One day prior to MCA occlusion, a cannula was implanted into the right lateral ventricle of each young adult (2-month old) rat. A dose of 0.87 μg of either NT-4/5 or a control protein (cytochrome c, cc) was administered immediately following cannula implantation. Twenty-four hours later, focal cerebral ischemia was induced by permanent ligation of the right common carotid artery and the intraluminal occlusion of the right MCA by a piece of 3-0 nylon suture thread. The same dose of NT-4/5 or cc was administered immediately following the procedure. Normal body temperature was monitored by a digital thermometer and maintained by a warming blanket. The animals were sacrificed after a survival period of twenty-four hours and 30 μm thick coronal sections of the perfusion-fixed brains were stained with cresyl violet. The areas of infarction were determined by computer-aided image analysis and the volume of infarction estimated from at least eight coronal levels.

While the volumes of infarction of the cc-treated animals were relatively consistent (n=4), four out of six of the NT-4/5-treated animals showed significant reduction of the infarct volumes. We are presently performing more surgeries to substantiate this preliminary finding.

673.11

PROTECTIVE EFFECTS OF bFGF AGAINST NEURONAL DAMAGES IN *IN VITRO* AND *IN VIVO*. Y. Morita*, N. Murayama, T. Inoue, R. Ogino and T. Ohno, Lab. of Exp. Pharmacol., SUNTORY Inst. for Biomed. Res., Osaka 618, JAPAN

Neuroprotective effects of bFGF was examined in the damaged brains with temporal ischemia and in primary neurons cultured under different experimental conditions. Male Wistar rats received a surgery of 60-min unilateral middle cerebral artery occlusion (MCAO). bFGF (25 μ g, i.c.v., [1 μ g/ μ l]) was administered 24 hr prior to MCAO, and the brains were treated according to a TTC protocol and measured volumetrically. Primary neurons from the neocortex, hippocampus and striatum of rat fetuses (E 18) were cultured in DMEM containing 10% serum. bFGF was applied at the concentrations of 5, 10 or 25 ng/ml 36 hr after plating. The types of injuries applied were glutamatergicity, hypoglycemia and hypoxia. The expression of FLG/FGF receptor was detected immunocytochemically in the brains and primary neurons.

Postoperative 48 hr after MCAO, brains were less damaged in the bFGF-treated rats compared to the control rats. The infarcted tissue-volume per the examined brain region in the bFGF-treated rats was $7.73\% \pm 1.09$ (n=19) (p<0.001), while that of the control rats $27.74\% \pm 2.08$ (n=15). Primary cultured neurons from 3 brain regions were protected from damages of glutamatergicity, hypoglycemia, and hypoxia at either 5, 10 or 25 ng/ml of bFGF. Those neurons expressed immunoreactive FLG/FGF receptor as early as 36 hr after plating.

It suggests that FGF receptor-mediated cellular events and gene regulation are involved in the neuroprotective effects of bFGF, because such protection of bFGF are eliminated when either transcription or translation is suppressed.

COCAINE EXACERBATES THE OUTCOME OF GLOBAL BRAIN ISCHEMIA. B. Lin*, W.D. Dietrich, R. Busto, S. Kraydieh, M.Y.-T. Globus, and M.D. Ginsberg. CVD Research Center, Univ. of Miami, Sch. of Med., Miami, FL, 33101.

To investigate whether acute cocaine would affect the outcome of global cerebral ischemia, fasted halothane-anesthetized rats received 10 min global forebrain ischemia by bilateral carotid artery occlusion plus hypotension (50 mm Hg). Brain temperature was maintained at 36.5-37°C. Cocaine, 2 mg/kg or 10 mg/kg was injected i.p. 20 min prior to ischemia. Control rats received water. Ischemic cell change (ICC) was assessed blindly at 3 days following the insult. Seven of 10 rats with 10 mg/kg cocaine, but no control rats, showed damage to hippocampal sector CA3 (p=0.0015, Fisher exact test); 5/10 cocaine rats (but no controls) showed injury to medial geniculate body (p=0.016), and 2 of 10 cocaine rats displayed subarachnoid hemorrhage. By contrast, injury to hippocampal CA1 sector, striatum, and neocortex were unaffected by cocaine. The 2 mg/kg cocaine dose did not accentuate ischemic injury. After i.p. cocaine, blood pressure increased 20-40 mm Hg for approx. 10 min in the 2 mg/kg series and decreased 20-40 mm Hg in the 10 mg/kg group but returned to normal prior to ischemia. Our findings suggest that high-dose cocaine adversely affects the outcome of normothermic global ischemia.

673.15

EXPERIMENTAL CEREBRAL ISCHEMIA IN MONGOLIAN GERBILS: EFFECTS OF JO 1784 ON HISTOLOGICAL PARAMETERS AND LOCOMOTOR ACTIVITY.

B. Earley*, M. Canney¹, M. O'Neill¹, B.E. Leonard¹, C. Benicourt² and J.-L. Junien¹, Pharmacology Department¹, University College, Galway, Ireland and Institut de Recherche Jouveinal², 94265, Fresnes, France.

In mongolian gerbils, 5 minutes of bilateral carotid occlusion (BCO) followed by reperfusion, causes forebrain ischemia, glutamate release and permanent brain injury to the hippocampus after a 24 hours window of vulnerability. During this period, use of NMDA receptor antagonists or blockers of the NMDA-regulated calcium channels, markedly reduces the extent of brain damage evaluated histologically one week later.

The purpose of the present series of experiments was to:

- 1) To determine the extent of hippocampal damage in gerbils following 5 min bilateral carotid occlusion.
- 2) Based upon the possibility that sigma ligands might modulate the NMDA receptor, JO 1784 (25, 50, 75 and 100 mg/kg p.o.) a sigma ligand was tested for its ability to reduce brain damage in the gerbil model. MK-801 (2.5 mg/kg i.p.) used as a standard neuroprotective agent, was administered 1 hour after the occlusion and JO 1784 at 1, 24, 48 and 72 hours after occlusion. Locomotor activity was used as an index of hippocampal damage.

In the first study, results showed that, following bilateral carotid occlusion, ischemia induced degeneration was observed with the cresyl violet stain after 72 hours and was maximal 96 hours post-occlusion. The damage was marked along the entire CA1 pyramidal cell layer of the hippocampus. In the second study, JO 1784 provided some degree of neuroprotection as assessed by histological examination, but locomotor activity was unchanged. MK-801 (2.5 mg/kg i.p.) produced significant protection and attenuated the hyperactivity induced by BCO. JO 1784 may be a useful ligand for minimizing brain hippocampal injury due to ischemia.

673.12

THE NEUROPROTECTIVE EFFECTS OF DEXMETETOMIDINE IN THE GERBIL HIPPOCAMPUS FOLLOWING TRANSIENT ISCHEMIA. J. Stivenius*, J. Kuhmonen and P. Riekkinen Sr. Univ. of Kuopio, Dept. of Neurology, P.O.B. 1627, SF-70211 Kuopio, Finland.

Excessive neuronal activity with an increased release of excitatory neurotransmitter glutamate is supposed to contribute to the delayed neuronal degeneration in animal models of transient cerebral ischemia. Since evidence is accumulating that agonizing of α -2-adrenergic receptors might depress glutamate release, the neuroprotective effects of dexmedetomidine, an α -2-adrenergic agonist, were investigated in a gerbil transient cerebral ischemia model, involving bilateral carotid occlusion of 5 min in ether inhaled normothermic animals. Dexmedetomidine (3 or 30 μ g/kg) was administered s.c. 30 min before and 3, 12, 24 and 48 h after occlusion; or the same doses only 3, 12, 24 and 48 h after occlusion. Control animals were subjected to cerebral ischemia without medication. After one week the animals were killed and brains fixed by transcardiac perfusion. Dorsal hippocampus was sectioned coronally into 60 μ m thick slices which were stained with silver. Delayed neuronal death of sector CA1 pyramidal cells was evaluated and the data was analyzed by Mann-Whitney U-test. The dose of 3 μ g/kg before and after ischemic insult decreased neuronal loss (p<0.05). We conclude that dexmedetomidine, an α -2-adrenergic agonist, is neuroprotective in this gerbil transient cerebral ischemia model.

673.14

EFFECT OF ACETYL-L-CARNITINE ON THE RECOVERY OF BRAIN ENERGY METABOLISM AND LACTIC ACID LEVELS FOLLOWING TRANSIENT FOREBRAIN ISCHEMIA IN THE RAT. A ³¹P AND ¹H NMR SPECTROSCOPY STUDY. T. Aureli, M.E. Di Cocco, O. Ghirardi, M. Vertechy, A. Giuliani, M.T. Ramacci, M. Calvani¹, E. Conti¹. Inst. for Res. on Senescence Sigma Tau, 00040 Pomezia, Italy; ¹ Dept. Chemistry, "La Sapienza" Univ. of Rome, Italy

The four-vessel occlusion (4-VO) model of transient ischemia in the rat produces a histological damage profile similar to that observed in man after total ischemia following a cardiac arrest. This coincident pathophysiology of ischemic brain damage suggested that 4-VO model can be very useful for the evaluation of a neuroprotective efficacy of novel compounds after global ischemia. Acetyl-L-Carnitine (ALCAR) is a molecule recently shown to exert a beneficial effect on brain energy and phospholipid metabolism in both adult and aged rats. In the present study, we tested by NMR spectroscopy the effectiveness of post-ischemic administration of ALCAR on the recovery of brain high-energy phosphates (i.e., phosphocreatine, ATP) and lactic acid levels following a 20-min global ischemia in Fischer 344-adult rats. Ischemia produced a remarkable change in all the measured parameters involved in energy metabolism, especially in the levels of lactic acid and inorganic phosphate. ALCAR was demonstrated to exert a significant effect on the recovery of energy phosphate levels and of brain lactic acid content. Principal component analysis of data at 2, 24, and 48 hours after reperfusion, indicated a significant ALCAR effect on brain energy metabolism as a whole. These results indicate that when administered immediately after ischemic insult, ALCAR exerted a significantly protective effect on ischemia-induced brain damage; in addition, ALCAR enhanced brain energy metabolism during reperfusion so as to ameliorate the overall activation of cellular recovery mechanisms.

673.16

POST-ISCHEMIC ADMINISTRATION OF ANIRACETAM AUGMENTS NEURONAL DAMAGE. A.K. Vinter, C.T. Nielsen, P. Jakobsen, L. Nordholm, H. Laursen, and A.J. Hansen*. Novo Nordisk A/S, Pharmaceuticals Division, Novo Nordisk Park, DK-2760 Måløv, Denmark, and Institute of Neuropathology, University of Copenhagen, DK-2100 Copenhagen, Denmark.

Compounds which block AMPA receptors have been repeatedly shown to ameliorate neuronal damage in the wake of cerebral ischemia. Stimulation of AMPA receptors by glutamate is coupled to a brief opening of an ion channel which gates an inward current. Prolongation of the channel opening is achieved by compounds which inhibit the rapid desensitization of the receptor. If AMPA receptor activation is the cause of neuronal damage, we would expect an aggravation of the damage when the desensitization is inhibited. Rats were exposed to 10 min of global ischemia (neck-cuff inflation and hypotension). One group (n=24) received aniracetam (75 mg/kg) 15 and 45 min after ischemia, another (n=18) was given the vehicle. Seven days later, histological sections of the hippocampus CA1 region were evaluated for dead (eosinophilic), normal pyramidal nerve cells and for glial cells. The aniracetam-treated animals had significantly fewer normal nerve cells and more glial cells, whereas the number of eosinophilic nerve cells was insignificantly increased. We concluded that aniracetam - hence augmentation of the AMPA-mediated transmission in the immediate post-ischemic period - aggravates neuronal damage after ischemia

673.17

CURATIVE EFFECT OF PIRIBEDIL, A D2 DOPAMINERGIC AGONIST, IN GERBIL CEREBRAL ISCHEMIA.

G. Delbarre*, B. Delbarre, C. Rochat and F. Calinon, F. de Médecine, 37032 Tours, Euthérapie, Neuilly sur seine, FRANCE.

Gerbil model of brain ischemia has been widely used to assess pharmacological protection from cerebral damage because of its incomplete circle of Willis in 40 to 60%. 120 gerbils (60 males and 60 females), 8 to 10 months old, were subjected to left carotid occlusion during 60 minutes. They were selected according to Delbarre method (Delbarre, G., *Stroke*, 19: 26, 1988). Piribedil, (5 and 2.5 mg.kg⁻¹, i.p.) was administered 30 or 60 min. after reperfusion. Neurological signs were evaluated as Stroke Index (SI) from 4h to 15 days after release of the clip. In acute curative treatment, Piribedil (5 mg.kg⁻¹), did not modify the SI versus the placebo group, while at the dose of 2,5 mg.kg⁻¹ i.p., 60 min. after reperfusion significantly improved the SI from 72h until 15 days after release of the clip and 30 min. significantly improved the SI from 24h to 72h and from 8 days to 10 days.

	4h	24h	48h	72h	96h	8 days	10 days	15 days
60 min.	Percentage of modifications versus control.

ENDOTHELIN-1 INDUCED MIDDLE CEREBRAL ARTERY OCCLUSION: PATHOLOGICAL CONSEQUENCES AND NEUROPROTECTIVE EFFECTS OF MK-801. J. Sharkey, S.P. Butcher* and J.S. Kelly. Fujisawa Institute of Neuroscience, and Department of Pharmacology, University of Edinburgh, Edinburgh, UK.

In the present study we utilise the potent vasoconstrictor properties of endothelin-1 (Et-1) in a model of middle cerebral artery (MCA) occlusion in the pentobarbital anaesthetized rat. We evaluate the reproducibility of the model and examine the neuroprotective efficacy of the potent anti-ischaemic agent, MK801.

Adult male SD rats received MK801 (5mg/kg, n=7) or saline vehicle (n=7) 30 mins prior to the microinjection of Et-1 (60pmols in 3µl) via a 31-g cannula stereotaxically positioned 0.5mm above the MCA (AP=-0.2mm; L=5.9; V=8.5). Three days after treatment, rats were perfusion fixed, the brain removed and immersed in fixative prior to cryostat sectioning and histological staining. Sections at 8 predetermined levels were examined by light microscopy and the volume of infarction calculated.

Following administration of Et-1, saline pretreated rats exhibited a similar pattern of ischaemic damage to that previously reported following permanent occlusion of the rat middle cerebral artery (1). This pattern was characterised by a large volume of infarction in dorsal and lateral neocortex (98 ± 12mm³) and in striatum (32 ± 3mm³) ipsilateral to the insult. Power analysis predicted a group size of 7 would be required for a 50% reduction in ischaemic damage to be recorded as statistically significant at the 5% level. Pretreatment with MK801 resulted in significant reductions (by 51%; p=0.026) in cortical tissue damage but did not significantly alter either the pattern or the volume (33 ± 4mm³; p=0.95) in the striatum.

The present studies show that perivascular microinjections of Endothelin-1 around the rat MCA results in a reproducible pattern of focal cerebral infarction similar to that produced by permanent occlusion of the artery and that the volume of infarction can be significantly reduced by the potent NMDA receptor antagonist MK801.

NMDA RECEPTOR INDEPENDENT REDUCTION OF PROTEIN SYNTHESIS BY MK-801 MAY BE MEDIATED BY ALPHA2 ADRENERGIC RECEPTORS. F. Dessi, Y. Ben-Ari, MP Junier* and C. Charriaut-Marlangue. INSERM U29, 123 Bld de Port-Royal, 75014 Paris, France.

MK-801 has been extensively utilised as a selective non competitive NMDA channel blocker. MK-801 is also a potent anti ischemic agent in several animal models and is as such frequently used to reduce the excitotoxic effects of glutamate. We now report that MK-801 (10 µM) inhibits [³⁵S]methionine incorporation into polypeptides by 45 ± 7.5% (n=10) after one hour incubation in adult rat hippocampal slices and by 35 ± 10% (n=8) in primary glial cell culture. This effect was NMDA-receptor independent since neither APV (50-500 µM, n=4), a competitive NMDA receptor antagonist, nor Mg²⁺ (10 mM, n=4) a NMDA channel blocker, reversed the inhibition of protein synthesis. GABA_{A/B} (10 µM) or adenosine antagonist receptors also did not reduce protein synthesis. In contrast this inhibition is reversed by clonidine (1 µM), an α2-adrenergic receptor agonist. Selective (efaroxan, 10µM) and non-selective (phentolamine, 10µM) alpha2-adrenergic antagonists also induce an inhibition of protein synthesis. We suggest that MK-801 could act on adenylate cyclase cascade and modulate transcription. This inhibition of protein synthesis may also mediate some of the observed effects by MK-801 *in vivo*.

673.20

NEUROPROTECTIVE EFFECT OF DEXTRORPHAN IN HYPOXIC SPINAL CORD. V. Iyer, A. Schurr* and C. Young. Depts. Neurology and Anesthesiology, Univ. of Louisville, Louisville KY 40292.

Spinal cord damage may result from pressure, stretch or ischemia during spinal surgical procedures. Abnormalities of stimulus-evoked potential (SEP) can prompt measures to correct the cord damage while it is reversible. This study was undertaken to evaluate the neuroprotective effect of dextrorphan, a non-competitive NMDA antagonist during spinal cord hypoxia, using SEP model described by Iyer et al.¹

Spinal evoked potentials (SEP) were recorded *in vitro*, in mouse spinal cord preparations which were subjected to hypoxia until the SEP became flat and continued for 30 minutes. The perfusate was artificial cerebrospinal fluid (ACSF) for the control and ACSF containing 100 µM of dextrorphan for the test group during hypoxia. 42% of the specimens recovered in the control and 83% in the dextrorphan group. The mean amplitude recovery was 43% of the pre-hypoxic value in the control and 92% in the dextrorphan group. It is concluded that dextrorphan has definite neuroprotective effect during spinal cord hypoxia.

7-CL-THIOKYNURENIC ACID: A GLYCINE ANTAGONIST AND FREE RADICAL SCAVENGER THAT REDUCES CA1 ISCHEMIC DAMAGE *IN VIVO*. D.E. Pellegrini-Giampietro*, A. Cozzi and F. Moroni. Dipartimento di Farmacologia, Università di Firenze, Firenze, Italy.

Glutamate and oxygen free radicals are thought to cooperate in the pathogenesis of excitotoxic neuronal damage. In this study we examined whether 7-Cl-thio-kynurenic acid (7-Cl-thioKYNA), a potent antagonist at the glycine site of the NMDA receptor that also inhibits lipid peroxidation (*Eur. J. Pharmacol.* 218, 145-151, 1992), protected CA1 pyramidal cells against posts ischemic damage. Sham-operated gerbils and gerbils subjected to 5 min of bilateral carotid occlusion were treated i.p. with either vehicle (0.5 ml) or 7-Cl-thioKYNA (100 mg/kg at 0, 30, 90, 180 and 270 min following reperfusion). Gerbils' temperature was maintained at 37°C throughout the surgery and for 30 min after reperfusion. Five days later, the extent of CA1 cell loss in brain sections was evaluated by toluidine blue staining. Transient bilateral carotid occlusion induced neurodegeneration of almost all (95±0.7%) CA1 pyramidal cells. 7-Cl-thioKYNA dramatically attenuated ischemia-induced CA1 cell loss to 5±2.6%: the protection was associated with a 4 degree reduction in the animals' temperature that developed between 90 and 180 min post-ischemia and lasted for several hrs. However, when the temperature was maintained at 37°C until 6 hrs following reperfusion, 7-Cl-thioKYNA still provided partial (54±11.8%) protection, indicating that the latter could not be simply ascribed to hypothermia alone. Our results indicate that glutamate receptor blockers possessing radical scavenger properties may be useful in the treatment of excitotoxic brain damage.

674.2

NOVEL GLYCINE ANTAGONISTS REDUCE NEURONAL DAMAGE IN GLOBAL AND FOCAL CEREBRAL ISCHEMIA MODELS. J.B. Patel*, L. Ross, K. Siddiqui, L. Walczak, T. Bare, M. Asif and B. Duncan. ZENECA Pharmaceuticals Group, a business unit of ZENECA Inc., Wilmington, DE 19897.

Several reports indicate that the N-methyl-D-aspartic acid (NMDA) receptor complex plays a critical role as a mediator of cell damage following cerebral ischemia. It is also well established that glycine acts as a coagonist on the NMDA receptor. This study examined the ability of novel glycine antagonists, 7-chloro and 7,9-dichloro 2,3-dihydro-10-hydroxypyridazino[4,5-b]quinoline-1,4-dione (M241247 and M244249 respectively) to protect against neurodegeneration in global (GI) and focal (FI) models of cerebral ischemia.

GI was induced by bilateral carotid occlusion (10 min) in gerbils and hippocampal CA1 area damage was determined 4 days post ischemia. FI was produced by permanent occlusion of the left middle cerebral artery (MCA) and ligation of ipsilateral carotid artery in SHR rats. Infarct volume was determined 24 hrs later. In GI, M241247 (20-80 mg/kg IP) exhibited significant (>75%) reduction in neuronal damage score. Additionally, in FI, M241247 (33.0 mg/kg/hr IV infusion for 4 hrs) resulted in 22% reduction in infarct volume. M244249 at 10.0 mg/kg IP demonstrated reduction (>75%) in neuronal damage in GI and at 66.0 mg/kg/hr IV infusion for 4 hr it produced 23% reduction in infarct volume. These findings provide the first evidence to suggest that glycine antagonists are efficacious in both global and focal models of cerebral ischemia and, consequently, may be beneficial in the treatment of cerebrovascular stroke.

674.3

GLYCINE NMDA RECEPTOR ANTAGONISTS REDUCE FOCAL BUT NOT GLOBAL ISCHEMIC BRAIN DAMAGE IN THE RAT. DS Warner*, H Wu, P Ludwig, MM Todd, Neuroanesthesia Research Group, Department of Anesthesia, University of Iowa, Iowa City, IA 52242

Glycine is a co-agonist at the NMDA receptor complex. Interstitial glycine concentrations are elevated during ischemia and early reperfusion. Thus, effects of the glycine NMDA receptor antagonist, ACEA 1021, were evaluated in outcome models of cerebral ischemia. First, rats underwent 90 min of reversible MCA occlusion while awake (filament technique). Rats (n=9/group) received either 10 mg/kg or 30 mg/kg ACEA 1021 i.p. prior to, during, and 3 hrs after ischemia. Control rats received vehicle (DMSO) only. Mean±SEM cortical infarct volume (4d recovery) was reduced in a dose-dependent manner (Control=160±41; 10mg/kg=76±26; 30 mg/kg=40±26 mm³, p<0.05). Subcortical infarct volume was not significantly different between groups. Neurologic scores correlated with infarct volume (p<0.01). Second, rats were prepared for 2-vessel occlusion forebrain ischemia (10 min). ACEA 1021 (10mg/kg or 30 mg/kg or vehicle) was administered i.p. (n=15/group) 60 min prior to ischemia, and repeated at 20 min and 180 min after reperfusion. Brains were graded for CA1 and striatal damage (5d recovery). No difference between groups was observed in either structure. ACEA 1021 caused sedation in the global ischemia experiment only. No difference between groups occurred for hemodynamic or respiratory values in either experiment. Antagonism of glycine at the NMDA receptor appears to provide protective properties similar to those previously observed for antagonists of glutamate at the NMDA receptor. To date, no psychotomimetic effects for this class of agents have been reported suggesting a potential role for glycine antagonism in stroke therapy.

674.5

EFFECTS OF BERAPROST Na (BPS) AND MK-801 ON CHRONIC CEREBRAL ISCHEMIA IN GERBIL.

S. UENO*, Y. MIYAUCHI, N. IZUMIMOTO, S. MATSUDA and T. ENDO, Basic Research Laboratories, Toray Industries Inc., Kamakura 248, Japan.

We previously reported that BPS, a new prostacyclin derivative, shows protective effects in various ischemic models. The present report describes the effects of BPS and MK-801 on chronic cerebral ischemia in gerbils. The unilateral carotid artery was repeatedly occluded (four times; total: 31min) at intervals of 24 h. The animals were given BPS (1 to 100 µg/kg, p.o.) or MK-801 (3 to 300 µg/kg, s.c.) after the first ischemic insult, and then twice daily for 4 weeks. Neuronal loss, acidophilic neurons, and progressive atrophy were observed with increasing time of reperfusion in the cerebral cortex of ischemic hemisphere. Cortical sections revealed no GFAP-positive astrocytes, while the hippocampal CA1 area showed neuronal loss accompanied by GFAP-positive astrocytes. In the controls, the area ratio and the cortical neurons ratio were 89.8±3.0% and 74.6±3.4%, respectively. BPS was found to inhibit atrophy and chronic, cortical neuronal loss in the ischemic hemisphere in a dose-dependent manner, while MK-801 showed no inhibitory effects at any dose tested. These results suggest that nature of neuronal degeneration differs between cortical and hippocampal areas, and that BPS has a protective effect on ischemia-induced progressive atrophy.

MK-801 IS BOTH AN NMDA AND A CALCIUM CHANNEL BLOCKER IN HYPOXIC HIPPOCAMPAL SLICES. A. Schurr, R.S. Payne and B.M. Rigor*, Department of Anesthesiology, University of Louisville School of Medicine, Louisville, KY 40292

We compared the potency of two NMDA antagonists as protectants of neuronal tissue against NMDA-enhanced hypoxic damage. MK-801, a noncompetitive NMDA antagonist, protected rat hippocampal slices not only from NMDA-enhanced hypoxic damage, but also from damage elicited by hypoxia in the absence of NMDA. APV, a competitive NMDA antagonist, blocked the enhanced hypoxic damage in the presence of NMDA, but did not protect against hypoxic damage in the absence of NMDA. Two plausible mechanisms were tested to explain the difference between the two antagonists' effects: 1) MK-801, while antagonizing the NMDA receptor, also blocks hypoxic glutamate (Glu) release and thus, the activation of non-NMDA (kainate, AMPA) Glu receptors; 2) MK-801 blocks not only the voltage-dependent NMDA channel, but other voltage-dependent calcium channels as well. The first possibility was tested by perfusing hypoxic hippocampal slices with both NMDA and non-NMDA antagonists at concentrations sufficient for a complete blockade of their corresponding receptors. A mixture of APV (100 µM), kynurenic acid (a mixed NMDA and kainate receptor blocker, 500 µM), and dihydroxyquinoxaline (a kainate/AMPA receptor blocker, 500 µM) did not produce the degree of protection produced by 100-200 µM MK-801 in slices that were exposed to severe hypoxia (15 min). To test the second possibility, we reduced the level of magnesium in the medium perfusing the slices (0.2-0.5 mM) to lessen the ion's blockade of voltage-dependent calcium channels. Although the tissue sensitivity to hypoxia was increased due to the reduction in magnesium level, MK-801 still provided strong protection.

These preliminary results indicate that MK-801 blocks NMDA and other voltage-dependent calcium channels.

674.4

PROTECTION FROM HYPOXIC NEURONAL INJURY WITH AMINOGLYCOSIDES, K.L. Panizon*, P. Marangos & R.A. Wallis, Dept. of Neurology, UCLA and Sepulveda VAMC, Sepulveda, CA 91343, and Cypros Pharmaceuticals, San Diego, CA 92121.

Release of neurotransmitters during hypoxia and ischemia may play a key role in the development of excitotoxic neuronal injury. N-type calcium channels modulate this release, and are inhibited by aminoglycoside antibiotics. Using the hippocampal slice, we tested the neuroprotective effect of aminoglycosides upon recovery of CA1 PS activity following hypoxic exposure. We found that neomycin 1.0 mM provided significant protection against hypoxia yielding CA1 PS orthodromic recovery of 88 ± 5% of original amplitude and antidromic recovery of 94 ± 0.3%. This compared to CA1 PS orthodromic recovery of 0% and antidromic recovery of 15 ± 6% in paired slices exposed to hypoxia alone. The EC₅₀ for neomycin was 573 and 458 µM for recovery of CA1 orthodromic and antidromic PS amplitude after hypoxic exposure. Hypoxic protection was also seen with gentamicin 2.5 mM which yielded recoveries of 60 ± 23% and 72 ± 16%, and with sisomicin 1.0 mM which produced recoveries of 76 ± 9% and 60 ± 15%. No significant protection was seen from streptomycin 10 mM. This order of aminoglycoside protection against hypoxia paralleled the affinity of these compounds for N-type calcium channel receptors. In receptor binding studies, neomycin, sisomicin, gentamicin and streptomycin inhibited [¹²⁵I]conotoxin binding with K_i's of 1.4 µM, 3.1 µM, 7.4 µM and 24.5 µM respectively. These results indicate that aminoglycosides can provide neuroprotection against hypoxic neuronal injury, and that inhibition of N-type calcium channels may represent a novel neuroprotective strategy.

DEPRENYL PROTECTS RAT HIPPOCAMPAL PYRAMIDAL CELLS FROM ISCHAEMIC INSULT. A.J. Barber(1)*, T.A. Paterson(1), D.L. Gelowitz(1) and C.L. Voll(2). (1)Neuropsychiatric Research Unit and (2)Dept. of Medicine, University of Saskatchewan, Saskatoon, SK, Canada S7N 0W0.

Adult male Wistar rats were given unilateral ischaemic lesions to the hippocampus by ligation of the left common carotid artery followed, 24 hrs later, by a 30 min exposure to carbon monoxide (1% mixture in air). The rats were injected with (-)deprenyl (0.25 mg/kg, s.c.) or saline just before the onset of carbon monoxide and then every day for 1, 7 or 14 days. Rats were killed by transcardiac perfusion of 4% formalin under deep anaesthesia, on the last day of drug treatment. The brains were removed, fixed, cryoprotected, frozen and 7µ coronal sections were cut and stained with thionin.

Morphological changes were observed in the pyramidal neurones at days 1 and 7 which were consistent with programmed cell death (intact neurones with cytoplasmic shrinkage). There was no difference in the survival of pyramidal neurones between the (-)deprenyl and saline treated groups after 1 and 7 days. After 14 days more CA1 and CA3 cells had survived in the (-)deprenyl treated animals (38% & 83% respectively) compared to those of the saline treated animals (5% & 47% respectively). This was statistically significant for CA1 cells (f(1, 28)=13.34, p<0.001).

These data demonstrate that (-)deprenyl can protect hippocampal pyramidal cells and increase survival of at least the cell bodies, following an ischaemic insult.

AMPHETAMINES PROMOTE ANATOMICAL PLASTICITY AND BEHAVIORAL RECOVERY FOLLOWING CORTICAL INFARCTION R.P. Stroemer*, T.A. Kent and C.E. Hulsebosch, Depts. of Anat. and Neurosci., Marine Biomed. Inst., Neurol., Univ. of Texas Med. Br., Galveston, TX 77550.

Amphetamine administration has been shown to accelerate recovery of behavioral dysfunction following cortical ablations. The mechanisms of this therapy are not understood. We hypothesize that the long term effects of amphetamines are due to increases in protein expression allowing for anatomical plasticity. Earlier work demonstrates the existence of axonal sprouting and synaptogenesis in the cortex of SHR rats following distal middle cerebral artery occlusion (MCAO), using antibodies to synaptophysin, a synaptic vesicle protein, and GAP 43, a growth cone associated protein.

The present study demonstrates that one week following MCAO, amphetamine therapy (5mg/kg) combined with behavioral experience increases the GAP 43 expression in areas surrounding the infarction when compared to the vehicle treated MCAO group. The optical densities of GAP 43 immunoreactivity in the cortex surrounding the infarction were 3 times higher than contralateral cortex in the amphetamine treated group, compared to 2 times higher than control cortex in the vehicle treated group. The amphetamine treated group also demonstrates improved scores on foot faults in behavioral testing when compared to the vehicle group. This supports the hypothesis that amphetamine therapy when accompanied with physical experience increases levels of proteins necessary for anatomical plasticity. Supported by NS 11255, NS 01217, and Bristol Myers-Squibb.

NS004 IS NEUROPROTECTIVE IN RODENT MODELS OF GLOBAL AND FOCAL CEREBRAL ISCHEMIA. S.L. Moon*, L. Lombardo, J. Hibbard, B. Myers, D. Lindell and N. Meanwell¹. CNS Neuro-pharmacology and ¹Central Chemistry, Bristol-Myers Squibb, Wallingford CT, 06492.

NS004 is an opener of calcium activated K_{maxi} channels. We have investigated the ability of NS004 to attenuate neuronal damage after cerebral ischemia.

In a model of transient global forebrain ischemia, gerbils were subjected to a 15-min. bilateral carotid occlusion. NS004 (10, 30, or 60 mg/kg, ip) or vehicle was administered at 1, 24, 48, and 72 hrs post-occlusion. Hippocampal histopathology was evaluated by means of a damage rating scale of Nissl-stained sections. Compared to vehicle-treated animals, NS004 at 60 mg/kg significantly reduced the hippocampal damage.

After permanent occlusion of the middle cerebral artery in the spontaneously hypertensive rat (SHR), a single dose of NS004 (0.3, 1, 5, and 10 mg/kg, ip) or vehicle was given at either 1, 2, or 3 hrs post-occlusion. At 24 hrs, the brains were perfused and incubated in 3% 2,3,5-triphenyltetrazolium chloride. Infarcts were measured by means of computer-assisted planimetry. When given one hr after occlusion, 0.3 mg/kg did not alter infarct volume, however all other doses were effective. Only the 5 mg/kg dose was tested at the later time points. NS004 at 5 mg/kg significantly reduced infarct size when given 2 hrs post-occlusion, but not when administered at the 3 hr time point.

In another group of SHRs with mean arterial blood pressures ≥ 150 mm Hg, NS004 at 10 mg/kg, iv, had no effect blood pressure, but at 20 mg/kg, iv, mean arterial blood pressure decreased by 15%. There was no effect on heart rate at either dose.

674.11

DELAYED TREATMENT WITH THE AMPA RECEPTOR ANTAGONIST NBQX, PREVENTS ISCHEMIC NEURONAL INJURY. H. Li, K. Barnes, H. Lesiuk* and A.M. Buchan. Neuroscience, Loeb Research Institute, Ottawa Civic Hospital, Ottawa, Ontario, Canada K1Y 4E9, from the *Canada/Fisons Fight Stroke* program.

Delayed treatment with NBQX, an AMPA glutamate receptor antagonist, was tested in a 4 vessel occlusion model of severe forebrain ischemia which reliably induces hippocampal CA1 injury. Adult male Wistar rats (n=29) were subjected to 10 min of forebrain ischemia and seven days of reperfusion. NBQX (30 mg/kg) was injected IP at the time of reperfusion, or following a delay of 6, 12 or 24 hr post-ischemia. Damaged CA1 neurons of the hippocampus were counted and expressed as a percentage.

Group (n)	% CA1 Injury (Mean \pm SD)
Saline (7)	79 \pm 16
NBQX	
immediate (6)	17 \pm 17*
delayed 6 hr (5)	27 \pm 32*
delayed 12 hr (6)	25 \pm 17*
delayed 24 hr (5)	50 \pm 28

*p < 0.01 Mann-Whitney U test with Bonferroni correction

AMPA receptor blockade delayed by up to 12 hr prevents CA1 injury, suggesting a causal relationship between selective injury and Ca^{++} entry through this glutamate-regulated but ischemia-modified ionophore.

674.13

POST-TREATMENT WITH THE NOVEL DEXTROMETHORPHAN ANALOG AHN-649 ATTENUATES ISCHEMIC DAMAGE TO CA1 NEURONS AND IMPROVES RECOVERY IN RATS. X-C. Lu*, L. Robles, J. Rose, C. Wingfield, M. DeCoster, A. Newman* and F. Tortella. Walter Reed Army Inst. Res., Washington, DC 20307 and *NIDA Addiction Res. Ctr., Baltimore, MD 21224.

AHN-649 is a novel 3-substituted 17-methylmorphinan analog of dextromethorphan (DM) possessing *in vivo* anticonvulsant activity (Newman et al., J. Med. Chem 35, 1992) and *in vitro* neuroprotective properties (Tortella et al., In Press, 1993). The purpose of the present study was to determine the neuroprotective capacity of AHN-649 in an *in vivo* model of brain injury. Using a rat model of severe forebrain ischemia (15 min of 4-vessel occlusion followed by 72 h reperfusion) we now report *in vivo* neuroprotection and improved functional recovery with AHN-649 (20 mg/kg, s.c.) administered 1, 2 and 4 h post occlusion. Functional recovery was evaluated using treadmill running performance (TRP) assessed at 6, 24 and 72 h post injury. Animals were perfused fixed 72 h post occlusion for histological quantification of CA1 damage. In saline-treated rats ischemia caused severe impairment of TRP which was most evident during the first 24 h but persisted throughout the 72 h course of study. Extensive and consistent loss of pyramidal CA1 neurons was measured (75 \pm 9% damage). Post-treatment with AHN-649 significantly attenuated the ischemia-induced CA1 injury (21 \pm 11% damage). TRP was significantly improved at 6 h, and normal by 24 h, post-injury. DM (20 mg/kg, s.c.) was less neuroprotective (44 \pm 14% damage), and comparisons of TRP indicate that it may be less effective, than AHN-649 in improving functional recovery, particularly during the early (6-24 h) stages post injury. Thus, AHN-649 appears to represent a new class of neuroprotective agents.

674.10

DELAYED TREATMENT WITH THE AMPA ANTAGONIST NBQX, REDUCES EDEMA FOLLOWING FOCAL ISCHEMIA. Z.G. Huang*, D. Xue, K.E. Smith, H. Lesiuk and A.M. Buchan. Neuroscience, Loeb Research Institute, Ottawa Civic Hospital, Ottawa, Ontario, Canada K1Y 4E9, from the *Canada/Fisons Fight Stroke* program.

NBQX, a potent AMPA receptor antagonist, protects against neuronal injury following brain ischemia¹. This study was conducted to determine whether NBQX attenuates brain edema in a well-characterized rodent model of transient middle cerebral artery occlusion (MCAO). Thirty male spontaneously hypertensive rats were subjected to 2 hours of reversible right MCAO. Ninety minutes following the onset of ischemia, saline or a known cytoprotective dose of NBQX (30 mg/kg) was administered ip. Subsequent doses were given at the time of reperfusion (RP) and 30 minutes following RP. Animals were kept normothermic throughout ischemia and RP, and sacrificed at 24 hours. Brain edema was calculated based on the differences between hemispheric volumes. Cortical infarct volume was also determined. The student T-test was used for statistical analysis.

Group (n)	Mean Volume \pm SD (mm ³)	
	Edema	Cortical Infarction
Saline (15)	45 \pm 18	137 \pm 24
NBQX (15)	29 \pm 15*	108 \pm 21**

*p < 0.05, **p < 0.01

Treatment with NBQX significantly reduced both neocortical infarction and significantly attenuated the accumulation of edema even when administered 90 minutes after the onset of ischemia.

PHARMACOLOGICAL PROFILE AND NEUROPROTECTIVE ACTIVITIES OF RP 66055, A RILUZOLE DERIVATIVE, IN RODENTS. J.M. Stutzmann, S. Mignani, F. Debarnot, J. Rataud, O. Piot, C. Pauchet, P. Jimonet, M. Reibaud, C. Malgouiris, A. Uzan*, J. Pratt, J.C. Blanchard and M. Barreau. Rhône-Poulenc Rorer, CRVA, 94403, Vitry sur Seine, France.

RP 66055, (3-[2-[4-(4-fluorophenyl)-1-piperazinyl]ethyl]-2-imino-6-trifluoromethoxy-benzothiazoline), prepared from riluzole in a five-step synthesis, shows potent anticonvulsant properties against glutamate-induced convulsions (ED₅₀ = 2.2 mg/kg ip in rats) and maximal electroshock (MES: ED₅₀ = 2.3 mg/kg ip in mice). Furthermore, it shows a long duration of action, indeed after po administration its ED₅₀s at 20 hrs are only 5 or 9 times higher than those at 1 hour (glutamate: ED₅₀s = 20 and 3.85 mg/kg po respectively; MES: ED₅₀s = 6 and 0.66 mg/kg po respectively). RP 66055 protects mice against tonic hindpaw extension in the pentylentetrazole test (ED₅₀ = 3.1 mg/kg po), but not against generalized clonic seizures. RP 66055 is a very potent neuroprotective agent in models of hypoxia and ischaemia in rodents. It produces a dose-dependent increase in mean survival time in mice under hypobaric hypoxia (ED₅₀ = 1.3 mg/kg ip). When administered at 4x8 mg/kg ip starting 30 minutes post bilateral carotid occlusion in the gerbils, RP 66055 reduces EEG spectrum shift towards the slow waves and hippocampal CA1 necrosis. In the rat from the low dose of 2 x 0.5 mg/kg iv, it significantly decreases the volume of cortical infarction and the neurological deficit induced by a focal and definitive ischaemia (the MCA model). Binding assays only reveal an affinity for voltage sensitive Na-channels (IC₅₀ = 0.4 μ M).

674.14

THE EFFECTS OF CGS-19755 IN RAT FOCAL CEREBRAL ISCHEMIA PRODUCED BY TANDEM IPSILATERAL COMMON CAROTID ARTERY AND MIDDLE CEREBRAL ARTERY OCCLUSION. J.T. Simmonds, T.L. Sailer, and J.A. Moyer*. CNS Division, Wyeth-Ayerst Research, CN 8000, Princeton, NJ 08543-8000.

It has been previously reported that CGS-19755 produces a 50% decrease in ischemic damage by modified proximal middle cerebral artery (MCA) occlusion (Simon, 1990) and a 28% decrease in a modified distal MCA occlusion model of focal ischemia (Takizawa, 1991). As a means of establishing a pharmacological model for evaluating known and novel EAAA (excitatory amino acid antagonists), ligation of the right common carotid artery and occlusion of the distal MCA was performed. In the present studies, male Fischer-344 (290-310 g) rats were administered a 10 mg/kg i.v. bolus of CGS-19755 five minutes post-occlusion and were sacrificed 24 hours later. Infarct volumes were determined by area measurements on every tenth section through the lesion by image analysis. Body temperatures were taken every hour out to 4 hours post-occlusion. Hemiparesis was recorded as present if the animals exhibited forelimb flexion within the first 4 hours following occlusion. In the initial study, infarct volumes for saline and CGS-19755 treated groups were 45.7 mm³ and 21.9 mm³, respectively. CGS-19755 also produced a 50% decrease in infarct volume (61.3 mm³) as compared to the saline control group (31.5 mm³) in a second study. In both studies, the body temperatures of the CGS-19755 group at the 2, 3 and 4 hour timepoints were significantly different from the saline control. Although significant, hypothermia produced was approximately 1° or less. Forelimb flexion was significantly reduced in both studies by CGS-19755. These results provide evidence that the focal ischemia produced by right common carotid artery and MCA occlusion provides reproducible results. These studies also replicate reduction in infarct volume produced by CGS-19755 in other focal ischemia models.

674.15

NEUROPROTECTIVE EFFECT OF U69593 AND DEXTROMETHORPHAN IN A MOUSE MODEL OF PERMANENT FOCAL CEREBRAL ISCHEMIA. I. P. Karachounov* and G. T. Pryor. Neuroscience Department, SRI International, Menlo Park, CA 94025.

U69593, a κ -opioid agonist, and dextromethorphan (DM), a (+)-opioid with affinity at the PCP/MK-801 channel site of the NMDA receptor complex, have been reported to reduce ischemic neuronal injury following transient global ischemia and infarct volumes following focal ischemia. To confirm further these neuroprotective effects, we tested them in a mouse model of permanent middle cerebral artery occlusion (MCAO) that we were establishing for use in screening new neuroprotective compounds. The left middle cerebral artery was occluded in 37 adult male Swiss-Webster mice (28-32 g) according to Welsh et al. (J. Neurochem. 49:846-851, 1987), anesthetized with tribromoethanol (600 mg/kg). Rectal temperature was monitored and maintained at $37 \pm 1^\circ\text{C}$ throughout the surgical procedure and up to 120 min after induction of ischemia. U69593 (20 mg/kg) or DM (20 mg/kg) were injected i.p. in saline 5 min, 1 hr, and 2 hr after cauterization. All mice were sacrificed after 48 hr and perfused transcardially with a suspension of carbon black. Cortical infarct areas were digitized using a Quantex image analyzing system. The mean (\pm SEM) infarct area in the saline-treated mice ($n=18$) was $25.7 (\pm 8.8) \text{ mm}^2$ compared with $17.7 (\pm 3.4)$ and $12.9 (\pm 3.7)$ in the mice treated with DM and U69593, respectively ($p < 0.05$). Our data confirm that U69593 and DM significantly alleviate ischemic cell damage and further support a potential therapeutic use for these compounds in cerebral ischemia.

674.17

α -TOCOPHEROL DEPLETION OF PERIPHERAL NERVE WORSENS DIABETIC NEUROPATHY. K. K. Nickander, J. D. Schmelzer* and P. A. Low. Neurophysiology Laboratory, Department of Neurology, Mayo Clinic, Rochester, MN 55905

In streptozotocin (STZ) induced diabetic neuropathy, endoneurial hypoxia is present and ischemia is associated with reduced endoneurial superoxide dismutase, norepinephrine, and increased endoneurial conjugated dienes. To evaluate the importance of endoneurial α -tocopherol on severity of neuropathy, we performed nerve conduction and blood-nerve barrier (BNB) studies in 4 groups of rats at 1 and 3 months of diabetes: (1) normal α -tocopherol Controls (CONT-N); (2) α -tocopherol deficient Controls (CONT-def); (3) normal α -tocopherol Diabetics (STZ-N); (4) α -tocopherol deficient Diabetics (STZ-def). Whole nerve α -tocopherol was significantly increased in STZ-N ($p < 0.001$). α -Tocopherol depletion significantly induced or worsened both amplitudes and conduction velocities of both sciatic-tibial and caudal nerves. Sciatic-tibial motor nerve conduction velocity (CONT-def vs CONT-N, $p < 0.001$; STZ-def vs STZ-N, $p < 0.001$), compound nerve action potential (STZ-def vs STZ-N, $p < 0.01$), caudal conduction velocity (STZ-def vs STZ-N, $p < 0.001$), and caudal nerve action potential (CONT-def vs CONT-N, $p < 0.01$; STZ-def vs STZ-N, $p < 0.001$) all showed significant abnormalities. The BNB indices were not worsened by α -tocopherol depletion. We suggest that the increase in α -tocopherol is compensatory and these findings support the notion that oxidative stress may cause neuropathy and worsen experimental diabetic neuropathy.

674.16

DIAZEPAM IS NEUROPROTECTIVE AND PRESERVES GABA_A RECEPTORS IN STRIATUM BUT NOT IN CEREBRAL CORTEX FOLLOWING TRANSIENT GLOBAL ISCHEMIA IN THE RAT. Xiao Yu, Huijing Li and Rochelle D. Schwartz*. Department of Pharmacology, Duke University School of Medicine, Durham, NC. 27710.

We studied the role of enhancing GABA_A neurotransmission following a moderately severe ischemic insult. Rats were subjected to 15 min of ischemia using the 4-vessel occlusion technique. Diazepam was administered systemically 1 hr and again 2 hrs following the onset of reperfusion. Four days later the rats were sacrificed and the brains were prepared for histologic analysis, receptor autoradiographic analysis of [³⁵S]TBPS binding to the GABA-gated chloride channel, and in situ hybridization of GABA_A receptor subunit mRNAs. Histological analysis of the dorsolateral striatum from 7 rats revealed that neuroprotection was complete in 5 rats, 75% protection was achieved in 1 rat and no protection was achieved in 1 rat. In receptor autoradiography studies, [³⁵S]TBPS binding was reduced by 75% in the dorsolateral striatum of occluded rats ($n=6$) and by 33% in the diazepam-treated rats. [³⁵S]TBPS binding in the somatosensory cortex (layers 1-4) was reduced by 25-33% in occluded rats; the diazepam treatment had no effect on cortical damage. The enhancement of GABAergic neurotransmission at a critical time following an ischemic insult suggests that loss of GABAergic neurotransmission may contribute to ischemia-induced neuronal injury.

ISCHEMIA: GLIA

675.1

INHIBITION OF ISCHEMIA-INDUCED GLUTAMATE RELEASE IN GERBILS BY AN ANION TRANSPORT INHIBITOR (L-644,711)

P.J. Feustel, L. Rodriguez, R.W. Keller, Jr., A.M. Snyder-Keller*, K. Barron, A.J. Popp and H.K. Kimelberg. Albany Medical College, Albany, NY 12208; and *NY State Dept of Health, Wadsworth Ctr, Albany, NY 12201

We have previously shown that an anion transport inhibitor (L-644,711) will inhibit swelling induced release of glutamate and aspartate from primary astrocyte cultures *in vitro* (see abst. by Kimelberg et al., this vol.; and Kimelberg et al., *J. Neurosci.*, 1990). Swelling of astrocytes is well-known to occur in ischemia, and therefore it is possible that some of the aspartate and glutamate release seen during ischemia could be coming from swollen astrocytes. Ten minute bilateral carotid occlusion of gerbils, with microdialysis probes implanted bilaterally into the dorsal hippocampus was used as the ischemia model. L-644,711 was infused at varying concentrations in one probe and the other served as the contralateral control. A relatively low dose of the drug (0.5mM) produced no basal changes in glutamate release but did inhibit the glutamate release seen during carotid occlusion by 70-80%. A decrease in glutamate levels during reperfusion was unaffected. At higher concentrations (1 or 5mM), the drug had no significant effect on glutamate or aspartate or caused increased levels of aspartate. At these concentrations of drug decreases in extracellular glutamine were observed. These data are consistent with work *in vitro* that showed that lower concentrations of L-644,711 inhibited cell swelling-induced release of glutamate from primary astrocyte cultures (Bednar et al., *Neurol. Res.* 14:53-56, 1992), but at higher concentrations glutamate uptake was inhibited. Preliminary studies also indicate that in the region adjacent to the probe containing L-644,711 there was less induction of *c-fos* than on the control side. (Supported by NS 30303).

675.2

O2A PROGENITOR CELLS DO NOT TOLERATE HYPERTHERMIC AND ISCHEMIA-RELATED STRESSES AS READILY AS TYPE-1 ASTROCYTES. B.H.J. Juurink*. Department of Anatomy & The Saskatchewan Stroke Research Centre, University of Saskatchewan, Saskatoon, SK, CANADA S7N 0W0

I have previously demonstrated that type-2 astrocytes have little ability to tolerate elevated temperature. The objective of this study was to examine the ability of O2A progenitor cells to tolerate stresses in the form of elevated temperature, hypoxia and ischemia. Experiments were performed on rat mixed glial cultures whose major populations consisted of type-1 astrocytes (T1As) and O2A progenitor cells (O2As). To examine the ability to withstand elevated temperature, cultures were subjected to 43°C and returned to 37°C for recovery. Although T1As could readily tolerate 6 hr of hyperthermia, the majority of O2As died during the recovery period if exposed to more than 1 hr of hyperthermia. As little as two hours of simulated ischemia resulted in the death of ~90% of the O2As during the first 24 hr of recovery whereas no death was observed amongst the T1As; however, following this period there was an increase in the rate of proliferation of the surviving O2As such that the cultures became repopulated by large numbers of O2As during days 2 and 3 following the ischemic insult. Similar results were observed following 24 hr of hypoxia in the presence of substrate. In conclusion, O2As appear to have a much lower ability to tolerate environmental perturbations than T1As. *I thank the Ralston Brothers Medical Research Foundation and the Melfort Memorial Hospital for supporting this research.*

675.3

CELLULAR LOCALIZATION OF QUINOLINATE FOLLOWING TRANSIENT FOREBRAIN ISCHEMIA. K.J. Blinder¹, J.R. Moffett¹, K. Saito², K. Suyama², M.P. Heyes² and MAA Nambodini¹. Dept. of Biol., Georgetown U., Washington, DC 20057; Sect. on Anal. Biochem., Lab. of Clin. Sci., NIMH, Bethesda, MD 20892; Clinical Pharmacology³, NIMH, Bethesda, MD 20892

Localized neurodegeneration of the hippocampus can be produced in the Mongolian gerbil (*Meriones unguiculatus*) by transient occlusion of both common carotid arteries. This lesion is considered a model of delayed-onset neurodegeneration in stroke. Excitotoxicity has been implicated in such ischemic brain damage. Quinolinic acid, a known NMDA agonist, is normally present in the brain in only nanomolar amounts, but is found in the brain in potentially excitotoxic concentrations in many acute inflammatory brain conditions, including ischemic brain damage. The source of the QUIN is not known. It has been hypothesized that the QUIN may be produced by activated resident or infiltrating macrophages.

We now report QUIN staining in microglia-like cells of the CA1 region of the hippocampus four days after the induction of transient forebrain ischemia in adult gerbils by 5 or 10 minutes occlusion of both common carotid arteries. Four days after the ischemic insult, the animals were sacrificed by intracardiac perfusion with a carbodiimide fixative to assure retention of soluble QUIN. Brain immunohistochemistry was done on using rabbit polyclonal antiserum against protein-conjugated QUIN, purified by extensive blocking with potential cross-reactants.

Degenerative changes were apparent in the hippocampus, in the pyramidal cell layer of CA1, which showed extensive neuronal loss. QUIN-positive cells of microglial morphology were numerous in the CA1 pyramidal cell layer, but not noted elsewhere. Sham-operated controls had no CA1 degeneration, and no QUIN-positive cells in CA1. This finding suggests that microglia may serve as a source of the potential excitotoxin, QUIN, in delayed-onset ischemic brain damage.

675.5

POTASSIUM HOMEOSTASIS IN ENERGY-DEPRIVED ASTROCYTES. W. Walz* Dept. of Physiology, Univ. of Saskatchewan, Saskatoon S7N 0W0, Canada.

One of the earliest events of an ischemic episode is an increase of the extracellular K^+ concentration to 30-80mM, which is followed by astrocytic swelling. The pathophysiological relevance of the phenomena was investigated with the use of ion-sensitive microelectrodes in primary cultures of type-1-like cortical mouse astrocytes. If these astrocytes are exposed to saline containing 60mM K^+ their K^+ concentration increases by about 40mM accompanied by Cl^- and HCO_3^- increases as well as swelling. If the cells are exposed to the metabolic inhibitors sodium fluoride and antimycin a they exhibit a slow depolarization that is caused by loss of intracellular K^+ ($E_m = E_k$). If such a depolarized astrocyte was exposed to 60mM K^+ the intracellular K^+ concentration increased rapidly to a level higher than the previous resting value. This increase was independent of the degree of depolarization and amount of K^+ left in the cells. Replacement of HCO_3^- and Cl^- by glucuronate and HEPES did not change these responses. The K^+ accumulation of metabolically intact cells was not inhibited by ouabain application. Thus, astrocytes possess a rapid K^+ uptake system that is energy-independent and is bound to play a role in cytotoxic swelling following metabolic interruption. A Boyle-Conway mediated mechanism involving voltage-dependent anion channels is not likely to be involved.

ISCHEMIA: HEAT SHOCK PROTEIN

676.1

Cloning of a novel hsp70 family member and its expression in brain ischemia. S.M. Massa*, F.M. Longo, S. Wang, J. Zuo and F.R. Sharp. Dept. of Neurology Univ. of California and SFVAMC, San Francisco, CA 94121

Stress proteins, including the heat shock (hsp) and glucose-regulated proteins (grp), are induced in the brain in response to ischemia, seizure, trauma and other stresses. The induction of these proteins has been hypothesized to protect the brain against subsequent more severe (supralethal) stresses. However, expression of the well characterized stress protein family members does not completely account for the observed protective effects. Since the involvement of undiscovered and uncharacterized members of these families has been hypothesized a search for such members was undertaken.

A fragment of a novel gene (hsl1, hsp70 related sequence) was generated from mRNA isolated from rat brain subjected to kainate-induced status epilepticus, using degenerate primer-PCR and screening to exclude known family members. Northern analysis revealed a single approximately 3.5 kb mRNA species in normal rat brain; slot blot analysis of mRNA derived from whole brain hemispheres subjected to 1 hr. of middle cerebral artery occlusion followed by 8 hrs of reperfusion, or kainate treatment, suggested the quantity of hsl1 message was slightly increased (1.2-1.3 fold) after injury. Database comparison of the amino acid sequence encoded by the longest open reading frame of the hsl1 fragment revealed many highly similar sequences, including the presumptive mitochondrial protein *c. elegans* hsp70 (73% identity), mitochondrial proteins *S. cerevisiae* SSC1 (64%) and *P. sativum* hsp70 (60%), and *E. coli* dnaK (56%). Hsl1 is less similar to hsp70 (33%), hsc73 (37%) and grp78 (41%) but like grp78, lacks the nuclear localization consensus sequence found in the cytoplasmic hsp70 and hsc73. The relationship of hsl1 to mitochondrial hsp in other species suggests the possibility that hsl1 is closely related or identical to grp75 (also called mhsp70), a vertebrate mitochondrial hsp70 family member.

REGIONAL ACCUMULATION OF MACROPHAGE/MICROGLIA AFTER HYPOXIC-ISCHEMIC (HI) BRAIN INJURY IN PERINATAL RODENTS. J.A. Shubitowski, R. Sun, F.S. Silverstein*. University of Michigan, Ann Arbor, MI 48109.

Macrophages (MØ) and microglia (MCG) may play important roles in CNS development, and may also contribute to neuronal injury after diverse CNS insults. To begin to study the role of MØ/MCG in perinatal CNS injury, we used 2 complementary detection methods to visualize their regional distributions after a focal HI insult in 7 day old (P7) rats. To elicit injury, P7 rats underwent right carotid ligation followed by 3h 8% O_2 exposure; rats were sacrificed 1-5 days later (n=3/group). A histochemical assay using Griffonia simplicifolia B4-isolectin enabled detection of activated MCG; MØ and vascular cells were also reactive. MØ were identified immunocytochemically using a MØ-specific monoclonal antibody, ED1 (which also labeled some MCG). In normal P7-12 brain MØ and MCG were concentrated in white matter. After HI, in the lesioned hemisphere, lectin staining of MCG peaked at 48h post-injury; reactive MCG were concentrated in cortex (C), hippocampus (HIP) (in particular CA1 and CA3), striatum (STR), septum (SEP), and habenula. MØ accumulation peaked 1-2 days post-injury, with prominent collections of immunoreactive cells in C, HIP, STR, and SEP. In brain sections in which no neuronal injury was evident, no MCG or MØ accumulation was detected. Yet, MØ and MCG did not accumulate uniformly in all regions where neuronal injury was apparent. Perinatal HI brain injury induced anatomically and temporally distinct patterns of MØ and MCG accumulation; these cells may be important mediators of progressive neuronal injury.

676.2

INDUCTION OF HEAT SHOCK PROTEIN IN CINGULATE AND RETROSPLENIAL CORTEX BY ANTI-ISCHEMIC AGENTS. R.P. Simon, J.Q. Lan, J.Chen, D.Ferriero*, F.R. Sharp, S.H. Graham. Department of Neurology, University of California, San Francisco 94143.

NMDA antagonists injure neurons in layers 2 and 3 of both cingulate and retrosplenial cortex, resulting in induction of heat shock protein (HSP70). The purpose of this study is to determine if alternative means of blocking excitotoxicity also induce HSP expression in these regions.

Five agents were studied in 74 rats: CGS19755 (10, 20, 30mg/kg) a competitive NMDA antagonist; 7-chloro-thiokynurenic acid (10, 20, 30 or 50mg/kg) a glycine site antagonist; NBQX (3, 10 or 30 mg/kg) an AMPA-kainate antagonist; and the lamotrigine congeners, BW1003 (6, 20, or 50mg/kg) and BW619 (1, 10, 20, 30 or 50mg/kg), which block excitotoxicity by reducing glutamate release. MK801 (1mg/kg) (n=50) was used as a positive control in all groups. Brains were removed and sectioned for HSP70 immunocytochemistry 24 hrs after i.p. injection of drug.

CGS19755 induced HSP70 in cingulate and retrosplenial cortex at doses as low as 20mg/kg (3/12 rats expressed HSP70), but not 10mg/kg (0/8 rats). The effect was maximal at 30mg/kg (4/6 rats). 7-chloro-thiokynurenic acid, NBQX, BW1003, and BW619 did not induce HSP70 at any dose tested. These results suggest that alternative approaches to ameliorating excitotoxicity may not share the neurocytopathologic toxicity of competitive and noncompetitive NMDA antagonists.

676.3

EXPRESSION OF HEME OXYGENASE, A CNS STRESS PROTEIN, IN E. COLI. B.E. Dwyer*, R.N. Nishimura, T. Yoshida. VA Medical Center, Sepulveda, CA 91343, USA.

Heme oxygenase catalyzes the rate-limiting step in the degradation of heme to biliverdin and ultimately bilirubin. Heme oxygenase is also a stress protein in many cell types including cells in the CNS. Rat heme oxygenase-1 was expressed in E. coli using the QIAexpress system (Qiagen, Inc). A DNA fragment comprising the coding region of the rat heme oxygenase gene (kindly supplied in plasmid pRHO1 by Dr. Shigeki Shibahara) was amplified by PCR and subcloned into plasmid QE-30 (Qiagen) to give pQE-30/HO-1. The coding region of rat heme oxygenase-2 gene was amplified from rat testes polyA⁺ by PCR and subcloned into QE-30 to give pQE-30/HO-2. pQE-30/HO-1 and HO-2 were used to transform M15p[rep4] cells and the synthesis of heme oxygenase-1 and 2, induced by addition of IPTG, was verified by gel electrophoresis/autoradiography and Western blotting. Probes based on full length sequences confirm that heme oxygenase-1 is a glial heat shock protein *in vitro*. Neuronal induction of heme oxygenase-1 is weak.

HSP72 AND UBIQUITIN CONJUGATE EXPRESSION IN THE POSTISCHEMIC AND POSTHYPOGLYCEMIC RAT BRAIN. INFLUENCE OF HYPOTHERMIA AND NBQX. Kerstin Bergstedt* and Tadeusz Wieloch, Laboratory for Experimental Brain Research, Lund Hospital, Lund University, S-221 85 Lund, Sweden.

HSP72 expression and ubiquitin conjugate immunoreactivity (UIR) was studied in the posts ischemic brain. HSP72 was observed at 24 hrs following ischemia in the hippocampus and neocortex layer IV, in both saline and NBQX treated rats. Two days posts ischemia, HSP72 IR was evident in the CA3 region in saline treated rats, but not in the degenerated CA1 region. In NBQX and hypothermia treated rats HSP72 was seen in the CA1 but not in the CA3 region. The UIR was absent in both CA1 and CA3 region at 24 hrs following normothermic ischemia, but was less depressed in the hypothermic animals. An increase in UIR was seen at 2 and 3 days following normothermic ischemia in the CA3 region and in the CA1 region in the hypothermic animals. Blockade of the AMPA receptor stimulated recovery of UIR in the CA1 region at 2 and 3 days posts ischemia. A functional ubiquitin system may be essential for the neuronal survival following ischemia. A defect in ubiquitination may cause an accumulation of damaged or defective proteins and lead to sequestration of HSP's into large protein aggregates, depleting the vulnerable neurons from the protective influence of HSP's. Expression of HSP72 despite AMPA-receptor blockade suggests that the receptor blockade dampens the posts ischemic stress on vulnerable neurons. Following insulin-induced hypoglycemia a delayed and expression of HSP72 in surviving neurons, which may be protective. Supported by the Swedish MRC.

676.7

POST-ISCHEMIC DEPOLARIZATION THRESHOLD FOR HSP72 FOS, AND JUN INDUCTION IN RATS. I.A. Halaby*, Y. Takeda, T.S. Nowak, Jr. and W.A. Pulsinelli, Dept. of Neurology, University of Tennessee, Memphis, TN 38163.

Following short periods of ischemia, HSP72 as well as the immediate early gene products, Fos and Jun, are induced in hippocampal neurons. Brief depolarizations are known to induce c-fos but not HSP72 in a number of experimental paradigms, and the mechanisms underlying the co-induction of these mRNAs after ischemia remain to be defined. In the present study, we examined the correlation between post-ischemic depolarization and the induction of HSP72, Fos and Jun. Extracellular electrodes were stereotactically positioned in CA1 and cortex of male Wistar rats, and forebrain ischemia was achieved by 4 vessel occlusion for 1 to 5 min. Brain and body temperature were maintained within physiological limits before, during, and after ischemia. At 3 h recirculation, animals were killed and consecutive frozen sections prepared for analysis. HSP72 mRNA was detected by *in situ* hybridization with a ³⁵S labelled oligonucleotide probe and the results quantitated by densitometry. Fos and Jun proteins were detected by immunocytochemistry using polyclonal antibodies (Oncogene Science). The length of post-ischemic depolarization varied for ischemic insults of apparently equivalent duration. Depolarization time was the better predictor of HSP72 and Jun expression with an apparent threshold of 2.5 min. Preliminary results identified a threshold of 1.5 min depolarization for Fos expression. These results implicate depolarization as a critical variable affecting gene expression after ischemia, and suggest that different thresholds may exist for Fos vs. Jun and HSP72 induction.

676.4

DEEP HYPOTHERMIA REDUCES POSTISCHEMIC HSP72 EXPRESSION IN PIGLET BRAIN. E.G. Shaver, L.N. Sutton, F.A. Welsh*, G. Mora, L.M. Gennarelli, C.R. Norwood, Div. of Neurosurgery, Univ. of Penn. Sch. of Med., Philadelphia, PA 19104.

The 72 kDa heat-shock protein, hsp72, has been induced in previous models of cerebral ischemia. Further, severe ischemia models which deplete ATP usually demonstrate hsp72 expression. The mechanism which triggers hsp72 induction is not clear. The objective of this investigation was to determine the ability of deep hypothermia (15°C) to alter the expression of hsp72 following severe cerebral ischemia.

Three-week-old piglets were placed on cardiopulmonary bypass and subjected to 60 min of cardiac arrest at 15°C or 24°C, followed by 2h of normothermic reperfusion. Regional expression of hsp72 mRNA was determined using *in situ* hybridization, and calculated as a percentage of total area of cortex. In the 24°C group, hsp72 was induced in a patchy pattern throughout most of the cerebral cortex (67±22%, N=9). In the 15°C group, the percentage of hsp72 expression was significantly reduced (23±20%, N=9). Hsp72 expression was patchy in both groups with no apparent anatomic localization.

This study demonstrates that hsp72 mRNA expression is strongly increased after global ischemia at 24°C, and the expression is significantly decreased if the temperature is lowered to 15°C. We speculate that deep hypothermia reduces cell stress below the threshold required to trigger hsp72 expression, despite depletion of ATP.

676.6

ENHANCEMENT OF hsp70 AND c-fos mRNA EXPRESSION FOLLOWING TRANSIENT FOCAL CEREBRAL ISCHEMIA IN TRANSGENIC MICE OVEREXPRESSING CuZn-SUPEROXIDE DISMUTASE. H. Kamii, H. Kinouchi, J. Koistinaho, F. R. Sharp, C. J. Epstein, S. F. Chen*, and P. H. Chan, Depts. of Neurology, Neurosurgery, and Pediatrics, Univ. of California at San Francisco and Dept. of Neurology, VA Medical Center, San Francisco, CA 94143.

A heat shock gene hsp70 and a proto-oncogene c-fos are activated by a variety of brain injuries including cerebral ischemia/reperfusion. Recently, these gene expressions are suggested to contribute to part of a survival mechanism. It is not known, however, whether oxidative stress produced by ischemia/reperfusion plays a role in these gene expressions. The purpose of the present study is to investigate the involvement of oxidative stress in these gene expressions following transient focal cerebral ischemia, using transgenic (Tg) mice overexpressing CuZn-superoxide dismutase (SOD). Male Tg mice and nontransgenic (nTg) littermates (30-35 g) were subjected to focal cerebral ischemia and reperfusion. After 10 min of middle cerebral artery occlusion, the mice were allowed variable periods of recovery up to 7 days. At each time point, the mice, both nTg and Tg (n=3 each), were decapitated and the brains were processed for *in situ* hybridization with a [³⁵S]-labeled hsp70 or c-fos oligonucleotide probe. After the hybridization experiments, the sections were counterstained with hematoxylin and eosin for histological examinations. In the ischemic cortex, expression of hsp70 mRNA was observed only up to 6 h after reperfusion in nTg mice, while it was seen up to 24 h in Tg mice. In the hippocampus, nTg mice showed the expression only at 1 h post reperfusion, whereas Tg mice revealed it up to 24 h with an intensive expression in the CA1 subfield. Likewise, prolonged expression of c-fos mRNA was observed in the hippocampus of Tg mice at up to 6 h, whereas it was observed at up to 1 h in nTg mice. There was no observable infarction for up to 7 days in both nTg and Tg mice. These results suggest that oxidative stress, along with other factors, affects the expression of hsp70 and c-fos mRNA following transient focal cerebral ischemia. We speculate that enhancement of these gene expressions in Tg mice may be associated with neuronal protection against ischemia/reperfusion injury.

676.8

PROTEIN SYNTHESIS AND EXPRESSION OF HSP72, FOS AND JUN AFTER TRANSIENT FOREBRAIN ISCHEMIA IN THE RAT. M. Okawa, I. Halaby, T.S. Nowak, Jr. and W. A. Pulsinelli* Dept. of Neurology, University of Tennessee, Memphis, TN 38163

Hsp72, c-fos and c-jun mRNAs are induced in brain after ischemia but their translation is impaired in vulnerable CA1 neurons in the gerbil. In this study, we investigated translational recovery and expression of proteins encoded by induced mRNAs after ischemia in the rat. Male Wistar rats were subjected to 2 min or 10 min 4-vessel occlusion. L-1-[¹⁴C]leucine (25 µCi) was given *i.v.* at various recirculation intervals, and incorporation measured by autoradiography of frozen sections (20 µm) extracted with 5% trichloroacetic acid. Other rats were perfused with 4% paraformaldehyde, and 50 µm vibratome sections processed for Fos, Jun and hsp72 immunoreactivity. After 10 min ischemia protein synthesis recovered progressively except in CA1, where a persistent 50% deficit remained at 24 h after the insult. CA3 showed more severe inhibition during early recirculation, reaching 25% of control at 1 h vs. 40% in CA1. This early selective deficit in CA3 was not seen after 2 min ischemia and recovery was almost complete in all regions at 24 h. Fos staining in CA3 was prominent after 2 min but not after 10 min ischemia, while CA1 Fos staining was more pronounced after 10 min vs. 2 min ischemia. Jun and hsp72 were detected in CA1 24 h after both insults, while CA3 staining was prominent after 10 min but not after 2 min ischemia. Thus protein synthesis recovery limits Fos expression in CA3 neurons that survive after 10 min ischemia, while there is sufficient recovery in vulnerable neurons of CA1 to allow Fos accumulation. It appears there is no simple relationship between expression of these induced proteins and neuronal survival after ischemia.

676.9

PROTEIN SYNTHESIS THRESHOLD FOR FOS EXPRESSION FOLLOWING TRANSIENT FOCAL ISCHEMIA IN RAT BRAIN. T. Kamiya, T. S. Nowak, Jr., M. Jacewicz* and W. A. Pulsinelli, Dept. of Neurology, Univ. of Tennessee, Memphis, TN 38163

The mRNA encoding the proto-oncogene c-fos is expressed in regions of a focally ischemic hemisphere in rats in which residual CBF remains above 40-50 ml/100g/min (30-40% of control). Cerebral protein synthesis begins to fail at somewhat higher residual blood flows (55-60 ml/100g/min or 50% of control). The present study investigated the relationship between protein synthesis recovery and expression of Fos protein after transient focal ischemia. The right middle cerebral artery (MCA) and common carotid artery were reversibly occluded for 1 h (n=4) or 3 h (n=3) in spontaneously hypertensive rats (1% halothane anesthesia, mechanical ventilation). After 1 h recirculation, 25 μ Ci L-1-[¹⁴C]leucine was infused intravenously and an additional 1 hr elapsed for radiolabeling cerebral proteins. Frozen brain sections (20 μ m) were collected on glass slides, extracted with 5% trichloroacetic acid, and imaged on Kodak SB-5 film. Regional [¹⁴C] incorporation into protein was determined by densitometry and expressed in the ischemic hemisphere as a percent of the average [¹⁴C] incorporation in the nonischemic hemisphere. Fos was detected in adjacent brain sections using a commercial antibody (Oncogene Science). Protein synthesis was severely reduced in the MCA territory after both 1 h and 3 h of ischemia. Fos immunoreactivity was not detected in cortex with less than 30% of control [¹⁴C] incorporation, was faintly detectable in cortex with 35-50% of control, and was striking in regions with above 50% of control. These results demonstrate that the lack of translational recovery may limit the expression of proteins encoded by induced mRNAs after focal ischemia.

HSP70 HEAT SHOCK GENE IN ISCHEMIC RAT BRAIN: CLONING, SEQUENCING AND CHARACTERIZATION. P. Narasimhan*, F. L. Longo, S. Wang and F. R. Sharp, Department of Neurology, Univ. of California and SFVAMC, San Francisco, CA 94121.

Heat shock genes are induced following ischemia and other injuries in mammalian brain. Five human and six mouse inducible hsp70 genes have been characterized. In this work, a rat ischemic forebrain cDNA library was screened with a reverse transcriptase PCR product from ischemic rat brain RNA to obtain an inducible rat hsp70 gene. The 1926 nucleotides in the open-reading frame of this gene codes for a 642 amino acid protein. The complete coding sequence of the rat hsp70 gene is most similar to the mouse hsp70 gene reported by Hunt and Calderwood (1990) and the human hsp70 gene characterized by Hunt and Morimoto (1985) with at least 90% similarity at the amino acid level. The rat hsp70 gene is distinct from the constitutive rat hsc73 and grp78 sequences. Northern blotting of rat ischemic brain RNA shows the rat hsp70 gene as a 2.9kb primary transcript. The rat hsp70 gene also showed low levels of basal expression in normal rat brain in northern analysis. This is consistent with similar expression reported by Hunt and Morimoto (1985). The cloning of the rat hsp70 gene should help in designing probes to study the other rat hsp genes in the CNS and help in defining their role in brain injury.

