only cerebellar but also pallidal transthalamic inputs.

497.17

CYTO- AND MYELOARCHITECTURE AND TRANSMITTER RECEPTOR DISTRIBUTION IN HUMAN SENSORY-MOTOR CORTEX. K. Zilles*, S. Geyer, K. Amunts, H.-J. Bidmon and A. Schleicher, C. & O. Vogt-Brain Research Institute, H. Heine Univ., D-4000 Düsseldorf, FRG.

Varying numbers of areas and positions of the areal borders in the human motor and somatosensory cortex have been reported. Since MR and PET need precise information about the extent and interindividual variability of the motor and somatosensory areas, these aspects were studied with quantitative cyto- and myeloarchitectonic methods and with quantitative receptor autoradiography.

Nissl- and myelin-stained serial sections through the region of the central sulcus of human brains with no history of neurological diseases were used. M1, M2, GABA_A, 5-HT₁, 5-HT₂, α_1 and L-glutamate receptors were demonstrated at regional and laminar levels. Cyto- and myeloarchitectonic studies were performed in adjacent sections. The primary motor cortex (Area 4 of Brodmann) can be subdivided into two areas on the basis of myeloarchitecture and receptor distribution. Area 4 can be reliably delineated from Area 6 (premotor cortex) on the basis of receptor autoradiography. The border between both areas is restricted to the precentral gyrus on the dorsolateral surface of the hemisphere. The somatosensory cortex shows a receptor pattern completely different from that of the motor cortex, and can be subdivided into different areas with architectonic and receptor techniques. The results were transferred to 3D-reconstructions of the human brain in order to demonstrate the interindividual variability of cortical areas in the region of the central sulcus. Supported by a grant of the DFG (SFB 194/A6)

497.14

SOMATOSENSORY AND MOTOR REPRESENTATIONS IN THE GRAY SHORT-TAILED OPOSSUM (*Monodelphis domestica*) R.J. Nudo*, S.B. Frost, G.W. Milliken and R.B. Masterton. Department of Neurobiology and Anatomy, University of Texas Medical School, Houston, Texas, 77030 and Department of Psychology, Florida State University, Tallahassee, Florida 32304

Previous studies suggest that somatosensory and motor representations in neocortex of neurologically primitive mammals are completely overlapping in a sensorimotor amalgam (Lende, '63). To examine this question using contemporary techniques, we used multi-unit recording and intracortical microstimulation (ICMS) to examine sensory and motor representations in the gray short-tailed opossum. In ketamine-anesthetized animals, sensory receptive fields were derived by determining the skin surfaces over which cortical neurons were driven by cutaneous stimulation. Motor fields were derived using ICMS techniques to determine the movement(s) evoked by minimum current intensities ($\leq 100\mu A$). Responsive sites typically evoked movement at $<30\mu A$.

The somatosensory map revealed a complete representation of the body surface, dominated by a large representation of the snout. In contrast, the motor representation was confined entirely to the face region, primarily the vibrissae, and overlapped the somatosensory face representation. Although extensively and repeatedly explored, movements could NOT be evoked in musculature caudal to the face.

These results confirm Lende's earlier reports of a sensorimotor amalgam in Marsupials. Further, if the motor cortex of *Monodelphis domestica* is representative of a primitive condition, these results suggest that motor cortex initially emerged to control muscles of the face. Supported by NIH NS27974 (RJN) and NS07726 (RBM).

DISTRIBUTION OF THALAMIC CELLS PROJECTING TO THE PRIMARY MOTOR CORTEX AND THE SUPPLEMENTARY MOTOR AREA.

K. Shindo, K. Shima and J. Tanji*. Dept. of Physiology, Tohoku Univ. Sch. of Med., Sendai, 980, Japan

The location and spatial distribution of thalamic cells projecting to the distal (Th-DIST) and proximal (Th-PROX) forelimb areas of the primary motor cortex and the forelimb area of the supplementary motor area (Th-SMA) were investigated by a multiple retrograde labeling technique using five Japanese monkeys (*Macaca fuscata*). The distal (MI-DIST) and proximal (MI-PROX) forelimb areas of the primary motor cortex were identified by effects of intracortical microstimulation and somatosensory responses. Retrograde fluorescent tracers (diamidino yellow and fast blue) were injected into the centers of each area. Two weeks later, the forelimb area of the supplementary motor area (SMA) was identified physiologically. Horseradish peroxidase conjugated with wheat germ agglutinin was injected into the center of the SMA. Labeled thalamic cells distributed basically in a topographic manner: Th-SMA cells medially; Th-DIST cells centrally; and Th-PROX cells laterally. In nucleus ventralis anterior (VA) and the anterior part of nucleus ventralis lateralis pars oralis (VLo), only Th-SMA cells were found. Posteriorly, the distribution of Th-SMA cells overlapped with that of Th-DIST cells in the dorsal part of the VLo, while, in the ventral part, they were separated from each other. The degree of the overlap increased anteriorly and decreased posteriorly. Only a small percentage of cells projecting to both the SMA and MI-DIST (double labeled cells) was seen. The distribution of Th-PROX cells were separated from others. In nucleus ventralis lateralis pars caudalis (VLc), the overlap of each cell group was small. In nucleus ventralis posterior lateralis pars oralis (VPLo), both Th-DIST and Th-PROX cells, but no Th-SMA cells, were labeled. In nucleus centralis lateralis (CL), cells with three different labels were intermixed.

APICAL DENDRITES OF SAME PROJECTION CELL TYPES MAY ASSOCIATE TO FORM CLUSTERS. D. Lev, D. Czeiger, G. Benschalom* and E.L. White, Center for Brain Research, Faculty of Health Sci., Ben-Gurion Univ., Beer Sheva, ISRAEL.

Based on analyses of the 3-dimensional organization of the primary visual areas in the monkey (Peters and Sethares, 1991a and b), cat (Peters and Yilmaz, 1992) and rat (Peters and Kara, 1987), it has been proposed that neurons in these cortices are organized into modules that center on clusters of apical dendrites belonging to layer V pyramidal neurons. By examining MAP-2 reacted sections with the light microscope, we observed that mouse primary motor cortex (Msl) is also composed of pyramidal cell modules and that the organization of neurons in these modules is similar to that in visual cortex. Here we report on efforts to determine if dendritic clusters are composed of apical dendrites belonging to one or to several types of projection cell. Callosal neurons in Msl cortex were labeled by the retrograde transport of horseradish peroxidase that had been deposited as a 40% aqueous solution onto callosal fibers in the contralateral hemisphere. Examination of tangential thin sections through layer IV of Msl cortex shows clusters of apical dendrites in which every dendrite is labeled with HRP. Co-existent with these clusters are clusters composed of unlabeled dendrites, suggesting that the apical dendrites of callosal neurons aggregate to form clusters that are composed exclusively of this type of projection cell. These findings suggest a hitherto unsuspected degree of specificity in the cellular composition of cortical modules, at least for Msl cortex. Supported by Binational Science Foundation 890005 and NIH 20149 to E.L.W.

D1 DOPAMINE ANTAGONIST SUPPRESSES NEURONAL ACTIVITY RELATED TO REACHING MOVEMENTS IN THE PREMOTOR CORTEX OF MONKEYS. T. Sawaguchi*, J. Yamane, and K. Kubota. Dept. of Behavioral and Brain Sciences, Primate Res. Inst., Kyoto Univ., Inuyama, Aichi 484, Japan.

To examine the roles of dopamine receptors in the premotor cortex, dopamine antagonists (SCH23390 for D1 receptors and sulpiride for D2 receptors) were applied iontophoretically to neurons of the premotor cortices (dorsal PM and ventral PM) of monkeys that performed a visual reaching task with a delay. The task was initiated when the monkeys pressed a central hold lever. This was followed by waiting (1 s), warning (a green lamp, 0.5 s), cue (a green lamp in either a left, upper, or right location, 0.5 s), delay (4 s), and go (<1.2 s) periods. During the go period, after the monkeys received a visual go signal (a red lamp), they released the lever, reached, and pressed a lever at the target location that had been indicated prior to the delay period. Iontophoretically-applied SCH23390 (usually applied with a current of 50nA) reduced the activity of most task-related neurons (72/108). By contrast, neither sulpiride nor an inactive analogue of SCH23390, SCH23388, had a significant effect (3/59 for sulpiride, 2/28 for SCH23388). Since it has been suggested that SCH23390 also binds 5HT-2 receptors, a selective 5HT-2 antagonist, ketanserin, was tested. This drug also had little effect on task-related activity (9/36). The effects of SCH23390 varied with the type of the task-related activity: i.e., while neurons which showed a peak activity during the go period were frequently suppressed by SCH23390 (64/79, 81%), those which showed a peak activity during the warning or cue periods were less frequently affected (5/22, 23%). Thus, the activation of D1 dopamine receptors appears to be critical for facilitating neuronal activity related to reaching movements in the premotor cortex.

FIELD POTENTIALS EVOKED IN HORIZONTAL PATHWAYS OF RAT MOTOR CORTEX CONTAIN AN APV-SENSITIVE COMPONENT

K. M. Jacobs*, J. P. Donoghue, and G. Hess. Dept. of Neuroscience, Brown University, Providence, RI 02912.

The contribution of NMDA receptors to horizontal transmission within layers III and V (termed: III-III, V-V) as well as to oblique interactions across these layers (V-III, III-V) was investigated in slices of rat motor cortex. Electrical stimulation evoked short latency responses consisting of a prominent negativity (-0.4 to -2.0 mV) horizontally at a distance of 500 μ m in both superficial and deep layers and in the oblique V-III pathway. The response in the III-V pathway was smaller (-0.1 to -0.6 mV) and of longer latency. Bath application of the NMDA receptor antagonist, 2-amino-5-phosphonovaleric acid (APV, 100 μ M) consistently reduced all field potentials. Decreases were observed in all components of the waveform, however, the primary effect was on the late phase of the response. In the III-III, V-V and V-III pathways APV produced on average a 22% decrease in the area, 12% of initial slope and 11% of peak amplitude of responses. The III-V path showed a greater percentage APV-induced decrease. All but a small, early, and presumably nonsynaptic component of the response was blocked by combined application of APV (100 μ M) and the non-NMDA glutamate receptor antagonist 6-cyano-7-nitro- or 6,7-dinitroquinoxaline-2,3-dione (CNQX/DNQX, 10-20 μ M). The relative contribution of the APV-sensitive component was unrelated to field potential magnitude in 22 out of 30 cases, while in the remainder this component was relatively smaller as the magnitude of response increased. It is concluded that glutamate is the major transmitter of local intracortical connections. Most glutamatergic transmission is relayed by non-NMDA receptors, however, NMDA receptor activation is a small but consistent part of ordinary transmission in these pathways. The results further suggest that a potential for NMDA receptor-mediated synaptic modification exists in intrinsic horizontal pathways of both superficial and deep layers of rat motor cortex. Supported by NIH grant NS 22517.

Activation Of M₁ Muscarinic Receptors Excites GABAergic Interneurons In Piriform Cortex. RL Gellman*. Yale Univ. Dept. of Psychiatry, New Haven, CT 06508 and Harvard Univ., MGH Dept. of Psychiatry, Charlestown, MA 02129.

During a recent study demonstrating that 5-HT₂, alpha₁ adrenergic and DA receptor expressing GABAergic interneurons in piriform cortex synapse onto layer 2 pyramidal cells (Gellman RL & Aghajanian GK, 1993) I noted that many of these interneurons were also activated by the cholinergic agonist carbachol. Subpopulations of putative interneurons were identified using extracellular electrodes to record from *in vitro* slices of piriform cortex in the presence of low concentrations of different agonists. Of 34 interneurons identified when 5-HT (20 μ M) was present in the bath, 94% were also excited by carbachol. Carbachol (10 μ M) activated an even larger population than did 5-HT; only 60% of the carbachol-sensitive interneurons were also excited by 5-HT (n=17). The carbachol-mediated excitation was concentration-dependent (1-100 μ M). Muscarine (0.5-25 μ M) was an even more potent agonist while (-)nicotine (up to 100 μ M) had no effect. Similarly, atropine (1-2 μ M) completely blocked the response (n=4) while hexamethonium (10 μ M) had no effect (n=4). Dose response curves were constructed for more selective muscarinic receptor antagonists. Pirenzepine (0.01-1 μ M) and 4-DAMP (1-100 nM) each inhibited the carbachol-mediated excitation with IC₅₀'s of ~80 nM and ~70 nM respectively (n=4-5). Gallamine had little effect at concentrations up to 10 μ M. The rank order of potency is consistent with mediation by the M₁ receptor subtype.

In approximately half (11/20) of intracellular recordings from layer 2 pyramidal cells, using KCl filled electrodes, carbachol induced postsynaptic potentials (PSPs). The frequency of PSPs was concentration dependent over the same dose range (1-100 μ M) as excited the interneurons. It will be important to determine how activation of this local network contributes to the complex effects of ACh in the piriform cortex.

498.2

CLOZAPINE INDUCES FOS EXPRESSION IN PYRAMIDAL CELLS AND INTERNEURONS IN THE PREFRONTAL CORTEX IN A REGIONALLY-SPECIFIC MANNER. D. S. Cameron*, R. S. Duman, and A. Y. Deutch. Departments of Psychiatry and Pharmacology, Yale University School of Medicine, New Haven, CT 06510.

Recent data suggest that all clinically effective antipsychotic drugs (APDs) increase expression of the immediate-early gene (IEG) *c-fos* in the shell compartment of the nucleus accumbens. However, the atypical APD clozapine is effective in the treatment of a group of patients that do not respond to pharmacotherapy with typical APDs, and clozapine ameliorates negative symptoms more effectively than do typical APDs such as haloperidol. It follows that there are CNS sites at which clozapine acts selectively. We therefore examined the effects of acute administration of clozapine (CLZ) or haloperidol (HPD) on Fos protein in the prefrontal cortex (PFC).

Clozapine selectively increased the number of neurons exhibiting Fos-like immunoreactivity in the medial prefrontal cortex (PFC); HPD had no effect. Western blot analyses suggested that the effect was mainly due to an increase in Fos (58 kD band), although certain FRAs were marginally increased. CLZ increased the number of Fos-ir neurons in the deep but not superficial PFC layers. The increase in Fos expression was observed in the infralimbic and prelimbic cortices, but not in the medial precentral (shoulder) cortex. Fos was expressed in both pyramidal cells and interneurons. Among the interneurons, Fos-ir was observed in a sub-set of calbindin but not parvalbumin neurons. Fos was not observed in NADPH diaphorase-positive neurons of the PFC or underlying white matter. These data indicate that clozapine selectively increases PFC Fos expression in pyramidal cells and a distinct subset of GABAergic interneurons. These data may explain the observation that patients who do not improve on clozapine exhibit frontal cortical atrophy.

498.4

CATECHOLAMINERGIC LESIONS IN MEDIAL PREFRONTAL CORTEX INCREASE RUNNING-WHEEL ACTIVITY IN THE RAT. S. Lottipour, C.H. Woodworth* and R.G. Robinson. Dept. Psychiatry, Univ. of Iowa Coll. Med., Iowa City, IA 52252.

Frontal cortical dopamine (DA) systems may play an inhibitory role in motor behavior, possibly mediated through the nucleus accumbens (NAc). Bilateral lesions of DA terminals in medial prefrontal cortex (MPFC) and bilateral electrolytic lesions in NAc both induce hyperactivity in rats. However, *unilateral* NAc lesions elicit hyperactivity only from the right hemisphere. The purpose of the present experiment was to determine whether unilateral lesions of catecholamine (CA) terminals in MPFC elicit an asymmetrical increase in locomotor activity, and whether this effect is dependent on norepinephrine (NE) or DA terminals.

Male Sprague-Dawley rats were housed in running-wheel cages for 21 days before and 30 days after receiving intracortical injections of the CA neurotoxin 6-hydroxydopamine (6-OHDA), either with or without pre-treatment with desmethylimipramine (DMI), a noradrenergic uptake blocker (n = 7 and 5 pair, respectively). Rats were paired according to baseline activity, and alternate members of each pair lesioned in either the left or right MPFC.

Lesioned animals *not* pretreated with DMI were significantly more active than pretreated rats, indicating that NE terminals were relatively more important than DA terminals in determining the effect. A tendency for non-pretreated animals with right-sided lesions to show greater hyperactivity than those with left-sided lesions suggested that the effect was lateralized. The finding that DMI-pretreated rats were no more active following neurotoxin injections than vehicle injections supported the conclusion that hyperactivity following MPFC lesions was not primarily due to focal destruction of mesolimbic DA terminals.

498.6

EFFECTS OF LESIONS OF THE ENTORHINAL CORTEX ON FOREBRAIN DOPAMINE SYSTEMS IN THE RAT. C. E. Lander* and A. Y. Deutch. Interdepartmental Program in Neuroscience and Departments of Psychiatry and Pharmacology, Yale University School of Medicine, New Haven, CT 06510.

The entorhinal cortex (ENT) projects to the medial prefrontal cortex (PFC), ventral striatum, and hippocampus, all regions in which changes in dopamine (DA) function have been suggested to occur in schizophrenia. Certain hypotheses of the pathogenesis of schizophrenia posit that changes in PFC DA function result in an increase in subcortical DA function. However, neuro-pathological and *in vivo* imaging studies suggest that there are changes in both temporal and prefrontal cortices in schizophrenia. We therefore examined the effects of ENT lesions on cortical and subcortical DA function.

6-hydroxydopamine (6-OHDA) lesions of the ENT resulted in a \geq 80% decrease in DA concentrations of the ENT and a much smaller but significant loss of ENT norepinephrine levels. The lesions did not alter DA utilization, as reflected by DOPAC/DA or HVA/DA, in subcortical areas including the nucleus accumbens (NAS) core or shell and the medial or lateral caudateputamen. 6-OHDA lesions of the ENT also did not change DA utilization in the PFC. These results are similar to those obtained after PFC 6-OHDA lesions, which do not alter basal DA utilization in subcortical regions (i.e., the NAS), but do augment DA utilization under challenge paradigms. NMDA lesions of the ENT significantly increased both DA and serotonin utilization in the PFC but did not alter dynamics of these transmitters in the NAS. These findings are similar to those observed after ibotenic acid lesions of the PFC, which do not alter subcortical DA function. However, the axon-sparing lesion of the ENT does appear to modify prefrontal cortical DA function, suggesting the presence of distributed cortical networks that may be involved in schizophrenia.

498.7

STRESS-INDUCED ALTERATIONS IN GAD₆₇ AND GAD₆₅ mRNAs IN THE PREFRONTAL CORTEX. A. C. Grobin*, A. J. Bourdelais, P. Z. Gallipoli, and A. Y. Deutch. Departments of Pharmacology and Psychiatry, Yale University School of Medicine, New Haven, CT 06510.

The benzodiazepine site on the GABA_A receptor complex allosterically modulates GABA-induced Cl⁻ flux. Anxiolytic benzodiazepines (BZ) reverse both behavioral and biochemical indices of exposure to stress. Among the latter are the stress-induced activation of the prefrontal cortical dopamine (DA) innervation, which is blocked by pretreatment with BZ agonists, and mimicked by administration of BZ inverse agonists such as FG 7142. GABAergic neurons in the prefrontal cortex (PFC) have recently been shown to be regulated by DA, such that DA enhances GABA release from interneurons. We therefore examined the effects of chronic stress on glutamic acid decarboxylase (GAD) mRNAs in the PFC and striatum.

Adult male Sprague-Dawley rats were subjected to 30 min restraint stress for seven consecutive days. This stressor results in an acute increase in DA metabolism and response in the PFC but not striatum. At the conclusion of the stress period on day seven, animals were sacrificed and the PFC and striatum removed. Northern blot analyses using GAD₆₅ and GAD₆₇ cDNAs were performed. Stress resulted in a decrease in GAD₆₇ (but not GAD₆₅) mRNA in the PFC; no change was observed in the striatum.

These findings suggest that stress may decrease GABA availability, and are therefore consistent with the fact that anxiolytic BZs, by enhancing the actions of GABA, augment the responsiveness of post-synaptic neurons to decreased GABA availability. Western blot analyses of GAD proteins are being performed. Since stress increases DA release, which in turn enhances GABA release from PFC interneurons, the present data may also suggest that DA regulation of GABA neurons is restricted to a distinct subset of interneurons.

498.9

MEDIODORSAL THALAMIC LESIONS DIFFERENTIALLY REGULATE DOPAMINE METABOLISM IN PREFRONTAL CORTICAL SUBFIELDS AND NUCLEUS ACCUMBENS COMPARTMENTS. D. Ongur* and A. Y. Deutch. Interdepartmental Neuroscience Program and Departments of Psychiatry and Pharmacology, Yale University School of Medicine, New Haven, CT 06510.

The prefrontal cortex (PFC) has been defined as the mediodorsal thalamic (MD) projection field. Dopaminergic projections onto the PFC overlap completely with the MD innervation, but also extend to include the infralimbic cortex (PFC_{il}). The PFC_{il} and the more dorsally situated prelimbic cortex (PFC_{pl}) project to the nucleus accumbens (NAS) shell and core, respectively. These accumbal compartments, in turn, have distinct projections to the medial and lateral ventral pallidum (VP). These VP sites project back to the ventral midbrain, where they appear to form relatively closed loops. However, these two parallel systems may interact via selective medial VP projections to the medial MD, which projects to the prelimbic but not infralimbic PFC, and thus provides an avenue of intercommunication between the two "loops".

We examined the effects of ibotenic acid lesions of the medial MD of the rat on regional PFC and NAS dopamine metabolism. MD lesions increased prelimbic but not infralimbic cortical DA utilization, i.e., altered DA function only in the projection target of the thalamic nucleus. In addition, the lesion increased DA utilization in the NAS_{core} but not NAS_{shell}, i.e., in the terminal field of the MD-recipient PFC_{pl}. Thus, lesions of the MD result in changes in DA function in the corticostriatopallidal loop that emanates from the MD, which in turn is selectively innervated by the parallel loop.

We have also observed that the atypical antipsychotic drug (APD) clozapine (but not typical APDs) increases expression of the immediate-early gene *c-fos* in the PFC and the MD. The effects of MD lesions on APD-induced changes in PFC and NAS expression of *c-fos* are under current investigation.

498.8

HALOPERIDOL AND CLOZAPINE DIFFERENTIALLY REGULATE GABA TRANSPORTER mRNAs IN THE PREFRONTAL CORTEX OF THE RAT. P. Z. Gallipoli*, J. Clark*, S. Amara*, and A. Y. Deutch*. Departments of Psychiatry and Pharmacology, Yale University School of Medicine, New Haven, CT 06510 and ²Vollum Institute, Portland, OR.

Dopamine (DA)-containing afferents to the striatum synapse with and regulate the activity of GABAergic medium spiny neurons. Antipsychotic drugs that result in extrapyramidal side effects increase GAD₆₇ expression in these striatal neurons. Recent data indicate that DA afferents to the prefrontal cortex (PFC) regulate the activity of pyramidal neurons both directly and indirectly, the latter mode occurring through facilitation of GABA release from interneurons. In addition, recent findings suggest a loss of a subset of frontal cortical GABA interneurons in schizophrenia. There have been no examinations of the effects of chronic DA receptor blockade on the expression of GABA transporters. We have therefore examined the effects of chronic administration of the typical antipsychotic drug (APD) haloperidol (HPD) and the atypical antipsychotic drug clozapine (CLZ) on two different striatal and cortical GABA transporter mRNAs.

Adult male Sprague-Dawley rats received daily injections of HPD (1.0 mg/kg, sc), CLZ (15 mg/kg), or pH-matched vehicle for three weeks. The prefrontal cortex and striatum were removed, RNA isolated, and GAT-A and GAT-B mRNA levels measured by Northern blot analyses. Both APDs significantly decreased GAT-B mRNA in the striatum; GAT-A mRNA levels were not altered. In the PFC, HPD but not CLZ significantly decreased GAT-A mRNA. There was a non-significant trend toward a decrease in GAT-B mRNA in the PFC after HPD treatment. These data suggest that APDs alter GABA uptake in a regionally specific manner, and also suggest that typical but not atypical APDs selectively regulate GAT mRNAs in the PFC.

A QUANTITATIVE ANALYSIS OF SYNAPTIC INPUTS ON BASKET CELL SOMATA IN THE CAT'S CEREBELLUM. Georgia A. Bishop*, Yi Fei Chen, Richard W. Burry and James S. King. Dept. of Cell Biology, Neurobiology and Anatomy and Neuroscience Program, The Ohio State University, Columbus, Ohio 43210.

Although the efferent connections of basket cells in the mammalian cerebellum are well established, only a few studies have analyzed afferent inputs to these neurons. Physiologically, stimulation of the inferior cerebellar peduncle elicits a low amplitude EPSP followed by a powerful all-or-none IPSP, suggesting the presence of numerous inhibitory inputs on the basket cell body. In the present study, an antibody to glutamic acid decarboxylase (GAD) was used to distinguish excitatory from inhibitory inputs to the basket cell body. Three basket cells from the same animal were serially thin sectioned at 90-100 nm. Every section was collected and analyzed for the proportion of labeled versus unlabeled contacts on these neurons. A total of 179 profiles were in direct apposition to the somata. Of these, 31 were GAD immunolabeled and 148 were unlabeled. When measured at their greatest dimension, the GAD immunoreactive and unlabeled profiles had average sizes of 1.4 μm (range 0.4-2.8 μm) and 1.0 μm (range 0.4-2.4 μm), respectively. The majority of unlabeled profiles had cytological characteristics of parallel fiber terminals. The largest GAD positive terminals were likely derived from Purkinje cell collaterals and the smallest GAD terminals may be of stellate cell origin. 85 of the 179 profiles examined formed confirmed synaptic junctions with the basket cell body. Of these 85 junctions, 13% (n=11) were GAD positive and 87% (n=74) were unlabeled. Although fewer in number, activation of the inhibitory terminals derived from a single Purkinje cell (O'Donoghue et al., 1989, J. Neurosci. 9:2141) perhaps superimposed on a tonic suppression mediated by stellate cells appears to have a more powerful influence on basket cells when compared to excitatory afferents derived from parallel fibers. (Supported by NSF grant BNS 8919796.)

499.2

THE PHYSIOLOGICAL EFFECTS OF SEROTONIN ON NEURONS IN THE CAT'S CEREBELLAR NUCLEI. P.H. Kitzman* and G.A. Bishop. Dept. of Cell Biology, Neurology and Anatomy, The Ohio State University, Columbus, OH 43210.

The indoleamine serotonin (5HT) is present in a dense beaded plexus within the cat's cerebellar cortex and deep nuclei (Karr and Bishop, 1991, JCN 304:502). The intent of the present study is to determine the physiological effects of 5HT on neurons within the cat's cerebellar nuclei. Serotonin was iontophoretically applied to individual neurons within the Interpositus nucleus and its effect on spontaneous firing rate was recorded. In addition, 5HT was applied in combination with quisqualate, aspartate, and GABA. The results showed that 5HT partially reduced the spontaneous firing rate of the cerebellar nuclear neurons in a dose dependent manner. Of the cells which were activated by either of the excitatory amino acids, 50% were completely suppressed by the application of 5HT, while 36% were only partially suppressed. The remaining 14% of the recorded neurons were not affected by 5HT. 57% of the neurons which demonstrated complete suppression of firing rate showed a delay of approximately 10 seconds before activity was modulated. 58% of the neurons demonstrated a partial recovery of firing activity during application of 5HT, while 14% of the neurons recovered to their control firing rate. 28% of the neurons demonstrated complete suppression during the entire time 5HT was administered. 5HT also was shown to potentiate the inhibitory effect of GABA on 50% of the spontaneously active cells and 62% of the neurons activated by the excitatory amino acids. The remaining neurons demonstrated an additive interaction between 5HT and GABA. These results indicate that 5HT may have a similar function in the cerebellar nuclei as was found in the cortex; even though the brainstem sources of 5HT afferents to the cortex and nuclei are different. Specifically, 5HT modulates the response of the deep nuclear neurons to excitatory and inhibitory neurotransmitters. (Supported by NSF grant 8919796.)

499.3

THE DISTRIBUTION OF MONOAMINERGIC FIBERS AND CELL BODIES IN THE CEREBELLUM IS NOT UNIFORM BETWEEN SPECIES. I.E. Nelson*, G.A. Bishop and J.S. King. Neuroscience Program, The Ohio State University, Columbus, OH 43210.

The indirect antibody peroxidase-antiperoxidase technique was used to determine the distributions of serotonergic and catecholaminergic afferents in the mouse, opossum, and cat cerebellum. Antibodies to either serotonin (5-HT) or tyrosine hydroxylase (TH) revealed a diffuse plexus of thin varicose fibers that exhibited a different density and distribution pattern for each species. The only species in which TH-positive Purkinje cells were found is the mouse. Their primary location is vermal lobules VI-X. In the mouse, 5-HT fibers were scattered sparsely within all lobules and laminae, as well as all cerebellar nuclei. TH fibers formed a dense plexus within all cerebellar lobules, laminae, and nuclei. In the opossum, scattered 5-HT fibers were present in the granule and Purkinje cell layers of all lobules; they were densest in vermal lobules VIII and IX, and sparse in lobules II-VI. By comparison, TH fibers were more uniformly and densely distributed in the same layers; they were more abundant in vermal lobules V-VI than in more anterior and posterior lobules, particularly I and X. Numerous 5-HT and TH fibers were found in all four cerebellar nuclei. In the cat, except for sparse labeling in lobule V, 5-HT fibers were uniformly distributed at a high density in the granule and Purkinje cell layers of all cerebellar lobules and were present in all four nuclei. In contrast, TH fibers were sparsely distributed to all lobules and nuclei except for an area of elevated density in ventral folia of lobules V and VI. The transmitter synthesized in the TH positive fibers is most likely norepinephrine. However, dopaminergic fibers and binding sites have been reported in the mouse and rat cerebellum (Panagopolous et al., 1991, Neurosci. Lett. 130:208). The present results show that although monoaminergic axons within the cerebellum have similar morphologies their relative densities within cortical layers, distribution patterns within lobules, and brainstem origins vary between species. 499.5

THE LOCALIZATION OF CORTICOTROPIN RELEASING FACTOR (CRF) BINDING SITES DURING PURKINJE CELL MIGRATION King, James S.* and Paul C. Madtes Jr. Neuroscience Program, The Ohio State University Columbus, Ohio 43210

The purpose of the present study is to determine the temporal and spatial expression of CRF binding sites during early stages of cerebellar development in the opossum. Serial frozen sections were analyzed at PD 3, 4, 6, 8 and 10 using the protocol of DeSouza and Insel 1990 (CRF: Basic and Clin. Stud. Neuropeptide, CRC Press p.69). Specific binding sites were determined by using [¹²⁵I]-labeled CRF and localized by apposing Kodak X-OMAT AR film to slides for specific time periods. The films were processed and analyzed using a computer-based densitometry system. An antibody to calbindin was employed at the same postnatal ages to identify Purkinje (PK) cells during early stages of cerebellar development. Cummings et al (1989, Neurosci. Abst. 15:405) reported the presence of CRF immunoreactive axons and their growth cones in the opossum cerebellum in areas through which PK cells are migrating between PD 4 and 14. They also reported the presence of CRF mRNA in the inferior olive on PD 2 suggesting the earliest arriving axons are olivary in origin. CRF binding sites could not be detected until PD 8 at which time they were located superficially in the cerebellar plate over the EGL and the nascent Purkinje cell layer. At this age Purkinje cells have begun, but not completed their migration from the ventricular layer. Thus, based on the distribution of silver grains at PD 8, CRF binding sites are located over Purkinje cells that have completed their migration. However, this is prior to the time that CRF afferents arborize and penetrate the nascent Purkinje cell layer. The temporal expression and location of the CRF binding sites suggest that they could function in the formation of the initial climbing fiber Purkinje cell synapses. (Supported by NS 08798.)

499.7

COMPARISON OF PURKINJE CELL ZEBRIN II ANTIGENIC BANDS AND THE CUNEOCEREBELLAR FIBER TERMINATION BANDS IN THE MOUSE. A. Akintunde* and L. M. Eisenman. Dept. of Anatomy, Thomas Jefferson Univ., Philadelphia, PA 19017

The parasagittal parcellation of the cerebellar cortex has been revealed using various techniques. Mossy fibers, apart from providing the largest afferent input to the cerebellum and originating from many sources in the neuraxis, have also been shown in some instances to terminate in longitudinal compartments. Several correlation studies have been carried out to determine whether a common organizational plan encompassing the various afferent, efferent and intrinsic maps may exist in the mammalian cerebellum. Unilateral injections of WGA-HRP tracer were made into the external cuneate nucleus (ECN) of adult mice. Adjacent frontal sections of the cerebellar cortex were processed either for Zebrin II antigenicity or WGA-HRP tracer anterogradely transported from the ECN injection site. Cuneocerebellar fibers in the mouse were found to project in a strictly ipsilateral fashion and in well-delineated parasagittal terminal distribution zones. This was particularly clear in the vermal regions of both anterior and posterior lobes. Comparison of the banding patterns in alternate sections revealed that the limits of the cuneocerebellar terminal fields in the granule cell layer obeyed the boundaries of some, but not all, of the Zebrin II antigenic bands in the molecular layer. NIH grant NS 16531 (LME) gratefully acknowledged.

499.4

AUTORADIOGRAPHIC LOCALIZATION OF CORTICOTROPIN RELEASING FACTOR (CRF) BINDING SITES IN THE ADULT OPOSSUM CEREBELLUM. P.C. Madtes Jr.* and J.S. King. Neuroscience Program, The Ohio State University, Columbus, OH 43210

A previous study has shown that CRF immunoreactive climbing fibers, mossy fibers and beaded axons are present in all lobules of the opossum's cerebellar cortex (Cummings et al 1989; JCN 280:501). The intent of the present study is to localize CRF binding sites in the cerebellum. Serial frozen sections were cut in both sagittal and transverse planes, and analyzed using the protocol of DeSouza and Insel 1990 (CRF: Basic and Clin. Stud. Neuropeptide, CRC Press p.69). Specific binding was determined using [¹²⁵I]-ovine labeled CRF by subtracting nonspecific binding (measured in the presence of unlabeled human/rat CRF) from total binding (measured in the absence of human/rat unlabeled CRF). Binding sites were localized by apposing Kodak X-OMAT AR film to slides for specific time periods. The films were processed and analyzed using a computer-based densitometry system. The K_d value (0.1nM) agrees with values reported for CRF receptors in other species. CRF binding sites are present in all lobules of the cerebellar cortex with the greatest density in lobules IX, X and the flocculus. Binding sites are present over the molecular, Purkinje cell and granular layers. Thus, the lobular and laminar distribution of CRF binding sites matches the CRF afferent fiber distribution. A previous report (Bishop and King 1992; Neuropeptides 22:167) based on the iontophoresis of CRF and extracellular recordings indicates that this peptide has a facilitatory effect on the glutamate- and aspartate-induced firing rate of Purkinje cells in the cerebellar cortex. The present data further support our hypothesis that CRF functions as a co-transmitter in two of the primary afferent systems (climbing fibers and populations of mossy fibers) to the cerebellar cortex. (Supported by NS 08798.)

499.6

ULTRASTRUCTURAL STUDY OF CGRP IMMUNOREACTIVITY IN THE NEONATAL CEREBELLUM. S. Morara 1*, J.J.L. van der Want 2, A. de Wolf 2, L. Provini 1,3 and A. Rosina 1, ¹Ist. Neuroscienze CNR, Milano, Italy, ²Dept. Morph., Neth. Ophthalm. Res. Inst., Amsterdam, Holland, ³Ist. Fisiol. Gen. Chim. Biol., Univ. Milano, Italy.

In the rat cerebellar cortex, that mostly develops postnatally, complex phenomena of synaptic rearrangement occur. Purkinje cells (PCs) are contacted at birth by perisomatic synapses of multiple olivary axons which undergo a process of retraction, to reach the adult one-to-one relationship with P cells at the end of the second postnatal week. During this period, CGRP immunoreactivity is transiently found in terminal-like boutons around PCs (Morara et al., Brain Res. 504,315, 1989).

An ultrastructural study was performed to get direct evidence for the presence of CGRP in the climbing fiber (CF) synapses on PCs. Vibratome sections from 0-15 day old rat cerebella were incubated in a polyclonal anti-CGRP antibody (Chemicon), visualized by means of DAB reaction followed by a gold-substituted silver peroxidase intensification (van den Pol and Gorcs, J. comp. Neurol. 252, 507, 1986). CGRP-IR terminals are found confined to PC layer. PC show an invaginated somatic outline with spine-like extrusions contacted by numerous terminals. Among them several CGRP-IR terminals are seen, forming asymmetric synapses on PC somata that show either a single membrane specialization or an interrupted synaptic complex.

We conclude that CGRP is present in CF synapses contacting PC during the period of transient perisomatic olivocerebellar synaptogenesis, suggesting that CGRP may play a role in the cerebellar maturation.

499.8

COMPARISON OF ZEBRIN COMPARTMENTS AND VIBRISAL RECEPTIVE FIELDS IN LOBULE IXa OF THE RAT CEREBELLUM

V. Chockkan and R. Hawkes*. Dept. Anatomy and Neuroscience Research Group, U. Calgary, Calgary, Alberta T2N 4N1, Canada.

Zebrin II is a 35 kDa polypeptide antigen of the cerebellum that is confined to parasagittal bands of Purkinje cells. In lobule IXa of the rat vermis anti-zebrin II staining reveals 4 zebrin⁺ bands on each side of the midline (P1⁺ - P4⁺), interposed by 3 zebrin⁻ zones (P1⁻ - P3⁻). In previous studies, electrophysiological micromapping has revealed prominent vibrissal receptive fields in the dorsal surface of IXa and so zebrin II immunocytochemistry was combined with RF mapping to compare the molecular and functional maps. Nine adult rats were mapped electrophysiologically, then perfused, sectioned and immunostained by using anti-zebrin II. After 3-D reconstruction, the antigenic and functional maps were superimposed. There are 3 discrete vibrissal receptive fields each side of the midline. These align reliably with the zebrin compartmentation with one centered on each zebrin⁻ band. However, the RFs consistently overlap the zebrin[±] borders at each side. A clear, reproducible relationship between the sensory and motor maps suggests that Purkinje cell compartmentation, which is present very early in cerebellar development, may serve as a substrate to organize cerebellar function into discrete modules.

SYNCHRONIZED OLIVARY OSCILLATIONS ARE TRIGGERED BY THE NEUROSTEROID PREGNENOLONE. Sheryl S. Smith, Dept. of Anatomy, Inst. of Neurosci., Hahnemann Univ., Phila., PA 19102-1192.

Elevations in circulating levels of sex steroids across the estrous cycle are associated with facilitation of rapidly alternating limb movements. One mechanism which may underlie this behavioral change is an increase in the synchronized oscillatory discharge of the rostral dorsal accessory olive (rDAO), a putative timing mechanism for rapid limb movements. Pregnenolone, a steroid elevated during estrous-enhanced performance state, was found in the present study to trigger this synchronized oscillatory discharge. This study was conducted in diestrous female rats chronically implanted with arrays of microwires (50 μ dia.) to record simultaneously from as many as 23 neurons within the rDAO, bilaterally, during locomotor paradigms or in the anesthetized state. During variable speed treadmill locomotion, pregnenolone (5 μ g, i.p.) increased the number of synchronized neurons by 150% and increased the amplitude of the 1-3 Hz oscillation by 60% compared to oil-injected controls. (n=10-23 neurons/rat recorded from 4 rats) This effect of the steroid was dose-dependent, with 100 ngs the minimal effective dose, and was not observed during non-movement. Under nembutal anesthesia (34 mg/kg, i.p.), pregnenolone triggered a fully synchronized oscillatory state from a previously non-synchronized population. This effect was specific for pregnenolone, as the two direct metabolites of this steroid, 17 α -OH-pregnenolone and progesterone, were not effective in this regard. Pregnenolone sulfate was slightly less effective than pregnenolone in triggering synchronization. The effect of pregnenolone may be due to its known actions at the level of the NMDA receptor (Wu et al, 1991) or voltage-sensitive calcium channel (French-Mullen and Spence, 1991), as MK-801 (1 mg/kg, i.p.) and, to a lesser extent, octanol (0.2 mg/kg, i.p.), blocked the synchronizing action of pregnenolone. ANISOTROPIC AND HETEROGENEOUS DIFFUSION IN THE CEREBELLUM: IMPLICATIONS FOR VOLUME TRANSMISSION. C. Nicholson*, Y. C. Okada and M. E. Rice. Dept. Physiology and Biophysics, New York University Medical Center, 550 First Avenue, New York, NY 10016.

Measurements of the extracellular diffusion parameters tortuosity (λ) and volume fraction (α) were made in three orthogonal axes of the molecular and granular layers of the isolated turtle cerebellum using iontophoresis of tetramethylammonium (TMA⁺) combined with ion-selective microelectrodes.

Diffusion in the molecular layer was characterized by an anisotropic tortuosity with three distinct values. Along the x-axis (the parallel fibers) $\lambda_x = 1.44 \pm 0.01$ (mean \pm S. E. M.), along the y-axis (perpendicular to parallel fibers and parallel to the pial surface) $\lambda_y = 1.95 \pm 0.02$, while $\lambda_z = 1.58 \pm 0.01$ (vertical axis). By contrast, the granular layer was isotropic with a single tortuosity value, $\lambda_{Gr} = 1.77 \pm 0.01$. There was a striking difference in α , for each layer. In the molecular layer $\alpha = 0.31 \pm 0.01$ while in the granular layer $\alpha = 0.22 \pm 0.01$.

One consequence of these results was demonstrated by measuring local changes in $[K^+]_o$ and $[Ca^{2+}]_o$ following micro-iontophoresis of the glutamate. The ratios of ion shifts in the x- and y-axes in the granular layer were 1.04 ± 0.08 for the rise in $[K^+]_o$ and 1.03 ± 0.17 for the decrease in $[Ca^{2+}]_o$. In contrast, ion shifts in the molecular layer had an x:y ratio of 1.44 ± 0.14 for the rise in $[K^+]_o$ and 2.10 ± 0.42 for the decrease in $[Ca^{2+}]_o$.

These data demonstrate that the structure of cellular aggregates can influence the migration of substances in the extracellular microenvironment and may play a role in volume transmission to extra-synaptic sites. This study was supported by NIH Grant NS 28642.

BRAIN METABOLISM AND BLOOD FLOW: MISCELLANEOUS

500.1

SPREADING DEPRESSION IS UNAFFECTED BY ANTI-MIGRAINE COMPOUNDS: A CEREBRAL BLOOD FLOW AND ELECTROPHYSIOLOGICAL STUDY. Peter J. Goadsby*, Karen L. Hoskin and Holger Kaube Department of Neurology, The Prince Henry Hospital, Sydney 2036 AUSTRALIA

Leao's cortical spreading depression (SD) is often cited as the pathophysiological substrate for the neurological symptoms of migraine with aura. If this is the case it might be expected that drugs useful as anti-migraine agents, particularly those useful in prophylaxis, may alter or prevent SD. In this study we attempted to further investigate the effects of DHE and other anti-migraine drugs on SD by measuring cortical blood flow with laser Doppler flowmetry (CBF_{LD}) and cortical single unit activity in the α -chloralose anaesthetized cat. The following substances were tested: DHE, acetylsalicylic acid, lignocaine, metoprolol, clonazepam and valproate. The NMDA-receptor blocker MK-801 and halothane (1.5%) were used as reference substances that reliably block SD. The outcome measures were speed of propagation of the wave of SD across the cortex and the CBF_{LD} increase during the hyperaemic phase of SD. Data were taken from three control episodes (60min apart) and after drug administration. The rate of propagation was significantly reduced from the first control period (3.0 \pm 0.3mm/min) to the subsequent 2 control observations (2.3 \pm 0.1mm/min) even without any drug treatment. Following the control observations the test drug was administered and a further SD elicited. This fourth SD was reliably blocked by MK-801 and halothane. None of other test drugs inhibited SD, reduced the rate of propagation or changed the amplitude of the CBF_{LD} increase. It is therefore possible that anti-migraine drugs that are active in prophylaxis do not have their effect through a modulation of SD. Indeed if SD is the explanation for the aura phase of migraine it may be an epiphenomenon driven by some further central process rather than the causal initiator of the migraine attack.

DISSIMILARITIES IN THE LINKAGE OF BLOOD FLOW AND GLUCOSE INFLUX TO GLUCOSE METABOLISM. J. Fenstermacher, L. Wei*, T. Otsuka, D. Bereczki, V. Acuff, K. Pettigrew and C. Patlak. Department of Neurological Surgery, SUNY at Stony Brook, NY 11794-8122

The coupling of local cerebral blood flow (LCBF) to local cerebral glucose utilization (LCGU) may vary fairly broadly among brain areas and between conditions, suggesting that the dependency of LCBF on LCGU differs considerably within the brain. To examine this suggestion LCBF, LCGU, and local 3-O-methylglucose (3MG) influx (3MGIn) were measured in control and hypercapnic (awake, breathing 8% CO₂) rats. Hypercapnia sizably raised arterial CO₂ and O₂, significantly elevated LCBF (25-230%), significantly lowered LCGU, and did not change 3MGIn. In control rats, LCBF/LCGU and 3MGIn/LCGU ratios varied significantly (2-fold) among brain areas; these ratio also varied significantly (3-fold) among brain areas in hypercapnic rats. This suggests that the linkage of LCBF and of 3MGIn to LCGU differs among brain areas. The pattern of the differences in these ratios between control and hypercapnia groups was dissimilar, indicating that hypercapnia did not have a uniform effect on the coupling of LCBF and 3MGIn to LCGU. The sensitivity of parenchyma arteriole to blood gases and local metabolites or the ability of them to respond may vary among brain areas. The permeability-surface areas product of 3MG was identical in control and hypercapnic rats, which implies little or no capillary recruitment during hypercapnia and little regulation of 3MG influx.

CHRONIC HYPOXIA INCREASES CAPILLARY DENSITY IN MOUSE BRAIN

J. Bocro, A. Arregui, J. Christensen*, C. Rovainen and T. Woolsey. ¹ Dept. of Neurology, Universidad Peruana "Cayetano Heredia", Lima, Peru, and Depts. of ² Neurology and Neurological Surgery and of ³ Cell Biol. and Physiol., Washington University, St. Louis MO 63110

A mouse model was developed to explore cerebrovascular pathophysiology associated with life at high altitude. We report here substantial changes in the cerebral capillaries in this model. Weanling *Swiss Webster* mice were put in an intermittent hypobaric hypoxic chamber simulating an altitude of 4,300 m. Littermate controls were at sea level. After 3 weeks, mice in both groups were anesthetized and perfused through the heart with photographic emulsion to fill brain capillaries (e.g., Wang et al, JCBF&M 12: 935 '92). Frozen 50 μ m serial sections through the brain were cut in the coronal plane. Selected areas were measured through a microscope with a video camera and Macintosh Computer using Image (W. Rasband, NIH). Qualitatively, capillaries in all parts of the hypoxic brains appeared larger, and were more numerous and tortuous. Measurements of L_v (vascular length density) increased by 20% in cortex, cerebellum and brainstem and were significant in the striatum (e.g., $p \leq 0.01$). These substantial changes indicate a significant capacity of the maturing cerebral vascular system to compensate for decreased O₂ tensions to meet sustained metabolic demands of the brain.

MEASUREMENT OF BRAIN TEMPERATURE IN MULTIPLE SITES DURING COLD STRESS REVEALS DYNAMIC AND NONUNITARY CHANGES. S.T. Ahlers*, C.L. Kish, and J.R. Thomas. Naval Medical Research Institute, Bethesda, MD 20889-5607.

Exposure to environmental cold stress has been shown to impair working memory. Previous research has shown that the level of cooling in which the deficit is observed also produces a temperature decrease of approximately 1°C in the hippocampus (HIPP), suggesting that subtle changes in brain temperature may play a role in the impairment of cognitive function. In the present study we examined the effects of cold stress on brain and body temperature in order to determine how closely coupled temperature is in the brain as a whole and what relationship brain temperature has to "core" temperature as measured in the peritoneal cavity. Accordingly, rats were implanted with thermistors into the prefrontal cortex (PFC), the medial preoptic area of the hypothalamus (MPA), and the dorsal hippocampal formation (HIPP) of the rat. Probes were attached to a six channel receptacle affixed to the rats' skull. During measurement, a cable was connected to a swivel and attached to the receptacle to allow on line measurement of brain temperature in three discrete brain regions simultaneously. A radio-telemetry probe (Mini-Mitter, Sun River, OR) was implanted into the peritoneal cavity. One week after surgery the brain and body temperature were measured in rats during exposure to ambient temperatures of 24°C and 5°C. Analysis indicated nonuniform changes in the regions of the brain and in the body during both nonstressed (normothermic) and cold stressed conditions. These data demonstrate that brain temperature is not homogeneous and that temperature in various regions of the brain show unique response patterns. The extent that these nonuniform changes in brain temperature relate to specific cognitive deficits observed during exposure to cold stress remains to be determined.

IS THERE RECRUITMENT OF CAPILLARIES AND/OR GLUCOSE TRANSPORTERS IN RAT BRAIN DURING STRESS? J.-L. Chen, T. Otsuka, D. Bereczki, L. Wei, V. Acuff, C. Padlak, and J. Fenstermacher*. Div. Neurosurg., Tri-Service General Hospital, NDMC, Taipei, Taiwan, and Dept. Neurol. Surg., SUNY, Stony Brook, NY 11794-8122.

Local cerebral glucose utilization (LCGU) and blood flow (LCBF) are often changed during stress. In order to understand the mechanism of LCBF alteration and its linkage to LCGU during stress, LCBF and the permeability-surface area products (PS) of antipyrine (PS-AN) and of 3-O-methylglucose (PS-3MG) were measured in many areas of rat brain in four different conditions. With hypoxia and hypercapnia, LCBF and plasma glucose levels were markedly elevated, PS-AN was only slightly raised, and PS-3MG was slightly lowered (hypoxia) or unchanged (hypercapnia). With nicotine treatment, plasma glucose was normal, LCBF was greatly increased in some brain areas, and PS-AN and PS-3MG were virtually unchanged in these areas. In view of the effects of plasma glucose on PS-3MG, these data indicate little or no capillary recruitment when LCBF is increased with these three conditions. After 24 hr of dehydration, LCBF was slightly lowered, plasma glucose and PS-AN were unchanged, and PS-3MG was raised throughout the brain. Dehydration does not appear to alter the number of perfused capillaries but may raise glucose transport, possibly by recruiting glucose transporters in capillary endothelial cells.

THE ROLE OF CALCIUM-ACTIVATED PROTEOLYSIS IN VASOSPASM AFTER SUBARACHNOID HEMORRHAGE. P.L. Foley*, P. Vanderklish*, Y. Goto, G. Lynch*, N.F. Kassell, K.S. Lee. Dept. of Neurological Surgery, Univ. of Virginia, Charlottesville, VA 22908, *CNLM, Univ. of California, Irvine, CA 92717.

A rise in cytosolic calcium levels in smooth muscle cells is believed to be a pivotal event in the development of chronic vasoconstriction after subarachnoid hemorrhage (SAH). Calcium-activated proteolysis via calpain may participate in vasospasm by damaging the function of key proteins regulating smooth muscle tone. The present studies investigated this issue by measuring levels of native calpain in the rabbit basilar artery following SAH. Two to four days following experimental SAH, basilar arteries were removed, thoroughly flushed with cold homogenization buffer to remove all blood, and placed into 100 μ l of cold buffer. The tissue was subsequently homogenized using glass tissue grinders. Western blot analyses were performed using an antibody for calpain, and an antibody for spectrin. Spectrin is a cytoskeletal protein and a preferred substrate for calpain.

Vessels from normal (non-SAH) rabbits exhibited high levels of native calpain and native spectrin. Vessels removed 2 to 4 days after SAH showed significant reductions in the levels of native calpain. In addition, an elevation in spectrin breakdown products was seen. The molecular weights of the spectrin breakdown products were typical of those observed following calpain proteolysis.

The decline in native calpain levels after SAH suggests that autolytic activation of this protease had occurred. This conclusion is supported by the finding that a preferred substrate of calpain, spectrin, is degraded at the same time. These findings indicate that calpain activation occurs following SAH, and that proteolysis could contribute to the pathophysiology of vasospasm.

DEVELOPMENT OF ACTIVITY STANDARDS FOR QUANTIFICATION OF CYTOCHROME OXIDASE HISTOCHEMISTRY D. Jones* and F. Gonzalez-Lima, Dept of Psych, Univ of Texas, Austin TX, 78712 USA

Taking advantage of quantitative image analysis systems we measured the enzyme activity in histochemically stained brain slices by calibrating the analysis system with internal standards of known amounts of cytochrome oxidase CO activity. Standards were prepared with homogenized brain or heart tissue. Different mixtures were obtained by adding to microwaved inactive paste increasing percent weight proportions of active paste. The mixtures were rehomogenized, placed in microcentrifuge tubes, frozen in isopentane, and sliced in a cryostat. Samples of each standard were prepared for enzyme assay according to Hess and Pope and the calculation of specific activity was performed spectrophotometrically based on Wharton and Tzagaloff. The staining procedure, a modification of Silverman and Tootell, involved cobalt preincubation, oxygenation and heating of reaction medium. Percent weight concentration was compared to spectrophotometrically assessed activity. The effects of length of incubation, section thickness, and activity on measured optical density (OD) were assessed. A regression curve for the known activities and the corresponding OD was matched to a regression curve for the section thickness and their corresponding OD to obtain predicted activity for the varying thicknesses of section. The effect of varying concentrations of heart or brain active tissue on measured activity and OD of histochemical staining were investigated. Validation of the procedure was assessed by testing the effect of varying each of the above parameters on measured activity and OD. The resulting quantitative CO method provides a superior approach for regional mapping studies of brain metabolic capacity. Examples of applications of this technique are presented using the auditory system of the gerbil. (supported by RO1 MH43353).

RETINAL BLOOD FLOW FOLLOWING OCULAR ISCHEMIA IN CATS. S. Roth* Z. Pietrzyk, Department of Anesthesia and Critical Care, University of Chicago, Chicago, IL 60637.

Retinal ischemia may occur after retinal vascular occlusion or may accompany systemic diseases such as diabetes mellitus. The mechanisms responsible for visual damage after retinal ischemia are not well understood. We hypothesized that retinal blood flow (RetBF) after ocular ischemia would be hyperemic, similar in time course and magnitude to that occurring after cerebral ischemia. Adult cats weighing 2.5-3.5 kg were anesthetized with chloralose 80 mg/kg and acepromazine 0.25 mg/kg IV. RetBF was measured using radioactively labeled microspheres injected into the left atrium with the reference blood sample method. Ocular ischemia was produced for 1 h by increasing intraocular pressure to 100 mmHg > systolic arterial blood pressure using a saline reservoir connected to an anterior chamber cannula. Blood flows were measured before and after ischemia in 6 cats. In 4 control animals, blood flows without ischemia were measured over the same time course. Results were analyzed using repeated measures ANOVA with $P < .05$ considered statistically significant. RetBF before ischemia was $17 \pm 9 \text{ ml} \cdot \text{g}^{-1} \cdot \text{min}^{-1}$ (mean \pm SEM). Within 15 min of the return of normal IOP after ischemia, RetBF increased significantly to $52 \pm 10 \text{ ml} \cdot \text{g}^{-1} \cdot \text{min}^{-1}$ ($P < .0001$). By 1 h after ischemia, RetBF had returned to baseline. In control animals, RetBF did not change significantly over a comparable time course. We conclude that retinal ischemia is followed by hyperemia after reperfusion, but not by delayed hypoperfusion, as others have shown in the brain. Hyperemia after ischemia may contribute to blood-retinal barrier dysfunction and macular edema, and therefore we are currently investigating its mechanism.

INTERACTIONS BETWEEN MITOCHONDRIA AND CYTOSOLIC FREE CALCIUM IN DISSOCIATED RAT HIPPOCAMPAL NEURONS. A.V. Nowicky and M.R. DuChen. Physiology Dept., Univ. College, London, U.K., WC1E 6BT.

Changes in mitochondrial function may play a central role in defining neuronal viability after metabolic disturbances such as hypoxia. We have examined the interrelationships between changes in mitochondrial energetics and $[\text{Ca}^{2+}]_i$ in central neurons. Cells were freshly dissociated from hippocampal slices of 14-22 day old rats. Fluorimetric measurements were made from cells loaded with the Ca^{2+} -sensitive dye Fura-2 and/or the lipophilic cation, rhodamine 123 (Rh 123), which selectively reports mitochondrial potential ($\Delta\psi_m$). Elevation of $[\text{Ca}^{2+}]_i$ by brief depolarization with 50mM K^+ depolarized $\Delta\psi_m$ in most cells. $[\text{Ca}^{2+}]_i$ rose on depolarization of $\Delta\psi_m$ with the uncoupler, FCCP. This response persisted in the absence of external Ca^{2+} suggesting that it reflects Ca_2^+ release from an internal store. This store could be loaded by K^+ induced depolarization, enhancing the response to FCCP. Dual loading allowed the direct examination of the temporal relationships between changes in $[\text{Ca}^{2+}]_i$ and of $\Delta\psi_m$. These data suggest that depolarization of the cell membrane is associated with mitochondrial Ca^{2+} uptake. (supported by Action Research)

REGULATION OF NUCLEAR- AND MITOCHONDRIAL- ENCODED CYTOCHROME OXIDASE SUBUNITS AND ENZYME ACTIVITY BY NEURONAL ACTIVITY IN DORSAL LATERAL GENICULATE NUCLEUS OF ADULT MONKEYS. S. Liu* and M. Wong-Riley. Dept. Cellular Biology & Anatomy, Med. Coll. Wis., Milwaukee, WI 53226

Cytochrome oxidase (CO), a mitochondrial enzyme of oxidative energy metabolism, is composed of 13 subunits derived from both nuclear and mitochondrial genomes. The goal of this study was to determine whether the expression of these two genomes was regulated coordinately at the subunit protein level by functional activity in neurons. To clarify this question, we examined the level of CO activity histochemically, and protein levels of subunit II, II/III (mitochondrial-derived) and subunit IV (nuclear-encoded) immunohistochemically in dorsal lateral geniculate nuclei (LGN) of normal and monoclonal TTX-treated monkeys. In the normal LGN, a similar staining pattern was found for all markers examined. After 3 or 7 days of TTX treatment, levels of CO activity and subunit proteins reduced disproportionately in the deprived laminae of LGN. Changes in levels of CO activity and subunit IV was significantly greater than subunits II and II/III ($P < 0.01$). We also found that the levels of CO activity and subunit proteins were up-regulated in cell bodies of the nondeprived laminae. These findings demonstrate that at subunit protein levels, mitochondrial and nuclear genomes are somewhat disproportionately regulated by neuronal functional activity. Changes in subunit IV parallel most closely that of CO activity, suggesting that subunit IV may play an important role in governing the level of CO holoenzyme activity in response to changes in neuronal functional activity. (Supported by NIH grant NS 18122).

HEXOKINASE I mRNA IN THE CENTRAL NERVOUS SYSTEM OF THE RAT: AN *IN SITU* HYBRIDIZATION STUDY

G. Jacobsson¹, K. Uvnäs-Moberg² and B. Meister^{1*}, ¹Departments of Histology and Neurobiology, and ²Pharmacology, Karolinska Institute, P.O. Box 60400, S-104 01 Stockholm, Sweden.

After glucose enters the cell by the aid of a glucose transport protein, it is rapidly converted into glucose 6-phosphate with ATP serving as the phosphoryl donor. In mammals, the phosphorylation of glucose to glucose 6-phosphate is catalyzed by at least four different hexokinases (isozymes I-IV). Glucose 6-phosphate is a necessary substrate for several metabolic pathways, including glycolysis, glycogen synthesis and the hexose monophosphate pathway. Recently, the rat brain hexokinase I was cloned. In the present study we have synthesized two complementary 48-mer oligonucleotide probes to rat brain hexokinase I and studied the distribution of its mRNA in the rat central nervous system by *in situ* hybridization. Both probes showed a wide distribution of labelled neurons of the brain. Particularly strong expression was demonstrated in the cerebral cortex, in the CA1-3 regions and dentate gyrus of the hippocampus, in the amygdala, olfactory bulb, thalamus, cerebellum and several brainstem nuclei. Motoneurons of the spinal cord and dorsal root ganglion cells were strongly labelled. Within the hypothalamus, strong expression of hexokinase I mRNA was demonstrated in the supraoptic, paraventricular, arcuate and ventromedial nuclei. Ependymal cells of the choroid plexus expressed hexokinase I mRNA. Expression of hexokinase I mRNA in the central nervous system was also demonstrated in the E15 rat fetus, where dense labelling in addition was observed in the liver, intestine and heart. After administration of hyperosmotic stimuli (2% saline in the drinking water) an increase in hexokinase I mRNA could be observed in the hypothalamic supraoptic and paraventricular nuclei. Further studies may show regulation of hexokinase I mRNA in individual brain nuclei after changes in plasma glucose.

THE ROLE OF ENDOTHELIUM IN RAT PIAL ARTERIOLAR DILATORY RESPONSES *IN VIVO* Q. Wang, D.A. Pelligrino*, H.M. Koening. Dept. Of Anesthesiol., Univ. of Illinois at Chicago, IL 60616.

In fentanyl (25 µg kg⁻¹ hr⁻¹)/70% N₂O/30% O₂ anesthetized, paralyzed (curare) and mechanically ventilated male Sprague-Dawley rats, we employed a light/dye (LD) *in vivo* endothelial injury model and studied pial arteriolar responses to adenosine 5'-diphosphate (ADP), S-nitroso-acetylpenicillamine (SNAP), and CO₂. LD treatment consisted of intravenous injection of sodium fluorescein and the illumination (for a period of ~90 sec) of a discrete area of the arterioles with light from a mercury lamp. The diameter changes in 30-60 µm pial arterioles were examined using a closed cranial window system and intravital microscopy/videometry. Before LD treatment, suffusion of 5 x 10⁻⁶ M Ach, 10⁻⁴ M ADP, 10⁻⁵ M SNAP and inhalation of 10% CO₂ increased the pial arterioles by 27 ± 3 (n = 16), 30 ± 3 (n = 14), 33 ± 4 (n = 13) and 32 ± 3% (n = 16) (means ± SE). After LD injury, the response of pial arterioles to Ach was completely abolished and the ADP response was reduced to 18 ± 3% (p < 0.05). In contrast, SNAP and CO₂ still produced diameter increases (26 ± 2 and 32 ± 3%, respectively) not different from control. It was previously reported that ADP induced vasodilation by a NO-dependent mechanism. The partial reduction in the response after endothelium damage suggests that there exists either a non-endothelial source of NO in ADP-induced dilatation or that a portion of the ADP response is NO-independent. The completely normal CO₂ response after endothelium damage suggests that the reported NO-dependence of hypercapnia-induced cerebral vasodilatation/hyperemia in rats cannot be attributed to an endothelial NO source. Supported by the Juvenile Diabetes Foundation International.

THE EFFECT OF AN ENDOTHELIN RECEPTOR ANTAGONIST ON ENDOTHELIN-1 - INDUCED CONSTRICTION IN CEREBRAL MICROVESSELS. O. Sagher*, Y. Jin, Q.-A. Thai, N.F. Kassell and K.S. Lee. Dept. of Neurosurgery, Univ. of Virginia, Charlottesville, VA 22908.

Endothelin-1 (ET-1) is a potent vasoconstrictor that has been implicated in the pathogenesis of cerebral vasospasm. ET-1 is thought to elicit constriction through activation of a membrane-bound receptor. Two receptor subtypes have been recognized, ET_A and ET_B. The effects of ET-1 and an endothelin receptor antagonist on rat cerebral microvessels were studied in submerged, *in vitro* brain slices using computerized videomicroscopy. Previous data have suggested that the effects of ET-1 on cerebral microcirculation are mediated by ET_A receptors. The effect of cyclo[D-Asp-L-Pro-D-Val-L-Leu-D-Trp] (ETant), an antagonist of ET_A receptors, on ET-1-induced vasoconstriction was examined. When vessels were pretreated with ETant (20nM), ET-1-induced vasoconstriction was effectively blocked. When ETant was administered following an established constriction with ET-1, it exerted a moderate vasodilatory response. These studies indicate that ETant is a potent competitive antagonist of ET-1 in cerebral microvessels, and that it may be able to reverse an established ET-1 induced constriction. Agents such as ETant may be useful in the treatment of ET-1-induced pathological vasoconstriction, such as cerebral vasospasm.

METABOLIC CORRELATES OF INTRINSIC OPTICAL SIGNALS IN RODENT CORTEX.

S. Narayan*, A.J. Blood and A.W. Toga

Laboratory of Neuro Imaging, Dept of Neurology, UCLA, Los Angeles CA.

We have investigated the nature of optical intrinsic signals (activity-related optical reflectance changes) in rodent primary somatosensory cortex (S-I).

S-I was exposed in male Sprague-Dawley rats and illuminated at 550 nm, 610 nm and 850 nm. Images were obtained before, during and after contralateral vibrissal deflection or forelimb stimulation. After pixel-by-pixel division of images by controls, intrinsic signals were seen over the posteromedial barrel subfield and forelimb sensory cortex, and included a strong venous component. Signal characteristics differed between wavelength and paradigm. Electrophysiologic recordings were performed using bipolar SNEX electrodes (100 µm diameter), advanced stereotactically at sites inside and outside the zone of reflectance change. Evoked responses were maximal over cortex showing the greatest optical activity, and both measures diminished in tandem. We compared signal localization with the density of cytochrome oxidase staining in 50 µm sections from these subjects, and found that signals may be affected by the activity of this enzyme.

Intrinsic signals have been observed over electrophysiologically active cortex, but commence, peak and extinguish over seconds. In addition to other etiologies¹, our studies indicate that optical reflectance activity in rodent cortex is related to cytochrome oxidase density and microvascular changes.

