In female prairie voles (*Microtus ochrogaster*), male contact increases blood estradiol (E_2) level and induces sexual receptivity. Male urine applied to the nose of a female increases posterior olfactory bulb LHRH content and serum E_2 levels. We investigated the importance of E_2 and cohabitation with males for the induction of female sexual receptivity. Naive, ovariectomized (ovex), and ovex low E_2 treated females were housed with a male for up to 70 hours and observed for sexual receptivity, or isolated for 70 hours and briefly tested for sexual receptivity with a stud male. While all isolated females were non-receptive, cohabitating naive and low E_2 females were receptive. After testing, females were perfused and brain LHRH-IR examined. The anatomical distribution of LHRH-IR was similar in all experimental conditions and resembled other rodent species, with the greatest concentration of LHRH-IR in the olfactory bulb and tubercle, the diagonal bands of Broca, and the septal, preoptic and rostral hypothalamic nuclei. Although the arcuate contained many LHRH-IR fibers, few LHRH-IR neurons found in this area. Male cohabitation reduced LHRH-IR across the different estrogen conditions. We infer that cohabitation with a male induces the release of LHRH, initiating a subsequent physiological or behavioral response in the female. (HD 22983-JIM)

GONADOTROPIN RELEASING HORMONE (GnRH) MESSENGER RNA (mRNA) EXPRESSION IN A FISH WITH TWO CLASSES OF ADULT MALES. C. M. Foran, M.A. Marchaterre*, T. R. Myers, A.H. Bass and D. A. Myers. Sect. Neurobiology and Behavior & Dept. Physiology at NYS College Veterinary Medicine, Cornell Univ. Ithaca, N.Y. 14853

The plainfin midshipman, *Porichthys notatus*, has three classes of sexually mature adults: type I males, type II males and females. Each morph has distinct reproductive tactics and neuronal traits (Bass, TINS 15:139, 1992). Since GnRH is considered to regulate the expression of adult reproductive behavior among vertebrates, GnRH gene expression is being studied in midshipman to identify molecular and cellular events that determine the expression of morph-specific behaviors. The cDNA for GnRH in midshipman was previously cloned and sequenced (Grober, Bass and Myers; Soc. Neurosci., 1992). Based on this sequence, oligonucleotide probes (40mers; ^{33}P -labelled) were generated for use with *in situ* hybridization histochemistry to identify GnRH-mRNA transcripts in the brain. Tissue was sampled from adult (6 Type I males, 2 Type II males, 7 females) and juvenile male (2) morphs. Adult tissues included those from both reproductively active and inactive individuals. GnRH-mRNA positive perikarya were identified in the olfactory bulb (OB), the ganglion of the nervus terminalis (NT) which is localized ventrally at the junction of the olfactory bulb and telencephalon, the magnocellular (PM) and parvocellular (PP) regions of the preoptic area, and the ventrolateral thalamus (VT). GnRH expression in NT was consistently high in all animals, suggesting it is functionally distinct and not related to reproductive status. Elsewhere, levels of expression varied among the morphs or between breeding and non-breeding states. Support from NSF.

MIF-1 acts as an opiate antagonist in the tail-flick test with lizards. G. M. Reed, M. L. Norez, L. Raibstein, A. J. Kastin, G. A. Olson*, and R. D. Olson. Department of Psychology, Univ. of New Orleans, New Orleans, LA 70148

Previous research suggests that MIF-1 (Pro-Leu-Gly-NH₂) may act as an opiate antagonist. Five doses of MIF-1, (0.00001, 0.00005, 0.0001, 0.0005, and 0.001 mg/kg), each combined with 10.0 mg/kg of morphine sulfate, a control dose of morphine sulfate (10.0 mg/kg), and control solutions of saline and diluent were injected IP in 256 lizards (*Anolis carolinensis*). Tail-flick latencies were obtained 15 min. after injection in a diagram-balanced design. The data were analyzed with a Blocks by Dose independent groups ANOVA. Results indicated a significant main effect for Blocks, with each block having quicker latencies than the previous one, $F(3, 224) = 3.35, p < .05$. Tukey's HSD test indicated that the first block had significantly longer latencies than the fourth block, but that none of the other comparisons were significant. The main effect for Dose was also significant, $F(7, 224) = 2.32, p < .05$. Tukey's HSD test indicated that the morphine control group had significantly longer latencies than all other groups, but that none of the other comparisons were significant. These results suggest that all doses of MIF-1 were able to block the effects of morphine. These findings further suggest that peptides may be active at lower doses than previously expected, and that all of the doses tested in this study appeared equally efficacious.

HRT, BRAIN AND BEHAVIOR: EPIDEMIC WITHOUT EPIDEMIOLOGY. H. Stowell*, Milledgeville GA 31061.

In 1991 US Govt. Accounting Office estimated 2.3 million American women to be purchasing via physicians "noncontraceptive estrogens". They failed to distinguish reversible, postsurgical & acute (≤ 2 years) Hormone Replacement Therapy (HRT) from irreversible chronic HRT in Women Otherwise Naturally Menopausal (HRT-WONM). In 1993 a Salk Institute report on hormonal chemoprevention of cancer described HRT-WONM as subject to "ever-changing practices of prescription" & suggested that its gonadal steroid combinations may produce circulating levels of non-SHBG-bound steroids approaching "that associated with the normal ovulatory cycle" [1,2]. WHO has no epidemiology of HRT-WONM, referring to "national Medical Associations" for desired data. Pilot research since 1991 confirms wide variability of steroid combinations, dose, dose-scheduling (daily, monthly or 6-monthly), dose route (oral vs. non-oral), & duration (10 year max to lifelong), but such data are informal. Current conventions of patient confidentiality (including a pair-bonded spouse) prevent a valid epidemiology. But current data from neurobiology of steroids, brain peptides & the mesolimbic dopamine system suggest strong effects of HRT-WONM on psychosexual & affiliative behaviors; effects supported by anecdotal evidence during the past 2 decades.

DRUGS OF ABUSE: ETHANOL AND BENZODIAZEPINES—TOLERANCE, DEPENDENCE, WITHDRAWAL

595.1

FAWN-HOODED (FH) RATS VOLUNTARILY DRINK ENOUGH ALCOHOL TO DEVELOP TOLERANCE.

Amir H. Rezvani, D. Overstreet, A. Ejanfar, D. Janowsky* and O. Pucilowski. Skipper Bowles Center for Alcohol Studies and Dept. of Psychiatry, Univ. of North Carolina Sch. of Med., Chapel Hill, N.C. 27599.

Recently, we reported that FH rats, which possess a genetic serotonin impairment, exhibit a high preference for alcohol. To further characterize this strain of alcohol preferring rats, FH rats were given either free access to food, a solution of 10% (v/v) alcohol and tap water or only food and water for three months. Then, rats were withdrawn from alcohol and about six hrs. later were injected (ip) with a dose of 1.5 g/kg alcohol (16% v/v). Change in body temperature was measured one hr after alcohol injection. In a separate experiment, FH rats were given only one hr access to alcohol every morning and their blood alcohol levels (BAL) were determined 30 mins. after exposure. To determine if FH rats regulate their alcohol intake, rats were injected either with saline or different doses of alcohol 15 mins. before one hr alcohol exposure and their alcohol intake was measured at the end of one hr session. Our findings show that a) FH rats drank high enough alcohol (5.3±1.3 g/kg/day) to develop tolerance to its hypothermic action, b) in a limited access paradigm, they drank 1.14±0.06 g/kg/hr alcohol and their BAL reached 81±4.4 mg/dl, and c) pre-administration of different doses of 10% (v/v) alcohol reduced the alcohol intake dose-dependently in the limited access paradigm. In conclusion, FH rats prefer alcohol for its pharmacologic but not taste-related effects, and they drink enough to develop tolerance to its hypothermic action.

595.3

SENSITIVITY AND TOLERANCE TO THE SEDATIVE EFFECTS OF ETHANOL IN THE HIGH- AND LOW-ALCOHOL-DRINKING (HAD AND LAD) RATS. J.M. Murphy*, W. Dyl. W.J. McBride, L. Lumeng, and T.-K. Li. Inst. Psychiat. Res. and VAMC, Indiana U. Sch. Med., and Dept. Psychology, Purdue Sch. Sci., IUPUI, Indianapolis, IN, 46202-4887.

The HAD and LAD lines of rats have been selectively bred for preference and nonpreference of a 10% (v/v) ethanol (E) solution, respectively, when food and water are available ad lib. The present study investigated the effects of 1, 2 and 3 g E/kg (i.p.) on the loss of righting reflex (LR), the duration of sleep time (regain of righting, RR), and the blood alcohol content (BAC) at RR in the HAD and LAD rats. Adult males (n=8/line) were housed with ad lib food and water. Each rat received the three E doses given in ascending order, separated by three weeks. A second 3 g/kg dose was tested 24 h after the first 3 g/kg injection. All rats had a shorter interval to LR as the E dose increased ($p < 0.05$), but HAD and LAD rats did not differ at any dose. The time to RR increased with dose. The HAD rats showed significantly ($p < 0.05$) longer time to RR than LAD rats at the 3 g/kg dose (395±37 vs 256±18 min) and BACs for HAD rats were significantly lower than for LAD rats (244±19 vs 172±22 mg%). When retested with 3 g/kg 24 h later, the HAD rats again showed a significantly longer RR than LAD rats (270±35 vs 210±16 min) but, relative to the first injection, only the HAD rats significantly decreased the duration of RR and increased BAC at RR (217±12 mg%), indicating that tolerance to the first dose of E had developed. The LAD rats are less sensitive than the HAD rats to an initial exposure to high-dose E. However, with E exposure, it appears that the HAD rats develop tolerance and approach the same level of sensitivity as exhibited by the LAD rats. (Support: Kosciuszko Fdn., AA08553).

595.2

A GENETIC COMPARISON OF TOLERANCE TO ETHANOL AND ANXIETY DURING WITHDRAWAL. T. K. Booker, A. Gonzales, A.C. Collins*. IBG, Univ. Co. Boulder, CO 80309.

The ethanol (EtOH)-sensitive LS mice develop more tolerance to EtOH and cross-tolerance to nicotine (Nic) than do the EtOH-resistant SS mice following 1-2 weeks of high-dose, EtOH-containing liquid diet treatment. This treatment also evoked substantial weight loss which may be a confound. Therefore, LS and SS mice were treated for 6 months with a low dose of EtOH (15% v/v in water), and were tested for sensitivity to EtOH and Nic as well as withdrawal anxiety. This method produced peak blood EtOH levels of 60-80 mg/dl, but did not elicit changes in EtOH metabolism or weight loss. The LS developed tolerance to EtOH as measured by the sleep-time, Y-maze activities, and temperature tests. SS mice showed tolerance to EtOH only for the sleep-time test which agrees with short-term high-dose EtOH treatment results. The LS mice showed increased anxious behavior in the mirrored chamber test as withdrawal progressed and the SS exhibited less. These results support the notion that initial sensitivity to EtOH influences the development of EtOH tolerance and severity of withdrawal. Neither LS or SS developed tolerance to Nic following low dose treatment unlike the results obtained following 1-2 weeks of high-dose EtOH treatment. High dose treatment evoked weight loss and a change in the volume of distribution of Nic. Perhaps low-dose EtOH did not result in tolerance to Nic because weight changes did not occur. Supported by AA-06391 and DA-00116.

Na⁺ CHANNEL ANTAGONISTS RESTORE DOPAMINERGIC FIRING IN ETHANOL-WITHDRAWN RATS.

Marco Diana*, Marco Pistis, Annalisa Muntoni & Gianluigi Gessa. "B.B. Brodie" Dept. of Neuroscience, Univ. of Cagliari, Italy.

We have previously shown that DA firing of the mesolimbic system is drastically reduced in rats withdrawn from chronic ethanol administration. This effect is accompanied by a reduction in DA release in the nucleus accumbens and by a prolongation of the refractory periods of the same neurons. Since the absolute refractory period (ARP) should reflect opening-closing of the Na⁺ channels, we tested different Na⁺ channel antagonists as they promote closing of the Na⁺ channels in order to verify if they would, by decreasing the length of the ARP, restore DA firing. Male Sprague-Dawley rats were made dependent on ethanol and upon cessation of chronic ethanol administration (12-14 hrs after last ethanol administration) were surgically prepared for extracellular recordings of antidromically-identified meso-accumbens DA neurons. Although ARP could not be measured after administration of the Na⁺ channel antagonists as they decrease conduction velocity, spontaneous DA firing, burst firing and spikes/burst were potentially stimulated by iv administration of bupivacaine (0.5-5.0 mg/kg) and lidocaine (5-20 mg/kg) in ethanol withdrawn rats. The effect of the drugs in saline-treated control rats was much milder and significantly different. The results are consistent with an alteration in Na⁺ channels kinetic of DA neurons in ethanol dependent rats. Further experiments using intracellular recordings will be required to confirm this possibility.

595.5

EFFECT OF NMDA ANTAGONIST (KETAMINE) ON CHRONIC TOLERANCE TO ETHANOL: IMPORTANCE OF INTOXICATED PRACTICE J.M. Khanna*, G.S. Morato, A. Chau, G. Shah and H. Kalant. Addiction Research Foundation of Ontario and the Department of Pharmacology, University of Toronto, Toronto, Canada M5S 1A8.

We have recently shown that NMDA antagonists ((+)-MK-801 & ketamine) inhibit the development of rapid and chronic tolerance to ethanol (E). The present experiments examined the possible importance of intoxicated practice for the effect of ketamine (K) on tolerance to E. Two groups of rats received daily practice (11 days) on the tilt-plane test under the influence of E, preceded by either K or saline (S). Two more groups had daily practice followed by E (preceded by either K or S). Two other groups had practice preceded and followed by K or S without E. All groups were tested under E on days 5 and 12. Tolerance occurred in both groups that received S + E, but it developed later in those that did not practise under E. No tolerance was seen at either time in the practice group receiving K + E, but K did not prevent tolerance in the non-practice group. These results suggest that NMDA antagonists will block only a learned component of tolerance and not that component acquired purely by pharmacological exposure. (Supported in part by RO1 AA08212-04)

595.7

CUE-INDUCED CRAVING IN ALCOHOLICS: CSF MONOAMINE PREDICTORS AND PHARMACOLOGIC MODULATION. I. Petrakis, E. Webb, N. Cooney, L. Trevisan, H. Krantzler, L.P. Karper*, D.S. Charney, J.H. Krystal. Alcoholism Research Center, VA Medical Center, West Haven, CT 06516

5-HT systems have been implicated in alcoholism, but there is no published data on the effects of 5-HT modulations upon craving for alcohol elicited in alcoholics by exposure to alcohol. This study evaluated tryptophan depletion effects on cue-induced craving for alcohol in alcoholics. **METHODS:** In an ongoing study, alcoholics (n=8) 1-3 months post-detoxification completed a lumbar puncture one day prior to exposure, but not consumption, of alcohol. Patients exhibiting at least a 20% increase in craving completed two additional cue-exposure tests. Placebo or active tryptophan depletion sessions were separated by a week. Depletion was achieved by giving an amino acid load devoid of tryptophan that increased utilization of remaining plasma tryptophan. Placebo depletion included tryptophan in the amino acid load. **RESULTS:** Preliminary results indicate a significant correlation between CSF MHPG levels and subsequent cue-induced craving. 5-HIAA and HVA showed non-significant correlations. Tryptophan depletion appeared to reduce cue-induced craving for alcohol. **IMPLICATIONS:** These preliminary data indicate that CSF monoamine metabolite levels may predict reactivity to alcohol cue exposure. They also suggest that 5-HT systems contribute to cue-induced craving in a tryptophan-dependent fashion.

SLOW RELEASE SILASTIC CAPSULES (SC) FOR CHRONIC ADMINISTRATION OF BENZODIAZEPINES (BZ). X. Jing, E. Wala, W.R. Martin, J.W. Sloan*. Dept. of Anesthesiology, Coll. of Med., Univ. of Ky., Lexington, KY 40536.

Release of diazepam (DZ), nordiazepam (ND), oxazepam (OX), halazepam (HL), flunitrazepam (FN) and lorazepam (LZ) from S/P medical grade Silastic tubing (.058 id x .077 od) 7 cm (A) or 11 cm (B) long and from Silastic Medical Grade Rx-50 tubing (.078 id x .090 od) 11 cm long (C) was determined *in vitro*. SC filled with different BZ were placed in 20 ml of saline and shaken at 37°C for 1 or 4 weeks. Concentrations of BZ were determined in saline every day by HPLC. Rate of release (mg/day) from SC (A) varied between BZs: DZ (0.9), FN (0.2), HL (0.1), ND (0.04) and OX (0.005). From longer SC (B) ND and OX were released faster than from SC (A). From SC with a thinner wall (C) all BZ were released with higher rate than from SC (B). Rats were implanted with SC (A) (90 mg/x1cap/week) or (90 mg/x2cap/week), SC (B) (180 mg/2cap/week) or (180 mg/x3cap/week) and SC (C) (180 mg/x2cap/week) or (270 mg/x2cap/week) and then stabilized on DZ for 4 weeks. Plasma levels of DZ and its metabolites were determined at weekly intervals. After the second implantation plasma levels of DZ were stable. With SC (A) stabilization plasma levels of DZ were related to the amount of implanted DZ. Despite the differences in *in vitro* release of DZ from SC (B) and (C) plasma levels of DZ are not different. Preliminary data indicate that *in vitro* and *in vivo* releases of DZ from SC are not totally in agreement. Supported by NIDA grant DA02195.

595.6

SUBCHRONIC 5HT_{1C/2} ANTAGONISM BY RITANSERIN PARTIALLY REVERSES ETHANOL WITHDRAWAL-INDUCED ANXIETY.

C.J. Wallis, S.M. Rezazadeh* and H. Lal. Department of Pharmacology, Texas College of Osteopathic Medicine, Fort Worth, TX 76107.

It has been suggested that the "anxiety-like" symptoms measured during ethanol withdrawal (EW) may be partially due to a disturbance in 5HT receptor activity (Lal, et al, Alcohol 8:467, 1991). In the present studies, we investigated the efficacy of ritanserin, a potent 5HT_{1C/2} antagonist, to modify an EW symptom in two animal models of anxiety: the elevated plus-maze (EPM) and the pentylenetetrazol (PTZ) discrimination paradigm. Long-Evans hooded rats were given a nutritionally balanced liquid diet containing 4.5% ETOH for 10 d (Lal et al., JPET 247:508, 1988). Twelve h after removal of the ETOH diet, rats were tested in the EPM. We observed a significant reduction in the open-arm activity and the number of total arm entries indicative of EW. Acute ritanserin (0.04-5 mg/kg, ip, 30 min) had no effect on EW induced "anxiety-like" behavior on the EPM. Subchronic ritanserin (0.04-0.64 mg/kg, ip, bid 12 hrs) administered concurrently with the last five (5) days of ETOH diet produced an inverted U-shaped dose related increase in the time spent on the open arms of the EPM (0.32 mg/kg optimal) and partial reversal of the EW-induced reduction in total arm entries. In animals trained to discriminate between saline and PTZ (an anxiogenic drug), EW generalized to PTZ, indicating an EW-induced PTZ-like interoceptive discriminative stimulus (EW-IDS). Neither acute nor chronic ritanserin blocked the EW-IDS, but acute ritanserin (0.32 mg/kg, 1h) did reduce the ED₅₀ for PTZ discrimination (from 5.55 mg/kg to 2.18 mg/kg). These data support the hypothesis that chronic ritanserin only partially blocks ethanol withdrawal-induced "anxiety". Supported by NIAAA grants AA06890 and AA09567.

595.8

APPARENT LACK OF ACUTE TOLERANCE DEVELOPMENT TO ETOH'S DISCRIMINATIVE STIMULUS ATTRIBUTES.

K.L. Goulden, R.L. Briscoe, B.D. Youngblood, D.V. Gauvin and F.A. Holloway*. Psychobiology Labs, Dept. Psychiatry & Behav. Sci., Univ. of Okla. Hlth. Sci. Cntr., Oklahoma City, OK 73190

Twenty male S-D rats were trained to discriminate between 1.0 g/kg ETOH and saline (SAL) in 10 min sessions under an FR-10 schedule of food reinforcement. Group 1 was injected i.p. 15 min prior to the sessions with SAL or ETOH, when blood levels were on the ascending limb of the BAC (152.2 ± 11 mg/dl). Group 2 was injected i.p. 60 min prior to the sessions with SAL or ETOH, when blood levels were on the descending limb of the BAC (79.3 ± 9 mg/dl). The number of training sessions to criterion discriminative performance (STIC) did not differ between groups. Various doses of ETOH were tested at the group's training pretreatment interval and in 15 min increments from 15 min to 180 min after injections. The group mean ED₅₀'s for the response-choice measure, when ETOH was administered at each groups' pretreatment interval, was not significantly different (Group 1: 0.49 ± 0.05 g/kg; Group 2: 0.57 ± 0.07 g/kg; T(18)=0.85, n.s.). Additionally, the groups' median effective time interval (METI) did not differ (Group 1: 110.2 ± 8.9 min; Group 2: 120.7 ± 8.8 min; T(18)=0.83, n.s.). The data from the present study suggest that tachyphylaxis or acute tolerance did not develop to the interoceptive subjective states associated with ETOH administration in the rat, across the ascending and descending limbs of the BAC.

595.10

TOLERANCE TO THE ANTICONVULSANT EFFECT OF DAILY DIAZEPAM INJECTIONS IS FACILITATED BY PREVIOUS DIAZEPAM INJECTIONS BUT NOT DIAZEPAM INJECTIONS PRECEDED BY CONVULSIVE STIMULATION. T.E. Kippin*, L.E. Kalynchuk, and J.P.J. Pinel. Dept. of Psychology, Univ. of British Columbia, Vancouver, B.C. Canada. V6T 1Z4

Mana et al. (1991) found that the development of tolerance to the anticonvulsant effect of bidaily diazepam on convulsions in amygdala-kindled rats is contingent upon the occurrence of convulsive stimulations during the periods of diazepam exposure. Subsequently, Mana and Pinel (1987) found that the critical factor in the dissipation of this contingent tolerance was the occurrence of convulsive stimulations in the absence of drug. Accordingly, we predicted that a drug-alone condition would produce tolerance more rapidly than a drug-after condition because in the latter condition each trial would reduce any tolerance that might have developed. During the 15-trial treatment phase, amygdala-kindled rats received either a daily injection of diazepam (2.5 mg/kg) 1 hr before a stimulation, diazepam 1 hr after a stimulation, diazepam with no stimulation, or saline with and without stimulation. At the end of the treatment phase only the diazepam-before rats displayed significant tolerance to diazepam's anticonvulsant effect. All rats were then given a series of daily diazepam-before-stimulation treatments in order to compare the rate at which tolerance developed. The diazepam-only group acquired tolerance significantly faster than did the diazepam-after and saline groups. These results support the drug-effect theory of tolerance, and they suggest that savings measures and drug-only control groups should be included in studies of contingent tolerance.

595.11

TOLERANCE TO THE ANTICONVULSANT EFFECT OF DIAZEPAM IS FACILITATED BY AN ASCENDING-DOSE REGIMEN IN AMYGDALA-KINDLED RATS. L.E. Kalynchuk*, C.K. Kim, T.E. Kippin, and J.P.J. Pinel. Dept. of Psychology, Univ. of British Columbia, Vancouver, B.C., Canada. V6T 1Z4.

In clinical practice, anticonvulsant therapy is often initiated at a low dose and then incrementally increased until a therapeutically effective dose is reached. On the basis of the drug-effect theory of tolerance, we predicted that this ascending-dose regimen would promote tolerance development in a manner akin to shaping. Accordingly, we recently found that such a regimen facilitates the development of tolerance to pentobarbital's anticonvulsant effect in amygdala-kindled rats. The purpose of this experiment was to assess the effect of an ascending-dose regimen on the development of tolerance to diazepam's anticonvulsant effect. During the 20 trials of the tolerance-development phase, amygdala-kindled rats received either a constant high dose (10 mg/kg), a constant low dose (1 mg/kg), an ascending-dose regimen (starting at 1 mg/kg and increasing by .2 mg/kg increments to 3 mg/kg), or saline. Diazepam was administered by i.p. injection once every 48 hr, and each injection was followed 1 hr later by a convulsive stimulation. On the tolerance test, all rats received diazepam (3 mg/kg) 1 hr before a convulsive stimulation. The ascending-dose rats displayed significantly more tolerance to diazepam's anticonvulsant effect than did the high-dose or the low-dose rats. In addition, both the ascending-dose and the high-dose rats displayed a withdrawal effect after the cessation of diazepam. These results support the drug-effect theory of tolerance and provide further evidence that ascending-dose regimens facilitate the development of tolerance to anticonvulsant drug effects.

595.13

LACK OF TOLERANCE TO MIDAZOLAM'S DISRUPTION OF AN OPERANT DURATION DIFFERENTIATION BY RATS. S. Das, S.C. Fowler, J.A. Stanford and M.C. Wilson*. Depts. of Psychol. and Pharm., Univ. of Miss., University, MS 38677

Thirsty rats were trained to maintain forelimb force on a silent, isometric, force-sensing operandum for a minimum of 3 s to receive a water reward. Separate groups were treated daily with 10 or 30 mg/kg midazolam (orally) either 30 min before or after 15-min sessions for 28 d. Rats dosed pre-session earned significantly fewer rewards than rats dosed post session, and this impaired performance, in the form of increased frequency of premature response terminations, continued throughout the 28 d (i.e., tolerance was not complete). Withdrawal from midazolam produced an improvement in performance in the groups previously dosed pre-session, but these same groups persisted in receiving significantly fewer rewards than the post-session rats after 14 d of withdrawal. The persistence of impaired performance long after drug removal suggests a role for learning processes in the maintenance of this behavioral deficit. Supported by DA05253.

595.15

CHRONIC BRETAZENIL (B) PRODUCES TOLERANCE TO THE RATE-DECREASING EFFECTS OF CHLORDIAZEPOXIDE (C), MIDAZOLAM (M) AND ABECARNIL (A), BUT NOT RU32698 (R). M.E. Bronson*. Auburn Univ. School of Pharmacy, Dept. of Pharmacol Sciences, Auburn Univ., AL 36849-5503.

The effects of C, B, M, A and R on fixed interval 1 minute responding were examined in 18 rats before and during chronic treatment with water (W), C or B. C and B were administered in a final dose of 30 mg/kg/day. Dose effect curves for B were redetermined weekly in the chronic B group and in 1/2 of the chronic W rats, while C was tested weekly in the other rats. All dose effect curves were cumulative and were preceded by a water injection (baseline). B (1-132 mg/kg) had no effect on responding before or during chronic B, whereas tolerance to C (3.2-56 mg/kg) developed by week 7. When all rats were tested with C at 8 wks, there was tolerance to C in all groups except the chronic W group that received weekly B. When B was tested at 9 wks, there was no change in response rates in any group. When rats received M (3.2-56 mg/kg) on wk. 10, there was tolerance in both the chronic B & C groups but not in the chronic W groups. In contrast, when A (0.1-32 mg/kg) was tested at wk. 11 there was tolerance in all groups. Tolerance to R (3.2-56 mg/kg) was also evident on wk. 12 in all groups except the chronic B group. When the dose-effect curve for C was redetermined at wk. 13, there was a further rightward shift in the chronic B group but not in the other groups. Interestingly, when the B dose-effect curve was redetermined on wk. 14, B produced an increase in responding in the chronic C group; and in the weekly B group, the highest dose of B now eliminated responding. Two wks. after the chronic regimen was terminated, redetermination of the C dose-effect curve showed loss of tolerance to the rate-decreasing effects of C in all groups but the chronic C group. Baseline rates in the chronic C group were increased more than 100% and a high (cumulative 56 mg/kg) dose was required to return responding to normal baseline, a finding that may indicate prolonged abstinence withdrawal. Furthermore, B has been shown to precipitate withdrawal in animals treated chronically with full benzodiazepine agonists, and the increased responding produced by B in chronic C rats at 14 wks. may represent a mild form of precipitated withdrawal. Supported by USPFS grant DA06637.

595.12

THE EFFECT OF CONVULSIVE STIMULATIONS ON THE DISSIPATION OF TOLERANCE TO THE ANTICONVULSANT EFFECT OF DIAZEPAM. C.P. McIntyre, L.E. Kalynchuk, T.E. Kippin, and J.P.J. Pinel*. Dept. of Psychology, Univ. of British Columbia, Vancouver, B.C., Canada. V6T 1Z4.

Mana and Pinel (1987) reported that the experience of convulsive activity in the absence of anticonvulsant drugs is a critical factor in the dissipation of tolerance to the anticonvulsant effect of ethanol. The purpose of this experiment was to extend this finding to diazepam and to assess the rate at which tolerance declines in rats that receive convulsive stimulations in a drug-free state. Tolerance was induced in amygdala-kindled rats by exposing them to 25 bidaily tolerance-development trials in which diazepam (2.5 mg/kg) was injected 1 hr prior to a convulsive stimulation. The rats were then divided into nine groups. Three groups received no treatment other than bidaily handling for one trial, three trials, or seven trials. Three other groups received an injection of saline 1 hr before bidaily convulsive stimulations for one trial, three trials, or seven trials. The final three groups received bidaily convulsive stimulations 1 hr before an injection of diazepam for one trial, three trials, or seven trials. Tolerance did not dissipate in rats that received neither diazepam nor convulsive stimulations over the retention interval. In contrast, tolerance dissipated gradually in the rats that received stimulations during the retention interval, even if they received diazepam after each stimulation. These results confirm previous findings that the occurrence of convulsive activity in a drug-free state is a key factor in the dissipation of tolerance to anticonvulsant drug effects, and they provide systematic evidence about the time-course of the dissipation--tolerance declined gradually over the 16-day retention period.

RO 15-4513 INCREASES NITROUS OXIDE WITHDRAWAL SEIZURE FREQUENCY IN MICE. L.K. Vaughn, D.K. Marsee. Marquette Univ., Milwaukee, WI 53233.

We have previously shown that nitrous oxide (N₂O) produces its anxiolytic effect by acting at the benzodiazepine (BZ) receptor (Quock et al., Psychopharmacology 107:310, 1992). It is not known, however, whether BZ receptors are involved in N₂O dependence and withdrawal. We tested the hypothesis that BZ receptors are involved in withdrawal from N₂O by examining whether Ro 15-4513, a partial BZ receptor inverse agonist which has been shown to exacerbate ethanol withdrawal seizures (Lister & Karanian, Alcohol 4:409, 1987), and flumazenil, a BZ antagonist, could increase N₂O-induced withdrawal seizure (WS) frequency. Male, Swiss Webster mice, 10-12 wk old, were exposed to a 75% N₂O: 25% O₂ atmosphere for 90 min during which they were injected i.p. with either vehicle or one of 4 doses of Ro 15-4513 (0.3 - 10 mg/kg) (80 min after placement in N₂O) or vehicle or one of 3 doses of flumazenil (5-20 mg/kg) (55 min after placement in N₂O). 10 min after removal from N₂O, the mice were tested for frequency of WS evoked by handling. WS frequency increased from 45% in vehicle-injected mice (n=20) to 80 - 90% in Ro 15-4513 injected mice (n=10 - 20). Ro 15-4513 or vehicle produced no seizures when injected into mice exposed for 90 min to a control gas mixture of 75% N₂: 25% O₂. Flumazenil did not produce a statistically significant change in seizure frequency from a vehicle-injected rate of 21% (n=14) to 20% at 5 mg/kg (n=15), and 0% at 10 and 20 mg/kg (n=15). Treatment with Ro 15-4513 significantly increased the frequency of WS and suggests that BZ receptors are involved in N₂O-induced withdrawal seizures. (Supported by NIH Grant DE-09998).

INCREASED ANXIETY AND SENSITIVITY TO CONVULSANTS FOLLOWING PRECIPITATED WITHDRAWAL FROM CHRONIC BENZODIAZEPINE TREATMENT IN MICE.

G.H. Jones*, D.N. Stephens, H. Schneider and B.J. Cole, Department of Neuropsychopharmacology, Schering AG, Müllerstrasse 170-178, D-1000 Berlin 65, Germany.

Chronic treatment with standard benzodiazepine (BZ) anxiolytics can lead to serious withdrawal symptoms following cessation of treatment. As this withdrawal can limit the clinical use of BZ's it is important to develop procedures in animals to predict the relative severity of these symptoms.

We compared the behavioural syndrome following precipitated withdrawal from chronic treatment with diazepam (DZ) or alprazolam (ALPR). Groups of mice (n=10 per group) were injected i.p. once a day for 10 days with either vehicle, DZ or ALPR. On day 11, 24 hours after the last drug treatment, all subjects received an i.p. injection of 25 mg/kg flumazenil (Ro 15-1788) to precipitate withdrawal. 5 min later the mice were tested in the mouse elevated plus-maze. Each test lasted 5 min. Immediately afterwards the mice were tested for their susceptibility to pentylenetetrazole (PTZ)-induced seizures. Withdrawal from equivalent doses of DZ and ALPR (based on tests of anxiolytic activity), significantly reduced the time spent in the open arms by approx. 30% (i.e. increased anxiety), but only DZ withdrawal increased the susceptibility to PTZ-induced seizures (by 37%).

These results show that it is possible to measure apparent increases in anxiety during withdrawal from BZ's using the mouse plus-maze test and that the level of anxiety is a more sensitive measure of withdrawal from BZ's than the proconvulsant effects. Furthermore, the results from these experiments suggest that different BZ's may produce different withdrawal syndromes.

INCREASED SEVERITY OF WITHDRAWAL SEIZURES IN MICE FOLLOWING REPEATED ETHANOL WITHDRAWAL EPISODES. H.C. Becker* and R.L. Hale. VA Medical Center and Medical University of South Carolina, Charleston, SC 29401

We have previously demonstrated that the severity of withdrawal seizures is exacerbated in adult C3H mice that have experienced multiple cycles of ethanol (EtOH) withdrawal in comparison to mice that have been withdrawn from EtOH a single time, even when total EtOH exposure is equated across groups. This study was designed to examine whether the differential withdrawal response is related to different rates of EtOH elimination following withdrawal from chronic EtOH exposure in inhalation chambers. One multiple withdrawal group (MW₁₋₄) was tested after each of four cycles of 16 hr EtOH vapor separated by 8 hr periods of abstinence; another multiple withdrawal group (MW₄) was tested only during the fourth withdrawal cycle; a single withdrawal group (SW) was tested during each cycle, but only received EtOH on the fourth cycle; and a control group (C) was repeatedly tested, but never received EtOH. Blood EtOH levels following the last 16 hr bout of intoxication were 116-147 mg/dl for all EtOH-exposed groups. The rate of EtOH elimination after the final cycle did not differ in MW and SW groups. The withdrawal response intensified with each cycle in the MW₁₋₄ group and mean areas under the 7 hr curve for handling-induced convulsions after the fourth cycle for MW₁₋₄, MW₄, SW, and C groups were 5±9, 8±1.3, 2±2, 0±0, respectively. These data support the "kindling" hypothesis of EtOH withdrawal and indicate that the potentiated withdrawal response after repeated episodes of withdrawal is not due to an alteration in the rate of EtOH elimination. Supported by VA Medical Research Service and NIAAA.

PRECIPITATED ABSTINENCE (PA) FOLLOWING INTRAVENOUS (IV) ADMINISTRATION OF FLUMAZENIL (FL) TO DIAZEPAM (DZ) DEPENDENT RATS. E.P. Wala, W.R. Martin* and J.W. Sloan. Dept. of Anesthesiology, Coll. of Med., Univ. of Ky., Lexington, KY 40536.

Rats implanted with silastic capsules containing DZ (1 x 90 mg/cap/week) had plasma levels of DZ and metabolites equal to about 6 ug/ml. After 5 weeks of stabilization on DZ rats were administered FL (dissolved in DMSO) or DMSO (bolus IV into tail vein) weekly in doses 10, 20 and 40 mg/kg (latin square) and observed for signs of PA for 10 min prior and 40 minutes after FL. Tonic-clonic (T-C) seizures, whose incidence was dose-related, emerged rapidly. Precipitated Abstinence Scores (PAS) were significantly greater at 5 min after 40 and 20 mg/kg of FL than after DMSO alone. Twitches and jerks (TJ), writhing, arched back, tachypnea, ear-twitching and head-bobbing were observed. Behavioral activation was also dose-related. Other rats were implanted with 2 guide cannulae, cortical (Co) and 2 hippocampal (H) electrodes and stabilized for 2 weeks on DZ (3 x 180 mg/cap/week). Total plasma levels of DZ and metabolites were about 17 ug/ml. Rats were administered IV FL (40 mg/kg) and DMSO control after completing 4 weeks of microinjections of FL or DMSO into the brain. ECoG and signs comprising the PAS were recorded simultaneously. Clonic (C) and T-C seizures and TJ were observed early and late after FL. ECoG indicated H convulsive activity. These data indicate that in rats IV FL evokes signs of abstinence which are similar to signs seen after focal H microinjections of FL as well as other signs. Supported by NIDA grant DA02195.

DRUGS OF ABUSE: OPIOIDS AND OTHERS—MISCELLANEOUS

596.1

EFFECTS OF SIGMA LIGANDS ON PHENCYCLIDINE-INDUCED EEG AND BEHAVIOR IN RATS. D.F. Sisson*, L.R. King, S. Teferi, and J.E. Moreton, Dept. Pharmacol. & Toxicol., Univ. MD Sch. of Pharmacy, Baltimore, MD 21201.

Phencyclidine (PCP) binds with high affinity to two distinct receptor classes. One class is within the ion channel of the NMDA receptor, where PCP acts as a non-competitive antagonist by blocking the ion channel. PCP also binds to sigma receptors. The physiological significance of sigma receptors is not well defined.

This study examined the interactions between PCP at a dose of 1.25 mg/kg⁻¹ iv and several sigma receptor ligands delivered iv in 5 µl distilled water. The sigma ligands and doses were as follows: 20 µg DTG, 2 µg DuP-734, 8 µg ifenprodil, 20 µg (+)-pentazocine, and 4 µg (+)-3-PPP. In these experiments, an initial 5 µl, iv injection of distilled water was administered, followed in 45 min by an iv injection of a sigma ligand, followed in 5 min by an iv injection of PCP. EEG was recorded continuously during this period. Behavior was scored on a five point rating scale for locomotion, ataxia and stereotypy 15 min after the injection of distilled water, 4 min after the injection of a sigma ligand, 1 min after the injection of PCP and every 5 min thereafter for 40 min. Power spectra of 1 min epochs of EEG coincident with the behavioral scorings were determined by FFT.

At 1 min post-PCP injection, DTG enhanced PCP-induced locomotion and stereotypies, pentazocine enhanced stereotypy, ifenprodil decreased locomotion, ataxia and stereotypy, and DuP-734 and 3-PPP reduced locomotion and stereotypy. DTG, and pentazocine enhanced the PCP-induced increase in EEG power in the delta, theta and beta bands, ifenprodil increased delta-band power only, DuP-734 decreased high frequency beta, and 3-PPP decreased low frequency beta power.

DTG and pentazocine increased, while DuP-734 and 3-PPP reduced, a subset of PCP-induced EEG and behavioral effects. The effects of ifenprodil were best explained as a general sedative effect. This work was supported by NIDA Grant DA03173. DuP-734 was a gift from The Du Pont Merck Pharmaceutical Company.

NMDA-LIKE ACTIVITY MEDIATES NALOXONE-INDUCED CONTRACTIONS OF ISOLATED GUINEA PIG ILEUM (GPI) AFTER INCUBATION WITH MORPHINE. R.Yu. Yukhananov* and A.A. Larson. Department of Veterinary Pathobiology, University of Minnesota, St. Paul, MN 55108 U.S.A.

The ability of competitive and noncompetitive antagonists of NMDA to inhibit opioid withdrawal supports a role of NMDA receptors in opioid dependence. In support of this, acute administration of morphine increases the behavioral response to intrathecally injected NMDA plus naloxone in mice. The GPI contains a glutamate receptor of the NMDA-type. To further characterize the role of NMDA receptors in acute opioid dependence, we examined naloxone-induced withdrawal contractions of the isolated GPI following incubation with morphine. Glutamate induced contractions with an ED₅₀ of 24.6 µM. Morphine (5-500 nM) dose-dependently inhibited contractions of the GPI induced by glutamate (10-500 µM) with a Ke of 10.2 nM. Naloxone prevented the inhibitory action of morphine on glutamate-induced contractions with a Ke of 19.3 nM. Naloxone also antagonized the inhibitory effect of morphine on electrically-induced contractions of the GPI through receptors with similar affinity (Ke=17.9 nM). Following continuous exposure to morphine (10-50 min), naloxone (0.1-4 µM) induced contractions of the GPI. Competitive (AP5, CPP) and noncompetitive (MK-801) antagonists of NMDA reduced naloxone-induced contractions at doses which also inhibit the contractile effect of glutamate. Incubation with morphine also decreased the ED₅₀ for glutamate by 3.2 fold. The present data show that activation of NMDA receptors is required for naloxone-induced contractions of the GPI following morphine. (Supported by NIDA 04090, 04190 and 00124)

596.2

COMPARISON OF THE EFFECTS OF COMPOUNDS WITH SELECTIVE ACTIVITY AT PCP/NMDA AND SIGMA RECEPTORS AND DOPAMINE REUPTAKE SITES ON THE HYPOTHALAMO-PITUITARY-ADRENAL AXIS IN THE RAT. R. N. Pechnick^{*1}, R. E. Poland² and B. De Costa³. ¹Department of Pharmacology, LSU Medical Center, New Orleans, LA 70119, ²Division of Biological Psychiatry, Harbor-UCLA Medical Center, Torrance, CA 90502, and ³Laboratory of Medicinal Chemistry, NIDDK, Bethesda, MD 20892.

Phencyclidine (PCP) binds to PCP/NMDA and sigma receptors and also inhibits the reuptake of monoamines. Aside from its behavioral effects, PCP stimulates the pituitary-adrenal axis in the rat, causing the release of ACTH and corticosterone. However, the mechanism(s) by which PCP produces these effects is not known. The s.c. administration of the PCP analog N-[1-(2-thienyl)cyclohexyl]piperidine (TCP), which has a high degree of selectivity for the PCP/NMDA binding site, increased plasma levels ACTH and corticosterone. The acute administration of 1,3-di-O-tolylguanidine (DTG), a highly selective sigma receptor ligand, also increased plasma levels ACTH and corticosterone. In contrast, N-[1-(2-benzo(b)thiophenyl)cyclohexyl]piperidine (BTCP), a PCP analog that is a potent dopamine reuptake inhibitor but has low affinity for the PCP/NMDA binding site, did not affect plasma levels of ACTH and corticosterone. These results indicate that whereas interactions with either PCP/NMDA or sigma binding sites might stimulate the hypothalamo-pituitary-adrenal axis, inhibition of dopamine reuptake probably is not involved in the activation of this axis by PCP. (Supported by NIDA grant DA-04113)

596.4

PCP-INDUCED DA RELEASE IS POSITIVELY CORRELATED WITH [³H]TCP, BUT NOT [³H]GBR 12935 BINDING, IN STRIATUM FROM TWO INBRED MICE STRAINS. A.L. Jewell*, J.M. Carnev, and L.P. Dwoskin. Colleges of Pharmacy and Medicine, University of Kentucky, Lexington, KY 40536.

Previous studies from our laboratory have demonstrated a positive correlation of phencyclidine (PCP)-induced locomotor stimulation with endogenous dopamine (DA) release from striatal and frontal cortex, but not olfactory tubercle, slices from DBA/2J and C57BL/6ByJ inbred strains. PCP produced greater effects in the DBA/2J than C57BL/6ByJ strain in both assays. To determine if this strain-related, differential responsiveness to PCP is correlated with differences at the DA transporter or PCP receptor, the current studies determined binding parameters for [³H]GBR 12935 and [³H]TCP in striatum, frontal cortex and olfactory tubercle homogenates from these inbred strains. No strain difference for [³H]GBR 12935 affinity (K_d) or number of binding sites (B_{max}) in striatum or olfactory tubercle was observed. However, the striatum exhibited a 2.6-fold higher B_{max} compared to olfactory tubercle, and binding in frontal cortex was not detectable. [³H]TCP binding in striatum revealed a significantly higher B_{max} (2691 ± 92 and 1916 ± 145 fmol/mg prot) for DBA/2J than C57BL/6ByJ strain, respectively. Olfactory tubercle exhibited a lower B_{max} (2351 ± 135 and 3094 ± 527 fmol/mg prot) for the DBA/2J than C57BL/6ByJ, respectively. No differences were observed in frontal cortex. Therefore, the differential, strain-related responsiveness to PCP in the DA release assay is positively correlated with [³H]TCP binding in the striatum, but not in frontal cortex and olfactory tubercle. THE ROLE OF SEROTONIN IN THE DISCRIMINATIVE STIMULUS EFFECTS OF MU- AND KAPPA-OPIOIDS. Kelly R. Powell*, Mitchell J. Picker and Linda A. Dykstra, Department of Psychology, University of North Carolina, Chapel Hill, NC 27599.

The effects the 5HT-1A agonists, 8-OH-DPAT, buspirone and NAN-190, and the 5HT-2 antagonist, ketanserin, were evaluated in rats trained to discriminate the mu-opioid agonist, morphine, or the kappa-opioid agonist, U50,488, from saline. In U50,488-trained rats, U50,488 dose-dependently increased drug-lever responding. When administered alone, 8-OH-DPAT, buspirone and NAN-190 partially substituted for the U50,488 discriminative stimulus whereas ketanserin produced predominantly saline-lever responding. The opioid antagonist, naltrexone, failed to antagonize the effects of 8-OH-DPAT, buspirone and NAN-190 suggesting that these effects are not opioid-mediated. When administered in combination with U50,488, 8-OH-DPAT and buspirone, but not ketanserin, attenuated the discriminative stimulus effects of the training dose of U50,488. In contrast, 8-OH-DPAT, buspirone and ketanserin all potentiated the discriminative stimulus effects of lower doses of U50,488. In morphine-trained rats, morphine dose-dependently increased drug-lever responding. 8-OH-DPAT, buspirone and NAN-190 all produced a moderate amount of morphine-appropriate responding however, these effects were not dose-dependent nor were they consistent across animals. Ketanserin produced predominantly saline lever responding. When administered in combination with morphine, 8-OH-DPAT attenuated the discriminative stimulus effects of the morphine training dose and potentiated the effects of lower doses of morphine. Buspirone and ketanserin failed to alter the morphine dose-effect curve. These results suggest that 5HT is involved in the discriminative stimulus effects of U50,488, but may not be involved in morphine's discriminative stimulus effects. NEUROANATOMICAL ANALYSIS OF HIPPOCAMPUS FROM MARIJUANA-EXPOSED RHESUS MONKEYS. M. Halks-Miller*, M.-Y. Yao, J. Ariomand, C. Rebert & G. Pryor, Dept. of Neuroscience, SRI International, Menlo Park, CA 94025.

Investigators have reported neuroanatomical changes in the brains of both rats and monkeys after exposure either to marijuana (MJ) smoke or to THC. The present studies were designed to use unbiased stereologic methods to assess putative structural changes in rhesus monkey brain after long-term exposure to MJ smoke. Our previous studies of the cerebellum from these subjects (Soc. Neurosci. Abst. 1992, 18: 1601) did not reveal any pathological or morphometric alterations after exposure to MJ. This study focuses on the hippocampus, a brain area that is rich in cannabinoid receptors and has been reported to show alterations in synaptic and neuronal morphology in monkeys and rats, respectively, after exposure to MJ.

Fifteen male rhesus monkeys were implanted with an array of intracerebral glass electrodes and divided into three groups for exposure to either placebo smoke (P), moderate MJ smoke (M), or high MJ smoke (H) for one year. Three untreated control monkeys were also included for study. All animals were sacrificed by per cardiac perfusion with an aldehyde fixative approximately six months after the last exposure to MJ. A selected level of the hippocampus was removed and embedded for light and electron microscopy (EM). The hippocampus was measured to estimate the volume of the dentate gyrus, CA3 & CA1. The number of neurons in different hippocampal layers and their volumes were also measured. The number of synapses in each layer was estimated from electron micrographs using the unbiased disector method (Gundersen et al. 1988, APMS 96: 881) on pairs of serial sections. Synaptic number was then normalized to number of neurons in the relevant cell layers. The three test and the untreated control groups were compared by analysis-of-variance (ANOVA) methods for possible marijuana-induced changes in the neuroanatomical parameters described above. These tests failed to reveal any differences among the marijuana-treated and control groups. These studies do not support the premise that chronic exposure to marijuana smoke leads to permanent structural changes in primate hippocampus.

596.9

DELTA-9-Tetrahydrocannabinol SUPPRESSION OF LUTEINIZING HORMONE SECRETION IN THE MALE RAT: EFFECTS OF N-METHYL-D,L-ASPARTATE. L.L. Murphy* and J. Ogan, Department of Physiology, Southern Illinois University School of Medicine, Carbondale, IL 62901.

Marijuana and its primary psychoactive cannabinoid constituent, delta-9-tetrahydrocannabinol (THC), have pronounced inhibitory effects on reproductive function in humans and experimental animals, presumably through the inhibition of pituitary gonadotropin secretion. There is abundant evidence that THC exposure can inhibit the secretion of luteinizing hormone (LH) in intact and gonadectomized animals. Activation of the excitatory amino acid receptors with N-methyl-D,L-aspartate (NMA) has been shown to stimulate LH secretion in a number of animal models. In the present study, we examined the effects of NMA and MK-801, a noncompetitive NMA receptor antagonist, on pulsatile LH secretion and determined the effects of NMA on LH release in animals pretreated with an inhibitory dose of THC. Adult male rats (250-300g) were orchidectomized and 2 weeks later were implanted with atrial cannula for 10 min interval blood samples and drug administration. A stimulatory dose of NMA (20 mg/kg b.w.) was administered 10 min after pretreatment with THC (0.5 mg/kg b.w.), MK-801 (0.1 mg/kg b.w.) or vehicle. Results indicated that within 20 min both MK-801 and THC significantly suppressed pulsatile LH secretion in the castrate male rat for 40 and 60 min, respectively. Moreover, NMA effectively stimulated LH release 10 and 20 min after its administration. Whereas NMA reversed the suppression in LH induced by MK-801, THC pretreatment prevented the ability of NMA to stimulate LH release. Thus, THC appears to block NMA-induced LH secretion in the castrated male rat. Whether THC elicits this action through a direct effect at NMA receptors or alters neurotransmitter or neuropeptides which may mediate the action of NMA on LH-releasing hormone neurosecretory neurons remains to be determined. (Supported by NIDA grant DA 05452).

596.6

ACUTE ADMINISTRATION OF THE 5-HT₂/5-HT_{1C} AGONIST 2,5-DIMETHOXY-4-IODOAMPHETAMINE (DOI) TO SOCIALLY HOUSED STUMPTAIL MACAQUES PRODUCES BEHAVIORAL EFFECTS SIMILAR TO THOSE OBSERVED WITH HALLUCINOGENS. D.C. Jolly*, L.A. Tonkovich, J.E. Young, J.M. Davis, and R.F. Schlemmer, Jr, Department of Pharmacodynamics, University of Illinois at Chicago, and Research Department, Illinois State Psychiatric Institute, Chicago, IL 60612.

Effects on social and solitary behavior of stumptail macaques (*Macaca arctoides*) may indicate therapeutic or toxic effects of psychotropic drug candidates. In monkeys, hallucinogens such as *g*-lysergic acid diethylamide (LSD) and 5-methoxydimethyltryptamine (5-MeODMT), reduce social interaction and induce both body shakes and myoclonic spasms of the limbs (limb jerks). The involvement of serotonin (5-HT) receptor subtypes in hallucinogen induced behavioral changes was investigated in monkeys. The behavioral effects of DOI, a 5-HT₂/5-HT_{1C} agonist and hallucinogen were assessed in a monkey social colony consisting of 4 adult females and one adult male. During daily 60 minute sessions, a blind observer recorded social and solitary behaviors of socially housed monkeys. Observations made in the 9 sessions prior to drug administration served as a baseline. The 4 females each received 5 acute doses of DOI (0.1 to 1.0 mg/kg), in a crossover design. DOI was given once per week, 15 minutes before each observation session. DOI reduced social interaction, in that treated monkeys exhibited less social grooming. The data suggested that DOI treated monkeys showed increased spatial separation from other monkeys, and increased visual scanning (checking). Treated monkeys showed a dose-dependent reduction in self grooming. Also DOI induced limb jerks, and increased body shakes. These behavioral findings support the contention that stimulation of 5-HT₂/5-HT_{1C} receptors is involved in the mediation of hallucinogen induced changes in social and solitary behavior of monkeys.

FUNCTIONAL EXPRESSION OF A CANNABINOID RECEPTOR USING THE BACULOVIRUS SYSTEM. D.A. Dove Pettit, V. Showalter, M.E. Abood*, and G.A. Cabral, Dept. of Microbiology/Immunology and Pharmacology/Toxicology, Virginia Commonwealth University, Richmond, VA 23298.

The baculovirus expression system was employed to express a rat cannabinoid receptor that was identified in a cerebral cortex cDNA library (Matsuda, Nature 346:561). The coding sequence for the receptor was inserted into a baculovirus transfer vector. Co-transfection of *Spodoptera frugiperda* (Sf9) cells with the recombinant transfer vector and linearized wild-type baculovirus DNA (AcNPV) allowed for the production of a cannabinoid receptor recombinant virus (SKR6-AcNPV). SKR6-AcNPV was plaque purified (3X) and was used to infect Sf9 cells. Northern analysis of SKR6-AcNPV-infected Sf9 cells revealed novel hyperproduction of a 3.7 kb transcript. To assess novel viral protein production, SKR6-AcNPV-infected Sf9 cells (MOI 20) were metabolically labeled with ³⁵S-Met. Limited expression of all viral proteins was observed. Transmission electron microscopy of infected Sf9 cells (MOI 20) revealed the presence of large vacuoles in the cytoplasm, loss of membrane integrity, and granular peri-nuclear membrane deposition, suggestive of glycoprotein accumulation. Collectively, these data suggest that high multiplicity infection of Sf9 cells with SKR6-AcNPV alters cellular integrity and limits recombinant viral protein expression. However, lower multiplicity infection of Sf9 cells (MOI of 5) revealed novel recombinant viral protein expression. Furthermore, radioligand binding studies using ³H CP55,940, a potent cannabinoid analog, revealed greater than 50% specific binding in crude P2 membrane preparations from SKR6-AcNPV-infected Sf9 cells (MOI 5). Uninfected Sf9 cells did not specifically bind CP55,940. Scatchard analysis of the saturation plot obtained determined the B_{max} to be equivalent to that observed in P2 preparations from rat brain. These data support the functional expression of the cannabinoid receptor in the baculovirus system. (Supported by DA-05832, DA-05274, F31-DA-05518)

596.10

ENDOGENOUS CANNABINOID ACTIVITY IS RELEASED FROM RAT BRAIN SLICES BY A DEPOLARIZING STIMULUS. D.M. Evans*, J.T. Lake, and A.C. Howlett, Dept. Pharm./Phys. Sci., St. Louis Univ. Sch. of Med., 1402, S. Grand Blvd., St. Louis, MO 63104

As previously reported by this laboratory, an endogenous factor capable of inhibiting the specific binding of the radiolabelled cannabinoid agonist [³H]CP-55940 to its receptor can be released from nerve terminals in response to an influx of Ca²⁺ induced by an ionophore (Evans et al. (1992), *J. Neurochem.* 58; 780-782). In the present report, we provide evidence that the endogenous ligand for the cannabinoid receptor can be released in response to a depolarizing stimulus (75mM K⁺) in the presence of extracellular Ca²⁺. K⁺-evoked release was not observed in the absence of extracellular Ca²⁺, and was reduced by the specific calcium channel blockers verapamil and ω-conotoxin. Efflux of cannabinoid receptor binding activity was maximal at short incubation times and was potentiated by inclusion of the protease inhibitors, captopril and thiorphan. Fractions from a semi-purified sample of the effluent inhibited adenylyl cyclase activity. These results suggest that the endogenous cannabinoid may be a peptide.

EFFECTS OF PROPRANOLOL PRETREATMENT ON DELTA-9-TETRAHYDROCANNABINOL-INDUCED SUPPRESSION OF LUTEINIZING HORMONE IN OVARIETOMIZED RATS. B.A. Adrian*, and L.L. Murphy. Department of Physiology, School of Medicine., Southern Illinois University, Carbondale, IL 62901.

Delta-9-tetrahydrocannabinol (THC), the primary psychoactive constituent of marijuana, potently, but transiently, inhibits luteinizing hormone (LH) secretion when administered to ovariectomized (OVX) rats. The current study was designed to determine if this effect of THC is mediated through inhibitory noradrenergic mechanisms by attempting to block the THC-induced inhibition of LH with the beta-adrenergic receptor antagonist propranolol. Four week OVX rats were pretreated with propranolol (0.5, 3 or 6 mg/kg in saline, iv) 10 min. before the start of the experiment. Ten minute serial blood samples were collected for 1 hour before animals received THC (0.5 mg/kg, iv, or vehicle (10% propylene glycol in 1% Tween 80-saline) and continued for 2 hours after treatment. Propranolol treatment alone did not have an effect on basal LH levels. The administration of THC significantly depressed plasma LH when compared to pre-THC treatment levels. Pretreatment with the 0.5 and 6 mg/kg doses of propranolol did not alter the ability of THC to suppress LH secretion. However, pretreatment with 3 mg/kg propranolol effectively prevented the suppression of LH by THC. Thus, the actions of THC on LH secretion can be prevented by blocking beta-adrenoreceptors with propranolol. However, high doses may produce nonspecific interactions that mask this effect. (Supported by NIDA DA 05452)

ANABOLIC STEROIDS AND BRAIN REWARD.

A.S. Clark*, R.C. Lindenfeld and C.H. Gibbons. Dept. of Psychology, Dartmouth College, Hanover, NH 03755.

Anabolic steroids are synthetic androgen-like compounds which are taken in high doses by athletes with the intention of enhancing muscular appearance, strength and/or athletic performance. Recent research indicates that steroid dependence develops with chronic anabolic steroid use in some individuals. This evidence led us to explore the extent to which anabolic steroids influence brain stimulation reward using the rate-frequency paradigm of intracranial self-stimulation. Adult male Long-Evans rats were implanted with electrodes in the medial forebrain bundle and tested for self-stimulation until stable rate-frequency curves were established. The anabolic steroid methandrostenolone (Dianabol) or oil vehicle were administered over a two week period, and rate-frequency responding monitored on a daily basis. No marked changes in the rewarding efficacy of the brain stimulation or alterations in motor/performance factors were observed in animals after short-term treatment with anabolic steroids. In a second experiment, animals which received a single injection of amphetamine (0.5 mg/kg, i.p.), displayed a curve-shift to the left of approximately 0.2 log units. Rate-frequency responding to amphetamine will be determined in the same rats following chronic treatment with anabolic steroids. These studies may reveal the neural substrates underlying anabolic steroid abuse.

596.15

ANABOLIC STEROIDS: ENHANCEMENT OF THE BEHAVIORAL ACTIONS OF TETRAHYDROCANNABINOL IN THE MOUSE RING-IMMOBILITY MEASURE. D.R. Compton*. Department of Pharmacology and Toxicology, Medical College of Virginia-Virginia Commonwealth University, Richmond, VA 23298.

Anecdotal evidence suggests adverse psychological and physiological effects of high dose, chronic anabolic steroid abuse. Polydrug abuse is also common, so possible pharmacological interactions between anabolic steroids and Δ^9 -tetrahydrocannabinol (THC; the active component of marijuana) are potentially of great importance.

Male ICR mice were pretreated with testosterone propionate (i.p.) or vehicle (sesame oil) one hour before administration of various doses of THC (i.v.). Catalepsy was assessed 1.5 hr following THC treatment using the ring-immobility procedure. Preliminary data indicated the effect of THC was increased from 27% to 44% by testosterone pretreatment, and immobility maintained (38%) up to 3 hr postinjection, a time at which the normal effects of THC have diminished to vehicle control levels. Dose-response analysis suggests the shift in potency of THC is a parallel shift. Anabolic steroids were evaluated in ligand binding assays, and did not bind to either the THC receptor or to the dopamine transporter, both implicated in the production of catalepsy.

In conclusion, pretreatment with anabolic steroids increases the potency and time course of action of THC. The mechanism of action of this phenomenon is unknown. However, it may be possible to use this indirect measure of steroid activity as a marker for further evaluation of the adverse effects of chronic high dose anabolic steroid abuse. ANDROGENIC-ANABOLIC STEROID REGULATION OF TACHYKININ- AND ENKEPHALIN-mRNA EXPRESSION IN THE RAT STRIATUM. C.S. Menard*, L.R. Lucas, C.Y. Lee, G.P. Dohanich, and R.E. Harlan. Dept. of Anatomy, Neuroscience Training Program, and Dept. of Psychology, Tulane Univ. Sch of Med., New Orleans, LA 70112.

Both motor abnormalities and addiction have been reported by athletes who abuse high levels of androgenic-anabolic steroids (AAS). In this study, expression of substance P/neurokinin A (SP/NKA) mRNA and preproenkephalin (PPE) mRNA was detected by *in situ* hybridization on coronal brain sections (20 μ m) obtained from male rats treated daily for 2 weeks with either sesame oil vehicle or high levels of AAS (a cocktail of 2 mg/kg testosterone cypionate, 2 mg/kg nandrolone decanoate, and 1 mg/kg boldenone undecylenate). AAS treatment resulted in increased expression of PPE mRNA in the dorsolateral and ventromedial aspects of the caudal caudate/putamen (CPU). In contrast, AAS resulted in decreased expression of SP/NKA mRNA in the caudal CPU. These results are consistent with previous reports of dopamine-induced PPE up-regulation and SP down-regulation in this region. Interestingly, moderate increases in androgen receptor immunoreactivity in the caudal CPU also were found in animals similarly treated with AAS. Collectively, these data may indicate one brain region where AAS modify central nervous system functioning. Since the effects of AAS treatment on PPE and SP/NKA mRNA expression, as well as androgen receptor immunoreactivity, were variable across other regions of the striatum, AAS-induced modifications of these peptide systems may be complex and region-specific. Supported by DA06194 (REH) and DA 05521-01 (CSM).

ANABOLIC STEROID ADMINISTRATION INCREASES VULNERABILITY TO AN ANIMAL MODEL OF ANOREXIA NERVOSA. P.E. Aravich*, J.J. Choi & T.S. Bleg. Eastern Virginia Medical School, Norfolk, VA 23501; Veterans Affairs Med. Ctr., Hampton, VA 23667; Governor's School for Science & Technology, Hampton, VA 23666.

Anabolic steroid abuse and anorexia nervosa (AN) are significant health concerns for competitive female athletes. Recent data from our laboratory (e.g., Bleg et al., this meeting) indicate that relative adiposity is inversely related to vulnerability to a rat model of AN. Since anabolic steroids increase lean body mass and decrease relative adiposity, it was predicted that they would increase susceptibility to the weight-loss syndrome. The syndrome incorporates two features of AN: restricted feeding (1.5 h/day food access) and exercise (22.5 h/day running wheel access). Three groups of female rats were injected daily with 0, 1 or 10 mg/kg (sc) of nandrolone phenylpropionate (NPP). Drug administration occurred before and during the weight-loss protocol. It was found that there was a dose-related increase in susceptibility to the syndrome, defined as fewer days to lose 25% of original body weight. This effect was not related to changes in terminal food intake or wheel running. As expected with NPP, relative kidney weight increased. Finally, NPP mitigated the syndrome's increase in relative adrenal weight but exacerbated its decreases in relative spleen and thymus weights. It was concluded that NPP increases susceptibility to the weight-loss syndrome and promotes immune organ atrophy. The possibility that anabolic steroid abuse may be a risk factor for AN in competitive female athletes and that it may worsen immunological function in the disorder should now be determined.

NITRIC OXIDE MODULATES OPIOID TOLERANCE IN LC NEURONAL ACTIVITY IN VITRO. D.A. Highfield*, S.J. Grant, R.S. Revay. Depts. Psychology, Biology and Neuroscience Prog., Univ. Delaware, Newark, DE, 19716.

Recent studies have shown that inhibition of nitric oxide synthesis attenuates analgesic tolerance and diminishes precipitated withdrawal in chronic morphine treated animals. Noradrenergic neurons in the locus coeruleus (LC) exhibit cellular correlates for both opioid tolerance and withdrawal. We therefore examined the effects of blocking nitric oxide synthesis with N^o-nitro-L-arginine (N-Arg) during chronic morphine treatment on the activity of LC neurons.

Rats were implanted with morphine pellets (75mg Morphine base, NIDA) for 7 days. Subjects were also given injections of 10 mg/kg N-Arg twice daily i.p. Sham pellets and saline injections were used as controls. Single unit extracellular recordings were obtained from LC neurons in brain slices. A dose response curve and ED50 for the selective μ agonist DAMGO was obtained for each cell. Changes in the ED50 across treatment groups were used to determine the interaction of chronic morphine and inhibition of nitric oxide synthesis.

As expected, chronic morphine induced substantial tolerance to DAMGO challenge, indicated by an increase in the ED50. In animals given N-Arg along with morphine, the ED50 of DAMGO challenge was intermediate between the chronic morphine alone group and the sham treated animals. These results support a modulatory role for nitric oxide in the development of tolerance to chronic opiate treatment in LC neurons. Supported by the State of Delaware, and ICI Pharma.

COMPARATIVE EFFECTS OF MK-801 AND N^G-MONOMETHYL-L-ARGININE (NMMA) ON MORPHINE ABSTINENCE SYNDROME. George A. Matwyshyn, Sanjay N. Thorat, Marc Barjavel, K.P. Gudchithlu* and Hemendra N. Bhargava, Dept. Pharmacodyn., Univ. Ill., Chicago, IL 60612.

NMDA receptor appear to be involved in opiate tolerance process possibly by modifying the formation of nitric oxide (NO). The effects of NMDA receptor antagonist, MK-801 and the inhibitor of NO synthase, NMMA on morphine abstinence syndrome have been compared in male Swiss - Webster mice rendered dependent on morphine by s.c. implantation of a morphine pellet containing 75 mg of morphine base for 3 days. Six hours after pellet removal, mice were injected i.p. with vehicle or MK-801 (0.03, 0.1 and 0.3 mg/kg). Thirty min later the animals were injected with NTX (50 µg/kg, s.c.). MK-801 had no effect on the stereotyped jumping behavior, body weight loss, body temperature or the formation of fecal boli. NMMA (2 and 4 mg/kg ip) or its vehicle injected 15 min prior to NTX (50 µg/kg, s.c.) blocked the stereotyped jumping response but did not affect the other withdrawal signs. It is concluded that inhibition of NO synthase, inhibits hyperactivity responses observed during withdrawal but the NMDA receptor antagonist has no effect on the morphine abstinence syndrome (Supported by NIDA grants DA-02598 and RSDA K02-0130).

EFFECT OF TOLUENE ON EVOKED RESPONSES IN THE HIPPOCAMPAL SLICE PREPARATION. N. Shinsky, B. M. Potter* and G. T. Pryor, Neuroscience Department, SRI International, Menlo Park, CA 94025.

Toluene (T), an ubiquitous industrial solvent, is subject to human abuse because of its euphoric effect. It has pharmacologic properties resembling those of other abused substances such as barbiturates and alcohol. Although studied extensively for its toxicologic potential, the mechanisms underlying its acute CNS effects have not received much attention. To begin to identify these mechanisms, we used the hippocampal slice preparation to examine T's effect on neurotransmission.

Population excitatory postsynaptic potentials (EPSPs) and population spikes (PSs) evoked by stimulation (0.1 Hz) of Schaffer collaterals in the *stratum radiatum* were recorded from pyramidal cells of area CA1 of transverse hippocampal slices from the right hemisphere of adult male Swiss-Webster mice (28-32 g). The corresponding left hippocampus was analyzed for norepinephrine (NE) content using HPLC-EC. Administration of 1 mg/kg of T (i.p.) 10 min before sacrifice did not affect the *in vitro* hippocampal response compared with control mice. Also, no significant difference in hippocampal NE level was observed. Applied *in vitro* at concentrations of 50, 150, 350 µM, T increased the amplitude and slope of the EPSP in a dose-dependent manner. When intensity of the stimulation was sufficient to evoke PS, T usually increased the amplitude of the descending limb and decreased the amplitude of the ascending limb of the PS. These results suggest that T causes a disturbance in K⁺ currents, presumably in I_A and I_C. It is known that several neurotransmitter receptors such as NE, DA, adenosine, and GABA, by being coupled to the same second messenger system or G protein, have an effect on two types of K⁺ channels. Therefore, our results suggest that T may affect K⁺ conductance by modulating neurotransmitter release, or by interacting specifically with receptors linked to the ion channel, second messenger systems, or with the ion channel itself.

596.18

EFFECT OF N^G-MONOMETHYL-L-ARGININE ON TOLERANCE TO U-50,488H IN THE RAT. Hemendra N. Bhargava* and George A. Matwyshyn, Dept. Pharmacodyn., Univ. Ill, Chicago, IL 60612.

The effect of N^G-monomethyl-L-arginine (L-NMMA) (2-8 mg/kg, i.p.) on the development of tolerance to U-50,488H, a k-opiate agonist, was determined in the rat. Male Sprague - Dawley rats were made tolerant to U-50,488H by twice daily injections of the drug (25 mg/kg, ip) for 4 days. This treatment resulted in the development of tolerance to the analgesic and hypothermic effects of U-50,488H as evidenced by the decreased responses (AUC_{0-300min}) to a 25 mg/kg dose of U-50,488H in chronically drug injected rats. L-NMMA (4 and 8 mg/kg, ip) injected 10 min prior to each injection of U-50,488H inhibited the development of tolerance to the analgesic but not to the hypothermic effect of U-50,488H. A dose of 2 mg/kg of L-NMMA although appeared to inhibit the tolerance to the analgesic action, the effect was not statistically significant. L-NMMA did not affect the body weight gain of rats injected with U-50,488H. It is concluded that the blockade of nitric oxide synthase results in the inhibition of tolerance to the analgesic effect of k-opiate agonist selectively (Supported by a grant DA-02598 and a Research Scientist Development Award K02-DA-00130 from the National Institute on Drug Abuse).

EXAMINATION OF MOTIVATED BEHAVIOR AND ITS CORRELATES IN HUMANS IN NATURAL SETTINGS. R. F. Mucha*, R. Weiss, G. Mutz and E. Stephan, Inst. of Med. Psychology and Behav. Neurobiology, U. of Tuebingen, 7400 Tuebingen* and Inst. of Psychology, Univ. of Cologne, 5000 Cologne 1, Germany.

Environmental cues can be used as conditioned stimuli for conditioning produced by such motivationally relevant events as application of addictive substances, natural reinforcers and pain. An important question is how laboratory data from humans compares to what is expressed in their natural environment. To approach this, we carried out studies on smoking in light to moderate smokers as a test model. They carried a small computer during their daily activities (Kölnner Vitaport System) which measured continuously simple psychophysiological and behavioral data. We developed an activity monitor to discriminate general activities typical of smokers: standing, walking and sitting. Without consideration of these activities, there was a clear decrease in heart rate as result of smoking a cigarette. Through application of the sensor it was possible to address the question why laboratory studies indicate that smoking a cigarette produces a significant increase in heart rate. Also presented will be data on procedures for monitoring the onset of smoking behaviour, including activation of an event recorder by the subject that smoking will occur, the activation of a switch indicating that the cigarette package is being removed and use of an inhalation sensor on a cigarette holder. ALTERATION OF MATERNAL RETRIEVING BY NEONATAL UNDERNUTRITION IN THE RAT. P. Carrillo*, C. Torrero, M. Regalado, and M. Salas. INE-Universidad Veracruzana, Xalapa, Ver.; IIB-Univ. Nal. Aut. de México. México, D.F. 04510.

The maternal retrieving (MR) is initiated by picking up the pup by a fold of skin on its dorsal or lateral surfaces and transporting it back to the nest. Neonatal undernutrition in the rat results in long-term alterations of maternal nest building, nursing time and pup retrieval. Because little is known about the effects of neonatal undernutrition upon MR we characterize the response during the lactating period. Undernutrition was performed by daily removal of half of the litter (n=4) to an incubator for 12h from postnatal days 1-24. Control dams were obtained from litters adjusted to 8 pups at birth and left undisturbed. Weaning was performed at 25 days of age. Subjects were kept in a room maintained at 24°C, 12h dark/12h light cycle, and water and food (Purina chow) ad lib. Maternal retrieving of dams was assessed in their own maternal cage by measuring the latency of the response, the body area (head, neck, body and pelvis zones) where pups were carried, and if pups vocalizations occurred. Data show that neonatally underfed mothers were slower, spent less time in retrieving and do not exhibit preferences for carrying pups in a particular body area; moreover pups retrieved by underfed dams vocalize more than controls. Data suggest that neonatal food deprivation of environmental cues related with the undernourishing procedure, interferes with the MR of newborns.

PAW PREFERENCE IN MICE WITH TOTAL AND PARTIAL CALLOSAL AGENESIS INDUCED BY PRENATAL IRRADIATION. A.C. Manhaes, E. M. Caparelli-Daquer, S. L. Schmidt*. Departamento de Fisiologia, Universidade do Estado do Rio de Janeiro, RJ, Brazil; Instituto de Biofisica UFRJ; and Department of Psychology, University of Alberta, Edmonton, Alberta, Canada.

The hypothesis that the development of the corpus callosum (CC) plays a role in the establishment of the direction of behavioral lateralization was tested by studying paw preference in mice with callosal defects induced by ionizing radiation. It is well known that exposure of pregnant mice at embryonic day 16 (E16) affects the CC in a dose-dependent manner: Three Gy produces total agenesis whereas a total dose of 2 Gy causes not only total but also partial callosal agenesis. Here we studied paw preference in adult male mice with callosal defects due to exposure to different doses of gamma irradiation (n=48, total dose of 2 Gy; n=26, 3Gy; n=93, nonirradiated controls), reasoning that directional laterality might also be disturbed in a dose-dependent manner. Every behavioral session consisted of 25 reaches of food and for most mice repeated measurements were done at least three times. Most mice maintained their initial paw preference throughout all subsequent testings and, thus, paw preference was considered a stable measurement of behavioral asymmetry. After the behavioral testings the animals were perfused and their brains were embedded in albumin-gelatin, frozen, cut, and stained with Cresyl-violet. The callosal area was measured with the aid of the Nissl-stained sections. The CC and the cortical extension were affected in all irradiated animals. When the cortical extension was taken into account, the callosal remnant of some animals in the 2 Gy group was considered analogous to a "normal" callosal size. The analysis of directional laterality indicated a tendency for right paw use in the 2Gy group (60%) that was markedly increased in the 3 Gy group (95%). In the 3Gy group, directional laterality was significantly different from chance level as opposed to an absence of such difference in normal controls (49%). In the 3 groups, most mice presented a significant individual paw preference. The present data are consistent with a previous study on paw preference in a strain of mice that present some animals with callosal defects. The dose-dependent effect indicates that the early absence of the corpus callosum disrupts the normal pattern of directional asymmetries, leaving intact individual asymmetries.

NEUROENDOCRINE STRESS HORMONES DURING THIRD TRIMESTER OF ADOLESCENT PREGNANCY. F.M. Crinella*, A. Chicz-DeMet, B. Simon, E.M. DeMet, C.K. Cho and J.E. Lee. State Dev. Res. Inst., Costa Mesa, CA 92626, Dept. Psychiatry & Human Behavior, UC Irvine, CA 92717 and Psychiatry Service, VAMC Long Beach, CA 90822.

Increases in stress-related peptide hormones have been reported during pregnancy. The present study examined plasma β -endorphin (β E), ACTH, and cortisol in 52 adolescent mothers (range 12 to 17 yr) during the third trimester (TTRI). Mean values for β E (49.0 ± 24.1 pg/ml), ACTH (35.4 ± 13.5 pg/ml), and cortisol (26.4 ± 10.2 μ g/dL; SD) generally agree with previously reported studies in adult mothers. Significant correlations were obtained between β E and ACTH during early TTRI (26-32 gestational weeks, GW; $r=0.463$, $p<0.02$) and late TTRI ($r=0.534$, $p<0.02$). Cortisol and ACTH were significantly correlated during early ($r=0.595$, $p<0.001$), but not late TTRI (33-39 GW; $r=0.402$, $p=0.079$). No significant mean differences were found for these three biochemical stress indices in early and late TTRI. Within late TTRI, however, ACTH ($r=0.424$, $p<0.06$), but not β E or cortisol, tended to correlate with GW at birth. Rising ACTH levels during the TTRI of pregnancy may be indicative of either elevated maternal anxiety as the delivery date approaches or may be due to the release of placental hormones in response to fetal stimulation.

597.5

LYMPHOCYTE PBR AND DBI MODIFICATIONS IN CHILD NEUROPSYCHIATRIC DISORDERS. C. Ferrarese^{1,2}, M. Perego¹, C. Marzorati¹, M. Molteni¹, G. Moretti¹, N. Pecora¹, M. Frigo², G. Bianchi², R. Riva² and L. Frattola². Scientific Institute "E. Medea", 22040 Bosisio Parini, Como (I) and Dept. of Neurology, Univ. of Milan, Osp. San Gerardo, 20052 Monza (I), ITALY.

Peripheral benzodiazepine receptors (PBR) and their endogenous ligand diazepam binding inhibitor (DBI) are present in lymphocytes, where they modulate immunologic functions. PBR modifications have been previously described in lymphocytes of anxious patients. We now investigated possible modifications of PBR and DBI in lymphocytes of children with various neuropsychiatric disorders.

80 children of the Scientific Institute "E. Medea", with diagnosis of epilepsy (50) affective disorders (23) and Down's syndrome (7) were compared to 10 age-related normal children for the levels of PBR and DBI in lymphocytes. Mononuclear blood cells were separated with a ficoll gradient; PBR density (Bmax) and affinity (Kd) were investigated by the binding of the specific ligand [³H] PK 11195 and DBI levels were determined by a specific radioimmunoassay (RIA).

Both PBR and DBI levels of Down patients were similar to the controls; on the contrary, DBI levels were significantly elevated in lymphocytes of untreated epileptic patients, while PBR density was increased only after anticonvulsant therapy. Two different groups were present in children with affective disorders: one with PBR levels similar to controls, one with PBR levels significantly decreased. DBI levels were also changed in same patients, without correlation with PBR changes. PBR and DBI modifications in affective disorders were not related to DSM III diagnosis, treatment or degree of mental retardation.

PBR and DBI modifications in epileptic patients might explain immunologic alterations in this disorder. PBR decrease in children with affective disorders may be linked to anxiety, which is often masked and difficult to assess in children.

597.7

MALE PREVALENCE FOR READING DISABILITY IS FOUND IN A LARGE SAMPLE FREE FROM ASCERTAINMENT BIAS J. Liederman* and K. A. Flannery, Psych Dept, Boston University, Boston, MA 02215.

It is widely believed that males are more vulnerable to neurodevelopmental disorders than females. This notion has been recently challenged in a highly publicized paper by Shaywitz, Shaywitz, Fletcher and Escobar (1990). They argued that male vulnerability for one neurodevelopmental disorder, reading disability, was an artifact of ascertainment biases rather than a true gender difference. The Shaywitz et al. (1990) paper was based on a longitudinal sample of about 400 children whereas the current paper analyzed 16,888 cases from the National Collaborative Perinatal Study. Results indicated that when children had a history of having been referred to special classes there was a 2.6 to 1 bias in favor of boys, but when classification of reading disability was based strictly on reading performance, (by two different classification methods) there was still at least a 2 to 1 bias in favor of boys. Analyses demonstrated that this gender bias for reading disability was not due solely to "bad behavior" in boys.

597.4

HPA AXIS AND DEPRESSION IN ADOLESCENT PREGNANCY. A. Chicz-DeMet*, B. Simon, J. Wiger, T. Kim, and E.M. DeMet. Dept. Psychiatry & Human Behavior, UC Irvine, CA 92717, State Dev. Res. Inst., Costa Mesa, CA 92626 and Psychiatry Service, VAMC Long Beach, CA 90822.

Disturbances in the hypothalamic-pituitary-adrenal (HPA) axis are associated with stress and depression. Depression in adolescent mothers has been proposed as a potential risk factor for child cognitive development in later years. The Child Depression Inventory (CDI) and Symptom Checklist 90 Revised (SCL-90R) self-report questionnaires were administered to 52 expectant mothers (age 15.5 ± 1.4 yr, SD) during the third trimester (TTRI) of pregnancy to assess depression, anxiety, and stress. Plasma β -endorphin (β E), ACTH, and cortisol were studied in maternal blood samples. As expected significant correlations were obtained between β E and ACTH ($r=0.688$; $p<0.001$), and ACTH and cortisol ($r=0.524$; $p=0.001$). Mothers with non-optimal birth outcome ($N=3$) had increased depression scores on both the SCL-90R (standardized difference = 0.84; $p=0.17$) and CDI (standardized difference = 0.72; $p=0.13$). Depression ratings, however, were not associated with increases in stress hormones in high risk pregnancies or in the total sample. The results support a putative role of depression as a risk factor in pregnancy, but fail to confirm a relationship between depression and stress in this small sample.

597.6

RISK PERIOD FOR INTRAVENTRICULAR HEMORRHAGE IS ATTRIBUTABLE TO PERINATAL INDUCTION OF GERMINAL MATRIX MICROVASCULAR MATURATION. Laura R. Meni*, William B. Stewart, Martin J. Asis, Miri F. Einal, Charles C. Duncan, Joseph A. Madri. Depts Pediatrics, Neurology, Surgery, Biology and Pathology, Yale University, New Haven, CT 06510.

Intraventricular hemorrhage (IVH) has been attributed to increased cerebral blood flow to the immature germinal matrix (GM) microvasculature. The risk period for IVH is the first 4 - 5 postnatal days and is independent of gestational age in preterm infants of less than 34 weeks. The newborn beagle pup provides a good model for IVH; the risk period for IVH in the beagle pup is the first 3 - 4 days. We used the newborn beagle pup model to study the hypothesis that the risk period for IVH is secondary to the rapid perinatal induction of maturation of the GM microvasculature. We isolated germinal matrix microvascular endothelial cells (BBMEC) from PND 1 beagle pups by differential centrifugation. BBMEC were cultured in DM high glucose medium with penicillin and streptomycin; low-passage BBMEC were placed in three dimensional culture. By day 6, BBMEC formed abundant tube-like structures which stained with the endothelial cell markers Bandeiraea and Factor-VIII related antigen. Northern blotting and hybridization analysis of 10 μ g of RNA from day 1 and day 6 BBMEC cultures demonstrated increased amounts of SPARC (secreted protein, acidic, rich in cysteine, O.D. 0.7 vs O.D. 0.84, day 1 vs day 6) and decreased amounts of alpha smooth muscle actin (O.D. 0.94 vs O.D. 0.71, day 1 vs day 6), consistent with endothelial cell differentiation. BBMEC were placed in coculture with fetal rat brain astrocytes (1:1 ratio, total cell count 80,000/ml). The extracellular matrix proteins laminin and collagen V were detected by day 6 using immunofluorescence. Electron microscopy demonstrated endothelial tight junctions at day 4. We conclude that the risk period for IVH in preterm neonates may be secondary to the rapid development by the GM microvasculature of the traditional characteristics of the blood brain barrier: basement membrane proteins and endothelial cell tight junctions.

597.8

BALLOON CELLS IN DYSPLASTIC HUMAN CEREBRAL CORTEX ARE LABELLED BY IMMUNOHISTOCHEMICAL MARKERS FOR BOTH NEURONAL AND ASTROCYTIC INTERMEDIATE FILAMENTS. M. J. De Rosa¹, R.S. Fisher^{1,2,4}, and H. V. Vinters^{1,3,4}. ¹Brain Research Institute, Departments of ²Anatomy and Cell Biology and ³Pathology and Laboratory Medicine and ⁴Mental Retardation Research Center, UCLA Sch. of Med., Los Angeles, CA 90024.

We have defined two aberrant cell types in resections of human cerebral cortex performed in the treatment of intractable childhood epilepsy involving cortical dysplasia. Hypertrophic neurons are large cells of apparently neuronal morphology and phenotype with coarse neurofilamentous cytoplasmic inclusions. Balloon cells are distended in appearance and contain a glassy, eosinophilic cytoplasm. We have, by immunohistochemistry, demonstrated colocalization of both neuronal and astrocytic elements within these cells suggesting that they may be an undifferentiated cell type. In this study, we attempt to further define the balloon cells' lineage with antibodies directed against neuronal (SMI 31 and 34 to phosphorylated neurofilaments and neurodegenerative tangles, respectively) and astrocytic (glial fibrillary acidic protein) intermediate filaments and an antibody against galactocerebroside (GC), a marker of oligodendrocyte differentiation. We have demonstrated balloon cell colocalization of SMI 34 but not SMI 31 with GFAP. Our initial studies suggest the balloon cells are not immunoreactive with the antibody to GC. Conclusion: The balloon cell appears to be an inappropriately differentiated cell type, perhaps a stem cell, which has ignored the oligodendrocyte lineage and expressed a split phenotype consistent, in some respects, with either a neuronal or astrocytic lineage.

597.9

ABNORMAL CLASSICAL EYEBLINK CONDITIONING IN AUTISM. L.L. Sears, P.R. Finn & J.E. Steinmetz*. Prog. in Neural Science and Dept. of Psychology, Indiana University, Bloomington, IN 47405.

Eleven subjects with autism (age range = 7 to 22) and age- and IQ- matched controls were classically eyeblink conditioned using a 450 ms tone conditioned stimulus (CS) coterminating with a 100 ms air puff unconditioned stimulus (US). Subjects with autism conditioned at a significantly faster rate than controls and exhibited a more rapid extinction of the conditioned response (CR). The magnitude of the difference in learning and extinction rates between matched subjects varied with age, suggesting developmental learning abnormalities in autism. Subjects with autism also exhibited an abnormal topography of the CR consisting of short latency, large amplitude responses. The rapid acquisition and extinction of the poorly-timed CRs may reflect developmental abnormalities in the cerebellum and hippocampus, as previously reported in autism (e.g. M. Bauman, *Pediatrics, Suppl.*, 1:791, 1991), since these brain areas are involved in classical eyeblink conditioning (e.g. Steinmetz et al., *J. Neuroscience*, 11:4403, 1992). The abnormalities in classical conditioning seen in autism suggest an ability to rapidly associate paired stimuli but with impairments in modulation of learned responses depending on processing of certain contextual information.

597.11

EXPRESSION OF MULTIPLE DYSTROPHIN ISOFORMS IN THE BRAIN POSTSYNAPTIC DENSITY (PSD) OF THE *MDX* MOUSE AND DUCHENNE MUSCULAR DYSTROPHY PATIENT. K. Wu^{1,2}, T.W. Kim^{1,2}, Y.Y. Huang³, T. Byers⁴, B.A. Sieber^{1,2} and J.B. Black^{1,2}. ¹Dept. of Neurosci. & Cell Biol., UMDNJ/RWJ Med. Sch., Piscataway, N.J. 08854; ²Grad. Program in Physiol. and Neurobiol., Rutgers-The State Univ. of N. J., Piscataway, N.J. 08854; ³Div. of Neurosci., NYSP, New York, N.Y. 10032; ⁴Dept. of Physiol. & Biophys., Indiana Univ., Indianapolis, IN. 46202.

Duchenne muscular dystrophy (DMD) is a fatal X-linked inherited disease affecting one in 3500 boys. Cognitive impairment is a common feature of DMD, but underlying mechanisms are unknown. DMD is characterized by a defect in dystrophin that has been detected recently in brain. We have previously found that the 427 kilodalton (kDa) brain dystrophin is a component of the PSD and that this synaptic protein is absent in the *mdx* mouse, an animal model of human DMD (Kim et al., *Proc. Natl. Acad. Sci. USA*, 1992). Recently, multiple novel spliced mRNAs generated from a single DMD gene were detected in brain. To begin defining potential functions of the protein products of these multiple mRNAs, we sought to localize dystrophin isoforms within the complex cortical synaptic structure. We focused on the PSD, since abundant evidence suggests that the density is crucial to synaptic function. We report here that an antibody against the C-terminal domain of dystrophin (anti-D1) recognized three distinct region-specific proteins with apparent molecular weights of 73, 71 and 69 kDa in purified PSD from rat cerebral cortex. The three proteins were differentially expressed during cortical development, suggesting role(s) in synaptic maturation and function. In contrast to the 427 kDa dystrophin, the multiple dystrophin isoforms were present at normal levels in cortical PSDs from *mdx* and human DMD brains. The *mdx* mutation does not affect expression of the various dystrophin isoforms, suggesting that they potentially subserve different, perhaps compensatory, synaptic functions.

597.13

MATERNAL ANTIBODIES ACCESS THE NEONATAL CENTRAL NERVOUS SYSTEM. R.H. Fabian^{1,3}, A.L. Welch^{2,3}, Y.C. Chen^{2,3}, C.E. Hulsebosch^{2,3}. ¹Dept. Neurol., ²Dept. Anat. Neurosci., and ³Marine Biomed. Inst., U. Tex. Med. Branch, Galveston, TX 77555.

To test the hypothesis that maternally derived antibodies have access to the developing neuraxis of the neonate, purified rabbit IgG, prepared by caprylic acid precipitation, was injected intraperitoneally into adult female rats immediately following parturition. The neonates were allowed to nurse and were sacrificed at 6, 12, 24, 36, 48 and 72 hours post-injection (N=5 per time point) by perfusion with saline followed by 4% paraformaldehyde. The neonatal neuraxis was removed and immunohistochemically stained for rabbit IgG. The antibody concentration, as determined by density of reaction product, reached a peak at 48 hrs. In a separate group of neonates (N=5), treated as above, the pups were sacrificed at 48 hrs. by perfusion with saline and the neuraxis (brain and spinal cord) was dissociated and extracted. Rabbit IgG was immunoprecipitated and identified by Western blot. The majority of rabbit IgG remained in an intact form in the neonatal brain tissue. We conclude that maternal IgG has access to the developing neonatal central nervous system via lactation and may have an effect on CNS development. THE GENE FOR FAMILIAL DYSAUTONOMIA IS LINKED TO CHROMOSOME 9 AND SHOWS STRONG LINKAGE DISEQUILIBRIUM WITH D9S58. A. Blumenfeld^{§*}, S.A. Slagenhaupt[§], D.E. Lucente[§], F.B. Axelrod[#], C.B. Liebert[§], C. Maayan⁺, M. Monahan[§], J.A. Trofatter[&], J.L. Haines[§], X.O. Breakefield[¶] and J.F. Gusella[§]. [§]Molecular Neurogenetics Unit, MGH and Harvard Med. Sch., Boston, MA 02129. [#]NYU Med. School, New York, NY 10016. ⁺Hadassah Univ. Hosp., Jerusalem, Israel.

Familial dysautonomia (DYS), the Riley-Day syndrome, is an autosomal recessive disorder characterized by developmental loss of neurons from the sensory and autonomic nervous system. It is limited to the Ashkenazi Jewish (AJ) population, where the carrier frequency is 1 in 30. We have mapped the *DYS* gene to the chromosomal region 9q31-q33 by linkage with ten DNA markers in twenty-six families. The maximum lod score of 21.1 with no recombinants was achieved with *D9S58*. This marker also showed strong linkage disequilibrium with *DYS*, with one allele present on 73% of all affected chromosomes compared to 5.4% of control AJ chromosomes ($\chi^2=3142$, 15 d.f. $p<0.0001$). The other nine markers distributed within 23 cM proximal or distal to *D9S58*, also yielded significant linkage to *DYS*. To define flanking loci, the phase of the markers was determined in dysautonomia families. Recombination events in the *DYS* families confirm the marker order based on reference pedigrees and define *D9S53* and *D9S105*, that were mapped 10cM apart, as the closest flanking markers for the familial dysautonomia gene.

PRENATAL AMPHETAMINE EXPOSURE ALTERS THE NUMBER OF CELLS IN THE ENTORHINAL CORTEX OF THE RAT. C.L. Lawrence, M. Lyon*, and W.O. McClure*. Dept. of Biological Sciences, Univ. Southern California, Los Angeles 90089-2520, and *Dept. Psychiatry and Behavioral Sciences, Univ. of Arkansas for Medical Sciences, Little Rock AR 72205.

A substantial amount of evidence suggests that at least some of the schizophrenia(s) are related to errors in fetal development. To test the fetal development hypothesis we have exposed rat pups *in utero* to dopaminergic agonists and have examined the behavior and neuroanatomy of these animals when they matured to young adulthood. Because of the known anomalies in the organization and number of cells in the parahippocampal gyrus of human schizophrenics, we were particularly interested in examining the entorhinal cortex of treated rats. Twenty-three pregnant Wistar rats were injected subcutaneously with d-amphetamine sulfate (5 mg/kg) or saline on specified days. Three "windows" of pregnancy were examined: I, 11-14 d; II, 15-17 d; and III, 18-20 d. Pups at 45-50 days of age were sacrificed by cardiac perfusion. Horizontal sections from -7.3 mm to -3.9 mm ventral to bregma were mounted and stained for cells with neutral red. Counts of cells were taken in the entorhinal cortex at each of 10-19 stations along the dorsal-ventral (DV) axis. Treatment with amphetamine had no effect upon the number of cells in either window II or III. In contrast, treatment with amphetamine increased the number of cells in window I by 21% ($p<0.05$). The amphetamine-induced increase was evenly distributed over all DV levels. In addition, the number of cells in control animals in window I was decreased by 28% ($p=0.004$) when compared to controls in windows II and III. The data suggest that *in utero* treatment can alter the neuroanatomy of adult rats, and indicate that certain aspects of human schizophrenia can be replicated in an animal model. Supported by the NIH and the Hedco Foundation.

SPONTANEOUS AND STIMULATION-INDUCED SYNCHRONIZED AFTERDISCHARGES IN THE ISOLATED CA1 OF KAINATE-TREATED RATS.

C. L. Meier*, F. E. Dudek†. Sandoz Research Institute, CH-3001 Bern, Switzerland; †Department of Anatomy and Neurobiology, Colorado State University, Fort Collins, Colorado 50283, U.S.A.

A subcutaneous kainate injection in rats (18 mg/kg, mean body weight: 200 g) causes neuronal damage in hippocampal areas leading to persistent reduction of functional inhibition and subsequent hyperexcitability (J. Neurophysiol. 68:2120,1992). In area CA1 (isolated with knife cuts), this hyperexcitability is characterized electrophysiologically by a partial loss of the Schaffer stimulation-evoked IPSP and a prolongation of the evoked EPSP, which gives rise to a short burst of action potentials. When GABA_A receptor-mediated inhibition was blocked by bicuculline in this previous study, afterdischarges of synchronized bursts following the initial Schaffer stimulation-evoked burst were only seen rarely (1 out of 21 slices [5%] from 13 kainate-treated animals). We performed a second series of experiments in younger rats (mean body weight: 100 g), and the exposure to the neurotoxin was prolonged by giving multiple injections of kainate (10x5 mg/kg, s.c.) over 10 hr. When this group was tested several months after the kainate injections, the probability for synchronized afterdischarges of bursts in the isolated CA1 was markedly increased. In normal Ringer solution, afterdischarges of multiple synchronized bursts occurred either spontaneously or upon stimulation of the Schaffer collaterals in 2 out of 56 slices [4%] from 2 out of 20 animals [10%]. Following blockade of the remaining inhibition by bicuculline, however, afterdischarges were observed more frequently (12 out of 53 slices [23%] from 5 out of 18 animals [28%]). The occurrence of prolonged afterdischarges of synchronized bursts in CA1 of kainate-treated rats (in the absence of input from CA3) suggests that recurrent excitatory connections may form in CA1 after kainate-induced damage to CA3.

EFFECT OF HYPOXIA ON HIPPOCAMPAL PYRAMIDAL CELLS AND INTERNEURONS FROM IMMATURE RATS.

J. Owens, Jr., C.A. Robbins, and P.A. Schwartzkroin. Depts. of Neurological Surgery and Physiology/Biophysics, Univ. of Washington, Seattle, WA 98195

The immature CNS manifests a well documented, but poorly understood, heightened seizure susceptibility. Hypoxia, a clinically important epileptogenic injury, differentially affects the adult and the developing nervous systems (Ann. Neuro. 29:629-637). To investigate the pathogenesis of hypoxic injury, Sprague Dawley rats were exposed on days P8, 9, and 10 to fifteen minutes of gradually decreasing O₂ concentration (minimum 4%). During the treatment, all animals showed behavioral signs of seizure activity, including wet dog shakes and clonic jerks. Preliminary morphological investigations using cresyl violet as well as the Gallay's silver degeneration stain have failed to reveal any consistent difference between treated and control animals one week after the last exposure. Hippocampal slices were prepared from experimental and age-matched littermate control animals at one day, five days, and one week after the third treatment and intracellular recordings were obtained under current clamp. In preliminary analyses, no statistically significant difference in pyramidal cell or interneuron membrane properties has been identified (CA3 n=53, CA1 n=20, interneuron n=7) between treated and control animals. However, input resistance of CA3 pyramidal cells from treated slices appears somewhat elevated one day after the last hypoxic episode, and returns gradually to control levels by one week post-treatment. (Supported by NIH grants NS15317, NS20482, and GM07266)

NEURAL NETWORK OF ABSENCE SEIZURES IN LETHARGIC (*lh/lh*) MICE: USE OF GABA-B AUTORADIOGRAMS, EEG RECORDINGS AND MICROINJECTIONS. D.A. Hosford†, F.H. Lin, Z. Cao, D. Kraemer, and A. Huin. Duke & Durham V.A. Medical Centers, Durham, N.C. 27705.

In previous studies we showed that GABA_B receptors are required for absence seizures in *lh/lh* mice, and we found increased numbers of GABA_B binding sites in neocortical membranes of *lh/lh* compared to coisogenic (+/+), nonepileptic littermates (Science 257:398, 1992). In this study we determined the neural network of absence seizures in *lh/lh* mice by identifying neuronal structures which satisfied 3 criteria: i) autoradiographic enhancement of GABA_B binding in homologous structures of *lh/lh* compared to +/+; ii) ability of the structure to generate seizures, recorded with bipolar electrodes; iii) ability of the structure to regulate seizures, after microinjection of GABA_B agonists or antagonists.

Slide-mounted brain sections from male, 8-week-old mice (n = 8 pairs) were incubated either: i) with 80 nM [³H]-GABA and 40 μM isoguvacine, with (total) or without (nonspecific) 200 μM baclofen, for 45 min at 4°C; or ii) with 200 nM [³H]-baclofen, with or without 200 μM baclofen, for 5 min at 24°C. Autoradiograms were quantitated by comparing optical densities (Loats RAS/R1000) to tritium standards. Compared to +/+, GABA_B binding in *lh/lh* was significantly greater in neocortex (49%, p < .005) and in 2 thalamic nuclei: ventroanterior lateral [VAL] (27%, p < .025) and reuniens [RE] (30%, p < .05).

Synchronous seizures were recorded by bipolar electrodes in frontal neocortex and VAL or RE (n = 77 *lh/lh*); but not in lateral amygdaloid nucleus or dentate hilus (0/7). Compared to vehicle, bilateral microinjections of baclofen (1-300 ng/side) into VAL but not RE increased seizures to status epilepticus.

Together, these data demonstrate that neocortex and VAL are critical to the neural network of absence seizures in *lh/lh* mice. Other experiments investigating the mechanisms of absence seizures will focus on these neuronal structures.

AGE-RELATED EPILEPTOGENIC EFFECTS OF CORTICOTROPIN RELEASING HORMONE ON EVOKED FIELD RESPONSES IN THE ISOLATED CA1 PYRAMIDAL CELL LAYER OF RAT HIPPOCAMPAL SLICES. B.N. Smith* and F.E. Dudek. Dept. of Anat. and Neurobiol., Colorado State Univ., Fort Collins, CO 80523.

Corticotropin releasing hormone (CRH) has been proposed to be involved in the generation of massive infantile spasms (Baram, T.Z., Ann. Neurol. 1993, 33:231). However, no correlate to this epileptogenic effect of CRH has previously been described *in vitro*. Possible age-dependent epileptogenic effects of CRH were investigated using extracellular field potential recordings from the CA1 pyramidal cell layer in 400-600 μm thick hippocampal slices from adult and juvenile (postnatal day 5-21) rats. Bath application of CRH (0.2 μM) to slices from adult animals resulted in a reversible 6 ± 3% (mean ± SEM; percentage of normalized control response) increase in population spike amplitude following stratum radiatum stimulation. Similar CRH application to slices from young animals resulted in a significantly larger increase in population spike amplitude (16 ± 2%; p<0.04). In 10-30 μM bicuculline methiodide, stratum radiatum stimulation resulted in interictal-like bursts of population spikes beginning at 8 days of age. Application of CRH to these slices lengthened evoked bursts by 25 ± 8% in adults and 75 ± 16% (p<0.04) in juvenile animals and also increased the number of spikes elicited per stimulus (32 ± 10% in adults; 96 ± 12% in juveniles; p<0.005).

The present findings suggest that CRH may be more effective in the augmentation of epileptiform activity in the CA1 region of young animals than in adults, supporting the proposition that centrally released CRH may play a role in the development of some types of pediatric epilepsy. Supported by NINDS Postdoctoral Fellowship #NS09289 (B.N.S.) and NIH grants #HD05958 and #NS16683 (F.E.D.).

Electrographic seizures (EGSs) in juvenile rat hippocampal slices in normal ACSF. L.S. Jones and J.H. Hamilton, Anatomy, U. South Carolina Sch. of Med., Columbia, SC 29208.

Hippocampal slices from juvenile (J) rats (21-28 days) were used to develop a model of *in vitro* EGSs in normal ACSF. We report here that with standard neurophysiological techniques, 625 μM slices from J rats (ave 25 days) can be stimulated tetanically to produce EGSs that, once initiated, could continue for several hours (ave. 2 hrs 13') without requiring further stimulation. The stimulation protocols tried were modifications of the stimulus train induced bursting (STIB) paradigm for interictal-like burst induction (Brn. Res. 344:296). The most successful protocol subjected slices initially to a less intense tetanus (designed to produce long-term potentiation (LTP) via the Schaffer collaterals (CA2-3) followed 15 min later by the STIB protocol through the same electrode. Extracellular recordings were in s.d.v.l. of CA3 and CA1. Slices from J rats tended to give high numbers of afterdischarges (ADs) in response to the first STIB tetanus (> 40) and 6 out of 10 of these slices produced EGSs. The slightly older rats (31.5 days) gave many fewer ADs after the first STIB tetanus (14.9) and never produced EGSs, but produced the expected, interictal-like bursts usually seen with STIB. Since the EGSs resembled those produced in 0-Mg⁺⁺, but continued for much longer and had a more consistent, organized appearance, we also tried evoking the EGSs by lowering the Mg⁺⁺ slightly (from 1.2mM to .7-.9mM) prior to and during the STIB; this also resulted in EGS production in J rats and the EGSs continued after the slices were returned to 1.2mM Mg⁺⁺. Work supported by NS27903.

THE GABA_B RECEPTOR IN EXPERIMENTAL MODELS OF GENERALIZED ABSENCE SEIZURES IN RATS. Q. C. Snead III*, P. K. Banerjee, and C.C. Liu, Dept. Neurology, Univ. Southern Calif. Div. Neurology, Childrens Hospital Los Angeles, Los Angeles, CA 90027

Petit mal or generalized absence seizures are characterized by the fact that they are uniformly exacerbated by enhancement of GABAergic activity. Although GABA_A agonists exacerbate experimental absence seizures, GABA_A antagonists do not block this phenomenon. However, experimental absence seizures in rats are both exacerbated by GABA_B agonists and blocked by specific GABA_B antagonists (Snead: Eur J Pharmacol 1992;213:343). Therefore, the object of these experiments was to study the binding of [³H]GABA to GABA_B receptors in brain in two pharmacologic models of absence seizures in rats.

Binding of [³H]GABA to GABA_B receptors was determined by autoradiographic techniques before, at the onset of, and at various intervals during and after absence seizures induced by pentylenetetrazole (PTZ) or γ-hydroxybutyrate (GHB). No significant difference was observed in binding between control, PTZ- and GHB-treated animal at any time point examined. These data do not support the hypothesis that the GABA_B receptor is up- or downregulated either immediately before or during absence seizures in the models tested.

NEURONAL AND GLIAL CELL ACTIVITY ACCOMPANYING HYPER- AND HYPOMETABOLISM INDUCED BY FOCAL EPILEPSY
C. Brühl¹, O.W. Witte^{1*}, K.A. Hossmann², Neurologische Klinik, Heinrich Heine Universität, Düsseldorf, and Max Planck Institut für Neurologische Forschung, Köln, Germany

The mechanisms underlying changes of brain metabolism during epileptic activity are not well understood. In this study metabolic changes caused by penicillin-induced interictal epileptic activity in the rat motor cortex were measured with [¹⁴C]-autoradiography. In addition membrane potential of neurons and glial cells was measured in several brain areas.

The metabolism in the focal area was increased up to 3fold. Contralaterally a metabolic "mirror focus" with an increase of metabolism by about 50% was found. The focus on the ipsilateral side was surrounded by a large area with a decrease of metabolism by 10 - 20%.

Within the focus the neurons displayed typical paroxysmal depolarization shifts. In the "mirror focus" pronounced inhibitions often followed by rebound excitations were found. In the hypometabolic areas also inhibitions were found though they were less often followed by rebound excitations. Average membrane potential of neurons within the hypometabolic areas was 10 mV more negative than that of neurons in the normometabolic areas. Glial cells within the focus showed large depolarizations up to 30 mV or more accompanying the interictal EEG discharges. In the "mirror focus" these depolarizations had amplitudes of 5 to 10 mV while they were absent or very small in the hypometabolic brain areas.

The experiments show that both inhibitions and PDS can be hypermetabolic. For each metabolic area typical changes of neuronal and glial cell activity can be observed. Hypometabolism was associated with a tonic disfacilitation of the neurons. *Supported by SFB 194 B2*

ENDURING INCREASE IN MEMBRANE-ASSOCIATED PROTEIN KINASE C ACTIVITY IN THE HIPPOCAMPUS OF THE AMYGDALA-KINDLED RAT.
K. Akiyama¹, M. Ono², I. Kohira² and S. Kuroda¹ Dept. of Neuropsychiatry and Dept. of Neurology, Okayama University Medical School, Okayama 700, JAPAN.

In our previous study (Kohira I. et al. Brain Research 593:82-88, 1992), we demonstrated that membrane-associated protein kinase C (PKC) activity in the amygdala/hippocampus (AM/PC) and both the right and left hippocampus (HIPP) of rats kindled from the left HIPP increased significantly 16 weeks after the occurrence of the last seizure compared with control rats. The present study examined the effect of kindling from the left AM on brain PKC activity. AM-kindled rats were decapitated either 1 week, 4 weeks or 16 weeks after the last full kindled seizure with matched controls. The AM/PC and HIPP were dissected and separated into the right (contralateral) and left (ipsilateral) sites. At 1, 4 and 16 weeks after the last seizure, the membrane-associated PKC activity increased significantly only in the left HIPP, but not in the other brain regions, compared with control rats. The cytosolic PKC activity did not differ in any brain region examined. In consistent with our previous finding in the HIPP-kindling, these results showed that AM-kindling induces enduring increase in the membrane-associated PKC activity in the HIPP, but only of left (ipsilateral to the stimulation) site, and further suggest that activation of membrane-associated PKC may be involved in the enduring seizure susceptibility induced by kindling.

598.11

EFFECT OF SEIZURE EXPERIENCE ON TRANSMITTER AMINO ACID ONTOGENY IN THE GENETICALLY EPILEPSY-PRONE RAT (GEPR). S.M. Lasley^{*} and M.C. Green. Dept. Basic Sciences, U. Illinois Coll. of Medicine, Peoria, IL 61656.

Past work has shown that the ontogeny of sound-induced seizure activity in GEPRs develops primarily within the 3rd and 4th postnatal weeks when audiogenic seizure (AGS) stimulation is applied to seizure-naïve (SN) animals. The current study was conducted to determine the effect of repetitive AGS induction on the ontogeny of transmitter amino acids in moderately severe (clonic) seizure GEPRs (GEPR-3s). GEPR-3s were divided into groups receiving AGS stimulation: 1) daily from day 15-22 or day 15-30; 2) daily from day 19-22 or day 27-30; or 3) not at all (SN). Animals were then sacrificed at day 22 or 30 along with a group at day 13 (prior to the emergence of seizure susceptibility), and brain regions analyzed for aspartic (ASP) and glutamic (GLU) acid, taurine (TAU) and GABA concentrations. Groups of seizure-resistant (SR) control animals were sacrificed at the same ages. GABA content was decreased in GEPR-3s relative to SR controls regardless of seizure history and independent of postnatal age. Conversely, TAU levels were elevated in GEPR-3s compared to SR controls in all seizure experience groups and at all postnatal ages. Furthermore, both GABA and TAU content decreased with age in all GEPR-3 and SR groups. In contrast, ASP concentrations were decreased by day 22 in frontal cortex and hippocampus of SN GEPR-3s relative to SR controls. However, increases in ASP in seizure-experienced GEPR-3s relative to SN animals abolished this distinction. These findings agree with previous observations in adult GEPR-3s (Lasley, Brain Research, 1991) that decreased GABA is a critical component of seizure predisposition while increased TAU is important in determining seizure severity. It is also apparent that increases in ASP in young GEPR-3s can occur as a result of seizure experience as in adults.

TYROSINE KINASES AND SEIZURES: A NEW PATHWAY FOR SEIZURE-INDUCED NEURAL REMODELING? CD Applegate^{*} and AM Moss. University of Rochester School of Medicine, Rochester, NY, 14642.

Tyrosine kinases (TK) are a potent family of enzymes known to promote permanent cellular changes during ontogeny, cellular differentiation and transformation. Post mitotic neurons are rich in TK's and hippocampal TK activity has been shown to be rapidly altered by MES-induced seizures. In this study we examined the effects of pentylenetetrazol (PTZ)-induced seizures and amygdala kindled seizures on phosphotyrosine (PY) production using immunocytochemical, western blot and autophosphorylation assays. Both seizure models resulted in increased PY immunostaining in hippocampal pyramidal neurons immediately following the ictal event and PTZ seizures consistently resulted in increased PY proteins in the 39-42 Kd range using western blot analyses at this time point. Together with previous reports, these results suggest that a common feature of generalized ictal events is an increase in hippocampal tyrosine phosphorylation. Preliminary studies indicate that amygdala kindling results in increased hippocampal PY protein production by western blot and increased autophosphorylation of a 39 Kd PY protein when assayed 2 weeks, but not at 2 days or 4 weeks after the last kindled seizure. These effects were variable however (2 of 4 rats), and may reflect variability in the involvement of hippocampal circuitry in amygdala kindling. In summary, data indicate that TK's are induced by seizures and further suggest, that TK's may contribute to long-term processes involved in kindling-induced neural reorganization.

CERULOPLASMIN DEFECT IN EPILEPTIC (EL) MICE. C.E. Garey^{*}, A.L. Schwarzman, and T.N. Seyfried. Department of Biology, Boston College, Chestnut Hill, MA 02167.

Epilepsy is an episodic disorder of the nervous system arising from the uncontrolled electrical discharge of neurons. The epileptic (EL) mouse has tonic clonic seizures with secondary generalization and serves as a model for human complex partial seizures. The epilepsy in EL mice is inherited as a dominant, multifactorial trait. We previously mapped the major gene responsible for the seizures, *El-1*, to distal chromosome 9. This region of chromosome 9 is highly conserved with a region on human chromosome 3q containing the gene for ceruloplasmin (*Cp*), a copper-binding protein. We recently reported a highly significant association between EL seizure susceptibility and an inherited DNA polymorphism at the *Cp* locus. Evidence is now presented for a partial duplication in the 5' end of the *Cp* gene in EL mice. The *Cp* duplication is: a) unique to EL mice and is not present in either normal mouse strains or in the non-epileptic EL parental strain, DDY; b) associated with enhanced expression of *Cp* mRNA in EL mice; c) coinherited with seizures in backcross generations. Moreover, the duplication is associated with localized negative interference, a classical genetic phenomenon involving an enhanced frequency of double recombinants. These findings are relevant to the basic mechanisms of epilepsy as well as to theories of genetic recombination and gene mapping. (Supported by NIH 23355 and Boston College REG.).

WIDESPREAD ABNORMALITIES IN NOREPINEPHRINE-STIMULATED INOSITOL PHOSPHATE ACCUMULATION IN BRAIN REGIONS OF GENETICALLY EPILEPSY-PRONE RATS. D.L. Yourick^{*}, M.R. Salter and J.L. Meyerhoff. Department of Medical Neurosciences, Walter Reed Army Institute of Research, Washington, DC 20307-5100.

Genetically epilepsy-prone rats (GEPR-9) have impaired function of brain noradrenergic systems including fewer α_2 -adrenergic receptors in amygdala, hippocampus and cerebral cortex. Our previous studies in this seizure-prone rat strain showed reduced inositol phosphate accumulation in cerebral cortex but not in hippocampus and amygdala/hippocampus (Yourick et al., Brain Res. 557:315-318, 1991). The purpose of the present study was to expand the regional analysis of norepinephrine (NE)-stimulated inositol phosphate accumulation based on our understanding of the involvement of NE in inhibitory processes in brain. NE-stimulated inositol phosphate accumulation was reduced significantly in parietal/occipital, frontal, entorhinal, cingulate and pyriform cortex of GEPR-9 when compared to controls. The same trend existed in hippocampus and amygdala. Inferior colliculus had numerically greater NE-stimulated inositol phosphate accumulation in GEPR-9, while no effect was found in superior colliculus, midbrain, brainstem, thalamus and cerebellum. The data support the hypothesis that in cortical subregions and possibly in amygdala and hippocampus, NE-coupled phosphatidylinositol metabolism is impaired in epilepsy. These results are consistent with the suggested inhibitory role of noradrenergic systems in seizure spread and intensity.

IDENTIFICATION OF REGIONS SUSCEPTIBLE TO SEIZURE-INDUCED DEGENERATION IN THE RAT BRAIN. M. Khurgel¹, R.C. Switzer III² and G.O. Ivy¹. ¹Dept. Anatomy & Cell Biology, Univ. of Toronto, Scarborough, ON M1C 1A4, ²Neuroscience Associates, Knoxville, TN 37922.

In this study we aimed to identify, with a greater precision than previously reported, the extent of neuronal degeneration following an episode of severe seizures induced by systemic kainic acid (KA). Nine adult Long-Evans rats were given KA (10 mg/kg, s.c.) and observed behaviorally for development of seizures. Seven out of nine animals experienced 1 h. of status epilepticus (SE), while 2 rats had only several stage 2 and stage 5 seizures, respectively. The animals survived for 12, 24, 48 and 72 hrs. Every 8th brain slice was stained with a cupric silver degeneration stain, as well as Nissl and Weil stains. The results showed a correlation between the severity of seizure activity and the resulting pathology. The earliest traces of degeneration were seen in the inner molecular layer of dentate gyrus following mild seizures. More intense seizure activity resulted in neuronal degeneration in the CA1 subfield of ventral hippocampus, in basomedial amygdala and in thalamic nucleus reuniens. Following SE, additional regions such as agranular cortex, dorsal endopiriform nucleus and area tempestas as well as the deep and superficial layers of the infralimbic region displayed prominent degenerative changes. More caudally, degenerating neurons and processes were present in the 3rd and 5th layers of the parietal cortex, in deep piriform cortex, in lateral amygdala as well as in selective thalamic nuclei and substantia nigra compacta. Also, degenerating interneurons in the stratum oriens of hippocampal CA1 and in the hilus were present in addition to dying pyramidal neurons in CA1 & CA3. Together, these findings should prove valuable for interpretation of other morphological changes as well as physiological observations in this widely used model of epilepsy.

MAGNETIC EVOKED FIELDS PRODUCED BY THE LONGITUDINAL CA1 AND CA3 HIPPOCAMPAL SLICES OF THE GUINEA PIG. Y. C. Okada^{*}, S. Kyuhou and C. Xu, Magnetophysiology Lab., V A Medical Center, Albuquerque, NM 87108 and Depts. Neurology & Physiol., Univ. New Mexico Sch. Med., Albuquerque, NM 87131

Magnetic evoked fields (MEFs) associated with synchronized population activities in the longitudinal hippocampal slices of the guinea pig were studied in order to help understand the genesis of MEG signals from this structure in vivo. The animal (Hartley, 250-400 g) was decapitated under pentobarbital anesthesia (60 mg/kg i.p.) and rectangular slices containing CA1, CA3 or both were harvested. The slice was placed on a nylon net and immersed in Ringer solution (concentrations in mM: NaCl, 117; KCl, 3; NaHCO₃, 35; NaH₂PO₄, 1.2; MgCl₂, 1.3; CaCl₂, 2.5; and glucose, 10; 36°C) containing 0.1 mM picrotoxin. Four pairs of bipolar Ag-AgCl electrodes stimulated the stratum radiatum or lucidum (50 μ s, 1.0-1.2 mA, 2 s/stim.). The MEF component normal to bath surface was recorded on a plane 3 mm away from the tissue with a magnetometer. The field potential was recorded simultaneously with the MEFs. Strong MEFs of as much as 25 pT peak-to-peak were recorded. They were in fact strong enough to be seen on single trials. The MEF from CA1 consisted of a series of 1-2 ms long spikes (7 pT peak-to-peak), presumably due to sodium and potassium currents, lasting about 10 ms, superimposed on a slow wave. The field potential in CA1 soma layer consisted of a series of spikes, having same latencies as those in the MEF, superimposed on a slow biphasic potential. The MEF from CA3 consisted typically of a triphasic wave of as much as 25 pT peak-to-peak. The train of spikes seen in CA1 could not be seen in the MEF from CA3, indicating that the population spikes may be less synchronized in CA3 than in CA1. Supported by NIH grant NS21149, NSF grant DIR8820556 and Dept. Veterans Affairs.

TIME-OFF FROM SEIZURES ATTENUATES ANTICONVULSANT DRUG EFFECTS S.R.B. Weiss^{*}, J.V. Ferrer, P.E. Anthony, R.M. Post, Biological Psychiatry Branch, NIMH, Bethesda, Md. 20892

Rats were electrically kindled in the amygdala until they were reliably experiencing stage 5 seizures. They were tested for their anticonvulsant response to carbamazepine (15mg/kg) and demonstrated a marked decrease in afterdischarge duration, seizure duration, and seizure stage. Half the animals were then given daily kindled seizures for two weeks and the other half received sham stimulation (no current) every day. No drugs were administered during this period. At the end of the interval, the rats were again tested for their anticonvulsant response to carbamazepine. Carbamazepine's anticonvulsant effects were diminished only in the animals that had not received seizures for two weeks. A time course study determined that this loss of efficacy was nearly complete by 4 days without intervening seizures. A similar set of experiments was conducted using diazepam (1-1.5 mg/kg), which also demonstrated this time-off-seizure loss of efficacy. However, in the case of diazepam, 10 days of sham stimulation was required before diazepam became ineffective. In a separate group of kindled animals, 5 days of sham stimulation was associated with a decrease in the seizure threshold compared to rats kindled 24 hours previously. Thus, seizures appear to produce endogenous anticonvulsant alterations, which can potentiate the anticonvulsant effects of drugs on amygdala kindled seizures. Elucidating the mechanisms of this phenomena may suggest endogenous neurotransmitter and peptide systems that could be exploited as novel anticonvulsant treatments.

MAGNETIC EVOKED FIELD FROM THE TRANSVERSE CA1 HIPPOCAMPAL SLICE OF THE GUINEA PIG. S. Kyuhou^{*} and Y. C. Okada, Magnetophysiology Lab., VAMC, Albuquerque, NM 87108 and Depts. Neurol. & Physiol., Univ. New Mexico Sch. Med., Albuquerque, NM 87131.

Magnetic evoked fields (MEFs) of the guinea pig hippocampal slice were characterized to help understand the genesis of magnetoencephalographic signals from this structure in situ. The animal (Hartley, 200-400g) was decapitated under pentobarbital anesthesia (60 mg/kg i.p.) and transverse slices containing only CA1 were prepared using a standard procedure. The longitudinal axis of pyramidal cells is arranged parallel to each other in this reduced slice; thus the cellular currents responsible for the MEFs could be readily inferred. The slice was placed on a nylon net resting on a plastic pedestal and immersed in oxygenated Ringer solution (concentrations in mM were: NaCl, 115; KCl, 5; NaHCO₃, 35; NaH₂PO₄, 1.2; MgCl₂, 1.3; CaCl₂, 2.5; glucose, 10) containing 0.05 mM picrotoxin. Evoked responses were elicited with a bipolar Ag-AgCl electrode placed in the stratum radiatum (50 μ s, 1-3 mA). The component of the MEF normal to the bath surface was measured on a plane 3 mm above the slice with a 4-channel magnetometer. Strong MEFs (1-6 pT) could be recorded with a latency of 2.5-3.5 ms. The spatial pattern of the MEF showed that it was due to the longitudinal currents of the pyramidal cells. The laminar field potential profile showed an MEF of as much as 6 pT arising from a 1 mm³ of active tissue (0.4 mm x 1 mm x 2.5 mm) 3 mm away from the detectors. Bath application of kynurenic acid extinguished most of the signals, indicating the dominant contribution of post-synaptic currents to the MEFs. The kynurenic acid-insensitive component was abolished by tetrodotoxin, indicating the remaining response was also neuronal in origin. Supported by NIH grant NS21149, NSF grant DIR-8820556 and Dept. Veterans Affairs.

PEPTIDE mRNA CHANGES CORRELATE WITH CONTINGENT TOLERANCE TO CARBAMAZEPINE'S ANTICONVULSANT EFFECTS. J.B. Rosen^{*}, M.A. Smith, S.R.B. Weiss, G.S. Massenburg, and R.M. Post, Biol. Psychiat. Br., NIMH, Bethesda, MD 20892.

Previous studies have shown that tolerance develops to carbamazepine's (CBZ) anticonvulsant effects on amygdala kindling. This tolerance is contingent upon when CBZ is given; tolerance develops only when rats are given CBZ before, and not after the kindling stimulus is delivered. Although contingent tolerance is robust and well documented, little is known about the biological substrates which may underlie this phenomenon. The present study demonstrates that contingent tolerance correlates with changes in the expression of various peptide mRNAs.

Rats were matched for both drug exposure (either before or after stimulation) and number of seizures. Once tolerance was evident, rats were sacrificed either 4 or 24 hours after the last seizure. A profound reduction in the normally seizure-induced expression in TRH mRNA was found in several limbic structures in the CBZ tolerant group but not in the CBZ non-tolerant group. However, TRH receptor binding was diminished in both the contingent and non-contingent rats. CRH mRNA expression in hilar cells was also reduced in the CBZ tolerant rats compared to the non-tolerant rats. Expression of enkephalin and neuropeptide Y mRNAs in limbic areas tended to be diminished in the CBZ tolerant but not the non-tolerant rats. These changes in gene expression may partially underlie contingent tolerance to CBZ.

CONTINGENT TOLERANCE TO CARBAMAZEPINE: ALTERATIONS IN GABA_A RECEPTOR BINDING AND SUBUNIT mRNA. M. Clark^{*}, G.S. Massenburg, S.R.B. Weiss and R.M. Post, Biological Psychiatry Branch, NIMH, Bethesda, MD 20892.

We have been studying tolerance to the anticonvulsant carbamazepine (CBZ) on amygdala kindled seizures. Tolerance in this model is a contingent process, since it only develops in rats treated with CBZ before the kindling stimulation and not in those animals treated after the stimulation. The present study was designed to investigate the GABA_A receptor system in CBZ contingent tolerance. Receptor autoradiography utilizing various radioligands that bind to different components of the GABA_A receptor system and in situ hybridization with oligonucleotides that recognize different subunits of the GABA_A receptor were performed.

Kindling increased binding to benzodiazepine, picrotoxin, and GABA recognition sites in the dentate gyrus. Rats tolerant to CBZ showed decreased [³H]muscimol and diazepam-insensitive [³H]Ro 15-4513 binding compared to non-tolerant rats, whereas [³H]flunitrazepam and [³⁵S]TBPS binding remained elevated. Kindling also increased mRNA for the α 1, α 4, β 1, and β 3 subunits (but no change in α 2). There was a selective decrease in the α 4 subunit in CBZ tolerant rats compared to non-tolerant rats.

The data suggest an indirect interaction of CBZ with the GABA_A receptor system, since CBZ does not bind to these receptors. However, CBZ does bind to mitochondrial benzodiazepine receptors (MBR), which were suggested to be involved in steroidogenesis. The changes observed in CBZ contingent tolerance could possibly result from CBZ binding at MBR with subsequent regulation of neurosteroids that bind to the GABA_A receptor system.

EXPRESSION OF GABA AND GLUTAMATE RECEPTORS IN A RAT MODEL FOR EPILEPSY. I. M. Germano, MD, L. K. Friedman, PhD, E. F. Sperber, PhD, R. S. Zukin, PhD, E. S. Goldensohn, MD*, S. L. Moshé, MD. Department of Neurology and Neuroscience, Albert Einstein College of Medicine, New York, NY, 10461

Neuronal migrational disorders in humans are often associated with medically refractory epilepsy. The present study was undertaken in an attempt to develop an animal model of neuronal migrational disorder. We treated pregnant rats with the alkylating neurotoxin methylazoxymethanol (MAM; 25mg/kg in saline, i.p.) to induce migrational disorders in the offspring.

Rat pups were sacrificed at 15 days of age. Histological examination revealed disruption of cortical layers II through IV and loss of striatal neurons in all MAM-treated rats. Neuronal ectopias in the CA1 area of the hippocampus were seen in 58% of MAM-treated rats. *In situ* hybridization was used to measure GABA α 1 and GluR2 (AMPA/kainate-type glutamate) receptor gene expression. In areas of neuronal ectopias in the hippocampus, GABA α 1 and GluR2 mRNA expression was reduced relative to that in control (vehicle-injected) rats. In the frontal cortex, GABA α 1 mRNA expression was markedly reduced in layers II through IV but near control levels in other cortical areas. Expression of GluR2 mRNA throughout the cortex was unchanged.

These results suggest that MAM-treated animals represent a useful experimental model to study changes in seizure susceptibility secondary to migrational disorders.

NEUROTRANSMITTER IMBALANCE IN SPONTANEOUS CANINE PRIMARY GENERALIZED AND PARTIAL EPILEPSY. M. Podell*, M. Hadjiconstantinou, W.R. Fenner. Depts. of Veterinary Clinical Sciences and Psychiatry and Pharmacology, The Ohio State Univ., Columbus, OH 43210.

Comparison of neurotransmitters in spontaneous canine epilepsy was performed to determine significant imbalances as a prognostic factor in response to antiepileptic therapy. Cerebrospinal fluid from 13 primary generalized epileptic, 6 primary partial epileptic, and 13 control dogs was analyzed for excitatory (ASP, GLU, TAU) and inhibitory (DA, 5-HT, GABA, ALA) neurotransmitters or their metabolites using high-pressure liquid chromatography with electrochemical detection. Initial general linear regression analysis yielded differences in GLU ($p=0.044$) and GABA ($p=0.002$) between epileptics and controls with respect to weight and gender. Stepwise regression analysis for seizure type, age of onset and duration demonstrated significantly lower values of ALA ($p=0.045$) and GABA ($p=0.040$) with generalized cluster seizures compared to all other seizure types. No differences in age of onset or seizure duration were detected. Significantly low levels of GABA ($p=0.023$) and high levels of GLU ($p=0.030$) were present in all male epileptics compared to control male dogs. Prospective evaluation of the response to antiepileptic therapy will be correlated with this neurotransmitter imbalance.

EPILEPSY: BASIC MECHANISMS IV

599.1

ANTIEPILEPTOGENIC AND ANTICONVULSANT EFFECTS OF NBQX, A SELECTIVE AMPA RECEPTOR ANTAGONIST, IN THE RAT KINDLING MODEL OF EPILEPSY. K. Morimoto* and T. Namba. Dep. Neuro-psychiatry, Okayama Univ. Med. Sch., Okayama, 700 Japan.

To investigate the role of non-NMDA receptors in epilepsy, we examined antiepileptogenic and anticonvulsant effects of 2,3-dihydroxy-nitro-7-sulfamoyl-benzo(F)quinoxaline (NBQX), a potent and selective antagonist of AMPA receptors, in the rat kindling model of epilepsy. Systemic administration of NBQX (10-40 mg/kg, i.p.) significantly suppressed the seizure stage (control: 5.0 vs NBQX 40 mg/kg: 0.8, $p<0.05$) and afterdischarge (AD) duration (84.5 \pm 9.7 sec vs 12.7 \pm 2.9 sec, $p<0.01$) of the previously kindled seizures from the amygdala (AM) in a dose-dependent manner. The maximal effects were observed 0.5-1 h after drug injection. When the stimulus intensity was increased to twice of the AD threshold, the effects were not reversed, suggesting that the effects are not due to non-specific elevation of the focal threshold. In contrast to AM kindled seizures, in hippocampal kindled seizures, NBQX (20-40 mg/kg) significantly suppressed only the kindled seizure stage without reducing the AD duration. Daily pretreatment with NBQX (15 or 30 mg/kg) prior to each electrical stimulation for 14 days potentially suppressed AM kindling development, in which the average of the number of stimulation required to produce the first stage 5 seizure was 9.9 (7-16) in control, 21.9 (14-28, $p<0.01$) in 15 mg/kg ($p<0.01$) and 26.1 (22-30, $p<0.01$) in 30 mg/kg ($p<0.01$) NBQX groups. These results indicate that AMPA receptors have the important role in seizure induction and propagation, at least, in AM kindling.

599.3

ANXIETY AND EPILEPSY IN SENSORY KINDLED, HABITUATED, AND NAIVE GERBILS. J.W. Collins* and W.B. Iturrian. Department of Pharmacology and Toxicology, University of Georgia, Athens, GA 30602-2356.

The link between epilepsy and anxiety is largely empirical and not well researched. Previous studies found increased anxiety in chemically or electrically kindled rats and increased emotionality after stress-induced seizures. No attempt has been made to show a decreased level of anxiety with habituated animal subjects. We examined the relationship of emotionality to seizure expression and tested for endogenous BDZ and opioid modulation in gerbils whose genetic seizure susceptibility (SS) is under behavioral control. We control SS in this model by altering the inter-test interval to produce groups with 100% (kindled), 40% (naive), or 0% (habituated) seizure expression. "Handling kindled" subjects tested in an open field showed an increased seizure frequency (76%), left behind more fecal boli, and displayed increased locomotor activity when compared to naive gerbils (28% SS). In contrast, habituated animals exhibited no seizures, had lower fecal defecation scores, and less response to novel stimuli during open field testing. In this battery of open field tests, both flumazenil, and naltrexone, or their combination (each at 1 mg/kg, ip) had subtle effects on SS. This contrasts with the marked effects of CGS8216 and naloxone on handling-elicited SS (Neurosci. Abs. 13:52, 1987). This data shows a definite link between the seizure susceptibility of this genetic epileptic gerbil and several measures of emotionality.

599.2

PERIRHINAL CONNECTIONS TO THE ORBITAL AND FRONTAL CORTEX: ANATOMY AND KINDLING. M.E. Kelly*, D.C. McIntyre and W. A. Staines§. Dept. of Psychology, Carleton Univ.; §Dept. of Anatomy, Ottawa Univ., Ottawa, Ontario, Canada, K1S 5B6.

Previously we have shown that the perirhinal cortex kindles faster and with shorter latencies to clonus onset than all other limbic sites tested (McIntyre et al., *Brain Res.*, in press). These data suggest an intimacy between the perirhinal area and areas controlling the motor convulsion. In experiment 1, using both anterograde and retrograde tracing techniques, we determined the efferents of the perirhinal cortex adjacent to the amygdala. In addition to its many subcortical projections of interest to epilepsy, including the basolateral amygdala and posterior thalamic nucleus, the PRh area also was shown to project heavily to the insular-orbital and frontal motor cortices. The insular-orbital cortex has been implicated previously in kindled seizure expression (Corcoran et al., *Kindling*, 1975; Holmes et al., *Brain Res.*, 1992).

In experiment 2, we assessed the speed, latency and form of kindling from the insular-orbital and frontal cortices compared to the perirhinal cortex. Only the frontal cortex kindled as rapidly as the perirhinal area (3 trials) and with similar latencies (1-2 sec), while the insular-orbital cortex kindled more slowly (6 trials) and with much longer latencies (15 sec). On the other hand, the form of the convulsive seizures triggered from the insular-orbital cortex, like the perirhinal cortex, were purely clonic, while the form of the convulsions triggered from the frontal cortex were clonic-tonic-clonic. A synthesis and interpretation of these results will be presented.

HIPPOCAMPAL DAMAGE INDUCED BY PERFORANT PATH STIMULATION FACILITATES KINDLING. Y. Shirasaka, R.A. Baldwin, C.G. Wasterlain*. Dept. of Neurology, BRI, UCLA Sch. of Med., Los Angeles, CA 90024 and Epi. Res. Lab. VAMC, Sepulveda, CA 91343.

24hrs perforant path (pp) stimulation causes selective damage to hilar neurons, but its potential epileptogenicity has never been investigated. In this experiment, we examined kindling susceptibility in pp stimulated rats.

Adult male Wistar rats were anesthetized with continuous i.v. Urethane and stimulating and recording electrodes cemented in pp and dentate hilus, respectively. Experimental rats (n=5) were stimulated at 2Hz (paired-pulses, 40msec apart) continuously with intermittent 10-sec trains of single stimuli (20V, 0.1msec, 20Hz) once/min. for 24hrs. Before and after stimulation, frequency dependent paired-pulse inhibition was examined at 0.1, 1, 2, and 4Hz. Control rats (n=4) were anesthetized and examined in the same way as stimulated rats. After 1-3 months, rats were given kindling stimulation (3 times daily, 1msec, 60Hz, 2sec total duration, 100 μ A above after discharge threshold (ADT)) and examined for ADT and number of ADs necessary to induce 3 generalized motor seizures.

Loss of inhibition peaked at the end of stimulation. The inhibition score ((1st-2nd spike amplitude)/(1st spike amplitude)x100) decreased significantly over the 24hrs stimulation (at 2Hz, stimulated rats, 20.9 \pm 13.0; controls, 92.1 \pm 9.7; $P<0.001$). There was a non significant decrease in ADT (stimulated rats, 280 \pm 84 μ A; controls, 475 \pm 171 μ A). The number of AD necessary to induce 3 generalized seizures was significantly smaller in stimulated rats (6.4 \pm 3.4) compared with controls (19.0 \pm 1.4, $P<0.001$).

These results show that hippocampal damage by perforant path stimulation is epileptogenic. Supported by EPA fellowship (YS), by the VA research service and by research grant NS13515.

BEHAVIORAL EVALUATION OF AUDIOGENIC KINDLING AND AMYGDALA KINDLING IN WISTAR AUDIOGENIC RATS. N. Garcia-Cairasco,* H. Wakamatsu, S.T.B. Bueno, O.Y. Galvis-Alonso, and J.A.C. Oliveira. Department of Physiology, Ribeirão Preto School of Medicine, University of São Paulo, 14049-900, Ribeirão Preto-SP-Brazil.

Acute audiogenic seizures (AS) and audiogenic kindling (ASK) are models of midbrain tonic-clonic seizures and acoustic-limbic interactions, respectively, while amygdala kindling (AMK) is a model of limbic seizures. However, it is unknown how limbic seizures are installed and interact with AS development during ASK. Also, it is not clear if the AMK induction is different in AS sensitive (S) or resistant (R) rats. For ASK induction S(n=18) and R(n=18) rats were acoustically stimulated (120 dB; 30 days). AMK was induced by 30 amygdala subthreshold electrical stimulations (four/day; 2 ms, 60Hz, 2 s) in S(n=4) and R(n=3) rats. AS, ASK and AMK were evaluated by cluster analysis (Garcia-Cairasco et al. Behav. Brain Res. 48:49-56, 1992), and by severity indexes (Racine, 1973; Pinel, 1978). S rats displayed wild running with tonic-clonic seizures at day 1. ASK decreased tonic-clonic seizures coincidently with the appearance of limbic seizures (ANOVA; p<0.0001). Class 1-2 limbic seizures appeared at days 3-5 of ASK initiation; class 3 and isolated galloping at days 4-6; galloping mixed with wild running and tonic seizures at day 7; class 4 at days 6-10 and class 5 at days 13-19. AMK in S rats appeared with higher scores (6-7), typical of midbrain recruiting. ASK and AMK in S rats gradually recruited new areas and interfered with the original epileptogenic site, phenomena which may be a temporal and spacial substrate for acoustic-limbic interactions. N.G.C., H.W., S.T.B.B. and J.A.C.O were supported by CNPq-Brazil.

RECURRENT AMYGDALA PENICILLIN FOCUS IN THE RAT. POWER SPECTRA INCREASE OF KINDLING-LIKE CORTICAL AND AMYGDALINE ELECTRICAL ACTIVITY PARALLELS BRAIN LEU- AND MET-ENKEPHALIN CONTENT AND RELEASE ENHANCEMENT. M. Asai, A. Martínez, R. Fernández-Mas and A. Fernández-Guardiola*. Inst. Mexicano de Psiquiat. and Fac. Psychol. UNAM. Mexico City, 14370. Electrical amygdaline kindling induces Leu- and Met-Enkephalin increase in the rat brain (Vindrola et al., Neurosci. Lett. 21:39-43, 1981). Interictal spiking is a prominent feature of Penicillin recurrent topical application in temporal lobe amygdala. In this work we tested the hypothesis of interictal spiking being the cause of endogenous opioid augmentation.

17 non anesthetized free moving rats with indwelling cortical (bi-frontal Cx) and both amygdalae electrodes plus a canula in left amygdala, 10 sham operated rats and 17 control rats were used. During 5 days Penicillin-G-Na was daily delivered (50 IU in 1 µL). With a short latency (from 1 to 60 sec) penicillin spikes appeared and propagated first to the ipsilateral and then to the contralateral frontal Cx in amygdala. Interictal activity lasted for about 6 h in waking stage reappearing occasionally during sleep. 20 min after the last Penicillin topical dose the animals were sacrificed. Enkephalin tissue content was measured in amygdala, striatum, hippocampus, hypothalamus, and cortex by RIA procedure. Enkephalin release in amygdala was evoked with 30 mM K⁺. The results were expressed in pmol/g. Content of Leu-enkephalin increased significantly (P<0.02 or less, using Student's "t" test) in all measured structures except in cortex. Met-Enkephalin only increase significantly in amygdala. *In vitro* release showed an important increase of both peptides in amygdala as a result of repetitive interictal spiking. CONACT (Mex.) 0778-N9110; 0694-N9109.

599.9

EFFECT OF INTRANIGRAL FLUOXETINE ON AUDIOGENIC SEIZURES IN GENETICALLY EPILEPSY-PRONE RATS (GEPRS). R.A. Browning¹*, M.A. Stalnack¹, J.W. Dailey², and P.C. Jobe². ¹Dept. Physiol. Southern Illinois University, Sch. of Med. Carbondale, IL 62901 and ²Dept. Basic Sci. Univ. Ill. Coll. of Med. Peoria IL 61656

Previous studies have shown that depletion of brain 5-hydroxytryptamine (5-HT) increases the severity of audiogenic seizures (AGS) in GEPRS, while elevations in 5-HT attenuate these seizures. Other studies indicate that an innate deficit in brain 5-HT contributes to the seizure-prone state in GEPRS. However, the site at which 5-HT exerts its anticonvulsant action on AGS is unknown. The substantia nigra (SN) has been shown to exert a modulatory role over both brainstem and forebrain driven seizures in non-epileptic rats and it receives a rich serotonergic innervation. Moreover, the systemic administration of fluoxetine, a 5-HT reuptake inhibitor, has been shown to exert anticonvulsant effects in brainstem seizure models and recent evidence indicates that these effects are mediated via an increase in extracellular 5-HT in the GEPR (Dailey et al. JPET 260: 533, 1992). In addition, bilateral infusion of fluoxetine into the SN inhibits forebrain evoked-seizures in rats (Pasini et al. Brain Res. 593: 287, 1992). The present studies were designed to determine if intranigral infusions of fluoxetine inhibit audiogenic seizures (brainstem seizures). Male severe seizure GEPRS (GEP-9s) were pretreated with DL-5-hydroxytryptophan (5-HTP, 75 mg/kg, i.p.) 30 min before seizure testing. Fluoxetine (7.2 nmol/side, in 0.5 ml) was infused into the SN 15 min before AGS. Rats treated with 5-HTP and intranigral fluoxetine displayed an increase in the latency to the run and to the convulsion when compared to 5-HTP treated saline infused controls (P<0.05), but no change in seizure severity score was observed. The present findings suggest that fluoxetine exerts some of its anticonvulsant action on AGS through an increase in extracellular 5-HT in the SN.

CHANGES IN RECURRENT HIPPOCAMPAL INHIBITION FOLLOWING EXTENDED KINDLING OF THE PERFORANT PATH OR AMYGDALA. N.W. Milgram*, E. Head, M. Michael, J. Ferbinteanu, S. Cammisuli, C. Reid, & R. Racine, Life Science Division, Scarborough Campus, University of Toronto, Ontario M1C 1A4.

Kindling is a procedure in which repeated electrical stimulation leads to a progressive increase in the severity of the evoked epileptiform responses and is typically terminated after animals have experienced two severe motor seizures. Several studies have reported that perforant path kindling produces an increase in recurrent inhibition in the dentate gyrus. In order to determine whether recurrent inhibition is further modified with increases in the severity of evoked seizures, we have been monitoring transmission in the dentate gyrus in animals undergoing an extended kindling procedure. As has previously been reported, progressive increases in the severity of elicited seizures were seen when kindling was extended. In animals kindled through the perforant path, inhibition increased over the early phase of kindling, and then stabilized. There was little change from the amygdala kindled rats. At this time, there is no evidence that extended kindling can lead to an inhibitory breakdown.

599.8

PERSISTENCE OF KINDLING ANTAGONISM IN RATS. R.D. Kirkby*, T.H. Gilbert, & M.E. Corcoran. Dept. of Psychology, U. of Victoria, POB 3050, Victoria, BC, Canada, V8W 3P5.

During concurrent alternating stimulation of two forebrain sites, one of the sites (dominant) supports typical kindling, culminating in generalized seizures. The other site (suppressed) supports only focal or partial seizures for as long as dominant site stimulation continues. Burchfiel and Applegate (1989) proposed that this phenomenon (kindling antagonism) reflects arrested kindling from the suppressed site; however, it may merely depend upon transient seizure inhibition. We have attempted to test this hypothesis.

We stimulated rats in the right septal area and the left amygdala (1 stimulation per day) until the latter site (always dominant) supported stage 5 seizures on 6 consecutive trials (Initial Phase). Control rats were stimulated only in the amygdala. During the Final Phase, which began either immediately, after 30 stimulation-free days, or after 30 additional days of Initial Phase treatments, we intermittently applied stimulation to the septal area only. We assessed the number of septal after-discharges (ADs) required to elicit a stage 5 seizure.

We found that the interposition of a prolonged stimulation-free period did not significantly reduce the number of septal ADs necessary to provoke a generalized seizure during the Final Phase. Also, fewer septal ADs were required by rats previously exposed to alternating stimulation as compared to control rats previously stimulated only in the amygdala. This disparity may depend upon the substantial growth in septal AD duration observed in alternately stimulated rats during the Initial Phase. The data are thus consistent with the view that kindling from the suppressed site is arrested at an intermediate stage during the induction of kindling antagonism.

INTRATHALAMIC INFUSIONS OF BOTH NMDA AND ITS ANTAGONIST, MK-801 SUPPRESS g-HYDROXYBUTYRATE INDUCED GENERALIZED ABSENCE-LIKE SEIZURES IN RATS. P.K. Banerjee* and Q.C. Snead III. Div. of Neurology, Childrens Hospital of Los Angeles, Department of Neurology, University of Southern California School of Medicine, Los Angeles, CA.

Absence-like seizures arise due to low frequency rhythmic oscillations of certain thalamocortical neurons. We have reported earlier that in two different rat models of absence-like seizures, electrographic seizures appear in various dorsal thalamic nuclei synchronously with that in the cortex (Banerjee and Snead, Soc. Neurosci. Abstr. 18: 909, 1992). Since most of the thalamocortical and corticothalamic neurons have been reported to utilize glutamate or aspartate as their neurotransmitter, the present study was undertaken to evaluate the effects of microinfusions of NMDA and its antagonist, MK-801 in different dorsal thalamic nuclei on the generation of absence seizures induced by g-hydroxybutyric acid (GHB). Bilateral infusions of NMDA (30-100ng/side) in mediodorsal (MD), central lateral (CL), paracentral (PC), ventroposterolateral (VPL) and reticular nucleus (RT) of thalamus dose dependently suppressed GHB-induced absence seizures from both thalamus and cortex. No behavioral or electrographic seizures were observed during or after NMDA infusion. Following GHB administration to NMDA treated animals, the appearance of burst suppression activity in the EEG served as marker for the inhibition of absence seizures. The anti-absence effects of NMDA were more prominent in MD, CL and PC because doses as low as 50-70 ng/side induced immediate burst suppression with no seizures following GHB administration. In VPL and RT, a higher dose of NMDA (100ng/side) was required for complete abolition of absence seizures with immediate appearance of burst suppression. Similar dose dependent inhibition of GHB-induced absence seizures after bilateral infusions of MK-801 (20-60 µg/side) in the above thalamic sites was also observed with EEG progressing to burst suppression.

These findings suggest that excitatory amino acid mechanisms in the thalamus, in general, and mediodorsal and intralaminar nuclei, in particular, are involved in the generation of experimental absence-like seizures.

599.11

NITRIC OXIDE POTENTIATES GENERALIZED CONVULSIVE SEIZURES ELICITED BY CHOLINERGIC STIMULATION OF THE VENTROPOSTERIOR THALAMUS. S. Mraovitch¹, J. Seylaz, Y. Calando. Laboratoire de Recherches Cérébrovasculaires, CNRS UA 641, Université Paris VII, Paris (France).

It has been recently suggested that nitric oxide (NO) synthesized from the amino acid L-arginine (L-Arg) by nitric oxide synthase (NOS) may contribute to the genesis of seizure activity. In the present study we sought to determine whether NO may modify convulsive seizures elicited by cholinergic stimulation of the ventroposterior thalamus (VP).

Wistar rats (300-350 g) were used in the experiment. Carbachol (CCh, 10 µg in 100 nl) was stereotaxically microinjected in the VP via a glass micropipette. Prior to CCh microinjection the animal received an i.p. injection of either 300 mg/kg of L-Arg (Sigma), 3 mg/kg of the NOS inhibitor, N^G-nitro L-arginine methyl ester (L-NAME) or L-NAME + L-Arg. After stereotaxic injection of CCh the animals were placed in an observation chamber for 2 hours.

As previously reported, microinjection of CCh alone resulted in the appearance of paroxysmal behavior known as wet-dog shakes (WDS) followed by several convulsive components (facial clonus, jaw clonus, and rearing) associated with limbic motor seizures (LMS) and generalized convulsive seizures (GCS). While pretreatment with L-NAME (n=4) abolished GCS (p<0.05), the occurrence of WDS, and LMS behavioral components remained unchanged. In contrast, L-Arg (n=4) significantly increased the number of episodes of WDS (p<0.05) and elicited generalized and continuous bilateral convulsive movements leading to death. Injection of L-NAME with L-Arg (n=3) prior to CCh, prevented the effect of L-Arg on generalized seizure activities. Neither L-NAME (n=3) nor L-Arg (n=3) alone produced changes in the rat behavior.

We conclude that NO has potentiating effects on generalized but not on limbic motor seizure activity elicited by activation of cholinergic receptors within the VP.

599.13

THE ANTICONVULSANT ACTION OF FLUOXETINE IN SUBSTANTIA NIGRA IS DEPENDENT UPON ENDOGENOUS SEROTONIN. A. Pasini¹, A. Tortorella, K. Gale. Dept. of Pharmacol., Georgetown University Med. Centr., Washington D. C. 20007.

Previously we reported that intranigral application of fluoxetine was anticonvulsant in rats (Brain Res. 593:287-90; 1992). In the present study, we investigated the role of 5HT in the anticonvulsant action produced by the focal application of fluoxetine into substantia nigra (SN). In order to inhibit tryptophan hydroxylase and deplete presynaptic stores of 5HT, rats were pretreated with p-chlorophenyl-alanine methyl ester HCL (PCPA). PCPA was given in 2 successive doses: 375 mg/kg i.p. and 100 mg/kg i.p., 2 days and 1 day, respectively, prior to the intranigral injection of fluoxetine. Fluoxetine (3.5 nmol), was injected into SN bilaterally. Seizures were evoked by the focal application of bicuculline into the area tempestas (AT), an epileptogenic site in the deep prepiriform cortex. In rats not treated with PCPA, fluoxetine, (3.5 nmol) bilaterally in SN, protected the rats from AT-evoked seizures. Pretreatment with PCPA, which by itself did not significantly alter seizure severity, blocked the anticonvulsant effect of intranigral fluoxetine. The directly acting 5HT receptor agonist 1-[3-(trifluoromethyl)phenyl]piperazine (TFMPP) when injected bilaterally into SN in a dose of 10 nmol also protected against AT-evoked seizures. However, pretreatment with PCPA did not interfere with the anticonvulsant action of TFMPP. Thus, the PCPA-induced depletion of endogenous 5HT selectively abolished the anticonvulsant action of intranigral fluoxetine but not of nigral 5HT receptor stimulation. This is consistent with a mechanism of action of fluoxetine as a 5HT uptake inhibitor which thereby enhances the synaptic action of endogenous 5HT. Our results support the proposal that endogenous serotonergic transmission in SN can limit the development and propagation of seizure activity generated in limbic circuits.

ROLE OF MUSCARINIC AND NON-NMDA RECEPTORS IN AREA TEMPESTAS FOR FOCALLY-EVOKED STATUS EPILEPTICUS. A. Tortorella¹, F. Fornai, B. Cassidy and K. Gale. Dept. Pharmacology, Georgetown Univ Med. Ctr., Washington, DC 20007

Blockade of GABA transmission, or enhancement of glutamate or muscarinic transmission, in area tempestas (AT) evokes episodic seizure activity which recurs at 3-7 min intervals over a 40-50 min period. In the course of examining interactions between these transmitters in AT, we found that combined treatment with a GABA antagonist (bicuculline, 118 pmol) and a muscarinic agonist (carbachol, 328 pmol) in AT, produced a severe and prolonged continuous seizure state (status epilepticus), frequently lasting for more than two hours. This response was not obtained with bicuculline (118 to 240 pmol) or carbachol (328 to 656 pmol) alone, nor with combinations of bicuculline and glutamate agonists (kainate, AMPA, or NMDA) in AT. In the presence of atropine (114 pmol) in AT, the status epilepticus produced by bicuculline and carbachol was converted to episodic seizure activity, characteristic of bicuculline alone. Whereas the seizure triggering effect of individual convulsant agents in AT was prevented by local blockade of NMDA receptors (by AP-7, 100 pmol), the effect of the combination of bicuculline and carbachol in AT was not sensitive to AP-7. In contrast, the non-NMDA antagonist, NBQX (500 pmol), when applied to AT, suppressed all seizure activity evoked by bicuculline and carbachol in AT. It therefore appears that, in the presence of a GABA antagonist in AT, focal muscarinic stimulation 1) prevents the operation of endogenous, seizure-suppressing processes, and 2) renders the seizures insensitive to blockade of NMDA receptors. The fact that status epilepticus evoked by carbachol + bicuculline was blocked by a non-NMDA glutamate antagonist suggests that glutamatergic neurotransmission is required for this phenomenon.

599.12

LOCALIZATION OF AN ANATOMICAL SUBSTRATE FOR THE ANTICONVULSANT ACTIVITY INDUCED BY D-CYCLOSERINE. S.L. Peterson¹. Department of Medical Pharmacology and Toxicology, Texas A&M University Health Science Center, College Station, Texas 77843.

Previous studies in this laboratory have demonstrated that both central and systemic administration of D-cycloserine (DCS) induces significant anticonvulsant activity in maximal electroshock seizures (MES). The purpose of the present study was to determine if local application of DCS to the nucleus reticularis pontis oralis (RPO) inhibits the tonic hindlimb extension (THE) component of MES.

Bilateral 50 nmol DCS microinfusion into a discrete region of the RPO 5.4 to 5.6 mm posterior to bregma inhibited the occurrence of THE in 14 of 17 rats. Microinfusion of 25 nmol/side DCS protected 1 of 11 rats from THE. Unilateral microinfusion of 50 nmol DCS (n=8) or bilateral microinfusion of saline (n=8) had no effect on the incidence of THE.

Browning has shown that the THE component of MES is dependent on the RPO (Fed. Proc. 44:2425, 1985). The present results would indicate that the anticonvulsant activity induced by DCS may be mediated specifically by the RPO.

LOCAL INTRACEREBRAL ADMINISTRATION OF L-LACTATE IS ANTICONVULSANT. F. Fornai, A. Tortorella, D. Dybdal and K. Gale¹. Dept. Pharmacology, Georgetown Univ. Med. Ctr., Washington, DC 20007.

Intense stimulation of neural activity in brain by sensory input or seizure activity has been shown to produce prolonged increases in regional lactic acid concentrations, reaching very high extracellular levels (10 mM) with seizures (Kuhr et al. J.Cereb. Blood Flow Met. 8: 848, 1988). To determine whether local neuronal excitability could be influenced by lactate, we evaluated its effect in modulating focally-evoked seizures. L-lactate, or equimolar acetate in controls, (adjusted to pH 5.5 with NaOH) was infused 1.5mm dorsal to AT at a rate of 500nmol/100nl/min for a period of 10 min. Pyruvate (50nmol/100nl/min) was included in the lactate solution to slow the metabolism of lactate by lactate dehydrogenase. Ten min after the end of the lactate or acetate infusion, rats received a microinjection of bicuculline methiodide (236pmol) in AT. This treatment evoked severe and prolonged limbic motor seizures in controls (facial and forelimb clonus with rearing and falling); in lactate pretreated animals, seizure activity was blocked. The lactate-induced seizure suppression was reversible by 3hr following lactate infusion. When the duration of lactate infusion was increased to 30 min, the duration of seizure suppression was prolonged to 5 hr, wearing off after 7-8 hr. These observations indicate that local elevation of lactate in brain can dampen neural responsiveness to excitatory influences. Thus, endogenous lactate may provide a signal linking metabolic state to neuronal excitability. In the case of seizures, increases in endogenous lactic acid may limit the duration of seizure activity, thereby avoiding the generation of cytotoxic levels of lactic acid.

HIPPOCAMPAL MICRODIALYSIS OF SOMATOSTATIN EVOKES A DISSOCIATED RESPONSE OF THE EXCITATORY AND INHIBITORY AMINO ACID NEUROTRANSMITTERS; EVIDENCE FOR A MODULATORY ROLE IN EPILEPTOGENESIS. A. Legido^{1,3,4}, J.G. McElliott², T.J. Parry², T.J. Lynch², J.L. O'Neill^{2*}, L.J. Greenstein³, and W.D. Grover^{1,3,4}. Temple University School of Medicine, Depts. of Pediatrics¹, Pharmacology², Neurology³, Philadelphia PA 19140 and St Christopher's Hospital for Children⁴, Philadelphia PA 19134.

The objective of this work was to study if somatostatin (SS) functions as a modulator of brain epileptogenesis in the hippocampus and to investigate if this modulatory role is mediated through excitatory (glutamate, aspartate) or inhibitory (GABA, glycine, taurine) amino acids. Hippocampal microdialysis was performed in head restrained awake rats in which the hippocampal and cortical EEG were recorded. Baseline EEG and microdialysis sampling (1µl/min) at 20 minute intervals were performed for two hours prior to the administration of two doses of SS (20 µg and 40 µg). Each dose was dialyzed into the hippocampus over a period of 20 minutes after which drug free dialysis fluid was perfused through the probe; samples were taken at the end of each SS perfusion as well as 20 and 40 minutes later. Amino acids were analyzed with HPLC. After SS administration, the amplitude and frequency of the cortical EEG increased significantly (p<0.05) when compared to baseline, whereas the changes of the hippocampal EEG were minimal. The hippocampal extracellular levels of excitatory amino acids glutamate and aspartate increased significantly (p<0.05) at 20, 40, and/or 60 minutes after the administration of 20 µg and 40 µg of SS. In contrast, there was only a slight increase in GABA (p<0.05) only at 40 minutes after the first dose of SS, and a small increase in glycine (p<0.05) only at 40 minutes after the second dose of SS. These results indicate that SS increases cortical neuronal excitability when applied to the hippocampus, and that this effect is probably due to the dissociated response of the excitatory and inhibitory amino acids. Thus, we hypothesize that neuropeptides, in particular SS, play a role in epileptogenesis by modulating amino acid neurotransmission. DIFFERENTIAL NEONATAL ONTOGENY OF HEIGHTENED SEIZURE DIFFERENTIAL IN TWO STRAINS OF GENETICALLY EPILEPSY-PRONE RATS (GEPRs). C.E. Reigel¹ and B.K. Lin. Dept. of Pharmacol., Texas Tech Univ. Health Sci. Ctr., Lubbock, TX 79430

The GEPR was derived by selective breeding of Sprague-Dawley (SD) rats for audiogenic seizure (AGS) susceptibility and currently exists as two strains. GEPR-9s exhibit full tonic extensor convulsions whereas GEPR-3s exhibit generalized clonus, each in response to sound. GEPRs also exhibit heightened sensitivity to exogenous seizure provoking stimuli, even at ages prior to AGS susceptibility. This study was conducted to determine the ontogeny of heightened seizure sensitivity in GEPRs. Flurothyl seizure thresholds were determined for paddling and tonic seizures at postnatal day (PD) 1, 3, 5, 7 and 10 in GEPR-9s, GEPR-3s and SD control pups. Paddling seizures occurred at lower doses of flurothyl than tonic seizures at any age. Flurothyl elicited a high incidence of tonic seizures in SD pups at PD 1 and 3. Tonic seizures disappeared in SD pups by PD 7. Tonic seizures were elicited in GEPRs from PD 1-10. GEPR-9s exhibited lower paddling and tonic seizure thresholds than GEPR-3s and SDs from PD 1-10. Seizure severity was greater in GEPR-9s than SDs from PD 1-10. Seizure severity was greater in GEPR-9s than GEPR-3s from PD 1-5 and thereafter similar. Paddling seizure thresholds were actually higher in GEPR-3s than SDs at PD 1. Thereafter (PD 3-10), paddling thresholds were equivalent in GEPR-3s and SDs. Tonic seizure thresholds were equal in GEPR-3s and SDs from PD 1-5. Tonic seizures disappeared in SDs by PD 7. Seizure severity was equal in GEPR-3s and SDs at PD 1-3 and greater in GEPR-3s than SDs at PD 5-10. Thus, heightened seizure sensitivity developed postnatally in the GEPR-3, appearing at PD 5 or 7. Heightened seizure sensitivity was fully present in GEPR-9s by PD 1. (Supported by NS 28118.)

EFFECTS OF ANTERIOR PERIRHINAL CORTEX MICROINFUSIONS OF NMDA ANTAGONISTS AND PROCAINE ON AMYGDALA-KINDLED SEIZURES. D.K. Bilkey¹ and K.H. Holmes. Department of Psychology and the Neuroscience Centre, University of Otago, Box 56, Dunedin, New Zealand.

Holmes et al (*Brain Res.* 587:285, 1992) have recently demonstrated that microinfusion of the N-methyl-D-Aspartate (NMDA) antagonist 2-amino-5-phosphono-valerate (APV, 1 μ l, 70 mM) into the anterior region of perirhinal (insular) cortex (PRC) produces a powerful block of an amygdala-kindled seizure elicited 5-10 minutes after the microinfusion. The most parsimonious explanation of these results is that a recurrent excitatory link between the amygdala and PRC is activated during kindling, thus allowing regenerative, NMDA-dependent excitatory activity to develop. One prediction of this model is that a lesion of the PRC should damage the recurrent circuit and suppress the kindled seizure. In order to test this hypothesis we monitored the effects of creating a functional lesion of perirhinal cortex by infusing procaine (1 μ l, 20%) into the PRC of five fully-kindled Sprague-Dawley rats in which NMDA antagonists had previously produced a seizure-modulating effect. Whereas 1 μ l infusions of both carboxypiperazine-phosphonate (CPP, 1mM) and APV had produced a large and statistically significant reduction in seizure stage and afterdischarge, procaine had only a small and non-significant effect. In contrast, procaine microinfusion into either the deep pyriform cortex (n=6) or the piriform cortex (n=5) of separate groups of fully kindled animals produced significant reductions in both seizure stage and AD duration. The above findings suggest that the relationship between amygdala and PRC is more complex than initially hypothesized. Alternative models of this interaction are currently being developed. Supported by grants from the New Zealand Neurological Foundation.

EFFECT OF NEONATAL CASTRATION AND ANDROGEN TREATMENT ON ELECTRICALLY-INDUCED SEIZURES IN THE ADULT RAT. M.L. Maring¹, R.W. Clough¹ and R.A. Browning. Depts. of Physiology and Anatomy¹, Southern Illinois University, Carbondale, IL 62901.

Gonadal hormones exert marked effects on seizure susceptibility and severity in both humans and experimental animals. Specifically, estrogen has seizure-promoting actions, while progesterone exerts anticonvulsant effects. Testosterone is proconvulsant in some seizure models and anticonvulsant in others. In addition, there are gender-specific differences in seizure susceptibility and severity in adult rats, with females displaying greater seizure susceptibility and severity than males. It is unclear whether gender differences in seizures are due to the activation effects of steroids in the adult brain or to organizational effects of gonadal steroids in the neonatal developing brain. To investigate the role of gonadal hormones during development in gender-specific seizure display of adults, the effects of neonatal castration of male rats and androgen treatment of female rats on minimal electroshock seizure threshold (EST) and maximal electroshock seizure (MES) pattern were determined. Male Sprague-Dawley rat pups were orchidectomized and female pups were given testosterone propionate (TP, 1.25 mg, subcutaneously), 4 days after birth. EST and MES seizure responses were evaluated at >100 days of age. Neonatal castration of males significantly reduced EST from 21.2 mA in intact males to 19.8 mA in castrated males (p<.01). Castration was also found to increase the incidence of tonic hindlimb extension (HLE) in the MES test (100% HLE in castrates vs 50% HLE in intact; p<.05). In addition, castration decreased the latency to HLE (p<.05), providing further evidence of increased seizure susceptibility. With the TP treatment strategy and dose employed, no differences were observed between neonatally androgenized and vehicle-treated females. Thus, it is hypothesized that testicular secretions during the critical period of neonatal development may be necessary for the expression of male-typical seizure patterns in the adult. The lack of an anticonvulsant effect in adult females following neonatal androgen exposure may be due to sexual divergence in brain development occurring prior to 4 days postpartum. Further study is needed to characterize the nature of the development of sexual divergence with respect to seizure behavior.

NMDA & NON-NMDA RECEPTOR INVOLVEMENT IN LOW MG²⁺-INDUCED BURSTING IN HIPPOCAMPAL AREAS CA1 AND CA3. R.F. Berman¹ and C.A. Janusz². Depts. of ¹Psychology and ²OB/GYN, Wayne State Univ., Detroit, MI 48201.

Hippocampal brain slices from rats were used to characterize the effects of magnesium, MK-801, a non-competitive NMDA antagonist, and CNQX, a non-NMDA glutamate receptor antagonist under conditions of low Mg²⁺-induced epileptiform bursting. Removal of Mg²⁺ from the superfusion medium of slices produced spontaneous and triggered bursts in both the CA1 and CA3 areas of the hippocampus, although the overall development and characteristics of bursting were different for the 2 areas. The CA1 area was more sensitive to the re-addition of Mg²⁺ to the bathing medium, as bursting could be inhibited with very low concentrations of Mg²⁺. The amplitude of the population spike (PS) remained elevated even after return to normal Mg²⁺ conditions in both areas indicating the development of LTP. MK-801, at a concentration that did not affect baseline synaptic activity, blocked bursting and LTP, but did not prevent an initial increase in the amplitude of the PS. CNQX blocked bursting as well as the initial increase in the PS. We conclude that an NMDA component, as well as a non-NMDA component, are involved in the enhanced synaptic activity under Mg²⁺-free conditions.

DEGENERATIVE DISEASE: ALZHEIMER'S- β -AMYLOID XI

600.1

A HEPARIN-BINDING DOMAIN IN AMYLOID PROTEIN PRECURSOR (APP) IS INVOLVED IN THE REGULATION OF NEURITE OUTGROWTH. D.H. Small¹, V. Nurcombe², G. Reed¹, H. Clarris¹, N.S. Cheung³, B.G. Livetti⁴, K. Beyreuther⁵ & C.L. Masters¹. Depts. of ¹Pathology, ²Anatomy and Cell Biology and ³Biochemistry, University of Melbourne, Parkville, Vic. 3052, Australia and ⁴Centre for Molecular Biology, Heidelberg, Germany.

While the identification of rare mutations in the APP gene has demonstrated the importance of APP in the pathogenesis of Alzheimer's disease (AD), the precise role of APP has yet to be established. One possibility is that certain forms of the amyloid protein (A β) are neurotoxic. A β 4 and homologous peptides reportedly enhance glutamate-mediated neurotoxicity, whereas intact APP may be neuroprotective. A defect in the normal function or cleavage of APP might therefore contribute to the pathogenesis of AD.

In the present study, substratum-bound APP dramatically increased the rate of neurite outgrowth from sympathetic and hippocampal neurons in culture. This effect was dependent upon the presence of heparan sulfate proteoglycans (HSPGs) purified from postnatal brain. A heparin-binding site was identified close to the N-terminus of APP (residues 96-110), using molecular modeling and site-directed mutagenesis. A peptide homologous to this domain was found to bind strongly to heparin and to block the neurite outgrowth-promoting effect of APP in culture. The results suggest that the binding of secreted APP to HSPGs in the extracellular matrix may stimulate the neurite outgrowth-promoting function of APP. A defect in the ability of APP to bind to HSPGs, perhaps due to defects in proteolytic processing, may contribute to the neurodegenerative process which occurs in AD.

600.2

CHONDROITIN SULFATE PROTEOGLYCAN FORM OF THE ALZHEIMER'S B-AMYLOID PRECURSOR IN BRAIN. D. Vassiliacopoulou¹, J. Ripellino¹, J. Shioi¹, M. Pangalos¹, S. Efthimiopoulos¹, R. Margolis², C. Mytilineou³, N. Robakis⁴. Dept. of ¹Psychiatry and Fishberg Ctr. Neurobiol. and ²Neurol., Mount Sinai Med. Ctr., ³Dept. of Pharmacology, NYU, Med. Ctr. NY, NY. Chondroitin sulfate proteoglycans (CSPG) are molecules with diverse biological functions including cell adhesion and cell-cell communication. Recently we showed that in a glial cell line Amyloid Precursor Protein (APP) exists as the core protein of a CSPG of about 140-250 kDa (Shioi et al., 1992, J. Biol. Chem. 267: 13819). Here we report the existence of CSPG-APP in rat and human brains. Brain tissue was homogenized, centrifuged and the resulting soluble fraction was applied to a DEAE Sepharose column and eluted with NaCl. Samples were digested with chondroitinase ABC and analyzed by SDS-PAGE/western blot using anti-APP antisera. Soluble CSPG-APP was detected and following chondroitinase treatment the high molecular weight PG was completely eliminated with a concomitant increase in the APP protein. To further investigate the cellular origin of CSPG-APP, rat neuronal and glial primary cultures were labelled with ³⁵S-sulfate. Conditioned media were immunoprecipitated with anti-APP antisera and analyzed by SDS-PAGE/fluorography. The CSPG-APP form was detected in glial but not in neuronal cultures. However, since we detected the CSPG-APP in neuroblastoma cell line N2a, we cannot exclude the possibility of neuronal expression for this molecule. Our findings suggest that the PG nature of APP may be important for the implementation of its biological function and may play a role in the development of Alzheimer's disease.

CHONDROITIN SULFATE PROTEOGLYCAN ARE A COMMON COMPONENT OF INCLUSIONS IN NEURODEGENERATIVE DISEASES
D.A. DeWitt, P. Richey, J. Silver, and G. Perry*. Case Western Reserve University, Cleveland, OH 44106

In order to determine whether chondroitin sulfate proteoglycans (CSPG) were present in lesions of Alzheimer's disease (AD), three monoclonal antibodies each to different forms of the chondroitin glycosaminoglycan were used. Sections from methacarn-fixed, paraffin-embedded tissues were treated with chondroitinase ABC to remove glycans and expose the antigenic site. Senile plaques (SP) were identified by Congo red or with antibodies to A β ; neurofibrillary tangles (NFTs) and dystrophic neurites with antisera to τ . Unsulfated chondroitin (1B5) was found in NFTs and dystrophic neurites around SPs. Chondroitin 4-sulfate (2B6), and chondroitin 6 sulfate (3B3) were localized to the extracellular matrix surrounding senile plaques, to dystrophic neurites and to NFTs. No immunostaining was observed when chondroitinase was absent or replaced with heparinase or heparitinase. The enzyme specificity indicates that the antibody binding is specific for chondroitin. We wanted to further describe CSPG immunoreactivity to determine whether it was associated with non-Alzheimer inclusions. Parkinson Lewy bodies and NFTs of progressive supranuclear palsy contained only chondroitin 4-sulfate and chondroitin 6-sulfate, however, diffuse Lewy bodies and Pick bodies contained all three forms of chondroitin. In order to determine whether neuronal CSPGs were associated with dying neurons lacking inclusions, the caudate of a Huntington's patient was examined. Neurons did not show chondroitin immunoreactivity suggesting that neuronal CSPGs were usually associated with inclusions but not always neuronal death. The presence of CSPG and other proteoglycans in many kinds of inclusions and the extracellular matrix of AD suggests a wider role for this family of molecules in the pathogenesis of neurodegenerative diseases. Supported by NIH grants AG 07552 and AG 09287.

POTENTIAL ROLE OF PROTEOGLYCAN IN THE ACCUMULATION AND PERSISTENCE OF β -AMYLOID (A β) IN ALZHEIMERS DISEASE (AD) SENILE PLAQUES. R. Gupta-Bansal, W. Ziebler, J. R. Wujcik* and K. R. Brunden. Gliatech, Inc., Cleveland, Ohio 44122.

The presence of senile plaques is a characteristic pathological feature of AD brain. In addition to large quantities of A β , senile plaques contain other components including chondroitin, heparan and dermatan sulfate proteoglycans. Proteases may exist within the brain whose normal function is to degrade A β before it can form deposits. These proteases may be inhibited by the specific association of plaque components with A β . We have examined the ability of several proteases to degrade A β in the presence of proteoglycans, and find that both chondroitin and heparan sulfate proteoglycans protect A β from proteolytic action. A β and chondroitin/heparan sulfate proteoglycans were allowed to interact at pH 6.5 or 7.4 in 100 mM Tris at room temperature. The mixture was digested for 18 hours at 37°C with either papain or pronase at an enzyme-to-protein ratio of 1:10 (w/w) and analyzed by 16.5% Tris-Tricine SDS-PAGE. Subsequently, the amount of proteolyzed A β was quantitated by densitometry. The data reveal that fibrillar A β is more resistant to proteolytic attack than non-fibrillar peptide. Furthermore, proteoglycans protect A β from degradation to a greater extent when the amyloid peptide is in a fibrillar structure compared to a non-fibrillar form.

Since the source of proteases that might degrade amyloid in the brain has not been identified, it is important to determine which cells secrete proteases that may play a role in A β degradation. We have investigated the ability of astrocyte and microglia conditioned medium to proteolyze A β *in vitro*. Our results suggest that microglia secrete proteases that are capable of degrading A β . Further studies will determine whether proteoglycans protect A β from microglial protease(s).

Interleukin-1 beta alters the degree of sulfation of heparan sulfate proteoglycan in endothelial cells and may contribute to the process of amyloidosis in blood vessels.

Jesse G. Eisler^{1,2}, Beatrice Leyeveugle², Van Hong Ding², Howard Fillit^{1,2}, Fishberg Center for Neurobiology¹, and the Department of Geriatrics², Mount Sinai School of Medicine, One Gustave L. Levy Place, New York, NY 10029

The glycosaminoglycan components of proteoglycans contain variable numbers of sulfate groups which confer some of the special binding properties of proteoglycans. Recently, it has been shown that the binding of the A β peptide to heparan sulfate proteoglycan (HSPG) may be mediated by the sulfate groups on HSPG (Fraser et al., J. Neurochem. 59:1531, 1992; Buee et al., Brain Res. 601:154, 1993). We examined the role of interleukin-1 β (IL-1 β) on the level of sulfation of proteoglycans secreted from endothelial cells grown in culture. Mouse aortic endothelial cells were grown to confluence in DMEM medium with 10% fetal calf serum. The medium was then replaced by serum free medium and the cells labelled with ³⁵S Na₂SO₄ (10 μ Ci/ml) and IL-1 β (10 ng/ml) for 48 hours. The cell culture medium was removed dialyzed against 7M urea, 0.15 M NaCl, 0.05 M NaOAc, 0.5% CHAPS, pH 6.0. The samples were then analyzed by ion-exchange chromatography with DEAE Sepharose CL-6B using a linear salt gradient from 0.15 M NaCl to 2.0 M NaCl. IL-1 β added to endothelial cells significantly altered the DEAE elution profile of proteoglycans secreted into the supernatant. In controls, two peaks were obtained at 0.33 M (peak A) and 0.45 M NaCl (peak B). IL-1 β caused a shift in the elution of peak A to 0.28 M NaCl and a shift in the elution of peak B to 0.5 M NaCl. The difference in the level of salt elution can be explained by an alteration in the level of sulfation of these molecules. Specific changes in sites of sulfation may alter the affinity of the heparan sulfate proteoglycans from capillary endothelial cells for the A β peptide and promote vascular amyloidogenesis.

β -AMYLOID PRECURSOR PROTEIN IS A HEPARAN AND CHONDROITIN SULFATE PROTEOGLYCAN IN BRAIN.

Olga Salinero, Maria Araujo, Juan José Garrido, Laura M. Lopez-Mascarague* and Francisco Wandosell.

Neurodegeneration Group, Inst. Cajal. Avd. Dr. Arce 37 CSIC Madrid 28002 Spain

Extracellular deposition of β 4A amyloid peptide is the most important feature of Alzheimer disease, and could be the base of neuronal degeneration. The β 4A is derived from a family of membrane glycoproteins, termed amyloid precursor proteins (APP). After glycosylation APP's are cleaved at the extracellular portion and secreted. We wish to analyze glycosylation of APP's in normal brain, and how after brain injury, these modifications can change. First, we have analyzed the glycosylation state of the APP in normal adults rat brains. We have selected APP using affinity chromatography from soluble and membrane fractions, from hippocampi and total brain. These fractions were treated with several glycosidases and analyzed by Western-blots with some antibodies against different regions of APP. Our data show clearly the presence of two populations of APP, chondroitin and heparan sulfate proteoglycans. Second, we have studied the expression of APP after controlled hippocampal damage, by intraventricular injection of glutamate analogs. We have used different antibodies against APP, in order to follow the time-course of the damage-induced APP expression. The number, intensity and the type of the labelled cells were different depending on the glutamate analogs used. The glycosylation pattern obtained from these damaged tissue show some differences from control brains. Supported by grants from CAM92/90 and DGYCT PB90-0160. O.S. is supported by a fellowship from M.E.C.

INFLAMMATORY FACTORS WHICH ALTER THE METABOLISM OF PROTEOGLYCAN THAT BIND A4 PEPTIDE MAY PROMOTE AMYLOIDOGENESIS. B. Leyeugle, L. Buee, W. Ding and H. Fillit*. Department of Geriatrics, Mt Sinai Medical Center, New York, NY 10029

High binding affinity occurs between APP/A4 and heparan sulfate proteoglycans (PGs). Although these interactions may have a physiologic function in regulating cell adhesion or neurite outgrowth, the pathophysiologic events which lead to codeposition of A4 and PGs into amyloid plaques are not known. We hypothesized that PG metabolism may be altered in Alzheimer's disease (AD) as a result of the acute phase response in AD brains. Thus, we investigated whether IL-1 and NGF alter the metabolism of neuroblastoma PGs which bind A4. PGs were purified by anion exchange chromatography on a DEAE column. The chromatograms showed that the net charge of PGs secreted into the culture medium or associated with the cells is increased after stimulation of the cells with IL-1 or NGF. In addition, the amount of PGs secreted into the culture medium increased whereas there is no such change in the cell associated PGs. Change in PG sulfation may alter PG binding affinity to A4 and enhance alternative APP proteolysis and amyloidogenesis. Increased secretion of PG induced by NGF/IL-1 may promote extracellular accumulation of amyloid.

β -AMYLOID PEPTIDE INTERACTION WITH GLYCOSAMINOGLYCAN. K.R. Brunden, N.J. Richter-Cook, N. Chaturvedi, and R.C.A. Frederickson. Gliatech Inc., Cleveland, Ohio 44122

The senile plaques found within Alzheimer's disease brain contain proteoglycans in addition to β -amyloid peptide (A β). Here we have examined the ability of synthetic A β peptides to bind to the glycosaminoglycan (GAG) moieties of proteoglycans. Both A β (1-28) and A β (1-40) associate with heparan sulfate and chondroitin sulfate, and the interaction of GAGs with these peptides results in the formation of large aggregates that sediment upon centrifugation. The precipitation of the amyloid peptides with GAGs is pH-dependent, with increasing interaction as pH values fall below neutrality. In addition, A β (1-28) interacts with a heparin affinity column at pH 4.0 but not at pH 8.0. The pH profile of A β -GAG association suggests that a consensus heparin-binding domain that contains histidine residues at positions 13 and 14 of A β may be the site of binding. The binding of GAGs to A β appears to be ionic in nature, as dextran sulfate associates with A β (1-28) whereas dextran does not. The interaction of GAGs with a defined motif of A β may be relevant to the etiology and pathology of Alzheimer's disease.

600.9

HEPARAN SULFATE PROTEOGLYCAN (HSPG) CORE PROTEIN IN SENILE PLAQUES AND CEREBROVASCULAR AMYLOID OF AGED MONKEYS.

L.C. Walker¹ and H.M. Fillit². ¹The Johns Hopkins Univ. Sch. of Med., Balto., MD 21205 and ²Mt. Sinai Medical Center, New York, NY 10029.

HSPG, a component of the vascular basal lamina, is associated with some amyloid deposits in Alzheimer's disease (AD) and Down's syndrome (Snow et al., *Am. J. Pathol.* 137:1253, 1990). HSPG binds with high affinity to β -amyloid (A β) and to some isoforms of the A β precursor protein (Buee et al., *Brain Res.* 601:154, 1993; Nanindrasorasak et al., *J. Biol. Chem.* 266:12878, 1991) and, thus, may be involved in the deposition of A β in the cores of senile plaques and in cerebral blood vessels. To determine whether HSPG is associated with A β in nonhuman primates, we used a monoclonal antibody (7E12) to the core protein of HSPG and a polyclonal antibody that recognizes both the core protein and HS glycosaminoglycans to stain tissues from three aged rhesus monkeys (*Macaca mulatta*) and one aged squirrel monkey (*Saimiri sciureus*). In rhesus monkeys, HSPG immunoreactivity was associated with a subset (~25%) of senile plaques, cerebrovascular A β , and diffuse A β . Preabsorption of 7E12 with purified basal lamina HSPG eliminated immunoreactivity associated with A β and with the vascular basal lamina. In the squirrel monkey, A β -associated HSPG was stained only by the polyclonal antibody. Because, in monkeys as in humans with AD, HSPG is in mature and diffuse plaques, these data indicate that HSPG deposition occurs in the early stages of amyloidogenesis and is persistent. The absence of staining for this specific basal lamina HSPG core protein in many lesions suggests that this molecule may characterize a subset of A β deposits with a unique cellular origin. Aged monkeys may be a useful model to study these issues as well as the possible role of HSPG in the formation of senile plaques and cerebrovascular amyloid.

CYTOSOLIC APPS ARE DECREASED FOLLOWING EXCITOTOXIC INSULT. L. Kent, C. Zobre, M. Lewis, M. Kelley, M. Miller, D. DeHaven-Hudkins, L. Fleissner, K. Rogers*. Sterling Winthrop Pharmaceuticals Research Division, Collegeville, PA 19426.

A hallmark of Alzheimer's Disease (AD) is neuronal degeneration in association and temporal cortex. These regions contain glutaminergic neurons which appear to degenerate in AD, possibly as a result of excitotoxic insult. We hypothesized that excitotoxic damage might alter APP processing, leading to A β deposition. This hypothesis was tested by treating mouse cortical neuronal cultures with 500 μ M NMDA for 0.5 hr and quantifying APPs by Western blot analyses using APP C-terminal directed antisera. A rapid 2-fold decrease in cytosolic APPs was observed at times which preceded markers of neuronal injury (ie. LDH release). MK801 prevented both the decrease in cytosolic APPs and the subsequent neuronal injury. Decreases in APPs were concentration and time-dependent. Similar decreases in membrane associated APPs were observed. Future studies will determine whether the decreases in APPs following injury are associated with concomitant increases in A β 4 or other APP fragments.

MICROTUBULE-ASSOCIATED PROTEIN 2-LIKE IMMUNOREACTIVITY IN SENILE PLAQUES OF ALZHEIMER DISEASE BRAIN. O. Yasuhara, I. Tooyama, T. Kawamata, K.

Hanai¹, H. Kimura¹, P.L. McGeer, and E.G. McGeer*. Kinsmen Laboratory of Neurological Research, University of British Columbia, Vancouver, Canada, V6T1Z3; ¹Institute of Molecular Neurobiology, Shiga University of Medical Science, Otsu, Shiga, Japan

Immunohistochemical localization of microtubule-associated protein 2 (MAP2) was examined in Alzheimer disease and control brain, using two monoclonal antibodies to MAP2. Staining of neuronal cell bodies and dendrites was observed in both Alzheimer disease and control brain, which was abolished by pretreatment of sections with trypsin. Senile plaques in Alzheimer brain tissue were labeled by only one of the antibodies to MAP2. The MAP2 staining of plaques, but not somatodendrites, was dramatically enhanced by formic acid pre-treatment of sections. However, plaque staining was relatively resistant to trypsin digestion, indicating reduced accessibility of the epitope incorporated into amyloid deposits. By a combination of pretreatment with formic acid and a low concentration of trypsin, all plaques, as well as diffuse amyloid deposits, became immunoreactive for an epitope of MAP2. Neurofibrillary tangles, dystrophic neurites and neuropil threads were not labeled with either antibody. The present study indicates that a MAP2 fragment is incorporated into amyloid deposits at an early stage of their formation. The data provide supporting evidence in favor of a neuronal origin of plaque amyloid.

FATE OF MEMBRANE-ASSOCIATED FORMS OF THE AMYLOID PROTEIN PRECURSOR (APP) OF ALZHEIMER'S DISEASE IN HUMAN PLATELETS DURING ACTIVATION. Q.-X. Li, M. Berndt, A. Friedhuber, K. Bevreuther and C. L. Masters*. Departments of Pathology, The University of Melbourne, and the Mental Health Research Institute of Victoria, Australia; The Baker Research Institute, Melbourne; Center for Molecular Biology, University of Heidelberg, Germany

Alzheimer's disease (AD) is characterized pathologically by the deposition of A β 4 protein which is proteolytically derived from part of the transmembrane domain of APP by an unknown mechanism. Study of the structure and function of the membrane-associated forms of APP may help to elucidate this process. We have shown that human platelets contain full-length APP in addition to abundant soluble APP. Full-length APP containing the A β 4 sequence is of interest as it may contribute to A β 4 amyloidogenesis. Immuno-electron microscopy showed APP to be localized in α -granules as well as on the cell surface. Surface labeling with iodine showed both the full-length APP and the C-terminal truncated APP were present on platelet surface. Labelled [¹²⁵I]-mAb 22C11 was used to demonstrate a 2.5-fold increase surface expression of APP during thrombin activation of platelets. Activation by thrombin also resulted in the loss of the cytoplasmic domain of the full-length APP. The precise cleavage site is yet to be determined. Studying the metabolism of the amyloid containing APP species in platelets may give insight into the metabolism of APP in neurons.

600.12

AN HYPOTHESIS CONCERNING DISTURBED AXOPLASMIC FLOW AS A COMMON PATHOGENIC MECHANISM LINKING AMYLOID GENESIS AND TANGLE FORMATION IN ALZHEIMER'S DISEASE. K. Shigematsu¹, E.G. McGeer², H. Sugiyama¹, Y. Kamioka¹, and P.L. McGeer². ¹Dept. Neurol., Natl. Minami Kyoto Hospital, Kyoto, Japan, and ²Kinsmen Laboratory of Neurological Research, Univ. of B.C., Vancouver, B.C., Canada.

The relationship between the two pathological hallmarks of Alzheimer's disease, intracellular neurofibrillary tangles and extracellular amyloid deposits is still a mystery. Tangles are characterized by argenophilicity and Alz-50 positivity, while amyloid deposits are characterized by accumulations of β -amyloid protein, derived from the amyloid precursor protein (APP). We hypothesized that a disturbance of axoplasmic flow may be the common pathogenic mechanism linking these main two pathological entities. To test this hypothesis, we injected kainic acid, colchicine or aluminum salts into rat brain as independent methods of damaging neurons and interfering with axoplasmic flow. We then examined brain sections by silver staining and by immunohistochemical staining for APP and Alz-50. In each case, affected neurons accumulated APP within hours and often showed Alz-50 immuno-positivity as well as an argenophilic reaction. After several days, APP immunoreactivity was seen extraneuronally, some within phagocytosing reactive microglia. These results support the hypothesis that an interference with axoplasmic flow could link cytoskeletal abnormalities and APP accumulation. Microglia may also play a role in disposing of excess neuronally produced APP. However, in these animal models, no production of β -amyloid protein from APP was noted.

IDENTIFICATION OF PROTEINS THAT BIND THE CYTOPLASMIC DOMAIN OF AMYLOID PRECURSOR PROTEIN.

L. A. Flanagan* and T. Saitoh. Dept. of Neuroscience, UCSD, La Jolla, CA 92093.

Much remains to be learned about the function, processing, and intracellular targeting of amyloid precursor protein (APP). Since APP is a transmembrane protein, intracellular proteins that bind its cytoplasmic domain will be critical for these biological processes. For example, APP has been suggested to interact with the cytoskeleton and has been shown to undergo endocytosis; both of which require binding to intracellular proteins. For this reason we have developed a system to identify proteins from a variety of sources, including human brain, that specifically bind the cytoplasmic domain of APP in biochemical assays. Utilizing a bacterial expression system we have produced the cytoplasmic domain of APP as a fusion protein with protein A, which enables a rapid purification of the protein for binding experiments. Purified, radiolabelled fusion protein has been used as a probe in blot overlay experiments. In addition, unlabelled fusion protein has been immobilized on columns for affinity chromatography. Preliminary evidence utilizing protein A as a negative control indicates that these methods will allow us to identify proteins that specifically bind to the cytoplasmic domain of APP. The analysis of these proteins will enable us to further reveal the biochemical mechanisms underlying the biological activity of APP.

CHANGES IN THE $\text{Na}^+/\text{Ca}^{2+}$ EXCHANGER GENE EXPRESSION IN AGING RAT BRAIN AND IN HUMAN BRAINS WITH ALZHEIMER'S PATHOLOGY. V. Janapsati*, L. Yu and R.A. Colvin. Department of Biological Sciences, Ohio University College of Osteopathic Medicine, Athens, OH-45701.

$\text{Na}^+/\text{Ca}^{2+}$ exchanger plays critical role in regulating the Ca^{2+} homeostasis in excitable cells like neurons and myocytes. Alterations in the $\text{Na}^+/\text{Ca}^{2+}$ exchange activity can be responsible for the functional deterioration of the cells in aging and disease. We have initiated studies on the expression of the exchanger in aging rat brain and in human brains with Alzheimer's pathology. Based on the published cDNA sequence for the human heart $\text{Na}^+/\text{Ca}^{2+}$ exchanger (Komuro I. *et al.*, PNAS 89, 4769-4773) we have generated a probe by PCR. RNA and DNA probes were used to perform the analysis of the RNA preparations made from rat brains of different ages from 6 months to 24 months of age and also in normal human brains and brains with Alzheimer's pathology. Northern blot analysis of the total RNA extracted from whole rat brain (Sprague-Dawley) reveals the presence of two transcripts for the exchanger corresponding to sizes 15kb and 7kb. In cerebral cortex the two transcripts are almost in equal intensity at all the ages studied (6, 12, 18 and 24 months) and no significant age dependent change in the intensity of the bands is observed. In cerebellum the 7kb transcript is predominant at all the ages and it appears to decrease with age. The 15kb transcript is clearly seen only at 12 months of age. No transcripts were identified on northern blots with RNA from human brain tissues. We suspect that the exchanger levels may be either lower than detectable or that the RNA prepared from postmortem tissue was degraded. We performed RNase protection assay with human brain RNA preparations with cRNA probes for the exchanger and beta actin. We observed that the ratio of exchanger/actin is lower in Alzheimer's brain compared to that of age matched normal brain. These preliminary studies have shown evidence of changes in gene expression for the $\text{Na}^+/\text{Ca}^{2+}$ exchanger in normal aging and Alzheimer's disease.

601.3

LEVELS OF GAP-43 MESSAGE IN ANTERIOR CEREBELLUM APPEAR UNCHANGED IN ALZHEIMER'S DISEASE COMPARED TO CONTROLS. J.E. Cheetham, M.R. Martzen*, L. Callahan and P.D. Coleman. University of Rochester School of Medicine and Dentistry, Dept. of Neurobiology and Anatomy, Rochester, NY 14642.

We have found that decreased GAP-43 message in frontal association cortex-area 9 is associated with increased density of neurofibrillary tangles (NFTs), (Coleman *et al.*, 1992). This finding leads to the hypothesis that decreased GAP-43 message in AD is related to NFTs, rather than to some other aspect of AD pathology. Therefore, we predicted that in areas of brain unaffected by NFTs in AD the GAP-43 message levels should be similar to those of controls. The cerebellum is known to have a number of pathologies of AD, including diffuse plaques, microglial activation and reactive astrocytes, however, NFTs are not found in cerebellum. mRNA was extracted from anterior cerebellum and hybridized with a GAP-43 probe which was obtained by polymerase chain reaction from a human brain cDNA library. Normalization probes of poly dT and G3PDH were obtained from Pharmacia and Clontech respectively. To quantify message levels, aliquots of mRNA were slot blotted and hybridized with the appropriate probe. Autoradiograms were quantified by scanning laser densitometry. In cases examined to date, GAP-43 message levels in the anterior cerebellum of Alzheimer's cases appear to be not statistically different relative to age matched controls.

These data are consistent with NFTs playing a role in modulating the expression of GAP-43. Preliminary data from combined IHC for identification of tangle bearing neurons and ISH for localization of GAP-43 message (see abstract by Callahan *et al.*) confirms and supports this conclusion.

CYTOKINE INDICES IN ALZHEIMER'S DISEASE BRAIN: INCREASES IN IL-6 AND THE ASSOCIATED ACUTE PHASE PROTEINS; ALPHA 2-MACROGLOBULIN AND C-REACTIVE PROTEIN. Julie A. Wood*, Paul L. Wood, Neill Graff-Radford, Randall Ryan, Carmencita Pilapil, Remi Quirion, and Yves Robitaille. Dept. Neurology, Mayo Clinic Jacksonville, FL; Douglas Hospital Research Centre, Montreal.

Recent immunocytochemical data have demonstrated increases in interleukin- 1β (IL- 1β), interleukin-6 (IL-6), and the acute phase protein, $\alpha 2$ -macroglobulin ($\alpha 2$ -M), in Alzheimer's disease (AD) brains. Therefore, we investigated the levels of these proteins and determined if increases in IL- 1β were compensated for by a parallel increase in the endogenous interleukin-1 receptor antagonist (IL-1RA). Mature IL- 1β , IL-1RA, IL-6, $\alpha 2$ -M and C-reactive protein (CRP) levels were compared in control vs AD brains via ELISA. There were no differences in the levels of mature IL- 1β or IL-1RA. However, IL-6 levels were detected in 14 of 16 Alzheimer samples but only 2 of 14 control samples. Significant increases were also seen in $\alpha 2$ -M and CRP levels in the AD group. These data further support the hypothesis of a possible up-regulation of neuroimmune function in AD, however, it is not clear if this reaction is initiated by IL- 1β .

601.2

GAP-43 MESSAGE IS DECREASED IN TANGLE-BEARING NEURONS OF ALZHEIMER'S DISEASE (AD) PARAHIPPOCAMPAL GYRUS (Callahan, L.M.*, Cheetham, J.E., Selski, D., Martzen, M.R. and Coleman, P.D., University of Rochester Medical Center, Neurobiology and Anatomy, Rochester, NY 14642).

Our lab recently reported a decrease in Gap-43 message, based on slot blot analysis, in superior frontal gyrus of AD patients containing high neurofibrillary tangle (NFT) densities (Coleman *et al.*, 1992). This suggested tangle-bearing neurons contained a decreased level of Gap-43 message.

The study reported here combined immunocytochemistry for NFTs with *in situ* hybridization for Gap-43 message on the same tissue section. NFT-bearing neurons were identified and their grain density (for Gap-43 message) compared to that of non-tangle bearing neurons within the same microscopic field. Gap-43 message appeared dramatically decreased in a majority of tangle-bearing neurons compared to non-tangle bearing neighbors in parahippocampal regions of AD patients. Preliminary semiquantitative analysis of tangle-bearing neurons indicated 80% showed a decrease in Gap-43 message level.

Study of neurodegenerative diseases is challenged by the need to identify the neurons actually affected by the disease. In AD, neurons containing tangles often appear next to neurons which morphologically appear healthy. Decreased Gap-43 in tangle-bearing neurons may indicate a subpopulation of neurons exhibiting decreased plasticity in AD. ALTERATIONS IN GROWTH-ASSOCIATED PROTEINS OCCUR EARLY IN ALZHEIMER'S DISEASE. E.Masliyah*, M. Mallory, M. Alford, T. Saitoh. Dept. Neurosciences, University of California, San Diego, La Jolla, CA 92093-0624

Although significant information is now available as to the possible progression of the neuropathological alterations in Alzheimer's disease (AD), the molecular events that occur in early stages of AD are not well known. We hypothesize that alterations in the patterns of expression of growth-related proteins occur early in the development of AD, and that they are related to the synaptic pathology in the hippocampus in early stages of AD. In order to test these hypotheses, we compared the relative levels and distribution of growth-related proteins and their mRNA in cases with incipient, mild and advanced AD. Cases with incipient AD presented increased amyloid precursor protein (APP), growth-associated protein 43 and platelet-derived growth factor (PDGF) immunoreactivity in the entorhinal cortex and hippocampus. These cases also displayed minimal cognitive alterations, variable numbers of diffuse amyloid deposits, tangles in the entorhinal region, and mild synaptic loss in the outer molecular layer of the hippocampus. Cases with mild and advanced AD presented moderate to severe synaptic loss in the hippocampus and neocortex. Furthermore, the antibody against PDGF-BB and p105 (a nuclear protein associated with proliferation and plasticity) immunolabeled the neurofibrillary tangles and neuritic plaques in the different stages of AD. *In situ* hybridization studies with digoxigenin-labeled oligo probes (40 mer) also showed increased message for APP and PDGF in cases with incipient AD. The involvement of growth-associated proteins in AD favors the possibility that in the early stages of the disease and abnormal sprouting response is mounted in response to the ongoing synaptic and cytoskeletal alterations.

BRAIN S-ADENOSYLMETHIONINE DECARBOXYLASE ACTIVITY IS INCREASED IN ALZHEIMER'S DISEASE.

Lesley D. Morrison*, Catherine Bergeron and Stephen J. Kish. Human Neurochemical Pathology Lab, Clarke Institute of Psychiatry and Center for Research in Neurodegenerative Diseases, Toronto, Ontario, Canada.

We measured the activity of S-adenosylmethionine decarboxylase (SAMDC), a key regulatory enzyme of polyamine biosynthesis, in autopsied brain from 13 patients with Alzheimer's Disease (AD). As compared with controls, mean enzyme activity was increased by 37 to 96% in all seven examined brain regions with statistically significant increases in temporal cortex (+96%), frontal cortex (+69%) and hippocampus (+90%). The elevation in SAMDC activity may have occurred as part of a generalized polyamine response to brain injury, which has been previously described in experimental animal conditions. Above-normal SAMDC activity implies increased levels/metabolism of spermidine and spermine, two polyamines which are involved in neuronal regeneration, growth factor production, and activation of excitatory N-methyl-D-aspartate-preferring glutamate receptors. Our data suggest the involvement of the polyamine system in the brain reparative and/or pathogenetic mechanisms of AD.

601.7

MEASUREMENT OF PHENYLETHANOLAMINE-N-METHYLTRANSFERASE mRNA, PROTEINS AND METABOLITES IN SAME SAMPLE. W.J. Burke*, C.A. Schmitt, K.N. Gillespie, R. Strong, V. Reddy, T.H. Joh, D.H. Park. Dept. Neurol., St. Louis U. Med. Sch., St. Louis, MO 63110; Cornell U. Med. Col, White Plains, NY 10605.

Measurement of specific mRNA, proteins and metabolites in scarce samples obtained from brain banks poses a problem for Alzheimer's disease investigators. Homogenizing buffer optimal for one compound may prevent measurement of others. A simple way to overcome this obstacle is to pulverize frozen tissue to a fine powder and use aliquots for different assays. However, are aliquots comparable for compounds unevenly distributed in the tissue? The adrenal provides a model to test this since all phenylethanolamine-N-methyltransferase (PNMT) protein, mRNA and metabolites are in the medulla. Adrenals, mortar and pestle were frozen overnight at -80C. Tissue was pulverized to a fine powder and replicate assays of 3-5 aliquots performed for PNMT mRNA by PCR, PNMT protein by Western blot and metabolites by hplc-ec. Differences between measurements in each aliquot were analyzed using a one way ANOVA. There was no difference between aliquots in the quantitation of PNMT mRNA, PNMT protein or epinephrine (Epi). For norepi one aliquot differed from one of the other and for dopamine two aliquots differed from two of the other samples using a Tukey HSD test. Pulverized frozen tissue can be used to measure mRNA, protein and major metabolites in the same sample. More efficient use of scarce tissue samples will result.

601.9

DECREASED ACTIVITIES OF THIAMINE MONOPHOSPHATASE (TMPase) AND THIAMINE DIPHOSPHATASE (TDPase) IN TEMPORAL CORTEX OF PATIENTS WITH ALZHEIMER DISEASE (AD) V.L. Raghavendra Rao and R.F. Butterworth*. Neuroscience Research Unit, Hop. St. Luc (University of Montreal), Montreal H2X 3J4, Canada.

Thiamine in the form of its diphosphate ester (TDP) is an essential cofactor for α -ketoglutarate dehydrogenase, pyruvate dehydrogenase in the TCA cycle and transketolase in the pentose phosphate pathway. Decreased activities of these three enzyme systems (Butterworth RF and Besnard, AM, Metab. Brain Dis., 5, 179, 1990) and a characteristic deficit of glucose utilization (Friedland et al., Neurosci. Lett., 53, 235, 1985) were reported in autopsied temporal cortex samples from patients with AD. These changes may be due to decreased availability and/or metabolism of thiamine and its phosphate esters. We now report decreased activities of TMPase and TDPase in temporal cortex samples obtained at post-mortem from seven patients with confirmed AD compared to age, sex and post-mortem time matched control subjects.

	Control (7)	Alzheimer (7)
TMPase	1.07 \pm 0.10	0.37 \pm 0.05*
TDPase	1.00 \pm 0.12	0.47 \pm 0.04*

Units: μ moles Pi liberated/mg protein/hr. * p<0.05.

Decreased activities of these enzymes and the consequently decreased synthesis of thiamine esters could explain the previous finding of decreased activities of thiamine-dependent enzymes in the brains of AD patients. (Funded by the Medical Research Council of Canada).

ANALYSIS OF THE cAMP SIGNAL TRANSDUCTION PATHWAY IN OLFACTORY NEUROBLASTS FROM ALZHEIMER'S DISEASE AND CONTROL DONORS. I. Little*, J. Basaric-Keys, R. S. Lebovics, M. Cantillon, T. Sunderland, and B. L. Wolozin. Section on Geriatric Psychiatry, Laboratory of Clinical Science, NIMH, Bethesda, MD 20892.

Recent studies (e.g. Cowburn, R. et al. *J. Neurochem* 58:409) have demonstrated G-protein abnormalities in signal transduction in Alzheimer's disease (AD) brain. Our investigations of amyloid precursor protein (APP) processing in olfactory neuroblasts (ON) obtained from AD patients show large increases in the amount of APP C-terminal derivative detectable on immunoblot. These changes can be reversed by treatment of the cells with cAMP agonists, which raises the possibility that the cAMP signal transduction pathway is altered in AD. In order to examine this issue we have begun analyzing this pathway in ON. Initial analysis indicates that basal cAMP levels are reduced by 67% in AD, which is consistent with comparisons of cAMP levels in postmortem AD and control brain tissue (Ohm, T. et al. *Brain Res* 540:229). This suggests that the abnormalities in APP metabolism may stem from changes in second messenger pathways. We are currently extending these studies by using GTP γ S and forskolin to probe Gs and adenylate cyclase activity respectively.

601.8

CORRELATION OF NAA AND NAAG LEVELS WITH SEVERITY OF ATROPHY IN ALZHEIMER'S AND HUNTINGTON'S DISEASE BRAIN. L. A. Passani*, R. E. Carter and J. T. Coyle, Dept. of Psychiatry, Harvard School of Medicine / MGH, Boston, MA 02129.

Excitotoxicity caused by elevated glutamate (GLU) levels may account in part for the neurodegeneration observed in Huntington's (HD) and Alzheimer's disease (AD). Previous studies have shown increased GLU levels in affected regions of AD brain (Mc Clure, et al., 1991) and in HD cerebrospinal fluid (Perry et al., 1992). It has been suggested that N-Acetyl-Aspartyl-Glutamate (NAAG), a putative neuromodulator in glutamatergic pathways, may also act as a GLU precursor, liberating GLU from NAAG via N-Acetylated Alpha-Linked Acidic Dipeptidase (NAALADase) at certain synapses. We therefore predicted excitotoxic GLU may originate in part from NAAG, hence, decreased NAAG levels, representing increased catabolism, would directly correlate to the severity of atrophy in AD and HD brain. In our present study, levels of N-Acetyl-Aspartate (NAA) and NAAG were determined by HPLC in three different regions of HD, AD and control brains (brains obtained from Mc Lean and MGH Alzheimer's Brain Bank). The degree of atrophy in individual samples was assessed by microscopic examination and by postmortem NAA levels. In AD, preliminary results indicate correlations between severity of atrophy and decreases in NAAG levels in hippocampus, amygdala and occipital cortex whereas in HD significant decreases were observed only in the putamen. Similar patterns of reduction found for NAA suggest that the NAAG and NAA decreases may be in part due to neuronal loss. To further investigate the mechanisms underlying NAAG reductions, we will determine GLU levels and NAALADase activity.

601.10

AGE DEPENDENT ALTERATIONS OF PHOSPHOMONOESTER LEVELS UNDER CHRONIC AND ACUTE HYPOXIA IN FISCHER 344 RATS. K. Panchalingam, J.W. Pettegrew. Lab. of Neurophysics, Univ. of Pittsburgh, Pittsburgh, Pa 15261.

Recent biochemical and clinical observations suggest that repeated energetic stress, could in some individuals, trigger molecular and metabolic mechanisms that result in the biochemical findings in the brains of Alzheimer's disease (AD) patients. In this study we report findings of age related changes of phosphomonoester (PME) levels in rats subjected to mild chronic and acute hypoxia. The chronic hypoxia animals were subjected to 30 seconds of 100% N₂ environment every day for two weeks. The acute hypoxia animals were subjected to a single episode of 30 seconds hypoxia. Among the PME's measured, a significant elevation of phosphoserine (PS) was observed in 1 month old animals subjected to chronic and acute hypoxia. However, there was no alteration of PS in 24 month old animals. Phosphoethanolamine (PE) and phosphocholine (PC) were unaltered in either age group. The chronic and acute hypoxia animals differ mainly in the change in ATP level. In animals subjected to chronic hypoxia, the ATP level was not significantly affected in younger group but decreased in older group subjected to chronic hypoxia. In animals subjected to acute hypoxia, ATP level was not altered in either age group. These results indicate that there is possible link between brief, mild hypoxia and altered membrane metabolism without significantly altering energy metabolism in young rats. The decrease in ATP levels in 24 month old animals under chronic hypoxia indicates that aged animals are more susceptible to energetic stress than young animals.

IMPAIRED ENERGY METABOLISM IN AGING AND ALZHEIMER'S DISEASE. E. M. Mutisya, A. C. Bowling, L. C. Walker, D. L. Price, L. C. Cork, L. Vecsei*, and M. F. Beal. Neurochemistry Lab., Neurology Service, Massachusetts General Hospital and Harvard Medical School, Boston, MA 02114 and Neuropathology Lab., Departments of Pathology, Neurology, and Neuroscience, and Division of Comparative Medicine, Johns Hopkins Univ. Sch. of Med., Baltimore, MD 21205.

Energy defects may play a role in aging and age-associated neurodegenerative diseases. Several studies revealed age-related impairments in the activities of some electron transport chain enzymes in rat brain and human myocytes. Studies have also shown reductions in several metabolic enzymes in patients with Alzheimer's disease (AD). To date, however, no one had shown age-related changes in energy metabolism in primate brain or systematically examined electron transport chain activity in AD patients.

In this study, we examined activities of all the oxidative phosphorylation enzyme complexes (I, II-III, IV, and V) in the frontoparietal cortices of 20 rhesus monkeys. We found significant age-dependent decreases in complex I and complex IV activities. Complexes II-III and V activities showed no significant changes. Complexes I and IV therefore appear vulnerable to changes with age.

We also examined activities of the aforementioned enzymes in postmortem frontotemporal cortical tissue from approximately 20 AD and 20 age-matched control patients. Although significant impairment of complex IV activity in AD patients was observed, similar decreases in the activities of complexes I, II-III, and V were not seen. A specific defect may therefore be associated with AD.

601.13

Up-regulated transcription of carboxyl methyltransferase gene in Alzheimer's disease brain. **H. Mori***, **T. Shirasawa***, **H. Takahashi***, **R. Endoh**, **K. Sakamoto***, **Y.-X. Zeng*** and **K. Hirokawa*** Department of Molecular Biology, Tokyo Institute of Psychiatry, 2-1-8 Kamikitazawa, Setagayaku, Tokyo 156, Japan*Tokyo Metropolitan Institute of Gerontology, Tokyo 173, Japan.

In order to isolate genes specifically or characteristically expressed in AD brain, we undertook the differential screening of an embryonic brain cDNA library with ³²P-cDNA prepared from AD brain and control brain. We isolated 17 genes and identified them as embryonic α -tubulin, embryonic β -tubulin, hn RNP, carboxyl methyltransferase (CMT), ferritin heavy chain, type IV collagen, cofilin, profilin and 9 novel sequences. First of 17 genes, we extensively investigated CMT gene because of its constant high up-regulation of mRNA in AD, Down syndrome and aged brains. CMT gene was expressed in an age-dependent manner in the brain tissue. A confocal imaging study conducted with both anti-CMT and anti-PHF antibodies unexpectedly showed the close association of CMT with NFTs, somata of degenerative neurons and neuropil threads. This suggested that factor(s) of the repair/degeneration system accumulated on racemized protein deposits in neurofibrillary tangles. The present observation was in good agreement with the previous finding that ubiquitin was a component involved in a collection system in neurofibrillary tangles. We discuss the possible function of CMT in AD brains in related to the well-known function wherein CMT catalyzes the reformation of D-amino acid in abnormally modified proteins. Taken together with the localization of CMT in degeneration neurons and their neuropil threads other than neurofibrillary tangles, it is likely that CMT plays a significant role in the pathogenesis of AD and aging.

601.15

EFFECT OF ETHANOLAMINE ADMINISTRATION ON PLASMA AND BRAIN EXTRACELLULAR FLUID (ECF) CHOLINE LEVELS IN AWAKE RATS. **D.L. Marshall**, **E. De Michel*** and **R. J. Wurtman**, Dept. Brain & Cognitive Sciences, M.I.T., Cambridge, MA 02139, U.S.A.

Ethanolamine (ETH) levels have been shown (Nitsch *et al.*, Proc. Natl. Acad. Sci. 89, 1671-1675, 1992) to be reduced in brains of patients with Alzheimer's disease. The sources of brain ETH and the results of its administration are poorly known. We thus studied the effects of ETH administration on plasma and brain ECF ETH and choline (Ch) levels using microdialysis of awake rats. ETH was administered (i.p.) at doses of 1, 5 or 10×10^{-3} m/kg, and plasma and microdialysate samples were analysed for ETH and Ch using HPLC. Plasma ETH peaked 5-10 min after administration, at 260 times the basal value [72.7 ± 4.1 pm/100ml plasma] after the 10×10^{-3} m/kg dose (n=3), 170 times basal for the 5×10^{-3} m/kg dose (n=4), and 30 times basal for 10^{-3} m/kg dose (n=3). Peak plasma Ch levels, attained after 3-5 min, were 300%, 260% and 150% of basal values [159.58 ± 12.81 pm/100ml plasma] respectively. ETH levels in ECF dialysates peaked 10-20 min post injection and were 1080% of the basal value [36.52 ± 7.43 pm/5min] after 10×10^{-3} m/kg (n=10); Ch levels were 210% of the basal value [8.03 ± 1.06 pm/5min]. 5×10^{-3} m/kg ETH increased dialysate ethanolamine levels to 630% of basal, and Ch levels to 150% of basal (n=8); 10^{-3} m/kg ETH increased dialysate levels only to 150% of basal (n=3) and failed to increase dialysate Ch levels significantly (n=12). These data suggest that circulating ETH may be a source of both brain ETH and Ch.

601.14

PROGRESSION OF ENTORHINAL NEUROFIBRILLARY CHANGES DURING INITIAL STAGES OF ALZHEIMER'S DISEASE AS SEEN IN FLATTENED WHOLE MOUNT PREPARATIONS. **H. Braak*** and **E. Braak**, Department of Anatomy, J.W.Goethe University, D-6000 Frankfurt/Main 70.

Early stages in the development of Alzheimer-related neurofibrillary changes reveal involvement of specific pyramidal cells in the transentorhinal region. From here the pathological process spreads into the entorhinal region gradually destroying the superficial cellular layer (Pre- α). The severity of the change decreases as the layer is followed from the transentorhinal to the parasubicular boundary. We studied the gradual progress of entorhinal involvement corresponding to stage I to III in the development of the neurofibrillary changes [1] in flattened whole mount preparations. This technique reveals the characteristic pattern of cellular islands of the superficial entorhinal layer (Pre- α) as seen from the free surface and allows one to draw the boundaries of major subdivisions of the entorhinal region. Furthermore, it enables one to recognize at a glance even subtle pathological changes throughout the entire extent of both the transentorhinal and the entorhinal region. Supported by the Deutsche Forschungsgemeinschaft.

NERVE GROWTH FACTOR RECEPTOR-TARGETED PSEUDOMONAS EXOTOXIN A FUSION PROTEINS: Tools for Studies of Development and Neurodegenerative Disease. **Cartwright, M.**, **Moehring, J.**, **Moehring, T.**, and **Heinrich G***, University Hospital, Boston University Medical School, Boston, MA 02118 and **Microbiology and Molecular Genetics, University of Vermont, Burlington, VT 05405**

To examine the role of nerve growth factor (NGF) in the development of the nervous system and to construct animal models of neurodegenerative disease we genetically linked functionally active NGF to domains 2 and 3 of Pseudomonas exotoxin A (PEA). The NGF portion of the fusion gene contains exon 4 and therefore a precursor region necessary for the folding and production of biologically active NGF. Domains 2 and 3 of PEA encode the translocating and enzymatic domains. DHFR minus CHO cells were mutagenized and toxin-resistant cells were selected. The fusion gene was expressed in these CHO cells and purified from medium by immunoaffinity chromatography using an anti-NGF MAb provided by Alkermes. Western blot analyses of the secreted NGF/PEA fusion proteins revealed bands of the expected as well as larger sizes. Enzyme immunoassay using anti-PEA as the first and anti-NGF as the second antibody demonstrated the presence of both epitopes. Gel permeation chromatography indicated that NGF/PEA forms stable dimers. Competition assay with ¹²⁵I-labelled NGF showed that NGF/PEA is targeted to the NGF receptor. We are using NGF/PEA to knock out cells carrying the high affinity NGF receptor in developing and adult animals.

SYMPOSIUM: NEUROTRANSMITTER TRANSPORTERS. **M.J. Kuhar**, NIH-NIDA (Chairperson); **S. Paul**, Lilly Research Labs; **G.R. Uhl**, NIH-NIDA; **R. Edwards**, UCLA Sch. of Med.; **D. Wong**, Johns Hopkins Univ. Sch. of Med.

Neurotransmitter transport is an important process in maintaining synaptic transmission. The synaptic plasma membrane transporters terminate synaptic transmission by removing the neurotransmitter from the synaptic gap; this also allows some neurotransmitter to be recycled. The synaptic vesicle transporters accumulate the neurotransmitter into vesicles for subsequent release. The plasma membrane transporter and the vesicular transporter differ in their mechanism of transport. These transporters are also important targets for various drugs. In the last couple of years, a large family of sodium, chloride and temperature dependent synaptic membrane transporters have been cloned; the cloned cDNAs encode proteins very similar in overall structure. The proteins have been shown to be glycoproteins with slightly heterogenous forms. The vesicular transporters have also been cloned and show some similarity to the synaptic membrane transporters. Neurotransmitter transporters appear to be involved in some diseases and toxicities. Imaging the transporters in the living brain of humans and nonhuman primates by PET and SPECT has proven feasible.

603

SYMPOSIUM. PREFRONTAL MECHANISMS OF DISORDERED COGNITION: RELEVANCE TO SCHIZOPHRENIA. **P.S. Goldman-Rakic**, Yale Univ. Sch. of Med. (Chairperson); **C.D. Frith**, Hammersmith Hosp., London; **R.T. Knight**, Univ. Calif., Davis; **D.R. Weinberger**, NIMH - St. Elizabeth's Hosp.; **J.W. Pettegrew**, Univ. of Pittsburgh.

The cerebral cortex has come to the forefront of research in schizophrenia. This symposium focuses on the prefrontal cortex and the relevance of its working memory functions to thought disorder. Advanced methods of brain imaging, electroencephalography, magnetic resonance spectroscopy and behavioral analysis in patients, and experimental research on nonhuman primates are providing neurobiological insights into this challenging psychiatric disease.

606.1

RETROGRADE TRANSPORT OF LEUKEMIA INHIBITORY FACTOR (LIF) BY CULTURED RAT SYMPATHETIC NEURONS. D.R. Ure* and R.B. Campenot. Dept. of Anatomy and Cell Biology, University of Alberta, Edmonton, Alberta, T6G 2H7.

We have previously demonstrated that the LIF-induced switch in cultured rat sympathetic neurons from an adrenergic to cholinergic phenotype can occur if LIF is applied only to neurites in compartmented cultures. This observation implies the existence of a signal which travels retrogradely from neurites to cell bodies where the transcriptional changes associated with the switch are elicited. Since it has traditionally been believed in the case of nerve growth factor (NGF) that the transport of intact ligand may be important for retrograde signaling events, we have investigated the transport of ^{125}I -LIF in rat sympathetic neurons in compartmented cultures. The retrograde transport of ^{125}I -LIF is observed in this system but to a level of only approximately 15% of the retrograde transport of ^{125}I -NGF. ^{125}I -LIF transport can be blocked by treatment with colchicine (0.5 μM), dinitrophenol (5 mM), or a 100-fold excess of unlabeled LIF. ^{125}I -LIF and ^{125}I -NGF transport is accompanied by the intracellular accumulation of intact and partially processed ligand, followed by the release of very low molecular weight products into the medium bathing the neurons. These results suggest that the transport of LIF may be important for retrograde signaling events.

606.3

REGULATION OF p75 BUT NOT trkB GENES BY DEPOLARIZING STIMULI OR BDNF IN BASAL FOREBRAIN NEURON CULTURES. R.C. Elliott*, J.B. Black, and C.F. Dreyfus. UMDNJ/Robert Wood Johnson Med. Sch., Piscataway, NJ 08854

We have previously described a rapid elevation of BDNF message levels after depolarization of hippocampal neurons. We now define potential complementary effects of depolarization on the putative BDNF receptor component genes p75 and trkB in afferent basal forebrain (bf) neurons. Potential regulation of afferent receptors by impulse activity may be mediated directly by depolarization or indirectly by increased BDNF released by the target hippocampus. Therefore, we assayed p75 and trkB mRNA in bf neuronal cultures treated with depolarizing concentrations of KCl or with BDNF.

E18 rat bf cultures were plated in fully-defined, serum-free medium and grown for seven days. Cultures were treated with either BDNF (100 ng/ml) or KCl (50 mM), added either at the time of plating (prolonged regimen) or one day prior to harvesting (acute regimen). To measure subtle changes in p75 and trkB mRNA, a highly sensitive and efficient solution hybridization technique was utilized.

Under control conditions, basal levels of p75 mRNA were an order of magnitude lower than trkB. In response to acute, 24 hour treatment with KCl or BDNF, p75 message levels rose 15-30% while trkB mRNA was unchanged. After a prolonged, 7 day exposure to depolarizing stimuli or BDNF, p75 message levels increased 2-fold; trkB mRNA levels, in contrast, remained unchanged. These results indicate that p75 expression may be responsive to environmental signals while trkB remains static, suggesting a potential role for p75 in the synaptic response to impulse activity.

606.5

NGF-INDUCED DIFFERENTIATION THROUGH TRKA IN HUMAN NEUROBLASTOMA CELLS LACKING p75^{NGFR}. D.S. Hartman*, R. Schubengel, and C. Hertel. Pharma Research, Preclinical Neurosciences, F. Hoffmann-La Roche AG, CH-4002 Basel, Switzerland.

Nerve growth factor (NGF)-induced activation of the trkA NGF receptor (NGFR) supports the survival and differentiation of neurons. Human trkA, however, has been studied extensively by expression of a hematopoietic cell-derived cDNA clone in heterologous mouse fibroblast cells, where NGF induces cell proliferation. We have now identified a human neuroblastoma cell line, IMR-32, which expresses trkA but not the low affinity NGFR, p75. Northern blot analysis of poly A+ mRNA revealed a primary trkA transcript of 2.3 kb, and a minor 4 kb transcript. Immunoblotting of crude membrane protein from IMR-32 cells with anti-trk 43.4 antiserum labeled two trkA bands with apparent molecular weights of 116 and 105 kD. Chemical crosslinking of ^{125}I -NGF affinity-labeled IMR-32 cells identified two bands of approximately 130 kD and 300 kD which were immunoprecipitated by anti-trk antiserum. Recombinant human NGF (rhNGF) was able to induce both early and late responses in IMR-32 cells. Neurite outgrowth was observed after 9 days in the presence of 5 ng/ml rhNGF. Increased autophosphorylation of trkA on tyrosine residues was detectable at 10 pM rhNGF, and maximal at 0.2 nM rhNGF; maximal levels were reached after 5 min rhNGF stimulation, and remained elevated for longer than two hours. rhNGF also induced tyrosine phosphorylation of phospholipase C γ and phosphotylinositol kinase-3, but not of MAP kinase. These results indicate that expression of p75 is not required for NGF-induced differentiation of human neuroblastoma cells, and suggest that tyrosine phosphorylation of MAP kinase may not play an essential role in this process.

606.2

POTENTIAL INVOLVEMENT OF p75^{NGFR} IN RETROGRADE TRANSPORT OF NEUROTROPHIN-4 (NT-4). R. Curtis*, K.-F. Lee¹, R. Jaenisch¹, J. Huber², M.V. Chao², R.M. Lindsay and P.S. DiStefano. Regeneron Pharmaceuticals, Inc., Tarrytown, NY 10591; ¹Whitehead Institute, MIT, Cambridge, MA 02142; ²Cornell University Medical College, New York, NY 10021.

Retrograde transport of the neurotrophins NGF, BDNF and neurotrophin-3 (NT-3) by sensory neurons is mediated through receptor-dependent mechanisms, consistent with utilization of TrkA, B and C, respectively. NT-4, like BDNF, binds with high specificity to TrkB. However, retrograde transport of NT-4 differs from that of BDNF, in that all four neurotrophins effectively compete ^{125}I -NT-4 transport to DRG sensory neurons. Conversely, excess unlabeled NT-4 inhibits transport of ^{125}I -NGF, whereas BDNF does not. ^{125}I -NT-4 transport is additive with ^{125}I -labeled NGF, BDNF or NT-3. ^{125}I -NT-4 is preferentially transported to p75^{NGFR} immunopositive sensory neurons. Of the neurotrophins, NT-4 transport is most sensitive to inhibition by co-injected soluble extracellular domain of p75^{NGFR} and is most severely reduced in mice with targeted mutation of the p75^{NGFR} gene. NT-4 is only transported to spinal cord motor neurons after axotomy, coincident with increased expression of p75^{NGFR} in these cells. In contrast, BDNF is readily transported to motor neurons of normal animals. These results support a role for p75^{NGFR} in binding, uptake and retrograde transport of NT-4 by adult neurons.

606.4

TRKA INTERACTS WITH LOW-AFFINITY NGF RECEPTOR AND REGULATES NEURAL DIFFERENTIATION. A.H. Ross*, M.-C. Daou, D.R. Kaplan, M.B. Lachyankar, C.A. McKinnon, D.K. Poluha, W. Poluha, R. Stephens and D.E. Wolf. Worcester Foundation for Experimental Biology, 222 Maple Ave., Shrewsbury, MA 01545.

Nerve growth factor receptors (NGFR) were expressed in the baculovirus-insect cell system, and the diffusion of the low-affinity NGFR gp75 was analyzed by fluorescence recovery after photobleaching (FRAP). Coexpression of gp75 with TrkA, but not with TrkB, resulted in immobilization of gp75. Addition of NGF to gp75+TrkA cells resulted in a further immobilization, but this NGF-induced immobilization did not occur with cells expressing gp75 and a mutant TrkA with a defective protein kinase. These results demonstrate an interaction between gp75 and TrkA which is modulated by activation of the TrkA kinase domain.

The functional role of TrkA was assessed, using neuroblastoma line SHSY5Y. This line undergoes terminal differentiation upon treatment with NGF and the DNA polymerase inhibitor aphidicolin. Starting about the time of commitment to differentiation, there is up-regulation of both gp75 and TrkA mRNA's. SHSY5Y cells were transfected with a TrkA expression vector. Although our characterization of the TrkA transformants is preliminary, it is clear that these cells are much more responsive to NGF than the parent line.

606.6

AN EXTENDED SURFACE OF BINDING TO TRK TYROSINE KINASE RECEPTORS IN NGF AND BDNF ALLOWS THE ENGINEERING OF A MULTIFUNCTIONAL PAN-NEUROTROPHIN. C.F. Ibáñez*, L.L. Ilag and H. Persson. Department of Medical Chemistry, Laboratory of Molecular Neurobiology, Karolinska Institutet, S-10401 Stockholm, Sweden.

Neurotrophin-mediated cell survival and differentiation of vertebrate neurons is caused by ligand-specific binding to the Trk family of tyrosine kinase receptors. However, sites in the neurotrophins responsible for the binding to Trk receptors and the mechanisms whereby this interaction results in receptor activation and biological activity are unknown. We show that in NGF and BDNF, discontinuous stretches of amino acid residues group together on one side of the neurotrophin dimer forming a continuous surface responsible for binding to and activation of TrkA and TrkB receptors. Two symmetrical surfaces are formed along the two-fold axis of the neurotrophin dimer providing a model for ligand-mediated receptor dimerization. Mutated neurotrophins inducing similar levels of receptor phosphorylation showed different biological activities, suggesting that structural differences in a ligand may result in dissimilar responses in a given tyrosine kinase receptor. Our results allowed us to combine structural elements from NGF, BDNF and NT-3 to engineer a pan-neurotrophin that efficiently activates all Trk receptors and displays multiple neurotrophic specificities.

COLOCALIZATION STUDIES OF TRKA, TRKB & TRKC RECEPTOR mRNAs EXPRESSION IN PRIMARY SENSORY NEURONS AND RESPONSES TO INJURY V.M.K. Verge¹, C. Wetmore² & T. Hökfelt³

¹Dept. of Anatomy, Univ. of Saskatchewan, Canada S7N 0W0; ²Dept. of Cell Biol. & Neuroanatomy Univ. of Minnesota, 55455; ³Dept. of Histol. & Neurobiol., Karolinska Institute, S104 01 Stockholm, Sweden.

In vitro studies indicate that in addition to NGF, at least two other members of the NGF family of neurotrophins (NTs) namely, BDNF and NT-3 act on primary sensory neurons. To gain insights to their roles in adult rat sensory neurons *in vivo* *in situ* hybridization studies to detect their respective putative trk receptor mRNAs (trkA-NGF; trkB-BDNF; trkC-NT-3) were performed on intact and 14 day injured (sciatic nerve transected) L5 DRG to determine whether 1- the populations of intact neurons presumably responsive to these NTs were distinct or overlapping; and 2- whether trkB and trkC downregulate their expression following injury as has been shown for trkA. In intact ganglia all three trk mRNAs are heterogeneously expressed in neurons, with the truncated form of trkB also expressed in the satellite cells surrounding the neurons. Preliminary colocalization analysis reveals detectable levels of trkA and trkB mRNAs to be expressed over what appear to be mutually exclusive populations of neurons while both trkA and trkB colocalize to varying degrees with trkC mRNA expression. Collectively, most DRG neurons appear to express one of the three trk receptors. Finally, data from paired ganglia injured unilaterally show neuronal trkA, trkB and trkC expression and truncated trkB expression in satellite cells to be reduced in ganglia ipsilateral to lesion. If BDNF and NT-3 regulate expression of their receptors as NGF does, then these results suggest that peripherally injured DRG neurons, are in a NT-deprived state, at least in regard to the NGF family of NTs. This work was supported by the Canadian and Swedish MRCs.

IMMEDIATE EARLY GENE RESPONSE IN PC12 CELLS EXPRESSING TRK FAMILY MEMBERS. Dan Soppet^{*}, Pantelis Tsoufas, Luis F. Parada. Molecular Embryology Group, Laboratory of Mammalian Genetics, NCI-FCRDC, Frederick, Md. 21702

To directly compare the signal transduction pathways for neurotrophin receptors we have established PC12 cell lines that express trkB, trkC and trkC isoforms. We have exposed these cell lines to specific neurotrophins and analyzed the neurite outgrowth response and mRNA levels of several immediate early genes including c-FOS, c-JUN, NGFIA, and NGFIB. We find that in PC12 cells expressing trkB both neurite outgrowth and rapid induction of immediate early genes are produced by exposure to NGF, BDNF, and NT-5 but not NT-3. In trkC expressing cells NGF and NT-3 treatment induce neurites and lead to a rapid increase in the levels of immediate early genes. However TrkC isoforms trkC14 and trkC25 do not significantly stimulate the levels of immediate early genes in PC12 cells upon exposure to NT-3 nor do they induce neurite outgrowth. These results will be discussed in terms of the mechanisms for regulating neurotrophin responsiveness of specific types of cells. Research sponsored by the National Cancer Institute, DHHS, under contract no. NO1-CO-74101 with ABL.

606.11

DIFFERENTIAL DISTRIBUTION OF trkC-LIKE IMMUNOREACTIVITY IN AXON TERMINALS IN THE SPINAL CORD MOTOR NUCLEI IN MONKEY AND CAT S. Cullheim^{*}, U. Arvidsson, J. Frisén, F. Piehl, K. Fried, T. Hökfelt and M. Risling. Department of Neuroscience and Anatomy, Karolinska Institutet, Stockholm, Sweden.

The trk, trkB and trkC genes encode for high affinity receptors for the nerve growth factor family. Of these receptors, the trkC gene product seems to be selective for neurotrophin (NT)-3. As part of a larger project aiming at identifying substances of potential interest for the plasticity of spinal motoneurons, we have included an immunohistochemical study of the distribution of trk proteins in the normal spinal cord motor nuclei. Thus, after transcardial perfusion with 4% paraformaldehyde and 0.2% picric acid, spinal cord sections of adult monkeys (*Macaca fascicularis*) and cats were incubated with a rabbit polyclonal antibody raised against a peptide corresponding to residues 798-812 mapping within the carboxy terminal domain of the predicted mouse trkC encoded protein (Santa Cruz Biotech). In order to reveal a possible coexistence of trkC and serotonin (5-HT) in bulbospinal nerve terminals, which in the monkey harbour the growth-associated protein GAP-43, the tissue sections were also incubated with a guinea-pig 5-HT antiserum for double labeling. In both monkey and cat, trkC immunoreactive (IR) nerve fibers were found at all spinal cord levels. The densest innervation was found in the autonomic intermediolateral and Onuf's nuclei, but also somatic motoneuron pools received a significant contribution of trkC-IR fibers. The coexistence patterns differed between species, however, in that the majority of trkC-IR fibers were also 5-HT-IR in the monkey, while in the cat no certain such coexistence was at hand. The results suggest a role for neurotrophins, in particular NT-3, in the regulation of motoneuron activity at the spinal cord level.

606.8

ALTERNATE SPLICING OF THE trkC TYROSINE KINASE DISSOCIATES PROCESS OUTGROWTH FROM SURVIVAL. A.S. Garner^{*} and T.H. Large. Department of Neurosciences, Case Western Reserve University, Cleveland, OH 44106-4975.

The trkC receptor transduces NT3 binding into cellular responses as diverse as proliferation, differentiation and survival. These heterologous effects may be regulated at the level of receptor structure and the differential activation of signaling pathways. The cloning of avian trkC cDNAs revealed two tyrosine kinase splice variants that are likely to alter signal transduction. A kinase insert variant adds 25 amino acids immediately after the double tyrosine residues (711 and 712) that have been shown to be important regulators of trk kinase activity. A kinase truncation variant utilizes the same splice acceptor site as the kinase insert to remove the middle third of the tyrosine kinase domain. This deletion switches the reading frame and replaces the last two thirds of the kinase domain with 33 novel amino acids. In order to investigate the ability of these kinase splice variants to mediate process outgrowth and survival in serum-free medium, trkC receptors containing either the full length kinase, kinase insert, or kinase truncation were stably expressed in PC-12 cells. NT3 stimulated process outgrowth and survival in clones expressing the full length receptor, but not the kinase truncation receptor. Although the response appeared to be attenuated, NT3 also stimulated process outgrowth from clones expressing the kinase insert receptor, but failed to rescue the cells in serum-free medium. Thus, the 25 amino acid kinase insert appears to dissociate receptor-stimulated process outgrowth from survival. Our data indicate that alternate splicing may be an important mechanism for regulating the structure and function of trkC receptors.

606.10

EXPRESSION OF p140^{trk} CONFERS NGF-RESPONSIVENESS IN A HYPOTHALAMIC NEURONAL CELL LINE. J. Zhou, D. Holtzman, R.J. Weiner, and W.C. Mobley^{*}, Dept. of Neurology, Pediatrics and the Neuroscience Program, and Reproductive Endocrinology Center, UCSF, San Francisco, CA 94143.

An immortalized hypothalamic neuronal cell line was recently developed by genetically targeted tumorigenesis using the promoter of the gonadotropin-releasing hormone (GnRH) gene to express the SV40 T-antigen. The cloned cell line GT1-1 shows several neuronal properties. These cells express neuronal, but not glial, markers. They contain a small amount of p75^{NGFR} mRNA, but they do not contain p140^{trk} mRNA and do not respond to NGF. We asked whether expression of p140^{trk} would confer NGF responsiveness. Cells transfected with the p140^{trk} cDNA made p140^{trk} and they differentiated and extended neurites in response to NGF. Also, NGF delayed the death of cells that results from serum deprivation. As it is true in other responsive cells, NGF treatment induced tyrosine phosphorylation of p140^{trk}. Our findings provide further evidence that signal transduction is mediated through the p140^{trk} receptor. They suggest that a functional NGF signaling apparatus can enhance differentiation in neural tumors.

606.12

IDENTIFICATION OF trkB RECEPTOR mRNA IN ASTROCYTES BOTH IN VITRO AND AFTER CORTICAL INJURY. R.J. McKeon^{*}, J. Silver and T. Large. Department of Neurosciences, Case Western Reserve Univ., Cleveland, OH 44106.

After cortical injury, factors that support neuronal survival have been shown to be present in the area of damage. It is also known that, *in vitro*, astrocytes express mRNA for the neurotrophins NGF and NT-3, but not BDNF. This expression is consistent with the observation that glial scars can support neurite outgrowth from DRG's in the absence of exogenous NGF. *In vitro*, astrocytes also express high affinity trkB receptors, although the significance of this expression is not yet clear. In fact, a number of different trkB transcripts have been isolated from whole brain, some of which lack the tyrosine kinase domain necessary for signal transduction. In order to determine the types of trkB receptors expressed by astrocytes, both *in vitro* and *in vivo* after cortical injury, we have probed Northern blots with a 1.7 kb trkB probe. Our results indicate that, *in vitro*, astrocytes express at least 5 different trkB transcripts ranging in size from 7.5 to 1.8 kb, including one (4.8 kb) previously reported to be a full length transcript. In contrast, after cortical injury, astrocytes express at least three trkB transcripts, one of which (9.0 kb) has been reported to be a full length trkB, while the other two (7.5 and 7.0 kb) are likely to represent C-terminally truncated transcripts. These data indicate that astrocytes express full-length and truncated trkB receptors and the pattern of expression differs in astrocytes obtained *in vitro* or *in vivo*. *In situ* hybridization studies are being performed to confirm the expression of full length trkB by astrocytes *in vivo*. The potential for autocrine stimulation of astrocytes via trkB receptors will be determined by examining the expression of appropriate neurotrophin ligands for this receptor, including NT-4. Supported by the Spinal Cord Research Foundation of the Paralyzed Veterans of America.