676.13

EFFECTS OF MILD HYPOTHERMIA ON EXPRESSION OF HEAT SHOCK PROTEIN-70 MRNA AND IMMUNOREACTIVITY FOLLOWING FOCAL ISCHEMIA IN RAT BRAIN. J. Chen, J. Q. Lan, M. Butman, R. P. Simon*, F. R. Sharp, and S. H. Graham, Department of Neurology, Univ. of Calif. San Francisco, CA 94143

Although hypothermia may reduce infarction after temporary focal ischemia, the degree of selective neuronal injury in the spared regions is difficult to assess using conventional histology. Therefore, we used the expression of HSP70, a sensitive marker of neuronal injury, to study the effect of hypothermia upon neuronal injury after ischemia.

Sprague-Dawley rats (n=16) underwent MCA occlusion for 2 hours followed by reperfusion. Brain temperature was maintained either at 37°C or 32°C during occlusion and at 37°C during reperfusion. Distribution of HSP70 mRNA in the brain was investigated by *in situ* hybridization 8 hours after reperfusion. Expression of HSP70 protein was determined at 24hrs after reperfusion by immunocytochemistry.

In normothermic brains: HSP70 mRNA was present throughout the ipsilateral MCA territory, most intense adjacent to the infarcted regions in caudate and border zone. Neuronal HSP70 immunoreactivity was only present in the narrow rostral border zone in cortex while glial and endothelial expression was present within the infarction. In hypothermic brains: Intense HSP70 mRNA was present in caudal cortex and caudate putamen, but reduced or absent throughout rostral cortex. HSP70 immunoreactivity was widespread in neurons of layers 3 and 5 in the caudal cortex but absent in rostral cortex.

These results suggest that while mild hypothermia prevents infarction of much of cortex, many neurons in this region are injured and express HSP70 protein. The lack of expression of HSP in the rostral cortex suggests that this region is protected by mechanisms other than HSP70 expression.

676.10

HEAT PRETREATMENT CAN PROTECT ASTROCYTES IN CULTURE FROM OXYGEN GLUCOSE DEPRIVATION INJURY. R. G. Giffard, S. M. Amagasa, V. M. G. Bruno, J. Cao* and A. J. Giaccia, Depts. of Anesthesia and Radiation Oncology, Stanford University School of Medicine, Stanford CA 94305

Heat and other stresses are known to induce production of heat shock proteins (hsps). Prior treatment with heat has been shown to protect many cell types from subsequent heat injury and retina from subsequent laser injury. To better understand the role of hsps in such protection we characterized the heat tolerance of primary cultures of astrocytes from mouse cortex to heat, and then determined their sensitivity to oxygen glucose deprivation (OGD) with or without prior heat treatment. An insult of about 2 hr at 44°C led to loss of essentially all the astrocytes, while durations of 15-30 min produced essentially no cell loss. Injury was quantitated by release of lactate dehydrogenase. Brief heat treatment induced production of hsp70, the inducible form of the 70 kd hsp, as detected by immunohistochemical staining (Amersham RPN 1197) 18 hr after heating. Astrocytes heated at 44°C for 30 min and allowed to recover at 37°C for 16-20 hr showed a significant reduction in injury due to 10 or 12 hr of OGD compared to sham washed sister cultures subjected to OGD. These results demonstrate sublethal heat pretreatment reduces astrocyte injury due to subsequent OGD.

IDENTIFICATION BY DIFFERENTIAL SCREENING OF HEAT SHOCK PROTEIN-86 INDUCED IN GERBIL HIPPOCAMPUS FOLLOWING TRANSIENT GLOBAL ISCHEMIA. R. M. Sklar, C. G. Caday, D. J. Berlove, A. Kemmou, R. H. Brown, Jr. and S. P. Finklestein*, CNS Growth Factor Research Laboratory, Department of Neurology, Massachusetts General Hospital and Harvard Medical School, Boston, MA 02114.

Transient global forebrain ischemia in gerbils selectively damages vulnerable neurons, most prominently in the CA-1 sector of the hippocampus. Immediately following global forebrain ischemia, CA-1 neurons appear normal and respond to electrical stimulation; but then go on to die within 2-4 days. Elucidation of the molecular events that lead to delayed neuronal death is key towards developing alternative therapies for stroke and related ischemic disorders.

Using a differential screening method, we selected 30 gene clones that are modulated in gerbil hippocampus following transient global ischemia. Dot blot analysis showed at least six different patterns of expression of these genes after ischemia. DNA sequencing revealed one of these genes to be homologous to heat shock protein (HSP)-86. Northern blot studies showed about 4- to 6-fold induction of HSP-86 gene in gerbil hippocampus at 4 hours to 1 day after ischemia; the mRNA levels declined to basal level at about 2-4 days after ischemia. Maximal expression of the putative HSP-86 occurred before the onset of delayed neuronal death in the hippocampus after ischemia.

The present study is consistent with the hypothesis that transient global ischemia initiates cascades of protein syntheses -- including those involved in either cell death or cell survival response pathways.

676.14

C-FOS, JUN-B, AND C-JUN mRNA EXPRESSION FOLLOWING FOCAL CEREBRAL ISCHEMIA IN RATS

H. Kinouchi, F. R. Sharp, J. Koistinaho, S. M. Sagar, T. Yoshimoto, R. A. Fishman*, P. H. Chan

Dept. of Neurosurgery, Tohoku Univ. Sendai 980, Japan, Dept. of Neurology, UCSF, CA 94143, Dept. of Neurology, VAMC, San Francisco, CA 94121

Thalamus and substantia nigra become atrophic following middle cerebral artery (MCA) occlusion by retrograde degeneration. Immediate early genes (IEG), c-fos, c-jun, and jun-B are induced by a wide variety of stimuli, including transsynaptic excitation. In the present study, we have investigated the IEG and heat shock protein (HSP) mRNA expression at 1, 4, 24 hrs. following MCA occlusion to demonstrate the neuronal network disturbance using *in situ* hybridization (ISH). The c-fos and jun-B mRNAs were co-induced rapidly outside the ischemic core, the cingulate gyrus and medial striatum at 1 hr. following MCA occlusion. At 4 hrs. of MCA occlusion, both c-fos and jun-B mRNAs were induced in both hippocampi and medial geniculate nucleus and in the ipsilateral substantia nigra and thalamus. These signals decreased after 24 hrs. of MCA occlusion. Only a slight induction of c-jun mRNA occurred in the ipsilateral cortex and striatum outside the ischemic core at 4 hrs. of MCA occlusion, whereas the signal was greater at 24 hrs. than at 4 hrs. of MCA occlusion. The ischemic core showed no hybridization signals for IEG throughout the time course. hsp70 mRNA was markedly induced in the peripheral regions of the ischemic cortex and the striatum of MCA distribution even at 24 hrs. of MCA occlusion. However, some animals showed hsp70 mRNA induction in the ipsilateral hippocampus, thalamus, substantia nigra, and medial geniculate nucleus. These data suggest that transsynaptic activation of neurons may account for the ipsilateral and contralateral expression of IEG in areas outside of the ischemic core.

FACTORS AFFECTING HIPPOCAMPAL BRAIN SLICE HISTOLOGY. G. C. Newman*, H. Qi, F. E. Hospod and Z. Bekele-Arcuri. Neurology Service, VAMC at Northport, NY and SUNY at Stony Brook, NY 11794.

Histology is useful both for assessing brain slice quality and as an assay of tissue injury in response to chemical insults. Pre-incubation at 22°C. for 45 min prior to warming to 37°C. yields slices with 90% of normal appearing neurons in CA1, CA2 and the suprapyramidal blade of dentate after 4 hours *in vitro*. Despite this, neurons in CA3 and CA4 show uniformly poor histology even after much shorter incubations. We have attempted to identify the factors which contribute to neuronal injury during slice incubation.

Hippocampal brain slices prepared from 250g male Sprague-Dawley rats were incubated at 22°C. for 45 min, warmed to 37°C. and incubated for up to 4 hours *in vitro*. Slices were fixed with Bouin's fixative, paraffin embedded, sectioned at 7 μ and stained with H&E. CA1, CA2, CA3, CA4 and dentate histology was assessed at 100X with a 5 point scale by a blinded observer.

Histologic injury of CA1, CA2 and dentate occurred within 15 min of slice isolation and did not increase after 4 hours while CA3 and CA4 histology was even more severely injured after 15 min and continued to worsen throughout the incubation. Incubating slices in buffer with 0 mM Ca⁺⁺ and 10 mM Mg⁺⁺ for the first 45 min produced slight additional improvement in CA1 and considerable improvement in CA3 after 4 hours *in vitro* but 0 mM Ca⁺⁺ without Mg⁺⁺ worsened histology of CA1, CA2 and dentate. Replacing Na⁺ with choline for the first 15 min of slice incubation improved histology of all regions but continuing choline beyond 30 min caused severe histologic injury. Incubation with 400 μ M ascorbic acid or acutely cutting the mossy fibers at the time of slice preparation failed to improve histology. The effects of technical issues such as animal size, depth of slice submersion and fixation temperature will also be presented.

GLOBAL ISCHEMIA IN RATS YIELDS STRIATAL PROJECTION NEURON AND INTERNEURON LOSS RESEMBLING HUNTINGTON'S DISEASE.

G. Figueredo-Cardenas*, K. Baxter, T.S. Nowak, W. Pulsinelli and A. Reiner. Dept. Anat & Neurobiol., Dept. Neurol., UT, Memphis, TN 38163.

Huntington's disease (HD) is characterized by complete sparing of striatal interneurons and profound loss of projection neurons. Among projection neurons, loss of enkephalinergic (ENK+) neurons projecting to the lateral globus pallidus and substance P-containing (SP+) neurons projecting to the substantia nigra pars reticulata (SNr) occurs more rapidly and earlier in the disease process than does loss of SP+ striatal neurons projecting to the medial globus pallidus. Since preferential sparing of striatal interneurons has also been demonstrated after transient ischemia, we examined in detail the pattern of both striatal projection and interneuron loss after global ischemia in rats. One week after 30 min bilateral carotid and vertebral artery occlusion, alternate brain sections from the animals were processed for the visualization of striatal interneurons or terminals in striatal targets using histochemical or immunohistochemical methods.

The ischemic episode produced profound loss of striatal neurons in the dorsolateral striatum, with survival of many neurons medially and caudally. We found complete sparing of diaphorase-containing, parvalbumin-containing, and choline acetyltransferase-containing interneurons even in striatal regions seemingly devoid of other neurons. We also found severe loss of ENK+ terminals in the lateral globus pallidus and SP+ terminals in the SNr, but much less loss of SP+ terminals in the medial globus pallidus (i.e. ento-peduncular nucleus) and the SN compacta. This pattern of striatal cell loss following transient ischemia resembles that in HD even more closely than previously realized, suggesting that the pathogenetic process in HD and ischemia may involve related mechanisms. Further study of the mechanisms producing ischemic striatal cell death may thus clarify the mechanisms involved in HD. HDF, NS-19620, NS-28721 (AR).

PERSISTENCE OF CHOLINE ACETYLTRANSFERASE-IMMUNOPOSITIVE NERVE FIBERS IN THE ISCHEMIC RAT HIPPOCAMPUS. A.B. Kopstein*, L.A. Sebring, B.K. Hartman, P.L. Faris, and W.C. Low. Depts. of Neurosurgery, Physiology, Psychiatry, and Graduate Program in Neuroscience, University of Minnesota Medical School, Minneapolis, MN 55455.

It has been demonstrated previously that intrahippocampal transplantation of fetal pyramidal neurons restores spatial navigation function in rodents with ischemic brain injury. These functional effects are thought to be mediated by graft-to-host projections to the subiculum and host-to-graft inputs from CA3 pyramidal neurons. In normal animals, these connections appear to convey precise information about the external spatial environment. Inputs of cholinergic fibers from the medial septal nucleus to the hippocampal formation (HF) have also been shown to play an important role in spatial memory function. We have used choline acetyltransferase (ChAT) immunohistochemistry to examine whether cholinergic afferent fibers persist in the HF after ischemic brain injury and thus may be available to form connections with transplanted pyramidal neurons. Unanesthetized Wistar rats were subjected to 20 minutes of global cerebral ischemia by the four-vessel occlusion technique of Pulsinelli and Brierty. Animals were subsequently processed for ChAT immunocytochemistry at 2, 4, and 8 weeks following the ischemic episode. At all of these time periods, we have found that ChAT-positive fibers persist in the stratum oriens and radiatum of the CA1 subfield of the rat HF. The presence of these cholinergic fibers within the CA1 hippocampal region long after ischemic injury provides the opportunity for these neurons to establish connections with transplanted pyramidal neurons and to incorporate the grafted cells within the neural circuitry of the host brain. [This work was supported in part by an American Heart Association Medical Student Research Fellowship Award (AHA-91005050) and PHS grant R01-NS-24464.]

677.2

QUANTITATION OF PERIVASCULAR MACROPHAGES IN THE BRAINS OF HYPERTENSIVE OR AGED RATS. Y. Liu, D.M. Jacobowitz, G. Feuerstein, J.M. Hallenbeck* and A.-L. Sirén. Dept. of Neurology, USUHS, Bethesda, MD 20814; Lab. of Clinical Science, NIMH; Stroke Branch, NINDS, Bethesda, MD 20892; and Dept. of Pharmacology, SmithKline Beecham, King of Prussia, PA 19406.

The numbers of perivascular macrophages in the brains of hypertensive or aged rats were studied using the immunohistofluorescence technique. Perfusion-fixed frozen brain sections (16 μ) of spontaneously hypertensive rats (SHR), stroke-prone SHR (SHR-SP) and normotensive Wistar-Kyoto (WKY) rats as well as 2-year-old (2Y) and 16-week-old (16W) Sprague-Dawley (SD) rats were exposed to specific monoclonal antibodies against rat macrophages (ED2). All slides were double stained with anti-Factor VIII antibodies for the identification of endothelial cells which showed no ED2 staining. The quantity of perivascular cells per square millimeter of high power field was significantly greater in SHR-SP (8.6 \pm 2.1, n=4) and SHR (6.7 \pm 0.9, n=6) than in normotensive WKY (4.0 \pm 0.5, n=6) (p<0.01). In addition, the number of perivascular macrophages was greater in 2Y-SD-rats (7.5 \pm 2.7, n=9) than in 16W-SD-rats (2.9 \pm 1.8, n=8, p<0.01). No ED2 staining was found in the parenchymal resident microglia or in the endothelial cells. The results suggest that an increased subendothelial accumulation of macrophages is associated with the stroke-risk factors, hypertension and advanced age. This could increase the tendency for the endothelium to convert from an anticoagulant to a procoagulant surface in response to proinflammatory and procoagulant mediators released from these subendothelial cells.

IMMEDIATE AND LONGTERM MORPHOLOGICAL CHANGES IN THE RAT HIPPOCAMPUS AFTER FOREBRAIN ISCHEMIA. M. Hsu*, F. Gallyas, A. Sik and G. Buzsáki. Ctr. for Neurosci., Rutgers University, Newark, NJ.

Ischemia-induced morphological changes in the rat hippocampus were studied 1-365d after induction of ischemia using the 4-vessel-occlusion model of Pulsinelli and Brierley (1979). Degenerative changes were assessed using the Gallyas "dark neuron" stain, microglia stain, and the Gallyas stain for degenerating terminals. In addition, short-term (1-7d) morphological changes were also studied using immunocytochemistry against heat shock protein (HSP72), the calcium binding proteins (CaBPs) parvalbumin, calbindin and calretinin, and the neuropeptides somatostatin (SS) and neuropeptide Y (NPY). The time course of degeneration of vulnerable cell populations determined using the "dark neuron" stain was similar to that previously reported, i.e. argyrophilic hilar cells were found 1d after the ischemic insult while CA1 pyramidal cells did not become argyrophilic until 3-4d postischemia. CA3 pyramidal cells and dentate granule cells were resistant. Other vulnerable cell populations included subicular neurons, CA2 pyramidal cells, and spiny interneurons in the stratum lucidum of CA3. Results from both silver-stained material and double immunolabelling of HSP and neuropeptides and CaBPs confirmed our previous results that many hilar cell groups (other than SS neurons) were susceptible. A continuous state of degeneration was evident 7-365d postischemia, as indicated by the presence of degenerating terminals, argyrophilic neurons, and reactive microglia. Reactive microglia could be detected at 1-9 mo postischemia, but only in areas where argyrophilic cells were found after ischemia, i.e. the dentate hilus, subiculum, stratum lucidum of CA3, and area CA1. Cell counts of both Nissl- and immunostained material in these areas provide further support that the argyrophilic (or "dark" neurons) degenerated after ischemia.

LOCOMOTOR ACTIVITY IN THE ISCHEMIC GERBIL. A.M. Babcock¹, and P. Lomax^{2,3*} Dept. of Psych., Montana State Univ, Bozeman MT, 59717; ²Dept of Pharm., UCLA, Los Angeles, CA 90024.

Previous studies have shown that gerbils exhibit increased locomotor activity within 24 hrs following an ischemic insult. Since activity gradually diminishes to normal levels with repeated testing, it has been argued that this behavior represents a reversible or transient effect of ischemia. We challenged this notion by testing ischemic gerbils at a time point where increased activity is not observed with repeated testing. Ischemic (5-min bilateral carotid occlusion) and sham gerbils were tested for 14 consecutive days following reperfusion in an open-field apparatus (n=6/condition). As previously reported, ischemic gerbils exhibited a significant increase in activity (days 1 and 2) which returned to sham levels with repeated testing (days 13 and 14). A second group of ischemic and sham gerbils (n=6/condition) were tested only on days 13 and 14 following reperfusion. In contrast to those tested repeatedly, these ischemic gerbils displayed increased locomotor activity as compared to sham controls. In addition, gerbils in the repeated testing conditions were evaluated in a semi-novel testing environment on days 15 and 16 following surgery. The locomotor activity of these ischemic gerbils significantly increased in response to the semi-novel environment. These results suggest that the effects of ischemia on locomotor activity are not limited to a brief period following occlusion and may represent a permanent deficit. In addition, as previously suggested, this behavior may represent a deficit in habituation or spatial mapping rather than motor hyperactivity.

LOCOMOTOR DEFICITS IN ADULT ANIMALS FOLLOWING NEONATAL ISCHEMIC-HYPOXIA. E.M. Jansen* and W.C. Low. Depts. of Neurosurgery and Physiology, Grad. Prog. in Neuroscience, Univ. of Minnesota, Mpls., MN 55455.

Perinatal ischemic-hypoxia in humans creates neurologic injury that often manifests as motor deficits throughout development and at maturity. In these studies, we utilized an established model of neonatal ischemic-hypoxia that creates unilateral striatal, cortical and hippocampal damage (Rice, et al, Ann. Neurol., 9:131-141, 1981) to investigate locomotor deficits in the animals as adults. Seven day-old Wistar rat pups underwent unilateral carotid artery ligation and were then exposed to 2.5 hours of hypoxia (8% O₂, 92% N₂, 37°C). Following this, animals were reared normally and locomotor ability was assessed throughout development using a rotating treadmill (Rota-Rod, Ugo Basile). Normal animals tested once a week for seven weeks improved significantly over time. Animals that experienced ischemic-hypoxia as neonates were not able to remain on the treadmill as long as their same-sex littermate controls at 3, 4, 5 and 6 weeks of age ($p < 0.027$, ANOVA). There were no significant differences after 6 weeks of age, suggesting that this motor task revealed a developmental delay rather than a permanent deficit. Upon examination of whole brains after perfusion, some brains showed generalized hypertrophy in the hemisphere contralateral to the ligation. The Rota-Rod performance scores for these animals were significantly better than those of the animals without contralateral hemisphere hypertrophy over all weeks tested ($p < 0.02$, ANOVA). These data suggest that 1) Rota-Rod performance is an appropriate test of motor ability for use in this model of neonatal ischemic-hypoxia to screen for animals with severe neural injury, and 2) in this model of neonatal ischemic-hypoxia, there may be compensatory mechanisms which occur in the undamaged hemisphere of some animals that may account for a recovery of function. BEAM WALKING WITHOUT ADVERSIVE STIMULI AS A TOOL TO RECORD MOTOR RECOVERY AFTER PHOTOCHEMICAL INDUCED UNILATERAL LESION OF THE SENSORY-MOTOR CORTEX. TRAINING EFFECT CONTRA d-AMPHETAMINE TREATMENT.

B. Bjelke*, S.A. Brown, S. Sabouri, K. Fuxe

Dept. of Histology and Neurobiology, Karolinska Institutet, Stockholm, Sweden. *Dept. of Physical Medicine and Rehabilitation, Mayo Clinic, Rochester, Minnesota USA

In various stroke models d-amphetamine has been shown to improve the rate of motor recovery after brain damage. Sprague-Dawley male rats b.w. 300g housed under standardised conditions were trained in beam walking until they achieved a score of 7 on a motor deficit rating scale from 1 (unable) to 7 (normal) on two consecutive 90 sec. daily trials. The home cage was used as a goal and no aversive stimuli were used in training or testing. A unilateral sensory-motor cortex lesion was photochemically induced using cold white light and Rose Bengal as the photosensitive dye. Recovery of the locomotor deficit was recorded as early as 4h after the lesion and up to ten days after the lesion. The most rapid recovery was seen in rats that received only one 2 hour training session 24 h after the lesion. Animals treated with a single 2mg/kg dose of amphetamine 24 h after the lesion recovered less rapidly than animals with lesion alone. Morphological analysis was done using immunohistochemical markers and Nissl staining. Thus, using nonaversive stimuli and photochemically induced sensory-motor cortex lesion no enhancement of locomotor recovery was obtained from amphetamine treatment.

BRIEF ASPHYXIA DURING BIRTH PRODUCES DEFICITS IN ACQUISITION, BUT NOT RETENTION, OF A SPATIAL LEARNING TASK IN THE ADULT ANIMAL. A. Krishnamurthy, W. Brooks, B. Noel, A. Gratton and P. Boksa*. McGill University, Depts. of Psychiatry and of Neurology & Neurosurgery, Douglas Hospital Research Center, Montreal, Quebec, Canada, H4H 1R3.

While birth complications are thought to contribute to major deficits in some neurological disorders, a role for brief asphyxia in more subtle alterations of CNS functioning is much less recognized. Morphological studies indicate that the hippocampus, an area which plays an important role in learning and memory, is particularly vulnerable to perinatal asphyxia. The present study examined consequences of brief asphyxia at birth on spatial learning in male rats in the Morris water maze. In the model of birth asphyxia (Bjelke et al, Brain Res., 1991, 543, 1), the entire uterus was removed on the day of birth and immersed in a water bath for 5-20 min before delivery. Control animals were either born vaginally or delivered by C section. At 1 month of age, rats who had undergone 15 min of birth asphyxia showed no deficit in acquisition of place learning (i.e. time to find the hidden platform). At 4 months of age, rats who had undergone 10, 15 or 20 min of birth asphyxia showed a deficit in initial acquisition of the place navigation task compared to control groups, while the 5 min group performed similarly to controls. With further training, all animals eventually learned the task effectively. Following overtraining, there was no difference among groups on retention of the place navigation task. There was also no difference in latency to find a visible platform, indicating no deficits in sensorimotor ability or motivation. In addition, there were no group differences in locomotor activity in an open field, indicating that motor activity is undisturbed. Our results indicate that a brief period of asphyxia during birth can produce subtle deficits in spatial learning that become evident only in adulthood. (Supported by the Medical Research Council of Canada.)

LOCOMOTOR DEFICITS IN RATS WITH A COLLAGENASE-INDUCED INTRASTRIATAL HEMORRHAGE. J. A. Chesney*, T. Kondoh and W.C. Low. Depts. of Neurosurgery and Physiology, Graduate Program in Neuroscience, University of Minnesota Medical School, Minneapolis, MN, 55455.

Previous studies have shown that injection of the metalloproteinase collagenase directly into the caudate nucleus of rats causes an intracerebral hemorrhage (Rosenberg et al., Stroke 21:801-807, 1990). In the present study we have examined the functional deficits associated with a hemorrhagic lesion of the striatum. Twelve adult rats received a 2 µl infusion of bacterial collagenase (0.5 unit in saline) into the right striatum. The rotational response to apomorphine (1 mg/kg, s.c.) injection was then examined at 1, 4, 7, 21, 35 and 70 days after the surgery. A net ipsilateral rotation was noted for all days. The average rotational asymmetries on these days were: 14.57 ± 2.9, 20.33 ± 2.7, 19.99 ± 4.4, 18.95 ± 4.9, 17.03 ± 4.9 and 14.4 ± 4.7, respectively (data expressed as mean clockwise rotations/5 min ± SEM). In addition to rotation studies, the initiation of stepping movements in each forelimb was determined 8 weeks after surgery. The average number of steps initiated by the forelimb ipsilateral and contralateral to the lesion was 28.3 ± 2.1 steps/min and 13.6 ± 1.5 steps/min, respectively. This significant difference ($P < 0.05$) was stable and reproducible for three consecutive days. We conclude that collagenase-induced intrastriatal hemorrhage results in long-term locomotor deficits and therefore is a useful model for developing strategies for the restoration of neurologic function after intracerebral hemorrhage. (Supported by grants from the American Heart Association and PHS grant RO1-NS-24464.)

677.10

N-tert-BUTYL-α-PHENYL-NITRONE (BPN), A FREE RADICAL SCAVENGER, FACILITATES LEARNING BY ELDERLY GERBILS FOLLOWING BILATERAL CAROTID OCCLUSION (BCO) J. A. Stanley*, C.O. Bull, S.L. Moon, and A. A. Ortiz. CNS Neuropharmacology, Bristol-Myers Squibb Company, Wallingford, CT 06492

Because of an anomalous circulatory pattern in the Mongolian Gerbil, temporary bilateral occlusion of carotid arteries (BCO) can be used to produce a reliable model of transient, global cerebral ischemia. Drugs have been shown to protect sensitive brain regions, e.g., the hippocampus, from damage resulting from BCO. Since the hippocampus is involved in spatial learning, tasks that rely on spatial discrimination are used to assess behavioral dysfunction following BCO. Elevated levels of free radicals (1) have been implicated in the damage that follows transient ischemia and (2) are associated with the detrimental effects of aging on memory. Free radical scavengers attenuate BCO-induced cell death in the hippocampus of young gerbils. They also reduce the number of errors made by normal old gerbils during training in a radial arm maze.

This study investigated the effect of short-term treatment with N-tert-butyl-α-phenyl-nitron (BPN), a free radical scavenger, on performance by elderly gerbils in a radial arm maze following BCO.

A total of 82 fasted old male gerbils were used; half underwent a 3-min BCO. In the remaining (shams) the carotids were exposed but not clamped. All were treated with 30 or 60 mg/kg BPN or saline 1 hr after reperfusion and every 12 hrs thereafter for 3 days. Starting 2 wks after surgery, spatial learning was assessed in an 8-arm radial maze using the number of errors made during 15 days of training. After the last trial, the brains were removed and the damage in the hippocampus was histologically analyzed.

When normal blood flow is interrupted for 3 mins in non-treated old gerbils, the rate of acquisition of spatial learning is significantly impaired when compared to sham gerbils. Gerbils treated with BPN following BCO made significantly fewer errors during acquisition of the task when compared with those who were occluded but not drug treated. Sham operated gerbils treated with BPN also tended to perform better than those given only saline.

The results of this study suggest that compounds that are free radical scavengers may be useful in the treatment of age-related memory impairment as well as in facilitating learning following stroke.

677.12

BMS-183729 PREVENTS MEMORY LOSS IN THE ISCHEMIC GERBIL. MA Kapin¹, AM Babcock². ¹Bristol-Myers Squibb Co., Wallingford, CT 06492; ²Dept. of Psych., Montana State Univ., Bozeman, MT, 59717

The present study evaluated the neuroprotective efficacy of the novel hypothermic producing agent, BMS-183729 (formally BMY-20862; 5,6-dihydro-11-methyl-1H-pyrimido[4,5-g][1,4]benzodiazepinemono-hydrochloride hydrate) using a standard step-down avoidance paradigm. In Exp. I, conscious gerbils were injected with BMS-183729 (30 mg/kg) or vehicle and changes in rectal temperature were monitored for 4 h. Drug, but not vehicle treated gerbils, exhibited a significant reduction in temperature within 10 mins. that continued for at least 240 mins. In Exp. II, the histopathological and behavioral changes following 5 mins. of carotid artery occlusion in gerbils pretreated with BMS-183729 were evaluated. As previously reported, BMS-183729 (30 mg/kg) attenuated cell death to the hippocampal CA1 sector following an ischemic insult. Step-down latencies of both sham and BMS-183729 treated gerbils 24 h following training were significantly increased, indicating successful avoidance learning. Ischemic control gerbils failed to exhibit any significant change in latency suggestive of no avoidance learning. Our findings indicate that, in addition to protecting the hippocampal CA1 sector from necrosis, BMS-183729 also prevents memory deficits typically associated with ischemia.

CHARACTERISTICS OF A NEW REVERSIBLE CEREBRAL ISCHEMIC STROKE MODEL IN THE RAT. K.H. LEE* and J.S. Han. Dept. of Neurosurgery, Sch. of Med., Hallym Univ., Kangdong Sacred Heart Hospital, Seoul, 134-701, Korea.

We have been tried to develop a new reversible ischemic model in the rat and to characterize it. Under chloral hydrate (300 mg/kg, IP) anesthesia, the common, internal and external carotid arteries exposed. Temporary trapping was done at the exposed common carotid artery with two microclips and a 5 cm 6-0 or 7-0 nylon monofilament topped with a ball (200-300 μ m in diameter) of iron powder and epoxy was inserted through a microhole at the mid-trapped area. After removal of microclips, the inserted monofilament was introduced about 2 cm to the origin of middle cerebral artery via internal carotid artery until feeling of some resistance. After 1, 2, 4 and 24 hours occlusion, each introduced monofilaments were withdrawn and all rats kept alive for 2 days. We have periodically checked behaviors from the time of awakening to death and measured the infarcted areas of each groups using 2% neutral red infusion for counter-staining. All rats revealed dense contralateral forelimb weakness at awakening but none of 1-hr occlusion group (9 rats), 2 of 2-hrs (9), 5 of 4-hrs (6) and 10 of 24-hrs (13) noted weakness before death. There was no infarction in 1-hr occlusion while definite and wider infarct areas in others according to occlusion times ($p < 0.001$, $p < 0.001$, $p < 0.001$). We have considered this animal model as a new, simple, reproducible, confident and reversible one.

677.15

CHANGES IN LESION VOLUME AND EDEMA OVER TIME FOLLOWING FOCAL CEREBRAL ISCHEMIA IN THE RAT. T.L. Sailer, T.L. Graessle, J.T. Simmonds, J.T. Haskins*, and J.A. Moyer. CNS Division, Wyeth-Ayerst Research, CN 8000, Princeton, NJ 08543-8000.

Ischemic damage caused by occlusion of cerebral arteries involves a dynamic process of events. While most studies of cerebral ischemia focus on relatively early time points (<48 hours post-occlusion), evolution of the infarcted region continues for several weeks post-insult. This continuing evolution may be responsible for some of the recovery seen in human stroke patients over time. To assess changes in the nature of ischemia-induced infarcts over time, infarct volume and edema were measured in a model of focal cerebral ischemia in the rat. Tandem permanent occlusion of the right common carotid and middle cerebral arteries was performed on male Fischer-344 rats. Infarct volume and edema were measured at 1, 2, 4, 7, and 14 days post-occlusion.

Infarct volume increased to a maximum of 48.88 mm³ at 2 days post-occlusion. Edema in the infarcted right hemisphere also peaked at 2 days at 79.59% water content. After 2 days, infarct volume and edema diminished rapidly. At 7 days infarct volume was reduced to 12.75 mm³ and by 14 days volume had further decreased to 4.62 mm³. Edema in the infarcted hemisphere was reduced to 79.17% by 4 days and decreased to a normal range by 7 days. These results suggest that while pharmacological assessment of neuroprotection at early time points may produce significant differences between groups, later time points should be used to assess the long term benefit of treatment.

677.17

A PHOTOTHROMBOTIC MODEL OF STROKE-IN-EVOLUTION P. Wester*, B.D. Watson, R. Prado, W.D. Dietrich, Umeå Stroke Research Group, Univ. of Umeå, Sweden and CVD Research Center, Univ. of Miami, School of Medicine, FL 33101.

This study aimed at developing a thrombotic cortical infarction model with a large, consistent and easy observable intrafocal "area at risk". A ring-shaped pattern of cortical vascular occlusion was induced photochemically by the intravascular interaction of the photosensitizing dye, Erythrosin B (ErB), with a 514.5 nm ring beam, derived from an argon laser and incident on the intact skull surface of anesthetized Wistar rats (n=84). The ring beam was generated by focussing the argon laser beam into an optical fiber at a 12° off-axis angle of incidence. At the fiber output end, the resultant 5 mm diameter, 0.5 mm thick ring beam was located within the coronal, sagittal and lambdoid sutures and the parietal bone crest. Transcardial carbon black perfusions (n=67) were performed at 1, 4 and 24 hr to study vascular patency at various irradiation powers (25-80 mW), duration's (2-5 min) and [ErB] from 8.5-34 mg/kg. To evaluate blood-brain barrier integrity, horseradish peroxidase (HRP) was administered i.v. followed by histopathological analysis of coronal and sagittal brain sections.

With [ErB] at 17 mg/kg, irradiation for 2 min at 65 mW produced at 1 hr a ring-shaped cortical deficit which expanded in time, as observed at carbon black perfusion; the ring interior was spared at 4 hr but was occluded by 24 hr (n=3 in each group). Coronal sections which bisected the irradiated ring region revealed two ischemic foci (originating from the ring segments) which expanded over a 24 hr period to include the region between. A ring pattern of severe HRP extravasation surrounding an area of minimal HRP leakage was observed 15 min following irradiation (n=3). Examination of hematoxylin and eosin stained coronal sections at 4 hr revealed a toroidal shaped cortical infarct with a central core of normal appearing neuropil extending to the subcortical white matter and containing a few scattered ischemic neurons (n=3). By 24 hr the central core progressed to infarction with only superficial cortical layers exhibiting some degree of neuropil conservation, but containing extensive ischemic neurons (n=3). This model of a controllable "penumbra zone" may facilitate reliable and reproducible tests of anti-ischemic drugs.

677.14

Recovery from anaesthesia improves outcome following transient but not permanent focal cerebral ischaemia in the rat. D.A. Dawson, J. McCulloch*, D.I. Graham and I.M. Macrae, Wellcome Surgical Institute, University of Glasgow, Glasgow G61 1QH, U.K.

Adult male Sprague-Dawley rats were anaesthetised with halothane in N₂O/O₂. The left middle cerebral artery was occluded (MCAO) permanently by diathermy, or transiently by application of endothelin-1 (2.5nmol). Physiological variables were monitored throughout. Following surgery rats were maintained under anaesthesia or allowed to recover consciousness. All rats were perfused fixed 4 hours post-MCAO and volumes of ischaemic damage assessed using quantitative histopathology.

In the anaesthetised groups mean arterial pressure (MAP) remained relatively stable whereas in the recovery groups MAP rapidly increased following withdrawal of anaesthetic. Volumes of ischaemic damage did not differ significantly between anaesthetised and recovery groups for permanent MCAO (n=6) but were significantly reduced in the recovery group compared to the anaesthetised group for transient MCAO (n=10-12). Data is presented as mean \pm S.E.M., *P < 0.05, unpaired Student's t-test.

	MAP (mmHg)			Volume of damage (mm ³)		
	MCAO	+1h	+4h	Hemisphere	Cortex	Striatum
Permanent						
Anaesthetised	91 \pm 8	85 \pm 3	88 \pm 4	107 \pm 6	69 \pm 5	30 \pm 2
Recovery	89 \pm 4	114 \pm 4	123 \pm 7	131 \pm 15	95 \pm 14	28 \pm 1
Transient						
Anaesthetised	86 \pm 3	82 \pm 2	87 \pm 2	48 \pm 8	32 \pm 7	13 \pm 3
Recovery	84 \pm 4	121 \pm 3	132 \pm 3	23 \pm 4*	17 \pm 3	5 \pm 1*

We have shown that recovery from anaesthesia does not improve early outcome following permanent MCAO but is of benefit in the endothelin-1 transient occlusion model where volume of infarct is reduced by 50%. In this model augmentation of blood pressure may improve reperfusion through the previously constricted MCA. It remains to be established whether this early beneficial effect may be superceded by a later increase in free-radical associated damage.

677.16

THE EFFECT OF TIME AFTER OCCLUSION ON INJURY VOLUME IN A RABBIT MODEL OF FOCAL CEREBRAL ISCHEMIA. J.L. Browning*, M.A. Widmayer, K.K. Hoffmann and D.S. Baskin Dept. of Neurosurgery, VAMC Houston and Baylor College of Medicine, Houston, TX 77030.

Studies by others have suggested that infarct volume changes as a function of post-occlusion survival time in rodents (Gonzales Soc. Neurosci. Abstr. 18:1260, 1992). Therefore, as a prelude to studies of the effects of drug treatment on survival and injury volume, the effect of time post-occlusion on injury volume was studied in rabbits with focal cerebral ischemia. Focal cerebral ischemia was induced in twenty-eight male rabbits, 2.6-3.5 kg, by occlusion of 1 mm of the middle cerebral and accessory middle cerebral arteries. At 28 hr, 7 days, and 3 weeks after occlusion, the animals were sacrificed, their brains removed, sliced coronally and stained with triphenyltetrazolium chloride (TTC). In a blinded fashion, areas of infarct (colorless), ischemic (lightly stained), and normal (fully stained) were delineated from photographic slides, and digitized to determine injury volume. No differences were found in any injury measure between animals surviving 28 hours and those surviving 7 days. However, at three weeks, infarct volume had decreased to 4.5 \pm 1.9% of the ipsilateral hemisphere as compared to 11.2 \pm 2.7% at 28 hr and 14.3 \pm 4.1% at 7 days ($p < 0.07$ for 3 weeks vs 28 hr; $p < 0.075$ vs 7 days). Additionally, total hemispheric volume decreased from 28.1 \pm 1.1 cm³ at 28 hr to 25.2 \pm 0.6 cm³ ($p < 0.01$) at 7 days and 22.4 \pm 0.7 cm³ ($p < 0.01$) and 3 weeks respectively. These results suggest that hemispheric volume must be considered when comparing injury volumes in animals at differing times after occlusion. However, injury volumes in rabbits surviving one day may readily be compared to rabbits surviving 7 days. At three weeks after injury, there is a trend that falls short of statistical significance. Thus, in experiments where drug treatments increase survival after focal cerebral ischemia, survival measurements of infarct volume should preferably be made within one week.

677.18

BOLD MR IMAGING OF ACUTE EMBOLIC STROKE. K. H. Taber*, S.R. Northrup. Herbert J. Frenslay Center for Imaging Research, Dept. of Radiology, Baylor College of Medicine, Houston, TX 77030

BOLD (Blood Oxygenation Level Dependent) is an exciting new natural-contrast method of magnetic resonance (MR) imaging. This method utilizes the fact that as blood becomes deoxygenated the RBCs change from their normal diamagnetic state to paramagnetic. Thus, deoxygenated intravascular blood becomes a naturally-formed MR contrast agent. We have performed BOLD MR imaging 30-360 minutes after induction of embolic stroke in rabbits. MR imaging was done on a Bruker BioSpec 2.35 Tesla system. A gradient echo (350/40/30) imaging sequence, 2 mm slice thickness, 128 gradient steps, 10 cm field of view and 4 averages were used. Following completion of the imaging session the brain was removed, sliced and placed in TTC for staining. Excellent delineation of areas of signal abnormality was obtained even at the earliest imaging times, and was maintained throughout the 4-6 hour imaging session. However, in some cases the areas of abnormality was smaller on the BOLD images than on the TTC stained sections, indicating that in some cases there was trapped intravascular blood in only a portion of the affected tissue.

INFARCTION IS NOURISHED BY DELAYS.—DITHIZONE DELAYS NEURONAL DAMAGE.—K. Shiraishi, MD, S. Kobayashi, MD, S. Nakazawa, MD, Dept. of Neurosurgery, Nippon Medical School, Bunkyo-ku, Tokyo, 113 Japan

We reported that zinc enhances kainate neurotoxicity in the rat hippocampus. Pre-treated zinc induces selective neuronal damage in the CA 3-4 of the hippocampus with an intravenous injection of kainate (a dose is 0.5 mg/kg, BW). On the contrary, zinc depletion might reduce neuronal damage caused by excitatory amino acids. We used dithizone (DZ) as a chelating agent for zinc in the ischemic models in the rat. (METHODS) (1) DZ dissolved in 0.2% ammonia and was injected to rat (100 mg/kg) intraperitoneally (Otsuka, N. Histochemie, 1966). (2) 30 minutes after the DZ i.p. injections, left middle cerebral artery (MCA) was occluded by cauterization at the proximal site (Shiraishi & Simon, J. Neurosci. Methods, 1989). 24 (group 1) and 72 (group 2) hours later, rats (each group had five) were sacrificed under general anesthesia and H. & E sections were made. (3) 30 minutes after the DZ i.p. injection, forebrain ischemia was induced by bilateral temporary occlusion of the carotid artery and systemic hypotension; mean blood pressure was maintained 60 mmHg for 10 minutes. 5 (group 3) and 7 (group 4) days later, rats (each had five) were also sacrificed and examined the pathological sections at the hippocampus. (RESULTS) In MCA occlusion model, infarction size was measured at the slice 5mm from the frontal pole; group 1 was 12.5 ± 3.1% and group 2 was 28.8 ± 3.6% (% hemisphere). And group 3 and 4 did not have any apparent neuronal damage at the hippocampus. (REMARKS) In global ischemia models, delayed neuronal damage is well known. But, focal ischemic models also have same kinds of issues in cortical infarction. In the proximal MCA occlusion model, the difference of cortical infarction size between 24 and 72 hours after is 3.1 ± 1.1% (unpublished data). In this experiment, zinc depletion could enlarge the time lag of cortical infarction and also could cancel delayed neuronal damage of the hippocampus, which might be due to the decrease of non-NMDA neurotoxicity.

ISCHEMIA: MOLECULAR BIOLOGY/IMMUNOCYTOCHEMISTRY

678.1

Comparison of the Effects of Global Ischemia on Hippocampal Morphology and Glutamate Receptor Binding Sites.—by John Steck, Kheir Zaobi, Ari Day, Joanna Peris, Judson Chandler and Fulton T. Crews. Dept. of Pharmacology and Neurological Surgery, University of Florida Brain Institute, Gainesville, Fla. 32610

Histological damage and autoradiographic distribution of glutamate receptor binding sites were compared following 20 min of global ischemia. Global ischemia was produced in Wistar rats through the four vessel occlusion model as described by Pulsinelli. Sham operated controls and ischemic animals were sacrificed 3 and 7 days following surgery. After both 3 and 7 days post-ischemia, hippocampal CA1 consistently showed severe neuronal loss whereas dentate gyrus (DG) showed no neuronal damage. CA3 showed variable damage at both time points and in CA4 the majority of hippocampi showed signs of ischemic injury characterized by eosinophilic cytoplasm and pyknotic nuclei after 3 days whereas 7 days post-ischemia only a few CA4 regions showed damage. In sham operated controls [³H]-AMPA sites were highest in dentate gyrus with similar amounts in CA1, CA3 and CA4. Ischemia reduced [³H]-AMPA sites in all hippocampal regions by approximately 30-40% in all hippocampal regions at both 3 and 7 days post-ischemia. [³H] kainate sites were lowest in CA1 and greatest in CA3 with intermediate levels in CA4 and DG. Ischemia produced progressive decreases in CA1 on 3 and 7 days post-ischemia, small changes in CA3 and CA4, and no change in DG. NMDA glutamate receptors were studied using [³H]-MK801, [³H]-CGS14859, and [³H]-glutamate-NMDA specific binding. All 3 NMDA ligands had the greatest number of sites in CA1 and DG, which were comparable. MK-801 and CGS binding were decreased approximately 30-40% in both CA1 and DG with smaller decreases in CA3 and CA4 at both 3 and 7 days. NMDA specific glutamate binding showed little or no change at 3 days post ischemia in CA1, CA3 and DG whereas after 7 days all regions showed a 25-35% decrease in binding. These findings suggest that NMDA receptor sites may change differentially following global ischemia and that changes in glutamate receptor sites do not correspond with histological changes. (Funded by AA06069).

MEF2C Immunoreactivity in Gerbil Brain Following Global Cerebral Ischemia. E.K. Speliotis*, N.W. Kowall, B.F. Shanti, S.P. Finklestein, D. Leifer. Massachusetts General Hospital, Children's Hospital, Boston University Medical School, and Harvard Medical School, Boston, MA, & Veteran's Administration Medical Center, Bedford, MA.

MEF2C (myocyte-specific enhancer binding factor 2C) is a transcription factor that is expressed in muscle and brain, and may play a role in the terminal differentiation of neurons during development (Leifer et al., this meeting). To examine the role of this factor in adult mammalian brain, we looked at MEF2C immunoreactivity (MEF2C-IR) in gerbils following global cerebral ischemia which results in the preferential death of hippocampal CA1 neurons within 2-4 days. Animals were sacrificed at 4hrs, 1,3,7,14, and 30 days after transient (10 min) bilateral carotid occlusion, and fixed brains were stained with antisera to MEF2C. MEF2C-IR was noted in the nuclei of many subpopulations of neurons and in microglia in normal brain, as well as in activated microglia in the CA1 region following cerebral ischemia. MEF2C-labeled neurons in the CA1 region, unlike CA1 pyramidal neurons which were not MEF2C-immunoreactive, survived the ischemic insult. A subpopulation of these surviving MEF2C immunoreactive cells stained with antibody against parvalbumin, a calcium binding protein found in a subset of GABAergic inhibitory interneurons. These findings suggest that MEF2C may play a role in the functioning of some normal subpopulations of neurons and microglia as well as in the functioning of activated microglia. Moreover, MEF2C may contribute to helping some types of cells survive ischemic insult.

THE RELATIONSHIP BETWEEN GLUTAMATE EXPOSURE, ³H-NIMODIPINE BINDING AND CBF IN RAT FOCAL ISCHEMIA. H. Osuga, A.M. Hakim*. Neuroscience Institute, University of Ottawa, Ottawa, Canada, K1H 8L6

The increase in extracellular glutamate concentration and intracellular calcium after ischemia are presumed to be major contributors to cell death. The purpose of this study is to define the relationship between the increase in extracellular glutamate, binding of ³H-nimodipine, a ligand of L-type voltage sensitive calcium channel (VSCC), and CBF in rat focal ischemia.

Materials and Methods: Eight rats weighing 275-300g were anesthetized with halothane. Microdialysis probes (OD:0.3mm, membrane length 2mm) and adjacent platinum wires for CBF measurements by means of H₂ clearance were placed in 6 cortical regions and perfused with Krebs-Ringer-Bicarbonate solution at 2µl/min. Dialysate was collected at 10min intervals and glutamate concentration measured using HPLC. Two hundred µCi of ³H-nimodipine were injected and ischemia was produced by inserting 4-0 nylon thread through common carotid artery toward anterior-middle cerebral artery bifurcation. CBF was measured frequently and was stable over the experimental duration. Animals were sacrificed by decapitation 30 min after occlusion and autoradiography was performed.

Conclusion: Regional CBF varied from 8 to 110% of preocclusion values. Glutamate concentration increased 6.9 fold from the base line after ischemia in parietal cortex but the course of extracellular glutamate was variable. The glutamate exposure index (GEI: integrated glutamate concentration in dialysate over duration of ischemia) correlated with CBF below 30% of control hemisphere (p<0.00003). ³H-nimodipine binding increases with severity of ischemia and is related to GEI.

678.4

REGIONAL ACCUMULATION OF AMYLOID PROTEIN PRECURSOR FOLLOWING A BILATERAL CAROTID OCCLUSION IN THE GERBIL. J.A. Oostveen* and E.D. Hall. CNS Diseases Research, The Upjohn Company, Kalamazoo, MI 49001.

Amyloid deposits comprise the major pathological characteristic of Alzheimer's disease. The primary component of these deposits is a peptide known as the β-amyloid protein which is derived from a larger precursor, the amyloid protein precursor (APP). The physiological function of APP is unclear, but evidence is accumulating that APP plays a role in the cerebral acute phase response to injury. Increased APP expression has been demonstrated in experimental and clinical cerebral trauma and, to a lesser degree, ischemic injury. We report the distribution of APP immunoreactivity in a model of transient global cerebral ischemia in the gerbil.

Male Mongolian gerbils (50-65 g) were exposed to a 10 min. bilateral carotid occlusion. Following 24 hrs of reperfusion, the animals were perfused intracardially and the brains frozen for free floating immunocytochemistry. Frozen coronal sections were processed and immunoreactivity to APP was visualized using clone 22C11 mouse monoclonal anti-APP, which recognized the mature and carboxytruncated forms of APP (Boehringer Mannheim).

APP immunoreactivity was found in the CA3 region of the hippocampus, the dentate gyrus, as well as layers III, V, and VI of the parietal cortex.

Following a cerebral insult, APP immunoreactivity increases and may provide a useful marker of neuronal injury. Elucidation of this protein's role in the neuronal stress response may have therapeutic implications.

678.5

EFFECT OF ISCHEMIA ON THE AMYLOID PRECURSOR PROTEIN. N. Komori*, T. Saitoh, B.-L. Chen, J.-M. Roch, and J. Zivin. Dept. of Neurosci, Univ. of California, San Diego, CA 92093.

Amyloid precursor protein (APP) and its trophic sequences (Roch et al., 1993 Neurosci. Abst.) have been found to promote neurite extension *in vitro*, to increase synaptic density in rat brain, and to alleviate ischemia-induced damage in a rabbit spinal cord ischemia model (RSCIM). Thus, one of the physiological functions of APP appears to be assisting cellular function and survival. Using RSCIM, we have studied APP mRNA and protein levels. The concentration of APP mRNA increased in the lumbar region after 15 min ischemia and/or 1 hr reperfusion, and then went down to near control. However, elevation of APP mRNA was not seen at 60 min ischemia. APP protein level was also examined by Western blot. We detected three distinct APP bands in the particulate fractions. The concentration of the highest molecular weight APP band decreased after 60 min ischemia and disappeared by the end of 18 hr of reperfusion. The ratio of the middle and the lowest APP bands changed after 15 as well as 60 min ischemia and also reperfusion periods following 60 min ischemia suggesting a differential effect of ischemia/reperfusion on different APP isoforms. The differential expression and/or disappearance of APP isoforms may be of significance in protecting neurons from ischemia-induced death.

IN SITU NICK TRANSLATION: A NOVEL APPROACH TO IDENTIFY NEURONAL INJURY AFTER ISCHEMIC LESIONS. L. MacKenzie, F.G. Szele, and M-F Chesselet*. Dept of Pharmacology, U. of Pennsylvania, Philadelphia, PA 19104

The identification of neuronal injury after ischemic insults has been hindered by the lack of reliable markers at the single-cell level. We have used *in situ* nick translation to identify increases in DNA strand breaks in individual neurons after ischemic lesions of the cerebral cortex induced by thermocoagulation of pial blood vessels. This procedure induces a progressive loss of cortical tissue, with a marked decrease in neuronal density already visible 6 hrs after surgery, and complete cortical atrophy by 7 days post-surgery (Szele and Chesselet, submitted). Rats were perfused with paraformaldehyde under anesthesia 6 hrs after surgery. Tissue sections (10 μ m) were cut on a cryostat and incubated with ³⁵S-DTP in the absence or in the presence of DNA polymerase for 120 min. at 16°C. Dense clusters of silver grains were observed at the periphery of the lesion in sections incubated in the presence of DNA polymerase I. In addition, numerous neurons within the ischemic area showed moderate labelling. These neurons did not show marked alterations in morphology, suggesting that increased DNA strand breaks is an early event in post-ischemic neuronal death. No specific labelling was observed in the striatum or in cortical regions distal from the ischemic lesion, which did not show neuronal loss at later time points. No labelling was observed in sections from rats without lesions, or in sections incubated without DNA polymerase. Supp. by NS-29230 and the Hereditary Disease Foundation.

IN VITRO NEUROPROTECTIVE ACTIVITY OF INHIBITORS OF POLY-ADP-RIBOSE POLYMERASE. M.S. Miller*, C. Zobre, and M. Lewis. Pharmaceuticals Research Division, Sterling Winthrop Inc., Collegeville, PA 19426.

Poly-ADP-ribose polymerase (PARP) is a 116 kD nuclear metalloenzyme which is activated by DNA strand breaks and utilizes intracellular NAD⁺ to ribosylate numerous proteins. Excitotoxicity-associated increases in intracellular Ca²⁺ may activate Ca²⁺-dependent nucleases to produce DNA fragmentation. Protein ribosylation and/or reduced NAD⁺ by PARP may contribute to excitotoxic neuronal injury. To investigate this potential mechanism, a small series of substituted benzamides with varying potencies for inhibiting PARP were evaluated for the ability to attenuate NMDA-induced neurotoxicity (LDH release) in primary cultures of mouse fetal cortex. Potency (IC50) for attenuating NMDA neurotoxicity varied within the series from 70-400 μ M. A correlation (r=0.904) was observed between reported potency to inhibit PARP and potency for neuroprotection. Efficacy was greatest when PARP inhibitors were coadministered with NMDA. Data suggest that selective inhibition of PARP may represent a useful neuroprotective mechanism.

TUMOR NECROSIS FACTOR α mRNA AND PEPTIDE ARE MARKEDLY EXPRESSED IN NEURONS PRESENT IN FOCAL CEREBRAL STROKE. G. Feuerstein*, R. Clark, T. Liu, R. White, F. Barone. Dept. of Cardiovascular Pharmacology, SmithKline Beecham Pharmaceuticals, King of Prussia, PA 19406

Ischemic stroke elicits inflammatory reactions marked by leukocyte adherence to microvessels and transendothelial migration. Tumor Necrosis Factor α (TNF α) is a cytokine known to initiate inflammation. In order to prove that TNF α is produced in ischemic cortex, molecular biology techniques and immunocytochemistry were employed to identify TNF α mRNA and peptide in the cortex of rats (300-350 gm) subjected to permanent middle cerebral artery occlusion (MCAO). TNF α mRNA (Northern blot) analysis revealed enhanced TNF α mRNA expression as early as 1 hr post MCAO, peak (104 \pm 8, vs control, 2 \pm 1, n=4, p<0.01) at 12 hr followed by partial decline over a 5 d period. Immunocytochemical (hamster anti-murine TNF α Mab) analysis using double fluorescence technique revealed TNF α positive immunofluorescence coinciding with neurofilament (neuronal) but not GFAP (astrocytes) or vimentin (microglia) immunofluorescence. Neuronal TNF α originated in the ischemic zone at 12 hr, but at 24 hr was primarily localized around the core zone. These data indicate that very early on in focal cerebral ischemia, TNF α transcripts and peptides are produced. Since TNF α possesses pro-inflammatory and pro-thrombotic actions on endothelium and direct cytotoxic effects, our data suggest a potential role of TNF α in the evolution of brain damage following stroke.

ISCHEMIC BUT NOT EXCITOTOXIC CELL DEATH IS ASSOCIATED WITH INTERNUCLEOSOMAL DNA CLEAVAGE. C. Charriaut-Marlangue, F. Dessi, H. Pollard, A. Heron, J. Moreau, M. Schumacher* and Y. Ben-Ari. INSERM U29, 123 Blvd de Port-Royal, 75014 Paris, France.

Transient forebrain ischemia induces in several species a delayed cell death of pyramidal neurons in the CA1 region of the hippocampus. Previous investigations, using *in vitro* systems, have demonstrated that anoxia induces an early increase of protein synthesis (C. Charriaut-Marlangue et al., Eur. J. N., 1992, 4, 766) and that protein synthesis inhibitors *in vivo* and *in vitro* reduces the CA1 neuronal death (Goto et al., Brain Res., 1990, 534, 299; Papas et al., Eur. J. N., 1992, 4, 758). In contrast, in cerebellar culture transcriptional and translational inhibitors do not prevent glutamate-induced neuronal death (Dessi et al., J. Neurochem, 1993, 60, in press). Physiological cell death or apoptosis which requires RNA and protein synthesis is characterized by the internucleosomal cleavage of DNA by a Ca²⁺, Mg²⁺-dependent endonuclease. Our purpose was to analyze the integrity of genomic DNA, by agarose gel electrophoresis, in a transient global ischemia model or after excitotoxic cell death in "*in vitro*" models. Electrophoresis of DNA extracted from the Ammon's horn and the striatum from ischemic rats showed a "ladder" pattern whereas no DNA degradation was observed in dentate gyrus and in cerebellum, which are less vulnerable. No DNA degradation was observed after NMDA (100 μ M)-induced neuronal death in hippocampal slices or glutamate treatment (100 μ M) in cerebellar culture. Our results were confirmed by DNA nick ends of histological sections from post-ischemic brains which were also labelled in CA1, cortical and striatum neurons. These results suggest that activation of an endonuclease is involved in ischemic but not in excitotoxic-induced neuronal death.

EVIDENCE OF APOPTOTIC LADDERED DNA FRAGMENTS IN BRAIN FOLLOWING ISCHEMIA. J.P. MacManus¹, I. Rasquinha¹, E. Preston¹, H. Li², D. Xue², Z.G. Huang² and A. Buchan^{2*}. ¹Institutes for Biological Sciences and Biodiagnostics, National Research Council Canada, Ottawa, Ontario, Canada K1A 0R6 and ²Ottawa Civic Hospital, Ottawa, Ontario, Canada K1Y 4E9, from the Canada/Fisons Fight Stroke program.

Biochemical evidence was sought for apoptosis in rat brain *in vivo* in three separate models of ischemia using a sensitive radioactive end-labelling technique to quantitate DNA breaks. Neocortex, hippocampus and striatum were sampled 24 and 48 hr following global ischemia induced by occlusion of two vessels (both common carotid arteries and hypotension to 50 mmHg) (2VO) or four vessels (common carotid and vertebral arteries) (4VO) for 5 to 30 min. Gel autoradiography showed greater ladder DNA fragmentation in the CA1 layer of the hippocampus than in the CA3. There was extensive DNA damage in the striatum after both 2 or 4VO. Little DNA fragmentation was seen in the neocortex. The extent of DNA damage in both hippocampus and striatum was dependent upon the duration of the ischemic episode in both 2 and 4VO models. Laddered DNA fragmentation was also shown 24 hr after temporary focal ischemia produced by occlusion of the middle cerebral artery (MCAO). The amount of DNA damage was greater in the core of the neocortical infarct than in the penumbra. Again, the extent of damage was proportional to the duration of MCAO (0.5 to 3 hr). Thus, ladder DNA fragmentation correlated with the known regional and temporal patterns of neuronal death in three established models of ischemic brain damage in the rat.

It is concluded that there is an apoptotic component to the cell death following ischemia.

HYPOXIA INDUCED PROGRAMMED CELL DEATH IN CULTURED NEURONS. D. M. Rosenbaum*, J. Kalberg, D. K. Batter and J. A. Kessler. Depts. of Neurology and Neuroscience, Albert Einstein College of Medicine, Bronx, NY 10461.

Apoptosis, a form of cell death ("programmed" cell death) in which the nucleus and cytoplasm shrink and often fragment, serves to eliminate excessive or unwanted cells during remodeling of embryonic tissues, during organ involution, and in tumor regression. In acute pathological states, such as ischemia, the cells tend to swell and lyse - a process called necrosis. We hypothesize that the delayed neural death associated clinically with hypoxia may, in part, represent apoptosis. A tissue culture model of hypoxia was employed using sympathetic neurons. Pretreatment with an endonuclease inhibitor (Aurintricarboxylic), a protein synthesis inhibitor (ActinomycinD), depolarizing conditions (55 mM KCl) as well as antisense c-myc were tried in order to ameliorate cell death (all have been shown to prevent apoptosis). In addition, cell nuclei were stained with propidium iodide (a DNA marker) to demonstrate nuclear chromatin condensation. After 24 hrs of hypoxia Aurintricarboxylic acid decreased cell death by 39%, depolarizing conditions decreased cell death by 33%, and Actinomycin by 26%. Antisense c-myc had no effect. Fluorescent staining demonstrated chromatin condensation. These data suggest that apoptosis may play a role in hypoxic cell death and that in this paradigm expression of c-myc is unnecessary. This would suggest a new approach to our understanding of hypoxia and open new strategies to lessen neuronal damage secondary to this process. We are currently studying this hypothesis utilizing an *in vivo* model.

678.13

RESPONSE OF IONOTROPIC GLUTAMATE RECEPTOR (GluR) SUBUNITS DURING EARLY STAGES OF REGIONAL BRAIN ISCHEMIA. C.A. Pardo, L.I. Martin, L.H. Monsein, C.D. Blackstone and R.N. Bryan*. The Johns Hopkins Univ. Sch. of Med., Balto., MD 21205

The response of non-NMDA ionotropic AMPA-GluR subunits in early stages of regional ischemia (3-18 hours) were studied in a baboon model. Ischemic injury by occlusion of the middle cerebral artery, using interventional neuroangiographic techniques, was used to produce either complete ischemia (CI; n=5) or incomplete ischemia with reperfusion (IIR; n=4). Antibodies that detect GluR1, GluR2/3, and GluR4 subunits [Martin et al., *J. Neurosci.* 13:782, 1993] of AMPA receptors were used to study the cellular expression of GluR in striatum and cortex. Changes in AMPA receptor immunoreactivity were correlated with neuronal-dendrite markers (e.g., microtubule-associated protein-2 [MAP-2]) that defined necrotic-perinecrotic areas. In the dorsolateral and posterior caudate/putamen, perinecrotic regions in the CI model showed decreased GluR1 and GluR2/3 and increased neuronal expression of GluR4. Different subtypes of striatal neurons appeared to be affected equally, and the GluR1 response was similar temporarily in striosomes and matrix in the CI model. However, in the IIR model, striatal neurons showed decreased GluR1 before striosomal neurons. In cortical perinecrotic areas, responses of GluR1, GluR2/3, and GluR4 were similar to striatal changes. In cortical penumbra areas, superficial layers showed reduced expression of GluR2/3 before deeper layers. In both striatum and cortex, early neuronal injury was correlated with dendritic collapse (reduced MAP-2 expression) and loss of specific AMPA receptor subunits. These studies show that AMPA receptor subunits are altered differentially during ischemic injury, perhaps as a result of cytoarchitectonic changes.

678.12

GLUTAMATE NMDA RECEPTOR mRNA EXPRESSION AFTER FOCAL ISCHEMIA IN THE RAT. C.Gonzales*, R.Franco, T.L.Sailer and L.A.Moyer. CNS Pharmacology Division, Wyeth-Ayerst Research, Princeton, NJ 08543-8000.

Neuronal cell death that occurs after focal ischemia in the rat is widely believed to involve overactivation of the NMDA subtype of the glutamate receptor. Recently, cloning of subunits of the NMDA receptor has been described. The NMDAR1 receptor subunit is expressed in most neuronal cells and possesses electrophysiological properties associated with the NMDA receptor. The NMDAR2A-D subunits, which are differentially expressed in brain regions, do not exhibit these properties, but when co-expressed with the NMDAR1 subunit, they potentiate NMDA receptor activity (Nakanishi, *Science* 258:597-603,1992). The molecular cloning of the rat NMDA receptor subunits makes it possible to design specific oligonucleotide probes to study the role of NMDA receptor subunit expression in ischemia induced cell death. We have used *in situ* hybridization histochemistry to look at the expression of three subunits of NMDA receptor mRNAs that are expressed in regions susceptible to ischemic damage in our model of rat focal ischemia. Sham operated rats or rats subjected to tandem occlusion of the right common carotid and right middle cerebral arteries were sacrificed 1, 3, or 24 hrs after surgery. Sections were processed for *in situ* hybridization for the NMDAR1, 2A, and 2B subunits and synapsin (control). Sections were apposed to film and optical densities between sham and lesioned cortices were compared. Our results show that after 24 hrs, mean NMDAR1, 2A and 2B expression in the lesioned hemisphere was reduced 37% from sham operated animals, 30% after 4 hrs., and there was no significant decrease 1 hr after ischemia. Decreases in NMDA mRNA followed the pattern of cell death seen with adjacent Nissl-stained sections and prior to cell death, no changes in mRNA were observed for either NMDA or synapsin. These results are consistent with decreasing mRNA levels being directly related to cell death.

ISCHEMIA: NEONATAL

679.1

THE NEUROPROTECTIVE EFFECTS OF MK-801 AND GM1 GANGLIOSIDE ON INJURY TO THE NEWBORN RAT CORTEX. G.D. Rosen*, E.A. Sigel, G.F. Sherman, and A.M. Galaburda, Beth Israel Hospital and Harvard Medical School, Boston, MA, 02215

Placement of a freezing probe on the skull of newborn rats results in the formation of a neuropathologic malformation resembling focal microgyria (Humphreys et al., *J Neuropath Exp Neurol* 50:145, 1991), a minor malformation seen in the brains of some dyslexics (Galaburda et al., *Ann Neurol* 18:222, 1985). The freezing injury likely acts as an ischemic/hypoxic event that leads to neocortical reorganization resulting in and the formation of the microgyria (Rosen et al., *J Neuropath Exp Neurol* 51:601, 1992). We hypothesized that neuroprotective agents, which ameliorate the effects of hypoxic/ischemic insults, might also reduce the effects of a freezing lesion and prevent or modify the reorganization of the developing cortex.

Newborn rats were given injections of GM1 ganglioside (30 mg/Kg b.w.) as either a pretreatment (6 h before freezing injury), posttreatment (2, 16, 40, and 64 h after freezing injury), or a combination of both. A second group of rats received treatment with MK-801 (1 or 2 mg/Kg b.w.) 0.5 h before the freezing injury and 6 and 14 hours afterward. Controls were given either vehicle (saline) injections along with freezing lesions or injections of neuroprotective agents only.

GM-1 ganglioside and MK-801 had significant ameliorating effects on the formation of microgyria which is most apparent in those animals receiving pre- and post-treatments.

This work was supported, in part, by NIH grant HD20806.

679.2

PHENYTOIN AND CI 953 ATTENUATE HYPOXIC-ISCHEMIC BRAIN DAMAGE IN NEONATAL RATS M.G. Vartanian*, J.J. Cordon, N.C. Kupina, J. Schielke, and C.P. Taylor. Dept. of Neuroscience Pharmacology, Parke-Davis Research Division, Warner-Lambert Co., Ann Arbor, MI, 48105.

Phenytoin and CI 953 (Urea N-(2-chloro-6-methylphenyl)-N'-4-pyridinyl-are anticonvulsant compounds that modulate voltage-dependent sodium channels (Rock et al., *Epilepsy Res.* 8:197-203,1991). Both compounds are neuroprotective *in vitro* against hypoxic damage in hippocampal slices (Taylor & Weber, *Soc. Neurosci. Abstr.*, 18:1135, 1992, and unpublished data).

We tested phenytoin and CI 953 using an *in vivo* model of hypoxic-ischemic brain injury in neonatal rats. To induce brain injury, seven day old Sprague-Dawley rats were anesthetized with ether and the left carotid was ligated. Pups were allowed recovery for 2 hours before to hypoxia for 3 hours (humidified 8% oxygen, balance nitrogen) in a sealed chamber. Temperature was accurately controlled before, and during hypoxia. Immediately before hypoxia, 60 pups received i.p., either phenytoin (30 mg/kg), CI 953 (30 mg/kg; 3 times, separated by 1.5 hours), or vehicle. Animals were sacrificed two weeks after hypoxia, and right and left hemisphere weight disparities were compared as percent damage $((L - R)/R \times 100)$. Phenytoin was most effective in reducing neuronal damage (vehicle treated, $38.06 \pm 4.74\%$ vs. $6.30 \pm 3.22\%$; $p < 0.001$). Multiple dosing of CI 953 resulted in a significant, (vehicle treated, $35.79 \pm 2.28\%$ vs. $20.36 \pm 6.50\%$; $p < 0.04$) but less effective inhibition of cerebral damage when compared to phenytoin. These data suggest that compounds that modulate voltage-dependent sodium channels may reduce injury from hypoxic-ischemic brain insult.

679.3

THE LAZAROID U-74389G AMELIORATES ISCHEMIC NEURONAL INJURY IN INFANT PIGS. J. Deshpande*, W.O. Whetsell, Jr., B. England, J. Stewart and C. Elkins, Depts. of Pediatrics, Anesthesiology, Neuropathology and Cardiac Surgery, Vanderbilt University Medical Center, Nashville, TN 37232.

U-74389G is a 21-amino-steroid antioxidant that inhibits lipid peroxidation. Related lazaroids have shown some efficacy in reducing ischemic CNS damage. This study was designed to investigate the ameliorative effects of U-74389G upon ischemia in hippocampal pyramidal cells in the infant mammalian brain. Three-week-old pigs, fasted overnight, were anesthetized with pentobarbital, intubated and mechanically ventilated. Anesthesia was maintained with isoflurane in N₂O/O₂. MABP and blood gases were monitored via femoral artery and venous catheters. Bitemporal EEG activity (Neurotrack) was monitored during all experiments. Ischemia was induced in one group of animals (n=6) by occlusion of the innominate trunk bilaterally for 18 minutes. In a second group (n=8), ischemia was induced in the same manner and U-74389G (3 mg/kg) was administered intravenously immediately and at two hours post-ischemia. All animals were extubated when they could sustain adequate spontaneous ventilation. Neurological examinations were performed daily. All animals were maintained for 7 days then sacrificed and brains were harvested and studied histologically. In both groups, neurologic function showed greatest impairment at 24 hours post-ischemia and improved over the remaining study period. There was no difference between groups. Histologic examination at 7 days showed significantly greater loss of hippocampal pyramidal cells (P < 0.05, Wilcoxin's RS Test) in the untreated animals. Results indicate that U-74389G may be effective in reducing ischemic CNS damage. [U-74389G was kindly supplied by Upjohn, Inc.]

POTENTIATION OF ENDOGENOUS ADENOSINE PROTECTS THE NEWBORN BRAIN FROM HYPOXIC-ISCHEMIC INJURY. J.M. Gidday*, J.C. Fitzgibbons, A.R. Shah, and T.S. Park. Departments of Neurosurgery, St. Louis Children's Hospital and Washington University School of Medicine, St. Louis, MO 63110.

While the ischemic cerebroprotective actions of adenosine have been investigated in adult animal models, comparable studies in neonates are lacking. We utilized the well-established 7-day old rat hypoxia-ischemia model (unilateral carotid ligation and 3h hypoxia) to separately test the neuroprotective potential of propentofylline (HWA 285), an adenosine transport inhibitor, and deoxycoformycin (DCF), an adenosine deaminase inhibitor, which were administered immediately after hypoxia. Injury analyses were undertaken one week later. Animals treated with HWA (10 mg/kg ip; n=14) showed a 31% decrease (p<0.03) in hemispheric necrosis ipsilateral to the carotid ligation, compared to saline-treated controls (n=15). Regression analysis showed a significant correlation (r>0.9) between these data and morphological determinations of cross-sectional area in coronal sections, which yielded improvements of 32% and 29% at the level of the striatum and dorsal hippocampus, respectively. Histological analyses of Richardson-stained coronal sections revealed a significant reduction (p<0.03 Mann-Whitney) in striatal neuronal injury in animals treated with HWA. DCF (2.5 mg/kg ip; n=12) yielded a 29% improvement (p<0.02) in necrosis relative to controls (n=13), a 21% and 22% increase in striatal and hippocampal cross-sectional areas (p<0.03), respectively, and a marked reduction in cellular injury in striatum and hippocampal CA4 region (p<0.03). These findings indicate that the potentiation of extracellular adenosine levels by HWA and DCF affords significant protection from hypoxic-ischemic injury in the brain of the newborn.

679.7

PERINATAL HYPOXIA CAUSES REDUCED ACCUMBENS DOPAMINE AND ALTERED RECEPTOR DENSITIES IN THE ADULT RAT STRIATUM. S.B. Schwarzkopf*, L. McCoy, E.K. Richfield, and M. Hadjiconstantinou.

Depts. of Psychiatry & Neurology, University of Rochester, Rochester, NY 14627; Depts. of Psychiatry & Pharmacology, Ohio State University, Columbus OH, 43210.

Perinatal hypoxia causes immediate and long term alterations in behavior and neurotransmitters in cortical and subcortical brain regions. Excitatory amino acid neurotoxicity mediated through NMDA receptors has been implicated in these effects. Previous findings indicated cortical changes in cholinergic, serotonergic, and dopaminergic indices 3 weeks following exposure to perinatal hypoxia. In this study we examined levels of striatal dopamine, its metabolites, and dopamine receptor and reuptake complex densities in adult rats exposed to perinatal hypoxia. Animals were male Sprague-Dawley rats exposed for 2 hours at age 7 days to 8% oxygen (HYPOX, N=26) and a control group (CTL, N=24). At 120 days of age animals were sacrificed and brains rapidly dissected and frozen. High performance liquid chromatography with electrochemical detection was used to measure dopamine (DA), 3,4-dihydroxyphenylacetic acid (DOPAC) and homovanillic acid (HVA) levels in the dorsal striatum (DSTR) and nucleus accumbens (NAC). DA autoradiography was used to assess striatal D1 and D2 receptors and DA reuptake complex (DAUC) densities. HYPOX animals exhibited decreased DA and DOPAC in the NAC but not in the DSTR. HYPOX animals also showed significantly increased DAUC and D1 densities compared to CTLs, with a highly significant reduction of D2 receptor binding. These results show that a relatively brief exposure to hypoxia during the perinatal period leads to marked alterations in striatal DA and DA receptor characteristics in adulthood. Findings suggest a compensatory increase in DA terminals (or diminished "pruning") in response to perinatal neurotoxicity. Diminished D2 density might indicate greater vulnerability to hypoxic injury of GABAergic neurons belonging to the "indirect" striatal efferent pathway. (Supported by MH00859 and MH40381)

679.4

HYPOGLYCEMIA ABOLISHES HYPOXIC DILATION OF PIAL ARTERIOLES IN NEWBORN PIG T.S. Park, E.R. Gonzales, A.R. Shah, R.G. Dacey*, and J.M. Gidday. Department of Neurosurgery, St. Louis Children's Hospital and Washington University School of Medicine, St. Louis, MO 63110.