INCREASE IN BLOOD CELL FLUX RATE, VELOCITY AND DIAMETER OF CEREBRAL CAPILLARIES DURING HYPERCAPNIA. U. Lindauer,

A. Villringer, U. Dirnagl. Dept. of Neurology, Univ. of Munich, 8000Munich 70,FRG

We studied blood cell flux rates, velocities and diameters of cerebral capillaries during normocapnia and changes of these parameters during hypercapnia. Male Wistar rats (n=6) were anesthetized with thiobutabarbital (100mg/kg), tracheotomized and artificially ventilated. The left femoral artery and vein were cannulated. Systemic arterial blood pressure, endexpiratory pCO₂ and body temperature were monitored continuously and arterial blood gases were measured periodically. A closed cranial window (dura removed) was implanted over the parietal cerebral cortex. Na-fluorescein was injected intravenously (2mg/100g body weight as a bolus, following the same dosage per hour of continuous infusion). We used a confocal laser scanning microscope and measured cerebral capillaries up to 200µm beneath the brain surface. Changes in blood cell flux rates and velocities and capillary diameters were monitored during normocapnia and hypercapnia (5% CO₂ in inspired gas) as a global stimulation of cerebral perfusion. During normocapnia all physiological parameters were within normal ranges. For results during normo- and hypercapnia see table below. Earlier experiments during normocapnia showed, that all capillaries are plasma perfused all the time and only less than 5% are not perfused with blood cells intermittently. More than 50% of all capillaries show blood cell flux rates and velocities in the lower fourth part of the range. During hypercapnia this functional reserve capacity is used, that is the flux rate- and velocity-distribution curve is shifted to the right and capillary diameters are increased (p<0.05). Supported by the DFG and the Wilhelm Sander Stiftung.

	pCO ₂ (mmHg)	flux-rate (n=36) (cells/s)	velocity (n=14) (µm/s)	diameter (n=38) (µm)
normocapnia	33.25	53.17 ± 48.46	990.29 ± 983.79	4.81 ± 1.10
hypercapnia	50.26	69.19 ± 49.50	1076.86 ± 888.30	5.28 ± 0.93

CHANGES IN BLOOD FLOW AND VASCULAR RESISTANCE OF CHOROID PLEXUSES OF POSTNATALLY DEVELOPING RATS. C.E. Johanson*, J. Szmydynger-Chodobska, and A. Chodobski. Program in Neurosurg., Dept. Clin. Neurosci., Brown University and R.I. Hospital, Providence, RI 02903.

Postnatal developmental changes in blood flow to choroid plexuses (CPs) of the lateral (LVCP) and fourth (4VCP) ventricles were studied in pentobarbital-anesthetized and artificially ventilated rats at the age of 2, 3, 5, and 7-8 wk. Blood flow was measured by the indicator fractionation method with ^{125}I -N-isopropyl-p-iodoamphetamine used as the marker. The period between the third and fifth week after birth was associated with a pronounced increase in choroidal blood flow. At the earliest stages of development analyzed in this investigation (between the second and third week postnatally), blood flow to both LVCP and 4VCP was low (ie, 2.5-2.8 ml g⁻¹ min⁻¹) and did not change significantly. There was also no difference in blood flow values between the two CPs at 2 wk vs 3 wk. However, during this same period of development, the vascular resistance of both CPs increased by 62-65% ($P < 0.01$), which was associated with concomitant elevation of arterial blood pressure (from 57±1 to 92±2 mmHg, $P < 0.01$). From the age of 5 wk on, blood flow to 4VCP was higher than that to LVCP. These two CPs seemed to differ not only in regard to their absolute blood flow values, but also in regard to the rate of maturation of their vascular beds during ontogenesis. Thus, in 5-wk-old rats, blood flow to LVCP was similar to that of adult animals (3.29±0.09 vs 3.30±0.07 ml g⁻¹ min⁻¹), whereas 4VCP at this postnatal age was still less perfused than fully matured tissue (3.74±0.11 vs 4.12±0.08 ml g⁻¹ min⁻¹, $P < 0.05$). The postnatal developmental changes in choroidal blood flow found by us correlate well with a progressive increase in choroidal ion transport and enzyme activity observed in rats after birth. These changes in choroidal blood flow represent a continuing adjustment of the choroidal vascular system to steadily increasing CSF secretory capabilities of maturing choroidal epithelium. The increase in choroidal vascular resistance observed between the second and third wk after birth may indicate the presence of the efficient blood flow autoregulatory mechanisms as the growth of choroidal vascular bed is probably slow during this period of development. Supported by NIH Grant NS 27601.

CEREBRAL BLOOD FLOW REDUCTION AND TRANSIENT CBF INCREASES INDUCED BY GLUCOSE AND MANNITOL: A LASER-DOPPLER STUDY.

Robert B. Duckrow,* Department of Neurology, The University of Connecticut School of Medicine, Farmington, CT 06030.

Cerebral blood flow (CBF) is reduced during acute hyperglycemia in awake restrained rats. Previous studies suggest that this reduction is not related to increased plasma osmolality or secondary to changes in hematocrit, viscosity, glucose utilization, or hyperinsulinemia. However, previous measurements of CBF were performed using iodoantipyrine, which provides a single measurement of flow integrated over a 30 s period. To remove this sampling restriction, CBF was measured during acute hyperglycemia in the anesthetized rat using continuous laser-Doppler flowmetry. After induction of pentobarbital anesthesia, the rat was fixed in a stereotaxic frame and the parietal bone was thinned with a dental burr. Body temperature was maintained and arterial pressure, pH, gas tensions, hematocrit, and osmolality were monitored. A Vasamedic BPM² 0.8 mm laser-Doppler probe was placed on the bone window away from dural vessels. Cortical CBF was measured relative to the zero flow reading obtained after death. Acute hyperglycemia was induced by intraperitoneal injection of 25% D-glucose, 4 gm/kg. An equal amount of mannitol was given to control rats. Maximum plasma osmolality was 349 mOsm. CBF decreased 19% 10 minutes after either glucose or mannitol injection. In addition, brief transient increases of CBF with peak magnitude 2 to 4 times baseline level occurred 25 s to 13 min following glucose or mannitol injection (mean latency: glucose, 6 min; mannitol, 8 min). These CBF transients occurred in 8 of 14 rats given glucose and in 9 of 10 rats given mannitol. They were not accompanied by EEG suppression, otherwise seen during spreading cortical depression induced by needle penetration of the cortex. They did not occur spontaneously and were not suppressed by pretreatment with indomethacin or N^o-nitro-L-arginine methyl ester. I conclude that reduced CBF measured during acute hyperglycemia in anesthetized rats may be directly related to increased plasma osmolality. Also, transient CBF increases may confound discontinuous measures of CBF during acute hyperosmolar states. (Supported by PHS NS24109)

QUANTITATIVE MATCHING AUTORADIOGRAPHIC IMAGES AND AVERAGING TECHNIQUES IN CEREBRAL BLOOD FLOW STUDIES W. Zhao*, K. Takagi, D.W. Smith and M.D. Ginsberg CVDRC (D4-5), Dept. of Neurology, Univ. of Miami, Sch. of Med., P.O. Box 016960 Miami, FL, 33101.

In the analysis of replicate autoradiographic studies of animals studied under controlled experimental conditions, the ability to average corresponding coronal levels from several animals would permit one to perform region-of-interest (ROI) analysis on the average image; this would increase the precision of analysis and diminish inter-pixel noise. We have employed a newly developed software package which provides efficient and accurate image-matching and alignment capability. Corresponding coronal sections from n animals are matched by a disparity analysis algorithm. Each section is linearly transformed using with bilinear interpolation to reduce quantitation errors. "Mean" and "standard deviation" images can then be easily obtained. We validated this approach in 3 control rats undergoing ^{14}C -iodoantipyrine cerebral blood flow studies. CBF values were compared from six regions read both in individual brains and on the computed mean and SD images (Table). This approach facilitates analysis while preserving accuracy and precision.

CORTICAL BLOOD FLOW (CBF) INCREASES ELICITED BY CONTINUOUS OR DISCONTINUOUS ELECTRICAL STIMULATION OF THE RAT SUBSTANTIA INNOMINATA (SI). F. Dauphin, P. Lacombe, E.T. MacKenzie* and J. Sevlaz. CNRS ERS 19, Caen and CNRS URA 641, Faculté de Médecine Villemin, Paris, France.

Discrepancies on the inhibitory effect of muscarinic receptor blockade on CBF increases elicited by electrical stimulation of the SI (Dauphin et al., Brain Res 553, 75, 1991; Arneric, Soc Neurosci Abs 14:488.2, 1988) led us to postulate differences between the two stimulation procedures (continuous (CS): 100 Hz, 0.5 ms, 50 μA , 10 s; discontinuous (DS): 100 Hz, 0.5 ms, 1 s on/1 s off, 0-100 μA , 1-20 min) so far investigated. We thus compared the effects of the nitric oxide synthase (NOS) inhibitor L-NAME on the CBF increases, as measured by laser-Doppler flowmetry, induced by SI CS and DS in the anesthetized rat (chloralose-urethane). First, both intracerebral stimulation paradigms resulted in CBF increases, however with different magnitude (+312 % for CS and +137 % for DS). Second, consistently sustained vasodilatation was obtained in the DS protocol for durations up to 20 min; at the end of a stimulus, CBF rapidly decreased, reaching resting level within 20-30 s. Third, when applied repeatedly with interstimulus time < 15 min, a fatigue phenomenon to CS was observed with the CBF response (up to -80%) while this effect was much less intense (-10%) for DS. Crossed investigations revealed that DS reduced the effect of CS (up to -69%), while no changes could be evidenced for the reverse experiments. Fourth, L-NAME (10 mg/kg, i.v.) induced a major (-60%) and long lasting blockade (> 160-180 min) of both CBF increases. Such data demonstrate that although different cholinergic mechanisms seem to be involved in the two stimulation paradigms, blockade of NOS induces similar reductions of SI-elicited cortical vasodilatation.

501.6

ESTIMATION OF RAT CEREBRAL BLOOD FLOW (CBF) DURING +G_z CENTRIFUGE EXPOSURES LEADING TO G-INDUCED LOSS OF CONSCIOUSNESS (G-LOC). P.M. Werchan¹, R.M. Echon², J.A. Barber², S. Galindo², A.R. Shahed¹, *M. Armstrong Laboratory, Brooks AFB TX 78235-5104, ²KRUG Life Sciences, San Antonio TX.

Research is currently in progress using a small animal centrifuge to identify causative factors leading to G-LOC (isoelectric EEG) during short duration high +G_z (head-to-tail inertial load) exposures. Previous measurements of the rat cerebral energy state at the point of G-LOC (10-15s) are consistent with static bench-top models of global cerebral ischemia (P.M. Werchan and A.R. Shahed, The Physiologist, 35(1); 1992.). However, it remains unclear if CBF completely ceases at the point of G-LOC. Four rats were chronically implanted with EEG electrodes and flowprobes on the common carotid artery (CA). Rats were given nine consecutive 30s exposures of 5 to 25 +G_z (increment of 2.5 +G_z). During all +G_z exposures, CA blood flow (CABF) was significantly reduced (45-100%) within the first 5 sec of onset and completely ceased by the end of the 20 to 25 +G_z exposures. G-LOC was observed only during the 22.5 and 25 +G_z exposures at 13.6 ± 3 sec. Hyperemia was observed within 5 sec after deceleration at all +G_z levels. The magnitude of hyperemia increased as the +G_z level increased up to 17.5 +G_z, but was significantly less at higher +G_z levels. It is concluded that a cessation of CABF of sufficient duration is required to elicit G-LOC in rats. Furthermore, the reduction in the magnitude of the hyperemic response at higher +G_z exposures indicates a compromised cardiovascular recovery.

EFFECT OF ELECTRICAL STIMULATION OF THE DORSAL RAPHE NUCLEUS ON LOCAL CEREBRAL BLOOD FLOW IN RAT. M.J. Bakalian*, M. D. Underwood, V. Arango, L. Peton, and J. J. Mann. Laboratories of Neuropharmacology, University of Pittsburgh, Pittsburgh 15213.

Electrical stimulation of the dorsal raphe nucleus (DRN) elicits heterogeneous cortical blood flow responses as measured by laser-Doppler flowmetry; stimulation of rostral DRN decreases cortical blood flow and stimulation of caudal DRN increases cortical blood flow (JCBFM, 1992;12:664-673). We sought to examine the distribution of local cerebral blood flow (LCBF) responses to electrical stimulation of the rostral DRN using quantitative autoradiographic methods.

Rats were anesthetized (α -chloralose), paralyzed and artificially ventilated. Arterial pressure (AP), heart rate and blood gases were continuously monitored and controlled. The rostral DRN was stimulated electrically (1s on/1s off, 200 Hz, 100 μA) and AP was maintained as needed by exsanguination. LCBF was measured in 32 regions autoradiographically using ^{14}C -iodoantipyrine (IAP) as tracer. Following infusion of IAP, the brain was quickly removed, frozen and sectioned (20 μm). The stimulation sites were verified histologically from Nissl-stained sections.

In unstimulated controls (n=8), LCBF ranged from 139±11 ml/100g/min in the nucleus tractus solitarius to 49±5 ml/100g/min in corpus callosum. Following DRN stimulation (n=6), LCBF was significantly reduced in 17 of the 32 regions ($p < 0.05$, grouped *t*) compared to controls and ranged from 61±7% of control in the presubiculum to 76±6% of control in corpus callosum. Greater LCBF changes were observed in forebrain (61-76% of control) than hindbrain (65-99% of control) regions. Increased LCBF was not observed in any region. Arterial pH, pCO₂, hematocrit and heart rate were not different between groups ($p > 0.05$).

Electrical stimulation of the rostral DRN elicits widespread decreases in LCBF. DRN neurons, possibly serotonergic, may be involved in the neurogenic regulation of cerebral blood flow throughout brain. (Supported by NARSAD and MH46745.)

HUMAN RCBF CORRELATES OF EEG FREQUENCIES BEFORE AND AFTER IV PROCAINE. P. Parekh, J. Spencer, M.S. George, D.S. Gill, T. Ketter, and R.M. Post*. Biological Psychiatry Branch, NIMH, NIH, Bethesda, MD 20892.

Introduction: The regional metabolic and blood flow changes associated with EEG frequencies in man are poorly understood.

Method: In a single-blind fashion, we simultaneously sampled rCBF (using ^{15}O -water PET) and recorded quantitative EEG in 23 healthy controls during injection of saline (baseline) and intravenous procaine. Raters (JS, DSG, PP) then meticulously screened the EEG data, rejecting subjects with prominent muscle or movement artifact, and included for analysis only artifact-free epochs in 7 subjects. Quantitative spectral EEG data from leads O2 and T6 were then correlated with each subject's PET rCBF values on a pixel-by-pixel basis, both at baseline and after high dose procaine. PET scans had been normalized across subjects and non-linearly fitted to the Talairach atlas.

Results: Injection of IV procaine increased omega activity and reduced alpha activity across all subjects, when compared with the baseline saline injection. At baseline, resting alpha and omega activity positively correlated with L frontal cortex rCBF. Following procaine, alpha activity failed to significantly correlate with rCBF, while omega activity positively correlated with increasing rCBF in the L caudate. The change in omega activity from baseline to high dose positively correlated with rCBF increases in the L mesial temporal cortex (amygdala). (All correlations are for both O2 and T6 and $p < 0.001$).

Conclusion: Human EEG-rCBF correlational maps may aid in understanding the neurobiological basis of EEG at rest and after pharmacologic neuroactivation.

LOCAL CEREBRAL BLOOD FLOW IN RAT TRIGEMINAL (WHISKER) SYSTEM.

L. Wei,¹ J. Fenstermacher,¹ C. Rovainen,² T. Woolsey,³ and R. Grubb^{3*}

¹Department of Neurological Surgery, SUNY at Stony Brook, NY 11794 and Departments of ²Cell Biology and Physiology and of ³Neurology and Neurological Surgery, Washington University School of Medicine, St. Louis Missouri 63110.

Changes in local cerebral blood flow (LCBF) with general physiological challenges are well known for different structures in the brain. However, relatively little attention has been paid to LCBF in or changes that occur in particular neural systems. We measured LCBF at rest, with hypoxia (10% O_2) and hypercarbia (8% CO_2) by ^{14}C iodoantipyrine autoradiography in the rat trigeminal (whisker) pathway (V). Structures measured include: V nerve and tract; V motor root and nucleus; V spinal nuclei and principal nucleus; V thalamus and cortex. Control values for white matter were = 40 ml/100g/min; these increased 30-40% with hypoxia and from 2-3 fold with hypercarbia. Control values for LCBF in gray matter throughout the V system were = 110-160 ml/100g/min which increased 60-120% with hypoxia and 3-4 fold with hypercarbia; flow changes were greatest for the cortex. Control values for cortex will be compared to LCBF measured from videomicroscopy and H_2 clearance. Their correspondence to changes in local metabolism, measured by glucose analogs, will also be considered. Such information is important for relating one-time measurements of LCBF throughout the brain to dynamic changes observed on the brain surface.

CEREBRAL HEMODYNAMICS IN MOTOR AND SOMATOSENSORY STIMULATION MEASURED WITH TRANSCRANIAL DOPPLER SONOGRAPHY. R. J. Seitz*, M. Sitzer, R. Baumgartner. Department of Neurology, Heinrich-Heine-University, 4000 Düsseldorf 1, FRGermany.

We studied the time course of cerebral blood flow velocity (CBFV) in the middle cerebral artery (MCA) using transcranial doppler sonography (TCD) during physiological stimulation of the ipsilateral sensorimotor cortex. Twenty healthy male right-handed subjects (17 to 35 years) were examined during blind-folded performance of right hand somatosensory discrimination, finger sequences, and vibratory stimulation. After an initial five-mins episode of rest three stimulation sessions were alternated with rest of two mins each. Continuous TCD recordings were performed with a 2 MHz pulsed-wave range-gated Doppler device (TC 2000S, EME), the end-expiratory pCO_2 was measured on-line using a face mask and a DRÄGER CO_2 -monitor. Somatosensory discrimination induced a significant increase of the mean CBFV (7.6 ± 2.9 (SD) cm/sec, $p < 0.05$) in the left MCA compared to rest (58.7 ± 9.1 (SD) cm/sec). No significant changes of the mean CBFV occurred in finger sequences and vibratory stimulation. In all three activations, the CBFV raised initially with a maximum 3.3 ± 1.6 (SD) seconds after stimulation onset. The first maximal CBFV increase (20.9 ± 7.3 %) was significantly higher in the first stimulation session compared to the third ($p < 0.02$), whereas the mean CBFV was not significantly lower in the third compared to the first stimulation task for each type of activation. In the two tasks involving finger movements the breathing and heart rates per minute accelerated significantly ($p < 0.01$) but were unrelated to the mean CBFV. Our data agree with the time course of task-specific signal changes in deoxy-hemoglobin magnetic resonance imaging and substantiate measurements of regional cerebral blood flow with positron emission tomography.

501.10

EVALUATION OF CEREBRAL BLOOD FLOW USING RADIOACTIVE Xe^{133} AFTER LONG TERM SURVIVAL OF ANIMALS EXPOSED TO PROFOUND HYPOTHERMIA AND COMPLETE BLOOD SUBSTITUTION. A. Elrifai, J. Bailes, S. Govindan, E. Teeple, M. Taylor, S. Shih, M. Leavitt, M. Adatepe and J. Maroon*. Allegheny-Singer Research Institute and Allegheny General Hospital, Pittsburgh, PA 15212.

rCBF was measured in dogs prior to and one week after exposure to a protocol of profound hypothermia $< 10^\circ\text{C}$ and complete blood substitution (Cryomedical Sciences, Inc.) to extend cardiac arrest time for $> 3\text{hr}$. A group of animals ($n = 6$) were observed for up to 80 weeks, 48 ± 20 (Mean \pm SD) & the rCBF was measured using a modified NOVO 10a Cerebrograph using two detectors on each side; the remaining detectors were shielded. Animals were anesthetized (Pentothal), endotracheally intubated & connected to the cerebrograph. ECG, heart rate, respiration and tidal volume were monitored. The end tidal PCO_2 was kept at 35-40 mmHg. Radioactive Xe^{133} (Dupont Pharmaceuticals) was mixed with low dissolved oxygen saline (LDO). Following registration of background activity for 0.5 min, a bolus of Xe^{133} in saline, 15.5 ± 1.9 mCi, was injected in a cephalic vein. Xe^{133} clearance was recorded throughout 11 minutes and expired air was monitored to supply the air curve. CBF results were expressed in ml/100gm/min as the initial slope index between 30 and 90 sec, as CBF15 and as the fast compartment flow F1. Corrections for hemoglobin and CO_2 were not instituted. Hemispheric CBF was treated as the average value of the 2 detectors on each side & an average for each animal was calculated. ANOVA showed no difference between pre- vs early (≈ 1 week) post- or late (≈ 1 year) post- hypothermia CBF. $P > .05$ was considered not significant.

501.12

LOCAL CEREBRAL BLOOD FLOW IN RAT SOMATOSENSORY CORTEX DURING WHISKER STIMULATION.

I. Dowling,¹ Y. Moskalenko,² D. Liu,¹ C. Rovainen^{3*}, M.E. Spence³, T. Woolsey¹. Depts of ¹Neurology and Neurological Surgery and of ³Cell Biol. and Physiol., Washington Univ. Sch. of Med., St. Louis, MO 63110 and ²Sechenov Institute of Evolutionary Physiol. and Biochem., Acad. of Sci. of Russia, St. Petersburg, K-223, Russia.

H_2 clearance methods were used to demonstrate changes in local cerebral blood flow (LCBF) with CO_2 inhalation and whisker stimulation. An array of four small Pt electrodes were inserted into or around the rat barrel cortex. H_2 electrolytically generated at a constant level from one electrode was detected by the other three electrodes. Changes in LCBF produced inversely proportional changes in the level of detected H_2 . These changes were calibrated against standard H_2 clearance curves to provide quantitative estimates of LCBF. CO_2 inhalation produced generalized LCBF increases, whereas contralateral whisker stimulation produced smaller increases more localized in the barrel cortex. Stimulation of one row of whiskers or a single whisker resulted in even smaller, but appropriately localized responses. Minimal latency in LCBF response was 0.75 s after stimulation (mean latency = 2.70 s, SD = 1.60, $n = 126$). Thus, measuring H_2 clearance in the rat barrel cortex is a useful method for testing the coupling between blood flow and neural activity. In particular, it provides sensitive, continuous monitoring of focal CBF changes within brain parenchyma itself.

BRAIN INCORPORATION OF ¹¹C-ARACHIDONATE IN NORMOCAPNIC AND HYPERCAPNIC MONKEYS: A PET STUDY. T. Arai, M.C.J. Chang, L.M. Freed, S. Wakabayashi, M.A. Channing, B.B. Dunn, M.G. Der, J.M. Bell, W.M. Williams*, P. Herscovitch, W.C. Eckelman and S.I. Rapoport. Lab of Neurosciences, NIA and PET Dept, CC; NIH, Bethesda, MD 20892.

Our lab has developed an *in vivo* method in rats to quantitatively study brain lipid metabolism following intravenous injection of radiolabeled long chain fatty acids (FAs). Arachidonic acid (AA) is selectively incorporated in the sn-2 position of phosphatidyl-inositol and -choline, and its metabolism and turnover in brain is correlated to functional activity. To extend the FA method to primates, we used ¹¹C-AA (33-72 mCi) with positron emission tomography (PET) to measure the regional rates of incorporation in isoflurane-anesthetized rhesus monkeys (n=6). For comparison, incorporation rate into brain, using ¹⁴C-AA (170 μCi/kg), was determined biochemically in isoflurane-anesthetized rats (n=3). In paired studies (n=3), the incorporation rate constant (k) at normocapnia and hypercapnia (to increase cerebral blood flow, CBF) in monkey and rat was also determined. Brain radioactivity in monkey was constant after 5 min infusion of ¹¹C-AA (corrected for ¹¹C-CO₂: 0.4 and 0.6x plasma concentration in normocapnia and hypercapnia, respectively). Plasma ¹¹C-CO₂ was 6.5%±2.3 at 30 min. Mean±SEM k (10-30 min), for temporal-, occipital-, frontal-, parietal-cortex, white matter and whole brain was 1.2±0.1, 1.3±0.1, 1.2±0.1, 1.2±0.1, 0.9±0.1 and 1.2±0.1 x10⁻⁴ ml/sec.ml, respectively. No significant difference in k, for any regions, was seen between normocapnia and hypercapnia in the monkey. For the rat, whole brain k, 3.1±0.1 x10⁻⁴ ml/sec.g, was not significantly different from that determined with hypercapnia. These results indicate that the incorporation rate coefficients for AA in monkey and in rat brain are comparable and independent of CBF. The the FA method with PET has the potential to be used in humans.

502.3

REGIONAL BRAIN GLUCOSE METABOLISM IN HABITUATION TO REPEAT PET SCANS. H. Szechtman*, S. List, R. Kaplan, S. Franco, B. Szechtman, G. Firnau, C. Nahmias and E.S. Garnett. Depts of Biomedical Sciences, Psychiatry, and Nuclear Medicine, McMaster Univ, Hamilton, Ontario, CANADA, L8N 3Z5.

Positron Emission Tomography (PET) studies often involve repeated scans on the same individual to compare a test condition or intervention with a 'resting' or 'baseline' state (eg., Cleghorn *et al.*, Psychiatry Research: Neuroimaging, 40:135, 1991). The present study assesses what changes in relative regional brain glucose metabolism are attributable to experiencing successive scans *per se*. Cerebral accumulation of ¹⁸F-fluorodeoxyglucose was measured by PET on two successive occasions 1 week apart in 8 healthy male volunteers lying quietly with eyes closed. Statistical analysis using the method of Friston *et al.* (JCBFM, 11:690, 1990) revealed that on the second scan, the left orbitofrontal cortex was significantly more active, and the hippocampus and hippocampal gyri (bilaterally) significantly less active, compared to activity on the first scan. No significant differences between two scans were observed when scan order was randomized. These findings suggest that a process of habituation is associated with repeat PET scans, possibly involving learning to suppress emotional-autonomic responses. (Supported by MRC and OMHF. HS is a Research Associate of the Ontario Mental Health Foundation).

A Linear Regression Approach to the Assessment of rCBF Change in Cognitive Paradigms John D. Van Horn*, Alex Terrazas, Karen Faith Berman, Terry E. Goldberg, Daniel R. Weinberger. Neurosciences Center at St. Elizabeth's, 2700 Martin Luther King Jr. Ave. SE, Washington DC 20032

The search for optimal methods for the statistical comparison of positron emission tomographic (PET) data has generated much debate in the functional brain imaging literature. A particular problem has been that the large intra- and inter-individual differences in global blood flow or metabolism that are generally observed obscure more subtle regional changes. Therefore, data transformation is often needed in order to "correct" or "adjust" PET data for differences in global activity. While no "best" method has yet been clearly established, a number of techniques have been presented (e.g. ratio of CBF to the whole brain mean; ANCOVA; Scaled Profile; etc.). We present a statistical approach that uses linear regression to predict the relationship between rCBF and global blood-flow. The regression equations computed for subjects performing a control task may be used to predict rCBF during a cognitive task. Statistical differences in residual values between observed and expected rCBF are indicative of changes in rCBF due to task performance. The advantages of this method include its ability to compare several groups to a single predictor, its ability to contrast different tasks, and its suitability for examining within- and between- group rCBF data.

502.2

EFFECT OF METHYL PALMOXIRATE (MEP) ON INCORPORATION OF PALMITATE INTO MONKEY BRAIN WITH PET. M.C.J. Chang, S. Wakabayashi, T. Arai, M.A. Channing, B.B. Dunn, M.G. Der, P. Baldwin, J.M. Bell, P. Herscovitch, W.C. Eckelman and S.I. Rapoport*. Lab of Neurosciences, NIA and PET Dept, CC; NIH, Bethesda, MD 20892.

Our lab has developed an *in vivo* method to quantify regional rates of incorporation into brain phospholipids (PLs) of intravenously injected radiolabeled long chain fatty acids (FAs). The rates of formation and turnover of brain PLs reflect functional activity and structural integrity of brain. Radiolabeled palmitic acid (¹⁴C-PA), which is selectively incorporated into phosphatidylcholine in the sn-1 position, was used with positron emission tomography (PET) to measure regional rates of incorporation in the brain of isoflurane-anesthetized rhesus monkey (n=6). For PA, this method has limitations because the tracer is readily oxidized to produce unincorporated metabolites in brain (¹¹C-glutamine, ¹¹C-glutamate and ¹¹C-CO₂). In an attempt to increase the incorporation rate of ¹⁴C-PA into brain lipids, an inhibitor of β-oxidation (MEP, McNeil Pharm.), was administered (iv) 2 hr before infusion of the radiotracer. In rats, MEP has been shown to enter the brain and allow 85% of ¹⁴C-PA to be incorporated into brain lipids. The incorporation rate constant (k) mean±SEM, calculated between 10-30 min, for temporal-, occipital-, frontal-, parietal-cortex, white matter and whole brain was 4.4±0.3, 3.6±0.3, 3.9±0.2, 4.2±0.2, 2.2±0.3 and 3.5±0.2 x10⁻⁵ ml/sec.ml, respectively. In a matched study, the percent plasma ¹¹C-CO₂ in vehicle- and MEP-treated monkeys reached 40.8%±3.3 and 19.1%±2.1, respectively, by 60 min. With the exception of white matter, k was significantly increased (35-40%) by MEP in all regions. These results demonstrate that regional incorporation rates of ¹⁴C-PA in brain can be measured with PET, and that MEP may be useful with ¹⁴C-PA for studying brain lipid metabolism *in vivo* in humans by PET.

502.4

DO WOMEN HAVE MORE ACTIVE BRAINS THAN MEN? A PET STUDY DURING COGNITIVE ACTIVATION. G. Esposito*, D. R. Weinberger, J. D. Van Horn, J. L. Ostrem, K. F. Berman. Clinical Brain Disorders Branch, NIMH, Washington, D.C. 20032.

A number of studies of sex related differences in cerebral blood flow or metabolism have suggested that women have higher values than men. However, not all studies agree. One explanation for these inconsistencies may be that cognitive conditions can influence the results. To examine this possibility we used the oxygen-15 water technique to study rCBF with positron emission tomography in fourteen normal volunteers, eight men and six women, during the performance of six tasks: three neuropsychological tasks linked to frontal cortex and three sensorimotor control tasks. The cognitive tasks were the Wisconsin Card Sorting Task (WCS), Delayed Alternation Task (DA) and Delayed Response Task (DR). A separate sensorimotor control task was designed for each frontal task. Data were collected on the Scanditronix 2048-15B scanner which has in-plane and axial resolution of 6-6.5 mm after reconstruction.

A main effect of gender on global CBF (ml/min/100 gm) was found (grand means across all conditions: women 60.9, men 53.2; ANOVA F = 9.35, p<.01). However, post hoc contrasts demonstrated that gender differences (women>men) significant at or above the p=.05 level were seen during the three neuropsychological tasks (WCS: 63.9±6 vs. 56.3±7; DA: 62.2±4 vs. 52.2±5; and DR: 62.2±6 vs. 51.5±6). Trends in the same direction were seen during two of the sensorimotor control tasks: WCS control (58.4±5 vs. 51.4±9; p=.10); and DA control (60.2±9 vs. 52.0±5; p=.06). No such trend was noted during the DR control (58.4±7 vs. 55.6±8; p=.52).

Data support the notion that higher rCBF levels in women compared to men can be demonstrated. However, these data also suggest that the cognitive state of the subject can affect the results.

502.6

GLYCOLYSIS INDUCED DISCORDANCE BETWEEN DEOXYGLUCOSE-BASED AND GLUCOSE-BASED ESTIMATES OF LOCAL CEREBRAL METABOLIC RATE IN CORTICAL SPREADING DEPRESSION.

R.F. Ackermann* and J.L. Lear. Nuclear Medicine, UCLA School of Medicine, Los Angeles CA 90024; Nuclear Medicine, Health Sciences Center, Denver CO 80262.

We previously reported that radiolabeled glucose (GLC)-based metabolic rate estimates normally are similar to the corresponding radiolabeled deoxyglucose (DG)-based estimates, but are strikingly dissimilar in activated structures; DG-based labeling was markedly elevated, while GLC-based labeling was hardly elevated in the same structures. Here, we used the same dual-label autoradiographic method to study spreading depression induced with KCl applied unilaterally to the neocortex of rats. The resulting DG images revealed marked hypermetabolism in the KCl-treated cortex, accompanied by hypometabolism in the functionally deafferented ipsilateral striatum and thalamus. The corresponding GLC images also revealed hypometabolism in the same subcortical structures, but nevertheless failed to register the KCl-induced cortical hypermetabolism. Much literature suggests that the increased cortical DG labeling must be due to the accelerated Na/K ATPase activity induced by the high extracellular K ion levels, and also suggests that the ATP used by the Na/K pump is derived specifically from glycolysis. Thus, we and others have hypothesized that GLC fails to register this increased glycolytic flux due to "overproduction" of labeled pyruvate, with subsequent clearance of labeled lactate.

CMR_{glc} during cortical spreading depression: Assays with [6-¹⁴C]glucose or [¹⁴C]deoxyglucose. K. Adachi, N. Cruz, L. Sokoloff, and G. Dienel*. Lab. of Cerebral Metabolism, NIMH, Bethesda, MD 20892.

It is assumed that all metabolites of [6-¹⁴C]glucose are trapped in the brain during the routine 5 min experimental period, and that [6-¹⁴C]glucose is the preferred tracer to assay rates of glucose utilization (ICMR_{glc}) in brain because errors in the steady-state assumption are minimized (Hawkins et al., *Am. J. Physiol.* 248: C170, 1985). To test these assumptions, rates of metabolism of ¹⁴C-labeled glucose and deoxyglucose (DG) were compared in rats with unilateral spreading depression during a 5 min experimental period for both tracers. Spreading depression was induced by application of 5 M KCl to the intact dura at 15 min intervals. After the second application, [¹⁴C]hexose was injected i.v., and samples of arterial blood were drawn at timed intervals for 5 min. Then the rats were anesthetized with thiopental (20 mg/kg), and their brains were frozen *in situ*. Portions of each hemisphere of each brain were dissected out in a cryostat at -25°C, weighed, extracted with ethanol, and assayed for their contents of labeled hexose and products by anion exchange HPLC. The remaining portions of each brain were cut into 20 μm sections, exposed to x-ray film, and their total ¹⁴C contents assayed by quantitative autoradiography. Left-right differences in total ¹⁴C contents of the cerebral cortex, whether measured by autoradiography or direct chemical measurement, were rather small when glucose was used as the tracer (10 ± 1%, n = 3) (mean ± SD). Increases in the ¹⁴C contents of experimental hemisphere were, however, easily detected with DG (50 ± 13%, n = 4). When precursor and products were separated by HPLC and assayed, a small rise in the metabolism of [¹⁴C]glucose was found in the experimental hemisphere (14 ± 16%, n = 6), but the increase was much smaller than that observed with DG (66 ± 46%, n = 5) (corrections were made for changes in the lumped constant). These results demonstrate that stimulation of ICMR_{glc} is registered by DG within 5 min, and they suggest that labeled products of [6-¹⁴C]glucose are lost from the brain.

502.9

THE RELIABILITY OF RELATIVE REGIONAL METABOLIC VALUES USING PET-FDG. D.R. Medoff, A. Summerfelt, H.H. Holcomb*, C.A. Tamminga. Maryland Psychiatric Research Center, University of Maryland, Baltimore MD 21228

One factor that makes the analysis of PET/FDG imaging data challenging is the influence of overall global metabolism. Global cerebral metabolism can be affected by a variety of factors both experimental and incidental. The appropriate statistical technique to control for this global factor depends on a number of factors, which may or may not always be discernible. In this study we have compared the reliability of four different methods of controlling the global factor. Global factors were controlled by: ratios of absolute regional level to whole brain grey, z-scores, residual scores, and difference scores. Test-retest reliabilities, interrater reliabilities and functional-anatomical sampling reliabilities were compared for fourteen regions of interest using the four different methods of transformations. Interclass Correlation Coefficients (ICCs) were compared across transformation method. For all regions, the ICC's for transformed scores were much lower than the ICC's for the absolute metabolic data. Although some regions had similar ICC's across transformation method, for certain regions (e.g. hippocampus, occipital cortex) the transformation method had a significant influence on the reliability. The reduced reliability of relative regional metabolic values and the influence of the type of transformation must be taken into consideration when attempting to interpret PET-FDG studies.

502.11

CEREBRAL METABOLISM IN ADULTS WITH GENERALIZED RESISTANCE TO THYROID HORMONE. J.A. Matochik*, P. Hauser, A.J. Zemetkin, M. Ernst, R.M. Cohen and B.D. Weintraub. NIMH, LCM, SCBI, Bldg. 10/4N317 and NIDDK, MCE, Bethesda, MD 20892.

Generalized resistance to thyroid hormone (GRTH) is characterized by elevated T3 and T4 levels and inappropriately normal or elevated TSH levels and reduced responsiveness of pituitary and peripheral tissues to thyroid hormone action. GRTH has been linked to the human thyroid receptor-β gene on chromosome 3. Attention deficit and hyperactivity are the major behavioral symptoms of GRTH. To measure cerebral metabolism by positron emission tomography, 8 adults with GRTH (all off thyroid treatment) and 9 normal controls received 4-5 mCi of 18-fluorodeoxyglucose while performing an auditory continuous performance task. Whole brain and 60 regional measures of glucose metabolic rate were extracted. GRTH adults were greatly impaired in performance on the attention task as measured by correct identifications of the target tone. There were no differences in global metabolism. With normalized data, GRTH adults had significantly reduced cerebral metabolism in 5 regions, predominately in the orbitofrontal cortex. Metabolism was increased in 6 regions, primarily in frontal and rolandic regions. Performance on the attention task was highly correlated with glucose utilization in the left posterior frontal and right rolandic areas in GRTH adults. The increased metabolism in these regions may reflect neural inefficiency in performing the attention task.

502.8

A CORTICAL VOLUME PATTERN ANALYSIS OF "ON-OFF" HALOPERIDOL FDG PET DATA. E.A. Gastineau, C.A. Tamminga, H.H. Holcomb, B. Gordon*, H.L. Loats. Maryland Psychiatric Research Center, University of Maryland, Baltimore MD 21228, Loats Associates, Inc., Westminster, MD 21158

Traditional Region of Interest (ROI) sampling of functional images such as FDG-PET have been on acquired axial slices. Reconstructing these slices into a volume allows for dynamic interaction with the data to render slices through any plane and generate surfaces. Here, an MRI and 3 FDG-PET scans were acquired from 8 patients enrolled in an on-off-off haloperidol experiment. PET and MRI images were registered by overlaying the three orthogonal midplanes and adjusting the PET for X,Y,Z, translation and roll pitch and yawl, matching the functional image to the anatomy of the MRI. Lateral surfaces were created for both the MRI and PET data sets using methods previously described (Gastineau, *Neurosci Abstr.* 18:726, 1992). Atlases were described for the surfaces and midbrain area using the anatomy of the reconstructed MRI and applied directly to the associated PET studies. Volume measurements from the atlases were correlated for "on" and "off" drug PET data. Spatial distribution of the rCMRglu values for a prescribed volume were compared across subjects for activity patterns. Registered "on" and "off" volumes were subtracted and the subsequent difference patterns analyzed. Anatomical sampling based on reconstructed volumetric MRI data provides precise location for functional image sampling and shows the variability of activity within a prescribed area. With the method described, volumetric as well as spatial relationships may be much more accurately reported.

502.10

RESTING STATE BRAIN GLUCOSE METABOLIC CORRELATES OF SUSTAINED ATTENTION CAPACITY IN HEALTHY AGING. A. Baraldi*, E. Gaillard, R. Parasuraman, P. Greenwood, C.L. Grady, J.V. Haxby. Lab. of Neurosciences, National Institute on Aging, NIH, Bethesda, M.D. 20892; Institute of Applied Psychology, Univ. of Lausanne, 1004 Lausanne-CH; and Cognitive Science Lab., Catholic Univ. of America, Washington, D.C. 20064.

Positron Emission Tomography (PET) brain activation studies of sustained attention in normal subjects using ¹⁵O or ¹⁸F-DG have found consistent increases in regional cerebral blood flow (rCBF) or in regional cerebral metabolic rates for glucose (rCMRglc) in the right prefrontal cortex; rCMRglc decreases in the anterior cingulate region; and increases in rCBF or decreases in rCMRglc in the right superior parietal cortex. The objective of this study was to determine whether these regions are also related to sustained attention in subjects undergoing resting state PET. Forty-seven optimally health-screened subjects in 3 age groups (young, middle age, old) were studied (mean age ± SD: 51 ± 14.7; range = 22-75). Sustained attention was measured using a high-event rate visual digit-discrimination task lasting 7.2 min. (six 1.2 min. blocks) at six levels of stimulus degradation. A decrement score was computed for the highest level of degradation in which all groups showed significant decrements (blocks 5 and 6 minus blocks 1 and 2). Resting state rCMRglc in the homologous right and left superior parietal, prefrontal, anterior cingulate and sensorimotor (control) regions were measured at rest (eyes patched, ears plugged) using 18F-fluoro-deoxyglucose and the Scanditronix PC1024-7B PET scanner. Because there were no age-related changes in sustained attention and in rCMRglc, the relationship of sustained attention decrements to normalized rCMRglc rates (rCMRglc/mean neocortical gray matter CMRglc) was examined in all subjects combined using partial correlations factoring out age. Significant positive partial correlations were found between sustained attention decrements and rCMRglc rates in the right prefrontal (r = .35, p < .05) and right anterior cingulate regions (r = .29, p < .05), confirming previous studies. No significant correlations were found in the right superior parietal cortex (p > .05), which has been linked to the efficiency of disengagement of spatial attention, nor with the sensorimotor cortices (p > .05). Sustained attention is associated primarily with right hemisphere activity as no correlations were found with any left hemisphere region (all p > .05). Our results indicate that differences in sustained attention capacity in humans are associated with functional resting state brain activity levels of rCMRglc.

502.12

PRELIMINARY RESULTS ON DEVELOPING A VOLTAGE SENSITIVE DYE FOR HUMAN BRAIN IMAGING WITH PET. B.M. Dasheiff and D.S. Sacks. Dept. of Veterans Affairs, VAMC, University Dr., PGH, PA, 15240 and Univ. of Pittsburgh Epilepsy Center.

A significant advance in human brain imaging could be made if three dimensional computed tomography could be combined with EEG. Presently, topographic maps of human scalp EEG are limited by the number of electrodes, and the inability to record deep brain structures. Positron emission tomography (PET) produces functional maps of blood flow, metabolism and neuroreceptors/transmitters, but not electrical activity directly. We are exploring the utility of using voltage sensitive dyes as tracers for human PET, which would allow direct measurement of the brain's electrical activity throughout its volume.

In vivo experiments in rats were conducted using our best voltage sensitive redistribution probes: diO-C(2)-5 and Rhodamine B. When mapping seizure pathways, the dye is injected via the carotid artery [Brain Res. 595:79-86, 1992]. We measured the percentage of dye which entered the brain using our standard vehicle: 30% mannitol, 5% EtOH. We found that 17% of diO-C(2)-5 and 6% of Rhodamine B entered the brain. Using EtOH alone as the vehicle yielded 10% and 7%, respectively. Because intravenous routes would be better tolerated by patients, we determined the percentage of injected dye in the brain via that route. Using only EtOH as vehicle, we found .01% for both dyes. We are presently investigating other vehicles, dye kinetics, distribution to other organ systems, washout parameters, and radiolabeling sites, which will be presented.

502.13

GENDER DIFFERENCES IN PATTERNS OF HEMISPHERIC REGIONAL GLUCOSE METABOLISM (rCMRglc): A MULTIPLE REGRESSION/DISCRIMINANT ANALYSIS OF POSITRON EMISSION TOMOGRAPHIC (PET) DATA. N.P. Azari¹, K.D. Pettigrew², M.B. Schapiro¹, and B. Horwitz¹ Lab of Neurosciences, NIA, ²Division of Epidemiology/Applied and Services Research, NIMH; NIH, Bethesda, MD 20892

Gender differences in the pattern of hemispheric rCMRglc correlations were reported in a prior correlational analysis of resting (eyes/ears covered) rCMRglc PET data. To further explore the effect of gender on patterns of hemispheric rCMRglc interactions, we applied a multiple regression/discriminant analysis to resting rCMRglc PET data from 17 men and 17 women (age < 40 yr). Two separate discriminant functions distinguished men and women: the first reflected rCMRglc interdependencies between hemispheres (left posterior medial temporal, left prefrontal, right temporal, right parietal, right sensorimotor) and correctly classified all women and 94% of the men; the second reflected rCMRglc interdependencies within the left hemisphere and correctly classified 82% of the women and 88% of the men. The results, which support and extend our prior correlational analysis, demonstrate gender differences in the pattern of hemispheric rCMRglc interdependencies.

502.14

GLUCOSE METABOLIC CORRELATES OF ATTENTIONAL PERFORMANCE IN ADULTS WITH A HISTORY OF INFANTILE AUTISM, SCHIZOPHRENICS, AND CONTROLS. B.V. Siegel, Jr.* and M.S. Buchsbaum. Dept. Psychiatry, Mt. Sinai School of Medicine, New York, NY.

Positron emission tomography (PET) was used to assess brain regions important in attentional deficits in autism and schizophrenia. 14 adults with a history of infantile autism, 25 schizophrenics, and 20 controls performed the degraded stimulus continuous performance test (CPT) during the 35 minute 18-fluoro-2-deoxyglucose uptake period preceding PET scan acquisition. CPT performance was impaired in schizophrenics compared to controls, but autistics did not differ from either group. In controls and schizophrenics, task performance correlated with medial frontal, medial temporal, and inferior temporal cortical metabolism, suggesting that activation of those regions is important in the normal performance of the task and that damage to those regions, which also showed low glucose metabolic rates (GMR) in schizophrenics, contributes to the attentional dysfunction in schizophrenia. In contrast, autistics showed negative correlations of medial frontal cortical GMR with attentional performance, suggesting that neuronal inefficiency in that region may contribute to poor performance. Positive correlations of performance with GMR in globus pallidus and midbrain suggest that damage to those regions contributes to impaired attention in autism.

502.15

BRAIN ACTIVITY DURING WORKING MEMORY ASSESSED WITH FUNCTIONAL MRI R.S.Sexton^a, V.S.Mattay^b, F.A.Barrios^{a,d}, J.A.Frank^b, G.Sobering^c, C.T.W.Moonen^c, D.R.Weinberger^a. CBDB, NIMH^a Washington, DC. Laboratory of Diagnostic Radiology Research^b, In Vivo NMR Research Center^c, NIH, Bethesda, MD. Computational Physics, Inc^d, Fairfax, VA.

It has been shown in prior blood flow studies with single photon emission and O-15 PET imaging techniques that activation of the dorsolateral prefrontal cortex (DLPFC) occurs while subjects perform the Wisconsin Card Sorting Test (WCST), a working memory cognitive task. We have explored whether similar regional activation can be seen using functional MR imaging, a rapidly evolving imaging modality with temporal and spatial resolution much superior to SPECT and PET.

5 subjects underwent Functional MR imaging on a 1.5 Tesla MR unit with a quadrature head coil during the WCST and a sensorimotor control task [BAR]. The functional images were obtained in an axial plane using a SPGR sequence and Blood "Oxygenation" Level Dependent technique without inflow suppression. Images were analyzed using a time-stimulus vs time-intensity cross-correlation method to detect the activated pixels. In all cases activated pixels were found with greater density and with greater frequency in the DLPFC during the WCST than during the BAR test. This is in agreement with previous findings obtained using radio nuclide imaging methods. The results suggest that assessment of the distribution of neural activity associated with higher order cognitive processing is possible with this technique.

BRAIN METABOLISM AND BLOOD FLOW: NITRIC OXIDE

503.1

COUPLING OF CEREBRAL BLOOD FLOW TO NEURONAL ACTIVATION: ROLE OF ADENOSINE AND NITRIC OXIDE K.Niwa, U.Lindauer, A.Villringer, U.Dirnagl, Dept. of Neurology, University of Munich, 8000 Munich 70, F.R.G. This study aims to evaluate the role of adenosine for coupling of neuronal activation and regional cerebral blood flow (rCBF) using a physiological somatosensory stimulation mode, and to investigate a possible correlation between the two putative mediators of coupling, adenosine and nitric oxide (NO). Somatosensory stimulation was carried out in α -chloralose anesthetized rats by stimulating the mystacial vibrissae for 60 seconds by manual deflection (2-3 s) while measuring the rCBF-response over the contralateral SI cortex with Laser-Doppler flowmetry. ● Adenosine receptor blockade (5×10^{-5} M theophylline in artificial cerebrospinal fluid, aCSF) or reduction of the extracellular adenosine concentration (adenosine deaminase, ADA, 1 U/ml in aCSF) reduced the rCBF response to whisker stimulation by approx. 40% (from $17.9 \pm 3.0\%$ to $10.6 \pm 2.7\%$ after theophylline, $n=24$; from $18.2 \pm 0.7\%$ to $10.7 \pm 1.9\%$ after ADA, $n=5$) without affecting baseline CBF. ● The reduction in the rCBF response to whisker stimulation afforded by theophylline was further reduced by coapplication of theophylline and the NOS blocker N^o-nitro-L-arginine (L-NA, 10^{-3} M in aCSF) (from $17.9 \pm 3.0\%$ to $7.5 \pm 1.3\%$, $n=24$). ● Blockade of NO synthase with L-NA (10^{-3} M in aCSF) reduced the reactivity of rCBF to adenosine (10^{-4} M in aCSF) by approx. 50% (from $39.4 \pm 10.4\%$ to $22.9 \pm 10.5\%$, $n=7$). This effect was stereospecific, since superfusion of D-NA (10^{-3} M in aCSF) did not affect the response to topical application of adenosine. We conclude that adenosine is involved in coupling of rCBF to physiological stimuli, and that in the cerebral circulation the vasodilator effects of adenosine are at least partially mediated by NO. Supported by the Deutsche Forschungsgemeinschaft.

503.2

NITRIC OXIDE SYNTHASE (NOS) BLOCKADE INDUCED CEREBRAL VASOMOTION: INFLUENCE OF HYPERCAPNIA AND EXTRACELLULAR ACIDOSIS U.Dirnagl, K.Niwa, U.Lindauer, G.-D.Borasio, A.Villringer. Dept. of Neurology, University of Munich, 8000 Munich 70, F.R.G. Blockade of the brain NOS blocks the rCBF response to CO₂ or H⁺ and induces cyclic variations of regional cerebral blood flow (rCBF) with a frequency of 10/min and amplitudes up to 60% of baseline. We investigated the influence of extracellular acidosis on NOS blockade induced vasomotion. Anesthetized (α -Chloralose) and ventilated Wistar rats were equipped with a closed cranial window (dura removed) over the right parietal cortex. Vasomotion was induced by topical application of 1 mM N^o-nitro-L-arginine (L-NA, in artificial cerebrospinal fluid, aCSF) for 30 minutes. rCBF was measured continuously with Laser-Doppler flowmetry with two separate probes at cortical sites 1 mm apart (group II: one probe only). Rhythmic activity in the rCBF was analyzed for frequencies and amplitudes by Fast Fourier Transformation. In group I ($n=5$), CO₂ was added to the inspiratory gas, in group II ($n=5$) extracellular acidosis was produced by superfusion of acidic aCSF (pH 7.08 ± 0.06). Superfusion of L-NA reduced the rCBF to $86 \pm 12\%$. L-NA induced vasomotion had a mean frequency of $10.3 \pm 1.1\%$ and a mean amplitude of $18.2 \pm 4.3\%$. Neither CO₂ nor acidosis affected baseline rCBF. However, the amplitude of vasomotion was significantly reduced by CO₂ ($-72 \pm 14\%$) and by acidosis ($-69 \pm 17\%$). Vasomotion frequency was unaffected. 76% of the time studied vasomotion at different cortical sites showed phases of relative synchronicity, the rest of the time shifts between phases and frequencies occurred. We conclude that CO₂/H⁺ may also have NO independent actions on the cerebral vasculature, and that vasomotion is only partially synchronized on the cortical surface. Supported by the DFG.

503.3

IN VIVO SPIN TRAPPING STUDY OF NITRIC OXIDE FORMATION FOLLOWING GLOBAL BRAIN ISCHEMIA IN THE RAT. T. Tominaga*, S. Sato†, T. Ohnishi and S. T. Ohnishi, Philadelphia Biomedical Research Institute, King of Prussia, PA19406, and †Division of Neurosurgery, Institute of Brain diseases, Tohoku Univ. Sch. of Med., Sendai, 980 JAPAN.

It has been suggested that Nitric Oxide (NO) is produced during brain ischemia. However, whether NO protects or injures the ischemic brain is a question that has raised controversy. Using electron paramagnetic resonance (EPR) with an in vivo spin trapping method, we attempted to detect NO in vivo during global brain ischemia and answer this question. Global brain ischemia in the rat was produced by the occlusion of the bilateral common carotid arteries and/or hemorrhagic hypotension. Diethylthiocarbamate (DETC, 400mg/kg) and Fe-citrate (20mg FeSO₄ · 100mg sodium citrate/kg) were used as spin-trapping reagents [1]. Under these ischemic conditions, NO signals were detected as NO-Fe-DETC spin adducts (triplet centered at $g=2.039$ with the hyperfine coupling constant a_N of 13 gauss). The size of NO signals increased as the extent of ischemia increased. During the early phase of ischemia, NO may play as an endothelium-derived relaxing factor to increase cerebral blood flow protecting the ischemic brain.

NITRIC OXIDE AND ADENOSINE MEDIATE THE NMDA-INDUCED INCREASE IN HIPPOCAMPAL BLOOD FLOW. Michael G. Kaiser*, Matthew J. During, Dept. of Neurosurgery, Yale Univ. School of Medicine, New Haven, CT 06510.

With the increasing use of noninvasive functional brain imaging methods which measure local cerebral blood flow, determining those factors which control regional cerebral blood flow is an area of increasing interest. In the present study we investigated the role of nitric oxide (NO) and adenosine (ADO) in coupling neuronal activity to local blood flow. Rats underwent unilateral placement of paired guide cannulae into the CA1 region of the hippocampus, through which a microdialysis and laser doppler probe were inserted. Blood flow changes were recorded with the doppler, and microdialysis samples were analysed for citrulline, produced in a 1:1 molar ratio with NO, and ADO. The first group of animals (n=6) received increasing doses of NMDA, and responded with mean blood flow increases of 2.7%±2.9%, 6.9%±1.4%, 16.9%±6.6%, and 32.9%±4.0% at 50, 100, 200, and 500µM respectively. The microdialysis data from this group indicated significant increases in both citrulline and ADO during the stimulation periods. In a second group of animals (n=6) 1mM S-Nitroso-N-acetyl-penicillamine (SNAP), a direct NO donor, was infused through the microdialysis probe. The mean increase in blood flow produced was 36.6% ± 5.8%. A third group of animals (n=7) received nitro-arginine methyl ester (NAME), a competitive NO synthase inhibitor. 5mM NAME resulted in a mean decrease of 22.7% ± 2.9% in basal flow, and attenuated the response of 200µM NMDA from 63.5%±17.8% to 24.8%±6.5%. The effects of 5mM NAME on basal flow were significantly reduced by infusing 100mM L-Arg, and 100mM L-Arg alone produced a mean increase of 13.3% ± 2.9% in blood flow (n=6). Citrulline decreased during the infusion of NAME and the NMDA-induced response was antagonized by NAME. When the adenosine receptor antagonist 8-(p-Sulfophenyl)theophylline was infused there were significant decreases in both basal blood flow as well as the response to 200µM NMDA. Preliminary results indicate that stimulation of the perforant pathway increases cerebral blood flow in CA1 hippocampus. Studies are presently underway to characterize the mediators of this response. Based on these results NO and ADO mediate in part the changes in regional cerebral blood flow associated with hippocampal excitatory neurotransmission.

REGIONAL CEREBRAL METABOLIC EFFECTS OF A1 AND A2 ADENOSINE RECEPTOR AGONISTS AND ANTAGONISTS. J.L. Daval* and A. Nehlig, INSERM U 272, 30 rue Lionnois, 54013 NANCY, FRANCE.

In order to study the specific metabolic responses mediated by A1 and A2 adenosine receptors in the brain, we investigated the effects of selective ligands for these receptors on local cerebral metabolic rates for glucose (LCMRglc) in rats, using chlorocyclopentyladenosine (CCPA, 0.01 mg/kg) and cyclopentylpropylxanthine (DPCPX, 0.01 mg/kg) as A1 agonist and antagonist, and CGS 21680 (0.01 mg/kg) and dimethylpropargylxanthine (DMPX, 0.3 mg/kg) as A2 agonist and antagonist, respectively. These doses were chosen to selectively interact with each type of receptor without inducing any significant systemic or peripheral effects. The 2 agonists, CCPA and CGS 21680 induced decreases in LCMRglc. These were limited to globus pallidus and hypothalamus for CCPA whereas CGS 21680 affected LCMRglc in 17 areas. The latter regions were mainly located in cerebral cortex, limbic and motor systems, and white matter. Conversely, the 2 antagonists had more variable effects, either decreasing or increasing LCMRglc. With DPCPX, LCMRglc were decreased in dentate gyrus and globus pallidus, and increased in 6 regions, i.e. thalamic, hypothalamic and cochlear nuclei. DMPX had more subtle effects, decreasing LCMRglc in globus pallidus and increasing it only in cochlear nucleus. In conclusion, although high-affinity A2 receptors are limited to striatum, accumbens and olfactory tubercles, metabolic effects of CGS 21680 are widespread. The reverse is true for CCPA, A1 receptors being distributed throughout the brain. The significance of metabolic increases or decreases induced by both antagonists remains to be elucidated.

503.4

ROLE OF NITRIC OXIDE FOR CORTICAL BLOOD FLOW DURING SPREADING DEPRESSION. M.Fabricius, B.Pakkenberg* and M.Lauritzen, Dep. of Medical Physiology, Univ. of Copenhagen, DK-2200 Copenhagen, Denmark.

We examined the relation between nitric oxide (NO) synthesis and regional cerebral blood flow (rCBF) changes during spreading depression (SD) in the parietal cortex of halothane-anesthetized rats. NMDA-receptor activation is essential for propagation of SD, which is associated with marked changes of rCBF. NMDA-receptor activation stimulates nitric oxide synthase (NOS), which in turn triggers vasodilation.

SD was elicited by needle stab in left frontal cortex and rCBF changes were measured by laser Doppler flowmetry. NOS was inhibited by i.v. (30 mg/kg) and/or topical (1 mM) application of N^G-nitro-L-arginine (NOLAG). L-arginine was given i.v. (50 mg bolus + 100 mg/kg/h) or topically (20 mM). TTX (20µM) was applied topically to test the role of perivascular nerves for the rCBF changes.

In untreated animals, the percentage rCBF changes accompanying SD was calculated at a) 1 min before SD: -13 ± 2%, b) SD (peak rCBF): +98 ± 7%, c) 1 min after SD: -23 ± 2%, d) 10 min after SD: -16 ± 3%, and e) 20 min after SD: -15 ± 3%. Pretreatment with i.v./topical NOLAG decreased a): -43 ± 7%* (*:p<0.05), and increased c): -2 ± 4%*, d), and e) did not differ from controls. Effects of NOLAG were independent of application mode. Topical L-arginine did not affect rCBF changes during SD. i.v. L-arginine increased d): +16 ± 7%*, but caused no other changes. TTX increased c): +49 ± 12%* but caused no other changes.

The results show that NO modulates rCBF changes during SD, but NO synthesis cannot account for the massive flow rise during the NMDA-receptor activation.

503.6

NEUROVASCULAR INTERACTIONS OF NITRIC OXIDE SYNTHASE-POSITIVE NEURONS IN RAT HIPPOCAMPUS.

F. Schottler, J. Collins, O. Sagher, D. Okonkwo, A. Martin, N.F. Kassell and K.S. Lee*, Department of Neurosurgery, University of Virginia, Charlottesville, VA 22908.

The anatomical relationship between nitric oxide synthase (NOS)-positive neurons and blood vessels was examined in the hippocampus of the rat. The distribution of NOS was evaluated using NADPH-diaphorase histochemistry. Many, but not all, NOS-positive neurons had processes located in close proximity with blood vessels. The somata and dendrites of neurons at times appeared to drape or engulf a vessel. With opportune section angles, neuronal processes were sometimes closely associated with vessels over several tens of micrometers. While NOS-positive processes were occasionally found near branching points of arterioles, no preferential relationship with arteriolar branching points was observed. Occasionally, axon-like processes originating in local NOS-positive neurons were also associated with vessels. In certain cases, axon-like processes generated varicosities around neighboring vessels.

The factors which couple local cerebral blood flow with changes in local neuronal activity remain a matter of considerable discussion. The present findings suggest the possibility of two distinct mechanisms of neurovascular signalling by local NOS-containing neurons: 1) direct vascular innervation by terminals generating nitric oxide, and 2) paracrine signalling from closely apposed somatic and dendritic neuronal elements.

THE ROLES OF ADENOSINE AND NITRIC OXIDE IN THE CEREBRAL BLOOD FLOW EFFECTS OF HYPOXIA AND HEMODILUTION. M.M. Todd*, B. Wu, D.S. Warner, Neuroanesthesia Research Lab, University of Iowa College of Medicine, Iowa City, IA 52242

Both adenosine and nitric oxide (NO) may be involved in the cerebral blood flow (CBF) changes produced by hypoxia. If the CBF increase which occurs during hemodilution is also related to arterial/tissue O₂ content or tension, these two compounds may also play a role. To examine this, male pentobarbital-anesthetized NZW rabbits were prepared for the measurement of CBF with radioactive microspheres. Arterial O₂ content (CaO₂) was then reduced in each animal to ~6ml O₂/dL, either by reducing PaO₂ (to ~24mmHg) or by hemodilution (hematocrit ~14.5%). Baseline CBF was measured. Animals were then sequentially given 3, 10, and 30mg/kg of L-nitroarginine methyl ester (L-NAME) or 2, 10, and 20mg/kg of 8-phenyltheophylline (8-PT). CBF was measured ~10min after each dose of drug. Baseline CBF was greater in hypoxic animals (124±37 ml/100gm/min, X±SD) than with hemodilution (73±16ml/100gm/min). These compared with normal CBF values (prior to hypoxia or hemodilution) of ~38ml/100gm/min. The administration of both L-NAME and 8-PT resulted in dose related decreases in CBF in hypoxic animals, with a minimum CBF=96±27ml/100gm/min with L-NAME and 91±30ml/100gm/min with 8-PT. By contrast, neither drug altered CBF in hemodiluted rabbits (minimum CBF's of 70±16 for L-NAME, 76±24 ml/100gm/min for PT). These results indicate that A) the CBF responses to an equal reduction in CaO₂ differ between hypoxia and hemodilution, B) both NO and adenosine play a role in the CBF response to hypoxia, and C) these two compounds play little or no role in the response to hemodilution, at least under the conditions studied here.

LEARNING AND MEMORY: SYSTEMS AND FUNCTIONS IX

504.1

THE FUNCTIONAL ANATOMY OF AMYGDALA EFFERENT PATHWAYS

Larry Cahill * and James L. McGaugh, Ctr. Neurobio. Learning and Memory, Dept. Psychobio., UC, Irvine, CA 92717

It is well established that intra-amygdala (AC) injections of a variety of neurotransmitter agents can modulate memory processes. We have recently begun a series of experiments designed to map out the brain systems involved in the memory-altering effects of intra-AC injections. Our strategy is to combine intra-AC injections of specific neurotransmitter agents with either 2-deoxyglucose autoradiography or c-fos immunohistochemistry to identify brain structures affected by the injections. Male Sprague-Dawley rats receive unilateral intra-AC injections via implanted cannulae of a specific neurotransmitter agent, and control injections into the opposite AC. The agents used to date are N-Methyl-D-aspartic Acid, naloxone, and Beta-endorphin. After the injections, the brains are processed using standard techniques for either 2-DG autoradiography or c-fos immunohistochemistry. Sections from throughout the brains are taken for analysis. Assymetries in structure labelling between the brain sides were taken as evidence of activation resulting from the unilateral intra-AC injection of the active agent. The results show strong labelling assymetries in several brain structures for both 2DG and c-fos, although the affected areas are not identical for both techniques. Among the areas most clearly affected by the intra-AC injections are the piriform cortex, caudate nucleus, and dentate gyrus (seen with c-fos), dorsal thalamic nuclei (2DG) and the auditory system (colliculi, geniculate, cortex- 2DG). We expect that this approach will allow us to create a relatively complete map of the brain systems involved in memory modulation after intra-AC injections. 504.3

EFFECTS OF NMDA LESIONS OF INSULAR CORTEX AND AMYGDALA COMPLEX ON THE RETENTION OF OVERTRAINED INHIBITORY AVOIDANCE TASK. I.B. Introini-Collison*, F. Bermudez-Rattoni, K. Coleman and J.L. McGaugh, Center for Neurobiol. of Learning & Memory and Dept. of Psychobio. U. of Calif., Irvine CA 92717 and Instituto de Fisiologia Celular, UNAM, Mexico, D.F. 04510.

Amygdaloid complex (AM) and insular cortex (IC) lesions produce severe impairment of the acquisition of aversively motivated tasks. The present experiment examined the effects of N-Methyl-D-Aspartate (NMDA) lesions on the retention of an overtrained step-through (two-compartment) inhibitory avoidance task. Male Sprague Dawley rats were trained in a multiple trial (10 trials) inhibitory avoidance task. After 7 days, animals were randomly divided into four groups, and were given NMDA injections (8.0 µg in 0.8 µl) in either the AM or IC, and two other groups received buffer injections in either the AM or IC as controls. Seven days after the injections the animals were tested in the same apparatus where they were trained. The results showed that the retention latencies for both the AM- and IC-NMDA lesioned groups were significantly lower than the buffer-injected groups. The number of crossings to the compartment where the footshock had been delivered and the time spent in that compartment were significantly increased as compared with the buffer controls. These results provide additional evidence that the AM and the IC are involved in long term retention of aversively motivated information. 504.2

EFFECTS OF POST-TRAINING D-AMPHETAMINE INJECTIONS INTO HIPPOCAMPUS, AMYGDALA, AND CAUDATE NUCLEUS ON RETENTION IN SPATIAL AND CUED WATER MAZE TASKS. M.G. Packard*, J.L. Cahill, & J.L. McGaugh, Center for Neurobio. of Learning & Memory and Dept. of Psychobio., U. of Calif., Irvine, CA 92717.