BLOCK OF CALCIUM CHANNELS IN CENTRAL AND PERIPHERAL RAT NEURONS BY ω -CONOTOXIN-MVIIC.

K. J. Swartz*, I. M. Mintz, L. M. Boland, and B. P. Bean. Dept. of Neurobiology, Harvard Medical School, Boston MA 02115.

The synthetic peptide ω -conotoxin-MVIIC (kindly furnished by Dr. George Miljanich) was tested against Ca channel currents in a variety of rat neurons. With 2-3 mM Ba as charge carrier, ω -CgTx-MVIIC reversibly blocked N-type channels in sympathetic neurons with an IC₅₀ of ~4 nM. Both onset and reversal of block were rapid (τ_{on} ~ 6 sec with 10 nM toxin, τ_{off} ~ 15 sec). Block of N-type channels was weaker with higher Ba concentrations (IC₅₀ ~ 25 nM with 5 mM Ba, ~ 600 nM with 25 Ba). The toxin also blocked P-type Ca channels in cerebellar Purkinje neurons, but both the development and reversal of block were far slower. At 80 nM toxin applied in 2 mM Ba, block developed with a τ of ~15 minutes; there was essentially no reversal with washing for 5-10 minutes. In hippocampal CA3 neurons, substantial current remains with 3 μ M nimodipine to block L-type channels, 3 μ M ω -CgTx-GVIA to block N-type channels, and 100 nM ω -Aga-IVA to block P-type channels. This current was reduced by ~60% by 10 μ M ω -CgTx-MVIIC.

607.3

FIVE PHARMACOLOGICALLY DISTINCT HIGH VOLTAGE-ACTIVATED Ca²⁺ CHANNELS IN CEREBELLAR GRANULE CELLS. A.D. Randall*, B. Wendland, F. Schweizer, G. Miljanich, M.E. Adams, & R.W. Tsien. Dept. Molecular & Cellular Physiology, Stanford University, Depts. Entomology and Neuroscience, UC Riverside & Neurex Corp. Menlo Park, CA 94025.

Whole-cell recordings from cultured rat cerebellar granule neurons (480 cells) revealed five components of Ca²⁺ channel current. In 5 mM Ba²⁺ the current was entirely high voltage-activated (HVA), with maximal current at 0 mV. L-type currents were inhibited by 10 μ M nimodipine and potentiated by FPL 64176. N-type currents were blocked by ω -CTx-GVIA (1 μ M). In the combined presence of nimodipine and ω -CTx-GVIA, 61 \pm 3% of HVA current remained, and could be blocked by 20 μ M Cd²⁺ or reversibly modulated by agonists of GABA_A, MGLuR and adenosine receptors.

Analysis of the nimodipine/ ω -CTx-GVIA-insensitive current demonstrated that only 9 \pm 1% of it was non-inactivating P-type current, inhibited by 30 nM ω -Aga-IVA. Most (71 \pm 3%) of it, however, was blocked by 5 μ M ω -CTx-MVIIC. Blockade by this agent was slow (τ = 55 s), like that afforded Class A Ca²⁺ channel clones expressed in *Xenopus* oocytes. A 2 h pre-incubation with 500 nM ω -CTx-MVIIC, completely occluded blockade by 5 μ M ω -CTx-MVIIC, but not the actions of ω -CTx-GVIA or nimodipine. The residual current, defined by its resistance to nimodipine (10 μ M), ω -CTx-GVIA (3 μ M), ω -Aga-IVA (100 nM) and ω -CTx-MVIIC (5 μ M), was HVA and rapidly inactivating (τ_D = 22 ms). This current was rather Ni²⁺ sensitive (IC₅₀ ~ 66 μ M), like the ω -Ca²⁺ channel (Zhang et al., Soc. Neurosci. Abs. 1993).

We refer to the ω -CTx-MVIIC-sensitive, nimodipine/ ω -CTx-GVIA/ ω -Aga-IVA-insensitive current as "Q-type", to distinguish it from L, N, and P-type currents. Q-type current was >2-fold larger than any another component (43% of the total current). Q-type current strongly resembles α_1 Ca²⁺ channels expressed in *Xenopus* oocytes in its pharmacology, voltage- and time-dependence (Sather et al. Soc. Neurosci. Abs. 18: 10, 1992). Q-type current is partially blocked (up to 50%) by high doses (100/200 nM) of ω -Aga-IVA. This suggests caution in using high doses (>30 nM) of ω -Aga-IVA to determine the presence or function of P-type channels.

607.5

OMEGA-CONOPEPTIDE SNX-230 (MVIIC) BLOCKS CALCIUM CHANNELS IN MOUSE NEUROMUSCULAR JUNCTION NERVE TERMINALS. S. Bowersox, C-P. Ko, Y. Sugiura, C. Z. Li, J. Fox*, B. B. Hoffman, G. Miljanich. NEUREX Corp., Menlo Park, CA 94025, Dept. of Biol. Sci., Univ. of Southern Calif., Los Angeles, CA 90089.

At least two binding sites for Ca²⁺ channel blocking ω -conopeptides exist in mammalian CNS. Site 1 correlates with N-type voltage-sensitive Ca²⁺ channels (VSCC) defined by sensitivity to ω -conopeptide SNX-111 (MVIIC). The identity of Site 2, defined by SNX-230 (MVIIC) sensitivity, is uncertain; being neither N, L, nor T, but possibly including P and/or P-like components. We used the mouse phrenic-nerve-diaphragm and ω -conopeptides to classify the VSCC mediating synaptic transmission at the mammalian neuromuscular junction (NMJ). SNX-111 did not block nerve-stimulated muscle contractions at concentrations up to 100 μ M. In contrast, SNX-230 produced complete blockade at 0.5 μ M. SNX-230-treated preparations continued to respond to exogenous acetylcholine. Potencies of twenty ω -conopeptides and analogues revealed a strong correlation between site 2 binding and NMJ blockade. Evoked endplate potentials (epps) and spontaneous miniature endplate potentials (mepps) were recorded in low Ca²⁺ and high Mg²⁺ saline. SNX-111 had negligible effects on epps or mepps up to 100 μ M. SNX-230 at 10 μ M inhibited epps completely with little effect on mepp amplitude and frequency. At 1 μ M, SNX-230 reduced quantal content to about 15% of control. 0.1 μ M showed no effect. Reduction in quantal content in 1 μ M SNX-230 was abolished by elevating extracellular Ca²⁺. SNX-230 also blocked the increase in mepp frequency induced by K⁺-elevated saline. Further, perineural focal recordings of presynaptic currents showed that SNX-230 (10 μ M) did not block the conducted action potential. Taken together these findings indicate that SNX-230 blocks transmitter release at the mammalian NMJ by blocking presynaptic VSCCs that correspond to the Site 2 non-L, N, T subtype. (Supported in part by NIH grant NS 30051 to CPK.)

607.2

VOLTAGE-DEPENDENCE OF P-TYPE CALCIUM CHANNEL BLOCK BY SYNTHETIC ω -AGA-IVA. I. M. Mintz* and B. P. Bean. Dept. of Neurobiology, Harvard Medical School, Boston MA 02115.

The effects of the synthetic peptide ω -Aga-IVA (Peptides International, Inc.) were found to be nearly identical to those of the purified spider toxin ω -Aga-IVA (Dr. M.E. Adams). The synthetic peptide blocked the predominant P-type Ca channel current in freshly isolated rat Purkinje neurons potently and completely (K_d ~ 3 nM with 5 mM Ba, K_d ~ 20 nM with 115 mM Ba). The peptide had no effect on T-type current (200 nM) or BAY K 8644-enhanced L-type current (200 nM) in rat sensory neurons or on N-type current in rat sympathetic neurons (200-800 nM). In rat spinal cord neurons, synthetic and purified peptides blocked the same component of high-threshold Ca channel current in a mutually occlusive manner. In Purkinje neurons, the on rate constant for toxin block varied linearly with toxin concentration, consistent with one-to-one binding. The off rate constant (k_{off}) was very slow at -80 mV but was dramatically increased by depolarizations to >+70 mV. The relief of block by big depolarizations was identical in cells recorded with permeant (Cs) or impermeant (TEA or NMDG) internal ions. In 5 mM external Ba, k_{off} increased with voltage according to a Boltzmann relationship (midpoint +120 mV and slope factor 24 mV). This relationship was shifted to more positive potentials in recordings with 110 mM Ba.

 ω -CONOTOXINS WITH NOVEL CA²⁺ CHANNEL SUBTYPE SPECIFICITY. D.R. Hillyard, J. Imperial, R. Schoenfeld, V. Monje and L.J. Cruz*. Depts. of Pathology and Biology, University of Utah, Salt Lake City, Utah, 84132 and College of Science, Univ. Philippines, Diliman, Quezon City, Philippines.

The dihydropyridines and ω -conotoxin GVIA (ω -CgTx) have become the standard pharmacological reagents for identifying L- and N-type Ca channels, respectively. Fish-hunting cone snails have evolved a large set of peptides of divergent sequence which inhibit neuronal calcium channels; we are identifying new ω -conotoxins which preferentially target ω -CgTx-resistant (i.e., non-N) Ca channels. Nine ω -conotoxins have been characterized from four different *Conus* venoms. The existence of non-N-type-targeting ω -conotoxins in the venoms of cone snails was revealed by a molecular cloning approach. Two new peptides, ω -conotoxins MVIIC and MVIID inhibit at least two classes of calcium channels which are both ω -CgTx- and dihydropyridine-resistant. MVIID in particular has a high index of discrimination against N-type binding sites. Sequence analysis of cDNAs encoding ω -conotoxins has revealed consistently conserved and variable domains in the toxin precursor sequences. The organization of ω -conotoxin coding sequences is ideal for amplification cloning strategies to rapidly access members of the ω -conotoxin family with novel specificity for Ca channel subtypes. (Supported by GM48677 and NS27219).

MULTIPLE CALCIUM CHANNEL TYPES COEXIST TO REGULATE STRIATAL DOPAMINE RELEASE AND HIPPOCAMPAL GLUTAMATE RELEASE. T.J. Turner* & K. Dunlap. Dept of Physiology and Neuroscience, Tufts University School of Medicine, Boston, MA 02111

We have used peptide toxins that block distinct Ca²⁺ channel types in order to identify which types regulate excitation-secretion coupling in mammalian nerve terminals. A superfusion system with subsecond temporal resolution was used to directly measure release of radiolabeled neurotransmitter from rat brain synaptosomes. We have shown previously that K⁺-evoked release of [³H]glutamate from cortex is mediated in part by P-type channels, based on partial block of release by ω -Aga-IVA (a specific P channel blocker) and resistance to ω -CgTx (a specific N channel blocker). In order to determine whether secretion of other transmitters is regulated in the same way, we tested the two toxins on release in two other systems-dopamine release from striatum and glutamate release from hippocampus. ω -Aga-IVA blocked release in both of these systems, and as before the extent of block was greatest at low levels of depolarization and diminished as the KCl concentration was increased. Unlike glutamate release from cortex, ω -CgTx blocked a small but significant portion of release in these systems. When release was evoked with 60 mM KCl neither toxin had much effect on release rates, but a combination of the two toxins produced a synergistic block of up to 60% of control values. Our conclusion is that multiple Ca²⁺ types coexist in individual nerve terminals, and that each type can contribute to neurosecretion under physiologically relevant conditions. This arrangement could lend a high degree of flexibility to the regulation of transmitter release under diverse conditions of stimulation and modulation.

FUNCTIONAL DIVERSITY OF DIHYDROPYRIDINE- AND W-CONOTOXIN-GVIA-INSENSITIVE CALCIUM CHANNELS IN RAT CEREBELLAR GRANULES. D. Pietrobon*, L. Forti, A. Tottene and A. Moretti. C.N.R. Mitoc. Physiol. Center, Dept. of Biomedical Sciences, Univ. of Padova, 35121 Padova, Italy.

After incubation of 6-11 days-old primary cultures of rat cerebellar granules with 3 μ M w-conotoxin GVIA (w-CgTx) in divalent-free solution, single cell-attached calcium channel recordings were performed with 90 mM Ba^{2+} and 3 μ M w-CgTx in the pipette. Using neuroblastoma IMR32 cells, whose whole-cell calcium current was ~80% irreversibly inhibited by w-CgTx, we had previously ascertained that this inhibition protocol was effective in completely blocking w-CgTx-sensitive single calcium channels. In cerebellar granule cells we observed two functionally different classes of calcium channels that were not inhibited by w-CgTx and were also dihydropyridine-insensitive, as judged by the lack of effect of (+)-S-202-791. The two classes, G_1 and G_2 , differed in single channel conductance (21 and 16 pS, respectively), elementary current (1.35 and 0.6 pA at 0 mV), threshold for activation (-10 and -40 mV) and mean open time (0.5 and 1.2 msec). Both G_1 - and G_2 -type calcium channels showed little inactivation during 700 msec long test pulses, but the majority of channels in both classes completely inactivated when the potential between successive depolarizations was held at -40 mV for 4 seconds. They were observed with similar frequency, in ~30% (lower limit) of patches. In both G_1 and G_2 classes we observed further subtle functional diversity. In agreement with the single channel recordings, the whole cell calcium current showed slow inactivation during test pulses, but was largely inactivated at holding potentials of -50 mV. Only 10-15% of the current was inhibited by w-CgTx, and most of this inhibition was reversible. We are currently testing the effect of w-Aga-IVA and w-conotoxin-MVIIIC on G_1 - and G_2 -type calcium channels.

PROTEIN KINASE C BLOCKS SOMATOSTATIN-INDUCED MODULATION OF CALCIUM CURRENT IN CHICK SYMPATHETIC NEURONS. A. Golard, L.W. Role and S.A. Siegelbaum. H. Hughes Med. Inst. and Ctr. Neurobiology & Behavior, Columbia Univ., New York, NY 10032

Protein kinase C (PKC) has been suggested either to mediate Ca channel inhibition by neurotransmitters or, conversely, to block the inhibition of Ca currents (I_{Ca}). Here we study the role of PKC in the inhibition of I_{Ca} by somatostatin (SS) in chick sympathetic ganglion neurons. PKC activation (1μ M PMA) had no effect on I_{Ca} , nor on the interaction between G-proteins and Ca channels. Pre-treatments of cells with PMA reduces the subsequent inhibition of I_{Ca} by SS. Modulation of I_{Ca} by SS normally desensitizes, with a time for half desensitization of about 3 minutes. PKC activation mimics the normal desensitization process in that high affinity responses are lost preferentially. However, while the specific PKC inhibitor Calphostin C largely reverses the effects of phorbol esters, it does not slow the normal rate of desensitization of SS responses. This indicates that PKC is not involved in the homologous desensitization of the SS receptor.

LSD ACTIVATES 5-HT_{1A} RECEPTORS ON DORSAL RAPHE NEURONS: EFFECTS ON Ca^{2+} AND K^+ CURRENT. N.J. Penington* and A.P. Fox. Univ. Chicago, Dept. Pharm/Phys., Chicago II, 60637 & Dept. Pharmacol. SUNY (Health Science Center Brooklyn), New York.

Previously, we reported that 5-HT inhibited whole-cell Ca^{2+} current (I_{Ca}) and potentiated a K^+ current (I_K) in dorsal raphe (DR) neurons. Now we find that LSD mimics the actions of 5-HT by dramatically suppressing I_{Ca} while activating an inwardly rectifying K^+ conductance. LSD was previously reported to activate I_K in DR neurons. We tested the hypothesis that LSD activates 5-HT_{1A} receptors thereby potentiating I_K while inhibiting Ca^{2+} influx into the cell. In 18 cells 5-HT (1μ M) inhibited I_{Ca} by $51.2 \pm 1.9\%$ and LSD (1μ M) inhibited by $46.2 \pm 2\%$ ($n=14$). The inhibition produced by LSD showed a voltage dependence identical to that of 5-HT. Spiperone (1μ M), a 5-HT_{1A} antagonist, blocked the actions of LSD (LSD inhibited I_{Ca} by only 6.9% in its presence). 2-Bol, a close structural analog of LSD that does not produce hallucinations, had no effect on I_{Ca} . However, 2-Bol (10μ M $n=7$) did block the effect of LSD (1μ M) by $59.2 \pm 8\%$. LSD also activated an inwardly rectifying I_K that measured -177 ± 52 pA at -90mV (1μ M, $n=6$) and reversed close to the potential expected of I_K in 20mM $[\text{K}^+]_o$ (-51mV). Incubation of the cell with 2-Bol (10μ M) did not activate I_K but it blocked the effect of LSD (LSD elicited only 38.2 ± 12 pA of I_K in 2-Bol). Inhibition of 5-HT release resulting from 5-HT_{1A} receptor activation, may play an integral role in LSD's hallucinogenic actions by reducing competition between 5-HT and LSD for other postsynaptic 5-HT receptors.

CHARACTERISTICS OF CALCIUM CURRENTS IN HERMISSENDA PHOTORECEPTORS. E. Yamoah* and T. Crow. Dept. Neurobiology & Anatomy, Univ. of Texas Medical School, Houston, TX 77030.

It has been proposed that the sequence of events important in plasticity of *Hermisenda* photoreceptors is mediated, in part, by Ca^{2+} . However, little is known regarding the properties of Ca^{2+} channels in these cells. Ca^{2+} currents were recorded from isolated photoreceptors using the whole cell variant of the patch-clamp technique. The composition of the external and pipette solutions in mM was; external- 300 Choline, 50 Mg^{2+} , 10 Ca^{2+} , 100 TEA, 5 4-AP, 10 Dextrose, 15 HEPES buffer, pH 7.7; pipette- 20 Na⁺, 2 Mg^{2+} , 45 HEPES buffer, 10 EGTA, 20 TEA, 250 Cs⁺, 300 N-methylglutamine, 5 MgATP, 1 GTP, 10 Glutathione, pH 7.4 with TEAOH). Ca^{2+} currents appeared at potentials positive to -70 mV from a holding potential of -90 mV. The current-voltage relationship showed three characteristic peaks around -60 mV, -20 mV and +10 mV; see Fig. 1. The low & intermediate-voltage-activated currents (LVA, IVA) have a fast activation profile but different inactivation kinetics. The LVA has a fast and the IVA has a slow time course of inactivation. The high-voltage activated current has a slow turn-on with no inactivation. These three sub-types of Ca^{2+} channels have different sensitivity to Co^{2+} , Ni^{2+} , Cd^{2+} , La^{3+} , Gd^{3+} , ω -conotoxin GVIA and nifedipine. However, pharmacological separation of the currents was inadequate since the three channels can be blocked, over time, by all the blockers. Individual currents were studied with varying holding potentials or in photoreceptors that expressed one particular type of current. The kinetics, pharmacology and functions of these subtypes of Ca^{2+} currents are under investigation.

A TYROSINE PHOSPHATASE DETERMINES THE RESPONSE OF A CALCIUM-PERMEABLE CHANNEL TO PROTEIN KINASE A. G.F. Wilson* and L.K. Kaczmarek. Dept. of Pharmacology, Yale Univ. Sch. of Med., New Haven, CT 06510.

In bag cell neurons of *Aplysia*, elevations in intracellular cAMP trigger a ~30 min discharge of action potentials. We have studied protein kinase A (PKA) modulation of a large conductance calcium-permeable cation channel which evidence suggests may provide the depolarizing drive underlying the discharge. The effect of 100 nM of the catalytic subunit of PKA depended on the channel's starting mode of activity. If the channel was continuously active, then PKA decreased the open probability ($n=14$); conversely, if the channel was bursting, then PKA increased the open probability by removing the channel's long-lived closed state ($n=7$). Bursting channels could be converted to the continuously active mode using the T-cell protein tyrosine phosphatase (PTPase; $n=6$), suggesting that the phosphorylation state of tyrosine residues determines both mode of activity and PKA response.

Additional experiments indicated that the PKA-induced increase in burster activity proceeds indirectly by increasing the activity of a PTPase endogenous to excised patches. If the endogenous PTPase is inhibited using 1 mM vanadate, PKA still appears to phosphorylate bursting channels, however this phosphorylation results in a decrease in activity ($n=4$) similar to that observed for continuously active channels. 2 nM microcystin produced no change in the normal burster response to PKA ($n=4$). These observations suggest that PKA-regulation of the tyrosine phosphatase may play a crucial role in triggering the discharge and illustrate that tyrosine kinases and phosphatases can directly and dynamically regulate neuronal signaling.

ANGIOTENSIN II INHIBITS Ca^{2+} CURRENTS IN RAT SYMPATHETIC NEURONS VIA A G-PROTEIN. M.S. Shapiro, J. Herrington, L.P. Wollmuth* and B. Hille. Physiology and Biophysics, Univ. Washington, Seattle, WA 98195.

We studied inhibition of N-type Ca^{2+} channels in adult rat superior cervical ganglion (SCG) neurons by angiotensin II (ATII) using the patch clamp. In whole-cell configuration with external 5 mM Ca^{2+} , 68 of 88 acutely dissociated SCG cells showed inhibition by 500 nM ATII. Peak currents elicited by 10-ms voltage steps from -80 mV to 5 mV were reduced by $32 \pm 2\%$ (mean \pm SE), with an IC_{50} near 12 nM. Dialysis with 2 mM GDP- β -S for >7 min reduced ATII inhibition (to $8 \pm 2\%$, $n=9$ vs. $30 \pm 5\%$, $n=10$), implicating G-proteins. For cells treated overnight with 500 ng/ml pertussis toxin or heat-inactivated controls, about half responded to ATII in either case (9/15 vs. 7/14). AT₁ receptors seem involved since 0.2-2 μ M of the AT₁-specific antagonist losartan abolished the action of 100 nM ATII ($n=13$). $[\text{Ca}^{2+}]_i$ measured by 100 μ M Indo-1 fluorescence was little increased by 500 nM ATII (14 ± 7 nM, $n=5$); nevertheless, inhibition of I_{Ca} by ATII was mostly blocked by 20 mM pipette BAPTA (to $10 \pm 3\%$, $n=12$ vs. $30 \pm 5\%$, $n=12$). This inhibition was not restored by pipettes with 20 mM BAPTA+10 mM Ca^{2+} to raise but still strongly buffer Ca^{2+} ($8 \pm 2\%$, $n=9$). We conclude that the ATII signaling pathway is BAPTA-sensitive and uses a G-protein in the inhibition of Ca^{2+} channels in SCG neurons. ONTOGENY OF P-TYPE CALCIUM CHANNEL IN THE RAT CEREBELLAR CORTEX. B.D. Cherksey*, M. Sugimori, D. Hillman and R. Llinás. Dept. of Physiology/Biophysics, NYU Medical Center, NY, NY 10016.

The time course of the development of P-channels in Purkinje cells was studied morphologically and functionally in rats of different ages: neonate (1 to 3 days), immature (6-8 days) and young (10-14 days). Morphologically, immunohistochemistry using anti P-channel polyclonal antibodies indicated a somatic location of reaction product in the neonate cells, becoming progressively more dendritic in immature cells and finally, mostly dendritic as the Purkinje cell develops over the next two weeks. Electrophysiologically whole cell patch clamp showed the presence of a low threshold calcium current at day 3, which was not FTX sensitive. A calcium current of the high threshold type appeared as the cell matured. This current was blocked by FTX and was indistinguishable from those in young or adult animals. Lipid bilayer study of neuronal membrane vesicles from the cerebellum confirmed the absence of P channel and the presence of a large (>50 pS) calcium channel, presumably of non-Purkinje cell origin, not blocked by FTX. P-type channels, blocked by FTX, were present in membranes obtained from the young animals. These results indicate that in early development, there is a transition from T-type to P-type channels, in the mammalian Purkinje cell and which correlates with the dendritic development in these cells. Support by NS13742 and AG09480.

AXON GUIDANCE MECHANISMS AND PATHWAYS VII

608.1

MOLECULAR GENETIC ANALYSIS OF TWO MEMBERS OF THE DROSOPHILA FASCICLIN IV GENE FAMILY. D. Matthes, A. Kolodkin*, and C. S. Goodman. HHMI, Dept. MCB, Univ. of California, Berkeley, CA

We previously reported on the cloning and characterization of the gene encoding a novel integral membrane protein, fasciclin IV (G-fasIV), that functions in growth cone guidance in the PNS of the grasshopper embryo (Kolodkin et al., Neuron, 1992). Fas IV is expressed on a subset of fasciculating axons in the CNS of the grasshopper embryo; it is also expressed in peripheral tissues. In the limb bud, a pair of growth cones that pioneer a sensory pathway make an abrupt circumferential turn at a stereotyped location. Fas IV is expressed on the epidermal cells where this turn is made. Antibody blocking experiments show that fas IV functions as a key guidance molecule for this turn. Consistent with its peripheral expression on epidermal cells but not growth cones, fas IV does not function as a homophilic adhesion molecule in an *in vitro* assay.

In order to further characterize the function of fas IV using genetic analysis, we used a PCR-based approach to clone the Drosophila fas IV homologue. Here we report on the cloning of two members of the fas IV gene family in Drosophila. Sequence analysis suggests that one gene is the true Drosophila homologue (D-fasIV), whereas the second gene (D-fasIV-related) is more divergent. Both genes, however, encode cysteine-rich integral membrane proteins that share structural features and sequence similarity. Together they define a novel gene family. Whole-mount *in situ* hybridization experiments show that both Drosophila genes are expressed in the embryonic CNS and in other tissues. A P-element located within the D-fasIV-related gene provides us with the starting point for a genetic analysis of the function of this gene. Given the previous evidence that at least one member of this new gene family (G-fasIV) plays an important role in growth cone guidance, it will be interesting to determine if other members of the gene family have related functions.

608.3

THE GLYPICAN FAMILY OF GLYCOSYLPHOSPHATIDYLINOSITOL-ANCHORED HEPARAN SULFATE PROTEOGLYCAN IN THE DEVELOPING RAT BRAIN. A.D. Lander*^{1,2}, A. Kumbasar¹, E.D. Litwack¹, and C.S. Stipp¹. ¹Dept. of Biology and ²Dept. of Brain & Cognitive Sciences, M.I.T., Cambridge, MA 02139.

Cell-surface proteoglycans (PGs) are thought to act as receptors or co-receptors for many of the extracellular molecules that control the differentiation, migration, and axonal projection of neurons. Of the ~25 major PGs of the developing rat brain, two of the most abundant, PGs M12 and M13, bear heparan sulfate (HS) glycosaminoglycan (GAG) chains, and are glycosylphosphatidylinositol (GPI)-anchored integral membrane proteins (Herridon and Lander, 1990, Neuron 4:949-961). To identify these molecules, they were purified from neonatal rat brain, and protein sequences obtained from tryptic fragments of their core proteins. These and other data indicate that PG M12 is the rat form of *glypican*, a GPI-anchored HSPG first identified in human fibroblasts. PG M13, in contrast, is distinct from glypican. Using PCR, a cDNA for this PG was obtained, and western blots using anti-fusion protein antibodies confirm that the cDNA encodes M13. The full sequence of this molecule, which we have named *cerebroglycan*, indicates that it is related to glypican, exhibiting strong conservation of cysteine motifs and consensus GAG attachment sites, and 38% overall identity. *In situ* hybridization studies indicate that glypican and cerebroglycan exhibit distinct patterns of expression: Glypican mRNA is found in some populations of projection neurons of the adult brain, especially parts of the hippocampus, the thalamus, and in 1^o motoneurons. Glypican is also expressed in the brain during development, as well as in non-neural tissues. Cerebroglycan mRNA, in contrast, is found only in the nervous system; its mRNA is expressed at least as early as E12 in the rat, is found throughout the nervous system at E16, but later becomes restricted to a few brain structures, before eventually disappearing entirely. The relationship of these expression patterns to those of HS-binding proteins will be discussed. Supported by NIH NS26862.

608.2

ALIGNMENT OF PIONEER GROWTH CONE MIGRATION WITH AN ORTHOGONAL ARRAY OF MOLECULARLY-DEFINED EPITHELIAL DOMAINS. M. A. Singer*, T. P. O'Connor, and D. Bentley. Department of Molecular and Cell Biology, University of California, Berkeley, CA 94720.

In embryonic grasshopper limb buds, guidance information for migration of pioneer growth cones along a stereotyped route to the CNS can be provided by the epithelium and by epithelium-derived cells. This epithelium is partitioned into sharply-defined domains characterized by molecular expression patterns. The *annulin* (Singer et al., 1992, Dev. Biol. 154, 143) and *fasciclin IV* (Kolodkin et al., 1992, Neuron 9, 831) proteins, and endogenous alkaline phosphatase activity (Chang et al., Development, in press) each are expressed in circumferential bands of epithelial cells at specific segmentally-iterated locations along the proximodistal axis of the limb. The borders of expression of a fourth gene product, the *engrailed* (Kornberg et al., 1985, Cell 40, 45) protein, lie orthogonal to the circumferential bands of the other three gene products. During circumferential growth, a major segment of the pioneer pathway, the growth cones migrate precisely between specific alkaline phosphatase and annulin bands, and in register with a fasciclin IV band. Subsequently, the growth cones make a 90° turn and migrate parallel to the ventral engrailed boundary. These four expression patterns thus demarcate an orthogonal grid of epithelial domains with which much of the pioneer pathway is aligned. Growth cone migration across the limb epithelium appears likely to be guided by at least three sources of information: (1) molecular gradients on the surface of the limb (Norbeck et al., 1992, Development 116, 467), (2) orthogonal molecular expression domains, and (3) local guidepost cells.

608.4

AN EXTRACELLULAR MATRIX MOLECULE PRESENT IN THE DEVELOPING VISUAL PATHWAY. S. Henke-Fahle*. Dept. of Ophthalmology, University of Tübingen, Germany.

Growth cone morphology of early growing axons varies in a position dependent manner while they navigate along their pathway, being more complex at choice points. In the optic pathway, growth cones entering the optic nerve head are the largest and most complex, suggesting that they are encountering an environment molecularly different from the retinal one they are leaving (Holt, J. Neurosci. 9, 3123-3145, 1989). A search for monoclonal antibodies that bind to cells situated along the route retinal ganglion cell axons normally follow led to the identification of a molecule present on neuroepithelial cells of the optic stalk. The monoclonal antibody (1e38) stains the cells of the optic fissure and the presumptive optic nerve in early chick embryos (E4), whereas the retina is devoid of label. At this stage, staining in the optic tectum is confined to radial cells and is displayed in a graded fashion (app). Immunofluorescence of living cells locates the antigen on the surface and in the immediate vicinity of cells. The solubilization properties of the antigen are consistent with those of extracellular matrix proteins. Western blot analysis of 4M urea extracts from 7d embryonic tecta revealed 3 bands of app. molecular weight 370, 400 and 440 kD. Whether this molecule provides guidance cues to retinal ganglion cell growth cones remains to be investigated. Supported by DFG He 1514/2-1.

CHONDROITIN SULFATE IS LOCALIZED AT THE MIDLINE DURING RETINAL AXON DIVERGENCE IN THE MOUSE OPTIC CHIASM. J. H. Lustgarten, R. C. Marcus, L. C. Wang, and C. A. Mason*, Dept. Pathology, Coll. Phys. Surg., Columbia Univ., NY, NY. 10032

A growing body of evidence suggests that the divergence of retinal ganglion cell axons occurs by interactions of growth cones with components of the developing optic chiasm. Previous studies using DiI-labeled fixed tissue or time-lapse video microscopy suggest that cues localized at or near the chiasm midline may selectively repulse fibers arising from the temporal retina that project to the ipsilateral side of the brain. The molecular identity of these cues remain unknown. Certain extracellular matrix proteoglycans have been implicated as inhibitors of axon growth in the nervous system, subserving a "boundary" function at midline regions in the developing spinal cord and optic tectum. We have localized one of these molecules, chondroitin sulfate, to the midline of the diencephalon and optic chiasm in E13-E15 mouse embryos, using the monoclonal anti-chondroitin sulfate antibody CS-56 (Sigma # C-8035) and immunofluorescence. At E13 labeling is concentrated at the midline in the ventral diencephalon. At E15 there is dense staining anteriorly in the region of the "glial knot". More posteriorly the staining localizes in the midline above the nerve fiber layer. In all cases staining is most intense at the interface of the fiber layer and the diencephalon.

To determine whether chondroitin sulfate plays a role in selective axonal guidance in the developing chiasm, we are studying the expression of the molecule by dissociated chiasm cells in culture. Under certain conditions dissociated cells from the developing chiasm aggregate to form "islands" that selectively repulse fibers growing from co-cultured explants of temporal-inferior ("TI") retina, the region giving rise to the ipsilateral projection [L.-C. Wang et al., Soc Nsci Abstracts, 1992]. Explants that give rise to crossing fibers generally grow over these islands. In many instances, chiasm cell islands express immunoreactivity for CS-56. Whether expression of this molecule correlates with selective repulsion of "TI" fibers is currently being studied. These analyses should help to elucidate whether this molecule plays a role in axon pathfinding in the optic chiasm.

IN VITRO RESPONSES OF NASAL RETINAL FIBERS TO MEMBRANE FRAGMENTS FROM SUPERIOR COLLICULUS IN MICE. B. Lirbat and P. Godement*, Institut Alfred Fessard, CNRS, 91198 Gif-sur-Yvette, France.

Studies done *in vitro* have shown that growth cones of fibers from temporal retina are inhibited by components which are present as a concentration gradient increasing along the anterior-posterior axis of the superior colliculus in mouse, chick, and fish. Such a gradient could influence the growth of fibers from temporal retina *in vivo*, leading them to avoid caudal aspects of the superior colliculus. Using the collapse assay in which membrane vesicles are added to cultures in which the growth cones of retinal fibers from nasal or temporal retina are viewed in real-time, we find that membrane fragments taken from the anterior aspects of the superior colliculus of embryonic mice (E15-17) lead to a collapse of the growth cones of nasal retinal fibers (E14), whereas posterior membranes have no such effect. Vice-versa, posterior membranes lead to a collapse of temporal fibers, but anterior membranes have no effect. Temporal growth cones react by withdrawing their lamellipodia, and the body of the growth cones retracts. Nasal growth cones react in a different manner. The lamellipodia are withdrawn, and the growth cone becomes filiform but within the next hour, some extension of the fiber tip is often observed. This response of nasal fibers is observed in cultures that are grown in serum-free conditions; in the presence of fetal calf serum, no effect is observed. These experiments suggest that complementary gradients of molecules in the retina and in the superior colliculus could be involved in setting up the polarity of retinal projections along the nasal-temporal axis of the retina. The observation of the different behaviors of nasal and temporal growth cones in response to anterior and posterior membranes suggests that different mechanisms are involved in each type of response and could be related to the fact that *in vivo*, nasal fibers first have to extend through anterior aspects of the superior colliculus before reaching its posterior aspects. Supported by C.N.R.S., I.N.S.E.R.M., and M.R.T.

CHEMOTAXIS OF GROWTH CONE OF XENOPUS SPINAL NEURON IN A GRADIENT OF ACETYLCHOLINE. J.Q. Zheng, M. Felder, J.A. Connor*, and M-m. Poo*, Dept. of Biol. Sci., Columbia Univ., New York, NY 10027; *Roche Inst. of Mol. Biology, Nutley, NJ 07110.

With repetitive pressure ejection of picoliters of concentrated acetylcholine (ACh) solution from a micropipette, a microscopic ACh gradient of about 10% in micromolar range was produced across single growth cones of embryonic *Xenopus* spinal neurons in cell culture. Facing such an extracellular gradient of ACh, the growth cones of cultured *Xenopus* spinal neurons exhibited a turning response toward the source of ACh. Control experiments with normal culture medium or NaCl solution did not produce such a chemotactic response. The chemotactic response of the growth cones to the gradient of ACh appeared to be mediated by neuronal nicotinic ACh receptors, since it was inhibited by d-tubocurarine. Furthermore, the chemotaxis of growth cones in ACh gradients was found to be blocked either by withdrawal of Ca^{2+} from the bath medium or addition of KN62, a specific inhibitor of calmodulin-dependent protein kinase II (CaM Kinase II). Preliminary experiments with Fura-2 ratio imaging demonstrated a small but detectable elevation of Ca^{2+} at growth cone after onset of ACh gradient but before the actual turning. Taken together, our results indicate that the chemotaxis induced by ACh gradient involved the activation of neuronal nicotinic ACh receptors and Ca^{2+} -CaM Kinase II signaling pathway. Our finding also indicates that neurotransmitters, besides serving as messengers at the chemical synapse, are potential neurotropic agents during development of the nervous system.

608.6

EARLY RETINAL AXON GROWTH IN THE MOUSE VENTRAL DIENCEPHALON. R.C. Marcus* and C.A. Mason, Dept. Pathology, Coll. Phys. Surg., Columbia Univ., NY, NY 10032.

Previous studies of retinal axon guidance suggest that both fiber-fiber interactions and the local cellular environment provide guidance cues for the growth of the permanent crossed and uncrossed projection in the mouse optic chiasm. Here we examine the pattern of growth of the earliest optic axons with reference to growth of fibers from each eye and to resident cells in the ventral diencephalon.

DiI and DiO labeling of the entire optic projection was combined with immunocytochemistry in wholemounts of the ventral diencephalon of E12.5-13.5 embryos. Several antigen markers were used based on our studies of later periods. Preparations were viewed first as wholemounts, then sectioned frontally. This method provided a 3-D analysis of axon trajectory in relation to resident cells that can only be appreciated in wholemounts.

MAB RC2 labels a midline palisade of radial glia which is penetrated by both crossed and uncrossed axons. However, all optic axons, regardless of destination, initially grow posteriorly in lateral, RC2-negative regions. Crossed axons do not grow directly into the contralateral optic tract but curve anteriorly as they approach the midline. This is in contrast to the pattern seen at E15-17, when crossed axons traverse the midline on the diagonal. Early axons course lateral to and under a population of SSEA-1-positive cells (Mason et al., Soc Neurosci Abstr, 1991) present in an inverted "V" (similar to CD44 - Sretavan et al., Soc Neurosci Abstr, 1992) suggesting these cells form an inhibitory boundary. Fiber-fiber interactions are not important in establishing the visual pathway since axons grow into the ipsilateral optic tract independent of interactions with crossed axons from the other eye. We are currently examining the relation of early axons to both F4/80-positive microglia and chondroitin sulfate (Lustgarten et al., this volume).

These analyses suggest that multiple cues are involved in the establishment of the visual pathway and that the relative contribution of cues to the divergence of retinal axons in the mouse chiasm may differ during initial vs. subsequent development.

DISTRIBUTION AND FUNCTION OF T-CADHERIN DURING THE PROJECTION OF MOTOR AXONS TO THE HINDLIMB. B. Fredette* and B. Ranscht, La Jolla Cancer Research Foundation, La Jolla CA 92037

The lipid-linked member of the cadherin family, T-cadherin, is expressed in the developing spinal cord and surrounding mesenchyme in regions not traversed by growing motoneurons, such as the floor plate and posterior sclerotome. Also, T-cadherin is expressed on motoneurons themselves, suggesting that T-cadherin's homophilic binding functions as a deterrent to growing motor axons. Immunofluorescence in the developing chick hindlimb region revealed a distribution that is consistent with this proposal. All lumbosacral motoneurons expressed T-cadherin as they projected segmentally through the T-cadherin-negative anterior sclerotome to the plexus region at the base of the limbud (st 20-25). T-cadherin then decreased on motor axons as they re-attached to form nerve trunks projecting to individual muscles, and remained negative until after their growth cones had invaded the T-cadherin-negative muscle masses at st 27. At st 28, T-cadherin was reexpressed heterogeneously among motor neuron pools. This may reflect differences in axonal branching patterns within muscles, since the heterogeneity arose while axons branched and formed synapses in the muscles. In muscle, T-cadherin slowly increased to extremely high levels on maturing myotube surfaces and persisted after hatching, but was excluded from synaptic junctions. *In vitro* experiments also indicated an inhibitory role for T-cadherin: neurite outgrowth from sympathetic and DRG neurons as well as from ventral spinal cord explants was inhibited by T-cadherin substrates. A comparison of neurite growth from T-cadherin-positive and -negative populations of motoneurons on T-cadherin substrates is presently underway to determine if the inhibition is due to homophilic T-cadherin adhesion. Thus T-cadherin in the floor plate of the neural tube and in the posterior sclerotome may act to prevent motor axon advance through these regions, and to arrest axonal growth in the maturing muscle.

THE NEUROTROPIC EFFECTS OF NERVE GROWTH FACTOR IN THE REGENERATING PERIPHERAL NERVE

W. Geoff Williams, M.D.* J.R. Perez-Polo, Ph.D. Linda G. Phillips, M.D. Martin C. Robson, M.D. UTMB, Galveston, TX.

Nerve growth factor (NGF) exerts neurotropic effects *in vitro*. Little is known about the neurotropic effects of NGF *in vivo*. Here a rat sciatic nerve model was employed where the nerve was transected (distal nerve was removed) and the proximal stump placed into the single end of a Y-shaped silicon nerve regeneration chamber. In four groups of rats, NGF at concentrations of 714, 178 and 71 μ g/ml and sheep antisera to NGF was infused over 2 weeks via subcutaneously-placed Alzet minipump and catheter into one arm of the Y implant. Corresponding concentrations of cytochrome-c solution were infused into the other implant arm via a separate pump and catheter. At four weeks, tissue from the two arms of the implant was evaluated histologically and myelinated axons counted in order to compare the effects of NGF and anti-NGF versus their respective controls. In the NGF groups, there was no statistical difference among the number of myelinated axons in NGF regenerates when compared to adjacent controls. In the anti-NGF group however, the antibody-treated arm of each regenerate contained significantly less myelinated and unmyelinated axons compared to its control counterpart. There was an increase in cellular inflammation and fibrosis in the anti-NGF-treated regenerates. We conclude that endogenous NGF exerts a neurotropic effect on regenerating axons, an effect that is not affected by exogenous NGF.

UPTAKE INHIBITORS SELECTIVELY ATTENUATE DEPLETIONS IN CORTICAL AND HIPPOCAMPAL SEROTONIN AND NOREPINEPHRINE CAUSED BY 2'-NH₂-MPTP IN TWO STRAINS OF MICE. A. M. Andrews* and D. L. Murphy, Lab. of Clinical Science, NIMH, Bethesda, MD 20892.

Recently, we reported that the novel MPTP analog 1-methyl-4-(2'-aminophenyl)-1,2,3,6-tetrahydropyridine(2'-NH₂-MPTP) administered to C57BL/6 mice produces substantial decreases in forebrain serotonin (5-HT), and norepinephrine (NE) with negligible effects on brain dopamine (DA). We now report that compared to C57BL/6 mice, 2'-NH₂-MPTP causes significantly greater decreases in hippocampal 5-HT and NE (80-90% vs. 60%), and similar magnitude changes in cortical 5-HT and NE (60-75%) in Swiss Webster mice. In C57BL/6 mice receiving either fluoxetine or desipramine (10 mg/kg) prior to 2'-NH₂-MPTP, decreases in 5-HT and NE, respectively, were moderately attenuated by ~30-40% 1 week post-treatment (p<0.05). In Swiss Webster mice however, pretreatment with 10 mg/kg fluoxetine or paroxetine, or 10 mg/kg desipramine, completely prevented decreases in cortical and hippocampal 5-HT and NE, respectively, 3 weeks after 2'-NH₂-MPTP (p<0.001). Therefore, not only are Swiss Webster mice more sensitive to the effects of 2'-NH₂-MPTP in hippocampus, but they also seem to be more fully protected from the toxic effects of 2'-NH₂-MPTP by pretreatment with uptake inhibitors. Finally, these results suggest that the differential effects of fluoxetine and paroxetine versus desipramine are most likely due to the inhibition of active transport of 2'-NH₂-MPTP, or possibly a neurotoxic metabolite of 2'-NH₂-MPTP, into serotonergic or noradrenergic nerve terminals via their respective transport systems.

2,5-HEXANEDIONE (2,5HD) AND ACRYLAMIDE (ACR) PRODUCE DIFFERENT PATTERNS OF ELEMENTAL ALTERATIONS IN PERIPHERAL NERVE. R.M. LoPachin*, E.J. Lehning and A.J. Saubermann, SUNY Stony Brook, Stony Brook, NY 11794-8480.

The structural and functional consequences of 2,5HD-induced distal axonopathy might be mediated by subaxonal disruption of elements (e.g., Na, K, Ca) and water. To examine this possibility, we used electron probe X-ray microanalysis to measure elemental concentrations (mmol element/kg dry or wet weight) and percent water in peripheral nerve myelinated axons and Schwann cells from control and 2,5HD (oral, 0.4% w/v) intoxicated rats. Regardless of the length of neurotoxicant exposure (78, 85 and 104 days), tibial nerve internodal axon regions exhibited moderate decreases in axoplasmic Na, K and water content. In proximal sciatic nerve regions, similar patterns of elemental change were noted, although the magnitude of change was not as pronounced. We interpret these elemental alterations as a manifestation of previously reported 2,5HD-induced axonal atrophy. Giant axonal swellings were observed in both tibial and proximal sciatic nerve regions. Independent of nerve area, neither elemental composition nor water content was altered in swollen axons. These changes are unlike the complete elemental derangement associated with swollen peripheral nerve axon areas of ACR-intoxicated rats (LoPachin et al., *Tox. Appl. Pharm.* 115:21, 1992). In both proximal and distal nerve regions, Schwann cells exhibited substantial derangement of Na, P, Cl, K, Ca and water. These glial alterations are injury-typic and are different from those associated with ACR neurotoxicity (LoPachin et al., *Tox. Appl. Pharm.* 115:35, 1992). The dissimilar patterns of elemental perturbation which characterize 2,5HD and ACR imply that the respective mechanisms of nerve injury are distinct. (Supported by NIH grant ES03830)

EFFECT OF 1-METHYL-4-PHENYL-PYRIDINIUM (MPP⁺) ON DNA SYNTHESIS IN THE MOUSE BRAIN CELL NUCLEUS. Nguyen T. Buu* IRCM, University of Montreal, Montreal (Quebec) H2W 1R7 Canada

MPP⁺ is the main product responsible for the pathogenesis of parkinsonism induced by 1-methyl-4-phenyl-1,2,3,6-tetrahydropyridine (MPTP) administration in humans, monkeys and mice, but not in rats. However the mechanisms by which MPP⁺ causes dopaminergic neurons to degenerate and inflicts more damage in some animal species than in others is not yet understood. Recently, we found that cell nuclei from C57 mouse brain, in contrast to cell nuclei from Sprague-Dawley rat brain, accumulate and contain uptake system for MPP⁺ (Buu, 1993). In this study, we determine what effect MPP⁺ may have on DNA synthesis in the isolated cell nuclei.

Cell nuclei were prepared from C57 mouse brains by standard methods using detergent Triton X-100 and sucrose gradient. They were incubated for 60 min at 37°C with ³H methyl thymidine in the presence and absence of 1 mM MPP⁺. DNA was precipitated in 15% TCA.

The results showed that MPP⁺ inhibits thymidine incorporation by almost 70 percent, indicating that MPP⁺ can affect a nuclear function. Whether the inhibitory effect of MPP⁺ on DNA synthesis may contribute to its degenerative effect on dopaminergic neurons is being investigated.

609.2

PEROXYNITRITE (POX) SCAVENGERS: POSSIBLE NEUROPROTECTANTS AGAINST NITRIC OXIDE (NO)-DEPENDENT TOXICITY. J.S. Althaus*, T.T. Oien, G.J. Fici, H.M. Scherch, A.F. Strautman, V.H. Sethy and P.F. VonVoigtlander, CNS Research, The Upjohn Company, Kalamazoo, MI 49001.

The toxic intermediate, POX, may form *in situ* when high concentrations of NO and O₂ generated during ischemia, react with each other. Once formed POX can then nitrate and/or hydroxylate proteins and lipids resulting in cell injury and death. The present study was undertaken to investigate the cysteine genus for POX scavengers.

POX scavengers were assayed by Attoflo[®], an automated radioimmunoassay. Briefly, POX, in a dose dependent manner (0.1 to 30 mM) destroyed antibody activity by inhibiting the binding of ¹²⁵I-cAMP to a polyclonal antibody used in the assay of cAMP. At 10 mM, POX caused a 90% loss of antibody activity. Drugs were tested as protectants of this loss in antibody activity. Actives were then tested as inhibitors of POX toxicity in cerebellar granular cells treated with buthionine sulfoximine (BSO), a drug which depleted cellular glutathione and potentiated toxicity.

At 10 mM, POX caused a 90% loss of antibody activity. Cysteine protected the antibody from this lost activity in a dose dependent manner (EC₅₀ = 10 mM). By comparison, the loss of activity caused by POX (10 mM) with cysteine, cysteine methyl ester or cysteine ethyl ester (at 3 mM) was only 80.7%, 55.4% or 45.3% respectively. BSO potentiated the toxicity of POX in cerebellar granular cells. Micromolar concentrations of cysteine and related compounds completely blocked this toxicity.

As research continues regarding the toxic role of NO, it is clearer that POX may be an important toxic intermediate. POX scavengers represent a new class of compounds that may be useful as neuroprotectants.

POWER SPECTRAL ANALYSIS (PSA): OVERNIGHT ELECTROENCEPHALOGRAPHIC (EEG) SLEEP STUDIES OF CHILDREN WITH ACUTE LYMPHOBLASTIC LEUKEMIA (ALL)

L. C. Parsons*, M. Peris, P. Jones, K. Applegate, S. Humble, T. Skinner, R. Tames, V. Townsend, L. Crosby, I. Moore, and J. Hutter, COH UofA Tucson 85721
Triple Intrathecal Chemotherapy (TIT/CTX) on the sleep awake cycles of children with ALL has not been studied. **Purpose:** to measure the PSA of the first three overnight EEG sleep cycles in four children, between the ages of 10 and 18 years, who were within 48 wks of diagnosis of ALL. Children, receiving TIT/CTX, were matched with four healthy control subjects according to age, gender, cultural ethnicity and socio-economic status. The eight children spent a conditioning night and a study night within the sleep lab. The methodology included downloading directly into a computer, from a polygraph, four channels of EEG data (F3-C3, F4-C4; frontal; C3-P3, C4-P4; central). Data were converted from an analog to digital format. EEGs were sampled at 128 samples/second for each of the overnight recordings. Rhythm Software V.7.10 (Stellate Corp.) carried out digitization in the following EEG bandwidths: δ (7.5-2.5), θ (2.75-7.25), α-1 (7.5-9.75), α-2 (10.0-11.75), Σ (12.0-14.0) and B (18-30). EEG data were submitted for PSA in the form of NREM and REM cycles. Prior to PSA analysis; artifacts > 2 sec. were removed. Data were collected for power in 4 sec. epochs. Multiple epochs were averaged to yield the average 4 sec. power spectral distribution for each NREM/REM cycle. **Data analysis:** Analysis of variance (ANOVA) was used to assess significant main effects for patient grouping (ALL/control), cycle (1-3), or their interaction. 24 ANOVAs were calculated for frontal and central montages, averaged over left and right hemispheres, for both REM and NREM cycles for each frequency. **Results:** Significant group effects for θ (p=.0411) and α-1 (p=.0452) in the non-REM cycle and θ (p=.0281) and B (.0441) in the REM cycle. A marginally significant effect for REM was also obtained in REM for α-1 (p=.0590). The pair by group interaction was highly significant for all frontal and central analyses with p-values ranging from .0001 to .0286. Means of the frontal and central data show that each leukemic pt had higher values when compared to his/her control except in the α-2 data. One pair displayed a consistent reversal in central data. Significantly elevated power density in frontal leads in the frequencies of θ and α-2 may suggest early side effects of TIT/CTX.

DISSOCIATION OF CIS-PLATINUM INDUCED NEUROTOXICITY AND CHEMOTHERAPEUTIC EFFICACY. N.Y. Lorenzo, M.M. Ames, A.J. Windebank*, Mayo Clinic and Foundation, Rochester, MN 55905 USA.

The chemotherapeutic efficacy of cis-platinum depends upon production of covalent inter- and intrastrand DNA crosslinks. The mechanism of neurotoxicity is unknown. In rat dorsal root ganglion neurons (DRG) in tissue culture, we have previously demonstrated that the melanocortin analog, ACTH₄₋₉ may prevent cis-platinum induced axonal damage *in vitro*. In the present studies, DNA crosslinking was studied using alkaline elution. L1210 mouse leukemia cells were incubated with ¹⁴C thymidine or ³H Thymidine x-irradiated, lysed, and passed through PVC filters using alkaline conditions (pH 10.1). As previously reported by others, exposure of cells to cis-platinum significantly retarded elution in a dose dependent manner. L1210 cells were then incubated with cis-platinum (5 and 10 μg/ml) and ACTH₄₋₉ (1 μg/ml). This did not alter the cis-platinum effect. Two cancer cell lines (L1210 and Hey, human ovarian epithelial cell cancer) were used. Viability was assessed by Coulter cell counting or neutral red assay. Cells were exposed to cis-platinum (1,3,5,7,10,20 μg/ml) for 3 hours followed by a 72 hour post-incubation in control medium. For both lines, cis-platinum produced dose dependent cell death (52.6% at 1 μg/ml; 96.6% at 20 μg/ml). Preincubation and coincubation with ACTH₄₋₉ did not alter this cytotoxicity.

Conclusion: Cis-platinum produces predictable cytotoxicity in murine and human cancer cells which is associated with DNA covalent crosslinking. This effect is not altered by concentrations of ACTH₄₋₉ which have been demonstrated to ameliorate neurotoxicity. This strongly suggests that the neurotoxic and chemotherapeutic effects may be dissociated.

609.7

CONVULSANT EFFECTS OF INTRAVENTRICULAR FOLATES. S.R. Snodgrass*, Z.H. Zhang, AND P.E. Bradshaw, Neurology Division, Dept. of Pediatrics, Childrens Hospital Los Angeles, Los Angeles, CA 90054 and University of Mississippi Medical Center, Jackson, MS 39216.

Past authors (Hommes, Olney) reported folate neurotoxicity in experimental animals. However, intraventricular folate administration has been used for human methotrexate (MTX) neurotoxicity. We compared intraventricular and intracisternal folate injections in rats with ether anesthesia, chloral hydrate anesthesia and no anesthesia. All folates tested produced seizures. Greater doses were needed to produce seizures when injected into the cisterna magna, or when chloral hydrate was used as anesthetic. Oxidized folates were more potent convulsants than 5-methyltetrahydrofolate, tetrahydrofolate or methotrexate. Folic acid and methotrexate convulsant effects were additive when both were given together. Folate convulsant effects were reduced by sodium ascorbate pretreatment, by simultaneous injection of the NMDA receptor blocker MK-801, and by benzodiazepines. Folate convulsant effects were seen with or without antioxidant. Folates, like penicillin, should never be injected into the ventricles or cisterna magna of humans (Snodgrass, Molec. Neurobiol. 6:41, 1992).

Rats convulsing after intraventricular injection

Folate dose	10 ug	30 ug	100ug
5-methyltetrahydrofolate		1/5	2/5
folic acid	1/5	2/5	6/7
methotrexate	0/5	0/5	2/5
dihydrofolate		1/4	4/5
FA (10) + MTX (30)	3/5	FA(30) + MTX (50)	5/5

AUTOANTIBODIES TO NERVOUS SYSTEM PROTEINS AS MARKERS OF LEAD NEUROTOXICITY. HAN El-Fawal, AS Little, ZL Gong and HL Evans, Nelson Institute of Environmental Medicine, NYU Medical Center, Tuxedo, NY, 10987.

Environmental toxicants may induce changes in the nervous system that are not easily detectable in humans. We have developed an ELISA to measure serum autoantibodies to neuronal and astrocyte structural proteins [neurofilament triplet proteins (NF68; NF160; NF200), myelin sheath (myelin basic protein: MBP) and glial fibrillary acidic protein (GFAP)] as early markers of neurotoxicity. Since the nervous system is "immunoprivileged", these proteins may act as autoantigens following neuronal degeneration and blood-brain barrier compromise. F344 rats (>42 d) were exposed to 0, 50 or 450 ppm lead acetate (Pb) in the drinking water. At 3, 7, 14, 21 and 42 d of exposure rats were euthanized and blood collected for assays and Pb determination. There were no overt signs of toxicity as indicated by body weight and home-cage behavior. Only serum from exposed rats had detectable autoantibody titers. Immunoglobulin (Ig) M and G to neural proteins, particularly IgM, were detected as early as 3 d of Pb exposure. There was a dose-dependent response in autoantibody levels between 50 and 450 ppm. The elevation of IgM vs IgG titers was consistent with a primary antigen (autoantigen) challenge. An early elevation in anti-NF, particularly NF68, and anti-MBP titers was consistent with Pb's targeting of axons and its ability to produce demyelination. Detection of anti-GFAP titers was consistent with decreased GFAP in brains of the same rats, suggesting damage to astrocytes. This study indicates that the assay of autoantibodies to nervous system proteins may provide a sensitive and accessible biomarker of neurotoxic effects. A pilot study of exposed humans showed the feasibility of this technique for occupational and environmental health surveillance. (Supported by API and grants ES00260 and ES04895)

CARDIOVASCULAR REGULATION: SPINAL AND PERIPHERAL CONTROL

610.1

EXERCISE INHIBITS BARORECEPTOR-SENSITIVE NEURONES IN THE NUCLEUS TRACTUS SOLITARIUS (NTS) OF THE ANAESTHETIZED CAT. P.N. McWilliam*, S.E. McMahon, J.C. Kaye

Cardiovascular Studies, Univ. of Leeds, Leeds, LS2 9JT, UK.
Afferent signals from receptors in skeletal muscle contribute to the increase in heart rate and blood pressure during exercise. This study investigates whether hindlimb contraction elicited by L7 ventral root stimulation inhibits evoked activity in NTS baroreceptor-sensitive neurones. Extracellular recordings were made from interneurons in the NTS activated by electrical stimulation of the carotid sinus nerve. The effect of a 2 second hindlimb contraction on the evoked activity of the neurones was studied. Hindlimb contraction significantly reduced the incidence of evoked firing in a large number of neurones. The majority of these were baroreceptor-sensitive, the remainder were either chemoreceptor-sensitive or unclassified. Ionophoresis of the γ -aminobutyric acid (GABA) antagonist, bicuculline methiodide, antagonised the inhibition produced by hindlimb contraction. Intravenous administration of the neuromuscular blocker vecuronium bromide abolished the inhibition of the evoked activity. Therefore evoked activity in baroreceptor-sensitive neurones in the NTS is inhibited by hindlimb contraction and this inhibition is GABA mediated. This inhibitory mechanism may contribute to the cardiovascular changes in exercise.

609.8

TRYPTOPHAN (TRP) PRETREATMENT ATTENUATES THE NEUROTOXIC EFFECTS OF PARA-CHLOROAMPHETAMINE (PCA). C.W. Bradberry*, R.N. Iyer, J.S. Sprouse, G.K. Aghajanian, R.H. Roth Yale Univ. Sch. Med., Dept. of Psychiatry and the West Haven VA Medical Center, West Haven, CT 06516.

The mechanism of toxicity of amphetamine analogs such as PCA and (+)-3,4-methylenedioxymethamphetamine (MDMA) on 5-HT neurons remains unclear, perhaps involving the release of dopamine (DA) and/or 5-HT (possibly peripheral 5-HT). We have previously demonstrated that TRP potentiates the ability of MDMA to release 5-HT from slices of dorsal raphe *in vitro*, suggesting it might also have this effect *in vivo*. We examined the impact of TRP pretreatment upon PCA (2 mg/kg i.p.) neurotoxicity, assessed by whole tissue levels of 5-HT one week following treatment. This is a low dose producing partial loss of 5-HT levels (30-50% depletion). TRP pretreatment (400 mg/kg of the methyl ester, i.p. 20 min prior to PCA) completely reversed the decrease in tissue 5-HT in striatum, partially reversed it in prefrontal cortex, and had no effect in the hippocampus. In order to determine what impact TRP had on PCA-induced neurotransmitter release, a separate group of animals had microdialysis probes implanted in striatum 24 hours prior to PCA/TRP administration. TRP pretreatment significantly increased PCA-induced 5-HT release from 7- to 24-fold, and increased PCA-induced DA release from 2.5- to 4-fold, indicating that enhanced central 5-HT release does not increase PCA neurotoxicity despite an accompanying increase in DA release. Supported in part by MH 14092, DA 08073, the State of Connecticut, and a NARSAD Young Investigator Award to C.W.B.

610.2

MICRODIALYSIS OF AN OPIOID AGONIST INTO THE L7 DORSAL HORN OF ANESTHETIZED CATS ATTENUATES THE EXERCISE PRESSOR REFLEX. A.F. Meinties, A. Ally and L.B. Wilson, Harry S. Moss Heart Center, UT Southwestern Med. Center, Dallas, TX 75235-9034.

We tested the effects of microdialyzing [D-Ala²]-Methionine-Enkephalinamide (MET-ENK), an opioid agonist, into the L7 dorsal horn of 5 anesthetized cats on the mean arterial pressure (MAP) and heart rate (HR) responses to static muscle contraction. A dialysis probe was inserted into the L7 dorsal horn, ipsilateral to the contracting triceps surae muscles. Contractions were induced by stimulating the distal cut ends of the L7 and S1 ventral roots for 1 minute. Tension, MAP and HR were recorded continuously. Control contractions (9.5±0.9kg) increased MAP and HR by 62±9mmHg and 20±6/min, respectively. After 40 minutes of microdialyzing MET-ENK (20µM), contraction (8.3±0.6kg) increased MAP and HR by 30±8mmHg and 10±2/min, respectively. The MAP response after MET-ENK was significantly less than control (p<0.05). Thus, microdialysis of MET-ENK into the L7 dorsal horn attenuates the pressor and HR responses to static muscle contraction, thereby implicating an opioid mechanism in the integration of muscle afferent nerve activity.

610.3

GESTATIONAL EFFECTS ON CENTRAL AND EFFERENT NEURAL COMPONENTS OF CARDIAC RECEPTOR REFLEXES IN THE RAT. I. Hines and S.W. Mifflin*. Univ. Texas Health Sci. Center, San Antonio, TX 78284.

To determine if gestational effects on central and efferent neural components of the cardiac receptor reflex contribute to the vasorelaxation of pregnancy, activity of cells in the nucleus tractus solitarius (NTS) receiving cardiopulmonary afferent input, and in renal sympathetic nerves (RSNA), as well as arterial and right atrial pressures (MRAP) were measured in response to intra-atrial boluses of saline (50-300 μ l) or phenyldiguanide (PDG, 1-16mg/kg) in anesthetized, sino-aortic denervated pregnant (P, n=9) and virgin (V, n=13) rats. Effects of acute volume expansion are as follows:

		50 μ l	100 μ l	200 μ l	300 μ l
% Δ MRAP	P	82.3 \pm 30.4*	105.4 \pm 46.4*	102.6 \pm 45.8*	192.4 \pm 84.8*
	V	11.81 \pm 2.36	11.36 \pm 1.84	13.77 \pm 1.89	19.62 \pm 2.85
% RSNA	P	95.25 \pm 1.18	92.88 \pm 1.7	92.36 \pm 1.84	91.17 \pm 1.9
	V	93.83 \pm 1.18	90.9 \pm 1.18	90.02 \pm 1.17	90.4 \pm 0.99

ACELL FIRING (spikes/sec)	P	0.5	3.2 \pm 1.9	3.9 \pm 0.4	2.9 \pm 1.5
	V	1.0 \pm 0.2	5.3 \pm 2.0	3.6 \pm 1.6	2.2 \pm 1.5

Graded doses of PDG produced dose-dependent hypotension and sympathoinhibition in virgin (n=8) but not pregnant (n=4) rats. Excitatory or inhibitory responses in NTS units were unrelated to dose of PDG in either group.

We conclude that despite markedly larger increases in MRAP in gravid rats during acute volume expansion, cardiac receptors mediate comparable NTS neuronal activity and renal sympathoinhibition in P vs V rats. Thus, gestational effects on reflex NTS and renal nerve activity do not contribute importantly to greater vasorelaxation in the pregnant rat. (Supported by HL36080 and HL08454)

610.5

ELECTRON MICROSCOPIC LOCALIZATION OF POSTSYNAPTIC GLYCINE RECEPTOR (93 KD) IN SYMPATHETIC PREGANGLIONIC NEURONS: RELATIONSHIPS TO GABA- AND NON-GABA-CONTAINING SYNAPTIC TERMINALS. J.B. Cabot*, A. Bushnell and V. Alessi. Dept. of Neurobiology and Behavior, SUNY at Stony Brook, Stony Brook, NY 11794-5230.

Recent anatomical data suggest that rat sympathetic preganglionic neurons (SPNs) receive both glycinergic and GABAergic synaptic inputs. In vitro physiological studies indicate that SPNs respond with Cf conductance increases after extracellular application of either GABA or glycine. Interestingly, the GABA responses are partially blocked by the glycine receptor antagonist strychnine at concentrations that completely block responses to glycine (Clendening and Hume, *J. Neurosci.* 10:3977). The present study sought to determine if the intracellular component of the glycine receptor complex (GlyR, 93 kd) was associated with GABAergic synaptic inputs to SPNs.

SPNs in 4 rats were retrogradely labeled with cholera β -subunit. Vibratome sections of T1-T3 were immunoreacted for GlyR and embedded. Serial thick (1 μ m) and thin sections were collected; most thin sections were immunogold labeled for GABA-like immunoreactivity. All but 1% of terminals on identified (somas, proximal dendrites) and unidentified processes in the SPN neuropil which were opposite GlyR (n=320) contained pleomorphic (58%), pleomorphic and dense core (17%), or pleomorphic and round (24%) vesicles. In tissue immunogold labeled for GABA: (a) 303 of 1112 terminals sampled were GABA⁺; 17% of GABA⁺ terminals were on identified SPN processes, and of these 49% were opposite GlyR; (b) 207 of 1112 terminals were opposite GlyR; 45% of these were GABA⁺ and 27% of that population were on identified SPN processes; (c) 60% of GlyR in unidentified (n=167) and 38% in identified (n=40) processes were opposite GABA⁺ terminals. GlyR in SPNs is not uniquely associated with non-GABAergic synaptic input. Supported by HL24103.

DETERMINISTIC MODEL OF EFFERENT SYMPATHETIC (SYM) ACTIVITY IN NEONATAL SWINE. H.P. Koepchen, A.W. Przybyszewski, L.P. Eberle, B.W. Hundley, P.M. Gootman. (SPON: ENA) Depts. Physiol., SUNY - Hlth. Sci. Ctr., Bklyn, NY 11203 and Freie Universität Berlin, Germany.

Simultaneous recordings of efferent cervical SYMP (CS), splanchnic (SPL) sympathetic and phrenic activity were obtained in Saffan-anesthetized, paralyzed and artificially ventilated piglets (1 - 38 days of age) along with aortic pressure, EKG, end-tidal CO₂. We have previously reported (*Neurosci. Abstr.*, 1992, 18:1182) that peaks in power spectra (ps) of CS and SPL were correlated in piglets > 19 days old. The ps of longer (10 sec) periods 10 times averaged has shown that the respiratory (RESP) rhythm dominated in CS and cardiac rhythm in SPL. Nitroprusside (NP) injection caused suppression of the cardiac rhythm in SPL. Observation of the CS and SPL activity showed that there were short periods in both nerves when cardiac or RESP rhythm dominated. In piglets > 19 days SPL and CS activity can be described as coupled nonlinear oscillators. The difference between both systems was only in their nonlinear properties. SPL was more nonlinear than CS. Both oscillators were forced with sinusoidal signals modulated with a cardiac rhythm at 4 times greater strength than RESP. This model elicited changes in the signals similar to those observed experimentally in CS and SPL. Characteristic broadening, obtained experimentally in ps peaks, were observed in our model only for quasiperiodic or chaotic oscillations. These properties were shown by plotting the relationship between CS and SPL in phase-space. In 10 sec time periods the attractor (att) changed its position in time, which appeared very similar to the Rössler hyperchaos. The structure of the att was very sensitive and disappeared after NP injection. (Supported by NIH grant HL-20864.)

MATHEMATICAL MODEL OF BARORECEPTOR-VAGAL CONTROL OF HEART RATE SHOWS ENTRAINMENT OF HEART BEAT TO VAGAL STIMULATION. W.C. Ross and J.S. Schwaber*. *Neural Computation Group, E.I. DuPont de Nemours & Co., Wilmington, DE 19880-0323.*

We have developed a mathematical model of vagal control of heart rate as part of our efforts to understand the neural computational aspects of baroreflex control of the heart. It has been observed experimentally that over some frequency ranges the vagus can entrain the heart, i.e. as vagal impulse frequency increases, the interbeat interval decreases, contradicting conventional expectation (Levy et al., *Circ. Res.* 30:286, 1972). Our model reproduces this counterintuitive behavior, as shown below, by incorporating phase-dependent resetting of an SA nodal oscillator. Although the overall trend shows interbeat interval lengthening as vagal shocks are delivered more frequently, there are ranges over which the opposite occurs. A vagal impulse arriving late in the cardiac cycle is more effective in delaying the onset of the next beat than an impulse arriving early; this property can lead to entrainment and may be due to the dynamics of I_{K(ACh)} (Dexter et al., *Circ. Res.* 65:1330, 1989). When combined with a model of baroreceptor control of vagal activity this leads to interesting behavior including increases in heart rate when frequency of baroreceptor pressure pulsations is increased.

GLYCINE MODULATION OF CARDIOVASCULAR RESPONSES EVOKED BY SPINAL NMDA RECEPTOR ACTIVATION IN CONSCIOUS RABBITS. Huang W. and West M.*, Dept Med, Uni Qld, Prince Charles Hospital, Brisbane, Qld 4032, Australia.

Recent in vitro studies indicate glycine enhances the effects of N-methyl-D-aspartate (NMDA) receptor activation. We have investigated the effects of intrathecal glycine on cardiovascular responses produced by intrathecal stimulation of spinal cord NMDA receptors in conscious rabbits. We also assessed plasma norepinephrine responses induced by hypotension. Following glycine, responses to NMDA and L-glutamate, but not α -amino-3-hydroxy-5-methyl-4-isoxazolepropionic acid (AMPA, 0.001-1 μ g), were greatly enhanced. Baroreflex induced elevation in plasma norepinephrine was greater following glycine (194 \pm 31 vs 439 \pm 38 pg/ml, n=4, p<0.05). In the presence of glycine antagonist cardiovascular responses to NMDA were abolished. The results show that (i) glycine amplifies cardiovascular tonic and baroreflex responses (ii) activation of spinal NMDA receptors depends upon the presence of glycine. We conclude that the glycine receptor site within the NMDA receptor complex has an important role in central regulation of the circulation.

610.8

REACTION OF ADRENAL SYMPATHETIC PREGANGLIONIC NEURONS (SPNs) TO DEAFFERENTATION CAUSED BY SPINAL CORD INJURY. A.V. Krassioukov* and L.C. Weaver. John P. Roberts Research. Inst. & Dept. of Physiol. Univ. of Western Ontario, London, Ont., N6A 5K6, Canada.

We hypothesized that arterial pressure instability due to exaggerated sympathetic reflexes after spinal cord injury results from changes in the SPNs in response to loss of their supraspinal afferent input. We examined morphological changes in SPNs retrogradely labelled by cholera toxin after spinal cord injury in rats. We also, we assessed changes in immunoreactivity to the growth associated protein GAP-43, to the synaptic vesicular protein synaptophysin and to the indicator of reactive astrogliosis, glial fibrillary acidic protein. After midthoracic cord hemisection all rats had paralysis of one hindlimb, indicating chronic spinal injury. A comparison of SPNs above and below the lesion revealed significant loss of dendrites and decreased cell size in response to loss of supraspinal input. Astrogliosis surrounded SPNs as far as 7 segments below the injury only on the side of the lesion but were found above the injury only at the lesion itself. Because expression of synaptophysin is normally high, differences above and below the injury were difficult to detect. GAP43 was increased in the gray matter below the site of the transection. These findings suggest that SPNs undergo significant structural change after deafferentation, associated with or dependent on astrogliosis and that exaggerated reactions may be due to new synapse formation. We also compared the morphology of SPNs below an injury to that of SPNs in cultured explants of the spinal cord taken from 7 day old rat pups. SPN morphology above an injury was compared to that of the normal 7 day pups. In culture, SPNs were smaller and had fewer processes, like SPNs below an injury *in vivo*. Numbers of SPN dendrites in 7 day rats were similar to numbers in SPNs above an injury. This shows that the living explant of the spinal cord *in vitro* can be a good model of deafferentation of the SPNs such as that occurring after spinal cord injury.

GROWTH OF EMBRYONIC CHICK HEART CELLS IN MEDIA SUPPLEMENTED WITH LIPOPROTEIN DEPLETED SERUM (LPDS) REGULATES EXPRESSION OF GENES CODING FOR G-PROTEINS AND MUSCARINIC RECEPTORS. A.P. Gadbut*, J.B. Galper. Cardiovascular division, Brigham and Women's Hospital and Harvard Medical School, Boston, MA 02115.

Growth of chick atrial cells in media supplemented with LPDS has previously been shown to increase intracellular cholesterol and parasympathetic responsiveness. These changes were associated with increased levels of muscarinic receptors (MR) as measured by [³H] QNB binding and G-protein α -subunits ($G\alpha$) as measured by ADP ribosylation with pertussis toxin (Haigh et al. JBC 263:15608). To determine whether these changes reflect increases in gene expression we used RNase protection to compare levels of mRNA coding for MR and $G\alpha$ in cells grown in medium supplemented with fetal calf serum or LPDS. In atrial cells from chicks 14 days *in vivo* growth in the presence of LPDS resulted in a 3 fold increase in mRNA coding for M2 and M3 MR subtypes while mRNA coding for α 2 and α 3 increased 2 and 3 fold respectively. These changes were reversed in cells grown in LPDS plus 30 μ M Mevacor (an HMG-Co A reductase inhibitor). However, incubation of cells in medium supplemented with LPDS and a squalene oxidase inhibitor decreased total cell cholesterol but, did not reverse the increase in mRNA levels. Hence some factor in the cholesterol biosynthetic pathway proximal to squalene may play a role in regulating the expression of genes coding for MR and G-proteins.

OMEGA-CONOPEPTIDE REDUCES THE EXTENT OF CALCIUM ACCUMULATION FOLLOWING TRAUMATIC BRAIN INJURY. H. Badia, M.L. Smith, D.A. Hoyda*, K. Fu, P. Pinarong, A. Samii and D.P. Becker. Division of Neurosurgery, UCLA School of Medicine, Los Angeles, Ca 90024.

The Omega-conopeptide SNX-111 (a N channel calcium (Ca^{++}) blocker) (NEUREX Corp.) was administered (3 or 5 mg/kg, i.v.) to rats 1 h following a lateral fluid percussion (2.4-2.6 atm) brain injury. Animals were subsequently assessed for Ca^{++} accumulation at 6, 12, 24, 48 or 96 hrs after injury utilizing ⁴⁵Ca⁺⁺ autoradiography. A total of 79 animals (223-367 g, male) were used with 28 serving as sham operated controls. All surgical procedures were conducted under general anesthesia (1.5-2.0% enflurane, 33% O₂, 66% NO₂). ⁴⁵Ca⁺⁺ was quantified using optical densitometry with relative asymmetry measurements (Left-Right/Total) conducted for 20 structures. The results indicated that following fluid percussion brain injury, saline treated animals exhibited a marked accumulation of ⁴⁵Ca⁺⁺ primarily within the ipsilateral cerebral cortex and hippocampus. This injury-induced accumulation of ⁴⁵Ca⁺⁺ lasted for as long as 48 hrs. However, in animals who received SNX-111, the Ca^{++} accumulation was attenuated both in terms of extent and duration. Within the parietal cortex, animals receiving SNX-111 exhibited a reduction of ⁴⁵Ca⁺⁺ accumulation at 24 hrs (Saline=0.312, 3 mg=0.048, 5 mg=0.061). This effect continued out to 48 h particularly in the higher dose (Saline=0.238, 3 mg=0.139, 5 mg=0.052). Within the dorsal hippocampus, ⁴⁵Ca⁺⁺ accumulation was reduced by administration of SNX-111, starting at 12 hrs post-injury (saline=0.0601, 3 mg=0.048, 5 mg=0.056). This drug-induced effect was even more pronounced when measured 48 hrs after the insult (saline=0.033, 3 mg=0.017, 5 mg=0.005). These results demonstrate that SNX-111 can reduce the injury-induced accumulation of Ca^{++} even when administered 1 h after surgery. (NEUREX Corp. & NS 30 308)

MACROPHAGE RESPONSE DURING AXONAL DEGENERATION ALONG THE PNS/CNS DORSAL ROOT PATHWAY MAY BE IMMUNE MEDIATED. D.B. Ellegala, A.M. Avellino, K.C. Andrus, and M. Klotz*. Dept. of Neurosurgery, Univ. of WA and Seattle VAMC, Seattle, WA 98108.

Wallerian degeneration of axons differs dramatically in the adult mammalian PNS and CNS. For example, macrophage invasion with clearance of myelin and axonal debris occurs more rapidly in the PNS than the CNS (Perry et al, 1987; Stoll et al, 1989). The mechanisms underlying this difference are unknown. One possibility is that macrophages respond to molecules preferentially expressed in the PNS (Avellino et al, 1992; Griffin, 1993). Alternatively, macrophages may be part of an immunologic response directed at antigens exposed at the site of injury. To test this latter hypothesis, we studied macrophage invasion along the PNS/CNS dorsal root pathway in adult Lewis rats following various types of axonal injury.

Initial experiments involved cutting lumbar dorsal roots in the PNS followed by immunostaining for macrophages (ED1 monoclonal antibody) at 3, 7, and 14 days. Macrophages invaded the PNS portion of cut dorsal roots but stopped abruptly at the interface with the CNS (i.e. dorsal root entry zone=DREZ). Following a crush injury to the DREZ, involving both PNS and CNS tissue, macrophages were no longer confined to the PNS but now appeared across the DREZ and in the white matter of the CNS at each time point. In order to distinguish the local effects of surgical trauma from the possibility that a DREZ lesion might be sensitizing macrophages to both PNS and CNS antigens, a crush injury to the DREZ of a thoracic dorsal root was combined with transection of lower lumbar dorsal roots on the contralateral side. Macrophages were now observed throughout the PNS and CNS portions of the cut lumbar dorsal roots at all time points. These results demonstrate that macrophage invasion during Wallerian degeneration along the PNS/CNS dorsal root pathway is influenced by the site of axonal injury. They suggest that this cellular response is immune mediated and directed at antigens exposed at the injury site.

MRI STUDY OF RAT BRAIN EDEMA AFTER HEAD TRAUMA: EFFECTS OF HU-211, A NONPSYCHOTROPIC CANNABINOID. A. Biegon*, L. Belajevy, P. Bendel, M. Novikov, R. Bass and E. Shohami Phrarmos Corp., Rehovot; Weizmann Inst. Sci., Rehovot and Hebrew University, Jerusalem, Israel

HU-211 is a nonpsychotropic cannabinoid which improves the neurological outcome following closed head injury in the rat. We have used magnetic resonance imaging (MRI) to assess the spread of brain edema following head trauma and the possible effect of HU-211 on this parameter. Head trauma was induced by dropping a calibrated weight from a specific height onto the exposed skull (left side, anterior to bregma) of ether-anesthetized rats. Animals were given chloral hydrate (350mg/kg i.p) and placed in a 4.7 Tesla magnet 30 minutes after the trauma for a 10 min T2 weighted scan (TR=2.5sec, TE=55msec, Slice thickness=1mm, center to center slice separation=1.2mm, 128x256 matrix, FOV=5cm). One hour after trauma, rats received an i.v injection of HU-211 5mg/kg in emulsion (N=9), or the appropriate vehicle (N=11). The scan was repeated 24 hours posttrauma. The extent (volume) of initial damage to the brain was calculated from the volume difference between the right and left hemispheres. The volume of edema 24 hours later was calculated from the area of hyperintense regions (besides ventricles) on all the slices where such regions were observed after thresholding, multiplied by 1.2mm. The ratio between the volume of initial damage and edema volume was calculated for each individual animal to control for variations in initial damage. This ratio was significantly lower in the treated group (mean \pm sem vehicle, 5.95 \pm 1.6; HU-211, 1.66 \pm 0.55; p<0.033, Student's t-test, two tailed), indicating that HU-211 reduced the spread of edema after head trauma.

611.4

REACTIVE AXONAL CHANGE IN A MICROPIG MODEL OF BRAIN INJURY: EVIDENCE FOR A HUMAN-LIKE PROGRESSION OF AXONAL CHANGE. Valadka, A.B., J.T. Povlishock*, J. Shah, and S. Walker. Dept. of Anatomy and Division of Neurological Surgery, Med. Col. of Va., Va. Commonwealth Univ., Richmond, VA 23298.

In an effort to develop an experimental animal model which better replicates the pathobiology and the temporal course of the reactive axonal change seen in human traumatic brain injury (TBI), we have evaluated a micropig model of fluid-percussion brain injury. Under anesthesia, 15 micropigs were subjected to mild to moderate TBI. Four hours to 5 days postinjury they were prepared for the LM and TEM visualization of antibodies targeted to the neurofilament (NF) subunits, tau, and ubiquitin. TBI elicited a temporal progression of reactive axonal change, comparable of that seen in humans. Within 4-6h of TBI, scattered axons showed a focal intraaxonal increase in the NF subunits which lost their normal alignment. Over 12-24h, this process of NF misalignment continued. Typically, these events were associated with impaired axoplasmic transport, causing focal axonal swelling and detachment. While these swollen reactive axonal segments predominated at 24h postinjury, scattered reactive profiles reminiscent of those seen at the 4-6h were also identified. At 2-5 days, these reactive changes continued with further expansion of the reactive axonal swellings. Again, swollen yet non-disconnected axons were also identified. Some showed complex multi-lubulated profiles with dilated NF and organelle-containing regions. Collectively, the evolution, the temporal course, and the heterogeneity of these reactive axonal changes are comparable to those seen in human TBI. This suggests that the micropig is an excellent model for better understanding the pathobiology of this injurious process. NS-20193

DISTRIBUTION OF DIFFUSE AXONAL INJURY FOLLOWING INERTIAL CLOSED HEAD INJURY IN MINIATURE SWINE
D.T. Ross,* D.F. Meaney, D.H. Smith, J. Brasko, L.E. Thibault, and T.A. Gennarelli Head Injury Center, Div. of Neurosurgery, Univ. of Pennsylvania, Philadelphia, PA 19104

Diffuse axonal injury (DAI) is one of the most frequently encountered types of brain damage resulting from closed head injury. The development of a non-primate model of DAI would greatly facilitate studies of the pathophysiological mechanisms of DAI and the testing of potential neuroprotective therapies in a final pre-clinical screening paradigm. The present study was designed to histologically verify whether inertial injury in the coronal plane could produce DAI in miniature swine.

Animals were anesthetized with 3% isoflurane, secured to the inertial injury device by a snout clamp, and their heads accelerated rapidly (msec) once through a 120 degree arc in the coronal plane. These injuries produced transient (<15 minute) posttraumatic unconsciousness. All animals made a good recovery and were sacrificed between 6 hours and 10 days after injury. Neurofilament immunohistochemistry with antisera to non-phosphorylated (SMI-32) and phosphorylated epitopes common to heavy and medium neurofilament proteins was used to identify axonal injury.

Axonal injury was present in 9 of 12 animals subjected to inertial acceleration. These lesions, characterized by SMI-31 positive axonal retraction balls, were present at the white matter/gray matter junction at the crests of gyri in the dorsolateral regions of the frontal, parietal and temporal cortices and along margins of the lateral ventricles. A high density of pyramidal neuron perikarya in layers III and V within cortical gyri associated with subcortical DAI were intensely positive for phosphorylated neurofilament (SMI-31) immunohistochemistry and a high density of moderately labeled pyramidal cell perikarya were present in gyri not associated with DAI. These results validate the use of miniature swine in studies of axonal injury and demonstrate that axonal injury analogous to that seen in the mildest form of DAI (grade I) can be produced in these animals without producing prolonged coma. (supported by NIH Center Grant NS-08803-22)

MAGNETIC RESONANCE NEUROGRAPHY REVEALS SPIN-SPIN RELAXATION RATE (T₂) CHANGES CORRELATED WITH ONSET AND RECOVERY FROM SYMPTOMS IN TRAUMATIC & COMPRESSIVE NEUROPATHY. A. G. Filler*, J. S. Tsuruda, C. E. Hayes, and M. Kliot. Dept. of Neurological Surgery and Dept. of Radiology, University of Washington, Seattle, WA 98195.

A series of advances over the past year have made it possible to non-invasively generate detailed 3D images of nerves in living human patients (Filler et al. *Lancet*, 341:659; Howe et al, *Mag. Res. Med.* 28:328). A striking characteristic of these magnetic resonance images is prolongation of the T₂ relaxation rate in the nerve proximal to sites of traumatic injury or compression. Upon resolution of weakness and numbness, we have observed reversion of the T₂ relaxation rate toward a normal range. The proximal extent of the T₂ changes extend over many centimeters and in several cases include changes in the dorsal root ganglion.

It is not yet clear whether these changes are due to alterations in the flow of axoplasm, blocked flow of endoneurial fluid, or shifts in some other nerve water compartment. However, this is the first image demonstration of altered physiology in nerve extending well proximal to sites of altered action potential conduction in clinical situations in humans.

These phased array MR images demonstrate the internal fascicular pattern of nerves both because of the fat content of the interfascicular epineurium and because this tissue retains very short T₂ under these conditions, appearing relatively unaffected by the pathology downstream. Thus, the perineurial portion of the blood/nerve barrier, which should be permeable to general edema fluid, does constrain movement of the altered fluid within the nerve.

With these new clinical tools, the evaluation of alterations in the various nerve water pools, (intra-organellar, Schwann cell cytoplasm, axoplasmic, etc.) will become an increasingly important focus for understanding the neurobiology of human pain and peripheral nerve dysfunction.

INCREASE IN TISSUE QUINOLINIC ACID AND INDUCTION OF INDOLEAMINE-2,3 DIOXYGENASE AFTER SPINAL CORD INJURY. A.R. Blight¹, M.P. Heyes² and K. Saito², Div. Neurosurgery¹, Univ. North Carolina, Chapel Hill, NC 27599, and Section on Analytical Biochemistry², NIMH, Bethesda, MD 20892.

Numerous mechanisms have been suggested to contribute to secondary cell damage and long-term neurological deficits following spinal cord trauma. Among these, is "bystander damage" from secretory activity of the large number of inflammatory phagocytes that accumulate in the tissue within the first few days. We therefore examined one of the neurotoxic products of activated macrophages, the NMDA receptor agonist, quinolinic acid (QUIN), which has been implicated in a wide range of neuropathologic states (*Brain* 115:1249, 1992). The lower thoracic spinal cord of 5 anesthetized, adult guinea pigs was injured by brief compression (*J.Neurol.Sci.* 103:156, 1991). Five days post-injury, animals were re-anesthetized and tissue samples (c.30mg each) were taken from the site of injury, upper cervical spinal cord, and somatosensory cortex and analyzed by mass spectrometry. A 10-fold elevation of QUIN concentration occurred at the injury site, with no significant changes in uninjured cervical spinal cord or cortex, compared with 5 normal and 5 sham-operated control animals. Concentrations of the kynurenine pathway enzyme, indoleamine-2,3 dioxygenase (IDO), and the pathway intermediate L-kynurenine (KYN) were increased approximately 3-fold at the site of injury, in proportion to QUIN changes. These measurements support roles for IDO and other KYN pathway enzymes in increased QUIN production in injured cord. The pathologic significance of such changes remains to be determined. (Partly supported by NINDS grant NS 21122)

REDUCED EVOKED IN VIVO HIPPOCAMPAL RELEASE OF ACETYLCHOLINE AT 2 WEEKS AFTER TRAUMATIC BRAIN INJURY (TBI). C. E. Dixon*, J. Bao, K. Johnson, and R. L. Hayes. ¹Department of Neurosurgery, University of Texas-Houston Health Science Center, Houston, TX 77030 and the ²Department of Pharmacology, University of Texas Medical Branch at Galveston, Galveston, Texas.

Recent findings suggest that chronic spatial memory deficits following experimental traumatic brain injury may, in part, be attributable to deficits in central cholinergic neurotransmission. Cholinergic deficits induced by TBI may be manifested by a decrease in the levels of evoked ACh released *in vivo*. This study employed microdialysis to measure scopolamine evoked release of ACh at 2 weeks post-injury, a time associated with significant spatial memory deficits. Two weeks prior to measurement, 10 rats were injured by controlled cortical impact (6 m/sec impact velocity, 1.7mm deformation). Sham rats (n=10) were identically prepared but not injured. All rats were anesthetized with an isoflurane mixture and a microdialysis probe (3 mm tip) was placed into their dorsal hippocampus. Samples (30 µl) were collected every 20 minutes. Two samples were collected to establish basal levels of ACh. Scopolamine (1 mg/kg) was then injected i.p. and 4 more samples were collected and analyzed by HPLC. The data show that at 2 weeks post injury, the injured animals release less ACh in response to scopolamine than sham animals. Impaired release may be a result of either denervation, an impairment of the presynaptic negative feedback system, or a deficit in the cholinergic neuron's ability to synthesize ACh. Supported by CDC-R49 CCR606659.

A STRESS-INDUCIBLE HEAT SHOCK PROTEIN (HSP68) IS EXPRESSED IN RAT DRG FOLLOWING AXOTOMY. B. Tedeschi, R.P. Ciavarrà, and C.W. Morgan*. Depts. of Anatomy & Neurobiology and Microbiology & Immunology, East. Virg. Med. Sch., Norfolk, VA 23501.

Direct exposure of most organisms or cells to potentially lethal metabolic stressors induces the expression of HSP68, a member of the 70kd heat shock protein family. In order to assess whether axotomy elicits a neuronal Stress Protein response, rat sciatic nerves (SN) were crushed at ~35mm from the L5 Dorsal Root Ganglia (DRG). Twenty-four hours following axotomy, DRG proteins were briefly radiolabelled (1 hr. pulse) *in vivo* and the radiolabelled proteins subsequently analyzed by two-dimensional polyacrylamide gel electrophoresis and fluorography. Results showed that prior SN axotomy, but not sham axotomy, resulted in the expression of the stress-inducible HSP68 protein in DRG. Moreover, such stress-inducible HSP68 expression was probably limited to the DRG neurons since no detectable HSP68 was expressed by the initial segment of SN following axotomy. These results suggest that the induction of Stress Proteins is one neuronal response to axotomy.

PHARMACOLOGICAL ACTIVITY OF THE GINKGO BILOBA EXTRACT (EGb 761) ON THE VESTIBULAR COMPENSATION PROCESS IN THE CAT. M. Lacour* and B. Tiphilet. Lab. Neurobiologie des Restaurations Fonctionnelles, URA CNRS 372, Univ. Provence, Ct St Jérôme, 13597 Marseille Cedex 20, France.

The effects of postoperative treatment with a Ginkgo biloba extract (EGb 761) has been studied in unilateral vestibular neurectomized cats in a previous work. It has been shown that systemic administration of EGb 761 (50mg / kg / d, i.p.) induced a more rapid recovery of the postural and locomotor functions as compared to control untreated groups, indicating that EGb 761 improved the plasticity mechanisms involved in vestibular compensation. The aim of the present work was to determine which of the two main biochemical groups made up of the various compounds contained in the EGb 761 (terpenes versus flavonoids) was the most active in this recovery process, to precise the best route of administration of the substance (i.p. versus p.o.) and to test the dose-dependent effects. For this purpose, we have compared the time course of the equilibrium function recovery in 7 groups of cats: one untreated group (n = 5 : controls), two groups treated with the total extract administrated p. o. at 40 mg / kg / d (n = 4) or 80 mg / kg / d (n = 4), two groups treated with the total extract injected i. p. at 50 mg / kg / d (n = 5) or 25 mg / kg / d (n = 4), and two groups treated with a special extract without the terpene fraction, i. p., at 25 mg / kg / d (n = 4) or 10 mg / kg / d (n = 4). Treatment was always given until complete recovery of the equilibrium function as quantified by the rotating beam test. Results showed that the efficacy of the special extract do not containing the terpenes was comparable to that of the total extract, suggesting that the non-terpene (flavonoids) fraction was the most active chemical constituent in this experimental model of CNS plasticity. Moreover, the pharmacological activity of the total extract (EGb 761) was significantly better when given i. p. as compared to the p. o. route of administration, and daily doses of 25 mg / kg were as effective as higher doses (50 mg / kg) but much more active than lower doses (10 mg / kg). These experimental data in the cat confirm that EGb 761 treatment serves as useful therapy in supporting functional recovery in the brain and improves the knowledge on the working and activity of such a complex substance.

FLUID PERCUSSION INJURY CAUSES LOSS OF SEPTAL AND VENTRO-BASAL FOREBRAIN CHOLINERGIC NEURONS. R. H. Schmidt* and M.S. Grady. Dept. Neurosurgery, Univ. Washington, Seattle, WA 98195. Although traumatic brain injury (TBI) disturbs consciousness, cognitive function, concentration, problem solving and behavior, the neural mechanisms of this are not known. Because these functions are mediated, in part, by various cholinergic (ACh) and catecholaminergic projections, we sought to determine how these systems were affected by experimental TBI. Fluid percussion injury (FPI), 3.2 atm, or sham injury was delivered to halothane-anesthetized rats via either midline or lateral injury cannulas (N=4-5 each group). Injury resulted in an average loss of righting reflex of 13-14 minutes without any gross damage to the brains. After 11-15 days, the brains were stained in serial section for choline acetyltransferase, tyrosine hydroxylase, dopamine beta-hydroxylase, acetylcholinesterase and NADPH diaphorase. Midline injury resulted in a significant decrease in septal and ventrobasal forebrain ACh neurons bilaterally, averaging 36% in area Ch1, 45% in area Ch2, and 41% in area Ch4, $P < 0.05$. Lateral injury resulted in ipsilateral ACh neuron loss of similar magnitude, $P < 0.05$, but only an 11-28% loss contralaterally. Surviving ACh neurons in Ch4 appeared shrunken and with shorter processes. There was no quantitative loss of ponto-mesencephalic ACh neurons (areas Ch5 and Ch6). Dopaminergic neurons in the ventral mesencephalon and diencephalon, noradrenergic neurons in the pons and medulla, their axon bundles and terminal ramifications did not show any evidence of injury, however quantitative cell counts were not done. This demonstration of a loss of ACh neurons shortly after FPI may serve to explain the cognitive dysfunction these animals demonstrate in water maze testing. Whether this neuron loss is permanent, what terminal fields may be affected, the mechanism of this decrease, and whether it occurs in human victims of TBI remains to be determined. DIFFERENTIAL EFFECTS OF MODAFINIL AND AMPHETAMINE IN CANINE NARCOLEPSY: EVIDENCE FOR A UNIQUE MECHANISM FOR MODAFINIL. J. L. Vaughn¹, S. Nishino², J. Shelton², W.C. Dement² and E. Mignot². ¹Cephalon, Inc. West Chester, PA., ²Sleep Disorders Center, Stanford University School of Medicine, Palo Alto, CA.

Modafinil [2-(diphenylmethylsulfonyl) acetamide] is a structurally unique and mechanistically novel stimulant approved in France and under development in the US for the treatment of narcolepsy. The purpose of the present study was to compare and contrast the effects of Modafinil and amphetamine in a canine model of narcolepsy. In polysomnographic studies on 4 narcoleptic canines with electrodes implanted for recording of the electroencephalogram, electroculogram and electromyogram, Modafinil dose-dependently suppressed slow wave sleep for up to 4 hours following dosages of 5 and 10 mg/kg iv. Amphetamine was also effective at dosages of 100 or 200 ug/kg iv. Preliminary results also indicate that Modafinil, unlike amphetamine, had no significant effects on cardiovascular parameters and rectal temperature at these effective dosages. In contrast, in the Food-Elicited Cataplexy Test, Modafinil in dosages up to 8 mg/kg had no effect on cataplexy. Amphetamine completely suppressed cataplexy at 120 ug/kg with an ED 50 of 50 ug/kg iv. These results are consistent with the known therapeutic effects of Modafinil in human narcolepsy. Moreover, these data indicate that Modafinil and amphetamine have clear differences in their pharmacological profile. Thus, Modafinil represents a mechanistically novel approach to the treatment of human narcolepsy.

TEMPERATURE COMPENSATION OF A CIRCADIAN CLOCK FROM A HOMEOTHERM. R. Keith Barrett* and Joseph S. Takahashi. NSF Center for Biological Timing, Department of Neurobiology and Physiology, Northwestern University, Evanston, IL 60208.

Temperature compensation is a fundamental property of all circadian clocks examined to date; however, temperature compensation in a eutherian homeotherm has not been demonstrated. Dispersed primary chick pineal cells were entrained for 3 days to a light cycle at temperatures between 31°C and 40°C then transferred to constant darkness (DD) at the same temperatures for 5 days. The rhythmic secretion of melatonin in DD was used as an assay of the period of the clock. Circadian period was temperature compensated between 34°C - 40°C with a temperature coefficient, Q_{10} , of about 0.83. Melatonin synthesis, in contrast, was strongly dependent upon temperature. Temperature also affected the expression of the rhythm: the rhythm persisted with minimal damping at 40°C (bird physiological body temperature) but damped rapidly at 34°C and was abolished at 31°C. A phase response curve (PRC) was measured from dispersed pineal cells exposed to a temperature pulse during the first cycle in DD. The pulses were presented every 3 hours over a 24 hour period and phase shifts in the melatonin rhythm were measured. The PRC was remarkably similar to the PRC to 6 hour light pulses in chick pineal cells. These results suggest that the effects of light and temperature on the circadian clock are similar and that the cellular and molecular mechanisms mediating these inputs could have common features. These findings are of interest because higher vertebrate clocks might not have a requirement for temperature compensation because the internal thermal milieu is homeostatically regulated.

SUPEROXIDE DISMUTASE IMPROVES POST-TRAUMATIC CORTICAL BLOOD FLOW IN RATS. J.K. Muir*, M. Tynan, R. Caldwell and E.F. Ellis. Department of Pharmacology and Toxicology, Medical College of Virginia, Richmond, VA 23298

Oxygen free radicals have been implicated in the cerebrovascular abnormalities that occur as a result of traumatic brain injury. These abnormalities include sustained dilation, decreased reactivity to hypocapnia, endothelial lesions and altered reactivity to vasoactive substances. The purpose of this study was to determine if pretreatment with superoxide dismutase (SOD), a superoxide radical scavenger, could alter post-traumatic cortical blood flow (CBF) in rats.

Sprague-Dawley rats (n=36) were initially anesthetized with thiopental (75 mg/kg, ip) and pentobarbital was used to maintain anesthesia. The animals were ventilated with room air and blood gases were maintained within normal limits. One craniectomy was made over each hemisphere and the dura left intact. The fluid percussion injury device was attached over the right parietal cortex and a laser-Doppler probe for measurement of CBF was positioned over the left parietal cortex.

SOD, 24,000 units/kg bolus followed by 1,600 units/kg/min continuous infusion, was administered i.v. beginning 10 minutes prior to an injury of 2.0-2.2 atmospheres. A second group of animals received a similar volume of saline throughout the protocol. The blood pressure and heart rate responses to trauma were not different between the two groups. The saline control group showed a pronounced reduction in CBF (~35%) between 10-60 minutes post-trauma. SOD significantly elevated CBF throughout the post-injury period and the improved CBF was mediated by enhancing cortical blood volume and blood velocity. One hour after injury, CBF in the SOD group was 12±8% below pre-injury baseline, while in the saline group this value was 34±6% below baseline. Supported by NS 27214 and DA 07027.

KETAMINE BLOCKADE OF NMDA-GATED CATION CHANNEL DURING WAKING INCREASES NREM DELTA INTENSITY IN THE RAT. L. Feinberg* and L.G. Campbell, VA/UCD Sleep Laboratory, UC Davis, Davis, CA 95616

The homeostatic model of NREM sleep (1) proposed that the brain recuperative processes of sleep occur during slow-wave sleep, and that the intensity of recuperative processes is reflected by the amplitude and density of delta waves. It further hypothesized that the amount of "recuperation" required is proportional to prior waking duration and the intensity of activity (reflected by metabolic rate) in plastic neuronal systems during waking.

Subanesthetic dosages of ketamine increase the metabolic rate of plastic brain systems, including the hippocampus and other limbic structures (2). This metabolic effect is thought due to blockade of the NMDA-gated cation channel. To test the intensity component of the homeostatic model, we administered ketamine during the dark (waking) period to rats. Three i.p. injections were given; each succeeding dose was injected when the behavioral effects of the previous dose had worn off. In separate experiments, doses of 15, 25 and 50 mg/kg were administered. Saline injections given similarly served as controls. Delta (1-4 Hz) EEG was measured with PASS PLUS a commercially-available method of period/amplitude analysis whose reliability and validity have been established.

Ketamine produced significant increases in delta wave amplitude ($F=7.9$, $p<0.05$) and density ($F=22.3$, $p<0.0001$) during subsequent NREM sleep. While consistent with the homeostatic model, these results are subject to several alternative explanations: ketamine produces widespread metabolic effects and it stimulates multiple receptors. In spite of these uncertainties, these results are of interest because they represent the most powerful pharmacologic stimulation of NREM delta EEG yet observed. They gain added interest because of recent evidence that EAAs are important transmitters in the suprachiasmatic nucleus.

DAILY MELATONIN ADMINISTRATION SYNCHRONIZES CIRCADIAN PATTERNS OF BRAIN METABOLISM AND BEHAVIOR IN PINEALECTOMIZED HOUSE SPARROWS. JUN LU* AND VINCENT M. CASSONE. Department of Biology, Texas A&M University, College Station, TX

The circadian system of house sparrows is composed of two primary oscillators: the visual suprachiasmatic nucleus (vSCN) and the pineal gland. Considerable evidence indicates that these two oscillators are mutually coupled. We have asked whether melatonin administration can synchronize cerebral metabolism as with synchronization of behavior in this species. To test this hypothesis, all house sparrows were pinealectomized. After recovery from surgery, each individual was placed in a chamber in which perch-hopping activity was recorded. Once birds' locomotor activity were completely abolished in constant dim light, 12 birds were periodically administered a melatonin drinking solution (862 µM in 0.01% ETOH) 12 of every 24 hrs. For control, 10 birds were periodically administered 0.01% ETOH only. The actograms showed that melatonin synchronized activity patterns while 0.01% ETOH did not. At ZT06 (6 hr after melatonin was administered to the experimental group or 6 hr after 0.01% ETOH was administered to the control group) and at ZT18 (18 hr after melatonin or 18 hr after 0.01% ETOH), birds (6/experimental group, 5/control group) were intra-muscularly injected with 2-[¹⁴C]-deoxyglucose (2DG, 200 µCi/kg). After 1 hr birds were anesthetized, decapitated, and brains were quickly removed and frozen. Brains were then transversely cut at 20 µm. Slides were processed for 2DG autoradiography while adjacent slides were incubated in 50 pM 2-[¹²⁵I]iodomelatonin (IMEL) to determine specific IMEL binding. Our results indicate that melatonin not only synchronizes locomotor activity but also synchronizes 2DG uptake and IMEL binding patterns in many cerebral structures associated with circadian and visual functions, but not in structures devoid of IMEL binding. PRENATAL INJECTIONS OF D₁-DOPAMINE RECEPTOR AGONIST SKF 38393 ENTRAIN CIRCADIEN RHYTHMS OF HAMSTER PUPS N.Viswanathan* and F.C.Davis. Dept. of Biology, Northeastern Univ., Boston, MA 02115.

Melatonin is a possible maternal entraining signal for the developing circadian pacemaker in hamsters. Prenatal injections of melatonin to pregnant hamsters predictably set the phases of the offspring's circadian rhythms. Induction of *c-fos* in the fetal rat SCN by the D₁-dopamine receptor agonist, SKF 38393 (Weaver et al., PNAS 89:9201, 1992) suggests that maternal entrainment could be mediated by the activation of a dopaminergic system in the fetus. The present study was undertaken to examine this possibility. Pregnant Syrian hamsters, maintained in constant dim light throughout the study, received SCN lesions on day 7 of gestation. Between gestation days 11-15, two groups of hamsters received two intraperitoneal injections each day 12 hours apart. One of the injections contained the SKF 38393 (8 mg/kg) and the other contained saline only. At weaning, pups from both groups were introduced individually into running wheel cages to measure their activity/rest rhythms. The phases of activity onset on the day of weaning were calculated from the freerunning rhythms. Prenatal injections of SKF 38393 unambiguously set the phases of the pups' circadian rhythms; SKF at 0800 established an average phase of 16.80 hr while SKF at 2000 established an average phase of 4.20 hr. Interestingly the average phases established by SKF 38393 were approximately 180° different from those established by melatonin as reported in previous studies. The different phases established by the SKF 38393 and melatonin suggest that there are different maternal signals which act in opposite ways on the developing circadian pacemaker to mediate entrainment. It is possible that melatonin acts as a signal representing night while an unidentified maternal signal which activates a dopaminergic system acts as a signal representing day. GASTRIN-RELEASING PEPTIDE (GRP₁₋₂₇) PHASE SHIFTS THE MAMMALIAN CIRCADIEN PACEMAKER. Hugh D. Piggins* and Benjamin Rusak, Department of Psychology, Dalhousie University, Halifax, Nova Scotia, CANADA B3H 4J1.

In mammals, a photoically entrainable circadian pacemaker is housed in the suprachiasmatic nuclei (SCN) of the hypothalamus. Cells of the rodent SCN contain a number of neuropeptides including the 27 amino acid gastrin-releasing peptide (GRP₁₋₂₇). We examined the effects of injecting GRP₁₋₂₇ into the SCN on circadian activity rhythms. Male Syrian hamsters with cannulas implanted in the SCN were maintained in constant dim red illumination (<5 lux, supplied by photographic safelights). At 10-14 day intervals, animals received SCN injections of 1 µl volumes of saline vehicle or GRP₁₋₂₇ (150 pmol) at various phases of the circadian activity cycle.

Saline injections had small or no phase-shifting effects on rhythms at any phase tested. In contrast, GRP₁₋₂₇ caused significant phase-delays in activity rhythms when injected at circadian times (CT) 10-14 (where CT 12=activity onset). GRP₁₋₂₇ also phase-advanced some animals when injected at CT 20-02. SCN injections of GRP₁₋₂₇ at lower doses (5.22, 16.66, and 50 pmol) at CT 12-14 also phase-delayed activity rhythms in a dose-related manner. These data indicate that injections of GRP₁₋₂₇ potentially reset the circadian pacemaker in hamsters, and that the phase response curve for GRP₁₋₂₇ is similar to that for light. These results raise the possibility that endogenous GRP₁₋₂₇ participates in photic entrainment processes.

THE REGULATION OF MULTIPLE CIRCADIEN OUTPUTS BY THE SUPRACHIASMATIC NUCLEUS AND SYMPATHETIC NERVOUS SYSTEM. Wade S. Warren and Vincent M. Cassone*, Department of Biology, Texas A & M University, College Station, Texas 77845

The mammalian suprachiasmatic nucleus (SCN) is the master pacemaker controlling a wide variety of circadian behavioral and physiological processes. However, the motor pathway(s) by which these diverse processes are controlled are unknown. The only known motor output of this system is the regulation of pineal melatonin synthesis via the sympathetic nervous system. It is therefore possible that other peripheral circadian rhythms are similarly regulated. To address this issue, we have employed intraperitoneal AM transmitters and a data acquisition control system (Dataquest III, Mini-Mitter Inc., Sunriver, OR) to simultaneously record body temperature (BT), general activity (GA), wheel running activity (WR) and heart rate (HR) in the same rat. Two experiments were performed: 1) the effects of SCN lesion (SCNX; N=5) vs sham-operated (SHAM; N=5) and 2) the effects of sympathectomy with the drug guanethidine (GUAN; N=7) vs saline control (SAL; N=5). SCNX abolished circadian patterns in all motor outputs. All SHAM animals showed robust rhythms in all measures. These data indicate that all circadian rhythms measured here are generated by the SCN, including BT, and that residual rhythmicity is the result of incomplete lesions. GUAN selectively abolished HR rhythmicity. This drug decreased HR circadian power to a level similar to the decrease caused by SCN lesions. Other rhythms (BT, GA and WR) were unaffected. These results suggest that the SCN may influence some peripheral targets via circadian regulation of the sympathetic nervous system, but that other circadian outputs are regulated via other, unknown pathways. Supported by AFOSR Grant 90-NL-0244.

612.6

COMPLETE LESIONS OF THE SUPRACHIASMATIC NUCLEI ELIMINATE CIRCADIEN RHYTHMICITY OF BODY TEMPERATURE AND LOCOMOTOR ACTIVITY IN GOLDEN HAMSTERS. R. Refinetti*, C. M. Kaufman and M. Menaker. Department of Biology, University of Virginia, Charlottesville, VA 22903.

The effects of suprachiasmatic and control lesions on the circadian rhythms of locomotor activity and body temperature were studied in golden hamsters maintained in constant light as well as in constant darkness. Large suprachiasmatic lesions, but not control lesions, eliminated circadian rhythmicity in both variables, as determined by inspection of actograms and chi-square-periodogram analysis. These results do not support the hypothesis that the body temperature rhythm is controlled by a circadian pacemaker distinct from the main pacemaker located in the suprachiasmatic nuclei. Comparison of the "robustness" of the rhythms of activity and body temperature in unlesioned and lesioned animals suggests that previous results supporting the hypothesis of distinct pacemakers may have been artifactual, resulting from inadequate data analysis of the expressed rhythms of animals sustaining incomplete lesions.

GFAP IMMUNOREACTIVITY DISTRIBUTION IN THE ASTROCYTES OF THE SYRIEN HAMSTER SCN: CIRCADIEN AND NYCTHEMERAL FLUCTUATIONS. M. Lavielle and J. Servière. INRA, 78352 Jouy-en-Josas, France.

Previous studies have shown that immunoreactivity (Ir) for the astrocyte-specific protein, glial fibrillary acid protein (GFAP), is particularly dense in the suprachiasmatic nuclei (SCN) of rodents. The SCN is an intrinsic pacemaker responsible for initiating, regulating and maintaining a variety of circadian rhythms. The SCN itself exhibits clear rhythms in glucose consumption, electrical activity and peptide expression which can be sustained in isolated explants. The present study was aimed to investigate whether the GFAP-Ir distribution might also oscillate according circadian time (CT) over the 24h period. Adult male hamsters raised in an LD 12:12 cycle were either maintained in LD, or transferred into darkness (DD) for 8 cycles. To assess internal clock time, locomotor activity was recorded (activity onset = CT12). Animals were perfused (4% paraformaldehyde) at different CTs (CT06, 10, 14, 18). Brains sections were processed for GFAP-Ir. The results revealed distinctive levels of Ir with the strongest staining at the end of the inactive phase (CT10) and the weakest at the beginning of the active phase (CT14). These GFAP-Ir fluctuations entrained by the LD cycle persisted in DD. Thus GFAP-Ir distribution exhibits a circadian rhythm with a profile similar to that of glucose consumption, characterized by a marked trough at CT14. The fluctuations in GFAP-Ir can be considered as another index of the rhythmic activity of the clock. The intense immunoreactivity, the circadian variations in the GFAP-Ir distribution and the synchrony with the oxidative metabolism rhythm strengthen the hypothesis of a functional syncytium improving neuron-astrocyte communication and increasing neuronal synchrony in the clock.

ISOLATION OF THE FIRST CIRCADIEN CLOCK MUTATION IN THE MOUSE. M.H. Vitaterna*, P.L. Lowrey, J.D. McDonald, W.F. Dove, L.H. Pinto, F.W. Turek and J.S. Takahashi. NSF Center for Biological Timing, Department of Neurobiology and Physiology, Northwestern University, Evanston, IL 60208, and *McArdle Laboratory for Cancer Research, University of Wisconsin Medical School, Madison, WI 53706.

In order to isolate mutations that define circadian clock genes in the mouse, we conducted a brute-force screen for mutants produced with N-ethyl-N-nitrosourea (ENU). Male C57BL/6J male mice were exposed to ENU, then bred with wild-type C57BL/6J females. The offspring, which would be heterozygous for induced mutations, were screened for circadian phenotype. 299 such offspring have been tested for abnormalities in circadian rhythmicity, using the rhythm of locomotor activity as a marker. Phase angle of entrainment to a 12 hours light: 12 hours dark cycle and free-running period in constant darkness were measured. For all the mice tested, the average time of activity onset coincided with the time of lights-off, and the average free-running period in constant darkness was 23.7 hours. One animal was found with a normal phase angle of entrainment but with a free-running period of 24.8 hours, a period 0.7 hours longer than any other animal. This male was bred with three females, to produce a total of 23 offspring. Upon testing the offspring, 13 were found with normal period, and 10 with long periods. Subsequent matings have supported the hypothesis that a single gene semi-dominant mutation is responsible for the lengthened period phenotype. Work is presently underway to characterize further the mutant phenotype and to map the mutation.

SEROTONIN MODULATES THE PHOTIC RESPONSE OF THE SCN CIRCADIAN OSCILLATOR IN THE SYRIAN HAMSTER.

M.A.Rea*, J.D.Glass¹ and C.S.Colwell² Circadian Neurobiol. Res. Group, Armstrong Lab. (CFTO), Brooks AFB, TX 78235, ¹Department of Biol. Sci., Kent State Univ., Kent OH, 44242, ²Mental Retardation Res. Ctr., UCLA Med Ctr, Los Angeles, CA 90024.

The SCN receive a major serotonergic (5-HT) projection from the midbrain raphe which terminates predominantly in the retinorecipient region of the nucleus. This fact together with the observation that disruption of the 5-HT projection alters the PRC for photic stimulation of the SCN suggests that serotonin may modulate the response of the SCN oscillator to light. We have investigated the effects of 5-HT and the selective 5-HT_{1A} receptor agonist, 8-OH-DPAT, on (1) optic nerve-stimulation-induced field potentials in the hypothalamic slice preparation, (2) light-induced phase shifts of the free running activity rhythm, and (3) light-induced c-fos expression in the SCN. Both 5-HT (0.5 - 25 μ M) and 8-OH-DPAT (0.1 - 10 μ M) dose-dependently inhibited optic nerve evoked field potentials in the SCN. Systemic administration of 8-OH-DPAT (5 mg/kg i.p.) completely blocked light-induced (40 lux for 10 min) phase advances (CT19; Saline = 67 ± 10 min; DPAT = 12 ± 15 min; $p < 0.05$) and delays (CT14; Saline = -48 ± 7 min; DPAT = -7 ± 9 min) of the free running activity rhythm. This effect was dose dependent between 0.05 - 5 mg/kg. In addition, DPAT (5 mg/kg) caused a regional attenuation in light-induced c-fos expression in the SCN which corresponded to the distribution of 5-HT terminals in the nucleus. These results indicate that 5-HT may serve to regulate the photic response of the SCN oscillator, possibly by acting through a 5-HT_{1A} receptor-dependent mechanism. POTENTIAL ROLE OF NITRIC OXIDE AS A TRANSMITTER IN THE CAROTID BODY. D. Chugh*, P. Grimes, M. Katayama, A. Mokashi, R. Stone and S. Lahiri. Department of Physiology and Department of Ophthalmology and Schele Eye Institute, University of Pennsylvania School of Medicine, Philadelphia, PA 19104.

The function of the richly vascularized and innervated carotid body (CB) could be altered by endogenous nitric oxide (NO), since NO is synthesized and released by both vascular endothelial cells and some peripheral nerve fibers. We studied the CB *in vitro* for effects of nitric oxide synthase (NOS) inhibitor on carotid chemosensory nerve (CCN) activity and for the localization of NOS. The CB was perfused-superfused with Tyrode's solution at 37°C, and CCN activity was recorded continuously. Graded doses of nitro-L-arginine-methyl ester (L-NAME, 25-300 μ M) were administered over a period of 2 to 40 min during normoxia. L-NAME stimulated CCN activity after a long latency of 2.9 ± 1.8 min, and the response reached peak (3-4 fold increase) at 9.9 ± 3.3 min. During prolonged perfusion with L-NAME, CCN activity remained high but fluctuated. Sodium nitroprusside (1-2 μ M) strikingly reduced the response to L-NAME. Hypoxia ($PO_2 = 60$ Torr) augmented and hyperoxia (>400 Torr) attenuated the effect of L-NAME. In the CB, NOS immunoreactivity and NADPH diaphorase activity were localized in varicose nerve fibers mainly associated with blood vessels, as well as in the soma and processes of several intrinsic ganglion cells. Taken together, the results suggest an inhibitory role of NO in the CB. (Supported in part by T32 HL-07027, HL-43413 and EY-05454.)

FAST RHYTHMS IN DISCHARGES OF EXPIRATORY RECURRENT LARYNGEAL SINGLE FIBERS. W.-X. Huang*, C.N. Christakos, M.I. Cohen, and Q. He. Dept. of Physiol., Albert Einstein Col. Med., Bronx, NY 10461.

In 5 unanesthetized decerebrate, paralyzed, vagotomized cats, discharges of decrementing expiratory (E) recurrent laryngeal (RL) fibers (94 units, comprising 120 unit pairs) were recorded simultaneously with bilateral RL population (multifiber nerve bundle) and phrenic nerve discharges. In 4/5 cats, spectral analysis revealed existence of uncorrelated rhythms in E activities. There were no significant coherences between bilateral populations, between 99/103 unit pairs, and between units and populations, even though 84/103 units had rhythmic discharges as indicated by autospectral peaks at 18-88 Hz. In contrast, 1 cat showed highly correlated rhythms (at 49 Hz), as indicated by: a) high coherences (> 0.9) between bilateral populations; b) for 7/17 unit pairs, high coherences (0.26-0.91); c) for 7/17 individual units, high unit-population coherences (0.43-0.94). Thus these rhythms resemble the high-frequency oscillations (HFO) found in inspiratory nerve activities (Cohen et al., Brain Res., 417:148-152, 1987). The rarity of comparable correlated rhythms in RL E activities indicates weakness of interactions in networks driving these activities; but their occurrence in some cases (1/5 cats) indicates the presence of connections in these networks that may be activated to produce coherence of rhythms. (Supported by N.I.H. Grant HL-27300.)

613.2

CAROTID BODY DENERVATION (CBD) ENHANCES HYPOVENTILATION INDUCED BY COOLING THE ROSTRAL VENTROLATERAL MEDULLARY SURFACE IN AWAKE GOATS. P.J. Ohtake, H.V. Forster, L.G. Pan, T.F. Lowry, M.J. Korducki, E.A. Aaron, and Z.J. Bosnjak*. Physiology, Anesthesiology, Med. Col. of Wis.; Phys. Ther.; Marquette U.; Zablocki VA; Milwaukee, WI 53226.

The traditional view is that ventrolateral medullary (VLM) structures contribute to the control of breathing through intracranial chemoreception but more recent data on anesthetized and decorticate animals suggests VLM structures may also integrate all chemoreception, tonically facilitate dorsal respiratory neurons and/or be the site of respiratory rhythmogenesis. The purpose of the present study was to investigate the role of carotid chemoreceptor afferents in relation to VLM contributions to respiratory control. Accordingly, we used our recently developed model (FASEB J 7:A403, 1993) to transiently cause VLM surface neuron dysfunction in the awake goat. Reversible neuronal dysfunction at specific sites was induced by flowing ice water (for 30 sec) through thermodes (3x3 mm) chronically implanted bilaterally on the surface of the VLM. Under halothane anesthesia, cooling (thermode = 20°C) of the rostral VLM caused apnea within 5 sec which was sustained for 20 sec after cooling ceased. In contrast during cooling at the same site in the awake state during eupnea, hypoxia, and hypercapnia, apneas were only 5-20 sec in duration. Following study in the intact state, CBD was performed and confirmed by the lack of respiratory response to i.v. bolus injection of NaCN. Following CBD, cooling the VLM surface produced apneas which were at least twice as long as apneas observed prior to denervation. This pattern of response was observed during all awake conditions (eupnea, hypoxia, and hypercapnia) and during anesthesia. Our present interpretation is that these data are consistent with the idea that rostral VLM structures and carotid chemoreceptors provide independent tonic facilitation to more dorsal medullary neurons involved in the control of breathing. CHARACTERIZATION OF VENTROLATERAL MEDULLARY NEURONS THAT DEPOLARIZE IN RESPONSE TO HYPOXIA. P.C. Nolan and T.G. Waldrop. Dept. of Physiology & Biophysics, Neuroscience Program and College of Medicine, Univ. of Illinois, Urbana, IL 61801.

This laboratory has shown that neurons in cardiorespiratory regions of the ventrolateral medulla respond to hypoxia by increasing their firing rate both *in vivo* and *in vitro*. This response persists in a chemical synaptic blockade (low Ca^{++} high Mg^{++}) medium *in vitro*. Recent studies employing the whole-cell patch clamp recording technique have demonstrated that this increase in excitability is due to a depolarization associated with an increase in membrane conductance. Current studies employed the use of a brain slice preparation with 400 μ m brain slices in an interface chamber perfused with nutrient media equilibrated with 95% O_2 /5% CO_2 . Exposure to one to three minutes of severe hypoxia (5% CO_2 /95% N_2) and/or moderate hypoxia (10% O_2 /5% CO_2 /85% N_2) elicited a rapid depolarization in eight-four percent of VLM neurons studied. The majority of these neurons responded to hypoxia with a gradual depolarization which was maintained throughout the stimulus; this response was partially TTX-sensitive. Another group of neurons proceeded rapidly into a recoverable depolarization blockade. Neurons that did not depolarize were either unresponsive or hyperpolarized during hypoxia. Neurons in this region of the medulla were demonstrated to monosynaptically project to the intermediolateral cell column by employing retrograde transport of rhodamine labeled microspheres. These results suggest neurons in this cardiorespiratory region of the medulla are inherently sensitive to low oxygen, and this sensitivity may be responsible for the increase in cardiorespiratory activity elicited by acute hypoxic insult. KAPPA OPIOID INFLUENCE ON CARDIORESPIRATORY AND STATE CONTROL DURING POSTNATAL DEVELOPMENT. I. R. Moss*, R. E. Faltus, J. G. Inman and A. Laferrière. Developmental Respiratory Lab., Dept. Pediatrics, McGill University, Montreal, Québec H3H 1P3.

Effects of specific kappa opioid antagonism with Norbinaltorphimine (NorBNI) on sleep-wake state (SWS), mean arterial pressure (MAP) and heart rate (HR), and on posterior cricoarytenoid and diaphragmatic electromyographic activities were assessed in 3 to 13 and 23 to 33 day-old, chronically instrumented and unanesthetized piglets. Each piglet was studied twice daily, once before and once after NorBNI, 4 mg/kg i.v., for five consecutive days while lying in a sling within a plexiglass box. Each study session included 10 min trials with ambient air followed by 10% O₂-N₂. SWS distribution, MAP, HR, and most respiratory-related measures matured with age. NorBNI enhanced MAP and HR in both age groups, but did not alter any SWS or respiratory functions in either group. Thus, in counterdistinction to the specific influences of mu and delta opioid systems on SWS and cardiorespiration in young neonates, as reported by us previously, the kappa opioid system influences cardiovascular regulation throughout ontogeny, but plays no role in the regulation of state or breathing in swine. MATURATIONAL DIFFERENCES IN 660 nm LIGHT SCATTERING FROM VENTRAL MEDULLARY SURFACE OF KITTENS DURING GRADED HYPERCAPNIA AND HYPOXIA.

D.M. Rector*, D. Gozal, X.-W. Dong, R.K. Harper and R.M. Harper. Dept. of Anatomy & Cell Biology, UCLA Sch. of Med.; Childrens Hospital Los Angeles, USC Sch. of Med., Los Angeles, CA.

Developmental differences in ventilatory responses to hypoxia and hypercapnia are well described in kittens. To determine whether these maturational effects parallel neuronal responses in the ventral medullary surface (VMS), we recorded the time course of VMS light scattering changes to varying concentrations of inhaled CO₂ in O₂ and O₂ in N₂. Imaging procedures allowed for simultaneous measurements of large neural populations with high spatiotemporal resolution. The VMS was surgically exposed in 18 anesthetized kittens aged either 10, 20, or 30 days, and in 6 adult cats. A 3.2 mm coherent optical fiber bundle, attached to a charge-coupled device (CCD) camera, was positioned over the VMS. Neural tissue was illuminated with 660 nm light emitting diodes, and ECG-synchronized images of reflected light were digitized every 3 seconds throughout ventilatory challenges. Mean pixel intensities, which measure overall neural activity, were plotted over time. Both types of stimuli induced accelerated initial response slopes in 20- and 30-day kittens relative to 10-day and adult animals. We speculate that the age-dependent slower VMS neural responses coincide with maturational contributions of peripheral chemoreceptor function.

ASSESSMENT OF VENTRAL MEDULLARY SURFACE ACTIVITY DURING GRADED HYPOXIA IN THE CAT WITH HIGH TEMPORAL RESOLUTION OPTICAL IMAGING.

D. Gozal*, D.M. Rector, R.K. Harper, X.-W. Dong and R.M. Harper. Dept. of Anatomy & Cell Biology, UCLA Sch. of Med.; Childrens Hospital Los Angeles, USC Sch. of Med., Los Angeles, CA.

The ventral medullary surface (VMS) displays divergent light scattering changes in response to varying degrees of ventilatory-induced hypoxia. We examined the temporal properties of VMS regions at high sampling rates to determine neural activity patterns associated with hypoxia. The VMS was surgically exposed in 7 adult anesthetized cats. A 3.2 mm coherent optical fiber bundle, attached to a charge-coupled device (CCD) camera, was positioned over the VMS. Neural tissue was illuminated with 660 nm light emitting diodes, and images were digitized at 60 fields/sec before and during ventilatory challenges with 6% and 12% O₂ in N₂. Spectral analysis of the overall reflectance changes revealed the existence of spectral peaks at 8-13 Hz, which increased in power and frequency during mild hypoxia (ANOVA, $p < 0.003$). However, during moderately severe hypoxia, multiple spectral peaks at frequencies within the 8-13 Hz range were consistently observed ($p < 0.02$). We conclude that significantly different activity patterns are elicited by varying degrees of hypoxia in the VMS. We speculate that mild hypoxia is associated with activation of discrete neural pools, while deeper hypoxia triggers activation of multiple neuronal populations within the structure.

EVIDENCE FOR CONCURRENT LOCAL AND REMOTE REGULATION OF IMPULSE SYNCHRONY IN BRAINSTEM NEURAL ASSEMBLIES. B. G. Lindsev*, K. F. Morris, Y. M. Hernandez, and R. Shannon. Dept. Physiol. & Biophysics, Univ. South Florida Med. Ctr., Tampa, FL 33612.

Cardiorespiratory-related neuronal assemblies defined by their impulse synchrony are found in the brainstem midline. (*J. Neurophysiol.* 67:905-930; *Soc. Neurosci. Abstr.* 15:1191). Their dynamic organization may reflect continuous cooperation that promotes appropriate expression of cardiorespiratory motor and autonomic activity. This work provides evidence that midline assemblies are coordinated with and influenced by neurons of the ventrolateral medulla. Neuronal spike trains were recorded simultaneously with planar microelectrode arrays. Sixteen groups of functionally linked neurons composed of both midline and ventrolateral cells were detected in 12 Dial-urethane anesthetized, vagotomized, artificially ventilated cats. Features in cross-correlograms and snowflakes provided evidence for concurrent serial and parallel regulation of impulse synchrony and suggested that elements of up to 3 "layers" of interneurons were monitored simultaneously. Gravitational representations demonstrated respiratory-phase dependent synchrony among neurons distributed in both domains. The data support two hypotheses. 1. Synchrony of some midline neurons is generated by divergent inhibitory actions of both midline and ventrolateral neurons. 2. Such putative distributed "synchrony-promoting" neurons are also functionally linked; changes in their effective connectivity contribute to temporal variations in the synchrony of midline assemblies. Supported by NS19814.

DEVELOPMENT OF RESPIRATORY PATTERNING TO ANTERIOR HYPOTHALAMIC WARMING IN THE KITTEN.

J. Zhang*, H. Ni, D. Gozal and R.M. Harper. Brain Research Institute and Dept. of Anatomy and Cell Biology, UCLA School of Medicine, Los Angeles, CA 90024.

Local warming of the preoptic area/anterior hypothalamus (POAH) modifies respiratory rate and elicits panting. We hypothesized that the respiratory responses to thermal POAH manipulation in the kitten vary with age. We examined changes of respiratory components following POAH warming during quiet sleep (QS) in 10-, 20-, 30-, and 40-day old kittens and in adult cats. The POAH was warmed (0.5MHz, 85-190mW) bilaterally by two electrode pairs and POAH temperatures were recorded by a thermocouple. EEG, ECG, diaphragmatic, neck EMG and core body temperature were simultaneously recorded.

During QS, warming of the POAH by 1.2-4°C elicited an increase in respiratory rate in all animals. However, an associated decrease in tidal volume occurred, together with a decrease in minute ventilation (V_i) in 10-day kittens. Despite similar decreases in tidal volume, modest increases in V_i occurred at 20-40 days, and marked increases were observed in the adult. The relative hypoventilation observed in the 10-day kittens directly resulted from insufficient increases in respiratory drive. We conclude that POAH warming during QS preferentially increases respiratory rhythm rather than volume. In general, this relationship will result in increased V_i. However, maturational changes significantly affect the magnitude of this effect, and indicate the presence of a potentially vulnerable period in the youngest animals.

A NEW METHOD FOR THE STUDY OF VESTIBULAR FUNCTION, EYE MOVEMENTS AND MULTISENSORY FUSION IN HUMANS AND ANIMALS: MOBILE ROBOTS.

A. Berthoz*, S. Glasauer and I. Israël. Lab. de Physiol. de la Perception et de l'Action. Collège de France-CNRS, Paris France.

Vestibular function has been studied with stimulators which could provide either angular rotation or translation and no method is yet available for the study of the motor or perceptual responses to combined angular and linear motion except eccentric rotation. This method has already been successfully used, with a smaller version of the robot, for the study of the influence of movement on hippocampal neurons in the monkey (O'Mara et al. Neurosc. Soc. Abstr. 18. 1992).

We have adapted a mobile robot (Robuter TM. ROBOSOFT Cie France) to provide complex quantified horizontal plane movements in human subjects. This four wheels robot contains a computer which can be tele-controlled by modem and has an odometry system for trajectory measurement. A multidirectional seat has been fixed on the platform.

This robot has been programmed to provide rotations of angular and linear velocity and accelerations in the range of vestibular receptors sensitivity. The robot can therefore give the traditional stimuli for independent stimulation of canals or otoliths. In addition it can move the subject along complex trajectories in the horizontal plane (squares, circles) by programming sequences of rotations and linear movements. Results concerning vestibular nystagmus, path integration and visual vestibular integration will be presented.

LONG-TERM SYNAPTIC PLASTICITY IN THE RAT MEDIAL VESTIBULAR NUCLEUS STUDIED USING PATCH-CLAMP RECORDING IN AN *IN VITRO* BRAIN SLICE PREPARATION. G.A. Kinney*, B.W. Peterson and N.T. Slater Dept. of Physiology, Northwestern Univ. Med. School, 303 E. Chicago Ave., Chicago, IL 60611.

The brainstem vestibular nuclei are believed to be a critical site for the long-term adaptive change in vestibulo-ocular reflex gain, but little information is available regarding potential cellular substrates of synaptic plasticity in this brain region. *In vivo* studies suggest that cerebellar projections to vestibular nuclei play an important role in this phenomenon. Neurons in the rat medial vestibular nucleus were recorded using whole-cell patch-clamp methods in 400 μ m thick transverse slices cut at the level of nVIII, and stimulating electrodes were placed in the nVIII and m.l.f. to evoke monosynaptic EPSPs. EPSPs evoked by stimulation of either site were not affected by the NMDA receptor antagonist D-AP5 (20 μ M), but were blocked by CNQX (10 μ M). An AP5-sensitive component of both EPSPs was revealed in Mg²⁺-free, bicuculline-containing medium. Tetanic stimulation of the nVIII or m.l.f. failed to produce consistent long-term changes in the AMPA receptor-mediated EPSP amplitude. Bath application of both the GABA_A receptor agonist baclofen (1-10 μ M) and the metabotropic glutamate receptor agonist 1S,3R-ACPD (100 μ M) produced a blockade of both EPSPs. The effects of 1S,3R-ACPD were reversible. However, following the washout of baclofen, the amplitude of the nVIII-evoked EPSP exhibited a long-term depression. A stable reduction of 40% was observed after the washout of baclofen, whereas the m.l.f.-evoked EPSP was not significantly affected. The results provide evidence for a GABA_A receptor-mediated form of long-term synaptic depression of the nVIII-evoked EPSP. This might be physiologically produced by descending cerebellar inputs to mediate long-lasting changes in the gain of the vestibulo-ocular reflex. Supported by USPHS Grants EY 06485 and NS 17489.

VOR ADAPTATION: EFFECTS ON THE VELOCITY-TO-POSITION INTEGRATOR. M. Shelhamer, D.S. Zee, C. Tiliak, D. Roberts and D.A. Robinson*, Johns Hopkins Hospital, Baltimore, MD 21287.

We investigated the effect of short-term vestibulo-ocular reflex (VOR) adaptation in normal humans on the velocity-to-position integrator that holds eccentric gaze. Following 1 hr of sinusoidal head oscillation (0.2 Hz), with the visual surround manipulated to produce an increase (X1.7), decrease (X0.5), or reversal (X(-2.5)) of VOR gain, we measured eccentric gaze-holding in darkness. Eccentric saccades were followed by sustained drift (1-2 deg/sec). The drift was centrifugal after X0.5 viewing, implying an unstable integrator. The drift was centripetal after X1.7 or X(-2.5) viewing, implying a leaky integrator. The gaze-holding deficits were context specific; they only appeared when the head was oriented in the same position (re gravity) as during training. We propose that 1) the changes in the neural integrator reflect an attempt to modify the phase (timing) relationships of the VOR, and 2) the relative directions of retinal slip and of eye velocity during training determine whether the integrator becomes unstable (producing more phase lag) or leaky (producing less phase lag).

We also assessed the effect of oscillation of the visual surround alone on VOR adaptation. This stimulus produced both a leaky integrator and an increase (10%) in VOR gain. Furthermore, during combined visual-vestibular stimulation, the gain decreased when the ratio of the movement of the visual scene to the movement of the head was relatively small (X(-2.5) viewing) and the gain increased when the ratio was relatively large (X(-7) viewing). These results suggest that one of the signals used for VOR adaptation is inferred head rotation based upon activity in central vestibular neurons that receive both labyrinthine and visual (optokinetic) signals.

INPUT-OUTPUT TRANSFORMATIONS IN MEDIAL VESTIBULAR NUCLEUS NEURONS *IN VITRO*. S. du Lac* and S.G. Lisberger, Dept. of Physiology and W.M. Keck Center for Integrative Neuroscience, UCSF, San Francisco CA 94143.

As a first step toward placing the membrane and synaptic properties of vestibular interneurons in a functional context, we have measured the transformations from intracellularly-injected current to firing rate in neurons recorded from the medial vestibular nucleus (MVN) in slices of chick brains. The intrinsic membrane properties and spike patterns of avian MVN neurons were similar to those reported for rodent MVN neurons *in vitro*. Chick MVN neurons fired spontaneously at regular intervals (firing rate ranged from 7 to 68 spikes/sec), displayed an inward rectification during hyperpolarizing current steps, and exhibited a rebound depolarization following current step offset.

Steps of depolarizing current produced increases in firing rate that depended linearly on the amplitude of the injected current. Firing rate was highest just after the onset of the step, declined slightly during the duration of the 1 sec step, and decreased transiently below baseline following step offset. Sinusoidal modulations of current produced sinusoidal modulations of firing rate with little harmonic distortion over the frequency range tested (0.1 to 10 Hz). Firing rate phase led that of injected current; phase lead increased from 1-4 deg at 0.1 Hz to 30-40 deg at 10 Hz. Firing rate gain (peak to peak firing rate/current amplitude) increased slightly or was flat with increasing frequency. In contrast, when cells were held hyperpolarized to spike threshold with DC current, small amplitude sinusoidal modulations of current produced sinusoidal modulations of membrane potential with the properties expected of a low-pass filter: as modulation frequency increased, phase lag increased and gain decreased. We conclude that active conductances in vestibular neurons change neuronal filtering properties but preserve linearity.

614.4

RESPONSES OF RAT VESTIBULAR NUCLEI NEURONS TO NATURAL STIMULATION AND LABYRINTH POLARIZATION.

J. Kleine and O.-J. Grüsser*. Dept. Physiol. Freie Univ. 1 Berlin 33, Germany

In exploring the rat neocortex for vestibular responses we applied electrical polarization of the labyrinth by means of interaural DC or sinewave stimulation ($\geq 20 \mu$ A). In order to evaluate the effects of labyrinth polarization, action potentials were recorded from the nerve cells of the brainstem vestibular nuclear complex (VNC) in pentobarbital anaesthetized pigmented rats.

- (1) Neurons responding selectively to semicircular canal stimulation, otolith stimulation, or to both as well as polymodal units (labyrinth responses and neck muscle responses) all responded well to DC- or sinewave labyrinth stimulation.
- (2) In many units phase-coupled responses were obtained even to low amplitudes ($\leq 50 \mu$ A) in a frequency range above 10 Hz.
- (3) Most units were activated either by positive or negative polarization of the labyrinth, whereby reversal of current led to inhibition.
- (4) Responses to natural stimulation (sinewave rotation in pitch, roll or yaw, steady inclination) could be systematically superimposed on the responses to simultaneous labyrinth polarization (sinewave or DC).
- (5) Low amplitude (0.5-1 Hz) transaural sinewave polarization of the labyrinths is a very handy method to evoke strong but selective vestibular responses while searching for higher-order vestibular neurons in the thalamus or in neocortical regions. Hereby the afferent vestibular neuron activity is highly synchronized.

614.6

THE ROLE OF THE NUCLEUS OF THE OPTIC TRACT (NOT) IN ADAPTIVE GAIN CONTROL OF THE VESTIBULO-OCULAR REFLEX (VOR). H. Reisine*, S.B. Yakushin, and B. Cohen. Depts. of Neurology and Physiology and Biophysics, Mt. Sinai Sch. of Med., New York, NY 10029.

Combined visual-vestibular (conflict) stimulation was used to reduce the step gain (eye velocity/head velocity) of the VOR in monkeys during forced rotation. Animals were sinusoidally oscillated (0.2 Hz, $\pm 60^\circ$ /s) about their yaw axis, with head fixed, while upright in light in the presence of a subject-stationary surround consisting of alternating black and white stripes. VOR gain (0.95 ± 0.05) was reduced 20 to 30% within two hours and maximally by $\approx 30\%$ after 4 hrs (n=6). Further stimulation (up to 8 hrs) brought no further reduction in gain. Muscimol, a GABA_A agonist, (0.8 μ g in 0.8 μ l) was injected unilaterally into NOT of animals who had had a gain reduction of $\approx 25\%$ after 2 hrs of conflict stimulation. The VOR gain of contralateral slow phase velocity (SPV_{el}), relative to the injection site, produced by ipsilateral rotation, returned to levels obtained before conflict stimulation, while the gain of ipsilateral slow phase velocity (SPV_{el}) to contralateral rotation remained at the reduced (adapted) levels following stimulation. In the same animals following muscimol injection into the NOT, suppression of the gain of SPV_{el} during conflict stimulation was reduced (from 0.2 to 0.8), while suppression of the gain of SPV_{el} remained at pre-injection levels. The similarity of the effects muscimol injection in NOT on VOR suppression and adaptive gain control (at least for a gain decrease) is consistent with previous findings of others demonstrating a relationship between them. Moreover, it suggests that NOT plays a role in producing both suppression and adaptive gain control of the VOR. Grants: EY00296, EY01867.

RESPONSES OF CAT PONTOMEDULLARY RETICULAR NEURONS TO HORIZONTAL ROTATION. R.H. Schor*, L.A. Cotter and B.J. Yates. Dept. Otolaryngology, Univ. Pittsburgh Sch. Med., Pittsburgh, PA 15213.

Is there a population of brainstem neurons which reflect the spatial and temporal properties of the vestibulocollic reflex (VCR)? Although few reticulospinal (RS) neurons appear to receive pure vertical semicircular canal input (Bolton et al., JNP 67:1992), previous work with electrical polarization of horizontal and anterior canal nerves (Peterson et al., JNP 43:1980) indicates that some RS neurons exhibit the low frequency phase lag characteristic of the horizontal VCR. In this study, we have examined the response dynamics of RS neurons to natural horizontal plane rotation.

Experiments were performed on decerebrate cats; recordings were made in the pontomedullary reticular formation. Responsive neurons were studied with sinusoidal horizontal rotation at 0.1 to 2 Hz. Fifteen neurons were identified as RS neurons by antidromic activation from C1 or L1.

Neurons responding to horizontal rotation were commonly encountered. 80% of the population, and all of the RS neurons, showed a Type II response. Most response dynamics resembled those of horizontal canal afferents, with gain and phase related to stimulus velocity. About a quarter of the neurons (4/15 RS neurons) had similar gain characteristics, but exhibited a progressive phase lag (re velocity) exceeding 45° at 1 Hz. The mean gain of the RS population (at 1 Hz) was 1.6 ± 0.3 spikes/sec/° (0.25 spikes/sec per %/sec).

We saw no neurons responding to horizontal rotation that exhibited the low frequency phase lag characteristic of the VCR. These data, in combination with previous studies of vestibulospinal and RS neurons, suggest that some of the spatial and temporal properties of the VCR arise from convergence of vestibular signals within the spinal cord. (Supported by NIH NS24930 and DC00693).

VERTICAL VESTIBULAR INPUT TO UPPER CERVICAL COMMISSURAL NEURONS. V.J. Wilson*, K. Endo, J. Kasper, and B.J. Yates. Lab. of Neurophysiology, Rockefeller Univ. New York, NY 10021.

We have investigated, in decerebrate paralyzed cats, whether upper cervical commissural (CO) neurons play a role in the vertical vestibulocollic reflex. We looked for the pattern of inter-receptor convergence, and for evidence that CO neurons could be in a polysynaptic otolith pathway to contralateral neck motoneurons (Bolton et al. J. Neurophysiol. 1992, 67:1695). Antidromic stimuli were delivered with 1 or 2 tungsten-in-glass electrodes in the contralateral ventral horn. Judging from thresholds, 10 neurons were driven from the ventral grey matter, 7 from the grey or nearby white matter; 25 were not driven from the electrodes available. There were no obvious differences between responses of these three classes. Most neurons had typical canal (n=18), otolith+canal (n=8) or otolith (n=12) responses. Like vestibulo- and reticulospinal fibers, neurons with canal input had response vector orientations near canal planes, or had convergence from ipsilateral canals. 27/38 neurons, whether otolith- or canal-driven, had vectors pointing contralaterally. In conclusion, CO neurons could be part of an otolith pathway to motoneurons. More generally, their actions could modify the effectiveness of VS and RS fibers that have similar spatial properties and make synapses with neck motoneurons. Supported by NIH grants NS02619 and DC00693.

614.11

VESTIBULAR AND VISCERAL INPUTS TO NUCLEUS SOLITARIUS AND ADJACENT STRUCTURES IN THE CAT BRAINSTEM. L. Grélot, J. Jakus, A.D. Miller* and B. J. Yates. Lab. Neurophysiology, Rockefeller Univ., New York, NY 10021.

Nucleus solitarius and adjacent structures receive inputs from a variety of visceral receptors; inputs from different sources are partially segregated in this region. There is also some evidence to suggest that the caudal dorsomedial brainstem receives vestibular inputs, but this possibility has not yet been investigated thoroughly. Vestibular connections with this region could elicit cardiovascular and respiratory changes that compensate for stresses to homeostasis which occur during movement and changes in posture, and could also have a role in motion sickness. In this study we sought to determine the locations of neurons in nucleus solitarius and adjacent structures that receive vestibular input, and to ascertain whether these neurons receive convergent visceral input.

Experiments were conducted on adult cats that were decerebrated or anesthetized using urethane + chloralose. Vestibular inputs were elicited by electrical stimulation of the vestibular nerve. In initial experiments we recorded from the medial portion of the solitary nucleus and nucleus intercalatus. Many of these neurons responded to vestibular nerve stimulation, some at latencies ≤ 4 ms suggesting that they received direct input from the vestibular nuclei. Many adjacent neurons responded to stimulation of the abdominal vagus nerves, but only 2/26 neurons received convergent vagal and vestibular input. Thus, the role of vestibular inputs to the medial solitary complex is currently unclear. Future experiments will explore the dorsolateral solitary nucleus, and determine whether cardiovascular and vestibular inputs converge in this region.

Supported by NIH grants NS20585 (ADM) and DC00693 (BJY), Irma T. Hirschl Trust (BJY), and Ministère des Affaires Étrangères, France (LG).

VESTIBULO- RESPIRATORY AND SYMPATHETIC REFLEXES IN THE DECEREBRATE CAT. B.J. Yates*, J. Jakus and A.D. Miller. Lab. of Neurophysiology, Rockefeller Univ., New York, NY 10021.

Previous studies demonstrated that vestibular stimulation can affect respiration rate and sympathetic outflow. However, little is known about the latency, pattern, or receptors of origin (semicircular canals or otolith organs) of vestibulo-sympathetic and vestibulo-respiratory reflexes. This study sought to determine: 1) the minimal reflex latencies, 2) which vestibular receptors elicit the responses, and 3) what direction of head movement is most effective in evoking the activity.

Electrical stimulation of the vestibular nerve produced short-latency (< 15 ms) responses recordable from the phrenic (inspiratory) and abdominal (expiratory) nerves; in contrast, vestibulo-sympathetic reflexes recorded from the splanchnic nerve had long latencies (≥ 100 ms). Vestibulo-sympathetic and vestibulo-respiratory responses elicited by natural vestibular stimulation (head rotation in animals with upper cervical dorsal root rhizotomies) were in phase with table position and had relatively uniform gain across stimulus frequencies (0.1-1 Hz), suggesting that these responses were elicited by otolith receptors. The best direction of head rotation for eliciting vestibulo-sympathetic responses was nose-up tilt. In contrast, vestibular responses elicited in the abdominal and phrenic nerves had preferred directions that differed from experiment to experiment.

These data are consistent with vestibulo-sympathetic reflexes playing a role in compensation for orthostatic hypotension, which could result during nose-up tilt (since the cat has a long longitudinal axis). The variability in preferred direction of vestibulo-respiratory reflexes suggests that these responses may be multi-functional.

Supported by NIH grants DC00693 (B.J.Y.) and NS20585 (A.D.M.) and the Irma T. Hirschl Trust (B.J.Y.).

614.10

CERVICAL STRAIN IN VESTIBULAR UNITS. James H. Fuller* Dept. Oral Anatomy, Univ. of Illinois, Chicago IL 60612

Visually evoked head movements in trained cats were briefly (ca 100 msec) interrupted mid-flight by an electro-mechanical brake and single units were recorded in the caudal vestibular nuclei. A class of units (Category 3) was characterized by perturbation-linked ultrashort (1-5 msec) and short (5-100 msec) latency responses.

The single spike (<0.1 msec jitter), ultrashort latency, responses (1.4-1.8 msec) to the brake were duplicated by purely mechanical stimuli. The monosynaptic response to both electro-mechanical and mechanical perturbation is evoked by minute (ca 10 micra), high frequency (>100Hz) vibration of the brake shaft by solenoid activation.

The short latency responses (idiosyncratic burst-pause intervals) were associated in time and intensity with 1) brake onset, 2) voluntary head torque undulations (the animal's attempts to overcome the brake), and 3) head release. Six other methods evoked the short latency responses by passive/active maneuvers: the unit firing was most consistently associated with cervical strain. This suggests the paciform receptors identified in the perivertebral area transduce a new modality in neck sensory information over a secure, direct, fast-conducting pathway from neck to the medial-inferior vestibular nuclei.

ULTRASTRUCTURAL EVIDENCE OF VESTIBULAR EFFERENT SYNAPSES OF INTRINSIC, AFFERENT ORIGIN. Muriel D. Ross* Biocomputation Center, NASA-Ames Research Center, Moffett Field, CA 94035.

Ultrastructural and computer-aided three-dimensional reconstruction studies of rat vestibular gravity sensors have shown that maculas are organized for weighted, distributed, parallel processing of sensory input. There are two main integrated circuits: highly channeled and distributed modifying. Type I cells provide highly channeled output to calyces but type II cells are part of the distributed modifying circuitry. Type II cells, calyces and afferents are under the modulation of efferent synapses that, historically, have been attributed entirely to terminals of nerve fibers of extrinsic origin. Work with serial sections has demonstrated that a specific subset of efferent endings has an intrinsic origin from processes of vestibular afferents. They are part of the intrinsic modifying circuit. This report deals primarily with those short processes that can be traced to a synaptic ending in a single electron micrograph, since these are the most convincing examples. Other efferent processes arise from afferents as small-diameter nerve fibers and travel for several micrometers before ending. The terminals of these short and long processes are filled with clear vesicles ~40-60 nm in diameter, but some vesicles are ~70-90 nm in diameter and have an electron-opaque core. Other vesiculated terminals have a more electron-opaque appearance and contain mostly the smaller diameter vesicles. Further research is necessary to distinguish better between the two kinds of efferent terminals since the latter subset is the group possibly of extrinsic origin. The present findings are conclusive anatomical evidence that a mechanism is in place for intrinsic modulation of macular output. This modulation would be driven by ongoing activity of the afferents and rapidly expressed through vesiculated terminals of processes contributing to the intrinsic distributed modifying circuit.

This research is supported by NASA and by NIMH Grant # MH47305-02.

615.1

GENERATED DIFFERENCES IN BRAIN VOLUME AND CEREBRAL BLOOD FLOW (CBF): A POSITRON EMISSION TOMOGRAPHY (PET) AND MAGNETIC RESONANCE IMAGING (MRI) STUDY OF NORMAL CONTROLS. N.C. Andreasen, L.A. Flashman, D.S. O'Leary, D.M. Mosnik, V.W. Swayze, G.L. Watkins, L.L. Boles Ponto, and R.D. Hichwa. Dept. of Psychiatry, and PET Imaging Center, Univ. of Iowa, Iowa City, IA, 52242.

Studies using both PET and SPECT have found women to have a higher rate of blood flow/metabolic activity than men, although there have also been reports of no gender differences. Gender differences in brain size have been independently observed in both postmortem and MR studies, but the effect of this variable on CBF is unclear. The present study investigated gender differences in brain size using MR and in CBF using PET. Forty-one male and 31 female healthy normal subjects were examined using both MR and PET. Male and female groups did not differ in age, years of education or socioeconomic status. The [¹⁵O] water radiographic method was used with a GE 4096 Plus Scanner to obtain quantitative measurements of perfusion (ml/min/100g) of tissue during a baseline condition. Females (mean=54.1 ml/min/100 g, sd=7.5) had a significantly higher rate of whole brain CBF ($t=2.1$, $p<.04$) than males (mean=50.1, sd=8.5). MR data were collected on a 1.5 Tesla GE Signa Scanner with an SPGR sequence generating contiguous 1.5 mm coronal slices. Males (mean=1322.2cc, sd=119.0) had significantly larger brain volumes ($t=4.5$, $p<.001$) than females (mean=1195.1, sd=108.4). The gender effect for CBF remained significant when brain volume was statistically controlled by analysis of covariance. In addition, a positive correlation between brain volume and CBF was found for males ($r=.37$, $p<.03$), but not females ($r=0.0$). These results indicate that women as a group have higher whole brain CBF than men, that this effect is independent of brain size, and that there is a gender difference in the relationship between brain size and blood flow.

615.3

POSITRON EMISSION TOMOGRAPHY AND EYE MOVEMENTS DURING REM SLEEP. C. C.-H. Hong, J. C. Gillin, B. M. Dow, J. Wu* and M. S. Buchsbaum**. Dept. of Psychiatry, UCSD and VAMC, Ia Jolla, CA 92093-9116; *Dept. of Psychiatry and Behavioral Medicine, UC Irvine, CA 92717; **Neuroscience PET Lab., Mt. Sinai School of Medicine, New York, NY 10029-6574

In order to study the neural substrate for eye movements (EMs) during REM sleep, we reanalyzed the ¹⁸F-DG PET scan data obtained from normal subjects in a previous study (Buchsbaum et al. Life Sciences 45:1349-1356, 1989). Nine subjects were studied during REM sleep, and six control subjects were studied during waking as they periodically moved their eyes. The number of EMs during REM sleep were positively correlated with local cerebral glucose metabolism (LCGM) in the areas corresponding to (1) the saccadic-EM system (frontal eye field & dorsolateral prefrontal cortex, only on the right side), (2) the midline attentional system (cingulate & medial frontal cortex, precuneus), and (3) the parietal visual spatial attentional system (bilateral superior parietal lobules, right inferior parietal lobule); and negatively correlated with LCGM in the left inferior parietal lobule. Positive correlation between waking EMs and LCGM were observed in the same areas except inferior parietal lobule. These findings suggest that EMs saccadically scan targets in the dream scene. Our data have implications for dream theories, cerebral lateralization, and schizophrenia research.

615.5

CORRELATIONS BETWEEN GLUCOSE UTILIZATION VALUES FROM PET AND PEAK AMPLITUDES OF ERP COMPONENTS IN A NORMAL STANDARDIZATION STUDY. C.E. Naylor*, F.B. Wood and D.L. Flowers. Section of Neuropsychology, Bowman Gray School of Medicine, Winston-Salem, NC 27157.

For N=40 normal males and females, local maxima and regional averages of glucose consumption using [¹⁸F]-2-deoxyglucose (FDG) uptake were compared to peak amplitude measures of averaged evoked potential components collected simultaneously with the uptake, during a visual single stimulus paradigm requiring letter discrimination. Subject paced stimuli occurred at an average rate of 1 per 2.5 seconds throughout the glucose uptake. Task accuracy was high, but with measurable variance, across all subjects.

By far the most robust correlations involved the late negative component (peaking at approximately 700 msec post stimulus), relating most scalp locations to most local glucose measures. More specific correlations were found in the ventral extrastriate visual processing pathways, involving early and mid-latency components such as P1 and N2, but these explained only relatively small fractions of the local glucose metabolic variance, compared to the large effects involving late negativity.

The results are interpreted as suggesting caution in the interpretation of underlying sources of task-related glucose activation.

615.2

CENTRAL CORRELATES OF SPEECH AND LANGUAGE PRODUCTION IN HUMANS STUDIED WITH H₂¹⁵O POSITRON EMISSION TOMOGRAPHY. A.R. Braun*, C.L. Ludlow, M. Yarga, S. Stager and G. Schulz. VSS, NIDCD, NIH, Bethesda, MD 20892

Eight right-handed normal volunteers underwent a series of rCBF PET scans following i.v. bolus infusions of 30mCi of H₂¹⁵O. Scans were performed on a Scanditronix PC2048-15B tomograph. Blood curves were generated automatically for derivation of arterial input functions and transmission scans were utilized for attenuation correction. Individual scans were stereotactically normalized to a common coordinate system and task conditions were compared by generating statistical parametric maps (SPM, MRC Cyclotron Unit, Hammersmith Hospital). When compared to rest, simple movements of the larynx, tongue, lips and mandible were associated with *bilateral* activation of anterior cerebellar cortices, inferior primary motor cortices, supplementary motor area, putamen, and ventral thalamus as well as superior temporal gyri in the region of the primary auditory cortices (in each instance $p<.01$, corrected for multiple comparisons). When compared to these simple movements, more complex production of phonemes *without* linguistic content was associated with activation - again *bilateral* - of the insular, anterior cingulate and supplementary motor cortices, superior temporal (anterior auditory association) cortices, as well as left lateral premotor cortex. Compared to both simple and complex motor tasks, language production - either spontaneous conversational speech or formal sentence construction - was associated with markedly *lateralized* effects: activation of the left lateral premotor cortex, left dorsolateral prefrontal cortices (Brodmann 8, 9, 10), and head of the left caudate nucleus as well as activation of the posterior temporal cortices (in the region of Wernicke's area), which was greater in the left than the right hemisphere. Both language tasks were also associated with bilateral activation of medial prefrontal (area 10), and posterior cingulate cortices, and spontaneous conversational speech was additionally linked to bilateral activation of the orbitofrontal cortices (area 11). In contrast *singing*, when compared with speaking the words to a familiar song, was associated with predominantly *right* cerebral hemispheric activation - in globus pallidus, insula, superior temporal, inferior prefrontal (area 47) and precentral gyri - as well activation of the *left* anterior cerebellar hemisphere. These results demonstrate that different cortical and subcortical brain regions subserve the motor and linguistic elements of speech production in humans and can be used as a baseline in future studies designed to evaluate the central correlates of disorders of speech and language.

615.4

POSITRON EMISSION TOMOGRAPHY (PET) STUDY OF REGIONAL CEREBRAL GLUCOSE METABOLISM (rCMRglc) IN DEMENTED PATIENTS WITH FRONTAL LOBE FEATURES. U. Fero*, P. Pietrini, A. Dani, C.L. Grady, J. Salerno, M.B. Schapiro. Laboratory of Neurosciences, National Institute on Aging, Bethesda MD 20892.

To examine the pattern of cerebral glucose metabolism associated to the cognitive decline seen in dementia with frontal lobe features (DFL), we studied 3 subjects (2 F, 1 M; 45, 56 and 58 year/old, respectively) with a slowly progressive dementia, characterized by early personality changes, behavioral disinhibition and later perseveration and apathy. High-resolution PET scan exams (Scanditronix PC1024-7B, Uppsala, Sweden; FWHM 6mm) with [¹⁸F]-2-fluoro-2-deoxy-D-glucose were performed in the "resting state" (ears plugged/eyes patched, minimal room noise). Attenuation correction was measured by transmission scan. Results were compared with two groups of 18 sex- and age-matched healthy volunteers by Z-score analysis. Absolute rCMRglc values were expressed in mg/100 g tissue/min; in addition, to minimize inter-subject variability, rCMRglc values were "normalized" to the mean global grey matter CMRglc. An average rCMRglc reduction greater than 50% ($p<.01$) was found in frontal, prefrontal and cingulate regions in all the 3 DFL patients as compared to the matched healthy controls. In addition, a significant, although smaller, rCMRglc reduction in association parietal and temporal areas (usually early affected in Alzheimer's disease) was seen in the two female patients, who also had a more severe and wider cognitive impairment. Primary sensory and motor neocortical areas, hippocampus, amygdala, cerebellum and basal ganglia were relatively spared in all patients. These results indicate that a specific pattern of rCMRglc reductions consistent with behavioral and cognitive deterioration is present in patient with DFL and further suggest that DFL should be considered a specific clinical entity.

615.6

UTILITY OF LOCAL GLUCOSE MAXIMA AS MEASURES OF TASK RELATED CORTICAL ACTIVATION WITH PET. D.L. Flowers*, F.B. Wood, J.W. Keyes, and F.H. Fahey. Section of Neuropsychology and Dept. of Radiology, Bowman Gray School of Medicine, Winston-Salem, NC 27157-1043.

N=40 normals performed a letter discrimination task, using subject-paced stimuli at an average rate of 1 per 2.5 seconds during uptake of [¹⁸F]-F fluorodeoxyglucose (FDG). In this PET validation, local maxima outperformed local averages as dependent measures because of:

- (1) Compatibility with the more veridical representation of actual activity in spherical and irregular phantoms;
- (2) Sharper correlational demarcation of a visual extrastriate cortical pathway in posterior cortex;
- (3) Demonstration of the expected dorsolateral prefrontal cortex couplings both to angular gyrus and to caudate; and
- (4) Demonstration of an inverse correlation between task accuracy and extrastriate visual cortical areas.

According to the phantom studies, local glucose utilization maxima combine information about size and activation intensity of small (1 cm.) cortical regions.

According to the correlational studies, local maxima measure cortical activation in terms that are compatible with known or expected models of task-related cortical connectivities.

NEW SINGLE-SUBJECT METHOD FOR PARAMETRIC ANALYSIS OF REGIONAL CEREBRAL BLOOD FLOW (rCBF) ACTIVATION EXPERIMENTS. J. Ma. Maisos¹, T. A. Zeffiro², K.D. Pettigrew³, M. Hallett⁴, S.I. Rapoport¹, P. Herscovitch^{4*}. LNS, NIA¹; MNB, NINDS²; DESR, NIMH³; and PETD, CC⁴; all from NIH, Bethesda, MD 20892.

In a new single-subject method to analyze functional images, the rCBF response to an experimentally controlled parameter was characterized with a linear regression model on a voxel-by-voxel basis. H₂¹⁵O positron emission tomography scans were obtained on 8 normal subjects at rest and during an alternating wrist movement at 0.25 Hz, 0.5 Hz, and 1 Hz. Each scan state was repeated, for a total of 8 scans per subject, and all scans were stereotactically normalized (Friston et al., 1991). For each subject, the global mean CBF of each activation scan was normalized to that of the resting runs, and then, again for each subject, linear regression was performed on every voxel, with frequency of movement as the independent variable and rCBF as the dependent variable; this generated a slope image. A t-statistic test for slopes significantly different from zero was performed on every voxel. Regional maxima in the slope image were localized with a stereotactic atlas. Results showed significant linear regressions between rCBF and frequency in contralateral motor cortex and ipsilateral cerebellum during the motor task, but the exact location and slopes varied from subject to subject. This parametric imaging method can be extended to experimental designs using other external parameters, and other mathematical models besides a straight line may be used.

On the Nature of the Signal Change in MR Functional Brain Mapping using Gradient Echo Pulse Sequences

M. Hutchinson and V. Nenov*. UCLA.
Several techniques are now available for MR functional brain mapping. Most prominent are Echoplanar imaging (EPI) and the so-called Gradient Echo imaging (GE). The GE image, although currently more time-consuming than EPI, holds the promise of greater spatial resolution than EPI. By acquiring a number of functional images at different values of the repeat time (TR), it is shown that the signal change in activated cortex is significantly more sensitive to T₁ than to T₂^{*}, when a GE sequence is used. Moreover this sensitivity increases as TR is shortened. Thus it is not due to a blood flow phenomenon. This dependence on T₁ is in contrast to EPI where the change depends almost exclusively on T₂^{*} and is presumably a susceptibility effect. Thus GE images are sensitive to a process fundamentally distinct from that seen in EPI. It is suggested that this effect is related to fluid shifts occurring at the neuronal membrane. Since such shifts probably occur in hundreds of milliseconds after neuronal activation, then GE imaging offers the possibility of demonstrating direct neuronal events on such a timescale. A pulse sequence (spoiled GRASE) capable of making a T₁-weighted image in under a second, is outlined.

TIME COURSE OF CEREBROVASCULAR RESPONSE TO NEURONAL ACTIVITY DEMONSTRATED WITH FUNCTIONAL MR IMAGING
MS Cohen*, JR Baker, JW Belliveau, TL Davis, RC Tootell, KK Kwong, BR Rosen MGH-NMR Center, Charlestown, MA

Neuronal activity, evoked with visual stimuli, is associated with increased signal in magnetic resonance images. Using ultra-fast magnetic resonance imaging methods sensitive to these functional changes ("fMRI methods") we examined regions of interest within primary visual cortex during exposure to flashing light stimuli. As has been shown previously, the fMRI signal change varies a function of the flash frequency. When the averaged image signal during a dark period is subtracted from the average obtained during visual stimulation, the largest signal change is observed with flash frequencies of about 8 Hz. These data are in good correspondence with cerebral blood flow changes observed by positron emission tomography (PET).

In repeated studies on a single subject the peak fMRI signal change in visual cortex at each flash frequency was similar. However, the response to 8 Hz flash was more sustained than for stimulation at either lower or higher frequencies. These data suggest that the graded response magnitudes observed in PET imaging to differing stimulus conditions may inadequately describe the cerebrovascular response to neuronal activity. By examining the signal response in single MRI voxels to repeated stimulation, we noted that the time course tended to be characteristic of particular brain locations and of particular stimulus properties. By analyzing both the locations and temporal response properties of fMRI-visible brain activity we believe that the method will lead to enhanced understanding of the neuronal response to complex stimuli.

ASSESSING TEST-RETEST RELIABILITY OF FUNCTIONAL MRI DATA
N. J. Cohen, M. T. Banich, A. F. Kramer, H. D. Morris, P. C. Lauterbur*, C. S. Potter, Y. Cao and D. N. Levin, Dept. of Psychology, Beckman Institute, Biomedical Magnetic Resonance Lab, NCSA, University of Illinois at Urbana-Champaign and Dept. of Radiology, University of Chicago

The use of magnetic resonance imaging for functional brain mapping studies allows the same subjects to participate in multiple studies on multiple occasions and holds out the promise of being able to identify brain regions active in various processing tasks *within individual brains*. For this potential to be realized, it must first be demonstrated that *within individual brains* the same areas are activated reliably by the same cognitive challenges on multiple occasions, requiring an assessment of test-retest reliability. This report presents preliminary data on our efforts to provide such an assessment.

Eight subjects were tested on 2-3 occasions separated by 1-4 weeks. On each occasion, subjects were presented with photic stimulation in full field, left hemi-field, and right hemi-field displays, each at a 7.5 Hz reversal rate and a 3.75 Hz reversal rate; the photic stimulation conditions were interspersed with an equal number of baseline (or rest) conditions. Data were acquired on a GE Signa 1.5T MRI scanner (General Electric Corp., Milwaukee, WI) using a standard 1H head coil and a modified spoiled GRASS pulse sequence. A series of T₂^{*} weighted 3-4 mm contiguous oblique slices was acquired with a 128x64 matrix over a 24cm FOV. Slice positions were chosen to maximally cover the visual cortex as judged by a series of T1 weighted sagittal scout images. Each set of slices was obtained in 11-16 s, followed by an 8 s delay. A typical experiment consisted of 36 such multislice acquisitions.

For the 16 data sets analyzed (8 subjects x 2 testing occasions), photic stimulation reliably produced local changes in signal intensity of 2-10%, with left hemi-field stimulation typically producing greater changes on the right and right hemi-field stimulation on the left. Of the 8 test-retest data sets, 6 were sufficiently free of artifacts to assess test-retest reliability. Qualitative analysis of the functional maps, as well as of the spatial extent and numerical magnitude of the statistically derived signal intensity changes in the different stimulus conditions demonstrated substantial intra-subject correspondence between testing occasions. All 6 showed the appropriate hemispheric lateralization of greatest signal intensity changes following hemi-field stimulation on both testing occasions, with similar magnitudes of effects from test to retest. The mean ratio of change in left versus right hemisphere regions for the various stimulation conditions was 1.1 (L/R) for full-field stimulation, 2.1 (L/R) for right hemi-field stimulation, and 2.2 (R/L) for left hemi-field stimulation.

SPURIOUS EFFECTS OF DRAINING VEINS IN MAGNETIC RESONANCE FUNCTIONAL NEUROIMAGING (MRFN). R. Turner*, P.H. Jezzard, D. Le Bihan, A. Prinster. Lab. of Cardiac Energetics and Diagnostic Radiology Department, NIH, Bethesda, MD20892.

The technique of Blood Oxygenation Level Dependent (BOLD) contrast MRI has been applied to imaging human brain function with excellent spatial and temporal resolution. Doubt has been raised recently regarding the location of apparently activated cortical regions. In many gradient-echo MRI studies, large signal changes correlated with the stimulation paradigm can clearly be seen in large veins draining relevant cortical areas. These correspond to increases in oxygenation of venous blood, mixing relatively slowly with blood draining from nonactivated tissue regions, and do not indicate regions of increased neural activity. The effect, analogous to artifacts in PET blood volume studies, complicates interpretation of MRFN data and may result in erroneous conclusions.

Another MRI sequence, spin-echo MRI with long echo-time, gives very little signal from blood in veins. Theory suggests that the effect of oxygenation changes in large draining veins is also suppressed, while that of microvessels remains, due to the relative motions of paramagnetic deoxygenated red cells and tissue water molecules which irreversibly dephase the water proton spin magnetization. We used spin-echo echo-planar imaging in photic stimulation studies at magnetic fields of 4.0 T and 1.5 T. The fractional changes in signal related to brain tasks are smaller than with gradient-echo studies, but the regions of apparent activation are correspondingly more reliable. The effect increases with magnetic field, as expected.

615.12

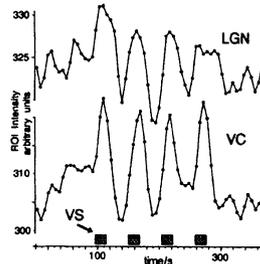

SPATIAL RELATIONSHIP BETWEEN PHYSIOLOGICALLY-DEFINED CINGULATE HAND REPRESENTATION AND MRI-DEFINED COURSE OF THE CINGULATE SULCUS.
T. Paus*, F. Tomaiuolo, M. Petrides and A.C. Evans, Montreal Neurological Institute, McGill University, Montreal, Canada and Institute of Human Physiology, University of Verona, Italy.

Approximately at the level of the anterior commissure, the human cingulate sulcus (CS) gives off a vertical branch in the majority of cases (see accompanying MRI study). Since changes in rCBF related to manual responses were observed previously in this region (Paus et al. J. Neurophysiol.70(2),1993), we have now examined whether there is a relationship between the location of the activation focus (PET) and the location of the change in the CS course (MRI) in a single subject. Coordinates of the PET- and MRI-defined landmarks were obtained in 13 subjects (15 hemispheres). A close spatial relationship was observed between the averaged location of the MRI-derived point (Y = -2.9 ± 7.2; Z = 44.6 ± 3.8) and the center of the PET-determined activation focus (Y = -1.9 ± 6.4; Z = 47.0 ± 4.8). A significant correlation was found between Y coordinates of the PET- and MRI-determined landmarks (r = 0.71, p = 0.003). These results suggest that the location of physiologically-defined hand representation in the CS of a given subject follows the individual pattern of CS morphology.

615.13

FUNCTIONAL MRI OF LATERAL GENICULATE NUCLEUS ACTIVATION DURING VISUAL STIMULATION. A. Kleinschmidt¹, H. Steinmetz¹, K.D. Merboldt², W. Hänicke², J. Frahm². ¹Neurolog. Klinik, H. Heine-Universität, D-40225 Düsseldorf, ²Biomed. NMR, MPI biophysikal. Chem. D-37018 Göttingen

High resolution neuroimaging techniques with MRI are promising in the attempt to analyze functional connectivity in living human subjects. In this study we addressed the issue of thalamocortical transmission within the primary visual pathway. MRI was performed at 2.0 T (Siemens Magnetom) using the standard headcoil and acquiring T1-weighted FLASH images (TR/TE/a=47ms/30ms/40deg, RF-spoiled, 128x256 matrix, FOV 200mm, 4mm slice thickness, temporal resolution 6s). Within horizontal sections parallel to the bicommissural plane signal intensity changes with time were measured both in regions of visual cortex (VC) and lateral geniculate nucleus (LGN) of 8 healthy subjects. Visual stimulation (VS) was achieved by a binocularly presented pattern of diodes flashing at 10 Hz. Both in VC and LGN (as opposed to control regions) signal intensity changed with a temporal pattern reflecting VS cycles (see figure). To our knowledge, this is the first noninvasive demonstration of coupled activation of the thalamic and cortical component of the primary visual system. Functional MRI renders studies of thalamocortical transmission and of activation in small subcortical nuclei feasible; given the strategic importance of such structures within neurocognitive networks this is relevant in the healthy and the diseased human brain.

FUNCTIONAL DIFFERENCES BETWEEN APICAL AND BASAL DENDRITES REVEALED FROM IMAGING CALCIUM DYNAMICS IN LAYER 5 NEOCORTICAL PYRAMIDAL CELLS. D. W. Tank* and R. Yuste. Biological Computation Research Dept., AT&T Bell Laboratories, Murray Hill, NJ 07974.

A general question in cortical physiology is if neurons contain functionally distinct compartments such as those suggested by differences in dendritic morphology. We have used optical imaging methods to explore this issue in basal and apical dendrites of layer 5 pyramidal neurons in slices of rat somatosensory cortex. Neurons were microinjected with the fluorescent calcium indicator fura-2 and the spatial pattern of changes in intracellular free calcium ion concentration ($[Ca^{2+}]_i$) produced by intracellular current injections and antidromic stimulation were imaged with a CCD camera.

In both intrinsically bursting (IB) and regular spiking (RS) cells, intrasomatic injection of depolarizing current pulses elicited action potential trains that were always correlated with $[Ca^{2+}]_i$ increases throughout the basal dendrites, cell body and the proximal 300 μ m of apical dendrite. Calcium levels in most of the apical dendrite (the distal regions up to 1000 μ m from the soma) were not significantly changed. Antidromic stimulation at frequencies of 20 or 100 Hz in the presence of the synaptic blockers AP5, CNQX and BMI also produced accumulations restricted to the basal dendrites and proximal apical dendrite. Since voltage-sensitive calcium channels exist in more distal regions of the apical dendrite (see next abstract), our results suggest that brief, msec duration, voltage changes are strongly attenuated with distance along the apical dendrite with an "effective space constant" of \sim 300 μ m. Thus, distal apical dendrites do not sense changes in the action potential output of the neuron.

This strong voltage attenuation has implications for synaptic learning rules in apical versus basal dendrites. The rule on basal dendrites may depend on the cell's action potential output, while on apical dendrites it may only reflect correlated activity of local inputs. This may underlie the specificity with which presynaptic cells choose postsynaptic apical vs. basal dendritic targets.

PRIMATE PREMOTOR CORTEX: EFFECTS OF GAZE ON THE NEURONAL CODING OF LIMB MOVEMENT DIRECTION. D. Boussaoud*, Vision et Motricité, INSERM-U94, 16 Ave. Doyen Lépine, Bron 69500, France.

Previous studies suggested that the neuronal activity of dorsal premotor cortex (PMd, the dorsal part of Brodmann's area 6) encodes limb movement direction. We studied the effects of eye position in the orbit on the properties of PMd neurons.

Single neurons' activity was recorded in a rhesus monkey seated in a primate chair, with its head fixed, while performing a previously learned conditional task. The monkey had to contact a central touch pad with its forelimb, direct gaze to a $0.3^\circ \times 0.3^\circ$ visual stimulus (the fixation point, FP) and maintain fixation throughout each trial. During fixation, a $2^\circ \times 2^\circ$ white square (the spatial attentional cue, SAC) appeared at one of nine possible screen locations and lasted for 0.5 s. Then, following a variable delay (0.4-0.8 s.), a red or green square (the motor instruction cue, MIC) of equal size was presented at the same location for 0.5 to 3.0 s. A red stimulus instructed the monkey to move its limb from the central pad to one located to the left, a green instructed a movement to a right pad. The offset of this stimulus served as the go signal, and the monkey had to execute the appropriate movement within 0.6 s in order to receive a liquid reward. The FP could appear at five different screen locations, but the stimulus remained at identical retinal co-ordinates.

The results from a sample of 120 PMd neurons show that, for a majority of them (63%), the activity following the MIC presentation was dramatically affected by eye position. In many cases, the activity during the instructed delay period (set) for the preferred limb movement direction was highest when the retinal position of the MIC and gaze angle were in that direction. For others, the discharge was highest when gaze was deviated in the direction opposite that of the instructed limb movement. In some neurons, gaze effect was such that it reversed the direction preference. We suggest that PMd neurons code limb movement direction using, among other parameters, retinal and eye position information.

616.2

SPATIALLY LOCALIZED CALCIUM ACCUMULATIONS IN APICAL DENDRITES OF LAYER 5 NEOCORTICAL NEURONS. R. Yuste*, K. R. Delaney, M. J. Gutnick and D. W. Tank. Biological Computation Research Dept., AT&T Bell Laboratories, Murray Hill, NJ 07974.

Given the length (up to 1mm) of neocortical apical dendrites and the strong spatial attenuation of short duration electrical events shown in the previous abstract, regenerative currents in apical dendrites may play an important role in relaying information from distal synaptic inputs to the cell body (Spencer and Kandel, 1961). We have examined the role of voltage-sensitive calcium channels (VSCCs) in apical dendrites by imaging fura-2 microinjected layer 5 neurons in rat neocortical slices during synaptic, pharmacological and intracellular stimulations.

Extracellular stimulation of layers 1, 2/3 or 4 always resulted in calcium increases in the apical dendrite that were most prominent in its middle third, 400-600 μ m from the soma. Lower calcium accumulations were observed in the soma and basal dendrites. All responses were blocked by AP5, suggesting that they were triggered by synaptic activation of NMDA receptors. When slices were perfused with NMDA in the presence of TTX, a rapid, local calcium accumulation was observed in the middle of the apical dendrite, which extended subsequently to the rest of the cell. To test whether these calcium accumulations were due to calcium entry through NMDA receptors or through VSCCs opened by the NMDA-induced depolarization, we impaled apical dendrites with microelectrodes and imaged their responses during intradendritic depolarizations. In all cells, calcium accumulations were triggered in the apical dendrite, indicating the existence of VSCCs. As an additional test, we injected depolarizing currents in the soma of cells bathed in TTX and TEA to increase their electrotonic length, and AP5 and CNQX to prevent stimulation by ambient glutamate. A localized calcium accumulation in the apical dendrite could be elicited by brief depolarizing currents. Coincident with the accumulations, long lasting calcium spikes were electrophysiologically observed.

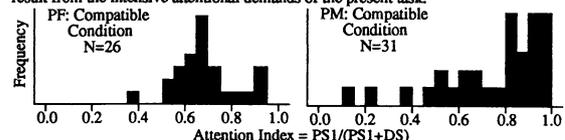

Taken together, these experiments demonstrate the existence of an area in the middle of the apical dendrite with abundant VSCCs. This area can be activated synaptically, can lead in some conditions to regenerative calcium spikes and may serve as a "trigger zone" that amplifies distal synaptic inputs.

616.4

EFFECTS OF ATTENTION ON VISUOMOTOR ACTIVITY IN THE PREMOTOR AND PREFRONTAL CORTEX OF A PRIMATE S.P. Wise* and G. di Pellegrino. Laboratory of Neurophysiology, NIMH, Poolesville, MD 20837

We examined neuronal activity in the premotor (PM) and prefrontal (PF) cortex while a rhesus monkey performed a demanding spatial matching task. The monkey fixated and held a manipulandum beneath a central light emitting diode (LED), which had 8 LEDs arranged in a circle around it. On each trial, after 1 of the 8 LEDs illuminated for 0.5 s (the first prime stimulus, PS1), 0 to 4 of the other LEDs illuminated sequentially for 0.1 s at delays of 0.55 or 0.75 s each as distractor stimuli (DS). At the end of this delay period, the PS illuminated again (PS2) for 0.1 s whereupon the monkey had to execute a forelimb movement within 650 ms (and could break fixation). There were 2 response conditions: the monkey moved the manipulandum (1) to a predetermined target regardless of PS location (the incompatible condition) or (2) to the PS location (the compatible condition).

The behavioral design required that the part of space cued by PS1 had to be either remembered or attended between PS presentations. Since PS2 triggered the movement, both PS1 and PS2 were highly behaviorally relevant, whereas the DS was irrelevant. We could thereby examine the activity that follows a stimulus when it is attended vs. when it is irrelevant and presumably unattended. We found that visuospatial attention affects neuronal activity in both PM and PF. The magnitude of attention effects exceeded that previously reported in PF or elsewhere, which may result from the intensive attentional demands of the present task.

616.5

DORSOMEDIAL FRONTAL CORTEX OF THE MACACA MONKEY: EYE-EAR RELATED NEURONS. L. Bon * and C. Lucchetti Istituto di Fisiologia, University of Trieste, Trieste 34127 Italy.

The dorsomedial frontal cortex is involved in eye motor control. We recorded the activity of 139 cells in the rostral part of dorsomedial frontal cortex of one monkey, trained for fixation and saccade tasks. We followed the rules of the European Community for animal care before, during and after the experiments. We recorded the eye and ear movements by a search coil device in two dimensions. This device allowed to define only the timing between unit activity and ear movement and not parametric characteristics of movements. In addition we recorded the ear movements by an infrared TV system in order to define the movement direction. The firing discharge of 116 cells was related to ear (73%), eye (8 %) and eye-ear (19 %) movements. These neurons showed three different patterns of activity: burst, tonic and burst-tonic. When the eye and ear movements started at the same time the cell showed an increase of activity. These preliminary results suggest that the rostral part of dorsomedial frontal cortex (area 8b) of the monkey is involved in ear movements and eye-ear coordination, probably in orienting processes.

Supported by CNR, MURST 40% and 60%.

EVIDENCE FOR INTRACORTICAL PLASTICITY IN HUMAN MOTOR CORTEX FOLLOWING AMPUTATIONS. L.G. Cohen*, J. Brasil-Neto, M. Daum, T. Findley, J. Macedo, A. Pascual-Leone and M. Hallett, Human Cortical Physiology Unit, Human Motor control Section, NINDS, NIH, Bethesda, U.S.A.)

Following amputation, the human motor system reorganizes (Brain 114:615-627). To determine the site along the human neuroaxis where motor plasticity takes place, we recorded from muscles immediately proximal to the stump and the homonymous contralateral muscles in eight patients with lower limb amputations. Stimulation was delivered to motor cortex with a 9 cm magnetic coil (TMS) and electrically with surface electrodes (TES, n=5) optimally positioned for activation of each muscle. Long descending tracts were stimulated electrically (SES, n=5) at C7(cathode). Intensity of stimulation was ~120% of threshold. Supramaximal muscle responses were elicited by peripheral nerve stimulation.

TMS recruited larger responses and thresholds for activation were lower from muscles ipsilateral to the stump than from homonymous muscles in the normal side. These differences were larger in patients who had the amputation more than 1 year before testing. TES and SES evoked responses with amplitudes that were not significantly different on the two sides. These results show that a substantial percentage of motor reorganization occurs intracortically. Since this phenomenon is time dependent, it might involve establishment of new synaptic contacts in neuronal nets targeting corticospinal tract neurons.

616.9

REORGANIZED CORTICAL BLOOD FLOW AND MAGNETIC STIMULATION MAPS FOLLOWING UPPER LIMB AMPUTATION IN MAN. J.M. Kew, MC Ridding, PN Leigh*, JC Rothwell, RSJ Frackowiak, DI Brooks, MRC Cyclotron Unit, Hammersmith Hospital, London, UK; Department of Neurology, Institute of Psychiatry, London, UK; and MRC Human Movement and Balance Unit, Institute of Neurology, London, UK.

We used positron emission tomography (PET) and transcranial magnetic stimulation (TMS) mapping to determine whether loss of peripheral afferent input induces cortical reorganization in human upper limb amputees. Regional cerebral blood flow (rCBF) was measured in traumatic and congenital amputees at rest and during repetitive, paced, flexion-extension movements of the shoulder ipsi- and contralateral to the amputation. TMS was used to map the cortical representation of the deltoid muscle ipsi- and contralateral to the amputation at rest and during tonic voluntary contraction of the deltoid.

Comparison of the rCBF changes during shoulder movements showed more extensive activation of the contralateral sensorimotor cortex (SMC) during movement of the amputated limb in both groups of subjects. Abnormal activation of the contralateral superior parietal cortex was present in traumatic, but not congenital, amputees. In traumatic amputees, the stimulation map for the deltoid ipsilateral to the amputation was abnormally expanded at rest, but relatively normal in size during voluntary activation.

The results suggest that a more extensive population of SMC neurons are recruited during arm movement ipsilateral to an amputation. Abnormal activation of the superior parietal cortex seems only to occur following traumatic amputation and may be related to the 'phantom limb' phenomena experienced by these patients.

MULTI-SLICE FUNCTIONAL MRI OF HUMAN MOTOR AND SOMATOSENSORY CORTEX CE Stern*, JR Baker, KK Kwong, JW Belliveau, BR Rosen Harvard Medical School and MGH-NMR Center, Charlestown, MA 02129.

Recent developments in functional magnetic resonance imaging (fMRI) allow for the non-invasive examination of changes in blood flow and blood oxygenation (Kwong et al., *PNAS*, 1992). Early fMRI reports examining motor cortex employed single slice, surface coil techniques, which limited the extent of brain that could be studied. Advances in multislice, high speed echo-planar imaging (EPI) techniques allowed us to obtain simultaneous, bilateral measurements of MR signal changes in motor, somatosensory and premotor cortical areas during baseline, motor, and somatosensory paradigms. Gradient echo (GE) and asymmetric spin echo (ASE) imaging sequences were used to track regional changes in signal intensity. Between six and 22 slices of 7mm thickness were positioned through the primary motor and somatosensory areas. Additional flow sensitive scans were used to locate blood vessels, and were subsequently used to dissociate vessel sensitive vs. gray matter signal changes. Each acquisition series started with the collection of resting baseline images, during which the subject remained still and relaxed. Subsequently, subjects performed a motor task, repetitively touching the thumb to each finger sequentially, alternating between movement of the right and left hand. For somatosensory stimulation, the experimenter sequentially stimulated the subject's finger tips in a passive version of the motor task. During active hand movement, MR signal intensity rose significantly in both the primary motor and somatosensory cortex. The passive somatosensory task was successful in dissociating regions selectively associated with motor vs. somatosensory processing. These recent advances in multislice, high speed EPI techniques, in combination with multiple behavioral tasks, allow for the examination of dynamic interactions at multiple cortical sites.

616.8

ECHOPLANAR IMAGING (EPI) OF FUNCTIONAL REORGANIZATION IN HUMAN SENSORIMOTOR CORTEX AFTER TRANSIENT ISCHAEMIC DEAFFERENTATION OF THE FOREARM. J.B. Fieldman¹, L.G. Cohen¹, P. Jezzard², T. Pons³, N. Sadato¹, D. LeBihan⁴, R. Turner², M. Hallen^{1*}, HMCS/NINDS¹, LCE/NHLBI², LN/NIMH³, and DRD/CC⁴, NIH, Bethesda, MD 20892

Somatosensory cortical reorganization has been demonstrated following amputation. EPI permits noninvasive image acquisition in fractions of a second and, in conjunction with a long echo-time (TE), also allows visualization of changes in blood oxygenation secondary to neural activity. Using EPI, we examined the pattern of activation in cortical areas representing muscles proximal to a transiently deafferented limb in order to study the temporal changes in size of the areas activated as well as their degree of activation.

A pneumatic cuff was placed just distal to the elbow and inflated to 30% greater than the systolic blood pressure. Images were obtained prior to inflation, every 10 minutes during ischaemia, and 10 minutes following cuff deflation. At these times, subjects performed 3 30-second sets of self-paced elbow flexions separated by 30-second rest periods. Images were acquired using T2*-weighted gradient-echo EPI sequences with a whole-body 1.5T MRI system and small z-axis head gradient coil. High resolution whole brain images were taken using a conventional gradient-echo sequence for anatomical reference. Z-score images ((activation data)-(baseline data)/(standard deviation during rest phase)) were compared over time for any changes in areas activated by the motor task.

Regions of interest (ROIs) showing good temporal correlation with the paradigm were defined from the z-score images. These ROIs increased in area proportional to the length of ischaemia. Increases in area were apparent 10 min. after cuff inflation, being largest at 40 min., just prior to cuff deflation. Ten minutes after deflation, size of activated areas had not yet returned to baseline. For a given ROI, percentage increase in signal intensity relative to baseline increased with length of ischaemia, from an initial 1.5% with baseline elbow flexion to 6% at maximal ischaemia.

616.10

SUBDIVISIONS OF THE ANTERIOR CINGULATE CORTEX IN MAN: RESPONSE SELECTION AND MOTOR OUTPUT. R. Kawashima, T. Klingberg, B.T. O'Sullivan and P.E. Roland*, Lab. of Brain Research, Karolinska Institute, S10401 Stockholm, Sweden.

Part of the anterior cingulate cortex has been coined as an anterior attentional area. Under the hypothesis that this area is functionally heterogeneous, we measured the regional cerebral blood flow with ¹⁵O-butanol and PET in subjects doing the following tasks. In three go/no-go tasks, stimuli in three sensory modalities were present simultaneously, but in one modality the stimulus changed. The subjects pressed a button each time the frequency decreased/light dimmed. The control was simultaneous presentation of constant stimuli. In length discrimination the subjects actually discriminated the length of cylinders. The control was similar surface exploring movements (without cylinders). In the two reaching tasks the subjects, eyes closed, pointed to targets they had seen previously. The control was rest. We subtracted the brain images of control from the respective test images, and by a consistency analysis of these images it was apparent that all go/no-go tasks and length discrimination, but not reaching, activated a field located just below the left cingulate sulcus (Talairach 8, 37, 42). Since there were no fields related to movements in the length discrimination image, and because reaching did not activate, the common denominator for activation was response selection. In the cingulate sulcus (4, 22, 46) there was another field activated in reaching and go/no-go tasks, but not by length discrimination (motor components subtracted). The common denominator for activation of this field was hand and arm movements, and it may mark the location of a supplementary motor area.

REGIONAL CEREBRAL BLOOD FLOW CHANGES DURING UNIMANUAL AND SIMULTANEOUS BIMANUAL MOVEMENT. E.A. Franz*, T.A. Zeffiro and S.Y. Bookheimer Psychology Dept, UC Berkeley; MNB-NINDS, NIH, Bethesda, MD 20892.

It has been suggested that the motor system exhibits regional specialization with regard to bilateral movement control, with the supplementary motor area (SMA) and putamen playing central roles. We investigated the neuroanatomical localization of these processes with positron emission tomography.

rCBF changes were recorded using bolus injection of $H_2^{15}O$ in 8 subjects performing a metronome-paced sequential finger opposition task with left, right, or both hands. Scans were spatially standardized to a common coordinate system and statistical parametric maps were generated by making planned comparisons of task and control conditions.

rCBF increases were seen in primary motor cortex, cingulate motor area, ventral premotor area, SMA, cerebellar nuclei and cortex, and putamen in relation to unilateral movement of either hand. The left-right asymmetry of the increase with respect to the hand used varied among regions, with the most asymmetry seen in primary motor cortex. Although no regions were active exclusively in relation to bimanual movement, regions more active during the bimanual than either unimanual task included the SMA, the cerebellar nuclei and the putamen, suggesting a special role for these areas in the planning or execution of simultaneous bilateral movement.

616.12

BILATERAL ACTIVATION OF THE HUMAN SOMATOMOTOR CORTEX BY DISTAL HAND MOVEMENTS. R. Hari*, R. Salmelin, N. Forss, J. Knuttila. Low Temp. Lab., Helsinki Univ. of Technology, 02150 Espoo, Finland.

We used a 122-channel whole-head neuromagnetometer to study cortical areas activated in relation to distal hand movements. Six normal human subjects performed self-paced index finger flexions, wrist flexions, and a sequence of complex digit movements in different sessions. The magnetic signals were averaged from a button press. High-amplitude signals were observed over the somatomotor hand areas within 100 ms from the button press. The sources were modelled with current dipoles, one in each somatomotor hand area. Index finger movements were associated with purely contralateral activation. However, wrist flexions and skilled finger movements evoked additional intense ipsilateral activity. The movements were also associated with dampening of spontaneous activity starting 1 s before the button press and a rebound within 1 s afterwards. The reaction was much stronger over the contralateral hemisphere but was also seen over the ipsilateral side. Some distal hand movements thus seem to be associated with bilateral activation of the human somatomotor cortex.

DRUGS OF ABUSE: COCAINE

617.1

INTERACTIVE EFFECTS OF PRENATAL COCAINE AND NICOTINE EXPOSURE ON POSTNATAL DEVELOPMENT AND BEHAVIOR IN THE OFFSPRING. S.K. Sobrian, K. Hodge, P. Webb, F. Racev, S. Aif, W. Slikker, Jr., and R.R. Holson. ¹Department of Pharmacology, Howard University College of Medicine, Washington, DC 20059 and ²Divisions of Reproductive and Developmental Toxicology and Neurotoxicology, National Center for Toxicological Research, Jefferson, AR 72079.

As prenatal exposure to either cocaine (C) or nicotine (N) has been shown to alter maternal variables and induce a variety of subtle changes in the offspring, the present study investigated the possibility of synergistic effects of co-administration on offspring development. On gestation days 8-21, Sprague Dawley rats were exposed daily to either 5.0 mg/kg of N (NS), 20 mg/kg of C (CS), or both N (5.0 mg/kg) and C (20 mg/kg) (NC). N was administered by osmotic minipump and C by sc injection. Saline injected dams fitted with saline-filled pumps (SS), and untreated dams pair-fed (PF) to NC females served as controls. Maternal toxicity was not observed in any of the groups. Offspring's body weight during the first four postnatal weeks were unaltered by prenatal drug exposure; however the development of surface righting was delayed in CS pups. Moreover, only CS offspring exhibited alterations in non-drugged and drug-challenged behaviors. CS offspring were under-responsive to the stimulatory effects of apomorphine; both activity and stereotypy were reduced. Behavioral responses to C and N challenge were similar in all groups. In contrast, a significantly larger number of CS offspring responded on both trials of an alternation task. Two measures of non-drugged activity, tested at 3 and 8 weeks of age revealed no prenatal treatment effect. Treatment effects on dopamine D₁ and D₂ binding in the caudate were not observed. Prenatal exposure to N alone did not alter any of the behaviors tested; moreover, the combination of N and C did not exacerbate any of the behavioral changes seen in CS offspring. These results support the hypothesis that C is a behavioral teratogen in rats.

617.3

PRENATAL EXPOSURE TO COCAINE DECREASES SENSITIZATION TO COCAINE IN ADULT MALE RATS. R.E. McGivern & M. Hutcheson. Dept. Psychology, San Diego State Univ., San Diego CA 92182.

Multiparous time-pregnant Sprague-Dawley dams (Charles River, Portage MI) were injected daily with cocaine HCl (3.3, 10.0 or 30.0 mg/kg, sc) at 0800 and 1630 hrs from days 14-21 of gestation; control dams were injected with saline or left undisturbed (7-8 dams/treatment group). Offspring were weaned at 24 days of age and group housed by sex and treatment. At approximately 120 days of age, male litter representatives were injected with cocaine (10 mg/kg, ip) or saline for 8 consecutive days 5 minutes prior to being placed in a 12" diameter open field for 60 min. On day 14, 6 days after the last daily injection, both saline and cocaine injected animals were injected with cocaine (10 mg/kg, ip) prior to being placed into the same arenas. Behavior was recorded on videotape on days 1, 8 and 14, and scored by blinded experimenters. Results revealed that males exposed to 3.3 or 30 mg/kg of cocaine prenatally were insensitive to the stimulatory effect of the drug on locomotor activity on day 1, while locomotor activity of animals exposed to 10 mg/kg increased similar to controls. 30 mg/kg animals remained insensitive on day 8 and were also insensitive to the stimulatory effect of cocaine on rearing behavior on days 1 and 8. 10 & 30 mg/kg saline injected males exhibited significantly less habituation from days 1-8 than controls. Sensitization was observed on day 14 in controls with respect to stereotypy when cocaine injected animals were compared with animals previously injected with saline. No sensitization was observed in animals exposed to cocaine prenatally. Prenatal cocaine exposure has been reported to increase striatal D₂ receptor binding in the rat (Scalzo et al., 1990), results which may be implicated in the response to cocaine in our males exposed prenatally to 30 mg/kg. However, our overall behavioral results indicate that cocaine has differential actions on the developing male brain which are non-linear and dose dependent, perhaps reflecting the drug's anesthetic vs reuptake blockade properties. (Supported by NIDA, DA-04490).

617.2

THE EFFECT OF IN UTERO COCAINE AND AMPHETAMINE ON STRIATAL NEUROTROPIC ACTIVITY. C.M. Buhriand, B.W. Santi, D.K. Siereys, and P.M. Carvey. Dept. Neurology, Rush-Presbyterian-St. Luke's Med. Ctr., Chicago, IL 60612.

We have previously shown that in utero cocaine (COC; 30 mg/kg/day) exposure during E8-15 in rabbits decreased striatal DA and striatal-derived neurotrophic activity. In order to determine if these results were the result of the DA agonist properties of cocaine or generalized vasoconstriction, we treated gravid females with COC (30 mg/kg b.i.d., s.c.), amphetamine (AMPH; 5 mg/kg/day), haloperidol (HAL; 1.5 mg/kg/day), HAL + AMPH, or vehicle (VEH) during E8-21. The rat pups were sacrificed on P14, P28, and P56, perfused, and the brains removed. Striatal tissue punches were evaluated for DA using HPLC and the remainder of the striatum was dissected, homogenized in Hanks Balanced Salt Solution (HBSS), centrifuged, and the supernatant extracts added to freshly plated primary, dissociated, rostral mesencephalic tegmentum (RMT) tissue cultures at equivalent protein concentrations. The number of cells with processes were assessed 40 hours later as an index of striatal trophic activity.

Striatal DA content in COC pups was reduced at P14 by 51% but was elevated c. 50% at both 1 and 2 months. In contrast, in utero AMPH exposure did not significantly affect striatal DA. Striatal trophic activity at 2 weeks was very low in all animals and similar to that observed in the cerebellum such that trophic assessments were not valid. By 1 and 2 months however, striatal trophic activity in control animals was elevated by 43 and 39% respectively, relative to COC exposed animals ($p < 0.05$; $p = N.S.$). Trophic activity in AMPH exposed animals at 1 and 2 months was reduced 39 and 63% respectively ($p < 0.05$ for both). Of perhaps greater importance was the observation that the DA antagonist HAL, did not prevent the amphetamine induced decreases in striatal trophic activity. These preliminary data suggest that reductions in striatal trophic activity accompany in utero cocaine and amphetamine exposure and are not necessarily related to alterations in DA. Since HAL did not prevent the AMPH-induced trophic reductions, it is likely that the trophic alterations are the result of the vasoconstrictive effects of AMPH and not its DA agonist properties.

617.4

COCAINE-INDUCED HYPOTENSION AND BRADYCARDIA ARE MEDIATED BY CNS BETA-ADRENERGIC RECEPTORS. R.A. Gillis, H.K. Erzuouki, and Y.M. Hernandez. Georgetown Univ. Med. Ctr., Washington, DC 20007.

We have shown that cocaine (COC) administered into the hindbrain via the vertebral artery (VA) decreases cardiac sympathetic nerve activity, mean arterial pressure (MAP) and heart rate (HR) and that these effects are not due to a local anesthetic action of the drug (JPET 257: 511, 1991). Presently, we investigated the possibility that COC's inhibitory effects are due to blockade of catecholamine reuptake. The effects of the beta-adrenoceptor blocker, propranolol (PR), on cocaine-induced hypotension and bradycardia were examined in 7 alpha-chloralose anesthetized cats. COC (1 mg) was injected into the VA 60 min before and 5 min after VA administration of PR (0.05 mg). PR blocked the decrease in MAP produced by COC (MAP decreased -44 ± 8 mm Hg, $p < 0.05$, before PR and -9 ± 5 mm Hg after PR) and attenuated COC's decrease in HR (-48 ± 22 beats/min before and -13 ± 2 beats/min after PR). Injection of COC 90 min after PR administration produced decreases in MAP (-43 ± 11 mm Hg, $p < 0.05$) and HR (-52 ± 20 beats/min, $p < 0.05$) that were almost identical to those seen prior to PR. PR alone produced a small decrease in HR (-11 ± 3 beats/min, $p < 0.05$) with no change in MAP. I.v. administration of the same dose of PR (0.05 mg) did not affect the hypotension elicited by COC in the VA. To determine whether the COC-induced decrease in HR was due to excitation of vagal outflow, 5 cats were pretreated with the peripheral muscarinic blocker, propantheline (PTH). PTH, 0.5 mg/kg, i.v. completely antagonized the decrease in HR elicited by COC (1 mg) in the VA. These data suggest that COC blocks the reuptake of catecholamines in the hindbrain and that the excess catecholamines act on beta-adrenoceptors to decrease sympathetic outflow and increase parasympathetic outflow.

617.5

REDUCED VTA DOPAMINE TRANSPORTER mRNA OCCURS AFTER CESSATION OF CHRONIC COCAINE ADMINISTRATION. C. Cerruti*, N.S. Pilotte, G.Uhl, and M.J. Kuhar. Neuroscience Branch NIH-NIDA, Balto., MD 21224.

Administration of cocaine to Lewis rats for two weeks using a schedule of intermittent delivery that mimics self-administration patterns results in a decrease in dopamine transporter (DAT) binding 10 days but not 1 or 3 days after cessation of treatment. The decrease in binding occurs in the nucleus accumbens (NAC) but not in the striatum, and is long lasting. We carried out *in situ* hybridization studies with a probe for DAT utilizing tissue prepared in the same manner as described for DAT binding studies. Animals were treated with cocaine or saline and then withdrawn from treatment for 10 days. In the ventral midbrains of saline-treated animals, highest mRNA hybridization grain densities were found in cells in the substantia nigra pars compacta, low grain densities were found in the interfascicular (IF) and caudal linear (CL) nuclei, and intermediate levels were found over cells in the paragrilar, rostral linear and parabrachial nuclei. In cocaine-treated animals DAT mRNA hybridization grain densities were significantly lower only in IF and CL nuclei that project to NAC rather than striatum. This reduction in DAT gene expression corresponded to the reduction in DAT binding in NAC. The number of cells labeled per section did not change in these nuclei. The data indicate that gene expression can be altered after cessation of cocaine treatment. Such changes might conceivably contribute to craving and relapse to cocaine use during periods of abstinence from cocaine.

617.7

CHRONIC COCAINE ADMINISTRATION IS ASSOCIATED WITH BEHAVIORAL SENSITIZATION AND DOPAMINE TRANSPORTER UPREGULATION. L.G. Miller*, J.M. Koff, L. Shuster. Dept. of Pharmacology and Exp. Therapeutics, Tufts Univ. School of Medicine, Boston, MA

Chronic cocaine administration has been associated with sensitization, an increase in drug effect, in contrast to the tolerance observed with many psychotropic compounds. Since cocaine acts at the presynaptic dopamine transporter, we evaluated sensitization and dopamine transporter binding *in vivo* in several mouse strains. All strains of mice evaluated showed increased activity after cocaine compared to saline injections. BALB/cByJ, DBA/2J and C57BL/6J mice exhibited sensitization after 5 daily injections of cocaine at 20 and 40 mg/kg/d, whereas B6AF1/J mice showed sensitization at 20 but not 40 mg/kg/d. CD1 mice did not exhibit sensitization at either dose. Dopamine transporter binding *in vivo* was increased in DBA/2J and B6AF1/J mice after 5 injections of cocaine, 40 mg/kg/d but not in the other strains evaluated. In contrast, continuous infusion of cocaine at the same daily dose and duration did not produce sensitization or binding changes in DBA/2J mice. The time course of transporter binding alterations after intermittent cocaine exposure indicated no change at day 1, increased binding at 3 days, a return to control levels at 7 days, and decreased binding at 14 days. These data indicate that both sensitization and alterations in dopamine transporter binding occur after chronic cocaine injections, but these changes are unlikely to be directly related.

617.9

REPEATED BOUTS OF CONTINUOUS COCAINE INDUCE PROGRESSIVELY CHANGING PATTERNS OF AXONAL DEGENERATION AND BEHAVIOR. G. D. ELLISON*, S. IRWIN, AND G. SULUR. Department of Psychology, UCLA, 405 Hilgard Ave., Los Angeles, CA 90024

We recently reported that rats given 3 to 5 days of either continuous amphetamine or cocaine showed a strong pattern of silver-stained degenerating axons in lateral habenula (LH) and fasciculus retroflexus (FR). Daily injections of these drugs did not induce degeneration. In order to determine whether subsequent bouts of continuous cocaine would continue to induce this effect, rats were implanted with slow-release cocaine pellets for 5 days and then sacrificed, or were then given either a 10 day or a 3 month recovery period and then a second 5 day cocaine bout and then sacrificed. Behavior was monitored every 3 hours round the clock throughout the 5 day period of drug administration.

During the first cocaine bout, the rats showed initial motor stereotypes which waned at about day 3 as other behaviors, including parasitotic grooming, emerged. With repeated bouts both of these stages were exaggerated, with striking parasitotic grooming appearing in the 3 month animals. The number of silver-stained axons in LH and FR following the second pellet was not reduced but was generally greater than following the first pellet. This suggests a similar potentiation of neurotoxicity and "late-stage" behaviors with repeated cocaine bouts.

HIGH AFFINITY PROBES FOR COCAINE RECOGNITION SITES ON THE DOPAMINE TRANSPORTER. L. M. Gracz*, B.K. Madras, R. Hanson, D. Elmaleh, P. Meltzer. Harvard Medical School, New England Reg. Primate Res. Ctr., Southborough, MA, 01722, Massachusetts General Hospital, Boston, Organix, Inc., Woburn, MA.

Accumulating evidence suggests that cocaine recognition sites on the dopamine transporter are important mediators of the behavioral effects cocaine. In order to improve the sensitivity of probes for these sites, three high affinity ligands for the dopamine transporter were radiolabeled and characterized in caudate-putamen of cynomolgus monkeys. [³H]Lu 19-005, a phenylindanamine, was approximately > 300 times more potent than [³H]cocaine for labeling sites on the dopamine transporter. The novel cocaine congener [³H]CDCT, one of the most potent drugs yet developed, also bound to these sites in the picomolar range. [¹²⁵I]IACFT, A novel high affinity iodinated probe distributed primarily to dopamine-rich brain regions following *i.v.* administration. Of these ligands, IACFT is the most selective for the dopamine over the serotonin transporter. Low densities of the dopamine transporter may be detected with these compounds. DA06303, MH14275, DA00499, RR00168.

SELECTIVE LABELING OF THE STRIATAL AND CEREBRAL CORTICAL DOPAMINE TRANSPORTER IN RAT AND HUMAN BRAIN BY THE COCAINE ANALOG [¹²⁵I]RTI-121. J.W. Boja*, T. Kopajtic, F.I. Carroll, H.H. Seltzman, C.D. Wyrick, J. Lever, J. Staley, D.C. Mash and M.J. Kuhar. Molecular Pharmacology Section, NIH-NIDA Addiction Res Center, Baltimore, MD 21224.

The cocaine analog RTI-121 has previously been shown to be very selective for the dopamine transporter (Boja et al., Neuroreport 1992). [¹²⁵I]RTI-121 bound to both a high (0.2 nM) and low affinity site (1.93 nM) with a density consistent with that of the dopamine transporter. The pharmacological profile of specific [¹²⁵I]RTI-121 binding was also consistent with that of the dopamine transporter. In the cerebral cortex [¹²⁵I]RTI-121 bound to both a high and low affinity site with affinities similar to that demonstrated in the striatum, however at a much lower density. Displacement of specific [¹²⁵I]RTI-121 binding by various pharmacologic agents also demonstrated a profile consistent with the DAT. Autoradiographic studies in the rat brain demonstrated intense labeling of the striatum, nucleus accumbens and olfactory tubercle. The substantia nigra was also labeled, but at a lower intensity. This is in contrast to the pattern of labeling of the dopamine and serotonin rich areas that is demonstrated when [¹²⁵I]RTI-55 ([¹²⁵I]β-CIT) is used as the ligand. [¹²⁵I]RTI-121 bound to both a high and low affinity site in the human caudate with affinities similar to that demonstrated in the rat brain. These results demonstrate that [¹²⁵I]RTI-121 with its high affinity and selectivity is a superior ligand for the DAT.

617.10

MOLECULAR AND PHARMACOLOGIC SPECIFICITY OF STRIATAL c-FOS ACTIVATION BY COCAINE IN JUVENILE RATS. Lisa M. Genova, Barry E. Kosofsky, Kathleen Gogas*, and Steven E. Hyman. Laboratory of Molecular and Developmental Neuroscience, Massachusetts General Hospital, Harvard Medical School, Boston, MA, 02129.

Cocaine acts acutely to potentiate dopaminergic neurotransmission in the striatum. *In situ* hybridization was used to characterize mRNA localization of various neuropeptides and receptors present in neurons that are activated by an acute dose of cocaine. The immediate early gene, c-fos, was used as a marker of cocaine-induced neuronal activation. We hybridized 35S-labelled c-fos cRNA and non-radioactive, digoxigenin-labelled D1, D2, Substance P, or Enkephalin cRNA on the same sections. Cocaine (30 mg/kg/ip) administration 45 min prior to sacrifice activated predominantly D1 rather than D2 striatal neurons. Almost all cells containing D1 receptor mRNA expressed c-fos mRNA, whereas c-fos and D2 mRNA were infrequently colocalized. In adjacent sections, Substance P mRNA was colocalized in striatal neurons that were simultaneously expressing c-fos mRNA, whereas striatal neurons containing Enkephalin mRNA seldom demonstrated c-fos induction. Rats treated with saline (vehicle control) displayed no detectable striatal c-fos mRNA.

Cocaine's induction of striatal c-fos was mostly abolished by pretreatment (30 min before cocaine) with SCH23390 (.5 mg/kg/ip), a D1 antagonist. In these animals, there was exclusive activation of a small subset of cells confined to the dorsolateral striatum. *In situ* analyses of sections labelled for c-fos and D2 mRNA or c-fos and D1 mRNA revealed that the dorsolateral striatal cells activated by SCH23390/cocaine pretreatment contained D2 and not D1 mRNA. These experiments suggest that the indirect aminergic agonist cocaine activates striatal neurons that contain predominantly Substance P and D1 mRNA and that cell activation is mediated almost entirely by a D1 mechanism.

617.11

CELLULAR AND DEVELOPMENTAL CORRELATES OF NEURONAL ACTIVATION BY COCAINE IN RAT STRIATUM. Barry E. Kosofsky*, Lisa M. Genova, and Steven E. Hyman. Laboratory of Molecular and Developmental Neuroscience, Massachusetts General Hospital, Harvard Medical School, Boston, MA 02129.

We have utilized in situ hybridization (ISH) to define the phenotype of striatal neurons activated at acute timepoints (45 minutes) after cocaine administration (30mg/kg/hip) to rat pups of different ages (P8, P15, P28, and adults). The immediate early gene *c-fos* serves as an acute marker of striatal cell activation by cocaine. We combined 35S-labelled *c-fos* cRNA probes with nonradioactive, digoxigenin labelled cRNA probes (Dopamine receptors D1 or D2, or the Neuropeptides Substance P or Enkephalin), and performed double ISH. Striatal sections of naive, saline, and cocaine exposed pups from litters of each age were analyzed to determine the topographic distribution and cellular correlates of cocaine induced *c-fos* expression. At each age examined, *c-fos* positive striatal cells were predominantly colabelled with Substance P cRNA and D1 receptor cRNA. There were occasional Enkephalin or D2 receptor positive striatal neurons in which *c-fos* was induced by cocaine. Conversely, not all striatal neurons which expressed either Substance P mRNA or D1 receptor mRNA demonstrated cocaine induced *c-fos* activation. The phenotype of activated striatal neurons was consistent across all postnatal ages examined. However, the topography of activated cells at each age varied with *c-fos*+/Substance P+ and *c-fos*+/D1+ cells restricted to medial predominant clusters on P8, a homogeneous lateral predominance on P15, and dorsocentral striatal predominance on P28 and in adults. These findings suggest that at all postnatal ages examined Substance P containing, D1 receptor bearing neurons comprise the majority of striatal cells induced by cocaine to express *c-fos*. Additional organizational features, with topographic and temporal specificity (perhaps extrinsic connections) may define which subset of Substance P+ or D1+ neurons are activated at each postnatal age.

617.12

COCAINE-INDUCED CONDITIONED TASTE AVERSIONS: COMPARISONS IN LEW/N & F344/N RATS. J.R. Glowa*, A. E. Shaw, and A. L. Riley. Laboratory of Medicinal Chemistry/NIDDK, National Institutes of Health, Bethesda, MD 20892 and Dept. of Psychology, The American University, Washington, DC 20016.

Differences in self-administration behavior between LEW/N and F344/N rats suggest a genetic predisposition toward drug abuse. The current study compared doses of cocaine required to produce a conditioned taste aversion (CTA) in these strains. Fluid, either a 0.1% saccharin solution, or water, was available during 20-min daily sessions. Saccharin sessions were always followed by a dose (0-50 mg/kg, sc.) of cocaine, and separated by three water sessions. Fluid consumption was assessed over four saccharin sessions. Vehicle had no effect on saccharin consumption. In contrast, when cocaine followed saccharin, rates of consumption decreased over successive saccharin sessions in a dose-related manner in both strains. The lowest dose (18 mg/kg) decreased consumption in LEW/N rats but not in F344/N rats. An intermediate dose (32 mg/kg) decreased consumption maximally in LEW/N rats, and only marginally in F344/N rats. The highest dose (50 mg/kg) decreased consumption completely in LEW/N rats, and almost completely in F344/N rats. The enhanced sensitivity of the LEW/N rat to the noxious effects of cocaine extends various behavioral and biochemical differences in effects of drugs of abuse in these strains. However, the increased sensitivity of the LEW/N rat to a noxious effect of a drug of abuse may suggest that this strain does not exhibit a genetic predisposition to factors related only to the abuse potential of drugs, to the extent that reinforcing and noxious effects differ.

VISUAL CORTEX: EXTRASTRIATE—FUNCTIONAL ARCHITECTURE

618.1

ANALYSIS OF RETINOTOPY IN OWL MONKEY EXTRASTRIATE CORTEX BY VISUAL FIELD SIGN. M.I. Sereno*, C.T. McDonald, M.O'Dell, and J.M. Allman. Cognitive Science Department, University of California, San Diego, La Jolla, CA 92093 and Division of Biology 216-76, California Institute of Technology, Pasadena, CA 92115.

Cortical visual areas can be divided into those with a mirror-image transformation of the visual field (e.g., V1, VP) and those with a non-mirror-image transformation of the visual field (e.g., V2, MT) (when viewed from the cortical surface). With densely sampled retinotopy, the local visual field sign (mirror vs. non-mirror) can be calculated from the angle, ϕ , between the direction of the gradients in eccentricity, r , and angle, θ , of the receptive field centers (r and θ are measured relative to the center of gaze). This measure was used to subdivide owl monkey visual cortex into regions that were then correlated with myeloarchitecture.

Detailed retinotopic maps (250-600 closely spaced penetrations) were obtained from the parietal and occipitotemporal cortices of 6 anesthetized owl monkeys. At the end of each experiment, the cortex was physically flat-mounted, sectioned parallel to cortical laminae, and stained with the Gallyas technique. The penetration map digitized from the cortical surface photograph was warped to align it with the final location of a set of marker lesions in the flattened cortex using a deformable template algorithm. Eccentricity and angle data were then interpolated onto uniform grids that were used to compute a fieldsign map.

V1, V2, and MT stand out as large expanses of uniform fieldsign. The areas in between show a more complex organization. There are three strips of cortex representing the lower visual field with alternating fieldsign that generally correspond to our previously described DLP (mirror-image), DLI (non-mirror-image), and DLA (mirror-image). The topography of these areas is much less regular than that of MT, with many interdigitating fingers; and DLP contains a small upper field representation. In the region previously labeled D1, we found an upper field representation with the same fieldsign as the directly adjoining lower field V2; the lower field of V2 continues rostrally into the upper field of D1 without a discontinuity. Area DM contains both lower and upper fields and it is situated medial to D1. Many of the details of the fieldsign map are correlated with subtle changes in the pattern of myelination. The fieldsign technique brings out a feature of cortical retinotopic maps that is difficult to see in raw receptive field plots; the resulting picture of retinotopy was more complex than expected.

618.3

FUNCTIONAL CONNECTIVITY WITHIN V1 AND V2: PATTERNS AND DYNAMICS. D.Y. Ts'o*, A.W. Roe and J. Shey. Division of Neuroscience, Baylor College of Medicine, Houston, TX 77030

We have studied the rules of functional connectivity within V1 and V2 by using cross-correlation analysis, guided by optical imaging maps of cortical organization. One issue that we have examined is the varying degrees of divergence and convergence of cortical connectivity. In some cases, interactions were found between V1 - V1 pairs and V1 - V2 pairs which had nonoverlapping receptive fields, separated by several receptive field diameters. However, V1 - V2 cross-correlogram peaks tended to be much broader than V1 - V1 peaks, suggesting a temporal dispersion perhaps due to a much greater degree of divergence and convergence in the connections of V2 cells. Particular pairings varied greatly in the dependence of the interactions on receptive field overlap, suggesting that different functional compartments have differing degrees of divergence and convergence.

Correlations also were observed to change with state. One factor that can govern such changes is the nature of visual stimulus. For example, among color cells, the type of color stimuli influenced the shape and strength of the correlogram. An analysis of the change in correlation over time also demonstrated substantial changes in the form and strength of correlograms. One such behavior was a gradual strengthening of the correlogram over time during repeated visual stimulation. Since in general the average firing rates of the cells did not alter substantially, these changes may reflect a modulation of synaptic efficacy or coupling. While each functional compartment exhibits a characteristic pattern of functional connectivity, this connectivity may be subject to state-dependent influences.

618.2

VISUAL FIELD REPRESENTATION AND FUNCTIONAL COMPARTMENTS WITHIN SINGLE V2 STRIPES. A.W. Roe* and D.Y. Ts'o. Division of Neuroscience, Baylor College of Medicine, Houston, TX 77030

The second visual cortical area, V2, of primates has been shown to contain a stripe-like organization. The canonical view is that there are three sets of functionally distinct stripes, subserving color, form and depth/motion. We have found that within single V2 stripes, however, the distribution of functional properties is far from uniform and homogeneous. Optical imaging and electrophysiological experiments show multiple distinct clusters or patches of various functional properties within individual V2 stripes. For example, within a single V2 stripe nominally identified as "thin", separate regions of color cells, luminance cells and even disparity cells may be found.

We have also examined the representation of the visual field within such single stripes, by making single tangential electrode penetrations along individual stripes. Our previous studies of the visual map in V2 have shown that across the stripes in V2, the visual field is multiply represented and discontinuous. Along a stripe, we also find such discontinuities at the boundaries between functionally distinct subcompartments. Our preliminary findings suggest that even within a single stripe, the parameters of visual field coverage, such as receptive field size and scatter are different within each functional subcompartment. These results suggest that the parcellation of visual processing, in terms of function and visual field representation is more complex than the original notion of only three distinct stripe compartments within area V2.

618.4

PATCHY INTRINSIC CONNECTIONS FOLLOW ISO-ORIENTATION SITES IN CAT VISUAL CORTICAL AREA 18. Z.F. Kisvárdy¹, D.-S. Kim², U.T. Eysel¹, T. Bonhoeffer^{2*}

¹Dept. Neurophysiol. Ruhr-Universität Bochum, Bochum PO Box 102148, F.R.G. ²MPI Brain Res., Frankfurt PO Box 710662, F.R.G. *Present address: MPI Psych. 8033 München-Martinsried, F.R.G. A general concept in the functional organization of the cerebral cortex is that lateral patchy connections link groups of neurons possessing similar functional properties⁽ⁱ⁾. Interestingly, experimental data obtained in area 18 violated this concept in that neuronal groups with dissimilar orientation preferences were connected⁽ⁱⁱ⁾. In order to know whether area 18 indeed represents a radically different organization scheme to that of area 17 we revisited the area 18 connections using a combination of optical imaging and iontophoretic injection of biocytin. Optical imaging provided orientation maps over 12-23 mm² regions. Biocytin labelling was analysed in series of horizontal sections. In two cats, axonal terminals of anterogradely and retrogradely labelled fibres were drawn from the entire depth of the cortex. Then a mesh-grid containing the same pixel-size as the optical image was overlaid the entire bouton map of each section in precise register. For aligning between the optical and the anatomical maps 5-8 identified electrode penetration marks were used. The number of labelled terminals was counted in each pixel and a frequency distribution according to different orientation values was calculated. The results show that all of the remote patches coexisted with sites showing statistically similar orientation preferences to that of the injection site. Thus according to our results the long-range excitatory system of area 18 follows the organization principle of area 17. Z.F.K. and U.T.E. are supported by the Deutsche Forschungsgemeinschaft.

OPTICAL IMAGING OF ORIENTATION AND BINOCULARITY IN VISUAL AREAS 1 AND 2 OF SQUIRREL MONKEY (*SAMIRI SCIUREUS*) CORTEX. G. Blasdel, M. Livingstone, and D. Hubel*, Department of Neurobiology, Harvard Medical School, Boston, MA 02115.

We used optical imaging combined with single unit recording to study the organization of orientation preferences and binocularity in visual areas 1 and 2 (V-1 and V-2) in squirrel monkeys whose lissencephalic cortex offers an obvious advantage. Single unit recordings were used to verify orientation maps obtained with optical imaging. In V-1 of these animals we found that orientation preferences repeated with a period of approximately 460 μ m, compared with periods of 640 and 760 μ m that are observed parallel and perpendicular to the ocular dominance columns in macaques. In V-2 orientation preferences repeated every 1.26 mm in directions parallel to the stripes of intense cytochrome oxidase staining that run perpendicular to the border between V-1 and V-2. Differential images of orientation, generated by subtracting images of responses to orthogonal orientations, were maximal along the edges of the thick cytochrome oxidase stripes, but were less pronounced along their centers as well as in the pale and thin stripes. Differential images of binocularity, obtained by subtracting responses to monocular stimulation from responses to binocular stimulation, showed single, narrow (370 μ m), dark bands running down the centers of the thick stripes, adjacent to one or two paler bands. These results thus indicate a substructure of the thick stripes that is not apparent from CO staining. In single unit recordings from the centers of the thick stripes we found cells that were selective for binocular disparity, and that were often unresponsive or poorly responsive to monocular stimulation. These cells were clustered in groups that preferred near, far, and zero disparity. (Supported by EY05403 and the Office of Naval Research)

RELATIONSHIPS BETWEEN FUNCTIONAL ORGANIZATION FOR DIRECTION OF MOTION AND FOR ORIENTATION SELECTIVITY IN CAT AREA 18. A. Shmuel, A. Arieli, D. Malonek and A. Grinvald*, Dept. of Neurobiology, Weizmann Inst., Rehovot, Israel 76100.

Previous electrophysiological studies in cat area 18 indicated that neurons preferring similar directions of motion are clustered together (Payne et al., *Brain Res.* 1980; Tolhurst et al., *Exp. Brain Res.* 1981; Swindale et al., *J. Neurosci.* 1987). Optical imaging based on intrinsic signals suggested that such clustering is much weaker than that observed for orientation selectivity in area 18, if it exists at all (Bonhoeffer et al., *J. Neurosci.* 1993). We improved the sensitivity of optical imaging, and here report the functional organization, parallel to the cortical surface, of direction of motion, and its relationship to that of orientation selectivity.

Achromatic rectangular wave gratings or random dot patterns, moving coherently in different directions, were presented binocularly. Single-condition functional maps for iso-orientation and iso-direction domains were generated using the standard procedure for obtaining optical maps from cortical images. In cat area 18 the iso-orientation domains activated by gratings moving in opposite directions exhibited a considerable overlap. However, closer analysis revealed a patchy distribution of cortical regions exhibiting preference for one direction of motion over the opposite direction. Thus, neurons exhibiting preference for a particular direction of motion are clustered, forming a mosaic of direction preference domains. We confirmed that orientation and direction selectivity are closely related. Each iso-orientation patch is divided into regions with opposite direction of motion preference. From the amplitude of the functional maps, we found that the clustering index (density) for orientation preference was 2-3 times larger than that observed for direction of motion preference. The organization for direction of motion preference revealed by random dot stimuli was nearly identical with that obtained from gratings stimuli.

FUNCTIONAL MRI (fMRI) EVIDENCE FOR MT/V5 AND ASSOCIATED VISUAL CORTICAL AREAS IN MAN. R.B.H. Tootell*, K.K. Kwong, J.W. Belliveau, J.R. Baker, C.E. Stern, R.L. Savoy, H. Breiter, R. Born, R. Benson, T.L. Brady, B.R. Rosen. Harv. Med. Sch., Boston, MA 02115; MGH-NMR Ctr. 149 13th St., Charlestown, MA 02129; Rowland Inst., Cambridge, MA 02142

Presumptive area MT homologues (aka V5 in Old World primates) have been demonstrated in prosimians and New and Old World monkeys. PET data (e.g. Zeki et al., 1991) and preliminary anatomical data suggest that it exists in man as well. Here MT and other motion-responsive areas of human visual cortex were functionally characterized using fMRI, and compared to macaque areas. Twelve subjects were scanned using gradient echo and control sequences in a 1.5 T EPI machine with surface coils. Five cortical areas were activated by moving stimuli (dot arrays or gratings): V1, V2, presumptive (p) pMT/V5, pMSTd, and pV3/V3a. Only pMT and pMST were highly selective for moving stimuli, as opposed to stationary stimuli during fixation. pMT is larger than pMSTd and both are located within the general region indicated previously in PET studies. Using moving square wave gratings of systematically varied contrast, contrast gain curves were obtained from each of the five areas within a given subject. Area V1 has a threshold of ~4%, and fMRI signal amplitudes increase monotonically at higher contrasts. Areas pMT, pMST and pV3 are much more sensitive to contrast than V1 (threshold < 1.5%, saturated above 5%): this is consistent with the magnocellular-stream dominance of their macaque namesakes, and with single unit evidence from macaque MT and V1 (Sclar et al., 1990). COMPARING MAPS OF FUNCTIONAL ARCHITECTURE OBTAINED BY OPTICAL IMAGING OF INTRINSIC SIGNALS TO MAPS AND DYNAMIC PATTERNS OF CORTICAL ACTIVITY RECORDED WITH VOLTAGE-SENSITIVE DYES. D. Shoham*, Z. Gottesfeld and A. Grinvald. Dept. of Neurobiology, Weizmann Institute of Science, Rehovot 76100, ISRAEL.

In previous years our group has used real-time optical imaging utilizing voltage-sensitive dyes to study the spatio-temporal organization of the activity of large neuronal populations in the visual cortex. In these earlier studies we used an array of 12x12 photodiodes to image the cortical activity in real-time at a high sampling rate (up to 1.5kHz). An additional imaging technique based on activity-dependent intrinsic changes of cortical reflectance was used for complementary measurements - to image the functional architecture of the cortex at a high spatial resolution. These two methods were never applied in the same experiment.

Recently we have developed a new imaging system that allows both high spatial resolution (64x64 detectors) and high temporal resolution (up to 2kHz), with a signal to noise ratio of about 3000:1. We are currently using this system to combine for the first time the two imaging techniques in a single experiment, on the same patch of cortex. In the first set of experiments using this combined approach we produced orientation maps of cat areas 17 and 18. The spatial maps obtained with the two methods were basically the same. However, when voltage-sensitive dyes were applied we could see not only the static architecture but also the temporal structure of the response, including for example its on and off components. These preliminary results demonstrate the power of using a fast, high-resolution camera and combining the two optical imaging techniques to get detailed measurements of both the spatial and the temporal aspects of cortical activity.

OPTICAL IMAGING OF ORIENTATION, DIRECTION AND RETINOTOPIC ORGANIZATION IN AREA MT OF THE OWL MONKEY - D. Malonek*, R.B.H. Tootell and A. Grinvald. Dept. of Neurobio., Weizmann Inst., Rehovot 76100, ISRAEL and Dept. of Neurobio., Harvard Med. School, Boston, Mass. 02115

Area MT (V5) is unique among cortical areas in that a large proportion of its neurons are directional selective. We have previously shown (Malonek et al. Neuroscience Abstracts 1992), using optical imaging, that in owl monkey area MT, populations of cells that have similar direction-of-motion preference are clustered together. In addition we showed that populations of cells that have similar orientation preference are also clustered, and that these orientation preference maps are 3-5 times stronger than the direction of motion preference maps. This pronounced organization for orientation, rather than axis-of-motion, preference led us to compare functional maps obtained with moving and stationary gratings.

Here we show that counterphase gratings activated the same regions as moving gratings but these stimuli were 4 times less effective than gratings moving at optimal velocity. We investigated further the relationship between functional organization for orientation and direction-of-motion. Orientation preference maps contain two types of pinwheels: 180° and 360°. These maps can be further subdivided in terms of their preference for direction-of-motion. These directionality maps showed that direction-of-motion preference changes smoothly across the cortical surface. However, several lines of discontinuity which separate opposite directions of motion preference were observed. We tested whether velocity was mapped across the cortical surface and found that maximal responses were obtained at velocities of about 10 °/sec but the overall organization for orientation and direction of motion preference was velocity independent. In addition we determined the retinotopic organization of area MT using stimuli that activated only parts of the visual field, and showed that a stimulus which subtends an elevation of $\pm 3^\circ$ around area centralis activated more than 70% area MT.

SEARCHING FOR STEREOPSIS IN HUMANS USING ULTRAFAST FUNCTIONAL MRI: STIMULI, ANALYSIS TECHNIQUES, AND PRELIMINARY DATA. R.L.Savoy*, K.K.Kwong, M.S.Cohen. The Rowland Institute for Science, 100 Edwin H. Land Blvd, Cambridge, MA 02142; MGH-NMR Center, 149 13-th St., Charlestown, MA 02129

A variety of visual stimuli were designed that shared the common feature of using changing fields of random dots presented to the two eyes during both "control" and "experimental" periods. During control periods, the dots were the same for each eye; during the experimental periods the dots were different for the two eyes, so as to elicit images in depth (random dot stereograms) via free-fusion. Thus, V1 activation was expected and found during both periods. Differences between the two types of periods would necessarily be due to the images seen stereoscopically. Furthermore, any motion signals perceived monocularly would be comparable during both periods.

Data analysis programs were developed to automatically highlight the pixels within a given slice that showed significant stimulus locking. Also, by examining the relative variance at each pixel, the data analysis programs could detect heartbeat artefacts, even though the sampling frequency was below that which would permit straightforward frequency filtering.

Preliminary data (one subject, two experimental runs in the same experimental session, each run consisting of 3 pairs of control versus motion-in-depth, slices parallel to the calcarine fissure) revealed an area that showed a highly significant stimulus locked response variation. This area was in the same slice and position in both runs, and, based on its location, was clearly not the putative human V1 nor MT homologue.

618.11

STIMULUS DEPENDENT MRI SIGNALS EVOCKED BY ORIENTED LINE-ELEMENT TEXTURES IN HUMAN VISUAL CORTEX A. Karni¹, L.G. Ungerleider¹, J. Haxby², P. Jezzard³, L. Pannier⁴, C.A. Cuenod⁴, R. Turner³ and D. LeBihan⁴ NIMH¹, NIA², NHLBI³ & DRD-CC⁴, NIH, Bethesda MD 20892.

A considerable number of neurons is devoted to the parallel extraction of the orientation of line elements. Here we use a set of simple textures - arrays composed of identical oriented line elements (0.5 deg. each) - to evoke event related changes in the local MRI signal (activation).

An echo planar imaging (EPI; TR = 3000ms; TE = 40ms) sequence and/or a conventional gradient echo (SPGR; TR = 60ms; TE = 40ms; flip angle 40) sequence were run on a 1.5T GE scanner. The stimuli were presented at a rate of 3Hz with element orientation alternating between horizontal and vertical. A consecutive baseline-test-baseline-test design was employed, with each interval 30 - 40 sec long, sampled (per slice) 6 - 12 times; 4 slices (2 - 4mm thick) were sampled in parallel. The observer's task was to fixate and discriminate small target letters at the center of display, ensuring consistent retinotopic mapping.

Results: I) For hemifield and quadrantic stimuli, a consistent, large activation (3 - 16% change, rise-time 6 - 9 sec) was measured by both sequences along the banks of the calcarine fissure (striate cortex) and on the convexity of the occipital lobe (extrastriate areas 18,19). II) A small texture target (6 line elements, subtending 1.5 x 2.0 deg. - presented at 5 - 7 deg. from fixation) induced a consistent, localized signal (2.4 - 6%) in both striate and extrastriate areas up to about 16 mm from the occipital pole. III) Preliminary data for a similar texture target embedded in a background of orthogonal line elements (compared to a homogeneous texture) showed consistent signals (2.4 - 6%, rise time 12 - 15 sec) evoked in the same locations as the target in (II).

Our results indicate that early stages of human visual cortical processing are strongly driven by oriented contours, including contours defined by local orientation discontinuities (gradients).

618.13

VISUAL SPATIAL COMPARISONS INVOLVE GYRUS CINGULI POSTERIOR: EVIDENCE FROM PET ACTIVATION STUDIES. P. Dupont¹, G.A. Orban, R. Vogels, A. Schoups*, G. Bormans¹, J. Nuyts¹ and L. Mortelmans¹. Lab. Neuro- en Psychofysiologie, K.U.Leuven GHB, Med. School; ¹PET Center, Dept. of Nuclear Medicine, UZ GHB, B-3000 Leuven, Belgium

Local cerebral blood flow was measured with PET in 14 subjects performing six tasks. In a first triplet a grating was presented centrally and the subject had either to detect the occurrence (DET), identify the orientation as vertical or not (ID) or compare the orientation of two successive gratings (TSD). In the second triplet two gratings (a vertical and an oblique one) were presented simultaneously on the vertical meridian (1.9° ecc). The subjects' task was either to detect the occurrence (DDET), to identify the side of the vertical orientation (SID), or to compare the orientation of the two gratings (SSD). Despite the small orientation differences, the subjects performed the tasks well at a rate of 50 trials/min. Compared to the DET, ID and TSD activated mainly areas 18 and 19 in the right hemisphere. Compared to the DDET, SID and TSD activated areas 18, 19 and 7 bilaterally. Comparing SSD with SID yielded a significant activation of right posterior cingulate (area 31).

These data confirm the task dependency of visual processing and suggest that area 31 elaborates the message from area 7 to achieve spatial comparisons.

618.12

VISUAL FORM DETECTION IN MAN USING COLOUR AND MOTION CUES: FUNCTIONAL ANATOMY BY POSITRON EMISSION TOMOGRAPHY (PET). B. Gulyás^{1*}, C. A. Heywood², D. Popplewell², P. E. Roland¹ and A. Cowey². ¹Laboratory for Brain Research and Positron Emission Tomography, Nobel Institute of Neurophysiology, Karolinska Institute, Box 60400, S-104 01 Stockholm, Sweden, and ²Department of Experimental Psychology, University of Oxford, Oxford OX1 3UD, South Parks Road, UK

With the purpose of mapping anatomical structures in the human brain participating in the processing and analysis of form information mediated by motion or colour cues, we measured regional cerebral blood flow (rCBF) changes in ten young male volunteers with PET, using 15O-butanol as tracer. During the measurements, the subjects performed two pairs of discrimination tasks, each related to a specific and a reference task (form from motion, motion discrimination; form from colour, colour discrimination). The individual rCBF images were standardized in shape and size with the help of the Karolinska Institute's computerized brain atlas system. 'Specific task - reference task' subtraction (Δ rCBF) images were determined, which were then averaged across the subjects. The resulting images were analysed for statistically significant changes between specific and reference tasks.