Compensatory increases in cerebral blood flow occur in hypoglycemic adult animals in response to cerebral hypoxia, but it is not known if such a preservation in cerebrovascular reactivity to hypoxia occurs in hypoglycemic neonates. Therefore, we investigated the effects of systemic hypoglycemia (blood glucose < 25 mg/dl; non-isolectric EEG) on the ability of pial arterioles of newborn pigs to dilate in response to systemic hypoxia. Arterioles 25-50 μ m in diameter under baseline conditions were studied by videomicroscopy in isoflurane-anesthetized piglets equipped with closed cranial windows over the parietal cortex. Systemic hypoxia (PaO₂=26±1 mmHg) increased mean arterial blood pressure (MABP) 31±6% (p=0.002) and dilated pial arterioles 57±9% (p=0.0007; n=8) in normoglycemic animals. Induction of hypoglycemia did not change MABP, but dilated pial arterioles 31±5% (p=0.002; n=7), significantly less (p=0.025) than the vasodilation resulting from hypoxia. When hypoxia (PaO₂=28±1 mmHg) was subsequently induced in these animals after 40 min of sustained hypoglycemia, MABP increased 22±11% (p=0.095), but pial arterioles did not dilate further (35±5% relative to baseline; p=0.339 vs. hypoglycemia alone). In summary, the arteriolar dilation in response to hypoxia in hypoglycemic animals was significantly less (p=0.045) than that occurring in normoglycemic animals. Thus, these results indicate that hypoglycemia impairs the ability of the pial microcirculation to dilate to hypoxia, suggesting that dysfunctions in cerebrovascular reactivity can result from hypoglycemia in the neonate.

CHRONIC HYPOXIA CAUSES DOWN-REGULATION OF GLUCOSE TRANSPORTER I mRNA IN ADULT BUT NOT IN FETAL RAT BRAIN. Y. Xia*, J. B. Warshaw and G.G. Haddad. Section of Respiratory Medicine, Department of Pediatrics, Yale University School of Medicine, New Haven, CT 06510

Recent work from our laboratory and others has shown that chronic hypoxia can up- or down-regulate membrane proteins such as sulfonylurea receptors and sodium channels. Since there are virtually no glucose stores in the brain, glucose transport becomes crucial for cell survival under stress and could therefore be regulated. As a first step, we asked whether glucose transporter isoform I (GlutI) mRNA was changed during chronic hypoxia in the brain. Since metabolism in fetal brain depends proportionally less on glucose as a substrate than the adult brain, we studied brain GlutI mRNA at birth and in the adult after exposure of pregnant rats (from E10 to E22) or adult rats (from P90 to P120) to hypoxia (8-9%, FiO₂) using Northern blot analysis with total RNA isolated from whole brain.

Our results show that i) GlutI mRNA was less than about 35% of adult level at birth and increased with age; by 30 days, GlutI mRNA was about 80% of adult level; ii) chronic hypoxia caused a decrease of 70% in GlutI mRNA in the adult brains and iii) no decrease of GlutI mRNA was seen in exposed fetal brains (100% vs 115%).

Our data suggest that 1) the increase in GlutI mRNA with age is a reflection of the increase in O₂ consumption in brain tissue and 2) although both the fetus and the adult may down-regulate brain metabolism during O₂ deprivation, glucose transporters in the adult seem to be more sensitive to hypoxic stimuli than in the fetus.

THE AGE-RELATED EFFECTS OF TEMPERATURE RESPONSES AND BRAIN DAMAGE FOLLOWING HYPOXIA-ISCHEMIA(HI) TO ANESTHETIZED RATS. J.A. Thornhill, E. West, M.C. Chubb*, A. Shuaib and J. Yager Saskatchewan Stroke Research Center, Saskatoon, Canada S7N 4J9.

Younger animals are believed to be more resistant to H-I than their adult counterparts. To study this hypothesis, male, Wistar rats (10 days, 3, 6 and 9 weeks), were anesthetized with halothane and rectal temperatures kept at 37°C via a heating blanket. Ipsilateral and contralateral temporalis muscles were measured using thermistor probes to indicate changes in brain temperatures. Hypoxia-ischemia was induced by ligation of the right common carotid artery followed by exposure to hypoxia (12% O₂) for 35 min. (modified Levine model). Animals were sacrificed 7 days later, brains perfusion-fixed and neuropathological damage assessed histologically. Ipsilateral and contralateral temporalis temperatures fell spontaneously with hypoxia in all groups except the 10-day old group, with greater decreases in the ipsilateral side. Brain damage was most severe and consistent in the 9 & 3 week old animals compared to the 10 day and 6 week old animals (p > 0.05). Thus, a direct correlation between age and brain damage following hypoxia-ischemia is not apparent.

AGE-DEPENDENT NEUROTOXIC RESPONSE TO L-CYSTEINE. J.G. Csernansky*, M.E. Bardgett, J. Labryere, J.J. Jackson, J.W. Olney. Psychiatry Dept., Wash. Univ. Sch. of Med., St. Louis, MO 63110 & Psychology Dept., Univ. of MO-St. Louis, St. Louis, MO 63121.

The common amino acid, L-cysteine, is neurotoxic to the developing rodent brain when administered orally or subcutaneously to a pregnant dam or her newborn offspring. The pattern of brain damage (hippocampus, neocortex, caudate, thalamus) and the mechanism (pathological stimulation of N-methyl-D-aspartate (NMDA)-type glutamate receptors) of L-cysteine neurotoxicity is similar to the pattern and mechanism of perinatal hypoxic/ischemic brain damage. Given its similarity to hypoxia/ischemia, L-cysteine neurotoxicity offers a tool to study developmental excitotoxic insults which may ultimately result in psychopathology. Since the neurotoxic response to NMDA injection or hypoxia/ischemia in the rat brain peaks at one week of age (Ikonomidou et al., J. Neurosci., 9:2809, 1989), we have examined initially whether the neurotoxic response to L-cysteine demonstrates a similar age-dependent profile. Sprague-Dawley pups were injected subcutaneously with 0.9 mg/kg of L-cysteine on either postnatal day 1, 4, 7, or 10, and killed 6 hrs later. Relative to the younger pups, pups at postnatal day 7 were rated as exhibiting greater damage (edematous degeneration, pyknotic cells, and/or overt cell loss) in the retrosplenial granular cortex, the cingulate cortex, the deep layers of piriform cortex, and mediodorsal and ventrolateral thalamic nuclei. All of the postnatal day 10 pups died 2-3 hrs after injection. These preliminary results indicate that the neuropathological sequelae of L-cysteine neurotoxicity differs as a function of age of exposure. We are currently examining the neurotoxic response to L-cysteine at other ages and after different doses. Supported by a grant from the Theodore and Vada Stanley Foundation to J.G.C. and M.E.B. M.E.B. was supported by a N.I.M.H. Training Grant (MH14677).

SELECTIVE LOSS OF PURKINJE CELLS FOLLOWING HYPOTHERMIC CARDIAC BYPASS AND ARREST IN THE NEONATAL PIG. J. Brasko*, H. Kasowski, and D.T. Ross. Head Injury Center, Division of Neurosurgery, University of Pennsylvania, Philadelphia, PA 19104

Cerebellar Purkinje cells are selectively vulnerable to ischemic degeneration following cardiac arrest or global ischemia in man and animals. We examined whether hypothermia during cardiac arrest/bypass was sufficient to prevent Purkinje cell loss.

Deeply anesthetized neonatal (21 day) pigs were placed on cardiopulmonary bypass, cooled to body temperatures of 15-27°C, and the bypass pump turned off. The pump was restarted 45 minutes to an hour later, the animal taken off bypass, and recovered. Animals survived for 7 days prior to sacrifice and transcardial perfusion. Four parallel sets of 40µm serial sections were cut; one was stained with cresyl violet, and the others were processed for immunohistochemistry using antisera to the calcium binding protein parvalbumin, heavily phosphorylated epitopes common to the heavy and medium neurofilament proteins (SMI-31).

In the cerebella from the animals arrested at 24-27°C the folia throughout the vermis and hemispheres were characterized by extensive selective loss of Purkinje cells particularly from the depths and sides of the folia. The density of granule cells in the affected foliar regions appeared normal and there was no evidence of focal infarction in the molecular layer. Sparing Purkinje cells at foliar crests were frequently abnormal in appearance, with a marked decrease in cytoplasmic basophilia, a ballooned appearance with perikaryal and nuclear swelling and nucleolar eccentricity, and perikaryal neurofilament phosphorylation. In cerebella from animals arrested at colder temperatures Purkinje cell loss was present but less extensive. These results suggest that hypothermic neuroprotection alone may not be sufficient to prevent the loss of Purkinje cells following hypothermic cardiac arrest open heart surgery procedures. Augmentation with the prophylactic administration of pharmacological agents may be necessary for insuring complete protection. THE EFFECT OF PRENATAL HYPOXIC INSULT ON REGIONAL BRAIN WEIGHT AND BEHAVIOR IN RATS. Z. Binienda*, S. A. Ferguson, F.D. Racey, N.R. Taylor, W. Slikker, Jr. and R.R. Holson. NCTR/FDA, Jefferson, AR 72079.

The effects of prenatal hypoxia on early behaviors, cognitive functions and regional brain weight were studied in rats. Hypoxic conditions were produced at gestational day 21 by submerging one isolated uterine horn in warm saline for 15 min. Fetuses were then delivered and cross-fostered as hypoxic pups. Fetuses of the adjacent horn (controls) were delivered by cesarean section and cross-fostered to the same surrogate mothers as the hypoxic pups. On postnatal day (PND) 30, regional brain weights were obtained. Negative geotaxis, olfactory discrimination, open field activity and complex maze performance were measured in hypoxic and control rats. Caudate nucleus and brain stem weights were significantly reduced in PND 30 hypoxic rats, to 95% of control values. Hypoxia was associated with lower activity on day 1 of open field testing (PND 18); other behavioral measures indicated control levels of performance in the hypoxic rats. These data, while preliminary, would suggest that a 15 min hypoxic insult has few dramatic effects on behavior.

679.10

NEONATAL ANOXIA REDUCES C-FOS EXPRESSION IN THE RAT HIPPOCAMPUS. M.E. Dell'Anna^{1,2}, M.C. Geloso¹, M. Magarelli¹. Institutes of Neurology¹ and Human Physiology², Catholic University, Rome (Italy).

The early expression of the proto-oncogene *c-fos* has been proposed as a marker of neuronal anoxic damage. Hippocampal sectors show different sensitivity to neonatal anoxia and CA1 neurons are the most damaged while CA3 cells appear less affected. In the present study we analyzed the expression of *c-fos* in hippocampal neurons at different time-points following neonatal anoxia (N₂ 100% for 25 minutes at 30 hours after birth - P2). Sagittal 40 µm sections, obtained from animals sacrificed at 1, 2, 4 and 6 hours and at 7 and 21 postnatal days after anoxia, were processed with ABC immunocytochemistry for *c-fos* (polyclonal rabbit antibody, kind gift of Dr. Jadarola and Draisci). At all stages of life studied, *c-fos* immunoreactivity (IR) was expressed in many neurons of CA1, CA2 and CA3 hippocampal sectors in both control and anoxic animals. In gyrus dentatus, only few neurons expressing *c-fos* were present at P2 and P7 while they were numerous at P21 in both groups. One hour after N₂ exposure, the number of *c-fos* IR neurons was significantly reduced in CA1 and CA2 sectors of anoxic rats in comparison with the controls, while it clearly rose in CA3. In the following hours, the number of neurons expressing *c-fos* decreased significantly in all CA regions. At P7, the number of *c-fos* IR neurons was still reduced in all hippocampal sectors of anoxic rats, while no clear changes were present at P21. In gyrus dentatus no effects of neonatal anoxia were seen at the different time-points.

The present data, in contrast with several observations in adult anoxic conditions, are suggestive for a prolonged inhibition of neuronal expression of *c-fos* after neonatal anoxia. Furthermore, the results obtained in this study indicate that the time-course of changes in *c-fos* IR in the CA1, CA2 and CA3 sectors correlates with the specific sensitivity of the different hippocampal regions to neonatal anoxia and suggest the reduction of *c-fos* expression, in early stages after neonatal anoxia, as a possible predictive index of the neuronal damage.

679.12

IN UTERO HYPOXIA AND CHOLINERGIC SIGNAL TRANSDUCTION IN THE DEVELOPING BRAIN. K. Hersey, Z.Y. Hu, P.K. Rudeen and G.Y. Sun. Depts Child Health and Biochem., Univ. Missouri, Columbia, MO 65212.

Hypoxic-ischemic insult to neonates at birth is associated with learning deficits and other functional abnormalities during brain development. In this study, a rat model was used to examine the effects of this type of insult on the cholinergic signal transduction activity of the developing brain. Pregnant rats at term were anesthetized with diethyl ether and the gravid uterus surgically exposed. Hypoxic treatment was carried out by clamping the uterine blood vessels to the individual fetuses for 5, 10 and 15 min. The fetuses were delivered and resuscitated, and were fostered until two-weeks of age. Prior to the brain slice experiment, each pup was injected intracerebrally with [³H]inositol (10 µCi in 10 µL) and the label was equilibrated in brain for 16 hr. Carbachol stimulation of poly-PI signaling activity was assessed by incubating the labeled brain slices in the presence of LiCl (10 mM) and measuring the levels of labeled inositol monophosphates (IP). Results indicated no obvious changes in labeled IP in pups that experienced a 5 min hypoxic treatment but an obvious decrease (20-30%) in this label could be found in pups that experienced 10 or 15 min hypoxic treatment at birth. This study clearly shows that hypoxic-ischemic insult at birth can lead to an alteration of the cholinergic signaling activity during brain development.

BRACHIOCEPHALIC ARTERY OCCLUSION IN SHEEP: A MODEL FOR PERINATAL HYPOXIC-ISCHEMIC BRAIN DAMAGE. K.J. Anderson¹ and D.J. Burchfield². Depts. of Physiological Sciences¹, Neuroscience¹ and Pediatrics², University of Florida, Gainesville, FL 32610.

To better delineate the roles of ischemia and hypoxia on cerebral injury in the fetal and newborn brain, we developed an animal model for cerebral ischemia using lambs. The major advantages of using sheep as a model are two-fold; first, a single brachiocephalic artery arises from the arch of the aorta and its occlusion provides ischemia to the head, while leaving other vital organs in a state of complete perfusion. Second, the fetal lamb is remarkably resistant to *in utero* surgical manipulations and will not be aborted by the ewe. This is important because a large portion of cerebral palsy is of prenatal origin and use of fetal sheep will allow us to study the neurotoxicity of excitatory amino acids during this critical time period. After performing a left thoracotomy in newborns, we placed a pneumatic cuff occluder around the base of the brachiocephalic artery, a pre-calibrated ultrasound flow probe around a carotid artery in the neck and electrodes on the dura for the measurement of ECoG. The wires, cable and tubing were tunneled subcutaneously and exteriorized, the wounds closed, and the animal allowed to awaken. Two days later, the pneumatic cuff occluder was inflated so that the carotid flow fell to between 10-20% of baseline values and the animal was made to breathe an hypoxic gas mixture of 10-12% oxygen. After several minutes, the ECoG went flat and the animal became apneic. This was maintained for 1-2 min while providing artificial ventilation to the animal, then the lambs were resuscitated with release of the occlusion and administration of 100% oxygen. A similar procedure was used to provide hypoxia-ischemia to fetal lambs. In both cases, the lambs were allowed to recover for 4 days, euthanized and their brains were examined for evidence of injury. These lambs showed clinical evidence of neurological deficit for 12-36 hours after the insult, and histologic examination of their brains showed clear evidence of neuronal damage in several brain regions including parasagittal regions of frontal and parietal cortex and area CA1 of the dorsal hippocampal formation. This pattern of injury is very similar to that seen in newborns having succumbed to asphyxia. This model therefore has the potential to help researchers understand the pathophysiology of perinatal hypoxic-ischemic encephalopathy.

680.1

EFFECT OF CHRONIC NITRIC OXIDE SYNTHASE INHIBITION ON HYPOTHALAMIC BLOOD FLOW IN RAT Z. Benyó*, M. H. Velkei and P. Sándor Experimental Research Department - 2nd Institute of Physiology, Semmelweis University of Medicine, H-1446 Budapest, POB 448, Hungary
Tonic basal release of endothelium derived nitric oxide (NO) contributes to the maintenance of normal cerebral blood flow. In a previous study the NO-synthase (NOS) inhibitor N^G-nitro-L-arginine (30mg/kg bolus iv. followed by 1 mg/kg/min infusion for 15 min) increased mean arterial blood pressure (MAP) by 43 mmHg and reduced hypothalamic blood flow (HBF) by 53% in cats (Kováč et al.; J.Physiol.(Lond.)1992;449:183-196). In the present study the effect of chronic oral administration of the NOS inhibitor N^G-nitro-L-arginine-methyl-ester (L-NAME) was investigated on the HBF in rats.

The experiments were carried out in 2 groups of male Sprague-Dawley rats: the first received tap water, while the second received 0.1 mg/ml L-NAME solution to drink. After 1 week the animals were anesthetized (1.3g/kg Urethan, ip.), and the HBF (ml/g/min) was determined by the H₂-clearance method. The MAP (mmHg), arterial CO₂ and O₂ tensions (mmHg) and pH were also determined during the HBF measurement. The hypothalamic vascular resistance (HVR) was calculated as MAP/HBF.

The daily fluid intake did not differ in the 2 groups of animals, the L-NAME intake was 8.5±0.4 mg/kg/day in the treated rats. The other measured parameters were as follows: *p<.02, **p<.001

Treatment	MAP	HBF	HVR	apCO ₂	apO ₂	apH
Control (n=9)	94±12	977±056	98±7	40.2±1.5	84.8±2.5	7.39±0.1
L-NAME (n=7)	129±6**	903±078	155±22*	41.0±1.2	85.0±3.4	7.38±0.1

The results indicate a significant increase of HVR following chronic NO blockade. A significant fall of HBF, however, was counteracted by the simultaneous substantial increase of the MAP.

REACTIVE ASTROCYTES EXPRESS INDUCIBLE NITRIC OXIDE SYNTHASE AFTER ISCHEMIA. M. Endoh*, K. Maiese, and L. A. Wagner. Neurol./Neurosci.; Cornell Univ. Med. College, 1300 York Ave., NY, NY 10021

We have recently demonstrated that astrocytes in the hippocampus CA1 region are NADPH diaphorase positive after transient forebrain ischemia (Endoh, et al, Neurosci. Lett.), and that nitric oxide is involved in the mechanism of cultured hippocampal neurons death after ischemia (Maiese, et al, J. Neurosci.). To determine whether reactive astrocytes express NOS, we studied pathological change of rat hippocampus by immunohistochemistry after ten minutes of transient forebrain ischemia which results in the selective delayed death of CA1 pyramidal cells and marked gliosis in the CA1 subfield. In the normal hippocampus, astrocytes do not show NADPH diaphorase activity nor express inducible NOS. After ischemia a population of reactive astrocytes (GFAP+ cells) are observed to express NADPH diaphorase activity by double staining. Moreover, the similar population of reactive astrocytes are stained with both anti-mouse macrophage NOS antibody (Drs. C. Nathan, J. Weinder, R. Mumford) and anti-GFAP antibody by double immunofluorescent histochemistry. This change is observed one day after ischemia and increases in prominence from one week to one month. Thus, we conclude that inducible NOS is present in reactive astrocytes after transient forebrain ischemia. This increase in NOS expression and, presumably, NO production by reactive astrocytes may contribute neuronal death after ischemia.

680.5

ACCUMULATION OF FREE FATTY ACIDS AND EDEMA FORMATION IN FOCAL ISCHEMIA. M. R. Prasad*, C. Ramiah, D. Donaldson, Y. Hu and R. J. Dempsey. Department of Surgery, University of Kentucky Chandler Medical Center, Lexington, KY 40536

The increase of free fatty acids in the brain has been well demonstrated in several models of ischemia in rodent species. Free fatty acids and arachidonate metabolites have been implicated as some of the factors that contribute to edema formation in brain ischemia. We examined the levels of free fatty acids in the cortices of cats after 8 hours of middle cerebral artery occlusion, and we correlated these levels with the water content of the cortex. Fourteen adult cats were subjected to 8 hours of right middle cerebral artery occlusion. Seven cats were administered difluoromethyl ornithine, an inhibitor of ornithine decarboxylase and polyamine synthesis (250 mg iv at 30 minutes before occlusion and 4 hours after occlusion). Eight hours after occlusion, a 300-mg section of cortex was quickly removed from both the right parietal (ischemic) and the left parietal (nonischemic) regions of each cat. These sections were frozen in liquid nitrogen and analyzed for free fatty acids. A square millimeter of cortex was also removed from these brain regions to measure specific gravity. The levels of palmitic, stearic, oleic, and docosahexenoic acids were two to three times higher (p<0.05) in the ischemic regions than in the nonischemic regions. The water content of the ischemic regions was 80.6±0.5% whereas that of the nonischemic regions was 77.48±0.3% (p<0.05). Administration of difluoromethyl ornithine did not significantly reduce either the free fatty acid level or the water content in the ischemic region of the cortex. These results suggest that free fatty acids may be a factor in edema formation of focal cerebral ischemia in nonrodents also. (Supported by funds from NIH NS 31816 and NS 2800.)

680.2

INHIBITION OF NITRIC OXIDE (NO) SYNTHESIS ATTENUATES THE RISE OF CYTOSOLIC CALCIUM ([Ca²⁺]_i) EXHIBITED BY CEREBELLAR GRANULE CELLS UNDER HYPOXIC CONDITIONS. J.M.Meir*, W.M.Chi*, M.W.Smith*, C.U.Eccles, and B.F.Trump*, Dept. of Pharmacol. and Toxicol. and Dept. of Pathol., Univ. of Maryland, Baltimore, MD 21201.

NO has been proposed as a neuronal messenger molecule in hypoxic/ischemic cell injury. We conducted preliminary studies in a model of O₂ deprivation (simple hypoxia) using cultured rat cerebellar granule cells. Experiments were designed to test the hypothesis that sustained elevations of [Ca²⁺]_i and NO generation act in concert to trigger neuronal injury after anoxic insult. A hypoxic state was achieved by perfusing the cells with medium pre-equilibrated with argon gas. [Ca²⁺]_i was monitored using digital-imaging fluorescence microscopy in cells loaded with fura-2 AM. Under short-term hypoxic conditions, cells displayed a gradual and sustained increase of [Ca²⁺]_i which returned to near basal levels upon restoration of O₂-containing medium. Prolonged hypoxic conditions (>60 min) often caused irreversible elevation of [Ca²⁺]_i, followed by disruption of cell membrane integrity as indicated by severe swelling and leakage of dye. Pretreatment with N^G-nitro-L-arginine (N-arg, 100 μM), a specific NO synthase inhibitor, markedly delayed the onset and intensity of the rise of [Ca²⁺]_i. The hypoxia-induced elevation of [Ca²⁺]_i was also greatly attenuated if N-arg (100 μM) was added to the argon-perfused medium before the cells demonstrated signs of irreversible injury. Prolonged or repeated hypoxic conditions, however, caused a rapid and intense increase of [Ca²⁺]_i which could not be blocked by the inhibition of NO synthesis.

680.4

SELECTIVE LOSS OF NITRIC OXIDE SYNTHASE-CONTAINING NEURONS IN THE DENTATE GYRUS AFTER TRANSIENT FOREBRAIN ISCHEMIA IN GERBILS. G. Lanzino*, S.C. Hong, J. Collins, N.F. Kassell, K.S. Lee. Dept. of Neurosurgery, University of Virginia, Charlottesville, VA 22908

Nitric oxide derived from nitric oxide synthase-containing (NOS+) neurons is suggested to participate in pathological damage to CNS neurons. Consistent with this hypothesis are observations that NOS+ neurons are selectively resistant to excitotoxic and ischemic damage. The present study further investigated this issue by examining the response of NOS+ neurons in the gerbil dentate gyrus to temporary ischemia. Transient forebrain ischemia was induced by reversibly occluding the carotid arteries for 10 minutes (n=9). Sham-operated animals (n=7) served as a control group. Seven days following surgery, NOS+ neurons were identified in the infragranular zone of the dentate gyrus using NADPH-diaphorase histochemistry. The number of NOS+ neurons in the infragranular zone of the dentate gyrus was reduced by approximately 50% following ischemia (p<0.001, Student t-test). Sham operated animals exhibited 6.47±0.62 cells/mm while the post-ischemic animals showed only 3.22±0.29 cells/mm. NOS-negative granule cells located nearby were resistant to this level of ischemia.

These observations demonstrate that NOS-containing neurons in the dentate gyrus are selectively vulnerable to brief ischemia. These findings stand in contrast to previous observations in which NOS+ neurons in the striatum were shown to be selectively resistant to ischemic damage. The hypothesis that NOS+ neurons may serve as 'killer' cells in CNS pathology does not appear to be applicable to ischemic death in the dentate gyrus.

680.6

DIFFERENTIATION OF INTRINSIC AND SYSTEMIC DIFFUSION PROPERTIES OF RAT NEOCORTEX FOLLOWING *IN VIVO* AND *IN VITRO* ISCHEMIA E. Syková, M. Pérez-Pinzón*, N. Zoremba, A. Lehmenkühler, O. Gil, L. Tao and C. Nicholson. Acad. Sci. Czech Rep, 180 85 Prague 8, Czech Republic; University of Münster, 48149 Münster, Germany; NYU Medical Center, New York, NY 10016.

Intrinsic and systemic properties of the brain extracellular micro-environment during and after ischemia were compared. We analyzed extracellular volume fraction (α) and tortuosity (λ) using tetramethylammonium (TMA⁺) in the somatosensory neocortex of the adult rat *in vivo* and *in vitro*. Concentration-time profiles of TMA⁺ applied by iontophoresis were quantitatively analyzed (Nicholson and Phillips, J. Physiol. 321:225, 1981). Transient ischemia *in vivo* was induced by clamping the carotid arteries for 10 min. and by concomitant reduction of inspiratory oxygen content to 6% in nitrogen. After releasing the clamps the animals were ventilated with pure oxygen again. *In vivo* ischemia was induced in submerged slices (400 μm thick), by replacing the oxygenated 10 mM glucose medium with aglycemic and anoxic medium for about 10 min. Normal values of α and λ averaged 0.20 and 1.60, respectively in both preparations. During re-oxygenation λ recovered from an immediate post-ischemic value of 1.8 to normal in 15 min. in both preparations. Differences between *in vitro* and *in vivo* preparations occurred in the behavior of α . *In vivo*, α increased in all layers up to a maximum of about 0.28 at 10 min. after ischemia then recovered during the next hour. *In vitro*, α simply recovered from a reduced value during ischemia to a normal value in about 30 min. The *in vitro* and *in vivo* differences during re-oxygenation point toward systemic mechanisms of injury such as edema in this phase. Partly funded by NIH grant NS 28642.

680.7

SOURCE OF EXTRACELLULAR ADENOSINE DURING OXYGEN/GLUCOSE DEPRIVATION IN CULTURED CORTICAL NEURONS. D. Lobner* and D.W. Choi. Dept. of Neurology and Center for the Study of Nervous System Injury, Washington Univ. School of Medicine, St. Louis, MO 63110.

Extracellular adenosine accumulates during reduced energy conditions in the brain, but the source of this adenosine is uncertain. Murine cortical cell cultures exposed to oxygen-glucose deprivation for 45-60 min, showed an increase in extracellular glutamate (1-3 μ M) and adenosine (0.5-2 μ M), and submaximal neuronal death by the next day. 10 μ M dipyrindamole, an adenosine transport inhibitor, decreased this adenosine accumulation by about 25% while increasing glutamate accumulation and neuronal death. In contrast, dipyrindamole increased the comparable increases in extracellular adenosine induced by 45 min exposure to 10 μ M NMDA, or 300 μ M kainate plus 10 μ M MK-801, without affecting glutamate accumulation or neuronal death.

These results support the idea that the extracellular adenosine accumulation induced by oxygen-glucose deprivation may be mediated, at least in part, by adenosine transporters. Inhibition of these transporters by drugs like dipyrindamole may worsen neuronal injury by reducing extracellular adenosine accumulation, and thereby permitting greater release of synaptic glutamate.

Ca²⁺ or NMDA ANTAGONISM DOES NOT ALTER THE EFFLUX OF ADENOSINE FROM RAT HIPPOCAMPAL SLICES DURING *IN VITRO* ISCHEMIA. J.C. Fowler*. Department of Physiology, Texas Tech University Health Sciences Center, Lubbock, TX 79430.

Submerged hippocampal slices release large amounts of adenosine into the medium within minutes of exposure to *in vitro* ischemia (ie. glucose-free medium equilibrated with 95% N₂ / 5% CO₂). Exposure to *in vitro* ischemia is also associated with NMDA receptor activation and enhanced Ca²⁺ influx, two conditions which elevate adenosine efflux under normoglycemic, normoxic conditions. Therefore, the effect of Ca²⁺ and NMDA antagonism on ischemic adenosine efflux was examined.

Hippocampal slices were initially superfused at 2 ml/min with physiological medium maintained at 33 - 34°C and equilibrated with 95% O₂ / 5% CO₂. Extracellularly recorded DC and evoked synaptic potentials were recorded. Slices were pre-exposed to medium that contained Co²⁺ (500 μ M), the NMDA antagonist MK-801 (10 μ M) or was Ca²⁺-free. Slices were then exposed to *in vitro* ischemic conditions until one minute after an anoxic depolarization occurred. One ml aliquots of superfusate were collected at 2 min intervals and adenosine was measured using absorbance HPLC.

While recovery of synaptic transmission was not apparent during reoxygenation of slices exposed to normocalcemic, drug-free *in vitro* ischemia, exposure to Co²⁺, MK-801 or Ca²⁺-free medium during ischemic-like conditions did result in significant recovery upon reoxygenation. Ca²⁺-free medium also significantly shortened the time to anoxic depolarization observed during *in vitro* ischemia. In spite of these differences in electrophysiology and functional recovery, levels of ischemic adenosine efflux were not different between treatments.

680.11

CHANGES IN DIALYSATE AMINO ACIDS AND PURINES DURING CEREBRAL ISCHEMIA: CHRONICALLY VERSUS ACUTELY IMPLANTED MICRODIALYSIS PROBES. M.C. Grabb*, V.M. Sciotti and D.G.L. Van Wylen. Departments of Physiology and Pathology, SUNY-Buffalo School of Medicine and Biomedical Sciences, Buffalo, NY 14215.

Although recent studies suggest that microdialysis probes should be implanted for 24 hours before the initiation of protocols, the responsiveness of the tissue surrounding chronically implanted probes is debatable. The purpose of this study was to compare the ischemia-induced changes in interstitial fluid purines and amino acids as determined by either acutely or chronically implanted microdialysis probes. Changes in dialysate levels of adenosine (ADO), inosine (INO), glutamate (GLU), serine (SER), and glycine (GLY) were determined during 90 min of cerebral ischemia (4-vessel occlusion). Probes were implanted bilaterally in the caudate nuclei of rats either 24 hours prior (CHRONIC, n=7) or 2.5 hours prior (ACUTE, n=7) to ischemia in rats whose vertebral arteries were previously cauterized. Baseline dialysate levels of all amino acids were higher in CHRONIC than in ACUTE, while both ADO and INO were 10x lower in CHRONIC. In ACUTE, ADO, INO and GLU increased within the first 20 min of ischemia (26x, 11x, 17x respectively) and remained elevated throughout ischemia. In CHRONIC, ADO and INO increased within the first 20 min of ischemia (22x, 13x respectively); however, GLU did not increase until after 60 min of ischemia (5x). SER and GLY levels tended to remain stable during ischemia in both ACUTE and CHRONIC. These data demonstrate that the responsiveness of tissue surrounding the probe varies with the duration of probe implantation, and suggest that dialysate profiles obtained with acute probe implantation best reflect ischemia-induced changes. Supported by NIH HL-40878.

EFFECT OF HYPOGLYCEMIA ON LOCAL CORTICAL BLOOD FLOW AND INTERSTITIAL ADENOSINE CONCENTRATION DURING POST-ISCHEMIC REPERFUSION Y.B. Kim**, I.S. Park*, A.R. Shah, E.R. Gonzales, and J.M. Gidday. Departments of Neurosurgery, St. Louis Children's Hospital and Washington University School of Medicine, St. Louis, MO 63110, and **Chung-Ang University, Seoul, Korea.

Cerebral ischemia often occurs in hypoglycemic (HG) neonates. The effect of HG on changes in neonatal cerebral blood flow (CBF) induced by ischemia-reperfusion are not known. We induced 10 min global cerebral ischemia in 32 isoflurane-anesthetized newborn pigs by occlusion of subclavian and brachiocephalic arteries; cortical CBF and interstitial adenosine concentration ([ADO]) were evaluated using hydrogen clearance and microdialysis. HG (blood glucose <25 mg/dl; induced by regular insulin; n=16) increased pre-ischemic CBF and [ADO] relative to normoglycemic (NG) animals (n=16). At 60 min of post-ischemic reperfusion, a significant hypoperfusion (42% reduction in CBF) associated with a significant 43% reduction in [ADO] was observed in the NG group. These post-ischemic changes in CBF and [ADO] were significantly exacerbated by HG.

	CBF (ml/min/100g)		ADENOSINE (nM)	
	NG	HG	NG	HG
Pre-Ischemia	38±2	51±4#	142±13	203±50#
Reperfusion	22±2**	17±1**	80±7**	50±10#*

(#p<0.05 vs NG; *p<0.05, **p<0.001 vs pre-ischemia). Thus, HG increases the magnitude of post-ischemic hypoperfusion, which may potentiate reperfusion injury in HG neonates. The concomitantly low [ADO] suggests that pharmacologic augmentation of [ADO] may improve post-ischemic CBF.

CYANIDE MEDIATED ADENOSINE RELEASE FROM RAT HIPPOCAMPAL NEURONS

J.M. Kurbat, R.J. Buchanan, S.C. Wulff, and K.-W. Yoon*. Division of Neurosurgery and Surgical Research Institute, Saint Louis University, St. Louis, MO 63110-0250.

Ischemic neuronal cell damage is mediated in part by glutamate. Glutamate is released by ischemic brain parenchyma by a synaptic mechanism and activates glutamate receptors which mediate neuronal cell death. Specific glutamate receptor antagonists (e.g. MK801) attenuate neuronal injury due to ischemia in several experimental models. Ischemic brain, in addition to glutamate, release adenosine. By activating the presynaptic adenosine (A1) receptors, adenosine may modulate the amount of glutamate released in the extracellular space. However, the origin of adenosine released in ischemia has not been well established. Rat glial cell cultures with or without dissociated hippocampal neurons were perfused continuously with artificial CSF and exposed to an ischemic condition by addition of potassium cyanide (KCN, 1mM, 1hr) (Sturm, et al., J of Neurosurg., in press). The perfusate was analyzed every 15 minutes with HPLC for adenosine. In four out of four glial cell cultures without neurons, the baseline adenosine level did not change with KCN. However, in cultures with glia and neurons there was a dramatic but reversible increase in baseline adenosine concentration (269% of control, n=6, p<0.005). This observation suggests that adenosine is released by ischemia and the origin of this adenosine is neuronal.

680.12

EFFECT OF ISCHAEMIA AND REPERFUSION ON THE EXTRA- AND INTRACELLULAR DISTRIBUTION OF AMINO ACIDS IN THE RAT HIPPOCAMPUS. R. Torp, B.S. Meldrum,† J. Storm-Mathisen*, O.P. Ottersen. Dep. of Anatomy, University of Oslo, P.O. Box 1105 Blindern N-0317 Oslo, Norway.†Dep. of Neurology, Inst. of Psychiatry, London SE5 8AF, U.K.

The redistribution of neurotransmitter amino acids resulting from 20 min of forebrain ischaemia was studied in the rat hippocampus by quantitative, EM immunocytochemistry and *in vivo* microdialysis in the same animals. Changes in the distribution of glu, gln, asp and GABA in various cell compartments of CA1 were analyzed immediately after ischaemia or after 60 min of reperfusion, by incubating ultrathin sections with antisera raised against the respective amino acids and subsequently with a secondary antibody coupled to colloidal gold particles. The extracellular concentrations of glu, asp and GABA showed the expected increase during ischaemia and returned rapidly to normal during reperfusion. Glu-like immunoreactivity was reduced in pyramidal cell somata both immediately after ischaemia and after 60 min of reperfusion. Ischaemia caused no consistent changes in terminals. The ratio between the intracellular levels of glu and gln was assessed by double labelling immunocytochemistry, using two different gold particle sizes. The glu/gln ratio in glial cells was several fold increased after ischaemia (glu up, gln down), but recovered to normal level within 1h of reperfusion. The present results suggest that postsynaptic neuronal elements as well as glial cells contribute to the extracellular overflow of excitatory amino acids during an ischaemic event: postsynaptic elements by leaking or releasing glu and asp, and glial cells by losing their ability to effectively convert glu to gln. The temporal association between the changes in the glial contents of glu and gln, and the extracellular amino acid fluctuations recorded by microdialysis in the same animals, underlines the strategic role of glia in regulating the extracellular level of glu.

WHITE MATTER GABA-B RECEPTOR MEDIATED AUTOPROTECTION INVOLVES PROTEIN KINASE C ACTIVATION. R. FERN^{1,2}, S.G. WAXMAN^{1,2} AND B.R. RANSOM¹ Department of Neurology¹, Yale University School of Medicine, New Haven, CT, and Neuroscience Research Center², VA Medical Center, West Haven, CT.

We have recently found that GABA, the major inhibitory neurotransmitter of the brain, acts to protect CNS white matter from the effects of anoxia. Thus, 1 μ M GABA increases recovery in the rat optic nerve following a 60 min period of anoxia from a control of 36% (+/-2.6%) to 55% (+/-3.1%), as determined by recording the evoked compound action potential. The effect of GABA was bicuculline insensitive, was not mimicked by selective GABA-A agonists but was mimicked by the selective GABA-B agonist baclofen (recovery=55% +/-5%). Thus GABA is acting via GABA-B receptors. Block of GABA uptake with nipecotic acid also protected against anoxia, while block of GABA-B receptors with phaclofen significantly reduced post-anoxic recovery. We have suggested a model where release of endogenous GABA during anoxia activates GABA-B receptors to limit subsequent white matter dysfunction via an unknown mechanism.

We now report that protein kinase C activation has a similar protective effect to that of GABA, increasing post-anoxic recovery to 57% (+/-7%). Furthermore, inhibition of protein kinase C by H-7 completely blocked GABA-mediated protection. It appears, therefore, that protein phosphorylation by protein kinase C is an essential step in the white matter GABA-B receptor mediated autprotective reflex. Protein phosphorylation of a number of possible sites could act to reduce white matter anoxic injury, including axolemma ion channels and ion exchangers. We are currently investigating which of these sites is important in this novel system. Supported by NIH (B.R.R.) and VA Med. Res. Serv. (S.G.W.).

MODIFICATIONS OF OXIDATIVE ENERGY METABOLISM INDUCED BY A UBIQUINONE-LIKE MOLECULE IN RAT CEREBRAL CORTEX SYNAPTOSOMES. D. Curti* and E. Izzo. Institute of Pharmacology, University of Pavia, 27100 Pavia, Italy.

Oxidative energy metabolism was evaluated by measuring: 1) the oxygen consumption rate (QO₂), a measure of the rate of ATP synthesis by oxidative phosphorylation in basal conditions and of the potential activity of the respiratory chain to cope with increased energy demands in stimulated states; 2) the activity of pyruvate dehydrogenase (PDHc), a mitochondrial multienzyme complex with critical functions in providing acetyl groups for energy metabolism and acetylcholine synthesis. PDHc is present in an active, dephosphorylated form (PDHa) and in an inactive, phosphorylated form. The fraction of active form over the total gives a measure of the activation state of mitochondrial energy metabolism. Synaptosomes of rat cerebral cortex have a QO₂ of 3.5 nmol/min/mg of protein and less than 60% of the PDHc in the active form. Persistent stimulation of energy consumption, induced by veratridine, increases both the QO₂ and the conversion of PDHc into the PDHa form. A structural analog of ubiquinone, idebenone (1 μ M), does not affect the QO₂ in basal conditions but counteracts the veratridine-stimulated increase of QO₂. The drug does not affect the increase of QO₂ induced by an uncoupler of oxidative phosphorylation. The effect of idebenone on veratridine-stimulated QO₂ is slightly enhanced by a preactivation of the Na⁺ channels. Idebenone (1-10 μ M) is also able to totally counteract veratridine-induced increase of PDHa. The observed effects of idebenone could result in some protection of the cerebral tissue against ischemic/hypoxic insults, in fact a slowing down of energy utilization might delay the depletion of energy stores and thus protect the cerebral tissue against the development of irreversible damage.

DIFFERENTIAL EFFECTS OF GLOBAL CEREBRAL ISCHEMIA/ REPERFUSION ON HIPPOCAMPAL [PH]NOREPINEPHRINE (NE) AND STRIATAL [PH]DOPAMINE (DA) RELEASE IN CANINE BRAIN SLICES. L.L. Werling*, K.J. Hurt, R.E. Rosenthal and G. Fiskum. Depts. of Pharmacology, Biochemistry and Molecular Biology, and Emergency Medicine, The George Washington Univ. Med. Ctr., Washington, DC 20037.

Striatum and hippocampus are selectively vulnerable to ischemic damage. While DA is thought to contribute to neuronal damage, NE is thought possibly to play a neuroprotective role in ischemia. We sought to compare changes in NE release from hippocampus in the same model used for the DA studies.

Canines were divided into one of five experimental groups: non-arrested controls (NA); global cerebral ischemia induced by 10 min cardiac arrest (CA); CA followed by 30min, 2hr, or 24hr restoration of spontaneous circulation (ROSC). Slices of brain were prepared, washed, and incubated with [PH]catecholamine. Striatal slices prepared from all groups accumulated about the same amount of [PH]DA. Hippocampal slices from CA accumulated less [PH]NE than did those from NA. Slices were washed and loaded into chambers of a superfusion apparatus. Release of DA or NE was stimulated by a 2 min exposure to 20 mM K⁺ or 50 μ M NMDA \pm 100 μ M GLY. Release of [PH]DA from striatum was more sensitive to K⁺-stimulation immediately following CA, and to NMDA or NMDA/GLY at all times after CA, but sensitivity of [PH]NE release from hippocampus was unchanged until 24hr ROSC, at which time it was greatly increased to K⁺-stimulation. These data suggest that changes in NE systems exhibit a different time course than changes in DA systems. Supported by Sigma Tau, S.p.A. and Souers Stroke Fund.

HIPPOCAMPAL NEURON LOSS AND PEPTIDE CHANGES FOLLOWING GLOBAL ISCHEMIA IN THE RAT. T.M. Wengenack*¹, R. Slemmon^{2,1}, W.P. Dunlap³ and P.D. Coleman¹. Depts. of ¹Neurobiol. & Anat. and ²Biochem., Univ. of Roch., Rochester, NY 14642 and ³Tulane Univ., New Orleans, LA 70118.

Global cerebral ischemia causes selective neurodegeneration and gliosis in the hippocampus. This has become of intense interest as a model for identification of molecular events of neurodegeneration and the plasticity of surviving neurons in response to injury. The specific aim of this study was to compare the posts ischemic progression of hippocampal neuron loss and molecular events which may play a critical role in neuronal vulnerability and plasticity in response to injury.

Rats were sacrificed 1, 3, or 7 days after 30 min of 4-VO global ischemia or sham surgery. Crude peptide fractions were isolated from supernatants of denatured hippocampal homogenates using gel and ion exchange chromatography and then separated by RP-HPLC. Peaks that exhibited a 25% or greater change after 4-VO were sequenced and identified. In two rats from each group, CA1 neurons were counted in three regions of CA1, in two sections of the dorsal hippocampus.

The number of CA1 pyramidal neurons was not decreased significantly on posts ischemic day 1, but was on days 3 and 7. Comparisons of posts ischemic differences in hippocampal peptides indicated significant changes in peptides of cellular and vascular origin on posts ischemic day 1, before neuron loss was histologically apparent, as well as on days 3 and 7, demonstrating a temporal dissociation between CA1 neuron loss and early peptide changes. For example, decreases were observed for the calcium-binding protein calmodulin. This may have reflected down-regulation in response to posts ischemic calcium influx and accumulation, which is believed to be a major cause of ischemic neuron death. Increases in peptides of vascular origin suggested increases in blood-brain barrier permeability that may also contribute to neurodegeneration.

INFLUENCES OF AGE ON MAINTENANCE AND RECOVERY OF SYNAPTIC TRANSMISSION AND ION HOMEOSTASIS IN HIPPOCAMPAL SLICES DURING AND AFTER ANOXIA. E.L. Roberts, Jr.^{1*} and Z.-C. Feng. Department of Neurology, University of Miami School of Medicine, and ¹Geriatric Research, Education, and Clinical Center, Miami VA Medical Center, Miami, FL 33136

Aging diminishes the capacity of brain tissue to maintain ion homeostasis during anoxia, and to recover ion homeostasis and synaptic transmission after anoxia (E.L. Roberts, Jr. *et al.*, *Brain Res.* 514 (1990) 111-118). The goals of this study were to determine (1) whether this capacity is constantly diminished with age and (2) whether age-related declines in glycolytic or oxidative metabolism underlie these changes. Experiments were carried out in hippocampal slices from young adult (6-9 month old), adult (16-19 mon.) and aged (26-29 mon.) Fischer-344 rats. Slices were exposed to physiological solutions containing 2.5-20 mM glucose or 5-40 mM sodium lactate. Lactate supports oxidative phosphorylation only in brain slices. Slices were exposed to anoxia (95% N₂, 5% CO₂), and returned to normoxia (95% O₂, 5% CO₂) one minute after catastrophic loss of ion homeostasis (anoxic depolarization). Extracellular K⁺ concentrations (K⁺) and magnitudes of orthodromically-evoked pyramidal cell population spikes were assessed in hippocampal subfield CA1 before, during, and up to one hour after anoxia. Maintenance or recovery of K⁺ homeostasis during and after anoxia in slices from adult rats was similar to that in slices from aged, but not young adult, rats. Age-related alterations in oxidative phosphorylation were not involved in these findings because recovery of K⁺ homeostasis and synaptic transmission following anoxia showed no differences between age groups and resembled that in 2.5 mM glucose. (Supported by research grants from NIA (AC08710) and the American Federation for Aging Research).

CHANGES IN BRAIN LIPID METABOLISM INDUCED BY ISCHEMIA-REPERFUSION. J.P. Zhang, P.M. Wixom* and G.Y. Sun Biochem. Dept., Univ. Missouri, Columbia, MO 65212.

Cerebral ischemic insult in brain is associated with the release of free fatty acids (FFA) although the exact source for the increase is not well understood. Using a rat model in which focal cerebral ischemia was induced by ligation of the middle cerebral artery (MCA), we observed previously an increase in FFA in the MCA cortex with time during ischemia and at 16 - 24 hr after a 60 min insult. The increase in FFA at 16 hr after reperfusion was correlated to a rise in levels of diacylglycerols (DG) and triacylglycerols (TG). In this study, [¹⁴C]arachidonic acid (AA) was used to trace the metabolism of glycerolipids in brain at different times after a 60 min ischemic insult. Labeled AA was incorporated into phospholipids as well as the neutral glycerides and labeled TG constituted about 20% of the total glycerolipids. At 8, 16 and 24 hr after a 60 min ischemic insult, incorporation of labeled AA into DG and TG in the ischemic right MCA cortex was higher than that in the left MCA cortex. The increase in labeling of TG could be further correlated to an increase in labeled phosphatidic acid, the precursor for glycerolipid biosynthesis. These results suggest an increase in DG and TG biosynthesis due to a disturbance in the *de novo* lipid synthesis. The sustained increase in DG may have an implication on protein kinase C activity, which in turn, may play an important role in the mechanism of delayed neuronal cell death.

MODIFICATION OF HYPOXIC INJURY TO CEREBRAL ENDOTHELIAL CELLS BY FRUCTOSE-1,6-BISPHOSPHATE BUT NOT GLUTAMATE RECEPTOR ANTAGONISTS. G.T. Gobbel, T.Y.-Y. Chan, G.A. Gregory, P.H. Chan. CNS Injury & Brain Edema Res. Center, Dept. Neurol., & Brain Tumor Res. Center, Dept. Neurosurg., Univ. of Calif., S.F., CA 94143.

Fructose-1,6-bisphosphate (FBP) has been shown to reduce the damage to astrocytes induced by hypoxia; similarly, antagonists of some of the glutamate receptors have been shown to ameliorate hypoxic injury to neurons. To determine whether FBP or glutamate receptor antagonists might also protect cerebral endothelial cells from hypoxic injury, cerebral endothelial cells were isolated from 2 week old Sprague-Dawley rats. At 5-7 days after plating, cells were treated with 48 hours of complete hypoxia \pm FBP (3.5 mM), MK-801 (50 μ M), Kynurenic Acid (KA; 0.5 mM), or 2,3-dihydroxy-6-nitro-7-sulfamoyl-benzo (F) quinoxaline (NBQX; 1 or 10 μ M). Hypoxia increased the release of lactate dehydrogenase (LDH) into the media relative to total LDH (released and intracellular) from 0.28 ± 0.14 (mean \pm SD) to 0.93 ± 0.02 . The ratio of dead to total cells (ethidium bromide and fluorescein diacetate staining) also increased from 0.03 to 0.34. None of the glutamate receptor antagonists, MK-801, KA, or NBQX, altered the amount of damage measured by either LDH release or viability staining. In contrast, LDH release in FBP treated cells was significantly reduced by 72% from 18.7 ± 2.8 U/mg protein in untreated hypoxic controls to 5.2 ± 1.1 . FBP treatment significantly increased the level of ATP under hypoxic conditions by 48% (6.4 ± 1.5 vs. 4.4 ± 0.8 μ moles/mg protein) but did not alter hypoxia-induced GSH depletion. These results suggest that glutamate receptor antagonists to the NMDA (MK-801 and KA), AMPA (NBQX), and kainate subtypes (NBQX) are not effective in ameliorating hypoxic injury to cerebral endothelial cells. However, FBP is effective, and this effect may be related to the increase energy charge induced by FBP, an effect similar to that seen in astrocytes. Supported by NIH Grants NS 14543, AG 08938, NS 25732, and the American Brain Tumor Association.

(3H)-D-ASPARTATE EFFLUX FROM RAT HIPPOCAMPAL SLICES DURING IN VITRO ISCHEMIA IS MIMICKED BY XANTHINE/XANTHINE OXIDASE EXPOSURE AND IS NOT BLOCKED BY DIHYDROKAINATE. V. Roetter* and P. Lipton. Dept. of Physiol., Univ. of Wisconsin, Madison, WI 53706

Excess glutamate release most likely contributes to ischemic brain damage. The release mechanism is unknown although reversal of the Na-dependent glutamate transporter has been suggested. Free radical formation has also been implicated in ischemic-induced release.

At 37°C, slices loaded with (3H)-D-Aspartate (ASP, transporter substrate) were exposed to a combination of in vitro ischemia (IVI) and veratridine (VER, 50 μ M). By 10 min, ASP efflux increased x6 over basal level; IVI or VER alone increased ASP efflux x3 or x4, respectively. Dihydrokainate (DHK, transporter inhibitor, 0.5mM) blocked VER-induced ASP efflux but did not block efflux induced by IVI alone or by the combination of IVI and VER.

The free radical generating system of xanthine (X, 0.5mM) and xanthine oxidase (XOD, 20mU/ml) increased ASP efflux x3 by 10 min; XOD alone produced the same increase in efflux. This suggests that endogenous X may be adequate to induce the observed effect. VER combined with either X/XOD or XOD alone increased ASP efflux x7 by 10 min. DHK did not block ASP efflux when XOD was present.

Therefore, X/XOD mimicked IVI in the following ways: (1) both conditions alone increased ASP efflux, (2) IVI or X/XOD-induced efflux was insensitive to DHK, (3) IVI or X/XOD-induced efflux was additive with VER-induced efflux and (4) IVI or X/XOD prevented DHK from blocking the VER-induced increase.

Increased ASP efflux may be due to IVI or X/XOD-induced Na influx. The loss of DHK sensitivity of VER-induced efflux may be due to effects of the conditions on the transporter itself or on DHK. An alteration in the transporter itself may enhance ASP efflux during IVI or X/XOD. These possibilities are being tested.

ISCHEMIA: NEUROCHEMISTRY II

681.1

TYROSINE PHOSPHORYLATION AND MAP KINASE ACTIVITY IS ENHANCED IN RESISTANT AREAS OF THE BRAIN FOLLOWING TRANSIENT CEREBRAL ISCHEMIA. Bing Ren Hu and Tadeusz Wieloch* Laboratory for Experimental Brain Research, Lund Hospital, Lund University, S-221 85 Lund.

Activation of trophic factor receptors stimulate tyrosine phosphorylation on proteins and support neuronal survival. We report, that in the recovery phase following reversible cerebral ischemia, tyrosine phosphorylation increases in the membrane fraction of the resistant hippocampal CA3/dentate gyrus (DG) region, while in the sensitive CA1 region or striatum, tyrosine phosphorylation is less marked or decreases. In the cytosolic fractions, a 42 kD protein, identified as the mitogen-activated protein (MAP) kinase, is markedly phosphorylated and activated immediately following ischemia, in particular in CA3/DG, but not in striatum. In the CA1 region, phosphorylation of MAP kinase is less intense and decreases later during reperfusion, which could explain the delay of neuronal degeneration in this structure. The data suggest that in resistant neurons, the growth factor receptor signalling cascade is stimulated, may support neuronal survival following ischemia. In vulnerable cells the cascade is depressed.

CHANGES IN EXTRACELLULAR STRIATAL DOPAMINE(DA) IN THE RAT DURING GRADED CEREBRAL ISCHEMIA: RESPONSE TO POTASSIUM STIMULATION AND DA REUPTAKE BLOCKADE. S.H. Lee*, T.Kondoh, R.C. Heros, W.C. Low. Depts. of Neurosurgery and Physiology, Univ. of Minnesota Medical School, Mpls., MN 55455.

The excitotoxic release of DA in the rat striatum is closely related to the severity of ischemia. Cerebral ischemia was induced by bilateral occlusion of the common carotid arteries with hemorrhagic hypotension. To study the kinetics of DA metabolism, potassium(100mM) and nomifensin, a DA reuptake blocker, (1mM) were infused through a microdialysis probe for 10 min. and DA changes were measured during graded ischemia. In control animals, high K⁺ resulted in a 20.4 fold increase in DA efflux. This returned to basal levels after one hour. During three hours of moderate ischemia, where CBF was maintained at 20-50% of basal levels, DA efflux showed a 28.6 fold increase. This returned to basal level after three hours. At this time, high K⁺ induced a two fold increase; this persisted for two hours. In the mild ischemia group, DA increased insignificantly after induction of ischemia but increased 72.6 fold after K⁺ injection at three hours. Severe ischemia, which showed 146.2 fold increase of DA efflux, revealed no additional increase after K⁺ infusion. In the same setting, response to nomifensin in control conditions showed a 14.9 fold increase in DA release. In comparison, the response during moderate ischemia increased 1.4 fold while in mild ischemia it increased 20 fold. In severe ischemia, no response occurred. In conclusion, in moderate ischemia, DA levels may return to normal after some time but the response to drugs affecting DA metabolism differs from control, suggesting underlying pathophysiological changes. (This work supported in part by grants from the American Heart Association and PHS grants NS-24464 and NS-23682).

INVOLVEMENT OF NMDA RECEPTORS IN THE REBOUND RELEASE OF 5-HT AFTER HYPOXIA FROM RAT HIPPOCAMPAL SLICES. K. E. Lee, D. W. Kang, D. G. Kim* and Y. S. Ahn. Dept. of Pharmacology, Yonsei Univ. College of Medicine, Seoul 120-752, Korea.

We have previously demonstrated that ischemia, induced by partial ligation of both carotid arteries, increased the concentration of 5-HT in rat hippocampus after 24 hours. Therefore, in the present study, we aimed to investigate whether hypoxia and/or NMDA was able to stimulate, directly, release of 5-HT from hippocampal slices. After 30 min's of preincubation, the slices were incubated for 20 min in a buffer containing [³H]-5-HT (0.1 nM) for uptake, and washed for 10 min. To measure the release of [³H]-5-HT from the buffer, the incubation medium was drained off and refilled every 10 min through a sequence of 13 tubes. When 1 mM NMDA was added at 5th tube, [³H]-5-HT release was increased, and NMDA-induced [³H]-5-HT release was prevented by adding AP5 (30 mM) 10 min before NMDA administration(4th tube). When slices were exposed to hypoxia, induced by gassing 95% N₂/5% CO₂ for 20 min, [³H]-5-HT release was markedly decreased (about 47 %) during hypoxic period. Curiously, a rebound release of [³H]-5-HT was observed 30 min after hypoxic period. The hypoxia-induced decrease in [³H]-5-HT release was not affected by treatment with AP5 while the rebound release was blocked by treatment with AP5. These results suggest that the rebound release of [³H]-5-HT during post-hypoxic period was mediated, at least in part, by the NMDA receptor.

ELEVATION OF N-ACETYL-ASPARTATE-GLUTAMATE (NAAG) IN ACUTE BRAIN ISCHEMIA: ANOTHER SCAVENGER METABOLIC PRODUCT OF GLUTAMATE? H. Igarashi, I. L. Kwee* and T. Nakada. Neurochem. Res. Lab., VANCSC, Martinez, CA 94553 and Dept. of Neurology, Univ. of Calif., Davis, CA 95616.

Excitatory amino acid accumulation, especially that of glutamate, is believed to play a significant role in the generation of ischemia induced brain damage, especially delayed neuronal death. Nevertheless, to date, little is known regarding the metabolic fate of glutamate accumulated *extracellularly*. The two principal anaerobic enzymatic activities which consume glutamate during ischemia are alanine transaminase and glutamic acid decarboxylase forming alanine and γ -amino-butyric acid (GABA), respectively. Both, however are *intracellular* reactions, indicating that they play a minor role, if any, in the fate of *extracellular* glutamate. In this study, we demonstrated that N-acetyl-aspartate-glutamate (NAAG) was significantly elevated in acute brain ischemia (maximum ca. 4 hours post ischemia and slowly declining thereafter) in rat, utilizing proton nuclear magnetic resonance (NMR) spectroscopy. The finding strongly indicates that the N-acetyl-aspartate-linked acid dipeptidase (NAALAD) reaction is likely to be an important *scavenger* metabolic pathway for *extracellular* glutamate during brain ischemia.

681.5

THE ROLE OF cGMP ON THE NEURONAL INJURY INDUCED BY HYPOXIA-HYPOGLYCEMIA IN THE ORGANOTYPIC CULTURE OF RAT HIPPOCAMPUS. X. Sun*, M. Colberg and C. Shin. Departments of Pharmacology and Neurology, Mayo Clinic/Mayo Foundation, Rochester, MN 55905

Excitatory amino acid (EAA), glutamate, is thought to play a key role in the development of neuronal injury through excitotoxic mechanism. Glutamate and the EAA analogues also induce elevation of cGMP in neurons. Since the cyclic nucleotides are known to modulate many cellular signaling pathways, one could hypothesize that rise in intracellular cGMP could be a part of the excitotoxic process underlying ischemia induced neuronal injury. We tested this hypothesis by using methylene blue, which has been shown to prevent the activation of guanylate cyclase.

The organotypic cultures were made from 6 day old rat pup hippocampus. At 10 DIV, they were subjected to ischemic condition by exposure to 2-deoxyglucose substituted HBSS equilibrated with 95% N₂ plus 5% CO₂ atmosphere. Methylene blue was applied for 30 min before, during and for 24 hours after ischemia. At 24 hours, neuronal damage was assessed by propidium iodide fluorescence and quantitated by assigning a severity index (0=none, up to 4=severe) to the intensity of fluorescence.

With 40 min exposure to ischemia, neuronal injury was induced in the pyramidal layers of hippocampus. The treatment with methylene blue (100 μM) blocked the ischemia induced neuronal injury as judged by propidium iodide fluorescence. Methylene blue (100 μM) by itself without ischemic treatment did not alter the histologic appearance of the cultures.

The results of the present investigation suggest that cGMP may play a significant role in the development of neuronal injury in brain produced by ischemic insults.

681.7

TYROSINE PHOSPHORYLATION OF GLYCOPROTEINS DURING ISCHEMIA IN RAT HIPPOCAMPUS. K. Au, J. Soulliere and J.W. Gurd. Scarborough Campus, University of Toronto, West Hill, Ont, M1C 1A4.

The effects of post-decapitative ischemia and *in vitro* ischemia on the tyrosine phosphorylation of hippocampal glycoproteins (gp) were investigated. Rats were sacrificed by decapitation, the heads immediately frozen in liquid N₂ and the hippocampus analyzed for the presence of tyr(P)-proteins by immunoblotting with α-tyr(P) antibodies. Under these conditions 10 tyr(P)-proteins and 2 major tyr(P)-Con A⁺ gp of app. Mr 110K (GP110) and 180K (PSD-GP180) were detected. Subcellular fractionation studies showed that GP110 was enriched in synaptic membranes. Maintaining brains at room temperature prior to freezing resulted in the rapid loss of tyr(P) from GP110 (t_{1/2} < 30 sec.) and the slower dephosphorylation of PSD-GP180 (t_{1/2} = 5-10 min.) and proteins of Mr 60K and 39K. The tyr(P) of other proteins remained unchanged. The effect of ischemia on tyr(P) in hippocampal slices was determined by preincubating slices for 60 min. prior to transfer to O₂ and glucose-free media. Fresh slices contained tyr(P)-PSD-GP180 but low levels of tyr(P)-GP110. Incubation in oxygenated media resulted in a rapid increase in the tyr-phosphorylation of GP110 (t_{1/2} < 1 minutes) as well as of p60, p39 and an additional protein, p116. Ischemia led to the loss of tyr(P) from GP110, PSD-GP180, p116, p60 and p39. Reperfusion with O₂ and glucose increased the tyr(P) of GP110 (t_{1/2} < 1 min.), but not of PSD-GP180 and resulted in a transient increase in tyr(P)-p39. The results demonstrate ischemia induced changes in the tyr(P) of several hippocampal proteins and identify GP110 as a synaptic gp capable of rapid changes in tyr-phosphorylation. Supported by NSERC.

ICAM-1 AND IL-6 CHANGES IN THE HIPPOCAMPUS FOLLOWING TRANSIENT FOREBRAIN ISCHEMIA IN THE RAT. W. M. Clark, J.D. Lauten, B.M. Coull, N. J. Cherry, W.R. Woodward*. Depts. of Neurology and Biochemistry, Oregon Health Sciences Univ., Portland, OR 97201.

Cytokine production and adhesion molecule expression appear to play important roles in the pathogenesis of CNS reperfusion injury. The rat two vessel occlusion model was used to investigate the time course of changes for IL-6 and ICAM-1 immunostaining in hippocampus following ischemic injury. Using a polyclonal antibody against IL-6, low levels of immunoreactivity were seen in sham surgery controls in the dentate granule and CA1 pyramidal cell layers. Staining increased in these areas at 24 hours post ischemia, but the CA1 staining had disappeared by four days. This pattern and time course was similar to that of Nissel stained sections with greater than 90% of CA1 neurons lost between days one and four. For ICAM-1, no immunoreactivity was seen with a monoclonal anti-ICAM-1 in sham controls. At 24 hours post ischemia a small increase in staining in the CA1 pyramidal layer was observed; however by four days there was a marked increase in immunoreactivity throughout CA1 and the dentate hilus. This time course and pattern was similar to that observed in sections stained with a specific microglial antibody (OX42). These results suggest that following CNS ischemia, increased IL-6 production occurs predominately in neurons, whereas ICAM-1 expression is increased in the microglial cell population.

TIME-COURSE OF NEUROCHEMICAL CHANGES IN INSULAR CORTEX AND AMYGDALA FOLLOWING FOCAL ISCHEMIA. R.T.F. Cheung, T. Diab and D.F. Cechetto*. Roberts Research Institute, University of Western Ontario, London, Ontario, Canada, N6A 5K8.

Occlusion of the middle cerebral artery (MCAO) using bipolar coagulation at two points above and below the rhinal fissure in anesthetized male Wistar rats reproduces stroke-associated autonomic changes that are observed clinically. There is evidence to suggest that these are due to involvement of insular cortex (IC). The amygdala (AMG) which receives afferents from the IC and projects to brain stem autonomic centers, may also be involved. We previously observed a striking increase in the immunoreactivity (IR) of neuropeptide-Y (NPY), leu-enkephalin (leu-ENK) and neurotensin (NT) over ipsilateral IC and ipsilateral basolateral AMG or central nucleus of AMG at 5 days after MCAO. In this investigation we studied the time-course of these changes. At 6 hours after MCAO, there was an increase in the density of NPY labelled fibers and terminals in IC. The change, however, was not quantifiable by a computerized-microscopic imaging system. Data from the imaging system showed that the changes in IR of NPY, leu-ENK and NT became just detectable at 1 day, peaked around 3-5 days and returned toward baseline at 10 days following MCAO.

Our results provide evidence for the time-course in neurochemical changes in IC and AMG following MCAO. The finding of an increase in NPY-IR in IC at 6 hours suggests a mechanism by which early autonomic changes can occur following MCAO in rats and in patients clinically while the delayed changes in the AMG may have implications for longer term changes in autonomic variables. NEUROCHEMICAL ALTERATIONS IN HIPPOCAMPUS CA1 PYRAMIDAL CELLS AND INTERNEURONS AFTER SPONTANEOUS STROKE IN SHR-STROKE PRONE RATS. G.I. De Jong, E.A. Van der Zee, B. Bohus and P.G.M. Luiten*. Dept. of Animal Physiology, University of Groningen, P.O.Box 14, 9750 AA Haren, The Netherlands.

GABA-mediated inhibition plays an important role in regulating the activity of pyramidal cells in the hippocampus CA1, which are the major output cells of the hippocampus. Previously, we demonstrated that activated CA1 pyramidal neurons express high levels of PKCγ-immunoreactivity (Van der Zee et al.; J. Neurosci. 12:4808, 1992). CA1 pyramidal cells are selectively vulnerable to abnormal brain perfusion (like ischemia), which was frequently attributed to an overexcitation due to an increased glutamatergic input. In the present study we examined the relationship between pyramidal cells and their inhibitory input after decreased brain perfusion by the spontaneous development of strokes in SHR-SP rats. Immunoreactivity for the γ-isoform of protein kinase C (in pyramidal cells) and parvalbumin and GAD (in interneurons) was determined in the dorsal hippocampus CA1 by way of immunocytochemistry. Because chronic treatment with the calcium antagonist nimodipine prevents the development of strokes in SHR-SP rats (Luiten et al.; Drugs in Development, in press), we compared SHR-SP animals (stroke) with age-matched nimodipine treated rats (non-stroke). After stroke in control animals, we observed a strikingly enhanced protein kinase Cγ-immunoreactivity in CA1 pyramidal cells, when compared to nimodipine treated rats, which can be interpreted as the result of an increased activation of these cells. This pathological increase of PKCγ-immunoreactivity in symptomatic SHR-SP rats was accompanied by a reduced level of parvalbumin- and GAD-immunoreactivity in interneurons innervating these pyramidal cells. Since parvalbumin and GAD are present in a subset of GABAergic inhibitory interneurons, these data suggest that increased activity of CA1 pyramidal cells after spontaneous stroke may partially be related to a decreased inhibitory input upon these cells.

IMMUNOCYTOCHEMICAL LOCALIZATION OF THE NEURON-SPECIFIC GLUCOSE TRANSPORTER (GLUT3) IN RAT BRAIN. M. Moholt-Siebert, A. van Bueren, N.J. Cherry, W.R. Woodward, F.P. Eckenstein* and A. McCall. Depts. of Cell Biol. & Anat. and Neurol., Oregon Health Sci. Univ. & VA Medical Ctr., Portland, OR 97201

Although GLUT3 has been shown to be neuron-specific in the CNS, immunolocalization of this glucose transporter has not been possible because the available antipeptide antisera have been of low affinity. To circumvent this problem and to ascertain the CNS localization of GLUT3, we produced a polyclonal antipeptide antiserum (ALM3-C) by a special immunization procedure with a GLUT3 C-terminal peptide. Based on detection of 25 ng of this peptide on a slot blot, the antibody titer was 1:8000. By Western blot analysis of rat brain membranes, ALM3-C identifies a 44 kD protein band, identical to that detected by two other GLUT3 antisera, but does not detect proteins in muscle or red blood cells, tissues devoid of GLUT3. Staining is completely blocked in Western blots and immunocytochemistry by pre-incubation of ALM3-C with 10 μg/ml of GLUT3 peptide but is unaffected by pre-incubation with an unrelated, GLUT1 peptide. This high affinity antiserum was used for immunocytochemical localization of GLUT3 in frozen coronal sections of rat brain. GLUT3 staining is seen in cerebellar molecular and granular layers but not in the Purkinje cell layer, and in hippocampal molecular layers but not in the pyramidal cell or dentate granule cell layers. In cortex more intense staining is observed over layers 1, 4 and 6 than in intermediate layers. The pattern of neuropil localization and paucity of perikaryal staining suggests that GLUT3 may provide the energy needed locally for synaptic transmission. Support: NIH Grants NS22213 and NS17493.

PROGRESSIVE HIPPOCAMPAL LOSS OF IMMUNOREACTIVE GLUT3 AFTER GLOBAL FOREBRAIN ISCHEMIA. A. McCall*, M. Moholt-Siebert, A. van Bueren, N.J. Cherry, N. Lessov, and W.R. Woodward. Depts. of Neurol., Pharmacol., and Cell Biol. & Anat., Oregon Health Sci. Univ. and VA Medical Ctr., Portland, OR 97201.

Brain damage from global forebrain ischemia is modified by glycemia; furthermore, ischemia/hypoxia itself may modify glucose transport. To assess whether GLUT3, the neuron specific glucose transporter, is affected by cerebral ischemia, we investigated the time course and pattern of GLUT3 immunoreactivity in the rat 2-vessel occlusion model of global forebrain ischemia. We used a newly generated, specific, C-terminally directed polyclonal antiserum against GLUT3 to stain coronal frozen sections. Preincubation of the antiserum with the C-terminal peptide used to generate the antiserum (10 µg/ml) abolished all specific staining. The microglial marker, OX42, indicated the extent of ischemic damage in hippocampus and correlated with GLUT3 loss. One day after ischemia, a small decrease in hippocampal immunoreactivity was observed; at 4 days the loss was more pronounced; and at 7 days loss of GLUT3 staining was maximal. The greatest loss of GLUT3 staining was in stratum oriens and stratum radiatum of Ammon's horn, with sparing in other hippocampal neuropil and in dense fibers in the lateral aspect of CA3. By contrast, GLUT3 staining was undiminished in the stratum lacunum moleculare and in all but the inner-most portion of the molecular layer of dentate gyrus, immediately adjacent to the granule cells. These data are consistent with the pattern of neuronal loss and microglial activation in hippocampus. Loss of GLUT3 may affect the availability of glucose to and possibly the viability of ischemically damaged neurons. Supported by NIH Grants NS22213 and NS17493.

FREE RADICAL MEDIATED INHIBITION OF CANINE CORTEX PYRUVATE DEHYDROGENASE (PDH) FOLLOWING ISCHEMIA/REPERFUSION: EFFECTS OF Ca^{2+} AND Mg^{2+} . Y.E. Bogaert, R.E. Rosenthal, and G. Fiskum*. Depts. of Biochemistry and Molecular Biology and Emergency Medicine The George Washington University Medical Center, Washington, DC USA 20037

This study tested the hypothesis that failure of post-ischemic brain tissue to establish normal energy metabolism may be due to inhibition of key regulatory enzymes, e.g. PDH, by free radical-mediated mechanisms. Anesthetized beagles were subjected to either; sham surgery; 10 min of cardiac arrest or; 10 min arrest followed by resuscitation and 0.5, 2, 4 or 24 hr of reperfusion. At the end of the experiment a sample of frontal cortex was freeze-clamped. Following tissue homogenization, PDH activity was measured isotopically and lactate dehydrogenase (LDH) was measured spectrophotometrically. PDH activity was unchanged following ischemia but was decreased by 30-70% following 0.5, 2, 4 or 24 hr of reperfusion. LDH activity remained unchanged throughout. Experiments were also performed to determine if PDH activity could be inhibited by an *in vitro* free radical generating system. The presence of a Fenton reagent (0.25 mM $FeSO_4$ + 0.5 mM H_2O_2 for 10 min, 37°C) resulted in a 45% inhibition of purified PDH activity but had no effect on the activity of purified LDH. The omission of 2 mM Mg^{2+} or the addition of 0.1 mM Ca^{2+} increased the extent of PDH inhibition observed with the Fenton reagent by 31.9% and 20.4%. The results of these experiments indicate that the post-ischemic inhibition of PDH may be due to its relative sensitivity to site-specific protein oxidation. Supported by Sigma Tau, S.p.A.