Extensive evidence suggests that different forms of memory involve different neural systems. In particular, the hippocampus and caudate nucleus appear to mediate and/or regulate different forms of memory. Other findings suggest a prominent modulatory role for the amygdala in memory storage processes. We examined independently the "type" of memory required for task acquisition. Rats received an 8 trial (30 second ITT) training session on a single-platform spatial or cued water maze task. In the spatial task, a submerged escape platform was located in the same quadrant of the maze on all trials. In the cued task, a visible escape platform was located in a different quadrant of the maze on each trial. Following trial 8 in both tasks, the rats received a unilateral post-training intracerebral (hippocampus, amygdala, or caudate nucleus), injection of d-amphetamine (10 µg/0.5 µl) or saline. On a retention test session 24 hours later latency to mount the escape platform was used as a measure of memory. In the spatial task, the retention test escape latencies of animals receiving intra-hippocampal, but not intra-caudate injections of d-amphetamine were lower than those of saline injected controls. In the cued task, the retention test escape latencies of animals receiving intra-caudate, but not intra-hippocampal injections of d-amphetamine were lower than those of saline injected controls. Post-training intra-amygdala injections of d-amphetamine enhanced retention of both tasks. The double dissociation of memory modulating influences observed following hippocampal and caudate nucleus injections supports the hypothesis that these two structures are parts of systems mediating or regulating different forms of memory. In contrast, the finding that amygdala injections enhance memory in both tasks suggests that the modulatory role of this structure in memory can be exerted independently of the type of memory involved.

504.4

The Right and Left Amygdalae are Differentially Involved in the Expression of Memory for an Aversively Motivated Task. K. Coleman* & J.L. McGaugh, Center for Neurobio. of Learning & Memory and Dept. of Psychobio. U. Of Calif., Irvine, CA 92717

Extensive evidence from studies of both humans and lower animals suggests that the two hemispheres contribute differentially to the evocation of emotional experience and emotional expression. That is, the brain mechanisms underlying negative emotion may be lateralized to the right hemisphere, and mechanisms underlying positive emotion may be lateralized to the left hemisphere. There is also evidence that emotionally influenced memory may be lateralized. That is, memory for affective aspects of an experience appear to be lateralized to the right hemisphere. Several lines of evidence implicate the amygdala in the integration and modulation of emotionally influenced memory. The purpose of this study was to investigate whether or not there is lateralization of amygdala involvement in the memory of an aversively motivated task. Male Sprague-Dawley rats (250-300 g) were implanted bilaterally with cannulae aimed at the amygdala. Nine days after surgery, rats were trained in a one-trial step-through inhibitory avoidance task with 1mA/1 sec footshock. After training, animals were returned to their home cages. 24 hours or 10 days later, animals received a pre-test microinjection of either buffer in both cannulae, 2% lidocaine in both cannulae, or buffer in one cannula and lidocaine in the other. Five minutes after the injections, retention was tested. The retention latencies of rats given lidocaine into the right amygdala and buffer into the left amygdala were significantly lower than rats in all other groups at both 24 h ($p < .01$) and at 10 d ($p < .05$). These results suggest that the right and left amygdalae may make differential contributions to the expression of memory, and that the contribution of the right amygdala may be more important to the expression of memory for an aversive task.

504.5

VARIATIONS IN FOOTSHOCK INTENSITY AND THE RETENTION IMPAIRMENT PRODUCED BY POSTTRAINING AMYGDALA LESIONS. GL. Ouirarte*, M.B. Parent & J.L. McGaugh. Center for the Neurobio. of Learning & Memory and Dept. of Psychobio., U. of Calif., Irvine, CA 92717-3800.

It is well established that retention of aversively-motivated learning is impaired by posttraining amygdala lesions. Previous findings from this laboratory indicate that the retention impairment is partially attenuated by extensive training prior to the induction of the lesions. The present experiment examined whether the degree of impairment is also affected by the footshock intensity used during training. Male Sprague Dawley rats were given one trial of inhibitory avoidance (IA) training using a footshock intensity of 0.45 mA, 0.75 mA, or 1.25 mA. One week later, large neurotoxic amygdala lesions were induced. Retention performance was assessed four days after surgery. The retention performance of amygdala-lesioned animals (AL) was significantly poorer than that of sham-lesioned animals (SL): AL-1.25 and AL-0.75 animals had significantly poorer retention performance than their respective SL controls. However, there was no difference in the retention performance of SL-0.45 and AL-0.45 animals. More importantly, variations in footshock intensity affected retention performance. The retention performance of SL-0.75 and SL-1.25 animals was significantly better than that of SL-0.45 animals. Likewise, the retention performance of AL-1.25 animals tended to be better than that of AL-0.45 animals. The retention performance of AL-0.75 animals was comparable to that of SL-0.45 animals; similarly, the retention performance of AL-1.25 animals was comparable to that of SL-0.45 and SL-0.75 animals. Thus, these findings indicating that the degree of impairment produced by amygdala lesions is influenced by the footshock intensity used prior to the induction of the lesion suggest that the amygdala is not a site essential for mediating the changes induced by IA training.

A CONNECTIONIST MODEL OF THE THALAMO-AMYGDALA NETWORK MEDIATING CONDITIONED FEAR REACTIONS. J.L. Armony, D. Servan-Schreiber, J.D. Cohen, J.L. McClelland* & J.E. LeDoux. Center for Neural Science, New York Univ., NY, NY 10003.

Sensory information reaching the lateral nucleus of the amygdala (AL) is processed along two parallel and possibly competing pathways with different physiological and functional properties. We developed a connectionist model to study this circuit. In the model, auditory thalamic nuclei (MGm, MGv), auditory cortical areas and AL are represented as layers of units connected by feedforward parallel pathways of excitatory weights. Within a layer, units are organized into clusters with lateral inhibition. Information processing capacity in a layer is set by the number of units and cluster size. The network is initially trained on simulated tones of different frequencies using a Hebb-type learning rule. As a result of this training, MGm units develop broad receptive fields (RFs) whereas the RFs of MGv units become sharply tuned around their best frequency (BF), as observed in single-cell recordings. Conditioning is then simulated by pairing a fixed frequency CS (tone) with a UCS. Units receiving converging CS-UCS input show frequency-specific changes in their RFs: (1) units with a BF close to the CS "retune" their BF towards the CS frequency; (2) units with BFs distal to the CS do not modify their RF; (3) units with BFs in an intermediate frequency range develop a minor peak in their RF for the CS frequency and decrease their BF response; (4) plasticity of RFs is largest for units with broad tuning (MGm and AL). The model demonstrates that our assumptions about connectivity between and within layers, number of units in each layer, and a Hebb-type correlational learning provide a sufficient basis for the RF changes observed empirically during conditioning.

LONG-TERM INCREASES IN AUDITORY-EVOKED RESPONSES ACCOMPANY TETANICALLY-INDUCED LTP IN THE THALAMO-AMYGDALA PATHWAY. M. Rogan*, F. Bordi, J.E. LeDoux. Center for Neural Science, New York University, NY, NY 10003

Projections from the medial geniculate body (MGB) to the lateral amygdala (AL) have been implicated in classical fear conditioning with an auditory CS. Previous studies demonstrated the induction of LTP in AL by stimulation of the MGB (Clugnet and LeDoux, 1991). The present study examined the effects of LTP induction in the thalamo-amygdala pathway on the processing of auditory stimuli as measured in the AL. Rats (n=4) were anesthetized with urethane and fixed in a stereotaxic frame equipped with a calibrated monaural sound source. Electrical stimulation was delivered through a concentric bipolar electrode placed in the MGB. A steel recording electrode was lowered into the AL until a position was reached where field potentials were recorded both in response to electrical stimulation in the MGB and a frequency modulated tone delivered to the contralateral ear. Baseline measures were taken of both the auditory-evoked and electrically-evoked responses prior to tetanic stimulation of the MGB (10 trains at 1Hz of 30 pulses at 300Hz; 3 repetitions, 5 min apart). After tetanization, evoked responses to the same auditory and electrical stimuli were measured every 15 minutes for an hour. Post-tetanus measures showed increases in both auditory-evoked and electrically-evoked field potentials. After 1 hour, auditory-evoked field potentials remained elevated 10-130% over baseline levels; electrically-evoked potentials remained elevated 13-202%. Across animals, increases in auditory evoked potentials were highly correlated with increases in electrically evoked potentials. These findings demonstrate a tetanically-induced change in the processing of natural auditory stimuli in a pathway known to be involved in classical fear conditioning with an auditory CS. TIME-DEPENDENT RETROGRADE IMPAIRMENT PRODUCED BY LIDOCAINE INJECTIONS INTO THE BASOLATERAL COMPLEX OF THE AMYGDALA. M.B. Parent* & J.L. McGaugh. Center for the Neurobio. of Learning & Memory and Dept. of Psychobio., U. of Calif., Irvine, CA 92717-3800.

Extensive evidence suggests that the basolateral complex (BL) of the amygdala is involved in the retention of aversively-motivated learning. Previously we reported that inhibitory avoidance retention performance is impaired by posttraining inactivation of the BL. The present experiment examined the temporal involvement of the BL in the consolidation of inhibitory avoidance learning. Male Sprague Dawley rats were implanted bilaterally with cannulae aimed at the BL (AP - 0.31; ML - 0.51; DV - 0.5 cm). One week after recovery, the rats were trained in a one-trial inhibitory avoidance task (0.45 mA footshock; 1 sec) followed by infusions of lidocaine hydrochloride (Sigma; 0.01 mg; 40mg/ml; 0.25 µl/1 min) either immediately, 6 hr, or 24 hr after training. On a retention test 48 hr after training, the latency to enter the dark/shock compartment and the total time spent in the lighted/safe compartment were recorded for 600 sec and used as indices of retention. Immediate posttraining injections of lidocaine into the BL significantly impaired retention performance. This impairment was also observed when the injections were administered 6 hr, but not 24 hr, after training. These results support the findings of Bucherelli, Tassoni, and Bures (1992), who found that inactivation of the amygdala immediately following or 90 min following aversive training significantly impaired subsequent retention performance, whereas inactivation of the amygdala 24 hr after training had no effect. The results of the present experiment suggest that the retention impairment produced by inactivation of the amygdala may be mediated by the BL and that BL signals are critical for regulating the consolidation of inhibitory avoidance learning for at least 6 hr after training.

SENSORY-SPECIFIC CONDITIONED PLASTICITY IN LATERAL AMYGDALA NEURONS. F. Bordi* and J.E. LeDoux. Center for Neural Science, New York University, New York, NY 10003.

Projections from the acoustic thalamus to the lateral nucleus of the amygdala (AL) have been implicated in auditory fear conditioning, which involves the associative pairing of an auditory conditioned stimulus (CS) and a noxious somatosensory unconditioned stimulus (US). Since frequency receptive fields in the acoustic thalamus can shift towards the CS as a result of conditioning (Weinberger et al, 1990), we examined whether AL neurons, which also have frequency receptive fields (Bordi and LeDoux, 1992), exhibit similar changes.

Unit activity was recorded in AL from awake, restrained rats (n=2) or urethane anesthetized rats (n=11). White noise bursts were used to search for auditory responsive cells. Frequency tuning was evaluated by presentation of a series of tones (1-30 kHz, 50-100 msec, 2-3 Hz). Threshold and best frequency (BF) of the cell 30 dB above threshold were determined. During sensitization training, a block of 10-20 unpaired CS (30 dB above threshold, 2 sec) and US (3-4 mA, 10 msec tailshock) presentations was given. Conditioning consisted of 5 blocks of 4 trials involving CS-US pairing. Frequency receptive fields were reevaluated immediately after and 30-45 min after conditioning.

Cells in AL showed different degrees of changes as a consequence of learning. A group of cells (5 from anesthetized and 2 from awake animals) increased their response to the CS frequency, with 3 of these also exhibiting increases in a number of adjacent frequencies as well. The main changes in other cells (n=2) were specific decreases at the BF (n=2) or decreases at the CS (n=2) frequency. In general, conditioned increases in firing occurred in the early latency responses (<25 ms) and increases were more common 30-45 min after conditioning than immediately afterwards. These changes in AL are similar to those reported for the thalamic neurons that project to AL.

504.10

DIFFERENTIAL CONTRIBUTIONS OF VENTRAL AND DORSAL AREAS OF MEDIAL PREFRONTAL CORTEX TO FEAR CONDITIONING. M.A. Morgan, E.E. Coons*, J.E. LeDoux. Center for Neural Science, New York University, NY, NY 10003

The medial prefrontal cortex (mPFC) includes cortical areas lying along the medial wall of the anterior frontal lobe, specifically the infralimbic (IL), prelimbic (PL), medial orbito-frontal (MO), and anterior cingulate (ACg) regions. Lesions of ventral portions of mPFC, particularly IL, PL, and MO, result in a greater resistance to extinction of conditioned fear but do not alter the amount of fear expressed on a given trial. We therefore examined the effects of lesions of areas which lie dorsally in mPFC and were, at most, minimally included in the previous lesions. Experimental rats received lesions of dorsal mPFC (n=8). Controls (n=8) received sham lesions or were unoperated. After 2 weeks, all rats were trained on a fear conditioning task that involved 2 pairings a day of a tone conditioned stimulus (CS: 10KHz, 80 dB) with a footshock unconditioned stimulus (US: 0.5mA, 0.5sec.) for 2 consecutive days, followed by 2 trials a day of the tone alone until extinction criterion was met. Dorsal mPFC lesioned rats exhibited more freezing than did controls and were in fact at ceiling on a far greater number of trials than controls. A second study was conducted employing the same experimental paradigm but using a weaker (0.3mA) footshock in an attempt to eliminate the ceiling effect. Dorsal mPFC lesioned rats (n=7) again exhibited more freezing than controls (n=10). Moreover, half of the lesioned rats were still at ceiling a much greater number of times than were controls. Thus, while ventral areas of mPFC appear to play a role in the regulation of fear extinction, the dorsal mPFC appears to be involved in the regulation of fear reactivity. Both of these functions may involve prefrontal projections to the amygdala. Supported by NSF9209646

NMDA RECEPTORS ARE INVOLVED IN SYNAPTIC TRANSMISSION IN THALAMO-AMYGDALA PATHWAYS. X.F. Li, R.G. Phillips, J.E. LeDoux,* Center for Neural Science, New York University, NY, NY.

Projections from the auditory thalamus to the amygdala have been implicated in fear conditioning. Previous studies suggest that the pathway, which exhibits LTP, utilizes an excitatory amino acid as a neurotransmitter. In the present study we examined whether synaptic transmission in this pathway is mediated by AMPA and/or NMDA excitatory amino acid receptors. Rats (n = 9) were anesthetized with urethane. Extracellular unit responses were recorded in the lateral nucleus of the amygdala (AL) in response to electrical stimulation (200-500 uA, 300-500 us, 0.5 Hz) of the acoustic thalamus. A total of 15 units were identified. The cells responded with latencies of 5-8 ms. Microiontophoresis of the NMDA antagonist, AP5 (50mM, pH 8.5), depressed the response in 12 units and had no effect on the remaining 3 cells. In contrast, the AMPA receptor antagonist, CNQX (1.95 mM, pH 5.0), depressed 4 cells, excited 6 cells, and had no effect on 5 cells. Three of the 4 cells depressed by CNQX were also affected by AP5. The excitation produced by AMPA antagonism may be due to the blockade of excitatory projections to inhibitory neurons and the consequent release from inhibition of cells postsynaptic to the inhibitory neurons. Thus, both NMDA and AMPA receptors appear to play a role in synaptic transmission in AL. The involvement of NMDA receptors raises questions about the effects of NMDA receptor blockade in the amygdala on learning. Supported by MH38774 & MH46516.

MUSCIMOL INJECTED INTO THE BASOLATERAL AMYGDALA BLOCKS BOTH ACQUISITION AND PERFORMANCE OF CONDITIONAL FEAR

E.J. Helmstetter* & P.S. Bellgowan, Department of Psychology, University of Wisconsin, Milwaukee, WI 53201

Recent data indicate that the amygdala is critical for learning associations between an observation chamber and footshock as well as for the performance or expression of fear-related behavioral responses when the stimulus that has been paired with shock is presented after learning has occurred. Prior results from our lab (Physiol. Behav. 51:1271) showed minimal disruption of fear conditioning when the amygdala was temporarily inactivated with lidocaine prior to learning while the same treatment significantly blocked performance 24 h later. In the present study we injected muscimol (0.5µg, bilateral) into the basolateral amygdala of rats 1 hr prior to pairing an observation chamber with footshock (1.6mA x 3). This treatment resulted in a dramatic reduction in conditional freezing behavior 24 h later relative to saline controls. As with lidocaine, injections made prior to the test session also blocked performance. The different pattern of results obtained with muscimol vs lidocaine may relate to large differences in the duration of functional inactivation that would be expected given the present parameters. Although our preliminary findings also provide some evidence that muscimol's effects may be "state-dependent", the results are generally consistent with a role for the amygdala in both learning and performance of conditional fear.

504.15

HYPOALGESIA ON THE FORMALIN TEST INDUCED BY NOISE STRESS IS ATTENUATED BY SYSTEMIC ADMINISTRATION OF NALTREXONE P.S. Bellgowan* & F.J. Helmstetter, Department of Psychology, University of Wisconsin at Milwaukee, Milwaukee, WI 53201.

Previous research has shown that a single presentation of moderately intense (75-95 dB) white noise (WN) is sufficient to induce opioid mediated hypoalgesia on the radiant heat tail flick test. The neural circuit responsible for noise stress hypoalgesia is also critical for the expression of hypoalgesia in response to an auditory stimulus that has previously been paired with footshock during Pavlovian conditioning. The presentation of such a conditional stimulus to a rat will result in an integrated pattern of defensive behaviors which includes freezing and hypoalgesia. The present study was conducted to further define behavioral responses to noise stress and to compare these responses with those observed during associative fear conditioning. Adult male rats received a 50 ul s.c. injection of 10% formalin solution in the right hind paw. Prior to being placed in a test chamber subjects were injected i.p. with either 3 mg/kg naltrexone or saline. Following four minutes of baseline behavioral observations subjects were exposed to a 60 second presentation of 0, 72, or 95 dB WN. Behavioral observations continued for five minutes following the onset of the noise. Presentation of WN induced a graded level of defensive freezing during noise presentation with the highest intensity of WN having the largest effect. Presentation of the 95 dB WN also induced a transient hypoalgesia that was attenuated by naltrexone. Non-stimulated controls showed no defensive behaviors throughout the test session. When returned to the test chamber 24 hrs later subjects showed no behavioral signs of Pavlovian fear conditioning to the context. This study, along with previous findings, suggests that noise stress hypoalgesia results from a state of sensitization or non-associative fear.

504.12

INVOLVEMENT OF DIFFERENT SUBDIVISIONS OF THE MEDIAL GENICULATE NUCLEUS AND OF THE PERIRHINAL CORTEX IN FEAR POTENTIATED STARTLE TO ACOUSTIC AND VISUAL CONDITIONED STIMULI S. Campeau* and M. Davis, Dept. of Psychology and Psychiatry, Yale Univ. Sch. of Med., 34 Park St., New Haven, Ct 06508.

Prior studies in our laboratory have indicated that post-training lesions of the entire auditory thalamus specifically block fear-potentiated startle using an auditory conditioned stimulus (CS), and post-training lesions of the perirhinal cortex block fear-potentiated startle to both auditory and visual CSs. The goals of the present studies were: 1- to test the involvement of different auditory thalamic subnuclei in fear-potentiated startle and; 2- to test the effects of pre-training lesions or retraining in animals sustaining damage to different auditory thalamic subnuclei or the perirhinal cortex. Anatomically, the posterior auditory thalamic nuclei project directly to the perirhinal cortex, whereas the ventral and dorsal divisions of the medial geniculate nucleus project indirectly to the perirhinal cortex via an auditory cortical relay.

Rats received 10 noise-footshock pairings, mixed with 10 light-footshock pairings on each of 2 consecutive days. They were then matched into groups having equivalent levels of fear-potentiated startle to both auditory and visual CSs. Twenty-four hr later, rats were given neurotoxic NMDA lesions of either the ventral and dorsal divisions of the medial geniculate nucleus (n = 10), the posterior auditory thalamic nuclei (n = 7), the perirhinal cortex (n = 10), or sham lesions (n = 22). Ten days later, a startle test revealed that only lesions of the ventral and dorsal divisions of the medial geniculate nucleus, but not lesions of the posterior auditory thalamic nuclei, specifically blocked fear-potentiated startle to the auditory CS. Lesions of the perirhinal cortex completely blocked potentiated startle to the acoustic and visual CSs. Importantly, rats sustaining pre-training NMDA lesions of the perirhinal cortex (n = 10), or retraining the rats initially sustaining lesions of different subdivisions of the auditory thalamus, showed levels of fear-potentiated startle similar to those of sham-operated and unoperated rats to both auditory or visual CSs.

The post-training lesion results indicate that the ventral and dorsal divisions of the medial geniculate nucleus and the perirhinal cortex are relays along a pathway normally mediating the expression of auditory aversive memories. However, the pre-training and retraining results strongly suggest that subcortical pathways may be used to express aversive memories following injury to the cortical pathway, but does not appear to be the primary neural circuit that normally mediates aversive conditioning. These results thus indicate the importance of performing lesions both before and after training to determine the most likely neural circuits mediating fear conditioning.

INJECTIONS OF CALCITONIN GENE RELATED PEPTIDE IN THE AMYGDALA BLOCK FEAR CONDITIONING TO CONTEXTUAL BUT NOT DISCRETE STIMULI

L. H. Poore* and F. J. Helmstetter, Department of Psychology, University of Wisconsin at Milwaukee, Milwaukee, WI 53201

Calcitonin gene-related peptide (CGRP) is localized in projections to the amygdala that may be important for fear conditioning. When injected intracerebroventricularly (ICV), CGRP produces freezing behavior and disrupts associative learning. CGRP was injected into the lateral nucleus of the amygdala in order to study its effects on fear conditioning using discrete and contextual conditional stimuli. Rats implanted with bilateral cannulae in the lateral amygdala were injected with either saline, 6.3nM or .63mM CGRP prior to fear conditioning using four white noise (72db, 10 sec) shock (2mA, 1 sec) pairings. Twenty-four hours later, all animals were injected with saline and observed for freezing to the observation chamber in which training occurred. On the same day, rats were also observed in a novel chamber in which the white noise CS was presented. CGRP had no effect on freezing prior to foot shock and did not change the amount of freezing in the presence of the discrete auditory CS. However, freezing to contextual stimuli present at the time shock was delivered was dose dependently blocked by CGRP when applied to the lateral amygdala prior to training. These results indicate that the disruption of associative learning seen with ICV injections of CGRP may be mediated by receptors in the amygdala, while the fear evoking effect of CGRP injected ICV is not.

PRETRAINING INJECTIONS OF CORTICOTROPIN RELEASING FACTOR INTO THE VENTRAL PERIAQUEDUCTAL GRAY ENHANCE FREEZING TO AN AUDITORY CONDITIONAL AVERSIVE STIMULUS.

S. A. Tershner* and F. J. Helmstetter, Department of Psychology, University of Wisconsin, Milwaukee, WI 53201.

The present study investigated the effect of corticotropin releasing factor (CRF) on fear conditioning using discrete and contextual conditional stimuli. Separate groups of rats received an infusion of CRF (.2ug) or isotonic saline into the ventral periaqueductal gray (vPAG). Twenty minutes after infusion, the rats were placed into observation chambers and their behavior was recorded for twenty minutes. This dose of CRF alone did not produce any significant behavioral changes during the observation period.

Later, all subjects were randomly reassigned to either the CRF (.2ug) or saline group. Twenty minutes after infusion, the rats were placed into the observation chambers where they received Pavlovian fear conditioning consisting of four presentations of white noise (74dB/10 sec) followed by footshock (1.6mA/ 1 sec).

On the next day, conditional fear responses to the observation chamber (context) and discrete auditory CS were measured. Rats were returned to the chamber in which conditioning was conducted and observed for twenty minutes. CRF given before training did not affect the amount of freezing behavior to this context. One hour later animals were given a single five minute presentation of the noise CS in a novel context. Animals given CRF prior to noise-shock pairings showed significantly more freezing to the CS. These results suggest that the vPAG may be an important site for the modulatory effects of CRF on fear conditioning and support the idea that different neural systems are involved in fear responses to discrete vs. contextual conditional stimuli.

INTEROCULAR TRANSFER IN THE SPLIT-BRAIN RAT. D.P. Crowne*, P. Forsyth, and J. Fitzgerald, Dept. of Psychology, Univ. of Waterloo, Waterloo, Ontario, CANADA N2L 3G1

Disruption of interocular transfer by division of the cerebral commissures was long ago established in cat and monkey with the evidence of unilateral engrams inaccessible to the isolated and untrained hemisphere. Interocular transfer was difficult to study in the rat because unocular exposure of one hemisphere was impossible. The optic chiasm in the rat was inaccessible, and split-brain experiments were limited by transmission of visual information to both hemispheres. In this experiment, using a recent method to transect the chiasm, we investigated IOT in split-chiasm rats, comparing groups with corpus callosum section and callosum intact. 8 split-brain and 8 chiasm sectioned rats were monocularly trained on an orientation discrimination, trained on a reversal with the other eye, and retrained with the first eye on either the 2nd-eye S⁺ (N = 4) or S⁻ (N = 4). ANOVA yielded a Groups X Tests interaction, $F(6,24) = 4.04, p = .006$. The critical comparisons are on retesting the original eye. We separately compared chiasm-section and split-brain groups given reversal or transfer tests. In rats with chiasm section alone, the 2nd-eye S⁺ showed significant transfer to the first eye; the reversal group did not and differed significantly from the transfer group. In the split-brain groups, those given the 2nd eye S⁺ showed a reversal effect with the original eye; the group retested with the original S⁺ showed significant savings. We definitively establish interhemispheric communication via the callosum, unilateral engrams, and the disruption of transfer by callosal section.

SPATIO-TEMPORAL PATTERNS OF VISUAL, AUDITORY, AND SOMESTHETIC EEGs IN PERCEPTION BY TRAINED RABBITS. W. J. Freeman*, J. M. Barrie. Dept of Molecular & Cell Biology, University of California at Berkeley, CA 94720

Perceptual information has been found to exist in paleocortical EEGs in the form of spatial patterns of amplitude modulation of a broad-spectrum aperiodic wave form in the gamma range of the EEG (20 - 80 Hz, often referred to as "40 Hz"). These occur only in subjects that have been trained to discriminate and respond to selected stimuli. We tested the hypothesis that similar patterns would be found in the EEG of neocortex. Arrays of 64 electrodes (8x8 at 0.8 mm spacing) were surgically fixed onto the epidural surface of the visual, auditory or somesthetic cortex of 12 rabbits. After recovery, the subjects were trained to respond to simple CS (+ and - on interspersed trials) in a classical aversive paradigm. The 64 EEG traces were recorded in 6 sec trials, stored on disk, segmented, and decomposed by Fourier or PC analysis. Spatial pattern differences were expressed for 120 msec segments at 40 msec intervals as points in 64-space. Pattern differences were determined by a Euclidean distance in the SD metric and given a probability value. Differences between CS+ and CS- segments were found in narrow time windows near 40, 300, and 450 msec after stimulus onset. We concluded that the neural processes for perception are similar for sensory paleo- and neocortex. In all of these systems, perceptions are constructed by chaotic dynamics. VISUAL ACUITY IN PIGMENTED AND ALBINO RATS. Ian Steele Russell* & Susan E. Maier. Human Anatomy, Texas A&M University Health Science Center, College Station, TX, 77843-1114

Interocular transfer (IOT) of visual information following monocular training is found to occur readily in pigmented rats while equivocal results are derived for albino rats. The extent to which differences in visual acuity are responsible for this fact was investigated in this study. Visual acuity was examined for intensity and orientation differences in groups of albino and pigmented rats. All animals were trained in a two choice discrimination apparatus using shock motivation. The groups were trained to discriminate black versus white circles followed by vertical versus horizontal striations. All animals were then tested using either the constant stimuli method or the staircase method over a comprehensive range of stimuli to determine intensity and angular difference thresholds. The results showed that the psychophysical curves were identical for both albino and pigmented rats for intensity and orientation suggesting that the difference between these animals in IOT must be accounted for by some other mechanism.

DIFFERENTIAL EFFECTS OF INSULAR CORTEX AND DORSAL STRIATUM LESIONS IN A PLACE CONDITIONING TASK. A.L. Piña, C.E. Ormsby, V. Ramirez-Amaya and F. Bermúdez-Rattoni. *Instituto de Fisiología Celular, UNAM, México, D.F. 04510.*

Insular Cortex (IC) and dorsal striatum (DS) lesions induce deficits in the acquisition of an Inhibitory Avoidance (IA) learning. This work examines the effects of IC and DS lesions on a positively motivated learning task.

Male Wistar rats were used. One half of animals were trained in the IA task and the other in a positively reinforced place conditioning (PPC). Subjects were divided in control (CON), IC and a DS lesioned groups. Electrolytic lesions were performed and all animals were trained in either of the two procedures, and tested 48 hrs later. All animals had restricted water access. Multitrial IA task was conducted conventionally. A modified PPC was developed for this work. The PPC was conducted in the same box, but 10 sec after the door was opened a drinking pipette was introduced in the lit compartment. The animal was allowed 3 sec of drinking, then the door was closed and the pipette retired. This procedure was repeated 12 times for each subject. The test session for both tasks consisted in the measurement of step through latency and time spent in the lit compartment during a 10 min period.

Both CON groups showed increased stay in the lit compartment in both tasks. In the IA task both IC and DS showed disruption of learning indicated by a short stay in this compartment. In the PPC task, however, the IC did not show any impairment at all, but the DS showed a markedly low stay. These results indicate that the IC is involved only in aversive motivated behaviors, whereas the DS is probably involved in both aversive and positive motivated conditioning. TASTE AVERSION LEARNING IN RATS LACKING GUSTATORY CORTEX USING MEASURES OF CONSUMPTION AND TASTE REACTIVITY.

S. A. Bailey*, S. L. Rock, and S. W. Kiefer. Dept. of Psychology, Kansas State University, Manhattan, KS 66506.

The ability of GC rats to develop sucrose aversions after repeated sucrose-illness pairings was examined in the present study using concurrent measures of consumption and videotaped recordings of the rats' orofacial responses. Rats lacking GC (n=12) and control rats (n=14) were given three, 10 min trials with a sucrose solution followed by LiCl illness. Each training trial was videotaped and later scored for taste reactivity. GC rats showed significant deficits in acquiring avoidance of sucrose although consumption did decrease with repeated trials. However, after water consumption in the test chamber returned to normal levels, sucrose consumption (mean=8.0 ± 1.6) approached pretraining levels (mean=12.5 ± 1.1); at the end of training, aversive reactivity to sucrose was low for all GC rats (mean=1.3 ± 0.4). Although sucrose consumption by control rats (mean=12.7 ± 0.8) was initially high, they quickly learned to avoid consumption of sucrose in the test chamber and also showed high levels of aversive reactivity (last trial mean=13.5 ± 4.3). It appears GC rats show relatively nonspecific reductions in consumption when given illness experiences and that a hedonic shift to the illness-paired taste does not occur as it does in control rats.

THE EFFECT OF AMYGDALOID LESIONS ON THE ACQUISITION OF EEG AND HEART RATE CONDITIONED RESPONSES (CRs) IN THE RABBIT. B.S. Kapp*, P.J. Whalen, A.J. Silvestri, M.P. Jordan, and J.H. Fichter, Dept. Psychol., Univ. of Vermont, Burlington, VT 05405.

We have recently demonstrated that conditioned EEG desynchronization in the rabbit, as reflected in the inhibition of high voltage delta wave activity (1-4 Hz), is rapidly acquired via Pavlovian conditioning and that electrical stimulation of the amygdaloid central nucleus (ACe) produces inhibition of delta activity (Kapp et al. 1990; Whalen et al. 1991). The present study was designed to determine if damage to the region of the ACe, previously demonstrated to produce deficits in the acquisition of Pavlovian bradycardic CRs, would affect the acquisition of EEG CRs.

New Zealand rabbits received either bilateral ibotenic acid (0.2-3µl; 1%) or vehicle injections aimed at the ACe and were administered either paired Pavlovian conditioning or pseudoconditioning trials using a tone as a conditioned stimulus and a brief electrical stimulus to the pinna as an unconditioned stimulus. A Fourier analysis of the cortical EEG demonstrated that animals receiving vehicle injections and paired conditioning trials demonstrated acquisition of EEG CRs at a rate similar to the acquisition of heart rate CRs. Animals with damage to the ACe and immediately adjacent regions of the dorsal amygdala and ventral globus pallidus/putamen demonstrated a significant attenuation in the magnitude of both EEG and heart rate CRs (p 's < .05). The results are consistent with the notion that the ACe may contribute to the expression of CRs indicative of enhanced arousal in the rabbit (Kapp et al. 1991). Supported by NSF grant BNS 9010760.

DIFFERENTIAL *c-fos* EXPRESSION IN RAT DORSAL PERIAQUEDUCTAL GREY (PAG) AFTER 2-WAY AVOIDANCE. J.F. Brennan*, C.A. COHEN and L. KACZMAREK. ¹Dept Psychology, Univ of Massachusetts/Boston, MA 02125, ²Dept Psychology, Tufts University, Medford, MA 02155, ³Dept Neurophysiology, Nencki Inst of Experimental Biology, Warsaw, Poland.

18 adult pigmented rats were trained for 100 daily trials in a 2-way shuttle box to avoid a footshock signalled by 5 s tones of 10 kHz, 62 dB. 6 rats received a single session, were sacrificed and perfused 1 hr after the session. 2 other groups of 6 rats each were likewise treated after the 2nd or the 3rd training session. 6 additional rats served as controls and were handled briefly 1, 2 or 3 times, matching the respective avoidance training groups. Rats showed increasing proportion of avoidance responding with progressive training sessions. Preliminary data suggest that there is a significant increase in Fos immunopositive nuclei in the dorsal PAG after 2 sessions as compared to handled controls. No significant differences were found between the 3 avoidance training groups. The results support *c-fos* expression as an index of the emotional state underlying the transition from classically control escape responses to instrumental behavioral=control.

LONG-TERM HABITUATION OF THE EMG STARTLE RESPONSE FOLLOWING LESIONS TO THE MESENCEPHALIC RETICULAR FORMATION IN RATS

W.P. Jordan*, C.J. Nelson, and T.B. Bodie, Psychology St. Mary's College of Maryland, St. Mary's City, MD 20686

The reflex pathway of the acoustic startle response is a fast-latency system within the brainstem of the rat. Short-term habituation of startle occurs within the reflex pathway, but long-term habituation relies upon the inhibition of the response by neural mechanisms outside of the reflex circuit. Acoustic startle stimuli provoke a bimodal electromyographic (EMG) response in the spinotrapezius muscle in the rat. The early EMG component has a latency of about 8 ms from stimulus onset, while the later component occurs with a latency of about 18 ms.

During long-term habituation, the late EMG component shows a more robust decrease in amplitude than does the early component (Poore & Jordan, 1992). Lesions to the mesencephalic reticular formation (MRF) in rats attenuate long-term habituation of acoustic startle. If the decreasing amplitude of the late EMG component represents the effects of a long-term habituation mechanism exerting its influence on the startle circuit, then lesions to the MRF should attenuate habituation of the late EMG component of startle.

The present study tested this hypothesis in 13 sham-operated rats and 21 animals with bilateral lesions of the MRF. The early EMG component showed small but reliable response decrements in both groups of animals, but the late EMG component decreased across days only in control animals. This result is consistent with the hypothesis that long-term habituation of the acoustic startle response in the rat is expressed within the late, but not the early, EMG component of startle.

505.4

COMPARISON OF LATERAL AND MEDIAL AMYGDALA LESION EFFECTS ON TWO-WAY ACTIVE AND PASSIVE AVOIDANCE. A. L. Beggs*, C. Burkhalter, and V. Melvin, Dept of Psychology, Univ. of Southwestern Louisiana, Lafayette, LA 70504.

Subjects in this experiment were 23 rats approximately one year of age weighing in excess of 550 g. The control group received sham surgery in which an electrode was lowered bilaterally proximal to the amygdala. The experimental groups received electrolytic lesions to either the lateral or medial amygdala. Subjects were placed in a two-way shuttle box and given adaptation trials consisting of a 10 s tone on two consecutive days. Intertrial interval crossings (ITCs) were recorded. This was followed by active avoidance training. This training was followed by 2 days of passive avoidance training. Analysis of the data indicated a significant group effect only during active avoidance training. Tukey's HSD comparison of the group means revealed that the medial lesioned group made longer latency responses than either the control or lateral lesioned group ($ps < .01$). This experiment indicates that the medial nuclei of the amygdala may play a more important role in acquisition of active avoidance responses.

DIFFERENTIAL EXPRESSION OF *C-FOS*, *C-JUN* AND *JUN-B* PEPTIDES IN THE RAT BRAIN FOLLOWING EXPOSURE TO NOVELTY. H. Welzl^{1,2}, M. Papa³ and A.G. Sadile¹. ¹Inst. Anatomia Umana Normale; ²Dip. Fisiologia Umana "F. Bottazzi"; ³2nd Univ. of Naples (SUN), Naples, Italy; ⁴Inst. Behavioral Biology, ETH, Zürich, Switzerland.

The neural consequences of exposure to spatial novelty on expression of immediate early genes (IEG) were mapped in the rat brain by immunocytochemistry for *c-fos*, *c-jun* and *jun-B* peptides. Adult male Sprague-Dawley rats were tested for 10 min in a Låt-maze and sacrificed at different time intervals (0.5, 2, 6 or 24 hr) thereafter. Unexposed handled rats or rats exposed for three days to the maze were used as controls. The former showed a low and scattered basal positivity. In the exposed rats, extensive *c-fos* and *c-jun* positive cells were the granular and pyramidal neurons of hippocampus, and later neurons in all layers of somatosensory cortex and the granule cells of the cerebellar cortex. The positivity was stronger in rats exposed for the first time to the maze. The *fos* and *jun*-like immunoreactivity was *time-dependent*, since it was present between 2 and 6 h after the first exposure, and it was *NMDA-dependent*, being prevented by pretreatment with the competitive NMDA receptor antagonist CPP at a high dose (5mg/kg). In contrast, *c-jun* and *jun-B* expressed in a non congruent manner, since *jun-B* was activated to a lower extent compared to *c-jun*. The results indicate that exposure to spatial novelty involves a differential expression of IEG in the hippocampus and in the cerebral and cerebellar cortex. Thus, IEG brain mapping reveals diffuse, distributed changes in IEG expression associated with a non-associative task. However, expression of some IEGs is not necessarily followed by gene expression that results from a complex orchestration of several transcriptional factors. ASPIRATION LESIONS OF THE DORSAL AND POSTSUBICULUM ATTENUATE CLASSICALLY CONDITIONED BRADYCARDIA IN RABBITS. Mark Chachich*, Brian Maxwell & D.A. Powell, VA Medical Center, and University of SC, Columbia, SC.

Much evidence suggests the participation of the medial prefrontal cortex (mPFC) in classically conditioned bradycardia. The present study is part of a systematic exploration of the role that structures afferent to the mPFC might play in modulating mPFC neuronal activity responsible for conditioned bradycardia. A major mPFC input from the hippocampus, which is known to be involved in associative learning, originates in the dorsal and postsubiculum in rabbits. In a previous study we found that ibotenic acid lesions of these structures had no effect on classical heart rate (HR) conditioning, but in no animal was the subiculum completely destroyed. Thus, in the present experiment aspiration lesions were employed to completely destroy both the dorsal and postsubiculum. Animals with subicular lesions were compared with cortical and sham control animals on differential classical HR conditioning. Although the HR orienting reflex, which also consists of bradycardia, was unimpaired in animals with subicular lesions, the latter animals showed a severe attenuation of classically conditioned bradycardia, compared to both the cortical and sham lesion controls.

LESIONS OF THE MEDIODORSAL NUCLEUS OF THE THALAMUS ATTENUATE CS-EVOKED NEURONAL ACTIVITY IN THE PREFRONTAL CORTEX, BUT HAVE NO EFFECT ON CONCOMITANTLY OCCURRING CONDITIONED BRADYCARDIA. Virginia Murphy*, Shirley Buchanan & D.A. Powell, VA Medical Center, and University of SC, Columbia, SC.

Much evidence suggests the participation of the medial prefrontal cortex (mPFC) in classically conditioned bradycardia. The present study is part of a systematic exploration of the role that structures afferent to the mPFC might play in modulating the mPFC neuronal activity responsible for conditioned bradycardia. Rabbits received ibotenic acid (IA) lesions of the mediodorsal nucleus of the thalamus, which is the thalamic projection nucleus to the mPFC. Chronic recording electrodes were also implanted in each animal for assessing multiple unit activity (MUA) in the mPFC. After recovery from surgery the animals were subjected to simple classical heart rate (HR) conditioning. CS-evoked increases in MUA recorded during conditioning were obtained in both the sham and lesioned animals, but they were significantly smaller in the lesion group. In spite of reduced mPFC MUA in the lesion group, the magnitude of the HR decelerative orienting reflex, as well as the decelerative classically conditioned HR response, was unimpaired compared to that of sham control animals.

FUNCTIONAL NETWORK INTERACTIONS AMONG LIMBIC CORTICES, BASAL FOREBRAIN AND CEREBELLUM DIFFERENTIATE A PAVLOVIAN CONDITIONED EXCITOR FROM AN INHIBITOR: FLUORODEOXY-GLUCOSE MAPPING AND COVARIANCE STRUCTURAL MODELING F. Gonzalez-Lima* and A.R. McIntosh¹, Dept of Psych, Univ of Texas, Austin TX, 78712 USA; ¹Lab of Neurosci, NIA, NIH, Bethesda, MD, 20892 USA

We examined how opposite learned behavioral responses to the same physical stimulus are represented by the pattern of interactions between neural networks. [¹⁴C]2-fluoro-2-deoxyglucose autoradiography (FDG) was used to compare mean activity and interregional covariances resulting from presentation of a tone trained as either a Pavlovian conditioned excitator or inhibitor. Rats were trained with reinforced trials of the conditioned stimulus (A⁺) intermixed with nonreinforced trials of a tone-light compound (AX⁻). For Group CE, the tone was the excitator (A⁺), while for Group CI the tone was an inhibitor (X⁻). After conditioning, both groups were injected with FDG and presented with the same tone. Regional differences in FDG incorporation were noted in the sulcal frontal cortex (SFC), medial (MS/DB) and lateral septum (LS), retrosplenial cortex (RS), and deep cerebellar nuclei. Structural equation models identified two functional networks that differentiated the conditions. One involved basal forebrain regions (MS/DB, LS, and n. accumbens) and the other limbic thalamocortical structures (SFC, RS, perirhinal cortex and the anteroventral thalamic n.). Differences in basal forebrain interactions were mainly in sign and may relate to the opposite affective properties of the tone-CS for the two groups, while sign differences in the thalamocortical circuit may have reflected the associative effects. The functional influence from the basal forebrain to perirhinal cortex was greater in the Group CI model suggesting that one key site of convergence for the information about the associative and affective components of the tone-CS was the limbic cortical circuit through perirhinal cortex. A CONDITIONING MODEL WHICH PROVIDES EVIDENCE FOR TWO MEMORIES, A CS AND A CS/US ASSOCIATION MEMORY. C. Rogers*, V. Ghanta, S. Demissie, N. Hiramoto, and R. Hiramoto. Departments of Biology and Microbiology, University of Alabama at Birmingham, Birmingham, AL 35294.

Natural Killer (NK) cell activity can be conditioned with one trial learning with camphor odor as the conditioned stimulus (CS) and poly I:C as the unconditioned stimulus (US). Ablation of the main olfactory bulb (MOB) or peripheral anosmia produced by zinc sulfate irrigation of the nose, abrogates NK cell conditioning. The olfactory system must be intact in order for the CS odor signal to be perceived. We believe that the olfactory system not only recognizes and perceives the specific CS odor signal, but it also forms a memory for it. When the CS/US signals were overlapped, a conditioned enhancement of both NK cell activity and body temperature was observed. However, when the memory for the CS signal was established one day before administration of the US, a conditioned enhancement of NK cell activity was observed, whereas a conditioned suppression of core body temperature resulted.

Since the memory for the CS is established one day before exposure to the US for both NK and temperature conditioning, the CNS processes the US (IFN- β) differently for NK cell activity and temperature. This divergence in responses suggests differences in efferent mechanisms and memory circuits. The results suggest that the CS must have access to multiple response pathways and that the memory for the CS/US association is made centrally whereas the CS (camphor odor) memory must reside within the sensory circuits. LEARNING AND MEMORY: SYSTEMS AND FUNCTIONS XI

506.1

PASSIVE AVOIDANCE LEARNING AND ANATOMICAL EFFECTS OF INTRA-VENTRICULAR IMMUNOTOXIN TO p75^{NF}. R.G. Wiley*, T.G. Berbos and D. Lappi. Lab of Experimental Neurology, DVAMC, Nashville, TN 37212-2637 and Whittier Institute, La Jolla, CA.

Cholinergic neurons of the basal forebrain (CBF) have been implicated in memory and attentional processes. However, all reported behavioral analyses of CBF lesions have been confounded by damage to non-cholinergic neurons. The immunotoxin, 192-saporin, selectively destroys CBF neurons that display the low affinity neurotrophin receptor, p75^{NF}. In the present study, we sought to determine the extent of forebrain cholinergic denervation resulting from destruction of p75^{NF}-positive CBF neurons and the correlation between the anatomical findings and performance in a step-through passive avoidance task. 8 adult, male Sprague-Dawley rats received pressure microinjections of 2-3.4 μ g of 192-saporin into the rostral left lateral ventricle. 8 rats received similar injections of 1.7-2.55 μ g of the anti-Thy 1 immunotoxin, OX7-saporin, and 8 naive rats served as unoperated controls. One month later, animals were trained on a step-through passive avoidance task using single daily trials for one week. In this task, rats were placed into a brightly lit chamber with an opening into a dark chamber. After acclimation trials, rats received a foot shock every time they entered the dark chamber. Latencies to enter the dark chamber increased with successive trials. Naive controls and OX7-saporin treated rats showed significantly greater increases in latencies to enter the dark chamber than did the 192-saporin rats. After behavior testing, rats were sacrificed and brain sections processed for immunocytochemical demonstration of choline acetyltransferase (ChAT), p75^{NF}, and acetylcholinesterase (AChE). There were no significant anatomical differences between OX7-saporin and control rats. All 192-saporin rats showed loss of CBF neurons with decreased AChE-positive fibers in the hippocampus and frontoparietal neocortex but not in the amygdala. Densitometric analysis revealed that cortical denervation was more complete in 192-saporin rats that did not learn the avoidance task (N=4) compared to those that learned normally (N=4). The results support the conclusion that the CBF projection to the neocortex, but not the projections to hippocampus or amygdala, is critical for passive avoidance learning.

506.2

DOSE DEPENDENT EFFECTS OF IMMUNOTOXIC LESION OF THE RAT CHOLINERGIC BASAL FOREBRAIN ON LEARNING, ACTIVITY, AND CHOLINE ACETYLTRANSFERASE. J.J. Waite*, and L.J. Thal. Dept. of Neuroscience & Neurology, UCSD & VAMC, San Diego, CA 92161.

In the adult rat, NGF receptors are preferentially located on membranes of cholinergic neurons originating in the basal forebrain. The immunotoxin IgG192-saporin targets low affinity NGF receptors and destroys basal forebrain cholinergic neurons with a high degree of specificity. This toxin therefore produces a more specific cholinergic lesion than infusion of excitotoxins. IgG192-saporin was infused into the left lateral ventricle of rats in 4 doses: 4 μ g, 1.34 μ g, 0.34 μ g, or 0 μ g in 10 μ l PBS. Beginning 9 weeks post-surgery, spatial memory acquisition in a water maze and open field activity tests were conducted. The activity of choline acetyltransferase (ChAT) was measured in homogenates of brain regions to assess lesion effects. Animals receiving 4 μ g of toxin were unable to learn the water maze task with either a hidden or visible platform. The other groups learned the task as well as controls (mean latencies of 20 trials, hidden platform, 4 μ g group: 89 sec; 1.34 μ g, 37 sec; 0.34 μ g, 34 sec; 0 μ g: 32 sec). The 4 μ g group exhibited hyperactivity in the open field test compared with all other groups (p<.001). Cortical ChAT activity was decreased in all groups infused with toxin in comparison with vehicle controls: 4 μ g: 18, 11, 15%; 1.34 μ g: 39, 21, 13%; 0.34 μ g: 84, 75, 48% of control activity remained in frontal, parietal, and occipital cortex, respectively.

506.3

PERFORMANCE IN A LATENT INHIBITION (LI) TASK BY RATS WITH QUISQUALIC ACID-INDUCED LESIONS OF THE NUCLEUS BASALIS MAGNOCELLULARIS (NBM). S.A. Welner*, A.P. Sen, Z.C. Koty and J. Rochford. Douglas Hospital Research Center, Department of Psychiatry, McGill University, Montreal, Quebec, Canada, H4H 1R3.

Rats with lesions of the NBM provide useful models with which to test the effects of treatments that can potentially ameliorate a lesion-induced behavioral deficit. As such, it is important to first characterize the deficits which ensue from such lesions. In the present experiments we assessed the effects of quisqualic acid NBM lesions in a LI paradigm. The LI phenomenon has been suggested to be an animal model of selective attention, insofar as it assesses the ability to ignore irrelevant stimuli.

Half of 38 male Sprague-Dawley rats were lesioned with 0.12M quisqualic acid bilaterally in the NBM; the remaining half were left unoperated. Choline acetyltransferase activity in the cortex was reduced 40% by these lesions, measured post-test. Following 7 days of recovery, animals were pre-trained to bar press for saccharin solution reinforcement. Subsequently, rats in each condition were preexposed to either 40 (PE) or 0 (NPE) presentations of a tone conditioned stimulus. Over the next 2 days all animals received two tone-shock (0.6 mA, 0.5 sec) pairings, and the acquisition of conditioned suppression to the tone was measured. LI was demonstrated by the finding that non-lesioned PE animals took longer to acquire the conditioned suppression response than nonlesioned NPE animals. Both lesioned groups took longer to acquire the conditioned suppression response than did the nonlesioned groups, indicating that lesioning the NBM provoked a deficit in associative learning. More importantly, there were no significant differences in the rates at which the PE and NPE lesioned groups acquired the response. This latter result shows that lesioning the NBM with quisqualic acid abolishes the LI effect, suggesting that these lesions produce deficits in selective attention (Funded by MRCC and FRSQ).

SPATIAL WORKING MEMORY AT LONG RETENTION INTERVALS: DEPENDENCE ON MAINTAINED CHOLINERGIC ACTIVATION IN SEPTO-HIPPOCAMPAL OR NBM-CORTICAL PATHWAYS?

T.P. Durkin*. Lab. Neurosciences Comportementales et Cognitives, CNRS URA n° 339, Univ. Bordeaux I, Av. des Facultés, 33405 Talence, France.

Studies of dynamics of cholinergic activity in the septo-hippocampal (S-H) and NBM-cortical (N-C) pathways at various stages during repeated testing of mice with selective memory protocols (DURKIN and TOUMANÉ, Behav. Brain Res. 1992, 50: 43-52) showed that the durations of cholinergic activation in each pathway varied as a function of the type of memory tested and the level of task mastery. Since 1) the hippocampus may act as a temporary memory buffer and 2) working memory items are not thought to be consolidated, we postulated that the duration of activation in the S-H pathway may govern the maintenance of the working memory trace over the retention interval. C57 Bl/6 mice were extensively trained (1 trial/day, 25 days) on a DNMTS task to attain high levels of retention (>80% correct) using either 5min (Gp 1) or 60 min (Gp 2) retention intervals. At various times (30sec-70min) following initial acquisition cholinergic activity in the hippocampus and frontal cortex was quantified using high-affinity choline uptake. Whereas cholinergic activation was observed in both pathways at 30sec post-acquisition and throughout the 5min retention interval in Gp 1, the situation in Gp 2 is different, S-H activation being maintained only for 15 min, while N-C activation is maintained for the totality of the 1hr retention interval. The N-C pathway, in addition to its role in reference memory processes may, thus, also subsume a consolidation-like role in working memory situations requiring retention intervals of longer than 15 min. This "backup" function would thus liberate the S-H complex from its active role in temporary trace maintenance in these cases.

506.7

CHOLINERGIC INVOLVEMENT IN RETENTION OF SERIAL-PATTERN STRUCTURE IN RATS. M.O. Wollan* and S.B. Fountain. Department of Psychology, Kent State University, Kent, OH 44242.

Rats are sensitive to the rule-based formal structure of patterned sequences of responses (i.e., of "serial patterns"). For example, during acquisition rats make more errors at places where the rules change, namely, on the first elements of chunks, than on within-chunk elements. Atropine is a muscarinic cholinergic antagonist which impairs retention performance on a variety of cognitive tasks. We examined the effects of atropine on retention of serial patterns. Rats were trained in an octagonal operant chamber equipped with a lever on each wall. They learned to press the levers in a particular order (the serial pattern) for brain-stimulation reward (BSR) in a discrete-trial procedure with correction to a criterion of 10 percent or fewer errors on each trial. Two groups learned a pattern composed of eight 3-element chunks:

123 234 345 456 567 678 781 812

where the numbers represent positions of levers in the chamber, spaces indicate 3-s pauses (Phrased group) or 1-s pauses (Unphrased group), and other ITIs were 1 s. After criterion was reached, rats received i.p. saline injections alternating with 50, 25, and 100 mg/kg injections of either atropine sulfate or atropine methyl nitrate. Atropine sulfate caused significant impairments in retention performance at the first elements of chunks for both phrased and unphrased patterns. Atropine methyl nitrate caused no significant changes in performance. The results support the idea that intact central cholinergic systems are required for proper performance at places in sequences where pattern structure changes.

PHARMACOLOGICAL EVIDENCE FOR LONG-TERM GRADUAL CHANGES IN THE INVOLVEMENT OF CHOLINERGIC MECHANISMS IN RETRIEVAL. S. Multon, J. Micheau* and R. Jaffard. Lab Neurosciences Comportementales et Cognitives URA CNRS 339 Av. des Facultés 33405 Talence cedex France.

Several studies have provided evidence for gradual and long-lasting changes in the neuronal substrates that subserve the retrieval of information. Among these studies, results from pharmacological investigations have suggested that synaptic efficiency of cholinergic neurones was altered as a function of time after learning and hence of the "age" of memory (Deutsch, 1971). The present study was aimed at determining the influence of individual differences in initial learning ability on subsequent sensitivity of short-term vs long-term retention performance to the antimuscarinic scopolamine. Mice were trained (one daily session for 12 days) in an appetitively reinforced conditional discrimination (if...then) task in a T-maze. Retention performance was assessed at either 1, 15 or 30 days after acquisition. For each training-to-test interval a different set of animals was tested under each of four drug treatments (0.1, 0.25 mg/kg scopolamine, 0.25 mg/kg methyl-scopolamine and saline,sc) administered 30 min before each testing session. Following training, the animals were divided into 2 groups on the basis of their acquisition performance and referred as "good learners" and "poor learners". Results show that (i) under saline treatment, retention performance decreased as a function of time in good learners whereas it increased in slow learners (ii) whatever the retention interval, scopolamine (0.25 mg/kg) dramatically impaired retention performance in good learners whereas at 30 days post-training the treatment induced a slight improvement in poor learners (interaction group x scopolamine 0.25: $p < 0.001$). These results might be accounted for (i) by an imbalance between the use of a "cholinergic-dependent" (if...then) and a "cholinergic independent" (go-nogo) strategy at the time of initial acquisition; (ii) as time passes, there would be a general weakening of the bringing into play of cholinergic mechanisms at the time of retrieval; (iii) this would facilitate performance of poor learners by upsetting the imbalance to the "cholinergic-independent" go-nogo strategy that they would preferentially use, while disrupting performance of good-learners that are hypothesized to solve the task using the "cholinergic-dependent" alternative strategy.

MK-801 IMPAIRMENTS OF PATTERN TRACKING UNDER TRANSFER FROM HIGHLY STRUCTURED TO LESS STRUCTURED SERIAL PATTERNS IN RATS. J.D. Rowan*, P.S. Fowler, and S.B. Fountain. Department of Psychology, Kent State University, Kent, OH 44242.

The NMDA antagonist, MK-801, impairs some aspects of serial-pattern learning in rats. The effects of MK-801 exposure on serial-pattern learning in a transfer task were examined. Rats were trained to anticipate the correct sequence of leverpresses in an array of levers mounted on the walls of an octagonally-shaped operant chamber. The training pattern used in the first phase of the experiment was highly structured

123 234 345 456 567 678 781

where digits represent the positions of levers in the chamber, spaces indicate 3-s pauses, and other ITIs were 1 s. After rats learned the pattern, they were transferred to one of two new patterns that contained all elements of the first pattern and three additional elements. For the Perfect group, the added elements (812) were consistent with the structure of the training pattern. For the Violation group, the last of the added elements (818) violated the structure of the pattern learned in training. At transfer, rats were exposed to 0.0625 mg/kg MK-801 by i.p. injection 30 minutes prior to testing. Rats in the violation group that were injected with MK-801, unlike comparably exposed rats in the perfect group, demonstrated impaired performance throughout the entire pattern when compared to saline controls. These results support the view that MK-801 impairs the integration of new information that is not consistent with previously-learned pattern structure. However, MK-801 may have little effect on acquisition of responses consistent with previously-learned lower-order rules.

THE ROLE OF THE SEPTOHIPPOCAMPAL CHOLINERGIC PROJECTION IN CONTEXTUAL LEARNING AND SHORT-TERM MEMORY PROCESSES. G.M. McAlonan, G.R. Dawson, L.O. Wilkinson, L.S. Wilkinson, T.W. Robbins, B.J. Everitt. (SPON: European Neuroscience Association). Depts Anatomy and Expt Psychology, University of Cambridge, U.K. & Merck Sharp and Dohme, Neuroscience Research Centre, Harlow, Essex, U.K.

These experiments investigated the effects of lesions of the septohippocampal cholinergic projection on learning and memory. AMPA (0.015M) infused at two sites in the medial septum/diagonal band (MS/BD) markedly destroyed cholinergic neurons, while sparing completely the lateral septal nuclei. There was a concomitant 65% reduction of ChAT activity in the hippocampus, while acetylcholine release in the hippocampus measured by *in vivo* dialysis was negligible. These MS/vDB lesions resulted in a significant, delay-dependent deficit in a spatial, delayed non-matching to sample test that was ameliorated following systemic physostigmine treatment. Hippocampal dysfunction following cholinergic depletion was further investigated using the water maze and an aversive CS/contextual learning paradigm. Previous work has shown that lesions of the hippocampus itself disrupt both spatial navigation and contextual learning, while sparing conditioning to an aversive CS. However, AMPA lesions of the MS/vDB resulted in only a mild disruptive effect in the final stages of acquisition of the water maze, but significantly enhanced contextual conditioning at the expense of conditioning to a weak aversive CS.

Cholinergic deafferentation of the hippocampus may thus allow a competitive advantage of context-mediated responses over CS-mediated strategies. However, the conditional retrieval of information in a short-term spatial memory task is significantly impaired by such cholinergic loss.

506.9

ANTERIOR, BUT NOT POSTERIOR, CINGULATE CORTEX LESIONS FACILITATE ACQUISITION OF A CONDITIONAL VISUAL DISCRIMINATION TASK. T.J. Bussey*, J.L. Muir, B.J. Everitt+ and T.W. Robbins. Departments of Experimental Psychology and Anatomy+, University of Cambridge, Cambridge CB2 3EB, U.K.

It has been suggested that anterior and posterior cingulate cortices are involved in non-spatial and spatial forms of learning and memory. For example, it has been proposed that anterior cingulate activity predominates during the early stages of learning, while the posterior cingulate predominates in later stages.

The present study examined the effects of excitotoxic lesions of either anterior or posterior cingulate cortex on the acquisition and performance of a conditional visual discrimination task. Rats were trained in a Skinner box to respond by lever pressing to fast and slow flashing lights. The animals were required to learn a rule of the type 'if fast flash, go left; if slow flash, go right'.

Paradoxically, anterior cingulate lesions facilitated acquisition of the task relative to posterior cingulate lesioned animals or sham controls. Detailed analysis revealed that this facilitation occurred predominantly as a result of enhanced learning over trials in which the fast flashing stimulus was presented. The data will be discussed with respect to performance of these animals on the task following various manipulations of the basic paradigm, including interpolation of delays, variation of inter-trial intervals and modification of discriminanda.

506.11

IMPAIRMENT OF REACQUISITION AND PERFORMANCE OF DELAYED NONMATCHING-TO-SAMPLE FOLLOWING LESIONS TO THE MEDIAL SEPTUM AND DIAGONAL BAND IN RATS. T.J. Komecook, T.E. Kippin, I.P.J. Pinel and E.R. Wood*. Dept. Psych., Univ. British Columbia, Vancouver, BC, Canada, V6T 1Z4.

Damage to the hippocampal complex and adjacent cortical tissue impairs object recognition-memory in rodents, monkeys, and humans. The neuronal cell bodies of the medial septal area (MSA) and vertical limb of the diagonal band of Broca (VDBB) are the primary source of cholinergic innervation of these medial temporal-lobe structures. We examined the effects of combined bilateral electrolytic lesions to the MSA and VDBB on object-recognition memory in rats using a nonrecurring-items delayed nonmatching-to-sample (DNMS) task that is similar to the task that is commonly used to study amnesia in monkeys.

Male Long-Evans food-deprived rats were trained to criterion on the DNMS task at a 4-sec delay, and then they were tested at retention delays of 4, 15, 30, 60, and 120 sec. Following surgery they were retrained and then tested again. Rats that received MSA-VDBB lesions (n=4) performed more poorly after surgery than did the sham-lesion controls (n=4). They acquired the task more slowly, and once they reached criterion, they performed more poorly at all of the delays. These results suggest that combined MSA-VDBB lesions produce retrograde amnesia for the reference memories involved in performing the DNMS task and anterograde amnesia for the retention of specific objects. However, it is also possible that either or both of these impairments reflect lesion-produced attentional deficits, motivational deficits, or changes in the strategy that was being used to solve the task. Lesions of the MSA and VDBB have previously been found to result in decreases in cholinergic activity at their target sites; such decreases at hippocampal and entorhinal target sites might underlie the deficits observed in this experiment.

506.13

BEHAVIORAL ALTERATIONS CAUSED BY NORADRENERGIC AND CHOLINERGIC DEPLETIONS IN RAT HIPPOCAMPUS AT NEONATE. H.-M. Hwang, G.-H. Yeh, S.-C. Weng, and E.H.Y. Lee*. Department of Anatomy, Chang Gung Medical College and Instit. Biomed. Sci., Academia Sinica, Taiwan, R.O.C.

Acetylcholine (ACh) and norepinephrine (NE) in the mammalian brain have been demonstrated to play a role in the hippocampal processing of sensory information. To elucidate their involvement, locomotor activity and spatial learning were measured in four groups of Long-Evans hooded rats: ACh-depleted, NE-depleted, ACh/NE-depleted, and control. ACh depletion was done by electrolytic lesions (DC current: 3 mA for 10 sec) of the medial septum 5-8 days after birth. NE was depleted by subcutaneous injection of DSP-4 (50 or 100 mg/Kg) at birth. Both depletions were confirmed at ages of 4-6 months. ACh/NE-depleted rats showed an increase in locomotor activity while ACh-depleted and NE-depleted rats did not show any activity change. In a series of spatial tasks with Morris's parameters, memory impairment was found only in rats depleted of both ACh and NE in the hippocampus. These results suggest that ACh and NE function integratively to modulate locomotion and spatial learning in rats.

506.10

DISSOCIABLE BEHAVIOURAL EFFECTS FOLLOWING EXCITOTOXIC LESIONS OF ROSTRAL AND CAUDAL ELEMENTS OF THE BASAL FOREBRAIN CHOLINERGIC SYSTEM. J.L. Muir*, B.J. Everitt+ and T.W. Robbins. Departments of Experimental Psychology and Anatomy+, University of Cambridge, Cambridge CB2 3EB, U.K.

The basal forebrain (BF) cholinergic system, comprising the nucleus basalis of Meynert (nbM), the medial septum and the diagonal band of Broca has been implicated in a variety of forms of learning and memory. The cortical targets of each of these components of the BF are dissociable and this anatomical dissociation may have important implications regarding the functions of these elements of the BF cholinergic system. The present study compared the effect of excitotoxic lesions of the nbM with those of the vertical limb of the diagonal band (VDB) on tasks assessing visual attentional function or conditional visual discrimination learning. The nbM lesions, which produced significant reductions in choline acetyltransferase (ChAT) activity in neocortex, had no effect on conditional learning, but profoundly affected attentional function. This impairment in task accuracy was reversed by physostigmine or nicotine, but not by the 5-HT₃ receptor antagonist, ondansetron. In contrast, lesions of the VDB, which cholinergically denervated the cingulate cortex, had no effect on attentional function but affected conditional visual discrimination.

Thus the consequences of lesions of BF cholinergic neurons depend initially on the functions subserved by the cortical area(s) to which they project. The VDB-cingulate cortex projections may subserve the learning and memory functions previously attributed to the nbM. The nbM-neocortical projection appears instead to be critical for visual attentional function.

506.12

GENDER DIFFERENCES IN THE EFFECT OF NEONATAL BASAL FOREBRAIN LESIONS ON SPATIAL NAVIGATION. J. Berger-Sweeney, K. Meadows, J. Mills and C.F. Hohmann*. Dept. of Biological Sciences Wellesley College, Wellesley, MA and The Kennedy Krieger Research Institute, Baltimore, MD.

We have previously shown that lesions of the basal forebrain [nBM] projections to cortex in neonatal mice result in persistent changes in cortical connectivity and cytoarchitecture. These persistent cortical abnormalities are correlated with dramatic behavioral deficits on a spatial navigation task (using the Morris water maze) in the adult mice. Since gender differences in performance have been observed in spatial navigation, we are interested in determining whether gender differences are present in this nBM lesion model.

A total of 22 BALB/cByJ mice were used in this experiment. We have analyzed data from 12 of these mice at this point. Mice received lesions to the nBM 12-24 hours after birth; litter mates served as controls. Spatial navigation testing began at 8 weeks of age and continued for 2 weeks. Following behavioral testing, mice were processed for Nissl and AChE histology to evaluate cortical morphology and lesion efficacy.