The discrimination of form by means of motion cues activated regions bilaterally in the inferior and lateral occipital gyri, in the lingual, anterior cingulate, medial frontal and orbitofrontal gyri, and in the left fusiform and right inferior temporal gyrus. Form discrimination by colour cues resulted in activation bilaterally in the inferior temporal, lateral occipital, and orbitofrontal gyri, in the left precuneus and intraparietal sulcus, and in the right precentral gyrus. The regions activated in the two kinds of form discrimination did not overlap. The present findings suggest that the human brain can use different functional pathways in processing and analysing information resulting in the very same perceptual entry.

EXCITATORY AMINO ACIDS: EXCITOTOXICITY V

619.1

THE TIME COURSE OF GLUTAMATE-INDUCED NEURONAL DEATH. Janet M. Dubinsky*, Dept. Physiology, Univ. Texas Health Science Center, San Antonio, TX 78238.

Glutamate excitotoxicity has been viewed as a multicomponent insult involving both a rapid osmotic lysis following influx of Na⁺, Ca²⁺, and Cl⁻, and a delayed calcium-mediated neuronal death. It has been widely assumed that the former mechanism operates initially, during exposure to excitatory amino acids while the later occurs over the course of the ensuing 24 hr. In order to study the mechanism of delayed toxicity, cell survival has been routinely assayed 24 hr after toxic insult. However, it is not known how quickly the neurons die or if the population declines synchronously, as might be expected from a simultaneously-triggered, calcium-mediated event. In this study, death among cultured hippocampal neurons was monitored by trypan blue cell counting at varying times in the 48 hr following a 5 min exposure to 500 μ M GLU. These time course measurements revealed that neuronal death occurred continuously, with a high initial death rate that steadily declined with time. The rate of cell loss was proportional to the size of the surviving population or dependent upon some product released in proportion to cell number. The survival curve followed an exponential decline, suggesting that death occurred in a stochastic fashion following the original insult. These experiments were supported by NIH grant AG10034.

619.2

THE QUANTITY OF Ca THAT ENTERS A NEURON TO CAUSE ITS DEATH IN GLUTAMATE TOXICITY.

M. Schramm* and S. Eimerl, Dept. Biological Chemistry, Hebrew University, Jerusalem 91904, Israel

Qualitative evidence shows that Ca mediates acute and delayed glutamate toxicity. However, the quantitative relationship, between Ca uptake and cell death has remained obscure. It has also been difficult to establish a quantitative correlation between toxicity and the rise in [Ca²⁺]_i during exposure to glutamate. We have determined the total amount of ⁴⁵Ca entering cultured rat cerebral granule cells (9 DIV) during exposure to NMDA and glutamate, and measured resulting cell death 45 min later. The amounts of endogenous Ca have also been monitored. Plotting ⁴⁵Ca uptake against % cell death, the experimental points fit well on a linear regression line (r 0.85; p < 0.001) which hits the ⁴⁵Ca axis at 2 nmol/5 x 10⁵ cells/40 μ g protein (0% cell death). At 6 nmol ⁴⁵Ca uptake, cell death reached 30%. Results obtained with cells cultured for another week (16 DIV) fit a parallel regression line (r 0.88; p < 0.001), touching the ⁴⁵Ca axis at 0.75 nmol. Cell death reached 60% at 6 nmol ⁴⁵Ca uptake/5 x 10⁵ cells (10 fmol ⁴⁵Ca/cell, about three times the endogenous Ca). The older cells thus demonstrate a higher toxicity, driven by the same amount of ⁴⁵Ca taken up. The calculated concentration of the total ⁴⁵Ca taken up, \approx 15 mM, exceeds that measurable in Ca²⁺ imaging by 4 orders of magnitude. The procedures developed furnish quantitative information on the dynamic relationship between calcium and neurotoxicity.

INTRACELLULAR CALCIUM BUFFERING IS IMPAIRED IN FIBROBLASTS FROM PATIENTS WITH MITOCHONDRIAL DEFECTS. A.M. Moudy*, D.C. DeVivo* and S.M. Rothman*. Dept of Anatomy & Neurobiology*, Washington Univ, St. Louis, MO 63110 & The Neurological Institute, New York, NY 10032.

Excitotoxic neuronal damage and cell death have been associated with toxic rises in intracellular calcium (Ca^{++}) levels. Recently, a number of investigators have speculated that nerve and muscle cells from patients with abnormal energy metabolism will be especially sensitive to excitotoxicity. We have now found that cultured fibroblasts obtained from patients with three mitochondrial disorders [MELAS syndrome; cytochrome oxidase deficiency (COX); and pyruvate dehydrogenase deficiency (PDH)] are unable to buffer Ca^{++} rises normally.

We induced Ca^{++} rises by abruptly depolarizing cultures with an extracellular solution containing 60 mM K^+ to trigger opening of voltage-gated Ca^{++} channels. In cultures loaded with the Ca^{++} sensitive dye fura-2, Ca^{++} was measured by ratiometric fluorescence intensity produced by flashes of 340 and 380 nm light. In control cells exposed to high K^+ , Ca^{++} increased transiently, then rapidly returned to baseline. The 340/380 fluorescence intensity ratio (R) at 20 min was not different from baseline (0.65 vs 0.64; $p = .06$, Wilcoxon; 99 cells of 8 patients). In MELAS fibroblasts, R increased from 0.89 at baseline to 1.01 at 20 min ($p < .001$; 83 cells of 2 patients). In COX fibroblasts, R changed from 0.94 to 1.06 ($p < .001$; 58 cells of 2 patients). In PDH cells, R rose from 1.02 to 1.06 ($p < .05$; 63 cells of 2 patients). Baseline and 20 min R values differed significantly between control and all disease groups ($p < .001$, Dunn). In toxicity studies, cells incubated for 24 hrs in high K^+ solution had >99% survival, suggesting that there is little, if any, acute cellular damage from these paradigms.

If Ca^{++} homeostasis is affected similarly in the nerves of patients with these disorders, this could explain the neuronal loss that characterizes a variety of inborn metabolic errors. Supported by NS19988.

MECHANISM OF QUINOLINIC ACID FORMATION AFTER INFECTION WITH EITHER THE HUMAN OR SIMIAN IMMUNODEFICIENCY VIRUS. M.P. Heyes*, K. Saito, S.P. Markey, A.A. Lackner and E.O. Major. Lab. of Clinical Science, NIMH; Lab. of Viral and Molecular Pathogenesis, NINDS, Bethesda, MD 20892; and California Primate Center, Davis, CA 95616.

Infection with the human- or simian- immunodeficiency virus (HIV, SIV) is associated with neurologic deficits and encephalitis, in conjunction with elevated levels of the neurotoxin quinolinic acid (QUIN) in brain. In the present study, infection of macaques with various serotypes of SIV or the type-D retrovirus was associated with induction of indoleamine-2,3-dioxygenase, kynurenine hydroxylase and kynureninase in brain, in proportion to tissue and CSF QUIN levels. No changes in 3-hydroxyanthranilate-3,4-dioxygenase occurred. The largest increases were found in macaques with local inflammatory cell infiltrates. In a second study, human macrophages (THP-1 cells) and/or human fetal brain cultures (neurons, oligodendrocytes and astrocytes) were infected with HIV or stimulated by interferon- γ (IFN- γ) or endotoxin in media containing [$^{13}C_6$]-L-tryptophan. Macrophages converted [$^{13}C_6$]-L-tryptophan to L-kynurenine and [$^{13}C_6$]-QUIN when infected with either HIV-1 or stimulated by IFN- γ . However, while mixed brain cultures alone converted [$^{13}C_6$]-L-tryptophan to L-kynurenine in response to HIV-1 or IFN- γ , no [$^{13}C_6$]-QUIN was formed, unless macrophages added to the culture. The synthesis of [$^{13}C_6$]-QUIN by activated macrophages was attenuated by 4-chloro-3-hydroxyanthranilate ($IC_{50} = 0.1 \mu M$), 6-chlorotryptophan ($IC_{50} = 53 \mu M$), norharmane ($IC_{50} = 54 \mu M$), indomethacin, superoxide dismutase, actinomycin-D, or interleukin-4. We conclude that macrophages are an important localization for induction of kynurenine pathway enzymes and QUIN formation in brain inflammation, and that QUIN synthesis can be modulated by either cytokines or inhibitors of the kynurenine pathway.

619.7

1-AMINOCYCLOPROPANECARBOXYLIC ACID (ACPC) PROTECTS AGAINST DYNORPHIN A (DYN)-INDUCED SPINAL CORD INJURY IN RATS. J.B. Long* and P. Skolnick*. ¹Neuropharm. Br., Dept of Med. Neurosci., Div. of Neuropsych., Walter Reed Army Inst. of Res., Wash., D.C. 20307 and ²Lab. of Neurosci., NIDDK, Bethesda, MD 20892.

Lumbar subarachnoid injection of DYN causes ischemia, neuronal degeneration, and persistent hindlimb paralysis in rats. The protective effects of a variety of competitive and non-competitive antagonists of the NMDA receptor complex indicate that excitatory amino acids (EAAs) mediate DYN-induced spinal cord injury. Moreover, spinal cord CSF concentrations of the EAAs glutamate and aspartate are increased 5-6 fold during the time that spinal cord blood flow is reduced by paralytic doses of DYN. ACPC is a high affinity partial agonist for the glycine binding site within the NMDA receptor complex, and acutely blocks NMDA- and cocaine-induced convulsions. Chronic treatment with this compound appears to yield a reversible desensitization of the NMDA receptor complex, suggesting that ACPC might provide an effective means of ameliorating degenerative mechanisms mediated through this ligand-gated ion channel. Therefore, we examined the effects of acute and chronic ACPC on recovery from the persistent hindlimb motor deficits elicited by L4-L5 subarachnoid injections of 20 nmol of DYN. When administered 30 min before DYN injection, ACPC (50, 100, & 200 mg/kg, i.p.) caused significant, dose-dependent improvements in motor scores by 24 hours postinjection. When given as 6 daily injections followed by 1 injection-free day immediately preceding DYN administration, ACPC (200 mg/kg, i.p.) also significantly improved neurological recovery. These results support earlier indications that: 1) ACPC provides an effective means of antagonizing excitotoxic phenomena, and 2) chronically-administered ACPC desensitizes the NMDA receptor complex.

619.4

AGE-DEPENDENT STRIATAL EXCITOTOXIC LESIONS PRODUCED BY THE ENDOGENOUS MITOCHONDRIAL INHIBITOR MALONATE. M. Flint Beal*, Emmanuel Brouillet, Bruce Jenkins, Ross Henshaw, Bruce Rosen and Bradley T. Hyman. Neurochemistry Laboratory, Neurology Service, and MGH-NMR Center, Department of Radiology, Massachusetts General Hospital and Harvard Medical School, Boston, MA 02114.

Intrastratial injection of the reversible succinate dehydrogenase (SDH) inhibitor malonate produced age-dependent striatal lesions, which were significantly greater in 4 and 12 month old animals than in 1 month old animals. Both histologic and neurochemical studies showed that the lesions were significantly blocked by the non-competitive NMDA receptor MK-801. Neurochemical characterization showed significant decreases in GABA and substance P concentrations with relative sparing of somatostatin concentrations. Histologic assessment showed sparing of NADPH-diaphorase neurons. Chemical shift magnetic resonance imaging showed that malonate produces age-dependent increases in striatal lactate concentrations. There were transient ATP depletions, which were less severe than those seen with 3-nitropropionic acid. The results strengthen the possibility that a subtle impairment of energy metabolism may play a role in the pathogenesis of HD.

619.6

PLATELET-ACTIVATING FACTOR (PAF) IN THE PATHWAY OF HIV-RELATED NEURONAL INJURY. Dongxian Zhang*, Yun-Beom Choi, J. Offermann, H. E. Gendelman*, and Stuart A. Lipton. Dept. of Neurology, Children's Hospital and Program in Neuroscience, Harvard Medical School, Boston, MA 02115; [†]Dept. of Microbiol., Univ. of Nebraska Med. Ctr., Omaha, NE 68198.

At least one pathway to neuronal injury in AIDS appears to involve the release of toxins by macrophages that have been either infected with HIV-1 or stimulated with the HIV coat protein gp120. This form of neurotoxicity can be largely prevented by NMDA antagonists (reviewed in Lipton, TINS 1992;15:75). Recently, cytokines and arachidonic acid metabolites have been shown to be produced by macrophages activated by gp120 exposure or HIV infection (Wahl et al., PNAS 1989;86:621; Genis et al., J. Exp. Med. 1992;176:1703). Here, we demonstrate that gp120 stimulates the release of toxins into retinal cultures and that the candidate macrophage toxins, PAF and TNF- α , lead to injury of retinal ganglion cell neurons. In the first experiment, overnight exposure of rat retinal cultures to 20 pM gp120 resulted in injury to approximately half of the retinal ganglion cells. A specific gp120 antiserum prevented this toxic effect. In each case, culture medium assayed by HPLC contained ~25 μM glutamate. When gp120-containing 'conditioned medium' (CM) from this first experiment was added to a second set of cultures, a similar degree of neuronal injury was observed. However, fresh gp120 antiserum did not completely ameliorate this toxic effect, suggesting that toxic substances other than gp120 had accumulated in the CM. In a third series of experiments, the addition of carbamyl-PAF (1 μM) and TNF- α (1000 U/ml), but not TNF alone, resulted in neuronal injury that could be attenuated with the NMDA antagonist memantine (6 μM).

619.8

Use-dependent binding demonstrates that NMDA receptor channels do not open during "ischemia" *in vitro*. J. J. Vornov* and K. E. Bruce Depts. of Neurology and Neuroscience The Johns Hopkins School of Medicine, Baltimore, MD 21205

In some models of ischemia, neuronal injury is dependent upon glutamate activation of the NMDA receptor. We now present evidence in a tissue culture model that toxic NMDA receptor activation begins not during ischemia, but upon restoration of oxidative metabolism.

Dissociated cultures of rat cortical neurons were subjected to a 15 min period of simulated ischemia by blockade of oxidative metabolism and glycolysis with potassium cyanide and 2-deoxyglucose. Injury was assessed after 24 hours by measurement of LDH release. NMDA receptor antagonists (CPP, MK-801) protected against injury if added after simulated ischemia, during recovery. Protection was completely lost if the antagonist was removed before the restoration of oxidative metabolism. We then directly measured NMDA receptor activation with [3H]-TCP binding. TCP binding is use-dependent because the binding site is in the open channel of the NMDA receptor. TCP binding was rapid, reversible and specifically displaced by MK-801. Binding was increased by toxic concentrations of glutamate or NMDA. However under ischemic conditions, binding was reduced from baseline by approximately 50%. Immediately after restoration of oxidative metabolism, binding had returned to near control levels. We found no evidence for massive NMDA receptor activation under ischemic conditions. During recovery, normal levels of NMDA receptor activation may injure vulnerable neurons. Alternatively, receptor activation may be transient or delayed.

619.9

POST-STROKE NEUROPROTECTION BY MEMANTINE MINIMALLY AFFECTS BEHAVIOR AND DOES NOT BLOCK LTP. PE Stieg^{*1}, S Sathi¹, SP Alvarado², PS Jackson², JW Pelligrini², H-SV Chen², SA Lipton², FE Jensen², Neurosurgery¹ and Neurology², Children's Hospital and Brigham and Women's Hospital, Harvard Medical School, Boston, MA 02115

In vitro studies demonstrate that memantine (Mte) antagonizes NMDA activity by open-channel blockade and decreases neurotoxicity (*J. Neurosci.* 1992;12:4427-4436). Mte is well-tolerated clinically, and this may be related to its faster off-rate compared to MK-801 at neuroprotective doses (*ibid.*). Pretreatment with Mte reduces infarct size in a rodent stroke model (*ibid.*). We evaluated infarct size and neurobehavior in rats administered Mte following stroke induction by photothrombosis (Mte 20 mg/kg i.p. 30 min after stroke, then 1 mg/kg b.i.d for 48 hours). Mte-treated rats did not exhibit sedation, alteration of withdrawal and righting reflexes, or weight loss. Mte treatment resulted in significantly smaller infarct volumes (mean = 36.7 mm³, n=7) compared to controls (mean = 81.0 mm³, n=6) (p<0.001). Because behavior was not significantly affected *in vivo*, we examined whether neuroprotective concentrations of Mte affected LTP in brain slices *in vitro*. Previous *in vitro* data revealed 6 μ M Mte to be neuroprotective (*ibid.*). In 4/4 slices, 6 μ M Mte did not block LTP (145% of baseline epsp slope 1hr post tetanus). In contrast, neuroprotective doses of APV (50 μ M) completely blocked LTP (3/3 slices). These results suggest that Mte may be clinically useful in stroke treatment, given its selective blockade of the NMDA receptor under ischemic conditions with preservation of physiologic NMDA activity.

FURTHER EVIDENCE THAT PYRROLOQUINOLINE QUINONE (PQQ) INTERACTS WITH THE NMDA RECEPTOR REDOX MODULATORY SITE. E. Aizenman^{*}, F.E. Jensen, P.A. Rosenberg, P.M. Gallop and L.-H. Tang. Dept. Neurobiology, Univ. of Pittsburgh, Pgh., PA 15261, and Depts. of Neurology and Biological Chem., Children's Hosp. and Harvard Med. Sch., Boston, MA 02115.

The putative essential nutrient PQQ has been shown to be an oxidizing agent for the NMDA receptor redox modulatory site (Aizenman et al., *J. Neurosci.* 12, 2362; 1992). In the present study, we have performed additional experiments to establish the mode of action of this substance. As shown previously, 50 μ M PQQ reverses the potentiating action of 4 mM dithiothreitol (DTT) on NMDA-induced whole-cell responses in rat cortical neurons in culture. However, following NMDA receptor alkylation with 500 μ M N-ethylmaleimide (NEM; Tang & Aizenman, *J. Physiol.* 465, 303; 1993) the effects of PQQ are largely abolished. Single channel measurements from outside-out patches revealed that 50 μ M PQQ could readily reverse the increase in frequency of NMDA channel openings produced by 1 mM DTT, similar to what was previously shown for another oxidizing agent, DTNB (Tang & Aizenman, *ibid.*). Furthermore, even higher concentrations (200 μ M) of PQQ did not alter NMDA single channel conductance or open time distribution. Together, these results indicate that PQQ modulates the NMDA receptor by directly oxidizing the redox site. Supported by NS29365.

ADMINISTRATION OF THE SOLUBLE REDOX COFACTOR PYRROLOQUINOLINE QUINONE (PQQ) FOLLOWING HYPOXIA/ISCHEMIA REDUCES INFARCT SIZE. FE Jensen^{1,2*}, G Gardner¹, A Williams¹, P Gallop¹, E. Aizenman², P.A. Rosenberg¹, Neurol., Children's Hosp.¹, Brigham and Women's Hosp.², Harvard Med. Sch., Boston, MA; Neurobiol., Univ. Pittsburgh Sch. Med, Pittsburgh, PA³

PQQ is a putative essential nutrient that has been shown *in vitro* to diminish NMDA-evoked current and neurotoxicity by direct oxidation of the NMDA receptor redox site (*J. Neurosci.* 1992;12:2362-2369). PQQ has also been shown to have antioxidant effects and function as a free radical scavenger (*J. Pharm. Exp. Ther.* 1990;281:980-985). Administration of PQQ prior to hypoxia/ischemia in a rodent stroke model significantly reduces infarct size (*Soc. Neurosci. Abs.* 1992;18:756). The present study evaluated the efficacy of a single dose of PQQ (20 mg/kg i.p.) administered immediately following bilateral carotid ligation and hypoxia (30 min at 8% O₂) in 7 d.o. rat pups. Analysis of histologic sections from animals sacrificed at 48 hrs post hypoxia/ischemia revealed a significant neuroprotective effect of PQQ. Infarct area was 59.4 +/- 15.6% of total cortical area (n=8) in PQQ-treated animals, compared to 99.8 +/- 0.3% in matched controls (p<0.02). Thus, post-treatment with PQQ resulted in a 59% reduction in infarct size. In conclusion, PQQ appears to be useful in the treatment of hypoxia/ischemia when administered following the acute insult. Future experiments will determine the maximal delay for post-treatment in this model. Given the known actions of PQQ, both as a free radical scavenger and a selective pro-oxidant at the NMDA receptor redox site, there may be multiple mechanisms of neuroprotection by PQQ *in vivo*. CULTURED NEURONS RESCUED FROM AMINO ACID EXCITOTOXICITY BY HU-211, A NON PSYCHOTROPIC CANNABINOID. N. Eshhar, S. Strim, M. Liscovitch* and A. Bigon. Pharmos Ltd. and Weizmann Inst. Sci., Rehovot, ISRAEL

Excessive stimulation of glutamatergic receptors is intimately involved in mechanisms of neurotoxicity and neuronal cell death. HU-211, a non-psychotropic cannabinoid-derived compound has been shown to act as a functional noncompetitive NMDA receptor antagonist *in vivo* and *in vitro*. In the present study, we examined the ability of HU-211 to prevent neuronal degeneration produced by different glutamatergic receptor agonists in culture. Primary cerebral cortical cell cultures were prepared from 18- to 20-day old rat fetuses by enzymatic dissociation. Resulting cell suspensions were plated on a confluent cortical glial-cell feeder layer (prepared 2 weeks earlier). Cells at 10 days in culture were exposed to 500 μ M NMDA and/or to 1000 μ M quisqualate, either alone or in the presence of 10 μ M HU-211. The percent of viable cells was assessed by ELISA measurements of oxidative metabolism 24 hours later. Exposure to the toxin was associated with 20-50% neuronal death, which was totally prevented by HU-211. The ability of HU-211 to prevent cell death mediated by quisqualate suggests that its neuroprotective activity may be mediated by more than one receptor and/or mechanism. Exploring this possibility, we found that HU-211 at 10 μ M totally displaced tritiated QNB binding from the cholinergic muscarinic receptor in brain homogenates, whereas it had no effect on phospholipase D activity in solubilized brain membranes. While the mechanism underlying the neuroprotective activity of HU-211 is still under investigation, the compound offers promise as a therapeutic agent for conditions such as stroke and head trauma, in which excitotoxicity has been shown to play a major role.

THE MORPHOLOGY OF CEREBELLAR PURKINJE CELLS GROWN *IN VITRO* FROM LURCHER AND WILD-TYPE MICE Keith W.T. Caddy^{*} and Martin L. Doughty. Department of Physiology, University College London, Gower Street, London, WC1E 6BT, U.K.

The Lurcher mutant mouse has been studied for a number of years and the development of the lesion in the animal characterized both qualitatively and quantitatively (Caddy and Biscoe, 1979, *Phil. Trans. Roy. Soc.* 287:167). We know that the Lurcher Purkinje cells (P-cells) exhibit characteristic abnormal ultrastructure by 10 days post natal (P10) and suffer complete degenerative loss by P26. As a consequence of this 90% of its granule cells are lost through trans-synaptic degeneration. Lurcher <-> wild-type chimeric studies (Caddy and Herrup 1990, *J. comp. Neurol.* 297:121 & 1991, *J. comp. Neurol.* 305:421) have shown that only the wild-type P-cells survive in these mice and they are morphologically abnormal. It was with this knowledge that an *in vitro* study was begun. We have been culturing explants of cerebellar cortical slices from 2 day old Lurcher and wild-type mice to compare the growth and development of the P-cells with those found in the above studies. We have analyzed explants grown for up to 25 days *in vitro* (DIV) using immunocytochemistry and electron microscopy (EM). The results of the EM study, presented here, indicate that the P-cells grown *in vitro* from the Lurcher mutant mouse are not significantly different morphologically to those grown from the wild-type. The fine structure of the P-cells in both genotypes *in vitro* are different from the cells seen *in vivo*. In the cultures we have found a range of synaptic profiles, both typical of those seen *in vivo* and abnormal structures unique to the culture environment. Quantitative analysis of Calbindin-D immunoreactivity indicates there is no significant difference in P-cell numbers in Lurcher and wild-type cultures (10-25 DIV). We are continuing this study with a quantitative analysis of the growth of the P-cell neurites in cultures of Lurcher and wild-type cerebellar cortex. (Supported by The Wellcome Trust).

TETRAHYDROAMINOACRIDINE HAS A LONG-TERM NEUROSURVIVING EFFECT ON CULTURED CEREBELLAR GRANULE CELLS. R. Ishitani, K. Sunaga, M. Kimura and D.-M. Chuang^{*}. 1) Group on Cellular Neuropharmacology, Josai Univ., Sakado, saitama 350-02, Japan. 2) Section on Molecular Neurobiology, BPB, NIMH, Bethesda, MD 20892, U.S.A.

The long-term neurosurviving effect of 9-amino-1,2,3,4-tetrahydroacridine (THA), a putative antidementia agent, was studied in cultured granule cells. Dissociated cerebellar granule cells from 8-day-old Sprague-Dawley rats were grown in BME medium, containing 10% fetal calf serum and 25 mM KCl. Without repeated glucose supplement these neurons died between 15 and 18 days later in culture. Ultrastructural changes included disruption of neurites, followed by cell body degeneration characterized by dilation of the rough endoplasmic reticulum and the condensed margined chromatin (pyknosis). By contrast, no primary alterations of mitochondria or lysosomes were observed. The addition of THA (1 to 10 μ M) to cultures clearly prolonged these neuronal survival, at least by 2 days *in vitro*. This long-term neurosurviving effect was reproduced by using cycloheximide or actinomycin D, but not carbachol, 4-aminopyridine, NMDA or leupeptin. Furthermore, SDS-PAGE analysis indicated that certain minor proteins were reduced by THA. These data suggest that THA maintains neuronal survival by suppressing an endogenous, active death program.

INTRACELLULAR CALCIUM AS SECOND MESSENGER IN MATURE CEREBELLAR GRANULE CELLS UNDERGOING APOPTOSIS. C. Galli, Q. Meucci, A. Scorziello, S. Schinelli*, G. Schettini. Ist. Neurobiologia, CNR, Roma; Dip. Farmacol., Fac. di Medicina, Università di Napoli Federico II, Ist. Farmacol., Fac. Farmacia, Università di Pavia. ITALY.

We have investigated the role of the intracellular calcium concentration, $[Ca^{2+}]_i$, in apoptosis in mature cerebellar granule neurons. Apoptosis was induced by lowering the extracellular potassium concentration from standard 25mM to 5mM. In healthy mature neurons cultured in 25 mM KCl the $[Ca^{2+}]_i$, measured by fura-2 fluorescence imaging, is 143 ± 22 nM. Upon downshifting the extracellular potassium concentration to 5mM KCl the $[Ca^{2+}]_i$, immediately decreased to 68 ± 11 nM. The time course of apoptosis was evaluated by intact nuclei counts and DNA fragmentation and subsequently correlated to measurements of $[Ca^{2+}]_i$. Levels of $[Ca^{2+}]_i$ remained low throughout the entire process. Depolarizing potassium rescues neurons previously kept in 5mM KCl and this effect was related to the restoration of high level of $[Ca^{2+}]_i$. Agents able to inhibit the apoptotic process (forskolin and IGF-1) were investigated in order to establish a possible involvement of $[Ca^{2+}]_i$, in their neuronal survival promoting activity. 10 μ M forskolin was able to counteract the decrease of $[Ca^{2+}]_i$; observed downshifting to 5mM KCl. The effect of forskolin was inhibited by 1 μ M KTS720, a specific protein kinase A inhibitor, showing that activated-protein kinase A is able to maintain elevated $[Ca^{2+}]_i$ levels, despite non-depolarising conditions. Contrary to forskolin, IGF-1 had no effect on the $[Ca^{2+}]_i$ in KCl deprived neurons. In fact, albeit their low $[Ca^{2+}]_i$, IGF-1 treated neurons were perfectly viable. These data support the notion of sustained $[Ca^{2+}]_i$ as a key component in the survival promoting action of forskolin and depolarising KCl and, on the other hand, show that IGF-1 bypasses this step, acting probably downstream the increase of intracellular Ca^{2+} .

PROTEIN-TYROSINE PHOSPHORYLATION AS A TARGET OF SUSTAINED LEVELS OF CYTOPLASMIC CALCIUM IN DIFFERENTIATING PC12 CELLS AND CEREBELLAR GRANULE CELLS. T. Koike* and S. Tanaka. Department of Natural Science, Saga Medical School, Saga 849, Japan.

There is ample evidence suggesting that membrane depolarization with elevated K^+ promotes neuronal survival *in vitro*. We have previously shown that neuronal survival under depolarizing conditions is well correlated with sustained levels of cytoplasmic free calcium in sympathetic neurons and cerebellar granule cells (Koike and Tanaka, *BBA*, 88:3892, 1991 etc). Data available so far (Tanaka and Koike, *BBA*, 1175:114, 1992 etc) indicate that elevated K^+ may act through the post-translational modification. In an attempt to identify a possible down-stream target of the death-preventing effect of elevated K^+ , we are utilizing differentiating PC12 cells that undergo neuronal death after withdrawal of NGF (Koike, *Prog. Neuro-Psychopharmacol. & Biol. Psychiat.*, 16:95, 1992). Immunoblotting with anti-phosphotyrosine antibody revealed that membrane depolarization stimulates tyrosine phosphorylation of p130 in a Ca^{2+} -dependent manner. The tyrosine phosphorylation of p130 was hampered when the cells were depolarized in the presence of herbimycin A, an inhibitor of tyrosine kinase activity. This drug also abolished the death-preventing effect of elevated K^+ in a dose-dependent manner ($IC_{50}=2\mu$ M) suggesting a correlation between the two. We also found that membrane depolarization stimulates tyrosine phosphorylation of a distinct set of proteins in cerebellar granule cells *in vitro*. These results suggest that protein-tyrosine phosphorylation is a common down-stream target of sustained levels of cytoplasmic free calcium under depolarizing conditions.

SURVIVAL OF SUBPLATE NEURONS IN CULTURES OF DEVELOPING NEOCORTEX. A. Hohn*, K.L. Allendoerfer, A. Torjan-Raymond, and C.J. Shatz. Dept. of Molecular and Cell Biology, U.C. Berkeley, CA 94720.

During mammalian cerebral cortical development, a transient population of early born neurons takes up a position underneath the forming cortical plate. These neurons, called subplate (SP) neurons, are essential for the formation of thalamocortical pathways, but by adulthood, most of these neurons have been eliminated by cell death. By studying SP neurons in culture, we examined the hypothesis that they might depend for survival on trophic support from their target cells in thalamus and superior colliculus or on incoming fibers from subcortical sources. SP neurons were labeled by injecting 3H -thymidine into ferrets at embryonic day 24 (E24), and survival was analyzed in three ways: 1) Cortices were analyzed for the presence of labeled SP neurons at ages from postnatal day 1 (P1) to 4 months, in order to establish a time course of SP cell death *in vivo*. Whereas little variation in the number of labeled cells was seen between P1 and P24, at 4 months few labeled cells could be detected. 2) Organotypic slice cultures from cortical tissue were prepared before the onset of SP neuron cell death and maintained throughout the period when cells die *in vivo*. In slices prepared at P1 and maintained in culture for 3 weeks, or in slices prepared at P15 and maintained for 7 weeks, large numbers of labeled SP neurons could be detected. Furthermore, neurons in the SP layer could be labeled with antibodies against neuropeptide Y, suggesting that at least some SP neurons maintain a normal phenotype in culture and are able to extend neurites into other cortical layers. 3) Fetal cortices were dissociated and cultured at E30, when SP neurons comprise about 50% of the neuronal population. The number of SP neurons, as measured by counts of 3H -thy+, MAP2+ cells, remained at high levels (55-70% survival) throughout the six days in culture. Taken together, these observations demonstrate that SP neurons are able to survive for extended lengths of time in culture, in the absence of their subcortical connections such as those to or from the thalamus. Thus, SP neuron survival may be regulated by local interactions within the cerebral wall. Supported by Swiss Natl. Found. (AH), EY02858 and the Alzheimer's Assn. (CJS).

REGULATION OF PROTEIN KINASE ACTIVITIES BY TAURINE AND β -ALANINE DURING EXCITOTOXICITY IN CAT AND MOUSE CEREBELLAR CULTURES. E. Trenkner, J.A. Sturmar* and D-J. Liu. NYS Institute for Basic Research, Staten Island, NY 10314.

Increased levels of protein kinase C (PKC) activity have been linked to excitotoxic cell death by demonstrating that PKC specific inhibitors prevent excitotoxicity. We have shown that glutamate induced excitotoxicity can be prevented by taurine in mice, while β -alanine rescues cerebellar cells in cat from taurine toxicity. This study suggests a mechanism for the preventive role of taurine and β -alanine respectively.

In mouse, which synthesizes taurine throughout life, glutamate ($10^{-3}M$) stimulates PKC activity up to 60% as compared to untreated cultures. In the presence of $10^{-2}M$ taurine, the glutamate induced PKC activity is down-regulated to untreated levels. β -Alanine had no effect on PKC activity in mice. Taurine alone had no significant effect on PKC activity. In contrast to mice, cat, monkey and man acquire taurine mostly through diet. We have shown that taurine is toxic in cat cerebellar cultures, whereas β -alanine promotes survival, suggesting a different mechanism. When treated with NMDA ($10^{-3}M$) PKC activity was raised by 35%, similar to that induced by β -alanine ($10^{-2}M$) alone; taurine had no significant effect. When added together NMDA-induced PKC activity was reduced, suggesting that β -alanine mimics the role of taurine in cats. We suggest that the rescue mechanism of taurine or β -alanine is based on the down regulation of glutamate induced PKC activity. NMDA RECEPTOR ANTAGONISTS AND ANTIBODIES AGAINST A NEURITE OUTGROWTH DOMAIN OF THE B2 CHAIN OF LAMININ ENABLE NEURITE OUTGROWTH OF THE WEAVER GRANULE NEURONS ON A LAMININ SUBSTRATUM. P. Liesi*, Department of Anatomy, University of Helsinki, Finland and Laboratory of Molecular and Cellular Neurobiology, NIAAA, NIH, Rockville, MD 20852.

Neurite outgrowth of the granule neurons from normal mouse cerebellum is supported by substrate bound laminin and synthetic peptides derived from the neurite outgrowth domain of the B2 chain of laminin. In contrast, the migration deficient weaver granule neurons fail to send out neurites or move on a laminin substratum. As glutamate excitotoxicity has been suggested as a putative mechanism for neuronal death in all neurodegenerative models, I studied the interrelationship of the glutamate system and the laminin system *in vitro*. The cerebellar neurons of the weaver mutant mice or normal control litter mates were trypsinized and plated on a laminin substratum in a serum free medium. The cells were allowed to attach for one hour after which the culture medium was changed and 7 μ M of MK801 or 100 μ M of APV or 20 μ g/ml of Fab-fragments of antibodies to neurite outgrowth domain of the B2 chain of laminin were added into the culture medium. The cells were cultivated for 24 hrs, fixed, and stained for L1 antigen to allow identification of the granule cells. Quantitative analysis of the cultures showed that the weaver neurons were rescued in terms of their neurite outgrowth potential by NMDA receptor antagonists as well as the domain specific laminin antibodies. Their immunohistochemical and biochemical properties also normalized during the short cultivation period exposed to these agents. These results indicate that the glutamate system and laminin system are interrelated, and offers new ways of thinking regarding neurodegenerative disorders.

DYING NEURONS IN DEVELOPING AND ADULT CEREBRAL CORTEX ARE DETECTED WITH IgG-SPECIFIC ANTIBODIES.

J.A. Dunn¹, J.D. Kirsch¹, J.R. Naeyege^{1,2} ¹Dept. of Biology, Wesleyan University, Middletown, CT 06459 and ²Child Study Center, Yale University School of Medicine, New Haven, CT 06473

Subplate neurons of the mammalian cerebral cortex die perinatally. During this period, they express a variety of proteins also contained in the surviving cortical plate neurons. In contrast, a 56 kDa cytosolic polypeptide identified by a monoclonal antibody SP1 (mAb SP1) is restricted to the subplate neurons (Naeyege et al. '91). Lesion studies, biochemistry, and immunocytochemistry were carried out to determine the identity of the SP1 antigen and its involvement in cell death. Lesions of adult cat cortex revealed the SP1 antigen in dying, but not healthy cortical cells. Biochemical analyses showed that the SP1 antigen is not limited to neurons but is also enriched in liver and serum. On Western blots, mAb SP1 recognized IgG purified from cat cortex and cat serum. Comparisons between mAb SP1 and a goat anti-cat IgG (Vector) demonstrated that mAb SP1 was specific for IgG heavy chains. Immunocytochemical staining of kitten cortex showed that both mAb SP1 and the IgG antiserum label only subplate neurons. Two distinct neuronal subsets were double-labeled. One, located deeper in the subplate, had small round somata. The other, located more superficially, had large, inverted pyramidal-shaped somata. Additionally, two-color immunofluorescent double-labeling studies demonstrated that cat IgGs and the SP1 antigen co-localize in the same subplate neurons, suggesting that they are the same molecules.

SHUNTING OF CYST(E)INE FROM PROTEIN SYNTHESIS TO GLUTATHIONE PROTECTS CORTICAL NEURONS FROM GLUTAMATE-INDUCED OXIDATIVE STRESS. R.R. Ratan, T.H. Murphy, and J.M. Baraban*. Department of Neuroscience, Johns Hopkins University, Sch. of Med., Baltimore, MD 21205.

Immature, embryonic rat cortical neurons are susceptible to glutamate neurotoxicity through a non-receptor mediated mechanism involving cystine transport inhibition, glutathione depletion and oxidative stress. We utilized this *in vitro* preparation and inhibitors of macromolecular synthesis to evaluate whether oxidative stress can activate a pathway of cell degeneration similar to growth factor deprivation. We found that glutamate-induced neuronal death is prevented by inhibitors of macromolecular synthesis. Protection is associated with enhanced availability of acid-soluble cyst(e)ine and restoration of cellular glutathione levels. N-acetylcysteine, an agent which delivers exogenous cysteine intracellularly and raises glutathione, is also protective; while buthionine sulfoximine, an inhibitor of glutathione synthesis, prevents protection by inhibitors of macromolecular synthesis. These results suggest that protection provided by these agents, in this paradigm, derives from shunting of the amino acid, cysteine, from global protein synthesis into the formation of the antioxidant, glutathione; and raise the possibility that oxidative stress may activate a pathway of cell degeneration similar to growth factor deprivation.

620.11

TOPOGRAPHICAL ORGANIZATION AND TIME COURSE OF LOSS OF RETROGRADE HRP LABELING OF CORTICOSPINAL NEURONS AFTER SPINAL CORD TRANSECTION. R.L. McBride*, P.I. D'Cruz, and E.R. Feringa. VA Medical Center and Department of Neurology, Medical College of Georgia, Augusta, GA 30910.

As indicated by the retrograde transport of HRP, axotomized rat corticospinal neurons progressively deteriorate after T-9 spinal cord transection. To understand why some neurons are affected more by axotomy than others (and thus may be less likely to regenerate if treated), we studied the organization of the temporal sequence of HRP labeling loss after cord transection. Complete T-9 cord transections were performed on 7-week-old female rats. An HRP pellet was placed at T-2, 3, 6 or 20 weeks after transection. Compared to controls [808 ± 38 (n=7)], the number of labeled corticospinal neurons in transected rats progressively decreased: 3 weeks, 592 ± 79 (n=9); 6 weeks, 459 ± 126 (n=7); 20 weeks, 348 ± 31 (n=7). Labeling loss in the cortical area representing the lower trunk and hindlimb began caudally and medially, and progressed laterally and rostrally. We conclude that labeling loss by corticospinal neurons is related to somatomotor cortex somatotopic organization.

ULTRASTRUCTURAL CHANGES IN SUPRAOPTIC NEURONS OF CHRONIC ALCOHOL-FED RATS. C. Ruela, N. Sousa, M.D. Madeira and M.M. Paula-Barbos*. Dept. of Anatomy, Porto Medical School, 4200 Porto, Portugal.

We demonstrated¹⁾ that the supraoptic nucleus (SON) of chronic alcohol-fed (A) and chronic dehydrated (D) rats were larger than that of controls (C). The volume increase of SON was mainly due to an increase in neuronal size, greater in (A) than in (D). By applying morphometric ultrastructural techniques we attempted to discern the underlying causes for the augment of the neuronal volume. Groups of six animals twelve month age were studied. The evaluations were carried out in 10 photomontages of SON neurons per animal and the following parameters were estimated: a) volume and surface densities of R.E.R. and Golgi apparatus and b) volume density of secretory granules. Based on these parameters and on the cytoplasmic volume, which was previously calculated by employing the nucleator, the absolute values of those organelles were calculated. An increase in the volume of all parameters was found in groups (A) and (D) when compared with (C), more marked in (A). We conclude that the larger size of SON neurons is dependent on an increase in the volume of the organelles related to peptide synthesis although in (A) it might also be related to changes in the neuronal transport mechanisms as demonstrated by the marked accumulation of secretory material.

AFFERENT INFLUENCES ON NEURON DEATH AND CELL BIRTH IN A FOREBRAIN MOTOR REGION THAT CONTROLS LEARNED VOCAL BEHAVIOR IN ZEBRA FINCHES. F. Johnson* and S.W. Botter. Dept. of Biology, University of Southern California, Los Angeles, CA 90089-2520.

We examined the ability of afferent input to influence the survival of neurons that form the descending motor pathway of forebrain song-control regions in the zebra finch brain. The robust nucleus of the archistriatum (RA) receives two afferent inputs (from the lateral magnocellular nucleus of the anterior neostriatum - IMAN, and from the higher vocal center - HVC) and RA projection neurons control the motoneurons that innervate the syrinx (vocal organ). Because the ingrowth of HVC input is delayed, IMAN provides the majority of afferent input to RA during early vocal learning. IMAN afferent input to RA is of particular interest since IMAN is necessary for vocal learning only during a restricted period of development. IMAN was electrolytically lesioned in birds of various ages to determine whether the survival of RA neurons depends on IMAN afferent input, and if so, whether such dependence varied as a function of the ingrowth of HVC afferent input (35 days of age), or the end of the period during which IMAN is necessary for vocal learning (60 days of age). Removal of IMAN afferent input induced widespread pyknosis and the loss of over 40% of RA neurons among 20 day-old birds that were in early stages of vocal learning. However, by 40 days of age, at which time HVC axons have elaborated terminal arbors within RA, IMAN lesions no longer induced neuron death in RA. These data indicate that many RA neurons require IMAN afferent input for their survival during early vocal learning, and that the ingrowth of axon terminals from HVC may provide an alternate source of afferent support in older birds. In 20 day-old birds, removal of IMAN afferent input also triggered a burst of intense mitosis in RA (1700 mitotic figures/mm³) at 2 days post-lesion. The early, acute nature of the mitotic events suggests that cell division in RA may be a specific response to the loss of IMAN afferent input.

DOES THE FLOOR PLATE INDUCE BASAL PLATE FORMATION? S. Hirano¹ and H. Tanaka². ¹Dept. Anatomy, Niigata Univ. Sch. Med., Niigata 951, JAPAN and ²Dept. Neuroscience & Immunology, Kumamoto Univ., Kumamoto 862, JAPAN

We have previously shown that motoneurons fail to develop when the neural tube is separated from the floor plate (Hirano et al., *Science* 251: 1991). However, the mechanisms which regulated motoneuron development have not yet been established. Two factors may influence motoneuron development: the neuroepithelial layer of the basal plate, which gives rise to the neuroblasts that form the ventral horn motoneurons, may fail to develop normally or the neuroblasts themselves die shortly after their formation. In order to evaluate these possibilities, the neural tubes of chick or quail embryos (HH stage 12-13) were incised along the lateral side of the floor plate at the level of the segmental plate. Embryos were then assayed for dorso-ventral differences in mitotic activity using BrdU and for cellular death using *in situ* labeling of DNA. Monoclonal antibodies DBM and VBM were used to identify the dorsal and ventral aspects of the neural tube, and SC1 and 23C10 to distinguish the motoneurons from non-motoneurons, respectively. In the floor plate-deprived half of the neural tube, the basement membrane expressed only DBM antigen, and neurons expressed only 23C10 antigen, indicating that both the ventral basement membrane and motoneurons failed to develop. BrdU analysis revealed no dorso-ventral differences in mitotic activity which might have resulted if the neuroepithelial layer failed to develop normally. Moreover, there was no localized concentration of cells containing DNA fragments indicating that neuroblasts did not die after formation. These data suggest that the development of the basal plate, and the subsequent development of motoneurons, is induced by the floor plate.

620.14

DNA FRAGMENTATION IS ASSOCIATED TO NEURONAL DEATH IN THE DEVELOPING RAT SUPERIOR COLLICULUS Grazia Galli¹, Maddalena Fratelli¹ and Lucia Galli-Resta². ¹Istituto Ricerche Farmacologiche Mario Negri - Milano - Italy and ²Istituto di Neurofisiologia CNR - Pisa - Italy.

Cell death is a peculiar aspect of the development of the nervous system. While the developmental strategies regulating death of vertebrate neurons have been well studied *in vivo*, the biochemical mechanisms of cell death have been largely analysed in various *in vitro* models. Cell death, as it has been best characterized *in vitro*, occurs through a process, named apoptosis, which involves in most instances the degradation of cellular DNA to discrete oligonucleosomal fragments. We show here that this distinctive biochemical event is also associated to death of developing mammalian neurons *in vivo*. As a model we have analysed the developing rat superior colliculus where naturally occurring cell death can be substantially increased by retinal afferent removal. After eye enucleation we dissected away the superior colliculus of postnatal rats and extracted DNA. Southern hybridization with labelled total DNA indicates the presence of a ladder of DNA fragments typical of apoptosis.

ACTIVATION OF COMPLEMENT AND UPREGULATION OF SULFATED GLYCOPROTEIN (SGP)-2 mRNA IN THE HYPOGLOSSAL NUCLEUS FOLLOWING PERIPHERAL NERVE INJURY. M. Svensson* and H. Aldskogius. Department of Anatomy, Karolinska Institutet, Box 60400 S-104 01 Stockholm, Sweden

In a previous study we observed expression of complement factors C3, C3d, C4d and C3 mRNA as well as endogenous immunoglobulin G in the rat hypoglossal nucleus following hypoglossal nerve transection, suggesting that activation of the complement cascade had taken place in the vicinity of the axotomized motoneurons. The complement factor and IgG expressions were associated with reactive microglial cells indicating that these cells have a central role in complement activation as a local source of complement factors.

In the present study we have used *in situ* hybridization to examine the expression of sulfated glycoprotein (SGP-2) mRNA in axotomized hypoglossal neurons. SGP-2 is the rat analogue to human clusterin, a potential complement inhibitor. Low levels of SGP-2 mRNA were expressed in the intact hypoglossal neurons. After injury, there was a marked increase in this expression. The results lend further support to the hypothesis that the complement cascade is activated in the vicinity of axotomized neurons, which in turn may be protected by an upregulation of complement inhibitor(s). The balance between activation of complement and complement inhibitors might have an impact on the degenerative components of the axon reaction, and in particular the events leading to nerve cell death.

VITAL ASSAY FOR NEURONAL CELL DEATH IN ORGANOTYPIC CULTURES. Richard Adams¹*, Zoltán Molnár², Matthew Nesbit² and Colin Blakemore^{1,2} MRC Research Centre in Brain and Behaviour¹ and University Laboratory of Physiology², Parks Road, Oxford OX1 3PT, UK.

Cell death is an important feature of the development of the nervous system. We have been investigating methods of assaying cell mortality. Our aim was to find a vital assay that can be used to map patterns of cell death and to use this to follow natural events as well as the effects of experimental manipulations. Acridine orange is a vital dye that crosses the plasma membrane and stains the nucleus with a green emission on excitation with light of 488nm. Propidium iodide also binds to chromatin but differs from acridine orange in two respects: it cannot cross the plasma membrane at normal resting membrane potentials and it has a longer Stoke's shift, giving a red emission of light when excited by the blue 488nm laser line. Thus, a short staining of tissue with a mixture of these dyes produces green fluorescence in all cell nuclei with an additional red fluorescence of the nuclei of those cells that are at a depolarized potential – largely indicative of dead or dying neurons in culture. We use confocal microscopy to image the 3-D distribution of stained nuclei within organotypic cortical and thalamic cultures and thalamo-cortical co-cultures stained for 30-60 minutes with 10µg/ml of each of these dyes. The red and green emissions were separated and collected simultaneously by two photomultiplier channels and the two 3-D datasets were reconstructed into a two-colour projection.

In slices of P0 rat cortex kept in culture for several days we see occasional dead cells throughout the depth of the tissue but a predominance of such cells within the subplate and marginal zone - regions of transient cells known to be lost at this stage of development (Luskin and Shatz, 1985 J. Neurosci 5:1062). Second, we have compared the survival of thalamic neurons in slices of E16 and P2 thalamus cultured with and without cortex in the same dish. Preliminary results are consistent with the idea that the cortex provides a soluble trophic component that prolongs the survival of neurons within the slice of thalamus (Cunningham *et al.* 1987 Dev. Brain Res. 37:133).

AUGMENTED STRIATAL ACETYLCHOLINE (ACH) RELEASE FOLLOWING PERINATAL HYPOXIC-ISCHEMIC INJURY: AN *IN VIVO* MICRODIALYSIS STUDY. T. Oo, R.E.Burke. Dept of Neurology, Columbia University, NYC, NY, 10032.

We have previously shown that following hypoxic-ischemic (H-I) injury to the developing brain, there is an increase in both morphologic and biochemical pre-synaptic markers of striatal cholinergic neurons. There are increases in the density of neurons, choline acetyltransferase-positive neuropil, and ³H-hemicholinium binding. In addition, there is preservation of total and M1 muscarinic receptor binding. To explore the functional significance of these changes, we have measured the striatal release of ACH under basal and muscarinic-antagonist stimulated conditions using microdialysis *in vivo*. 7 day rat pups underwent unilateral carotid ligation and exposure to 8% O₂ for 3-3.5 hours. At 9-12 weeks of age rats received a stereotaxic implantation of a striatal guide cannula. After >48 hour recovery, microdialysis was performed for 6 hours under awake free-roaming conditions. In the 6 hour studies of basal ACH release rats with striatal H-I injury (N=8) were not significantly different from rats subjected to H-I showing no injury (N=10), sham-operated (N=5) or normal (N=7) controls. However, following stimulation of release by infusion of atropine (3 µM) there was a significantly higher induced release of ACH in the H-I injury group (859 ± 459 percent change; N=6) than in the non-injured H-I injury group (99 ± 23; N=24) or Sham controls (152 ± 58; N=7) (p < .01, ANOVA). A similar augmentation of induced release was observed with infusion of the M1 antagonist pirenzepine (30 µM): H-I injury 405 ± 155 (N=4); H-I no injury 74 ± 21 (N=29) (p < .01). We conclude that there is a functional increase in striatal ACH release under stimulated conditions following H-I injury. NS26836, UCP, PDF.

HYPERBARIC OXYGENATION INCREASES AROUSAL AND INDUCES BREATHING MOVEMENTS DURING NREM SLEEP IN THE FETAL LAMB < 135 DAYS GESTATION. M.H. Tiktinsky, S.U. Hasan**, B. Bishop*, F.C. Morin III, Dept. of Physiol. and Ped. SUNY-Buffalo, Buffalo, N.Y. 14214. U. of Calgary**, Calgary, AB, Canada T2N 4N1.

Fetal breathing movements (FBMs) occur 40% of the total time and almost exclusively during rapid eye movement sleep (REM). Oxygenation via lung distension increases the duration of fetal arousal and induces FBMs during non rapid eye movement sleep (NREM) in fetal lambs > 135 d gestation (ga). We studied the effect of O₂ without lung distension on behavioral states and FBMs. Seven fetal lambs (129-132 d ga) were chronically instrumented to record electrocorticogram, electro-oculogram, nuchal EMG, diaphragm EMG, and carotid arterial blood pressure, pH and gas tension to assess fetal behavioral states, FBMs, and cardiovascular status. Fetal arterial O₂ (PaO₂) was raised from 25 ± 1 to 46 ± 1 torr by mechanically ventilating the ewe with 100% O₂ at 3 ATA in a hyperbaric chamber. Hyperbaric oxygenation (HBO₂) increased the duration of fetal arousal and the occurrence of FBMs during arousal and NREM. The duration of arousal tripled from 13 ± 11 to 38 ± 12% of the total time. The mean longest period of arousal increased from 3 ± 5 to 18 ± 6 mins. The mean time from the start of HBO₂ to the onset of arousal was 8 ± 4 mins. The occurrence of FBMs increased from 37 ± 13 to 63 ± 30% of the total time. During arousal, the occurrence of FBMs tripled from 24 ± 23 to 72 ± 34% of the time. During NREM, FBMs occurred in 5 of 7 fetuses from 15 and 100% of NREM time. The mean longest episode of FBMs increased from 16 ± 6 to 49 ± 29 mins. We conclude that oxygenation without lung distension increases fetal arousal and FBMs, especially during arousal and NREM. In fetuses 129-132 d ga. The increase in PaO₂ at birth may contribute to the transition from placental to lung gas exchange.

FUNCTIONAL ASYMMETRY OF THE SPINAL CORD IN NORMAL CHILDREN AND AFTER BRAIN DAMAGE. M.S.Sivvaya*, A.M.Shelyakin, D.U.Pinchuk and O.V.Bogdanov. Pavlov Institute of Physiology, Russian Academy of Sciences, Institute of Experimental Medicine, St.Petersburg, 199034, Russia.

The goal of this study was to compare the excitability of the motoneurons. We have recorded the H- and M-responses of the muscle gastronemius and calculated the asymmetry coefficient in the three following groups: 1) in normal children (from 8 to 13 years of age, right-handed persons); 2) in children with spastic type cerebral palsy (CP) (right hemiplegia) before and after rehabilitation of motor functions; 3) in the adult. It was observed that the normal children have a functional asymmetry of the spinal cord. A decrease of excitability of the right muscle gastronemius as compared with the left one was found in this group of children. The asymmetry was found to disappear in the adult and was absent in children with CP. The application of the functional biofeedback method has led to the normalization of electrophysiological parameters (EEG, EMG) and has created the asymmetry of the spinal cord and brain. We suppose that the functional asymmetry of the spinal cord is one of the mechanism of the formation and development of the interhemisphere asymmetry.

621.4

DIFFERENTIATION OF MOTONEURON ELECTRICAL PROPERTIES IN ORGANOTYPIC CULTURE OF RAT SPINAL CORD. H. Xie and L. Ziskind-Conhaim*. Dept. of Physiology and Ctr. for Neuroscience, Univ. of Wisconsin, Madison WI, 53706.

To compare the pattern and time course of motoneuron differentiation *in vitro* to that *in vivo*, thin slices (300 µm) of embryonic spinal cords (E15-E16), with or without dorsal root ganglia, were placed on porous, collagen-coated membranes (Costar Co.) and incubated at 30°C for 3-8 weeks. The frequency of spontaneous synaptic activity significantly increased in organotypic culture, but the increase was not correlated with the presence of dorsal root ganglia. Furthermore, dorsal horn stimulation produced synaptic potentials in most motoneurons.

Intracellular recordings were used to determine the changes in motoneuron resting potential, input resistance, action potential threshold, action potential maximum rate of rise, and motoneuron repetitive firing. The electrical properties of E15-E16 motoneurons cultured for 3-4 weeks were similar to the properties of E18-E21 motoneurons in hemisectioned spinal cord. Motoneuron electrical properties change significantly at birth, but similar differentiation did not occur in culture.

Prolonged depolarization (300 ms) generates a train of action potentials in neonatal but not embryonic motoneurons. However, such depolarization generated a train of action potentials in 31% of cultured motoneurons. The development of repetitive firing was not correlated with the level of synaptic activity or the presence of dorsal root ganglia.

Our findings suggested that differentiation of motoneuron electrical properties was halted in culture, despite the significant increase in the level of spontaneous activity. Supported by RCDA (NS01314) and NS23808 to L. Z.-C.

621.5

CORTICORUBRAL AND CORTICOTHALAMIC PROJECTIONS FOLLOWING UNILATERAL FRONTAL CORTEX LESIONS IN FETAL CATS. P. Carlson-Kuhta*, L.D. Loopyjii and J.R. Villablanca. Mental Retardation Research Center, UCLA, Los Angeles, CA 90024.

We have shown (e.g., *Behav. Brain Res.* 19: 205-226, 1986) that behavioral recovery is greater in the cat when a cerebral hemispherectomy is sustained neonatally (N-HEMI) as compared to the same lesion sustained in adulthood (A-HEMI). Coexisting with the better behavioral outcome is a greater "reinnervation" of the red nucleus (n.) and thalamus in the N-HEMI than in A-HEMI cats (e.g., *Brain Res.* 453: 17-31, 1988). In the present study we sought to determine if a robust "reinnervation" would also be present in cats when a unilateral resection of the frontal neocortex occurred fetally. An unilateral frontal cortex lesion, including the cruciate sulcus and surrounding areas, was performed in 4 cats prenatally (E43-E55). Cats grew to adulthood and then received an injection of [³H]leucine-proline into the remaining sensorimotor cortex. Terminal field densities were estimated in the red n. and thalamus by computer, using video analysis software (Jandel Scientific). Bilateral corticorubral projections were found in the red n. of fetally lesioned cats. The average labeling amount for the red n. ipsilateral to the injection was 543 particles/mm² and the contralateral red n. was 66 particles/mm². Thus the contralateral red n. only had 12% as much label compared to the ipsilateral red n. By comparison, in control cats the red n. contralateral to the injection had particle counts of only 2% of the amount in the ipsilateral red n. (N = 4 cats). For the thalamus three areas were examined: 1) intralaminar nuclei, 2) ventrobasal complex, and 3) ventrolateral n. Initial analysis of the thalamic nuclei also suggests only a small amount of contralateral corticothalamic projections. Our preliminary results suggest that the "reinnervation" of the red nucleus and thalamus following a prenatally sustained, frontal-cortex lesion is less than has been reported for similar lesions in neonatal cats (*Dev. Brain Res.* 32: 15-30, 1987; *Neurosci. Res.* 12:122-139, 1991). Behaviorally, our fetal-lesioned cats showed less recovery (sparing) of function than neonatal cats (P8-P14) with the same lesion (*Soc. Neurosci. Abstr.* 17: 894, 1991) Grants USPHS HD-05958 and 04612.

NORADRENERGIC AND SEROTONERGIC PATHWAYS MAKE SPECIFIC CONTRIBUTIONS TO RECOVERY OF MOTOR FUNCTION AFTER NEONATAL SPINAL CORD LESIONS AND TRANSPLANTS B.S. Bregman*, H.N. Dai, D. Gao, E. Kunkel-Bagden. Dept. of Anatomy and Cell Biology, Georgetown University, Washington, D.C. 20007.

Transplants of fetal spinal cord tissue mediate recovery of locomotor function after spinal cord injury in newborn and adult rats. This recovery of function is dependent upon the anatomical integration of the transplant with the host spinal cord. In order to determine the mechanisms underlying transplant mediated recovery we have begun to examine the contribution of particular pathways to recovery. Rats received spinal cord lesions and transplants at birth, and recovery of locomotor function was assessed quantitatively. After development and recovery were complete rats received intracisternal 6-OHDA injections to remove the noradrenergic input to the transplants or 5,7 DHT injections to remove the serotonergic input to the transplants and the effects on locomotor function were again assessed. Quantitative analysis of locomotion indicates that 6-OHDA lesions results in loss of transplant mediated recovery in some, but not all, aspects of locomotor function. There were significant deficits in base of support, stride length and limb rotation. Individual limb responses (hopping) and accurate locomotion over grid runways were not altered. The consequences of removing 5-HT input differed from that observed after removing noradrenergic input. For example, there were no alterations in hindlimb rotation following loss of serotonergic input. These results suggest TP mediated recovery is not simply a generalized influence on the host spinal cord, rather, particular pathways make specific contributions to recovery of function. Supported by NIH NS 27054 and American Paralysis Association to BSB.

A COMPARISON OF THE TENSION TRANSDUCTION DEVICE AND GAIT ANALYSIS MODEL FOR NERVE INJURY AND REGENERATION. P.M. Santos, S.L. Williams, S.E. Seinko Thomas, B. Spyropoulos, H.R. Konrad*. Division of Otolaryngology, Southern Illinois University, Springfield, IL 62794

We have developed two animal models to study the function of the peroneal nerve and anterior tibialis muscle group. Presently the study of nerve regeneration is mostly limited to electrophysiological and histological techniques which lack direct measurement of nerve-muscle force and function. The models described herein utilize the anterior branch of the sciatic nerve, i.e. the peroneal nerve which primarily innervates the anterior tibialis muscle to dorsiflex the foot through the ankle.

The tension transduction device allows accurate force measurements of muscular contraction of dorsiflexion upon peroneal nerve surgical exposure and electrical stimulation. Within animal and between animal testing has revealed very low variability of testing (<2% difference for left/right force development for eight animals). The gait analysis model is designed after human gait studies relating to "drop foot" secondary to decreased function of the peroneal nerve-anterior tibialis muscle group. High speed frame videotaping of rat gait captures the increased ankle angle and other parameters. Data analysis demonstrated no significant left/right differences of gait parameters within non-injured nerves. Nerve crush injury resulted in obvious decreased function with both models. The ankle angle using gait analysis returned to normal by week five; however, force development using the tension transduction device demonstrated a persistent decrement of function two months after injury.

The tension transduction device is more sensitive than the gait analysis model but requires a surgical procedure thereby incurring a slight but reproducible decrement (7%) in nerve muscle force compared to the contralateral control with repeat testing.

DEVELOPMENT OF CORTICOSPINAL PROJECTIONS TO THE CERVICAL AND LUMBAR SPINAL CORDS OF THE RAT. D.L. O'Donoghue*, R.E. Small, D. McFeeters, S. Fuller, C.R.D. Poff and (+) D.R. Humphrey. Dept. of Anatomical Sci., Univ. of Oklahoma Health Sci. Center, Oklahoma City, OK, 73190; + Lab. of Neurophysiology, Emory Univ. Sch. of Med., Atlanta, GA, 30322.

The precise projection pattern in the corticospinal system serves as a substrate for the control of fine motor functions in most mammalian species. The current series of experiments were designed to test the specificity of the growing corticospinal projections at a time of apparent imprecision in the numbers of corticospinal cells. The collateralization of corticospinal axons were analyzed using multiple retrogradely transported dyes. These studies were intended to quantify branching of corticospinal axons early in development of the rodent tract. The number, distribution, and overlap of cells labeled from the cervical spinal cord (labeled with one dye) were compared with those projecting into the lumbar cord (labeled with a second dye). Roughly only 3.5% of the labeled corticospinal cells showed both dyes when the dyes were placed in a six day old animal. Thus, few cells, even at this early age, showed widely divergent axons. This early pattern is further refined into adulthood. These data indicate the early growth of the corticospinal tract shows a high degree of specificity even though the number of labeled cells is greatly increased. Grant support by the Presbyterian Health Foundation (DOD) & NIH-NS20146 (DRH).

621.8

PATTERNS OF EXPRESSION OF MYOSIN HEAVY CHAIN AND SARCOPLASMIC RETICULUM CA²⁺-ATPase ISOFORMS IN DEVELOPING CAT HINDLIMB MUSCLES G.A. Unguez*, R.J. Talmadge, D.J. Pierotti, R.R. Roy, and V.R. Edgerton. Dept. Physiological Science and Brain Research Inst., UCLA, LA, CA 90024.

Although the contractile and histochemical properties of muscle fiber types have been extensively investigated in the adult cat, there has been minimal characterization of the immunohistochemical properties of muscle fiber proteins to match the physiological properties during development. The present study provides an immunohistochemical analyses of soleus (Sol), medial gastrocnemius (MG) and tibialis anterior (TA) of fetal (E55 in utero), newborn (P1), 10- (P10), 15- (P15), 20- (P20), 30- (P30), 40-day (P40), and adult cats. Muscles were frozen in isopentane cooled in liquid nitrogen. Immunolabelling was performed on serial cryostat sections using monoclonal antibodies (mAbs) specific for fast and slow muscle isoforms for the Ca²⁺-ATPase of the sarcoplasmic reticulum (SR) and for embryonic/neonatal (emb/neo), slow, and subtypes of fast myosin heavy chains (MHCs). The mAbs against slow and fast SR labelled mutually exclusive populations of fibers in TA, MG, and Sol at all stages investigated. In contrast, the MHC mAbs demonstrated co-labelling of different isoforms in some fibers in each muscle at all, except adult, stages. The slow mAb labelled fibers exclusive to one population in the TA, Sol, and MG in the adult. The emb/neo mAb labelled all fibers until P10 when the label was lost only from those fibers labelled with the slow MHC and SR mAbs, but not labelled with fast MHC mAbs. A population of slow fibers appeared to reach an adult phenotype by P10 in Sol. Further, these early differentiated adult slow fibers had a larger cross-sectional area than those fibers co-labelled with the emb/neo mAb in each muscle from E55 to P30. In contrast, fibers labelled with fast MHC mAbs also labelled with emb/neo mAbs until P40. Thus, it appears that SR and MHC protein systems within individual fibers reached a differentiated state asynchronously and the adult MHC pattern of expression was established after P40 in the cat. Supported by NIH Grants NS-16333 and NIDR NRSA DE07212.

POSTNATAL DEVELOPMENT OF RAT CORTICOSPINAL MOTOR NEURONS: DETAILED QUANTITATIVE EVIDENCE FOR MASSIVE COLLATERAL ELIMINATION AND MINIMAL CELL DEATH S. Dale*, M. Oudega, S. Varon and T. Hagg

Dept of Biology, University of California San Diego, La Jolla, CA 92093.

The postnatal development of rat corticospinal motor neurons (CSMN) was studied using the sensitive neuronal tracer cholera toxin B subunit (CTB), injected into the upper cervical dorsal spinal cord on the first postnatal day (P0), P3, P10, P20 and at adulthood. CTB labeled neurons were visualized using immunocytochemistry and counted throughout the whole cortex. At P0, CSMN were found to an extent similar as that previously reported in P3 animals with other neuronal tracers. Between P0 and P3, the total number of labeled neurons increased by 24% to a maximum. At P10, the number of labeled CSMN had decreased to 60% of the number at P3. At P20, the number of CSMN had decreased to 52% and remained essentially constant throughout further development and adulthood. The number of labeled neurons in rats injected at P0 and analyzed at P20 was approximately 10% lower than the number in similarly injected littermates which were analyzed at P3, suggesting that only a small portion of the 'disappearing' CSMN die. Thus, the remaining 38% apparently undergo elimination of their spinal projection between P3 and P20. Detailed quantitative analysis of the CSMN distribution demonstrates that neuronal death occurs predominantly in the lateral cortex (parihinal and entorhinal cortex). The neurons whose spinal projection is "pruned" are localized throughout the cortex, but especially in the parietal and lateral cortex. Support: NINCDS grants NS-16349 and 27047.

621.11

DEVELOPMENT OF CYCLIC MOTILITY IN POSTNATAL RATS. M. Dyer* and C. R. Alml. Lab. of Develop. Neuropsychobiol., Wash. Univ. Sch. Med., St. Louis, MO 93110

Newborn and fetal rats display cyclic spontaneous movements (CSM) at 1 min periodicity. This study assessed the development of the CSM pattern from PN 1 to PN 40.

Rat pups were individually videotaped for 20 min, and movements of individual limbs were scored to computer. Time series for summed forelimb/hindlimb movements were analyzed with FFT.

Results show that on PN 1, forelimbs and hindlimbs exhibit CSM at a 1 min periodicity. At approximately PN 10, the predominant periodicity of CSM is 4 min, with no differences between forelimbs and hindlimbs. Most of these spectra also show the 1 min periodicity. This dual periodicity pattern of CSM does not change substantially with further development.

These results suggest that the fetal/neonatal CSM pattern with a 1 min periodicity continues postnatally, but becomes integrated into a 4 min periodicity that may represent a basic rest-activity cycle.

621.13

ALTERATIONS IN MOTONEURONAL α CGRP, GAP-43 AND ChAT mRNA LEVELS FOLLOWING MONONEUROPATHY PRODUCED BY FIXED DIAMETER NERVE "CONSTRICTION" IN THE RAT. C.E. Blanco*, T. Mosconi, L. Kruger and P. E. Micevich. Dept. of Anatomy & Cell Biology, Brain Research Institute, UCLA School of Medicine, Los Angeles, CA 90024-1763.

Mononeuropathy induced by cuffing the sciatic nerve with polyethylene tubing of fixed diameter results in degeneration of a large proportion of heavily myelinated axons distal to the sleeve. This suggests that the motor component of the sciatic nerve is damaged, and the procedure may result in muscle denervation (Mosconi and Kruger, Soc. Neurosci. Abstr., 18:289, '92). Behavioral observations suggest that motor function is maximally impaired within two weeks after nerve "constriction" and is noticeably recovered after four weeks. The purpose of this study was to determine whether the motoneuronal expression of specific mRNAs associated with axonal regeneration (growth associated protein 43; GAP-43), synaptic remodelling (α -calactinin gene-related peptide; α CGRP) and neuromuscular transmission (choline acetyltransferase; ChAT) were altered by acutely-induced mononeuropathy. Two weeks after slit polyethylene rings were placed on one sciatic nerve, animals were transcardially perfused under pentobarbital anesthesia. The lumbosacral spinal cords were removed and subsequently processed for GAP-43, α CGRP or ChAT *in situ* hybridization histochemistry using 35 S-labelled ribonucleic acid probes. GAP-43 and α CGRP mRNA levels were significantly greater in the retrodorsal lateral nucleus (RDLN; sciatic nerve motoneuron pool) of the lumbosacral spinal cord ipsilateral to the site of nerve reaction as compared to the contralateral RDLN. In contrast, ChAT mRNA levels were lower in the ipsilateral RDLN. These observations suggest that the molecular response of motoneurons to "constriction" mononeuropathy is similar to the alterations in mRNA expression during denervation-reinnervation of skeletal muscles. Supported by HD 7228, NS 9176 and NS 5685.

621.15

CORRELATED REORGANIZATION OF CERVICAL CORTICOSPINAL TERMINATIONS AND MOTONEURON DENDRITIC FIELDS DURING POSTNATAL DEVELOPMENT IN THE RAT. M.H.J.M. Curfs, A.A.H. Gribnau and P.J.W.C. Dederen (SPON: European Neuroscience Association). Dept. Anatomy and Embryology, University of Nijmegen, P.O. Box 9101, 6500 HB Nijmegen, The Netherlands.

In order to study the development of the corticospinal tract (CST) in relation to that of two motoneuron (MN) pools supplying extensor and flexor muscles in the distal forearm as described previously (Curfs et al., Development 117 (1993) 535-541), HRP gels were implanted in the sensorimotor cortex of Wistar rats varying in age from postnatal day 0 (P0) to P60. After 48 hr 30 μ m transverse sections were made of the spinal cord and reacted for HRP using an intensifying incubation method. Drawings of the labelling in the seventh and eighth cervical spinal segments were made being the segments in which the above mentioned MN pools are located.

A delay of 2 days was found between the arrival of the first labelled CST axons in the dorsal funiculus (P2) and their outgrowth into the adjacent gray matter (P4). More fibres are gradually added in an almost radially proceeding way until maximal number and extension is reached by P10. By then the entire gray and large parts of the white matter are covered by labelled CST axons. From P10 onwards the number of labelled fibres decreased and they even disappeared from particular areas such as the lateral part of the ventral and dorsal horn and large parts of the ventral and lateral white matter.

The main conclusion is that the postnatal development of the CST and the MNs in the rat is correlated: both show an overshoot in the first postnatal week, and from the second week onwards, when progressively more mature coordinated movements appear, axons and dendrites respectively are selectively eliminated.

621.12

MOTOR CORTICAL PLASTICITY IN AGED RATS THAT SUSTAINED UNILATERAL CORTICAL LESIONS AT BIRTH. G.L. Tillotson*, T.P. Hogan, E.J. Neafsey and A.J. Castro. Dept. of Neurology, Hines VA/Loyola and Dept. of Cell Biology, Neurobiology and Anatomy, Loyola University School of Medicine, Maywood, IL 60153.

This study was undertaken to examine the long term effects of neonatal cortical lesions on motor cortical organization. On postnatal day 1, animals sustained large right cortical lesions by aspiration under hypothermic anesthesia. Littermate controls received only hypothermic anesthesia. At 20-24 months of age, animals were anesthetized with ketamine hydrochloride (100mg/kg i.p. with supplemental doses given as needed) and the hair over the forelimbs and hindlimbs was clipped to permit better observations of evoked movements. Animals were placed on a heating pad in a stereotaxic frame, and the cisterna magna was opened to prevent cortical swelling. A craniotomy was made over the left frontal/parietal cortex, the dura removed and the exposed brain covered with saline. Using the method of intracortical microstimulation (ICMS), electrode penetrations were made in a systematic fashion throughout the motor cortex. Observed evoked movements were recorded with threshold currents (the lowest current reliably evoking the response). Following mapping, animals were overdosed with sodium pentobarbital and perfused with saline and buffered formalin. Brains were removed and cut on a cryostat for inspection of the cortical lesions.

Control animals showed no change in the motor map, indicating that normal aging does not affect the motor cortical efferent system when studied with ICMS. However, animals that sustained large neonatal cortical lesions showed reorganization with shifting of the motor map 2.5-3mm anteriorly, indicating cortical remodeling that is persistent into senescence. (Supported by NIH Grant NS 13230).

621.14

EARLY POSTNATAL ANTAGONISM WITH MK-801 EXTENDS THE SPARING OF FUNCTION EFFECT AFTER MIDTHORACIC SPINAL TRANSECTION. D.L. Maier* and D.J. Stelzner. Dept. of Anatomy & Cell Biology, SUNY Health Science Center, Syracuse, NY 13210.

Weber and Stelzner ('77) found that many hindlimb responses recover after complete midthoracic spinal transection (MTST) in neonatal rats (birth-12 days of age) that do not recover in 15 day-adult operates. Developmental events in the second postnatal (PN) week of life serve to limit plastic processes in the spinal cord. This critical period may be related to N-methyl-D-aspartate (NMDA) receptor-mediated remodeling and stabilization of synapses as descending inputs mature. We hypothesized that chronic blockade of the NMDA receptor during development would extend the sparing of function effect to older operates. Treatment with MK801 from PN day 7-17 significantly facilitated hindlimb recovery after MTST on PN day 18, compared to saline treated operates. The recovery response was characterized by postural and locomotor abilities, reflexivity and tonus, contact placing and coordinated stepping abilities. To determine if the MK801-mediated effect on recovery was due to a reduction in injury-induced ischemic damage to the spinal cord, animals received MK801 30 min prior to MTST on PN day 18. To determine if the MK801-mediated effect was due to manipulation of plasticity only during spinal cord maturation, older animals received MK801 from PN day 19-29 and received a MTST on PN day 30. In each case, recovery of function did not occur. Thus, sparing of function in MK801 treated MTST rats depends on chronic disruption of events during early PN development of the spinal cord that limit the adaptive capabilities of the spinal motor system. Supported by grant NS 14096 (DJS) and NRSA 1F32NS09235-01 (DLM).

DISCHARGE PATTERNS IN DEVELOPING HYPOGLOSSAL MOTONEURONS OF THE RAT. P. A. Nuñez-Abades*, G. Barrionuevo and W. E. Cameron. Departments of Behavioral Neuroscience and Psychiatry, University of Pittsburgh, PA 15260.

We have investigated time dependent changes in the discharge pattern of a population of brainstem motoneurons *in vitro* (n=74) during the first month of postnatal life. At birth, all ventromedial hypoglossal (genioglossal) motoneurons displayed an adaptation in their repetitive discharge; the number of adapting cells decreased during the first week of postnatal life to 27% giving rise to an almost exclusive (90%) non adapting cell type at ages older than 13 days. These changes in the discharge pattern were accompanied by changes in the shape of the action potential. Specifically, in the first postnatal week, there were significant decreases in the spike half-width and in the duration of the medium AHP (mAHP_{dur}), and a more rapid repolarization of the action potential. The spike half-width was positively correlated with the mAHP_{dur} (r=0.61, P<0.001) implying that broaden spikes permitted a greater influx of Ca²⁺ which, in turn, produced the prolonged mAHP_{dur} recorded at 1-2 days. Genioglossal motoneurons also showed a trend to increase their maximal frequency (highest discharge rate achieved prior to inactivation of the firing mechanism) from 25.5±10.1 Hz at 1-2 days to 42.2±19.7 at 19-30 days. This ability to discharge more rapidly was positively correlated (r=0.54, P<0.001) with a more rapid repolarization of the action potential. We propose that new channels shaping the action potential and the mAHP_{dur} and ultimately shaping the pattern of discharge are developed during the first week.

TARGET SPECIFIC GROWTH OF DOPAMINERGIC NEURONS IS ENHANCED BY STRIATAL-NIGRAL CO-GRAFTS IN AFRICAN GREEN MONKEYS.

J.R. Sladek, Jr.¹, S.K. Schilling¹, B.C. Blanchard¹, T.J. Collier², J.D. Elsworth³, J.R. Taylor³, R.H. Roth³, and D.E. Redmond, Jr.³. ¹Dept. of Neurosci., Chicago Med School, North Chicago, IL 60064, ²Dept. of Neurobiology and Anatomy, Univ. of Rochester, Rochester, NY 14642, ³Depts. of Psychiat. and Pharm., Yale Univ. Sch. of Med., New Haven, CT 06510.

We examined the ability of embryonic striatum to enhance survival and growth of dopaminergic (DA) neurons co-grafted into the striatum of adult monkeys. Earlier experiments in rats resulted in enhanced fiber outgrowth from grafted DA neurons and more rapid improvement in agonist-induced rotational behavior (Yurek et al., Exp. Neur. 109:191, 1990). Grafts of embryonic striatum and ventral mesencephalon were implanted simultaneously into the left caudate nucleus, either juxtaposed (in caudate caudate), or separated by at least 2mm (in rostral caudate); single grafts of only ventral mesencephalon were placed into two sites in the contralateral caudate as controls for DA cell survival and fiber outgrowth. Grafts were placed into seven adult, male, monkeys that previously received MPTP, were DA-depleted, but were asymptomatic. Brains were examined for tyrosine hydroxylase (TH) immunohistochemistry and DA and HVA levels six months after grafting. Grafts contained large numbers of well developed DA neurons that ranged from 3000 to 22,000 per host (mean of 11,000). Fibers from grafted DA neurons grew preferentially toward and into the striatal graft. Striatal grafts contained dense patterns of TH fibers that either filled the striatal graft neuropil or formed "patches." DA levels were markedly increased in the vicinity of the grafts. Striatal grafts that were placed at a distance to nigral grafts appeared to receive TH fibers from the host brain; nigral grafts also appeared to be the source of TH fibers that coursed toward the striatal grafts from contralateral nigral grafts. This study suggests that maximal DA cell survival and target-specific neurite outgrowth occur when mesencephalic grafts are placed in a position to benefit from putative target-derived trophic factor(s) and that striatal grafts can stimulate a regenerative response by the partially depleted nigrostriatal system. EFFECTS OF FRONTAL CORTICAL AND SUBSTANTIA NIGRA LESIONS ON GLIOSIS IN THE RODENT STRIATUM. H.E. Cannon-Spoor*, R. Helm, A.S. Herranz, M. Poltorak and W.J. Freed. Neuropsychiatry Branch, NIMH Neuroscience Center at St. Elizabeths, Washington, DC 20032.

We have previously shown that lesions of motor and somatosensory cortex induce astrogliosis in almost the entire striatum. The areas of increased gliosis do not correlate well with damage of the corticostriatal projections, since there is an additional intense periventricular gliosis ipsilateral to the lesions. In order to examine the effect of lesion location, we studied GFAP immunoreactivity in the striatum of the mouse brain after lesions of the medial (cingulate) cortex and lateral (motor and somato-sensory) cortex, after 3 and 12 weeks of survival, and compared it to the immunoreactivity in non-lesioned controls. Numbers of GFAP+ astrocytes were significantly increased in the entire striatum after both medial and lateral lesions at 3 weeks, but remained increased in only the dorso-lateral striatum after 12 weeks. Periventricular gliosis was also found after both medial and lateral lesions, but disappeared by 3 months. To determine the influence of the nigrostriatal pathway on gliosis after cortical lesions we also studied rats with unilateral damage to the substantia nigra (SN). Animals received either small or very large lesions of the frontal cortex. In both groups, dorso-medial striatal gliosis was evident and the striatal localization of increased GFAP+ immunoreactivity did not differ from mice with cortical lesions alone. The results indicate that the periventricular dorso-medial striatum tends to preferentially develop gliosis after cortical lesions, and may be relatively sensitive to disturbances in corticostriatal circuits.

NEURONS IN THE MEDIAL SEPTAL NUCLEUS (MS) ARE CAPABLE OF RESTORING THEIR TRANSMITTER SYNTHESIS AFTER FIMBRIA-FORNIX TRANSECTION

T. Naumann*, P. Kermer and M. Frotscher. Institute of Anatomy, University of Freiburg, D-7800 Freiburg, Germany.

Most MS neurons lose their capability to synthesize transmitter-related enzymes after fimbria-fornix transection (ff-t). We recently showed that identified septohippocampal neurons survived axotomy for up to 10 weeks and displayed fine-structural characteristics of controls. However, the fate and functional role of these neurons remained unclear.

A total of 35 adult Sprague-Dawley rats received a bilateral ff-t. In 10 animals MS projection neurons were pre-labeled with Fluoro-Gold (FG) 1 week prior to axotomy by intrahippocampal injections. After various survival times these animals as well as age-matched control rats were processed for choline acetyltransferase (ChAT) immunocytochemistry. The completeness of the bilateral lesions was controlled by acetylcholinesterase staining of both hippocampi.

Three weeks post lesion only 18.8% of ChAT-positive neurons in controls were counted. Six months after axotomy this value increased nearly 3-fold to 51%. A fine-structural analysis of backlabeled, axotomized ChAT-positive neurons showed that most of them contained FG resulting from retrograde transport before ff-t. We conclude that many neurons in the MS have the capacity to restore their transmitter synthesis after long survival times. This long-lasting process could not be detected at 10 weeks post lesion where ChAT-positive neurons were still reduced to 22% of controls. (Supported by the DFG: Leibniz Program and Fr 620/4-1)

SPROUTING OF HOST DOPAMINE FIBERS IN RESPONSE TO GRAFTS OF EMBRYONIC STRIATUM IN ADULT AFRICAN GREEN MONKEYS.

R.T. Wechsler¹, J.R. Sladek, Jr.¹, B.C. Blanchard¹, T.J. Collier², J.D. Elsworth³, J.R. Taylor³, R.H. Roth³, and D.E. Redmond, Jr.³. ¹Dept. of Neurosci., Chicago Med Sch., N. Chicago, IL 60064, ²Dept. of Neurobiol. & Anat., Univ. of Rochester, Rochester, NY 14642, ³Depts. of Psychiat. and Pharm., Yale Univ. Sch. of Med., New Haven, CT. 06510

We are examining the ability of embryonic striatum to influence growth from host DA systems by intrastriatal implantation into partially DA-depleted animals in an effort to understand the potential for this approach to repair and protect against neurotoxin degeneration. Ten male monkeys received multiple implants of embryonic striatum from one of several embryonic stages ranging from E41 to E59. Brains were analyzed immunohistochemically for TH-positive neurons and fibers six months after transplantation. Concurrent analysis of DA and HVA was performed. Striatal origin of grafts was verified by dual staining for choline acetyltransferase (ChAT) and TH. Eight animals received grafts within the caudate nucleus; two received grafts within the putamen. Dense DA fiber staining was seen within these grafts. In some instances, it appeared in the form of patches; in others it appeared to completely fill the striatal graft. The source of this DA pattern for caudate grafts is most likely from nigrostriatal fibers. Additionally, a putamen graft received fibers from the basal forebrain. ChAT-positive neurons occurred within the grafts in a density comparable to normal striatum and gave origin to patterns of neurites that overlapped with DA-rich areas. This study suggests that the embryonic striatum may possess a strong trophic influence on DA neurons that can result in regenerative sprouting either from partially damaged DA neurons or collateral sprouting from unaffected DA neurons. The partially DA-depleted animal model used here, represents a useful system for comparison to the early stages of Parkinson's disease at which time repair and/or protection of the DA systems may be possible through the use of a specific trophic factor delivered through an intrastriatal graft of embryonic striatum. Supported by PO1-NS24032, RSA MH00643 to DER and the Axion Research Foundation.

A transgenic model of dopaminergic synaptogenesis using the thymidine kinase obliteration technique to ablate melanotopes of the mouse pituitary. Richard G. Allen*, Charles Carey, Joel D. Parker, Marty T. Mortrud, and Malcolm J. Low. The Oregon Health Sciences University, Portland, OR 97201

We produced 3 founder lines of transgenic mice harboring a fusion gene composed of the pituitary-specific promoter of the pre-pro-opiomelanocortin gene, driving the herpes simplex viral-1 thymidine kinase. Treatment of these mice with 70 mg ganciclovir/kg body weight (i.p., twice daily for 10-12 days) results in >99% ablation of the pituitary intermediate lobe (IL), a major target for dopaminergic fibers emanating from the hypothalamus. The extent of ablation was determined by immunocytochemistry (ICC) and RIA and was >85% effective between days 3-6 of treatment. Initial ICC indicated that corticotropes are also substantially reduced. ICC staining for tyrosine hydroxylase shows the presence of dense, bundled catecholamine nerve fibers in the vicinity of the ablated IL, compared to diffuse, punctate staining seen in the normal IL. The ablation of the dopamine target cell group, the IL melanotopes, suggests to us the usefulness of this model for the study of neuroendocrine plasticity and synaptogenesis. It has been demonstrated that dopaminergic nerve endings regenerate in the IL within 4 weeks of 6-OH-dopamine destruction, L.C. Saland et al. 1991. By ablating the IL during postnatal catecholamine innervation of the IL, and by ablating the IL in adult mice, we can determine the requirements for growth and/or regeneration of the terminals for their target IL cells. In summary, we have developed three lines of transgenic mice which can serve as models of neuroendocrine plasticity and dopamine synaptogenesis. This work was supported by NSF grant BNS9108426 to RGA.

CELL ADHESION AND EXTRACELLULAR MATRIX MOLECULES ASSOCIATED WITH REGENERATING CNS AXONS AND SCHWANN CELLS OF PERIPHERAL NERVE GRAFTS IMPLANTED IN ADULT RAT THALAMUS. Yi Zhang, G. Campbell*, P.N. Anderson, A.R. Lieberman, R. Martin* and M. Schachner*. Dept of Anatomy, Univ Coll London, *Dept of Neurobiol., Swiss Fed Inst Tech Zürich.

In order to gain insight into the possible molecular mechanisms underlying axonal regeneration of CNS neurons, we have investigated the localization of the neurite outgrowth-promoting cell surface molecules L1, N-CAM, its highly sialylated form E-N-CAM and of the neurite outgrowth-promoting extracellular matrix component tenascin in peripheral nerve grafts implanted into the thalamus of adult SD rats. After 1-13 wk, sections were processed for EM immunocytochemistry using a monoclonal antibody against E-N-CAM and polyclonal antibodies against N-CAM, L1 and tenascin. In normal adult rat thalamus, some nonmyelinated axons were N-CAM+ and L1+ but E-N-CAM- and tenascin-. Between 1 and 10 wk after graft insertion, sprout-like regenerating CNS axons in both the brain adjacent to the graft and in the graft were strongly labelled for N-CAM, E-N-CAM and L1. L1 and N-CAM were also found on Schwann cell (SC) surfaces where they were apposed to other SCs, but not on the surface abutting the basal lamina. Tenascin was found at the surface of SCs abutting the basal lamina but not deep within the columns in the absence of axons. In contrast to regenerating PNS axons which frequently lie between SC basal laminae and SC surfaces and are often tenascin-, CNS axons in the grafts were predominantly clustered in the L1+ and N-CAM+ regions at the centre of SC columns and were tenascin+. A few tenascin+ sprouts were identified in the thalamus adjacent to grafts at 2 wk post operation and their numbers increased at 8-13 wk. These results show that regenerating CNS axons express both L1 and N-CAM, which are known to promote neurite extension on SC surfaces *in vitro*. Furthermore, these axons were also immunoreactive for E-N-CAM and tenascin, suggesting that these molecules may play a role in interactions with neighbouring cells.

MOLECULAR CHANGES IN PURKINJE CELLS (PC) AND DEEP CEREBELLAR NUCLEI (DCN) NEURONS AFTER LESION OR INSERTION OF A PERIPHERAL NERVE GRAFT INTO THE ADULT RAT CEREBELLUM. E. Yaudano^{1,2,*}, C. Woolhead¹, P.N. Anderson¹, A.R. Lieberman¹ and S.P. Hunt². ¹Dept. of Anatomy, University College London, London, WC1E 6BT, and ²Div. Neurobiology MRC LMB, CB2 2QH, Cambridge, UK.

Adult rat DCN neurons can regenerate their axons along a peripheral nerve (PN) graft implanted into the cerebellum, while the PC of cerebellar cortex appear not to be able to do so. To find out if such dichotomy might be correlated with differences in the molecular response of DCN neurons and PC to injury or to the presence of a PN graft, a segment of autologous sciatic nerve was implanted in the cerebellum of adult rats deeply anaesthetized with halothane, and after 7-28 days survival the immunohistochemically detectable levels of the product of the immediate early gene *c-jun*, of the growth associated protein GAP-43, of phosphorylated neurofilaments (NF) and of the low affinity NGF receptor (NGFr) as well as the expression of GAP-43 mRNA as shown by *in situ* hybridization, were compared in these two types of neuron. In another group of animals a simple stab wound was made in the cerebellum and the animals were examined at 7 days survival. Neurons immunopositive for *c-jun*, and expressing GAP-43 mRNA, were found in the DCN ipsilateral to a lesion/graft in all cases examined, while neurons immunopositive for NF and GAP-43 were found in the DCN after simple lesion but not after PN graft. In all cases the DCN neurons were immunonegative for NGFr. PCs adjacent to a lesion/graft had increased immunoreactivity for the NGFr, but were always found negative for the other molecules investigated. Thus injured DCN neurons, which have the established capacity to regenerate their axons along a PN graft, show a prolonged expression of *c-jun* and have high levels of GAP-43, as has been described for regenerating peripheral neurons. In contrast cerebellar PCs seem not to be able to mount such a response and this might be an important factor in their failure to regenerate axons into PN grafts.

INGROWTH OF SEROTONERGIC AXONS INTO INAPPROPRIATE TARGETS ARISES FROM AXON COLLATERALS. H. Bernstein-Goral*, P. Diener-Ostfield, M. M. McAtee, and B. S. Bregman. Georgetown University School of Medicine, Washington, DC 20007.

Axotomized raphe-spinal neurons are capable of permanent regenerative axonal growth into and through fetal spinal cord (SC) transplants placed into the site of either a spinal cord hemisection or transection in the neonatal rat. If an inappropriate target such as fetal hippocampus (HC) is introduced into a neonatal hemisection, serotonergic (5HT) axons initially innervate the transplant, but are later withdrawn during development. After a neonatal transection, however, 5HT axons do not regenerate into an inappropriate target. The current study was designed to determine whether the transient ingrowth of 5HT axons into an inappropriate transplant arises from axonal sprouting of neurons which maintain collaterals to uninjured spinal cord targets. A retrogradely transported fluorescent tracer (FB or DiO) was injected into the transplant and a second tracer (DY or DiI) was injected in spinal cord caudal to the lesion site in 10 day old rat pups with a neonatal hemisection, plus either a fetal SC or HC transplant. Double labeled neurons were present in brain within the caudal raphe nuclei, red nucleus and sensorimotor cortex with a HC transplant at the site of the hemisection. Long distance growth of regenerating axons through a SC transplant was reflected by a large proportion of single labeled (DY or DiI) neurons in the axotomized raphe and RN. We suggest that 1) the transient serotonergic innervation of inappropriate targets arises from axon collaterals and 2) the requirements for axonal growth after injury differ for regenerating axons and sprouting axons. EVIDENCE THAT THE RETROGRADE TRANSPORT - NUCLEAR IMPORT PATHWAY CONVEYS AN INJURY SIGNAL AFTER AXOTOMY OF APLYSIA NEURONS. B. T. Ambron*, R. Schmied, and A. Osipov. Anatomy and Cell Biology, Columbia University, New York, NY 10032

A pathway in Aplysia neurons conveys proteins from the distal axon to the cell body and then into the nucleus. We believe this pathway communicates the needs of the axon periphery to the biosynthetic centers in the cell body. Transport through the axon is rapid and exclusively in the retrograde direction and access to the transport and import processes requires the same 7 amino acid signal peptide (sp). Using an affinity-purified antibody to the sp, we identified several endogenous sp-containing proteins, including 75, 83, and 110 kDa species that were present in both axoplasm and the nucleus, indicating that they use the pathway (Schmied et al. *J. Neurosci.* 1993).

One function of the pathway might be to convey a signal back to the nucleus after axonal injury. To test this idea, we crushed Aplysia peripheral nerves *in situ* and placed a ligation between the crush site and the cell soma. Other nerves were ligated only, as controls. 1-2 days later, axoplasm was extruded from the retrograde side of each ligation and equal amounts were subjected to SDS-PAGE. In 3 experiments, employing nerves from a total of 11 animals, Western blots showed that sp83 and sp97 were enriched in the axoplasm behind the ligation of crushed relative to non-crushed nerves; presumably both constituents would have been transported to the cell body and into the nucleus had the ligation not been present. In addition, the amount of sp97 was greatly diminished on the cell body side of the crush site. These results are consistent with a role for the transport/import pathway in conveying these proteins during regeneration. This can be tested by injecting these proteins into neurons in order to mimic the electrophysiological properties elicited by axotomy.

BANDS IN THE TRANSCOMMISSURAL OLIVOCEREBELLAR PROJECTION FOLLOWING UNILATERAL PEDUNCULOTOMY IN THE NEWBORN RAT ARE ALIGNED WITH ZEBRIN II-DEFINED PURKINJE CELL COMPARTMENTS. M. Zagrebelsky¹, F. Rossi¹, R. C. Hawkes² and P. Strata^{*1}. 1: Dept. of Human Anat. & Physiol., Univ. of Turin, Italy; 2: Dept. of Anatomy and Neuroscience Research Group, Univ. of Calgary, Canada.

Following the unilateral transection of the inferior cerebellar peduncle in neonatal rats, a process of transcommissural sprouting of the olivocerebellar projection is observed. Anterograde tracing of the surviving olivary axons, two months after the pedunculotomy, shows that the compensatory projection follows a parasagittal band pattern highly symmetrical with that seen in the not-denervated hemisphere. The anti-Zebrin II monoclonal antibody reveals a subset of Purkinje cells that are arranged into parasagittal compartments separated by similar bands of unlabelled cells. These compartments are related to the normal distribution of the olivocerebellar projection. In the present study we have combined PHA-L tracing and anti-Zebrin-II immunocytochemistry to determine if the alignment between climbing fibre stripes and Purkinje cell bands is maintained by the compensatory projection. Numerous PHA-L labelled olivocerebellar axons crossed the midline in the cerebellar white matter to terminate in the denervated hemiserebellum in distinct parasagittal climbing fibre stripes, symmetrical with those in the intact side. In both hemiserebella there was a strict correlation, up to the single cell level, between climbing fibre stripes and Purkinje cell compartments. These observations indicate that target specificity is maintained during the process of transcommissural sprouting. Therefore we conclude that transcommissural reinnervation in the neonate is not random, but rather is directed by specific cues.

622.10

FATE OF PROTEINS INJECTED INTO AXONS OF APLYSIA NEURONS: RETROGRADE TRANSPORT VERSUS UPTAKE INTO MULTIVESICULAR BODIES. R. Schmied*, X-P Zhang, and B.T. Ambron. Anatomy and Cell Biology, Columbia Univ., New York, NY 10032.

During axonal growth and remodeling, newly synthesized proteins arrive from the cell body while those that are obsolete must be removed. To identify factors that regulate the fate of proteins in axoplasm, we injected a variety of proteins into axons of neurons regenerating *in vitro*. The proteins either: 1) remained diffusely distributed at the injection site; 2) were retrogradely transported to the cell body; or 3) were taken up into organelles. Transported proteins included human serum albumin (HSA) coupled to a 7 amino acid signal peptide (sp). The sp is important, since HSA without sp was taken up into organelles, as was HSA coupled to another peptide similar to sp.

To identify organelles that take up the HSA, we injected 15 nm colloidal gold particles (Au), coated with either HSA or HSA-sp, into the axon. 1 hour after injection, the cells were fixed and examined by EM. Almost all of the HSA-Au (n=120) were inside organelles. 24% were inside multivesicular bodies (MVBs); organelles with similar morphology contained acid phosphatase. Other HSA-Au were in vesicles and large vacuoles. In contrast, 62% sp-HSA-Au (n=671) were associated with an amorphous, electron-dense material in axoplasm. Of the rest, 16% were inside vacuoles or vesicles, 10% were in MVBs, and 9% were on the surface of vesicles. These findings indicate that soluble proteins can be removed from axoplasm by lysosomal structures and that sp protects HSA from uptake, either by enabling it to gain access to the retrograde transport system, or by blocking a feature of HSA that makes it susceptible to uptake.

623.1

A GOLGI STUDY OF OLFACTORY BULB TRANSPLANTS IN THE RAT. M. D. Gooden¹, J. N. Kott¹, B. R. Fink^{3*}, L. E. Westrum^{1,2}. Depts. of Neurosurgery¹, Biol. Struct.², and Anesthesiol.³ Univ. of Washington, Seattle, WA 98195.

Studies in this laboratory have shown that olfactory bulb transplants (OBTXs) differ from normal OBs in regard to cellular architecture. In contrast to the distinct laminar organization found in normal OBs, OBTXs manifest a more disorganized composition. Cellular types tend to "cluster" together; glomeruli likewise seem to fuse, losing their distinct ovoid shape. In addition, the various cell types and glomeruli are found in aberrant places throughout the OB. Our study was undertaken to examine the atypical features of OBTXs, using variations of the rapid Golgi method. This procedure has the advantage of delineating whole-cell configurations in detail, thereby permitting a more definitive look at bulbar structure in terms of specific cell types, neuronal orientation, and glomerular composition. Golgi processing also allows comparisons between the overall architectures of OBTXs and normal OBs. Tritiated thymidine autoradiography is used in conjunction with Golgi processing in order to distinguish donor from host tissue. Donor OBs are taken from 14 day old rat fetuses and TX into 1 day old (unilaterally bulbectomized) rats of the same strain. At 8-12 weeks, the rats are anesthetized, sacrificed, and the brains processed by variations of the rapid Golgi method. Results demonstrate that all cell types [mitral, tufted, juxtglomerular (JG), granule and fusiform] are present in the TX. There is, however, a preponderance of fusiform cells as compared to normal OBs. Apical and basal dendritic processes of mitral cells are sometimes atypically oriented. Olfactory nerve axons frequently penetrate clusters of glomeruli after traveling in long, cable-like fascicles. Several cell types participate in the clustering, and their dendrites seem to contribute to glomerular structures. Results therefore suggest that, although all cell types are present in the TX, there are significant architectural differences between normal and TX OBs. (Supported by NIH Grant NS09678. 623.3

SYNAPTIC RECONNECTIVITY OF TRANSPLANTED OLFACTORY BULBS IN RATS. B. L. Goheen^{1*}, J. N. Kott¹, N. L. Anderson¹, and L. E. Westrum^{1,2}. Depts. of Neurosurgery,¹ Biol. Struct., Univ. of Washington, Seattle, WA 98195.

Previous studies suggest that transplanted olfactory bulbs (TX OBs) display reactivity between host olfactory nerve (ON) and donor TX OB at the behavioral and light microscopic levels. In this study TX OBs are examined with the electron microscope (EM) using immunolocalization with an antibody against olfactory marker protein (OMP)* enabling us to differentiate between host ON axon terminals and donor TX OB processes. Subjects are anesthetized and perfusion fixed with an aldehyde mixture, and the TX OB is dissected out and embedded directly in medcast/araldite without osmium fixation. Ultrathin sections of the tissue for EM are reacted for OMP which is subsequently conjugated to colloidal gold labeled secondary antibody for visualization. The sections are stained using osmium vapors, followed by uranyl acetate and lead citrate. ON fibers are OMP reactive, allowing us to visualize mature neurons from host innervating the TX OB. OMP positive axonal terminals establish synaptic contact with unlabeled donor processes, which correlates with the observed reinnervation in host animals. These findings suggest that host ON axons are able to innervate the TX OB and clearly demonstrates that synaptic connectivity is established between host ON and donor OB. (Supported by NIH Grants NS09678 and NS07144. LEW is a research affiliate of the CDMRC. *Anti-OMP kindly provided by Dr. Frank Margolis.)

EFFECTS OF AMPA LESIONS OF NBM AND SUBSEQUENT EMBRYONIC TRANSPLANTS ON CORTICAL SEROTONERGIC MECHANISMS IN RATS. F. A. Abdulla, M.-R. Calamini, M. A. Simmonds^{*}, J. D. Sinden and J. D. Stephenson, Institute of Psychiatry, Departments of Psychology and Neuroscience, Denmark Hill, London SE5 8AF and School of Pharmacy, Department of Pharmacology, Brunswick Sq, London WC1N 1AX, U.K.

The effects of destroying the cholinergic innervation to the cerebral cortex by unilateral 5-AMPA (2 injections of 0.5µl of 10 mM) lesions of nbm and of subsequent transplants to the cortex on the sensitivity of frontal cortex neurones to raphé nuclei stimulation (a 300 µA square wave for 5ms) and to 5HT applied iontophoretically (30 nA ejection current for 20s) were studied in anaesthetized rats. Responses were sought within 2s of raphé nuclei stimulation or during or within 20s of drug application and compared to baseline firing rates.

The percentage of frontal cortex neurones responding to raphé stimulation 8-10 weeks post-lesion, when AChE-positive fibres were almost completely absent from the area, was significantly reduced, 31/83 compared to 46/79 neurones ($\chi^2=7.07$, $P<0.05$, 5 rats in each case) while the percentage of neurones responding to 5-HT increased, 70/83 compared to 49/79 neurones ($\chi^2=10.33$, $P<0.005$). Six-8 weeks after cholinergic-rich transplants of basal forebrain (E-15) to the lesioned frontal cortex, when transplant-derived fibres were distributed to the recording area, sensitivity of frontal cortex neurones to raphé nuclei stimulation and to iontophoretic 5-HT was partly restored. Non-cholinergic transplants of hippocampus (E-17) to frontal cortex were ineffective. Sensitivity to glutamate was not affected by the procedures.

The observed changes in frontal cortex neurones sensitivity to raphé nuclei stimulation and to 5-HT applied iontophoretically could be due to functional changes in the serotonergic cortical input following nbm lesion and may account for dysfunction of the serotonergic system in aging and in Alzheimer's disease.

623.2

DIFFERENCES BETWEEN NERVE GROWTH FACTOR RECEPTOR (NGFR) AND PLATELET DERIVED GROWTH FACTOR B-CHAIN (PDGFB) EXPRESSION IN THE ENSHEATHING GLIA OF THE DEVELOPING AND TRANSPLANTED RAT OLFACTORY BULB. J. N. Kott^{1*}, B. L. Goheen¹, M. E. Lee², M. A. Bothwell³, L. E. Westrum^{1,2}. Depts. of Neurosurgery¹, Biol. Struct.², and Physiol. and Biophys.³ Univ. of Washington, Seattle, WA 98195.

Ensheathing cells (EC) are a glial subtype that is interposed between the peripheral and central nervous system (CNS) along the pathway of incoming axons of the olfactory receptor neurons. These neurons are replaced throughout life, and of necessity, the axons of newly generated ONs must pass from the periphery into the CNS. It has been hypothesized that it is some unique characteristic(s) of the ECs that enable(s) this re-penetration into the CNS. At least two growth associated molecules have been attributed to the layer of ECs surrounding the olfactory bulbs (OBs): 1) p75NGFR and 2) PDGFB*.

Using immunolocalization in adjacent paraffin sections, we are examining the distribution of these two molecules in developing and transplanted (TX) OBs. Such examinations suggest nearly separate sublayers within the overall EC layer. In the normal immature OB, PDGFB reactivity is common to most if not all components of the internal sublayer of ECs, while NGFR reactivity is more sparse, and restricted to the external sublayer. In the TX OB, NGFR reactivity appears to be limited to a small subpopulation of PDGFB reactive cells. These studies clearly demonstrate that the EC layer is not made up of a homogenous population of cells, but rather is separable on the basis of the two growth associated molecules. (Supported by NIH Grants NS09687, NS29582, and NS07144. LEW is an affiliate at the CDMRC.)

623.4

CROSS-STRAIN TRANSPLANTATION OF OLFACTORY BULBS IN RAT. M. E. Lee¹, J. N. Kott^{1,2}, L. E. Westrum¹, R. D. Lund¹. Depts. of Neurosurgery and Biol. Struct., Univ. of Washington, Seattle, WA 98195 USA; ³Dept. of Anatomy, Univ. of Cambridge, Cambridge, England CB2 3DY.

We have previously shown that olfactory bulb (OB) transplants (TXs) into rat hosts of the same strain survive, are reinnervated and become connected with host brain, whereas mouse OB TXs placed in rats are rejected. In an attempt to evaluate the usefulness of cross-strain TXs we are transplanting OBs from Long-Evans (LE) rat fetuses into Sprague-Dawley (SD) rat hosts of similar ages to our previous studies. Time-mated LE dams received injections of tritiated thymidine on embryonic days (E) 12-14. OBs from LE fetuses (E14-15) are immediately transplanted into newborn SD rats in the site from which the host OB was removed. At 2 weeks and later sagittal frozen sections of forebrain were stained for cells and fibers or immunoreacted for olfactory marker protein (OMP antibody kindly provided by Dr. Frank Margolis), the latter a label for mature primary olfactory nerve fibers. Autoradiography was carried out on alternate series of sections to identify and characterize the donor OB TX. The LE OB TXs occur in a high proportion of SD hosts, are attached to the olfactory peduncle and are robust, often near the size of the normal OB. The cytoarchitecture is somewhat disorganized as in SD only TXs, but autoradiography demonstrates large numbers of heavily labeled donor cells of various sizes. OMP material shows primary olfactory nerve fibers innervating the LE OB TX whereas the cell-fiber stains show continuity between the TX and the ventral forebrain. These results indicate that cross-strain transplantation in this system is successful and suggests that this model might hold promise for immunological manipulations, similar to but less problematic than cross-species TXs (xenografts). CORTICAL GRAFTED C6 RAT GLIOMA AND XENOGRAFTED FRESH HUMAN GLIOBLASTOMA CELLS EXPRESS GUANIDINO BENZOATE. W. J. Goldberg^{*} and J. J. Bernstein. Stroke & Trauma Lab. and Lab. of CNS Injury and Regeneration, Dept. Veterans Affairs Medical Center, Washington, DC 20422.

C6 rat glioma cells and fresh human glioblastoma cells grafted to rat cortex migrate throughout the host brain. C6 cells form large tumor masses in immunocompetent rats whereas fresh human glioblastoma cells do not. In the present experiments 10⁶ C6 cells were grafted as suspensions into freshly made implantation pockets in host rat cerebral cortex. In a second series of animals, suspensions of human malignant glioma cells were xenografted into athymic host cortex to test tumor mass formation. Animals were sacrificed at 1,3,5,7,14,21 and 30 days post-implantation. Using the fluorescent active-site probe 9-aminoacridine, paraffin sections were examined for the presence of the serine protease guanidinobenzoate (GBZ), which is associated with many metastasizing malignant tumors. Paraffin sections of the original human gliomas were also examined. A class of GBZ+ cells was observed in the original human gliomas and cultures of C6 rat glioma cells. Grafted cells retain the ability to express GBZ. Individual GBZ+ rat and human cells migrated on the glia limitans and parallel and intersecting nerve fiber fascicles of the corpus callosum. Large tumor masses containing GBZ+ cells formed in the implantation pocket. Secondary tumor foci containing GBZ+ cells formed around blood vessels. Supported by DVA and NIH, NCI, CA48956.

IMMUNOCYTOCHEMICAL EXPRESSION OF SOME METABOLIC MARKERS IN NEOCORTICAL TRANSPLANTS. J. Rosenstein and R. Walsh. Depts. of Anatomy and Neurosurgery, The George Washington University Medical Center, Washington, D.C. 20037.

By its nature transplantation defines a different developmental status for fetal tissue when it is divorced from its normal environmental cues. It is not yet understood if connectivity levels are a reflection of the biochemical nature of grafted neurons which may discourage appropriate contacts or conversely if the connectivity levels are indicative of neuronal metabolism. In order to determine potential metabolic maturity in neocortical grafts, a series ranging between 10 days and 15 months postoperative was examined for the immunocytochemical expression of neuron specific enolase (NSE) and the glucose transporter (GT). Anesthetized rats were perfused with 4% paraformaldehyde. NSE is a reliable marker for neuronal developmental and synaptic maturity and GT is a marker for barrier competent cerebral vessels. When compared to a normal developmental series where all neurons express NSE, at early times NSE in the grafted neurons was practically non-existent and at later times remained weak; at 15 months only a minority of grafted neurons which appeared normal by Nissl staining standards, had normal NSE expression. GT which is expressed on embryonic vessels, was repressed on graft vessels for up to 4 weeks following surgery but reached near normal levels at later times. These results demonstrate a reduced expression in two metabolic markers, NSE and GT, following neocortical grafting. The presumed metabolic reduction when compared to normal activity may be due to incomplete migration patterns, reduced connectivity or potential ischemia causing lowered protein synthesis. (NS-17468).

DO EMBRYONIC NEURAL GRAFTS INDUCE REPAIR BY THE INJURED JUVENILE NEOCORTEX?

J. Ourednik, W. Ourednik, H. Van der Loos & B. M. Riederer. Institute of Anatomy, University of Lausanne, 1005 Lausanne, Switzerland.

Pieces (0.02mm²) of presumptive neocortex from 14 day old mouse embryos were placed into freshly prepared cavities (2mm²) in the parietal cortex of 20 day old mice (n=21; one graft per cavity). The survival times of the hosts were 3 days (n=10) or 2 months (n=11), and for each group, sham-operated animals (cavities without graft, n=10 and 7, respectively) were prepared in parallel. The identification of graft and host tissue in mice with long-term survival was made possible by the choice of two mouse substrains (C57BL/16) which express two different allelic forms of the Thy-1 antigen and therefore are distinct in their immunohistochemical staining pattern. Moreover, ³H-thymidine (³H-T) was used to monitor cell division by injecting either host or donor.

At 3 days after operation, the graft, labeled with ³H-T prior to transfer, could be well distinguished from the host tissue as a compact mass of undifferentiated radioactively labeled (DNA synthesizing) cells, while ³H-T labeling of the host showed a significant number of radioactive cells in the tissue surrounding the grafted cavity. Haematoxylin staining revealed cells with mitotic figures in graft and host. When immuno-stained for cell type-specific markers, dividing graft and host cells were either positive for the glial marker GFAP or for the neuronal marker MAP2. At 2 months after operation, in 8 out of 11 grafted mice new and organized cortical tissue had taken the place of the cavity. In 6 of these animals, the grafted region contained, however, no cells positive for the donor-specific Thy-1 antigen, but the area was positive for the Thy-1 antigen of the host.

Our data suggest that the graft may induce some restorative mechanism within the injured cortical area and that cellular proliferation in the host may contribute to the final restoration of the grafted region in an unexpectedly important way. Support: Swiss NSF 31-30932.

NEGATIVE LONG-TERM EFFECTS OF INSULAR CORTEX GRAFTS ON LEARNING. M. L. Escobar*, C. E. Ormsby, N. Jiménez and F. Bermúdez-Rattoni. Instituto de Fisiología Celular, UNAM, México, D.F. 04510.

It has been shown that insular cortex (IC) grafts induce recovery on the ability to acquire learning tasks on previously IC lesioned animals at 60 days after graft. Moreover, we have demonstrated that cortical grafts with nerve growth factor accelerates recovery of the acquisition of learning abilities at 15 days post-implantation.

In the present work, we evaluated the long-term effects of IC-grafts, alone or combined with neurotrophic factors, on the ability to learn. Four groups of male Wistar rats received bilateral lesions in the IC and one group remained as an unoperated control. Ten days later, three of the lesioned groups received homotopic fetal IC grafts combined with either nerve growth factor (20µg/ml), epidermal growth factor (20µg/ml), or vehicle. The fourth group remained as a lesioned control. All groups were trained 130 days later in an inhibitory avoidance and Morris water maze tasks. We found that at 130 days after grafting the animals that received IC grafts with or without neurotrophic factors did not show recovery in the ability to learn both tasks, compared with control and lesioned animals. These results showed that rats with homotopic IC grafts, despite the presence of neurotrophic factors, failed to show behavioral recovery, after 130 days post-transplantation.

RELATIONSHIP BETWEEN β -ADRENERGIC RECEPTORS AND ANTIDEPRESSANT ACTIVITY OF MONOAMINERGIC NEURAL TRANSPLANTS IN THE RAT NEOCORTEX. D. Dougherty*, J.R. Unnerstall, C.E. Sortwell and J. Sagen. Dept. Anat. and Cell Biol., University of Illinois at Chicago, Chicago, IL 60612.

We have shown that the transplantation of monoaminergic tissue into the frontal neocortex of rats can reduce behavioral deficits in rodent depression models. Further, both α - and β -adrenergic antagonists not only reverse the effects of the transplants on the behavior but in fact exacerbate the deficit, suggesting changes in receptor sensitivity. Although our previous α_1 - and β -receptor binding studies showed no significant changes in the number of monoaminergic sites between transplant and control in the small area around the transplant, we decided to look for more widespread receptor changes. Therefore, this study investigates changes in β -receptor density in coronal sections of brain associated with the transplants using receptor autoradiography. Monoaminergic tissue (adrenal medulla, pineal gland or a combination of both) was transplanted into the frontal cortices of separate groups of rats. Striated muscle was transplanted for control in other groups. Another group was treated with imipramine daily for six weeks. All animals were tested for behavioral deficits using the forced swimming test six weeks post-transplantation. Significant reductions in immobility scores were obtained in imipramine treated animals and all three monoaminergic transplant groups, but not in control transplanted animals. Following testing, animals were decapitated and 10 µm coronal sections were taken through the transplant region. [¹²⁵I]iodopindolol (600 pM) was used as the ligand to investigate β binding sites. As previous receptor binding studies have shown, significant decreases in β -receptor binding following imipramine treatment were seen. In contrast, no such decreases were seen in any of the transplant groups. These results suggest that previously seen behavioral and pharmacological changes in the transplanted animals are not associated with large changes in β -receptor density. Supported by NIMH MH47491.

MORPHOMETRIC STUDY OF FETAL BRAIN TRANSPLANTS IN THE INSULAR CORTEX AND NGF EFFECTS ON NEURONAL DEVELOPMENT. S. Díaz-Cintra*, P. Rivas-Manzano, E. Pérez-Torrero, M. Escobar, L. Parra, Bermúdez-Rattoni F. and L. Cintra. Investigaciones Biomédicas, Fisiología Celular, y Facultad de Ciencias, UNAM., México D.F.

Twelve rats previously insular bilaterally cortex lesioned, received one of the three similar neural grafts, one with only insular fetal cortex (IC), other with IC, and NGF plus fetal DMEM, and third one, with IC and DMEM. The IC tissue was from fetuses of E16 and applied into the lesioned area. After 15 days of recovery, all animals underwent to silver techniques. The histological analysis showed well impregnated neurons, glial cells and mitotic figures in all grafts. Morphometric study was made, in a total of 175 cells arising from these groups, and analyzed using an imaging (BIOCOM) system. Results showed significant increase in the minor axis of neurons in the DMEM group. Astrocytes, had significant reductions in their minor axis in the DMEM and NGF groups and mitotic figures presented significant increases in number and mayor and minor axes in the NGF group. (Support DGAPA IN204689 and IN204892).

FATE SHIFTING OF CEREBELLAR PRECURSOR CELLS UPON TRANSPLANTATION INTO THE DEVELOPING DENTATE GYRUS. C. Vicario, M.G. Cunningham and R.D.G. McKay*. NIH, NINDS, Laboratory of Molecular Biology, Building 36, Room 3D02, Bethesda, MD 20892, USA.

The aim of this work was to ask if environmental factors might determinate the final fate of cerebellar precursor cells. Cell suspensions prepared from the cerebella of postnatal-day-2 (P-2) rat and mouse were stereotactically transplanted into the developing dentate gyrus of rat (P-2) or mouse (P-4). The implanted cells were distinguished by thymidine labelling or by the expression of a transgene, the lacZ gene under the control of a neuron-specific enolase promoter. Cryostat sections from grafted animals were stained for cell-type specific antigens, reacted with 5-Br-4-Cl-3-indolyl- β -galactoside (X-Gal) and processed for autoradiography. Cerebellar cells grafted into the dentate gyrus integrated into the granule cell layer expressing calbindin (CBP) and, during kainic acid-induced seizure activity, upregulated c-FOS proteins. Transplanted cells expressed glial fibrillary acidic protein (GFAP) when found in the hilar region and in the molecular layer of the dentate gyrus. These results indicate that there are cells in the developing cerebellum of rat and mouse which can give rise to hippocampal neurons and astrocytes in response to local signals. These observations suggest that there is an equivalent multipotential stem cell in different regions of the developing mammalian CNS.

TRANSPLANTATION OF NORMAL EMBRYONIC CEREBELLAR CELL SUSPENSIONS INTO THE CEREBELLUM OF LURCHER MUTANT MICE.

J.A. Heckroth* and M.H. Foster. Indiana University School of Medicine, Biomedical Research Institute, Terre Haute, IN, 47809.

Cerebellar cell suspensions of normal embryonic day 12 embryos were injected into the cerebellar parenchyma of *lurcher* mutant hosts of 10-12 days (n=8), 17-20 days (n=12), or 1-3 months (n=10) of age. Following a 1-2 month survival period the graft hosts were sacrificed, transcardially perfused, and their brains processed for immunohistochemistry using anti-CaBP (28 kilodalton vitamin D dependent calcium binding protein) serum provided by Dr. Anthony Norman (University of California, Riverside). Adult *lurcher* cerebella without grafts exhibit only a few isolated Purkinje cells. Successful grafts were visible as clusters of immunoreactive cells surrounding the transplantation site. Grafted Purkinje cells infiltrated all layers of the cerebellum, but exhibited a predilection for occupying the host molecular layer. Dendrites of grafted Purkinje cells which ramified within the molecular layer did not appear to adopt their characteristic planar morphology. In some cases immunoreactive axons were observed to connect the region of the graft with the host cerebellar nuclei. Grafts placed into the 17-20 day old hosts were occasionally very large with extensive innervation of the host nuclei by grafted neurons. Grafts in 10-12 day old hosts exhibited less extensive spread in the host cortex, but still displayed significant infiltration of the host molecular layer, and in some cases innervation of host cerebellar nuclei. Successful grafts in juvenile *lurcher* hosts may permit the trophic rescue of host neurons which would undergo retrograde transneuronal degeneration in the absence of transplanted target neurons. Supported by the National Ataxia Foundation, and by grant 5 S07 RR5371 awarded by the BRSG Program, Division of Research Resources, NIH.

SUCCESSFUL DEVELOPMENT OF MAMMALIAN EMBRYONIC EYE TRANSPLANTS WITHIN THE ANTERIOR CHAMBER. H. Klassen*, M. K. Klassen, N. Chaudhry, P. Liggett, C. Barnstable, Dept. of Ophthalmology, Yale Univ. Sch. of Med., New Haven, CT 06510

Retinal grafts can respond to photic stimuli in a phasic, intensity dependent manner and transmit this information to the host neural circuitry, resulting in a motor response. A major limitation of retinal grafts is the failure to maintain topography when innervating host visual centers. It is not known why retinotopy is lost in this model. Transplantation of isolated retina disrupts the normal relationship between adjacent tissues, as well as the normal semi-spherical retinal shape. Conversely, by preserving these relationships, grafted whole eyes might achieve a more accurate axonal projection pattern. The survival of such grafts is, however, less assured given the greater immunogenic load presented to the host. Furthermore, it has not been established that a complex organ, such as the eye, can develop from an early embryonic graft in mammals. Eyes were removed from Long Evans rats at embryonic day (E) 15-17 and transplanted to the anterior chamber of adult albino or pigmented rats. Similarly, embryonic eyes from both rat and rabbit (E14-18) were grafted to the anterior chamber of adult rabbits. After 14 days host eyes were fixed for histology. Grafted eyes survived without immunosuppression and were extensively vascularized by host vessels. The eye grafts exhibited a substantial degree of tissue differentiation, with distinct retinal laminae and a high degree of spherical geometry. Of particular interest was the intimate apposition of photoreceptors and RPE. Taken together, these results show that early embryonic eye can differentiate into a normal-appearing organ following transplantation. This finding has important functional implications and suggests that such grafts may be capable of extending topographic projections.

REINNERVATION OF TRANSPLANTED LANGERHANS' ISLETS IN LIVER AND UNDER THE KIDNEY CAPSULE. H. Houwing, R. van Asperen, P.T.R. van Suylichem, J.H. Strubbe, S.F. de Boer* and A.B. Steffens. Dept. of Animal Physiology and Dept. of Surgery, University of Groningen, The Netherlands.

In islets of Langerhans, cholinergic stimulation leads to an enhanced insulin release in the early phase of a meal. Noradrenergic stimulation inhibits insulin release during exercise. Former physiological studies indicated that a low meal-induced early insulin response and a clear exercise-induced reduction in insulin concentration was returned after islet transplantation in diabetic rats. We aimed to study whether islets, transplanted in the liver or under the kidney capsule, become reinnervated with both cholinergic and noradrenergic nerve fibers. Diabetic rats were provided with isogenic islet grafts of 50 % of the normal pancreatic endocrine volume via the portal vein in the liver or under the kidney capsule. After 2 weeks immunocytochemical stainings were performed on the noradrenergic enzymes tyrosine hydroxylase (TH) and dopamine- β -hydroxylase (DBH), on the cholinergic enzyme choline acetyltransferase (ChAT) and on neuron specific enolase (NSE). In the grafts under the kidney capsule, ChAT staining was more pronounced at the capsule site and seemed to originate from the capsule, while TH staining was more pronounced at the parenchyma site. The TH and DBH staining was mainly visible around blood vessels in the islets in the liver and under the kidney capsule. In both transplantation sites NSE was present in the islets. These results give evidence for a reinnervation of islets grafts, which might be responsible for increasing and decreasing insulin levels.

623.14

SPINAL CORD GRAFTS IN OCULO: FUNCTIONAL CONNECTIONS WITH COGRAFTS OF SPINAL CORD OR SKELETAL MUSCLE, EFFECTS OF CNTF. K. Trok, M. Eriksdotter-Nilsson*, M. Palmer¹, B. Hoffer¹, J. Olson. Dept. of Histology & Neurobiology, Karolinska Institutet, Stockholm, Sweden, and ¹Dept. of Pharmacology, Univ. of Colorado Health Sciences Center, Denver, CO 80262, USA.

Fetal spinal cord tissue survived grafting to the anterior chamber of the eye of adult rat hosts. We have previously demonstrated that such grafts can receive inputs from co-grafts of serotonin as well as noradrenergic neurons and also become functionally connected to cortex cerebri co-grafts. In this study we wished to examine how treatment with ciliary neurotrophic factor (CNTF), co-grafting with another fetal spinal cord and co-grafting with fetal skeletal muscle can influence development and maturation of spinal cord tissue. (1) E18 fetal spinal cord grafts treated with CNTF at grafting and, by intraocular injections 5, 10, 15, and 20 days after grafting did not differ in volume increase compared to controls as measured through the cornea. Animals were sacrificed after 6 weeks and the grafts examined histologically. We observed a larger number of large neurons in the CNTF-treated grafts. (2) Fetal rat E15 spinal cord was grafted together with E20 skeletal muscle to the anterior chamber. Controls received single grafts of either spinal cord or skeletal muscle. Spinal cord grafted together with skeletal muscle grew to larger volumes than single spinal cord grafts. Contractions in the skeletal muscle co-grafts after stimulation of the spinal cord demonstrated specific functional contacts between the grafts. After maturation in oculo the double grafts were examined histologically and immunohistochemically using antisera to neurofilament (NF), glial fibrillary acidic protein (GFAP), acetylcholinesterase (AChE) and calcitonin gene-related peptide (CGRP). The immunohistochemical results also demonstrate that spinal cord can innervate skeletal muscle. (3) The pieces of fetal E15 spinal cord were sequentially co-grafted to the anterior chamber. The double grafts were allowed to mature in oculo. Preliminary electrophysiological examinations indicate functional contacts between these spinal cord double grafts. We conclude that spinal cord grafts can establish functional contacts with both adjacent spinal cord grafts and skeletal muscle and that CNTF appears to stimulate the grafted motoneurons.

623.16

HISTAMINERGIC INNERVATION OF CENTRAL AND PERIPHERAL TARGET AREAS IN INTRAOCULAR DOUBLE GRAFTS. H. Bergman*, C. Bäckman¹ and A.C. Granholm¹. Dept. Cell Biology, Univ. of Linköping, Sweden, and Dept. Basic Science, University of Colorado Health Science Center, Denver, CO¹.

Histaminergic neurons of the tuberomammillary nucleus (TM) in the posterior hypothalamus send projections to virtually all regions of the rat brain. In order to investigate innervation pattern and plasticity of histaminergic neurons into different central and peripheral target areas, fetal hypothalamic tissue containing histaminergic neurons was grafted into the anterior chamber of the eye of adult Fisher 344 albino rats. Four weeks later, a second graft was placed in contact with the TM graft, and the double grafts were left to mature for 4-5 weeks *in oculo*. The co-grafts were fetal medial forebrain, hippocampal, cerebellar or lung tissue. Growth curves revealed that all central target tissues survived transplantation well and grew *in oculo*. The hippocampal target tissue seemed to benefit from a double transplant of TM tissue, and grew at least 3 times larger than single hippocampal control grafts *in oculo*. The lung tissue did not survive well, and some grafts showed signs of rejection 2-3 weeks after grafting. Immunohistochemical evaluation with antibodies against histamine, synapsin, glial proteins and choline acetyltransferase was performed. A dense pattern of synapsin-positive profiles was found in all transplants. Histamine-immunoreactive neurons in TM grafts innervated central target tissues to a variable degree. Highest densities of histamine-positive fibers were found in medial forebrain and hippocampal tissues, while cerebellar grafts contained very sparse fibers. The lung grafts did not appear to be innervated by histamine-positive fibers. These results indicate that the TM area of the hypothalamus may influence brain tissue growth, and that histaminergic innervation can be target specific.

GUIDANCE CHANNELS CONTAINING ADULT SCHWANN CELLS INDUCE CHOLINERGIC NERVE REGENERATION IN THE SEPTO-HIPPOCAMPAL SYSTEM. D. Hoffman¹ and E. Aebischer^{1,2}. ¹Division of Biology and Medicine, Brown University, Providence, R.I. 02912; ²Division of Surgical Research, CHUV, University of Lausanne, Switzerland.

The limitation of CNS axonal regeneration after injury may be due in part to an inhibitory post-lesion environment. While endogenous CNS components do not support axonal elongation, regeneration can occur with the provision of exogenous tissue from the peripheral nervous system, particularly Schwann cells. The means by which Schwann cells mediate CNS regeneration and the nature of the Schwann cell-axonal relationship have not yet been determined. The present study examines the ability of Schwann cells to induce septo-hippocampal regeneration when pre-seeded within a polymer nerve guidance channel, and the subsequent Schwann cell-axonal association at the transmission electron microscope (TEM) level. Schwann cells isolated from adult Fisher rat sciatic nerves were suspended in an extracellular matrix-containing gel, and surrounded by a hollow permselective poly(acrylonitrile/vinyl chloride) polymer tube. Following a unilateral aspirative lesion of the fimbria-fornix, adult Fisher rats received cell-containing tubes in the lesion cavity, placed so as to abut the septum and the hippocampus. Cholinergic axons regenerated through the channel lumen of tubes containing Schwann cells. A complete absence of cholinergic ingrowth was noted in control channels which contained extracellular matrix alone. Examination under TEM demonstrated the regeneration of numerous unmyelinated axons, groups of which were engulfed by Schwann cells. Few unmyelinated axons grew into control tubes. These studies show that when transplanted into the lesioned brain, Schwann cell-seeded nerve guidance channels provide directionally oriented biosynthetic bridges which induce CNS regeneration via a direct association between Schwann cells and groups of regenerating axons.

623.19

NGF-PRODUCING GRAFTS IMPLANTED INTO UNILATERALLY LESIONED RAT FIMBRIA-FORNIX ELICIT HIPPOCAMPAL REINNERVATION AND FUNCTIONAL RECOVERY. K.L. Eagle*, G.R. Chalmers, M.H. Tuzynski, and F.H. Gage. Dept. of Neurosciences, UCSD, La Jolla, Ca. 92093

Nerve growth factor (NGF) has been shown to induce regeneration of axotomized NGF receptor-positive (NGFr-IR) cholinergic neurons. We have demonstrated that primary fibroblasts genetically modified to produce NGF, when suspended in a collagen matrix and implanted into a rat fimbria-fornix (FF) lesion cavity, promote growth of axons across the graft and into the hippocampus (HPC). In the present experiment, rats were given unilateral aspirative FF lesions and then either grafts of NGF-producing (NGF) or β -galactosidase-producing (β Gal) fibroblasts, or no graft (FFx). After 6 months, NGF-producing grafts exhibited growth of neurofilament-positive processes in close association with astrocytic glial fibrillary acidic protein immunoreactive (GFAP-IR) processes. Similarly, NGFr-IR fibers often paralleled GFAP fibers, passing through the thick layer of astrocytic processes both to enter the graft from the host and to enter the HPC from the graft. The density of HPC NGFr-IR fibers was measured in four different hippocampal sites: the most caudal point of the dentate gyrus (DG1), just rostral to DG1 on the dorsal blade of the dentate gyrus (DG2), CA2, and the most caudal region of CA1. NGF-grafted animals show no significant NGFr-IR difference from normal control rats in the four sites measured, while β Gal-grafted rats have significantly less NGFr-IR density than control or NGF rats in DG2 and CA1. In a locomotor habituation task, all rats displayed the same baseline level of activity during initial exposures, but after a 24 hour delay both NGF-grafted and normal rats showed significantly greater habituation than β Gal-grafted or lesion-only rats. These results suggest that rats grafted with NGF-producing fibroblasts exhibit regrowth of neurites, that they receive enhanced reinnervation of the graft and HPC, and that this morphological effect is reflected in attenuated deficits in locomotor habituation.

SYNAPTIC STRUCTURE AND FUNCTION IV

624.1

ACTIVITY DEPENDENT PLASTICITY OF ELECTROTONIC SYNAPSES ON THE MAUTHNER (M) CELL. Alberto Pereda* and Donald S. Faber. Dept. of Anatomy & Neurobiology, Medical College of Pennsylvania, Philadelphia, PA 19129.

Single eighth nerve afferents establish both gap junctions and chemical synapses with the M-cell's lateral dendrite, such that low threshold extracellular stimulation of the posterior eighth nerve produces a mixed electrotonic and chemical excitatory post-synaptic potential (VIIIth EPSP). Different tetanizing paradigms evoke long term potentiation or depression of both components of this response, depending in part on the initial level of synaptic efficacy. We are further investigating the determinants of activity-dependent plasticity of the gap junctions. Short or long duration tetanic stimulations of the eighth nerve produced transient (3-6 min.) and pronounced enhancements of coupling ($m=509.6\%$, $s.e.m.=173.2\%$, $n=11$), accompanied in all but one case by an increase in the chemical EPSP. Plasticity of electrical synapses was also illustrated in three experiments in which spontaneous decoupling occurred. Under those conditions stimulating tetani were able to re-establish the electrotonic potential. Paired pre- and postsynaptic recordings have been used to correlate changes observed at single connections with modifications of the population VIIIth EPSP. Unitary electrotonic potentials recorded at the input site (lateral dendrite) had a wide range of amplitudes (0.3-1.2 mV), suggesting the junctional conductance may vary appreciably among individual afferents (dendritic filtering may also contribute to this variability). Tetanic nerve stimulation can produce persistent (>5 min) changes in the amplitude of the unitary coupling potential. However, in 7 of 10 trials where the population response was modified, the size of the unitary potential either was unaffected or was altered in the opposite direction. These findings suggest that the electrical synapses of this group of afferents have different levels of efficacy and that activity dependent modifications of the VIIIth EPSP represent the net effect on this population.

624.3

THE PASSIVE ELECTROTONIC STRUCTURE OF MOTONEURONS IN SLICE CULTURES ESTIMATED BY COMBINING PATCH CLAMP AND MORPHOLOGICAL DATA. D.Ulrich* and H.-R.Lüscher. Dept. of Physiology, University of Bern, 3012 Bern, Switzerland

Motoneurons in slice cultures were filled with biocytin during whole cell recording. Na^+ and K^+ conductances were blocked with TTX in the bath and Cs^+ in the pipettes, respectively. The cells were stained with HRP and reconstructed using a semi-automatic reconstruction system (Eutectic 3D NTS). Voltage and current transients were generated by short pulses of current or voltage, respectively and could be fitted by 3-4 exponential functions. The motoneurons consisted of a polygonal soma with 3-6 dendritic trees of different length. The slowest time constants of the voltage and current decay were used to calculate the electrotonic length (L_{pass}) of an equivalent cylinder. The mean electrotonic length of the different trees (L_{tree}) was estimated from the dendrograms assuming a cytosolic resistivity of $250\Omega cm$ and a capacity of $1\mu F cm^{-2}$. The resulting L_{pass} of 0.76 ± 0.18 ($n=6$) was close to the L_{tree} of 0.68 ± 0.16 . However, estimates of L_{pass} by the use of higher order time constants overestimated L_{pass} by a factor of 2-4. We conclude that the cable parameters describe an average electrotonic structure of the motoneurons although the conditions by which dendritic trees can be reduced to an equivalent cylinder are not exactly met in the cells examined. (SNF 31-27553.89)

624.2

EVIDENCE FOR ACTIVE CONDUCTANCES IN THE DENDRITES OF MOTONEURONS. M.E. Larkum, M.G. Rioult, H.-R. Lüscher*. Physiologisches Institut, University of Bern. CH-3012 Bern, Switzerland.

We recorded electrical activity in the dendrites of presumed motoneurons using organotypic slice cultures from embryonic rat spinal cord stained with a voltage-sensitive dye (di-8-ANEPPS). Fluorescence changes were measured with an array of 124 photodiodes (each $16\mu m \times 16\mu m$ using a 40X oil immersion objective) and the signal sampled and digitized at 3000 Hz per diode for up to 150 ms. We recorded evoked action potentials (AP) using an intracellular microelectrode by injection of current (0.1 to 1.0 nA, 50 msec) at the soma. By comparing the decay in amplitude of the AP's along the dendrites with the electrotonic decay of hyperpolarizing pulses (-0.4 to -0.6 nA, 50 msec) we were able to compensate for the decrease in fluorescence signal in the dendrites due to the decrease in membrane surface area and also for the inhomogeneities due to dendrites not in the focal plane. The decay of the AP amplitude along the dendrites up to $130\mu m$ from the soma was less than the decay of the hyperpolarizing pulse. To examine the possibility that calcium ions were involved in the active propagation of the AP we measured accompanying changes in calcium concentration using the photodiode array and the calcium indicator Fluo-3. Fast increases in calcium concentration could be observed that were restricted to the soma. Calcium increases were not seen in the dendrites.

These observations lead us to suspect by exclusion that sodium ions are probably responsible for AP propagation in the dendrites of motoneurons. (SNF 31-37553.89 to H.-R. L.)

624.4

Electrophysiological and Ultrastructural Properties of Identified Mesopontine 5-HT Neurons in Culture. M.D. Johnson* and A.G. Yee. Dept. of Neurobiology, Harvard Medical School, Boston, MA 02115.

Studies indicate that mesopontine 5-HT neurons are electrophysiologically and morphologically heterogeneous *in vivo*. To examine the relationship between the electrophysiological and ultrastructural properties of 5-HT neurons, neonatal Long-Evans rats (P0 - P3) were decapitated, the mesopontine raphe nuclei were removed and enzymatically dissociated, and the cells were maintained in microcultures for several weeks. The small area of the microcultures confined growing processes, increased the probability that neurites would form synapses with target cells, and facilitated the ultrastructural study of identified neurons. Intracellular recordings from 5-HT-immunoreactive neurons revealed the presence of short latency glutamatergic, GABAergic, and serotonergic potentials in these cells. 5-HT neurons also formed serotonergic and glutamatergic synapses on target cells (Johnson, Soc Neurosci Abstr 18:1530). For electron microscopy, 5-HT neurons in 8 microcultures were identified by peroxidase-linked 5-HT immunocytochemistry or by a 15-30 minute exposure to the autofluorescent 5-HT analogue, 5,7-dihydroxytryptamine, prior to embedding in Epon. 5-HT and non-5-HT axon terminals formed synaptic contacts on both labeled and unlabeled target neurons. Most 5-HT axons contained round or pleiomorphic, as well as large dense-cored vesicles. In 3 microcultures containing solitary 5-HT neurons, intracellular recordings and subsequent EM analysis suggested that differences in synaptic physiology may be reflected in the number and type of synapses present. Thus, this system is useful for studying correlations between synaptic electrophysiology and ultrastructural morphology in 5-HT neurons. Supported by NS02253 and the Freudenberg Fund. FAST DEACTIVATION OF NON-NMDA RECEPTORS IN OUTSIDE-OUT PATCHES. B. Edmonds*, R. A. Silver, D. Colquhoun and S. G. Cull-Candy. Dept. of Pharmacology, University College London, London WC1E6BT, England.

The response of non-NMDA receptors to rapid application of glutamate was investigated in outside-out patches from granule cells cultured from rat cerebellum (4 days in culture, age 7-8 days). A near saturating concentration (1-5 mM) of glutamate was applied for varying durations to investigate the time course of deactivation upon removal of glutamate, and desensitization in response to a long application. The deactivation time courses resulting from 0.2 & 1.0 ms applications were not found to be different, and single exponential fits to the data gave an overall mean time constant of 0.64 ms. Desensitization was slower; the mean time constant for an exponential fit was near 3 ms. Since the non-NMDA component of the synaptic current decays with a time constant of about 1 ms in these cells (Silver *et al.*, 1992), our results suggest that desensitization alone is too slow to account for the decay, supporting the idea that transmitter is present only briefly in the synaptic cleft. However, deactivation appears to be faster than the synaptic decay rate, so the latter may well be influenced by the time course of glutamate concentration in the cleft.

ENGINEERING CHARACTERIZATION OF SYNAPTIC JUNCTIONS IN THE HIPPOCAMPUS. F. G. Ascarunz, K. Flach, L. E. Adler* and R. J. MacGregor. Dept. of Aerospace Engineering Sciences, Univ. of Colorado, Boulder CO 80309

In this study we compile the quantitative data available in the literature, on the anatomy and electrophysiology of the hippocampal system. The objective is to characterize the synaptic junctions to establish a means of comparing the dynamics of these junctions. The quantitative data are used to derive a set of parameters that express the connectivity and dynamic characteristics of the junctions. We tentatively organize synaptic junctions into 4 broad categories, diffuse excitatory junctions, discrete excitatory junctions, selective inhibitory junctions, and discrete inhibitory junctions. Diffuse excitatory junctions are characterized by post-synaptic potentials (PSP) which are small compared to the threshold of the receiving neuron. The synaptic junctions are generally on distal dendrites and the convergence - divergence. At discrete excitatory junctions, the PSP sizes are comparable to threshold and the divergence is much greater than the convergence. Selective inhibitory junctions control the inputs to the neuron and are characterized by small PSP's of long duration. The synapses are on distal dendrites and seem to be activated in a feed forward sense. The discrete inhibitory connections control the outputs of a neuronal network through recurrent inhibition. These junctions are characterized by large PSP's of short duration, and a high redundancy factor. These synapses are on proximal dendrites, cell bodies and axon initial segments. We compare the afferents to different neuronal populations in the hippocampus in terms of these parameters. We show that by identifying and characterizing the operational constraints of synaptic junctions, one can provide a basis for choosing a modeling approach that can best represent the anatomy and electrophysiology of the neuronal system investigated. HOW THE SIZE DISTRIBUTION OF THE POSTSYNAPTIC AREAS ON HIPPOCAMPAL (CA1) DENDRITIC SPINES MIGHT INFLUENCE THE AMPLITUDE HISTOGRAMS OF MINIATURE SYNAPTIC CURRENTS.

K.M. Harris* Dept. Neurology, Children's Hospital and Harvard Medical School, Boston, MA 02115

Amplitude histograms of excitatory postsynaptic currents (epcs) in area CA1 of the hippocampus can show broad, positively skewed distributions ranging from 2 to 30 pA.^{1,2} There is however, considerable heterogeneity in the shapes of the histograms. Several explanations could account for this heterogeneity and for the occurrence of peaks in their distributions, including variation in the number of vesicles released, in the amount of neurotransmitter per vesicle, and in the size of the postsynaptic response. Here we have examined the possibility that the surface area of the dendritic spines occupied by the postsynaptic density (PSD), i.e. the receptive region, may be an anatomical marker of the postsynaptic contribution to these amplitude histograms. In previous studies^{3,4} we have reconstructed through serial electron microscopy the entire area of PSDs occurring on 572 dendritic spines in the middle of s. radiatum in hippocampal area CA1. The frequency histogram of these PSD areas is positively skewed ranging in size from 0.01 to 0.76 μm^2 ; and PSDs spanning most of this range in size can occur along a 5-8 μm segment of a single CA1 dendrite. A Chi-square analysis revealed that this distribution is not likely to be unimodal ($\chi^2 = 89$, $df = 34$, $p < 0.01$, for bin widths of 0.02 μm^2 , excluding the two end bins) suggesting the possibility that postsynaptic size may contribute to variation in the size of epcs thereby influencing the shape of the amplitude histograms. Supported by NS21184, The Alfred P. Sloan Foundation, and the MR center grant P30-HD18655.

MODEL OF THE QUANTAL ACTIVATION OF NMDA RECEPTORS AT A HIPPOCAMPAL SYNAPTIC SPINE. T.M. Bartol Jr., T.J. Sejnowski*. Computational Neurobiology Laboratory, Salk Institute, 10010 N. Torrey Pines Rd., La Jolla, CA 92037.

A Monte Carlo simulation of a hippocampal area CA1 synaptic spine was undertaken. The simulation included the three-dimensional geometry of a synaptic spine, the release and random-walk diffusion of each transmitter molecule in a quantal packet of glutamate, and the activation by glutamate of NMDA receptors present on the postsynaptic membrane. The kinetic rate constants used to model the NMDA receptor were held fixed at the values reported by Lester & Jahr (The Journal of Neuroscience, 1992, 12:635-643). Thus, the free parameters in the model were the number of transmitter molecules contained in a quantal packet (N), and the NMDA channel density on the postsynaptic membrane (σ_{NMDA}). N and σ_{NMDA} were adjusted so that ~10 NMDA channels would be in the open state at the peak of receptor activation (Bekkers & Stevens, *Nature*, 1989, 341:230-233). The time course of glutamate concentration in the cleft following quantal release had a rapid component decreasing from ~2 mM to 0.5 mM in <100 μs and a slower component which kept glutamate concentration at ~0.1 mM for over 1 ms. In agreement with experimental results (Lester & Jahr) the ensemble average time course of the modeled NMDA receptor activation was unaffected by the value of N or σ_{NMDA} . It was also found that over a limited range of values for σ_{NMDA} , a best fit to the peak activation criteria could be achieved by keeping the product of $N \cdot \sigma_{\text{NMDA}}$ constant and that outside this range a fit could only be obtained by increasing N at a given value of σ_{NMDA} . This result suggests that $N \cdot \sigma_{\text{NMDA}}$ may be operating at a minimum value in vivo and that the actual value of N could be determined if one could measure σ_{NMDA} .

Diversity in EPSC size and release probability of synapses on individual CA1 cells in the rat hippocampus.

Morten Raastad* and Rupert Lipowski

Institute of Neurophysiology, University of Oslo.

If the excitatory synapses on CA1 pyramidal cells can undergo modifications of efficacy in vivo, different axons synaptically connected to the same cell would be expected to present different release properties and/or postsynaptic amplitude. We have studied the question of diversity of synaptic properties by using a technique for reliable activation of a single synaptically connected axon.

Tight-seal voltage clamp recordings from CA1 cells in hippocampal slices were used to record excitatory postsynaptic currents (EPSCs). Inhibitory currents were blocked by 10 μM bicuculline. Schaffer collaterals were activated with a limited range of stimulus intensities around the threshold for the occurrence of EPSCs. Activation of a single fibre was inferred when EPSCs appeared at a certain stimulation intensity, and a stable distribution of EPSC amplitudes was observed over a range just above this stimulation intensity.

EPSC recordings with stable electrode series resistance, membrane resistance, Ca^{++} concentration, stimulation frequency and comparable rise times showed clearly different EPSC amplitude distributions and different proportion of release failures when different single fibre inputs to the same cell were activated. There was no apparent correlation between probability for failures and mean EPSC size, speaking for a diversity in postsynaptic response between different inputs.

HIGH-SPATIAL RESOLUTION IMAGING OF Ca^{2+} TRANSIENTS IN LIVING HIPPOCAMPAL NEURONS USING CONFOCAL MICROSCOPY D.B. Jaffe^{1*}, and T.H. Brown^{1,2}. Depts. of Psychology¹ and Cellular & Molecular Physiology², Yale Univ., New Haven, CT 06520.

Long-lasting forms of synaptic plasticity, such as LTP or LTD, are believed to be triggered by synaptically-mediated changes in $[\text{Ca}]_i$. The high-spatial resolution of confocal microscopy in combination with recently developed Ca-sensitive dyes can now be used to visualize changes in $[\text{Ca}]_i$ at the synaptic level.

Living CA1 and CA3 pyramidal neurons in thick rat hippocampal slices (300 μm) were filled with long-wavelength Ca-sensitive dyes (Fluo-3 or Ca-green) using standard sharp microelectrode techniques. Cells near the surface of the slice (within 50 μm) were chosen to facilitate high-spatial resolution imaging of dendrites and dendritic spines. Fluorescence imaging was performed using laser scanning confocal microscopy (Bio-Rad MRC-600) either with a 63x oil, 1.2 NA objective (inverted system) or a 40X, 0.75 NA water immersion objective (upright system).

We have examined the spatial distribution of dendritic Ca^{2+} accumulation produced by two different sets of afferent synapses, demonstrating specific patterns of $[\text{Ca}]_i$ increases for separate inputs. We have also begun studying increases in $[\text{Ca}]_i$ in the large proximal dendritic spines of CA3 pyramidal neurons, the thorny excrescences or thorns. We are currently applying DIC optics and video techniques to patch clamp in the whole-cell configuration identified neurons close to the surface of the slice. This will further facilitate high-spatial resolution imaging of changes in $[\text{Ca}]_i$ within the dendrites and dendritic spines of hippocampal neurons. Supported by ONR and NIMH.

THE 3-D LOCATIONS OF THORNY EXCRESCENCES ON HIPPOCAMPAL CA3 PYRAMIDAL NEURONS. R.B. Gonzales*, Y.M. Rangel, and B.J. Claiborne, Division of Life Sciences, The University of Texas at San Antonio, San Antonio, TX 78249.

Hippocampal CA3 pyramidal neurons demonstrate prominent spines, or thorny excrescences, at the site of mossy fiber innervation. These postsynaptic structures are found on both the apical and basal dendrites of those pyramidal neurons located near the hilar region. Because synaptic currents decay as they spread toward the cell body, the location of thorny excrescences is an important variable in predicting the effect of mossy fiber inputs on CA3 pyramidal neurons (Siegel et al., Soc. Neurosci. Abst., 18:566). Here we compare the locations of thorny excrescences on the apical and basal portions of the dendritic tree.

CA3 neurons (n=15) in hippocampal slices from adult rats were intracellularly labeled with HRP and reconstructed in three-dimensions using a computer-microscope system (Claiborne, B.J., in *Methods in Neuroscience*, p. 315, Academic Press, 1992). Results showed that the excrescences on apical dendrites were located an average of 64 ± 2 μ m from the cell body (mean \pm SEM; n=181), whereas excrescences on basal dendrites were located only 30 ± 1 μ m from the cell body (n=146). These values were significantly different (Mann-Whitney, P<0.001). The lengths of the excrescences were also measured. The mean aggregate length of apical excrescences was 7 ± 0.6 μ m, while the average length of basal excrescences was 6 ± 0.4 μ m. These results show that although excrescences on basal dendrites are similar in length to those on apical dendrites, they are located much closer to the cell body. We are presently using computer simulations to investigate the possible functional significance of this anatomical variation. Hippocampal microisland cultures as a model of CNS synaptic transmission. S.J. Mannerick*, J. Que, A. Benz, D.B. Clifford, and C.F. Zorumski. Depts. of Psychiatry and Neurology, and Program in Neuroscience, Washington Univ. Med. Sch., St. Louis, MO 63110.

There are many advantages of models of vertebrate CNS synaptic transmission that are not influenced by complex network properties. We have begun to characterize one such model by comparing properties of postnatal rat hippocampal neurons grown on microislands (MIs), where synaptic connections are restricted to one or two cells, with control neurons from the same animals grown in high density cultures (HDCs).

Using whole cell patch clamp techniques, differences were found in passive membrane properties of MI neurons versus HDC neurons matched for age and somal diameter. MI neurons displayed significantly less contribution of a slow-charging component of the membrane capacitance toward total membrane capacitance. This result may reflect less extensive neuritic arborizations in neurons grown under the physical constraints of MI cultures.

There was a much higher probability of encountering monosynaptic responses in MIs versus HDCs. Single-cell MIs more frequently displayed excitatory autaptic responses (6/8 neurons) than HDC cells (1/8 neurons). Two-cell MIs also displayed a higher incidence of monosynaptic connections than pairs in HDCs (81% vs. 38%, p<0.01; n=42). Despite the higher incidence of evoked synaptic responses and a trend toward larger responses on MIs, no differences were detected in the timecourse, amplitude, or frequency of miniature excitatory postsynaptic currents.

These studies demonstrate two advantages of the MI preparation for the study of CNS transmission: simpler passive membrane properties and a higher probability of encountering monosynaptic connections than in typical culture systems. The results also suggest that MIs could be exploited to study the convergence and divergence of synaptic connections during development.

BLOCK OF ENDOGENOUS ADENOSINE DEAMINASE (ADA) HAS LITTLE EFFECT ON SYNAPTIC TRANSMISSION IN RAT HIPPOCAMPAL SLICES. P.J. Zhu* and K. Kmjević, Anaesthesia Res. Dept. McGill Univ. Montréal, PQ, H3G 1Y6, Can.

Adenosine is a potent inhibitory neuromodulator in the CNS. ADA, which breaks down adenosine, might have an important role in the control of adenosine levels. In field recordings from CA1, the role of endogenous ADA in synaptic transmission was studied by applying the specific ADA inhibitor pentostatin (1-30 μ M). There was no consistent effect on responses elicited by Schaeffer collateral stimulation (n=20). Exogenous ADA (0.5 U/ml) enhanced the field EPSP and population spike (n=9), but not the afferent volley (n=6); stimulus strength for 50% maximum of EPSP and population spike was decreased by 8.7% and 10.7%, respectively. These actions of exogenous ADA were blocked by pentostatin (n=6). Similar effects were seen in intracellular recordings (n=2). The present results confirm previous evidence that ongoing adenosine release depresses synaptic transmission hippocampus (Haas and Greene, 1988 Naunyn-Schmiedeberg's Arch Pharmacol. 337:561); but they suggest that endogenous ADA plays little, if any, role in modulating this effect - in keeping with the reported low ADA content of the hippocampus (Geiger and Nagy 1986, J. Neurosci. 6:2707). Supported by Medical Research Council of Canada.

COMPONENTS OF EPSCS IN RAT CA1 PYRAMIDAL CELLS: SHAPE, SPACING AND PAIRED-PULSE POTENTIATION. J. Isaac, Y. Chen, D.A. Turner and H.V. Wheal*, Dept. Physiol. & Pharm., Univ. Southampton, Southampton, U.K. SO9 3TU and Neurosurg. & Neurobiol., Duke Univ. and Durham VAMC, Durham, NC 27710.

Components of evoked EPSCs recorded in CA1 neurons are often assumed to be equally spaced and "quantal" in the sense of uniform dendritic termination and amplitude. We have recorded "minimal" EPSCs and analyzed the data for components, using the waveform shape, amplitude and also an unconstrained Bayesian statistical approach, using paired-pulse manipulations.

Stationary EPSCs (n=16) showed variable rise time (1.3-7.9 msec), half-width (18.2-51.7 msec) and could often be separated by subgroup analysis into components with different shape and amplitude. The mean amplitude was 6.89 ± 4.1 pA, consisting of an average of 5 components, with a background mean $nsd = 1.61 \pm 0.5$ pA. The average component spacing was 3.9 ± 0.9 pA, with a ratio of components to $nsd = 2.54 \pm 0.72$. The components were often irregularly spaced (n=12); combined with the variable shape this likely indicates multiple dendritic sites of origin. The paired-pulse paradigm resulted in an average of 30% increase in amplitude; however, this altered primarily component probability rather than spacing.

These data suggests that electrotonically separated synaptic events exhibit different site-specific amplitudes and shapes. Thus, differences between sites should be explicitly considered in EPSC analysis rather than simply assuming uniformity of dendritic synaptic events. Supported by grants from the Wellcome Trust, NINDS and VAMC.

DENDRITIC SPINES IN CULTURED HIPPOCAMPAL NEURONS: DEVELOPMENT AND MORPHOLOGY. M. Papa, M. Bundman*, V. Greenberger and M. Segal. Dept. Neurobiol., The Weizmann Institute, Rehovot, 76100, ISRAEL.

Dendritic spines are the sites of excitatory synaptic communication among central neurons. The small size of the spines and the complexity of synaptic connectivity among neurons prohibits their systematic analysis in-vivo. We have, therefore, developed conditions for monitoring dendritic spines in cultured neurons. Embryonic rat hippocampal neurons were dissociated, plated on polylysine-coated glass cover slips and grown in culture for 1-3 weeks. Cultures were fixed with 10% formalin and individual neurons were stained with DiI and visualized in a confocal laser scanning microscope. Some cultures were immunostained for synaptophysin and others prepared for EM analysis.

About 99% of the neurons contained spiny dendrites. The mean length of the spines decreased from 1.77 μ m to 1.16 μ m between 1 and 3 weeks in culture. There were clearly-defined spine heads at 3 weeks in culture. The density of spines increased 2.7 fold between 1 and 3 weeks, reaching a mean density of 4.3 spines per 10 μ m of dendrite length. At 3 weeks, spines were associated with synaptophysin-immunoreactive labeling, resembling synaptic terminals. At the EM level, dendritic spines were similar to those in-vivo. They contained no microtubules or polyribosomes, but were filled with a fluffy, flocculent material, and made asymmetric synapses with terminals containing spherical vesicles. These studies provide the basis for further analysis of the rules governing the formation, development and plasticity of dendritic spines under controlled, in-vitro conditions.

624.16

HIPPOCAMPAL PYRAMIDAL NEURONS EXCITE NONPYRAMIDAL CELLS VIA SINGLE RELEASE SITES. A.I. Gulyás*, R. Miles*, K. Tóth*,² and T.F. Freund*
*Inst. Exp. Medicine, Hungarian Acad. Sci., Budapest, P.O.B. 67, Hungary; ²Lab. Neurobiologie Cellulaire, INSERM U261, Inst. Pasteur, 75264 Paris, France.

Combined physiological and anatomical experiments were carried out to study excitatory synaptic transmission between pyramidal cells and nonpyramidal cells in the guinea-pig hippocampus in vitro. Simultaneous intracellular recordings were made from CA3 pyramidal cells and inhibitory cells located close to stratum pyramidale. Both neurons were filled with biocytin, and were subsequently visualized with the ABC method. Excitatory interactions were detected in about 10% of the recorded pairs. EPSPs evoked by pyramidal cell action potentials in the postsynaptic interneuron had a mean amplitude of 0.5-1.5 mV and a rise time of 1.2-2.8 ms (n=18). The transmission failed with a probability of 0.05 to 0.45. At the end of the electrophysiological session three cell pairs were successfully recovered with complete axonal and dendritic trees. A basket cell and two dye-coupled pyramidal cells were labelled in the first slice (EPSP amplitude 0.75 \pm 0.3 mV), a basket cell and a single pyramidal cell in the second (0.65 \pm 0.25 mV), and a pyramidal cell together with an interneuron arborizing in strata lacunosum moleculare and oriens in the third (1.15 \pm 0.25 mV). Reconstruction in the light microscope showed that pyramidal cell axons in each slice established a single contact on the dendrites of the nonpyramidal cells. All three contacts were shown to be asymmetrical synapses in the electron microscope.

We conclude that pyramidal cells excite CA3 inhibitory cells by liberating transmitter from a single morphologically identified site. This arrangement permits direct measurements of the probability of transmitter release, and variation in the effects of transmitter released from a single site. The present findings suggest that there is a high degree of divergence and convergence in the pyramidal cell \rightarrow interneuron connection, and place an important constraint on different mechanisms of synaptic plasticity.

PHYSIOLOGY AND ANATOMY OF LOCAL CIRCUIT CONNECTIONS BETWEEN PYRAMIDAL CELLS IN RAT NEOCORTEX. A.M. Thomson, J. Deuchars & D.C. West Department of Physiology, Royal Free Hospital School of Medicine, London NW3 2PF, UK

Pairs of synaptically connected pyramidal neurones were recorded intracellularly in slices of rat motor cortex. After recording the excitatory postsynaptic potentials (EPSPs) evoked in one neurone by action potentials in the other, the two cells were filled with biocytin. Slices were fixed in 2% glutaraldehyde/2% paraformaldehyde, sectioned at 60 μ m and incubated in Avidin-HRP, which was localized using DAB as chromogen. Sections were subsequently processed for light and electron microscopy. Connections between deep layer pyramidal neurones could involve either basal or apical postsynaptic dendrites, but the input from one presynaptic neurone was relatively restricted in its distribution. Preliminary correlations between fluctuation analysis and morphology indicate that i) EPSP time course is determined by electrotonic distance from the recording site and ii) coefficient of variation may correlate with the number of contributory presynaptic terminals. In one example, the postsynaptic recording site was in the apical dendrite, 140 μ m from the soma and the EPSP evoked by apparent terminals onto branches of this dendrite evoked slow spikes and fast spike bursts.

NEW PREPARATORY METHODS DO NOT AFFECT FIELD POTENTIALS IN HIPPOCAMPAL SLICES. D.L. Tauck*, J.E. Tullis, and R.L. Sasich, Laboratory of Neurophysiology, Department of Biology, Santa Clara University, Santa Clara, CA, 95053.

Accumulated evidence suggests that hypothermia protects against anoxia in a variety of neuronal preparations. Hippocampal slices initially incubated for 45 minutes at 21°C have many more normal CA1 pyramidal cells than slices incubated at 37°C (Newman, et al., 1992, *Brain Res.* 575:159-163). Similarly, preventing the neuronal swelling caused by anoxia allows preparation of brain slices from adult rats with electrophysiologically viable motoneurons (Aghajanian & Rasmussen, 1989, *Synapse* 3:331-338). This is accomplished by substituting sucrose for NaCl in the artificial cerebrospinal fluid (ACSF) used during the dissection and subsequent recovery period.

The present study shows that neither hypothermia nor the use of sucrose-ACSF affects the maximum amplitude of the population spike recorded in hippocampal area CA1 at 33°C. Slices initially incubated at 20°C in normal ACSF generated an average maximal population spike of 17.4 \pm 4.2 mV (mean \pm S.D.; n=4); incubation at 33°C resulted in a maximal response of 16.7 \pm 2.0 mV (n=4). In slices initially perfused with sucrose-ACSF, the average maximal response was 20.7 \pm 3.1 mV (n=4) in slices incubated at 20°C and 18.8 \pm 5.7 mV (n=4) in slices incubated at 33°C.

PRESYNAPTIC MECHANISMS IV

625.1

4-AMINOPYRIDINE (4-AP) DOES NOT AFFECT PRESYNAPTIC INHIBITION BY MUSCARINE IN RAT HIPPOCAMPAL CA1 *IN VITRO*. B.J. Mack, P.A. Smith & W.F. Colmers* Dept. Pharmacology, Univ. of Alberta, Edmonton, Canada

Multiple receptors mediate presynaptic inhibition of excitatory transmission at the Schaffer collateral-CA1 pyramidal cell synapse. Neuropeptide Y (NPY) and baclofen appear to share a common mechanism, with a common response to application of 4-AP and 4-AP, low Ca²⁺, while adenosine's actions differ in their response to these conditions. Here we test the hypothesis that muscarinic inhibition at this synapse would respond to 4-AP and low Ca²⁺, 4-AP in the same manner as NPY.

The slope of the population EPSP evoked by stratum radiatum stimulation and recorded in stratum radiatum of CA1 was adjusted to between 70% and 90% of the maximum response and maintained under all conditions. Concentration-response curves to muscarine (0.1-30 μ M) were constructed in control saline (1.5 mM Ca²⁺), in 30 μ M 4-AP, in 4-AP with low (0.75 mM) Ca²⁺, and in saline with low (1.0 mM) Ca²⁺ alone. 4-AP had no effect on the concentration-response curve to muscarine, in contrast to previous findings with NPY, baclofen or adenosine. Low Ca²⁺, or low Ca²⁺, 4-AP both increased the inhibition caused by muscarine.

The results suggest that presynaptic muscarinic receptors in hippocampus mediate inhibition of transmitter release by a different mechanism than do NPY, baclofen or adenosine. While results from similar experiments suggest that NPY and baclofen may inhibit Ca²⁺ influx into presynaptic terminals, it is still unclear how muscarinic receptors act there. It is possible that a change in excitability, e.g., activation of a large potassium or chloride current, may underlie muscarine's action. It is certain, however, that the mechanism of muscarinic presynaptic inhibition differs from those of the other three receptors studied.

PHYSIOLOGY AND ANATOMY OF LOCAL CIRCUIT CONNECTIONS BETWEEN PYRAMIDAL NEURONES AND INTERNEURONES IN RAT NEOCORTEX. J. Deuchars, A.M. Thomson & D.C. West, SPON: Brain Research Association. Department of Physiology, Royal Free Hospital School of Medicine, London NW3 2PF, UK.

In slices of rat motor cortex, simultaneous intracellular recordings were obtained from an interneurone and a pyramidal cell. Synaptic connections were demonstrated electrophysiologically and connected cells filled with biocytin. Both inhibitory postsynaptic potentials (IPSPs) recorded in the postsynaptic pyramidal and excitatory postsynaptic potentials (EPSPs) recorded in the postsynaptic interneurone were studied. However, in no case was a reciprocal connection observed. Fast spiking interneurons that evoked fast IPSPs in pyramidal neurones had aspiny dendrites, axons that ramified extensively in the vicinity of the soma and appeared to contact basal dendrites and somata of postsynaptic pyramids. Single axon IPSPs could be several mV in amplitude, and followed high presynaptic firing rates with a decline in IPSP amplitude, but only rare complete failures of transmission. These IPSPs fluctuated in amplitude, but CV (coefficients of variation) were small. Pyramidal neurones evoked fast EPSPs in postsynaptic interneurons which typically displayed profound paired pulse facilitation and large CVs.

625.2

NEUROPEPTIDE Y PRESYNAPTICALLY INHIBITS EXCITATORY SYNAPTIC TRANSMISSION ONTO CA3 PYRAMIDAL CELLS BY A Ca²⁺-DEPENDENT MECHANISM. A. Rory McQuiston* and William F. Colmers. Department of Pharmacology, University of Alberta, Edmonton, Alberta, Canada.

Although neuropeptide Y (NPY) inhibits all feedforward and recurrent excitatory synaptic inputs to CA3 pyramidal cells in hippocampus *in vitro*, the mechanism of NPY's action remains to be determined. We investigated the mechanism of presynaptic inhibition of NPY on CA3 pyramidal cells by recording spontaneous excitatory postsynaptic currents (sepsc's) in acutely prepared rat hippocampal slices utilizing the whole cell patch clamp method.

Slices were perfused with aCSF containing 100 μ M picrotoxin to eliminate spontaneous inhibitory synaptic currents and cells were acquired with electrodes (3 to 7 M Ω) made from 1.5 mm borosilicate glass. Bath application of NPY (1 μ M) reversibly decreased the sepsc frequency distribution and also decreased the amplitude distribution, as determined by a Kolmogorov-Smirnov test. However, further evaluation of the sepsc amplitude distribution (by plotting the cumulative mean sepsc amplitude against the sepsc amplitude) demonstrated that there was a selective reduction in the number of large amplitude sepsc's without a subsequent change in the distribution of the smaller amplitude sepsc's (in the amplitude range of the unitary event). These results are consistent with an exclusively presynaptic site of NPY action, reducing the likelihood that multiple, summing sepsc's are observed. Furthermore, in the presence of tetrodotoxin to eliminate action potential-dependent sepsc's (and thus presumably calcium-dependent sepsc's), neither the frequency nor amplitude distribution of sepsc's were affected by 1 μ M NPY.

These data are consistent with a presynaptic site of NPY action in CA3, and suggest that NPY inhibits Ca²⁺-dependent transmitter release in hippocampus.

Supported by MRC (Canada).

625.3

ADRENERGIC EXCITATION OF HIPPOCAMPAL INTERNEURONS. V. A. Doze*, D. E. Bergles, S. J. Smith and D. V. Madison. Department of Molecular & Cellular Physiology, Beckman Center, Stanford University School of Medicine, Stanford, CA 94305-5426.

Whole-cell recordings were made from pyramidal cells and from identified interneurons in the CA1 region of adult rat hippocampal slices. Epinephrine-10 μ M (EPI) increased both the frequency and the amplitude of spontaneous action potential-dependent IPSCs recorded in CA1 pyramidal neurons. This action was mediated by an alpha adrenoceptor. In contrast, EPI did not affect either the frequency or the amplitude of spontaneous action potential-independent (miniature) IPSCs recorded in CA1 pyramidal cells.

EPI depolarized interneurons causing them to fire action potentials more frequently. This action was also mediated by an alpha adrenoceptor. The EPI-induced depolarization of the interneuron membrane was accompanied by an increase in input resistance (with a reversal potential of \sim -40mV) consistent with an increase in a non-selective cation conductance. These results suggest that alpha adrenoceptors are selectively localized on inhibitory interneurons and are coupled to a non-selective cation channel. Activation of these adrenoceptors by EPI causes excitation of the inhibitory interneurons. These results further confirm that the adrenergic system modulates interneuron activity and thus may have an important role in regulating tonic inhibition.

ACTIVATION OF METABOTROPIC GLUTAMATE RECEPTORS MODULATES FEEDFORWARD EXCITATION OF HIPPOCAMPAL INTERNEURONS.

D. E. Bergles* and S. J. Smith, Department of Molecular and Cellular Physiology, Stanford University, Stanford, CA 94305-5426.

The metabotropic class of glutamate receptors has been recently shown to have diverse modulatory actions on hippocampal neurons, including suppression of synaptic inhibition in area CA1 and modulation of Ca²⁺ channels. To examine the modulatory effects of this receptor class on the excitation of interneurons in the hippocampus, we have developed a combined imaging and electrophysiology setup which allows us to visualize and record from interneurons 50 - 200 μ m deep in adult rat hippocampal slices (400-500 μ m) through a combination of infrared imaging with a CCD camera and Nomarski optics.

The selective agonist for these receptors, (1S,3R)-1-aminocyclopentane-1,3-dicarboxylic acid (1S,3R-ACPD)(50-100 μ M) reversibly increases the frequency of spontaneous excitatory postsynaptic currents (EPSCs) recorded from interneurons located in stratum radiatum and lacunosum-moleculare, presumably reflecting the known excitatory action of 1S,3R-ACPD on CA3 pyramidal neurons. However, the amplitude of the evoked EPSC into these interneurons, obtained through stimulation of the Schaffer collaterals, is depressed in the presence of 1S,3R-ACPD, suggesting that this agonist has an additional action at the CA3 pyramidal neuron - interneuron synaptic terminals. Consistent with this hypothesis, 1S,3R-ACPD reduced the frequency of spontaneous miniature EPSCs (recorded in 1 μ M TTX). These results suggest that activation of metabotropic receptors can modulate the release of excitatory transmitter through an action at the presynaptic terminal, and may play an important role in the feedforward excitation of stratum radiatum and lacunosum-moleculare interneurons and thereby inhibition of CA1 pyramidal cells.

HIPPOCAMPAL EXCITATORY SYNAPSES: EVIDENCE FOR PREFERRED SUB-LEVELS IN THE AMPLITUDE DISTRIBUTION OF MINIMAL ALL-OR-NONE SYNAPTIC CURRENTS (EPSCs).

J. E. Storm, Inst. of Neurophysiology, University of Oslo, Norway.

Single-fiber EPSCs in CA1 neurons may be due to a single quantum each: the amplitude distribution of minimal evoked EPSCs resembles that of minis (Raastad & al., 1992, Eur. J. Neurosci. 4:113); and facilitation gives no clear increase in the mean non-zero EPSC amplitude (Storm & Raastad, Soc. Neurosci. Abstr. 17:1486). Still, the size of minis and minimal evoked EPSCs fluctuate much (Bekkers & al. PNAS 87:5359; Manabe & al. Nature 355:50). Here I report evidence that minimal evoked EPSCs exhibit preferred amplitudes.

EPSCs were recorded (whole cell) from CA1 pyramidal cells in slices from young rats. Afferent fibers were stimulated via a patch pipette, with pairs of stimuli (40-60ms interval) of minimal intensity (>50% failures). The facilitation (mean EPSC1 > EPSC2) was usually entirely due to a reduced failure rate, with no detectable increase in the mean amplitude of non-zero EPSCs. This suggests that each EPSC is not due to multiple independent units (e.g. quanta) but either a single unit (quantum), or multiple coupled units. The EPSC amplitude varied 2-10-fold from trial to trial, but often clustered at 2-5 "preferred" levels for periods of 50-500 trials. The "preferred" amplitudes were 2-20 times more frequent than expected from the overall distribution. When the non-zero EPSC2 was reduced (<EPSC1), indicating depression coexisting with facilitation (Storm, Soc. Neurosci. Abstr. 18:1340), EPSC2 sometimes showed a stepwise reduction, as if composed of subunits, although the mean of EPSC1 and EPSC2 preceded by failures were equal, suggesting all-or-none EPSCs.

These observations suggest that single-fibre EPSCs are determined at two steps: one for failure rate, another for amplitude. And: single fibre EPSCs show (periods of) preferred amplitudes. Possible mechanisms include concerted release of multiple quanta or subquanta, or alternation between synaptic sites.

CHOLINERGIC INHIBITION OF MINIATURE EPSCS IN THE RAT HIPPOCAMPUS. G. A. Cohen* D. E. Bergles, S. J. Smith and D. V. Madison. Dept. of Molecular and Cellular Physiology, Stanford University School of Medicine. Beckman B-115, Stanford, CA 94305-5426.

Muscarinic receptor activation is thought to presynaptically inhibit the release of glutamate in the hippocampus. To test this hypothesis directly, the effect of the cholinergic agonist carbachol was studied on miniature excitatory post-synaptic currents (mEPSCs) in the rat hippocampus. Recordings were obtained using whole-cell electrodes filled with cesium gluconate or potassium gluconate based solutions. In pyramidal cells, the average tonic frequency of observed mEPSCs was less than 0.1 Hz, with a range of 0 to 1.5 Hz. Events had slow rise times (2-10 msec) and average amplitudes of 2-3 pA, only slightly larger than the 1 to 1.5 pA background noise. Carbachol (10 μ M) was applied to < 5% of cells which exhibited mEPSCs with sufficiently large frequency and amplitude. In these cells, carbachol induced a significant decrease in frequency.

Whole cell recordings from lacunosum-moleculare and stratum radiatum interneurons revealed mEPSCs with an average frequency of 5 Hz (range 2-15 Hz), amplitude of 8 pA (> 100 pA maximum), and rise times of 0.5 to 2 msec. Carbachol (10 μ M) caused > 50% reduction in the frequency of these events. These results provide further evidence for a presynaptic inhibitory action of cholinergic receptors on glutamergic terminals.

INTERACTIONS BETWEEN PRESYNAPTIC INHIBITION AND FREQUENCY FACILITATION AT HIPPOCAMPAL SYNAPSES. K. P. Scholz* and R. J. Miller, Dept. of Pharm. and Physiol. Univ. of Chicago, 60637.

Conditions that reduce the probability of transmitter release are known to increase the degree of facilitation at the neuromuscular junction (c.f. Rahamimoff, 1968). This may be a general property of synaptic transmission. Presynaptic inhibition induced by adenosine or GABA_B receptors has been shown to increase paired-pulse facilitation in the hippocampal slice. However, at hippocampal synapses, the properties of facilitation during paired-pulses or during longer trains of stimuli are poorly characterized. We have begun to examine the properties of two-pulse and four-pulse facilitation and the interactions of facilitation with inhibition of release induced by elevated extracellular Mg²⁺, activation of A1 adenosine receptors and block of presynaptic Ca²⁺ channels by ω -CgTX GVIA. These experiments were performed on hippocampal pyramidal neurons cultured on a photolithographically defined substrate that limited the number of presynaptic neurons to one. Upon switching the extracellular solution from 1 mM Ca²⁺/2 mM Mg²⁺ to 2 mM Ca²⁺/1 mM Mg²⁺, the amplitude of the excitatory postsynaptic current (EPSC) increased by 319 \pm 43% (n=8). In addition, the facilitation ratio (amplitude of second/amplitude of first) for 2 EPSCs evoked at a 60 msec inter-stimulus interval (ISI) shifted from 1.5 to 0.93. Addition of the adenosine receptor agonist cyclopentyladenosine (CPA; 100 nM) inhibited the EPSC by 65 \pm 7% and shifted the facilitation ratio to 1.5. This effect was readily reversible. Application of ω -CgTX GVIA (250 nM) until the block of the EPSC resembled the inhibition produced by CPA resulted in an increase in the facilitation ratio to 1.3, which was not significantly different than in CPA. During four-pulse facilitation (ISI=25 msec) CPA inhibited the first EPSC by 57 \pm 8% (n=5) whereas the fourth EPSC of a train was inhibited by only 26 \pm 7. Similar results were obtained in low Ca²⁺ solution. The results do not support a role for voltage-dependent recovery of Ca²⁺ channel inhibition in the increase in facilitation that accompanies presynaptic inhibition.

625.8

ADENOSINE INHIBITS SYNAPTIC TRANSMISSION BY REDUCING THE PRESYNAPTIC CALCIUM INFLUX AT CA3-CA1 SYNAPSES OF GUINEA PIG HIPPOCAMPUS. J. G. Wu* and P. Saggau. Division of Neuroscience, Baylor College of Medicine, Houston, TX 77030.

Adenosine is an important regulator of excitatory transmitter release in the central nervous system and at the neuromuscular junction. Recent evidence suggests that adenosine presynaptically inhibits synaptic transmission. Such a presynaptic inhibition could result from either a reduction of voltage-dependent Ca²⁺ current or an inhibition of the transmitter releasing machinery downstream from Ca²⁺ influx. Using a technique to selectively load presynaptic terminals of CA3-CA1 synapses in hippocampal slices with the Ca²⁺ indicator fura-2, we investigated the effects of adenosine on both the presynaptic Ca²⁺ influx and the corresponding field EPSP (fEPSP) induced by a single electrical stimulation of the Schaffer collateral/commissural pathway. Application of 50 mM adenosine reduced the amplitude of the Ca²⁺ influx by 24 \pm 2% and the initial slope of the fEPSP by 73 \pm 5%. These effects were dose-dependent, partially occluded by the N-type Ca²⁺ channel blocker ω -conotoxin, mimicked by the adenosine A1 receptor agonist cyclopentyladenosine, and blocked by the A1 receptor antagonist 8-cyclopentyl-1,3-dipropylxanthine (DPCPX). DPCPX by itself enhanced both presynaptic Ca²⁺ influx and fEPSP, suggesting a tonic action of adenosine on synaptic transmission. We have demonstrated previously by applying the nonspecific Ca²⁺ channel blocker cadmium, that there is an approximately fourth power relationship between fEPSP and Ca²⁺ influx. Taken together, these results suggest that activation of presynaptic adenosine A1 receptors inhibits evoked transmitter release primarily by reducing the presynaptic Ca²⁺ influx.

625.9

BACLOFEN INHIBITS SYNAPTIC TRANSMISSION PRIMARILY BY REDUCING THE PRESYNAPTIC CALCIUM INFLUX AT CA3-CA1 SYNAPSES OF GUINEA PIG HIPPOCAMPUS. P. Saggau*, L.G. Wu and R.H. Thalman*. Division of Neuroscience & *Department of Cell Biology, Baylor College of Medicine, Houston, TX 77030.

The predominant inhibitory neurotransmitter in the hippocampus is γ -aminobutyric acid (GABA). Activation of presynaptic GABA_B receptors has been found to cause an inhibition of transmitter release. Two possible mechanisms may couple the activation of GABA_B receptors to the inhibition of transmitter release: 1) decrease of the presynaptic Ca²⁺ influx induced by the action potential, 2) inhibition of the transmitter release machinery downstream from the presynaptic Ca²⁺ influx. Following a selective loading of presynaptic terminals of CA3-CA1 synapses in hippocampal slices with the Ca²⁺ indicator fura-2, we investigated the effects of baclofen, a GABA_B agonist, on both the presynaptic Ca²⁺ influx and the corresponding field EPSP (fEPSP) induced by a single electrical stimulation of the Schaffer collateral/commissural pathway. Application of 50 μ M baclofen reduced the amplitude of the Ca²⁺ influx by 31 \pm 4% and the initial slope of fEPSP by 83 \pm 4%. These effects were: 1) dose-dependent, 2) partially occluded by the N-type Ca²⁺ channel blocker ω -conotoxin (0.5 μ M), and 3) blocked by the GABA_B antagonist CGP35348 (500 μ M). The relationship between the decrease of fEPSP and Ca²⁺ influx caused by baclofen followed about the same fourth power function as found by applying the voltage-dependent Ca²⁺ channel blocker cadmium. As it is unlikely that interneurons significantly contribute to the detected Ca²⁺ signals, these findings suggest that activation of presynaptic GABA_B receptors causes the inhibition of evoked synaptic transmission primarily by reducing the presynaptic Ca²⁺ influx.

MACROSCOPIC CURRENTS FROM HIPPOCAMPAL MOSSY FIBER PRESYNAPTIC TERMINALS. R. Gray*, Division of Neuroscience, Baylor College of Medicine, Houston, TX 77030

Little is known about the types of voltage-gated ion channels present in presynaptic terminals. We have approached this problem by studying the mossy fiber presynaptic terminal in the hippocampal formation. Their large size (3–8 μ m diameter) and location adjacent to the CA3 cell body region make them excellent candidates for biophysical analysis. We have used enzyme treatment, microdissection, and trituration to dissociate the CA3 area of the hippocampus from adult guinea pigs and isolate CA3 pyramidal neurons with attached mossy fiber terminals as well as single isolated mossy fiber terminals.

Totally isolated mossy fiber presynaptic terminals were identified with the carbocyanine fluorescent dye 3,3'-diethyloxadiazocarbocyanine iodide and those still attached to CA3 pyramidal neurons with the dye and by their position on the proximal apical dendrite of the neuron. Whole-terminal currents were measured using perforated-patch recording. We used high-potassium internal saline and HEPES-buffered artificial cerebral spinal fluid (aCSF) bath saline in these experiments to study the activity of potassium and sodium channels. Currents observed varied from single channels to small macroscopic currents.

A putative "A" current was recorded from 3 presynaptic terminals. This outward current was transient (half inactivation in 50 ms) and displayed steady-state voltage-dependent inactivation (50% inactivation near -60 mV). Inward sodium currents were recorded from 4 presynaptic terminals. Activation occurred at potentials positive to -60 mV from a holding potential of -80 mV, and peak inward currents occurred at -20 mV. Activation was half maximal at -32 mV with a steepness of 7.6 mV and half inactivation was at -80 mV with a steepness of -6 mV. (Supported by NIH NS29871 and MH44754.)

GABA_B RECEPTOR-INDEPENDENT PAIRED-PULSE DEPRESSION OF SYNAPTIC INHIBITION IN AREA CA3 OF THE RAT HIPPOCAMPUS. N.A. Lambert* and W.A. Wilson Dept. Pharmacology, Duke University Medical Center, Durham, NC 27705.

We have observed paired-pulse depression (PPD) of inhibitory postsynaptic currents (IPSCs) in CA3 pyramidal neurons that is not occluded by the GABA_A receptor agonist baclofen or blocked by the antagonist CGP 35348 (*J. Neurophysiol.* 69:630). When pairs of IPSCs were evoked (in the presence of DNQX, APV and 1mM CGP 35348) at intervals of 15ms-4s the second response was depressed by ~20%. This depression was not due to a shift in E_{rev}, and was not blocked by naloxone (10 μ M) or phorbol-12,13-didecylate (10 μ M). It was, however, reversibly attenuated by increasing external Mg²⁺ from 1 to 5mM.

In separate experiments IPSCs were evoked by minimal stimulation. Minimal IPSCs were evoked at stimulus intensities that occasionally failed to evoke a response, had amplitudes that fluctuated and were similar to the amplitude of spontaneous IPSCs, and were completely and abruptly blocked by TTX (1 μ M). Minimal IPSCs, which presumably resulted from activation of single inhibitory fibers, also displayed GABA_A receptor-independent PPD. Unexpectedly, minimal IPSCs were unaffected by baclofen or CGP 35348 in many of these experiments, despite a coincident reversible depression of spontaneous IPSC amplitude and frequency.

These results suggest that, in addition to PPD resulting from activation of presynaptic GABA_B receptors, a separate mechanism produces PPD of synaptic inhibition in the hippocampus. In addition, the release of GABA from some inhibitory synapses is apparently not regulated by GABA_A receptors. Supported by the VA, NS-17771 and MH-15177-15.

TIME COURSE OF POTENTIATION OF SYNAPTIC INPUTS IN RAT MOSSY CELLS. B.W. Strowbridge* and P.A. Schwartzkroin. Dept. of Neurological Surgery, University of Washington, Seattle, WA.

Mossy cells, the major cell type in the rat dentate hilus, receive strong excitatory input from collaterals of granule cell axons enroute to the CA3 region of hippocampus. We and others have demonstrated that spontaneously-active granule cell axons generate the spontaneous, large-amplitude EPSPs that are observed frequently in mossy cells. We also observed that strong depolarization of a single mossy cell can potentiate these EPSPs for periods lasting several minutes.

We now extend these findings by demonstrating that this form of potentiation, as well as potentiation evoked by repetitive perforant path stimulation, have a common, stereotyped time course. We quantified spontaneous EPSPs by measuring membrane potential variance in 1 sec. windows of a continuously-sampled record, filtered to remove action potentials. We found that 2-3 minute periods of depolarizing current pulses (approximately 1 nA, 300 ms on, 400 ms off) often triggered a transient period of potentiation, which built up over a period of 30-60 seconds. The peak variance reached was consistent between trials and was similar to the maximum variance attained during "spontaneously-occurring" potentiation epochs. The period of maximal potentiation ranged from a few seconds to minutes, then decayed at a rate usually slower than during the onset. A similar time course was observed after a 30 second period of 2 Hz perforant path stimulation. Short periods of potentiation (lasting a few seconds) also were observed following interictal discharges in CA3. These findings suggest that potentiated EPSPs may reflect a common mode of circuit activity in the dentate that can be triggered by a variety of excitatory inputs.

IS THE LONG LASTING INFLUENCE ON REFLEX EXCITABILITY RELATIVE TO PRESYNAPTIC ACTIVATION HISTORY PRODUCED BY GABA_B-MEDIATED PRESYNAPTIC INHIBITION? F.J. Thompson*, R. Parmer*, R.G. Fessler*. Depts. of Neuroscience¹, Neurosurgery², Univ. of Florida Brain Institute, Gainesville, Florida 32610-0244

We recently reported a decrease in rate-sensitive depression of lumbar monosynaptic reflexes (MSRs) subsequent to midthoracic spinal injury (Thompson *et al.*, 1992; 1993). The reflex magnitudes produced by repetitive sensory inputs were 250% increased over those in normal animals. These changes emphasize basic questions regarding fundamental mechanisms which regulate reflex excitability. To identify a more specific neurosubstrate essential for the expression of rate-depression we analyzed tibial MSR excitability before and following pharmacologic stimulation or blockade of specific receptors in ketamine anesthetized adult rats. Intrathecal application of a specific GABA_B agonist (-L-baclofen) to the L₅ spinal cord resulted in an increase in rate-depression of 250%. In contrast, following intrathecal application of 50 μ g of a specific GABA_B antagonist (CPG-35348, CIBA-Geigy) to the L₅ spinal cord, decreased rate-sensitive depression of tibial monosynaptic reflexes (MSRs) resulted in 10 Hz MSRs that were 250% larger than observed in the pretreatment controls. Intraspinal injection using micropipettes to deliver < 5 μ g CGP-35348 resulted in more robust changes with a faster time course of onset. These data support the conclusion that reflex excitability is modulated by a GABA_B-mediated rate-depression of reflex magnitude relative to activation history. These preliminary findings indicate that focal application of a specific GABA_B antagonist produced changes which mimicked, in part, those observed subsequent to thoracic cord lesions. DYNAMIC INTERCONVERSION BETWEEN TONIC AND TRANSIENT RELEASE OF GABA IN CULTURED RAT HIPPOCAMPAL NEURONS.

J. Vautrin*, A.E. Schaffner and J.L. Barker.

Lab. of Neurophysiology, NINDS, NIH, Bethesda, MD 20892.

18 day-old embryonic rat hippocampal neurons cultured for 3-20 days were clamped with CsCl patch pipettes. Transient synaptic currents and random baseline fluctuations reversed at E_{Cl}⁻, were blocked by bicuculline and exhibited the identical channel kinetics, indicating the presence of both tonic and "quantal" forms of GABA release in these cultures. Transient synaptic signals are traditionally ascribed to the release of transmitter quanta preformed in vesicles, while tonic, random activations of synaptic receptors have been interpreted as a "non-vesicular" form of neurosecretion. Remarkably, rapid conversions from tonic to transient or from transient to tonic GABA_A receptor-coupled Cl⁻ channel activity were recorded in these neurons during experimental conditions that are known to modify internal Ca²⁺ homeostasis like the addition of Zn²⁺, or ionomycin or tetrodotoxin (TTX) or depolarizing the presynaptic neuron. These experimental treatments also changed the amplitude and time course properties of the Cl⁻ transients in the presence of TTX. These results suggest that pulsatile release of GABA, rather than representing the release of preformed quanta, might be directly driven by intracellular, quantal transient increases in the local Ca²⁺ concentration supplied by extracellular and/or internally-stored Ca²⁺.

625.15

ATP TRANSMITS SYNAPTIC RESPONSES AND STIMULATES INTERNAL Ca INCREASE IN RAT CULTURED HIPPOCAMPAL NEURONS. K. Inoue*, K. Nakazawa, S. Koizumi, T. Watano, T. Obama, K. Fujimori & A. Takanaka. Division of Pharmacology, National Institute of Health Sciences, 1-18-1 Kamiyoga, Setagaya, Tokyo 158, Japan.

We have reported that ATP directly activates small sustained currents, and indirectly transient currents, presumably by evoking glutamate release in rat cultured hippocampal neurons (Neurosci. Lett., 134, 215, 1992). Here we show the synaptic currents transmitted by ATP using whole-cell recordings and mutual connections between ATP- and glutamate-neurons using the fura-2 method. A subpopulation of cultured neurons evoked repetitive inward currents (-10 to -380 pA at -60 mV of a holding potential). They were abolished in low-Ca (100nM) buffer, and were decreased to the level of miniatures in the presence of 3 μ M tetrodotoxin. These currents were blocked reversibly by ATP-receptor blockers, suramin (100 μ M), reactive blue 2 (RB2, 100 μ M) and α , β -methylene ATP (100 μ M). ATP (10 μ M) also increased internal Ca which was blocked by suramin (100 μ M) or RB2 (100 μ M). These data suggest that ATP has a role of synaptic transmission with internal Ca increase in rat cultured hippocampal neurons.

GTP γ S BLOCKS SYNAPTIC RELEASE OF GLUTAMATE AT RAT HIPPOCAMPAL SYNAPSES IN CULTURE. P. S. Jackson*, K. M. Harris, and L. L. Benowitz, Departments of Neurosurgery and Neurology, Children's Hospital and Program in Neuroscience, Harvard Medical School, Boston, MA 02115.

Non-hydrolyzable guanine triphosphate analogs have been shown to alter regulated exocytosis in a variety of cellular systems such as mast cell degranulation and to alter synaptic release at the squid giant terminal² through their effects on a small G-protein. The present study was designed to test the role of small G-proteins in exocytosis at mammalian central nerve terminals. Whole cell recordings were made from pairs of synaptically coupled neurons in tissue culture. Guanine nucleotide analogs were introduced into the presynaptic cell and allowed to diffuse down the axon to the presynaptic terminal. When GTP γ S (1mM) was included in the presynaptic patch pipette solution, the magnitude of the postsynaptic response began to decline ~8-10 minutes following the initiation of whole cell access. Within five minutes following the beginning of the decline, there was no detectable post-synaptic response following presynaptic stimulation. This pattern of inhibition was mimicked by GppNHp (1mM) but not by GTP (0.5mM) nor by the inclusion of F⁻ in the patch solution (135mM). These results suggest that the cycling of a small G-protein at the presynaptic terminal is necessary for synaptic release. The failure of F⁻ to block release argues against the involvement of a large, heterotrimeric G-protein in this inhibition. We are currently evaluating whether there is a morphological correlate of this inhibition by using electron microscopy to examine the vesicle distribution in affected nerve terminals. In addition we are evaluating approaches to selectively manipulate specific G-proteins.

PRIMING OF GLUTAMATE RELEASE PERSISTS FOLLOWING REMOVAL OF PHORBOL ESTER AND IS CALMODULIN-INDEPENDENT. D.M. Terrian*, C.M. Manning, D.K. Wasy¹, and D.A. Zetts. Depts. Anatomy and Medicine, East Carolina University School of Medicine, Greenville, NC 27858.

The K⁺-evoked release of endogenous glutamate, but not opioid peptides, from isolated hippocampal nerve endings (synaptosomes) is significantly enhanced following the sustained activation of protein kinase C (PKC). Although a phorbol ester (phorbol 12,13-dibutyrate, PDBu) was used to sustain PKC activation, the selective enhancement of glutamate release persisted for at least 20 min after the complete removal of PDBu (Terrian et al., *Hippocampus* 3:205-220, 1993). In contrast to the acute effects of PDBu, sustained PKC activation lead to an enhancement of the slow phase of glutamate release that was no longer sensitive to PKC inhibitors. This effect of PDBu cannot be attributed to a reduction in membrane potential, since PDBu pretreatment did not alter the Ca²⁺-independent component of K⁺-evoked release. Moreover, this novel effect of PDBu displayed a strict requirement for localized Ca²⁺ entry, increasing glutamate release evoked by depolarization but not the Ca²⁺ ionophore, ionomycin. A plausible explanation for these results might be that PDBu-induced phosphorylation of calmodulin (CaM)-binding substrates of PKC could enhance the release of glutamate through the phosphorylation-induced liberation of free CaM and activation of CaM kinase II. However, three lines of evidence argue against the involvement of such a PKC-CaM kinase II "cross-talk" mechanism: 1) enhancement of glutamate release is not diminished under conditions which do not support CaM kinase II activity in intact synaptosomes, equimolar of BaCl₂ for CaCl₂; 2) the level of cytosolic free CaM is not altered in synaptosomes following pretreatment with PDBu and its removal; and 3) the level of autonomous CaM kinase phosphotransferase activity is not altered following an identical pretreatment with PDBu. Thus, the persistent activation of synaptosomal PKC selectively primes the glutamate release apparatus to respond to localized Ca²⁺ entry by a CaM-independent mechanism.

ENDOCYTTIC UPTAKE OF GLUTAMATE BY CHOLINERGIC GROWTH CONES ENABLES ESTABLISHMENT OF GLUTAMATERGIC SYNAPTIC TRANSMISSION. Y. Dan*, H.-j. Song, R. Wong and M.-m. Poo. Dept. Biol. Sci., Columbia University, N.Y., N.Y. 10027. +SUNY Hlth. Sci. Ctr. at Brooklyn.

Growth cones of cholinergic spinal neurons from *Xenopus* embryos rapidly establish functional synapse with co-cultured myotomal myocyte after growth cone-myocyte contact, as shown by immediate appearance of spontaneous and nerve impulse-evoked synaptic currents in the contacted myocyte. In the present study, these cholinergic neurons were incubated in a medium containing 60 mM of glutamate for 30 min and their growth cones were tested for the ability to establish functional synaptic transmission using glutamate as transmitter. Acutely dissociated hippocampal pyramidal neurons were isolated from CA1 regions of adult rat hippocampi by the method of Kay and Wong (J. Neurosci. Methods, 16, 227, 1986), and whole-cell clamped before manipulated into contact with the growth cone of glutamate-incubated *Xenopus* cholinergic neurons. Spontaneous synaptic currents were observed in many of the neurons tested. Pharmacological evidence suggests these currents were induced by glutamate secretion from the incubated neurons. The currents exhibited a skewed amplitude distribution in the range of 10 to 200 pA, similar to that observed for the ACh secretion from same neurons and for glutamate secretion from other glutamatergic terminals. Impulse-evoked synaptic currents were also detected in some cases, but repetitive presynaptic stimulation resulted in rapid depression of the evoked release. Taken together, these results suggest (1) direct topological relationships between endocytic pathways and transmitter secretion pathway in the growth cone of developing neurons, and (2) phenotypic transformation of neuronal types using different transmitter molecules may involve little more than a supply of transmitters and transporter proteins for vesicular accumulation of the transmitter.

625.18

MULTIPLE VESICULAR RELEASE OF TRANSMITTER FROM HIPPOCAMPAL NEURONS. G. Tong* and C. E. Jahr. Vollum Institute, Oregon Health Sciences University, Portland, OR 97201.

Transmitter is thought to be released in quantal units by vesicular exocytosis but it is unclear how many vesicles can be released simultaneously from a single bouton. If more than one vesicle is released, the peak concentration of free transmitter in the synaptic cleft and the time during which it is elevated above an effective concentration will increase. We have monitored the concentration time course of synaptically released transmitter in conditions of low and high release probability by measuring the percent inhibition of the NMDA receptor component of the epsc in cultured hippocampal neurons produced by the low affinity competitive antagonist, L-AP5 (Clements et al., *Science* 258:1498,1992). If transmitter remains elevated for longer periods, less inhibition will result because more receptors will become available for transmitter binding as antagonist dissociates. In the presence of 3 mM extracellular Ca²⁺, the amount of block of NMDA epscs by L-AP5 (400 μ M) (46.2 \pm 3.3%) was significantly less than that in the presence of 1 mM Ca²⁺ (59.6 \pm 2.2%; n=7, p<0.0001, paired t-test). The percent inhibition of whole-cell NMDA responses by L-AP5 was unaffected by extracellular [Ca²⁺] (1-3 mM; n=6). The amount of block of NMDA epscs by L-AP5 was also reduced when 4-AP (300 μ M) was used to increase the release probability (57.3 \pm 3.3% in the presence of 4-AP, 70.8 \pm 1.8% in control, n=5, p=0.0033). Furthermore, when paired-pulse facilitation of NMDA epscs was induced, inhibition of the second NMDA epsc by L-AP5 (54.9 \pm 3.5%) was less than that of the first epsc (62.9 \pm 3.3%; n=6, p=0.0013). AMPA receptor component of the epsc remained the same in the presence and absence of L-AP5 (n=5) indicated that L-AP5 has no effect on presynaptic release. These data suggest that multiple vesicular release of transmitter occurs in the central synapse. Supported by NIH grant NS21419.

CALCIUM INDUCES VESICULAR GLUTAMATE RELEASE FROM PERMEATED SYNAPTOSOMES. J.L.H. Hens, W.E.J.M. Ghijsen*, W.H. Gispen and P.N.E. De Graan*. Rudolf Magnus Inst., Vondellaan 6, 3521 GD Utrecht, and *Exp. Zoology, Amsterdam, the Netherlands.

Glutamate (glu) is the most important excitatory transmitter implicated in long-term potentiation (LTP). To unravel the presynaptic mechanisms leading to enhanced glu release during LTP, fundamental knowledge about the molecular mechanisms underlying recruitment, docking and fusion of glu-containing small clear-cored vesicles is required. Therefore, we developed a permeated synaptosome preparation, which enables us to introduce macromolecules and to study their effects on Ca²⁺-induced glu release. Highly purified synaptosomes were permeated with streptolysin-O (SLO) and glu release was measured in supernatant samples by HPLC. Ca²⁺/EGTA buffers were used to control [Ca²⁺]_i. Increasing [Ca²⁺]_i from 10⁻⁸ M (basal level) to 3x10⁻⁵ M induced a release of 2 nmol glu/mg of synaptosomal protein. This Ca²⁺-induced glu release is clearly from vesicular origin, because it was completely inhibited by tetanus toxin light chain (300 nM). Ca²⁺-induced glu release is measured on top of a basal cytosolic efflux of glu (at 10⁻⁴ M Ca²⁺), which is about 55% of the total glu content. Significant stimulation of vesicular glu release was observed at [Ca²⁺]_i \geq 3x10⁻⁶ M, and maximal at 3x10⁻⁵ M. The maximal amount of glu released from permeated synaptosomes is about the same as Ca²⁺-dependent K⁺-induced glu release from intact synaptosomes. The Ca²⁺ sensitivity of glu release from SLO-permeated synaptosomes (EC₅₀ ~10⁻⁵ M) does not markedly differ from that of noradrenaline and cholecystokinin-8 release from the same preparation. Ca²⁺-induced glu release was not inhibited by protein kinase C (PKC) inhibitors PKC₁₉₋₃₆ (3x10⁻⁵ M) and H-7 (10⁻⁴ M), whereas polymyxin B (200 IU/ml) blocked it completely. At these concentrations all three compounds inhibited the phosphorylation of the nervous tissue-specific PKC substrate B-50/GAP-43 in SLO-permeated synaptosomes. Our data show that the SLO-permeated synaptosome system is suitable to study vesicular glu release, and indicate that PKC activation and PKC-mediated B-50 phosphorylation are not involved in steps in the mechanism of glu release after the Ca²⁺ trigger.

MEASUREMENT OF GLUTAMATE RELEASE FROM HIPPOCAMPAL SLICES WITH MICROSCOPIC PHOTON-COUNTING DETECTION SYSTEM L. Li, M. Arnold, R. Malinow*

Departments of Chemistry and Physiology & Biophysics, U. of Iowa.

Glutamate is the major excitatory neurotransmitter in the vertebrate central nervous system. The long-term goal of this project is to develop a chemical sensor capable of real-time detection and quantification of glutamate during its release from neurons. A bicatalytic/chemiluminescence reaction sequence using glutamate oxidase and horseradish peroxidase has been developed in which light is generated in the presence of glutamate. The light is monitored by a microscopic photon-counting detection system. Millisecond temporal resolution and micromolar detection limit have been obtained based on this sensing system. A calcium-dependent release of glutamate has been successfully measured during potassium depolarization of rat hippocampal slices. This sensing approach will be used to measure glutamate transients during electrical stimulation of rat hippocampal slices. The kinetics of the signal may provide an estimate of the distance between the enzymatic sensor and the site of glutamate release and thereby allow an estimate of peak glutamate concentration at the synaptic cleft during synaptic transmission. Changes in transmitter release after different perturbations such as LTP may also be monitored.

POSTSYNAPTIC MECHANISMS II

626.1

REGULATION OF AN NMDA-MEDIATED EPSP BY A SLOW DENDRITIC GABA_A-MEDIATED IPSC IN PIRIFORM CORTEX. A. Kapur*, R.A. Pearce and L.B. Haberly. Neuroscience Training Program and Departments of Anatomy and Anesthesia, Univ. of Wisconsin, Madison, WI 53706.

The observation that blockade of GABA_A-mediated inhibition is necessary for the induction of associative LTP in piriform cortex (Kanter & Haberly, J. Neurosci., in press) has prompted study of the regulation of NMDA-mediated EPSPs by inhibitory processes. As previously reported (Kapur et al, Soc. Neuro. Abs. 18:1497), blockade of GABA_A receptors by bath applied bicuculline (BIC) resulted in a large increase in the NMDA component of the response to burst stimulation of afferent fibers (4 pulses at 100 Hz). Subsequent study has revealed that local application of BIC in the distal dendritic region facilitated the NMDA component whereas BIC application at the soma did not. Dendritically applied BIC had little or no effect on the large feedback IPSP evoked by stimulation in the association fiber layer that was blocked by somatic application. This suggests the presence of a previously unrecognized GABA_A-mediated IPSP in the dendritic region that is mediated by a feedforward pathway. One factor that could contribute to the stronger action of the dendritic than somatic IPSP on release of the NMDA component is spatial proximity; however the recent demonstration of fast and slow Cl⁻ mediated IPSPs in hippocampus (Pearce, Neuron 10:189, 1993) suggests that differences in the duration of dendritic and somatic IPSCs could also contribute. To test this hypothesis, timecourses of GABA_A-mediated IPSCs evoked by stimulation in layer Ia (distal dendrite-afferent fiber zone) and layer II-deep Ib (proximal dendrite-cell body zone) were compared. IPSCs were isolated by addition of DNQX (20 μM) and D-APV (15 μM) to the bath (to block EPSPs) and 5 mM QX-314 to the recording pipette (to block the GABA_A-mediated IPSC). Whole-cell recordings were obtained under voltage clamp. Time courses of decay of IPSCs evoked at both depths were best fit with the sum of 2 exponentials with time constants of 8-16 ms and 30-80 ms (28°C). However, the slow component was significantly (p<0.005) larger from layer Ia than from layer II stimulation (relative amplitude of slow component: 54±6.9(SE)% n=4, for Ia vs 21±5.5%, n=8, for II). This suggests that the slower time course of the dendritic IPSC may contribute to its ability to strongly regulate the NMDA component. Supported by NS19865 (LBH) and NS01548 (RAP).

DIFFERENCES BETWEEN SPONTANEOUS INHIBITORY POSTSYNAPTIC CURRENTS (sIPSCs) RECORDED IN GRANULE CELLS AND HILAR NEURONS OF THE DENTATE GYRUS. I. Soltesz* and J. Mody. Depts. of Anesthesiology & Neurology, UT Southwestern Med. Ctr., Dallas, TX.

Recordings with sharp microelectrodes have failed to demonstrate notable sIPSCs in hilar neurons (HNs). Yet, receptor binding and molecular biological studies have clearly identified GABA_A receptors on HNs, and morphological investigations have revealed a specific GABAergic innervation of HNs.

We have examined characteristics of sIPSCs in HNs using whole-cell voltage-clamp recordings in standard 400 μm thick horizontal adult rat brain slices maintained at 35-36°C. All recordings were done in the presence of the glutamate receptor antagonists CNQX (10 μM) and D-APV (40 μM). The frequency of sIPSCs recorded in this manner in HNs in symmetrical Cl⁻ was between 15-50 Hz, comparable to that found in granule cells (GCs). The decay kinetics of sIPSCs in HNs were examined, and the single channel conductance together with the number of active subsynaptic GABA_A receptor channels were determined by non-stationary noise analysis. Consistent with different molecular subunit assemblies of subsynaptic GABA_A receptor channels, HNs differed from GCs in having a 24% longer decay time constant and a 22% smaller single channel conductance. The average number of subsynaptic GABA_A receptor channels contributing to sIPSCs were similar in GCs and HNs. Cell attached recordings of K⁺ channel activity were performed to ascertain the relationship between the resting membrane potential (MP) and E_{Cl} in HNs and GCs. A change in the MP following bath application of GABA or muscimol should be reflected in the altered size of K⁺ channel openings. Invariably, GCs were depolarized (15-25 mV) by GABA_A receptor agonists, whereas HNs responded with either a small change in the MP (<5 mV) or a GC-like depolarization. No significant GABA-induced hyperpolarizations were noted in HNs.

FUNCTIONAL DIVERSITY OF GABA-ACTIVATED CURRENTS IN PURKINJE VERSUS GRANULE NEURONS IN RAT CEREBELLAR SLICES. G. Puia*, E. Costa, and S. Vicini, FGIN, Georgetown Univ., Washington DC.

In rat cerebellar slices, we compared spontaneous inhibitory postsynaptic currents (sIPSCs) to Cl⁻ currents produced by the fast application (<0.2 ms) of GABA pulses to outside-out membrane patches excised from Purkinje and granule neurons. We used whole-cell recording with a symmetrical Cl⁻ solution and after blockade of excitatory synapses with excitatory amino acid receptor antagonists. sIPSCs had largely variable peak amplitude and were reduced in frequency and amplitude by TTX (1 μM) and abolished by bicuculline methiodide (10 μM). In 42 granule neurons, sIPSCs had a rise time of 0.6 ± 0.3 ms (mean ± SD of the average of 50 events/cell) while in 49 Purkinje cells sIPSCs had a rise time of 1.5 ± 0.7 ms. At a holding potential of -60 mV, average sIPSCs in Purkinje cells decayed with a single exponential curve with a time constant (τ) of 17 ± 6.5 ms, while in granule cells sIPSCs' decay was best described by the sum of two exponential curves with a fast τ of 7 ± 1.6 ms and a slow τ of 59 ± 16.8 ms; the contribution of the slow component to the peak current ranged from 15 to 100%. The fast application of a brief pulse of GABA (1 mM) to 9 patches excised from granule cell elicited rapidly rising Cl⁻ currents with decay best described by the sum of two exponential with a fast τ of 3 ± 1.8 ms and a slow τ of 102 ± 48 ms. In 6 outside-out patches from Purkinje neurons the decay of the currents produced by fast GABA application was described by a double exponential curve with a large preponderance of a fast τ of 5.1 ± 2.3 ms and the presence (<10%) of a slow τ of 95 ± 36 ms. The fast decay of GABA-activated Cl⁻ currents in excised patches could be related to the presence of a fast component of desensitization produced by the sustained application of 1 mM GABA. These results demonstrate distinct functional properties of GABA receptors Cl⁻ channel complexes perhaps related to the large heterogeneity in the molecular assembly of subunits forming various GABA_A receptor subtypes. Supported by NIH grant R01 MH49486-01A1.

RECEPTOR SATURATION, CHANNEL KINETICS, AND THE APPLICABILITY OF NOISE ANALYSIS DETERMINED THROUGH MODELING OF QUANTAL SYNAPTIC CURRENTS. Y. De Koninck* and J. Mody. ¹Dept. Neurology & Neurological Sci., Stanford Univ., Stanford, CA, and ²Depts. of Anesthesiology & Neurology, UT Southwestern Med. Ctr., Dallas, TX.

The method of non-stationary noise analysis (Sigworth, *J. Physiol.* 307:97, 1980; *Biophys.J.* 35:289, 1981) can be used to extract information about the properties of single channels underlying synaptic currents (Robinson et al. *Biophys.J.* 59:295, 1991). However, the technique relies heavily on the appropriate scaling of ensemble averages to individual synaptic currents. The large intrinsic variance that occurs at different phases of a given synaptic current (Faber et al. *Science* 258:1494, 1992) may preclude proper scaling of the ensemble averages and lead to systematic errors.

We used stochastic simulation of synaptic currents to determine the relationship between the kinetic properties of subsynaptic channels and the resulting intrinsic variance during the time-course of unitary synaptic currents. We estimated the accuracy of the noise analysis in evaluating the properties of channels underlying synaptic currents that were generated with different kinetic properties and receptor saturation.

The accuracy of the non-stationary noise analysis was mainly dependent on the relationship between the onset kinetics of the current and the open times of subsynaptic receptor channels but not on receptor saturation. For currents with rapid onset, accurate estimates of the properties of subsynaptic channels could be obtained even at low levels of saturation. Moreover, the level of saturation of the underlying receptor channels could be resolved by spectral analysis. Thus, such analysis appears more appropriate for the study of synaptic currents with rapid kinetics of onset (e.g., AMPA, GABA_A) than for slower onset synaptic currents (e.g., mediated by NMDA receptor channels; see Edmonds & Colquhoun, *Proc. Roy. Soc. Lond. B* 250:279, 1992).

EVOKED SHIFTS IN EXTRACELLULAR pH, BICARBONATE AND CO₂ IN RAT HIPPOCAMPAL SLICES. *M. Chesler* & J.C.T. Chen.* Dept. Physiol. & Biophys./Dept. Neurosurg., NYU Med. Ctr., 550 First Ave., NY, NY 10016.

To elucidate the nature of synaptically evoked extracellular pH (pH_o) shifts (1), we determined the dynamics of extracellular bicarbonate ([HCO₃]_o) and CO₂ in the CA1 region of rat hippocampal slices, using pH and CO₃⁼ microelectrodes (2). Baseline & evoked acidosis (stim. of Schaffer collaterals, 20 Hz, 5 s) were due entirely to elevation of PCO₂. Baseline pH_o was 7.14 ± 0.078 (mean ± SD, n=90 trials in 17 slices) with a PCO₂ of 78 ± 18 torr. Evoked acid shifts & associated increases in PCO₂ averaged 0.062 ± 0.01 pH units/12 ± 6.0 torr (n=17). The early alkaline shift (0.059 ± 0.025 pH units, n=76) was associated with a [HCO₃]_o rise of 0.98 ± 1.32 mM & PCO₂ fall of 7.0 ± 6.1 torr. Picrotoxin (PTX) had no consistent effect on [HCO₃]_o & PCO₂ transients. In the presence of the carbonic anhydrase (CA) inhibitor benzolamide, the alkaline shifts were amplified 5-fold (1), however, the calculated [HCO₃]_o paradoxically decreased by 4.99 ± 4.53 mM, suggesting that in the absence of catalyzed HCO₃⁻ formation, a HCO₃⁻ uptake mechanism was unmasked. In a smaller number of untreated slices, stimulus-evoked decreases in [HCO₃]_o were also sometimes noted, suggesting a transient CO₂/HCO₃⁻ disequilibrium under "normal" conditions. Thus, the amount of extracellular CA may be insufficient to insure maximum buffering of rapid base loads. Indeed, recordings with pH/CO₃⁼ and CO₂ electrodes indicated that the equilibrium-based Henderson Hasselbach equation does not hold in many instances of repetitive stimulation. Extracellular buffering power is therefore a time-dependent variable in the brain extracellular space, which may depend on the degree of synchronous synaptic activity. MORPHOELECTROTONIC TRANSFORMS IN THREE CLASSES OF RAT HIPPOCAMPAL NEURONS. *K.Y. Tsai^{1,3}, N.T. Carnevale^{1,3}, B.J. Claiborne⁴, and T.H. Brown¹⁻³.* Depts. of Psych.¹ and Cell. & Mol. Physiol.², the Center for Theoretical and Applied Neuroscience³, Yale Univ., New Haven, CT 06520 and Div. of Life Sci.⁴, Univ. of Texas at San Antonio, San Antonio, TX 78285.

We compared the electrotonic structure of three classes of rat hippocampal neurons by applying morphoelectronic transforms (METs) [Brown et al, 1992. In: *Single Neuron Computation*] to realistic compartmental models [Claiborne et al, *op. cit.*]. This generates an intuitive graphical display of voltage or current/charge attenuation [Carnevale & Johnston, *J. Neurophysiol.* 1982] by recasting the branched architecture of the cell using branch lengths proportional to the logarithm of the attenuation for each segment.

The METs disclosed several facts about these cells. First, voltage attenuation is asymmetric (worse for signal transfer toward the soma (V_{in}) than away from it (V_{out})). Second, significant voltage attenuation for V_{in} occurs along major processes, even at DC and low frequencies (~5 Hz). Third, voltage attenuation in both directions worsens rapidly as frequency increases. Fourth, the V_{in} and V_{out} METs of dentate granule cells are comparable to METs of the basilar dendrites of CA1 and CA3 pyramidal neurons, although granule cells have a simpler branching pattern. Finally, V_{out} METs of the apical dendritic trees of CA1 and CA3 neurons are qualitatively different. CA1 neurons appeared to have one or two long main trunks with many short side branches; whereas in CA3 neurons the ramifications were more equal in length. The CA1 neurons had a greater overall electrotonic length.

We conclude that the MET is a useful approach to understanding comparative electrotonic structure. Supported by ONR, ARPA & CTAN.

CABLE PROPERTIES AND MORPHOLOGY OF LATERODORSAL TEGMENTAL (LDT) NEURONS IN VITRO. *A. Surkis*, B. Taylor, C. Peskin and C.S. Leonard.* Center for Neural Science, New York University, 6 Wash. Pl., NY, NY 10003.

Considerable evidence supports a role for brainstem cholinergic neurons of LDT in controlling the alternation between rapid eye movement and slow wave sleep. Since an understanding of the integrative properties of these cells is necessary to further elucidate this role, we have investigated the passive membrane properties of guinea pig LDT neurons with intracellular recordings in a brain slice preparation. Electrophysiological data were obtained by direct current injection using long (300msec, -0.5nA) and short (1msec, -1nA) pulses. Morphological data were obtained by computer reconstruction of the same neurons after biocytin injection and DAB visualization. The studied cells (n=5) were presumed to be cholinergic due to the correspondence of their physiology with that of LDT type II cells of which 93% (n=60) were identified as cholinergic based on NADPH-diaphorase histochemistry. Analysis of dendritic shape revealed the cells to be poor candidates for an equivalent cylinder approximation. Specifically, electrotonic lengths of the branching paths of a given dendrite were highly variable, dendrite diameter was non-uniform, and branching deviated from the Rall 3/2 power law, particularly for higher order branches. As a result, a numerical solution of the cable equation for cells of arbitrary geometry was implemented and solved for each of the filled cells. This solution does not assume a square pulse stimulus, so a more varied data set can be used. Cable parameters were determined by choosing values which produced the best fit to the recorded voltage traces. Synaptic inputs will be included in the model to investigate the integrative properties of the cells. Supported by NS27881.

SYNAPTIC MECHANISM OF STIMULATION-INDUCED ALKALINE pH SHIFTS IN THE RAT HIPPOCAMPAL SLICE. *K. Kaila*, P. Paalasmaa, T. Taira and J. Voipio.* Departments of Zoology and Physiology, P.O. Box 17, SF-00014 Univ. Helsinki, Helsinki, Finland.

The synaptic basis of stimulation-evoked alkaline transients was studied in rat hippocampal slices (300-400 um) kept in an interface chamber. The interstitial pH was recorded in the pyramidal layer of area CA1 using double-barrel H⁺-selective microelectrodes. Stimulus trains (10-100 Hz) with a constant number (100) of pulses or with a constant duration (5-10 s) were applied to the Schaffer collaterals. Inhibition of extracellular carbonic anhydrase (CA) activity by benzolamide (BA) or protosil-dextran 5000 (PD 5000) was used to distinguish between HCO₃⁻/CO₂-dependent (GABA_A receptor-mediated) and H⁺-dependent (glutamatergic) alkaline shifts: the former are known to be inhibited, and the latter enhanced, upon CA_v inhibition. Regardless of the number of stimuli applied, alkaline shifts evoked by stimulation at a relatively low frequency (5-10 Hz) were enhanced by BA and by PD 5000, and they were not blocked by picrotoxin (PTX). In sharp contrast to this, the alkaline shifts induced by trains of 100 pulses applied at 50-100 Hz were attenuated by BA, PD 5000 and by PTX. We conclude that the relative contributions of glutamate and GABA_A receptor-mediated effects to activity-induced alkaline shifts depend on the pattern of stimulation. In particular, the GABA_A-mediated component dominates initially in trains given at a high frequency. The results also suggest that, even when elicited using low-frequency stimulation, the alkaline shift is not solely attributable to excitatory synaptic activity. This view gains support from the finding that, in the presence of 100 uM pentobarbital, the alkaloses evoked by 5-10 Hz trains were attenuated following CA_v inhibition. Taken together, our observations fit well with the excitatory and inhibitory synaptic circuitry of the CA1 region and with the fatigue properties of GABAergic transmission.

ESTIMATING VOLTAGE-DEPENDENT CONDUCTANCE PARAMETER VALUES FOR DENTATE GRANULE CELL MODELS. *W.R. Holmes*.* Neurobiology Program, Dept. of Biological Sci., Ohio U., Athens, OH 45701.

Models that include voltage-dependent ionic conductances need values for parameters used in the equations that describe the conductances. These values are usually determined by "trial and error" or an exhaustive stochastic search scheme. However, selecting values (i.e., gbars) for conductances in dendrites is difficult. Spruston and Johnston (1992) and Staley et al. (1992) report that input resistance (R_N) and τ₀ are larger at depolarized potentials in dentate granule cells. These data and voltage-dependent conductance descriptions modified from Yuen and Durand (1991) were used in a model of a dentate granule cell to constrain estimates of dendritic conductance values.

When voltage-dependent conductances were restricted to the soma, R_N and τ₀ were only slightly larger at depolarized potentials. To match the experimental data, soma conductance would have had to increase 10-fold for a 10 mV subthreshold change in potential. No acceptable soma conductance gbar values could be found to do this.

When voltage-dependent conductances were included on the dendrites, much larger changes in R_N and τ₀ were obtained at depolarized potentials. When soma gbar values were fixed and dendritic conductance distributions were uniform, dendritic conductance gbar values could be found to produce the same magnitude of R_N and τ₀ changes at depolarized potentials as observed experimentally.

Different conductance kinetics or adding other conductances could affect these results. However, if the model conductance descriptions have a solid experimental basis, data for R_N and τ₀ at different potentials allow one to constrain estimates of gbar values in the dendrites. Of course such estimates will be non-unique, especially if conductance distributions are non-uniform.

626.10

DOSE ACTIVATION OF CALCIUM-DEPENDENT CHLORIDE CHANNEL CAUSE POST-TETANIC DEPOLARIZATION IN RABBIT PARASYMPATHETIC NEURONS? *M. Ishimatsu, T. Nishimura, T. Tokimasa* and T. Akasu.* Dept. of Physiol., Kurume Univ. Sch. of Med., Kurume 830, Japan

Intracellular recordings were made from neurons in rabbit parasympathetic ganglia on surface of the urinary bladder *in vitro* at 36 ± 1 °C. Direct action potentials were evoked by brief (4-20 ms) cathodal current injection (0.1-1 nA) through a recording electrode. Cells were classified into two groups regarding the duration of afterhyperpolarization (AHP) of spikes. In a majority of neurons tested (n=250), a single action potential was followed by fast and slow AHPs (*J. Auton. Nerv. Syst.*, 1988). In contrast 21 cells consisted of a distinct sub-population having a short duration of AHP (<50 ms) following a single spike. A train of direct action potentials at frequency of 5-20 Hz for 1-30 s was followed by a post-tetanic depolarization (PTD) instead of a post-tetanic hyperpolarization (PTH) in neurons of the latter sub-population (PTD-neuron). The amplitude and duration of the PTD were a function of the number of action potentials in the train. The PTD was associated with a decrease in input resistance. The amplitude of the PTD was increased by membrane hyperpolarization. The estimated reversal potential of the PTD was -25 mV. Low chloride solutions augmented the amplitude and duration of the PTD. Low sodium, high potassium or low potassium solutions did not significantly affect the PTD. Nominally free calcium solutions and ω-conotoxin (500 nM) abolished the PTD. These data suggest that activation of the calcium-dependent chloride channels is responsible for the PTD. In a particular PTD-neuron, the PTD was converted to the PTH during experiments without changing a resting potential. Contrary, the PTH was converted to the PTD by apamin (5 nM). These data imply that the rabbit parasympathetic neurons are endowed with a mechanism switching from the PTD to the PTH and vice versa. Supported in part by The Ishibashi Research Fund.

DO DEPOLARIZING MEMBRANE OSCILLATIONS REGULATE SPONTANEOUS DISCHARGE OF ACTION POTENTIALS IN FELINE PARASYMPATHETIC NEURONS? T. Nishimura¹, T. Akasu¹ and J. Krier.
¹Dept. of Physiol., Kurume Univ. Sch. of Med, Kurume 830, Japan and Dept. of Physiol., Michigan State Univ., East Lansing, MI 48824, U.S.A.

The properties of depolarizing membrane oscillations (DMOs) of neurons in colonic parasympathetic ganglia (CPG) were studied *in vitro* using intracellular recording techniques. Neurons were classified into two types, spontaneously discharging or quiescent neurons. For quiescent neurons, action potentials (APs) and DMOs were evoked by injection of cathodal currents of long duration (3 s-5 min) and at varying intensities (0.01-1.5 nA). Each action potential was preceded by a prepotential with rates of rise ranging between 0.12-0.25 V/s. DMOs had rates of rise ranging between 0.05 and 0.23 V/s and occurred for the duration of the cathodal depolarizing pulses. Their amplitude and frequency increased with larger membrane depolarization, suggesting that DMOs are voltage-dependent. Hexamethonium (100 μ M), d-tubocurarine (3 μ M), atropine (1 μ M), phenoxybenzamine (1 μ M) and propranolol (1 μ M) did not affect DMOs, suggesting that they are an intrinsic property of CPG neurons. DMOs were blocked by tetrodotoxin (0.3-3 μ M) and by low sodium solutions whereas high and low potassium solutions and low chloride solutions had no effect. These data suggest that a non-inactivating sodium current is involved in the generation of DMOs. For spontaneous discharging neurons, prepotentials associated with APs and DMOs also occurred. Muscarine (100 nM) initiated DMOs in quiescent neurons and converted to spontaneous discharging neurons. In contrast, UK14304 (100 nM), an α_2 -adrenoceptor agonist, abolished DMOs and converted spontaneous discharging neurons to quiescent neurons. These data suggest that DMOs regulate the excitability of feline CPG neurons. Supported in part by The Ishibashi Research Fund and NIH-DK29920.

ELECTROPHYSIOLOGICAL CHARACTERISTICS OF STELLATE GANGLION NEURONS OF THE GUINEA-PIG. R.Hendriks, M.M.Gad-El Karim, J.B.Angevine* and D.L.Kreulen. University of Arizona, Departments of Pharmacology and Medicine, Tucson, AZ 85724.

The stellate ganglia form part of the upper paravertebral chain and lie below the mid - cervical ganglia. They variously control activity of the heart, lungs, trachea and gastrointestinal tract. We report here, for the first time, electrophysiological characteristics of stellate ganglion neurons of the guinea-pig. Intracellular recordings were made from neurons in both right and left stellate ganglia *in vitro* via glass microelectrodes (tip resistances: 45-100 M Ω). The average resting membrane potential of the neurons was -42.1 ± 1.2 mV (n=8). Input resistances for these cells ranged from 33-138 M Ω . Tonically firing cells accounted for 87% of the total sample. Firing rates in response to intracellular current pulses attained instantaneous peak values of between 50 & 80 Hz. Stimulation of surrounding interganglionic nerve trunks, elicited action potentials (1/2 width = 1.8 ms, peak amplitude = 42 mV) in all the neurons. Antidromic action potentials were also observed. Synaptic input onto the recorded cells were of three types: slow EPSPs, fast EPSPs and intermediate IPSPs. Supported by DK36289, HL 27781.

EXCITATORY INPUTS FROM DISTAL COLON/RECTUM TO NEURONS IN PELVIC PLEXUS GANGLIA OF MALE GUINEA-PIG. L. Lin and J. Krier.* Dept. Physiol., Mich. State Univ., East Lansing, Michigan 48824.

Intracellular recording techniques were used *in vitro* to study the electrophysiological properties and excitatory synaptic inputs to neurons in pelvic plexus ganglia. The preparation consisted of pelvic ganglia (PG), pelvic nerves (PN), hypogastric nerves (HGN), rectal nerves (RN), colonic nerves (CN), urethra/urinary bladder nerves (UUN) with or without an attached segment of the distal colon/rectum which extended 5-7 cm orad from the external anal sphincter. PG neurons had a mean resting transmembrane potential of -55.1 ± 0.6 mV (n=124), mean action potential amplitude of 75.0 ± 1.3 mV (n=124) and mean cell input resistance of 44.1 ± 3.0 M Ω (n=44). Forty-eight % of neurons exhibited a repetitive discharge of APs during cathodal current injection of long duration (5-10 sec) into cells. Electrical stimulation of all nerve trunks attached to PG elicited fast excitatory post-synaptic potentials (f-EPSPs) and action potentials (APs) (76 % of neurons tested) that were reversibly blocked by hexamethonium (C_6 1-10 μ M). Electrical stimulation of nerve trunks also evoked antidromic APs (37 % CN/RN; 27 % UUN; 8 % HGN; 16 % PN). Antidromic APs were resistant to hexamethonium (1-3 μ M) and were abolished at stimulus frequencies between 20 and 50 Hz. In preparations where a fluid-filled segment of distal colon/rectum was attached to the pelvic ganglia via CN and RN, and intraluminal pressures recorded under non-isovolumetric conditions, 30% of neurons exhibited spontaneous f-EPSPs and APs. The spontaneous electrical activity was reversibly abolished by C_6 (1-10 μ M) or gamma-aminobutyric acid (1-10 μ M) and irreversibly abolished by sectioning CN and RN nerves. When punctate mechanoreceptive stimuli were applied to the serosal/longitudinal muscle layer, the amplitude of spontaneous f-EPSPs and the frequency of spontaneous f-EPSPs and spontaneous APs increased. Under isovolumetric recording conditions, colonic distension increased spontaneous electrical activity that rapidly adapted. The data indicate that some pelvic plexus neurons receive sensory inputs either directly or indirectly from rapid adapting mechanoreceptors in distal colon/rectum. These sensory inputs involve nicotinic cholinergic synapses. (NIH-DK-29920)

OPIOID MODULATION OF K AND Ca CURRENTS IN MAMMALIAN NERVE TERMINALS. M.I. Banks*, K. Bielefeldt and M.B. Jackson Department of Physiology, University of Wisconsin-Madison, WI 53706

Opioid peptides modulate transmitter release from nerve endings in the central and peripheral nervous system. In the posterior pituitary, dynorphin A (DYN) reduces secretion of oxytocin by an unknown mechanism. We characterized the effects of DYN on K and Ca currents using patch clamp recordings from nerve terminals in thin slices of the posterior pituitary. DYN (2 μ M) increased the peak and late K current, elicited by steps from -100 to 0 mV, by $29 \pm 21\%$ and $48 \pm 29\%$, respectively (n=5), an effect that was blocked by the opioid antagonist naloxone (10 μ M, n=5). This process involved a G protein-stimulated phosphorylation, as it was blocked by intracellular application of GDP- β -S (0.1 mM, n=5) and the protein kinase inhibitor staurosporine (50 nM, n=5). In 4 of 6 single channel recordings from cell attached patches, DYN increased the activity of large conductance K channels by ~70%, while channel activity decreased by ~15% when DYN was given in the presence of naloxone (n=4). In recordings of whole-terminal Ca currents, DYN reduced the peak and late Ca current, elicited by steps from -60 to 0 mV, by $13 \pm 3\%$ and $23 \pm 6\%$, respectively (n=4), while Ca currents increased slightly when DYN was applied in the presence of naloxone (n = 4). Thus, DYN may reduce neurosecretion in the posterior pituitary by two mechanisms: a decrease in terminal excitability due to activation of K currents, and a decrease in the Ca^{2+} trigger for secretion via a reduction in Ca currents.

MUSCARINIC EXCITATION OF RAT DORSOLATERAL SEPTAL NUCLEUS (DLSN) NEURONS *IN VITRO*. H. Hasuo* and J. P. Gallagher. Dept. of Pharmacol. and Toxicol., Univ. Texas Med. Br., Galveston, Texas 77555.

Whole-cell patch-clamp recordings were made from rat DLSN neurons *in vitro*. Under current clamp mode, muscarine (5-20 μ M) caused bursting activity and markedly enhanced a depolarizing afterpotential (ADP). These facilitatory actions are similar to those reported previously using sharp electrodes (Hasuo & Gallagher, 1990). This ADP was dependent on extracellular calcium and sodium ions. Directly evoked calcium spikes were either enhanced, depressed or not affected by muscarine (10 μ M). The amplitude of ADPs was increased even when the preceding calcium spike was slightly suppressed by muscarine. When cesium ions were used intracellularly, muscarine (10 μ M) caused an inward current in neurons voltage-clamped at -80 mV (HP = -80 mV). In the majority of neurons, the current induced by muscarine was independent of potential over the range -60 to -120 mV and was associated with an increase in conductance. Extrapolation of the I-V relationship during the inward current yielded a reversal potential of -8 mV (n=6). This inward current was reduced by lowering extracellular sodium ions. In some neurons at HP of -40 mV, muscarine produced an inward current associated with a decrease in conductance whose reversal potential was -80 mV. These results suggest that muscarine increases the excitability of DLSN neurons by multiple conductance systems and the augmentation of the ADP is not simply due to an increase of calcium influx through voltage dependent calcium channels. Supported by MH-39163.

ELECTROPHYSIOLOGICAL RECORDINGS FROM NEURONS IN RAT MEDIAN PREOPTIC NUCLEUS (MnPO) *IN VITRO*. D. SPANSWICK, R. NISSEN, M. HERMES, C.R. YANG, L.P. BENAUD*. Neuroscience, Loeb Research Institute, Ottawa Civic Hospital, Ottawa, Canada, K1Y 4E9.

The MnPO, which plays a critical role in body fluid homeostasis, receives a prominent input from the subfornical organ (SFO). To evaluate their intrinsic and synaptic properties, whole-cell patch-clamp recordings were obtained from MnPO neurons in rat brain slices that retained afferents from the SFO. MnPO neurons had mean resting potential and input resistance of -60 ± 8 mV and 961 ± 84 M Ω , respectively. These cells exhibited two prominent intrinsic membrane features that were evoked by hyperpolarizing current pulses: 1) an inward rectification; 2) a low-threshold spike (LTS) evoked at the break of a hyperpolarizing pulse. Some neurons possessed a transient outward rectification typically indicated by a delay in the return to rest of a hyperpolarizing square pulse. Other MnPO neurons responded to a brief depolarizing pulse (10 ms) with a prolonged (1-5 s) discharge of action potentials. MnPO neurons also displayed spontaneous reversed IPSPs which summated to give rise to bursts of spikes and were reversibly reduced by GABA_A antagonist bicuculline (15 μ M). Electrical stimulation of the SFO evoked fast EPSPs that were reversibly blocked by a glutamate non-NMDA antagonist CNQX (10 μ M). These results indicate that MnPO neurons possess diverse electrophysiological properties and receive both GABAergic and glutamatergic inputs. (Funded by the Canadian Heart and Stroke Foundation).

WHOLE-CELL RECORDINGS FROM VISUALLY IDENTIFIED AMYGDALA NEURONS IN RAT BRAIN SLICES. S. Chattarji*, D.B. Jaffe and T.H. Brown, Department of Psychology, Yale University, New Haven, CT 06520.

Interest in the amygdala stems from its critical role in certain forms of rapid learning. Until recently, very little was known about the basic cellular neurophysiology of amygdala neurons. Previous efforts to bridge this information gap combined three complementary experimental methods – the amygdala brain slice preparation, the single-microelectrode clamp, and video-enhanced contrast, differential interference contrast microscopy (VEC-DICM) (Chapman et al., *Synapse* 6:271-278, 1990; Keenan et al., *Brain Res. Bull.* 21:373-383, 1988). The present study extends this strategy by using whole-cell recording in conjunction with VEC-DICM adapted to an upright microscope (Stuart et al., *Pflügers Archiv*, in press, 1993).

Male Sprague Dawley rats (14-28 days) were used to cut amygdala slices (300 μ m) in the horizontal plane. Slices were placed in a submerged-type recording chamber at room temperature mounted on a fixed-stage, upright microscope (Zeiss Axioskop) with a water immersion lens (40X, 0.75 NA) and DIC optics. Standard whole-cell patch-clamp techniques were used to record from basolateral and central amygdaloid neurons observed on a video monitor.

Cells showed considerable diversity with respect to passive and active membrane properties (n=15). The overall mean (\pm SEM) values of the three passive membrane properties that were measured were as follows: resting potential, $V_m = -68.7 \pm 1.2$ mV; input resistance, $R_N = 293.6 \pm 34.7$ M Ω ; time constant, $\tau_m = 54.0 \pm 5.2$ msec. There was also considerable variability in the firing patterns produced by depolarizing current injections. Physiologically identified neurons are also being characterized morphologically using intracellular labeling with fluorescent dyes in conjunction with confocal microscopy. ACTIVITY OF BULLFROG SYMPATHETIC NEURONES *IN VIVO*.

A-Y Ivanoff and P.A. Smith*, Dept. Pharmacol., Univ. Alberta, Edmonton, Canada, T6G 2H7 and Bogomoletz Inst., Kiev, Ukraine, 252024.

Although the biophysical properties of B- and C-neurons in bullfrog sympathetic ganglia (BFSG) have been carefully analysed (Adams et al., *J. Exp. Biol.* 124, 259, 1986) little is known about their electrical activity *in vivo*. For example, it is not known whether the muscarinic and peptidergic 'slow' responses play any role in ganglionic transmission *in vivo*. Bullfrogs were anaesthetised with urethane (2mg/g) and their IXth paravertebral sympathetic ganglion exposed by a ventral incision. Ganglia were supported on a small plastic ring attached to a micropositioner and the ongoing activity in ganglionic neurones monitored with microelectrodes (3M KCl) and with suction electrodes placed on the postganglionic nerves. 37 out of 87 cells were silent and the remainder produced action potentials (a.p.) and/or subthreshold e.p.s.p.s. The average frequency of activity in B-cells was 0.11 ± 0.01 Hz (n=60). C-cells exhibited bursts of 3-8 spikes or e.p.s.p.s (at 15-40 Hz) once every 2-4s. Mild stimulation of the skin evoked a slow depolarization in B-cells which was accompanied by discharge of a.p.s. A spike-triggered averaging technique (Skok & Ivanoff, *J. Auton. Nerv. Sys.* 7, 263, 1983) showed that a pre-ganglionic volley evoked a suprathreshold synchronous discharge in about 21 cells (range=13-36, n=14). Tetanic stimulation of C-fibres evoked a slow depolarization in B-cells which was associated with a.p. generation. This reflected the late-slow e.p.s.p. and 'neuropeptide action at a distance' *in vivo* (Jan et al., *Proc. Natl. Acad. Sci. USA* 76, 1501, 1979). Thus, non-nicotinic 'slow' responses may play a role in *in vivo* transmission in BFSG. Since the B-cells innervate mucous glands in the skin (Horn et al., *J. Comp. Neurol.*, 278, 570, 1988), non-nicotinic transmission may mediate a 'sympathetic reflex' activated by stimulation of the skin. Supported by the MRC of Canada.