MECHANISM OF THE POST-ISCHEMIC RISE IN HIPPOCAMPAL SLICE CYCLIC GMP. C.M. Jenkins, D.H. Pennington, T.L. Hoffman, W.D. Lust* and T.S. Whittingham. Department of Neurosurgery, Case Western Reserve University, Cleveland, OH 44106.

Both cyclic GMP (cGMP) and cyclic AMP levels increase during recirculation following ischemia *in vivo*. These increases are thought to be involved in mediating the recovery of the tissue, with the rise in cGMP potentially producing reactive hyperemia. We initially found that 80% of the rise in hippocampal cGMP following carotid artery occlusion was blocked by antagonists of nitric oxide synthase (NOS). We have subsequently investigated what may trigger the activation of NOS using the hippocampal slice model of *in vitro* ischemia.

Transverse hippocampal slices were prepared from male mongolian gerbils and allowed to recover in control artificial cerebrospinal fluid (ACSF) for 60 minutes. Slices were transferred to ACSF devoid of oxygen and glucose (*In vitro* ischemia) for 10 minutes, and then returned to control ACSF for recovery. Cyclic GMP levels were measured by radioimmunoassay and are expressed as femtomoles per mg protein.

Cyclic GMP levels peaked within 6 minutes of recovery (rising from 0.5 to 9.5 fmol/mg protein) and began to fall at 14 minutes. Inclusion of 100 µM N-nitro-L-arginine (NNLA) to inhibit NOS before, during and after the ischemic insult reduced the cGMP response to 2.1 fmol/mg protein ($p < 0.05$). A similar inhibition of the cGMP response was obtained if MK-801 was used instead of NNLA, or if the ischemic insult and recovery period were performed in the absence of extracellular calcium. Taken together, these results suggest that glutamate release during ischemia results in NMDA receptor stimulation, accumulation of intracellular calcium, and resulting stimulation of NOS. However, the inclusion of 1 mM glutamate or 100 µM NMDA in the ACSF with no ischemic insult failed to trigger an increase in tissue cGMP levels in hippocampal slices, indicating the possibility that there is an additional permissive effect produced by ischemia which allows the post-ischemic triggering of cGMP via glutamate NMDA receptor stimulation.

CEREBRAL EXTRACTION OF OXYGEN (CEO) AND ARTERIOJUGULAR DIFFERENCES IN CARBON DIOXIDE IN PATIENTS WITH SUBARACHNOID HEMORRHAGE. J.B. Bederson, R. Horowitz, J. Orpello and D. Weisz*. Department of Neurosurgery, Mount Sinai Medical School, New York, New York 10029.

Delayed ischemia after subarachnoid hemorrhage can be difficult to diagnose in patients who are already stuporous from their bleed. In this study, indwelling 4 - French catheters were placed in the right jugular bulb to measure venous pH, oxygen content, CO_2 and lactate. Results were compared with radial artery samples and were correlated with neurological grade and angiography.

Seven patients (age $59 \pm 1.2y$) were monitored for 5 - 9 days with 188 simultaneous arteriovenous comparisons. Average initial CEO, defined as the arteriojugular difference, was 5.5 ± 0.1 ml/dl. Two patients developed delayed ischemia and their CEO rose significantly to 8.5 ± 0.3 ml/dl ($p < .05$, ANOVA). CEO was inversely correlated with arterial pCO_2 in the patients with vasospasm ($p < .001$), indicating increased oxygen extraction during hyperventilation. The arteriojugular difference in CO_2 (A-Jd CO_2), a measure of ischemia, was positively correlated with CEO in all patients ($p < .001$). A-Jd CO_2 was 9.2 ± 0.6 mm Hg on admission and rose to 12.2 ± 0.8 in the patients with vasospasm ($p < .001$, ANOVA). Both CEO and A-Jd CO_2 were inversely correlated with neurological grade $p < .0001$, Kruskal-Wallis test).

Jugular bulb monitoring can be a useful bedside method of detecting the onset of cerebral ischemia in stuporous patients with subarachnoid hemorrhage.

HIBERNATION INDUCED CHANGES IN BRAIN AND PLASMA PROTEINS. J.E. Joy*¹, K.U. Frerichs², G.J. Creed¹, C.R. Merrill¹, J.M. Hallenbeck². ¹Laboratory of Biochemical Genetics, NIMH, St. Elizabeths Hospital, Washington D.C. 20032 and ²Stroke Branch, NINDS, NIH, Bethesda, MD 20892.

Mammalian hibernation is characterized by a metabolic suppression so profound as to be lethal in non-hibernating species. Cerebral blood flow is reduced to ischemic levels during entrance into hibernation and yet hibernating animals show no neuropathological changes. As part of a larger study investigating factors that enable hibernating animals to tolerate ischemia, we analyzed brain and plasma protein changes in thirteen-lined ground squirrels during hibernation. Plasma samples were serially collected through an indwelling jugular catheter from animals before and during hibernation bouts. Brains were collected from active and hibernating animals. The total protein concentration of plasma was not significantly different between samples collected before or during hibernation. We found several plasma proteins that were altered during hibernation. One of these showed an increase during hibernation and two (one of which appears to be B-haptoglobin) showed decreases. In the brain samples, two proteins were twofold more abundant in the brains from hibernating animals and another protein was twofold less abundant.

SPECIES-DEPENDENCE OF ASCORBATE AND GLUTATHIONE LEVELS IN BRAIN: ASCORBATE IS HIGH IN TURTLE; GSH IS HIGH IN GUINEA PIG. M. E. Rice* & Y. Choy, Depts. Neurosurgery and Physiology and Biophysics, NYU Medical Center, New York, NY 10016.

Ascorbate (Asc) and glutathione (GSH) are water soluble antioxidants and free-radical scavengers. In rat brain, both are about 2 mM. We have reported (Pérez-Pinzón et al. *Neurosci. Abstr.* 18: 154) that the Asc content of turtle brain is much higher, reaching 5-6 mM in cerebral cortex. The present studies addressed two follow-up questions: 1) are high levels of Asc in anoxia-resistant turtle unique? and 2) is turtle GSH also high? We determined CNS Asc and GSH levels for several species, using HPLC with electrochemical detection. In all species, Asc varied regionally, with highest levels in cortex or hippocampus. GSH distribution was similar, but with much less variation. Data for cortex ($\mu\text{moles/g}$ tissue wet wt) are summarized below (mean \pm S.E.M.):

SPECIES NAME	ASCORBATE	GSH	(N)
Painted turtle (<i>Pseudemys scripta</i>)	5.59 \pm 0.35	2.35 \pm 0.14	(12)
Box turtle (<i>T. carolina triunguis</i>)	5.00 \pm 0.29	1.98 \pm 0.13	(10)
Garter snake (<i>Thamnophis sirtalis</i>)	3.72 \pm 0.20	1.83 \pm 0.04	(8)
African clawed toad (<i>Xenopus laevis</i>)	2.37 \pm 0.16	2.53 \pm 0.10	(12)
Rat (Sprague-Dawley)	2.46 \pm 0.05	1.91 \pm 0.06	(34)
Guinea pig	1.71 \pm 0.03	2.66 \pm 0.06	(37)

Asc content varied among species (2-3-fold, depending on region), while GSH was again more nearly constant. Relatively high GSH accompanied the exceptionally low Asc of guinea pig brain. These data suggest that the brain of air breathing vertebrates requires an intracellular antioxidant concentration of about 5 mM and that complementary regulation of Asc and GSH provides this.

DIFFERENT RESPONSES OF BRAINSTEM AND CORTICAL NEURONS TO GRADED HYPOXIA. J.P. O'Reilly*, C. Jiang and G.G. Haddad. Depts. of Biology and Pediatrics, Yale Univ. and Yale Sch. of Med., New Haven, CT 06510

It is known that different areas of the central nervous system exhibit different sensitivities to O_2 deprivation. However, the responses in the initial period of hypoxia are not well documented when neurons from different areas of the brain are compared. In order to better define these responses, we studied hypoglossal (XII) and neocortical (layer 2/3) neurons in the rat (21-35 days) during hypoxia (20% O_2 /75% N_2 /5% CO_2) and anoxia (95% N_2 /5% CO_2) using the *in vitro* slice preparation. Although all neurons studied showed a membrane depolarization (ΔV_m) and a decrease in input resistance (R_n) during both hypoxia and anoxia, major differences in the responses were evident. After three minutes in hypoxia, ΔV_m in cortical neurons was 4.0 ± 3.2 mV, whereas XII neurons showed a ΔV_m 3x greater (12.2 ± 10.7 mV). Similarly, the reduction in R_n (% change from control) for the XII neurons was 3x greater than in the cortex (XII = $31.4 \pm 23.6\%$; cortex = $9.3 \pm 6.1\%$). After two minutes in anoxia, XII neurons depolarized 29.2 ± 20.2 mV compared to only 7.2 ± 4.0 mV for the cortex. The change in R_n was again greatest (4x) in the XII ($81.1 \pm 4.2\%$) when compared with the cortex ($17.9 \pm 14.9\%$). The pattern of ΔV_m with graded hypoxia was characterized as a biphasic depolarization. An initial slow phase (1-5 mV/min) was followed by a rapid, major ΔV_m (> 15 mV/min). The slow phase in the cortex lasted 2x-6x times longer (4-18 mins) when compared with the XII (< 3 mins). Hypoxia elicited the fast ΔV_m (2-5 mins) in 50% of the XII cells studied, while all of the cortical cells studied failed to show the fast ΔV_m during hypoxia (10-20 minutes). We conclude that cortical neurons are more tolerant than brainstem neurons to reduced O_2 availability. The mechanism for this increased tolerance may involve intrinsic membrane properties, better maintenance of energy stores, and/or extrinsic influences such as synaptic input and extracellular milieu.

682.3

INFLUENCES OF TISSUE OXYGENATION ON RECOVERY OF EVOKED POTENTIALS AFTER GLOBAL ISCHEMIA IN RAT CEREBRAL CORTEX. Y.S. Zagvazdin, Z.C. Feng, T.I. Sick* and M. Rosenthal, Dept Neurology, Univ of Miami Sch. of Med., Miami, FL 33101

Prior studies suggested that increasing the fraction of inspired oxygen (FiO_2) may impair acute recovery of evoked potentials after global cerebral ischemia; while transiently decreasing FiO_2 may enhance EP recovery. In those studies, EPs were elicited by stimulation of the facial nerve. Present studies were conducted in rats anesthetized with pentobarbital during (and for 3 hrs after) 20 min cerebral ischemia (4-vessel occlusion). Goals were to determine whether early EP recovery was indicative of such recovery when the animals were reanesthetized 3 days later. Stimulating electrodes were implanted in the VPL nucleus of the thalamus and EPs were recorded in a somatosensory projection area. In contrast to recovery of evoked potentials provoked by stimulation of the facial nerve, we found that increasing FiO_2 from 0.3 to 1.0 during the first 30 minutes of reperfusion did not influence recovery of EPs provoked by stimulation of the VPL nucleus at 3 hrs or 3 days after ischemia. Differences between data derived from stimulation of the facial nerve or VPL nucleus may be due to the differences in EP pathways or to the intensity of ischemia (the effects of changes in FiO_2 on facial nerve EPs were greater after 30 than 20 min ischemia). Present data suggest that acute hyperoxygenation may not impair the recovery of at least one type of evoked potential, at least after short (20 min) ischemia.

682.2

EFFECTS OF K_{ATP} -CHANNEL AGONIST AND ANTAGONISTS ON ANOXIC OUTWARD CURRENT OF CA1 HIPPOCAMPAL NEURONS J.M. Godfraind, G. Erdemli, A.T. Tan* and K. Krnjević, Anaesthesia Research Dept., McGill University, Montréal, Québec H3G 1Y6 Canada.

If the outward current (I_{OUT}) induced by anoxia is mainly an ATP-sensitive K current, this I_{OUT} and the associated increase in input conductance (G_N) should be occluded by a K_{ATP} -channel opener, such as cromakalim (CROM), and suppressed by sulphonylurea blockers. Indeed, bath applications of CROM (50-300 μM) reduced anoxic I_{OUT} - both at constant V (in 8/10 cells) and when evoked by depolarizing ramps (in 5/5 cells) - as well as anoxic G_N increases (in 8/10 cells). However, in the same cells, CROM produced no consistent changes in holding current (-31 ± 72 pA) or G_N ($2.8 \pm 12.1\%$, $n=11$), and there was no correlation between CROM-induced changes in holding current and anoxic currents ($r=-0.089$) or the corresponding changes in G_N ($r=-0.060$). Of the sulphonylurea blockers of K_{ATP} channels, glyburide (GLYB 10-30 μM) had little effect on anoxic I_{OUT} (in 5/5 cells); but tolbutamide (TOLB 0.5-2mM) caused a major reduction of both I_{OUT} and G_N increase in all 10 cells tested with anoxia. In most cells, both GLYB and especially TOLB potentiated the suppression of steady anoxic I_{OUT} (and G_N rise) - but they tended to restore large I_{OUT} 's evoked by depolarizing ramps.

Judging by the inconstant effects of CROM and GLYB, "classical" K_{ATP} channels are not prominent in CA1 cells, nor do they contribute greatly to the anoxic I_{OUT} . On the other hand, the marked suppression of I_{OUT} by TOLB may indicate the presence of K_{ATP} channels of the type observed by Ashford et al. 1990 (Br. J. Pharm. 101: 531) in some hypothalamic and neocortical neurons. Supported by MRC of Canada, FRSQ (J.M.G.) and a Nato Fellowship (G.E.).

PROTECTIVE EFFECT OF SPREADING DEPRESSION(SD) IN CARDIAC ARREST CEREBRAL ISCHEMIA(CACI). N. Kawahara, L. Penix, C.A. Ruetzler, H.G. Wagner, I. Klatzo*, Stroke Branch, NINDS, NIH, Bethesda, MD 20892

A deleterious effect of spreading depression has been recently demonstrated. However, our recent studies on cardiac arrest cerebral ischemia revealed an unexpected protective effect of SD when it was applied several days preceding ischemic insult. The present study represents an effort to elucidate the nature of this phenomenon. Cortical SD was elicited in male Sprague-Dawley rats on the left side 3 days prior to CACI(10 min.) by applying 5M KCl over the intact dura for 1 hr. This method induced more than 10 DC deflections which were confined to the ipsilateral cortex. The rats were sacrificed 14 days after the ischemia, sections stained with cresyl violet, and surviving CA1 pyramidal neurons were counted in the SD and sham groups. In the second experiment, SD was elicited in the left hippocampus by microdialysis with 100 mM K+ perfusion for 1 hr., which was associated with elevation of ECF glutamate. The rats were processed the same way as in the cortical SD group. Our study indicated that induction of cortical SD protected CA1 neurons bilaterally by 20 %, and decreased the incidence of audiogenic seizure (33% vs. 100%). Induction of hippocampal SD protected CA1 neurons by more than 40 % on the ipsilateral side when compared to the contralateral side and sham group. Our results demonstrated a neuroprotective effect of SD when it was induced 3 days prior to ischemia.

GABA-INTERNEURONS ARE FUNCTIONALLY DISCONNECTED BY ANOXIA FROM EXCITATORY INPUTS IN RAT HIPPOCAMPUS. R.N. Khazipov, P. Bregestovski, G. Barbin*, Y. Ben-Ari. INSERM Unite 29, Paris, France 75014.

The effects of brief anoxic episodes on the inhibitory and excitatory postsynaptic currents (EPSC and IPSC) were studied in adult rat hippocampal CA1 neurons of adult rats using whole-cell patch-clamp technique. In keeping with earlier studies with conventional 'distant' stimulation of Schaffer collaterals, anoxia preferentially inhibited GABA-mediated polysynaptic IPSC prior to the glutamatergic EPSC. The former recovered also slower than the latter after reoxygenation. We then examined the effects of anoxia on the GABA_A and GABA_B monosynaptic response evoked by 'close' (<0.5mm) stimulation in the stratum radiatum in presence of CNQX (20µM), APV (50µM) to block glutamate receptors and CGP35348 (100µM) or bicuculline (15µM) to record pure GABA_A or GABA_B receptors mediated components. Monosynaptic GABA_A-mediated component and responses to pressure application of isoguvacine (GABA_A-agonist) were not changed significantly during and after anoxia. Monosynaptic GABA_B receptors mediated component and responses to baclofen (GABA_B-agonist) were strongly but reversibly suppressed by anoxia. We conclude that GABA_A receptors mediated component of monosynaptic IPSCs is in fact highly resistant to anoxia. Thus, the block by anoxia of the polysynaptic IPSCs evoked by 'distant' stimulation is due to an impairment of the excitatory input to GABA interneurons. Furthermore, anoxia preferentially impairs by a postsynaptic mechanism GABA_B receptors mediated currents.

TRANSHemispheric Electrophysiologic Diaschisis During the Hyperacute Period of Focal Cerebral Ischemia. N. Panahian, G.K. Steinberg*, Department of Neurosurgery, Stanford University School of Medicine, Stanford, CA 94305

Although transhemispheric diaschisis has been well described days to months following focal cerebral ischemia, few studies have examined the contralateral electrophysiological functions within the first few hours after ischemia. We studied 20 rabbits under halothane anesthesia, following 2-hour occlusion of the internal carotid, middle cerebral and anterior cerebral arteries followed by four hours of reperfusion. Bilateral somatosensory evoked potentials (SEPs) were recorded using median nerve stimulation. The ischemic hemisphere (ipsilateral) SEPs in 10 rabbits were completely abolished within five minutes of arterial occlusion ("severely ischemic group"). In another 10 rabbits the ipsilateral SEPs did not decrease below 35% of their pre-ischemic values ("mildly ischemic group"). Within five minutes of arterial occlusion the contralateral SEPs in the severely ischemic group increased to 163±40% of pre-ischemic values, while the control group showed no change (p=0.012). This elevation in contralateral SEPs persisted for 90 minutes following induction of ischemia and subsequently returned to pre-ischemic values (p=0.028). This study suggests that disinhibition or facilitation of contralateral electrophysiologic activity during the first 90 minutes of focal, cerebral ischemia is a manifestation of transcallosal diaschisis that is closely linked to the degree of cortical ischemia.

CHANGES IN MEMBRANE CURRENT FLUCTUATIONS OF HIPPOCAMPAL NEURONS INDUCED BY ANOXIA. P. Miu*, G. Erdemli, M. Glavinovic, and K. Krnjevic. Anaesthesia Research and Physiology Depts., McGill Univ., Montreal, Que. H3G 1Y6 Canada.

Short intervals of anoxia are associated with hyperpolarization of pyramidal cells. The underlying membrane changes can be complex and may be caused by opening or closing of various ion channels, but also by activation of ion pumps - the transport systems that extrude or accumulate ions against an electrochemical gradient. To obtain more information on the nature of membrane changes associated with brief anoxia (2-3 min of 95% N₂ + CO₂), CA1 neurons were voltage-clamped (with single, 3 M KCl electrodes) in the presence of TTX, and membrane currents and current fluctuations were recorded and analyzed. The experiments were done at a 33°C, in slices from Sprague-Dawley rats. The anoxic outward currents evoked at holding potentials of -70 to -30 mV were associated with a change in variance (S²) of the current fluctuations. Power spectra analysis of current fluctuations revealed that, as reported previously, anoxia elicits opening and closing of certain ion channels. A non-Lorentzian component of power spectra (with a minor contribution at low, but a major one at high frequencies) can also be observed, suggesting the activation of a transport mechanism or a pump (Läuger 1984 *Eur. Biophys. J.* 11:117; Glavinovic & Trifaro 1991 *Soc. Neurosci. Abstr.* 17:719).

FUNCTIONAL MODIFICATIONS IN MOUSE NEOCORTEX FOLLOWING PERMANENT OCCLUSION OF THE MIDDLE CEREBRAL ARTERY.

T. Mittmann and H.J. Luhmann*, Inst. of Neurophysiol., D-5000 Cologne 41, FRG.

The middle cerebral artery (MCA) of tribromethanol-anesthetized adult male mice (>8 weeks) was unilaterally permanently occluded to induce a focal cerebral infarct. After survival times of 1-3 (n=7) and 28 (n=5) days, neocortical slices of 400 µm thickness were analyzed with conventional electrophysiological *in vitro* techniques. Untreated age-matched mice served as controls. Nissl staining revealed massive necrosis in the parietal and partly in the frontal neocortex. At lateral distances between 1.5 and 2 mm from the lesion center neuronal activity was suppressed. With increasing distances the orthodromically evoked field potential (FP) responses rose to 1.6 ± 0.5 mV (mean ± STD, n=34). After 28 days survival time, the FP duration was significantly (p<0.001, t-test) larger in ischemic animals (25.4 ± 12.3 ms, n=34) as compared to controls (17.9 ± 1.1 ms, n=24). Intracellular recordings revealed no significant difference in the resting membrane potential (V_m) and input resistance (R_{in}) between ischemics (V_m = -79.6 ± 10.5 mV, R_{in} = 45.5 ± 18.1 MΩ; n=18) and controls (V_m = -81.8 ± 11.21 mV, R_{in} = 43.4 ± 18.1 MΩ; n=29). Biphasic IPSPs could be observed in every cell of both experimental groups to suprathreshold synaptic stimulation of the afferent pathway. After 28 days survival time the peak conductance of the GABA_A-mediated I-IPSP was significantly (p<0.05) increased in cells of ischemic animals (23.9 ± 5.2 nS, n=14) as compared to control neurons (12.2 ± 2.1 nS, n=19). Furthermore, the reversal potential of the I-IPSP and the GABA_A-mediated f-IPSP was significantly (p<0.01 and p<0.001, respectively) different in cells recorded in ischemic (f-IPSP: -65 ± 1.9 mV, n=15; I-IPSP: -81.3 ± 2.1 mV, n=14) and control cortex (f-IPSP: -77.1 ± 1.7 mV; I-IPSP: -94.5 ± 3.2 mV, n=19). These data indicate functional alterations in the intracortical GABAergic system. However, in contrast to other models of cerebral ischemia, the efficacy of IPSPs is enhanced and hyperexcitability is only weakly expressed in this stroke model.

REDUCTION OF CORTICAL INHIBITION IN THE BRAIN TISSUE SURROUNDING PHOTOCHEMICALLY INDUCED CORTICAL INFARCTS IN THE RAT

O.W. Witte, R. Domann, M. Kraemer, G. Hagemann, H.-J. Freund (Spon.: European Brain and Behaviour Society). Neurologische Klinik, Heinrich Heine Universität, 40001 Düsseldorf, Germany

The correlation between the size of ischemic lesions and the ensuing functional deficits is often poor. Such observations indicate that the functional deficits are not solely caused by the damaged area, but also by functional alterations of neurons in the vicinity of such lesions. An example for such alterations is the occurrence of focal epileptic seizures in 5 to 15 % of cerebral lesions due to trauma or ischemia.

The aim of the present experiments was to investigate functional changes in brain areas surrounding focal cerebral infarctions. Small infarctions in the parietal cortex of Wistar rats were produced photochemically using the Rose Bengal technique. The infarctions evoked reproducible cortical lesions of about 2 mm diameter. In the surrounding brain tissue changes in electrophysiological responses occurred. Whereas in control animals without infarction a paired-pulse inhibition could be evoked all over the neocortex, in infarcted animals the paired-pulse inhibition was significantly reduced or even absent within an area extending up to 5 mm lateral from the lesion center. The changes in paired-pulse inhibition were already present on the first day and persisted at least up to 60 days after infarction. Such functional changes may contribute to neurological deficits occurring after cerebral infarcts.

ENHANCED UTILIZATION OF NMDA RECEPTOR IN AFTERDISCHARGES OF CA1 PYRAMIDAL CELLS FOLLOWING TRANSIENT CEREBRAL ISCHEMIA IN THE RAT HIPPOCAMPUS IN VIVO. M. Furuichi, T. Kano, A. Yoshino, T. Kawamata*, S. Mizazaki, Y. Katayama, T. Tsubokawa. Department of Neurological Surgery, Nihon University School of Medicine, Tokyo, Japan 173.

We previously demonstrated post-ischemic potentiation (PIP) of synaptic efficacy in hippocampal Schaffer collateral/CA1 responses of the rat beginning at 6-8 hours following 10-15 min transient cerebral ischemia *in vivo*. The present study demonstrated that repetitive stimulation, which produces a short-lasting non-NMDA receptor-mediated afterdischarges (ADs) in sham-controls, results in a prolonged ADs at the same period after ischemia. Pre-treatment with systemic administration of MK-801 prevented the development of the prolonged ADs as well as PIP, indicating that NMDA activation is required for initiation of these phenomena. The PIP was not affected, however, by AP5 administered via microdialysis at 6 hours post-ischemia. The same procedure blocked the prolonged ADs after ischemia. These observations indicate that, during reperfusion period, while there is no NMDA receptor-mediated component in the increased synaptic efficacy, NMDA receptor can be activated more easily than in normal condition by appropriately timed multiple synaptic inputs. If the increased synaptic efficacy underlies ischemia-induced hippocampal damage, it appears that delayed treatment with NMDA antagonists may not be as potent as other drugs which blocks more upstream synaptic events in protecting CA1 pyramidal cells.

MEMBRANE CURRENTS AND CALCIUM TRANSIENTS INDUCED BY HYPOXIA-AGLYCEMIA IN RAT HIPPOCAMPAL NEURONS AND GLIAL CELLS Y. Fujito*, A. Mizuguchi, H. Shimizu, Y. Nakazono and M. Aoki. Dept. Physiology, Sapporo Medical University, School of Medicine, Sapporo 060, Japan.

We examined the effects of hypoxia-aglycemia (HA) on membrane currents (I_{ms}), membrane potentials and [Ca²⁺]_i of neurons and glial cells in the CA1 of rat hippocampal slices at 34 ± 0.5°C. I_{ms} were measured by single-electrode voltage clamp (SEVC) with KCl, K acetate and Cs acetate electrodes. Fifteen min of HA elicited an initial slow hyperpolarization and a succeeding depolarization which caused an irreversible depolarization and disappearance of action potentials in CA1 pyramidal neurons. In SEVC recording with K electrodes at a holding potential adjusted to each resting potential from -60 to -70 mV, 6-8 min HA elicited a slow outward current with an increase in membrane conductance and a succeeding inward current in CA1 pyramidal neurons. The outward current in CA1 pyramidal neurons induced by HA was almost disappeared with Cs electrodes, indicating that the outward current is, at least in part, K current. By contrast, in glial cells, SEVC recording showed a slow inward current without initial outward currents during HA at a holding potential adjusted to each resting membrane potential from -75 to -85 mV. When exposed to 8-15 min HA, [Ca²⁺]_i increased significantly and returned to the prehypoxic levels after reoxygenation both in neurons and glial cells. However, in some glial cells, [Ca²⁺]_i began to decrease in 10-13 min of HA. These results indicate the differential responses to HA in membrane currents and [Ca²⁺]_i between neurons and glial cells.

CHANGES OF NEURONAL ACTIVITY AND IMMUNOHISTOCHEMICAL REACTIONS ASSOCIATED WITH PHOTOCHEMICALLY-INDUCED THROMBOSIS IN CAT VISUAL CORTEX. U.T. Eysel*, U. Kretschmann & R. Schmidt-Kastner. Department of Neurophysiology, Faculty of Medicine, Ruhr-Universität Bochum, D-44780 Bochum, F.R. Germany.

Changes of neuronal activity occur in the surrounding of cortical lesions and the resulting dysfunction can spread far beyond the region of actual cell death. In the present study we have used photochemically-induced thrombosis as a model of an ischemic infarction in the visual cortex of adult cats (n=3). Local illumination (2 mm diameter, 570 nm, 5 minutes) of the visual cortex 3 minutes after systemic administration of Rose Bengal (10 mg/kg) led to circumscribed ischemic lesions sparing the lower cortical layers. Single cell recordings were performed with glass micropipettes in the surrounding and below the lesions between 18 and 24 hours following thrombosis. The recording sessions were immediately followed by perfusion fixation with 4% paraformaldehyde solution. Histology and immunohistochemistry revealed thrombosis of small vessels and infarction in the core region. A narrow borderzone showed distorted neurons and abnormal processes of parvalbumin-positive interneurons, damaged astrocytes (GFAP-stain), and vasogenic edema (serum-proteins). Single cell recordings (n=77) showed increased maintained activity often associated with epileptiform high-frequency burst discharges (N = 29, 38%). Stimulus-evoked responses to moving light-bars were significantly increased (p<0.05) and orientation and direction specificity reduced (p<0.05). Increased glutamate release and reduced inhibition in the surrounding of infarction may contribute to the effects. (Supported by DFG Ey 8/13-2).

HYPOXIC DEPOLARIZATION AND CORRELATED HISTOLOGICAL INJURY IN HIPPOCAMPAL SLICES IN VITRO: NEUROPROTECTION WITH LIDOCAINE. M.L. Weber* and C.P. Taylor. Parke-Davis Pharmaceutical Research, Div. of Warner-Lambert Co., Ann Arbor, MI 48105

Hypoxic depolarization (HD) has been associated with irreversible neuronal injury in CNS tissue. We have previously shown that EPSPs are irreversibly lost in hippocampal slices in vitro within ~2 min of HD from oxygen/glucose deprivation. Here we demonstrate a correlation between loss of EPSPs and morphological damage in hippocampal slices using histology as an endpoint. Rat hippocampal slices were maintained in a Haas-type superfusion chamber at 36°C with oxygenated artificial CSF (95% O₂, 5% CO₂, 10 mM glucose). EPSPs were evoked each minute in CA1 stratum radiatum and extracellular DC potential was recorded to show HD. Slices were subjected to 12 min of oxygen-glucose deprivation (95% N₂, 5% CO₂, 0 mM glucose) with or without 200 μM lidocaine and then returned to oxygenated media with glucose for 3.5 hr before fixation, sectioning and staining. All untreated hypoxic slices had HD with irreversible loss of EPSPs and had grossly swollen or lysed perikarya with pyknotic nuclei in CA1. Treatment with lidocaine (200 μM) did not markedly reduce EPSPs but prevented HD and irreversible loss of EPSPs from hypoxia; cell bodies were also well-preserved (6 of 14 slices). In cases with lidocaine treatment that had HD and EPSPs that did not recover (6 of 14 slices), CA1 perikarya were grossly damaged. Treated slices with HD near the end of the hypoxic period with EPSPs that recovered only slightly (2 of 14 slices) had extensive damage to some but not all CA1 cell bodies. Continuously oxygenated slices did not have HD or histological damage. Our experiments demonstrate that HD with permanent loss of evoked EPSPs in hippocampal slices correlates closely with severe histopathological damage to CA1 pyramidal cells.

LOSS AND RECOVERY OF SYNAPTIC RESPONSE IN HIPPOCAMPAL AREA CA1 PARTIALLY PROTECTED FROM ISCHEMIC DAMAGE. M.M. Okazaki*, K.H. Neill, B.J. Crain and J.V. Nadler. Depts. Pharmacology, Pathology and Neurobiology, Duke Univ. Med. Ctr., Durham, NC 27710.

Area CA1b of the gerbil hippocampus can be partially protected from ischemic damage by interruption of glutamate pathways, glutamate receptor antagonists and cerebral hypothermia. These protected CA1b pyramidal cells can remain intact for at least 4 weeks after ischemia, but they appear histologically abnormal. We now report that abnormal histologic appearance predicts a loss of response to excitatory synaptic input and that both morphologic and physiologic defects appear to be reversible. Gerbils were subjected to a 5-min carotid occlusion under halothane anesthesia with maintenance of body temperature. Responses to stimulation of the commissural input to area CA1b were recorded simultaneously in stratum radiatum and the pyramidal cell body layer.

In sham-operated gerbils, commissural input-output curves remained essentially unchanged for 3 days after surgery. In gerbils subjected to ischemia without neuroprotective intervention, synaptic responses never recovered to baseline values and could hardly be evoked 3 days after ischemia. In animals partially protected from ischemic damage, the remaining CA1b pyramidal cells were histologically abnormal and the loss of synaptic response markedly exceeded the loss of cells. When cases of partial protection were studied 4 months after ischemia, however, the great majority of CA1b pyramidal cells appeared histologically normal and the loss of synaptic response was proportional to cell loss. These results suggest that neuroprotective interventions arrest the process of ischemic degeneration at a stage of damage from which the cell eventually recovers. (Supported by NIH grant NS 06233.)

SQUARE WAVES SIGNAL IMPEDANCE METHOD FOR TISSUE WATER CONTENT MEASUREMENT.

M. Itkis, Ph.D., * L. Roberts, M.S., R. Hariri, M.D., Ph.D., L. Ghajar, M.D., Ph.D. Dept. of Surgery, Aitken Neurosurgery Lab. Cornell University Medical College, New York, NY 10021

It was shown that low frequency electrical signals propagate only through extracellular space; while high frequency signals can propagate through the cells membrane as well, due to the membranes high capacitance. Presently, using a sine wave signal with changing frequency, one could obtain information of both extra- and intracellular resistance. We found that using the square wave signal in lieu of the sine, will help avoid the need for expensive frequency control and amplitude-phase measuring devices, and to ease on-line data processing.

The isolating-calibration device developed for the present studies was used to condition and stabilize current through the brain tissue. This device was also used for impedance calibration before and/or after experiments. For generation, amplification and recording signals a Macintosh based data acquisition system was used.

Preliminary experiments were carried out with a 0.49 mm stainless-steel electrode tetrapolar system on the rat brain. This study showed good linearity between stimulating current I = 5 - 25 microA and drop of voltage, which was measured by an inner pair of electrodes. Results of the device and program accuracy test, shown in the paper, allow us to propose a method for use in the animal research, for analyses of intra- and extracellular water content.

IONIC MECHANISMS UNDERLYING NEOCORTICAL ANOXIC DEPOLARIZATION. A. S. Rosen* and M. E. Morris. Dept. of Pharmacology, Univ. of Ottawa, Ottawa, Canada K1H 8M5.

In submerged rat neocortical slices, brief anoxia (4-6 min) induces a moderate membrane depolarization (2-5 mV) of pyramidal neurons (Rosen & Morris 1991, *Neurosci. Lett.*, 124:169-173). This anoxic depolarization (AD) is recorded at resting potentials between -55 and -100 mV and is reversible upon reoxygenation. In slices superfused with 1 μM tetrodotoxin, AD amplitude was reduced to almost 50%. A 68% reduction of AD amplitude was obtained when [Na⁺]_o was decreased to 28% of control, by substituting NaCl in the superfusate with an equimolar concentration of choline chloride. These results, together with the sensitivity of AD to the non-specific excitatory amino acid (EAA) antagonist, kynurenic acid (1 mM), suggest that Na⁺ influx -- possibly through voltage-dependent channels, but mainly through EAA-activated synaptic channels -- is strongly implicated in the production of AD. The finding that the NMDA antagonist, DL-aminophosphonovaleric acid (DL-APV) (100-250 μM) had no effect on AD amplitude, strengthens the evidence for a Na⁺ influx through non-NMDA channels, (rather than one of Ca²⁺ through NMDA channels), as being the major cation influx during brief anoxia in neocortical pyramidal neurons.

682.17

MECHANISM OF ANOXIA-INDUCED SUPPRESSION OF INHIBITORY CURRENTS IN THE HIPPOCAMPUS. A.N. Katchman, S. Vicini and N. Hershkowitz, Georgetown University Medical Center, Dept. Neurol. and FGIN, Washington DC 20007.

While the mechanism of anoxia-induced depression of excitatory postsynaptic currents (EPSCs) results from a presynaptic reduction in transmitter release, the mechanism of depression of the inhibitory postsynaptic currents (IPSCs) is less clear. Whole-cell patch clamp recordings were obtained from CA1 neurons of hippocampal slices in an interface chamber. Anoxia was induced by switching perfusion and ambient gas from a 95%O₂/5%CO₂ to a 95%N₂/5%CO₂ mixture. Using a K gluconate micropipette, containing QX-314 (1mM), a GABA_A IPSC was recorded following stimulation to interneurons in the stratum radiatum in the presence of the glutamate blockers, CNQX (50 uM) and CPP (20 uM). I/V curves were constructed during control and at various time periods following the onset of anoxia in 10 cells. These plots indicated that while conductance was not significantly altered, the IPSC reversal potential exhibited a significant positive shift (from -74 mV to -47 mV) following 5 min of anoxia. Miniature IPSCs (mIPSCs) were also examined as spontaneous inward currents, using a KCl filled micropipette containing QX-314 (V_h = -60 mV), from slices preincubated in CNQX (50 uM), CPP (20 uM) and tetrodotoxin (1uM). 2 min following the onset of hypoxia a moderate increase in mean peak amplitude (from 21.7 pA to 26.3 pA) and a small decrease in half decay time (from 11.0 ms to 9.2 ms) of the mEPSCs were observed in 11 cells. These data suggest that the apparent early anoxia-induced suppression of the IPSC is a result of a shifting of the reversal potential for GABA_A current. This observation is consistent with those made by other investigators of an anoxia-induced decrease in extracellular chloride concentration. (Supported by NINDS grant NS 14600-02).

ACUTE ELECTROPHYSIOLOGICAL CONSEQUENCES OF BCO IN THE GERBIL: A CORRELATION WITH DELAYED BEHAVIORAL AND ANATOMICAL CHANGES. James D. Slittsworth, Jr., E.J. Drower and T.H. Lanthorn Neurological Diseases Research, Searle, Skokie, IL 60077.

Few studies have investigated the electrophysiological consequences of BCO in the gerbil. Of these studies the primary focus has been in the cortex. However, the most susceptible structure to 5 minute BCO is the hippocampus. This study investigated the electrophysiological consequences of 1 min and 5 min BCO on responses recorded from the CA1 region of the gerbil hippocampus *in vivo* under two different anesthetic conditions and two different temperature conditions. In animals anesthetized with urethane, loss of the hippocampal population spike was observed within one min of BCO. An ischemic depolarization was observed in the D.C. trace at 4.63 ± 1.1 min following the loss of the population spike. The mean amplitude of the depolarization was 23.1 ± 1.4 mV (n = 9). Animals anesthetized with 0.5% halothane/60% nitrous oxide also lost synaptic function within one min of the onset of BCO. However, an ischemic depolarization was observed at 0.30 ± 0.76 min following loss of the population spike with a mean amplitude of 24.4 ± 2.4 mV (n = 10). Hyperlocomotion was observed in all BCO animals, however only in those animals whose temperature was maintained at 37°C was a significant difference observed. This temperature effect was also important for neuronal damage.

ISCHEMIA: TEMPERATURE

683.1

EFFECT OF INTRAISCHEMIC HYPOTHERMIA ON ISCHEMIA-INDUCED CHANGES IN REGIONAL LEVELS OF INOSITOL 1,4,5-TRISPHOSPHATE (IP₃). R. Busto*, M.Y.-T. Globus, E. Martinez, I. Valdés, and M.D. Ginsberg. CVD Research Center, Univ. of Miami, Sch. of Med., Miami, FL, 33101.

Extracellular glutamate release and histopathological outcome following ischemia are sensitive to intraschemic brain temperature. Since 1,4,5-trisphosphate (IP₃) is implicated in glutamate receptor-mediated events and intracellular calcium homeostasis, the relationship between intraschemic brain temperature and regional IP₃ levels following ischemia was evaluated. Twenty min of 2-vessel occlusion plus hypotension was induced in rats whose intraschemic brain temperature was maintained at 30°C or 37°C. Using a D-myo-IP₃[³H] assay system, IP₃ was determined in hippocampal, striatal, cortical, and thalamic homogenates at the end of ischemia or following 1h of recirculation. Significant (p<0.05) decreases of IP₃ were observed during normothermic ischemia in hippocampus (by 74%), striatum (81%) and cortex (66%), whereas thalamic levels were unchanged. During recirculation, hippocampus, striatum and cortex showed increases over ischemic levels though not fully to control. Thalamic levels remained unaltered. Following hypothermic ischemia, only the striatum showed a significant (p = 0.02) decrease in IP₃ levels. Our results demonstrate that following ischemia and recirculation, there is a decrease in IP₃ levels in vulnerable brain regions, a process which is partially sensitive to intraschemic hypothermia. These results do not confirm that breakdown of phosphatidylinositol and the generation of IP₃ occur at the end of ischemia or early recirculation (1h).

682.18

RESPONSES OF RAT NEOSTRIATAL AND HIPPOCAMPAL NEURONS TO TRANSIENT GLOBAL ISCHEMIA: AN *IN VIVO* INTRACELLULAR RECORDING STUDY. Z. C. Xu* and W. A. Pulsinelli Dept. of Neurology, University of Tennessee Memphis, Memphis, TN 38163.

Specific populations of CNS neurons, such as spiny neurons in the neostriatum and CA1 pyramidal neurons in the hippocampus, are highly vulnerable to transient ischemia. The pathogenesis of such selective injury after ischemia may involve alternations of these neurons' electrophysiological properties. We examined, *in vivo*, the changes of neuronal and synaptic activities in rat neostriatal and hippocampal neurons after transient global ischemia with intracellular recording techniques.

We evoked the synaptic potential of neostriatal or hippocampal neurons by stimulation of frontal cortex or commissural and perforant path fibers respectively in the anesthetized Wistar rat. Severe forebrain ischemia was induced by 4-vessel occlusion in normothermic animals for 5 minutes. The recorded neurons were identified by intracellular iontophoresis of neurobiotin.

Approximately 3 minutes after the onset of forebrain ischemia, the baseline membrane potential depolarized from ~ -70 mV to ~ -20 mV and remained at that level throughout the ischemia. One to two minutes after reperfusion, the membrane potential quickly returned to the control level. Spontaneous synaptic activities were reduced immediately after occlusion and were abolished shortly before anoxic depolarization. Although both inhibitory (IPSP) and excitatory (EPSP) postsynaptic potentials were suppressed by ischemia, the IPSPs disappeared earlier and recovered later than the EPSPs. The membrane input resistance increased and the time constant decreased after reperfusion. These results begin to characterize the effects of *in vivo* ischemia on electrophysiology of vulnerable neurons.

683.2

EFFECT OF MILD HYPERTHERMIA AND ANOXIA ON PHYSIOLOGICAL RECOVERY, SODIUM, POTASSIUM, CALCIUM AND ATP IN THE CA1 REGION OF THE RAT HIPPOCAMPAL SLICE. P. Amorim, I.S. Kass, J.E. Cottrell and G. Chambers. Anesthesia Dept., SUNY Health Science Center, Brooklyn, NY 11203.

It is well known that large changes in temperature affect neuronal damage. Recently small changes in temperature have also been examined. Mild hypothermia improves neurological recovery from anoxia/ischemia; mild hyperthermia has the opposite effect. We decided to examine the effect of a small increase in temperature on anoxic damage.

Adult rat hippocampal slices were incubated in artificial CSF, aerated with 95%O₂+5%CO₂ (normoxia) and subjected to anoxia (95%N₂+5%CO₂) either at 37 or 39°C. Recovery of the CA1 population spike (PS) after anoxia was used as an indicator for anoxic damage. After 5 min of anoxia at 37°C the PS recovered to 56±13% of its pre-anoxic amplitude; when the temperature was increased to 39°C the PS recovered to only 13±5% (p<.05). ATP measured in the CA1 region (luciferin-luciferase assay) after 5 min of anoxia at 37°C was 2.8±.2 nM/mg; when the temperature was increased to 39°C, ATP fell to 0.9±.1 (p<.05). Intracellular Na and K were measured in the CA1 region by flame-photometry after 5 min of anoxia. Na increased from 171±16 uM/g at 37°C to 253±24 at 39°C (p<.05) and K fell from 130±10 uM/g at 37°C to 97±12 at 39°C (p<.05). Ca⁴⁵ influx, measured in the CA1 region after 10 min of anoxia (the method is less sensitive to shorter periods of anoxia), increased from 9.15±.32 nM/mg at 37°C to 9.95±.29 at 39°C (p<.1).

Our results demonstrate that a mild increase in temperature significantly worsens anoxic damage in the *in-vitro* hippocampal slice. The marked depletion in ATP levels and the significant increase in Na and decrease in K intracellular levels observed with hyperthermia are likely explanations for its harmful effect.

683.3

DOES HYPOTHERMIA CONTRIBUTE TO THE NEURO-PROTECTIVE ACTION OF NBQX? S.M. Nurse* and D. Corbett. Div of Basic Medical Sciences, Fac of Med, Memorial University of Newfoundland, St. John's, NF, Canada, A1B 3V6.

Hypothermia during or within the first 30 min of an ischemic event is neuroprotective. Studies using putative anti-ischemic agents have been confounded by hypothermia during this period. However, little attention has been paid to potential confounding effects of hypothermia when drug administration is delayed.

We found that NBQX (30mg/kgx3) reduces brain temperature ~3°C for several hours, in normal rats and gerbils. We tested whether these temperature alterations contributed to its protective action against ischemic insults of 3 or 5 min in a gerbil model of global ischemia. NBQX (30mg/kgx3) was administered 1 or 6 hr after carotid artery occlusion. Brain temperature was either uncontrolled, or regulated to simulate the pattern of ischemic controls for 24 hr post-occlusion. NBQX provided greater protection of CA1 neurons against a moderate insult (3 min occln) versus a severe insult (5 min occln). NBQX at 1hr post-occlusion was more beneficial than delaying treatment for 6 hr. However, regulating brain temperature decreased the protection afforded by NBQX. Thus, the potential confound of hypothermia should be ruled out even when drug administration is delayed several hours after the ischemic event. Supported by the Medical Research Council of Canada.

683.5

THE EFFECT OF PREISCHEMIC SPINAL CORD HYPOTHERMIA ON AMINO ACID RELEASE AND NEUROLOGICAL RECOVERY INDUCED BY REVERSIBLE AORTIC OCCLUSION IN RAT. M.Marsala*, L.S.Sorkin, T.L.Yaksh, Dept. of Anesthesiology, University of California, La Jolla, San Diego, CA 92093

Preischemic brain cooling has been shown to suppress glutamate release during global cerebral ischemia and to provide neurological protection for extended periods of reflow. In the present work, we characterized the neurological changes and amino acid release that occur in spinal cord after 20 min of transient normothermic or hypothermic ischemia in rat. Extracellular changes in spinal cord amino acid concentration were measured using microdialysis in conjunction with HPLC and UV detection. In the hypothermic group (n=12) temperature was lowered using an underbody cooling system to 34.2±0.7°C 2 min before spinal cord ischemia was induced by the occlusion of the descending thoracic aorta. After ischemia, the animals survived 2 hr (microdialysis study) or 8 hr (behavioral study) of normothermic reperfusion. In normothermic animals, glutamate concentration was significantly elevated during the ischemic and immediate reperfusion periods. Taurine increased significantly 0.5 hr postocclusion and remained elevated for the full 2 hr. No consistent changes in aspartate or asparagine concentration were detected. In the hypothermic group, no significant changes in glutamate concentration were detected during the ischemic or reperfusion periods. Taurine was significantly elevated 30 min after reperfusion and returned close to baseline after 60 min of reperfusion. In contrast to the normothermic group in which majority of animals displayed spastic paraplegia and extensive hypersensitivity, hypothermic animals showed no deficit of motor or sensory function at any time of reperfusion. The data from the present study showed that mild spinal cord hypothermia can significantly suppress glutamate release and prevent neurological deficits otherwise induced by normothermic spinal cord ischemia of the same duration. TEMPERATURE MODULATION OF NMDA-INDUCED HISTOPATHOLOGICAL DAMAGE IN THE ADULT RAT BRAIN. M.Y.-T. Globus*, L. ElDeiry, W.D. Dietrich, J. Valdés, and R. Busto, CVD Research Center, Univ. of Miami, Sch. of Med., Miami, FL, 33101.

Extracellular glutamate release and histopathological outcome following ischemia are sensitive to intraschemic brain temperature. However, whether postsynaptic NMDA mediated events are sensitive to mild temperature alterations is unknown. We evaluated the relationship between brain temperature and the magnitude on NMDA-induced histopathological damage in the adult rat's brain. Excitotoxic lesions were performed by unilateral striatal injections of NMDA (50 or 150 nmols). Animals were divided into three groups in which brain temperature was maintained at 30°C (n = 7), 37°C (n = 8), or 39°C (n = 6) five min prior to and for a period of three hours following injection of NMDA. The extent of hemispheric lesion was quantitated 3 days following injections by morphometric analysis of lesion area. No association was observed between brain temperature and the extent of the lesion induced by 150nmols of NMDA (Integrated lesion volumes were: mean±SD, mm³; 30°C = 57.7±18.5; 37°C = 44.4±13; 39°C = 61.57±20). Hypothermia significantly increased lesion volume induced by 50nmols of NMDA (30°C = 33.08±12.8; 37°C = 19.92±5.1; 39°C = 32.5±18.6). Results indicate that postsynaptic effects of NMDA and the subsequent neuronal damage are not attenuated by mild hypothermia. Therefore, the modulatory effects of hypothermia on the excitotoxic process during ischemia involves mainly presynaptic mechanisms.

683.4

DELAYED AND PROLONGED POSTISCHEMIC BRAIN HYPOTHERMIA IS NEUROPROTECTIVE IN GERBILS. E. Colbourne* and D. Corbett. Memorial University of Newfoundland, St. John's, NF, CANADA A1B 3V6

A brief period of global ischemia in the gerbil produces extensive delayed neuronal death in the hippocampal CA1 sector with a concomitant spatial mapping impairment. Intra- or immediate postischemic hypothermia (PH) lessens this injury. We assessed whether PH (brain temp. = 32°C) initiated one hour after occlusion and maintained for 12 hr was neuroprotective in gerbils exposed to either 3 or 5 min of normothermic ischemia. CA1 integrity was assessed at either 10 or 30 days after ischemia and spatial mapping ability was determined by an open field test given 3, 7 and 10 days after ischemia. A 5 min occlusion in control animals (no hypothermia) produced complete CA1 cell loss at days 10 and 30. PH slowed and attenuated this death, such that there was about 50% savings at day 10, but < 20% with 30 day survival. Three min of ischemia also produced severe CA1 loss (~70%) in controls, which PH greatly attenuated at both days 10 and 30. Finally, PH reduced associated spatial mapping deficits caused by both 3 and 5 min ischemic episodes.

HYPOTERMIA AND HYPERTHERMIA AFFECT THE NEURONAL SURVIVAL SEVERAL HOURS AFTER BRAIN ISCHEMIA IN RATS Cicero Coimbra, Fredrik Boris-Müller*, Mikael Drake and Tadeusz Wieloch, Laboratory for Experimental Brain Research, Lund University, Lund Hospital, S-221 85 Lund.

Hypothermia (HT) is recognized as a powerful protectant when induced intraschemically, but is generally considered not to improve neuronal survival if initiated as late as 30min into recirculation (R) phase. We report that HT (33.0°C) with a minimal duration of 5 hrs reduced the neuronal damage in the lateral hippocampal CA1 region by approximately 50%, when initiated up to 12hr-R from 10min of 2VO + hypotension in rats. When initiated at 2hr-R, 5h-HT also provided protection to regions with fast maturation of damage, such as the striatum. Shorter periods provided minor or no protection and, when the cooling was delayed for 24hrs, 5hr-HT did not protect the brain. The effect on CA1 neurons was reduced by prolonging HT for 10hrs from 2hr-R. On the other hand, as opposed to the 24hr-cycle observed in normal rats, the mean core temperature (CT) was spontaneously held above 38.5°C from 21 to 63hr-R (39.2°C peak at 33hrs). When administered during this period, the antipyrogen dipyrene depressed CT to normothermic values and diminished the neuronal damage. The results point to an optimal duration of moderate HT induced within 2-12hrs after transient ischemia to achieve neuronal protection, and indicate that hyperthermia occurring quite late after recirculation may be detrimental to neuronal survival. Prolonged CT control seems to be required for proper evaluation of drugs in ischemia models. Supported by the Swedish MRC and Brazilian CNPq.

INTRASCHEMIC HYPOTHERMIA REDUCES TISSUE INJURY BY REDUCING OXIDATIVE STRESS AFTER TEMPORARY FOCAL ISCHEMIA IN RATS. H. Karibe, S. F. Chen, G. J. Zarow, J. Gafni, S. H. Graham, P. H. Chan and P. R. Weinstein*, Neurosurgery and Neurology, Univ. of California San Francisco and V.A.M.C., San Francisco, CA 94121

To investigate the influences of intraschemic hypothermia on oxidative injury after prolonged focal ischemia followed by reperfusion, 32 Sprague-Dawley rats underwent 3 hours middle cerebral artery occlusion followed by 3 hours reperfusion, with hypothermia (brain temperature = 33°C) or normothermia (37°C) maintained throughout ischemia. Normothermia was maintained throughout reperfusion for all animals.

In the first study (n=8/group), intraschemic hypothermia suppressed the reduction of tissue concentrations of endogenous antioxidants, ascorbic acid (p<0.05) and glutathione (p<0.05), in ischemic cortex. In a parallel second study (n=8/group), laser-Doppler estimates of cortical blood flow revealed that intraschemic hypothermia significantly attenuated early post-ischemic hyperperfusion (p<0.01) and delayed post-ischemic hyperperfusion (p<0.01). Hypothermia also reduced infarct volume as estimated from semi-serial Nissl stained slides (p<0.01), blood-brain barrier disruption as estimated from the extravasation of Evans blue dye (p<0.01), and brain edema as calculated by subtracting the volume of the non-ischemic hemisphere from that of the ischemic hemisphere (p<0.01).

These results demonstrate that intraschemic hypothermia reduces oxidative stress as well as tissue injury following prolonged temporary ischemia. Reduction of oxidative stress may protect tissue through the attenuation of both postischemic hyperperfusion and vasogenic edema.

HYPOTHERMIA DECREASES ASTROGLIAL INJURY AND ARACHIDONATE RELEASE DURING COMBINED GLUCOSE-OXYGEN DEPRIVATION. SE Haun*, VL Trapp, and LA Horrocks. Depts. of Pediatrics and Medical Biochemistry, The Ohio State University, Columbus, OH 43210.

Hypothermia provides significant protection when initiated before or after cerebral ischemia *in vivo*. However, the mechanisms producing this protective effect are not known. We studied the effect of hypothermia on lactate dehydrogenase (LDH) efflux and [³H]arachidonic acid metabolite ([³H]AAM) release from prelabeled cultures of astroglia during combined glucose-oxygen deprivation (CGOD). Four groups (n=12, each group) were studied: control and CGOD at 37°, 34°, and 31°C. Hypothermia reduced cellular injury, i.e. LDH efflux (expressed as a percent of total LDH) after 12 h of CGOD was 0.8 ± 0.4, 84.2 ± 6.2, 64.5 ± 24.3, and 31.4 ± 15.8 (mean ± SD) in the control, CGOD 37, CGOD 34, and CGOD 31 groups, respectively. [³H]AAM release was also reduced by hypothermia. [³H]AAM release (expressed as dpm/culture × 10⁻⁴) after 6 h of CGOD was 7.4 ± 0.6, 13.1 ± 0.5, 9.6 ± 0.8, and 6.9 ± 0.4 (mean ± SD) in the control, CGOD 37, CGOD 34, and CGOD 31 groups, respectively. We speculate that inhibition of phospholipid degradation may be one mechanism, but not the only mechanism that contributes to the neuroprotective effect of hypothermia. NEUROTROPIC CAPABILITY IN JC VIRUS COINCIDES WITH VIRAL REGULATORY REGION REARRANGEMENT IN THE HOST. G.S. Ault and G.L. Stoner. Lab. of Exp. Neuropathology, NIH, Bethesda, MD 20892

The ubiquitous polyomavirus JC is the agent of PML, a rare demyelinating disease in the immunocompromised host. Comparison of the promoter/enhancer structure of isolates from 11 PML brains revealed that sites of strand breakage in the promoter were not random; four or five preferred sites or areas exist. Alignment of the unduplicated archetypal promoter, isolated from kidneys of these patients, with the prototype strain defines six blocks of sequence, A through F, which are delineated by the preferred sites of strand breaks. Region A, containing the TATA box, the first half of region C, and region E, were consistently retained. Region B, the 23-bp "insertion" in archetype relative to the prototype, was also retained in all 11 isolates. Region D, the 66-bp "insertion", was retained in 3 isolates. Regions A and D were never duplicated, whereas regions C and E usually were duplicated or triplicated. All regions contain transcriptional promoter or enhancer elements, indicating that the virus can operate with various combinations of elements, certain ones of which are required while others are expendable or interchangeable. Variation in the exact breakage point within the preferred sites, alternate use of the sites in different isolates, and occasional short deletions at other sites result in sequences which are unique in each case. At the same time, the limited choice of break sites and the characteristic fates of the regions themselves result in three broad patterns of duplication and deletion. The patterns do not correspond to our previously described viral genotypes 1 and 2 defined by coding region base changes, and do not appear to be a stable feature of the virus. Rather, neurotropic genomes appear to arise infrequently within an individual host as unique rearrangements of a basic archetypal sequence.

IMMUNE-MEDIATED MECHANISMS OF RESISTANCE TO DEMYELINATING DISEASE IN BALB/c SUBSTRAINS. S.M. Nicholson*, J.L. Hoeft, C.E. Elliott, W.J. Karpus, S.D. Miller, M.C. Dal Canto, and R.W. Melvold. Department of Microbiology-Immunology, Northwestern University Medical School, Chicago, IL, 60611.

Theiler's Murine Encephalomyelitis Virus (TMEV), upon access to the central nervous system (CNS), induces a demyelinating disease, similar clinically and histopathologically to multiple sclerosis, in susceptible strains of mice. TMEV-induced demyelinating disease (TMEV-IDD) is believed to result from bystander damage mediated by TMEV-specific CD4+ T lymphocytes homing to the CNS. These T cells recruit activated macrophages to the CNS which, while attempting to clear the virus, damage myelin. We have previously reported that BALB/c substrains are differentially susceptible to TMEV-IDD. We have further shown that an active mechanism may mediate resistance to TMEV-IDD in resistant BALB/cByJ, as low dose γ irradiation administered 2 days prior to intracerebral inoculation of virus converts this substrain to 90-100% susceptible. Resistance can be restored by the transfer of spleen cells from unirradiated, TMEV-infected BALB/cByJ. The same population of cells also protects susceptible BALB/cAnNCr from TMEV-IDD.

We report here that protection to TMEV-IDD appears to be mediated by T cells from unirradiated, TMEV-infected BALB/cByJ. Experiments are underway to determine the precise T cell subset responsible.

PSEUDORABIES VIRUS INFECTS AND REPLICATES IN CELLS OF NEURONAL ORIGIN. R.J. Wyborski*, G.

Subramanian*, & A.O. Fuller*. †Biotechnology Department, Parke-Davis Pharmaceuticals & ‡Department of Microbiology, University of Michigan Medical School, Ann Arbor, MI 48105.

Pseudorabies virus (PRV) naturally infects swine and cattle and is closely related to herpes simplex virus (HSV). In studies to understand the mechanism of entry and determinants of tropism for these herpesviruses, we have determined that PRV replicates poorly in several common cultured human cell-lines that efficiently replicate HSV (Subramanian & Fuller, submitted). We were interested in determining if human neuronal cells are also capable of being infected with PRV, but are not competent for viral replication. As one model cell for this study we utilized the human neuroblastoma cell line SY5Y. When cells were infected with PRV at low multiplicity, harvested and titered after 48 hrs, titers from SY5Y cells were comparable to the high titers normally seen from Vero cells and all porcine cells tested. Of other human cell lines tested, HEL, HEp-2, and 549 produced very poor virus yields while E1A transformed human 293 cells produced yields comparable to Vero, porcine, and SY5Y cells. These results suggest that PRV is capable of infecting a wide variety of human cells *in vitro* but is not capable of productive infections in all of these cells. Further examination will focus on the susceptibility of neuronal cells, both primary and transformed, for productive PRV infection and if PRV can be developed as a possible vector for gene delivery to neurons.

CYTOKINE RECEPTOR GENE EXPRESSION IN LYMPHOCYTIC CHORIOMENINGITIS (LCM). A. Stalder and J. L. Campbell*. Department of Neuropharmacology, The Scripps Research Institute, La Jolla, CA 92037

Intracerebral (ic) inoculation of immunocompetent adult mice with Lymphocytic Choriomeningitis virus (LCMV) results in a vigorous immune response in the brain culminating in death of the host around day 6 - LCM represents a prototypic model for viral meningitis. In recent studies we have shown that LCM is accompanied by the coordinate expression of multiple cytokine genes. To further define the role of cytokines in the molecular pathology of LCM, in the present study we analyzed cytokine receptor gene expression in mice following ic infection with LCMV.

To analyze cytokine receptor gene expression a RNase protection assay (RPA) was developed which permits the simultaneous detection of IL-1 p60 and p80, TNF p60 and p80, IL-6 and IFNγ receptor mRNAs. PolyA⁺RNA was isolated from brain and kidney at day 3 and day 6 post infection and analyzed in the RPA. In non-infected mice levels of TNF p60, TNF p80, and IFNγ receptor mRNA were higher in kidney than in brain. IL-1 p60 and IL-6 receptor transcripts were expressed at comparable levels. The levels of IL-1 Rp60, TNF Rp80 mRNA were upregulated both in kidney and brain by day 6 of infection. IL-1 p80 receptor mRNA was only detectable at day 6 of infection in brain and kidney. Parallel studies in nude mice, which do not develop LCM revealed a generally lower expression for all the cytokine receptor mRNAs, and no regulation was observed following LCMV infection. Particularly the IL-1 p80 receptor transcript was not detectable at any time pre or post infection.

These findings indicate significant upregulation in the expression of specific cytokine receptor genes in the development of LCM. The absence of such a response in nude mice suggests the upregulation seen in LCM is linked to the immuno-inflammatory response. The anatomic distribution of cytokine receptor mRNA expression in LCM is not defined and is the subject of ongoing studies.

PRODUCTION OF GRANULOCYTE-MACROPHAGE COLONY STIMULATING FACTOR BY HUMAN T-LYMPHOTROPIC VIRUS TYPE I-INFECTED HUMAN GLIOMA CELLS. Y. Nishiura, T. Nakamura, S. Shirabe*, K. Ichinose, M. Tsujihata and S. Nagataki First Department of Internal Medicine, Nagasaki University School of Medicine, Nagasaki, Japan 852.

We investigated the production of granulocyte-macrophage colony stimulating factor (GM-CSF) by human T-lymphotropic virus type-I (HTLV-I)-infected human glioma cells (KG-1-C and T98G). When glioma cells were co-cultured with HTLV-I producing T-cell lines (HCT-1 and MT-2) after which treated with mitomycin C, GM-CSF were detected in the culture supernatant by ELISA. In co-cultures using Millicell (Millipore Products Div.) and in the presence of anti-HTLV-I antibody, there was suppression of GM-CSF production. Double-label immunostaining showed that about 10% of the glioma cells co-cultured with HTLV-I producing T-cells were stained by monoclonal antibody to HTLV-I gag protein (GIN 14) and the cells stained by antibody to GM-CSF always were stained by GIN-14, indicating that HTLV-I infection of glioma cells caused GM-CSF production. These data showed that human glial cells infected with HTLV-I gain the ability to produce cytokines, suggesting infection of HTLV-I to astrocytes in vivo may play a part of role in pathogenesis of HTLV-I associated myelopathy.

ELECTROPHYSIOLOGICAL STUDIES OF FELINE IMMUNODEFICIENCY VIRUS (FIV)-INFECTED CATS. O. Prospéro-García*, N. Herold, T. Phillips, J. Elder and S. J. Henriksen, Dept. Neuropharmacology, The Scripps Research Inst. La Jolla, CA 92037.

We have evaluated visual and brainstem auditory evoked potentials (VEP and BSAEP) and sleep recordings of FIV-infected cats to characterize comparative neurological deficits observed in HIV-1-infected humans. Two groups of specific pathogen free cats were systemically infected with 1000 TCID₅₀ units of the Mount Airy strain. The first group (2 controls and 4 infected cats) was studied 13 months post-inoculation of the virus whereas the second group (4 controls and 9 infected cats) was evaluated six months post-inoculation. All infected cats were virus isolation positive by eight weeks post-infection. FIV cats developed a persistent reduction in CD4/CD8 antigen ratio, lymphadenopathy, anisocoria and abnormalities in pupillary reflexes. In the FIV group, BSAEP revealed a delay in the latency of the waves P1, P2 and P3. Likewise VEP's exhibited prolonged latencies, and a reduction in the amplitude. The sleep-wake cycle as assessed by 3 consecutive 8 hour recordings also exhibited deficits, showing a prolonged latency to sleep onset and a significant reduction in REM sleep in the FIV group. In addition, preliminary data has shown that a surface fragment of the FIV envelope protein, selectively reduces REM sleep in rats when injected intraventricularly. As these electrophysiological findings resemble those observed in HIV-1 infected patients, the FIV model shows potential as a small animal model of lentivirus effects on CNS.

NO EFFECT OF HIV gp120 ON CHOLINERGIC CURRENTS IN CULTURED HUMAN NEURAL CELLS. Edward K. Stauffer* and Richard J. Ziegler, Depts. of Med. & Molec. Physiol. and Med. Microbiol. & Immunol., Univ. Minn.-Duluth, Duluth, MN 55812

HIV infection often produces neurological disorders which occur despite the lack of viral presence in neurons. This situation has led to the hypothesis that viral products from other infected cells might be disrupting neural function. Indeed, a recent report (*FEBS Lett.* 311:115) shows that gp120 can block the binding of α -bungarotoxin (Bgt) in TE671 cells indicating that gp120 might be attaching to the acetylcholine receptor (AChR). We have investigated whether gp120 affects ionic currents associated with activation of AChRs. Whole-cell patch clamp experiments were performed on human SH-SY5Y (neuronal AChRs) and TE671 (muscle AChRs) cells, both of which produce pronounced inward currents when nicotine (100 μ M) is superfused over the cells with micropressure ejection. No membrane currents were observed when gp120 (0.1 nM) was applied to the surface of either cell line. When gp120 (0.1 nM) was present in the bath, there was no inhibition of nicotine-evoked inward currents (NEICs) in either cell line. In the presence or absence of gp120, Bgt completely abolished all NEICs. If gp120 is, in fact, attaching to the Bgt-binding site of the AChR, our results indicate that it has no effect on the ionic current commonly associated with these ligand-gated channels. NEUROBIOLOGY OF VACCINE-INDUCED PROTECTION FROM HERPES SIMPLEX VIRUS TYPE 1 (HSV-1) IN MICE. JR Martin¹, WJ Mitchell¹, DB Henken¹, P Gressens¹, E Kern², Lab Exptl Neuropath, NIH, Bethesda MD; ²U Alabama, Birmingham AL.

Neurotropic HSV-1, which spreads cell-to-cell to and within the nervous system, is a target of vaccine development. As a measure of vaccine efficacy, prevention of virus spread was examined in tissue sections. Mice were immunized with vaccinia virus recombinants expressing HSV-1 glycoprotein D (gD) or control β -galactosidase genes (*Science* 228:737), and 1 month later were intranasally challenged with a lethal HSV-1 dose. HSV-1gD immune but not control mice survived, had high HSV antibody titers, and much reduced virus titers in olfactory bulb, cerebrum, brainstem, cord, and trigeminal and superior cervical ganglia. HSV antigen tests on decalcified tissue sections indicated 4 neural pathways for virus spread from the nasal sinus: (i) olfactory: ethmoid epithelium to olfactory bulb to limbic structures (ii) sensory: trigeminal ganglion to brainstem (iii) sympathetic: superior cervical ganglion to thoracic cord (iv) parasympathetic: to pterygopalatine ganglion. In controls, peripheral and neural tissues were extensively infected but in HSV immunized, infection was minimal and neural spread appeared restricted to trigeminal ganglia and brainstem. By this approach, HSV spread in otherwise relatively inaccessible tissues and vaccine efficacy could be evaluated.

REACTIVE ASTROCYTES IN CONTIGUITY WITH HIV INFECTED HUMAN LYMPHOCYTES IN THE RECONSTITUTED SCID MOUSE. F. J. Denaro*, Dept. of Neurology, Texas Tech University Health Sciences Center, Lubbock, TX 79430.

Careful histochemical studies in humans have demonstrated that the HIV infected cell types in the brain are restricted to monocytes, macrophages, microglia and CD4+ cells (T cells). Neuronal infection with HIV and its effect have not been identified. Consequently, alternate hypotheses of HIV induced pathology have had to be proposed. One hypothesis is that the infected lymphocytes release toxic substances: cytokines, viral proteins or as yet unidentified agents. It is these hypothesized substances that induce the pathology which is now attributed to HIV infection. In the present study, HIV infected human CD4+ cells or monocytes/macrophages have been used to reconstitute the SCID mouse. At varying time points post-reconstitution, the brains were examined for evidence of neuropathology. Double label studies have demonstrated HIV infected monocyte/macrophages to be in contiguity with reactive astrocytes. Uninfected cells in control animals have not been found to induce the responses. Further studies will map the distribution patterns of HIV infected human cells and the topography of the reactive gliosis. Such a correlational study will reveal the magnitude of the observed trend and thus provide evidence of HIV induced pathology in a model system. Examination for other neuropathologic changes is underway.

HIV gp120 EFFECTS ON TYROSINE PROTEIN PHOSPHORYLATION AND $[Ca^{2+}]_{int}$ IN HUMAN NEURAL CELLS. R.J. Ziegler*, J. DiSalvo, G. Trachte, L. Semenchuk, and M. Sheve, Depts. of Medical Microbiology & Immunology and Medical and Molecular Physiology, Univ. of Minnesota Sch. of Med., Duluth, MN 55812

AIDS dementia complex, a clinical syndrome consisting of specific neurological signs and symptoms, is the result of human immunodeficiency virus (HIV) invasion of the central nervous system (CNS). The causative mechanisms underlying the dementia remain unknown. Virological and pathological data, however, suggest that the observed neurological impairment is not the result of HIV infection of the functional elements of the CNS: neurons, oligodendrocytes and astrocytes. Several mechanisms have been proposed. They include possible toxic, inhibitory, or stimulatory effects of HIV gene products, or activated immune cell or HIV-infected microglial cell products on these functional cells. We have studied possible effects of recombinant strain IIIB and SF-2 gp120 on several processes including electrogenic mechanisms and second messenger systems in human neuroblastoma (SK-N-MC and SK-N-SY5Y) and astrocytoma (U-373 MG) cells which are known to bind this HIV envelope glycoprotein. We have observed no gp120-induced effect on electrogenic mechanisms in the SK-N-MC and SY-5Y cells and no induction of the second messenger cAMP, IP₃ and NO in any cells. However, 10⁻⁸ M SF-2 gp120 (Chiron Corp.) induced a ~7-fold increase in $[Ca^{2+}]_{int}$ in the U-373 MG cells, but had no effect on the neuroblastoma cell lines. IIIB gp120 (AGMED, Inc.) had no effect. 1.0 μ g/ml of IIIB gp120 did induce a significant increase in tyrosine protein phosphorylation in several SK-N-MC cellular substrates. This increase was maximum one minute following gp120 exposure. Possible similar increases in U-373 MG cells have not been studied yet. These two gp120-induced effects document two mechanisms by which gp120 may cause functional impairment of human neural cells. (Supported by NIH NS29320.)

GP-120 ADMINISTERED INTRATHECALLY INDUCES MONOARESIS IN RATS. J.L. Steinman*, B.R. Komisaruk, L. Gomez, R. Cueva-Rolon, C. Pert and M. Ruff. Rutgers-The State Univ. of New Jersey, Newark, NJ 07102, USA.

Neurological deficits have been observed in neonatal rats following systemic administration of gp-120 (Hill et al, 1992, *Brain Res.*), an envelope protein of HIV. Furthermore, direct injection of gp-120 to the cerebral ventricles results in memory impairments in adult rats (Glowa et al, 1992, *Brain Res.*). The present study found that direct administration of gp-120 to the spinal cord via intrathecal (IT) catheters induced forelimb monoparesis in adult female rats.

IT catheters (PE-10 tubing, 7 cm length) were implanted under anesthesia 7-10 days prior to testing. Motor performance (hindlimb and forelimb use, walking patterns) was videotaped before and up to 12 hrs after rats received either gp-120 (1 ng/5 μ l saline) or vehicle alone. The experimenter was blind to treatment.

Seven of 10 rats receiving IT gp-120 showed monoparesis of either the left or right forelimb; none of the saline control rats exhibited paresis ($\chi^2 = 6.39$, $df = 1$, $p < 0.02$ comparing the two treatment groups). The onset of monoparesis was variable (mean \pm sem = 22.2 ± 7.4 min), appearing as early as 4 min post IT injection. The mean recovery time was 6 hrs. In 3 of the 7 rats, the monoparesis appeared intermittently during the first two hours, then persisted for the next 3-4 hrs; in the other 4 rats, monoparesis was continuously present from its onset. In 5 of the 7 rats, forelimb monoparesis was accompanied by hindlimb rigidity during walking or when pressure was placed manually against the footpad.

At autopsy, it was found that the monoparesis was ipsilateral to the side of the spinal cord where the tip of the IT catheter was positioned. This points to the specificity of the effect of gp-120 in acting locally, at or near the level of the motoneurons, to produce forelimb paresis. These findings demonstrate that an envelope protein of HIV induces discrete motor deficits when administered directly to the spinal cord, providing a unique model for studying gp120-induced neuronal deficits. Findings using rotarod performance to assess motor deficits will be presented.