In the spatial navigation task, mean latencies to find the submerged platform decreased steadily during the first 3 days in the male controls to asymptotic performance by day 4. Female controls took longer to find the submerged platform on virtually all 9 days and their asymptotic performances were never as low as that of the control males. In the nBM neonatal lesion groups, both females and males performed worse (had longer latencies) than the control groups. In contrast to controls, the lesioned females performed better than the lesioned males on all 9 days of behavioral testing. Histological analysis confirmed lesion sites and cortical morphological abnormalities in the nBM groups. These data suggest that neonatal nBM lesions produce differential patterns of spatial learning in females and males. Cortically-projecting basal forebrain neurons could, therefore, play a critical role in the development of gender differences in spatial memory in adult mice.

EFFECTS OF SELECTIVE MODULATION OF SEPTAL NORADRENERGIC AFFERENTS ON ANXIETY AND SPATIAL WORKING MEMORY PARADIGMS IN MICE. M. Belotti, D. Galey*. Lab. de Neurosciences Comportementales et Cognitives. CNRS URA 339. Avenue des Facultés 33405 Talence Cedex. FRANCE.

Substantial data now provide evidence that the septal area is involved in the regulation of anxiety-related behaviors and memory processes. Using C57Bl/6 mice, we have attempted to elucidate the role of septal noradrenergic afferents in these two processes.

The anxiety level was evaluated by comparison between exploratory activities measured in an elevated plus-maze and in a four-hole board. The spatial working memory investigations, achieved in a radial-maze, were based on the acquisition of the delayed non-matching to place rule.

In these conditions, selective blockade of noradrenergic activation by bilateral intraseptal infusion of an α_1 antagonist, BE 2254 (500 ng/ 0.2 μ l) did not induce changes in anxiety level. Similar lack of modification was observed on working memory performance evaluated in two different conditions. However, when the treatment was applied before the habituation session, when animals were initially exposed to the context, they were impaired in subsequent acquisition of the rule. An inverse effect was obtained by intraseptal infusion of idazoxan (0.5ng/0.2 μ l).

These data suggest that septal noradrenergic activation is essential at initial stages of learning, when animals process new environmental features, according to the Nadel and O'Keefe contextual cognitive map theory. This interpretation is presently under investigation.

NITRIC OXIDE IN BASAL FOREBRAIN NEURAL DEGENERATION. CA Harrington*, S Mobley and GL Wenk. ARL Div. of Neural Systems, Memory and Aging, University of Arizona, Tucson, AZ, 85724.

Degeneration of the basal forebrain (BF) cholinergic system may underlie the cognitive deficits seen in Alzheimer's disease. Animal models of this disease often employ Ibotenate (IBO) and Quisqualate (QUIS) to lesion the BF. While both neurotoxins destroy BF cells, only IBO impairs memory. One explanation for this differential effect on behavior may be that IBO destroys a neuronal population within the BF that QUIS does not. Recently it was shown that NADPH-diaphorase positive neurons in the BF are destroyed by QUIS, but not by IBO. NADPH-diaphorase is found in neurons that contain the nitric oxide (NO) generating enzyme, NO synthase. Therefore the memory deficit produced by IBO may be due to the differential sparing of NO generating neurons. Cell culture studies have shown that NMDA agonists, such as IBO, produce a NO-mediated neurotoxicity via the generation of high levels of cGMP. Therefore IBO, by generating NO, may be destroying a neuronal population that QUIS does not. We investigated whether excessive NO production is responsible for the memory impairment seen following IBO lesions. Rats were given injections of either IBO, IBO coinjected with the guanylyl cyclase inhibitor methylene blue, methylene blue alone, QUIS, QUIS coinjected with the NO generating compound nitroprusside, or nitroprusside alone. Injections of IBO, but not QUIS, elevated cGMP in the BF. A second group of rats with the same lesions were tested in a food motivated, continuous alternation task on a T-maze. Only the IBO, alone or coinjected with methylene blue, impaired performance on this task. Taken together these results suggest that the generation of NO by injection of IBO into the BF does not result in the loss of a neuronal population that is critical to working memory. Supported by NSF BNS 89-14941.

ALTERATION IN DENDRITIC MORPHOLOGY OF NEOCORTICAL NEURONS AFTER BASAL FOREBRAIN LESIONS IN ADULT RATS. CL Wellman* and DB Sengelau. Program in Neural Science and Department of Psychology, Indiana University, Bloomington, IN 47405.

The nucleus basalis magnocellularis (NBM) is the major cholinergic projection to neocortex in the rat and appears to play a role in the modulation of cortical neuron activity. We have demonstrated that bilateral NBM lesions produce deficits in radial arm maze performance, reductions in laminar thickness, and decreases in average neuronal soma area in lamina II-III of frontoparietal cortex. In the present study, to test the hypothesis that decreased dendritic arborization could also contribute to reductions in laminar thickness, we have assessed dendritic morphology of neocortical neurons in adult rats with unilateral lesions of the NBM. Five rats received unilateral ibotenic acid lesions of either the left or right NBM, as well as sham lesions on the contralateral side. Three months after surgery, the rats were killed and their brains removed and stained using a Golgi-Cox procedure. Pyramidal neurons in lamina II-III of frontal cortex were drawn and morphology of basilar arbors quantified in three dimensions (Eutectic NTS), with the experimenter blind to condition. While average length of individual branches was unaffected by lesion, total dendritic length of neurons ipsilateral to the lesion was over 25% less than that of neurons from the sham-lesioned side ($p < .05$). This relative reduction in total dendritic length was due to significantly less branching on the lesioned side (over 20%; $p < .01$). Therefore, decreases in both neuronal soma size and dendritic branching contribute to reductions in thickness of lamina II-III after NBM lesion. Thus, the behavioral deficits seen after lesion of the NBM may be related to regressive changes in the morphology of lamina II-III neurons in frontoparietal cortex.

LEARNING AND MEMORY: PHARMACOLOGY—OTHER II

507.1

NEFIRACETAM (DM-9384): AN EFFECTIVE COGNITION-ENHANCING AGENT IN NM CLASSICAL CONDITIONING IN OLDER RABBITS. D.S. Woodruff-Pak*, L.P. Conway, & Y-T. Li. Department of Psychology, Temple University, Philadelphia, PA 19122.

Previously, we reported that rabbits administered 10 mg/kg Nefiracetam (DM-9384) attained the highest conditioning rates that we had ever observed in older animals. Here, we report additional results with this nootropic compound. Nefiracetam was evaluated in 40 older rabbits in a 750 msec delay paradigm of classical conditioning of the nictitating membrane (NM)/eyeblink response. Rabbits (mean age = 30.3 months) were assigned in groups of 8 to one of five conditions: Paired tone conditioned stimulus (CS)-corneal airpuff unconditioned stimulus (US) presentations and 5 10, or 15 mg/kg Nefiracetam or sterile saline vehicle (Conditions 1-4, respectively); explicitly unpaired CS and US presentations and sterile saline vehicle (Condition 5). Rabbits in Conditions 1-4 received 15 daily sessions of 90 paired trials. In Condition 5 they received 15 daily sessions of 90 unpaired CS and US presentations. All dependent measures (percentage conditioned responses (CRs), trials to criterion, CR amplitude, response latency) indicated significantly better conditioning in Nefiracetam-treated rabbits in the paired CS-US condition. Whereas Nefiracetam did not elevate motor responding, it facilitated acquisition of NM/eyeblink classical conditioning in older rabbits. Eyeblink conditioning is performed poorly by older humans and is seriously impaired in Alzheimer's disease. These preclinical data in an animal model with clear parallels in humans suggest that Nefiracetam may prove effective as a cognition enhancer in clinical trials. BEHAVIORAL PROFILE OF (R) and (S) RS-56812, NOVEL 5-HT₃ RECEPTOR ANTAGONISTS WITH COGNITION-ENHANCING PROPERTIES. D. J. Fontana*, C. A. Henderson, S. Daniels, J. Nunes, E. H. F. Wong, R. L. Whiting, and R. M. Eglon. Institute of Pharmacology, Syntex Discovery Research, Palo Alto, CA 94304, U.S.A.

Using several tests of learning and memory, we studied the behavioral action of the (R) and (S) isomers of RS-56812 (1-azabicyclo[2.2.2]octan-3-yl)aminocarbonyl-1-methylindole hydrochloride, potent 5-HT₃ receptor antagonists, in rodents. In a spatial memory task in the Morris Water Maze, both isomers (0.1-10 µg/kg, i.p.) partially reversed the atropine deficit in young adult rats. In addition, cognition-impaired aged rats treated with (S) RS-56812 (0.1-100 µg/kg, i.p.) performed better than impaired rats treated with vehicle. In behavioral tests of anxiety; such as the Conditioned Suppression of Drinking conflict test (CSD) in rats, neither isomer affected punished or unpunished drinking (3-1000 µg/kg, i.p.). In contrast, in the light:dark box, (S) RS-56812 reduced the behavioral suppression associated with aversion to the brightly illuminated side of the box (0.3 ng-30 mg/kg, i.p.). The (R) isomer did not affect activity in the light:dark box. (R) and (S) RS-56812 did not affect locomotor activity (0.01-1000 µg/kg, i.p.). Furthermore, they did not affect cocaine-induced or scopolamine-induced hyperactivity (0.1-1000 µg/kg, i.p.) and did not affect motor coordination in a rota-rod test (0.01 µg/kg-10 mg/kg, i.p.). In addition, neither isomer produced any changes in gross behavior in the Irwin Profile test (10 ng/kg-1 mg/kg, p.o.). Our results suggest that (R) and (S) RS-56812 are potent pro-cognitive agents which lack deleterious effects on the central nervous system. Thus, RS-56812 may be a valuable therapeutic agent for disorders associated with cognitive dysfunction (also see abstract by Terry et al., this meeting).

507.2

EFFECTS OF T-588, A NOVEL COGNITIVE ENHANCER, ON VARIOUS AMNESIA MODELS IN RODENTS.

S. Ono*, T. Yamafuji, H. Chaki, M. Maekawa, K. Kitamura, K. Hirata, Y. Nakada, H. Hayakawa, T. Hiraiwa and H. Narita, Research Laboratory, Toyama Chemical Co. Ltd., Toyama 930, Japan.

We investigated the cognitive enhancing effect of T-588 ((-)-α-[[2-(Diethylamino) ethoxy] methyl] benzo [b] thiophen-5-methanol hydrochloride) on impairment of passive avoidance tasks induced by CO₂ and scopolamine in mice, on scopolamine-induced amnesia for the 8-arm radial maze task in rats and on acquisition of the active avoidance response of cerebral embolized rats in comparison with those of tacrine (THA). The impairment of passive avoidance tasks was more effectively ameliorated by T-588 (M.E.D.: 0.1-0.3 mg/kg, p.o.) than tacrine (M.E.D.: 1 mg/kg, p.o.). T-588 (3 and 10 mg/kg, p.o.) significantly improved the scopolamine-induced disruption of spatial cognition. Tacrine (3 mg/kg, p.o.) also improved. The cerebral embolization, produced by injecting 1000 microspheres into the internal carotid artery, caused marked impairment of the acquisition of the active avoidance response. In the embolized rats, significant decreases in ACh, DA, NA and 5-HT were observed in the left side of the brain. T-588 (3 and 10 mg/kg, p.o.) significantly improved the impairment of the acquisition of the active avoidance response. But, tacrine (0.3-3 mg/kg, p.o.) had no effect. After oral administration of T-588 (10 mg/kg) to rat, the serum and brain levels of T-588 at 30 min were 87 ng/ml and 1050 ng/g, respectively. The level in brain was 12 times higher than that in serum. These results suggest the usefulness of T-588 in clinical treatment of cerebrovascular disorders and Alzheimer's disease.

507.4

SPATIAL LEARNING PERFORMANCE IN CD1 MICE: EFFECTS OF CGP 36742. V. Libri, R. Carletti and N.G. Bowerly*, Dept. Pharmacology, School of Pharmacy, 29/39 Brunswick Square, London WC1N 1AX.

CGP 36742 (3-aminopropyl-n-butyl phosphinic acid) is the first selective orally active GABA_B antagonist which improves cognitive functions in experimental animals. Recent finding have shown that systemic injection of (-)baclofen decreases cGMP levels in several areas of the rat brain. This was antagonized by CGP 36742. In addition cGMP was increased by CGP 36742 and this was blocked by competitive inhibitors of nitric oxide synthase, suggesting a possible involvement of nitric oxide in GABA_B-mediated effects such as cognition. In the present study CGP 36742 was examined on the performance of CD1 mice in an 8-arm radial maze. Animals (8 per group, 25-30 g) were treated daily for 10 consecutive days with CGP 36742 (1, 10 or 100 mg/kg), (-)baclofen (2 or 4 mg/kg), scopolamine (1 mg/kg) or saline (10 ml/kg), given alone or in combination, and tested on the maze 15 min after the injection (i.p.). Differences between groups were determined by a one-way analysis of variance (ANOVA). In comparison with control animals injected with saline, CGP 36742 (10 and 100 mg/kg but not 1 mg/kg) significantly ($p < 0.05$) enhanced the radial maze acquisition (occurrence of first error) whereas (-)baclofen (2 and 4 mg/kg) produced a significant impairment of performance. This depressant effect was completely reversed by pre-treatment (15 min before) with CGP 36742. On the contrary, CGP 36742 did not affect scopolamine-induced amnesia. In order to verify whether the amnesic action of (-)baclofen was related to possible muscle relaxation, animals treated with 2 and 4 mg/kg (-)baclofen were submitted to a rota-rod test (accelerating from 8 to 16 rpm over 360 s period) 15 and 30 min after injection. At these concentrations (-)baclofen failed to affect rota-rod performance. The results are consistent with the suggestion that GABA_B receptor is involved in the control of learning and memory processes. Supported by Ciba Baseli.

SCOPOLAMINE AS A PHARMACOLOGICAL TOOL TO STUDY MEMORY PROCESSES; APPLICATION OF A COGNITION ENHANCER. T. Duka*, B. Redemann, T. Mager and B. Voet. Department of CNS Human Pharmacology, Schering AG, Sellerstrasse 31, D-1000 Berlin 65, Germany

Given the current level of concern over cognitive dysfunction in old age and in certain pathological states, amnesic substances may be useful in characterising human models of cognitive disturbances or in allowing to draw parallels between neurotransmitter changes and changes in cognitive functions. We applied scopolamine as a pharmacological tool to investigate its effects on various stages of mental functioning. Tests used concern hierarchically arranged cognitive performance and included tests of vigilance, continuous attention, cognition and memory. In a double blind placebo controlled study 36 healthy volunteers were assigned to receive either scopolamine 0.5 mg or placebo subcutaneously. Shortly before and 60 min after scopolamine treatment the psychometric battery has been applied. Scopolamine impaired performance in tasks measuring vigilance and continuous attention; number of correct responses to a brief stimulus were decreased and the time required for a correct response was increased. Scopolamine on the other hand in a memory test in which immediate and delayed recall of a series of pictures was tested, impaired only the immediate recall. In a further study with the same design the effects of a possible cognition enhancer, ZK 93426 a β -carboline benzodiazepine receptor antagonist, administered intravenously in the dose of 0.04 mg/kg, have been investigated in combination with scopolamine. ZK 93426 has partially antagonised the effects of scopolamine on the attentional and vigilance tasks but not on the immediate recall in the memory test. It is assumed that this effect of scopolamine does not involve mechanisms which can be influenced by a benzodiazepine receptor antagonist.

507.7

PARADOXICAL SLEEP PREDICTS MEMORY DEFICITS A YEAR LATER, WHICH ARE REVERSED BY GLUCOSE, IN RATS PRENATALLY EXPOSED TO ALCOHOL. W.S. Stone*, G. Arankowsky-Sandoval, H.J. Altman and P.E. Gold. Dept. Psychology, U. of Virginia, Charlottesville, VA 22903, and Inst. of Gerontology, Wayne State U., Detroit, MI 48202.

We previously demonstrated parallel deficits in paradoxical sleep and memory in young adult rats (6 months old). These results suggest the possibility that measures of paradoxical sleep could predict memory deficits later in life, and glucose, which we previously found attenuates memory deficits in old rodents and humans, could reduce the deficits.

To address this issue, sleep measures (3 hr records via cortical electrodes) were obtained from adult female rats (6 months old) either prenatally exposed to alcohol (their mothers received a liquid diet which included 35% ethanol-derived calories from gestation days 8-19; N=5), or prenatally exposed to an (pair-fed) isocaloric diet (N=6). One year later, rats from both groups were assessed for spontaneous alternation behavior in a Y-maze (8 min), 30 min after glucose (100 mg/kg) or saline administration (IP, using a counterbalanced, crossover design).

At 18 months of age, alcohol-exposed rats showed significantly lower alternation scores than did pair-fed controls. Glucose reversed this deficit. Paradoxical sleep levels at 6 mo. were significantly correlated with spontaneous alternation levels one year later in alcohol-exposed but not pair-fed rats. These findings provide evidence that sleep measures can predict cognitive deficits over large portions of the lifespan, and glucose can attenuate memory deficits in a variety of impaired populations. Supported by NSF BNS-9012239, ONR N0001489-J-1216, and NIA AG 07648. We gratefully acknowledge the Fetal Alcohol Res. Ctr. at Wayne State U. for providing the alcohol-exposed rats.

THE EFFECT OF ETHYLESTRENOL ON ACQUISITION AND RETENTION. J.A. Varner, P.E. Yoder, and R.L. Isaacson*, Psychology Dept., Binghamton Univ., Binghamton, NY 13902.

Ethylestrenol, a synthetic steroid with testosterone and estrogen components, was administered to adult male Long-Evans rats to investigate its role in acquisition and retention. Animals were injected i.p. daily with either 100 μ g of ethylestrenol dissolved in 10% ethanol further diluted with double-distilled water or with the vehicle alone (volume of 0.1 cc). Injections began one week prior to testing and continued throughout the study. A modified hole board task was used. The animals were required to find a food reward which was placed in a given hole. Acquisition of the task was measured as the time required to reach the food hole over each of five days, eight trials per day. Following a ten day rest period a one day, eight trials (only), retention test was given. Then, the rats were trained with a new food location hole for the two subsequent days. There were no differences between the groups in performance during either the original five day period or the final two day new hole period. During the retention test after the ten day interval indicated above, however, a significantly reduced time to reach the food reward was found for the ethylestrenol treated rats. This suggests that retention was enhanced by the administration of ethylestrenol.

COMPARABLE MODULATION OF RECENTLY ACQUIRED MEMORIES BY GLUCOSE AND FRUCTOSE.

W.A. Rodriguez*, A. Horne, A.N. Mondragon, and D. Phelps. Dept. Behav. Sci., New Mexico Highlands Univ., Las Vegas NM 87110.

A passive avoidance to active avoidance negative transfer paradigm was used to investigate in rats the effects of glucose and fructose on recently acquired memories. Immediate post-passive avoidance conditioning injections of glucose, fructose, or saline were followed 24 h later by active avoidance conditioning. Equimolar 3.2 mg/kg SC doses of both glucose and fructose had no significant effect on acquisition of the reversal task, whereas 10, 32, 100, and 2000 mg/kg SC doses of both sugars significantly impaired subsequent performance and 320 mg/kg SC doses of both sugars significantly enhanced subsequent performance. The cubic trends for both dose-response functions were statistically significant and did not differ from each other. This is the first demonstration that glucose and fructose affect recently acquired memories in accord with similar cubic functions, and that both glucose and fructose can enhance and impair memory compared to saline treatment. The comparable cubic dose-response functions strongly suggest that the mechanisms of action for peripherally injected glucose and fructose are similar. In addition, because fructose does not readily pass the blood-brain barrier, our results suggest that these monosaccharides operate via a common peripheral pathway.

INHIBITORY AVOIDANCE DEFICITS RESULTING FROM INTRA-AMYGDALA PROPRANOLOL ARE NOT REVERSED BY GLUCOSE. R.C. Lennartz*, E.R. Mook, K.L. Hellems, and P.E. Gold. Department of Psychology, University of Virginia, Charlottesville, Virginia 22903.

Systemic glucose administration reverses neural and behavioral effects of drugs directed at several neurotransmitter systems. When injected directly into brain targets, intra-septal and intra-amygdala injections of glucose attenuate deficits for inhibitory avoidance learning produced by morphine injections into the same site. However, in contrast to results obtained with systemic injections, direct septal or amygdala injections of glucose do not appear to reverse the effects on learning and memory of other drugs such as scopolamine or AP5. This study determined whether intra-amygdala injections of glucose reverse inhibitory avoidance deficits produced by intra-amygdala injections of the β -adrenergic antagonist, propranolol. When administered 10 min before inhibitory avoidance training (2 ma, 1 s), bilateral intra-amygdala injections (0.5 μ l) of propranolol (10, but not 1-5 μ g) impaired retention on tests 24 hr later. The propranolol-induced deficit was not seen in rats with placements near but outside of the amygdala. Footshock (flinch, jump) thresholds were not significantly altered by propranolol. Glucose co-injected with propranolol did not attenuate the deficit at any dose tested (1.5, 3, 6 μ g). Thus, in contrast to results obtained with intra-amygdala morphine, glucose does not attenuate inhibitory avoidance deficits produced by a noradrenergic antagonist. Such differences in interactions between glucose and neurotransmitter systems should help to define the actions by which glucose enhances memory. Supported by NIA (AG 07648), NIMH (5-T32-MH1811), and NSF (BNS-9012239).

NEUROSTEROIDS BLOCK ETHANOL-INDUCED AMNESIA. C.L. Melchior*, A. Glasky and R.F. Ritzmann. West Los Angeles Veterans Administration Medical Center, Los Angeles, CA 90073

The neurosteroids (NS) dehydroepiandrosterone (DHEA), its sulfate (DHEAS), pregnenolone (PE), its sulfate (PS), and pregnanolone (PA) have been shown to improve memory in avoidance tasks and in the win-shift test of working memory. The win-shift test consists of placing a mouse in a T-maze with a reward in both goal boxes. The mouse is allowed to choose one of the goal boxes. On the next trial, if the mouse remembers which box it entered on the previous trial, it will enter the other box (correct). By increasing the delay between trials the length of time a mouse can remember can be determined. The longest delay at which C57BL/6 mice can remember is 120 seconds. At this delay, control mice went to the correct side 80% of the time. Ethanol (0.5 g/kg, IP), 10 minutes prior to testing, reduced the correct responses to 65%, without altering the time to leave the start box or the time to traverse the maze. When 50 μ g/kg NS were given IP 20 minutes prior to ethanol, DHEA, DHEAS, PE, PS, and PA all blocked ethanol-induced amnesia. PA was found to block at doses from 15 mg/kg to 5 ng/kg; lower doses were devoid of activity. Doses of PA above 5 μ g/kg also increased the latency to leave the start box and time to traverse the maze. Epipregnanolone (5 β -pregnan-3 β -ol-20-one), which has been shown to antagonize some biochemical effects of PA and was devoid of any effect on ethanol-induced amnesia at doses of 50 μ g/kg to 1.0 mg/kg, when co-administered (50 μ g/kg) with 5 μ g/kg PA prevented PA from blocking the ethanol amnesia. However, it did not alter the effect of 50 μ g/kg PE. Thus, the NS appear to act in more than one way to block ethanol-induced amnesia.

ESTROGEN/PROGESTERONE TREATMENT REVERSES THE EFFECT OF SCOPOLAMINE ON T-MAZE PERFORMANCE. *A.I. Fader, D.L. Rawls, and G.P. Dohanich.** Department of Psychology and Neuroscience Program, Tulane University, New Orleans, LA 70118.

Scopolamine, a muscarinic receptor blocker, inhibits behaviors associated with mating in female rats including the dorsoflexive posture lordosis. Recently, we reported that the inhibition of lordosis by scopolamine was reversed by repeated administration of high doses of estrogen in combination with progesterone. The purpose of the present experiments was to determine if hormone treatment might attenuate the effects of scopolamine on other behaviors. Ovariectomized rats were trained to complete a reinforced T-maze alternation task. Then, females were treated at 72, 48, and 24 hours before T-maze testing with estradiol benzoate (25 µg, i.m.) or oil vehicle and at 4 hours before testing with progesterone (500 µg, i.m.) or oil vehicle. Fifteen minutes following administration of scopolamine hydrobromide (0.2 or 0.4 mg/kg, i.p.), females were given the opportunity to alternate between the arms of the T-maze on 10 consecutive trials. In the absence of hormone treatment, females failed to alternate between the arms successfully, performing at only chance levels. Administration of estrogen in combination with progesterone prevented this effect of scopolamine on T-maze performance. Estrogen also attenuated the inhibitory effect of scopolamine when administered without progesterone, although its effectiveness was reduced. Similar results were obtained in two series of experiments. Gonadal hormones can prevent the impairment of T-maze performance induced by scopolamine. NSF-BNS9021447

COMPARING THE EFFECTS OF COCAINE, LIDOCAINE AND COCAINE METHIODIDE ON ACQUISITION OF AN AUTOSHAPED LEVER-TOUCH RESPONSE. *R.R. Rule*, P.H. Janak, and J.L. Martinez, Jr.* Dept. of Psychology, Univ. of California, Berkeley, CA 94720.

The effects of daily peripheral (i.p.) post trial injections of cocaine, lidocaine and cocaine methiodide were investigated. Male Sprague-Dawley rats received 10 daily pairings of a retractable lever (conditioned stimulus; CS) and food delivery (unconditioned stimulus; UCS). If the subject touched the lever, then the lever retracted and food delivery occurred immediately; otherwise the lever was retracted and food was delivered at the termination of the 10 second CS interval. Cocaine at a dose of 7.5 mg/kg, but not at a dose of 5.55 mg/kg, impaired acquisition of the lever-touch response, as compared to the saline-treated control group. Because the injections were given after each conditioning session, we suggest that cocaine affects the neural processes involved in consolidation of memory. Lidocaine administered at doses (5.97 and 4.42 mg/kg) which were equimolar to those of cocaine, did not affect lever-touch responding, as compared to the saline-treated control subjects. Because lidocaine has similar anesthetic properties to cocaine, we suggest that the impairment of acquisition observed in cocaine-treated rats is not due to its anesthetic properties. Cocaine methiodide, a quaternary derivative of cocaine, which does not readily cross the blood-brain barrier does not effect acquisition when administered at a dose equimolar (9.82 mg/kg) to the effective dose of cocaine; however a higher dose (29.46 mg/kg) impairs acquisition. This may indicate that cocaine's effect on autoshaping are at least partially due to peripheral effects. (Supported by a Ford Predoctoral Fellowship and DA06192)

LEARNING DURING GENERAL ANESTHESIA: EVIDENCE FOR CLASSICAL CONDITIONING BUT NOT LATENT INHIBITION

*R. Panq, H. Turndorf and D. Quartermain **

Departments of Anesthesiology & Neurology, NYU Medical Center, 550 1st Ave. New York, N.Y.10016

Conditioned emotional response (CER) and latent inhibition (LI) were employed to test for the presence of memory formation during anesthesia in mice. In the CER, mice were given 3 CS-UCS presentations (ITI 5 min) while anesthetized with halothane. The CS was a 10 sec tone and the UCS 0.4mA shock delivered intramuscularly to the hind limbs via needle electrodes. Control groups received CS only, UCS only or CS followed by a 3 min delayed UCS. In the LI procedure, mice were exposed under halothane anesthesia to 3 sessions of 60 unreinforced tone presentations prior to being conditioned in the unanesthetized state. A control group was given 3 sessions of anesthesia without tone presentation. Strength of fear conditioning was assessed 24 hr later by measuring duration of suppression of drinking induced by the tone in a test session. Results showed that mice conditioned under anesthesia exhibited significantly more suppression than the 3 control groups. Mice preexposed to the tones during anesthesia showed no evidence of the weakened conditioning (LI) that was present in mice preexposed while awake. This suggests this form of learning cannot occur in unconscious subjects. The results were interpreted as evidence that implicit but not explicit memories can be formed under anesthesia.

NEUROSTEROIDS DECREASE HIPPOCAMPAL RECURRENT INHIBITION AND INDUCE UNIT SYNCHRONY TO THETA RHYTHM Young, W.G.*, Steffensen, S.C. and Henriksen, S.J., Scripps Research Institute, La Jolla, CA 92037

Several neurosteroids have been shown to have proconvulsant and memory enhancing properties and to be potent modulators of the GABA/benzodiazepine receptor-chloride ionophore complex. We evaluated the effects of the natural sulfate esters of the neurosteroids dehydroisoandrosterone (DHEAS) and pregnenolone (PREGS) as well as trilostane, an inhibitor of 3β-hydroxysteroid dehydrogenase, on EEG recordings, field responses and single-unit activity in the dentate gyrus and CA1 hippocampus of halothane-anesthetized rats. Microelectrophoretic application of DHEAS into CA1 had no effect on field EPSPs but increased population spikes (70%), whereas DHEAS increased dentate field EPSPs (50%) but population spikes were not significantly altered. Microelectrophoretic application of DHEAS abolished the early paired-pulse (PP) inhibition in both the dentate and CA1, whereas microelectrophoretic application of PREGS increased CA1 PP inhibition but had no effect on dentate PP responses. Intraperitoneal administration of DHEAS (2 mg/kg) markedly decreased dentate and CA1 PP inhibition similar to locally applied DHEAS. Application of the GABA_A antagonists picrotoxin or saclofen antagonized the effects of DHEAS on field potentials and PP responses in CA1, but not the dentate. Three days following intraperitoneal administration of trilostane (3-120 mg/kg), dentate PP inhibition was significantly reduced and CA1 PP inhibition was increased. In control animals under halothane anesthesia, the hippocampal EEG showed periodic episodes of theta rhythm. Neither DGCS, hilar cells, CA1 pyramidal cells nor alveus/oriens cells followed the theta rhythm with significant fidelity; however, all cell types synchronized to the theta rhythm following administration of trilostane. Microelectrophoretic DHEAS markedly increased the firing rate of dentate granule cells (DGCS, 200%) and synchronized their firing to the theta EEG. These results demonstrate that the increased hippocampal excitability produced by the neurosteroid DHEAS is mediated by GABA_A receptors and suggest that endogenously released neurosteroids may serve to entrain hippocampal neurons to the theta rhythm.

DAILY POSTSESSION COCAINE IMPAIRS DEVELOPMENT OF AN INSTRUMENTALLY-CONDITIONED LEVER-TOUCH RESPONSE IN RATS. *P.H. Janak* and J.L. Martinez, Jr.* Dept. of Psychology, University of California, Berkeley, CA 94720.

Previously, we found that postsession cocaine (5.55 mg/kg IP) impaired response development in an autoshaped lever-touch task that contains both classical and instrumental contingencies (Janak et al., 1992). Therefore, in separate studies, we examined the effects of daily postsession cocaine on the development of conditioned responding in tasks with either purely instrumental or purely classical contingencies. In each study male Sprague Dawley rats received 10 daily presentations of a retractable lever. In the instrumentally-conditioned task, if the subjects contacted the lever, then the lever immediately withdrew and food was delivered; however, if the subjects failed to contact the lever within 10-sec, the lever was retracted and no food was delivered. In contrast, in the classically-conditioned task, contact with the lever had no effect and food delivery always followed lever retraction. All subjects received a IP injection of cocaine or saline immediately after each session. Cocaine (5.55 mg/kg) impaired development of lever-touch responding under instrumental contingencies [$F(1,24)=4.64, p < .05$], but not under classical contingencies. These results suggest that cocaine-induced impairment of responding in the autoshaped task is due to disruption of the formation of the instrumentally-, rather than the classically-conditioned association. CHRONIC ADMINISTRATION OF DCOOSAHEXAENOIC ACID REDUCES THE SPATIAL LEARNING DEFICIT FOLLOWING TRANSIENT FOREBRAIN ISCHEMIA IN RATS. *M.Okada¹, Y. Ohgami¹, K.Yazawa², K.Mine^{*3}, K.Iwasaki¹, M.Fujiwara¹*

¹Dept. Physiol.&Pharmacol., Fac. Pharmaceut. Sci., Fukuoka Univ., Fukuoka 814-01, ²Sagami Chem. Res. Cent., Kanazawa 229, ³Dept. Psychosom. Med., Fac. Med. Kyushu Univ., Fukuoka 812, Japan.

The present study is to determine whether oral treatment of purified docosahexaenoic acid (DHA) can reduce the spatial learning deficit following transient forebrain ischemia in rats.

Rats subjected to 10 minutes of transient forebrain ischemia by the method of four-vessel occlusion and then cerebral reperfusion were tested on a radial 8-arm maze task 24 hours after occlusion. DHA was administered singularly 1 hour before occlusion or chronically administered for 21 days before occlusion. The neuroprotective effect of chronic administration of 200 mg/kg of DHA was assessed by measurement of lactate dehydrogenase (LDH) release from the hippocampus slices exposed to the medium lacking oxygen for 60 minutes. Single treatment of DHA (1, 10, 100, 200 mg/kg) did not affect significantly any aspect of the spatial learning deficit following occlusion. On the other hand, chronic treatment of DHA (10, 100, 200 mg/kg) reduced significantly the spatial learning deficit following occlusion. The LDH release from the hippocampus slices induced by oxygen deprivation was almost completely blocked by chronic treatment of DHA.

From these results, the increase in the concentrations of DHA in the hippocampus may be occurred by chronic oral treatment of DHA and it might also play a role in the counteraction of spatial learning deficits induced by transient forebrain ischemia.

507.17

EFFECTS OF NEWLY DEVELOPED T-588 ON HIPPOCAMPUS OF THE RAT, *in vitro* AND *in vivo* STUDIES. T. Kimura, T. Ono, T. Kobayashi*, M. Fukuda and S. Ono. Department of physiology, Faculty of Medicine, Toyama Medical and Pharmaceutical University, Toyama 930-01, Japan, and Research Laboratory, Toyama Chemical Co. Ltd., Toyama 930, Japan.

The effect of newly developed T-588 ((-)- α -[2-(Diethylamino)methyl] benzo [b] thiophen-5-methanol hydrochloride), which is reported to improve learning disorders and memory processes, on membrane potential, membrane resistance and current-voltage-relations of CA1 hippocampal pyramidal cells in rat brain tissue slices was studied by intracellular recording. T-588 had an ACh-like excitatory action on pyramidal cells, causing depolarization, increased firing, and increased membrane resistance. But this effect was not through cholinergic nor NMDA receptor activation. In another experiment, acquisition of spatial memory was evaluated in a hippocampal lesioned animal model of cerebral ischemia. Rats with selective neuronal death in the hippocampal CA1 subfield after 15 min transient forebrain ischemia were allowed to recover; and were then tested in a spatial navigation task. Posts ischemic rats tended to have a persistent spatial memory deficit with no motor behavior deficit compared to controls ($p < 0.01$). This spatial memory deficit was effectively ameliorated by T-588 (3mg/kg, p.o.). The results suggest that T-588 has a direct excitatory effect on pyramidal cells in the hippocampal CA1 subfield, acting on a different site of action in a different way than cholinergic and NMDA agonists, and ameliorates memory deficit due to selective neuronal death.

507.19

AUDITORY SIGNAL DETECTION IN RATS: EFFECTS OF DISTRACTORS, SIGNAL RATE, AND TOLUENE ON VIGILANCE. P.J. Bushnell¹ and K.L. Kelly². ¹Neurotoxicology Division, US EPA and ²ManTech Environmental Technology, Inc., Research Triangle Park, NC 27711.

Vigilance involves maintaining attention to repeated stimuli over time; a vigilance decrement (reduced accuracy or speed over time) can be demonstrated under some testing conditions. Male Long-Evans rats performed a discrete-trial operant task in which an auditory signal (a 20-msec increase of 2, 4, or 6 dB(A) in the intensity of continuous 60-dB white noise) was presented on half of the trials. A food pellet was delivered if the rat pressed one of two retractable levers on a signal trial, and if it pressed the other lever on a blank (no signal) trial. Signal detection analysis showed that both sensitivity (sensitivity index, SI) and bias (response index, RI) increased with increasing signal intensity. Presentation of distractor events (intermittent decreases in the intensity of the background WN: -4 dB, 200-800 msec, 2 to 16 per trial) reduced SI at all intensities without affecting RI. Increasing the signal presentation rate from 4 to 13 signals/min reduced SI at 4 and 6 dB, increased RI at 2 dB, and decreased RI at 6 dB. No parametric manipulation induced a reliable vigilance decrement; however, inhalation of toluene during performance of the task did, by reducing SI and increasing response latencies across trial blocks. The toluene-induced vigilance decrement depended upon the concentration of inhaled toluene vapor but was independent of the duration of toluene exposure prior to testing. The toluene-induced reduction in SI was not exacerbated by high signal presentation rates, while its ability to slow responding was.

507.18

PRENATAL ETHANOL EXPOSURE AND NONSPATIAL VERSUS SPATIAL LEARNING/MEMORY IN RATS. C.K. Kim#, L.E. Kalynchuk, T.J. Kornecook, V.A. Redila, C.P. McIntyre, D.G. Mumby, J.P.J. Pinel and J. Weinberg*#. Departments of Anatomy# and Psychology, University of British Columbia, Vancouver, B.C., Canada.

Fetal ethanol exposure (FEE) can cause cognitive deficits and behavioral problems in the offspring. This study examined the effects of FEE on learning/memory. The subjects were adult male offspring from prenatal ethanol exposed (36% EDC)(E), pair-fed (PF), and ad libitum-fed control (C) conditions.

We have previously reported that E rats do not show deficits on a nonrecurring-item delayed nonmatching-to-sample (DNMS) task at retention delays of 4 to 600s, or in relearning this task after a 10 week rest period. Furthermore, these same rats do not display increased distractibility or perseveration of response during the DNMS task. These data suggest that FEE does not affect nonspatial learning/memory. In the present experiment, these same rats were tested for spatial navigational learning/memory using the Morris water maze. The E rats displayed performance deficits on this task. This finding is consistent with other reports of spatial learning/memory deficits following FEE. Taken together, these data suggest that FEE may affect spatial but not nonspatial learning/memory in the same rats. (Supported by NIAAA to JW; NSERC and BCFRF to JPP)

ANTAGONIST TIMING DETERMINES SPATIAL NAVIGATION PERFORMANCE FOLLOWING ENVIRONMENTAL NEUROEXCITOTOXIN EXPOSURE. B.F. PETRIE*(1), C. PINSKY(2), G. GLAVIN(2)

(1) Department of Psychology, Red Deer College, Red Deer, Alberta, Canada, T4N 5H5; (2) Department of Pharmacology, University of Manitoba, Winnipeg, Manitoba, Canada R2E 0W3.

The present study examines the effect of parenteral injection of the neuroexcitotoxin domoic acid (DOM), and the non-competitive NMDA antagonist dextramethorphan (DEX) on spatial navigation performance in mice. DOM impaired acquisition of the place task in the Morris water maze, while animals administered DEX subsequent to DOM performed at levels equal to those of saline controls. Animals administered DEX prior to DOM however, showed acquisition rates similar to those of DOM mice. The results indicate that the timing of antagonist administration following environmental neuroexcitotoxin ingestion appears to be a fruitful area of investigation in assessing functional and neuroanatomic deficits associated with neurodegenerative disorders, including senile dementia of the Alzheimer's type.

Thanks to A. Petrie for her skillful assistance in swimming the animals.

CALMODULIN ANTAGONISTS: EFFECTS ON ANTIESTROGEN BINDING IN BRAIN, FOOD INTAKE AND BODY WEIGHT. J.M. Gray*, C. Monian, R. Seaman, J. Bogdany and T. Bialy. Program in Biopsychology, Vassar Coll., Poughkeepsie, NY 12601

Previous data from this lab demonstrated the presence of two distinct antiestrogen binding sites (AEBS) in brain and pituitary, as measured using *in vitro* binding techniques. In this study we explored the competition of several calmodulin antagonists for the AEBS, using [3H]tamoxifen as the ligand. The calmodulin antagonists all effectively competed with [3H]tamoxifen, with the order of efficacy being tamoxifen > fluphenazine > W-7 > bepridil >> ACTH, ACTH₁₋₂₄.

In a second study we examined whether or not daily bepridil administration to ovariectomized rats affected food intake and body weight regulation in ways similar to previously studied drugs, estradiol benzoate, tamoxifen and fluphenazine. While daily administration for 2 weeks of 2 ug estradiol benzoate or 1 mg tamoxifen decreased both food intake and body weight gain, and daily administration of 0.05 mg fluphenazine decreased body weight gain but not food intake, daily administration of 1 mg bepridil had no effect on either food intake or body weight.

508.2

DIENCEPHALIC SITES MEDIATING PROLACTIN-INDUCED HYPERPHAGIA IN DOVES. R. M. Hnasko and J.D. Bunin*. Dept. of Biological Sciences, Univ. Wisconsin-Milwaukee, Milwaukee, WI 53201.

Microinjections of prolactin (PRL) into the ventromedial nucleus of the hypothalamus (VMN) or the preoptic area (POA) have been previously shown to increase food intake and body weight in ring doves. In order to provide a more complete map of PRL-sensitive brain sites mediating this response, we investigated the effects of delivering small volumes (10 nanoliters/injection) of PRL or saline vehicle to a variety of diencephalic sites in dove brain that had been previously demonstrated to contain high concentrations of PRL receptors. Food intake of cannulated male doves was monitored daily during a 6 day baseline period, an initial 4 day treatment period, a 6-12 day post-treatment recovery period, and a second 4 day treatment period. Approximately half of the birds received PRL first (50 ng/10nl twice-daily) and saline vehicle second (10 nl twice-daily), while remaining birds received these treatments in the reverse order. No significant changes in food intake were observed following PRL injections in the lateral POA, paraventricular nucleus of the hypothalamus (PVN), or the region between the tuberal hypothalamus (TU) and VMN. In contrast, injections of PRL into the VMN area, medial POA, or TU resulted in average daily food intake values that significantly exceeded those recorded during vehicle treatment. Nevertheless, the 58% increase in food intake observed following PRL injections into the VMN was significantly greater than the 26% increase recorded following medial POA injections and the 32% increase seen after TU injections. These findings suggest that the VMN may be a primary site of PRL action in promoting hyperphagia in this species, although PRL effects at other diencephalic loci, such as the medial POA and TU, may also contribute to the response. (Supported by grant MH 41447)

508.3

ESTRADIOL INTERACTS WITH GASTRIC OR POSTGASTRIC FOOD STIMULI TO INHIBIT FEEDING IN OVARIECTOMIZED RATS. N. Geary*, D. Trace and G.P. Smith. E. W. Bourne Behavioral Research Laboratory, New York Hospital-Cornell Medical Center, White Plains, NY 10605.

We tested estradiol benzoate's (EB) effects on sham feeding (SF). Ovariectomized rats with chronic gastric cannulas received 10 µg EB (n=6) or oil vehicle (n=6) sc on Tues and Wed mornings, a regimen that elicits behavioral estrus on Fri but does not produce the carry-over effects of continuous EB replacement (*Science* 250:691, 1990). Rats were adapted to daily real feeding (RF) of 0.8 M sucrose test meals after 21 hr food deprivation. Rats sham fed with open cannulas only twice, on two consecutive Fri. EB inhibited RF, but not SF. Inhibition of RF began within 6 min (see Table) and was maintained throughout the meal (for example; on a RF Thurs, wk 2, 45 min sucrose intake was 11.8 ± 1.6 ml in control rats vs. 8.0 ± 1.2 ml in EB-treated rats, t-test, p < .05).

Initial 6-min Sucrose Intake (M ± SEM)

	Control	EB
RF Thurs, wk 2	6.7 ± 0.8	5.0 ± 0.5*
SF Fri, wk 2	7.0 ± 0.8	8.0 ± 0.6
RF Fri, wk 3	8.0 ± 0.7	6.3 ± 0.4**

*Different from control, t-test, p < 0.05.

**Different from SF, paired t-test, p < 0.025.

Because food does not accumulate in the stomach or enter the intestine in appreciable amounts during SF, these data indicate that EB must interact with gastric or postgastric food stimuli in order to inhibit intake of sucrose after 21 hr food deprivation. Further, food stimuli sufficient for this interaction occur within 6 min of meal onset.

A MONOSODIUM GLUTAMATE (MSG)-INDUCED DELAY OF WEIGHT GAIN IN GENETICALLY OBESE MICE. F. A. Caputo*, G. L. Wolff and A. C. Scallet. FDA/National Center for Toxicological Research, Jefferson, AR 72079.

The yellow mouse is a model of obesity induced by the *A^y* gene at the agouti locus on chromosome 2. Obesity also results from postnatal MSG administration. The present study was to determine if environmental factors such as MSG administration, imposed on a genetically susceptible model such as the yellow mouse, would result in an augmented form of obesity. Both yellow obese and black lean males (n's=8) were injected on postnatal days 1,3,5,7,9 with 2.0 mg/g body weight MSG sc. Control mice of both genotypes (n's=8) received an equal volume of saline. Mice were weaned on postnatal day 28 and given food and water ad libitum.

Paradoxically, MSG interacted with the yellow genotype to delay the rapid rate of weight gain characteristic of this model [F(4,112)=4.4, p<0.05]. By postnatal week 8, saline-treated yellows (S-Y) were 28% heavier than saline-treated blacks (S-B; means 32 vs 25g, p<0.05). However, prior MSG-treatment completely reversed this effect with MSG-treated yellows (M-Y) weighing less than S-Y (23 vs 32g, p<0.05). By week 24, the S-Y were up to 44% heavier than S-B (52 vs 36g, p<0.05), while M-Y compared to S-Y were still significantly lighter (49 vs 52g, p<0.05). Effects of MSG on body weight may depend on factors such as developmental stage and genetic context and warrants further consideration.

EVIDENCE THAT D₁ AND D₂ DOPAMINE RECEPTOR ACTIVATION ANTAGONIZES FEEDING ELICITED BY PERIFORNICAL HYPOTHALAMIC NEUROPEPTIDE Y. E.R. Gillard*, and B.G. Stanley. Depts. Neurosci. & Psych., Univ. Ca., Riverside, CA 92521, USA.

Recent evidence suggests that dopamine (DA) in the perifornical hypothalamus (PFH) may act to suppress neuropeptide Y-elicited eating. However, the identity of the DA receptor subtypes mediating this suppression is unknown. To begin to address this, the D₁ agonists SKF 38393 and SKF 82958 (0.01 to 100 nmol), and the D₂ agonists quinpirole (3 pmol to 300 nmol) and bromocriptine (3.3 to 248 nmol), or vehicle (0.3 µl) were injected prior to NPY (78 pmol/0.3 µl) into the PFH of adult male rats and subsequent food intake was measured. NPY alone stimulated feeding in all groups of subjects (5.0 g on the average, 1 hr postinjection) and each DA agonist reduced the response by at least 49% at the most effective dose. The D₁ agonists SKF 38393 (1.0 nmol) and SKF 82958 (0.1 nmol) reduced 1 hr intake by at least 73%; the D₂ agonist bromocriptine (33.0 nmol) reduced intake by at least 49%, and the D₂ agonist quinpirole (3 pmol) abolished peptide-elicited eating for up to 4 hrs. These findings may suggest that PFH DA antagonizes the eating-stimulatory effect of NPY via at least two distinct DA receptor subtypes.

TCDD COMPLETELY REVERSES THE HYPERPHAGIA DUE TO VMH LESION. J. Tuomisto*, J.T. Tuomisto, M. Unkila and R. Pohjanvirta. Dept. of Toxicol., Nat'l Public Health Inst., POB 95, SF-70701 Kuopio, Finland.

Acute toxicity of TCDD (2,3,7,8-tetrachlorodibenzo-p-dioxin) seems to correlate with its ability to cause anorexia and a typical wasting syndrome. Han/Wistar (Kuopio) strain of rat (H/W) is remarkably resistant to TCDD, and survives a large dose, but seems to become hypersensitive to satiety signals and hyposensitive to hunger signals. In this study ventromedial hypothalamic nuclei (VMH) were lesioned electrolytically in eleven-week old H/W rats, and after a two-week recovery and weight gain period given a large dose (1000 µg/kg) of TCDD. The average starting weight was 194±8 g (mean±SD), feed intake after lesioning 23±5 g and after sham-lesioning 14±2 g, and weight gain 27±8% and 5±2%, respectively (p<0.01). After TCDD administration VMH lesioned overweight rats (N=6) stopped eating completely for at least 1 week. Three of the animals started to eat again, and their feed intake and body weight increased to the level of sham-operated TCDD-treated rats, but three succumbed after a total fast of about 3 weeks. The results suggest that TCDD regulates weight to a new level, and it is also able to completely reverse the effect of VMH lesion.

508.6

THE RELATIVE CONTRIBUTIONS OF BETA-1 AND BETA-2 ADRENORECEPTORS TO ISOPROTERENOL-INDUCED DRINKING. C. Novak, M. Blumberg*, R. Thunhorst, A. Johnson, & R. Kirby. Dept. of Psychology, Univ. of Iowa, Iowa City, IA 52242.

The renin-angiotensin system has been shown to be a primary mediator of isoproterenol-induced drinking. As a mixed beta adrenoceptor agonist, isoproterenol can stimulate renin release via two independent mechanisms. First, isoproterenol acts directly on beta-1 adrenoceptors in the kidney to stimulate the release of renin. Second, isoproterenol decreases blood pressure by stimulating beta-2 adrenoceptors located in the skeletal muscle vasculature and the decrease in blood pressure stimulates the release of renin. Therefore the present study examined the relative contribution of beta-1 and beta-2 adrenoceptor stimulation on drinking behavior and plasma renin activity induced by isoproterenol. Selective pharmacological antagonism of each adrenoceptor type was achieved by administering atenolol (2.5 mg/kg), a beta-1 adrenoceptor antagonist, or ICI 118,551 (1mg/kg), a beta-2 adrenoceptor antagonist before treatment with isoproterenol (25µg/kg). Neither adrenoceptor mechanism alone could account for all of the water intake due to isoproterenol treatment; plasma renin activity due to isoproterenol was similarly affected by selective beta-adrenergic antagonism. Cardiovascular recordings confirmed that the beta-adrenoceptor antagonists were selective to their respective adrenoceptors. The results suggest that both the direct stimulation of renin release and the indirect stimulation due to decreased blood pressure contribute to isoproterenol-induced drinking.

α-METHYLNOREPINEPHRINE (α-MeNorEpi)—A POTENT ANORECTIC DRUG WITHOUT STIMULATORY ACTIVITY IN RATS. S.Y. Yeh† Lab. of Neurobiology, Addiction Research Center, NIDA/NIH, P. O. Box 5180, Baltimore, MD 21224.

Reduction of body weight of rats treated with 3,4-methylenedioxamphetamine (MDA) and its metabolites, α-MeNorEpi, have been observed. The present study is to investigate the anorectic and stimulatory effects of dl-MeNorEpi and l-3,4-dihydroxynorephedrine (l-MeNorEpi) in free feeding rats. As compared with that of saline control rats, S.C. injection of dl-α-MeNorEpi at doses larger than 2.5 mg/kg significantly inhibited the food intake on days 1 to 3 from 3 to 24 hr intervals. Profound inhibition on food intake of rats was observed when the drug was given twice daily. Similar results were observed in rats treated with l-α-MeNorEpi. The ED₅₀ (to reduce 50% of food intake) values of dl-α-MeNorEpi on inhibition of food intake at 1, 3, 14, and 24 intervals were estimated to be 0.76, 0.79, 1.96 and 2.6 mg/kg, respectively. The ED₅₀ values of l-α-MeNorEpi on inhibition of food intake at 1, 3, 14, and 24 intervals were estimated to be 0.73, 0.95, 1.27 and 1.55 mg/kg, respectively. Body weight and locomotor activity, but not water intake, of rats treated with both dl-α-MeNorEpi and l-α-MeNorEpi, were decreased. It was concluded that both dl-α-MeNorEpi and l-α-MeNorEpi are potent anorectic drugs without stimulatory effects.

HYPOTHALAMIC 5-HT_{1A} RECEPTOR BINDING IS INCREASED IN GENETICALLY OBESE AND DIABETIC RATS. J.A. Finkelstein* and M. Jhanwar-Uniyal. Northeastern Ohio Univ. Col. Med., Rootstown OH 44272 and Rockefeller Univ., New York NY 10021

Both genetically obese Zucker rats and streptozotocin-induced diabetic rats (STZ-D) have abnormalities in insulin levels and hypothalamic serotonergic (5-HT) activity which could play a role in their impaired feeding behavior and body weight regulation. Obese Zucker rats are characterized by hyperinsulinemia, whereas STZ-D rats are hypoinsulinemic. The 5-HT_{1A} receptor agonist, 8-OH-DPAT, induces feeding behavior and modulates circulating levels of insulin and glucose. Binding of [³H] 8-OH-DPAT to 5-HT_{1A} receptors was measured in the medial (MH) and lateral hypothalamus (LH) of male and female, lean and obese Zucker rats, and of control and STZ-D Sprague-Dawley rats; the latter animals were sacrificed three weeks after IP injection of 60 mg/kg STZ. Non-specific binding was determined in the presence of 10 μM 5-HT, and the results expressed as fmoles/mg protein. Genetically obese rats of both sexes have higher binding in MH than lean rats (male: 84+9 vs. 38+4; female: 62+5 vs. 32+3). STZ-D rats have higher binding in MH than controls (48+5 vs. 22+3). There were no differences in LH for any of the groups. These results suggest that hyperphagia coinciding with abnormalities in peripheral insulin metabolism may operate via medial hypothalamic 5-HT_{1A} receptors.

PERIPHERAL SEROTONIN (5-HT) REDUCES FEEDING IN RATS WITH AREA POSTREMA LESIONS. V. Adipudi* and K. J. Simansky. Department of Pharmacology, Medical College of Pennsylvania, Philadelphia, PA 19129 USA.

Peripherally administered serotonin (5-HT) reduces food intake in rats. Both 5-HT₁ and 5-HT₂ type receptors have been implicated in this serotonergic action but the neural substrates for 5-HT-induced anorexia remain to be defined. The area postrema (AP) is a circumventricular organ of the hindbrain that provides a potential target site for 5-HT in regulating food intake. This study assessed the effect of ablating the AP on the acute anorectic action produced by 5-HT (0, 1.6, 4.0 and 10.0 μmol/kg, i.p.) in 11 lesioned rats (APX) and 10 sham-operated controls (APC). The rats were maintained on standard pelleted chow and deprived at 09:30 h each day for testing 3 h later during a 30-min period with access only to a sweetened mash. Experiments were conducted with each rat receiving each dose of 5-HT in a randomized order beginning 6 wk postoperatively. Lesioned rats weighed less than controls at this time (APC, 472±9 g vs. APX, 343±26 g, p<0.01) but ate more than controls during the 30-min after injection with vehicle (0 dose) (APC, 4.8±0.4 g; APX, 11.0±1.2 g; p<0.01). 5-HT reduced intake in a dose-related fashion: Two-way ANOVA on the actual intakes revealed significant effects of Lesion (p<0.01) and Dose (p<0.01) but no interaction between these factors (p>0.10). Conversion of the data to percentages demonstrated that 5-HT produced similar anorectic actions in the two groups (APC, -32%, -45% and -69%, for the 3 doses, respectively, from baseline; APX, -27%, -46% and -52%). These data establish that peripherally administered 5-HT decreases food intake in rats with AP lesions. The apparent blunting of the effect at the highest dose suggests further studies testing whether AP damage might alter anorexia produced by more selective 5-HT₁ and 5-HT₂ analogs. SEROTONIN ATTENUATES FEEDING INDUCED BY INFUSING NEUROPEPTIDE Y INTO THE PERIFORNICAL HYPOTHALAMUS C.M. Brown and D.V. Coscina*. Sect. of Biopsychology, Clarke Inst. of Psychiatry, 250 College St., Toronto, Ontario, CANADA M5T 1R8.

Recent research has shown the perifornical hypothalamus (PFH) to be particularly sensitive to the feeding-stimulatory effects of locally infused neuropeptide Y (NPY). Conversely, earlier work suggested that PFH infusion of exogenous serotonin (5-HT) may suppress feeding, although some controversy exists about these findings. Furthermore, recent work shows that endogenous 5-HT is released in this site during meal-taking behaviors, making unclear the exact role 5-HT may play in PFH feeding controls. To determine what effects PFH 5-HT infusions might have on NPY-induced feeding, unilateral cannulae were implanted into freely-feeding adult male Sprague-Dawley rats. Using a within-subjects, repeated-measures design, NPY (0 or 235 pmol in 0.4 ul saline) was infused into the PFH, followed 15 min later by infusions of 5-HT (0, 6.3, 12.5, 25 or 50 nmol in 0.4 ul in saline). Food intake was measured 1 and 2 hrs after the second injection. NPY alone elicited strong, reliable (p < .001) feeding as expected. 5-HT attenuated this response, largely blocking it at the highest dose tested. These data confirm that infusing exogenous 5-HT into the PFH can suppress intake. Extending this observation to feeding stimulated by NPY implies that these two neuroactive agents may normally interact at this site to modulate ingestive behaviors. (Supported by NSERC of Canada)

EFFECT OF CHRONIC 8-OH-DPAT ON GENE EXPRESSION OF HYPOTHALAMIC NEUROPEPTIDES. A.H. Kahn, S. E. Bachus, R.C. Arora*, and M. Jhanwar-Uniyal, The Rockefeller Univ., NY 10021, NIH, Maryland and VA Hosp, Hines IL 60141.

Numerous studies have presented evidence for a strong relationship between the serotonergic (5-HT) and the hypothalamo-pituitary-adrenal (HPA) axis. This relationship has also been implicated in the regulation of insulin (INS) and glucose (GLU) levels. This study examines the levels of messenger RNA (mRNA) of corticotropin releasing factor (CRF), dynorphin (DYN) and galanin (GAL) in the paraventricular (PVN) and supraoptic (SON) hypothalamic nuclei, after the chronic administration of 5-HT_{1A} receptor agonist, 8-OH-DPAT (60 μg/kg BW, IP for 10 days). Purina lab chow and water were available ad libitum to male Sprague-Dawley rats (325-375 g BW). Rats were sacrificed 24 h after the last injection. Levels of blood INS were assessed by RIA, and GLU levels were estimated by YSI glucose analyzer. *In situ* hybridization histochemistry was used to determine the area and density of mRNA for these neuropeptides in the PVN and SON. The results demonstrate that, as compared to the saline treatment, chronic 8-OH-DPAT-treatment caused: 1) an increase in the circulating levels of GLU (123%; P<0.05), and no change in INS levels; 2) a significant reduction in density for CRF mRNA in PVN and not in SON; 3) an increase in DYN mRNA area in both PVN and SON, but decreased density in PVN, resulting in no net change in label in PVN, but an increase in SON; and 4) a significant increase in area for GAL mRNA, in the PVN, but not in the SON. Thus, 8-OH-DPAT treatment influences the gene expression of certain neuropeptides in specific hypothalamic regions that regulate HPA and INS/GLU levels.

DULOXETINE, A MIXED INHIBITOR OF SEROTONIN (5-HT) AND NOREPINEPHRINE (NE) UPTAKE, LOWERED MEAL-FEEDING AND BODY WEIGHT AND IMPROVED GLUCOSE TOLERANCE IN OBESE ZUCKER RATS. D.T.Wong* and W.N.Shaw. Lilly Research Laboratories, Eli Lilly and Company, Indianapolis, IN 46285

Duloxetine, an antidepressant drug candidate, suppressed food intake in normal rats after 20 hr of fasting (1) and of nocturnal feeding, which was persistently reduced during chronic drug treatment (15 mg/kg i.p. daily up to 11 days) and resulted in lowering body weight (2). In obese Zucker rats, duloxetine and its racemate, during chronic administration (10 mg/kg i.p. daily), lowered meal-feeding and body weight. After 7 days of treatment, increase of oxygen consumption and decrease of epididymal adipose tissue mass became evident. Clearance of blood glucose after an oral glucose bolus was progressively improved between day 6 and 21 of duloxetine administration. An exogenous dose of insulin (0.25 unit/kg s.c.) produced changes in basal levels of blood glucose in rats chronically treated with duloxetine compared with the vehicle-treated group. There was no evidence of change in glucose intolerance in streptozotocin-induced diabetic obese Zucker rats after 7, 14 and 26 days of duloxetine administration. Thus, long-term treatment with duloxetine lowered food intake and body weight of obese Zucker rats, which show improved glucose tolerance possibly resulting from an increase of sensitivity to insulin. Moreover, besides the known involvement of central 5-HT and NE neurons in regulation of food intake, the present findings suggest their involvement in improving glucose utilization and insulin sensitivity in obese Zucker rats. DIFFERENTIAL EFFECTS OF THE 5-HT_{1A} AGONIST 8-OH-DPAT ON NOCTURNAL FEEDING IN THE RAT. P.J.Currie* and D.V. Coscina. Section of Biopsychology, Clarke Institute of Psychiatry, 250 College Street, Toronto, ON, M5T 1R8 CANADA.

Intra-raphe injection of 8-OH-DPAT preferentially stimulates somatodendritic 5-HT_{1A} receptors leading to a suppression of 5-HT cell firing, transmitter synthesis and terminal release. Since other evidence suggests that 8-OH-DPAT may also exert both excitatory and inhibitory effects on feeding, we examined the impact of this compound administered at various times throughout the nocturnal/active cycle. Rats with cannulae implanted in either the dorsal (n=9) or median (n=9) raphe were injected with 8-OH-DPAT (0.4, 0.8 and 1.6 nmol) or saline immediately following dark onset, or during the mid or late portions of the nocturnal cycle. Food intakes were measured 1.5 h postinjection. Analysis of baseline feeding across the nocturnal period indicated that rats exhibited an increase in spontaneous feeding at the onset of the dark period compared to a reduced intake found later in this cycle. Injection of 8-OH-DPAT potentiated feeding but only when injected in the mid or late-dark cycle when baseline feeding was low; whereas treatment during the early dark period actually suppressed feeding. These findings suggest that 8-OH-DPAT's effects on feeding may be dependent on the animal's motivational state and are consistent with recent reports of a biphasic action of this agent on ingestive behaviour. ROLE OF CHOLINERGIC AND ADRENERGIC PATHWAYS OF THE MEDIAL SEPTAL AREA ON THE PRESSOR AND DIPSOGENIC RESPONSES INDUCED BY CENTRAL CHOLINERGIC ACTIVATION AND ANGIOTENSIN II IN RATS. S.P. Barbosa, W.A. Saad*, L.A.A. Camargo, A. Renzi, L.A. De Luca Jr., J.E.N. Silveira and J.V. Menani. Dept. of Physiology, School of Dentistry, UNESP, Araraquara, SP 14801-903, Brazil.

In the present study we investigated the effect of previous injection of atropine (cholinergic antagonist) or prazosin (α_1 -adrenergic antagonist) into the medial septal area (MSA) on the pressor and dipsogenic responses induced by intracerebroventricular (ICV) injection of carbachol (CARB, cholinergic agonist) and angiotensin II (ANGII). Male rats with cannulae in the lateral ventricle and MSA were used. Atropine (0.05 nmol to 5 nmol) reduced the pressor and dipsogenic responses induced by ICV carbachol (7 nmol), but not the responses induced by ANGII (25 ng). Prazosin (40 nmol) reduced only the dipsogenic response induced by ANGII. The results show the involvement of α_1 -adrenergic pathways of the MSA in the dipsogenic response to ICV ANGII, while cholinergic pathways of the MSA mediate the pressor and dipsogenic responses to ICV cholinergic activation. Therefore, they suggest a dissociation of the pathways of the medial septal area involved with the responses induced by central cholinergic activation and ANGII in rats.

ACETYLCHOLINE IS INCREASED IN THE NUCLEUS ACCUMBENS AND PREFRONTAL CORTEX DURING OPERANT RESPONDING FOR FOOD. G.P. Mark*, P.V. Rada & B.G. Hoebel. Dept. of Psychology, Princeton University, Princeton, NJ 08544

We previously reported that free feeding was accompanied by an increase in ACh in the nucleus accumbens (NAC)¹. In the present experiments, microdialysis was used to determine the impact of operant responding on ACh release in the NAC and prefrontal cortex (PFC). Microdialysis probes (2 mm tip for NAC, 3 mm for PFC) were perfused with a neostigmine Ringer (0.3 μ M) and ACh was measured in 10 min intervals before, during and after responding for food (fixed ratio 1: FR1) in mildly food-deprived rats. ACh was increased in both sites (48% in NAC, 73% in PFC; $p < .05$) during 30 min bar pressing for food pellets. In rats trained to bar press on an FR25 schedule, the ACh response in the NAC was dampened (35% increase) whereas PFC ACh was increased to 90% ($p < .05$). Response extinction was accompanied by a transient 24% increase in extracellular ACh in the NAC. In contrast, cortical ACh increased by 127% during extinction. These data suggest that accumbens ACh may be released as a concomitant of reinforcement whereas ACh release in the prefrontal cortex may be more closely related to motor activity.

PERIPHERAL ATROPINIZATION DOES NOT CHANGE MEAL SIZE CONTROLLED BY PREPYLORIC MECHANISMS. E. Rauhofer, G.P. Smith, J. Gibbs* and D. Greenberg. E.W. Bourne Behavioral Research Laboratory, New York Hospital-Cornell Medical Center, White Plains, NY 10605.

When gastric emptying is prevented by a pyloric cuff, meal size (MS) is not different from when gastric emptying occurs. Thus prepyloric mechanisms are sufficient for the normal control of MS. To determine if peripheral cholinergic, muscarinic mechanisms are necessary for prepyloric control of MS, we compared MS in rats ($n=7$) administered atropine methyl nitrate (AMN, 3mg/kg, ip, at -30 min) with MS in rats ($n=6$) administered 0.15 M NaCl. There were 3 tests of 30-min access to 0.8M sucrose after 1 hour food deprivation. The pylorus was closed prior to all tests by inflating a pyloric cuff. AMN did not change meal size (Table).

TREATMENT	TESTS	1	2	3
SALINE		5.3 \pm 2.1	5.7 \pm 1.9	6.7 \pm 1.9
ATROPINE		6.1 \pm 2.5	6.7 \pm 2.7	4.9 \pm 2.9

Note: Data are mean \pm SEM 30-min intakes (ml).

These results suggest that peripheral cholinergic, muscarinic mechanisms are not necessary for the prepyloric control of meal size.

Supported by MH15455 and MH00149.

THE LATERAL HYPOTHALAMUS: A PRIMARY LOCUS FOR EXCITATORY AMINO ACID-ELICITED EATING. B.G. Stanley*, H.W. Donias, V.L. Willett III, L.H. Ha, L.C. Spears, Depts. Neurosci. & Psych., Univ. California, Riverside, CA 92521.