PHARMACOLOGY OF SYNAPTIC TRANSMISSION II

627.1

INHIBITION OF HIPPOCAMPAL ACETYLCHOLINE RELEASE BY MUSCARINIC AUTORECEPTORS EXHIBITS NO RECEPTOR RESERVE. T.W. Vickroy*, W.L. Malphurs and N.M. DeFiebre, Depts. Physiological Sciences and Neuroscience, Univ. Florida, Gainesville, FL 32610.

The extent of reserve among muscarinic autoreceptors on hippocampal cholinergic nerve terminals was examined in superfused calcium-naïve synaptosomes. Autoreceptors were occluded with the irreversible muscarinic cholinergic receptor (mAChR) antagonist propylbenzylcholine mustard (PrBCM) and then tested for acetylcholine (ACh)-induced inhibition of calcium-evoked [3 H]ACh release. PrBCM reduced the density of [3 H]quinuclidinyl benzilate binding sites (46, 72 and 90% reductions after 3, 6 or 10 nM PrBCM, respectively), while having no apparent influence on the binding affinities or relative proportions of high- and low-affinity binding sites for the M_1 -selective antagonist pirenzepine nor the agonist ACh. In control tissues, ACh was a potent ($EC_{50} = 240$ nM) and efficacious (maximum inhibition [E_{max}] of stimulated [3 H]ACh release = 65%) autoreceptor agonist. However, following PrBCM treatment, E_{max} for ACh was greatly attenuated (35% and 17% for 3 and 6 nM PrBCM, respectively) with no concurrent changes in the EC_{50} or slope factor. Comparisons of equieffective agonist concentrations before and after receptor occlusion revealed a direct linear relationship between autoreceptor occupancy and inhibition of [3 H]ACh release with close agreement between the calculated agonist dissociation constant ($K_A = 220$ nM) and the EC_{50} for ACh. Pretreatment with 100 nM atropine completely prevented PrBCM-induced reductions in mAChR binding and autoreceptor function. These results indicate an absence of spareness among inhibitory muscarinic autoreceptors on hippocampal nerve endings (supported by NS-28568).

Prejunctional M2-Muscarinic Inhibition of Sympathetic Neurotransmission in the Guinea-Pig Inferior Mesenteric Artery. T.L. Anthony, S.R. Knoper* and D.L. Kreulen, University of Arizona, Department of Pharmacology, Tucson, AZ 85724.

Activation of muscarinic receptors inhibits adrenergic neurotransmission to the vascular system. Our aim was to characterize the subtype of pre-junctional muscarinic receptor on sympathetic nerves in the mesentery. Intracellular recordings were made in arterial muscle cells through glass micropipettes (tip resistance: 60-100 M Ω). The average resting membrane potential of the mesenteric arteries was -60 ± 4 mV (n = 17). Excitatory junction potentials (e.j.p.s) were evoked via stimulation of post-ganglionic sympathetic nerve fibers. The average amplitude of the stimulation-evoked e.j.p.s. was 5.3 ± 0.3 mV (n = 5). Superfusion of muscarine (1 μ M; n = 5) resulted in a 18% reduction in e.j.p. amplitude. Superfusion of carbachol (1 μ M; n = 5) reversibly blocked the stimulation-evoked e.j.p.s. In either of the muscarinic agonists there was no effect on the resting membrane potential. Pretreatment with muscarinic antagonists reversed the inhibitory effects of carbachol on e.j.p.s with the following rank order of potency: atropine > AF-DX 116 > pirenzepine (IC_{50} 's (μ M) = 0.1, 0.2, 0.8). These results demonstrate the presence of inhibitory M2-muscarinic receptors on the sympathetic nerve terminals that innervate mesenteric arteries in the guinea pig. Supported by DK36289, HL 27781.

627.2

MUSCARINIC RECEPTOR ACTIVATION MODULATES NEURONAL ACTIVITY IN THE CENTRAL SUBNUCLEUS OF THE NUCLEUS TRACTUS SOLITARI (NTS). W.Y. Lu, R.S. Neuman, J. Reynolds, D. Bieger*, Faculty of Medicine, Memorial Univ., St. John's, Canada A1B 3V6

Muscarinic acetylcholine receptor (mAChR)-mediated neuronal activity in the NTS plays a pivotal role in generating premotor programs for esophageal peristalsis in the rat (Bieger, *Dysphagia* 6:147-164, 1991). Esophageal distension induces rhythmic unit discharges in the NTS, as well as rhythmic esophagomotor output. After application of methscopolamine (MSP) to the NTS surface, distension-induced NTS neuronal activity persists but its rhythmicity along with peristalsis is abolished. To examine the cholinergic input to the NTS in more detail, whole cell recordings were made from rat NTS neurons in horizontal brainstem slices. Electrodes contained (in mM): K-gluconate 145; MgCl₂ 2; Hepes 5; EGTA 1.1; CaCl₂ 0.1; K₂ATP 5. Electrical stimulation (0.1 ms, 1-5 V) of solitary tract afferent fibres in the slice evoked EPSPs that were resistant to 100 μ M MSP but dramatically reduced by 1 mM kynurenate or γ -D-glutamyl-glycine. High intensity (6-10 V) stimulation elicited EPSPs with spikes riding on top. The bursting pattern of spikes was altered by 5-10 μ M (+)-cis-dioxolane, a mAChR agonist. Pressure-ejection of L-glutamate (0.1 nmol) in the NTS region produced a short term (8-12 s) membrane depolarization (15-25 mV). Pulse-application of muscarine (10-20 pmol) produced a low amplitude (3-5 mV), long lasting (> 10 min) depolarization, and enhanced the glutamate response. These data suggest: (1) the esophageal afferent input is not cholinergic, but instead excitatory amino acidergic; (2) the pattern of NTS neuronal activity can be modulated by activation of mAChR. ADENOSINE RECEPTORS MODULATE INSPIRATORY DRIVE TO PHRENIC MOTONEURONS. X-W. Dong*, G. Liu, & J. L. Feldman, Systems Neurobiology Lab., Dept. of Physiological Science, UCLA, Los Angeles, CA 90024-1527.

Activation of brain adenosine receptors depresses ventilation. We examined the effects of adenosine on transmission of endogenous excitatory amino acid mediated inspiratory activity to phrenic motor neurons (PMNs) in the isolated brainstem-spinal cord preparation from neonatal rats. PMN activity was recorded under whole cell patch-clamp conditions. Drugs were applied via pressure ejection from micropipettes positioned over the PMN pool. The adenosine analogue N⁶-cyclopentyladenosine (CPA; 25 μ M) reversibly reduced peak inspiratory-modulated synaptic current (I_{insp}) to $74 \pm 6\%$ (n=6) of control. To examine the role of endogenous adenosine, we applied the antagonist 3-isobutyl-1-methylxanthine (IBMX, 0.5-1 mM) which increased I_{insp} by $\approx 15\%$ above control; similar effects were produced by the selective A₁ receptor antagonist 8-cyclopentyltheophylline (CPT; 50 μ M). This indicates a tonic endogenous release of adenosine. To elucidate underlying mechanisms, we performed analysis during the expiratory period. None of these drugs produced significant changes in steady-state membrane current, but the frequency and peak amplitude of spontaneous excitatory postsynaptic currents (EPSCs) were reduced by CPA and increased by IBMX and CPT. Moreover, following 1 μ M TTX perfusion, bath application of CPA reduced the frequency of miniature EPSCs to below half of their pre-CPA value. This reduction was reversed with bath application of IBMX. We suggest that adenosine receptors are involved in the modulation of the transmission of endogenous inspiratory drive to PMNs, possibly by a presynaptic mechanism. Supported by NIH Grant NS 24742.

BLOCKADE OF GABAERGIC INHIBITION REVEALS A NMDA RECEPTOR MEDIATED COMPONENT IN EPSPS ELICITED BY STIMULATION OF THE THALAMIC AFFERENTS TO CAT PRIMARY AUDITORY CORTEX. T. Krucker, C.L. Meier, P.L. Herrling*. Sandoz Research Institute, P.O.Box, CH-3001 Bern, SWITZERLAND.

Processing of sensory information within the auditory system has been well characterized using histological and electrophysiological techniques. However, relatively little is known about the neurotransmitters involved. The present study was performed to elucidate the possible role of excitatory (EAA) and inhibitory (i.e., GABA) amino acids in neurotransmission within the primary auditory cortex (AI). The main afferent to the AI, the ipsilateral medial geniculate body (MGB), was electrically stimulated and evoked responses were recorded intracellularly in the AI region in halothane anesthetized cats. A seven-barrelled iontophoresis pipette glued alongside the recording electrode allowed localized application of EAergic and GABAergic compounds onto the recorded neuron. In most AI neurons, MGB stimulation evoked a short latency, short duration EPSP followed by a long-lasting IPSP. Pattern, duration, and amplitude of synaptic potentials were highly variable and strongly dependent on stimulation intensity. Reduction of GABA_A receptor-mediated inhibition by iontophoretic application of either bicuculline or SR95531 markedly enhanced MGB stimulation-evoked EPSPs. Only the late component of this enhanced EPSP was reversibly blocked by the competitive NMDA receptor antagonists AP7 at currents which selectively blocked neuronal excitation induced by iontophoretic application of NMDA. Our results demonstrate that in the cat 1) NMDA receptors in AI are activated following MGB stimulation and that 2) a dominant GABA_A receptor mediated inhibition usually masks this NMDA receptor activation under our experimental conditions.

627.7

EFFECTS OF TERRITREM-B ON MOTOR NERVE TERMINALS OF MOUSE SKELETAL MUSCLES AND CHOLINERGIC RESPONSES OF SNAIL NEURON. M.C. TSAI*, W.H. HSIEH, H.C. CHOU, V.L. ARVANOV, F.T. PENG and K.H. LING. Institute of Pharmacology and Toxicology, College of Medicine, National Taiwan University, Taipei, Taiwan, R.O.C.

Effects of territrein-B (TRB), a mtcotoxin, on (1) twitch tension of mouse diaphragm, (2) motor nerve terminal activity of mouse *triangularis sterni* nerve-muscle preparation and (3) cholinergic responses of snail central neuron were studied. TRB increased the indirectly elicited twitch tension and it also induced spontaneous muscle twitching of mouse diaphragm. The spontaneous muscle twitching induced by TRB was blocked if d-tubocurarine was further added. TRB potentiated the ACh induced current of snail neuron, while it had no effect on GABA or glutamate elicited currents. The perineural waveforms were recorded with extracellular electrodes placed in the perineural sheaths of motor nerves. At 10 µg/ml, TRB decreased the component of waveform associated with potassium current while it had no effect on the sodium, calcium as well as calcium activated potassium currents of the nerve terminal. It is concluded that TRB affected potassium current in the nerve terminal. The effect may contribute to its actions on synaptic transmission. (This study was supported by a grant, NSC-81-0412-B-002-536, from National Science Council, Taipei, Taiwan, R.O.C.)

[³H]BIMU-1 selectively labels sigma₂ binding sites in guinea-pig hippocampus. Douglas W. Bonhaus*, Dana N. Louny, Lyn B. Jakeman, Zung To, Andrea DeSouza, Richard M. Eglon and Erik H.F. Wong. Dept. of Neurosciences, Institute of Pharmacology, Syntex Discovery Research, 3401 Hillview Avenue, Palo Alto, California, 94304 USA

The binding of [³H]BIMU-1 ([³H]endo-N-(8-methyl-8-azabicyclo [3.2.1]oct-3-yl)-2,3-dihydro-3-ethyl-2-oxo-1H-benzimidazole-1-carboxamide hydrochloride), a benzimidazolone with high affinity for 5-HT₂ and 5-HT₁ receptors, was characterized in guinea pig hippocampal membranes. [³H]BIMU-1 binding was insensitive to serotonin but was displaced by haloperidol, and 1,3-di-o-tolylguanidine (DTG) with affinities appropriate for the labelling of a sigma site (K_i of 6.3 and 31 nM respectively). The affinity profile of ligands displacing [³H]BIMU-1 binding in guinea pig hippocampus was consistent with the selective labelling of a sigma₂ site since the sigma₂ selective benzomorphans (+) pentazocine and (+)N-allylnormetazocine only weakly displaced the binding (K_i greater than 1 µM). The affinity of BIMU-1 for sigma₂ binding sites (K_i = 32 nM) was more than 200 fold greater than that for sigma₁ binding sites (K_i = 6.3 µM), dopamine (D₁ and D₂), other serotonin (5-HT_{1A}, 5-HT_{2A}, 5-HT_{2C}) and muscarinic (M₁, M₂, M₃ and M₄) receptors (K_i > 10 µM).

These data suggest that [³H]BIMU-1 selectively labels sigma₂ sites in guinea-pig hippocampus. [³H]BIMU-1, under appropriate experimental conditions, is thus the first sigma₂ binding site radioligand to be characterized.

BRAIN-DERIVED PEPTIDES DEPRESS SYNAPTIC TRANSMISSION VIA GABA_A RECEPTORS IN RAT HIPPOCAMPUS IN VITRO. H. Xiong*, J.M. Wojtowicz and A. Baskys. Depts. of Physiology and Psychiatry, Univ. of Toronto and Clarke Inst. of Psychiatry, Toronto, Ont. M5S 1A8, Canada

Cerebrolysin (CB) is a brain-derived peptide preparation which consists of free amino acids (AAs) and biologically active peptides (MW < 10kD), and has been found to have therapeutic effects on neurodegenerative, ischaemic and traumatic brain disorders. To understand the actions of CB on central neurons, we studied its effects on evoked field potentials (FPs) in hippocampal slices taken from young (14-30 d) Wistar rats of either sex. In agreement with a preliminary study (Wojtowicz et al., Soc. Neurosci. Abstr. 18:987, 1992), bath applied CB (10µl/ml) was found to strongly and consistently depress the FPs evoked in CA1 area by 65.9±4.1% (mean±S.E., n=24) in a concentration dependent manner. Interestingly, CB-induced depression of FPs was consistently and reversibly antagonized by a GABA_A receptor antagonist CGP35348 (50-100µM, n=15). In contrast, GABA_A receptor antagonist bicuculline (20-50µM) had no apparent effect (n=14), indicating that CB selectively acts on GABA_A receptors. Bath applied baclofen (2µM), a GABA_B receptor agonist had similar depressant effects (84.9±3.2%) on FPs, and this action was blocked by CGP35348 (n=3). Application of CB peptide fraction (PF, 10µl/ml, n=4) or AAs (10µl/ml, n=3) caused 43.1±13.8% and 37.9±4.6% depression of FPs respectively. CGP35348 was found to have much stronger effects in antagonizing the actions induced by CB (46.9±3.7%, n=14) and PF (45.2±9.3%, n=4) than AAs (21.0±12.5%, n=3), suggesting that the major active component of CB is a peptide or peptides, and that the mechanism mediating AAs-induced depression is different from that caused by CB. These results indicate that CB inhibits synaptic transmission via acting on GABA_A receptors. Supported by EBEWE Initiative, Austria and MRC of Canada.

AMINOPYRIDINES REVERSE SAXITOXIN (STX)- AND TETRODOTOXIN (TTX)-INDUCED CARDIORESPIRATORY DEPRESSION. R.M. Bauer*, B.J. Benton and F.-C.T. Chang. Pathophysiology Div., USAMRICD, APG, MD.

Aminopyridines have been shown to reverse TTX blockade of synaptic transmission *in vitro*. In the present study, we examined the effects of 4-aminopyridine (4-AP) and 3,4-diaminopyridine (3,4-DAP) on STX- and TTX-induced cardiorespiratory depression. Anesthetized guinea pigs were instrumented to record respiratory-related medullary units, arterial pressure, diaphragm electromyogram (DEMG), electrocorticogram, electrocardiogram, end-tidal CO₂ and arterial pH, CO₂ and O₂. STX or TTX infusion (0.3 µg/kg/min, IV) elicited vascular hypotension, bradycardia and bradypnea leading to DEMG inhibition. Artificial ventilation was provided when DEMG was reduced by 50%. Toxin infusion was stopped upon DEMG inhibition and subsequently, 4-AP (2 mg/kg, IV) or 3,4-DAP (8 mg/kg, IV) was given. Arterial pressure and heart rate returned to pre-toxin levels and DEMG reappeared rapidly after 4-AP or 3,4-DAP. Spontaneous breathing resumed within minutes and was sustained for several hours without additional aminopyridine therapy. These findings should aid in designing new strategies for therapy against STX or TTX intoxication.

627.10

EFFECT OF 2,4-DITHIOBIURET ON SMOOTH ENDOPLASMIC RETICULUM OF PC12 CELLS. D.M. Autio, M.B. Rheuben and W.D. Atchison*. Depts. of Anatomy, Pharmacology and Toxicology, and the Neuroscience Program, Michigan State University, East Lansing, MI 48824.

2,4-Dithiobiuret (DTB) causes a delayed onset neuromuscular weakness in rats which is associated with decreased quantal content, alterations in postsynaptic ion channel properties, and abnormalities in the ultrastructure of the nerve terminal. The latter include features typical of degenerating or diseased nerve terminals as well as a proliferation of smooth endoplasmic reticulum (SER), swelling of mitochondria and evidence for a decrease in intraterminal calcium concentrations at early stages of neurotoxication (Jones, 1989, Acta Neuropathol. 78: 72). To evaluate the possibility that DTB affects neurotransmission and initiates its toxic effects by interfering with the ability of the SER to modulate cytoplasmic calcium concentrations, we examined DTB treated PC12 cells. The toxicity of DTB to cultured cells was assessed with a fluorescent viability assay. An increase in the proportion of dead cells over the 8-9% seen in control cultures first occurred at exposures of 10µM for 24 hours and reached 30% at 100µM. In moderately differentiated cells having processes up to 10 cell diameters and several varicosities, the SER did not seem to be specifically targeted by 10-40µM DTB, 4-72 hrs; gross abnormalities in the structure of the smooth ER were not seen with TEM, and large changes in the quantity were not detected at the light microscope level with fluorescent stains DiOC₆ or Rhodamine B. Other signs of neuronal degeneration (blebbing of the plasmalemma, large intracellular droplets, mitochondrial abnormalities) preceded or accompanied any evidence for abnormalities in the SER. The effect of DTB on the SER *in vivo* may occur secondary to a more general toxic action, or may require a greater degree of differentiation of the neuronal cells than examined in this study. Supported by NIH Grant NS20683.

627.11

EFFECTS OF DIISOPROPYLFLUOROPHOSPHATE (DFP), PARAOXON AND ALDICARB (ALD) ON PRESYNAPTIC NERVE TERMINALS AND POSTSYNAPTIC RECEPTORS. W.M. Cintrá^{1,2*}, E.S. Rocha¹, L.E.F. Almeida¹, Y. Aracava^{1,2} and E.X. Albuquerque^{1,2}. ¹Lab. Mol. Pharmacol., IBCCF/UFRJ, RJ, Brazil 21944; ²Dept. Pharmacol., Univ. MD Sch. Med., Baltimore, MD 21201.

The non-anticholinesterase effects of organophosphorus compounds and carbamates have been well demonstrated (*Fundam. Appl. Toxicol.* 5:S182, 1985). Here we have obtained evidence of diverse effects of DFP, paraoxon, and ALD on synaptic transmission in various preparations. The effects of ALD on directly and indirectly elicited muscle twitch were studied in the frog (*Leptodactylus ocellatus*) sciatic nerve-muscle preparation. At concentrations that completely inhibit ChE, ALD (0.1-10 μ M) increased nerve-elicited twitch tension to 125% of control. At 100 μ M, ALD initially increased twitch tension to 200% of control, followed by a return to control levels within 30 min. At 800 μ M, ALD increased twitch tension to only 150%, which decreased to 85% of control after 30-min exposure and then returned to 140% after a 30-min wash. With the nicotinic acetylcholine receptor (nAChR) blocked by d-tubocurarine (100 μ M), ALD (100 μ M) only caused a 40% decrease of direct-elicited twitch at 30 min, indicating that the above mentioned potentiation was not due to an effect of ALD on the muscle contractile properties. The patch-clamp technique was used to study miniature excitatory postsynaptic currents (mEPSCs) in cultured fetal rat hippocampal neurons (15-30 days) and nicotinic whole-cell currents in cultured rat myoblasts (15 days). In the neurons, paraoxon (100 μ M), but not DFP or ALD (each up to 10 μ M), enhanced the frequency of mEPSCs, an effect that was insensitive to tetrodotoxin. Paraoxon and DFP (100 μ M-1 mM) also shortened the decay phase of the mEPSCs. In myoblasts, paraoxon (> 100 μ M) reduced the peak amplitude of ACh (50-500 μ M)-induced currents. Thus, it is likely that a blockade of postsynaptic neuronal nAChRs may at least in part underlie the shortening of mEPSCs. These results indicate that modulation of transmitter release and direct interactions with post-synaptic nAChRs may be involved in the effects of these anti-ChEs in synaptic transmission. MODULATION OF EXCITATORY SYNAPTIC RESPONSES IN RAT SPINAL DORSAL HORN NEURONS BY (1S,3R)-1-AMINOCYCLOPENTANE-1,3-DICARBOXYLIC ACID. L.J. Kolic* and M. Randic. Dept. of Vet. Physiol. and Pharmacol., Iowa State University, Ames, Iowa 50011

We examined the effects of the activation of metabotropic glutamate receptor (mGluR) by (1S,3R)-1-aminocyclopentane-1,3-dicarboxylic acid (1S,3R-ACPD), a selective agonist, on the excitatory synaptic transmission in the rat spinal dorsal horn (DH). The excitatory synapse between small primary afferent fibers (0.5-8.5 m/s) and neurons in the laminae I-IV was examined by intracellular recording from DH neurons in the longitudinal spinal slice preparation of rats (20-26 days). The strength of primary afferent transmission was assayed by recording the size of the presumed monosynaptic (n=10) and/or polysynaptic (n=7) EPSPs that result from stimulation of L4 and L5 spinal nerves with electrical shocks of low (5-10V, 10-50 μ s) and/or high (20-35V, 0.5ms) intensity. Bath application of 1S,3R-ACPD (10-100 μ M for 4-18 min) caused a prolonged depolarization (5.4 \pm 0.6mV, n=14) of the membrane potential accompanied by an increase in membrane noise and the burst firing. During the superfusion of 1S,3R-ACPD (25-100 μ M) the peak amplitude of the presumed monosynaptic and polysynaptic EPSPs was reversibly depressed (to 49 \pm 8% of control; m \pm SEM, n=13). With smaller doses of the drug (\leq 50 μ M) a long-lasting potentiation of EPSPs, especially those evoked by high intensity stimulation, was observed (178 \pm 16%, n=7). Following removal of 1S,3R-ACPD a potentiation (up to 30 min) of synaptic transmission (by 200 \pm 30%, n=9) was observed in 11 of 17 cells. However, 4 of 8 monosynaptic EPSPs exhibited a long-lasting depression (to 38 \pm 10%). The effects of 1S,3R-ACPD on the burst firing and EPSPs were reduced by (RS)-4-carboxy-3-hydroxyphenylglycine (500 μ M). The results demonstrate that distinct and long-lasting modulation in synaptic efficiency can be induced by metabotropic receptor activation which may have important implications for synaptic transmission and plasticity (LTP/LTD) in the spinal DH (supported by NS-26352 and IBN-9209462).

A FUNCTIONAL ROLE FOR NITRIC OXIDE IN LOCUS COERULEUS: IMMUNOHISTOCHEMICAL AND ELECTROPHYSIOLOGICAL STUDIES Z.-Q. Xu, V.A. Pieribone, X. Zhang, S. Grillner¹ and T. Hökfelt. Dept. of Histology and Neurobiology and ¹Nobel Institute of Neurophysiology, Karolinska Institute, P.O. Box 60400, 10401 Stockholm, Sweden

The present study was undertaken to examine a possible role of nitric oxide (NO) in synaptic transmission in the locus coeruleus (LC). Using immunohistochemical methods, the localization of nitric oxide synthase (NOS)-like immunoreactivity was examined at both the light- and electron microscope levels. After incubation with antiserum to NOS, immunoreactive cell bodies were seen close to the LC, extending dendritic processes into the LC. Also a few large and small NOS-positive cell were seen intermingled with the numerous tyrosine hydroxylase (TH)-positive cells of the LC. There NOS-positive cells were always TH-negative. Single NOS-positive processes, often with a varicose appearance, could be seen in the LC. Some processes, mainly of dendritic nature, closely approached blood vessels in the LC. At the ultrastructural level NOS-positive cell bodies, axonal terminals and dendrites were seen in the LC. Synaptic contacts were observed between unlabelled boutons and labelled dendrites, often with spines but also between labelled boutons and unlabelled dendrites, and between labelled and unlabelled dendrites. Intracellular recordings were made from LC neurons in rat brain slices. Focal electrical stimulation of the area around the LC evoked an EPSP which could be blocked by CNQX (10 μ M, n=12). Bath application of the NOS inhibitors, nitro-L-arginine methyl ester (L-NAME, 15 μ M) or N^G-monomethyl-L-arginine (L-NMMA, 80 μ M), potently enhanced the EPSP up to 127.71% \pm 4.12% (p<0.001, n=16) and 121.7% \pm 3.78% (p<0.0015, n=7) of the control, respectively. The enhancement caused by L-NAME was reversed by co-administration of L-arginine (n=6), a precursor of neuronal NO. Hemoglobin, which binds extracellular NO, also enhanced the EPSP up to 118.84% \pm 4.86% (p<0.025, n=6) of the control. Neither NOS inhibitor, L-arginine nor hemoglobin had effects on resting membrane potential or impedance. The results suggest a role for NO in excitatory synaptic transmission in the LC.

EFFECTS OF ANAESTHETIC AGENTS ON REGIONAL DOPAMINE RELEASE IN THE RAT BRAIN: A 3-METHOXYTYRAMINE STUDY. S.-J. Chrapusta, M.F. Egan, F. Karoum and B.J. Wyatt. Neuropsychiatry Branch, NIMH Neuroscience Center at St. Elizabeths, Washington, D.C. 20032.

According to a number of microdialysis and voltammetry reports, anaesthetics may differentially affect dopamine (DA) release. For example, halothane was shown to elevate extracellular DA in the rat striatum, while most other anaesthetics were found to depress it. We investigated the effects of a variety of anaesthetics using tissue 3-methoxytyramine (3MT) levels as an index of DA release. 3MT was measured using combined gas chromatography-mass spectrometry with negative chemical ionization.

Male Sprague-Dawley rats weighing 340-420 g were anaesthetized with either a mixture of halothane (about 2%) and oxygen, or 400 mg/kg ip chloral hydrate, 50 mg/kg ip pentobarbital sodium, 150 mg/kg ip ketamine or 1.25 g/kg ip urethane. An injection of the MAO inhibitor pargyline (75 mg/kg, ip) was given at 50 min, and the animals were killed 10 min later by microwave brain irradiation. No effect was found in the hypothalamus or substantia nigra. Ketamine elevated 3MT (155% of control, p<0.01) in the frontal cortex, indicating an enhancement of DA release, while no change was observed in the nucleus accumbens and striatum. Halothane, chloral hydrate, pentobarbital sodium and urethane decreased 3MT levels in the frontal cortex (by 40%, 47%, 54% and 53%, respectively; p<0.05), nucleus accumbens (by 25%, 24%, 48% and 40%, respectively; p<0.05) and striatum (by 31%, 35%, 38% and 46%, respectively; p<0.01), indicating marked decreases in DA release. 3MT formation normalized 24 hours after halothane, pentobarbital sodium, and chloral hydrate treatment (other drugs were not tested). The results indicate that anaesthesia significantly affects DA release from neuron terminals but not cell bodies. The reason for the discrepancy between the halothane-induced changes in 3MT formation found here and extracellular DA reported by others is not clear.

MEDIATORS OF THE S-EPSP IN CAT PANCREATIC GANGLIA.

L. Sha, L. L. Ou and J. H. Szurszewski*. Dept. of Physiology, Mayo Clinic, Rochester, MN 55905.

Repetitive stimulation of intrapancreatic nerves evokes a S-EPSP in the majority of pancreatic neurons. Exogenous acetylcholine (ACh) or 5-HT evokes a slow depolarization through muscarinic or 5-HT_{1P} receptors. The purpose of this study was to determine the percentage of neurons which have a S-EPSP and respond to either ACh or 5-HT. Intracellular recordings were made from 176 neurons from 90 cats. A S-EPSP was evoked in 138 neurons. ACh (20 mM, 5-300 mS, 40 lb/in²) evoked a slow depolarization in 61 of 81 neurons tested. Of the responding neurons, 77% also had a S-EPSP while 50% of the non-responding neurons had a S-EPSP. These data suggest that a cholinergic muscarinic mechanism accounted for the S-EPSP in approximately 30% of the neurons which had a S-EPSP. 5-HT (20 mM, 500 mS, 40 lb/in²) evoked a slow depolarization in 61 of 137 neurons tested. Of the responding neurons, 85% also had a S-EPSP. A S-EPSP was recorded in 71% of the non-responding neurons. These data suggest that a serotonergic mechanism accounted for the S-EPSP in approximately 8% of the neurons which had a S-EPSP. These data suggest that S-EPSPs are mediated by ACh, 5-HT and other neurotransmitters which have yet to be identified. (Supported by DK 17632.)

P-TYPE CALCIUM CHANNELS ARE RESPONSIVE FOR TRANSMISSION AT THE PARALLEL AND CLIMBING FIBER SYNAPSES IN PURKINJE CELLS. M. Sugimori* B. Cherksey and R. Llinás. Dept. Physiology/Biophysics, New York University Medical Ctr., NY, NY 10016.

Patch current and voltage clamp studies in adult guinea pig cerebellar slices were implemented to test the effect of different calcium channel blockers on synaptic transmission at the Purkinje cell level. Both climbing fiber and parallel fiber postsynaptic responses were evoked by electrical stimulation at the granular layer level. In agreement with previous pharmacological results indicating that inferior olivary cells express P-type calcium channels (Manfridi et al., *Soc. Neurosci. Abst.* 18:974, 1992), it was found that the climbing fiber transmission was blocked by the addition of purified FTX at a concentration of 1:1000. Quite unexpectedly, given that the somata of granule cells demonstrate mostly L channels (Slesinger & Lansman, *J. Physiol.* 435:101-121, 1991), parallel fiber activity in Purkinje cells was also blocked at similar FTX doses. By contrast, Ω conotoxin at 1 to 5 μ M concentration and dihydropyridine at 10 μ M concentration, had no effect on this transmission. Finally, the effect of local application of glutamate on Purkinje cells was unaffected by any of the three calcium blockers. We conclude that synaptic transmission by both climbing and parallel fibers are mediated by the activation of P channels. Support by NS13742 and AF9620-92.

17 β -ESTRADIOL INHIBITS ω -CONOTOXIN SENSITIVE (N-TYPE) CALCIUM CHANNELS IN RAT STRIATAL NEURONS. P.G. Mermelstein*, J.B. Becker and D. J. Surmeier. Neuroscience Program, Reproductive Sciences Program and Psychology Dept., Univ. of Michigan, Ann Arbor, MI 48104 and Dept. of Anatomy and Neurobiology, Univ. of Tennessee, Memphis, TN 38163.

Until recently, steroid hormones had been believed to act only upon cells containing genome activating receptors. However, recent evidence suggest that steroids can also have specific and rapid effects at the cellular membrane. Neurons in the female rat striatum are candidates for immediate actions of 17 β -estradiol. 17 β -Estradiol has previously been reported to rapidly influence striatal dopamine release, dopamine receptor concentrations and behaviors mediated by the striatum. Yet, traditional estrogen receptors are not found within the striatum, suggesting estradiol may be acting via a non-established mechanism.

Using whole-cell patch clamp, we have found 17 β -estradiol able to reversibly block calcium currents in dissociated striatal neurons from 3-5 week and 10 week old female rats. Inhibition of calcium current by 17 β -estradiol was not seen after application of ω -conotoxin, an N-type calcium channel blocker, suggesting 17 β -estradiol's effects are specific to N-type calcium channels. 17 β -Estradiol's inhibition of N-type calcium channels was reliably seen within seconds of administration and at picomolar concentrations. Stereospecificity of this response was demonstrated with 17 α -estradiol, which required at least 100x more concentrated doses than 17 β -estradiol to produce a similar effect. These results suggest that at physiological concentrations, 17 β -estradiol can have immediate actions upon neuronal membrane activity.

PROPERTIES OF MEMBERS OF THE α -BUNGAROTOXIN SENSITIVE ACETYLCHOLINE RECEPTOR FAMILY. K. Maury¹, C. Gotti², F. Clementi^{2*}, M. Ballivet¹ and D. Bertrand¹. ¹Dpt of Physiology, CMU, CH-1211 Geneva 4 and ²CNR Center of Cytopharmacology, Milan, Italy.

Using polyclonal antibodies raised against synthetic peptides unique to the $\alpha 7$ and $\alpha 8$ subunits, two α -Bungarotoxin receptors subtypes ($\alpha 7$ and $\alpha 7$ - $\alpha 8$) have been purified from chick optic lobe. Both have the same affinity for nicotinic antagonists but the $\alpha 7$ - $\alpha 8$ subtype has higher affinity for agonists. Intranuclear injection of $\alpha 8$ cDNA in *Xenopus* oocytes led to the expression of functional receptors whose EC₅₀ to acetylcholine was about 100 fold lower than for $\alpha 7$. However co-injection of $\alpha 7$ and $\alpha 8$ in equimolar concentrations gave receptors indistinguishable from those obtained with $\alpha 7$ alone. These results suggest either that $\alpha 7$ masked the properties of $\alpha 8$ or that these two subunits could not co-assemble in vitro. However, the difference in agonist sensitivity between $\alpha 7$ and $\alpha 8$, found both in vitro and in vivo, indicates that assembly of these two subunits in different ratios may be one mechanism involved in the generation of functional receptor diversity.

ATX-MODIFIED Na⁺ CHANNELS FROM LOBSTER WALKING LEG NERVES IN PLANAR LIPID BILAYERS. C. Castillo, C. Piernavieja, E. Recio-Pinto* Instituto Internacional Estudios Avanzados (IDEA), Caracas 1015A, Venezuela. Cornell University Medical College, Depts. of Anesthesiology and Physiology, New York 10021.

ATX-modified, voltage-dependent Na⁺ channels from lobster walking leg nerves were studied in symmetrical 0.5M NaCl. ATX-activated channels underwent long and short openings and closings (msec to min range) at all potentials. Channel openings occurred in a burst-like manner. Two open states were observed, a short-lived (msec-sec) large conductance (60pS) state and a long-lived (sec-min) low conductance (10pS) state. 98% of the channels displayed the low conductance state, and 86% of the channels displayed both conductance states. The probability of the channel displaying the large conductance state was highest between +40 and -40mV. At positive potentials, the channel slowly inactivated (entered an irreversible non-conductive state). The channel's fractional open time (f_o) increased with depolarization, with a midpoint potential (V_{1/2}) value of -13mV and an apparent gating charge of 0.9. At -60mV, the mean burst life-time was 22sec, and the channel's mean f_o was 0.05. At +60mV, there were two bursts types, with mean-life times of 3 and 24 min, and the channel's mean f_o was 0.33. At +60mV, the mean open time was 4.1min and the mean closed time was 6.8min. The permeability ratio of Na⁺ over K⁺ was 1.93 for the low conductance state, and 4.01 for the large conductance state. TTX SENSITIVITY OF SODIUM CHANNELS IN ELECTROCYTES FROM *STERNOPYGUS* ELECTRIC ORGAN. L. McAnelly*, M. B. Ferrari and H. Zakon. Dept. of Zoology, Univ. of Texas, Austin, TX 78712

Action potential (AP) duration of the myogenically derived electrocytes of the weakly electric gymnotid fish, *Sternopygus*, covaries with the electric organ discharge (EOD) of the individual fish: electrocytes from fish with low frequency EOD's produce longer duration APs. Variation in the electrocyte AP duration is in turn correlated with variation in Na channel inactivation kinetics (Ferrari, 1993): sodium channels in electrocytes from fish with low frequency EODs display slower inactivation kinetics than those from fish with high frequency EODs.

In some cell types (mammalian muscle, dorsal root ganglion) different Na channel kinetics may be associated with TTX sensitivity: quickly inactivating TTX-sensitive Na channels and more slowly inactivating TTX-insensitive channels. We examined the TTX sensitivity of Na channels in *Sternopygus* electrocytes over a range of EOD frequencies using a two electrode voltage clamp. Na current in all electrocytes is totally blocked by 250-600 nM TTX. Thus, there is no evidence for a TTX-insensitive Na channel in this preparation. Preliminary dose response curves of TTX block of Na current show no systematic variation in TTX sensitivity across EOD frequency. Average Kd was 22 nM (range 12-35 nM, n=4).

CESIUM INHIBITS BOTH THE TTX-INSENSITIVE SLOW SODIUM CURRENT (I_{NaS}) AND DEPOLARIZING AFTER-POTENTIALS IN HIPPOCAMPAL CA1 PYRAMIDAL NEURONS K. Hoehn* and B.A. MacVicar. Neuroscience Research Group, University of Calgary, Alberta, Canada, T2N 4N1

We have reported a novel voltage-dependent, TTX-insensitive, slow Na⁺ current (I_{NaS}) which is present in striatal and hippocampal neurons (Neuron, 10:543-552, 1993). This current appears to underlie the Na⁺-dependent depolarizing afterpotentials (DAPs) recorded from hippocampal CA1 pyramidal neurons under conditions in which Ca²⁺- and K⁺-dependent processes are blocked. It may contribute to alterations in neuronal firing and epileptiform bursting. To investigate I_{NaS} further, whole-cell voltage clamp techniques were used on hippocampal CA1 pyramidal neurons acutely isolated from 21-28 day postnatal rats using trypsin and hyaluronidase. I_{NaS} was observed when the pipette solution contained either Tris phosphate, Tris chloride, N-methyl-D-glucamine phosphate, or N-methyl-D-glucamine fluoride. I_{NaS} was not observed with pipette solutions of cesium with either chloride, fluoride or phosphate. However, I_{NaS} was still observed when up to 30 mM cesium was added to the Tris phosphate intracellular solution. These observations suggest that high concentrations of intracellular Cs⁺ block I_{NaS}. Extracellular Cs⁺ also blocked I_{NaS} and this block was reversible. In the presence of 2mM extracellular Cs⁺, I_{NaS} was decreased by about 60% while 16 mM Cs⁺ blocked about 90% of I_{NaS}. In another set of experiments, current-clamp recordings were obtained from CA1 hippocampal pyramidal neurons in the *in vitro* slice preparation. Under conditions in which Ca²⁺-dependent processes were blocked using medium containing 3mM MnCl₂, 5 mM MgCl₂ and 0.05 mM CaCl₂, we have shown previously that the DAPs are Na⁺-dependent. While DAPs were still observed in the presence of 2 mM Cs⁺ in the extracellular solution, they were blocked reversibly in 16 mM extracellular Cs⁺. These data support the hypothesis that I_{NaS} underlies the DAPs observed in hippocampal neurons following spike activation and suggest a means whereby the involvement of I_{NaS} in epileptiform activity (e.g. epileptiform bursting observed in hippocampus in 0 mM extracellular Ca²⁺) can be investigated. (Supported by the M.R.C of Canada and AHFMR).

ANDROGEN MODULATION OF A VOLTAGE-SENSITIVE SODIUM CURRENT. M. B. Ferrari* and H. H. Zakon. Zoology Dept., Univ. of Texas, Austin, TX 78712

Sternopygus macrurus is a weakly electric gymnotiform fish which serves as a model system to study the effects of sex steroids on cell excitability. The *Sternopygus* electrocyte action potential (AP) displays a large natural variation in duration (3-14 msec) among individual fish. This natural variation in the AP is a sexually dimorphic character, with longer duration APs found in males. Chronic androgen treatment in fish of either sex increases AP duration.

In electrocytes, the variations in AP duration are correlated to variations in the macroscopic sodium current. Long duration APs are correlated with slow sodium current kinetics. Therefore, we examined if chronic androgen treatment would alter the sodium current kinetics in these cells. Voltage-clamp recordings of the sodium current were made before and 3-4 weeks after implanting fish with either 5 α -dihydrotestosterone or empty silastic capsules. When compared to baseline recordings, the androgen implants resulted in significantly slower sodium current inactivation kinetics compared to controls (p < 0.008, Mann-Whitney U, n = 6 fish per group). This provides the first direct evidence for chronic androgen modulation of a voltage-sensitive ionic current. Electrocytes are ideal model cells for studying the biophysical and molecular mechanisms underlying androgen modulation of cell excitability, and are particularly useful to study modulations of sodium current kinetics. Supported by ONR, NSF, and NIH.

DISTRIBUTION OF CYCLIC GMP-GATED SODIUM CHANNELS AMONG TISSUES: IN SITU HYBRIDIZATION AND RNASE-PROTECTION ASSAY STUDIES IN RAT. E.D. Potter*, C. Ding, M.A. Levine, and S.E. Guggino. The Johns Hopkins Univ. Sch. of Med., Baltimore, MD 21205.

What is the distribution of cyclic GMP (cGMP)-gated sodium channels, similar to those found in retinal rod neurons, throughout the body? Are these channels (nearly) identical to the retinal rod sodium channel? To answer the first question, we performed *in situ* hybridization upon various tissues in rat. Silver grain autoradiographs developed following hybridization of ³⁵S-labeled synthetic oligomer probes (whose sequences were based upon rat and human retinal cGMP sodium channel sequence), indicate presence of mRNA coding for a cGMP-gated channel in: rat retina, pineal, lung, epithelial layer of trachea and jejunum, and possibly in kidney. Negative controls include RNase-pretreatment of tissues, "sense" probes, and excess "cold" competing probe. Probes based upon different areas of channel sequence, showed similar tissue distribution.

To answer the second question, we are performing RNase-protection assay (RPA) studies upon total RNA from various rat tissues. If RPA studies indicate that cGMP-gated channels in certain tissues are related, but not identical to the retinal rod channel, partial sequence of such channels will help resolve the question of channel identity. However, *in situ* studies indicate that similar cGMP-gated channels exist in various rat tissues.

HETEROGENEITY OF VOLTAGE-DEPENDENT Na⁺ CONDUCTANCE IN DORSAL ROOT GANGLION NEURONS OF ADULT RAT. M.A. Rizzo, S.G. Waxman, and J.D. Kocsis*. Dept. of Neurology, Yale School of Medicine, New Haven, CT and Neuroscience Research Center, VAMC, West Haven, CT 06516.

Electrical diversity of dorsal root ganglion neurons (DRGs) is conferred in part by differences in the properties of their voltage-dependent Na⁺ channels. Using the whole-cell patch-clamp method, Na⁺ currents were recorded from adult rat DRGs maintained in culture from 1 to 3 days. Small (≈20 μm diameter) neurons had a predominantly slow Na⁺ conductance whose properties varied among different neurons tested. In most neurons, activation began at -50 to -30 mV (conditioning potential -120 mV). The Na⁺ conductance in one population of small neurons was saturated at test potentials between 0 and +20 mV, while in others, saturation could not be achieved at potentials up to +50 mV. Steady-state inactivation was weakly voltage-dependent and complete removal of inactivation often could not be achieved at very negative (-160 mV) conditioning potentials. Activation half-times were voltage-dependent and varied among cells from 0.8 to 2.5 ms at +40 mV (19 °C) and included a variable delay. Inactivation half-times were voltage-dependent and a variable fraction of the conductance did not inactivate during >20 ms depolarization. Although inactivation half-times varied over a greater than three-fold domain among different neurons, they remained uniform and stable within a given neuron. Slow conductances were TTX insensitive (100 nM). Most medium-sized (≈40 μm diameter) neurons had only a fast, TTX-sensitive Na⁺ conductance which also showed neuron to neuron variations. Fast conductances were consistently saturable. Some medium-sized neurons had both fast and slow conductances. In conclusion, DRG neurons appear to be individually tuned. The expression of Na⁺ channels is constrained within each neuron to one or two kinetic species despite the potential for broad diversity. In addition to a fast Na⁺ conductance necessary for action potential generation, DRG neurons contain slow, weakly voltage-dependent and nonsaturable Na⁺ conductances which may have a role in subthreshold excitatory activity.

RT-PCR AMPLIFICATION OF VOLTAGE-SENSITIVE Na⁺ CHANNEL mRNAs IN CULTURED RAT SPINAL CORD ASTROCYTES. Y. Oh, J.A. Black, S. Yokoyama, and S.G. Waxman*. Dept. of Neurology, Yale Univ. Sch. of Med., New Haven, CT 06510 and Neuroscience Research Center, West Haven, CT 06516

Astrocytes have been shown to express voltage-sensitive Na⁺ channels with regional and developmental variation. So far, three major subtypes (Form I, II and III) of the Na⁺ channel from rat brain and recently a partial cDNA of a putative glial-specific Na⁺ channel from rat cerebral astrocytes have been cloned. In the present study, we have applied a combined technique of reverse transcription and polymerase chain reaction (RT-PCR) to identify the type(s) of voltage-sensitive Na⁺ channel expressed in cultured rat spinal cord astrocytes. Spinal cord astrocytes were isolated from neonatal Sprague-Dawley rats and cultured for 7 days before RNA extraction and RT-PCR. We have designed three different primer sets to amplify coding regions and three different primer sets to amplify 3' non-coding regions of these cloned Na⁺ channels. Interestingly, we were able to amplify all three major subtypes of rat brain Na⁺ channels as well as a putative glial-specific Na⁺ channel in spinal cord astrocytes. Adult rat brain, used as a positive control, was also shown to express all these Na⁺ channels. However, in adult rat liver we were unable to amplify any of these Na⁺ channels. We have also found that rat skeletal muscle could express form I and III but no form II of rat brain Na⁺ channels. The present study provides the first direct evidence that astrocytes can express rat brain voltage-sensitive Na⁺ channel mRNAs, which have been considered as mainly neuronal type Na⁺ channel messages, in addition to a putative glial-specific Na⁺ channel. DISTRIBUTION OF SODIUM CHANNELS ON DENDRITES OF NEURONS IN HIPPOCAMPAL, CORTICAL AND CEREBELLAR RAT BRAIN SLICES

T. A. Benke* and K. J. Angelides, Departments of Neuroscience and Cell Biology, Baylor College of Medicine, Houston, TX 77030

Neuronal dendrites have long been thought to be largely passive, but recent information suggests otherwise and that the presence of excitatory voltage-dependent channels can have a great effect on neuronal excitability and even plasticity. The presence of sodium channels on neuronal dendrites has been inferred by electrophysiological and optical methods using sodium-sensitive fluorescent dyes. However, immunocytochemistry using type-specific antibodies has failed to demonstrate their presence anywhere but neuronal somata and axons, though the techniques to demonstrate their presence were not as sensitive as current methods employing scanning confocal fluorescent laser microscopy (SCFLM). Using SCFLM and previously characterized polyclonal antibodies prepared against purified sodium channels and anti-peptide antibodies to type II sodium channels, we have found that sodium channels are distributed on dendrites in the hippocampus, cortex and cerebellum of rat brain. Structures which co-stained with monoclonal antibodies to MAP-2 dendritic protein were classified as dendrites and could be followed for several hundred micrometers through 50 μm slices of fixed rat brain. Dendrites of pyramidal and apyramidal neurons in the CA1-CA3 regions and cortex contained sodium channels from their soma to nearly the tips of their dendrites. Dendrites of cerebellar purkinje neurons also contained sodium channels. We have found no evidence to indicate that sodium channels are present on dendritic spines. The presence of sodium channels on dendrites conveys the dendrites with greater information processing and storage capabilities. Compared to passive dendrites, as few as two neighboring sites of synaptic input to a dendrite can become potentiated without depolarizing the entire dendrite, minimizing the necessary length of the dendrite over which the inputs take place as well as the number of inputs or associations. Thus, local regions of the dendrite can serve as individual information processing and storage units. We have confirmed this theoretical possibility with computer models that incorporate the latest information on channel distribution and kinetics.

628.8

A PHARMACOLOGICALLY AND KINETICALLY DISTINCT Na⁺-DEPENDENT AFTERPOTENTIAL IS PRESENT ON RAT CUTANEOUS BUT NOT MUSCLE AFFERENT FIBERS. O. Honmou*, D. A. Utschneider, C. M. Bowe, S. G. Waxman, and J. D. Kocsis*. Dept. of Neurology, Yale Med. Sch., New Haven, CT. 06510; and VAMC, West Haven, CT. 06516, ² Dept. of Neurology, Univ. California, Davis, CA. 95616.

The effects of the potassium channel blocker, 4-aminopyridine (4-AP) and tetraethylammonium (TEA) on myelinated cutaneous (sural nerves) and muscle afferent fibers (deafferented muscle branches in tibial nerves) were investigated using intra-axonal recording techniques *in vitro*. The nerves were removed from 5 week old Wistar rats and placed in an *in vitro* recording chamber. Application of 4-AP (1 mM) on muscle afferents but not cutaneous afferents led to a slight broadening of the action potential; cutaneous afferents developed a pronounced delayed depolarization with burst firing which was followed by an afterhyperpolarization (AHP). TEA (10 mM) alone had little effect on both fiber types, but in combination with 4-AP the AHP was eliminated and a single stimulus induced repetitive firing on cutaneous fibers. The delayed depolarization was Na⁺-dependent and Ca²⁺-independent. Hyperpolarization increased and depolarization decreased the amplitude of the delayed depolarization. In cutaneous afferents tetrodotoxin blocked both the action potential and the delayed depolarization. However, the delayed depolarization but not the action potential was blocked by low concentrations (100 μM) of lidocaine; higher concentrations of lidocaine effected the action potential as well. These results indicate that cutaneous afferents can be distinguished from muscle afferents based on their sensitivities to 4-AP. Moreover, evidence is presented to suggest that the delayed depolarization of cutaneous afferents is generated from a pharmacologically and kinetically distinct Na⁺ conductance not present on muscle afferents.

628.10

SODIUM CHANNEL mRNAs IN SPINAL CORD ASTROCYTES *IN VITRO*. J.A. Black*, S. Yokoyama, Y. Oh, K.B. Zur, H. Higashida, B.R. Ransom and S.G. Waxman. Dept. Neurology, Yale Sch. Med., New Haven CT and VAMC, West Haven CT, and Dept. Biophysics, Kanazawa Univ. Sch. Med., Japan.

Voltage-sensitive sodium channels are most often responsible for generating action potentials in neurons; these ion channels have also been described in astrocytes *in vitro* and *in situ*, though their function is less clear. Three distinct sodium channel mRNAs (R₁, R₂, and R₃) have been cloned from rat brain; a fourth mRNA (R₄) may represent alternative splicing. Recently, a partial clone of a putative glial cell-specific mRNA (NaG) has also been described. Since morphologically and antigenically distinct cultured astrocytes possess different electrophysiological properties, which may reflect specific sodium channel isoforms, we examined the expression of sodium channel mRNA in these glial cells utilizing non-isotope *in situ* hybridization methods.

Digoxigenin-substituted riboprobes were constructed for specific coding and 3'-noncoding regions of R₁, R₂, and R₃, and for a coding region in NaG. In addition, 40-mer probes specific for R₁, R₂, and R₃ were synthesized and tailed with digoxigenin-dUTP. Astrocyte cultures were established from P0 rat spinal cords and maintained for up to 21 days *in vitro* (div).

The results demonstrate a developmental progression of mRNA expression. At 4 div, flat, fibroblast-like and stellate astrocytes expressed R₂ mRNA, and to a lesser extent R₁ mRNA. By 7-14 div, R₁ mRNA expression was predominant and R₂ mRNA expression was attenuated; within this timespan, NaG mRNA became weakly expressed. Stellate astrocytes typically were more intensely labeled than flat astrocytes. At all times in culture and for all astrocytes, R₃ was not detectable. These observations suggest that differences in electrophysiological properties of cultured astrocytes do not reflect expression of a single sodium channel isoform. [Supported in part by DVA, NMSS and NIH]

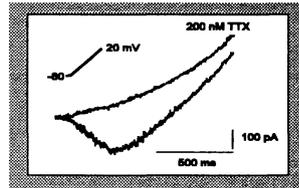

628.11

A SURVEY OF PERSISTENT Na⁺-CURRENTS IN RAT AND HUMAN NEURONS. A. Alonso, J.A. White, A. Olivier & A.R. Kay†, Dept. Neurology & Neurosurgery, McGill Univ., MNI, Montreal, Canada H3A 2B4; and †Dept. of Biol. Sci., Univ. of Iowa, Iowa City, IA 52242

A persistent sodium current (I_{Na}^P) plays a fundamental role in determining the nonlinear properties of some neurons. I_{Na}^P activates and deactivates rapidly (<1ms) and inactivates only very slowly (< 20% over 1 sec) and is completely blocked by 100 nM TTX.

Neurons were acutely dissociated from rat and human brain. I_{Na}^P was observed in whole-cell voltage clamp recordings in neurons derived from rat neocortex, entorhinal cortex, basal forebrain & cerebellum. When I_{Na}^P was present, it displayed the stereotyped behavior described above. The ratio of I_{Na}^P to rapidly inactivating Na current was not fixed, suggesting that if I_{Na}^P does arise through "mode-switching" the switching may be modulated, or alternatively the channels might be distinct.

I_{Na}^P was observed in acutely dissociated neurons from human entorhinal cortex (below) with kinetic properties similar to those found in the rat.

Whole-cell recording from acutely dissociated neurons from human entorhinal cortex. Voltage-clamp response to slow ramp command. Intracellular solution (nM): 120 CaCl₂, 1 CaCl₂, 10 Hepses, 10 EGTA, pH 7.25. Extracellular: 120 NaCl, 2 CaCl₂, 2 MgCl₂, 15 TEA Cl, 5.4 AP, 0.5 CaCl₂, 10 Hepses, 25 Glucose, pH 7.4

A FAST, ZINC-SENSITIVE, TTX-RESISTANT Na⁺-CURRENT IN THE MEDIAL ENTORHINAL CORTEX. J.A. White*, A. Alonso† and A.R. Kay, Dept. of Biol. Sci., Univ. of Iowa, Iowa City, IA 52242; and †Dept. Neurology & Neurosurgery, McGill Univ., MNI, Montreal, Canada H3A 2B4

Acutely dissociated neurons from the superficial layers of the medial entorhinal cortex (mEC) of the mature rat were studied under voltage-clamp using the whole-cell patch-clamp configuration. In addition to the normal TTX-sensitive Na⁺ current (I_{TTX-S}) traditionally found in neurons from the adult mammalian CNS, neurons from the mEC exhibit a tetrodotoxin-resistant Na⁺ current (I_{TTX-R}). I_{TTX-R} was found in both putative stellate and pyramidal neurons from the mEC. I_{TTX-R} is blocked by high levels of TTX ($IC_{50} \approx 500$ nM) and is abolished by replacement of NaCl with TrisCl in the recording medium. The TTX-resistant current is kinetically indistinguishable from I_{TTX-S} with a half-activation voltage of -36 mV, a half-inactivation voltage of -64 mV, very fast activation kinetics ($\tau_m < 1$ ms) and fast inactivation kinetics ($\tau_h = 3$ ms at $V = -20$ mV). However, I_{TTX-R} can be distinguished from I_{TTX-S} based on its enhanced sensitivity to block by cadmium ($IC_{50} \approx 1$ mM), lanthanum ($IC_{50} \approx 10$ μ M), and zinc ($IC_{50} = 9$ μ M). I_{TTX-R} shares many characteristics with the TTX-resistant Na⁺ current found in cardiac muscle, including high sensitivity to block by divalent cations. The sensitivity of I_{TTX-R} to block by Zn²⁺ and the presence of Zn²⁺ in the neuropil surrounding neurons in layers II and III of the mEC suggest the possibility that synaptically-released zinc may reduce the excitability of neurons in the mEC by blocking I_{TTX-R} . Modeling results support this hypothesis.

ANTIBODIES TO RAT BRAIN SODIUM CHANNEL SUBTYPE III PURIFIED FROM THE EGGS OF IMMUNIZED HENS. M. Jarnott*, F.J. Alvarez†, D.A. Harrington†, R.E.W. Fyffe† and A.M. Corbett†, Depts. of Anatomy† and Physiology and Biophysic†, Wright State Univ., Dayton, OH 45435.

Antibodies to synthetic peptides corresponding to specific regions of the voltage-gated sodium channel from rat brain have been produced by several groups to study the distribution of channel subtypes within the brain. However, these antibodies, commonly produced in rabbits, are not usually present in high titers and must be used at very low dilutions in immunohistochemistry. Egg yolks from immunized hens have been shown to be a rich alternative source of antibodies against both synthetic peptides and purified proteins, with higher titers than are normally found in serum. In this study, laying hens were immunized with a synthetic peptide corresponding to a unique region of the carboxyl terminus of sodium channel subtype III from rat brain (amino acids 1980-1995) coupled to keyhole limpet hemocyanin. IgY (50-60 mg/yolk) was extracted from 5 days' pooled egg yolks using a PEG-chloroform isolation procedure (Polson, 1990). Antibodies were purified by passage over an antigen affinity column containing the peptide coupled to bovine serum albumin immobilized on Sepharose, followed by elution at low pH. Analysis of the resulting fractions by ELISA and with immunoblots of crude brain membranes demonstrated specific labeling with postimmune but not preimmune extracts, which could be blocked by preincubation of the antibody with peptide. No cross-reactivity was observed with peptides corresponding to similar regions of sodium channel subtypes I and II. Specific staining of cell bodies of adult rat brain and spinal cord was observed in tissue sections using antibody dilutions up to 1:200. This work supported by NIH Grants NS28377 and NS25547.

ION CHANNEL MODULATION AND REGULATION III

629.1

REGULATION OF THE NUMBER OF VOLTAGE-DEPENDENT Na AND K CHANNELS IN CULTURED NEUROBLASTOMA CELLS. J. K. Hirsh* and F. N. Quandt, Dept. Physiology, Rush Univ., Chicago, IL 60612.

The expression of proteins in neurons may be regulated by various factors such as electrical activity, however factors which control the expression of Na and K channels have not been extensively investigated. The number and type of voltage-dependent channels expressed in N1E-115 mouse neuroblastoma cells were found to be dependent on growth conditions. Expression of voltage dependent currents was quantified by measuring whole-cell currents recorded from neurons 25 to 35 μ m in diameter in normal saline solution. Differentiated neurons express two types of voltage-dependent K channels. One type (K_f), rapidly activates and inactivates following a step depolarization while a second type (K_s) exhibits much slower gating. The ratio of K_f to ($K_s + K_f$) increased when cells were inhibited from dividing by growing them in solution having low serum and dimethylsulphoxide. These non-dividing cells, grown in media also containing 1 μ M A23187 for three days had a low ratio of I_{Na} to total I_K . However cells grown in 50 mM external K, had a factor of 2 higher ratio of K_f to total K current. In order to determine whether regulation occurs at the level of transcription, levels of mRNA for voltage-dependent channels are being assayed for cells grown under various conditions. Genes for the expressed Na and K channels in N1E-115 cells are being identified using polymerase chain reaction-specific amplification of cDNA from isolated mRNA. Amplified products indicate that these cells express channels from both K_{V1} and K_{V3} families. Supported by the National Multiple Sclerosis Society.

629.2

MODULATION OF SINGLE ATP-GATED CHANNEL ACTIVITY BY EXTRACELLULAR ZINC IONS IN RAT SYMPATHETIC NEURONS. R. Cloues* and D.A. Brown, Department of Pharmacology, University College London, London WC1E 6BT, U.K.

Adenosine 5'-triphosphate (ATP) is a neurotransmitter in both the central and peripheral nervous systems. We examined ATP-activated currents and their modulation by extracellular zinc (Zn^{2+}) in cultured rat superior cervical ganglion cells. In whole-cell recordings, ATP activated a non-specific cation current with a null potential near 0 mV. The current was carried in part by Ca^{2+} and was blocked by the P_2 -purinoceptor antagonist, suramin. Low concentrations of Zn^{2+} (0.5-10 μ M) strongly potentiated the current amplitude. The effect of Zn^{2+} was dependent on the concentration of agonist: Zn^{2+} lowered the threshold of activation without increasing the maximum response. The ATP-induced rise in intracellular Ca^{2+} , measured using Indo-1 fluorescence, was also enhanced by Zn^{2+} . Single channels activated by ATP were recorded using outside-out, nystatin-perforated vesicles. The channels were small (1.2 pA at -80 mV) and showed considerable flicker in the open state. Zn^{2+} significantly increased the ATP-evoked channel open probability without affecting the unitary current amplitude. Thus, changes in the concentration of extracellular Zn^{2+} may modulate activation of the receptor by ATP, thereby affecting ATP-mediated Ca^{2+} entry into the cell. Supported by the Wellcome Trust.

A NOVEL SUBTYPE OF SULFONYLUREA-SENSITIVE K⁺ CHANNEL MODULATED BY DOPAMINE IN RAT STRIATUM. Yong-Jian Lin*, Gabriela J. Greif and Jonathan E. Freedman. Dept. Pharmaceutical Sciences, Northeastern Univ., Boston, MA 02115.

We studied the ability of the sulfonylurea drugs tolbutamide and glibenclamide (glyburide) to block the 85 pS K⁺ channel activated by D_{2/3/4} dopamine receptor agonists in dissociated rat corpus striatum (caudate-putamen) neurons. In cell-attached patch-clamp recordings in the presence of 10 μM quinpirole, tolbutamide (IC₅₀~60 nM) was 10-100 times more potent than glibenclamide (IC₅₀~2 μM), a rank-order potency opposite to that typically observed at ATP-sensitive K⁺ channels. Furthermore, the K_{ATP} channel opener diazoxide (50 μM) was relatively ineffective at opening the 85 pS channel. However, these channel openings were elicited in the absence of dopamine receptor agonist when the cells were treated with the metabolic inhibitor rotenone (5 μM), demonstrating activation of these channels under energy-depleting conditions. These results suggest that the 85 pS K⁺ channel modulated by dopamine receptors in rat striatum belongs to a new class of sulfonylurea- and metabolism-sensitive K⁺ channels. Thus, there may be a link between dopaminergic transmission and mechanisms protecting against excitotoxicity. (Supported by NIH FIRST award MH-48545.)

ACTIONS OF INACTIVATION PEPTIDES ON VOLTAGE-ACTIVATED K⁺ CURRENTS IN RAT DRGs AND A CLONED BRAIN K⁺ CHANNEL, MK-1 (mKv1.1). F. Hebllich, B. Robertson, A. Opaiko & D.G. Owen*. Wyeth Research (U.K.) Ltd., Taplow, Berkshire SL6 0PH, U.K.

It has been shown that in the *Shaker B* potassium channel, an N-terminal sequence mediates fast inactivation (Zagotta et al. Science 250 568, 1990). Using standard patch clamp techniques, we have examined the effects of this peptide (MAA-VAGLYGLGEDRQHRKKQ) (*Sh20-mer*) on a cloned potassium channel from mouse brain (MK-1) expressed in CHO cells, and on native voltage-activated K⁺ currents in rat DRG neurones, which are known to express the rat homologue of MK-1, RCK-1 (rKv1.1). The *ShB* peptide transformed MK-1 from a non-inactivating current into a rapidly decaying current (τ_d = 12 ± 1.2 ms at +60 mV, n=12). Similarly, the decay of K⁺ currents (principally the transient outward current) in DRGs were accelerated when exposed to the *ShB* peptide internally. We have extended these observations to include another inactivation particle, a 28 amino acid peptide (*h28-mer*) based on the N-terminal sequence of a human K⁺ channel (MISS-VCVSSYGRKSGNKPPSKTCLKEE), hKShIIc (hKv3.4) (Rudy et al., J. Neurosci. Res. 29 401, 1991). This peptide also enhanced inactivation of DRG outward currents and produced rapid inactivation in MK-1 channels, with a τ_d of 66 ± 9 ms at +60 mV (n=24). The results imply a degree of conservation in N-type inactivation mechanisms across both species and K⁺ channel sub-families.

We would like to thank Bruce Tempel for the stable expression of MK-1 in CHOs, and Janette Scott for tissue culture.

SINGLE DELAYED RECTIFIER K⁺ CURRENTS OF FROG SKELETAL MUSCLE ARE MODULATED BY G PROTEINS. M. Vazquez and J. A. Sanchez*. Department of Pharmacology CINVESTAV-IPN, A. Postal 14-740, Mexico D.F. 07000 and Department of Physiology UNAM, Mexico, City D.F. Mexico.

Modulation of delayed rectifier K⁺ channels (I_K) of frog muscle was investigated in isolated vesicles formed from the sarcolemma of twitch skeletal muscle (*Rana montezumae*). **Methods:** Patch clamp recordings in the inside-out patch configuration in vesicles formed as described by Standen et al. (J. Physiol. (1985) 364:339-358). Solutions (mM): Pipette contained KCl=120, CaCl₂=2, HEPES=5. Bath contained KCl=120, MgCl₂=2, EGTA=5, HEPES=5, ATP=2. pH=7.2 and T=22-25°C. **Results:** I_K were identified by their sensitivity to TEA and by reversal potential measurements in asymmetrical solutions. The single channel conductance (γ) was ca. 60 pS. Continuous recordings for 50 s revealed the presence of bursts followed by silent periods of ca. 5 s. Substitution of Cl⁻ by F⁻ greatly increases the duration of the silent periods in a concentration dependent manner. In [F⁻]_i ≥ 30 mM I_K virtually disappears. The effects are reversible. No significant changes in τ were observed. GTPγS (100 μM) had similar effects and GDPβS and Pertussis toxin prevented the effects of both F⁻ and GTPγS. Modulation did not involve changes in open time. Supported by CONACyT grant #0287N.

629.4

DIRECT G-PROTEIN COUPLING OF D₂ DOPAMINE RECEPTORS TO K⁺ CHANNELS IN RAT STRIATAL NEURONS. Gabriela J. Greif*, Yong-Jian Lin and Jonathan E. Freedman. Dept. Pharmaceutical Sciences, Northeastern Univ., Boston, MA 02115.

We studied the coupling of D_{2/3/4} dopamine receptors to an 85 pS K⁺ channel in cell-attached patch-clamp recordings from freshly dissociated rat corpus striatum (caudate and putamen) neurons. Multipolar cells of ≥10 μm diameter were most likely to display this channel activity. Openings of the 85 pS channel were observed on these cells when 10 μM dopamine or quinpirole was present in the patch pipette (26% of 172 cells tested), but were never observed in the absence of agonist (n=130 cells). Application of dopamine via a macropipette to the cell membrane outside the patch did not elicit openings (n=41), suggesting spatial proximity between the receptor and the channel. Substituting the GTP-binding protein activator mastoparan (100 μM) for agonist in the pipette also elicited 85 pS channel openings. The membrane-permeable cyclic AMP analogs Rp-cAMPS and Sp-cAMPS (100 μM via macropipette) did not have gross effects on channel opening, arguing against a major, direct role for cAMP. This suggests that receptor-channel coupling may be through a mastoparan-sensitive G-protein, independently of a diffusible second messenger. (Supported by NIH FIRST award MH-48545.)

629.6

STUDIES ON THE SITE OF ACTION OF 4-AMINOPYRIDINE ON THE CLONED POTASSIUM CHANNEL MK-1 (mKv1.1). B. Robertson*, J. C. Garratt, D. G. Owen & G. J. Stephens Wyeth Research (U.K.) Ltd, Taplow, Berkshire SL6 0PH, U.K.

The interaction between 4-AP and the first 20 amino acids from the N-terminus sequence of the *Shaker B* channel (inactivation peptide) was studied using the whole-cell patch clamp technique in Chinese hamster ovary (CHO) cells transfected with the vector containing the DNA encoding MK-1 potassium channels. Transfected cells expressed an outward current that activated from -40 mV, and reversed at the potassium equilibrium potential. The half maximal conductance of MK-1 was at -10 mV and had a slope factor of 11 when fitted with a Boltzmann function. There was only a very slight (<10%) inactivation of MK-1 even at very large positive voltages. 4-AP caused dose- and time-dependent block of the outward current when applied extracellularly or intracellularly with IC₅₀'s of 147 and 117 μM respectively. Inclusion of the inactivation peptide in the patch pipette solution (at 2 mg/ml) transformed MK-1 into a rapidly inactivating current with a time constant of decay of 12 ± 1.2 ms at +60 mV (n=12). In the presence of the inactivation peptide, extracellular 4-AP was less potent with an IC₅₀ of 537 μM. Since the inactivation peptide is known to have a receptor on the cytoplasmic side of MK-1 these findings would support the hypothesis that 4-AP acts intracellularly; possibly at the same site as the inactivation peptide.

We would like to thank Bruce Tempel for MK-1 and expressing CHOs, and Janette Scott for tissue culture.

629.8

MODULATION OF DELAYED RECTIFIER POTASSIUM CHANNEL FROM ANTERIOR PITUITARY CELL LINE BY PROTEIN PHOSPHORYLATION.

S. Chung*, L.K. Kaczmarek. Dept. of Pharmacology, Yale Medical School, New Haven, CT 06510

The perforated-patch configuration was used to record the delayed rectifier currents in metabolically intact GH₄C₁ cells. The current was isolated by removal of bath Ca²⁺. The inactivation of the current was well fitted by a sum of exponentials (500-900 ms, and 1.2-3 s). Bath application of a cAMP analog, dibutyryl cAMP, decreased the current at all voltages. The peak currents decreased by 12%, while the end currents of the 500 ms step from -80 to +40 mV decreased by 28%. Both of the inactivation times were reduced (300-500 ms, and 0.8-1.3 s). Cell-attached patch recordings were made of the delayed rectifier channel activity at the single channel level. The most frequent channel in the patch was 5 pS channel which inactivated with time constant of 3-7 s. Dibutyryl cAMP reduced the inactivation time to 2-4 s. Ensemble currents of single channel activities showed that the effect of dibutyryl cAMP was to decrease the current. The neuropeptide somatostatin, which is known to activate a protein phosphatase in this cell [White et al. Nature 351, 570 (1991)], reversed the effect of dibutyryl cAMP. These studies strongly suggest that the delayed rectifier channel of this cell is modulated by protein phosphorylation.

ACTIVATION OF PKC BLOCKS THE METABOTROPIC GLUTAMATE RECEPTOR MEDIATED INHIBITION OF CALCIUM CURRENTS IN DENTATE GRANULE NEURONS. T. A. Valiante, M. A. Abdul-Ghani, P. S. Pennefather, P. L. Carlen. MRC Nerve Cell and Synapse Group, Playfair Neuroscience Unit, University of Toronto, Canada.

Intracellular calcium has been implicated in several neuronal processes including modulation of transmitter release, enzymatic activity like protein kinases and phosphatases, neuronal plasticity, and neurotoxicity. Since calcium influx through the cell membrane alters intracellular calcium levels, modulation of calcium currents plays a fundamental role in altering neuronal function. We have studied the modulation of calcium currents recorded from dentate granule neurons in the hippocampal slice preparation by the metabotropic glutamate receptor (mGluR) and protein kinase C (PKC) using the whole cell configuration of the patch clamp technique. Activation of mGluRs by trans-ACPD (50 μ M) produced a reversible reduction in calcium currents, that was blocked by the inclusion of 1.2 mM GDP- β -S in the patch pipette. Activation of PKC by the phorbol ester PMA (5 μ M) reduced calcium currents, and blocked the inhibition of calcium currents by trans-ACPD. Our results show that activation of mGluR on dentate granule cells, as on CA3 neurons (Schwartz et al., Nature 361:165-168 1993), inhibits calcium currents by a process that is modulated by PKC.

RUN-UP OF NMDA-ACTIVATED CURRENT IN *XENOPUS* OOCYTES EXPRESSING NMDA RECEPTOR SUBUNITS IS SENSITIVE TO CYTOSOLIC Ca^{2+} . U. Brauneis, K. Masood, C. Yi and F. F. Weight. Lab. Molecular & Cellular Neurobiology, NIAAA, NIH Rockville, MD 20852

The recent cloning of the NMDA receptor has presented the opportunity to investigate functional differences between subunits and subunit combinations. In this study different subunit combinations were expressed in *Xenopus* oocytes and currents elicited by NMDA were measured using two-electrode voltage-clamp. In some combinations, repeated application of NMDA for 20-50sec at 5-7min intervals resulted in an increased current amplitude with each subsequent application, until a level was attained that was stable for several hours. This "run-up" in Ca^{2+} -containing bath solution, expressed as $\% \pm SE$ of the first measured current, was: $e2/\gamma1 = 144 \pm 13\%$, $e1/\gamma1 = 115 \pm 13\%$. No "run-up" was observed using the $e3/\gamma1$ subunit combination ($98 \pm 7\%$). With the $e2/\gamma1$ combination, the injection of 10nM EGTA (50mM) into oocytes 15min-3h prior to recording abolished current "run-up" ($106 \pm 4\%$). "Run-up" also occurred in both solutions containing Ba^{2+} instead of Ca^{2+} ($126 \pm 7\%$). This makes unlikely the possibility that the increased current is merely due to a Cl⁻ conductance activated by the influx of Ca^{2+} through NMDA channels. As $e1/\gamma1$ and $e2/\gamma1$ but not $e3/\gamma1$ show sensitivity to protein kinase C (PKC) activators, we looked at the role of PKC in "run-up" and found that pretreatment of the oocytes with the PKC inhibitor staurosporine (5 μ M for 1h) had no apparent effect on "run-up". These observations suggest that "run-up" of NMDA-activated current with repeated receptor stimulation is dependent upon cytosolic Ca^{2+} , but may not involve PKC.

629.13

HISTAMINE MODULATES NMDA-CURRENTS IN HIPPOCAMPUS. H.L. Haas*, I.N. Sharonova, D.R. Stevens, V. Uteshev, V.S. Vorobjev and I.B. Walsh Institute of Physiology II, Heinrich-Heine-University, DW-4000 Dusseldorf, Germany.

N-methyl-D-aspartate (NMDA) currents were recorded from isolated rat hippocampal neurones, using patch-clamp techniques and a rapid perfusion system. Histamine, at 0.5 to 100 μ M, reversibly enhanced NMDA currents up to 150%. The effect cannot be ascribed to activation of the known histamine receptors (H₁, H₂, H₃) or to an action on the NMDA agonist site or the glycine co-agonist site. It is occluded by spermine and suppressed by the putative polyamine site antagonist diethylenetriamine (DET). NMDA channel mean open time and mean amplitude were minimally affected but mean burst duration was enhanced from 27 ± 3 ms to 51 ± 11 ms by 5 μ M histamine.

In hippocampal slices, in the CA 1 area, AP5-sensitive multiple population spikes in Mg^{2+} -free medium were enhanced by histamine, but NMDA-currents evoked by local pressure application and epsps following stratum radiatum stimulation in the presence of DNQX and bicuculline were depressed by about 20%.

These results suggest an interaction of histamine with the polyamine binding site on the NMDA receptor complex. This new modulatory action enables the histaminergic system to determine time and loci of NMDA-receptor mediated events such as memory formation according to behavioral state.

629.10

NMDA CURRENT IN SUPRACHIASMATIC NEURONS AND ITS MODULATION BY CALCIUM IONS. M. Ragenbass, S. Aliberi and J.J. Dreifuss*. Department of Physiology, University Medical Center, CH-1211 Geneva 4, Switzerland.

Due to their small size, suprachiasmatic neurons have been difficult to study with standard intracellular recording techniques. We have used whole cell patch clamp recordings and hypothalamic slices of the rat in order to characterize the effect of N-methyl-D-aspartate (NMDA). Cell input resistances ranged from 500 to 1000 M Ω . In current clamp conditions, NMDA at 50-100 μ M induced a 10-30 mV depolarization in most neurons. In the voltage clamp mode, NMDA generated an inward current of 10-60 pA, which was insensitive to 1 μ M TTX and which reversed at about 0 mV. The current/voltage relation contained a region of negative slope conductance. The NMDA current was reversibly reduced or suppressed by D(-)-2-amino-5-phosphonopentanoic acid (D-AP5) at 20-40 μ M. It could be enhanced by lowering the extracellular magnesium concentration from 1 to 0.01 mM, or by adding 10 μ M glycine to the perfusion solution. In 7 out of 8 neurones, lowering the extracellular calcium concentration from 2 to 0.01 mM caused a 1.5- to 2.5-fold potentiation of the NMDA current. Increasing the calcium concentration from 1 to 5 mM did not affect significantly the amplitude of this current. These results indicate that NMDA receptors are present on suprachiasmatic neurons and suggest that these receptors may in part mediate glutaminergic synaptic transmission in the suprachiasmatic nucleus. They also suggest that, in addition to magnesium ions, calcium ions may also exert a modulatory action on the NMDA-induced current.

TIME COURSE OF NMDA RECEPTOR CALCIUM-DEPENDENT INACTIVATION WITH INTACT INTRACELLULAR ENVIRONMENT. A. Kyrozis* and A.B. MacDermott. Dept. Physiology & Cellular Biophysics and Center for Neurobiology & Behavior, Columbia Univ., New York, NY 10032.

The kinetics and amplitude of the response to NMDA receptor (NMDA-R) activation varies with intracellular $[Ca^{2+}]_i$ ($[Ca^{2+}]_i$). Using perforated whole-cell recording to avoid exogenous Ca^{2+} buffering and wash-out of critical intracellular molecules, we have observed that the peak but not the steady state response to exogenous NMDA is invariably suppressed when preceded by a voltage step that elicits Ca^{2+} entry. This indicates that $[Ca^{2+}]_i$ can regulate NMDA-R under normal cellular buffering conditions. To determine the kinetics of Ca^{2+} -dependent modulation of NMDA-R, we briefly applied a saturating dose of glutamate (Glu, 30 μ M) to embryonic dorsal horn neurons grown in culture under 2 different experimental conditions. NMDA-R component was isolated by including (in μ M) CNQX(30), Gly(100) & strychnine(5) in all drug solutions. First, fast application of Glu in 20 μ M Ca^{2+} was followed by Glu in 2mM Ca^{2+} . The switch to 2mM Ca^{2+} caused current decay to a steady state amplitude of $26 \pm 2\%$ of the amplitude in low Ca^{2+} , with time to 2/3 of total relaxation $t_{2/3} = 90 \pm 10$ msec (mean \pm SEM, n=4). Second, following application of Glu in 20 μ M Ca^{2+} , the solution was rapidly switched to APV (25 μ M) to avoid Glu rebinding to NMDA-Rs, a condition designed to simulate synaptic transmission. When APV was in 2mM Ca^{2+} , the current decay in 4 of 5 cells was significantly faster ($t_{2/3} = 139 \pm 17$ msec) than the decay with APV in 20 μ M Ca^{2+} (230 ± 6 msec for the same cells). These results indicate that Ca^{2+} -dependent NMDA-R inactivation has a faster onset than previously described and that it may enhance the decay of NMDA-R-mediated synaptic events. (supported by GM32099)

629.14

MODULATION OF NMDA AND AMPA RESPONSES BY cAMP-DEPENDENT PROTEIN KINASE AND PROTEIN KINASE C IN SPINAL DORSAL HORN NEURONS. R. Cerne* and M. Randić. Dept. of Vet. Physiol. and Pharmacol., Iowa State University, Ames, IA 50011

Glutamate-gated ion channels mediate excitatory synaptic transmission in the central nervous system, including spinal dorsal horn, and are involved in synaptic plasticity, neuronal development and excitotoxicity. These ionotropic glutamate receptors are classified according to their preferred agonists as AMPA (α -amino-3-hydroxy-5-methyl-4-isoxazolepropionic acid), KA (kainate), and NMDA (N-methyl-D-aspartate) receptors. The present study of NMDA and AMPA receptors expressed in acutely isolated spinal dorsal horn (DH) neurons of young rats (7-15 days) reveals that these receptors are subject to modulation through the adenylate cyclase cascade and protein kinase C (PKC). Whole-cell voltage-clamp recording mode was used to examine the effects of adenosine 3',5'-monophosphate (cAMP)-dependent protein kinase (PKA) and protein kinase C on the responses of DH neurons to NMDA and AMPA. Whole-cell current responses to NMDA and AMPA were enhanced by 8 Br-cAMP, a membrane permeant analog of cAMP or by intracellular application of cAMP, or catalytic subunit of PKA (cPKA) in a proportion of DH neurons. In addition, the AMPA responses were potentiated by phorbol esters, the agents that activate protein kinase C and by intracellularly applied PKC. Our results indicate that NMDA and AMPA receptors are modulated by PKA and PKC and that this modulation is potentially an important mechanism to control excitability of spinal DH neurons and the efficacy of synaptic transmission (Supported by NS-26352 and IBN-9209462).

629.15

ANCHORING OF THE REGULATORY SUBUNIT (RII) IS REQUIRED FOR cAMP-DEPENDENT PROTEIN KINASE MODULATION OF AMPA/KAINATE RECEPTORS ON HIPPOCAMPAL NEURONS. C. Rosenmund*, D.W. Carr, J.D. Scott and G.L. Westbrook. Vollum Institute, Oregon Health Sciences University, Portland, OR 97201.

Neuronal regulation by cAMP is largely mediated by phosphorylation of target proteins by the cAMP-dependent protein kinase (PKA). Rapid and preferential phosphorylation of key target substrates can be facilitated by receptor-specific activation of localized pools of PKA. Compartmentalization occurs via binding of the regulatory subunit (RII) to A-Kinase-Anchoring-Proteins (AKAPs) that are themselves attached to cell membranes or cytoskeletal structures such as the postsynaptic density.

AMPA/kainate receptors that mediate fast EPSCs at central synapses have been shown to be regulated by PKA (Wang et al., 1991; Greengard et al., 1991). We examined the role of AKAPs in mediating this action of PKA in cultured hippocampal neurons. Multiple AKAPs were demonstrated in cell extracts from these neurons by overlay assays probed with RII. The binding of RII to AKAPs was competitively inhibited by a 24 amino acid peptide derived from the RII binding domain, but not by a 16 amino acid fragment from the same region. If PKA localization is necessary for modulation of AMPA receptors in intact neurons, whole-cell dialysis with the 24mer should displace bound RII, and therefore prevent phosphorylation. Currents evoked by kainate (10 μ M) or (S)-AMPA (1 μ M, in the presence of 100 μ M cyclothiazide) were well maintained in the presence of ATP (5 mM, n=12). However, in the presence of PKA inhibitory peptide (PKI, 1 μ M), currents evoked by either agonist ran down to ~60% of the initial amplitude during 30 minutes of whole-cell recording (n=16). This is consistent with the reported role of PKA in maintaining AMPA channel activity. Intracellular dialysis with the 24mer peptide mimicked the effect of PKI (n=9), but the 16mer peptide had no effect (n=7). The inhibition could be overcome by intracellular dialysis with the catalytic subunit of PKA (n=6), suggesting that the peptides did not directly interfere with catalytic activity of the kinase. Our results suggest that PKA-mediated regulation of AMPA receptors or an associated regulatory protein requires anchoring of the kinase near the receptor. 2,3-BUTANEDIONE MONOXIME (BDM) BLOCKS GABA-AMINOBUTYRIC ACID (GABA) GATED CHLORIDE CURRENT OF ACUTELY ISOLATED MURINE HYPOTHALAMIC NEURONS. T. Carino, J.H. Ye, and J.J. McArdle. Dept. Pharmacol., New Jersey Med. Sch. (UMDNJ), Newark, NJ 07103-2714.

We have investigated the effects of BDM on GABA activated chloride current (I_{GABA}) of hypothalamic neurons acutely isolated from young mice. The nystatin perforated patch technique was used to record whole cell I_{GABA} from neurons rapidly superfused with drug containing solutions. When neurons were subjected to a holding potential of -50 mV, application of 300 μ M GABA produced a rapidly rising inward current which slowly decayed in the continued presence of agonist. Superfusion of neurons with a solution containing GABA and BDM concentrations ranging from 2 to 50 mM caused a progressive suppression of peak I_{GABA} . This effect of BDM was completely reversible upon washout. BDM is known to suppress voltage activated calcium and potassium currents of neurons. Our preliminary data demonstrate that BDM can also suppress a ligand-gated ion channel. Supported by NIAAA AA08025 and NIH NS31040.

³H-PROPOFOL BINDING AND PROPOFOL ACTION ON RECOMBINANT GABA_A RECEPTORS EXPRESSED IN HEK 293 CELLS AND XENOPUS OOCYTES. E. Sanna*, J.E. Dildy-Mayfield, S.J. McQuilkin, R.L. Klein, P.J. Whiting, M.P. Mascia, G. Biggio and R.A. Harris. Dept. of Pharmacol., Univ. of Colorado & Denver VAMC, Denver, CO 80262, Merk, Sharp & Dohme Res. Lab., Essex, U.K., and Dept. Exper. Biology, Univ. of Cagliari, Italy.

The general anesthetic propofol (Pro) potentiates GABA_A receptor function, but the precise mechanism and specificity of this action are still unclear. We measured ³H-Pro binding in HEK 293 cells transiently transfected with human GABA_A receptor subunit cDNAs and used *Xenopus* oocytes to assess the effect of Pro on GABA-gated Cl⁻ currents. Specific ³H-Pro binding was not greater in HEK 293 cells transfected with either homomeric (α 1, β 1, or γ 2S) or dimeric subunits (α 1 β 1, α 1 γ 2S, or β 1 γ 2S) than in non-transfected cells. Significantly higher (4-5 fold) specific ³H-Pro binding was detected in HEK 293 cells transfected with α 1 β 1 γ 2S or α 5 β 1 γ 2S subunit cDNAs. Stimulatory action of Pro on GABA-gated Cl⁻ currents recorded in oocytes was consistent with the above binding data. In oocytes expressing α 1 β 1 γ 2S receptors, Pro (1-25 μ M) induced a reversible and dose-dependent potentiation of GABA-gated currents (~800% at 25 μ M), whereas in oocytes expressing α 1 β 1 receptors, its effect was much lower (~200% at 25 μ M). Conversely, pentobarbital induced a larger potentiation of GABA responses in oocytes expressing α 1 β 1 compared to α 1 β 1 γ 2S receptors. Comparing Pro's effects on glutamate receptors, no detectable ³H-Pro binding was observed in 293 cells transfected with GluR6 receptor cDNA, and Pro had no effect on kainate responses in oocytes expressing either GluR6, GluR1 or brain mRNA. NMDA responses in oocytes expressing brain mRNA were inhibited 8 and 34% by 25 and 300 μ M Pro, respectively. These binding and functional results indicate that the anesthetic effects of Pro may be largely mediated through actions on GABA_A receptors, and this interaction may be influenced by the GABA_A subunit composition.

2,3-BUTANEDIONE MONOXIME (BDM) BLOCKS GLYCINE GATED CHLORIDE CURRENT OF ACUTELY ISOLATED MURINE HYPOTHALAMIC NEURONS. J.H. Ye and J.J. McArdle. Dept. Pharmacol., New Jersey Med. Sch. (UMDNJ), Newark, NJ 07103-2714.

Data from this lab, and others, demonstrate that BDM suppresses voltage gated calcium, sodium and potassium currents of various preparations. In an attempt to determine whether BDM also blocks ligand-gated currents, we evaluated its effects on glycine activated chloride current (I_{Gly}) of hypothalamic neurons acutely dissociated from young mice. The nystatin perforated patch technique was used to record I_{Gly} from neurons rapidly superfused with drug containing solutions. Pulses of 0.01 to 1 mM glycine alone rapidly induced a peak I_{Gly} . Desensitization caused a gradual decay of I_{Gly} . BDM concentrations ranging from 0.05 to 50 mM caused a dose dependent suppression of I_{Gly} . BDM appears to cause open channel block since the peak I_{Gly} remained largely unaltered while the slowly decaying portion was greatly diminished. This block occurred rapidly and was completely removed upon washout of the BDM containing solution. Other work in this laboratory demonstrates that BDM also blocks GABA gated chloride current. Thus, BDM acts non-selectively to suppress voltage and ligand gated ion currents. Supported by NIAAA AA08025 and NIH NS31040.

ACETYLCHOLINE RECEPTORS: NEURONAL NICOTINIC II

630.1

NICOTINIC ANTAGONISTS DISTINGUISH BETWEEN SYNAPSES ON SYMPATHETIC B AND C NEURONS IN THE BULLFROG. W-X Shen* and JP Horn. Department of Neurobiology, University of Pittsburgh, School of Medicine, Pittsburgh, PA 15261.

The block of nicotinic EPSPs in sympathetic B and C neurons by curare, hexamethonium, and mecamylamine was compared using trains of 40 preganglionic stimuli at frequencies between 0.5 and 20 Hz. Antagonism of nicotinic transmission had 2 components.

Use-independent IC₅₀s were measured from block of the first extracellular compound action potential in the train. The C cell AP was more sensitive than the B cell AP to all 3 drugs. However, the relative selectivity (B_{IC50}/C_{IC50}) varied from 1.5 (curare) to 5.7 (mecamylamine).

Use-dependent effects appeared as rundown or fade of the compound AP during trains. In the B cell system, fade occurred at frequencies as low as 0.5 Hz and at drug doses which had little effect on the first AP in the train. By contrast, fade of C-cell responses in all 3 drugs occurred only at higher frequencies (10-20 Hz). Intracellular recording was used to analyze differences in fade between B and C cells. In curarized (20 μ M) B cells, EPSPs but not iontophoretic responses to ACh faded at 2 Hz. This suggests fade is presynaptic (eg. depression). EPSCs recorded from B cells in control Ringer under single-electrode voltage-clamp faded in a frequency-dependent manner between 2-20 Hz. By contrast, EPSCs in C cells grew during trains at 2 Hz and the apparent facilitation was larger at 10 Hz. Fade appeared in C cell EPSCs at 20 Hz.

The data suggest that B and C cells may differ in terms of their nicotinic receptors and the dynamics of ACh release.

NICOTINIC ACETYLCHOLINE RECEPTOR FUNCTION IN NEURONAL SUBPOPULATIONS. M. E. McNamary and J. E. Margiotta* Dept. of Physiology & Biophysics, Mount Sinai School of Medicine, NY, NY 10029.

The chick ciliary ganglion contains choroid and ciliary neuron subpopulations, which both express functional nicotinic acetylcholine receptors (AChRs). Choroid and ciliary neurons can be distinguished by criteria that include differences in their preganglionic terminals, peripheral targets, ganglionic position, receptor pharmacology and soma size. We are now examining the two populations for differences in the expression and regulation of functional AChRs. Size measurements from ~700 ciliary ganglion neurons, that were freshly-isolated at embryonic day 14 (E14), revealed a bimodal distribution of soma surface areas; calculation of 95% confidence limits for each mean demonstrated that the two populations could be segregated by size. Choroid neurons were identified as having soma areas $\leq 550 \mu$ m², and ciliary neurons as having soma areas $\geq 1200 \mu$ m², in accord with observations from other laboratories. ACh responses were obtained from E14 neurons in subsequent whole cell recordings at -70 mV following microperfusion with 10 or 500 μ M ACh. In each trial, the peak conductance response was normalized to the neuron's membrane capacitance, which varies directly with membrane area. The normalized responses to 10 μ M ACh were about two-fold greater for choroid than for ciliary neurons. A similar distinction in the normalized peak responses to 500 μ M ACh was observed, while no differences between the two populations in rates of receptor desensitization were detected. Preliminary single channel recordings reveal that two AChR conductance classes of roughly 25 pS and 40 pS are present on both choroid and ciliary neurons. Characterization of the relative abundance and kinetic properties of the individual AChR channel classes is in progress. These results reveal distinct ACh responses in neuronal subpopulations that may be explained by differential regulation of AChR function or density. Supported by NIH # NS24417.

THREE DISTINCT NICOTINIC RECEPTOR-MEDIATED RESPONSES RECORDED INTRACELLULARLY IN DIFFERENT REGIONS OF CHICK BRAIN. V.A. Chiappinelli*, L.L. McMahon, K.M. Wolf and L. Yum, Dept. Pharm. and Phys. Sci., Saint Louis Univ. Sch. of Med., St. Louis MO 63104

We used whole-cell patch-clamp and sharp electrode recordings to examine nicotinic responses in embryonic chick brain slices. We find very distinct responses to receptor activation in three different brain nuclei.

Lateral Spinal Nucleus (SPL). In this nucleus, we have identified postsynaptic nicotinic receptors with a high affinity for nicotine that are insensitive to blockade by alpha-bungarotoxin (ABGT) and kappa-bungarotoxin (Neuron 5:307, 1990). We now report that nicotinic agonists also produce a large increase in the frequency of spontaneous inhibitory postsynaptic currents (IPSCs), an effect which is blocked by 30 μ M dihydro- β -erythroidine. The increase in IPSC frequency is totally blocked by 1 μ M tetrodotoxin (TTX).

Ventral Lateral Geniculate Nucleus. One cell type in this nucleus shows little direct response to nicotinic agonists, but exhibits a marked increase in bicuculline-sensitive IPSCs in response to 30 μ M carbachol. Unlike the SPL response this effect is not blocked by 1 μ M TTX, indicating that presynaptic nicotinic receptors are likely to mediate the increase in IPSCs.

Edinger-Westphal Nucleus. Cells in this nucleus exhibit an excitatory response to nicotinic agonists that is very sensitive to blockade by methyllycaconitine (MLA; ED₅₀=3 nM). By contrast, the direct nicotinic response in SPL neurons is blocked only at much higher doses of MLA (ED₅₀=3 μ M). Separate binding experiments indicate that MLA has high affinity (IC₅₀=4 nM) for ¹²⁵I-ABGT sites in chick brain, and suggest that the Edinger-Westphal nicotinic receptor is of the ABGT-sensitive type. NS17574.

FUNCTIONAL PROPERTIES OF THE SUBTYPES OF NICOTINIC ACETYLCHOLINE RECEPTOR (nAChR) IN RAT HIPPOCAMPAL NEURONS. M. Alkondon¹ and E.X. Albuquerque², ¹Dept. Pharmacol. Exp. Ther., Univ. Maryland, Sch. Medicine, Baltimore, MD 21201; ²Lab. Mol. Pharmacol, IBCCF, Fed. Univ. Rio de Janeiro, Brazil, 21944.

Recent work from our laboratory indicated the presence of functionally distinct nAChRs in rat hippocampal neurons grown in primary culture (Alkondon & Albuquerque, *JPET*, in press, 1993). In the present work, the diversity in the functional subtypes of the hippocampal nAChRs was further explored by studying the characteristics of the macroscopic currents measured using the whole-cell mode of the patch-clamp technique. Application of ACh (3 mM) evoked the following current variants: (i) A rapidly decaying current (named type IA) elicited in a majority of neurons (83%) and potentially blocked by α -bungarotoxin (α -BGT), κ -bungarotoxin (κ -BGT), and methyllycaconitine (MLA); (ii) A slowly decaying current that was elicited either alone (type II) or together with the rapidly decaying current (type IB), and was potentially blocked by dihydro- β -erythroidine but less so by α -BGT, κ -BGT and MLA; (iii) A slowly decaying current (type III) elicited in a small population of neurons (~2%) and relatively insensitive to blockade by α -BGT, κ -BGT and MLA, but that could be blocked by low concentrations of mecamylamine. The three current types, which most likely represent three distinct subtypes of nAChR in hippocampal neurons, showed further differences in their functional properties. Type IA currents exhibited little or no rectification, whereas type II showed a marked rectification. Another striking difference was reflected in the presence in type IA, but not in the other two current types, of a marked run-down in the current amplitude during the first 30 min of whole-cell recording. Addition of ATP-regenerating solution (consisting of 4 mM Tris ATP, 20 mM phosphocreatine, and 50 units/ml creatine phosphokinase) to the pipette solution prevented the run-down of IA currents to a great extent, suggesting that the high-energy phosphate compounds, which are dialysed away during the whole-cell recording, may be required for the maintenance of nAChR-mediated currents. Thus, the proposed subtypes of nAChR found in hippocampal neurons varied not only in their sensitivities to pharmacological agents, but also in their intrinsic properties, such as rectification and their regulation by phosphorylation-dephosphorylation mechanisms. A HETERO-BETA NEURONAL NICOTINIC ACETYLCHOLINE RECEPTOR EXPRESSED IN XENOPUS OOCYTES. L. Colquhoun*, K. Dineley & J. Patrick. Division of Neuroscience, Baylor College of Medicine, One Baylor Plaza, Houston, Tx, 77030.

Functional neuronal nicotinic receptors possessing distinct pharmacological properties can be expressed in *Xenopus* oocytes by pairwise injection of DNA encoding one alpha ($\alpha 2, \alpha 3, \alpha 4$) and one beta ($\beta 2, \beta 4$) subunit (1). Both alpha and beta subunits contribute to the specific pharmacological differences between pairwise combinations. There are many cases where the properties of nAChR channels measured *in situ* do not correlate with any pairwise combinations expressed in oocytes. One possible explanation is that more than 2 types of subunit are involved in receptor formation and there is evidence for involvement of 3 subunit types ($\alpha 3, \alpha 5$ and $\beta 2$) in a nicotinic receptor out of chick ciliary ganglion (2). DNA for the subunits $\alpha 3, \beta 2$ and $\beta 4$ were intranuclearly injected into oocytes and voltage clamp recordings made after 3-7 days incubation. When the 3 subunits were injected together a receptor with mixed properties was obtained. The irreversible open channel blocker chlorisondamine was used to show that the major receptor population contained both $\beta 2$ and $\beta 4$. Cytisine was a potent agonist suggesting the presence of $\beta 4$ and neuronal bungarotoxin partially blocked the response, indicating the presence of $\beta 2$. We are currently using subunit specific antibodies to show the association of $\alpha 3, \beta 2$ and $\beta 4$ immunoreactive protein in a receptor expressed in *Xenopus* oocytes.

ACETYLCHOLINE-BINDING SUBUNITS OF α -BUNGAROTOXIN-SENSITIVE AND α -BUNGAROTOXIN-INSENSITIVE NICOTINIC ACETYLCHOLINE RECEPTORS: PATTERNS OF EXPRESSION IN CHICK RETINAL NEURONS. Kent T. Keyser*, Harvey Karten and Jon Lindstrom. Dept. of Neurosci., University of California, San Diego, CA 92093 and Dept. of Neurosci., University of Pennsylvania, Philadelphia, PA 19104.

α subunits of α -bungarotoxin-insensitive acetylcholine receptors (nAChRs; $\alpha 3, \alpha 4, \alpha 5$) and α -bungarotoxin-sensitive nAChRs (α BgtAChRs; $\alpha 7, \alpha 8$) have been purified, their cDNAs cloned, and antibodies have been raised against them. Studies have shown that receptor subtypes containing the different α subunits differ pharmacologically. We have used antibodies against $\alpha 3, \alpha 4, \alpha 5, \alpha 7$, and $\alpha 8$ to determine the patterns of expression of these subunits in chick retinal neurons.

Populations of amacrine and ganglion cells contained $\alpha 3$ subunits while $\alpha 4$ subunit labeling was weak throughout the retina. $\alpha 5$ subunits were found in amacrine, bipolar and ganglion cells while $\alpha 7$ subunits were found only in amacrine and ganglion cells. The distribution of $\alpha 3$ and $\alpha 5$ subunits in the IPL was very similar and closely matched that of dendrites of cholinergic amacrine cells. $\alpha 8$ was found in both the inner and outer plexiform layers, but $\alpha 7$ subunit labeling was found only in the IPL in a pattern distinct from that of $\alpha 8$ labeling. The distributions of $\alpha 7$ and $\alpha 8$ in the IPL overlapped, but were more extensive than, that of dendrites of cholinergic amacrine cells. In summary, the five α subunits are widely distributed throughout the retina. Since receptors containing different subunits differ pharmacologically, the effects of ACh or its agonists depends upon what receptor subtype(s) is/are expressed by the neurons in various retinal circuits. CALCIUM ION INFLUX IN CLONAL CELL LINES EXPRESSING NICOTINIC ACETYLCHOLINE RECEPTORS. Cynthia M. Eisenhour, Elzbieta Puchacz* and Ronald J. Lukas. Div. Neurobiology, Barrow Neurological Institute, Phoenix, AZ 85013, USA.

Ca^{2+}/Na^{+} permeability ratios for muscle nicotinic acetylcholine receptor (nAChR) channels are reported to be lower than those for neuronal nAChR and for putative alpha-bungarotoxin-sensitive nAChR (Bgt-nAChR). Bgt-nAChR have been implicated in the intracellular accumulation of Ca^{2+} in neuronal cells. We studied agonist-stimulated ion flux in rat PC12 or human SH-SY5Y cells, which express both neuronal (ganglia-type) nAChR and Bgt-nAChR, and in human TE671/RD cells, which express muscle-type nAChR. Agonist dose-response profiles for $^{45}Ca^{2+}$ influx are similar to those for $^{86}Rb^{+}$ efflux for each cell type (e.g., maximum flux occurs at 100 μ M nicotine for ganglia-type nAChR). $^{45}Ca^{2+}$ flux is much smaller in TE671 cells than in PC12 or SH-SY5Y cells and in every case is reduced rather than enhanced when cell membrane potentials are reduced. Antagonism of $^{45}Ca^{2+}$ influx or $^{86}Rb^{+}$ efflux by d-tubocurarine or pancuronium is identical for a given cell type. Alpha-bungarotoxin (Bgt) blocks both types of fluxes in TE671 cells but fails to block either $^{45}Ca^{2+}$ or $^{86}Rb^{+}$ fluxes in PC12 or SH-SY5Y cells. While we may have failed to detect Bgt-nAChR-mediated $^{45}Ca^{2+}$ influxes and/or to discount the possibility that Bgt-nAChR can activate release of Ca^{2+} from intracellular stores, these data indicate that toxin-insensitive nAChR can mediate Ca^{2+} influxes in neural crest-derived PC12 or SH-SY5Y cells.

PARTICIPATION OF $\alpha 5$ IN NEURONAL NICOTINIC AChR CHANNELS. J.A. Ramirez Latorre, X. Qu and L. Role* Dept. Anat. & Cell Biol. in the Ctr. Neurobiol. & Behav., Columbia University P&S, 630 W 168th St NY, NY 10032.

In spite of a broad expression pattern of the $\alpha 5$ gene, this nAChR subunit has not been shown to form a functional channel either alone or in combination with known β subunits. Examination of the $\alpha 5$ sequence reveals substitutions in both the ligand binding and putative ion permeation domains. Previous studies of muscle AChRs predict that changes in these regions would decrease agonist affinity (Yellen et al., 1991) and increase single channel conductance (Moto et al., 1986). To test whether $\alpha 5$ can participate in functional AChR complexes we examined the properties of channels expressed in *Xenopus* oocytes injected with $\alpha 5$ cDNA alone or $\alpha 5$ in combination with other α and β subunit cDNAs ($\alpha 4, \alpha 5, \beta 4$ sequences gift of Ballivet). Injection with $\alpha 4$ and $\beta 2$ produced a 22pS channel and injection of $\alpha 5$ alone produced no detectable current in response to applied ACh as previously reported. Co-injection of $\alpha 5$ cDNA with both $\alpha 4$ and $\beta 2$, however, produced a new nAChR channel with conductance states of 45 and 50 pS. When the ratio of $\alpha 5$ cDNA was increased to 5-10x that of the co-injected $\alpha 4$ and $\beta 2$, the 45pS openings were more frequent than the 22pS. Determination of the dose-dependence of ACh-evoked currents for both the $\alpha 4\beta 2$ and the $\alpha 4\alpha 5\beta 2$ combinations revealed a K_m of 7 μ M for $\alpha 4\beta 2$ as reported, but a K_m of 300 μ M for $\alpha 4\alpha 5\beta 2$. Cysteine replacements in the M2 region of $\alpha 5$, and subsequent treatment with cysteine reactive reagents will be used to further test participation of the $\alpha 5$ subunit in the new channels. (supported by NS22061).

630.9

IMMUNOHISTOCHEMICAL LOCALIZATION OF THE $\alpha 6$ SUBUNIT OF THE NEURONAL NICOTINIC ACETYLCHOLINE RECEPTOR IN THE ADULT RAT BRAIN. F.M. Goldner¹, M. Quik² and J.W. Patrick^{1*}. ¹Division of Neuroscience, Baylor College of Medicine, Houston, TX 77030 and ²Department of Pharmacology, McGill University, Montreal, Canada

Nine different rat genes which code for putative subunits of the neuronal nicotinic acetylcholine receptor have been identified, cloned and sequenced. One of these, $\alpha 6$, shows the sequence characteristics of a nicotinic receptor subunit, but no contribution of this clone to a functional receptor has been demonstrated in the *Xenopus* oocyte expression system. To determine whether the receptor protein is expressed in the brain, a polyclonal antibody against recombinant protein representing the predicted extracellular domain of the receptor was raised and the serum purified over a peptide column. Western analysis with the $\alpha 6$ antibody identified two bands with apparent molecular weights of about 98 and 60KD. The latter band is consistent with the size for $\alpha 6$ as predicted from the cDNA sequence. Preincubation of the antibody with an excess of the $\alpha 6$ peptide used in the purification step prevented its interaction with the above two protein bands suggesting a specific interaction. The antibody was used in immunohistochemical studies to assess the anatomical distribution of the receptor protein in frozen sections of adult rat brains. $\alpha 6$ immunoreactivity is restricted to neurons, staining the cytoplasm and plasma membranes of cell somata and proximal processes whereas cell nuclei are devoid of immunostaining. Immunoreactivity was highest in the substantia nigra and ventral tegmental area as expected from previous *in situ* hybridization data. Other areas that were previously shown to be positive for $\alpha 6$ mRNA such as the reticular nucleus of the thalamus, the anterior pretectal area and the locus coeruleus also showed immunoreactivity with the anti- $\alpha 6$ antibody. Overall, there was a good correspondence between *in situ* hybridization and immunohistochemistry, although immunoreactive neurons were seen in the cerebral cortex where no $\alpha 6$ mRNA has been detected. These data suggest that the $\alpha 6$ protein is expressed in rat brain.

ACETYLCHOLINE RECEPTORS: NICOTINIC ANTAGONISTS AND AGONISTS

631.1

TOXINS, BUT NOT OTHER ANTAGONISTS, STABILIZE THE RESTING STATE OF THE NICOTINIC ACETYLCHOLINE RECEPTOR. Marjorie Moore¹, Frederick Kauffman², and Michael P. McCarthy¹. ¹CABM/Pharmacology, UMDNJ-RWJMS, Piscataway, NJ, 08854. ²College of Pharmacy, Rutgers U., Piscataway, NJ 08855.

We have used 3-(trifluoromethyl)-3-(*m*-[¹²⁵I]iodo-phenyl) diazepam ([¹²⁵I]TID) to characterize the effects of antagonists on the conformation of the neuromuscular, nicotinic acetylcholine receptor (AChR) from *Torpedo californica*. [¹²⁵I]TID labels all four subunits of the AChR, and is a sensitive probe of AChR conformation. The snake venom toxins α -bungarotoxin and *Naja naja* toxin both increase the degree of [¹²⁵I]TID incorporation. The small molecule antagonists tubocurarine and gallamine have no effect on [¹²⁵I]TID labelling at low concentrations, but at higher concentrations reduce [¹²⁵I]TID incorporation. *In vitro*, preparations of AChR are mixtures of both resting state and desensitized AChR. The effects of snake venom toxins are most likely due to their stabilization of the resting state form of the AChR, leading to increased [¹²⁵I]TID incorporation. However, the snake venom toxins will not induce the resting state in AChRs which have been desensitized by reconstitution in desensitizing lipids or by solubilization in desensitizing detergents. Tubocurarine and gallamine appear to act as partial agonists. At low concentrations they do not induce the resting state, but desensitize the AChR at higher concentrations (>0.5-1mM), leading to diminished [¹²⁵I]TID incorporation.

631.3

THE EFFECTS OF STRYCHNINE, CHLORISONDAMINE (CHL) AND CYTISINE ON THE INHIBITORY NICOTINIC RESPONSE OF DORSOLATERAL SEPTAL NUCLEUS (DLSN) NEURONS. E.M. Sorenson* and J.P. Gallagher. Dept. of Pharmacol. and Toxicol., Univ. of Texas Med. Br., Galveston, TX 77555-1031.

This laboratory has previously demonstrated that 1,1-methyl-4-phenylpiperazine (DMPP) produces a direct inhibitory response at rat DLSN neurons which is blocked by mecamlamine (50 μ M) and kappabungarotoxin (0.5 μ M). We have now examined the effects of the antagonists CHL and strychnine on this response. CHL is believed to have a mechanism of action similar to that of mecamlamine while strychnine blocks the nicotinic receptor consisting of α subunits expressed in oocytes (Séguela et al., *J. Neurosci.* 13:596, 1993). We have also determined whether the nicotinic agonist cytisine, which appears to be an antagonist at nicotinic receptors containing the β_2 neuronal nicotinic subunit (Luetje and Patrick, *J. Neurosci.* 11:837, 1991), blocks the inhibitory response.

A control response to DMPP was recorded intracellularly from DLSN neurons. The cells were then superfused with strychnine, CHL, or cytisine for at least 10 min and the response of the cell to DMPP was retested. Strychnine 10-100 μ M did not block the effects of DMPP. CHL (50 - 500 μ M) reduced the magnitude of the hyperpolarization in response to DMPP but only completely blocked the DMPP response when superfused at 500 μ M. This inhibition was not always reversible, even after prolonged washing. Cytisine (500 μ M) was ineffective as either an agonist or an antagonist.

These results suggest that the α subunit is not a constituent of the inhibitory nicotinic receptor. Since low levels of β_2 subunit are expressed in the DLSN (Wada et al., *J. Comp. Neurol.* 284:314 1989), the possibility exists that the inhibitory receptor contains the β_2 subunit in combination with an as yet uncloned α subunit. Supported by DHHS 1F32 DA 05447-02 and The Council for Tobacco Research, USA, Inc.

631.2

THE REDUCED FORM OF NEREISTOXIN IS RESPONSIBLE FOR REDOX EFFECTS ON NEURONAL NICOTINIC RECEPTORS (nAChRs). Y. Xie*, R.H. Loring & G.S. Jones, Jr. Dept. of Pharmaceut. Sci., Northeastern Univ., Boston, MA 02115

We have shown that nereistoxin (NTX, 4-dimethylamino-1,2-dithiolane) blocks nAChRs in chick retina and ciliary ganglion by reducing the disulfide bond within the agonist binding site. We hypothesized that NTX is reduced intracellularly to dihydro-NTX (DHNTX; 2-dimethylamino-1,3-propanedithiol) as the reactive species that reduces nAChR's. In whole-cell patch-clamp recordings from isolated ciliary neurons, inclusion of 100 μ M NTX in the pipette has no effect, but 100 μ M DHNTX slowly blocks nicotinic responses, and this effect is reversed by external application of the oxidizing agent dithiobisnitrobenzoic acid (DTNB). 100 μ M NTX applied externally acts only as a reversible nicotinic antagonist, but recovery from external DHNTX blockade requires reoxidation with DTNB. The quaternary derivative of NTX, (4-trimethylamino-1,2-dithiolane) acts as a weak oxidizing agent on nAChR's of chick ciliary ganglia treated with the reducing agent dithiothreitol, while the reduced quaternary version (4-trimethylamino-1,3-propanedithiol) readily reduces ciliary ganglion nAChR's. Preliminary studies with reduced charatoxin (2-methylthio-1,3-propanedithiol, another analog of DHNTX) also demonstrate reduction of nAChR's in chick retina. These data suggest that analogs of NTX that diffuse through membranes can reduce nAChR's, while the quaternary derivatives must be reduced to dithiols to affect the nAChR redox state. (Supported by NS22472 and the STRC).

631.4

THE NICOTINIC ANTAGONISTS, MECAMYLAMINE AND PEMPIDINE, ARE NONCOMPETITIVE INHIBITORS OF BRAIN NICOTINIC RECEPTOR FUNCTION. W. Cao, M.J. Marks, A.C. Collins. IBG Univ. Colorado, Boulder, CO 80309

Mecamylamine (Mec) and pempidine (Pem) do not inhibit binding to brain nicotinic receptors, but several studies indicate that these two compounds block behavioral effects of nicotine (Nic). This suggests that Mec and Pem are noncompetitive inhibitors of brain nicotinic receptors, perhaps acting by binding to the ion channel associated with the receptor. This possibility was assessed by determining the inhibition profiles of Mec and Pem for three behavioral responses to Nic and for a recently-developed ion flux assay that seems to measure the activity of a brain nicotinic receptor that binds L-[³H]nicotine with high affinity; this is probably a receptor that contains the $\alpha 4$ variant of the receptor. Dose-response curves were constructed for inhibition of Nic responses using Nic doses of 0, 0.5, 1.0 and 1.5 mg/kg. Both Mec and Pem inhibited the behavioral actions of Nic, but the IC_{50} values did not vary depending upon Nic dose. Similar results were obtained with the *in vitro* test. Both Mec and Pem inhibited Nic-induced (0, 10, 100 μ M) increases in ⁸⁶Rb⁺ efflux from synaptosomes prepared from mouse brain. The IC_{50} values for inhibition of ion flux were not affected by Nic concentration. Thus, both *in vivo* and *in vitro* tests produced data that are consistent with the argument that Mec and Pem are noncompetitive inhibitors of brain nicotinic receptor function. PARAOXON AND DIISOPROPYLFLUOROPHOSPHATE (DFP) INDUCE OPEN CHANNEL BLOCKADE OF NICOTINIC ACETYLCHOLINE RECEPTORS (nAChR). J.A.J. Santos¹, R.S. Nascimento¹, Y. Aracava^{1,2*} and E.X. Albuquerque^{1,2}. ¹Lab. Mol. Pharmacol., Fed. Univ. Rio de Janeiro, Brazil and ²Dept. Pharmacol. Exp. Ther., Univ. Maryland Sch. Med., Baltimore, MD 21201.

It has been shown that DFP interacts with the nAChR, blocking nerve-elicited endplate currents in a manner similar to that of certain local anesthetics (*JPET* 189:499, 1974). We further investigated the actions of DFP on the muscle nAChR, comparing them with those of the pesticide paraoxon and the local anesthetic piperocaine. Single-channel currents activated by acetylcholine (ACh) were studied in frog (*Leptodactylus ocellatus*) interosseal muscle fibers under the cell-attached patch-clamp condition. DFP (0.1-1 mM) produced a voltage-dependent blockade of the open state of ACh-activated channels, increasing the frequency of closures and decreased intra-burst open times at negative potentials. The DFP-induced closures, corresponding to the blocked state, were 10 times longer than those detected in control currents. Paraoxon (1 mM) applied together with ACh (0.2 μ M) also blocked the nAChR channels in their open conformation. However, paraoxon induced randomly separated brief events, with no detectable burst pattern, thus indicating a more stable blockade. Both OPs mildly reduced the frequency of openings induced by ACh. Piperocaine, on the other hand, blocked the nAChR more potently, decreasing both the frequency and the duration of the open state at 1 to 10 μ M and at negative membrane potentials completely the openings at concentrations higher than 25 μ M. In consonance with the voltage- and time-dependent blockade reported on macroscopic currents (*Mol. Pharmacol.* 16:909, 1979), we observed that under the conditions of single channel current recordings the blockade by piperocaine was favored. In addition, paraoxon at 1 mM exhibited agonist activity, activating currents resembling those activated by ACh and also a population with an increased level of noise in the open state. Both currents were not inhibited by α -bungarotoxin. Support: CNPq, Finep, Mol. Pharmacol. Training Program, U.S. Army Med. Res. Devel. Comm.

CENTRAL NICOTINIC BLOCKADE BY CHLORISONDAMINE ADMINISTERED IN VITRO OR IN VIVO. H. El-Bizri* and P.B.S. Clarke. Dept of Pharmacology and Therapeutics, McGill Univ., Montreal, Canada H3G 1Y6.

Chlorisondamine (CHL) is a nicotinic antagonist which produces a persistent central nicotinic blockade lasting for at least 12 weeks after a single in vivo administration. We used (-)-nicotine induced ³H-dopamine release from rat striatal synaptosomes as a functional assay to investigate the mechanisms of nicotinic blockade produced by CHL. After *in vitro* administration of CHL, nicotinic blockade was concentration-dependent (10^{-8} - 10^{-6} M), and the potency of CHL was increased 26-fold by concurrent administration of a brief pulse of nicotine prior to nicotine challenge. Block following *in vitro* CHL was not surmounted by nicotine (10^{-7} - 10^{-6} M) challenge. After *in vivo* administration of CHL, blockade persisted *in vitro* and was also not surmounted by nicotine (10^{-7} - 10^{-6} M) challenge. CHL (given *in vitro* or *in vivo*) also blocked nicotinic responses to ACh but did not affect responses to amphetamine or high K⁺. Prolonged wash reversed nicotinic blockade resulting from *in vitro*, but not *in vivo*, administration of CHL. This suggests that *in vitro* and *in vivo* administration of CHL produces CNS nicotinic blockade by different mechanisms. Funded by the MRC of Canada.

RECEPTOR BINDING AND FUNCTIONAL EFFECTS OF A SERIES OF KNOWN AND NOVEL NICOTINIC LIGANDS. P.M. Lippello*, K.G. Fernandes*, W.S. Caldwell*, M.J. Marks* and A.C. Collins*. Research & Development, R.J. Reynolds Tobacco Co., Winston-Salem, NC 27102 and Institute for Behavioral Genetics*, University of Colorado, Boulder, CO 80309.

A number of potential nicotinic ligands were evaluated in inhibition binding assays to assess their relative potencies in displacing L-[³H]-nicotine binding to rat brain membranes and [¹²⁵I]- α -bungarotoxin binding to mouse brain membranes. These compounds were classified into six structural series, representing both minor plant and tobacco alkaloids and synthetic compounds. Of the compounds tested in binding assays, those having the lowest K_d values for [³H]-nicotine binding (<10 μ M) were studied using ligand-evoked dopamine release from rat brain striatal synaptosomes. The most potent compounds were further evaluated using Rb⁺ efflux from mouse brain thalamic synaptosomes, and a physiological test battery in mice (heart rate, body temperature, respiration, y-maze rears and crosses, acoustic startle). Based on dopamine release and/or Rb⁺ efflux, compounds were classified as full or partial agonists. Although the K_d values for inhibition of [³H]-nicotine binding by the most potent agonists differed by more than two orders of magnitude (2 nM - 900 nM), the range of EC₅₀ values for dopamine release (100 nM-1.3 μ M) and for Rb⁺ efflux (200 nM-2.5 μ M) differed only by a factor of ten. In general, [³H]-nicotine binding affinity did not correlate well with the EC₅₀ or maximal effect for Rb⁺ efflux and dopamine release or with *in vivo* behavioral effects, which may reflect varying degrees of receptor desensitization by these ligands. However, relative potencies in the *in vitro* functional assays were reasonably good predictors of *in vivo* effects. The information gained from these studies may provide a useful basis for identifying and developing novel nicotinic ligands as research tools and potential therapeutics for neurodegenerative diseases. (A.C. Collins was supported by a Research Scientist Development Award from NIDA DA-00116).

EFFECTS OF BUPIVACAINE ON NEURONAL NICOTINIC ACETYLCHOLINE RECEPTORS IN RAT HIPPOCAMPAL NEURONS. Y. Yu¹, R.A. Siodin^{2*} and E.X. Albuquerque^{1,3}. Depts. ¹Pharmacol. Exp. Ther. and ²Biophysics, Univ. Maryland, Sch. Medicine, Baltimore, MD 21201; ³Lab. Mol. Pharmacol., IBCCF, Fed. Univ. Rio de Janeiro, Brazil 21944.

The local anesthetic, bupivacaine, has been shown to act as an open-channel blocker at the nicotinic acetylcholine receptor (nAChR) in frog sartorius muscle (*Mol. Pharmacol.*, 26:293,1984). In the present work, we investigated the effects of bupivacaine on neuronal nAChRs, which have subunit compositions different from that of their muscle counterpart. Using the patch-clamp technique, nicotinic single-channel and whole-cell currents were studied in fetal rat hippocampal neurons cultured for 10-30 days. The agonist, acetylcholine (ACh), in the absence or presence of bupivacaine, was applied to the patches through a U-tube. In agreement with a recent report (M. Alkondon & E.X. Albuquerque, *JPET*, *in press*, 1993), four types of whole cell currents (IA, IB, II, and III) could be induced by ACh (100-500 μ M). Bupivacaine (50-500 μ M) decreased the peak amplitude of these currents, in a concentration- and voltage-dependent manner, and shortened the decay phase of slowly desensitizing currents in a concentration-dependent manner. These effects were all reversible upon washing. At the concentration of 500 μ M, bupivacaine blocked nearly 50% of the peak amplitude of the ACh response, but did not affect the NMDA, quisqualate, and kainate responses in the hippocampus. In an outside-out patch excised from a neuron cultured for 16 days, the mean open and burst times of ACh (30 μ M)-activated single channels were decreased by bupivacaine (0.5 μ M). These results suggest that bupivacaine may act as an open-channel blocker of neuronal nAChRs. This is the first report of an open-channel blocker of neuronal nAChRs in the rat hippocampus, and illustrates that in spite of the difference in subunit composition between neuronal and muscle nAChRs there might be a highly conserved region in the ion channels of these receptors at which open channel blockers can bind and exert their effects. ESERINE (PHYSOSTIGMINE) BLOCKS NICOTINIC RESPONSES IN THE RAT CNS. P.B.S. Clarke*, M. Reuben, and H. El-Bizri. Dept of Pharmacology and Therapeutics, McGill Univ., Montreal, Canada H3G 1Y6.

The AChE inhibitor eserine (physostigmine) exerts agonist and antagonist actions at Torpedo electroplaque nicotinic receptors (Shaw et al 1985, *Mol. Pharmacol.* 28:527-538). We tested for both actions in the rat CNS, by studying ³H-dopamine release induced by (-)-nicotine from superfused rat striatal synaptosomes. Superfusion of eserine (0.3 - 300 μ M) for 30 min resulted in a concentration-dependent blockade of a subsequent nicotine 1 μ M challenge (IC₅₀ approx. 30 μ M). Neostigmine produced a similar effect, whereas DFP somewhat reduced nicotinic responses only at 300 μ M. Eserine (0.3 - 300 μ M), given as a brief pulse, did not mimic nicotine. Nicotinic blockade by eserine (30 μ M) was noncompetitive and was selective; responses to the nicotinic agonists cytosine and DMPP were reduced, whereas responses to high K⁺ were not. Eserine (300 μ M) completely blocked responses to nicotine, slightly reduced responses to amphetamine, and did not alter responses to high K⁺. Thus, it appears that eserine blocks CNS nicotinic responses in a pharmacologically selective manner, possibly independent of its ability to inhibit acetylcholinesterase. Funded by the MRC of Canada.

α -CONOTOXINS: SMALL PEPTIDE LIGANDS OF THE NICOTINIC ACETYLCHOLINE RECEPTOR. M.M. Grilley and B.M. Olivera.* Department of Biology, University of Utah, Salt Lake City, UT 84103.

α -conotoxins, a family of competitive antagonistic peptides isolated from *Conus* snail venoms, have emerged as useful tools for the elucidation of nicotinic acetylcholine receptor (nAChR) structure and function. At least seven distinct α -conotoxins have been identified and sequenced, ranging in size from 13 to 19 amino acid residues. We have used a subset of these toxins, one of whose structure has been solved by 2D-NMR, to examine the subunit organization of the nAChR. Sites of photoaffinity labeling of derivatized toxins on nAChR from *Torpedo* electroplax were determined, and, considering the placement of photoreactive groups within the toxin tertiary structure, it was possible to map the portions of the receptor surrounding the ligand binding site. Ordering of subunits about the established pseudo-symmetrical rosette structure of the receptor most consistent with the results obtained is $\alpha\gamma\alpha\beta\delta$.

The α -conotoxins also show great potential for use as discriminators of phylogenetic or receptor subtype differences. Some phylogenetic and subtype specificities have been observed among the α -conotoxins that have been examined to date. In addition, no two species have yet been found to produce conotoxins of identical sequence, and only a small fraction of the members of the genus have been screened for the presence of nAChR antagonists. OSTREOTOXIN I, A FRACTION FROM A TOXIC CARIBBEAN DINOFLAGELLATE, ALTERS THE IONIC CONDUCTANCE OF NICOTINIC ACh RECEPTOR CHANNELS. J.A. Mercado, G. Escalona de Motta*, T.R. Tosteson* and J. Gonzalez*. Inst. of Neurobiology and Dept. of Biology, UPR Rio Piedras 00931 and *Dept. of Marine Sciences, UPR Mayaguez 00968.

Ostreopsis lenticularis is one of the benthic dinoflagellates implicated in the Caribbean as producers of toxins related with human ciguatera intoxication. Methanolic extracts obtained from three different clonal cultures of *O. lenticularis* were toxic to mice and inhibited with approximately equal potency the acetylcholine (ACh)-induced contractions of frog sartorius muscles. In addition, these extracts reduced the average amplitudes of miniature endplate potentials (mepps). After one hour of exposure to 0.3 mg of dried extract/mL average mepps amplitude was reduced by 72% but neither the time course of individual mepps nor their frequency were altered. Reverse phase High Pressure Liquid Chromatography (HPLC) was used to fractionate an extract according to polarity. In single channel patch clamp experiments addition of the more polar of the resulting fractions to an ACh-containing pipette caused the appearance of lower conductance ACh-activated channels in cultured chick embryo myocytes. No effect on channel lifetime was observed. We conclude that a component of this toxic dinoflagellate extracts is a polar toxin (ostreotoxin I) that reduces the ionic conductance of nicotinic ACh receptor channels. THE EFFECTS OF DIHYDRO-B-ERYTHROIDINE (DHBE) ON METHYL-CARBAMYLCHOLINE (MCC) - INDUCED CHANGES IN BRAIN NICOTINIC RECEPTORS AND RELATED BEHAVIORS IN THE RAT. X-H. Yang* and J.J. Buccafusco, Department of Pharmacology and Toxicology, Medical College of Georgia, and the DVAMC, Augusta, GA 30912.

Chronic intracerebroventricular (icv) treatment with MCC, a selective nicotinic agonist produced up-regulation (increased Bmax) of cortical nicotinic receptors (nAChR). The purpose of this study was to determine whether this regulation is associated with the development of changes in sensitivity to the behavioral effects of MCC, and also whether these changes could be influenced by icv pretreatment with the competitive nicotinic antagonist DHBE. Rats were injected twice daily with 30 µg, icv of MCC over 10 days. The development of changes in Bmax for nAChR paralleled the development of tolerance and return to normal sensitivity to a characteristic nicotinic behavior, the prostration syndrome. In contrast, the MCC-induced water drinking response evoked in the same animals actually was sensitized over the same period. When icv injection of DHBE (6 or 60 µg) preceded each MCC injection, MCC-induced prostration (but not MCC-induced water drinking) was inhibited. DHBE pretreatment also significantly inhibited the MCC-induced increase in Bmax for nAChR. Thus, activation of the agonist recognition site on the nAChR by MCC was required for the expression of changes in binding parameters. Also, since DHBE pretreatment reduced MCC-induced changes in receptor binding, but did not block all behaviors induced by MCC, it appears that MCC may act through both DHBE-sensitive and DHBE-insensitive receptor subtypes. Supported by a grant from the DVAMC.

IN VITRO PHARMACOLOGY OF ERYSDINE: A HIGH AFFINITY ANTAGONIST OF NEURONAL NICOTINIC ACETYLCHOLINE RECEPTORS D.J. Anderson*, S.P. Arneric, S. Swanson, J.L. Raszkievicz, and J.P. Sullivan, Neuroscience Research, Pharmaceutical Discovery Division, Abbott Laboratories, Abbott Park, IL 60064.

Very few high affinity, competitive antagonists for neuronal nicotinic acetylcholine receptors (nAChRs) have been identified. Dihydro-β-erythroidine (DHBE) serves as the best example. Erysdine (ERY) is a related alkaloid also isolated from the *Erythrina* seed. The purposes of this study were: 1) to characterize the binding properties of ERY, and 2) to characterize ERY in a functional response assay.

Initial characterization of ERY by concentration-inhibition of [³H]cytisine ([³H]CYT) binding revealed a K_i of 5 nM as compared to 35 nM for DHBE. Both compounds at 1 µM blocked 0.1 µM (-)nicotine (NIC) induced release of [³H]dopamine ([³H]DA) from striatal slices. Additionally, ERY displayed 40-fold selectivity for displacing [³H]CYT binding over [¹²⁵I]α-bungarotoxin binding.

In saturation isotherms of 0.1-5 nM [³H]CYT binding to rat brain washed membranes, increasing concentrations of ERY effected increases in apparent K_Ds with no change in B_{MAX}, indicating competitive binding. A K_D of 7 nM was determined from a kinetic plot of apparent K_Ds.

ERY shifted to the right concentration-response curves of NIC facilitation of [³H]DA release from preloaded rat striatal slices. The shifts were parallel with no effect on the maximal response to NIC. A pA₂ of 8.34 was determined from a Schild plot of the resulting dose ratios.

Here it is shown that ERY is a high affinity competitive antagonist at neuronal nAChRs for both receptor binding and a functional nicotinic response. It has been recently demonstrated (Kang et al., *Soc for Neurosci*, 1993) that ERY accumulates in the brain where it blocks the effects of NIC on behavior. Therefore, ERY has potential for use as a peripherally administered, centrally active neuronal nAChR antagonist.

ANTAGONISM OF NICOTINIC RECEPTORS BY DELPHINIUM ALKALOIDS. P. Dobeis¹, J. E. Madl¹, G. D. Manners², J. A. Pfister³, J. P. Walrond^{1*}. ¹Dept. of Anatomy & Neurobiol., Colo. State Univ., Ft. Collins, CO 80523 USA, ²Western Regional Res. Ctr., USDA, Albany, CA 94710 USA, ³Poisonous Plant Res. Lab., USDA Logan, UT 84321 USA.

Delphinium spp. contain the norditerpenoid alkaloid methyllycaconitine (MLA), a nicotinic antagonist in the central and peripheral nervous systems. We have purified several related norditerpenoid alkaloids (MLA; 14-deacetylnudicaline, 14-DN; Barbinine; and Anthranoyllycoctonine, ALC) and tested their ability to block neuromuscular transmission in an *in vitro* lizard neuromuscular preparation. Intracellular recordings of miniature end plate potentials and extracellular recordings of compound muscle action potentials showed all of these toxins to be nicotinic antagonists. Our studies indicate that 14-DN is the most potent (EC₅₀ = 0.5 µM), followed by barbinine (3 µM), MLA (7 µM), and ALC (20 µM). In contrast, the order of LD₅₀'s is ALC > barbinine >> MLA = 14-DN with MLA and 14-DN being the most potent. The apparent disparities in potency suggest that the mechanism of toxicity of these alkaloids may derive, at least in part, from effects on non muscle nicotinic acetylcholine receptors. It will be of interest to determine the effectiveness of these norditerpenoid alkaloids as nicotinic antagonists in the autonomic and central nervous systems. (Supported by USDA Agricultural Research Service and the Colorado Experiment Station).

PHARMACODYNAMIC AND PHARMACOKINETIC STUDIES ON ERYSDINE: A POTENT NEURONAL NICOTINIC RECEPTOR ANTAGONIST. C.-H. Kang*, J.L. Raszkievicz, S. Swanson, J.D. Brioni, M.W. Decker, S.P. Arneric and J.P. Sullivan, Neuroscience Research, Pharmaceutical Products Division, Abbott Laboratories, Abbott Park, IL 60064.

The CNS pharmacology of erysdine, a natural alkaloid isolated from the *Erythrina* seed, is poorly understood. We have recently reported (Anderson et al., *Soc for Neurosci*, 1993) that erysdine is a potent (K_i = 5 nM) neuronal nicotinic acetylcholine receptor (nAChR) antagonist. In these experiments, we sought to determine 1) Is erysdine a centrally active nAChR antagonist in rat? and 2) How do the brain and plasma pharmacokinetics correlate with the CNS pharmacodynamic responses?

Erysdine (30 µmol/kg, i.p.) had no effect on locomotor activity in rats when administered on its own. When administered 4 mins prior to (-) nicotine (1.9 µmol/kg, i.p.), erysdine attenuated the initial (10 min) (-) nicotine-induced suppression of locomotor activity and the stimulatory effect of (-) nicotine on activity at 40 min. The effect of (-) nicotine on locomotor activity is also blocked by mecamylamine (5 µmol/kg, i.p.) and chlorisondamine (10 µg i.c.v.) (Decker et al. *Behav. Neural Biol.*, in press). Brain levels of erysdine, comparable to (-) nicotine were rapidly achieved. At 10 min, brain levels of erysdine and (-) nicotine were 280 ± 31 and 318 ± 42 ng/g brain (n=3), respectively. Brain levels of erysdine remained elevated (306 ± 45 ng/g brain; n=3) at 40 mins. The brain:plasma ratio for erysdine was 1.5 at 10 mins and 1.3 at 40 mins. In contrast, plasma levels of (-) nicotine were much lower (5 fold) than the corresponding brain levels. Following i.v. administration, erysdine (4.3 µmol/kg) was found to have an elimination half-life of 29 mins but was not bioavailable following p.o administration (38 µmol/kg).

This study demonstrates that erysdine is rapidly accumulated into brain where it blocks the behavioral effects of (-) nicotine at brain levels similar to the behaviorally effective brain levels of (-)nicotine.

631.16

IN VIVO CHARACTERIZATION OF ERYSDINE, AN ERYTHRINA ALKALOID THAT BINDS TO NEURONAL NICOTINIC ACETYLCHOLINE RECEPTORS (nAChRs). D.B. O'Neill, J.D. Brioni, M.J. Buckley*, C.H. Kang, J.P. Sullivan, J.L. Raszkievicz, S. Swanson, S.P. Arneric, and M.W. Decker, Neuroscience Research, Pharmaceutical Products Division, Abbott Laboratories, Abbott Park, IL 60064.

Erysdine is an erythrina alkaloid related to the potent competitive nAChR antagonist dihydro-β-erythroidine (DHBE), but the effects of erysdine at nAChRs are not well-characterized. Binding studies conducted in our group suggest that erysdine binds with high affinity to nAChRs (Anderson et al., this meeting). In the current study, we explored the effects of systemically-administered erysdine in mice.

Erysdine (0, 3, 10, or 30 µmol/kg IP) was administered prior to a nicotine (6.2 µmol/kg IP) challenge in male, CD-1 mice. Nicotine significantly reduced rectal temperature in mice pretreated with saline. Erysdine, by itself, did not affect body temperature but dose dependently attenuated the hypothermic effect of nicotine. In a separate experiment, we found that DHBE (0, 1.5, 3, or 5 µmol/kg IP) also produced a dose-related blockade of nicotine-induced hypothermia. In contrast to its effects on nicotinic receptor mediated hypothermia, erysdine (10 µmol/kg) did not affect muscarinic receptor mediated hypothermia produced by oxotremorine. These doses of erysdine were found to be inactive in the elevated plus-maze model of anxiety, but pretreatment with erysdine (30 µmol/kg) effectively blocked the increase of open-arm exploration seen with nicotine (0.62 µmol/kg). Brain and plasma levels for mice administered 30 µmol/kg of erysdine were determined to be 92.2±13.6 ng/g and 30.5±5.3 ng/ml, respectively.

Thus, erysdine readily enters the brain after systemic administration and antagonizes the hypothermic and anxiolytic-like effects of nicotine in mice.

631.17

BOROCAPTATE REVERSAL OF RESPIRATORY PARALYSIS INDUCED BY BLOCKADE OF NICOTINIC CHOLINERGIC RECEPTORS. G. Daniel and T. R. LaHann¹. Center for Toxicology Research, College of Pharmacy, Idaho State University, Pocatello ID 83209.

Borocaptate sodium, a boronated drug developed for boron neutron capture therapy of cancer, rapidly reverses respiratory paralysis induced by i.v. injection of the neuromuscular junction (NMJ) blockers, gallamine and pancuronium. Gallamine triethiodide (15 mg/kg) or pancuronium bromide (2 mg/kg) administered intravenously to Long-Evans rats caused prolonged skeletal muscle paralysis and respiratory failure. In the absence of artificial respiration, these doses of NMJ blockers were fatal. If artificially respired, however, animals recovered within 45 to 60 minutes. Borocaptate sodium (75-200 mg/kg, i.v., rate: 28 mg/kg/min) was infused 5-15 minutes after full NMJ blockade was established. Rats regained their ability to spontaneously breathe within 3 minutes of the start of borocaptate infusion, demonstrating a reversal of the skeletal muscle paralysis induced by the NMJ blockers. Borocaptate infusion re-established a normal respiratory pattern, and stable cardiovascular function was maintained throughout the time period that control (NMJ antagonist without borocaptate) rats remained paralyzed. The rapid, effective and sustained reversal of respiratory paralysis by borocaptate sodium suggests that this drug might be a useful antidote for treating overdose of NMJ blockers. The mechanism by which such reversal occurs is currently under investigation.

631.19

THE NOVEL AGONIST SITE ON NICOTINIC RECEPTOR (nAChR): ACTIVATION BY PYRAZOLES, AMANTADINE, AND POLYAMINES. T. Tano^{1,2}, M.C. Heluy-Dantas¹, M. Marchiori¹, W.M. Cintra¹, Y. Aracava^{1,2}, E.X. Albuquerque^{1,2}, A. Schratzenholz² and A. Maelicke². ¹Lab. Mol. Pharmacol., IBCCF, UFRJ, Brazil 21944; ²Dept. Pharmacol. Exp. Ther., Univ. Maryland Sch. Med., Baltimore, MD 21201; ³Inst. Physiol. Chem., Johannes-Gutenberg Univ. Mainz, Med. Sch., Duesbergweg, D-6500, Mainz, Germany.

It has been shown that pyrazole, 4-methylpyrazole (4MP), and dipyrone increase significantly the binding of perhydropyridylacetylcholine and do not affect the binding of α -bungarotoxin (α -BGT) to *Torpedo* nicotinic acetylcholine receptors (nAChRs) (*Abstr. Neurosci. Soc.*, 18:1510, 1992), suggesting that these pyrazoles could activate the nAChR via a site different from that for ACh. Recently, a novel agonist site was described on *Torpedo*, muscle, and neuronal nAChRs. The nAChR activation via this site is not blocked by competitive nicotinic antagonists, can be detected even after the nAChR has been desensitized by high concentrations of ACh, and is blocked by the nAChR-specific mAb FK1 (*FEBS Lett.*, 279:216, 1991; *J. Rec. Res.*, 13:413, 1993). In the present work we investigated the actions on muscle nAChRs of these pyrazoles, as well as of some polyamines and amantadine. Nicotinic, single-channel currents were studied in frog (*Leptodactylus ocellatus*) interosseal muscle fibers under cell-attached patch-clamp configuration. All compounds (1-100 μ M) activated single-channel currents. 4-MP was the most potent compound among the pyrazoles, and putrescine was more potent than spermidine. The channels activated by these drugs had higher noise levels during the open state than channels activated by ACh. The activation of the noisier channels usually began 2-3 min after formation of the GQ seal, and was facilitated by membrane hyperpolarization. The channel activity induced by all the drugs was not blocked by α -BGT and was seen even in the presence of high, desensitizing concentrations of ACh. FK1 (1:1000) completely abolished the agonist response of those substances, and did not affect that of ACh. The results revealed that these agents activate the muscle nAChR via the newly described agonist site, and raise the questions whether the polyamines might play a physiological role as modulators of nAChR activation and whether interaction of amantadine with the new nAChR agonist site could account for the therapeutic efficacy of this drug. Supp: FINEP/UMAB Mol. Pharm. Training Program, CNPq.

PHYSTIGMINE (PHY) ACTIVATES α 4 β 2 NEURONAL NICOTINIC ACETYLCHOLINE RECEPTORS (nAChRs) VIA A NOVEL AGONIST SITE. E.F.R. Pereira^{1,2*}, J. Lindstrom³, A. Maelicke⁴, S. Reinhardt-Maelicke⁴ and E.X. Albuquerque^{1,2}. ^{1,2}Dept. Pharmacol. Exp. Ther., Univ. MD Sch. Med., Baltimore, MD 21201, USA; ³Lab. Mol. Pharmacol., IBCCF, UFRJ, RJ 21944, Brazil; ⁴Univ. Pennsylvania, Philadelphia, PA 19104, USA; ⁵Inst. Physiol. Chem., Johannes-Gutenberg Univ. Mainz, Med. Sch., Duesbergweg, D-6500, Mainz, Germany.

It has been shown that PHY activates the α -BGT-sensitive nAChRs of frog muscle, *Torpedo* electroplax, and rat hippocampal neurons, and that its agonist effect is not blocked by competitive nicotinic antagonists, but instead by the nAChR-specific monoclonal antibody FK1 (*J. Rec. Res.*, 13:393 & 413, 1993). It has been suggested that the agonist effect of PHY could be caused by its binding to a novel nAChR agonist site. The residue Lys-125 on the receptor α subunit is an essential feature of the PHY-binding site on the nAChR (*Ann. N.Y.A.S.*, 681:140, 1993) and is highly conserved in nAChRs from different sources (Pereira *et al.*, *J.P.E.T.*, in press, 1993). To determine whether the novel site is present on α -BGT-insensitive neuronal nAChRs, we took advantage of a cell line of fibroblasts that stably express the α -BGT-insensitive neuronal α 4 β 2 nAChR (M10 cells; *Mol. Pharmacol.*, 40:463, 1991). In outside-out patches excised from M10 cells that were primed with dexamethasone (1 μ M), single-channel currents were activated by AnTX or PHY (each at 1 μ M). Dihydro- β -erythroidine (DH β E, 1-30 nM), but neither methylcaconitine nor FK1 blocked the channel activity induced by AnTX. The frequency of channel openings induced by PHY was unaffected by DH β E, but was decreased by FK1. Indirect immunofluorescence revealed heavy labeling of all cells with FK1, while no binding of α -BGT could be detected. Neither FK1 nor α -BGT was able to bind to M10 cells in which nAChR expression had not been induced by dexamethasone. Our findings agree with previous reports that the α 4 β 2 neuronal nAChR is insensitive to α -BGT, and demonstrate that the newly described agonist site is also present in α -BGT-insensitive nAChRs. TEMPERATURE DEPENDENCY OF LIGAND BINDING TO THE RAT BRAIN NICOTINIC RECEPTORS. R.J.Prince, K.G.Fernandes* and P.M.Lippiello. Duke University Medical Center, Durham, NC 27710 and Research & Development, R.J.Reynolds Tobacco Co., Winston-Salem, NC 27102

The thermodynamic properties of ligand binding to the neuronal nicotinic acetylcholine receptor were examined using a filtration assay. The affinity of L-[³H]-nicotine in rat cortical membranes decreased from 1.72 \pm 0.16nM (5) at 23°C to 2.47 \pm 0.29nM (5) at 37°C (P<0.1) and 3.40 \pm 0.18nM (4) at 37°C (P<0.001) (mean \pm SEM (n)). A van't Hoff plot of these data yielded values of 14.79 \pm 2.94 kJ mol⁻¹ for ΔH° and 114.7 \pm 10.1 J.K⁻¹mol⁻¹ for ΔS° indicating a large entropic component in the binding reaction. In contrast, previous studies have shown other ligand-gated ion channel ligands such as the benzodiazepines have largely enthalpy-driven binding reactions. An affinity-shift similar to that of nicotine was noted for carbamylcholine (K_i 185.6 \pm 4.9nM (3) at 4°C; 294.2 \pm 9.2nM (3) at 37°C). The rigid nicotinic-agonist, cytisine, however, showed a much smaller decrease in affinity between 4°C (K_i = 0.53 \pm 0.004nM (3)) and 37°C (K_i = 0.69 \pm 0.07nM (3)). In contrast, tetramethylammonium showed an increase in affinity at 37°C (K_i = 471.5 \pm 46.4nM (4)) compared with 4°C (K_i = 650.7 \pm 38nM (4)) while decamethonium showed no significant change in its K_i (4560 \pm 293nM (4) at 4°C; 4350 \pm 668nM (4) at 37°C). These differences may be due to these ligands possessing only the positively charged centre of the classical nicotinic pharmacophore. Our results further suggest that receptor protein conformational changes and deviations of some ligands from the ideal pharmacophore geometry both contribute to the binding process.

GABA RECEPTORS: FUNCTION—NEUROSTEROIDS

632.1

CHRONIC PENTOBARBITAL TREATMENT PRODUCE UNCOUPLING OF THE GABA-BENZODIAZEPINE RECEPTOR COMPLEX IN MAMMALIAN CORTICAL NEURONS. B. Yu* and M.K. Ticku. University of Texas Health Science Center, San Antonio, TX 78284-7764.

We have investigated the effect of chronic pentobarbital treatment on the binding of [³H]flunitrazepam and its coupling to various sites associated with the GABA_A receptors in cultured cortical neurons. Chronic treatment with pentobarbital sodium failed to alter the basal [³H]flunitrazepam binding to the intact cortical neurons. Studies of enhancement of [³H]flunitrazepam binding by various modulators showed that while the EC₅₀ value of GABA, pentobarbital sodium and 5 α -pregnane-3 α -ol-20-one (5 α 3 α) were unaltered, their EMAX value decreased after chronic pentobarbital sodium treatment (200 μ M for 5 days). The EMAX value of GABA decreased from 120% to 28%; while the EC₅₀ value was not altered by the chronic treatment (12 μ M v/s 10 μ M). The EMAX value of pentobarbital sodium decreased from 155% to 75%; while the EC₅₀ value was not altered (210 μ M v/s 200 μ M). The EMAX value of 5 α 3 α decreased from 60% to 45%; while the EC₅₀ value was not altered (100 nM v/s 80 nM). Using western blot analysis it was found that after chronic pentobarbital treatment (200 μ M; 5 days) there was a change in the amount of the α subunit subtypes: α 1 increased 122%; α 2 increased 36%; and α 3 decreased 39%. Taken together, these preliminary results indicate that there is a functional uncoupling of allosteric sites of GABA receptor complex after chronic pentobarbital treatment. This uncoupling appears to be heterologous in nature. The mechanism of this uncoupling appears to be a switch in the assembly of the subunits, resulting in decreased coupling. (Supported by NIH-NINDS grant # NS-15339)

632.2

CHRONIC BENZODIAZEPINE AGONIST TREATMENT PRODUCES UNCOUPLING OF THE GABA_A-BENZODIAZEPINE RECEPTOR IONOPHORE COMPLEX IN CORTICAL NEURONS. Xian-Jue Hu* and Maharaj K. Ticku. Dept. of Pharmacology, University of Texas Health Science Center, San Antonio, TX 78284-7764

We have investigated the effect of chronic flurazepam HCl treatment on the GABA_A receptor complex in cultured mammalian cortical neurons. Chronic flurazepam (1-5 μ M) treatment (1-10 days) did not produce any changes in the morphological appearance or the cell protein content of the cortical neurons. The basal [³H]flunitrazepam binding was also not altered following the chronic treatment. However, chronic flurazepam treatment produced uncoupling between GABA and pentobarbital sites with the [³H]flunitrazepam binding site. The EC₅₀ values of GABA and pentobarbital were not significantly altered following the chronic flurazepam treatment; however, their E_{max} values were decreased by ~50%. Chronic flurazepam treatment did not alter the effect of GABA on ³⁶Cl⁻influx; however, it significantly attenuated the effects of diazepam and inverse agonist (DMCM) on GABA-induced ³⁶Cl⁻influx. Taken together, these results suggest that chronic benzodiazepine treatment produces uncoupling of GABA and pentobarbital sites with the benzodiazepine site and between benzodiazepine site and GABA receptor gated Cl⁻ channels. This decreased coupling may be responsible for the tolerance associated with chronic benzodiazepine treatment.

632.3

REGIONAL COMPARISON OF THE EFFECTS OF FOUR NATURALLY OCCURRING PREGNANE DIOLS ON THE GABA_A RECEPTOR COMPLEX (GRC). Linda D. McCauley* and Kelvin W. Gee. Dept. of Pharmacology, University of California, Irvine, CA 92717.

It is well known that the progesterone metabolite 5 α -pregnan-3 α ,20 α -diol (5 α ,20 α) is a potent modulator of the GRC. The current studies were initiated to compare 5 α ,20 α with the three other naturally occurring pregnane diols 5 β -pregnan-3 α ,20 β -diol (5 β ,20 β), 5 α -pregnan-3 α ,20 β -diol (5 α ,20 β) and 5 β -pregnan-3 α ,20 α -diol (5 β ,20 α), all derivatives of progesterone. Each diol was evaluated for its ability to inhibit [³⁵S]-t-butylbicyclophosphorothionate ([³⁵S]TBPS) binding and allosterically enhance [³H]flunitrazepam ([³H]FLU) binding in rat brain homogenates. The rank order of efficacy for the inhibition of [³⁵S]TBPS binding in the presence of GABA in cortex, thalamus and cerebellum was 5 α ,20 α < 5 β ,20 β < 5 α ,20 β ≤ 5 β ,20 α . 5 α ,20 α was quite potent in modulating [³⁵S]TBPS binding (IC₅₀ < 100 nM) while the other three diols had IC₅₀'s in the high nanomolar range. In the absence of GABA, 5 α ,20 α lost efficacy while the remaining diols had potencies in the micromolar range. In the cortex, 5 α ,20 α enhanced [³H]FLU binding minimally, whereas the effect of 5 β ,20 β was similar to 5 α ,20 β but less than that of 5 β ,20 α . In the thalamus and cerebellum, again 5 α ,20 α showed little efficacy, but the other three diols had similar efficacies. Generally, the EC₅₀ for the enhancement of [³H]FLU binding was highest for 5 α ,20 β and lowest for 5 α ,20 α . These studies underscore the importance of stereochemical configuration at positions 5 and 20 in determining neurosteroid efficacy and potency. NEUROMODULATORY EFFECTS OF PROGESTERONE ON ISOLATED WHOLE TURTLE CEREBELLUM. C.Y. Chan*, J. Choe, M. Kumar. Dept. Physiol., CUNY Med. Sch., 138th St., Convent Ave., New York, 10031.

Numerous recent studies have shown the novel effects of steroids on CNS neuronal membranes. We are interested in the possible neuromodulatory actions of progesterone (P) in the integrally intact circuitry of the isolated whole turtle cerebellum, which may serve as a model for other brain regions not linked to reproduction. The tissue was continuously perfused with artificial CSF solution. Synaptic responses were evoked by stimulation of parallel fibers or the ipsilateral peduncle using bipolar electrodes. These population (field potential) responses were recorded using 2 extracellular glass micropipettes inserted in the molecular and granular layers and aligned in the same vertical axes. Data were then frame averaged. Doses of bath-applied P were typically limited to below 300 nM to avoid its anesthetic effect which could be readily discerned as suppression of the presynaptic volley. Postsynaptic excitation in both layers were dose-dependently suppressed by P by up to 30%. In 5/6 experiments, the amplitudes of EPSPs (inferred from latency) was slightly reduced or unchanged. The amplitude of IPSPs especially in the granular layer was enhanced. In other experiments, there was an apparent 20% diminution of the granular layer IPSP, which we attribute to suppression of its polysynaptic activation. In yet another 4 cases, in the presence of 100 μ M picrotoxin, P showed little or no reduction of the remaining EPSP. Intracellular recording from Purkinje cells showed little evidence of direct effect of P on EPSPs though some changes in rise time and input resistance was noted. Further intracellular studies are underway to isolate P effect on EPSPs and IPSPs.

RU5135 Antagonizes Neurosteroid and Pentobarbital Modulation of [³⁵S]TBPS Binding to GABA_A Receptors. D.W. Sapp* and R.W. Olsen. Dept. Pharmacology, Brain Research Institute, UCLA, 90024.

The amidine steroid RU5135 is an androstan derivative that lacks hormonal activity, but acts as a convulsant in the rat. RU5135 is a potent inhibitor of GABA binding and of the allosteric actions of GABA at the receptor complex. We were interested to determine whether RU5135 might also act as an antagonist at the steroid binding site on the GABA_A-receptor complex. We reported earlier that the steroid anesthetic alphaxalone has a biphasic effect on [³⁵S]TBPS binding in rat cortex, enhancing at low steroid concentrations (500nM) and inhibiting TBPS binding at higher steroid concentrations (> 10 μ M). RU5135 has no effect on the enhancement of TBPS binding by steroids, but it does block the inhibition produced by higher concentrations. With increasing RU5135 concentrations the inhibitory effect of steroids are reversed and TBPS binding is enhanced to the same level as that observed with lower steroid concentrations. Bicuculline produces the same effect as RU5135, but with a much lower potency. RU5135 also reverses pentobarbital inhibition of TBPS binding similar to the neuroactive steroids. Pregnenolone-SO₄ and dehydroepiandrosterone-SO₄ have been reported to inhibit the neuroactive steroids, but they had no effect on alphaxalone modulation of TBPS binding. Both RU5135 and bicuculline appear to act as antagonists of the inhibitory effects of the neuroactive steroids and pentobarbital, acting at an unknown allosteric site on the GABA_A receptor complex. PROGESTERONE CAN REGULATE GABA_A RECEPTORS IN THE CEREBRAL CORTEX. M.I. Al-Dahan, and R.H. Thalmann*, Dept. of Cell Biology and Division of Neuroscience, Baylor College of Medicine, Houston, TX 77030.

Well-washed synaptic plasma membranes were prepared from rat neocortex for filtration assays of the binding of the GABA_A agonist (³H)-baclofen. We found that the binding of baclofen to these membranes varied systematically as a function of the estrous cycle, with the lowest binding occurring during the estrus stage. We then replaced ovarian steroids in animals that had been ovariectomized for 3 weeks according to a standard paradigm that approximately mimics the onset of each hormone during the estrous cycle: estrogen, followed by progesterone 48 hours later, followed by sacrifice 4 hours after progesterone. An identical protocol but without estrogen or without progesterone treatment was also included. Surprisingly, progesterone-only produced as large an increase in binding as estrogen + progesterone. The increased baclofen binding following a progesterone-only treatment could be elicited by as little as 100 μ g progesterone per 100 g body weight, and was evident 4 but not 1 hour following progesterone. This effect of progesterone is unlike the classic ones in which progesterone effects are dependent upon prior treatment with estrogen. Supported by National Institutes of Health grant NS21713.

632.6

EFFECTS OF PHENOBARBITAL AND 5 β -PREGNAN-3 α -OL-20-ONE ON THE GABA_A RECEPTOR FROM CA1 PYRAMIDAL CELLS. L.L. Celentano*, and R.K.S. Wong. Dept. of Pharmacology, SUNY Health Science Center, Brooklyn, NY 11203.

Single channel analysis of the steady state GABA response reveals prolongation of open time and burst duration by barbiturates and neurosteroids, suggesting an effect on the gating mechanism (Tymann and Macdonald, J Physiol 1989, 1992). We have begun to explore the effects of GABA receptor modulators on the initial response to rapidly applied GABA. Rapid application of 1 mM GABA to outside-out patches induces both fast and slow desensitization, while lower concentrations (<30 μ M) induce only slow desensitization (Neuroscience Abstr 487.9, 1992). In the present study, we examined the effects of 500 μ M phenobarbital (PB) and 1 μ M 5 β -pregnan-3 α -ol-20-one (5 β) on the response to 3, 30 and 1000 μ M GABA. Patches were excised from acutely isolated pyramidal neurons of guinea pig hippocampus (Kay and Wong, J Neurosci Meth 1986). Extracellular buffer was (in mM): NaCl 145, CaCl₂ 1, MgCl₂ 1, glucose 25, Hepes 10, pH 7.4, and intracellular buffer was: Tris HCl/base 130, NaCl 3, MgCl₂ 4, Na₂ATP 4, EGTA 10, HEPES 10, pH 7.3 methane sulfonic acid (final Cl⁻ 46). Drugs were applied by a 7-barrel flow-tube capable of displacing the solution surrounding an electrode within 1 ms. The peak response to 3 μ M GABA was enhanced by 106 \pm 39% (n=8) by PB and 81 \pm 7% (n=3) by 5 β . The peak response to 30 μ M GABA was unaffected by PB, consistent with an increase in affinity for GABA. In the presence of either PB or 5 β , the response to 30 μ M GABA desensitized with only slow kinetics. Neither drug significantly affected the peak response to 1mM GABA or the rate or extent of desensitization. This may be the first time these agents have been studied on the maximum GABA response free of limitations imposed by series resistance error or slow drug application. If these modulators act on the gating mechanism, their effects seem to be overcome by high GABA. Experiments are underway to examine the effects of other modulators.

MODULATION OF GABA_A RECEPTORS BY STEROIDS IN POSTERIOR PITUITARY NERVE TERMINALS. S. J. Zhang* and M. B. Jackson. Dept. of Physiology, Univ. of Wisconsin, Madison, WI 53706.

Patch clamp techniques were used to investigate the modulation of the GABA_A receptor by alphaxalone (3 α -hydroxy, 5 α -pregnane, 11,20-dione), allopregnanolone (3 α -hydroxy-5 α -pregnan-20-one) and estradiol-17 β (E2) in the rat posterior pituitary. Both alphaxalone and allopregnanolone strongly enhanced GABA activated Cl⁻ current in nerve terminals. Application of GABA (40 μ M) and alphaxalone (5 μ M) produces responses 2.5 times (n = 10) as large as controls. Allopregnanolone (100 nM) enhanced GABA responses by a factor of 1.9 (n = 5). Estradiol-17 β (100 nM) reduced GABA responses by 10%. In single channel recordings, alphaxalone (5 μ M) with GABA (40 μ M) increased by a factor of 1.8 (n = 4) GABA_A receptor Cl⁻ channel activity. Allopregnanolone (100 nM) with GABA (1 μ M) produced a similar effect (2.1 times as high as the controls, n = 4). However, estradiol (100 nM) with GABA (40 μ M) resulted in 74% (n = 4) of the single channel activity of the controls. The rate of desensitization of the GABA_A receptor in nerve terminals was not altered by the steroids tested (n = 8). These results demonstrated modulation of the GABA_A receptor of peptidergic nerve terminals by steroids at both the whole-cell and single-channel level. This finding can explain the reciprocal relation between circulating oxytocin and allopregnanolone. The identification of this previously unknown link between steroids and the neurohypophysis has broad implications for endocrine function at the system level.

632.9

SIMULATION OF SPIKE PROPAGATION BLOCK BY GABA IN POSTERIOR PITUITARY NERVE TERMINALS. Meyer B. Jackson* and Shuanglin J. Zhang, Dept. of Physiology, University of Wisconsin, Madison, WI 53706.

We have recently shown that activation of GABA_A receptors in the posterior pituitary depolarizes nerve terminals and blocks action potentials evoked by local current injection (Zhang and Jackson, *Science* 258, 531-534, 1993). In order to establish the relevance of this result to the active spread of excitation through nerve terminal arborizations, we used the computer program NODUS to simulate action potential propagation in a realistic model of the posterior pituitary. Morphological features for this simulation were based on cable analysis and neurobiotin filling data. Sodium and potassium channel parameters were based on patch clamp experiments in both the whole-cell and outside-out patch configuration. Action potential propagation was then simulated in an axon with a single large spherical swelling in the middle. With only active sodium and potassium currents, simulations showed that action potentials initiated at one end of the axon propagate successfully through the swelling. We then introduced a chloride conductance comparable in magnitude to that activated by GABA in this preparation. The chloride conductance was added only to the swelling membrane, but this resulted in failure of action potentials to pass through the swelling. Propagation was blocked. This simulation strengthens the argument that GABA acts at nerve terminal membranes to prevent the active spread of excitation.

632.11

PROGESTIN METABOLITES, EFFECTIVE AT THE GABA RECEPTOR, ALTER PAIN SENSITIVITY IN FEMALE RATS. J. E. Duncan* and C.A. Frye, Dept. of Psychology, Bates College, Lewiston, ME 04240.

To investigate whether progestin metabolites alter pain sensitivity in a manner consistent with their efficacy at the GABA receptor complex (GBR), seven progestin metabolites were administered SC, via ICV implantation, and then ICV infusion. Listed from most to least efficacious at the GBR, administered metabolites were THP [5 α -pregnan-3 α -ol-20-one], THDOC [5 α -pregnan-3 α , 21-diol-20-one], P [4-pregnen-3,20-dione], DHP [5 α -pregnan-3, 20-dione], 17-OH-P [17 α -hydroxy-progesterone], DHEAS [5-androsten-3 β -ol-17-one sulfate], and PS [5-pregnen-3 β -ol-20-one sulfate]. Pain sensitivity was measured using the tailflick apparatus at 0, 5, 20, 40, 60, 80, 100, and 120 minutes post SC steroid administration of 0.0, 0.1, 0.2, 1.6, 3.2, or 6.4 mg/kg. Although peripheral administration of potent to moderate agonists of the GBR (i.e. THP, THDOC, P, and DHP) significantly elevated tailflick latencies above baseline, changes in nociception were inconsistent across dose and time. Findings from both ICV implantation and ICV infusion (0.0, 0.5, 1.0, 2.0 μ g/rat) of the progestins were clearer. Potent to moderate agonists of the GBR, i.e. THP, THDOC, P, and DHP, all significantly increased tail flick latencies above baseline, whereas 17-OH-P did not. Furthermore, the GABA receptor antagonists, DHEAS and PS, did not significantly elevate tailflick latencies compared to controls. Changes in pain sensitivity occurred within 0-5 minutes post ICV administration of potent to moderate agonists of the GBR. These immediate differences were not due to stress effects given that corticosterone levels were not elevated in any of the groups. These findings indicate that progestins may alter pain sensitivity via an interaction with the GBR.

632.13

IMMORTALIZED GnRH-SECRETING NEURONS ARE SENSITIVE TO GABA_A RECEPTOR AGONISTS. M. El-Etr, R.J. Fiddes, Y. Akwa, M. Amalric*, P. Robel and E.E. Baulieu, Lab. Hormones, 94276 Bicêtre Cedex and Lab. Neurobiol. Fonc., BP71, 13402 Marseille Cedex, France.

A variety of neuromodulators appears to be involved in the control of GnRH secretion: among these, GABA has been reported to stimulate GnRH release by rat arcuate nucleus median eminence fragments through GABA_A receptors (GABA_A-R) (Masotto et al., *Endocrinology*, 125:548-553, 1989). An immortalized hypothalamic GnRH-secreting neuronal cell line has recently been developed by genetically targeted tumorigenesis (Mellon et al., *Neuron*, 5:1-10, 1990). We detected saturable (³H)-muscimol binding on GT1-1 cell membranes (460 \pm 40 fmol/mg of protein at 50 nM) indicating the presence of GABA_A-R. Using Northern and Western blot analyses, we are characterizing the subunits expressed by these cells. Some steroids, such as 3 α ,5 α -tetrahydroprogesterone (3 α ,5 α -THP), modulate GABA_A-R and we are testing their effect on the binding of (³H)-muscimol to GT1-1 cell membranes. Progesterone has been shown to facilitate GnRH release, but since no classical intracellular progesterone receptor has been detected in hypothalamic GnRH neurons, the regulatory effect of progesterone could imply nuclear receptors in connecting neurons. However, the action of progesterone might also be exerted on GnRH neurons through its 3 α ,5 α -THP metabolite via the GABA_A-R and we are currently investigating this intriguing possibility. It is also worth noting that we found GT1-1 cell cultures synthesize 3 α ,5 α -THP from progesterone.

632.10

INHIBITION OF 5 α REDUCTASE SUPPRESSES PROGESTERONE INDUCED ANESTHESIA BY BLOCKING THE ACCUMULATION OF BRAIN ALLOPREGNANOLONE. A. Komeyev*, A. Guidotti, E. Costa, Fidia-Georgetown Institute for Neurosciences, Georgetown Univ Med Sch, Washington, DC 20007.

Administration of high doses of progesterone induces sedation and anaesthesia in human and rat. Presumably this phenomenon is related to the conversion of progesterone into allopregnanolone (3 α ,5 α tetrahydroprogesterone) a high affinity positive modulator of GABA induced Cl⁻ current. We present direct evidence in favor of this hypothesis by demonstrating that inhibition of 5 α reductase, the enzyme which participates in the conversion of progesterone to allopregnanolone, with 17 β -(N,N-diisopropylcarbamoyl)androst-3,5-diene-3-carboxylic acid (IN) kindly provided by SmithKline Beecham, suppresses both the accumulation of allopregnanolone in the brain and the occurrence of anaesthesia following the progesterone perfusion in rat. Freely moving adrenalectomized/castrated rats were perfused at a rate of 0.3 ml/min with progesterone (6 mg/ml) solution. In the first experiment perfusion was terminated at the time of the loss of righting reflex, which was 5.9 \pm 1.1 min in control rats and 11.2 \pm 1.4 in rats treated with 50 mg/kg of IN 1 h before the experiment. In the second experiment, in order to evaluate brain steroid content rats were perfused for 7 min (independently of the loss of righting reflex) and sacrificed 20 min later. In the forebrain of control rats levels of progesterone and allopregnanolone were 150 \pm 25 μ M and 7.5 \pm 2.1 μ M, respectively. In the forebrain of IN treated animals, the level of progesterone was 230 \pm 49 μ M and that of allopregnanolone was 0.8 \pm 0.3 μ M. Interestingly, administration of IN did not change the latency of the loss of righting reflex following the perfusion with allopregnanolone nor its brain content. In conclusion IN can be used as a pharmacological tool in the study of neurosteroid functions. Supported in part by grant RO1 MH49486-01.

632.12

ESTRUS CYCLE AND SENSITIVITY TO CONVULSANTS AND THE ANTICONVULSANT EFFECT OF 3 α -HYDROXY-5 α -PREGNAN-20-ONE (3 α ,5 α -P). D.A. Finn*, R. Ostrom and K.W. Gee, Dept. Pharmacology, Univ. of Calif., Irvine, CA 92717.

Recent work in our laboratory suggests that sensitivity of the GABA_A receptor complex (GRC) to the progesterone metabolite 3 α ,5 α -P may change to maintain homeostatic regulation of brain excitability. Therefore, the current studies were conducted to evaluate estrus cycle-related differences in sensitivity to convulsants and the anticonvulsant effect of 3 α ,5 α -P. The threshold dose for onset to first myoclonic jerk, generalized and tonic convulsions was measured by constant infusion of (+)bicuculline, picrotoxin, pentylenetetrazol, strychnine and methyl-6,7-dimethoxy-4-ethyl- β -carboline-3-carboxylate (DMCM). Females in estrus were more sensitive than females in diestrus 1 or males to (+)bicuculline and DMCM. Administration of 3 α ,5 α -P (15 mg/kg in β -cyclodextrin, i.p.) 15 min prior to infusion of pentylenetetrazol significantly increased the threshold dose for onset to all three convulsions and provided equal protection against tonic convulsions. The dose for onset to first myoclonic jerk was significantly higher in females in diestrus 1 than females in estrus or males. Blood levels of 3 α ,5 α -P are currently being evaluated. These results suggest that there is a selective interaction between convulsant drugs specific for the GRC and estrus cycle-related changes in neurosteroid levels and potency. 633.1

POTENTIATION OF GABA_A RECEPTOR-MEDIATED CURRENTS BY HALOGENATED BUTANES CORRELATES WITH THEIR ABILITIES TO INDUCE GENERAL ANESTHESIA. S.J. Mihic, P.J. Whiting and R.A. Harris, Dept. Pharmacology, Univ. Colorado Sch. Med., Denver VAMC and Merck Sharp and Dohme Res. Lab., U.K.

The Meyer-Overton rule correlating a compound's anesthetic potency with its lipid:water partition coefficient is one of the cornerstones of modern anesthetic theory. Recently, a number of chlorinated/fluorinated butane compounds have been synthesized, some of which deviate from the Meyer-Overton rule. We tested three of these compounds (one anesthetic and two non-anesthetic *in vivo*) for their abilities to potentiate GABA_A responses in *Xenopus* oocytes expressing $\alpha_1\beta_2$ and $\alpha_1\beta_2\gamma_{2S}$ GABA_A receptor constructs. The anesthetic 1-chloro-1,2,2-trifluorocyclobutane (F3) strongly potentiated chloride currents produced by 5 μ M GABA. This potentiation was greater in oocytes expressing the $\alpha_1\beta_2\gamma_{2S}$ subunits (300%) than in eggs expressing just the $\alpha_1\beta_2$ subunits (150%). In both constructs, the percent potentiation produced by F3 decreased as the GABA concentration was raised. The two non-anesthetics, 1,2-dichlorohexafluorocyclobutane and 2,3-chlorooctafluorobutane, had no effects on GABA_A currents, at any concentrations tested. Even though all three of these agents are predicted to be anesthetics by the Meyer-Overton rule, only F3 behaved as an anesthetic *in vivo*, and only F3 potentiated GABA_A responses in oocytes. These results further support the involvement of the GABA_A receptor in general anesthesia. Support by VA, NIAAA and the Medical Research Council of Canada (to SJM).

633.3

THE GENERAL ANESTHETIC PROPOFOL SELECTIVELY ENHANCES GABA_A RECEPTOR-MEDIATED RESPONSES FROM BOTH HIPPOCAMPAL AND CEREBRAL CORTICAL NEURONS IN RAT BRAIN SLICES. W.R. Proctor, J.M. Brundage, E. Sanna and T.V. Dunwiddie, University of Colorado Health Sciences Center, and Veterans Admin. Medical Res. Service, Denver, CO.

We have examined the effects of the general anesthetic, propofol, on synaptically evoked responses in pyramidal cells located in the CA1 region of the hippocampus and in the frontal cerebral cortex from young adult rats. Initial studies showed very potent and irreversible inhibitory effects on EPSPs and on the resting membrane potential (RMP) of CA1 hippocampal neurons using conventional intracellular electrophysiological recordings. Further analysis showed that these effects were due to small concentrations of a breakdown product in fresh, commercially obtained propofol. Following fractional distillation, purified propofol (40 μ M) added to the superfusing artificial CSF media produced no significant changes in RMP, membrane input resistance (R_{in}), EPSP amplitude, or the late IPSP (GABA_B) amplitude in both hippocampal CA1 neurons and cortical neurons (level IV-V). However, significant potentiation (20-100%) of the GABA_A receptor-mediated chloride conductance was seen in both brain regions during application of 40 μ M propofol. This result is comparable to what we have previously observed with other general anesthetics (e.g., pentobarbital and etomidate), but stands in contrast to what we have observed with ethanol, which enhances synaptically evoked GABA_A mediated response in cortical neurons, but not in CA1 hippocampal neurons.

Supported by AA03527 and VA Medical Research Service.

GABA_A Receptor Cl⁻ Current Potentiation Correlates with General Anesthetic Potency. S.A. Zimmerman, M.V. Jones, S.M. Minaglia and N.L. Harrison*, Depts of Anesth & Crit Care and *Pharm & Phys Sci, University of Chicago, Chicago, IL 60637

The molecular mechanisms of general anesthetics (GAs) are unknown. We studied the effects of the GAs chloroform, enflurane, halothane, isoflurane, methohexital, pentobarbital, propofol, trichloroethanol, and urethane at known concentrations on GABA_A receptor function in cultured rat hippocampal neurons. Recordings were made at 25°C using the whole-cell patch clamp technique, with an intracellular solution based on K gluconate and externally perfused with HEPES-buffered saline. GABA was applied to individual neurons by brief pressure pulses from a micropipette containing 10 μ M GABA positioned near the cell body. Neurons were held at -40mV under voltage clamp. Application of GABA elicited transient outward currents that reversed in polarity around -70 mV. Anesthetic solutions were applied via the perfusion line and volatile anesthetic concentrations were determined by gas chromatography. Transient current responses to brief pulse applications of GABA were prolonged by the general anesthetic agents. Time to half decay ($T_{1/2}$) of the GABA response was measured under control and anesthetic conditions. All the GAs studied increased $T_{1/2}$ in a concentration dependent manner. A plot of the increase in $T_{1/2}$ vs log[Anesthetic] was constructed for each GA. These plots were fit using an exponentially increasing function. The concentration of each GA which increased $T_{1/2}$ for the GABA current by 50%, C_{50} , was interpolated from this function. C_{50} was then plotted against the published clinically effective concentration (EC₅₀) on a log-log plot for the entire range of GAs studied. The log-log plot of C_{50} against EC₅₀ was fit with the linear equation: $Y=1.45X+1.05$, $r=0.994$. Concentrations of GAs which potentiate GABA_A receptor current are positively and linearly correlated with clinical anesthetic concentrations. This correlation spans at least four orders of potency. This result suggests the GABA_A receptor as a possible site of anesthetic action.

GABA RECEPTOR ACTIVATION OF CUTANEOUS NOCICEPTIVE AFFERENTS. B. Ault* and L. M. Hildebrand, Dept. Neurosciences, Sterling Winthrop Pharmaceuticals Research Division, Rensselaer, NY 12144.

Allogens such as capsaicin, bradykinin, acetylcholine and potassium ions applied to exposed tail skin in the rat isolated spinal cord-tail preparation evoke a nociceptive ventral root response consisting of depolarization and spiking activity. Glutamate and kainate, which depolarize C-fibers, also evoke a similar reflex. GABA has now been examined because it is known to depolarize unmyelinated afferent fibers.

GABA superfused over exposed tail skin (for 3 sec) evoked a ventral root reflex comparable to that produced by capsaicin (3 μ M). The EC₅₀ was 37±9 μ M, n=12. The GABA_A receptor agonists muscimol and isoguvacine had comparable effects to GABA, with EC₅₀s of 13±7 μ M and 64±20 μ M respectively. The GABA_A agonist baclofen (100 μ M) and glycine (10 mM) had no effect. Bicuculline applied to the tail antagonized GABA (Schild slope = -1.0) with a pA₂ of 5.8. Spinal application of 1 μ M morphine blocked the actions of GABA and capsaicin, and was reversed by naloxone. These data indicate that GABA_A receptors can activate nociceptive afferents, and thus could be involved in nociception.

THE VOLATILE ANESTHETICS ENFLURANE AND HALOTHANE POTENTIATE MUSCIMOL-STIMULATED ³⁶CL⁻ EFFLUX RATE

B. Longoni*, G.C. Demontis and R.W. Olsen, Dept. of Pharmacology, School of Medicine, University of California, Los Angeles, CA 90024.

The volatile anesthetic halothane increases ³⁶Cl⁻ efflux rate in rat brain cortical slices. Halothane also increases the GABA_A receptor binding affinity for ³H-muscimol in rat brain membranes (Longoni et al. 1993 JPET in press). To assess the possibility that the GABA_A receptor represents a common target for different volatile anesthetics, we studied the effect of enflurane on ³⁶Cl⁻ efflux rate in rat brain cortical slices. Like halothane, enflurane in a clinical useful range (0.46 - 4 mM) potentiates the muscimol stimulated efflux rate: moreover the effect was stronger for 2 μ M muscimol than for 10 μ M an almost saturating concentration. Enflurane increases monotonically the ³⁶Cl⁻ efflux rate in the absence of exogenous GABA_A agonist, at variance with the biphasic dose-effect relationship found for halothane. Our data suggest that different volatile anesthetics share a common molecular target, namely the GABA_A receptor, in their mechanism of action.

MODULATION OF GABA_A RECEPTOR CHANNEL KINETICS BY THE VOLATILE ANESTHETIC ENFLURANE. M.V. Jones*, R.E. Twyman and N.L. Harrison†, Depts of *Pharm & Phys Sci, †Anesth & Crit Care, Univ of Chicago, Chicago, IL 60637 and ‡Human Mol Biol & Gen, Univ of Utah, Salt Lake City, UT 84112

The volatile anesthetic enflurane (ENF) induces EEG seizure activity¹, neuronal spike firing² and modulates GABA_A receptor-mediated inhibitory postsynaptic currents (IPSCs) in a complex manner.³ We have examined ENF's effects on the kinetics of single chloride channels activated by GABA. Hippocampal neuron culture⁴, single channel⁵ and anesthetic measurement⁶ techniques were similar to those previously described. Outside-out membrane patches were voltage-clamped at -80 mV. 1 μ M GABA and 460 μ M ENF (1 MAC), were bath applied. GABA activated 28 pS channel currents (97% of openings). ENF appeared to produce brief closures within openings, reducing mean open duration and causing an increase in openings and closings within bursts. The average current per second was reduced by ENF. Open durations were best fitted⁵ by three exponential components (time constant (relative area)) (0.7 (0.68), 2.8 (0.22) and 6.9 (0.10) ms). ENF altered this distribution to favor fewer components and briefer durations (1.14 (0.99) and 4.39 (0.01) ms). The closed time distribution (0.50 (0.32), 5.8 (0.16), 64 (0.5) and 577 (0.02) ms) was also shifted by ENF to favor briefer events (0.31 (0.64), 2.98 (0.18), 41 (0.14) and 242 (0.04) ms). Removal of ENF reversed these effects. One possible explanation of these results is that ENF acts as an open channel blocker. Many drugs which reduce total GABA_A receptor channel current also produce seizures *in vivo*. Analysis of ENF's effects on burst and cluster structure may help to reconcile these observations with the observed amplitude depression and prolongation of the IPSC³. 1) *Prog Drug Res* 26:225-228,1982; 2) *Br J Anaesth* 62:301-310,1989; 3) *Soc Neurosci Abstr* 17:102.2,1991; 4) *J Physiol* 449:279-293,1992; 5) *J Physiol* 456:215-245,1992. Molecular characterization of cDNAs encoding an NPY-like molecule and a NPY receptor-like receptor from the CNS of the mollusc *Lymnaea stagnalis*. E. Vreugdenhil¹, H. van Heerikhuizen², K. Cox², J.F. Burke², E. van Kesteren¹, R.J. Planta¹ and C.P. Temesvári¹ Department of Biochemistry and Mol.Biology, Vrije Universiteit, de Boelelaan 1083, 1081 HV Amsterdam The Netherlands. ²Sussex Centre for Neuroscience, IRC, School of Biological Sciences, University of Sussex, Brighton BN1 9QG, UK.

We have cloned a cDNA encoding an NPY-like precursor from a lymnaean cDNA CNS library by a degenerate PCR strategy. The primary structure of the predicted *Lymnaea* NPY is very similar with that of *Aplysia* NPY. Although the overall homology with the human NPY precursor is low (25%) the structure of the lymnaean precursor is similar in having a signal peptide, a NPY-like peptide that is flanked by a classical Lys-Arg processing site and a carboxy terminal peptide. Interestingly, like *Aplysia* NPY, the carboxy terminal end of *Lymnaea* is having structural elements in common with the well-characterized invertebrate neuropeptide FMRFa; this might indicate that *Lymnaea* NPY and FMRFa influence similar target cells.

To determine whether NPY receptor-like receptors are present in the CNS of *Lymnaea* we have used a similar PCR strategy to clone several cDNAs that putatively encode neuropeptide receptors. One of these cDNA clones (GRL106) exhibits a high amount of sequence identity with the human NPY receptor and also contain specific secondary structural features that are also found in its vertebrate counterpart. Therefore, this predicted protein is a serious candidate to be the cognate receptor for the lymnaean NPY or, alternatively, lymnaean FMRFa.

In situ hybridisation experiments showed that *Lymnaea* NPY is expressed in many neurons that are scattered throughout the CNS of *Lymnaea*. In contrast, GRL106 is specifically expressed in the multidisciplinary studied caudo-dorsal cells (CDCs), which are giant peptidergic neurons controlling egg laying and associated behaviour and which are strongly inhibited by FMRFa. Whether GRL106 is activated by *Lymnaea* NPY and/or FMRFa, has to await the functional expression of this receptor clone.

CLONING OF HUMAN KAPPA OPIATE RECEPTOR cDNA J. Nystrom^{*}, H.Kong, K. Yasuda, G. Bell and T. Reisine, Dept. Pharmacol., Univ. Pennsylvania, Philadelphia, PA 19104 and HHMI, Univ. Chicago, Chicago, Ill 60637.

Dynorphin induces its biological actions by interacting with kappa opiate receptors. Kappa receptors are one of three opiate receptor subtypes. Agonists at this receptor can induce psychotomimetic effects in humans, as well as analgesia. We recently cloned a mouse kappa opiate receptor cDNA. To investigate the properties of the human kappa receptor, a human genomic library was screened with the mouse kappa receptor cDNA. The human kappa receptor gene was identified. Since the gene has introns, the mouse receptor cDNA was used to screen both human temporal lobe and hippocampal cDNA libraries to isolate human kappa receptor cDNA. Following initial screening, nine positive plaques were identified and isolated for further purification. Presently we are characterizing the inserts to identify a human kappa receptor cDNA that could be used in subsequent expression studies. These studies will be important to establish that the cDNA encodes the kappa receptor and to determine whether the human and mouse receptors have similar properties. Supported by MH45533 and MH48518.

IMMUNOLOGICAL DETECTION OF MULTIPLE FORMS OF THE SOMATOSTATIN RECEPTOR SUBTYPE SSTR2 M. Theveniau^{*}, K. Raynor and T. Reisine Dept. Pharmacology, Univ. of Pennsylvania, Philadelphia, PA 19104.

Five somatostatin (SRIF) receptors have recently been cloned. One subtype, SSTR2, has unique pharmacological properties and may selectively mediate SRIF inhibition of growth hormone release. To investigate its physical properties, we developed two peptide directed antisera against SSTR2. One antiserum, 2e3, specifically detects 93 kDa proteins in CHO cells stably expressing cloned SSTR2. This is a similar size as the affinity labeled SSTR2 from these cells. 2e3 also immunoprecipitates 93 kDa proteins from these CHO cells. A second antiserum, 2i4, specifically immunoprecipitates high affinity SRIF binding sites from these CHO cells. These studies and others show that 2e3 and 2i4 specifically interact with SSTR2. 2e3 detects proteins of 148 kDa in rat brain and both 2e3 and 2i4 specifically immunoprecipitate high affinity SRIF binding sites solubilized from rat brain, indicating that the 148 kDa protein is likely to be SSTR2. 2e3 also detects 148 kDa proteins from AR42J and 293 cells which express SSTR2. To determine whether the differences in size of the cloned SSTR2 and SSTR2 expressed in AR42J cells is due to processing, mRNA was extracted from CHO and AR42J cells, translated and the radiolabeled products immunoprecipitated with 2e3. Similar proteins of 41 kDa were immunoprecipitated. Since this is the predicted size of unprocessed SSTR2, these findings indicating that the size differences of SSTR2 detected in CHO cells versus AR42J cells are due to differential processing of SSTR2. These antisera will be useful in further investigating the nature of the differential processing of SSTR2 as well as determining other physical properties of this receptor. Supported by MH45533 and MH48518.

ISOLATION OF FOUR NOVEL HUMAN PEPTIDE G-PROTEIN COUPLED RECEPTORS. T. Nguyen, A. Marchese, P.H. Wu, H. Ma, H. Heng, L.C. Tsui, X. Shi, S.R. George and B.F. O'Dowd^{*}. Addiction Research Foundation and Depts. Medicine and Pharmacology, University of Toronto, and Research Institute, Hospital for Sick Children, Toronto, Ont, CANADA.

The cloning of the first opioid receptor (OR) has recently been reported [Evans et al, Science 258:1952-1955 (1992)], and this mouse delta OR has identity with the somatostatin receptors and other peptide G protein-coupled receptors. We planned experiments to search for the human delta OR gene and other opiate receptor genes in the human genome and prepared two degenerate oligonucleotides based on the nucleotide sequence encoding the third and seventh transmembrane regions of the opioid and somatostatin receptors. The gene structure for the OR has not yet been reported, however, many of the G protein coupled receptors are encoded on single exons. Thus we used the oligonucleotides to amplify human genomic DNA and also human hippocampus cDNA library. The amplified DNA's in the size range 500 to 1000bp were subcloned into Bluescript and 150 of the resulting clones were sequenced. None of the clones encoded the orthologue of the mouse delta OR, however three clones, #11, #12 and #14 obtained from the amplification of the genomic DNA shared some identity with the delta OR and somatostatin receptor genes. We have screened a human genomic library and the full length genes are intronless in their coding regions. Clone 12 has been mapped to chromosome 10, at q11.2-21.1. Clone 33, isolated from the hippocampus cDNA library, and not found in the genomic amplification, also shared identity to the delta OR and somatostatin receptor genes. Northern blot analysis, using clone 33 as a probe, has revealed hybridization signals in rat striatum, cortex, hippocampus and cerebellum.

634.4

DESENSITIZATION OF THE SOMATOSTATIN RECEPTOR SSTR2 INVOLVES BETA-ADRENERGIC RECEPTOR KINASE (BARK) J. Hines^{*}, M. Theveniau, J. Benovic, and T. Reisine Dept. Pharmacol. Univ. Pennsylvania and Jefferson Medical Cent., Philadelphia, PA 19104.

Somatostatin (SRIF) induces its biological actions by interacting with a family of receptors. One of the recently cloned subtypes, SSTR2 selectively binds the peptide MK 678. Continuous exposure of this receptor to agonists reduces the ability of the receptor to be labeled by ¹²⁵I-MK 678. This regulation of agonist binding to the receptor is dependent on the time and concentration of agonist treatment and is reversible. To investigate the molecular mechanisms involved in this regulation, we developed a peptide-directed antisera against SSTR2. The antisera detects similar levels of SSTR2 from control and agonist treated CHO cells by immunoblotting, indicating that the reduced agonist binding is not due to receptor down-regulation. For a number of receptors, desensitization involves kinase catalyzed phosphorylation of the receptor. To determine whether SSTR2 becomes phosphorylated during agonist treatment, CHO cells expressing SSTR2 were preloaded with ³²P-orthophosphate, stimulated with agonist, solubilized and SSTR2 immunoprecipitated with the peptide directed antisera. These studies showed that agonist pretreatment of SSTR2 induced the phosphorylation of the receptor. Agonist induced phosphorylation and regulation of SSTR2 is not likely to involve cAMP or Ca⁺⁺ dependent kinases since SRIF inhibits these kinases and agents that activate these kinases, such as forskolin, PMA and calcium ionophore do not affect agonist binding to SSTR2. However, the second messenger independent kinase BARK, may be involved in SSTR2 regulation since in preliminary studies, a BARK dominant negative mutant partially blocked agonist induced regulation of SSTR2. Studies are in progress to test the role of BARK in agonist-induced regulation and phosphorylation of SSTR2. Supported by MH45533.

634.6

DEVELOPMENT OF SELECTIVE AGONISTS AT THE CLONED SOMATOSTATIN RECEPTORS SSTR2, SSTR3 AND SSTR4 T. Reisine^{*}, W. Murphy, A.M. O'Carroll, D. Coy, J. Taylor, H. Kong, K. Yasuda and K. Raynor Dept. Pharmacol., Univ. Pennsylvania, Philadelphia, PA, 19104; LCB, NIMH, Bethesda MD, 20892; Dept. Medicine, Tulane Univ. New Orleans, LA, 70112; Biomeasures Inc. Hopkinton, MA 01748 and HHMI, Univ. Chicago, Chicago, Ill 60637

Somatostatin (SRIF) induces its biological actions by interacting with membrane associated receptors. Five SRIF receptors have recently been cloned. To develop ligands selective for the receptor subtypes that can be used to investigate their individual functions, the five cloned receptors were expressed in either CHO or COS cells and tested for their affinities for a large number of SRIF analogs. SSTR2 could be specifically labeled by the cyclic peptides BIM23027 and NC4-28B having over 1000-fold selectivity for these compounds. SSTR3 could be specifically labeled by the linear peptide BIM23056 and SSTR4 selectively interacted with the linear peptide BIM23052 and the cyclic peptide L362855. No peptides were identified that selectively interacted with SSTR1 or SSTR5. This is the first observation of very high affinity binding of linear peptides to SRIF receptors. Correlational analysis of the affinity of the receptors for these different peptides and the potencies of the compounds to inhibit growth hormone release indicates that SSTR2 selectively mediates the regulation of growth hormone secretion by SRIF. These subtype selective peptides will allow for the determination of the specific functions of the SRIF receptor subtypes. Development of these subtype selective peptides as radioligands will also be useful in detecting the expression of the individual SRIF receptors in brain, the endocrine system and in SRIF responsive tumors. Supported by MH45533 and MH48518.

G α 1 SELECTIVELY COUPLES THE SOMATOSTATIN RECEPTOR SUBTYPE SSTR3 TO ADENYLYL CYCLASE. Susan F. Law*, Silvio Zaina, Raymond Sweet, Kazuki Yasuda, Graeme I. Bell, Jeffrey Stadel and Terry Reisine. Dept. of Pharm., U. of Pennsylvania, Phila., Pa. 19104; SmithKline Beecham Pharm., King of Prussia, Pa. 19406; U. of Chicago, Chicago, Ill. 60637.

Three Somatostatin (SRIF) Receptors have recently been cloned and only one, SSTR3, appears to functionally couple to adenylyl cyclase. However, SRIF does not inhibit cAMP formation in CHO cells stably expressing SSTR3 and G α 2 or G α 3 but lacking G α 1. In contrast, SRIF does inhibit forskolin stimulated cAMP formation in CHO cells stably expressing SSTR3 and G α 1, indicating that G α 1 selectively couples SSTR3 to adenylyl cyclase. To investigate the functional domains of G α 1 necessary for interaction with SSTR3, a chimeric alpha subunit (G α 2/G α 1) was constructed consisting of the amino-terminal two thirds of G α 2 ligated to the carboxy-terminal third of G α 1. SRIF inhibited cAMP formation in cells expressing SSTR3 and the G α 2/G α 1 chimera. In contrast, a similar G α 2/G α 3 chimera did not couple SSTR3 to adenylyl cyclase further indicating that G α 3 does not contribute to SRIF inhibition of adenylyl cyclase activity. These findings demonstrate that G α 1 selectively couples SSTR3 to adenylyl cyclase and indicates that the carboxy-terminal region of this alpha subunit is involved in mediating SRIF inhibition of adenylyl cyclase activity. Supported by MH45533 and MH48518.

634.9

ISOLATION OF MELANOCORTIN RECEPTOR cDNAs FROM LOCUS COERULEUS AND VENTRAL TEGMENTUM BY PCR. J.D. Alvaro*, E.J. Nestler, and R.S. Duman. Interdepartmental Neuroscience Program, Laboratory of Molecular Psychiatry, Depts. of Psychiatry and Pharmacology, Yale Univ. School Med., New Haven, CT 06508.

Previously we described the use of the PCR technique to amplify G-protein coupled receptor cDNAs from bovine locus coeruleus (LC) and rat ventral tegmentum (VT) cDNA (Soc. Neurosci. 18, Abstract 193.12). Of the putatively novel receptor fragments that were subcloned and sequenced, two have since been identified. Both of these clones share significant amino acid identity with each other and are homologous to the newly discovered family of melanocortin receptors. The PCR clone isolated from the VT is identical to the recently published MSH-3 receptor. The LC PCR clone may correspond to the as yet unpublished MSH-4 receptor. Rat and human brain cDNA libraries have been screened with the LC clone, and several positive clones have been identified. Northern blot analysis of bovine poly (A)+ mRNA from various brain regions reveals that the LC clone detects two distinct messages between 4.7kb and 5.3kb in length. Levels of the smaller message are highest in the dorsal raphe and pons whereas the larger message is most abundant in pons and cortex. The sequence and pharmacological properties of this LC MSH receptor are currently being investigated.

634.11

CLONING AND EXPRESSION OF NPY AND PYY IN THE RIVER LAMPREY. C. Söderberg¹, V. A. Pieribong¹, J. Dahlstrand², L. Brodin², and D. Larhammar. Dept of Medical Genetics, Uppsala Univ., Box 589, S-751 23 Uppsala, Sweden, 1) Rockefeller Univ., New York, NY, USA, 2) The Karolinska Institute, Stockholm, Sweden.

The evolutionary relationships of the members of the NPY family have been unclear despite sequence information from many vertebrates. We have recently shown that NPY has remained extremely well conserved during vertebrate evolution (Blomqvist et al., PNAS 89, 2350-2354).

We present here two NPY-related cDNA clones from the river lamprey (*Lampetra fluviatilis*) isolated by low-stringency hybridizations with a shark NPY probe. The first clone corresponds to NPY as it has 83% identity to human NPY. *In situ* hybridizations detected mRNA in neurons of the dorsal spinal cord, lateral brainstem and retina. The sequence of the second clone is equally similar to NPY and PYY (61% identical to human NPY). Anatomically, it corresponds to PYY as its mRNA is found in gut cells and in a reticulospinal neuron system.

These results show that the gene duplication leading to NPY and PYY had already occurred in the common ancestor of lampreys and teleost fishes more than 450 million years ago. The anatomical similarities of these peptide systems between lamprey and rat (Pieribone et al., J. Neuroscience 12(9), 3361-3371) suggest that their functions have been strongly conserved during vertebrate evolution.

We have also isolated candidate clones for the lamprey NPY receptor Y1. They were isolated by low stringency hybridization with a rat Y1 probe to a lamprey genomic library. Partial sequencing of one clone has revealed features characteristic for 7TM receptors.

634.8

IDENTIFICATION OF G-PROTEIN COUPLED RECEPTORS IN A LOCUS COERULEUS-LIKE CELL LINE BY PCR. M.E. Charlton*, J.D. Alvaro, Nestler, E.J. and R.S. Duman. Laboratory of Molecular Psychiatry, Depts. of Psychiatry and Pharmacology, Yale University School of Medicine, New Haven, CT 06508.

In recent years, studies in our laboratory have examined the molecular mechanisms underlying the actions of psychotropic drugs on locus coeruleus (LC), the major noradrenergic nucleus in brain. A unique *in vitro* model for the study of this system is a transformed murine cell line derived from a brainstem tumor which is LC-like (Suri et al., J. Neuroscience 13, 1280, 1993). This cell line has been demonstrated, through regulation of adenylyl cyclase activity, to express specific G-protein coupled receptors including the VIP, CRF, GABA β , α 2 adrenergic, NPY, and opiate. We have used PCR and degenerate primers derived from conserved regions of three different subfamilies to isolate novel G-protein coupled receptors. Messenger RNA isolated from the cells was reverse transcribed, second strand cDNA was synthesized, and cDNA fragments which encode putative receptor amino acid sequences were PCR amplified. As visualized on agarose gels, each primer set produced PCR fragment(s) of the approximate size predicted for that receptor subfamily. One set of primers which has been extensively used (Libert, et al., Science 244, 569, 1989) resulted in PCR amplification of 2 major bands which were subsequently subcloned, sequenced, and determined to encode a previously published receptor (adenosine) as well as a putative MSH receptor isolated from LC (see Alvaro et al., Soc. Neuro. Abst. 1993). Primers based on the opiate and secretin receptor subfamilies each resulted in amplification of a single major band. Further studies are in progress to identify and characterize full length clones encompassing these sequences.

634.10

ISOLATION OF VERTEBRATE CLONES ENCODING THE NPY/PYY Y1 RECEPTOR - IMPLICATIONS FOR MUTAGENESIS OF THE HUMAN Y1 RECEPTOR. A. G. Blomqvist*, E. Roubost, G. Martens, J. Lundell, C. Wahlestedt, & D. Larhammar. Dept of Medical Genetics, Box 589, S-751 23 Uppsala, Sweden, †Department of Animal Physiology, Nijmegen, The Netherlands, #Cornell Univ. Med. Coll., New York, USA.

Our recent cloning of a human NPY/PYY receptor of the Y1 subtype (Larhammar et al., J. Biol. Chem. 267, 10935-10938, 1992) allows detailed studies of the receptor's structure-function relationships by site-directed mutagenesis. We have used computer modelling to identify several potentially interesting amino acid positions whose importance will be tested by functional studies after transfection of the mutated clone into mammalian cells. Another way of identifying such positions is by comparison of Y1 receptor sequences from different animal species. The sequences of human, rat and mouse Y1 receptors display only a few amino acid replacements and seem to respond identically to most or all NPY-related peptides. Therefore, we decided to isolate Y1 clones from more distantly related vertebrate species, among others the frog *Xenopus laevis* and the zebrafish (*Brachydanio rerio*).

cDNA clones from both species have been isolated and are now in the process of being subcloned and sequenced. Primary sequence information indicates about 60-70% homology between the frog and human NPY/PYY receptor Y1. The sequence will provide useful information about conserved amino acid residues that may be important in, for example, ligand interactions, second-messenger coupling, and overall tertiary structure. Amino acid replacements in the zebrafish Y1 receptor may be possible to correlate with replacements in the zebrafish NPY peptide. We have previously shown that the NPY sequence of the closely related goldfish differs at five positions from the human sequence (Blomqvist et al., PNAS 89, 2350-2354). Also zebrafish NPY clones are being characterized.

634.12

ZEBRAFISH 7TM RECEPTOR CLONES ISOLATED WITH A RAT NPY RECEPTOR PROBE. J. Lundell, Anders G. Blomqvist, and D. Larhammar*. Department of Medical Genetics, Uppsala University, Box 589, S-751 23 Uppsala, Sweden.

The G-protein-coupled receptors with seven TM (transmembrane) regions are encoded by a gene family consisting of several hundred members. The neuropeptide Y (NPY) receptors belong to this family and include at least three different subtypes called Y1, Y2, and Y3. Recently, we have isolated clones encoding the Y1 receptor subtype from rat, human, and *Xenopus laevis*. As we have previously isolated clones for NPY from the zebrafish, we also wished to isolate NPY receptor clones from this species to allow correlation of ligand and receptor expression in studies of tissue distribution and developmental regulation.

PCR was used to generate an NPY receptor probe corresponding to almost the entire coding region of a rat Y1 cDNA clone. The probe was labelled with P-32 and used to screen a zebrafish genomic library (kindly provided by A. Fjose, Bergen, Norway) under conditions of low stringency. Hybridization was in 6X SSC at 42°C, and final washes in 2X SSC and 42°C. Sixteen clones were isolated and their cross-hybridizing regions transferred to Bluescript II KS+ for cDNA sequencing. Analysis of the first clone revealed that it encodes a 7TM receptor with similarity to several mammalian receptors for peptide ligands. Its seventh TM region appears to be a mosaic of several other receptors why its exact identity has not yet been possible to ascertain. Sequence analyses of this as well as the other receptor candidate clones will be presented.

634.13

MOLECULAR CLONING OF A G-PROTEIN COUPLED RECEPTOR WITH HIGH HOMOLOGY TO THE DELTA-OPIATE RECEPTOR. Jean E. Lachowicz*, Yong Shen, Frederick J. Monsma, Jr. and David R. Sibley. Molecular Neuropharmacology Section, NINDS, NIH, Bethesda, MD 20892.

We have used the polymerase chain reaction technique to selectively identify G protein-coupled receptor cDNA sequences from rat brain mRNA. A partial length cDNA fragment of a novel receptor was amplified using degenerate primers derived from conserved sequences found in the third and sixth transmembrane domains of previously cloned receptors. This fragment was found to exhibit high homology to a number of peptide receptors. In order to isolate a full-length clone, a rat cerebral cortex cDNA library was screened using the randomly primed PCR fragment as a probe. A 2.4 kb cDNA clone was isolated which encodes a 367 amino acid protein containing seven putative transmembrane spanning domains. Within these regions, the closest homology was found to the δ -opiate receptor (64%). Other features which are shared with the δ -opiate receptor are two glycosylation sites in the amino terminus, a cAMP-dependent protein kinase phosphorylation site in the third cytoplasmic loop, an aspartic acid residue in the second transmembrane domain, which was previously thought to be found only in biogenic amine receptors, and a palmitoylation site in the intracellular carboxyl terminus. The receptor is also homologous with members of the somatostatin receptor family (48% with SSTR-1 in the transmembrane regions). Despite the high degree of homology to these peptide receptors, radiolabeled somatostatin-14, somatostatin-28, and opiate ligands such as naloxone, naltrindole, diprenorphine, CTOP, U-69593, ethylketocyclazocine, and bremazocine fail to bind to membranes from transfected COS-7 or CHO-K1 cells. Northern blot analysis reveals 3.2 kb and 8.2 kb transcripts in the hippocampus, hypothalamus, prefrontal and cerebral cortices. No transcript was observed in the cerebellum, medulla, striatum, olfactory bulb and spinal cord. The identity of this novel receptor subtype is currently being explored using a variety of expression strategies.

634.15

IDENTIFICATION OF A PARTIAL cDNA CLONE OF THE INTERLEUKIN-2 RECEPTOR- β IN NORMAL MOUSE BRAIN

JM Petitto¹, Z Huang¹, K Suzuki². ¹Department of Psychiatry, University of Florida, Gainesville, FL, 32610, ²Brain and Development Research Center, University of North Carolina, Chapel Hill, NC, 27599.

Interleukin-2 (IL-2), the prototypical cytokine, has been implicated in important CNS processes including glial cell differentiation, and more recently, as a neuromodulator. Although considerable attention has been given to the molecular biology of lymphocyte IL-2 receptors, little is known about the molecular pharmacology of IL-2 receptors in brain. Because it is essential to intracellular signal transduction, the leukocyte IL-2 receptor- β (IL-2R β) subunit has been the focus of much interest. In the immune system, the IL-2R β subunit is constitutively expressed (without the IL-2 α accessory subunit), forming a high affinity receptor for IL-2 (referred to as the "intermediate" affinity IL-2 receptor). We sought to determine whether the IL-2R β gene is expressed in normal mouse brain, and to compare the sequence of IL-2R β from brain with that from immune tissue. Using PCR, we amplified a partial IL-2R β cDNA fragment (ca. 350 bp) from mouse brain. Brain cDNA was subcloned, and three independent clones were isolated and sequenced. Sequences for all three clones share identical nucleotide sequences with the corresponding sequence of the extracellular domain of the mouse lymphocyte IL-2R β . Using the same strategy, several clones obtained from two neuroblastoma cell lines are currently being sequenced. To our knowledge, these studies are the first to demonstrate IL-2R β gene expression in normal brain tissue. In situ hybridization studies shall be important to determine the brain regional and cell-specific localization of the IL-2R β receptor subtype in the CNS.

IDENTIFICATION OF RESIDUES OF THE HUMAN NEUROPEPTIDE Y RECEPTOR (Y1) IMPORTANT FOR LIGAND BINDING. Ph. Walker*, R. Martinez and M. Munoz. Division of Hypertension, CHUV, CH-1011 Lausanne Switzerland

Neuropeptide Y (NPY) is one of the most abundant peptide found in the mammalian brain. By activating specific G protein-coupled receptors, NPY is a mediator of diverse physiological responses. In the cardiovascular system, NPY exerts a number of important regulatory actions. NPY acts as a potent vasoconstrictor on certain blood vessels. In addition, administered at non-pressor doses, NPY can strikingly potentiate the action of a number of vasopressor substances such as norepinephrine or angiotensin II. The aim of our work is to understand the molecular basis of the interactions between neuropeptide Y (NPY) and the human Y1 receptor. To work towards this goal, we first designed a transient expression system allowing a rapid testing of various mutants. In this assay, HeLa cells are first infected with vaccinia virus and subsequently transfected with an expression vector in which expression of the Y1 cDNA is driven by a vaccinia gene promoter (11K late promoter). Vaccinia specific transcription factors transactivate the 11 K promoter resulting in the rapid synthesis of 1.5 to 3 x 10⁶ binding sites per transfected cell with a K_d of about 2 nM. Using site-directed mutagenesis we generated a collection of single point mutants at candidate residues and tested these clones following transient expression into HeLa cells. We will describe the effect of various amino acid substitutions on the ability of the mutants to bind NPY. We could identify single point mutations that abolish any ligand binding activity. We have now tagged the receptor with a foreign epitope and are currently using antibodies to assess whether the mutant receptors are expressed at the cell surface.

MOLECULAR CLONING OF A NOVEL G-PROTEIN COUPLED RECEPTOR FROM RAT. J.K. Harrison*, C.M. Barber and K.R. Lynch. Dept. of Pharmacology, Univ. of Virginia Health Sci. Center, Charlottesville, VA 22908.

G-protein coupled receptors (GCRs) comprise a large gene superfamily whose encoded proteins are characterized by the presence of seven transmembrane spanning regions. Low stringency hybridization (using a radiolabeled cDNA encoding the rat angiotensin (AT₁) receptor) was used to isolate a novel member of the rhodopsin family of GCRs from a rat brainstem cDNA library. This cDNA (RaBS11) was used subsequently to isolate cDNAs from other rat brainstem, pituitary, and spinal cord cDNA libraries. From these cDNAs an open reading frame (orf) was identified that encodes a protein of 354 amino acids (40 kDa). The orf does not contain sites for N-linked glycosylation (N-X-S/T). A search of the Genbank (release #73) revealed that RaBS11 was most similar to chemokine receptors for MIP-1 α and IL-8 (45% and 37% identical, respectively) identified previously. Northern analysis demonstrates that RaBS11 mRNA is widely and unevenly distributed in rat tissues. RaBS11 mRNA was most prominent in the rat spinal cord, brain (where it is evenly distributed over 8 discrete regions), testes, uterus, kidney, and gut. Southern analysis of restriction-digested rat genomic DNA indicated the gene for RaBS11 is single copy in the rat. We speculate that RaBS11 encodes a receptor for a chemokine. MOLECULAR CLONING OF A NOVEL TRANSMEMBRANE SERINE KINASE FROM RAT BRAIN.

K.Tsuchiida and W.W.Yale*. The Clayton Foundation Laboratories For Peptide Biology, The Salk Institute, La Jolla, CA 92037.

Activin and other members of the transforming growth factor- β (TGF- β)/superfamily are involved in the regulation of many biological functions including neuronal modulation and development. This gene family includes the TGF- β s, inhibins, activins, the drosophila *dpp* protein, bone morphogenetic proteins and the Vg-related proteins. The activin and subsequently the TGF- β type II receptors were cloned and characterized and found to be putative transmembrane serine/threonine kinases. In order to identify additional members of the activin/TGF- β receptor superfamily, we designed degenerate primers based on the conserved kinase domains of type II receptors for activin and TGF- β for polymerase chain reaction (PCR). We have undertaken RT-PCR using the RNAs from rat brain and pituitary gland, and succeeded in obtaining a novel fragment which has the serine/threonine kinase motif. Subsequently, we isolated a full length clone from rat brain cDNA library. The predicted protein consists of 509 amino acids with a cysteine-rich extracellular domain, a single transmembrane domain and an intracellular kinase domain. The kinase domain shows 39% and 36% homologies to activin and TGF- β type II receptors, respectively. The single transcript of 3.7 kbs was detected in rat brain and pituitary. Functional characterization of the structurally related receptors should provide a basis for exploring the roles of these receptors in signal transduction and in the regulation of development and differentiated functions of various systems.

MUTATIONS IN THE THIRD CYTOSOLIC LOOP OF THE RAT NEUTROTENSIN RECEPTOR: EFFECTS ON PEPTIDE BINDING AND SECOND MESSENGER RESPONSE. M. Watson, M. Yamada, M. Yamada, and E. Richelson*. Mayo Clinic and Foundation, Jacksonville, FL 32224

The neurotensin receptor belongs to the super-family of seven transmembrane, G-protein coupled receptors. Studies of receptors from this family show that the third cytosolic (C3) loop contains sites for G-protein binding. Among these receptors, the C3 loop is not well conserved, making each receptor unique in its second messenger response. We made deletion mutations of the C3 loop of the rat neurotensin receptor in an effort to identify regions important to G-protein binding. Previous studies in our laboratory with the rat neurotensin receptor transfected into CHO-K1 cells show that it mediates cAMP formation and phosphoinositide (PI) hydrolysis. Initial investigations showed that deletion of all but the nine N-terminal and eight C-terminal amino acids of the C3 loop results in neurotensin binding with the same affinity (K_d=3 nM) as found in the transfected wild-type receptor for membrane preparations. In addition, receptor-mediated cAMP response was unchanged (EC₅₀=30 nM). Binding in whole cells and PI hydrolysis was undetectable. However, preliminary results with another mutant construct having only five additional C-terminal amino acids showed whole cell binding, but no PI hydrolysis. These results suggest that the site for cAMP response resides in the N- or C-terminal ends of the C3 loop, or another internal domain. The data also suggest that at least part of the site for the G-protein binding responsible for PI hydrolysis is found in the 26 amino acids which were deleted. Further mutational analysis is being conducted to determine specific amino acids that may comprise the actual binding sites. (Supported by Mayo Foundation and USPHS grant MH27692)

CONFORMATIONAL STUDIES OF THE SEVENTH TRANSMEMBRANE DOMAIN OF THE DOPAMINE D₂ RECEPTOR. Valerie L. Williams*, Scott H. Courtney, David I. Schuster, and Randall B. Murphy, Department of Chemistry and Center for Neural Science, New York University, New York, NY 10003.

Highly hydrophobic peptides in small unilamellar vesicles is a commonly used model for membrane-embedded receptor proteins. However, the insolubility of these hydrophobic peptides presents many obstacles in determining the critical physical parameters of this type of model system. Using a novel reverse-phase-HPLC methodology, we have synthesized and purified the following sequence: NH₂-D-V-L-Y-S-A-F-T-W-L-G-Y-V-N-S-A-V-N-P-I-I-Y-T-T-F-N-V-COOH. This sequence represents the seventh transmembrane domain of the dopamine D₂ receptor, a membrane-embedded protein. Fluorescence spectroscopy was used as a tool in determining the microenvironment of the peptide in synthetic lipid vesicles. Studies of the peptide in its most denatured state were used as a starting point in determining the conformational changes induced by increasing the lipid/peptide ratio. The results of these studies yield information on the conformational differences of the dopamine D₂ receptor in its interaction with ligands and suggest that this peptide can be used as a biophysical model for the dopamine D₂ receptor system. (Supported by NSF and New York University).

PEPTIDES: RECEPTORS V

LOCALIZATION OF mRNAs OF ENDOTHELIN RECEPTORS IN THE RAT BRAIN. J. Zhu*, S. Fitzpatrick-McElligott, J.K. DeReil, and L.-Y. Liu-Chen. Dept. of Pharmacology and Fels Institute, Temple Univ. Sch. of Medicine, Philadelphia, PA, and E.I. DuPont & Co., Wilmington, DE.

Endothelins (ETs) are a family of vasoactive peptides. Intracerebroventricular administration of ETs causes profound vasoconstriction and hypertension. Specific binding sites for [¹²⁵I] ET-1 have been identified in the brain. Recently two types of ET receptors have been cloned and named ET_A and ET_B receptors based on differential affinities for ETs. In this study, we examined the distribution of both ET_A receptor (ET_AR) and ET_B receptor (ET_BR) at mRNA levels in the rat brain by *in situ* hybridization histochemistry. mRNAs coding for the ET_AR or ET_BR were detected by using antisense oligonucleotides probe (30-mer) labeled at 3'-end with ³⁵S by terminal transferase. The probes correspond to 1270-1299 of ET_AR and 188-217 of ET_BR sequences. Frozen rat brains were sectioned (20 μm) and sections were fixed with 4% paraformaldehyde, prehybridized for one hour and hybridized with one of the probes overnight at 37°C. The posthybridization washing was 2 x SSC at room temperature and 0.5 x SSC at 45°C, each for one hour. Sections were exposed to Hyperfilms for 2-4 days, and then undergone emulsion dipping for localization at the cellular level. High levels of both ET_AR and ET_BR mRNAs were found in the cerebellum, hippocampus, piriform cortex, anterior dorsal thalamic nucleus, medial habenular nucleus, supraoptic nucleus, median eminence, arcuate hypothalamic nucleus, red nuclei, pontine nuclei, oculomotor nuclei, mesencephalic trigeminal nucleus, motor trigeminal nucleus, locus coeruleus, trapezoid body, facial nuclei, nucleus of solitary tract and hypoglossal nucleus. In some regions, there were differential distribution of ET_AR and ET_BR mRNAs. Olfactory tubercle expressed high level of ET_AR mRNA, yet low level of ET_BR mRNA. In contrast, ventromedial hypothalamic nucleus had high density of ET_BR mRNA, yet low density of ET_AR mRNA. These results suggest that ETs may play important roles in the central nervous system, particularly in the regulation of cardiovascular and motor functions.

635.3

CNS EXPRESSION AND ISOLATION OF A PROMOTER FOR THE RAT VASOPRESSIN V_{1a} RECEPTOR GENE. P. Szot*, T.L. Bale, A.M. Kallikoni, M.W. Hamblin and D.M. Dorsa. GRECC, Seattle VAMC, WA 98108 and Dept. of Pharmacology, Univ. Washington, Seattle, WA 98195.

Vasopressin binding sites with the pharmacologic properties of V_{1a} receptors (V_{1a}R) have previously been demonstrated in various regions of the rat brain including the septum/bed nucleus of the stria terminalis, hippocampus, amygdala and hindbrain. The location and identity of the cells responsible for the synthesis of the receptor protein are as yet undetermined. Based on the recently reported sequence of a cDNA encoding the vasopressin V_{1a}R, *in situ* hybridization using an oligonucleotide "cocktail" was performed on coronal sections throughout the rat brain. The "cocktail" consisted of 3 oligonucleotides complementary to nucleotides 61-109, 573-621 and 810-858 of the vasopressin V_{1a}R mRNA which were end-labeled with ³³P-dATP. Specific hybridization signal was observed in the internal granular layer of the olfactory nucleus, islands of Calleja, piriform cortex, superchiasmatic nucleus, dentate gyrus, paraventricular hypothalamic nucleus, ventromedial hypothalamic nucleus, medial habenular nucleus, and the molecular and granular cell layers of the cerebellum. The cerebellum, olfactory nucleus and dentate gyrus appeared to be the most intensely labeled areas. *In situ* hybridization using these probes was also performed on peripheral tissues known to express vasopressin receptors, and the most intense labeling was observed in the liver. To verify the specificity of labeling observed, *in situ* hybridization using a ³³P-cRNA probe complementary to nucleotides 31-177 of the V_{1a}R mRNA was performed on a set of alternate brain slices. The anatomical distribution of hybridization signal using this riboprobe was similar to that obtained with the oligonucleotides.

We have also isolated a genomic clone from a rat testis library which contains the 5'-upstream region of the V_{1a}R gene. The nucleotide sequence of this clone has suggested regulation by several transacting factors, and includes at least two hormone response elements. (Support by the VA Research Service and NS 20311)

635.2

CHARACTERIZATION OF THE PROXIMAL PROMOTER REGION OF THE RAT SOMATOSTATIN RECEPTOR GENE, SSTR4. Yun Xu, Jinfen Song, Michael Berelowitz* and John F. Bruno. Div. Endocrinology and Metabolism, SUNY at Stony Brook, NY 11794

Primer extension and solution hybridization nuclease protection analysis were used to determine the transcriptional initiation site(s) of the rat somatostatin receptor gene, SSTR4. Four major transcriptional start sites have been identified and are located 22, 72, 123, and 125 bp upstream of the translational initiation site. Sequence analysis of the proximal promoter region of rSSTR4 gene revealed this region lacks TATA and CCAAT boxes. Moreover, the promoter region was found to be highly GC rich containing several potential Sp1 binding sites. These are characteristics typically found in promoter regions of 'housekeeping' genes which are not highly regulated. In addition, the promoter region included a consensus octamer binding motif (ATGCAAAT) which binds a group of related transcription factors that are believed to regulate genes that specify organ development and cell phenotypes.

635.4

THE GENE STRUCTURE OF THE MOUSE GONADOTROPIN RELEASING HORMONE RECEPTOR. W. Zhou*, S.C. Sealton^{1,2}

¹.Fishberg Center for Research in Neurobiology and ². Dept. of Neurology, Mount Sinai School of Medicine, New York, NY 10029.

We previously isolated the functional mouse gonadotropin releasing hormone receptor (GnRHR) cDNA (Tsutsumi, Zhou, et al Mol. Endocrinol. 6, P.1163, 1992) as well as variant receptor transcripts (Zhou et al, Soc. Neurosci. Abstr. V.18, Part 1, P.451, 1992). The primary structure of the receptor protein revealed that GnRHR is a member of the G protein coupled receptor (GPCR) family with putative 7 transmembrane helices (TMHs). All the variants conserved the first 3 TMHs but ended with distinct carboxyl termini. None of the variant transcripts was capable of encoding complete 7 TMHs. To elucidate the gene structure of GnRH receptor, the mouse gene was cloned. Our results showed that the coding region of the mouse GnRHR gene was composed of three short exons. ExonI covered the first 522 base pairs (bp) of the coding sequence and terminated in the middle of TM4, followed by an intron gap of >10 kilobases. ExonII was 217 bp in length and continued the coding region through TM5. ExonIII, following an intron of about 5 kilobases, contained the 3' coding region. The variant transcript cDNA sequences are generated by alternative splicing of the mouse GnRH receptor. This work is funded by NSF91-06877.

5' FLANKING DNA SEQUENCE DIRECTS TISSUE-SPECIFIC EXPRESSION OF MOUSE NPY-1 RECEPTOR. Carola Eva*, Alessandra Oberto, Rita Musso, Silvana Ricci Gamalero and Enrico Genazzani. Institute of Pharmacology, University of Torino, Italy.

Using a previously identified rat cDNA clone, we isolated the murine gene for the NPY-1 receptor subtype for NPY. The 5' flanking region of the NPY-1 receptor gene contains binding sequences for various transcription factors, including cAMP and glucocorticoids responsive elements. A 1,300 bp genomic fragment of the 5' flanking region of the gene drives the expression of the reporter gene luciferase in NG108-15 cells and primary cultured neurons, but not in glial and human embryonic kidney cells. Deletion of sequences 5' to nucleotide -636 did not decrease the transcriptional activity of the gene in NG108-15 cells, while greater than 70% of the activity was lost when sequences between -636 and -223 were deleted. Moreover the addition of forskolin increases luciferase activity by 2 to 4 folds. These data indicate that the information between -636 and -223, which include an AP1 site and cAMP responsive elements, is essential for full transcriptional activity of the NPY-1 receptor gene and that the gene is controlled at the transcriptional level by cAMP.

CROSS-REACTIVITY BETWEEN AMYLIN-NH₂ AND [¹²⁵I]hCGRP α BINDING SITES IN RAT BRAIN AND PERIPHERAL TISSUES. D. van Rossum¹*, D. Ménard¹, A. Fournier², S. St-Pierre² and R. Quirion¹. ¹Douglas Hosp. Res. Centre and Dept. of Pharmacol. & Ther. and Psychiatry, McGill Univ., Montréal, QC, ²INRS-Santé, Pointe-Claire, QC, Canada.

Amylin or Islet Amyloid Polypeptide is a 37 amino acid peptide that shows ~50% sequence homology with the Calcitonin Gene-Related Peptides (CGRP). Amylin and CGRP also share several biological actions including inhibition of glucose uptake and glycogen synthesis, hypotension and anorexia. It remains to be determined if amylin acts exclusively through a unique amylin receptor class such as reported in lung membranes and/or via CGRP receptors. We have therefore investigated the cross-reactivity between amylin-NH₂ and [¹²⁵I]hCGRP α binding sites by performing competition experiments (nM-1 μ M) on adjacent rat brain coronal sections using *in vitro* receptor autoradiography, as well as in membrane preparations and functional bioassays on the guinea pig atria (CGRP₁ enriched tissue) and vas deferens (CGRP₂ enriched tissue). [¹²⁵I]hCGRP α binding in the nucleus accumbens and ventral striatum was clearly more sensitive to amylin-NH₂ (IC₅₀ 50 and 20nM, respectively) than all the other areas of the rat brain examined (IC₅₀ >100nM). Amylin-NH₂ was ~15 times more potent in the vas deferens (0.2 μ M) than in atria (2.5 μ M) to produce its effects. Moreover, [¹²⁵I]Tyr³⁷-amylin binding sites were detected in nucleus accumbens, hypothalamus, tegmental nucleus and the locus coeruleus. In summary, although revealing much lower affinity (50-100) than CGRP for [¹²⁵I]hCGRP α binding sites in either brain, atria or vas deferens, amylin showed highest affinity for CGRP binding sites in the nucleus accumbens and ventral striatum followed by CGRP₂ and CGRP₁ putative receptor subtypes. Supported by the MRCC.

635.9

IN VITRO MODULATION OF HUMAN NEUROPEPTIDE Y-Y1-RECEPTORS BY ANTISENSE OLIGONUCLEOTIDES. F. Yee*, G. Weng, D. Erlinge, C. Bjennig and C. Wahlestedt. Div. Neurobiology, Dept. Neurology and Neuroscience, Cornell University Medical College, NY, NY, 10021.

We have recently used an antisense oligodeoxynucleotide (ODN) technique to downregulate the rat neuropeptide Y (NPY)-Y1-receptor *in vitro*, i.e. cultured cortical neurons, as well as *in vivo* (Wahlestedt et al., *Science* 259: 528, 1993). Based on the nucleotide sequence of the human NPY/PYY Y1-receptor (Larhammar et al., *JBC* 267:10935, 1992; Herzog et al., *PNAS* 89:5794, 1992), we have also applied the antisense strategy to study the regulation of this human Y1-receptor, primarily in a neuroblastoma cell line, SK-N-MC, which has previously been shown to exclusively express the Y1-receptor subtype. Several 18-mer antisense ODNs, corresponding to different regions of the receptor message, were synthesized in order to determine which site(s) would be most sensitive to downregulation by the antisense ODNs. In addition, phosphorothioate analogs, which are more stable than unmodified ODNs, have also been studied *in vitro*. Mismatched oligonucleotides, where 3-4 of the 18 bases are interchanged, were used as controls. The ODNs were tested in a dose range of 0.3-30 μ M. Following treatment of SK-N-MC cells with antisense ODNs directed to a region near the amino terminus of the Y1-receptor, the density of Y1 binding sites, labeled by [¹²⁵I]peptide YY, was most efficaciously reduced. Using a solution hybridization assay for quantitating Y1-receptor message, we are currently investigating whether the Y1-receptor mRNA concentrations are affected by antisense treatment. Antisense oligonucleotides may represent a novel class of therapeutic agents which have greater selectivity/specificity over traditional drug therapies and this approach is particularly useful in a case like the human NPY-Y1-receptor since specific antagonists are not yet available.

635.6

ANTISENSE INHIBITION OF BRAIN AT₁ RECEPTORS REDUCES HYPERTENSION IN SHR. Robert Gyurko, Donna Wielbo and M. Jan Phillips*. Department of Physiology, University of Florida, Gainesville, FL, 32610

Angiotensin II receptors (AT₁R) are increased in localized brain regions of spontaneously hypertensive rats (SHR). Based on antisense mediated gene expression inhibition in biological systems we hypothesized that a specific antisense oligodeoxynucleotide (ODN) to AT₁ receptor mRNA in the brain would decrease the number of AT₁ receptors, thereby decreasing hypertension in the SHR model. 12 week old male SHR's were cannulated intracerebroventricularly (ICV). After recovery, baseline blood pressure was measured by tail cuff monitor. Animals were divided into three groups: Antisense (AS) ODN, and control groups; Sense (S) ODN and vehicle (C). Each group was injected ICV with 5 μ l (10 μ g/ μ l) of ODN or 5 μ l isotonic saline. Doses were administered at 12 hour intervals. Two hours after the injections blood pressure was measured. The AS ODN treated group showed significant decrease (*, p<0.05) in systolic blood pressure on the second and third day of the treatment when compared to pre-treatment level, whereas neither the sense ODN, nor the saline treated control group showed significant decrease during the four-day monitoring period.

	Pre-treatment	2h	26h	50h
Control	205.3 \pm 5.52	209.3 \pm 4.62	184 \pm 13.14	186 \pm 14.13
Sense ODN	93.3 \pm 10.88	180 \pm 10.59	176 \pm 1.7	175 \pm 2.67
Antisense ODN	197.5 \pm 8.27	199.5 \pm 8.38	154 \pm 7.54*	160.5 \pm 8.02*

Preliminary autoradiographic studies showed 40% decrease in AT₁ receptor binding in the AV3V region. These data suggest that intraventricular administration of specific antisense ODN attenuates AT₁ receptor gene expression, decreasing the synthesis of the receptor protein, and significantly lower blood pressure in the SHR model.

635.8

IN VITRO AUTORADIOGRAPHIC LOCALISATION OF AMYLIN BINDING SITES IN RAT BRAIN. P. M. Sexton¹, G. Paxinos², M. A. Kenney³, and K. Beaumont¹. ¹St. Vincent's Institute of Medical Research, Fitzroy, Victoria 3065, Australia, ²School of Psychology, University of NSW, Kensington, NSW 2033, Australia and ³Amylin Pharmaceuticals Inc., San Diego, CA 92121.

Amylin is a 37 amino acid peptide hormone, structurally related to calcitonin gene-related peptide, which is co-secreted from the pancreas with insulin and acts to modulate carbohydrate metabolism. Recently high affinity binding sites for [¹²⁵I]-rat amylin have been identified in the rat central nervous system (Beaumont et al., *Br. J. Pharm.* 108: 241P, 1993). Analysis of these sites, in accumbens nucleus membranes, revealed highest affinity for rat amylin but also high affinity for salmon calcitonin and somewhat lower for the β -CGRPs. In the present study we have used *in vitro* autoradiography to map the distribution of [¹²⁵I]-rat amylin binding sites in rat brain. For this purpose 12 μ m cryostat sections were incubated at 22°C for 60 min with 74 pM [¹²⁵I]-rat amylin. The sections were subsequently washed, dried and then exposed to X-ray film for 12 days. Anatomical identifications were based on comparison of the autoradiographs with the corresponding Nissl stained sections. Moderate to high levels of binding were present in mid-caudal accumbens nucleus, fundus striati and parts of the bed nucleus of the stria terminalis and substantia innominata. This binding extended caudally into parts of the amygdalostriatal transition zone and the central and medial amygdaloid nuclei. Moderately high levels of binding also occurred in much of the hypothalamus including the medial preoptic, dorsomedial hypothalamic and medial tuberal nuclei as well as the ventrolateral subnucleus of the ventromedial hypothalamic nucleus. Other regions of high level binding included the subfornical organ, the vascular organ of the lamina terminalis, area postrema, locus coeruleus, dorsal raphe and caudal parts of the nucleus of the solitary tract. The distribution of amylin binding sites supports a potential role for these sites in regulation of fluid and electrolyte homeostasis, appetite, autonomic function and mood.

ANGIOTENSIN II (AII) STIMULATION OF GLUT-1 GENE EXPRESSION IN ASTROGLIA. C. Summers*, W. Tang, J.M. Cummings, E.M. Richards and M.K. Raizada. Dept. of Physiology, College of Medicine, Univ. of Florida, Gainesville, FL 32610.

AII elicits trophic actions in the CNS via specific AT₁ receptors located on astroglia (Rydzewski et al. in, *Cellular and Molecular Biology of the Renin-Angiotensin System*; eds. Raizada et al. CRC Press, 1993, pp. 485-512). Since glucose is a major nutrient required for growth, we have investigated the effects of AII on glut-1 mRNA and deoxy D-glucose (dGlc) uptake in rat astroglia in primary culture. In these cells AII (10 nM-1 μ M) caused a time-dependent stimulation of [³H]-dGlc uptake which was evident as early as 3 min, reached a maximum of ~140% by 4 hr, and persisted for 24 hr. This stimulation was a result of an increase in the V_{max} and was blocked by the AT₁ receptor antagonist Losartan (1 μ M), but not by the AT₂ receptor blocker PD123177 (1 μ M). The levels of glut-1 mRNA were measured to determine if the AII stimulation of dGlc uptake involved transcriptional regulation. Incubation of astroglia with AII (1 nM-1 μ M) resulted in time and concentration-dependent increases in glut-1 mRNA levels mediated via AT₁ receptors. Contrary to its effect on [³H]-dGlc uptake, the stimulation of glut-1 mRNA by AII (100 nM) was not evident until 1 hr, reached a maximum of ~60% at 4 hr and persisted for 24 hr. These data suggest that AII causes an acute increase in dGlc uptake by activation/translocation of glucose transporters, and a longer term increase following a stimulation of glut-1 gene expression. (Supported by PHS grants NS-19441 and HL-36610).

ISOLATION AND BIOCHEMICAL CHARACTERIZATION OF TWO DISTINCT ANGIOTENSIN AT₂ RECEPTOR POPULATIONS IN MURINE NEUROBLASTOMA N1E-115 CELLS. I.R. Siemens*, L.P. Reagan, D.K. Yee, and S.J. Fluharty. Depts. of Animal Biology and Pharmacology, and Institute of Neurological Sciences, University of Pennsylvania, Phila., PA 19104.

The murine neuroblastoma N1E-115 cell line contains a high density of angiotensin Type 2 (AT₂) receptors whose density is regulated in concert with the neuronal phenotype of these cells. We have shown that CHAPS solubilizes exclusively AT₂ receptors from N1E-115 cell membranes, as evidenced by their high affinity for CGP42112A but not Losartan. In contrast, displacement of [¹²⁵I]-AngII with the AT₂ nonpeptide antagonist PD123319 resulted in a biphasic curve suggesting heterogeneity of the AT₂ receptor population in N1E-115 cells. Heparin-sepharose chromatography efficiently separated these two AT₂ receptor populations into two distinct protein peaks termed peak I and III. Pharmacological analysis revealed that both peaks contained exclusively AT₂ receptors insofar as they exhibited high affinity for CGP42112A and little or no affinity for Losartan. However, while PD123319 completely displaced the binding of [¹²⁵I]-AngII from Peak I in a monophasic fashion (IC₅₀ 9.1 ± 4.1 nM; mean ± SEM; n=3), PD123319 was much less effective in displacing [¹²⁵I]-AngII from Peak III (IC₅₀ 196 ± 27; mean ± SEM; n=3). Treatment of individual peaks with the reducing agent dithiothreitol caused a large increase in [¹²⁵I]-AngII specific binding in peak III, whereas a decrease in binding was observed in peak I. Moreover, GTPγS significantly reduced high affinity agonist binding in peak I but not peak III further suggesting heterogeneity in the AT₂ receptor family. Finally, immunoprecipitation studies with polyclonal antisera raised against AT₂ receptors in Peak I specifically immunoprecipitated [¹²⁵I]-AngII binding activity in peak I but were ineffective in peak III. Collectively, these results suggest that heparin-sepharose chromatography can efficiently isolate two distinct populations of AT₂ receptors. Supported by NS23986 and MH43787.

635.12

ANGIOTENSIN TYPE 1 ANTISENSE OLIGONUCLEOTIDES INHIBIT RECEPTOR EXPRESSION AND FUNCTION IN CULTURED CELLS AND RAT BRAIN. R.R. Sakai*, X.D. Yang, P.F. He, L.Y. Ma, Y.F. Guo, J.R. Reilly, C.N. Moga, and S.J. Fluharty. Depts. of Animal Biology and Pharmacology, and Institute of Neurological Sciences, University of Pennsylvania, Philadelphia, PA 19104. Many of the physiological, endocrine and behavioral actions of angiotensin II (AngII) are mediated by specific AT₁ receptors located in peripheral tissues and the brain. In an effort to study the regulation and function of these receptors, we have developed short AT₁ antisense oligonucleotides. In an initial series of studies, the efficacy of the antisense oligonucleotides was examined in cultured cells. Antisense oligonucleotides were incubated with liver epithelial WB or neuroblastoma N1E-115 cells for 24 hours, and AT₁ receptor density was determined by radioligand binding assay. In both cell lines, the AT₁ antisense oligonucleotide inhibited binding by 60-70%. In a second set of experiments, the antisense oligonucleotides were used to assess AT₁ receptor expression and function in conscious rats. Three daily intracerebroventricular (ICV) injections of AT₁ antisense significantly attenuated drinking elicited by a pulse ICV injection of AngII whereas random antisense oligonucleotides were ineffective. These antidipsogenic effects were dose-dependent, reversible, and specific in that water intake elicited by carbachol was unaffected. Radioligand binding analysis of selected brain regions revealed that ICV antisense decreased AT₁ receptor density by approximately 40% in hypothalamic-thalamo-septum and brainstem membrane preparations. Collectively, these results demonstrate that both *in vitro* and *in vivo* administration of antisense oligonucleotides attenuate angiotensin receptor expression and function. Supported by NS23986, MH43787 and HD 25857.

PEPTIDES: PHYSIOLOGICAL EFFECTS III

INTRACEREBROVENTRICULAR BOMBESIN INDUCES FOS PROTEIN IN THE DOPAMINE NEURONS OF THE ARCULATE NUCLEUS IN OVARIECTOMIZED RATS. C.W. Copen*, A. Ghadebo, P. Strutton, R. Persaud and I. Kalló†. Biomedical Sciences, King's College, London WC2R 2LS, UK. [†]Anatomy Dept, Pécs, Hungary.

We have recently demonstrated that intracerebroventricular bombesin administered to ovariectomized rats suppresses pulsatile LH release, reduces core temperature and induces FOS expression in various sites including the arcuate, periventricular and preoptic regions. Since dopaminergic activation also suppresses LH pulses and induces hypothermia, the present study was undertaken to establish whether bombesin-induced FOS-immunoreactivity occurs within dopamine cells. Ovariectomized rats were fitted with an indwelling cannula in the third cerebral ventricle and an intraperitoneal temperature-sensitive radiotransmitter (Mini-Mitter Co.) at least 10 days before the experiment. In order to minimize any effects of handling, the administration of the bombesin (1µg) or vehicle was performed from outside the cage; this occurred 3 hours after the injection cannula had been inserted into the guide cannula. The animals were perfused transcardially 90 mins after the infusion, a time at which core temperature had dropped by at least 4°C in the animals given bombesin (no change in temperature was observed after the vehicle). FOS-immunoreactivity was detected using streptavidin peroxidase together with diaminobenzidine (DAB) and ammonium nickel sulfate; the subsequent detection of tyrosine hydroxylase (TH) involved PAP and DAB. The dark blue nuclear reaction product associated with FOS was readily distinguishable from the brown cytoplasmic staining for TH. Following bombesin treatment FOS-immunoreactivity was detected in the majority of the TH-positive cells within the arcuate nucleus, but in a smaller proportion of the periventricular and in very few of the preoptic TH-positive cells. FOS was not observed in the zona incerta or substantia nigra. Further studies on the possible involvement of dopamine in bombesin-induced LH pulse suppression and hypothermia are in progress.