EFFECTS OF CYTOKINES ON *TOXOPLASMA GONDII* MULTIPLICATION IN HUMAN MICROGLIA. S. Hu*, G. Gekker, P. K. Peterson and C. C. Chao. Minneapolis Medical Research Foundation and the University of Minnesota, Minneapolis, MN 55404

Microglia may play an important role in host defense of the central nervous system against *Toxoplasma gondii*. Cytokines released from these glial cells may participate in their host defense activity against *T. gondii*. In the present study, the anti-toxoplasma activity of human fetal microglia was investigated. The RH strain of *T. gondii* multiplied readily after 20 h incubation in these cells (155 ± 6 tachyzoites/100 cells). Activation of microglia with interferon (IFN)- γ plus lipopolysaccharide suppressed ($P < 0.01$) *T. gondii* growth (68 ± 7 tachyzoites/100 cells). Greater than 90% of the anti-toxoplasma defense of activated microglia was blocked ($P < 0.01$) by neutralizing antibodies to tumor necrosis factor (TNF)- α and interleukin (IL)-6, but not to IL-1, suggesting that these cytokines play a role in the inhibitory process. Consistent with this hypothesis, treatment of microglia with TNF- α or IL-6 (in the presence or absence of IFN- γ) inhibited ($P < 0.01$), in a dose dependent manner, *T. gondii* multiplication. Since N^G -monomethyl-L-arginine (500 μ M) did not affect cytokine-mediated anti-toxoplasma activity of microglia, the finding suggests that nitric oxide is not involved in this inhibitory process. The present study suggests that the host defense function of human microglia against *T. gondii* is dependent primarily upon the activating properties of IFN- γ , TNF- α , and IL-6.

PURIFICATION AND BIOLOGICAL ACTIVITIES OF AN INTERFERON- γ IMMUNOREACTIVE MOLECULE IN SENSORY GANGLIA. T. Olsson, M. Bakhtiet, C. Edlund, B. Højeberg, S. Kelic and K. Kristensson*. Department of Neurology, Huddinge Hospital and Department of Neuroscience, Karolinska Institutet, Stockholm, Sweden.

Two monoclonal antibodies (mabs DB-1 and DB-16) directed against non-competitive epitopes of rat lymphocyte derived interferon- γ (IFN- γ) cross-react immunohistochemically with an antigen in small neurons in trigeminal and dorsal root ganglia of the rat. A homogenate was prepared from rat trigeminal ganglia and centrifuged. The supernatant was applied to two consecutive affinity columns, one immobilized with mab DB-1, the other with mab DB-16. The eluate was concentrated and then diluted in phosphate buffered saline, pH 7.2.

This doubly affinity purified preparation shared biological activities with lymphocyte derived IFN- γ : a) it induced major histocompatibility complex antigens class I and II in macrophage cultures, b) it stimulated the proliferation of *Trypanosoma brucei* *in vitro*, and c) it enhanced the number of myotubes in cultures of rat skeletal muscle. In the latter cultures, both lymphocyte derived IFN- γ and the purified molecule caused an increased myoblast proliferation and a decrease in number of dorsal AChR aggregates in myotubes. SDS-electrophoresis of the affinity purified preparation displayed three bands after silverstaining between 54 and 62 kD in size. No bands corresponding to the size of IFN- γ molecules, 14-25 kD, could be detected.

CIRCULATING gp120-INDUCED NEUROTOXICITY. W. Carragher III, M. Ruff, Candace Pert* and Ian Creese. Center for Molecular and Behavioral Neuroscience, Rutgers-Newark, NJ 07102.

The paradox of neuroAIDS is that frank neuronal damage occurs in patients who show neurocognitive and motor symptoms although neurons themselves do not appear to be directly infected with HIV. A current hypothesis is that infected CNS macrophages and microglia are responsible for the concurrent neurotoxicity. One potential mechanism is that free viral envelope protein, gp120, is a neurotoxic agent. Indeed, neuronal culture systems have demonstrated that addition of gp120 can lead to neuronal death, if glial cells are present, suggesting an indirect glial-mediated neurotoxicity. However, cell culture tells us what could happen *in vitro* - but does not tell what does happen. We have found that 1) in the neonatal rat, systemic administration of exogenous gp120 (5ng/day for 1 week) is neurotoxic, 2) that its neurotoxicity can be reduced by co-administration of the novel drug Peptide T, and 3) that administration of serum (equivalent dose of 1-10 μ l/day for 1 week) from HIV+ve patients with neurocognitive deficits shows a similar Peptide T-reversible neurotoxicity. Neurotoxicity was studied with a silver stain, modified from Gallyas, which detects the acute morphological consequences of neuronal damage over a window of about 5 days. Most "dark" neurons were concentrated in cortical areas, especially entorhinal and perirhinal, layer II and the hippocampus, areas previously reported to be rich in CD4 receptors as visualized with monoclonal antibodies (Pert, C.B. et al, *P.N.A.S. USA* 83:9254-58, 1986). Only scattered "dark" neurons were found in subcortical areas. This indicates that frank neuronal killing occurs in the neonatal animal and not simply reduced dendritic arborization as has been reported previously. These studies suggest a potential critical role for a maternal circulating neurotoxic agent (gp120) that can cause neonatal CNS damage, with or without frank HIV infection of the infant, and that Peptide T may be a beneficial treatment.

684.14

AN INTRAOCULAR MODEL MODEL OF HUMAN CYTOMEGALOVIRUS (CMV) RETINITIS. D.A. DiLoreto, Jr., L.G. Epstein, E. Lazar, W. Britt and M. del Cerro. University of Rochester School of Medicine, Rochester, New York, 14642.

CMV infection of the human retina is a devastating complication in immunocompromised patients, especially those with HIV-1 infection. AIDS related CMV retinitis leads to blindness in 20 to 25% of these patients prior to death. *In vitro* viability of CMV is largely limited to human fibroblast cultures. There is an acute need to develop a model based on the infection of retinal cells in order to better understand and treat the disease. Here we report on a model based on grafting human fetal retina into the anterior chamber of immunodeficient mice.

We transplanted 2nd trimester human fetal retina into the anterior chambers (A.C.) of 15 SCID mice. One week later 15 of 30 grafts were infected in the A.C. with CMV strain AD169. Infected and non-infected specimens were compared for histopathological changes using H&E staining. Polyclonal antibodies to GFAP and PGP 9.5 were used to characterize the effects of virus on glial and nervous elements of the retina. Virus was characterized using monoclonal antibodies to various replicative phases of CMV.

At 30 days, healthy control grafts were seen within the A.C. consisting mostly of photoreceptor cells in the characteristic rosette pattern that is seen in A.C. retinal transplants. Infected grafts also showed a rosette pattern, but of noted difference was the fact that they also included larger cells, both giant and multinucleated, that had intranuclear and intracytoplasmic inclusions pathognomonic of CMV infection.

We have now achieved a model of CMV infectivity of human retinal tissue in a small animal model. This will allow the study of the replicative properties of CMV and the specific effects of CMV on the human retina. In addition to this, we can now assay multiple types of drug therapy to combat CMV infection of the human retina. This *in vivo* model will allow a greater understanding CMV retinitis and permit the study of various anti-CMV agents. QUANTITATIVE ANALYSIS OF HERPES SIMPLEX VIRUS (HSV) PERSISTENCE AND RNA EXPRESSION IN LATENTLY INFECTED CELLS OF RAT BRAIN. D.J. Fink*, G. Jiang, M. Levine, and R. Ramakrishnan. Dept. of Neurology, GRECC VAMC, and Dept. of Human Genetics, University of Michigan, Ann Arbor, MI 48104.

Previous studies have demonstrated that when attenuated herpes simplex viruses are injected into focal brain regions, viral DNA persists for at least 1 year (Fink *et al.*, 1992). In order to study this phenomenon quantitatively, we have determined the amount of viral DNA, represented by the gB gene, and latency associated transcript (LAT) RNA by competitive quantitative PCR and rt-PCR respectively, at 2d, 7d, and 8wk after injecting 5 μ l containing 1×10^6 pfu of a ribonucleotide reductase deletion mutant HSV into rat hippocampus.

DNA and RNA were extracted from tissue scraped from the hippocampus of 10 μ m frozen sections of brain, and serial dilutions of known amounts of a standard template, identical in sequence to the target except for an altered internal restriction site, were co-amplified with the extract, using the same set of primers.

The number of viral genomes in the hippocampus decreased approximately 4-fold from 2d to 7d post-injection, but then remained constant out to 8wk. No evidence for viral replication was seen. The amount of LAT RNA in the same region remained constant from 7d to 8wk post-injection, and represents approximately 16 LAT RNA molecules/HSV-1 genome equivalent.

We conclude that latency in the brain has many similarities to that in peripheral ganglia, and that once established, the amounts of viral DNA and RNA remain constant in the brain over at least several months.

UNALTERED PROTEIN PATTERNS OF CULTURED POSTMITOTIC SYMPATHETIC NEURONS AFTER INFECTION WITH WILD-TYPE HSV-1: FURTHER EVIDENCE THAT NEURONS DO NOT UNDERGO VIRION-INDUCED HOST SHUTOFF. P.F. Nichol*, P.D. Olivo, and E.M. Johnson, Jr. Washington University School of Medicine, St. Louis, MO 63110.

Previously, we reported that the rate of methionine incorporation does not decrease in sympathetic neurons after infection with HSV-1. This suggests that neurons are resistant to the HSV phenomenon of virion-induced host shutoff or VHS. The VHS phenomenon, as mediated by the viral gene UL 41, occurs in a wide variety of dividing cells after infection with HSV-1. Genetic studies indicate that the UL 41 gene product induces the disaggregation of polyribosomes and promotes degradation of transcripts. These effects result in a decrease in the rate of protein synthesis and methionine incorporation of the infected cell. We have observed that no such decrease is detectable in neurons in the first 30 hours after infection with wt HSV-1. The effects of the UL 41 gene product is also manifested by a change in the pattern of ³⁵S-methionine-labeled protein seen on denaturing gels. This pattern is characterized by the disappearance of cellular proteins and the appearance of viral proteins. We report here that such an alteration did not occur in the protein pattern of ³⁵S-methionine-labeled sympathetic neurons after infection. Viral proteins were detectable by 36 hours after infection on SDS/acrylamide gels, but there was no alteration in the pattern of cellular proteins. We are presently in the process of confirming viral infection of these cells by immunoprecipitation. We take this as further evidence that peripheral neurons are resistant to the VHS phenomenon as mediated by the UL 41 gene product and that the time course of expression of viral proteins is much slower in peripheral neurons than in mitotic cells. These two phenomena may be important in the establishment of viral latency in these neurons. (Supported by the American Paralysis Foundation and the Monsanto Corporation.)

SUBCELLULAR COMPARTMENTALIZATION OF MHC CLASS II AND SIALOADHESIN PROTEINS IN BRAINS INFECTED WITH HSV-1. M. Morales*, G. A. Lewandowski and E. E. Bloom. The Scripps Research Institute, Neuropharmacology, 10666 N. Torrey Pines Rd., La Jolla CA 92037.

The immune response to herpes simplex virus type 1 (HSV-1) infection in the brain has been studied in detail; intraocular inoculation of mice with wild type HSV-1 resulted in a latent infection with cell surface expression of MHC class II proteins. In contrast, inoculation with a mutant strain resulted in a lethal infection and intracellular accumulation of MHC class II proteins (Lewandowski et al., PNAS '93). We have now extended our observations on this model to the ultrastructural level. Six days after viral inoculation, mouse brains were fixed by perfusion and sections of the superior colliculus (SC) were incubated with polyclonal antibodies against viral antigens and examined by fluorescence microscopy. Sections containing viral antigens were processed for the ultrastructural immunodetection of MHC class II and sialoadhesin proteins. Viral particles are abundant in SC cells of brains infected with the mutant strain but are absent in brains infected with the wild type. The SC of infected material (both groups) contained microglia and macrophages with sialoadhesin protein in their plasma-membrane (PM). In wild type infected animals, MHC class II was located on the PM of macrophages and microglia. In contrast, the microglia of animals infected with the mutant strain contain both virus and MHC class II-immunoreactivity in their nuclei, macrophages here lack virus in their nuclei but contain MHC class II on their PM. Through serial sections, we observed an apparent association between the virus and the MHC class II marker. The expression of sialoadhesin protein on the PM of infected microglia indicates that MHC class II in the nuclei is not due to non-specific accumulation of proteins in the nuclei of moribund cells but rather represents a selective transport of MHC class II to the nuclei. Our results support the hypothesis that evasion of immune response by viral interference with antigen presentation results in lethal infection. (Antibodies against sialoadhesin were provided by Dr. S. Gordon, University of Oxford. Supported by AIDS center MH 47680 and AA 06420).

DANTROLENE PREVENTS MUMPS VIRUS-INDUCED NEURODEGENERATION *IN VITRO*.

T. Andersson* and K. Kristensson. Department of Neuroscience, Karolinska Institutet, S-104 01 Stockholm, Sweden.

Persistent mumps virus infection of dorsal root ganglia neurons cause a transient, early reduction in calcium influx during the action potential. The virus-induced neurodegeneration in these cells was markedly enhanced by increasing the calcium concentration of the medium and could be almost totally inhibited by the dihydropyridine calcium channel antagonist Nifedipine. Dispersed primary cultures of embryonic rat hippocampal neurons, prepared as described by Rothman (J. Neuroscience, 4, 1884-91, 1984), were grown in Petri dishes and infected with the hamster adapted RW-strain of mumps virus. The virus replication was restricted with expression of nucleocapsid, but not envelope proteins as determined by immunohistochemistry. The neurons in well defined areas of the dishes were counted daily in a phase-contrast microscope. During the first 4 days of infection, 30-40% of the neurons died, but later there was no further cell loss. The effects on the degeneration of antagonists of voltage-dependent and receptor-operated calcium channels were studied, as was the effect of Dantrolene, which inhibits mobilization of intracellular calcium stores. It was found that 30 μM Dantrolene in the medium significantly reduced the neurodegeneration caused by the virus. Our observation indicates that a virus infection of neurons may lead to a disturbed calcium homeostasis.

MECHANISM OF IMMUNOSUPPRESSION IN THE BRAIN BY A LETHAL STRAIN OF HSV-1. G. Lewandowski*, K. Kogel and E.E. Bloom. Dept. of Neuropharmacology, The Scripps Research Institute, La Jolla, CA 92037.

Recently we reported on a lethal strain of Herpes simplex virus type-1 (HSV-1) that produces a widespread infection in the CNS of mice following intraocular inoculation. The immune response to HSV-1 infection in the brain is characterized by recruitment of CD4+ and CD8+ cells to the viral infection centers, and an unusual intracellular expression of MHC class II antigens (Lewandowski, et al PNAS 90:2005 1993). With two color fluorescence confocal microscopy we determined that MHC class II antigens were expressed primarily in the nucleus in cells that were also positive for HSV-1 antigens and at the cell surface of cells that were negative for viral antigens. The nuclear localization of MHC class II antigen expression was confirmed by co-localization with the nuclear stain, DAPI. Furthermore, the induction of synthesis and nuclear sequestering of MHC class II antigens was reproduced *in vitro*, following the infection of trigeminal nerve explants with the HSV-1 mutants. We postulate that HSV-1 is causing suppression of the normal immune response in the brain by inhibiting viral antigen presentation to the recruited CD4+ cells. We are currently investigating the pattern of cytokine induction in the CNS following HSV-1 infection in order to determine whether recruited CD4+ cells become activated.

Immunoblot analysis of extracts from trigeminal ganglion nerves and the superior colliculus of mice infected with either the non-lethal control strain of HSV-1 or the lethal HSV-1 strain indicated that the HSV-1 mutant does not interfere with the induction of synthesis or post-translational processing of the MHC class II protein. Further investigation of the nature of the HSV-1-MHC class II complex is underway.

ALTERED VIRAL mRNA EDITING IN MEASLES VIRUS INFECTIONS OF THE CENTRAL NERVOUS SYSTEM. J.A. Vanchiere*, J.G. Wood, W.J. Bellini. Respiratory and Enterovirus Branch, Centers for Disease Control and Neuroscience Program, Emory University, Atlanta, GA 30333.

As a model for the study of measles virus infection of the nervous system, the Hamster Neurotropic Strain (HNT-1) of measles virus was derived by serial passage of the Philadelphia 26 (Ph26) wild type isolate in suckling hamster brain and then passaged in Vero cells to produce a persistent infection (HNT-2). In order to assess the distribution of phosphoprotein (P) mRNA editing in these viruses, a fragment of PCR-amplified DNA reverse-transcribed from poly-A(+) RNA was cloned and sequenced for 208, 121, and 116 clones of Ph26, HNT-1, and HNT-2, respectively. As these clones were derived from poly-A(+) RNA, the statistics of editing *in vivo* are reflected in the distribution of edited clones. The distribution is nearly identical for HNT-1 and HNT-2 ($p=0.63$), and both are different from that of Ph26 ($p<0.001$). Compared to Ph26, HNT-1 and HNT-2 editing is shifted toward a higher proportion of unedited transcripts (66.9% and 72.4% vs. 61.5%). Insertions of more than one G are 2.4% of the clones from Ph26 and represent 11.6% and 10.3% of the clones from HNT-1 and HNT-2. These editing distributions are unlike those previously reported for measles virus derived by other methods. The shift in editing may play a role in persistence, as decreased expression of the V and W proteins may favor transcription over replication.

685.1

HEAT-SHOCK PROTEINS AND NEUROTROPHINS IN THE HIPPOCAMPAL FORMATION FOLLOWING METHYLMERCURY, AS REVEALED BY IN SITU HYBRIDIZATION. H. Lindström, E. Lindqvist, J. Luthman* and L. Olsson. Dept. of Histology & Neurobiology, Karolinska Institute, Stockholm, Sweden.

Methylmercury (8 mg/kg i.p.) was injected in adult Sprague-Dawley male rats. After 4 h animals were decapitated, and brains were dissected out and frozen on dry ice. Coronal sections at the dorsal hippocampal level were hybridized in situ with oligonucleotide probes for heat-shock protein 70 (HSP70), heat-shock cognate protein (HSC70) or nerve growth factor (NGF) family members. Heat-shock proteins may function to protect cells from the adverse consequences of heat and other stresses. HSC70 mRNA was observed in most nerve cell populations of control brains. In contrast, only little HSP70 mRNA was found in control hippocampus. No significant effect on the induction of HSP70 mRNA was seen after the methylmercury administration, although a tendency to reduced HSC70 mRNA was observed in the dentate gyrus (DG). Growth factors are known to exert striking effects on neuronal survival and neurite outgrowth. Specific sets of neurons in the brain have been demonstrated to synthesize proteins belonging to the NGF family, namely NGF, BDNF (brain-derived neurotrophic factor) and NT-3 (neurotrophin 3). BDNF mRNA was highly expressed in pyramidal neurons in hippocampus as well as in neurons of the DG. NGF mRNA was primarily expressed in neurons scattered throughout the pyramidal cell layer and stratum oriens as well as in the hilar region of the DG. NT-3 mRNA was abundantly expressed in the DG and the CA2 pyramidal cell area. No significant alterations in NGF and NT-3 mRNA hybridization patterns were observed, although a decrease in BDNF mRNA was seen in the DG. The local reduction in BDNF mRNA 4 h after methylmercury administration indicates that the DG may be more vulnerable than other hippocampal regions to an acute injection of methylmercury. Cerebellum is particularly vulnerable to exposure to methylmercury. Further investigations are under way to determine the effects of methylmercury in cerebellum at 1, 4 and 24 hours after different dosages.

685.3

EFFECTS OF DEVELOPMENTAL AND CONTINUOUS EXPOSURE TO EXCESS DIETARY ALUMINUM ON THE AUDITORY STARTLE RESPONSE OF MICE. M.S. Golub*, B. Han, C.L. Keen, and M.E. Gershwin. Dept. Internal Medicine, Univ. California Davis Sch. of Med., Davis, CA 95616.

Swiss Webster mice were exposed to a high aluminum diet (1000 µg Al/g, Al as Al lactate) from conception to weaning (20 days of age) or from conception through adulthood. Controls were fed 7 µg Al/g diet. Amplitude and habituation of an auditory startle response were assessed in separate groups of mice (6-7 males and 6-7 females per group) at 22 and 52 days of age using an automated apparatus (San Diego Instruments; 50 msec, 120 db noise; 8 sec inter-trial interval; 50 trials). Body weight was not influenced by diet. At 22 days of age, startle response amplitude was lower in Al-exposed mice than controls ($p < .02$); effects on habituation rate could not be assessed because the response had habituated by the second trial in all groups. At 52 days, response amplitude was not significantly lower in Al-exposed groups but initial habituation was more rapid than in controls. Response amplitude decreased between the first and second 5-trial block in the continuously exposed group ($p < .005$) but not in controls ($p > .10$). The developmentally exposed group had an intermediate decrease ($p < .05$). This finding supports previous reports of reduced activity and responsiveness in mice fed excess dietary aluminum. Supported by ES04190.

ALUMINUM TOXICITY IN DISSOCIATED RAT HIPPOCAMPAL NEURONS

S.R. Brenner* and K.-W. Yoon, Department of Neurology and Division of Neurosurgery, St. Louis University School of Medicine, St. Louis, MO 63110-0250

Aluminum toxicity was investigated in rat hippocampal cells upon exposure to concentrations from 10^{-3} to 10^{-12} M of $AlCl_3$. The toxicity was assessed 24 hours after a one hour exposure to the artificial CSF solution containing $AlCl_3$ by counting the cells that were stained by Trypan Blue. At 1mM, there was only minimal toxicity. However, the neuronal toxicity increased as the concentration of aluminum was decreased to 10^{-4} to 10^{-9} M, and gradually decreased though persisting even at 10^{-12} M. The neuronal toxicity to potassium cyanide which is blocked by MK801, an NMDA receptor antagonist (Sturm, et al., J. of Neurosurg., in press) was also blocked by the high concentration (10^{-3} M) of $AlCl_3$. At 10^{-12} M $AlCl_3$, MK801 (10µM) blocked the toxicity. It appears that aluminum is toxic to the rat hippocampal neurons. However at the high concentration of 10^{-3} M it exerts a protective effect against cyanide and itself. Since MK801 reduces cell death, NMDA receptor may be involved in aluminum toxicity at lower concentrations while at high concentrations aluminum may protect the cells from cyanide and its own toxicity by attenuating NMDA mediated cell injury.

VOLTAGE GATED CALCIUM CHANNEL CURRENTS IN RAT DRG AND APLYSIA NEURONS ARE REDUCED BY MERCURY (Hg^{2+}). D. Büsselberg*, Pekel, M., and B. Platt; Universität Düsseldorf, Physiology II, Moorenstraße 5, 4000 Düsseldorf, FRG.

The effects of inorganic mercury (Hg^{2+}) on voltage-gated calcium channel currents were investigated in two different preparations. We used the whole-cell patch-clamp technique with cultured rat dorsal-root-ganglion (DRG) neurons and the two-electrode voltage-clamp method for measuring calcium channel currents of abdominal ganglion neurons of *Aplysia californica*. All voltage activated calcium channel currents were irreversibly reduced by Hg^{2+} in both preparations but with different time courses.

In rat neurons there was a rapid and concentration-dependent decrease of the L/N-type current to a steady state with an IC_{50} of 1.1 µM and a Hill coefficient of 1.3. T-type currents were blocked by Hg^{2+} in the same concentration range (0.5-2 µM). Effects with effective concentrations this low of Hg^{2+} on voltage activated calcium channels have not been reported before. The IV relation of the calcium currents shifted to more positive values, suggesting a binding of Hg^{2+} to the channel protein and/or modification of gating properties. With increasing Hg^{2+} concentrations a slow membrane current was additionally activated which was most obvious at concentrations over 2 µM Hg^{2+} . This current was not reversible and might be due to the opening of other (unspecific) ion channels by Hg^{2+} .

In *Aplysia* neurons a continuous decrease of the calcium channel currents was observed during application even with low concentrations of Hg^{2+} (5 µM). A steady state was never reached. There was no obvious influence on resting membrane currents even with high concentrations (up to 50 µM) and no shift of the current-voltage (IV) relation.

We conclude that neurotoxic effects of inorganic mercury could be partially due to a reduction of voltage-activated calcium currents.

685.4

ALUMINUM-BLOCKADE OF VOLTAGE-ACTIVATED CALCIUM CHANNELS: MODULATION BY EXTRACELLULAR PH. B. Platt, M. Thewissen*, H.L. Haas and D. Büsselberg Univ. Düsseldorf, Physiology II, Moorenstr. 5, 4000 Düsseldorf, FRG.

Mammalian voltage-activated calcium channels are blocked by Aluminum (Al) in the micromolar range. The mechanism of this blockade is not yet entirely clear. A dependency of Al-toxicity on its chemical properties is considered. Therefore we examined the influence of different pH-values (pH 6.7, 7.3 and 7.7) of the extracellular solution on this effect. Significant changes of extracellular H^+ -concentration may occur during neuronal activity and under a variety of pathological conditions. Voltage-activated calcium channels were studied in rat dorsal-root ganglion (DRG) cells using the whole-cell patch clamp technique.

For pH 7.3 threshold concentration for reduction of the peak calcium channel was about 20 µM Al, with concentrations above 200 µM a blockade over 80 % was obtained. The IC_{50} for blockade of calcium channel currents was 83 µM Al and the Hill slope was calculated to be 2.2. For pH 7.7 a decrease of blockade was found with an IC_{50} of 115 µM and an Hill slope of 2.8. Increasing the H^+ -concentration to pH 6.7 induced a dramatic shift of the concentration-response relation to lower concentrations. The IC_{50} was calculated to be 21 µM and the Hill slope to be 1.5. Steady state of the reduced calcium channel currents was achieved within 1 to 5 min. In general, a faster stabilization was found for increasing Al-concentrations as well as for increasing H^+ -concentrations. Wash-out of the Al-containing solution lead to a recovery between 15 to 30%.

Modulation of the Al-effect on voltage activated calcium channels by H^+ might be related to its neurotoxicity. Beside the findings of the specificity of Al for voltage activated calcium channels, its use-dependence and the partial irreversibility of the block, the pH-modulation is another hint to the complex and wide-ranging action of Aluminum in the nervous system.

685.6

ORAL ALUMINUM ADMINISTERED DURING PREGNANCY AND LACTATION PRODUCES GASTRIC AND RENAL LESIONS IN RAT MOTHERS AND DELAY IN CNS DEVELOPMENT OF THEIR PUPS. B.K.Poulos*, M. Perazzolo*, V.M.-Y. Lee*, H.M. Wisniewski* and D. Soifer*, CSI/IBR Ctr. for Dev. Neurosci., Ctr. for Trace Metal Studies and Environmental Neurotoxicol., Staten Island, NY 10314, Univ. Penna., Phila., PA 19104.

The heavy neurofilament protein [NF-H] is developmentally regulated. For example, a monoclonal antibody (RMO 24.9) directed against a phosphorylated epitope in the tail domain of NF-H, binds to specific tracts within the rat brain stem on postnatal day one, but does not bind to tracts within the diencephalon until postnatal day 12 [P12]. A diet providing 300mg/kg/d Al (as aluminum lactate) to rat dams throughout gestation causes behavioral deficits in their offspring (Bernuzzi et al. '89). We repeated this regimen by substituting 120 mM aluminum lactate (pH 6.5) for drinking water during gestation and lactation and looked at the distribution of binding of RMO 24.9 by the developing pup CNS. Tracts within the diencephalon that normally bind RMO 24.9 on P12 did not bind the monoclonal antibody until P15. Aluminum treatment of the mothers seemed to cause a developmental delay in the expression of phosphorylated NF-H in the pups. However, the neuropathological deficits we have found - and those reported by other investigators using similar aluminum levels - may not be due to the direct effects of aluminum on the pup but rather secondary to its effects on the dam. Throughout lactation, treated dams appeared progressively more cachectic. Unlike the viscera of pair-watered controls, the stomachs of treated dams were ulcerated and their kidneys contained stones. These lesions suggest that the ability of the treated dams to absorb nutrients and to excrete toxins and regulate water and electrolytes were compromised and, by extension, that their ability to provide their pups with an adequate diet might also be compromised.

DIFFERENTIAL EFFECTS OF LOW-LEVEL LEAD ON SUSTAINED AND TRANSIENT RETINAL GANGLION CELLS IN DEVELOPING RATS. D.Y. Ruan*, L.X. Tang and C. Zhao, Dept. of Biology, Univ. Sci. Tech. China, Hefei, Anhui 230026 P.R. China

Neonatal rats were exposed to Lead from parturition to weaning via the milk of dams drinking 0.2% Lead acetate solution. The alterations in excitability and temporal response properties of retinal ganglion cells from optic tract in adult rats following developmental lead exposure were studied. 45 sustained and 24 transient cells in 11 control rats and 45 sustained and 32 transient cells in 10 lead-exposed rats were recorded. Compared with controls, electrophysiological alterations of retinal ganglion cells in lead-exposed rats showed that the mean peak response increased 83% for sustained cells and 215% for transient cells, mean optimal temporal frequency decreased 27.5% for sustained cells and 38.7% for transient cells, mean bandwidth at half amplitude decreased 29.1% for sustained cells and 40.8% for transient cells, mean temporal resolution decreased 27.5% for sustained cells and 38.7% for transient cells. No significant difference in response phase was observed between control- and lead-sustained cells. However, 0.1 cycle response phase of 37.5% transient cells in lead-exposed rats was advanced. These results indicate that lead-induced alterations in excitability and temporal response properties of transient cells were greater than that of sustained cells in retinal ganglion cells. Supported by NSFC grant 39070287 (DVR).

INTERACTIONS OF GLUTATHIONE AND LEAD (PB) IN CULTURED ASTROGLIA. L. A. Schneider, M. E. Legare, R. Barhoumi, R. C. Burghardt, and E. Tiffany-Castiglioni*. Dept. Vet. Anatomy and Public Health, College Station, TX 77840.

We have previously shown that astroglia in culture take up and store Pb intracellularly without significant cytotoxicity, suggesting that astroglia adapt to the presence of Pb. One possible mechanism of adaptation is an upregulation in the synthesis of glutathione (GSH), a tripeptide abundant in astroglia. We have recently shown by interactive laser cytometry that the cytosolic GSH content of cultured astroglia is initially depleted after brief exposure to 0.1 or 1.0 μ M Pb, after which it becomes elevated above normal levels. We also noted a decrease in mitochondrial membrane potential (MMP), which may be causally related to the transient GSH depletion. We tested the hypothesis that the a cell permeant GSH monoester would elevate intracellular GSH content as a first step in protecting astroglia from the Pb-induced decrease in MMP. The monoester failed to elevate GSH, suggesting a non-causal relationship to altered MMP.

685.11

A CHRONIC INCREASE IN CALCIUM BUT NOT SODIUM INTAKE IS OBSERVED AFTER A SINGLE SUBCUTANEOUS INJECTION OF LEAD CHLORIDE, BUT NOT BY MERCURY CHLORIDE, IN FEMALE RATS. G.F. Alheid¹, C.A. Beltramo², J. Savory³. ¹Psychiatric Medicine, ²Otolaryngology, and ³Pathology, Univ. of Virginia, Health Sciences Center, Charlottesville, Va. 22908

Heavy metals differ in crossing the blood-brain barrier depending upon their chemical species, but most metals do accumulate in circumventricular organs of the brain. Since these areas are known to be important in a variety of regulatory and reproductive functions, we are examining the impact of metal loading on a subset of these behaviors. Sodium appetite is known to be under the control of forebrain mechanisms proximal to circumventricular areas, while the chemical similarity of lead and calcium suggested the inclusion of the test for calcium ingestion. Injections of inorganic lead (25-200 mg/kg) or mercury (0.5-2.5mg/kg) were made in adult female rats. Intake of water, concentrated sodium or calcium solutions was measured during in the post-injection period. Sodium intake was unchanged from baseline, while a delayed dose-related increase in calcium ingestion occurred following only the lead injections, and which persisted for the remainder of the experiment (approximately 3 months). Since it has been reported that calcium deprived animals increase their intake of lead solutions, the present result suggests that lead intoxication could lead to a destructive positive feedback loop. SELECTIVE TOXICITY TO CENTRAL SEROTONERGIC NERVOUS SYSTEM IN PRENATALLY AND POSTNATALLY LEAD-EXPOSED RATS. D.O. Seo, E.Y. Jung, J.H. Cheong, C.Y. Shin, U.T. Oh and K.H. Ko. Department of Pharmacology, College of Pharmacy, Seoul National University, Seoul 151, Korea.

Possibility whether lead ingestion can cause selective toxicity to central serotonergic nervous system in rats was tested. Three groups of wistar rats; 1) Control, 2) Low dose and 3) High dose groups, were prepared. In prenatally lead-exposed rats, until parturition from dams, rat pups were intoxicated via placenta of mother rats having received drinking water containing either 0% (control), 0.05% (low dose) or 0.2% (high dose) of lead acetate respectively. In postnatally lead-exposed rats, right after parturition from dams rat pups received drinking water containing either 0% (control), 0.05% (low dose) or 0.2% (high dose) of lead acetate. At 2, 4, 6 and 8 weeks of age, tryptophan hydroxylase (TPH) activity and Na⁺/K⁺-ATPase activity were measured in 4 areas of rat brain: Telencephalon, Dienecephalon, Midbrain and Pons/Medulla. TPH activities were assayed by modified method of Beavers *et al.* (1983) using L-[5-³H]-tryptophan as substrate. TPH activity was determined as a criterion of lead poisoning to central serotonergic nervous system and Na⁺/K⁺-ATPase activity as a criterion of nonspecific lead poisoning to any kinds of tissues. Selective toxicity of lead poisoning to central serotonergic nervous system was evaluated by the changes of TPH activities without concomitant changes of Na⁺/K⁺-ATPase activities. In prenatally lead-exposed rats, this selectivity was found in Telencephalon (2 weeks of age), Dienecephalon/Midbrain (2 weeks of age), Midbrain (4 and 6 weeks of age), Pons/Medulla (2, 4 and 6 weeks of age) in rats exposed to low dose of lead and Pons/Medulla (2 weeks of age) to high dose of lead. In postnatally lead-exposed rats, this selectivity was found in Telencephalon (8 weeks of age), Dienecephalon (8 weeks of age), Pons/Medulla (6 and 8 weeks of age) in rats exposed to low dose of lead and Pons/Medulla (8 weeks of age) to high dose of lead. These results suggest that lead poisoning may exhibit selective toxicity to central serotonergic nervous system.

ATTENTIONAL AND MNEMONIC EFFECTS OF LOW-LEVEL LEAD EXPOSURE. B.J. Strupp*, B. Saelens, T. Meyer, D. Levitsky, S. Alber and J. Barnabe. Dept. of Psychology and Div. of Nutritional Sciences, Cornell Univ., Ithaca, NY 14853.

Despite the increasing evidence that low-level lead (Pb) exposure is associated with small, but significant, IQ deficits in humans, relatively little is known about the specific cognitive processes that are affected. The animal studies that have identified specific areas of cognitive dysfunction have generally examined blood Pb (BPb) levels much higher than those commonly seen in humans. The present study was designed to study the effects of mild-moderate elevations in BPb level on several specific functions in the rat: sustained attention, distractibility, impulsivity, short-term memory, and long-term memory. Preliminary analyses revealed robust increases in impulsivity and distractibility in the lead-exposed animals, as well as a transient deficit in a delayed spatial alternation (DSA) task when delays were imposed. The attentional deficits were seen in rats with chronic BPb levels averaging as low as 19 μ g/dL, while the DSA impairment was only seen in the higher exposure group averaging 39 μ g/dL. This study substantiates anecdotal evidence that children with even modest elevations in BPb level often display symptoms characteristic of Attention Deficit Hyperactivity Disorder.

Supported by grants from NIEHS (T2ES05950A) and the March of Dimes Birth Defects Foundation (#12-0515).

GLUCOCORTICOID TREATMENT MODIFIES THE ASTROCYTES OF CHRONICALLY LEAD-EXPOSED RATS. A. Selvin-Testa, F.C. Loidl, E.M. López, J. Pecci Saavedra * Instituto de Biología Celular, Facultad de Medicina, U.B.A., Paraguay 2155, (1121) Buenos Aires, República Argentina.

Chronic lead exposure (1% lead acetate solution-started when rat pups were 7 days old) increased the concentration of glial fibrillary acidic protein (GFAP) in astrocytes of the hippocampus. Glucocorticoids regulate the expression of the GFAP in physiological conditions, but it is not clear how the excessive exposure to hydrocortisone (HC) affects hypertrophic astrocytes in the hippocampus. 3-month lead-intoxicated male rats were injected daily with HC (5 mg/100g s.c.) or its vehicle for 15 days. Rats were sacrificed at 1, 7, 14, 21, and 30 days after the last dose of HC. GFAP immunohistochemistry and computerized image analysis were used to study astroglial morphology. After 1, 7 and 14 days of HC administration, the positive-GFAP cells showed a shape and distribution similar to that of hypertrophic astrocytes (mean area: 191.78 \pm 5.01 μ m²). The astroglial area decreased after HC administration to 150.61 \pm 2.50 μ m². The decrement of GFAP was similar to that seen in the normal HC treated astrocytes: 80.67 \pm 4.54 μ m² versus 131.74 \pm 2.50 μ m² in control rats. Such decrease of GFAP in the hypertrophic astrocytes after HC treatment showed values close to those seen in normal ones. The observed HC effects probably improved specific glial functions.

MANGANESE TOXICITY: EXCITATORY AMINO ACIDS RECEPTORS IN MOUSE BRAIN. G. Cano and E. Bonilla*. Fundacite-Zulia and Inst. de Inves. Clínicas, Univ. del Zulia, Maracaibo, Venezuela.

Chronic manganese poisoning is characterized by neuronal destruction of the striatum, as well as degeneration of substantia nigra and cortex. Since it is known that primary corticostriatal neurotransmitters are excitatory amino acids (EAA), we analyzed the (^3H) -Glutamate (Glu) binding to the NMDA, Quisqualate (Quis) and Kainate (Kai) receptor subtypes and also the total Glu receptors on mouse brain, using "in vitro" quantitative autoradiography.

Male albino mice were injected i.p. with manganese chloride (5mg Mn/Kg/day) five days per week, during eight weeks. Control animals were treated with saline. Binding procedures were carried out using (^3H) -Glu 20 nM as a ligand, in the presence or absence of NMDA (100 μ M), Quis (2.5 μ M) and Kai (10 μ M). Non specific binding was determined using 1nM Glu. Among all the regions studied, Glu receptors were significantly decreased in cortex, olfactory nucleus (ON), lateral septum (LS), striatum, hippocampus (Hp) and cerebellum of intoxicated animals. NMDA receptors were reduced in olfactory bulb, ON, cingulate cortex, LS and Hp. Quis receptors were decreased in orbital and frontal cortex, globus pallidum, Hp and cerebellum. It was difficult to quantify Kai receptors due to the weak signal obtained.

The decrease in EAA binding could be caused by neuronal destruction, a decreased receptor synthesis in these areas or by down-regulation of receptor binding sites due to increased glutamatergic activity. Given the potential neurotoxicity of Glu, the changes in the EAA receptor densities found in different regions may help to explain the damage in the brain of manganese treated animals.

EFFECTS OF NMDA ANTAGONIST AND NON-NMDA ANTAGONIST ON TRIMETHYLITIN INDUCED BRAIN DAMAGE.

N. Ishida, H. Kanai, N. Kato*, A. Masui, M. Akaike and S. Tsutsumi. Dept. of Psychiatry, Shiga Univ. of Med. Science, Otsu 520-21 and Pharma Res Labs., Hoechst Japan Ltd., Kawagoe 350, Japan.

Male rats were treated with trimethyltin hydroxide (TMT, 9mg/kg, p.o.) and then MK-801 as a NMDA antagonist (0.5 or 1.0 mg/kg, i.p.) or an analogue of Joro spider toxin as a putative non-NMDA antagonist (1-naphthyl acetyl spermine; 1-NA-Spm, 20ug, icv) was injected. Depth EEG electrode was implanted into the right hippocampus and the seizure susceptibility was tested by subthreshold dose of pentylenetetrazol (PTZ, 30mg/kg, i.p.). The susceptibility for PTZ-induced seizure elevated after TMT administration with the maximal effect at 4 post-TMT days. Histological examinations revealed marked loss of hippocampal CA 3/4 pyramidal cells after TMT. While MK-801 showed no antagonizing effect on PTZ-seizure, 1-NA-Spm exacerbated the seizure susceptibility to PTZ exposure. The loss of pyramidal cells was less marked in 1-NA-Spm injected side than in the contralateral side. It is suggested that the hippocampal lesion induced by TMT is mediated by non-NMDA receptors.

DISTRIBUTION OF GLIAL FIBRILLARY ACIDIC PROTEIN (GFAP) IMMUNOREACTIVE ASTROCYTES IN RATS EXPOSED TO TRIMETHYLITIN (TMT) AT SEVERAL POST-EXPOSURE TIME INTERVALS. R. L. Qualls, R. H. Baisden and M. L. Woodruff*. Department of Anatomy, J. H. Quillen College of Medicine, East Tennessee State University, Johnson City, TN 37614.

Based largely on the effects of TMT in rodents expression of GFAP by astrocytes has been proposed as a sensitive indicator of exposure to neurotoxins. But a detailed description of TMT-induced GFAP within specific neocortical areas of the rat brain has not been reported. The areal and laminar distribution of GFAP-immunoreactive astrocytes within the cortex of rats (5 per time period and 5 controls) 3, 5, 10, 15, 20, and 30 days after exposure to 6 mg/kg TMT (p.o.) was studied. The ABC immunocytochemical procedure was used to visualize GFAP. The number of GFAP-immunoreactive astrocytes increased from day 3 through day 15, and decreased by day 30. The orbital frontal, pyriform and entorhinal cortices showed more GFAP-positive astrocytes than other cortical areas and superficial layers of cortex had more GFAP than deeper layers at early time points. These results confirm that GFAP is a good marker for dynamic changes occurring in cortex after TMT. (Supported by PHS Grant ES 04070-07 to MLW)

SELECTIVE DEGENERATION OF CA1 PYRAMIDAL CELLS BY CHRONIC APPLICATION OF BISMUTH. Michael Müller*, Lotty Rietschin, Franziska Grogg, Peter Streit and Beat H. Gähwiler. Brain Research Institute, University of Zurich, Switzerland.

Many neurodegenerative disorders in the brain are characterized by the loss of particular populations of neurons in specific brain regions. We report a new type of selective neuronal degeneration which is induced by a heavy metal and which shares some common aspects with those seen following hypoxia and ischemia. Continuous application of 3 μ M bismuth tartrate to organotypic slice cultures of rat hippocampus resulted after 2 - 3 weeks in a selective degeneration of CA1 pyramidal cells, while only few CA3 pyramidal and subicular cells were affected. At 10 μ M bismuth, the cytoarchitecture of the culture was completely destroyed. Incubation with comparable concentrations of sodium tartrate did not induce degeneration. Furthermore, acute application of 100 μ M bismuth did not change the electrophysiological properties of CA1 pyramidal cells. Interestingly, an important subclass of hippocampal interneuron, the GABAergic cells, were slightly less sensitive to bismuth than neighbouring pyramidal cells as assessed by post-embedding immunocytochemistry on thin sections.

Effects of neonatal exposure to trimethyltin on auditory and associative processes in the rat: Evidence from reflex modification procedures. Ellen S. Goldey and Kevin M. Crofton*. Neurotoxicology Div., MD-74B, U.S. EPA, RTP, NC, 27711.

Trimethyltin (TMT) is an organotin compound which is neurotoxic to adult and developing rats. The present study assessed the effects of neonatal TMT exposure on auditory thresholds, auditory temporal acuity and associative conditioning. Long-Evans male and female rat pups were acutely exposed to 0 (vehicle control) or 6 mg/kg TMT on postnatal day (PND) 5 and were tested as young adults (PND 60 - 70). Auditory thresholds for 1, 5 and 40 kHz tones were determined using reflex modification audiometry. In a separate group of animals, auditory temporal acuity was assessed using an associative conditioning paradigm. Animals were tested over 7 consecutive days by pairing an eliciting stimulus (120 dB, 13 kHz) with an antecedent gap in background noise (80 dB, white noise) of variable duration (0, 2, 4, 6, 8, 10 and 20 msec; 190 msec inter-stimulus interval).

Whereas rats given TMT as adults showed only high-frequency hearing loss (Crofton et al., 1990), early postnatal TMT exposure resulted in a 20-30 dB increase in auditory thresholds at all frequencies tested. This finding suggests that the developing auditory system may be more sensitive to TMT ototoxicity than the mature system. By the seventh day of gap testing, control and TMT animals showed very similar response inhibition across all gap durations, indicating that TMT did not affect auditory temporal acuity. However, whereas control animals demonstrated significant gap inhibition by day two, and maximal inhibition by day 4, TMT-exposed rats showed significantly less inhibition than controls until day 7. These findings support earlier work suggesting that a learning component is involved in gap perception (Crofton et al., 1990), and indicate that relative to controls, TMT-exposed animals required more training before achieving maximal performance in this task. Whether impaired performance in the associative conditioning procedure is causally related to the auditory deficits remains to be determined.

THE EFFECT OF LEAD ON CAMK OF RAT HIPPOCAMPAL SLICES. Y. Z. XU*, N. LIU, Y. B. JIANG, Y. WU, D. Y. RUAN DEPT. OF BIOLOGY, UNIV. OF SCIENCE & TECH. OF CHINA, HEFEI, ANHUI, P. R. CHINA.

Pregnant rats were treated with lead (0.2% lead acetate) daily. The newborns received lead through milk from 1 day until 28 days of age. Compared with latent period of the slices of the control and the poisoning rats. The control rats was 2.33 ± 0.85 ms (n=6), but the poisoning was 3.02 ± 0.85 ms (n=9). The excitability of the lead poisoning rats was more than that of the control rats. Before tetanic stimulation, the PS amplitude of the control was 0.98 ± 0.33 mv (n=4), but that of the poisoning was 1.42 ± 0.23 mv (n=4). After tetanic stimulation 20 minutes, the amplitude of PS of the control rats increased by 3.03 times, but the lead poisoning slices increased by 1.87 times. These results suggested that the amplitude of LTP of the lead poisoning rats was less than that of the control rats. For the lead poisoning rats, after LTP maintaining 20 minutes the amplitude of PS decreased. According to the results, there are effects of lead on the acceptor of the postsynapse membrane, and therefore on the depolarization of it, that resulted in the delayed latent period. According to the mitochondrion hypothesis, there are effects of lead on CAMK and therefore the PS amplitude is reduced during LTP.

686.1

REPEATED EXPOSURE TO CYANIDE ATTENUATES PENTYLENTETRAZOLE (PTZ) SEIZURES AND FOS INCREASE IN RATS. G. Pavlakovic*, A. Kanthasamy and G. E. Isom, Department of Pharmacology and Toxicology, Purdue University, West Lafayette, IN 47907.

Prolonged exposure to cyanide leads to pathohistological changes in select brain areas. These changes may alter CNS response to physiological and pharmacological stimuli. In order to test this hypothesis, the ability of rats treated for 8 days with KCN (5 mg/kg, ip.) or saline to respond to a convulsant challenge (PTZ) was assessed. The ED50 for PTZ-induced clonic seizures was almost doubled in the cyanide pretreated animals, while ED50 for clonic-tonic seizure induction was increased by 50%. In control, but not cyanide-treated animals, PTZ (60 mg/kg, ip.) produced an increased expression of Fos in pyriform and cingulate cortex and dentate gyrus of hippocampus. These data show that multiple dosing of cyanide increases the threshold for PTZ-induced seizures. Further, the ability of cells in select brain areas to increase their Fos levels is reduced in cyanide-treated animals. (Supported by NIH Grant ESO4140)

686.3

A NEUROTOXIC REGIMEN OF METHAMPHETAMINE DAMAGES STRIATAL DOPAMINE TERMINALS AND DECREASES RADIOLIGAND BINDING TO STRIATAL GLUTAMATE RECEPTORS. S.J. O'Dell*, F.B. Weihmuller, A.J. Eisch, J. Ulas, C.W. Cotman and J.F. Marshall. Dept. of Psychobiology, University of California, Irvine, CA 92717.

Multiple injections of methamphetamine (m-AMPH) [4 mg m-AMPH/kg (sc) at 2 hr intervals for a total of 4 injections] produces large increases in striatal dopamine (DA) overflow and subsequent damage of striatal DA terminals. The involvement of striatal glutamate synapses in this process is suggested by: 1) neurotoxic schedules of m-AMPH produce a delayed but prolonged increase in striatal glutamate overflow and 2) NMDA receptor antagonists can protect against m-AMPH-induced striatal DA terminal damage. We used quantitative receptor autoradiography to determine the relationship between m-AMPH-induced damage to striatal DA terminals and alterations in radioligand binding to striatal glutamate receptors (NMDA and kainate subtypes). Rats given a neurotoxic regimen of m-AMPH showed marked reductions in [3H]mazindol-labeling of DA terminals in the ventral (-35%) and lateral (-43%) regions of the striatum with sparing of nucleus accumbens DA terminals. Adjacent striatal sections from these animals showed decreases in radioligand binding to NMDA and kainate receptors, with the greatest reductions found in the dorsal (-27%) and medial (-25%) striatum. Regional mismatches between losses of [3H]mazindol binding and decreases in striatal glutamate receptors suggest that the changes seen in glutamate receptors are not a direct consequence of DA terminal injury.

686.5

THE ONTOGENY OF 3,4-METHYLENEDIOXYMETHAMPHETAMINE (MDMA)-INDUCED NEUROTOXIC SENSITIVITY IN THE RAT. H.W. Broening, L. Bacon, W. Slikker, Jr. Div. of Toxicology, Univ. of Arkansas Medical Science, Little Rock, AR 72205 and Div. of Neurotoxicology, Nat. Center Toxicological Res., Jefferson, AR 72079.

The ontogeny of neurotoxic sensitivity to MDMA was studied in the rat to determine if the development of such sensitivity coincided with the development of the serotonergic neurotransmitter system. Sprague Dawley rats were dosed orally with 40 mg/kg MDMA at various stages of development and adulthood. 5-HT and 5-HIAA levels and [³H]paroxetine (PRX) receptor binding (5-HT reuptake carrier) were evaluated at several time points after treatment. MDMA administered at postnatal day (PND) 10 acutely reduced 5-HT and 5-HIAA levels by 78% and 62%, respectively, in frontal cortex (FC), which recovered to control levels within 72 hours. No changes in PRX binding were observed. MDMA administered at PND 40 acutely reduced 5-HT and 5-HIAA levels by 89% and 76%, respectively, in FC. At one week, 5-HT and 5-HIAA levels were still reduced by 40% and 32%, and PRX binding was decreased by 21%. MDMA administered at PND 70 acutely reduced 5-HT and 5-HIAA levels by 87% and 76%, respectively, in FC. At one week, 5-HT and 5-HIAA levels were still depleted by 59% and 51%, and PRX binding was decreased by 40%. The development of the serotonergic neurotransmitter system (characterized by the ontogeny of 5-HT levels, 5-HT receptor populations, tryptophan hydroxylase activity, 5-HT reuptake sites, etc.) is approximately 70%-80% complete by PND 21 in the rat. These results demonstrate that MDMA can acutely deplete 5-HT and 5-HIAA at an early age in the rat, but that neurotoxic sensitivity to MDMA develops only after the majority of serotonergic development has occurred.

686.2

CYANIDE-INDUCED DOPAMINERGIC TOXICITY IN MICE A.G. Kanthasamy*, J.L. Borowitz, J.J. Turek¹, G. Pavlakovic and G.E. Isom, Dept of Pharmacol & Toxicol., ¹Dept of Vet. Anatomy, Purdue Univ., W. Lafayette, IN 47907.

Our previous studies demonstrate that cyanide produces a dose-dependent release and depletion of dopamine (DA) in PC12 cells. In humans, cyanide can produce a delayed and progressive Parkinsonism following acute intoxication. These observations suggest that cyanide interacts with the central dopaminergic system. Preliminary studies indicated that subchronic cyanide treatment produces dopamine depletion in striatum and induces locomotor dysfunction in mice. To study whether cyanide produces neuronal damage in basal ganglia, mice were treated with cyanide (KCN, 6 mg/kg, sc) twice a day for 7 days and 16 hrs after the last dose histological observations were made in striatum and substantia nigra. Brain sections were made at 10 and 50 micron thickness and processed for thionin nissl staining and immunohistochemical staining using tyrosine hydroxylase (TH) antibody. Thionin staining in striatum showed a bilateral vacuolation indicating neuronal damage. TH immunohistochemical examination of brains from cyanide treated mice had a reduced number of TH-positive cells in the substantia nigra, indicating loss of dopaminergic cell bodies. These changes were noted in 30-35% of cyanide treated animals, suggesting a sub population of animals are susceptible to neurotoxic lesions. These findings indicate that the loss of dopaminergic neurons are associated with DA depletion and behavioral changes following subchronic cyanide exposure. (supported by NIH grant ESO4140).

ALTERATIONS IN STRIATAL GLUTAMATE RECEPTORS FOLLOWING 6-OHDA-INDUCED DAMAGE TO NIGROSTRIATAL DOPAMINE NEURONS. F.B. Weihmuller*, S.J. O'Dell, and J.F. Marshall. Dept. of Psychobiology, Univ. of California, Irvine, CA 92717 USA

Recent evidence suggests that an important modulatory relationship exists between the nigrostriatal dopamine (DA) and corticostriatal glutamate (GLU) systems. This relationship has recently been highlighted by the finding that L-[3H]glutamate binding to the NMDA receptor subtype is elevated in Parkinsonian striatum. The present study used the 6-OHDA-treated rat to determine whether loss of nigrostriatal DA neurons induces GLU receptor changes in the striatum. Rats were given unilateral intracerebral injections of 6-OHDA, sacrificed 1 week or 1 month later and their brains processed for quantitative receptor autoradiography using [3H]mazindol (15 nM) to label striatal DA terminals, L-[3H]glutamate (200 nM) to label NMDA receptors and [3H]kainate (50 nM) to label kainate receptors. In the 6-OHDA-injected hemisphere, rats had 95% or greater loss of [3H]mazindol binding to striatal DA terminals accompanied by a small (5-10%) but statistically reliable ($p < .01$) reduction of glutamate binding to NMDA receptors as compared to the intact hemisphere. Moreover, these animals had a small but statistically significant increase (5%; $p < .01$) in striatal [3H]kainate binding in the 6-OHDA-injected as compared to the intact hemisphere. These results suggest either that a small population of NMDA receptors (5%) exist on striatal DA terminals or that the DA terminals help maintain postsynaptic NMDA receptor expression. The bases for differences between 6-OHDA-treated rats and Parkinsonian tissue will be discussed.

NEUROTOXICITY PROFILES OF SUBSTITUTED AMPHETAMINES IN THE C57/B16/J MOUSE. J. P. O'Callaghan* and D.B. Miller. U.S. Environmental Protection Agency, Research Triangle Park, NC 27711.

Dopaminergic (DA) and serotonergic (5-HT) neurons have been implicated as the primary targets of amphetamine-induced neurotoxicity, however, unequivocal evidence of damage to these systems has been difficult to obtain. Here, we evaluated the potential neurotoxic effects of methamphetamine (D-METH), methylenedioxyamphetamine (D-MDA), methylenedioxyamphetamine (D-MDMA) and fenfluramine (D-FEN) in the C57/B16/J mouse. Astrogliosis and argyrophilia were taken as indices of amphetamine-induced neural damage. Astrogliosis was quantified by assaying glial fibrillary acidic protein (GFAP); the silver degeneration stain of de Olmos was used to detect argyrophilic neurons. Assays of tyrosine hydroxylase (TH), DA and 5-HT were used to assess effects on DA and 5-HT systems. Mice received either D-METH (10 mg/kg), D-MDA (20 mg/kg), D-MDMA (20 mg/kg) or D-FEN (25 mg/kg) every 2 hours for a total of 4 s.c. inj. D-METH, D-MDA and D-MDMA caused a large (300%) increase in striatal GFAP that resolved by 3 weeks and a 75% decrease in TH and DA that did not resolve. D-METH, D-MDA and D-MDMA also caused terminal degeneration in striatum as revealed by silver staining. D-FEN did not affect any parameters in striatum. D-METH, D-MDA and D-MDMA also increased GFAP in cortex, effects which were associated with small (10-25%) and transient decrements in cortical 5-HT. D-FEN caused prolonged (weeks) decrements (20%) in cortical 5-HT but did not affect any other measures. The effects of D-METH, D-MDA and D-MDMA were blocked by pretreatment with MK-801. The L-forms of all compounds did not affect any measure. D-METH, D-MDA and D-MDMA, but not D-FEN, appear to be toxic to neural elements of mouse striatum and cortex.

686.7

ENVIRONMENT-, STRESS- AND DRUG-INDUCED ALTERATIONS IN BODY TEMPERATURE AFFECT THE NEUROTOXICITY OF SUBSTITUTED AMPHETAMINES IN THE C57/B16/J MOUSE. D. B. Miller and J. P. O'Callaghan, U.S. Environmental Protection Agency, Research Triangle Park, NC 27711

The putative toxic effects of substituted amphetamines (AMPs) in the rat have been linked to an elevation of core temperature (CT). Here, we examined the influence of CT changes on the potential neurotoxic effects of methamphetamine (D-METH), methylenedioxymethamphetamine (D-MDMA) and fenfluramine (D-FEN) in the C57/B16/J mouse. Astroglia, quantified by immunoassay of glial fibrillary acidic protein (GFAP), was taken as an index of AMP-induced neural damage. Assay of dopamine (DA) was used to assess effects of AMPs on the striatal DA system. Female mice were given D-METH, D-MDMA or D-FEN at a dosage (s.c., as the base) of 20.0, 10.0, or 25.0 mg/kg, respectively. An inj of AMPs or saline vehicle was given every 2 hrs beginning at 11:30 AM for a total of 4 inj. Mice were restrained in plastic 50 ml centrifuge tubes at 22°C or single-housed with no bedding at 15 or 22 °C. In mice housed at 22°C, D-METH and D-MDMA elevated CT 1.0 °C and D-FEN and restraint lowered CT by as much as 3°C. At this housing temp (22°C), D-METH and D-MDMA caused a large (300%) increase in striatal GFAP and a large (75%) decrease in striatal DA at 72 hrs after the last inj.; D-FEN and restraint did not alter striatal GFAP or DA. In mice housed at 15°C, D-METH and D-MDMA did not elevate CT, increase GFAP or decrease DA. Restraint or administration of D-FEN prior to each inj of D-MDMA blocked (restraint) or attenuated (D-FEN) the D-MDMA-induced increase in GFAP and the decrease in DA in mice housed at 22°C. The glutamate antagonist, MK-801 (1.0 mg/kg x 2 inj.), which blocked the D-METH and D-MDMA increase in GFAP and decrease in DA at 22°C, did not alter CT when given alone. When MK801 was given in combination with D-METH and D-MDMA, however, CT fell by as much as 3°C. The data suggest that an elevation in CT is an important determinant of the dopaminergic neurotoxicity of D-METH and D-MDMA in the mouse.

686.9

THE ROLE OF BODY TEMPERATURE IN METHAMPHETAMINE (METH) LETHALITY AND NEUROTOXICITY, AND IN THE EFFECTS OF COMPOUNDS WHICH PROTECT AGAINST SUCH NEUROTOXICITY. R.R. Holson*, B. Gough, G. Newport, W. Slikker Jr. and J.F. Bowyer, Div. of Develop. Toxicol. and Neurotoxicol., NCTR/FDA, Jefferson, AR 72079-9502.

Repeated exposure to METH (5mg/kg, 4 times at 2 hr intervals) increases body temperature, sometimes producing extreme hyperthermia (41°F and above) and lethality, and depletes striatal dopamine (DA). The magnitude of striatal DA depletions correlates ($r = -0.58$) well with the peak body temperatures attained during METH administration. This correlation may be causal, since increased room temperature (27°C) substantially increases METH-induced body temperature and DA depletion. Further, several agents, including haloperidol and diazepam, diminish the METH-induced hyperthermia, DA depletions and lethality. The correlation between maximum body temperature and DA depletion remains high even with these protective agents present, and the DA depletion for a given maximum temperature is almost that of METH alone. Therefore, protection from METH-induced DA depletion by these compounds may be solely through reducing METH-induced hyperthermia.

At 50 mg/kg the interleukin-1 receptor antagonist (IL-1ra, from Synergen Inc.), decreased the incidence of lethal hyperthermia produced by METH without substantially reducing striatal DA depletion, or the correlation between body temperature and DA depletion. Therefore, the thermogenic effects of METH may play a role in the lethality and striatal DA depletions produced by METH, and pharmacological protection against these effects often involves a reduction in the hyperthermia produced by METH.

686.11

Differential effects of amfonelic acid on dopaminergic nerve terminal degeneration and reactive astroglia induced by methamphetamine in rat striatum C. Pu, J. E. Fisher, C. V. Vorhees*, Children's Hosp. Res. Found. and Neurosci. Prog. Univ. Cincinnati, Cin., OH 45229.

Administration of methamphetamine (MA) induces degeneration of dopaminergic terminals and astroglia, such as hypertrophy and increase in apparent number, in the neostriatum. In this experiment adult rats were treated with MA (10 mg/kg, i.p.) 4 times in one day at 2 hour intervals. Amfonelic acid, a dopamine reuptake blocker, was administered (20 mg/kg, i.p.) at the same time the last MA dose was given. Three days later, dopaminergic terminals and astrocytes were examined immunohistochemically. The contents of striatal dopamine and its metabolites were analyzed by HPLC 7 days after treatment. The results showed that MA alone induced the typical depletion of dopaminergic terminals, reduction of dopamine content and astroglia in the neostriatum. Amfonelic acid treatment completely prevented the effects of MA on the dopaminergic system, both morphologically and biochemically. However, the reaction of astrocytes remained in the region where the most severe depletion of dopaminergic terminals was seen in MA treated animals (ventral lateral portion of neostriatum). The results support the concept that dopamine reuptake is involved in the MA-induced dopaminergic nerve terminal degeneration. The results also indicate that blocking DA reuptake cannot prevent the reaction of astrocytes in the neostriatum, which indicates that the astrocytic reaction can be induced by factors other than degeneration of dopaminergic terminals in this region.

686.8

6-HYDROXYDOPAMINE (6-OHDA or 6-HDA) NEUROTOXICITY: INVESTIGATIONS INTO THE MODE OF ACTION. RUSSELL J. LEWIS, SU MA, DONG-DONG ZHANG, R. RHAGAVAN, ROLAND E. LEHR, and C. LEROY BLANK*, Department of Chemistry & Biochemistry, University of Oklahoma, Norman, OK, USA, 73019.

Following a previous report on the peripheral neurotoxic effects of various 6-HDA analogs (J.-P. Tranzer & H. Thoenen, *Experientia*, (1973) 29, 314-5), we have synthesized and tested a series of 6-HDA related species to, hopefully, establish relationships between the observed destruction and the chemical and/or physical nature of the toxins. The extent of destruction afforded by a toxin was measured as both the ability to create long-term depletion of the endogenous transmitter substance (NE, DA, and 5-HT) and the ability to create long-term disruption in the transport of the endogenous transmitter. The chemical properties examined to establish quantitative relationships to these long-term effects included (1) the ability to effect *in vitro* blockade of the transporter for the transmitter, (2) the ease of oxidation of the toxin, (3) the reactivity of the oxidized form of the neurotoxin with respect to attack by nucleophiles, (4) the autooxidation of the neurotoxin and concomitant production of malevolent oxygen species, and (5) similar effects for oxidation products of the parent toxin. Initial results indicate surprisingly poor correlations between the extent of destruction and either the ability of the neurotoxin to block transport or the ease of oxidation of the neurotoxin. Uptake blockade is, thus, a necessary but not sufficient condition for the neurotoxic properties of these compounds. Quantitative predictions of the degree of neuronal loss afforded by such neurotoxins may require a more complex combination of a number of the chemical properties possessed by such species.

686.10

EFFECTS OF NITRIC OXIDE SYNTHETASE (NOS) INHIBITION AND ADENOSINE (AD) RECEPTOR ANTAGONISM ON EXTRACELLULAR DOPAMINE (DA) LEVELS DURING METHAMPHETAMINE (METH) EXPOSURE. B. Gough*, R.R. Holson, W. Slikker Jr. and J.F. Bowyer, Div. of Repr. & Develop. Toxicol. and Div. of Neurotoxicol., NCTR/FDA, Jefferson, AR 72079-9502.

When 100 μ M nitro-arginine (N-ARG, a NOS inhibitor) was present in the microdialysis buffer for 2 hrs no effects on the extracellular levels of DA, DOPAC or HVA in the striatum were observed. However, the subsequent increase in extracellular DA produced by 4 sequential doses of METH (5 mg/kg i.p./2 hrs) was reduced by approximately 50%. The inclusion of 100 μ M L-ARG in the microdialysis buffer did not markedly enhance DA levels in the absence or presence of METH. In contrast, neither N-ARG or L-ARG (1 to 100 μ M) affected either 5 or 50 μ M METH-evoked release of [³H]DA from striatal slices. Therefore, *in vivo* the N-ARG inhibition of METH-evoked DA release, possibly due to NOS inhibition, may be mediated by either multi-neuronal activity or changes in blood and CSF circulation. The effects of the AD receptor antagonist 8(p-sulfophenyl)theophylline (at 2 to 200 μ M) were similar to that of N-ARG in that *in vivo* it had no effect on extracellular DA release in the absence of METH but decreased extracellular DA levels during METH exposure. Other investigators have observed that adenosine inhibits DA release via presynaptic mechanisms *in vitro*, therefore, the effects of the AD antagonist *in vivo* appear to again be mediated by either multi-neuronal activity or changes in blood and CSF circulation. The results of these studies indicate that multi-neuronal pathways may play a role in the *in vivo* release of DA evoked by METH.

686.12

THE PRETREATMENT OF RATS WITH ACETONE POTENTIATES THE SEROTONIN DEPLETING EFFECT OF 3,4-METHYLENEDIOXYAMPHETAMINE (MDA). R. E. Michel* and W. J. George, Department of Pharmacology, Tulane University School of Medicine, New Orleans, Louisiana, 70112.

The neurotoxicity associated with the administration of 3,4-methylenedioxyamphetamine (MDA) is thought to be produced by a metabolite of the parent compound and not by MDA directly. The objective of this study was to investigate the role of cytochrome P450 activity in the mediation of the neurotoxicity induced by MDA. Cytochrome P450 activity was induced by pretreating animals with 1% acetone that was added to their drinking water. Acetone induces several P450 isozymes including P4501A2, P4502B1/2, and P4502E1. Male Sprague Dawley rats were exposed to acetone through their drinking water for seven days. Exposed animals were compared to a control group that received tap water without acetone. Following the seven day pretreatment period, animals in both groups received 20 mg/kg MDA, subcutaneously. The animals were sacrificed 7 days post drug administration (day 14) and selected brain regions were analyzed for serotonin and 5-hydroxyindole acetic acid (5-HIAA) content. Animals that were pretreated with 1% acetone had significantly lower serotonin and 5-HIAA levels than control animals in all brain regions assayed (5-40% of control values). The present findings indicate that P4501A2, P4502B1/2 or P4502E1 may be involved in the formation of a neurotoxin responsible for the serotonergic toxicity associated with the use of MDA.

686.13

PREFERENTIAL INJURY TO TYROSINE HYDROXYLASE IMMUNOREACTIVE FIBERS OF THE VENTRAL CAUDATE-PUTAMEN [CPu] AFTER A NEUROTOXIC METHAMPHETAMINE REGIMEN. **A.J. Eisch***, **F.B. Weihmuller**, **J.F. Marshall**. Dept. of Psychobiology, University of California, Irvine, CA 92717.

Repeated administration of moderate doses of methamphetamine [m-AMPH] injures dopaminergic afferents to the striatum, as indicated by changes in striatal dopamine [DA] content, DA metabolites, DA uptake sites, tyrosine hydroxylase [TH] activity and TH-immunoreactivity. Of particular interest to us is the fact that striatal subregions are differentially vulnerable to the neurotoxic effects of m-AMPH (Eisch et al., *Br. Res.* 598: 321-6, 1992). The ventral CPu, but not the nucleus accumbens or the dorsal CPu, shows a significant loss of DA content and DA uptake sites one week after m-AMPH administration. Here, we extend the characterization of m-AMPH-induced neurotoxicity by examining TH-immunoreactivity and DA content separately in the two hemispheres of rats given m-AMPH (4 s.c. injections of 4 mg/kg, 2 hrs apart). A regionally-selective decrease in striatal DA content was accompanied by a similar pattern of TH-immunoreactivity one week after the m-AMPH regimen. Specifically, both measures were decreased in the ventral CPu, while the nucleus accumbens and dorsal CPu remained relatively intact. We believe the striking susceptibility of the ventral CPu will be important in understanding the processes underlying m-AMPH neurotoxicity. Several hypotheses concerning the preferential vulnerability of this region will be discussed.

ATTENUATION OF 1-METHYL-4-PHENYLPYRIDINIUM (MPP⁺) NEUROTOXICITY BY DEPRENYL (DP) IN ORGANOTYPIC CULTURES OF CANINE SUBSTANTIA NIGRA. **D.E. Schmidt***, **J.C. Lynn**, **M.H. Ebert** and **W.O. Whetsell, Jr.**, Depts. of Pathology and Psychiatry, Vanderbilt University School of Medicine, Nashville, TN 37232.

The mechanisms responsible for the neuroprotective effects of DP in 1-methyl-4-phenyl-1,2,3,6-tetrahydropyridine (MPTP) models of Parkinsonism are not clear. To determine the role of MAO-B mediated conversion of MPTP to MPP⁺, mature (43 day) organotypic cultures of canine substantia nigra were directly exposed to 100 nM MPP⁺ for 3 days in the presence or absence of 10 μ M DP. Additional cultures were incubated with 10 μ M DP for 4 days prior to similar MPP⁺ exposure. Dopamine metabolism was measured by determining HVA release (fmoles/culture/day). Morphological alterations were assessed by light microscopy. MPP⁺ exposure alone reduced HVA release by 90% as compared to pretreatment release. In contrast, HVA release in cultures previously incubated with DP, then exposed to MPP⁺, was reduced by 35%; HVA release from cultures simultaneously exposed to MPP⁺ and DP was reduced by 50%. Microscopic examination demonstrated that MPP⁺ exposure alone produced widespread neuronal damage. Such damage was reduced by simultaneous presence of DP in the culture media and this effect was greater when DP treatment preceded MPP⁺ exposure. These *in vitro* data indicate that, like previous reports of the effect of DP *in vivo* (*J Neurosci Res* 30:666, 1991), dopaminergic neuroprotection by DP in the MPTP model does not depend on blockade of conversion of MPTP to MPP⁺.

686.17

MPP⁺-LIKE NEUROTOXICITY OF A PYRIDINIUM METABOLITE OF HALOPERIDOL. **J. Bloomquist***, **E. King**, **A. Wright**, **C. Mytilineou**, and **N. Castagnoli, Jr.** Departments of Entomology¹ and Chemistry², Virginia Polytechnic Institute and State University, Blacksburg, VA 24061 and Department of Neurology³, Mount Sinai Medical Center, New York, NY 10029.

The neurotoxic action of HPP⁺, a pyridinium metabolite of haloperidol, was compared to that of MPP⁺ using cell culture and synaptosomal techniques. In 2 hr exposures of rat mesencephalic cultures to 25 μ M HPP⁺, dopamine uptake was inhibited approximately 30% and serotonin uptake about 75%. In 4 hr incubations at 50 μ M and 1 hr incubations at 100 μ M, both toxins inhibited dopamine uptake at least 80%, and this effect was accompanied by a generalized cell loss with HPP⁺, but not with MPP⁺. These data suggest that HPP⁺ may be a less selective neurotoxin at high concentrations. The interaction of MPP⁺ and HPP⁺ with aminergic transporters was studied in more detail in mouse brain synaptosome preparations. The IC₅₀ values for inhibiting dopamine uptake by MPP⁺ and HPP⁺ were 4 and 25 μ M, respectively, and for inhibiting serotonin uptake were 3 and 4 μ M, respectively. The parent compound haloperidol was much less effective, showing <20% inhibition of dopamine uptake at 300 μ M and an IC₅₀ for inhibiting serotonin uptake of 200 μ M. These results demonstrate that HPP⁺ possesses *in vitro* neurotoxic properties similar to MPP⁺, and these actions may contribute to the development of tardive dyskinesia observed in some patients given haloperidol.

686.14

IN VIVO TRANSLOCATION/ACTIVATION OF PROTEIN KINASE C (PKC) BY MDMA: A POSSIBLE LINK TO NEUROTOXICITY. **H.K. Kramer***, **J.C. Poblete** and **E.C. Azmitia**. Dept. of Biology, New York University, New York, NY 10003.

3,4-methylenedioxyamphetamine (MDMA) is a substituted amphetamine found to elicit its psychotropic and neurotoxic effects through its ability to release serotonin (5-HT) from central neurons. Interestingly, MDMA also increases the uptake of Ca²⁺ into rat brain synaptosomes, an effect independent of those which stimulate 5-HT release. Elevated levels of intracellular calcium, possibly leading to the destabilization of [Ca²⁺]_i homeostasis, has been observed in several models of delayed neuronal death. The disruption of normal [Ca²⁺]_i levels may begin a cascade of metabolic events that eventually contribute to neuronal degeneration. One of these events is the translocation/activation of the phospholipid and Ca²⁺-dependent protein kinase C (PKC). It was our desire to examine if acute MDMA administration had an effect on the translocation/activation of PKC *in vivo*, in order to elucidate the precise metabolotropic events that underlie MDMA-induced neuropathology.

Male Sprague-Dawley rats were injected twice (10 hrs. apart) with either saline or MDMA (25 mg/kg, s.c.). 24 and 48 hours after the last injection the animals were sacrificed, their brains removed, and subsequently assayed for PKC translocation by high-affinity [³H]phorbol-12,13-dibutyrate (³H-PDBu; 20.0 Ci/mmol) binding to cortical membrane fractions.