We have recently demonstrated that an intense transient eating response is elicited in rats by lateral hypothalamic (LH) injection of glutamate or the excitatory amino acid (EAA) agonists kainic acid (KA), D,L- α -amino-3-hydroxy-5-methyl-isoxazole propionic acid (AMPA), and N-methyl-D-aspartic acid (NMDA), among the most selective agonists of receptor subtypes of the same name (Brain Res. in press). In order to determine whether the LH is the actual locus of these effects, a cannula-mapping study was conducted in satiated adult male rats ($n=117$) to compare the eating responses elicited by LH injection of glutamate, KA, AMPA, and NMDA to those elicited by injections into diencephalic sites bracketing this area. In the LH, food intakes one hour postinjection were markedly and consistently increased in a dose-dependent manner by each agonist (e.g., 5.2 gm for glutamate at 900 nmol; 13.3 gm for KA at 1.0 nmol; 10.9 gm for AMPA at 3.3 nmol; and 13.9 gm for NMDA at 3.3 nmol). In contrast, injections into nearby sites including the anterior and posterior tips of the LH, the perifornical and paraventricular hypothalamus, the amygdala and thalamus only occasionally elicited significant eating. These findings, suggesting that each of these agonists actually act within the LH to elicit eating, argue that multiple subtypes of EAA receptors may exist on LH neurons involved in eating stimulation.

A SINGLE AMPHETAMINE PRETREATMENT RESULTS IN A CALCIUM DEPENDENT ENHANCEMENT IN DOPAMINE RELEASE FOLLOWING AN AMPHETAMINE CHALLENGE. E.C. Warburton¹, S.N. Mitchell, I.A. Gray and M.H. Joseph (SPON EBBS). Dept. Psychology, Inst. of Psychiatry, London SE5 8AF, UK. ¹current address Dept. Anatomy, Univ. of Cambridge CB2 3DY, UK

Using *in vivo* microdialysis in a between-subjects design, the effects of one and two administrations of *d*-amphetamine on the release of dopamine (DA) and metabolites from the nucleus accumbens of a freely moving rat, were compared. On the day prior to recording rats were pretreated with either saline or *d*-amphetamine (1mg/kg i.p.) and a microdialysis probe implanted 2.5h later. Twenty-four hours later the subjects were connected for dialysis and were given an amphetamine challenge.

Acute administration of *d*-amphetamine (1mg/kg) produced a 350% increase in DA release 30mins post-injection. The effect of *d*-amphetamine was significantly enhanced by a prior amphetamine pretreatment. In this group, DA levels increased to 650% of baseline 30mins post-injection and remained elevated for 2.5h post-injection. Levels of DOPAC and HVA decreased following acute administration of amphetamine, but were unaffected by the pretreatment. The enhanced increase in accumbens DA was reflected in increased locomotor activity, recorded in a group of non-dialysed animals, but the difference did not reach significance.

The removal of calcium from the perfusate did not affect DA release produced by an acute amphetamine injection but attenuated the enhanced response to a second amphetamine injection, suggesting that the sensitized DA release produced by the single amphetamine pretreatment was calcium-dependent. These data are discussed in terms of possible presynaptic changes relating to autoreceptor down-regulation that may occur following a single amphetamine administration. (Supported by Glaxo Group Research Ltd.)

A COMPARISON OF STEREOTYPED BEHAVIOR AND NEUROCHEMICAL CHANGES FOLLOWING ACUTE ADMINISTRATION OF METHYLPHENIDATE AND DEXTROAMPHETAMINE IN THE WEANLING RAT. C.J. Truman, H.Y. Lee, and L.A. Raskin*. Dept. Psychology, Neuroscience Program, Amherst College, Amherst, MA 01002.

This experiment compared the stereotyped behaviors elicited by injections of high doses of two psychomotor stimulants, and assessed the neurochemical changes produced by these injections. Animals aged 4-6 weeks were administered acute intraperitoneal injections of 5 mg/kg dextroamphetamine sulfate (DEX), 30 mg/kg methylphenidate hydrochloride (MPH), or saline. Observations were made via videography of 27 motor behaviors. Stimulant-injected animals spent more time engaged in stereotypy. Most interestingly, the two stimulants produced differential motor effects. Animals given DEX spent more time sniffing near walls than both their MPH and saline-injected counterparts. DEX also tended to produce more sniffing at chips than did MPH and saline. In contrast, MPH-injected animals showed a trend towards more gnawing behavior than DEX or saline-injected animals. HPLC analysis of biogenic amines in these animals showed that 5 mg/kg DEX produced elevated 5HIAA levels in the striatum, hippocampus and frontal cortex whereas 30 mg/kg MPH did not. MPH decreased levels of NE in the frontal cortex although DEX did not. These differential motor effects have implications for clinical stimulant use.

PREEXPOSING RATS TO INTRA-VTA AMPHETAMINE SENSITIZES THEIR LOCOMOTOR RESPONSE TO NUCLEUS ACCUMBENS AMPHETAMINE. M. Perugini* and P. Vezina. Neurosciences, Loeb Medical Research Institute, Ottawa Civic Hospital, Ottawa, Ontario K1Y 4E9 Canada.

Low doses of amphetamine produce behavioral stimulation in rats that increases after repeated systemic administration. Evidence suggests that the induction of this sensitization to the locomotor effects of amphetamine occurs in the ventral tegmental area (VTA). Repeated microinjections of amphetamine into the VTA, but not the nucleus accumbens (N.Acc.), produces an enhanced locomotor and N.Acc. dopaminergic response when rats are subsequently challenged with systemic amphetamine. These findings suggest that amphetamine acts in the VTA, site of the mesolimbic dopamine cell bodies, to produce behavioral sensitization and that its expression occurs in the terminal region of these cells in the N.Acc. The present experiment more directly evaluated this possibility.

Rats were implanted with chronic bilateral injection cannulae aimed at both the VTA and N.Acc. Following recovery, they received intra-VTA injections of either amphetamine (2.5 µg/0.5 µl/side) or saline (0.5 µl/side), one injection every third day and locomotor activity was measured. Seven to ten days following the last injection, all animals received an intra-N.Acc. injection of amphetamine (1.5-2.5 µg/0.5 µl per side) and locomotor activity was again measured. As previously reported, intra-VTA amphetamine produced no behavioral effects acutely. However, when subsequently tested with intra-N.Acc. amphetamine, animals preexposed to intra-VTA amphetamine dose-dependently showed a significantly greater behavioral response (horizontal locomotion and rearing) than saline preexposed animals. These results together with those above indicate that the induction of behavioral sensitization results from drug-induced changes in the VTA while its expression occurs in the N.Acc.

DIFFERENTIAL EFFECTS OF AMPHETAMINE ON THE ATTACK AND DEFENSE COMPONENTS OF PLAY FIGHTING IN RATS. Evelyn Field and Sergio M. Pellis*. Dept. Psychology, Univ. Lethbridge, Lethbridge, AB T1K 3M4.

Treatment with d-amphetamine has been shown to cause a decrease in play fighting by juvenile rats. Previous studies, however, did not determine whether all behavioral components of play were equally diminished. In this study the effects of amphetamine on both the attack and defense behavior patterns of play fighting was analysed. Experiment 1 shows that a 0.5 mg/kg dose, injected subcutaneously in the nape, decreases both attack and defense. In contrast, experiment 2 shows that the same dose, injected subcutaneously in the hip, decreases the frequency of playful attack to a similar level, but only mildly decreases defense. This suggests that the 0.5 mg/kg dose of amphetamine is primarily affecting the offensive components of play via its action on the central nervous system. The reduced likelihood of defense for those rats injected in the nape, is likely due to a local anesthetic effect, which numbs the area of the body defended during play fighting. Further doses (0.15 & 1.0 mg/kg), injected in the hip, were also tested. The highest dose decreased both components of play. The lowest dose had no effect on the attack and defense components. Nonetheless, both the treated and non-treated partners showed a disruption to some of their social behavior. This suggests that even a low dose of amphetamine may affect the style, if not the quantity of playful interactions of juvenile rats. The data suggest that the offensive and defensive components of play fighting may be mediated by different neural systems.

509.7

CONTINGENT AMPHETAMINE ADMINISTRATION PRODUCES BEHAVIORAL SENSITIZATION IN RATS. D. Crippens*, H.S. Crombag¹, T.E. Robinson. Psychology and Neuroscience Program, Univ. of Michigan, Ann Arbor, MI 48104, ¹Experimental Psychology Program, Univ. of Leiden, Leiden, The Netherlands.

Although it is well established that the repeated intermittent administration of many drugs of abuse induces sensitization to their psychomotor activating effects, in nearly all of these studies drug administration was not contingent on the animal's behavior. In studies of drug reinforcement, however, drug administration is usually contingent on an animal's behavior. It has been suggested that sensitization enhances the propensity for drug self-administration, and is critical in the development of addiction. It is important, therefore, to know if contingent drug administration also induces sensitization. This was done in the present experiment by use of a task (Ettenberg, 1990) in which drug administration was contingent on the animal running down a runway to a holding cage where the experimental group received an i.p. injection of 2.0 mg/kg of d-amphetamine (AMPH) and the control group received an injection of saline. Running speed served as a measure of the reinforcing property of the drug. The psychomotor effects of AMPH were determined by monitoring animals inside the holding cages and rating stereotyped behavior using a nine-point scale. Locomotor activity was quantified by the number of cross-overs from one side of the cage to the other. Preliminary results indicate that the psychomotor activating effects of AMPH are progressively enhanced with repeated exposure. These results indicate that AMPH induces sensitization even when the drug treatment is contingent on an animal performing a specific operant.

INDUCTION OF BEHAVIORAL AND DOPAMINERGIC SENSITIZATION TO SYSTEMIC OR INTRA-VTA AMPHETAMINE IS BLOCKED BY SCH-23390. P. Vezina* Neurosciences, Loeb Medical Research Institute, Ottawa Civic Hospital, Ottawa K1Y 4E9 Canada.

The ability of the D-1 dopamine (DA) receptor antagonist, SCH-23390, to block the induction of sensitization to the locomotor and DA-activating effects of amphetamine was assessed in two experiments. In the first, different groups of rats were administered either saline, SCH-23390 (0.2 mg/kg, s.c.) or the D-2 DA receptor antagonist eticlopride (1.0mg/kg, i.p.) prior to each of five injections of saline or amphetamine (1.0mg/kg, i.p.) given one every third day. Both antagonists completely and repeatedly blocked the acute locomotor effects of amphetamine. However, on a subsequent test for sensitization when all animals received saline prior to an injection of amphetamine (0.5mg/kg, i.p.), only SCH-23390 was found to have blocked the induction of behavioral sensitization to the drug. In the second experiment, rats received three intra-VTA injections of either saline, amphetamine (2.5µg/side) or amphetamine+ SCH-23390 (0.25-1.0µg/side), one injection every third day. Two weeks following the last injection, *in vivo* microdialysis was used to assess DA neurotransmission in the nucleus accumbens following a challenge injection of amphetamine (1.0mg/kg, i.p.). Animals previously exposed to intra-VTA amphetamine showed significantly greater DA levels in nucleus accumbens in response to challenge than VTA saline preexposed animals. This effect was completely blocked in animals previously exposed to intra-VTA amphetamine+ SCH-23390. These findings support the view that D-1 DA receptor activation plays a critical role in the induction of sensitization to amphetamine.

509.6

THE ACUTE EFFECTS OF COCAINE ON BEHAVIOR AND EXTRACELLULAR DOPAMINE IN THE NUCLEUS ACCUMBENS OF LEWIS AND FISCHER 344 RATS.

Dianne M. Camp* and Terry E. Robinson. Dept. of Psychology and Neuroscience Program, Univ. of Michigan, Ann Arbor, MI 48109.

Lewis (LEW) and Fischer (F344) rats differ in their response to a variety of drugs of abuse. For example, LEW rats show a greater propensity to self-administer opiates, cocaine and alcohol than F344 rats. In addition, we have reported that both amphetamine-stimulated motor activity and dopamine (DA) release are enhanced in LEW rats compared to F344 rats (Camp et al. *Soc. Neurosci. Abst.* 18, 1992, 719). The purpose of this experiment was to determine whether there are similar strain differences in the ability of cocaine (COC) to elevate the extracellular concentration of DA in the nucleus accumbens by use of *in vivo* microdialysis. Each rat received saline (i.p.) plus one of 4 doses of COC (5, 10, 15 or 30 mg/kg, i.p.) during the dialysis test. Preliminary analyses indicate that the effect of COC on behavior (crossovers and rears) and extracellular DA are different between the two strains, but in contrast to amphetamine, these differences are dose-dependent. LEW rats generally showed a more pronounced behavioral response than F344 rats at all four doses. However, differences in extracellular DA were seen only at the two lower COC doses, with LEW rats showing a more prolonged increase than F344 rats. As reported previously, the basal extracellular concentrations of DA and the DA metabolites did not differ between the two strains. Experiments are currently in progress to address whether the effects observed are due to pharmacokinetic differences between LEW and F344 rats. Supported by NIDA grant #04294.

509.8

CONTEXT-DEPENDENT AMPHETAMINE SENSITIZATION AND S. Anagnostaras, A. Badiani and T. E. Robinson*. Psychology and Neuroscience Program, Univ. of Michigan, Ann Arbor, MI 48104

The context in which amphetamine (AMPH) is administered influences subsequent drug effects. We report here on experiments designed to explore context-dependent sensitization in rats given repeated injections of AMPH. The behavioral effect of AMPH was quantified by measuring rotational behavior in rats with unilateral 6-OHDA lesions. Animals were given ten injections of 2-3 mg/kg d-AMPH or saline (daily or every 3-4 days) in a group-specific environment (e.g., home cage, rotometer, alternate environment, or multiple environments). All animals given AMPH showed marked sensitization in the drug-paired environment. However, when given a challenge injection of AMPH in a test environment (rotometer), that was novel to some groups but not to others, only animals that had previously received AMPH in this environment showed evidence of sensitization. Animals for which this was a new environment behaved like saline-pre-treated controls, despite showing marked sensitization in their drug-paired environment. However, animals that received injections in multiple environments (but not the rotometer) showed moderate sensitization in the rotometer. These context-specific effects of AMPH were not diminished by a ten trial extinction procedure in which all animals received saline in the challenge environment. In summary, these experiments illustrate that the behavioral sensitization produced by AMPH can be highly context-dependent, even following the repeated administration of relatively high doses. Studies are in progress using microdialysis to assess the neurochemical consequences of context-specific AMPH sensitization on dopamine neurotransmission.

509.9

CHARACTERIZATION OF BEHAVIOR AND EXTRACELLULAR DOPAMINE IN THE NUCLEUS ACCUMBENS DURING AMPHETAMINE WITHDRAWAL. P. E. Paulson* and T. E. Robinson. Dept. of Psych. and Neuroscience Program, Univ. of MI, Ann Arbor, MI 48109

The discontinuation of chronic amphetamine (AMPH) use results in a 'distress syndrome' in humans, including symptoms of depression and dysphoria. In rats, the discontinuation of repeated AMPH treatment produces a 'behavioral depression', including marked nocturnal hypoactivity. In rats, this symptom of AMPH withdrawal persists for 1-2 weeks following the discontinuation of pretreatment with escalating, but non-neurotoxic, doses of AMPH. The present experiment was designed to further characterize the behavioral and neurochemical consequences of this AMPH withdrawal syndrome. To do this, spontaneous locomotor activity and the extracellular concentrations (EC) of DA in the nucleus accumbens were continuously monitored over 20 minute intervals across the entire day-night cycle in AMPH pretreated and saline pretreated control rats at 3, 7 and 28 days after the discontinuation of AMPH pretreatment, using a fully automated *in vivo* microdialysis system. Hypoactivity was evident during the initial 3-7 days of AMPH withdrawal, however, preliminary analyses indicate that there was no effect of AMPH withdrawal on the basal EC of DA in the nucleus accumbens. In addition, there was no effect of AMPH pretreatment during the initial 3-7 days of AMPH withdrawal on AMPH-stimulated DA release. However, a challenge injection of AMPH given 28 days after the discontinuation of AMPH treatment produced enhanced locomotor activity and AMPH-stimulated DA release, relative to saline pretreated controls.

NOVELTY ENHANCES THE DEVELOPMENT OF SENSITIZATION TO THE PSYCHOMOTOR STIMULANT EFFECT OF AMPHETAMINE. A. Badiani*, S. Anagnostaras and T.E. Robinson. Dept. of Psychology and Neuroscience Program, University of Michigan, Ann Arbor, MI 48104, USA.

It has been suggested that the activation of the hypothalamic-pituitary-adrenal (HPA) axis plays an important role in the development of sensitization to the psychomotor activating effects of amphetamine. To explore this hypothesis we compared the rate of sensitization in rats treated repeatedly with amphetamine, either in their home cages or during exposure to a novel test environment, which is known to activate the HPA axis. The animals first received a unilateral 6-OHDA lesion of the nigrostriatal DA system. Following at least two weeks of recovery from surgery, the rats received ten daily IP injections of 2 mg/kg of amphetamine, either in their home cages (group HOME) or in test cages (group TEST), and rotational behavior was quantified. The HOME cages and TEST cages were physically identical. The rats in group TEST, however, lived in stainless steel hanging cages and were transferred to the TEST cages described above for each test session. Group HOME rats lived and received drug injections in these cages. The first injection of amphetamine produced significantly more rotational behavior in group TEST than in group HOME. Furthermore, the rate of sensitization was greater in group TEST ($p < 0.001$). It is possible that the effect of novelty on the initial response to amphetamine was due to differential activation of the HPA axis, and that learning factors magnified this effect with repeated drug pairing. Studies to further examine the role of the HPA axis in this phenomenon are in progress.

AMPHETAMINE ANALOGS HAVE DIFFERENTIAL EFFECTS ON BEHAVIOR. J.B. Richards*, K.E. Sabol, K.E. Layton, L.S. Seiden. University of Chicago, Department of Pharm/Phys Sci., Chicago, IL 60637.

The effects of amphetamine (AMPH), methamphetamine (METH), methylenedioxymethamphetamine (MDMA), para-chloroamphetamine (PCA), and fenfluramine (FEN) were determined in rats trained on a differential-reinforcement-of-low-rate-36-second schedule (DRL 36-s). The DRL 36-s schedule requires animals to wait at least 36 seconds between responses in order to gain access to a reinforcer (.05 ml water). Training on the DRL 36-s schedule results in a highly organized pattern of behavior. This behavioral pattern can be visualized by examining the distribution of interresponse times (IRTs). The IRT distributions of rats trained on the DRL 36-s schedule have large well defined peaks near the 36-s requirement for reinforcement. These peaks can be quantitatively characterized by determining the peak area (PKA) and peak location (PKL). AMPH and METH induced large increases in response rate of 298% and 212% respectively (% = percent of control). MDMA and PCA caused smaller increases in response rate 120% and 129% respectively. FEN did not increase response rate. All five drugs decreased response rate at high doses. AMPH, METH, MDMA and PCA shifted the PKL toward shorter intervals (AMPH = METH > PCA > MDMA). FEN did not shift the PKL. All five drugs (including FEN) caused a dose dependent decrease in PKA, indicating a loss of schedule control by the DRL 36-s contingency. The differential effects on behavior are consistent with the different capacities of the amphetamine analogs tested to release dopamine and serotonin. Dopamine release induced by amphetamine analogs may increase response rate, shift the PKL toward shorter IRT durations and decrease PKA. Serotonin release (in the absence of dopamine release) may simply decrease PKA. (Supported by: MH-11191; RSA-10562, L. Seiden)

BEHAVIORAL SENSITIZATION TO AMPHETAMINE IN LEWIS AND FISCHER RAT STRAINS. K. E. Browman*, K. J. Kerwin, and T. E. Robinson. Department of Psychology and Neuroscience Program, The University of Michigan, Ann Arbor, MI 48104.

Lewis (LEW) and Fischer (F344) rats are two inbred strains that represent genetically divergent populations known to differ in their propensity to self-administer a variety of drugs of abuse. LEW rats more readily self-administer opiates, cocaine and ethanol, and also show enhanced amphetamine (AMPH)-stimulated motor activity and AMPH stimulated dopamine (DA) release, relative to F344 rats. The susceptibility to self-administer AMPH has been linked to the susceptibility to sensitization produced by repeated AMPH treatment. The purpose of this experiment, therefore, was to determine if the LEW and F344 rat strains differ in the rate or extent of behavioral sensitization to AMPH. In one experiment, rats were given unilateral 6-hydroxydopamine (6-OHDA) lesions of the nigrostriatal bundle, so the sensitization of rotational behavior could be quantified. In a second experiment, AMPH-induced locomotor activity and stereotyped behavior was quantified. All animals received either 2 mg/kg of AMPH or saline every three to four days for a total of five injections. Preliminary data suggest that genetic differences play a role in an animal's susceptibility to sensitization, in strains known to differ in their propensity to drug self-administration. Results will be presented at the meeting.

INDIVIDUAL DIFFERENCES IN RESPONSIVENESS TO NOVELTY AND AMPHETAMINE IN RATS P.M. Robinet*, J.K. Rowlett & M.T.

Bardo, Dept Psychol, Univ Kentucky, Lexington, KY 40506. Previous

work has shown that individual differences in locomotor behavior in an inescapable novel environment predicts the locomotor-stimulant effect of amphetamine. This study assessed if novelty-seeking behavior in a free choice situation also predicts the locomotor-stimulant effect of amphetamine. Rats were first confined to an inescapable novel environment in which activity was recorded. After two habituation days, the animals were allowed free access between this environment (familiar) and a novel environment to assess their place preference. To further assess free choice novelty-seeking behavior a novel object was introduced into the animal's home cage. Approach and contact behaviors with the novel object were recorded for 15 min. All animals then received amphetamine (cumulative dose 0.0, 0.1, 0.4, 1.6 mg/kg) and locomotor activity was recorded. Correlational analyses showed a relationship between locomotor activity in the inescapable novel environment and locomotor response to amphetamine at low doses. However, novelty-seeking behavior, as defined by the place preference and novel object tests, was not correlated with the locomotor response to amphetamine at any dose. This suggests the possibility of different mechanisms mediating novelty-induced reward and novelty-induced locomotor activity.

CONDITIONED TASTE AVERSION IN RATS INDUCED BY THE α 1-ADRENOCEPTOR AGONIST CIRAZOLINE L.R. McMahon, A. Morien, P.J. Wellman* and B. Davies. Dept. of Psych., Texas A&M Univ., College Station, TX 77843.

Recent studies have indicated that α 1-adrenoceptor agonists such as phenylpropranolamine (PPA), cirazoline, amidephrine, and SK&F-89748 suppress food intake in rats. These compounds activate α 1-adrenoceptors within the paraventricular hypothalamic nucleus (PVN) and may excite efferent fibers which inhibit feeding. Studies of the effects of α 1-agonists suggest a specificity for feeding behavior, but no study to date has evaluated whether these agonists may suppress feeding behavior by the induction of malaise. Accordingly, the present experiment compared cirazoline (0, 0.1, 0.2, 0.4 mg/kg, IP) with lithium chloride (32 mg/kg, IP) using the conditioned taste aversion (CTA) paradigm. Systemic administration of 0.1, 0.2 and 0.4 mg/kg cirazoline as well as 32 mg/kg lithium chloride induced significant conditioned aversion to saccharin compared to the vehicle treatment. In contrast to its activity on food intake, cirazoline did not induce dose-dependent aversion to saccharin. This difference in activity suggests that malaise is not a prominent factor in the feeding-suppressive activity of cirazoline. These results may support the use of cirazoline as an effective appetite suppressant.

510.1

ENVIRONMENTAL MODULATION OF BOTH LOCOMOTOR RESPONSE AND LOCOMOTOR SENSITIZATION TO THE DOPAMINE AGONIST QUINPIROLE. H. Einat^{1*} and H. Szechtman^{1,2} Departments of Biomedical Sciences¹, Psychiatry and Psychology² McMaster University, Hamilton, Ontario, Canada L8N 3Z5

The study tested whether differences in locomotor activation during chronic treatment result in differential behavioral sensitization induced by the D2/D3 dopamine agonist quinpirole. One group of rats received repeated injections of quinpirole in their home-cage and another group received this treatment in an alternate environment of similar size. In the home-cage, quinpirole induced less locomotion than in the non-home environment. When tested in activity monitors at end of chronic treatment, the home-cage group showed less sensitized locomotion to quinpirole than the non-home-cage rats. Thus, extent of locomotor sensitization to quinpirole appears related to the amount of locomotion characteristic of the training environment. Such differential sensitization may reflect experiential and environmental factors modulating the hierarchy of expression of quinpirole-enhanced hyperactivity.

LEVELS OF TYROSINE HYDROXYLASE ARE ELEVATED IN THE LOCUS COERULEUS FROM SUICIDE VICTIMS. Gregory A. Ordway¹ & John W. Haycock. Depts. of Psychiatry & Pharmacology, Case Western Reserve Univ., Cleveland, OH 44109, and Dept. of Biochemistry & Molecular Biology, Louisiana State Univ. Med. Center, New Orleans, LA 70119

Alterations in brain norepinephrine have been implicated in depression, schizophrenia, and anxiety. The locus coeruleus (LC) is the principal source of brain norepinephrine, and biosynthesis of this monoamine is controlled by tyrosine hydroxylase (TH). TH expression in LC neurons can be influenced by psychoactive drugs (e.g. antidepressants) and by environmental stimuli (e.g. stress). The present study investigated whether aberrant levels of TH would be found in the LC from brains of suicide victims. Blot immunolabeling techniques were used to quantitate TH protein levels in tissue sections containing LC from 9 pairs of antidepressant-free suicide victims and age-matched, sudden death controls. More TH protein was present in sections from suicide victims in each of the 9 matched pairs (108 to 172% of controls, $\bar{x} = 136\%$, $p < 0.005$). By contrast, there were no differences in neuron-specific enolase in the same samples (90 to 114% of controls, $\bar{x} = 103\%$) or in the number of cells containing neuromelanin in adjacent sections of LC. Elevated TH in LC of suicide victims may reflect increased expression resulting from exposure to higher levels of stress. Alternatively, higher TH levels in LC may be a primary factor in the pathophysiology leading to suicide. [Supported by NARSAD, and USPHS MH46892, MH00967, and MH46653.]

STRIATAL DOPAMINE AND ITS RELATIONSHIP TO OPEN FIELD MOTOR BEHAVIOR IN NORMAL RATS. L. McCoy, S.B. Schwarzkopf, E.K. Richfield¹, and M. Hadjicostantinou. Depts. of Psychiatry and Neurology, University of Rochester, Rochester, NY 14627 and Depts of Pharmacology and Psychiatry, The Ohio State University, Columbus OH, 43210.

Midbrain dopamine circuits modulate the complex cognitive and sensorimotor activities of the striatum. The dorsal striatum is involved in gross motor control while the ventral striatum may be more critical to motivation-linked motor behavior. Previous data has shown higher striatal dopamine to be associated with more exploratory behavior and less freezing behavior in the normal rat. In the present study, we were interested in the relationship between regional striatal dopamine (DA) measures and open field behavior in adult male Sprague-Dawley rats (N=24). Behavioral measures included global locomotor, exploratory, vertical (rearing) and fine repetitive motor activity. DA measures included DA and its metabolites (DOPAC and HVA), and D1, D2 and dopamine uptake complex (DAUC) densities. Brains were obtained after rapid decapitation (age 120 days), halved through the midline then immediately frozen. One half-brain was used for determining dorsal or caudate/putamen and ventral or nucleus accumbens (NAC) dopamine chemistries using high performance liquid chromatography. The second half-brain was used for measuring DA receptor and reuptake complex densities using quantitative autoradiography. In these animals, specific motor behaviors were found to correlate with regional differences in striatal DA activity. DAUC, or the density of dopaminergic terminals in the striatum, was positively correlated ($r=.62$, $p<.005$) with exploratory behavior. Amount of exploratory behavior also predicted a higher D2 receptor dorsal/ventral gradient (trend). NAC dopamine was associated with rearing ($r=.74$, $p<.01$). These results suggest that normal variation in rat open field motor behavior is associated with central dopaminergic interactions between the dorsal and ventral striatum. (Supported by MH00859 and MH40381)

510.2

RELEASE OF BEHAVIORAL INHIBITION BY DOPAMINE DEPLETIONS OF THE PREFRONTAL CORTEX IN THE RAT. J.D. Sokolowski^{*}, M.S. Cousins, & J.D. Salamone Dept. of Psychology, University of Connecticut, Storrs, CT 06269-1020.

Experiments were conducted to characterize the behavioral effects of medial pre-frontal cortex (MPFC) dopamine (DA) depletions. Using an active avoidance paradigm, in which nucleus accumbens DA depletions previously were demonstrated to produce profound impairments in avoidance responding, there was no impairment in MPFC DA-depleted animals. In a passive avoidance punished lever pressing paradigm, MPFC DA depletions resulted in a slight increase in punished responses. MPFC DA depletions also increased amphetamine-induced locomotor activity and stereotypy. Finally, in a study investigating performance on a DRL30 schedule of reinforcement, in which animals must withhold their responses for 30 seconds in order to receive reinforcement, rats receiving DA-depleting lesions in the MPFC exhibited several different impairments. These animals had a higher number of total lever presses, a lower efficiency (reinforcers/lever presses), and showed a bursting pattern of responses as calculated by an inter-response time measure. These results support the notion that MPFC DA is involved in behavioral inhibition.

510.4

BEHAVIORAL AND BIOCHEMICAL RESPONSES TO STRESS IN RATS SELECTIVELY BRED FOR SWIM TEST ACTIVITY. C.H.K. West^{*}, P.M. McCurdy, R.W. Bonsall and J.M. Weiss. Lab of Behavioral Neuroscience & Neuroimmunology, Dept. Psychiatry, Emory Univ. Sch. Med., Atlanta, GA 30306.

Performance in a swim test has been used as the criterion by Weiss and colleagues (Cierpial et al.[1989] *Soc. Neurosci. Abstr.*, 15: 1176) for selectively breeding rats in an attempt to improve animal models of depression. Animals have been selectively bred for high (SwHi) or low (SwLo) activity in the swim test, with SwHi's showing much struggling and little floating and SwLo's showing the reverse. Since previous testing revealed that SwHi's and SwLo's do not differ in their home-cage day or night activity under non-stressful conditions, here we compared them for their motor and corticosterone responses in two additional stressful situations which may be expected to evoke active responses. Male and female SwHi's and SwLo's (13th generation) were tested for (1) activity in the swim test, (2) locomotor activity in a novel environment (LocAct), and (3) immobility in the Porsolt test. Following testing, rats were sacrificed and serum corticosterone levels determined. In the swim test, SwHi's as expected spent much time struggling whereas SwLo's spent most of their time floating. In LocAct tests, SwHi's were more active than SwLo's during the first few min of the 1 hr test, and this difference was more pronounced for females than males. In the Porsolt test, time of immobility differed moderately, but jumping behavior differed dramatically. SwLo's jumped very little (max. = 17) whereas the mean jumps by SwHi's was 75 ± 12 for males and 61 ± 4 for females. Corticosterone levels were elevated by behavioral testing compared to home-cage controls, but levels for SwHi's and SwLo's did not differ significantly. The results indicate that SwHi's and SwLo's, which do not show behavioral differences under non-stressful conditions, also differ little in steroid reactivity to stress, but these lines of selectively-bred animals differ distinctly in their initiation of motor responses to stressful, arousing conditions. Supported by the Stanley Foundation of the National Alliance for the Mentally Ill.

PHARMACOLOGICAL EFFECTS OF MKC-242: A NOVEL POTENTIAL ANXIOLYTIC AND ANTIDEPRESSANT COMPOUND WITH SELECTIVE 5-HT_{1A} AGONISTIC PROFILE. M.Egawa, M.Abe, R.Tabata, K.-I. Saito^{*}, A.Tobe, T.Matsuda# and A.Baba#. Pharmaceuticals Laboratory I, Research Center, Mitsubishi Kasei Co, Yokohama 227, Japan. #; Dept of Pharmacology, Faculty of Pharmaceutical Science, Osaka University.

The new alkylenedioxybenzene derivative, MKC-242, showed selective and high affinity for 5-HT_{1A} receptors in radioligand binding study in rat brain ($K_i=0.11nM$). The affinity for other 5-HT receptor subtypes, dopamine D₁ and D₂, 2 adrenoceptor, GABA_A and benzodiazepine receptors were low. MKC-242 was found to inhibit forskolin-stimulated adenylyl cyclase activity ($IC_{50}=2.4nM$). MKC-242 (3 mg/kgpo) reduced the 5-HT synthesis in rat midbrain and hippocampus without any influences on dopamine. Head weaving behavior was produced by MKC-242 alone (1mg/kgpo) and MKC-242 antagonized this syndrome induced by 8-OH-DPAT. In behavioral testing, MKC-242 showed a long-lasting anticonflict activity in rats at very low doses (MED=0.0625mg/kgpo). There was no reduction in this effect by repeated treatments of MKC-242. MKC-242 clearly shortened immobility time in forced swimming test (MED=0.25mg/kgip) and its potency was equal to that of amitriptyline (10mg/kgip). In restraint stress model of depression, the ability of MKC-242 to antagonize the decreased locomotion was observed, dose-dependently. These results suggest that MKC-242 may be of therapeutic value in the treatment of anxiety or depressive disorders.

INFANT RATS' DOPAMINERGIC RESPONSE TO THE STRESS OF ISOLATION IN A NOVEL ENVIRONMENT. P. Kehoe*, H. Chandler, K. Skipsey, & K. Clash, Neuroscience Program, Trinity College, Hartford, CT 06106

Stress in adult rats produces an increase in both dopamine (DA) turnover and levels of synaptic DA. In guinea pig pups, isolation in a novel environment produces an increase in DA turnover. The present study assessed rat pup DA response to isolation with and without familiar cues. Pups were isolated for 5 min in a familiar (cup with bedding) or novel environment (plain box) and compared to siblings remaining in the nest. In Exp. 1, following isolation the striatum and septum were assayed by HPLC for DA utilization. In Exp. 2, pups were injected with the radioactive D2 antagonist raclopride following isolation. After 20 min the brain was removed and the striatum, septum and hypothalamus were assessed for radioactivity. In Exp. 3, punches of striatal, septal and hypothalamic tissue were incubated *ex vivo* with 3H-raclopride. The results showed that DA turnover was significantly higher in striatal and septal tissue for pups isolated in a novel environment. In both binding experiments, radioactivity in all 3 brain parts was significantly less in animals isolated in the novel environment which implies fewer available D2 receptors. Taken together, these data suggest that isolation in the novel environment and not one with familiar cues causes a DA release at the synapse.

510.9

THE EFFECTS OF L-DEPRENYL ON MOTORIC CAPACITY AND NOVELTY-INDUCED BEHAVIOR IN THE RAT. M.P. Murphy, N.W. Milgram and G.O. Ivy*, Univ. of Toronto, Div. of Life Sciences, Scarborough, ONT, Canada, M1C 1A4.

We have investigated the possibility that l-deprenyl (DEP), an MAO-B inhibitor used in the treatment of Parkinson's Disease, may attenuate the decay of motoric function in the aged rat. Male and female F344 rats (N=20 of each; 13-14 months old) were given either oral DEP (1.0 mg/kg) or vehicle (0.9% saline) 3 times/week for either 4 or 11 months. Animals were evaluated in several tests sensitive to motor function (tilting plane, wire suspension, horizontal bar), and in a novel open-field arena (10 minutes/day for 3 days). DEP had no effect on measures of motor performance, and did not alter locomotor/exploratory activity in the open-field, but was found to increase grooming ($F_{1,32} = 9.57, p < 0.01$). Since novelty-induced grooming (linked to mild anxiety in the rat) is known to be mediated by dopamine (DA), this effect may be due to increased DA availability. Alternatively, elevated phenylethylamine, a known DA agonist with mild anxiogenic properties, may be responsible. These results raise the possibility that chronic DEP treatment may result in a mildly elevated stress response in the rat. Supported by Deprenyl Animal Health.

510.11

AN INVESTIGATION OF STARTLE REACTIVITY, PREPULSE INHIBITION, AND HABITUATION IN FLINDERS SENSITIVE HYPER-CHOLINERGIC, AND FLINDERS RESISTANT RATS. A. Markou*, K. Matthews², M.A. Geyer³, D.H. Overstreet⁴, and G.F. Koob¹. ¹Dept of Neuropharmacology, The Scripps Research Institute, La Jolla, CA, U.S.A. ²Dept of Mental Health, Univ of Aberdeen, Scotland, U.K. ³Dept of Psychiatry, Univ of California, San Diego, U.S.A. ⁴Univ of North Carolina, Chapel Hill, NC, U.S.A.

The Flinders Sensitive (FSL) and Resistant (FRL) Lines of rats have been selectively bred to differ in their sensitivity to the anticholinesterase diisopropyl fluorophosphate (DFP). The hypercholinergic FSL rats, which exhibit enhanced oxotremorine-induced hyperthermia, have been proposed as an animal model of depression based on behavioral, endocrinological, and pharmacological evidence. Because FSL rats have been reported to be "hyper-responsive" to environmental stimuli, the response of the FSL, FRL and outbred Sprague-Dawley control rats to startling acoustic stimuli was investigated. Both FSL and FRL rats showed decreased startle thresholds compared to controls, even though no differences were observed in startle response magnitude at high (120dB) stimulus intensities. Further, all three groups demonstrated robust prepulse inhibition. Interestingly, the FRL showed a sensitization of startle response magnitude across trials, while the FSL rats exhibited habituation of the startle response, similar to that observed in the control animals. Further, the FRL exhibited increased latency to peak startle response compared to both FSL and controls. The decreased startle thresholds exhibited by both FSL and FRL rats further demonstrate the "hyper-sensitivity" of Flinders rats to environmental stimuli, while the sensitization of startle response magnitude exhibited across trials by the FRL provides one of the few indications that the FRL exhibit behavioral differences in relation to control animals.

UNILATERAL 6-HYDROXYDOPAMINE LESIONS OF THE MEDIAL PREFRONTAL CORTEX INTERACT WITH INTRINSIC DOPAMINE ASYMMETRY TO DIFFERENTIALLY ALTER NUCLEUS ACCUMBENS DOPAMINE TURNOVER FOLLOWING A FOOTSHOCK STRESSOR. J.N. Carlson*, E.M. Rutledge, K.E. Visker, R.W. Keller, Jr. and S.D. Glick, Dept. of Pharmacology and Toxicology, Albany Medical College, Albany, NY 12208

We have previously shown that a footshock stressor causes lateralized changes in the metabolic activation of dopamine (DA) neurons whose terminals project to the medial prefrontal cortex (PFC) in the rat. The nature of these changes was dependent upon the animal's prior experience with coping with stressors as well as its preexisting turning bias. Animals responding to stress with predominant left or right PFC DA activation displayed effective and ineffective footshock escape behavior, respectively. PFC DA activity has been shown to modulate DA activity in the nucleus accumbens (NAC) and striatum. In the present study we have attempted to assess a specific role for lateralized PFC DA function in the stress response by determining the effects of unilateral lesions on behavior and subcortical DA function. Male Long-Evans rats displaying left or right turning preferences received unilateral PFC 6-hydroxydopamine (6OHDA) lesions and were then tested three weeks later. Both left and right lesions caused a leftward shift in turning behavior of all rats. Lesions on either side caused an increased DOPAC/DA ratio in the NAC of left-biased rats in response to a footshock stressor. However, right-sided lesions in right-biased rats caused a diminished NAC DOPAC/DA ratio as compared to sham lesioned controls. Lesions on either side interacted with turning bias to alter asymmetrically striatal DOPAC levels following footshock. These findings demonstrate a lateralized interaction between cortical and subcortical DA systems during stress and suggest an explanation for the previously observed increased susceptibility of right-biased rats to the aftereffects of uncontrolled stressors. AN INVESTIGATION OF BRAIN STIMULATION-REWARD THRESHOLDS AND SPONTANEOUS LOCOMOTOR ACTIVITY IN FLINDERS SENSITIVE HYPERCHOLINERGIC RATS. B.A. Baldo*¹, K. Matthews², A. Markou, I. O. Lown¹, D.H. Overstreet³, and G.F. Koob¹. 1- The Scripps Research Institute, La Jolla, CA, U.S.A. 2- Dept of Mental Health, Univ. of Aberdeen, Scotland, U.K. 3- Univ of North Carolina, Chapel Hill, NC, U.S.A.

The Flinders Sensitive (FSL) and Resistant (FRL) Lines of rats have been bred based on their thermic response to the cholinesterase inhibitor, diisopropyl fluorophosphate. The hypercholinergic FSL rats, which display augmented oxotremorine-induced hypothermia, have been proposed as an animal model of depression. Since anhedonia is one of the core symptoms of depression, an attempt was made to determine whether FSL rats differed from FRL rats and outbred Sprague-Dawleys with regard to brain stimulation-reward (BSR) thresholds. Changes in BSR thresholds were measured in all strains following systemic administration of the indirect dopamine agonist cocaine (10 mg/kg), the dopamine D1 receptor antagonist SCH 23390 (0.02 mg/kg), the cholinergic muscarinic antagonist scopolamine (0.1 mg/kg), and the serotonin reuptake blocker fluoxetine (10 mg/kg). Cocaine significantly lowered BSR thresholds, and SCH 23390 and scopolamine significantly elevated BSR thresholds, in all strains. Fluoxetine produced non-significant elevations in BSR thresholds. No statistically reliable between-strain differences were detected in baseline BSR thresholds, or in response to any of the drug challenges. In a second experiment, unconditioned locomotor activity was monitored in all strains. In agreement with previous research, FSL rats were found to show significantly lower levels of spontaneous locomotor activity than FRL rats or outbred Sprague-Dawley control rats. In summary, functional assessment of CNS reward pathways using the BSR technique did not differentiate FSL rats from FRL or control animals. However, it was determined that FSL rats exhibit decreased activity levels, which may reflect alterations in their cholinergic systems.

EFFECTS OF LESIONS OF THE DORSAL NORADRENERGIC ASCENDING BUNDLE ON SHOCK-INDUCED FREEZING AND VOCALIZATION IN RATS.

Artur H. Swiergiel* and Adrian J. Dunn.

Dept. of Pharmacology, Louisiana State University Medical Center, Shreveport, LA 71130-3932.

Previously, we reported that lesioning of the noradrenergic (NE) neurons in the locus coeruleus (LC) with the neurotoxin DSP-4 potentiated the duration of footshock-induced freezing and increased ultrasonic vocalization. Conditioned freezing and vocalization were not affected. Because peripherally administered DSP-4 lesions both ascending and descending LC projections, we studied 6-OHDA lesions of the dorsal noradrenergic ascending bundle. Footshock-induced freezing and vocalization and conditioned freezing and vocalization were observed 96 and 120 hr, respectively, after the lesions, and in another group of rats 6 weeks after the lesions. There were no significant changes in behavioral patterns in rats observed shortly after the lesions. However, 6 weeks after the lesions, footshock-induced vocalization was potentiated by 292%. The lesions did not alter the responses evoked by re-exposure to the cages in which footshock was administered. Thus vocalization was affected by painful stimuli (footshock), but not by nonpainful (conditioned) stimuli. The LC-NE system is considered to play an important role in mediating behavioral responses observed in animal models of fear and anxiety. These results suggest that LC-NE system may play a role in stress induced vocalization, perhaps by modifying sensitivity to pain during footshock.

LOW DOSES OF APOMORPHINE (APO) RESEMBLE HALOPERIDOL (HAL) AND NOT AMPHETAMINE (AMPH) AS REVEALED BY HIGH RESOLUTION ANALYSIS OF MOTOR PERFORMANCE. X. Liu, R.E. Strecker*, and J. Brener*. Depts of Psychology and *Psychiatry, SUNY, Stony Brook, NY.

Sensitive behavioral measures are needed to detect subtle changes in motor and sensorimotor performance in subjects with neurological impairment. Operant cages, equipped with 3 force beams serving as levers, were coupled to custom software allowing high resolution analysis of the kinematics of individual responses, as well as analysis of sequential behavior. As a first step toward addressing the role of dopaminergic mechanisms and the basal ganglia in motor performance, rats were injected with dopaminergic (DA) drugs prior to testing. Low doses of Apo (.03, .1, .3 mg/kg, sc) and Hal (.04, .08, .16 mg/kg, ip) had qualitatively similar effects on kinematic performance that differed from the effects of Amphetamine (.1, .3, 1.0 mg/kg, ip). Apo and Hal produced dose dependent decreases in response rate, peak force and the rate of change of force (dF/dT), and increases in response duration. In contrast, Amphetamine produced no change in response rate or dF/dT, a slight increase in peak force and an increase in response duration. These data indicate that Apo and Hal produced less frequent and weaker beam presses, effects that are consistent with a decrease in dopaminergic tone. Analysis of behavior sequences revealed that all 3 drugs produced dose-dependent suppression of normal response sequences and increases in abnormal sequences. Non-productive repetitive behavioral sequences (stereotyped behavior) were also observed, especially for Apo and Hal. The behavioral effects of selective DA lesions will also be presented. The behavioral effects of DA drugs measured with this high resolution behavioral analysis are consistent with previous reports based on low resolution analysis (ambulation); however, the present method was more sensitive and provided additional information about motor control processes.

EFFECT OF NOVEL STRESSORS ON THE BEHAVIOR AND CENTRAL NORADRENERGIC SYSTEM IN SPRAGUE-DAWLEY (SD) AND WISTAR-KYOTO (WKY) RAT STRAINS. W. P. Pare*, J. Yang* & S. M. Tejani-Butt*, 1VA Med. Center, Perry Point, MD 21902 and 2Dept. Psychiatry, Univ. of Penn. Sch. of Med., Phila, PA 19104.

This study compared the effects of repeated novel stressors on "depressive behavior", defined by the forced-swim and open-field tests, in SD and WKY rat strains. Since stress appears to alter brain norepinephrine (NE) activity, this study also investigated the effects of the stressors on β -adrenoceptors (β ARs) and NE transporter (NET) sites in SD and WKY rats. Stress did not alter 125 I-iodopindolol (125 I-IPIN) binding to β ARs, nor 3 H-nisoxetine (3 H-NIS) binding to NET sites in SD rats, compared to non-stressed controls. However, WKY-stressed rats showed a significant reduction ($p < 0.05$) in 125 I-IPIN binding to β_1 ARs in the hippocampus (HIP) and amygdala (AMYG) and to β_2 ARs in the AMYG and hypothalamus (HYPO). 3 H-NIS binding to NET sites in WKY-stressed rats was also reduced in the cortex (CTX), HIP and AMYG. When control rats from both strains were compared, the most surprising finding was a significantly higher density of NET sites in the CTX, HIP, AMYG and HYPO in WKY rats compared to SD rats. These results indicate that stress not only exacerbates "depressive behavior" in WKY rats, but selectively alters β ARs in the HIP and AMYG and NET sites in the CTX, HIP and AMYG. Thus the WKY strain may serve as an useful animal model of depressive behavior. (Research funds from the VA Medical Research Service and from USPHS grant MH 45472 (S.T-B)).

TOPOGRAPHIC ANALYSIS OF BRAIN DOPAMINERGIC NEURON SYSTEMS IN RATS SHOWING SELF-MUTILATION BEHAVIOR FOLLOWING NEONATAL 6-HYDROXYDOPAMINE TREATMENT. 1. IMMUNOCYTOCHEMICAL STUDY OF DOPAMINERGIC NEURONS. C. Yokoyama, H. Okamura*, T. Nakajima, Y. Iwata. Depts. of Psych. & Anat., Kyoto Pref. Univ. of Med., Kyoto 602, Japan.

Neonatal intracisternal treatment of 6-hydroxydopamine (6-OHDA) destroys brain dopaminergic (DA) neurons, and induces self-mutilation behavior (SMB) at adult age after loading L-DOPA. Although behavioral and pharmacological studies have made important discoveries, precise mechanism of SMB is still obscured. To localize the brain region important for SMB, in the series of experiments, we analyze region-specific alternation of neurotransmitters and receptors in rats showing SMB. In the first step of this experiment, we investigated the extent of the damaged DA neuronal area in SMB rats by ABC-immunocytochemistry using anti-tyrosine hydroxylase serum. Desipramine pretreated (20 mg/kg) neonatal Wistar rats were injected with 6-OHDA (100 μ g/5 μ l with 0.1% ascorbic acid in saline) intracisternally, and for control, the same solution without 6-OHDA was injected. The behavior after Ro-4-4602 (50 mg/kg) and L-DOPA (100 mg/kg) loading was evaluated at 6 weeks of age, and the rats were divided into three groups; neonatal 6-OHDA treated rats showing SMB (SMB+) group, neonatal 6-OHDA treated rats not showing SMB (SMB-) group, and neonatal saline treated rats (control group). The DA depleted area of SMB(-) group was restricted in the nigrostriatal DA system, while that of SMB(+) group was observed in both the nigrostriatal and the ventral tegmental area (VTA)-ventral striatal DA systems. The DA neurons and terminals in the hypothalamus, the central nuclei of the ventral midbrain, the cerebral cortex and the insula of Calleja were affected in neither SMB(-) nor SMB(+). The results revealed that the neuronal damage on brain DA neurons following intracisternal neonatal 6-OHDA treatment shows region-specificity, and the severe destruction of VTA-ventral striatal DA neuron system is particular in SMB(+) group. The destruction of VTA-ventral striatal DA system may alter the neuronal activity in the ventral striatum, and that change may be one of causes of SMB.

510.14

SEROTONERGIC AND NORADRENERGIC LESIONS DO NOT ABOLISH THE BEHAVIORAL EFFECTS OF ANTIDEPRESSANTS IN THE FORCED SWIMMING TEST. A. Singh*, C.M. Andrews and J. Lucki Dept of Psychiatry, Univ of Pennsylvania, Philadelphia, PA 19104.

This study examined whether the functional integrity of the serotonergic or the noradrenergic system is necessary for the reductions of immobility time produced by antidepressants that are uptake inhibitors in the forced swimming test (FST). The ability of the serotonin and the norepinephrine selective uptake inhibitors, sertraline and desipramine respectively, to reduce immobility time was assessed following the destruction of serotonergic or noradrenergic neurons.

The FST was conducted as described previously (Wieland and Lucki (1990) Psychopharmacology 101: 497-504). Serotonin neurons were destroyed by bilateral injections of 5,7-DHT (200 μ g, icv), 30 min following pretreatment with desipramine (25 mg/kg, i.p.), to protect NE neurons. Noradrenergic neurons were destroyed using DSP-4 (50 mg/kg, i.p.), 1 h following pretreatment with fluoxetine (5 mg/kg, i.p.) to protect 5-HT neurons. The FST was conducted 10-15 days following neurotoxin administration. Rats received three subcutaneous injections, of sertraline or desipramine at time points corresponding to 0.5, 19 and 23 hours after the 15 min pretest swim session. Behavioral immobility was measured during a 5-min test session, which occurred one hour after the last injection. Doses of sertraline (80 mg/kg, s.c.) and desipramine (10 mg/kg, s.c.) were chosen from preliminary studies and represent doses that produced similar behavioral effects.

Destruction of 5-HT or NE neurons did not disrupt immobility time. Sertraline and desipramine were effective at reducing immobility time following the destruction of 5-HT or NE neurons, suggesting that intact nerve terminals are not necessary for their behavioral effects in the FST. These findings are at variance with our current understanding of the mechanism of therapeutic action of these compounds and suggest that their therapeutic effects *in vivo* may not be related only to their ability to block neurotransmitter uptake *in vitro*. Supported by USPHS grants MH 36262 and MH 48125.

SUCROSE CONSUMPTION AND CONTRAST SHIFTS IN SOCIALLY ISOLATED RATS. ES Hall*, T Humby, LS Wilkinson, TW Robbins. Dept. of Exp. Psych., Cambridge University, Cambridge, U.K.

Previous neurochemical and behavioral data suggesting altered mesolimbic dopamine (DA) function in rats reared in social isolation may predict altered response to rewarding stimuli, such as sucrose. In Experiment 1 socially-reared and isolation-reared rats were allowed to consume sucrose for 15 minutes each day in a lick chamber. Five concentrations of sucrose (0.7%, 2.1%, 7.0%, 21.0%, and 34.0%) were given in an ascending order, each for 3 days. There were no differences in consumption between the two rearing groups. In Experiment 2 socially-reared and isolation-reared rats were food and water deprived and allowed to consume sucrose at each of 3 concentrations (0.7%, 7.0%, and 34.0%). Again, there were no differences in consumption between groups. In Experiment 3 isolation-reared rats and socially-reared rats were exposed to 5 sucrose concentrations within the same 3 hour test session - five 5 minute periods of access to sucrose separated by 25 minutes. Subjects received sucrose in either an ascending or descending order of presentation to maximize positive and negative contrast effects respectively. Under these conditions, socially isolated rats consumed more sucrose regardless of the order of presentation. Thus socially isolated rats are more sensitive to positive contrast effect and less sensitive to negative contrast effects. These experiments suggest increased incentive-motivation in isolation-reared rats, perhaps as a consequence of altered mesolimbic DA function.

TOPOGRAPHIC ANALYSIS OF BRAIN DOPAMINERGIC NEURON SYSTEMS IN RATS SHOWING SELF-MUTILATION BEHAVIOR FOLLOWING NEONATAL 6-HYDROXYDOPAMINE TREATMENT. 2. RECEPTOR AUTORADIOGRAPHIC STUDY OF DOPAMINE D1 AND D2 RECEPTORS. H. Okamura, C. Yokoyama, F. Kawakami*, Y. Iwata, Department of Anatomy and Psychiatry, Kyoto Prefectural University of Medicine, Kawaramachi-Hirokoji, Kyoto 602, Japan.

The foregoing our immunocytochemical study has demonstrated that the neonatal 6-hydroxydopamine treatment induces region-specific destruction of dopaminergic neurons, and the extensiveness of the damaged area is related to the occurrence of self-mutilation behavior (SMB). As for the dopamine D1 and D2 receptors, however, no studies are performed focusing on SMB with particular attention to region specificity. In the present study, we investigated the alternation of D1 and D2 receptor bindings in the 6-OHDA treated rats showing SMB (=SMB+) group, not showing SMB (=SMB-) group, and the saline treated rats (=control group), by quantitative *in vitro* receptor autoradiography using [3 H]SCH-23390 for D1 site and [3 H]YM-09151-2 for D2 site. Autoradiography was performed in brain sections from rats at age 10-15 weeks, and sections were incubated with 0.5 nM [3 H]YM-09151-2 or 1 nM [3 H]SCH-23390 at 22 C, for 2 or 3 hours, respectively. Nonspecific bindings were determined in 10 nM (+)-butaclamol. The densities of [3 H]SCH-23390 and [3 H]YM-09151-2 binding in the caudate-putamen, the nucleus accumbens and the tuberculum olfactricum were not different among three groups. The binding densities of [3 H]YM-09151-2 in the substantia nigra pars compacta were decreased both in SMB(+) and SMB(-), while in the ventral tegmental area the binding densities were decreased only in SMB(+) compared with control. The binding densities of [3 H]SCH-23390 were increased in the substantia nigra pars reticulata in SMB(+) compared with that of SMB(-). The present results suggest that the induction of SMB following L-DOPA or dopamine D1 receptor agonist loading may be through the activation of upregulated D1 receptor in the substantia nigra pars reticulata.

511.1

IN SITU HYBRIDIZATION ANALYSIS OF NEUROPEPTIDE mRNA LEVELS IN LOCUS COERULEUS NEURONS FOLLOWING MORPHINE WITHDRAWAL IN RATS. P.V. Holmes*, A. de Bartolomeis, V. Koprivica, and J.N. Crawley. Section on Behavioral Neuropharmacology, Experimental Therapeutics Branch, NIMH, Bethesda, MD 20892.

The locus coeruleus (LC) contains galanin-like immunoreactivity or neuropeptide Y-like immunoreactivity coexisting with neurons containing tyrosine hydroxylase-like immunoreactivity. The firing rate of LC neurons is greatly enhanced during withdrawal from morphine. The hypothesis that this phenomenon is associated with altered expression of neuropeptide genes was tested. Rats received incremental doses of morphine or saline for one week. Withdrawal was induced in half of the morphine-treated rats by a single injection of naloxone. The remaining morphine-treated rats received an injection of saline. Characteristic signs of withdrawal, including wet dog shakes, teeth chattering, and diarrhea, were observed in morphine-treated rats injected with naloxone. Levels of mRNA encoding galanin and neuropeptide Y in the LC, and corticotropin-releasing factor and somatostatin in dorsal tegmental areas projecting to the LC, were analyzed by *in situ* hybridization. Neither the chronic morphine treatment nor naloxone-precipitated withdrawal consistently altered the expression of any of the peptide genes studied.

511.3

DOES MK-801 BLOCK NALOXONE-PRECIPIATED OPIATE WITHDRAWAL? K.A. Trujillo* and H. Aki, Mental Health Research Institute, University of Michigan, Ann Arbor, Michigan, 48109-0720.

We previously reported that the non-competitive N-methyl-D-aspartate (NMDA) receptor antagonist MK-801 inhibited the development but not the expression of physical dependence on morphine. In other words, MK-801 prevented the acquisition of physical dependence when coadministered with morphine, but would not block naloxone-precipitated withdrawal in animals in which dependence had already been acquired. Other laboratories, however, have reported that MK-801 blocks naloxone-precipitated withdrawal in morphine-dependent animals. The present experiment was performed to further examine the effects of MK-801 on naloxone-precipitated opiate withdrawal. Adult, male Sprague-Dawley rats received morphine (10 mg/kg s.c.) twice daily for 10 days. On day 11, animals received morphine, followed 30 minutes later by saline or MK-801 (0.1, 0.5 or 1.0 mg/kg i.p.). Withdrawal was precipitated by administration of naloxone (2 mg/kg s.c.) 30 minutes following the second injection, and animals were observed for signs of withdrawal and gross behavioral effects. MK-801 dose-dependently inhibited signs of naloxone-precipitated withdrawal, including jumping, paw shakes, mouth movements and ptosis, as well as the overall withdrawal rating. The inhibition of withdrawal, however, was accompanied by gross behavioral disturbance in these animals. The 0.1 mg/kg dose of MK-801 produced mild behavioral activation, while the 0.5 and 1.0 mg/kg doses produced effects ranging from ataxia and stereotyped head-weaving to flaccid paralysis. These results lead us to suggest that the effects of MK-801 resulted from the non-specific motor disturbance produced by this drug, rather than from a specific inhibition of the naloxone-precipitated withdrawal syndrome. The results are consistent with our suggestion that non-competitive NMDA receptor antagonists inhibit the development rather than the expression of opiate tolerance and dependence.

ATTENUATION OF CONDITIONED OPIATE WITHDRAWAL FOLLOWING EXCITOTOXIC LESIONS OF THE BASOLATERAL AMYGDALA. B.J. Everitt¹, G. Schulteis², and G.F. Koob². ¹Dept. of Anatomy, University of Cambridge, Cambridge, U.K., and ²Dept. of Neuropharmacology, The Scripps Research Institute, La Jolla, CA 92037.

The basolateral nucleus of the amygdala (BLA) participates in the acquisition of secondary reinforcing properties by stimuli paired with primary positive reinforcers, including drugs of abuse (Robbins & Everitt, *Seminars Neurosci.* 4:119, 1992). To test whether the BLA participates in conditioning of the aversive consequences of drug withdrawal, male Wistar rats were trained to press for food (FR 15) in daily 30 min sessions. After responding stabilized, half the rats received bilateral quinolinic acid (0.09 M) lesions of the BLA, with the other half receiving SHAM lesions. Following re-establishment of stable responding, all rats received morphine pellets (2 x 75 mg s.c.). Five days later, half of each group received an injection of naloxone (30 µg/kg s.c.) and was exposed to a light/ tone stimulus (CS) during a 20 min operant session, followed 4 hours later by a saline injection in their home cages (conditioned/COND). The other half received a saline injection paired with the CS, and naloxone 4 hours later in their home cages (pseudo-conditioned/PSEUDO). Responding was significantly suppressed during the naloxone/CS pairing in both COND-LESION and COND-SHAM groups. On the following day, when given a saline injection and presented with the CS a second time, the COND-SHAM group showed a significant reduction in responding relative to the COND-LESION group. PSEUDO-SHAM and PSEUDO-LESION animals showed no response suppression during the first or second CS presentation. Thus, conditioned withdrawal may be seen with one pairing of a CS and precipitated withdrawal, and lesions of the BLA significantly attenuate this conditioning process. Supported by DA04043.

511.2

IMMEDIATE EARLY GENE INDUCTION IN PRECIPITATED OPIATE WITHDRAWAL. Pastor Couceyro* and James O. Douglass. Vollum Institute, Oregon Health Sciences University, Portland, OR.

Physical dependence is perhaps the most detrimental liability of addictive drugs. No where is this better illustrated than in heroin addicts undergoing detoxification. "Withdrawal" is a rebounding homeostatic response to drug induced changes. This response could therefore serve as a model of adaptation and plasticity and hence, gene expression may be involved. To this end we have examined the expression of immediate early genes in the rat brain after precipitated opiate withdrawal. Gene expression for *c-fos*, *zif-268*, *junB* and *fosB*, was determined by slot blot and Northern blot analysis. The severity of dependence was controlled by varying the duration and dosage of opiate administration as well as the dose of naloxone (from 0.01 to 100 mg/kg) utilized to precipitate withdrawal. No alterations in mRNA levels for any of these transcripts was seen in withdrawal precipitated 72 hrs after implantation of a single morphine base pellet (75 mg). Transcriptional changes were noted after longer and larger morphine doses in two other studies. In the first, rats were implanted with one pellet every day for 7 consecutive days and withdrawal precipitated on day 8. In the second study, rats were treated on days 1 (1 pellet), 4 (2 pellets) and 7 (3 pellets) and withdrawal precipitated on day 10. Expression of *c-fos* was dramatically altered in the hypothalamus, cerebellum and striatum 1 hr after precipitated withdrawal in a naloxone dose-dependent fashion. Less robust changes were seen in other brain areas. Smaller and more brain region selective changes were noted for *zif-268* but the levels of *junB* and *fosB* mRNA were unaffected. Qualitatively greater changes were seen in the former study. We are in the process of a more detailed analysis using *in situ* hybridization. These observations suggest a role for altered gene expression in the homeostatic response of opiate withdrawal.

INTRACRANIAL SELF-STIMULATION DURING REPEATED MORPHINE TREATMENT AND MORPHINE WITHDRAWAL: A CURVE-SHIFT ANALYSIS. P. Baucó* and R.A. Wise. Center for Studies in Behavioral Neurobiology and Dept. of Psychology, Concordia Univ., Montréal, Canada, H3G 1M8.

Pothos et al. (*Br Res*, 1991, 556; 348-350) have reported a naloxone-induced decrease in nucleus accumbens dopamine (DA) levels after termination of a low-dose chronic morphine regimen. We studied the effects on intracranial self-stimulation (ICSS) of the same opiate treatment regimen. Rats were given daily morphine (20 mg/kg i.p.) for 7 days; ICSS was tested prior to and following the morphine on Days 1 and 7, and prior to and following naloxone (20 mg/kg i.p.) on Day 8. On Day 1 the rats failed to respond for the first 2h after injection but then responded for 3h with reduced thresholds (rate-frequency functions shifted 0.3 log units to the left). The same pattern was seen following the 7th morphine injection, except that the animals continued to respond—at slightly elevated thresholds—during the first 2h after injection. On Day 8, thresholds were normal during the pre-injection baseline period but were significantly elevated after naloxone; naloxone shifted rate-frequency functions to the right by 0.3 log units. Tooth-chattering, wet-dog shakes, and diarrhea confirmed that naloxone, but not 24h abstinence, caused opiate withdrawal distress correlated with the observed elevations in reward threshold.

511.6

Comparison of butorphanol withdrawal syndromes precipitated by opioid receptor antagonists: nor-binaltorphimine (nor-BNI), naltrexone (NTI) and naloxone (NLX). S.P. Jaw, B. Hoskins and I.K. Ho. Dept. Pharmacol. and Toxicol., Univ. of Mississippi Medical Center, Jackson, MS 39216.

Male Sprague-Dawley rats (251-300 g) were rendered dependent upon butorphanol by continuous i.c.v. infusion of butorphanol tartrate (26 nmol/h) for 3 days via osmotic minipumps. Control animals received saline infusion (1 µl/h) for the same period of time. Three hours after the termination of butorphanol or saline infusion, rats were randomly divided into different groups and challenged with various doses of nor-BNI, NTI, or NLX (kappa-, delta-selective, or non-specific antagonist) i.c.v. Results indicate that nor-BNI was more potent than NLX in eliciting withdrawal signs, e.g., teeth-chattering (TC), wet shakes (WS), forepaw tremors, yawning (YA), ptosis, and salivation. Both nor-BNI and NLX increased the number of animals exhibiting ejaculation (EJ) at high doses. The potency ratios of ED₅₀s for NLX over nor-BNI in eliciting TC (1.25), YA (2.13) and EJ (0.72) were not significantly different. Nor-BNI was more potent than NLX in causing urination (NLX/nor-BNI: 290). There were no significant differences in ED₅₀s of NTI and NLX in eliciting TC, WS, and YA in butorphanol-dependent rats. These studies appear to indicate that both kappa- and delta-opioid receptors are involved in butorphanol dependence in rats. (Supported by DA 05828)

MOTIVATIONAL CONSEQUENCES OF NALOXONE-PRECIPIATED OPIATE WITHDRAWAL: A DOSE-RESPONSE ANALYSIS. G. Schulteis, R. Carrera, A. Markou, L. H. Gold*, and G. F. Koob. Dept. of Neuropharmacology, The Scripps Research Institute, La Jolla, CA 92037.