ELECTROPHYSIOLOGICAL EFFECTS OF CHOLECYSTOKININ PEPTIDES ON ACUTELY ISOLATED DOPAMINERGIC NEURONS OF THE RAT MIDBRAIN

Tohy, Wu*¹ and H. L. Wang. Dept. of Physiology, Chang Gung Medical College, Kwei-San, Tao-Yuan. ¹ Dept. of Neurology, Chang Gung Memorial Hospital, Taipei, Taiwan.

Autoradiographic studies indicated that cholecystokinin (CCK) receptors are expressed in the substantia nigra (SN) and ventral tegmental area (VTA) and may be located on dopaminergic cell bodies. Previous extracellular recording studies reported that sulfated CCK-8 has an excitatory effect on midbrain DA neurons. To understand ionic and molecular mechanisms by which CCK peptides regulate membrane properties of midbrain DA neurons, we are investigating electrophysiological effects of CCK peptides on acutely isolated DA neurons using whole-cell patch-clamp recording techniques.

SN and VTA neurons were acutely isolated from 3 to 4 weeks old Sprague-Dawley rats. DA neurons were identified by following electrophysiological characteristics: (1) Spontaneous action potentials with the firing rate of 4-5 Hz. (2) A broad action potential (>2 ms). (3) Prominent afterhyperpolarizations. (4) Hyperpolarization currents induce inward rectifications. Under whole-cell current-clamp recordings, sulfated CCK-8 depolarizes midbrain DA neurons and triggers action potentials when DA neurons were hyperpolarized to near their spike thresholds. During whole-cell voltage-clamp recordings, sulfated CCK-8 induces an inward current at the holding potential of -60mV. These findings are consistent with previous studies that CCK has an excitatory effect on midbrain DA neurons. Currently, we are studying (1) Pharmacological characterization of CCK effects. (2) The identity of ionic conductances regulated by CCK peptides. (3) Molecular mechanisms by which CCK peptides modulate ion channels of DA neurons.

CHROMOGANIN A IN RAT RETINA: INHIBITION OF DOPAMINE RELEASE. D.G. Munoz* and C.J. Gibson. Department of Pathology, The University of Western Ontario, London, Ontario, Canada N6A 5C1.

Chromogranin A (CgA) is a soluble protein of secretory granules in neuroendocrine cells, and large dense-core synaptic vesicles in neurons. Proteolytic fragments of CgA inhibit calcium influx and block release of noradrenaline from adrenal medullary cells. In spite of the widespread expression of CgA in the CNS, no central actions have been documented. Using an antibody donated by H. Winkler we demonstrated expression of CgA in both inner and outer plexiform layers of rat retina. Ganglion cells and some perikarya in the inner nuclear layer were also stained. We tested the actions of CgA in an *in vitro* retinal perfusion system (Gibson, J. Neurosci. Methods 32:75,1990). A ten min pulse of K⁺ resulted in a five-fold increase in endogenous dopamine (DA) release (from basal levels of 26 ± 3 to 130 ± 17 pg) and a second K⁺ pulse, 50 min later, also significantly increased DA release to 85 ± 13 pg. This release was calcium-dependent. Addition of 100 nM of CgA purified from human adrenal completely abolished K⁺-stimulated DA release. The inhibition was dose dependent with an IC₅₀ of 3nM, similar to that previously found in adrenal medullary cells (5 nM). Thus the actions of CgA in the first CNS tissue tested resemble those documented in the periphery. Supported by separate MRC grants to CJG and DGM.

636.4

CHOLECYSTOKININ-B RECEPTOR AGONISTS EXCITE LOCUS COERULEUS NEURONS *IN VITRO*. L.S. Reynolds* and A.H. Ganong. Department of Neuroscience, Pfizer Inc, Central Research Division, Groton, CT 06340.

Cholecystokinin (CCK) is present in many brain regions including the ventral medial hypothalamus (VMH), the hippocampus and the locus coeruleus. CCK-8 is known to excite neurons in the VMH and to increase excitability in hippocampal CA1 neurons. We have investigated the effects of CCK agonists and antagonists on spontaneously active neurons found in the locus coeruleus. Extracellular single unit recordings were made in slices of guinea pig brainstem containing the locus coeruleus. Applications of CCK-8 at 10 or 100 nM resulted in reversible increases in the firing rate of locus neurons. The selective CCK-B receptor agonists, CCK-4 and pentagastrin, also induced increases in firing of locus cells. Pentagastrin produced a dose dependent increase in locus neuron firing rates with an ED₅₀ of 17 nM. A three minute application of 10 nM pentagastrin caused a rapid excitation that returned to baseline when the drug was washed out. Excitations induced by 10 nM pentagastrin could be repeated with a 15 minute interval between applications. Pentagastrin-induced excitations could be antagonized dose-dependently by the selective CCK-B antagonists CI-988 and L-365,260. L-364,718, a CCK A antagonist, did not effectively block the pentagastrin-induced excitation. These data indicate the presence of CCK-B receptors on guinea pig locus coeruleus neurons which could be related to the behavioral effects of CCK-B agonists and antagonists reported in both animal and human studies.

CCK_B RECEPTORS TONICALLY MODULATE A10 DOPAMINERGIC NEURONS SELECTIVELY: NEUROCHEMICAL EVALUATION OF LY288513. D. Li, R.M. Simmons, J.J. Howbert, K. Rasmussen, and S. Iyengar. CNS Research, Eli Lilly and Company, Indianapolis, IN 46285.

The octapeptide CCK has been postulated to modulate dopaminergic function presumably via the mesolimbic A10 dopamine pathways. Recently, it has been shown that selective CCK_B receptor antagonists, including LY262691, decrease the number of spontaneously active A9 and A10 dopaminergic cells [Rasmussen et al., Eur. J. Pharmacology, 209 (1991)135-136; J.P.E.T., 264 (1993) 480-488] in anesthetized rats. The effect of LY288513, the active isomer of LY262691, was evaluated in unanesthetized rats on dopamine metabolism and release in olfactory tubercles (OLT), a mesolimbic region innervated by dopaminergic cell bodies from the VTA, by GC/MS. LY288513 was found to dose dependently decrease the levels of dopamine as well as those of its metabolites dihydroxyphenylacetic acid (DOPAC), homovanillic acid (HVA) and 3-methoxytyramine (3-MT) in the OLT 60 mins. after peripheral injection (i.p.). The decrease in dopamine and its metabolites closely paralleled observed decreases in spontaneous activity of A10 cells in the VTA, both in terms of onset of action and dose response, corroborating the electrophysiological observations. In comparison, the effects of LY288513 on striatal dopamine metabolism and release were very transient and did not show evidence of a strong tonic modulation of A9 neurons, consistent with the lack of activity of this antagonist on catalepsy. This neurochemical finding is the first demonstration of the selective tonic modulation of mesolimbic A10 dopaminergic neurons by CCK_B receptors in drug-naïve, awake, freely moving animals. More importantly, these data further support the contention that CCK_B antagonists may be useful in antipsychotic and/or anti-anxiety therapy.

636.7

EFFECT OF IONIZING RADIATION ON CORTICAL, HIPPOCAMPAL, AND HYPOTHALAMIC CHOLECYSTOKININ LEVELS IN RATS. S.B. Kandasamy*, C. Turkelson* and A.H. Harris. Behavioral Sciences Department, Armed Forces Radiobiology Research Institute, Bethesda, MD 20889, *VA Medical Center, Kansas City, MO 64128.

The effects of ionizing radiation on cortical, hippocampal, and hypothalamic CCK levels "immediately after" and "3 hr after" exposure were determined. Rats were bilaterally exposed to doses from 1 to 10 Gy of ⁶⁰Co γ radiation. Exposure to 1 and 3 Gy of γ rays decreased hippocampal and cortical CCK levels but had no effect on hypothalamic CCK levels. Exposure to 5 Gy decreased hippocampal CCK levels but had no effect on cortical and hypothalamic CCK levels. Exposure to 10 Gy decreased hippocampal, and hypothalamic CCK levels but had no effect on cortical CCK level. There was significantly less CCK in the cortex, hippocampus, and hypothalamus of all "immediately after" groups than in the cortex, hippocampus, and hypothalamus of the corresponding "3 hr after" groups. These results demonstrate that radiation decreases CCK levels in the cortex, hippocampus, and hypothalamus.

636.9

INTRACEREBROVENTRICULAR ADMINISTRATION OF TYR-W-MIF-1 (TYR-PRO-TRP-GLY-NH₂) INDUCES PROLONGED ANALGESIA IN THE RAT. Yelga Kenigs¹, James E. Zadina, Laszlo Hackler, Richard D. Olson² and Abba J. Kastin Veterans Affairs Medical Center and Dept. of Medicine and Neuroscience Program, Tulane Univ. Sch. of Med. New Orleans, LA 70146 and ²Dept. of Psychology, University of New Orleans.

Tyr-W-MIF-1 (Tyr-Pro-Trp-Gly-NH₂) is a peptide recently isolated from human and bovine brain. It was shown to have opiate agonist activity in the guinea pig ileum and to bind to mu opiate receptors. In this study, Tyr-W-MIF-1 was tested for its effects on nociception in the tail-flick test after ICV injection in the rat. Guide cannulae were implanted in the right lateral ventricle of anesthetized male Sprague Dawley rats (250-350 g). At least a week was allowed for recovery. The animals then received 200 μg Tyr-W-MIF-1 in 5 μl vehicle. Tail-flick latencies, measured every 10 min, were significantly increased with a rapid onset and remained significantly elevated for at least 50 min. Naloxone injected 11 min after the peptide (1 min after the first test) reversed the effect of the peptide, indicating opiate receptor involvement in the response. Met-enkephalin at the same dose produced only slight antinociception, and only on the first test. Some animals showed "barrel-rolling" behavior in addition to the analgesia; this behavior was not a prerequisite for the analgesia, was unusually short-lived, and had no apparent persistent effects. The results show that in addition to previously described opiate-like actions (inhibition of electrically-induced contractions of the guinea pig ileum and binding to the mu opiate receptor), Tyr-W-MIF-1 can induce significant and prolonged analgesia.

636.6

INTRACISTERNALLY-ADMINISTERED CHOLECYSTOKININ PREVENTS β-ENDORPHIN FROM INHIBITING BRAIN AND LIVER DNA SYNTHESIS IN 10-DAY-OLD RATS: A MODULATORY ROLE FOR ENDOGENOUS BRAIN CHOLECYSTOKININ IN THE CONTROL OF GROWTH BY β-ENDORPHIN? J. V. Bartolome*, B. A. Lorber and M. B. Bartolome. Dept. of Pharmacology, Duke University Medical Center, Durham, N.C. 27710.

We have previously reported that intracisternal (i.c.), but not subcutaneous, administration of β-endorphin (BE) suppresses DNA synthesis (an index of cell replication) throughout the body in developing rats. The effect is restricted to the first three postnatal weeks. These findings, together with other observations, led us to postulate that endogenous CNS BE may play an important role in controlling postnatal growth.

The gut peptide cholecystokinin (CCK) is now known also to be abundant in the brain, predominantly as the sulfated octapeptide (CCK-8S) of CCK. It is believed that brain CCK may function physiologically as an opioid antagonist. We found that 0.75 μg of CCK-8S co-injected with 0.25 μg of BE i.c. prevented BE from inhibiting brain and liver DNA synthesis. CCK-8S i.c. given alone had no effect on basal DNA synthesis in the brain, but produced small but consistent increases in liver. The same exact pattern of response was obtained when unsulfated CCK-8 (also naturally-occurring in the brain) was used instead of CCK-8S, suggesting the involvement of the CCK-B receptor subtype. CCK-8S given subcutaneously did not alter liver DNA synthesis, indicating that the suppression of liver DNA synthesis by i.c. CCK-8S occurs via brain-based mechanisms, and not through direct peripheral actions after leakage from the central locus of injection into systemic blood.

These results suggest that changes in the basal levels of brain CCK during early development may alter growth by modulating tissue DNA effects of BE. Accordingly, normal development may require a fine-tuned balance of the activities of both BE and CCK brain systems. (Supported by US PHS Grant NS 25738)

636.8

INDUCTION OF FOS PROTO-ONCOGENE BY INTRACEREBROVENTRICULAR ADMINISTRATION OF TYR-W-MIF-1 (TYR-PRO-TRP-GLY-NH₂). K. GERGEN, S.L. CHANG¹, A.J. KASTIN*, AND J.E. ZADINA VA Med. Center and Dept. of Medicine and Neuroscience Training Program, Tulane University Sch. of Med., New Orleans, LA 70146, and ¹Dept. of Physiology, LSU Sch. of Dentistry, New Orleans, LA 70119.

A peptide recently isolated from brain, Tyr-W-MIF-1, has been shown to bind to mu opiate receptors, to have opiate agonist activity in the guinea pig ileum, and to induce prolonged analgesia after intracerebroventricular (ICV) injection. In this study, we explored brain areas that may be activated by Tyr-W-MIF-1. We and others have used immunocytochemical (ICC) detection of FOS proto-oncogene protein as an anatomical marker for brain sites activated by extracellular stimuli. In this study, we provide a preliminary mapping of areas in the thalamus and hypothalamus where FOS immunoreactivity is induced by ICV injection of an analgesic dose of Tyr-W-MIF-1. Guide cannulae were implanted in the lateral ventricle of anesthetized male Sprague Dawley rats (250-350 g). Ten days later, the animals received 200 μg Tyr-W-MIF-1 or the vehicle (5 μl lactated Ringer's solution). The analgesic effect of the peptide was confirmed because all 3 animals given peptide showed the maximum (15 sec) tail-flick latency for 60 min while the mean of the 3 controls did not exceed 6 sec at any time. Three hr after the injection, the animals were perfused. Coronal brain sections were stained with anti-FOS antiserum (Ab-2, Oncogene Science) by the avidin-biotin peroxidase method. FOS was activated in the preoptic area and the paraventricular and periventricular nuclei of the hypothalamus. In the thalamus, the paraventricular nucleus showed the greatest activation. The results show that Tyr-W-MIF-1 activates FOS in several diencephalic areas, including areas associated with nociception.

PITUITARY ADENYLATE CYCLASE-ACTIVATING PEPTIDE (PACAP) STIMULATES CYCLIC AMP (cAMP) FORMATION IN CULTURED CEREBELLAR GRANULE CELLS. A. Favit¹, U. Scapagnini and P.L. Canonico. Institute of Pharmacology, University of Catania School of Medicine, Catania, Italy.

PACAP is a novel 38-residue neuropeptide, structurally similar to vasoactive intestinal peptide, which stimulates adenylate cyclase activity in rat pituitary cells as well as in other neuronal and non-neuronal tissues (Matsuo Y. et al., Brain Res., 1992, 575:113-123). In this study we have investigated whether PACAP may modify cAMP formation in cultured cerebellar granule cells, a rather pure and homogeneous population of neurons. In cultures at 9 days of maturation *in vitro*, a 15-min exposure to PACAP triggered a concentration-dependent increase in intracellular cAMP content. PACAP's effect started to be significant at 1.5 nM and was maximal (about a 3-fold increase) between 10-100 nM. In the presence of the phosphodiesterase inhibitor, 3-isobutyl-1-methylxanthine (IBMX) (200 μM), the concentration-response curve was shifted to the left with a stimulatory effect being present already at a concentration of 0.1 nM, and the maximal effect reaching about a 6 fold-increase. To assess whether this effect was time-dependent, granule cells were exposed to 10 nM PACAP for times ranging from 30 sec to 60 min. A rapid elevation of intracellular cAMP (about 80%) was observed after a 1-min exposure. The stimulatory effect was maximal between 15 and 30 min and progressively declined at 60 min. These results provide evidence for the presence of PACAP receptors linked to the adenylate cyclase-cAMP system in cerebellar granule cells.

636.11

ELECTROPHYSIOLOGICAL ACTIONS OF SOMATOSTATIN AND PACAP ON CULTURED DORSAL ROOT GANGLION (DRG) NEURONS
D. Crute* and E. R. Perl. Dept. Physiology, CB #7545 Univ. No. Carolina, Chapel Hill, NC 27599.

To test effects of somatostatin (SRIF) and pituitary adenylate cyclase activating peptide (PACAP), two peptides identified by immunocytochemistry in subsets of the diverse DRG population, organotypic monolayer DRG cultures were prepared from 16-18 day fetal pups taken from euthanized rats. In these cultures, SRIF-like immunoreactivity (SRIF-LI) appeared in 12% of DRG neurons, all less than 30µm diameter, similar to observations on adult rat DRG. SRIF and PACAP were applied by U-tube during whole-cell and perforated patch recordings. SRIF (25nM) hyperpolarized 27%, and depolarized 14% of neurons tested under current clamp conditions (n=170). SRIF (up to 10µM) did not affect action potential duration. Synaptic blockade with Cd⁺⁺ eliminated the SRIF depolarization but not the SRIF hyperpolarization. Neurons both larger and smaller than 30µm were hyperpolarized by SRIF. SRIF-LI was demonstrated only in neurons unaffected by SRIF. PACAP (2nM) directly depolarized (via an increased g_{Cl^-}) 15% of tested neurons (n=26), all also vigorously depolarized by GABA (1.5mM) but not hyperpolarized by SRIF. Thus, SRIF and PACAP produce different inhibitory actions on separate subpopulations of DRGs. Supported by USPHS grant NS-10321 and NRSA NS-08691 to DC.

Gender Differences in Choline Acetyltransferase, Somatostatin, and Swim Maze Performance in Somatostatin Transgenic and Control Mice. C.F. Hohmann, S.L. Kinsman, T.H. Moran, G. Wenk, W. Gibson, B.N. Ladenheim, and M.L. Oster-Granite*. The Kennedy Krieger Inst. and Dept. of Psychiatry, Johns Hopkins Univ. Sch. of Med., Balto, MD; Div. of Neural Sciences, Univ. of AZ, Tucson, AZ; Div. of Biomedical Sciences, Univ. of CA, Riverside, CA 92521-0121.

Alterations previously observed in both choline acetyltransferase (ChAT) activity and numbers of somatostatin (SOM) immunoreactive neurons in the cerebral cortex of SOM transgenic mice (TgSmst13) versus control mice resulted from pooled female and male samples that were quite variable. Therefore, we studied gender differences in TgSmst13 mice versus controls. Since both SOM and ChAT levels affect cognitive function, we correlated neurochemistry and swim maze behavior.

Neocortical ChAT activity in young adult TgSmst13 and control mice (male=12; female=14) was elevated significantly (42%; p<0.01) in male controls versus female controls, but only slightly increased (not significant) in TgSmst13 males versus TgSmst13 females. In contrast, SOM peptide levels were significantly lower (52.2%, p=0.03) in male versus female controls, but only slightly decreased (not significant) in TgSmst13 males versus TgSmst13 females. In all groups, however, there was an inverse relationship between ChAT activity and SOM levels. Thus, SOM expression and cholinergic neuronal activity may interact developmentally. Further, sex hormones and their receptors may affect SOM expression and peptide levels, leading to the attenuated gender differences in the TgSmst13 mice versus controls.

Five TgSmst13 and control mice of each sex were subjected to a visible platform trial, an invisible platform trial, and a probe trial, respectively, in the Morris water maze. We found no statistically significant differences among any of the groups. However, control males performed worse than TgSmst13 males and than all females, particularly on the invisible platform task. These surprising results may be influenced by mouse strain (C57BL/6J). BALB/cByJ males perform significantly better than females on the invisible platform task. Furthermore, our control males had the highest ChAT activity levels, yet, the lowest SOM peptide levels in neocortex. Supported by MH46529 and HD19932.

EFFECTS OF SOMATOSTATIN ON MEMBRANE PROPERTIES OF RAT SUBICULAR NEURONS *IN VITRO*. J.R.T. GREENE and A.J.R. MASON*. University Department of Pharmacology, Oxford, OX1 3QT, UK.

The peptide somatostatin and its receptors are found at relatively high levels in the human and animal hippocampus. Changes in brain somatostatin levels occur in some mental disorders, including schizophrenia. We have investigated some effects of somatostatin on the subiculum, which provides the major output pathway of the hippocampal formation. Slices of the ventral hippocampus and parahippocampal region were taken from young adult, male Wistar rats, and maintained in an interface chamber at 34 °C. Intracellular impalements were made with conventional, sharp micropipettes and membrane potentials recorded using an intracellular amplifier in bridge mode. All drugs were applied in the bathing medium. The 39 cells studied were of the type described previously (Mason, 1993, Brain Research, 600, 174-178) that show voltage-sensitive burst-firing responses to depolarising current pulses. Application of somatostatin-14 (SOM-14) for 2 minutes (0.5 - 5 µM) caused a slow hyperpolarisation and a decrease in input resistance (Rin) in 17 of 18 cells. A sample of 13 cells had control resting potentials of 67 ± 3 mV (mean ± SD) and Rin of 24 ± 4 MΩ. Exposure to 5 µM SOM-14 caused a hyperpolarisation of 3.8 ± 1.4 mV and a decrease in Rin of 24 ± 12%. The change in Rin was reduced but not abolished when the membrane potential was returned to control values by depolarising current injection. Repeated responses to SOM-14 were obtained from the same cell when 20 - 30 minutes elapsed between doses. The actions of SOM-14 were mimicked by [D-Trp⁸] SOM-14 (5 of 6 cells), but not by somatostatin-28 [1-12] at 10 µM (8 cells). The SOM-14 induced hyperpolarisation and decrease in Rin survived exposure to tetrodotoxin (1 - 3 µM, 10 cells), indicating that these effects are mediated by a direct, post-synaptic action on the recorded cells. The voltage sensitivity of burst-firing suggests that somatostatin-induced hyperpolarisation could have important consequences for information processing by subicular neurons.

636.14

SOMATOSTATIN TRANSGENIC MICE: BEHAVIORAL AND NEUROCHEMICAL CONSEQUENCES. S.L. Kinsman*^{1,2}, C.F. Hohmann^{1,3}, T.H. Moran³, B.N. Ladenheim¹ and M.L. Oster-Granite². ¹The Kennedy Krieger Research Institute, Baltimore, MD; Depts. of ²Neurology and ³Psychiatry, The Johns Hopkins Medical Institutions, and ⁴Dept of Anatomy, UC Riverside CA.

The peptide somatostatin is abundantly expressed in many brain regions in the adult mouse. Somatostatin has been implicated in the control of many nervous system functions including several behaviors and the modulation of various neurotransmitter systems. Transgenic mice containing extra copies of a mouse genomic fragment containing the preprosomatostatin gene were produced to study further the role that somatostatin plays in these functions. In a preliminary analysis of the phenotypic consequences of the insertion and function of this transgene we examined spontaneous activity and regional levels of biogenic amines in two independent lines of transgenic mice. One line of homozygous transgenic mice [Tg Smst 13] exhibited abnormalities in locomotor behavior and regional levels of norepinephrine. Multiple measures of horizontal and stereotypic activity were significantly elevated in this line of transgenic mice as compared with controls. In this hyperactive line, levels of norepinephrine in the cortex and cerebellum were significantly higher in both males and females compared to controls Using 2x2 ANOVA, in cortex, males were 13.5% elevated and females 15.3% (p<0.05). In cerebellum, males were 20.7% and females 12.7% elevated (p<0.01). The other line of transgenic mice were no different from their correspondingly derived controls. These results suggest long lasting effects on brain function in one line of these somatostatin transgenic mice. Further study will be required to determine whether these changes are due to somatostatin overexpression or whether they are dependent on transgene insertional effects.

PEPTIDES: PHYSIOLOGICAL EFFECTS IV

637.1

MICROINJECTION OF THYROTROPIN-RELEASING HORMONE INTO THE PARAVENTRICULAR NUCLEUS OF THE HYPOTHALAMUS STIMULATES GASTRIC CONTRACTILITY. N.S. Morrow,^{1,2} D. Novin,² and T. Garrick,^{1,3} Center for Ulcer Research and Education, Dept. of Veteran Affairs Medical Center, Los Angeles, CA 90073, Depts. of Psychology¹ and Psychiatry,² UCLA, Los Angeles, CA 90024.

Changes in gastric contractility following microinjection of TRH into the PVN were examined in fasted, urethane-anesthetized rats. Gastric contractility was measured with extraluminal force transducers and analyzed by computer. Unilateral and bilateral PVN microinjections of TRH (.5 µg, 1 µg) significantly increased the force index of gastric contractions 0-60 m postinjection, when compared to animals microinjected with .1 µg TRH, .1 % BSA or TRH (.5 µg, 1.0 µg TRH) in sites adjacent to the PVN. The gastric force index was also significantly elevated from 61-120 m postinjection in rats receiving bilateral PVN microinjections of TRH (.5 µg, 1 µg). The excitatory action of TRH (1.0 µg) on gastric contractility was completely abolished by subdiaphragmatic vagotomies. These results suggest that TRH acts within the PVN to stimulate gastric contractility via vagal-dependent pathways (Veteran Affairs, CURE/UCLA Digestive Disease Center, NIH Grant DK 41301, UCLA University Grant SF86).

637.2

ENDOTHELIN-INDUCED C-FOS EXPRESSION IN THE RAT HYPOTHALAMUS. K. KUROKAWA, H. YAMADA, M. KAWATA* and J. OCHI. Dept. of Anatomy Shiga Univ. of Med. Sci., Otsu, 520-21, Kyoto Pref. Univ. of Med., Kyoto, 602, JAPAN

Endothelin(ET-1, 2 and 3), a vasoconstrictive peptide, is known to exist in the brain. In order to elucidate the central action of each ET, the expression of c-Fos protein was immunohistochemically analyzed after injection of ET-1,2 and 3 into the lateral ventricle of the rat brain. During the injection experiments, animals (male Wistar rats weight 180-200g) were under anesthesia with the sodium pentobarbital (50mg/kg, intraperitoneal injection). The immunoreactivity of c-Fos was observed from 30min throughout 6hrs after intraventricular administration of each ET(0.1-1 µmol). After the injection of ET-1 or 2, the reactivity was found in the paraventricular(PVN) and supraoptic (SON) nuclei of the rat hypothalamus. It was found that these positive neurons were immunohistochemically double-stained with oxytocin or vasopressin-antibodies. In the case of ET-3, the c-Fos positive neurons were also seen in the organum vasculosum laminae terminalis (OVLT) in addition to PVN and SON.

637.3

INFLUENCE OF DIMETHYLSULFOXIDE ON THE INCIDENCE OF DYNORPHIN-INDUCED PARALYSIS AND LOSS OF THE TAIL-FLICK REFLEX IN THE RAT. Z-X. Qu and L. Isaac* Department of Pharmacology, Univ. of Ill. Coll. of Med., Chicago, IL 60680

We showed that dynorphin (DYN) administered i.i. results in hindlimb reversible paralysis and loss of the tail-flick reflex (TFR) (Brain Res. 610:340, 1993). Also, we reported that DYN enhances the C-fiber evoked reflex resulting in excitotoxicity and loss of the TFR (JPET 246:508, 1988). Becker, *et al.*, (Exp. Neurol. 24:272, 1969) showed that dimethylsulfoxide (DMSO) blocks conduction in C-fibers. We hypothesized that DMSO would interrupt DYN-induced loss of the TFR but not paralysis.

We administered DMSO 5 min (0.4 - 3.0 g/kg i.p.) before DYN (30 nmol i.i.) and observed a dose-dependent protective effect on loss of the TFR. DMSO did not influence the incidence of paralysis but it improved recovery from paralysis.

These data indicate that DMSO is neuroprotective in our *in vivo* model of excitotoxicity and suggest that its mechanism may be to interrupt enhanced C-fiber activity. Additionally, these data support our hypothesis that DYN-induced loss of the TFR is neurally mediated. In conclusion, DMSO is a useful pharmacologic tool to facilitate exploration of the interaction of DYN with spinal reflexes. Supported by NIH NS-30295

INTRACISTERNALLY INJECTED GALANIN (1-15) MODULATES CARDIOVASCULAR RESPONSES OF GALANIN (1-29). J.A. Narváez*, Z. Díaz, P.B. Hedlund, J.A. Aguirre, S. González-Barón and K. Fuxe. Dept. of Physiology, Faculty of Medicine, University of Málaga, Spain. §Dept of Histology and Neurobiology, Karolinska Institute, Stockholm, Sweden.

The presence of specific binding sites for the Galanin (1-15) fragment [GAL(1-15)] in the rat brain has recently been reported. Since they are located in cardiovascular areas of the brainstem, the aim of this work has been to study the functional significance of such binding sites. GAL(1-15) has been injected intracisternally (i.c.) in anaesthetized male rats (dose range 0.3-10 nmol/10 µl) and mean arterial pressure (MAP), heart rate (HR) and respiratory rate (RR) were recorded during 1 hour period. GAL(1-15) injection leads to a dose-dependent increase of MAP in the first minutes after the injection (peak effect) which is maintained during the whole recording period (overall effect). Also an increase of HR was obtained for the peak and overall effects, but no significant changes in RR were observed. To study the possible modulation of GAL(1-29) on the cardiovascular responses by GAL(1-15) an effective vasodepressor dose of GAL(1-29) (3 nmol) and a subthreshold dose of GAL(1-15) (0.1 nmol) were co-injected i.c. under the same experimental conditions. GAL(1-15) reversed the vasodepressor effect of GAL(1-29) an even induced an increase in MAP of about 15% from basal values. Nevertheless, the tachycardic and bradypneic responses of GAL(1-29) are not modified. Since MAP responses after the co-injection of both GAL molecules resembles the MAP increases observed with higher doses of GAL(1-15) it could be suggested that GAL(1-15) receptors might be sensitized by the parent molecule GAL(1-29) acting on another subtype of GAL receptor. This fact and the absence of modulation of GAL(1-29) induced HR responses could suggest that GAL(1-15) may be involved mainly in the central control of blood pressure while GAL(1-29) could be involved mainly in the central control of heart rate. This work was supported by Spanish CICYT (Sal91-0458) and from the Swedish MRC (04X-715).

ANXIOLYTIC AND SEDATIVE EFFECTS OF MELATONIN AND 8-OH-DPAT IN MICE. E.B. Naranjo-Rodríguez, E.B. and C. Reyes-Vázquez*. Secc. de Farmacología. Depto. de Farmacia. Fac. de Química and Depto. de Farmacología. Fac. de Medicina, UNAM, México, D.F. 04510.

The sedative and anxiolytic actions of melatonin and 8-OH-DPAT, a specific 5-HT_{1A} receptor ligand were compared in mice. Animals underwent a free exploratory test especially adapted to reveal sedation, and they were introduced to a two-box light-dark choice situation widely used for the detection and screening of anti-anxiety substances. The effects of both drugs were compared with those induced by chlorodiazepoxide and buspirone, two classical anxiolytics. Both, melatonin and 8-OH-DPAT induced sedative properties when they are applied at high doses (4-10 mg/Kg); whilst, when administered at lower doses they displayed anxiolytic-like effects, in a very similar fashion. However, the execution of such effects were different to those elicited by chlorodiazepoxide and buspirone, suggesting a different mechanism of action.

DEVELOPMENT OF TOLERANCE TO MORPHINE IN THE RAT SPINAL CORD: SELECTIVE INTERACTION WITH CALCITONIN GENE-RELATED PEPTIDE. D. Ménard¹, D. van Rossum¹, S. Kar¹, F. Jolicœur², K. Jhamandas³ and R. Quirion¹. ¹Douglas Hosp. Res. Centre and Dept. of Psychiatry and Pharmacol. & Ther., McGill Univ., Qué. ²Dept. of Psychiatry and Pharmacol., Univ. of Sherbrooke, Qué. ³Dept. of Pharmacol., Queen's Univ., Ont., Canada.

Tolerance to the antinociceptive effects of morphine develops rapidly after its chronic administration. The mechanism involved in this phenomenon likely does not involve a direct regulation of spinal opioid receptors. A variety of neuropeptides including neurokinins and calcitonin gene-related peptide (CGRP) are found in sensory fibers that project to the substantia gelatinosa and hence may play a significant role in nociception, and the development of tolerance to morphine. We have therefore investigated the possible regulation of CGRP, neurokinins, galanin, neurotensin and neuropeptide Y receptors and immunohistochemical labelling in the dorsal horn of the spinal cord along with the development of tolerance induced by morphine. Morphine sulfate (7.5 µg/µl/h) was continuously administered at lumbar level L4 using Alzet mini-osmotic pumps for 3, 5, 7 and 14 days. Tolerance was monitored by tail-flick test and was evident on day 5 of the treatment. After the respective time periods, animals were sacrificed and L4 segments processed for either immunohistochemistry or quantitative *in vitro* receptor autoradiography. No changes were detected for all peptides tested at any time periods examined except for CGRP where decreases in [¹²⁵I]CGRP binding sites (30-45%) in the lamina II were observed after 5, 7 and 14 days of morphine treatment whereas CGRP-like immunoreactivity was increased at these same time points. These results suggest a selective interaction between CGRP innervation and the development of tolerance to the antinociceptive effects of morphine. Supported by the MRCC.

PHARMACOLOGICAL COMPARISON OF TWO CORTICOTROPIN-RELEASING FACTOR (CRF) ANTAGONISTS: *IN VIVO* AND *IN VITRO* STUDIES. R.J. Valentino*, A.L. Curtis, D.E. Grigoriadis, M.E. Page and J. Rivier. Dept. of Mental Health Sci., Hahnemann University, Philadelphia, PA 19102, Du Pont Merck Pharmaceutical Co, Wilmington, DE 19880 and The Clayton Fdn. Labs. for Peptide Biology, Salk Institute, La Jolla, CA 92037.

The present study compared the effects of two analogues of CRF, D-PheCRF₁₂₋₄₁ and α helical CRF₉₋₄₁, as antagonists of CRF in *in vivo* and *in vitro* assays. In halothane-anesthetized rats, intracerebroventricular (i.c.v.) administration of both analogues inhibited the activation of locus coeruleus (LC) neuronal discharge produced by CRF (3.0 µg, i.c.v.). LC activation by hypotensive stress elicited by intravenous (i.v.) infusion of nitroprusside was antagonized by the same doses of the CRF antagonists that were effective in antagonizing CRF, suggesting that the receptors involved in LC activation by CRF and by hypotensive stress are similar. However, D-PheCRF₁₂₋₄₁ was approximately 100 times more potent than α helical CRF₉₋₄₁ when administered i.c.v. The IC₅₀'s for D-PheCRF₁₂₋₄₁ against CRF and nitroprusside were 0.16 and 0.14 µg i.c.v., respectively. The IC₅₀'s for α helical CRF₉₋₄₁ against CRF and nitroprusside were 18 and 27 µg, i.c.v., respectively. In contrast, D-PheCRF₁₂₋₄₁ was only slightly more potent than α helical CRF₉₋₄₁ in antagonizing CRF-stimulated cyclic AMP production in rat brain homogenates, with EC₅₀'s of 50 and 200 nM for D-PheCRF₁₂₋₄₁ and α helical CRF₉₋₄₁, respectively. Moreover, the antagonists had similar affinities for CRF binding sites in rat brain homogenates, with K_i's of 17.6 and 9.9 nM for D-PheCRF₁₂₋₄₁ and α helical CRF₉₋₄₁, respectively. The results support previous studies suggesting that CRF serves as a neurotransmitter to activate the LC during hypotensive stress. The relatively lower potency of α helical CRF₉₋₄₁ *in vivo*, but not *in vitro*, may be due to a differential distribution of the antagonists after i.c.v. administration or to relative affinity differences at non-receptor CRF binding sites or proteins. Supported by PHS Grants MH 40008, MH 00840 and DK 26741.

GLUTAMATE UP-REGULATES α1 AND α2 SUBUNITS OF THE SODIUM PUMP IN GLIA OF MIXED TELEENCEPHALIC CULTURES BUT NOT IN PURE GLIAL CULTURES. Michael L. Brines* and Richard J. Robbins. Neuroendocrine Program, Yale School of Medicine, New Haven, CT 06510

Prior work employing an *in vitro* model of the cerebral cortex (Brain Res. 591 (1992) 94ff) has shown that sodium pump activity is a critical determinant for neuronal survival of glutamate stimulation. We have hypothesized that up-regulation of total brain sodium pump activity will protect against potential excitotoxins. Increased sodium pump activity could theoretically occur by changes in the reaction rate (short-term) and/or by increased levels of sodium pump protein (long-term) and is potentially complex since the three catalytic (α) subunit isoforms of the sodium pump are distributed in a highly variable, cell-specific pattern in the brain. Short-term regulation (seconds to minutes) has been well studied: brain sodium pump exhibits a large dynamic range. In contrast, the possibility of long-term modulation of sodium pump activity has not been extensively explored. We used isoform specific antibodies and ³H-ouabain binding to determine whether prolonged stimulation of sodium pump activity in rodent telencephalic cultures increased total sodium pump enzyme. Exposure of mixed neuronal-glial cultures to high levels of glutamate (10mM) for 18 hours, which is highly toxic to neurons, was associated with an ~80% increase in α1 and α2 subunit expression by glia. Induction of α2 subunit immunoreactivity was also associated with comparable changes in ³H-ouabain binding, suggesting that the up-regulation corresponded to functional α2 protein. Shorter (30 m) glutamate treatments, which also killed neurons, did not produce similar changes in sodium pump expression. In contrast to mixed cultures, pure astrocytic cultures had undetectable α2 and α3 and moderate levels of α1 protein, as confirmed by low levels of ³H-ouabain binding. Glutamate treatment using this protocol was associated with a decrease in α1 sodium pump expression. We conclude that long-term regulation of the sodium pump can be demonstrated in glia which have developed in the presence of neurons. Both α1 and α2 isoforms of the sodium pump are involved in this response to glutamate.

GLYCYL-L-GLUTAMINE ANTAGONISM OF α -MSH: INVOLVEMENT OF PGE₂. G.E. Resch* and W.R. Millington Division of Molecular Biology & Biochemistry, Univ. Missouri, Kansas City MO 64108-2792.

Glycyl-L-glutamine (Gly-Gln; β -endorphin-30-31), antagonizes certain behavioral and physiologic effects of β -endorphin and α -MSH. Preoptic area/anterior hypothalamus (POA/AH) sites were selected for a rise in colonic temperature (Tc) first with PGE₂ injections (0.35 fmol in 1 μ l) and second with α -MSH injections (0.06 nmol in 1 μ l) vs saline vehicle. Injection of α -MSH (0.06 nmol) mixed with Gly-Gln (3 nmol) abolished the Tc response ($0.0 \pm 0.02^\circ\text{C}$) elicited by α -MSH alone ($0.64 \pm 0.17^\circ\text{C}$; $P < 0.01$ vs control) in the same POA/AH sites. The antagonism did not occur to equimolar Gly and Gln ($0.55 \pm 0.05^\circ\text{C}$) nor to repeated exposure to α -MSH since serial α -MSH injections 4 h apart showed an undiminished rise in Tc. The PGE₂ antagonist, SC19220, did not consistently block α -MSH, suggesting α -MSH does not act by stimulating PGE₂ synthesis. Preliminary studies show that Gly-Gln also antagonized the PGE₂ elicited rise in Tc, suggesting Gly-Gln does not act by blocking α -MSH receptors but may act through independent receptors to reduce membrane excitability. THE EFFECT OF A FMRFamide-LIKE PEPTIDE (SDPNFLRFamide) ON SYNAPTIC TRANSMISSION IN THE PARASITIC NEMATODE *Ascaris suum*. Holden-Dye, L., & Walker, R.J*. Dept of Physiol & Pharmacol., Bassett Crescent East, University of Southampton, UK. SO93TU.

Recently FMRFamide-like peptides have been identified in a number of nematodes and the widespread distribution of FMRFamide-like immunoreactivity suggests an important role for these peptides in nematode nervous system. Here we have investigated the effect of the peptide SDPNFLRFamide (PF1), first identified in *Panagrellus redivivus* (Geary et al, 1993) on excitatory neuromuscular transmission in the parasitic nematode *Ascaris suum*. Intracellular recordings were made from *Ascaris* ventral muscle cells and the ventral nerve cord was stimulated with bipolar electrodes immediately rostral to the retrovesicular ganglion. The preparation was perfused with artificial perieric fluid (APF, composition in mM; NaCl 67, NaAcetate 67, CaCl₂ 3, MgCl₂ 15.7, KCl 3, Tris 5, pH 7.6 with glacial acetic acid with 3 mM glucose at 36°C) and drugs were added to the preparation in the perfusate. EPSPs of 5-35 mV amplitude were recorded. The EPSPs were blocked by the nicotinic receptor antagonist benzoquinonium (10 μ M, n=5) and by cobalt (1 mM, n=7). PF1 (0.01-1 μ M) decreased the amplitude of the EPSP in a dose-dependent manner with an EC₅₀ of 300 nM (n=5). The block was partially reversible after a wash of 15 min or longer. The results suggest a physiological role for a FMRFamide-like peptide at the neuromuscular junction in *Ascaris*.

INCREASED INTRANEURONAL Ca²⁺ INDUCED BY THE DIPEPTIDE N-ACETYL-ASPARYLGLUTAMATE. M.L. Koenig*, P.M. Rothbard, and J.L. Meyerhoff. Dept. Med. Neurosci., Div. Neuropsychiatry, Walter Reed Army Inst. Research, Wash., DC 20307-5100.

N-acetyl-aspartylglutamate (NAAG) is one of the most abundant peptides in the vertebrate brain. Since there is evidence to suggest that NAAG can act as an excitatory neurotransmitter, we have evaluated the effect of this dipeptide on neuronal Ca²⁺ homeostasis.

Primary neurons derived from fetal rat forebrain were loaded with the Ca²⁺-sensitive dye indo-1 (2 μ M; 60 min; 37°C), and NAAG-induced changes in intraneuronal Ca²⁺ ([Ca]) were measured in single, identified neurons (5-20 per 150 μ m² field) using an ACAS 570C interactive laser cytometer (Meridian, Okemos, MI). An HPLC analysis of the NAAG used in these studies revealed that the dipeptide represented 99.5% and free glutamate only 0.4% of what was added to the neuronal cultures. The concentration of contaminating glutamate therefore, did not contribute significantly to the observed effects.

In Ca²⁺-containing medium, NAAG (50 μ M) promoted an immediate and transient four-fold increase in [Ca], from a basal level of 133 nM to a mean level of 520 nM. With increasing concentration of the dipeptide, a second, more sustained phase of increased [Ca], became evident suggestive of prolonged influx. In the absence of extraneuronal Ca²⁺, NAAG was completely without effect. Because the excitatory properties of NAAG were reduced in the presence of extraneuronal Mg²⁺, and inhibited by pretreatment of the neurons with either MK-801 (200 nM) or 2-amino-5-phosphonovaleate (500 μ M), we are investigating the possibility that NAAG-induced increases in [Ca], are mediated by the ionotropic NMDA type of glutamate receptor.

ENKEPHALINERGIC MODULATION OF THE CRAYFISH X ORGAN - SINUS GLAND SYSTEM. Garcia, U.* and Garduño, J. Depto. de Fisiología, Biofísica y Neurociencias, CINVESTAV del IPN, Apartado Postal 14-740, 07000 México, D. F.

Immunocytochemical studies showed immunoreactive fibers to enkephaline in the medulla terminalis of lobster and shore crab eyestalks (Mancillas et al., 1981 and Jaros et al., 1985).

In the present work we show evidences of the enkephalinergic synaptic regulation of the electrical activity of the crayfish X organ - sinus gland system.

Isolated eyestalks were dark adapted during 30 minutes and inhibitory synaptic potentials were evoked by brief light pulses and recorded from XO neurons with microelectrodes filled with potassium acetate (2.6 M). These inhibitory potentials reduced the firing rate of spontaneous action potentials, both frequency and amplitude of IPSPs were dependent the intensity and duration of the light pulses and they were blocked by naloxone (3-50 μ M). Enkephaline addition (10 μ M) to the bathing solution during intracellular recordings in XO cells, induced a small hyperpolarization (about 2-3 mV). However when XO cells were cultured, they showed a higher sensitivity to enkephaline micropulses of the same concentration, the hyperpolarization was dose dependent and neurons which were cultured during 48 hours showed higher sensitivity in the lamellipodium than in the cell body. Our results suggest that enkephaline increases a potassium conductance in XO cells, since TEA addition (20 mM) to the recording medium enhanced action potential duration to 10-50 ms and enkephaline reversed this prolongation. Finally, enkephaline response did not modified IK and IA currents present in these neurons.

OPIOIDS: RECEPTORS IV

638.1

BOTH DELTA-1 AND DELTA-2 OPIOID RECEPTORS REGULATE ADENYLYL CYCLASE IN NG108-15 CELLS

B. Búzás, P.S. Portoghese* and B.M. Cox*. Uniformed Services Univ., Bethesda, MD and *Univ. of Minnesota, Minneapolis, MN.

Heterogeneity of delta receptors has been suggested on the basis of *in vivo* studies: the analgesic effect of DPDPE was antagonized by [D-Ala², Leu⁵, Cys⁶]-enkephalin (DALCE), but not by naltrindole-5'-isothiocyanate (5'NTII), while deltorphin II (DT-II) and DSLET-mediated antinociception was antagonized by 5'NTII, but not by DALCE. This and other evidence suggests that these agonists act at different sites, which have been designated δ_1 (sensitive to DPDPE and DADLE) and δ_2 (activated by DT-II and DSLET). Seeking functional evidence at a biochemical level, we investigated the role of delta receptor subtypes in the regulation of adenylyl cyclase in NG108-15 cell membranes, using two reversible antagonists, naltriben (NTB) (δ_2) and 7-benzylidenenaltrexone (BNTX) (δ_1), which were subtype-specific in antinociceptive assays. DPDPE, DSLET and DT-II diminished the formation of cAMP in a concentration-dependent manner and with similar efficacy producing a maximal inhibition of about 50% of control. NTB significantly antagonized all the delta ligands, but not to the same extent. At 1 and 10 nM it showed significantly better antagonism of DT-II and DSLET, than of DPDPE. BNTX (100 nM) diminished the inhibition by DPDPE to a greater extent than either by DT-II or DSLET. In conclusion, on the basis of differential antagonism by NTB and BNTX these data suggest the existence of delta receptor subtypes regulating adenylyl cyclase in NG108-15 cells. We have previously shown a similar differential antagonism of δ -inhibition of adenylyl cyclase in rat brain. (Supported by grants from the National Institute of Drug Abuse.)

THE μ -OPIOID RECEPTOR AGONIST D-Ala²-NMe-Phe⁴-Gly⁵ol MODULATES INHIBITORY AND EXCITATORY SYNAPTIC TRANSMISSION IN RAT NEOCORTICAL NEURONS *IN VITRO*. G. Martin, H. Pawelzik, R.A. Deisz and W. Zieglgänsberger*. Max-Planck-Institute of Psychiatry, Clinical Institute, Clin. Neuropharmacology, Kraepelinstr. 2, 8000 München 40, Germany.

Activation of opioid receptors has been considered to produce mainly inhibitory effects on neuronal activity. In the present study the μ -opioid receptor agonist D-Ala²-NMe-Phe⁴-Gly⁵ol (DAMGO) was found to differentially affect glutamatergic transmission. It enhanced NMDA receptor-mediated excitatory postsynaptic potentials (EPSPs), and diminished non-NMDA receptor-mediated EPSPs. DAMGO also reduced inhibitory postsynaptic potentials (IPSPs).

Pyramidal neurons of the somatosensory neocortex (lamina II/III) of the adult rat were recorded intracellularly employing standard *in vitro* slice techniques. EPSPs and IPSPs were elicited by electrical stimulation in lamina V/VI and lamina III/IV, respectively. Substances were added to the perfusion medium. Pretreatment with CNQX and D-APV, respectively, was used to differentiate NMDA from non-NMDA receptor mediated components of the EPSP.

DAMGO (10^{-7} - 10^{-5} M) did not significantly affect resting membrane potential or input resistance. The amplitude of EPSPs evoked by low stimulus intensities was reduced by DAMGO, whereas EPSPs elicited by high stimulus intensities were not altered or were enhanced. After blockade of non-NMDA receptors by CNQX (2 μ M), DAMGO concentration-dependently increased EPSP time integrals up to 200% compared to control (n=34). Under conditions where NMDA receptors were blocked by D-APV (100 μ M), DAMGO decreased the EPSPs to 10% (n=21). The conductance during the early Cl⁻-mediated and late K⁺-mediated GABAergic IPSPs (EPSPs blocked by 100 μ M D-APV and 10 μ M CNQX) was decreased by DAMGO (1 μ M) to below 20% (n=6). The actions of DAMGO were antagonized by naloxone (10 μ M; n=14).

The present results suggest that DAMGO has a differential effect on excitatory glutamatergic synaptic transmission depending on the receptor subtype modified by the peptide. The enhancement of NMDA receptor-mediated excitatory synaptic transmission and the decrease of inhibitory synaptic processes caused by the opioid peptide may be relevant for synaptic plasticity following chronic opioid exposure.

638.3

EVALUATION OF OPIOID ANTINOCICEPTION IN A RAT MODEL OF VISCERAL PAIN FOLLOWING LOCAL AND SYSTEMIC ADMINISTRATION. Rebecca M. Craft*, Steven R. Henley and Frank Porreca. Department of Pharmacology, University of Arizona Health Sciences Center, Tucson, AZ 85724.

The antinociceptive effects of systemically or locally administered opioid μ , κ and δ agonists were evaluated in a rat model of visceral pain involving direct administration of compounds into the urinary bladder (intravesical, *i.ves.*) via an indwelling cannula. *I.ves.* resiniferatoxin (RTX, 3 nmol), a capsaicin-like irritant, produced intense abnormally directed licking behavior, quantified by determination of time spent licking. Systemic (*s.c.* or *i.p.*) pretreatment with the μ agonists morphine (1-10 mg/kg) or [D-Ala², NMPhe⁶, Gly-ol]enkephalin (DAMGO, 1-10 mg/kg), the κ agonists U50,488 (1-10 mg/kg) and CI-977 (0.01-0.1 mg/kg), or the non-peptidic δ agonist BW 373U86 (1-10 mg/kg) decreased time spent licking in a dose-dependent manner. The rank order of potency for inhibition of licking was CI-977 > morphine > U50,488 > BW 373U86 > DAMGO, and all agonists produced maximal suppression of abdominal licking except DAMGO (maximal effect 48% at the highest dose tested). Antinociceptive effects of systemically administered morphine, U50,488 and BW 373U86 were blocked by the receptor-selective antagonists β -funaltrexamine (μ), norbinaltorphimine (κ) and naltrindole (δ), respectively. Local (*i.ves.*) pretreatment with DAMGO (10-1000 nmol) or BW 373U86 (1-1000 nmol) also decreased RTX-induced abdominal licking; maximal effects were 34 and 46% with DAMGO or BW 373U86, respectively (both at 100 nmol). Local U50,488 was ineffective up to 1000 nmol. Thus, systemically administered μ , κ and δ agonists all produced antinociception against a visceral chemical stimulus in the rat. Locally, only μ and δ , but not κ , agonists were effective, though less so than following systemic administration. This study suggests that opioid μ and δ receptors may be present on nociceptive afferents of the bladder and may be amenable to activation for production of peripheral analgesia.

638.5

OPIATE RECEPTOR SUBTYPE INVOLVEMENT IN THE STIMULATION OF GROWTH HORMONE RELEASE BY β -ENDORPHIN IN FEMALE RATS. James Janik*, Rebecca Parman, Shannon Klosteman and Phyllis Callahan. Miami University, Department of Zoology, Oxford, Ohio 45056

We have reported that β -endorphin (25 ng) produced a prolactin secretory response in virgin female rats which was similar in magnitude to the suckling induced prolactin increase (Kehoe, et al., Neuroendo, 1993, IN PRESS). This secretory response seemed to involve an interaction among the μ , δ and κ opiate receptor subtypes. The purpose of this study was to determine whether or not there was interaction among these opiate receptors in the GH secretory response to β -endorphin.

Virgin female Sprague-Dawley rats in the diestrous stage of the estrous cycle were used for all experiments. Animals were surgically implanted with chronic intraventricular (ivt) cannula into the lateral ventricle and all drugs were administered ivt. On the day of the experiment, animals were variously pretreated with either vehicle, β -funaltrexamine (1 or 5 μ g; a μ specific antagonist), ICI 154,129 (5, 10 or 25 μ g; a δ specific antagonist), or Nor-binaltorphimine (8 μ g; a κ specific antagonist) followed by β -endorphin (0.5 μ g). All three antagonists were capable of abolishing the stimulatory effect of β -endorphin on GH release. As was the case for prolactin release, β -endorphin appears to increase GH secretion via actions at all three receptor subtypes (Supported by Ohio Board of Regents Research Challenge Program Grant to P. Callahan).

OPIOID INHIBITION OF CALCIUM CHANNELS: A ROLE FOR PHOSPHORYLATION IN A LOCALIZED SIGNAL TRANSDUCTION PATHWAY. T.J. Wilding, R.E. Melford†, M.D. Womack*, and E.W. McCleskey. Dept. of Cell Biology and Physiology, Washington University School of Medicine, St. Louis, Missouri 63110, U.S.A.

Previous work from this laboratory has shown that the μ opioid agonist, DAMGO, inhibits Ca channels in rat sensory neurons (Schroeder et al., Neuron, 6: 13-20, 1991). We have been investigating the signal transduction of this inhibition using the whole-cell patch clamp method. Incubation of the cells in 500 ng/ml PTX for 16-24 hr reduced μ opioid induced inhibition from $23 \pm 2\%$ to $4 \pm 1\%$. This result demonstrates the involvement of PTX-sensitive GTP-binding proteins in the pathway. Using fast solution changes, we found transduction to be complete in 4 s and to begin with a latency of 150 ms. Recording simultaneously from a perforated patch electrode and an on-cell electrode, we found that bath-applied DAMGO inhibited whole-cell Ca current but did not affect Ca channels in the small patch of membrane protected from the agonist. The rapid time course and localized transduction path suggest a direct GTP-binding protein link between the μ opioid receptor and the Ca channel. Intracellular perfusion of ATP- γ -S, which irreversibly phosphorylates proteins, rendered DAMGO inhibition irreversible. Okadaic acid (5 μ M), a phosphatase inhibitor, enhanced the DAMGO-induced inhibition of Ca current from $20 \pm 6\%$ to $40 \pm 4\%$. To date, phosphorylation/dephosphorylation have only been seen in signal transduction pathways involving second messengers; here, phosphorylation appears to play a role in a localized pathway. (†Howard Hughes Medical Institute Medical Student Research Fellow)

DYNORPHIN A (1-17) ANTAGONIZES MORPHINE ENHANCEMENT OF THE DORSAL ROOT POTENTIAL. H. Ristic, P. Stewart and L. Isaac. Dept. of Pharmacology, Univ. Ill. Coll. of Medicine at Chicago, Chicago, IL 60680

Previously, we showed that dynorphin (DYN) applied to the spinal cord results in depression of the dorsal root potential (DRP) lasting 30 min which is insensitive to nor-binaltorphimine antagonism. DYN is both a κ agonist and a μ antagonist. To determine whether DYN affected the DRP through a μ action we tested its ability to influence morphine on the DRP and we challenged both DYN and morphine with β -funaltrexamine (β FNA), a μ antagonist.

We performed a laminectomy on rats under urethane anesthesia and recorded a DR-DRP from L4 after stimulation of L5. β FNA (20 nmol) or saline was administered i.t. 24 hr prior to recording whereas morphine (20-300 nmol) was applied topically 2 hr after DYN (9 nmol) or saline applied topically.

Morphine, dose-dependently, enhanced the DRP. Its action peaking at 30 min. This effect was antagonized by β FNA and DYN. β FNA did not affect DYN nor did it influence the DRP.

These data indicate that morphine enhances the DRP through an interaction with μ receptors whereas DYN-induced depression of the DRP is non-opioid in nature. These data suggest that DYN may act as an endogenous modulator of μ receptor mediated effects. Supported by NIH NS-30295

CALCIUM CHANNEL INHIBITION BY SOMATOSTATIN AND AN OPIOID IN HIT AND NG108-15 CELLS. E. Piro*, C.J. Evans, B. Ribale, T.G. Hales. Depts Psychiatry, Physiol. and Anesthesiol., Ctr Hlth Sci. UCLA. Los Angeles, CA. 90024

We have compared modulation of voltage-activated Ca²⁺ channels by DADLE and somatostatin (SRIF) in insulinoma (HIT) and neuroblastoma x glioma (NG108-15) cells. Like SRIF, opioids inhibit insulin secretion *in vivo* (Giugliano et al. 1989, Am.J.Physiol. 257:B361). However, a direct effect of opioids on channel activity in insulin secreting cells has not been reported.

The whole-cell patch-clamp technique was used to record currents through Ca²⁺ channels carried by Ba²⁺ in both cell lines, with NMDG chloride or CsCl based internal solutions. Drugs were bath or pressure applied.

Ba²⁺ currents in NG108-15 (n = 115) and HIT (n = 18) cells, activated by depolarizing voltage steps from -80mV, had a threshold and were maximum at around -50 and 0mV, respectively. Both cell lines exhibited Ba²⁺ current run-down proportional to the frequency of depolarization. Stimulation at 0.3 Hz caused a 40% Ba²⁺ current reduction in HIT cells (n = 6), and a 20% decline in NG108-15 cells (n = 6) in 5 min. Reducing the frequency to 0.1 Hz reduced the rate of run-down in both cell types. Under these conditions DADLE (0.3-10 μ M) dose-dependently inhibited Ba²⁺ currents in both cell lines. DADLE (1 μ M) reduced HIT and NG108-15 cell Ba²⁺ currents by $12.8 \pm 1.0\%$ (\pm SEM, n = 4) and $14.9 \pm 2.9\%$ (n = 6). SRIF (1 μ M) inhibited Ba²⁺ currents by $12.5 \pm 0.5\%$ (n = 4) and by $15.9 \pm 2.1\%$ (n = 5) in HIT and NG108-15 cells.

Our data suggest that like NG108-15 cells, HIT cells express SRIF and opioid receptors. We are investigating which opioid receptor and Ca²⁺ channel subtypes are modulated by DADLE in the insulin secreting cell line. (NIDA Center Grant #DA-05010).

INSENSITIVE GUANINE NUCLEOTIDE MODULATION OF SIGMA LIGAND BINDING IN GUINEA-PIG BRAIN MEMBRANES. J.H.Connick*, G.Hanlon, C.P.Nicholson and R.J.Marshall. Organon Labs., Newhouse, Lanarkshire ML1 5SH, U.K.

We have previously investigated whether subtypes of sigma site(s) exist using [³H]-DTG and [³H]-3PPP as ligands and examining the modulation of self and cross displacement curves by Gpp(NH)p (Connick et al., Brit. J. Pharmacol. 107, 726-731 1992). However, the use of relatively nonselective radioligands may lead to an overestimation of the number of subtypes. Such observations may be further complicated where one or more sites is G-protein linked since several states of a single receptor site may exist due to G-protein equilibria (Kent et al., Mol Pharmacol. 17, 14-23 1980). It is therefore of critical importance to determine whether one or more sigma sites is G-protein coupled. We have examined this using a variety of guanine nucleotides to inhibit the binding of sigma ligands with differing subtype selectivity's; [³H]-pentazocine, [³H]-3PPP and [³H]-DTG. Gpp(NH)p inhibited the binding of all 3 ligands with IC50's of 953 ± 24 , 918 ± 24 and $950 \pm 21 \mu$ M respectively (n=4). The slope of all displacement curves was significantly greater than 1. Similar results were obtained with GTP, GDP, GMP and GTPys.

These results suggest that the ability of guanine nucleotides to modulate the sigma site(s) is 1000 fold less than classical G-protein linked receptors. Furthermore, no significant differences were observed between the three ligands used, even though the sigma 1/sigma 2 and the putative agonist/antagonist properties of these ligands differ. It is possible that under the conditions used, binding was predominantly to an uncoupled state(s). If this is not the case, these data do not support the contention that sigma sites are G-protein linked.

638.9

DIFFERENTIAL DOWN- AND UP-REGULATION OF RAT BRAIN OPIOID RECEPTOR TYPES AND SUBTYPES BY BUPRENORPHINE. M.M. Belcheva¹, J. Barg², R.J. McHale¹, S. Dawn¹, M. T. Ho¹, E. Ignatova¹, F.E. Johnson¹ and C.J. Coscia¹. Depts. of ¹Biochem. and Mol. Biol. and ²Surgery, St. Louis Univ. Sch. Med., St. Louis, MO 63104.

Induction of opioid receptor adaptation by mixed agonist-antagonists such as buprenorphine (BP) has not been studied. Neonatal rats were injected with BP (0.1-2.5 mg/kg/d) and μ binding (K_d and B_{max}) to brain membranes was measured with ³H-[D-Ala²,MePhe⁴,Gly-ol⁵] enkephalin. At BP doses ≥ 0.5 mg/kg, μ sites were reduced 47-75% without change in affinity. Administration of the structurally-related partial agonist diprenorphine (2.5-75 mg/kg) failed to alter μ binding. Receptor blockade by residual BP was ruled out by several lines of evidence. B_{max} values of δ (³H-[D-Ser²,L-Leu⁵]enkephalyl-Thr [DSLET]) and κ (³H-U69593) binding were elevated 1.9-4.2-fold by BP treatment. In adult rats BP (0.5-2.5 mg/kg) reduced μ opioid binding to forebrain membranes dose-dependently (25-77%). ³H-DSLET-labeled δ subtype and κ sites in adult forebrain membranes were up-regulated 2-3-fold. The δ subtype that binds ³H-[D-Pen²,D-Pen⁵]enkephalin in neonatal or adult brain membranes was unaffected by 0.5-2.5 mg/kg BP treatment. Down-regulation (70-74%) of μ sites and up-regulation (1.9-6.7 fold) of δ and κ receptors were observed in synaptic plasma membrane-enriched and microsomal fractions from BP-treated adult rat brain.

REGIONAL VARIATION IN THE RATIO OF σ_1 TO σ_2 BINDING IN RAT BRAIN. M. L. Leitner, A.G. Hohmann, S.L. Patrick and J.M. Walker. Schrier Research Laboratory, Dept. of Psychology, Brown University, Providence, RI 02912.

Recent work has postulated the existence of multiple subtypes of the sigma receptor termed σ_1 and σ_2 (reviewed by Quirion et al., *Trends Pharmacol. Sci.* 13: 85), and behavioral studies have postulated a role of σ_2 sites in motor behavior (Walker et al., *Eur. J. Pharmacol.* 231: 61). This study examined the distribution of subtypes of the σ receptor in discrete regions of rat brain and in whole guinea pig brain. Rat brains were dissected into nine regions (hindbrain, midbrain, hypothalamus, thalamus, septum, hippocampus, striatum, cortex, cerebellum), pooled and used to prepare membranes for ligand binding studies. Whole guinea pig brains were prepared in an identical manner. σ_1 Binding was labeled using the selective σ_1 compound [³H](+)-pentazocine and σ_2 receptors were labeled with [³H]1,3 di-o-tolylguanidine (DTG) in the presence of 1 μ M dexlalthorphan to mask σ_1 sites. Nonspecific binding was determined in the presence of 10 μ M haloperidol. Experiments revealed a marked variation in the ratio of σ_1 to σ_2 sites across rat brain regions as well as a consistently higher proportion of σ_2 sites in all areas studied. Guinea pig brain showed a preponderance of σ_1 receptors. These data support prior evidence for a biological role of the σ_2 site in motor function, because areas showing the highest levels of σ_2 binding included the cerebellum, cortex, hindbrain and midbrain. The data also clearly demonstrate a significant difference in receptor abundance between species. Finally, these experiments lend support to the notion that σ_1 and σ_2 sites are biologically distinct entities. This work was supported by MH48869 and DA04988 (JMW).

SEX DIFFERENCES IN DTG-INDUCED ROTATORY BEHAVIOR: FURTHER EVIDENCE OF A FUNCTIONAL INTERACTION OF SIGMA RECEPTORS WITH NIGROSTRIAL DOPAMINERGIC TRANSMISSION. M.K. Hemstreet¹, S.L. Patrick², and J.M. Walker². ¹Dept. of Neuroscience and ²Schrier Research Laboratory, Dept. of Psychology, Brown University, Providence, RI 02912.

The influence of physiological and surgical changes in hormonal status upon the behavioral and binding characteristics of DTG were examined in male and female rats. In the first set of experiments, induction of rotatory behavior following unilateral intranigral microinjection of 4nmol DTG was examined in intact cycling female rats and compared with that of male littermates. Estrous stage was determined by daily vaginal lavage and cytological examination. In the second set of experiments, male and female rats gonadectomized or sham-operated as adults were tested behaviorally 30 days after surgery. Intranigral injections of 4nmol DTG were again used to quantify efficacy of the sigma ligand. In the third set of experiments, male and female rats were neonatally gonadectomized or sham-operated, then received intranigral DTG (4nmol) as adults. Rotatory behavior was quantified and compared with that of intact littermates. All animals were sacrificed following behavioral studies and their brains processed for both histological confirmation of intranigral injections and radioligand binding studies using [³H]DTG.

Overall, females had a significantly greater rotatory response to intranigral DTG than did males ($p=0.0003$); this was especially apparent in proestrus/estrus females. Adult gonadectomy had no effect on DTG-induced behavior in either sex, although neonatal gonadectomy significantly potentiated the behavioral effects of DTG in males ($p=0.05$). This suggests a developmental rather than tonic interaction of steroidal hormones with sigma receptors and dopaminergic function. Sham operations were without effect at either age. Binding of [³H]DTG did not differ significantly among the various groups, and multiple regression analysis indicated that the best predictor of DTG-induced rotatory behavior was sex of the animal regardless of sigma binding parameters. As sigma ligand-induced circling is dopamine-dependent, potentiation in intact females is consistent with the known facilitatory effect of ovarian steroids upon dopamine tone.

638.10

OPIOIDS INHIBIT ENDOTHELIN-MEDIATED PHOSPHATIDYLINOSITOL TURNOVER, Ca²⁺ MOBILIZATION AND DNA SYNTHESIS IN RAT C6 GLIOMA CELLS. Z. Vogel¹*, M.M. Belcheva¹, R. Levy¹, R.J. McHale¹, F.E. Johnson¹, C. J. Coscia¹, J. Barg²† #Dept. of Neurobiol. The Weizmann Inst. of Sci., 76100 Rehovot, Israel, †E.A. Doisy Dept. of Biochem. and Molec. Biol., ‡Dept. of Surgery, St. Louis University School of Medicine, St. Louis, Missouri 63104, U.S.A.

Desipramine (DMI) induces opioid binding in rat glioma C6 cells and opioid agonists inhibit DNA synthesis in DMI-treated but not untreated cells. Endothelin is a known mitogen of C6 cells and in the presence of DMI it increased thymidine incorporation dose dependently up to 1.7 fold. This increase was reversed by the antidiabetic anti-opiate receptor antibody Ab2AOR, which has opioid agonist properties. The opioid antagonist, naltrexone blocked the inhibition by Ab2AOR. Endothelin also enhanced phosphatidylinositol (PtdIns) turnover and this effect was inhibited by morphine or Ab2AOR (35% and 33%, resp.) in DMI-treated but not in untreated C6 cells. The actions of morphine and Ab2AOR were reversed by naltrexone. Moreover, blockade of PtdIns turnover and thymidine incorporation by Ab2AOR or morphine were insensitive to pertussis toxin. Since PtdIns turnover is known to induce Ca²⁺ mobilization, it was of interest to examine the mechanism by which opioids may alter intracellular Ca²⁺ concentrations. We found that Ab2AOR reversed endothelin-induced Ca²⁺ mobilization in DMI-treated but not untreated C6 cells. The effect of Ab2AOR was again blocked by naltrexone. The results indicate that glial cells can be a target of an opioid receptor-mediated anti-mitogenic action and that an abatement in PtdIns turnover and Ca²⁺ mobilization may be involved in this mechanism. Supported by the Anti-drug Authority of Israel, the United States-Israel Binational Science Foundation, and the Israel Cancer Research Fund.

EFFECTS OF SIGMA LIGANDS ON STRIATAL DOPAMINE SYNTHESIS AND ROTATIONAL BEHAVIOR IN RATS. SD Weiser, SL Patrick, SW Mascarella, X Bai, FI Carroll, JM Walker, RL Patrick. Depts of Psychology & Neuroscience, Brown University, Providence, RI 02912, and Research Triangle Institute, Research Triangle Park, NC 27709.

The present studies were undertaken to investigate the biochemical and behavioral effects of sigma ligands on nigrostriatal dopamine activity. We examined the *in vivo* effects of unilateral intranigral injections of two high affinity sigma compounds, 1,3-di-o-tolylguanidine (DTG) and (-)-deoxy-N-benzylnormetazocine (RTI-4612-58), on striatal tyrosine hydroxylase activity and rotational behavior in rats. The rate of dopamine synthesis was determined by measuring the accumulation of L-3,4-dihydroxyphenylalanine (DOPA) following inhibition of dopa decarboxylase with NSD 1015. DTG and RTI-4612-58 dose-dependently increased striatal dopamine synthesis and rodent turning behavior following intranigral administration. These findings provide direct evidence that sigma sites in the substantia nigra play a role in the modulation of dopamine neurotransmission. We also explored the possibility that nigral NMDA receptors mediate the dopaminergic effects of sigma ligands by examining whether the NMDA antagonist, (+)-3-(2-carboxypiperazin-4-yl)-propyl-1-phosphonic acid (CPP), reversed the effects of DTG. CPP, when co-injected with DTG in the substantia nigra, failed to alter DTG-induced increases in striatal DOPA accumulation. CPP also failed to inhibit DTG-evoked rotational behavior. However, this finding is difficult to interpret in view of the fact that CPP elicited vigorous contralateral turning behavior when administered alone. Finally, we determined whether some commonly used anesthetic agents interfered with sigma ligand-induced stimulation of dopamine synthesis. Pre-treatment with halothane and ketamine completely eliminated the effects of DTG, while pretreatment with chloral hydrate did not impede DTG-induced enhancement of dopamine synthesis. These results suggest that chloral hydrate would be the most reliable anesthetic agent to use with *in vivo* neurophysiological experiments.

KAPPA₂ OPIOID RECEPTORS INHIBIT NMDA RECEPTOR-MEDIATED SYNAPTIC CURRENTS IN THE CA3 OF GUINEA PIG HIPPOCAMPUS. R.M. Caudle¹, C. Chavkin¹, R. Dubner¹, NAB, NIDR, NIH, Bethesda, MD 20892, ²Dept. Pharmacol., Univ. Washington, Seattle, WA 98195.

The role of the endogenous opioid dynorphin A (1-17) in regulating N-methyl-D-aspartate (NMDA) receptor-mediated synaptic currents was examined in guinea pig hippocampus. Shaffer collateral/commissural fiber-evoked NMDA synaptic currents were recorded using whole cell patch clamp techniques in CA3 pyramidal cells. Dynorphin was found to have dual effects on NMDA synaptic currents: increasing them at low concentrations (10 - 1000 nM) and decreasing them at high concentrations (5 μ M). Only the inhibitory action of dynorphin was sensitive to naloxone indicating that this effect was mediated by an opioid receptor. The inhibitory effect was mimicked by bremazocine, but not by U69,593, U50,488, [D-Ala², N-Me-Phe⁴, Gly-ol⁵]-enkephalin or [D-Pen²,5]-enkephalin. In addition, the inhibitory effect of 1 μ M bremazocine was blocked by 1 μ M naloxone, but not by the selective kappa₁ antagonist nor-binaltorphimine (1 μ M) or the selective mu antagonist cyprodime (1 μ M). By process of elimination these data suggest that the inhibitory effect of bremazocine and dynorphin was mediated by the kappa₂ subtype of opioid receptor. In addition, 1 μ M naloxone and anti-sera to dynorphin A (1-17) were found to increase NMDA mediated synaptic currents. Nor-binaltorphimine, cyprodime and anti-sera to met-enkephalin did not increase the NMDA synaptic current. Overall, these findings indicate that dynorphin is an endogenous agonist for kappa₂ receptors in the CA3 region of the guinea pig hippocampus and that these receptors regulate NMDA receptor function.

638.15

ROLE OF DELTA- AND KAPPA-OPIOID RECEPTORS IN MODULATING COCAINE-INDUCED BEHAVIORAL SENSITIZATION IN THE RAT. Christian Heidbreder, Mohammed Shoaib & Toni Shippenberg*. Behavioral Pharmacology and Genetics Section, Preclinical Pharmacology Laboratory, National Institute on Drug Abuse, P.O. Box 5180, Baltimore, MD 21224, USA.

The effects of treatment with the selective kappa-opioid receptor agonist U69593 and the delta-opioid receptor antagonist naltrindole upon cocaine-induced changes in locomotor activity and extracellular dopamine levels were examined in rats. Daily injections of cocaine resulted in a dose-dependent sensitization to its locomotor activating effects. In contrast, such sensitized responses failed to develop in animals which had previously received U69593 (0.16-0.32 mg/kg s.c.) or naltrindole (0.3-3.0 mg/kg s.c.) in conjunction with daily cocaine treatment. Interestingly, such pre-treatment was unable to modify the behavioral sensitization induced by another psychostimulant, e.g. nicotine. *In vivo* microdialysis studies indicate that the doses of U69593 which attenuate the behavioral effects of cocaine fail to modify cocaine-induced increases in extracellular dopamine levels within the nucleus accumbens. Taken together, these data thus demonstrate that the selective blockade of delta-opioid receptors or the activation of kappa-opioid receptors prevents the development of cocaine-induced sensitization. In view of the postulated role of sensitization in the maintenance of cocaine abuse, our results suggest that selective kappa agonists and delta-opioid receptor antagonists may be useful in the pharmacological management of cocaine addiction.

[³H](+)-AZIDO-PHENAZOCINE: CHARACTERIZATION AS A SELECTIVE PHOTOAFFINITY PROBE FOR SIGMA-1 RECEPTORS. W.E. Williams, R. Wu, B.R. de Costa, and W.D. Bowen*. Laboratory of Medicinal Chemistry, NIDDK, NIH, Bethesda, MD 20892.

Heterogeneity of sigma binding sites has been suggested on the basis of differences in ligand selectivity profiles using various radioligands and tissues (for reviews, Walker et al., *Pharmacol. Rev.* 42: 355-402, 1990; Quirion et al., *Trends Pharmacol. Sci.* 13: 85-86, 1992). Sigma-1 and sigma-2 receptors differ in their affinity for (+)-benzomorphan, with sigma-1 receptors having much higher affinity for these compounds than sigma-2. These two subtypes have also been differentiated on the basis of photoaffinity labeling using [³H]azido-DTG ([³H]Az-DTG) and determination of molecular weight by SDS polyacrylamide gel electrophoresis (Hellewell and Bowen, *Brain Res.* 527: 244-253, 1990). Sigma-1 receptors have an apparent molecular weight of 25 kDa, whereas sigma-2 receptors have a molecular weight of 18-21 kDa. Since [³H]Az-DTG labels both sigma-1 and sigma-2 sites, we attempted to design a selective photoaffinity probe for sigma-1 sites. The benzomorphan, (+)-phenazocine was found to be highly selective for sigma-1 receptors (sigma-1 K_i = 3.90 nM; sigma-2 K_i = 1,269 nM) (Di Paolo et al., *Soc. Neurosci. Abstr.* 17: 814, 1991). On this basis, we synthesized unlabeled and radiolabeled (+)-azido-phenazocine. Unlabeled (+)-azido-phenazocine exhibited a sigma-1 K_i = 1.34 ± 0.21 vs. the selective sigma-1 probe, [³H](+)-pentazocine in guinea pig brain. Competition studies (carried out in the dark) revealed that 5 nM [³H](+)-azido-phenazocine ([³H](+)-Az-PHEN) labeled a site in guinea pig brain with a typical sigma-1 profile, similar to that labeled by [³H](+)-pentazocine and [³H](+)-3-PPP: (+)-pentazocine > haloperidol = DTG > (+)-3-PPP > (+)-SKF 10,047 > (-)-pentazocine > (-)-SKF 10,047. Ligands for other receptors were inactive. Thus, [³H](+)-Az-PHEN appears to selectively label sigma-1 receptors, as predicted. Results of studies to determine the ability of this probe to photolabel sigma-1 receptor polypeptides will be discussed.

638.19

MODULATION OF I_h BY cAMP-DEPENDENT PROCESSES. S.L. Ingram¹ and J.T. Williams² Department of Pharmacology¹ and Vollum Institute², Oregon Health Sciences University, Portland, OR 97201.

Opioid receptors are known to both inhibit adenylate cyclase (AC) and suppress the activity of CNS neurons. It is not known, however, whether these two actions are linked. We have made whole-cell electrophysiological recordings from the soma of primary afferent neurons in culture and looked at the effects of opioids on a cAMP-activated ion current (I_h). Forskolin (10 μM), an AC stimulator, shifts the activation curve for I_h to more depolarized potentials and augments the current. [Met]⁵-enkephalin (1-10 μM) can reduce the forskolin-mediated augmentation of I_h in some neurons. It is possible that other compounds linked to AC stimulation can also increase I_h and be depressed through opioid inhibition of AC. Since I_h is a hyperpolarization-activated, mixed Na/K current which seems to be important in stabilizing resting membrane potential, modulation of I_h by nociceptive agents may play a role in the increased neuronal excitability of primary afferents associated with pain and inflammation. Modulation of ion currents suggests a possible mechanism for a peripheral pain-relieving action of opioids.

SIGMA INHIBITION OF THE CHOLINERGIC PHOSPHONOSITIDE RESPONSE: CHARACTERIZATION OF PARTIAL AGONISTS AND ANTAGONISTS AT SIGMA-1 RECEPTORS. K.K. Hsu, J.M. Cutts*, B.R. de Costa, and W.D. Bowen. Lab. Med. Chem., NIDDK, Bethesda, MD 20892.

Our previous work has suggested that activation of sigma-1 receptors results in non-competitive inhibition of the muscarinic phosphonositide response in rat brain synaptosomes (in: *Multiple Sigma and PCP Receptor Ligands; Mechanisms for Neuromodulation and Neuroprotection?*, J.-M. Kamenka and E.F. Domino, eds., NPP Books, Ann Arbor, pp. 155-167, 1992). Examination of the "efficacy ratio" [sigma-1 K_i (nM)/PPI inhibitory ED₅₀ (μM)] for several sigma compounds allows an approximate ranking in order of intrinsic activity as sigma-1 agonists in this assay, where lower values represent lower efficacy. Sigma compounds tested to date have efficacy ratios in the general range of 0.40 - 1.71. For example, haloperidol, 0.40; (+)-pentazocine, 0.43; dextrallorphan, 0.72; fluphenazine, 0.73; and DTG, 1.71. The novel aryl ethyl(pyrrolidinyl)cyclohexylamine BD737 exhibits an efficacy ratio of 1.3 nM/3.1 μM = 0.42. Removal of the cyclohexane ring from BD737 and opening of the pyrrolidine ring produces the aryl ethylene diamines, BD1008 and BD1139. These compounds maintain high affinity for sigma-1 sites, but have over 10-fold lower efficacy than the parent compound: BD1008, 0.34 nM/10.3 μM = 0.033; BD1139, 5.78 nM/150 μM = 0.039. These data suggest that these compounds may have partial agonist properties. BD1139 produced dose dependent, non-competitive inhibition of oxotremorine-M (oxo-M) stimulated PPI turnover at concentrations above 50 μM. However, at 50 μM and below, BD1139 had little or no effect on oxo-M-stimulated PPI turnover. At 50 μM, BD1139 significantly attenuated the ability of 30 μM (+)-pentazocine and 30 μM SH311 to non-competitively inhibit oxo-M-stimulated PPI turnover. These data appear to confirm that BD1139 is a partial agonist at sigma-1 sites, with antagonist activity in the lower concentration range. Other sigma compounds in this and related series which have low efficacy ratios will also be tested for antagonist activity using this assay.

638.18

ANTAGONISM OF OPIOID ANALGESIA: A FUNCTIONAL ROLE FOR SIGMA₁ RECEPTORS. Chih-cheng Chien*, Gavril W. Pasternak*.

*The Cotzias Laboratory of Neuro-Oncology, Memorial Sloan-Kettering Cancer Center and Depts. of Neurology/Neuroscience and Pharmacology, Cornell U. Medical College, NY, NY 10021 and *Cathay General Hospital, Taipei, Taiwan.

Sigma binding sites have been well described. Recent studies have identified several subtypes, including the sigma₁ site which is highly selective for (+)pentazocine. However, the functional significance of these sites remains unclear. It has been assumed that (±)pentazocine reverses morphine analgesia due to its partial-agonist action on mu receptors. However, both (+) and (-)pentazocine antagonize morphine analgesia equally well, implying that this antagonism does not involve opioid receptors. Similar antagonism can also be observed with kappa₁ and kappa₃ analgesia. In additional experiments, DTG [1,3-Di(2-tolyl)guanidine] also significantly attenuates morphine analgesia. Together, these results imply a sigma₁ mechanism of action. Haloperidol is a known D₂ and sigma₁ antagonist. Haloperidol reverses the action of either (+) or (-)pentazocine on morphine analgesia in doses as low as 0.5 mg/kg. In contrast, the selective D₂ antagonist (-)sulpiride has no effect, implying that haloperidol is acting as a sigma₁ antagonist. Haloperidol also enhances analgesia in the absence of pentazocine, particularly for kappa drugs. Our results indicate that sigma₁ activity suppresses mu, kappa₁ and kappa₃ analgesia. The potentiation of opioid analgesia by haloperidol suggests the presence of a tonically active antioioid system involving sigma₁ receptors.

638.20

THE EFFECTS OF AGING ON SPINAL OPIOID-INDUCED

ANTINOCICEPTION. D.L. Hoskins, J.L. Stafinsky and T.

Crisp*. Department of Pharmacology, Northeastern Ohio

Universities College of Medicine, Rootstown, OH 44272-0095.

This study compared the effects of aging on the spinal antinociceptive properties of the mu opioid agonist DAMPGO and the delta agonist DPDPE. Young, mature and aged Fischer 344 rats (6,16, and 26 months respectively) were injected intrathecally (i.t.) with different doses of DAMPGO or DPDPE, and the antinociceptive efficacy of these agents was tested on the tail-flick analgesiometric assay. All three age groups responded to i.t. DAMPGO in a dose-dependent manner, but higher doses were required to produce significant elevations in tail-flick latency (TFL) in the aged cohort. The spinal effects of DPDPE were also age and dose-dependent. Whereas the antinociceptive effects of DPDPE were dose-dependent in the 6 and 16 month old animals, even the highest dose tested (300 nmol) failed to significantly elevate TFL in the 26 month old group. The aging process apparently alters the pain-inhibitory function of the delta opioid receptors in the rat spinal cord. The present finding that spinal opioid-induced antinociception is diminished in older animals may be attributable to an age-related decline in the number and/or affinity of spinal opioid receptor sites.

NGF REGULATION OF 5HT₃ RECEPTOR EXPRESSION. I.A. Ukhun^{1*}, S.G. Holstad^{1*}, S. Jafri¹, I. Uchida², J. Yang², & K.E. Isenberg¹.

¹St. Louis College of Pharmacy; ²Dept. of Psychiatry, Washington University School of Medicine, St. Louis, MO 63110; *Dept. of Pharmacology, University of Maryland, Baltimore, MD 21201.

PC12 cells show detectable expression of 5HT₃ receptors upon exposure to NGF. We cloned the rat 5HT₃ receptor and sought to understand its regulation by NGF. We report electrophysiologic, and polymerase chain reaction (PCR) data supporting regulation of receptor expression via increases in PC12 cell steady-state mRNA levels. Rat 5HT₃ receptor clones were selected from a rat superior cervical ganglion cDNA library employing an oligonucleotide that detected nicotinic receptor clones; sequence analysis revealed strong homology (95% amino acid similarity) with the previously published mouse receptor subunit. PC12 cells (ATCC) were cultured with and without 50ng/ml of NGF. Whole cell patch clamp recording did not reveal a detectable response to serotonin (10uM) in the absence of NGF; exposure to NGF resulted in steadily increasing peak current in response to serotonin over 8 days. RNA was harvested from PC12 cells after exposure to NGF for 1, 2, 4, 6, and 8 days; PCR was performed quantitatively by varying cycle number over the linear range of the assay. Exposure of PC12 cells to NGF increases the steady-state mRNA levels for the 5HT₃ receptor in a fashion that precedes and parallels sensitivity to serotonin. The induction of 5HT₃ receptor expression by NGF involves increasing steady-state mRNA levels and occurs on a time scale suggestive of induction via primary response genes.

639.3

ELECTROPHYSIOLOGICAL STUDIES OF THE SEROTONERGIC (5-HT) MODULATION OF GLUTAMATE-EVOKED ACTIVITY IN AMYGDALA NEURONS. E.J. Mah¹ and K.A. Cunningham¹, Dept Pharmacol, Univ TX Med. Branch, Galveston, TX 77555-1031.

Serotonin (5-HT) receptor subtypes designated as 5-HT_{1A} and 5-HT₂ have been implicated in the actions of compounds showing anxiolytic activity. The amygdala is thought to be important in mediating anxiogenic, emotional and fear responses; it also has a significant population of both 5-HT_{1A} and 5-HT₂ receptors. Little information, however, is available concerning the electrophysiological responses to 5-HT in this region. Previous research has indicated that microiontophoretic application of 5-HT predominantly inhibits the activity of neurons found in subnuclei of the rat amygdala (Callahan & Cunningham, SN Abst 21: 679), although the specific 5-HT receptors which mediate this response are currently uncharacterized. In the present experiment, single unit extracellular and microiontophoretic techniques are being used to study the effects of the 5-HT_{1A} agonist 8-hydroxy-2-(di-n-propylamino)tetralin (8-OHDPAT; 1 mM) and the 5-HT₂ agonist methyl-chlorophenylbiguanide (MCPB; 10 mM). Both spontaneously-active and glutamate-stimulated (50 mM; -3.0 to -35.0 nA) neurons in the central, lateral, and basolateral amygdala were studied. Neither 8-OHDPAT (2.5-40 nA; N=4) nor MCPB (2.5-40 nA; N=4) significantly altered spontaneously-active amygdala neurons; however, both 8-OHDPAT and MCPB elicited current-related inhibitions of glutamate-stimulated activity, with a maximal 40-50% inhibition at 40 nA. As glutamate plays a major role in feed-forward transmission in the amygdala, these data suggest that 5-HT_{1A} and 5-HT₂ receptor modulation of glutamate-evoked activity may be of important functional significance to information processing in this area. Experiments with additional 5-HT_{1A} and 5-HT₂ agonists and antagonists are underway to further characterize the electrophysiological effects of 5-HT on glutamate transmission in the amygdala. Supported by NIDA DA05708 and DA06511.

639.5

REGULATION OF 5-HT₂ RECEPTOR BINDING SITES BY PERTUSSIS TOXIN AND PHORBOL ESTER IN CEREBELLAR GRANULAR CELLS. H. CHEN¹ AND D.-M. CHUANG¹. Section on Molecular Neurobiology, Biological Psychiatry Branch, NIMH, NIH, Bethesda, MD 20892.

We have documented that persistent stimulation of 5-HT₂ receptors in cerebellar granule cells causes an increase in the Bmax of 5-HT₂ receptors. (Akiyoshi et al., Mol. Pharmacol. 43:349-355, 1993). To investigate the role of 5-HT₂ receptor - mediated phosphoinositide turnover in this paradoxical receptor up-regulation, we examined the effects of suppression of IP₃/DAG production by pretreatment with pertussis toxin (PTX) or phorbol dibutyrate (PDBu). Cells were pretreated with PTX (100 ng/ml) for 16 hr before stimulation of 5-HT₂ receptors with DOI (10mM) for 24 hr. PTX alone was unexpectedly found to increase [³H] ketanserin binding to 5-HT₂ receptors in intact cells. Pretreatment with both PTX and DOI produced a binding increase greater than that elicited by either drug alone, indicating that the DOI induced up-regulation was not inhibited. The effect of PTX was time- and dose- dependent and appeared to be unrelated to a increase in basal cAMP level. Moreover, PTX pretreatment did not influence [³H] QNB binding to muscarinic receptors. Cells were also exposed to PDBu (500 nM) for 15 min or 16 hr before the 24-hr pretreatment with DOI. PDBu alone caused a significant increase in 5-HT₂ receptor binding and in conjunction with DOI produced an effect greater than that elicited by DOI alone. Our results suggest that production of IP₃/DAG by 5-HT₂ receptor stimulation is not a prerequisite for the delayed up-regulation of 5-HT₂ receptor binding sites.

THE SEROTONIN-3 RECEPTOR AGONIST 1-(M-CHLOROPHENYL)-BIGUANIDE INCREASES EXTRACELLULAR DOPAMINE AND SEROTONIN CONCENTRATIONS IN THE NUCLEUS ACCUMBENS OF RATS. A.D. Campbell¹ and W.J. McBride¹. Department of Psychiatry, Institute of Psychiatric Research, Indiana University School of Medicine, Indianapolis, IN 46202-4887.

Serotonin (5-HT) and dopamine (DA) neuronal systems projecting to the nucleus accumbens (NA) have been implicated in the rewarding properties of many drugs of abuse, including ethanol. Both systemic and local administration of pharmacologically relevant doses of ethanol have been shown to enhance DA and 5-HT release in the NA. Since this effect is inhibited by 5-HT₃ receptor antagonists, the present study was conducted to examine further the role of this receptor subtype in stimulating the release of DA and 5-HT. Application through the dialysis probe of 1-(m-chlorophenyl)-biguanide (CPBG), a 5-HT₃ agonist, dose-dependently enhanced the extracellular concentrations of both DA and 5-HT in the NA, as measured by HPLC with electrochemical detection. CPBG appeared to be more potent at enhancing DA efflux, however it was more efficacious in enhancing the 5-HT response. Indeed, the highest concentration used (100 μM) caused an approximately 1500% increase in extracellular DA, whereas the same concentration caused an approximately 3000% increase in 5-HT levels. Corresponding decreases in the major metabolites occurred with the increases in these two monoamines. The CPBG-stimulated release of DA and 5-HT was partially inhibited by the 5-HT₃ antagonist ICS 205-930 and was partially Ca²⁺-dependent. The mechanism of CPBG-induced release of DA and 5-HT is not known, however, the results suggest that the effect may be mediated at least in part by 5-HT₃ receptors. (Supported by PHS Grants AA 09090 and AA 08553.)

A slow excitatory postsynaptic potential mediated by 5-HT₂ receptors in guinea-pig central neurons. D.H. Bobker¹. Dept of Neurology and Vollum Institute, Oregon Health Sciences University, Portland, OR 97201

Intracellular recordings were made from neurons of the nucleus prepositus hypoglossi in slices of guinea-pig medulla *in vitro*. 5-hydroxytryptamine (5-HT, serotonin) caused a hyperpolarization followed by a late depolarization. The hyperpolarization was mediated by 5-HT_{1A} receptor activation and could be selectively blocked by pindobind-5HT_{1A} (PBD). 5-HT then caused a depolarization only, with an EC₅₀ of 21 nM (in cocaine 10 μM). A selective 5-HT₂ agonist, (±)-1-(2,5-dimethoxy-4-iodophenyl)-2-aminopropane (DOI), also caused a depolarization, with an EC₅₀ of 2.6 nM. Ketanserin and spiperone, 5-HT₂ antagonists, blocked the depolarization due to both compounds.

Focal electrical stimulation caused an inhibitory postsynaptic potential (IPSP) mediated by 5-HT acting upon 5-HT_{1A} receptors, and a slow excitatory postsynaptic potential (s-EPSP). PBD blocked the IPSP, leaving an isolated s-EPSP. Both spiperone and ketanserin antagonized the s-EPSP, while DOI occluded it. The s-EPSP was from 2-10 mV in amplitude, 35-50 sec in duration and showed voltage-dependence consistent with a potassium-mediated current. Cocaine increased the s-EPSP amplitude by 108%, while having little effect on duration. Both the IPSP and the s-EPSP were presynaptically inhibited by the 5-HT_{1D} agonist sumatriptan. This data indicates that the s-EPSP is mediated by 5-HT acting upon 5-HT₂ receptors and expands the role of 5-HT as an excitatory neurotransmitter in the central nervous system.

639.6

CHARACTERIZATION OF THE FUNCTIONAL RESPONSES OF THE CLONED RAT 5-HT_{2B} (5-HT_{2F}) RECEPTOR. D.L. Nelson¹, M. Baez, L.A. Mercurio, P. A. Hyslop, D. V. Pearson, and V. L. Lucaites. Lilly Research Labs, Eli Lilly and Company, Indianapolis, IN 46285

The 5-HT_{2B} receptor (originally called 5-HT_{2F}) belongs to the 5-HT₂ subfamily of receptors, which is known to stimulate phosphatidylinositol (PI) hydrolysis. The functional aspects of the 5-HT_{2B} receptor were explored by looking at its effect on the production of inositol 1,4,5-trisphosphate (IP₃). In AV-12 cells expressing the 5-HT_{2B} receptor, 5-HT potently stimulated IP₃ production (EC₅₀ = 15.7 ± 3.1 nM, n=16). The IP₃ response to 5-HT was rapid, with peak IP₃ production (6-21 fold increases over basal levels) occurring within 5-10 seconds. The peak response fell to a new plateau (1.6-2.7 fold over basal levels) within 60 seconds. The IP₃ response to 5-HT was paralleled by the 5-HT-induced increase in Ca²⁺ flux. Pretreatment of the cells with the potent antagonists 1-naphthylpiperazine (1-NP) and methysergide resulted in apparent noncompetitive inhibition of 5-HT-stimulated IP₃ production. For comparison, total PI hydrolysis was examined by measuring the accumulation of inositol monophosphate (IP) in the presence of LiCl. This response was linear for 30 min. Methysergide or 1-NP preincubated with cells before measuring 5-HT-induced IP accumulation also showed noncompetitive antagonism, suggesting that the initial IP₃ peak may be the major contributor to the overall accumulation of IP even at 30 min. The rapid and transient nature of the 5-HT_{2B}-mediated IP₃ response precludes the calculation of pA₂ values for antagonists by traditional methods that assume equilibrium kinetics between receptors, agonists, and antagonists.

EFFECTS OF AGONIST & ANTAGONIST ON SEROTONIN-INDUCED INTRACELLULAR CALCIUM MOBILIZATION IN 5-HT_{1C} RECEPTOR TRANSFECTED CELL. J. Akiyoshi¹, R. Kohara¹, H. Ono¹, H. Yamamoto¹, K. Yamada¹, A. Nishizono², K. Mifune² and I. Fujii¹. ¹Dept. of Neuropsychiatry, ²Dept. of Microbiology, Oita Medical University, Hasama-Machi, Oita 879-55, Japan.

The 5-HT_{1C} receptor is one of the major serotonin receptor subtypes and a functional cDNA of this receptor was cloned and characterized. The 5-HT_{1C} receptor is widely distributed in the CNS.

We have studied effects of 5-HT_{1C} receptor agonists (5-HT, mCPP) and antagonists (mianserin, mesulergine) on 5-HT_{1C} receptor transfected cells. 5-HT or mCPP-induced changes in the levels of intracellular Ca²⁺ were analyzed in 5-HT_{1C} receptor transfected cells, using the Ca²⁺-sensitive dye fura-2/AM. The fluorescence of fura-2/AM was measured in a fluorescence spectrophotometer with excitations at 340 and 360 nm. 5-HT or mCPP mobilized intracellular Ca²⁺ in a dose-dependent fashion from basal level. A second stimulation by 5-HT did not produce a rise in intracellular Ca²⁺ after previous exposure to 5-HT in the plateau phase. Mianserin, mesulergine, 5-HT_{1C} receptor antagonists, reversed the 5-HT-induced Ca²⁺ increase in a dose-dependent manner.

These results show that 5-HT_{1C} receptor agonists induces 5-HT_{1C} receptor desensitization and 5-HT_{1C} receptor antagonists blocks this response in 5-HT_{1C} receptor transfected cell.

SEROTONIN INDUCTION OF AP-1 AND CRE DNA BINDING ACTIVITIES IN RAT C6BU-1 GLIOMA CELLS. M. IKEDA*, C. YAMAZAKI, M. MIKUNI AND K. TAKAHASHI. Department of Mental Disorder Res., Natl. Inst. of Neurosci., NCNP, Kodaira, Tokyo 187, Japan

Neurotransmitters regulate the transcription of genes and may be involved in the modulation of cellular functions. Previously, we have found that serotonin induced intracellular Ca²⁺ mobilization in rat C6BU-1 glioma cells through the stimulation of 5HT₂ receptors. To better understand the effect of serotonin on transcriptional control of genes, it is important to know its effect on transcriptional factors. Using gel shift assay, we detect the increases of AP-1 and CRE DNA bindings in C6BU-1 cells with serotonin treatment. The affinity and/or levels of protein binding to the AP-1 element was increased in nuclear extracts isolated from C6BU-1 cells treated for 4hr. with serotonin (10 μM). The CRE DNA binding was also increased after 4hr. of serotonin treatment. The bindings of proteins to the AP-1 and CRE element were shown to be specific in gel shift assays utilizing competitor DNAs. These inductions of DNA bindings were blocked by pretreatment of ketanserin. These findings suggests that the activities of AP-1 and CRE DNA binding in C6BU-1 cells may be modulated by the stimulation of 5HT₂ receptors.

5-HT_{1A} AND GABA_B RECEPTORS COUPLE TO THE SAME PERTUSSIS TOXIN SENSITIVE G PROTEIN IN HIPPOCAMPAL AREA CA3. D. Y. Okuhara* and S. G. Beck. Department of Pharmacology, Loyola University Chicago, Maywood, IL. 60135.

The activated 5-hydroxytryptamine (5-HT) receptor 5-HT_{1A} hyperpolarizes hippocampal pyramidal CA3 and CA1 cells through an increase in an inward rectifying potassium conductance. However, 5-HT has a greater efficacy and lower EC₅₀ value in area CA3 as compared to area CA1. In area CA1, the activated 5-HT_{1A} and GABA_B receptor increase potassium conductance through the same Pertussis toxin sensitive G protein. An investigation was conducted to determine if the 5-HT_{1A} and GABA_B receptors also couple to the same Pertussis toxin sensitive G protein in area CA3. Male Spague-Dawley rats were bilaterally injected with either saline or 2-4 ug Pertussis toxin into the lateral ventricles. After three to five days, the rats were sacrificed and hippocampal slices prepared for *in vitro* electrophysiological recording. In cells taken from saline treated animals, there was no significant difference in the baclofen and 5-HT elicited hyperpolarizations (5-HT -13.7 ± 1.7 mV, mean ± SEM, n=3; baclofen -13 ± 0.6 mV, n=3). Pertussis toxin treatment significantly (p < 0.001) attenuated the 5-HT induced hyperpolarization (-1.3 ± 0.8 mV, n=8) and baclofen induced hyperpolarization (-1.9 ± 0.5 mV, n=8) as compared to saline treated animals. There was no significant difference between the baclofen and 5-HT elicited hyperpolarization in Pertussis treated cells. Under voltage clamp conditions, the 5-HT and baclofen induced outward currents were not additive. These results suggest the 5-HT_{1A} and GABA_B receptors couple to the same Pertussis toxin sensitive G protein in hippocampal area CA3. Supported by USPHS NS28512 and MH 00880

5HT_{1A} RECEPTORS (5HT_{1AR}) EXPRESSED IN XENOPUS OOCYTES CAN COUPLE EITHER POSITIVELY OR NEGATIVELY TO DIFFERENT ISOFORMS OF ADENYLYL CYCLASE (AC) OR PHOSPHOLIPASE C (PLC) THROUGH G-PROTEIN β SUBUNITS. Y. Uezono*, C. Min, J. Bradley, C. Chavkin#, N. McCarty, M. Quick, J.R. Riordan@, H.A. Lester, K. Zinn and N. Davidson. Division of Biology, Caltech, Pasadena, CA 91125; #Dept. of Pharmacol. SJ-30, Univ. of Washington, Seattle WA 98125; @Hospital for Sick Children, Toronto, Ontario, Canada.

We have reported that the A-kinase-activated Cl⁻ channel encoded by the cystic fibrosis transmembrane conductance regulator gene (CFTR) can act as a reporter for changes in cAMP concentration in *Xenopus* oocytes (Soc. Neurosci. Abstr. 18:106, 1992). In oocytes injected with CFTR cRNA, we can differentiate between cAMP changes and PLC activation by measuring currents from CFTR and endogenous Ca²⁺-activated Cl⁻ currents, respectively. 5HT_{1AR}s are reported to couple to Gi-proteins and thus inhibit AC. However, in oocytes coinjected with cRNAs for the CFTR, 5HT_{1AR} and adrenergic β₂ receptor, activation of the 5HT_{1AR} enhances, instead of inhibiting, the β₂-induced CFTR current. We believe that this effect is through Gβγ and that oocytes contain one of the isoforms of AC for which Gβγ subunits enhance the stimulation of AC by Gαs subunits. In the present case, the Gβγ subunits are activated by agonist stimulation of the 5HT_{1AR}. The effect is augmented two fold by coinjection of cRNA for AC type II, but not AC type III, as expected given this interpretation. Coinjection of cRNA for the Gαz subunit abolishes the 5HT_{1AR} enhancement by scavenging the liberated Gβγ, and an 80% inhibition of β₂-induced CFTR current due to the usual action of Gi is revealed.

PLCβ2 is reported to be activated by Gβγ. In agreement with this, coexpression of PLCβ2 and 5HT_{1AR} results in a 5HT-induced Ca²⁺-activated Cl⁻ current. Thus, depending on the effector subtypes present and the network of interactions of Gα and Gβγ subunits, agonist activation of a particular receptor will have different effects. FUNCTIONAL EXPRESSION OF 5-HT_{1A} RECEPTORS IN EMBRYONIC GLIAL CELLS

J. Liu*, R.P. Hellendall and J.M. Lauder. Dept. of Cell Biol. & Anat., Univ. N.C., Chapel Hill, NC 27799-7090.

These studies were designed to determine whether 5-HT_{1A} receptors, expressed by glia in the vicinity of developing 5-HT neurons or their axons, regulate synthesis of the serotonergic growth factor, S-100β. Purified glia (PGLIA) were prepared from embryonic day 14 (E14) rostral raphe (GRR) or substantia nigra (GSN) and cultured in 10% fetal calf serum + BME. At 2 days *in vitro* (DIV), cultures were switched to serum-free medium (BME + ITS + 1%BSA) and grown for another 3-6 days. Immunocytochemistry revealed that both 5-HT_{1A} receptors and S-100β were maximally expressed between 5-8 DIV. Cultures were treated at 5 DIV with 10 nM 8-OH-DPAT to stimulate 5-HT_{1A} receptors. Effects of DPAT on S-100β protein and mRNA were quantified by immunobinding and *in situ* hybridization assays. cAMP was measured by an ¹²⁵I-radioimmunoassay. Exposure to DPAT elevated cAMP, and differentially regulated S-100β mRNA and protein in GRR and GSN. These results indicate that embryonic glia from RR and SN express functional 5-HT_{1A} receptors, but respond differently to agonist. This raises the possibility that activation of glial 5-HT_{1A} receptors could differentially regulate neurotrophic activity for developing 5-HT neurons in the vicinity of their cell bodies and axons.

639.12

THE EFFECT OF PHORBOL ESTERS ON 5-HT_{1A} RECEPTOR FUNCTION IN RAT HIPPOCAMPAL SLICES. Y. Chen¹, K.A. Berg², J.M. Danley¹ and W.P. Clarke^{1*}. Departments of Pharmacology¹ and Anesthesiology², Mount Sinai School of Medicine, CUNY, New York, NY 10029.

Activation of the 5-HT_{1A} receptor in rat hippocampus elicits two distinct responses: inhibition of adenylyl cyclase activity and an increase in K⁺ conductance (which causes cell hyperpolarization). In CHO cells transfected with the human 5-HT_{1A} receptor, activation of protein kinase C (PKC) with phorbol esters phosphorylates and desensitizes the 5-HT_{1A} receptor (Raymond, 1991). To investigate the PKC mediated desensitization of responses coupled to the 5-HT_{1A} receptor in cells which naturally express the 5-HT_{1A} receptor, we have developed a method to measure 5-HT_{1A} mediated inhibition of forskolin-stimulated cAMP accumulation (FScA) in rat hippocampal slices maintained under similar conditions as those used to measure hyperpolarization of pyramidal cells.

Incubation of hippocampal slices (250 μ) with 5-carboxamidotryptamine (5-CT, 15 min) reduced FScA (E_{max} = 30-50%; EC₅₀ = 4 nM). The response to 100 nM 5-CT was blocked by spiperone (100 nM) and did not occur in slices incubated in the absence of O₂. 5-CT hyperpolarized CA1 pyramidal cells in hippocampal slices (400 μ) with an EC₅₀ of 4 nM and an E_{max} of 11 mV. Treatment (15 min) of hippocampal slices (250 μ) with phorbol 12-myristate 13-acetate (PMA, 100 nM) or phorbol 12,13-dibutyrate (PDBu, 100 nM) produced translocation of PKC activity and potentiated FScA, but did not reduce inhibition of FScA by 5-CT (100 nM). The inactive phorbol ester 4α-phorbol 12,13-didecanoate (4αPDD, 1 μM) did not alter FScA or the inhibition by 5-CT. Treatment with 100 nM PMA or PDBu for up to 1 hr did not reduce the 5-CT (100 nM) induced hyperpolarization, however, larger doses of PDBu (1 μM; 15 min) reduced the hyperpolarization to 5-CT (>90%). These results suggest that activation of PKC in hippocampal slices, as in CHO cells, may desensitize the 5-HT_{1A} receptor. (Supported by USPHS HD 26437; MH 48125; GM 34852).

639.13

G-PROTEIN ACTIVATION BY HUMAN 5-HT_{1A} OR 5-HT₂ RECEPTOR IS RELATED TO ITS EXPRESSION LEVEL F. van Huizen¹, N.J. Stam² and P. Vanderheyden¹. Dept. of ¹Neuropharmacology and ²Biotechnology and Biochemistry, Organon Intl, B.V., P.O. Box 20, 5340 BH Oss, The Netherlands.

Swiss 3T3 cells were stably transfected with the human 5-HT_{1A} or 5-HT₂ receptor genes (Stam et al, *Eur. J. Pharmacol.-Mol. Pharmacol. Section*, 227:153-162, 1992). By limiting dilution, single cell clones were obtained, which displayed different levels of receptor number. [³H]GTP binding was performed on frozen cell pellets by incubation in the presence of 5-HT at room-temperature for 5 min followed by centrifugation for 10 min, 18000 rpm, at 4 °C. The pellet was dissolved in 500 µl Soluene and a 400 µl aliquot was mixed with scintillation cocktail. Nonspecific binding was measured by adding 10 µM GppNHp. In the absence of 5-HT, basal binding of [³H]GTP was present in untransfected and, at a higher level, in transfected cells, relative to the number of receptors expressed. Dose-dependent stimulation of [³H]GTP binding by 5-HT was observed in both the 5-HT_{1A}R and 5-HT₂R transfected cells, but the higher the expression level the higher the potency and efficacy of stimulation by 5-HT. No stimulation was observed in the control 3T3 cells. These data indicate that i) in the absence of agonist a spontaneous receptor-mediated G-protein activation is present and ii) potency and efficacy of G-protein activation by agonist is dependent on the number of receptors expressed.

INDIVIDUAL DORSAL RAPHE (DR) NEURONS PROJECT BILATERALLY TO THE ROSTRAL RETICULAR THALAMIC NUCLEUS IN RAT. K.L. Simpson, T.M. Fisher, R.C.S. Lin, B.D. Waterhouse, J.K. Chapin, and G.C. Salmoiraghi^{*}. Department of Physiology and Biophysics, Hahnemann University, Philadelphia, PA 19102.

Monoaminergic and cholinergic projections from the brainstem are known to innervate the reticular thalamic nucleus (RT). It has been suggested that the cholinergic and noradrenergic projections control the oscillatory state of the thalamocortical network by modulating the activity of the RT. However, no function has been ascribed to the serotonergic (5-HT) input to the RT. Since the raphe nuclei contain the majority of 5-HT neurons found in the brain, the aim of this study was to characterize the organization of DR projections to the RT in order to gain insight into the function of this probable 5-HT pathway. Specifically, we examined the ipsi- vs contralateral distribution of DR efferents to the RT, the degree of collateralization of individual DR neuron efferents, and topography of cells projecting from the DR to the rostral RT. Bilateral injections (0.7 to 1 µl) of different fluorescent retrograde tracers were placed into a functionally identified zone of the rostral RT in anesthetized rats (n=4). Labeled cells observed in the caudal 2/3 of the DR were located in the dorsomedial region of the nucleus and distributed equally on both sides of the midline. This site overlaps a region of the DR previously shown to contain a dense concentration of 5-HT containing neurons. Although sparse labeling was seen in the ventral aspect of the DR, no label was observed in the lateral wing region. In every case studied, the majority (~85%) of the retrogradely labeled DR cells were double-labeled. In the locus coeruleus (LC) and in cholinergic nuclei, such as the parabrachial (PB), laterodorsal tegmental (LDT), and pedunculopontine tegmental (PPT) nuclei, labeled cells were found predominantly ipsilaterally to the injection site. Double-labeled LC, PB, LDT and PPT cells were rarely observed. In conclusion, the projections from individual DR cells to RT are highly collateralized and provide for bilateral innervation of the rostral RT. This pattern is in striking contrast to the predominantly unilateral projection pattern of the LC, PB, LDT and PPT nuclei to RT. Such bilateral input from single raphe neurons to the RT may provide the anatomical substrate for a bilateral, synchronizing role of this probable 5-HT projection in regulating the functional state of the thalamocortical network. *NIDA DA05117 to BDW and NIH NS29161 to RCSL.*

ANOREXIC MUTATION CAUSED ABNORMAL DEVELOPMENT OF MONOAMINERGIC NEURONS IN MICE. J. Son^{*}, H. Baker, N. Min, D. Park, T. Houpt, C. Peng and T. Joh. Lab. of Molec. Neurobiol., Cornell Univ. Med. Coll., Burke Med. Res. Inst., White Plains, NY 10605.

In rodents, neonatal suckling is an essential behavior for normal mammalian development and continues until 10 to 15 days postnatally. Subsequent transition to adult ingestive behavior occurs while monoamine neurotransmitter systems are maturing. Pharmacological manipulations have revealed serotonergic influence on suckling behavior. Interestingly, an autosomal recessive lethal mutation in mice was identified which caused starvation in preweaning mice due to suckling dysfunction. In addition, the anorexia mice (*anx/anx*) showed distinct phenotypic characteristics such as, retarded growth, emaciated appearance and behavioral dysfunction including body tremors, hyperactivity, headweaving and uncoordinated gait. The anorexic mutation has been located close to pallid (*pa*) locus on mouse chromosome 2.

We examined catecholaminergic tyrosine hydroxylase (TH) and serotonergic tryptophan hydroxylase (TPH) expression by immunohistochemistry and in situ hybridization to delineate any abnormality in monoaminergic innervation and its expression in anorexia mutant mouse brains. We found strikingly abnormal innervation by serotonergic fibers in various brain regions and apparently normal distribution of TH. In addition, expression and binding affinity studies of serotonin receptors will be presented.

640.2

SEROTONIN TERMINALS FORM EXCITATORY-TYPE SYNAPSES ON NEURONS PROJECTING TO THE NUCLEUS ACCUMBENS OR CONTAINING DOPAMINE IN THE VENTRAL TEGMENTAL AREA. E.J. Van Bockstaele^{*}, D. Cestari and V.M. Pickel, Dept. of Neurol. & Neurosci., Cornell Univ. Med. Coll., New York, N.Y. 10021.

Serotonin activates mesolimbic neurons in the ventral tegmental area (VTA; Guan and McBride, *Brain Res. Bull.*, 23, 1989). Thus, we combined immunoperoxidase labeling for 5-hydroxytryptamine (5-HT; serotonin) with silver enhanced retrogradely transported protein gold particles in the same section of tissue to determine whether 5-HT terminals directly contact ventral tegmental area neurons that project to the nucleus accumbens in the rat brain. By light microscopy, thick and non-varicose or thin and beaded 5-HT-ir processes were interspersed between retrogradely labeled perikarya and proximal dendrites. By electron microscopy, 5-HT immunoreactivity was seen primarily in unmyelinated axons and axon terminals. The 5-HT-ir terminals contained a mixed vesicle population (small, clear and large dense core vesicles) and were 0.3 µm to 1.4 µm in cross sectional diameter. 5-HT-ir terminals preferentially formed asymmetric junctions with retrogradely labeled perikarya and dendrites, but formed symmetric contacts with other unlabeled neurons. A second set of experiments combined immunoperoxidase labeling for 5-HT with immunogold labeling for the catecholamine synthesizing enzyme, tyrosine hydroxylase (TH). This demonstrated that 5-HT-ir terminals also preferentially formed asymmetric junctions with TH-labeled, presumably dopaminergic, neurons in the ventral tegmental area. These findings suggest that formation of the asymmetric, excitatory-type synapses by 5-HT terminals may be limited to a subpopulation of neurons in the ventral tegmental area that project to the nucleus accumbens and contain dopamine. Supported by NS09100-01, MH40342 and 00078.

SYNAPTIC LOSS IN THE CEREBRAL CORTEX FOLLOWING INJECTIONS OF PCPA IN THE RAT. N. Okado^{*}, L. Cheng, and S. Hamada. Dept. Anat., Inst. Basic Med. Sci., Univ. Tsukuba, Tsukuba, Ibaraki 305, Japan.

To know a role of serotonin fibers in the cerebral cortex, p-chlorophenylalanine (PCPA) was injected in the young rat (6 weeks after birth). Following four times injections of 200 mg, 400 mg or 800 mg PCPA (per kg weight) for a week synaptic structures in the sensory cortex were examined, and the density of synapses was determined in laminae I, IV and V. The density of axodendritic synapses in lamina I decreased in a dose-dependent fashion: 19 %, 25 % and 34 % of synapses were eliminated following injections of 200 mg, 400 mg and 800 mg PCPA, respectively. In lamina IV the density of axodendritic and axosomatic synapses decreased following injections of PCPA, and the magnitude of decrement of synapses was similar to that of lamina I. In lamina V the reduction rate was smaller compared to those found in laminae I and IV. Although fine serotonin positive fibers were frequently found in all the laminae by the use of an immuno-electron microscopic technique, few of them had the synaptic structure. Virtually all the synapses disappeared following injections of PCPA seemed non-serotonergic synapses. A similar result has shown following injections of p-chloroamphetamine.

DEVELOPMENT OF 1-METHYL-4-(NAPHTHOTHIAZOLYL)-METHYL-PIPERAZINE DERIVATIVES HAVING IN VITRO 5-HT₃ ACTIVITY. R. Perrone, F. Berardi, N. Colabufio, V. Tortorella, E. Daniele, S. Govoni, V. Olgiati*, M. Logranò#, Pharmacochimistry and #Pharmacobiology Depts., Univ. of Bari; *R&D Dept. Kabi-Pierrel, Milan; #Inst. Pharmacol. Sci. Univ. of Milan, Italy.

The effects of 5-HT₃ receptor antagonists in CNS include control of emesis, modulation of the inhibition of K⁺ stimulated acetylcholine release, reduction of dopamine release elicited by systemic administration of addictive substances. In particular 5-HT₃ receptors appear to modulate mesolimbic dopaminergic systems. These observations have fostered the interest in the development of new 5-HT₃ receptor antagonists and of structure-activity studies. In the present investigation the activity of (naphthothiazolyl)-methyl-piperazines on 5-HT₃ as well as on other serotonergic and dopaminergic receptors were investigated by in vitro binding assays. Serotonin receptors were evaluated using the following tritiated ligands and tissues: 5HT₁, serotonin, hippocampus; 5-HT₂, ketanserin, cerebral cortex; 5-HT₃, BRL 43694, cerebral cortex. D₂ receptors were studied using rat striatal membranes and tritiated spiperidol. Among the compounds tested at this time 1-methyl-4-(dihydronaphthothiazolyl)-methyl-piperazine and 1-methyl-4-(benzothiothiazolyl)-methyl-piperazine presented an IC₅₀ in the nanomolar range (10-50) against 5-HT₃ receptors. The introduction of a methoxy group in the benzene ring of the dihydronaphthothiazolyl moiety abolished the 5-HT₃ activity. The compounds appear to be a new class of 5-HT₃ ligands.

DIFFERENTIAL ANTAGONISM OF 5-HTP-INDUCED PROLACTIN RELEASE. P. J. Little² and C. M. Kuhn. Dept. of Pharmacology, Duke Univ. Med. Ctr. Durham, NC 27710.

Serotonin (5-HT) is an important regulator of prolactin (PRL) secretion in rats. Studies using specific 5-HT receptor agonists have shown that multiple 5-HT receptors may be involved in the control of PRL release. To characterize the 5-HT receptor subtype(s) involved in physiological control of PRL release we utilized specific 5-HT antagonists to block the release of PRL in rats treated with fluoxetine (Fluox, 5-HT uptake inhibitor) and 5-HTP (5-HT precursor).

Male rats were injected with fluoxetine (10 mg/kg sc) and the specific 5-HT₂ antagonists, ketanserin and LY 53857 or saline 30 min prior to administration of 5-HTP (50 mg/kg, ip). Thirty min after 5-HTP treatment, rats were killed, blood was collected for serum and PRL levels determined by RIA. LY 53857 completely abolished Fluox+ 5-HTP-stimulated PRL release. Ketanserin significantly attenuated, but did not abolish Fluox+ 5-HTP-stimulated PRL release. An even clearer difference between ketanserin and LY 53857 was observed to the blockade of m-CPP (5-HT_{1B/1C})-induced PRL release. LY 53857 significantly inhibited m-CPP-induced PRL release, whereas ketanserin did not block the response of m-CPP.

In conclusion, 5-HT₂ receptors appear to be involved in 5-HT-mediated PRL release. Additionally, the strategy of using selective antagonists rather than selective agonists represents a useful tool in characterizing the nature of 5-HT regulation of PRL release. (Supported by DA-02739 and MH-15177).

SEROTONIN IS RELEASED BY SMALL CELL LUNG CARCINOMA CELLS AND ACTS AS A MITOGEN. L.N. Vicentini¹, A. Codignola², M.G. Cattaneo¹, P. Clementi^{1,2} and E. Sher²
¹Dept. of Pharmacology, ²CNR Center of Cytopharmacology, Univ. of Milano, Milano, Italy.

Small cell lung carcinoma (SCLC) is an aggressive human tumor, often associated with tobacco smoking; it synthesizes and releases hormones and neuropeptides (including cholecystokinin, bombesin, vasopressin, neurotensin) for some of which an autocrine role on cell proliferation has been proposed. Membrane receptors and ion channels possibly controlling hormone release are expressed by SCLC cell lines. In particular, we have recently revealed the presence of nicotinic receptors subtypes and of three distinct voltage-dependent Ca²⁺ channels in GLC8 cells (see Carbone et al, this meeting). We have found that serotonin (5HT) is present at significant levels in three human SCLC cell lines: GLC8, NCI-H-69 and NCI-H-592. Nicotine induces a dose- and Ca²⁺-dependent 5HT release from these cells which is sensitive to the action of the nicotinic antagonist mecamylamine. Moreover depolarization of the cells with high KCl also induces a Ca²⁺-dependent 5HT release. Addition of exogenous 5HT to the culture medium induces a dose-dependent increase in their proliferation rate. 5HT-stimulated cell proliferation is antagonized by methiopepine and metergoline, while sumatriptan possesses a stimulatory effect. In conclusion, we have shown that 5HT is present in SCLC cell lines and is able to act as a mitogen for these cells. Furthermore, 5HT is released in response to depolarization and activation of nicotinic receptors. This "classic" neurotransmitter should be added to the list of autocrine growth factors produced and released by SCLC cells.

KINETICS OF TRYPTOPHAN HYDROXYLASE AND AROMATIC-L-AMINO ACID DECARBOXYLASE IN HUMAN CARCINOID TUMORS. J.A. Gilbert*, L.A. Bates, and M.M. Ames, Div. of Oncology Res., Mayo Clinic & Foundation, Rochester, MN 55905

The carcinoid tumor is a relatively rare neuroendocrine malignancy whose hallmark is excessive production of serotonin (5-hydroxytryptamine; 5-HT). 5-HT is synthesized by conversion of tryptophan (trp) to 5-hydroxy-trp (5-OH-trp) by trp hydroxylase and decarboxylation of 5-OH-trp by aromatic-L-amino acid decarboxylase (AAAD). In our efforts to develop agents selective for the therapy of carcinoid tumors, we have characterized trp hydroxylase and AAAD in individual human carcinoid tumors. Enzyme assay reaction products were quantitated by HPLC with radiometric or fluorescence detection. Kinetics were determined in twelve human carcinoid tumors, five obtained with adjacent normal tissue. Trp hydroxylase was detected in all twelve tumors ($K_m=189 \mu M \pm 14.7$ [mean \pm S.E.]; $V_{max}=2.66$ nmol/h/mg protein ± 1.02). AAAD was detected in eleven tumors ($K_m=47 \mu M \pm 4.8$; $V_{max}=11$ nmol/min/mg protein ± 1.4). The K_m of trp hydroxylase was comparable in carcinoid and corresponding normal tissue ($142 \mu M \pm 10$ vs. $205 \mu M \pm 28$; $n=4$), as was the V_{max} (5.14 nmol/h/mg protein ± 2.72 vs. 5.05 nmol/h/mg protein ± 0.49). The K_m of AAAD was comparable in carcinoid and normal tissue ($35 \mu M \pm 3.1$ vs. $48 \mu M \pm 8$; $n=5$); carcinoid V_{max} was 60-fold higher (15 nmol/min/mg protein ± 2.5 vs. 0.25 nmol/min/mg protein ± 0.04). The large V_{max} of carcinoid AAAD was the primary difference in 5-HT biosynthetic enzyme kinetics in tumor vs. normal tissue. Supported in part by grant CA 31224, NCI, DHHS.

BACTERIAL EXPRESSION OF RABBIT TRYPTOPHAN HYDROXYLASE: THE RECOMBINANT ENZYME IS A SUBSTRATE FOR THE cAMP-DEPENDENT PROTEIN KINASE. K.E. Vrana, P.J. Rucker, S.C. Kumer and S.L. Vrana¹. Dept. Physiology and Pharmacology, Bowman Gray School of Medicine, Winston-Salem, NC 27157-1083.

Tryptophan hydroxylase (EC 1.14.16.4; TPH) is the rate-limiting enzyme in serotonin biosynthesis. A full-length cDNA clone for rabbit TPH (Grenett *et al.*, PNAS **84**, 5530, 1987) was engineered and subcloned into a bacterial expression vector (under the control of a T7 bacteriophage promoter). Expression of this gene in the protease-deficient strain of bacteria, BL21(DE3), produced TPH-specific immunoreactive protein. A specific radioenzymatic assay for TPH was developed based on the release of ³H₂O followed by charcoal adsorption of substrates and products. Using this procedure, the recombinant protein displayed significant amounts of TPH activity. The recombinant TPH was expressed at levels representing approximately 1% of the total bacterial protein. Treatment of the recombinant protein (in bacterial extracts) with the purified catalytic subunit of the cAMP-dependent protein kinase and [γ -³²P]-ATP resulted in phosphorylation of the TPH. This represents the first bacterial expression system for native TPH and provides a means of generating and purifying large amounts of this important enzyme. Moreover, these experiments establish that TPH is a direct substrate for the cAMP-dependent protein kinase.

MELATONIN IN AN INSECT NERVOUS SYSTEM: DIEL CHANGES ASSOCIATED WITH PHOTOPERIOD CUES. Charles E. Linn Jr.*, Wendell L. Roelofs. Dept. of Entomology, New York State Agric. Expt. Station, Cornell Univ., Geneva, NY 14456.

Melatonin has been demonstrated to have a prominent role in the regulation of circadian-based activities in many vertebrates. The possible role of this compound in invertebrates is less well known, with only scattered reports of its occurrence and possible action relating to reproductive activities. As part of our program to understand the neuroendocrine control of pheromone perception in male moths (Lepidoptera) we are using HPLC with electrochemical detection to understand the dynamics of biogenic amine metabolism in nervous and non-nervous tissues of the cabbage looper moth. We have shown that octopamine and serotonin can affect male response thresholds for sex pheromone and levels of locomotor activity, and that levels of dopamine, serotonin, and octopamine decrease in dynamic ways in the nervous system of male moths as a function of photoperiod cues and associated changes in locomotor and mating activities during the dark. We now have demonstrated that injection of serotonin leads to increases in melatonin, indicating that the compound can be produced by the insect. We have further demonstrated that melatonin is found naturally in the nervous system of this insect, that its level increases significantly in the protocerebrum and thoracic ganglia, from undetectable levels in the light to levels of 3 to 10 pmols/tissue in the latter half of the 10 hour dark period. These increases parallel decreases in serotonin levels in these tissues. We are investigating the potential physiological and behavioral role of this compound in the circadian-based locomotor and mating activities of this insect.

SEROTONINERGIC NEUROHEMAL SYSTEMS ASSOCIATED WITH CEPHALIC NERVES IN THE COLORADO POTATO BEETLE.

T. van Haefen¹ and H. Schooneveld. Dept. of Entomology, Wageningen Agric. Univ., Binnenhaven 7, 6709 PD Wageningen, The Netherlands.

¹ Present address: Dept. of Anatomy, Vrije Universiteit, Van der Boechorststraat 7, 1081 BT Amsterdam, The Netherlands.

Serotonin has been shown to exert physiological effects on certain visceral muscles of the Colorado potato beetle, *Leptinotarsa decemlineata*. These physiological effects can be explained only by assuming that serotonin is released into the hemolymph as a neurohormone. Release of serotonin in most species occurs through specialized neurohemal organs, usually the corpora cardiaca. However, this is not the case in the Colorado potato beetle. The corpora cardiaca in this species could not be shown to contain serotonin. Instead, another release system is in operation: a diffuse neurohemal system in the head comprising a frontomedial and a lateral neurohemal plexus. The lateral system is formed by axons from two bilateral pairs of neurons in the frontal margin of the subesophageal ganglion that enter the ipsilateral mandibular nerve, emerge from this nerve at some distance of the ganglion and cover all branches of the mandibular nerve with a dense plexus of immunoreactive axon swellings. The frontomedial system is formed by axons from two large neurons in the frontal ganglion that enter the ipsilateral frontal connectives, emerge from these connectives, and form a network of axon swellings on the labrofrontal, pharyngeal, and antennal nerves and on the surface of the frontal ganglion. Electron microscopy demonstrated that all axon swellings are located outside the neural sheaths of the nerves, and hence in direct contact with the hemolymph. Many swellings are closely associated with the muscles of mandibles, labrum, and anterior pharynx, as well as with the salivary glands. Therefore, it seems likely that these organs are under serotonergic control.

HYPOTHALAMIC-PITUITARY-GONADAL REGULATION: STEROID RECEPTORS

FURTHER EXPERIMENTS ON ESTROGEN RECEPTOR-IMMUNOREACTIVITY IN DENDRITES AND AXON TERMINALS IN FEMALE GUINEA PIG BRAIN USING TWO ANTIBODIES. I.C. Turcotte* and J. D. Blaustein. University of Massachusetts, Neuroscience and Behavior Program and Psychology Department, Amherst, MA 01003.

We have observed estrogen receptor-immunoreactivity (ER-IR) in the female guinea pig hypothalamus within dendrites and axon terminals using the H 222 antibody directed against the ligand binding region of the receptor. In order to confirm the presence of ER-IR in these atypical hypothalamic sites, we used an antibody directed against a distinct epitope on the estrogen receptor (the ER 21 antibody directed against the N-terminus).

At the light microscopic level, immunostaining with ER 21 was similar to H 222-immunostaining with densely labeled nuclei and more lightly labeled cytoplasmic processes. At the ultrastructural level, ER 21-immunoreactivity also was seen in dendrites and axon terminals.

In further immunocytochemical studies using the H 222 antibody, we observed ER-IR in dendrites and axon terminals of a major hypothalamic target site, the midbrain central gray. This suggests that this ultrastructural finding is not limited to the hypothalamus. Furthermore, we have observed ER-IR in axon terminals and distal dendrites within the hypothalamus using two antibodies directed against very different domains on the estrogen receptor. This suggests that the ER-IR that we have observed in extranuclear subcellular locations within the hypothalamus is unlikely to be only a cleaved portion of the receptor.

TISSUE-SPECIFIC CHANGES OF ESTROGEN RECEPTOR PROTEIN IN THE PREOPTIC AREA OF THE BRAIN AND UTERUS DURING THE RAT ESTROUS CYCLE. Y. Zhou, P.J. Shughue and D.M. Dorsa*. Departments of Pharmacology and Psychiatry and Behavioral Sciences, University of Washington, and GRECC, VAMC, Seattle, WA 98195.

The regulation of estrogen receptor plays a vital role in female reproduction. Previous studies in our laboratory have shown that the levels of estrogen receptor (ER) mRNA in the preoptic area of the rat brain varied during the estrous cycle, being the highest on estrus and metestrus and low on diestrus and proestrus. The present study examined the changes of ER protein in the preoptic area and uterus during the estrous cycle and compared changes in the female brain with the level of ER in the male. Adult female rats were sacrificed throughout the cycle. Preoptic area and uterine tissue collected. Additional intact male rats were also sacrificed. ER protein was detected by Western blot and measured by densitometric analysis of the resulting autoradiographs. In the preoptic area of the brain, ER protein levels were elevated on estrus, highest during metestrus, and attenuated during diestrus and proestrus. A comparison of the male and female preoptic area revealed that the level of ER protein was significantly lower in the male than at any stage of the female cycle. In contrast, the level of uterine ER was low during metestrus, diestrus and estrus and highest on proestrus. The results suggest that the level of ER protein in the preoptic area changes during the estrous cycle and is sexually dimorphic. These changes of ER protein paralleled previously measured changes of ER mRNA in the preoptic area. While the level of ER protein changed in the uterus during the cycle, the pattern of change was different from the changes detected in the brain. These observations suggest that the changes of ER protein are tissue-specific. The regulatory mechanism involved is under further investigation. Supported by the VA and NS20311.

ESTROGEN RECEPTOR GENE EXPRESSION IS NOT REDUCED IN THE FOREBRAIN OF AGING FEMALE RATS. M.A. Miller*, P.E. Kolb, B. Planas, and M.A. Raskind. Department of Psychiatry and Behavioral Sciences, University of Washington, Seattle, WA 98195.

Aging is associated with an alteration in the sensitivity of the brain to gonadal steroids. Both cell nuclear and cytosolic estrogen binding are reduced in the brain with age suggesting that the age-related loss of steroid responsiveness may result in part from a loss of estrogen receptors. Here we have used in situ hybridization and quantitative autoradiography to test the hypothesis that expression of the estrogen receptor gene is reduced with age. Fischer 344 female rats (3 mo, 11 mo, 20 mo; n=5-7/group) were ovariectomized and implanted for 2 weeks with sham capsules or Silastic capsules filled with estradiol (plasma E levels: 34±1.8, 33±1.5, 36±2 pg/ml for young, middle-aged, and old rats, respectively). Sections through the forebrain were hybridized with a ³⁵S-labeled 850 bp cRNA probe complementary to estrogen receptor mRNA and then apposed to B-Max Hyperfilm. A computerized image analysis system was used to measure the relative optical densities over five forebrain regions in the film autoradiographs.

GROUP	AVP-r	MPO	StHy	BSTL-d	BSTL-v
OVX 3 mo	.88±.02	.80±.05	.64±.03	.49±.04	.42±.04
11 mo	.89±.04	.83±.06	.69±.04	.57±.04	.38±.03
20 mo	.80±.05	.80±.03	.60±.06	.44±.03	.34±.02
OVX 3 mo	.56±.03	.48±.06	.30±.04	.25±.04	.14±.02
+ E 11 mo	.56±.07	.57±.04	.44±.05	.41±.03	.23±.03
20 mo	.54±.07	.53±.04	.35±.04	.30±.04	.19±.03

Estrogen receptor gene expression in ovariectomized animals did not differ with age in any region studied. Estradiol treatment reduced estrogen receptor mRNA levels in all regions measured in all age groups. These results indicate that estrogen receptor gene expression in forebrain regions does not decline with age and suggests that factors other than reduced expression of the estrogen receptor gene account for decreased sensitivity to steroids in aging animals.

641.4

DISTRIBUTION OF THE ANDROGEN RECEPTORS IN VASOPRESSIN AND OXYTOCIN IMMUNOREACTIVE NEURONS IN RAT BRAIN. L. Zhou, J. D. Blaustein, G. J. DeVries*. Neurosci. Behav. Prog., Dept. of Psychol., Univ. of Mass., Amherst, MA 01003.

Vasopressin immunoreactive (AVP-ir) cells in the bed nucleus of stria terminalis (BST) and medial amygdaloid nucleus (MA) are very responsive to gonadal hormones. These cells lose their AVP immunoreactivity and AVP messenger RNA labeling after gonadectomy. Testosterone treatment can reverse these changes, acting via androgen as well as estrogen receptor-mediated mechanisms. Although AVP-ir cells are also immunoreactive to estrogen receptors, it is unclear whether this is also true for androgen receptors. To answer this question, brains of intact males were stained immunocytochemically for AVP as well as androgen receptors. In the BST and MA, almost all AVP-ir cells contained androgen receptors immunoreactivity (AR-IR). In the supraoptic nucleus and suprachiasmatic nucleus, none of the AVP-ir cells contained AR-IR. In the paraventricular nucleus (PVN), about half of the AVP-ir and oxytocin-immunoreactive (OT-ir) cells in the medial parvocellular part of PVN contained AR-IR, but no AR-IR was found in AVP-ir and OT-ir neurons in other divisions of the PVN. The results suggest that androgens can act directly on AVP-ir cells in the BST and MA to influence AVP expression. Since AVP expression in these cells is more responsive to androgens in males than in females, we also stained the brains of gonadectomized male and female rats that were treated with testosterone to see whether females have a lower proportion of cells that contain AR-IR. However, no sex differences were found in distribution of AR-IR.

641.5

ABSENCE OF ANDROGEN RECEPTORS IN LUTEINIZING HORMONE RELEASING HORMONE (LHRH) IMMUNOREACTIVE NEURONS. X. Huang* and R. E. Harlan. Dept. of Anatomy, Tulane Med. School, New Orleans, LA 70112.

Androgen has a negative feedback effect on reproductive neuroendocrine functions. Previous studies have suggested that this effect is mediated, at least in part, at the hypothalamic level, to regulate the LHRH pulse generator. However, it is not clear whether the action is mediated directly on LHRH neurons or indirectly on neurons that interact with LHRH neurons. The present study was conducted to answer this question, using double immunocytochemistry to localize LHRH and androgen receptors in the same tissue sections. Three adult male and three adult female rats were used. Androgen receptor immunocytochemistry with the PG21-3 antibody (gift of Dr. G. Prins) was performed first, followed by LHRH immunocytochemistry with the LR1 antibody (gift of Dr. R. Benoit). The chromogen for androgen receptor was Nickel-DAB, while the chromogen for LHRH neurons was DAB. Despite the detection of numerous LHRH neurons and large numbers of neurons with androgen receptors, no double-labelled neurons were observed. We conclude that the negative feedback effect of androgen on the central nervous system is mediated by indirect pathway(s), since the absence of androgen receptors within LHRH neurons would rule out any direct genomic actions. We also attempted to characterize potential androgen sensitive neurons. The preliminary results showed that a small percentage of tyrosine hydroxylase immunoreactive neurons in the arcuate nucleus and ventral tegmental area contain androgen receptor, while no forebrain cholinergic neurons have androgen receptors. Thus, the vast majority of neurons with androgen receptors are uncharacterized. Supported by NS24148 and DA06194 (R. E. H)

ANDROGEN RECEPTOR IMMUNOREACTIVITY IN BRAIN AND ACCESSORY ORGANS OF REPRODUCTION OF MALE RHESUS MACAQUES, J.V.A. Choate* and J.A. Resko. Dept. of Physiology, Oregon Health Sciences Univ., Portland, OR 97201

Androgens produce their effects by binding to intracellular receptors in target tissues. We studied the distribution of androgen receptor (AR) in brain and in accessory organs of reproduction from male rhesus macaques (n=2) by immunocytochemistry. Fresh tissues were quickly frozen in dry ice-chilled isopentane. Ten μ m sections of brain, prostate (P) and seminal vesicle (SV) were incubated with 5 μ g/ml anti-AR antisera (directed against amino acids 201-222 of human AR; Choate and Resko, *Brain Res.* 597:51, 1992) and visualized using a Vector Elite ABC kit with DAB as the chromogen. Immunopositive neurons were found in the medial preoptic and periventricular nuclei of the hypothalamus, the amygdala and in stromal cells of the P and ductular epithelial cells of P and SV. In all tissues, immunostaining was confined to the cell nucleus. This study agrees with similar observations from other species. Supported by NIH grants T32 HD07133 and HD18196.

641.7

REGULATION OF PROGESTIN RECEPTORS IN RAPHE NEURONS OF STEROID-TREATED MONKEYS C. L. Bethea*, Division of Reproductive Sciences, Oregon Regional Primate Research Ctr., Beaverton, OR 97006.

Progesterone (P) administration to estrogen (E)-primed primates increases prolactin secretion. This effect of P is probably mediated through the CNS since lactotropes do not have progesterin receptors (PR). Recent work from this laboratory colocalized PR in serotonin (5HT) neurons of macaque with double immunocytochemistry (ICC). 5HT is stimulatory to prolactin and may play a role in mediating the action of P. To perform this function, 5HT neurons should show an induction of PR after E-treatment and PR should be maintained during P treatment. This prediction was examined by counting 5HT+ and PR+ neurons in the raphe nuclei of spay, E-treated and E+P treated monkeys. Macaques (n=12) were spayed and treated with a 3 cm E-filled silastic capsule for 28 days or additionally supplemented with a 6 cm P-filled capsule for the last 14 of 28 days. Controls received an empty capsule. At autopsy, pontine blocks were obtained and processed for ICC. Sections at 100 μ m intervals were stained for 5HT (Incstar, 1/2000). The following section was stained with a monoclonal antibody against human PR (B39, 2.5 μ g/ml, gift of G. Greene). Stained cells were counted in the same fields at 4 levels using computer assisted image analysis. The mean number of 5HT+ cells and the average ratio of PR+/5HT+ cells was obtained for the left and right dorsal raphe and the ventral raphe. There was no difference in the number of 5HT+ cells with steroid treatment. There was a significant increase in the PR/5HT ratio with E-treatment and this ratio was unchanged with addition of P. Thus, E induced PR in the raphe nuclei and PR were maintained after 14 days of P-treatment. This data is consistent with the possibility that 5HT neurons mediate the effect of P on prolactin secretion. Supported by HD17269, HD18185, and RR00163.

NEUROENDOCRINE REGULATION: MISCELLANEOUS

642.1

GROWTH HORMONE SECRETAGOGUES MODULATE POTASSIUM CURRENTS IN RAT SOMATOTROPHS. J.E. McGurk*, S.S. Pong, L-Y. Chaung, M. Gall, B. Butler and J.P. Arena. Merck Research Laboratories Rahway, NJ 07065.

Growth hormone releasing peptide (GHRP6) is a synthetic six amino acid peptide that induces growth hormone (GH) release in somatotrophs via a pathway independent of growth hormone releasing hormone. Voltage-clamp recordings were done using the perforated patch technique on somatotrophs identified with the reverse hemolytic plaque assay. In normal ringer GHRP6 (1-1000 nM) induced a transient decrease in outward current elicited by depolarizing pulses (c.f. Leonard *et al.* 1991. *Biophys. J.* 59:254a). Steady-state currents induced by a pulse from -40 mV to 50 mV were reduced by ~36% by 100 nM GHRP6. Reduction in current reached a maximum within 1 min of exposure to GHRP6 but, in most cells, currents recovered to control levels within 5 min even in the continued presence of GHRP6. The non-peptidyl secretagogue L-692,429 (1 μ M) also produced a transient reduction in current similar in time-course and magnitude to GHRP6 (100 nM) while the less active isomer L-692-428 (1 μ M) produced a much smaller reduction. GHRP6-induced reduction in current did not require Ca^{2+} influx, since it was unaffected by Ca^{2+} (500 μ M) in the bath. In addition, GHRP6 reduced outward current when the large conductance Ca^{2+} -activated K^{+} channel was blocked in the presence of TEA (1-3 mM) and Ca^{2+} (500 μ M). It is probable, therefore, that reduction of potassium current is an initial step in GHRP6 transduction.

642.2

INDUCTION OF FOS-LIKE IMMUNOREACTIVITY IN THE RAT ARCUATE NUCLEUS FOLLOWING INTRACEREBROVENTRICULAR (ICV) ADMINISTRATION OF GROWTH HORMONE-RELEASING PEPTIDE (GHRP-6). S.L. Dickson, G. Leng and P.C. Emson.* AFRC Babraham Institute, Cambridge CB2 4AT, UK.

In rats, administration of the synthetic hexapeptide GHRP-6 releases growth hormone (GH) from the pituitary gland both *in vitro* and *in vivo* via a direct action at the pituitary (Bowers *et al.* *Endocrinol.* 114:1537, 1984). Recently, we reported that systemically administered GHRP selectively induces Fos expression in the hypothalamic arcuate nucleus (where the cell bodies of GH-releasing hormone (GRF) neurones are located; Dickson *et al.* *Neurosci.* 53:303, 1993). We sought further evidence for a central site of action by examining the distribution of Fos-like immunoreactivity within the brain following an i.c.v. injection of GHRP. Conscious adult male rats bearing a chronically implanted i.c.v. catheter were given either 1 μ g GHRP (n=5) or an equal volume of artificial cerebrospinal fluid (aCSF; n=4). Ninety minutes following injection, rats were killed and the brains processed for immunocytochemistry using a polyclonal anti-Fos antibody. Dense nuclear staining was observed throughout the ventrolateral arcuate nucleus of GHRP-treated rats (mean \pm SE = 66.0 \pm 7.8 nuclei/section/rat) but not in aCSF-treated controls (mean \pm SE = 0.8 \pm 0.1 nuclei/section/rat). Importantly, in GHRP-treated rats, Fos-like immunoreactivity was absent from other hypothalamic structures. Thus, centrally administered GHRP selectively activates arcuate neurones in an identical manner to that described previously for systemic administration of this peptide. (Research supported by Merck & Co., Inc.).

INTERLEUKIN-2 INHIBITS PULSATILE GROWTH HORMONE SECRETION AT THE LEVEL OF THE BRAIN: MEDIATION IN PART BY SOMATOSTATIN. G.S. Tannenbaum* and A. Beaudet. Departments of Neurology & Neurosurgery and Pediatrics, McGill University, Montreal, Quebec H3H 1P3.

Cytokines have been proposed to mediate cross-talk between the neuroendocrine and immune systems, although the mechanism/site of action remains unclear. In the present study, interleukin-2 (IL-2) mRNA was localized by *in situ* hybridization in the hypothalamus of normal CD-1 mice with moderate to high levels of expression apparent in the medial preoptic/anterior hypothalamic areas as well as in the supra-chiasmatic, paraventricular, ventromedial and arcuate nuclei. We subsequently examined the effect of centrally administered IL-2 on pulsatile growth hormone (GH) secretion and assessed the possible involvement of the hypothalamic peptide somatostatin (SRIF). Free-moving adult male rats bearing intracerebroventricular (icv) and intracardiac cannulae were icv administered rat IL-2 in doses of 15 and 30 units, or the vehicle solution. Central administration of IL-2, at both doses, caused a 3-fold suppression in amplitude of the spontaneous GH pulses and significantly ($P < 0.01$) reduced mean 6-h plasma GH levels, compared to vehicle-injected controls. Passive immunization of IL-2 icv-treated rats with SRIF antiserum reversed the IL-2-induced inhibition of GH pulses and restored mean 6-h plasma GH levels to values similar to those in vehicle-injected controls. These results demonstrate that: 1) IL-2 is produced in brain in areas of relevance to neuroendocrine function; 2) IL-2 exerts potent inhibitory effects on pulsatile GH secretion at the level of the brain; and 3) the blunting of GH pulse amplitude by IL-2 is mediated, at least in part, by increased release of endogenous SRIF. Such a mechanism of IL-2 action in brain may be important for immune-neuroendocrine communication.

642.5

BLOCKER OF NITRIC OXIDE SYNTHASE ATTENUATES WATER INTAKE IN DEHYDRATED RATS. M. Kadekaro*, M. L. Terrell, P. Harmann, V. Bui*, S. Mantz*, E. Kochler*, J. Y. Summy-Long*. Division of Neurosurgery, Univ. of Texas Medical Branch, Galveston, TX, *Dept. of Pharmacology, Pennsylvania State Univ., Hershey, PA.

Nitric oxide synthase (NOS), the synthetic enzyme of nitric oxide (NO), is present in magnocellular neurons of the supraoptic (SON) and paraventricular nuclei (PVN) and their projections to the neural lobe, as well as in the subfornical organ (SFO). These structures participate in the maintenance of body fluid homeostasis by regulating secretion of vasopressin (VP) and oxytocin (OT). NO could, therefore, modulate water balance by influencing activity of neurons at these sites. Our previous studies showed that intracerebroventricular (icv) blockade of NOS by N^G -monomethyl-L-arginine (NMMA) enhances secretion of OT, but not VP, in 24 h water deprived rats (Summy-Long et al. Neurosci. Lett. 1993, in press). This effect occurred in the absence of increased glucose utilization in the neural lobe, indicating removal of an inhibitory mechanism at nerve terminals. Glucose metabolism decreased in the SFO, suggesting an action of NO on thirst mechanisms. We therefore investigated the effects of icv NMMA (500 μ g/5 μ l) on drinking behavior following 24 h of dehydration in male Sprague-Dawley rats ($n=42$). NMMA attenuated water intake (ml/60 min; $p < 0.05$) in dehydrated (8.7 ± 0.6 vs. 7.0 ± 0.5 ml), but not in water sated rats (0.09 ± 0.09 vs. 0.09 ± 0.09 ml; values represent means \pm SEM, $n=10-11$).

These results, in conjunction with our previous studies, indicate that NO promotes rehydration by regulating neural mechanisms controlling drinking behavior and preferential release of VP over OT during dehydration. [Supported by NIH grants NIDS 2R01 NS23055 (M.K.) and HD25498 (J.Y.S-L.).]

642.7

GALANIN GENE EXPRESSION AND PEPTIDE SECRETION IN MtTW-10 PITUITARY CELLS. J.F. Hvide*, D.G. Morrison, I.P. Moore, Jr. and G. Howard. Depts. Anatomy & Neurobiol. and Pharmacol. & Exp. Ther., Univ. of Kentucky, Lexington, KY 40536.

Estradiol (E2) increases galanin mRNA and peptide levels in the rat pituitary. Moreover, mammatropic pituitary tumors (MtT) are induced by long periods of exposure to E2. These transplantable tumors secrete copious amounts of prolactin (PRL) and growth hormone (GH). Our objectives were to 1) determine if galanin is secreted from MtTW-10 cells *in vitro*, and 2) assess whether galanin gene expression in MtTW-10 tumors is stimulated by E2. MtTW-10 tumors (provided by Dr. U. Kim) were transplanted to female Wistar-Furth rats. Three weeks later, rats were ovariectomized or implanted with E2-containing capsules. E2-treated tumor cells were cultured after trypsin dispersion, and hormone secretion was determined after 4 days in culture by RIA. MtTW-10 cells secreted galanin, PRL and GH in a time-dependent manner. Dopamine, GHRH, CRH, LHRH, and TRH failed to alter hormone release during a 3 hr static incubation. Somatostatin (10 and 100 nM) inhibited the secretion of all 3 hormones in a dose-dependent manner. HPLC fractionation of MtTW-10 culture medium showed one major peak of galanin immunoreactivity which coeluted with synthetic rat galanin. E2 increased galanin mRNA levels \approx 50-fold as quantified by solution hybridization. Conclusions: 1) Galanin is secreted from MtTW-10 cells *in vitro* and is inhibited by somatostatin. 2) E2 increases galanin gene expression in MtTW-10 tumors. These data show that MtTW-10 tumors may be a useful model to study the regulation of galanin gene expression, peptide synthesis and secretion. (Supported by DK-45981)

VOLTAGE-DEPENDENT K^+ CURRENTS IN OVINE SOMATOTROPHS AND THEIR FUNCTION IN GH SECRETION. C. Chen*, J. Zhang, D. Wu and I. J. Clarke. Prince Henry's Institute of Medical Research, P. O. Box 152, Clayton, Vic 3168, Australia

To investigate the role of voltage-dependent K^+ currents in the control of GH secretion, nystatin perforated whole-cell recordings were made on ovine somatotrophs identified by post-recording immunocytochemistry. Using Ca^{2+} -free, TTX containing (1 μ M) bath solution, inward rectifying (I_{IR}), outward transient (I_A) and outward delayed rectifying (I_K) K^+ currents were recorded under voltage-clamp conditions. I_{IR} was very small at 5mM K^+ bath solution and enhanced by taking the bath solution to 55mM K^+ ; this was blocked by TEA but not by 4-AP. I_A appeared at -50mV and was selectively diminished by 4-AP (2-4mM). I_K occurred when membrane potential was depolarized to -20mV and was blocked by TEA (2mM) but not 4-AP (4mM). Under current-clamp conditions, 4-AP but not TEA (up to 5mM) depolarized the cell and triggered action potentials when Ca^{2+} (2mM) was in the bath solution and no TTX was used. 4-AP but not TEA also increased intracellular free Ca^{2+} concentration ($[Ca^{2+}]_i$) and GH release. Therefore, 4-AP sensitive I_A may be a major component of the voltage-dependent K^+ currents involved in maintaining the resting potential and may play a role in regulating basal $[Ca^{2+}]_i$ and GH release. Funded by Australian NH & MRC.

ALTERED GLIAL FIBRILLARY ACIDIC PROTEIN EXPRESSION IN RAT PITUITARY INTERMEDIATE LOBE GLIAL CELLS FOLLOWING ADRENALECTOMY, LACTATION, AND SALT-LOADING. K.A. Gary* and B.M. Chronwall. School of Biological Sciences, University of Missouri-Kansas City, Kansas City, MO 64108.

The majority of cells in rat pituitary intermediate lobe (IL) are melanotrophs which produce proopiomelanocortin, the precursor molecule for β -endorphin and α -MSH. A smaller population of cells interspersed among the melanotrophs are characterized by stellate cell bodies with long processes and have been described by EM studies and localized immunohistochemically by S-100 protein and glial fibrillary acidic protein (GFAP) antisera. Similarity in morphology to CNS fibrous astrocytes and expression of generally accepted glial-specific protein suggests to some investigators that these cells are glial cells. In light of recent findings regarding expanding functional roles of glia in the CNS and glial-like cells in the pituitary, we have performed an LM level immunohistochemical study of serially sectioned rat pituitaries to characterize the distribution of IL glial cells by localization of cells containing GFAP and S-100 protein. Analysis of GFAP immunoreactivity (IR) performed in male and female rat ILs demonstrated a specific rostro-caudal distribution of IR cells and this distribution began more rostrally in females (900 μ m from rostral) than males (1200 μ m). Examination of several altered physiological states, e.g. adrenalectomy, lactation, and salt-loading revealed state-specific changes in GFAP-IR. Adrenalectomy and lactation increased GFAP-IR glial cell numbers within the IL, whereas salt-loading decreased the numbers of cells expressing GFAP and abolished the typical pattern of its expression. In contrast, S-100 expressing cells were found evenly distributed throughout the rat IL and its expression was not affected by the experimental conditions. Double-label immunocytochemistry indicated that GFAP-IR cells are a sub-population of S-100-IR cells. These results suggest that S-100 only expressing cells may be induced to express GFAP under altered physiologic conditions.

THE IDENTIFICATION OF AN NF-KB LIKE DNA BINDING PROTEIN AND ITS ACTIVATION IN GH3 CELLS. L. Grandison (+), G. Nolan and D.W. Pfaff* +RW Johnson Med School, Piscataway, NJ; Rockefeller Univ., NY, NY.

The transcription factor NF-KB is present in many tissues in an inactive complex restricted to the cytosol by an inhibitory subunit IKB. Appropriate cell activation induces phosphorylation of IKB releasing NF-KB to translocate to the nucleus where it then binds cognate DNA sequences in responsive genes. Several neuropeptide genes including preproenkephalin and genes for neuroactive cytokines contain NF-KB binding sites within their promoter. To examine the involvement of NF-KB in gene expression within the neuroendocrine system, we investigated the presence and regulation of NF-KB in a neuroendocrine cell model, the GH3. An electrophoretic mobility shift assay employing nuclear extracts from GH3 cells and a 32P labeled oligonucleotide probe corresponding to the NF-KB binding site was used to determine NF-KB like DNA binding proteins. Several protein-DNA complexes were observed. One band showed properties consistent with the presence of an NF-KB like protein in GH3 cells. There was little NF-KB like protein in nuclear extracts of untreated GH3 cells. However exposure to phorbol ester (PMA, 100 nM) produced a marked increase in NF-KB like protein. In contrast the releasing factor TRH which generates diglycerides that like PMA activates protein kinase C was ineffective in activating NF-KB. Tumor necrosis factor alpha (TNF α , 10 ng/ml) also induced NF-KB like protein. The combination of TRH and TNF α produced greater stimulation than TNF α alone. Treatments reported to induce NF-KB in other cell types such as okadaic acid (1-100 nM) and hydrogen peroxide (150 μ M) were found ineffective in GH3 cells. Combination of PMA with other treatments (TRH, A23187, somatostatin, forskolin) produced no modulation of the PMA-induced response. In summary GH3 cells contain an NF-KB like protein which can be activated by PMA and TNF α . However the receptor ligand TRH which is a strong stimulus for secretion is by itself an ineffective activator of NF-KB in these cells.

PITUITARY NEUROPEPTIDE FF: RELEASE AND RECEPTORS
C. AKAR, E.A. MAJANE AND H.Y.T. YANG*. LBG, NIMH
Neuroscience Center at St. Elizabeths, Washington, D.C. 20032.

Neuropeptide FF (NPFF, FLFQQR-NH₂) is an endogenous neuropeptide with opiate modulating activity. NPFF is unevenly distributed in the rat CNS with the highest concentrations in the spinal cord and pituitary. In this study, NPFF binding in the rat pituitary was determined and the NPFF release from the posterior lobe was examined. Using ¹²⁵I-YLFQQRFa as the radioligand we detected specific NPFF binding sites in the pituitary. These binding sites were G protein coupled and were localized in both the posterior and anterior lobes. In an *in vitro* perfusion system we demonstrated that NPFF can be released from the posterior lobe of the pituitary gland by 54 mM K⁺ in a calcium dependent manner. In this study the release of AVP was also examined. The peak of AVP release induced by K⁺ was found to be 15 min after the peak of NPFF release. Interestingly naloxone can cause a release of NPFF from the pituitaries of rats chronically treated with morphine. These results suggest that hypothalamo-neurohypophysial NPFF may exert its action at the pituitary gland.

C-FOS EXPRESSION IN THE MEDULLA IN RESPONSE TO CHOLECYSTOKININ (CCK) OR HYPERTENSION. R.G. Mayne*¹, S.L. Bealer², W.R. Crowley³ and W.E. Armstrong¹. Depts. of ¹Anat. & Neurobiol., ²Physiol. & Biophys., and ³Pharmacol., Univ. Tenn., Memphis, TN 38163.

In rats, elevated blood pressure inhibits vasopressin secretion, whereas systemic injection of CCK enhances oxytocin secretion. This provides an opportunity to examine differences in the responsiveness of nuclei of the medulla that are known to mediate both effects using *c-fos* as a marker.

Conscious male rats received either CCK (100 µg/kg, i.p.) or were made hypertensive (30-40 mm Hg over controls) by constant intravenous infusion of phenylephrine (5-10 µg/kg/min) for 90 mins, then perfused. Tissue sections were processed immunocytochemically for *c-fos* and/or dopamine β-hydroxylase (DBH).

As others have shown, CCK injections increased the number of *c-fos* immunoreactive neurons over controls throughout the rostral-caudal extent of the nucleus of the solitary tract (NTS), including commissural neurons and the medial subnuclei but to a lesser degree dorsolaterally. Some reactive neurons in NTS were also positive for DBH, but most were not, and most DBH-positive NTS neurons were not *c-fos*-positive. The area postrema (AP) was prominently labeled. In contrast, after hypertension a more restricted distribution of *c-fos*-positive neurons was observed in the NTS, with most neurons confined to a dorsolateral strip containing few DBH-positive neurons. The medial NTS at the level of the AP and the AP itself were largely unresponsive, but rostral to the AP the medial NTS was labeled, including some DBH-positive neurons. Both treatments produced labeling in the ventral lateral medulla, including many DBH-positive neurons. These results suggest that subpopulations of NTS neurons may mediate the CCK-induced oxytocin release and the hypertension-related inhibition of vasopressin neurons. EFFECT OF PRENATAL PHOTOPERIOD ON REPRODUCTIVE DEVELOPMENT IN SIBERIAN HAMSTER. D.Shaw, W.D.Chappel*, and B.D.Goldman, Dept. of Physiology & Neurobiology, University of Connecticut, Storrs, CT 06269

Paired testis weight and hormone levels of hamsters were measured at different ages to examine the role of prenatal photoperiod on reproductive development. Breeding pairs were housed either in 16L:8D or 10L:14D. Litters from both groups were reared in 14L:10D beginning on the day of birth. They were bled from the retroorbital capillary bed at 1200 h at various ages, and for males paired testes weights were taken following decapitation.

For male hamsters, testis weight was greater for animals from the short day prenatal environment as compared to those from the long day prenatal environment. This difference was apparent at all times from day 27 to day 52 of life. The males from the short day prenatal environment also had 1) higher serum prolactin (Prl) concentrations at days 42 and 52 and 2) higher serum follicle stimulating hormone (FSH) concentrations at day 18 and 22. In female hamsters, 1) animals from the short day prenatal environment had higher serum Prl concentrations between days 27 and 62 and 2) serum FSH concentrations did not differ between females from long and short day prenatal environments except at day 62, when FSH was higher in the animals from the long day prenatal environment.

These observations indicate sex differences in the effects of prenatal photoperiod on the rate of postnatal reproductive development. These results will be discussed in relation to our observation of a sex difference in the effect of prenatal photoperiod on the pineal melatonin rhythm of juvenile hamsters.

RELEASE OF JOINING PEPTIDE FROM PERFUSED RAT HYPOTHALAMIC SLICES. T.Hamakubo* and T.Inagami. Department of Biochemistry, Vanderbilt University, Nashville, TN 37232.

Joining peptide (JP) is one of the derivatives of the multifactorial precursor molecule proopiomelanocortin (POMC). Although JP is known to be processed by specific enzymes from POMC in several tissues such as pituitary and hypothalamus, the biological relevance of this peptide has not been identified. Recently we reported the cardiovascular effects of JP in genetically hypertensive rats with central administration (Hamakubo et al., Soc. Neurosci. Abstr. 426.2, 1992). To characterize JP as a neuropeptide, a polyclonal antibody specific to rat JP (rJP) was produced in rabbit. The hypothalamic slices from adult male Sprague-Dawley rats were perfused continuously with Krebs-Ringer bicarbonate (KRB) medium. Fractions were set apart every 5 min and immunoreactive rJP (rJP-ir) level of each fraction was evaluated by RIA. The basal release of rJP-ir in normal KRB was 5pg/5min/8 hypothalamic corresponding to 0.05% of the total hypothalamic content. Potassium (50mM) significantly stimulated rJP-ir release about 800% of the basal level in a Ca⁺⁺-dependent manner. rJP-ir released by K⁺ depolarization eluted in one peak at the same elution time as synthetic rJP from C18 reversed phase HPLC column. These results demonstrate that fully processed rJP is released by K⁺-depolarization from the hypothalamus.

ETHANOL DISRUPTS STIMULUS-INDUCED SYNTHESIS-SECRETION COUPLING IN TRH NEURONS OF THE PVN. R.T. Zoeller*, O. Butnariu, A. Simonvi, D.L. Fletcher, I. Stafford-Seger*, S. McCrone and S.L. Petersen. Depts of Anat. & Neurobiol. and [#]Psychology, Univ. Missouri, Columbia, MO 65212.

TRH neurons of the PVN project to the median eminence and regulate pituitary-thyroid function. Hypothyroidism increases TRH secretion and TRH mRNA levels in PVN. Cold exposure, believed to act through an adrenergic mechanism, increases both TRH release and TRH mRNA levels. Ethanol (E, 3g/kg ip) blocks the cold-induced increase in TRH mRNA, but not the cold-induced increase in TRH release. To examine the mechanism of action, we tested the effects of E on rapid changes in TRH and *c-fos* mRNAs after cold. Using *in situ* hybridization (ISH) with oligonucleotide probes and dual-label ISH with a variety of cRNA probes, we found that cellular levels of TRH mRNA increases in the PVN within 60 minutes of cold exposure, and that E blocks this. In contrast, *c-fos* mRNA is expressed in TRH neurons following cold, and this is not blocked by E. Therefore, E does not block the cold-activation of TRH neurons, but specifically blocks the cold-induced increase in TRH mRNA levels. E alone resulted in a pattern of *c-fos* expression in PVN and somatosensory cortex similar to cold, suggesting that E may affect TRH neurons by modifying afferent activity rather than acting directly. We have found that α1 adrenoceptor mRNA is expressed in TRH neurons of the PVN. To address effects of E on α1-stimulated TRH expression, we are applying agonists directly to the PVN. MOLECULAR CHARACTERISTICS OF LUTEINIZING HORMONE-RELEASING HORMONE IN OPIOID-RESPONSIVE SK-N-SH NEUROBLASTOMA CELLS.

Anna Ratka*, Bruce E. Torian, Becky Flores, James W. Simpkins¹, Lee Ann Berglund, Dept. of Pharmaceutical Sciences, Coll. of Pharmacy, Idaho State University, Pocatello, ID 83209, ¹ Dept. of Pharmacodynamics, Coll. of Pharmacy, University of Florida, Gainesville, FL 32610.

The results of our previous *in vivo* studies strongly implied the functional interactions of Luteinizing Hormone-Releasing Hormone (LHRH) with the opioid systems. To elucidate the nature of this interaction at the neuronal level we have employed an *in vitro* model; μ and δ opioid receptors-containing human SK-N-SH neuroblastoma cells. We have found that LHRH can attenuate the function of opioid receptors in SK-N-SH neuroblastoma cells by preventing the inhibitory effect of morphine on the accumulation of cAMP. Immunocytochemical staining of LHRH revealed antigenic determinants of LHRH in opioid-responsive SK-N-SH cells. A 470 base pair cDNA probe derived from human hypothalamic LHRH positive cells was radiolabelled, and hybridized with genomic DNA isolated from SK-N-SH cells in a slot blot assay. The results of the hybridization study strongly imply the presence of the LHRH gene in opioid-responsive SK-N-SH neuroblastoma cells. Recent efforts are directed at quantitative evaluation of the LHRH mRNA levels. We conclude that, in addition to μ and δ opioid receptors, the SK-N-SH neuroblastoma cells possess the gene to express the LHRH system. TARGET-DIRECTED SPROUTING OF PRIMARY AFFERENTS IN THE ADULT SPINAL CORD. By Inna A. Belyantseva & Gary R. Lewin Neurobiology & Behavior, SUNY at Stony Brook, New York, NY 11794.

We have examined the projection of myelinated primary afferents to the spinal cord after appropriate and inappropriate peripheral nerve regeneration. Transganglionically transported cholera toxin B subunit (CT-B) was detected in synaptic boutons with immunocytochemistry after transport from skin, muscle, or nerve. Somatotopically organized terminals were observed in lamina III in the L5 segment after injection of CT-B into the hairy skin of the lateral ankle. This labelling was presumed to originate from sural nerve (SN) afferents as all other hindlimb nerves were cut. The area of this labelling was around 30% of that seen from the whole SN. Ten weeks after the SN was cut the position and extent of labelling from the reinnervated ankle skin was indistinguishable from control intact animals. In further experiments the medial gastrocnemius nerve GN was redirected to reinnervate the same ankle skin. Under these circumstances myelinated muscle afferents become newly capable of activating dorsal horn neurones (Lewin and McMahon, 1993 Eur. J. Neurosci. in press). When CT-B was injected into ankle skin inappropriately innervated by the GN, labelled terminals were observed in lamina III of the dorsal horn. The labelling was present in a restricted portion of the L5 segment and was symmetrical with labelling from the contralateral ankle reinnervated by the SN. In control experiments it was shown that the central terminals of intact or self-anastomosed GN afferents could be labelled in the intermediate grey and ventral horn without labelling in lamina III. These results suggest that mature muscle afferents can be directed to sprout into the dorsal horn in a somatotopically appropriate manner by a novel cutaneous target. Supported by the APA.

PLASTICITY OF DORSAL HORN CELL RECEPTIVE FIELDS FOLLOWING PERIPHERAL NERVE REGENERATION. H.R. Koerber, & K. Mimics. Dept. of Neurobiology, Univ. of Pittsburgh, School of Med., Pittsburgh, PA 15261.

Adult cats were anesthetized with α -chloralose 5-9 months after tibial and sural nerve transection and self union. Microelectrode (3M K-acetate) recordings were made from 95 dorsal horn neurons in 4 animals. Results were divided into two groups based on post-axotomy survival time. Group 1 (5-6 mos.) contained data from 50 cells recorded in 2 animals and Group 2 (9 mos.) from 45 cells. In Group 1 intracellular recordings were made from 20 cells and extracellular recordings from 30. Of these, 19 were characterized as wide dynamic range (WDR) cells, 12 as low threshold only (LT-only) and 2 as high threshold only (HT-only). Of 18 WDR cells examined only 2 had HT-RF components that were larger than their LT ones. The average size of the LT-RFs of cells in this group was 13.04 ± 1.08 cm² (SE); (n = 48). In addition, five of these cells had LT-RFs from two separate locations on the hindlimb. The cells with small RFs always had components of their RFs supplied by intact fibers and these RFs were always continuous across the border between reinnervated and intact skin. Group 2 contained data from 45 cells (24 intracellular, 21 extracellular). Of these 28 were classified as WDR; 12 as LT-only; 1 as HT-only and 3 cells had split LT-RFs. In contrast to group 1 these cells had significantly smaller low-threshold RFs (7.52 ± 0.01 cm²; n=41; p < .001) which is in agreement with results in the rat (Lewin & McMahon; Neurosci. Abstr. 92). Fourteen of the 26 WDR cells examined had HT-RF components that were larger than their LT ones. These findings suggest that DH cells which receive input primarily from regenerated fibers initially have large RFs that usually cover the entire reinnervated area. However, cells that receive substantial input from both intact and regenerated fibers have more restricted RFs at short survival times. With time the large LT-RFs of some DH cells are reduced in size, while at the same time HT-RFs either remain the same or increase in size. Supported by NS 23725 (HRK).

LARGE CALIBER PRIMARY AFFERENT NEURONS PROJECTING TO THE GRACILE NUCLEUS EXPRESS NEUROPEPTIDE Y AFTER SCIATIC NERVE LESION. X. Zhang, B. Meister, R. Elde, V. M. K. Verge and T. Hökfelt* Departments of Histology and Neurobiology, Karolinska Institute, 10401, Stockholm, Sweden.

Using immunohistochemistry and in situ hybridization, we studied changes in expression of some neuropeptides in large and medium-sized neurons in lumbar 4 and 5 rat dorsal root ganglia projecting to the gracile nucleus, in response to peripheral axotomy. Fourteen days after unilateral sciatic nerve transection, many large neurons and some medium-sized neurons in ipsilateral dorsal root ganglia were strongly neuropeptide Y (NPY)-positive. Galanin (GAL)-, vasoactive intestinal polypeptide (VIP)/peptide histidine-isoleucine (PHI)-like immunoreactivities (LI) coexisted with NPY-LI in some of these neurons. After axotomy numerous large and medium-sized cells contained NPY mRNA in the ipsilateral ganglia, whereas no hybridization was seen in the contralateral or control ganglia. Cross-sectioned, large NPY-positive fibers were observed in a somatotopically appropriate zone within the ipsilateral gracile fasciculus. A dense network of NPY-immunoreactive (IR), large nerve fibers and terminals was seen in the ipsilateral gracile nucleus. A small number of GAL- and VIP/PHI-IR nerve fibers and terminals were also observed in adjacent sections. NPY-LI colocalized with GAL- or VIP/PHI-LI in some nerve fibers. None of these neuropeptide immunoreactivities could be detected in nerve fibers and terminals in the control or contralateral gracile nucleus. These findings suggest that neuropeptides, in addition to their role in small dorsal root ganglion neurons, may have a function in large and medium-sized dorsal root ganglion neurons projecting to laminae III and IV in the dorsal horn as well as to the gracile nuclei, as a part of their response to peripheral axotomy.

PERIPHERAL AND CENTRAL MECHANISMS OF NGF-INDUCED HYPERALGESIA IN ADULT RATS. By Alain Rueff*, Gary R. Lewin & Lorne M. Mendell, Dept. of Neurobiology & Behavior, SUNY, Stony Brook, New York, NY 11794-5230.

Acute treatment of adult rats with a single dose of NGF induces a prolonged hyperalgesia to thermal and mechanical stimulation which lasts for at least 3 days (Lewin et al. 1993, J. Neurosci., 13, 2136-2148). In contrast to NGF-induced mechanical hyperalgesia, which develops around 7 hours, thermal hyperalgesia is apparent within 30 minutes after NGF. In addition to its action on sensory neurons, NGF has been shown to induce mast cell degranulation *in vitro* (Mazurek et al. 1987, FEBS Lett., 315-320). Here we pretreated adult rats for 4 days with increasing doses of the mast cell degranulating agent compound 48/80 (i.p.) prior to NGF (1 μ g/g i.p.) administration. This delayed the onset of the thermal hyperalgesia by 3h, as measured by the foot withdrawal latency to a constant radiant heat source. Initial thermal hyperalgesia was also blocked in the presence of ICS 205-930 (100 μ g/kg, i.p.), a selective 5-HT_{3A} receptor antagonist. In addition administration of the non-competitive NMDA-antagonist MK-801 for 14 days (15-30 μ g/kg/h via osmotic pumps) limited thermal hyperalgesia after NGF to only 3h. No change was seen in the mechanical hyperalgesia following NGF in 48/80 or MK-801-treated animals (thresholds measured with von Frey hairs). These results suggest that the initial (30 min - 3h) NGF-induced thermal hyperalgesia is due to a peripheral mechanism involving release of serotonin following the acute degranulation of mast cells. The sustained thermal hyperalgesia (7h-3 days), however, appears to involve a central NMDA-dependent mechanism. NGF-induced mechanical hyperalgesia seems to be independent of mast cell degranulation or central NMDA receptor sites. Supported by NIH; NS 14899, NS16996.

REINNERVATION OF HINDLIMB MUSCLES BY NONHINDLIMB MOTOR AXONS AND PRIMARY AFFERENTS. R.R. Pindzola*, K. Mimics, H.R. Koerber. Dept. of Neurobiology, University of Pittsburgh, Pittsburgh, PA 15261.

In this study we have examined the feasibility of rerouting motor axons and their segmental primary afferents to novel targets. Adult rats were anesthetized with a mixture of ketamine and xylazine and the L2-L5 dorsal root ganglia and spinal roots were exposed. The L5 and L4 DRGs were removed and the L4 ventral root cut and ligated. The L5 ventral root was traced rostrally to the level of L2 ganglia where it was cut and the proximal end ligated. The ventral ramus of the L2 spinal nerve was dissected free from surrounding tissue, cut and the proximal end abutted with the distal stump of the L5 ventral root within a polymer cuff. The anastomosed nerve and ventral root were secured in the cuff using fibrin glue. After allowing 3.5-4.5 months for regeneration the animals were anesthetized with the same anesthetic. For anatomical confirmation of successful regeneration the ipsilateral sciatic nerve was exposed, crushed and injected with a mixture of 2% WGA-HRP and 20% HRP in distilled water. The animals were allowed to recover and 3 days later were anesthetized and perfused with 1% paraformaldehyde and 1.25% glutaraldehyde. Labeled L2 motoneurons and DRG cells were visualized using TMB histochemistry. Electrophysiological confirmation of functional reinnervation was determined by stimulating the exposed L2 ventral roots and recording EMGs from hindlimb muscles normally innervated by L5 motor axons and the stimulation of peripheral nerves while recording from the L2 dorsal roots. Motoneuron and DRG cell counts showed that 20-30% (n=2) of the L2 somata were labeled from the sciatic nerve injection. In two other animals EMGs were evoked in hindlimb muscles (e.g. medial and lateral gastrocnemius, soleus, plantaris) in response to electrical stimulation of the regenerated motor axons. In these same preparations EMGs were also evoked in these muscles by stimulation of the L2 dorsal roots (CV=22-26m/s) confirming that the central connections remain functional after regeneration. Furthermore, stimulation of peripheral nerves evoked compound action potentials in the L2 dorsal roots. These findings suggest that regenerating peripheral fibers can successfully reinnervate peripheral targets while maintaining functional central connections. Supported by NS23725 (HRK).

CELLULAR LOCALIZATION OF F8FAMIDE RECEPTORS IN THE SPINAL CORD EVIDENCED BY QUANTITATIVE AUTORADIOGRAPHY FOLLOWING CHEMICAL AND SURGICAL DEAFFERENTATION.

C. Gouarderes¹, S. Kar², J.A.M. Tafani³, J. Martial², R. Quirion² and J.-M. Zajac¹. ¹Laboratoire de Pharmacologie et de Toxicologie Fondamentales, CNRS, Toulouse, FRANCE; ²Douglas Hospital, Research Center, Department of Psychiatry, McGill University, Montreal, Quebec, CANADA H4H 1R3; ³Biophysique et Med. Nucl. CHU Purpan, Toulouse, FRANCE.

(1DME)Y8Famide, a synthetic analog of F8Famide resistant to degradation and possessing high affinity for the related receptors was radiolabeled. Binding properties of this ligand were shown similar to that of F8Famide. This peptide offers the possibility to examine the precise localization of F8Famide-receptors in the rat spinal cord (Lumbar4) after sciatic nerve section, dorsal rhizotomy and neonatal capsaicin (50 mg/kg) treatment. In control spinal cord, the highest density of [125I]1DME binding sites was noticed in the superficial layers of the dorsal horn whereas low-to-moderate densities were detected in the deeper laminae of the cord. In neonatally treated capsaicin rats, a significant bilateral decrease (25%) in the labelling was observed in laminae I and II of the dorsal horn. Unilateral dorsal rhizotomy and unilateral peripheral axotomy also produced a significant depletion (20-25%) in the same area of the dorsal horn ipsilateral to the surgery. These results suggest that a portion of F8Famide receptors is located on the primary afferent fibers of the superficial layers of the dorsal horn. Thus, F8Famide could play an important role in the modulation of nociceptive transmission by acting directly on primary afferent terminals as well as on receptors located post-synaptically to these terminals. (Supported in part by FRSQ and MRCC).

DIFFERENTIAL ACTIVATION OF PRESYNAPTIC INHIBITORY CIRCUITS BY PUDENDAL AND PELVIC NERVE AFFERENTS. R.D. Johnson* and V.P. Dugan. Department of Physiological Sciences, University of Florida, Gainesville, FL 32610-0144.

Polysynaptic reflex discharges in pudendal motoneurons regulating bowel, bladder, and sexual function in male rats can be elicited by stimulating myelinated afferents in the pudendal and pelvic nerves. We have shown that these reflex discharges are subject to attenuation by presynaptic inhibition of incoming afferents, although the pelvic nerve circuit is far less vulnerable (SN Abstracts 18:128, 1992). For this study, we used the same paradigm while also monitoring the amount of primary afferent depolarization (PAD). Mature male rats were anesthetized with urethane and acutely spinalized at T8. Stimulating electrodes were placed bilaterally on the dorsal nerve of the penis (DNP), pelvic nerve (PN), and superficial perineal nerve (SP). Recording electrodes were placed bilaterally around the L6 dorsal roots. Dorsal root potentials were recorded in response to electrical stimulation of several two-nerve combinations (20-60ms interval conditioning-test paradigm). By computer subtraction of individual stimuli, the level of PAD produced by each set of afferents was quantitated. Bilaterally, there was significantly greater PAD initiated by incoming DNP and SP afferents than PN afferents. A subset of dorsal root axons, subject to PN induced PAD, is also inhibited by SP afferents. Since SP afferents do not drive pudendal motoneurons or inhibit PN driven reflexes, we suggest that a second subset of PN afferents, unlike most pudendal afferents, does not activate PAD producing neurons. Supported by NS27511.

DECREASED DORSAL SPINAL CORD CGRP AND INCREASED HEAT SENSITIVITY IN RATS WITH LOW BACK DYSFUNCTION.

J. Hulse Neufeld*. VA Medical Center (151), San Diego, CA 92161.

Low back dysfunction (1991 mtg #120.4) and increased resting levels of corticosterone (1992 mtg #643.1) were documented in rats forced to ambulate in an extreme posture. Now, sensitivity to heat in hot plate testing and concentrations of calcitonin gene-related peptide (CGRP) in the dorsal spinal cord are reported so as to assess the degree of heat hyperalgesia between groups of rats and to determine the correlational relationship between heat sensitivity and CGRP. Three groups of male rats were compared: rats forced to ambulate on a flat surface (AF, normal posture), rats forced to ambulate in rotating cylinders (AC, extreme posture) and rats not forced to ambulate (NA). After six weeks of forced ambulation, concentrations of CGRP were dependent upon an experience two weeks earlier with a general anesthesia containing ketamine and dependent upon the group: anesthesia increased and forced ambulation decreased CGRP. In repetitive hot plate testing, the AC rats were most sensitive and the NA rats the least sensitive to the second hot plate experience. Also as the CGRP levels decreased, sensitivity to hot plate testing increased and the heat sensitivity behavior was significantly described by CGRP but best described by CGRP, corticosterone levels and interactions between predictors. It is hypothesized that the CGRP levels in the spinal cord reflect the amount of afferent stimulation to the brain so that rats given a general ketamine anesthesia are assumed to have depressed levels of brain stimulation and high levels of CGRP and rats forced to ambulate in an extreme posture are assumed to have the most stimulation and the lowest CGRP. In this hypothesis concentrations of CGRP in exercising animals tend to maintain, in a homeostatic manner, the degree of afferent input via the spinal cord.

INTRADERMAL CAPSAICIN (CAP) OR COLD INJURY INCREASES FOS-LABELING IN THE SUPERFICIAL DORSAL HORN OF THE RAT SPINAL CORD. C.M. DeLisle^{1,3}, H.D. Gilchrist^{3,4}, D.A. Simone^{3,4}, C.N. Honda^{2,4*}, and K.C. Kajander^{1,2,4}. Departments of ¹Oral Science, and ²Cell Biology & Neuroanatomy, ³Neuroscience Research in Psychiatry, and ⁴Graduate Program in Neuroscience, University of Minnesota, Minneapolis, MN 55455.

Immunocytochemical labeling of spinal neurons for Fos-protein increases after nociceptive stimulation, inflammation, and peripheral injuries (Morgan and Curran, 1991). We evaluated Fos-labeling in rats after intradermal injection of CAP (30 µg in 10 µl Tween-saline) into the plantar surface of the hindpaw or after contact cold stimulation (-15°C for 5 minutes, 1 cm² area) of the dorsum of the hindpaw. One hour after injury, rats were deeply anesthetized and perfused transcardially with ice-cold normal saline followed by ice-cold 4% paraformaldehyde. Spinal segments L2-L6 were removed, post-fixed, and cryoprotected. Spinal sections (40 µm thick) were processed immunocytochemically using a polyclonal antiserum against a portion of the Fos-protein (M.J. Iadarola, NIH, Bethesda, MD). Sections were evaluated using light microscopy; labeled nuclei were counted using computer-assisted image processing. As compared to the contralateral side, greater Fos-labeling occurred in the spinal gray matter ipsilateral to the injuries. Labeling was restricted primarily to segments L3-L5, and the majority of labeled nuclei were in the superficial dorsal horn (laminae I-II). Few nuclei were labeled in deeper regions of the gray matter. These experiments demonstrate that Fos-labeling increases in the superficial dorsal gray matter of somatotopically appropriate spinal segments one hour after either injection of CAP or cold injury to the rat hindpaw. INCREASED SUBSTANCE P AND CALCITONIN GENE-RELATED PEPTIDE IMMUNOREACTIVITY IN FELINE KNEE JOINT AFFERENT PROJECTIONS IN CHRONIC ARTHRITIS. D. Homonko*, E. Theriault and K.W. Marshall. Playfair Neuroscience Unit and Dept. of Surgery, University of Toronto, TORONTO, Ontario Canada MST 2S8.

The level of joint innervation in inflammatory joint disease is a controversial area, with conflicting reports of both increases and decreases in the levels of several peptides in the affected joints and in the central projections of joint afferents. We have recently provided evidence of maintained joint innervation by substance P (SP) and calcitonin gene-related peptide (CGRP) in chronic inflammatory joint disease in the cat (Theriault et al., 93). In the present report we describe statistically significant increases in the distribution and intensity of immunoreactivity for SP and CGRP in areas of the spinal cord known to receive specific knee joint afferent input: the cap of the dorsal horn in L3 and L6, and the intermediolateral cell (Clarke's) column in L3. Commercially available rabbit polyclonal antisera raised against SP and CGRP were used to detect the presence of the peptides in paraformaldehyde-fixed cat spinal cord. Tissues from 3 normal animals and from 5 chronic animals in which methylated bovine serum albumin was used to induce a mono-arthritis inflammatory response (cf, Inman et al., 89) were processed using appropriate methods controls. In addition to increased immunoreactivity, particularly for CGRP, in the dorsal horn, we also found an increase in the numbers of dorsal root ganglion (DRG) cells expressing CGRP from ganglia on the inflamed side, in agreement with previous reports (Hanesch et al., 93). These anatomical data, in conjunction with evolving electrophysiological studies (e.g., Neugebauer and Schaible, 90) may help to delineate the functional pathways subserving joint pain.

643.10

VAGINOCERVICAL STIMULATION INDUCES C-FOS EXPRESSION IN LUMBOSACRAL SPINAL CORD NEURONS THAT PROJECT TO THE DIENCEPHALON - A DOUBLE-LABELING STUDY. S.Chinapen*, J.M. Swann, R. Burstein¹, and B.B. Komisaruk. Inst. Animal Behavior, Rutgers-The State Univ., Newark, NJ 07102 and Harvard Medical School Boston¹, MA 02115.

Vagino-cervical stimulation (VS) affects neuronal activity in hypothalamic and thalamic regions that contain neurons that control neuroendocrine and autonomic reflexes or modulate pain. Our hypothesis is that lumbosacral spinal cord neurons that project directly to the diencephalon provide at least part of this input. To determine whether lumbosacral neurons that project to the thalamus and hypothalamus respond to VS, we have combined the immunocytochemical method for the detection of c-Fos (an activity marker) with the retrograde tracer Fluoro-gold (FG) for the localization of projecting neurons. FG was injected into the thalamus (n=3) or hypothalamus (n=5) of ovariectomized rats. 1-2 wk later, VS (400g force) was applied (10 sec on/10 sec off) for 5 min. 2h later, rats were anesthetized, perfused, and the lumbosacral spinal cord removed and, after appropriate processing, sections were examined for neurons expressing c-Fos only, FG only or both. VS induced c-Fos in the superficial (lamina I) and deep (laminae IV,V,VI) dorsal horn, and in the area around the central canal (lamina X), confirming earlier findings. FG injections into the thalamus or hypothalamus labeled neurons in the same regions of the spinal cord gray matter and in the lateral spinal nucleus. Retrograde labeled neurons expressing c-Fos were located in the superficial and deep dorsal horn, the sacral parasympathetic nucleus, and the area around the central canal. More double-labeled neurons were found to project to the thalamus than to the hypothalamus. These findings indicate that lumbosacral spinal cord neurons that project to the diencephalon respond to VS.

Distribution of Fos like immunoreactive cells within the spinal cord of rats with partial sciatic nerve constriction. O.C. Dollberg-Stolik*, C.S. Schlhorst and M.M. Behbehani. Depts. of Physiology and Biophysics and Anesthesia, Univ. of Cincinnati College of Medicine, Cincinnati, OH 45267-0576.

Partial nerve injury was produced by placing a tight ligature around 1/2 of the sciatic nerve in a proximal location. This procedure caused a behavioral syndrome suggestive of hyperalgesia, hyperpathia, allodynia and spontaneous pain.

Fos like immunoreactivity (FLI) patterns in the dorsal horn (DH) regions in response to mechanical and chemical stimulation were mapped. We examined the effect of anesthesia by comparing FLI patterns in awake and anesthetized animals. Fifty male Sprague Dawley rats (200-300gr) were operated. Twenty animals showed symptoms of neuropathy. These animals were divided in 4 groups, 5 animals per group. Animals in group 1 and 2 were stimulated by either injection of 0.1cc of 5% Formalin or by noxious mechanical stimulation applied to both hind paws while awake. Group 3 and 4 animals received similar stimuli while under chloral hydrate anesthesia. The rats were perfused 150 minutes after the stimulation started. FLI cells in the lumbar regions were counted and the data were normalized as the ration of ipsi/contralateral FLI cells. The data is presented as the mean of this ratio ±std (MER).

In awake animals stimulated with mechanical stimulation, MER was 2.4±0.83. The MER using similar stimulation in anesthetized animals was 0.87±0.07. Formalin injection produced MER of 0.32±0.16 in awake and 0.41±0.15 in anesthetized animals respectively.

It is concluded that: (1) hypersensitivity to mechanical stimulation in this model is mediated by A-delta and/or A-beta rather than C fibers, and (2), anesthesia significantly alters the response properties of DH neurons in this animal model.

643.13

IMMEDIATE EARLY GENE EXPRESSION IN THE RAT-PAW FORMALIN MODEL-THE EFFECT OF ENADOLINE. J.A. Poat, E.K.E. Pettersson, J.C. Hunter* and J. Hughes, Parke-Davis Neuroscience Research Centre, Addenbrookes Hospital Site, CAMBRIDGE CB2 2QB.

The kappa opioid agonist, enadoline (CI-977) has a number of actions, it is anticonvulsant, neuroprotective in models of global and focal ischaemia and analgesic in models of pain such as the rat-paw formalin test. In the first two situations immediate early gene (IEG) expression is markedly increased and this increase is unaffected by enadoline. This report examines the effect of enadoline on IEG expression in the formalin model. Injection of 50ul of 5% formalin intraplantar into one hind paw of 70-80g rats caused a pronounced behavioural licking response which lasted up to 60 min. Rapid, transient increases in *c-fos* and NGFI-A mRNA (100 and 200% above saline-treated controls) in the spinal cord followed the injection. The IEG stimulation peaked at 1h and there was a strong correlation between increased expression and the behavioural response. The changes in IEG were confined to the lumbar region (lamina II and weaker expression in laminae III-IV) of the cord ipsilateral to the side of the injection. Enadoline (100ug/kg) and morphine (10mg/kg) totally abolished the behavioural response to formalin-injection. In contrast morphine reduced the formalin-induced IEG expression (80% inhibited) while enadoline attenuated the response (30% inhibited for *c-fos* and 41% for NGFI-A). The results highlight the importance of IEG expression in this model but demonstrate that analgesia can be obtained in the presence of increased IEG mRNA.

643.14

THE TERMINATION PATTERN AND POSTSYNAPTIC TARGETS OF AXONS ARISING FROM THE NUCLEUS RAPHE MAGNUS IN THE RAT SPINAL CORD. M. Antal*, M. Petkó¹ and C.W. Heizmann², ¹Dept. Anat., Univ. Med. School, Debrecen, H-4012 Hungary; ²Dept. Pediat. Univ. Zurich, Zurich, CH-8032 Switzerland.

The spinal projections of the nucleus raphe magnus were traced in the rat by using the anterograde tracer Phaseolus vulgaris leucoagglutinin (PHA-L). After injecting PHA-L into the nucleus raphe magnus, labeled fibers and terminals were detected at cervical, thoracic as well as lumbar segments of the spinal cord. Descending fibers were located in the dorsolateral funiculus on both sides of the spinal cord. More than 50% of the terminals were revealed in laminae IV-V, while nearly 20% of them were found in laminae I-II₀. Labeled axon terminals, however, were only sparsely distributed in laminae II₁-III and in the ventral horn.

Synaptic contacts of raphe-spinal terminals in laminae I-II₀ and in laminae IV-V as well as GABA and glycine immunoreactivities of their postsynaptic targets were investigated in a correlative electron microscopic study.

To obtain a more global view of the relationship between raphe-spinal terminals and spinal interneurons sections were stained for both PHA-L and calbindin-D28k (CaB) or parvalbumin (PV), calcium-binding proteins that have been reported to be markers of certain subsets of islet and stalked cells as well as supraspinally projecting neurons in the spinal dorsal horn. Both CaB- and PV-immunoreactive neurons in laminae I-II₀ and IV-V were found to receive contacts from raphe-spinal axons. Terminals of descending fibers impinged mainly upon dendrites of immunostained neurons, but somatic contacts were also revealed.

SOMATOSENSORY CORTEX AND THALAMOCORTICAL RELATIONSHIPS III

644.1

EFFECTS OF DIFFERENT ISOMERS OF PROPRANOLOL ON SOMATOSENSORY TRANSMISSION IN THE URETHANE-ANAESTHETIZED RAT. A.B.A. Majeed*, H.M. Arebi and A.Z. Ibrahim. School of Pharmacy, Universiti Sains Malaysia, 11800 Minden, Pulau Pinang, Malaysia.

We have previously reported that dl-propranolol suppresses somatosensory transmission in the urethane-anaesthetized rat (Proc. IUPS XVII, 1989). We now look at whether this action is due to the membrane stabilizing effects or β -adrenoceptor blockade of propranolol. Eighteen female Wistar rats (190 - 210g) were anaesthetized with urethane (1.0 - 1.25 g/kg). The mass evoked cortical responses (MECR) to electrical stimulation (0-90V, 1/s) of the forepaw were recorded from the primary somatosensory cortex. Records were divided into the latencies of response (L_1 & L_2) and the primary positive (P_1) and negative (N_1) secondary positive (P_2) and negative (N_2) waves. After a good baseline response have been achieved, 10 mg/kg R(+)- or S(-)-propranolol (Sigma) or saline, was injected separately (i.p.). The percentages of change from baseline of the above parameters after injection were recorded and the means of 6 animals per group were generated 10, 20, 30 and 40 min post injection and subjected to unpaired Student's t-test. The S(-)-isomer which is 7-10 times more potent than the R(+)-isomer in β -blockade, consistently showed a statistically different response from saline during both the synchronized and desynchronized stage of the EEG. The R(+)-isomer failed to cause significant alterations in any of the recorded MECR parameters. We conclude that suppression of somatosensory transmission by propranolol in the urethane-anaesthetized rat is due to β -blockade.

MEMBRANE POTENTIAL OSCILLATIONS UNDERLYING FIRING PATTERNS IN NEOCORTICAL NEURONS. Y. Amitai*, Dept. of physiology, Center for Brain Research, Ben-Gurion University, Beer-Sheva, 84105, Israel.

Rhythmic activity in the neocortex varies with different behavioral states, and may encode sensory information. Oscillations of membrane potential (MPO) might contribute to the generation of these rhythms, but little is known about their prevalence or functional significance in the cortex.

Intracellular recordings were made from cells in layers 2/3 and 5, using brain slices from mature rat SI neocortex. Subthreshold MPOs were observed in a few cells; however, pronounced MPOs appeared in most cells following slow spike inactivation. The MPO frequency was voltage dependent, and ranged between 7 and 40 Hz. In each cell, the actual firing rate was faster than the MPO frequency for comparable membrane potentials. The MPOs were dependent on slow Na^+ and K^+ conductances, and Ca^{2+} seemed to be involved in some cells. The degree of periodicity of the oscillations correlated with the cells' firing patterns; it was highest in a group of layer 5 rhythmically firing neurons (Silva et al., 1991).

From this data I would propose that the oscillations reflect slow ion conductances that operate in the subthreshold voltage range to shape the cells' firing patterns, but which do not dictate its final firing rate.

DEVELOPMENT OF SPONTANEOUS GENERALIZED THALAMOCORTICAL ACTIVITY IN RAT THALAMOCORTICAL SLICES IN LOW Mg^{2+} MEDIUM.

Douglas A. Coulter* and Yun-Fu Zhang. Department of Neurology, Medical College of Virginia, Richmond, VA 23298-0599

We have been studying mechanisms underlying the development of rhythmic thalamocortical burst activity in mouse thalamocortical slices. To expand these studies, a similar slice is being developed in rat. Thalamocortical slices from 20-30 day-old rats were prepared using the slice angle described by Agmon and Connors (*Neuroscience* 41, 365) for mice. Slices were exposed to a medium containing no added Mg^{2+} to elicit spontaneous thalamocortical bursting, as has been described for mouse slices in our laboratory. Multiple simultaneous field potential recordings from thalamic and cortical sites within the slice disclosed low- Mg^{2+} activated spontaneous generalized thalamocortical burst activity, consisting of 2-10 sec long periods of synchronized 8-10 Hz bursting, reoccurring every 10-60 sec. Synchronized thalamocortical discharges could also be triggered by thalamic or cortical stimulation, either with single stimuli, or brief trains of stimuli at 3-10 Hz. Thalamic activity was abolished by transection of thalamocortical connections, while cortical activity was reduced but not abolished by similar cuts. The principal differences between mouse and rat generalized thalamocortical activity in low- Mg^{2+} medium were: rat slices had a greater tendency to trigger tonic-clonic-like discharges, and had reduced ventrolateral cortical connections to thalamus, evident both through microscopic examination of slices, and in evoked potential studies of thalamocortical responses. We conclude that rat thalamocortical slices may be a promising system in which to study thalamocortical rhythm generation. Supported by NIH grant NS 31000.

INTRINSIC OSCILLATOR CONTRIBUTIONS TO RESPONSE PROPERTIES OF SI CORTICAL NEURONS. K. Sameshima and M.M. Merzenich*, Keck Center for Integrative Neurosciences and Coleman Laboratory, UCSF, San Francisco, CA 94143.

The discharges of somatosensory cortex neurons in pentobarbital-anesthetized rats are often marked by transient oscillatory bursting in the theta range, initiated by tactile stimulation. To study the significance of this oscillatory variation in cortical excitability for stimulus-evoked neuronal responses, PSTHs were recorded for neurons in trials consisting of pairs of 5 ms stimulus taps, with interstimulus intervals (ISI) varied from 10 to 600 ms in 5 or 10 ms increment steps, and with 3 s long intertrial intervals. Trials with different ISIs were conducted in random order, with stimulation applied at the centers of trunk or hind paw receptive fields by use of a displacement-controlled tactile stimulator.

Following the response to the first stimulus tap, there was a period of response suppression in which no responses were evoked by second stimuli, typically lasting between 50 to 100 ms, depending on the amplitudes of the first and second stimuli. This period of profound response suppression was longer for larger first stimuli and/or smaller second stimuli. Cortical neuronal response magnitude for the second stimulus changed systematically with increasing ISI beyond this suppression period. Within about 80 to 150 ms, the response evoked by an equivalent intensity second stimulus usually equaled or exceeded that evoked by the first. At greater ISIs, the response to the second stimulus was usually *again* suppressed, with maximum suppression recorded at ISIs between 130-200 ms. At still longer ISIs, the response to progressively delayed second stimuli commonly waxed and waned, with changes in response magnitudes following the oscillation frequency revealed by shorter-ISI stimulus pairs.

Response latencies for first and second stimuli were determined by a Gaussian convolution of spikes. Latencies for the first stimulus ranged from 14 to 24 ms, varying with stimulus intensity. For stimulus of equal intensity, response latencies for the second stimulus were almost always longer than for the first. For a given stimulus intensity, second-stimulus response latencies varied by more than 7 ms, with that variation systematically associated with the oscillatory cycle revealed by changes in response magnitude. Thus, shortest latencies were recorded when evoked responses were strongest, and progressively longer latencies for ISIs that resulted in progressively greater response suppression. INTRINSIC MEMBRANE PROPERTIES AND SOMATOSENSORY CONVERGENCE IN SI CORTEX OF RACCOON. P. Istvan* and P. Zarzecki, MRC Group in Sensory-Motor Physiology, Department of Physiology, Queen's University, Kingston, Ontario, Canada, K7L 3N6.

Timing and rate of neuronal discharge, important for sensory coding, are regulated by synaptic inputs and by intrinsic membrane properties. Knowledge of both of these regulators is needed to understand how patterns of discharge are created during sensory processing. We investigated intrinsic membrane properties and somatosensory EPSPs and IPSPs in raccoon SI, *in vivo*. Intracellular injection of identical current pulses elicited various patterns of discharge. Regular spiking (RS) neurons (58% of sample) discharged at their highest rate at the beginning of the pulse and this was followed by spike frequency adaptation. Intrinsic bursting (IB) neurons (32%) had reoccurring slow depolarizations that led to bursts. Fast spiking (FS) neurons (10%) had brief spikes, and no frequency adaptation. The RS and IB groups both had well-defined subtypes. All neurons responded with EPSPs or EPSPs/IPSPs to stimulation of digit 4 ("on-focus" digit). Neurons (40%) also responded to stimulation of digits 3 or 5 ("off-focus" digits). Monosynaptic thalamocortical EPSPs from digit 4 were common for RS, IB and FS neurons, but few of the responses from off-focus digits were mediated by monosynaptic thalamocortical connections.

The precise pattern of neural discharge cannot be a reliable estimate of sensory input. Ionic conductances governing patterns of neuronal discharge seem almost identical in intact cortex of rat, cat and raccoon, and in slices of rodent cortex, because matching varieties of intrinsic firing patterns are found. Our studies give new information about thalamocortical connectivity of neurons defined by their firing patterns.

SIMPLIFIED COMPUTATIONAL MODELS OF NEOCORTICAL NEURONS FOR USE IN ANATOMICALLY REALISTIC NETWORK SIMULATIONS OF INTERAREAL CORTICAL OSCILLATIONS. Mark E. Jackson* and Larry J. Cauler, GR41 Cognition and Neuroscience Program, University of Texas at Dallas, Richardson, TX 75083-0688.

Pyramidal and nonpyramidal neurons of rat SI neocortex were physiologically studied *in vitro*, filled with biocytin, morphologically reconstructed (NeuroLucida, Glaser, 1991) and simulated using NEURON (Hines, 1992) as in Cauler and Connors (*Single Neuron Computation*, 1992). Models of these complex morphologies were simplified to a few major dendritic compartments that conserved passive electrotonic properties (similar to Stratford *et al.*, 1989). Intracellular R_a was set at 100 Ω -cm and R_m was adjusted to make the somatic input impedance approximately equal to the experimentally observed values (sharp electrodes: 10-50 M Ω). Spine area (1.25 spines / μ m) was simulated by simply increasing compartmental C_m because the conductance per spine area ($\sim 1 \mu$ m²) corresponding to these R_m values ($\sim 0.1-1$ pS) is less than established channel conductances. By this assumption, spine area directly increases the time constant independently of impedance or length constant. Models of pyramidal neurons were specifically designed with elaborated apical dendrites including the distal tufts, multiple obliques and the long, thick apical trunk that characterizes these cells. Apical trunk conductances were adjusted to retain the sensitivity to layer I synaptic inputs observed experimentally. The resulting pyramidal neuron involves two dendritic domains, apical and basal, separated by an intervening trunk which serves as a gate for selective modulation of apical inputs. This computationally efficient but realistic model was then incorporated into a network using GENESIS (Wilson and Bowers, 1989) which is organized with reciprocal connections between simulated primary and secondary cortical sensory areas. This network model examines the conditions under which reciprocal interactions can synchronize interareal oscillations.

THE SIZE AND LOCATION OF THE TAIL REPRESENTATION AREA IN THE PRIMARY SOMATOSENSORY CORTEX (SI) OF THE RAT. C.-T. Yen* and C.-Y. Lin, Departments of Zoology and Electrical engineering, National Taiwan University, Taipei, Taiwan, 10764, ROC

The size and the location of the tail representation area in the SI region of the rat were studied with evoked potential and unit recording methods. The rats were anesthetized with i.p. pentobarbital initially and with slow continuous i.v. infusion. The medial portion of their parietal cortex were searched with glass microelectrodes for responsiveness to tail stimulations. For evoked potential studies, regular penetrations consisted of rectangular grids separated by either 0.5 or 0.3 mm. Recording depth was 1.0 mm deep in the cortex. The tail of the rat was stimulated electrically. Isopotential maps of the evoked potentials were used to delineate the tail representation area. An average area of 0.51 mm² was found if 1/2 maximal response were used as the cutoff threshold. If the cutoff threshold was lowered to twice the height of the baseline noise level, an average area of 1.7 mm² was found. For unit recording studies, denser penetrations of 0.2 to 0.3 mm separations were used. Single units whose receptive fields included a part of the tail could be found inside an average 0.35 mm² region. When multiunit were studied, the area was larger, averaged 0.78 mm². The center of the tail representation area found with all methods was 2.0 to 2.3 mm posterior and 2.5 mm lateral to the Bregma, with the tailtip pointed medioanteriorly.

SYNAPTIC PATTERNS ONTO BURSTING VS. REGULAR SPIKING NEURONS. E.L. White*, Y. Amitai and M. J. Gutnick, Center for Brain Research, Faculty of Health Sci., Ben-Gurion Univ., Beer Sheva, ISRAEL.

Regular spiking (RS) and intrinsically bursting (IB) neurons show distinct differences in their morphologies, as assessed at the level of the light microscope (Chagnac-Amitai *et al.*, 1990; Larkman and Mason, 1990; Larkman, 1991a,b,c) and in their inhibitory responses. Under various conditions, the synaptic responses of RS cells display marked IPSPs, whereas most IB cells do not (Silva *et al.*, 1988; Chagnac-Amitai and Connors, 1989a,b; Connors and Gutnick, 1990). This investigation is designed to determine if differences in the inhibitory responses of RS vs. IB cells are reflected in differences in the concentration of inhibitory synapses onto their somata. 4 RS and 5 IB neurons in rat somatosensory cortex were identified using intracellular recording and labeling, examined with the light microscope, and then serial thin sectioned prior to examination with the electron microscope. Synapses onto their somata and proximal dendrites were identified, classified using criteria described by Peters and coworkers (Peters *et al.*, 1990; Peters and Harriman, 1990, 1992), and plotted onto computer-assisted, 3-D reconstructions made from the serial thin sections. Our analysis showed no significant difference in the types and concentration of synapses made onto the cell bodies and proximal dendrites of intrinsically bursting vs. regular spiking neurons. Thus the differences observed in the inhibitory responses of intrinsically bursting vs. regular spiking neurons cannot be explained by differences in the concentrations of synapses onto their somata. MULTIUNIT NORMALIZED CROSS CORRELATION DIFFERS FROM THE AVERAGE SINGLE UNIT NORMALIZED CORRELATION IN RAT SOMATOSENSORY CORTEX. P.H. Bedenbaugh* and G.L. Gerstein, Department of Neuroscience and Bioengineering, University of Pennsylvania, Philadelphia, PA 19104

As the technology for simultaneously recording from many brain locations becomes more available, more and more labs are measuring the cross correlation between single units and between multiple unit clusters. The relationship between single unit correlations and unit cluster correlations has not yet been fully explored.

We calculated the normalized cross correlation (NCC) between single unit spike trains, between small clusters of units and between multiunit clusters recorded in the rat somatosensory cortex. The NCC between small clusters of units was 2-3 times larger than between single units, and the NCC between multiunit clusters was and order of magnitude larger than between the small clusters of units. To understand this result we investigated the scaling of the NCC with the number of units in a cluster.

Consider four cells, two recorded on each of two electrodes. Assume that the NCC between cells recorded on the same electrode is ρ_{close} and between cells recorded on different electrodes is ρ_{dist} , both constants. The NCC between the clusters made up of the unit pairs recorded on each of the two electrodes increases linearly as a function of ρ_{dist} , with a slope determined by ρ_{close} . When $\rho_{close} = 0$, the slope is 2. When $\rho_{close} = -\frac{1}{3}$, the slope is $\frac{2}{3}$, and when $\rho_{close} = 1$ (identical spike trains) the slope is 1. In some circumstances it is easier to detect negative NCC between unit clusters than between single units. These results assume perfect spike sorting, even of overlapping waveforms. We are exploring how spike sorter dead time affects single/multiunit scaling. Supported by NIH MH46428 and DC01249.

THE ORGANIZATION OF THE FOREPAW REPRESENTATION IN SOMATOSENSORY CORTEX (SI) OF RAT: A COMBINED ELECTROPHYSIOLOGICAL AND MORPHOLOGICAL STUDY. C.A. McCandlish*, C.X. Li, R.S. Waters, Dept. of Anatomy and Neurobiology, Col. of Medicine, UT, Memphis, Memphis, TN 38163.

Few investigators have taken advantage of the forepaw barrel subfield (FBS) in rat SI cortex for studies relating cortical function to the underlying barrel field organization. We describe results of electrophysiological mapping studies where specific parts of the forepaw are associated with individual FBS barrels.

Adult rats were anesthetized with Nembutal (35mg/kg), the head was stabilized in a custom-made holder. An opening was made in the skull overlying SI cortex, a chamber was fashioned out of acrylic and placed around the opening on the skull, the dura was removed, and the cortex was covered with warmed silicon fluid. Carbon fiber electrodes were used to record evoked responses elicited by a hand-held probe, and the FBS was completely mapped, or rows of 3-4 electrode penetrations were made across an entire digit representation. Lesions were placed to identify specific recording sites. Following mapping, the cortex was removed, hemispheres were sectioned coronally or flattened and cut in a tangential plane. Tissue was stained with cytochrome oxidase and/or cresyl violet. The following results are noteworthy:

1. A single representation of the digits was found in FBS.
2. The representation of the glabrous aspect of digits 2-4 is composed of 3-4 barrels, whereas digit 1 is represented by a single barrel.
3. The glabrous digit tip, is represented by the two most anterolaterally located glabrous digit barrels.
4. Other barrel-like structures are associated with the palmar pads, and dorsal digits.

DISTRIBUTION OF PARVALBUMIN- AND CALBINDIN-IMMUNOREACTIVE NEURONS IN CAT SOMATOSENSORY CORTEX. J. Li, H. Huang and H.D. Schwark. Dept. of Biological Sciences, University of North Texas, Denton, TX 76203

In many areas of neocortex, the calcium binding proteins parvalbumin and calbindin are contained in separate populations of neurons which differ in their laminar distributions. In the present study, we have compared the laminar distributions of parvalbumin- (PV-IR) and calbindin-immunoreactive (CALB-IR) neurons across the four cytoarchitectonic areas of cat primary somatosensory (SI) cortex. Sagittal sections were cut through SI and stained for parvalbumin, calbindin, cytochrome oxidase activity, or Nissl substance. The locations of all PV-IR and CALB-IR neurons in SI were plotted from three series of six closely spaced sections each.

PV-IR neurons were found in all layers except layer I, with highest densities in layers III and IV. Laminar distributions of PV-IR neurons varied significantly among cortical areas, primarily due to differences in layers II and IV. For layer II, the density of PV-IR neurons was highest in area 2, declined through areas 1 and 3b, and was lowest in area 3a. In contrast, layer IV in area 3b contained over 50% higher density of PV-IR neurons than in the other areas. 97% of the CALB-IR neurons were found in layers II and III, with highest densities in layer II. The laminar distributions of CALB-IR neurons were similar across cytoarchitectonic areas. The results suggest that the laminar distributions of PV-IR neurons in the cytoarchitectonic areas of SI may reflect functional differences between these areas.

RELATIONSHIP OF CALBINDIN WITH CORTICOCORTICAL PROJECTION NEURONS IN THE RAT SECOND SOMATOSENSORY CORTEX. K.A. Baskerville*, H.T. Chang, and P. Herron. Dept. of Anatomy and Neurobiology, The Univ. of Tennessee, Memphis, Col. of Medicine, Memphis, TN 38163

Most calbindin-immunoreactive (CaBP+) neurons in the cerebral cortex are GABAergic nonpyramidal neurons. In initial studies, we found that CaBP+ interneurons were located in the same laminae (II/III, V, and VI) as corticocortical projection neurons in the rat second somatosensory cortex (SII). In this study, we investigated the possible synaptic contacts between corticocortical projection neurons and CaBP+ neurons in SII of the rat. To study these relationships, we combined retrograde tracing (Fluoro-Gold) and anterograde tracing (Phaseolus vulgaris-leucoagglutinin or Fluoro-Ruby) with immunocytochemistry for calbindin. The tracers were injected into the forepaw subdivision of the primary somatosensory cortex (SI). At the light microscopic level, CaBP+ neurons and processes were found adjacent to the retrogradely labeled corticocortical neurons in both upper and lower layers of SII. Likewise, anterogradely labeled corticocortical terminals were found in close proximity to CaBP+ cell bodies and dendrites, particularly in the upper layers of SII. Using a combined immunoperoxidase and silver-intensified colloidal gold technique, we observed that anterogradely labeled axon terminals were in close apposition to CaBP+ neurons at the electron microscopic level. (Supported by NIH grant AG05944 and The Center for Neuroscience of The Univ. of Tennessee, Memphis).

DIVERGENCE IN THE PROJECTION OF VENTROBASAL THALAMIC NEURONS TO MONKEY SOMATOSENSORY CORTEX. E. Rausell¹, A. Viñuela², M. Molinari³ and E.G. Jones⁴. Autonomia University, 28029 Madrid, Spain^{1,2}; Catholic University, 00168 Roma, Italy³; and University of California Irvine, CA 92717⁴.

The degree to which thalamocortical axons diverge and innervate separate patches of somatosensory cortex (SI) was examined in *Macaca fasciata* and *Macaca mulatta* monkeys by combining extracellular recording and retrograde tracing. In anesthetized monkeys, two loci 1mm or less apart and containing neurons with the overlapping receptive fields were identified by recording responses to stimulation of the contralateral face and leg, and Diamidino Yellow (DY) or Fast Blue (FB) was injected in each focus. The animals survived for two weeks and were then anesthetized and perfused with 4% paraformaldehyde. Retrogradely labeled neurons in the thalamus were plotted and the sections were re-processed for cytochrome oxidase (CO) and Nissl staining.

The injections involved an area of 400-600 μm^2 , were separated by less than 1mm, affected only layers I-V, and never overlapped. No retrogradely double-labeled neurons were found in VB. Single DY- and FB- labeled neurons were generally found to be neighbors and included within elongated anteroposterior groups of neurons or CO-"rods" in VPM or VPL. Usually most of the DY neurons were contained in rods adjacent to but separate from those containing most of the FB neurons, conforming to the well known topography of thalamocortical organization. Invariably, however, a small but consistent number of DY cells were found in the FB rod(s) and vice versa.

Because no double labeled neurons were found, the implication of these results is that a small population of thalamic neurons innervated by lemniscal fibers representing a localized area of the periphery project to "inappropriate" parts of the SI map. In this, there is a possible substrate for plasticity of representational maps under activity-dependent conditions.

CALCIUM-BINDING PROTEIN PHENOTYPE AND FUNCTION OF GABA-ERGIC NEURONS IN BARREL CORTEX. J.S. McCasland*, L.S. Hibbard, and T.A. Woolsey. Dept. of Neurology and Neurological Surgery, Washington University School of Medicine, Saint Louis, MO 63110.

GABA-ergic neurons in cerebral cortex are subdivided on the basis of co-localized calcium-binding proteins, parvalbumin and calbindin (e.g. Hendry et al., Exp. Brain Res. 76: 467-72). A high resolution 2DG/immunostaining method was used (McCasland et al., Soc. Neurosci. Abstr. 18:1546) to label a set of large GABAergic neurons at the layer IV-V boundary that have heavy 2DG uptake during active behavior, and which are activated ectopic to zones of direct whisker stimulation in barrel cortex of the behaving hamster. Consistent with reports from other cortical areas, we find that both calbindin and parvalbumin stain mostly nonpyramidal cells. The parvalbumin-stained neurons are larger than those staining for calbindin. Most heavily 2DG-labeled neurons are parvalbumin+, and virtually every parvalbumin+ neuron is moderately to heavily 2DG-labeled. The opposite pattern is observed for calbindin; heavily 2DG-labeled neurons at the IV-V boundary show no calbindin staining, and the numerous calbindin+ cells in layer IV and elsewhere show very light 2DG label. We conclude that functional subtypes of GABAergic neurons in barrel cortex can be defined by the phenotypic expression of a particular calcium-binding protein.

IMMUNOCYTOCHEMISTRY OF THALAMOCORTICAL TERMINALS IN LAYERS I AND IV. Y.N. Kharazia*, A. Rustioni and R.L. Weinberg. Dept. of Cell Biology & Anatomy, University of North Carolina, Chapel Hill, NC 27599.

Pharmacologic evidence implicates glutamate as thalamocortical neurotransmitter. Given the inconclusive anatomical evidence available, we have combined anterograde transport with immunocytochemistry to further study this question. Anterogradely-labeled terminals were identified after iontophoretic injections of WGA-HRP in the thalamus of anesthetized rats. Injections were made into the ventroposterior thalamus and the lateral geniculate to label fibers terminating in layer IV of SI and V1. Injections in the ventromedial thalamic nucleus labeled terminals in superficial layer I throughout most of frontal and parietal cortex.

Thalamocortical terminals in layer IV were large, rich in mitochondria, and contained loosely-packed round clear synaptic vesicles. They made asymmetric synapses, mainly with dendritic spines. Terminals in V1 resembled those in SI, though V1 terminals were more elongated, often encapsulated by glia, and with smaller active zones. Thalamocortical terminals in layer I generally resembled those in layer IV. However, they contained fewer mitochondria and contacted apical dendritic shafts more often than terminals in layer IV; in addition to small synaptic vesicles, many layer I terminals contained large dense core vesicles.

Post-embedding immunocytochemistry was performed for glutamate (Glu), aspartate (Asp) and GABA singly or in pairs (using different sizes of gold particles). Thalamic terminals in both layers I and IV were enriched in Glu in comparison to GABA-positive terminals and dendrites postsynaptic to them, random dendrites, and astroglia; layer I terminals contained higher levels of Glu than layer IV terminals. Layer I terminals contained less Asp than layer IV terminals. Dendritic spines postsynaptic to thalamic terminals in both layers were also enriched in Glu and Asp, raising the possibility that released amino acids may be taken up by spines. These observations support pharmacological evidence that thalamic terminals use Glu as neurotransmitter; specific sensory relays projecting to layer IV may also release Asp. Supported by NIH #NS29879 (to RJW).

PHYSIOLOGICAL PROPERTIES OF HORIZONTAL EXCITATORY SYNAPTIC CONNECTIONS IN THE NEOCORTEX. A.E. Telfeian, H.G. Kim*, and B.W. Connors. Dept. of Neuroscience, Brown University, Providence, RI 02912.

We have compared the length, strength, conduction velocity and divergence of layer 5 and 2/3 horizontal (i.e. parallel to the pial surface) connections in slices of rat SI neocortex. Slices were cut along laminar boundaries to eliminate most vertical connections, and EPSPs were recorded from pyramidal cells in adjacent uncut tissue. When electric stimuli were delivered within the same layer as the recorded cell, EPSPs could be evoked up to 2000 μm away for both layer 2/3 and 5 pyramids. Staining with biocytin showed that some axons of layer 2/3 and 5 pyramids project horizontally over 2000 μm . Estimates of horizontal axonal conduction velocities (~ 0.4 m/s) and the thresholds for activation also did not differ between layers. However, layer 2/3 cells rarely responded to stimuli delivered to isolated deeper layers, while layer 5 neurons were often excited by horizontal inputs from isolated layers 2/3 and 4. Within layer 5 neurons, the rise-time and half-width of EPSPs evoked by minimal stimuli were not correlated with vertical stimulation distance from the soma; it is likely that the active properties of apical dendrites significantly influence the vertical propagation of EPSPs. We conclude that horizontal excitatory connections in layers 5 and 2/3 are similar in length, strength, and conduction velocity, and that layer 5 neurons can effectively respond to stimuli over a wide vertical distance.

CHOLINERGIC MODULATION OF THE EXTRACELLULAR RESPONSE EVOKED BY ISOLATED HORIZONTAL INPUTS TO LAYER I OF THE PRIMARY SOMATOSENSORY AREA OF THE RAT NEOCORTICAL SLICE. Elizabeth Rich-Bennett*, Hui-Fang Li, and Larry J. Cauler, Cognition and Neuroscience Program, University of Texas at Dallas, Richardson, TX 75083-0688.

Horizontal inputs to layer I of SI neocortex were isolated *in vitro* by a vertical cut through deeper layers of the cortical slice. Stimuli applied in layer I on one side of the cut evoked a monophasic field potential in layer I on the opposite side associated with EPSPs recorded intracellularly from pyramidal neurons in layers II, III and V. Current source-density (CSD) analysis of this layer I response revealed a current sink restricted to layer I and upper layer II with smaller current sources distributed immediately below down to layer V. This response was reversibly eliminated by bath application of the non-NMDA glutamate channel blocker, DNQX (10 μ M). Bath application of the muscarinic blocker, benztropine (20 μ M), slightly reduced the amplitude (~10%) of the layer I response, although the muscarinic agonist, carbamyl-beta-methylcholine (Bethanecol, 10-100 μ M) had no consistent effect. The acetylcholinesterase inhibitor, physostigmine (Eserine, 10 μ M), greatly increased the amplitude (50-100%) and duration of the layer I evoked field potentials and currents. In addition, physostigmine slightly shifted the site of maximal current sink from layer I to upper layer II. Subsequent application of benztropine (20 μ M) returned the response to subcontrol levels as when applied alone. These results indicate the layer I response is modulated by endogenous acetylcholine maintained *in vitro* acting upon muscarinic receptors.

EFFECT OF FOCAL COOLING OF AREA 1 ON IPSILATERAL AREA 3b RESPONSES IN FLYING FOXES AND MARMOSETS. J.C. Clarey*, R. Tweedale, L.A. Krubitzer, and M. Calford, Vision, Touch, and Hearing Research Centre, Department of Physiology and Pharmacology, University of Queensland, Australia 4072.

We have shown previously that focal cooling of area 3b in one hemisphere in flying foxes and macaque monkeys leads to an expansion of neuronal receptive fields (RFs) recorded from area 3b in the opposite hemisphere. We inferred that blocking the callosal pathway(s) interconnecting area 3b produces a disinhibition that allows unmasking of large RFs. Since the distal limb representations in area 3b are acallosal in both species, we suggested that this effect was mediated by the interhemispheric connections of area 1 (termed area 1/2 in the flying fox) via its intracortical connections with area 3b. We confirmed that focal cooling of area 1 (1/2) led to expansion of cortical RFs in contralateral area 3b in both species. The present series of experiments reports on the effect of area 1/2 cooling on ipsilateral area 3b responses and aimed to confirm the findings in another species, namely the common marmoset (*Callithrix jacchus jacchus*). Experiments performed in adult, ketamine-anesthetized flying foxes (*Pteropus scapulatus*; n=4) showed that cooling the forelimb digit 1 (D1) representation of area 1/2 resulted in an expansion of multi-unit D1 RFs recorded in area 3b of the same hemisphere. The RF contracted to its original dimensions within the cooling period in all cases. These results indicate that area 1/2 input modulates area 3b responses and that this input is inhibitory. We have demonstrated similar ipsilateral effects in two ketamine-anesthetized marmosets using controlled brush stimulation and recording from single- and multi-units in area 3b. Area 1 has not previously been described in marmosets; however, electrophysiological maps (n=5) in relation to myeloarchitecture (n=3) and cortical connections (as revealed by fluorescent tracers; n=2) have confirmed the existence of this field immediately caudal to area 3b. Mapping experiments have indicated that neurons within area 1 respond to cutaneous stimulation and have a tendency to habituate to repetitive stimulation.

INTRACORTICAL CONTRIBUTIONS TO SHORT-TERM NEOCORTICAL PLASTICITY: CORTICAL AND SUBCORTICAL EFFECTS OF MICROSTIMULATION IN S-BARREL CORTEX. D. Skusek and E. Liand, Animal Biology, Sch. Vet. Med. and Neurology, Sch. Med., Univ. of Penna., Phila., Pa. 19104

We previously showed that 3-6 hours of electrical microstimulation (MS) confined to a layer IV "barrel" with a clearly defined principal-whisker (PW) receptive field resulted in an expansion of that whisker's cortical functional representation using 2-deoxyglucose (2DG) and electrode mapping techniques. In this study, we used a chronic electrode array (up to 4 electrodes) to simultaneously record multi-unit activity prior to, during, and following cortical MS; in many of the same animals the 2DG technique was also used to determine spatial representational changes of the PW throughout the central trigeminal nucleus following MS.

A micro-electrode array with tip separations of 500 μ m was positioned over the barrel cortex and lowered to a depth of 800 μ m; the assembly was attached to the skull. 3 weeks later the animal was lightly anesthetized and the receptive field of neurons at each electrode tip was determined. One electrode with a non-overlapping PW-receptive field was chosen as the MS site. The response latency and magnitude (# spikes/deflection) of cortical neurons to deflection of the PW was determined for each electrode position. MS began and consisted of a 40ms train of charge-balanced 7uA monophasic pulses @330Hz; 1 train per second. MS continued for 3-6 hours and was interrupted at 1-hour intervals to re-examine the response properties of neurons at each electrode position to deflection of the PW. The 2DG technique was then used in awake animals that received MS to determine the distributed CNS metabolic (functional) representation of the PW.

Response latency (RL) in the PW-stimulated barrel pathway was significantly shortened following MS (5.4ms \pm 0.27 vs. 7.2ms \pm 0.2; p<0.001). The RL in the PW-unstimulated barrel pathways was also significantly shortened following MS (11.3ms \pm 0.36 vs. 13.8ms \pm 0.26; p<0.001). The # spikes/whisker deflection did not change with MS (PW-1.2 spk/deflection; nonPW-0.7 spk/deflection). 2DG also showed a significantly increased spatial representation of the PW in the barrel cortex following MS; 2DG labeling in the thalamus and brainstem was unchanged (ie, NO expansion). We conclude that short-term cortical plasticity following MS is mediated in large part by intrinsic cortical network properties; other possibilities are discussed.

IMMEDIATE REORGANIZATION IN SOMATOSENSORY CORTICAL AREAS 3B AND 1 IN SQUIRREL MONKEY AFTER COMBINED ULNAR AND MEDIAN NERVE TRANSECTION. C.X. Li, E.F. Johnson, R.S. Waters*, Dept. of Anatomy and Neurobiology, Col. of Medicine, UT, Memphis, Memphis, TN 38163.

The phenomenon of immediate cortical reorganization following nerve transection has been documented in squirrel monkey somatosensory cortical areas 3b and 1 (Merzenich et al. 1983). We reexamined this phenomenon in squirrel monkey by mapping somatosensory cortex (SI), transecting one or more peripheral nerves, and immediately remapping SI cortex.

Adult squirrel monkeys were anesthetized with Ketamine (35mg/kg), the head and left arm were stabilized in custom made holders, and the skin over the ulnar and median nerves was opened, the nerves identified and tagged with suture. Following forepaw preparation, the contralateral SI cortex was exposed, and an acrylic recording chamber was fashioned on the surrounding bone. Carbon fiber electrodes were used to record evoked responses elicited by mechanical and/or hand held stimulators, and the forepaw region of SI cortex was identified and mapped. Following complete mapping of the forepaw representation, the ulnar and/or median nerve was cut and the cortex remapped. Using these techniques the following results are noteworthy:

1. Ulnar nerve transection alone was not sufficient in eliminating digit 5 glabrous input into SI cortex.
2. When ulnar and median nerve transections were combined, glabrous digit stimulation was ineffective in driving SI cortex.
3. In those cases where immediate cortical reorganization was observed the region of SI cortex formerly served by stimulation of the glabrous skin was driven by stimulation of the corresponding hairy skin.

PARVALBUMIN AND CALBINDIN IMMUNOREACTIVITY IN THE SOMATOSENSORY BARREL CORTEX AND EFFECT OF TACTILE EXPERIENCE. M.H. Cohen, R. Zatezalo and P.W. Land*, Dept. of Neurobiology, Univ. of Pittsburgh, Pittsburgh, PA 15261.

Calcium-binding proteins parvalbumin (PV) and calbindin D-28K (CB) differentiate populations of neocortical GABAergic neurons. We used immunocytochemical methods to study the distribution of PV-immunoreactive (IR) and CB-IR neurons and processes in the somatosensory barrel cortex of rats. PV-IR and CB-IR neurons and processes occur in all cortical laminae, except lamina I which contains processes only. Lamina IV has the highest density of PV-IR neurons and processes, where they define the sides and hollows of cortical barrels. PV-IR puncta nevertheless surround unreactive somata in all laminae below lamina I. By contrast with PV-IR neurons, CB-IR neurons are least numerous in lamina IV, and fall within the septae between barrels. The density of CB-IR processes parallels the distribution of CB-IR somata, being particularly robust in lamina Vb. Interestingly, we observe no CB-IR puncta in any laminae.

Tactile deprivation by simple whisker trimming has no visible effect on immunostaining for either protein, though GABA levels are reduced by this procedure. However, destroying vibrissa follicles by electrocautery leads to decreased PV-IR in corresponding lamina IV barrels. The data indicate that neurons containing different calcium binding proteins are segregated according to structural and functional subdivisions of the barrel cortex. Further, within barrel hollows PV synthesis can be modulated by peripheral deafferentation. (Supported by NSF grant BNS 9110731)

645.5

LESION-INDUCED MODULATION OF α_7 NICOTINIC RECEPTORS IN DEVELOPING RAT SOMATOSENSORY CORTEX. R.S. Broide*, R.T. Robertson and F.M. Leslie. Depts. of Pharmacology; Anatomy and Neurobiology, Univ. of California, Irvine, CA 92717.

The rat somatosensory cortex (SS1) displays a unique cytoarchitecture which is developmentally influenced by afferent neuronal activity. Several cholinergic markers have been found to label the barrel field within the SS1 during a critical period of development. [¹²⁵I] α -Bungarotoxin (BTX) exhibits a unique, transient developmental binding pattern that delineates columnar bands, extending through all layers of the SS1. These bands, which correspond to the barrel field, are most clearly distinguished in tangential cortical sections of laminae IV and VI. Studies have indicated that, in the CNS, the toxin binds to the α_7 neuronal nicotinic receptor subunit and have suggested that this site may be involved in the formation of neural connections. In order to elucidate the potential mechanism, it is important first to determine whether this site is found on thalamic terminals or on their cortical targets during the early stages of synaptogenesis. We placed unilateral electrolytic lesions in the ventrobasal thalamic nucleus of P6 rat pups. Pups were then sacrificed at P7, 8, 9, and 10. Both cortical hemispheres were sectioned in the tangential plane and processed for acetylcholinesterase (AChE) histochemistry, receptor autoradiography, and *in situ* hybridization. While there was no change to the contralateral side, the ipsilateral cortex showed a marked decrease in both [¹²⁵I] α -BTX binding and α_7 mRNA distribution levels within barrel-like structures in laminae IV and VI. This decrease was apparent as early as P7 and correlated well with a loss in AChE staining within lamina IV. These findings suggest that the α_7 nicotinic receptor may be localized on presynaptic thalamocortical terminals, although this may also reflect a dynamic transynaptic modulation of receptors.

SELECTIVE ISCHEMIC BLOCK OF THE SURAL NERVE: EFFECTS ON SCALP POTENTIAL TOPOGRAPHIES EVOKED BY NOXIOUS STIMULATION. R. Dowman*, Dept. Psychology, Clarkson University, Potsdam, N.Y., 13699-5825.

Scalp potential topographies evoked by electrical stimulation of the sural nerve were obtained in 10 human subjects. Two different stimulus levels were used: innocuous (elicited a just-maximal sural nerve compound action potential and was rated as non-painful) and noxious (elicited a spinal nociceptive withdrawal reflex and was rated as painful). At 30-50 min following ischemic block of the lower leg none of the subjects could detect the innocuous stimulus. No scalp potentials were evident at this level. All subjects detected the noxious stimulus. In 5 subjects there were no scalp potentials at the noxious level. These subjects described the noxious stimulus as having a burning quality. A positive scalp potential occurring 280-400 ms following the stimulus was evident at the noxious level in the remaining subjects. Most of these subjects described this stimulus as having a sharp, prickling quality. These results suggest that the pain-related scalp potentials are elicited by the smaller diameter myelinated afferents. A quantitative analysis of the topographic patterns will be performed to determine whether the configuration of the sources generating the pain-related positive potential changed during the selective block.

NMDA RECEPTOR BLOCKADE PREVENTS MOST CORTICAL REORGANIZATION AFTER PERIPHERAL NERVE INJURY IN ADULT MONKEYS. P.E. Garraghy*, N. Muia, and R. Hoard, Dept. Psychology, Indiana University, Bloomington, IN 47405.

After median nerve transection in adult New World monkeys, neurons in the part of somatosensory area 3b deprived of their normal inputs eventually regain responsiveness to inputs from skin surfaces with intact innervation. Merzenich et al. (*Neuroscience*, 10:639, 1983) showed this reorganizational process to be essentially a two-stage process, one immediate, and one more protracted, with the recovery of cortical responsiveness taking no more than 3-4 weeks. In the present experiments, we have investigated the role of the NMDA receptor system in these two phases of injury-induced reorganization. In 6 monkeys (5 squirrel monkeys, 1 owl monkey), we studied the immediate, or more protracted cortical response to median nerve transection in area 3b. In 2 monkeys (1 pre-treated with CPP, an NMDA receptor blocker), the immediate effects of median nerve transection were assessed. In 3 monkeys, NMDA receptor blockade and nerve transection were contemporaneous, with terminal recording at 11, 25, or 28 days after nerve injury. In a final monkey, cortical mapping 30 days after median nerve transection (with no NMDA receptor blockade) revealed virtually complete reorganization. Acute post-nerve injury mapping revealed immediate unmasking within approximately 20% of the deprived cortex whether NMDA receptors had been blocked or not. In the 3 monkeys with longer survival times and NMDA receptor blockade, there was no indication that any of the protracted recovery had occurred. In each case, approximately 20% of the presumed deprived cortex showed reorganization while the remainder remained unresponsive to cutaneous stimulation. These results suggest that the immediate "unmasking" phase of cortical recovery is not dependent on NMDA receptor activation while the more protracted phase can be prevented by NMDA receptor blockade. (Supported by Indiana University 22-314-31)

645.6

MECHANISMS OF SOMATOSENSORY PLASTICITY IN ADULT PRIMATES. S. Seto*, C.E. Schroeder, J.P. Noonan, J.C. Arezzo and P.E. Garraghy. Depts. Neurosci. and Neurol., Albert Einstein Coll. Med., Bronx, NY 10461 and Dept. Psych., Indiana Univ., Bloomington, IN 47405.

The time course and underlying physiology of reorganization in the somatosensory cortex of squirrel monkeys were examined by sampling both prior to, and at biweekly intervals after, median nerve transection and ligation. Linear array, multicontact electrodes were chronically implanted in the median nerve representation of Area 3B, as defined by somatic stimulation. Laminar current source density (CSD) and concomitant multiunit activity (MUA) profiles were recorded from anesthetized monkeys using electrical stimulation applied to the median, radial and ulnar nerves near the elbow. Isolation of peripheral nerve stimulation was confirmed by simultaneous recording of EMG from appropriate distal muscles. Prior to nerve section, no ulnar nerve cortical response was evident, but radial nerve stimulation produced a "nondominant" response in median nerve territory (see also Schroeder et al., *Neurosci. Abst.*, 1992). The initial (10-30 ms) epoch of this response was characterized by small current sources and sinks without clear MUA correlates, suggestive of subthreshold activation. Acute recordings after the nerve cut did not reveal any changes. By the next sample point (day 5), this initial epoch of the radial nerve response had undergone a two-fold increase in CSD amplitude that was accompanied by the emergence of a large increase in MUA. These changes progressed over time and appeared to stabilize by the 3rd week. Qualitatively, the post-section radial response greatly resembled the pre-section median response. These findings support the view that reorganization of somatic representation is based on the unmasking of pre-existing, but "silent", radial nerve inputs. (Supported by MH06723, MH47939 and DC00657).

NEURAL ACTIVITY AFTER NOMINAL DEPRIVATION OF THE SOMATIC-SENSORY CORTEX: ³H 2-DEOXYGLUCOSE EVALUATION IN THE RAT. G. Gutierrez¹, D. Riddle¹ and D. Purves². Dept. of Neurobiology, Duke University, Durham, NC 27710.

Deprivation paradigms have often been used to explore the role of neural activity in the development of the sensory cortex. The actual acute and long-term effects of such manipulations on cortical activity, however, are not usually known. We have therefore used ³H 2-deoxyglucose (2-DG) to evaluate neural activity in the primary somatic-sensory cortex (SI) of the rat after deprivation of input from peripheral sensors. Juvenile rats (7 days old) were unilaterally deprived by clipping, plucking or cauterizing the 36 mystacial vibrissae represented in the posteromedial barrel subfield of the contralateral SI. After 10 weeks, a femoral catheter was implanted and 3uCi/gr of 2DG injected in the awake behaving animal. The rats were sacrificed 45 minutes later by an overdose of pentobarbital; the brains were then removed, hemisected, flattened and frozen. Tangential cryostat sections (20µm) through layer IV of each cortex were overlaid with autoradiography film and maintained at 4°C for 12 days. The film was developed and analyzed by video densitometry. We found no differences in 2DG uptake between the deprived and non-deprived PMBSF in any of the experimental groups. Nor did comparison of experimental and normal (control) animals show any difference of 2DG accumulation in this representation. Evidently, neural activity in the PMBSF is little diminished following peripheral deprivation, at least after few weeks. This ongoing activity may explain the absence of appreciable morphological changes in the somatic-sensory system following peripheral manipulations performed after the critical period.

LAMINAR COMPARISON OF PLASTICITY IN ADULT RAT BARREL CORTEX. M.E. Diamond*, W. Huang, and F.F. Ebner, Jr. for Developmental Neurosci., Vanderbilt Univ., Nashville, TN 37203.