At 24 hrs., ³H-PDBu binding demonstrated a K_d of 11.44 nM and a B_{max} of 7.58 pmol/mg prot. (saline treated) and 18.94 nM and 13.81 pmol/mg prot. (MDMA treated). MDMA treatment produced an 82.2% increase in the amount of membrane-bound ³H-PDBu binding sites. By 48 hrs., no significant difference was observed between the two treatment groups.

Our results indicate that acute, *in vivo* MDMA exposure produces a transient increase in the translocation of PKC from the cytosol to the plasma membrane (believed to be an indicator of PKC activation). Pathological PKC translocation/activation has been hypothesized to contribute to glutamate excitotoxicity in cerebellar neurons by allowing the enzyme prolonged proximity to many of its Ca²⁺-dependent substrate proteins (Favaron et al., 1990). These preliminary results provide further information on the metabolic effects of MDMA. (NIDA contract # 271-90-7403)

PHARMACOKINETICS AND NEUROTOXICITY OF MPTP IN THE BRAIN OF CHICK EMBRYO. **A. B. Naini**, **H. Jiang**, **L.J. Côté*** and **S. Przedborski**. Dept. of Neurology, College of P & S of Columbia Univ., N.Y., N.Y. 10032.

The administration of 1-methyl-4-phenyl-1,2,3,6-tetrahydropyridine (MPTP) to mammals produces a profound disruption in the nigrostriatal dopaminergic pathway, which is similar to that observed in Parkinson's disease. We have investigated the pharmacokinetics of MPTP in the brain of the chick embryo.

MPTP (100 μ g) dissolved in saline, was injected into the fertilized egg at 14 days of gestation and the level of MPP⁺ formed was measured at 7 different time points within 48 hr post-injection. The concentration of MPP⁺ in the brain increased rapidly, reached its maximum level at about 8 hr post-injection and was still detectable after 48 hr post injection. This is in contrast to the observation in mice, in that MPP⁺ is not detectable after 12 hr post i.p. injection. The brain 5-HT and DA levels measured at 5 days post MPTP injection were decreased by 86% and 92%, respectively. Pre-treatment of the fertilized egg with Selegiline (L-deprenyl), a specific MAO-B inhibitor, profoundly decreased the rate of MPP⁺ formation and its effects on the levels of 5-HT and DA in the chick brain. Herein, we report the pharmacokinetics of MPTP in the brain of the chick embryo and its profound effects on the biogenic. The chick embryo is a promising model for studying the effects of MPTP on the developing brain.

EFFECTS OF A SALEN-MANGANESE COMPLEX, A SOD-MIMIC, IN VARIOUS MODELS OF NEURONAL PATHOLOGY. **A. Bruce***, **W. Musleh**, **B. Malfroy†** and **M. Baudry**. Neuroscience Program, USC, Los Angeles, CA 90089-2520, and † Eukarion Inc., Arlington, MA 02174.

Oxygen free radicals (OFRs) have long been proposed to play an important role in most forms of neuronal injury. To test this hypothesis, we evaluated the effects of EUK-8, a salen-manganese complex with Superoxide Dismutase (SOD) activity, on various markers of neuropathology in different models of neuronal damage. Adult rat hippocampal slices were subjected to a brief period of anoxia which resulted in an irreversible alteration of synaptic responses in field CA1. Incubation of slices in the presence of 50 μ M EUK-8 provided a significant degree of protection against anoxia-induced reduction of evoked synaptic responses. The dopaminergic neurotoxins, MPTP and 6-OHDA were administered to mice (i.p. and i.c.v., respectively) to produce a selective degeneration of dopaminergic neurons, as indicated by the decreased binding of ³H-mazindol, a ligand for the dopamine transporter in membranes or tissue sections. Treatment of mice with EUK-8 (i.p., 66 mg/kg, for 3 days in the MPTP model; or 1.8 μ g, i.c.v. in the 6-OHDA model) resulted in a significant reduction in the decreased binding of ³H-mazindol elicited by the toxins, one week after toxin administration. The results indicate that OFRs participate in both acute and long-term consequences of neuronal insults and suggest potential benefits for the use of low molecular weight SOD-mimics after brain injury. (Supported by a grant from Eukarion, Inc.)

SYMPOSIUM. VIEW OF A NEURAL SYSTEM IN THE BLINK OF AN EYE. THE EYEBLINK REFLEX: CONTROL, LEARNING, AND CELLULAR MECHANISMS. J. R. Blodgel (Chairperson); N. H. Donegan, Yale Univ.; R. E. Thompson, Univ. Southern Cal.; V. Bracha, Barrow Neurol. Inst.; I. F. Distenroft, Northwestern Univ.; C. Evinger, SUNY-Stony Brook.

This Symposium will present an overview of the eyeblink reflex emphasizing its modification during adaptation and associative conditioning and the role of specific central systems in mediating these phenomena. Dr. Donegan will characterize the properties of the unconditioned reflex system as well as changes in stimulus processing resulting from the pairing of the conditioned and unconditioned stimuli. Next, Dr. Thompson will present evidence supporting the hypothesis that the cerebellum and its associated circuitry constitute the essential circuit for classical delay conditioning and that the "memory trace" for this conditioning is formed and stored in a localized region of the cerebellum. Based on the effects of modifying interactions in cerebellar and brainstem nuclei and the responses of simultaneously recorded brainstem neurons obtained during conditioning, Dr. Bracha will address the role of the cerebellum and associated brainstem structures in the "on-line" control of both the conditioned and unconditioned eyeblink reflexes. Dr. Distenroft will discuss the modifications in the membrane and receptor properties of hippocampal neurons produced during trace conditioning and new experiments in humans showing PET images of specific central structures during delay conditioning. In the final lecture Dr. Evinger will focus on the mechanisms and brainstem sites which mediate eyeblink reflex adaptation induced by altered properties of the motor units responsible for eyelid closure and the relation of these observations to pathological conditions observed in human patients.

688

SYMPOSIUM. THE CONTRIBUTION OF IDENTIFIED NEURONS TO NEUROSCIENCE: A TWENTY-FIVE YEAR RETROSPECTIVE. J. L. Leonard, Oregon State Univ. (Chairperson); R. R. Hoy, Cornell Univ.; R. C. Eaton, Univ. of Colorado; S. S. Kater, Colorado State Univ.; A. I. Selverston, Univ. of Calif., San Diego.

It is now roughly 25 years since uniquely identifiable neurons, neurons that can be identified from one individual and/or species to another, became an established tool in neuroscience research and we are now at a point where the information from these studies is causing reappraisal of our ideas about the organization of neural circuits. Studies of identified neurons, *in vivo*, *in vitro*, and in cell culture, have produced a wealth of information on regeneration, synapse formation and function, neuromodulation, multifunctionality of neurons, and the dynamic rewiring of circuits as a normal part of behavioral organization that have led to a reevaluation and redefinition of fundamental concepts of neuroscience. This symposium will focus on two subthemes: 1) The organization of systems of neurons for behavior; 2) Dynamic and plastic properties of nervous systems. Four speakers will describe the progress made in each of four popular and powerful model systems. Dr. Hoy will discuss what identified neurons have taught us about the organization and control of behavior using a neuroethological perspective and focussing on insects. Dr. Eaton will describe how studies of the Mauthner cell and its role in the brainstem escape network of lower vertebrates have led to changes in the command cell concept. Dr. Kater will focus on the use of gastropod identified neurons in cell culture in understanding the mechanisms of establishment and modulation of neural circuits. Dr. Selverston will address the issue of how the study of small systems of identified neurons, particularly the crustacean stomatogastric ganglion, has changed our ideas of neural "wiring diagrams" and the function of neural circuits.

NEUROTROPHIC FACTORS: BIOLOGICAL EFFECTS IX

690.1

NGF Reduces Striatal Excitotoxic Neuronal Loss Without Affecting Concurrent Neuronal Stress or NMDA Receptors. O. Isacson*, D. M. Frim, U. Wullner, W. M. Yee. Neuroregeneration Laboratory, McLean Hospital, Belmont, MA, 02178, and Program in Neuroscience, Harvard Medical School, Neurology and Neurosurgery Services, Massachusetts General Hospital, Boston, MA, 02114.

Nerve Growth Factor (NGF) has protective effects against striatal excitotoxic injury in the adult brain. To help define the mechanism of NGF-mediated sparing, we determined the effects of biologically delivered NGF on the degree of neuronal stress, NMDA receptor binding and the development of excitotoxic lesions in the rat striatum. Immortalized fibroblasts genetically altered to secrete NGF (NGF+), or control fibroblasts (NGF-), were stereotactically implanted near the striatum 7 d before striatal infusion of an NMDA-receptor agonist. Two days after excitotoxic infusion, the volume of neuronal loss was reduced by 34% ($P < 0.01$) in the NGF+ group when compared to the NGF- group; however, there was no difference in the volume of 72 kD heat shock protein (HSP72) immunoreactivity expressed in the two groups after 2 d. The final volumes of neuronal loss at 10 d were significantly greater than seen at 2 d, with the volume of neuronal loss in the NGF+ group reduced by 20-40% ($p < 0.01$) when compared to the NGF- group. Interestingly, the volume of neuronal loss at 10 d in the NGF- group, but not the NGF+ group, closely approximated the HSP72 immunoreactive volumes seen at 2 d. These results suggest that the cell stress marker, HSP72, is predictive of neuronal loss after striatal excitotoxic insult and while NGF treatment does not alter the overall HSP72 response, it significantly reduces subsequent neuronal loss. NGF+ grafts also did not affect striatal [3 H]glutamate binding or NMDA receptor mRNA levels as measured by *in situ* hybridization. We conclude that NGF-mediated neuroprotective mechanisms alter neuronal response to injury without affecting the primary cell stress response to NMDA-receptor activation.

690.3

BDNF AMELIORATES AMPHETAMINE-INDUCED ROTATIONAL ASYMMETRY IN HEMI-PARKINSONIAN RATS. S. J. Wiegand, C. Alexander, C. Jackson, K. D. Anderson, R. M. Lindsay, C. A. Altar and C. Hyman. Regeneron Pharmaceuticals, Inc., Tarrytown, NY 10591.

The ascending nigrostriatal dopamine (DA) system was lesioned by injecting 6-OHDA*HBr (8 μ g/2 μ l) into the right medial forebrain bundle of adult rats. Rotational bias in response to injections of apomorphine (APO, 1 mg/kg) and amphetamine sulfate (AMPH, 4.5 mg/kg) was assessed one and two weeks following 6-OHDA administration. Animals were assigned in a counterbalanced manner to experimental or control groups, and BDNF (12 μ g/day) or normal saline vehicle (VEH) were infused via osmotic minipumps into the region of the substantia nigra on the side of the lesion. APO- and AMPH-induced rotations were again assessed one and two weeks following the initiation of BDNF or VEH treatment. Animals were then sacrificed and DA and DA metabolite levels determined by HPLC. In animals exhibiting the greatest loss of striatal DA (99 \pm 0.2%), administration of BDNF but not VEH significantly attenuated AMPH-induced rotations towards the side of the lesion (317 \pm 40 vs. 153 \pm 69 net ipsiversive rotations/hr, pre- vs. post-BDNF). Animals with moderate DA depletions (88 \pm 2%) exhibited a reversal in the direction of AMPH-induced rotational bias, from ipsiversive (113 \pm 45) to contraversive (-40 \pm 50) following BDNF treatment. AMPH did not induce asymmetric rotation in animals with the smallest depletions of striatal DA (36 \pm 3%) either before or after BDNF or VEH treatment. Rotational behavior exhibited in response to APO was not significantly altered by BDNF treatment in any group. These findings suggest that in hemi-Parkinsonian rats BDNF infusion into the vicinity of the substantia nigra modulates the effect of amphetamine on rotational behavior through non-dopaminergic mechanisms.

690.2

Effects of biologically delivered NGF, BDNF, and bFGF on striatal degeneration caused by 3-nitropropionic acid induced mitochondrial blockade. D. M. Frim*, T. A. Uhler, M. P. Short, X. O. Breakefield, and O. Isacson. Neuroregeneration Laboratory, McLean Hospital, Belmont, MA, 02178; Molecular Neurogenetics Unit, Neurosurgery and Neurology Services, Massachusetts General Hospital and Program in Neuroscience, Harvard Medical School, Boston, MA

Consistent with the notion that a defect in cellular energy metabolism can be a cause of human neurodegenerative disease, systemic treatment with the mitochondrial complex II inhibitor, 3-nitropropionic acid (3-NPA) closely models the striatal neurodegeneration seen in Huntington's disease. Previously, we have found that Nerve Growth Factor (NGF) and Basic Fibroblast Growth Factor (bFGF), but not Brain-Derived Neurotrophic Factor (BDNF), can protect *in vivo* against striatal degeneration induced by infusions of high doses of glutamate receptor agonists. We now report that implantation of NGF-secreting fibroblasts 7 days before systemic 3-NPA treatment reduces the size of adjacent striatal 3-NPA lesions by an average of 64% ($p < 0.001$). bFGF causes a similar decrease in striatal lesion size. BDNF, however, did not affect striatal 3-NPA-mediated degeneration. We conclude that biologically delivered NGF and bFGF protect striatal neurons against excitotoxicity and mitochondrial blockade--both energy depleting processes. This observation implies that appropriate neurotrophic support in the adult brain could protect against striatal neurodegeneration caused in part by energy depletion.

690.4

PLATELET-DERIVED GROWTH FACTOR (PDGF): EXPRESSION AROUND INTRACEREBRAL LESIONS AND GRAFTS AND EFFECTS ON DOPAMINE NEURONS IN VITRO. P. Odin¹, A. Othberg¹, M. Grabowski¹, A. Smits², W. M. Duan¹, P. Brundin¹, H. Widner¹, C. H. Heldin², B. Johansson¹, O. Lindvall¹ and K. Funa². ¹Restorative Neurology Unit, University Hospital, S-221 85 Lund, Sweden. ²Ludwig Institute for Cancer Research, Biomedical Centre, University of Uppsala, S-751 24 Uppsala, Sweden.

The level of platelet-derived growth factor (PDGF) shows dynamic changes in and around intrastriatal grafts of fetal dopamine (DA)-rich mesencephalic tissue in a rat model of Parkinson's disease. Furthermore, PDGF-BB but not PDGF-AA increases the survival of rat and human DA neurons and the neurite outgrowth from human DA cells *in vitro*. The objective of the present study was to characterize in more detail the changes of PDGF expression following insults to the brain and after intracerebral neural grafting and to further analyze the mechanism of action of PDGF-BB on DA neurons. Immunohistochemical, *in situ* hybridization and primary cell culture techniques were used. The PDGF beta-receptor was found to be expressed on neurons in cultures of fetal mesencephalic cells including DA neurons. This indicates that the effect of PDGF-BB on DA neurons could be direct and not mediated via other cell types. Using different concentrations of PDGF-BB, maximal effect on DA cell survival was found at 30 ng/ml of PDGF-BB. We have also studied the effects of PDGF-BB and brain-derived neurotrophic factor (BDNF), separately and in combination, on DA neurons in culture. Survival of DA neurons was comparable after addition of each of the factors but no additive effects were seen when combining them. Following a focal ischemic infarction, increased expression of PDGF was observed in the tissue surrounding the lesion. Taken together with the role of PDGF in other systems, these findings indicate that PDGF could be important both as a survival factor and in wound healing processes in the central nervous system.

690.5

HYPOTHALAMIC ASTROCYTES RESPOND TO TRANSFORMING GROWTH FACTOR ALPHA (TGF α) WITH PROSTAGLANDIN E₂ (PGE₂) RELEASE. K. Berg-von der Emde, Y.J. Ma, M.E. Costa and S.R. Ojeda*. Div. Neurosci., Oregon Regional Primate Research Center, Beaverton, OR 97006.

Previous studies have suggested that TGF α stimulates the release of luteinizing hormone-releasing hormone (LHRH), the neurohormone controlling sexual development, via an indirect mechanism that involves an action of TGF α on glial cells, followed by the release from these cells of neuroactive substance(s) that act on LHRH neurons to stimulate their secretory activity. The ability of TGF α to stimulate PGE₂ release from the median eminence and the inhibition of TGF α -induced LHRH release by blockade of cyclooxygenase activity suggested that PGE₂ may be one of the neuroactive substances secreted by astroglial cells in response to TGF α . To examine this hypothesis, hypothalamic (H) astrocytes cultured in defined medium were exposed to either TGF α (50 ng/ml) or a phorbol ester (TPA, 10 ng/ml) for 4, 8, 16 and 24h and the effect of these agents on PGE₂ release was assessed by RIA. Astrocyte cultures from the cerebellum (Cb), a brain region not involved in neuroendocrine regulation, were used as controls. While H astrocytes responded to TGF α with a 2-3-fold increase in PGE₂ release after 8-16h of exposure, Cb astrocytes failed to respond. Activation of protein kinase C, an intracellular mediator of TGF α biological effects, increased PGE₂ release 10-fold from H astrocytes, but only 1.5-fold from Cb astrocytes. These results and the previous finding that TGF α increases its own gene expression in H but not in Cb astrocytes support the notion that brain astrocytes are regionally specialized and functionally diverse. They also indicate that PGE₂ may be one of the glial signals involved in mediating the stimulatory effect of TGF α on LHRH release. (NIH Grants HD-24870, RR-00163, HD-18185).

690.7

DIFFERENTIAL REGULATION OF AXONAL BRANCHING OF DENTATE GYRUS NEURONS BY NGF, BDNF AND BASIC FGF. M. N. Patel* and J. O. McNamara. Duke University and VA Medical Centers, Durham, N C 27710.

The axons of dentate granule cells (mossy fibers) undergo morphological rearrangement (sprouting) following experimental seizures and in human epilepsy. The molecular mechanisms underlying mossy fiber sprouting are unknown. Recent evidence indicates that the growth factors NGF, BDNF and bFGF are differentially expressed by seizure activity *in vivo* and promote neurite-outgrowth *in vitro*, suggesting that these might be involved in the molecular events of mossy fiber sprouting. To test this idea we developed an *in vitro* model in which dentate gyrus neurons were maintained in low density culture in defined media (Brewer and Cotman; Brain Res. 494:65-74, 1989). MAP2 and GAP43 immunocytochemistry was used to distinguish axons from dendrites. Axonal branching, an early step in the sprouting response, was measured using a digital image analyzer. Phase-contrast images of axons and dendrites extended from neurons grown in the presence of varying concentrations of NGF, BDNF and bFGF were quantitated. We find that BDNF and bFGF produce selective increases in axonal but not dendritic branches. In contrast, NGF has no effect on either axonal or dendritic branching of dentate gyrus neurons. The selectivity and specificity of growth factor action may provide clues to the molecular basis of mossy fiber sprouting following seizures *in vivo*.

690.9

NGF AND BDNF MODULATE EXCITATORY SYNAPSES IN RAT VISUAL CORTICAL NEURONS. G. Carmignoto*, A. Negro, and S. Vicini. FGIN, Georgetown Univ., Washington DC.

Whole-cell patch-clamp recordings from layer IV visual cortical neurons in coronal slices from 13-18 days old rat brain were used to analyze the effect of Nerve Growth Factor (NGF) and Brain Derived Neurotrophic Factor (BDNF) on spontaneous as well as evoked excitatory post-synaptic currents (EPSCs). Whole-cell recordings of synaptic currents were performed with patch-pipette filled with a Cs MethylSulfonate solution, in the presence of picrotoxin (50 μ M) and glycine (10 μ M). NMDA and AMPA receptor-mediated EPSCs were recorded in response to focal stimuli applied through a bipolar tungsten electrode in appropriate experimental conditions such as various holding voltages, the presence and the absence of Mg²⁺ and selective receptor antagonists. Spontaneous and evoked EPSCs amplitude and kinetics were studied before and after perfusion for 15 minutes with either NGF (100 ng/ml) and BDNF (10-50 ng/ml). Both neurotrophins consistently increased the amplitude of spontaneous EPSCs recorded in the presence of tetrodotoxin (TTX, 1 μ M). Probably due to the large heterogeneity of neuronal types and to the uneven distribution of neurotrophin receptors in visual cortex, in some neurons we failed to observe any effects of NGF and BDNF. In other neurons, instead, the increase of spontaneous EPSC amplitude was accompanied by an increase of evoked EPSCs amplitude. The AMPA and NMDA-mediated component contributing to the peak amplitude of the average of at least 20 evoked EPSCs were differentially affected in distinct neurons. Our results suggest a functional role of NGF and BDNF in modulating excitatory synaptic transmission in visual cortical neurons. These results may represent the molecular mechanism of the reported effects of NGF in the modulation of visual cortical plasticity observed in developing rat (Domenici et al. '91, PNAS 88:8811) and kitten visual cortex (Carmignoto et al. '93; J.Physiol. 464:343). Supported by NIH grant PO1 NS28130-04.

690.6

IMPLANTATION OF GENETICALLY-MODIFIED FIBROBLASTS PRODUCING NEUROTROPHIN-3 INTO THE DAMAGED BRAIN.

Ernest Arenas* and Håkan Persson. Lab. of Molecular Neurobiology, Karolinska Institute, Box 60400, S-10401 Stockholm, Sweden.

Neurotrophin-3 (NT3) is a member of the neurotrophin family of trophic factors that support the survival of vertebrate neurons. Little is known about their function in the central nervous system *in vivo*. NGF prevents the degeneration of lesioned septal cholinergic neurons in the brain. BDNF supports the survival of developing spinal cord motoneurons and prevents the death of axotomized motoneurons and of a partial population of septal cholinergic neurons. No function *in vivo* has been described for NT3 or for the recently isolated, NT4/5.

In order to investigate the role of NT3 *in vivo*, we established a stable cell line producing recombinant NT3. Using the calcium phosphate transfection technique, Fisher rat 3T3 fibroblasts were cotransfected with the neomycin-resistance gene and a rat NT3 cDNA insert in the OVEC-expression plasmid. Transfected cells resistant to the neomycin analogue G-418 were analyzed by Southern blots, Northern blots and bioassays. The cell line designated F3A-NT3 contained more than one hundred copies of the NT3 gene and expressed high levels of NT3 mRNA. Conditioned media from the F3A-NT3 cell line promoted survival of dissociated E9 chick sensory neurons in a manner indistinguishable from purified recombinant NT3 protein. Dose response curves in comparison to pure NT3 protein revealed that the F3A-NT3 cells produced 150-300 ng of NT3 protein/10⁶ cells/day. We are currently implanting this cell line after brain insults, at different developmental stages, in order to determine whether recombinant NT3 prevents neuronal death *in vivo*.

690.8

NERVE GROWTH FACTOR CAUSES ACTIVITY-DEPENDENT SYNAPTIC MODIFICATION IN ADULT CAT VISUAL CORTEX. Q. Gu*, Y.L. Liu and M.S. Cynader. Department of Ophthalmology, University of British Columbia, Vancouver, British Columbia, Canada.

We have been testing the hypothesis that NGF, in addition to its known functions such as for neuronal survival, growth and differentiation, also plays a role in synaptic modification in the CNS. Our previous studies indicate that NGF-treatment could increase ocular dominance plasticity in adult cat visual cortex (Gu *et al.* 1992), suggesting that NGF is involved in activity-dependent synaptic modification. Intracortical NGF-infusion into adult cat visual cortex coincident with monocular deprivation could induce an ocular dominance shift toward the deprived eye, implying that under NGF-treatment, synaptic modification favours the less-active input. To investigate further the mechanism of NGF-effects, single unit recordings were performed during the NGF-infusion period, since it has been shown that complete blockade of postsynaptic activity in kitten visual cortex by muscimol-infusion could cause an ocular dominance shift toward the deprived eye (Reiter and Stryker, 1988, PNAS 85:3623). We found that cortical neurons did not show abnormal responsiveness to visual stimulation while NGF was infused, and that the postsynaptic activity was not blocked by NGF-infusion. Thus, the possibility of an acute pharmacological effect of NGF similar to that of muscimol may be excluded. These results, together with anatomical evidence (Liu *et al.* Soc. Neurosci. Abstr. 1993) support the idea that NGF plays a trophic role in activity-dependent synaptic modification.

690.10

EFFECTS OF NGF AND BDNF ON VOLTAGE-GATED CALCIUM CHANNELS IN EMBRYONIC BASAL FOREBRAIN NEURONS. E. S. Levine*, M. B. Plummer, C. F. Dreyfus and I. B. Black. Dept. Neurosci. & Cell Biol., UMDNJ/Robert Wood Johnson Med. Sch. and Dept. Biol., Rutgers Univ., Piscataway, NJ 08854.

Nerve growth factor (NGF) and other members of the neurotrophin family have well characterized effects on the survival and differentiation of basal forebrain neurons. Recent studies have suggested that some trophic molecules may also modulate the excitability of neuronal membranes. The present studies therefore investigated the effects of both NGF and brain-derived neurotrophic factor (BDNF) on voltage-gated calcium channels of neurons in the basal forebrain.

Whole-cell patch clamp recordings of calcium currents were obtained from embryonic day 17 basal forebrain neurons grown in culture for 4 - 6 days. Neurons were grown in serum-free medium (SFM) with either NGF, BDNF, or a vehicle control added at the time of plating. Peak calcium currents were obtained using a -90 mV holding potential and a +10 mV test potential. In neurons grown in SFM alone, the mean calcium current density was 46.5 \pm 5.62 pA/pF. Addition of NGF elicited a 40% increase in the mean calcium current density (mean = 62.9 \pm 7.92 pA/pF; p < 0.01). This increase appeared to reflect a change in both the sustained and inactivating components of the recorded current. In contrast, the current density of neurons grown in the presence of BDNF was not significantly different from control. These studies indicate that NGF modulates the voltage-gated calcium conductance in basal forebrain neurons, most probably by increasing channel number. Consequently, calcium entry may mediate some of the important neurotrophic effects of NGF.

DIFFERENT TREATMENT EFFECTS WITH NERVE GROWTH FACTOR IN NBM-LESIONED RATS USING IBOTENIC ACID, QUISQUALIC ACID, AND AMPA. J. Winkler and L.J. Thal¹. Dept. of Neuroscience & Neurology, UCSD & VAMC, San Diego, CA 92161.

Rats received bilateral lesions of the nucleus basalis magnocellularis by infusion of ibotenic (Ibo, n=20), quisqualic (Quis, n=17) and AMPA (n=20). Two weeks after the lesion, osmotic minipumps were implanted that released 5 µg human recombinant nerve growth factor (NGF) or 0.3 µg cytochrome c per day through intraventricular cannulas. Starting one month after the lesion, spatial learning of the animals was tested using the Morris water maze. Lesions with all 3 toxins impaired acquisition of the task, but NGF reduced the average latency to find the platform significantly for the Ibo-lesioned animals only. The 3 toxins reduced Chat activity in frontal/parietal cortex: Ibo 31%/18%, Quis 38%/32%, and AMPA 52%/49%. Six weeks of NGF treatment increased Chat activity for all 3 toxin-treated groups in the hippocampus by about 30%. A significant increase in Chat activity in frontal/parietal cortex was seen in Ibo- (25%/52%) and Quis- (62%/40%) lesioned rats and in frontal cortex (17%) only in AMPA-lesioned rats. These data suggest that treatment with NGF results in an improvement of spatial learning for Ibo-lesioned animals. In addition, Chat activity can be restored for Ibo as well as Quis-lesioned animals possibly because these toxins did not lower Chat activity to the same extent as AMPA did.

NGF GENE DELETION PRODUCES SEVERE DEFECTS IN SENSORY NEURONS. H.S. Phillips¹, M.C. Nishimura, M.P. Armanini, L.H. Ling, S.B. McMahon, S. Pitts-Meek, A. Levinson, S. Broz, and C. Crowley. Depts of Neuroscience and Cell Genetics, Genentech, Inc. S.S.F., CA 94080 and Dept. Physiology, UMDS, London SE1 7EH.

Homologous recombination was employed to generate mice with a deletion in the coding sequence of the nerve growth factor (NGF) gene. Animals heterozygous for the NGF gene deletion were indistinguishable from normal littermates by visual inspection, but displayed a slight prolongation of tail flick latency. At birth, animals homozygous for the deletion displayed no gross morphological abnormalities and displayed normal spontaneous behavioral patterns. However, homozygotes could be readily distinguished by their failure to respond to noxious mechanical stimulation (tail pinch) and by their reduced size. As homozygous animals exhibited reduced viability, examination of the sensory nervous system was confined to the first few days of postnatal life. Animals homozygous for NGF gene deletion demonstrated an absence of small cells within dorsal root ganglia (DRG), with an approximate cell loss of 70% for the 4th and 5th lumbar ganglia. DRG neurons remaining in these animals expressed trkB and trkC, but not trkA. Homozygotes displayed a complete loss of CGRP-immunoreactive afferents to both the dorsal horn of spinal cord and the epidermis of hairy and glabrous skin. These results confirm earlier antibody-deprivation studies by demonstrating that selective deprivation of NGF by gene deletion has marked selective effects on development of primary sensory neurons.

ASSESSMENT OF LEARNING AND MEMORY PERFORMANCE IN MICE HETEROZYGOUS FOR NERVE GROWTH FACTOR DELETION. K.S. Chen^{*}, M.C. Nishimura, S. Broz, C. Crowley, and H.S. Phillips. Dept. of Neurosciences and Dept. of Cell Genetics, Genentech Inc., 460 Point San Bruno Blvd., South San Francisco, CA 94080.

The cholinergic system has been shown to be important in learning and memory function. Lesions of basal forebrain cholinergic neurons or their afferent pathways produce severe memory deficits. These cholinergic neurons have been also shown to respond to nerve growth factor (NGF) and to contain receptors for NGF. Intraventricular infusions of NGF can rescue lesioned cholinergic cells and reverse the observed memory deficits. Additionally, NGF infusions can ameliorate age-related memory deficits as well as reverse the degeneration of basal forebrain cholinergic cells associated with the memory deficits. In the present study heterozygous mutant mice were generated that contained only one normal copy of the NGF gene. These mice did not exhibit any gross morphological or behavioral abnormalities. At 5 months of age the heterozygous mice and normal littermates were tested on the water maze task, a test of spatial learning and memory. The heterozygous mice were significantly impaired in the acquisition of the location of a hidden platform compared to their normal littermates, although the heterozygotes were able to learn the platform location during the two week acquisition period. The deficit exhibited by the heterozygotes in retention of the hidden platform location following a two week retention interval was not as great as the acquisition deficit. Quantitative morphometric analysis of ChAT-positive cells in the basal forebrain will be presented for these animals.

NEURAL-IMMUNE INTERACTIONS: NEUROENDOCRINE CONTROL OF IMMUNE RESPONSE

691.1

DECREASED TYPE II GLUCOCORTICOID RECEPTOR GENE EXPRESSION IN TRANSGENIC ANIMALS ALTERS THE DEVELOPMENT OF NEUROIMMUNE CONNECTIONS. B. Marchetti^{*}, M.C. Morale, N. Batticane, A. Peiffer and N. Barden. Dept. of Pharmacology, University of Catania Medical School, 95125 Catania Italy, and Molecular Psychogenetics, CHUL, Québec, G1V4G2, Canada.

In the immune system, glucocorticoids inhibit the cascade of immune and inflammatory responses at multiple levels, both directly via action on immunocompetent cells, and indirectly via effects on leukocyte migration and release of inflammatory mediators. To study the glucocorticoid feedback effect on the hypothalamic-adrenal-immune axis, we have used a transgenic mouse with impaired type II glucocorticoid receptor (GR) function caused by GR antisense RNA expression (Pepin et al. 1992, Nature 355:725). Northern blot analysis of endogenous type II GR mRNA indicates a maximal 50-70% decrease in the hippocampus and a 40-60% decrease in the thymus in animals bearing the antisense RNA transgene. In intact mice, age- and sex-dependent changes of type II GR mRNA levels within the thymus accompanied the development of cell-mediated immune response, while transgenic mice showed a significant shift in blastogenic potential, with an almost 3-fold increase in maximal proliferative capacity, and a higher degree of proliferative activity after sexual maturation. While normal adult mice displayed a time-dependent down-regulation of thymic GR mRNA following an antigenic stimulus, in transgenic mice basal immune reactivity was at high levels, and a shift in the time-course of the immune response followed immunogenic challenge, suggesting that type II GR is a critical component of the immune system-hypothalamic-pituitary-adrenal axis loop.

691.2

CHANGES IN LYMPHOCYTE SUBPOPULATIONS IN RESPONSE TO CRH IN NORMAL SUBJECTS. C.M. Bamberger¹, A.M. Bamberger¹, H. Sheng^{*2}, J. Barth¹, H. Eisen-Ziem¹, H.M. Schulte¹. ¹I. Medizinische Klinik, University of Kiel, Germany, ²LDN, NICHD, NIH, Bethesda, Maryland 20892

Acute stress results in activation of the hypothalamic-pituitary-adrenal (HPA) system. It is also known that stress induced activation of the HPA axis is accompanied by changes in the immune response. We previously demonstrated activation of the HPA axis and elevation of serum interleukin-1 alpha (IL-1) and interleukin-2 (IL-2) levels in patients with coronary heart disease undergoing angioplasty as well as in normal subjects receiving CRH by intravenous injection. The purpose of this study was to investigate the influence of CRH on lymphocyte subpopulations in normal subjects. Furthermore, IL-1 levels were measured in CRH-incubated blood monocyte cultures in order to determine the origin of IL-1 demonstrated in our *in vivo* studies. Ten normal volunteers (20-28 years) received 100 µg human CRH intravenously at 6:00 p.m. Blood was drawn at -15, 0, and 15 min. intervals. Lymphocyte subpopulations (IL-2 receptor positive cells, CD-3, CD-4, CD-8, natural killer (NK), and B cells) were distinguished by immune peroxidase reactions. For the *in vitro* studies CRH (1 nmol/l) was added to cultured monocytes isolated from venous blood of normal volunteers. IL-1 concentrations were measured in the culture medium in 2 h intervals up to 24 h. In response to intravenously administered CRH, the relative number of IL-2 receptor positive lymphocytes rose from 3.9±1.2 to 6.2±1.6% (n=10, mean±SEM, p<0.05). CD-3 cells increased from 74.5±1.6 to 78.3±2.0% (p<0.05). No significant change was observed in the other lymphocyte subsets. *In vitro*, no significant difference in IL-1 concentrations was measurable between CRH-incubated and control cultures. We conclude that CRH administration in normal subjects results in significant changes in the immune response. Our *in vitro* data suggest that the origin of increased IL-1 levels *in vivo* may be different to blood monocyte sources. In summary, our studies demonstrate a major role of CRH in neuroendocrine-immune interactions during stress.

691.3

CORTISOL INFLUENCES IN A DIFFERENT WAY LYMPHOCYTE SUBSETS DISTRIBUTION IN ANXIETY AND AFFECTIVE DISORDERS. GI Perini *, Preti A, Zara M, Carraro C, Gava F, Tosin C. Department of Psychiatry, Padua Univ. Sch. of Med., Italy, 35128 PD

The aim of our study was to determine if the distribution of subsets of the major lymphocytes population shows a specific pattern in distinct mental illness. We studied 15 patients with Major Depression, 7 with Panic Disorder, 6 with Generalized Anxiety Disorder that were drug free and without concomitant medical diseases. MD patients showed significantly higher T helper % (46 ± 6) compared to PD (38 ± 5) and GAD (34 ± 4) patients (ANOVA: $F = 9.18$, $p = 0.001$). T suppressor % was higher in PD patients (31 ± 9) than in MD (24 ± 6) (ANOVA: Fisher post hoc = 6.54, $p = 0.05$). There was a trend toward higher Urinary Free Cortisol levels in MD (467 ± 348 nmol/24 hrs) compared to PD (217 ± 119 nmol/24 hrs) and GAD (198 ± 128 nmol/24 hrs) patients. In MD patients UFC levels correlate negatively with percentage of T helper cells (Spearman rank test: $r = -.73$, $p = 0.03$), whereas in PD patients they correlate positively with T helper % (Spearman rank test: $r = .88$, $p = 0.04$). Activation of HPA axis has been described as a characteristic marker in MD. We speculated that the distribution of T cell subsets in MD and in PD patients is influenced in an opposite way by different levels of cortisol.

691.5

ASTROGLIAL CELLS IN PRIMARY CULTURE RELEASE FACTORS THAT PROMOTE THE GROWTH OF GT1-1 LHRH NEURONAL CELLS AND STIMULATE LEUKOCYTE PROLIFERATION. F. Gallo*, R. Avola, A. Costa & B. Marchetti. Depts of Pharmacology and Biochemistry, University of Catania Medical School, 95125 Catania, Italy.

Glial mechanisms are hypothesized to be involved in the marked changes in synaptic and interneuronal organization that occur under various physiological conditions. Recent evidences indicate that astrocytes are immunologically competent cells that share many important functional characteristics with macrophages, including the ability to both produce and respond to a broad spectrum of soluble immune mediators. The hormonal sensitivity of the glia and its involvement in estrous cycle-related changes in synaptic circuitry prompted us to study the trophic interactions between astroglial cells and the luteinizing hormone-releasing hormone (LHRH) neuron. For this aim, an immortalized hypothalamic LHRH neuronal cell line (Mellon et al. 1990, Neuron 5: 1) was used. In this experimental design LHRH neuronal cells (GT1-1 subclone) were cultured alone, in the presence of astroglial cells, or in medium conditioned (CM) from developing astroglial cell cultures. Media from cultured LHRH neurons were collected 2, 4, 6 and 8 days following coculture with glial cells obtained from cerebral hemispheres of newborn rats, or after addition of astroglial cell CM. A significant stimulation of GT1-1 neuronal cell proliferation and increased LHRH secretion followed coculture with astrocytes at late stages of differentiation. Moreover, a marked stimulation of cell proliferation followed CM addition to leukocyte cultures, indicating that the astroglial cells produce trophic factors that participate in CNS intercellular communications and in the interactions between the nervous and immune systems.

Cocaine and Cocaine/ β -Endorphin Mixtures: Effects on Transmembrane Signaling in Normal Human T Cells. F. Chiappelli*, P. Frost & C. Bender. Anatomy & Cell Biology, UCLA-1763, Los Angeles, CA 90024; Human Immunol. Psycho-neuroimmunol., Brentwood VAMC (151).

Cocaine abuse is associated with a significant modulation of cellular immune responses. We have shown that cocaine alters the expression of several membrane markers of T cell activation *in vitro* (CD25, CD71 and HLA-Dr). Because cocaine administration leads to activation of the pituitary-adrenal axis *in vivo* in both experimental animals and in control human subjects, and because we previously showed that β -endorphin modulates membrane signaling events during human T cell activation, we have characterized the effects of cocaine and cocaine/ β -endorphin mixtures on certain transmembrane signaling outcomes in human T cells during activation with T cell mitogens, or via the CD3/TcR pathway either in the absence or in the presence of CD28 co-stimulus. Our experiments include testing the small GTP-carrying protein, p21^{ras}, because of its important role during T cell activation. (NIDA 07683).

TWENTY-FOUR-HOUR CONCENTRATIONS OF INTERLEUKIN-2 IN HEALTHY WOMEN EXHIBIT EPISODIC FLUCTUATIONS: ANALYSIS OF INTEGRATED BASAL LEVELS AND DISCRETE PULSE PROPERTIES. J. Licinio*, M.-L. Wong, M. Altemus, P. B. Bongiorno, A. Bernat, L. Tamarkin, P. W. Gold. Department of Psychiatry, Yale University School of Medicine, West Haven V.A.M.C./116A, West Haven, Connecticut 06516.

Circulating interleukin-2 (IL-2) levels have been measured at one time point in healthy subjects and in patients with a wide variety of inflammatory disorders. It has not been determined if IL-2 is present in the circulation throughout the 24-h period, and whether IL-2 levels are constant or show episodic fluctuation (pulsatility). We examined these points by measuring 24-h levels of IL-2 in six healthy females. Blood samples were collected every 15 min for 24 h, starting at 0800. Cluster analysis was used to identify pulses in the IL-2 time; immunoreactive IL-2 was detectable in all 582 time points, IL-2 concentrations exhibiting pulsatility throughout the 24-h period. The total integrated IL-2 concentration (IIL2C) was 6788 ± 3142 min. μ g/L (mean \pm SD); the integrated pulse IL-2 concentration was 93.1 ± 28.9 min. μ g/L; the overall pulsatile IIL2C was 1205 ± 319 min. μ g/L, or $20 \pm 7\%$ of the total IIL2C. The mean IL-2 concentration was 4.71 ± 2.18 μ g/L; mean pulse frequency was 13.3 ± 2.3 ; mean pulse height was 6.16 ± 2.44 μ g/L, and mean pulse width was 75.7 ± 13.7 min. Pulsatility of circulating IL-2 throughout the 24-h period suggests that IL-2 may function as a classical hormone, being secreted in the blood stream and acting at distant sites. Future studies of IL-2 blood levels should consider these findings that circulating IL-2 levels are pulsatile.

691.6

PAVLOVIAN CONDITIONING OF MORPHINE-INDUCED IMMUNE ALTERATIONS: EVIDENCE FOR INVOLVEMENT OF THE β -ADRENERGIC SYSTEM. Mary E. Coussons*, Linda A. Dykstra, and Donald T. Lysle. Departments of Psychology and Pharmacology, University of North Carolina at Chapel Hill, Chapel Hill, NC 27599-3270

Previous work in our laboratory has shown that reexposure to an appetitive stimulus developed through pairings with morphine can elicit profound conditioned changes in immune status. The observed pattern of conditioned immunomodulation is very similar to that of a conditioned aversive stimulus previously paired with electric shock. Work in our laboratory has clearly demonstrated that the β -adrenergic system is involved in the immunomodulatory effects elicited by an aversive conditioned stimulus. The present studies were aimed at determining the involvement of this system in the establishment and expression of morphine-induced conditioned immune alterations. During the training phase, rats received conditioning sessions during which injections of morphine were paired with exposure to a distinctive environment. On the test day, animals were reexposed to the distinctive environment or remained in their home cages prior to sacrifice. Saline or nadolol (0.002, 0.02, 0.2, or 2.0 mg/kg) was administered either prior to training or to test. Administration of nadolol prior to training did not diminish the conditioned changes in immune status; nadolol administration prior to testing antagonized a subset of the conditioned immune alterations elicited by exposure to the conditioned appetitive stimulus. These findings suggest that the β -adrenergic system is involved in the expression, but not the establishment, of conditioned morphine-induced immune alterations. 691.8

NE TURNOVER IN SPLEENS FROM YOUNG AND OLD F344 RATS. D.L. Bellinger*, N. Costello, S.Y. Felten, & D.L. Felten. Dept. Neurobiol. & Anat., Univ. Rochester Sch. Med., Rochester, NY 14642.

With normal aging, the frequency of viral infections, cancer, and autoimmune diseases increases, cell-mediated immune responses decline, degenerative brain changes occur, and psychosocial factors have a greater impact on health. Studies from our laboratory, as well as others, have revealed a role for noradrenergic (NA) sympathetic innervation of primary and secondary lymphoid organs in modulation of immune function. Further, we have demonstrated a striking decline in the presence of NA nerves and norepinephrine (NE) content in spleens from aged F344 rats that parallels the time course of age-associated decline in cell-mediated immunity in these rodents. The present study examines NE turnover in spleens from 3- and 21-month-old rats by measuring the rate of splenic NE degradation following α -methyl-p-tyrosine inhibition of tyrosine hydroxylase, the rate-limiting enzyme in the synthesis of NE. Mean NE turnover rate was elevated in aged rats compared with their young adult counterparts. This finding suggests an increase in the activity of NA nerves in spleens from aged F344 rats. Increased NE metabolism probably occurs as a compensatory mechanism resulting from the loss of NA nerve terminals that occurs with aging. Enhanced NA nerve activity with age may be contributory to further decline in NA innervation of spleen through elevated oxidative metabolites, like 6-hydroxydopamine, that are neurotoxic to NA nerves. Supported by R29 MH47783-02, and Sandoz Foundation for Gerontological Research.

691.9

LOCALIZATION AND CELLULAR DISTRIBUTION OF INTERLEUKIN-1 RECEPTOR ANTAGONIST mRNA IN RAT BRAIN. M.-L. Wong*, J. Licinio. Department of Psychiatry, Yale University School of Medicine, West Haven V.A.M.C./116A, West Haven, Connecticut 06516.

Interleukin-1 (IL-1) is a potent inflammatory cytokine with a vast range of biological effects. There are three forms of IL-1, namely IL-1 α and IL-1 β , which occupy IL-1 receptors and elicit biological responses, and IL-1 receptor antagonist (IL-1ra), which occupies IL-1 receptors with the same affinity as IL-1 α and IL-1 β , but elicits no biological responses, being a pure endogenous IL-1 antagonist. IL-1 antagonism by means of exogenous IL-1ra administration has been shown to protect neurons from ischemia. We therefore hypothesized that IL-1ra might be present in brain, possibly as an endogenous neuroprotective agent. The recent cloning of rat IL-1ra mRNA has permitted us to conduct *in situ* hybridization histochemistry (ISHH) studies using a rat riboprobe to localize IL-1ra mRNA in rat brain. We performed ISHH with a ³⁵S-labelled antisense riboprobe for rat IL-1ra mRNA and localized IL-1ra mRNA in hippocampus, hypothalamus, choroid plexus, and cerebellum. Control hybridizations revealed no specific binding to those or other regions. Anatomical distribution of the probe at the cellular level was performed by dipping the slides in photographic emulsion, exposing for 45 days, developing, and counterstaining. IL-1ra mRNA was localized in neurons in glia, in the same regions where IL-1 β mRNA has been described. We conclude that endogenous IL-1ra exists in brain, where it might function as an endogenous neuroprotective agent.

691.10

ELECTRICAL STIMULATION OF THE RAT MIDBRAIN PERIAQUEDUCTAL GRAY SUPPRESSES PERIPHERAL BLOOD NATURAL KILLER CELL ACTIVITY. M.K. Demetrikopoulos*, S.E. Keller, S.J. Schleifer, and A. Siegel. Dept. of Neurosciences, Grad. School of Biomedical Science, and Dept. of Psychiatry, N.J. Med. School, UMDNJ, Newark, NJ 07103

It has been previously reported that electrical stimulation of the periaqueductal gray (PAG) leads to suppression of splenic natural killer cell (NK) activity (Weber & Pert. *Soc. for Neuroscience Ab.*, 1990). The present study examined the effect of PAG stimulation on both splenic and peripheral blood NK function as well as the blastogenic response of lymphocytes to phytohemagglutinin (PHA) mitogen. Male Sprague-Dawley rats were implanted with bipolar electrodes in rostral aspects of the dorsal PAG. Two weeks following recovery, bipolar electrical stimulation was delivered once per min. for 30 min. to the freely moving rats (biphasic, rectangular electrical pulses (0.4 mA, 62.5 Hz, 1ms half cycle duration) from a Grass S-88 stimulator). Peripheral blood NK activity was determined by use of a modified 4 hr chromium release 'whole blood' micro-assay, and splenic NK activity was determined by a standard 4 hr chromium release assay. There was no effect of PAG stimulation on blastogenic response to mitogen. While PAG stimulation did not suppress splenic NK activity, PAG stimulation produced a marked decrease in peripheral blood NK response ($F = 5.49$, $p < .03$). Differences from previous reports may relate to stimulation localization, sampling time, and cell purification. These results suggest that the central mechanisms involved in the modification of NK function may differ for peripheral and splenic subsets.

CONTROL OF POSTURE AND MOVEMENT XI

692.1

ENTRAINMENT OF RAPID WRIST MOVEMENT BY ESSENTIAL TREMOR. R. J. Elble*, C. Higgins and L. Hughes. Dept. of Neurology, Southern Illinois Univ. Sch. of Med., Springfield, IL 62794-9230.

The effect of 4- to 7-Hz essential tremor on the timing of rapid wrist flexion was examined in ten patients with moderate to severe disability, using a computer-controlled torque motor and manipulator. The mean reaction time and motor time of the patients did not differ from the mean values of 10 healthy age- and sex-matched controls. The latencies of the triphasic agonist and antagonist EMG bursts did not differ between patients and controls. The initiation of movement was time-locked to the tremor cycle in all patients. The activation of the agonist muscle occurred in phase with the rhythmic bursts of EMG, but the onset of rapid wrist flexion occurred during the wrist extension phase of the tremor cycle, when the momentum of essential tremor opposed the volitional movement. Similar phase relationships occur with Parkinson tremor (Staudte et al., *Z. EEG-EMG* 1992;23:108-113), but normal people extend their index finger with the momentum of the 8- to 12-Hz physiologic tremor, as though physiologic tremor served to facilitate movement (Goodman and Kelso, *Exp. Brain Res.* 1983; *Exp. Brain Res.* 49:419-431). The rhythmic entrainment of motor units dictates the timing of volitional muscle activation in all three forms of tremor. The timing of movement with respect to the joint oscillation will be determined by the motor time, the tremor period (frequency), and the phase between EMG and joint tremor. The seemingly beneficial phase relationship between volitional movement and physiologic tremor is possibly a fortuitous result of the latter two factors. (Supported by NINDS NS20973).

692.3

THE CENTRAL COMMAND FOR VOLUNTARY MOVEMENT: DOES IT EXPRESS A NOMINAL FORCE OR A VIRTUAL TRAJECTORY? G.L. Gottlieb*. Rush Medical Center, Chicago, IL, 60612.

The voluntary movement of a single joint or a single limb can be regarded as a realization of some command by the central nervous system, expressed at the segmental motoneuron pools. This command is carried out by the contraction of the activated muscles, interacting with the physical load. One school of thought has regarded the command as intrinsically spatial in nature, specifying the kinematic trajectory of a moving equilibrium point, towards which the limb is attracted. An alternative to this is to consider the plan as a nominal force trajectory, interacting compliantly with the load. In either case, movements of a limb are always sufficiently slow that reflexes of many sorts may potentially play a role in the activation of the muscles but the degree and timing of this role have long been a source of dispute.

We will present data on both single and multi joint arm movements, performed under different speed, load and distance conditions. These movements can be interpreted as emerging from central force plans that rely little on concurrent reflex action. This perspective provides a more comprehensive description of and better insight into the mechanisms of voluntary motor control than any current version of the equilibrium point hypotheses.

692.2

PROGRESSIVE SPECIFICATION OF RESPONSE AMPLITUDES IN A POINTING TASK. W. A. Hening*^{1,2}, M. Roller¹, and J. Gordon³. Neurology Depts. VAMC¹, Lyons, NJ & UMDNJ-RWJohnson Med Sch², New Brunswick, NJ; and Ctr for Neurobiology & Behavior³, Columbia Univ, NY, NY

In a reaction time (RT) task, RTs were modulated by instructions about how soon subjects should initiate their responses (Favilla et al, *Neurosci Abstr* 13:13). Isometric jerks aimed at predictable targets (Simple Condition, SIM) were accurate at all RTs. However, responses to unpredictable targets (Choice condition, CHO) made at short RTs were deficiently specified and their amplitudes clustered near the center of the target range while, with increasing RT, amplitudes were progressively more accurately specified. We have now examined how subjects specify the accuracy of a pointing movement. With arms hidden, 3 normal adult subjects moved a cursor over a digitizing tablet to match 4 visual targets requiring 2.4 to 24 cm movements. Their SIM responses were accurate at all RTs, but they gradually improved specification of CHO responses with longer RTs. 2 subjects achieved this by increased preprogramming of responses, evidenced by peak accelerations highly correlated with target amplitude ($R^2 > 75\%$) at RTs greater than 300 ms. One subject used a strategy of adaptive modification of late trajectories to achieve accuracy. Subjects almost invariably overshoot the small target at RTs <200 ms, but could extend movements to match larger targets. In conclusion, the subjects showed a progressive specification of CHO responses, but they used a somewhat different means for achieving accuracy than observed with isometric jerks. Early matching of large targets was facilitated by the longer duration of these arm movements. This research supported by the Dept of Veterans Affairs Medical Research Council.

692.4

MOVEMENT PERFORMANCE IN A DOUBLE-STEP POINTING PARADIGM. O. Bock*. Human Perf. Lab, Inst. f. Space & Terrest. Sci., York Univ., Toronto, Ont. M3J 1P3, CANADA.

The present study investigates how double-step pointing responses in different orientations with respect to Earth's field of gravity.

Human subjects pointed, without seeing their arm, at mirror-viewed visual targets presented in a frontal plane at eye level 40 cm ahead. Targets could be displaced after 25-100 ms, requiring a modification of movement direction in the frontal plane. Index fingertip position was measured contact-free by the WATSMART® system.

If the time between target displacement and movement onset (RT2) was brief, initial movement direction (ID) was towards the original target; with longer RT2, ID gradually changed towards the displaced target. This confirms earlier studies that internal target representation changes gradually. The slope of ID versus RT2 was 270 deg/s if ID changed from horizontal to oblique, and 420 deg/s if ID changed from vertical to oblique, whether the changes were assisted or opposed by gravity. Direction early after movement onset didn't remain constant but rather changed at a rate of 580 deg/s (hor. to oblique) and 360 deg/s (vert. to oblique); values were smaller when the changes were resisted, and larger when they were assisted by gravity.

We conclude that the gravity vector provides a spatial reference for movement preparation, that initial differences between hor. and vert. directions are adjusted early in the movement, and that gravitational force is not fully compensated when movement direction is changing.

692.5

NORMAL DEVELOPMENT OF HUMAN LIMB CONTROL REQUIRES FOVEAL INPUTS FROM AREA V₁. M. Rizzo*, W. Darling. Department of Neurology, University of Iowa, Iowa City, IA 52242.

We studied the reaching movements in a 21 year old man with severe bilateral occipital lobe lesions acquired at birth. MR imaging showed that the right occipital lobe was nearly absent; the lesion on the left fully damaged the foveal representation. Our aim in the current study was to evaluate how the loss of a foveal representation affected limb control during reaching tasks. Visual acuity was 3/500 and the patient could navigate without bumping into objects. This relied on extrafoveal fixation which was mediated by a region of intact left superior visual cortex. Hand movements were recorded using an optoelectronic technique. The patient was asked to reach for different targets under a variety of conditions. Self-directed movements were normal with both hands. Right hand movements to suprathreshold visual targets showed near normal velocity and accuracy. However, there were curved handpaths and high endpoint variability with the left hand. Moreover, in comparison to normal control subjects, the patient made hand movements to remembered visual targets that showed large overshoot errors for both far and near targets. Azimuth and elevation errors were also noted. The pattern of findings suggests that the neural system that transforms visual representation of target locations into a kinesthetic coordinate system to program reaching movements requires the influence of foveal cortex for normal development.

692.7

DIRECTIONAL BIASES IN TARGETED ARM MOVEMENTS RESULT FROM DISTORTIONS IN THE REPRESENTATION OF THE WORKSPACE. M.F. Ghilardi, J. Gordon*, C. Ghez. Ctr. for Neurobiol. & Behav., Prog. in Phys. Ther., Columbia Univ. and NYS Psych. Inst., New York, NY 10032.

We have previously shown that, when subjects use a computer screen to aim hand movements on a horizontal digitizing tablet, movements show directional biases that vary with the initial position of the hand. The nature of these biases suggested that in planning movement direction the nervous system underestimates the distance of the hand from the midline. In the present report, we further characterized these errors.

The directional biases are independent of the location of the computer screen; they vary systematically with the mediolateral distance of the initial position of the hand from the midline but are independent of its anteroposterior distance from the body. They disappear when targets are presented directly within the workspace. Therefore, these biases initially appeared to represent errors in transforming the direction of the required movement from screen to hand coordinates. However, the same errors occurred when targets were not presented on the screen and subjects were verbally instructed to perform straight movements in one of the four cardinal directions without viewing their limb. Thus, the error results from the transformation of a distorted representation of space into actual workspace coordinates. Similar biases were present in visual discrimination and proprioceptive matching tasks performed in the horizontal plane.

We conclude that subjects' representation of peripersonal space is distorted and proprioception does not provide adequate information to accurately plan movement direction. (NS 22715)

GEOMETRIC STRUCTURE OF THE ADAPTIVE CONTROLLER FOR ARM MOVEMENTS. R. Shadmehr*, and FA Mussa-Ivaldi. Dept. of Brain and Cognitive Sciences, MIT, Cambridge, MA 02139.

In order to investigate how the CNS adapts a motor behavior, we considered a task which required subjects to interact with a virtual mechanical environment. The environment was a force field produced by a robot manipulandum. The subjects made reaching movements while holding the end-effector of this manipulandum. Initial movements in the field were grossly distorted compared to movements in free space, but practice led to convergence of the hand trajectories to a path very similar to that observed in free space. This indicated that for reaching movements, there was a kinematic plan independent of task dynamics. In order to investigate how subjects adapted to the force field, for some movements during the practice trials the field was temporarily removed (unknown to the subject). The resulting trajectories, named *after-effects*, were approximately mirror images of those observed in the field, suggesting that the motor controller was gradually composing an *internal model* of the virtual environment. In order to explore the structure of this internal model, we asked whether adaptation to a force field, as presented in a small region, led to after-effects in other regions of the workspace. We found that there were after-effects in workspace regions where no exposure to the field had taken place, i.e., there was transfer. From the coordinate system in which this transfer took place we inferred the geometric structure of the internal model. The transfer was consistent with an internal model which represented the field in an intrinsic, e.g., joint centered, coordinate system. Our observations are in line with a theoretical framework where the process of adaptive control is viewed as that of composition of an internal model through force field approximation. This approximation may be accomplished by the CNS through co-activation of a small set of pattern generators, each producing a time varying force field. The result is a highly structured adaptive controller which learns interaction with a novel environment through co-activation of a set of elementary behaviors. VISION OF THE LIMB ALLOWS DEAFFERENTED PATIENTS TO CONTROL MULTIJOINT DYNAMICS R.L. Sainburg, M.F. Ghilardi, H. Poizner, and C. Ghez*. Columbia Univ., Ctr. for Neurobiol. & Behav., NY 10032; CMBN, Rutgers U., Newark, NJ 07120.

We have recently shown that proprioceptive deafferentation produces severe deficits in interjoint coordination due to failure to control interaction torques that develop across joints (Neurosci. Abs. 18:647). We now ask whether these deficits are reduced when patients view their limb. We analyzed muscle activation patterns and joint torques at the elbow during the performance of two-joint, horizontal arm movements in two patients with large-fiber sensory neuropathy and 5 control subjects. Subjects were to trace a series of straight paths in different directions from a central starting position and to reverse direction without stopping. Target paths were chosen to keep elbow joint excursion constant while varying shoulder excursion. Whether or not they viewed their limb, control subjects made straight, accurate movements that reversed direction sharply. They synchronized shoulder and elbow joint movements by varying the time and magnitude of muscle activation, utilizing or dampening the effects of interaction torques to regulate elbow kinematics. Without vision of their limbs, the patients were unable to temporally coordinate the movements of their elbow and shoulder joints at movement reversals. This resulted from failure to control large interaction torques at the elbow due mainly to shoulder deceleration. Muscle patterns were not adapted to direction-dependent variations in interaction torques and showed excessive co-contraction. When patients viewed their limbs during movement, reversal errors and interjoint coordination deficits were dramatically reduced. The timing of muscle activities were better adapted to direction-dependent variations in interaction torque. We conclude that visual information about limb movement can be used to partially control limb multi-joint dynamics, but proprioceptive information is critical for optimal control. MINIMUM-JERK PRINCIPLE, ISOCHRONY, AND THE TWO-THIRDS POWER LAW: CONVERGING APPROACHES TO MOTOR PLANNING.

P. Viviani and T. Flash. Dept. of Psychology, FAPSE, University of Geneva, Switzerland; INB-CNR, Milan, Italy and The Weizman Institute, Rehovot, Israel¹

One approach to the logic of motor planning is based on the assumption that voluntary movements comply with an optimality criterion concerning their smoothness. It was shown (Hogan, 1984; Flash & Hogan, 1985) that a minimum-jerk constraint, associated with appropriate boundary conditions, predicts both trajectory and kinematics of point-to-point movements. An independent line of research (Viviani & Schneider, 1991) has demonstrated that most end-point movements are constrained by two empirical covariations between kinematic and geometrical parameters; the *Isochrony Principle* states that average velocity is an increasing (power) function of the linear extent of the trajectory, while the *Two-thirds Power Law* relates the instantaneous values of velocity and curvature. A body of experimental data on drawing movements was used to test whether the minimum-jerk logic predicts these empirical covariations. With the help of a digitizing table (sampling: 100 Hz), we recorded the motor performances of adult subjects who traced continuously three complex, closed trajectories (cloverleaf, asymmetric lemniscate and oblate limaçon), at three imposed rhythms. We found that the convergence of the two approaches is satisfactory insofar as the relation between instantaneous velocity and curvature is concerned. Moreover, the durations of the movement sub-units - which, according to the isochrony principle, scale with the length of the corresponding segments of trajectory - is also accurately predicted by the minimum-jerk model. By contrast, the global scaling of average velocity as a function of total trajectory length cannot be derived from the optimality hypothesis. The implications of this pattern of convergence vis à vis the general issue of movement planning are discussed with an emphasis on the format in which the motor control system represents the intended trajectories.

THE GRASPING HAND: AN OPPOSITION SPACE MODEL OF PREHENSION. T. Iberall* and C. L. MacKenzie. Computer Science, U. of Southern Calif., L.A., CA 90089 Kinesiology, Simon Fraser U., Burnaby, B.C., Canada V5A 1S6

Using a triangle strategy to integrate conceptual, computational, and experimental models, we study the nature of prehension. Prehension is the application of functionally effective forces to an object for a task, given numerous constraints. These constraints include: task requirements, object properties, environmental characteristics, and the performer's biological structure and past experience. Reaching and grasping are controlled by parallel distributed processing in the CNS within a multidimensional constraint space, conceptualized by Arbib's coordinated control program (1981) and expanded in MacKenzie and Iberall (in press). An opposition space, as a collection of virtual fingers, defines the hand's functional capabilities for executing stable grasp and object manipulation. This abstraction focuses on key dimensions of task requirements (force, movement, sensation). Real fingers group together into virtual fingers to apply functionally effective force using pad, palm and/or side opposition. See MacKenzie and Iberall.

AN OPPOSITION SPACE MODEL OF PREHENSION: THE GRASPING HAND. C. L. MacKenzie* and T. Iberall, Kinesiology, Simon Fraser U., Burnaby, B.C., Canada V5A 1S6 Computer Science. U. Southern Calif., Los Angeles, CA 90089

MacKenzie and Iberall (in press) identify unique phases of prehension: planning, setting up, using, and releasing an opposition space by the grasping hand. For each phase, we present experimental evidence and computational models of the role of information from various sensory modalities, levels of motor commands, triggering events, and coordinate frames of reference. For example, in using an opposition space, active touch information (dominant over vision) combines with mechanical characteristics of skin (adhesion and friction, e.g., by papillary ridges and eccrine sweat glands) to enable the neuromuscular system to apply appropriate forces for grasping and manipulative stability, demonstrating anticipation of task mechanics. Integrating conceptual, computational, and experimental models of prehension, we identify areas for further experimentation and modelling. See Iberall and MacKenzie.

THE DYNAMICS OF RISING FROM A SITTING POSITION. P. Roberts and G. McCollum*, R.S.Dow Neurological Sciences Institute, Good Samaritan Hospital & Medical Center, Portland, OR 97209.

Rising from a sitting position is an important task for stroke and trauma patients to master during rehabilitation. Although the movement involved can be functionally described as moving from one position of stability to another, the physical details of the movement may vary broadly. For instance, physical therapists teach patients to lean far forward in the chair, *nose over toes*, so that the center of mass is brought over the ankles and stable stance results from extending the knees. In contrast, healthy people often utilize the *momentum method* in which they flex the abdominal muscles to give momentum to the upper trunk before extending the knees and thereby "hop" from stable sitting to standing.

In this study we take advantage of global analysis used in the modern approach to non-linear dynamics, and apply these techniques to the problem of body movement. After writing a set of coupled first order differential equations describing the possible movements, we are able to take relevant slices of the resultant phase space diagrams to elucidate the different strategies available to rise from sitting. The objective is to unite continuous physical properties of a multijointed system with discrete functional properties found in goal directed behavior.

Nose over toes (angular momentum vs. ankle angle)

RESPONSES OF SACULAR NERVE FIBERS AND TORUS SEMICIRCULARIS UNITS OF THE GOLDFISH TO TWO-TONE STIMULI. Z. Lu* and R. R. Fay, Parmlly Hear. Ins. and Dept. Psychol., Loyola Univ. Chicago, 6525 N. Sheridan Rd., Chicago, IL 60626.

Responses of single units were recorded from saccular nerve (SN) and torus semicircularis (TS) of the goldfish. Frequency-response functions (FRF), PSTHs, and rate-level functions were obtained in response to single- and two-tone stimuli. For all units, a single-tone FRF was determined as an iso-level, spike-rate function of tone frequency (75-1250 Hz). Rate level functions were determined at characteristic frequency (CF). In two-tone experiments, FRFs at three levels above CF threshold were determined in the presence of a simultaneous probe tone at CF. Two-tone rate-level functions were determined for the CF tone in the presence of "suppressor" tones fixed at various frequencies and levels. The magnitude of two-tone suppression or inhibition was defined as the horizontal distance (in dB) between the single-tone and two-tone rate-level functions. For some torus units, FRFs for both single- and two-tone stimuli resemble those of saccular nerve fibers, and exhibit features due to single-tone suppression, two-tone suppression, and response entrainment to the stimulus frequency. However, qualitative and quantitative differences were observed in FRFs, PSTHs and rate-level functions between SN and the TS units. Some TS units exhibit complex inhibitory areas above and below CF that are not observed in SN units. For suppressor tones above CF, the magnitude of suppression in torus units is generally greater than SN units, suggesting that the FRFs of some torus units are shaped by inhibition in the auditory CNS. CNS REPRESENTATION OF ACOUSTIC CLICK TRAINS IN A SONIC FISH. J.D. Crawford, *Psychology Dept., U. of Pennsylvania, Philadelphia, PA 19104.

In the African mormyrid fish *Pollimyrus isidori*, acoustic signals are important in communication. These animals produce 5 different low frequency (< 1 KHz), pulsatile, sounds. Neurophysiology shows that these fish are sensitive to sound, and specialization of the inner ear seems to allow sound pressure detection: the sacculi (otolithic organs) are each attached to one of a bilateral pair of gas bladders in the head. Since the temporal spacing of clicks, comprising fish sounds, appears to carry important communication information, I have conducted experiments to examine responses of neurons in relation to inter-click-interval (ICI) and level.

Extra-cellular, recordings were made in the auditory mesencephalon (nucleus MD) while fish were 30 mm sub-surface in a water-filled, calibrated, tank. Each neuron was initially stimulated with tones to estimate its best excitatory frequency (BEF), best excitatory sensitivity (BES), temporal response characteristics at BEF, and BEF rate-level-function. Subsequently, 400 ms click-trains were presented, with 8 ICIs ranging from 6 to 80 ms. Within an experiment, level and click waveform were constant, and ICI sequence was randomly determined. By the end of 256 stimulus presentations, each ICI was used 32 times. For neurons that appeared to have a preferred ICI, additional data were collected with different stimulus levels.

Over 40 neurons have been examined, about a third showed clear ICI-dependent responses. Several distinct response types have been found, including highly click-locked responses, non-locked responses with a dominant inter-spike-interval (ISI, ISI \neq ICI), and non-locked responses without a dominant ISI. Among these, ICI-tuned responses, ICI long-pass, and ICI short-pass profiles have been observed. ICI-tuned neurons most often respond best in the 20-40 ms range, but several best ICIs have been in the 7-10 ms range. ICI-selective neurons are probably important in processing sounds that these animals produce (R01DC1252-01A1 & DC00293-06).

COCHLEAR NUCLEUS ENHANCEMENT OF AMPLITUDE MODULATION ENCODING IS PRESERVED IN BACKGROUND NOISE. R.D. Frisina*, K.J. Karcich, and J.P. Walton, Otolaryngology Div., Physiology Dept., U. Rochester Sch. of Medicine & Dentistry, Rochester, NY 14642.

Sound envelope temporal fluctuations are important for effective processing of biologically-relevant acoustic information including speech, animal vocalizations, sound-source location and pitch. Amplitude modulation (AM) of sound envelopes can be encoded in quiet with high fidelity by many auditory neurons including those of the auditory nerve (AN) and cochlear nucleus (CN). From both neurophysiological and clinical perspectives, it is critical to understand the effects of background masking noise on the processing of AM. To further this goal, single-unit recordings were made from 106 CN units and 36 AN fibers in 18 anesthetized chinchillas. Units were classified and located in the CN according to PSTH response patterns, 1st spike latencies, shape of best-frequency (BF) rate-intensity functions, regularity analyses and mapping with extracellular HRP injections. BF pure-tone bursts, wideband noise bursts, and AM (10 to 500 Hz) BF tone bursts were employed as stimuli at several sound levels, both in quiet and in the presence of a continuous wideband noise. Data analyses indicate that 1) CN units can enhance their AM coding relative to the AN even in the presence of loud (0 or 6 dB S/N) background noise and at high sound levels (up to 75 dB SPL); 2) In the dorsal CN this enhancement is achieved by lowering the average firing rate and increasing the synchronous (fundamental frequency) response; 3) For AN fibers and in some dorsal CN units, the AM coding stays the same or declines in the presence of the background noise. In these cases, the synchronous and average responses both decline. These findings suggest that part of a CN unit's abilities to preserve or enhance AM coding in the presence of a continuous masking noise results from shifts in the operating ranges of AN fibers whereas part comes from intrinsic neural circuitry or cellular mechanisms within the CN.

ABSTRACTION OF THE MISSING FUNDAMENTAL FOLLOWING BILATERAL LESIONS OF AUDITORY CORTEX. L.I. Bharucha, M.J. Tramo* & R.J. Zatorre, Dept of Psychology, Dartmouth Coll, Hanover, NH; Dept of Neurobiology, Harvard Med Sch, Boston, MA; Dept of Neuropsychology, Montreal Neurological Inst

The pitch of a harmonic complex tone corresponds to the pitch of its fundamental frequency (F0), even when energy at F0 is missing. While information about this "virtual pitch" is present in the temporal discharge pattern of auditory nerve fibers (Delgutte & Cariani 1992), dichotic studies indicate that the abstraction process is central (Houtsma & Goldstein 1972). One study of anterior temporal lobectomy patients has demonstrated that, in most cases, right-sided excisions extending posteriorly into Heschl's gyrus impair the abstraction of virtual pitch (Zatorre 1988). Employing a similar experimental design, we examined a 34 year old stroke patient with bilateral lesions of Heschl's gyri and portions of the superior temporal gyri (Tramo et al. 1990). Judgments of the relative pitch of two harmonic complex tones presented at 75 dB SPL were significantly less accurate when energy at F0 was missing (65%) than when energy at F0 was present (92%). Although the patient's performance was significantly above chance for stimuli missing F0, it was significantly worse than that of right temporal lobectomy patients with Heschl's gyrus excisions. These results suggest that: 1) normal abstraction of virtual pitch relies on the integrity of primary auditory cortex; 2) the magnitude of the deficit may depend on the amount of the damage to primary and non-primary auditory cortical areas; and 3) in the chronic stage following ischemic stroke, the contributions of non-primary cortical areas and/or subcortical structures are sufficient to sustain above-chance performance. PATTERNS OF RESPONSE PLASTICITY IN THE RECEPTIVE FIELD OF THE RAT AUDITORY CORTEX AFTER CONDITIONING. M.E. Taylor and H.K. Rucker. Meharry Medical College, Nashville, TN. 37208.

The specific aim of these studies was to characterize the patterns of response plasticity in receptive fields of the auditory cortex of rat after conditioning. During conditioning, acoustic stimulation was paired with rewarding medial forebrain bundle (MFB) stimulation. Twenty-one neuronal multiunit clusters isolated in the non-primary auditory cortex of urethane anesthetized were characterized with regard to their frequency receptive fields. Neuronal activity was recorded after tone presentations from 4 kHz to 28 kHz (increments of 4) at 80 dB to establish a baseline. After establishing the baseline, neuronal activity was recorded and characterized after sensitization and after conditioning. Prior to sensitization training, neurons exhibited increased firing at best frequency (BF) and decreased firing at other frequencies. After sensitization, there were either a generalized increase in neuronal firing throughout the frequency receptive field or no significant changes in firing from baseline. After the conditioning training, the receptive fields were analyzed for changes in neuronal activity at BF and at the conditioned stimulus (CS) frequency. After conditioning, approximately 48% (8/18) neurons exhibited a decrease in neuronal firing at BF with an increase in firing at CS frequency. There were differences in the incidence of increase neuronal firing at CS frequency with decreased BF if the CS frequency came before rather than after the BF. Approximately, 37% (3/8) demonstrated an increased CS frequency firing with decreased BF firing when the CS frequency was before the BF; while, 63% (5/8) exhibited the same response patterns when the CS frequency was after the BF. When the BF and the CS frequency were the same (3/3), there were no significant changes in the receptive field profile; increased firing remained at best frequency. Overall, the CS exerted significant effects on neuronal firing at that frequency. 67% (12/18) of neurons exhibited an increase in neuronal firing at CS; while, 11% exhibited a decrease in firing. However, the CS caused no significant changes in 22% (4/18) of neuronal firing at that frequency. These results are interpreted to indicate that plasticity of information processing, herein represented as frequency receptive field alterations, can occur in a context-specific manner in the rat auditory cortex. SOUND LOCATION REPRESENTED IN THE FIRING PATTERNS OF AUDITORY CORTICAL NEURONS. J.C. Middlebrooks*, A.E. Cloek, and D.M. Green. Depts. of Neuroscience, Otolaryngology, and Psychology, Box 100244, University of Florida, Gainesville, FL 32610-0244.