Opiate withdrawal is known to have aversive motivational consequences as measured by disruptions of operant responding for food and conditioned place aversions (Gellert & Sparber, *J. Pharmacol. Exp. Ther.* 201:44, 1977; Koob et al., *Psychopharmacology* 98:530, 1989; Stinus et al., *Neuroscience*, 37:767, 1990). In the current series of studies, male Wistar rats were implanted subcutaneously (SC) with either morphine (2 x 75 mg) or placebo pellets. No sooner than 3 days after implant the rats were given a SC injection of naloxone (0 - 1.0 mg/kg) and tested in one of several behavioral paradigms. In dependent rats, very low (0.01 - 0.03 mg/kg) doses of naloxone produced the following behavioral effects: 1) a reduction in spontaneous locomotor activity, 2) a disruption of schedule-controlled (FR15) operant responding for food, 3) an elevation in intracranial self-stimulation thresholds, and 4) an increase in heroin self-administration (decrease in the inter-injection interval). These doses of naloxone produced no significant effects in non-dependent, placebo-pelleted rats. Importantly, a dose of 0.01 mg/kg naloxone, which in dependent rats produced significant effects on all of the behavioral measures employed, produced only minimal physical signs of withdrawal. The behavioral measures employed in our studies appear to be highly sensitive indices of the aversive motivational consequences of opiate withdrawal and these measures can be used to study the neural substrates contributing to opiate dependence and withdrawal. Supported by grant DA04043.

511.9

INCREASED GLUTAMATE RELEASE IN THE LOCUS COERULEUS (LC) DURING OPIATE WITHDRAWAL: A MICRODIALYSIS STUDY G.K. Aghajanian*, J.H. Kogan, and B. Moghaddam. Depts. of Psychiatry, Pharmacology, and Cellular and Molecular Physiology, Yale School of Medicine, New Haven, CT 06508.

Noradrenergic LC neurons in opiate-dependent rats are markedly activated by antagonist-induced withdrawal. This activation may be due in part to an increased release of glutamate in the LC since either glutamate antagonists or lesions of the nucleus paragigantocellularis (a major excitatory amino acid input to the LC; Ennis and Aston-Jones, 1988) reduce substantially the withdrawal response (Rasmussen and Aghajanian, 1989). The present study examined directly by *in vivo* microdialysis whether an increased release of glutamate can be detected biochemically in the rat LC following opiate withdrawal.

Opiate dependence was induced by the pellet method (one 75 mg morphine pellet (s.c.)/day x 3 days). Two days after the last pellet implantation, microdialysis probes were placed in or near the LC under chloral hydrate anesthesia; glutamate in the perfusate was derivatized and measured by HPLC/fluorescence detection. To improve the accuracy of probe placements, the stereotaxic location of the LC was determined first by unit recording; placements were confirmed histologically. A sustained, 2-3 fold increase in glutamate efflux was found following naltrexone-induced withdrawal (100 mg/kg, s.c.) in rats where the microdialysis probe was in the LC proper; only slight if any increases were seen in pericoerulear sites and no increase was seen in surrounding brainstem areas or in non-dependent rats. These results support the hypothesis that an increased release of glutamate contributes to withdrawal-activation of LC neurons in opiate-dependent rats.

511.11

SPINAL CORD FOS-LIKE IMMUNOREACTIVITY (FLI) DURING PRECIPITATED ABSTINENCE: COMPARISON WITH PATTERNS EVOKED BY NOXIOUS STIMULATION D.S. Rohde, D.J. Detweiler, and A.I. Basbaum*. Depts. Anesthesia, Anatomy and Physiology, UCSF, San Francisco, CA.

The abstinence syndrome that is precipitated in opioid tolerant animals includes hyperalgesia. To identify the population of spinal cord neurons that underlies this state and to compare this with populations of neurons that are activated by noxious stimulation, we monitored the FLI after naltrexone precipitated abstinence and by noxious stimulation in normal and morphine-tolerant male, Sprague Dawley rats. After daily implantation of morphine or placebo pellets (75 mg/kg, 5 days), the rats received an injection of naltrexone, 10 or 100 mg/kg, sc or 5.0% formalin (100 μ l) into the plantar hindpaw and then behavior was monitored for one hour. Next, the rats were anesthetized and perfused with a 4% paraformaldehyde fixative. Transverse 50 μ m frozen sections of the spinal cord were immunoreacted with a fos polyclonal antiserum using the ABC method.

Contrary to a previous report (Abbott et al, 1981) formalin did evoke pain behavior in both placebo-treated and morphine-tolerant rats. Although the patterns of fos expression in these groups were comparable (dense labelling in laminae I, II and V-VIII), there was enhanced FLI (including increased rostrocaudal and bilateral staining) in the morphine-tolerant rats. Naltrexone-precipitated abstinence in awake rats evoked FLI bilaterally with the most dense staining in laminae I, III, IV, X and in sacral parasympathetic preganglionic neurons. Naltrexone injection in the placebo group did not increase spinal cord FLI. When abstinence was precipitated under Halothane anesthesia, there was a significant decrease in FLI in laminae III and IV, but much less change in lamina I. This suggests that the induction of FLI in lamina I is not secondary to the behavior associated with withdrawal and that spinal cord nociceptive neurons (mainly in lamina I) are sensitized during the development of tolerance. This is manifested as increased FLI in lamina I with precipitated abstinence and more extensive staining when FLI is induced by a noxious stimulus in morphine-tolerant rats. Supported by DE/NIDA 08973 and NS14627.

LONG-TERM GLUTAMATE DESENSITIZATION IN LOCUS COERULEUS NEURONS: A VOLTAGE CLAMP STUDY IN RAT BRAIN SLICES J.H. Kogan* and G.K. Aghajanian. Depts. of Cellular & Molecular Physiology, Psychiatry, & Pharmacology, Yale Univ. School of Medicine, New Haven, CT 06508.

We have previously demonstrated that long-term glutamate desensitization (LTGD) occurs in locus coeruleus (LC) neurons following both naltrexone-precipitated opiate withdrawal and during a prolonged application of glutamate to a rat LC brain slice. Using extracellular recording techniques in brain slices it was shown that a maximal desensitization of 50-60% can be induced with a 20 min application of glutamate (1mM). The desensitization gradually reversed within 3 hours after wash-out of glutamate.

We now report that LTGD can be induced in LC neurons voltage clamped below firing threshold. The induction and recovery are similar to that observed during the extracellular studies. The glutamate inward current desensitizes about 50% with a 20 min application of glutamate (1mM) and recovery occurs within 3 hours after wash-out. Glutamate inward currents are accompanied by an increase in the apparent membrane conductance. During the development of LTGD as the glutamate current decreases there is a proportional reduction in the membrane conductance suggesting that the reduced response to glutamate is not due to the development of an opposing outward current. No change was seen in the membrane conductance before and after the glutamate applications indicating no change in the passive membrane properties of the cell or an excitotoxic action of glutamate. Cyclothiazide (50 μ M), which inhibits the acute desensitization of glutamate receptors, results in an initially enhanced response to glutamate but does not block the induction of LTGD indicating that LTGD is distinct from rapid receptor desensitization. These results indicate that LTGD in LC neurons occurs independently of action potential generation or membrane depolarization.

A ROLE FOR ACCUMBAL D2 RECEPTOR ACTIVITY IN THE INITIATION AND PREVENTION OF THE OPIATE WITHDRAWAL SYNDROME. Glenda C. Harris* and Gary Aston-Jones. Hahnemann University, Department of Mental Health Sciences, Philadelphia, PA 19102.

The nucleus accumbens is well known for its role in mediating the rewarding aspects of opiate use. In the current series of experiments we report that it is also a site involved in opiate withdrawal symptoms. Male Sprague-Dawley rats were made dependent on morphine by daily ip injections (increasing doses of 10 mg/kg up to 80 mg/kg/day). The non-selective dopamine agonist, apomorphine (300 μ g - 2 mg/kg ip) or the more selective D2-agonist, propylnorapomorphine (R-NPA, 50-500 μ g/kg ip) significantly reduced the majority of naloxone-precipitated (0.5 mg/kg) somatic withdrawal signs. The D1 receptor agonist, SKF-38393 (2-5 mg/kg) was ineffective. To determine if the effects of these dopamine agonists were mediated by actions within the accumbens, R-NPA (3-10 μ g) was microinjected into the accumbens prior to naloxone-precipitated withdrawal. At all doses, R-NPA significantly prevented the occurrence of somatic withdrawal signs when administered into the accumbens but not when administered into the nearby striatum. Dopamine receptor antagonists completely blocked the effects of accumbal R-NPA. SKF-38393 (3 μ g) in the accumbens did not prevent the occurrence of withdrawal signs. In addition, the administration of the dopamine antagonists (3 μ g) flupentixol (D1/D2) and eticlopride (D2) alone into the accumbens of morphine dependent rats precipitated several somatic withdrawal signs. These data indicate D2 receptors within the accumbens are important in the manifestation of opiate withdrawal and furthermore, that D2 agonists could be useful in the treatment of opiate addiction. NALOXONE-PRECIPIATED OPIOID WITHDRAWAL FOLLOWING CHRONIC TREATMENT WITH TRIMU-5, A μ 2-OPIOID AGONIST. R. M. Eisenberg and D. J. Forbes*. Dept. Pharmacology, Univ. Minn. Duluth, Duluth, MN 55812.

TRIMU-5 is an enkephalin analog with high affinity for both μ 1 and μ 2-sites, with poor affinity for other opioid receptors. Binding studies have characterized this agent as a μ 2 agonist and a μ 1 antagonist. The objective of this study was to determine whether opioid dependence could be produced by treatment with this agent by comparing naloxone (NX)-precipitated withdrawal to that following DAMGO. The primary indicator of withdrawal was an increase in plasma corticosterone (CS) following NX. Experiments were conducted on conscious unrestrained male Sprague-Dawley rats with chronic i.v. catheters, and ALZET osmotic pumps or i.c.v. cannula guides allowing for serial blood sampling and drug injection into the right lateral ventricle. During blood sampling, animals remained isolated in sound-attenuated one-way vision boxes. Rats receiving TRIMU-5 (2 μ g/ μ l/hr) showed a significant elevation of CS when NX (0.4 mg/kg bwt i.v.) was given approx. 3 d later. Occasionally wet-dog shakes were observed. Similarly, after DAMGO (1 μ g/ μ l/hr), CS showed a sustained increase. A variety of characteristic behavioral manifestations were observed (though not scored). Rats given DAMGO, though not TRIMU-5, i.c.v. on an increasing schedule over 3 d showed a significant CS response. Acute dependence did not appear to occur as NX injected 3 hr after a single administration of either TRIMU-5 or DAMGO did not result in a significant CS change. Results indicate that chronic stimulation of the μ 2-receptor can produce physical dependence and subsequent NX-precipitated withdrawal. Supported by DA 07186.

INCREASED DOPAMINE METABOLISM IN THE ROSTRAL VENTRAL MEDULLA (RVM) DURING MORPHINE ANALGESIA, TOLERANCE AND NALOXONE-PRECIPITATED WITHDRAWAL. B.K. Taylor* and A.I. Basbaum. Depts. Anatomy and Physiology, UCSF, San Francisco, CA.

Although most studies have emphasized the contribution of medullary serotonergic and noradrenergic mechanisms through which morphine influences nociceptive controls, others have implicated dopaminergic mechanisms. Since we have demonstrated increased *fos* expression in the RVM during abstinence, we used *in vivo* microdialysis to evaluate changes in dopaminergic metabolism (namely, extracellular concentration of homovanillic acid, HVA, in the RVM) during morphine analgesia, tolerance and naloxone-precipitated withdrawal. We instrumented adult male rats with dialysis probes (2.0mm x 200µm) in the RVM and chronic catheters in the femoral vein. In one group (n=7), we tested the effect of an acute analgesic dose of morphine (3.0 mg/kg iv). In a second group (n=6), we produced tolerance with subcutaneous implantation of morphine pellets (75mg x 5 days), and then precipitated withdrawal with naloxone (0.5mg/kg iv). HPLC with electrochemical detection was used to quantify changes in the concentration of HVA (percent change relative to basal concentrations) in sequential 30-minute samples collected at a perfusion rate of 1.0 µl/min. Morphine analgesia was associated with an immediate increase in HVA levels that peaked (218±35%) after 150-180 min, and then gradually returned to basal levels within 240 min. Naloxone-precipitated withdrawal was associated with an almost five-fold increase in HVA levels that peaked (491±156%) after 90-120 min, and then gradually returned to basal levels. These studies provide evidence that dopaminergic systems in the RVM are involved in opiate analgesia and withdrawal mechanisms. Our present studies are directed at measuring changes in dopamine release in the RVM and elucidating the origin of the presumed dopaminergic inputs. Supported by NS-21445 and NS-07265.

TOLERANCE AND WITHDRAWAL AFTER INTRACEREBROVENTRICULAR INFUSION OF THE SELECTIVE µ-OPIOID AGONIST TYR-D-ARG²-PHE-(NME)GLY⁴ (TAPS). B. Gudka, M.O. Adeyemo* and A.L. Sirén. Dept. of Neurology, Uniformed Services University of the Health Sciences, Bethesda, MD 20814.

The development of tolerance and withdrawal after continuous intracerebroventricular (i.c.v.) infusion of Tyr-D-Arg²-Phe-(NMe)Gly⁴ (TAPS), a proposed µ₁-opioid agonist, was compared to that elicited by morphine or D-Ala²-MePhe³-Gly-ol⁵-enkephalin (DAMGO) in male Sprague-Dawley rats (n=40). The drugs were delivered via an Alzet brain infusion cannula attached to a subcutaneous minipump pre-filled with either TAPS (3, 10, or 30 pmol/µl/h), DAMGO (300 or 1000 pmol/µl/h), morphine (10 or 30 nmol/µl/h), or vehicle. Antinociception was measured by the radiant heat tail-flick latency method before minipump implantation and over the next 5 days. On infusion day 5, withdrawal severity was assessed for 60 min following a bolus of naloxone (20mg/kg, i.p.). The opiates produced a dose dependent increase in the tail-flick latency on day 1 with a rank order of potency and efficacy of TAPS >> DAMGO > morphine. Tolerance developed within 2-4 days in all opiate treated rats. The rate of tolerance development as estimated by calculating the exponential decay half-life from the peak effect on day 1 was in order: DAMGO > TAPS = morphine. The order of magnitude of withdrawal was DAMGO = morphine > TAPS. TAPS, 30 pmol/µl/h, resulted in minimal withdrawal which was similar to vehicle while lower doses of TAPS did not significantly differ from DAMGO or morphine. The data indicate that TAPS is a potent antinociceptive agent with less degree of opiate dependence than morphine or DAMGO.

SUBCUTANEOUS INJECTION OF AN ANALOG OF NEUROPEPTIDE FF PRECIPITATES MORPHINE ABSTINENCE SYNDROME. J.R. Lake¹, B. Pai¹, K. Burgess¹, K.R. Arcangeli, K.D. Deshotel, D.D. Hausam, W.E. Witherspoon, V.A. Carter, H.-Y.T. Yang² and D.H. Malin. Univ. of Houston-Clear Lake, Houston, TX 77058¹ Dept. of Chemistry, Texas A&M Univ., College Station, TX 77843 and ²NIMH, St. Elizabeths, Washington, D.C. 20032.

Neuropeptide FF (NPFF, FBFamide, FMRFamide-like mammalian octapeptide) has been shown to exert various antiopiate actions, including precipitation of opiate abstinence syndrome when injected into the third ventricle of morphine dependent rats (Malin et al. *Peptides* 11:277, 1990). In the present study, dansyl-Pro-Gly-Arg-Phe amide (dansyl-PQRFa), a lipophilic analog containing the C-terminal fragment of NPFF, was injected subcutaneously into morphine dependent rats and appropriate sham controls. Comparison groups were injected with vehicle alone (30% ethanol in distilled water). In Expt. 1, 14 rats were continuously infused for 7 days with 1.33 mg/kg/hr morphine sulfate prior to receiving either 9 mg/kg dansyl-PQRFa (n=7) or vehicle alone (n=7) s.c. Dansyl-PQRFa precipitated a vigorous opiate abstinence syndrome in the morphine dependent rats; peptide-injected rats had significantly more, p<.01, overall abstinence signs than vehicle-injected rats. In Expt. 2 with 14 sham implanted, non-dependent controls, there was no significant difference between rats injected with dansyl-PQRFa and rats injected with vehicle alone. (NIDA DA06554 and Texas Advanced Technology Program.)

WITHDRAWAL FROM CHRONIC MORPHINE TREATMENT PRODUCES ALTERATIONS IN THE BETA-ADRENERGIC RECEPTOR-COUPLED ADENYLATE CYCLASE SYSTEM. J.M. Ackerman* and H.M. Moises. Dept. of Phys., Univ. of Mich. Sch. of Med., Ann Arbor, MI 48109. Studies of chronic opiate treatment have demonstrated changes in the β-adrenergic receptor system and suggest that central noradrenergic mechanisms may play an important role in the mediation of opiate withdrawal. We have previously shown that β-adrenergic receptor density increased in rat hippocampus after chronic morphine treatment and decreased after morphine withdrawal. These changes were accompanied by corresponding supersensitivity and subsensitivity, respectively, in β-adrenergic receptor sensitivity assessed electrophysiologically in the hippocampal slice. In the present study, intracellular recordings were obtained from pyramidal neurons in slices from morphine-pellet implanted rats to determine whether changes in the β-adrenergic receptor response found during morphine dependence and withdrawal might be due in part to alterations occurring beyond the receptor level. The dose-response curve for isoproterenol inhibition of the calcium-activated potassium conductance, *I_{KHP}*, which occurs in pyramidal neurons following activation of postsynaptic β-adrenergic receptors, was shifted to the left following chronic morphine treatment. In contrast, the curve was shifted to the right after a 32 to 48h withdrawal period. The dose-response curve for forskolin inhibition was unchanged following treatment but shifted to the right after withdrawal. The results suggest that changes in the β-adrenergic system in morphine-dependent animals may result from changes at the receptor level, but alterations beyond the level of the receptor may be involved in the mediation of morphine withdrawal.

LASTING CHANGES IN STIMULUS-SECRETION COUPLING IN CENTRAL NERVE TERMINALS UPON MORPHINE WITHDRAWAL. A.N.M. Schoffelmeer*, A.H. Mulder and H.K. G.Tjon Tien Ril. Dept. Pharmacol., Free Univ., Med. Fac., 1081 BT Amsterdam, The Netherlands.

In superfused rat brain slices, depolarization-induced release of noradrenaline (NA, cortex), acetylcholine (ACh, striatum) and dopamine (DA, striatum) is liable to inhibition by presynaptic mu, delta and kappa opioid receptors, respectively. Moreover, morphine enhances *in vivo* DA release in the striatum, acting on mu receptors in the mesencephalon, which is assumed to be critically involved in opiate reward and reinforcement. One day after chronic morphine treatment, the electrically evoked release of NA (cortex slices) and that of ACh (striatal slices) was enhanced, whereas that of DA (striatal slices) was reduced. Presynaptic opioid receptor efficacy remained unchanged in brain slices of morphine abstinent rats. Since these adaptive changes in neurotransmitter release *in vitro* were still observed 3 weeks after opiate withdrawal, i.e. in the absence of physical dependence, persistent changes in the exocytotic release mechanism in central nerve terminals are suggested to play an important role in the maintenance of opiate dependence.

511.18

ENHANCED ANTIOPATE ACTIVITY AND ENZYME RESISTANCE IN PEPTIDOMIMETICS OF FMRFamide CONTAINING E-2,3-METHANOMETHIONINE. L.S. McDermitt, J.R. Lake, K. Payza¹, T.M. Benson, T.L. Garber, M.L. Waller, T.-A. Luu, R.S. Kelley, D.A. Smith, K.-K. Ho², K. Burgess² and D.H. Malin*. Univ. of Houston-Clear Lake, Houston, TX 77058, ¹NIMH, St. Elizabeths Washington, D.C. 20032 and ²Texas A&M Univ., College Station, TX 77843.

FMRFamide is a molluscan peptide which has shown antio-piate activity in a number of mammalian test systems. The current study determined the antio-piate potency of FMRFamide and two conformationally constrained peptidomimetics of FMRFamide containing stereoisomers of E-2,3-methanomethionine. Peptidomimetic 3 contained 2R,3R-E-cyclo-Met, while peptidomimetic 4 contained 2S,3S-E-cyclo-Met. Morphine abstinence signs were observed for 20 mins. after varying doses (0.25 - 25.0 ug) of these substances were injected into the third ventricle of morphine dependent rats. Both peptidomimetics were significantly more potent than FMRFamide itself, and peptidomimetic 3 was significantly more potent than peptidomimetic 4. Although peptidomimetics 3 and 4 bound with lower affinity than FMRFamide to rat spinal cord receptors for NPFF (the mammalian FMRFamide-like peptide), they were 191 and 42 times, respectively, more resistant than FMRFamide to enzymatic degradation by leucine aminopeptidase. Thus, the increased potency of these FMRFamide analogs may be due to increased bioavailability. (NIDA DA06554 and Texas Advanced Technology Program.)

INHIBITION OF MORPHINE TOLERANCE AND DEPENDENCE BY DIAZEPAM. P.Sribanditmongkol, Ming-Jyh Sheu, G.A.Teiwani*, Department of Pharmacology, Ohio State University, College of Medicine, Columbus, OH 43210-1239

Effect of a benzodiazepine receptor agonist diazepam on the development of morphine tolerance and dependence has been investigated. Male Sprague-Dawley rats were randomized into 8 groups (n=8). Rats in four groups were implanted with pellets containing 75 mg morphine each, and in other four groups were implanted with placebo pellets. Two pellets were implanted subcutaneously on the first day and another four pellets on the second day. Morphine- or placebo-pellet implanted rats were injected with ip saline (1 ml/kg) or diazepam (DZP) 0.025, 0.25 or 2.5 mg/kg after the first day of implantation, then everyday for 5 days. Antinociception was measured by the tail-flick (TF) and hot plate (HP) tests, and sedation by a rotarod test everyday before and one hour after ip injection. On the last day of experiment (day 5), a withdrawal syndrome was induced by injecting naloxone (10 mg/kg sc) and rats were observed for abstinence behaviors for 30 min. Rats were then sacrificed and various brain regions were saved for analysis of met-enkephalin by RIA. We observed that DZP (0.25 and 2.5 mg/kg) inhibited tolerance to morphine antinociception as measured by TF test. Rats implanted with morphine and daily injected with DZP 0.25 mg/kg exhibited less severity of an abstinence syndrome as determined by jumping behavior compared to that in the morphine treated group. DZP did not influence the levels of met-enkephalin in the placebo-implanted rats but antagonized a decrease in the met-enkephalin levels in the hypothalamus, hippocampus, cortex and spinal cord induced by morphine implantation. We conclude from this study that DZP can inhibit morphine tolerance and dependence partly by enhancing the met-enkephalin levels in morphine treated subjects.

DRUGS OF ABUSE: OPIOIDS AND OTHERS—DEVELOPMENTAL EFFECTS

512.1

EFFECTS OF PRENATAL MORPHINE ON BRAIN OPIATE RECEPTORS OF ADULT MALE RATS. Agnes Rimanóczy¹ and Ilona Vathy². Dept. Psychiatry, Albert Einstein College of Medicine, Bronx, NY 10461. ¹Dept. Neurology and Psychiatry, A. Sz-Györgyi Medical School, Szeged, Hungary,

Saturation binding assays were carried out on membranes of different brain regions of adult male rats exposed to morphine *in utero* (10 mg/kg twice a day on days 11-18 of gestation). Using the highly selective tritiated ligand D-Ala-Gly-N-Methyl-Phe-Gly-ol (DAMGO) to label the μ opioid receptor subtype the maximal binding capacity (B_{max}) and affinity (K_d) in the frontal cortex, striatum, hypothalamus (HYP), preoptic area (POA), ventral tegmental area and cerebellum were estimated. Nonspecific binding was assessed by 1,000-fold excess of DAMGO. Prenatal morphine treatment increased the B_{max} of DAMGO binding by 30% in the POA and decreased it by 20% in the HYP without altering the binding affinity. In contrast, the binding capacity was not affected by prenatal morphine treatment in any of the other brain regions examined. Thus, it seems that prenatal morphine selectively affects the hypothalamic opioid system as was demonstrated for hypothalamic catecholamine turnover and content (Vathy and Katay, Dev. Brain Res. 68:125-131, 1992). These changes may account for the alterations in adult male sexual behavior previously shown to be induced by prenatal morphine. Supported by DA 05833.

512.3

PERINATAL EXPOSURE TO THE KAPPA AGONIST U-50,488 ALTERS THE SENSITIVITY OF D2 BUT NOT D1 RECEPTORS IN THE BRAIN OF RAT OFFSPRING. G.-J. Shieh and D.E. Walters. Div. Pharmacol., Dept. Pharmacol. Sci., Auburn Univ., AL 36849.

To determine the effects of chronic perinatal exposure to kappa agonists on the motor development of offspring, 28-day Alzet pumps containing U-50,488, 79 mg/ml, or 0.9% saline vehicle were implanted into Sprague-Dawley rats on G14. The dose of U-50,488 on G14, 20 and P10 was 18, 13.6 and 17.6 mg/kg/day, respectively. On P10, male offspring were injected with the D2 agonist quinpirole, 0.05 mg/kg, or the D1 agonist SKF 38393, 10 mg/kg. Their locomotor activity was then monitored for 1 hr.

Perinatal exposure to U-50,488 significantly decreased the locomotor response to quinpirole but not SKF 38393. There were no significant differences between treated and control mothers in body weight gain during gestation, body weight at P10, or food consumption during gestation or postpartum. Litter sizes were not significantly different between groups; nor were any dead pups born to mothers in either group. Birth weights of offspring exposed to U-50,488 were significantly decreased but there was no significant difference between body weights of experimental and control offspring at P10. The results suggest that chronic perinatal exposure to kappa opioid agonists alters the sensitivity of brain D2, but not D1, receptors mediating locomotor activity. Supported by the AACP and the PMA Foundation.

512.2

EFFECTS OF PRENATAL MORPHINE ON CATECHOLAMINE TURNOVER OF ADULT MALE RATS. Eaton, R., Rimanóczy, A., Kátay, L. and Vathy, I. Dept. Psych., Albert Einstein Coll. Med., Bronx, NY 10461 and ¹Dept. Neurol. and Psych., A. Sz-Györgyi Med. Sch., Szeged, Hungary.

Norepinephrine (NE) and dopamine (DA) turnover rates were estimated in several brain regions of adult male rats exposed to morphine *in utero* (10 mg/kg twice a day on days 11-18 of gestation). Animals were injected with the catecholamine synthesis inhibitor α -methylparatyrosine (AMPT) at 0 and 3 hr with 250 and 125 mg/kg, respectively. They were sacrificed at 0, 1.5, 3, 4, 6 or 8 hrs after the AMPT injection and turnover rates of NE and DA measured in the hypothalamus, preoptic area (POA), striatum, cortex and cerebellum. The turnover rate of NE was 40% lower in the hypothalamus ($p < 0.05$), but was 42% higher in the POA ($p < 0.01$) of morphine-exposed animals when compared to controls. In contrast, the turnover rates of DA were similar in the hypothalamus and POA of saline- and morphine-exposed animals. These results suggest that prenatal morphine exposure selectively targets hypothalamic NE systems, an observation in agreement with our previous findings of elevated hypothalamic NE content in morphine-exposed males (Dev. Brain Res., 68:125-131, 1992). Because our previous work demonstrated reduced hypothalamic NE content in drug-exposed females, studies on NE and DA turnover in prenatally morphine- and saline-exposed female rats are also in progress. Supported by DA 05833.

512.4

PRECIPITATED WITHDRAWAL FROM CHRONIC MORPHINE IN THE WEEK-OLD RAT PUP. K. Jones, S. Wang* and G. A. Barr. Biopsychology Doctoral Program, Dept. of Psychology, Hunter College-CUNY, NY, NY 10021 and New York State Psychiatric Institute, 722 W. 168th Street, NY, NY 10032.

Morphine dependent adult animals manifest a complex withdrawal syndrome but there are few reports on the morphine withdrawal syndrome in infants. In this study, we examine the behavioral effects of precipitated withdrawal in morphine dependent 7 day-old rat pups. Each infant rat was injected with morphine sulfate (3 mg/kg or 10 mg/kg, i.p., b.i.d.) from the first to the seventh day of life at approximately 9:30 AM and 5:30 PM. Controls included saline injected and untreated groups. The last injection was on the morning of the 7th day. All pups in the same litter received the same treatment. One hour after the last morphine treatment, a single pup was injected with one of several doses of naltrexone (0, 0.3, 1.0, 3.0, 10.0, mg/kg) and placed in an observation chamber with the remainder of the litter. The pup was observed for a total of 20 minutes and ongoing behaviors recorded every 15 seconds. When the observation period ended, the pup was anesthetized and placed back into the observation chamber with the remainder of the litter. The second pup was then tested similarly with a different dose of naltrexone. We tested five pups in each litter and averaged those scores to obtain a litter score. All observations were scored in a blind manner.

Naltrexone injected pups that had been chronically treated with morphine showed dramatic alterations in their behavior, including increased head movements (rises and sways), rolls, stretches, walking, and wall climbing. They also spent less time with littermates. These results indicate that week-old morphine treated pups experience behavioral changes following opiate antagonist treatment although these behaviors differ from the classical withdrawal syndrome seen in adult animals. (Supported in part by DA-06600)

ALTERATIONS IN OPIOID PEPTIDES AND THE cAMP SYSTEM IN BRAINS OF MORPHINE ADDICTED NEWBORNS. A. Tempel*, J. Yang and R. Bashear. Lab of Molecular Pharmacology, Hillside Hospital, Long Island Jewish Medical Ctr./Albert Einstein College of Medicine, Glen Oaks, NY 11004.

The mechanisms involved in the development of morphine tolerance are still unknown. Recently much attention has been directed towards the possible changes in post receptor events. In order to understand the interaction between opiod receptors, G-protein/cAMP system and endogenous opiods, we examined alterations in these systems in brains of morphine exposed newborns. Pregnant dams were implanted on gestation day 16 with either one morphine pellet each (75mg) or with placebo pellets. Rat pups were sacrificed on day of parturition and brains dissected. Total RNA was extracted and hybridized with a ³²P-labeled RNA probe for G_α message (1.9kb), PPE message (1.4kb) and the constitutively expressed 1B15 message (1.0kb). cAMP and met-enkephalin levels were measured by radioimmunoassays. Data were analyzed by a MANOVA followed by Post-hoc univariate analysis. Prenatal morphine treatment produced a significant reduction (-16%; p<.01) in cAMP levels in striatum of offspring with no significant alterations in G_α mRNA levels. Met-enkephalin levels were decreased by 43% (p<.05) while preproenkephalin levels were increased by 37% (p<.01) in striatum. These data suggest that prenatal morphine treatment down regulates the endogenous opiod system via the cAMP system and then strives to maintain equilibrium by increasing production of preproenkephalin. (Supported by NIDA-DA-05440 & LJMC Faculty Research Award.)

DEGENERATIVE DISEASE: ALZHEIMER'S—β-AMYLOID IX

DECREASED SURVIVAL OF HIPPOCAMPAL NEURONS IN THE PRESENCE OF β/A₄ AMYLOID PROTEIN IS NOT ALTERED BY CALCIUM CHANNEL BLOCKADE. J. S. Whitson* and S. H. Appel. Dept. of Neurology, Baylor College of Medicine, Houston, TX 77030.

In cortical cultures, β/A₄ protein increases vulnerability to glutamate insult possibly reflecting the ability of β/A₄ to destabilize calcium homeostasis [1]. Direct neurotoxicity of β/A₄ is not observed [1,2]. In hippocampal cultures, we and others find treatment with β/A₄ protein alone decreases neuronal survival [3], but the mechanism of neurotoxicity is unknown. Low density, serum-free cultures of hippocampal neurons were used to determine whether the neurotoxicity of β/A₄ protein *in vitro* could be altered by voltage- or ligand-gated calcium channel antagonists or cyclic nucleotides.

Cultures from E-18 rat hippocampus were treated with either antagonist (4μM omega-Conotoxin, 1μM Nifedipine, 100nM Diltiazem, 10μM APV, 10μM MK801) or cyclic nucleotide (100μM dibutyryl cAMP, 100μM 8-bromo cAMP, 100μM dibutyryl cGMP, 100μM 8-bromo cGMP). After 20 minutes, synthetic β/A₄ 1-40 was added for 48 hours; then neurons were fixed and counted.

With only one exception, neither calcium channel antagonists nor cyclic nucleotides altered the survival of neurons exposed to 20μM βA₄. The N-channel antagonist Diltiazem decreased βA₄ toxicity repeatedly, but slightly, perhaps indicating some involvement by this channel in the molecular cascades preceding neuronal cell death. Nevertheless, the toxicity of beta protein does not appear to be directly altered either by calcium channel blockers or by the addition of cyclic nucleotides. 513.3

β-AMYLOID(25-35) INDUCES COMPROMISE OF MITOCHONDRIAL SDH ACTIVITY IN RAT HIPPOCAMPAL NEURONAL COCULTURES AND NEUROBLASTOMA CELLS. J.C. Chisholm, J.N. Davis, and E.J. Hunnicutt, Jr. Miles Inc., Institute for Dementia Research, West Haven, CT 06516 USA.

The ability to demonstrate neurotoxicity of a β-amyloid protein (βAP), deposited in plaques characteristic of Alzheimer's disease, varies considerably with known and unknown factors, even *in vitro*. Of the various fragments tested, βAP(25-35) was most potent in some protocols (e.g. Yankner, *Science* 250:279;90; Mattson, *J. Neurosci.* 12:376;92). This 11 amino acid peptide was examined for effects on mitochondrial function (MIT), by measuring the activity of succinate dehydrogenase (SDH) after exposure of cells to the peptide. Formazan production from tetrazolium (MIT) by SDH was decreased by 18-26% in rat hippocampal neuronal cocultures after 24 hr of exposure to 60 μM βAP(25-35), indicating significant MIT compromise. Likewise, in four neuroblastoma cell lines, SDH activity was decreased [e.g. in NIE-115 by 34% (±7%SE n=6)] after 24-48 hr of exposure to 60 μM βAP(25-35), indicating significant MIT compromise in these cell lines also. Correlated measurements of cell viability in the neuroblastoma cells, however, showed no effect of the peptide on esterase-dependent calcein uptake, nor on nuclear staining with ethidium homodimer during MIT compromise. These results indicate that a potentially toxic βAP fragment impairs MIT function in neurotypic cells. In cultured neuroblastoma cells tested, this occurs independently of measurable cell death. This suggests that cell vulnerability to this peptide may be related to the level of cell dependence on aerobic vs. anaerobic energy production.

CULTURED GABA-IMMUNOREACTIVE NEURONS ARE RESISTANT TO β-AMYLOID-INDUCED TOXICITY. C.L. Pike* and C.W. Cotman. Irvine Research Unit in Brain Aging and Department of Psychobiology, University of California, Irvine, CA 92717 USA.

Alzheimer's disease (AD) is characterized in part by the loss of particular neuronal populations. Previous studies have shown that cholinergic, glutamatergic, serotonergic, and noradrenergic neuronal populations are selectively vulnerable to degeneration within affected brain regions, whereas neurons containing the neurotransmitter γ-aminobutyric acid (GABA) appear relatively resistant. Although GABAergic neurons in AD generally retain somal integrity, they can exhibit neuritic alterations. Neurodegenerative changes in AD have been widely hypothesized to be mediated in large part by β-amyloid protein (Aβ), which exists in insoluble aggregates as the major component of senile plaques. We have previously demonstrated that aggregated Aβ peptides are directly neurotoxic to cultured neurons. Consistent with the selective degeneration observed in AD, we now report that GABA-immunoreactive cultured neurons exhibit relative resistance to Aβ-induced toxicity. After 10 days *in vitro*, cultures comprised of rat hippocampal neurons plated on a monolayer of astrocytes were treated in serum-free medium with 25 μM Aβ peptide. Thirty-six hours post-treatment, an average of over 75 % of the total neuronal population had degenerated. However, GABAergic neurons (approximately 15 % of the total neuronal population) exhibit only a non-significant 13 % reduction in cell number. Interestingly, viable GABAergic neurons often exhibited neuritic pruning. Determination of the intrinsic neuronal characteristics responsible for Aβ resistance may benefit attempts to both understand the mechanism of Aβ-induced toxicity and delay the progression of AD.

513.4

THROMBIN STIMULATES PRODUCTION OF BETA-AMYLOID IN CULTURED HIPPOCAMPAL NEURONS, G.J. Brewer* Southern Illinois Univ. Sch. Med., Springfield, IL 62794.

In senile plaques of Alzheimer disease (AD), the presence of thrombin and the overall reduction in levels of its specific inhibitor, protease nexin I, suggests a possible pathologic role for this protease. In considering sources for the altered processing of proteins in AD lesions, we studied the effects of serum from AD patients on cultured rat hippocampal neurons and found increases in β-amyloid immunoreactivity (Brewer & Ashford, *J. Neurosci. Res.* 33:355 (1992)). Now we find that the purified serum protease thrombin stimulates β-amyloid and Alz-50 immunoreactivities in a dose and time-dependent fashion in these serum-free cultures. Maximum 4G8 anti-βA4 (Kim and Wisniewski) response was observed after a 24 hr. exposure to 27 nM thrombin. As previously reported for PC12 cells, thrombin inhibits sprouting of newly plated hippocampal neurons. In contrast, neurons cultured for 4 or 7 days were not affected morphologically but were stimulated to increase their mean immunofluorescent area by more than 2 fold. Anti-βA4 (4G8) immunoprecipitates of ³⁵S-methionine labeled neuron cell fractions suggest sources of a thrombin-stimulated 4 kD substance.

BEHAVIORAL AND HISTOLOGICAL ASSESSMENT FOLLOWING BILATERAL INTRAHIPPOCAMPAL INJECTIONS OF β -AP25-35. David E. Kang, Wayne A. Dorman*, Alex McCampbell, Esther E. Kang. Dept. of Psychology, Illinois Wesleyan University, Bloomington, IL 61702.

Pathologically Alzheimer's disease (AD) is characterized by deposits of neuritic plaques (NP) and neurofibrillary tangles typically found in the cerebral cortex, hippocampus, and basal forebrain. Increasing evidence suggests that the major constituent of NP, a β -amyloid protein composed of 39-42 amino acids, possesses neurotoxic properties. Recent studies have demonstrated *in vitro* that the putative neurotoxic fragment, β -AP25-35, disrupts intracellular calcium homeostasis, decreases neuronal survival, and potentiates the toxicity of excitatory amino acids (EAA). Others have shown that the neurotoxic properties of β -AP25-35 may be dependent on the aggregational state of the peptide. While some evidence supports the direct *in vivo* toxicity of β -AP, the extent of neuronal damage has not been compared with a standard lesion made by EAAs. Therefore, a comparative behavioral and histological assessment was conducted following bilateral intrahippocampal injections of β -AP25-35, ibotenic acid (IBO), β -AP25-35 + IBO, and incubated β -AP25-35 (1 week at 37°C). A radial arm maze and Morris water maze were utilized for comparative learning and memory assessment. Preliminary results indicate that there is a clear disruption of learning performance in animals co-injected with low doses of β -AP25-35 (4nmol/ul) and IBO (1.2 nmol/ul) while identical doses injected separately had no effect. Bilateral injections of the incubated β -AP25-35 also affected learning when compared to saline-injected controls. In support of the behavioral results, preliminary histological analyses revealed cytotoxic effects in the hippocampus following injections of β -AP25-35 + IBO or a high dose of IBO. This study suggests that the injection of β -amyloid into the hippocampus potentiates the toxicity of EAA *in vivo* through a Ca^{2+} -mediated mechanism and disrupts learning/memory in rats.

513.7

TRANSFORMING GROWTH FACTOR- β PROTECTS HUMAN NEURONS AGAINST β -AMYLOID-INDUCED INJURY. C. C. Chao*, S. Hu, W. R. Anderson, F. H. Kravitz, and P. K. Peterson. Minneapolis Medical Research Foundation and the University of Minnesota Medical School, Minneapolis, MN 55404

Deposition of amyloid fibrils in the brain is the pathologic hallmark of Alzheimer's disease (AD). The principal component of amyloid fibrils is amyloid β -peptide (A β), a 40 amino acid protein which has been implicated in the neurodegeneration associated with AD. In the present study, we investigated the protective effect of transforming growth factor (TGF)- β on A β -induced neurodegeneration in human fetal cerebral cortical cultures. When these cultures were exposed to A β_{1-40} , marked ($P < 0.01$) neuronal loss (>50%) was observed within 4 days of incubation as assessed by counting surviving neurons and by the uptake of 3H -gamma aminobutyric acid, a functional marker of neuronal viability. A β -induced neurodegeneration was dose-dependent. Simultaneous addition of A β (40 μ M) with TGF- β (20 ng/ml) but not with proinflammatory cytokines tested, reduced ($P < 0.01$) by 60% the A β -induced neuronal injury. Furthermore, TGF- β dose-dependently protected against A β -induced neuronal injury with an ED $_{50}$ of 1 ng/ml. The finding that TGF- β , an anti-inflammatory cytokine, protects against A β -induced neurodegeneration supports the hypothesis that AD is an immunologically mediated disease, and suggests that certain immunosuppressive agents may have a role in the treatment of this neurodegenerative disease.

513.9

SECRETED FORMS OF β APP PROTECT HIPPOCAMPAL NEURONS AGAINST A β TOXICITY AND OXIDATIVE INJURY. Y. Goodman¹, R. E. Rydel², A. R. Culwell² and M. P. Mattson^{*1}.

¹Sanders-Brown Center on Aging and Dept. Anatomy & Neurobiology, Univ. of Kentucky, Lexington, KY 40536. ²Athena Neurosciences Inc., 800 F. Gateway Blvd., South San Francisco, CA 94080.

Alternative processing of β -amyloid precursor protein (β APP) can liberate either secreted forms of β APP (APP^s) via secretase action, or amyloid β -peptide (A β) by alternate pathways. APP^s can protect neurons against excitotoxic and ischemic insults by a mechanism involving stabilization of intracellular free calcium levels ($[Ca^{2+}]_i$) (*Neuron* 10:242-254; V. L. Smith-Swintosky et al.; Barger et al., this meeting). In contrast, A β destabilizes neuronal $[Ca^{2+}]_i$ homeostasis and renders neurons vulnerable to excitotoxicity (*J. Neurosci.* 12:376-389). A β , in an aggregated form, was neurotoxic and caused an elevation of $[Ca^{2+}]_i$ which was directly correlated neuronal degeneration; A β toxicity was prevented by removal of extracellular Ca^{2+} . Confocal laser scanning microscopy and E.M. studies revealed that A β accumulated in or on the plasma membrane which may be the site at which it disrupts $[Ca^{2+}]_i$ homeostasis. Pretreatment of cultures with APP^s695, APP^s751, or APP^s596 (1-10 nM) protected neurons against A β toxicity and attenuated the elevation of $[Ca^{2+}]_i$ caused by A β . Since oxidative damage has been implicated in the pathogenesis of AD, we determined whether APP^s would modify free-radical-mediated neuronal injury. APP^s protected neurons against oxidative damage elicited by iron.

513.6

JUN AND FOS IMMUNOREACTIVITY IN ALZHEIMER'S BRAIN AND INDUCTION BY β -AMYLOID IN CULTURED NEURONS. A.J. Anderson*, B.J. Cummings, C.J. Pike, D.L. Loo and C.W. Cotman. IRU in Brain Aging, Dept. of Psychobiology, U. C. Irvine, Irvine, CA 92717.

The protein products of the Jun and Fos immediate early gene (IEG) families are cooperative transcriptional regulatory factors implicated in regulating the expression of many genes. It is now clear that the expression of a variety of proteins such as the amyloid precursor protein and basic fibroblast growth factor are altered in Alzheimer's disease (AD), thus the events regulating these changes are of interest. Both of these genes contain an AP-1 consensus sequence responsive to regulation by the IEG c-Jun. We have examined the distribution of Jun- and Fos-related protein immunoreactivity in control and AD brain, and the correspondence of this immunoreactivity to paired helical filament-1 (PHF-1: a marker for neurofibrillary tangles which recognizes abnormally phosphorylated tau), glial fibrillary acidic protein (GFAP) and thioflavin staining in double-labeling experiments. An intensification of both Jun and Fos immunoreactivity was observed in AD cases; in addition, both Jun and Fos immunoreactivity were co-localized with PHF-1 in some neurons in AD brain. Jun and Fos immunoreactivity were also co-localized with GFAP-positive astrocytes distributed in the cortex of AD and control cases, and surrounding thioflavin-stained plaques in AD brain. We also examined the role of Jun in cultured rat hippocampal neurons treated with β -amyloid peptide (A β). Basal levels of Jun expression in these cultures were low; however, after exposure to A β Jun was detected within 2 hours, peaked in glia at approximately 6 hours, and peaked in neurons at approximately 12 hours. Jun expression was maintained at high levels 24 hours after exposure to A β . These observations suggest that members of the Jun and Fos IEG families may play a role in cellular response to A β both *in vitro* and in AD.

513.8

PROTECTION OF CULTURED HIPPOCAMPAL NEURONS FROM β -AMYLOID TOXICITY BY ANTIOXIDANTS. Raj K. Lartius* and Etsuro Uemura. Neuroscience Program, Iowa State University, Ames, IA 50011.

β -amyloid (β AP) is a peptide that abnormally deposits in diseases such as Alzheimer's disease (AD). Recent evidence has suggested that the active portion of β AP corresponds to amino acids 25 to 35 (β 25-35). This peptide has both neurotrophic and neurotoxic effects on cultured neurons. Because amyloid in the mature AD plaque is aggregated and relatively immobile, in a previous study we attempted to simulate effects of an established AD plaque by exposing hippocampal neurons to aggregated β 25-35 coated on the culture surface. Neurons had an affinity for β 25-35 and β 25-35 supported the attachment, growth and survival of cultured hippocampal neurons when grown in the presence of serum. However, β 25-35 neurotoxicity occurred when neurons were serum deprived. In the present study, using the same culture system, we have further examined β 25-35 toxicity using culture medium supplemented with modified N2 (MN2) or each of its components (ie. progesterone, insulin, rat apotransferrin, putrescine and sodium selenite). When medium was supplemented with MN2, β 25-35 supported the attachment, growth and survival of cultured hippocampal neurons. When neurons were exposed to each component of MN2 individually, only rat apotransferrin and sodium selenite significantly protected against β 25-35 toxicity. In view of the antioxidant properties of these compounds, vitamin E was also tested. Vitamin E supplemented medium significantly protected against β 25-35 neurotoxicity. This survival was comparable to neuronal survival in medium containing MN2. These findings are supportive of the theory that free radical generation may be involved in amyloid related disease such as Alzheimer's and that antioxidants may be useful to prevent further neurodegeneration.

SECRETED FORMS OF β APP PROTECT CA1 HIPPOCAMPAL NEURONS AGAINST ISCHEMIC INJURY. V. L. Smith-Swintosky^{1*}, L. C. Pettigrew², S. D. Craddock², R. E. Rydel², J. Joseph¹, A. R. Culwell² and M. P. Mattson¹.

¹Sanders-Brown Center on Aging and Department of Anatomy and Neurobiology, ²Department of Neurology and VAMC, University of Kentucky, Lexington, KY 40536; ³Athena Neurosciences Inc., S. San Francisco, CA 94080.

Despite the intensive study of the β -amyloid precursor protein (β APP) because of its possible role in Alzheimer's disease, the normal function of β APP is unclear. A major processing pathway for β APP involves an enzymatic cleavage within the amyloid β -peptide sequence which liberates secreted forms of β APP (APP^s) into the extracellular milieu. We recently reported that both APP^s695 and APP^s751 protect cultured hippocampal neurons against glutamate toxicity and hypoglycemic damage (*Neuron*, 10:243-254 (1993)). The present study extends these experiments to a four-vessel occlusion model of ischemia in rats. Male Wistar rats were divided into four groups: sham, cannula only (n=3); ischemia, saline-treated (n=5); ischemia, APP^s695-treated (n=5); and ischemia, APP^s751-treated (n=5). After 20 min of ischemia, either saline or an APP^s (1 μ g/ml) was infused through an intracerebroventricular cannula at the rate of 5 μ l for 20 min. Three days later, rats were killed, the brains removed, sectioned and Nissl-stained. Both APP^s695 and APP^s751 significantly protected CA1 neurons from ischemic damage ($p < 0.05$ and $p < 0.001$, respectively). APP^s treatment led to a 200-300% increase in cell survival compared to controls. The data indicate that APP^s normally play a neuroprotective role.

513.11

VALPROIC ACID ATTENUATES EXCITOTOXICITY AND NEUROFIBRILLARY TANGLE-LIKE ANTIGENIC CHANGES IN HIPPOCAMPAL NEURONS. R. Mark*, J. W. Ashford, Y. Goodman, and M. P. Mattson. Sanders-Brown Research Center on Aging and Dept. Anatomy & Neurobiology, Univ. of Kentucky, Lexington, KY 40536.

Perhaps the most rational approach to treating Alzheimer's disease (AD) is to prevent or retard the progression of the underlying neuronal degeneration. An excitotoxic mechanism of neuronal injury mediated by increased intracellular calcium levels may underlie the pathogenesis of AD. Previous studies showed that glutamate and calcium influx can elicit antigenic changes in neurons similar to those seen in neurofibrillary tangles, and that amyloid β -peptide (A β) can destabilize calcium homeostasis and render neurons vulnerable to excitotoxicity (*J. Neurosci.* 12:376-389). We previously reported that anticonvulsants (e.g., phenytoin, carbamazepine, diazepam) can attenuate glutamate toxicity in hippocampal neurons (*Brain Res.*, 478:337-348). In the present study we examined the neuroprotective potential of valproic acid (VA), using paradigms of neuronal injury relevant to the pathogenesis of AD. Glutamate neurotoxicity was significantly reduced in hippocampal cultures pretreated with VA (100 nM - 10 μ M). VA attenuated the glutamate-induced increase in neuronal immunoreactivity with antibodies that recognize epitopes in the neurofibrillary tangles of AD (tau antibodies and anti-ubiquitin). The elevation of $[Ca^{2+}]_i$ induced by glutamate was attenuated by VA suggesting that the mechanism of neuroprotection involves stabilization of neuronal calcium homeostasis. Our data suggest that VA may retard neurodegeneration in AD. (supported by the NIH and the Metropolitan Life Foundation).

DEGENERATIVE DISEASE: ALZHEIMER'S—NEUROPHARMACOLOGY AND NEUROTRANSMITTERS IV

514.1

NOVEL, LONG-ACTING AND SELECTIVE PHYSOSTIGMINE ANALOGUES AS POTENTIAL THERAPEUTICS FOR ALZHEIMER'S DISEASE. N.H. Greig, D.K. Ingram, A. Bossi, H.W. Holloway, X-F. Pei, S. Asthana*, T.T. Soncrant. Labs. of Neurosciences and of Cellular and Mol. Physiology, NIA, NIH, and Department of Chemistry, Georgetown Univ.

The loss of cortically-projecting basal forebrain cholinergic neurons consistently correlates with the decline in mental abilities in Alzheimer's disease (AD). Previous attempts to augment central cholinergic function in AD probably have failed to dramatically enhance memory as optimal, steady-state brain drug levels were not achieved or maintained during the period of cognition assessment. Most cholinergic agents have a poor pharmacokinetic profile for single administration studies and/or have poor specificity. The alkaloid physostigmine possesses potent anti-cholinesterase (ChE) activity and has effects on memory when administered to humans. However, it has a short plasma half-life and duration of ChE inhibition (18 and 80 min, respectively). Thus, we developed novel physostigmine analogues, with substitutions in the carbamoyl and N(1) positions, to prolong action and increase enzyme specificity. Studies indicate that: (i) our novel agents possess anti-ChE activity similar to or greater than that of physostigmine, but with a dramatically longer duration of action (>8 hr). (ii) Unlike other physostigmine analogues, our agents are highly selective for either AChE or BChE, separately. (iii) Specific agents do not generate active metabolites. Physostigmine and its analogues generate the analgesic metabolite eseroline, equipotent to morphine. Finally, (iv) specific compounds possess a high brain uptake, low toxicity and dramatically attenuate scopolamine-induced learning impairments in rats, a classic model for assessing cognition enhancers. These represent interesting candidate therapeutics for AD treatment.

514.3

THA AND PHYSOSTIGMINE ATTENUATE HEMICHOLINIUM-3 INDUCED AMNESIA AND ACh DEPLETION. D.S. Chapin, S.B. Jones, J.A. Nielsen and D. Liston*. Pfizer Central Research, Groton, CT 06340

The most prominent neurochemical and clinical features of Alzheimer's disease (AD) are the loss of cholinergic neurons and memory. Hemicholinium-3 (HC-3), a selective inhibitor of high-affinity choline uptake, can produce decreases in brain ACh stores and memory deficits in rodents, providing an animal model for AD. We have examined the effects of two AChE inhibitors, tetrahydroaminoacridine (THA) and physostigmine (PHY), on HC-3-induced changes in mouse forebrain ACh levels and amnesia in a mouse passive avoidance (PA) model. HC-3 decreased mouse forebrain ACh levels and produced amnesia in a dose- and time-dependent manner. HC-3 (1.78 μ g i.c.v.) decreased forebrain ACh levels to 15-25% of control. In PA, the test step-through latency was reduced by 50-60% following pre-treatment with HC-3 two hours prior to the training session. THA (17.8 mg/kg p.o.) or PHY (0.32 mg/kg i.p.) attenuated both HC-3-induced amnesia and forebrain ACh depletion. Both compounds produced statistically significant reversal of amnesia when forebrain ACh was increased to about 40-60% of control ACh levels. Higher doses of THA or PHY produced further increases in brain ACh, but interfered with ability to perform the PA task due to hypocomotion and tremors. THA possessed a greater therapeutic index (TI) than PHY as measured by a greater separation in doses required to reverse HC-3-induced amnesia and lethal doses. This improved TI may explain, in part, the greater clinical efficacy reported for THA.

513.12

MECHANISTIC STUDIES OF THE DEPRESSION OF INTRANEURONAL CALCIUM CONCENTRATION BY SECRETED FORMS OF β -AMYLOID PRECURSOR PROTEIN. S. W. Barger*, B. R. Fiscus*, R. E. Rydel*, A. R. Culwell*, I. Lieberburg*, and M. P. Mattson*. Sanders-Brown Center on Aging, University of Kentucky, Lexington, KY 40536, and *Athena Neurosciences Inc., 800F Gateway Blvd., S. San Francisco, CA 94080.

The predominant peptide in amyloid plaques associated with Alzheimer's disease, beta A4, is derived from a larger, transmembrane protein termed the beta amyloid precursor protein (BAPP). Proteolytic processing of BAPP results in secretion of large extracellular domains (APPs) which have been shown to protect neurons from toxicity associated with glutamate, hypoglycemia, iron, and free radicals (Mattson, et al. 1993. *Neuron* 10: 242-254; and Goodman, et al., this meeting), activities which may involve the ability of APPs to depress intracellular free calcium concentrations ($[Ca^{2+}]_i$). Here we demonstrate a potent elevation of cyclic GMP by APP^s695 in cultures from E18 rat hippocampus. The ability of APP^s695 to depress $[Ca^{2+}]_i$ in hippocampal neurons was blocked by inhibitors of cGMP-dependent protein kinase, and the abilities of APP^s to depress $[Ca^{2+}]_i$ and protect neurons from hypoglycemic damage was mimicked by a cGMP analog (8-bromo-cGMP; 0.1-0.5 mM). At resting levels, $[Ca^{2+}]_i$ could not be depressed by APP^s in the presence of thapsigargin, an inhibitor of calcium uptake into intracellular stores. However, removal of extracellular calcium also prevented the $[Ca^{2+}]_i$ depression by APP^s, and thapsigargin was ineffective after elevation of $[Ca^{2+}]_i$ by removal of extracellular sodium. These data suggest that cGMP elevated by APP^s lowers $[Ca^{2+}]_i$ in hippocampal neurons by at least two mechanisms, dependent or independent of intracellular sequestration.

514.2

CHOLINESTERASE INHIBITORS DIFFERENTIALLY MODIFY RELEASE OF ACETYLCHOLINE AND BIOGENIC AMINES IN RAT CORTEX IN VIVO. G. Cuadra, F. Mori, E. Williams, X-D. Zhu and E. Giacobini*. Dept. Pharmacology, Southern Illinois University Sch. Med., Springfield, IL 62794-9230

Cholinesterase inhibitors (ChEI) are, so far, the only drugs demonstrating clinical efficacy in the treatment of Alzheimer disease (AD). Since the disorder involves a loss of cholinergic as well as monoaminergic synapses in cortex, it is important to determine the effect of ChEI on several neurotransmitters. We have modified the HPLC-ECD method to detect femtomole levels of acetylcholine (ACh) in microdialysis from rat frontal cortex without using an AChEI in the probe to elevate ACh levels (Messamore et al., 1993). We have examined the effect of single and multiple doses of several first generation (physostigmine, THA/tacrine, metrifonate) and second generation (MDL 73,745, heptyl-physostigmine) on ACh, norepinephrine (NE), dopamine and 5-hydroxytryptamine cortical extracellular levels. Our results show that cortical neurotransmitters could exert reciprocal modulatory effects. Cortical ACh and NE in particular, influence each other's extracellular levels. These interactions probably reflect differences in pharmacological effects on cholinergic and adrenergic receptor mechanisms. Further characterization of different pharmacological profiles of these ChEI may improve prediction of therapeutic effects and helps design new drugs to treat AD. [Reference: Messamore E. et al., *Neuropharmacology*, 32(3):291-296, 1993.] (Supported in part by NIA Core Grant #P30 AG08014; and Mediolanum Farmaceutici, Milan, Italy)

514.4

DIFFERENTIAL RESPONSES OF ALZHEIMER'S DISEASE PATIENTS TO TREATMENT WITH PHYSOSTIGMINE AND ARECOLINE; COMPARISON OF OPTIMAL DOSES FOR VERBAL AND VISUO-SPATIAL TASKS. K.C. Raffaele*, A. Berardi, S. Asthana, M.B. Schapiro, J.V. Haxby, and T.T. Soncrant. Laboratory of Neurosciences, National Institute on Aging, Bethesda, MD 20892.

Because of the consistent finding of decreased cholinergic function in Alzheimer's disease (AD), many treatment strategies have focused on enhancing the function of the cholinergic system. During treatment of AD patients with escalating doses of arecoline (a direct muscarinic cholinergic agonist), we found that performance on verbal tasks improved at low doses, while performance on visuo-spatial tasks improved at higher doses. We have now completed a similar treatment protocol with physostigmine (a cholinesterase inhibitor). During inpatient stays, patients received infusions of escalating doses of physostigmine. Performance on 10 neuropsychological tests was measured at baseline and during infusions of 2, 6, 12, 18, and 25 mg/day physostigmine. The dose at which a patient's performance on a particular test was optimal was designated as that patient's 'best dose' for that test. Mean best doses were compared across tests to determine whether performance improved at similar doses across all types of neuropsychological tests or whether performance on different types of tests improved at different physostigmine doses. In contrast to results with arecoline, mean best doses for physostigmine were similar for all task types and were clustered toward the top of the administered dose range. These results reinforce the functional consequences of the differences in mechanisms between the two drugs and may have implications in the development of treatment strategies for AD.

514.5

BIOCHEMICAL AND OVERT BEHAVIORAL EFFECTS OF HUPERZINE IN RODENTS. T.D. Steele*, K.M. Barbieri and K.W. Locke. Interneuron Pharmaceuticals, Inc., Lexington, MA 02173.

Studies were conducted to evaluate the biochemical and behavioral properties of (+)-huperzine, an acetylcholinesterase (AChE) inhibitor that may be useful in the treatment of Alzheimer's disease. Biochemical studies of the inhibition of AChE and butyrylcholinesterase *in vitro* indicated that HUP was a more specific inhibitor of AChE than either physostigmine (PHYSO) or tacrine (THA). In overt behavioral studies, rats and mice were administered huperzine (0.3-3.0 mg/kg, ip or po) and observed for overt behavioral changes at various times post-injection. The overt effects of huperzine were compared with those of PHYSO (0.1-1.0 mg/kg) and THA (3.0-30 mg/kg). Huperzine produced overt effects characteristic of AChE inhibitors (i.e., SLUD syndrome and muscle fasciculations) at doses greater than 0.3 mg/kg by either route of administration. The duration of these effects was longer with huperzine with either PHYSO or THA. Convulsions were observed only after THA. Relative to the overt behavioral studies, huperzine was active in improving scopolamine-induced amnesia in a one-trial passive avoidance procedure in rats at 30- to 100-fold lower doses (0.003-0.01 mg/kg). Thus, huperzine appears to be an orally-active specific inhibitor of AChE, with a long duration of action and a wide margin of safety.

514.7

PERFORMANCE OF AGED RATS IN A 14-UNIT T-MAZE IS IMPROVED FOLLOWING CHRONIC TREATMENT WITH PHENSERINE, A NOVEL ANTICHOLINESTERASE. H. Ikari, N. Greig, E. Spanoler, A. Brossi, X-F. Pei, T. Soncrant, D.K. Ingram*. Lab. of Cellular Mol. Physiol. NIA, NIH, Baltimore, MD 21224 and Lab. of Neuroscience, NIA, NIH, Bethesda, MD 20892.

The physostigmine derivative, phenserine, has proven to be a potent and long-acting inhibitor of acetylcholinesterase with a wide therapeutic window for reversing scopolamine-induced learning impairments of young rats in a 14-unit T-maze (Iijima et al. *Psychopharm.*, in press). In the current study we examined the effects of chronic phenserine treatment on performance of aged (21 mo) male F-344 rats in the same maze, which has produced evidence of robust age-related performance declines (Ingram, *Neurobiol. Aging*, 9:475, 1988). Rats were given phenserine tartrate as daily injections (0, 1, 2, 3 mg/kg i.p.) for Days 1-5. On Day 3 they were pretrained in 1-way active avoidance to a criterion (13/15 avoidances) in a straight runway. On Days 4-5, each rat received 4 trials during 2 daily sessions in the 14-unit T-maze. During each trial, the rat was required to locomote through each of 5 segments within 10 s to avoid footshock (0.8 mA). Performance variables included errors (deviations from correct pathway), runtime from start to goal, shock episodes and duration. Drug injections were administered 30 min prior to training on Days 3-5. Pilot histochemical studies indicated that this chronic phenserine regimen produced marked inhibition of acetylcholinesterase in rat forebrain. Relative to controls, the maze performance of aged phenserine-treated rats was improved as measured by all the variables, with the most effective dose at 2 mg/kg. These results support the potential of phenserine as a cognitive enhancer for further evaluation.

514.9

CHEMISTRY OF PYRIFORM CORTEX IN EARLY AND END-STAGE ALZHEIMER'S DISEASE. D. L. Sparks*, T. Landers and C. Hackney. Sanders-Brown Center on Aging, UKMC, Lexington, KY 40536

The activity of cholinergic enzymes (ChAT and AChE) and the levels of aromatic monoamine neurotransmitters and their metabolites were determined in the pyriform cortex of 8 end-stage AD patients, 2 patients dying within 18 months of initial clinical diagnosis of AD, and 14 non-heart disease controls.

The maximum velocity (V_{max}) of ChAT activity was decreased 90% in end-stage AD patients compared to control. In contrast, the V_{max} of ChAT was doubled in the subjects recently diagnosed with AD compared to control. This same pattern of change was observed for AChE activity; decreased in end-stage AD and increased in early AD - both compared to controls.

Highly significant reductions of 5-HT and 5-HIAA were found in both end-stage and early AD. Dopamine levels were decreased only in the early AD patients (p < 0.05). The level of the direct catabolite of dopamine, DOPAC, was equally decreased (p < 0.05) in both end-stage and early AD. In early AD HVA levels were double that found in end-stage AD; only the decrease in end-stage disease was significant.

Previous reports indicate the pyriform cortex is affected early, and possibly initially, in the progressive spread of characteristic pathology in AD brain. The presented data may suggest that reduced serotonergic neurotransmission occurs early in the course of AD while cholinergic hyperactivity may precede precipitous decrements. MEMORY ENHANCEMENT IN AGED MONKEYS WITH VELNACRINE MALEATE (HP 029). WJ Jackson¹, JJ Buccafusco², AV Terry², DK Rush¹. Depts. of ¹Physiology & Endocrinology, ²Pharmacology-Toxicology, Medical College of Georgia, Augusta, GA 30912 and ³Hoechst-Roussel Pharmaceuticals, Inc., Neurosciences Strategic Business Unit, Somerville, NJ 08876.

Velnacrine maleate is a novel orally active acetylcholinesterase inhibitor of the acridine class with a longer duration of activity than physostigmine. Velnacrine has shown efficacy in the treatment of Alzheimer's disease and in improving both normal and experimentally impaired mnemonic function in animals and humans. In the present study, velnacrine was studied for its ability to ameliorate the decline in short-term memory observed in aged nonhuman primates. In the first phase of the study, doses of 1, 2, 4, 6, and 8 mg/kg po (free base corrected) were administered once to each of six aged (25-40 yr) macaques. Memory was assessed 30 min later by a delayed matching-to-sample (DMTS) paradigm. In the second phase of the study, each animal's best dose, i.e., the dose at which each animal had exhibited the greatest phase one improvement, was administered an additional three times. In the second phase, velnacrine induced a significant improvement in memory at the longest of three individually titrated delay intervals. Correct Long-delay matching increased from 58.9% during placebo sessions to 66.8% following velnacrine administration. This level of improvement represents 13% of the baseline value. In reference to other compounds tested by this paradigm, orally administered velnacrine appears to induce about the same degree of DMTS enhancement as physostigmine (i.m.) and tacrine (i.m.). The finding that velnacrine improved long-delay DMTS performance in a group of aged memory-impaired primates suggests potential value for treatment of age-related memory dysfunction.

EEL ACETYLCHOLINESTERASE (AChE) IS NOT A PROTEASE. R.T. Carroll¹, L. Grassi² and M.R. Emmerling¹. ¹Parke-Davis, Pharmaceutical Research, Division of Warner-Lambert, Ann Arbor, MI, 48106 and ²Service de Pharmacologie et d'Immunologie, C.E. Saclay, 91191 Gif sur Yvette, France.