Previous experiments have shown that the receptive fields (RFs) of neurons in layer IV of barrel cortex are significantly altered by a 3-30 day period of "whisker pairing." The present study compared the modifiability of different cortical layers, with the aim of identifying the sites in barrel cortex that first express RF changes. Whisker D2 and one neighbor, "D-paired" (either D1 or D3), were spared and all other whiskers on one side of the face were clipped to a length of 3 mm. Rats were anesthetized 24 hours later and the response of single units in barrel-column D2 to stimulation of whiskers D2, D-paired, and 3 surrounding cut whiskers ("D-cut," C2, and E2) was measured. In control rats, neurons in all layers of barrel-column D2 gave equal responses (on average) to the 2 neighboring whiskers, D1 and D3. After 1 day of whisker pairing, the RFs of layer IV barrel D2 cells (n=39) did not yet show any significant bias (bias = number of spikes evoked by D-paired / number of spikes evoked by D-cut = .96). In contrast, cells located above layer IV (n=30) had a significant RF shift in favor of the paired whisker (D-paired / D-cut = 1.90). Cells located below layer IV (n=20) also showed an RF bias (D-paired / D-cut = 1.29), though not as pronounced as above-barrel cells. These findings suggest that the initial cortical modifications induced by pairing whiskers arise from changes in the linkage between cortical barrel-columns, rather than from the relay of altered sensory information directly from VPM to layer IV. The earliest experience-dependent plasticity seems to occur among cells located above and below the barrel, and is subsequently relayed to layer IV.

BCM MODEL OF EXPERIENCE-DEPENDENT PLASTICITY IN RAT BARREL CORTEX. L. Benuskova, M.E. Diamond, M. Armstrong-James, M. Ebert and F.F. Ebner Institute for Developmental Neuroscience, Vanderbilt University, Nashville, TN 37203.

Previous experiments showed that the receptive fields of neurons in adult rat barrel cortex are modified by 3-30 days of "whisker pairing". Whiskers D2 and either D1 or D3 were spared while all others on one side of the face were clipped daily. Physiological recordings from barrel D2 suggested 3 types of cortical plasticity: (1) monotonic increase in the strength of thalamocortical input, (2) initial potentiation (during 3-10 days) followed by a progressive depression (during 10-30 days) of the intracortical inputs from whisker D2 and its paired neighbor, (3) monotonic depression of the intracortical inputs from clipped whiskers. In the present study we used the Bienenstock, Cooper and Munro (BCM) theory to address these observations. The BCM rules, according to which a neuron's threshold for synaptic modification is a dynamic function of its average firing rate, were applied to a model barrel D2 neuron with input from VPM barreloid D2, from within barrel-column D2, and from surrounding barrels. Computer simulations show that the threshold for synaptic modification decreases during the first 10 days of whisker pairing, allowing thalamocortical input and intracortical inputs related to the paired whiskers to potentiate; however, the threshold remains sufficiently high that purely 'noisy' inputs from the barrels of cut whiskers become depressed. After 10 days of whisker pairing, the thalamocortical input continues to potentiate. As a result, the modification threshold now begins to increase, causing the intracortical inputs from both paired and unpaired whiskers to become depressed. The sequential decrease and increase in the BCM synaptic modification threshold provides a possible mechanism for experimental observations of experience-dependent cortical plasticity. ACQUISITION OF DIGITAL DEXTERITY AND PARALLEL REMODELING IN AREA 3B REPRESENTATIONS IN ADULT OWL AND SQUIRREL MONKEYS. C. Xerri*, W. M. Jenkins, B. Peterson, S. Santucci and M. M. Merzenich. Keck Center, UCSF, San Francisco, CA 94143-0732, USA.

The capacity for representational changes within the primary somatosensory cortex (S1) following behaviorally controlled tactile stimulation has been demonstrated in a series of studies conducted in our laboratory. These studies examined post training reorganization of the area 3b cortical map within the zone of cutaneous representation of hand digits. The present experiments were designed to document representational remodeling in area 3b resulting from a sensorimotor training requiring digit use. Seven owl and 2 squirrel monkeys were trained to retrieve banana-flavored food pellets from different size wells on a Klliver board. Animals were tested on pellet retrieval from each well according to a random sequential order (20 pellet presentations for each well size/session). A camera and video tape recorder were used to quantitatively determine and analyze the number of grasping movements, and to identify the digits and specific skin surfaces stimulated in the retrieval task (RT). A map of the cortical representation of the hand used in the RT was derived on the basis of multiunit recordings at the completion of testing. As a consequence of successive attempts, the most effective digit patterns were progressively selected, depending on the well size, i.e., on the degree of difficulty of the RT. Acquisition of digital dexterity was found to occur over training sessions. This sensorimotor learning was characterized by: 1) A gradual decrease in the average number of digit grasps for pellet retrieval (this held true for all well sizes); 2) A progressive reduction in the variability of the RT performance; 3) A continuous increase in the percentage of correct retrievals (pellet neither released nor ejected from the wells). Analysis of the cortical maps showed: 1) A greater cortical magnification for the skin territories of the distal phalanges of the digits most heavily engaged in the RT; 2) smaller receptive fields located on the trained skin surfaces; and 3) a decrease in the percent overlap of receptive fields in the cortical zone of representation of the trained phalanges. Some implications of these findings will be summarized.

CHANGES IN WHISKER USE MODIFY RECEPTIVE FIELDS IN ADULT RAT BARREL CORTEX. M. Armstrong-James*, M. Diamond and F. Ebner. Institute for Developmental Neuroscience, Vanderbilt University, Nashville, TN 37203.

In adult rats all but an adjacent pair of whiskers (D2 + D1 or D3) were trimmed for 3, 7 or 30 days. Then, under controlled urethane anesthesia, all whiskers were trimmed to equal length and receptive fields of cells in the D2 cortical barrel were quantitatively compared with controls. For control animals responses to the surround receptive field (SRF) inputs to the D2 barrel (D1 + D3 and C2 + E2) were symmetrical. With paired whisker experience a profound bias developed in response to the paired SRF D-Row whisker relative to the trimmed SRF D-Row whisker, which was maximal at 30 days. D2 barrel neurons responded decrementally to trimmed whiskers in the arc (C2 + E2). PSTH analysis revealed major changes in long latency discharges at 3 & 7 days consistent with intracortical modification. At 30 days of pairing shortest latency discharges to both paired whiskers increased, commensurate with potentiation of thalamo-cortical transmission. The results suggest that novel sensory experiences, in this study paired whisker use, produce changes in RF configuration, with early alterations in synaptic strength in intracortical circuits and later changes in thalamocortical relays. PERCEPTUAL CORRELATES OF SOMATOSENSORY PLASTICITY IN MAN. V. S. Ramachandran and D. Rogers-Ramachandran*. R. Grush, UCSD, La Jolla, CA 92093.

Twelve years after deafferentation of one upper limb in adult monkeys, the area in S1 corresponding to the hand gets "taken over" by input from the face. In human patients we found that 4 weeks after amputation of one arm, touching the face elicits referred sensations (RS) to the missing (phantom) hand. Two "maps" were found, one on the face, and one just proximal to the amputation line -- as one might predict from the Penfield map (Ramachandran, 1992, *Science*). We now report that: a) The map on the face is modality specific; when water trickles on the face, it is felt to trickle down the phantom. b) Only a subset of the patients have a face map, but almost all have the map (or set of maps) near the line of amputation. c) After finger amputation, topographically organized referred sensations from adjacent fingers were seen in 2 out of 8 patients. Perhaps the other patients had learned to "ignore" the RS. d) When a normal volunteer stimulated his left forearm for 2 months (6 hrs a day) using a TENS, there was a 50% improvement in 2-point discrimination and point localization. Furthermore, intermittent muscular twitching was seen in the fingers of both hands and persisted for a week after the unit was removed! e) In one patient we saw a beautifully organized map 6" above the amputation line. When the patient *imagined* he was pronating the phantom, the entire map shifted by 1 cm and returned again only when he supinated the phantom. Thus the maps in S1 (or their subsequent "readout") might be modulated by refference signals from motor commands sent to the phantom.

PAIN: PATHWAYS III

646.1

IRRITATION OF THE LOWER AIRWAYS: NEURONAL RESPONSES IN THE THORACIC SPINAL CORD. T. Hummel*, J.N. Sen Gupta, S.T. Meller, G.F. Gebhart, Dept. of Pharmacology, Univ. of Iowa, Iowa City, IA 52242

Numerous studies have investigated the response properties of afferents from the lower airways after application of irritants. However, little is known about integration of these responses in the spinal cord. The aim of this study was to analyze responses of T2-T3 neurons after stimulation with ammonia or smoke. Experiments were performed in 35 pentobarbital anesthetized, pancuronium paralyzed male Sprague-Dawley rats (430-530 g). Ammonia or smoke (5 or 15 respiratory cycles, respectively; interval > 8 s) were applied in 2 concentrations each via the tracheal canula. The irritants produced excitatory, inhibitory and biphasic responses in a concentration-related manner (ammonia, 40/40; smoke, 23/39). Latencies of typical responses ranged between 4 and 10 s. Almost all neurons (39/40) responded to distension of the esophagus which was used as the search stimulus. Tracheal distension elicited responses in only 3/39 neurons. Cutaneous receptive fields, sensitive predominantly to pinch, were located on the thorax, axillary region or the forearm. Since the irritants generally produced changes in arterial pressure, only neurons were tested in which sodium nitroprusside (10 µg/kg i.v.) induced no or only marginal activity. Most neurons (20/23) excited by ammonia/smoke also responded to bradykinin (20 µg/kg i.v.) while phenyl diguanide (40 µg/kg i.v.) produced responses in 13/29 neurons. Responses to irritation could still be obtained after both reversible or irreversible block of the thoracic vagi, and reversible or irreversible spinalization at C2. The current data suggest that, after irritation of the lower airways, the thoracic spinal cord receives its major input via pathways different from the vagal nerves or fibers descending from supraspinal centers. This study was supported by NS19912, NS29844, and a fellowship of the Feodor-Lyden-Stiftung, Germany.

NITRIC OXIDE, NMDA RECEPTORS, AND TRIGEMINOTHALAMIC NEURONS IN THE SPINAL TRIGEMINAL NUCLEUS. C.S. Dohm*, L. Kus and A.J. Beitz. Department of Veterinary Pathobiology, University of Minnesota, St Paul, MN 55108

The spinal trigeminal nucleus (STN) is involved in the transmission of orofacial sensory information and is divided, both functionally and anatomically, into three subnuclei: oralis, interpolaris, and caudalis. Neither the distribution of the neuromessenger, nitric oxide (NO), within the trigeminal system nor the possible relationship of this simple gas with trigeminothalamic neurons has been carefully studied to date. Using both immunocytochemical (against nitric oxide synthase) and histochemical (i.e., NADPH-diaphorase staining) techniques, we have found that NO neurons are more predominant in the subnucleus caudalis than in the other two nuclei (n=8). To study the relationship of NO to trigeminothalamic neurons (TTN), STN neurons were retrogradely labeled by thalamic (VPM/VPL/Po) injections of fluorogold (FG;1%). NOS-stained cells were not colocalized with TTN in any of the subnuclei (n=8), but some NOS positive processes were found in close proximity to TTN. Additional *in situ* hybridization studies of NMDA NR1 receptor mRNA revealed that TTN in the subnucleus caudalis of the STN contained a significantly greater amount of NR1 receptor mRNA than retrogradely-labeled neurons in either of the other subnuclei (n=3; p<0.001, unpaired t-tests). These data suggest that TTN may be influenced by NO and further indicate that TTN in subnucleus caudalis have more NMDA receptor mRNA than the subnucleus oralis or interpolaris, which implies that the NMDA receptor may play a greater role in TTN nociceptive neurons.

646.3

EXPRESSION OF EGR-1 IN SPINAL CORD CORRELATES WITH PAW INFLAMMATION IN SLEEP DEPRIVED RATS C.A. Landis*, Dept of Physiological Nursing SM-28, Univ. of Washington, Seattle, WA 98195; Sleep Research Lab, Univ. of Chicago, Chicago, IL 60637.

We have previously reported (*Sleep Res 21*, 1992) that chronic sleep deprived (SD) rats had more intense immunocytochemical staining of Egr-1 protein in specific regions of brain and in the spinal cord dorsal horn compared to control rats. Since SD rats develop lesions on the plantar paw surface (Kushida et al., *Sleep 12*, 1989), increased immunoreactivity localized in cells of the dorsal horn could reflect increased neural activity from persistent sensory stimulation. In this analysis, we compared extent of Egr-1 expression in cells in the dorsal horn of the spinal cord with paw lesion severity scores in SD and in their yoked control rats.

Sprague-Dawley rats were subjected to SD by the disk-over-water method for 10 days (experimental procedures were approved by the University of Chicago Animal Care and Use Committee). As expected, severity of lesions in 4 SD rats for right (1.9±0.25, X±SD) and for left (1.75±0.5) hind paws were significantly (both $p < 0.02$) greater than yoked control rats (right, 0.88±0.5; left, 0.38±0.5; ordinal scale range 0 to 3). For this analysis, mean cell counts from the right and from the left dorsal horn were obtained from camera lucida drawings of 4 randomly chosen sections through the lumbar enlargement (L4-5) for each rat, and compared to mean paw lesion severity scores. For all rats, there was a significant ($p < 0.01$) correlation, $r_s = +.89$, between lesion severity of the left hind paw and mean Egr-1 cell counts from superficial lamina of the left dorsal horn. For the right paw lesions and right superficial dorsal horn Egr-1 cell counts, the corresponding correlation (+.35) was not significant. Thus, there is evidence for a relationship between severity of inflammation and extent of Egr-1 expression, possibly reflecting chronic nociceptive stimulation.

ENHANCED VENTRAL ROOT REFLEX RESPONSES IN THE NEONATAL RAT SPINAL CORD *IN VITRO* FOLLOWING UV-INDUCED PERIPHERAL INFLAMMATION Dray.A*, Urban.L. and Thompson.S.W.N., Sandoz Institute for Medical Research, London WC1E 6BN, UK.

Brief exposure of the plantar surface of the rat hindpaw to UVA irradiation induces a prolonged period of mechanical and thermal hyperalgesia (Perkins et al., 1993 *J.Physiol.*, 459 205P). Here we report changes in reflex activity, recorded *in vitro* following the induction of a behavioural hyperalgesia in 12-14 day old rat pups.

Hemisectioned spinal cords were prepared and maintained *in vitro*, from naive animals and from animals in which both a mechanical and thermal hyperalgesia had been established following UVA irradiation of the left hindpaw. Synaptic activity was recorded as a ventral root potential (VRP) from the L5 ventral root following electrical stimulation of the ipsilateral L5 dorsal root (DR).

Single shock low intensity electrical stimulation (5V, 20µs) evoked a brief VRP, which lasted significantly longer in UV treated animals than in naive (naive, 1.64±0.31s n=11; UV, 4.28±0.65s, n=11, $p < 0.01$, *t* test). High intensity single shock electrical stimulation (50V, 200µs) evoked a long duration slow VRP which was also significantly longer in UV treated animals (15.6±1.5s n=8) than in naive (9.6±0.78s n=10, $p < 0.05$, *t* test). Low frequency (1.0Hz) short duration (20s) high intensity DR stimulation evoked a cumulatively depolarizing VRP (CDVRP), indicative of windup, which was significantly greater in UV treated animals (0.65±0.1mV n=11) than in naive animals (0.36±0.05mV n=10). Repetitive low intensity DR stimulation rarely evoked a sustainable CDVRP in naive animals. In contrast, a substantial CDVRP was evoked following repetitive low intensity stimulation in UV treated animals (0.41mV±0.08mV n=8).

These data indicate that increased central excitability occurs during UV-induced peripheral inflammation which may contribute to the hyperalgesia observed.

MORPHOLOGICAL TYPES OF RETROGRADELY LABELED LAMINA I SPINOTHALAMIC NEURONS IN THE CAT. E.-T. Zhang, Z.-S. Han and A.D. (Bud) Craig, Div. Neurobiology, Barrow Neurological Institute, Phoenix, Arizona 85013

Spinothalamic tract (STT) neurons in the marginal zone (lamina I) of the cervical (C5-8) and lumbosacral (L5-S1) spinal enlargements were studied after large thalamic injections of cholera toxin subunit B and development with the ABC technique, which produced excellent dendritic staining. Morphological examination of a total of 1495 labeled cells (3 cats) in serial horizontal sections disclosed at least 3 cell types: 1) fusiform (F) cells with longitudinal perikarya and bipolar dendritic arbors within superficial lamina I; 2) pyramidal (P) neurons with triangular somata and dendritic arbors oriented mainly rostrocaudally; and, 3) multipolar (M) cells with larger multiangular perikarya and dendritic arbors oriented rostrocaudally as well as mediolaterally. In addition, a small number of cells with round or oval perikarya were included with others as unclassified (U) cells. Overall, the F (39%) and P (35%) cells formed the majority, followed by M (18%) cells and the unclassified cells (8%).

The labeled lamina I STT cells were not distributed uniformly. Different proportions of F cells and P cells were found in the cervical (41% F, 33% P) and lumbosacral segments (33% F, 40% P). Cells were more numerous in the caudal portions of both enlargements. In addition, the presence of clusters of F and P cells was obvious in this material.

The lamina I STT cells, which form half of the STT, are considered to transmit pain and temperature activity in several species. Several different physiological cell types are thought to be included: nociceptive-specific, cold-specific, multireceptive (responsive to heat, pinch, and cold), and wide dynamic range. The hypothesis that the morphological types of lamina I STT cells observed in this study may correspond to these functional classes must be considered. (Supported by NS 25616)

JAW ELECTROMYOGRAPHIC (EMG) ACTIVITY INDUCED BY APPLICATION OF ALGESIC CHEMICALS TO THE RAT TOOTH PULP. M.Sunakawa, C.Y.Chiang, D.A.Haas, J.W.Hu* and B.J.Sessle, Faculty of Dentistry, University of Toronto, Toronto, Ontario M5G 1G6, Canada.

The aim of this study was to test for jaw EMG activity induced by application to the rat maxillary molar pulp of various algescic chemicals which especially activate C-fibre afferents. Experiments were performed in rats anaesthetized with 1/3 O₂, 2/3 N₂O, and 0.5-0.8% halothane. EMG activity was recorded from the masseter muscle (Mass) bilaterally and digastric muscle (Dig) ipsilaterally, before and after application to the exposed pulp of 9.88M mustard oil, 1.64x10⁻¹⁰M capsaicin, 10⁻⁴M capsaicin, 9.43x10⁻⁹M bradykinin or mineral oil (as control). Mustard oil evoked a significant increase in ipsilateral EMG activity, often with early and late phases. Mean (±S.E.) latency, EMG increase magnitude, and duration of early and late responses respectively were 50 ± 13s, 330 ± 73%, 87 ± 16s and 933 ± 166s, 188 ± 50%, 152 ± 83s (Mass) and 29 ± 11s, 160 ± 12%, 100 ± 36s and 895 ± 447s, 155 ± 17%, 143 ± 75s (Dig). Capsaicin (10⁻⁴M) evoked no noticeable responses, but capsaicin (1.64x10⁻¹⁰M) evoked a prolonged 120 - 150% EMG increase lasting > 20 min in all three muscles. Bradykinin elicited only an early response (latency: 6 ± 5sec, EMG increase: 169 ± 41%, and duration: 20 ± 10s) in Dig, and no responses were observed in either Mass. No EMG changes occurred following mineral oil application to the pulp or mustard oil application to pulpctomized teeth. While these data demonstrate that algescic chemical excitation of pulp afferents can evoke jaw muscle activity, the variations in EMG responses between the different algescic chemicals suggest differences in their efficacy in exciting pulpal afferents or in the CNS connectivity of the afferents. (Supported by NIH grants DE04786 and DE09559).

COMPARISON OF NEURAL ACTIVITY IN THE LUMBAR DORSAL HORN WITH LATENCY FOR HEAT-EVOKED HINDPAW WITHDRAWAL. M.M. Morgan*, Dept. Neurology, Univ. California, San Francisco, CA 94143-0114.

Noxious cutaneous stimuli evoke activity in wide dynamic range (WDR) and high threshold (HT) neurons in the spinal dorsal horn. Although the sensory coding properties of these neurons have been well studied, little is known about the role these neurons play in nociceptive reflexes.

Single unit activity from neurons in the lumbar enlargement (primarily laminae V and VI) and the latency for hindpaw withdrawal were measured simultaneously in lightly halothane-anesthetized male rats (Sprague-Dawley). Light mechanical stimulation and noxious pinch were used to characterize neurons as WDR or HT and to map the receptive field (RF). Hindpaw withdrawal and the evoked activity of a WDR or HT neuron to noxious radiant heat applied to the RF were measured every 3 min.

The activity of 112 WDR and 58 HT neurons was studied in 76 rats. Only those rats in which noxious heat evoked a hindpaw withdrawal reflex (82% of the experiments) were used in data analysis. WDR neurons (78%) were more likely to fire prior to the withdrawal reflex than HT neurons (57%). In addition, neural activity preceded the reflex in 81% and 84% of the WDR neurons with medium and large RFs and 62% with small RFs. Likewise, 69% and 62.5% of the HT neurons with medium and large RFs fired prior to hindpaw withdrawal compared to only 30% with small RFs.

Since dorsal horn neural activity must precede spinal reflexes, the present data suggest that WDR neurons with medium or large RFs are more likely to underlie heat-evoked withdrawal reflexes than HT neurons or neurons with small RFs.

GLUTAMATE-LIKE IMMUNOREACTIVITY IN PRIMATE SPINOTHALAMIC TRACT TERMINALS. A.-C. Ericson*, J. Broman and A. Blomqvist, Department of Cell Biology, Faculty of Health Sciences, University of Linköping, S-581 85 Linköping, Sweden.

In order to identify the neurotransmitter content of primate spinothalamic tract (STT) terminals, an antiserum to glutaraldehyde-coupled glutamate was used in a postembedding immunogold procedure at the ultrastructural level. In adult owl monkeys (*Aotus trivirgatus*) WGA:HRP was injected into the dorsal horn of the cervical or lumbar spinal cord. STT terminals in the posterior nuclei (Po) of the thalamus that included the lamina I STT termination zone, were identified by tetramethyl benzidine histochemistry. The density of gold particles over the STT terminals was compared with that over peroxidase-negative terminals of the same type as the STT terminals (RL terminals), terminals of presumed cortical origin (RS terminals), presynaptic dendrites (PSDs), large cell bodies, dendrites of presumed relay cells (RCDs) postsynaptic to STT terminals, and randomly selected areas throughout the EM section. The density of gold particles over STT terminals, RL terminals and RS terminals was significantly higher than that over PSDs, cell bodies, RCDs and tissue average. Since many of the STT neurons that project to Po respond to noxious stimulation, the present results indicate that glutamate may serve as a neurotransmitter for ascending nociceptive information in primates.

Supported by the Swedish Medical Research Council, project # 7879.

ANTIDROMIC IDENTIFICATION OF NOCICEPTIVE LAMINA I CELL TERMINATIONS IN THE CAT THALAMUS. J.O. Dostrovsky* and A.D. (Bud) Craig. Dept. of Physiology, University of Toronto, Toronto, Canada, M5S 1A8 and Div. of Neurobiology, Barrow Neurological Inst., Phoenix, AZ 85013.

The anatomically identified thalamic projections of lamina I cells in the cat occur most prominently in the medial thalamic n. submedius (Sm), the ventral aspect of the basal ventral medial n. (vVMB), the dorsomedial aspect of the ventral posterior medial n. (dmVPM), and in the ventral posterior inferior n. (VPI) and laterally adjacent paralamina zone (pl). In previous antidromic mapping work we found that nearly all thermoreceptive-specific lamina I spinothalamic and trigeminothalamic cells projected to dmVPM and vVMB but only about half projected to Sm. In this study, we have used the antidromic method to map the projections of single nociceptive lamina I neurons.

A roving array of 8 concentric bipolar electrodes was initially positioned such that an electrode was in Sm or vVMB. Antidromic maps with 0.25 mm vertical and 0.5-1.0 mm horizontal resolution were made for 19 neurons (12 trigeminal and 7 spinal) recorded with tungsten microelectrodes in 17 barbiturate-anesthetized cats. Of these neurons, 9 were nociceptive-specific (NS), 9 were multireceptive (HPC: heat, pinch, and cold), and 1 was wide dynamic range. The units' projections were mapped in 1-8 planes. Nearly all (16/19) projected to Sm, vVMB, and VPI/pl. Only 6/15 cells tested projected to dmVPM, and fewer projected to other sites (eg. PO, Pf, CL). The projection patterns of NS and HPC cells were not different.

We conclude that (1) nociceptive and thermoreceptive lamina I cells have different though not exclusive projection patterns, (2) dmVPM may be involved primarily in thermoreception, and (3) vVMB is the only thalamic target common to all afferent lamina I cell axons. Finally, the dense nociceptive input to Sm, vVMB, and VPI/pl from trigeminal and lumbar lamina I cells supports their involvement in pain. (Supported by NIH grants NS25616, DE05404)

646.11

Microstimulation in the Area of Human Vc can evoke the Sensation of Angina. F.A. Lenz*, R.H. Gracely*, E. Hope, F.H. Baker, L.H. Rowland, P.M. Dougherty, R.T. Richardson. Departments of Neurosurg., Neurosci. and Cardiology, Johns Hopkins University, Baltimore, MD, USA 21287-7713 and NAB-NIDR-NIH¹.

The previous abstract suggests that Vc may mediate some of the symptoms of chronic pain syndromes of somatic origin.

We report results of microelectrode studies (see preceding abstract) prior to implantation of deep brain stimulating electrodes for treatment of pain secondary to arachnoiditis in a patient with a history of angina effectively treated by transluminal coronary angioplasty. Along a trajectory through Vc, cells were encountered with receptive fields to innocuous cutaneous stimulation of the chest wall. At and postero-inferior to the location of these cells TMS evoked pain identical to her angina, as described using the questionnaire. However, unlike her angina, the TMS evoked pain started suddenly, stopped suddenly and completely, and was not associated with dyspnea, diaphoresis or aftereffects. In addition to the chest pain stimulation at this site evoked a sensation of non-painful tingling in the left leg. The onset and termination of the sensation in the leg was instantaneous and identical to that for the chest pain. During previous procedures, TMS evoked sensations referred to the chest wall at 10 sites in 7/50 patients, none with angina. The sensations were described as paresthesiae at 9 sites and sharp pain at one site.

This report demonstrates that stimulation in Vc may provoke the sensation of angina in a patient who has previously experienced angina. Since stimulation of cardiac afferents evokes activity of spinothalamic tract cells and cells in the area of the thalamic principal sensory nucleus the present result may suggest that Vc mediates the sensation of angina. (Support: E Lilly Corp, NIH NS28598 and K08-NS1384).

646.13

INCREASED INCIDENCE OF PAIN EVOKED BY THALAMIC STIMULATION IN POST-STROKE PAIN PATIENTS. K.D. Davis*, J.O. Dostrovsky, R.R. Tasker, Z.K. Kiss and W.D. Hutchison, Department of Physiology and Division of Neurosurgery, University of Toronto, Toronto, Ontario, Canada M5S 1A8

The ventrobasal complex (VB) has been implicated in mediating the sensory aspect of pain and yet stimulation in this region only evokes pain in some patients and at limited sites. The present study examined whether the incidence of stimulation-evoked pain is similar in patients with different neurological disorders.

Data were obtained during stereotactic exploration of the thalamus in three groups of patients with: 1) post (supra)thalamic stroke pain (PSP), n=10, 2) non-stroke pain (NSP) (e.g., peripheral deafferentation), n=23, 3) movement disorders, n=24. Microelectrodes were used to record neuronal activity to identify VB and for microstimulation at regular intervals within VB.

In the PSP patients, 31% of the VB sites stimulated evoked painful sensations often described as burning. At 61% of the VB sites, stimulation elicited paraesthesia. The thresholds to elicit paraesthesia ($20 \pm 3 \mu A$) or pain ($26 \pm 3 \mu A$) were similar in these patients. However, threshold stimulation never evoked pain in the NSP patients and evoked pain at only 2% of VB sites in the movement disorder patients. In these latter 2 groups of patients stimulation at >98% of VB sites evoked paraesthesia. The thresholds to evoke paraesthesia in the NSP ($13 \pm 2 \mu A$) and movement disorder ($9 \pm 1 \mu A$) patients were significantly less ($p < .05$) than the thresholds in the PSP patients.

The increased incidence of thalamic-evoked pain in PSP patients may be due to 1) a selective loss of low threshold mechanoreceptive thalamic neurons such that nociceptive neuronal output is now prominent, 2) reduced tonic inhibitory control of thalamic or cortical nociceptive neurons, and/or 3) unmasking or strengthening of nociceptive pathways.

Sensations Evoked by Microstimulation in the Area of the Ventrocaudal Nucleus of Thalamus (Vc) in Patients with Chronic Pain. Y.C. Lin*, R.H. Gracely*, F.A. Lenz, F.H. Baker, L.H. Rowland, P.M. Dougherty, R.T. Richardson. Departments of Neurosurg. and Neurosci. Johns Hopkins University, Baltimore, MD, USA 21287-7713 and NAB-NIDR-NIH¹.

It has often been suggested that the sensations evoked by stimulation of the CNS are altered in patients with neuropathic pain. We now report results of microelectrode recording and threshold microstimulation (TMS) prior to thalamic procedures for treatment of chronic neuropathic pain (n=12) or movement disorders (n=5). Patients were trained to use a questionnaire to describe the location (projected field - PF) and quality of sensations evoked by cutaneous stimulation preoperatively and by TMS intraoperatively. TMS evoked pain at 17% (22/127) of stimulation sites in the region of Vc representing the 'painful' part of the body but only 4% (10/253) of those in the representation of 'non-painful' part of the body ($p < 0.001$, Chi square). Non-painful thermal sensations were evoked by stimulation at 5% (7/127) of sites representing the 'painful' part of the body and 16% (36/242) of sites in areas representing the 'non-painful' parts of the body. Therefore, the increase in the proportion of sites where pain sensations are evoked is accompanied by a decrease in sites where non-painful thermal sensations are evoked, in 'painful' body parts.

The quality of the patient's spontaneous pain and TMS evoked pain was assessed by overlap between ideal type pain descriptors of these two sensations. Thalamic stimulation produced pain sensations in 7 of 12 patients with chronic pain, all of whom had pain evoked by stimuli which are normally non-painful (hyperalgesia). Quality of the evoked sensation was similar to the patients pain at 83% (20/24) of sites where the PF was located in the 'painful' part of the body. These results suggest that activity of neurons signalling thermal sensations is related to ongoing pain in patients with hyperalgesia. (Support: E Lilly Corp, NIH NS28598 and K08-NS1384).

646.12

ALTERATIONS IN HUMAN SOMATOSENSORY THALAMUS IN VARIOUS DEAFFERENTATION SYNDROMES. Z.H.T. Kiss, J.O. Dostrovsky, R.R. Tasker, K.D. Davis, W.D. Hutchison and A.M. Lozano. Division of Neurosurgery and Department of Physiology, University of Toronto, Toronto, Ontario, Canada M5S 1A8

Experimental studies indicate that deafferentation results in reorganization of the somatosensory map at various levels of the CNS, such that the representation of a body part adjacent to a region that is denervated expands into the deafferented area. Recent data suggest that in the human this occurs at the cortical level, but subcortical structures have not been systematically investigated.

To test the hypothesis that the human thalamus is capable of significant reorganization as a result of changes in afferent input, microelectrode recording and stimulating techniques were used to define thalamic somatotopy in 33 patients undergoing stereotactic procedures. Five groups were compared: those with pain in the deafferented body part, face (n=9), upper limb (n=2), lower limb (n=4) and hemibody (n=3) and those with neither pain nor deafferentation, i.e., movement disorder (n=15).

Microstimulation induced paresthesia in the face (projected field) from a significantly larger region of thalamus in the facially denervated group compared to the movement disorder group ($p < 0.001$). Similarly, in patients with hemibody hypesthesia, stimulation produced paresthesia in the entire hemibody from a significantly greater region of thalamus ($p < 0.001$). However, there were no significant differences in body representation based on neuronal recordings (receptive fields) or in sampling of ventrobasal thalamus in the five groups.

These results suggest that deafferentation results in alterations in thalamocortical processing of somatosensory information from the affected region. These changes may be involved in the pathophysiology of this type of deafferentation pain.

FEMALE MICE DISPLAY LESS PAIN BEHAVIOR THAN MALES FOLLOWING ACETIC ACID OR FORMALIN ADMINISTRATION. W.E. Sternberg, B. Kest, J.S. Moqil, and J.C. Liebeskind. Department of Psychology, University of California, Los Angeles, CA 90024.

Several investigators have previously reported that female rodents display shorter tail-flick, hot-plate, and jump test latencies than do males. These algometric tests all assess thresholds for brief, phasic noxious stimuli. These models of acute, cutaneous pain have been shown to differ from models of tonic, continuous pain, in both neurochemical and neuroanatomical substrates. Thus, sex differences previously noted in studies assessing pain thresholds may not be indicative of sex differences in tonic pain states. The formalin test and the acetic acid writhing test are two such models of tonic pain. Male and female Swiss-Webster mice were tested for nociceptive responses on formalin and writhing tests. In one experiment, animals were injected with 0.6% acetic acid (10 ml/kg; i.p.), and 5 min later, the number of abdominal constrictions was assessed during a 6 min period. In the second experiment, animals were injected with .02 ml of 5% formalin in the plantar surface of the left hindpaw. Time spent licking the injected paw was assessed for a 10 min period following injection. In both experiments, females exhibited less pain behavior than males. Contrary to previous reports of females displaying lower nociceptive thresholds for phasic stimuli, these findings demonstrate that females exhibit less pain behavior than males in response to tonic pain conditions. These findings have potential clinical implications since tonic pain models, because of their longer duration and association with tissue damage, provide a more accurate representation of clinical pain states. This research was supported by NIH grant NS07628 and an Unrestricted Pain Research Grant from the Bristol-Myers Squibb Company.

CEREBRAL BLOOD FLOW (CBF) DURING TONIC PAIN IN MAN. R.C. Coghill*, C. Morin, A. Evans, E. Meyer, A. Gjedde, G.H. Duncan and M.C. Bushnell. Univ. Montréal and Montreal Neurological Inst., Montréal, Canada.

Experimental models using continuous or tonic noxious stimulation have been proposed to study cerebral processes of pain in man. However, initial imaging studies of tonic or chronic pain (Apkarian et al, 1992; Di Piero et al, 1991) have revealed only decreases in CBF, while those using phasic pain (Talbot et al, 1991; Jones et al, 1991; Casey et al, 1992; Coghill et al, 1992) show primarily pain-related increases in CBF. We now examine in greater detail CBF changes during tonic pain in 10 males, using dynamic PET, with $H_2^{15}O$ and arterial sampling for quantitative CBF measurements, and correlated 3-D MRI/PET analysis.

The effect of stimulus intensity (70-s immersions of the index finger in 35-49°C circulating water) on CBF was examined in primary and secondary somatosensory cortices (SI and SII), anterior cingulate (AC) and thalamus—regions known to be activated by phasic noxious stimuli. Although subjects showed monotonic increases in ratings of intensity and unpleasantness (ANOVA, $p < 0.001$), these tonic stimuli did not evoke detectable CBF changes in SI, SII or AC; in thalamus, only 49°C produced an increased CBF relative to 35°C ($p < 0.05$). Whole brain CBF (K_i) was not influenced by stimulus intensity, indicating that global CBF changes did not mask regional activation. A comparison with previous data (Coghill et al, 1992) shows that tonic 48°C stimuli evoke smaller CBF increases than did phasic 48°C stimuli (ANOVA, $p < 0.01$), although similar tonic stimuli generate higher ratings of pain (Morin et al, 1993).

Since human pain perception has been shown to correlate with both tonic and phasic noxious stimulus intensity, and with nociceptive single-unit activity recorded in primate SI and thalamus, our findings suggest a possible decoupling of CBF from neuronal mechanisms underlying pain perception during tonic stimulation. THE THERMAL GRILL ILLUSION: A UNIQUE TOOL FOR STUDYING PAIN AND TEMPERATURE SENSATION. A.D. (Bud) Craig and M.C. Bushnell*, Barrow Neurol. Inst., Phoenix AZ and Univ. Montreal, Canada.

In 1896 Thunberg reported that simultaneous warm and cool stimuli applied to the skin elicit an unusual sensation of strong heat or pain similar to the burning sensation of cold pain. We are exploiting this remarkable, unique illusion by examining its psychophysical characteristics and by applying the same stimulus paradigms in physiological single unit studies.

Five subjects used VAS and verbal descriptors to rate the sensations in their right hand, which they placed on a 20x14 cm thermal grill made of 1 cm wide silver bars on computer-driven Peltier elements. Using randomized, double-blind procedures, either a warm (40°C) step, a cool (20°C) step, or an interlaced (alternate bars) warm and cool stimulus ("W+C") was presented from a base of 34°C. Subjects rated W+C more painful and hotter than warm or cool ($p < 0.05$, ANOVA), more pain descriptors were assigned to W+C ($p < 0.05$), and words such as "burning", "stinging", and "smarting" were used exclusively for W+C.

A smaller thermal grill was applied to the hindpaw of anesthetized cats during recordings from lamina I spinothalamic tract (STT) cells. Nociceptive-specific cells ($n=3$) were unresponsive to these stimuli. The average response of cold-specific cells ($n=7$) to W+C was only 50% of their response to cool alone. In contrast, the average response of multireceptive cells (MR-HPC: heat, pinch, and cold; $n=4$) to W+C remained high at 82% of their response to cool alone ($p < 0.003$). A detailed hypothesis will be presented, based on this shift in the ratio of the activities of MR-HPC and cold cells, that offers an explanation for the thermal grill illusion and a substrate for the sensation of cold pain.

We conclude that the Thunberg thermal grill illusion is a robust phenomenon useful for studying the central integration of pain and temperature. (Supported by NIH grants NS 25616 and DA 07402)

PAIN INTENSITY DURING PHASIC AND TONIC HEAT STIMULATION. C. Morin, R.C. Coghill, B. Lisak, M.C. Bushnell and G.H. Duncan*. Université de Montréal, Montréal, Québec, Canada. H3C 3J7.

Imaging studies of pain perception, using phasic noxious stimuli (Talbot et al 1991; Jones et al 1992; Coghill et al 1992), have shown both cortical and subcortical regions of increased cerebral blood flow (CBF), while those using tonic noxious stimuli (Apkarian et al 1992; Coghill et al 1993) have not. This study tests a number of hypotheses that might account for this discrepancy in Δ CBF evoked during phasic and tonic pain, including differences in evoked sensations of pain intensity or unpleasantness, the habituation of the pain sensation, and the total fluctuation in perceived pain during the testing period.

Subjects (11 males) evaluated phasic and tonic presentations of noxious and innocuous heat stimuli; each paralleled procedures used in PET studies of Δ CBF performed in our labs. Phasic stimuli were six 6-s presentations (4-s ISI) of 47-48°C and 34°C heat pulses delivered to the left arm by a 1-cm contact thermode; tonic stimuli were 70-s immersions of the right index finger in 49°C and 35°C circulating water. Subjects gave continuous ratings of pain intensity on a computerized visual analog scale (VAS), and summarized rating of pain intensity and unpleasantness following the sessions.

Mean ratings of pain intensity (continuous VAS) were higher in the tonic than in the phasic condition ($p < 0.001$), a finding confirmed by summary ratings of pain intensity ($p < 0.001$) and unpleasantness ($p < 0.01$). Neither tonic nor phasic paradigms showed habituation of evoked pain ($p > 0.5$). Only the total fluctuation in pain intensity proved greater for phasic than for tonic pain ($p < 0.005$), suggesting that increases in regional CBF during studies of phasic pain may reflect total variation in pain perception better than maximum intensity of perceived pain. PAIN AND FLARE IN HUMAN SUBJECTS: EVIDENCE THAT SEPARATE GROUPS OF NOCICEPTIVE AFFERENT FIBRES ARE INVOLVED. F. Cervero, M.D. Gee & A. Hill (SPON: European Neuroscience Association). Department of Physiology, University of Bristol Medical School, Bristol, U.K.

An injury to the skin evokes pain and induces an area of vasodilatation (flare) around the injury site. These two phenomena are commonly interpreted as being mediated by a single class of nociceptive afferent that evokes pain centrally and flare peripherally via an axon reflex mechanism. This interpretation has recently been questioned; therefore we decided to investigate if flare and pain could be dissociated, and thus whether several categories of nociceptive afferent fibre are involved, some mediating mainly pain and some mediating mainly flare.

In seven normal human volunteers three types of thermal and chemical noxious stimuli were applied to the skin of their forearms: i) short duration ramps of radiant heat raising skin temperature from 30 to 54°C at a rate of 0.4°C/sec, ii) 30 seconds applications of mustard oil at concentrations from 15 to 40% and iii) prolonged heat stimuli that evoked pain sensations with profiles similar to those produced by mustard oil applications.

No differences in pain sensation or flare areas were detected between the right and left arms of the subjects with the exception of a consistently lower heat pain threshold in the right arm. Heat stimuli evoked flare and pain that correlated with the stimulus intensity whereas mustard oil induced dose dependent flares but similar pain sensations regardless of concentration. In six of the seven subjects the prolonged heat stimuli produced significantly different areas of flare than mustard oil applications with the same pain profile. These results are consistent with the hypothesis that pain and flare are mediated by different categories of nociceptive afferent fibre, all of which are sensitive to both thermal and chemical noxious stimuli.

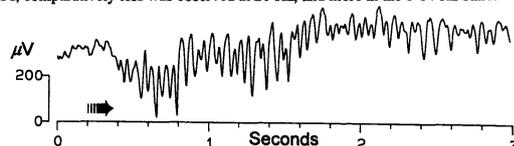

STRIATE CORTEX: RESPONSE PROPERTIES II

647.1

MOTION DRIVEN 20 HZ OSCILLATIONS IN TURTLE VISUAL CORTEX. J.C. Prechtl* & T.H. Bullock. Dept. Neurosciences, UC San Diego, CA. 92093-0201.

We previously reported that abrupt visual stimuli such as single flashes and flashes omitted after a series can evoke 17-23 Hz oscillations in the visual cortex of the turtle. The oscillations typically last a few hundred milliseconds and are not phase-locked to the stimulus. Recently, we observed similar but longer-lived oscillations that spontaneously occur with shifts in gaze and/or the presence of moving stimuli.

To further characterize these oscillations awake, attentive turtles (*Pseudemys scripta*; $N=6$) were stimulated with a horizontally moving black bar (9° wide, 11°/s, 7 s movement on white video) while field potentials were recorded bilaterally from 8 cortical electrodes, plus an electro-oculogram. Individual electrode depths varied but in each specimen 2-5 electrodes showed stimulus-bound "high" frequency (F; ~20 Hz) oscillations with and without eye movements; the plot below is an example. All Fs sampled from the power spectrum (8, 14, 20, 26 Hz) were maximally elevated in the 1st second and declined over the 7 s stimulus period. 20 Hz activity was $432 \pm 80\%$ greater than the control period and the other Fs were 230-290% greater. The 20 and 26 Hz activity remained significantly elevated (2-tailed, paired t-test, $P_s < 0.05$) for 6 of the 7 seconds, whereas, the 8 and 14 Hz activities were not different after 2.5 and 4 s, respectively. Complex stimuli, such as moving fingers at 15 cm, evoked the greatest amplitude 20 Hz discharge for tens of seconds. Although arousing cutaneous stimuli under lights or complete darkness also evoked activity increases in all Fs, comparatively less was observed at 20 Hz, and more in the 8-14 Hz band.

HIGH FREQUENCY OSCILLATIONS IN CAT VISUAL CORTEX: INFLUENCE OF INCOHERENT STIMULI ON CORRELATIONS BETWEEN NEURONS WITH NON-OVERLAPPING RECEPTIVE FIELDS. M. Brosch, R. Bauer, R. Eckhorn and H.J. Reitböck*. Dept. Biophysics, Philipps-University, Renthof 7, D-3550 Marburg, Germany.

The finding of stimulus related synchronized oscillations (40-80 Hz) in cat visual cortex supported the hypothesis that correlated neural activity can define the continuity of a visual object while uncorrelated activity is indicative for different objects in a visual scene (Eckhorn et al., Biol. Cybern. 60:121-130, 1988). The present study concentrated on the potential contribution of oscillations for such scene segmentation. Multi-unit activities (MUA) and local field potentials (LFP) were pairwise recorded at spatially distant sites in areas 17 and 18 of anesthetized cats. The correlations of oscillatory signals of neurons with non-overlapping receptive fields (RFs) were compared under 3 different stimulus conditions (1 vs 2 and 1 vs 3): 1. Coherent stimuli: whole field grating or long bars moving slowly across the RFs in both recording positions. Incoherent stimuli: 2. Masking of the region between the RFs while stimulating the remaining visual field as in (1); 3. Two separate bars or gratings moving in opposite directions (anti-phase). In both incoherent stimulus paradigms the correlation strengths and the incidence of significantly correlated pairs was reduced compared to coherent stimulation. In the masking paradigm the correlation index of LFP oscillations dropped from 0.22 (± 0.12) to 0.15 (± 0.11) (43 pairs, $U = -4.71$, $p < 0.001$) and in the anti-phase paradigm from 0.20 (± 0.12) to 0.14 (± 0.12) (25 pairs, $U = -4.71$, $p < 0.001$). Similar results were found for MUA: 8 of 10 pairs were weaker correlated in the anti-phase condition than during whole-field stimulation (10/15 in the masking paradigm). Our results are consistent with previous findings for neurons with overlapping RFs (Engel et al., PNAS 88:6048-52, 1991), and, in conclusion, compatible with the hypothesis that synchronized activity can support scene segmentation and feature linking.

HIGH FREQUENCY (50 - 90 Hz) OSCILLATIONS IN VISUAL CORTICAL AREAS V1 AND V2 OF AN AWAKE MONKEY ARE PHASE-LOCKED AT ZERO DELAY. R. Eckhorn*, A. Frien, R. Bauer, H. Kehr, T. Woelbern and W. Kruse. Dept. Biophysics, Philipps-University, Renthof 7, 3550-Marburg, Germany.

The representation of a visual object is distributed over several visual cortical areas. It was proposed that synchronization of the distributed activities, evoked by an object, is the basis for its coherent perception [1]. This hypothesis was supported by the discovery of stimulus-dependent synchronization between different cortical areas of anesthetized cats [1-3]. We now demonstrate the presence of and the phase-locking between high amplitude oscillations in V1 and V2 of an awake monkey. For this we recorded spikes (single and MUA) and local field potentials (LFP) with a 7-electrode array [4]. Visual stimuli were a small fixation spot and a moving light bar on a computer screen (94 Hz). The latter stimulated the receptive fields in V1 and V2 simultaneously. A synchronization index SI was calculated for LFP (interareal: SI(V1-V2) = 0.40 ± 0.16 (N=114); intraareal: SI(V1) = 0.54 ± 0.15 (N=21) and SI(V2) = 0.50 ± 0.15 (N=48)). The average phase difference of oscillatory events of all V1-V2 recording pairs was zero, while individual pairs were distributed at SD = 3.2 ms. Zero phase difference is of particular interest, because V1 and V2 are serially arranged with respect to the afferent visual stream and V1-V2 conduction delays are several milliseconds. The present and previous data suggest that V1-V2 synchronization is mainly due to cortico-cortical feedback interactions and not to a common subcortical "oscillator". Our discovery of synchronized high frequency oscillations between two visual cortical areas of an awake monkey at high amplitudes and zero phase lag implies that synchronization supports the combined processing of common visual features and it supports the "feature-linking-hypothesis".

647.5

STIMULUS-DEPENDENT CHANGES IN THE CORRELATION STRUCTURE OF THE ACTIVITY OF NEURONAL POPULATIONS IN PRIMARY VISUAL CORTEX OF THE MACAQUE. J. Victor*, A. Canel, and K. Purpura, Dept. of Neurology and Neuroscience, Cornell University Medical College, New York, NY 10021.

Standard quantitative approaches to the analysis of the responses of visual neurons (peri-stimulus histograms, Fourier analysis, and cross-correlations) are fundamentally averaging methods. Since these methods are based on the notion that activity which is not temporally locked to the stimulus represents "noise", they aim to remove this "noise" from the response characterization. However, visual stimuli may affect the ongoing activity of neurons in a manner which is not synchronized to the stimulus -- e.g., modulation of the overall level of spontaneous activity or induction of oscillations. Since these phenomena are suppressed by standard averaging methods, we developed a new approach, phase-locked spectral analysis (PLSA), to examine responses to periodic visual stimuli.

In essence, PLSA has two stages: (i) estimation of the average response to a periodic stimulus, and (ii) spectral analysis of the difference between individual sweeps and the estimated average response. PLSA goes beyond power spectral estimation, by exploiting covariances of components whose frequencies differ by multiples of the stimulus frequency. PLSA has a time-domain counterpart, phase-locked cross-correlation (PLCC), which describes how auto- and cross-correlations vary over the stimulus period. We have applied these methods to multichannel recordings of local field potentials in the striate cortex of the anaesthetized macaque monkey. Modulation of auto- and cross-spectra elicited by checkerboard stimulation occurs over a broad range (at least 3 to 25 Hz), and is not confined to a narrow frequency range, as would have been expected for oscillations.

647.7

SPONTANEOUS ACTIVITY AND RESPONSE PROPERTIES OF NEURONS IN STRIATE CORTEX OF TRAINED MONKEYS. D. M. Snodderly* and M. Gur¹. Schepens Eye Res. Inst. and Harvard Med. Sch., Boston MA, 02114; ¹Biomed. Eng., Technion, Haifa, Israel.

In awake monkeys, zones of strong spontaneous activity in striate cortex correspond closely to the regions of high cytochrome oxidase activity, laminae 4A, 4C, and 6. Spontaneous activity in layer 6 implies a tonic corticofugal influence on subcortical centers. This activity is suppressed by sleep or anesthesia. In combination with dye-marking of the electrode track, the spontaneous activity facilitates assignment of cells to individual cortical laminae. DII marks have remained localized for at least 5 weeks and they correspond well to the electrode depth. Among the easiest cells to determine their distribution among the layers are the directionally selective (DS) neurons. With one exception, they were confined to layers 4B, 4C (mostly 4C alpha), or 6. This agrees well with the laminar distribution reported for anesthetized animals and it justifies our combination of physiological and anatomical criteria. The width of the activating region (AR) of the receptive field does not simply increase with distance from the main geniculorecipient layer 4C but has a profile such that neurons in the more spontaneous layers 4A and 6 often have larger AR's while neurons in the quieter layers tend to have smaller AR's. DS neurons in layer 4 have AR's that are among the smallest in striate cortex, whereas those in layer 6 that are spontaneously active can have much larger AR's. This raises the question how cells in MT that receive inputs from the DS cells in V1 utilize those inputs within the large receptive fields reported in MT.

647.4

20 Hz BURSTS OF ACTIVITY IN CORTICO-THALAMIC PATHWAY DURING ATTENTIVE PERCEPTION A. Wróbel¹, M. Bekisz¹ and G.L. Gerstein². ¹Dept. of Neurophys., Nencki Institute of Exp. Biol. 02-093 Warsaw, Poland and ²Dept. of Physiol., Univ. of Penna., PA 19104

Cats were taught to attend to the location of disappearance of either visual or acoustic moving stimuli which signaled reward in the left or right foodwell. Simultaneous frequency analysis of EEG activity, recorded from the primary visual cortex (VCx) and lateral geniculate nucleus (LGN), revealed a significant elevation of the 20 Hz band only during visual trials that ended with successful response. Such elevation was not observed either during acoustic or erroneously ended visual trials. This specific activity was characterized by 0.1 - 1 s bursts of oscillations appearing coincidentally in VCx and LGN. The mean frequency of their appearance, amplitude and average duration observed during visual trials exceeded the relevant values for acoustic trials. The calculation of directed transfer function suggested that this frequency was propagated by descending visual pathway. Finally, during visual trials we observed also the relevant changes of potentials evoked by paired electrical stimulation of the optic chiasm, as recorded in both LGN and VCx.

We hypothesize that short synchronized bursts of 20 Hz frequency in the cortico-thalamic system might set the gain of geniculate relay during attentive perception.

647.6

ACCURATE FIXATION DOES NOT SUBSTANTIALLY REDUCE THE NOISE OF COMPLEX CELLS IN PRIMARY VISUAL CORTEX. T.W. Kjaer, T.J. Gawne, J.A. Hertz and B.J. Richmond*. Laboratory of Neuropsychology, National Institute of Mental Health, Bethesda, MD 20892.

When a primate fixates on an object many times in succession the actual eye position has substantial scatter. These small changes in eye position could make a major contribution to the variability in the responses of neurons in primary visual cortex. It is essential to know how much of the observed variation in neuronal recordings from awake animals can be attributed to these fluctuations and how much is intrinsic to the functioning visual system. We have investigated how much of the variance in the neuronal response of V1 neurons is due to variability in eye position. 13 neurons with peripheral receptive fields were recorded from V1 of fixating monkeys while black and white patterns were presented on a projection screen. Eye position was measured to a resolution of 3' using a magnetic search coil. The typical observed shifts were of about the same size as the smallest features in the patterns, so one might expect substantial related changes in the neuronal responses.

We have been unable to detect such changes. We have quantified this result in two ways. First we calculated the information about the stimulus set available in the response from two sets of data: the most central 50% of fixations (these were within 40' of the mean fixation position), and the remaining 50% of the data. For 9 neurons, restricting the eye position to the central region did not increase the transmitted information. For the other 4 neurons, restricting the eye position did increase the information, but by less than 5% of the maximum possible. Second, linear regression showed no correlation between eye position and response variance.

We conjecture that the circuitry of V1 is able to compensate for these small shifts of fixation by some as-yet unknown mechanism.

PAN: A NEURAL NETWORK MODEL OF MAMMALIAN VISUAL CORTEX RECEPTIVE FIELD AND COLUMN FORMATION

Frank W. Grasso.* Neuroscience and Behavior Program
University of Massachusetts, Amherst, MA 01003

The Primitive Acquisition Network (PAN) models layer IV of V1 as a 2^d sheet of neuron-like elements with local lateral inhibitory connections and excitatory local retinotopic input connections from 'on' and 'off' pre-processing layers. PAN networks self-organize representations of the input 'world' by means of a Hebbian learning rule and a modification threshold that increases in each element. The learning rule permits an evolution of receptive fields (RFs) via modification of the input connections. PAN does not favor a specific RF organization a priori. The modification threshold induces a stochastic experience-dependent, critical-period for the evolution of network connections. In computer simulations, separate PAN networks with initial random weights were trained with oriented sinusoidal gratings, digitized natural images of forest scenes or pseudo-random images. All three training sets produced aggregates of elements in the layer with like orientation selectivities (iso-orientation domains). Pseudo-random image sets led to PAN elements with weaker orientation selectivity compared to those from nets trained with the other sets. Natural image sets produced aggregates of elements with selectivity for specific natural images that exist in parallel with the orientation selective aggregates. These results suggest multiple representations that can be dynamically evoked by input context might be stored in the synapses of a 2^d patch of layer IV in primary visual cortex.

ADAPTING RETARDS RESPONSE TIMING IN SINGLE NEURONS OF CAT VISUAL CORTEX. A.B. Saul*. Dept. of Neurobiology, Univ. of Pittsburgh Sch. of Med., Pittsburgh PA 15261.

Previous studies have demonstrated the existence of adaptation aftereffects in single cells in cat visual cortex. Reports of aftereffects have heretofore discussed reduced response amplitudes, or, equivalently, shifts of the contrast response function toward higher contrasts.

This study extends the concept of aftereffects in single neurons to changes in timing as well as in amplitude. Simple cells were recorded in anesthetized, paralyzed cats. Stimuli were sinusoidally-modulated gratings and bars. Responses in all cells were therefore modulated at the stimulus temporal frequency, and had phase as well as amplitude values. Response phase measurements are extremely reliable. Adapted response phase values were consistently and significantly later than control values. Thus, adaptation aftereffects in single cells consist of reduced amplitudes and delayed responses. The change in response timing was not due to transient effects from the switch between adapting and test stimuli; 2 seconds after the end of adapting the effect was still present. The retarded response phase reflects a delayed onset of the excitatory discharge. Offsets were similar in control and adapted histograms.

Like amplitude aftereffects, the tuning of these timing aftereffects was related to the adapting stimulus. Nonetheless, the amplitude and phase aftereffects were poorly correlated.

These results are consistent with the hypothesis that adapting potentiates inhibitory inputs. Inhibition can affect timing as well as amplitude. These physiological data may also be related to Menees' psychophysical finding that adapting increases reaction time (ARVO 92).

THE LATERAL POSTERIOR-PULVINAR COMPLEX INFLUENCES OF THE FAR SURROUND ON CELLS IN AREAS 17 AND 18 OF CATS. S. Shumikhina, S. Molotchnikoff* and C. Casanova, Dépt. Sc. biologiques, Université de Montréal, Montréal, Québec, Canada, H3C 3J7.

Although the lateral-posterior-pulvinar complex (LP-P) sends fibers to visual areas 17 and 18 of cats, the role of this thalamic input is not yet understood. It has been proposed that this complex is involved in the perception of salient features of visual targets. The aim of the present investigation is to look at possible functions of the LP-P afferents to cortex. Cats were anesthetized and prepared for single cell recordings in areas 17 and 18. In parallel a micro-injecting-recording pipette filled with GABA was introduced into the LP-P. In all experiments the position of this electrode was histologically verified. Cells were stimulated either with slits or drifting sinusoidal gratings centered in the receptive field. These targets were presented either with low (20%) or high (80%) contrasts. The far surround of the receptive field was masked or invaded by both types of stimuli. Out of 37 cortical cells which were tested during LP-P blockade, 67% modified their responses. With high contrast stimuli the difference (> 25%) in response magnitude between masked and unmasked far surround was suppressed or inverted when LP-P was injected. This effect appeared to be more pronounced in complex cells. With low contrast stimuli LP-P injections increased the response difference between the two conditions of stimulation (mask-no-mask). Thus it appears that the LP-P modulates the contribution of the far surround to responses of targets located within the receptive-field. This contribution may be one mechanism through which the LP-P is associated to the salience of the visual targets.

647.10

ORIENTATIONS TUNING OF CELLS IN AREA 18 DURING LOCAL BLOCKADE OF AREA 17, IN CATS. A. Chabli* and S. Molotchnikoff. Dept. of Biology, University of Montreal, Montreal, Quebec, Canada, H3C 3J7.

The hierarchical model of Hubel and Wiesel proposes that complex cells of area 18 are mostly contacted by simple units of area 17. This model has been challenged, and it is still unclear what is the role of long-horizontal cortico-cortical connections (LHC)? Specifically are LHC organized along iso-orientational or cross-orientational lines of connectivity? As we recently suggested that LHC can be subdivided along simple and complex cell types, the present experiments intend to further clarify the role of LHC. Cats were anesthetized and prepared for single cell recordings. In area 17, a pressure injecting-recording pipette filled with GABA depresses neuronal activity. The same pipette allowed recording of multiunit activity and the determination of the orientational bias of the column under GABA injection site. Cells of area 18 were stimulated with drifting sinusoidal gratings (optimal spatial and temporal frequencies). Orientation tuning curves were plotted for each neuron of area 18 prior to, during and after blockade of area 17. Thus we could analyze the modifications of the tuning curves of units in area 18 after the depression of specific orientational columns in area 17. Under stable conditions the same cell was tested with the successive depression of two columns whose orientations were 90° apart. Although results are preliminary it appears that simple cell responses to optimal orientation are depressed when both orientations (in 17 and 18) are similar, while the responses are augmented if the depressed column exhibit orthogonal orientation relative to the tested cells. The converse situation appears to hold for complex cells.

STRIATE CORTEX: RESPONSE PROPERTIES III

648.1

Y-CELL SIGNATURE IN MONKEY V1 NEURONS.

S. Hochstein^{1,2}, E. A. Stern^{1,2}, V. Yakovlev^{1,2} and E. Vaadia^{1,3}.

¹Center for Neural Computation, ²Dept. of Neurobiology and ³Hadassah Medical School, Hebrew University, Jerusalem, Israel.

Cat retinal and geniculate Y-cells show a characteristic response to sinusoidal stimulus gratings, which has been termed "the Y-cell signature". The response is spatial-frequency (SF) dependent, so that its Fourier transform is dominated by the odd portion (especially the fundamental component) at low spatial frequencies, and the even portion (DC and second harmonics) at high spatial frequencies. The ratio of even:odd spatial frequency cut-off is generally about 3:1. The Y-cell signature has not been demonstrated in cat area 17 neurons.

We recorded from supergranulate layers of V1 in an awake monkey performing a fixation task, and presented drifting sinusoidal grating stimuli. Many cells showed sustained and modulated responses under different stimulus conditions. As in most cat area 17 neurons, the SF dependences of the even and odd portions of the response were often similar. However, at least 20% of the cells showed the 3:1 even:odd spatial-frequency cut-off, i.e. the Y-cell signature. This characteristic could only be uncovered by using tests at a full range of SFs. In addition, sometimes the tuning of the modulated and the DC components to other stimulus dimensions also differed considerably.

The source of this activity could be from Y-like input to the cortex from subcortical areas or *de novo* from cortical processing. We propose the latter as we only found this type of activity in the upper cortical layers.

INFLUENCE OF STIMULUS SIZE ON RESPONSES OF CELLS IN CAT'S AREA 17 AND IN LPI TO MOVING RANDOM DOT PATTERNS. C. Casanova*, T. Savard, D. Arseneault. Department of Ophthalmology and Department of Physiology and Biophysics, Fac. Med, University of Sherbrooke, Sherbrooke, Quebec, Canada, J1H 5N4.

We reported that most simple cells in the cat's striate cortex respond to the motion of a random dot pattern (Casanova, 1992, Soc. Neurosci. Abstr. 18, 1033) supporting then the claim that both simple and complex cells in area 17 could be driven by visual noise (Skottun et al. 1988, J. Neurophysiol. 59, 1719). We are now investigating the cells' responses as a function of the size of the stimulus i.e. the area of the visual field stimulated with noise. Experiments were performed with anesthetized normal adult cats. Receptive fields (RFs) in area 17 and in its thalamic target (LPI) were characterized with drifting sine-wave gratings and moving bars. Under computer control, a random texture field (256x256 elements subtending each 0.08°) moving at optimal direction and speed was presented in a circular window with varying diameter. Results indicated that 1) many cells responded poorly when the noise only covered the classical RF. 2) for most units, the response increased with diameter and was either saturated or did not level off. In the cortex, the mean size of the stimuli necessary to evoke half-maximal cell responses was respectively 7.4° and 3.8° for noise and grating (t-test: p < 0.05). When stimulated with the noise, inhibition from the periphery of the classical RF does not manifest itself as strongly as for the bars of a grating. Overall, our results suggest that the minimal excitatory field for noise may be larger than the classical RF.

INHIBITATORY SPATIAL INTERACTIONS OF LOCAL FIELD POTENTIALS IN CAT VISUAL CORTEX. K. Niiyama, T. Kasamatsu*, E. E. Sutter and A. M. Norcia. The Smith-Kettlewell Eye Research Institute, San Francisco, CA, 94115

Cortical neurons in area 17 have dendritic and axon collateral arborizations which spread well beyond the limit of hypercolumns. We have found a local field potential whose receptive field extends far beyond the range of classical receptive fields of single neurons. Here, we studied the spatial organization of these large receptive field by simultaneously stimulating multiple areas within the field. A pair of tungsten-in-glass microelectrodes (tip separation, ~300µm) was placed in area 17 of anesthetized and paralyzed cats. Receptive-field properties of single cells were characterized by an oriented moving light slit. At the same cortical location, field potentials were evoked by contrast reversal of bar gratings (1.0 c/deg) in a 3-deg hexagonal patch. The gratings were presented at one, two or all of the 61 hexagons that covered 25-deg of the central visual field. Contrast reversal was modulated in time using a pseudorandom, binary sequence and responses were extracted by a multi-input nonlinear systems analysis method (Sutter, 1992). The stimulus array was centered on the classical receptive field. With single-area stimulation, a slow component (SC) of field-potential showed a very large receptive field. With simultaneous stimulation at two or all of the 61 patches, the SC decreased in amplitude. Amplitude reductions in two-area stimulation extended over a considerable distance and were largest when the two areas were close together. This nonlinear inhibitory interaction within the non-classical receptive field is interpreted as being due to the presence of long-range intercortical connections within visual cortex. NEURONS IN PRIMATE VISUAL CORTEX MULTIPLEX INFORMATION ABOUT RED/GREEN, BLUE/YELLOW, AND BLACK/WHITE OPPONENCIES USING TEMPORAL CODES. J.W. McClurkin*, J.A. Zarbock, and L.M. Optican. Laboratory of Sensorimotor Research, National Eye Institute, Bethesda, MD 20892.

Last year we reported that visual cortical neurons represented stimulus *pattern* with a temporal code that was common to all neurons within an area, and similar across visual areas. This year we report that visual cortical neurons also represent stimulus *color* with a temporal code that is common to all neurons within an area, and similar across visual areas.

Responses of neurons in cortical areas V1, V2, V3 and V4 were recorded in a monkey trained to fixate a spot while red, green, yellow, and blue bars, isoluminant with the background, or black and white bars were flashed on their receptive fields. The bars were presented at eight different orientations. The amount of information the neurons could transmit about the color or the luminance of the bars, independent of orientation, was measured assuming codes based on either the number of spikes, or the temporal distribution of spikes in the responses. The temporal codes enabled neurons to transmit six times as much information about color and three times as much information about luminance as did the spike count codes. This suggests that these neurons used temporal codes for color and luminance. We expected to find neurons with codes for either red/green, blue/yellow, or black/white opponencies. However, we were able to extract codes representing all three opponencies from the responses of each neuron.

These results suggest a change in the color and luminance encoding mechanisms from LGN to cortex. In LGN, different opponencies are represented by different neurons. However, in cortex different opponencies are represented by different temporal codes within the same neuron. This is consistent with our hypothesis that, as you proceed into the visual system, information shifts from strength codes carried by different neurons, to temporal codes shared by all neurons.

NEURONAL ELEMENTS ACTIVATED BY ELECTRICAL STIMULATION IN THE CORTICAL GRAY MATTER.

L.G. Nowak* and J. Bullier. Inserm U371, 69500 BRON/LYON, FRANCE.

Despite its extensive use in neurobiology, the effects of electrical stimulation are not well understood. In particular, the neuronal elements activated in the cortical gray matter are not clearly identified. To identify these elements, we have conducted two sets of experiments on slices of rat visual cortex, using monopolar, cathodal electrical stimulations through tungsten in glass micro-electrodes. In the first series of experiments, we made chronaxie measurements, which give an indirect estimate of the time constants of the activated elements (Ranck 1975, Brain Res. 98:417-440). Using intracellular recordings, we found that the chronaxies for eliciting small, presumably unitary, EPSPs have an average value of 0.424 msec (SD = 0.178 msec). This is not different from values corresponding to the activation of axons, as determined by recording antidromic action potentials (0.363 ± 0.196 msec). These results suggest that the unitary EPSPs observed after electrical stimulation did not result from activation of cell bodies, which have time constant of at least 10 msec.

It was then important to determine whether the axonal elements activated by electrical stimulation were initial segments or axonal branches. To clarify this point, we applied glutamate in the close vicinity of the stimulating electrode to produce a depolarization block in dendrites, cell body and axon initial segment. In that situation, electrical stimulation cannot lead to spike initiation in these elements. On the other hand, axons, which lack glutamate receptors, should not be affected. We compared the amplitudes of field potentials obtained by electrical stimulation before, during and after the glutamate-induced depolarization block. So far, in 4 out of 4 cases, we found that the field potentials were not modified.

These results, together with the results from chronaxie measurements, suggest that the large majority of neuronal elements activated by electrical stimulations are *en passant* axons. Given that axons can come from, or project to, many different cortical and subcortical structures, results obtained with electrical stimulation in the cortical gray matter should be interpreted with caution.

COMPUTING STEREO DISPARITY WITH KNOWN BINOCULAR CELL PROPERTIES. N. Qian*, B. J. Geesaman and R. A. Andersen. Dept. of Brain and Cognitive Sciences, MIT, Cambridge, MA 02139.

Cells sensitive to binocular disparity have been found in the visual cortex, but it is not clear how these cells might be used collectively to compute disparity maps from stereograms. Although many models for stereo disparity computation have been proposed, few, if any, adhere rigidly to physiological data. Here we propose a model for biological stereo vision based on known receptive field profiles of binocular cells described by Freeman and Ohzawa (1990, *Vision Res.*, 30:1661-1676), and provide the first demonstration that filters similar to real binocular cells can be used to effectively solve random dot stereograms. More specifically, we found through analysis and computer simulations that binocular simple cells do not have consistent disparity tuning behavior because their responses are also dependent on the Fourier phases of the stimuli, and that reliable tuning can be achieved by properly combining simple cell outputs to construct model complex cells. A family of such complex cells can then form a distributed representation of disparity and the actual disparity values of the stimuli can be easily estimated from such a distribution. Our model also allows a natural integration of stereo vision and motion detection. One attribute of the unified model is that motion along fronto-parallel planes is favored over motion in depth. To test this prediction we generated displays containing ambiguous stereo matches that could potentially give rise to both types of motion. Perceptually, motion was perceived only along the fronto-parallel plane, and ambiguities in stereo correspondence were resolved. Another prediction of the model, verified by our psychophysics, is that disparity cues are found to facilitate representation of more than one motion vector at a given spatial location. Thus, the model is not only physiologically plausible, but it also explains several novel psychophysical phenomena.

CORTICO-GENICULATE AND CORTICO-CLAUSTRAL CELLS OF LAYER VI- OPPOSITE ENDS OF A RECEPTIVE FIELD LENGTH SPECTRUM?

K.L. Grieve* and A.M. Sillito. Dept. of Visual Science, Inst. of Ophthalmology, Bath St., London EC1V 9EL, UK.

We have now shown that the majority of cells in layer VI of the cat striate cortex have relatively short receptive field (RF) lengths, in contradistinction to the traditional view of a layer dominated by cells with extremely long RF's. Layer VI has also been shown to play a critical role in the production of length selectivity at the level of the dLGN, and its maintenance within the cortex, by enhanced intrageniculate inhibition and intracortical facilitation respectively. This dual nature is in keeping with morphology and synaptology of corticogeniculate layer VI cells, which also have extensive intrinsic collateral axons within cortex - cells lacking such collaterals project to other targets, such as the visual claustrum. Although evidence suggested that the influence of the corticogeniculate cells was probably restricted in the length domain, our previous study could not directly identify cells projecting to the dLGN, and a small but significant proportion of cells with very long RF's were found, leaving open the question of RF length vs axonal target. Here we report length response curves of cells shown to project to the dLGN or claustrum, identified by antidromic activation. We recorded from single cortical cells of anaesthetized, paralysed cats, electrically stimulating via electrodes in the dLGN and visual claustrum. Length tuning curves were derived from responses to randomly interleaved bar stimuli of varied length drifted over the RF at the optimum orientation. For the vast majority of the corticogeniculate projecting cells, RF lengths were short, with a mean value of around 3°. On the other hand, corticoclaustally projecting cells were exclusively of the very long RF type, very similar to the known properties of claustral cells themselves, which also have very long RF's. Our data therefore supports the view that the short field layer VI cells provide both corticogeniculate feedback and intracortical interlaminar information transfer.

Synaptic potentials in visual cortical neurons: temporal variability and spatial structure. L.J.Toth*, S.B.Nelson, S.C.Rao, M.Sur. Department of Brain and Cognitive Sciences, MIT, Cambridge MA.

Using *in vivo* whole-cell recording from area 17 of cats, we examined the intracellular responses of cells to high contrast stationary and moving bars of light. These stimuli evoked a complex combination of excitatory and inhibitory potentials which underlied the spiking response. In general, responses to flashed bars were phase locked to stimulus onset or offset and highly repeatable (consistently present from trial to trial). Some responses to moving bars showed temporally locked onsets and offsets; other responses were less tightly locked to the stimulus and showed more gradual onsets and offsets. One interpretation of these data is that flashed bars evoke temporally correlated responses from cells earlier in the visual pathway than those we recorded, and such inputs lead to better phase locked responses in our cells than do inputs activated by moving bars.

These data were collected to study the feasibility of measuring receptive fields inclusive of subthreshold potentials. Preliminary results with moving bars indicate that the region generating a cell's spike response is only a subset of the larger region over which it sums inputs. It is possible that inputs from outside an extracellularly measured receptive field produce the temporal variability in intracellular responses to moving stimuli. Supported by EY07023.

THE DISTRIBUTION OF NMDA RESPONSES ALONG THE APICAL DENDRITES OF PYRAMIDAL CELLS IN RAT VISUAL CORTEX. S.N. Currie*, X.F. Wang and N.W. Daw. University of California, Riverside and Yale University, New Haven.

In adult cortex NMDA receptors are concentrated in layers II and III. This raises the question: do pyramidal cells in layers V and VI, that send apical dendrites to layers II and III, have a substantial response to NMDA iontophoresed along their apical dendrites away from the cell body, but not near the cell body? We recorded 40 cells by the whole cell technique in slices of rat visual cortex; electrodes contained 1% biocytin. NMDA was iontophoresed at a series of positions, then TTX was introduced into the solution and a second set of records taken. In general, the response to NMDA increased as the electrode was moved closer to the cell body. One cell had a response in layers II and III that was as large as in layer IV. When reconstructed, this cell had an exceptionally large arborization in layer II, suggesting that the large NMDA response was due to the anatomy of the cell, rather than the density of NMDA receptors. Several cells that had little response to NMDA in layers II and III after infusion of TTX responded with action potentials before infusion of TTX. We conclude that the NMDA receptors found in layers II and III reside primarily on the bodies of cells in layers II and III, rather than on the apical dendrites of cells in layers V and VI.

SYNAPTIC ORGANIZATION OF LATERAL PYRAMIDAL CELLS IN VISUAL CORTEX: GEOMETRY OF PYRAMIDAL CELLS. Matthew T. Calef and Philip S. Ulinski*. Department of Organismal Biology and Anatomy, Univ. Chicago, Chicago, IL 60637.

The visual cortex of freshwater turtles is divided into cytoarchitecturally distinct lateral and medial parts. Pyramidal cells in these two parts differ significantly in their morphology. Since an understanding of the integrative physiology of a neuron depends upon a knowledge of its geometry, lateral pyramidal cells were studied in Golgi preparations of turtle forebrain. Lateral pyramidal cells have a total surface area of about $19,500 \mu\text{m}^2$, of which about 7% is on the fusiform somata. Apical and basal dendritic trees originate from a primary dendrite about $2.6 \mu\text{m}$ in diameter and bear 1 to 4 secondary and tertiary dendrites with diameters that taper from $1.7 \mu\text{m}$ to $1.2 \mu\text{m}$. The ratio $(\Sigma d_b r^{3/2})/(d_p)^{3/2}$ varies from 1.4 proximally to 1.2 distally. The total path lengths of dendrites are about $320 \mu\text{m}$ from the soma to their tips. Dendrites bear about 260 spines per dendrite that vary in shape from stubby, to mushroom-like to pedunculated. The spine density increases along the dendrites from about 0.3 spines/ $10 \mu\text{m}$ near the soma to a peak of about 12 spines/ $10 \mu\text{m}$ about $170 \mu\text{m}$ from the soma and then gradually declines. Spines contribute about 32% of the total surface area of the cell. These data are being used to construct compartmental models of lateral pyramidal cells. Supported by PHS grant EY 08352.

SYNAPTIC ORGANIZATION OF LATERAL PYRAMIDAL CELLS IN VISUAL CORTEX: SPATIAL DISTRIBUTION OF GABA_A RECEPTORS. M. Fowler* and P. S. Ulinski. Departments of Psychology and of Organismal Biology and Anatomy, University of Chicago, Chicago, IL 60637.

GABAergic neurons in visual cortex access both GABA_A and GABA_B receptors, but the spatial distribution of the two types of receptors upon cortical neurons is not known. This study uses an *in vitro* brain-eye preparation of freshwater turtles (*Chrysemys picta*) to characterize the spatial distribution of GABA_A receptors upon pyramidal cells in lateral visual cortex. Conventional recording methods were used to record postsynaptic potentials from neurons characterized as lateral pyramidal cells. Spontaneous IPSPs with shape parameters and reversal potentials characteristic of GABA_A-mediated IPSPs occur when the retina is in the dark. The electrotonic lengths of the cells were estimated using the method of peeled exponentials and an equivalent cable model for each cell was constructed. IPSPs were simulated using this cable model and parameters for GABA_A-mediated IPSCs. Amplitudes of simulated IPSPs generated for known distances from the soma were used to estimate the positions of the real IPSPs. GABA_A-mediated IPSPs are generated with low frequency on the soma and then increase to a maximum frequency between 150 and 250 μm from the soma. Supported by PHS Grant EY 08352.

AUDITORY, VESTIBULAR, AND LATERAL LINE: HAIR CELLS

649.1

ACTION OF ACETYLCHOLINE ON COCHLEAR OUTER HAIR CELLS C. Erőstegui^{1,2}, C.H. Norris^{1*} and R.P. Bobbin², ¹ Dept. Otolaryngology, Tulane University School of Medicine, and ²Kresge Hearing Research Laboratory, Dept. of Otolaryngology, LSU Medical Center, New Orleans, LA 70112 USA

Acetylcholine (ACh) hyperpolarizes outer hair cells (OHCs) by increasing an outward K⁺ current (Housley & Ashmore, Proc. R. Soc. Lond. B 244, 1991; Erőstegui et al., ARO Abstr. 83, 329, 1993). ACh may induce Ca²⁺ entry which activates a K_(Ca) channel. However the mechanism of action of ACh is unclear. Thus we investigated the conductances involved in ACh induced current. OHCs were isolated from guinea pig cochleae and placed in Ringer containing 10 mM Cs⁺. Recordings from cells were made with the whole-cell configuration of voltage-clamp technique. Pipettes were filled with intracellular solutions containing 145 mM Cs⁺. Cs⁺ shifted the I-V plot of OHCs decreasing the outward and inward currents. This indicates that Cs⁺ blocked both the K⁺ conductance at rest and K_(Ca) conductance. Application of 100 μM ACh induced an outward current which reversed about -60 mV. As the cell was depolarized the current increased. This outward current was blocked by 100 μM Cd²⁺. We conclude that ACh activates an outward current through a channel that is different from the K_(Ca) channels described in these cells, but similar to the non-specific cationic channel in chick short hair cells (Fuchs & Murrow, J. of Neurosci. 12 1992). Supported by NIH research grant DC00722.

649.2

VOLTAGE-DEPENDENT CURRENTS IN HAIR CELLS OF THE CULTURED NEONATAL MOUSE UTRICLE. A. Rüscher and R.A. Eatock*, Dept. of Otolaryngology, Baylor College of Medicine, Houston, TX 77030

Using the whole-cell, voltage-clamp configuration of the patch-clamp technique, we recorded voltage-activated membrane currents from utricular hair cells, cultured on postnatal day 1 to 4 and maintained *in vitro* for up to 8 days. Cells were grouped in three classes based on their conductances.

In one class of hair cells (resting potential, RP: -64 ± 5.4 mV (mean \pm S.D.; n=33 cells), depolarizations from a holding potential of -83 mV to potentials above -63 mV activated large outward currents with a sigmoidal onset (peak values ≤ 7 nA at 0 mV). These currents inactivated partially, reversed close to the potassium equilibrium potential, and were reversibly reduced by about 90% by 5 mM 4-AP. We assume these currents to be of the delayed rectifier type. In all cells of this class an inward current through an inwardly rectifying conductance was recorded upon hyperpolarization below -83 mV (up to -250 pA at -123 mV). In 12 cells fast transient inward currents (up to -800 pA) were recorded after the end of hyperpolarizing voltage steps.

A second group of hair cells (RP: -76 ± 4.3 mV, n=24) also had potassium currents similar to those described above (≤ 16 nA at 0 mV). In the absence of drugs this conductance was masked by another large outwardly rectifying conductance (≤ 1 nA at -63 mV) which activated with slow kinetics above -93 mV after voltage steps to -103 mV. This conductance was completely and reversibly blocked by 5 mM 4-AP, but less effectively reduced by 25 mM TEA. Its reversal potential, close to the potassium equilibrium potential, identified it as a potassium conductance.

In a third group of hair cells (RP: -66 ± 5.2 mV, n=5), outward currents activated above -73 mV from a holding potential of -83 mV.

THE EFFECTS OF EXTERNAL CESIUM ON THE VOLTAGE-DEPENDENT CONDUCTANCES INVOLVED IN TUNING OF TURTLE HAIR CELLS. **M. B. Goodman*** & **J. J. Art**, Comm. on Neurobiology, Univ. of Chicago, Chicago, IL 60637.

In the basilar papilla of the turtle, hair cells are tuned to different frequencies in an acoustic stimulus by voltage- and ion-sensitive conductances whose magnitude and kinetics vary systematically (Art & Fetipplace, 1987, *J. Physiol.* 385: 207). Calcium and calcium-activated K⁺ currents have previously been implicated in this resonant behavior. These cells also possess an inwardly rectifying current (I_{IR}) that is readily observed at potentials negative to E_K, and is most prominent in cells tuned to lower frequencies. The significance of this current and its contribution to frequency selectivity and sensitivity remains obscure.

The reversal potential of I_{IR} is insensitive to removal of external Na⁺ and shifts with external K⁺ in a manner predicted for a K⁺ conductance. The slope conductance is also increased with elevation of external K⁺. For hair cells tuned to frequencies between 9 and 260 Hz, the maximum chord conductance of the inward rectifier is inversely proportional to the characteristic frequency of the cell. In the lowest frequency cells, the maximum chord conductances of the inward and outward K⁺ currents are comparable. Superfusion of 5 mM CsCl in voltage clamp blocks the inward rectifier and decreases the apparent voltage-sensitivity of the net whole-cell current near the cell's resting potential. The same manipulation in current clamp depolarizes the cell slightly, decreases the resonant frequency and dramatically reduces the quality of resonance. These results suggest that currents sensitive to external Cs⁺ contribute significantly to electrical resonance in the turtle cochlea, particularly in low frequency cells. REGIONAL VARIATIONS IN SYNAPTIC INNERVATION OF THE SQUIRREL MONKEY CRISTA. **A. Lysakowski*** and **J.M. Goldberg**, Committee on Neurobiology, The University of Chicago, Chicago, IL 60637

There are regional variations in synaptic innervation of the chinchilla crista (Lysakowski and Goldberg, *SNA*, 1989). Here, we apply similar methods to the squirrel monkey crista. We had previously shown that the ratio of type I to type II hair cells was higher in the monkey (3:1) than in the chinchilla (1:1) (Fernandez et al., *SNA*, 1991). We were interested in how the difference in hair-cell ratios would be reflected in the synaptic organization of the crista in the two species. Results are based on 5 samples from 2 cristae in 2 monkeys.

In the monkey, there are 6-10 ribbons per type I hair cell and some indication that central type I hair cells have more ribbons than peripheral type I hair cells. In addition, each central type I hair cell had ~20 calyceal invaginations, whereas each peripheral type I hair cell had ~2 invaginations. Although qualitatively similar gradients were observed in the chinchilla, the numbers of ribbon synapses and calyceal invaginations were smaller in the monkey.

Type II hair cells in the monkey had similar numbers of ribbons and afferent boutons; there were fewer boutons and ribbons centrally, than peripherally (~13 vs ~40 per type II hair cell). Very few ribbons from type II hair cells onto the outer surface of calyces were seen in the monkey as compared to the chinchilla. In the latter species, outer-face synapses are so common that most calyx afferents could be functionally dimorphic; this is not the case in the monkey.

The number of efferent boutons per hair cell differs between the central and peripheral zones in the monkey with ~2 efferent boutons per type I hair cell in the central zone, and ~0.5 per hair cell in the periphery. Type II hair cells had ~4 in the central zone and ~10 in the periphery. In contrast, the efferent innervation of type I and type II hair cells was more uniform in the chinchilla.

HAIR BUNDLES CONTAIN A FORM OF MYOSIN I. **P. G. Gillespie*** and **A. J. Hudspeth**, Department of Cell Biology and Neuroscience, University of Texas Southwestern Medical Center, Dallas, TX 75235-9039.

Although current models suggest that a myosin isozyme mediates adaptation of mechano-electrical transduction in hair cells, identification of hair-bundle myosins has been hampered by small numbers of bundles. Using purified hair bundles and photoaffinity crosslinking of vanadate-trapped [α -³²P]UTP, we characterized hair-bundle myosin candidates of molecular masses 120, 160, and 230 kD (Gillespie & Hudspeth, *Soc. Neurosci. Abstr.* 18: 1398, 1992). Because the 120-kD protein was observed most consistently, and because Ca²⁺ affects its ATPase cycle as anticipated for an adaptation motor, we examined this protein in more detail.

To identify the 120-kD protein, we employed two monoclonal antibodies, M2 and M3, that were raised against bovine adrenal myosin I and that display cross-reactivity between species (Wagner et al., *J. Cell Biol.* 119: 163-170, 1993). Protein immunoblot analysis indicated that hair bundles purified from the bullfrog's sacculus contain a 120-kD protein recognized by both antibodies. Assuming that the immunoreactivity of the bundle myosin matches that of bovine adrenal myosin I, the bundles in a frog's sacculus together contain about 2.5 μ g of myosin I. As observed with the photolabeled protein, the immunoreactive 120-kD protein resisted extraction by high salt, detergent, or ATP. An immunoreactive 120-kD protein was also present in the hair- and supporting-cell somata, where it again resisted extraction by conditions that solubilize many other myosin isozymes. Both antibodies labeled isolated hair cells or hair bundles in a punctate pattern focussed towards the stereociliary tips. These results indicate that the 120-kD myosin is a strong candidate to be the hair cell's adaptation motor.

SPEED OF SOMATIC SHAPE CHANGES OF COCHLEAR OUTER HAIR CELLS. **B.N. Evans, B. Clark, D.Z.Z. He, J. Sziklai, P. Dallos***, Auditory Physiology Laboratory (Hugh Knowles Ctr.), Dept. of Neurobiology, Northwestern University, Evanston, IL 60208.

Somatic shape changes of mammalian outer hair cells may participate in a local mechanical feedback process in the cochlea. It is likely that these shape changes are produced by voltage-sensing molecular motors located in the plasma membrane. While the speed of the motile response *in vivo* is likely limited by the low-pass filter properties of the cell membrane, it is of interest to determine the speed with which the ensemble of molecular motors may act, when not limited by membrane properties. Using the partitioning microchamber technique [Evans et al., *Hearing Res.* 52: 288 (1991)], it is possible to deliver constant amplitude ac stimuli to the isolated outer hair cell up to approximately 30 kHz. With the electrical partitioning, the two cell segments form a series-parallel combination of filters, reducing frequency-dependence, and thus producing a quasi all-pass system. Using low-level, wide-band pseudorandom ternary electrical noise stimuli or sequences of sinusoidal voltage commands, we show that the motile response persists up to at least 24 kHz, only limited by our system. The frequency following motile response is also accompanied by a tonic contractile response component. This dc response is also maintained up to the highest frequencies tested. Furthermore, above ~100 Hz, and at low and modest levels, the dc response changes linearly with signal amplitude. This dc component could be of significance *in vivo*. [Supported by the NIDCD and the Amer. Hrg. Res. Foundation.]

649.6

LOCALIZATION OF GABA_A RECEPTOR-LIKE IMMUNOREACTIVITY IN MAMMALIAN VESTIBULAR END ORGANS. **J. D. Foster^{1,2*}, M. J. Drescher^{1,2}, and D. G. Drescher^{1,2,3}**, ¹Lab. of Bio-otology, Depts. of ²Otolaryngology and ³Biochemistry, Wayne State University, Detroit, MI 48201.

Immunohistochemical analyses by several investigators have indicated that γ -aminobutyric acid (GABA) and its enzymes of synthesis and metabolism, GAD and GABA-T, respectively, are present in mammalian vestibular end organs. The localization of GABA-like immunoreactivity to the receptor cell or hair cell has been cited as evidence that GABA may act as a hair cell transmitter. However, immunoreactivity for this amino acid in the vestibular end organ has been associated with several, and in some investigations, multiple cell types, giving rise to a number of possible interpretations. In the current study, we demonstrate the presence of GABA_A receptor-like immunoreactivity in vestibular end organs of the hamster by use of immunohistochemical methods (immunofluorescence and immunoperoxidase), incorporating a monoclonal antibody specific for the β_2/β_3 subunits of the GABA_A receptor protein.

In the crista ampullaris and utricular and saccular maculae, GABA_A receptor-like immunoreactivity was observed in close association with afferent nerve calyces surrounding vestibular type I hair cells. The cytoplasm of vestibular type I hair cells did not appear to be immunoreactive. Some nerve fibers entering the epithelium were positive for GABA_A receptor-like immunoreactivity. There was no clear indication that vestibular type II hair cells or nerve fibers innervating them were immunoreactive. In the crista ampullaris, immunoreactivity appeared to be preferentially localized to calyces around vestibular type I hair cells located in the crest of the crista.

The localization of GABA_A receptor-like immunoreactivity to afferent nerve calyces is compatible with a receptor that is post-synaptic to the hair cell or to efferent neurons utilizing GABA as a transmitter, or alternatively, a presynaptic autoreceptor for the afferent nerve releasing GABA as a neuromodulator.

649.8

A CALMODULIN INHIBITOR SLOWS CHANNEL GATING AND ADAPTATION IN MECHANO-ELECTRICAL TRANSDUCTION BY HAIR CELLS. **R. G. Walker, P. G. Gillespie, and A. J. Hudspeth***, Department of Cell Biology and Neuroscience, University of Texas Southwestern Medical Center, Dallas, TX 75235-9039.

When a hair cell is stimulated by deflection of its hair bundle, mechanically sensitive ion channels rapidly open. If the stimulus persists, some of the channels then reclose during an adaptation process. The rate and extent of adaptation are influenced by the concentration of Ca²⁺ in the hair bundle. Calmodulin, a cytoplasmic receptor for Ca²⁺ in many cellular processes, occurs in the bundle in association with several receptor proteins (Walker et al., *Proc. Natl. Acad. Sci. USA* 90: 2807-2811, 1993). To investigate the possibility that calmodulin mediates the effects of Ca²⁺ on transduction, we sought to perturb calmodulin's actions by dialyzing cells with a potent peptide inhibitor of calmodulin binding. This peptide, which corresponds to the calmodulin-binding domain in Ca²⁺/calmodulin-dependent protein kinase II, inhibits several calmodulin-dependent enzymes at nanomolar concentrations. Upon including this peptide at a concentration of 250 nM in tight-seal, whole-cell recording pipettes, we observed slowing of mechano-electrical-transduction currents; the opening time constant increased from less than 1 ms to ~6 ms and the closing time constant to ~17 ms. In addition, adaptation to sustained stimuli was virtually abolished several minutes after rupturing the cell's membrane. The effects of the inhibitory peptide resembled those of treatments that lower the concentration of free Ca²⁺ in the hair bundle, including cellular depolarization and dialysis with a Ca²⁺ chelator.

FINITE ELEMENT ANALYSIS OF CILIARY BUNDLE STIFFNESS. R. K. Duncan¹, J. W. Grant¹, and E. H. Peterson^{2*}, ¹Biomedical Engineering Program, Virginia Polytechnic Institute, Blacksburg, VA 24061 and ²Neurobiology Program, Ohio U., Athens, OH 45701.

We are using finite element analysis to help understand mechanisms of mechanotransduction in hair cells. This method uses information about the dimensions and material properties of a structure to estimate the structure's mechanical response to deformation. Previous work dealt with the effects of ciliary numbers and dimensions (DiCaprio, Duncan, Grant, and Peterson, ARO abs., 1993) and interconnections (Duncan and Grant, ARO abs., 1993). Here we focus on the material properties of stereocilia.

Stereocilia are bundles of cross-linked actin filaments surrounded by membrane. Estimates are available in the literature for material properties for filamentous actin and actin gels, but not for actin bundles. We first modeled the ciliary shaft material as isotropic (material properties not directional; Poisson's ratio estimated at 0.4). Over a modulus range of 10^6 to 10^{10} N/m² there was a distinct change in the slope of Bundle Stiffness vs. Ciliium Modulus. This change in slope was associated with a change in the mode of deformation. Above modulus values of 10^8 , stereocilia bend at the base but the shaft remains straight, as observed experimentally, but the resulting bundle stiffness is higher than is generally observed experimentally. Below this modulus value, overall bundle stiffness falls within physiologic range, but the ciliary shafts buckle in response to an applied force. These observations, coupled with ultrastructural data on the internal structure of stereocilia (Tilney and Tilney, 1988) indicate that the ciliary material should be modeled as transversely isotropic.

A PROTEIN WITH TGF α -LIKE IMMUNOREACTIVITY IS EXPRESSED IN THE COCHLEA AND MAY BE UP-REGULATED DURING HAIR CELL REGENERATION. X.-M. Xu and J.T. Corwin*. Dept. of Otolaryngology-HNS and Dept. of Neuroscience, University of Virginia, Charlottesville, VA 22908.

Transforming growth factor alpha (TGF α) is a 50 amino acid protein that shares homology with EGF and has mitogenic effects on ectodermally derived tissues. Variants of TGF α range from roughly 5 to 20 kDa depending on differential processing. We have used western blots to look for TGF α -like proteins in the hair cell sensory epithelia of the inner ear. Eleven groups of 6 juvenile white leghorn chicks were each given an injection of gentamicin at 100 mg/kg body weight and then exposed to tonal sound stimulation at 1.5 kHz and 120 dB SPL for 24 hr, so as to damage hair cells and trigger regeneration in the cochlea. Immediately after the treatment, the chicks were euthanized and their cochleae were removed. The sensory epithelium was collected from each cochlea and homogenized in a detergent buffer together with other cochleae from the same treatment group. After centrifugation, supernatants were run through SDS-PAGE along with samples from age-matched controls. Nitrocellulose blots were reacted with a commercial mouse monoclonal antibody against recombinant human TGF α .

A single protein band that runs at approximately 12 kDa was labeled by the anti-TGF α in both experimental and control cochlear samples. In the majority of the experiments the labeling of this band was stronger in samples from the experimentally damaged cochleae than the labeling in samples from control cochleae. The increased expression of this protein is detectable after a treatment which causes extensive hair cell loss and which evokes hair cell regeneration. The results suggest that a protein that contains a potentially mitogenic TGF α -like domain may have a role in triggering cell divisions during the regeneration of hair cells in the cochlea.

VESTIBULAR HAIR CELL ABNORMALITIES IN CONGENITALLY HEARING IMPAIRED CANARIES. T. J. Park*, Y. Lu, and P. Weisleder, Goodhair-Day Laboratories, Dept. of Zoology, Univ. of Texas, Austin, TX 78712.

Recent reports have demonstrated that the hearing impairment of the Belgian Waterslager canary (BWC) strain is caused by severe hair cell anomalies (Dooling & Gleich, 1993 ARO Abs 16:88). Given that the auditory portion of the inner ear develops as an outgrowth of the sacculus (Streeter, 1906 Am J Anat 6:139), we were interested in ascertaining if the vestibular parenchyma of BWCs displayed abnormalities similar to those observed in the basilar papilla. The inner ear of adult BWCs and non-BWCs were examined by scanning electron microscopy. Hair cells in the basilar papilla and vestibular organs of non-BWCs had normal appearance. In BWCs, the hair cells in the basilar papilla displayed the same abnormalities previously reported by Dooling & Gleich. Hair cells in the sacculus and utricle were also abnormal. The severity of the abnormalities varied among animals and organs. Aberrant hair cells exhibited the following: 1) absence of kinocilium, 2) shorter than normal stereocilia, 3) stereociliary bundles not arranged in a staircase pattern, and 4) stereociliary bundles without a distinct orientation. In contrast, hair cells in ampullary organs had normal morphology. Given that all inner ear sensory structures develop from the otic placode, it is not surprising that otolithic and auditory hair cells in BWCs display similar abnormalities. For the same reason, it is puzzling that the surface morphology of semicircular canal hair cells appeared normal. (Supported by the Deafness Research Foundation, NIH DC 01522 & DC 20068, Dr. L. Popejoy, and the Cell Research Institute at U. of Texas)

CILIA OF HAIR CELLS FROM THE MACULAE LAGENAE OF Gallus gallus. A. Illescas* and S. Gómez. Departamento de Anatomía, Facultad de Medicina y Unidad de Microscopía Electrónica. Facultad de Medicina Veterinaria y Zootecnia. UNAM, México, D. F. 04510.

In certain number of species, the existence of cilia in hair cells has been widely reported. However important questions still are open over the characteristics of these structures. The objective of the present study was to analyze the structural pattern of the cilia in the maculae lagenae of *Gallus gallus*. Anaesthetized with sodic pentobarbital (ip), 3mg/100g of body weight. Beheaded internal ear was processed for electron microscopy transmission. We found in the apical end a bundle of stereocilia and one quincilium on the periphery of the hair cells Type I and II. The maculae lagenae presents a morphological polarization in the saccular type. This bundle of sensory hair face a significant likeness with the pattern of cilia of vestibular hair cell of the avian group. This fact agrees with the point of view that the maculae lagenae functions as a vestibular organ. All these data suggest that in this birds with flying habits, they were structurally involuted.

SPATIAL GRADIENT OF CELL PROLIFERATION IS GUIDED BY HAIR CELL DEGENERATION IN THE CHICK COCHLEA. E. Hashino*, E.K. TinHan and R.J. Salvi. Hearing Research Lab., SUNY at Buffalo, NY 14214.

Sensory hair cells in the avian cochlea regenerate after being destroyed. The replacement of new hair cells is more protracted after aminoglycoside ototoxicity (2-20 weeks) than after acoustic trauma (7-10 days). It is possible that different cellular events are involved in triggering cell proliferation following the different types of hair cell degeneration. In order to understand the cellular mechanisms underlying cell cycle regulation in the avian cochlea, we investigated the relationship between hair cell degeneration and cell proliferation after aminoglycoside ototoxicity.

Hair cell lesions were produced in neonatal chicks using kanamycin (KM; 400 mg/kg/d x 10d). Hair cell damage was monitored by phalloidin staining or SEM and cell proliferation was evaluated by bromodeoxyuridine (BrdU) pulse-fix analysis. Hair cell loss began 6d after the start of KM-injections, whereas cell proliferation was first observed between days 6-8 of KM injections. Thus, the latency of cell proliferation after the hair cell loss is less than 48 hrs. Both the hair cell loss and cell proliferation were first identified in the basal region and moved toward the apical region of the basilar papilla in a parallel manner during the KM treatment. The direction of cell proliferation appeared to be guided by hair cell loss, suggesting that some aspect of hair cell degeneration provides trigger signals for cell proliferation. TEM studies are currently underway to describe the early events of hair cell degeneration. (Supported by NSF BNS9007822 and NIH DC01685)

INCREASE IN HAIR CELL NUMBER DURING DEVELOPMENT OF THE XENOPUS LAEVIS SACCULUS. M. E. Díaz de Lodrón*, D. López, A. Varela-Ramírez, and E. E. Serrano. Dept. of Biology, New Mexico State University, Las Cruces, New Mexico, 88003.

This research focuses on a quantitative analysis of the development of inner ear sensory hair cells, using the *Xenopus laevis* sacculus as an experimental model. Embryonic animals (developmental stages 47, 52 and 56 according to Nieuwkoop & Faber, 1975) and adults (3.5 to 60 gms) were utilized. Sacculi were dissected, fixed by immersion in a dialdehydic mixture (2.5% glutaraldehyde, 1.5% paraformaldehyde in 0.1M sodium cacodylate buffer, pH=7.4) and postfixed in 2% osmium tetroxide. The sacculi were critical point-dried with CO₂, sputter-coated with gold and examined with a Phillips 501B scanning electron microscope. The entire saccular epithelium was photographed in serial sectors at 1250X and posteriorly reconstructed in order to count all the hair cells. The results show that the youngest animals had about 600 saccular hair cells, and this number increased to 2500 in the adults. The increase in hair cell numbers was most pronounced during embryogenesis and reached a stationary number in the postembryonic stages. This research was supported by grants to E.E.S. from NIH (S06-GMO8136-18, RO3 DC01460-01) and the Whitehall Foundation.

ONGOING AND GENTAMICIN-INDUCED HAIR CELL REGENERATION IN THE BULLFROG VESTIBULAR OTOLITH ORGANS. R.A. Baird*, M.A. Torres, and N.R. Schuff, R.S. Dow Neurological Sciences Institute, 1120 NW 20th Ave., Portland, OR 97209.

Hair cells in the bullfrog otolith organs have been shown to regenerate following exposure to the aminoglycoside antibiotic gentamicin sulfate (Baird et al., *Hear. Res.* 65:164-174, 1993). To examine the role of mitotic division in this recovery, the thymidine analogue bromodeoxyuridine (BrdU) was used to measure ongoing and gentamicin-induced cell proliferation in the otolith organs. Cell proliferation, measured with BrdU immunocytochemistry, was seen throughout the sensory maculae of both normal and gentamicin-treated animals and was significantly higher in the saccular than in the utricular macula. The number of proliferating cells in gentamicin-treated animals was initially lower than in normal animals, presumably because of the death of many BrdU-labeled cells. The rate of cell proliferation, however, was larger in gentamicin-treated than in normal animals. At early times, BrdU-labeled cells were seen adjacent to the peripheral macular margin and, within the maculae, in a subset of supporting cells immediately adjacent to the basement membrane. These cells were the first cells to incorporate BrdU labeling, suggesting that they are the progenitors of new hair cells. At later times, BrdU-labeled cells within the maculae were smaller and located further from the basement membrane, suggesting that the progeny of these cells had migrated to more apical positions. Our results also indicate that the rate of mitotic division is too low to explain the rapid replacement of hair cells in the otolith organs, suggesting that hair cell recovery in these organs is due largely to the migration of undamaged hair cells or the transdifferentiation of supporting cells.

MORPHOLOGY, DISTRIBUTION AND INNERVATION OF CEPHALIC SUPERFICIAL NEUROMASTS IN GOBIES (TELEOSTS). J. Song, Div. of Fishes, NMNH, Smithsonian Institution, Washington D.C. 20560.

Several lateral-line head canals of gobiid fishes are replaced by superficial neuromasts (SNM) in a great variety of patterns. This study compares two topographic patterns of cephalic SNM in two goby genera (*Bathygobius* and *Gobiosoma*). The distribution and hair cell orientation of the neuromasts were examined by using scanning electron microscopy, and the innervation patterns were observed on specimens cleared and triple stained (alizarin, alcian, Sudan Black B). All the specimens were from museum collections. The results indicate that orientation of the neuromasts are determined by their innervation rather than their topographic location. A set of SNM lines innervated by the same ramule possesses the same orientation. The primary SNM (pit-organs) orient perpendicular to the axis of their line. The canal replacement SNM orient parallel to the axis of their line. For example, the segments of the horizontal primary SNM line are distinguished from infraorbital canal replacement lines in a SNM complex of the cheek region by their innervation and orientation. The segments of vertical primary SNM and mandibular line are distinguished from the preopercular and mandibular canal replacement at the preopercular-mandibular region by their innervation, orientation and hair cell morphology. The innervation pattern is also a criterion for homologizing individual SNM lines in different patterns among gobies and other fishes. This study was supported by a Smithsonian Postdoctoral Fellowship to the author.

LOCATIONS OF VESTIBULAR HAIR CELLS IN DEVELOPING ZEBRAFISH EMBRYOS VISUALIZED WITH A FLUORESCENT VITAL DYE. Barbara Chapman* and Scott E. Fraser, Division of Biology, Mail code 139-74, Caltech, Pasadena CA 91125.

To study the development of vestibular sensory receptors, we utilize a fluorescent dye injected into the lumen of the otocyst in living zebrafish at different stages. We have found that 4-(4-diethylaminostyryl)-N-methylpyridinium iodide (4-Di-2-ASP), which has previously been used to visualize nerve terminals, selectively labels hair cells in the zebrafish inner ear. Confocal microscopy was used to localize the labeled hair cells within the complex three dimensional structure of the developing ear.

We began 4-Di-2-ASP injections at 19 hrs (development at 28.5°C), when two otoliths are clearly visible. The first specific labeling was seen at 26 hrs when one or a few brightly labeled cells are seen in epithelial thickenings adjacent to each otolith. By 36 hrs the maculae of both otoliths are well formed, with brightly labeled hair cells forming a shallow cup closely opposed to each otolith. Hair cells in the rostral macula are oriented vertically and located ventral to the otolith, while those in the caudal macula are oriented horizontally and located medial to the otolith.

The hair cells of the semicircular canal cristae are not visible until 48 hrs when one brightly labeled cell is seen within each of three epithelial thickenings on the lateral wall of the otocyst. At this stage the cranial and lateral projections, which will fuse to create the first of the canal walls, are just touching. Thus the sensory receptors of the semicircular canals begin to develop before the canals themselves are formed. More hair cells are gradually added in each of the cristae over the next several hours. The otoliths and their maculae move to a more medial position in the otocyst, while the cristae move ventrally. During this period, ending around 60 hours, the epithelial projections forming the walls between the semicircular canals fuse. At about this time the zebrafish begin to exhibit a dorsal-up attitude and righting reflex.

Over the next several weeks of development the morphology of the semicircular canals continues to change, with the canals becoming more elongated. No major changes in the maculae or cristae are seen during this period.

DENERVATION AND SUBSEQUENT RECEPTOR CELL DEATH INCREASE BASAL CELL PROLIFERATION IN TUBEROUS ELECTRORECEPTOR ORGANS OF A WEAKLY ELECTRIC FISH. P. Weisleder*, Y. Lu, and H. H. Zakon, Dept. of Zoology, Univ. of Texas, Austin, TX 78712.

Weakly electric fish generate electric fields for the purposes of electrolocation and communication. The fields are detected by specialized receptor organs: the tuberous organs. Tuberous organs contain four different cell types: electroreceptor cells (sensory cells), basal cells, plug cells, and capsule cells. Previous studies have shown that basal cells are the progenitors of electroreceptor cells. In the present study we investigated the effect of denervation on the rate of proliferation of basal cells. The left, infraorbital, anterior lateral line nerve of sixteen brown ghosts (*Apteronotus leptorhynchus*) was sectioned, and the proximal stump was dipped in ricin to prevent regrowth. In groups of four, the animals were given twice daily injections of the cell proliferation marker bromodeoxyuridine (BrdU) at one, two, three, or four weeks following denervation. Following two days of BrdU injections, a piece of cheek skin, ventral to the eye, was removed from the left (denervated) and the right (innervated) sides and processed for immunocytochemistry. Our results show: 1) there is progressive receptor cell death and tuberous organ degeneration following denervation; 2) at all survival times the number of labeled basal cells is greater in denervated organs; 3) the number of labeled basal cells increases steadily with survival time and tuberous organ degeneration. These results suggest that innervation is essential for electroreceptor cell survival, and that receptor cell death is a plausible trigger for basal cell proliferation.

ULTRASTRUCTURAL CORRELATES TO PHYSIOLOGICALLY DISTINCT HAIR CELL TYPES IN THE GOLDFISH SACCCULE. P.J. Lanford and A.N. Popper*, Dept. of Zoology, Univ. Maryland, College Park, MD 20742.

Dissociated hair cells from rostral vs. caudal regions of the goldfish saccule are physiologically and morphologically distinct (Sugihara & Furukawa, *J. Neurophys.* 1989, 62:1330). We present ultrastructural evidence that confirms these regional variations *in situ* and provides further morphological distinctions between cell types.

Cells in the rostral half of the saccular epithelium are pear-shaped, with round nuclei, small synaptic bodies, and evenly distributed mitochondria. Rough endoplasmic reticulum (RER) is generally scattered, with occasional subnuclear layering. This morphology continues through the central to mid-caudal regions of the epithelium, with subnuclear RER layering becoming more prominent and well organized caudally. In these areas, cells have some resemblance to striolar cells found in the utricle of the oscar, *Astronotus ocellatus* (Chang et al., 1992, *J. Comp. Neurol.* 302:629). At the extreme caudal end, however, cells exhibit a taller, cylindrical morphology with elongate nuclei, no RER subnuclear layering, large synaptic bodies, and mitochondria clustered at the basal region of the cell. These resemble the oscar utricular extrastricular hair cells.

Our data demonstrate substantial differences in hair cell ultrastructure along the length of the goldfish saccule. This variation may provide an ultrastructural basis for functional differences within this endorgan.

MUSCLE ACTIVITY EVOKED BY PAIRED-PULSE STIMULATION OF SUBSTANTIA NIGRA PARS RETICULATA: THE EFFECT OF TECTAL, PONTINE, & RETICULAR FORMATION LESIONS. J.A. Moretti, & D. Asdourian*. Dept. of Psychology, Wayne State Univ., Detroit, MI 48202

The substantia nigra pars reticulata (SNr) is a major output for information processed by the basal ganglia. Multiple ascending and descending SNr efferents have been identified, indicating that SNr exerts control over motor behavior via many pathways. Previous work from our laboratory has shown that unilateral electrical stimulation of SNr elicits bilateral activity from neck muscles in the rat. It was also observed that antecedent stimulation of one SNr differentially affected the amplitude of the muscle response elicited by stimulation of the other SNr, depending upon the delay between the first and second stimulus. The present study attempts to locate the area(s) responsible for the differential effect on the amplitude of muscle activity resulting from bilateral stimulation of SNr by making lesions in either SNr output pathways or target nuclei. The lesion targets were PPN, the tecto-and rubrospinal tracts, VA/VL, and the ponto-medullary RF. The only significant lesion effect on overall response amplitudes was seen following PPN lesions. None of the lesions influenced changes in muscle amplitude resulting from the delays between the first and second stimulus during bilateral SNr stimulation.

REGIONALLY SPECIFIC, NMDA-RECEPTOR MEDIATION OF ORAL MOTOR CONTROL IN THE RAT'S STRIATUM AND ITS INTERACTION WITH LOCAL CHOLINERGIC SYSTEMS.

M. Pisa* and D. Bosiljevac. Dept. Biomed. Sci., McMaster Univ., Hamilton, Ont., Canada, L8N 3Z5.

In rats, bilateral injections of the wide-spectrum glutamate receptor antagonist kynurenic acid (12-72 nmol) in the lateral striatum induce an increase of nondirected (in vacuo) oral movements (NDOM), suggesting a role of corticostriatal glutamatergic transmission in oral motor control. In the present study, we examined the roles of both striatal subregions and distinctive types of glutamate receptors in this effect. Injections (0.2 - 0.5 µl) of the competitive NMDA-receptor antagonist CPP (0.4 - 10 nmol) into the ventrolateral striatum (VLS) produced a powerful, dose-dependent increase of NDOM (threshold dose 1 nmol) that could be attenuated by co-injections (0.5 µl) of the muscarinic receptor antagonist atropine sulphate (1 - 10 µg). The effect was regionally specific because similar injections of CPP into the dorsomedial striatum did not increase NDOM. Injections (0.5 µl) of either the noncompetitive NMDA-receptor antagonist MK-801 (10 nmol) or the QUIS/KA receptor antagonist DNQX (10 nmol) into the VLS failed to increase NDOM. The results indicate regionally selective roles of NMDA and muscarinic receptors of the VLS in the control of oral behavior (Supported by the Natural Sciences and Engineering Research Council of Canada and the Scottish Rite Schizophrenia Research Program, N.M.J., U.S.A. M. Pisa is a Research Associate of the Ontario Mental Health Foundation).

THE PEDUNCULOPONTINE TEGMENTAL NUCLEUS AS A STRIATAL OUTPUT STATION. I. EFFECTS OF PPTg OR CUNEIFORM NUCLEUS LESIONS ON LOCOMOTION ELICITED BY STIMULATION OF NUCLEUS ACCUMBENS. P. Winn*, M.P. Latimer, W.L. Inglis, J.S. Dunbar and L.F. Allen. Dept. Psychol., Univ. St Andrews, Fife, Scotland KY16 9JU.

The role of the PPTg in mediating locomotion stimulated from nucleus accumbens (NAS) is controversial. Some authors have shown that PPTg interference attenuates NAS locomotion; others have not. We used excitotoxins to make complete lesions of PPTg to examine this further. Ibotenate (IBO) and quinolinate (QUIN) destroy cholinergic PPTg neurons but QUIN has less effect on non-cholinergic neurons (Rugg E.L. *et al.* 1992 Brain Res. 589:181-193). The following groups were tested: bilateral IBO or QUIN PPTg lesions (0.12M: 2 X 0.2µl injections/hemisphere) and bilateral sham lesions (2 X 0.2µl PB). Bilateral guide cannulae were aimed at the NAS; each rat received (randomized order) bilateral infusions of 10, 20 and 30µg AMPH and vehicle control (all 0.5µl per hemisphere via 30ga cannulae, 0.25µl/60sec). Spontaneous locomotion (measured in photocell cages) was unaffected by either IBO or QUIN lesions of PPTg; AMPH increased locomotion dose-dependently in all rats regardless of lesion, suggesting that the PPTg does not mediate locomotion induced by intra-NAS AMPH. One possibility however is that the adjacent cuneiform nucleus (CNF), identified by some authors as an essential component of the mesencephalic locomotor region, mediates NAS locomotion. This hypothesis was tested by making sham control and IBO lesions of the CNF (0.12M in 0.2µl phosphate buffer/hemisphere) in rats equipped with guide cannulae aimed at the NAS (as above). Neither spontaneous locomotion nor that elicited by intra-NAS AMPH was affected by CNF lesions (which did not encroach into the PPTg). Overall these data suggest that locomotion induced by NAS AMPH is not mediated solely (if at all) by these pontine nuclei.

650.2

STIMULATION OF DOPAMINERGIC D1 RECEPTORS IN THE SUBTHALAMIC NUCLEUS ELICITS ORAL DYSKINESIA IN RATS. T.J. Parry*, I. Lucki¹, M.F. Chesselet. Dept. of Pharmacology and Psychiatry¹, Univ. of Pennsylvania, Philadelphia, PA 19104.

The subthalamic nucleus (STN) plays a critical role in regulating basal ganglia function. Although the STN receives dopaminergic input from the substantia nigra pars compacta and contains dopaminergic D1 binding sites, the role of dopaminergic stimulation of the STN on motor behavior is unknown. We tested the hypothesis that dopaminergic stimulation of the subthalamic nucleus induces motor behaviors in the conscious rat. Unilateral injections of apomorphine (0.1 to 3.2 µg in 100 nl) into the STN caused a dose-dependent increase in abnormal orofacial movements and no change in turning, sniffing, grooming, or rearing behaviors. Peripheral administration of SCH 23390, a D1 receptor antagonist, markedly reduced the number of orofacial movements elicited by STN injections of apomorphine at a dose of 0.1 mg/kg sc while sulpiride, a D2 selective antagonist, failed to block these oral movements at a dose of 50 mg/kg. Further, simultaneous injection of SCH 23390 (1 µg) with apomorphine (1 µg) within the STN prevented oral movements normally observed with apomorphine alone. In contrast, a similar experiment using the D2 antagonist sulpiride (5 µg) did not reduce abnormal orofacial movements normally observed with apomorphine alone. Finally, lesions of the STN by local injection of kainic acid prevented orofacial dyskinesia induced by local administration of apomorphine. These results suggest that local dopaminergic D1 receptor stimulation of the STN induces abnormal orofacial movements and highlights the importance of dopaminergic input to the STN in the regulation of motor function. This work was supported by PHS grants MH-44894, GM-34781 and MH-14654.

650.4

GABAERGIC RECEPTORS IN THE ANTERIOR AND POSTERIOR SUBSTANTIA NIGRA PARS RETICULATA ARE DIFFERENTIALLY INVOLVED IN EXPRESSION OF AMPHETAMINE-INDUCED OROFACIAL STEREOTYPY. P. R. Dickson* and A. E. Kelley. Dept. Psychology, Northeastern Univ., Boston, Ma, 02115.

Microinjection of amphetamine into the ventrolateral striatum (VLS) induces intense orofacial stereotypy (licking, biting, and self-gnawing) in rats. GABAergic striatonigral neurons may be involved in the expression of VLS-mediated oral stereotypy. To test this hypothesis, several experiments were carried out. In the first experiment, animals were implanted with bilateral cannulae aimed at either the anterior (ant) or posterior (post) substantia nigra pars reticulata (SNR). Behavior was recorded via observation in the home cage following infusions of either saline (0.5 µl), muscimol (75 ng/0.5 µl), or picrotoxin (75 ng/0.5 µl). In the antSNR, muscimol induced a strong oral stereotypy, including intense self-gnawing, at 30, 60, and 90 minutes post-injection. Picrotoxin had no behavioral effects at this site. In the postSNR, picrotoxin induced strong oral stereotypy which was apparent in the first 30 minutes and subsided thereafter. Muscimol induced no alteration of oral behavior in the postSNR, although there was significant general behavioral activation. These results suggest that striatonigral fibers terminating in the antSNR (presumably on nigrotectal neurons) mediate amphetamine-induced orofacial stereotypies, and that these nigrofolgal neurons are inhibited during oral stereotypy. Nigrofolgal neurons in the postSNR are also involved in orofacial stereotypy, but appear to be disinhibited during this behavior. Moreover, neurons in the postSNR may be preferentially influenced by striato-pallidogenic input, rather than direct striatonigral input.

650.6

THE PEDUNCULOPONTINE TEGMENTAL NUCLEUS AS A STRIATAL OUTPUT STATION. II. EFFECTS OF PPTg LESIONS ON RESPONDING FOR CONDITIONED REINFORCEMENT ELICITED BY STIMULATION OF NUCLEUS ACCUMBENS. W.L. Inglis* and P. Winn. Dept. Psychol., Univ. St Andrews, Fife, Scotland KY16 9JU.

Despite suggestions that the PPTg is an output station for the nucleus accumbens (NAS) we found that excitotoxic lesions of the PPTg did not block spontaneous locomotion or that induced by intra-NAS *d*-amphetamine (AMPH). Other behaviours stimulated by intra-NAS AMPH may however be affected by PPTg loss. We have examined responding for conditioned reinforcement stimulated by intra-NAS AMPH in rats with either ibotenate (IBO) or quinolinate (QUIN) lesions of the PPTg. IBO and QUIN both destroy cholinergic PPTg neurons but QUIN has less effect on non-cholinergic neurons (Rugg E.L. *et al.* 1992 Brain Res. 589:181-193). Rats were trained to associate food in a standard operant chamber with a compound visual/auditory stimulus after which bilateral IBO or QUIN PPTg lesions (0.12M: 2 X 0.2µl injections/hemisphere) or sham lesions (2 X 0.2µl PB) were made. Rats were also implanted with bilateral guide cannulae aimed at NAS and were retrained for 8 sessions after surgery. In test trials one lever produced CR, while the other did not (NCR). Sham lesioned rats showed dose-dependent increases in CR lever pressing, but there was no substantive effect of NAS AMPH on the NCR lever or the food hopper panel. QUIN lesioned rats showed a strikingly similar pattern of responding to controls. IBO lesioned rats showed relatively normal responding on the CR lever but exaggerated responding on the NCR lever in response to intra-NAS AMPH. Panel pressing was low in these rats. These data suggest that IBO lesioned rats had not associated the presence of the CR with a particular lever. The data also indicate that the non-cholinergic neurons of the PPTg affect NAS outflow: but why should they affect CR but not locomotion?

650.7

THE PEDUNCULOPONTINE TEGMENTAL NUCLEUS AS A STRIATAL OUTPUT STATION. III. EFFECTS OF PPTg LESIONS ON BITING ELICITED BY STIMULATION OF VENTROLATERAL CAUDATE-PUTAMEN. L.F. Allen*, M.P. Latimer and P. Winn Dept. Psychol., Univ. St Andrews, Fife, Scotland KY16 9JU.

We have previously observed that bilateral ibotenate (IBO) lesions of the PPTg increase the incidence of biting in response to systemic *d*-amphetamine (AMPH). In the present experiment, biting induced by microinjection of AMPH into the ventrolateral caudate-putamen (VLCP) was examined in rats with either quinolinolate (QUIN), IBO or sham lesions of the PPTg. Both IBO and QUIN destroy cholinergic PPTg neurons but QUIN has less effect on non-cholinergic neurons (Rugg E.L. *et al.* 1992 *Brain Res.* 589:181-193). The following groups were tested: bilateral IBO or QUIN PPTg lesions (0.12M: 2 X 0.2µl injections/hemisphere) and bilateral phosphate buffer sham lesions (2 X 0.2µl). All rats were also equipped with bilateral guide cannulae aimed at the VLCP; each rat received (in a randomized order) bilateral infusions of 5, 10 and 20µg AMPH and a vehicle control injection (all injections 0.5µl per hemisphere via 30ga cannulae, 0.25µl/60sec). Sham lesioned rats showed a dose response effect to AMPH microinjected into the VLCP. Biting (assessed by observation of video recordings) was principally directed at the cage floor and paws. All doses of AMPH elicited biting (20>10>5µg). QUIN lesions had no substantial effect on the response to VLCP AMPH but IBO lesions produced a significant shift to the left in the dose response curve. These data suggest that the non-cholinergic neurons of the PPTg are involved in the mediation of biting elicited from the VLCP by AMPH. Under normal circumstances these neurons presumably work to inhibit orofacial activity. How information is transmitted from the VLCP to PPTg (through the pallidum? through SNr? through both?) is unclear. Further experiments will clarify this issue.

GLUTAMATE IN THE VENTRAL STRIATUM CAN AFFECT PSYCHOMOTOR FUNCTIONS IN OPPOSITE DIRECTIONS DEPENDING ON THE DOPAMINERGIC TONE. A. Svensson*, M.L. Carlsson and A. Carlsson, Department of Pharmacology, University of Göteborg, S-413 90 Göteborg, Sweden.

The psychomotor effects of glutamate blockade in the nucleus accumbens were studied in male NMRI mice with different tones in the dopaminergic system.

A unilateral injection of the competitive N-methyl-D-aspartate (NMDA) receptor antagonist AP-5 into the nucleus accumbens caused the animals to rotate. The rotation was predominantly *ipsilateral* in animals with intact monoaminergic systems. In contrast, in monoamine-depleted mice, pretreated with reserpine and α -methyl-tyrosine, the rotation was consistently *contralateral*.

This shift in the direction of rotation was apparently due to the lack of dopamine D-2 receptor stimulation, because in monoamine-depleted mice systemically treated with the selective D-2 receptor agonist quinpirole, AP-5 caused the animals to rotate *ipsilaterally*. Pretreatment with the D-1 agonist SKF 38393 failed to induce this shift in the direction of rotation. The crucial involvement of the dopamine D-2 receptor was also confirmed in experiments with intact mice pretreated with either the selective D-1 receptor antagonist SCH 23390 or the selective D-2 antagonist raclopride.

These results show that, depending on the dopaminergic tone and the stimulation of dopamine D-1/D-2 receptors, the glutamatergic neurons projecting to the ventral striatum can affect psychomotor functions in opposite directions.

LOCOMOTOR RESPONSE TO MICROINJECTION OF PICROTOXIN INTO VENTRAL PALLIDAL REGION DOES NOT SHOW LATERALIZATION. N.A. Otmakhova, C.H. Woodworth and R.G. Robinson*, Dept. Psychiatry, Univ. of Iowa Coll. Med., Iowa City, IA 52242.

The nucleus accumbens (NAS), a locus for interactions between limbic and motor processes, plays a role in mediating locomotion in rodents. A major mesolimbic efferent pathway arising within the NAS is a dense GABAergic projection into the substantia innominata/ventral pallidum region (SI/VP). Previously we have demonstrated an asymmetrical locomotor response to discrete, unilateral lesions of either parietal cortex (PC) or NAS: only right-hemisphere lesions resulted in a significant change in locomotor activity. The goal of the present study was to ascertain whether locomotion elicited from the SI/VP is also characterized by behavioral asymmetry.

Unilateral microinjections of the GABA antagonist picrotoxin (PTX), a chloride-channel blocker, were used to produce locomotor activation. Male Sprague-Dawley rats were implanted bilaterally with cannulae in the SI/VP and injected (0.5 µl over 1 min) every other day with either saline (SAL) or PTX in either the right or left hemisphere (4 injections in all). Each animal was treated with one of 7 doses of PTX (0.005, 0.010, 0.015, 0.020, 5, 15, and 25 ng in saline vehicle; n = 6-9 each dose group). Rats were placed in Omnitech activity chambers immediately following injection, and horizontal and vertical activity monitored at 20-min intervals for 2 hours.

Results were analyzed separately for each group, using a 3-way MANOVA with treatment (SAL vs PTX), injection side (right vs left), and time (successive intervals) as within-subject factors. Injection side was found to be either insignificant or inconsistent, leading to the conclusion that the SI/VP does not contribute to the locomotor asymmetry elicited from PC or NAS.

NEURONAL ENSEMBLES IN RAT NEOSTRIATUM COACTIVATED ACROSS DIFFERENT BEHAVIORS. A.B. Kirillov, S.F. Sawyer and D.J. Woodward*, Department of Physiology and Pharmacology, Bowman Gray School of Medicine, Winston-Salem, NC 27157.

The aim of this work was to study the characteristics of ensemble activity of neostriatal neurons in awake rats which emerge across behaviors. Up to 24 neostriatal neurons were concurrently recorded from chronically implanted arrays of microwires. Rest and treadmill walk was employed to generate the substantial activity needed to detect groups. Crosscorrelation analysis with standard parameters (1 ms bin within 200 ms window) did not reveal peaks or dips, characteristic of monosynaptic interactions. On the other hand, a considerable fraction of neurons showed statistically significant positive or negative offshoots in crosscorrelograms, calculated with a large bin size (10 ms) and large window size (2 sec). Wide central peaks of these crosscorrelograms (100-500 ms) suggest that groups of neurons may receive some common excitatory inputs. The expression of crosscorrelations was increased during the 30 sec treadmill walk periods as compared with the 30 sec resting periods between treadmill walks. Based on pairwise cross-correlograms, in one experiment two groups of coactivated neurons (5 and 6 units of 24) were identified. The groups of neurons that showed pairwise correlations also exhibited significant increases in the frequency of instantaneous coactivation patterns in which 80% of neurons fired in the same time bin, as compared to the expected frequencies of such patterns for independent spike trains. Perievent histograms around coactivation times in one group revealed existence of simultaneous inhibition of the other group. The demonstration that coherent patterns vary across behavioral states provide an initial analysis of coordinated neural activity within neostriatum.

CHARACTERIZATION OF NEURONAL ACTIVITY IN THE PATCH-MATRIX COMPARTMENTS OF THE STRIATUM IN FREELY MOVING RATS. E.S. Trytek*, J.M. White, D.M. Schroeder and G.V. Rebec, Prog. Neural Science, Depts. Anatomy and Psychology, Indiana University, Bloomington, IN 47405.

Sensorimotor and limbic cortices provide inputs to both patch and matrix compartments of the rat striatum, but in terms of their relative contributions, sensorimotor inputs dominate the matrix, whereas limbic inputs project primarily to patch. This differential distribution of afferents implies important functional distinctions between these compartments (Gerfen, *Annu. Rev. Neurosci.*, 15:285-320, 1992). To assess such distinctions, we recorded from neurons in either the patch or matrix compartment in awake, behaving rats. All animals were prepared for single-unit recording and allowed 7-10 days for recovery. On the recording day, a glass electrode (2-7 MΩ), filled with 2M NaCl and pontamine sky blue (PSB) dye, was lowered into the striatum. After the sensorimotor responsiveness of individual neurons was characterized, the recording site was marked by ejection of PSB. Immunostaining for calbindin by the avidin-biotin-peroxidase method (Hsu *et al.*, *J. Histochem. Cytochem.*, 29:577-580, 1981; Vector Laboratories) was used in conjunction with microscopic examination to assign the recording site to the patch or matrix compartment. Preliminary findings indicate that neurons increasing activity in close association with movement are located either entirely within the matrix or along the patch-matrix border. Neurons responding to tactile stimulation of specific body parts also are located in the matrix. These results, which link the processing of sensorimotor information with the striatal matrix compartment, demonstrate the feasibility of combining electrophysiological and neuroanatomical procedures for elucidating patch-matrix function.

SINGLE CELL RECORDING IN THE FREELY MOVING, UNILATERALLY 6-OHDA LESIONED RAT. J. CHO, L. MANZINO*, P.K. SONNALLA, and M.O. WEST, Dept. of Psychology, Rutgers Univ., New Brunswick, NJ 08903., Dept. of Neurology, UMDNJ-Robert Wood Johnson Medical School, Piscataway, NJ 08854*.

The basal ganglia (BG) are essential for initiating movements, and for processing sensory (e.g., proprioceptive) information in order to guide ongoing movements. In particular, the role of the BG in movement depends upon dopaminergic innervation of these structures. The depletion of striatal dopamine can produce severe behavioral deficits such as hypokinesia, akinesia, tremor, rigidity, adipsia, hypodipsia, and sensory inattention. This study examined the effects of unilateral depletion of striatal dopamine on single neurons in the lateral striatum of awake, unrestrained rats (N=5). Injection of 4µl of 6-OHDA (6-OHDA HBr Salt 3 mg/mL) into the medial forebrain bundle (and desmethylimipramine intraperitoneally to protect NE projections) resulted in >98% depletion of dopamine unilaterally in all cases (N=5). Two months after the lesion, animals exhibited robust rotational responses to L-DOPA (10 mg/kg plus carbidopa, 10 mg/kg), i.e., at least 500 turns contralateral to the lesioned side during the 3 hr post-injection period. Animals were then prepared for chronic single-cell recording. The striatal neurons that were studied were of the type that fire phasically in relation to active movement, passive manipulation or cutaneous stimulation of particular body parts. No changes were observed in clustering or somatotopic organization after the lesion. However, the main effect on the lesioned side was that in all cases, a percentage of these striatal neurons (mean=17%) fired in relation to sensorimotor activity of multiple body parts, as opposed to the normal relation of such neurons to only one body part. It is possible that sensorimotor deficits observed in dopamine-depleted animals, such as the failure to orient to discrete somatosensory stimuli, may involve a loss of selectivity by some striatal neurons, resulting in disrupted sensorimotor integration.

SINGLE NEURONS IN THE VENTROLATERAL STRIATUM OF THE RAT RELATED TO LICKING. T.Mittler, J.Cho, L.L.Peoples and M.O.West*. Dept. of Psychology, Rutgers Univ., New Brunswick, NJ 08903.

Recent evidence indicates that the ventrolateral subregion of the striatum (caudate-putamen) is a component of the circuitry controlling oral behavior. This study examined the relationship of single-neuron activity (n=728), recorded from the striatum of awake, unrestrained rats (n=4), to oral movements involved in licking. Neuronal firing was evaluated during licking of single drops of water or sucrose solution, and during cutaneous stimulation and motor activation of the mouth and perioral area. Peri-event histograms were constructed around licking, by using frame by frame analysis (30 frames/sec) of computer-synchronized videotape recordings. Firing rates of 75 neurons ("lick-related") increased specifically during licking but showed no change during a full sensory examination and motor activation of all other body parts, including other orofacial movements. 15 additional neurons ("orofacial-combination") fired during licking and also fired in the absence of licking, during one or more other orofacial sensorimotor functions. Lick-related neurons were located in the lateral striatum, throughout the entire anterior-posterior range studied (from +1.5 mm to -1.5 mm A-P). Initial analysis showed that lick-related neurons were located ventral to representations of the body and limbs. These findings extend the characterization of the somatotopic map in the striatum of the rat to include representations of oral sensorimotor functions by single neurons, and provide the potential for using this preparation to study oral motor dysfunctions (e.g. tardive dyskinesia) at the single cell level. Supported by grant DA 04551.

REPEATED L-DOPA ADMINISTRATION INCREASES THE NUMBER OF SPONTANEOUSLY ACTIVE A9 DOPAMINE NEURONS IN THE PARTIAL DOPAMINE-DEPLETED RAT. D.G.Harden* and A.A.Grace. Depts. of Behavioral Neuroscience and Psychiatry, Center for Neuroscience, University of Pittsburgh, Pittsburgh, PA 15260

Using 6-OHDA-induced dopamine (DA) depletion as a model for Parkinson's disease, we investigated the effect of repeated L-DOPA treatment on the proportion of spontaneously active A9 DA neurons. One week following i.c.v. injection of a sufficient level of 6-OHDA to deplete approximately 70-90% of striatal DA, animals were divided into control and L-DOPA treatment groups. L-DOPA administration consisted of two daily i. p. injections of 50mg/kg of L-DOPA and 50mg/kg of benserazide dissolved in isotonic saline. In parallel, control depleted animals were injected with isotonic saline. Administration was between the hours of 8:30 and 10:30 A.M. and 4:30 and 6:30 P.M.. Following at least 4 weeks of treatment, nine electrode tracks were made through a predefined region of the substantia nigra. In saline-treated, depleted animals, the average number of active DA neurons per track was 0.22 whereas in animals treated with L-DOPA there were substantially more DA cells found (0.72 neurons/track). The results of this study indicate that repeated L-DOPA treatment increases the number of active DA neurons following partial 6-OHDA-induced DA depletion. This increase in active DA neurons may contribute to some of the therapeutic actions and side effects observed upon the initiation of L-DOPA treatment in humans with Parkinson's disease.

DEFICIENT STARTLE GATING AFTER QUINOLINIC ACID (QA) LESIONS OF THE RAT STRIATUM MIMICS DEFICITS IN HUNTINGTON'S DISEASE (HD). M.H.Kodsi* and N.F.Swerdlow. Depts. Neuroscience and Psychiatry, UCSD Sch. of Med., La Jolla, CA 92093.

The acoustic startle reflex is normally inhibited, or "gated", when the startling noise is preceded by a weak "prepulse". "Prepulse inhibition" (PPI) is impaired in patients with neuropsychiatric disorders associated with limbic and basal ganglia dysfunction, including Schizophrenia, OCD and HD. This failure of sensorimotor gating in HD patients may reflect striatal pathology that underlies their inability to inhibit involuntary movements.

Previous studies in rats suggest that striatal modulation of PPI is effected through striato-pallidal GABAergic efferents; degeneration of these same projections is implicated in the etiology of HD. In the present study, we assessed whether PPI deficits in HD patients can be modeled in rats by QA lesions of the striato-pallidal projection. QA, an endogenous neurotoxin, has been implicated in striatal neurodegeneration in HD.

Startle was measured in rats after QA-induced lesions of the ventral striatum. Lesioned animals had elevated startle amplitude and significantly reduced PPI. Similar deficits were noted after QA lesions of the posterior dorsolateral striatum. In addition, reduced PPI after QA lesions of the ventral striatum was significantly reversed by muscimol infusion into the ventral pallidum. These findings suggest that a loss of PPI in HD patients may reflect neuronal degeneration within striato-pallidal GABAergic circuitry.

TWO-DIMENSIONAL AND THREE-DIMENSIONAL VISUALIZATION OF FUNCTIONAL REPRESENTATION IN RAT NEOSTRIATUM.

E.Lubin†, L.L.Brown†, D.Smith† and S.M.Feldman*‡. †Department of Neurology, Albert Einstein College of Medicine, Bronx, NY 10461 and ‡Center for Neural Science, New York University, New York, NY 10003.

We previously reported the use of feature detection procedures in conjunction with deoxyglucose autoradiography to reveal a combinatorial map of somatosensory activity in rat neostriatum (Brown, *PNAS*, 1992). We here report the use of *Voxel View* software for 3D image analysis, to further examine functional activity in the region of rat neostriatum that receives input from sensory and sensorimotor cortex.

Tactile stimulation was applied to awake rats during iv injection of radiolabeled deoxyglucose. Image analysis was carried out on digitized autoradiograms of coronal brain sections, with optical density initially coded as grey level. Subsequent color coding was used to identify the areas of maximal and minimal glucose utilization in striatal regions of interest. Textural characteristics of each image were demonstrated by use of a seed function, image enhancement and boundary extraction procedures.

The creation of a series of 2D images that display bounded areas of maximal activation revealed a patchy array that corresponds both to known neuroanatomic patterns of corticostriate terminal distribution and to clustered regions of neural activity; we previously identified these regions as *features*, using different image processing algorithms (Brown, 1992). The images have the advantage of obviating the user-interactive thresholding procedures required in our earlier studies. In addition, for each rat we rendered the series of 2D images as a 3D volume, which showed the shapes and spatial arrangements of the features. The technique affords an opportunity to view in three dimensions the regional metabolic activity produced under physiological conditions.

LONG-TERM ENHANCEMENT OF PRESYNAPTIC EXCITABILITY OF GLUTAMATE (GLU) AFFERENTS TO ACCUMBENS. M.Garcia-Munoz, P.Patino, S.J.Young and P.M.Groves. Dept. of Psychiatry., Sch. of Medicine, University of California San Diego, La Jolla CA 92093-0603.

We have reported that tetanic stimulation of cortical afferents can induce an enduring modification in striatal terminal excitability. The induction does not appear to depend on postsynaptic actions, but on alterations occurring in the presynaptic membrane since these changes in excitability can be obtained in animals in which most postsynaptic neurons are destroyed with kainic acid. We now report that long-term changes in presynaptic excitability can also be induced in GLU afferents to accumbens following tetanic stimulation of prefrontal cortex (PC), amygdala (Amyg) or hippocampal subiculum (Hipp). Extracellular action potentials were recorded either in PC, Amyg or Hipp in urethane anesthetized, male Sprague-Dawley rats. Excitability was assessed by determining the threshold current for antidromic activation of the terminal field before and after tetanization. Tetanic stimulation (100 Hz/250ms/6s, 5 times) to the ipsilateral Amyg or the contralateral PC produced a long-lasting (>1h) increase in the excitability of their respective terminal fields in accumbens. In contrast, similar to corticostriate terminals hippocampal high-frequency stimulation produced a transient increase followed by an enduring decrease in excitability, and an enduring increase if a second tetanus was administered at the time of the occurrence of the initial transient increase. Experiments are underway to examine these effects in animals with kainate lesions in accumbens. We propose that the induction of striatal and accumbens long-term changes in presynaptic excitability occurs via a positive feedback system in which increases in firing rate increase GLU release, which in turn increases the activation of presynaptic autoreceptors (KA, NMDA or *t*-ACPD), to locally modify terminal membrane conductance and/or polarization and thereby increase electrical excitability and release.

650.18

DEPLETION OF DOPAMINE IN THE CAUDATE NUCLEUS BUT NOT DESTRUCTION OF VESTIBULAR INPUTS IMPAIRS SHORT-INTERVAL TIMING IN RATS. Nancy L.Dallal* and Warren H.Meck. Department of Psychology, Columbia University, New York, NY 10027.

Impairment of the dopaminergic system in the striatum induced by dopamine-receptor antagonists or by specific neurotoxin terminal lesions results in both motor and cognitive disturbances in rats trained in psychophysical tasks involving the discrimination of durations in the seconds to minutes range. In order to specify further the role of the striatum in timing and time perception, the performances of rats trained in two sets of operant peak-interval (PI) timing procedures (10s & 60s or 20s & 80s) was examined after specific destruction of dopamine neurons by 6-hydroxydopamine perfusion into the caudate nucleus or by destroying vestibular inputs to the striatum with intratympanic injections of sodium arsenate. Destruction of vestibular inputs to the striatum did not affect sensitivity to time but did result in a higher response rate in the PI timing task that was associated with identical start times for responding in lesioned and control rats, but significantly earlier stop times for the rats with vestibular lesions. In contrast, the effects of dopamine depletion from the caudate resulted in a severe impairment in the sensitivity to time. Rats with caudate lesions were unable to exhibit temporal control of their behavior, but were able to show discrimination of the relative reward value of a signal by differentially modifying their response rates. These results suggest that areas of the basal ganglia receiving vestibular input influence the determination of response thresholds for timing, whereas the dorsal striatum may serve an accumulator function for temporal integration.

650.19

SYNCHRONIZATION AMONG GABAergic NEURONS IN A GLOBALLY COUPLED NETWORK. D. Golomb¹, X.-J. Wang² and J. Rinzel^{1*}.

¹Mathematical Research Branch, NIDDK, NIH, Bethesda, MD 20892; ²Depart. of Mathematics and James Franck Inst., Univ. of Chicago, Chicago, IL 60637.

We explore computationally, with a globally-coupled network of conductance-based inhibitory model neurons, the hypothesis that the reticular thalamic nucleus (RTN) is a synchronized pacemaker for sleep spindle rhythms. A single cell shows post-inhibitory rebound due to a T-type calcium current that deactivates with hyperpolarization. We showed previously (Wang & Rinzel, *Neuroscience* 33:899-904, 1993) that such a network can oscillate *synchronously*, if the synaptic conductance decays slowly (as do GABA_B synapses) and if the synaptic strength is large enough. Here we consider the separate effects on synchronization of conductances G_A and G_B (for GABA_A and for GABA_B synapses). G_A is fast, while G_B decays slowly. If, with only G_B present, our homogeneous network oscillates synchronously, adding a sufficiently strong G_A leads to desynchronization: the population subdivides into several groups which burst alternately. For moderately strong G_A, the oscillation's frequency increases with G_A strength. This effect is from slowing of T-current de-inactivation with deeper hyperpolarization. Increasing G_A, for which the reversal potential is less negative than for G_B, decreases the level of post-burst hyperpolarization, thereby avoiding the voltage region of slower de-inactivation. We also study the effects of heterogeneous intrinsic properties amongst the neurons, by assuming that the T-type calcium conductance density varies from cell to cell. The level of synchrony decreases as the variability increases. When the neurons are nearly identical they still synchronize, with modest phase shifts. With large variability, the network is totally asynchronous; individual cells are either periodic or quiescent. For intermediate variability, there are two regimes of complex behavior. In one, some neurons burst every cycle, while others burst every few cycles or not at all. In the second, there are two groups of neurons bursting alternately, while other neurons burst at lower rate or are quiescent.

BASAL GANGLIA AND THALAMUS IX

651.1

INCREASE OF GLUCOSE CONSUMPTION IN BASAL GANGLIA AND THALAMUS OF PATIENTS WITH SPASMODIC TORTICOLLIS.

D. Perani^{*}, G. Galardi, F. Grassi, S. Amadio, L. Maderna, GC. Comi, N. Canal, F. Fazio.

INB-CNR, Scientific Institute H S Raffaele, University of Milano, Italy.

The pathophysiology of spasmodic torticollis, a focal dystonia involving neck muscles, is still unclear. In the present study, 2-[18F]fluoro-2-deoxy-D-glucose ([18F]FDG) positron emission tomography (PET) was used to compare rCMRglu in 7 patients with spasmodic torticollis (mean age 50.37 ± 11.47) and 10 age matched controls. All cases with a short disease duration, were untreated, except one patient with 15 years history, treated with anticholinergic drugs. An inter-groups analysis (patients vs controls) using Statistical Parametric Mapping (Friston et al. 1989) revealed a significant bilateral increase of glucose consumption in putamen and thalamus (p < 0.001). An individual analysis, with mean ± 2 SD of normal rCMRglu values as the cut-off scores, demonstrated a significant increase of rCMRglu in putamen (6 cases bilaterally), caudate (4 cases bilaterally, 2 unilaterally) and thalamus (5 cases bilaterally, one unilateral). The patient treated, with a long history, had a hypometabolism in caudate and putamen. Enhanced glucose metabolism in basal ganglia and thalamus is possibly the functional correlate of focal dystonia. A recently proposed model suggests that dystonia would be the consequence of a putaminal hyperactivity, leading to the breakdown of the pallidal inhibitory control on thalamus and thalamo-cortical projections.

651.3

NEURONAL ACTIVITY IN THE INTERNAL (GPI) AND EXTERNAL (GPe) SEGMENTS OF THE GLOBUS PALLIDUS (GP) OF PARKINSONIAN PATIENTS IS SIMILAR TO THAT IN THE MPTP-TREATED PRIMATE MODEL OF PARKINSONISM. J. Vitek^{*}, Y. Kaneoke, R. Turner, M. Baron, R. Bakay, M. DeLong. Dept. of Neurology, Emory University, of Medicine, Atlanta, GA, USA.

Previous studies of neuronal activity in the GP of MPTP-treated monkeys have demonstrated increased tonic discharge rates in GPI and decreased rates in GPe as well as widened receptive fields to proprioceptive input. These findings have lent support to a current model whereby increased (inhibitory) output from GPI results in the cardinal signs of parkinsonism. In patients with Parkinson's disease (PD) undergoing micro-electrode guided pallidotomy, we recorded the spontaneous discharge of cells in GP and surrounding structures and examined the response of cells to active and passive limb movements.

The discharge pattern of cells in the striatum, GPe, GPI, and the basal forebrain were similar to those reported previously in the monkey. Most striatal neurons exhibited very low discharge rates (< 1 Hz). A small number of tonically active cells discharged at low rates (3.5 ± 1.4 Hz, n=7). The mean discharge rate of high frequency discharge cells in GPe (n=66) was 49.9 ± 20.6 Hz. In GPI the mean discharge rate was 81.9 ± 23.7 Hz (n=54). Nucleus basalis neurons located in the laminae of the pallidum (border cells) discharged at a rate of 34.1 ± 18.6 Hz (n=13).

Of 105 cells examined in GPI, 18% responded to passive and/or active movements of the arm and 16% to the leg. In general, leg cells were located dorsal and medial to arm cells. Receptive fields were confined to movements about a single joint in the contralateral limbs and responses were strongly directional in all cases.

These findings indicate that the neural discharge patterns and somatotopic organization is similar in man and monkey. Furthermore the finding that discharge rates in GPI neurons are significantly (p < 0.001, t-test) higher than in GPe neurons, as observed in the MPTP-primate model of PD, lends strong support for the current pathophysiological model of Parkinson's disease.

651.2

LESIONS IN THE SENSORIMOTOR REGION OF THE INTERNAL SEGMENT OF THE GLOBUS PALLIDUS (GPI) IN PARKINSONIAN PATIENTS ARE EFFECTIVE IN ALLEVIATING THE CARDINAL SIGNS OF PARKINSON'S DISEASE. M. Baron, J. Vitek, R. Turner, Y. Kaneoke, R. Bakay, M. DeLong. Dept. of Neurology, Emory University Sch. of Med., Atlanta, GA. 30322

Previous studies have reported that lesions placed in GPI are effective in reducing or abolishing many of the cardinal signs of Parkinson's disease. These studies, however, did not directly correlate lesion location to outcome nor were standard clinical rating scales or quantitative motor assessments performed.

In patients (n=7) undergoing microelectrode-guided pallidotomy, we performed (pre- and post-operatively) a series of standard clinical assessments [United Parkinson's Disease Rating Scale (UPDRS), Schwab and England (S & E)], as well as quantitative measures of motor function, including reaction and movement time. Using microelectrode mapping for guidance radiofrequency lesions (65-80 degrees F for 1 minute) were placed in the caudal sensorimotor territory of GPI. Immediate improvement in parkinsonian signs was often observed in the contralateral limbs. At 1 and 3 months we noted substantial improvement in the UPDRS with patients' total scores decreasing from 102 to 84. The S & E scores improved from 41 to 67 % independence. Improvement was reflected in decreased reaction and movement times, with some patients showing bilateral improvement. In addition, tremor and rigidity were reduced and gait was improved. Furthermore, drug-induced dyskinesias were markedly diminished, in some cases bilaterally. Lesion locations were confirmed by high-resolution MRI to lie within the caudal and lateral portion of GPI in regions where neurons intra-operatively responded to passive or active movement of the limbs.

These studies provide direct evidence that lesions of GPI within the motor territory are effective in reducing parkinsonian motor signs. Mapping boundaries of GPI and assessing neuronal responses to limb movement are helpful means of guiding the placement of lesions and improving the surgical results of pallidotomy.

651.4

ACTIVITY OF PALLIDAL NEURONS DURING SEQUENTIAL MOVEMENTS. H. Mushiake and P.L. Strick. Research Service, VAMC and Depts. of Neurosurgery & Physiology, SUNY-HSC@Syracuse, NY 13210

We recorded the activity of single neurons in the globus pallidus (GP) while a monkey performed sequential pointing movements under two task conditions. The monkey faced a panel with 5 touch pads and started the task with his hand on a hold key in front of him. In the Remembered Sequence Task (SEQ task), LEDs over 3 touch pads were illuminated in a pseudo-random sequence as an instruction to the monkey. After a delay period, an auditory 'Go' signal told the monkey to release the hold key and press the touch pads according to the instructed sequence. In the Tracking Task (TRAC task), the monkey was required to press 3 touch pads immediately after the LED over each of them was illuminated. We recorded from over 100 GP neurons that displayed activity related to the tasks. For approximately one-third of the related neurons, activity changes occurred only during the SEQ task or were more pronounced during the SEQ task than during the TRAC task (SEQ neurons). SEQ neurons tended to be in regions of GP that were dorsal to the other task related neurons. For some SEQ neurons the activity changes were limited to one phase of the movement sequence (e.g., a phasic decrease only between the second and third button presses). These observations raise the possibility that the neural mechanism which solves the 'serial order of motor behavior' problem involves a portion of the GP. Supported by the VA Medical Research Service.

651.5

ACTIVITY OF DOPAMINE NEURONS IN MONKEY PERFORMING AN ACTIVE AVOIDANCE TASK. *L. Mironowicz** and *W. Schultz** (SPON: European Neuroscience Association). Institut de Physiologie, Univ. Fribourg, CH-1700 Fribourg, Switzerland.

Dopamine (DA) neurons of the substantia nigra of the monkey show phasic electrophysiological responses to external stimuli with particular behavioral significance. Previously tested stimuli included reward, reward-associated stimuli and unexpected novel stimuli, all being appetitive. A more comprehensive account of the activity of DA neurons requires the assessment of their responsiveness to aversive stimuli. Furthermore, numerous studies using dialysis or voltammetric techniques revealed an increase in DA turnover in the prefrontal cortex and the striatum of animals submitted to stressful situations or to aversive stimuli, which suggests the activation of DA neurons in such situations.

We investigated the activity of DA neurons in an active avoidance task. The monkey withdrew its hand from a resting key in response to a light in order to avoid a mild air puff to the hand. Of 52 tested DA cells, 40% responded phasically to the conditioned light. On the rare instances where the monkey did not succeed in withdrawing its hand from the key when the light appeared, most DA neurons were activated phasically by the air puff. For reasons of comparison, the animal was presented with appetitive stimuli in randomly alternating trials. Here, the monkey released the resting key on hearing a conditioned sound and pressed a lever in order to receive a drop of apple juice. Of the tested DA neurons, 75% responded phasically to this conditioned stimulus. Almost all neurons activated by the aversive conditioned stimulus also responded to the appetitive conditioned stimulus.

This study suggests that DA neurons respond to aversive stimuli. Thus, DA neurons are activated by the two most important classes of external stimuli with behavioral significance, appetitive and aversive stimuli. The fact that most neurons activated by aversive stimuli also responded to appetitive stimuli suggests that there is no segregation within the population of DA cells activated by motivationally significant stimuli.

PREPARATORY AND MOVEMENT-RELATED ACTIVITY OF NEURONS IN PALLIDAL-RECEIVING THALAMUS. *J.A. Buford** and *M.E. Anderson*. Depts. of Rehabilitation Medicine and Physiology & Biophysics and the Regional Primate Research Center, RJ-30, University of Washington, Seattle, WA 98195, U.S.A.

Prior knowledge of target location or movement direction may elicit preparatory activity in striatal, cortical, and pallidal neurons. We have now examined the effect of a precue on neural activity in pallidal-receiving areas of the thalamus.

Two monkeys performed arm movements to one of 8 target lights that were either lit coincident with a trigger tone and kept visible (V task) during the movement or flashed briefly as a precue (P task) before the tone triggered the movement. Forty-four neurons were studied in arm-related, pallidal-receiving areas of thalamus. Seventy-five percent had early (Q) responses following the precue in the P task and movement-related (M) responses in both tasks; 2/3 of those also had more sustained, set-related (S) activity between the precue and trigger in the P task. For 60% of the cells, the M response was different for the P and V tasks. However, the M response in the P task could be either an enhancement (27%) or a depression (33%) of that in the V task. Directional tuning of Q and S responses for the P task as well as M responses for both tasks was common (50%). Only 10% of the neurons studied had no directional tuning for either task.

Task-related neurons in premotor areas of cortex or in striatum may have instruction-related or movement-related activity, but few cells have both (Wise and Tanji 1985, Alexander and Crutcher 1990, Schultz and Romo 1992). Pallidal neurons, in contrast, often have both instruction-related and movement-related activity (Turner and Anderson 1989). Our data imply some integration of preparatory and movement-related signals in the pallidum that is reflected in the discharge of pallidal targets in the thalamus.

TONICALLY ACTIVE NEURONS IN THE PRIMATE STRIATUM ACQUIRE RESPONSES TO SENSORY STIMULI DURING BEHAVIORAL CONDITIONING. *T. Aosaki**, *H. Tsubokawa*, *K. Watanabe*, *A. M. Graybiel* and *M. Kimura*. Jichi Med. Sch. Dept. of Physiol., Tochigi 329-04, Japan; M.I.T. Dept. of Brain and Cog. Sci., Cambridge, MA 02139; Osaka University, Osaka 560, Japan.

Tonically active neurons (TANs) in the primate striatum are known to respond to conditioned sensory stimuli that elicit behavioral reactions. We have studied how these unit responses develop during the acquisition of a sensorimotor association. The activities of 682 TANs were recorded extracellularly in alert behaving monkeys before, during and after conditioning. Two monkeys were trained to lick reward juice delivered simultaneously with the presentation of a click. Before conditioning, the animals made almost no licking movements. During conditioning they learned to lick after the clicks sounded, and by three weeks, the onset of the licking movements became time-locked to the clicks. Population peristimulus-time histograms of TANs showed almost no response to the clicks. The average activity of TANs followed daily in one monkey during conditioning showed initially (1-4 da, n=51) a small transient suppression response to the click followed by a rebound activation, then (by 5-8 da, n=53) an initial activation and stronger transient suppression/rebound, and finally (by 3 wk, n=91) initial activation with strong ca. 100 msec suppression and rebound. By prolonged recording from single TANs (n=4), we found that by ca. 2 weeks, individual TANs can acquire the response to the click within 10 minutes. Histological reconstruction showed that the TANs that became responsive were widely distributed through the striatum, suggesting that, after conditioning, the activity of TANs can become synchronized in widespread parts of the striatum. These results suggest that TANs of the striatum may serve to organize striatal activity during conditioned movements. Supported by Human Frontier Science Program.

ACTIVITY OF MONKEY DOPAMINE NEURONS IN A LEARNING SET PARADIGM. *J. Hollerman** and *W. Schultz*. Institut de Physiologie, Univ. Fribourg, CH-1700 Fribourg, Switzerland.

Previous studies have shown that dopamine neurons respond to reward presentation during early stages in the learning of an appetitive task but this response is transferred to the conditioned stimuli after the task is well learned. These studies involved comparisons of the responses of different dopamine neurons recorded at different stages of task acquisition across weeks of learning. In order to investigate the activity of individual dopamine neurons during the course of learning, we attempted to use a more circumscribed learning situation, namely, a learning set paradigm. We used a conditional motor task in which the animal performed, or refrained from performing, an arm movement in response to a trigger signal depending on a preceding instruction (go-nogo task). Responses of dopamine neurons were recorded in two basic conditions: 1) a standard condition, in which the instruction stimuli were previously well learned (stimulus-response associations previously formed), and 2) a learning condition in which the instruction stimuli consisted of previously unseen stimuli (new stimulus-response associations forming). Responses of dopamine neurons to reward were compared in the two conditions.

Consistent with previous studies, a very small percentage of dopamine neurons responded to reward in the well established standard condition. However, there were very few individual cells which exhibited greater reward responses in the "new learning" than in the standard condition. This seems to indicate that dopamine neurons are not actively involved in the learning of new stimulus-response associations in the context of a previously learned task. This may be due to the fact that in the context of the task, the delivery of reward is reasonably well predicted, even in the learning condition. This is supported by the observations that the dopamine neurons did respond to unexpected reward presentation, delivered either outside the task or within the task (on correct trials) at other than the usual post-response delay. Thus dopamine neuron responses to reward appear to be highly sensitive to the predictability or expectedness of the reward.

ALTERED SOMATOSENSORY RESPONSE PROPERTIES OF NEURONS IN THE CEREBELLAR RECEIVING AREA OF THE MOTOR THALAMUS IN MPTP TREATED PARKINSONIAN MONKEYS. *Y. Kaneoke*, *J. L. Vitek*, *J. Ashe*, *M. R. DeLong*, *M.D. Crutcher**. Dept. of Neurology, Emory University, Atlanta, GA. 30322.

Previous studies in monkeys rendered parkinsonian by injections of the neurotoxin MPTP have found that neurons in the globus pallidus, pars interna (GPi) show increased sensitivity and decreased specificity of somatosensory responses. We have previously described similar alterations in the pallidal receiving portion of the motor thalamus, ventralis lateralis, pars oralis (VLo). In order to determine whether alterations in the somatosensory responses of thalamic neurons are restricted to the pallidal portion of the motor thalamus or are more widespread we examined the sensorimotor response properties of neurons in the cerebellar receiving portion of the motor thalamus, ventralis posterior lateralis, pars oralis (VPLo) and ventralis lateralis, pars caudalis (VLC) in African Green monkeys both prior to and following treatment with MPTP (0.5 mg/kg/day x 3 days i.m.). African Green monkeys were conditioned to permit a detailed somatosensory examination consisting of passive joint rotation, muscle palpation, tactile stimulation and the elicitation of active movements of the limbs and orofacial structures. The same electrode was used to map the sensorimotor response properties of neurons in VPLo and VLC both before and after MPTP treatment, thus it was possible to keep the physiologic maps in precise register. Treatment with MPTP resulted in severe parkinsonism, including akinesia, bradykinesia, rigidity, tremor and postural instability. Prior to MPTP treatment neurons in VPLo and VLC typically responded to somatosensory stimulation to passive movements about a single joint of the contralateral limb. Neuronal responses were directionally specific. Following treatment with MPTP somatosensory responses in VPLo and VLC were less specific and it was common to find neurons responding to movements of multiple joints, in more than one direction, and often more than one limb. Although ipsilateral responses were never seen prior to MPTP treatment, such responses were commonly observed following treatment with MPTP. We conclude that proprioceptive responses are altered in both the pallido- and cerebello-thalamocortical pathways and suggest that dysfunction in both these circuits may play a significant role in the pathogenesis of parkinsonian signs. Supported by NIH grant NS01328.

DIFFERENTIAL LOCALIZATION OF TONICALLY ACTIVE NEURONS OF PRIMATE STRIATUM IN THE MATRIX AND AT STRIOSOME/MATRIX BOUNDARIES. *M. Kimura**, *T. Aosaki*, and *A. M. Graybiel*. Osaka University, Faculty of Health and Sport Sciences, Osaka 560, Japan; M.I.T. Dept. of Brain and Cognitive Sciences, Cambridge, MA 02139, USA.

Primate striatal neurons can be classified into at least two types in terms of wave form, spontaneous activity and behavioral response relationships. Numerous slowly firing cells (type II), presumed medium spiny projection neurons, show phasic discharges prior to or during movements. Rarely encountered tonically active neurons (TAN or type I), presumed striatal interneurons, do not exhibit burst discharges in relation to behavioral events, but acquire conditioned responses to sensory stimuli that trigger conditional motor behavior during behavioral training. They are activated synchronously across widespread regions of the striatum. The present study was carried out to determine whether the TANs are located in one or in both of the neurochemically distinguished compartments, striosomes and matrix.

TANs were electrophysiologically identified at 151 sites in 5 anesthetized squirrel monkeys, and extracellular marks were made at these sites by injecting the dye, Chicago sky blue, through a glass microelectrode. We encountered TANs at ca. 400 μ m intervals and held the neuronal discharges of the same cell for ca. 100 μ m. Brains were processed for enkephalin immunostaining to distinguish striosomes from matrix. Some marks were as large as 200 μ m, but most were less than 100 μ m wide. None of the marks recovered (n=82) was in a striosome. However, 44 out of 82 marks were either close to or precisely on striosome/matrix borders. Of the 38 marks in the matrix beyond the borders, 14 were found at visible borders between inhomogeneous zones of staining in the matrix. These results suggest that the distribution of TANs is not random, and that the conditional activation of many TANs during learning may depend in part on their differential distribution at borders of striosomes. EFFECTS OF BICUCULLINE INJECTION INTO THE SUBSTANTIA NIGRA PARS RETICULATA ON ELECTRICALLY INDUCED VOCALIZATION IN KETAMINE ANESTHETIZED CATS. T. Sakamoto*, K. Shiba and Y. Nakaiima, Dept. of Physiol., Sch. of Med., Chiba Univ., Chiba, JAPAN 260.

To examine whether the substantia nigra pars reticulata (SNr) is the plausible origin of the inhibitory GABAergic projection to PAG vocalization area or not, a GABA antagonist, bicuculline methiodide (BIC) was microinjected into SNr.

Vocalization was induced by electrical stimulation (0.2 ms pulses, 20 to 100 μ A, 100 Hz, for 5-10 s) to the ventrolateral periaqueductal gray (PAG). After injection of 0.1 μ l of 2 mM BIC into SNr (n=8), the stimulus threshold of PAG area for vocalization increased for more than 60 min, and it returned to the preinjection level after 2 hrs. Saline injection induced slight increase of the stimulus threshold (less than 0.2 T), which lasted for about 5 min. Effective sites were localized within SNr. After injection of BIC, respiration cycle of spontaneous breathing became longer. However, PAG stimulation induced vocalization with the similar respiration cycle to that of before injection, although the higher stimulus intensity was necessary.

These results suggested that the GABAergic inhibition from SNr regulated the excitability of PAG neurons which send the motor command for vocalization to respiratory and laryngeal control systems within the pons and medulla.

HALOPERIDOL-INDUCED MORPHOLOGICAL ALTERATIONS ARE ASSOCIATED WITH CHANGES IN CALCIUM/CALMODULIN KINASE II ACTIVITY AND GLUTAMATE IMMUNOREACTIVITY. C.K. Meshul* and S.E. Tan. V.A. Medical Center and Oregon Health Sciences University, Portland, OR. 97201.

Subchronic treatment with haloperidol (HAL)(0.5 mg/kg/d) for 14-30d results in an increased density of synapses within the striatum containing a perforated or discontinuous postsynaptic density (PSD). These 'perforated' synapses are asymmetric and show immuno-gold labelling for glutamate. Thus, the HAL-induced increase in perforated synapses may involve glutamatergic neurons. Co-administration of MK-801, a NMDA antagonist, and HAL blocks the HAL-induced increase in striatal perforated synapses. Since calcium/calmodulin kinase II (CaMK II) is the major protein constituent of the PSD, the activity of this enzyme was determined within the caudate nucleus following 30d treatment with HAL or saline (SAL). Glutamate immunoreactivity was evaluated within the striatum from another group of treated rats. There was a 75% increase in the activity of CaMK II in the HAL-treated animals compared to the SAL controls. This was associated with a significant decrease in calmodulin binding to CaMK II in the drug treated group. There was a concomitant 50% decrease in the density of immunogold labelling for glutamate within perforated synapses of the HAL-treated group compared to the SAL controls. The increase in CaMK II activity and the decrease in glutamate immunoreactivity would be consistent with the hypothesis that there is an increase in release of neurotransmitter at glutamate synapses, resulting in greater CaMK II activity. Increased CaMK II activity could lead to a conformational change of the PSD and the formation of a perforated PSD. Supported by the Dept. of Veterans Affairs and NIH.

EFFECTS OF CHRONIC LEVODOPA ON DOPAMINE, EXCITATORY AMINO ACID AND GABA RECEPTORS IN BASAL GANGLIA. S.M. Papa*, T.N. Chase and T.M. Engber. Experimental Therapeutics Branch, NINDS, NIH Bethesda, MD 20892.

Chronic levodopa treatment of Parkinson's disease is usually associated with motor response complications whose pathogenesis remains obscure. We examined the effect of chronic levodopa treatment (25 mg/kg i.p., b.i.d.) on binding to dopamine (D1 and D2), excitatory amino acid (NMDA and AMPA) and GABA receptors in the basal ganglia of 6-hydroxydopamine lesioned rats using receptor autoradiography. Binding to both D1 and D2 dopamine receptors in striatum increased due to the lesion (20% and 27%, respectively). Levodopa treatment increased D1 binding by 32% and reduced D2 binding by 9%; D1 binding in substantia nigra pars reticulata (SNr), which was unaffected by the lesion, increased by 19% in response to levodopa treatment. Striatal NMDA binding was not significantly affected by dopamine denervation, but was increased by 39% by levodopa treatment; binding to both NMDA and AMPA receptors in SNr was decreased by the lesion (by 16% and 18%, respectively), but levodopa treatment did not affect either receptor in this region. GABA receptor binding decreased by 17% in globus pallidus (GP) but increased by 14% in subthalamic nucleus (STN) and 28% in SNr following dopamine denervation; chronic levodopa reduced binding to nigral GABA receptors but had no effect in other regions. Levodopa treatment thus reversed the effect of the lesion on GABA binding in SNr but not in GP and STN, nor on NMDA and AMPA receptors in SNr. These findings suggest that chronic levodopa treatment differentially affects striatal output through the direct and indirect pathways.

NEOSTRIATAL LESIONS IN THE CAT PRODUCE APRAXIA AND CHANGES IN PALLIDAL NEURONAL ACTIVITY. J.W. Aldridge*, J.F. Thompson, R.C. Meyer and S. Gilman. Dept. of Neurology, Univ. of Michigan, 1103 E. Huron, Ann Arbor, MI 48104.

We studied the effects of a unilateral excitotoxic lesion of the neostriatum on motor behavior and neuronal activity in the pallidum (globus pallidus and entopeduncular nucleus). Cats were trained to make a forelimb reaching movement in response to a visual cue (GO) and to withhold movement with a different (NO-GO) cue. Animals were prepared for chronic recording of neuronal activity. After control data were collected, large lesions of the caudate nucleus and putamen were made by multiple (15-17) small injections (25-1.25 μ l) of 200 nM quinolinic acid. Short term lesion effects consisted of disturbed locomotion, persistent circling and sensory inattention. These effects peaked within hours of the lesion and subsided in 1 to 3 days. Although there were no noticeable long term deficits in free range behavior, in the context of the GO/NO-GO reaching task, a severe, permanent apraxia of movement appeared. An inability to complete the reaching movement sequence in GO trials was most conspicuous even though initial postural movements were triggered by the cue and the animal could perform the reaching movement in other contexts. Over time, limited recovery occurred, however, inability to withhold movements in NO-GO trials became more noticeable. Pallidal neuronal activity correlated to the motor task persisted in spite of striatal deafferentation. Indeed, the proportion of neurons exhibiting increases of activity rose from 31% to 61%. The proportion of neurons with decreases of activity fell from 13% to 4%. Thus, the basal ganglia appears to have a critical role in performance of skilled movements. Striatal damage produces an apraxia in which the animal has the capabilities to make a movement but fails to do so in specific behavioral contexts. The loss of GABAergic afferents to the pallidum appears to unmask excitatory inputs; possibly these arise from the subthalamic nucleus. Support: NIH grant NS19613 and United Cerebral Palsy Foundation.

CHRONIC EXPOSURE TO NEUROLEPTICS ALTERS EXCITATORY AMINO ACID TRANSMISSION (EAA) IN SPECIFIC REGIONS OF THE RAT BRAIN. A. E. Johnson*, U. Liminga, L. Källström, L. Gunne and F.-A. Wiesel. Department of Psychiatry, Uppsala University, S-75017 Uppsala, Sweden.

The treatment of schizophrenia often involves chronic administration of neuroleptics (NL). While NL act primarily on the dopaminergic system, several other transmitter systems are also affected by these compounds. In the following experiments, we examined the consequences of long-term exposure to fluphenazine decanoate (FLU) on EAA transmission as indicated by changes in [³H]AMPA and [³H]MK-801 binding. Adult female Sprague-Dawley rats received 6 monthly depot injections of FLU (30mg/kg/month i.m.) or vehicle (N=7/group). Animals were killed 60 days after the last injection and their brains were processed for receptor autoradiography. AMPA binding sites were labelled with 10nM [³H]AMPA and nonspecific binding was defined with 100 μ M quisqualate. The noncompetitive binding site of the NMDA receptor was labelled with 10nM [³H]MK-801 and 200 μ M Ketamine HCl was used to define nonspecific binding. Densitometric analysis of [³H]AMPA autoradiograms showed that FLU exposure significantly decreased binding relative to controls in the entopeduncular n. and in the ventrolateral thalamic n. by 20% and 14% respectively. Small but significant decreases in [³H]MK-801 binding were detected in the medial geniculate n. Binding in striatum, substantia nigra and other thalamic nuclei were not affected by FLU treatment. These data suggest that changes in EAA transmission occur after chronic FLU exposure. Changes in some of these areas may be related to the increased display of the extrapyramidal side effects that often are associated with long-term NL exposure. Supported by grant #8318 (F.-A.W.) and #4546 (L.G.) from the Swedish Medical Research Council.

STIMULATION OF LOCAL DOPAMINE D1 RECEPTORS ENHANCES RELEASE OF STRIATAL ACETYLCHOLINE IN 6-HYDROXYDOPAMINE LESIONED RATS. J.L. Anderson*, S. Kuo, T.N. Chase, and T.M. Engber. Experimental Therapeutics Branch, NINDS, NIH, Bethesda, MD 20892.

Systemically administered dopamine D1 receptor agonists stimulate release of striatal acetylcholine (ACh) *in vivo*. It is not clear, however, if D1 receptors which modulate striatal ACh release are intra- or extra-striatal. We, therefore, examined the effects of local perfusion of the D1 agonist SKF 38393 on striatal ACh release using *in vivo* microdialysis in freely moving rats with a unilateral 6-hydroxydopamine lesion of the nigrostriatal pathway. Lesioned rats were implanted with chronic guide cannulae and after at least a three day surgical recovery period, microdialysis probes were inserted through the guide into the dorsal striatum. The reversible AChesterase inhibitor neostigmine (1 μ M) was included in the perfusion solution to improve recovery of ACh. Perfusion for 20 min with 1 and 10 μ M (\pm)SKF 38393 increased extracellular ACh by 37 and 67%, respectively. Perfusion with the less active enantiomer S(-)-SKF 38393 (10 μ M) did not appreciably influence extracellular ACh levels. Co-perfusion of the D1 antagonist R(+)-SCH 23390 (100 μ M) prevented the increase in extracellular ACh induced by (\pm)SKF 38393 (1 μ M). These results suggest that activation of local intra-striatal D1 receptors stimulates release of ACh in the striatum and point to the important role of local D1 receptors in regulating striatal cholinergic transmission.

INCREASED CALBINDIN-D28K IMMUNOREACTIVITY IN STRIATAL SPINY NEURONS IN HUNTINGTON'S DISEASE BRAINS IS ALSO SEEN IN RAT STRIATAL CELLS TREATED WITH QUINOLINIC ACID. Q. Huang, D. Zhou, E. Sapp, P. Ge, H. Aizawa, E. Bird, J.P. Vonsattel and M. DiFiglia. Lab. of Cell. Neurobi., Mass. General Hospital, Boston, MA 02114.

During the process of cell death in Huntington's disease (HD), the dendrites of medium spiny neurons undergo marked regenerative and degenerative changes (Graveland, *et al.*, 1985, *Science*, 227:720-723) which are accompanied by an increase in immunoreactive calbindin-D28K (iCalb) (Ferrante, *et al.*, *J. Neurosci.* (1991) 11:3877-3887), a calcium binding protein enriched in striatal spiny neurons. Study of grade 1-3 HD brains in our laboratory indicates that increased iCalb in dendritic spines can be detected more ubiquitously in higher grades (grades 2 and 3) where neuronal loss is more severe. Since excitotoxic injury has been proposed as a potential cause of cell death in HD, we examined in rat striatal neurons, *in vivo* and *in vitro*, the effects of quinolinic acid (QA) on iCalb. Results showed that 2-3 weeks following intrastratial injection of QA (6-20 ng) in rats (n=3), striatal neurons in the transition zone around the lesion core exhibited a marked increase in iCalb within dendrites and spines. *In situ* hybridization with a ³⁵S-labeled oligonucleotide probe revealed a slight reduction or no change in Calb mRNA levels in neurons within the transition zone. In 12-day-old striatal cultures derived from neonatal rats, a significant increase (p<0.05) compared to untreated controls was seen in iCalb cells and dendrites following exposure for 2-6 hours to 500 μM QA. This effect was blocked by treatment with the NMDA receptor antagonist, AP-5. Results in rat suggest that an excitotoxic mechanism may account for the marked increase in iCalb in dendrites in HD and that the increase may involve a post-translational change in protein turnover and/or transport. (Supported by NIH grants NS09349 to QH and NS16367 to MD).

PREFRONTAL CORTEX INJURY ALTERS AMPHETAMINE-INDUCED *c-fos* EXPRESSION IN STRIATUM. J.M. Vargo and J.F. Marshall. Department of Psychobiology, University of California, Irvine, CA 92717.

An important issue in understanding the effects of neocortical injury is the determination of the impact of that injury on subcortical functions. *C-fos* expression induced by dopamine agonists has been used as one marker of neuronal response within the caudate-putamen (CPU). In this study, Fos immunohistochemistry was used to determine whether a circumscribed cortical lesion would alter neuronal functioning in those regions of the CPU known to receive afferents from the lesioned site. Rats received unilateral aspiration lesions of the medial agranular (AGm) region of the prefrontal cortex. Five days later, 2 hours after 5 mg/kg d-amphetamine (i.p.), they were perfused, the brains were sectioned and reacted with antisera to Fos, and the numbers of Fos immunoreactive nuclei (ir-nuclei) in the CPU were determined through image analysis. The numbers of amphetamine-induced ir-nuclei in the CPU ipsilateral to the cortical lesion were reduced 25-40% compared to those in the contralateral CPU. These reductions were seen in the dorsolateral CPU, the region receiving afferents from AGm. The numbers of ir-nuclei were similar in both hemispheres in the ventral CPU, an area receiving little or no AGm input. In surgical controls, the numbers of ir-nuclei were symmetrical in both dorsal and ventral regions of CPU. These findings suggest that prefrontal injury affects striatal neuronal response to dopamine agonists in a regionally specific manner, i.e., in those regions partially deafferented by the cortical injury.

DEGENERATION OF STRIATONIGRAL NEURONS FOLLOWING VOLKENSIN INJECTION IN THE SUBSTANTIA NIGRA. M.B. Harrison¹, G.F. Wooten^{1*}, R.G. Wiley² and L. Zaborszky¹. ¹Univ. of Virginia, Charlottesville VA 22908; ²DVAMC and Vanderbilt Univ., Nashville TN 37212.

Volkensin is a suicide transport agent which produces retrograde degeneration of neurons projecting to injection sites in the CNS. Previous studies in the striatum using receptor autoradiography, *in situ* hybridization and immunocytochemical techniques suggest that the initial effects of nigral injection of volkensin are selective for striatonigral neurons. Neuronal degeneration has not been directly demonstrated in suicide transport lesions of the CNS. In this study, the silver method of Gallyas *et al.* (1990) was used to evaluate time course and distribution of neuronal degeneration following nigral injection of volkensin. This method produces selective, Golgi-like staining of neurons whose cytoskeletal system is damaged by various pathologic events. 2.5 ng of volkensin was injected stereotactically into the left SN of adult rats perfused at 5 (n=5), 10 (n=4) or 20 (n=5) days postlesion. At 5 days, the ipsilateral striatum contained numerous Golgi-like impregnated medium-sized spiny neurons, located according to the exact topography of the injection site. Many neurons showed pathologic alterations (corkscrew-like or beaded dendrites). Degeneration of axon terminals was also seen in the striatum. At later times, there was marked gliosis in the striatum and progressive loss of impregnated neurons. Other regions of the CNS occasionally showed neuronal degeneration based on variations in lesion size and both anterograde and retrograde connections. This study confirms that nigral injection of volkensin produces an early, consistent and pronounced retrograde effect in the striatum and demonstrates the utility of the Gallyas silver method for direct visualization of degenerating neurons in this and other models of neurodegenerative disease.

THE SYNAPTIC ORGANIZATION OF THE STRIATUM FOLLOWING VOLKENSIN INJECTIONS IN THE SUBSTANTIA NIGRA OR OX7-SAPORIN INJECTIONS IN THE GLOBUS PALLIDUS. R.C. Roberts¹ and R.G. Wiley². Maryland Psychiatric Research Center¹, Baltimore, MD 21228, and DVAMC and Vanderbilt University², Nashville, TN 37212.

Suicide transport agents and retrograde immunotoxins produce degeneration of neurons projecting to an injection site. Injections of the substantia nigra (SN) or globus pallidus (GP) with these agents produce selective and profound lesions of the striatonigral and striatopallidal pathways based on receptor binding and neuropeptide mRNA studies. Also, anatomical analysis indicates a moderate and selective cell loss of projection neurons. In the present study, we sought to determine the events occurring at the electron microscopic (EM) level. Thus, the neostriata of adult rats were examined at the EM level 10 days after unilateral injections of volkensin into the SN (n=4) or of OX7-saporin into the GP (n=4). Blocks were taken from the striata on both the ipsi- and contralateral sides to the injections. EM pictures of striatal neuropil were analyzed for synaptic density and type. Both injections of the SN and GP produced similar degenerative changes in the ipsilateral striata. Synaptic density in the striatum was reduced to 70% of contralateral values in both injection paradigms. Dark degenerating profiles, though very rare in the contralateral striata, were present throughout the neuropil in the ipsilateral striata. Moreover, approximately 12% of the degenerating profiles were forming synapses and were located in both pre- and postsynaptic locations. In spite of the damage to the striata, the proportion of axospinous and axodendritic synapses remained unchanged ipsilateral to the injections. These data show that the damage to the striatal neuropil (30% loss of synaptic density and accompanying degeneration) is greater than the neuronal cell loss (12-14%) observed in a previous study using the same experimental paradigms and suggests a pruning of processes in response to loss of projection neurons. Supported by DRIF, Univ. of MD.

CEREBELLUM V

652.1

INDEPENDENCE OF CEREBELLAR AND OTHER PROJECTIONS TO SUPERIOR COLLICULUS AND MESOPONTINE TEGMENTUM. Grunberg, B.S., Krein, H. and Krauthamer, G.M.

Neurosci. & Cell Biol. UMDNJ-R.W. Johnson Med. Sch., Piscataway, NJ 08854
Neurons of the substantia nigra, pars reticulata (SN-r) terminate in the pedunculo-pontine tegmental nucleus (PPTn) and the deep layers of the superior colliculus (SC-d). The deep cerebellar nuclei (DCN) project to SC-d but a definite projection to PPTn has not been established. Converging projections to PPTn and SC-d from the basal ganglia and the cerebellum may be important for the organization of orienting responses. The extent to which these projections are provided by axon collaterals has important bearings on the nature of information transmission in this system. The present study addresses these two issues. Eight rats received double injections of 0.1-0.5 μl diamidino yellow (DY) and true blue (TB) in PPTn and SC-d. Four additional rats received single dye deposits. Brain sections were examined for retrogradely labeled cells after a 48 hr. survival period. The contralateral DCN were labeled from PPTn and SC-d. Labelling was heaviest ventrally in the intermediate nucleus and much less in the medial and lateral nuclei. As expected, DY and TB labeled many neurons in SN-r neurons and zona incerta (ZI) bilaterally with an ipsilateral concentration. In all 3 structures DY and TB labeled neurons were intermingled but no double labeled cells were seen. In agreement with earlier reports, numerous other structures were also labeled. Thus, PPTn deposits labeled SC-d and the entopeduncular n. ipsilaterally. SC-d deposits labeled PPTn bilaterally with a contralateral preponderance. Although the presence of a small number of SN-r, DCN and ZI projection neurons with axon collaterals to PPTn and SC-d cannot be ruled out because the injection sites were small, the results strongly favor the hypothesis of largely independent cerebellar and nigral projections to PPTn and SC-d. (Supported by NIH DE00203 and Dystonia Med. Res. Found.)

DENDRITES OF PROJECTION NEURONS IN THE RAT PONTINE NUCLEI RESPECT BORDERS OF CORTICAL AFFERENT FIELDS. C. Schwarz* and P. Thier. Neurologische Universitätsklinik, Hoppe-Seyler Str. 3, W-7400 Tübingen, Germany.

The pontine nuclei (PN) are the major relay for information originating in the cortex destined for the cerebellum. As it is known that cortical afferents terminate in the PN in a columnar fashion, we posed the question of whether the dendritic fields of pontine projection neurons are related to that columnar structure. In order to reveal the dendritic morphology of identified projection neurons in the rat PN, we used a combination of retrograde labeling (large injection of fluorogold into the cerebellar cortex) and intracellular fills (lucifer yellow) in slightly fixed slices of pontine brainstem. Cortical afferent fields in the PN were visualized by small injections of the anterograde tracer Dil into the primary visual (A17) or somatosensory (SI) cortex. Projection neurons (n = 85) in the PN shared common characteristic features in the morphology of their dendrites. Proximal dendrites were relatively thick and often branched abruptly into 2 to 4 thin daughter branches. Typically, these thin distal dendrites branched profusely and were irregularly covered with spine-like processes and dendritic appendages. In contrast to the uniform morphology of the dendrites, a striking variability of dendritic field shapes was shown by the PN projection neurons. Dendritic fields displayed circular or elliptic as well as highly asymmetric forms. 43 somata of projection neurons were located within 200 μm of the border defined by cortical afferent fields. Most of the dendritic trees of these neurons respected the border. Proximal dendrites which were oriented towards the border often bent in order to avoid the boundary. In only 6 cases we observed proximal dendrites clearly crossing it. These results suggest that the PN is organized in modules which process different sets of cortical information independently from each other. Supported by DFG SFB 307-A1

MOSSY FIBER BRANCHES OF NEURONS IN THE PONTINE NUCLEUS AND NUCLEUS RETICULARIS TEGMENTI PONTIS PROJECTING TO THE CEREBELLAR NUCLEUS RECONSTRUCTED IN THE CAT AND RAT. I. Sugihara*, H. Wu, T. Futami, J. Na and Y. Shinoda. Dept. of Physiology, Tokyo Medical and Dental Univ. School of Med., 1-5-45 Yushima, Bunkyo-ku, Tokyo 113, Japan.

Previous studies using intracellular recording and HRP-labelling demonstrated a collateral projection to the cerebellar nucleus of the mossy fiber originating from the pontine nucleus (PN) in the cat (Shinoda et al., 1992, *J. Neurophysiol.* 67, 547-60). Similar intracellular labelling was done for axons from the nucleus tegmenti pontis (NTRP) in the cat. Labelled axons projected to the cerebellar cortex as mossy fibers, some of which were found to give rise to collaterals terminating in the cerebellar nucleus. These intracellular labelling showed that virtually all axon terminals found in the cerebellar nucleus were axon collaterals of mossy fibers projecting to the cerebellar cortex. To further examine the possibility that there might be PN and NTRP neurons that project only to the cerebellar nucleus, *Phaseolus vulgaris* leucoagglutinin (PHA-L) was injected ionophoretically into the right PN (n=1) and NTRP (n=2) in the rat. After immunohistochemical visualization of PHA-L, labelled arborized terminal branches were seen in the bilateral dentate (DN) and posterior interpositus nuclei for the NTRP injections and in the bilateral DN for the PN injection. Labelled fibers terminating in the cerebellar nucleus were identified and traced backward from serial sections. So far six NTRP (one contralateral and five ipsilateral to the injection site) and one PN (contralateral) fibers were traced and reconstructed. All of these fibers in the cerebellar nucleus were found to be axon collaterals of mossy fibers terminating in the cerebellar cortex.

RAT CEREBELLAR GRANULE CELL ACTIVITY MONITORED WITH CHRONIC IMPLANTS. M.J. Hartmann* and J.M. Bower. Division of Biology, Caltech, Pasadena, CA 91125.

Experiments on cerebellar cortex in the anesthetized animal are inadequate to determine the nature of cerebellar responses in a natural context. Here we describe the results of experiments in which activity from populations of cerebellar granule cells has been recorded in awake, freely moving rats using a lightweight microdrive developed in our lab. The microdrive allows up to eight electrodes to be independently positioned, and can remain implanted for several months. Granule cell activity was recorded from multiple sites in Crus IIa, a region known to contain representations of the perioral surfaces. Implanted rats were trained to elicit a tactile stimulus which was followed by a water reward. Activity was also recorded during some natural, untrained behaviors, including grooming, chewing, and exploration. Using these procedures we have investigated the temporal and spatial patterns of granule cell activity that immediately follow self-elicited tactile stimulation.

We compare these granule cell responses to those seen during tactile stimulation of the anesthetized rat. Both the characteristic granule cell bursts and double-peaked field potential are present. However, we find significantly more spontaneous activity in the awake animal; this activity is not uniform, but rather has distinct, burst-like increases. During natural behaviors, self stimulation of perioral regions leads to clear and distinct granule cell responses. Short stimulations give short bursts, but longer stimulations (e.g. dragging the lip along a surface) give prolonged bursts of granule cell activity. Supported in part by a grant from Medtronic Corporation and by NIH grant GM07737-14

INTERACTIONS BETWEEN PARALLEL AND ASCENDING FIBER INPUTS IN A PURKINJE CELL MODEL.

E. De Schutter* and J.M. Bower.

Div. of Biology 216-76, Caltech, Pasadena, CA 91125.

We have constructed a detailed compartmental model of a Purkinje cell, based upon anatomical and physiological data. We used this model to explore the response to synchronous synaptic inputs, expected to result from activation of synapses from the ascending branch of the granule cell axon, during continuous background asynchronous inputs from the parallel fibers.

We have previously shown that dendritic P-type Ca^{2+} channels amplify synaptic inputs, so that the somatic response is independent of the dendritic location of synchronous inputs. This response depended strongly on the preceding pattern of asynchronous inputs. The amplitude of somatic EPSPs to identical synchronous stimuli had an average standard deviation of 52% and sometimes there was no response at all. This modulation of EPSP size by parallel fibers was independent of the location of the synchronous inputs. For identical patterns of random inputs, the size of EPSPs generated from different synchronous input locations was correlated by 78 to 98%. The modulation effect was also prolonged, i.e. a particular pattern of asynchronous inputs affected EPSP amplitudes for inputs up to 20 ms afterwards. The responsiveness of the Purkinje cell dendrite to small synchronous stimuli thus seemed to be controlled globally over time periods of at least several ms by the parallel fiber inputs. This responsiveness was determined by the voltage-dependent activation of the P-type Ca^{2+} channel and the Ca^{2+} -activation of Ca^{2+} -activated K^+ channels in the model.

MODULATION OF ASCENDING INPUTS TO CEREBELLAR CORTICAL NEURONS DURING FICTIVE SCRATCHING IN THE CAT. K.V. Baev*, J.R. Bloedel, M.S. Milak, Yu.P. Shimansky. Barrow Neurological Institute, Phoenix, Arizona 85013.

Both field potentials and responses of single neurons of the cerebellar cortex were recorded in cats in response to stimulation of different peripheral nerves during periods of fictive scratching potentiated by the application of bicuculline solution to the cord dorsum at C₁-C₂. The amplitude of field potentials activated from the ipsilateral hindlimb as well as other sites on the body surface diminished significantly or even disappeared during spontaneous scratching or scratching evoked by stimulation of the periauricular area, the natural target for the limb tip during cat scratching. This effect also could be observed even before bicuculline application in the absence of fictive scratching. In addition, oscillatory field potentials in the rhythm of fictive scratching were observed in some regions of the cerebellar cortex. These data together with the data obtained in experiments with lidocaine microinjections in different structures and results of single unit recordings suggest that cerebellar inputs evoked from afferents of the scratching limb are substantially modified by the central pattern generator for scratching and by interactions evoked by stimulating the target of the scratch reflex which are not dependent exclusively on the rhythmic activity. PROLONGED DEPOLARIZATION OF CEREBELLAR PURKINJE CELLS FOLLOWING PERIPHERAL STIMULATION: CONVERGENCE AND TIMING OF INPUT FROM BRAIN STEM AND CEREBRAL CORTEX.

D. Jaeger* and J.M. Bower. Div. of Biology 216-76, California Institute of Technology, Pasadena, CA 91125

Previously we showed that Purkinje cells react to brief excitatory input with prolonged depolarizations and increases in spike rate both *in vitro* (Jaeger and Bower, Soc. Neurosci. Abstr. 17, 552.10) and *in vivo* (Jaeger and Bower, Soc. Neurosci. Abstr. 18, 438.12). In the present study we investigated how this intrinsic property of Purkinje cells contributes to the integration of input from brain stem and cerebral cortex. This question was addressed by *in vivo* intracellular recordings from Purkinje cells of rat crus IIa, which has a known fractured somatotopic representation of perioral areas. Cerebral cortical input to crus IIA following peripheral stimulation was transiently suppressed by lidocaine injection into S1, or permanently by decerebration.

The results show that a burst of brain stem input following peripheral stimulation can trigger prolonged depolarizations in Purkinje cells located in a small region directly overlying the matching granule cell receptive field. This activation is enhanced by a subsequent burst of cortical input present in most trials with intact cortex. Therefore, the prolonged activation following brain stem input leads to an interaction of brain stem input with temporally non-overlapping cortical inputs. Strong IPSP's, likely derived from basket cells, were often seen to transiently interrupt prolonged depolarizations, or to abolish them completely. We suspect that this modulation of prolonged activation by inhibitory interneurons plays an important functional role in creating a pattern of interaction between input from brain stem and cerebral cortex.

PATTERNS OF CEREBELLAR PURKINJE CELL ACTIVATION TO MULTIMODAL SENSORY INPUTS. L.J. Larson-Prior*. Penn State College of Medicine, M.S. Hershey Medical Center, Hershey PA 17033.

The cerebellar cortex is known to be a site of sensory-to-motor signal transduction. Incoming sensory signals from all modalities are carried by mossy fiber inputs to the cortex while the output neurons, the Purkinje cells, show discharge patterns which are correlated to movement features. Thus, the cerebellar Purkinje cell has been assumed to be the final site of integration and transformation of incoming sensory signals. In order to perform this task, Purkinje cells must receive multimodal inputs. To examine the ability of incoming sensory information to access specific subsets of Purkinje cells, the activity dependent marker, sulforhodamine 101 (Keifer et al., *J. Neurosci.* 12:3187,1992) was applied to an *in vitro* turtle brainstem-cerebellar preparation during stimulation of either the spinocerebellar tract, the vestibular nuclear complex, or the anterior division of the vestibular nerve. In this preparation, the inferior olivary nucleus was removed in order to prevent activation of the climbing fiber system.

Stimulation of each of these sites resulted in a circumscribed pattern of Purkinje cell activation. No Purkinje cells in the caudal 25% of the cerebellar cortex were activated by stimulation of any of these sensory systems. In response to stimulation of the vestibular system, by far the greatest activity was observed in the most rostral 14% of the cerebellum. Spinocerebellar mossy fiber inputs activated two populations of Purkinje cells: one overlapping those in the rostral cortex which were activated with vestibular inputs, and the second in the intermediate zone of the middle 20% of the cortex. Thus, Purkinje cells show a pattern of activation that is dependent upon incoming sensory signals. Supported by NS 30759.

SPECIFIC RESPONSES OF RAT CEREBELLAR CORTEX TO MOVING INPUT: DEPENDENCE ON DISTANCE COVERED BY THE MOVEMENT. D. Heck and V. Braitenberg, * Max-Planck-Institute for Biological Cybernetics, 72076 Tuebingen, FRG.

It has been suggested that the anatomical arrangement of parallel fibers and Purkinje cells enables the cerebellar cortex to act as a movement detector (1). This idea received strong support from experimental data (2). In those experiments a multi-electrode array (consisting of 11 tungsten stimulating electrodes regularly placed at distances of about 140 μm) was inserted into the granular layer of horizontally cut slices of rat cerebellar cortex. The mass parallel fiber activity was recorded from the molecular layer. A "moving" stimulus was produced by switching the current in an orderly fashion from one electrode to the next (e.g. 1,2,3,...,11). We found that amplitudes of parallel fiber responses depend on direction and velocity of the "movement" in the way predicted. The largest amplitudes were found when the stimuli "moved" towards the recording site with velocities being in the range of the parallel fiber conductance velocity.

Using the same experimental setup as described above we investigated the dependence of the response amplitudes on the distance covered by the "movement" (number of neighbouring electrodes used to produce a "moving" stimulus). Preliminary results show that the amplitudes become larger when the movement distance is increased, e.g. responses to stimulation sequence 4,3,2,1 were larger than those to sequence 3,2,1. Surprisingly, saturation often occurred already when the distances covered by the "movement" were even shorter than 0.5 mm.

AUTOMATED SEGMENTATION OF CEREBELLAR PURKINJE CELL DENDRITES. FW Prior, RM Bushey, RJ Milner* and LJ Larson-Prior. Penn State College of Med, MS Hershey Med Center, Hershey, PA 17033 USA

Computational models of single cell response properties require analysis of the diameter distribution and branch patterns of dendritic arbors. As a precursor to automated compartmentalization, an algorithm has been developed that extracts this information from high resolution confocal micrograms.

A Zeiss Laser Scan Confocal Microscope was used to acquire 512 x 512 pixel images from 50 m sections of turtle cerebellar Purkinje cells which had been intracellularly filled with Biocytin (Sigma). Images were transferred to a Sun workstation and processed to accentuate the boundary between the dendrite and the extracellular matrix. The coordinates of the origin of the dendritic tree were determined visually and input as the starting point for the segmentation algorithm. The center of the primary dendrite was determined by scanning the indicated image row. An iterative search technique was used to determine the minimum diameter of the dendrite at the center point. This diameter (D) was stored and the center of action moved a distance ΔL along a line perpendicular to the diameter at the center point. The algorithm was repeated at each new center of action until the cell boundary was encountered. A threshold was applied to the resulting function D(L) to locate spikes of amplitude $\geq \epsilon$ and the coordinates of each spike used as a new origin. Each potential branch was explored by recursive application of the algorithm. The parameters ΔL , ϵ , and δ (the cell boundary search limit) were determined empirically. Output data was stored in a linked list data structure to facilitate future processing. Supported by NS30759.

MUSCARINIC AGONISTS MODULATE PURKINJE CELL RESPONSES TO GLUTAMATE AND GABA. Q. Pompeiano*, P. Andre, and S.R. White. Dept. of Physiol., Univ. of Pisa, Pisa, Italy and Dept. of VCAPP, Washington State Univ., Pullman, WA, USA 99164.

The cerebellar cortex contains diffusely distributed cholinergic fibers and both muscarinic and nicotinic receptors. The present study used microiontophoretic techniques to examine the effects of the muscarinic agonist bethanechol (Beth) on Purkinje cell (PC) excitability in urethane-anesthetized Sprague-Dawley rats. The effects of Beth (10-60 nA for 300 sec) on the spontaneous firing rates of PC were compared to effects on responses of PC to the excitatory transmitter glutamate and the inhibitory transmitter GABA. Beth increased the glutamate responses of 22/33 PC regardless of whether it increased (4 cells), decreased (3 cells) failed to alter (10 cells) or had a bimodal effect (5 cells) on the basal firing rate of the cells. In other experiments, Beth increased the GABA-induced inhibition of 22/25 PC. The facilitatory effects of Beth on the PC responses to glutamate or GABA lasted 15-30 minutes after the offset of the muscarinic agonist and were prevented by simultaneous application of the selective antagonist scopolamine. Thus the cholinergic muscarinic system appears to exert a prominent modulatory effect on PC activity by increasing responses to both excitatory and inhibitory neurotransmitters.

DISTRIBUTION OF VARICOSITIES ALONG CEREBELLAR PARALLEL FIBERS IN THE CAT POSTERIOR VERMIS. C. Huang* and R. Huang. Univ. Missouri-Kansas City, Kansas City, MO 64110.

A point-to-point but fractured somatotopic representation has been found in the granule cell layer of the posterior cerebellum in the rat and the cat. However, the functional consequence of this precise somatotopy is uncertain considering the orthogonal relationship between the parallel fibers, which are the axons of the granule cells, and the Purkinje cells, which are the output neurons of the cerebellar cortex. Could Purkinje cells retain response specificity when each Purkinje cell is innervated by 80,000 parallel fibers? In this preliminary morphometric analysis, we made the assumption that varicosities along the parallel fibers are the primary sites of parallel-fiber-to-Purkinje-cell synapses. We examined the distribution of varicosities along 300 HRP-labeled parallel fibers in a restricted region (500X500 μm) in the posterior vermis of the cat with light microscopy. (1) Varicosities were classified as either large or small, (2) the number of small varicosities in a given axon appeared to be Gaussian, and (3) there was a bimodal pattern in the number of the large varicosities and the total number of varicosities among parallel fibers. Hence, different parallel fibers may deliver information differently along their length, thereby generating zones of Purkinje cells with unique response characteristics. (supported by UMKC FRG)

INVOLVEMENT OF INSULIN-LIKE GROWTH FACTOR-I (IGF-I) IN CEREBELLAR LONG-TERM DEPRESSION OF GLUTAMATE INDUCED GABA RELEASE. M.A. Castro-Alamancos and I. Torres-Aleman (SPON: European Brain and Behaviour Society). Cajal Institute, CSIC. Avda. Dr. Arce 37, 28002-Madrid, Spain.

The Purkinje cell is a target for the trophic effects of IGF-I during development. Thus, we became interested in the possibility that IGF-I could act as a neuromodulator in the adult cerebellar cortex. By using microdialysis techniques we first determined that IGF-I is released in the cerebellar cortex during electrical stimulation of the inferior olive. Using a microdialysis probe implanted into the cerebellar cortex and deep cerebellar nuclei we further determined that infusion of glutamate induces the release of gamma-aminobutyric acid (GABA). Moreover, the conjoint infusion of glutamate with IGF-I induced a depression in the release of GABA, and to subsequent pulses of glutamate alone, while the separate application of glutamate and IGF-I did not. Furthermore, the release of GABA by KCl was not affected by IGF-I, nor was glutamate-induced GABA release affected by another cerebellar trophic factor (bFGF). Furthermore, conjoint electrical stimulation of the inferior olive and infusion of glutamate in cerebellum produced a depression in the subsequent release of GABA by glutamate pulses in a manner that resembled the conjoint application of IGF-I and glutamate. Recent results indicate that this IGF-I induced depression of GABA release is not mediated through the activation of the metabotropic receptor by glutamate. In conclusion, these findings indicate that IGF-I may be involved in the long-term depression of the parallel-fiber-Purkinje cell synapse efficacy which has been described electrophysiologically in the cerebellar cortex, and which is believed to mediate motor learning processes.

EFFECTS OF SUPERSMALL DOSES OF ETHANOL ON THE ACTIVITY OF CEREBELLAR PURKINJE CELLS IN RATS. R.A. Grigorian* G. Zernova, A.D. Khorkov. Sechenov Institute, 194223, St. Petersburg, Russia.

In the experiments on adult Wistar rats the effects of intravenous injections (for 1 min) 0.1, 0.25, 1.0 g/kg of ethanol on Purkinje cell (PC) discharges were studied. The ethanol level in blood was determined using gas chromatography method. The next statistical parameters were studied: mean interspike interval (ISI) of PC discharge, standard deviation (SD), current frequency of PC discharges. The mean ISI of spontaneously active PC fluctuated from 9.77+0.1 up to 14.+9.07 ms. However, for 70% of PC it was in range 20-45 ms. This means that a mean discharge frequency of PC was within 50-20 imp/s respectively. After injection of 0.1-0.5 g/kg ethanol the frequency of PC discharges did not change. At the same time, regularity of PC discharge sharply increased and SD was 1.5-2.0 times lower than in spontaneously active PC before the ethanol injection. It should be pointed out that unlike the moderate doses (over 1.0g/kg) the doses of ethanol lower than 1.0g/kg usually do not increase the rate of PC activity. In conclusion, the main effect of supersmall doses of ethanol is an increase of the excess (mode) of PC discharges, but not its frequency.

IPSPs IN RAT DEEP CEREBELLAR NUCLEI EXHIBIT A POST-TETANIC LONG-TERM DEPRESSION. W. Morishita* and B. R. Sastry. Neuroscience Research Laboratory, Dept. of Pharmacology & Therapeutics, The University of British Columbia, Vancouver, Canada, V6T 1Z3.

Repetitive activation of certain synapses in the CNS produces long-term changes in synaptic efficacy. In the cerebellar cortex this is characterized by a long-term depression of excitatory synaptic transmission. We report that synaptic plasticity can also occur following repetitive activation of the cerebellar Purkinje axon-deep nuclear cell synapses. Intracellular recordings were obtained from the deep nuclei in cerebellar slices. Stimulation of the white matter produced IPSPs that reversed around a membrane potential of -75 mV and were blocked by 50 μ M picrotoxinin. Paired-pulse depression of the IPSPs was observed over inter-pulse intervals of 100-400 ms with maximal suppression occurring around 100 ms. When the stimulation frequency was changed from 0.033 to 0.2 or 5 Hz the amplitude of the IPSP was decreased. Recovery from the depression occurred 3-5 min after the stimulation frequency was returned to 0.033 Hz (IPSP 1 min after a tetanus [5 Hz, 1 s] as a % of control: 58.6 \pm 10.3%; n=5 neurons). When the afferents were tetanized at 100 Hz for 1 s, a post-tetanic long-term depression (LTD) of the IPSPs occurred (IPSP 30 min post-tetanus as a % of control: 53.7 \pm 3.4%; n=7 neurons). No changes in input resistance, resting membrane potential or the reversal potential for the IPSP were observed during LTD.

These results suggest that deep nuclear IPSPs are suppressed by repeated activation. In addition, LTD can be induced when the IPSPs are tetanically stimulated. Supported by a grant from the NIH (NS 30959) to B. R. S. and a Ciba-Geigy/MRC studentship to W. M.

HIGH-RESOLUTION IMAGING OF ELECTRICAL SIGNAL SPREAD WITHIN THE GRANULE CELL LAYER OF THIN RAT CEREBELLAR SLICES USING A VOLTAGE-SENSITIVE DYE

I. Vranesic*, T. Iijima, M. Ichikawa, G. Matsumoto and T. Knöpfel*. Electrotechnical Laboratory, 1-1-4 Umezono, Tsukuba, Ibaraki 305, Japan and *Pharmaceuticals Division, R&D, ciba, CH-4002 Basel, Switzerland

Optical recordings using voltage-sensitive dyes provide a tool for monitoring the propagation of electrical signals along the membrane of single cells as well as within neuronal circuits. We used a low-noise imaging system (frame rate 1.7 kHz, 64 x 64 pixels) to record absorption signals in thin slices of rat cerebellum stained with the voltage sensitive dye RH-155.

Brief electrical stimuli applied to the granule cell layer of slices cut in parasagittal planes gave rise to a decrease in light transmission, corresponding to membrane depolarization. From the site of stimulation these optical signals propagated within the granule cell layer over considerable portions of single folia. The signals were abolished by tetrodotoxin and the spread of excitation in the granule cell layer was abolished in nominally Ca-free medium.

These observations indicate that there are calcium-dependent mechanisms that can mediate a spread of excitation in the granule cell layer over appreciable distances.

VINCRIStINE-INDUCED DEGENERATION OF PURKINJE CELLS FOLLOWING SYSTEMIC ADMINISTRATION. G.R. Stewart*, S.M. Little, J.R. Bringas and D.G. Fairchild. Dept. of Neurosciences, Inst. of Pharmacology, Syntex Discovery Research, Palo Alto, CA 94303, USA.

The clinical use of vincristine sulfate (VCR) in the treatment of cancer is often associated with the presence of a mixed sensory and motor neuropathy that is usually attributed to peripheral nerve damage or dysfunction. However, we have observed that intraperitoneal (ip) administration of VCR causes a selective degeneration of Purkinje cells within the cerebellum of mice.

Adult male CD-1 mice were treated ip with VCR (Oncovin®, Lilly, Indianapolis, IN) at doses ranging from 0.0 (Vehicle) to 2.0mg/kg, 2x/wk for 4 weeks. VCR-treated animals displayed abnormal gait, impaired sensorimotor function and decreased locomotor activity. After animals were sacrificed and transcardially perfused with formalin fixative, nervous tissues were processed for paraffin histology. In sections through the cerebellum there was a dose-dependent loss of Purkinje cells ranging from 5 to 80% relative to vehicle-treated animals. Cell loss was primarily restricted to the medial aspects of the anterior lobe. Throughout this region were numerous hyperchromatic cells at the base of the granule cell layer that appeared to be Purkinje cells undergoing degeneration. In contrast, granule cell numbers were not significantly reduced by VCR treatment, nor was there evidence of degeneration elsewhere in the brain. Neuropathy, characterized by vacuolization of axons and/or myelin, was present to only a minimal degree in spinal cord and peripheral nerves (sciatic and brachial plexus).

These studies indicate that VCR can directly cause CNS damage. The selective action of VCR on Purkinje cells in the cerebellum and the clinical significance of this observation remains to be determined.

RETROGRADE TRANSNEURONAL TRANSPORT OF HSV-1 FROM PRIMARY MOTOR CORTEX TO CEREBELLAR DEEP NUCLEI AND PURKINJE CELLS. J.E. Hoover* and P.L. Strick*. Dept. of Biology, Millersville Univ., Millersville, PA 17551¹; Research Service, VAMC and Depts. of Neurosurgery & Physiology, SUNY-HSC, Syracuse, NY 13210².

We injected the McIntyre-B strain of herpes simplex virus type 1 (HSV-1) into the arm area of the primary motor cortex in cæbus monkeys (n=7). Animals were allowed to survive for 2-7 days post-inoculation. In animals that survived less than 3 days, virus transport was limited to first order neurons in regions known to project to the cortical injection sites. For example, labeled cells were observed in VPLo of the ventrolateral thalamus. Second order neurons, labeled by retrograde transneuronal transport, were only observed in animals that survived longer than 4 days. For example, labeled neurons were found in a localized region of the dentate nucleus known to project to VPLo and to be active during arm movements. In animals that survived 7 days, we observed an additional stage of transneuronal transport to third order neurons in cerebellar cortex. Patches of labeled Purkinje cells were found at sites in paravermal and lateral cerebellar cortex known to innervate the dentate nucleus. These observations provide further evidence for retrograde transsynaptic transport of the McIntyre-B strain of HSV-1 through projection-specific neural circuits. Furthermore, our results indicate that careful adjustment of survival time can be used to reveal different stages in cerebello-thalamocortical circuits.

NITRIC OXIDE SYNTHASE IS INDUCED IN PURKINJE CELLS AND NEURONS OF THE INFERIOR OLIVE, NUCLEUS X AND EXTERNAL CUNEATE NUCLEUS FOLLOWING CEREBELLAR DAMAGE. D.W. Saxon* and A.J. Beitz. Department of Veterinary Pathobiology, Univ. of Minnesota, St. Paul, MN 55108.

Nitric oxide synthase (NOS) has two distinct isoforms based on molecular and immunocytochemical techniques. The constitutive isoform is Ca²⁺ dependent, while the induced isoform is Ca²⁺ independent. NADPH-diaphorase histochemistry identifies both NOS isoforms while antibodies to constitutive neuronal NOS are specific and do not recognize the induced isoform found in non-neuronal cell types. Glass micropipettes were used to make unilateral stereotaxic stab wounds in the cerebellum of 14 rats. A further 10 rats received stereotaxic injections (0.05-1.0 μ l) of Fluoro-gold. Following treatments the rats were sacrificed at various time intervals ranging from 6 hours to 21 days. Variable numbers of NOS positive Purkinje cells were initially found in the immediate vicinity of the pipette wound between 72-96 hours. NOS positive Purkinje cells were found to persist in the cerebellum at 21 days and these cells were morphologically similar to those identified at shorter times. Cerebellar afferent cell groups including the contralateral inferior olive and ipsilateral external cuneate nucleus and nucleus X also showed marked increases in the number of NOS positive neurons. In cases where Fluoro-gold was injected some of the NOS neurons in the brainstem nuclei mentioned above contained the retrograde tracer. Immunocytochemical identification of neuronal NOS in adjacent sections to those processed for NADPH-diaphorase revealed Purkinje cells positive for neuronal NOS at the site of damage. In light of this evidence two possibilities exist: 1) Purkinje cells contain an inducible form of neuronal NOS. or 2) neuronal NOS exists in undetectable amounts under normal conditions but can be increased in response to injury. (NIH DA06687 DE06682 and DC01086).

NEUROANATOMICAL EVIDENCE FOR GLYCINE AS THE TRANSMITTER OF SACCADIC OMNIPAUSE NEURONS

A.K.E. Horn*, J.A. Büttner-Ennever, P. Wahle, Inst. Neuropathology, LMU Munich, 8 Munich 2; Dept. Zoology & Neurobiology, Ruhr-University Bochum, 4630 Bochum; F.R.G.

Omnipause (OPNs) are considered to participate in the gating of saccadic eye movements. They have been identified cytologically as the nucleus raphe interpositus (rip) in the monkey, and shown to project to the burst neuron area in the paramedian pontine reticular formation (PPRF) and rostral interstitial nucleus of the medial longitudinal fascicle (riMLF), where they are thought to provide a tonic inhibition of the burst neurons. A saccade would be induced by the inhibition of the OPNs, thereby disinhibiting burst neurons. In the present study we used several different neuroanatomical methods to investigate the transmitters of OPNs in the monkey. We found:

1. The somata of OPNs are glycine-immunoreactive, but they are devoid of GABA- and 5-HT-immunostaining.
2. In situ-hybridisation revealed no detectable levels of the GABA-synthesizing enzyme glutamate decarboxylase (GAD) mRNA within OPNs.
3. OPNs were selectively labelled after ³H-glycine injection into the riMLF.
4. The somata and dendrites of putative burst neurons in the riMLF were contacted by numerous glycine-immunoreactive terminal-like puncta.
5. OPN somata and dendrites receive a strong input from glycine- and GABA-positive terminals, whereas glutamate-immunostained terminals are mainly confined to the dendrites. Very few 5-HT- and catecholamine-positive puncta contacted OPNs. Our results provide strong evidence for the fact that OPNs use glycine as an inhibitory transmitter. The results contrast with iontophoretic studies where glycine and GABA had little or no effect on OPN firing rates.

HETEROGENEOUS CHEMICAL PHENOTYPES IN THE INTERSTITIAL NUCLEUS OF THE MEDIAL LONGITUDINAL FASCICULUS OF THE RAT. X.J. Hu*, W.J. Crossland, and J.A. Rafols*, Dept. Anatomy & Cell Biology, Wayne State Univ. Schl. Med., Detroit, MI 48201.

The putative transmitters of the morphologically diverse types of neurons found in the rat interstitial nucleus of Cajal (IC) and the adjacent nucleus of the medial longitudinal fasciculus (IMLFG) are unknown. We used polyclonal antibodies and postembedding immunocytochemical methods at light microscopic levels to detect the presence of GABA-, glutamate (GLU)-, and glycine (GLY)-like immunoreactivity in these nuclei. In addition, a monoclonal antibody for choline acetyltransferase (ChAT) was used on midbrain cross-sections to localize cholinergic neurons. Adjacent 1-2 μ m, serial sections were stained for GLU or GABA to show colocalization of amino acids, and with toluidine blue for normal morphology.

Medium and small cell bodies show GLU-like immunoreactivity (GLU+) in both IC and IMLFG, although IC contains greater numbers of reactive neurons. A few, large (37-40 μ m) GLU+ cell bodies are also found in IMLFG. Most GABA+ cells in both nuclei are medium to small, the latter having similar features of local circuit neurons. Colocalization of both amino acids appears to be restricted to a few medium to small cells in IC. GLY immunostaining failed to show the presence of GLY+ cell bodies in these nuclei although GLY+ myelinated axons and terminals were found in relation to nonlabeled somata. ChAT+ staining was restricted to dendrites of oculomotor neurons, a few fine caliber axons and terminals, and an occasional cell body in IC.

The findings reveal a variety of chemical phenotypes, some of which can be correlated with the morphological types in these nuclei. (Supported in part by NIH grant GM08167 to J.A.R.)

INTERLAMINAR CONNECTIONS IN THE SUPERIOR COLLICULUS OF THE TREE SHREW. P. Lee and W. C. Hall*, Department of Neurobiology, Duke University, Durham, N. C. 27710

In the tree shrew, the superficial grey layer gives rise to a prominent pathway that terminates in the zone of optic fibers, stratum opticum. We have attempted to identify the cells of origin for this pathway by tracing axons from single cells in the superficial grey layer that were labelled by small extracellular injections of biocytin in living brain slices. Cells located in the deep half of the superficial grey layer have axons that contribute a prominent terminal arbor in the subjacent zone of stratum opticum. These cells have narrow, vertically oriented dendritic fields that ascend through the upper half of the superficial grey layer; they resemble, in soma size and location, the cells that project to the pulvinar in the dorsal thalamus. They may also be the source of an intracollicular pathway to the deep, premotor layers, either by terminating on stratum opticum cells that project in turn to the deeper layers or by contacting the apical dendrites of deep layer cells that ascend to the stratum opticum. SUPRAOCULOMOTOR AREA AND OCULOMOTOR INTERNUCLEAR NEURONS IN THE CAT. Paul J. May*, Departments of Anatomy and Neurology, University of Mississippi Medical Center, Jackson, MS 39216.

The supraoculomotor area has been implicated as the anatomical correlate of the near response region. However, one of its inputs is a conjugate eye movement center, the superior colliculus. A combined light and EM study of the tectal input to this region has been initiated in the cat. Fine, biocytin labelled, tectal axons enter the ipsilateral supraoculomotor area and extend parallel to the oculomotor nucleus border. Small enlargements are scattered along the axon. In addition, numerous terminal puncta are found on single and branched, very thin collaterals that emerge from the main axon at right angles. Some axons extend across the midline and similar, but fewer, labelled axons are observed contralaterally. Ultrastructurally, the biocytin labelled profiles are small (long axis = 0.7-1.2 μ m), contain spherical vesicles, and make asymmetric synaptic contacts. They terminate along the entire somatodendritic membrane with a distal preference. Preliminary experiments, in which the supraoculomotor area neurons projecting to the abducens and medial pons were retrogradely labelled with WGA-HRP, suggest these cells are not the target of the tectal input. However, these supraoculomotor area cells do receive reciprocal input from the pons; for WGA-HRP labelled terminals containing pleomorphic vesicles contact their somata. These neurons displayed few axosomatic contacts, their distal dendrites were primarily contacted by small profiles with numerous spherical vesicles that made asymmetric synapses, and their proximal dendrites receive multiple short contacts with postjunctional bodies from large, dark-matrix terminals. Cells with this ultrastructure are present bilaterally in the caudal supraoculomotor area with a distal preference. Within the oculomotor nucleus, however, the labelled neurons are concentrated within the contralateral medial rectus subdivision. This result suggests that the oculomotor internuclear neurons and supraoculomotor area neurons may be two distinct populations. Supported by NEI grant EY07166.

MORPHOLOGICALLY DISTINCT CELL TYPES IN THE RAT INTERSTITIAL NUCLEUS OF CAJAL PROJECT TO NUCLEI OF THE OCULOMOTOR SYSTEM. D. Liu, X.-X. Hu, J. A. Rafols*, and W. J. Crossland, Dept. Anatomy & Cell Biology, Wayne State Univ. Schl. Med., Detroit, MI 48201

The interstitial nucleus of Cajal (IC) is an important center for the control of eye and head movements, however the functional circuitry underlying this control is unknown. We used the Golgi method to determine the morphological types of neurons present in the rat IC and related them to previously characterized neuron types in the primate IC. We also used Dil labeling to identify which morphological types projected to the oculomotor system.

Based on Golgi-stained characteristics of the cell body and dendrites 6 morphological types (I-VI) of neurons were distinguished in the IC and the adjacent midbrain tegmentum (IMLF). Types I-IV in the monkey have been described previously by us (Soc. Neurosci. Abstr. 17: 859). Type V is a large multipolar neuron with long, tapering dendrites found in the lateral IMLF. Type VI has a large multipolar body issuing short, stout, rapidly tapering dendrites. Placements of Dil in the oculomotor and trochlear nuclei revealed that Type Ia, Ib, II, and III project to these centers.

Our results show that the rat IC contains similar morphological types of neurons to those found in the primate, plus at least 2 additional types. Furthermore, at least 3 of these types project to the oculomotor system and are presumed to function in the control of vertical eye movements. The combination of Golgi and Dil techniques will extend data obtained from other techniques in order to build functional circuit models of eye and head movement control.

CONTRACTILE PROPERTIES OF ORBITAL AND GLOBAL LAYERS OF EXTRAOCULAR MUSCLE. J.J. Jacoby* and K. Ko. Dept. of Ophthalmology, NYU Med. Ctr., NY, NY 10016

Extraocular muscles (EOM) are composed of two major layers, the orbital and global, with fiber populations that differ structurally and with respect to patterns of myosin heavy chain expression. The isometric contractile properties of each layer were investigated *in vitro*. The inferior rectus was dissected from euthanized adult S-D rats and either the global or orbital layer was isolated.

Electrically stimulated orbital strips produced twitches with slower rise and 1/2 relaxation times than global strips (figure), and slower tetanic rise times. Fatigability was similar. 0-Ca²⁺ saline reduced baseline tension in both layers, and dramatically so in orbital strips (1.5 x twitch amplitude).

In high K⁺, tonic contractures were generated in orbital strips, although the orbital MIF population expresses fast myosin along part of its length. Supp. by EY06232, Eye Surgery Fund and an unrestricted grant from RPB.

DIFFERENTIAL TOPOGRAPHY OF THALAMIC PROJECTIONS TO PRIMATE FEF. J.Yin*, M.Schlag-Rey and J.Schlag. Dept. of Anatomy & Cell Biology, UCLA, Los Angeles, Ca. 90024.

The projections of the arcuate frontal eye field (FEF) to the superior colliculus (SC) have been shown to be topographically organized according to saccade amplitude (Stanton et al., 1988). The intermediate layer of SC projects to the central thalamic region relaying saccade related signals to the FEF. Is there evidence for a topographical organization of the thalamic projections to the FEF regions of large (IFEf) and small (sFEF) eye movements?

WGA-HRP was injected in the sFEF region, electrophysiologically defined, in a trained monkey. The resulting thalamic labeling was compared to that previously obtained by similar methods (Shook et al. '91) after injecting WGA-HRP in the IFEF. The boundaries of nuclei were determined by Nissl staining and AChE histochemistry.

In the 2 cases, the injections yielded dense anterograde and retrograde label in lateral parts of n.medialis dorsalis (MD) and in medial aspects of the ventral anterior complex (VA), bordering n. paracentralis (Pcn). Patches of IFEF and sFEF labeled cells appeared to overlap at some thalamic levels. But, whereas the densest label produced by the IFEF injection was found dorsally, in MDpc, the densest label yielded by the sFEF injection was found more ventrally located, in MDmf.

The dorso-ventral trend in the organization of MD afferents to IFEF and sFEF fits with that of efferents (Stanton et al., 88) and with the observation that electrically evoked saccades progressively decrease in amplitude at successively deeper levels in penetrations along MD/Pc border. TOPOGRAPHY OF SUPERIOR TEMPORAL SULCUS (STS) AFFERENTS TO FRONTAL EYE FIELD (FEF) IN MACAQUE J.D. Schall*, D.J. King & A. Morel. Dept. Psychology, Vanderbilt University, Nashville, TN 37240

FEF maps saccade amplitude with shorter saccades ventrolateral, and longer saccades, dorsomedial. We investigated the topographic organization of the afferents to FEF from STS in macaque monkeys. Distinct retrograde tracers (FB, DY, FG, WGA-HRP, NY) were injected into medial and lateral FEF; the distributions of labeled cells in the STS were analyzed in two-dimensional reconstructions. The density of afferents to FEF decreased from caudal to rostral STS. Afferents from MT were topographic; the MT representation of the central visual field projected to lateral FEF and the peripheral field representation projected more medially in FEF. Whereas MSTl projected throughout FEF, the densely myelinated MSTd projected predominately to the long saccade representation in medial FEF. Retrogradely labeled neurons in FST, PGa and IPa were commonly intermingled from both medial and lateral FEF injections. Cells in TEO and TEa on the ventral bank were labeled by the lateral FEF injections. Neurons in TPO and TAA on the dorsal bank were labeled by medial FEF injections. Thus, the region of FEF responsible for generating short saccades and pursuit eye movements receives visual motion information representing the central visual, and the longer saccade representation receives motion information from peripheral visual field. Moreover, areas with distinct functional properties project differentially to medial and lateral FEF. Whereas TEO and TEa, which subserve object recognition, project only to the shorter saccade representation in FEF, MSTd which responds to optic flow of the whole field projects to the longer saccade representation in FEF. These findings suggest that qualitatively different visual information is utilized in guiding saccades of different amplitudes. (Supported by R01-EY08890 and the Alfred P. Sloan Foundation.)

OCULOMOTOR SYSTEM: VERTICAL MOVEMENTS, INTEGRATION, TORSION

654.1

RESPECTIVE CONTRIBUTIONS OF THE PREPOSITUS HYPOGLOSSI AND MEDIAL VESTIBULAR NUCLEI TO THE OCULOMOTOR NEURAL INTEGRATOR. P. Mettens*, E. Godaux, G. Cheron and H.L. Galiana. Lab. of Neurophysiology, Univ. of Mons, 7000 Mons, Belgium.

For horizontal eye movements, previous observations led to the hypothesis that the legendary integrator necessary for correct gaze holding and adequate vestibulo-ocular reflex (VOR) was located in the region of the complex formed by the nucleus prepositus hypoglossi (NPH) and the medial vestibular nucleus (MVN). In the present study we studied whether the oculomotor neural integrator was affected by an injection of 0.1-0.2 µl of muscimol into three regions of the brain stem of the alert cat: (1) the NPH, (2) the rostral part of the MVN and (3) the central part of the MVN.

The search coil technique was used to record (1) spontaneous eye movements and (2) the VOR induced by a constant-velocity rotation (50 deg/sec for 40 sec). Recording of the antidromic field potentials evoked by stimulations of the abducens nerve helped to locate the aimed sites.

A leakiness of the neural integrator was assessed by the time constant of an eventual postsaccadic drift and by the time constant given by the transient analysis of the VOR.

Muscimol caused a failure of the oculomotor neural integrator when it was injected into the NPH or into the adjacent central MVN, but not when it was injected into the rostral MVN. Furthermore, a vestibular imbalance at the expense of the injected side also appeared: it was severe after injection into the rostral MVN or the central MVN, but moderate after injection into the NPH.

We conclude that both the NPH and the adjacent central MVN are key sites of the horizontal neural integrator, whereas the rostral MVN is not.

654.2

AN ASYMMETRY ADAPTATION MECHANISM IN THE NEURAL INTEGRATOR OF THE OCULOMOTOR SYSTEM. T. Ogawa* and T. Kasai. Communications Res. Lab., Koganei-shi, Tokyo 184, Japan.

It is thought that some kinds of eye commands are generated as an eye velocity signal and that these commands are integrated mathematically by the neural integrator (NI) to supply an eye position signal to the eye-muscle plant. It is also thought that the horizontal NI consists of the nucleus prepositus hypoglossi and the medial vestibular nucleus, so we have modeled the structure of NI with a neural network based on the anatomical and physiological data of those nucleus. As input signals to NI, we consider an eye velocity signal from the burst neurons and a resting rate signal from the canal. This NI model can integrate only the eye velocity signal without integrating the resting rate signal. To give the proper time constant to NI, we proposed a simple learning rule. The learning is done during saccadic eye movements. The synaptic weights are divided into two types, belonging to the right or the left half-NI, and the synaptic weights of each half-NI are modified uniformly, one being modified more and the other being modified less, according to the postsaccadic retinal slip signal. This learning rule directly uses the retinal slip signal in modifying the synaptic weights, and requires no complex calculations. If saccadic targets are presented at random in the oculomotor range, this learning rule tends to keep the resting eye position at the center of the oculomotor range. We theoretically analyze the proposed NI model and the learning rule and present simulation results. Our adaptation mechanism model can give the NI a sufficiently large time constant and the proper resting eye position using only the retinal slip signal, without complex calculations.

VERTICAL AND HORIZONTAL COMPONENTS OF VERTICAL PHORIA ADAPTATION COMBINE LINEARLY. J.S. Maxwell* and C.S. Schor. University of California at Berkeley, Berkeley, CA 94720

Phoria is often defined as the relative alignment of the eyes when one eye is occluded and the other is fixating a distant target, i.e., the open loop alignment of the eyes. Phoria adaptation is the process by which alignment of the eyes is maintained despite changes in extraocular muscle stiffness, orbital fascial tissue, etc. In previous experiments we demonstrated that changes in vertical phoria following training to a single disparity presented at a single locus in space spread uniformly to all eye positions. Following training to two disparities of opposite sign presented at two sites along either the primary vertical or primary horizontal meridians, the change in vertical phoria conformed to the demands of the stimulus at the eye positions at which the training was given with a graded spread in between. The change was uniform at eye positions orthogonal to the one containing the training sites. We predicted that phoria adaptation to two different disparities presented at tertiary eye positions would follow the same pattern, conforming to the stimulus demands along a line containing the two sites and spreading uniformly in the orthogonal direction. A 1 deg right hyperdisparity was presented in the upper right visual field and a 1 deg right hypodisparity was presented in the lower left field. The subject alternated between these two stimuli every 10 sec for 40 min after which his phoria was measured at 45 different eye positions. The results were compared to those obtained when the subject trained to two disparities presented on the primary horizontal and vertical meridians. It was found that the response to training at tertiary positions could be predicted by a linear combination of the phoria produced in the horizontal and vertical separation trials. SHORT-LATENCY VESTIBULO-OCULAR REFLEX CANCELLATION IN NORMAL HUMANS. J.L. Johnston* and J.D. Miller. Section of Neurology, Depts. of Medicine, Otolaryngology and Ophthalmology, University of Manitoba, Winnipeg, Canada R3E 0Z3

We measured vestibulo-ocular reflex cancellation (VORc) in normal humans using magnetic search coil oculography and unpredictable head and target accelerations (82-644 deg/s/s). Accelerations occurred while tracking a head-fixed target 1) from 0 velocity onset, or 2) while moving at constant velocity (30 deg/s) or 3) constant acceleration (300 deg/s/s). In some subjects, VORc gains from 0 velocity onset were reduced compared to VOR gains in darkness, when measured over the first 60 ms after head and target motion. Similar reductions in VOR gain occurred in darkness without a target, if the subject was instructed to track an imaginary head-fixed target. In all subjects, VORc gains were reduced at short-latency (<60ms) when accelerations were made during constant velocity rotations and established tracking of the head-fixed target. When the accelerations were superimposed on a constant acceleration, VORc gains were again reduced, even though effective tracking of the target had not been achieved prior to the accelerations. These results suggest that 1) parametric modulation may play an important role in VOR cancellation from 0 velocity onset; 2) short-latency VOR cancellation occurs in humans when accelerations are made during established eye-head tracking; and 3) retinal slip prior to head and target acceleration may be important in improving initial VOR cancellation.

MODEL OF THREE DIMENSIONAL VELOCITY-POSITION TRANSFORMATION IN OCULOMOTOR CONTROL. C. Schnabolk* and T. Raphan, Inst. for Neural and Intell. Systems, Department CIS, Brooklyn College of CUNY, 2900 Bedford Avenue, Brooklyn, N. Y., 11210.

We developed a three dimensional dynamical eye movement system model to study velocity-position transformation in oculomotor control. The main point of the model is that the eye muscles generate torque to rotate the eye. When the eye reaches an orientation where the restoring torque of the orbital tissue counterbalances the torque applied by the muscles, a unique equilibrium point is reached. The eye trajectory followed to reach equilibrium, depends on the starting eye orientation and eye velocity. According to Euler's theorem, eye orientation at any instant of time can be represented as an angle of rotation about some axis from a primary position. The restoring torque was approximated as proportional to the product of this angle and a unit vector along this axis. Thus, the dynamical system representing the eye and its orbital tissue gives the torque-orientation transformation associated with eye rotations from the primary position. *The velocity-position integrator can be modelled as a dynamical system such that a linear combination of the integrator state and a direct pathway signal is converted to a torque signal that activates the muscles to rotate the eyes.* Because torque signals are vectors, they commute. Thus, our model indicates that the signals in the central nervous system (CNS) can be treated as vectors. The non-vector orientation properties of the eye result from the dynamic torque-orientation properties of the globe and its underlying tissue. Listing's law is explained by our model as being a property of the vector nature of the signals in the CNS driving the eyes, and not localized to any specific location within the CNS. If a neural vector command is confined to Listing's plane, then eye orientation will obey Listing's law. Model simulations were run to show that Listing's law is obeyed for both saccades and smooth pursuit eye movements, consistent with experimental findings. 654.7

TORSIONAL EYE POSITION AND MOVEMENTS AFTER LESION OF THE ROSTRAL INTERSTITIAL NUCLEUS OF THE MLF.

Y Suzuki*, D Straumann, B.J.M. Hess, V Henn, Neurology Department, University Hospital, CH-8091 Zürich, Switzerland.

The rostral interstitial nucleus of the MLF (riMLF) contains premotor burst neurons for torsional and vertical rapid eye movements. In three rhesus monkeys, we have investigated the effects of unilateral and bilateral riMLF kainic acid lesions (0.3-1.2µl, 8-16µg/µl) during spontaneous eye movements in upright and in different static roll positions which induce ocular counter-rolling.

After a unilateral lesion, all monkeys showed an increased thickness of Listing's plane together with a shift to the counter-torsional direction, e.g., in a positive direction after a left-sided lesion. The torsional shift in the light was 8.2 to 16.2 deg, but always less in the dark. After the second lesion was placed on the other side, Listing's plane displaced to the opposite torsional direction. On average, the residual torsional shift reduced to 22% of the shift after the first lesion, and the thickness of Listing's plane decreased to the level of the pre-lesion state. Counter-rolling in response to static tilt was well preserved after bilateral lesions.

The results suggest that symmetrical activity of burst neurons in the riMLF is essential to keep the torsional component of eye movement around zero and to minimize its scatter. Yet, after bilateral riMLF lesions, Listing's law is still preserved, suggesting its neural implementation downstream of the riMLF.

Dynamical Properties of Torsional Quick Phase Eye Movements in Rhesus Monkeys

D Straumann*, Y Suzuki, V Henn, Neurology Department, University Hospital, CH-8091 Zürich, Switzerland

In humans and monkeys, eye movements have a position range which is about three times smaller in the torsional than in the horizontal direction. We have investigated whether this anisotropy in range is associated with dynamical differences of rapid eye movements in the torsional and horizontal directions. Rhesus monkeys were given velocity steps about an earth-vertical axis in the dark. Body position was upright for horizontal and supine for torsional nystagmus. Eye movements were recorded with the 3D search coil technique. Quick phases of vestibular nystagmus were collected and sorted according to amplitude. Although torsional quick phases on average had lower amplitudes than horizontal quick phases, a considerable number of both horizontal and torsional movements were obtained in the 10-15 deg bin and further analyzed: Torsional quick phases generally showed a higher peak velocity and a greater peak/mean velocity ratio than horizontal quick phases, reflecting differences in the shape of velocity profiles. We hypothesize that these dynamical differences could be a consequence of different mechanical properties of the eye plant for horizontal and torsional movements.

EFFERENT NEURONS IN THE INTERSTITIAL NUCLEUS OF CAJAL (INC) MEDIATING VERTICAL EYE POSITION SIGNALS. Y. Iwamoto*, S. Chimoto, E. Nambu, K. Yoshida, Dpt. Physiology, Inst. Basic Med. Sci., Univ. of Tsukuba, Tsukuba, Ibaraki, 305 Japan

The behavior, projection and vestibular response of vertical eye position-related INC neurons were studied in alert cats. Efferent neurons were identified by their antidromic response to stimulation of the ipsilateral (i-) vestibular nucleus (VN) and/or contralateral (c-) INC. Thirty of 102 downward-on neurons were antidromically activated from i-VN. These neurons received disynaptic excitation from c-VIIIth nerve and inhibition from i-VIIIth nerve. Their firing rate was best modulated for rotation in c-posterior canal (PC) plane, increasing in the nose-up direction. Fifteen of 39 downward-on neurons examined were antidromically activated from c-INC. These neurons were also modulated by rotation in c-PC plane but received very weak, if any, short-latency effects from VIIIth nerves. No neurons were activated from both i-VN and c-INC. Eight of 17 upward-on neurons tested showed antidromic responses from c-INC. Some of these upward-on neurons were disynaptically excited from c-VIIIth nerve. None of 50 upward-on neurons tested were activated from i-VN. For 11 downward-on neurons with antidromic activation from i-VN, depth profiles of threshold were obtained by tracking in VN. Double low-threshold peaks and variation in latency were observed for 8 neurons, suggesting the existence of branches. Results show that vertical eye position signals are sent from INC to both i-VN and c-INC and that different groups of neurons contribute to these two efferent pathways.

654.8

CHARACTERISTICS OF RAPID EYE MOVEMENTS AFTER LESIONS OF THE ROSTRAL INTERSTITIAL NUCLEUS OF THE MLF IN THE RHESUS MONKEY.

V Henn*, Y Suzuki, D Straumann, Neurology Department, University Hospital, CH-8091 Zürich, Switzerland.

The rostral interstitial nucleus of the MLF (riMLF) contains premotor burst neurons for torsional and vertical rapid eye movements. In four rhesus monkeys, we have investigated the dynamics of saccades after unilateral and bilateral riMLF kainic acid lesions. Fast phases of nystagmus were collected during animal oscillation in the light (+/-10deg 0.1-0.8Hz, +/-40deg 0.2Hz).

After bilateral lesions, all torsional and vertical rapid eye movements were permanently lost. After unilateral lesions, torsional rapid movements were lost to one side only, while vertical movements were still possible. The velocity and amplitudes of downward movements were decreased in all four monkeys. Upward rapid eye movements were decreased in amplitude, but velocity was slowed in only two monkeys. The velocity of vertical compensatory movements was not affected.

Output information of riMLF neurons seem to be redundant enough that vertical movements can still be generated, even if about 50% of the burst neurons are inactivated. We speculate that the asymmetry of deficits in vertical rapid eye movements can be attributed to a partially segregated anatomical localization of neurons.