We trained an artificial neural network to classify the firing patterns of neurons according to the location of a sound source. We recorded from single units in auditory field AES in chloralose-anesthetized cats. Noise bursts were presented from the horizontal plane, ranging through 360° of azimuth in 20° steps. Units typically responded with a 10-to-30-msec burst that varied in spike number and temporal pattern according to the sound location. The network took spike trains as input and produced locations in degrees azimuth as output. For each unit, we trained a network with spike trains from half of the trials, then used the network to classify the other half of the trials. In the first 39 units studied, the network correctly identified the stimulus location in as many as 23% of trials (average 11.1% across 39 units; chance performance would be 5.6%), and median values of the magnitude of errors were as small as 25° (average 54.5°; chance=90°). Performance showed no systematic relationship to conventional measures of sharpness of spatial tuning. When stimulus sound pressure varied among levels 10, 25, and 40 dB above threshold, classification of stimulus locations was comparable to that under fixed-level conditions. Classification performance was roughly constant across locations. That is, the spike train from a single unit could "point to" a target about equally well throughout 360° of azimuth. These results offer a new way to think about spatial representation in the auditory cortex, in which a stimulus location is coded, not by the location of activity within a map of sharply tuned neurons, but by the firing patterns of individual neurons. (supported by NIH grant DC000420)

NEURONAL RESPONSES TO VARIATIONS IN BINAURAL CROSS-CORRELATION IN BARN OWLS. Yehuda Albeck and Masakazu Konishi* Division of Biology 216-76, California Institute of Technology, Pasadena, CA 91125

Barn owls localize phantom sound sources in response to dichotically presented broad-band binaural signals containing interaural time and intensity differences. Similarly, the space-specific neurons in the external nucleus of the owl's inferior colliculus translate combinations of interaural time and intensity differences into two dimensional spatial locations or receptive fields. Just as owls fail to respond to uncorrelated signals delivered to the two ears, so do the space-specific neurons. We synthesized broad-band dichotic signals in which the coefficient of binaural cross-correlation could be systematically varied. Using these signals, we recorded the responses of space-specific neurons and their precursors to interaural time differences. When the signals contained neurons' preferred combination of interaural time and intensity differences, the rate of firing increased monotonically with the coefficient of binaural cross-correlation. The rate augmented non-linearly, but it did not indicate any abrupt changes that could be regarded as threshold of detection. This non-linear response function resembles the cross-correlogram of half-wave rectified versions of the stimulus waveforms, but exceptions to this pattern were also found.

693.6

SERIAL AND PARALLEL PROCESSING IN MACAQUE AUDITORY CORTEX. J.P. Rauschecker*, B. Tian, T. Pons and M. Mishkin. Lab. of Neurophysiology, NIMH, Poolesville, MD 20837 and Lab. of Neuropsychology, NIMH, Bethesda, MD 20892.

Electrophysiological recording techniques were used to map the exposed supratemporal plane in six anesthetized rhesus monkeys with both pure-tone and digitized broad-band complex stimuli. We confirmed the existence of at least three tonotopic areas (AI, RL, and CM; Merzenich and Brugge, 1973), plus several surrounding areas where neurons responded best to broad-band complex sounds and a tonotopic organization was not obvious. Neurons in the three tonotopic areas also responded to some of the complex sounds, most frequently in CM and least in AI. After mapping, area AI was aspirated in four of these monkeys and the remainder of the cortex on the supratemporal plane was remapped. Pure-tone responses in area CM were abolished in all animals but one, in which tonal responses were restricted to the high-frequency range. Some CM sites were still responsive to complex stimuli in all four monkeys. In contrast to the effects on CM, no significant changes were detectable in RL after the AI ablation, with most RL neurons maintaining brisk pure-tone responses.

After mapping the exposed supratemporal plane with pure tones in four additional anesthetized monkeys, injections (0.3-1.0 µl) were made with different tracers (fast blue, diamidino yellow, and fluoro ruby) into matched best-frequency regions of AI, RL, and CM in each monkey. Injections in AI and RL led to dense retrograde labeling of neurons in all three major subdivisions of the medial geniculate nucleus (MGv, MGd, and MGm), whereas CM injections led to only sparse labeling of neurons in a restricted zone of the lateral portion of MGd. In one case with an injection of DY into the border zone between AI and CM, cells were also labeled in MGv.

The combined results suggest that the main nucleus of the medial geniculate body (MGv) sends a direct projection in parallel to areas AI and RL, through which neurons in both areas are driven by tonal stimuli. Pure-tone responses in area CM, on the other hand, seem to be driven by serially relayed input from AI. The direct input to CM from MGd may only be capable of mediating responses to broad-band complex sounds.

693.8

EFFECT OF INTERAURAL TIME DIFFERENCE ON THE MIDDLE LATENCY AND LATE AUDITORY EVOKED MAGNETIC FIELDS.

L.K. McEvoy, J.P. Mäkelä*, M. Hämäläinen. Low Temp. Lab., Helsinki Univ. of Techn., 02150 Espoo, Finland

To determine if middle latency and late auditory evoked fields differ in their sensitivity to perceived sound location, we recorded the neuromagnetic responses from 5 subjects using a 122-channel whole-head magnetometer. Binaural clicks were delivered with interaural time differences (ITDs) of 0.8 ms favoring the left or right ear, or with no ITD. Current dipole models were used in data interpretation. The N100m was largest to contralaterally-perceived clicks. The N100m latency was not affected by ITD. The 35-ms middle latency deflection was 3-5 ms later to stimuli perceived at the left than to stimuli perceived at the right or midline. The amplitude of this response was slightly but not significantly larger to contralaterally- than to medially- or ipsilaterally- perceived clicks. The 60-ms deflection was not affected by ITD. The generators of the N100m response are sensitive to ITD and may play a role in sound localization. The middle latency responses do not demonstrate a clear ITD specificity, and may be generated by neurons in auditory cortex which are not involved with sound localization.

SPACE-SPECIFIC NEURONS IN THE BASAL GANGLIA OF THE BARN OWL: BINAURAL CHARACTERISTICS. Y.E. Cohen* and E.L. Knudsen. Dept. Neurobiology, Stanford University, Stanford, CA 94305

Recent behavioral studies in our laboratory have demonstrated that the forebrain contributes to sound localization in the barn owl. In order to determine the forebrain pathway responsible for sound localization, we surveyed a number of auditory fields for evidence of neural tuning to binaural localizing cues: interaural timing differences (ITD) and interaural level differences (ILD). We found a region in the basal ganglia, paleostriatum augmentum (PA), that almost exclusively contains units sensitive to both ILD and ITD.

We recorded extracellular activity of PA neurons during dichotic stimulation with digitally synthesized noise or tone bursts. Almost all PA cells were broadly tuned for frequency and were sensitive to ITD and ILD. The majority (125/155) of PA units were sharply tuned for both ITD and ILD. Overall sound level had little effect on either ITD or ILD tuning. When measured at 20 dB above threshold, average ITD tuning width, at 50% of maximum, was 69 µsec (range 13 to 199 µsec) and average ILD tuning width was 22 dB with a range from 5 to 53 dB. Although, best ITDs and ILDs ranged from ipsi 72 µsec to contra 128 µsec and from ipsi 12 dB to contra 19 dB, most PA units were tuned to ITD and ILD values near zero corresponding to the frontal region of space.

The large proportion of binaurally-tuned cells in PA suggests that this forebrain region plays an important role in sound localization.

TINNITUS-RELATED ABNORMALITIES OF THE SPONTANEOUS ACTIVITY IN THE INFERIOR COLLICULUS IN RATS INDUCED BY SALICYLATE. P.J. Jastreboff, G.D. Chen. Dept. of Surgery, University of Maryland School of Medicine, Baltimore, MD 21201.

The neuronal activity that yields the perception of tinnitus remains elusive. In search for a neuronal basis of tinnitus, the spontaneous activity of single units from the inferior colliculus (IC) was examined in 11 anesthetized pigmented rats (Nembutal 50 mg/kg) before and after injection of sodium salicylate, in a dose (233 mg/kg) shown, by our behavioral paradigm, to induce tinnitus.

358 units were recorded from the IC with 131 units recorded before, and 137 after salicylate; 46 before and 44 after saline. The characteristic frequency (CF) of each unit was determined and 5 minutes of spontaneous activity collected for off-line analysis. Cells with bimodal interval histograms with a Short Interval (SI) mode were marked.

The injection of salicylate resulted in an increased proportion of SI units from 12 to 56% for cells with CF between 8 and 12 kHz, whereas this ratio decreased from 18 to 7%, and from 38% to 19% for units with CF of 4 to 8 kHz, and above 12 kHz, respectively. Importantly, tinnitus pitch evaluated by behavioral paradigm was 10 kHz, which corresponded to CF range where a high increase in proportion of abnormal activity is observed. Consistent with these findings temporal analysis revealed that SI units exhibited high frequency, epileptic-like bursting discharges, with the intervals between spikes down to around 1.5 ms. These data show the presence of salicylate-induced abnormal bursting activity which may be related to tinnitus.

CATECHOLAMINERGIC CELL ATROPHY IN A TRANSGENIC MOUSE OVEREXPRESSION MAO-B IN NEURONS. J.K. Andersen*, D.M. Frim, O. Isacson, and X.O. Breakefield. Neurosci. Ctr., Mass. Gen. Hosp., Charlestown, MA 02129, Harvard Med. Sch., Boston, MA 02115, and Neuroreg. Lab., McLean Hosp., Belmont, MA 02178.

Transgenic mice were created to neuronally overexpress the mitochondrial enzyme monoamine oxidase B (MAO-B). MAO-B is normally expressed in the brain predominantly in astrocytes and serotonergic neurons. MAO has been hypothesized to play a role in dopaminergic cell death both during normal aging and in neurodegenerative disease: 1) MAO levels in the brain increase with age, 2) the oxidant species hydrogen peroxide is produced during the enzymatic reaction, 3) MAO-B can convert substances like MPTP to neurotoxins resulting in a Parkinsonian-like syndrome in mammals, and 4) deprenyl, an MAO-B specific inhibitor, appears to slow the course of Parkinson's disease.

A human MAO-B cDNA placed under the control of the neuron-specific enolase (NSE) promoter was microinjected into early mouse embryos by standard transgenic techniques. Resulting offspring were evaluated for genomic insertion of the transgene by PCR amplification of tail DNA and positives were confirmed by Southern blot analysis. Transgenic mice were bred to create new lines, and expression of MAO-B in these lines was analyzed using a RT-PCR based method. Transgene-specific transcripts were found to be brain-specific and MAO-B protein expression by immunocytochemistry mimicked that found for endogenous NSE. One line, MAO20, was found to have a 3-4 fold increase in brain MAO-B activity compared to normal littermates. Numbers and sizes of tyrosine hydroxylase immunopositive (TH+) cells in the substantia nigra and locus coeruleus from MAO-B transgenic animals were compared with controls at 4 months of age. TH+ perikaryon size was decreased by 20% (p<0.001). In contrast, there was no change in cell size of non-TH+ neurons. These results suggest that the overexpression of MAO-B in neurons results in atrophy of cells containing enzyme substrate due to an increased production of hydrogen peroxide. These mice are currently being analyzed for their susceptibility to the neurotoxin MPTP.

CELL-TYPE SPECIFIC NEUROFILAMENTOUS ACCUMULATIONS IN TRANSGENIC MICE EXPRESSING THE HUMAN MID-SIZED NEUROFILAMENT SUBUNIT. J.C. Vickers*1, R.A. Lazzarini2, V.L. Friedrich Jr1,2, W.G. Janssen1, G.A. Elder2 and J.H. Morrison1. 1 Fishberg Research Center for Neurobiology, 2 Brookdale Research Center for Molecular Biology, Mount Sinai School of Medicine, New York, NY 10029.

The pathological processes underlying many human neurodegenerative diseases involve an alteration in neurofilament (NF) triplet proteins and subsequent formation of hallmark filamentous inclusion bodies. Age-associated accumulations of NFs also occur in the central nervous system of the transgenic mouse line NF(M)27, which contains an 8.5 kb DNA fragment of the human mid-sized NF subunit gene. Furthermore, only specific neuronal subpopulations develop these accumulations and the intracellular localization, morphological features and immunoreactivity for specific NF epitopes of these pathologic structures varied in a cell-type specific manner. For example, NF accumulations resembling neurofibrillary tangles were localized to the subpopulation of cortical pyramidal cells that normally contain abundant NF triplet proteins. In contrast, many of the cortical neurons that normally lack NF triplet proteins developed spherical NF accumulations in their cell bodies that could be further distinguished from the tangle-like pathologic structures by their immunoreactivity for phosphorylation-dependent NF epitopes normally present in axons. Ultrastructural studies demonstrated that the spherical NF accumulations consisted of intertwining bundles of intermediate filaments. Other examples of pathologic heterogeneity include the presence of proximal axonal swellings in cerebellar Purkinje cell axons and tangle-like neurofilamentous accumulations in the perikarya of cranial motor neurons as well as the alpha ganglion cells of the retina. These studies indicate that there are widespread and yet cell-type specific alterations in the cytoskeleton of neurons in this transgenic mouse line, which partially resemble homologous perturbations of NFs that occur in several human neurodegenerative diseases. Supported by the N.I.H. and the American Health Assistance Foundation. J.C.V. is an Australian N.H.&M.R.C. C.J. Martin Research Fellow.

ABNORMAL ACCUMULATION OF THE SUBUNIT c OF MITOCHONDRIAL ATP SYNTHASE IN THE MOTOR NEURON DEGENERATION (Mnd) MUTANT MOUSE. B.A. Rabin1, C.A. Pardo1, D.N. Palmer2, J.D. Glass1* and D.L. Price1. 1The Johns Hopkins Univ. Sch. of Med., Balto, MD 21205 and 2Massey Univ., New Zealand.

The *Mnd* mutant mouse is a mutant with an autosomal dominant degenerative disease characterized by progressive loss of motor activities and accumulation of lipofuscin-like material in neurons and nonneuronal cells. Ultrastructurally, the storage material is composed of multilamellar, fingerprint, and granular profiles surrounded by limiting membrane and associated with degenerating mitochondria. Immunocytochemical, Western blot, and ultrastructural studies demonstrate that this storage material is associated with the lysosomal accumulation of subunit c of mitochondrial ATP synthase in an age-dependent pattern. The accumulation of subunit c first appears in neurons of the thalamus, hippocampus, and cortex and eventually involves virtually all nerve cells, including the retina and enteric nervous system. Subunit c also accumulates in extraocular muscle fibers, myocardium, pancreas, kidney, and other nonneuronal cells. Heterozygous *Mnd/Ola* and *Mnd/wild-strain* mice show the accumulation of subunit c, but the course of disease is slower than *Mnd/Mnd* mice. The morphological and biochemical findings in *Mnd/Mnd* are similar to those described in some human forms of neuronal ceroid lipofuscinosis (NCL) or Batten's disease and neurodegenerative disorders in children and young adults. These findings suggest that an abnormal assembly or degradation of the ATP synthase complex is responsible for the accumulation of subunit c in *Mnd* mutant mouse and, rather than a model for amyotrophic lateral sclerosis, *Mnd* is an excellent animal model to study the neurodegenerative and pathogenic processes that occur in NCL.

OVEREXPRESSION OF THE HUMAN DOPAMINE D3 RECEPTOR IN THE BRAIN OF TRANSGENIC MICE. B.G. Sahagan*, R.J. Focht, D.S. Conklin, K. Sperle, B. Levant, M.I. Turner, R.S. Senick, S. Ebner, D.E. Grigoriadis, and G.J. Ionak. CNS Diseases Research and Biotechnology, The Du Pont Merck Pharmaceutical Co., Wilmington, DE 19880-0400.

Using an FVB/N strain of mice, transgenic mice were constructed with the human dopamine D3 receptor cDNA regulated by the murine *thy-1* promoter. By Northern blot analysis, D3 receptor mRNA was detected in the brains of transgenic mice from five independent lines. Only a very low level of expression of the transgene was detected in the spleen and none in the liver or the kidney. By receptor autoradiography with the D3 selective ligand [³H]7OH-DPAT, dense binding was found throughout the brains of transgenic animals. Control animals exhibit the expected pattern of binding in olfactory tubercles, nucleus accumbens and Islands of Calleja. In contrast to control animals, mice from several independent transgenic lines manifest elevated aggressive and/or circling behaviors. The penetrance of these phenotypes varies among the transgenic lines, and between females and males. In females, up to 40% are aggressive and 25% circle. In males, up to 70% are aggressive and 10% circle. The behaviors were temporarily suppressed upon administration of the dopamine antagonist eticlopride. The age of onset of phenotypes also varies. For example, male transgenics show aggressivity towards their cagemates as early as 3-6 weeks after birth. The onset of the circling phenotype is at the age of 1-2 months. The aggressive and circling phenotypes severely hinder mating performance of both sexes. These transgenic mice are a valuable model in further studying the human dopamine D3 receptor and the *in vivo* binding and functional properties of subtype specific dopaminergic ligands.

HISTOLOGICAL ANALYSIS OF THE MALE-STERILE PHENOTYPE SEEN IN THE NEUROLOGICAL MOUSE MUTANT *WEAVER*. S.M.W. Harrison* and S. Roffler-Tarlov. Program in Neurosciences & Dept. of Anatomy and Cell Biology, Tufts Univ. Sch. of Med., Boston, MA 02111.

The *weaver* mutation affects the terminal differentiation of several distinct cell populations in the brain. Granule cells in the cerebellum fail to differentiate or migrate properly and die during early postnatal development. Purkinje cells in the cerebellum have an abnormal morphology and some of these cells also die. Dopamine-containing cells of the substantia nigra, pars compacta and the retrorubral nucleus die, also during postnatal development, resulting in the absence of projections to the caudoputamen. These neurons are the mouse homologues of the dopamine-containing neurons lost in patients with Parkinson's disease.

Sterility in homozygous mutant males is also associated with the *weaver* mutation. We have begun a detailed histological analysis of the *weaver*'s testis in an effort to describe the basis for this sterility and to gain clues about the molecular defect underlying all of the phenotypes associated with this mutation. Testicular and early germ cell development in the *weaver* male are indistinguishable from the wild-type mouse. However, as the first wave of spermatids progress through spermiogenesis, the spermatogenic process in *weaver* males is slowed with respect to normal animals. The onset of delay occurs between 21 and 28 days after birth. Although sperm in the *weaver* develop to the late spermatid stage, mature sperm were never seen to be released from the testes at any age in the *weaver*. In addition, gradual degeneration of germ cells occurs culminating in the virtual absence of cells within more than half of adult *weaver*'s seminiferous tubules. There is no detectable spermatogenic defect in the heterozygous mutant male. The lack of mature sperm produced by this mutant explains the infertility of homozygous *weaver* males and suggests that *weaver* may be a gene shared by testes and brain. NIH NS 20181.

GENOTYPIC DIFFERENCES IN THE EFFECT OF CHRONIC COCAINE ADMINISTRATION ON GABAERGIC FUNCTION. R. Marley & K. Shimosato*. Genetics Sec., Mol. Neurobio. Branch, NIDA-Addict. Res. Ctr., Box 5180, Baltimore, MD 21224.

Repeated injections of subconvulsant doses of cocaine result in changes in the susceptibility of rodents to cocaine's convulsant properties. The nature of these changes in susceptibility to cocaine seizures is under genetic control. We have identified 3 strains of mice that differ qualitatively in their response to repeated cocaine administration. Five daily injections of 50 mg/kg of cocaine result in the development of sensitization and tolerance to cocaine-induced seizures in SJL/J and C57BL/6J mice, respectively. This same treatment regimen has no effect on the susceptibility of BALB/cByJ mice to cocaine seizures. We have been using these animal models to examine possible biochemical mechanisms underlying these changes in seizure susceptibility. In the present study, we examined the effect of this treatment regimen on GABA-stimulated $^{36}\text{Cl}^-$ uptake into cortical and cerebellar membrane preparations from SJL, C57 and BALB mice. Five daily injections of 50 mg/kg cocaine resulted in an increase in GABA-stimulated $^{36}\text{Cl}^-$ uptake into cortical tissue from the SJL mice and into cerebellar tissue from the C57 mice. No changes in $^{36}\text{Cl}^-$ uptake were observed in either region in tissue preparations from BALB mice. These results suggest an association between the development of sensitization and/or tolerance to cocaine seizures and changes in GABAergic function.

A HERPES SIMPLEX VIRUS FOR GENE TRANSFER INTO NEURONS IN ORGANOTYPIC HIPPOCAMPAL SLICE CULTURES. B.A. Bahr¹, J. Sharp¹, R.L. Nev², A.I. Geller³ & G. Lynch¹. ¹Center for Neurobiology of Learning and Memory, Univ. of California, Irvine, CA 92717, ²McLean Hospital, Harvard Medical School, Belmont, MA 02178, ³Children's Hospital, Harvard Medical School, Boston, MA 02115

Enhanced-expression and antisense-intervention are both good strategies to target specific gene products in order to elucidate mechanisms of neurophysiology. Viral vectors have proved useful in this respect to deliver sense or anti-sense mRNAs to brain neurons. In this study, a defective herpes simplex viral vector (pHSVlac) containing a gene (*lacZ*) encoding β -galactosidase (β -gal) was used to infect organotypic hippocampal slice cultures. Cultured slices were utilized since they retain many *in vivo* features and are comparable to intact hippocampus with regard to anatomy, circuitry, electrophysiology, synaptic plasticity, pathology, and synaptic composition. Slices infected with pHSVlac (5,000-150,000 infectious particles) expressed the β -gal enzyme in a dose-dependent manner as measured on immunoblots; no β -gal was detected in slices infected with control virus (pHSVsyn) lacking the *lacZ* gene. β -Gal was evident as early as 2 h post-infection with pHSVlac and was maximal after ~35 h. Expression of the *lacZ* gene (mRNA and protein) persisted for at least 12 days as measured by immunoblots and by reverse transcription-PCR using primers specific for the recombinant *lacZ* RNA. The level of the intrinsic synaptic marker synaptophysin was not affected by the virus. Staining the infected slices with the β -gal substrate X-gal revealed that the density of β -gal-positive blue cells is highest in CA3 and dentate gyrus and lowest in CA1. X-Gal also stained somata and dendrites of infected interneurons. Double labeling with anti-MAP2 confirmed that most of the infected cells were neurons. In conclusion, HSV allows transfer of foreign genes with no evident cytopathology (NIA AG00538 supported).

A RAT MUTANT WITH BRAIN AMYLOID DEPOSITS, LOW NMDA RECEPTOR BINDING AND BEHAVIORAL DEFICITS: A PRELIMINARY REPORT. P. Romanelli, L. DiMatteo, M.P. Pellicano and A.G. Sadile*, Dipt. Fisiologia Umana "F. Bottazzi", 2nd Univ. of Naples (SUN), Naples, Italy.

A new rat mutant has been obtained by genetic techniques, the NLE/AD, that features at 12 months of age some histochemical, neurochemical and behavioral aspects of Alzheimer's disease (AD). **Histochemistry:** Congo red staining on paraffin embedded brain sections revealed deposits of amyloid substance varying in size in the hippocampus mainly in CA1, amygdala and somatosensory cortex. They are birefringent at polarized microscope and immunoreactive for a β -APP polyclonal antibody. **NMDA binding:** twenty μm thick unfixed cryostat sections were incubated with 150nM ^3H -glutamate (56 Ci/mmol) at 4 °C alone or in presence of 100 μM N-methyl-D-aspartate (NMDA) or 2.5 μM quisqualate (QA). Non specific binding was determined in presence of 1mM unlabelled glutamate. The sections were exposed to tritium-sensitive films for 3 weeks at 4 °C. Quantitative analysis revealed (i) lower levels of ^3H -glutamate binding in NLE/AD in the somatosensory cortex, hippocampal CA1, dentate gyrus and amygdala; (ii) in the hippocampus, the displacement by NMDA was lower in NLE/AD. **Behavior:** rats were tested in a L $\bar{\text{a}}$ t-maze, in a six-arm tunnel maze, and in a shuttle box. NLE/AD rats showed (i) lower activity in the L $\bar{\text{a}}$ t-maze with impaired short-term and long-term habituation; (ii) poor working and reference memory in the tunnel maze; (iii) no retention of two-way avoidance. In conclusion, the NLE/AD rats with amyloid deposits, lower NMDA receptor binding and a distorted behavioral profile, feature some of the aspects of AD and may help understanding the relationships between amyloid deposits and dementia.

STRUCTURE/FUNCTION ANALYSIS OF MEC-4: A PROTEIN INVOLVED IN MECHANOSENSORY NEURON FUNCTION AND NEURODEGENERATION. M. Driscoll* and K. Hong. Dept. of Molecular Biology and Biochemistry, Rutgers University, New Brunswick, NJ 08855

mec-4 is a member of a family of genes, termed degenerins, that can mutate to cause swelling and degeneration of specific groups of neurons in *C. elegans*. Because death-inducing *mec-4(d)* alleles appear to alter osmotic balance, we have suggested that MEC-4 may normally function to regulate membrane permeability. The deduced primary structure of MEC-4, which includes two hydrophobic domains (MSDI and MSDII), is consistent with the idea that MEC-4, expressed in and required for the function of mechanosensory neurons, might be a subunit of a mechanosensory ion channel. The cloning of a member of the degenerin gene family from rat (*Nature* 361:467) by virtue of its ability to induce an amiloride-sensitive Na^+ current in frog oocytes supports the hypothesis that MEC-4 is a channel component.

We have conducted a structure/function analysis of MEC-4 to gain insight into normal MEC-4 function and into how this protein can be altered to induce inappropriate death. Our analysis has highlighted the functional importance of charged and polar amino acid residues that align on one face of the predicted α helix that spans MSD2. We have introduced various point mutations in *mec-4(+)* or *mec-4(d)* that alter amino acids in MSD2 to test for disruption of normal function or degeneration, respectively.

We have identified two additional regions where amino acid substitutions disrupt MEC-4 function. One frequently altered region is within a Cys-rich domain and the other affects a putative intracellular region that may be phosphorylated by cAMP kinase.

TRANSGENIC MICE WITH ABNORMAL ACETYLCHOLINE RECEPTOR (AChR) CHANNELS: THE SLOW CHANNEL PHENOTYPE. CM Gomez*, B Bhattacharyya, EH Lambert Dept. of Neurology, Univ. of MN, Minneapolis, MN 55455.

The slow channel syndrome (SCS) is an autosomal dominant progressive myopathy in which abnormal neuromuscular transmission (NT) and degenerative changes in the postsynaptic membrane are postulated to arise from an inherited abnormality of AChR causing delayed closure of AChR ion channels of the neuromuscular junction. To test this hypothesis we generated transgenic mice using a DNA construct that expresses an AChR δ subunit with a mutation (δS6T) that prolongs mean single channel open time 3-fold. Three founder lines have several-fold higher levels of muscle mRNA for δS6T than for wild type subunits. We studied miniature endplate currents (mepc) and endplate currents (epc) in diaphragm *in vitro* using 2 electrode voltage clamp. Both mepc and epc of δS6T transgenic mice have significantly increased decay time constants (τ) (Control τ_{mepc} : 1.21 \pm 0.05ms vs transgenic τ_{mepc} : 2.7 \pm 0.17ms, $p<0.01$; Control τ_{epc} : 1.94 \pm 0.23 vs transgenic τ_{epc} : 5.6 \pm 0.84, $p<0.01$). Mepc amplitudes of transgenics are also significantly reduced (Control: 2.57 \pm 0.1nA vs transgenic: 1.76 \pm 0.1 nA, $p<0.01$). To test whether increased τ_{epc} affects NT in transgenic mice, we recorded compound muscle action potentials (CMAP) evoked by direct stimulation of sciatic nerve *in vivo*. All transgenic mice tested (N=18) had repetitive CMAP after a single nerve stimulus, while no control mice (N=9) had repetitive CMAP. Thus, expression in muscle of a mouse AChR δ subunit with a single amino acid substitution causes altered synaptic currents, reduced mepc amplitudes, and repetitive CMAP following single nerve stimuli, as are seen in the SCS. Supported by NIH, MDA.

DRD4 DOPAMINE RECEPTOR ALLELE FREQUENCIES IN ALCOHOLICS AND CONTROLS FROM VARIOUS POPULATIONS.

M. Adamson, J. Kennedy, A. Petronis, M. Dean, M. Virkkunen, M. Linnoila, D. Goldman*, Lab. of Neurogenetics, NIAAA, Bethesda, MD 20892

The DRD4 gene contains a 48 bp repeated segment in Exon III of the coding region (*Nature* 358, pp 149-152; 1992). Alleles coding for 2 to 8, and 10 repeats have been found. Varying the numbers of repeated segments changes the length, structure and function of the receptor, which makes this gene an intriguing candidate as a genetic determinant of dopamine-related behaviors.

Using a PCR method developed by Kennedy et al (in press), the frequency of DRD4 repeat alleles was determined in a population of Finnish alcoholics and controls, and in four other populations (Blacks, Pima Indians, Cheyenne Indians, and Jemez-Pueblo Indians). Finnish alcoholics were of the early onset, impulsive type. The homogeneity of this population and of their alcoholic phenotype would allow us to detect an association to alcoholism. However, these 98 Finnish alcoholics were not significantly different from 96 ethnically matched controls. The distribution of repeat alleles (2-8) in this more isolated Finnish population was similar to that seen in Caucasians (Kennedy et al). Caucasians, Finns, and Jemez-Pueblo Indians were multiallelic but Pima Indians, Cheyenne Indians, and Blacks showed less variability and lacked the shorter repeat alleles. Selection or random genetic factors, including founder effects and drift, may have determined these differences in allele frequency. Further investigation of the DRD4 variants may elucidate whether these population differences are behaviorally significant.

695.3

THREE-METHOXYTYRAMINE (3MT) IS THE MAJOR METABOLITE OF RELEASED DOPAMINE (DA) IN THE RAT FRONTAL CORTEX (FC), NUCLEUS ACCUMBENS (NAC) AND STRIATUM (ST): REASSESSMENT OF THE EFFECTS OF NEUROLEPTICS ON DOPAMINE RELEASE AND METABOLISM. F. Karoum*, S.J. Chrapusta and R.J. Wyatt, Neuropsychiatry Branch, NIMH Neuroscience Center at St. Elizabeths, Washington, D.C 20032

3MT and DOPAC rates of formation were estimated in the FC, NAC and ST of rats 60 min. after the administration of 0.4 mg/kg haloperidol (HAL), and 10 mg/kg clozapine (CLZ). The rates of formation were calculated from the respective increase and decrease in 3MT and DOPAC concentrations following 75 mg⁻¹, I.P. pargyline. 3MT rate of formation (53 ± 2 fmol/mg protein/min.) was found to be comparable to that of DOPAC (39 ± 4 fmol/mg protein/min) in the FC. In contrast, 3MT rates of formation in the NAC and ST were about 10% of the rates of formation of DOPAC. Both HAL and CLZ significantly increased 3MT and DOPAC production in the FC, indicating that DA release and metabolism were stimulated. While 3MT and DOPAC rates of formation were significantly increased by HAL in the ST and NAC, only DOPAC production was elevated by CLZ. It is concluded that: 1) O-Methylation is a prominent step in the catabolism of DA in the FC under both physiological conditions and following acute treatment with antipsychotics; 2) While stimulation of DA release in the FC by neuroleptics may be involved in the antipsychotic properties of these drugs, HAL stimulation of DA release in the ST and perhaps in the NAC may underlie its extrapyramidal effects; 3) most DOPAC in the NAC and ST apparently originates from intraneuronal deamination of unreleased DA.

695.5

Fe²⁺ CATALYZES THE OXIDATION OF 3,4-DIHYDROXYPHENYLALANINE (DOPA) TO AN EXCITOTOXIN T.A. Newcomer* & E. Aizenman, Dept. of Neurobiology, Univ. of Pittsburgh School of Medicine, Pittsburgh, PA 15261.

2,4,5-Trihydroxyphenylalanine (TOPA)-containing solutions oxidize to form a quinone derivative that is a non-NMDA agonist and excitotoxin (Rosenberg et al., *P.N.A.S.* 88: 4865;1991). We have recently reported that TOPA quinone exists as the dominant species in TOPA-containing physiological salt solutions. In addition, we observed that DOPA partially autooxidizes at neutral pH to form TOPA compounds (Newcomer et al., *J. Neurochem.* in press). In this study, we have examined the influence of Fe²⁺ and Fe³⁺ on the rate and amount of this conversion. In Hanks' balanced salt solution neither 1 mM FeNO₃ (Fe³⁺) nor 100 μM ascorbate alone had any effect over baseline conversion rates (0.2% at 3 hours). However, in the presence of 100 μM ASC, 1 mM Fe³⁺ increased the amount of conversion to 1.3% at 3 hours. In contrast, the effects of 1 mM FeCl₂ (Fe²⁺) were independent of ascorbate and significantly faster (1.7% conversion at 24 min). These data suggest that Fe²⁺ can catalyze the conversion of DOPA to TOPA, and that Fe³⁺ must be reduced to Fe²⁺ by ascorbate to produce this oxidation. These results may have implications for disorders involving high levels of transition metals near catecholaminergic neurons such as in Parkinson's disease.

PREPUBERTAL CASTRATION AUGMENTS AMPHETAMINE INDUCED DOPAMINE INCREASE IN ADULT MALE RATS. E. Murzi*, L. E. González, X. Páez, T. Baptista and L. Hernández. Laboratory of Behavioral Physiology, Medical School, Los Andes University, Mérida 5101, Venezuela.

The impact of puberty on the mesolimbic dopamine system was assessed in male rats castrated before puberty. The dopamine function was evaluated by a pharmacological challenge with amphetamine. Eight male rats, three weeks old were castrated by escrotal incision. Seven controls only had the surgical wound (sham group). After two months guide shafts aimed to the nucleus accumbens were permanently implanted in each rat. Seven days after surgery, microdialysis probes were inserted in the accumbens with the technique described elsewhere¹. Dopamine, DOPAC and Homovanillic Acid were measured in the dialysates by high pressure liquid chromatography and electrochemical detection. After obtaining a stable base line, amphetamine sulfate (1 mg/kg) was injected i.p. Dopamine increased three folds more in castrated than in normal rats. This difference was statistically significant. Dopac and HVA decreased more in the castrated rats than in the normal rats. These results indicate that androgens might increase dopamine receptor sensitivity lowering the response to amphetamine in normal rats. If this is correct, these results might provide an explanation for the onset of schizophrenia symptoms after puberty and the greater severity of those symptoms in males than in females².

DO VTA DOPAMINE NEURONS RELEASE A GLUTAMATE-LIKE COTRANSMITTER? D. Sulzer* and S. Rayport, Dept Psychiatry, Ctr Neurobiology & Behavior, Dept Anatomy & Cell Biology, Columbia Univ; Dept Neuropathology, NYS Psychiatric Inst, NY 10032.

Immunocytochemical studies suggest that ventral tegmental area (VTA) neurons are mostly inhibitory, releasing either dopamine or GABA. However, in VTA cultures derived from postnatal rats, neurons recorded in whole cell patch clamp mode commonly receive excitatory input that can be blocked by glutamate receptor antagonists, including the AMPA antagonist CNQX (10 μM), the NMDA antagonist APV (30 μM), or the broad-spectrum glutamate antagonist kynurenatate (500 μM). The EPSPs appear to have both AMPA and NMDA components.

To determine whether dopamine neurons might be the source of the excitation via the release a glutamate-like cotransmitter, we cultured single VTA neurons on 100 μm diameter glial islands surrounded by an agar substrate inhospitable to neurite outgrowth (Segal & Furshpan, *J Neurophysiol* 64:1390, 1990). In these single neuron cultures, where all synaptic input must be autaptic, neurons frequently produced stimulation-dependent EPSPs that could be abolished by glutamate receptor antagonists. A subset of these neurons were dopaminergic by tyrosine hydroxylase immunocytochemistry. Therefore, some dopamine neurons both release and respond to a glutamate-like transmitter.

These results are consistent with immunolabeling studies in the intact brain that suggest that a classical neurotransmitter other than DA may be released from midbrain dopamine neurons (Hattori et al, *J Comp Neurol* 309:391, 1991; Kaneko et al, *Brain Res* 507:151, 1990). Constrained by the expression of autoreceptors, the single neuron microculture technique provides a novel method to identify the transmitters released by identified mammalian neurons.

IDAZOXAN-SPECIFIC ANTISERUM RECOGNIZES AN ENDOGENOUS CLONIDINE-DISPLACING SUBSTANCE (CDS) IN HUMAN SERUM AND CSF. H. Wang*, D. McGowan, S. Regunathan, S. Bramwell, G. Li and D.J. Reis. Div. Neurobiol., Dept. Neurol. & Neurosci., Cornell Univ. Med. Coll., New York, NY 10021.

Clonidine-displacing substance (CDS) is an endogenous, non-peptidergic, low molecular weight (<500 Da) material present in brain, other tissues and serum which, like clonidine, binds to both α₂-adrenergic and imidazoline receptors (IRs). CDS may be an endogenous ligand for IRs. It also cross-reacts with antibodies to PAC (although with low sensitivity and some non-selectivity) (Meeley et al., *Hypertension*, 13:341, 1989). Therefore, we sought to develop a more selective, sensitive and clinically applicable radioimmunoassay (RIA) for CDS based on its ability to cross react with idazoxan. Antibodies were produced in rabbits against an idazoxan-hemocyanin conjugate. The anti-idazoxan antiserum had high affinity for unconjugated ³H-idazoxan (K_d=26nM) in RIA. In competition experiments of various drugs and relevant endogenous molecules, only idazoxan potently (IC₅₀<100nM) inhibited ³H-idazoxan binding. A few drugs weakly (IC₅₀>1mM) inhibited binding (cirazoline>UK 14304>guanabenz>amiloride). Other relevant agents including clonidine, naphazoline, moxonidine, rauwolscine, histamine and catecholamines did not inhibit binding even at 1mM. CDS highly purified from bovine brain dose-dependently and totally inhibited specific ³H-idazoxan binding. The antiserum was more sensitive than the anti-PAC antiserum (4 idazoxan RIA Unit=1 PAC RIA Unit) and more selective. CDS activity was also detected by the antibody in human (0.9-4.1U/ml) and rat sera (1-2U/ml). Human CSF samples tested contained CDS activity ranging from undetectable to 1.3U/ml. We conclude that a RIA using an anti-idazoxan antibody can detect CDS activity in human serum and CSF.

695.7

EXPRESSION OF IMIDAZOLINE RECEPTOR PROTEIN IN HUMAN BRAIN AND LIVER. P.V. Escriba, M. Sastre, H. Wang, S. Regunathan, D.J. Reis* and J.A. Garcia-Sevilla. Lab of Neuropharmacol., Univ. of Balearic Islands, SPAIN and Div. of Neurobiol., Cornell Univ. Med. Coll., New York, NY 10021.

Clonidine, idazoxan and associated ligands bind to both α_2 -adrenergic receptors and a nonadrenergic binding site, the imidazoline receptor (IR). We have purified, by idazoxan-affinity chromatography, an imidazoline receptor binding protein (IRBP) from bovine adrenal chromaffin cells (Wang et al., *Mol. Pharmacol.* 42:792, 1992) and generated antibodies (Ab) thereto (Wang et al., *Mol. Pharmacol.* 43:509, 1993). Ab specificity was established by immunocytochemistry, inhibition of ligand binding, immunoprecipitation and immunocytochemistry. We examined whether the IRBP is expressed in human and rat cerebral cortex, caudate nucleus, hypothalamus, medulla oblongata, cerebellum, and liver and also rat adrenal medulla, tissues expressing IRs by ligand binding. Tissues were processed for Western blotting using HRP-linked donkey anti-rabbit IgG detected by enhanced chemiluminescence. All expressed a double band of 29-30kDa, and a lesser band of 47kDa (with the exception of cerebellum, liver, and adrenal). A less intense band of 66kDa was seen in most rat tissues (except cerebellum and liver) but only in human liver. Human medulla oblongata had bands of 44 and 50kDa and rat adrenal bands of 58 and 86kDa. We conclude that (a) human brain and liver express an IRBP which is immunologically similar to that of rat; (b) the IRBP exists in several molecular forms representing either receptor isoforms or degradation products; (c) the IRBP of brain and liver share comparable elements; (d) the IRBP may be common to the two major subclasses of IRs, the I-1 and I-2, since these are differentially concentrated in medulla oblongata and adrenal medulla/liver. Since adrenal medulla expresses only IRs, the results further indicate that the IR is molecularly distinct from α_2 -adrenergic receptors.

695.9

NEUROPEPTIDE-PROCESSING ENZYME PEPTIDYLGLYCINE ALPHA-AMIDATING MONOOXYGENASE (PAM) AND CHOLECYSTOKININ (CCK) EXPRESSION IN THE CATECHOLAMINERGIC SYSTEM FOLLOWING AXOTOMY. T.C. Wessel*, T.A. Houpt, H. Baker, and T.H. Joh. Laboratory of Molecular Neurobiology, Burke Medical Research Institute, and E.W. Bourne Behavioral Research Laboratory, Cornell Univ. Medical College, White Plains, NY 10605.

Medial forebrain bundle (MFB) transection is a model system for degenerative brain disorders such as Parkinson's disease, which are characterized by a decline in neurotransmitter-synthesizing enzymes and ultimately cell death of specific neuronal populations. We have previously shown a close correlation between resumption of tyrosine hydroxylase (TH) gene expression after MFB transection and long-term cell survival: the majority of substantia nigra compacta (SNc) neurons lose TH gene expression and gradually degenerate, while locus ceruleus (LC) neurons regain basal TH expression between 2 and 4 weeks after axotomy.

These experiments determined whether the neuropeptide CCK, the neuropeptide-processing enzyme PAM and the catecholamine-synthesizing enzyme TH exhibit differential spatial and temporal regulation following MFB transection. The production of bioactive CCK and galanin in the SNc and LC, respectively, is dependent on PAM which is co-expressed with TH in these neurons. Rats were examined with *in situ* hybridization and immunohistochemistry at various time points from 4 days to 6 weeks after unilateral MFB transection: in the SNc, TH and CCK mRNA and protein levels as well as PAM mRNA levels decreased irreversibly over 6 weeks, although a small number of neurons were resistant to the effects of unilateral axotomy. In contrast, PAM mRNA levels in the LC followed a similar time course to that previously described for TH mRNA and protein levels. These results suggest that TH and PAM gene expression may be co-regulated in degenerating and regenerating axotomized catecholaminergic neurons. Supported by MH44043.

EGR1 ACTIVATES EXPRESSION OF THE RAT PNMT GENE S.N. Ebert*, S.L. Balt and D.L. Wong. Department of Psychiatry and Behavioral Sciences, Stanford University School of Medicine, Stanford, CA 94305

Phenylethanolamine N-methyltransferase (PNMT) catalyzes the conversion of norepinephrine to epinephrine and is subject to neural and hormonal controls. However, the intracellular factors which mediate the effects of these stimuli on PNMT gene expression remain undefined. Examination of rat PNMT genomic sequences revealed consensus DNA-binding sites for Egr1, an immediate-early transcription factor which is known to be rapidly and transiently induced by a variety of neural stimuli. In order to evaluate the potential Egr1 interactions with the PNMT gene, the rat PNMT promoter/regulatory DNA sequence was fused to the firefly luciferase reporter gene and co-transfected into transformed PC12 (RS1) cells with a vector which provides strong constitutive expression of Egr1. The presence of Egr1 caused a marked stimulation (300-400%) in PNMT promoter-dependent luciferase activity. RNase protection assays show that the endogenous PNMT gene was also activated by Egr1. The consensus DNA-binding sites for Egr1 are located approximately 45 and 165 bp 5' of the PNMT transcriptional initiation site. Deletion and site-directed mutagenesis of the PNMT promoter/regulatory region in combination with transient co-transfection assays suggest that maximal Egr1 stimulation of the PNMT promoter is dependent on the integrity of both of the putative Egr1 binding sites, although either site alone appears capable of conferring partial Egr1 responsiveness. Gel mobility-shift assays confirm that Egr1 binds to both sites. These results demonstrate that Egr1 can activate PNMT gene expression and that this activation is likely to occur through direct binding of Egr1 to its target DNA sequences within the promoter/regulatory region of the PNMT gene. The fact that Egr1 is itself induced by neural stimulation suggests that it may participate in neural activation of PNMT gene expression.

L-DOPA FORMATION AND PHOSPHORYLATION OF TYROSINE HYDROXYLASE (TH) IN AIT-20 CELLS EXPRESSING WILD TYPE TH OR A SERINE 40 MUTANT OF TH. M. Goldstein*, J. Wu, D. Tang and J. Haycock. Neurochem. Res. Labs., N.Y.U. Med. Ctr., N.Y., N.Y. 10016 and Dept. Biochem. Mol. Biol., LSU Med. Ctr., New Orleans, LA 70119

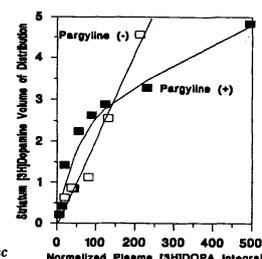

Substitution of Leu for Ser-40 in tyrosine hydroxylase (TH-S40L) produces an enzyme with *in vitro* properties similar to wild type TH (TH-WT) that has been phosphorylated by protein kinase A (PKA) (Wu, J. et al. *J. Biol. Chem.* 267:7373, 1992). In the present study we have determined the *in situ* activities of TH-WT and TH-S40L in stably transfected AIT-20 cells by measuring DOPA accumulation in the presence of 50 μ M NSD 1015 (30 min, 37°C) to inhibit DOPA catabolism. The majority of DOPA was present in the incubation medium. In separate experiments, site-specific phosphorylation of TH was determined after preincubation with 32 P. DOPA formation in AIT-20 cells expressing TH-S40L was 6-8 fold higher than that in the cells expressing TH-WT. Addition of 10 μ M forskolin, an activator of adenylyl cyclase, increased DOPA synthesis in the cells expressing TH-WT, but slightly decreased DOPA formation by the cells expressing TH-S40L. TH-WT was phosphorylated at Ser-8, -19, -31, and -40, whereas 32 P incorporation into TH-S40L was restricted to Ser-8, -19 and -31. Basal phosphorylation of TH-S40L was approx. 2-fold higher than that of TH-WT, due primarily to increased S-31 phosphorylation. Whereas forskolin increased TH-WT phosphorylation (primarily at S-40), TH-S40L phosphorylation was decreased by forskolin. While the data suggest that S-40 mediates PKA-dependent activation of TH *in situ*, they also suggest that phosphorylation of the other sites is important in TH regulation. Supported by NIMH Grants 02717 and 43230 and NS 25134.

DETERMINATION OF IN VIVO DOPA DECARBOXYLASE ACTIVITY IN RAT STRIATUM: THE EFFECT OF PARGYLINE. P. Cumming*, H. Kuwabara, and A. Gjedde. Montreal Neurological Institute, McGill University, Montreal, Canada H3A 2B4.

Experiments were conducted to test for regulation of DOPA decarboxylase in striatum of Wistar rats. Conscious rats were treated with saline or pargyline (50 mg/kg, i.p.) 30 minutes prior to [3 H]DOPA injection (200 μ Ci, i.v.) which circulated for 3-240 minutes. Radioactivities in arterial plasma and striatum were fractionated by HPLC. The distribution volume for [3 H]dopamine in striatum was plotted as a function of the normalized plasma [3 H]DOPA input. Results indicate that DOPA decarboxylase activity declines after prolonged blockade of [3 H]dopamine metabolism with pargyline. The finding also suggests that pargyline initially prevents efflux of dopamine metabolites.

Experimental Condition	DOPA Decarboxylase Activity [$\text{ml hg}^{-1} \text{min}^{-1}$]
pargyline (-)	
initial rate	2.1 \pm 0.2
final rate	2.1 \pm 0.2
pargyline (+)	
initial rate	5.4 \pm 1.7
final rate	0.5 \pm 0.2

PHENYLETHANOLAMINE N-METHYLTRANSFERASE GENE ACTIVATION: EGR-1 AND GLUCOCORTICOID RECEPTOR SYNERGY. D. L. Wong*, S. N. Ebert, S. L. Balt and J. P. B. Hunter. Department of Psychiatry and Behavioral Sciences, Stanford University School of Medicine, Stanford, CA 94305.

Rat adrenal phenylethanolamine N-methyltransferase (PNMT) is neurally controlled through its synthesis while glucocorticoids (GC) control its degradation. GCs and the GC receptor (GR) also may be important in PNMT transcription, consistent with a GRE in the PNMT gene. However, GCs will not induce premature PNMT expression developmentally, and only weakly stimulate its expression *in vitro* in cells with the potential for PNMT expression. Recently, we have demonstrated that the transcriptional factor Egr-1 activates reporter gene and endogenous PNMT from the PNMT promoter using a PC12 derivative cell line (RS1). The transcriptionally activated cells show high nuclear expression of Egr-1. Similarly, *in vivo*, Egr-1 is markedly elevated in adrenal medullary cell nuclei in rats administered reserpine (10 mg/kg i.p.), a drug elevating PNMT mRNA 8-fold through neural mechanisms. Reserpine elevates adrenal corticosterone 11-fold coincident with transcriptional activation, suggesting interaction between neural and hormonal controls. Transient co-transfections assays have been used to further investigate this interaction. In the presence of the functional Egr-1 binding sites (-45 and -165 bp) and GRE (-513 bp) in the PNMT promoter/regulatory sequences, dexamethasone (1 μ M) enhances reporter gene activity from PNMT-luciferase constructs 2-fold above induction seen with Egr-1 alone. When the GRE or GRE and distal Egr-1 binding site are eliminated dexamethasone will not similarly activate luciferase although Egr-1 activation of luciferase still occurs. Thus, Egr-1 appears to be an important activator of PNMT gene transcription, with the GR playing a modulatory role in controlling this catecholamine enzyme.

EVIDENCE FOR A NEUROPEPTIDE Y → GALANIN → β-ENDORPHIN PATHWAY IN THE RAT HYPOTHALAMUS. Horvath, T.L.,¹ S.P. Kalra,³ F. Naftolin,¹ and C. Leranth.^{1,2} ¹Dept. of Ob/Gyn, and ²Section of Neurobiology, Yale University, Sch. of Med., New Haven CT. 06510 and ³Dep. of Ob/Gyn, University of Florida, Gainesville, FL 32610.

We provided morphological evidence of an NPY → β-endorphin connection (Horvath et al. Endocrinology 1992), suggesting an indirect effect of NPY on gonadotropin secretion. This hypothesis was confirmed by a pharmacological experiment, which revealed that naloxone blocks the inhibition of gonadotropin release induced by NPY. On the other hand, communication between the hypothalamic NPY and galanin systems has been postulated to play a role in the active feeding cycle. Furthermore, galanin was demonstrated to induce prolactin release, which involves opioidergic mechanisms. This study was designed to discern the morphological interconnections between NPY and galanin, and galanin and β-endorphin neurons. Correlated light and electron microscopic double-immunostaining analysis demonstrated synaptic contacts between NPY boutons and galanin cells in the arcuate-, paraventricular-, and supraoptic nuclei. The density of these synaptic contacts was highest in the paraventricular nucleus and lowest in the supraoptic nucleus. Furthermore, galanin-immunoreactive fibers were found in synaptic connection with a population of mediobasal hypothalamic β-endorphin neurons. These results indicate that: 1) in the paraventricular nucleus NPY probably influences galanin-producing neurons, shifting the animal's preference for macronutrients; 2) galanin, at least in part, exerts its effect on prolactin secretion via β-endorphin cells of the arcuate nucleus; and 3) that in the rat hypothalamus, there is an NPY → galanin → opiate pathway, which is involved in both reproduction and ingestive behavior in a site specific manner. Supported by NIH grants HD-23830 (to C.L.), HD-13587 (to F.N.), and HD-08634 (to S.P.K.).

INHIBITORY PARASYMPATHETIC NERVES BECOME EXCITATORY FOLLOWING ORBITAL SYMPATHETIC DENERVATION P. G. Smith* and C. L. Beauregard. Department of Physiology, University of Kansas Medical Center, Kansas City, KS 66160

Autonomic nerves can regulate target activity directly through effects on postjunctional cells and indirectly through actions on other nerves. Parasympathetic innervation normally mediates its actions on orbital smooth muscle solely indirectly by prejunctionally inhibiting adjacent sympathetic nerves. The present study investigated alterations in orbital parasympathetic function following removal of sympathetic nerves.

Adult Sprague-Dawley rats were sympathectomized by unilateral superior cervical ganglion excision. Five weeks later, parasympathetic innervation to the intact or sympathectomized orbit was stimulated by an electrode placed stereotaxically in the superior salivatory nucleus and changes in superior tarsal smooth muscle tone were measured.

Stimulation of parasympathetic innervation to the intact muscle caused a small decrease in resting tension (-106 ± 8 mg). In contrast, parasympathetic stimulation of the sympathectomized side caused a large contraction (619 ± 76 mg), which was abolished by atropine. Excitation after sympathectomy is not attributable to changes in smooth muscle muscarinic receptor sensitivity, as responses to the muscarinic agonist bethanechol were not altered significantly.

We conclude that following sympathetic denervation, changes occur in cholinergic neurotransmission that result in the functional conversion of orbital smooth muscle parasympathetic nerves from prejunctional inhibition to postjunctional excitation. Supported by NS23502.

PERIPHERAL GASTRIC EFFECTS OF CCK-8 ON BRAINSTEM UNITARY RESPONSES IN THE *IN VITRO* NEONATAL RAT. C.S. Yuan and W.D. Barber*. Dept. of Anatomy, College of Medicine, University of Arizona, Tucson, AZ. 85724.

Subdiaphragmatic vagally-evoked unitary responses were recorded extracellularly in the nucleus tractus solitarius (NTS) in an *in vitro* neonatal rat brainstem-gastric preparation. The preparation was maintained in a chamber containing a superfused Krebs' solution. A partition divided the chamber into a gastric and a brainstem compartment. A suction stimulating electrode was placed on the vagi at the gastroesophageal junction. The peripheral gastric effects of sulfated CCK-8 were evaluated on 93 evoked NTS responses in 0-6 days old rats. Peripheral gastric application of CCK-8 (300 nM) increased the excitability (283 ± 9.8%, mean ± S.E.) in a majority of NTS neurons tested. Surgical removal of the distal stomach containing the pylorus significantly decreased the effect of the peptide on the NTS neurons. The peripheral gastric effects of CCK-8 on the subdiaphragmatic vagal evoked responses in NTS were also evaluated in three age groups between 0 and 6 days of age. The gastric effects of CCK-8 produced a 30% greater increase in the NTS response in the 5-6 day old age group than in the < 1 or 2-3 day old age groups. These results suggest that gastric receptors, served by vagal afferents, responded to CCK-8 resulting in an increase in NTS neuronal activity. The peripheral gastric effects of the peptide on NTS activity were more pronounced in 5-6 day old rats. (Supported by USPHS Grant DK 36289).

BOTH HIGH AND LOW AMBIENT TEMPERATURES ELEVATE HYPOTHALAMIC CYCLO(HIS-PRO) (CHP) CONTENT IN MASTOMYS NATALENSIS. R. Shukla¹, H. Mizuma², C.W. Hilton¹, R.C. Srimal¹ and C. Prasad². Div. Pharmacology¹, CDRI, Lucknow, and Dept. Medicine², LSUMC, New Orleans, LA.

Many neuropeptides, including CHP, have been suggested to regulate body temperature through undefined mechanism(s) that may involve the central thermostat, the set-point mechanism or the heat production or loss pathways. To understand the role of CHP in thermoregulation, we have examined regional changes in brain CHP in *M. natalensis*, a rodent capable of maintaining normothermia during extreme changes in environmental temperatures. *M. natalensis* were maintained at 24°, 40° and 10° C for four hours at a relative humidity of 50%. After treatment, CHP levels in 7 brain regions were measured. At 24°C, CHP was unevenly distributed throughout the brain with striatal level being over 8 times higher than that of mid-brain. Both at 40°C and 10°C, the total brain CHP content decreased significantly (p<0.01). What is more interesting, however, is that at both temperatures, there was a rearrangement in regional distribution with hypothalamus (Ht) becoming the region with the highest CHP level. It is tempting to speculate that the rise in Ht CHP may attenuate the sensitivity of the trigger responsible for setting off the changes in the heat balance.

GLP-1(7-36)AMIDE BINDING SITES IN RAT BRAIN - PUTATIVE ROLE FOR GLP-1 IN THE BRAIN-GUT AXIS.

R. Göke, P.J. Larsen, J.d. Mikkelsen, M. Treiman* and S.P. Sheikh Depts. of Clinical Biochemistry, Medical Anatomy & Physiology, University of Copenhagen, 2200 Copenhagen, Denmark

The preproglucagon-derived gut hormone glucagon-like peptide 1(7-36) amide (GLP-1) is present in the A-cells of the pancreas and the L-cells of the gut. GLP-1 has also been found in discrete regions in the brain. However, little is known about brain GLP-1 receptors.

Using autoradiography binding sites for [¹²⁵I]-GLP-1 were identified on frozen sections of rat brain. Highest concentration of GLP-1 binding sites (10-18 pmol/mg tissue) were found in the following regions: In the hypothalamus and the arcuate nucleus and the median eminence; in the thalamus, especially in the laterodorsal nucleus and the posterior nuclear group; in the lateral part of the interpeduncular nucleus; in the posterodorsal tegmental nucleus; in the subfornical organ; in the brain stem, especially in the area postrema, the inferior olive and the nucleus of the solitary tract; in the neurohypophysis. Binding of [¹²⁵I]-GLP-1 was inhibited by unlabeled GLP-1 and the structurally related exendin-4 but not by glucagon or vasoactive intestinal peptide (VIP). Cross-linking studies with hypothalamic membranes revealed a molecular mass of the GLP-1 receptor of 66,000 dalton. These results indicate that GLP-1 may have a role as neurotransmitter in the brain. Furthermore, the presence of binding sites for GLP-1 in regions which are out of the blood-brain barrier (subfornical organ, median eminence, area postrema, neurohypophysis) suggests that GLP-1 may also play a role in the brain-gut axis.

696.6

INNERVATION OF THE RAT PYLORIC SPHINCTER BY VAGAL AFFERENTS AND EFFERENTS, AND BY VIP, CGRP, GAL AND NADPH-DIAPHORASE-POSITIVE FIBERS. H.-R. Berthoud¹, Q. Lin, M. Kressel and W.L. Neuhuber, Pennington Biomedical Research Center, LSU, 6400 Perkins Rd., Baton Rouge, Louisiana, 70808 USA, Anatomy Institute, Univ. of Zürich, Switzerland, and Anatomy Institute, Univ. of Erlangen, Germany.

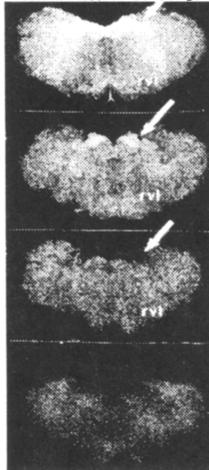

The pyloric sphincter with its ability to control gastric emptying plays important roles in the rate of nutrient absorption, the regulation of food intake, and pathological states such as duodenal ulceration and obesity. Because of this strategic role, we used specific vagal labeling, and immunohistochemical techniques to better characterize its afferent and efferent innervation.

Vagal efferent terminal-like structures were present in small ganglia within or just outside the circular sphincter muscle, in myenteric ganglia of the distal antrum and proximal duodenum, and in a few submucosal ganglia. The sphincter muscle contained very dense networks of varicose GAL, VIP and NADPH-diaphorase positive fibers with GAL and NADPH-diaphorase positive cell bodies in myenteric and small intramuscular and VIP positive cell bodies mainly in submucosal ganglia, delineating the potential vagal postganglionic innervation. Vagal afferents formed many trellis-like structures with numerous varicose endings running parallel to the circular muscle bundles, and were often in close anatomical contact with fibrocyte-like cells. Afferent endings were also present in the large myenteric ganglia of distal antrum and proximal duodenum, in the modified small intramuscular ganglia, in submucosal ganglia, and throughout the mucosal lining. The branching patterns of some vagal afferents suggested that individual axons produced multiple collaterals in different compartments, serving local reflex action. The large majority of CGRP-positive fibers in the sphincter muscle, submucosa and mucosa was not of vagal origin, but most likely represented the dorsal root afferent innervation.

AUTORADIOGRAPHY OF I₁-IMIDAZOLINE AND α_2 -ADRENERGIC SITES IN RAT BRAINSTEM: RETICULAR LOCALIZATION OF I₁-SITES P. Emsberger & L.A. Collins Depts of Medicine & Neuroscience, Case Western Reserve School of Medicine, Cleveland OH 44106

The cardiorespiratory actions of imidazolines in the rostral ventrolateral medulla (rvl) may be mediated not only by α_2 -adrenergic but also by putative I₁-imidazoline receptors. In order to map the distribution of I₁ relative to α_2 sites, adjacent 15 μ m sections of rat brainstem were preincubated 1h, then incubated 1h with 0.5nM [¹²⁵I]p-iodoclonidine and either vehicle (**top**, total binding), 0.1mM cimetidine to mask I₁ (**second**), 10 μ M epinephrine to mask α_2 (**third**), or 0.1mM BDF-6143 to define nonspecific binding (**bottom**). Labeling in NTS (arrows mark solitary tract) and other dorsal nuclei is mainly α_2 , since it is blocked by epinephrine but not cimetidine. I₁-imidazoline sites (**third**) are absent in NTS but are widely distributed across reticular areas, including rvl. Similarly, in the pons the locus coeruleus expresses mainly α_2 while I₁ are present in A5 and ventral tegmental areas. I₁-Imidazoline sites are putative receptors located in the reticular formation which may participate in autonomic control.

696.8

ACTIVATION OF NORADRENERGIC NEURONS IN THE LOCUS COERULEUS BY CORTICOTROPIN-RELEASING HORMONE. C. Schulz, M. Kretz, A. Bock, J. Beyer, H. Lehnerf Dept. of Endocrinology, University Hospital of Mainz, FRG

The locus coeruleus (LC) is involved in the behavioral activating and anxiogenic effects of corticotropin-releasing hormone (CRH). Stress increases CRH in the LC and CRH dose-dependently increases the firing rate of noradrenergic neurons in the LC.

The aim of our present study was to examine the activating effects of different doses of CRH on the noradrenergic neurons of the LC. A microdialysis probe was implanted in one projection area of these neurons, the parietal cortex. To rule out the influence of locomotor activity, the experiments were performed in urethane anesthetized male Wistar rats. The probe was perfused with artificial CSF, samples were collected in 20 min intervals. Substances (0.17, 0.51 nmol CRH, saline) were applied via a stainless steel canula (250 μ m od) into the LC. The samples were analysed by HPLC-ECD for noradrenalin (NA) and its metabolite MHPG.

While after administration of saline the level of NA in the parietal cortex remained stable at the baseline level (0.0279 pmol/sample), both doses of CRH increased the firing rate of noradrenergic neurons, as documented by a marked augmentation of NA release (0.51 nmol CRH: from 0.0200 to 0.0274 pmol/sample). The amount of MHPG released did not change after application of either saline or 0.17 nmol CRH. Only following 0.51 nmol CRH a slight increase of MHPG could be observed.

The results of our experiments clearly demonstrate an activation of noradrenergic LC-neurons by CRH.

696.9

TIME-DEPENDENT INHIBITION OF SOMATIC AFFERENT-EVOKED ACTIVITY IN NUCLEUS TRACTUS SOLITARIUS (NTS) NEURONS INVOLVES REDUCED EXCITATORY POST SYNAPTIC POTENTIAL (EPSP) MAGNITUDE G.M. Toney* and S.W. Mifflin Dept. of Pharmacol. University of Texas Health Science Center, San Antonio, TX 78284.

In previous studies, extracellular recording techniques were used to demonstrate time-dependent inhibition of NTS cell activity following repetitive stimulation of visceral and somatic afferent inputs. In this study, experiments were performed in anesthetized, paralyzed, rats using intracellular recording techniques to examine possible synaptic mechanisms underlying this inhibition. NTS cell activity was evoked by electrically stimulating the contralateral tibial nerve (skeletal muscle afferents) with 500-600 μ A conditioning stimuli followed 50 msec later by identical test stimuli. Among NTS cells responding to tibial nerve stimulation (n=20), the resting membrane potential (RMP) was 52.7 \pm 1.8 mV. Membrane potential responses to conditioning stimuli were characterized by discrete EPSPs. The magnitude (area) and dV/dt of test EPSPs were significantly (p<0.001) reduced (50.7 \pm 14.2% and 65.5 \pm 15.5% respectively) compared to responses following initial conditioning stimuli. In 18 cells, the reduction in EPSP magnitude occurred with no change in RMP. In 2 NTS cells, EPSPs were followed by inhibitory postsynaptic potentials (IPSPs) of 5.25 \pm 0.75 mV. The lack of IPSPs in the majority of NTS neurons tested indicates that the synaptic mechanisms responsible for time-dependent inhibitory interactions between somatic afferent inputs to NTS involve disfacilitation of excitatory inputs and is consistent with results obtained for visceral afferent inputs to NTS in cats. Taken together, this indicates that in both species similar synaptic mechanisms mediate time-dependent inhibitory interactions and that similar synaptic mechanisms appear to underlie the integration of multiple types of sensory inputs within NTS. (Supported by HL 36080).

BUTORPHANOL DECREASES RATS' LATENCY TO BEGIN LEVER PRESSING AND INCREASES AMOUNT OF FOOD CONSUMED IN OPERANT CHAMBERS. J.M. Rudski*, C.J. Billington, J.P. Cleary, & A.S. Levine, VAMC, Minneapolis, MN 55417.

Opiate administration typically reduces food-reinforced operant responding, yet increases food intake under conditions of free-access. Butorphanol, a mixed opioid agonist-antagonist, produces robust feeding in free access experiments, but its characteristic effects on responding in operant chambers have not been well documented. In Experiment 1, 8.0 mg/kg butorphanol administered for 4 consecutive days 1 hour before sessions significantly increased pellets (45 mg) eaten under an FR 10 reinforcement schedule over 60 minutes (vehicle= 74.7 \pm 8.1, butorphanol= 148.6 \pm 13.5; F_(1,11)= 17.42, p<0.002). Experiment 2 examined whether butorphanol affected initiation or maintenance of food intake. Butorphanol's effects (0, 0.3, 1.0, 3.0, and 10.0 mg/kg) on responding under an FR 80 (1st pellet) FR 3 (all subsequent pellets) reinforcement schedule were examined. Each rat received each dose for 4 consecutive days. Food intake above baseline was increased (range = -0.38 pellets for vehicle to +48.0 pellets for 10.0 mg/kg; F_(4,368) = 11.4, p<0.0001) and latency of the first response was decreased (range = +112.8 sec for vehicle to -363.1 sec for 10.0 mg/kg; F=3.15, p<0.02) by butorphanol, but amount of time to complete the FR 80 following commencement of responding was not. Repeated drug administration increased intake (F_(3,368) = 4.98, p<0.001). In sum, butorphanol, in contrast to other opiates, increases lever pressing contingent food intake in addition to increasing free feeding.

697.2

NALOXONE'S ANORECTIC EFFECT IS DEPENDENT UPON LENGTH OF DEPRIVATION AND PALATABILITY OF FOOD. A. S. Levine*, D.T. Weldon, M. Grace, J.P. Cleary and C.J. Billington, VA Medical Center and University of MN., Minneapolis, MN 55417.

Blockade of opioid receptors results in decreased food intake. In the current study we evaluated the effect of peripherally administered naloxone on intake induced by chronic deprivation (80% of body weight), 24 and 48 hour food deprivation; and by offering rats a palatable food (laboratory chow containing sucrose). To control for schedule-induced feeding effects of the chronic deprivation, a group of rats were given food ad libitum for 2 hours per day. Naloxone was injected subcutaneously at doses ranging from 0.001 to 10 mg/kg and ED₅₀'s were calculated from log/linear plots (table):

	Hour 0-0.5	Hour 0-1	Hour 0-2
24 hr. deprive	5.7 mg/kg	5.6 mg/kg	6.7 mg/kg
48 hr. deprive	5.8 mg/kg	7.0 mg/kg	>10 mg/kg
Chronic deprive	>10 mg/kg	>10 mg/kg	>10 mg/kg
Schedule fed	>10 mg/kg	>10 mg/kg	>10 mg/kg
Sweet/satiated	0.03 mg/kg	0.03 mg/kg	0.05 mg/kg
Sweet/deprive	0.8 mg/kg	1.3 mg/kg	>10 mg/kg

Naloxone was most effective in decreasing food intake induced by palatability (sweetened chow) and least effective when rats were extremely "hungry". Although not deprived, the schedule fed rats ate a large amount of food in a short time and thus simulated the consummatory behavior of a chronically deprived rat. These data suggest that opioids are involved in taste perception and palatability (reward) rather than nutrient seeking behavior.

697.3

2-MERCAPTOACETATE (MA) AND 2-DEOXY-D-GLUCOSE (2DG) INDUCE QUALITATIVELY DIFFERENT MACRONUTRIENT APPETITES. L. Cromer, F.H. Koepler and S. Ritter*. Dept of VCAPP, Washington State University, Pullman, WA 99164.

2DG and MA block glucose utilization and fatty acid oxidation, respectively, and stimulate feeding by these distinct metabolic actions in brain and periphery. In this study, we examined the effects of 2DG and MA on macronutrient selection. Rats were maintained until intakes had stabilized (~3 wks) on a diet consisting of 3 separate macronutrient sources: carbohydrate (corn starch), protein (casein) and fat (corn oil), supplemented with vitamins, minerals and fiber. Intake of these diets in response to MA (400 and 600 $\mu\text{mol/kg}$, ip), 2DG (100 and 200 mg/kg , sc) and saline was then measured in 4-hr tests with all 3 macronutrients present. MA produced a highly selective increase in protein intake, while 2DG increased intake of all 3 macronutrients. In vagotomized rats, however, 2DG increased carbohydrate intake selectively, as did injection of the glucoprivic agent into the 4th ventricle. Vagotomized rats did not eat in response to MA. Finally, in collaboration with M. Friedman we found that 2,5-anhydro-D-mannitol, which impairs carbohydrate metabolism peripherally but does not enter the brain, selectively increased protein intake. Results suggest that glucoprivation elicits a carbohydrate appetite that is centrally-mediated. MA-induced protein intake and intake of protein and fat after systemic 2DG are vagally-mediated.

DIETARY INDUCED OBESITY IN AGING FEMALE C57BL/6J MICE: SENSORY AND HYPOTHALAMIC NORADRENERGIC RESPONSES. JA Grinker*, R Lipman and M. Jhanwar-Uniyal. Sch Pub Health, Univ. MI, Ann Arbor MI 48109; HNRC USDA Tufts Univ. Med. Cent. Boston, MA 02111 and Rockefeller Univ., NY, NY 10021.

Variability and stability in weight/fatness to palatable diets were examined in C57BL/6J female mice (retired breeders). Mice were 10 months (27 g) at the start of dietary manipulations [(S) high CHO: lab chow +30% Borden's sweetened condensed milk; 3.26 kcal/g]; [(O) high fat: lab chow +15% wt/wt corn oil: 5.01 kcal/g]; lab chow: (3.44 kcal/g). Mice became obese in 4-6 wks with wts of S mice plateauing by 10 wks (peak wt. =36 g). O mice continued to gain wt. (46.3g at end). At sacrifice brains were removed for determination of medial hypothalamic α_2 -noradrenergic receptor binding to [3H] p-amino- clonidine. Results show that sensory responsiveness on chow (Grinker & Block, 1992) was associated with increased wt/fatness on O but unrelated to gain on S diet. Mice on both palatable diets consumed similar calories (S: 20.5 kcal/day; O: 20.6 kcal/day). No decrements in body wt/fatness occurred with return to chow after 16 wks (confirmed by tissue and carcass analysis). The enhanced adiposity and heightened variability in wt gain were greatest in O fed mice compared with S fed mice. Higher hypothalamic α_2 -noradrenergic receptor binding occurred in S ($S=231.95 \pm 38.6$ fmol/mg protein; +205%; $P<0.05$) and O (284 ± 23.4 fmol/mg protein; +251%; $P<0.01$) compared to chow (113 ± 9.1 fmol/mg protein). Ongoing research clarifies whether higher noradrenergic receptors are related to diet, degree of wt gain or sensory predisposition. Current results demonstrate that hypothalamic receptors are involved in the hyperphagia and enhanced wt gain in dietary induced obesity.