Our earlier studies show that, of the AChE studied thus far, only commercially obtained eel AChE has an associated trypsin-like activity. Velocity sedimentation of purified Sigma eel AChE (type V-S) produces two peaks of trypsin-like activity, of which the faster sedimenting 11S peak overlaps with the peak of AChE activity. The protease activity remains associated with AChE upon resedimentation of the gradient fractions containing AChE and after shifting the sedimentation of eel AChE with monoclonal antibody Elec-106. Protease activity is also found in AChE purified from several other commercial preparations of eel enzyme. However, the overlap between the AChE and proteases activities in these preparations is less than the Sigma enzyme. The protease activity can not be attributed solely to contamination by trypsin since Boehringer Mannheim eel AChE has associated protease activity but is solubilized by autolysis. Nondenaturing zymography gel electrophoresis separates the protease activity from the commercial eel AChE. The protease activity runs as multiple bands with molecular weights different from that of AChE. Further characterization of the protease(s) was not possible because of the low abundance. Eel AChE solubilized directly from eel electric organs with 2 M MgCl₂ has no apparent intrinsic or associated protease activity, although contaminating protease activity is detected. Contrary to published reports, our results indicate that eel AChE has no detectable intrinsic protease activity. We found an associated protease activity only in commercial eel enzyme. The source of the protease activity is unclear but may result from contamination by endogenous eel proteases during the isolation of the AChE. Based on our results, it seems unlikely that this protease activity has any physiological significance.

CHOLINE ACETYLTRANSFERASE IN RETINAS OF PATIENTS WITH ALZHEIMER'S DISEASE. K.V. Porrello^{1*}, B. Knusel², F. Hefti², C. Spee¹, M. Guidoni¹, S. Schmidt¹ and J.C. Blanks^{1,3}. ¹Doheny Eye Institute, ²Andrus Gerontology Center, U. of So. Calif., and ³USC School of Medicine, Los Angeles, CA 90033.

Alzheimer's disease (AD) is characterized by a significant loss of cholinergic neurons and a decrease in the biosynthetic enzyme, choline acetyltransferase (ChAT), in the hippocampus and cerebral neocortices of the brain. Some AD patients also exhibit retinal degeneration, which is demonstrated by a loss of neurons in the ganglion cell layer (GCL) and atrophy of the nerve fiber layer. To determine whether retinal degeneration in AD is associated with a cholinergic defect, we have examined the biochemical activity and immunolocalization of ChAT in 9 AD and 12 age-matched control retinas. After dissection, a punch of neural retina was taken from each quadrant, homogenized, and assayed for ChAT activity. Comparable areas were fixed and processed for immunocytochemistry with anti-ChAT antibody. The activity of ChAT was comparable in different retinal quadrants of each eye in both the AD and the control groups. The overall mean ChAT activity for the AD group was higher than that of the control group, and was found to have borderline significance (p=.053). ChAT immunoreactivity (ChAT-IR) was localized to the somas and dendritic processes of amacrine cells in the inner nuclear and ganglion cell layers. In some cases, knobby-appearing cells, presumably an amacrine cell sub-type, showed ChAT-IR. The localization of ChAT-IR in retinas of AD eyes was similar to that in normal retinas. The findings based on biochemical and immunocytochemical analyses suggest that ChAT has a uniform regional distribution in human retinas from normal and AD eyes. Further studies are in progress to determine if elevated ChAT activity is a significant feature in AD retinas that can be substantiated biochemically and histochemically. Nevertheless, our findings provide evidence that retinal degeneration in AD, unlike that of the brain, is not accompanied by a cholinergic deficit.

OVARECTOMY REDUCES ChAT ACTIVITY AND NGF mRNA LEVELS IN THE FRONTAL CORTEX AND HIPPOCAMPUS OF THE FEMALE SPRAGUE-DAWLEY RAT. M. Singh*, E.M. Meyer, E.S. Huang, W.J. Millard, and J.W. Simpkins. Center for the Neurobiol. of Aging, Univ. of Fla., Gainesville, FL 32610.

It has been postulated that a decrease in target-derived trophic support may contribute to the neuropathology seen in Alzheimer's Disease (AD). Based on recent reports that suggest an interaction between estrogens and nerve growth factor (NGF), we hypothesized that estradiol (E2) may serve a neurotrophomodulatory role on basal forebrain cholinergic neurons. We assessed choline acetyl transferase (ChAT) activity and both NGF protein and mRNA levels in the frontal cortex (CTX) and hippocampus (HIPP) of 3 groups of animals: the ovary-intact animals (INTACT), ovariectomized (OVX) and E2-replaced (E2) animals. Neurochemical analysis was done at 5 weeks and 28 weeks post-ovariectomy while NGF levels were assessed at 3 months post-ovariectomy. Previous studies from our laboratory have demonstrated that OVX animals perform relatively poorly in a 2-way active avoidance paradigm. (Neurosci. Abst. # 518.19, pp 1246, 1992). Also we demonstrated that OVX reduced and E2 replacement increased high affinity choline uptake (Endocrine Soc. Abst. 1993). In the present study, we found that 5 weeks of ovariectomy was sufficient to reduce ChAT activity in the HIPP while levels in the CTX were relatively unaltered. E2 replacement reversed this effect. Interestingly, there was a 56% reduction in ChAT levels between the 5- and 28-week time points in the CTX of OVX animals while reduction in ChAT activity in E2 animals was less severe (16%), suggesting a cytoprotective effect of E2 on basal forebrain cholinergic neurons. We also addressed the possibility that E2 may mediate its 'trophic' actions through a classical neurotrophic factor, NGF. While 2-site ELISA failed to reveal any significant treatment-related differences in NGF protein levels, dot blot analysis revealed a 45% reduction in NGF mRNA in the CTX of 3 month OVX animals. E2 replacement resulted in a partial recovery of mRNA levels. Collectively these data suggest that estrogens may play a vital role in the normal function of basal forebrain cholinergic neurons and offer promise as therapeutic agents in neurodegenerative disorders such as AD. DEGENERATIVE DISEASE: ALZHEIMER'S—OTHER VI

515.1

GENERATION OF MONOSPECIFIC ANTIBODIES AGAINST THE PRECURSOR PROTEIN OF NOVEL AMYLOID COMPONENT (NAC) IN ALZHEIMER'S DISEASE.

A. Iwai*, K. Uéda, M. Yoshimoto, D. Otero, and T. Saitoh. Dept. of Neurosciences, University of California at San Diego, La Jolla, CA 92093-0624, USA

Recently we have identified a novel amyloid component (NAC) as a new constituent of Alzheimer's disease (AD) amyloid and cloned a cDNA for its precursor protein (NACP) composed of 140 amino acids. From the identified NACP sequence, new rabbit antisera were raised against N-terminal 9 aa and C-terminal 10 aa of NACP, and a portion of NAC (15 aa). In Western blots of both the human cerebral cortex cytosolic fraction and the bacteria made NACP from its cDNA, the NACP antibodies stained a protein of relative molecular mass of 19,000 (Mr19K). They showed 2.5 - 10 times higher sensitivity and better linearity than the previous anti-NAC antibodies that stained amyloid well in brain sections, suggesting that anti-NAC antibodies have higher affinity for amyloid form of NAC than its precursor, NACP. These data suggest that these antibodies should be useful to study the processing of NACP to NAC/amyloid with a potential for diagnostic use. (Supported by American Health Assistance Foundation and Yamanouchi Pharmaceutical Co., Ltd.)

35kDa PROTEIN IN SENILE PLAQUE AMYLOID IN ALZHEIMER'S DISEASE. Y. Takamaru, R. Fukatsu, K. Tsuzuki, H. Chiba, K. Kobayashi, Y. Aizawa, N. Takahata, T. Ishikane* and T. Ueno. Dept. of Psychiatry and Neurology, ¹Dept. of Laboratory Medicine, Hokkaido Univ. Sch. of Med., ²Dept. of Neuropsychiatry, ³Dept. of Microbiology, Sapporo Medical Univ. Sch. of Med., Sapporo 060, Japan

To understand the components of amyloid and the process of amyloid formation in Alzheimer's disease (AD) brain, we established monoclonal antibodies recognizing senile plaque amyloid.

Native amyloid and brain homogenate were used for immunogen. Monoclonal antibodies immunohistochemically reacted with senile plaque were selected. Among these mAb's, four mAb's recognized 35kDa antigen in brain homogenate, cerebrospinal fluid or plasma proteins. Reactive antigen was purified from human plasma using PEG fractionation and some chromatographies. Amino-terminus amino acid sequence was determined, and the results showed that 35kDa antigen was identical to apolipoprotein E (apo E).

The mAb's also reacted with approximately 35kDa band in soluble fraction prepared from brain homogenate of AD similar to plasma protein. Immunohistochemical study showed that various type of senile plaque and vascular amyloid were stained by the mAb's reacted with apo E, and fibrous background structure was also stained diffusely.

Our data show that apo E seems to be expressed in AD brain and play an important role in amyloid plaque formation.

515.2

NOVEL AMYLOID COMPONENT (NAC) DIFFERENTIATES ALZHEIMER'S DISEASE FROM NORMAL AGING PLAQUES

K. Uéda*, E. Masliah, Y. Xia, A. Iwai, M. Yoshimoto, and T. Saitoh. Dept. of Neurosciences, UC San Diego, La Jolla, CA 92093

Recently, we have identified a novel amyloid component (NAC) from Alzheimer's disease (AD) brain, and cloned the corresponding cDNA. NAC is derived from the precursor protein (NACP) composed of 140 amino acids with a calculated *Mr.* of 14.5 kDa. Hydrophathy analysis of the predicted amino acids sequence showed NAC to be most hydrophobic, possibly a membrane-binding domain of NACP. Secondary structure predictions show that the NAC peptide has a strong tendency to form β -structures, like amyloid β /A4 protein. Antibodies to NAC peptides detected a 19 kDa protein in Western blot of brain homogenate. Quantitative immunohistochemical analyses showed that 30% of the diffused plaques and 55% of the immature and mature plaques as well as vascular amyloid are strongly stained in AD, while the plaques of the normal aged cases are not. This could imply that a sub population of the plaques as found in normal aged cases represents physiological products that are not stained with the anti-NAC antibody, whereas the plaques with extensive neuritic changes and amyloid condensation represent AD specific plaques that are positive with anti-NAC antibody. We conclude that NAC might be a critical component in the pathogenesis of the AD plaque.

515.4

THE REGULATION OF AMYLOID PRECURSOR PROTEIN PROCESSING BY cAMP AND NITRIC OXIDE IN OLFACTORY NEUROBLASTS FROM ALZHEIMER DONORS. B.L. Wolozin*, J. Basaric-Keys, R.M. Pluta, R.S. Lebovics and T. Sunderland. Laboratory of Clinical Science, NIMH, Bethesda, MD 20892

Previous studies of olfactory neuroblasts (ON) have demonstrated a 7-fold increase in the levels of amyloid precursor protein C-terminal derivative (CTD) seen on immunoblots of Alzheimer vs. control ON subjected to treatment with the lysosomal inhibitor, chloroquine. Further investigations have shown that the amount of CTD detected can be regulated by agents that influence second messenger systems. One axis of regulation appears to be cAMP. Treatment of ON with 0.5 mM dibutyryl-cAMP and 0.5 mM IBMX elicits a 92% decrease in CTD levels. We now show that other agents that modulate cAMP levels, such as pertussis toxin, isoproterenol or theophylline also elicit decreases in CTD levels. A second axis of regulation may be mediated through nitric oxide, which is known to regulate cGMP metabolism. Treatment of ON with nitroprusside shows a bimodal response of CTDs seen on immunoblot. At 0.1-1 μ M nitroprusside, CTD levels are reduced, whereas at 100 μ M nitroprusside there is a small increase in CTDs. Studies using free radical scavengers, which capture endogenously produced free radicals, suggest that nitric oxide or a related free radical is produced endogenously. Treatment of ON with oxyhemoglobin or free radical scavengers, such as ascorbic acid, N-acetylcysteine or dimethylthiourea, all elicit increased CTDs. This also suggests that the decrease in CTD is the most physiologically relevant effect. We are currently using nitric oxide synthase inhibitors to determine whether this mechanism involves nitric oxide synthase directly. These data suggest that second messengers are capable of regulating APP, and raise the possibility that abnormalities in signal transduction pathways can influence APP metabolism.

APP MEDIATES CELL ADHESION AND CELL-MATRIX INTERACTIONS. H. Mechler*, U. Mönning, C. L. Masters & K. Beyreuther. Center for Molecular Biology Heidelberg, University of Heidelberg, D-6900 Heidelberg, Germany. § Department of Pathology, University of Melbourne, Parkville, Victoria 3052, Australia.

We have analysed cellular and cell-matrix interactions of F98 rat glioma cells mediated by the amyloid precursor protein (APP). The cells were transfected with the cDNAs coding for APP695, 751 and 770 under the control of the strong human CMV promoter. Stable cell lines, termed F695, F751 and F770, were established by G418 selection. In a cocultivation assay, we used F695, F751 and F770 cells as a culture substrate for nontransfected F98 cells seeded on microporous membranes. We observed accelerated adhesion of F98 cells in response to all three overexpressed secretory APP isoforms. Compared to APP751 and APP770, secreted APP695 induced a higher increase of bound cells, indicating different mechanisms involved in the regulation of adhesion-promoting activity. To study further biological effects of APP695, 751 and 770, transfected and nontransfected F98 cells were grown in a collagen matrix to mimic a three-dimensional tissue-like situation. While wild type F98 cells formed smooth spherical cysts in the gel, F695 cells grew in large aggregates extending long branching cords radially into the surrounding matrix. In contrast, F751 and F770 cells showed a random distribution of individual cells throughout the collagen gel. These results show that the APP isoforms share an activity promoting cell adhesion and specifically regulate cellular outgrowth in an extracellular matrix.

ISOLATION OF THE FAMILIAL ALZHEIMER'S DISEASE GENE ON CHROMOSOME 14. R. E. Tanzi, S. M. Gaston, W. Wasco, D. M. Romano, J. Peppercom, A. Crowley, M. Paradis, K. B. Sims*, A. J. Bush, J. Haines, J. F. Gusella and P. St George-Hyslop. Laboratory of Genetics and Aging and Molecular Neurogenetics Unit, Mass. General Hospital, Boston, MA 02129 and Tanz Neurosciences Inst., University of Toronto, Ontario.

Familial Alzheimer's disease (FAD) is a genetically heterogeneous disorder. While a small subset of families (2-3%) contain mutations in the gene encoding the amyloid β -protein precursor (APP) the vast majority of early-onset (65 years) FAD is caused by a mutation in a gene on the long arm of human chromosome 14. The greatest evidence for genetic linkage to FAD is observed with DNA markers in the region 14q24.3. We will present the results of our efforts to isolate the FAD gene defect for chromosome 14. We have genetically determined a minimal candidate region of approximately 1-2 megabases by recombination analysis and have cloned this region in the form of yeast artificial chromosome (YAC) and cosmid clones. These clones are being used to generate polymorphisms to search for linkage disequilibrium to further narrow down the minimal candidate region and to isolate expressed sequences from this region by either exon trapping or direct cDNA screening. Candidate genes obtained in these experiments, along with known candidate genes mapping to 14q24.3 (HSP70 and FOS) are being assessed for potentially pathogenic mutations by single stranded conformational polymorphism analysis and by direct sequencing. While the coding region of FOS has been found to contain no FAD associated mutations, we are still examining the 5 prime and 3 prime untranslated regions. We are also attempting to determine whether the HSP70 gene resides in the minimal candidate region. Assessment of known and novel genes found to reside in the minimal candidate region will be discussed.

515.9

CLONING OF THE cDNA FOR A CANDIDATE GENE FOR ALZHEIMER'S DISEASE. G. Ali, X.-G. Cai, P. Szabo and J.P. Blasz*. Burke Medical Research Institute and Division of Geriatrics, Cornell University Medical College, White Plains, NY & NY, NY. 10605

Because of confirmed evidence of a deficit of activity of the α -ketoglutarate dehydrogenase complex (KGDHC) in Alzheimer disease (AD) brain (15-50% of normal) and evidence of a decrease in KGDHC activity in cultured AD fibroblasts (55% of normal), we obtained a full-length human cDNA clone for the E2k component of KGDHC. A 1.4 kb cDNA probe obtained by PCR amplification from human fetal fibroblast mRNA, with primers chosen from the published rat E2k sequence, had 95% homology with the coding region of rat E2k cDNA. This probe was used to screen a human fetal brain library in λ -ZAP II (Stratagene). The full-length cDNA which was obtained and sequenced was 3.0 kb, in good agreement with the size of the human E2k message. We localized the human E2k gene to chromosome 14 (14q24); no other component of KGDHC is on C14. Studies are underway to determine if the human E2k gene is in the precise region of C14 associated with AD. We have found genetic heterogeneity in E2k in human populations, but further studies are needed to determine whether mutations of this gene associate with the occurrence of clinical AD in specific kindreds. E2k is a candidate gene for the C14-linked form of AD.

515.6

THE AMYLOID PRECURSOR PROTEIN (APP) IN NEURO-IMMUNE REACTIONS U. Mönning¹, R. Banati^{2*}, C. Masters³ and K. Beyreuther¹ ¹Center for Molecular Biology (ZMBH), University of Heidelberg, Im Neuenheimer Feld 282, D-6900 Heidelberg F.R.G. ²Department of Neuromorphology, Max-Planck-Institute for Psychiatry, Martinsried, F.R.G. ³Department of Pathology, University of Melbourne, Parkville, Victoria 3052, Australia

The mechanism of proteolytic breakdown of the β A4-amyloid precursor (APP) has attracted much attention because of its relevance for Alzheimer's disease. Apart from the role of APP during amyloidogenesis, many efforts have been made to identify the functional significance of this widely expressed protein in various biological processes. Employing biochemical techniques, we demonstrated that APP under pathological conditions might have characteristics of an acute phase protein.

Since the presence of brain macrophages (activated microglia) is closely associated with various neuropathological states including neurodegenerative and inflammatory diseases in human brain, we studied the biosynthetic behavior of APP in cultured microglial cells upon immunological activation. We also compared their APP-specific biosynthesis to that of immunocompetent cell of the peripheral immune system. From these studies we conclude that APP is associated with early response mechanisms in the central nervous system involving the brain's intrinsic immune system. The results support that microglia may play a critical role in plaque formation in Alzheimer's disease.

GENETIC AND CLINICAL LINKS BETWEEN TRISOMY 21, DOWN SYNDROME, AND ALZHEIMER'S DISEASE. L.N. Geller,* @L.F.M. Scinto, M.B. Benjamin, @K.R. Daffner, @S. Weintraub, @M.M. Mesulam, D. Dressler, and H. Potter. Dept. Neurobiology, Harvard Medical School and @Beth Israel Hospital, Boston, MA 02115.

A connection between Alzheimer's disease (AD) and Down syndrome (trisomy 21) is indicated by the fact that Down syndrome individuals develop AD neuropathology by the third or fourth decade of life. We have also found that AD, like Down's patients, are hypersensitive to the effect of the cholinergic antagonist, tropicamide, on pupil dilation. One explanation for this connection would be that the overexpression of a gene or genes on chromosome 21 results in Alzheimer's disease. However, mutations in the amyloid precursor protein gene on chromosome 21 have been found to be associated with only a very small percentage of familial AD cases. Instead, some Alzheimer's disease cases may be caused by sporadic trisomy of chromosome 21, resulting from mutations or toxins that cause chromosome nondisjunction. Quantitative fluorescence *in situ* hybridization has been used to determine the number of trisomy chromosome 21 cells in cultured fibroblasts from AD and unaffected individuals. Results suggest that there is a small, but significant increase in the number trisomy 21 in cells from AD individuals. To explore the possibility that a defect in the mitotic spindle apparatus may underlie this aneuploidy, cultured lymphoblasts from AD and unaffected individuals were briefly exposed to the microtubule-disrupting agent colchicine. As assayed by the subsequent appearance of metaphase chromosomes showing centromere separation, cells from AD patients were significantly more sensitive to colchicine treatment compared to cells from unaffected individuals.

515.10

ALTERED SENSITIVITY TO NGF OF DORSAL ROOT GANGLION CELLS CULTURED FROM MOUSE TRISOMY 16, A MODEL OF DOWN SYNDROME. R.J. Pearce*, A. Balbo, Z. Galdzicki & S.J. Rapoport. LNS, NIA, NIH, Bethesda, MD 20892.

Nerve growth factor (NGF) is an endogenously derived protein necessary for survival of certain populations of embryonic neurons. In culture, NGF significantly enhances survival of sensory neurons. We compared the sensitivity to NGF of primary cultures of dorsal root ganglion (DRG) neurons from trisomy 16 (Ts16) mouse fetuses with normal diploid neurons. Mouse Ts16 is a model for human trisomy 21, which gives rise to Down syndrome (DS). All DS subjects develop Alzheimer disease neuropathology after the age of 35 years. Dorsal root ganglia from E15-E17 fetuses were dissociated into a cell suspension by trituration and then plated onto 35mm laminin-coated dishes (50-150,000 cells/dish). Plating media consisted of Minimum Essential Medium supplemented with 10% horse serum, 10% fetal calf serum (FCS) and 7S-NGF (1-160ng/ml). Cells were maintained for 3-4 weeks and media were exchanged every 3-4 days (media same as above with FCS excluded).

In both Ts16 and normal preparations, the proportion of DRG neurons plated which adhered to the laminin coated culture dishes depended on the amount of 7S-NGF included in the media ($p < 0.001$). Neuronal survival was assessed as adhesion to the substratum with the extension of neurites. We previously showed that, at 40ng/ml NGF, only 20% of Ts16 DRG neurons seen 24hr after plating survive the first week in culture, as compared to 50% for normal diploid neurons (Orozco *et al.*, 1987). This has now been repeated for a range of NGF levels. We found that survival in culture was not only NGF dependent for both populations ($p < 0.001$), but also that the degree of survival across this range was significantly different between trisomic and diploid neurons ($p = 0.002$). Also, the initial survival of the normal DRG neurons over the first 5 days correlated significantly with the density of the cells 24hr after plating ($r = 0.661; p = 0.001$), whereas the same was not the case for the trisomic neurons ($r = 0.077; p = 0.803$).

515.11

ELECTROPHYSIOLOGICAL PROPERTIES OF SEPTAL NEURONS CULTURED FROM FETAL TRISOMY 16 MOUSE. L.D. Acevedo*, Z. Galdzicki, R.J. Pearce, and S.I. Rapoport. Laboratory of Neuroscience, National Institute on Aging, NIH, Bethesda, MD 20892.

Mouse trisomy 16 is a model for human trisomy 21, which gives rise to Down's syndrome (DS). All DS subjects eventually develop Alzheimer disease (AD). To better understand these disorders, we examined the electrophysiological properties of septal and hippocampal neurons from the trisomy 16 mouse fetus, as in humans, homologous regions develop AD pathology. Fetal mouse trisomy 16 hippocampal neurons in culture have abnormal electrical characteristics [Galdzicki et al., 1993, *Brain Res* 604:69-78].

Septal brain regions from trisomic and diploid fetuses at 16 days gestation were triturated to yield dissociated neurons which then were cultured on poly-L-lysine-coated plastic dishes. The cultures were grown in MEM supplemented with 5% horse serum and 40 ng/ml 7S-NGF. Under these conditions, we obtained neurons of diverse morphology having some diameters ranging from 5 to 30 μ m and surviving 3 weeks or longer.

We first examined whole-cell voltage clamp records from septal neurons at 9-16 DIV. The passive properties and current/voltage relations of trisomic neurons were compared to those of septal neurons derived from normal diploid fetuses. For this comparison we chose neurons having a capacitance between 7 and 9 pF, and included records from 6 normal and 13 trisomic neurons. We found the two groups did not differ significantly in their passive properties ($P < 0.05$), including input resistance and resting potential. The maximum inward current, maximum inward conductance, and maximum outward conductance, when normalized by capacitance, also were not different between the groups. The ratio of inward to outward conductance also was not significantly different. Based on this preliminary analysis, we find no difference between the electrophysiological properties of trisomy 16 and normal diploid septal neurons.

DISTRIBUTION OF HSV-1 DNA IN SELECTED AREAS OF NORMAL AND ALZHEIMER'S DISEASE BRAINS: A PCR STUDY. Guillaume D., Bertrand P., Hellauer K., Dea D., Lindsay J., Kogan S., Gauthier S., Poirier J. Douglas Hospital Research Center, the McGill Center for Studies in Aging, Montreal and the Laboratory for Disease Control, Ottawa, CANADA, H4H 1R3.

The possibility exists that reactivated Herpes Simplex (HSV) viruses travelling by centripetal force from the trigeminal ganglia affect the CNS areas subject to degeneration in Alzheimer's disease (AD). We addressed whether the HSV-1 genome was present more often in AD brains than in those of controls (C), and whether it was detected preferentially in those brain areas where the AD pathological changes occur. We used formalin-fixed brains of 57 C and 98 AD, preparing genomic DNAs from 5 areas (hippocampus, frontal cortex, occipital cortex, cerebellum and striatum). The DNA was PCR amplified for the presence of a 138bp piece from the glycoprotein D gene of HSV-1. Results show that elderly often exhibit HSV-1 DNA in their brain genome: 72% of C and 75% of AD had at least one HSV-1 infected region, while 46% of C and 43% of AD had all 5 regions infected. The prevalence of HSV-1 DNA within each brain area was similar between the two groups and within the C and AD groups: the 5 regions which were examined, were affected in about 60% of all C and AD individuals. Thus, end-stage AD does not correlate with a preferential HSV-1 gradient through the CNS. Nevertheless, chronological links between AD and HSV-1 infection need to be determined. (Supported by the Center for Disease Control, Canada).

515.12

LONG-TERM EXPRESSION OF LAC-Z GENE FROM LATENT HSV IN RAT HIPPOCAMPAL NEURONS. N.T. Maidment*, D.C. Bloom, A. Tan, L.T. Feldman and J.G. Stevens. Dept of Psychiatry and Dept of Microbiology and Immunology, UCLA School of Medicine, Los Angeles, CA 90024.

A major hurdle in the development of the Herpes Simplex Virus (HSV) approach for gene transfer in the CNS has been the need for a promoter that facilitates long-term expression during latency. Using the LAT promoter to drive the lacZ gene, we were able to see B-galactosidase (B-gal) activity in mouse sensory ganglia for over 2 months. However, no B-gal mRNA could be detected at this time-point, either by *in situ* hybridization or PCR. This suggested that the enzyme is very stable and highlighted the need for transcript analysis in the evaluation of latent gene expression.

Using an ICP4- construct (8117/43) with the Mo-MuLV LTR driving the lacZ gene we have previously demonstrated transcripts in mouse dorsal root ganglia. We now report on the utility of this construct for long-term expression in the rat brain. 8117/43 or KDe6 (an ICP4-, LAT+ control virus) was stereotactically injected into the hippocampus (1×10^6 p.f.u.) and the animals subsequently sacrificed at various intervals up to 2 months. PCR analysis of viral DNA at 2 months demonstrated that both viruses establish a latent infection in this brain region. Using both x-gal staining and *in situ* hybridization we were able to demonstrate that 8117/43 expresses B-gal for at least 2 months in hippocampal neurons whereas LAT expression is minimal at this time. Staining for x-gal was also apparent in cells of the medial septum suggesting retrograde transport of the construct within septo-hippocampal neurons. These studies indicate that the LTR promoter affords long-term expression of foreign genes in the septo-hippocampal system.

SYMPOSIA

THURSDAY AM

SYMPOSIUM. GABA AS A DEVELOPMENTAL SIGNAL. J.L. Barker, NINDS, NIH (Chairperson); A.J. Tobin, UCLA; N.C. Spitzer, UCSD; P.R. Gordon-Weeks, King's College London; D.A. Redburn, Univ. of Texas Health Science Center, Houston.

Recent evidence indicates that γ -aminobutyric acid (GABA) is expressed during CNS development in all vertebrate species. Tobin, who has studied the molecular biology of glutamate decarboxylase (GAD), the rate-limiting enzyme in GABA synthesis, will review data that shows GAD is derived from two different genes each encoding proteins of similar molecular weight but different intracellular distributions. Both enzymes become co-expressed in subsets of GABAergic neurons throughout the well-differentiated CNS. Spitzer has studied the signal transduction cascade in amphibian spinal neurons that is associated with the initial appearance of GABA. He will relate fluctuations in intracellular Ca^{2+} levels to the control of transcriptional events. Gordon-Weeks has investigated the mechanisms underlying GABA release from the growth cones of developing neurons. Regulated release of GABA suggests that GABA plays extracellular autocrine and paracrine roles in neurite outgrowth and synaptogenesis. Redburn has examined the role of GABA in retinal development. Her observations in the rabbit indicate that GABA is a critical signal in the very establishment of the primary visual pathway. Barker will review studies in the rat that indicate GABAergic cells and signals are co-expressed during the last half of embryonic development throughout most of the CNS. All of these results in different vertebrate species support the idea that GABA is a developmental signal involved in the morphogenesis of the CNS before it transmits fast transients at synapses.

SYMPOSIUM. NEURONAL FUNCTIONS OF CALMODULIN-DEPENDENT PROTEIN KINASE II. T.R. Soderling, Vollum Institute (Chairperson); H. Schulman, Stanford Univ.; H. Hidaka, Nagoya Univ.; A. Silva, Cold Spring Harbor.

Multifunctional CaM-kinase II (CaM-K II) is the most abundant protein kinase in brain where it regulates both presynaptic and postsynaptic functions. This symposium will focus on recently discovered functions of CaM-kinase II with an emphasis on its involvement in cellular learning and memory. CaM-K II is of particular interest as it constitutes the major postsynaptic density protein at excitatory synapses, and it becomes constitutively active after autophosphorylation. Dr. Schulman will describe another function of autophosphorylation which allows the kinase to act as a unique Ca^{2+} spike frequency detector. He will also describe cellular mechanisms of "cross-talk" between CaM-K II and PKC. Dr. Hidaka will discuss the use of recently developed, cell-permeable inhibitors of CaM-K II (e.g., KN-62) to probe neuronal functions such as tyrosine hydroxylase activation, immediate early gene expression and long term potentiation. Dr. Soderling will focus on the activation of CaM-K II in cultured hippocampal cells by NMDA receptor stimulation and the resultant phosphorylation and regulation of non-NMDA glutamate receptor ion channels by CaM-K II. The role of CaM-K II in learning and memory will be further explored by Dr. Silva who will describe behavioral studies on mice lacking the major alpha subunit isoform of CaM-K II.

519.1

Morphology of the Blue-ON ganglion cell type in macaque retina. D.M. Dacey, Dept. of Biol. Structure, Univ. of Washington, Seattle, WA 98195.

We have been studying the physiological properties of identified ganglion cell types by combining intracellular recording and cell filling in an in vitro preparation of the macaque retina. The intact retina, choroid and pigment epithelium are dissected from the eyecup and placed in a superfusion chamber on the stage of a light microscope; oxygenated culture medium is continuously superfused over the retinal surface and temperature is maintained at 37°C. The cell bodies of midget, parasol and other ganglion cell types were selected for recording under direct microscopic control after staining with a vital fluorescent dye. Ganglion cell responses to chromatic and luminance flicker were studied with a light-emitting diode-based stimulator (Smith et al., J. Physiol. 1992, 458:191). A two degree stimulus field was projected onto the retinal surface via the camera port of the microscope. Using the LED stimulus, red-green, blue-ON and phasic non-opponent types have been identified. The dendritic morphology of the recorded cells was shown by intracellular injection of Neurobiotin. Results confirm the expectations that parasol cells are phasic, non-opponent cells and midget ganglion cells give sustained, color-opponent responses. However, all midget cells recorded from thus far showed only red-green opponency. To date we have also recorded from 12 cells classified as Blue-ON; all of these cells displayed a distinctive non-midget, bistratified dendritic morphology. Dendritic field size and coverage of these bistratified cells suggest that they make up ~6-8% of the ganglion cells in the retinal periphery. Dendritic stratification suggests direct input from blue-cone bipolar cells near the inner border of the inner plexiform layer. Thus, the red-green and blue-yellow opponent pathways of the macaque visual system arise in parallel from morphologically distinct ganglion cell mosaics.

COLOR OPPONENT NEURONS IN MOUSE RETINA

S. Yamamoto, P. Gouras*
Harkness Eye Institute, Columbia University,
New York, NY 10032

We have been examining the activity of single retinal ganglion cells to full field spectrally defined stimuli in normal and dystrophic rats and mice. We have examined 122 single units in 23 normal mice. All units had spontaneous activity but only 91% were driveable by light. 82/111 (74%) had broad-band action spectra; 8/82 (10%) of these had a uniquely high sensitivity to short wavelengths which we consider a short wavelength sensitive (S) cone input. 21/82 (26%) showed color opponency between an S-cone and a middle wavelength mechanism. The S-cone input was either excitatory or inhibitory. Color opponent units were found throughout the retina although twice as frequent in the lower half than the upper half. Since recent anatomical studies indicate that the lower half of the mouse retina contains only S-cones (Szel, et al., J Comp Neurol 325:327, 1992) the color opponency in the lower retina may occur between rods and S-cones. The existence of color opponent units in mouse retina implies that mice have color vision.

NEW LAGOMORPHIC PERSPECTIVE ON X- AND Y- GANGLION CELLS IN MAMMALIAN RETINA. E. Y. Famiglietti*

Dept. Anat. & Lions' Sight Ctr., Univ. Calgary, Calgary, AB Canada T2N 4N1.

X and Y retinal ganglion cells (GCs) were characterized physiologically in cat retina, where their morphological counterparts are beta/class II and alpha/class I cells, respectively. In primate retina, a bipartite physiological subdivision of GCs with "brisk" characteristics is problematical. Yet the well-established distinction between "midget" and "parasol" GCs suggests strong parallels with beta/class II and alpha/class I cells. X and Y cells, collectively called "brisk", have also been identified in rabbit. Unlike those of cat, they are similar in (large) receptive field size and in (rapid) axonal conduction velocity. "Alpha" but no "beta" GCs were identified in one study of rabbit retina (Peichl et al., '87), but in an earlier brief report we identified class I and class II cells (Famiglietti and Siegfried, '79), the analysis of which is now complete. Class I cells have the largest GC bodies and axons; those of class II cells are slightly smaller on average. Dendritic field sizes are similar in the visual streak, but class I cells are larger in the periphery. Branching patterns are similar, but class I cells are "radiate" and class II cells are commonly "tufted", by the criterion of m_p (Famiglietti, '92). Dendritic stratification of class II cells in cat is broad, overlapping that of class I cells, but in rabbit it is narrow, and similar to that of midget ganglion cells, in that two sets of class II cells (IIa1, IIb2/blue ON-centre?) lie nearer the boundaries of the inner plexiform layer (IPL), flanking the two principal sets of class I GCs (Ia2, Ib2). Additional sets of class I/II GCs (Ia1, Ib1, IIb1) may include "large field" units. Rabbit class I and class II GCs appear to reflect an early phylogenetic stage in the structural and functional separation of mammalian X and Y cells.

SOME SUPPRESSIVE ROD-CONE INTERACTIONS INVOLVE CENTRAL VISUAL PATHWAYS. G. Lange, M. Schütte, N. Denny, and T. E. Frumkes*. Dept. Psychol., Queens College CUNY, Flushing, New York 11367.

Dark adapted rods of vertebrate retina exert tonic suppression upon cone-mediated vision. We have discerned two classes of mechanisms. (1). Sensitivity to rapid flicker progressively decreases during rod-dark adaptation, and increases if rods are adapted to increasing intensity backgrounds. Neurophysiological, pharmacological, and psychophysical data indicate that this "flicker effect" is consistent with a distal retinal mechanism involving a prominent role for horizontal cells. (2). Sensitivity to high spatial frequency gratings similarly decreases during rod-dark adaptation, and increases if rods are adapted to increasing intensity backgrounds. However, this "grating effect" is as prominent with interocular adapting fields as with one-eyed stimulation, and psychophysical data are inconsistent with an electrical coupling model accounting for the flicker effect. We suggest that this spatial effect could be mediated by a monoaminergic, hypothalamo-retinal pathway which we have recently described in mammals. However, we cannot rule out involvement of some intrinsic cerebral mechanism.

DIFFERENT EFFECTS ON CYTOCHROME OXIDASE ACTIVITY AND AXOPLASMIC TRANSPORTATION OF RETINAL GANGLION CELLS FOLLOWING INT ROACULAR HYPERTENSION IN RAT. Yaping Chu, Zhonghao Liu and Xuegang Luo*. Dept. of Neurobiology, Hunan Medical University 410078, Changsha, Hunan, P.R. China

The retrograde horseradish peroxidase (HRP) tracing method combined with cytochrome oxidase (C.O.) histochemistry was used to investigate the effects of intraocular hypertension on oxidative metabolism and axoplasmic transportation of the retinal ganglion cells (RGCs) in rats. Isotonic saline was perfused into the anterior chamber of the left eye, as experiment, with intraocular arterial perfusion pressure for 1 hr and then the intraocular hypertension was decreased to normal. The anterior chamber of the right eye was only pierced by needle (no injection), as control, for 1 hr. During the intraocular hypertension, 0.3ul 30% HRP (sigma VT) was injected into each of 8 sites which were distributed symmetrically in the superficial layer of bilateral superior colliculi and 4 sites in bilateral dorsal lateral genicular nuclei. After the rats were survived for 48 hrs, the retinal whole-mounts were prepared in the fixative and then incubated with DAB method for HRP reaction followed by C.O.-cobalt chloride procedure for C.O. reaction. For a quantitative analysis, the numerical density of double-labeled (C.O./HRP) RGCs in experimental group was 607/mm², 2175/mm² in control group; while the single C.O. positive RGCs in experimental group was 1145/mm², 775/mm² in the control group. The double labeled RGCs in the experimental group decreased significantly (P<0.01) but the single C.O. labeled RGCs increased relatively (P<0.05) as compared with the control group. According to the early experiment, the restoration of C.O. activity in various degrees followed by prolonging survival time (X. Luo et al., Acta Anatomica Sinica, 19 (1988) 85). It was presumed that the restoration of the C.O. activity was earlier than those of axoplasmic transportation. supported by NSFC 3870621 and Research Grant from HMU.

DENSITY OF MIDGET AND NON-MIDGET GANGLION CELLS IN MACAQUE FOVEA D.J. Calkins*, S.J. Schein*, Y. Tsukamoto*, P. Sterling. U. of Penn., Phila., Pa 19104, ¹UCLA, 90024, ²Hyogo Col. Med., 663 Japan.

The number of ganglion cells per cone in primate fovea has been estimated at 2-4. The fraction of the total ganglion cell population that are midget ganglion cells has been estimated at 80-95%. We identified in electronmicrographs of serial sections every ganglion cell and cone pedicle in a small foveal patch and found 150 ganglion cells (non-displaced) and 55 pedicles, for a ganglion cell/cone ratio of 2.7. Of the ganglion cells 110 (73%) were midget and 40 (27%) were non-midget. Of the non-midget cells, 9 were bistratified (also parvocellular) and 31 were monostatified. The 55 cone inner segments corresponding to the pedicles occupied 735 μm^2 at an eccentricity of 1.1 - 1.25° nasal. The densities (cells/mm²) corresponding to this retinal locus were: cones and midget ganglion cell pairs, 74,830; bistratified ganglion cells, 12,245; monostatified cells, 42,177. The resolution limit (Nyquist) for the array of midget ganglion cell pairs is 32 c/deg, and for the array of bistratified ganglion cells, it is 13 c/deg. Thus, enough non-midget ganglion cells are present in foveal retina to support several subcomponents of the "M" and "P" pathways.

SPATIO-TEMPORAL RECEPTIVE FIELD (STRF) OF RETINAL GANGLION CELLS. J.L. Wang and Ken-ichi Naka², Dept of Ophthalmol., NYU Medical Center, New York, NY 10016

The neuron network in the vertebrate retina processes information in the joint domains of time and space. The neurons' receptive field, including that of ganglion cells, must be defined in time and space. A ganglion cell's STRF can be defined by cross-correlating spatio-temporal white-noise input against a train of spike discharges (transformed into a unitary pulses) evoked by such a stimulus. Our past studies have shown that spatial or color information is carried largely by the linear component in a spike train. The resulting correlograms, the linear part of a STRF, are, therefore, an adequate description of the ganglion cell's receptive field.

A spatio-temporal white-noise stimulus, a checker matrix of 16x16 elements modulated by M-sequence, was produced by VSG2/2 visual stimulus generator (Cambridge Research Systems, UK) and spike discharges were recorded extracellularly by means of a tungsten electrode. We used two preparations, the retinas of a channel catfish, *Ictalurus punctatus*, and of kissing gourami, *Helostoma temminckii*. All measurements were made under photopic condition. There is only one class of cone in the catfish retina and there are two classes of cone, red and green, in the gourami retina. We will cross-reference results from these retinas to analyze how signals are processed in time and space in the retinal neuron network.

EXTRA RECEPTIVE FIELD FACILITATION IN RABBIT'S RETINAL DIRECTIONAL SELECTIVITY. N. M. Grzywacz^{*}, F. R. Amthor and D. K. Merwine, Smith-Kettlewell Inst., 2232 Webster St., San Francisco, CA 94115 and Univ. Alabama at Birmingham.

Amthor et al. (1989), and Yang and Masland (1992) showed that the sizes of dendritic trees and excitatory receptive field centers (RF) of On-Off directionally selective (DS) ganglion cells of rabbit are similar. This led to the suggestion that directional selectivity models based on asymmetric, excitatory amacrine synapses onto DS cells cannot be correct. These models might predict an RF displaced asymmetrically relative to the DS cells' dendritic tree. However, another possible prediction is that the RF might coincide with the ganglion cells' dendrites due to bipolar-cell inputs and that facilitation for preferred-direction motion might be transmitted asymmetrically to ganglion cells. To test this alternative, we recorded extracellular responses of DS cells to preferred- and null-direction apparent motions beginning outside the RF and ending just inside it. We also recorded responses to motions beginning just outside the RF and ending in various positions in it.

The data show that stimuli from outside RF positions can facilitate responses to stimuli inside the RF during preferred-direction motions. In contrast, null-direction motions only elicit inhibition. Positions that elicit facilitation can be at least 180 μ m outside the RF. Moreover, stimuli near the border of the RF can cause facilitation even if the motions terminate in or past the middle of the RF. For the majority, but not all cells, the strongest facilitation occurs for the shortest distance tested, that is, 60 μ m. Bell-shaped facilitation distance dependence argues that extra RF facilitation is not due to ganglion cell threshold. In conclusion, asymmetric extra RF facilitation supports an excitatory asymmetric amacrine model for directional selectivity and suggests that traditional RF, which might be due to bipolar-cell inputs to ganglion cells, may be different from the region of motion facilitation.

A MODEL WITH COUPLED NONLINEAR OSCILLATORS CAN DESCRIBE SPIKE TRAINS OF CAT RETINAL GANGLION CELLS. A. W. Przybyszewski^{*}, M. J. M. Lankheet and W. A. van de Grind, Dept. Physiol., Freie Universität Berlin, Germany and Utrecht Biophysics Research Institute, Dept. Comp. Physiol., Utrecht University, The Netherlands.

Ganglion cell activity was recorded intracellularly in the optically intact *in vivo* eye of the cat. Using a wavelet method, the recorded intracellular responses were separated into a "slow" G-potential and the corresponding spike train. We had shown previously (Przybyszewski et al., *Vis. Res.*, 33 (1993): 861-875) that the G-potential responds to sinusoidally modulated light spots with at least two kinds of oscillations and only the slower one is always locked to the stimulus. The G-potential oscillations can be simulated with the modified van der Pol oscillator. On the basis of the patch clamp data (Lipton & Tauck, *J. Physiol.*, 385 (1987): 361-391) it appears that local membrane properties can be simulated by another nonlinear oscillator. The two nonlinear oscillators were coupled to model spike trains obtained experimentally. Irregularities appear in the experimental and the simulated data when the temporal stimulus frequency is increased. Changing the coupling strength causes changes in irregularities, which are suggestive of a noise-reduction mechanism. If the coupling coefficient depends on the synapse position in the dendritic tree, the membrane could filter psp's in a position-dependent manner. Such a mechanism might generate signals that look more or less noisy, whereas in fact there is no noise but rather the complex dynamic interaction of the two nonlinear oscillators.

AMINO ACID RECEPTORS OF PRIMATE MIDGET AND PARASOL CELLS IN A RETINAL SLICE. Z.J. Zhou¹, D.W. Marshak² and G.L. Fain¹, ¹Jules Stein Eye Inst., UCLA Sch. of Med., Los Angeles, CA; ²Dept. Neurobiol. & Anatomy, U. of Texas Med. Sch., Houston, TX.

Primate parasol and midget ganglion cells are known to have different response properties, but we do not know if these functional differences are due to differences in synaptic receptors and/or voltage-gated channels or to differences in synaptic inputs. We have studied the effects of bath-applied amino acid transmitters on both parasol and midget ganglion cells of baboon and macaque monkey retina in a retinal slice preparation. Parasol and midget cells were whole-cell voltage-clamped at -70 mV using Lucifer yellow-filled electrodes. In Ringer containing 1mM Cd²⁺ to block synaptic transmission, both the excitatory and inhibitory amino acid agonists kainate (20 μ M), AMPA (60 μ M), NMDA (200 μ M), GABA (200 μ M), and glycine (200 μ M) elicited inward currents in both on- and off- parasol and midget cells. The kainate- and AMPA-induced currents reversed near the equilibrium potential for cations and were antagonized by DNQX (10 μ M). Responses to NMDA recorded in Cd²⁺-free Ringer were reversibly blocked by D-AP7 (200 μ M) and by Mg²⁺ (1mM) in a voltage-dependent manner. Responses to GABA and glycine had reversal potentials close to the Cl⁻ equilibrium potential and were antagonized by bicuculline (10 μ M) and strychnine (4 μ M), respectively. We conclude that primate midget and parasol cells have similar types of excitatory and inhibitory amino acid receptors.

RELATION BETWEEN PREFERRED DIRECTION AND DENDRITIC ORGANIZATION OF IDENTIFIED, CONTACTING ON-OFF DS GANGLION CELLS AND ACH. AMACRINE CELLS IN RABBIT RETINA.

F.R. Amthor^{*} and C.W. Oyster, Depts. of Psychology & Physiological Optics, University of Alabama at Birmingham 35294.

We have perfected a visualized recording system for isolated rabbit retina in which multiple ganglion and amacrine cells in a given field may be recorded and stained to determine their dendritic inter-relationships. We report that On-Off directionally selective (DS) ganglion cells of the same preferred direction form exclusive, tiling-like domains in which dendrites of same-direction neighbors terminate at close appositions at their first point of contact. This tiling is independent for the inner and outer dendritic ramifications, similar to that of Neurobiotin coupled cells shown by Vaney and colleagues. In contrast, dendrites of On-Off DS ganglion cells with different preferred directions overlap extensively and fasciculate together frequently, which almost never occurs for dendrites of same-direction neighbors. We thus, by these findings, demonstrate a separate tiling coverage of the rabbit retina by each of the four directional subtypes of On-Off DS ganglion cells.

We have also intracellularly stained DAPI-accumulating (presumed Ach.) amacrine surrounding physiologically identified and intracellularly stained On-Off DS ganglion cells. Our initial results indicate many more close appositions, and therefore opportunities for synaptic contact, between processes of DAPI amacrine on the preferred than on the null side of On-Off DS ganglion cells. This finding, if confirmed on further analysis to be done shortly, has strong implications for models of directional selectivity such as proposed by Vaney and colleagues, and by Borg-Graham, Grzywacz and Amthor.

THE DECODING OF MULTI-NEURONAL SIGNALS FROM THE RETINA. D. K. Warland and M. Meister^{*}, CDB Department, Harvard University, Cambridge, MA 02138.

How is information about a visual scene represented in the optic nerve? How could higher processing centers extract this information in real time using known neuronal mechanisms? To unravel the rules by which the eye encodes a visual scene, we have attempted to reconstruct the visual input directly from the simultaneous spike trains of many ganglion cells. A small randomly flickering spot of light was imaged on the photoreceptor layer of a salamander retina, while the action potentials from about 50 ganglion cells were recorded extracellularly using a microelectrode array. We then constructed a decoding algorithm that estimates the instantaneous light intensity of the spot from the recorded patterns of ganglion cell spikes. The parameters of this retinal decoder, which is based on linear filtering, were adjusted to optimize the correspondence between the estimated and the actual stimulus. This simple method of interpreting neural spike trains appears to extract much of the information transmitted by the retinal ganglion cells. Performance of the decoder degrades significantly for flicker frequencies above 2 Hz, consistent with the poor flicker response of cone photoreceptors. Signals from ON and OFF retinal ganglion cells complement each other; by contrast, the information from two cells of the same type is often highly redundant. Our results indicate that retinal ganglion cells cannot be considered as independent information channels; rather, the visual scene is at least in part encoded via concerted firing patterns involving many neurons.

EVIDENCE FOR AN INHIBITOR OF GANGLION CELL DIFFERENTIATION IN THE EARLY EMBRYONIC CHICK RETINA. C.P. Austin and C.L. Cepko. Dept. of Genetics, Harvard Medical School, Boston, MA 02115.

The factors affecting cell type determination and differentiation in the vertebrate retina are largely unknown. Ganglion cells (GC) are the first cell type to be produced in the chicken retina, and we have used an *in vitro* system to study possible factors influencing their development. Though the percentage of retinal cells which are GC at any time during development is never more than 15%, when retinas from E4 chick retinas were dissociated into single cells and cultured in collagen gel or monolayer conditions at low density, the percentage of cells expressing GC-specific markers increased to 70%. Time-course experiments showed that most of this increase occurred rapidly, between 6 and 10 hours after the cells were placed *in vitro*. When cells were cultured at progressively higher cell densities, the percentage of cells which turned on GC-specific markers incrementally declined; when cells were spun into a pellet before culturing, the percentage of GC after 24 hours was the same as in a retina left *in vivo*. This phenomenon is developmentally variant: the most GC-marker positive cells were produced *in vitro* when the starting population was from the period of maximal GC generation *in vivo*. Experiments to test the commitment state of the cells differentiating as GC *in vitro* suggested that only a subset of the marker positive cells irreversibly committed to the GC phenotype under these conditions, and that a majority of the cells differentiated as GC without being committed to this pathway. These experiments suggest the possibility that at an early stage in chick retinal histogenesis, many more cells than normally become GC are competent to commit to and/or differentiate along this pathway, but are prevented from doing so by an inhibitor that is diluted out by the low density culture conditions. MUSCARINIC ACTIVATION OF PNMT GENE EXPRESSION MAPS TO UPSTREAM PROMOTER REGIONS. L.M. Hemmick* and M.J. Evinger. Dept. of Pediatrics, SUNY Stony Brook, Stony Brook, NY, 11794.

Molecular mechanisms underlying neural regulation of phenylethanolamine N-methyltransferase (PNMT) gene expression are elucidated by expressing PNMT promoter-reporter gene constructs in primary cultures of bovine adrenal chromaffin cells. Our previous studies show that the cholinergic agonist muscarine stimulates expression of the PNMT gene by (a) increasing the rate of PNMT gene transcription in run-on assays, (b) stimulating steady-state levels of PNMT mRNA, and (c) enhancing expression of transfected reporter genes by the rat PNMT promoter. Transfected constructs containing nested size deletions of the rat PNMT gene were expressed in primary bovine adrenal chromaffin cells. Luciferase activity was measured in lysates of cells treated with muscarine (100 μ M) 16-24 hr. Muscarine stimulates reporter gene expression by 1.5 to 2-fold for constructs bearing promoter regions from -900 to -440 bp but not downstream sequences (proximal 440 bp). To resolve whether muscarine induces production of specific nuclear protein factors in chromaffin cells, gel retardation analyses have been performed using a -765 to -440 bp fragment of the PNMT promoter. Muscarine treatment for 16 hr induces a protein(s) which alters the migration of the PNMT fragment. This shift also occurs with nuclear extracts from bovine adrenal medulla and adrenal cortex, but not from bovine liver or cytoplasmic extracts of these tissues. DNase I footprinting analysis of this fragment reveals a region spanning -480 to -460 bp of the promoter protected by nuclear proteins from muscarine-treated cells. Thus, muscarine appears to stimulate PNMT gene transcription in chromaffin cells by inducing specific nuclear proteins which interact positively with upstream PNMT promoter elements.

520.3

THE ROLES OF DYAD SYMMETRY AND GC-RICH ELEMENTS IN THE EXPRESSION OF BOVINE TYROSINE HYDROXYLASE GENE. E. Kim, S. Maltchenko, M.K. Stachowak, Barrow Neurological Inst., Phoenix, AZ, 85013

Computer analysis has revealed several dyad symmetry elements (DSEs) within proximal 430 bp promoter region of the bovine, human, and rat TH genes. Those DSEs do not share sequence homology with known protein binding sites. Their length and localization are conserved in the TH genes from different species. Bovine and human TH gene promoters contain also GC-rich sequence of similar length and relative position. To examine the roles of DSEs and GC-elements we have constructed a set of bovine TH promoter mutants in which individual elements were deleted. The wild type TH promoter (-430/+25) and its deletion mutants were linked to luciferase gene in pGL2 plasmid. pGL2TH plasmids were transiently expressed in cultured catecholaminergic cells - bovine adrenal medullary (BAMC) and human neuroblastoma SH5YSY. Deletion of the longest DSE4, positioned close to the TATA box (-105/-75bp), led to an increase in luciferase expression in SH5YSY and BAMC. Point mutation that disrupted dyad symmetry of DSE4 had an opposite effect on promoter activity. Deletion of DSE0 or DSE1 in the distal region of TH promoter (-430/-302), decreased promoter activity in SH5YSY and in BAMC. In cells that do not express endogenous TH gene (TE671) the same deletion increased expression of TH-Luciferase construct. Thus, DSE0 and DSE1 could contribute to a cell-specific regulation of the TH gene. Deletion of GC-rich element led to a 3-4-fold increase in promoter activity in SH5YSY and in BAMC. We conclude that the novel dyad symmetry and GC-rich elements found in TH gene may play a role in the regulation of basal promoter activity. Together with classical regulatory elements (AP1, CRE, etc.) they could confer regulation specific for the TH gene. The mechanisms by which they act are now under investigation.

520.2

THE NEUROPEPTIDE PACAP REGULATES PNMT GENE EXPRESSION IN BOVINE CHROMAFFIN CELLS. E.C. Tonshoff, L.M. Hemmick, T.H. Joh* and M.J. Evinger*. Dept. of Pediatrics, SUNY, Stony Brook, NY, 11794 and *Cornell Univ. Med. Col., NY, NY, 10021.

Nicotinic and muscarinic components mediate the cholinergic response of the gene for the epinephrine synthesizing enzyme phenylethanolamine N-methyltransferase (PNMT) in the adrenal medulla. Moreover, the pituitary adenylyl cyclase activating polypeptide (PACAP) stimulates via non-cholinergic mechanisms catecholamine release and tyrosine hydroxylase mRNA levels in the adrenal medulla (rev. by Arimura, 1991).

We sought to determine whether PACAP influences PNMT mRNA production. Northern analyses of total RNA from primary bovine adrenal chromaffin cell cultures reveal that PACAP increases steady state levels of PNMT mRNA in a dose-dependent manner. 10^{-9} M PACAP elicits maximal response (equivalent to that of depolarization by 50 mM K⁺) and its effects are additive with those of K⁺-depolarization and nicotine, consistent with action through separate intracellular mechanisms. Transient transfections using constructs containing 5' upstream regions of the PNMT gene linked to luciferase reporters were performed in chromaffin cell cultures. After 24 hr treatment with PACAP, -500 to -900 bp constructs on heterologous promoters showed slight (20-30%) stimulation. No stimulation of reporter gene activity was observed with 300 or 3000 bp constructs. This information in conjunction with absence of canonical cAMP responsive elements on the PNMT gene, indicates that the primary mode of PACAP stimulation of PNMT mRNA is not transcriptional. Transcriptional and stabilization analyses are in progress to investigate further mechanisms for PACAP-mediated regulation of PNMT expression.

In Vivo Deletion Analysis of the Rat Preproenkephalin Promoter Using a Defective Herpes Simplex Viral Vector M.G. Kaplitt¹, J. Yin¹, A.D. Kwong², S.P. Kleopoulos³, C.V. Mobbs², D.W. Pfaff¹
¹Laboratory of Neurobiology and Behavior, The Rockefeller University, NY, NY, 10021; ²Schering-Plough Research, Bloomfield, NJ, 07003; ³Fishberg Center for Neurobiology, Mount Sinai School of Medicine, NY, NY, 10029.

We have previously reported that a 2.7kb fragment of the rat preproenkephalin (PPE) promoter can yield region-specific expression of the bacterial lacZ gene within the rat brain from a herpes simplex virus (HSV) defective viral vector. In the current study, PPE promoter deletions were generated in the amplicon pHENK by restriction digestion and re-ligation of the plasmid. The resulting defective HSV vectors were infused into the amygdala, piriform cortex and caudate nucleus. Three days following infusion, animals were sacrificed and brain sections were histochemically processed to detect β -galactosidase expression. While substantial expression was demonstrated in these regions with the 2.7kb PPE promoter, confirming earlier observations, there was a large decrease in the number of lacZ-positive cells in these regions when 1.5kb, 0.8kb or 0.5kb of the PPE promoter was employed. This suggests that there is an element between 2.7kb and 1.5kb which positively influences PPE expression in these brain regions. Finally, we continue to see a complete absence of expression in the dorsolateral neocortex from the 2.7kb promoter. Interestingly, however, some cells were observed with the 1.5kb promoter, but again no positive cells were detected with the 0.8kb or 0.5kb promoter fragment.

CHARACTERIZATION OF THY-1 REGULATORY ELEMENTS IN TRANSGENIC MICE. K.A. Kelley*, A. Sonshine, Y. Hu, J. Li, J. Lax, V.L. Friedrich Jr. Fishberg Research Center for Neurobiology, and Brookdale Center for Molecular Biology, The Mount Sinai School of Medicine, New York, NY 10029.

Three Thy-1.2/*lacZ* hybrid genes were constructed and used for the production of transgenic mice. Two of the hybrid genes consist of the Thy-1.2 promoter (up to the ATG translational start site within the second exon) fused to the *lacZ* coding region with either an SV40 or Thy-1.2 polyadenylation signal. The third construct consists of the entire Thy-1.2 gene with the *lacZ* coding region inserted into the second exon such that the only protein encoded by this fusion gene is the bacterial reporter. Although a Thy-1.2 transgene (modified by the addition of a unique oligonucleotide sequence to the 3' untranslated region) was expressed in a position-independent manner as expected, the Thy-1/*lacZ* hybrid genes were only weakly expressed in a position-dependent manner in the CNS of some of the transgenic mice examined. There is wide variability in the cell-type specific expression patterns observed by β -galactosidase histochemistry in the Thy-1 *lacZ* mice. Finally, mice produced from a Thy-1.2 hybrid gene containing the promoter, a segment of exons 2 and 3 in an antisense orientation and the polyadenylation signal expressed this transgene in a position-independent manner at levels which are very similar to those of the endogenous gene. These results suggest that either the Thy-1.2 sequences which are necessary for appropriate neuron-specific expression are not contained solely within the proposed CNS enhancer in the first intron, or that the placement of the *lacZ* coding region within the second exon may disrupt normal Thy-1 regulatory signals.

ANTISENSE OLIGONUCLEOTIDE OF c-myc IN PROBING THE DIFFERENTIAL REGULATION OF METALLOTHIONEIN BY ZINC. A. Takeda, J.S. Norris, J.E. Mata, P.L. Iversen, and M. Ebadi. Dept. of Pharmacology, Univ. Nebr. Coll. Med., Omaha, Nebraska 68198-6260.

The metallothionein II genes, whose structure is highly conserved throughout the animal kingdom is composed of three exons and two introns. By using synthetic antisense oligonucleotides with sequences complementary to the mRNA coding for human metallothionein II, we have shown that A) inhibition of metallothionein synthesis causes cells to die from metal toxicity; B) metallothionein possesses an essential gene; and C) modification in oligonucleotide structures exhibit specificity in inhibiting metallothionein synthesis. Furthermore, we have prepared a synthetic antisense oligodeoxyribonucleotide with sequence complementary to the mRNA specific for human c-myc and tested its potential to regulate metallothionein synthesis in cells in culture. The results of this study revealed that the c-myc antisense oligodeoxyribonucleotide lead to induction of zinc promoted but not cadmium- or dexamethasone initiated induction of metallothionein. The results of these studies are interpreted to suggest that c-myc acts as a repressor of at least one of the six human metallothionein isoforms and demonstrates a unique regulation capable of discriminating between zinc- and dexamethasone-induced synthesis of metallothionein. GROWTH HORMONE RELEASING FACTOR INDUCES SOMATOSTATIN MRNA LEVELS IN THE RAT PERIVENTRICULAR NUCLEUS BY ACTIVATING A GUANYLATE CYCLASE VIA NITRIC OXIDE. M.C. Aguilar* Dept. of Physiology, UT Southwestern Med. Ctr., Dallas, TX 75235.

Growth hormone releasing factor (GRF) stimulates somatostatin (SRIF) release and cGMP accumulation from median eminences *in vitro* by activating calmodulin. GMP analogues can increase SRIF mRNA levels and its release from periventricular nucleus (PeN). Thus, this study was undertaken to evaluate the effect of GRF and the possible role of cGMP on SRIF mRNA levels and its release in the PeN of male rats incubated *in vitro*. PeN explants were incubated in Waymouth's medium with GRF (10^{-9} M), methylene blue ($10 \mu\text{M}$, a guanylate cyclase inhibitor) and Rp8BrcGMPs [$1 \mu\text{M}$, a protein kinase G (PKG) inhibitor]. Levels of SRIF mRNA were determined by S_1 nuclease protection assay using a ^{32}P labelled rat SRIF riboprobe. SRIF release and cGMP formation were measured at 30 min and 6 hr by RIA. GRF (10^{-9} M) increased SRIF mRNA levels ($P < 0.001$). SRIF release and cGMP formation were also stimulated by GRF (10^{-9} M) at 30 min and 6 hr. The stimulating effect of GRF was abolished by N^G -monomethyl-L-arginine (10^{-3} M, L-NMMA), but not by D-NMMA. The GRF evoked SRIF mRNA levels and release was abolished by methylene blue and Rp8BrcGMPs. By themselves they did not modify basal values. These results indicate that GRF-induced cGMP formation from the PeN via nitric oxide. The cGMP generated activates PKG and increases SRIF mRNA levels and SRIF release. (NIH grant NS26821).

c-JUN SYNERGISTICALLY ACTIVATES NEUROTENSIN GENE EXPRESSION IN COMBINATION WITH GLUCOCORTICOIDS AND ADENYLATE CYCLASE ACTIVATORS IN PC12 CELLS. P.B. Dobner*, R.H. Harrison and G.P. McNeil. Dept. of Mol. Genetics and Micro., Univ. of Mass. Med. Cent., Worcester, MA 01655.

Neurotensin (NT) gene expression is synergistically regulated in PC12 cells by combinations of nerve growth factor, dexamethasone, and adenylate cyclase activators. A consensus AP-1 site located within a 200 bp region flanking the start site of transcription of the rat gene is a critical *cis*-regulatory element required for full induction, but functions only in the context of adjacent inducible sites resulting in the integration of multiple signals at the level of the promoter. To determine whether specific AP-1 complexes are involved in mediating NT gene activation, various AP-1 expression plasmids were co-transfected by electroporation into PC12 cells and the cells were grown either in the presence or absence of dexamethasone ($1 \mu\text{M}$) and forskolin ($1 \mu\text{M}$). Co-transfection of individual AP-1 expression plasmids revealed that c-Jun transactivated reporter gene expression most effectively and acted synergistically with dexamethasone and forskolin to increase reporter gene expression by up to 2,500-fold. Co-transfection of pairs of AP-1 expression plasmids revealed that both c-Fos and Fos B potentiated the synergistic effect of c-Jun, while Fra-1 or Fra-2 in combination with c-Jun resulted in negative regulation by glucocorticoids and forskolin. Surprisingly, c-Fos potentiated synergistic interactions between c-Jun and glucocorticoids over a wide range of input c-Fos expression plasmid concentrations. This contrasts sharply with the ability of c-Fos to reverse the direction of interaction between c-Jun and glucocorticoids in the regulation of the proliferin composite GRE. These results indicate that specific AP-1 factors, namely c-Jun homodimers and either c-Jun/c-Fos or c-Jun/Fos B heterodimers, selectively activate the NT promoter due to functional interactions with the glucocorticoid and cAMP signalling pathways.

BOTH BASAL AND cAMP-INDUCIBLE TRANSCRIPTION OF THE DOPAMINE- β -HYDROXYLASE GENE REQUIRE cAMP-DEPENDENT PROTEIN KINASE (PKA). K.S. Kim, H. Ishiguro, D.H. Park, J.A. Wagner and T.H. Joh*. Cornell Univ. Med. Coll. at the Burke Med. Res. Inst., White Plains, NY 10605.

The human DBH gene has a cAMP response element (CRE)-like sequence motif (5'-TGACGTCC-3') at -181 to -174 bp upstream of the transcription initiation site. Site-directed mutation of this element not only diminished >95% of basal transcription activity, but also significantly reduced its responsiveness to elevation of intracellular cAMP, thus defining this CRE as an essential *cis*-acting element for both basal and cAMP-inducible transcription of the human DBH gene (Hiroshi et al., Soc. Neuro. Abst. 18, 243, 1992). Based on this result, it is tempting to speculate that PKA regulates both basal and cAMP-inducible transcription of the human DBH gene via the CRE. To test this hypothesis, we transiently transfected plasmids coding for either catalytic subunit of PKA (PKA_c) or a specific inhibitor of PKA (PKI), and assessed the effect of each on expression of a co-transfected reporter gene construct, DBH-CAT. Expression of PKI, but not an inactive mutant form of PKI, specifically blocked transcriptional induction following treatment with forskolin. Moreover, co-transfection of PKA_c robustly stimulated transcriptional activity of the DBH promoter, but not that of the Rous Sarcoma Virus (RSV) promoter, in a dose-dependent manner. Primer extension analysis demonstrated that reporter gene activity represented correctly initiated transcripts. Furthermore, we analyzed several PC12 cell lines rendered PKA-deficient by either genetic manipulation or chemical mutagenesis. Notably, DBH gene expression and regulation were substantially altered in all cell lines tested. This study strongly indicates that PKA regulates both basal and inducible expression of the human DBH gene at the transcriptional level. Supported by MH48866 (KSK) and MH24285 (THJ).

DIFFERENTIAL INDUCTION OF EARLY GENES IN THE CNB BY TYPICAL AND ATYPICAL NEUROLEPTICS. P. J. Rogue*, G. Vincendon and A. N. Malviya. Centre de Neurochimie, 5 rue Blaise Pascal, Strasbourg, 67084 France.