LESION OF THE CEREBELLAR NODULUS AND THE VENTRAL UVULA MODIFY THREE-DIMENSIONAL VESTIBULO-OCULAR AND OPTOKINETIC REFLEX B.J.M. Hess* and D.E. Angelaki, Neurology Department, University Hospital CH-8091 Zürich, Switzerland

3D eye movements were studied following lesions of the nodulus and ventral uvula in rhesus monkeys. A spontaneous horizontal and vertical nystagmus, present acutely after the lesion, recovered largely within the first 4 weeks. Abnormal torsional eye movements persisted, and a torsional pendular nystagmus developed in light and dark consisting of slow phase oscillations of about ± 5° at about 0.05 Hz. Torsional pendular nystagmus was suppressed in ear-down but not in prone or supine positions. The vestibulo-ocular reflex (VOR) and the optokinetic nystagmus (OKN) were altered as follows: (i) The dynamics of the horizontal VOR became underdamped, exhibiting periodic alternating nystagmus with period of more than one minute during the per- and postrotatory response phase as well as during optokinetic afternystagmus. (ii) The time constant of torsional VOR decreased to a value similar to that characterizing the semicircular canal afferent responses. No torsional OKN and OKAN could be elicited. (iii) During constant velocity off-vertical axis rotation, there was no steady-state response component suggesting a loss of the ability to detect head angular velocity from dynamic otolith information. (iv) Transformation of postrotatory eye velocity from head- to gravity-centred coordinates was abolished following passive head tilts. The results suggest that the cerebellar nodulus and ventral uvula play a crucial role in processing otolith information and in the proper function of the velocity storage network.

655.1

GENERALIZATION OF VISUO-MOTOR LEARNING. H. Imamizu*, Y. Uno and M. Kawato ATR Human Information Processing Research Labs, Kyoto, Japan.

Some recent computational studies propose that the biological motor system acquires internal models of the inverse kinematics and/or inverse dynamics transformations by learning (Kawato & Gomi, 1992, *TINS*, 15, 445-453). Computationally, internal models can be characterized by two alternative representations, i.e., parametric and tabular (Atkeson, 1989, *Ann. Rev. Neurosci.*, 12, 157-83). Tabular models do not need prior knowledge about the structure of the musculo-skeletal system but it lacks the capability of generalizing learned movements. Parametric models can generalize movements but requires the analytical description of the system. To investigate which type of representation the human motor system might use, we examined spatio-temporal characteristics of aiming behavior of normal human subjects at various target locations before and after excessive training at one fixed location. A marker was attached to the subject's hand and its current position was displayed as a cursor on the CRT screen. Subjects moved their hands within a horizontal plane so as to move the cursor from the starting position to the target. The visual feedback displayed on the CRT was rotated by 75 deg. around the center of the screen and the subjects learned how to achieve the target under this rotated condition. The effect of learning was most prominent when the subjects aimed at the target used during the training session but it was also obtained when they aimed at different targets not used during the training session. These results suggest that the internal representation corresponding to the inverse kinematics is basically parametric, but not so completely as represented by mathematical equations.

FUNCTIONAL CHANGES WITH STRETCH REFLEX CONDITIONING. S.L. Wolf, R.L. Segal, T.R. Nichols, J.L. Vitek, and R.L. Watts*. Departments of Rehab Medicine, Physiology and Neurology, Emory University School of Medicine, Atlanta, GA 30322

Eighteen normal subjects, were randomly assigned by pairs to receive conditioning designed to reduce the magnitude of the biceps brachii spinal stretch reflex (N=9) or as controls (N=9) who were not provided feedback about reflex responses. All subjects were given 6 baseline sessions followed by an additional 24 training or extended baseline trials. Stretches (250 per session) were delivered through a motor which provided a brief extension torque when specific joint angle and background EMG criteria were met. Measurements of passive joint stiffness and speed of upper extremity, task-specific movements were also made. Training subjects reduced their median biceps reflex sizes by 30% while controls showed virtually no change. Brachioradialis reflex responses covaried with those of biceps for the training group while the antagonist triceps declined by about 40% in both experimental and control subjects. There were no noticeable changes in elbow joint stiffness but speed of upper extremity movements, especially those specifically related to the elbow joint improved. The entire procedure may be "relaxing" to all subjects, but specific training may reduce cocontraction, facilitate the recruitment of elbow extensor motoneurons, or produce greater inhibition of elbow flexor motoneurons, thus enabling faster movements.

ERROR CORRECTION STRATEGIES: IMPLICATIONS FOR ONE-TRIAL LEARNING. A.G. Feldman*, M.F. Levin, Y. Lamarre. Neurological Research Centre, University of Montreal, Montreal, Quebec, Canada H3C 3J7

The question of how subjects attain the same final joint position under varying load conditions was studied. Subjects trained to make fast wrist flexion movements with no load to a target. They then repeated the same movements (like-training trials) but in random trials (test trials), movements were either opposed or assisted by a load generated by linear position feedback to a torque motor. In two other experiments, subjects initially trained to reach the target with opposing or assisting loads respectively, while on random test trials, the load was not presented. Subjects were instructed to correct errors as soon as possible. In most of the test trials, the wrist arrived initially in a static position outside the target zone and then subjects made corrections by secondary movements. These errors were either positional undershoots or overshoots. EMG signals and movement kinematics were load-dependent. However, these reflex EMG changes did not, in themselves, prevent positional errors. Subjects made errors and corrections not only in the test but also in a significant number of like-training trials. When two test trials occurred in a row, the second movement usually had an error similar to the first or was accurate. The findings were interpreted in the framework of the model showing how control variables for the upcoming movements may be formed based on the previous movement. The model predicts movement errors and may also explain one-trial learning.

SEQUENTIAL MOVEMENT PATTERNS DURING THE LEARNING OF NOVEL TYPING RESPONSES. A.M. Gordon*, A. Casabona, and J.F. Soechting. Dept. of Physiology, University of Minnesota, Minneapolis, MN 55455 and Inst. of Human Physiology, University of Catania, Italy

We previously have shown that typing movements normally involve characteristic patterns of movement for each keystroke (flexion-extension and rotation in the horizontal plane) and that sequences of key presses entailing both hands occur in parallel (i.e., the movements of each hand overlap). The present study characterizes the execution of a novel bimanual sequence of movements (typing) and the changes that occur during learning. Pairs of letters on the keyboard were transposed (e.g., the letters 'n' and 'u,' which are normally typed with the right index finger) while the time of each keypress and the kinematics of the hands and fingers were recorded. Skilled typists typed words in which all of the letters required the use of only one hand, except the transposed letter, which required the use of the other (e.g., 'sadness'). Temporal delays were seen for words containing transposed keys immediately before the first letter of the word and directly before and after the transposed key compared to words without transposed keys. Initially the movements were highly sequential, with initiation of the keystroke to the transposed key beginning only after completion of the previous keystroke with the other hand. However, once the movement to the transposed key was initiated, the wrist and finger movement trajectories and the movement durations were in most instances similar to those used for the letter normally corresponding to the given key location. With practice the movement of the two hands began to overlap (i.e., they were performed more in parallel) and the temporal delays decreased. The results suggest that typing movements are organized at both the word and individual keystroke level and that novel bimanual sequences of movement are initially performed sequentially but are performed more in parallel following practice.

INFLUENCE OF INCREASING THE NUMBER OF UNPREDICTABLE PERTURBATION FEATURES ON EVOKED POSTURAL RESPONSES. B.E.Maki, W.E.McIlroy and J.D.Brooke*. Sunnybrook Health Science Centre, University of Toronto, Toronto, Ontario, CANADA

Prior expectation of perturbation characteristics has the potential to greatly influence evoked postural responses. However, only certain features of perturbations are typically varied (ie. duration, magnitude and directional "polarity"). The present study examines the effect of expectation on postural responses under a wider range of unpredictability, by including: 1) different perturbation waveforms (biphasic vs tri-phasic acceleration) and 2) multiple perturbation directions. Perturbations were applied as horizontal platform translations, and ground reaction forces and EMG responses were compared across trial blocks involving different levels of unpredictability, as determined by the number of perturbation features which were randomized. In the first series, 10 subjects were tested over a range of trial blocks involving various degrees of randomization of perturbation velocity, displacement, duration, directional polarity (forward vs. backward) and waveform (biphasic vs. triphasic). In the second series, multiple horizontal perturbation directions (antero-posterior, medio-lateral and oblique axes) were also tested. In 6 of the 10 subjects, changes in the number of unpredictable features had a significant influence on center-of-pressure (COP) and EMG responses. These effects were most commonly seen as changes in later response characteristics (ie. after peak COP, ~300ms), but the direction and magnitude of change was strongly dependent on the individual subject. The results of our study suggest that contributions of central processes to postural control may be overestimated in experimental paradigms that lack sufficient unpredictability.

SPEED SCALING AND ADAPTIVE CEREBELLAR CONTROL OF RENSCHAW CELL AND MOTONEURON GAIN.

D. Bullock*, J.L. Contreras-Vidal, and S. Grossberg. Cognitive and Neural Systems Department, Boston University, Boston, MA 02215, USA.

Research has established that interpositus-receiving areas of the Red Nucleus often show velocity-like responses during limb movements in well-trained subjects, and that stimulation of rubral sites can facilitate motoneurons while simultaneously inhibiting Renshaw cells. We have conducted large-scale neural network simulations to assess how best to incorporate these data into a comprehensive movement generation model. Specifically, we tested ideas about how cerebellar processing may cooperate with spinal processes to produce desired limb dynamics during rapid voluntary arm movements. Simulation results supported three functional hypotheses: (1) Mossy fiber conduction of movement velocity commands to both cerebellar cortex and related deep nuclear cells would allow generation of phasic deep nuclear outputs whose feedforward action can greatly improve upon spinal feedback control of tracking. (2) Phasic cerebellar excitation of motoneurons must be coupled with phasic inhibition of Renshaw cells to achieve good tracking. (3) Cerebellum mediated learning generalizes better across movement speeds if motoneuron pools obey the size principle. Both monoarticular and biarticular arm simulations are described, and modeled cell activation patterns compare well with activation history recordings from various labs. Simulated motoneuron pool activations also compare well with parametric EMG data. These results show that accurate rapid movements can be explained without recourse to the concept of a virtual trajectory that deviates markedly from the observed trajectory.

HEIGHT AND SURFACE SPECIFIC ADAPTATIONS WHEN LANDING FROM A JUMP. M.Cincera^{1,2}, P.McKinley^{2*}, R.Rodano¹, & A.Pedotti¹. C. Bioingegneria, I. Politecnico, Milano¹, Italia & McGill University², Montreal, Canada H3G 1Y5

EMG, kinematics and kinetics of the landing phase of jump downs were analyzed in two groups (n=4) of adolescent females: trained sprinters, and active, but untrained, using the ELITE motion analysis system and a force plate (Kistler 9261A). Subjects jumped from 2 heights (45 & 60cm) onto both rigid and foam surfaces (n=5/condition). The major findings of this study were that as a group, the subjects trained as runners absorbed more energy at the hip than the untrained, and were highly individualized, but consistent in the pattern of energy absorption across conditions. By contrast, the untrained individuals showed adaptation in their pattern of energy absorption, with increased energy absorption at the hip or decreased ankle absorption when landing on a foam as compared to rigid surface and with increased height. Differences in joint adjustments and Range Of Motion post-landing were parallel kinematic adaptations. Both groups showed kinematic adjustments at the ankle related to surface effects, but little adjustment related to height. Time to stabilization was also significantly less in trained subjects, when landing on a rigid surface. Results are attributed to the way in which sprinters are trained to land and push off almost simultaneously and to the stereotypic way in which they are encouraged to land regardless of external conditions. supported by NSERC (PMc), Telethon (M Cincera) and Fondazione pro Juventute, Don Gnocchi

FACTORS CONTRIBUTING TO INITIAL REACHING ERRORS AND ADAPTATION TO CORIOLIS FORCE PERTURBATIONS. J.R. Lackner* and P. DIZIO. Ashton Graybiel Spatial Orientation Laboratory, Brandeis University, Waltham, MA 02254.

We studied (1) whether reaching errors made in the center of a rotating room (DIZIO & Lackner, 1992. *Soc Neurosci Abstr*, 18(1):516) are caused by Coriolis (F_{Cor}) or centrifugal (F_{cent}) forces and (2) whether information about endpoint errors contributes to adaptation (Lackner & DIZIO, 1992. *Soc Neurosci Abstr*, 18(1):515).

We used the DIZIO & Lackner, 1992, paradigm but reversed rotation direction. This reversed F_{Cor} but kept F_{cent} constant. Opposite endpoint and trajectory errors resulted, thus F_{Cor} was responsible. F_{Cor} is zero once a movement ends, so the results are inconsistent with current equilibrium point models of movement control.

We used the cited paradigm and allowed subjects (N=8) to correct for any proprioceptively perceived endpoint errors following each reach. Prior to correction, the pattern of F_{Cor} -induced errors, adaptation and aftereffects were quantitatively the same as in our cited work. Corrective attempts were no more frequent while subjects were adapting to rotation or readapting to being stationary again than pre-rotation, and only partially eliminated endpoint errors. The lack of accurate proprioceptive appreciation of endpoint errors means that dynamic information about trajectory errors is essential for adaptation. Supported by NASA Grant NAG 9-515.

655.11

EFFECTS OF CLONIDINE AND YOHIMBINE ON STEPPING IN CHRONIC SPINAL CATS. R. D. de Leon, W. Seto, S. Bautista, A. Soliman, J. A. Hodgson, R. R. Roy, and V. R. Edgerton*. Department of Physiological Science and Brain Research Institute, UCLA, L.A., CA 90024.

The effects of clonidine and yohimbine on stepping in cats spinalized at T12-T13 were studied and compared to pre-spinal stepping. EMG from 3 flexors and 3 extensors were recorded during bipedal stepping before and at various times following spinalization. Three cats were trained to step on a treadmill at various speeds (0.2-1.0 m·s⁻¹) and 3 other cats were trained to stand. Each cat was trained for 30 min/day, 5 days/week beginning 1 week after spinalization. Approximately six months later, the training regimens for the two groups were switched. Two of 3 cats initially trained to walk were able to step with full weight support after 3 weeks of training. In contrast, the stand-trained cats were unable to walk throughout the training period. The effect of clonidine (15-75 µg) and yohimbine (0.25-4 mg) on stepping were studied. In two cats undergoing standing training, clonidine enabled stepping (0.2-0.8 m·s⁻¹) that resembled pre-spinal stepping, including full-weight support on the plantar surface of the paw. The step-trained cat that was unable to walk 3 weeks after spinalization walked (0.2-0.8 m·s⁻¹) after clonidine. Another cat trained to step for 5 months walked more consistently and reached a higher maximum speed (0.8 vs 1.0 m·s⁻¹) after clonidine. Clonidine increased extensor and flexor EMG burst durations near to or sometimes greater than pre-spinal durations. Three cats that could perform excellent stepping during the step trained period were unable to step after administration of yohimbine. The stand-trained cats remained unable to walk after yohimbine. These data suggest that at least some of the acquired plasticity in the spinalized, stand- and step-trained cats involved a modulation of noradrenergic dependent spinal networks. (Supported by NIH Grant NS16333)

TRANSFER OF ADAPTATION TO CORIOLIS FORCE PERTURBATIONS FROM THE EXPOSED TO THE NON-EXPOSED ARM. P. DIZIO* and J.R. Lackner. Ashton Graybiel Spatial Orientation Laboratory, Brandeis University, Waltham, MA 02254.

When subjects reach forward during body rotation (10 rpm), movement endpoints are deviated in the direction of the transient Coriolis forces on the arm. Endpoint accuracy is regained within 40 per-rotation reaches made without visual feedback. Mirror-image trajectory and endpoint errors occur when subjects are again stationary.

We studied whether adaptation to Coriolis force perturbations achieved with the right arm (RA) transfers to the left arm (LA). Subjects (n=10) reached to a midline visual target without ever receiving visual or tactile error feedback about accuracy. The RA endpoint was deviated 25mm rightward initially during body rotation (10 rpm CCW) but returned within 4mm of baseline after 48 reaches. Post-rotation, LA endpoints were significantly deviated 12mm leftward of baseline value but returned to within 5mm after 8 reaches. RA movement endpoints when first measured after 8 post-rotation LA reaches, were deviated 9mm left of pre-rotation baseline, and returned to baseline after 24 reaches.

These results indicate significant intermanual transfer of adaptation to Coriolis forces, and transfer of readaptation. They point to adapted central motor planning partly independent of effector appendage.

Supported by NASA Grant NAG9-515.

MOTOR LEARNING OF A SEQUENTIAL AIMING TASK IN PARKINSON'S DISEASE. A.L.Smiley-Oven, C.J.Worringham*, & C.L.Cross. Center for Human Motor Research, University of Michigan, Ann Arbor, MI 48109-2214.

Motor learning in patients with Parkinson's Disease (PD) was studied using a three-dimensional sequential aiming task. Six PD and six healthy age-matched control subjects contacted a series of five targets with a hand-held stylus. The targets ranged in size from 1.5 to 6 cm in diameter and in center-to-center distance from 9.5 to 21 cm. A direction change was required at each target. Response time (reaction time plus movement time) was to be minimized while maintaining a 90% accuracy rate per target. A total of 90 trials were practiced for each of two days. Reaction times, execution times and movement kinematics were measured to determine if learning took place. Results indicated that both groups improved performance with practice. While, in general, the rate of improvement did not differ significantly between groups, specific components of the movement indicated that the improvement in PD relative to control subjects occurred earlier in the practice trials. These results extend earlier findings that PD patients can improve their motor performance with practice.

CONTRALATERAL EFFECTS OF CONDITIONING THE BICEPS BRACHII SPINAL STRETCH REFLEX. P.A. Cattin, S.L. Wolf, L. Gabrielson, T. Kassel, and S. Martin. Div. Physical Therapy, Dept. Rehab. Med, Emory University, Atlanta, GA 30322 Supported by NINDS Grant R01 NS28784.

This study examined the effects of conditioning the biceps brachii spinal stretch reflex (BBSSR) on the contralateral homologous reflex. Ten healthy subjects between the ages of twenty to thirty years participated in this study. The method of conditioning the BBSSR included the use of a torque motor to elicit a stretch from the biceps brachii muscle and feedback to shape the response in the direction of training. Each subject underwent six baseline sessions without feedback. Subjects were randomly assigned to either an uptraining group (N=5) or a downtraining group (N=5). Each subject participated in ten training sessions receiving feedback based on assignment to groups.

The percent change in EMG amplitude between baseline and training sessions was statistically significant for the ipsilateral M₁ response in the uptraining group and the ipsilateral M₂ response in the downtraining group. With the elimination of data from one unsuccessful downtrainer and one unsuccessful downtraining session for another subject, the percent reduction in EMG amplitude of the BBSSR was also significant for the ipsilateral M₁ response. Although statistical significance was not found for the M₁ or M₂ response on the contralateral side for either group, a trend was observed in the appropriate direction for all data according to the training regimen. The results support the concept that uptraining or downtraining of the ipsilateral BBSSR can occur and that contralateral reflex responses show parallel changes of lesser magnitude. Although changes in the contralateral BBSSR responses found in this study were not statistically significant, an actual carry-over effect in the clinical setting or with functional activities among patients with either hypo- or hyperactive reflexes remains to be demonstrated.

REVERSIBLE MOTOR LEARNING IN A SPATIALLY ROTATED, TWO-DIMENSIONAL REACHING TASK. L. Shen*, G. E. Alexander. Dept. of Neurology, Emory Univ. Sch. Med., Atlanta, GA 30322.

Two macaque monkeys were trained to position a cursor presented on a video display by moving a two-dimensional joystick with the right upper extremity. The subjects were prevented from viewing either the joystick or their limbs; they were given only indirect visual feedback about hand/joystick position via the cursor. On each trial, the subject was required to move the cursor from a starting position, indicated by a fixation target located in the center of the display, to one of four possible peripheral targets located at 0/360°, 90°, 180° or 270°. Once each subject had learned the basic task, the two-dimensional mapping between the joystick and the cursor was rotated by + or - 90°. Each subject was gradually able to adapt to this transformation in the course of a single training session. Prior to the spatial rotation, all hand trajectories had been nearly straight. Immediately after the rotation was imposed, the initial component of each trajectory was the same as it would have been before the transformation; this required a second, corrective component in order for the subject to acquire the target with what then became a curvilinear trajectory. During the process of adaptation, each of the target-directed trajectories became gradually more straightened, with the behavior stabilizing when the trajectories again approached straight lines. Reaction times were unaffected. When the joystick/cursor mapping was rotated back to the original condition, the subjects required the same amount of time to adapt to this as to the 90° transformation. The time course for adaptation remained quite stable across numerous such reversals. The adapted behavior remained stable over several days until the next reversal. The rate of adaptation varied systematically across the four quadrants of the hand's work space, irrespective of the target location or the position of the cursor on the screen. Taken together, these results suggest that the observed adaptation represents a readily reversible form of task-specific motor learning.

655.14

PARTICIPATION OF CHOLINERGIC SYSTEMS OF NEOSTRIATUM AND NUCLEUS ACCUMBENS IN INSTRUMENTAL BEHAVIOUR IN DOGS. K. B. Shapovalova, E. V. Pominova & M. Robinson*. I.P. Pavlov Inst. of Physiol., St. Petersburg, 199034, Russia & Dept. of Physiol. Univ. of Western Ont., London, N6A 5K8, Canada.

The chronic experiments were carried out on seven dogs with defensive instrumental reflex (IR) associated with the maintenance of flexor posture. The influence of carbachol (CAR) microinjections (0.05 to 0.1 µg) in the left and right caudate nucleus head (HNC) and in the nucleus accumbens (NAC) was studied for the occurrence of IR and for behavioral differentiation of acoustical signals under defensive situation. These microinjections showed that the cholinergic systems of HNC and NAC participate in both the motor and sensory mechanisms connected with the occurrence of motor responses to defensive and differentiation signals. This participation has common and specific features. The dorsal striatum (HNC) is structurally involved in the initiation and occurrence of IR. Its cholinergic structures have complex and unequal influences on the components of postural adjustment and instrumental movement. The ventral striatum (NAC) also participated in regulation of voluntary movement, but this influence is mainly excitatory and is of a nonspecific and prolonged character. Activation of cholinergic systems of HNC or NAC leads to "improvement" of signal differentiation due to better sensory attention. In comparison to ventral striatum the participation of cholinergic structures of dorsal striatum is more complicated in this process.

CIRCUITRY AND PATTERN GENERATION IV

656.1

CENTRAL PATTERN GENERATION WITHOUT CENTRAL PATTERN GENERATORS. J.L. Leonard*, Mark O. Hatfield Marine Science Center, Oregon State Univ., Newport, OR 97365.

A major question in neuroethology is whether or not the existence of a FAP/MAP implies the existence of a central pattern generator or whether have suggested behavior patterns can also be "self-organized" i.e. arise through network properties of the nervous system (Mptsos and Cohan 1986; Mptsos et al. 1988). Current ideas as to the organization of behavior patterns by neural circuits consisting of unique combinations of neurons are summarized in the "alphabet" model, whereby a neuron may participate in many different behaviors but each behavior can be produced by only one combination of neurons. The "equation model" is a simple, explicit model of the self-organization of stereotyped behavior which makes falsifiable predictions as to anatomical and physiological properties of the system. In this model neurons make quantitative rather than qualitative contributions to the behavior and the same value may be attained by any of several combinations of neurons. This system will produce a set of discrete behaviors (rather than a continuum), if the set of neurons is small, with discrete values, and/or the structure of the periphery is such that only a limited set of behavioral outputs is possible. The peripheral filter might consist of a skeletal system that limits the degrees of freedom of movement of a limb (i.e. hinge joint, etc.) or it might represent the limited range of receptors or ion conductances at muscle. The organization of motor units would, in vertebrates, represent part of the peripheral filter. The values of the neurons may or may not be variable and they may interact according to a variety of rules, "the equation". Inhibitory neurons might (but need not) be included in the network. This "equation" model is conceptually distinct from the "alphabet model" and represents one possible form of "self-organization" of behavior by the nervous system, in that the role of a given neuron in a specific behavior depends on the activity of the other neurons in the network. Supported by NIMH and NSF.

656.3

GENETIC ALGORITHMS THAT OPTIMIZE MODELS OF RHYTHMIC FEEDING BEHAVIOR IN APLYSIA: THE EFFECTS OF VARIATIONS OF THE PARAMETERS. D. Deodhar*, I Kupfermann, S.R. Rosen, and K.R. Weiss. Center for Neurobiology and Behavior, Columbia University, 722 W. 168 St. New York, NY 10032 and Fishberg Center, Mt. Sinai School of Medicine, New York, NY 10029.

We have continued our studies designed to explore how behavior is optimized. We use simple neural models, in which the effective parameters are discovered by genetic algorithms (Goldberg, 1989) that roughly simulate a process of natural evolution. As previously reported, we have attempted to define the simplest model of the process by which food is rhythmically drawn into the buccal cavity and swallowed. The operation was determined using an integrate-and-fire model. As a first approximation, the fitness of our system was defined as the difference between the energy expended by the muscles and the energy gained. The defined systems lack any modulatory mechanisms, and therefore, as predicted, their fitness dramatically fell when the system was challenged by even small variations of the evolved parameters. For example, after a "good" solution was reached, we tested the function of the network when the force of contraction was systematically varied by altering the excitatory drive to the muscle.

656.2

ATTRACTORS IN NEURAL ACTIVITY AND A CONJECTURE REGARDING THEIR ROLE IN FORMING NEURONAL AND NETWORK ARCHITECTURE. G.J. Mptsos*, M. O. Hatfield Marine Science Center, Newport, OR 97365.

For a number of years now, we have proposed and examined the ability of networks to sustain attractors. These phase-space structures may help to explain how high-dimensional networks, arising from widely converging and diverging connections, can often exhibit low-dimensional activity. Less persistent "attracting states" may underlie high-dimensional activity (akin to turbulence) representative of motor pattern blending and of one mechanism by which neurons may vary with one another in contextual groups.

In simulation studies reported here we examine the ability of synaptic strengths (as well as of the firing frequency of neurons that have inputs to the network) to act as bifurcation parameters to cause the network to exhibit multiple patterns of activity.

Additionally, we propose that attractor gradients (basins) and, to a lesser extent, gradients relating to attracting states, act as global organizing forces that set synaptic strengths (and firing thresholds) "optimally" with respect to one another in developing and trainable synapses, and impose a variety of other network characteristic. Thus, the real architect of the structure of individual neurons and of the network as a whole may be the dynamics that a network can increasingly sustain, rather than, for example, whether a neurotransmitter evokes particular electrical changes in postsynaptic cells or whether it effects the movement of calcium ions which in turn affect growth. That is, there may be an inseparable dialectic between dynamical state and the cellular elements that become used by such states. Exclusion of dynamics may lead to misinterpretations of the causative factors that one might attribute to cellular elements examined in isolation.

PATTERN RECOGNITION AND GENERATION IN SENSORIMOTOR NEURAL ASSEMBLIES: SYNAPTIC CHANGE AND TEMPORAL DYNAMICS. J. E. Dayhoff* and D. T. Lin. Institute for Systems Research, University of Maryland, College Park, MD 20742.

We have examined alternative models for neural circuits that recognize patterns, generate patterns, and respond to stimuli with dynamic activity traces. We have modeled a neural circuit that recognizes temporal patterns - stimuli that occur over a period of time, such as a spoken word. This model uses time delays on interconnections, and recognizes spatiotemporal stimulus patterns. Training involves adjustment of synaptic weights and time delays, and we propose how intracellular signals could mediate these adjustments. Circuits that generate temporal patterns such as spatiotemporal activity traces or spatial trajectories have also been examined. A neural network model has been trained to produce a spatial trajectory that is pre-chosen, and the network utilizes time delays along interconnections. Another model generates complex spatiotemporal variations in assembly activity stimulated by static patterns as input. This model relies on adaptive thresholds to cause the network to activate in complex ways.

656.5

DYNAMIC BEHAVIOR OF A BINEURAL NETWORK MODEL. Budelli, R.*, Catsigeras, E. and Gómez, L. Sección de Biomatemática, Inst. de Biología, Facultad de Ciencias and Inst. de Matemática, Facultad de Ingeniería, Universidad de la República, Montevideo, Uruguay.

Two synaptically interacting pacemaker neurons were studied mathematically. Each neuron was modelled as a general relaxation oscillator; the synaptic action was simulated as jumps in the postsynaptic membrane potential. The model indicates that the network behaves as a discontinuous nonlinear dynamical system on the torus.

We prove that generic noninhibitory systems necessarily exhibit a periodic behavior, a finite number of limit cycles, and two (at most) binary codes. In the particular case of the leaky integrator model, the number of limit cycles cannot be more than two.

Our study also showed that when both neurons are inhibitory, either the system presents a periodic asymptotic behavior or it has a non trivial compact set attracting all the orbits. For the leaky integrator model, the first behavior occurs for almost any set of parameters.

In addition, our study on the structural stability of these bineural networks indicates that the system may act as a stable memory. Supported by the Universidad de la República and the CCE [contract C.I. 1.10165 U (H)].

656.7

LARGE-SCALE SIMULATION OF SPINAL MOTOR CIRCUITS. D. P. Bashor* and G. C. Alig. Dept. of Biology, University of North Carolina at Charlotte, Charlotte, NC 28223.

The dynamics of interacting spinal motor cell populations were investigated with a computer simulation composed of twelve interacting cell populations driven by five or more fiber populations. The simulation was based on R. J. MacGregor's SYSTM11 and SYSTM20 programs (MacGregor, 1987). Two motoneuron populations represented a single agonist and antagonist. The associated interneurons were organized as 5 pairs of populations, including Renshaw cells, IA and IB interneurons, and excitatory and inhibitory interneurons. About 2300 cells (fewer than 400 of them motoneurons) were used, interconnected by about 600,000 terminals. Four types of synapses represented short- and long-time constant excitation and inhibition. Five or more input fiber populations (more than 680 fibers and 130,000 connections) drove the cell populations at selected times and rates. These represented, for example, IA and IB afferent input, and general excitatory drive. Simulation results were dependent on the properties of the interneurons and their connections, since they comprised the majority of cells. The addition of a small fraction of long-time-constant synapses had a profound effect on network dynamics. Their presence dramatically altered the number of terminals in the network required to maintain (or quench) internally-sustained activity, when that was used as an index of effect.

656.9

A DYNAMIC COMPUTATIONAL MODEL OF THE NEMATODE TAP-WITHDRAWAL REFLEX. B. Hutcheon*¹, C. Roehrig², and S. Wicks¹. ¹Program in Neuroscience and ²Dept. of Computer Science. University of British Columbia. Vancouver, B.C., Canada.

The nematode worm *C. elegans* exhibits a surprisingly broad behavioural repertoire despite possession of only 302 neurons. Several characteristics of the worm's neurobiology make it a candidate for behavioural based computational modeling: 1) the neurons are simple processes with at most three bifurcations 2) the circuitry is defined accurately to synaptic levels 3) the modeled behaviour can be manipulated by laser ablation of individual neurons which underlie the behaviour.

A computational model of the nematode tap-withdrawal reflex was formulated using simplified biological assumptions. Neurons were assumed to be isopotential and non-spiking. Groups of like synapses with the same pre- and post-synaptic neurons were modeled as a single functional synapse.

Previous reports (Wicks and Rankin, 1992) have defined the circuitry underlying the tap-withdrawal reflex using single-cell laser microsurgery. These ablation results were used to fit the models parameters. A total of seven "lesion states" were tested by optimizing the models free parameters to behavioural data obtained *in vivo*. Because the polarities of the individual connections were unknown, those corresponding model parameters were also exhaustively adjusted and tested against the ablation study data. A close match between the model and behavioural data was obtained.

656.6

MODELLING CENTRAL PATTERN GENERATION FOR MAMMALIAN LOCOMOTION WITH ARTIFICIAL NEURAL NETWORKS. C.J. Brown, D.J. Kriellaars*, and D. Scuse. Department of Computer Science, University of Manitoba, Winnipeg, Manitoba, Canada, R3T 2N2.

In order to provide further insight into the potential structure of the network of neurons that constitute the spinal central pattern generators (CPG's) involved in locomotor activity in mammals, a developmental model CPG was designed that has half-centre or bipartite characteristics, has distinct frequency and amplitude control, and responds to descending spinal control signals and muscle length afferents. To explore the behaviour of the model and to facilitate future enhancement, the model was implemented in software as a system of interconnected feedforward and recurrent Artificial Neural Networks interacting with another subsystem that simulates a pair of opposing muscles. Data from computer simulations will be presented to demonstrate how the CPG model is able to imitate its biological counterpart while driving and receiving feedback from muscles during "normal" locomotion, while involved in "fictive" locomotion, and while being "entrained" by external manipulation of muscle length.

656.8

FREQUENCY CONTROL IN RECIPROCAL INHIBITORY NEURAL NETWORKS. F.K. Skinner*, A.A. Sharp, N. Kopell, and E. Marder. Ctr. for Complex Systems and Dept. of Biology, Brandeis University, Waltham MA 02254, Dept. of Mathematics, Boston University, Boston MA 02215.

Four mechanisms describe oscillatory behaviour that occurs in two cells connected by reciprocal inhibitory synapses: (a) Intrinsic Release (I.R.); inhibited cell released from inhibition by free intrinsically oscillatory cell, (b) Intrinsic Escape (I.E.); intrinsically oscillatory inhibited cell escapes from inhibition, (c) Synaptic Release (S.R.); free cell stops liberating transmitter allowing inhibited cell to be released, (d) Synaptic Escape (S.E.); inhibited cell starts liberating transmitter thus inhibiting free cell. If synaptic activation is described by a step-like function and oscillations are in relaxation mode, then there are well-defined boundaries between the mechanisms as the synaptic threshold changes. Network frequency does not change with synaptic threshold for I.R. and I.E. mechanisms, and increases and decreases with increasing synaptic threshold for S.R. and S.E. mechanisms respectively. Minimum network frequency occurs during intrinsic mechanisms. As oscillations become less relaxation-like and approach sine-waves, the dependence of the network frequency on synaptic threshold for the different mechanisms does not change significantly. As synaptic activation slope decreases, boundaries between the different mechanisms as the synaptic threshold is changed become less distinct. These mechanisms are investigated theoretically with model simulations, and experimentally with the dynamic clamp in stomatogastric neurons. Supported by NIMH MH46742 and NSF BNS9009251.

656.10

A MULTICOMPARTMENTAL MODEL OF HEART INTERNEURONS OF THE LEECH, J.M. Crumb, R.L. Calabrese* Department of Biology, Emory University, Atlanta, Georgia 30322

In previous studies, the laboratory has used a single-compartment model to reproduce the oscillatory behavior of heart interneurons. The model used soma-based single electrode voltage clamp data on ionic currents and a presynaptic Ca^{2+} synaptic transfer function.

We are interested in Ca^{2+} current distribution throughout the cell. To achieve this, we injected two neurons with Lucifer yellow and mapped their dimensions in unfixed ganglion whole mounts.

Using these maps, we constructed a 60-compartment model. To account for the observed variance in time constant and input resistance, we assumed that microelectrode penetration injury decreased the specific membrane resistance of the soma. Varying the membrane resistance of the soma compartment reproduced the observed distribution in passive properties. We then chose a passive model that best approximates the typical physiological behavior.

Using this passive cell model, we plan to determine the calcium current distribution and amplitude in different compartments of the cell. We will construct a series of models in which the calcium current will vary from evenly distributed to isolated only in the tips of the dendrites. In each model, the calcium currents measured in the soma compartment through a cell-body voltage clamp will approximate voltage clamp data. We will then elicit calcium plateau potentials in each model, and determine which current distribution best fits the electrophysiological data.

At the end of these studies, we should have a model that reproduces the calcium current activity in the cell, and be able to determine the possible magnitude of errors introduced by cell-body recordings.

656.11

DYNAMICAL CHANGES OF FUNCTIONAL CONNECTIVITY IN CULTURED NETWORKS. Guenter W. Gross* and David C. Tam; Center for Network Neuroscience and Department of Biological Sciences, University of North Texas, Denton, TX 76203.

We have studied the dynamical properties of neuronal networks using dissociated embryonic mouse spinal tissue in culture because they form robust monolayer networks displaying complex spontaneous activity patterns, histiotypic responses to pharmacological perturbations, and long-term cell-electrode coupling on photoetched multielectrode surfaces (cf. Gross et al., In: Neurobionics, Bothe and Samii, eds, Elsevier, 1993).

Multichannel data from such cultures were analyzed with conditional probability statistics (Tam et al., 1987, J. Neurosci. Meth.) where interspike intervals of one reference neuron were correlated with the pre-cross intervals from other neurons in the network. The conditional coupling probability statistics revealed highly dynamic interactions within the network, suggesting that the functional connectivity between neurons was not constant. We have observed that: (1) Neurons could switch their functional connections to other neurons dynamically in time. (2) During disinhibition with bicuculline or strychnine, individual neuronal firing patterns remained relatively constant, while coupling among neurons fluctuated. (3) Such fluctuations in conditional coupling probability were swift and were often observed to develop in about one minute. (4) In addition to changes in spatial coupling, the conditional probability plots also revealed how such spatial coupling varied with the temporal burst firing of these neurons.

Stochastic versus Deterministic Variability in Hippocampal CA1 Population Spikes. P. G. Aitken, T. Sauer and S. J. Schiff*, Dept. of Cell Biology, Duke University Medical Center, Durham, NC 27710.

Reflex variability is well described in the spinal cord monosynaptic reflex. We have studied similar input-output variability in the evoked population spikes generated in rat hippocampal CA1 pyramidal cells by Schaffer collateral stimulation. Stimuli were 100 usec square wave pulses at 0.1 Hz at current intensities sufficient to produce half maximal responses.

Presynaptic volley and population spike peak to peak amplitude was calculated for each unaveraged event, and voltage determined by measurement of a calibration pulse coupled to each stimulus. Both the population spike amplitude, as well as the input-output transfer function of population spike divided by presynaptic volley, were calculated. Two independent methods were used to test for deterministic structure in these time-series: a nearest neighbor approach (Phys. Rev. Lett. 70; 580-582, 1993), and a discrete adaptation of a local flow approach (Phys. Rev. Lett. 68; 427-430, 1992). For each time-series, a surrogate data set was constructed that was a randomized control data set with the same linear correlation (autocorrelation) as the original experimental series. In addition, a known deterministic chaotic time-series (Henon) was used to confirm the reliability of the 2 algorithms.

Both approaches demonstrated no evidence of determinism in either the population spike or the input-output function time-series. In both cases, the matched surrogate data sets produced results that were identical to the experimental data. In this isolated simple neuronal network, we found no suggestion of chaotic deterministic behavior.

IDENTIFICATION OF SPIKE PROFILES USING FUZZY-LOGIC CLASSIFIERS. G. Zouridakis*† and D. C. Tam‡. †Department of Electrical Engineering, University of Houston, Houston, TX 77204-4793, and ‡Center for Network Neuroscience, Department of Biological Sciences, University of North Texas, Denton, TX 76203.

A new procedure for extracting transient signals embedded in continuous waveforms has been developed. Specifically, we formulated a technique to extract multiple spike trains from a single channel of data obtained from biological neurons. The same method can also be used in the study of other electrophysiological signals, such as the EEG and evoked potentials.

The procedure consists of two steps: spike-template creation and individual spike classification. Initially, fuzzy-logic techniques are employed to identify the number of neurons contributing to the extracellularly recorded signal and to create spike templates. In real-time processing of spike patterns, class templates are constructed using a small number of representative spikes which are often contaminated by the presence of noise or other simultaneous events, such as overlapping spikes. Fuzzy classifiers are well suited to deal with such incomplete and/or ambiguous information, because class templates are constructed using all patterns in the data set. In fact, each spike pattern belongs to all possible classes but the degree of membership is different for each class.

Finally, the templates created in the above steps are used to classify individual spikes according to their neurons of origin, utilizing a shift-invariant wavelet transformation. This particular representation has the advantage of both reducing the effect of noise present in the data and correcting the phase of individual components in a waveform.

Results from both simulated and actual recordings show that transient signals hidden in the noise-contaminated original time series can be recovered efficiently. (†Supported by ONR N00014-93-1-0135)

SPIKE TRAIN SERIAL DEPENDENCE, BURST RATE, BURST REGULARITY, AND NETWORK SYNCHRONY ALL INCREASE WITH INCREASING TEMPERATURE IN CULTURED SPINAL CORD NETWORKS. B.K. Rhoades*, J.C. Weil and G.W. Gross, Department of Biological Sciences and Center for Network Neuroscience, Univ. of North Texas, Denton, TX 76203.

Neuronal networks cultured from embryonic mouse spinal cord tissue display high levels of spontaneous activity, characterized by coordinated network bursting. We have previously shown that the temporal pattern and degree of network synchrony can be systematically influenced by changes in the ionic makeup of the culture medium as well as by pharmacological additions.

Dissociated spinal cord tissue from 14-day mouse embryos was seeded onto multimicroelectrode plates (MMEPs) and cultured for 20-60 days at 38°C, to form monolayer neuronal networks of 50-200 neurons. The MMEP is a glass plate with 64 photoetched microelectrodes in a central 1mm² array, which provides a stable culture substrate for multisite extracellular recording. During each recording session culture temperature was varied between 30-44°C in 2° ± 0.1° increments.

Increasing temperature produced a reduction in the amplitude and a shortening of the repolarization period of action potential profiles. Mean, maximal, and modal spike rates increased with increasing temperature. First-order spike train serial dependence increased with temperature, especially for interspike intervals near the short end of the distribution. Burst rate, burst regularity, and network burst synchrony also increased with increases in bath temperature. Simultaneously elevating both temperature and bath potassium concentration could induce the high-amplitude periodic bursting characteristic of pharmacological network disinhibition. These responses suggest that cultured networks might serve as a useful generic model of febrile seizure onset.

A NEW POST-CONDITIONAL CORRELATION METHOD FOR EXTRACTING EXCITATION-INHIBITION COUPLING BETWEEN NEURONS. D. C. Tam* Center for Network Neuroscience and Dept. of Biological Sciences, University of North Texas, Denton, TX 76203.

A new post-conditional correlation statistical method is introduced to extract excitation-inhibition coupling between neurons based on their firing intervals. Since conventional cross-correlation spike train analysis methods primarily detect the probability of firing of neurons given that another neuron has fired, the statistic is built on occurrence of spikes which is a suprathreshold event. But it often fails to detect subthreshold events that may contribute to the decrease in probabilities of firing. Subthreshold inhibitory effect may suppress the firing of spikes such that there may not be sufficient statistical samples of suprathreshold events (i.e., spikes) due to the fact that cross-correlation statistic is based on the firing of neurons rather than non-firing of neurons.

A new post-conditional correlation method is developed to detect the probability of firing and non-firing of neurons based on the post-conditional cross-interval after the reference spike has fired. This statistical method is an estimation of the conditional probability of subsequent firing of a spike in a neuron based on the probability of firing of another neuron after the reference spike has occurred. By examining the lag times of post-interspike intervals and post-cross intervals, the excitatory-inhibitory effects on the firing of the reference neuron can be revealed. Inhibitory effects can be uncovered when interspike interval occurrence is limited to a time window where post-cross interval occurrence time either precedes it by a fixed amount or succeeds it. Thus, such post-conditional correlation method can detect the conditions under which the non-occurrence of spikes may occur, rather than the condition under which the occurrence of spike may occur as in conventional cross-correlation. This method is very useful in detecting inhibitory effects as well as excitatory effects of coupling between firings of neurons. (Supported by ONR N00014-93-1-0135)

THE MUSCULAR HYDROSTATIC STRUCTURE OF THE BUCCAL MASS OF *APLYSIA CALIFORNICA*. Richard F. Drushel,¹ Patrick E. Crago,² and Hillel J. Chiel.^{1,3*} ¹Departments of Biology, ²Biomedical Engineering, and ³Neuroscience, Case Western Reserve University, Cleveland, Ohio 44106 U.S.A.

A muscular hydrostatic structure is composed of muscles and other fluid-filled spaces. The constant volume constraint of a muscular hydrostatic structure transforms forces and movements along the line of action of the muscle into forces and movements in other directions. These transformations are performed without a hard skeleton. The buccal mass of the marine slug *Aplysia californica* is a model system for the study of muscular hydrostatic structures. Histological analysis of serial cross sections of the buccal mass reveal a bilateral array of cartilaginous, fluid-filled, closed-ended tubes (termed *bolsters*), parallel to the antero-posterior axis, each array positioned lateral to each radula half. Numerous fibers of the I4 muscle originate on the radula halves and course laterally, crossing perpendicular to the bolster tubes. India ink perfusion of the vascular system shows that the I4 muscle is richly supplied with hemolymph vessels; however, there do not appear to be any direct connections between the vasculature and the bolster tubes. Compression of the closed-ended bolster tubes by I4 muscle contraction could result in both elongation of the radula/odontophore complex (by isovolumetric lengthening of the bolster tubes) and closure of the radula (by pressure against the radula halves). Indeed, since there are no direct transverse muscle connections between the radula halves, the forces involved in radula closure in *Aplysia californica* are best explained in terms of muscular hydrostatic structures. Support: HL-25830-13.

REGENERATION OF IDENTIFIED BUCCAL MOTONEURONS FOLLOWING PERIPHERAL NERVE LESION IN *APLYSIA CALIFORNICA*. T.L. Ross and M.D. Kirk*. Div. Biol. Sci., Univ. Missouri-Columbia, Columbia, MO 65211.

To study the plasticity of buccal motoneurons (MNs) in *Aplysia*, we studied regeneration following peripheral nerve crush. Buccal nerve 4 (n4 or BN3) was unilaterally crushed, and the animals allowed to recover for 3 to 12 wks. Central and peripheral connections of selected buccal MNs were tested in a semi-intact preparation. For B15, the earliest reinnervation of the I5 muscle (ARC) was observed at 4 wks; EPSP amplitudes at this time were small, and with longer periods of recovery, neuromuscular EPSP amplitudes increased. No inappropriate innervation of target muscles was observed during MN regeneration. The proximal stumps of injured motor axons produced a myriad of fine regenerating processes, or regenerites, which could be followed through the site of injury. Between 30 and 50 regenerites have been counted for a single MN, but we found no evidence for reinnervation of the axon's distal stump. However, our results suggest that distal stumps survive beyond 10 wks and are able to produce large-amplitude synaptic responses in target muscles. In collaboration with Dr. C.K. Govind (Univ. of Toronto, Dept. Zool.), E.M. analysis was used to compare the ultrastructure of crushed nerves following regeneration with contralateral control nerves. Our results may relate to mechanisms underlying learning and memory as well as regeneration, and this system can be used to test hypotheses regarding target specificity, rates of reinnervation, and cellular responses to injury. Supported by NIH grant R01 NS30832 to MDK.

A PAIR OF PEDAL MOTONEURONS INITIATE THE STARTLE PHASE OF ESCAPE SWIMMING IN THE PTEROPOD MOLLUSC *CLIONE LIMACINA*. R.A. Satterlie*. Dept. of Zoology Arizona State Univ. Tempe, AZ 85287-1501.

Clione exhibit three forms of forward locomotion, including slow, fast and escape swimming. Escape swimming includes an initial startle response, in which the wings produce one or two extremely powerful wing cycles, followed by a variable period of fast swimming. A pair of motoneurons has been identified in each pedal ganglion, which appear to be involved in the startle phase of escape behavior. Spike bursts in these cells produce wing contractions that are up to five times larger than the largest contractions recorded during fast swimming. In addition, they have high activation thresholds and receive large inhibitory inputs from wing retraction circuitry. These "startle neurons" do not affect the swim pattern generator or swim motoneurons. Likewise, the swim generating circuitry does not influence the startle neurons. Startle neurons monosynaptically activate both types of swim muscles, fast-twitch fatigable and slow-twitch fatigue-resistant, indicating that the startle response utilizes the same musculature used during slow and fast swimming.

CHANGES IN BUCCAL MOTOR ACTIVITY DURING RECOVERY FROM BILATERAL CBC CRUSH IN *APLYSIA*. M.L. Scott*, Y. Li, and M.D. Kirk, Div. Biol. Sci., Univ. Missouri-Columbia, Columbia, MO 65211

Aplysia consummatory feeding behavior is selectively abolished by bilateral cuts of the cerebral-buccal connectives (CBCs); however, we recently showed that consummatory feeding recovers following bilateral CBC crushes, indicating the potential usefulness of crush lesions in studies of premotor organization and regeneration in the buccal system. Here we compare behavior with buccal motor activity using *in vivo* recordings during recovery from bilateral CBC crushes. Consummatory feeding behavior was tested using bite magnitude (BM), interbite interval (IBI), and interswallow interval (ISI) (Rosen et al., 1989). Motor activity was recorded during recovery and in unlesioned controls with cuff electrodes implanted on buccal peripheral nerve n4 (BN3). Control recordings show rhythmic activity correlated 1:1 with repetitive bites and swallows. After bilateral CBC crushes, BM decreased and IBIs became long and variable. A rhythmic bite criterion was used to evaluate animals during recovery. Animals not meeting criterion showed prolonged bursts of impulses occurring without overt behavior, and occasional bursts associated with infrequent, small magnitude bites. Rhythmic n4 activity could be reliably evoked beginning around day 9, with burst period (BP) and IBI longer than controls. Animals meeting criterion during recovery showed rhythmic n4 activity with bite BP similar to controls, however, bursts were not correlated 1:1 with behavior. ISIs and swallow BPs were normal as soon as they were observed after lesions. Our results suggest that separate subcircuits of the buccal CPG control biting and swallowing, and these subcircuits have different activation pathways. We are currently examining the cellular mechanisms of behavioral recovery *in vitro*. Supported by NIH grant RO1 NS30832 to MDK and Sigma Xi Grant-in-Aid of Research to MLS.

CANDIDATE COMMAND NEURONS FOR *APLYSIA* SWIMMING ARE TENTATIVELY IDENTIFIED IN CEREBRAL GANGLION.

J.E. Blankenship*, P.J. Laurienti and G.N. Gamkrelidze, Marine Biomed. Inst., Univ. Tx. Med. Branch, Galveston, TX 77555.

The marine mollusc *A. brasiliana* swims by rhythmic flapping of its bilateral parapodia. Each pedal ganglion contains motoneurons and serotonergic modulator neurons (POP cells) that innervate the parapodia and fire in phase with parapodial movements, generating a swim motor program (SMP) recorded from peripheral nerves. POP cells and a CPG in each pedal ganglion are driven by cerebral input(s) that initiate and maintain the SMP. A pair of candidate "swim command cells" in the cerebral ganglion have now been identified. Using fluorescence microscopy of fixed frozen sections, these cells were first localized in the C cluster of the cerebral ganglion by retrograde labelling with rhodamine-conjugated latex microspheres injected into pedal ganglia. One cell in each C cluster was found that, when penetrated with microelectrodes, made appropriate direct EPSPs onto POP cells and produced a weak SMP. Further characterization of these neurons will aid in understanding the neural circuitry underlying *Aplysia* locomotion. Supported by NIH, NINDS NS27314 and grant 2503-92 from the John Sealy Memorial Endowment Fund.

CO-ACTIVATION OF FUNCTIONALLY ANTAGONISTIC MOTONEURONS UNDERLIES THE HIGH SPEED OF HYDRAULIC EXPANSION OF PREY CAPTURE APPENDAGES IN *CLIONE LIMACINA*. T.P. Norekian* and R.A. Satterlie, Dept. of Zoology, ASU, Tempe, AZ 85287 and Friday Harbor Laboratories, Univ. of Washington, WA 98250.

The predatory pteropod mollusc *Clione limacina* catches its prey (pteropods of the genus *Limacina*) with specialized oral appendages called buccal cones, which become tentacle-like and grasp the *Limacina* shell. The eversion and elongation of buccal cones is a hydraulic phenomenon and is accomplished by squeezing hemocoelic fluid into the central cavities of the cones. This reaction is remarkably rapid and occurs within 50-70 msec. Two groups of motoneurons have been identified in the cerebral ganglia which underlie functionally opposite movements of buccal cones: extrusion and retraction. The high speed of buccal cone extrusion is presumably achieved through initial co-activation of antagonistic neurons which produces high pressure in the head hemocoel prior to buccal cone extrusion. Sudden inhibition of retractor motoneurons results in a very rapid and powerful inflation of buccal cones. Interneurons which evoke such co-activation are identified in cerebral ganglia.

INTERJOINT COORDINATION AND MUSCLE ACTIVITY IN LEGS OF DIGGING SAND CRABS. Z. Faulkes* and D. H. Paul. Dept. Biol., U. Victoria, Victoria, B.C., V8W 2Y2. E-mail: "zenf@uvvm.uvic.ca".

Sand crabs use their thoracic legs for digging into the sand. We analyzed digging movements of *Blepharipoda occidentalis* (Albuneidae) by videotaping animals and simultaneously recording electromyograms (EMGs) from their leg muscles. In some cases, EMGs do not completely predict the timing of the final joint movements. E.g., the opener and stretcher muscles move the dactyl and propus, respectively, and their EMGs are exactly synchronous, due to a shared excitatory motor neuron. Although the movements of both joints are temporally encased by the EMGs, the stretcher-generated movement *always* precedes the opener-generated movement, with *no* significant overlap of the two.

Serially homologous legs differ in their interjoint coordination: e.g., the sequences of joint movements in leg 4 differ from those of legs 2 and 3 (the most active digging legs), which are similar to each other. Similarly, muscle activity varies in serial homologues: e.g., leg 1's closer EMG bursts are significantly shorter than the other legs'. These specializations change the movements' final form: e.g., the tip of leg 4, when seen from the side, moves in the opposite direction from 2 and 3 (e.g., when leg 4 moves clockwise, 2 and 3 move counterclockwise).

A related species, *Emerita analoga* (Hippidae), digs much like *Blepharipoda*; the phasing of legs 2 and 3 is the same in both. There is, however, at least one marked difference between them: *Blepharipoda* switches gait during digging (from moving its contralateral legs alternately to synchronously) but *Emerita* does not.

NON-NMDA ANTAGONISTS AFFECT THE ABILITY OF TRIGGER NEURONS TO EXCITE GATING NEURONS IN THE SWIM MOTOR CIRCUITRY OF THE MEDICINAL LEECH. M.S. Thorogood* and P.D. Brodfuehrer, Dept. of Biology, Bryn Mawr College, Bryn Mawr, PA 19010

Using antagonists to glutamate, we have investigated the role of the excitatory neurotransmitter in the swim motor program of *Hirudo medicinalis*. In the medicinal leech, previous studies have shown that pressure ejection of L-glutamate onto the unpaired segmental gating neurons (cells 204) led to (1) prolonged excitation of cell 204 and (2) swimming of the intact, isolated ventral nerve cord. Stimulation of the paired subesophageal trigger neuron (Tr1) almost always elicits sustained depolarization of cell 204, often followed by swimming. In the presence of non-NMDA blockers i.e., Kynurenic acid, DNQX, GAMS, and L(+)-AP-3, Tr1 stimulation no longer produces sustained excitation of cell 204, and Tr1-induced swim episodes never occur. However these blockers do not eliminate the direct connection between Tr1 and cell 204, suggesting that Tr1 acts via an indirect, as well as a direct, pathway to depolarize cell 204. Further support of this hypothesis stems from previous immunocytochemical studies which revealed five pairs of glutamate-like immunoreactive neurons, none of which co-localized with Tr1. Additional experiments are currently underway to identify the putative glutaminergic cell(s), important in the activation of cell 204 and possibly swimming.

COMPARATIVE ANATOMY OF THE BASALAR MOTOR SYSTEM IN THE BLOWFLY, CALLIPHORA. A. Fayyazuddin*¹, M. Hummon², & M. Dickinson¹. ¹Dept. of Organismal Biology & Anatomy, Univ. of Chicago, Chicago, IL 60637; ²College of Osteopathic Medicine, Ohio Univ., Athens, OH 45701.

Unlike the large fibrillar muscles that power flight, the 17 pairs of tubular muscles responsible for turning behaviors in flies are under direct neural control. Because of their relatively large size and firing patterns during flight, we have focused on the three steering muscles that insert upon the Basalar process, the B1, B2, and B3. As a complement to ongoing physiological and biomechanical studies, we present here a basic anatomical description of motor neuron morphology and muscle ultrastructure.

By using multiple fluorescently labeled dextran probes, we have been able to compare the central dendritic morphology of the basalar motoneurons in the same preparations. Two the motor neurons, the B1 and B2, possess very similar branching patterns and presumably share many inputs, including a strong monosynaptic input from the haltere campaniform sensory neurons. In contrast, the B3 cell shows little common overlap with the B1 and B2. Peripherally, all three motor neurons branch extensively within their muscles and virtually cover the muscle fibers with synaptic varicosities. Despite this elaborate multiterminal pattern of innervation, the muscle fibers do fire overshooting action potentials.

Analysis of muscle ultrastructure has also revealed both differences and similarities within the Basalar motor system. All the muscles possess an extensive network of SR expected of direct flight muscles. Sarcomere length is shorter in the B1 than the B2, as is the distance between concentric rings of mitochondria in cross section. These structural differences may reflect the varied functional specializations of the Basalar muscles in flight, such as the B1 muscle's ability to fire continuously at wing beat frequency, and the B2's potent effect on wing stroke amplitude.

657.8

REGULATION OF SEGMENTAL SWIM-INITIATING INTERNEURONS BY A PAIR OF IDENTIFIED INTERNEURONS IN THE LEECH HEAD GANGLION. P.D. Brodfuehrer*, A. Burns and M. Berg. Dept. of Biology, Bryn Mawr College, Bryn Mawr, PA 19010.

The motor pattern evoked in a medicinal leech by the same mechanosensory stimulus varies from trial to trial. A large part of this variability stems from neural signals emanating from the head ganglion. With respect to initiation of swimming activity, it is clear that strong excitation of segmental-swim initiating interneurons (cells 204) is necessary. Thus one way that descending signals could bias the isolated nerve cord towards generating swimming in response to a given mechanosensory stimulus is by influencing the level of excitation in cells 204.

In the head ganglion of the leech we have found a pair of interneurons (cell Tr4) that can control the level of excitation in cells 204. Cells Tr4 are located in R2 on the dorsal surface of the subesophageal ganglion and have axons that extend at least until segmental ganglion 14. Brief intracellular depolarization (approx. 1 s) of a single cell Tr4 can, in some trials, trigger swimming activity. More striking, however, is the positive correlation between cell Tr4 spike frequency and cell 204 spike frequency. In fact, the level of excitation in cell 204 can be almost completely accounted for by Tr4's spike activity level. Each cell Tr4 spike matches one-for-one with all EPSPs in cell 204 and hyperpolarizing cell Tr4 eliminates all spiking activity and EPSPs in cell 204. Thus by modulating the spike frequency in cell Tr4 the general level of excitation in the swim generating system will simultaneously be affected and should directly influence the motor response produced in the leech by a given mechanosensory stimulus.

657.10

COMPARATIVE STUDY OF THE SENSORY SYSTEMS BETWEEN CAVE AND SURFACE AMPHIPODS. B. Hoyte, A. Nadel and I. Chow*. Dept. of Biology, The American Univ., Washington, DC 20016.

The antennae of the cave amphipod *Gammarus* are significantly longer and their eyes are notably smaller than their surface counterparts (Jones and Culver, 1988, *Evolution* 43:688-693; Fong, 1989, *Am. Midl. Natur.* 121:361-378). Whether these external differences are also expressed in the central nervous system of these amphipods was investigated using semi-serial sections of the supraesophageal ganglion and tracing the sensory inputs into the ganglion. The diameter of the optic ganglion was found to be significantly larger and the diameter of the olfactory lobe was smaller in the spring populations than in the cave animals. Tracing of the antennae sensory and the optic neurons with DiI and HRP will show if there is a replacement of the smaller visual system by the larger olfactory system, as a result of adaptation. (supported in part by a TAU Senate Research Award to I.C.)

ACTIVITY OF THE WING HINGE STRETCH RECEPTOR IN IMMATURE AND MATURE ADULT LOCUSTS. J.R. Gray & R.M. Robertson*, Dept. Biology, Queen's University, Kingston, Ontario, Canada, K7L-3N6.

The wingbeat frequency of the locust, *Locusta migratoria*, increases from 13 Hz at 1-2 days after imaginal ecdysis to approximately 23 Hz 14 days later. Comparison of intact and deafferented immature and mature locusts suggests that proprioceptive input is involved in flight maturation. We examined changes in the conduction velocity of afferent signals from the forewing stretch receptor and stretch receptor sensitivity to fixed and rhythmical wing elevation. The conduction velocity increased from 2.51 m/s in immature animals to 3.32 m/s in mature locusts. Fixed elevation of the forewing resulted in an initial increase in the firing frequency of the stretch receptor followed by a decrease to a constant, adapted frequency. Initial frequencies increased proportionally with wing elevation in immature and mature animals, however the mature frequencies were approximately three times higher. The response of the mature stretch receptor to rhythmic wing movements was characterized by bursts of four spikes precisely timed during maximum elevation. In immature animals there was only a single spike and in day 7 animals there were three spikes per burst with a lower intraburst frequency than that of a mature locust. We propose that the described changes in stretch receptor input during maturation may increase the output frequency of the central flight motor.

657.13

COMPARATIVE ANALYSIS OF FLIGHT INITIATION IN *DROSOPHILA MELANOGASTER* INDUCED BY VISUAL AND OLFACTORY STIMULI. J.R. Trimarchi* and A.M. Schneiderman. Sec. of Neurobiology and Behavior, Cornell Univ., Ithaca, NY, 14853.

We have identified two distinct types of flight initiation: visually elicited (escape) and non-visually elicited ("voluntary"). Although these behaviors differ in the movements of the wings prior to takeoff, the jumping phases of these behaviors are remarkably similar. The jumping phase of visually elicited flight initiation is coordinated by a pair of large interneurons, the giant fiber neuron. Through their connections with other interneurons and motor neurons, the giant fiber neuron sequentially activate escape response muscles that coordinate the stereotyped escape behavior. By monitoring activity in three escape response muscles—a dorsal longitudinal muscle (DLMa), a dorsal ventral muscle (DVMic) and the tergotrochanteral muscle (TTM)—we have confirmed that the pattern of muscle activation resulting from giant fiber neuron stimulation is identical to the pattern observed during visually elicited flight initiation. We analyzed the pattern of muscle activation during non-visually elicited flight initiation and found that although the sequence of muscles activated is identical to those activated during visually elicited flight initiation, the timing of specific muscle activation differs. In addition, we have found that the pattern of muscle activation elicited by a noxious olfactory stimulus (10% benzaldehyde) is identical to the pattern observed during non-visually elicited flight initiation. We are presently investigating the neural substrate coordinating muscle activation during non-visually elicited and olfactory-induced flight initiation.

FMRamide-RELATED PEPTIDES ASSOCIATED WITH THE VENTRAL NERVE CORD AND LEG MUSCLES OF THE COCKROACH (*PERIPLANETA AMERICANA* (L.)). A.J. Elia* and I. Orchard, Dept. of Zoology, University of Toronto, Toronto, Ont., Canada M5S 1A1.

The interphyletic existence of FMRamide-related peptides (FaRPs) is now well established. Less well established are the physiological roles these peptides play in the normal functioning of an animal or their effects on a known target tissue. We are studying the innervation and putative physiological roles of FaRPs on a known target tissue in the cockroach *Periplaneta americana* (L.). Using immuno-histochemistry we show the innervation pattern of FaRP-containing axons to muscles of the metathoracic legs. Of the peripheral nerve roots, only nerve 5 of each thoracic ganglion has FaRP-containing axon profiles which appear to project from the ganglion. The effects on muscle contraction of FaRPs isolated from nerve 5 have also been investigated. Using immunohistochemical, RIA, and HPLC techniques we outline the distribution of FaRP-containing cells associated with the nervous system.

ANALYSIS OF LEG MOVEMENTS EVOKED BY INTRACELLULAR STIMULATION OF NEURONS IN THE COCKROACH. J.T. Watson* and R.E. Ritzmann. Department of Biology, Case Western Reserve University, Cleveland, OH 44106.

A complete understanding of motor control circuitry requires detailed analysis of the movements produced by the circuitry as well as the connections between individual neurons. To implement biological principles into the design of legged robots, we are combining high speed video motion analysis of leg movements in the cockroach with electrophysiological techniques such as intracellular stimulation/recording from thoracic neurons and EMG recording from leg muscles. By incorporating motion analysis into our recording paradigm, we can derive the transfer functions from electrical activity to movements. We are currently using a restrained preparation to quantify movements by unloaded legs evoked by intracellular stimulation of individual motor neurons (MNs) and local interneurons (LIs).

We have observed slow MN activity which produced no movement of the leg, as well as activity which produced a slow movement to a new, maintained position. Fast and intermediate MNs produced transitory, highly damped movements with a consistent return point. Our results suggest that slow MN activity may interact with resting tonus to set limb positions, and to constrain and dampen movements. Stimulation of single MNs in unloaded legs consistently evoked single and multi-joint reflexes, showing a prominent role for proprioceptors in modulating MN activity.

We have also observed LIs which produce coordinated movements in multiple joints. Spiking LIs were found in which each action potential evoked a twitch in two muscles in separate leg segments. We plan to explore further the roles of fast and slow MNs, LIs and reflexes in the loaded leg and the walking animal. ONR grant N00014-90-J-1545 and NIH grant NS 17411.

657.14

MODULATION OF THE MECHANICAL OUTPUT OF A STEERING MUSCLE FROM THE BLOWFLY *CALLIPHORA* UNDER CONDITIONS MIMICKING FLIGHT. M.S. Tu and M.H. Dickinson*. Department of Organismal Biology and Anatomy, University of Chicago, Chicago IL 60637.

Of the 17 direct synchronous steering muscles in flies, the First Basalar (B1) stands out due to its ability to fire each and every wing beat at frequencies exceeding 200 Hz. Moreover, changes in the phase of B1 firing correlate with changes in the phase of wing pronation during turning maneuvers. Because of the potentially large aerodynamic forces generated during wing pronation, rapid modulation of the B1 output by changes in stimulus phase may be crucial for flight control.

We found that changing the phase of muscle activation significantly modulates the B1 output under conditions relevant to its function in flight. Because the B1 is mechanically coupled to the wing hinge and is subjected to cyclic length changes during each wing stroke, we measured muscle work output during forced length oscillations and phasic stimulation. At wing beat frequency (150 Hz), the B1 work output was negative. The mean energy dissipation increased monotonically with strain amplitude from 1.6 J/kg-cycle-1 at an amplitude of 1% resting length to 36 J/kg-cycle-1 at 7% resting length. Changes in stimulus phase at physiological strain amplitudes resulted in modulation of energy dissipation of $\pm 34\%$, and modulation in dynamic stiffness of $\pm 22\%$.

Negative work output at wing beat frequency may reflect underlying activation kinetics of the B1 necessary for dual functions during flight. Based on its isometric twitch duration of 19ms, the optimum operating frequency for positive work generation should be 26 Hz, and indeed the B1 can generate positive work at 50 Hz or less. During flight, the B1 muscle may function as an elastic element which can be fine tuned by the nervous system. Our observations indicate that the mean muscle tension has a tonic effect on wing kinematics, while changes in neural input can significantly alter the oscillatory component of the B1 output.

STROLLING ON THE CEILING: EFFECTS OF LOAD INVERSION IN COCKROACH WALKING. G.S. Larsen, S.F. Frazier and S.N. Zill*. Dept. Anat., Marshall Univ. Sch. Med., Huntington, WV 25755

In order to maintain dynamic postural stability, animals must generate movements and muscle contractions to adapt walking patterns to variations in load. We have examined how cockroaches resolve this problem in an extreme case, when they walk upon an inverted surface. Animals were videotaped while myograms were recorded in the tibial extensor and flexor muscles of the middle or hindlegs. In upright walking, tibial muscles showed stereotyped discharges: the flexor fired during swing and the extensor in stance, although co-contractions occurred early in stance at slow walking speeds. In inverted walking, leg movements and patterns of muscle activities were adaptively altered. Flexor bursts were prolonged and served both to move the leg in swing and support the body early in stance by pulling the animal toward the substrate. Extensor firing occurred only late in stance to propel the animal forward. These findings are compatible with a model in which stance is divided into an early support and subsequent propulsion phase. Muscle activities are apparently adapted in the support phase to variations in leg loading. We are currently examining the types of leg sense organs that can contribute to these adaptive modifications.

A BIOMECHANICAL MODEL OF THE COCKROACH LEG. W.J. Marx, R.D. Beer*, G.M. Nelson, R.D. Quinn, G.A. Crocker. Depts. of Biomedical Eng., Computer Eng. and Science, and Mechanical and Aerospace Eng., Case Western Reserve University, Cleveland, OH 44106.

We are in the process of creating a computer model of walking in the American cockroach. An important step of this research program is the construction of a realistic model of the insect's periphery. This model must ultimately include some representation of the insect body and realistic models of the legs and associated musculature and sensory structures. To date, we have formulated a dynamic model of a single leg with five degrees of freedom. The Thorax-Coxa joint is modeled with three degrees of freedom, while the Coxa-Femur and Femur-Tibia joints are modeled with one degree of freedom each. By modifying the basic geometric and kinetic parameters of this model, it can be applied to all three pairs of legs.

Our initial studies with this model are focusing on the Femur-Tibia joint of the metathoracic leg. This joint provides one of the simpler neuromuscular structures of the leg and yet is very important in both walking and turning movements. Eventually neurobiological data on neural control (see poster by Watson and Ritzmann) will be incorporated into this peripheral model. The model will be integrated into an existing graphical simulation environment which allows the experimenter to observe the behavior of the model and manipulate it interactively.

We hope to use this model to address the following properties: (1) The synthesis of data on individual motor neurons and interneurons into an understanding of total leg movement; (2) The relative roles of fast, slow and intermediate motor neurons in generating various leg movements; (3) The role of complex leg reflexes in smooth and accurate movement.

CRAYFISH ABDOMINAL POSITIONING INTERNEURONS DRIVE MOTOR ACTIVITY IN THE TAIL FAN J.A. Burdohan and J.L. Larimer*. Dept. of Zoology, University of Texas, Austin, TX 78712.

The role of interneurons producing abdominal positioning behaviors (flexion or extension), in crayfish (*Procambarus clarkii*), has been reviewed recently (Larimer TINs 11:506, 1988). Our goal in this study was to determine whether abdominal positioning interneurons (APIs) are capable of coordinating both abdominal positioning movements and those of the tail fan. Intracellular recording and dye injection techniques were used to locate and identify interneurons that originated in abdominal ganglia, and were able, when stimulated, to drive motor activity in anterior abdominal and/or uropod motor roots.

Over 60 interneurons have been examined thus far. Two general groups of neurons can be defined physiologically: Those that activate motor neurons only within anterior abdominal segments, and those that drive motor activity in the uropods as well. Among the latter class are interneurons that drive postural activity both anteriorly and posteriorly with respect to the recording site, and those with output biased in only one direction. There are APIs that increase (and/or recruit additional) motor activity in both main uropod motor roots, those that drive activity in only one of the uropod motor roots, and those that excite motor neurons in one uropod root while inhibiting activity in the other root.

Dye filling revealed several classes of neurons, some of which resemble APIs described previously. Interneurons of the abdominal positioning system are therefore concerned not only with the control of the abdominal segments but the uropods as well. Finally, we have shown in previous studies that abdominal positioning interneurons affect the swimmerets as well as the abdominal segments (Murchison and Larimer J. Comp. Physiol. 170:739, 1992). We are now examining the effects these APIs have on the swimmeret and thoracic leg motor systems. (Supported by NIH NS05423 to JLL).

MIXED CHEMICAL AND ELECTRICAL SYNAPTIC INPUTS TO THE LATERAL GIANT INTERNEURON OF CRAYFISH S.R. Yeh, C.A. Opydyke and D.H. Edwards* Dept. of Biology, Georgia State University, Atlanta, GA 30302-4010

The crayfish responds to a sharp tap on the abdomen with a tailflip triggered by the Lateral Giant (LG) interneuron. The tap excites mechanosensory receptors on the abdominal surface that excite LG through monosynaptic connections. These synapses were identified as electrical because their transmission delay is near zero and their EPSPs follow reliably at stimulus rates up to 400 Hz (Zucker, 1972). More recently, the EPSPs have been shown to vary with post-synaptic membrane potential in a manner consistent with rectifying electrical synapses (Edwards, et al., 1991). We report that the afferents can be dye-coupled to LG, which indicates that the synapses contain gap junctions that should pass electrical current as well as dye molecules. We also report that the LG EPSP can be partially and reversibly blocked with bath-applied nicotinic cholinergic blockers (mecamylamine, hexamethonium), consistent with the presence of chemical synapses between the afferents and LG. We do not yet know whether the same afferent can mediate both forms of transmission. The cholinergic blockers have their greatest effect on just-subthreshold EPSPs, and little effect on much smaller EPSPs. The low-threshold afferents may excite LG only through electrical synapses, whereas the high-threshold afferents make cholinergic and possibly electrical synapses with LG. Dye coupling and synaptic blockage occur in 1-2 cm juvenile crayfish and in 8-12 cm adults, showing that both forms of synaptic input to LG are present in early postembryonic development. Supported by NIH research grant NS26457.

SEGMENTAL VARIATION IN MECHANOSENSORY REFLEX CIRCUITS IN *MANDUCA SEXTA* W.C. Lemon* and R.B. Levine. Div. of Neurobiol., Univ. of Arizona, Tucson, AZ 85721.

Stimulation of mechanosensory hairs on any abdominal segment of larval *Manduca sexta* produces a prolonged bending reflex involving the whole abdomen. When they later become part of pupal gin traps, stimulation of sensory neurons in segments 5-7 evokes a rapid bend of the abdomen only in the gin trap segments. In this study, we asked the extent to which motor activity in all segments was influenced by stimulation of sensory neurons in one segment, and how the motor patterns differed among the segments. Electrical stimulation of the sensory nerve in isolated nerve cords and mechanical stimulation of the sensory hairs in semi-intact preparations were used to evoke reflex responses that were recorded intracellularly and extracellularly from motor neurons of fifth instar larvae and day 0 pupae. Although the motor responses are quite different in larvae and pupae, stimulation of one segment evokes motor responses in many segments in both stages despite the segmentally restricted movement observed in pupae. Furthermore, stimulation of sensory nerves in all abdominal segments, including pupal segments that do not contain gin traps, evokes motor responses. The motor patterns differ, however, according to the segment stimulated, with anterior segments causing weaker, delayed responses. These findings indicate that developmental changes in mechanosensory reflex circuits occur throughout the abdominal nerve cord, although the expression of the pupal behavior is limited to the three articulated segments. COMPUTATIONAL MODELING OF THE MUSCULOSKELETAL SYSTEM OF THE LOBSTER GASTRIC MILL K. Doya*, M. E.T. Boyle, M. Beauchamp, and A. J. Selverston. Dept. of Biology, U. C. San Diego, La Jolla, CA 92093-0332.

The lobster stomatogastric ganglion (STG) is one of the best-studied neural systems at the circuit, cellular, synaptic, and molecular levels. However, little is known about the relationship between oscillation patterns recorded from *in vitro* preparations and the actual digestive motion patterns of live animals. In order to fill the gap between neural activity and physical movements and to elucidate the role of STG network as the controller circuit, we built a computer model of the musculoskeletal system of the gastric mill.

The lobster gastric mill is a set of ossicles (teeth) that grind food in the foregut. Semi-intact animals were used to video record the movement of the ossicles and the muscles both from the dorsal side with the shell removed and from inside the stomach using an endoscope. Some of the muscles were dissected out and then stimulus-tension characteristics were measured.

The model consisted of five ossicles, six muscles, and associated connective tissue. The muscles were modeled based on A. V. Hill's formulation. The mechanical system had 10 degrees of freedom and a quasi-static approximation was used because the movement of the teeth were very slow (0.1-0.2 Hz). The output pattern of five motoneurons from the *in vitro* preparations were used as the input to the muscles. The model reproduced movement patterns that are qualitatively similar to the actual motion of the gastric mill observed by the endoscope. Supported by ONR N00014-91-J-1720 and NIH RO109322.

POSTEMBRYONIC REORGANIZATION OF A REFLEX CIRCUIT IN *MANDUCA SEXTA* J.L. Casagrand* and R.B. Levine. Div. of Neurobiol., Univ. of AZ, Tucson, AZ 85721.

Manduca pupae possess three paired gin traps that develop during the last 4-5 days of the larval stage (wandering). Stimulation of the gin trap sensory hairs in pupae results in a contraction of the intersegmental (ISM) muscles in the ipsilateral half of the next anterior segment. Although the sensory neurons are retained from the larval stage, larvae do not possess gin traps and stimulation of the sensory hairs evokes either no response, or a slow bending of the animal towards the stimulated side. As wandering stage animals approach pupation, they become more responsive to sensory hair stimulation, and the evoked behaviors more resemble those in pupae. Immediately after pupal ecdysis, there is a dramatic increase in the reliability of the reflex and less habituation of the behavior.

The activity recorded intracellularly in ISM motor neurons evoked by stimulation of the sensory nerve is quite different in larvae and pupae. Pupal responses are shorter in duration and exhibit a triphasic pattern of activity not seen in larvae. We have found that the responses recorded in ISM motor neurons in isolated nerve cords changes gradually during the wandering stage. Motor responses on the first day of wandering more closely resemble those from larvae, whereas activity in ISM motor neurons on the day before ecdysis are often indistinguishable from pupae. Thus, the circuit for the pupal behavior appears to develop gradually during the wandering period, and an abrupt increase in reliability of the reflex coincides with ecdysis.

DESCENDING THORACIC INPUTS TO AN IDENTIFIED MOTONEURON REGULATE ITS RHYTHMIC ACTIVITY DURING ECDYSIS BEHAVIOR AND ITS SUBSEQUENT DEVELOPMENTAL DEATH A.W. DeLorme¹, K.A. Klukas¹, S.E. Fahrback², and K.A. Mesce¹. ¹Dept. of Entomology and Graduate Program in Neuroscience, University of Minnesota, St. Paul, MN 55108 and ²Dept. of Entomology and Neuroscience Program, University of Illinois at Urbana-Champaign, Urbana, IL 61801.

In the moth *Manduca sexta*, abdominal motoneuron 12 (MN-12) undergoes developmental cell death within four days of adult ecdysis. Ecdysis is the shedding of the old cuticle. If anterior neuronal inputs to MN-12 are removed, the MN-12 neuronal soma is spared from programmed cell death. Until now, the sparing effect on the cell's overall morphology and electrophysiology was not known. We provide quantitative evidence of a robust sparing effect. Electrophysiological measurements of spike height, spike duration at half amplitude, resting membrane potential, and input resistance show no significant differences between normal pharate adult MN-12 cells and spared MN-12 cells. Comparisons of the major arborization patterns show no difference between spared and pharate adult MN-12 cells. Currently, we are examining the changes in MN-12 cells as they undergo the normal progression of programmed cell death. Preliminary evidence suggests that MN-12 cells function normally 2 days after ecdysis, when they can no longer be spared and show initial histological evidence of degeneration. We have also developed an *in situ* preparation in which we can record intracellularly from MN-12 as the animal undergoes adult ecdysis. Our data show that MN-12 cells undergo massive depolarizations that correlate with rhythmic thoracic wing shrugging, an adult specific component of ecdysis behavior. This indicates that MN-12 is involved in adult ecdysis behavior and receives descending neuronal inputs from the thorax during ecdysis. We are attempting to determine what role these anterior, descending, neuronal inputs may have in the developmental death of the MN-12 neurons.

MULTISEGMENTAL ORGANIZATION OF THE PUPAL GIN TRAP CLOSURE REFLEX IN THE MOTH, *MANDUCA SEXTA*. B. Waldrop* Department of Zoology, University of Oklahoma, Norman, OK 73019

Movement of tactile hairs in a pupal gin trap triggers a rapid and specific closure. The reflex requires at least three segments: sensory axons from a gin trap in the fifth abdominal segment (A5) ascend ipsilaterally in the CNS to A4, and the motor neurons are in A3. In an isolated nerve cord, the motor response consists of a stereotyped pattern of excitation and inhibition of ipsilateral and contralateral motor neurons. This response pattern corresponds to closing and reopening a stimulated gin trap.

Isolation of ganglia A3-A5 allows production of the normal motor pattern. After cutting the right A4-A5 hemiconnective, normal motor responses can be elicited by stimulating the (uncut) left A5 sensory axons. Stimulation of (cut) right A5 sensory axons produces ipsilateral excitation, but not the full closure response. The sensory axons coming into right A5 must reach ascending neurons on the left side, but they do not seem to have access to the normal patterning circuitry. Stimulation of the rostral end of the cut hemiconnective can elicit a normally patterned response. Cutting the entire A4-A5 connective eliminates all physical access of the A5 sensory axons to the motor neurons. Stimulation of sensory axons in A3, however, can elicit patterned motor responses in the A3 motor neurons, although the patterns are generally not typical of the closure reflex. Isolation of ganglion A3 still permits some ipsilateral-contralateral patterning by stimulation of A3 sensory axons, but again, these patterns are not typical closure reflex responses. The results are consistent with a patterning circuit located in A3 with the motor neurons' dendrites, but accessed differently depending on the pathway used.

CRAWLING IN LEECHES: INVOLVEMENT OF NEURONS IN MIDBODY GANGLIA AND THE TAIL BRAIN. A.P. Baader* and W.B. Kristan, Jr., Dept. of Biology 0322, University of California, San Diego, La Jolla, CA92093-0322.

In addition to swimming, leeches locomote by crawling, a complex rhythmic behavior comprising alternating extensions and contractions of the whole body. Transection experiments have shown that the nervous system in both the head and the tail ends of the animal are sufficient to produce all the behavioral subcomponents of crawling. Experiments with tethered crawling leeches, have uncovered interneurons and motoneurons in the tail brain that are modulated at various phases of crawling steps. The morphology of these neurons is unlike any seen in the midbody ganglia. The activation patterns of some neurons in the tail brain indicate very fast-conducting pathways to the head brain.

Electrical stimulation of mechanosensory cells in midbody ganglia increase the probability of the initiation of crawling steps. Some but not all of these sensory units also receive rhythmic postsynaptic re-afferent drive during the performance of crawling steps. Future studies on the tail ganglion will determine its role in the initiation and coordination of crawling behavior. Supported by an NIMH research grant (MH43396 to W.B.K.), and a DFG fellowship (A.P.B.).

HUMAN COGNITION: VISION, METHODS

658.1

INTERACTION OF MULTIPLE CUES IN 3D SHAPE DISCRIMINATION. Scott McDaniel and William H. Merigan*, Center for Visual Science, University of Rochester, Rochester, N.Y. 14642.

These experiments attempted to discover how observers base their discrimination on more than one object feature during an object discrimination task. We chose two feature dimensions along which objects may vary (curvature of the long axis of symmetry and shape of the object cross section), and constructed a series of photorealistically rendered objects which differed along one or both dimensions.

Subjects discriminated among objects varying only in curvature, only in cross sectional shape, or in both features together, using a same-different task. There were five levels of curvature and five levels of shape; separated by one just noticeable difference (jnd) along the respective dimension. Subjects' thresholds for discrimination of objects varying in both shape and curvature was close to their thresholds for discriminating either shape or curvature alone. The effect of uncertainty was measured by mixing trials in which object differed in either curvature or cross sectional shape. Unlike previous experiments in which uncertainty caused a small elevation of both thresholds, this manipulation devastated curvature discrimination, but had little effect on shape discrimination. This result suggest that when faced with difficult discriminations, subjects may monitor multiple dimensions despite decreased sensitivity for both, or monitor only a single dimension, thus losing sensitivity only on the dimension not monitored.

PSYCHOPHYSICAL DEACTIVATION OF THE MAGNOCELLULAR CHANNEL WITH PERCEPTION AND RECOGNITION OF TWO-COLOR PICTURES OF FACES. H.R. Bliem (SPON: European Neuroscience Association). Department of Psychology, University of Innsbruck, Inrain 52, A-6020 Innsbruck, Austria.

Fast and reliable recognition of faces depends mainly on the processing of configurational information reflecting relational properties of eyes, nose and mouth within a face. The well known information processing properties of the magno-system (Livingstone and Hubel, *J. Neurosci.* 7:3416, 1987) include linking properties probably underlying the processing of configurational information of faces. It is, therefore, predicted that face perception and recognition should fail at isoluminant stimuli conditions. To test this hypothesis five two-tone picture categories were derived from multi-tone original b/w pictures of faces displaying only internal facial features: two-color pictures and two-tone b/w pictures at high (90%) and low (9%) luminance contrast, and two-color pictures at isoluminance.

The first experiment demonstrates that 35% of all subjects without any experience with two-color faces, who were shown a two-color face at isoluminance for 10 sec, did not perceive a face or even a face-like structure. There was no difficulty in perceiving a face with the other four picture categories. In the second experiment subjects had to recognize faces in the above described five different picture categories. In the inspection phase faces had been presented as multi-tone original b/w pictures. Error score was significantly ($p < 0.001$) higher with isoluminant face stimuli compared to all other stimuli conditions.

These results strongly support the view that the color-blind and luminance contrast-sensitive magno-channel is important for the processing of configurational information of faces and innervates face specific neural mechanisms in the temporal lobe. This work is complemented by previous experimental investigations on movement-specific activation of the magno-channel with face recognition (Bliem, *Perception* 19:405, 1990).

ELECTROPHYSIOLOGICAL CORRELATES OF THE ADAPTATION TO LEFT-RIGHT REVERSED VISION. Y. Sugita* K. Mimura and T. Ohta. Lab. for Neural Systems, Toyohashi Univ. of Technology, Toyohashi, 441 Japan.

The reversal, inversion, or displacement of the retinal image leads to extreme disruption of visually guided behavior. But, after an extended period of visual transformation, the seen would appear stable and the subjective visual normalcy is gradually restored. Adaptation to such optical distortions appeared to result in a change in visual perception. It has been claimed, however, that the adaptation consists mainly of learning specific motor response, adjusting the state of the relevant sensorimotor control system, or a proprioceptive change in the felt position of parts of the body. We report here an electrophysiological correlate of the adaptation recorded from the human visual cortex. Light flash presented on the left or right side of the fixation elicited visually evoked potentials (VEPs) of different waveforms in the two hemispheres. Wearing the left-right reversing spectacles resulted in the change in the distribution of the VEP components over the occipital region. However, after prolonged exposure to the spectacles, the VEP distribution changed again and even became similar to those measured at prewearing period, indicating that the adaptation takes place even in the relatively early stage of the visual information processing.

VISUAL RECALL WITH EYES CLOSED AND COVERED ACTIVATES EARLY VISUAL CORTICES. H. Damasio*, T.J. Grabowski, A. Damasio, D. Tranel, L. Boles-Ponto, G. L. Watkins, R. D. Hichwa. Depts. of Neurology & Radiology, Univ. of Iowa College of Medicine, Iowa City, IA 52242.

We are all able to generate internally images of entities with which we are familiar in the absence of those entities. Varied visual properties (e.g. shape, movement, color) can be conjured up coherently and attended in consciousness. In order to investigate the pattern of neural activity that correlates with visual recall, we investigated the activity in early visual cortices in 5 normal subjects tested under 3 conditions [each of which was performed twice] using [^{15}O]- H_2O PET. In condition #1 the subjects were instructed to listen intently to a selection of music. In condition #2 they created mental images of specific places and persons familiar to them, and inspected them in detail. New images were suggested by an audioverbal cue, every 10 sec. In both of these conditions, the eyes were closed and covered. In condition #3, subjects viewed passively a series of nonrepresentational black and white slides, presented at a rate of one every 5 sec. Data were analyzed with two approaches using (a) PET-Brainvox, an anatomically based method, with regions of interest defined *a priori*, and (b) change distribution analysis [CDA] (adapted from Fox et al, 1988).

During visualization, both methods demonstrated increases in cerebral blood flow in a region containing V_1 and V_2 . CDA identified a local maximum with a Z-score 3.1, and stereotactic coordinates which corresponded to calcarine cortex in all subjects. Analysis of activity confined to the region of V_1/V_2 , defined *a priori* on coregistered MR images using PET-Brainvox, suggested that the increase in cerebral blood flow was distributed throughout the posterior half of the calcarine region.

These findings are consistent with the hypothesis that the neural correlate for explicit mental visual representation is a set of transient activity patterns in early visual cortices, in conformity with the convergence zone framework.

658.5

A TECHNIQUE FOR THE NEUROANATOMICAL ANALYSIS OF FUNCTIONAL BRAIN IMAGES. T.J. Grabowski*, H. Damasio, R. Frank, L.L. Boles Ponto, G.L. Watkins, R.D. Hichwa, M. Rizzo, M. Nawrot. Depts. of Neurology, Radiology and the Image Analysis Facility, University of Iowa, Iowa City, IA 52242.

We have developed a technique for the neuroanatomical interpretation of functional brain images (PET-Brainvox). This interactive brain rendering software clarifies individual structural-functional anatomical relationships in coregistered MRI and PET datasets. *A priori* registration depends on a pair of spectacles with paramagnetic fiducial markers. These markers are fixed with respect to the PET slice planes using the gantry lasers at the time of PET acquisition. PET-Brainvox resamples the MR volume in the PET planes.

The reliability of the positioning of the glasses across serial scans in 4 normal subjects was assessed with the *post hoc* registration method of Woods, *et al.*, 1993. We obtained root mean square errors of $< 1.5^\circ$ of rotation around all axes and translational errors of $< 2\text{mm}$ in all axes. Brain phantom studies demonstrated an average 3D mapping error of 2.6mm. In human subjects, average in-plane (x- and y-axis) translational errors of 2.3 and 2.8 mm, and in plane rotational errors of 1.0° have been encountered. Analytical techniques sensitive to the residual misregistration (e.g. pixel-by-pixel subtraction) may require a *post hoc* mathematical registration step, but our approach provides the requisite starting point, permitting automated fitting.

This method offers the following advantages: 1) the interrogation of the functional image with regions of interest based *a priori* on the MR images. This approach was validated for retinotopic mapping with $[^{15}\text{O}]\text{-H}_2\text{O}$ PET (after Fox, *et al.*, 1987); 2) the modelling of PET gantry movement permits the advance planning of PET slice position; 3) construction of a stereotactic coordinate system (Talairach space) directly from brain landmarks, and 4) the assessment of anatomical structures corresponding to specific stereotactic coordinates.

COMPONENTS OF THE VISUAL EVOKED POTENTIAL IDENTIFIED BY TOPOGRAPHIC MAPPING: EVIDENCE FOR MULTIPLE VISUAL STREAMS IN HUMANS. V.P. Clark, F. Silu, N. Herold, T.C. Rubin, and S.A. Hillyard. Dept. of Neurosciences, U. C. San Diego, La Jolla, CA 92093-0608.

Multi-channel visual evoked potentials (VEPs) were recorded in 24 normal human subjects in response to a small circular checkerboard stimulus (radius 1.15° , check size $35'$, luminance 70cd/m^2) that was flashed over a range of isocentric visual field positions. Temporally and spatially overlapping components were distinguished and characterized by differences in retinotopic sensitivity and source location, as evidenced by changes in amplitude and topography of scalp voltage and current density. The Brain Electric Source Analysis (BESA) source localization algorithm, and magnetic resonance images (MRIs) of cortical topography, were also employed to help determine the identities of VEP generators. Using these methods, the C1 and P1 components have been localized to striate and lateral extrastriate cortex, respectively.

The N1 complex of components (90-180 msec) was found to originate from several distinct generators. The N100p was present in occipito-parietal scalp locations, and varied little in amplitude across visual field locations. Immediately afterwards, the N150op component increased in negative amplitude (by a sigmoid function) and changed somewhat in topography with decreasing stimulus elevation. In contrast, the contralateral N160ot and ipsilateral N170ot were largest at occipito-temporal scalp sites, and showed almost no change in voltage or current density amplitude with changes in stimulus elevation. The topography and retinotopic properties of the N150op and N160/N170ot components displayed characteristics of the dorsal and ventral visual pathways, respectively, which have been described in lower primates. The N150f was maximal at frontal scalp sites and also showed little change in amplitude across visual field locations. An additional sink in the right temporal lobe (the N140t) was observed for both left and right field stimuli. No symmetric left hemisphere sink was observed. This sink did not change its topography systematically as a function of stimulus position. Further research is being performed to determine the sensitivity of these components to manipulations of selective attention.

658.9

A COMPUTERIZED SYSTEM FOR DETERMINING PIXEL-BY-PIXEL CORRELATIONS OF FUNCTIONAL ACTIVITY MEASURED BY POSITRON EMISSION TOMOGRAPHY (PET) B. Horwitz*, J. Maisog, P. Kirschner, M. Mentis, K. Friston† and A.R. McIntosh. Lab. Neurosci., NIA, NIH, Bethesda, MD 20892, and †The Neurosciences Institute, New York, NY 10021.

Pixel-based approaches to analyzing functional neuroimaging data (such as PET measurements of regional cerebral blood flow - rCBF) have been used to study the functional organization of the human brain. One widely used method is Statistical Parametric Mapping (Friston *et al.*, 1989,1990,1991). There have also been many studies evaluating the integration and connectivity of distributed areas using interregional correlations in PET functional data (e.g. Horwitz *et al.*, 1984,1992). We have developed a system for performing such correlational analysis on a pixel-by-pixel basis. The system, which is compatible with SPM programs, starts with PET data that have been stereotactically normalized to the Talairach space (Friston *et al.*, 1990) and smoothed, which results in each pixel representing the regional activity of its local neighborhood. Correlations, calculated on values normalized to global activity, can be performed on data from each run of an rCBF study separately, or on a weighted averaging of data across runs. Options for correlation analysis include: (1) correlations between one pixel and every other pixel, and (2) mutual correlations within a list of pixels. Examples of each will be provided using data obtained during a study of visual processing (Haxby *et al.*, 1991).

658.6

NETWORK ANALYSIS OF OBJECT AND SPATIAL CORTICAL VISUAL PATHWAYS MAPPED WITH PET. A.R. McIntosh*, C.L. Grady, L.G. Ungerleider¹, J.V. Haxby, S.I. Rapoport and B. Horwitz. Lab. of Neurosciences, National Institute on Aging, ¹Lab. of Neuropsychology, National Institute of Mental Health, NIH, Bethesda, MD 20892 USA

Brain imaging with positron emission tomography (PET) can provide information about the functional interactions within entire neural systems, and therefore a network analysis is necessary to quantify these complex interactions. A network analysis was performed on data from a PET study of regional cerebral blood flow (rCBF) during performance of a face matching (object vision) and dot-location matching (spatial vision) task in 17 young adult right-handed males. Brain areas for the network were selected from comparisons of regional means and covariances between tasks. An anatomical network connecting selected areas represented two parallel pathways: a ventral pathway involving occipital and temporal areas extending into frontal area 46 and a dorsal pathway involving occipital and parietal areas also extending into area 46. The anatomical network and interregional correlations were analyzed using structural equation modeling to quantify the functional influence of each directional path. This created a functional network for each task. The functional network for the right hemisphere showed that in the object vision task, dominant interactions were in the ventral pathway while in the spatial vision task, interactions in the dorsal pathway were stronger. The network for the spatial vision task also had a strong feedback path from area 46 to occipital cortex, an effect which was absent in the object vision task. Functional networks for the left hemisphere did not differ between tasks. Networks for the interhemispheric interactions showed strong contralateral effects from the right hemisphere on homologous left hemisphere areas suggesting that intrahemispheric interactions were greater in the right hemisphere in both tasks, and that these influences were transmitted callosally to the left hemisphere.

658.8

VISUAL EVENT-RELATED POTENTIALS TO COLOR, LOCATION, AND ORIENTATION DISCRIMINATION. B.F. O'Donnell*, J.M. Swearer, & L. Smith. Psychiatry, Brockton VAMC & HMS; Neurology, U Mass Medical School. Neurophysiological studies suggest that the anatomical substrates of color, orientation, and location discrimination differ in primates, but these differences have been less well documented in humans. We measured scalp recorded event-related potentials (ERPs) during discrimination tasks from 28 electrode sites using a nose reference from 12 subjects. ERPs were collected both to low-probability ($p = .16$), target stimuli and high-probability, non-target stimuli in order to generate the cognitively modulated N2 and P3 components as well as the earlier N1 component (at 170 ms). 400 trials were presented for each condition with a 1400 ms ISI and a stimulus duration of 200 ms. EEG was sampled with a bandpass of 0.15 to 40 Hz. N1 topography was sensitive to the visual field of stimulation, with contralateral activation to lateralized stimuli across the entire hemisphere, and symmetric activation primarily over the occipital region to central stimuli ($p < .01$). N2 topography varied as a function of discrimination task (color, position, and orientation, $p < .03$). P3 did not vary as a function of spatial location or discrimination task. These data suggest that the N2 component may reflect activation of neuronal populations supporting a task-specific perceptual representation, while the P3 component reflects a cognitive process which is independent of a specific representation.

SPATIAL IMAGING AND TEMPORAL DYNAMICS OF VISUAL BRAIN-ACTIVATION THROUGH INTEGRATION OF ELECTROPHYSIOLOGICAL (ERP) AND HEMODYNAMIC (fMRI) MEASURES. G.V. Simpson*, J.W. Belliveau², J.J. Foxe¹, J.R. Baker², and H.G. Vaughan Jr.¹ Depts. Neurology & Neuroscience, Albert Einstein College of Medicine, Bronx NY 10461 and ²MGH-NMR Ctr., Dept. Radiology, Harvard Medical School, Boston MA 02114

Use of fMRI activation maps to improve the spatial estimates of ERP dynamic source activity may yield unprecedented spatial and temporal characterization of the dynamic networks underlying perceptual and cognitive operations. Sources of brain activation to identical visual stimuli were obtained for both physiological measures (event related brain potential source analyses and functional magnetic resonance imaging). Retinotopic stimulation was used in order to examine the spatial convergence of the two methodologies with reasonably well defined cortical regions. Checkerboard wedges (50 deg annuli) were presented at central (1-4 deg.) and peripheral (4-10 deg.) locations in each quadrant (30 ms duration, 365 ms ISI). ERPs were recorded from 64 channels (Neuroscan system) and sources were estimated with a spatiotemporal dipole source analysis system (Brain Electromagnetic Source Analysis-BESA). fMRI cortical activation was measured (1.5 Tesla GE Sigma modified by Advanced NMR) using an oxygen-sensitive gradient echo imaging sequence (TR=500 ms, TE=50 ms) and a T1-sensitive (blood-flow) spin echo inversion recovery sequence. The expected retinotopic pattern of activation was found for both hemodynamic and electrophysiological measures, i.e., left vs right and inferior vs superior visual field stimulation resulted in right vs left and superior vs inferior calcarine activation, and more peripheral visual field stimulation (1-4 vs 4-10 degrees eccentricity) resulted in more anterior calcarine activation. There was good convergence of both cortical activation measures, reinforcing the electrophysiological location estimates and providing temporal activation characteristics (in milliseconds).

INTEGRATION OF P300 EVOKED POTENTIALS WITH MAGNETIC RESONANCE IMAGES (MRI) TO IDENTIFY DIPOLE SOURCES IN HUMAN BRAIN. **S.E. Lukas¹, M. Sholar¹, D.L. Stredney², M.W. Torello², S. May², and F. Scheepers²**. ¹Alcohol and Drug Abuse Research Center, McLean Hospital/Harvard Medical School, ²Ohio State University Advanced Computer Center for the Arts and Design.

Most procedures for identifying the source of brain electrical activity rely on mathematical models that assume that the head and brain are a perfect sphere making the precise location of a calculated dipole difficult to determine. The present study was conducted to match the calculated source of the P300 evoked potential with MR images. Adult male subjects provided informed consent and were prepared with 21 scalp EEG electrodes. P300 waveforms were generated using an auditory "oddball" paradigm and estimates of the equivalent dipole were made using a 1-source inverse procedure (Bio-Logic). EEG electrodes were then removed and vitamin E capsules were glued to the electrode sites with collodion to provide a common set of reference points between modalities. MRI images were generated (G.E. Sigma 1.5 Tesla Whole Body Imager) and volumetric representations were built from contiguous MR slices. These consisted of three-dimensional arrays of voxels containing intensity values. Voxel coordinates were converted to millimeter-unit coordinates by a simple scaling transformation. Dipole data provided an estimate of the location, direction and magnitude of the P300 source. A common reference frame was developed using the voxel locations most representative of the nasion/inion and preauricular points (FPz, Oz, T3 and T4). An orthonormal reference frame based midway between the closest approach of FPz/Oz and T3/T4 was constructed. The Y-axis (superior/inferior) of the reference frame is perpendicular to both FPz/Oz and T3/T4, and the X and Z axes are approximately parallel to FPz/Oz and T3/T4, respectively. Finally, the required transformation was derived by taking the inverse of the transformation that takes the voxel reference frame to the dipole reference frame. All calculations and resultant visualizations were performed on a Silicon Graphics CRIMSON VGXT or a Sun IPX. These images provided direct visualization of both electrical and anatomical information and suggest that the hippocampus is the most likely source of the P300. SOURCE LOCALIZATION AND INTERBRAIN COMPARISONS USING CORTICAL SURFACE RECONSTRUCTIONS. **A.M. Dale^{*} and M.L. Sereno**. Cognitive Science Department 0515, University of California San Diego, La Jolla, CA 92093.

The cortical surfaces from 10 human hemispheres have been completely reconstructed from MRI images and computationally unfolded (Sereno & Dale, Neurosci. Abstr., 1992). Subjects' heads were stabilized through the use of a dental impression bite bar to prevent image blurring. The unfolded representations greatly facilitate comparisons of cortical folding patterns among individual brains, and between the two hemispheres of the same brain. Although the overall layout of the major sulci (e.g., lateral, central, intraparietal, lunate, parieto-occipital, calcarine, lateral occipital, superior temporal) is relatively constant across individuals, the locations and angles of the major sulci as well as the pattern of minor sulci vary considerably. The topology of the sulcal connections also varies to a surprising degree.

These differences in cortical folding lead to substantial variability in the spatial pattern of scalp recorded electrical potentials (EEG) and magnetic fields (MEG). By combining event-related EEG and MEG information with the cortical surface reconstruction for an individual subject, it is possible to obtain estimates of the evoked cortical electrical activity with temporal resolution on the order of milliseconds, and spatial resolution comparable to PET (See Dale & Sereno, Neurosci. Abstr., 1991 and 1992). This technique has been used successfully to localize multiple cortical sources with overlapping time courses evoked by auditory and somatosensory stimulation. The instantaneous estimates of cortical activity are displayed on a 3-D rendering of the unfolded cortical surface. The spatio-temporal pattern of cortical activity can be observed by animating the instantaneous solutions for an entire epoch.

STRATEGIES FOR SOURCE SPACE LIMITATION IN NEUROMAGNETIC INVERSE PROCEDURES. **P.S. Lewis, I.S. George^{*}, H.A. Schlitt, & C.C. Wood** Los Alamos National Laboratory, MS: M-715 Los Alamos, NM 87545

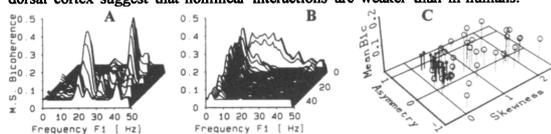

The use of magnetic recordings for localization of neural activity requires the solution of an ill-posed inverse problem: i.e. the determination of the location, spatial configuration, strength and timecourse of the currents that give rise to a particular observed field distribution. Inverse procedures that produce distributed estimates of neuronal currents have received increasing attention because they do not require *a priori* estimates of model order and parameter values, they are suitable for automated analyses, and they allow localization of sources that are not point-like. To combat the parameter explosion and resulting underdetermination associated with distributed reconstructions, we have explored both algorithmic and knowledge-based strategies to limit the effective reconstruction space: variable resolution hierarchical models; anatomical constraints on the reconstruction volume; iterative procedures that effectively eliminate putative source locations that are not relevant to the specific reconstruction, such as the FOCUSS algorithm described previously; and methods that consider an evolving subspace of the reconstruction volume. We have recently achieved encouraging results by explicitly limiting the reconstruction space at each step so that the inverse problem is always well conditioned. Using a genetic algorithm, we specify a number of distinct subsets of the full reconstruction space using strings consisting of ones and zeros. At each step a metric is evaluated for the best linear reconstruction over the subspace specified by each string. Depending on this measure of "fitness", the string is either retained or removed from the evolving population of strings. New strings are produced by piecewise recombination of older strings. Under some conditions new "genetic material" is introduced into the population by stochastic processes. Genetic algorithms appear to hold particular promise for the neuromagnetic inverse problem because once a suitable subspace configuration has evolved to account for some domain within the target solution, it will tend to be preserved, and combined with other partial solutions.

HUMAN COGNITION: ELECTROPHYSIOLOGY

NONLINEAR PROPERTIES OF EEG: BISPECTRUM IN HUMAN AND ANIMAL BRAINS. **J.Z. Achimowicz^{*} and T.H. Bullock**, Neurobiol. Unit, Scripps Inst. Oceanog. & Dept. of Neurosci., U.C.S.D., La Jolla, CA 92093-0201.

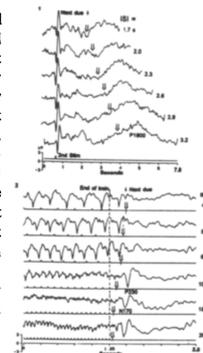

Spatio-temporal features of EEG were analyzed with higher order spectra. Bispectrum and its derivatives: *skewness, asymmetry and bicoherence* which shows nonlinear interactions (e.g. *quadratic phase coupling*) between different frequencies in the same or between different channels were used. Auto- and cross-bicoherence estimates for 17s segments of human EEG, from 16 scalp or subdural electrodes were plotted in different states. The traditional (linear) model of independent oscillators should be modified as phase couplings are common between nonharmonics as well as harmonics. Most common (Fig. A, awake, scalp) are wideband mountains indicating significant coupling of many frequencies up to 100 Hz, probably due to *events with sharp corners*, recurrent or transient. Narrow peaks also occur, possibly reflecting *amplitude or frequency modulation* plus extra energy at modulating frequency. Bicoherence signatures change with subject state and sensory stimulation. In slow wave sleep the fraction of nonlinearly coupled energy is usually highest <4 Hz; in the awake state the contribution from the *gamma band* is more often significant. During seizures both low and high bands are coupled (Fig. B). The dynamical pattern can differ among brain regions. Fig. C shows right lateral-frontal (●) and temporal (○) areas in the awake human. Bispectra of turtle dorsal cortex suggest that nonlinear interactions are weaker than in humans.

659.2

TWO TYPES OF EVENT RELATED POTENTIALS TO OMISSION OF STIMULI IN HUMANS. **T.H. Bullock¹, S. Karamürsel² and J.Z. Achimowicz¹** ¹Neurobiol. Unit, Scripps Inst. Oceanog. & Dept. Neurosci., UCSD, La Jolla, CA 92093, & ²Dept. Physiol., Medical Faculty, Univ. Istanbul, 34390 Istanbul, Turkey.

Short term temporal memory was studied parametrically via the scalp-recorded SSR (Steady State Response) and the OSP (Omitted Stimulus Potential) over a wide range of stimulus (flash) rates (0.3 to 40 Hz) in 18 healthy subjects. In a high (>6 Hz) and a low frequency (<1 Hz) conditioning stimulus range the OSP has different shapes and latencies after the due-time of the first omitted stimulus (DT). The OSP is essentially absent from 2-5 Hz. Both types of OSP have nearly constant latencies after the DT. The "slow" (low frequency range) OSP (Fig. 1), seen clearly at centro-fronto-parietal regions, is a large, slow, positive wave, with a peak latency usually 500-1100 ms after the DT; it requires special attention such as counting omissions; it can be crossmodal (a click after a flash train can act like a flash); it can appear after a train as short as two stimuli; it almost totally disappears with jittered interstimulus intervals (ISI). The "fast" OSP (Fig. 2), mainly occipital, has a shorter latency after the DT (N120-P170), does not need close attention or counting, but good fixation and requires >3 or 4 flashes, is not crossmodal or much affected by jittered ISIs.

659.3

NON-LINEAR COMPLEXITY OF NEURAL ACTIVITY. N. Birbaumer*, W. Lutzenberger, H. Flor and T. Elbert. Inst. Med. Psychology and Neurobiology, Univ. Tübingen, D-7400 Tübingen, Germany.

A series of experiments with adult male and female human subjects of different levels of intellectual capacity (IQs) using non-linear analysis ("deterministic chaos") of the EEG is reported. The hypothesis was tested that the complexity of the human EEG reflects the competition of neuronal cell-assemblies. The competition of cell assemblies was operationalized by the use of cognitive tasks of increasing cognitive complexity. During processing of the different tasks the EEG from 16 electrodes was analyzed by using a.) conventional power spectra and b.) a dimensional complexity algorithm as used in deterministic chaos analysis. Simple sensory tasks (tactile, visual, acoustic perception of objects) were compared with complex ones (imagery of the same objects and complex scenes) and various resting control conditions (e.g. eyes closed vs. eyes open).

Subjects with higher mental abilities (IQ) show an increased dimensional complexity of the EEG compared to resting conditions. The execution of complex cognitive tasks with a high degree of intermodal information exchange (e.g. imagery) have higher complexity of the EEG than simple sensory tasks. This is in agreement with the assumption of focused attention in highly emotionally involved Ss and thus reduced cell assembly competition. Conventional power spectra were unable to discriminate the different tasks and groups.

P300 TOPOGRAPHY IS ALTERED BY STIMULUS MODALITY BUT NOT BY TASK DIFFICULTY. S.F. Faux* and S. Law. Dept. of Psych., Drake Univ., Des Moines, IA 50311

P300 event-related potentials were recorded from 20 college-aged students while performing visual discriminations of digits (0 vs. 1 through 9) and auditory discriminations of digitized syllables (ba vs. ga, za, etc.). Stimuli were presented singly; targets occurred with 0.15 probability. Age-matched subjects were assigned to one of two levels of stimulus discriminability ("undegraded" [U] $N = 10$; "degraded" [D] $N = 10$). Both groups performed identical visual/auditory tasks, except that in the D condition the stimuli were degraded by altering visual picture elements or superimposing white noise. The signal detection measure of task difficulty (A') was statistically equal across stimulus modalities, but differed by task difficulty (U: $A' = 0.98$; D: $A' = 0.93$, $F(1, 16) = 11.18$, $p < 0.001$). Mean P300 peak component latencies (Pz site) differed only by task difficulty (U = 430 msec; D = 471 msec; $F(1, 16) = 4.78$, $p < 0.05$). Normalized P300 peak amplitudes (Fz, Cz, Pz sites) showed statistically different topographic profiles by modality ($F(2, 17) = 18.11$, $p < 0.001$), but not by task difficulty. Results suggest that P300 neural sources are not identical by stimulus modality.

WITH NETWORK MODELING, TOPOGRAPHIC EEG PREDICTS MEMORY CAPACITY AND RT IN CONTINUOUS PERFORMANCE TASKS. J.R. Moeller, B. Luber, E. Rubin* & H.A. Sackeim Dept. of Biological Psychiatry, NY State Psychiatric Institute, New York, NY 10032

In neuroimaging studies of cognitive activation, images from different task conditions are subtracted to isolate local changes in physiological activity that are associated with specific cognitive operations. However, given the multiple interconnections among brain regions, it is doubtful whether functional changes that occur at local sites can be limited by experimental design to one particular type. To address this critical measurement issue, we have used linear covariance modeling to capture the multidimensional nature of functional activity at individual brain locations. We have in applied PCA techniques to topographic EEG data to extract both "networks of regional physiological activity" and between-condition changes in "network load." Regional networks are interpreted as physiological manifestations of individual cognitive operations; and, between-condition alterations in network load, as changes in the magnitude of information processing transacted by a cognitive operation. In the analysis of group EEG data, our capacity to segregate not only a subject-dependent global factor from subject differences in network load, but also subject load differences from subject variation in structural and functional anatomy, is a critical new component of network analysis. Topographic EEG was collected from 15 male subjects who performed visual recognition tasks consisting of either novel figure or word stimuli. Two levels of memory load were used: a set size of one, and a set size that was titrated so that every subject performed at an accuracy level of 65% correct. Subject differences in network load, but not in activity at individual electrode sites, were significantly correlated with subject differences in performance. Different networks predicted: RT(set size one) with $R^2 > 76\%$ for words and figures; RT(titrated set size) with $R^2 > 80\%$; and, titrated set size with $R^2 > 62\%$. The network topographies with performance correlates had reasonable interpretations in terms of the current neurobiological information about declarative and implicit memory systems. The same modeling principles are applicable to 3D metabolic imaging.

SPATIOTEMPORAL DYNAMICS OF PHASE TRANSITIONS IN THE HUMAN BRAIN. G.V. Wallenstein, S.L. Bressler*, A. Fuchs, J.A.S. Kelso. Program in Complex Systems and Brain Sciences, Center for Complex Systems, Florida Atlantic University, Boca Raton, FL 33431 USA.

Human brain electric potentials show abrupt state transitions that coincide with changes in sensorimotor coordination. Whole-head EEGs (61 electrode sites) were recorded (128 Hz, passband = 0.3 to 30 Hz) while a subject produced right index finger flexions in syncope with auditory stimuli (1.1 KHz tone pulses, 80 ms duration). Stimuli were presented at a rate that increased after every ten stimuli in steps of 0.25 Hz from 1.0 Hz to 3.0 Hz. It is known (Kelso, DelColle & Schöner, 1990) that at a critical stimulus rate a spontaneous change occurs from the syncope relation between stimulus and finger movement to one of synchronization. Spatiotemporal analysis of the electric field patterns revealed: a) a widespread dominant EEG power spectral peak at the frequency of coordination; b) a 60 degree phase lag of the EEG relative to the stimulus during syncope behavior at central, antero-central and left frontal sites, c) a transition at those sites from EEG phase lag to phase lead coincident with behavioral switching from syncope to synchronization (at 1.75 Hz); d) no such change in a control condition in which finger movement was in synchrony with the stimulus throughout the trial.

INFLUENCE OF TASK DIFFICULTY AND EXPECTEDNESS ON THE P300 ELICITED BY A WARNING STIMULUS. C. Busch*, G. Wilson* and P. Ullsperger*. 1) LTSI Inc., Dayton, OH 45431-7258 2) Armstrong Laboratory, AF, WPAFB, OH 45433-7022 3) Bundesanstalt für Arbeitmedizin, Berlin, Germany.

The topographical distributions of scalp field potentials were evaluated during explicit tests of Helson's Adaptation-Level (AL) Theory (1964). This model posits the intensity of response to be a function of the mental distance from a prevailing level of adaptation with respect to the task-relevant internal dimension and has recently been adapted by those interested in evaluating the P300 component of the ERP. According to AL theory, the greater the stimulus information from the reference point, the greater the P300 amplitude expected.

In the present studies, we manipulated set size (difficulty), probability and randomness (expectedness) of number sequences presented for memorization on a CRT. Each task stimulus was preceded by a single digit warning stimulus (1 to 5) announcing the difficulty of the subsequent memory set (varied from 1 to 8 digits). Eleven subjects participated in three separate studies manipulating probability (10%-60%) and randomness (equiprobable random or blocked). Scalp EEG were recorded from 21 sites distributed according to the International 10-20 system and stored on disk for off-line analysis.

Evaluation of topographical maps indicated that between 250-650 ms post-stimulus onset, sites Cz, P3, Pz and P4 differed more than 1 sd from the calculated average across the scalp and these sites were selected for further analysis. Results indicated that, as predicted by AL theory, the P300 area increased as a function of distance from the level of adaptation (ie the geometric mean of stimulus occurrence) when the level of difficulty varied randomly and further suggested an interactive contribution of expectedness (adaptation) and preparedness (difficulty) in a non random paradigm.

659.8

ELECTROPHYSIOLOGICAL DIFFERENCES ASSOCIATED WITH THE DETECTION OF SIMPLE FEATURES AND FEATURE CONJUNCTIONS. R. Soria*, R. Srebro. Vision Research Lab., Univ. of TX Southwestern Med. Ctr., Dallas, TX 75235.

Evoked potential (EP) scalp topography was studied during visual search tasks which involved either parallel or serial processing. The parallel processing tasks required the detection of a simple feature either color or orientation. The serial processing task involved the detection of the feature conjunction color and orientation. Identical stimuli were used for both parallel tasks and a similar stimulus for the serial task. The subjects made a button press response. Both stimulus-locked and response-locked averages were calculated across 31 electrodes equally spaced over the posterior half of the scalp. The global field power (GFP) was used as a reference free index pointing to EP scalp fields of interest. A chi-square test was used to test for significant differences in shape of scalp fields. Results ($n=4$) revealed no significant differences in scalp fields for the two parallel processing tasks. However, significantly different scalp fields between both parallel processing tasks and the serial processing task were identified for the epoch surrounding the button press (peri-decisional epoch), and for ca. 200ms after stimulus presentation. This suggests that different neural populations subserved the decision making process during parallel and serial tasks. Differences found at ca. 200 ms suggest that serial processing tasks require visuo-spatial processing for the conjoining of features.

NORADRENERGIC MODULATION OF AUDITORY AND VISUAL P300 IN PARIETAL-TEMPORAL CORTEX. J.A. Pineda*, K. Shafer, M. Belmonte. Depts of Cognitive Science and Neuroscience, University of California, San Diego, La Jolla, CA 92093

Human clinical studies have suggested that the parietal-temporal junction may be an important source of cortical P300 activity. This area is also characterized by one of the densest noradrenergic projections from the locus coeruleus. Our previous studies have argued that this widely distributed system plays a critical role in the genesis and modulation of P300-like components. In this study, we examined the relationship between noradrenergic activity in the parietal-temporal junction and auditory and visual P300-like activity.

Event-related potentials (ERPs) were recorded from chronically implanted epidural electrodes in squirrel monkeys (*Saimiri sciureus*). Recordings occurred before and after microinjections of L657,743, an adrenergic alpha-2 antagonist, or clonidine, an alpha-2 agonist, into the left parietal-temporal area. An 80-10-10 oddball paradigm was used consisting of stimuli presented every 2 secs. One tone was presented on 80% of the trials, a higher pitched tone on 10% of the trials, and a small, yellow rectangle on the remaining 10% of the trials. Baseline ERPs showed large, widely distributed P300-like responses to both infrequent stimuli. The amplitude of the auditory but not the visual P300-like component was significantly reduced over both hemispheres following L657,743 injections. In contrast, clonidine enhanced the magnitude of these potentials relative to baseline ERPs. These data suggest that the parietal-temporal junction is a source of auditory P300-like potentials, that noradrenergic activity in this region is critical for their genesis, and that modulation of P300 sources in the left hemisphere affects potentials recorded over the right hemisphere.

659.11

APPEARANCE OF PARIETO-FRONTAL MIDLINE (PFM) THETA ACTIVITY RELATED TO PERFORMANCE IN HYPERACTIVE AND NORMAL CHILDREN S.J. Laukka*, P. Silven, J. Lindqvist, T. Järvillehto. Laboratory of Developmental Neuropsychology, University of Oulu, Linnanmaa P.O. BOX 222, SF-90571, Oulu, Finland.

Theta-activity (PFM theta, 4-7Hz) was investigated during goal-directed behavior. In a simulated traffic situation subject had to find the right way for driving a 'car' through a set of roads. Two interdependent decisions had to be made at two crossroads. Feedback about quality of performance was given. EEG was recorded from Fz and Pz. Theta-activity during seven consecutive phases (1610 ms) of behavior was analysed.

Correct driving at the first crossroad was associated with significantly more theta in the frontal area in the hyperactive children than in normal ones. On the other hand, for the normal children during wrong driving the first traffic sign was associated with significantly more theta in the parietal area than for the hyperactive children.

The results indicate a maturational lag in the hyperactive children.

659.13

LONGITUDINAL EVENT-RELATED POTENTIAL MEASURES INDEX STAGES OF HIV-1 INFECTION. M.M. Schroeder*, L. Handelsman, W. Ritter, Albert Einstein College of Medicine, Mt. Sinai College of Medicine.

HIV-1 infection of the brain causes delays in auditory event-related potentials (ERPs). The purpose of this study was to investigate the stability of these group differences over a short time period suitable for monitoring the progression of cognitive impairment, and/or effects of anti-viral treatments.

We recorded auditory ERPs at two time points, 3 months apart. Subjects were 17 former parenteral drug users (PDUs): seronegative (6); seropositive, stage II (7); and seropositive, stage IV (4). Also 8 non-PDUs were normal controls. The stimuli were presented in an auditory oddball paradigm: there were five response conditions: Go/No-go, Count, Simple Response, Simple Count, and Ignore. ERPs were recorded from Fz, Cz, and Pz. Peak latencies and change scores of P1, N1, N2, and P3 were submitted to repeated measures ANOVAs.

N1 was delayed for the stage IV subjects compared to the other three groups ($p=.02$). P1 exhibited a similar, non-significant trend. N2 was delayed for both seropositive groups ($p=.008$) compared to both seronegative groups. P3 showed a similar non-significant trend. Change scores for P1 and N1 increased more for the stage IV group compared to the other three groups. Change scores for N2 and P3 indicated practice effects for seronegatives in the second recording which augmented group differences.

Group differences remained stable over two recordings and a trend for progression in latency was seen in the change scores for both seropositive groups.

659.10

HUMAN AND MONKEY N400-LIKE RESPONSES TO FACES IN A PRIMING PARADIGM. C. Nava*, J.A. Pineda, G. Stickney. Dept of Cognitive Science 0515, University of California, San Diego, La Jolla, CA 92093

Face recognition is important for social communication in humans and non-human primates. Recent human event-related potential (ERP) studies have investigated whether the recognition of semantically associated pairs of faces elicits components similar to the linguistic N400. It has been found that incompatible faces produce these components presumably because memory representations must be activated for matching to occur, and only incompatible matches elicit N400-like responses. The focus of this study was to compare human and monkey N400-like responses related to the perception and recognition of faces.

ERPs were recorded from scalp electrodes in humans and from epidural electrodes in squirrel (*Saimiri sciureus*) and macaque (*Macaca fascicularis*) monkeys. Paradigms consisted of slides of real faces presented upright in match or mismatch pairs. Humans and squirrel monkeys were shown species match (human-human; monkey-monkey) or mismatch (monkey-human; human-monkey) pairs. All faces were familiar to human subjects but only the human faces were familiar to the squirrel monkeys. In a second paradigm, macaque monkeys were exposed to familiar (roommates) and unfamiliar faces (different monkey species) in match or mismatch pairs. Human ERPs exhibited larger N400s to mismatch trials for both monkey and human faces. Squirrel monkeys showed larger negativities to the unfamiliar mismatch monkey faces. In macaque monkeys, larger potentials occurred to the familiar match compared to the mismatch trials. These data indicate that human and non-human primates display N400-like negativities to faces. However, the conditions that elicit these components are different, suggesting that although analogous mechanisms exist, there are different overlapping processes involved.

REGIONAL RESPONSE CHARACTERISTICS OF AUDITORY P3 IN YOUNG ALCOHOLICS H.L. Cohen*, W. Wang, B. Porjesz and H. Begleiter. Neurodynamics Lab, Hlth Sci. Ctr, Bklyn, Bklyn, N.Y. 11203

An auditory oddball paradigm was used to assess the P3 component of the event related potential (ERP) in a group of medication - free, chronic alcoholics ($N = 25$, $\bar{X} = 29.3$) and an age - matched control ($N = 25$, $\bar{X} = 27.2$) group. Each subject received a binaurally presented series of high (1600 Hz) and low (600 Hz) frequency tones. Either tone could be designated as the rare tone (12.5% probability) depending on whether the subject number was odd or even. When the subject detected the rare tone, he made a button press as quickly as possible that recorded his reaction time (RT). Scalp recordings using the entire 10/20 System, as well as interpolated placements, were made from 31 electrodes. For statistical analyses, five electrode groups were created: frontal (F), central (C), parietal (P), occipital (O) and temporal (T). MANOVA were used to compare group differences in P3 amplitudes and latencies in each region. The results indicated that control amplitudes were significantly greater in C, P, O and T regions and control latencies were significantly longer in C and P regions. Regional response differences between the groups were also compared with measures of surface energy density (SED; Wang et al., in press). In the control group, surface energy components in both temporal regions and in the right parietotemporooccipital region, were greater than those in the alcoholics. Our results demonstrate that young, abstinent alcoholics manifest regional deficits in auditory P3 morphology. These findings are further supported by measures of surface energy density.

P300 AND SIMULATED WEIGHTLESSNESS. K.L. Murray, S.J. Benshoff and D.L. Molfese*. Southern Illinois University at Carbondale, IL 62901.

Weightlessness has effects on both the physiological and cognitive functioning of humans. The Head-Down-Tilt (HDT) model has been used to simulate weightlessness on Earth. This electrophysiological (ERP) study assessed the effects of HDT on P300 amplitude and latency. Peak analyses were performed and then input to separate ANOVAs for the amplitude and latency data. The amplitude data showed main effects for Position (HDT vs: control) and for Electrode (frontal, temporal, and parietal). A Position X Electrode interaction was also noted. The latency data ANOVA showed a main effect for Hemisphere (left vs. right). These data, particularly the amplitude data, indicate that there are attentional deficits (as indexed by an attenuated P300) associated with HDT. The implications for astronauts engaged in space exploration are significant.

COMPUTATIONAL CONSTRAINTS THAT MAY INFORM HIPPOCAMPAL & HIPPOCAMPO-CORTICAL CONNECTIONS. A. Treves¹ and E.T. Rolls². ¹SISSA, Biophysics, via Beirut 2, 34013 Trieste, Italy and ²Dept. of Exp. Psychology, Univ. of Oxford, Oxford OX1 3UD, UK.

A candidate theory regards the hippocampus as an intermediate-term buffer store for certain types of information, and its CA3 region as an autoassociative memory network where a highly compressed neuronal representation of the data is generated, is immediately stored on recurrent collateral connections, and is later retrievable and available for directing longer-term storage in neocortex. We have previously shown (Treves and Rolls, 1992, *Hippocampus* 2, 189) how this theory constrains the organization of CA3 connections in a way consistent with observation. Here we report that the theory, coupled with the principle of maximal informational efficiency, implies further constraints on CA1 organization as well as on return projections to neocortex. First, an analytical estimate of the information content of the firing pattern induced in CA1 by retrieval of a given CA3 representation indicates the need for a) Hebbian plasticity of the Schaffer collaterals and b) nearly equal numbers of such inputs for each CA1 pyramidal cell. Second, an analytical estimate of the number of firing patterns that can be recalled in neocortex via hippocampo-cortical backprojections indicates the need for c) Hebbian plasticity of the backprojections, d) gradual divergence through several stages of the back-projecting system and e) extensive numbers of backprojecting inputs of hippocampal origin for each neocortical pyramidal cell.

Supported by the HFSP, the MRC of the UK and the INFM.

SENSORY GATING IN SCHIZOPHRENIA: A COMPUTER MODEL OF THE CA3 HIPPOCAMPAL NEURAL NETWORK. K.A. Flach¹*, P. Bickford², L. Adler², G.A. Gerhard², R. Freedman², R. MacGregor¹. ¹Dept. Of Aerospace Engineering, University of Colorado, Boulder, 80309, ²Dept. Of Psychiatry, University of Colorado Health Sciences Center, Denver, 80262

Sensory gating deficits in schizophrenic patients have been demonstrated with an auditory evoked potential (EP) conditioning-testing paradigm. In this paradigm, the amplitude of the P50 EP is greatly decreased in response to the second of two paired auditory click stimuli in normal control subjects, but not in schizophrenic patients. Animal studies in rats, which also show a decreased response to the second click, have suggested that this gating occurs in the CA3 region of the hippocampus. Gating in the rat is lost if nicotinic binding sites are blocked. In schizophrenic patients, this gating is briefly enhanced by nicotine. A computer model of the CA3 region, using techniques discussed in R. MacGregor, *Theoretical Mechanics of Biological Neural Networks*, Academic Press, 1993, is used to study this phenomena. A scaled down model of the CA3 region is simulated with a 660 cell network which is defined in terms of twelve synaptic junctions: 4 internal and 8 external. Two cell populations are modeled, pyramidal cells and GABAergic cells, each by a single compartment circuit model. Using this model, the amplitude of the response to the second tone is decreased, in agreement with the data from normal controls. By modeling the blockade of nicotinic input to the CA3 system, gating is lost, as has been found in the animal research. The schizophrenia model hypothesizes that there is an increase in excitability of CA3 neurons due to the decreased nicotinic input from the septum. By doing this, the system showed a slight decrease in response to the first of the two paired stimuli, and a marked increase in response to the second, consistent with the findings of impaired auditory gating in schizophrenic patients. Thus, auditory sensory gating deficits can be successfully modeled using a biological neural network approach. Supported by NIMH: SP50 MH44212-06.

MODULAR ORGANIZATION OF CORTICAL NETWORKS OPTIMIZES INFORMATION PROCESSING CAPACITY. J. Ambati* and R.K.S. Wong. Neural & Behavioral Science Program and Dept. of Pharmacology, SUNY Health Science Center, Brooklyn, NY 11203.

Information is likely processed in cortical networks through coordinated spatiotemporal neuronal activity. Synchronous firing of neuronal assemblies is found in many cortical areas (e.g., Miles & Wong, *J. Physiol.* 388: 611, 1987; Gray & Singer, *Proc. Natl. Acad. Sci. USA* 86: 1698, 1989). Interestingly, the number of neurons per radial column in the neocortex of most mammals is virtually identical (Rockel et al. *Brain* 103: 221, 1980). We suggest that this remarkable invariance serves to optimize the information processing capacity (IPC) of these networks. A model is developed to demonstrate that IPC of a network is optimized by partitioning it into neuronal ensembles, each of which has an identical number of neurons, independent of the total network size. This model predicts that the fundamental unit of representation in the CA3 region of hippocampus should contain about 2,500 neurons, which is in accord with experimental evidence (Thompson & Best, *J. Neurosci.* 9: 2382, 1989; Muller, et al. *Hippocampus* 1: 243, 1991) and simulation data (Traub & Miles, *Neuronal Networks of the Hippocampus*, 1991).

UNIQUE CONTRIBUTION OF HIPPOCAMPAL FIELD CA3 TO INTEGRATION OF DISPARATE CUES OVER TIME. M. Taketani, R. Granger*, J. Ambros-Ingerson, R. Myers, G. Lynch. CNLM, U. Calif., Irvine, CA 92717.

Hippocampal field CA3 is a unique exception to the extremely sparse connectivity characterizing most telencephalic networks: CA3 exhibits relatively dense recurrent associational fibers, enabling dynamical activity over time, and suggesting its possible role as a reverberating short-term memory system.

Anatomically and physiologically rich simulations of field CA3 have shown that brief afferent activation can generate recurrent activity lasting for 100s of milliseconds, with some specificity to the initial input. These findings led to the suggestion that field CA3 might function as a kind of "holding memory," serving to bridge the temporal gap between transient neural signals over behavioral time (Taketani et al., *Soc. Neurosci. Abs.*, 506.6, 1992). To serve as a holding memory, however, recurring activity patterns would have to contain patterns repeated regularly over time, so that two cues separated by time could become integrated.

Physiological rules for the induction and expression of LTP in response to time-varying afferent signalling (Larson & Lynch, *Brain Res.*, 489:49, 1989) were incorporated into simulations of CA3. Repeated afferent stimulation at the theta rhythm leads to the potentiation of a small number of synapses in the model, strengthening a sequential chain of target cells. Subsequent brief (10 msec) stimulation with a learned input pattern sets up a sequence of recurring responses in the model, specific to the input, and repeating regularly with every theta wave.

Learning of these recurring patterns by CA3's primary target projection structure, CA1, enables field CA1 to recognize the sequence of two cortical (perforant path) afferents A and B even when they are separated by many seconds. The coordinated activity of fields CA3 and CA1 can therefore recognize the constituents of a coherent scene even when viewed from different vantage points, and at different rates of scanning. The specific hypothesis is therefore forwarded that this coordinated functional capability of fields CA3 and CA1, arising from their unique anatomical designs and the physiological operation of their LTP induction and expression rules, is what the hippocampus uniquely contributes to the processing of spatial information, as well as to non-spatial tasks requiring the integration over time of disparate sensory cues. MEMORY CAPACITY OF REALISTIC HETEROASSOCIATIVE NETWORKS. E.P. Cook* & D. Johnston, Division of Neuroscience, Baylor College of Medicine, Houston, TX 77030

We have examined the hypothesis that realistic levels of synaptic potentiation can be used as a mechanism for selective associative memory storage and recall in a biological neural network. We compared the memory capacity of heteroassociative feedforward networks in which the individual elements varied in their biophysical realism. Networks constructed from three types of neuron models, each with an increasingly realistic complement of membrane channels, were compared to the ideal network constructed from binary threshold elements.

Our three realistic models were reconstructed hippocampal pyramidal neurons with the following different channel distributions and types: 1) passive dendrites with H&H-like Na⁺ and K⁺ channels in the soma, 2) passive dendrites with a biophysically realistic soma, and 3) a complete biophysically realistic model that included active dendrites (M. Migliore et al. *Soc. Neurosci. Abstr.* (1993)). Individual synapses, uniformly distributed in the dendrites, were randomly potentiated by changing peak synaptic conductance from 250pS to 500pS. The effects of recurrent and feedforward inhibition were also examined. NEURON by Michael Hines was used in all computer simulations.

Using the artificial binary threshold neuron, it can be shown that the memory performance of the feedforward heteroassociative network is dependent on the model's ability to detect small changes in synaptic inputs. Only the two most realistic models (2 and 3) showed enough sensitivity to small changes in synaptic strength to be effective in our heteroassociative memory network. This sensitivity was expressed as a nonlinear increase in the latency of the first action potential after a small reduction in synaptic input. In model 3, this effect on latency was influenced by voltage and Ca²⁺-dependent channels in the dendrites. When this model was used in a realistic heteroassociative memory network that included recurrent inhibition, the memory performance approached that of the ideal artificial model. (Keeck Foundation and MH48432).

660.6

MODELING OF SPATIAL VS BEHAVIORAL FIRING OF HIPPOCAMPAL COMPLEX SPIKE CELLS.

R.E. Hampson*, T. Bunn, D.R. Byrd, S.A. Deadwyler. Bowman Gray School of Medicine, Wake Forest Univ., Winston-Salem, NC 27157.

A neural network model of hippocampal complex spike cells has been developed to simulate both spatial and task-specific correlates of neural activity for the same neurons. The model is based on a three-layer forward-only counter-propagation network (Hecht-Nielsen, 1987) which has been designed to incorporate position, movement trajectory, and behavioral significance of locations within the modeled environment. Inputs to the first layer consisted of position sequences designed to simulate the movement trajectories exhibited by freely-moving rats (Deadwyler et al. 1989). Connections to the hidden and output layers "self-organized" in response to trajectory inputs such that firing probabilities of individual simulated neurons corresponded to adjacent positions along the trajectories. Units of the output layer showed strictly spatial firing correlates similar to those of hippocampal place cells. Task-contingent behavioral constraints were incorporated into the model via additional inputs at the hidden and output layers as defined in the design of a counter-propagation network. These additional inputs provided modulation of the trajectory-based place fields similar to the effects of rotating environmental cues as well as alteration of the behavioral relevance associated with particular locations.

Simulated neural activity derived from the model is compared with recordings of CA1 and CA3 neurons to test validity of the model. Patterns of activity between the simulated neurons (i.e. connections and weights) are examined to determine what aspects of hippocampal functional connectivity may be used to differentiate spatial and cognitive correlates of hippocampal neural activity. A NEURAL NETWORK FOR STABLY SELF-ORGANIZING ARBITRARY RECOGNITION CODES. **J. W. L. Merrill**, Center for Complex Systems, Florida Atlantic University, Boca Raton, FL 33431.

Recognition of items similar to those which have been encountered before is essential for behaving organisms. This recognition can be mediated by a self-organized abstract code, which might be either a *maximally compressed* code, in which individual codewords provide mutually exclusive information about a percept, or a *distributed* code, in which individual codewords provide complementary information about a percept. A major goal of neural network research has been the construction of neural architectures capable of stably self-organizing such codes in a non-stationary environment. Neural architectures for the self-organization of maximally compressed codes have been previously described by Carpenter and Grossberg and their colleagues. Here, a neural architecture for the stable self-organization of arbitrary recognition codes in a non-stationary environment is presented.

Self-organization of a distributed code is complicated by the possibility of interactions among the various codewords that represent a given item. Activity in one codeword could distort the class of patterns recognized by a different codeword, leading to instability in the representation of input patterns. The spectrum of instabilities arising in this fashion is shown to be completely characterizable in terms of two particular examples, the hybrid learning problem and the spurious generalization problem. It is shown that the hybrid learning problem can be avoided if the number of codewords being changed at any given instant never exceeds one, even if the number of codewords altered during a single learning bout is large. A neural mechanism for enforcing this requirement through serialization is proposed and discussed. This mechanism requires that at least one signaling pathway has a time constant much slower than that of other important pathways. Analysis of the spurious generalization problem shows that it arises in distributed coding systems because a collection of codewords could represent an input pattern well, even when some element of that collection matches the pattern very poorly. Resolution of this problem is shown to depend upon distinguishing between the match provided by a broad collection of codewords and the match provided by each individual element of that collection. It is shown that the serialization mechanism proposed for the solution of the hybrid learning problem provides exactly the extra degree of freedom necessary to make this distinction.

660.9

A STOCHASTIC MODEL OF CEREBELLAR GRANULE→PURKINJE SYNAPSES. **M. D. Mauk* & G. T. Kenyon**, Univ. of Texas Medical School, Houston, TX 77225.

Empirical studies suggest that granule cell to Purkinje cell (Gr→PC) synapses in the cerebellum decrease in strength when active during a climbing fiber (CF) input, and increase in strength when active in the absence of a CF input (i.e. generalized Long-Term Depression or LTD). LTD involvement in Pavlovian eyelid conditioning is suggested by observations that activating CFs is necessary and sufficient for the reinforcing properties of the US, yet this idea is complicated by the low but regular spontaneous activity displayed by CFs. Specifically, how can US-evoked CF activity convey significant information against this background of spontaneous activity? Since this spontaneous activity gives rise to probabilistic pairings between Gr→PC synaptic activity and CF inputs (US-evoked and spontaneous), we propose that generalized LTD is a stochastic process. We investigate this idea using a formal, stochastic description starting with the three equations shown below. Equation 1 is the expected change at the *i*th Gr→PC synapse predicted by generalized LTD stated in terms of the probability of synapse activity, probability of CF input, and constants for the unit increases and decreases in strength, equation 2 is the probability of PC activity stated in terms of the sum of its Gr inputs, and equation 3 is the probability of CF activity in terms of its intrinsic and US-evoked excitatory drives and modulation via cerebellar output. These equations yield several predictions: *i*) in the absence of USs, CF activity is regulated so that the expected net change in Gr→PC synaptic strength is zero, *ii*) average synaptic input to PCs is maintained constant, *iii*) during an idealized CS-US trial the strength of Gr→PC synapses either remains constant or decreases thus, after the trial, some synapses must increase in strength to renormalize average synaptic input, and *iv*) the expected change in synapse strength for a CS-US trial and subsequent renormalization is described by equation 4. This equation predicts that the change in the strength of a given synapse for a CS-US trial is proportional to the extent to which the synapse encodes more information about the CS than the population of synapses.

$$1) \Delta w_i = p_i(1 - P_{CF})\delta_n - P_{CF}\delta_p \quad 2) P_{PC} = \sum w_i p_i \quad 3) P_{CF} = (E_I + E_{US} + P_{PC})$$

$$4) \Delta w_i = \delta_p \left(\frac{p_i \sum p_i p_i^{CS}}{\sum p_i^2} - p_i^{CS} \right)$$

660.11

FORAGING IN AN UNCERTAIN WORLD USING PREDICTIVE HEBBIAN LEARNING. **P. R. Montague^{1,2}, P. Dayan¹, T. J. Sejnowski¹**, Computational Neurobiology Lab, The Salk Institute¹, La Jolla, CA 92075, and Division of Neuroscience, Baylor College of Medicine² Houston, TX 77497.

There is evidence in both vertebrates and invertebrates that diffuse systems may report prediction errors to their target structures through appropriate modulation of firing rates in response to events in the world that predict future reward. We present a neural model which utilizes diffuse modulatory systems to implement a predictive version of a Hebbian rule and embed this rule in a simple neural architecture. The predictions in such a model represent the expected amount of reinforcement. We demonstrate the connection between this model and an adaptive technique called the method of temporal differences and we propose a specific hypothesis for how such predictions are made in a real brain. Moreover, we challenge this neural model with a behavioral task involving foraging for food. When required to forage in a stochastic environment, the model exhibits the foraging strategies seen in the behavior of bees and a number of other animals and provides insight into how the stochasticity of the world drives this behavior. This predictive model suggests a unified way in which neuromodulatory influences are used both to bias cell activity and to control synaptic plasticity - two roles previously suggested for diffuse ascending systems. Taken together, these results suggest that predictive Hebbian rules for synaptic plasticity offer a simple yet powerful framework for learning and provide a specific and testable role for diffuse neuromodulatory systems.

660.8

A CORTICAL NEURAL NETWORK MODEL OF TEMPORAL INFORMATION PROCESSING. **D. Buonomano* & M. Merzenich**, Keck Center, UCSF, San Francisco, CA 94143-0732.

The majority of neural network models have focused on processing spatial information, i. e., the relevant information is carried in the spatial pattern of active input channels. Biological information processing relies on utilizing spatial and temporal information. For example in speech recognition, information is encoded not only by which channels are active, but by the temporal relationships within and between activated channels. Our hypothesis was that known properties such as slow inhibitory currents and paired-pulse facilitation (PPF) would permit extraction of temporal information by altering the dynamics of the network in a state-dependent fashion. As an initial step toward understanding temporal information processing, we focused on a purely temporal task: frequency discrimination. We modeled a cortical circuit composed of modified integrate-and-fire elements with a slow inhibitory current ($\tau=50$ ms), and PPF (peak=80ms). The architecture of the network was based on thalamo-cortical \rightarrow L-IV \rightarrow L-III connectivity with feed-forward excitation, and feed-forward and feed-back inhibition. The network was initially trained to discriminate between pulses at 5 frequencies (20-60 Hz). Thus, there were 5 output units which received input from all LIII excitatory units (LIII-E). The only plasticity in the network was between the LIII-E units and the output units (all time constants were nonvarying). The plasticity obeyed a supervised learning rule; during presentation of a given input frequency, active connections to the corresponding output unit were increased while active connections to other output units were decreased. Our results show that after training the output units not only respond preferentially to their trained frequency, but generalized as demonstrated by exhibiting a tuning curve that peaked at approximately their trained frequency. In the absence of noise, the first pulse will always produce the same activity pattern, but depending on when the second pulse arrived a different spatio-temporal activity pattern was generated that could be used to encode temporal information. These results suggest that time-dependent properties such as slow inhibitory currents and PPF generate enough state-dependence to alter the dynamics of the network in a time-dependent manner. NEURAL NETWORK BACKPROPAGATION IS ANALOGOUS TO RETROSYNAPTIC CHEMICAL TRANSMISSION. **Daniel Gardner*** Dept. of Physiology, Cornell Univ. Med. Coll., New York, NY 10021.

Neural network models use variable-strength synapses to interconnect layers of simplified neuron-like elements. By using learning rules to adjust synaptic weights so as to reduce error, such networks evolve successful algorithms for information processing. However, backpropagation and similar learning rules for error minimization require retrosynaptic transmission of error signals. Is this property sufficiently non-neuromorphic to make such nets uninteresting to neurobiologists?

Toward the development of neuromorphic network models, I analyze backpropagation neurobiologically to suggest a hypothetical yet plausible correspondence to retrosynaptic chemical transmission, recently implicated in LTP and other synaptic plasticity (Gardner, D. *The Neurobiology of Neural Networks*. Cambridge, MA: MIT Press, 1993).

In these nets, convergent and divergent presynaptic and postsynaptic cells with activity *y* are linked by synapses of weight $w_{post,pre}$. Synaptic weight optimization utilizes error δ_{post} backpropagated from each postsynaptic cell and used two ways. Presynaptic error depends on δ_{post} and synaptic weight $w_{post,pre}$: $\delta_{pre} \propto \sum_{post} \delta_{post} w_{post,pre}$. The same δ_{post} scaled by presynaptic activity y_{pre} affects $w_{post,pre}$: $\Delta w_{post,pre} \propto \delta_{post} y_{pre}$.

Via two presynaptic receptors, a retrosynaptic transmitter signalling postsynaptic error δ_{post} could implement this dual role—contributing to presynaptic error by activation of a presynaptic receptor encoding synaptic strength, perhaps uniformly distributed at terminals, and changing synaptic weight via another presynaptic receptor modulated by depolarization or increased Ca^{2+} , thereby combining error and presynaptic activity.

DISSIPATIVE STRUCTURES: A UNIFIED HIERARCHICAL APPROACH TO BRAIN FUNCTION. **Wayne Hoss*** Department of Medicinal and Biological Chemistry and Center for Drug Design and Development, University of Toledo, Toledo, OH 43606

The thermodynamics of irreversible processes provides a unified framework for a consideration of the nervous system in terms of a hierarchical set of components. At each level, properties can be described in terms of steady states and dissipative structures that impose order in the face of continuous entropy production. This occurs because these phenomena are coupled to other irreversible processes, e.g., diffusion and chemical reaction, that maintain sufficient overall rate of entropy production. Familiar examples of steady states include resting membrane potential and resting neuronal discharge rate. Action potentials and neuronal bursting activity are the corresponding dissipative structures, which are ordered states beyond an instability (e.g., neuronal threshold) and share a common requirement for at least one positive feedback or feedforward step in their mechanisms. Expressions for the rate of entropy production for these and other steady states and dissipative structures together with their hierarchical linkages are presented. Long-term potentiation and calcium-induced calcium release are additional examples of dissipative structures, having received recent attention at the biochemical level. The central hypotheses of this line of reasoning are that dissipative structures occur naturally and pathologically within the CNS at many levels, that they are linked in a hierarchical fashion and that they are important for higher brain functions, including perception, cognition, emotion, learning and memory. It is suggested that research directed towards the detection, formation, maintenance and relaxation of dissipative structures is fertile ground for developing new tools for understanding brain function and novel diagnostic and therapeutic approaches to neurological diseases.

THE GEOMETRY OF WIN-SHIFT AND WIN-STAY BEHAVIOR.

A.G. Gittis* and J. Falleroni, Psychology Department, Westminster College, New Wilmington, PA 16172.

As a task thought sensitive to both limbic and neocortical working memory circuits, win-shift and win-stay have been conceptualized as a rodent analog of the primate match and non-match to sample memory procedures. As with primates, rodents find tasks with a shift (non-matching) contingency much easier. This study investigates whether the ease in shifting (non-matching) is due to the geometric arrangement of the arm choices.

Long-Evans hooded rats were tested in an apparatus in which a start alley led into arena in an X configuration. A task trial consisted of a forced and free component. On the forced component access to only one arm was possible. On the free component animals had a choice between two arms, the one open on the forced component and one of the remaining alternative arms. Animals were assigned to groups in which there was a shift or stay contingency. On each of 5 days an animal received 24 test trials in which the various permutations of arm pairs were investigated.

It was found that maximal shifting behavior occurs when the midline is crossed. Little shifting behavior occurs when two choices were to one side of midline. Staying was not induced by any geometric configuration but stay animals exhibited preferences for turns which tended to "circle" them back to the point of origin. It is concluded that alternation behavior is not so much a "working memory" phenomena but a pattern co-determined by the geometry of choices and the task contingencies.

WITHIN SESSION VARIATION IN BEHAVIOR: AN UNTAPPED SOURCE OF DATA AND POTENTIAL CONFOUNDS FOR BEHAVIORAL PHARMACOLOGY.

J. M. Roll*, F. K. McSweeney, R. E. See, B. P. Kelly and W. M. Meil. Dept. of Psychology, Washington State Univ., Pullman, WA 99164-4820.

Inherent in both the methodology and theory of operant psychology is the assumption that rate of responding is constant within an experimental session. The incorporation of operant methodology by behavioral pharmacologists has resulted in the constant rate assumption becoming central to behavioral pharmacology as well. Recent research (McSweeney, 1992; McSweeney & Hinson, 1992; McSweeney & Roll, 1993) has unequivocally demonstrated that rate of responding varies in a robust, systematic fashion within experimental sessions. This constitutes a major source of uncontrolled variation in studies that utilize operant methodology, introducing a potentially major confound. However, systematic changes in rate of responding within an experimental session also provide a potentially rich source of untapped dependent measures. This paper outlines and discusses the potential confounds introduced by recognizing within session changes in response rate. It also presents preliminary data demonstrating the effects of several drugs (cocaine, ethanol, and caffeine) on within session patterns of responding and shows how interpretation of these results can further our understanding of within session patterns of responding.

660.15

MICRO AND MACRO-STRUCTURE OF LEARNING IN THE ACTIVE AVOIDANCE.

A. Giuliani, O. Ghirardi, A.M. Mancini, M.T. Ramacci, A. Carta* and A. Colosimo¹. Inst. for Res. on Senescence Sigma Tau, 00040 Pomezia, Italy; ¹ Dept. Biochem. Sci., "La Sapienza" Univ. of Rome, Italy

The dynamics of learning in the Active Avoidance (shuttle-box test) was analyzed at the level of the trials as well as at the level of daily sessions formed by many trials.

The two temporal scales (small scale of the trials and large scale of the sessions) highlighted very different features with no linear relation between them. By means of a renormalization group approach we investigated the intermediate scales which resulted to be coherent with the small scale but unrelated with the large scale.

This result is dynamically explained by the enormous difference between the rates of learning at the two extreme scales (4 orders of magnitude) and points out to the existence of two distinct processes of learning occurring at different temporal scales. The learning occurring at the session level (large scale) is by far more efficient of the small scale one. Nevertheless the small scale learning could be responsible for the presentation of the stimulus to be analyzed at the large scale as well as for the extinction processes.

MOTIVATION AND EMOTION III

661.1

FO5 IMMUNOREACTIVITY INCREASES IN THE MEDIAL NUCLEUS OF THE AMYGDALA AFTER PUP EXPOSURE IN PRAIRIE VOLE MALES B. Kirkpatrick*, T.R. Insel. Maryland Psychiatric Research Center, UMAB, Baltimore, MD 21228 and Lab. of Neurophysiology, NIMH, Poolesville, MD 20837.

Although there is an extensive literature on the neural substrates of maternal behavior, there have been few neurobiological studies of paternal care. The prairie vole is a biparental, monogamous rodent in which both juvenile and adult males approach and huddle over pups. We previously reported that axon-sparing lesions of the medial nucleus of the amygdala of male prairie voles reduce paternal behavior, as measured by pup contact. This reduction in paternal behavior appears both anatomically specific (lesions of the basolateral nucleus are ineffective) and behaviorally selective (large medial nucleus lesions do not affect a number of non-social behavioral measures and small lesions reduce paternal behavior while sparing other forms of social interaction). In the current study, prairie vole males exposed to 3-5 day old vole pups for the first time showed extensive contact throughout the 3 hour test period. Compared to males exposed to a novel, non-social stimulus, pup-exposed males showed increased staining for *fos* peptide in the medial nucleus of the amygdala as well as areas with established anatomical connections to it: medial preoptic area, bed nucleus of the stria terminalis, midline thalamic nuclei, and lateral septum. Other areas also showed increased *fos* expression. These results support the involvement of the medial nucleus of the amygdala in paternal behavior and suggest that several limbic regions may be activated by exposure to conspecific pups.

661.2

SPINAL PATHWAY MEDIATING SUCKLING-INDUCED NURSING BEHAVIOR AND NEUROENDOCRINE REFLEXES. J. M. Stern*, Y.-L. Yu, and D. C. Crockett. Dept. of Psychology, Rutgers Univ., and Dept. of Neurosci. & Cell Biol., UMDNJ, Piscataway, NJ 08854.

Maternal behavior (MB) in rats consists of active behaviors (retrieval, licking of pups) and quiescent nursing (typically, upright crouch with rigid splayed legs). Because the latter requires suckling, we assessed whether the lateral columns (LC), the spinal pathway known to mediate the milk-ejection reflex, also mediate the upright crouching posture. Bilateral lesions of the lateral (Lx, n=8) or dorsal (Dx, n=6) columns at C5 were made on day 5-8 postpartum; controls (C, n=8) were subjected to a sham-procedure. Ventral trunk cutaneous sensitivity was not impaired in any rat. All aspects of MB and lactation were present in C and Dx dams soon after treatment. Among Lx dams, lactation ceased in all, and 6 showed good ambulatory and ingestive recovery; of these, retrieval and licking recovered in 4 and 6 rats (in 2-5 days) and all were quiescent for long periods in response to suckling by foster pups, but their nursing posture was impaired (i.e., prone or hunched over). Thus, the LC mediate both suckling-induced neuroendocrine and postural maternal reflexes. (Supported by MH40459 to JMS).

661.3

ADULT ACTIVITY AND CORPUS CALLOSUM SIZE IN THE RAT: EFFECTS OF SEX AND NEONATAL HORMONE TREATMENT. C.M. Mack* and V.H. Denenberg. Biobehavioral Sciences Graduate Degree Program, The University of Connecticut, Storrs, CT 06269.

The presence of sex differences in both nonreproductive behaviors and corpus callosum (CC) size in the rat suggest a possible relationship between these variables. As a preliminary test of this hypothesis, multiple measures of activity using the Digiscan apparatus were obtained in adulthood for males, females, testosterone propionate (TP) treated females (Day 4), and ovariectomized (Ovx) females (Day 12). Callosal parameters, based on prior factor analysis of the rat CC, were assessed following testing. As previously reported, males had a larger CC than females, and both TP treatment and Ovx enlarged the female CC. Behavioral analyses showed females to be more active than males for horizontal movements. TP treatment reduced activity levels for both horizontal and vertical measures, whereas Ovx had no effect on activity measures. Correlations between activity and CC parameters revealed significant relationships in females between CC size and all activity measures. No relationship was found in males, TP treated females, or Ovx females. These findings indicate that 1) the enlarging effects of Ovx and TP on the CC are dissociable at the behavioral level, and 2) a relationship between CC size and activity is present in females, possibly due to the presence of estrogen in this group.

661.5

AGGRESSION AND SOCIAL BEHAVIOR AFTER FOUR DIFFERENT MEDIAL HYPOTHALAMIC LESIONS. M.E. Oakes* and G.D. Coover. Department of Psychology, Northern Illinois University, DeKalb, IL 60115.

Lesions of the medial hypothalamus appear to increase defensive behavior, particularly in response to handling or attack. However, both decreases and increases have been reported in offense and social aggression. Olivier (1977, *Aggressive Behavior* 3:47-56) found evidence for increased offense after lesions of the caudal as opposed to rostral ventromedial hypothalamus (VMH).

The present study examined the effects of bilateral electrolytic lesions of either the rostral VMH (rVMH), medial VMH (mVMH), posterior VMH (pVMH) or the dorsal medial hypothalamus (DMH). Behavioral testing involved placing an intruder (stimulus rat) into the plastic home cage (with wood chip bedding) of an experimental rat for 5 min on two separate occasions.

All four types of lesion reduced the time spent plowing and kicking wood chips compared to controls ($p < .05$, Newman-Keuls). Rats with lesions of the rVMH and mVMH spent more time immobile than controls (p 's $< .005$, t -tests). The rVMH group also showed more defensive kicks plus lateral postures than the control group ($p < .005$, t -test). Fights were more likely to occur in tests of rVMH or mVMH rats than of control, pVMH or DMH rats ($p < .05$, Newman-Keuls). These data indicate increased defense after lesions rostrally in the VMH. Rats with DMH and pVMH lesions showed more on-top contact with the intruder than the controls (p 's $< .05$, t -tests), with frequencies, respectively, of 16.5 ± 7.1 (Mean \pm SE), 20.9 ± 7.5 and 4.0 ± 1.3 . For the rVMH and mVMH groups, the values were 4.0 ± 1.2 and 7.1 ± 3.8 . This behavior has been called aggressive grooming and suggests initiation or solicitation of social interaction. Caudal or dorsal medial hypothalamic lesions increase what appears to be an aspect of social aggression.

661.7

CONCURRENT EXPLORATION OF A COMPLEX FIELD BY RATS WITH SHAM AND FORNIX LESIONS. T.L. Steele* & S.M. Olson. Dept. of Psychology, Univ. of Wis. Oshkosh, Oshkosh, WI 54901.

Atypical exploration by rats with hippocampal or fornix lesions has been attributed to stereotypy, hyperactivity, and memory deficits (1). Since exploration is a product of the environment, this study sought to determine which abnormalities still occur when lesioned rats explore complex familiar and novel environments with an intact conspecific.

Sham- (S) and fornix-lesioned (F) female hooded rats were housed in pairs for 22 days. Rats had continuous access to a "familiar" field containing 32 semi-enclosed compartments and several permanently located objects. Over the last 10 days rats were given concurrent 30 min/day free access to a similar "novel" field in which objects were replaced daily by new objects located in different compartments.

Investigation of novel compartments, especially those containing objects, was extensive by all rats. Habituation to certain characteristics was evident. Although all rats investigated the majority of novel compartments, visits by F rats were generally brief but numerous. F rats were also more active and shuttled between the fields frequently, exploring familiar compartments more extensively than S rats. A social influence on exploration was also noted.

Field complexity and presence of a conspecific likely contributed to the apparent normal exploration of the novel environment by F rats. However, brief contacts in the novel field coupled with repeated investigation of the familiar field suggests cognitive and motor deficits may have affected exploration. The effect of fornix lesions thus appears to be strongly, but not exclusively, influenced by environmental factors.

GENDER DIFFERENCES IN CROWING AND AGGRESSION IN TESTOSTERONE-TREATED CHICKS.

L. Normansell* and J. Swope, Dept. of Psychology, Muskingum College, New Concord, OH 43762.

Testosterone (T) administration in young chicks induces an adult-like morphology and a number of adult-like behaviors including crowing and aggressive pecking, and a decrease in the distress vocalization (DV) which normally accompanies social separation. The present series of studies investigated some of these T-induced emotional effects, with an analysis of gender differences. Effects of drugs known to modulate vocalizations were also assessed.

When tested in groups of four, control males were three times more aggressive than females. T-treatment raised that level of aggression in females up to the level of males. T-treated males crowed four times more often than treated females, while no control chicks of either gender ever crowed. Scopolamine (1mg/kg) decreased crowing slightly, but had no effect on pecking. When chicks were tested individually, T-treatment decreased the number of DVs emitted, with males more affected than females. Scopolamine increased the number of DVs emitted in all test groups. Morphine (1mg/kg) had no effect on either pecking or crowing, but reduced the number of DVs in males and females in both treatment conditions. While naloxone (1mg/kg) had no effects on DVs, it blocked the morphine-induced suppression of vocalization.

Males were also tested by being paired with a like-treated weight-matched chick from their same small flock or from a different flock. Chicks crowed over eight times more often and pecked each other five times more often when they were paired with a stranger than with a fellow from their own flock.

EFFECTS OF ROUGH-AND-TUMBLE PLAY ON C-FOS EXPRESSION IN THE JUVENILE RAT BRAIN. S.M. Sivity*, S. Huguenin, L.A. Kerrigan, S.J. Kuhlman, S.W. James and K. Hirazumi. Departments of Psychology and Biology, Gettysburg College, Gettysburg, PA 17325.

Proto-oncogenes, such as *c-fos* and *c-jun*, have been used extensively during recent years as markers of metabolic activity in the brain and to map areas of the brain which are active during discrete behaviors. In the rat, rough-and-tumble play occurs during discrete bouts and, thus, may be expected to activate *c-fos*. At 21 days of age, rats were housed individually and given a 5 minute daily opportunity to engage in rough-and-tumble play from post-natal days 22 to 34 (P22-P34). On P35, half of the rats were deeply anesthetized and perfused intracardially 90 minutes after a 5 minute opportunity to play, while the other half had no opportunity to play prior to being anesthetized. Brains were carefully removed and 70 μ m sections of selected brain areas were processed immunohistochemically for the presence of c-Fos using a primary antibody which recognizes both Fos and Fos-related proteins. In both groups of rats (no-play and play), very little immunoreactivity was detected in subcortical areas, including thalamus, hippocampus and amygdala. While Fos-like immunoreactivity was detected in the parietal cortex of rats from both the no-play and play groups, there was significantly more labelling in those rats allowed to play ($p < 0.02$). These data suggest that play behavior may selectively activate *c-fos* expression in cortex. Studies are currently in progress to quantify *c-fos* mRNA as an additional measure of *c-fos* activation in the playing rat.

661.8

HUMAN CHORIONIC GONADOTROPIN AFFECTS OPEN FIELD BEHAVIOR, NEOPHOBIA AND MEMORY TEST PERFORMANCE IN RATS H. Lukacs*, E. S. Hiatt, Ch. V. Rao. Dept. OB/GYN, Univ. of Louisville, Louisville KY 40292

Our laboratory has reported the presence of luteinizing hormone(LH)/human chorionic gonadotropin (hCG) receptors in several rat brain areas with highest density in hippocampus. 125 I-hCG injected in peripheral circulation can cross blood brain barrier. We conducted a series of studies to ask whether hCG affects behavior patterns associated with hippocampus. Female rats (n=10) were injected with 50 IU hCG (ip) or sal at 9AM on proestrus and monitored for 4 days. hCG injection decreased locomotion/exploratory behavior in open field: distance rats travelled and frequency of rearing ($p < 0.05$). However, time to enter open field (reaction to novel stimulus) was unchanged by hCG. To investigate whether reduced activity of hCG-treated rats within open field might be due to increased anxiety of a novel stimulus, rats (n=7) were tested for taste neophobia. hCG-treated rats greatly preferred a novel food over rat chow ($p < 0.01$), suggesting not only lack of neophobia, but increased interest. Working memory tested in a T-maze showed no effect on the correctness of choices, however, the hCG-treated rats (n=8) exhibited fewer head turns ($p < 0.05$). In summary, hCG administration affects certain behavioral parameters primarily regulated by the hippocampus, suggesting that hippocampal LH/hCG receptors may be functionally coupled to regulation of rat activity, neophobia and other associated behaviors. Food preference and decreased activity have parallels in women during the first trimester of pregnancy when serum hCG is highest.

UNCONDITIONAL APPROACH PREFERENCES IN THE QUAIL: EFFECTS OF THALAMIC AND MIDBRAIN LESIONS. A. Csillag*, P. Kabai and J.K. Kovach. 1st Dept. of Anatomy, Semmelweis Univ. Med., Budapest, Hungary and The Menninger Clinic, Res. Dept., Topeka, KS, U.S.A.

Selected genetic lines of Japanese quail chicks exhibit unconditional preferences for blue and red stimulus in approaching flickering light (Kovach JK, 1980, Science 207: 549). The initial manifestation of preferences is spared by bilateral hemispherectomy (Kabai P, Kovach JK, 1993, Physiol. Behav. 53:). Newly hatched quail chicks were exposed to stereotaxic radio-frequency lesions in thalamic areas or sub-total ablation of optic tecta. The birds' approach response and color preference were tested before and 24 hours after surgery in a mass screening apparatus. Lesions to the n. rotundus, opticus princip. thalami (OPT) and geniculatus lateralis p. ventralis did not attenuate the approach behavior in BL and RL chicks, nor the approach preference in BL birds. In RL birds, lesions to these nuclei had a slight effect on red preference. Lesions to the nuclei dorsomed. ant., post.; and dorsointermed. post. attenuated both the preference and the elicibility of approach response in RL but not in BL chicks. Lesions of the nuclei of ansa lenticularis, subrotundus, ovoidalis, reticularis thalami and occipitomesencephalic and tectothalamic tracts attenuated the approach response in both RL and BL birds and had greater effect on red than on blue preference. Conversely, only blue preference was impaired by tectal ablation.

It is suggested that the deep thalamic lesions affect primarily the motor component of approach response, whereas the dorsomedial (limbic) thalamic region is likely to form a link between the visual information and the initiation of (red-biased) approach response. Thalamic and tectal centres may play different roles in the mediation of red and blue preferences.

PATTERNED DOPAMINERGIC ACTIVITY UNDERLIES THE MOTIVATIONAL EFFECTS OF MORPHINE WITHDRAWAL. K. Nader* & D. van der Kooy. Dept. of Anatomy, Univ. of Toronto, Toronto, ON, M5S 1A8.

Animals were made dependent with 3 weeks of 3 injections a day of 20 mg/kg/inj. morphine (Development). Animals were then exposed to one conditioning environment over 4 trials, each trial 18 hr after abstinence from morphine (Training). Neuroleptic pretreatment (*cis*-flupentixol 0.8 mg/kg) prior to conditioning in the training phase blocked the normal conditioned avoidance of the withdrawal paired side. In order to test if dopamine is necessary for the development of dependence, and in turn withdrawal, animals were pretreated with the same neuroleptic prior to each morphine injection during the development phase and then conditioned with morphine abstinence in the absence of neuroleptics. At testing neuroleptic pretreated animals demonstrated conditioned avoidance of the withdrawal paired side equivalent to that of animals injected with saline prior to each morphine injection. This suggests that dopamine's role is limited to the expression, rather than development, of withdrawal's motivational effects.

To further characterize the nature of the dopaminergic withdrawal signal, dependent animals were again conditioned to avoid an environment paired with morphine withdrawal. Prior to conditioning, animals were pretreated with a 1.0 mg/kg dose of either amphetamine (AMPH) or apomorphine (APO). If the aversive effects of withdrawal are mediated by an overall decrease in post-synaptic dopamine receptor activation, then we predict that both AMPH and APO pretreatment should block the acquisition of a place aversion to the withdrawal paired side. On the other hand, if withdrawal is mediated by a specific pattern of activation of post-synaptic dopamine receptors, then APO pretreatment should block, but AMPH (which potentiates dopamine release) should intensify the aversive motivational effects of withdrawal. AMPH pretreated animals demonstrated larger aversions to the withdrawal paired side compared to controls, whereas APO treated animals showed no significant aversion to the withdrawal paired side. This suggests that the aversive motivational effects of withdrawal are mediated by a patterned activation of post-synaptic dopamine receptors.

661.13

CENTRAL CHOLINERGIC MECHANISM OF THE REACTIVE CARDIAC EFFECTS OF FG 7142. K.S. Quigley*, S.L. Hart, M.F. Sarter, & G.G. Berntson, Department of Psychology and Neuroscience Program, Ohio State Univ., Columbus, OH 43210.

We have previously demonstrated an enhancement of the cardioacceleratory response to a moderate intensity auditory stimulus following administration of the benzodiazepine inverse agonist, FG 7142 (FG), a putative anxiogenic agent. In the present study, rats were given light/shock (CS/US) pairings (conditioned, CND) or random presentations of the CS and US (pseudoconditioned, PSD). CND subjects showed an enhanced cardioacceleratory response to the CS relative to PSD. In contrast, PSD subjects, like subjects administered FG showed an augmented response to an irrelevant probe tone relative to CND.

Possible mechanisms for the augmented cardioacceleratory response after FG were examined. Intracerebroventricular administration of the cholinergic agonist, carbachol mimicked the cardioacceleratory enhancement effect of FG. Moreover, this effect was blocked by central atropine. In addition, central atropine normalized the FG-enhanced cardiac response. In sum, these data are consistent with the hypothesis that unpredictable shock produces a cardioacceleratory enhancement like that observed after FG. Additional data indicate that FG may evoke a sympathetic mechanism having a central cholinergic basis.

MORPHINE FAILS TO PRODUCE DISCRIMINATIVE EFFECTS IN THE VENTRAL TEGMENTAL AREA (VTA). T.V. Jaeger* and D. van der Kooy. Dept. of Anatomy, Univ. of Toronto, Toronto, Canada M5S 1A8.

Previous studies have implicated ascending visceral and gustatory pathways (parabrachial nucleus), but not dopamine terminal fields (nucleus accumbens) as a possible substrate for opiate discriminative effects. These discriminative substrates are distinct from the medial forebrain bundle pathways mediating the rewarding effects of opiates. To extend these findings, we investigated the discriminative actions of morphine in the VTA, an area known to mediate morphine's rewarding actions. Rats were injected with morphine (5 mg/kg, i.p.) 15 min prior to the presentation of a 0.1% saccharin solution. Lithium chloride (130 mg/kg) was injected immediately after 20 min of exposure to the flavour. On alternate days, an injection of 0.9% saline both preceded and followed the presentation of saccharin. Animals learned to consume significantly less saccharin after morphine than after saline injections. Unilateral guide cannulae were then implanted into the ventral tegmental area and generalization to central routes of administration was evaluated following the microinjection of 2.5, 5, 10 and 20 µg of morphine. At doses as high as 10 µg, morphine failed to produce responses reliably different from the saline training condition. Decreases in saccharin consumption were observed only at the 20 µg dose of morphine. However, control data showed that these effects could not be attributed to the cueing properties of morphine. Rather, morphine produced unconditioned decreases in saccharin consumption. The absence of discriminative effects of morphine in areas known to mediate its motivational effects implies the presence of a distinct neural pathway for the processing of the perceptual effects of morphine. To confirm this hypothesis, we are using a taste conditioning procedure to assess the motivational properties of morphine in the parabrachial nucleus.

661.12

HALOPERIDOL & PENTOBARBITAL PRODUCE DIFFERENT PATTERNS OF ELEVATIONS IN OPERANT RESPONSE FORCE & DURATION IN RATS E. O'S. Hammond*, M. A. Raven, & A. Ettenberg Behavioral Pharmacology Laboratory, Dept. of Psychology, Univ. of California, Santa Barbara, CA 93106

Although haloperidol (HAL) and pentobarbital (PEN) produce comparable deficits in rats' spontaneous locomotor activity, it was of interest to determine whether the biophysical response capacity of treated subjects would differ in an operant task. Hungry rats were trained to press a force-sensing operandum for 2 sec access to sweetened milk. Responses were analyzed for temporal and force characteristics during vehicle or drug trials. While both drugs produced elevations in the mean peak force emitted during responding, within-session patterns differed. Peak force exerted by HAL animals increased over the session whereas peak force of PEN animals remained stable. Similarly, while both drugs produced response duration increases, HAL effects increased over the session while PEN durations decreased. These results demonstrate the utility of force-time data in identifying differences between classes of motor-impairing drugs.

WHOLE-CELL PATCH-CLAMP ANALYSIS OF NEURONAL EXCITABILITY IN THE SUPRACHIASMATIC NUCLEUS (SCN). Y. Bouskila^{1,2} and F. E. Dudek². ¹Interdept. Neurosci. Grad. Prog., UCLA Sch. of Med., Los Angeles, CA 90024 and ²Dept. of Anatomy & Neurobiol., Colorado State Univ., Fort Collins, CO 80523.

The neurons of the SCN exhibit a circadian rhythm in firing rate which may result from modulation of their excitability. To examine neuronal excitability and membrane properties, coronal hypothalamic slices (400 μ m) were prepared and neurons were recorded in the whole-cell patch-clamp mode. Spike trains were elicited by graded current pulses (producing 1.6-2.4 mV steps for 200 ms) near spike threshold. Most neurons (n=6) exhibited a high accommodation constant (2.32 ± 0.46 , defined as the ratio of last interval to first in a spike train) and had profound spike broadening and spike amplitude reduction (except for one cell). A few neurons (n=2) showed almost no spike accommodation (accommodation constant of 1.28 ± 0.06 , $p < 0.003$) at all firing rates. The accommodating neurons differed from the non-accommodating neurons by their lower whole-cell capacitance and input resistance. It is unlikely that these differences are due to recording quality since the two cell groups were not significantly different in first spike amplitude, half-peak duration and threshold, resting membrane potential or slope of current-frequency (I-F) relation. Spike accommodation may be important in modulating neuronal excitability and it should now be possible to identify the underlying currents. Supported by AFOSR.

EVIDENCE FOR EXPRESSION OF PLASTICITY IN THE BRAIN OF THE ADULT SIBERIAN HAMSTER: PHOTOPERIODIC CHANGES IN NCAM. W. Lee, J.D. Glass, M. Watanabe and J.M. Walro¹. Dept. Biol. Sci. Kent St. Univ. Kent, OH 44242. ¹Dept. Anat. Northeastern Ohio Univ. Col. Med. Rootstown, OH 44272.

The polysialylated form of the neural cell adhesion molecule (PSA-NCAM) is thought to facilitate plasticity in the adult brain. The aim of the present study was to examine the distribution of PSA-NCAM and NCAM polypeptide in a species that exhibits photoperiod-induced reorganizations in neuroendocrine functions. In hamsters maintained under long day photoperiod (LD 16:8), immunostaining for both moieties was strongest in the supraoptic, suprachiasmatic, ventromedial (VM) and arcuate (ARC) nuclei. Immunostained tanyocyte-like processes radiating from the 3rd ventricle were particularly noticeable in the median eminence (ME) as well as the VM and ARC nuclei. In gonadally-regressed animals held under short day photoperiod (LD 8:16) for 8 wks, there was a striking decrease in NCAM staining of the tanyocyte-like processes in the VM and ARC nuclei. The resulting increase in the ratio of PSA-NCAM to NCAM in these structures could favor the occurrence of morphological rearrangements associated with short photoperiod. Supported by AFOSR F49620-93-0086 (JDG).

A DISTINCT SUBNUCLEUS OF CALBINDIN-LI IMMUNOREACTIVE CELLS IN THE HAMSTER SUPRACHIASMATIC NUCLEI (SCN). H.R. Besner^{*}, R. Khan, J. LeSauter, J.M. Nuñez, and R. Silver. Barnard College of Columbia University, New York, N.Y. 10027.

The SCN of mammals are known to serve as a biological clock regulating circadian rhythms. At least 25 neuroactive substances or synthetic enzymes have been found in the SCN (Card and Moore, 82:84). Identification of pacemaker cells of the nuclei however, has not been achieved, and there is substantial interest in further characterization of SCN neuron types. In this study, we report the distribution of a calcium-binding protein, calbindin-D28K (CaBP), in the SCN of hamsters. Though the physiological functions of calbindin are not fully understood, it is thought to play a role in buffering calcium ions. Calcium is involved in transmembrane signaling and the intracellular transmission of signals.

In coronal sections through the hamster SCN, calbindin-like immunoreactivity (CaBP-ir) occurs in a very discrete, tightly packed subregion, positioned near the center of the nucleus. No CaBP-ir cells or fibers are seen at any peripheral borders of the SCN (delineated with antisera to VIP and VP), although CaBP-ir is abundant in the rest of the hypothalamus. Analysis of alternate sections indicates that CaBP-ir cells overlap in their distribution with substance P (SP)-like ir cells. Light induced fos-ir nuclei occur in this region as well but are more widely distributed than the distinct subnucleus characterizing CaBP- and SP-like ir. In contrast, parvalbumin, another calcium-binding protein, is noticeably absent from all hypothalamic nuclei. It is interesting that the rat does not have a subnucleus characterized by either SP- (Morin et al., '92) or CaBP- (Celto, '90) containing cells. The functional significance of this species difference, and the function of this distinct subnucleus in the hamster remains to be assessed. Supported by NIH grant NS-24292.

AMINO-ACIDS-MEDIATED INHIBITION AND EXCITATION OF CHARACTERIZED RAT HYPOTHALAMIC PARAVENTRICULAR NEURONS FOLLOWING SUPRACHIASMATIC NUCLEUS STIMULATION. M.L.H.J. Hermes^{*} and L.P. Renaud. Neuroscience Unit, Loeb Research Institute, Ottawa Civic Hospital, Ottawa, Canada K1Y 4E9.

The suprachiasmatic nucleus (SCN) generates circadian rhythms in endocrine and autonomic processes. Electrophysiological data obtained *in vivo* show that the SCN influences the excitability of neurosecretory and brainstem-projecting neurons in the hypothalamic paraventricular nucleus (PVN). The transmitter candidates that mediate the responses are unknown. *In vitro* intracellular recordings were made in coronal slices of the rat hypothalamus to characterize the synaptic responses of PVN neurons to SCN stimulation. In PVN neurons that displayed linear V-I relationships with evidence of 1a but a lack of low-threshold potentials (i.e. putative magnocellular neurons), electrical stimulation of the SCN ($\leq 75\mu$ A, 1Hz) evoked short latency (8-10ms) IPSPs with a reversal potential between -63 and -75 mV that could be blocked by bath application of 20 μ M bicuculline. In the majority of neurons in the PVN that had linear or inwardly rectifying V-I relationships with no 1a but with small low-threshold depolarizations (generating at most one action potential: putative parvocellular neurons), short latency (7-10 ms) EPSPs were observed following SCN stimulation which could reversibly be attenuated or blocked by 0.5-1 mM bath-applied kynurenic acid.

The data suggest that the amino acids GABA and glutamate are primary transmitters involved in the relay of SCN information to the PVN (Supported by the International Human Frontier Science Program Organization and the Canadian Heart & Stroke Foundation).

662.4

POLYSIALYLATED NCAM IN THE SCN: EVIDENCE FOR PLASTICITY IN THE ADULT CIRCADIAN PACEMAKER. J.D. Glass, W. Lee, R.V. Dorman and M. Watanabe¹. Department of Biol. Sci., Kent St. Univ. Kent, OH 44242. ¹Div. Pediatric Cardiol., Dept. Pediatrics RB&C, Case Western Reserve Univ., Sch. Med. Cleveland, OH 44106.

In the adult brain the highly polysialylated form of neural cell adhesion molecule, PSA-NCAM, is associated with regions that exhibit neuronal plasticity. Immunohistochemical procedures were used to study PSA-NCAM and its NCAM polypeptide in the SCN of the Siberian hamster. Immunoreactive polysialic acid (PSA) (visualized using a monoclonal antibody against the PSA of NCAM) was evident throughout the SCN, but was most intense in the ventrolateral region. Immunoreactivity was present in the neuropil, which delineated many cellular aggregations. Preincubating sections in endoneuraminidase (endo-N) abolished staining. Staining for NCAM also was limited to the neuropil, but was more diffuse than PSA staining. The ventral SCN had the most labeling for NCAM. Immunoblots showed the PSA-NCAM as a broad band between 150-300 KDa. Immunoreactive NCAM polypeptides appeared as major bands at 120, 140, and 180 Kda. Removal of PSA from PSA-NCAM with endo-N markedly increased the intensity of the 180 and 140 Kda bands implicating these NCAM isoforms as PSA carriers. These results are evidence that cellular elements of the SCN have the capacity to undergo physiologically-regulated morphological adjustments. Supported by AFOSR F49620-93-0086 (JDG).

IMMUNOREACTIVITY OF HAMSTER INTERGENICULATE LEAFLET (IGL) CELLS PROJECTING TO SUPRACHIASMATIC NUCLEUS AND DORSOMEDIAL THALAMUS. E. Meyer^{*}, J. Blanchard and L.P. Morin. Dept. Psychiatry, Health Science Center, SUNY at Stony Brook, NY 11794.

The hamster IGL is a 2 mm long lamination between the dorsal and ventral (VLG) lateral geniculate nuclei. It contains NPY-IR cells many of which project to the SCN in both rat (Card & Moore, JCN '89) and hamster (Morin et al., Vis. Neurosci., '92). The hamster also has a probable ENK-IR path to the SCN not evident in rat. We have compared the geniculate distributions of hamster NPY-IR and ENK-IR cells projecting to the SCN, contralateral IGL and dorsomedial thalamic nuclei.

Fluoro-Gold, placed in the SCN, IGL or dorsomedial thalamus, was used for retrograde tracing in conjunction with immunohistochemical techniques (Vis. Neurosci., '92). Colchicine (100 μ g/each lateral ventricle) was administered 24 hr before perfusion. NPY-IR cells are found throughout the IGL, as previously reported. ENK-IR cells are also abundant in the IGL. At mid-levels of the IGL, both NPY-IR and ENK-IR cells are found ventral to the leaflet proper. In the VLG, NPY-IR cells tend to be more medial than the ENK-IR cells. Both ENK- and NPY-IR cell types project to the SCN. Unlike the rat, ENK-IR cells of the hamster IGL do not project to the contralateral IGL. IGL cells also project to the dorsomedial thalamus and some of these are NPY-IR. We are presently determining whether any of these are ENK-IR and whether the NPY- and ENK-IR are found in identical cells. Supported by NIH grant NS22168.

662.7

THE SUPRACHIASMATIC NUCLEUS AND INTERGENICULATE LEAFLET OF THE OCTODON DEGUS, A DIURNAL RODENT. L. Smales*, N. Goel and T. Lee. Depts. Psychology, Michigan State University, East Lansing, MI, 48824, and University of Michigan, Ann Arbor, MI, 48104

Little is known about the functional neuroanatomy of circadian rhythms in diurnal mammals. One reason has been the absence of a suitable diurnal model. The degu is a caviomorph rodent that breeds well in captivity and exhibits diurnal wheel-running and temperature rhythms (Labyak and Lee, unpub. data). To provide the groundwork for future experimental studies, we examined retinal projections to, and the distribution of peptides in the SCN and IGL of 6 adult degus. Two animals received an intraocular injection of cholera toxin 2 days prior to sacrifice. Brains were processed for immunohistochemical identification of various antigens. The degu SCN contained VIP and VP immunoreactive (IR) cell bodies, a relatively small plexus of NPY-IR fibers, and a few sparse M-enk-IR fibers; a dense plexus of SP-IR fibers completely surrounded but did not enter the SCN. Retinal fibers projected evenly to ipsi- and contralateral SCN. The IGL contained some NPY-IR cell bodies, and M-enk-IR and SP-IR fibers. Retinal fibers projected to both IGL. In summary, many basic features of the SCN and IGL are fundamentally the same in the diurnal degu as in nocturnal rodents.

THE POSTNATAL DEVELOPMENT OF RETINAL PROJECTIONS TO THE RAT SUPRACHIASMATIC NUCLEUS. D. M. Murakami*, I.-H. Tang, A. Kaplan, C. Kim, and C. A. Fuller. Section of Animal Physiology, University of California, Davis, California 95616-8519.

The suprachiasmatic nucleus (SCN) has been suggested to be the critical neural pacemaker for circadian rhythms, and the retinohypothalamic projection (RHT) mediates the effect of light on circadian rhythms. This study examined the development of the RHT to the SCN. Rat pups from birth (P0) to postnatal day 10 (P10) were sacrificed and perfused with fixative and post fixed for at least 1 week. The cornea and lens were reflected away and Dil crystals placed onto the retina. The cornea and lens were replaced, the eye sealed, and the pup placed back into fixative for a minimum of 3 months for anterograde transport. Rat brains were removed, sectioned on a microtome, and examined under a fluorescence microscope. From P0 to P2 the retinal projections through the nerve and optic chiasm were relatively light and did not appear to innervate the SCN. However, by P3 the optic nerve and chiasm exhibited dense retinal axons and the first retinal input to the SCN was revealed. Individual axon terminals were revealed that exhibited very simple arborizations primarily from the ipsilateral eye. These projections continued to become more dense for the next 7 days.

662.11

CLASSIFICATION AND DISTRIBUTION OF RETINAL GANGLION CELLS THAT PROJECT TO THE SUPRACHIASMATIC NUCLEUS (SCN) OF THE RAT J.C. Speh*, J.P. Card and R.Y. Moore. Depts. of Psychiatry, Neurology, Behavioral Neuroscience and the Center for Neuroscience, University of Pittsburgh, PA 15261

Recent studies have identified an alphaherpes virus, the Bartha strain of the pseudorabies virus, as a quite specific marker of the retinal projections to nuclei of the circadian timing system (Card et al., 1991). Virus injected into the eye is transported to the retinorecipient fields in the hypothalamus, particularly the SCN, and the intergeniculate leaflet and to accessory optic nuclei but not to other retinal recipient areas. Once the virus reaches the central nervous system it travels transynaptically in a retrograde direction to the next order of neurons. We have analyzed the temporal parameters of viral retrograde transport and have determined the time when the contralateral eye would have maximal retrograde labeling from the SCN. Utilizing the Bartha virus injected into the eye and the retrograde tracer Fluorogold (FG), injected into the SCN, we have identified a subset of retinal ganglion cells that projects to the SCN. The distribution of these viral infected and FG+ cells is predominantly in the peripheral temporal retina. The labeled cells range 10-18µm in diameter and the majority of labeled ganglion cells is a homogeneous population with a mean diameter of 12µm. These ganglion cells have very few extremely thin dendrites. Injections of FG directly into the chiasm retrogradely labels a full range of retinal ganglion cell types. The cells that project to the SCN are a subset of small ganglion cells that corresponds to a component of the gamma or W cell classification.

662.8

NEURAL-GLIAL INTERACTIONS: DIFFERENCES BETWEEN THE ANTERIOR HYPOTHALAMUS AND THE VENTROLATERAL SUPRACHIASMATIC NUCLEUS OF THE RAT. A.S. Elliott* S.M. Krauchunas and A.A. Nunez. Dept. of Psych., Neuroscience Program, Michigan State University, East Lansing, MI 48824.

Previous publications have suggested that neural-glia interactions in the suprachiasmatic nucleus (SCN) are different from other areas of the hypothalamus. For example, glial fibrillary acid protein staining is more intense within the SCN than in adjacent neural tissue (*Neuroscience Letters* 99: 55; *Cell and Tissue Research* 242: 9). We measured the amount of somal membrane in apposition to glia (astrocytes and astrocytic processes), neural membrane (synapses, adjacent somas, unmyelinated axons and dendrites), and other components of the neuropil (oligodendrocytes, myelinated axons) from electron micrographs of the ventral lateral SCN (vSCN) and the anterior hypothalamus (AH). The data were collected from animals entrained to a 12:12 LD cycle and sampled at 4 different time points across the circadian cycle. The initial data show that there are more glial-somal contacts in the vSCN than in the AH, and that there are more neural-somal contacts in the AH than in the vSCN. Circadian variations in other aspects of cell morphology are currently being investigated. Supported by grant IBN 9209437 from NSF.

662.10

THE RAT SUPRACHIASMATIC NUCLEUS: POSSIBLE ROSTRAL-CAUDAL ORGANIZATION AND ASSOCIATED NEURONS. I.-H. Tang, D.M. Murakami, C.A. Fuller*. Section of Animal Physiology, University of California, Davis, California 95616-8519.

This study examined the rostral-caudal organization of the rat suprachiasmatic nucleus (SCN) by investigating the cell types and their axo-dendritic distributions. Male Wistar rats were perfused with oxygenated Krebs-Ringer's solution, the brains removed and SCN exposed by vibratome with cold oxygenated Ringer's solution in the cutting chamber. Horseradish Peroxidase (HRP) crystals were injected into specific portions of the nucleus. The brains were incubated in Ringer's at room temperature for 3-4 hrs. Fixed brains were sectioned horizontally as well as coronally on a freezing microtome at 50µ. Several distinct neuron types were identified, e.g., bipolar, pyramidal and radial shaped cells. Bipolar neurons have shorter axons and dendrites than the radial and pyramidal neurons. More bipolar cells were located in the ventrolateral portion of the SCN, while pyramidal cells were more numerous in the dorsomedial area. Bipolar cells in the ventrolateral SCN primarily project to dorsomedial SCN. Horizontal sections of ventrolateral injections showed pyramidal and radial cells projecting to the contralateral SCN and to ipsilateral hypothalamus. Dorsomedial injections showed more fibers oriented rostral-caudal in horizontal sections. The caudal SCN exhibited projections toward the retrochiasmatic area. These observations suggest that the SCN exhibits distinct functional subdivisions, interconnections and efferent patterns of projection.

662.12

A PUTATIVE RETINOHYPOTHALAMIC TRACT (RHT) IN THE HUMAN DEMONSTRATED BY SUBSTANCE P (SP) IMMUNOREACTIVITY. R.Y. Moore* and J.C. Speh. Center for Neuroscience and Departments of Psychiatry, Neurology and Neuroscience, University of Pittsburgh, Pittsburgh, PA 15261.

The RHT is now recognized to arise from two sets of retinal ganglion cells. One set projects to the suprachiasmatic nucleus (SCN) and intergeniculate leaflet (IGL) and probably uses glutamate as a transmitter. The second set, originally described by Takatsuji et al (1991), projects to the SCN and the olivary pretectal nucleus and is SP-containing (SP+). In the rat, SP+ fibers form a dense plexus in the ventrolateral SCN and this plexus is lost after optic nerve section (Takatsuji et al, 1991). In the present study, we analyzed serial coronal sections through the SCN prepared with antisera to SP, vasopressin (VP) and vasoactive intestinal polypeptide (VIP) from 6 human brains obtained at routine postmortem examination from individuals of both sexes with ages from 22 to 75 at the time of death.

The SCN in non-human primates and other mammals (Moore, 1992) is characterized by a population of VIP+ neurons that overlap the distribution of the RHT and is surrounded by a population of VP+ neurons. In the human, VIP+ neurons are present in the ventral part of the SCN surrounded by VP+ neurons. The area occupied by the VIP+ neurons contains a dense plexus of SP+ axons which is separate from plexuses in the periventricular and anterior hypothalamic areas. If the human is homologous to other mammals in this respect, this plexus should represent the portion of RHT projections that is SP+. Supported by a grant from the AFOSR.

A COMPARATIVE STUDY OF VASOACTIVE INTESTINAL POLYPEPTIDE (VIP) IMMUNOHISTOCHEMISTRY IN RAT, MONKEY AND HUMAN HYPOTHALAMUS. R.P. Weis*, M.M. Moga, N.M. Suhay, J.C. Speh and R.Y. Moore. Depts. of Psychiatry, Neurology, Behavioral Neuroscience and the Center for Neuroscience, Univ. of Pittsburgh, PA 15261.

Vasoactive intestinal polypeptide (VIP) is a putative neurotransmitter of circadian pacemaker neurons in the suprachiasmatic nucleus (SCN). In the rat the hypothalamic distribution of VIP-immunoreactive (-ir) fibers closely corresponds to the pattern of SCN efferents as demonstrated by anterograde tracing studies. To determine the possible course of SCN efferents in the monkey and human, we compared the distributions of VIP-ir fibers in the rat, monkey and human hypothalamus. In all three species, a dense cluster of VIP-ir fibers was found in the subparaventricular zone with fibers also present in the preoptic/chiasmatic region, the paraventricular nucleus, the dorsomedial nucleus and the tuberomammillary nucleus. In monkey and human but not in rat, we observed a second dense cluster of VIP-ir fibers along the dorsomedial border of the VMH as well as additional fibers in the median eminence, the arcuate nucleus and the lateral tuberal nucleus. A VIP-ir fiber plexus was also found in the monkey paraventricular nucleus of the thalamus. In general, the VIP-ir fiber distribution in the monkey and human is more extensive than in the rat suggesting more direct circadian control of hypothalamic function. Supported by NIH grant NS-16304.

STIMULATION OF LOCUS COERULEUS (LC) PHASE-SHIFTS THE CIRCADIAN ACTIVITY RHYTHM IN HAMSTERS.

P. D. Penev*, P. C. Zee and F. W. Turek, Dept. of Neurobiology and Physiology, Northwestern University, Evanston, IL 60208.

Non-photoc stimuli that phase-shift hamster circadian rhythms are associated with increased activity and/or arousal. The LC neurons are particularly responsive to similar novel or unexpected environmental events suggesting a possible involvement of the LC in the mechanisms of non-photoc phase-shifting. Nine male golden hamsters (b.w. 120-140g) were kept in constant dim light (50-100 lux) and their circadian rhythms of wheel-running activity were monitored with an on-line computer. The animals were chronically implanted with bipolar electrodes (SNEK-100S) aimed at the right LC. Seven to ten days post surgery the freely-moving animals received electrical (60-120 uA, 20 Hz, 0.5 msec pulses) or sham (no current) stimulation trials for 1 h between CT 8 and CT 9. Six of the animals received both sham and electrical stimulation with at least 7 days between trials. LC stimulations induced prolonged exploratory activity, anxiety-like behavior and considerable phase-advances in all trials (range 35-90 min). Sham stimulations were associated with short initial arousal and small or absent phase-shifts (range 0-25 min). The phase-advances following LC stimulation (58 ± 7 min) were significantly larger than the phase-shifts (14 ± 4 min) associated with sham trials (ANOVA; $p < 0.001$). Our data suggest that LC stimulation mimicks the effects of arousal and/or activity inducing stimuli upon the circadian system in hamsters suggesting a possible role for LC in the mechanisms of non-photoc phase-shifting.

COMPARISON OF CIRCADIAN RHYTHMS RESTORED BY TRANSPLANTATION OF ONE OR TWO SUPRACHIASMATIC NUCLEI. F.C. Davis* and N. Viswanathan. Dept. of Biology, Northeastern Univ., Boston, MA 02115.

In rodents, transplantation of the suprachiasmatic region of the fetal hypothalamus to the brains of adult hosts restores circadian rhythms disrupted by the bilateral ablation of the host's own suprachiasmatic nucleus (SCN). In the present study, transplantation was used to test three hypotheses about the role of the SCN in circadian rhythm regulation: 1) Each bilateral representation of the SCN is a competent circadian pacemaker, 2) A single SCN is sufficient to regulate a bimodal activity pattern, and 3) The period of circadian rhythms is determined in part by the size of the SCN. Adult, SCN-lesioned hamsters (*Mesocricetus auratus*) received grafts with either one or both SCN from a single fetus. Eleven pairs of hamsters each received SCN from a single fetus and 12 hamsters each received both SCN from a single fetus. Wheel-running activity was continuously recorded in dim constant light for several weeks before and after transplantation. In four pairs that received SCN from a single fetus, both hosts showed robust restored rhythms indicating that each bilateral representation of the SCN is capable of independently regulating overt rhythms. The restored rhythms of two hosts that received a single SCN showed symmetrical bimodal patterns of activity, indicating that this pattern does not require both bilateral representations of the SCN. The average freerunning period of hosts that received a single SCN (23.98 hrs. ± 0.045 [SE], $n=13$) was significantly shorter than that of hosts that received two SCN (24.23 hrs. ± 0.076 , $n=7$). Although the actual sizes of the grafts have yet to be determined, these results suggest that the total amount of SCN tissue within a graft is one determinant of freerunning period. This result is consistent with the hypothesis that an age-related shortening of period is due to a loss of cells within the SCN during aging. Supported by PHS grant P01 AG09975.

EFFERENT PROJECTIONS OF THE PARAVENTRICULAR NUCLEUS OF THE THALAMUS IN THE RAT. M.M. Moga*, R.P. Weis, and R.Y. Moore. Depts. of Psychiatry, Neurology, Behavioral Neuroscience and the Center for Neuroscience, Univ. of Pittsburgh, PA 15261.

The paraventricular nucleus of the thalamus (PVT) receives input from all major components of the circadian timing system, including the suprachiasmatic nucleus (SCN), the subparaventricular zone, the intergeniculate leaflet and the retina. Retrograde studies have demonstrated that the PVT projects to the amygdala and hippocampus (Su and Bentivoglio, '90) and to the vicinity of the SCN (Pickard, '82) but its terminal distribution within these areas is unknown. To better understand the role of this nucleus in circadian timing, we iontophoresed the anterograde tracer phaseolus vulgaris leucoagglutinin (PHA-L) into the PVT to map the distribution of its efferent projections. Major terminal fields of the PVT include: the suprachiasmatic nucleus, the dorsomedial and ventromedial hypothalamic nuclei, the lateral septum, the central and basomedial amygdaloid nuclei, the bed nucleus of the stria terminalis, the olfactory tubercle, and the insular and entorhinal cortices. The dense axonal labeling within the SCN was evenly distributed across the dorsomedial and ventrolateral subdivisions; this terminal field extended caudally into the subparaventricular zone and the retrochiasmatic area. These anatomical findings suggest that the PVT may: 1) provide feedback to the SCN, 2) relay circadian information to limbic areas, and/or 3) serve as an entraining pathway for some as yet unspecified stimulus. Supported by NIH grant NS-16304.

A 3-DIMENSIONAL MAP OF THE AFFERENT NEURONAL NETWORK OF THE LONG-TERM REM SLEEP ENHANCEMENT SITE IN THE PONTINE BRAINSTEM. O.K. Hsu, S. Datta, J. Quattrochi*, J. Hobson. Laboratory of Neurophysiology, Harvard Medical School, Boston, MA 02115.

Microinjection of carbachol into the feline caudolateral peribrachial nucleus (C-PBL), produces a short-latency increase in state-independent ipsilateral PGO waves for 72 hrs followed by a long-term REM sleep enhancement (LTRE) lasting 7-10 days (NeuroReport 2: 619-622, 1991). Using retrogradely transported fluorescent nanospheres, ChAT/AMCA immunohistochemistry, and 3-D computer-assisted imaging, afferent inputs to this pharmacologically active site were mapped and quantified.

We found that the pedunculopontine tegmentum (PPT, Ch5) contributes the predominant input to the LTRE site: 51.8% of retrogradely labeled ChAT+ neurons, and 22.0% of non-ChAT retrogradely labeled neurons. The PBL contributes significantly less input: 23.1% of ChAT+ projection neurons, and 10.8% of non-ChAT projection neurons. The dorsolateral tegmentum (DLT, Ch6) contributes 20.8% of ChAT+ projection neurons, and only 1.7% of non-ChAT retrogradely labeled projections. Thus, within Ch5 & Ch6 we interpret these data to indicate that the PPT exerts the predominant cholinergic and non-cholinergic influence on the LTRE site compared to significantly less influence by labeled cells found within the DLT.

Spatial analysis of the topographic distribution of ChAT+ projection neurons revealed that the ipsilateral PPT, PBL, and DLT form a contiguous and continuous afferent network, suggesting that these cholinergic projection subpopulations converge upon the LTRE site as a single integrated unit. This unified network organization of ChAT+ projection neurons identifies a unique structural substrate within the context of a functional map of afferent connectivity which may help the understanding of the pharmacological activation of prolonged REM sleep state behavior. (Supported in part by NIH grant MH13923)

WHEN DOES HOST RESET GRAFTED SCN? INFLUENCE OF IMPLANT SITE, TISSUE TYPE AND PINEAL SECRETION. J. Servière¹, G. Gendrol¹, J. le Sauter² and R. Silver². ¹INRA Jouy en Josas, France; ²Barnard Coll. of Columbia Univ., New York, N.Y.10027.

In mammals, the suprachiasmatic nuclei (SCN) serve as the dominant pacemaker controlling circadian rhythms. The SCN have daily fluctuations in energy metabolism with higher glucose utilization during the day. Using ¹⁴C-2-deoxyglucose (2-DG) uptake as an index of phase we previously showed that in intact hamsters bearing SCN grafts in the 3rd ventricle (3V), the phase of the native and grafted SCN become synchronized to each other and have the phase of the host clock. In this study we explored the effect of placing 1) SCN grafts in the 3V of pinealectomized hamsters, and in intact animals, 2) cortical grafts in the 3V and 3) SCN grafts in the lateral ventricle (LV). To this end, adult males (to serve as hosts) and pregnant females (source of donor tissue) were housed in opposite LD cycles. 2DG was injected either subjective day (CT05) or subjective night (CT14). The results show that the circadian rhythm of the host resets the phase of the transplanted SCN in pinealectomized, as in intact hosts. Cortical grafts in 3V do not have circadian rhythm of glucose utilization. SCN grafts in the LV tend to fluctuate in 2DG uptake in parallel with native SCN, but the variation is not significant. We conclude that in the hamster the coupling signal from the SCN acts specifically on pacemaker cells, does not require pineal melatonin, and cannot reach pacemaker targets located at far outside the 3V. Whether the coupling signal from the host SCN is direct (via locally diffusible signals or neural efferents to the graft) is not clear, though indirect cues, such as hormonal, thermal or metabolic factors are unlikely. Supported by grants from INRA (JS), AFOSR (RS) and NATO (JS & RS).

2-MERCAPTOETHANOL AND SUCCINYLATED CONCANAVALIN A INCREASE THE NUMBER OF NEUROPEPTIDERGIC CELLS IN PRIMARY CULTURES OF THE SUPRACHIASMATIC NUCLEUS. K.A. Zimmert, R.J. Grill, S.K. Pixley, H.T. Jansen*, and M.N. Lehman. Dept. Anat. & Cell Biol., Univ. Cincinnati, Cincinnati, OH 45267; † Div. Infect. Dis., Children's Hos. Med. Ctr., Cincinnati, OH 45229.

Transplants of the fetal hamster hypothalamic suprachiasmatic nucleus (SCN), the site of a circadian pacemaker, restore rhythmic behavior to SCN-lesioned hamsters (Lehman et al., J. Neurosci. 7:1626). The presence of peptidergic cells characteristic of the SCN is correlated with the restoration of rhythmic behavior (Silver et al., Brain Res. 525:45). We explored the use of 2-mercaptoethanol (2-ME) and succinylated concanavalin A (SCA) as additives to our standard medium for culturing SCN cells prior to use in grafting studies. Fetal (E13) anterior hypothalamic cells were dissociated by a combination of gentle trituration and enzymatic treatment. Cells were rinsed and plated at 5×10^5 cells/ml/16mm well on either poly-L-lysine coated coverslips or on an astroglial bed layer. At the time of plating cultures were seeded in either control standard medium (DMEM), DMEM with 25 μ M 2-ME, or 250 μ g/ml SCA. Cultures were exposed to SCA media for 48 hrs. 2-ME cultures were maintained in 2-ME media. At ten-twelve days following seeding cultures were fixed with 4% paraformaldehyde and immunostained for a variety of neuronal and glial markers. Both 2-ME and SCA cultures showed a 3-fold increase in the number of neurons immunoreactive for vasoactive intestinal polypeptide. Because they lead to an increase in the number of peptidergic cells in dissociated SCN cultures, 2-ME and SCA may also be useful as additives to the medium used for grafting studies in which dissociated and cultured SCN cells are tested for their ability to restore rhythmicity. WHOLE CELL CURRENTS IN CULTURED CIRCADIAN PACEMAKER NEURONS OF BULLA. S. Michel*, K. Manivannan, J.J. Zaritsky and G.D. Block. NSF Center for Biological Timing, Dept. of Biology, Univ. of Virginia, Charlottesville, VA 22903.

Basal retinal neurons (BRNs) from the eyes of the marine snail Bulla gouldiana continue to express a circadian rhythm in membrane conductance for at least two cycles in primary cell culture (Michel et al. 1993, Science 259: 239).

Cultured BRNs generate action potentials that have Na^+ and Ca^{2+} components. We used the perforated patch-clamp technique to characterize the ionic currents present in these dispersed pacemaker neurons. Three distinct K^+ currents were evoked by depolarizing voltage steps. A calcium-dependent K^+ current, blocked by quinine (100 μ M) and 9-aminoacridine (400 μ M), an inactivating (A-like) K^+ current blocked by 4-aminopyridine (400 μ M), and a delayed rectifier current blocked by tetraethylammonium (10 mM). The total normalized current amplitude for voltage steps from -80 mV to +50 mV of all perforated patch recordings before projected dawn ($n=31$, Zeitgeber Time (ZT) 19 to ZT 22) is significantly higher ($p<0.01$) than after projected dawn ($n=22$, ZT 2 to ZT 4), confirming the previous results with intracellular recordings. We are now measuring the separate outward currents at different circadian times to identify the specific conductance(s) controlled by the pacemaker and ultimately investigate its type of modulation. Supported by NS15264 to GDB. SM, KM and JJZ were supported by the NSF Center for Biological Timing.

EFFECTS OF THE LIGHT QUALITY ON THE PHASE RESPONSE CURVE (PRC) OF THE ERG CIRCADIAN RHYTHM IN JUVENILE INSTARS CRAYFISH Procambarus clarkii. M.L. Fanjul-Moles*, M. Miranda-Anaya and A. Bernal-Moreno. Depto. Biología, Fac. Ciencias, U.N.A.M. Ap. Pos. 70-371, 04510, México, D.F.

In previous investigations we proposed, during the ontogeny of crayfish, the existence of two independent systems involved in the synchronization of the electroretinographic (ERG) circadian rhythm (a short and a long wave system). The aim of this work was to test this hypothesis by studying the phase shifts evoked with two monochromatic lights of the same intensity in the ERG circadian rhythm of juvenile instars. A group of 72 animals showing an overt circadian rhythm were individually housed under constant temperature and darkness. The eye's electrical response to white test flashes (ERG) delivered every 15 min was recorded by the usual technique. Each crayfish was left in free running conditions during at least four days; on the fifth day, and at different circadian time, a 30 min. pulse of monochromatic light (blue or red) was applied. Its effect on the phase of the ERG oscillation was determined on the fourth day after. PRCs for each monochromatic light were constructed. The results showed the blue pulses elicited predominantly delays shifting phase during the subjective day and subjective night. The red pulses evoked advances shifting phase in the subjective night and delays in the subjective day. The magnitude of the changes depends both on the wave length and the circadian time. These results seem to support the hypothesis proposed. Supported by CONACYT Ref 91866FFPN/92/92, and PADEP, FC-9212.

IDENTIFICATION OF P34 AND CYCLIN HOMOLOGS IN THE OCULAR CIRCADIAN PACEMAKER OF BULLA GOULDIANA, Michael H. Roberts* and Nancy K. Leader. Dept. of Biology, Clarkson University, Potsdam, NY, 13699-5806

The eye of the marine snail, Bulla gouldiana contains a circadian pacemaker. The circadian rhythm is expressed as a change in optic nerve impulse frequency driven by an alteration in potassium conductance (Michel et al. 1993). Two key modulators of potassium conductance are intracellular calcium concentration and channel phosphorylation. Thus, a rhythmic alteration in kinase activity may be a component of the circadian clock's output pathway. Our central hypothesis is that members of two protein families, some of whom regulate the eukaryotic cell division cycle through rhythmic kinase activity, are involved in circadian rhythm generation.

Using Western blotting and immunohistochemical techniques, we have identified several proteins related to the cell division kinase, p34cdc2, in the B. gouldiana eye and brain. Interestingly, one of these proteins (p40) is specific to the ocular pacemaker. We have also identified a 66kDa homolog (p66) of the regulatory phosphoprotein cyclin. Furthermore, the level of p66 is affected by treatments (100 μ M genistein) that have been previously shown to shift the phase of the ocular rhythm.

Our current work is aimed at identifying circadian changes in the content, phosphorylation state, and association of these proteins. Supported by NS26272.

SHIFTING PHASE ON ELECTRORETINOGRAM CIRCADIAN RHYTHM INDUCED BY LONG DARK STIMULUS IN CRAYFISH Procambarus. V. Inclán-Rubio* and A. Borgonio-Aguilar. Departamento de Fisiología, Facultad de Medicina, Universidad Nacional Autónoma de México, México, D.F.

Due to their ability to be synchronized, circadian rhythms couple well to environmental signals. It is known that electroretinographic response (ERG) in the compound eye of crayfish, presents circadian changes with a predominantly nocturnal activity. This rhythm is capable of displaying phase shifts when short white or monochromatic light signals are applied on the eye photoreceptors. In these cases, conspicuous differences in the phase response curve (PRC) can be observed in basis a wavelength used. The objective of this work is to analyze the changes upon ERG light-adapted rhythm, when we applied a long term-dark stimulus (6h), during different circadian time (CT), so as to explore the complete 24h. cycle. We worked with adult crayfish Procambarus clarkii, in constant conditions of light (30 lx) and temperature (19°C). The ERG was obtained by means of a metal microelectrode (1 a 5 mv) and continuously recording at least 12 days. The results show one bimodal PRC, with advances if the stimulus was applied at 18:00-24:00 CT; delays at 24:00-06:00 CT, and any change at 12:00-18:00 CT. The transitory advances have a 12-48 hours duration, meanwhile delays occur a day after stimulus application. Studies with retinal shielding pigments pointed out the possibility of a neural mechanism as the responsible of these responses.

PINEAL PHOTORECEPTOR CELLS IN THE ANOLE LIZARD RHYTHMICALLY SECRETE MELATONIN. W.X. Tang and G.E. Pickard*. Department of Psychiatry, University of Pennsylvania, Philadelphia, PA 19104-6141.

The pineal gland of the lizard (Anolis carolinensis) rhythmically secretes melatonin both in vivo and in vitro. Using a modified reverse hemolytic plaque assay for the detection of melatonin secretion from dispersed pineal cells in culture, we recently demonstrated that individual pineal cells function as circadian oscillators and rhythmically secrete melatonin (Pickard and Tang, Soc. for Neurosci. 18:879 '92).

To determine the organization of the anole pineal, EM analysis was conducted. This analysis revealed three principle cell types: sensory, support and ganglion. The most common cell is the photoreceptor, the outer segment of which is poorly developed and variable in both size and shape. The finger-shaped cell has a basal nucleus and an expanded apical region, the inner segment. Photoreceptors are found most distally in the layered pineal gland. At the light microscopic level, the photoreceptor stratum is positive for S-antigen immunoreactivity.

To ascertain whether pineal photoreceptors secrete melatonin in vitro, melatonin secreting pineal cells (as identified using the reverse hemolytic plaque assay) were tested for S-antigen immunoreactivity. All plaque producing pineal cells were S-antigen positive. Some S-antigen positive cells did not form plaques. The data suggest that pineal photoreceptors rhythmically secrete melatonin. Supported by NIH grant RR 08052.

AN ENDOGENOUS LOCOMOTOR CIRCADIAN RHYTHM IN *LYMNAEA STAGNALIS*. J. A. Tobin and T. J. Mueller*. Department of Biology, Harvey Mudd College, Claremont, CA 91711.

Endogenous circadian rhythms have been demonstrated in several marine and terrestrial gastropods (*Aplysia*, *Bursatella*, *Bulla*, *Navanax*, *Helix*, *Limax*, *Arion*). However, a literature search indicates that no endogenous circadian rhythms have been demonstrated or disproved in any freshwater gastropod, or in any gastropod belonging to the order Basommatophora. As a freshwater pulmonate basommatophore, the Minnesota pond snail *Lymnaea stagnalis* is a member of both these categories.

We measured average speed of locomotion of *Lymnaea* as a function of time both during normal light-dark cycling, and in constant darkness. We used infrared illumination and an infrared-sensitive CCD TV camera to image the snails crawling on the side of a glass aquarium. The images were digitized and processed to calculate crawling rate variations over time. In multi-day, replicate experiments for both light-dark and dark-dark conditions, average crawling rate showed significant peaks and troughs in each 24 hour period. Fourier analysis of these data indicated a dominant period of approximately 24 hours. Ecological implications for circadian rhythms in these snails will be discussed.

NEUROETHOLOGY: BEHAVIORAL STRATEGIES

663.1

THE EFFECT OF HYPOGLOSSAL AND GLOSSOPHARYNGEAL NERVE TRANSECTION ON THE PREY CATCHING BEHAVIOR OF FROGS (*RANA PIPIENS*). A. Weerasuriya* and C. Baker. School of Medicine, Mercer University, Macon, GA 31207.

Frogs strike at prey with their tongues and retrieve them into the mouth in a rapid movement requiring the coordination of at least 30 muscles within a period of less than 200 msec. It has been postulated that a motor pattern generator interposed between the output elements of the sensory analyzers and the motoneuron pools is responsible for the elaboration of the spatio-temporal sequence of neuronal activation necessary for successful prey capture. In *Bufo bufo*, bilateral transection of the hypoglossal nerves causes the toad to lunge at prey without any accompanying jaw movements (Weerasuriya, 1989). We extended these studies in frogs and examined the interactions among these muscles with a more extensive series of nerve transections coupled with high speed video recordings. In frogs, anesthetized with MS-222, either one or both hypoglossal nerves or both glossopharyngeal nerves were transected and ligated. The ability of these frogs to capture live mealworms, and manipulate mealworms and other objects placed in their mouth was observed and recorded for two months after the transections. After two months the transections were verified by postmortem dissection. Following bilateral glossopharyngeal transection, the frogs were able to capture mealworms successfully. A unilateral hypoglossal transection did not preclude the frogs from capturing mealworms, but the protruded tongue deviated to the unlesioned side. A bilateral transection precluded jaw movement during the lunge, but these frogs moved their jaws to swallow mealworms placed in their mouths and to reject unpalatable objects. Even after two months the mouth did not open during a lunge.

663.3

THE FREE-WILL PROBLEM: MOTOR CHOICE AND INTRINSIC VARIABILITY IN FROG AND LEECH. P. Grobstein*, P. Brodfuehrer, and J. Cristaglio. Dept. of Biology, Bryn Mawr College, Bryn Mawr, PA 19010.

The Harvard Law of Animal Behavior has it that "Under carefully controlled circumstances, an animal will behave as it damned well pleases." Many investigators presume this law to reflect a failure of experimenters to adequately control surrounding experimental conditions, and so discount observed variability. We have undertaken studies from a different perspective, treating variability as a significant phenomenon in its own right rather than an experimental inconvenience.

The movements made by a given frog for a prey item at a given location vary from trial to trial. The variability does not reflect absolute limits in the precision of neural processing: reduced variability is observed under particular circumstances (increased complexity in the visual scene). The variability is not reduced by further confining the moving prey, nor increased by increasing variation in frog initial posture. The findings suggest that the variability originates in the nervous system, rather than in afferent pathways, and reflects a controllable element significant in understanding input/output relations. Variability may reduce predator predictability, and support the creation of novel motor sequences to solve novel problems.

Leeches sometimes but not always respond to cutaneous stimulation by swimming. In an isolated leech nervous system, peripheral nerve stimulation at an appropriate constant voltage triggers a swimming motor pattern on some trials but not others. Intrinsic nervous system variability, hypothesized for the frog, exists in the leech. The unpredictability of the isolated leech nervous system can be reduced by removal of the head ganglion. This suggests that intrinsic variability in leech, as in frog, is not a reflection of inevitable limits in the precision of neural processing, and that it may be possible to localize distinct variability enhancing elements.

We conclude that intrinsic variability is an important and characterizable element of nervous system function, of substantial significance for understanding input/output relationships in behavior. Organisms endowed with a probabilistic variability, as well with a capacity to monitor potential outputs and to control which will be expressed in behavior may be those that exhibit "free will."

663.2

SENSORY MODALITIES THAT INFLUENCE MOTOR PATTERN CHOICE IN THE LEOPARD FROG, *Rana pipiens*. C.W. Anderson* and T.A. Brand. Dept. of Biology, Northern Arizona University, Flagstaff, AZ 86011.

Previous researchers have shown that multiple motor patterns can be elicited from a given stimulus. In this study, we were interested in the stimulus parameters that elicit particular feeding behavior motor patterns. If the frog can produce differing motor outputs from the same sensory input, how is the behavioral output decided?

In previous studies, we have shown that the leopard frog, *Rana pipiens*, exhibits distinctly different feeding behaviors in response to different prey types. When feeding on waxworms (approximately 1.5-2.0 cm), *R. pipiens* captures prey using tongue protraction. When offered earthworms (approximately 4.5-6.0 cm), it captures prey using jaw prehension. In this study, we have tried to elucidate the sensory modalities that determine the feeding motor pattern choice in *Rana pipiens*. *Rana* was offered 1.5, 3.0, and 4.5 cm earthworm pieces. Motor patterns elicited by the 1.5 cm piece of earthworm were very similar to the behavior observed when feeding on similar sized waxworms. *Rana* captured the 4.5 cm earthworm piece using jaw prehension, as when feeding on whole earthworms. The 3.0 cm piece of earthworm elicited both the tongue protraction and the jaw prehension feeding behaviors at approximately equal frequencies. This appears to represent a random choice between two discrete motor patterns. Additional experiments are in progress to determine the contribution of olfaction to feeding behavior. These studies suggest that a visual analysis of prey size is used to choose between alternative feeding motor patterns.

A SMALL BENTHIC ROBOT FOR STUDIES IN MARINE ANIMAL CHEMOSENSING. T.R. Consi*, C.A. Goudey and J. Atema†. MIT Sea Grant College Program, AUV Laboratory, Cambridge, MA 02139, †Boston University Marine Program, Woods Hole, MA 02543

A great variety of marine animals navigate using chemical signals to locate food sources, mates and spawning grounds. The sensory systems and behaviors exhibited by these animals are well adapted for robust operations in turbulent and chemically complex environments. The algorithms used by an animal to rapidly extract navigational information from a discontinuous and chaotic chemical signal are presently unknown and are the topic of current research. We are developing a small benthic robot which will be used as an algorithm test bed for ideas in biological chemosensing behavior. The robot is designed to mimic the basic features of a lobster relevant to chemical sensing and associated behaviors. The lobster was chosen as a model system because its chemosensing capabilities are sophisticated and have been well studied.

Our robot is a small wheeled vehicle with the size, speed and maneuverability of an adult lobster. It is driven by two DC gear motors and is battery powered. A pair of conductivity electrodes serve as the robot's "antennae", the analogs to the chemical sensors of the lobster antennules. Vehicle control is provided by an MC68332-based microcontroller system.

The basic experimental paradigm is to set up a plume of saltwater in a freshwater flow-through flume and program the vehicle to follow the plume to its source. A saltwater plume was chosen as a reasonable approximation to an underwater chemical plume. Plume following algorithms which have been proposed for the lobster will be programmed into the vehicle and the experiments will determine the effectiveness of the various algorithms. The flow-through flume and measuring apparatus are the same as are used in studies of lobster chemosensing behavior, thus making the data from the vehicle directly comparable to that of the animal. We will present the design details of this vehicle along with initial experimental results.

663.5

SPATIAL BEHAVIOR IN THE BRAZILIAN SHORT-TAILED OPOSSUM, *MONODELPHIS DOMESTICA*: COMPARISON WITH *RATTUS NORVEGICUS* IN MORRIS WATER TASK AND RADIAL ARM MAZE. D. P. Kimble* and I. O. Whishaw, Institute of Neuroscience, University of Oregon, Eugene, OR 97403 and Department of Psychology, University of Lethbridge, Lethbridge, AL TIK 3M4. Six opossums (three male, three female) and an equal number of male and female rats were tested in a Morris water task with both hidden and visible platforms. Opossums were inferior on both tasks, but did show significant learning in the visible (but not hidden) platform task. Opossums tended to swim around the outer edges of the pool when the platform was hidden, rarely venturing into the middle, while rats displayed a more efficient search strategy. Opossums and rats showed distinctly different defecation patterns in the water task. Both rats and opossums were naive swimmers prior to the experiment. All animals were then tested in an 8-arm radial maze, in which they were given 14 trials with four arms baited and an additional 14 trials with the other four arms baited. Both opossums and rats reduced errors across the two tasks, with rats showing superior performance. Differences in search strategies were found, with rats showing a systematic "arm by arm" strategy on a high percentage of the trials, while opossums displayed arm by arm strategy on far fewer trials. Opossums, on the other hand, showed higher levels of a "cross maze" strategy, but overall lower levels of any discernible search strategy. Opossums were inferior to rats in both spatial situations. Differences between placental mammals and marsupials in brain morphology and evolutionary paths are considered.

DOMINANCE STATUS, BEHAVIOR IN THE ELEVATED PLUS MAZE AND ULTRASONIC VOCALIZATIONS IN TRIAD-HOUSED RATS. L.A. Pohorecky*, S.A. Larson, and D. Benjamin. Center of Alcohol Studies, Rutgers University, Piscataway, NJ 08855.

Group housing of rodents results in the rapid establishment of dominance status. While dominance status has well known consequences on aggressive and sexual behaviors, effects on other behaviors are less known. We report on the effects of social status on body weight, and on two measures of anxiety: the elevated plus maze test (EPM) and ultrasonic vocalizations elicited by air-puffs (USV). Two sets (consisting of 10 and of 15 colonies) of male Long-Evans hooded rat triads, matched for initial body weight, were maintained and tested over a period of 38-40 days. Weight gain differences between the dominant (D), subdominant (SD) and subordinate (SO) rats developed rapidly, were significant and persistent throughout the experimental period. D rats had the greatest weight gain, while it was least in the SO rats (overall ANOVA $F=7.566$, $p=0.001$). In the EPM, an established test of anxiety, there was a rank related gradation in anxiety (overall contrast analysis of D vs SO $p=0.033$): D rats exhibited least anxiety (more open arm entries and more time in open arms), SO rats exhibited the most anxiety. Startling air puffs resulted in more USVs in SD rats in the first (contrast analysis of SD vs SO $p=0.034$), but did not reach significance, in the second experiment. Nevertheless the number of air puffs needed to elicit USV in the second experiment were greater for the SD rats. These preliminary findings indicate that there are significant rank-related differences in anxiety levels in group housed male rats which suggest differences in underlying neurochemical mechanisms subserving behavior in the EPM and the USV tests. ON THE USE OF VISUAL MOTION PERCEPTION TO CONTROL LOCOMOTION: SYNTHESIS OF A BIOLOGICALLY-INSPIRED VISUALLY-GUIDED CREATURE USING PARALLEL ANALOG PROCESSING. N. Franceschini*, J.M. Pichon, C. Bianes, C.N.R.S.

Lab. Neurobiology, 31, Ch. J. Aiguier, 13009 Marseille (France). In trying to understand how photoreceptor cells can be linked to muscle cells to achieve smart visually guided behavior we used biologically-inspired synthetic neural modeling to design, simulate and build a completely autonomous creature which can move about in complex environments using exclusively visual motion perception. This project was derived from our optical and electrophysiological analyses on directionally selective motion sensitive neurons, the working principle of which was first transcribed into analog optoelectronic circuits.

A battery of such smallfield neurons analyse the panoramic visual world in the azimuthal plane. The layout of obstacles in the environment is discovered step-by-step by the creature whose sensory map is transformed into a motor map that controls steering. The creature can negotiate an obstacle course to a target at a relatively high speed (50 cm/s).

We have proposed one solution to the problem of how a retina can be interfaced to a motor system for the sake of survival in cluttered environments and how multisensory fusion can be achieved by purely analog, brainlike networks. The creature we have built shows specific features common to advanced animals, such as nonuniform retinal sampling, saccadic suppression and corollary discharges. It requires no digital computer on-board and no long-term memory.

MODULATING EFFECTS OF VISION ON JUVENILE PLAY BEHAVIOUR IN RATS. Mario M. Mckenna, Vivien C. Pellis*, Glen Prusky and Sergio M. Pellis, Dept. Psychology, Univ. Lethbridge, Lethbridge, AB T1K 3M4.

Play fighting behaviour in juvenile rats consists of two elements: playful attack and playful defense. Playful attack consists of snout to nape contact in which one animal gently nuzzles the nape area of its partner. Playful defense involves strategies in which the animal avoids snout to nape contact via removal of the nape area from attack (evasion) or blocking contact to the nape (rotation to a supine position). While studies have shown that vision is not necessary for normal frequencies of play fighting, previous studies have not explored the effects of vision on the components of play fighting. Specifically, is vision necessary for the organization of playful attack and defense? Eight juvenile female rats were enucleated at birth and their juvenile play behaviour compared to that of eight control females. High speed video analysis revealed that vision can be used to orient playful attacks toward the nape of the partner. Enucleated females appeared to arbitrarily attack the body of the partner and when contact was attained, relied on tactile input to direct their attack to the nape of the defender. In contrast to this, control females consistently contacted that nape area of its partner when attempting to initiate playful contact. Similarly, for defense against nape attack, enucleated rats responded when the attacker was closer to the nape. The results of this study suggest that while vision is not necessary for play to occur, it has a role in modulating playful attack and defense.

CORTICAL 5-HT_{1A} RECEPTOR BINDING IS INVERSELY RELATED TO DOMINANCE STATUS IN TRIAD-HOUSED RATS. D. Benjamin*, E.I. Saiff, K.R. Goldstein, S.A. Larson, A. de Adrianza, and L.A. Pohorecky, Center of Alcohol Studies, Rutgers University, Piscataway, NJ, 08855.

Male rats housed in triads rapidly form a dominance hierarchy characterized by aggression and initial weight loss in subdominant (SD) and subordinate (SO) rats as compared with the dominant (D). A behavioral profile indicative of anxiety was observed in the nondominant rats (see Pohorecky *et al.*, this volume). To characterize the neurochemical basis for the significant behavioral changes induced by triad housing, 5-HT_{1A} and 5-HT_{1B} receptor binding was assessed autoradiographically in four colonies of triad-housed rats previously classified by status and behavior. Subjects were sacrificed after 38 days of colony housing, and brains were sectioned in the coronal plane for autoradiographic analysis of binding. In the present sample, no significant differences were detected in 5-HT_{1A} receptor binding as assessed using [³H]-8-OH-DPAT. 5-HT_{1B} receptor binding was assessed using [³H]-mesulergine (2 nM); binding to frontal and prefrontal cortex layer 4 differed significantly within colonies, with less labelling in D rats and the most in SO rats ($p = 0.011$). This effect was confined to frontal and prefrontal cortex, with no dominance-related differences in the claustrum or more posterior cortex. Interestingly, cortical 5-HT₂ receptors have previously been shown to be associated with anxiety. These preliminary results indicate that the frontal cortical 5-HT_{1B} receptor system is affected by dominance status, which may underlie some of the observed behavioral effects. Experiments are in progress to evaluate the involvement of other receptor subtypes. (Supported by the Smithers Foundation and NIAAA grant AA05306).

INTRAVENTRICULAR DPDPE ADMINISTRATION FOLLOWING ACUTE STRESSOR APPLICATION: DIFFERENTIAL INFLUENCE ON ACTIVITY, HEAD DIPPING AND EXPLORATION. Paul Mendella¹, Jill Irwin^{2*} and R.M.Zacharko¹, ¹Unit for Behavioral Medicine and Pharmacology, Life Sciences Research Centre, Carleton University, Psychology Department, Ottawa K1S 5B6 and ²Queen's University, Psychology Department, Kingston, Ontario K7L 3N6

Uncontrollable stressors provoke behavioral disturbances in a number of paradigms. The nature of these alterations have been attributed to variations of central CA and 5-HT activity. Neuropeptides appear to modulate neurotransmitter turnover and to influence the profile of behavioral change. We investigated the effects of intraventricular administration of DPDPE, a relatively selective δ receptor agonist, on activity, exploratory behavior and investigatory head dipping, following acute, uncontrollable footshock in the CD-1 mouse. The stressor produced a reduction of activity in the immediate post-stressor interval. Low dose administration of the neuropeptide (1 and 2.5 ug) provoked an enhancement of activity which exceeded baseline performance for at least 30 min post-drug administration. However, 1 ug of DPDPE appeared to have a greater effect on locomotor activity than the higher dose of the neuropeptide in non-shocked animals. Long term alterations attributable to either the stressor or the neuropeptide appeared (or persisted) after 1 week. In contrast to activity, a dose dependent reduction in exploration was evident both immediately and 24 hr after stressor exposure. The influence of 1 and 2.5 ug doses of DPDPE was negligible in stressed animals but produced behavioral alterations in non-shocked mice at more protracted intervals. Uncontrollable footshock reduced investigatory head dipping which was unaffected by drug administration at either dose. Taken together, these data suggest that the immediate and long term behavioral consequences of δ receptor activation are dose dependent and vary as a function of stressor imposition. Such alterations conceivably underlie sensitization effects at protracted intervals. Supported by Gustavus and Louis Pfeiffer Research Foundation and NSERC of Canada

FREQUENCY OF EXPOSURE BUT NOT DIET AFFECTS ANALGESIA PRODUCED BY INTERMITTENT COLD WATER SWIMS.

R.B. Kanarek*, M. Ryu, R. Olivardia, E. Chang and R. Marks-Kaufman, Dept. of Psychology, Tufts Univ., Medford, MA 02155.

Previous work using a tail flick apparatus demonstrated that chronic sucrose intake in rats decreased baseline pain sensitivity, but enhanced morphine-induced analgesia. To examine the generality of this finding, the effect of sucrose intake on analgesia resulting from intermittent cold water swims was studied in adult male Sprague-Dawley rats. Using a tail flick apparatus, analgesic responsiveness [% maximal possible response (%MPE)] was measured 30, 60 and 90 mins after 9 or 18, 10 secs swims in 2° C water separated by 10 secs rest periods in rats given ad lib access to a 32% sucrose solution, Purina chow and water (n=20), or only chow and water (n=20). Rats given the sucrose solution consumed more calories per day and gained more weight than rats not eating the sugar. Sucrose availability had no effect on analgesic responsiveness following cold water swims. However, 60 mins after swimming, rats given 9 swims had significantly (p < 0.05) greater %MPE than rats given 18 swims. To determine if opioid mechanisms were involved in analgesia resulting from intermittent cold water swims, rats were injected (sc) with 10 mg/kg naltrexone. Naltrexone significantly (p < 0.05) reduced %MPE 30 and 90 minutes after swimming in rats given 18 swims, but had no effect on %MPE in rats given 9 swims. The present results indicated that diet does not have equivalent effects on morphine and stress-induced analgesia. These data suggest that the number of experiences an animal has with a stressful stimulus is important in determining the analgesic potency of the stimulus.

LOCOMOTOR RESPONSE TO NOVELTY CORRELATES WITH AMPHETAMINE- AND STRESS-INDUCED ACTIVITY IN RATS: RELATION TO HIPPOCAMPAL NOREPINEPHRINE EFFLUX. L.A. Rosario* and E.D. Abercrombie, Center for Molecular and Behavioral Neuroscience, Rutgers University, Newark, NJ 07102.

Previous studies demonstrate that the locomotor activity (LA) response of rats placed in a novel environment is predictive of the LA response to systemic amphetamine (AMPH) administration, suggesting common mechanism(s) of behavioral reactivity in these two conditions. In such studies, rats are designated as high responders (HR) or as low responders (LR) according to LA counts obtained during 60 min exposure to a novel environment. Since the norepinephrine- (NE) containing neurons of the locus coeruleus (LC) have been implicated in brain mechanisms of arousal and stress, we are interested in whether differences in forebrain NE release might exist in HR and LR rats. We compared the LA response to 30 min tail-pinch stress and AMPH administration (1.5 mg/kg, i.p.) in HR and LR rats. Extracellular NE level in hippocampus also was monitored during these manipulations using *in vivo* microdialysis. Rats were pre-screened for assignment to HR (n=5) or LR (n=4) groups on the day before dialysis probe implantation. All animals were run blind as to group assignment. Baseline LA counts and extracellular NE levels were not significantly different in the HR versus LR groups. In response to the tail-pinch stress, LA counts were significantly greater in HR rats compared to LR rats. Preliminary neurochemical results show that the stressor produced a 65% increase in extracellular NE of the HR group whereas NE levels increased 40% in the LR group. Similar to the results obtained with stress, AMPH-stimulated LA activity was significantly greater in HR rats than in LR rats. Hippocampal NE efflux in response to AMPH was increased by a maximum of 563% in the HR group and 384% in the LR group. These data support the hypothesis that individual differences in behavioral reactivity and behavioral activation produced by stress or AMPH may share common neural substrate(s). Further, the preliminary neurochemical data suggest that evoked NE release may contribute at least in part to such behavioral differences. [Supported in part by USPHS Grant MH43947]

664.2

SOCIAL STRESS MODULATES MORPHINE SENSITIVITY IN MALE AND FEMALE ROMAN RATS M. Haney*, N. Castanon, M. Le Moal and P. Mormède, INSERM U 259, Université de Bordeaux II, Bordeaux FRANCE

Roman low avoidance (RLA) rats freeze, while Roman high avoidance (RHA) rats remain motorically active in response to mild stress. What is the long-term effect of an aggressive attack on morphine-induced analgesia and locomotor activity in rats with genetically distinct responses to stress? Male and female, RHA and RLA rats (n=64) were either exposed to 2 brief attack encounters (2 min) from an aggressive, same-sex conspecific or were left undisturbed. Attack encounters were separated by a 30 min. interval, during which rats were threatened but protected from attack by wire mesh. Morphine was cumulatively administered (3, 6, 10 mg/kg IP) 1 week later. Injections occurred every 30 min, following tailflick measurement; locomotion was measured between injections (30 min) in an activity cage. There were no strain differences in defensive behavior, with both RHA and RLA rats actively attempting to avoid attack. The experience of attack greatly reduced sensitivity to morphine-induced analgesia 1 wk later, while having no effect on morphine's locomotor properties. Strains did not differ in sensitivity to morphine-induced analgesia. Yet only the RHA line showed an excitatory locomotor response to morphine, while activity in RLA rats was unchanged. Therefore: (1) RHA rats are more motorically active in response to morphine, as they are to cocaine or mild stress, and (2) Analgesia is a more sensitive measure of the long-term consequences of social stress on the opioid system than locomotor activity.

THE EFFECTS OF 6-OHDA LESIONS OF THE MEDIAL PREFRONTAL CORTEX ON ELEVATIONS IN CORE TEMPERATURE INDUCED BY RESTRAINT STRESS IN THE RAT. D. Funk* and J. Stewart, Center for Studies in Behavioral Neurobiology, Dept. Psychology, Concordia University, Montreal, Canada, H3G 1M8.

The dopamine (DA)-containing projections to the medial prefrontal cortex (MFC) are activated in response to stress. The functional role of MFC DA release in the stress-induced activation of the autonomic nervous system (ANS), however remains undefined. This study examined the effects of DA depletion of the MFC with 6-hydroxydopamine (6-OHDA) on a response mediated by ANS activation, the increase in core temperature induced by physical restraint.

Male rats pretreated with desipramine or its vehicle received infusions of either 6-OHDA (4µg in 1µl ascorbic acid vehicle/site) or vehicle bilaterally into the MFC. The 3 groups consisted of rats with DAergic lesions (L-DA), DA and norepinephrine (NE) lesions (L-DA/NE) or sham lesions (VEH). Three weeks after surgery, temperature transmitters were implanted i.p. Four days later temperature samples were taken every 10 min throughout 4 contiguous 1-h periods: a 1-h baseline, 1 h of restraint, and a 2-h post-restraint period. Restraint for 1 h elevated core temperature significantly in all groups. Group L-DA failed to attain as high a level of core temperature as the other groups during restraint. These results suggest that the DAergic projection to the MFC plays a role in stress responses mediated by the ANS. Studies are in progress to assess the effects of MFC lesions on the activation of the cardiovascular and hypothalamo-pituitary-adrenal systems by stress.

MODERATE STRESS ENHANCES ACQUISITION OF A SPATIAL MEMORY TASK. C. Martinez, M. Villegas, V. Luine* and B.S. McEwen, Dept. Psychology, Hunter College and Rockefeller University, N.Y., N.Y. 10021

Chronic restraint stress, 21 days, causes impaired acquisition of a spatial memory task in rats (Villegas, et al, Soc. Neurosci. Abs., 1993). We examined the effect of fewer days of restraint stress on acquisition of a spatial memory task. Rats (n=10-12) were placed in plexiglass restrainers for 6h/day for 7 or 13 consecutive days. Controls (n = 11-12) were weighed only. After the last restraint, rats were food deprived, then received 9 shaping trials on the eight arm radial maze (days 3-7 post stress), 4 regular trials (days 10-13) and 5 trials with delays after the 4th choice (days 14-15). Daily restraint for 7 days did not affect performance, but rats stressed for 13 days performed better than controls: number correct in the first 8 choices was 7.32 ± 0.11 vs. 6.8 ± 0.11 (F_{1,19} = 13.1, P < .002). It also took stressed rats fewer total choices to finish the maze than controls (9.6 ± 0.34 vs. 10.59 ± 0.40, F_{1,19} = 5.35, P < .03). Serum corticosterone was measured after 2 and 6 h. of restraint on the 3rd, 8th and 13th day of stress. Performance of the stressed rats correlated with corticosterone levels at 13 days (r = -.63, P < .05); rats with higher levels took fewer choices to finish. Enhanced performance was not permanent since trials with delays, conducted immediately following the regular trials, showed no differences between the groups. These results, taken together with Villegas et al, 1993, suggest that a short duration of stress does not affect acquisition of the 8-arm maze, while a moderate duration may serve an adaptive function, and longer durations of stress are maladaptive for learning/memory. (GM08176 & GN41256)

CHLORDIAZEPOXIDE IN THE DORSAL RAPHE NUCLEUS ELIMINATES THE EFFECTS OF INESCAPABLE SHOCK ON SHUTTLEBOX ESCAPE LEARNING AND FEAR CONDITIONING. R.E. Grahn*, B.A. Kalman, L.R. Watkins, and S.F. Maier. Behavioral Neuroscience Program, Department of Psychology, University of Colorado, Boulder, CO 80309.

Increases in the excitability of the dorsal raphe nucleus (DRN) have been argued to be involved in the mediation of the behavioral changes produced by inescapable shock (IS). DRN activity is reduced by the systemic administration of benzodiazepines (BZs) and this BZ treatment before IS eliminates the escape learning deficits produced by prior exposure to IS. However, BZs given before behavioral testing fail to alter the effects of IS. It is possible that BZ actions at other brain sites resulting from systemic administration mask effects of BZ activity at the DRN. In the present experiment, rats were exposed to IS or control treatment and tested for fear conditioning and shuttlebox escape 24 hr later. Chlordiazepoxide (CDP) (30mg) was microinjected into the region of the DRN either before IS or before testing 24 hr after IS. CDP restricted to the DRN did block both the exaggerated fear conditioning and escape learning deficits produced by IS, whether administered before IS or before testing. CDP (3µg) administered intracerebroventricularly (ICV) blocked fear conditioning whether given before IS or testing, but blocked the escape deficit only when administered before IS. These findings indicate that administration of BZ isolated to the region of the DRN blocks the effects of IS, whereas this treatment administered in a nonspecific manner (either peripherally or centrally) is only effective if that administration occurs before IS.

BEHAVIORAL SENSITIZATION FOLLOWING ACUTE STRESSOR APPLICATION: INFLUENCE OF EXPERIENTIAL FACTORS. G. MacNeil* and R.M. Zacharko. Unit for Behavioral Medicine and Pharmacology, Life Sciences Research Centre, Carleton University, Psychology Department, Ottawa, Ontario, CANADA K1S 5B6

Exposure to aversive life events in infrahuman subjects has been associated with the induction of behavioral disturbances which may be reminiscent of symptoms associated with major affective and post-traumatic stress disorder (PTSD). The present investigation determined whether prior experience with major laboratory stressors sensitizes an organism to the subsequent effects of acute, uncontrollable footshock. In the absence of a stressor, general levels of activity ordinarily decline and stabilize as a function of time. In contrast, levels of exploration remain relatively stable. Application of an acute stressor (mild footshock) in CD-1 mice produced marginal alterations of locomotor activity in the immediate post-stressor interval, while profound perturbations appeared with exploratory behavior. Such stressor induced behavioral variations were transient. Interestingly, however, among animals previously exposed to the stress of a surgical intervention (applied two weeks earlier), uncontrollable footshock exacerbated the reduction in both exploration and activity ordinarily evident in animals subjected to the stressor alone. In addition, experience with a qualitatively different laboratory stressor (unpredictable fire alarm) produced effects on exploration that were reminiscent of those seen in animals sensitized to footshock by surgery. Taken together, these data suggest that sensitization (and cross sensitization) may occur more readily for some aspects of behavior (activity of exploration) and that the time course of such behavioral change may be fundamentally different. The implications of these data for psychological disturbances are discussed. Supported by The Gustavus and Louis Pfeiffer Research Foundation and NSERC of Canada.

CHRONIC CALORIC RESTRICTION AND "ACTIVITY-STRESS" EFFECTS IN RATS: A COMPARISON OF TWO STRESS MODELS.

J.K. Nishita* and M.D. Kawamoto. Dept. of Psychology, San Jose State Univ., San Jose, CA 95192-0120.

When housed in our novel apparatus, rats must crawl through a Plexiglass cylinder to obtain daily food and water. Because food is always located on one side of the cylinder and water is on the opposite side, rats learn to restrict their eating and drinking in order to negotiate the cylinder each day. We hypothesized that these rats will manifest behavioral and physiological changes similar to those produced by other stress-related paradigms. In the present study, physiological correlates of stress associated with the physical restriction produced by two different cylinder sizes [Small (SM) = 3.3 cm, Large (LG) = 4.2 cm, i.d.] were compared to those in the wheel-running "activity-stress" paradigm (Paré, 1974).

Both SM and LG rats showed weight loss and decreased linear growth compared to controls housed with No Cylinder (NC). Furthermore, adrenal weights and plasma corticosterone (CORT) levels were significantly different among SM, LG, and NC female rats following 100-120 days of continuous housing. Male SM, LG, and NC also showed significantly different adrenal weights, CORT, and body temperature when housed continuously for 80-, 100-, and 140-days. These measures and the incidence of gastric ulcerations were compared to rats reared using the 1-hr feeding "activity-stress" paradigm: (a) 22-hr continuous access to running wheels, (b) partial access, consisting of 22-hr continuous access to running wheels every other day, and (c) no access.

These data show similar stress effects between the two models and are important in understanding physiological correlates of "conflict" behavior and stress in the context of chronic caloric restriction.

CRH BLOCKADE REDUCES NALOXONE-REVERSIBLE, BUT NOT NALOXONE NON-REVERSIBLE STRESS-INDUCED ANALGESIA.

M.Bianchi, P.Sacerdote, A.F. Panerai* Dept. Pharmacology, University of Milan, 20129 Milan, Italy.

Depending on its temporal characteristics, inescapable foot-shock causes analgesia in rats by activating different mechanisms (1,2). Inescapable foot-shock is currently used in order to investigate the effects of stress on different biological functions (3). Since corticotropin-releasing hormone (CRH) is considered the main mediator of stress response, we evaluated the effect of the CRH antagonist alpha-Helical CRH 9-41 on the analgesia obtained by the exposure of rats (8 in each experimental group) to intermittent (naloxone-reversible) or continuous (naloxone non-reversible) electric foot-shock (2.5 mA, 60Hz). The intracerebroventricular administration of the CRH antagonist (20 µg/10 µl) significantly reduced the increase of tail-flick latencies induced by the intermittent foot-shock. On the contrary, the CRH antagonist did not modify the analgesic effect of continuous foot-shock. Our results confirm that stress-induced analgesia can be obtained by the activation of different endogenous systems and suggest that intermittent foot-shock represents the more suitable model for the stress studies.

BEHAVIORAL DIFFERENCES OF DOMINANT AND SUBORDINATE RATS IN A VISIBLE BURROW SYSTEM. Errol B. Yudko*, Chris Bjornson, and Robert J. Blanchard, Dept. of Psychology, University of Hawaii, Honolulu, HI 96822.

Subordinate male rats of groups maintained in semi-natural visible burrowing situations (VBS) show enhanced defensive behavior, but reduced social, sexual, exploratory and aggressive activity, within the habitat. They have higher plasma corticosterone and lower plasma testosterone than dominants, and display increased voluntary alcohol consumption and higher mortality.

In the present study VBS subordinates were removed to single cages and allowed free access to food and water during 5 hour periods every other day of a two-week grouping period. Under this regimen, they increased their intake to levels higher than those of dominants or singly-housed controls but continued to lose weight, a pattern suggesting altered metabolism.

In an open field test run at intervals throughout the grouping period, dominants and subordinates initially showed reduced activity compared to controls, but the dominants gradually increased activity to control levels while subordinates continued to be inactive. Subordinates also appeared to be deficient in risk assessment behaviors measured in both a cat-odor apparatus or in an elevated plus-maze. These findings suggest that, although subordination is generally associated with increased defensiveness, it may produce specific changes in particular components of the defense pattern.

IMMEDIATE AND LONG TERM ALTERATIONS INDUCED BY AN ACUTE STRESSOR: VARIATIONS IN ACTIVITY, EXPLORATION AND HEAD DIPPING FOLLOWING INTRAVENTRICULAR U50,488 ADMINISTRATION. R. Dickson and R.M. Zacharko*, Unit for Behavioral Medicine and Pharmacology, Life Sciences Research Centre, Carleton University, Psychology Department, Ottawa, CANADA K1S 5B6

Stressors produce behavioral alterations ordinarily attributed to changes in central NE, DA and 5-HT activity. Increasingly greater attention has been devoted to an analysis of the influence of neuropeptides to the induction, amelioration and/or exacerbation of behavioral pathology. The nature of the opioid receptor (μ , δ , κ), their distribution in the CNS and the region specific influence of various stressors affect expression of behavioral disturbance. Moreover, κ receptor activation, unlike that of μ or δ , cannot produce behavioral change in the absence of prior activation of the associated neurochemical substrate. We examined the dose and time dependent variations of U50,488 in the CD-1 mouse in several behavioral paradigms following exposure to footshock. Low dose administration of U50,488 provoked modest reductions of activity and exploration in the absence of footshock suggesting an interaction with the stress of handling. Higher doses of U50,488 had no effect immediately but augmented exploration and activity at protracted intervals, comparable to that of no drug-stress animals. When exploratory head dipping was assessed, footshock reduced performance only in the immediate post-stressor interval. While the immediate effects of U50,488 were masked by footshock, a dose dependent differentiation was apparent at more protracted intervals. These data suggest that (a) U50,488 is ineffective in provoking immediate behavioral change in the absence of a stressor (b) the long term behavioral effects (exploration, activity) of U50,488 may mimic the effects of a stressor (c) the immediate effects of U50,488 and footshock are similar to those of footshock alone although a dose dependent behavioral differentiation appears at longer post-stressor intervals. STRESS-INDUCED BEHAVIORAL DEFICITS: BEHAVIORAL AND NEUROPHARMACOLOGICAL FACTORS. Y. Zhang* and E. A. Stone, Dept. Psychiatry, New York University School of Medicine, New York, NY 10016.

Stress is known to induce in rats a number of behavioral changes which resemble signs of anxiety and depression in humans. These include heightened defensiveness, anorexia, anhedonia and hypo-exploratory activity. The following experiments were undertaken to explore some of the behavioral and neurochemical factors eliciting certain of these changes. Rats were either housed singly or in pairs and were subjected to either restraint in a mesh pouch or immobilization (four limb restraint). Some rats received an injection of clonidine prior to the stress to suppress central noradrenergic activity. Exploratory activity and saccharine consumption were measured in the post-stress interval. It was found that the stressors used produced a decrease in saccharine consumption and exploratory activity. The decrease in saccharine consumption was more severe for immobilization than pouch restraint and for the single-housed as compared to the pair-housed rats. Exploratory activity was less consistently affected by these factors. The experiments on the effects of clonidine are currently in progress. It is concluded that the type of stress and the housing condition of the animal are key factors that markedly influence the severity of behavioral impairments resulting from stress. EFFECTS OF EARLY STRESS ON THE BEHAVIORAL RESPONSE OF ADULT RATS TO AN AMPHETAMINE CHALLENGE. C. Arons^{1,2}, C. Cartegenes², W. Shoemaker¹ and P. Kehoe². Dept. of Psychiatry, UCONN Health Center, Farmington CT 06030; Neuroscience Program, Trinity College, Hartford CT 06106.

In the adult rat repeated administration of psychomotor stimulants or repeated exposure to stress produces enduring enhanced responses to subsequent drug or stress challenges. We tested whether repeated exposure of neonates and pre-weanlings similarly enhances response to an amphetamine (AMPH) challenge and whether such effects endure into adulthood. Newborn rat pups were assigned to 1 of 4 treatment groups: 1) 1-hour daily isolation, postnatal day (PND) 2-9; 2) 3-minute daily cold water swim (CWS), PND21-25; 3) isolation+CWS; or 4) no stress. When the rats reached adulthood (PND70-90) they were tested for spontaneous and AMPH induced activity. Rats that had been stressed had higher stereotypy and rearing scores than non-stressed rats. Rats exposed to both isolation and CWS generally had higher scores than rats exposed to only one stress. Gender differences were also apparent. Overall, females had higher scores than males and more clearly showed the effects of stress. The data indicate that early stress results in enhanced response to challenges in adulthood.

664.17

EFFECTS OF NOCTURNAL AND DIURNAL WHEEL RUNNING ON GASTRIC EROSION FORMATION AND SURVIVAL DURING EXPOSURE TO ACTIVITY-STRESS. P. J. Geiselman¹, N. S. Morrow^{2,3} and D. Novin². Dept. of Psychology, Pennington Biomedical Research Center, LSU, Baton Rouge, LA, 70803, Depts. of Psychology and Psychiatry, UCLA, Los Angeles, CA 90024.

The effects of differential wheel availability on running activity, estrous cyclicity, gastric erosion formation and survival were examined in 14 female rats housed in Wahman activity cages. For 4 days rats had free access to the running wheel, food and water. Over the next 4 days all rats had food and water ad libitum, but one group was blocked from the running wheels during the dark period (1000-2115 h), whereas the second group was blocked from the running wheels during the light period (2130-0830). Rats were then restricted to eating for 1 h each day for 18 days. Running activity, body weight, body temperature, estrous cyclicity, food and water intake were monitored daily. Regardless of wheel availability all rats significantly increased wheel running from baseline values, developed gastric erosions and became moribund. Rats blocked from the running wheels from 1000-2115 lost their estrous cyclicity earlier in the testing period than rats blocked from 2130-0830. On the peak day of running there were no significant group differences in any of the behavioral variables. These results suggest that rats exposed to activity-stress do not increase wheel running in anticipation of the feeding hour (NIMH Fellowship ST32MH17140, NSF Grants: BNS 87-09982 and BNS 9196142).

DIFFERENTIAL SENSITIVITY OF THE ELEVATED PLUS-MAZE AND SOCIAL INTERACTION TESTS OF ANXIETY TO PRIOR STRESSOR CONTROLLABILITY. B.A. Kalman*, R.E. Grahn, F.X. Brennan, L.R. Watkins, and S.F. Maier. Behavioral Neuroscience Program, Department of Psychology, University of Colorado, Boulder, CO 80309.

Inescapable shock (IS), but not an equal amount of escapable shock (ES), results in a series of consequences collectively termed learned helplessness effects. These effects include poor shuttlebox escape performance, increased fear responding, increased analgesia, decreased aggression, alterations in neurotransmitter release and other behavioral and physiological changes. The goal of the present research was to address the possible role of anxiety in mediating these various effects of IS. The social interaction test of anxiety (File and Hyde, 1978) was previously used to demonstrate that IS subjects were more anxious than their ES counterparts 24 hours after shock (Short, 1991). Recent work indicates that different putative tests of "anxiety" are sensitive to changes in different underlying neurochemical systems. We therefore explored the effect of stressor controllability on the elevated plus-maze, a test that has a profile of pharmacological sensitivity different than that of social interaction. Male Sprague-Dawley rats (350-400g) were exposed to escapable shock, yoked-inescapable shock (100 1.0mA shocks, average ITI 60s) or restraint and subsequently tested on the elevated plus-maze. Anxiety was assessed by measuring the duration of open arm activity and the percentage of open arm entries 2, 24, and 48 hr after shock. The effects of manipulating subject handling, shock intensity and test area illumination were also assessed. In some instances the level of anxiety in shocked subjects was higher than in controls, but the clear difference between IS and ES subjects that was evident in the social interaction test of anxiety was not demonstrated using the elevated plus-maze. These results lend support to the idea that these tests of anxiety measure different aspects of that state.

DEVELOPMENT OF EPISODIC STRESS REACTIONS IN ADULT RATS TREATED NEONATALLY WITH AN ANTIDEPRESSANT. I.J. Goodman, L. Beeler and A.J. Azzaro. Depts. of Psychology and Behavioral Medicine & Psychiatry, West Virginia University, Morgantown, WV 26506.

Studies report paradoxical, "major depression-like" signs in adult rats after chronic, neonatal antidepressant injections. This study attempted to confirm and extend such findings, determining whether one might distinguish between such rats and those also experiencing later-life episodic stress. Rats 7-20 d old were injected daily with clomipramine HCl (CLO) (15 mg/kg, sc) with drug controls receiving saline (SAL). Open field (OFT) and swim tests (ST) were run on same rats at ages 4 and 10 mo. On 4 d prior to testing, half of CLO and SAL rats were stressed with footshock (Sh) (15 min sessions, 2 sec/min, .6 ma), other half not shocked (NS). CLO rats' body wts at 4 and 10 mo. were less than SALs'. At 4 mo., signif. OFT activity difference between CLO vs SAL rats in novel, large but not small open field; less struggle in CLO/Sh than SAL/Sh rats in ST. At 10 mo. coherent differences between CLO/NS and CLO/Sh groups emerged: novel, large OFT hyperactivity in CLO/NS and hypoactivity in CLO/Sh rats; in ST, more floating in CLO/Sh than CLO/NS rats. Results support prior findings and provide a developmental animal model for post-traumatic stress disorder.

CHRONIC STRESS IMPAIRS SPATIAL MEMORY IN RATS. M. Villegas*, C. Martinez, V. Luine and B.S. McEwen, Hunter College and Rockefeller University, New York, N.Y. 10021.

Excess corticosterone, through repeated restraint stress or injection, causes atrophy in apical dendrites of CA3 pyramidal neurons. We examined whether chronic stress has a deleterious effect on spatial memory in young male rats. Rats (n=14) were placed in plexiglass restrainers for 6 h/day for 21 consecutive days (lights off 0700-1900 h). Controls (n=13) were weighed only. Immediately following the last restraint, rats were food deprived, and then received 9 training trials on the eight arm radial maze (days 2-8 post stress), four regular trials (days 9-11), and 6 trials with delays after the 4th choice (days 13-16). Stressed rats made fewer correct choices in the 1st eight visits (6.7±2 vs 7.1±1, F1,25=3.90, P<.05) and also made their first mistake earlier (6.2±3 vs 7.3±3, F1,25=5.31, P<.03) than controls. The effects on performance were not necessarily permanent since on days 13-16 trials with delays after the 4th choice showed no stress effect. Phenytoin interferes with excitatory amino acid function and blocks stress dependent atrophy of CA3 cells (Watanabe et al Hippocampus 2 431, 1992). Phenytoin (40 mg/kg) was administered s.c. to stressed (n=14) and control (n=14) rats daily before restraint. Injections and restraint were given for 21 days, and then spatial memory was assessed as in the 1st experiment. No differences between the groups were noted, strongly suggestive that phenytoin blocks stress dependent effects on spatial memory. Results suggest that stress dependent alterations in hippocampal morphology are associated with small impairments of a spatial memory task. (GM08176 & GN41256).

BEHAVIORAL INDICES OF ISOLATION STRESS AND INFLAMMATORY NOCICEPTION IN DOMESTIC FOWL.

R. A. Hughes*, K. J. Sufka, and N. C. Weed. Depts. of Psychology, Iowa State University, Ames, IA 50011 and University of Mississippi, Oxford, MS 38677.

Isolation from conspecifics can elicit a variety of behavioral responses in young domestic fowl. These include, among others, increased distress calling, ventral recumbency posturing, hypoalgesia, and hyperthermia. However, systematic evaluation of whether these behaviors reflect converging indices of stress remains to be determined. In the present study, 7-day-old chicks received IPL formalin (.05%) or saline (.05 ml) and were placed in sound-attenuating chambers with or without 2 conspecifics for a 3 min. observation period. The following measures were recorded: vocalizations (VOC), footlift frequency (LFT) and duration (DUR), pecks (PKS), ventral recumbency latency (VRL), body temperature, respiration, and body weight. Principal component analyses revealed the presence of two oblique and negatively correlated (-.25) factors, one consisting of pain-related behaviors (i.e., LFT, DUR & PKS) and the other consisting of stress-related behaviors (VOC & VRL). These findings support the construct validity of these behavioral indices of pain and stress, respectively, and are consistent with the notion of stress-effects on nociception.

HORMONAL CONTROL OF REPRODUCTIVE BEHAVIOR: NEUROPEPTIDES AND TRANSMITTERS

665.1

INCREASE IN OXYTOCIN (OT) mRNA IN THE PARAVENTRICULAR NUCLEUS (PVN) AFTER LONG TERM EXPOSURE TO ESTROGEN (E₂) AND PROGESTERONE (P). R.S. Crowley, N.B. Kim, and J.A. Amico* University of Pittsburgh School of Medicine and VA Medical Center, Pittsburgh, PA 15261.

The hypothalamic peptide OT is an important mediator of reproductive behaviors including parturition, lactation, and production of sexual and maternal responsiveness. In rats, maternal behaviors can be elicited by long term exposure of ovariectomized females to E₂ and P. In particular, work by Bridges (*Endocrinol* 114:930, 1984) has determined the specific requirements for dosage, duration and sequence of steroid exposure necessary to produce the earliest induction of maternal behavior. In this study, we utilized this well-established endocrine model to examine a possible role for OT in production of steroid-induced maternal responsiveness. Female rats ovariectomized 1 week prior to study were implanted with s.c. 2mm E₂ or sham silastic capsules on day 1. Three 30 mm P or sham capsules were implanted on day 3 and then removed on day 14. Rats were sacrificed 36 hours later. Plasma levels of E₂ and P closely corresponded to those reported by other authors. Blot hybridization was performed with a ³²P-labeled cDNA to Exon C of the OT gene using total cytoplasmic RNA extracted from microdissected PVN of steroid-treated and sham animals. Steroid-treated animals (n = 12) had a nearly four-fold increase in OT mRNA (p = .01, Student's t-test) when compared with control animals (n = 8). Long-term E₂ and P treatment is associated with increased PVN OT mRNA. This finding supports a role for OT in the production of steroid-induced maternal responsiveness.

INTRA- AND INTERSEXUAL COMPARISONS OF FOREBRAIN NEUROPEPTIDE LEVELS. C. A. Marler*, S. K. Boyd, and W. Wilczynski. Depts. of Zool. and Psychol., Univ. of Texas, Austin, TX, 78712 and Dept. of Biol., Univ. of Notre Dame, IN, 46556.

Reproductive and sexual behaviors are influenced by several peptide hormones, including arginine vasotocin (AVT) and its mammalian homologs. We previously showed that increasing AVT levels in cricket frogs, *Acris crepitans*, increases the probability that a male will call and increases the aggressiveness of his calls (Chu et al., *Neurosci. Abst.* 18:894, 1992). Here we examine AVT correlates of alternative male reproductive behaviors and intersexual differences in cricket frogs. Calling males had greater densities of AVT immunoreactivity than sexually active satellite (noncalling) males in the amygdala and nucleus accumbens. AVT density was lower in females than males in the amygdala but in the nucleus accumbens female levels were intermediate between calling and satellite males. Our data suggest that alternative mating strategies in males may be influenced by fast acting neuropeptides and also that intrasexual variation in peptide levels can be greater than intersexual variation. QUANTITATIVE MICRODIALYSIS DETERMINATION OF EXTRACELLULAR STRIATAL DOPAMINE CONCENTRATIONS IN FEMALE RATS ACROSS THE ESTROUS CYCLE. L. Xiao* and J. B. Becker. Department of Psychology, Neuroscience Program, University of Michigan, Ann Arbor, MI 48104

Estrogen modulates mesostriatal dopamine (DA) activity *in vitro* and *in vivo*. Female rats in estrus exhibit greater amphetamine-induced activity, such as locomotor and stereotyped behaviors than those in diestrus or ovariectomized (OVX) females. Using quantitative microdialysis (the no net flux method) we looked to determine whether there are differences in extracellular striatal DA concentrations across the estrous cycle. Subjects were assigned to one of six groups (females in proestrus, estrus, diestrus or OVX females, and intact or castrated males). For intact females, the stage of estrous cycle was determined by daily vaginal cytology. Two weeks after bilateral guide cannulae were aimed at dorsolateral striatum, subjects underwent microdialysis. During dialysis, Ringer solutions with 0.4, or 16 nM DA were infused through dialysis probe and the gain or loss of DA was computed by subtracting the concentrations in the dialysate from that in the perfusate. DA was measured by HPLC-EC. A regression line was drawn for each animal to find basal DA concentrations (i.e., the point of no gain/loss).

Preliminary results indicate that females have significantly higher extracellular striatal DA concentrations in proestrus and in estrus than in diestrus or after OVX. We found no difference between intact and castrated males. Thus, endogenous ovarian hormones appear to modulate basal extracellular striatal DA concentrations in female rats.

CHANGES IN VIP AND GNRH ASSOCIATED WITH SEASONAL CYCLES IN BIRDS. C.J. Saldanha¹, P.J. Deviche² and R. Silver¹. ¹Barnard Coll. of Columbia Univ., New York, NY 10027. ²Univ. Alaska, Fairbanks, AK 99775.

Temperate zone birds, such as the dark-eyed junco (*Junco hyemalis*) used here, have dramatic seasonal reproductive cycles. Long days of spring stimulate the gonadal axis and the birds are said to be photosensitive. Indeed, LH secretion increases after one long day (Follet et al., 92). In the late summer, birds no longer respond to long days, their gonads regress, and they are said to be photorefractory. After several weeks of refractoriness the birds regain sensitivity.

It is well established that peripheral hormonal fluctuations result from changes in the brain rather than the pituitary or gonads. We studied central expression of VIP (stimulates prolactin secretion in birds), GnRH, and neurophysin (NP) in photorefractory birds (housed in 16:8 LD) and in photosensitive birds (housed in 8:16 LD) and transferred to long days (16:8 LD) for one day, one month, or not at all. VIP expression was similar in all photosensitive birds. However, photorefractory birds had 3-4 times as many VIP-positive neurons in the infundibulum as photosensitive birds. GnRH-positive cell number in the preoptic area was significantly higher in one-month photostimulated and significantly lower in photorefractory birds than in other groups. NP expression was similar in all groups. The data suggest that the inverse relationship between circulating levels of prolactin and LH during refractoriness may result from neural changes in VIP and GnRH respectively. Future studies will examine how photic input influences the expression of these peptides. Supported by NIMH 029380 (RS) and NSF BNS-9121258 (FD).

IMMUNOHISTOCHEMICAL INTERACTIONS BETWEEN GnRH I OR II WITH ENKEPHALIN IN TURKEY HENS. J.R. Millam, P.L. Paris*, M. Kram, P.E. Kerr, and C. Cozzari. Dept. Avian Sciences, University of California - Davis 95616, Division of Neuroscience Research, Department of Psychiatry, University of Minnesota 55455, and Institute Biologia Cellulare CNR, Roma (Italy).

The present study sought to determine the anatomical interactions between cGnRH I or II and methionine-enkephalin. A double-label immunohistochemical procedure was used to simultaneously visualize enkephalin (ENK) and one of the GnRH's in the same tissue section. This procedure involves using diaminobenzidine and alpha-naphthol/pyronin B as the chromagens in two sequentially performed peroxidase-antiperoxidase reactions. Two main potential interactions were evident in the medial extreme of the lateral septum. GnRH II fibers were observed in close association with large ENK-ergic dendritic fragments. In adjacent sections, staining in the same region was suggestive of ENK-ergic terminals juxtaposed to GnRH I immunoreactive perikarya. Despite the heavy labeling of ENK processes, only scattered, extremely small enkephalin perikarya were observed in the lateral septum. ENK staining was virtually absent in the medial septal nucleus. These findings suggest that the ENK cells in the lateral septum may be small interneurons with extensive dendritic arborizations and highly branching axonal processes. Based on these findings, we hypothesize that an ENK interneuron links GnRH II axonal terminals to GnRH I soma, thus providing a potential anatomical substrate for GnRH II modulation of reproductive function. Supported by USDA (Prime 91-37203-6606).

A SECOND GENE FOR GNRH: COMPLEMENTARY DNA AND EXPRESSION PATTERN FOR THE PRE-PROHORMONE IN A TELEOST FISH. SA White*, CT Bond, RC Francis, TL Kasten, RD Fernald & JP Adelman. Neuroscience Program, Stanford University and Vollum Institute, Oregon Health Sciences University. Gonadotropin-releasing hormones (GnRHs) are a family of decapeptides whose importance for reproductive success throughout 500 million years of vertebrate evolution is evidenced by the striking conservation of its primary sequence: Five of the ten amino acids are identical from lamprey to mammal, including the cyclized amino- and amidated carboxy-termini. Significant variation occurs only in the remaining five positions as seen in the seven peptide forms that have been sequenced to date. Frequently, more than one form has been found within a single species and immunocytochemistry indicates that these forms are expressed in distinct but overlapping neuronal populations. Hypothalamic GnRH regulates the release of pituitary gonadotropins; the bioactivity of the other forms remains unclear. Enigmatically, of the two GnRHs found in chicken, the one with greatest releasing hormone potency *in vitro*, Chicken II, is not released in detectable amounts from the median eminence. Despite the existence of multiple peptides, the gene for only one form of GnRH has been identified. Thus, the evolutionary origins and putative physiological functions of the alternate members of this potent peptide family remain unknown. To address these questions, we employed a novel PCR strategy to amplify the Chicken II-like GnRH from a teleost fish brain where multiple peptide forms were known to occur from HPLC analysis. Here we report, for the first time, the existence of a second gene for GnRH. The sequence of this precursor differs dramatically from previously described GnRH prohormones, including at least two potential peptides in addition to GnRH, and indicates that the genes encoding the GnRH family of peptides arose independently. Using *in situ* hybridization we also show that this second form is expressed only within a mesencephalic neuronal population which does not project to the pituitary, raising an obvious question about its potential role(s) in reproduction. Supported by HD23799, MH09986 and NS28504.

665.6

AN EXAMINATION OF irGnRH NEURONS IN THE PREOPTIC AREA OF THE CICHLID FISH - HAPLOCHROMIS BURTONI. R.D. Fernald* and T. Bushnik Harris. Department of Psychology, Stanford University, Stanford CA.

In the African cichlid fish, *Haplochromis burtoni*, there are two distinct kinds of male behaviour. Territorial (T) males, comprising about 10% of the male population, have bright body coloring, mature gonads, and aggressively defend a territory; non-territorial (NT) males have cryptic coloring, smaller gonads, and behavior indistinguishable from that exhibited by juveniles and females. Only the T males are able to reproduce. It has been previously reported that the soma sizes of cells immunoreactive for gonadotropin releasing hormone (irGnRH) in the preoptic area (POA) are strongly correlated with the social status of the fish. That is, T males have large soma sizes, NT males have significantly smaller soma sizes, and males that have been forced to change their social status, from NT to T and vice versa, exhibit large and small soma sizes, respectively (Francis, Soma & Fernald, 1993). It has been proposed that this population of irGnRH cells mediates the difference/change in reproductive status between T and NT males. In order to directly address this hypothesis, the cells in the POA were double labelled to determine if this population of irGnRH cells projects to the pituitary. Crystals of Dil were applied to the damaged pituitary stalks of paraformaldehyde fixed brains taken from T and NT males. After sufficient time for retrograde diffusion of the Dil to the POA had elapsed (2 to 3 weeks), the brains were sectioned on a vibratome and immunostained for GnRH using a fluorescein label. In addition to determining whether the irGnRH POA neurons exhibited Dil labelling, the morphology of these neurons in T and NT males was examined in order to determine whether the complexity of the neuronal processes could be correlated to social status in a manner analogous to the relationship between irGnRH POA cell soma sizes and social dominance. Supported by NIH HD 23799 to RDF and NSERC post-doctoral scholarship to TBH.

665.8

GNRH, BUT NO GNRH MRNA, IN THE PREOPTIC AREA OF THE CICHLID FISH, *HAPLOCHROMIS BURTONI*. R.C. Francis*, S.A. White and R.D. Fernald. Department of Psychology, Stanford University, Stanford, CA.

The decapeptide, gonadotropin releasing hormone (GnRH), plays a central role in the regulation of reproductive function in vertebrates. Taxonomically, the most widely distributed form of GnRH is chicken GnRH-II, which has been identified in most vertebrates with the exception of some mammals. But its expression is largely confined to the mesencephalon and it has not been implicated (*in vivo*) in the regulation of gonadotropin release from the pituitary. A number of other forms of GnRH have been identified in various taxa that are expressed in neurons of placodal origin in the ventral forebrain. In teleost fishes the most abundant form is salmon GnRH (sGnRH), which has been localized in neurons of the terminal nerve (TN) and preoptic area (POA). We have shown previously that in male *Haplochromis burtoni* the POA irGnRH neurons mediate the effects of social status on gonadal development through changes in soma size. These neurons also respond plastically to changes in gonadal hormone levels. In contrast, TN irGnRH neurons do not respond to social cues and do not project directly to the pituitary. TN irGnRH neurons project diffusely and extensively throughout the brain and may serve a neuromodulatory function (Oka et al. 1992). We used *in situ* hybridization and immunocytochemistry, alone and in combination, to explore sGnRH expression in *H. burtoni*. ICC revealed abundant sGnRH in both the TN and POA neurons. However, we were surprised to find that while sGnRH mRNA was abundant in TN irGnRH neurons, it was absent in the POA. Nor was cGnRH-II mRNA present in the POA. There are two possible explanations for this puzzling result. Either the peptides found in the TN and POA, though they cannot be distinguished by our antibody, are produced by different genes; or both the POA and TN contain sGnRH, and the sGnRH found in the POA is produced in the TN.

PSYCHOTHERAPEUTIC DRUGS: ANTIPSYCHOTICS AND OTHER AGENTS

666.1

CP88,059: A NEW ANTIPSYCHOTIC WITH MIXED DOPAMINE D2 AND SEROTONIN 5HT2 ANTAGONIST ACTIVITIES. J.F. Seeger*, A.W. Schmidt, L.A. Lebel, B.K. Koo, S.H. Zorn, D.W. Schulz, H.R. Howard, and J.H. Haym. Neuroscience Dept., Pfizer Central Research, Groton, CT 06340.

CP88,059 is a new antipsychotic which binds with high affinity to D2 receptors ($K_i = 4.8$ nM) and 5HT2 receptors ($K_i = 0.42$ nM). CP88,059 is distinguished from risperidone by its high affinity for 5HT1A ($K_i = 3.3$ nM) and 5HT1C ($K_i = 1.4$ nM) receptors, both of which may benefit antipsychotic drug action. Receptor autoradiography using 3H-CP88,059 reveals a binding pattern consistent with a 5HT2 receptor ligand. Functional studies indicate that CP88,059 is a 5HT1A agonist and an antagonist at D2 and other receptors which bind it with high affinity (see also Zorn et al., this meeting). CP88,059 has a weak affinity for alpha-1 adrenoceptors ($K_i = 11$ nM) relative to its D2 affinity, suggesting the potential for reduced sedative and hypotensive effects when compared to other antipsychotics. Finally, CP88,059 is a blocker of norepinephrine uptake ($IC_{50} = 26$ nM), but is relatively inactive against dopamine and serotonin reuptake. Thus, CP88,059 has a biochemical profile which predicts antipsychotic efficacy with low side effect liability, and also shares some features with known anxiolytic and antidepressant agents.

666.2

CHRONIC HALOPERIDOL ALTERS SUBSTANTIA NIGRA GABA AND EXTRACELLULAR GLUTAMATE IN THE STRIATUM. B.K. Yamamoto* and M.A. Cooperman. Dept. of Psychiatry, Case Western Reserve Univ., Cleveland, OH 44106

Striatal efferent pathways are regulated by GABA, glutamate and dopamine. These pathways have been implicated in mediating the motoric side effects of chronic antipsychotic drug treatment. The present study examined the effects of chronic haloperidol (HAL) treatment on extracellular concentrations of glutamate and GABA in the striatum and substantia nigra (SN), respectively, of awake-behaving rats.

Male rats were administered either HAL (0.5 mg/kg IP) or tartaric acid vehicle (pH 6.0) for 21 days. One or 7 days after the last injection, extracellular concentrations of glutamate and GABA were simultaneously measured *in vivo* in the caudate and SN by a dual-probe microdialysis method. One day after the cessation of chronic HAL administration, striatal glutamate was markedly elevated (500%) compared to vehicle-treated rats. Basal extracellular concentrations of GABA in the SN were also increased (240% of control). One week after the termination of HAL treatment, striatal glutamate levels remained elevated (216%), albeit lower than after only one day of withdrawal. In contrast, GABA concentrations in the SN were decreased (51% of control) following 1 week of withdrawal from chronic HAL treatment. Results will also be presented with regard to the effect of HAL on GABA in the globus pallidus. These data indicate that chronic haloperidol treatment alters striatal glutamatergic and nigral GABAergic function. These corticostriatal and striatonigral alterations are also dependent on the duration of withdrawal from chronic treatment and may be related to the motor side effect liability of chronic treatment with typical antipsychotic drugs.

666.3

EFFECT OF REPEATED HALOPERIDOL ADMINISTRATION ON PHENCYCLIDINE (PCP) DISCRIMINATION IN RATS. J.L. Wiley*. Dept. of Pharmacology & Toxicology, Medical College of Virginia, Richmond, VA 23298.

Acute doses of haloperidol (dose range = 0.1-0.32 mg/kg) produce partial attenuation of the PCP stimulus in rats trained to discriminate PCP from vehicle (R. Browne, In: Clouet, ed., *Phencyclidine: An update*, pp. 134-147, Rockville, MD: NIDA, 1986). This study examined the effects of repeated administration of haloperidol (HAL) on PCP discrimination in rats. Rats were trained to discriminate PCP (2.0 mg/kg) from saline in a two-lever drug discrimination procedure. Following acquisition, rats were tested with cumulative doses of PCP before and after repeated administration of saline and of HAL (0.5 mg/kg/day). Discrimination training was suspended during the two 14-day repeated dosing regimens. The post-saline PCP dose-effect curve for %PCP-lever responding showed little change from the pre-saline curve (pre ED₅₀ = 0.6 mg/kg vs. post ED₅₀ = 0.4 mg/kg). After repeated administration of HAL, the ED₅₀ was 1.4 mg/kg, compared to the pre-HAL ED₅₀ of 0.7 mg/kg. These results are consistent with those of acute dosing studies that tested haloperidol in PCP-trained rats and suggest that repeated administration of haloperidol may disrupt PCP's discriminative stimulus effects, although most rats were still able to discriminate the higher doses of PCP. Research supported by NIDA Grants DA-01442 and DA-07027.

EFFECT OF A NEUROLEPTIC, NEMONAPRIDE (YM-09151), ON C-FOS EXPRESSION IN THE RAT FOREBRAIN. T. Nishio, M. Narita# and K. Satoh*# Nagahama Inst. Biochem. Science, Oriental Yeast; #Shiga Univ. Medical Science, Dept. Psychiatry, Otsu, Japan;

Neuroleptics have pharmacological effect on many neurotransmitter systems in the central nervous system. However, the mechanism of action of these drugs is still unknown. In the present study, the effect of a new neuroleptic, nemonapride (YM-09151), on the expression of immediate early gene, c-fos, was investigated. After an injection of nemonapride (0.5 - 4.0 mg/kg), the distribution of Fos immunoreactive neurons was examined in the rat forebrain, and the result was compared with that obtained after an administration of haloperidol (1-2 mg/kg). Both neuroleptics induced Fos immunoreactivity in many forebrain structures, such as the striatum, anterior olfactory nucleus, olfactory tubercle, nucleus accumbens, lateral septal nucleus, medial prefrontal cortex, and the thalamic and hypothalamic paraventricular nuclei. In addition, nemonapride enhanced Fos-immunoreactivity in cells located in the island of Calleja. In contrast, haloperidol induced many Fos-immunoreactive neurons in the lateral septal nucleus and hypothalamic paraventricular nucleus. The present findings indicated that two neuroleptics with different therapeutic potentials have effect on different population of cells in the rat forebrain.

666.7

POTENT AND SELECTIVE SIGMA₁ LIGANDS BASED ON CARBETAPENTANE. S.N. Calderon, S. Izenwasser, B. Heller, S. Gutkind*, A.H. Newman, Drug Development Group, NIDA-ARC, Baltimore, MD 21224, *Molecular Signaling Group, LCDO, NIDR, NIH, Bethesda, MD 20892.

The structural and pharmacological diversity of compounds that interact with sigma binding sites (σ_1 and σ_2) has prompted an intensive search for selective sigma ligands with discrete biological actions that could be undeniably attributed to their interaction at these sites. Carbetapentane (CBP, 2-[2-(diethylamino)ethoxy]ethyl-1-phenyl-1-cyclopentylcarboxylate) is a drug with anticonvulsant, antitussive and neuroprotectant actions that binds to σ_1 sites. We have prepared several series of compounds based on this drug to 1) identify structural features responsible for potent and selective binding to sigma sites, 2) identify novel anticonvulsant and neuroprotectant agents, and 3) determine whether binding to sigma sites correlates with these activities. Previously described sigma ligands that structurally resemble CBP possess one or more of the following moieties that were deemed important for potent and selective binding to these sites: a 3,4-dichlorophenyl ring, an alkyl-diamino side chain, a piperidino or morpholino function and a cycloalkyl group. All of these structural moieties were incorporated into the CBP molecule. The general synthesis began with preparing the appropriately substituted cycloalkylphenyl-carboxylate and reducing or directly reacting it with prepared side chains to give the desired ethers, esters and amides. Reduction and alkylation of the amides resulted in diamino analogs. [³H](+)-SKF 10,047 (in the presence of cold MK 801) and [³H]DTG (in the presence of cold (+)-SKF 10,047) were used to radiolabel σ_1 and σ_2 binding sites respectively, in rat brain. Optimal σ_1 binding properties resulted when the 3,4-dichlorophenyl, cyclohexyl, and morpholino or piperidino rings were simultaneously incorporated into CBP. Structure-activity relationships for this series of compounds including σ_1 , σ_2 , muscarinic (m1 and m2) and PCP receptors will be discussed.

666.4

EFFECTS OF CHRONIC SM-9018, A CENTRALLY ACTING 5-HT₂ AND D₂ ANTAGONIST, ON DOPAMINE AND 5-HT RECEPTORS IN RATS. Y. Ohno*, K. Okada, K. Ikeda, K. Ishida, T. Ishibashi and M. Nakamura. Res. Lab., Sumitomo Pharmaceuticals Co., Ltd., Konohana-ku, Osaka 554, Japan.

SM-9018 is a potential atypical neuroleptic with combined 5-HT₂ and D₂ blocking activities. Receptor binding and behavioral studies were performed to compare the effects of chronic treatment with SM-9018 and with haloperidol (HAL) on dopamine and 5-HT receptors in rats. SM-9018 treatment, at a dose sufficient to block D₂ receptors (10 mg/kg/day p.o.), for 14 days did not significantly change the density (B_{max}) of striatal D₂ receptor (labeled by ³H-raclopride) or the stereotyped behaviors induced by apomorphine (APO). By contrast, a typical neuroleptic HAL (3 mg/kg/day p.o., for 14 days) significantly increased the striatal D₂ receptor density by about 55% and markedly enhanced the response to APO. The incidence of SKF 38393 (D₁ agonist)-induced vacuous oral movements was also increased by HAL but not by SM-9018. The density of 5-HT₂ receptor (labeled by ³H-ketanserin) in the cerebral cortex was unaffected by HAL but slightly decreased (about 20%) by SM-9018. However, 5-HT₂ receptor-mediated hyperthermia with p-chloroamphetamine (a putative 5-HT releaser) was unaltered following SM-9018 treatment. These findings suggest that SM-9018 is weaker than HAL in inducing up-regulation and supersensitivity of dopamine receptors in rats after chronic treatment and has low propensity to induce tardive dyskinesia.

SERUM HALOPERIDOL AND TOXICITY IN GERIATRIC PATIENTS J.J. Weisbard, R.C. Young*, B. Kalayam, J. Birnbaum, B. Meyers, T. Kakuma. New York Hospital-Cornell Medical Center, Westchester Division, White Plains, NY 10605.

Haloperidol is widely prescribed in the geriatric population. While it can be therapeutically effective, it may produce toxicity including reduced cognitive capacity. Serum haloperidol levels differ widely among geriatric patients receiving similar doses, and optimal treatment conditions need definition. In young patients, serum muscarinic receptor binding activity has been correlated with cognitive deterioration during neuroleptic treatment. We reviewed charts of psychiatric inpatients treated with haloperidol for a primary psychotic disorder in whom serum haloperidol had been determined. They had been routinely assessed prospectively by trained nursing staff using behavioral ratings including memory impairment and disorientation. In geriatric (age \geq 60 yrs) patients (n=16) higher serum haloperidol levels, but not doses (mg/kg), were associated with cognitive deterioration since admission reflected in changes in ratings of memory impairment ($r = -.56$; $p < .02$) and disorientation ($r = -.45$; $p < .08$). In patients aged <60 yrs (n=13) these associations were not observed. Further prospective assessment of haloperidol levels and clinical effects in geriatric patients is needed.

666.8

OPPOSITE EFFECTS ON LCGU IN RATS BY THE PRESYNAPTIC DOPAMINE AGONIST ORG 20223 AND APOMORPHINE. J.A.D.M. Tonnaer*, P.C. Fedder, Th. de Boer, C.L.E. Broekkamp and A.M.L. van Delft, Scientific Development Group, Organon International B.V., P.O. Box 20, 5340 BH Oss, The Netherlands.

Org 20223 is a DA agonist which exhibits moderate affinity for D₂ (pK_i=7.0) and 5-HT_{1A} (pK_i=6.8) binding sites, whilst lacking substantial affinity for other DA, 5-HT, α or β adrenergic, muscarinic or histaminergic binding sites. Org 20223 reduces DOPA accumulation (1 mg/kg, i.p.), induces yawning and penile erections, and inhibits ambulation in rats, and reduces motor activity in mice (0.5-10 mg/kg, s.c.). In rats the compound does neither induce severe symptoms of DA-related stereotyped behaviour (doses up to 100 mg/kg, s.c.), nor 5-HT_{1A} receptor mediated behaviour (doses up to 46 mg/kg, s.c.).

Upon i.v. administration in freely moving rats (0.1 and 0.3 mg/kg) Org 20223 dose-dependently decreases local cerebral glucose utilization (LCGU) in core structures of the extrapyramidal system and in several thalamic brain areas. LCGU is not or non-significantly decreased in limbic and neocortical brain structures, and is unaffected in amygdaloid, cholinergic, serotonergic or in cerebellar brain structures. The effects induced by Org 20223 on LCGU in the thalamic nuclei are opposite to those induced by the postsynaptic DA agonist apomorphine but resemble those seen with DA receptor blocking antipsychotic drugs such as haloperidol and clozapine. Thus, Org 20223 reduces LCGU in the anteroventral, laterodorsal and ventroposterior nuclei of the thalamus and tends to increase LCGU in the lateral habenula. Plasma glucose levels and plasma corticosterone levels are not affected by treatment of the animals with Org 20223.

The neurochemical and behavioural data indicate Org 20223 has the profile of a preferential DA autoreceptor agonist. The typical pattern of LCGU changes indicates that Org 20223 is a compound with potential antipsychotic properties.

666.9

EFFECTS OF SDZ ENA 713 ON AF64A-INDUCED RATS.

H. Endo¹, T. Tajima², T. Goto², H. Ikari², F. Kuzuyama² and A. Iguchi².

¹Dep of Geriatrics, Chubu Hospital, Obu, Japan, 474. ²Dep of Geriatrics, Nagoya Univ. Sch. of Med., Nagoya, Japan, 466.

SDZ ENA 713 is a potent, long-lasting, orally active acetylcholine esterase inhibitor (AChE-I). This produces a greater inhibition of AChE-I activity in brain regions than in peripheral organs, because it was developed as a brain-selective drug. This kind of drugs is expected for the treatment of Alzheimer's disease (AD). First, we studied memory and learning on AF64A-induced rats by 8 radial maze. Secondly we measured acetylcholine (ACh) levels by micro-dialysis in freely moving rats administered SDZ ENA 713 (3mg/kg). ACh levels in rats with the drug were higher than controls. Correct response was reduced in AF64A-induced group, this effect was reversed by SDZ ENA 713. This drug might be useful in the treatment for AD.

666.11

DISCRIMINATIVE STIMULUS PROPERTIES OF LITHIUM CHLORIDE. P. J. Winsauer^{*}, J. F. Verrees and P. C. Mele. Behav. Sci. Dept., Armed Forces Radiobiology Res. Inst., Bethesda, MD 20889-5603.

Although much is known about the aversive properties of LiCl, little is known about the discriminative stimulus properties of this drug. For this reason, eight rats were trained to discriminate between an injection of LiCl (i.e., 56 or 75 mg/kg, i.p.) and saline in a two-lever operant chamber during a 20 min session. On training days, responding on the designated lever was reinforced under a fixed-ratio 20 (FR 20) schedule of food presentation, whereas responding on the other lever had no programmed consequences. Generalization testing with LiCl (10-100 mg/kg) was conducted after each subject reached a criterion of nine of ten sessions where 95% of overall responding occurred on the designated lever, and fewer than twenty responses were made on the other lever before presentation of the first reinforcer. On test days, responses on both levers were reinforced under an FR 20 schedule. In general, all subjects reliably discriminated between saline and the training doses of LiCl. Substituting both lower and higher doses produced graded decreases in responding on the LiCl-appropriate lever while only higher doses decreased overall response rate. Following generalization tests, subjects were divided into two groups and varying doses of LiCl were given in combination with i.p. injections of either ondansetron (0.32 and 1 mg/kg) or dexamethasone (1 and 3.2 mg/kg). At doses that had little or no effect alone, neither ondansetron nor dexamethasone pretreatment blocked the discriminative stimulus properties of LiCl. This research shows that LiCl can act as a highly discriminable stimulus in an operant drug-discrimination paradigm and suggests that the stimulus properties of LiCl do not derive from direct activation of serotonin type-3 receptors or release of adrenocorticotrophic hormone.

EFFECTS OF THE SELECTIVE 5-HT₂ ANTAGONIST MDL 100,907 ON STIMULANT- ENHANCED LOCOMOTION IN RATS. J.H. Kehne^{*} and H.J. Ketteler. Marion Merrell Dow Research Institute, 2110 E. Galbraith Rd., Cincinnati, OH 45215.

Previous studies suggested that the potent and selective 5-HT₂ antagonist MDL 100,907 has the profile of a potential antipsychotic with minimal extrapyramidal side effect liability (Sorensen et al., *Soc. Neurosci. Abstr.*, 18: 1381, 1992). The present study further extended these findings using two models of stimulant-enhanced locomotion in rats.

MDL 100,907, like haloperidol and clozapine, significantly reduced d-amphetamine-stimulated locomotion in rats. In marked contrast, the 5-HT₂ antagonist ritanserin did not alter d-amphetamine-stimulated locomotion in doses of up to 8 mg/kg. These results suggest that MDL 100,907, but not ritanserin, would have potential antipsychotic activity. The difference in activity between MDL 100,907 and ritanserin may result from the selectivity of MDL 100,907 for the 5-HT₂ receptor.

Both MDL 100,907 and haloperidol attenuated the stimulation of locomotor activity produced by the 5-HT/DA releaser, 3,4-methylenedioxymethamphetamine (MDMA; Kehne et al., *Soc. Neurosci. Abstr.*, 18:352, 1992). Interestingly, haloperidol primarily affected the early (0-30 min) component of the MDMA effect, whereas MDL 100,907, and to a lesser extent, ritanserin, primarily affected the late (30-60 min) component. In the present study, clozapine also primarily attenuated the late component of MDMA-enhanced stimulation. Thus, the pattern of activity of MDL 100,907 in the MDMA-stimulated locomotion test more closely resembles that of clozapine than haloperidol.

These data further support the conclusion that MDL 100,907 is a potential antipsychotic agent with a unique behavioral profile.

666.10

IN VIVO NEUROCHEMICAL EFFECTS OF WAY-124486: A POTENT DOPAMINE AUTORECEPTOR AGONIST. J.H. Andrea^{*}, L. Cortes-Burgos, R. Scemi, T. Wasik, T. Spanoler, G. Stack, K. Marquis, C. Routledge¹ and G. Guidelsky². Wyeth-Ayerst Research, CN 8000, Princeton, N.J. 08543, ¹Wyeth Research Limited, Maidenhead, UK SL60PH and ²Departments of Psychiatry and Neuroscience, Case Western Reserve University, Cleveland, OH 44106.

WAY-124486 (S)-3-[[[3-(3-aminophenoxy)propyl] amino] methyl]-2,3-dihydro-1,4-benzodioxin-6-ol dihydrochloride is a potent D₂ autoreceptor agonist as demonstrated in neurochemical, behavioral and electrophysiological assays (1992 Neuroscience abstracts, 158.20, 158.21 and 158.22, respectively). Since dopamine autoreceptor agonists are known to decrease dopaminergic transmission by inhibition of DA release, synthesis and impulse flow, *in vivo* microdialysis studies were performed in conscious male SD rats to confirm WAY-124486's suspected effects on extracellular concentrations of DA. WAY-124486 (1 and 5 mg/kg, sc) markedly (60-65%) reduced extracellular concentrations of DA which remained depressed during the 3 hr collection period. A slight (approx. 20%) decrease in DOPAC was also observed. Following the perfusion of Ringer's buffer containing 55 mM K⁺, extracellular DA was increased 3.5 fold. This increase was inhibited by quinpirole (0.75 mg/kg, sc) and WAY-124486 (5 mg/kg, sc). These results are consistent with the DA autoreceptor actions of WAY-124486. Since D₂ agonists have also been shown to have effects on the neuroendocrine axis to inhibit prolactin secretion (Caron et al., *J. Biol. Chem.* 253:2244, 1978) and to increase corticosterone secretion (Fuller et al., *Neuroendoc.* 36: 285, 1983), WAY-124486 was likewise examined for its effects on these hormones. WAY-124486 (5 mg/kg, sc) and quinpirole (0.75 mg/kg, sc) produced marked elevations of corticosterone serum levels. Results on prolactin secretion and protection against EEDQ-induced inactivation of D₂ receptors *in vivo* will also be presented.

666.12

EFFECTS OF THE SELECTIVE 5-HT₂ ANTAGONIST MDL 100,907 ON FENFLURAMINE-, MDMA-, OR DOI-INDUCED DISRUPTION OF AUDITORY OR VISUAL PREPULSE INHIBITION IN RATS. R.A. Padich^{*}, T.C. McCloskey, J.M. Hitchcock, and J.H. Kehne. Marion Merrell Dow Research Institute, 2110 E. Galbraith Rd., Cincinnati OH 45215.

Prepulse inhibition is a model of sensorimotor gating useful for preclinical and clinical studies exploring the neurochemical basis of schizophrenia and for identifying new antipsychotic agents. The present study investigated the role of 5-HT₂ receptors in the modulation of prepulse inhibition. Agents which selectively (fenfluramine) or non-selectively (3,4-methylenedioxymethamphetamine, MDMA) release serotonin consistently reduced both auditory and visual prepulse inhibition in rats. The reduction of auditory prepulse inhibition was prevented by the selective 5-HT₂ antagonist MDL 100,907, but not by the dopamine antagonist haloperidol. The disruption of visual prepulse inhibition was not affected by either MDL 100,907 or haloperidol. The directly-acting 5-HT₂ agonist 1-(2,5-dimethoxy-4-iodophenyl)-2-aminopropane HCl (DOI) selectively reduced auditory prepulse inhibition, and this effect was prevented by MDL 100,907, but not by haloperidol. These data support the conclusion 5-HT₂ receptor stimulation specifically disrupts auditory prepulse inhibition in rats. Although 5-HT release potentially disrupts visual as well as auditory prepulse inhibition, the identification of the receptor(s) mediating the effect on visual prepulse inhibition requires further investigation. Finally, dopaminergic receptors are not required for the expression of the effects of DOI or the releasing agents on prepulse inhibition. These results support an independent role of 5-HT in prepulse inhibition.

666.14

METABOLISM OF PSYCHOACTIVE DRUGS BY HUMAN BRAIN MICROSOMES-IMPLICATION IN PHARMACOTHERAPY. V. Ravindranath¹, S. Bhamre¹, S.V. Bhagwat¹, S.K. Shankar² & S.H. Koslow². Depts. of Neurochemistry¹ & Neuropathology², National Institute of Mental Health & Neuro Science, Bangalore-560 029, India & ²Div. of Neuroscience & Behavioral Science, NIMH, Rockville, MD-20857, USA.

Microsomal flavin-containing monooxygenase (FMO) is involved in the metabolism of nitrogen and sulfur containing xenobiotics including drugs. A number of psychoactive drugs are metabolized by hepatic FMO. We examined the presence of FMO in human brain regions obtained at autopsy using model substrates and the antidepressants, imipramine (IMI) and fluoxetine (FLUO). Microsomes from human brain metabolized IMI and FLUO efficiently. The human brain FMO demonstrated high affinity for IMI and FLUO (K_m=22 & 16 μM) as compared to the model substrate N,N-dimethylaniline (K_m=2.2 mM). Immunocytochemical studies using the antibody to the pulmonary FMO revealed the preferential localization of FMO in neuronal soma and co-localization of FMO and cytochrome P-450 in human brain. FMO mediated metabolism of antidepressants varied between individuals and this may explain the variable drug response typically seen in a diverse patient population.

PHENCYCLIDINE (PCP) AND (+)-AMPHETAMINE (DEX)-INDUCED STIMULATION - A PHARMACOLOGICAL STUDY. D. M. Jackson, C. E. Johansson, A. Bengtsson and M. Lindgren Department of Behavioural Pharmacology, Preclinical CNS R & D, Astra Arcus AB, Södertälje 151 54, Sweden.

Both DEX and PCP are especially interesting drugs because they can produce in man symptoms that resemble aspects of schizophrenia (SCHIZ). DEX produces symptoms that resemble some of the positive symptoms of SCHIZ, while PCP can cause symptoms that may better reflect the negative symptomatology of SCHIZ. In the present study, we have examined the effects of DEX and PCP on locomotion in rats. Both DEX and PCP caused dose dependent increases in locomotion in rats as measured in computerised activity cages. An analysis indicated that both drugs caused dose dependent increases in total activity, forward locomotion and peripheral activity. While DEX dose dependently but non-significantly increased rearing, PCP significantly decreased the incidence of this behaviour. This is in agreement with earlier studies. A variety of drugs were tested for the ability to block PCP and DEX-induced excitation. The selective dopamine (DA) D1 antagonists, SCH23390 and NNC-01-0112, were 7 to 8 times more potent in blocking the DEX-induced increase in total activity than in blocking PCP-effect. In contrast, the DA D2 receptor antagonists raclopride and remoxipride, as well as haloperidol, were only 1 to 2 times more potent against DEX-induced stimulation. Non-selective DA D2 antagonists, as well as sertindole, were also tested. Chlorpromazine resembled the DA D1 antagonists in its pattern of blockade. Buspirone and sertindole were more potent in blocking PCP than DEX-induced stimulation. The selective $\alpha 1$ antagonist prazosin partially blocked, while the 5HT1A agonist 8-OH-DPAT potentiated, both DEX and PCP-induced stimulation. The selective 5HT2 antagonist ritanserin was inactive. The effect of the various test agents on locomotion was also tested. The data indicate that there are clear qualitative, quantitative and pharmacological differences between DEX and PCP-induced locomotor excitation. This difference could be of interest in the development of new antipsychotic agents.

GENETIC MODELS OF NERVOUS SYSTEM DISORDERS II

667.1

OVER-EXPRESSION OF TGF- $\beta 1$ IN ASTROCYTES OF TRANSGENIC MICE RESULTS IN HYDROCEPHALUS. A. Messing, S.-J. Kim, E.J. Galbreath, and M. Brenner. School of Veterinary Medicine, Univ. Wisconsin-Madison, Madison, WI 53706; Division of Cancer Etiology, NCI, and Stroke Branch, NINDS, NIH, Bethesda, MD 20892.

Transforming growth factor $\beta 1$ (TGF- $\beta 1$) has been proposed to play a number of roles in both the development of the CNS and its response to injury. Astrocytes produce TGF- $\beta 1$, and also express receptors for this regulator. To more critically examine the roles of TGF- $\beta 1$ in the CNS, we created transgenic mice that constitutively over-express TGF- $\beta 1$ in astrocytes by using a construct in which the TGF- $\beta 1$ coding region is under the control of the promoter of the human glial fibrillary acidic protein gene. Nineteen founder animals were produced, of which 11 developed severe hydrocephalus and died between birth and 3 weeks of age. Pathologic examination of multiple organs showed no significant abnormalities outside of the brain. Preliminary immunohistochemical studies indicate that the hydrocephalic phenotype correlated with elevated expression of TGF- $\beta 1$ in the brain. These results show that the developing CNS is highly sensitive to TGF- $\beta 1$, and suggest a role for aberrant expression of TGF- $\beta 1$ in the pathogenesis of developmental disease of the CNS.

667.3

TRIPHASIC RELAPSE IN DYSTONIC HAMSTER DURING PREGNANCY AS A RIGOROUS NEUROCHEMICAL MODEL FOR MOVEMENT DISORDER. A.E. Khalifa and W.B. Iturrian. Dept. of Pharmacology and Toxicology, Univ. of Georgia, Athens, GA 30602-2356

A genetic paroxysmal dystonia occurs transiently in weanling dt sz (UGA 700) hamster with virtual complete remission by age 60 days (Movement Disorder 4:219, 1989). We now report a triphasic relapse associated with pregnancy, parturition and nursing. Over 60% have the distinctive tonic torsion and spasms of dystonia during late pregnancy and almost all being maximally susceptible on parturition day. On the third day post-partum few show dystonia even when elicited by anxiogenic doses of pentylenetetrazol. 100% of nursing mothers show full paralytic attacks on the 7th day of lactation while non-nursing individuals are resistant.

We suggested the dt sz hamster as a model of BDZ receptor deficits (Soc. Neurosci. Abst. 10:1065, 1984) and interpret current results to implicate hormonal modulation of the BDZ ligand/receptor complex. We think pregnancy produces an inverse agonist BDZ ligand, stress of parturition induces a transient antidystonic/anticonvulsant protein and that lactogenic hormone(s) exacerbate the influence of inverse agonist. Regardless of hypothesis this pregnant and nursing model of paroxysmal dystonia is an exciting opportunity to understand the underlying neuropathology of movement disorders and leads to a rigorous method of testing pharmacological and molecular theory with in-vivo response.

667.2

DISTURBANCES IN THE BIOGENIC AMINE RATIOS IN THE BEHAVIORAL MUTANT, JERKY, OF XENOPUS LAEVIS. R. Tompkins*, T. Nguyen, A. Crago, D.C. Reinschmidt. Cell and Molecular Biology Dept., Tulane Univ. New Orleans, LA 70118

Tadpoles homozygous for the recessive mutant jerky begin displaying abnormal swimming behavior grading to paralysis beginning at stage 48 and ending at metamorphosis. The degree of expression of the syndrome is influenced by the amount and kind of food, photoperiod and drug treatment. The mutant also causes a lethal maternal effect on brain development and function. Measurements of the neurotransmitters norepinephrine, epinephrine, and serotonin, along with certain of their metabolites using HPLC indicate disturbed biogenic amine ratios in mutants, depending on their physiological state. In tadpole, affected animals kept in constant conditions always show a higher serotonin to dopamine ratio than normal. Under certain conditions, this is because of an elevated serotonin level; in other circumstances, it is because of depressed levels of dopamine. The biogenic amines of embryos showing the maternal effect are normal. Therefore, differences in neurotransmitter levels are not necessarily causally related to the maternal or zygotic effects of this mutant.

667.4

Analysis of Astrocyte Phenotype and Proliferation in S100 β Transgenic Mice. Dana C Hilt¹, Suzanne Buck¹, Hao Jiang¹, George Dmytrenko^{1*}, Paul Yarowsky³, and Roger Reeves². ¹ Dept. of Neurology and ³ Dept. of Pharmacology, University of Maryland School of Medicine, 22 S. Greene St., Baltimore, Md. 21201, ² Dept. of Physiology, The Johns Hopkins Hospital School of Medicine, Wolfe St., Baltimore, Md. 21205.

S100 β is a small Ca²⁺-binding protein synthesized and secreted predominantly by glial cells in the nervous system. In vitro, S100 β disulfide bonded dimers have been shown to induce alterations in astrocyte phenotype and proliferation. The brains of patients with Alzheimer disease (AD) have greatly elevated levels of S100 β as well as reactive astrogliosis and abnormal neurite proliferation. In order to determine if S100 β functions in vivo to control astrocyte phenotype and proliferation two S100 β transgenic (tg) mouse lines have been constructed utilizing a full length mouse S100 β gene. Focal S100 β -dependent astrogliosis (hippocampus, cerebellum, and olfactory bulb) are found in the tg mouse brains when compared to control animals. These same regions have abnormal neurite proliferation. Astrocyte changes seen in the S100 β tg mouse brains include increased astrocyte size, GFAP immunoreactivity, and complexity of glial processes. However, there is no increase in the number of astrocytes in the hippocampus or Bergmann glia in the cerebellum. These results suggest that elevated S100 β expression in vivo leads to a reactive glial phenotype but that S100 β does not function as a glial mitogen in the intact nervous system.

667.5

DEVELOPMENTAL ABNORMALITIES IN PROTEIN EXPRESSION IN THE LURCHER MUTANT MOUSE. L.M. Eisenman, G.B. Grunwald and C.M. Steger. Dept. of Anatomy and Devel. Biology, Thomas Jefferson University, Philadelphia, PA.

The phenotype of the mutant mouse *lurcher* is characterized by the postnatal death of all cerebellar Purkinje cells (PC). This cell death commences on postnatal day 9-10 and all PC are gone by postnatal day 60. We have examined the organization of the olivocerebellar projection in the adult and during early postnatal development when there are significant interactions between the olivocerebellar afferent and the PC target. The analysis in *lurcher* clearly demonstrates defective development of this projection beginning on postnatal day 9. Olivocerebellar fibers in *lurcher* do not translocate from the PC somas, their initial targets, onto the developing PC dendrites as occurs in wildtype animals. Recent biochemical studies have been directed at determining the molecular mechanisms of this specific olivocerebellar afferent-Purkinje cell target defect in *lurcher*. One dimensional SDS-PAGE analyses were conducted on cerebellar homogenates of postnatal day 11, 15, 19 and adult *lurcher* and wildtype littermates. The results of this initial protein characterization demonstrate clearly that there are two high molecular weight proteins expressed in the wildtype which are absent from the *lurcher* at all developmental ages studied. Further analyses will be designed to more fully characterize these deficient proteins and to determine if these differences are related to the abnormal olivocerebellar development. Supported by NIH grant NS22093.

667.7

A GENETIC FACTOR UNDERLIES THE BEHAVIORAL RESPONSE OF INBRED MICE TO THE PORSOLT TEST AND THE RESTRAINT STRESS TEST. B.J. Tarricone*, J.N. Hingtgen and J.I. Nurnberger, Jr. Institute of Psychiatric Research, Department of Psychiatry and Program in Medical Neurobiology, Indiana University School of Medicine, Indianapolis, IN 46202-4887.

To determine if mice exhibit different vulnerabilities to animal models of depression, the effect of the Porsolt swim test and the restraint stress test on behavior was examined in C57BL/6J, DBA/2J, AKR/J, and A/J inbred mice. Only the C57BL/6J mice exhibited "despair" during the Porsolt swim test ($p < 0.05$), as well as a significant decrease in open field crossings after the Porsolt test ($p < 0.05$) and the restraint stress test ($p < 0.05$). Swiss Webster mice were found to have an increase in the rate of high affinity choline uptake in the frontal cortex after the restraint test ($p < 0.05$). To identify those genes associated with the behavioral differences between C57 and DBA mice, the response of the BXD recombinant inbred mice to these models was examined. During the swim test, BXD 1, 5, 11, 12, 13, 14, 15, 16, 18, 22, and 29 floated significantly more ($p < 0.05$). After the Porsolt swim test, a decrease in open field crossings was exhibited by BXD 5, 12, 14, 29, and 31 ($p < 0.05$). Following restraint, BXD 1, 5, and 6, exhibited a decrease in open field crossings ($p < 0.05$). The identification of quantitative trait loci using behavioral and genetic strain distribution patterns is in progress. Because significant homology exists between mouse and human chromosomes, this may be a preliminary step in identifying those genes associated with affective disorders. (Supported in part by a grant from Indiana Department of Mental Health.)

667.9

Expression of the NMDA receptor in a late-onset inherited motor neuron disease in mice (*Mnd*).

M. Didier*, S. Bursztein, A. Cataldo, R. Nixon and S.A. Berman. Lab. for Mol. Neurosci. Harvard Med. School/McLean Hospital, 115 Mill St. Belmont MA 02178

Motor neuron degeneration (*Mnd*) is a genetic neurodegenerative disease of mice displaying many characteristics of human amyotrophic lateral sclerosis (ALS). Several studies have reported a decrease in presynaptic glutamatergic mechanisms in ALS. However, a recent report suggests that such a decline of glutamate uptake would be only a consequence of the motor neuron disease in the *Mnd* mouse. In this study, we investigated the expression of the NMDA receptors at the postsynaptic level during the development of the *Mnd* disease. NMDA-sensitive L-[³H] glutamate binding experiments showed a progressive increase in NMDA binding sites that correlated with the development of behavioral symptoms in *Mnd* mice. At 5-6 months, a 2 fold increase over controls was detected only in the lumbosacral level- the first affected region of the spinal cord. By 8-10 months, mutants displayed 2-3 fold increases in NMDA binding in both lower and upper cord. Interestingly, no differences in benzodiazepine or non-NMDA glutamate binding were found in either presymptomatic or affected *Mnd* mice. Autoradiography showed NMDA receptor localization mainly in the substantia gelatinosa of normal mice. In 8 month symptomatic animals, a dramatic increase of NMDA-sensitive glutamate binding was observed in the ventral horn of the lumbar spinal cord and appears to be associated with a higher expression of NMDA receptor in motor neuron during the *Mnd* disease. Preliminary results support an elevation in the NMDAR1 mRNA level in spinal cord motor neurons of 3 month-old *Mnd* mice before any behavioral modifications. These results suggest that alterations in NMDA receptor expression could be an early marker of the neuronal degeneration in the *Mnd* mouse. M.D was supported by a postdoctoral fellowship from the Human Frontier Science Organization.

CHANGES IN THE LEVEL OF PROTEIN KINASE C (PKC) IN PC12 CELLS TRANSFECTED WITH THE A4-C-TERMINAL PORTION OF AMYLOID PRECURSOR PROTEIN. R.E. Majocha*, J. Newton and C.A. Marotta. Dept. Psychiatry and Human Behavior, Miriam Hosp. and Brown University, Providence, R.I. 02906.

In order to understand the affects of $\beta/A4$ amyloid on cell function we have previously examined changes in cell morphology, production of neuronal-specific proteins and response to trophic factors which are all changed in transfectants overexpressing amyloid relative to untransfected or mock-transfected PC12 cells. In the present study, we examined the levels of PKC, an enzyme which is involved in signal transduction, as a possible mechanism by which amyloid exerts its effects in these cells. Using a monoclonal antibody to PKC, we found that there is a immunohistologically significant decrease in the level of PKC as determined by optical density using an image analyzer. Changes in transduction pathways have the potential to disrupt the normal relationship of a cell with its environment.

667.8

CHROMOSOMAL MAPPING OF GENES WHICH ALTER THE TIMING OF DISEASE IN THE *mnd* MOUSE. J. Plummer*, A. Messer, M.C. MacMillen and W.N. Frankel. Wadsworth Ctr. for Labs. and Research, N.Y. State Dept. of Health and Dept. of Biomed. Sci., SUNY, P.O. Box 509, Albany, NY 12201-0509; and The Jackson Laboratory, Bar Harbor, ME.

The mouse mutant *motor neuron degeneration (mnd)* displays an adult-onset progressive degeneration of upper and lower motoneurons, with mild symptoms recognizable at 6 months, leading to spastic paralysis and premature death at 10 - 12 months on the C57Bl/6 (B6) background. When *mnd* was outcrossed to the AKR background, 35 - 39% of the *mnd/mnd* F2 progeny of the outcross/intercross show early onset (mild symptoms by 4.5 - 5 months, moderate symptoms by 6 months, and death by 7 months.) This accelerated timing effect seems to be strain-specific, and unlinked to the *mnd* gene itself. DNA from a series of 49 outcross/intercross F2 mice showing early-onset *mnd* was screened for endogenous polymorphic proviral fragments, with strain-specific dinucleotide repeat fragments (generated by PCR) used to assay chromosomal regions not excluded in the first assay. Data were analyzed using a chi square test.

The strongest deviation from the expected ratio of AKR vs B6 alleles occurs with markers on proximal half of Chr. 1. Additional loci on Chr's 5, 10 and 17 have also been marked for further study. Our current working hypothesis is that the timing effect is due to 2 or 3 unlinked dominant genes with incomplete penetrance at any single locus. One of these genes is on Chr. 1.

An additional series of F2 intercross and F3 backcross mice is currently aging, and will provide at least 100 additional meioses to analyze. These will also create an early-onset *mnd* strain in which to follow symptoms and pathology, while mapping and identifying the genes responsible. The mechanism of interaction of these modifying genes with the primary *mnd* gene may offer new therapeutic avenues.

IMMUNOHISTOCHEMICAL DIFFERENCES IN MESOLIMBIC DOPAMINERGIC NEURONS IN FISCHER AND LEWIS RATS. Herbert W. Harris* & Eric J. Nestler. Dept. of Psychiatry, Yale Univ., New Haven, CT 06519.

Inbred Lewis (LEW) and Fischer (F344) rat strains have served as models of mechanisms of addiction. LEW rats show greater inherent preference for opiates, cocaine, cannabinoids and alcohol than do F344 rats (see Nestler, 1992 *J. Neurosci.* 12, 2439). In comparison to F344 rats, LEW rats also have higher levels of tyrosine hydroxylase (TH) and lower levels of neurofilament proteins in the ventral tegmental area (VTA); and higher levels of the cAMP pathway and lower levels of TH in the nucleus accumbens (NAc). To investigate structural correlates of these biochemical changes, immunohistochemical studies of VTA dopaminergic neurons in these strains were undertaken. Results show that the density of TH-positive neurons in the VTA in LEW rats is about 50% of that found in F344 rats ($n=3$, $p < 0.001$). In contrast, examination of substantia nigra in the same sections revealed no differences in the density of TH-positive cells between these strains. The finding of 50% fewer TH-positive neurons in the VTA of LEW rats, with our earlier results showing 45% higher levels of TH by immunoblotting, would suggest much higher levels of TH per VTA neuron in this strain. However, no obvious strain difference in the intensity of TH staining could be detected by immunohistochemistry. This observation may reflect differences in sensitivity between immunoblotting and immunohistochemical staining or differences in the subcellular pools of TH detected by these methods. These anatomical findings shed new light on the functional differences between LEW and F344 rats that may be associated with drug preference. The observation of lower numbers of TH-positive VTA neurons in the LEW strain is consistent with a model of addiction in which dopaminergic VTA neurons play a central role in the drug-preferring state.

LOCALIZATION OF P70-LIKE IMMUNOREACTIVITY IN GERBIL BRAIN. A. Seto-Ohshima^{1*}, M. Onozuka², S. Imai³ and S. Ozono⁴. ¹Institute for Developmental Research, Aichi Prefectural Colony, Kasugai 480-03, ²Gifu Univ. Sch. of Med., Gifu 500, ³Kitasato Institute, Tokyo 108, ⁴Kanagawa Den. Col., Yokosuka 238, Japan.

Recently, we found a specific 70-kDa protein (P70) in a cobalt-induced cortical epileptic focus of rat that is capable of inducing epileptiform seizure activities (1), suggesting its possible linkage to epileptogenesis. In the present study, in order to more precisely evaluate the involvement of P70 in the epileptogenesis, we immunohistochemically examined the localization of this protein in the brains of Mongolian gerbils (registered as a seizure-prone strain, MGS/ldr). The animals were anesthetized, perfused intracardially and then the brain slices were prepared, followed by analysis of the localization of P70 by immunohistochemistry with an antibody to this protein. When the cerebral motor cortex was applied with cobalt, immunoreactivity to P70 was found mainly in the epileptic focus region. In cobalt-untreated animals, the significant immunoreactivity was detected only within the cell nuclei in several brain regions including substantia nigra. A similar observation was also obtained in cobalt-untreated young gerbils without any behavioral seizure activity. The cytoplasm of most of these immunoreactive cells was positive to neuron-specific enolase. Thus, P70 may be related to the inherent instability of the neuronal system of this epileptogenic animal. 1. Onozuka, M. *et al.*, *Exp. Neurol.*, 111: 190-197 (1991)

QUANTITATIVE ANALYSIS OF GRANULE CELL AND PURKINJE CELL POPULATIONS IN SHAKER MUTANT RATS WITH HEREDITARY CEREBELLAR ATAXIA. M. LaRegina, M. Ewald, J. Haring, R. Marks, K. Smith* and D. Tolbert. Dept. Comp. Med. Washington Univ. and Depts. Anat. & Neurobiol. and Surg. St. Louis Univ. St. Louis, MO.

In preliminary characterization of Shaker rat mutants, morphometric analysis of the cerebellum revealed degeneration of many Purkinje cells (PCs) and reduction in the area of the gray matter especially in the molecular layer. Differences in severity of clinical signs between mild (no tremor) and strong (tremor) ataxic Shakers appears correlated to the overall numerical and spatial degeneration of PCs. In this study, we report the abnormal morphology of surviving PCs, the linear spatial interrelationships of surviving PCs in mild Shakers (partial PC degeneration), and granule cell density in strong Shakers (severe PC degeneration). PCs were studied using calbindin immunostaining, granule cell density was determined from cresyl violet stained sections. The somata and dendrites of Shaker PCs appeared normal. Three abnormalities of PC axons were observed: retraction from the cerebellar nuclei, large spheroids or varicosities of PC axons in the granule cell layer, and recurrent collaterals with abnormal trajectory. Compared to controls, PCs in mild shakers were decreased/unit linear length, and inter-PC distance was increased. Granule cell density in strong Shakers was greater than controls (12.18 ± 1.05 vs $10.28 \pm 0.38/1000\mu m^2$). This above normal density of granule cells in strong Shaker rats was attributed to the overall shrinkage of the cerebellar gray matter. (Supported by NIH grants RR07013 and NS20227).

ENDOGENOUS SEROTONIN RELEASE FROM THE DOPAMINE DEFICIENT STRIATUM OF THE WEAVER MUTANT MOUSE. E.H. Stotz*, B. Ghetti and J.R. Simon. Indiana Univ. Sch. of Med., Indianapolis, IN 46202

The striatum (STR) of the weaver mutant mouse has major deficits in dopamine (DA) content, tyrosine hydroxylase activity and DA uptake. Striatal serotonin (5-HT) is also altered in weaver mice compared to wild-type as seen by increased 5-HT levels in weaver STR with the dorsal aspect being the primary site of the increase. 5-HT uptake is also elevated in the dorsal portion of the weaver STR. The functional relevance of the 5-HT increase was investigated by studying endogenous 5-HT release. Endogenous 5-HT release was measured in a superfusion system at a flow rate of 0.25 ml/min. Basal fractions were collected prior to a 5 minute exposure to either high K^+ or fenfluramine. Aliquots of the superfusate fractions were analyzed for 5-HT by HPLC-EC. The effects of stimulation on 5-HT release were calculated as evoked release, which is the amount of 5-HT released above basal release. Data are presented on a fractional basis. Basal 5-HT release is decreased by 50% in the weaver STR compared to wild-type in spite of the weaver STR having higher 5-HT levels. The evoked release elicited by high K^+ was lower in the weaver STR than in the wild-type STR. The evoked release elicited by fenfluramine was greater in the weaver STR than in the wild-type STR. Conclusions drawn from the evoked release stimulated by high K^+ and fenfluramine are not consistent in as much as high K^+ release data suggest the increased 5-HT content is in a nonreleasable pool while the fenfluramine data suggest that the 5-HT is in a releasable pool. Since high K^+ is a nonselective releaser, it is possible that a second neurotransmitter is released during high K^+ stimulation and it could affect 5-HT release. This neurotransmitter would be less likely to be released during fenfluramine stimulation as the drug is more selective for 5-HT. Another explanation of the decreased 5-HT release seen in the weaver STR is that the 5-HT system is a primary site of action for the weaver mutation and the decreased release is a direct result of the mutation. (R01 NS14426 and P01 NS27613)

DEVELOPMENTAL/BEHAVIORAL STUDIES IN SHAKER MUTANT RATS WITH HEREDITARY CEREBELLAR ATAXIA. L. Wolf, J. Cribb, M. LaRegina, R. Clark*, A. Bastian and D. Tolbert. Dept. Comp. Med. & Prog. Phy. Ther., Washington Univ. and Dept. Anat. & Neurobiol. St. Louis Univ., St. Louis MO.

We are characterizing a rat mutant (Shaker) which displays hereditary cerebellar ataxia coincident with degeneration of Purkinje cells and inferior olivary neurons. Ataxic Shaker rats are characterized as mild or strong depending upon the absence or presence of tremor. We report our analysis of somatic development and locomotor behaviors and the temporal onset of clinical signs in mild and strong Shakers. Somatic development was similar in Shaker and controls from birth to 6 months of age. No differences were seen in the temporal development of surface and mid-air righting reflexes in Shaker and control rats. The development of postural/placing reactions was delayed in Shaker rats. Analysis of gait revealed a longer stride length and width in 3 month old mild and strong Shakers consistent with clinical ataxia. Preliminary data from Peak Performance 2-D motion analysis suggests the average gait cycle is shorter and time spent in stance longer in Shaker rats compared to controls. Whole body tremor in strong Shakers becomes apparent as early as 6 PNW. Mild Shakers never develop tremor. These behavioral observations correlate with the magnitude and spatial pattern of Purkinje cell degeneration. (Supported by NIH grants RR07013 and NS20227)

667.14

SPATIAL DISTRIBUTION OF PURKINJE NEURONS IN SHAKER MUTANT RATS WITH HEREDITARY CEREBELLAR ATAXIA. D.L. Tolbert*, M. Ewald, J. Gutting, and M. LaRegina. Dept. Anat. & Neurobiol., St. Louis Univ. and Div. Comp. Med., Washington Univ., St. Louis, MO 63104.

Shaker rat mutants display characteristic clinical signs: mild Shakers are ataxic, strong Shakers are ataxic and have tremor. The onset of these clinical signs occurs coincident with cerebellar Purkinje cell (PC) degeneration. To quantitatively analyze the spatial pattern of PC degeneration, calbindin immunostaining was used to identify surviving PCs in 3, 6 and 18 month old strong Shakers. The spatial distribution of immunoreactive PCs was plotted (Bioquant) in unfolded 2-D reconstructions of the cerebellar cortex. In 3 month old strong Shakers, many PCs in the vermis and paravermis of lobules I-V had degenerated. In the other lobules significant PC loss occurred in anterior lobule VI, posterior lobule IV, lobule VIII and anterior IX. In other parts of these lobules and in lobule X, PC density appeared relatively normal. In 6 month old strong Shakers almost all PCs in the anterior lobe had degenerated. In anterior lobule VI, posterior lobule VII, lobule VIII and anterior IX there was further degeneration of PCs in the vermis and hemispheres. At 18 months the majority of surviving PCs were localized to the vermis: posteriorly in lobule VI, anteriorly in lobule VII, posteriorly in lobule IX, and in lobule X. In 3 and 6 month old Shakers many of the surviving PCs in the posterior lobe were aligned sagittally. (Supported by NIH grants RR07013 and NS20227)

A GENETIC ANALYSIS OF NEOCORTICAL ECTOPIAS IN NEW ZEALAND BLACK MICE. G.F. Sherman*, L.V. Stone, A.M. Galaburda, V.H. Denenberg, and D.R. Beier. Department of Neurology, Beth Israel Hospital, and Harvard Medical School, Boston, MA 02215; Biobehavioral Sciences Graduate Degree Program, University of Connecticut, Storrs, CT 06269; and Genetics Division, Brigham and Women's Hospital, and Harvard Medical School, Boston, MA 02115.

Approximately 30-40% of New Zealand Black mice (NZB/BIN) develop prenatal ectopic collections of neurons in layer I of the neocortex (Sherman *et al.*, *Acta Neuropathol.*, 74:239-242, 1985). These ectopias are similar in appearance to those seen in the brains of dyslexic individuals (Galaburda *et al.*, *Ann. Neurol.*, 18:222-233, 1985). In earlier studies we hypothesized that the cortical malformations in NZB mice resulted from intrauterine influences arising in the affected offspring's mother. However, embryo transfer experiments with mice, in which the influence of the intrauterine environment was examined, failed to show a significant role for this mechanism (Denenberg *et al.*, *Brain Res.*, 563:114-122, 1991). Furthermore, both the incidence of ectopias in the F₁ crosses from NZB and normal control strains and the incidence in the recombinant inbred strains NXSMM (NZB x SM; provided by E. Eicher) suggested that the predisposition to cerebral ectopias in NZB mice is heritable. The present study was a mendelian breeding experiment designed to test the hypothesis that a single recessive gene is involved in the development of ectopias.

NZB and control DBA/2 mice were bred, and the F₁ offspring were backcrossed to DBA or NZB resulting in eight reciprocal combinations of breeding pairs. All brains were processed for celloidin embedding and serially sectioned at 30 μ m. Every fifth section was stained with cresyl violet and examined for the presence of ectopias. Thirty-eight percent of the NZB progenitor strain had ectopias, whereas the DBA and the F₁ offspring had an incidence of 1-2%. The incidence of ectopias in the DBA backcross (1.5%) was not different from the DBA progenitors, whereas the incidence in the NZB backcross (14.2%) was half that seen in the NZB progenitors ($\chi^2=19.71$, $df=1$, $p<0.01$). The NZB backcross did not differ from the expected distribution based on the hypothesis that a recessive gene was involved ($\chi^2=1.99$, $df=1$, n.s.). The results support the hypothesis that the predisposition to cerebral cortical ectopias in NZB mice is a recessively inherited trait with incomplete penetrance. Supported in part by NIH grant HD 20806.

BEHAVIORAL AND IMMUNOLOGICAL ASSOCIATIONS OF CORPUS CALLOSUM ABNORMALITIES IN NZB-RELATED MICE. L.M. Schrott*, G.F. Sherman*, S. Ansar Ahmed*, N.S. Waterst., R. Wimer*, C. Wimer*, G.D. Rosen*, A.M. Galaburda*, and V.H. Denenberg†. †Biobeh. Sci. Grad. Deg. Prog., Univ. of CT, Storrs CT 06269; *Beth Israel Hosp., Harvard Med. School, Boston MA 02215; ^VA-MD Reg. Col. Vet. Med. VPI, Blacksburg VA 24061; °Beckman Res. Inst., Duarte CA, 91010; +Univ. of CO Health Sci. Cen., Denver CO 80262

NZB mice have been used to explore relationships among learning disorders, brain anomalies, and autoimmunity. Prior studies related learning deficits to brain anomalies (cortical ectopias and hippocampal anomalies) or degree of autoimmunity. NZBs also display a low incidence of corpus callosum agenesis (CC Agen). To assess the influence of CC Agen on behavior and autoimmune parameters, recombinant lines with NZB as one progenitor were examined. NXSM (n=179) and NXRF (n=112) mice were behaviorally tested. Brains were examined for CC Agen and sera samples were examined for autoantibodies to dsDNA and cardiolipin.

CC agenesis was found in 3/15 NXSM and 1/4 NXRF lines. Comparisons were made among mice with CC Agen, mice from the same lines with Intact CC and mice from lines with no neural anomalies (Controls). CC Agen mice did not learn a spatial water escape task, while Intact CC and Control mice did. In NXSMs Intact CC mice had better performance than Control mice. NXRFs had a similar pattern on the last 2 trials. In the spatial Morris maze task, CC Agen mice traveled a greater distance and spent more time in the quadrant opposite the escape platform. Intact CC NXRF mice traveled a greater distance than Controls. CC Agen was also associated with high levels of antibodies to dsDNA in NXSMs.

CC Agen led to poor spatial learning, implying that inter-hemispheric transfer of information facilitates this learning. These mice had high levels of antibodies to DNA suggesting an altered neural-immune axis. Supported in part by NIH grant HD 20806 and RR 01183. We thank Dr. E. Eicher for generous donation of mice.

THE SPONTANEOUS AGE-RELATED INCREASE IN THE NUMBER OF REVERTANT VASOPRESSIN CELLS IN THE HOMOZYGOUS BRATTLEBORO RAT DECLINES AFTER 100 WEEKS OF LIFE. F.W. van Leeuwen* and M.A.F. Sonnemans. Neth. Inst. Brain Res., 1105 AZ Amsterdam, The Netherlands.

The homozygous Brattleboro rat suffers from hypothalamic diabetes insipidus caused by a single base deletion in exon B as a result of which the frame-shifted mutant vasopressin (VP) precursor cannot be translocated over the membranes of the endoplasmic reticulum. Therefore this mutant precursor does not reach the Golgi apparatus and cannot be processed enzymatically.

We found a remarkable age-dependent increase (until 100 weeks of life) in the number of cells displaying the wild type VP phenotype. Through an unknown mechanism a low number of cells become phenotypically heterozygous. The wild-type precursor can again be translocated in the endoplasmic reticulum and is axonally transported towards the neural lobe (van Leeuwen et al., PNAS USA, 86, 6417, 1989).

Using a new antiserum directed against the C-terminus of VP-neurophysin (# THR, obtained through A.G. Robinson, Univ. Pittsburgh) we could label these solitary neurons. The immunoreactivity obtained with THR indicates that the sequence alteration leading to the phenotypic repair occurs in a region upstream of the C-terminus of neurophysin (Evans et al., Soc. Neurosci. 18, 1334, 1992).

In addition, the increase in solitary cell number declines after 100 weeks of life in females. The number of cell profiles was assessed in female rats with an age of 92, 100, 110 and 120 weeks. Their mean number was respectively 119, 120, 97 and 110. This suggests that the mechanism leading to phenotypic repair of the wild-type can change after 100 weeks of life. Alternatively there is no change, but the increase is compensated by cell death.

GENDER DIFFERENCES IN THE BEHAVIOR OF AN ANIMAL MODEL OF ATTENTION DEFICIT HYPERACTIVITY DISORDER. D.F. Berger and T. Sagvolden. Department of Neurophysiology, University of Oslo, Norway. (SPON: European Brain and Behaviour Society).

There is general agreement among investigators that the prevalence of Attention Deficit Hyperactivity Disorder (ADHD) is greater in male than in female children. The goal of the present experiment was to determine if a gender difference could also be observed in the behavior of the spontaneously hypertensive rat (SHR), an animal model of the disorder. The operant behaviors of 32 approximately 90-day old male versus female SHR, and their normotensive progenitor control strain, the Wistar-Kyoto rat (WKY), were compared (n = 8). All were trained to leverpress on a multiple 120-s fixed interval (FI), 5-min extinction (EXT) schedule, for water. Gender differences were observed with the SHRs, but not the WKYs. Males SHRs responded considerably more during EXT than female SHRs; and both WKY groups, which did not differ. Male SHRs also had relatively more short interresponse times than the other groups. These findings increase the generality of the animal model, and suggest that the gender difference in the prevalence of ADHD may have a physiological, rather than social etiology.

667.18

SEVERE GAUCHER DISEASE IN NEONATAL MICE AND HUMANS. E. Sidransky, and E. I. Ginns*. Section on Molecular Neurogenetics, Clinical Neuroscience Branch, NIMH, NIH, Bethesda, MD 20892.

A group of infants with Gaucher disease is described with a devastating course similar to that of transgenic Gaucher mice created by targeted disruption of the mouse glucocerebrosidase gene. These mice have lipid storage in macrophages of liver, spleen, bone marrow and brain. They are cyanotic, lethargic, have an unusual skin appearance at birth and die within 24 hours of life. The severely affected humans also die in the neonatal period and many have associated congenital ichthyosis. Both the affected mice and ichthyotic Gaucher patients have a similar histologic appearance with a thickened overlying keratin layer. Thus, specific clinical phenotypic manifestations of the transgenic Gaucher mouse have contributed to the recognition of a new human phenotype of Gaucher disease. The anticipated generation of other, less severe mouse phenotypes, should similarly provide insight into other aspects of the human disease.

667.20

MAGNETIC RESONANCE IMAGING OF CEREBRAL ANOMALIES IN SUBJECTS WITH GENERALIZED RESISTANCE TO THYROID HORMONE. C. M. Leonard*, S. An, N. Sorensen, L. DeBuse, E. Wiggs, P. Martinez, B. Vitiello, B. D. Weintraub, and P. Hauser. Dept. Neuroscience, Univ. Fl. Gainesville 30610, NIDDK, and NIMH, Bethesda, MD 20892.

Individuals with generalized resistance to thyroid hormone due to a mutation in the human thyroid receptor beta gene on chromosome 3 have an increased incidence of attention deficit hyperactivity disorder and language deficits. We have used magnetic resonance imaging (MRI) to determine whether mutations in this gene are associated with an increased incidence of the cerebral anomalies that have been described in other inherited language disorders. Subjects [20 male (AM), 22 female (AF)] with the gene and unaffected first degree relatives [18 male (UM), 16 female (UF)] underwent MRI brain scans that provided contiguous 2 mm thick sagittal images. Films of images taken at standard sagittal positions were analyzed by an investigator blind to subject characteristics. Affected male subjects had a significantly higher incidence of duplicated Heschl's gyri (primary auditory cortex) combined with anomalous gyri in the left parietal association cortex (AM: 40%; AF: 5%; UM: 6%; UF: 0%). There were no differences in the incidence of right sided anomalies. These findings suggest that an inability to utilize thyroid hormone early in development has a greater impact on the left hemisphere in male than female brains, providing indirect support for the "Geschwind hypothesis." This mutation provides a potential model system for the study of interacting genetic and environmental effects on human neural and cognitive development.

668.1

FAST AND SLOW NA CHANNEL INACTIVATION AND THE ACTION OF PHENYTOIN IN RAT HIPPOCAMPAL NEURONS. **Chung-Chin Kuo and Bruce P. Bean***. Dept. of Neurobiology, Harvard Medical School, Boston MA 02115

Previous experiments have shown that the anticonvulsant phenytoin (DPH) interacts with Na channels. In rat hippocampal neurons, DPH up to 100 μ M had little effect on Na current elicited by short (~20 ms) depolarizations from -100 mV, suggesting very weak binding to channels in the resting state (apparent $K_d > 1$ mM). Potent block ($K_d \sim 10$ μ M) could be observed only with protocols containing long-lasting (~20 s) depolarizations, suggesting either slow binding of DPH to the fast inactivated state (which is reached within msec) or selective binding of DPH to the slow inactivated state (reached ~1000 times slower). Binding to the fast inactivated state seems to occur, since at potentials where there was almost only fast inactivation (< -50 mV), DPH still potentially affected recovery from inactivation. Nevertheless, other experiments showed that DPH could also bind to the slow inactivated state, with a K_d similar to or slightly smaller than ~10 μ M. The findings explain why Na channels should be strongly inhibited by DPH in the therapeutic range (~10 μ M) during a long paroxysmal depolarization shift but would be almost unaffected during normal action potentials.

CHRONIC ADMINISTRATION OF SODIUM VALPROIC ACID RETARDS PUBERTAL MATURATION IN INBRED DBA/2J MICE. **P.J. Snyder* and L.L. Badura**. Psychiatry Research & Neurology, Long Island Jewish Med. Ctr., and Behavioral Neuroscience, Univ. of Connecticut, Storrs, CT, 06269.

Sodium valproic acid (VPA), a widely prescribed anticonvulsant, appears to act on GABAergic systems although its precise mechanisms of action remain controversial. Because VPA has been reported to occasionally delay pubertal maturation in children, the current study sought to establish a valid animal model with which to further investigate the neuroendocrinological sequelae of VPA administration.

Male DBA/2J mice, raised from birth under a 12L:12D photoperiod, were weaned at 2 weeks and administered either VPA (17-20 mg/kg/day) or control solution via drinking water. Animals were weighed, blood sampled via retro-orbital puncture, and sacrificed via anesthetic overdose at 4, 6, or 8 weeks of age. Testes were removed, weighed, and fixed in 10% formalin for later histological analyses. In addition, the lengths (mm) of the left humerus bone from each animal were obtained as an index of skeletal growth.

The testes weights of the animals receiving VPA were significantly smaller than the control animals at both 6 and 8 weeks of age (148 ± 9 vs. 175 ± 5 , and 179 ± 4 vs. 200 ± 5 mg respectively), and a strong trend in the predicted direction was found for the animals sacrificed at 4 weeks. No between-group differences were found for humerus length or body weight at any sampling age. These data indicate that chronic administration of VPA delays reproductive (but not skeletal) maturation in mice. Further work will center on: 1) the investigation of an hypothesized attenuation of reproductive function via histological analyses of gonadal tissue; and 2) RIA analyses of blood serum for determination of anterior pituitary and gonadal steroid content.

668.5

ADC1, A NOVEL ANTICONVULSANT, DOES NOT IMPAIR AVOIDANCE OR SPATIAL LEARNING IN THE RAT. **L. Rajachandran, A.D. Kastello, J.V. Cassella, A. Thurkauf, L. Marshall, A.J. Hulchison and J.F. Tallman***. Neurogen Corporation, Branford, CT 06405.

Seizure disorders are prevalent CNS disorders. A notable side effect of many anticonvulsant compounds is a disruption of learning and memory processes. This study assessed the effects of enantiomers of the novel broad spectrum anticonvulsant ADC1 (30,100 mg/kg,PO), originally synthesized as a hybrid of Carbamazepine and MK801 (Rogawski et al., J. Pharmacol. Exp. Ther., 259, 1990), in a step down passive avoidance procedure and a Morris water maze task in adult male Sprague Dawley rats. (+) ADC1 competitively antagonizes the high affinity binding of MK801 to rat brain cortical membranes with an IC_{50} of 15 μ M. In contrast, (-) ADC1 has an IC_{50} of 300 μ M while Carbamazepine's IC_{50} is >300 μ M. ADC1, Carbamazepine (10,35 mg/kg,PO) and the noncompetitive NMDA antagonist MK 801 (0.25-1.0 mg/kg,PO) as well as Phenobarbital (30,60 mg/kg,PO) were administered 30 min prior to acquisition training in both of these paradigms. At the doses tested (3x and 10x the ED_{50} in maximal electroshock test for anticonvulsant activity), Carbamazepine did not produce deficits in passive avoidance. In contrast MK801 and Phenobarbital produced marked deficits in the avoidance and spatial learning task. Neither enantiomer of ADC1 produced significant deficits in either task. Therefore, ADC1 lacks amnesic effects in these rodent models of learning and memory and thus may offer distinct advantages over the existing pharmacological therapies for the treatment of seizure disorders.

668.2

ADDITIVE CALCIUMANTAGONISTIC EFFECTS OF CARBAMAZEPINE AND BUSPIRONE AS MECHANISM OF ACTION IN EPILEPSIES AND AFFECTIVE DISORDERS. **J. Walden^{1,2}, J.v. Wegerer¹, D. Bingmann³**. 1=Psychiatr. Clni, Frei burg, 2=Tropon Köln, 3=Inst. Physiol. Essen, FRG

Carbamazepine (CBZ) in addition to its antiepileptic properties has been shown to be effective in the treatment of affective and schizoaffective disorders. In previous investigations calcium antagonistic actions of CBZ were described as a common mechanism in the efficacy in both pathological states (Walden et al., Pflügers Arch. 420,R35, 1992). The aim of the present study was to compare effects of CBZ with those of the calcium antagonist verapamil (VERA) and the 5HT_{1A}-agonist buspirone (BU). In hippocampal slices of guinea pigs (CA1 and CA3) threshold concentrations of 10 μ mol/l CBZ, 5 μ mol/l BU and 10 μ mol/l VERA had no effect on the frequency of extracellular field potentials (EFP). Combinations of these concentrations resulted in reduction of EFP frequencies. The relative decrease was 0.66 (range 0.44-0.82) for 5 μ mol/l BU + 10 μ mol/l CBZ; 0.33 (range 0.1-0.53) for 5 μ mol/l BU + 10 μ mol/l VERA and 0.39 (range 0.28-0.55) for 10 μ mol/l CBZ + 10 μ mol/l VERA. The results indicate that the VERA induced reduction of EFP is intensified by CBZ and BU.

668.4

NEUROCHEMICAL CHANGES AND SEIZURE SEVERITY IN MALE GERBILS AFTER CHRONIC MELANOTIN ADMINISTRATION. **TH Champney* and JC Champney**. Dept Human Anat, Coll Med, Texas A&M Univ, College Station, TX 77843-1114.

Recently, melatonin's anticonvulsant action has been demonstrated in gerbils (*Neuroreport* 3:1152-1154, 1992). The present studies explored changes in γ -aminobutyric acid (GABA) and amine content from selected brain regions of animals tested for melatonin's anticonvulsant activity. Male Mongolian gerbils (*Meriones unguiculatus*) received daily afternoon injections of melatonin (MEL, 25 μ g/inj, sc), biweekly MEL implants (1 mg/imp, sc) or no treatment for 12 weeks. One half of each of these groups was exposed to long photoperiods (LP, 14L:10D) while the other half was exposed to short photoperiods (SP, 10L:14D). At the end of the treatment period, the gerbils were challenged with pentylenetetrazol (60 mg/kg, sc) to produce convulsions, were monitored for convulsive behavior and 3 minutes prior to death received 3-mercaptopropionic acid (100 mg/kg, ip) to prevent GABA degradation. The gerbils were anesthetized with metofane, killed by decapitation and cortex, hippocampus and hypothalamus collected. These regions were assayed for GABA, dopamine, serotonin (5HT) and 5-hydroxyindoleacetic acid (5-HIAA) content (*J Chromat. Biomed Appl* 579:334-339, 1992). MEL injected gerbils were able to survive and respond to seizures better than control animals. Total convulsion scores were reduced in LP-MEL injected gerbils (2.47 ± 0.90 vs 7.67 ± 1.83 in LP-CONTROLS, $p < 0.05$). No MEL injected gerbils died during seizure-induction (0/31 compared to 5/33 in control animals). MEL implants were ineffective in preventing seizures (4/30 died). Hippocampal GABA levels were depressed in all SP exposed gerbils and in LP-MEL injected animals ($p < 0.05$ vs LP-CONTROLS). Dopamine content was unchanged in all brain regions examined. Hippocampal 5HT was increased in LP-MEL injected gerbils and hypothalamic 5HT was increased in SP-MEL injected gerbils ($p < 0.05$ vs LP-CONTROLS). Hippocampal and hypothalamic 5-HIAA levels were increased in SP-MEL injected gerbils and hypothalamic 5-HIAA was increased in LP-MEL injected animals ($p < 0.05$ vs LP-CONTROLS). These results suggest that MEL's anticonvulsant activity does not correlate with changes in neurochemicals in the regions studied.

FOREBRAIN AREAS SENSITIVE TO THE CONVULSANT EFFECTS OF THE ANTICHOLINESTERASE AGENT VX. **J.H. McDonough*, T.-M. Shih and N. Adams**. U.S. Army Med. Resch. Inst. Chem. Def., APG, MD 21010-5425

This study mapped brain sites sensitive to the convulsant effects of VX to identify areas responsible for initiation of nerve agent seizures. Rats previously implanted with cannula and recording electrodes were infused with VX (0.47-1.88 μ g; 0.94 mg/ml; 0.25 μ l/min); EEG and behavior were monitored for 4 h after infusion. Varying levels of sensitivity were found among limbic structures. The basolat. amygdala, amygdala-cortex transition zone, the piriform cortex, and ant. accumbens were most sensitive; other piriform sites, post. accumbens and entorhinal cortex were moderately sensitive; dorsal hippocampus, cent. and ant. amygdala were least sensitive. Preseizure behaviors were site-dependent. The mildest seizures consisted of episodic spike trains accompanied by class I-III kindled seizure behaviors. In the extreme form, spike trains merged to become continuous and class IV-VII behaviors occurred. Of the 20 sites studied, only limbic forebrain areas were sensitive to the convulsant effects of VX. Since there are multiple areas with slightly different levels of sensitivity, no single area may be critical to the initiation of seizures after systemic intoxication with nerve agents.

ISOBLOGRAPHIC ASSESSMENT OF ANTICONVULSANT AND NEUROTOXIC INTERACTION BETWEEN DIAZEPAM AND NEW BENZODIAZEPINE RECEPTOR LIGANDS: INDICATIONS FOR SUBTYPE SPECIFICITY
C. Rundfeldt¹, C.D. Torchio², I.M. Kapetanovic², C. Jennings³, and H.J. Kupferberg²
¹School of Vet. Med., Dept. Pharmacol., Toxicol. & Pharmacy, Bunteweg 17, 3000 Hannover 71, FRG. ²Epilepsy Branch, NINDS, NIH, Bethesda, MD 20892. ³Med. Coll. Virginia, Dept. Biostatistics, Richmond, VA 23298-0032.

Benzodiazepine (BZ) receptor ligands are potent anxiolytic, anticonvulsant, sedative, and hypnotic drugs; partial BZ agonists are limited in their maximum effect. Recent work revealed that multiple isoforms of the GABA-BZ₁ receptor complex exist. The aim of this study was to investigate if isobolographic analysis (IA) of drug-drug interaction is a tool to get information on the pharmacological profile of partial BZ ligands. The IA was based on the estimation of a three-dimensional response surface using the logistic regression. We tested 4 new partial BZ ligands for interaction with diazepam (DZ) using the s.c. pentylenetetrazole (PTZ) test for anticonvulsant effect and the horizontal screen test for motor impairment. For both tests each of the drugs, DZ, Ro 17-1812 (1), Ro 18-5607 (2), Ro 40-4214 (3) and Ro 42-5787 (4), was administered i.p. alone and in fixed combinations with DZ in a range of doses to groups of 7-16 mice. The dose-response curves obtained with the PTZ test indicated median effective doses of 0.19 mg/kg for DZ, 0.15 mg/kg for 1, 0.06 mg/kg for 2, 0.33 mg/kg for 3 and 0.23 mg/kg for 4. Co-administration of DZ with the Ro-compounds showed that all 4 drugs shifted the dose-response curve of DZ to the left. The IA indicated for all 4 drugs no significant deviation from additivity. DZ induced motor impairment with a TD₅₀ of 1.96 mg/kg. The TD₅₀ of 1 and 2 was 20 and 35.8 mg/kg, respectively; 3 and 4 did not evoke motor impairment up to 200 mg/kg. The IA revealed a subadditive or antagonistic interaction for motor impairment with 1, 2, and 3; the data obtained with 4 were not sufficient for the IA, but the effect of diazepam was antagonized. The results indicate that the IA is a suitable tool to get information on the pharmacological profile of partial BZ agonists. Further work is needed to elucidate, if the difference between the two tests used can be explained only by differences in receptor reserve or if the results indicate subtype specific effects of the new BZ receptor ligands.

668.9

THE ANTICONVULSANT LAMOTRIGINE BLOCKS SODIUM CURRENTS FROM CLONED ALPHA-SUBUNITS OF RAT BRAIN Na⁺ CHANNELS IN A VOLTAGE-DEPENDENT MANNER BUT GABAPENTIN DOES NOT. C.P. Taylor^{*}, Dept. Pharmacology, Parke-Davis Pharm. Res., Div. of Warner-Lambert Co., Ann Arbor, MI 48105.

Lamotrigine (6-(2,3-dichlorophenyl)-1,2,4-triazine-3,5-diamine) and gabapentin (1-(aminomethyl)cyclohexaneacetic acid) each prevent seizures in animal models and clinical trials. This study compares their action on rat brain type IIA sodium channel α subunits stably expressed in Chinese hamster ovary cells (West et al., *Neuron* 8:59-70, 1992). Sodium currents were recorded by whole-cell voltage clamp and drugs were pressure-applied from blunt micropipettes or added to the bathing medium.

Within 2 min, lamotrigine (5-50 μ M) increased steady-state inactivation of sodium currents and at high concentrations (50 μ M) slowed the time course of recovery from inactivation and reduced peak currents. Lamotrigine (5 μ M) decreased peak current progressively for 50 sec when holding potential was stepped from -120 to -60 mV and current was restored by holding at -120 mV for 25 sec, whether or not depolarizing pulses were applied. Blockade of peak current by 50 μ M lamotrigine was increased even by short (1 msec) prepulses to 0 mV. Voltage-dependence of activation and rate of activation or inactivation were not consistently changed.

Gabapentin (200 μ M) was applied by blunt pipettes, by bath application for 24 hr, or by the recording micropipette but sodium currents were unchanged.

These results show that lamotrigine modulates voltage-dependent sodium channels in much the same manner as lidocaine or phenytoin (Ragsdale, et al., *Mol. Pharmacol.* 40:756-765, 1991), while gabapentin does not.

ANTICONVULSANT DRUGS INHIBIT NMDA STIMULATED [³H]-NOREPINEPHRINE EFFLUX IN RAT BRAIN CORTEX AND HIPPOCAMPUS. Gladys Yi-Ping Lee^{*}, Timothy J. Teyler and Laurie M. Brown. Departments of Pharmacology and Neurobiology, Northeastern Ohio Universities College of Medicine, Rootstown, Ohio 44272-0095.

Some investigators have observed inhibitory effects of anticonvulsant agents on NMDA mediated processes (Sethy and Sage, *Neuropharmacol.* 31 (1992) 111-114; Cotariu et al., *Proc. Neurobiol.* 34 (1990) 343-354). The anticonvulsant drugs phenobarbital, phenytoin, and valproic acid were used to assess their interaction with NMDA mediated [³H]Norepinephrine ([³H]NE) efflux.

Brain slices (350 μ m) from the cortex and hippocampus of adult Long-Evans hooded rats were used. The slices were washed and incubated in 37°C oxygenated Krebs-Ringers bicarbonate buffer and allowed to accumulate [³H]NE. After uptake of the label, the slices were washed again and aliquots placed into baskets which were transferred through a series of vials containing 100 μ M NMDA and varying concentrations of the anticonvulsant drugs. Phenobarbital and valproic acid were used in concentrations of 0.001, 0.01, 0.1, and 1 mg/ml, and phenytoin was used in concentrations of 0.0001, 0.001, 0.01, and 0.1 mg/ml. The human therapeutic serum concentrations of phenobarbital, phenytoin, and valproic acid are 0.035, 0.02, and 0.1 mg/ml respectively.

Phenobarbital at the concentration of 1 mg/ml caused a 52 and 48% inhibition of NMDA stimulated [³H]NE efflux in the cortex and hippocampus, respectively. Phenytoin at 0.1 mg/ml caused a 39 and 17% inhibition of [³H]NE efflux in the cortex and hippocampus, respectively. Valproic acid had a tendency to inhibit [³H]NE efflux at the 1 mg/ml concentration in cortex. These results indicated that some anticonvulsants may inhibit NMDA mediated processes in the therapeutic range.

SINGLE UNIT RECORDINGS IN THE SUBSTANTIA NIGRA OF RATS: INFLUENCE OF THE ANESTHESIA ON SPONTANEOUS ACTIVITY OF GABAERGIC NEURONS AND ON THE EFFECT OF THE ANTICONVULSANT DRUG VALPROATE. A. Rohlfis, C. Rundfeldt and W. Löscher^{*}, Dept. of Pharmacol., Toxicol. & Pharmacy, School of Veterinary Medicine, Bunteweg 17, D-3000 Hannover 71, FRG.

The substantia nigra pars reticulata (SNR) is in current discussion to play a critical role in the propagation of epileptic seizures. Valproic acid (VPA) reduces SNR output by decreasing the spontaneous activity of GABAergic SNR neurons. We wanted to test if this effect is influenced by the anaesthesia used to measure SNR neuron activity. Three different forms of anaesthesia were compared: 1) Chloral hydrate (CH), 360 mg/kg i.p., followed by i.v. infusion of 140-160 mg/kg/h CH. 2) Fentanyl, 50 μ g/kg, combined with methohexital, 60 mg/kg i.p., for induction, followed by an i.p. bolus of methohexital 20 mg/kg after 20 min. After preparation, the rats were relaxed with an i.p. bolus of 20 mg/kg gallamine; analgesia and relaxation were maintained with a co-infusion of fentanyl (100 μ g/kg/h) and gallamine (20 mg/kg/h). 3) Ketamine, 200 mg/kg i.p., followed by i.v. infusion of 30 mg/kg/h ketamine. For the experiments, female Wistar rats were ventilated and carbon dioxide in expiratory air, heart rate, blood pressure, and rectal temperature were continuously monitored. The spontaneous firing rate of one identified GABAergic neuron in the SNR was monitored over 10 minutes after stabilization and for further 40-50 min after i.v. application of 100 mg/kg VPA. The mean (x \pm SD) basic firing rate of SNR neurons was 19.9 \pm 7.1 Hz under CH anaesthesia. The maximum depression after 100 mg/kg VPA was 14%. VPA deepened the anaesthesia; to maintain a stable state, the infusion rate of CH had to be reduced to 70 mg/kg/h. Under fentanyl analgesia, the basic firing rate of 23.5 \pm 6.5 Hz was significantly higher than under CH anaesthesia. The maximum depression by VPA of 49% was significantly higher than under CH anaesthesia; the infusion of fentanyl had to be reduced to 75 μ g/kg/h. Under ketamine anaesthesia, the basic firing rate of 22.7 \pm 10.7 Hz was not significant different from the rate under CH anaesthesia. The maximum depression by VPA of 36% was significantly higher than under CH anaesthesia.

The results indicate that the anaesthesia can influence the results obtained from single unit recordings in rats in the SNR. Both the basic activity and the effect of the drug differed depending on the anaesthesia used.

Effects of Antiepileptic Drugs on Seizure Activity in Cultured Rat Hippocampal Neurons.

Flora W. Jow^{*} and Stephen S. Lin. Departments of CVMD and CNS, Wyeth-Ayerst Research, CN 8000 Princeton, NJ 08543.

The type of medication used for treating epilepsy depends on the kind of seizure. We investigated the effects of seven different anticonvulsants on epileptic seizure activity in cultured rat hippocampal neurons (initially described by Furshpan and Potter, *Neuron*, 1989). Phenytoin, one of the most effective drugs against partial and generalized tonic-clonic seizures, reduces the frequency of paroxysmal depolarization shifts (PDSs) in these cells at 10 μ g/ml, and completely blocks seizure activity at 20 μ g/ml. Phenobarbital, the drug of choice for febrile seizures, reduces the frequency of seizure activity at 20 μ g/ml and blocks all activity at 40 μ g/ml. Drugs that are effective against absence seizures, such as ethosuximide and valproate, also reduce the frequency of PDSs at 50-100 μ g/ml. The benzodiazepine, diazepam, inhibits seizure activity at 1 μ g/ml. However, nitrazepam, is ineffective at 1-10 μ g/ml. Carbamazepine also has no effect at 1-20 μ g/ml.

668.12

ANTICONVULSANT EFFECTS OF NS004 AGAINST PENTYLENETETRAZOLE-INDUCED SEIZURES

A. Ortiz^{*}, S. Ward, and N. Meanwell.

Neuropharmacology and Division of Chemistry, Bristol-Myers Squibb, Wallingford, CT 06492-7660.

The selective opening of K⁺ channels has been described as a possible therapeutic strategy for the treatment of seizure disorders. Recent work suggests that NS004 [1-(5-chloro-2-hydroxyphenyl)-5-trifluoro-methyl-1,3-dihydro-2H-benzimidazol-2-one] behaves as a maxi-K potassium channel opener: NS004 activates maxi-K channels in cerebellar granule cells and smooth muscle cells in culture (Olesen & Wätjen, Eur. Patent 477,819). We have studied the anti-convulsive activity of NS004 in the iv. pentylenetetrazole (PTZ)-induced seizure model. Fasted CD2F₁ mice were pretreated with vehicle or NS004 at 1, 30, or 60 mg/kg, ip. After 30 min, 10 mg/ml of PTZ was infused iv. at 0.20 ml/min. The freely moving animal was observed for five minutes and the amount of PTZ (mg/kg) required to produce the following seizure components was calculated: the "first twitch", the "clonic seizure", the "tonic seizure", and PTZ-induced lethality. The thresholds for the "tonic seizure" and the "clonic seizure" were significantly increased by 30 and 60 mg/kg of NS004. Moreover, NS004 at 60 mg/kg increased the threshold of PTZ-induced lethality. Results from this experiment demonstrate the anticonvulsive activity of NS004 and suggest the potential of maxi-K channel openers as candidates in the treatment of seizure disorders.

CHARACTERIZATION OF FELBAMATE'S ACTIONS ON NMDA AND GABA RECEPTORS IN CULTURED RAT HIPPOCAMPAL NEURONS. Jong M. Rho*, Sean D. Donevan, and Michael A. Rogawski, Neuronal Excitability Section, Epilepsy Research Branch, NINDS, NIH, Bethesda, MD 20892.

Felbamate (FBM, 2-phenyl-1,3-propanediol dicarbamate) is a promising new antiepileptic and neuroprotective agent that may interact with the glycine site on NMDA receptors (McCabe et al., *J. Pharmacol. Exp. Ther.* 264:1248-1252, 1993) and is generally believed not to modulate GABA_A receptors (Ticku et al., *Epilepsia* 32:389-391, 1991). In the present study, we characterized the functional effects of FBM on NMDA and GABA_A receptors using whole-cell voltage clamp recordings in cultured rat hippocampal neurons. FBM caused a concentration-dependent (1 mM, 20 ± 2%, n=6; 3 mM, 49 ± 4%, n=6), voltage-independent block of responses evoked by 10 μM NMDA in the presence of 10 μM glycine. The blocking action of FBM could not be overcome by increasing the concentrations of either NMDA or glycine, indicating that the block may, at least in part, occur at a site distinct from the NMDA or glycine recognition sites. In the same range of concentrations that blocked NMDA responses, FBM produced a marked potentiation of Cl⁻ currents activated by 3 μM GABA (1 mM, 141 ± 6%, n=3; 3 mM, 437 ± 24%, n=3). The effect of FBM on GABA responses was unaffected by 10 μM flumazenil (Ro 15-1788), indicating that FBM is not a benzodiazepine site agonist. In the presence of supramaximal pentobarbital (3 mM), FBM produced no further potentiation of GABA responses, suggesting that FBM may be a barbiturate-like modulator. Thus, FBM appears to both inhibit NMDA responses and potentiate GABA responses. This novel combination of actions may account for FBM's unique clinical profile.

668.15

LACK OF ANTICONVULSANT TOLERANCE FOLLOWING CHRONIC (21 DAY) ADMINISTRATION OF THE GABA UPTAKE INHIBITOR TIAGABINE. P.D. Suzdak*, Novo Nordisk A/S, Pharmaceuticals Division, Novo Nordisk Park, DK-2760 Måløv, Denmark.

Tiagabine (NNC-05-0328) is a potent and selective GABA uptake inhibitor currently in Phase II/III clinical trials for epilepsy. The present investigation focused on determining if tolerance developed to the anticonvulsant effects of tiagabine following chronic (21 day) administration. NMRI mice received either vehicle, or tiagabine (at either 15 or 30 mg/kg) p.o. twice daily for 21 days. Subsequent behavioral testing was conducted 24 hours following the termination of chronic treatment. There was no tolerance to the anticonvulsant effect of acutely administered tiagabine (ED₅₀ for inhibiting DMCM-induced seizures were 1.7, 1.9 and 2.0 mg/kg i.p., respectively). However, there was a significant decrease in the ability of acutely administered tiagabine to impair rotarod performance (ED₅₀ of 6, 12 and 19 mg/kg i.p., respectively), inhibit traction (10, 23 and 32 mg/kg i.p., respectively) and to inhibit spontaneous locomotor activity (10, 19 and 29 mg/kg i.p., respectively) following chronic tiagabine administration. The lack of anticonvulsant tolerance following chronic administration of tiagabine further suggests that inhibition of GABA uptake is a highly promising, and novel, mechanism for future antiepileptic agents.

668.17

VALPROATE CONCENTRATION IN THE OLFACTORY BULB OF THE PURKINJE CELL DEFICIENT MUTANT MOUSE. T. J. Hoepfner* Department of Neurological Sciences, Rush Medical College, Chicago, IL 60612.

Previously we have shown that in the rat the anticonvulsant valproate (VPA) concentrates in the olfactory bulb. To help determine the cell type in which VPA concentrates tritiated sodium valproate (300 uCi/kg, i.p.) was administered to eight month old purkinje cell deficient (PCD) mutant mice and unaffected littermates. (By this age PCD mutants lose almost all of their cerebellar purkinje cells and their mitral cells). Thirty minutes later mice were perfused with saline and formalin and the brain frozen. Thaw mounted sections were apposed to X-ray film for autoradiography. The distribution and concentration of radiolabel was similar in PCD mutants and in unaffected littermates despite the marked loss of mitral cells in the mutants. VPA concentrated in the dorsal and medial portions of the glomerular layer of the olfactory bulb. VPA was undetectable in other parts of the brain. These findings indicate that the concentration of VPA in the olfactory bulb is not in the principal cells of the bulb: the mitral cells. This suggests that VPA concentrates in the olfactory nerve terminals or in periglomerular cells.

668.14

Gamma-vinyl GABA (GVG) reverses activity-dependent disinhibition in the rat hippocampus in vitro. M. Jackson, B. Esplin and R. Čapek*, Department of Pharmacology and Therapeutics, McGill University, Montreal, Quebec H3G 1Y6.

GVG is an irreversible inhibitor of GABA transaminase (GABA-T) which increases brain GABA levels and is an anticonvulsant in both animals and humans. Although it is generally believed that GVG prevents seizures by enhancing GABA-mediated inhibition, direct evidence in support of this is unconvincing. The goal of this study was therefore to determine whether an increase in GABA-mediated inhibition could be demonstrated using the antidromic-orthodromic stimulation test during conventional field potential recordings in hippocampal slices obtained from GVG-treated rats.

Slices were obtained from male Sprague-Dawley rats 24 hours after a single i.p. injection of either an anticonvulsant dose of GVG (1500mg/kg) or saline. Population spikes (PS) were recorded from the CA1 region following orthodromic stimulation delivered to the stratum radiatum. They were inhibited by conditioning antidromic stimulation delivered to the alveus at various interpulse intervals (IPI). The conditioning antidromic stimulation consisted of either a single pulse or a train of 20 pulses delivered at 5 or 100 Hz.

In slices taken from saline-treated animals the inhibition produced by stimulation of the alveus at 5 Hz was less than the inhibition following a single conditioning stimulus. In contrast to this, GVG pretreatment caused the inhibition at 5 Hz to be greater than that produced by a single pulse. GVG pretreatment did not affect the inhibition produced by a single pulse or by a train of pulses at 100 Hz.

These results suggest that GVG may suppress seizures by preventing activity-dependent disinhibition. (Supported by MRC of Canada and FCAR)

668.16

EFFECTS OF N⁶-CYCLOPENTYLADENOSINE AND 8-CYCLOPENTYL-1,3-DIPROPYLXANTHINE ON N-METHYL-D-ASPARTATE-INDUCED SEIZURES IN MICE. Dag von Lubitz, Jan A. Paul, Kenneth A. Jacobson*, NIDDK, National Institutes of Health, Bethesda, MD 20892.

Adenosine agonists prevent convulsions in several chemical and electrical seizure models and protect against excitotoxic neurodegeneration involving NMDA receptors. However, the effect of receptor specific adenosinergics on NMDA evoked seizures is poorly known. Therefore, the effect of acute and chronic administration of a selective adenosine A1 receptor agonist N⁶-cyclopentyladenosine (CPA) and antagonist 8-cyclopentyl-1,3-dipropylxanthine (CPX) on NMDA-evoked seizures was studied in C57BL/6 mice (20/group). In acute experiments, animals were injected i.p. either with CPA (0.5, 1, 2 mg/kg) or CPX (1, 2 mg/kg) 15 min prior to administration of NMDA (30, 60, 125 mg/kg). In chronic studies, mice were given either CPA (1 mg/kg) or CPX (1 mg/kg) for 9 days. One day later they were challenged with a single i.p. injection of 60 mg/kg NMDA. Administration of NMDA alone resulted in a dose-dependent increase in the intensity of clonic/tonic seizures and mortality. Acute administration of CPA delayed seizure onset, eliminated tonic episodes, and reduced mortality. Acute pretreatment with CPX significantly exacerbated the effect of NMDA. Conversely, compared to NMDA controls, chronic treatment with CPA led to a significantly increased mortality, while chronic CPX caused an equally impressive protection against seizures and postictal deaths (p<0.01) These results indicate that A1 receptor agonists may protect against NMDA-evoked seizures and that A1 receptors may be directly involved in these actions.

668.18

THE EFFECTS OF ANTICONVULSANT AGENTS ON 4-AMINOPYRIDINE-INDUCED EPILEPTIFORM ACTIVITY IN RAT HIPPOCAMPUS IN VITRO. W.D. Yonekawa*, I.M. Kapetanovic and H.J. Kupferberg, Epilepsy Branch, NINDS, NIH, Bethesda, MD 20892.

The Antiepileptic Drug Development (ADD) Program is attempting to identify novel anticonvulsants by their effects on various parameters of a stimulated hippocampal slice. We examined the effects of known anticonvulsant drugs, including phenytoin (PHT) and carbamazepine (CBZ), and a potent experimental compound, ADD 172014 (D20443 Asta Medica AG, Germany), on epileptiform activity evoked by the K⁺ channel inhibitor, 4-aminopyridine (4-AP). Evoked extracellular population spikes (PS) and spontaneous activity with or without 4-AP and/or test compound addition were recorded from areas CA1 and CA3. The results indicate that EPSP duration is very sensitive to 4-AP perturbation, increasing approximately 2.6x in both CA1 and CA3 compared to control. PHT, CBZ, and ADD 172014 affected this increase by 1.1x, .8x, and .6x in CA1 and .8x, .9x and .7x in CA3. The PS amplitude increased with 4-AP by 1.6x in CA1 and 1.1x in CA3 and, while PHT and CBZ had little effect on these increases (1x-1.1x), ADD 172014 increased the amplitude by 1.4x. ADD 172014 also abolished spontaneous bursting, while both PHT and CBZ merely reduced the frequency and amplitude by .8x. These data indicate that ADD 172014 may act differently than PHT or CBZ and that this in vitro model can be useful in differentiating mechanisms of action.

ANTICONVULSANT EFFECTS OF MAGNESIUM SULFATE IN HIPPOCAMPAL KINDLED RATS. C.A. Janusz*, S.M. Irtenkauf, R.F. Berman and D.B. Cotton. Dept. OB/GYN, Wayne State Univ., Detroit, MI 48201.

The purpose of the present study was to determine whether magnesium sulfate has anticonvulsant actions in the hippocampal-kindled rat model of epilepsy. Fully kindled rats received acute intraperitoneal injections of magnesium sulfate (270 mg/kg), phenytoin (20 mg/kg) or saline in random order. Seizure duration, behavioral seizure stage and duration of postictal EEG depression were examined at 15, 30 and 60 minutes post-injection. A second experiment was initiated to examine the effect of chronic (2 hour) i.p. injections of magnesium sulfate on fully kindled seizures. There was a significant decrease in seizure duration ($p < 0.01$) and behavioral seizure stage ($p < 0.01$) with magnesium sulfate compared to saline. Phenytoin had no statistically significant effects on hippocampal kindled seizures. Chronic magnesium sulfate treatment significantly reduced behavioral seizure stage at 2, 24 and 48 hours ($p < 0.05$). There was a significant time by treatment effect for magnesium sulfate on postictal EEG depression ($p < 0.01$). We conclude that magnesium sulfate has anticonvulsant effects in this model of hippocampal seizures.

668.20

THE ANTICONVULSANT EFFECT OF IMIDAZENIL ON ELECTRICAL AND PENTYLENTETRAZOLE (PTZ)-INDUCED KINDLING. G. Bregola@, D. Ferrari@, M. Simonato@, A. Zanotti, P. Giusti, and F. Fadda*. @ Dept of Pharmacology, University of Ferrara, Dept. of Pharmacology, University of Padova, Italy.

The anticonvulsant effect of Imidazenil, a new imidazobenzodiazepine carboxamide, was studied in Sprague-Dawley rats underwent to PTZ or electrical kindling. The former was produced injecting i.p. a subconvulsant dose of PTZ (217 $\mu\text{mol/kg}$) every second day until tonic-clonic convulsion were evoked. Electrical kindling was obtained stimulating the right amygdala once daily with a single 1 sec train of 60 Hz bipolar pulse.

One week after reaching the criteria for kindling, animals were orally treated with the reference drug Diazepam or with Imidazenil. After 30 min, they were challenged with the appropriate stimulation. ED₅₀ (95% C.L.) of Diazepam and Imidazenil for full suppression of convulsion were 19 (8.3-37) and 0.75 (0.21-2.6) $\mu\text{mol/kg}$ respectively in PTZ-kindling, 18.8 (12.3-28.8) and 7.5 (4.9-11.3) $\mu\text{mol/kg}$ in the electrical kindling. Furthermore, Imidazenil, but not Diazepam, appeared to increase the latency to amygdala kindling convulsion in non-responsive rats.

The present data are consistent with other reports of a potent anticonvulsant effect of Imidazenil.

DEGENERATIVE DISEASE: ALZHEIMER'S— β -AMYLOID XII

669.1

DEGRADATION OF THE BETA-AMYLOID PRECURSOR PROTEIN IN A CELL-FREE SYSTEM. S. Mistretta, J.T. Durkin, S. Murthy, R.W. Scott, B.D. Greenberg and R. Siman*. Cephalon, Inc., West Chester, PA 19380

It is now established that βA4 (1-40) is normally secreted from a variety of cells, but the proteases responsible for generating the βA4 protein from the β -amyloid precursor proteins (APP) and the subcellular compartments involved in βA4 protein production have not been identified. To address these issues, we report here on the use of a cell-free system for analysis of APP degradation. In human cells overexpressing APP751, the APP was tagged by metabolic labelling for 45 minutes. This permits some radiolabelled APP to enter constitutive processing pathways, as evidenced by the appearance of label in fully glycosylated full-length APP as well as in a number of COOH-terminal derivatives. Following homogenization, cell-free extracts were incubated under various conditions, and APP degradation was assessed by immunoprecipitation, Tris/Tricine SDS-PAGE, and phosphor-imaging. Both mature and immature full-length APPs were subject to processing *in vitro*. Among the COOH-terminal derivatives produced from degradation of full-length APP is a 12 kDa fragment. This derivative likely has the same NH₂-terminus as βA4 protein and may be an intermediate in βA4 protein formation (Durkin et al., this vol; Cai et al., Science 259, 514 (1993)). The 12 kDa derivative is selectively immunoprecipitated by anti β (1-9), an antibody that also labels a single identically-sized fragment generated by intact cells. The method is amenable to the identification of distinct subcellular fractions, and the protease(s) within them, which generate the 12 kDa derivative and, therefore, which may be involved in βA4 protein formation.

669.3

IDENTIFICATION AND CHARACTERIZATION OF A PROTEASE WHICH PROCESSES A PEPTIDE CORRESPONDING TO THE AMINO-TERMINUS OF β -AMYLOID. J. Koehn, A. Boon, L. Kent, K. Rogers, L. Fleissner, M. Ator, G. Trakshel, S. J. Ward*, and M. Miller. Pharmaceuticals Research Division, Sterling Winthrop Inc., Collegeville, PA 19426.

βA4 protein is a major component of AD plaques. It is thought to be proteolytically derived from one or more larger amyloid precursor proteins (APPs). We report here the purification and characterization of a peptidase from normal and AD brain which cleaves a peptide substrate, SEVKMDAE. Cleavage occurs on the carboxyl side of Met, mimicking the cleavage yielding the amino terminus of βA4 . Using ion exchange, size exclusion, and affinity chromatography, this activity has been purified approximately 4000-fold. Class-specific protease inhibitors suggest this activity is a thiol-dependent metalloprotease. No proteolytic cleavage was observed using native full-length human APP isoforms or baculovirus expressed APP₇₅₁, or APP C-terminal fragments from human brain, human cell-lines, or a baculovirus expression system. Data suggest that hydrolysis of the βA4 N-terminus is regulated by factors in addition to primary peptide sequence.

CLEAVAGE OF THE AMYLOIDOGENIC SITE OF APP BY CATHEPSIN D AND BRAIN EXTRACTS. US Lador*, SW Snyder, TF Holzman, GT Wang, GA Krafft. Abbott Labs. Abbott Park, IL 60064.

A new fluorogenic substrate that mimics the N-terminal cleavage site (positions 649-656

of APP751) of Alzheimer's β -amyloid peptide was used to assay cathepsin D and proteinase activities from human and bovine brains. Ether spacers were used to distance the Edans and Dabyl chromophores from the amino acid sequence to avoid artifacts previously observed with smaller substrates.

Proteinase from human and bovine brain extracts cleaved this substrate at pH 3.5 and 7.5, primarily at the Met-Asp bond, consistent with the most frequently reported amyloidogenic cleavage of APP. Human brain extract produced an additional cleavage at the Ala-Glu bond, as we reported previously with smaller substrates. This cleavage was absent in bovine brain extract. Purified cathepsin D also cleaved at the Met-Asp bond.

A similar substrate that incorporates the Lys-Met \rightarrow Asn-Leu mutation, reported in a Swedish family with early onset Alzheimer's disease, was cleaved by cathepsin D at a rate 72-fold higher than the rate with the wild type substrate. Both cathepsin D and bovine brain activity at pH 3.5 cleaved this substrate at the amyloidogenic Leu-Asp site. At pH 3.0, bovine brain activity against the mutated substrate was 70 fold higher than the rate against wild type substrate. At pH above 5.5, bovine brain activities against both substrates were similar. These results suggest that Cathepsin D is a prime candidate for the "N-terminal amyloidogenic proteinase".

CATHEPSIN S, AN ATYPICAL CYSTEINE LYSOSOMAL PROTEASE. S. Petanceska, S. Cvejic and L. Devi*. Department of Pharmacology, New York Univ. Medical Center, New York, 10016.

The cysteine lysosomal proteases are a large family of highly conserved enzymes that are essential for intracellular protein turnover. These enzymes are strongly implicated in processes of cell growth, malignant transformation, inflammation, and in the metabolism of the amyloid precursor protein.

We have cloned and characterized a rather atypical member of this family of enzymes, cathepsin S. Unlike the other cysteine lysosomal proteases that are mostly inactive at neutral pH, cathepsin S retains around 70% of its activity at neutral pH. Also it is not expressed in detectable levels in many transformed rat embryo fibroblast cell lines of different tumorigenic potential that express large amounts of cathepsin B and cathepsin L. In a separate study, we compared the distribution of the mRNA for rat cathepsins S, B, and L in adult rat brain by *in situ* hybridization histochemistry; the distribution pattern of cathepsin S mRNA is profoundly different from the distribution of cathepsin B and L mRNA. Cathepsin S has a wide distribution throughout the grey and white matter and in cells that have microglial morphology.

Here we present the results of a comparative study of the expression of cathepsins S, B, and L during brain development and after entorhinal cortex lesions. During development, unlike cathepsin B and L, cathepsin S mRNA has a different (biphasic) temporal expression pattern in the time between E13 and P11. Also, unlike cathepsin B and L, after entorhinal cortex lesion cathepsin S is highly upregulated at the site of lesion and in the hippocampus in cells that have the morphology of activated microglia and reactive astrocytes. These data support the possibility that cathepsin S is involved in the Alzheimer's pathology.

TISSUE- AND CELL SPECIFIC EXPRESSION OF A NOVEL BRAIN SERINE PROTEASE. **B. Meckelein***, K.J. Conn and C.R. Abraham. Arthritis Center, Boston Univ. Sch. of Med., Boston MA 02118

Brain proteases are believed to play a crucial role in the development of Alzheimer's disease (AD). Among those are the enzymes of the different secretory and lysosomal pathways which process the amyloid precursor protein (APP) to yield a variety of potentially amyloidogenic and non amyloidogenic fragments, as well as enzymes which are involved in inflammatory or "acute phase" processes. The identification of such proteases is important towards understanding the development of AD and may provide promising targets for a therapeutical approach.

We screened a human fetal brain cDNA library with anti cathepsinG antibodies, and isolated four crossreacting clones. They comprise a cDNA population which is derived from three differentially spliced RNA transcripts of one gene encoding a hitherto unknown serine protease.

The tissue distribution of these three differentially spliced RNAs was determined by PCR using isoform-specific primers. Examination of a variety of monkey tissues demonstrated that RNA for the novel serine protease is found in most of the tissues investigated. The tissue distribution of the differentially spliced forms, however, varies greatly. Interestingly, one of the transcripts is expressed predominantly in brain and testis. This could indicate a role for the enzyme in the processing of neuropeptides or hormones, but it is also intriguing in light of the fact that brain and testis are two of the organs with the highest levels of APP synthesis.

On brain sections, antibodies directed against peptide fragments of the novel protease stain blood vessel walls and reactive astrocytes. The same antibodies specifically precipitate a population of 28-35 kDa proteins from conditioned media of cultured astrocytes and glioblastoma cells.

The possible involvement of the novel brain serine protease in APP processing or acute phase reactions is under investigation.

CHARACTERIZATION OF AMYLOID PRECURSOR PROTEIN-ASSOCIATED SERINE ESTERASE ACTIVITY IN DIFFERENT CELL LINES. **U.S. Kayvali***, and H. Potter. Dept. Neurobiology, Harvard Medical School, Boston MA 02115.

The precursor of the Alzheimer amyloid β A4 protein, β -APP, is generated in at least three forms by alternative mRNA splicing. Two of the forms contain an extra domain with a Kunitz-type protease inhibitor (KPI) function. The secreted isoforms of the APP molecules that contain the KPI domain have been shown to be identical to the known protease inhibitor, protease nexin 2, and are therefore presumed to have as their function the inhibition of trypsin- and chymotrypsin-like proteases released during inflammation. We have obtained evidence that the 695 amino acid isoform of β -APP has an esterase enzyme activity that is capable of cleaving acetylcholine and other ester substrates such as p-nitrophenylacetate. The APP-associated esterase activity has been shown by inhibitor profile determination to be distinct from other serine esterases/proteases such as acetylcholinesterase. Site-directed mutagenesis of selected amino acid residues is being performed to test the hypothesis that the esterase active site serine is inside the beta protein itself. In addition the consequences on cellular physiology of abolishing that esterase activity in mutant cells will be characterized to ascertain the normal function of this novel esterase. We propose that the various isoforms of β -APP constitute a family of serine esterases and inhibitors whose normal function may be to control an important physiological process. The increase in acetylcholinesterase activity due to over-expression or aberrant processing of β -APP695 may also be significant to the pathology of Alzheimer's disease by reducing the level of the key neurotransmitter, acetylcholine.

AMYLOID PRECURSOR PHOSPHOINOSITIDE-REGULATED " α -SECRETASE" LEADS OTHER MEMBRANE PROTEASES AS THERAPEUTIC TARGET. **D.M. Bowen¹**, G.C. Stratmann¹, M.T. Webster¹, I.P. Chessell¹, R.C.A. Pearson² & P.T. Francis¹. ¹ Inst. Neurol., London, ² Univ. Sheffield, UK.

Gelatinase A (Miyazaki et al *Nature*, 362, 89, 1993) is the most recent of a myriad of membrane proteases being considered as candidates. Here "Clipsin" (Savage and Siman, *Soc. Neurosci. Abst.* 16, 787, 1990) has been studied as activity has only been reported towards precursor protein (APP) with enzyme from immature rat. APP from adult rat cortical membranes was partially purified (heparin-agarose), incubated (2h, pH 7.5, with EDTA) with enzyme (detergent- high ionic strength buffer extracts of purified cortical membranes of samples subject to short, 2h, and routine postmortem delay) and then analysed by Western blotting (mcab 22C11, Boehringer Mannheim; *Biochem. Soc. Trans.* 21, 241S, 1993). Substrate (APP, 116 kDa) was subject to slight (9%) autodegradation (product, 100 kDa). This was not increased by adult rat extract but it was enhanced to $62 \pm 21\%$ (n=6) by extract of human control temporal cortex (2h delay). This was not different (Mann Whitney U test) from Alzheimer's disease ($69 \pm 23\%$, n=9) as was also found with frontal cortex, 2 series with short and routine postmortem delays (control in parenthesis) $51 \pm 14\%$, n=8 ($58 \pm 26\%$, n=6) and $70 \pm 22\%$, n=8 ($66 \pm 27\%$, n=8), respectively. As product formation by this method was not different by diagnosis but was altered based on studies of phosphoinositide-regulated " α -secretase" (Francis P.T. et al, this meeting) the use of a cholinomimetic agent, in combination with a drug to block cortical pyramidal neurone hyperpolarization, is indicated for treating Alzheimer's disease. Support, in part, from Astra Arcus and Brain Research Trust.

BRAIN SERINE PROTEASES GENERATE AMYLOIDOGENIC FRAGMENTS. **B.L. Razzaboni***, K.J. Conn, M. Pietropaolo, and C.R. Abraham. Arthritis Center and Biochemistry Dept.#, Boston Univ. Sch. of Med., Boston, MA 02118.

A serine protease appearing as a 26-28kDa doublet has been characterized from adult monkey brain. The protease(s) are able to cleave a synthetic substrate (P1) made according to the sequence flanking the N-terminus of β -protein (A β) and to degrade APP (Razzaboni et al., *Brain Res.* 589:207-216). Using aged monkey and aged human brains, similar serine protease(s) have been found. Further purification techniques enabled us to separate the two serine proteases from each other. Following chromatofocusing two bands were identified: a 26kDa band with a pI around 5.5 and a 28kDa band with a pI around 6.5. Both enzymes are cross-reactive with cathepsin G antibodies. The two may exist as isoforms since they both cleave P1 in the same position, APP degradation is blocked by preincubation of the enzymes with an antibody made to the N-terminus of the A β (gift of E. Koo), and both are inhibited by an inhibitor specific for chymotrypsin-like proteases (gift of J. Oleksyszyn). Additionally, the 26kDa serine protease is inhibited by α 1-antichymotrypsin (ACT) and aprotinin and the 28kDa serine protease is not.

Furthermore, we observed an increase in the specific activity for the serine protease inhibited by ACT and aprotinin from AD brains versus aged matched controls indicating that the enzyme may have a role in increased production of A β . We are in the process of determining the relevance of these serine proteases to the in vivo degradation of APP and to the pathogenesis of AD.

669.8

SECRETASE-LIKE ENZYMES IN THE HUMAN AND RAT BRAIN. **C. Schönlein¹**, A. Probst² and G. Huber^{1,*}. ¹Pharma Division, Preclinical Research, F. Hoffmann-La Roche LTD and ²Institute of Pathology, 4002 Basel, Switzerland.

In the brain of Alzheimer's disease (AD) patients proteolytic deposition and accumulation of β A4-amyloid in extracellular plaques is one of the pathological hallmarks of the disorder. Proteolysis of the amyloid precursor protein (APP) may occur through different cellular pathways, one of which gives rise to extracellularly secreted APP isoforms. The enzyme responsible for this cleavage, the secretase, is not yet clearly characterized. Using chromogenic peptide substrates derived from the secretase cleavage site within APP, proteolytic enzymes were investigated in the brain of Alzheimer patients and control individuals. Mean differences in enzyme activity were observed between the two groups, yet no statistical significance was reached. Further analysis of the enzymes suggest that under these experimental assay conditions secretase-like activity may be attributed to different enzymes and may be slightly altered under pathological conditions.

669.10

Identification of the Cleavage Site Involved in Increased Production of A β from a mutant β APP (Δ NL) Linked to Familial AD. **T.T. Cheung¹**, J. Ghiso¹, X. D. Cai¹, M. Shoji¹, B. Frangione¹ and S. G. Younkin. Case Western Reserve University, Cleveland, OH 44106; New York University, NY, NY 10012

We have previously shown that normal processing of the amyloid β protein precursor (β APP) in cultured cells produces a complex set of four COOH-terminal β APP derivatives with molecular weights between 8.7 and 11.4 kD. We have also shown that the "Swedish" mutant β APP (Δ NL) linked to familial AD produces increased amounts of the 11.4 kD COOH-terminal derivative and of 4 kD amyloid β protein (A β). To identify the NH2 terminus of the various COOH-terminal fragments produced by β APP695-transfected human neuroblastoma (M17) cells, we metabolically labeled these cells with [³H]-phenylalanine and then sequenced or radiosequenced them (A β has phenylalanines at positions 4, 19, and 20). Direct sequencing of the excised 8.7 kD derivative yielded LVFFAED at the 2 to 4 pmole level confirming that this derivative begins at A β 17. Radiosequencing of this fragment showed [³H]-Phe at cycles 3 and 4 as expected. These data confirmed that the 8.7 kD protein is a COOH-terminal β APP derivative beginning at A β 17, and they validated the utility of the radiosequencing methodology. Similar analysis of the 11.4 kD derivative showed a phenylalanine at position 4 indicating that this derivative begins with the sequence DAEF and thus has the entire A β at its NH2 terminus. Analysis of the intervening ~10.9 and ~9.6 COOH-terminal derivatives, although less definitive, indicated that they begin at A β 4 and A β 10 respectively. Examination of the 11.4 kD COOH-terminal derivative and the 4 kD A β produced from β APP Δ NL showed that, like the corresponding derivatives from wild type β APP, both begin with the sequence DAEF. Thus the mutation replacing KM on the NH2 side of A β with NL appears to accelerate a normal β APP cleavage thereby producing increased amounts of an A β -bearing COOH-terminal derivative from which A β is released.

SPECIFIC INHIBITION OF BETA AMYLOID 1-42 AGGREGATION BY BETA AMYLOID 1-40. S. W. Snyder, U. S. Lador, G. W. Wang, G. A. Krafft* and T. F. Holzman. Drug, Design and Delivery, Abbott Laboratories, Abbott Park, IL 60064.

One of the hallmarks of Alzheimer's disease is the presence of extracellular senile plaques composed primarily of aggregated beta amyloid (β A4). β A4 is a 40-43 residue protein proteolytically derived from the transmembrane region of amyloid precursor protein (APP). Using analytical ultracentrifugation, we have characterized the size of aggregates, as well as the distribution between monomeric and aggregated populations, formed by β A4. Using turbidity, we have investigated the kinetics of aggregation from a well-defined monomeric starting state to a fibrillar aggregated state as a function of β A4 sequence and environmental conditions. Aggregation was several orders' of magnitude faster for the more hydrophobic β A4 1-42 protein than the more soluble β A4 1-40. We observed a specific, and dose dependent, kinetic inhibition of aggregation of 1-42 by 1-40. In addition, we observed a kinetic enhancement of 1-40 aggregation by pre-formed β A4 aggregates. These results reveal that the rate of β A4 aggregation is strongly dependent upon relative concentrations of its shorter and longer forms. Therefore, specificity in the carboxy-terminal cleavage of APP might play a critical role in partitioning between deposited aggregates of β A4 and cleared protein. This work was supported in part by the NIH-NIA grant AG10481-02.

AMYLOID β PROTEIN ($\text{A}\beta_{1-40}$) IS DEGRADED BY PROTEASES PRESENT IN AND RELEASED FROM RAT MICROGLIA. L. M. Shaffer,* K. R. Brunden, S. G. Younkin and M. L. Cohen. GliaTech, Inc., Cleveland, OH 44122 and Case Western Reserve University, Institute of Pathology, Cleveland, OH 44106.

Microglial cells are closely associated with the amyloid cores in the mature senile plaques of Alzheimer's Disease (AD) brain. Plaques contain a high concentration of fibrillar aggregates of $\text{A}\beta$, an ~40 residue peptide. To examine processing of $\text{A}\beta$ by microglia and to determine whether the physical state of $\text{A}\beta$ alters this processing, Synthetic $\text{A}\beta_{1-40}$ (0.01-40 $\mu\text{g/ml}$) + ^{125}I - $\text{A}\beta_{1-40}$ was added to cultures of primary rat microglia and incubated for various periods of time. The peptide was either in a soluble (1 day in neutral solution at 4°C) or aggregated form (1 day in pH 5.0 NaOAc). In some cases, "labeling" medium was subsequently replaced with "chase" medium containing no peptide. Labeling medium, cell lysates and chase medium were analyzed by gamma counting and/or SDS-PAGE (16.5% tris-tricine) and autoradiography. The amount of $\text{A}\beta$ associated with the exterior surface of microglia increased linearly as peptide concentration was increased over a large range. For both soluble and aggregated $\text{A}\beta$, (i) intracellular accumulation was maximal in one hour, and (ii) during a 24 hr chase after a 3 hr pulse, 70% of the intracellular ^{125}I -dpm were externalized in 4 hrs, and 15% over the next 20 hrs. The released ^{125}I -dpm were in a form that was virtually undetectable on gels that readily detected equivalent dpm of ^{125}I - $\text{A}\beta$. Further investigation showed (i) substantial dose-dependent breakdown of $\text{A}\beta$ by conditioned medium alone, and (ii) most of the intracellular ^{125}I -dpm were undetectable on gels when compared to equivalent ^{125}I - $\text{A}\beta$ dpm. Thus $\text{A}\beta$ is degraded by proteases present in and released from rat microglia, and microglia may remove aggregated as well as soluble $\text{A}\beta$ released during normal processing of the $\text{A}\beta$ precursor protein. Several factors could account for the resistance of plaque core amyloid to microglial proteolysis, including association of the peptide with additional plaque components.

CHRONIC INTRAVENTRICULAR AMYLOID INFUSION: A PARADIGM FOR INDUCTION OF AMYLOID ACCUMULATIONS IN THE RAT BRAIN. B.A. Tate*, R. Tovar, R.E. Majocha and C.A. Marotta. Dept. Psychiatry and Human Behavior, Miriam Hosp. and Brown University, Providence, RI 02906.

The production of a rodent model for the neuropathological and behavioral features of the human disorder of Alzheimer Disease would be economically and scientifically advantageous. We have used subcutaneously implanted osmotic pumps and indwelling intraventricular cannulae to chronically infuse synthetic amyloid peptide 1-40 into the rat brain over a period of two weeks. The vehicle we use does not contain acetonitrile. The combination of intraventricular infusion and this vehicle eliminates the nonspecific brain damage induced by other methods of amyloid administration. Immunopositive amyloid accumulations are present in the brain parenchyma several weeks post infusion. The cell body of cells lining and immediately adjacent to the ventricles are immunopositive. The processes of some cells immediately adjacent to the ventricles are also immunopositive for amyloid. Behavioral and neuropathological studies are underway.

669.12

NEURONAL TYPE IV COLLAGENASE DEGRADES THE AMYLOID BETA PEPTIDE ($\text{A}\beta$ 1-40) AND SUBSTANCE P. J. R. Backstrom and Z. A. Tokes*. Department of Biochemistry and Molecular Biology, University of Southern California, Los Angeles, CA 90033.

The 100 kD type IV collagenase (matrix metalloproteinase-9, MMP-9) was immunologically detected in pyramidal neurons and plaques in the hippocampus from Alzheimer affected tissues. Therefore, experiments were designed to determine which cells produce MMP-9 mRNA, which structures bind exogenous biotinylated MMP-9, and whether the enzyme cleaves the amyloid beta protein ($\text{A}\beta$ 1-40). MMP-9 riboprobes labeled pyramidal neurons in the CA1 to CA4 fields, but not neurons in the dentate gyrus. Although biotinylated MMP-9 attached to subendothelial, perivascular structures, antibodies to MMP-9 did not detect the endogenous enzyme in this region. Thus, basement membrane constituents such as collagen may not be the primary substrate in the brain. Since the antisera labeled amyloid plaques, synthetic $\text{A}\beta$ 1-40 was incubated with purified MMP-9. The peptide was cleaved at several sites including the Phe-Phe region. This region shares homology with the tachykinins and somatostatin. Therefore, the metalloproteinase was incubated with substance P, neurokinin A, neurokinin B, kassinin, and somatostatin. The enzyme cleaved substance P but not the other peptides. The results suggest that the main function of the metalloproteinase MMP-9 may be to process peptides, and not collagen, within the central nervous system. Supported by NIA grant AG09681.

THE ALZHEIMER'S β (1-40) PEPTIDE FORMS SOLUBLE MULTIMERIC COMPLEXES IN DILUTE SOLUTION. H. LeVine, III*. Department of Neuroscience Pharmacology, Parke-Davis Pharmaceutical Research Division of Warner-Lambert Co., Ann Arbor, MI 48106-1047.

Multimers of synthetic β (1-40) Alzheimer's amyloid peptide can be detected in solution at sub-microgram per ml concentrations by cross-linking with glutaraldehyde followed by borohydride reduction. SDS-Tricine SDS-PAGE suggests the formation of up to pentameric or hexameric complexes. Under amyloidogenic conditions of pH and high peptide concentrations, sedimentable and filterable structures display the characteristic amyloid fluorescent binding of Thioflavine T. Similar cross-linked products at high and low peptide concentrations indicate that intramultimer reactions predominate over intermultimer reactions for glutaraldehyde, supporting a non-random association of β (1-40) peptides in amyloid fibril. The presence of such pre-amyloid structures at low peptide concentrations suggests that amyloid plaques could accrete additional material by cooperative rather than by monomeric growth.

670.1

INDUCTION OF COMPLEMENT MRNAS AND PROTEINS IN ENTORHINAL CORTEX AND HIPPOCAMPUS AFTER PERFORANT PATH TRANSECTION. S.A. Johnson*, N.J. Laping, C.S. Young-Chan, G.M. Pasinetti and C.E. Finch, Neurogerontology Division, Andrus Center, Dept. Biol. Sci., Univ. of Southern California, Los Angeles, CA 90089-0191.

We and others have shown the presence of complement (C) system mRNAs in normal and diseased mammalian brain; the presence of C proteins in AD pathological structures; and induction of C mRNAs and proteins in AD and in response to experimental brain lesions. The entorhinal cortex (EC) perforant path lesion is a well documented acute model of EC neurodegeneration and hippocampal reactive synaptogenesis found in Alzheimer disease (AD). We are using this model to further examine the potential role of the complement system, a cytotoxic arm of the immune system, in both neurodegenerative (EC) and synaptogenic (hippocampus) mechanisms that occur simultaneously in AD.

Unilateral perforant path transection using a stereotaxically placed Scouten retractable wire knife caused detectable increases of C1qB, C4 and clusterin (SGP-2) mRNAs in ipsilateral EC within 1 day post lesion, as assayed by x-ray film exposure after *in situ* hybridization. Immunocytochemistry on adjacent sections shows the lesion specific presence of both C1 and C9 proteins in the ipsilateral EC; C9 detection suggests, but does not prove, C cascade activation leading to the presence of membrane attack complex, the terminal cytolytic component of the classical C pathway. These studies provide further evidence for C involvement in neurodegenerative lesions. Supported by grants from the NIA to SAJ (AG10673) and CEF (AG07909).

670.3

TG3: A BETTER ANTIBODY THAN ALZ-50 FOR THE VISUALIZATION OF ALZHEIMER-TYPE NEURONAL PATHOLOGY. P. Davies, H. Ghanbari*, A. Issacs, D.W. Dickson, L.A. Mattiace, M. Rosado, and I.J. Vincent, Dept. Pathology, Albert Einstein College of Medicine, Bronx, NY 10461, ¹Molecular Geriatrics, Lake Bluff, IL 60044

TG3 is a mouse IgM produced from mice immunized with Alz-50-reactive proteins purified from Alzheimer's Disease brain tissue. By immunocytochemistry, TG3 appears to be more sensitive and specific than Alz-50. Alz-50 stains small numbers of neurons and neuronal processes in the normal adult human cerebral cortex, and in the rat and human hypothalamus. TG3 does not stain these neurons in either species; to date, no neuronal staining has been found in the normal adult human or rat, although small numbers of fibers are found in sub-cortical regions of the rat brain. In AD brain tissues, TG3 intensely labels neurons, neuritic processes, neurofibrillary tangles and neurites in plaques. The antibody appears to work equally well in vibratome sections of fixed tissue (even after 20 years in formalin) in paraffin embedded tissue, and in cases with a wide range of disease severity. In cases with early AD, TG3 intensely labels neurons of the entorhinal cortex and CA1 pyramidal neurons many of the latter appearing free of tangles. These neurons are much less evident in Alz-50 stained sections.

By western blotting, TG3 reacts with a phosphorylated epitope on the same A68 or PHF-tau proteins recognized by Alz-50, but may also detect additional associated proteins. TG3 does not appear to have significant reactivity with normal adult human, rat or mouse tau, nor with any other proteins in brain homogenates.

670.5

INHIBITION OF PHOSPHATASES IN NEUROBLASTOMA CELLS INDUCE THE FORMATION OF ALZHEIMER-TYPE TAU PROTEINS. P.E. Sautière, M.L. Cailliet, A. Watez, and A. Delacourte*, INSERM U156, 59045 Lille, France.

Pathological Tau proteins are the basic components of Paired Helical Filaments (PHF) found in degenerating neurons during Alzheimer's disease (AD). They have a Molecular Weight (MW) of 55, 64 and 69 kDa and are abnormally hyperphosphorylated. They differ from normal Tau by their apparent higher MW, their more acidic isoelectric point and their conformation generating Alzheimer epitopes.

In order to set up an experimental model of the Alzheimer-type degenerating process, we induced the hyperphosphorylation of Tau by incubating human differentiated neuroblastoma cells (SKNSH-SY 5Y) with okadaic acid (OA), a potent inhibitor of protein phosphatases 1 and 2A. After OA treatment (0,25 µM), neurites quickly disappeared, cells rounded up and detached. In control cells, a doublet of normal Tau isoforms, with a MW of 48 and 53 kDa, was detected by Tau 1 and not detected by our specific anti-PHF serum. After OA treatment, in parallel with morphological changes, we observed the formation of Tau 55 and Tau 64 isoforms incorporating 32P, with a more acidic isoelectric point, a loss of Tau 1-immunoreactivity and an apparition of Alzheimer epitopes detected in a dose-dependant fashion with anti-PHF.

1 nM Calyculin A, another inhibitor of phosphatases 1 and 2A, also produced the formation of pathological Tau 55, 64. The formation of abnormal Tau proteins is likely related to an hyperphosphorylation of preexisting proteins because cycloheximide did not perturb their detection.

Such a model of degenerating process with a production of Alzheimer-type Tau proteins will be useful to elucidate the biochemical dysfunctions occurring during AD and to screen for neuroprotective drugs able to slow down or to stop the dementing process.

Supported by Laboratoires Glaxo and the Conseil Régional Nord Pas-de-Calais.

670.2

TWO DIMENSIONAL ELECTROPHORETIC ANALYSIS OF A68 FROM ALZHEIMER'S DISEASE BRAIN. B. Miller*, G. Johnson, H. Ghanbari, and P. Davies, Molecular Geriatrics Inc, Lake Bluff, IL 60044

To characterize the various polypeptide components of the Alzheimer's disease (AD)-specific protein, A68, we used two dimensional (2D) gel electrophoresis and computer assisted analysis. A68 was affinity purified from an AD brain showing characteristic pathology using antibodies which show high affinity for PHF. The purified A68 was then separated by 2D gel electrophoresis and either silver stained or electroblotted to membrane. Silver staining revealed a pattern of three distinct groups of A68-related polypeptides of Mr of 60 to 68 kD and pI 5.0-6.3. Within each of the three A68 groups, 10-20 individual polypeptides were present that appeared to be related by differences in post-translational modification. Individual polypeptides were further characterized by Western blot analysis according to their reactivity with a series of monoclonal antibodies specific for identified tau epitopes including Alz50 and Tau-1. Post-translational modifications of A68 including phosphorylation were characterized by alterations in both the 2D silver stain and Western blot pattern of A68 after enzymatic removal of the modification. Biochemical and immunochemical characterization of the individual polypeptides comprising A68 may lead to a greater understanding of the alterations and/or modifications of this protein unique to the AD brain.

670.4

TG1: A MARKER FOR NUCLEAR TAU WITH SPECIFICITY FOR NEURONAL NUCLEI IN ALZHEIMER'S DISEASE. I.J. Vincent, R.N. Katen II, A. Isaacs, L.A. Mattiace & P. Davies, Department of Pathology, Albert Einstein College of Medicine, Bronx, NY 10461.

The monoclonal antibody TG1 was derived from mice immunized with PHF preparations isolated from Alzheimer's Disease (AD) brain tissue by immunoaffinity chromatography on a column of Alz-50. On immunoblots of immunoaffinity purified PHF, TG1 reacts with only the 60 and 64 kDa components of the characteristic triplet proteins, as well as a 24 kDa protein. The antibody has some reactivity with tau from human fetal brain but none with normal adult tau. Immunocytochemical analysis of AD brain tissue reveals intense reactivity localized to nuclei in neurons of cerebral cortex, but no staining of the typical pathological features of the disease. Although the antibody does not stain normal adult brain tissue, it labels neuronal nuclei in human fetal brain and in adult rat and mouse brain tissues. In order to identify the TG1 antigen in neuronal nuclei, proteins were extracted from enriched nuclear fractions of rat brain by formic acid treatment. Immunoblot analysis of these extracts with TG1 shows a triplet in the 60-68 kDa range. These proteins are recognized by the antibodies Tau-1 and PHF-1, indicating that they are tau-like. However, TG1 does not display any reactivity with the heat stable cytoplasmic tau fraction in which Tau-1 and PHF-1 immunoreactivities are enriched. The appearance of nuclear TG1 reactivity in AD and in fetal brain reinforces the idea of reexpression of developmental programs in AD. The widespread staining of neuronal nuclei suggest that tau-pathology in AD is more diffuse than is indicated by the more localized neurofibrillary aberrations.

670.6

COLOCALIZATION OF CHOLINESTERASES WITH ABNORMALLY PHOSPHORYLATED TAU PROTEIN IN AGED AND ALZHEIMER'S BRAINS. M.A. Morán* and P. Gómez-Ramos, Dpto. Morfología, Fac. Medicina, Universidad Autónoma, Madrid, Spain.

Both acetyl- and butyryl-cholinesterases colocalize with the β-amyloid protein (Morán et al '93), and are ultrastructurally located over paired helical- and straight-filaments, in aged and Alzheimer brains (Gómez-Ramos et al '92). In free-floating sections from 10 Alzheimer's and 4 non-demented brains, two double protocols were performed: A) Tau immunocytochemistry followed by cholinesterase histochemistry and B) cholinesterase histochemistry followed by tau immunocytochemistry. A modified Karnovsky-Roots method for cholinesterases and the mAb 5E2 against abnormally phosphorylated tau were used. Either alkaline phosphatase with fast red or extravidin-peroxidase with naphthol allowed the distinction of the tau precipitate from the cholinesterases reaction product. In any case, after the second protocol, sections were re-mounted, using previously drawn section outlines, and re-photographed. Cholinesterases were present in a certain proportion of all the structures with neurofibrillary degeneration: neurons with either extra- or intra-cellular neurofibrillary tangles, neuropil threads and plaque-associated neurites. Colocalization was clearly demonstrated in some of these structures, whereas others were either only tau positive or only cholinesterase positive. Triple staining procedures for cholinesterases, tau and thioflavin-S, showed that some of these degenerated structures did not have neither cholinesterases nor tau precipitates. These results are discussed in relation to the evolution of the neurofibrillary degeneration. Supported by FISs nº 93/0189, Spain.

DYNAMICS OF TAU PHOSPHORYLATION AND BINDING AFFINITY FOR MICROTUBULES IN A HUMAN NEURONAL (NT₂N) CULTURED SYSTEM Sandra E. Merrick*, Virginia M.-Y. Lee, Inst. Neurol. Sci. and Dept. of Path. and Lab. Med., Univ. of Pennsylvania, Philadelphia, PA 19104.

Tau isolated from paired helical filaments (PHFs), the major building blocks of neurofibrillary tangles of Alzheimer's disease, has been shown to be abnormally phosphorylated and unable to bind microtubules (MTs), but enzymatic dephosphorylation of PHF tau restores the ability to bind MTs. Previous studies have shown that increased phosphorylation of tau decreases the affinity of tau for MTs. To examine the dynamics of tau phosphorylation and to identify specific phosphorylation sites on tau that are involved in the stabilization of MTs we have used various agents that may alter tau phosphorylation in postmitotic neurons (NT₂N) derived from a human teratocarcinoma cell line. When NT₂N cells, were treated with drugs (i.e. colchicine or nocodazole) that depolymerize MTs, both tau and tubulin subunits were recovered in the supernatant fractions. However, the tau that was recovered was found to be dephosphorylated as monitored by an increase in electrophoretic mobility, a decrease in ³²P PO₄ incorporation and a lack of immunoreactivity to specific phosphorylation dependent tau antibodies. In contrast, treatment of NT₂N cells with a calcium ionophore resulted in degradation of tau protein with no change in MT binding or sites of tau phosphorylation. Finally, treatment of NT₂N cells with okadaic acid resulted in an increase in tau phosphorylation at specific sites and eliminated the binding of tau to MTs. We conclude that tau phosphorylation/dephosphorylation in cultured neurons is dynamic and can be modulated by exogenous factors.

UBIQUITIN IS CONJUGATED WITH AMINO-TERMINALLY PROCESSED tau IN PAIRED HELICAL FILAMENTS. M. Morishima-Kawashima¹, M. Hasegawa¹, K. Takio², M. Suzuki³, K. Titani³, K. Murayama^{1*}, and Y. Ihara¹ ¹Institute for Brain Research, University of Tokyo, Tokyo 113, ²Institute of Physical and Chemical Research (RIKEN), Saitama 351-01, ³Institute for Comprehensive Medical Science, Fujita Health University, Aichi 470-11, Japan.

In a subset of neurons in Alzheimer's disease (AD), paired helical filaments (PHF) appear to progressively accumulate despite their ubiquitination. To obtain an insight into the ubiquitin pathway in the brain affected with AD, we have investigated ubiquitinated PHF, which show a smear in SDS-polyacrylamide gel electrophoresis and immunoblotting. Smearing materials with both tau- and ubiquitin-immunoreactivities were purified and their digests were subjected to protein sequence and mass spectrometric analyses. The smear consisted largely of the carboxyl-terminal portion of tau and ubiquitin. Several peaks specific for the smear peptide map were found to contain a ubiquitin-ubiquitin and ubiquitin-tau conjugates. Thus the ubiquitin-targeted protein was tau in PHF and the conjugation sites were localized to the microtubule-binding region. Most ubiquitin in PHF occurred as a monoubiquitinated form and only a small proportion of ubiquitin formed multiubiquitin chains. There was a ubiquitin-negative smear in which tau is much less processed in the amino-terminal portion. This strongly suggests that the amino-terminal processing of tau in PHF precedes its ubiquitination.

TAU IMMUNOREACTIVITY IN THE HIPPOCAMPAL FORMATION OF YOUNG DOWN SYNDROME AND NON-DEMENTED ELDERLY PATIENTS. I. Leverenz*, C.B. Saper and M. Raskind. Depts. of Medicine (Neurology) and Psychiatry & Behavioral Sciences, Univ. of Washington, Seattle, WA 98195, Dept. Neurology, Beth Israel Hosp./Harvard Med Sch., Boston, MA 02115

Post-translational modification of tau protein may be an early event in the development of neurofibrillary tangles in Alzheimer's disease. Alz-50, a monoclonal antibody to the amino terminus of tau, has been noted to stain some neurons in a granular fashion in regions susceptible to neurofibrillary tangles, before tangles are present. This granular staining may represent pre-tangle alterations of tau protein. We examined the expression of the Alz-50 antigen, and two tau phosphorylation epitopes (Tau-2 and PHF-1) in the hippocampal formation of two "models" of early Alzheimer's disease: young Down syndrome patients with little or no evidence of neurofibrillary tangle formation, and elderly non-demented patients with amyloid deposition and few neurofibrillary tangles. The findings in the two groups were similar. Prior to substantial development of neurofibrillary pathology in hippocampal neurons, we saw granular staining of neurons with all three antibodies. Using double labeling and consecutive sections, Alz-50 and Tau-2 immunostaining were more extensive than PHF-1. These results support the contention that phosphorylation of tau is an early event in the development of neurofibrillary tangles. It also appears that phosphorylation of the Tau-2 epitope and exposure of the Alz-50 epitope occur earlier than the development of PHF-1 antigenicity. Further study of the development of antigenic changes in these groups may yield important clues to the instigating factors in neurofibrillary tangle formation.

TOTAL UBIQUITIN IS NOT ELEVATED IN ALZHEIMER BRAIN AND FIBROBLASTS. RS Black*, ES Kelman, SG Greenberg, HT Smith, VA Fried Cornell Univ. Med. Coll. at Burke Medical Res. Inst., White Plains, NY and New York Med. Coll., Valhalla, NY Levels of ubiquitin have been reported to be elevated in postmortem brain samples from Alzheimer's disease (AD) (Wang et al. 1991). We developed a solid phase dot blot immunoassay to measure ubiquitin in brain and cultured cell samples using both polyclonal and monoclonal antibodies, and ¹²⁵I-conjugated Protein A. Bovine ubiquitin was used as the standard. Ubiquitin was measured in samples of Alzheimer and control brain matched for age, sex and postmortem delay, with the longest postmortem delay in this series being 3 hours. Values for Alzheimer and control frontal cortex were 2.81±0.24 and 2.76±0.23 mg ubiquitin/gm protein, respectively. In contrast, an abnormally phosphorylated form of tau (assayed in parallel with the antibody PHF-1) was elevated six to 30 fold in AD frontal cortex. Cultures of fibroblasts from cases of familial and sporadic AD were examined and compared to control cultures matched for age and sex of donor, and age in culture (cPDL); no differences in ubiquitin content were found. Reported differences in ubiquitin content between AD and control brain may reflect preferential recognition of ubiquitin conformations present in AD brain, or increased postmortem stability of tangle-associated ubiquitin.

670.10

THE EXTENT OF PHOSPHORYLATION OF FETAL TAU IS COMPARABLE TO THAT OF PHF-TAU FROM ALZHEIMER PAIRED HELICAL FILAMENTS A. Kenessey, D. W. Dickson*, and S. H. Yen. Department of Pathology, Albert Einstein College of Medicine, Bronx, New York, 10461

The relationship between Alzheimer's disease (AD) and expression of fetal proteins was examined by (i) determining the phosphate content of tau prepared from fetal brains (F-tau), (ii) comparing F-tau, tau from normal adult human brains (N-tau) and tau from paired helical filaments in AD brains (PHF-tau) for phosphate content, and (iii) testing the reactivity of F-tau with five antibodies known to recognize PHF-tau. The antibodies have been reported to recognize phosphate dependent epitopes at the carboxy terminal half of the tau molecule. Our data shows that on the average, F-tau contains 7 mol phosphate/mol protein, which is comparable to the phosphate content of PHF-tau, but is 3-4 times higher than that of N-tau. Immunoblotting shows that all of the tested antibodies reacted with F-tau on immunoblots, indicating that F-tau and PHF-tau are phosphorylated at similar sites. A difference between PHF-tau and F-tau is the state of phosphorylation in the Tau-1 epitope, an epitope reactive with a monoclonal anti-tau antibody, Tau-1. This epitope, which is phosphorylated in all PHF-tau, is phosphorylated only in some of the F-tau. Our results suggest that tau phosphorylation does not necessarily lead to AD type cytoskeletal abnormalities, since fetal brains are free of such pathology.

670.12

CORTICAL MAPPING OF ALZHEIMER PATHOLOGY IN BRAINS OF AGED NON-DEMENTED SUBJECTS. P. Vermersch^{1*}, J. Ph. David², B. Frigard¹, C. Fallet-Bianco², A. Delacourte¹. 1) INSERM U156, 59045 Lille; 2) Department of Neuropathology, Hôpital Sainte-Anne, Paris, France.

The presence of neurofibrillary pathology of the Alzheimer type and amyloid deposits within the brains of aged non-demented subjects were investigated by immunoblotting and immunohistochemistry using antibodies directed against abnormal tau proteins 55, 64 and 69 (Tau-PHF) and BA4 respectively.

As part of a prospective study on aging, only brains from non-demented patients were included. All of them, aged from 69 to 97, had a MMS score higher than 24/30. The abnormal tau triplet, a biochemical marker of neurofibrillary degeneration (NFD) was quantified by western blot and densitometric analysis of several cortical areas including entorhinal cortex (EC), hippocampus, Brodmann areas (BA) 20, 22, 38, 9, 45 and 39, as previously described (Vermersch et al., Acta Neuropathol 1992; 85: 48-54).

The abnormal tau triplet was detected in the EC of all controls over 65 and in the hippocampus of controls aged over 80 years. In some of the oldest cases the degenerating process was also detected in the isocortex in BA38 alone or also in BA20 and BA22. These observations suggest that there is a continuum between aging and AD. Some cases and especially those with tau pathology in BA38 contained numerous senile plaques (SP) in the isocortex and were likely to be subclinical stages of AD. However, approximately fifty per cent of controls with tau pathology in the EC and hippocampus were almost devoid of SP in the isocortex (detection with different antibodies anti-A4 and thioflavine). We conclude that this last group is more likely to be related to normal aging than to AD. A higher vulnerability of the hippocampal region to numerous injuries during life could explain this group.

INTRAHIPPOCAMPAL COLCHICINE INJECTION ALTERS TAU IMMUNOSTAINING BUT DOES NOT MODEL ALZHEIMER'S DISEASE PATHOLOGY. J.W. Geddes*, V. Bondada and J.N. Keller. Sanders-Brown Center on Aging and Dept. Anatomy & Neurobiology, Univ. Kentucky, Lexington, KY 40536.

The microtubule disrupting agent, colchicine, has been used to model several aspects of Alzheimer's disease (AD)-related neuropathology. This study examined the effects of colchicine on microtubule-associated proteins (tau, MAP2, and MAP5) to determine if changes in their levels or distribution might be similar to those which have been suggested to precede the formation of neurofibrillary tangles in AD. Six hours following intrahippocampal colchicine injection (3.5 µg injected into two rostral-caudal locations) tau immunostaining was increased in CA1 s. radiatum and decreased in the outer molecular layers of the dentate gyrus. In addition, a downward shift in the electrophoretic mobility of some tau isoforms was observed in Western blots, indicative of dephosphorylation. Three days postinjection, there was a loss of MAP2 and MAP5 which coincided with a loss of cresyl violet staining in granule cells, CA3, subicular and entorhinal neurons. Accumulation of the MAPs in neuronal perikarya was not observed at any postinjection time points. The results demonstrate that although intrahippocampal colchicine does alter tau immunostaining, it does not model the cytoskeletal alterations that are suggested to precede or accompany the formation of neurofibrillary pathology in AD.

670.15

DISTRIBUTION OF PROLINE-DIRECTED PROTEIN KINASES AND REGULATORY ENZYMES IN PRIMARY HIPPOCAMPAL CULTURES. C.A. Reich and J.G. Wood*, Emory Univ. Sch. of Med., Atlanta, GA 30322

Recent reports indicate that the proline-directed protein kinases, MAP kinase and cdc2 kinase, have the ability to phosphorylate tau *in vitro* in a manner that mimics many of the changes associated with Alzheimer's disease pathology, yet little is known about the distribution of these kinases and their regulatory enzymes in neurons. Although these kinases have been isolated from brain, typically considered a non-proliferating tissue; studies characterizing the *in vivo* activities of these enzymes reveal that they play a key role in the control of cell division. Therefore, these enzymes might actually be located in glia, rather than neurons, and have little opportunity to interact with tau. Using antibodies to the proline-directed protein kinases, cdc2 and MAP kinase, as well as to the potential regulatory components, MAP kinase kinase, raf-1, phosphoinositide-3 kinase, protein phosphatase 2A, cdc25, wee-1 kinase and fyn kinase, we have immunohistochemically characterized the cellular distribution of these enzymes in primary rat hippocampal cultures. Our results indicate that many components of this kinase/phosphatase system are predominantly present in neurons. The relative absence of staining for these enzymes in the abundant, actively dividing glia in these cultures is a significant observation as well. The neurons in this culture system, like their *in vivo* counterparts, are post-mitotic and terminally differentiated. Therefore, enzymes which function strictly to regulate mitosis or merely initiate differentiation are less likely to be present. The fact that these proline-directed protein kinases and their regulatory enzymes are found in neurons suggests additional physiological roles for these kinases in addition to cell cycle control. The presence of these kinases in a primary neuronal culture system provides the opportunity to study factors which may influence regulation of the protein levels and the activation state of these enzymes. DEGRADATION OF TAU BY A MAJOR EXTRALYSOSOMAL PROTEINASE, THE MULTICATALYTIC PROTEINASE COMPLEX (PROTEASOME). M.E. Figueiredo-Perreira, S. Wilk* and G.V.W. Johnson*. Dept. of Pharmacology, Mount Sinai Medical School of C.U.N.Y., N.Y., N.Y. and *Dept. of Psychiatry and Behavioral Neurobiology, University of Alabama at Birmingham, Birmingham, AL.

Tau is a family of microtubule-associated proteins which plays a significant role in the structure and function of the neuronal cytoskeleton. It is a major component of PHFs of Alzheimer's disease. Although the mechanism of formation remains unknown, it can be suggested that impaired proteolysis of tau may be associated with its accumulation. Tau in PHFs is abnormally phosphorylated. It was shown that tau is a substrate for the proteinase calpain, and that phosphorylation decreases its susceptibility to calpain degradation. In this report we demonstrate that tau is rapidly degraded by another major proteinase, the multicatalytic proteinase complex (MPC). MPC is a unique high molecular mass proteinase (700 kDa) with multiple distinct proteolytic activities. It is found both in cytosol and nuclei, and is present in brain in relative high concentrations (0.12% of soluble brain protein). Tau was purified from fresh bovine brains and MPC from frozen bovine pituitaries. Assay mixtures (100 µl) containing 7 µg of tau, 2 µg of MPC and 0.05M Tris-HCl buffer, pH 8.0 were incubated at 37°C, aliquots were removed at various times, subjected to SDS-PAGE and immunoblotted with Tau2. Virtually all of intact tau was proteolyzed after 30-min of incubation. The rate of degradation of tau by MPC was approximately 30 mg of tau degraded/mg of MPC/hour. This is the highest described rate of degradation of an endogenous protein substrate by MPC, under physiological conditions. Malfunction or changes in the catalytic activities of MPC, and/or alterations in the phosphorylation state of tau could result in abnormal degradation of tau, and contribute to neuronal dysfunction and pathological lesions in neurodegenerative diseases. CALCIUM/CALMODULIN-DEPENDENT PROTEIN KINASE II IN ALZHEIMER'S DISEASE. N.A. Simonian*¹, T. Eivhage¹, A.J. Czernik², P. Greengard² and B.T. Hyman¹. ¹Dept. of Neurology, Mass. General Hospital, Boston, MA 02114 & ²Lab. of Molec. & Cell. Neurosci., The Rockefeller University, NY, NY 10021 USA.

Calcium/calmodulin-dependent protein kinase II (CaM K) has been implicated in the regulation of synaptic transmission and in the induction of long term potentiation (LTP). The hippocampal formation, a structure important in memory formation, is highly enriched in this enzyme. Transgenic mice lacking the alpha subunit of CaM K show abnormalities in some memory tasks and slices from the CA1 region of these animals exhibit deficiencies in LTP. In Alzheimer's disease (AD), memory loss is universal but the molecular basis is unknown. We examined whether changes in CaM K occur in AD by performing immunohistochemistry using an antibody to the alpha subunit of CaM K. The diffuse density of the immunohistochemical product was quantitated in hippocampal sections from 11 AD and 9 aged control individuals. CaM K immunoreactivity was decreased by 50% in CA1, but not in dentate gyrus or presubiculum in individuals with AD (p<.002). In contrast to the dentate gyrus and presubiculum, CA1 is severely affected by neurofibrillary tangles and cell loss in AD. The decrease in CaM K immunoreactivity in CA1 may be due to loss of neurons and/or to an alteration in function of remaining neurons. A selective decrease of CaM K immunoreactivity in remaining neurons suggests that alterations in second messenger systems important in synaptic transmission may accompany these changes. MAP KINASE p44^{mapk} INDUCES ALZHEIMER TYPE ALTERATIONS IN TAU FUNCTION AND IN PRIMARY HIPPOCAMPAL NEURONS. Q. LU*, J.P. SORIA and J.G. WOOD, Dept. of Anatomy and Cell Biology, Emory Univ. Sch. of Med., Atlanta, GA 30322

Abnormally phosphorylated tau protein is a major component of the cytoskeletal pathology of Alzheimer's disease (AD) found in the neurofibrillary tangle and neuritic plaque. Identification of the kinase responsible for this phosphorylation has been difficult. In the test tube, several proline-directed kinases, particularly mitogen activated protein (MAP) and cdc2 kinase phosphorylate tau on sites that appear to mimic the abnormally phosphorylated sites in AD. Important unanswered issues include: 1) whether this phosphorylation event occurs in the tightly regulated environment of a living cell, 2) whether this phosphorylation of tau affects its functional properties, and 3) what is the subcellular relationship of proline-directed kinases and tau. We show here that tau can be phosphorylated in cultured hippocampal neurons by the MAP kinase p44^{mapk} and the effects appeared to be mimicked by microinjection of the phosphatase inhibitor okadaic acid. In addition, phosphorylation of aged non-demented human brain tau compromises its functional ability to assemble microtubules. We show further that a number of protein kinases including p34 cdc2 and MAP kinase copurify with microtubule fractions. Both p44 and p42 MAP kinases are tyrosine phosphorylated and presumably active. These studies address and raise several important issues regarding the regulation of tau phosphorylation in normal and AD brain. AG 11123 and NS 27847.

670.18

CLONING AND CHARACTERIZATION OF AN ALZ50 IMMUNOREACTIVE GENE PRODUCT FROM FETAL BRAIN THAT IS NOT TAU. R. Bowser*, A. Giambrone and P. Davies. Dept. Pathology, Albert Einstein College of Medicine, Bronx, NY 10461.

By immunocytochemistry the monoclonal antibody Alz50 identifies a tau epitope that is present in the brain of individuals with Alzheimer's disease (AD) but not apparent in age-matched controls. Alz50 also recognizes a developmentally regulated antigen that appears to be present in subplate and marginal zone neurons of fetal and neonatal brain but absent by age 6. It is possible that an Alz50 immunoreactive protein(s) may function in programmed cell death and is re-expressed in AD. To identify such a protein we immunoscreened a fetal cDNA expression library with Alz50. A 1.3 kb cDNA clone was isolated and sequenced. Comparison with the GenBank database revealed no homologies to known proteins. The 1.3 kb clone, designated FAC1 (Fetal Alz50 reactive Clone 1), encodes a 41 kD open reading frame with 3 in-frame stop codons near the 3' end of the clone. Additional 5' upstream coding sequences are currently being identified by PCR cloning techniques. The FAC1 gene is expressed in multiple human tissues and is conserved across species. 9 monoclonal antibodies, FA1-9, were produced to purified recombinant FAC1 protein. Immunoblots of fetal brain tissue have determined that the full-length FAC1 protein is ~120 kD. Immunocytochemical analysis indicates that the FAC1 protein is located in the nucleus of neurons throughout the fetal brain. Decreased levels of FAC1 protein are detected in normal adult brain sections but increases in FAC1 protein are often observed in AD. Therefore the FAC1 gene encodes a novel ~120 kD Alz50 immunoreactive protein that is developmentally regulated and may be re-expressed in AD.

670.19

DISTRIBUTION OF ALZ-50- AND AMYLOID P COMPONENT-IMMUNOREACTIVE NEUROFIBRILLARY TANGLES IN ALZHEIMER'S DISEASE. T. Duong* and P.J. Acton. Biomedical Research Institute, Indiana Univ. Sch. of Med., Terre Haute, IN 47809.

Alz-50 monoclonal antibody labels the A68 protein which is abundantly expressed in neurofibrillary tangles (NFT) in Alzheimer's disease (AD). Amyloid P component (AP) is derived from the normal circulating serum AP and it has been localized by immunohistochemistry to AD brain lesions, including NFT. In this study, NFT immunoreactive to ALZ-50 and/or to AP were compared in the AD hippocampal gyrus. Paraformaldehyde-fixed AD brain samples were cut on a cryostat and free floating sections were processed by double-antigen immunohistochemistry. ALZ-50- and AP-labeled NFT formed 2 separate populations which overlapped partially. In layer II of the entorhinal cortex, NFT derived from the stellate neurons showed either strong immunoreactivity to ALZ-50 or to AP. Occasional patches of neurons displayed immunoreactivity to both antibodies. In CA1 region of the hippocampus, ALZ-50-, AP- and double-labeled NFT accounted for 60%, 24% and 16% of immunoreactive NFT respectively. In CA4 region of the hippocampus, the majority of NFT were AP-immunoreactive. ALZ-50- and double-labeled NFT were occasionally observed. In double-labeled NFT, AP-immunoreactivity was seen in the perikaryon and ALZ-50 labeling in the proximal portion of dendrites. The results showed that the majority of NFT is immunoreactive to either ALZ-50 or AP and that a small population of NFT is immunoreactive to both. This small group of NFT may represent a transition phase from ALZ-50 to AP labeling in NFT, suggesting changing patterns of immunoreactivity in NFT. This work was supported in part by a Turken Scholarship from the ADRDA.

TRANSGLUTAMINASE CATALYZES THE FORMATION OF HOMO-POLYMERS OF TAU AND β -AMYLOID: IMPLICATION FOR A ROLE IN ALZHEIMER'S DISEASE. G. Y. W. Johnson* and S. M. Dudek. Dept. of Psychiatry, University of Alabama at Birmingham, Birmingham, AL 35294-0017

Transglutaminases are a family of calcium-activated enzymes which catalyze the formation of covalent crossbridges between certain proteins. Previous studies in brain have led to suggestions that transglutaminase may play a role in neuronal differentiation, programmed cell death, aging, and Alzheimer's disease (AD). Here we describe experiments aimed at determining if transglutaminase could contribute to the formation of two hallmarks of AD pathology: neurofibrillary tangles (NFTs) and β -amyloid (β A) aggregation.

Since paired helical filaments (PHFs), a constituent of NFTs, consist primarily of the microtubule-associated protein, tau, we tested the hypothesis that tau is a substrate of transglutaminase. Purified bovine or human tau was incubated with transglutaminase and examined on immunoblots. Crosslinking of tau was evident with the loss of monomeric tau and the formation of higher molecular weight complexes. Aggregates too large to enter the gel were also formed, since tau immunoreactivity was detected (on slot-blots) in pellets after centrifugation. These aggregates remained insoluble in SDS and β -mercaptoethanol, in guanidine-HCl and in urea, indicating that covalent crosslinking of tau was likely. Interestingly, an increase in the Alz-50 immunoreactivity of tau was also observed in the aggregates after treatment with transglutaminase. Electron microscopy revealed the polymers to be filamentous in structure.

As insoluble fibrils of β -amyloid are also abundant in AD brain, the susceptibility of the β A peptide to crosslinking by transglutaminase was studied. Like tau, β A was readily crosslinked. Distinct dimers, trimers, tetramers (up to very high multiples of the peptide) were clearly visible on immunoblots. No covalent aggregation was observed when β A was incubated under similar conditions without transglutaminase or in the presence of EGTA. Though it remains to be shown that these reactions occur *in vivo* in AD, these studies suggest a possible mechanistic link between the processes mediating NFT formation and β A aggregation. (NIH #s NS27538 and AG06569)

MODULATION OF THE IN SITU PHOSPHORYLATION OF TAU IN RAT BRAIN CEREBRAL CORTICAL SLICES. L.M. Fleming* and G.Y.W. Johnson. Dept. of Psychiatry, Univ. of Alabama at Birmingham, Birmingham, AL 35294.

Tau is a neuronal microtubule-associated phosphoprotein which plays a role in the normal development and maintenance of the axon. In Alzheimer's disease brain, inappropriately phosphorylated tau is an integral component of paired helical filaments (PHFs). It has been postulated that this aberrant phosphorylation precedes PHF formation. Although tau has been shown to be a substrate for many kinases *in vitro*, little is known about its *in situ* phosphorylation. In this study we examined the phosphorylation of tau in rat brain cerebral cortical slices and how the phosphorylation state is modulated by agents which increase intracellular cAMP or calcium concentrations.

Rat brain slices were labeled with 32 P; prior to incubation in the presence or absence of drugs. The incubations were terminated and tau was immunoprecipitated from 250 μ g of each sample. Tau was 32 P-phosphorylated under basal conditions *in situ*. Treatment of the slices with forskolin plus rolipram significantly enhanced the incorporation of 32 P into tau, suggesting that tau is an endogenous substrate for cAMP-dependent protein kinase. Incubation of the slices with either KCl or the excitatory amino acid, NMDA did not significantly alter tau phosphorylation. In contrast, incubation of the slices in the presence of both NMDA and KCl greatly increased incorporation of 32 P into tau in a calcium-dependent manner. This data suggests that depolarization of the slices is required for the NMDA-mediated calcium influx into the cell and activation of calcium-dependent protein kinases. (Supported by NIH grants NS27538, AG06569, and a grant from the Alzheimer's Association.)

ISCHEMIA: ACIDOSIS

671.1

MILD ACIDOSIS DELAYS HYPOXIC SPREADING DEPRESSION AND IMPROVES NEURONAL RECOVERY IN RAT HIPPOCAMPAL SLICES. G.C. Tombaugh*, P.G. Aitken, and G.G. Somjen. Dept. of Cell Biology, Duke Univ. Med. Ctr., Durham, NC 27710.

Severe tissue acidosis has been viewed traditionally as a damaging component of cerebral hypoxia. However, a protective action of moderate acidosis (pH_o=6.5-7.0) against hypoxic neuronal injury has been described in primary cell cultures. To determine whether a similar effect occurs in mature brain tissue, we subjected adult rat hippocampal slices to a fixed period of hypoxia after ambient pH was changed slightly with HCl or NaOH. Slices were maintained in an interface chamber at 35°C. Ion-selective microelectrodes were positioned in CA1 to record evoked field potentials, extracellular voltage (V_o), pH_o, and [Ca²⁺]_o. Orthodromic population spike amplitude was used as a measure of slice recovery 2hr after reoxygenation. When compared to control conditions (bath pH=7.4; pH_o=7.22), mild acidosis (pH_o=6.9-7.1) caused a reversible decrease in the population spike, an increase in the latency of hypoxic spreading depression (HSD=anoxic depolarization), and a decrease in the magnitude of the negative V_o shift; mild alkalinity (pH_o=7.53) had the opposite effect for each measurement. All slices became markedly acidotic during hypoxia; following restoration of O₂ and bath pH to 7.4, slice pH_o returned to its pre-treatment level regardless of experimental treatment or the degree of slice recovery. A reduction of pH_o by as little as 0.1pH unit resulted in a dramatic improvement in post-hypoxic recovery. Because the duration of HSD has been inversely correlated to the degree of slice recovery and could have explained this protective effect, additional experiments were performed in which the duration of HSD was held constant (5). Under these conditions, acid-treated slices exhibited a more modest though significant improvement in recovery. In neither paradigm did the recovery of alkaline-treated slices differ from controls. Both acid-treated and control slices exhibited an identical decrease in [Ca²⁺]_o during HSD that recovered with a similar time-course after reoxygenation. These results suggest that mild acidosis may limit hypoxic neuronal injury in the CNS by delaying SD onset in addition to other direct, though currently undefined mechanisms.

671.2

HYPOXIA AND ACIDOSIS ACT SYNERGISTICALLY TO CAUSE ASTROCYTE DEATH AND DYSFUNCTION. K. Farrell* and R.A. Swanson. Dept. of Neurology, Univ. of California and V.A.M.C., San Francisco, CA 94121.

Cerebral ischemia may spare glia and cause selective neuronal death, or may cause infarction with pan-necrosis of all cellular elements. We used primary rat cortical astrocytes to study factors that may determine these outcomes. Acidosis was induced with PIPES- and bicarbonate- buffered media, and chemical hypoxia with the mitochondrial poisons sodium azide (25mM), 2,4 dinitrophenol (0.1mM), or antimycin A (10 g/ml). Glutamate uptake was followed with [¹⁴C] GLU, and cell death was assessed by measuring LDH activity in lysates of surviving cells.

With hypoxia alone or acidosis alone (pH 6.2) glutamate uptake was maintained at 50%-70% of control rates. Combined hypoxia plus acidosis reduced uptake to <10% of control rates. Similarly, 6 hrs exposure to either pH 6.2 or hypoxia alone caused little or no cell death, whereas combined acidosis plus hypoxia caused >70% cell death. These results support acidosis as a critical variable determining type and extent of brain injury during ischemia.

671.3

EFFECT OF ANOXIA ON INTRACELLULAR pH IN ISOLATED NEWBORN AND MATURE RAT HIPPOCAMPAL CA1 NEURONS. T.R. Cummins*, D.A. Levy and G.G. Haddad. Section of Respiratory Medicine, Dept. of Pediatrics, Yale University School of Medicine, New Haven, CT 06510.

Brief periods of anoxia can lead to loss of excitability and neuronal damage. However, newborn animals are more resistant to these effects than mature animals. The mechanism(s) for this difference in sensitivities is not known, but could be related to many factors. One such factor is intracellular pH (pH_i), which can modulate a number of cellular properties, including calcium levels and excitability. Anoxia may have a different effect on pH_i in newborn animals than mature animals, and this difference may contribute to the newborn's resistance to anoxic damage. To study the effect of anoxia on pH_i, we freshly isolated pyramidal neurons from mature (20-30 days old) and newborn (4-7 days old) rat hippocampal slices using enzymatic and mechanical dissociation techniques. pH_i was measured using the pH-sensitive dye SNARF-1 and a LASER confocal microscope.

In HEPES buffered saline (34°C) bubbled with oxygen, mature and newborn isolated neurons had a resting pH_i of 7.06±0.23 (mean±SD; n=20) and 7.20±0.13 (n=22), respectively. Single neurons in slices were also studied, in which mature neurons had a resting pH_i of 7.09±0.16 (n=37) and newborn neurons had a resting pH_i of 7.29±0.17 (n=40). Anoxia was induced by perfusing with nitrogen bubbled HEPES saline containing 1mM sodium dithionate (an oxygen scavenger) for 10 minutes. pH_i in both mature and newborn isolated neurons decreased during anoxia and the mean decrease was smaller in newborn than mature neurons (newborn 0.19±0.13, n=20; mature 0.25±0.16, n=22). Compared to mature, newborn neurons tended to have a longer latency to the anoxic pH_i drop, and showed a significantly faster rate of fall in pH_i (p<0.05) and a faster rate of recovery with re-oxygenation (p<0.05).

Our data indicate that anoxia induces a different pattern of pH_i drop in newborn than in mature neurons. This differential response could be related to differences in production of acid from intermediary metabolism, rates of proton and other exchangers and intracellular buffering capacity.

THAM BUFFERS CEREBRAL ACIDOSIS DURING FOCAL ISCHEMIA. J.E. Duldner, K.R. Wagner*, M. Kleinholz, G.M. deCourten-Myers, R.E. Myers. Research Service, Veterans Affairs Medical Center; Depts. of Neurology and Pathology, Univ. Cincinnati, College Medicine, Cincinnati, Ohio 45220.

Hyperglycemia leading to markedly elevated brain lactic acid concentrations during cerebral ischemia exacerbates injury. Treatment of cerebral acidosis during focal ischemia may reduce tissue infarction. We determined if treatment with the buffer tromethamine (THAM) during middle cerebral artery (MCA) occlusion in hyperglycemic cats (serum glucose = 20 mM) would reduce hydrogen ion accumulation in the ischemic territory. THAM (0.3 M) was infused (i.v.) at 0.9 mmol/kg/hr for the first hour post-occlusion and at 0.2 mmol/kg/hr until *in situ* brain freezing at 4 hr. Brain tissue lactate and high energy phosphates were determined topographically in 14 MCA territory sites by standard enzymatic-fluorometric methods. Intracellular pH (pH_i) was derived from the creatine kinase equilibrium.

MCA territory sites in THAM-treated cats (N=4) had significantly (p<0.05) higher pH_i's (6.63 ± 0.06) versus comparable sites in control cats (6.24 ± 0.11, N=5). THAM treatment also resulted in fewer MCA territory sites with pathologic pH_i's (pH_i<6.50) (30.4%, 17/56 sites versus 50.0%, 29/58 sites in controls). THAM treatment effectively reduces tissue acidosis during focal cerebral ischemia and may reduce infarction following stroke.

mRNA LEVELS OF Ca²⁺ INDEPENDENT FORMS OF PROTEIN KINASE C IN POSTISCHEMIC GERBIL BRAIN BY NORTHERN BLOT ANALYSIS. K. Kumar*, S. Savithiry. Dept. of Pathology, Michigan State University, E. Lansing, MI 48824.

To investigate the role of Ca²⁺ independent forms of protein kinase C (PKC) in ischemic neuronal injury, their mRNA expression was studied by Northern blot analysis in the gerbil model with global forebrain ischemia produced by 10 min of bilateral carotid artery occlusion. RNA was prepared from forebrains of nonischemic controls and posts ischemic (PI) animals following 15 min, 6 h and 24 h of recirculation (n = 3 to 4 in each group) and hybridized with synthetic oligonucleotide probes for PKC, δ, ε, and ζ, based on cDNA sequences in rat and labelled with ³²P. Increase in mRNA levels of all three forms of PKC was noted in the 6 h PI group which continued through 24 h PI. Of these, the increases in PKC δ, and ζ mRNA were statistically significant (p<.05). These results suggest that the mRNA expressions of PKC δ, and ζ, in particular, are temporally stimulated by ischemic injury in the brain and imply an important role of the enzyme in posts ischemic neuronal damage. However, since the protein itself was not examined, it cannot be said whether the increased expression translates into increased synthesis of the protein.

RELATIONSHIP BETWEEN SPECTRIN-BREAKDOWN AND LDH RELEASE IN CORTICAL NEURONAL CULTURE CHALLENGED WITH GLUTAMATE. A. Posner, G.W. Campbell, K.K.W. Wang*, and D.M. Rock. Neuroscience Pharmacology, Parke-Davis Pharmaceutical Research, Division of Warner-Lambert Company, 2800 Plymouth Road, Ann Arbor, MI 48105, USA.

Excess amounts of glutamate can cause excitotoxicity in neurons by raising intracellular calcium levels. It has been suggested that calpain overactivation may play a key role in this neurodegeneration. Fetal rat cortical neurons were subjected to 500 μM glutamate for 5 min and the cells were then returned to normal medium. The time course of LDH release and spectrin breakdown were measured. After the glutamate challenge, both spectrin isoforms (α, β) (220 kDa) were found partly degraded to immunostained spectrin breakdown products (SBDP) of 150 kDa and 145 kDa, presumably originated from the two spectrin isoforms, respectively. The 150 kDa product was formed very rapidly (present after 15 min), followed by the appearance of the 145 kDa SBDP. Maximal levels of both SBDP were reached after 1 h. In contrast, LDH release continued to rise after 1 h and plateaued out at about 4 h. SBDP formation was shown to be largely dependent on extracellular calcium, suggesting the involvement of calpain. MK-801 (1 μM) effectively blocked LDH release and spectrin breakdown when added before and during the glutamate challenge, but was ineffective when added after the challenge. Calpain inhibitor I (Ac-Leu-Leu-Nle-H) at 50 μM reduced the level of 150 kDa SBDP and blocked formation of the 145 kDa SBDP at 45 min post-glutamate but did not significantly reduce LDH release.

672.2

BIPHASIC CHANGES IN MEMBRANE PROTEIN KINASE C (PKC) ACTIVITY CORRELATE WITH CA1 NEURONAL CELL DAMAGE FOLLOWING CEREBRAL ISCHEMIA. B. Chakravarthy, H. Li*, A. Buchan and J. Durkin. Institute for Biological Sciences, National Research Council Canada, Ottawa, Ontario, Canada K1A 0R6 and Ottawa Civic Hospital, Ottawa, Ontario, Canada K1Y 4E9 from the *Canada/Fisons Fight Stroke program*.

Previous studies, using a conventional PKC assay, indicate that a rapid and sustained loss in activatable membrane PKC occurs in hippocampal neurons subjected to ischemic insult. However, the nature of the conventional assay is such that it measures 1) only PKC that is tightly associated with membranes, and b) the amount and not the activity of the enzyme present in that fraction. Our recently developed *direct PKC assay* gives an actual measure of the enzyme activity associated with both the tightly-associated and peripherally-bound pools of membrane PKC. This direct assay was used to explore the effects of ischemia on membrane PKC activity in CA1 neurons. Transient global ischemia was induced in male Wistar rats by a 15 min 4 vessel occlusion at 37°C followed by reperfusion for up to 72 hr. The PKC activity in the membranes from CA1 neurons was found to follow a biphasic pattern. A rapid 2-fold increase in membrane PKC activity was observed during ischemia, and this was followed by a rapid decline in activity upon reperfusion until levels 50% below that of sham-operated animals was reached 6 hr post-reperfusion. These subnormal levels of activity were maintained during the ensuing 48 hr. Mild hypothermia during ischemia (32°C) did not affect the initial increase in PKC activity but prevented enzyme activity from dropping below basal levels upon reperfusion. Hyperthermia (39.5°C), which exacerbated neuronal injury, triggered a decline in PKC activity to levels 80% below that of matched sham-treated animals. A tight correlation was found between the extent of CA1 neuronal cell damage and the levels of PKC activity 6 hr. post-ischemia.

672.4

THE INVOLVEMENT OF CALCIUM-CALMODULIN PATHWAY IN THE NEURONAL INJURY INDUCED BY HYPOXIA-HYPOGLYCEMIA IN THE ORGANOTYPIC CULTURE OF RAT HIPPOCAMPUS. C. Shin*, X. Sun and M. Colberg. Departments of Pharmacology and Neurology, Mayo Clinic/Mayo Foundation, Rochester, MN 55905

We have previously reported that the NMDA receptor is involved in the process of neuronal injury produced by ischemia (Shin et al., *Neurosci. Abstr.*, 1992). The NMDA receptor gates channel permeable to Ca²⁺ which subsequently activates many intracellular mechanisms. The present study was designed to test the hypothesis that activation of Ca²⁺-calmodulin pathway plays a key role in the development of neuronal injury after ischemic insults.

The organotypic cultures from 6 day old pups were exposed at 10 DIV to 2-deoxyglucose substituted HBSS equilibrated with 95% N₂ plus 5% CO₂ atmosphere. Calmidazolium, which was shown to inhibit the activities of calcium calmodulin dependent kinase (CaMKII), was applied 30 min before, during and for 24 hours after the ischemia. At 24 hrs, a severity index of neuronal injury (0=none, up to 4=severe) was assigned to propidium iodide fluorescence.

With 40 min exposure to ischemic treatment, CA1 specific pattern of injury to the pyramidal neurons in the hippocampal formation was obtained. Calmidazolium reduced the injury index to 0.4 ± 0.13 (1 μM; n=13) from 1.83 ± 0.26 (vehicle control; n=30) [p < 0.05; Mann-Whitney U]. There was also dose-dependent protection at lower doses.

The results showed that calmidazolium, a specific inhibitor of CaMKII, suppresses neuronal injury induced by ischemia. These data support the hypothesis that activation of Ca²⁺-calmodulin pathway may play a key role in the development of brain injury produced by ischemic insults.

672.5

N-METHYL-D-ASPARTATE RECEPTORS AND EXTRACELLULAR CALCIUM CHANGES DURING ISCHEMIA IN THE NEWBORN AND ADULT BRAIN IN VIVO. H. Hagberg, P. Andiné*, M. Puka, J. Lazarewicz, R. Gadamski, Institute of Neurobiology, University of Göteborg, 41390 Göteborg, Sweden.

The objectives were to 1. follow extracellular (ec) calcium during complete anoxia in the immature brain after blockade of N-methyl-D-aspartate (NMDA) receptors and 2. compare the calcium changes induced by NMDA in the adult and immature striatum. In the anoxia experiments, ec calcium was measured with ion-sensitive microelectrodes placed into the parietal cortex of 9-11 days old rats before and during 60 min of complete anoxia. One group was treated with MK-801 (0.3 mg/kg) and the other served as control. In the NMDA-experiments, microdialysis probes were placed into the striatum of 8-10 days old and adult rats. Calcium changes, induced by 5 mM of NMDA in the perfusion solution, were monitored with the 45-calcium washout method. In addition, 14C-sucrose was measured as a marker of ec volume. After induction of anoxia e.c. calcium increased from 1.1 ± 0.1 mM to 1.4 ± 0.2 mM in control and to 1.9 ± 0.2 mM in MK-801 treated rats (NS). Thereafter, e.c. calcium decreased to 0.3 mM after 58 ± 2.2 min in the control and after 39 ± 7.5 min in the MK-801 group ($p < 0.05$). NMDA induced a 50% decrease of 45-calcium in the 8-10 days old rats in opposite to a 30% increase followed by a <10% decrease in the adult striatum. Changes in 14C-sucrose were similar in immature and adult rats. In conclusion, ec calcium movements during anoxia were considerably slower in neonatal than in adult rats. The NMDA receptor antagonist, MK-801, delayed the ec decrease of calcium after anoxia. NMDA induced a marked uptake of 45-calcium in 8-10 days old rats which may be important to explain the hypertoxicity of NMDA in the immature striatum.

SYSTEMIC ADMINISTRATION OF A CALPAIN INHIBITOR IS NEUROPROTECTIVE IN A RAT MODEL OF FOCAL CEREBRAL ISCHEMIA. S.C. Hong*, Y. Goto, G. Lanzino, S. Soleau, N.E. Kassell, and K.S. Lee. Dept. of Neurosurgery, Univ. of Virginia, Charlottesville, VA 22908.

Excessive elevation of intracellular calcium, and uncontrolled activation of calcium-sensitive events are believed to play a central role in ischemic neuronal damage. Calcium-activated proteolysis by calpain is a candidate to participate in this form of pathology because it is activated under ischemic conditions and its activation results in the degradation of crucial cytoskeletal and regulatory proteins. The present studies examined the effects of a cell-penetrating inhibitor of calpain on the pathological outcome following transient, focal ischemia in the brain. Rats treated with the calpain inhibitor, Cbz-Val-Phe-H (MDL28170), exhibited significantly smaller volumes of infarction than saline-treated, or vehicle-treated control animals. Intravenous injections of cumulative dosages of 30 mg/kg or 60 mg/kg of Cbz-Val-Phe-H were effective in reducing infarction, while only the higher dosage reduced cerebral edema following ischemia. These results demonstrate the neuroprotective effect of a cell-penetrating calpain inhibitor when administered systemically. The findings suggest that targeting intracellular calcium-activated mechanisms, such as proteolysis, represents a potentially useful therapeutic strategy for limiting neurological damage following ischemia. (Supported by NS30671)

MECHANISMS OF INTRACELLULAR CALCIUM ALTERATIONS DURING ENERGY DEPLETION AND REPERFUSION INJURIES. M.H. Kim-Lee*, B.T. Stokes Dept. of Physiology, The Ohio State University, Columbus, OH 43210.

Fura-2 microspectrofluorometry was used to examine the intracellular calcium ($[Ca^{2+}]_i$) alterations produced by energy depletion or reperfusion injury. The mechanisms by which local anesthetics (lidocaine) are able to alter changes induced by these insults *in vitro* were also investigated. The $[Ca^{2+}]_i$ increase during energy depletion was determined to be mostly from internal calcium stores. Furthermore, intracellular Na^+ played a major role in $[Ca^{2+}]_i$ release from such stores during energy depletion. Addition of lidocaine (0.5 mM) after de-energization effectively blocked $[Ca^{2+}]_i$ increases with normal perfusate calcium but failed to block after calcium removal. This may indicate that lidocaine stimulates forward activity of the surface Na/Ca exchanger. In addition, 0.5 mM lidocaine prevented $[Ca^{2+}]_i$ increases during reverse Na/Ca exchanger activity associated with reperfusion protocols. Therefore, these data support the hypothesis that local anesthetics can alter Na/Ca exchanger activity and suggest that they may be effective in a variety of ischemic and reperfusion-induced cytotoxic insults *in vitro*.

672.6

KINETICS OF CALCIUM AND EXTRACELLULAR RADIOTRACERS IN BRAIN SLICES. F.E. Hospod*, G.C. Newman, H.Qi, C.S. Padiak. Depts. of Neurology and Neurol. Surgery, SUNY at Stony Brook, NY and VAMC at Northport, NY.

In an effort to understand ion and water fluxes in the ischemic penumbra we are studying the movement of ^{45}Ca and several "extracellular" markers, along with water spaces and histology, in 500 μ and 1000 μ hippocampal slices.

Equilibrium measurements of ^{45}Ca indicate that total tissue calcium is linearly dependent on the extracellular calcium concentration between 1 μ M and 4.5 mM when slices are incubated in standard Krebs-Ringer (K-R). 500 μ hippocampal slices incubated for 4 hours in standard K-R gain up to 80% more water than that present *in vivo* with most of the increase prior to 2 hours. The "extracellular" space of slices incubated for 2 hours is 35% when measured with 3H -sucrose or ^{14}C -inulin and 28% when measured with PEG-4000. Sucrose space rises to 45% and PEG space rises to 33% after 4 hours *in vitro*. Lajtha and co-workers (*Brain Res.* 65:265, 1974) have reported that incubation of parietal slices in the presence of 4% PEG-4000 or 80,000 MW dextran prevents this water gain. We have reproduced their results with PEG and also confirm that, despite preventing water gain, there is only minimal change in the "extracellular" space measured with 3H -sucrose or ^{14}C -PEG when PEG is varied from 0 to 4%. Our histology reveals that the CA1 and CA3 regions respond very differently to increasing concentrations of PEG in the buffer, 4% PEG improves the CA3 histology after 4 hours but induces severe pyknosis of CA1 pyramidal neurons and dentate granular cells.

These results are not consistent with a simple two compartment model of homogeneous intracellular and extracellular water spaces. Histology suggests that there is regional heterogeneity within the slice and that PEG should be used in slices only with caution. Further studies with dextran and additional ^{45}Ca kinetics in both thin and thick slices will also be presented.

672.8

KETOAMIDE CALPAIN INHIBITORS PROTECT HIPPOCAMPAL SLICES FROM HYPOXIA. H. Ton, A. Arai, D. Eveleth*, R. Bartus and G. Lynch, Cortex Pharmaceuticals, Inc., Irvine CA, Center for the Neurobiology of Learning and Memory, University of California, Irvine CA, and Alkermes, Inc., Cambridge MA.

Several lines of evidence suggest that the calcium-activated protease calpain might be involved in various types of pathology, in particular ischemia/hypoxia. Previously, we have shown that calpain inhibitors improved the recovery of the synaptic transmission after a brief period of hypoxia in the field CA1 of hippocampal slices. The present experiments sought to examine whether a different class of calpain inhibitors (ketoamide) shows a protective effect against hypoxia-induced acute neuronal dysfunction and also examined the effects of various classes of drugs, such as NMDA receptor antagonists (CPP, MK-801 and dl-AP5), free radical scavengers (D-mannitol, superoxide dismutase together with catalase, PBN) and a PAF receptor antagonist on this system.

In our system, the PAF antagonist was ineffective. Among the free radical scavengers, only the spin adduct PBN caused a significant improvement in the recovery of EPSPs after hypoxia. Protection was provided by the NMDA receptor antagonists CPP (20 μ M) and MK-801 (50 μ M), but not by dl-AP5, even at a concentration of 100 μ M.

Two newly synthesized calpain inhibitors (CX269 and CX275) are more potent and selective than those reported previously ($K_i = 2$ μ M for CX269; $K_i = 37$ μ M for CX275 against purified human calpain). Both drugs at 20 μ M showed significant effects on the recovery of synaptic transmission after hypoxia. This protection appears not to be due to a drug action on NMDA receptors. These results give further support to the idea that activation of calpain is involved in acute pathophysiology caused by hypoxia.

672.10

EARLY ANOXIA-INDUCED VESICULAR GLUTAMATE RELEASE RESULTS FROM MOBILIZATION OF CALCIUM FROM INTRACELLULAR STORES. N. Herschkowitz, K.L. Kelner* and A.N. Katchman, Georgetown University Medical Center, Dept. Neurol., Washington, DC 20007.

Glutamate release is thought to contribute to cell injury during anoxia of the brain. An understanding of mechanisms by which this release occurs may assist in the development of effective therapeutic agents. Whole-cell patch clamp recordings (K gluconate electrodes) were made in CA1 neurons of hippocampal slices in the presence of 1 μ M of tetrodotoxin using an interface chamber. Anoxia was induced by switching perfusion and ambient gas from a 95%O₂/5%CO₂ to a 95%N₂/5%CO₂ mixture. Transient inward currents, representing miniature excitatory postsynaptic currents (mEPSCs), are observed under control normoxia conditions. Following the onset of anoxia a significant (paired t test; $P < 0.05$), 3.17-fold increase in the mEPSCs frequency is observed ($n = 9$). The kinetics of the mEPSCs (i.e. amplitude, rise time and half decay time) did not significantly change following anoxia. In calcium-free extracellular medium, 8 cells still exhibited a significant 3.37-fold increase in the frequency of mEPSCs; in calcium-free extracellular medium plus 0.2 mM CdCl₂, 11 cells showed a significant 3.38-fold increase. In contrast, in cells preincubated in 20 μ M of dantrolene ($n = 20$) or 10 mM of caffeine ($n = 11$), agents which can inhibit release or deplete calcium from intracellular stores, there was no significant anoxia-induced increase in mEPSC frequency (1.20- and 1.44-fold). Thus, a component of the early glutamate release after anoxia results from calcium mobilization from intracellular stores. The absence of changes in the kinetics of the mEPSCs following anoxia supports a presynaptic locus to the early anoxia-induced synaptic depression of the orthodromically elicited EPSC. (Supported by NINDS grant NS 14600-02).

CALCIUM CHANNEL ACTIVATION DURING SPREADING DEPRESSION IN NORMAL RATS. Osuga S, Osuga H, Hakim AM, Hogan MJ. Institute of Neuroscience and Molecular Genetics, University of Ottawa, Ottawa, CANADA K1H 8M5.

We have used *in vivo* binding of the L-type voltage sensitive calcium channel (VSCC) antagonist [³H]nimodipine to identify calcium channel activation during repeated spreading depression in normal rats. In cerebral ischemia we have previously demonstrated increased *in vivo* [³H]nimodipine binding to be specific to the L-type VSCC and to be a sensitive indicator of impending injury. We undertook these studies to assess [³H]nimodipine binding in a non ischemic model of cell membrane depolarization. Male 250g Sprague Dawley rats were anesthetized with Halothane and a 300 μ m diameter microdialysis probe was inserted stereotactically 2 mm into the right occipital cortex. Repetitive waves of spreading depression (every 7 to 12 minutes) were induced by instilling 20 μ l of 3M KCl. After 1 hour [³H]nimodipine was infused intravenously (250 μ Ci, 130 Ci/mmol) and circulated for 15 minutes. The rats were then decapitated, brains removed, frozen and sectioned for autoradiography. [³H]nimodipine binding was determined in both hemispheres and was observed to be increased by 20% in the dorsal aspect of the frontal and parietal cortex, remote from the site of KCl application, on the side of spreading depression ($p < 0.025$, $n = 4$). We hypothesize that increased nimodipine binding in spreading depression is the result of L-type VSCC activation. This observation may be relevant to studies on the pathophysiology of cerebral ischemia where recurrent spreading depression has been reported to result in increased ischemic injury.

IMMUNOLocalIZATION OF SPECTRIN DEGRADATION IN VULNERABLE REGIONS OF ISCHEMIC GERBIL BRAIN. L.M. Roberts-Lewis*, M. I. Savage, V. R. Marcy, L. R. Pinsky and R. Siman Cephalon, Inc., West Chester, PA 19380

The calcium-activated cysteine protease calpain I (μ -calpain) has been suggested to play a vital role in the mechanisms underlying ischemia-induced, calcium-mediated neuronal degeneration. Several studies have linked the pathological induction of calpain-mediated spectrin proteolysis to neuronal death. Using an antibody selective for calpain-generated spectrin breakdown products, we have examined the time course and localization of calpain activation in the gerbil brain following transient global ischemia. Immunoreactivity for spectrin breakdown products was present in the hippocampus as early as 30 minutes following a five minute occlusion of the carotid arteries. This effect was maximal in the CA1 region of the hippocampus at two days, and essentially absent by 5 days following ischemia. Intense immunoreactivity was neuron-specific, and present in both perikarya and dendrites. In contrast, spectrin degradation was also present in the cortex, striatum and thalamus at 30 minutes following a 5-minute insult, but virtually absent in these regions by two days post-ischemia. Silver impregnation histochemistry confirmed that only neurons in areas exhibiting prolonged calpain activation degenerated. Treatment of gerbils with the non-competitive NMDA antagonist, MK-801, substantially reduced staining for spectrin breakdown products in all brain regions. Together, these results suggest that ischemia triggers NMDA receptor-mediated calpain activation in several regions of the brain within at least 30 minutes following a modest ischemic insult; however, only those neurons showing sustained calpain activation are destined to die.

ISCHEMIA: DRUG TREATMENT I

673.1

ACADESINE REDUCES INDIUM LABELED PLATELET DEPOSITION IN RAT BRAIN FOLLOWING PHOTOTHROMBOSIS OF THE COMMON CAROTID ARTERY. L.P. Miller*, W.D. Dietrich, R. Prado, M.K. Dewanjee, & H. Gruber. Gensia Pharm, San Diego, CA 92121 and Univ. Miami Sch. of Med., Miami, FL 33101.

Adenosine regulating agents (ARAs) are a class of compounds designed to enhance the beneficial effects of adenosine (Adn) in an event and site-specific manner. Acaesine (ACA)(5-amino-1- β -D-ribofuranosyl-imidazole-4-carboxamide), a prototypical ARA, has cardioprotective effects in animal models and reduces the incidence of myocardial infarction and stroke following bypass surgery. The present study was designed to determine whether the beneficial effects of ACA could be observed in a model of photothrombotic stroke. Rats were anesthetized with halothane and preloaded with indium 111-tropolone labeled platelets 30 min prior to common carotid artery (CCA) thrombosis induced by a rose bengal-mediated photochemical insult. Intravenous infusion of ACA ($n = 10$) at 0.5, 1, 2 mg/kg/min or vehicle was begun 30 min prior to CCA thrombosis and continued for an additional 15 min. Animals were then sacrificed and brains processed for autoradiographic visualization of labeled platelets. The ratio of right-to-left CCA radioactivity was not affected by ACA administration. However, ACA at 1 and 2 mg/kg/min significantly decreased ($p < 0.01$) platelet deposition within the ipsilateral cerebral cortex, hippocampus and striatum. These results support a prophylactic role for ACA in reducing the deposition of platelet emboli in brain during periods of acute thrombus formation.

673.3

FLUNARIZINE FAILS TO REDUCE INFARCT VOLUME IN A NOVEL MODEL OF FOCAL ISCHAEMIA IN THE MARMOSET A.J. Hunter*, N.A. Milkowski, N.I. Wood, S. Patel, and A.L. Rothau SB Pharmaceuticals, Coldharbour Road, The Pinnacles, Harlow, Essex, CM19 5AD, UK.

We have used a light sensitive dye to produce a novel, minimally invasive, model of primate focal ischaemia. Flunarizine, a T-type calcium antagonist, has been claimed to reduce photothrombotic lesions in rodents (van Reempts et al, 1987, Stroke 18: 1113-9); therefore we have tested this compound in our primate model. Common marmosets (*C. jacchus*) weighing 300-450 gms were anaesthetised with Saffan and placed in a stereotaxic frame. Rose bengal dye (20 mg/kg⁻¹) was infused via the tail vein at the same time as bilateral illumination of the exposed anterior skull surface. Flunarizine (1 or 10 mg/kg⁻¹) or 0.9% saline was given i.p. 30 minutes post ischaemia and b.i.d. for 3 days. Animals were euthanased at 7 days post surgery and serial transverse sections taken. The lesion volumes were similar in both hemispheres in all groups eg saline left side = 50.9 \pm 3.7, right = 50.4 \pm 4.1 mm³. Treatment with flunarizine failed to reduce lesion size eg left side 1 mg/kg⁻¹ = 53.2 \pm 2.4; 10 mg/kg⁻¹ = 55.6 \pm 3.7 mm³. We conclude that post ischaemia dosing of flunarizine is ineffective in this primate focal ischaemia model.

673.2

EFFECTS OF PERIPHERAL IL-1RA TREATMENT AFTER FOCAL CEREBRAL ISCHAEMIA IN THE RAT. J.K. Relton, D. Martin* and D. Russell. Preclinical Pharmacology, Syngene, 1885 33rd St. Boulder, CO80301.

The objective of these experiments was to determine the effect of peripherally administered recombinant human interleukin-1 receptor antagonist (rhIL-1ra) on infarct size and cerebral oedema formation after focal cerebral ischaemia in the rat. Ischaemia was induced by permanent unilateral occlusion of the left middle cerebral artery (MCAo) under isoflurane anaesthesia (2% in O₂). The histological assessment of neuronal damage was performed on tetrazolium stained 500 μ m coronal brain sections and tissue H₂O composition (as an index of cerebral oedema formation) determined by wet and dry weight measurements. Animals were injected (iv and sc) immediately after MCAo (0h) with either vehicle (0.25-0.5ml) or rhIL-1ra (10mg/kg, 50mg/kg or 100mg/kg) followed by further injections (sc) 4, 8, 12 and 18h after MCAo. All animals were sacrificed after 24h to assess brain damage. Treatment with IL-1ra (100mg/kg) significantly reduced infarct size by 48% compared to vehicle-treated control rats (76.17 \pm 12.06mm², $n = 16$ vs 39.96 \pm 8.68mm², $n = 12$, $P < 0.05$ Mann Whitney U-test). Lower doses of IL-1ra (50mg/kg and 10mg/kg) had no significant effect on infarct size compared to controls. Cerebral oedema was significantly reduced by 36% and 33% in 100mg/kg and 50mg/kg IL-1ra-treated rats respectively (left-right hemisphere %H₂O: 100mg/kg; 1.69 \pm 0.25%, $n = 14$ vs 1.08 \pm 0.1%, $n = 14$, $P < 0.05$ one way ANOVA with Tukey's post hoc test; 50mg/kg; 2.39 \pm 0.23%, $n = 10$ vs 1.58 \pm 0.15%, $n = 10$, $P < 0.01$ one way ANOVA with Tukey's post hoc test). A dose of 10mg/kg IL-1ra had no discernible effect on cerebral oedema 24h after MCAo. These data indicate that IL-1ra may be of considerable therapeutic benefit in the treatment of stroke.

673.4

PROTECTIVE EFFECTS OF U-92032, A NOVEL T-TYPE CALCIUM CHANNEL BLOCKER, ON CEREBRAL ISCHEMIC INJURY. S.Y. Liou*, M. Takahashi, H. Takagi, M. Takashima, C. Itoh, W.B. IMM and M. Kuniyara. Upjohn Pharmaceuticals Limited, Tsukuba Research Laboratories, Wadai 23, Tsukuba 300-42, Japan.

U-92032, (7-[[4-bis(4-Fluorophenyl)methyl]-1-piperazinyl]methyl]-2-[(2-hydroxyethyl)amino]4-(1-methylethyl)-2,4,6-cycloheptatrien-1-one) proved to be a selective T-type calcium channel blocker using the whole-cell version of the patch-clamp technique. We also investigated the anti-ischemic and anoxic effects of U-92032 in a number of models in rodents. In *in vitro* hypoxia injury, U-92032 at 3x10⁻⁶ M had protective action against functional failure of CA1 neuron in hippocampal slice after 10 min hypoxia/hypoglycemia. In KCN anoxia, U-92032 at a dose of 10 mg/kg, i.v. or 100 mg/kg, p.o. prevented lethality in mice. In stroke model in gerbils, U-92032 at 10 mg/kg, p.o. reduced stroke index induced by unilateral ligation of the carotid artery. Following transient global ischemia, U-92032 had protective action against delayed neuronal death in hippocampus and improved impairment of passive avoidance performance. In addition, unlike dihydropyridine Ca channel blockers (nifedipine and nicardipine), U-92032 potentially blocked ⁴⁵Ca uptake evoked by glutamate and hypoxia in the hippocampal brain slice preparation. These results suggest that the selective T-type Ca channel blocking effect of U-92032 might contribute to its cerebroprotective efficacy in these cerebral ischemic models.

SNX-111 REDUCES NEOCORTICAL INFARCTION DESPITE INTRA- AND POST-ISCHEMIC HYPOTENSION FOLLOWING FOCAL ISCHEMIA. **D. Xue***, Z.G. Huang, K. Barnes, H. Lesiuk, K.E. Smith and A.M. Buchan. Ottawa Civic Hospital, Ottawa, Ontario, Canada K1Y 4E9, from the *Canada/Fisons Fight Stroke* program.

The potent N-type calcium channel blocker, SNX-111 (NEUREX Corp.), was used to see if it would reduce cortical infarction in focal stroke. Adult male spontaneously hypertensive rats (n=18) had permanent occlusion of the right common carotid artery and transient occlusion of the right middle cerebral artery (2 hr), followed by 22 hr reperfusion. To mimic the further reduction in cerebral blood flow that may follow the hypotensive actions of SNX-111 (and to replicate the resulting ischemic insult), a second group of control rats were subjected to additional transient occlusion (4 hr) of the left carotid artery (LCCAO). Rats were given saline or SNX-111 (5 mg/kg) injected 1 hr after the onset of ischemia. Regional cerebral blood flow was monitored. The volume of cortical infarction was then quantified with frozen-sectioned brain slices.

Group (n)	Cortical Infarction (mm ³ ±SD)
Saline (6)	211 ± 51
Saline + LCCAO (6)	271 ± 35
SNX-111 (6)	141 ± 49*

*p<0.001 vs. saline + LCCAO group (ANOVA)

Despite the hypotensive effect of SNX-111, which may further compromise intra- and post-ischemic cerebral blood flow, a 33% reduction in mean cortical infarction was demonstrated in the treatment group compared with the saline control group. Striking protection (48%) was shown in the SNX-111-treated animals compared with control animals with cerebral blood flow depressed to comparable levels to that seen with SNX-111 treatment.

(The authors thank the NEUREX Corporation for providing SNX-111).

AUTORADIOGRAPHIC ANALYSIS OF [¹²⁵I]OMEGA-CONOTOXIN BINDING IN CANINE CORTEX AND HIPPOCAMPUS FOLLOWING GLOBAL CEREBRAL ISCHEMIA / REPERFUSION. **D.C. Perry***, E. Sidel, R.E. Rosenthal and G. Fiskum. Depts. of Pharmacology, Biochemistry and Molecular Biology, and Emergency Medicine, George Washington University Medical Center, Washington, D.C. 20037.

Changes in Ca²⁺ flux may contribute to selective neuronal damage occurring after cerebral ischemia. We used [¹²⁵I]ω-conotoxin to look for changes in N-type VDCC in selected regions in ischemic brain. Canines were divided into one of five groups: non-arrested controls; complete global ischemia induced by 10 min cardiac arrest (CA); or CA followed by 30 min, 2 hr or 24 hr restoration of spontaneous circulation (ROSC). Frozen sections from parietal and temporal cortex and hippocampus were incubated with 0.5 nM [¹²⁵I]ω-conotoxin, ± 1 μM unlabeled peptide to define specific binding. Sections were exposed to film and resultant images analyzed by computerized densitometry. No effect of cerebral ischemia on binding was seen after CA or early time points after ROSC, but at 24 hr after ROSC, binding over the outer laminae was increased by 43% in the parietal cortex. This binding increase was not apparent over inner laminae or in temporal cortex. In contrast, hippocampal binding over strata radiatum and oriens was sharply decreased after CA and even more at short times after ROSC (up to 70%), but largely recovered by 24 hr. This effect was seen in CA1 and dentate gyrus molecular layer, but not CA3. We are currently examining whether other calcium channels, both voltage- and receptor-activated, show parallel alterations post-ischemia. Supported by Sigma Tau, S.p.A. and the Souers Stroke Fund.

CYCLOTHIAZIDE POTENTIATES AMPA NEUROTOXICITY AND OXYGEN-GLUCOSE DEPRIVATION INJURY IN CORTICAL CULTURE. **M.C. Bateman***, M.R. Bagwe, K.A. Yamada, and M.P. Goldberg. Center for the Study of Nervous System Injury, Dept. of Neurology, Washington Univ. School of Med., St. Louis MO 63110.

Rapid desensitization may limit the contribution of AMPA/kainate (A/K) receptors to glutamate neurotoxicity. The benzothiadiazide compound, cyclothiazide (CYC) prevents desensitization of AMPA responses and potentiates hippocampal glutamate toxicity (Yamada et al, Soc. Neurosci. Abs. 18:757, 1992; Moudy et al., *ibid*). We examined the effects of CYC on excitotoxic injury in murine neocortical cultures (15-17 days *in vitro*). 10-100 μM CYC markedly potentiated [Ca²⁺]_i elevation induced by AMPA or kainate application on both neurons and glia, assessed by fura-2 fluorescence ratio imaging. Furthermore, CYC (30 μM) significantly increased neuronal injury during 24 hr exposure to AMPA or kainate and had no effect on NMDA toxicity. CYC-enhanced neurotoxicity of AMPA could be blocked by A/K antagonists CNQX or GYKI 52466.

Neuronal injury produced by deprivation of oxygen and glucose (45-60 min) was enhanced by addition of 10-100 μM CYC (Neurology 43:A339, 1993). In the absence of CYC, neuronal injury could be blocked by NMDA antagonists but not by A/K antagonists alone. In contrast, the enhanced neuronal loss produced by oxygen-glucose deprivation in the presence of CYC could be blocked by CNQX. This CYC-enhanced neuronal injury occurred even with the addition of MK-801. These observations suggest that AMPA receptor desensitization may limit calcium entry and alter glutamate receptor pharmacology of hypoxic-ischemic cerebral injury.

MARKEDLY DELAYED TREATMENT WITH SNX-111, AN N-TYPE CALCIUM CHANNEL BLOCKER, PREVENTS THE DEATH OF HIPPOCAMPAL CA1 NEURONS FOLLOWING GLOBAL ISCHEMIA. **A. Buchan**, H. Li, K. Barnes, K.E. Smith* and H. Lesiuk. Neuroscience, Loeb Research Institute, Ottawa Civic Hospital, Ottawa, Ontario, Canada K1Y 4E9, from the *Canada/Fisons Fight Stroke* program.

SNX-111 (NEUREX Corp.), a potent N-type calcium channel antagonist, was tested following ischemia using a 4-vessel occlusion model of severe global (forebrain) ischemia which reliably induces hippocampal CA1 necrosis. Adult male Wistar rats (n=22) were subjected to 10 min of forebrain ischemia and seven days of reperfusion. A single dose of SNX-111 (5 mg/kg) was injected either at 6 or at 24 hr post-ischemia. Damaged CA1 neurons of the dorsal hippocampus in surviving animals (n=22) were counted and the percentage of injured cells calculated.

Group (n)	% CA1 Injury (Mean ±SD)
Saline (9)	77 ± 14
SNX-111 (13)	
delayed 6 hr (6)	36 ± 28*
delayed 24 hr (7)	44 ± 31*

* p < 0.001 Mann-Whitney U test with Bonferroni correction

Twenty-four hours after ischemia, CA1 cells could still be resuscitated with SNX-111. This suggests that calcium fluxes 24 hours after ischemia are critically involved in the pathogenesis (and reversibility) of selective neuronal death. (The authors thank the NEUREX Corporation for providing SNX-111).

HEMODILUTION WITH DIASPIRIN CROSS-LINKED HEMOGLOBIN (DCLHb) REDUCES NEUROLOGICAL DAMAGE FOLLOWING REVERSIBLE BUT NOT IRREVERSIBLE CNS ISCHEMIA IN RABBITS. **M.P. Bowes**, J.A. Zivin*, and K.E. Burhop. Univ. California San Diego, Dept. of Neurosciences, La Jolla, CA 92093-0624 and Baxter Healthcare Corp. Blood Substitutes, Round Lake, IL, 60073.

Hemodilution using hemoglobin (Hb) solutions may reduce ischemic or hemorrhagic injury. Cell-free Hb may be intramolecularly cross-linked, enhancing O₂ offloading to tissues and increasing intravascular retention time without systemic side effects. We evaluated the ability of purified diaspirin cross-linked hemoglobin (DCLHb) to reduce neurological damage in two rabbit CNS ischemia models. Reversible spinal cord ischemia [Zivin et al., Arch. Neurol. 39: 408-412, 1982] was produced by temporary occlusion of the abdominal aorta. DCLHb was infused (1 ml/min; .1 g Hb/ml) 5 min after ischemia as either a 10 ml/kg infusion, 10 ml/kg exchange transfusion, or a 20 ml/kg infusion. Control animals received 20 ml/kg oncologically matched human serum albumin (HSA). Neurological status was evaluated 18 hr and 4 days following ischemia/reperfusion. Neurological outcome was significantly improved in the 10 ml/kg exchange transfusion and 20 ml/kg conditions, compared to HSA-treated controls. In an irreversible model of cerebral ischemia, rabbits were embolized with 50 μM plastic microspheres injected into the carotid circulation [Zivin et al., Brain Res. 435: 305-309, 1987]. DCLHb (20 ml/kg, 5 min post ischemia) did not significantly reduce neurological damage in this model. These data suggest that cross-linked hemoglobin may improve neurological outcome in reversible but not irreversible ischemia, and this is not attributable only to hemodilution or hypervolemia.

EFFECTS OF NEUROTROPHIN-4/5 TREATMENT ON INFARCTION VOLUME INDUCED BY FOCAL CEREBRAL ISCHEMIA IN THE ADULT RAT. **K.M. Chan***, H.R. Widmer and F. Hefti. Andrus Gerontology Center, Univ. of Southern California, Los Angeles, CA 90089-0191.

We are studying the effects of neurotrophin-4/5 (NT-4/5) treatment on a rat model of focal cerebral ischemia induced by intraluminal occlusion of the middle cerebral artery (MCA).