Dopamine D₂ receptors regulate the expression of a specific set of immediate early genes (IEG) in the rat striatum. A single injection I.P. of haloperidol (2 mg/kg) or sulpiride (100 mg/kg) produces a rapid and transient increase in *c-fos*, *c-jun*, *jun B* and *zif268* mRNA, but has no influence on the expression of *ETRI* or *jun D* (Brain Res Bull 29, 469). These inductions are specifically blocked by pretreatment with a D₂ agonist (1 mg/kg quinolorane). We further studied the effect of clozapine and dopamine D₂ receptor antagonists on IEG expression in different regions of the CNS by northern analysis and ISH. Both clozapine (20 mg/kg) and haloperidol (2 mg/kg) induce *zif268*, *c-fos*, and *jun B* in the nucleus accumbens. However, only haloperidol induces all of these proto-oncogenes in the striatum, whereas in the frontal cortex clozapine induces *c-fos* but not *zif268*. The effects of the prolonged administration of these compounds will also be presented. The significance of these specific IEG activation patterns will be discussed with respect to the mechanism of action of antipsychotics and to the expression of dopamine D₂ receptor gene upon prolonged treatment with antagonists (European J Pharmacol 207, 165).

DIFFERENT ELECTRICAL ACTIVITY PATTERNS SELECTIVELY REGULATE GENE EXPRESSION A. Buonanno*, R. Beers, and S. Basu, Laboratory of Developmental Neurobiology, NIH, Bethesda, MD 20892

We have analyzed how motoneuron innervation selectively regulates gene expression in skeletal muscle. The selective expression of the two troponin I isoforms in fast- or slow-muscle is controlled by innervation. We found that TnIs (slow) and TnIf (fast) mRNA levels were dramatically reduced 2 days after denervation. However, if the rat soleus (composed of slow-twitch myofibers) was denervated and immediately stimulated with extracellular electrodes using a "slow" muscle pattern (20 Hz, 10s every 30s), expression of the TnIs mRNAs was maintained at the same levels of innervated muscle. The response to the activity pattern was selective, because stimulation with a pattern typical of fast-twitch muscle (100 Hz, 1s every 100 sec) could not prevent the down-regulation of the TnIs gene after denervation. Interestingly, stimulation using 100 Hz activated transcription of the TnIf gene in this slow-type muscle. The TnIs gene was cloned and sequences required for its transcriptional regulation were studied in transfected cells and transgenic mice. We found that TnIs sequences upstream of the CAP site, as well as in the second intron, were necessary for high level CAT reporter expression in transfected C2C12 myotubes. Deletion analysis of the TnI 5'-flanking sequence demonstrated that 200 bp are sufficient to confer tissue- and differentiation-specific expression in transfected cultured cells. Interestingly, the MyoD-related factors were found to transactivate the TnI-CAT constructs differentially in transfected NIH-3T3 fibroblasts. In transgenic mice, TnIs upstream sequences conferred specific skeletal muscle expression, as well as confined transcription to slow-type muscle. Recent experiments suggest that the MyoD-related factors do not underlie the confined expression to muscle-types. In summary, activity patterns selectively activate different programs of gene expression underlying the plasticity of muscle phenotype.

ION CHANNEL MODULATION AND REGULATION II

521.1

OPENING OF LARGE-CONDUCTANCE CALCIUM-ACTIVATED POTASSIUM CHANNELS AND DEPRESSION OF SYNAPTIC TRANSMISSION BY THE SUBSTITUTED BENZIMIDAZOLONE, NS004. V. K. Gribkoff¹*, M.C. McKay¹, S.L. Dworetzky¹, N.A. Meanwell¹, C.G. Boissard¹, J.T. Lum-Bagan¹, P.H. Reinhard², I.B. Levitan³, J.P. Adelman⁴, and S.P. Olesen⁵. ¹Bristol-Myers Squibb Co., Wallingford CT 06492, ²Dept. Neurobiology, Duke Univ. Med. Cntr., Durham NC 27710, ³Grad. Dept. Biochem. & Cntr. For Complex Systems, Brandeis Univ., Waltham MA 02254, ⁴Vollum Institute, Oregon Hlth. Sci. Univ., Portland ORE 97201, ⁵NeuroSearch, A/S, Glostrup Denmark DK-2600.

The ability of 5-trifluoromethyl-1-(5-chloro-2-hydroxyphenyl)-1,3-dihydro-2H-benzimidazole-2-one, NS004, to open large-conductance Ca²⁺-activated K⁺ (maxi-K, BK) channels was examined with channels in membrane patches from a clonal pituitary cell line (GH3), with channels from rat brain plasma membrane preparations reconstituted into planar lipid bilayers, and with the recently-described *Slo* BK clone from *Drosophila* expressed in *Xenopus laevis* oocytes. In GH3 cells and in oocytes expressing the *Slo* gene product, NS004 produced an increase in an iberiotoxin or TEA-sensitive whole-cell outward current, and produced a significant increase in the activity of single BK channels characterized by an increase in channel mean open time, a decrease in interburst interval, and an apparent increase in channel Ca²⁺/voltage sensitivity. In hippocampal slices, NS004 produced a concentration-dependent depression of population synaptic potentials that was largely blocked by iberiotoxin. NS004 reduced orthodromically-driven population spikes to a significantly greater extent when compared to its effects on antidromically driven responses. These data indicate that NS004 is a useful tool for investigating the properties of BK channels, and for delineating the roles of BK channels in neuronal function.

521.3

INHIBITION BY ATP OF A Ca²⁺ CURRENT AND Ca²⁺-ACTIVATED K⁺ CHANNEL IN ISOLATED NEUROHYPOPHYSIAL TERMINALS. G. Wang* and J.R. Lemos, Worcester Found. Exp. Biol., Shrewsbury, MA 01545.

Since ATP is known to act as a neurotransmitter and is co-released with neuropeptides from neurohypophysial terminals, we examined the effects of externally applied ATP on terminal activity. Elicited action potentials exhibited a slower second phase of repolarization in the presence of 0.5 mM external ATP. 1 mM ATP had no effect on the fast, transient K⁺ or A current, which is involved in the first phase of repolarization, nor on the Na⁺ current of these terminals.

In contrast, externally applied ATP did block the Ca²⁺-activated K⁺ current, which appears to be responsible for the latter phase of repolarization, with an IC₅₀ of ca. 0.5 mM. At mM concentrations ATP could also inhibit the transient, but not the long-lasting, component of the terminal Ca²⁺-current. It thus seemed possible that ATP's inhibition of the K⁺ current was solely due to a reduction in Ca²⁺ entry. When ATP was directly applied to outside-out patches, however, the open probability and apparent amplitude of the type II Ca²⁺-activated K⁺ channel were greatly reduced. The inhibition by ATP was unaffected by H-7, indicating that it was not mediated by activation of a kinase. We are determining if these are direct effects of ATP or if they are mediated by a purinergic receptor. (Supported by grants from NIH and NSF).

521.2

ACTIVATION OF Ca²⁺-DEPENDENT K⁺ CHANNELS BY THE BENZIMIDAZOLONES NS 004 AND NS 1619. S.-P. Olesen, E. Munch, P. Moldt & J. Drejer*. NeuroSearch A/S, 26B Smedeland, DK-2600 Glostrup, Denmark.

The ability of novel benzimidazolone derivatives to activate large-conductance Ca²⁺-dependent K⁺ channels (BK channels) was studied in cultured cerebellar granule cells by the patch-clamp technique.

In nystatin-perforated whole-cell recordings the granule cells expressed an outward BK current, which was strongly increased by the compounds NS 004 and NS 1619. The BK channel openers shifted the activation curve towards more negative membrane potentials, and the average effects of the most potent compound, NS 1619, at 10 and 30 μM concentrations were shifts of -26 and -55 mV, respectively. The effects were fully reversible and were antagonized by TEA⁺ (0.3-1 mM). The compounds did not significantly modulate the Na⁺ and K_v currents, which were also recorded in the granule cells. NS 1619 (30 μM) hyperpolarized the cells by an average -13 mV. In single channel recordings the compounds increased the channel open probability in a dose-dependent way by up to 24 fold (30 μM NS 004) and 92 fold (30 μM NS 1619). On inside-out patches the compounds increased the channel activity at a wide range of free Ca²⁺ concentrations (10-300 nM), and the activation did not require internal ATP.

The compounds also activated BK channels in cultured cortical neurones, PC12 cells and smooth muscle cells from calf aorta.

We have developed novel activators of BK channels in neurons and smooth muscle, which may significantly modulate cell excitability.

521.4

MODULATION OF SLO AND LARGE-CONDUCTANCE Ca²⁺-ACTIVATED K⁺ CHANNELS FROM RAT CORTEX. I. Krause, F.M. Schmalz, and P.H. Reinhard*. Dept. of Neurobiology, Duke University Medical Center, P.O. Box 3209 Durham, NC 27710.

We have characterized the modulation of two large-conductance (240 pS) Ca²⁺-activated K⁺ channels from rat cortex vesicles, and the modulation of *SLO*, a 120 pS Ca²⁺-activated K⁺ channel from *Drosophila*. All three channels are modulated by protein kinases and protein phosphatases. The modulation of *SLO* is similar to that of Type-II Ca²⁺-activated K⁺ channels from rat cortex in that the addition of Mg-ATP (in the absence of any exogenously added protein kinase) can up-modulate this channel in inside-out patches from *Xenopus* oocytes. The effect can be enhanced by the addition of phosphatase inhibitors and partially reversed by the addition of protein phosphatases to the cytoplasmic side of the channel. The hydrolyzable ATP analog ATP-γ-S can mimic this effect but the non-hydrolyzable analog AMP-PCP cannot indicating that a channel-associated protein kinase is mediating this effect of ATP. Mg-ATP has a second effect on both rat cortex Type-II and on *SLO* channels. This effect is to induce both sub-conductance states, and long-lived closed states. The non-hydrolyzable ATP analog AMP-PCP can mimic this effect, indicating that it is due to ligand binding rather than phosphorylation. We are currently examining these modulatory phenomena in more defined conditions by reconstituting *in vitro* translated *SLO* channels into planar lipid bilayers. (Supported by NIH grant NS31253-01 to PHR)

521.5

HALOTHANE BLOCKS BK CHANNEL ACTIVITY BY ALTERING ITS STATE OF PHOSPHORYLATION. R.A. Pearce* and K. Bielefeldt Departments of Physiology, Anatomy, and Anesthesiology, Univ. Wisconsin, Madison, WI 53706.

Many channels that are affected by volatile anesthetics are also modulated by phosphorylation. To test the hypothesis that volatile anesthetics affect channel activity by altering channel phosphorylation state we examined the effect of halothane on calcium activated potassium channels (BK) from posterior pituitary nerve terminals. These channels are modulated by a protein kinase and a protein phosphatase that remain associated with the channel and functional even upon excision of membrane patches containing single channels. Excised inside-out patches were exposed to symmetrical solutions containing (mM) KCl 150, MgCl₂ 2, CaCl₂ 0.1-0.5, EGTA 0.5, HEPES 10 at pH 7.2. Halothane 2% (gas phase concentration) was blown across the recording chamber, reaching a concentration of 0.22 mM.

In the presence of MgATP (1 mM), halothane significantly reduced single channel activity by shifting the voltage of half-activation by approximately +40 mV (n=6). This effect was independent of the concentration of free calcium, was identical to the effect of dephosphorylation, and was reversible upon washing out halothane. Single channel conductance was not altered, and halothane had no effect on the unphosphorylated channel in the absence of MgATP.

To test whether halothane altered channel activity by altering its state of phosphorylation, channel activity was recorded in the presence of MgATP and the phosphatase inhibitor okadaic acid (50 nM). By preventing channel dephosphorylation, okadaic acid blocked the effect of halothane (n=5). This effect appeared to be due to inhibition of the protein kinase rather than activation of the phosphatase, since even in the presence of okadaic acid halothane prevented recovery of channel activity upon addition of MgATP.

Supported by NIH grants NS30016 (M.B. Jackson) and NS01548 (R.A. Pearce).

521.7

CALCINEURIN INVOLVEMENT IN 5-HT STIMULATION-PRODUCED REDUCTIONS IN MBK1 CHANNEL ACTIVITY. J. Farley*, J. Hoyer, N. Davison and H. Lester, Program in Neural Science, Indiana University, Bloomington, IN 47405 and Division of Biology, California Institute of Technology, Pasadena, CA 91125.

Stimulation of *Xenopus* oocytes expressing serotonin type 1c (5-HT_{1c}) receptors and KV1 type potassium channels from mouse brain (MBK1) with 5-HT results in a calcium-dependent suppression of MBK1 channel activity which is unaffected by the general kinase inhibitor H-7 (Hoyer et al., *Neuron*, 1991). We have examined the possibility that the calcium-activated phosphatase PP2B (calcineurin) may participate in this modulation by testing the effects of 5-HT upon MBK1 channels following exposure of oocytes to several potent phosphatase inhibitors. Exposure of oocytes to cyclosporine A -- a specific inhibitor of PP2B -- greatly attenuated 5-HT-produced reduction of MBK1 channels despite the absence of any large or consistent effect upon the 5-HT-induced Cl⁻ current. In contrast, neither Calyculin A nor okadaic acid, potent inhibitors of PP1 and PP2A, prevented 5-HT-mediated reduction of MBK1 channels when bath-applied at concentrations 10-100 times greater than their reported IC₅₀-values. As judged by their effects on several of the currents endogenous to the oocyte, both compounds appeared to enter the cell. In preliminary experiments, injection of pre-activated PP2B into oocytes resulted in a clear decrease in MBK1 activity. Collectively, our results suggest that calcium-dependent dephosphorylation regulates the functional activity of MBK1 channels.

521.9

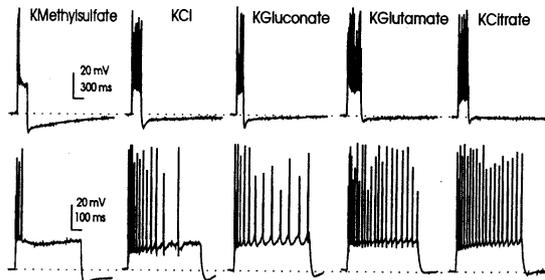

HETEROTYPIC GAP JUNCTION CHANNELS FORMED OF HUMAN CONNEXINS 43 AND 45 IN MAMMALIAN CELLS CONSERVE THE PROPERTIES OF HEMICHANNELS. Alonso P. Moreno*, Glenn I. Fishman, Eric C. Bever and David C. Spray, Dept. of Neuroscience, A. Einstein College of Medicine, Bronx N.Y. 10461 and Dept. of Medicine, Washington University, St. Louis MO. 63110.

Some cells express multiple connexins (Cx), raising the possibility of heterotypic channels formed by homomeric hemichannels. Studies in exogenous expression systems (*Xenopus* oocytes or mammalian cell lines) have revealed that conductance of homotypic mammalian gap junctions is reduced by transjunctional voltage of either polarity. Homotypic human Cx43 (hCx43) expressed in SKHept1 cells forms channels with unitary conductance (γ₁) of ~60 and ~90 pS with modest voltage dependence (V₀=61 mV, A=-.085 and g_{min}=0.37), whereas hCx45 forms more voltage dependent (V₀=14 mV, A=0.115 and g_{min}=.06) channels of 30 pS. Cells expressing hCx45 were loaded with a red fluorescent dye (λ=680 nm) and cells expressing hCx43 were loaded with a green fluorescent dye (λ=520 nm); subsequently they were split and plated together. Pairs of bi-color cells exhibited junctional properties expected for the sum of the corresponding hemichannels. Gates of both hemichannels closed for relatively negative potentials. Total junctional conductance in these pairs was 5 times higher than for hCx45 pairs, suggesting that hCx43-hCx45 interactions are favored over homotypic hCx45 coupling. γ₁ values ranged between 30 and 50 pS, corresponding to the Ohmic sum of conductances from each connexon. Dye coupling was also connexon-specific; homotypic hCx43 pairs were Lucifer yellow permeant, but homotypic hCx45 (n=50) and hCx45-hCx43 pairs (n=16) were not. All pairs were permeable to Neurobiotin. Thus, heterotypic channels conserved the voltage dependence, permeability and unitary conductance properties, characteristic of the constituent hemichannels.

521.6

EFFECTS OF INTERNAL ANIONS AND Ca BUFFERS ON Ca²⁺-DEPENDENT I_{AHP} IN HIPPOCAMPAL CA1 NEURONS. L. Zhang* & P.L. Carlen, Playfair Neurosci. Unit, MRC group "Nerve Cell and Synapse", Bloorview Epilepsy Prog., Univ. of Toronto, Canada M5T 2S8.

We studied the slow AHP and underlying Ca²⁺-dependent K⁺ current (I_{AHP}) in mature rat hippocampal neurons using whole-cell recordings in brain slices with internal solutions containing different potassium salts (see below). The AHP and strong firing adaptation could only be reliably recorded with KMethylsulfate-containing electrodes. The I_{AHP} was not affected by ryanodine or dantrolene, but was blocked by BAPTA (K_d = 160 nM). However, it is greatly prolonged by the low-affinity Ca²⁺ chelator difluoro BAPTA (K_d = 4.6 μM), but not by APTRA (K_d = 25 μM). We conclude that cytoplasmic Ca²⁺ homeostasis is greatly influenced by internally applied anions and Ca²⁺ buffers.

521.8

ANALYSIS OF ION CURRENTS MEDIATING MODULATION OF CONTRACTIONS OF THE ARC MUSCLE OF *APLYSIA* BY SIMULTANEOUS ON-LINE LENGTH MEASUREMENT AND CURRENT/VOLTAGE CLAMP. V. Brezina* and K. R. Weiss, Dept. of Physiology and Biophysics, Mt. Sinai School of Medicine, CUNY, New York, NY.

In response to behavioral demands, ACh-induced contractions of the ARC muscle of *Aplysia* are modulated by serotonin (5-HT) and a variety of peptide cotransmitters released from the muscle's own motoneurons, among them the small cardioactive peptides (SCPs), myomodulins (MMs) and FMRFamide-related peptides (FRFs). The SCs, 5-HT and MM, predominantly potentiate the contractions, the FRFs depress them, and MMs, both potentiates and depresses. Previously, working with single dissociated ARC muscle fibers, we found that this pattern of effects on contractions is reproduced in the pattern of the modulators' effects on two ion currents: the potentiating modulators enhance the L-type Ca current, while the depressing modulators activate a large K current. We have now combined current and voltage clamp (CC, VC) with on-line video measurement of contractions of the single fibers to obtain the following direct evidence that these actions on ion currents indeed underlie the modulation of contractions: (1) Ca²⁺ entry through the L-type Ca channels is essential for normal contraction. Depolarization beyond the activation threshold of the Ca current is both necessary and sufficient for contraction, equally with ACh application and CC/VC steps in the absence of ACh. All such contractions cease in Ca²⁺-free solution or when the Ca channels are blocked with nifedipine. (2) All contractions involving activation of the Ca current, whether due to ACh or CC/VC steps, are equally potentiated by the potentiating modulators, whereas contractions that bypass its activation, e.g. induced by the Ca²⁺-ionophore A23187 or caffeine, are not. (3) Depression of ACh or CC contractions is associated with a reduction in the depolarization attained, and thus the degree to which the Ca current is activated. This reduction is both sufficient and necessary (VC contractions are not depressed). Both the reduction in depolarization and the depression of contractions are blocked by low-micromolar 4-AP, which selectively blocks the modulator-activated K current. It thus appears likely that the enhancement of the L-type Ca current is in large part responsible for the potentiation, and activation of the 4-AP-sensitive K current for the depression, of ARC-muscle contractions by the SCs, MMs, FRFs and 5-HT.

PHOTORELEASE OF ATP REVERSES THE EFFECTS OF 2-DEOXYGLUCOSE ON Ca²⁺-ACTIVATED CHLORIDE CURRENTS RECORDED FROM CULTURED DRG NEURONES. S.R. Stapleton, J.F. Wootton+ and R.H. Scott*. Dept. Physiology, St. George's Hospital Medical School London SW17 0RE.UK and +Dept. Physiology, Cornell University, Ithaca, N.Y.

In this study we have used whole cell Ca²⁺-activated Cl⁻ currents (I_{Cl(Ca)}) recorded from cultured dorsal root ganglion neurones as a physiological index of intracellular Ca²⁺ homeostasis. I_{Cl(Ca)} was activated as a tail current following Ca²⁺ current evoked by 500ms steps to 0mV or by intracellular photorelease of Ca²⁺ from DM nitrophen (4mM with 2mM Ca²⁺). Under control conditions I_{Cl(Ca)} tail currents deactivated by 63% (t63%) in 2990±660ms (n=7) and this did not change when 4 currents were activated at 1 min⁻¹. However, with no ATP in the patch pipette solution and substitution of glucose with 2-deoxyglucose (2DG) (5mM) the I_{Cl(Ca)} was greatly prolonged. The t63% under these conditions were 4000±800ms and 7350±2080ms (n=11) for the 1st and 4th currents respectively. The deactivation of I_{Cl(Ca)} evoked by photorelease of Ca²⁺ was also slowed with 2DG compared with controls. The effects of 2DG were prevented by including fructose 1,6-diphosphate (500μM) in the patch pipette solution or by intracellular photorelease of about 300μM ATP from a caged precursor. Our results suggest that efficiency of intracellular Ca²⁺ handling is reversibly attenuated by metabolic stress as reflected by prolongation of I_{Cl(Ca)}.

521.11

THE GTP-ANALOGUE 2',3'-DIALDEHYDE GTP ABOLISHES THE MODULATION OF NEURONAL CALCIUM CURRENTS BY VARIOUS NEUROTRANSMITTERS. S. Boehm, C. Nanoff, M. Hohenegger, M. Freissmuth, S. Huck. (SPON: European Neuroscience Ass.) Depts. of Neuropharmacology and Pharmacology, Univ. of Vienna, Waehringerstrasse 13a, A-1090 Vienna, Austria.

Neurotransmitter modulation of calcium currents (I_{Ca}) is mediated by pertussis toxin (PTX)-sensitive G proteins in many neuronal cell types. In order to study the regulation of ion channels by G proteins, we have synthesized 2',3'-dialdehyde GTP (oGTP), a ligand which is predicted to irreversibly inactivate G proteins via Schiff's base formation; this assumption was verified as follows: (i) oGTP inhibited the binding of [³⁵S]GTPγS to the recombinant stimulatory G protein α-subunit ($G_{\alpha s}$) with an affinity comparable to that of GTP; (ii) in contrast to GTP, oGTP was bound in a quasi-irreversible manner, since dissociation could not be achieved by an excess of GTPγS; (iii) following borohydride reduction, oGTP was covalently incorporated into rG_{αs}; (iv) in the S49 cyc⁺ reconstitution assay, oGTP supported a single cycle of activation as determined by using a GTPase-deficient mutant of rG_{αs}, R187E, but oGTP prevented the GTPγS-dependent activation of adenyllyl cyclase by rG_{αs}, since it trapped the G protein in the inactive conformation.

Using the whole-cell patch-clamp technique, we applied the GABA_B agonist baclofen in chick sensory neurons, somatostatin in chick sympathetic neurons, the muscarinic agonist oxotremorine in rat sympathetic neurons, and the α₂-agonist bromoxidine in all these neurons. With 2mM GTP included in the recording pipette the inhibitory effect of bromoxidine (30%-45%) was smaller than the action of baclofen (48%), somatostatin (55%), or oxotremorine (45%) (n=4). After a 24h treatment with 100ng/ml PTX inhibition of I_{Ca} 's in sympathetic neurons was <4%, and with intracellular GDPβS (10μM) the I_{Ca} 's of sensory neurons were reduced by <5% (n≥3), indicating an involvement of G proteins. Inclusion of 10μM oGTP in the recording pipette progressively reduced the inhibitory action of all agonists (when recordings were started 90s after formation of the whole-cell configuration), and agonist effects were entirely abolished within ≤15min (<5% inhibition, n.s. vs controls, n=4). To confirm the site of action we added increasing concentrations of GTPγS to the internal solution containing 10μM oGTP: 100μM GTPγS suppressed I_{Ca} , as determined by the reversal through large depolarizing prepulses, and prevented an additional inhibition by external agonists.

These results indicate that oGTP inactivates G proteins involved in the modulation of I_{Ca} and render the drug a versatile tool for patch-clamp experiments, particularly for delineation of signalling pathways via PTX-insensitive G proteins.

TACHYKININS, METABOTROPIC GLUTAMATE AGONISTS, AND NEUTROTENSIN EXCITE NEURONS FROM THE RAT VENTRAL TEGMENTAL AREA. R.H. Farkas¹, S. Nakajima² and Y. Nakajima^{1*}. Depts. of Anat. and Cell Biol.¹ and Pharmacol.², Univ. of Illinois, College of Med. at Chicago, IL, 60612.

The slow depolarization caused by many excitatory neurotransmitters results from the simultaneous induction of nonselective ionic current and suppression of potassium conductance. Using whole cell patch clamp recording, we found that neurokinin B, the metabotropic glutamate agonist 1S3R-ACPD, and neurotensin excited, by such dual ionic mechanisms, neurons cultured from the rat ventral tegmental area. Each induced an inward current and suppressed inwardly rectifying potassium conductance elicited by the D2 agonist quinpirole. The inward current could be greatly reduced by lowering external sodium. Lowering intracellular Ca²⁺ by loading neurons with 5.5 mM BAPTA, did not reduce the inward current, indicating that it was not due to calcium activated non-specific cation (CAN) channels. When the neurokinin B or 1S3R-ACPD responses were desensitized by continuous drug application, the neurotensin response remained, suggesting receptor level desensitization. The neurotensin antagonist SR48692 reversibly and selectively blocked the neurotensin response. In neurons loaded with GTPγS, neurotensin irreversibly suppressed inwardly rectifying potassium conductance but failed to irreversibly induce the nonselective conductance, suggesting that the potassium conductance is gated by a G protein while the nonselective conductance is G protein-independent. ROLE OF GASTRIC AFFERENT VAGUS IN THE MEDIATION OF CCK SATIETY. T.H. Moran^{*}, C.F. Salorio, I. Tominack, P.R. McHugh and G.J. Schwartz. Department of Psychiatry, Johns Hopkins University School of Medicine, Baltimore, MD 21205

Previous work has shown that either sectioning of both gastric vagal branches or subdiaphragmatic vagal deafferentation were sufficient to eliminate the feeding inhibitory actions of CCK. Together these results suggested that gastric vagal afferents were the necessary vagal components for CCK satiety. The present work directly assessed this hypothesis. Five surgical groups were prepared. To replicate the results of prior studies, we included animals with bilateral gastric branch vagotomy, unilateral afferent or efferent rootlet transections combined with contralateral subdiaphragmatic vagotomy and animals receiving sham surgery. To specifically address the present question, we also prepared a group with unilateral afferent rootlet transection combined with contralateral gastric branch vagotomy. Following surgery animals were maintained on a liquid diet (Ensure) and the responses to CCK (1-16 μg/kg) were assessed in 1 hr glucose consumption tests following daytime deprivation. The results demonstrated that either bilateral gastric branch vagotomy or subdiaphragmatic vagal deafferentation were sufficient to eliminate CCK satiety. However, neither subdiaphragmatic vagal deafferentation nor specific gastric vagal deafferentation significantly affected the ability of CCK to inhibit intake. These results demonstrate that gastric vagal afferents are not the necessary component for CCK satiety and suggest that CCK may interact with multiple vagal components. (DK19302).

522.3

SUPPRESSION OF FEEDING BY BOMBESIN (BUT NOT CCK) IS MEDIATED BY CENTRAL HISTAMINE. Z. MERALI^{1*}, K. BANKS, P. KENT and G.D. PRELL². ¹Psychology & Pharmacology, Univ. of Ottawa, Ottawa, Ont. Canada, K1N 9A9. ²Dept. Pharmacology, Mt. Sinai Sch Med., 1 Gustave Levy Pl, N.Y. 10029.

Systemically administered bombesin (BN) suppresses food intake in most mammals. The mechanism(s) by which this satiety-like state is achieved is not known. Blockade of central histamine receptors has been reported to induce feeding in *ad libitum* fed rats. We hypothesized that BN may mediate its satiety effect through release of histamine. Male Sprague-Dawley rats were trained to consume the daily ration during a 4 hr food access period in the light phase. BN (6 μg/kg; i.p.) suppressed (by about 50%) food intake for up to 2 hr. α-methyl histamine (α-MH), a histamine H₃ autoreceptor agonist that prevents the release of histamine, blocked BN's satiety effect. This effect was specific as α-MH failed to alter food intake on its own and also failed to alter the satiety effect of CCK. Since α-MH can bind to heteroautoreceptors, the specificity of the observed effects were further validated. Binding of BN to its receptors (assessed autoradiographically) was not inhibited by α-MH. Furthermore, direct blockade of histamine postsynaptic receptors by mepyramine (H₁ antagonist) and famotidine (H₂ antagonist) administered centrally, also blocked the satiety effects of systemically administered BN. We thus believe that BN may mediate satiety through the release of central histamine.

522.2

PUSH-PULL PERFUSION REVEALS MEAL-DEPENDENT CHANGES IN THE RELEASE OF BOMBESIN (BN)-LIKE PEPTIDES. H. Plamondon^{1*} & Z. Merali^{1,2}. ¹Sch. of psychology & ²Dept. of Pharmacology, University of Ottawa, Ontario, K1N 6N5.

Post-prandial increases in central BN-like immunoreactivity (BLI) have recently been reported. Many factors may contribute to this increase including changes in the synthesis, release and/or uptake of BN-like peptides. The present study was designed to assess the physiological release profile of BN-like peptides in relation to food intake. Male Sprague-Dawley rats were implanted with push-pull cannulae aimed at the paraventricular nucleus of the hypothalamus (PVN). Our data revealed significant differences between pre-prandial, prandial and post-prandial extracellular BLI, with an approximate 3-fold diminution during meal as compared to before and after a meal. Prior to the first spontaneous meal, the BLI levels were 2-fold higher than those detected during the meal. Post-prandially, the levels shot up by 3-fold. In the present study we also simultaneously monitored levels of biogenic amines and metabolites, using HPLC. The PVN perfusate contained detectable levels of NE, EPI, HVA, 5-HIAA and DOPAC, none of which changed in a clear meal-related pattern. These results strongly support a physiological role for BN-like peptides in the control of food intake and suggest that the state of satiety is maintained by elevated interstitial levels of BLI at the PVN and that a drop in the peptide levels may trigger and/or maintain a meal.

522.4

THE EFFECT OF BOMBESIN AND ANTAGONISM OF BOMBESIN BY BW2258U89 ON SALT APPETITE. S.P. Frankmann^{*}, J.H. Dokko and J. Gibbs. Bourne Lab, Cornell Med. Ctr, White Plains, NY 10605.

Little is known of the signals for the satiation of salt appetite. Peripheral injection of the peptide, bombesin (BN), elicits satiety for liquid food in overnight food-deprived rats. The present study asked whether BN would decrease the salt intake elicited by sodium depletion and whether a selective BN antagonist, Burroughs Wellcome 2258U89 (BW), would reverse this effect.

Male, Sprague Dawley rats (n = 10) were sodium depleted by injection of the natriuretic/diuretic drug, Lasix (furosemide, 10 mg, sc) and overnight sodium deficient diet and water. Twenty-four hours later, 0.3M NaCl and water intakes were recorded for 1 h in a salt appetite test. Rats were injected with BW (50 μg/kg) or vehicle (V) at -15 min and BN (4 μg/kg) or V at -5 min before the start of the appetite test. Thus the rats were tested three times (1 test/week) under the following conditions: 1) V-V, 2) V-BN and 3) BW-BN. As can be seen below, BN reliably suppressed NaCl intake and the BW partially reversed this suppression. There were no differences in water intake among the groups.

0.3M NaCl Intake, ml (mean ± SEM)					
Condition	5 min	10 min	15 min	30 min	60 min
V-V	4.1 ± 0.7	6.9 ± 0.6	9.6 ± 0.6	12.9 ± 0.6	16.4 ± 1.0
V-BN	3.3 ± 0.7	3.7 ± 0.6*	3.8 ± 0.5*	4.8 ± 1.1*	8.7 ± 1.3*
BW-BN	5.4 ± 0.8	7.0 ± 0.8#	7.0 ± 1.0#	9.4 ± 1.0#	12.2 ± 1.5#

* = p < .05 vs V-V, # = p < .05 vs V-BN

These data demonstrate that BN decreases salt intake after salt depletion and this decrease is partially reversed by the BN antagonist, BW2258U89. BN-like peptides may be endogenous signals for the satiation of salt intake.

THE HINDBRAIN, FEEDING, AND NEUROPEPTIDE Y-RELATED PEPTIDES: EVIDENCE FOR COMPLEX RECEPTOR INTERACTIONS. E.S. Corp.* C. Wahlestedt¹ and J.A. McQuade, Bourne Lab and ²Division of Neurobiology, Cornell University Medical College, White Plains, NY 10605

Injected into the hypothalamus, NPY_{2,36} is a more potent stimulus of feeding than NPY. Its potency in the hindbrain, another sensitive site of action for NPY in feeding, is not known. Thus, we examined the dose-response effect of NPY_{2,36} on food intake following fourth ventricular administration in comparison with the effects of related NPY-receptor agonists including: NPY; peptide YY (PYY); the Y1 receptor agonist [Leu³¹,Pro³⁴]NPY (LP-NPY); and the Y2 agonist, NPY_{13,36}. Food intake was measured in non-deprived rats two hours after peptide administration. Data are presented below. MAX = maximal intake (g) above baseline in the dose-range tested. ED₅₀ = dose (pmole) eliciting the half-maximal response for the given peptide.

PEPTIDE	PYY	NPY	NPY _{2,36}	LP-NPY	NPY _{13,36}
MAX	6.9 ± 1.2	3.7 ± 0.6	2.5 ± 0.6	2.1 ± 0.6	0.9 ± 0.2
ED ₅₀	84 ± 2.0	304 ± 1.2	184 ± 1.7	947 ± 2.3	370 ± 1.2

NPY_{2,36} displayed relatively low efficacy compared with NPY and PYY. At low doses, however, NPY_{2,36} was more potent than NPY suggesting that the full response in feeding involves multiple NPY-receptor components. A high affinity component recognizes NPY_{2,36} (and PYY) in preference to NPY, while NPY_{13,36} is relatively inactive at the low-affinity component. Alternatively, NPY, unlike NPY_{2,36} and PYY, may interact with an additional population of receptors functionally-linked to inhibition of feeding. The relatively low potency of the Y1 agonist LP-NPY suggests that typical Y1 receptors are only marginally involved in feeding. The Y2 agonist NPY_{13,36} had the lowest efficacy; however, this peptide initiated feeding at lower doses than LP-NPY suggesting some orexigenic activity associated with Y2 receptors, or the interaction of this fragment with another receptor (other than Y1). These results are consistent with multiple NPY-receptor interactions in feeding.

HYPOTHALAMIC NEUROPEPTIDE Y (NPY) REGULATION MAY BE INDEPENDENT OF ENERGY INTAKE IN LONG-EVANS RATS.

Beck* B., Stricker-Krongrad A., Buriel A., Nicolas J.P., Buriel C. - INSERM U.308 - MRCA - 38, rue Lionnois, 54000 NANCY (France)

Neuropeptide Y (NPY) is the most powerful orexigenic peptide actually known. Overeating in the obese Zucker rat is associated with elevated concentrations of NPY in the hypothalamus. In the normal rat, overeating can be induced by diet manipulation i.e. by feeding the animals on high caloric density diets. Furthermore, we have recently shown that diet composition influences hypothalamic NPY levels. So, the aim of the present experiment was to determine if there was a relationship between diet-induced overeating and hypothalamic NPY. For this purpose, 3 groups of 21 day-old male LE rats were fed during 14 weeks on either a well-balanced control diet, a high carbohydrate (starch + 25% sucrose solution) diet (HC) or high fat diet (HF). Food intake and body weight were recorded and NPY was measured in several microdissected nuclei involved in the regulation of eating behavior. Final body weight of the HF rats was significantly greater than that of the HC rats (+13.6%, p<0.006). During the last week of the experiment, energy intake of the control rats was significantly smaller than that of the HC rats (-14.7%, p<0.02) and significantly greater than that of the HF rats (+14.8%, p<0.001). However, both variations of food intake were specifically associated with diminished NPY concentrations in the arcuate nucleus (-22.2% (HC vs control); p<0.02 and -35.3% (HF vs control); p<0.001) as well as in the parvocellular part of paraventricular nucleus and more particularly in its for the HF group only (-32.8%; p<0.001). These variations in the functional pathway of regulation of feeding behavior by NPY can be explained by either a relative independence towards energy intake or by the existence of 2 distinct sensor systems specific of each macronutrient and that may differentially regulate NPY concentrations.

CNS INSULIN DEFICIENCY CONTRIBUTES TO OVEREXPRESSION OF HYPOTHALAMIC NPY mRNA AND HYPERPHAGIA IN DIABETIC RATS. A.J. Sipols*, D.G. Baskin, S.C. Woods and M.W. Schwartz. Seattle VA Med. Ctr. and Depts. of Psych., Medicine and Bio. Str., U. of Washington, Seattle, WA 98195.

Untreated insulin-deficient diabetes mellitus is characterized by low plasma insulin levels and significant weight loss despite marked hyperphagia and polydipsia. We hypothesized that a deficiency of CNS insulin contributes in part to diabetic hyperphagia by increasing neuropeptide Y (NPY) biosynthesis, since (a) diabetes is associated with elevated production and release of hypothalamic NPY, and (b) insulin infused into the 3rd cerebral ventricle of fasted rats decreases arcuate nucleus NPY mRNA levels and reduces food intake during refeeding. To test this hypothesis, adult male Wistar rats were made diabetic with streptozotocin (55-65 mg/kg i.v.), and 10 days later received continuous infusions of either insulin (3 mU/24µl/day; n=11) or saline (24 µl/day; n=10) into the 3rd ventricle (ivt) for 6 days. Compared to ivt vehicle-treated, nondiabetic controls (n=15), food intake was increased 2-fold in diabetic rats receiving ivt saline (25.3 ± 0.7 vs 48.8 ± 1.3 g/day, p<0.001). Treatment of diabetic rats with ivt insulin reversed this hyperphagia by 64% (33.8 ± 1.4 g/day, p<0.05 vs ivt vehicle-treated diabetic and nondiabetic rats). This reduction in food intake was associated with a 69% greater loss of body weight in insulin- vs. vehicle-treated diabetics (32.4 ± 2.3 vs 19.2 ± 3.5 g, p<0.05). NPY mRNA was detected by in situ hybridization and measured by computer densitometry. Preliminary analysis indicates a strong correlation between levels of NPY mRNA in the hypothalamic arcuate nucleus and food intake (r=-.75, p<0.01) across all animals. In contrast to its effect on food intake, ivt insulin did not alter either hyperglycemia (blood glucose: 667 ± 27 vs 622 ± 32 mg/dl) or polydipsia (water intake: 224 ± 10 vs 233 ± 11 ml/day) in diabetic animals. In summary, (a) insulin infused into the CNS results in a marked reduction of the hyperphagia of diabetic rats, and (b) a significant correlation exists between arcuate nucleus NPY gene expression and food intake. We conclude that a relative insulin deficiency in hypothalamic nuclei associated with NPY-stimulated food intake contributes to diabetic hyperphagia.

IMMUNONEUTRALIZATION OF NEUROPEPTIDE Y (NPY) SUPPRESSES NIGHTTIME FEEDING: A PHYSIOLOGICAL ROLE. M.G. Dube*, B. Xu, P.S. Kalra and S.P. Kalra, Dept. Obstet. & Gynecol., Univ. Florida, Gainesville, FL 32610

The potent orexigenic effects of NPY are well-recognized. Continuous intracerebroventricular (ivt) infusion of NPY elicits insatiable appetite and feeding occurs in episodes resembling the pattern seen during the night when rats normally eat. Further, NPY levels and release are augmented selectively in the hypothalamic paraventricular nucleus in association with increased appetite. We tested the hypothesis that NPY secretion is responsible for normal nighttime food intake in rats. Adult male rats, maintained on a controlled light-dark cycle (lights off 1900-0500 h), were implanted with permanent cannulae in the third cerebroventricle. One week later food and water intake were monitored for 24 h to ensure recovery from surgical stress. Rats were then implanted s.c. with osmotic mini-pumps (Alza, Corp.) attached to the ivt cannula to deliver either NPY antiserum (NPY-Ab) or normal rabbit serum (both diluted 1:1 with artificial cerebrospinal fluid) at a rate of 9 µl/h. Infusion was started at 1500 h and continued for 24 h. NPY-Ab infusion significantly suppressed 24 h cumulative food and water intake: food intake: 3.7 ± 0.9 g vs 10.5 ± 2.6 g for controls (p < 0.03, n = 9/group); water intake: 10.6 ± 1.5 ml vs 26.6 ± 5.3 ml for controls (p < 0.02). Rats receiving NPY-Ab also showed a significantly greater body weight loss than controls (p < 0.02). Since passive immunoneutralization of endogenous NPY suppressed food intake, these results support the hypothesis that NPY is a physiological orexigenic signal that is responsible for normal nighttime feeding. (Supported by NIH DK 37273).

522.8

SPECIFIC INHIBITION OF ENDOGENOUS NEUROPEPTIDE Y SYNTHESIS IN THE ARCUATE NUCLEUS (ARC) BY ANTISENSE OLIGONUCLEOTIDES SUPPRESSES FEEDING BEHAVIOR AND INSULIN SECRETION. A. Akabayashi*, C. Wahlestedt*, J.T. Alexander¹, W.K. Cheung¹, I. Silva¹, and S.F. Leibowitz².

The Rockefeller University¹ and Cornell University Med. College², New York, NY 10021.

Neuropeptide Y (NPY), which is synthesized in neurons of the ARC, is known to have potent effects on eating behavior and hormone secretion. To test the hypothesis that endogenous NPY is essential for the normal expression of these responses, the present study used two unmodified antisense oligodeoxynucleotides (ODNs) to disrupt the synthesis of NPY in the ARC and to examine the impact of this disturbance on nutrient intake, as well as on circulating hormone levels. Brain-cannulated rats on macronutrient diets were given daily, bilateral injections, over a 4-day period, of NPY antisense ODNs, sense ODNs or saline into the ARC. The NPY antisense ODNs significantly reduced (-33% relative to sense ODNs and -40% relative to saline, p<0.05) NPY levels in this nucleus examined by RIA. In association with this reduction in the NPY, the antisense-treated animals exhibited a significant decrease in feeding behavior measured during the first 90 minutes of the natural feeding cycle, as well as over the 24-hour period. In the 90-minute interval, both carbohydrate and fat intake were suppressed by 65-70% (p<0.05, relative to both saline and sense ODNs). In addition, circulating insulin levels were significantly reduced by 50-55% (p<0.05 relative to both saline and sense ODNs). These findings provide the first evidence for physiological disturbances that may result from an inhibition of endogenous NPY production within neurons of the ARC.

INTRAVENTRICULAR (IVT) INSULIN DECREASES NET mRNA IN DIABETIC RAT LOCUS COERULEUS. D. Figlewicz, Lattemann*, P. Szot, A.J. Sipols, D.G. Baskin, and S.C. Woods. Dept. of Cell Biol. and Anat., Oregon Health Sciences U., Portland OR 97201, Depts. of Psychiat., Med., Biol. Struct., and Psychol., U. of Washington, Seattle WA 98195, and the VA Medical Center, Seattle WA 98108.

We have reported that insulin (INS) increases endogenous noradrenergic activity in rat CNS, and one potential mechanism is the inhibition of norepinephrine (NE) re-uptake secondary to decreased membrane concentrations and synthesis of the NE re-uptake transporter (NET). CNS NE transmission or activity may be decreased in diabetes; reported changes are corrected by peripheral INS. We tested whether insulin can alter one aspect of NE transmission--synthetic capacity of locus coeruleus (LC) neurons for NET--directly within the diabetic CNS. Streptozotocin-diabetic Wistar rats (65 mg/kg iv) received IVT vehicle (STZ) or 3 mU/day INS (STZ-INS) for 6 days. NET mRNA was assayed in LC with a 226 bp riboprobe labelled with ³⁵S-UTP (2 pmol/ml). Hybridization was determined on emulsion-coated slides after 2 wk exposure. IVT IRI significantly suppressed NET mRNA levels (STZ=4337±1143 pixels, n=4; STZ-IRI=1113±294 pixels, n=5; p<0.05, ANOVA). We conclude that the ability of insulin to decrease NET mRNA in STZ rats is a direct CNS action, and that INS may directly increase CNS aminergic activity independent of any effects on metabolic substrates. (Studies were supported by NIH R01 DK40963 and the Veterans Administration. The NET clone was kindly provided by Dr. Susan Amara.)

522.11

EXOGENOUS INSULIN INCREASES THE RATE OF GASTRIC EMPTYING AFTER BUT NOT DURING INGESTION. W. Siemers, J.M. Kaplan*, and H.J. Grill. University of Pennsylvania, Philadelphia, PA 19104.

The administration of insulin has many metabolic and physiological consequences, including the acceleration of gastric emptying. We have recently shown that the gastric emptying of glucose solutions is described by different rules during and after stomach fill. It is therefore necessary to determine whether insulin affects both phases of emptying equivalently. On each test day, 5 male rats consumed 12 ml of an introrally infused glucose solution (12.5%) 3 hours following the injection of either insulin (5U/kg) or saline. Stomach contents were removed either during or after the infusion and the glucose concentration determined. Insulin significantly increased gastric emptying after the termination of the infusion, however, it did not affect the rate of emptying during ingestion. The results suggest that insulin does not effect the distribution of glucose solutions during meal-taking; but may influence nutrient distribution between meals.

GABA RECEPTORS: FUNCTION—IN VIVO STUDIES

523.1

GABAergic inhibition is absolutely limited in the RAT NEOCORTEX. D.S.F. Ling¹ and L.S. Benardo². Depts. of Pharmacology¹ and Neurology², SUNY-HSCB, Brooklyn, NY 11203.

Neuronal excitability in the neocortex is gated by inhibitory mechanisms. Several physiological and pathological conditions occur as a consequence of the failure of GABAergic inhibition to limit glutamatergic excitation. The specific mechanisms underlying such behavior are unknown. These issues were addressed by detailed examination of excitation-inhibition interplay in isolated, coronally sectioned slices (400µm) of somatosensory cortex. Layer V neurons were recorded in whole-cell patch clamp configuration to gain information about synaptic strength. We examined stimulus-response characteristics under physiological conditions, and in the presence of magnesium-free solution. Recordings were obtained using cesium-gluconate-containing electrodes. EPSCs were recorded at holding potentials of -70 to -80 mV. Isolated GABA_A-IPSCs (slow GABA_A-IPSCs blocked) were recorded at the EPSC reversal potential (-0 mV). Under physiological conditions, EPSC amplitude increased steadily as stimulus intensity was increased, with no apparent maximum reached. By contrast, the fast IPSC reached a maximum magnitude at a stimulus strength of approximately 1.5-2X the threshold stimulus. When slices were exposed to magnesium-free solutions, IPSCs reached their maximum at lower stimulus strengths, but there was no change in the magnitude of the absolute maximal current. These results suggest that GABA_A-inhibition is limited in the neocortex regardless of the level of excitation. (Supported by NS 01386)

KINETICS OF ULTRAFAST ACTIVATION OF GABA-A RECEPTOR CHANNELS IN EXCISED PATCHES OF RAT CORTICAL NEURONS. R.E. TWYMAN*. Departments of Neurology, Pharmacology and Physiology, University of Utah, Salt Lake City, UT, USA 84112.

GABA-A receptor channels in outside-out patches of fetal rat cortical neurons in culture were exposed to GABA (0.5µM-10mM) using a piezoelectric ultrafast ligand delivery system (100µs exchange time). Receptor activation and closing kinetics were studied using two paradigms: a) brief, repetitive pulsed applications (800µs duration, 1-5Hz, 25 applications) to simulate serial quantal synaptic events and, b) step application for continuous GABA exposure. Patches contained 1-30 channels and were voltage clamped at -75mV in symmetrical Cl⁻ solutions; rapid kinetic data were digitized at 125kHz, 5-10kHz bandwidth; responses were analyzed individually and as ensemble averages for each patch. In pulsed paradigms, τ onset of averaged currents (fit to steep phase) decreased with increased concentration up to 1mM (e.g. 3.5-4ms at 100µM; 0.3-0.35ms at 1 and 10mM). At 1-10mM, currents decayed with τs ranging 20-35ms and average burst durations from patches with <3 channels were ~30ms, indicating that current decay depended on channels exiting intrinsic bursting states rather than on duration of GABA exposure. Initial current onset was sigmoidal in shape, indicating >1 GABA molecule participated in activation. In step paradigms, onset shape and rates were similar. In pulse paradigms, peak currents decreased with time and was faster at higher pulse frequencies; this was slower compared to continuous exposure, which at 10mM, initial rapid decrement (τ ~8ms) was followed by a slower phase (τ ~150ms). These data indicate that for GABA-A receptors: a) activation is slower than ACh receptors, and b) rapidly entered desensitized states exist. Rates of current rise (10-90% time ~1ms) and decay at saturating GABA concentrations are similar to that reported elsewhere for miniature inhibitory currents and suggests that synaptic concentration of GABA is at least 1mM.

523.2

PAIRED PULSE DEPRESSION IN CULTURED HIPPOCAMPAL NEURONS IS DUE TO A PRESYNAPTIC MECHANISM INDEPENDENT OF GABA_B AUTORECEPTOR ACTIVATION. K.S. Wilcox*¹ & M.A. Dichter². Departments of Neurology¹ and Pharmacology², University of Pennsylvania, School of Medicine, and Graduate Hospital, Philadelphia, PA 19104

GABAergic neurotransmission exhibits frequency-dependent modulation and sequential inhibitory postsynaptic currents (IPSCs) evoked with interstimulus intervals between 25 msec and 4 seconds routinely result in the attenuation of the amplitude of the second IPSC. This synaptic plasticity is known as paired pulse depression (PPD). These experiments were designed to directly determine the location of the mechanism of PPD in hippocampal neurons maintained in low density tissue culture. Evoked IPSCs were recorded between isolated pairs of neurons that were patch clamped simultaneously. Miniature IPSCs (mIPSCs) originating from the same synapses that were being stimulated during evoked release were measured. PPD occurred routinely, but the amplitudes of mIPSCs following IPSCs were unchanged; thus, a presynaptic mechanism mediates PPD. The inability of GABA_B receptor antagonists (2-OH-saclofen and phaclofen) to block PPD indicated that this plasticity was not due to autoinhibition of transmitter release via activation of presynaptic GABA_B receptors. Manipulations which lowered the probability of release of neurotransmitter during the first action potential of a trial, (low calcium & baclofen), prevented the development of PPD. These results indicate that inhibitory synaptic vesicles have a relatively high probability of release following a single action potential, but the probability rapidly falls such that subsequent action potentials release much less transmitter for periods as long as 4 seconds. Supported by NS24260 (M.A.D.).

523.4

MODULATORY EFFECT OF ANTIDEPRESSANTS ON PERIPHERAL-TYPE BENZODIAZEPINE RECEPTORS. M. Gavish¹*, R. Burgin¹ and R. Weizman². ¹Dept. of Pharmacology, Bruce Rappaport Fac. of Med., Technion-Israel Inst. of Technology, 31096 Haifa, and ²Tel Aviv Community Mental Health Center and Sackler Fac. of Med., Tel Aviv Univ., Tel Aviv, Israel.

The effect of 21 days of imipramine hydrochloride (10 mg/kg) and phenelzine sulfate (10 mg/kg) administration followed by a 7-day period of withdrawal on peripheral-type benzodiazepine receptors (PBR) was studied in male Sprague-Dawley rats. Both imipramine and phenelzine down-regulated adrenal PBR (-18% P<0.05; and -32%, P<0.01, respectively) and up-regulated hepatic PBR (+27%, P<0.05; and +76%, P<0.0001, respectively), while no alteration was observed in the kidney. Adrenal PBR decreased further (-30% vs. controls) after the withdrawal from imipramine, while a full restoration to normal values occurred following phenelzine withdrawal. [³H]PK 11195 binding to the liver did not differ significantly from the control values after withdrawal from both drugs. The observed changes can be explained as adaptive responses to antidepressant-induced hormonal and cellular alterations.

IMIDAZENIL: A NEW PARTIAL POSITIVE ALLOSTERIC MODULATOR OF GABA ACTION AT GABA_A RECEPTORS. A. Guidotti, P. Giusti*, R. Arban*, G. Paia, I. Ducic, E. Costa. Fidia-Georgetown Institute for the Neurosciences, Georgetown Univ Med Sch, Washington, DC 20007 USA and Department of Pharmacology*, University of Padua, Italy.

When tested on a broad spectrum of native or recombinant GABA_A receptor subtypes, imidazenil positively modulates the GABA-elicited Cl⁻ current with a potency 5 to 10 fold higher than that of diazepam. But it has an efficacy 30 to 50% lower than that of diazepam and it antagonizes the effect of diazepam. Imidazenil also possesses a marked anticonvulsant action in the rat and is more potent than bretazenil, diazepam, or alprazolam in antagonizing bicuculline or pentylenetetrazol (PTZ) induced seizures. Unlike diazepam and alprazolam, imidazenil does not produce ataxia, sedation nor potentiates the effect of ethanol or barbiturates in rats and monkeys. Moreover, imidazenil, unlike diazepam and alprazolam, fails to produce tolerance in the antagonism of bicuculline-induced convulsions even after 5 months of continuous treatment. PTZ, in subconvulsant doses, has been reported to induce a panic-like syndrome in human and animals. Thus, the potential antipanic action of imidazenil was evaluated in the PTZ facilitation of punishment suppressed behavior in the proconflict Vogel test paradigm (*J. Pharmacol. Exp. Ther.* 257:1062, 1991). The antiproconflict potency of imidazenil (EC₅₀ 0.06 μmol/kg, i.v.) was 50 fold higher than that of diazepam and 5 to 10 fold higher than that of other known antipanic drugs (i.e., alprazolam, bretazenil, clonazepam). Thus, imidazenil is a partial allosteric modulator at GABA_A receptors. It possesses a potent anticonvulsant and antipanic action and is devoid of side effects such as ataxia, sedation, ethanol potentiation, and tolerance liability. COMPARISON OF TOLERANCE PRODUCING EFFECTS OF α-ETHYL, α-METHYL THIOBUTYROLACTONE AND CLONAZEPAM. J.A. Ferrendelli, A.C. McKeon, K. Xu, J.W. Miller*, D.F. Covey. Washington University School of Medicine, St. Louis, MO 63110.

Benzodiazepines and butyrolactones act at benzodiazepine and picrotoxin receptors, respectively, on the GABA receptor/chloride ionophore, but both can augment chloride conductances and have similar acute behavioral effects. We now compare some effects of chronic treatment of mice with α-ethyl, α-methyl thiobutyrolactone (α-EMTBL) or clonazepam (CZP) in chronically treated animals to determine if α-EMTBL produces tolerance similar to benzodiazepines. Mice (CF-1) were treated for 10 or 14 days with a TD₉₀ dose of either α-EMTBL or clonazepam. All animals treated with CZP (n=109) became tolerant to the toxic effects of a TD₉₀ dose of this drug whereas 91% of the animals treated with α-EMTBL (n=69) continued to be toxic after treatment with a TD₉₀ dose of this drug. Brain membranes from animals chronically treated with CPZ had no change in benzodiazepine receptor binding affinity (K_d), but had decreased number of benzodiazepine receptors (B_{max}). Chronic treatment with α-EMTBL did not change the number or affinity of benzodiazepine or picrotoxin receptors. CPZ treatment did not affect picrotoxin receptors and α-EMTBL did not alter benzodiazepine receptors. These results demonstrate that α-EMTBL, unlike clonazepam, does not produce tolerance after chronic administration and leads to the conclusion that α-EMTBL and perhaps other butyrolactones would be better therapeutic agents than benzodiazepines in patients requiring prolonged treatment.

ACCUMULATION OF CIRCULATING ENDOZEPINES AS PRECIPITATING FACTOR OF ENCEPHALOPATHY IN CIRRHOTIC PATIENTS. R. Avallone, J. Venturini*, M.L. Zeneroli*, A. Monzani, M. Di Bella, M. Baraldi*. Dept. of Pharmaceutical Sciences and Chair of Clinical Methodology*, Modena University, 41100 Modena, Italy.

During the last ten years evidence has been provided that an increased sensitivity of the GABAergic neurotransmission affects the level of consciousness in animal models and in human with hepatic encephalopathy (HE) due to acute or chronic liver diseases. Several pathogenetic agents, such as ammonia, seem to be responsible together with metabolic alterations (hypoglycemia, hypoxia) of glutamate-related neurotoxicity leading to gliosis and neuronal degeneration which in turn could explain the denervation supersensitivity of the GABAergic system. The demonstration of endogenous benzodiazepine-like compounds (EBz) in mammalian tissues, mainly of alimentary origin, prompted several groups to study the levels of these EBz in animal and patients with HE. Indeed few reports on small groups of patients with HE have been shown to have an increased level of EBz in serum and CSF. Herein we report an extensive study on the levels of EBz in the serum of 156 patients comprising 53 controls and 89 liver cirrhosis (LC) patients free of exogenous Bz and 14 Bz consumers. The levels of EBz in LC were about 8 fold higher than in controls (mean ± SE: 2.81 ± 0.33 vs 0.44 ± 0.07 pmol DE/ml; p < 0.0001). The levels of EBz were found progressively increased in LC with the severity of the liver disease: in compensated LC the values were 0.50 ± 0.11; in decompensated LC were 2.51 ± 0.47 (p < 0.001 vs compensated); in severely decompensated were 4.80 ± 0.57 pmol DE/ml (p < 0.0001 vs decompensated). The HE was present in these last two groups of patients severely. From these data we can surmise that the increase of EBz in LC might be a contributing factor in precipitating HE, but only in the presence of an increased sensitivity of the cerebral GABAergic system. In fact LC patients with HE never reach the levels found in the 14 normal subjects assuming modest amount of exogenous Bz (9.21 ± 1.6 pmol DE/ml) which were free of any consciousness disturbance.

IMIDAZENIL ATTENUATES THE DISRUPTIVE EFFECTS OF ALPRAZOLAM ON COMPLEX LEARNING AND PERFORMANCE IN MONKEYS. D. Thompson*, A. Guidotti*, E. Costa. Department of Pharmacology* and Fidia-Georgetown Institute for the Neurosciences, Georgetown Univ Med Sch, Washington, DC 20007.

Imidazenil is a partial allosteric modulator of GABA action at GABA_A receptors, whereas alprazolam is a full allosteric modulator at these receptors. To determine whether this difference is reflected in their behavioral effects, we studied these two drugs, alone and in combination, in monkeys working in a complex behavioral task. In one component of a multiple schedule (repeated acquisition or "learning"), patas monkeys acquired a different four-response chain each session by responding sequentially on three keys in the presence of four geometric forms. In the other component (performance), the four-response chain was the same each session. The response chain in each component was maintained by food presentation under a fixed-ratio schedule. When alprazolam (0.01 - 0.32 mg/kg, po) was administered alone, the overall response rate in both learning and performance decreased and the percent errors in both components increased with increasing doses. Learning, however, was more sensitive than performance; i.e., error-increasing effects were seen in learning at doses that had no effect on performance accuracy. When imidazenil, at a dose having little or no effect when given alone (1 mg/kg, po), was administered 60 min before alprazolam (0.1 or 0.32 mg/kg, po), the large disruptive effects of alprazolam on learning and performance were greatly attenuated. The results indicate that the partial allosteric modulator imidazenil can partially antagonize the disruptive behavioral effects of a full allosteric modulator at GABA_A receptors.

DIAZEPAM, BUT NOT ZOLPIDEM, IMPAIRS MOTOR REFLEX IN THE MUTANT ANT RATS. E.R. Korpi* and M. Sarvijarju. Biomedical Research Center, Alko Ltd, POB 350, SF-00101 Helsinki, Finland.

ANT (Alcohol Non-Tolerant) rats are abnormally sensitive to motor-impairing effects of benzodiazepine agonists. These rats have a point mutation in their cerebellar GABA_A receptor α6 subunit, which alters the resulting receptor subtype from normal diazepam insensitive to diazepam sensitive (Korpi et al. *Nature* 361: 356-359, 1993). In the present autoradiographic study, we found that zolpidem, a potent benzodiazepine receptor agonist, failed to displace "diazepam-insensitive" component of the [³H]RO 15-4513 binding in cerebellar sections of the ANT rats, whereas diazepam at micromolar concentrations fully displaced it. Correspondingly, in behavioral experiments with ANT rats, zolpidem failed to produce any motor impairment in the tilting plane test 30 min after IP injection (1-10 mg/kg), whereas diazepam significantly impaired the performance (10-20 mg/kg, IP). The results support the hypothesis that the abnormal benzodiazepine sensitivity of the ANT rats is caused by the altered drug sensitivity of their mutant cerebellar granule cell-specific GABA_A receptors.

CORRELATION OF NEUROACTIVE STEROID MODULATION OF [³⁵S]TBPS AND [³H]FLUNITRAZEPAM BINDING AND GABA_A RECEPTOR FUNCTION. J. E. Hawkinson*, C.L. Kimbrough, R.H. Purdy, and N.C. Lan. CoCensys, Inc., Irvine, CA, 92718.

Neuroactive steroids, including both progesterone metabolites and their derivatives, are positive allosteric modulators of the GABA_A receptor-chloride ionophore complex (GBRC). They potentiate GABA-activated chloride currents and GABA- and muscimol-stimulated ³⁶Cl⁻ uptake, enhance the binding of [³H]flunitrazepam ([³H]FLU), and inhibit the binding of [³⁵S]TBPS. However, the relationship between neuroactive steroid modulation of binding and effect on receptor function has not been demonstrated.

We examined the abilities of a series of 31 neuroactive steroids to modulate [³⁵S]TBPS and [³H]FLU binding in rat brain cortical preparations and correlated these two measurements with each other and with potentiation of chloride uptake as an indicator of receptor mediated function. There is a good correlation (r > 0.9) between [³⁵S]TBPS IC₅₀ and [³H]FLU EC₅₀ indicating that the allosteric modulation of [³⁵S]TBPS and [³H]FLU binding by neurosteroids occurs via similar neurosteroid binding sites. However, there is a lower correlation (r ~ 0.7) between the efficacies in the two binding assays. Furthermore, a similar correlation (r = 0.7-0.8) was observed between [³⁵S]TBPS or [³H]FLU binding and the abilities of these steroids to potentiate muscimol-stimulated ³⁶Cl⁻ uptake in rat cortical synaptosomes (Purdy et al., 1990, *J. Med. Chem.* 33:1572-1581). These data indicate differential coupling efficacies among neuroactive steroids for various functional sites on the GBRC which may in turn suggest receptor heterogeneity for neurosteroid action.

THE BIOCHEMICAL AND BEHAVIORAL PHARMACOLOGICAL EFFECTS ON THE INTRODUCTION OF A DOUBLE BOND AT THE 16,17 POSITION OF NEUROACTIVE STEROIDS. S. Wieland*, J. Hawkinson, H. Xia, R. Upasani, M. B. Bolger¹, N.C. Lan, CoCensys, Inc., Irvine, California 92718, ¹University of Southern California, School of Pharmacy, Los Angeles, California 90033

Neuroactive pregnane steroids have been shown to be potent anticonvulsants, anxiolytics and hypnotic agents. Previous studies have shown that introduction of a double bond at the 16,17 position of the sedative/anesthetic compound, alphaxalone (3 α -hydroxy-5 α -pregnane-11,20-dione), completely eliminated its anesthetic properties. It is of particular interest to examine whether such a structural modification selectively alters the sedative action, but maintains the potent anticonvulsant activity of neurosteroids. We have studied the biochemical and behavioral effects of introducing a 16,17 double bond into the naturally occurring steroids 3 α -hydroxy-5 α -pregnan-20-one (3 α ,5 α -P) and 3 α -hydroxy-5 β -pregnan-20-one (3 α ,5 β -P).

The 16-ene analog of 3 α ,5 α -P was 8-fold less potent in inhibiting [³⁵S] TBPS binding in rat cortical membranes, whereas the 16-ene analog of 3 α ,5 β -P was 10-fold less potent than the parent compound. In behavioral activity measurements, the 16-ene analog of 3 α ,5 α -P and 3 α ,5 β -P had reduced potency against metrazol-induced seizures in mice by 10-20 fold and 15-fold, respectively, compared to their parent compounds. Similarly, the sedative potency was reduced by 25- and 7-fold for the 16-ene analogs of 3 α ,5 α -P and 3 α ,5 β -P, respectively.

Taken together, the data suggests that although introduction of a 16,17 double bond decreased the sedative potency of 3 α ,5 α -P and 3 α ,5 β -P, it also reduced their anticonvulsant potency, thereby limiting the potential clinical usefulness of this structural modification.

THREE MECHANISMS FOR INCREASED GABAERGIC INHIBITION AFTER KINDLING-INDUCED EPILEPSY. T.S. Otis*¹ and I. Mody*². ¹Dept. Neurology & Neurological Sci., Stanford Univ., Stanford, CA, and ²Depts. of Anesthesiology & Neurology, UT Southwestern Med. Ctr., Dallas, TX.

The hypothesis that a reduction in GABAergic inhibition necessarily takes place in chronic epilepsies is controversial. We studied synaptic inhibition of granule cells (GCs) from slices of control and kindled dentate gyrus (DG) using whole-cell recordings to examine GABA_A-mediated spontaneous inhibitory postsynaptic currents (sIPSCs), and to measure stimulus-evoked monosynaptic GABAergic input to GCs.

The frequency of sIPSCs impinging on a given GC was measured under three successive conditions: (1) in control solutions, (2) in the presence of 10 μ M CNQX and 40 μ M D-AP5, and (3) in CNQX/D-AP5 and 1 μ M tetrodotoxin (TTX). In all conditions, sIPSCs frequencies in kindled GCs were equal to or higher than in controls. On average, CNQX/D-AP5 reduced the frequency of sIPSCs in kindled GCs by 22%, but had no effect on the frequency in control cells (2% increase), indicating the emergence of a tonic excitation of GABAergic neurons during kindling. Addition of TTX reduced sIPSC frequency more in control (47%) than in kindled slices (19%). Finally, the mean conductance, but not the kinetics, of miniature IPSCs was significantly larger (76% increase) in kindled neurons, suggesting an increased quantal size.