ACCUMBENS D_1 AND D_2 RECEPTORS SUPPORT SHAM-FED SWEET REWARD. L.H. Schneider, C.A. Sikorsky, E.A. Rauhofer and G.P. Smith Department of Psychiatry, N.Y. Hospital-Cornell Med. Center, Bourne Lab, White Plains, NY 10605, and Dept. of Chemistry, New York University, NY NY 10003

We have previously reported that dopaminergic (DA) mechanisms are necessary for the positive reinforcing effect of sucrose to sustain sham feeding in the rat. In these studies, selective D_2 antagonists were administered intraperitoneally or infused into the lateral ventricle. In the present study, we attempted to identify a central DA site at which the blockade of D_2 receptors is critical for the positive reinforcing effect of sucrose to maintain sham feeding. Rats ($n=9$) were chronically implanted with a gastric cannula for sham feeding and bilateral brain cannulas aimed stereotaxically at the nucleus accumbens (NACC). Rats were adapted to 30-min tests sham feeding a 40% sucrose solution following an 18h food deprivation and bilateral infusions of 0.5 μl /side of artificial csf, raclopride, or SCH 23390. Raclopride at 2.5, 10 and 40 $\mu\text{g}/\text{rat}$ produced a significant dose-related inhibition in the animals tested [$F=6.9(3,9)$; $p<.01$] from saline baseline [45.9 ± 2.8 ml/30 min] of 35%, 41% and 55%, respectively. The inactive (+)-enantiomer or raclopride was without effect at the highest dose (40 $\mu\text{g}/\text{rat}$) tested. The selective D_1 antagonist SCH 23390 produces similar effects in a dose-related manner, indicating that either D_1 or D_2 mechanisms are required in the NACC. Analyses of the microstructure of licking in the sucrose sham feeding rat as well as behavioral time-sampling support the conclusion that blockade of NACC DA receptors reduces the reinforcing potency of the sucrose solution without interference with rats' ability to lick and swallow the sweet solution. COMPARISON OF THE EFFECTS OF ADRENALECTOMY AND RU486 ON FOOD INTAKE AND WEIGHT GAIN OF DIET INDUCED OBESE SPRAGUE-DAWLEY RATS. Q.Trocki, D.J. Baer and T.W. Castonguay*. Dept of Human Nutrition and Food Systems, Univ. of Maryland, College Park, MD 20742 and USDA Beltsville, MD 20705

The effects of adrenalectomy (ADX) or RU486 on food intake and body weight were investigated in Sprague-Dawley rats made obese by giving them free access to Crisco in addition to AIN-76 diet. Control groups were given free access to AIN-76 diet only. Animals were given their respective diets for 4 wk before they were randomly assigned to one of 7 treatments. Rats in the dietary control groups adrenalectomized (C-ADX) or given sham operations (C-SHAM). Rats assigned to the dietary obese groups received ADX (O-ADX), sham operation (O-SHAM), ADX with corticosterone replacement (O-CORT, 2mg/d s.c.), RU486 (O-RU, 20mg/kg/d s.c.) or vehicle of RU486 (O-VEH). Daily food intake and body weight were monitored for additional 3 wk. ADX significantly decreased weight gain ($p<0.01$) but the effect was greater in animals that had the fat option (O-ADX vs C-ADX, $p<0.05$). CORT replacement significantly increased weight gain of ADX animals ($p<0.01$). RU486 significantly decreased weight gain ($p<0.01$) but not as much as ADX. Body composition analysis showed that ADX, not RU486, decreased carcass fat content ($p<0.01$). Both ADX and RU486 decreased daily caloric intake, and food intake ($p<0.01$). RU486 also decreased fat intake ($p<0.01$). These results indicate that the effect of ADX on weight gain is greater than RU486. (Supported in part by NIH grant DK44486).

ALPHA₂ NORADRENERGIC RECEPTORS IN THE PREPIRIFORM CORTEX DECLINE WITH AMINO ACID IMBALANCE. D.W. Gietzen* and M. Jhanwar-Uniyal. Dept. VM:Physio.Sci. and Food Intake Lab., Univ. Calif. Davis, CA 95616 and The Rockefeller Univ. N.Y., N.Y., 10021.

The anorectic responses to imbalanced amino acid diets (IMB) have been associated with decreased norepinephrine (NE) and cAMP in the prepiriform cortex (PPC), an area essential for the initial feeding responses to IMB. Also, the α_2 agonist, clonidine, injected into the PPC, increased intake of IMB. Therefore, we measured α_2 -noradrenergic receptor binding in the PPC of rats fed threonine IMB or a control diet, either low-protein (BAS) or corrected (COR). After prefeeding BAS for 10 days, rats were given IMB, BAS or COR for 2.5 hours. The PPC ($N=6$), anterior cingulate cortex (AC, $N=7$), ventromedial hypothalamus (VMH, $N=3$) and lateral hypothalamus (LH, $N=3$) were assayed. Binding of [^3H]p-amino-clonidine to α_2 receptors was determined using radioligand binding techniques. Non-specific binding was determined in the presence of 10 μM phentolamine. Data were calculated as fmol/mg protein. In the PPC, α_2 binding expressed as a % of AC (a control brain area that does not show NE changes with IMB) was decreased over 6 fold in the IMB group compared with the BAS group, with COR intermediate. Values were BAS: 94.7 ± 25.6 (%AC, $X \pm SE$), IMB: 15.6 ± 4.9 , COR: 50.2 ± 8.5 , $p = 0.005$. α_2 binding in the PPC, but not AC, was correlated with food intake, PPC: $r^2 = 0.61$, $p < 0.001$, AC: $r^2 = 0.31$, NS. There were no significant changes in LH or VMH, but binding in VMH tended to decrease with IMB. These data support our suggestion that NE acts at the α_2 receptor in the PPC in mediating the anorectic responses to IMB diets.

COMPARATIVE ANORECTIC EFFICACY OF SEROTONERGIC ANTIDEPRESSANT AGENTS ASSESSED IN SUCROSE SHAM-FEEDING RATS. R.B. Murphy*, L. Bajdeki, S.M. Feldman, and L.H. Schneider, Dept. of Chemistry and Center for Neural Sciences, New York University, NY NY 10003

We have employed the model of the sucrose sham-feeding rat to examine the anorectic actions of various serotonergic (5-HT) reuptake blockers and amphetamines. These included (\pm)-fluoxetine, sertraline, d-fenfluramine, and d-amphetamine. In this preparation, all of these agents produced anorectic actions in a highly significant dose-dependent manner; the ED_{50} doses were 9 mg/kg , 6.7 mg/kg , 2 mg/kg , and 1.0 mg/kg , respectively. Microstructural analysis of each agent indicated characteristic differences in rates and patterns of licking. For example, the size of bursts of licks was significantly reduced only under sertraline, whereas the number of intercluster intervals was significantly reduced only under d-fenfluramine. The distribution of interlick intervals was not significantly shifted at the doses of these agents which were used. These results indicate that the sucrose sham-feeding rat may be a useful system in which to explore activity of novel anorectic agents [Supported by INNOVA BIOMED INC].

SUCROSE AND SACCHARIN DRINKING BOUT ANALYSIS: EFFECTS OF D-FENFLURAMINE. S.J. Cooper* and D.A. Morris. School of Psychology, Univ. Birmingham, Edgbaston, Birmingham B15 2TT, U.K.

Studies have shown that a primary effect of d-fenfluramine (d-fen) in suppressing sucrose solution consumption is to reduce the duration of drinking bouts. In the present work, analysis of bout duration (and rates of licking) was conducted for both saccharin and sucrose drinking to investigate the effects of i) manipulating solution concentrations, and ii) 1.8 mg/kg, i.p. d-fen on drinking bout durations. D-Fen reduced the consumption of both types of solution, and the overall mean bout duration appeared to be more sensitive to d-fen's effects in rats consuming sucrose solutions. There was a strong relationship between the duration of early bouts of drinking sucrose and the concentration of the solutions. These long bout durations rapidly diminished as the test proceeded. Bout duration, in the case of sucrose drinking, appears to be sensitive to both palatability and satiety factors. Since d-fen did not affect the duration of the initial drinking bout for either solution, but did reduce the average bout duration of the first 5 min of the test, we surmise that d-fen did not reduce solution palatability directly, but may have affected it secondarily.

AGE DEPENDENT EFFECTS OF CCK AND DEVAZEPIDE ON FOOD INTAKE IN BOTH MALE AND FEMALE RATS. C.F. Salorio, P.B. Hammond, G.J. Schwartz, P.R. McHugh* and T.H. Moran. Dept. of Psychiatry, Johns Hopkins Univ. School of Medicine, Baltimore, MD. 21205, Dept. of Environmental Health, Univ. of Cincinnati, Cincinnati, OH 45267.

Peripheral administration of the brain gut peptide CCK has been demonstrated to inhibit food intake in a variety of species and recent data have demonstrated that administration of a specific type A CCK receptor antagonist increases food intake in a variety of experimental paradigms. The potency of CCK to inhibit food intake varies across deprivation schedules and can be shown to be significantly lessened under conditions of elevated food intake (i.e. genetic obesity, lactation and during the long photoperiod in Siberian Hamsters). To examine the potential for differences in the relative role of CCK in feeding control at different ages, we examined the effects of administration of CCK (1-16 µg/kg) and the CCK antagonist devazepide (32-320 µg/kg) on 1 hr glucose consumption in male and female rats at 45-70 and 110-130 days of age. CCK was more potent in older rats as measured by the absolute magnitudes of suppression at any dose of CCK and the lowest dose at which significant suppressions were obtained. Administration of the CCK A antagonist devazepide had no effect on intake in the younger rats but significantly increased intake in both male and female older rats in a dose dependent fashion. These data demonstrate that during a period of rapid growth and high levels of food intake relative to body weight, adolescent rats are relatively insensitive to exogenous CCK and endogenous CCK does not appear to play a significant role in controlling their intake. (DK19302)

BEHAVIORAL ANALYSIS OF A KETANSERIN-SENSITIVE ANORECTIC ACTION OF LYSERGIC ACID DIETHYLAMIDE (LSD) IN RATS. K.J. Simansky*, J.F. Kampherstein and W. Kachelries. Dept. Pharmacology, Medical College of Pennsylvania, Philadelphia, PA 19129.

LSD and other hallucinogens disrupt operant responding maintained by appetitive reinforcement. The present study: 1) assessed the potency of LSD to reduce food intake in male rats consuming sweetened milk diet after 18 h food deprivation; 2) analyzed the effects of LSD on the gross pattern of prandial behaviors; 3) determined the ability of ketanserin to block LSD-induced anorexia; and 4) characterized the action of LSD on the distribution of licking during gastric sham-feeding. Tests were conducted for 30-min with behaviors rated by a time-sampling observational method and licking detected using on-line computer acquisition. LSD (0, 0.1, 0.33 and 1.0 µmol/kg, i.p., 6 min before access to milk, n=6-7/grp) reduced intake (control = 34.0 ± 2.4 ml) in a dose-related manner (p<0.01) with an approx. ED₅₀=0.33 µmol/kg. Rats began feeding normally after all treatments but the two highest doses of LSD decreased the incidence of resting normally observed in satiety and produced an abnormal prone posture. Ketanserin (5.0 µmol/kg) blocked completely the anorectic effect, the prone posture and the inhibition of resting. LSD also reduced milk intake when high rates of consumption were sustained during sham-feeding without satiation (control = 50.1 ± 3.3 ml). During sham-feeding, 0.33 µmol/kg LSD did not significantly disrupt feeding behavior but did reduce intake by 40%. Rats given this dose displayed smaller bursts of licking and decreased efficiency of licking. This pattern is also observed after fenfluramine and fluoxetine and may reveal an action to reduce the palatability of the tastant (Asin et al., 1993). Thus, the data suggest that, besides disrupting appetitive patterns sustained during behavior, LSD may probe physiologically important processes involved in feeding. Further studies will better define the role of 5-HT₂ receptors in these processes. Supported by NIMH 41987

EFFECTS OF PREWEANLING LOSORTAN TREATMENT ON HUMORAL SYSTEMS REGULATING BODY FLUID BALANCE. R. Kirby*, A. Alt, C. Novak, L. Flanagan, M. Henry & A. K. Johnson. Dept. of Psychology Univ. Iowa, Iowa City, IA. 52242.

We have found that blockade of the renin angiotensin system (RAS) during preweaning development produces long-term increases in water intake and urine output. The present study examined the humoral mechanisms responsible for body fluid regulation following preweaning RAS blockade. Male WKY pups were administered daily the angiotensin receptor antagonist Losortan potassium (10 mg/kg) or vehicle subcutaneously on postnatal days 11-20. On day 22 animals were weaned to metabolism cages with water and chow available. Fluid intake and urine output were measured on a weekly basis. Blood was sampled for hormone measurement from day 22 to adulthood. Preweaning Losortan treatment led to a 600% increase in plasma renin activity on day 22. However, levels were comparable between Losortan and vehicle treated animals from day 29 to adulthood. Losortan did not alter vasopressin or aldosterone levels at any age examined. These results suggest that increased renin release may be involved initially in the increased water intake and urine output following early RAS blockade. However, other mechanisms must be involved as the increases in plasma renin activity are present only briefly following blockade while increased intake and output persist into adulthood.

EXCITATORY AMINO ACIDS: EXCITOTOXICITY VI

698.1

TRANSNEURAL PROPAGATION OF EXCITOTOXICITY BY L-CCG-IV FOR BILATERAL DEATH OF CA1 NEURONS. T. Shigeno*¹, M. Sasaki², G. Kato³, Y. Yamasaki⁴, M. Miyamoto⁵, M. Ishida⁵, and H. Shinozaki⁵. ¹Neurosurgery, Saitama Medical Center, ²Fuchu Metropolitan Hospital, ³Chiba College of Medical Science, ⁴Taiho Pharmaceuticals, ⁵The Tokyo Metropolitan Institute of Medical Science, Bunkyo, Tokyo 113, JAPAN

We have previously reported that intracerebral injection with a potent NMDA receptor agonist, the (2S,3R,4S) isomer of α-(carboxycyclopropyl)glycine (L-CCG-IV) induced selective death of the CA1 neurons in the rat hippocampus. Although the injection site was unilateral CA1, neuronal death frequently occurred in the bilateral CA1 sectors. However, when combined with severance of dorsal hippocampal commissure together with corpus callosum, there was no neuronal death in the bilateral CA1 sectors. This indicates a presence of transneural mechanism for selective death of CA1 neurons by glutamate excitotoxicity. Therefore, we investigated EEG changes recorded from bilateral CA1 sectors before and after injection of L-CCG-IV (50 nmole in 1 µl vehicle) into the unilateral CA1. We observed immediate spike discharges in the ipsilateral CA1 that propagated to the contralateral CA1 in a few minutes. The rats showed intermittent seizure and wet-dog shaking. By contrast with severance of dorsal hippocampal commissure and corpus callosum, no spike discharges were seen in both CA1 sectors. We further investigated whether or not NMDA itself could cause the same neuropathology as observed by L-CCG-IV. NMDA was injected from 10 to 100 nmole in 1 µl vehicle in a separate series of rats. Beyond the dose of 30 nmole, most of rats died after severe seizure. However, death of CA1 neurons was only observed in the ipsilateral side to injection. Severance of dorsal hippocampal commissure and corpus callosum did not ameliorate the death of ipsilateral CA1 neurons. These findings indicate that (1) receptor for L-CCG-IV distributes differently from NMDA and (2) neural connection governed by L-CCG-IV is different from that of NMDA. The intrinsic neuronal circuitry in and around the hippocampus would underlie this phenomenon.

STUDY OF LATHYRISM: SOME NEW FINDINGS. A. Haque*, F. Lambein, M. Hossain, J. DeReuck, J.K. Khan, Y.H. Kuo. Institute of Postgraduate Medicine & Research, Dhaka 1000 and State University of Gent. B-9000.

Lathyrism is a type of human spastic paraparesis caused by an excitatory amino acid ODAP present in *Lathyrus sativus* L. cultivated and consumed in the tropics. 882 lathyrism patients were studied between 1991-92 in Bangladesh to assess epidemiological, clinical and some biochemical aspects of lathyrism. 80% of the patients were below 30 yrs during onset. The disease is prevalent in male (87%). The disease is static in 73% for 19±4 yrs and 27% started deterioration after a static state for 14±2 yrs showing features of Amyotrophic lateral sclerosis. The deterioration does not correlate with habit of lathyrus consumption (p < .001). Radiological investigation revealed features of osteolathyrism in 2 of 60 patients x-rayed. Study for HTLV-1 association showed 4% positive results. Serum Zn level was .78±.24mg/L compared to .92±.24mg/L in control raised suspicion of low Zn level and affinity to ODAP. Tolperidone HCl gave symptomatic improvement in 60% (p < .01). Analysis of CSF amino acid revealed raised glycine and glutamate level.

698.3

LITHIUM-PILOCARPINE-INDUCED STATUS EPILEPTICUS PRODUCES CHANGES IN EXTRACELLULAR AMINO ACID CONCENTRATIONS IN THE RAT AMYGDALA. D.G. Fujikawa*, J.S. Kim, A.H. Daniels and A.F. Alcaraz. Exp. Neurol. Lab., VA Med. Ctr., Sepulveda, CA 91343 and Dept. of Neurology and Brain Res. Inst., UCLA Sch. of Med., Los Angeles, CA 90024.

It has been hypothesized that excessive release of glutamate (GLU) *in vivo* produces seizure-induced neuronal damage. The amygdala is one of many limbic structures which are damaged by lithium-pilocarpine-induced status epilepticus (SE). We measured extracellular amino acid concentrations in this structure during SE. Six Wistar rats underwent stereotaxic placement of microdialysis probes into basolateral amygdaloid nuclei. Probes were perfused with Krebs-Ringer-bicarbonate solution, and dialysate samples were obtained during a 2-h baseline period, 3-h SE and a 2-h recovery period. Diazepam and phenobarbital were given 3 h after SE onset to stop the seizures. Extracellular GLU (GLU_e) decreased to 64-70% of baseline levels during the first 60 min of SE and at 150 min of SE. Extracellular glutamine (GLN_e) decreased to 55-71% of baseline during the first 150 min of SE. Extracellular taurine (TAU_e) increased to 166-194% of baseline at 60 min and 120-180 min of SE and remained elevated at 209% of baseline 2 h later. Aspartate, glycine and serine were unchanged. Increased TAU_e occurs when extracellular osmolarity increases, as a result of cell swelling and a decrease in the size of the extracellular space (ECS). GLN_e probably falls because of increased presynaptic uptake of this GLU precursor. Decreased GLU_e in the face of a smaller ECS suggests that the rate of GLU uptake may exceed its rate of release during SE. GLU_e measured by MD probes do not necessarily reflect synaptic concentrations, and GLU_e alone is not adequate for assessing *in vivo* activation of postsynaptic GLU receptors. Other strategies are necessary for *in vivo* confirmation of the excitotoxic hypothesis for SE.

698.5

PHENCYCLIDINE INDUCES THE HSP70 HEAT SHOCK GENE IN INJURED CORTICAL NEURONS VIA MULTIPLE RECEPTORS: DISINHIBITION AS A MECHANISM OF INJURY. F.R. Sharp*, M. Butman, K. Aardalen, R. Nakki, J. Koistinaho, S. Massa, S.M. Sagar. Dept. Neurology, Univ. of California and SFVAMC, San Francisco, CA 94121.

Phencyclidine and other NMDA receptor antagonists induce the HSP70 heat shock gene in injured, vacuolated rat cingulate cortical neurons. PCP (50mg/kg) induces hsp70 mRNA and HSP70 protein in neurons in cingulate cortex, neocortex, insular cortex, piriform cortex, amygdala and hippocampus. Induction of HSP70 by PCP could be prevented by haloperidol (D2), clozapine (D4), valium (GABA_A), SCH 23390 (D1), muscimol (GABA_A), scopolamine (M1), and rimcazole (sigma). Baclofen had no effect. Nifedipine blocked HSP70 induction in some regions (cingulate and neocortex) and not others.

These results are interpreted to mean that PCP injures cortical pyramidal neurons by disinhibiting them because PCP blocks NMDA receptors on GABAergic neurons in cortex that would normally inhibit the pyramidal neurons. This would make cortical pyramidal neurons sensitive to injury produced by excitatory inputs from dopamine acting on D1, D2, and D4 receptors, ACh acting on M1 receptors, actions at sigma receptors, and by actions of other transmitters at other excitatory receptors. Injury is mediated by calcium entry through L-type voltage gated calcium channels in some brain regions. In addition, GABA_A but not GABA_B agonists decrease the injury produced by PCP, with GABA actions at the benzodiazepine site appearing to be more effective than at the GABA (muscimol) site itself.

698.7

ANTI-PSYCHOTIC AGENTS PREVENT NMDA ANTAGONIST NEUROTOXICITY J.W. Olney*, N.B. Farber, M.T. Price, J. Labryere, J. Nemnich, H. St. Peter. Washington Univ., St. Louis MO 63110.

PCP (phencyclidine), MK-801 and ketamine - all PCP receptor ligands (PRL) and antagonists of NMDA glutamate receptors - acutely injure cerebrocortical neurons when administered subcutaneously to adult rats. Normal humans anesthetized with PCP or ketamine experience acute psychotic episodes sometimes termed an "emergence reaction," and patients with quiescent schizophrenia respond to PCP by relapsing into a protracted acute psychotic state. We have proposed that the neurotoxic and psychotic effects of PRL may represent morphological and psychological manifestations of the same toxic process, since both of these effects show similar patterns of age dependency (onset of susceptibility in early adulthood) and can be prevented by the same drugs (benzodiazepines and barbiturates). A possible link to schizophrenia might also be proposed in view of the early adult onset of schizophrenia. Consistent with this proposal, we now report that the neurotoxic effects of PRL in the adult rat can be prevented by pretreatment with various drugs that have either putative or proven anti-psychotic activity (e.g., haloperidol, thioridazine, DTG, rimcazole and clozapine). A sigma receptor may be involved in the neural circuitry mediating PRL neurotoxicity since all of the above agents, with the exception of clozapine, are sigma receptor ligands. Because clozapine is not a sigma receptor ligand, it is difficult to identify a single characteristic that all of the effective agents have in common other than anti-psychotic potential. In summary, PRL cause psychotic symptoms in humans and cerebrocortical neuronal injury in rats, and we now find that various agents with proven or potential antipsychotic activity in schizophrenia prevent PRL from injuring neurons in rat brain. We propose that PRL neurotoxicity is a promising animal model for studying mechanisms underlying human psychotic processes. Supported by DA 05072, DA 06454, AG 05681 and RSA MH 38894 (JWO).

POSTNATAL DEVELOPMENT OF NEURONAL VULNERABILITY TO INDIRECT AND DIRECT EXCITOTOXINS: A COMPARATIVE STUDY OF γ -ACETYLENIC GABA AND QUINOLINIC ACID IN THE RAT HIPPOCAMPUS. O.G. McMaster*, F. Du and R. Swarczew. Maryland Psychiatric Research Center, Baltimore, MD 21228.

Indirect and direct excitotoxins can produce axon-sparing brain lesions via excitatory amino acid-mediated mechanisms (Ann. Neurol. 31: 119, 1992). We have now studied, in a comparative fashion, the development of vulnerability of rat hippocampal neurons to focal injections of γ -acetylenic GABA (GAG) and quinolinic acid (QUIN). At 10, 14, 18, 22 and 28 days of age, rats were injected intrahippocampally with 30 nmol QUIN or 240 nmol GAG - doses which produce virtually identical patterns of neurodegeneration in hippocampal CA1 and CA3 fields in the adult rat. Three days later, the animals were perfused, and their hippocampi were examined by light microscopy with Nissl staining. GAG did not produce cell death until postnatal day 22, when relatively mild neuronal damage was observed in CA1 and CA3. Notably, the 18 day-old rat was even resistant to 360 nmol GAG. By day 28, GAG produced an adult-like hippocampal lesion. QUIN did not cause neuronal damage until day 14 when cell loss was observed in CA1. By day 18, QUIN caused neuronal loss in both CA1 and CA3. These data confirm that the mechanism of GAG toxicity is distinct from classical ("direct") excitotoxicity and may depend on processes which have not developed in the hippocampus of 18 day-old rats.

CEREBELLAR TOXICITY OF PHENCYCLIDINE. R. Nakki, L.J. Noble, J. Koistinaho, F.R. Sharp, S.M. Sagar*. Depts. of Neurology and Neurosurgery, VA Medical Center and University of California, San Francisco, CA 94121.

Phencyclidine (PCP), as well as other NMDA antagonists, are toxic to cortical neurons, especially in the cingulate and retrosplenial cortex. To determine if other neurons are damaged, the distribution of microglial activation following the administration of PCP, 50 mg/kg i.p., was studied immunohistochemically using the monoclonal antibody OX-42. In addition to microglial activation in cingulate and retrosplenial cortex, coronal sections of cerebellar vermis of PCP-treated rats contained vertical stripes of activated microglia in the molecular layer. In sagittal sections, the microglial activation occurred in irregularly shaped patches, consistent with damage to Purkinje cells. Only a small minority of Purkinje cells were associated with activated microglia. In contrast to the cingulate cortex, where PCP induces the synthesis of the HSP70 heat shock protein, no HSP70 immunoreactivity was detected in the cerebellum after PCP administration. However, *in situ* hybridization histochemistry demonstrated the expression of hsp70 mRNA widely in the Purkinje cell layer 6 hr after PCP, 50 mg/kg i.p.

These observations indicate that PCP is toxic to cerebellar Purkinje cells and support the usefulness of microglial activation and heat shock protein induction as markers of neurotoxicity. The findings raise the clinically important question of whether NMDA antagonists other than PCP are also toxic to the cerebellum.

698.8

ELECTROENCEPHALOGRAPHIC SEIZURE ACTIVITY PRODUCED BY MK-801 BUT NOT BY THE GLY-SITE NMDA ANTAGONIST L-687,414. F.C. Tortella* and R.G. Hill. Walter Reed Army Inst. Res., Washington, DC 20307 and +MSDRL Neurosci. Res. Ctr., Harlow, UK, CM20 2QR.

L-687,414 is a novel partial antagonist for the glycine site of the NMDA receptor that displays anticonvulsant and neuroprotective properties *in vivo* (Foster et al., Mol. Neuropharm. 2: 97, 1992). In a differential study of EEG and behavior in adult rats L-687,414 (5-100 mg/kg as salt, i.v.) was compared to MK-801 (0.1-0.5 mg/kg, i.v.) and a weaker glycine site partial agonist, (+)-HA966 (12.5-100 mg/kg as salt, i.v.). MK-801 produced typical head-weaving and locomotor ataxia along with intermittent EEG spike complexes and associated myoclonic responses even at the lowest doses tested. In contrast, high doses of (+)-HA966 caused sedation accompanied by disruption in normal EEG patterns seen as high-amplitude, slow-wave synchronizations centered on the 4-5 Hz band. L-687,414 caused mild locomotor ataxia at the highest doses tested, but otherwise behavior and EEG patterns were indistinguishable from controls. These results suggest that L-687,414 is likely to be free of some of the undesirable properties of MK801. In addition, there appear to be differences between the actions of (+)-HA966 and L-687,414 on the EEG of the conscious rat.

GLUCOCORTICOIDS AND STRESS EXACERBATE KAINATE-INDUCED ANTIGENIC ALTERATIONS IN TAU AND NEURON LOSS IN RAT HIPPOCAMPAL NEURONS. B.A. Stein-Behrens¹, I. Chang¹, M.P. Mattson², B.M. Sapolsky¹. ¹ Dept. Biological Sci., Stanford Univ., Stanford CA, 94305. ² Sanders-Brown Center on Aging, U. Kentucky, Lexington KY 40536.

Glucocorticoids (GCs), the adrenal steroids released during stress, can endanger hippocampal neurons such that an insult (seizure, hypoxia/ischemia, hypoglycemia) results in more neuron damage in the presence of GCs. These steroids have been shown to exert their compromising effects by increasing levels of extracellular glutamate and free cytosolic calcium concentrations in the post-synaptic neuron. If GCs enhance calcium mobilization induced by neurological insults to the hippocampus, the hormones should enhance Ca⁺⁺-dependent degenerative events as well. In support of this, we have previously observed that GC concentrations at the peak physiologic range, as compared to very low GC controls, exacerbate kainate-induced degenerative events such as antigenic changes in tau and spectrin proteolysis. In the present study, we found that this GC exacerbation occurs under more subtle physiological conditions. We found that increasing GC concentrations from low- to high-basal and low- to high-stress values as generated by exogenous GC pellet implantation caused incremental increases in neuronal immunoreactivity with tau antibodies 5E2 and ALZ-50 and neuron loss after kainate infusion to the hippocampus. We then found that stress makes kainate-induced tau alterations and neuron loss worse. Interestingly, we have also found that stress alone, in the absence of kainate excitation, results in some tau accumulation. This is the first evidence that stress itself, rather than exogenous GCs, can exacerbate neurodegenerative events in the hippocampus.

698.10

PREGNENOLONE SULFATE ATTENUATES EXCITOTOXIC NEURONAL INJURY IN MURINE CORTICAL CELL CULTURES. M.B. Wie¹, C. Tian and D.W. Choi, Dept. of Neurology, and Center for the Study of Nervous System Injury, Washington Univ. School of Medicine, St. Louis, MO 63110.

The ability of the endogenous neurosteroid pregnenolone sulfate (PS) to modulate CNS glutamate receptor function, NMDA receptor-gated currents while reducing AMPA and kainate receptor-gated currents has been recently reported (Wu et al., Mol. Pharmacol. 40:333, 1991). We therefore examined the ability of PS to modify excitotoxicity in murine cortical cell cultures.

Cultured cortical cells exposed to 100 μM NMDA for 5 min or 10 μM AMPA for 24 hr developed widespread submaximal neuronal death by the next day. Addition of 1 - 100 μM PS to the exposure solution produced a modest, concentration-dependent attenuation of NMDA-induced neuronal death, with 30-50% reduction at 10 μM PS. Somewhat weaker attenuation was seen of AMPA-induced neuronal death. These results support the possibility that endogenous PS may modify excitotoxic neuronal death - at least that mediated by NMDA receptors - under certain pathological conditions.

IDENTIFICATION OF NOVEL cDNA CLONES CONTAINING CAG OR CCG TRINUCLEOTIDE REPEATS FROM HUMAN BRAIN. S-H. Li, R.L. Margolis, M.G. McInnis, C.A. Ross. Laboratory of Molecular Neurobiology, Departments of Psychiatry and Neuroscience, Johns Hopkins Univ. Sch. of Med., Baltimore, MD 21205

A new form of human mutation, expansion of trinucleotide repeats, has recently been shown to cause Huntington's disease, myotonic dystrophy, Kennedy's disease, and fragile X syndrome, diseases with neuropsychiatric features and a pattern of inheritance known as anticipation. Identification of additional genes containing trinucleotide repeats may provide clues to other diseases exhibiting anticipation, including bipolar affective disorder and possibly schizophrenia and autism. We have previously identified eight novel clones containing CAG or CCG repeats (Li et al, *Genomics*, in press); we now report the isolation of additional novel cDNA clones containing long CAG and CCG repeats. A human cerebral cortex cDNA library was screened at high stringency using CAG₆₀ or CCG₆₀ oligonucleotides as probes. Clones representing 28S ribosomal RNA were excluded with a pooled 28S rRNA oligo probe. Clones likely to have brain selective expression were identified by excluding clones reacting strongly with a probe made from human liver poly A⁺ RNA. So far, we have identified seven CAG- and eleven CCG-containing novel clones. The nature and length of the repeat within each novel clone was determined by sequencing through the repeats. All seven novel CAG-containing clones have eight or more consecutive repeats and all 3 of CCG-containing clones which have been sequenced through the repeats have more than nine consecutive repeats. Work is in progress to further characterize these clones. The novel sequences that we have identified should provide useful linkage markers for the human genome project, and are candidate genes for bipolar affective disorder and other neuropsychiatric conditions.

699.2

IDENTIFICATION OF NOVEL cDNA CLONES CONTAINING AAT OR CCA TRINUCLEOTIDE REPEATS. R.L. Margolis*, S-H. Li, Melvin G. McInnis, C.A. Ross. Departments of Psychiatry and Neuroscience, Johns Hopkins Univ. Sch. of Med., Baltimore, MD 21205

A new form of human mutation, expansion of trinucleotide repeats, has recently been shown to cause Huntington's disease, myotonic dystrophy, Kennedy's disease, and fragile X syndrome, diseases with neuropsychiatric features and a pattern of inheritance known as anticipation. Identification of additional genes containing trinucleotide repeats may provide clues to other diseases exhibiting anticipation, including bipolar affective disorder and possibly schizophrenia and autism. We have previously identified eight novel clones containing CAG or CCG repeats (Li et al, *Genomics*, in press); we now report the isolation of novel cDNA clones containing AAT and CCA repeats. A human cerebral cortex cDNA library was screened at high stringency using CCA₃₀ or AAT₆₀ oligonucleotides as probes. After plaque purification, plasmid isolation, and partial sequencing, the nature and length of the repeat within each novel clone was determined. Preliminary data indicate that at least two of eleven novel clones with eight or more consecutive repeats are polymorphic, containing at least four different alleles. Work is in progress to further characterize these clones. The novel sequences that we have identified should provide useful linkage markers for the human genome project, and are candidate genes for bipolar affective disorder and other neuropsychiatric conditions.

HZF-3, A NOVEL NEURAL HORMONE RECEPTOR RELATED TO NGFI-B. S. Peña de Ortiz, R. Pun* and G.A. Jamieson Jr. Toxicology Program, Department of Environmental Health, University of Cincinnati College of Medicine, Cincinnati Ohio 45267-0056.

We hypothesize novel members of the nuclear hormone receptor superfamily play important roles in signal-transcription coupling in the hippocampus. To isolate rat hippocampal cDNAs encoding novel nuclear hormone receptors, a systematic search for members of this family expressed in the hippocampus was initiated. We report here the isolation of HZF-3, a novel member of the superfamily related to the inducible orphan nuclear receptor NGFI-B. The sequence of HZF-3 predicts a protein 69Kd in size which overall is 58% homologous to NGFI-B. Highest homology between HZF-3 and NGFI-B is observed in their DNA and ligand binding domains, 92% and 72% respectively, suggesting they may interact at a functional level. Reverse transcription coupled to PCR analysis determined HZF-3 mRNA within the brain to be preferentially localized to the hippocampus (hippocampus >>> cortex > cerebellum). *In situ* hybridization experiments will define the precise neuroanatomical localization of HZF-3. Studies aimed at identifying stimuli which regulate HZF-3 expression in PC12 cells have determined that unlike NGFI-B, the expression of HZF-3 is not induced by NGF, TPA, or calcium ionophore treatments. Additional experiments seek to determine whether HZF-3 expression is induced in the rat brain subsequent to seizures and whether HZF-3 interacts with NBRE, the NGFI-B DNA target site. If so this would suggest a complex set of interactions between HZF-3 and NGFI-B serve to regulate transcriptional responses in the hippocampus. CLONING AND REGIONAL DISTRIBUTION OF THE RAT MAP2d, A NOVEL MAP2c SPLICE VARIANT ENCODING FOUR MICROTUBULE BINDING DOMAINS, WHOSE EXPRESSION IS REGULATED BY bFGF. M. Khrestchatsky*, L. Ferhat, H. Pollard, A. Bernard, G. Charton, I. Moreau, G. Barbin and Y. Ben-Ari, INSERM U-29, 123 Bd de Port Royal, 75014 Paris, France.

High and low molecular weight forms of MAP2 proteins, MAP2a-MAP2b and MAP2c respectively coexist with different ratios in the embryonic and postnatal rat brain. MAP2c is predominantly expressed in the immature brain. MAP2 variants are encoded by distinct mRNAs of 9 and 6 kb, both transcribed from a single gene. Using reverse transcription-coupled PCR (RT-PCR) and various primer pairs, we have characterized MAP2d, a novel MAP2c transcript comprising a 93 bp insertion encoding 31 additional amino acids in the carboxy terminal region. This insertion, absent from the MAP2b mRNA is highly homologous to the three microtubule binding domains found in MAP2 proteins and to the fourth microtubule binding domain encoded by the alternatively spliced exon 10 of the Tau gene. Splicing of the additional exon is developmentally regulated, the MAP2d being predominantly expressed over the MAP2c in the young and adult rat brain. A study of the regional distribution of both isoforms, using RT-PCR and *In Situ* Hybridization reveals that MAP2c/MAP2d ratios differ in various structures of the CNS. Finally, we show that in primary cultures of hippocampal neurons, bFGF exposure promotes the MAP2c-MAP2d switch. The MAP2c/MAP2d ratios found at the mRNA level suggests assuming ratios are conserved at the protein level- that in the young adult brain, a major proportion of low-molecular weight MAP2 comprises 4 rather than 3 microtubule binding domains.

699.5

THE SAXITOXIN-BINDING PROTEIN, SAXIPHILIN, IS A NEW MEMBER OF THE TRANSFERRIN FAMILY. M. A. Morabito* and E. G. Moczydlowski. Departments of Pharmacology and Cellular and Molecular Physiology, Yale University School of Medicine, New Haven, CT 06518.

Saxitoxin (STX) is a potent neurotoxin that inhibits electrical excitability by blocking voltage-dependent Na-channels. Saxiphilin is a ~91 kd soluble protein that binds STX with high affinity ($K_D = 0.2$ nM) and has been previously purified from bullfrog (*Rana catesbeiana*) plasma (Li and Moczydlowski, 1991. J. Biol. Chem. 266: 15481-7). We cloned saxiphilin cDNA from bullfrog liver by combining PCR amplification with screening of a cDNA library. We isolated a cDNA clone with an open reading frame of 845 amino acids. Identity of the clone with saxiphilin is verified by the presence in the cDNA of the amino terminal sequence and the sequence of five tryptic fragments of native saxiphilin. Primary sequence analysis of saxiphilin reveals significant homology to the transferrin family of proteins with amino acid identity as high as 51% for transferrin from *Xenopus laevis* and 44% for human transferrin. A 19-residue signal secretion sequence, internal duplication characteristic of transferrin and 14 disulfide bonds common to the transferrin family are conserved in saxiphilin. In contrast to transferrins, saxiphilin does not bind Fe^{3+} which is explained by mutation in saxiphilin of nine out of ten highly conserved residues in the two homologous Fe^{3+} -binding sites of transferrin. In addition, saxiphilin contains a unique insertion of 144 residues, a region of which is highly homologous (61%) to a 46-residue domain of nidogen, an ubiquitous cell matrix protein. Tissue distribution analysis of saxiphilin mRNA in the bullfrog shows the highest level of expression in liver, followed by lung, pancreas and brain. The unique features of saxiphilin and strong homology to transferrin identify saxiphilin as a new member of the transferrin family that does not function in iron transport but may bind a different ligand, such as saxitoxin, that interacts with the nervous system. REGULATION OF POMC TRANSLATION BY POMC STEM-LOOP RNA-BINDING PROTEINS IN AtT-20 CELLS. C.M. Spencer* & J.H. Eberwine. Dept. of Pharmacology, University of Pennsylvania School of Medicine, Philadelphia, PA 19104

Regulation of proopiomelanocortin (POMC) gene expression in the anterior pituitary is an important component of the stress response. There is evidence to suggest that translational control is involved in the acute response. POMC mRNA contains a stable (-45 kcal) stem-loop structure that may play an important role in its translational control. We have previously reported that cytoplasmic extracts of mouse corticotroph AtT-20 cells interact specifically with a 60-nt riboprobe corresponding to this stem-loop structure. We are presently investigating the role of these RNA-protein interactions in the translational control of POMC gene expression. In this study we examined the effects of POMC stem-loop RNA and various cytoplasmic extracts on the translatability of full-length POMC RNA in a rabbit reticulocyte lysate *in vitro* translation system. Increasing amounts of AtT-20 cytoplasmic extract reduce the amount of POMC protein synthesized *in vitro*, but do not affect the translation of BMV control RNA. Cytoplasmic extracts of rat pituitary also inhibit POMC translation; however, COS cytoplasmic extracts have no effect on the amount of POMC protein synthesized. These data suggest that cytoplasmic factor(s) present in rat pituitaries and AtT-20 cells, but absent in green monkey kidney COS cells, are involved in the inhibition of POMC translation. Furthermore, this inhibition can be attenuated in a dose-dependent manner by the addition of the 60-nt POMC stem-loop RNA, suggesting that POMC stem-loop RNA-binding proteins are able to modulate the translation of POMC.

IDENTIFICATION OF CHROMOSOME 16 cDNA CLONES FROM A MOUSE NEWBORN $wv/w+$ LIBRARY. M.E. Hodges, L. Sangameswaran, Y. Wang, S. Dlouhy and B. Ghetti*. Indiana University School of Medicine, Indianapolis, IN 46202.

The weaver mutation was mapped previously to mouse chromosome 16. Our approach to weaver gene identification is by mapping and characterizing cerebellar cDNAs that have been obtained by different screening methods. In previous studies, we described a number of novel cDNAs that were obtained by immunoscreening an expression library and we are in the process of genetically mapping them. In addition, we have now screened a newborn $wv/w+$ cerebellar cDNA library with a probe prepared by subtracting cDNA from a $wv/w+$ neonatal library with cRNA from a P31 wv/wv library. This was done because the expression of the weaver gene might be transient, or, in adult cerebellum, might be limited primarily to granule cells. In the first of a series of experiments, we screened 200,000 phage and pulled 27 positive plugs. PCR analysis indicated that the plugs consist of pools of phages that contain different inserts. These amplified inserts were evaluated by Southern blot analysis with a hamster x mouse cell line that contains mouse chromosome 16. Four of the 27 pools contain an insert(s) that appears to derive from mouse chromosome 16. These clones are being characterized further. We conclude that this approach will lead to cDNAs derived from chromosome 16. (Supported by grant PHS P01-NS27613)

IS THE NEURON-SPECIFIC SPLICING MECHANISM OF CLATHRIN LIGHT CHAIN B EXON EN USED BY OTHER NEURON-SPECIFIC EXONS? S. Stamm¹, D. Casper^{2*} and D.M. Helfman¹
¹Cold Spring Harbor Laboratory, Cold Spring Harbor, NY 11724, ²Fishberg Research Center for Neurobiology, Mount Sinai School of Medicine, One Gustave L. Levy Place, New York, NY 10029

Clathrin light chains are components of clathrin coated vesicles which are involved in endocytosis and membrane recycling. The light chain B (LCB) gene encodes two isoforms, termed LCB2 and LCB3, via an alternative RNA splicing mechanism. The neuron-specific LCB2 isoform is generated by the inclusion of a single exon, termed exon EN. We analyzed *cis* elements involved in splice site selection by transfecting minigene constructs into primary neuronal and HeLa cell cultures. Both the 5' and 3' splice sites of exon EN deviate from the vertebrate consensus sequences. Changing either the 3' or 5' splice site of exon EN into the consensus sequence leads to the use of exon EN in HeLa cells. If both splice sites are converted into the consensus sequence, exon EN is constitutively used in HeLa cells. We noticed sequence identity between exon EN and other neuron-specific exons. Changing this shared sequence eliminates the use of EN in neurons. UV cross linking experiments detect specific RNA-binding proteins in brain nuclear extract that bind to EN but not to EN probes lacking the sequence motif shared by several neuron-specific exons. We demonstrated that one of the brain-specific exons sharing sequence identity (exon 9c of the α tropomyosin gene) is also neuron-specific and is first expressed at the same time (E16) as EN during rat brain development. We propose that the use of exon EN is regulated as follows: Exon EN is not spliced in HeLa cells because its 3' and 5' splice sites differ from the consensus. In neurons, a protein factor binds to EN and promotes its use. We postulate that a developmentally regulated neuron-specific exon binding factor is partially responsible for the regulation of a variety of neuron-specific exons, such as LCB exon EN and α tropomyosin exon 9c.

699.8

HUD BINDS TO THE STABILITY ELEMENT OF FOS MRNA. J. Liu, E. Wong and H. M. Furneaux*. Lab. of Mol. Neuro-Oncology, Sloan Kettering Institute for Cancer Research, N.Y., N.Y. 10021.

Hud is a human neuronal-specific RNA binding protein which is the target antigen in autoimmune encephalitis sensory neuropathy. By virtue of its high homology to the *Drosophila* protein, Elav, it is thought that Hud regulates neuronal development and maintenance. Many intermediate early gene products (such as Fos Jun Myc) which are involved in neuronal signal transduction pathways are regulated at the post transcriptional level by an element in their 3' untranslated region which controls message stability. Using North Western Blot and gel retardation assay we have shown that Hud selectively binds to the stability element of fos mRNA. No complex was detected with a deleted fos mRNA which lacked the stability element. Deletions of Hud have shown that the third RNA binding domain is essential for complex formation. These results suggest that Hud may control neuronal development and maintenance, at least in part, by regulation of cfos expression.

699.10

QUANTITATIVE MEASUREMENT OF CALRETININ AND β -ACTIN mRNA FROM RAT BRAIN MICROPUNCHES WITHOUT PRIOR ISOLATION OF RNA. K.I. STRAUSS* & D.M. JACOBOWITZ, Lab of Clinical Science, NIMH, Bethesda, MD 20892.

A microdissection technique for quantitation of neurochemicals in discrete brain nuclei has been coupled with a quantitative lysate ribonuclease protection assay (RPA). Discrete microdissected nuclei and other brain regions (10-500 μ g protein) are solubilized in 6 M guanidine thiocyanate solution and directly hybridized with riboprobes. Concurrent detection of mRNA(s) of interest with the β -actin "housekeeping" gene and total sample protein permits normalization and quantitation in terms of these internal controls. This method eliminates the necessity for isolation of RNA from solid tissue. Assumptions regarding RNA recovery are not necessary since solid tissue specimens are solubilized, hybridized and treated with RNase in a single tube. We have determined the mRNA levels of calretinin, a predominantly neuron-specific calcium binding protein in discrete rat brain nuclei and developing embryos. Calretinin mRNA ranged from 281 ± 35 fg/ μ g protein in the thalamic paraventricular nucleus to 2.3 ± 0.5 fg/ μ g protein in the cerebral cortex. Calretinin: β -actin ratios for the same specimens ranged from $79.9 \pm 9.3\%$ to $1.3 \pm 0.1\%$, respectively. The "micropunch RPA" bypasses the uncertainties associated with RNA isolation from solid tissue; is quantitative for detection of high and low abundance mRNAs from microdissected tissue specimens; and enables the analysis of large numbers of samples in 2-3 days.

TRANSIENT EXPRESSION OF GLIAL FIBRILLARY ACIDIC PROTEIN (GFAP) mRNA IN RETINAL MÜLLER CELLS.

V. Sarthy*, H. Egal and L. Verderber, Department of Ophthalmology, Northwestern University, Chicago, IL 60611.

The Glial Fibrillary Acidic Protein (GFAP) gene is not normally expressed in Müller (glial) cells in the mouse retina. The GFAP gene is, however, activated in response to retinal injury, degeneration and detachment. Recently, we examined the time course of GFAP mRNA and GFAP formation in mice with light-induced retinal degeneration. BALB/c mice were maintained under constant light source for one to six weeks to induce photoreceptor degeneration. GFAP accumulation was examined by immuno-cytochemistry while GFAP mRNA formation was determined by *in situ* hybridization and Northern blotting. GFAP immunostaining in Müller cells was first observed on day 4 and reached maximal intensity after two weeks of light exposure. GFAP was present in Müller cells even after two months. GFAP transcripts were first noted in Müller cells around day 4 and GFAP mRNA levels were increased after two weeks. Surprisingly, no GFAP transcripts were detected in Müller cells after four weeks of light exposure. The retinal astrocytes expressed high levels of GFAP mRNA in all cases examined. In RNA blotting studies, a small amount of GFAP mRNA was present initially in the mouse retina. Following two weeks of light damage, GFAP mRNA levels were elevated about 5-fold. After six weeks in constant light, little GFAP mRNA was found in the retina. Our results show that GFAP is found in Müller cells long after initial synthesis probably as a consequence of its low turnover in the Müller cell cytoskeleton while GFAP mRNA levels rise and decline rapidly due to transient induction of the GFAP gene.

CIRCUITRY AND PATTERN GENERATION V

700.1

THE ROLE OF GLUTAMATE IN THE SWIM NEURAL CIRCUIT OF TRITONIA. G.D. Brown* and A.Q.D. Willows. Friday Harbor Laboratories, Friday Harbor, WA 98250

Predatory starfish elicit an escape swimming response from the sea slug *Tritonia diomedea*. The neural circuit which underlies this rhythmic behavior is comparatively well understood (Getting, 1983). We are currently trying to identify the neurotransmitters used in this circuit and to determine their role in pattern generation. We report here that glutamate may have a role in activating the escape swim in *Tritonia*.

Tritonia brains were isolated and perfused with filtered sea water. The swim neural program (SNP) can be activated in this preparation by brief electrical stimulation of a nerve root. The SNP was monitored with intracellular electrodes in identified swim circuit neurons. We found that puffing 100 μ l of 10 mM glutamate onto the cerebral-pleural ganglion reliably activated the SNP. Lower concentrations were sometimes effective as well. We also monitored cells in the swim neural circuit during addition of several common glutamate agonists. NMDA most closely mimicked the SNP response to glutamate. Quisqualate also activated the SNP and produced tonic activity in some of the cells. Kainate given at a much lower dose (25 μ l of 1 mM) produced tonic activity in many, if not most cells in the brain. Glutamate and each of these agonists inhibited SNP activation by nerve root stimulation when applied in sufficient amounts (see also McClellan et al, 1993).

The glutamate receptor antagonist CNQX applied at concentrations of 200-500 μ M blocked activation of the SNP by nerve root stimulation. Our observations indicate that this block occurs prior to the central pattern generator which produces the rhythmicity in this system, but CNQX may have effects further downstream as well.

700.3

A NETWORK OF CELLS INITIATING PATTERNED ACTIVITY IN THE BUCCAL GANGLIA OF APLYSLIA. I. Hurwitz, R.S. Goldstein, & A.J. Susswein*. Dept Life Sci, Bar Ilan Univ, Ramat Gan, Israel 52 900.

The B31/B32 cells in the buccal ganglia of *Aplysia* initiate a patterned burst of activity in many cells. The pattern resembles that caused by CBI-2, a feeding command neuron. Brief depolarization of B31/B32 initiates a sustained, regenerative depolarization, followed by a hyperpolarization that is correlated with excitation of cell B4. We have now identified a number of cells that are activated by B31/B32, and that in turn feed back onto it. The input from these cells onto B31/B32 can account for much of the activity pattern seen in B31/B32 during bursts of buccal ganglia activity.

B34 is probably involved in coordination between the 2 buccal hemi-ganglia. It is depolarized along with B31/B32, and monosynaptically excites contralateral B31/B32 cells with facilitating EPSPs. Firing B34 initiates a burst in the buccal ganglia.

B63 is part of a positive feedback loop with B31/B32. The cell is excited by B31/B32 activity, and also monosynaptically and polysynaptically excites B31/B32. Monosynaptic and polysynaptic EPSPs show facilitation. B63 is active during the sustained depolarization of B31/B32, and firing it initiates a burst in the buccal ganglia.

B64 causes the large hyperpolarization at the end of a B31/B32 burst. It is active during the hyperpolarization. Firing it produces IPSPs in B31/B32 and in B34, and EPSPs in B4 resembling those seen during feeding bursts. Firing B64 can prevent B31/B32 from initiating a burst. B64 is apparently unable to fire single action potentials: depolarization sufficient to cause firing always elicits a train of spikes. Depolarization of B64 does not initiate a feeding burst in the buccal ganglia. An intracellular fill of B64 revealed a ~20 mm bipolar cell, with one process entering the buccal commissure. The morphology and position of B64 suggest that it may be a previously-identified dopaminergic neuron.

Future studies will be required to determine whether these connections can account for the entire activity pattern of B31/B32 during feeding bursts.

700.2

SEROTONIN FROM DSI NEURONS ACTS AS BOTH A NEUROTRANSMITTER AND AN INTRINSIC NEUROMODULATOR IN THE TRITONIA ESCAPE SWIM CPG CIRCUIT. P.S. Katz* and W.N. Frost. Dept. of Neurobiol. & Anat., Univ. of Texas Health Science Center, Houston, TX 77030.

The dorsal swim interneurons (DSI) are integral components of the swim pattern generating circuit in the mollusc, *Tritonia diomedea*. In addition to its conventional synaptic actions, DSI also evokes neuromodulatory effects, enhancing the strength of connections made by the C2 interneuron onto other CPG neurons and motor neurons (Frost & Getting, Soc. Neurosci. Abstr. 1989, Brown & Willows, Soc. Neurosci. Abstr. 1991). We are interested in the role of this "intrinsic neuromodulation" in the functioning of the network. As a first step, we have investigated the role of serotonin (5-HT), since the DSIs had been shown to be immunoreactive to 5-HT (Getting et al, Soc. Neurosci. Abstr. 1985). In the present study, several lines of evidence indicate that 5-HT may be responsible for both the synaptic and modulatory actions of DSI. First, we found that 5-HT applications mimicked and occluded both the synaptic and modulatory actions of DSI. Second, the 5-HT antagonist, gramine (0.1 mM), blocked the rapid synaptic potential evoked by DSI onto a motor neuron as well as the depolarization caused by pressure-applied 5-HT; we have not yet tested gramine's effects on the modulation. Third, within a few hours of a brief exposure of the ganglion to 5-HT or its precursor, 5-hydroxy-L-tryptophan, both the synaptic and modulatory effects of DSI were greatly enhanced, consistent with the possibility that these treatments increased the quantity of 5-HT released by DSI. These results suggest that DSI utilizes 5-HT both to produce conventional synaptic effects and to simultaneously modulate network properties.

DIFFERENT FORMS OF GATING OF A PEPTIDERGIC MECHANOAFFERENT NEURON BY CENTRAL PATTERN GENERATOR NEURONS IN THE FEEDING SYSTEM OF APLYSLIA. S. C. Rosen*, M. W. Miller, K. R. Weiss, and I. Kupfermann, Cntr. Neurobiol. & Behav., NYS Psychiat. Inst., New York, NY 10032; Inst. of Neurobiol., Univ. of Puerto Rico, San Juan, PR 00901; Dept. Physiol. & Biophys., Mount Sinai Sch. of Med., New York, NY 10027.

B21 is a low threshold radula mechanosensory neuron containing the neuropeptides SCPa and SCPb. It makes different kinds of plastic chemical synaptic connections and electrical synaptic connections to motor neurons that control radula closure (e.g., B8a, B8b, B15, B16). B21 also makes a nonrectifying electrical synapse with CPG interneuron B19. B19 is a powerful regulator of the biting command-like interneuron CBI-2. B21 activity can potentiate the biting motor program via the B21, B19, CBI-2 loop. To determine whether signals across the B21-B19 electrical synapse might be transmitted in the other direction so that phase information generated by the CPG might gate B21's synaptic output, we manipulated B19's membrane potential while recording synaptic potentials evoked by the sensory cell in its motor neuron followers B8a and B15. Depolarization of B19 dramatically enhanced the chemical synaptic output of B21 to its follower cells, whereas hyperpolarization had the opposite effects. Moreover, we found that multifaceted, CPG neuron B4 produced monosynaptic IPSPs in B19 and B21, as well as in motor neurons B8a and B15. When B4 was fired in bursts it also gated the sensory input from B21 to the motor neurons. The data indicate that the output of a single sensory neuron can be gated by multiple CPG elements utilizing different mechanisms and that electrical synapses might produce subtle forms of bidirectional gating between sensory cells and CPG neurons.

MULTIPLE INTRACELLULAR RECORDINGS FROM IDENTIFIED NEURONS IN *APLYSIA* DURING EVOKED FEEDING-LIKE ACTIVITY

P. L. Church* and P. E. Lloyd. Committee on Neurobiology, The University of Chicago, Chicago, IL 60637.

Consummatory feeding behavior in *Aplysia* consists of biting, swallowing, and rejection. It has been postulated that the neuronal control of these behaviors is hierarchically organized with the stimulation of a few command-like neurons necessary and sufficient to elicit buccal motor programs (BMPs). Previous studies suggest that neurons located in the cerebral ganglia may be responsible for the initiation and modulation of these BMPs and that motor neurons in the buccal ganglia generate the cyclic motor output underlying ingestion and egestion. We have identified a large number (>25) of these buccal motor neurons and have characterized the conventional transmitters and peptide cotransmitters which they express. In several cases, the stimulation paradigms necessary for release of those transmitters has been determined. In order to determine the behavioral firing patterns of these neurons we have recorded intracellularly from identified buccal neurons during evoked feeding-like BMPs. By recording simultaneously from up to seven neurons we were able to determine the relative firing rates and phase relationships of many identified neurons. In addition this activity can be correlated to specific aspects of feeding behavior. We have found that during evoked BMPs these neurons fire in paradigms capable of releasing peptide cotransmitters. Supported by NRS-A 1-F31-MH10240 to PJC.

FUNCTIONAL MODIFICATION OF RHYTHMIC MOTOR ACTIVITY BY A MODULATORY PROJECTION NEURON. M.J. Coleman, B.J. Norris and M.P. Nusbaum. Neurobiology Research Center and Dept. of Physiology & Biophysics; Univ. of Alabama at Birmingham; Birmingham, AL 35294.

In the stomatogastric ganglion (STG) of the crab, *Cancer borealis*, the pyloric and gastric mill motor patterns are produced by distinct but overlapping subsets of STG neurons. The Inferior Cardiac (IC) neuron participates in both patterns, so that when these two rhythms occur concurrently, the impulse bursts in this neuron are time-locked to both rhythms. However, its synaptic effects on the other STG network neurons tend to be relatively weak. We have recently identified Modulatory Commissural Neuron 7 (MCN7) and have found that it selectively enhances IC neuron activity. MCN7 projects an axon from its soma in the commissural ganglion to the STG, via the superior oesophageal and stomatogastric nerves.

MCN7 enhances the membrane potential oscillations in the IC neuron, causing it to fire more intense impulse bursts. During these times, IC has stronger synaptic effects on all other gastric mill and pyloric neurons. Moderate activation of MCN7 enhances the pyloric-timed impulse bursts in IC. Stronger activation of MCN7 causes IC to become the pacemaker for a distinct gastric mill motor pattern in which there is a co-activation of two gastric mill neurons that otherwise exhibit an alternating activity pattern. This enhanced IC neuron activity also rhythmically suppresses the pyloric motor pattern by inhibiting the pyloric pacemaker neuron ensemble. This MCN7-evoked rhythm resembles the IC-driven gastric mill rhythm resulting from bath-application of the peptide proctolin (Heinzel et al., J. Neurosci. 13:1793-1803), suggesting that MCN7 is proctolinergic. We are examining whether MCN7 does indeed contain proctolin and, if so, why its effects differ from those of the other two proctolin neurons that influence the STG networks. Supported by NS29436 & HFSP (MPN).

REAL TIME IMAGING OF ANTIDROMIC, SYNAPTIC AND RHYTHMIC ACTIVITY OF MOTONEURONS IN THE ISOLATED SPINAL CORD OF THE NEONATAL RAT. A. Lev-Tov* and M. O'Donovan, Dept. of Anatomy, Hebrew University Medical School, Jerusalem Israel and *The Lab. of Neural Control, NIH, NINDS, Bethesda, MD, 20892.

L3-L6 motoneurons in the lumbar cord of the neonatal rat (P1-P4) were retrogradely filled with the fluorescent calcium indicator calcium green (25% w/v) coupled to dextran (O'Donovan et al., J. Neurosci. Meth., 91-106, 1993). Fluorescent responses were monitored from the cut face of the spinal cord using real-time intensified video microscopy during antidromic stimulation of ventral roots, orthodromic stimulation of dorsal roots or pharmacologically-induced rhythmic motor activity. Backlabelled motoneurons were restricted to lamina IX and often formed 2-3 discrete clusters of cells. Fluorescent changes could be detected in motoneurons following a single antidromic stimulus and progressively increased in amplitude during stimulus trains (1-5 sec) at frequencies from 5-50Hz. Synaptic responses were detected in motoneurons following stimulation of either ipsi- or contralateral dorsal roots. Rhythmic motor activity was induced by acetylcholine (ACh, 50-100µM) and edrophonium (100-500µM), strychnine (10µM), bicuculline (10-20µM) or 4-Aminopyridine (4-AP, 10µM-2.5mM). Rhythmic oscillations of free intracellular calcium were detected during rhythmic activity induced when ACh, Edrophonium and one of the inhibitory antagonists was applied or when 4-AP was applied alone. Our results indicate that elevations of free intracellular calcium accompany several forms of motoneuronal activity in the neonatal spinal cord of the rat and suggest that this technique may be useful for optical studies of single cell and network function in this preparation.

A POPULATION OF CEREBRAL INTERNEURONS IN *APLYSIA* MEDIATES THE COORDINATION OF VASCULAR RESPONSES WITH "SKELETOMOTOR" RESPONSES INVOLVING HEAD MOVEMENTS. Y. Xin, K.R. Weiss, and I. Kupfermann*. Center for Neurobiology and Behavior, Columbia University, 722 W. 168 St. New York, NY 10032 and Fishberg Center, Mt. Sinai School of Medicine, New York, NY 10029.

As an approach toward locating cerebral interneurons that might be involved in head turning responses we backfilled the cerebral pedal and pleural connectives. A population of neurons in the C cluster were identified which produce synaptic effects on a wide variety of pedal and pleural-ganglion neurons. CC5 receives unilateral input from the lips and produces unilateral synaptic effects to presumptive motor neurons of the body wall, and most notably a monosynaptic input to Pas, a motor neuron previously identified by Skelton and Koester, which produces shortening of the ipsilateral pedal artery. Tactile stimuli applied to the tentacle evokes spikes in the ipsilateral CC5, together with a contraction of the ipsilateral pedal artery. Hyperpolarization of CC5 blocks the contraction, and firing of CC5 produces a similar contraction, suggesting that under some circumstances CC5 may be acting as a true command neuron for reflex contraction of the pedal artery. CC5 and the Pas motor neuron also appear to be activated during locomotion, at the phase in which head shortening occurs, during feeding when the buccal mass moves backward, and perhaps during an ipsilateral turn of the head during various behaviors. Other C cluster neurons similarly produce responses appropriate for coordinating movements of the buccal mass, body wall and foot with responses of the circulatory system.

MODIFICATION OF RHYTHMIC MOTOR ACTIVITY BY RECRUITMENT OF A NEWLY IDENTIFIED PROJECTION NEURON. B.J. Norris, M.J. Coleman and M.P. Nusbaum. Neurobiology Research Center & Dept. of Physiology & Biophysics; Univ. of Alabama at Birmingham; Birmingham, AL 35294.

Modulatory transmitters enable single neural networks to produce many neural activity patterns by altering neuronal membrane properties and/or synaptic efficacies. We have been studying how modulatory substances influence the gastric mill network, in the stomatogastric ganglion (STG) of the crab, *Cancer borealis*. The STG is one of four ganglia of the stomatogastric nervous system (STNS). Bath-application of the muscarinic agonist oxotremorine (OXO: 10⁻⁵ M) to the isolated STNS evokes either of two distinct gastric mill rhythms. The rhythm that is elicited is determined by whether an additional neuron, located in the commissural ganglion (CoG), is sufficiently excited to enable it to participate in the gastric mill rhythm. This newly identified neuron, called Modulatory Commissural Neuron 2 (MCN2), projects to the STG via the superior oesophageal and stomatogastric nerves.

The gastric mill rhythm that includes MCN2 activity is characterized by MCN2 firing together with the LG and GM neurons, and in alternation with the DG and IC neurons. When MCN2 does not participate in the gastric mill rhythm, IC fires along with LG and GM. MCN2 is instrumental in producing this motor pattern by way of its excitatory synaptic effects on LG and GM and its inhibitory synaptic effects on DG and IC. Interestingly, the rhythmic activity in MCN2 results partly from effects of OXO on MCN2 membrane properties and partly from synaptic input that MCN2 receives from one of the gastric mill neurons. Additionally, in the presence of OXO, an MCN2-type gastric mill rhythm can be elicited by rhythmic (but not tonic) stimulation of MCN2. Thus, modulatory transmitters can elicit a novel motor pattern by recruiting activity in an additional neuron. Supported by NS29436 and HFSP (MPN).

MODIFICATION OF THE LEECH SWIM OSCILLATOR PERIOD. C.G. Hocker and W.O. Friesen*. Center for Biological Timing and Department of Biology, University of Virginia, Charlottesville, VA 22901

Swimming in the leech, *Hirudo medicinalis*, is an example of a fixed complex behavioral act that is created within the CNS. The leech propels itself through water by undulating its body wall. The movement is generated by a traveling wave of motor neuron activity, which sweeps from the anterior to the posterior end of the nerve cord. The pattern repeats with a period of 0.4 to 2 s. To examine the nature of the dynamic control of the CNS network underlying the coordination of the swimming behavior, several methods for comparing time series (graphic, spectral, and statistical) were applied to the fictive swims of the isolated leech CNS (20 midbody ganglia (M2-M21) plus the tail ganglion). Swimming activity occurred spontaneously or by shocking the dorsal posterior nerve of M16, M17 or M18. The time series data are composed of bursts of action potentials recorded extracellularly (spike events) from the dorsal excitor motor neuron (cell 3) of four midbody ganglia. Careful examination of the structure of the swim period variation was done with actograms created by plotting the time of spike events along a vertically stacked set of horizontal lines with a fixed time width. Upon converting the spike events to instantaneous frequency vs. time, the approximate entropy statistic of the continuous time series was found to be useful for comparing the regularity of ten second intervals of data.

For both spontaneous and induced fictive swims, the two most reproducible features, which could be an expression of a dynamic control within the CNS, are the abrupt shifts in the mean period and the frequency modulation (FM) with a period of about 10 swim oscillations. The FM of the posterior ganglia tends to precede ganglia more anterior. Unambiguous identification of the FM peak in frequency spectrum estimates was achieved.

EFFECTS OF LOCAL OSCILLATOR FREQUENCIES ON PHASE LAG IN SIMULATED CHAINS OF COUPLED OSCILLATORS. T.L. Williams* and K.A. Sigvardt. Physiology Dept, SGHMS, Univ London, SW17 0RE, UK, and Neurology, Univ California-Davis, VAMC, Martinez CA 94553.

The lamprey spinal CPG for locomotion can be considered as a chain of coupled oscillators, in which each oscillator has an intrinsic frequency that can be modified by coupling from its neighbors. Theoretical work indicates that chains with uniform intrinsic frequencies have uniform phase lags along the chain if coupling is asymmetric (Kopell and Ermentrout, SIAM J Appl Math 50:1014, 1990). Changing the intrinsic frequency in the rostral or caudal half of a chain changes the phase lags in one half but not the other. The half in which the phase lag changes depends not on which half has the higher intrinsic frequency but on whether ascending or descending coupling is dominant. We will compare the behavior of simulated chains of oscillators with the theory and with experimental data on the lamprey spinal cord. Our results indicate that ascending inter-segmental coupling is dominant for setting intersegmental phase lags along the cord.

COMPUTER SIMULATION OF MOTOR PATTERN GENERATION FOR VARIABILITY IN SNAPPING IN ANURANS. J.-S. Liaw, A. Weerasuriya and M.A. Arbib*. Center for Neural Engineering, University of Southern California, Los Angeles, CA 90089 and School of Medicine, Mercer University, Macon, GA 31207.

Anuran prey capture, released by specific stimuli, consists of a sequence of motor synergies. Snapping the consummatory event of this sequence has been thought to be a ballistic motor pattern. We have developed a model to address the variability recently observed in our laboratory of this rapidly executed behavior (<200 msec). Current evidence suggests that the motor pattern generator (MPG) for snapping is located bilaterally in the rostral portion of the medial reticular formation of the medulla oblongata. A biologically constrained neural network model for such an MPG is proposed. This model incorporates separate but interacting modules for the control of the depressor mandibuli (jaw opener), genioglossus (tongue protractor), and hyoglossus (tongue retractor) muscles. Activation of this MPG produces spatio-temporal patterns of activity in the above three motoneuron pools that are strikingly similar to EMG patterns recorded from these muscles during prey capture. A push-pull mechanism built into each module facilitates the coordination of the motoneurons and also provides a flexibility to motoneuron activation. Two schemes, mediation and modulation, for achieving this flexibility are explored to simulate variable tongue extension by having a 'closeness' signal to control the synchronization of tongue protractor and retractor. In the mediation scheme, the signal is used to control the onset time of the retractor, whereas in the modulation scheme, it changes the time-constant of the retractor thus leading to a variation in its rate of peaking.

QUANTITATIVE ANALYSIS OF *Per* PROTEIN CYCLING IN NUCLEI AND CYTOPLASM OF *Drosophila* PHOTORECEPTORS. M.G. Folwell, W. Bug*, and K.K. Siwicki. Biology Department, Swarthmore College, Swarthmore, PA 19081

A circadian rhythm in the expression of the *Drosophila period* gene appears to underlie the effects of *per* mutants on behavioral rhythms. Evidence for rhythms in *per* mRNA and *Per* protein, which are opposite in phase, suggests a feedback loop in which *per* transcription is inhibited when nuclear *Per* levels are high. We have developed a photometric method using indirect immunofluorescence to characterize the kinetics of *Per* cycling in specific cell types. We use a cooled CCD camera (Photometrics, Inc.) to acquire two digital images of each eye section: nuclear staining (DAPI) and *Per* immunofluorescence. Using IPLab software (Signal Analytics) on a Macintosh Quadra 800, the edges of the nuclei are defined with the DAPI image, then superimposed on the Cy3 image to obtain the average value of anti-*Per* fluorescence within the nuclei. When applied to photoreceptors of *per*⁺ flies, this analysis revealed robust daily and circadian rhythms in nuclear *Per*, confirming previous results. Levels of nuclear *Per* were lowest near dusk, and increased 4-fold to peak near dawn. The combination of sensitivity and spatial resolution of this method have revealed, for the first time, significant levels of cytoplasmic *Per*. In photoreceptors of flies from 12:12 LD, cytoplasmic *Per* levels were lowest near dawn, and highest near dusk (i.e., opposite in phase to the nuclear *Per* rhythm). Thus, cytoplasmic *Per* increased several hours earlier than nuclear *Per*, suggesting that nuclear translocation may be regulated. Experiments are in progress to examine the effects of entrainment cues and *per* mutations on the relative levels of cytoplasmic vs. nuclear *Per*.

INTRACELLULAR CALCIUM RESPONSES OF CIRCADIAN PACEMAKER NEURONS MEASURED WITH FURA-2. M. Geusz*, S. Michel, and G. Block. NSF Center for Biological Timing, Department of Biology, Gilmer Hall, University of Virginia, Charlottesville, VA 22903.

A neural pacemaker in the eye of the mollusk *Bulla gouldiana* generates a circadian rhythm in optic nerve activity. The basal retinal neurons (BRNs) of the eye contain the pacemaker and retain circadian rhythmicity while in cell culture. Light and other depolarizing stimuli shift the phase of the pacemaker in the eye through a process that is blocked by [Ni²⁺]_i or low [Ca²⁺]_i. To test if an influx of Ca²⁺ is present throughout depolarizing treatments that produce phase shifts, dissociated BRNs in cell culture were loaded with the calcium-sensitive dye Fura-2 AM, and then depolarized with elevated [K⁺]_o.

Calcium levels in the BRNs remained elevated during treatments with 50 mM [K⁺]_o, lasting at least 1 h, a stimulus capable of phase shifting the pacemaker. [Ca²⁺]_i reached a peak near 1 μM within minutes of beginning the treatment, and then persisted at a lower plateau level until the stimulus ended (n=23 cells). Elevated [K⁺]_o produced significantly larger Ca²⁺ responses (p=0.03) when given during the subjective night (n=9) versus the subjective day (n=14). EGTA treatments administered during depolarization blocked the sustained rise in [Ca²⁺]_i, verifying that the elevation requires a Ca²⁺ influx. The [Ca²⁺]_i increase during depolarization was also prevented with 50 mM Ni²⁺, which blocks phase shifts to depolarization, but not with 5 mM Ni²⁺, which does not block phase shifts. The Ca²⁺ changes occurred throughout the cell body, suggesting that a Ca²⁺ signal due to depolarization spreads into the nucleus. The results show that a phase-shifting stimulus generates a prolonged Ca²⁺ signal, and that BRNs in cell culture retain a critical part of the entrainment mechanism. Supported by NS15264, NS08806 and the NSF Center for Biological Timing.

GENETIC ANALYSIS OF A CIRCADIAN PACEMAKER OUTPUT PATHWAY. F.R. Jackson* and L.M. Newby. Worcester Foundation For Experimental Biology, Shrewsbury, MA 01545.

All circadian-period mutations of *Drosophila* affect the temporal patterning of locomotor activity and pupal eclosion, consistent with the idea that a single neural pacemaker governs the properties of both endogenous rhythms. Evidence suggests, however, that genetically separable neuroendocrine output pathways couple the pacemaker to eclosion and activity. To understand the physiology of a specific pacemaker output pathway, we are studying several mutations which alter the daily timing of eclosion but do not perturb the expression of the activity rhythm. One mutant named *gate* has completely arrhythmic patterns of eclosion in constant darkness but normal activity rhythms, indicative of a lesion in the output pathway controlling pupal eclosion. Studies are underway to cytogenetically map the *gate* mutation in order to facilitate molecular analyses of the relevant gene. A different mutant named *lark* has been identified, for which daily peaks of eclosion occur abnormally early in either light/dark or temperature cycles. The temporal distribution of locomotor activity, however, is normal in *lark* mutants, as is the free-running period of the circadian pacemaker. Interestingly, the *lark* mutation has a dominant effect on the timing of eclosion, but causes a recessive embryonic lethal phenotype. Both the behavioral and essential functions of the *lark* gene are encoded by a single transcription unit which expresses mRNAs throughout the embryonic central nervous system. Studies are in progress to document the expression pattern in pupae to understand how LARK protein contributes to the timing of eclosion. Based primarily on the observed mutant phenotypes, we propose that the LARK product might mediate the response of neural tissues to an endocrine signal.

TWO CHANNEL CANDIDATES UNDERLYING CIRCADIAN RHYTHMOGENESIS IN ISOLATED PACEMAKER NEURONS OF *APLYSIA* RETINA. J.W. Jacklet¹ and S. Barnes², Department of Biological Sciences, SUNY Albany, NY 12222¹ and Neuroscience Research Group, University of Calgary, Alberta, Canada, T2N 4N1².

Several cell types (including pigmentless monopolar and bipolar neurons, pigmented support cells and pigmented large and small photoreceptors) are obtained from enzymatic dispersion of the *Aplysia* retina. Whole-cell tight-seal recordings in current- and voltage-clamp were made with 2-5 Mohm KCl, CsCl or K gluconate-filled electrodes from small (15-20 μm dia.) monopolar neurons, the putative circadian pacemaker neurons. They had resting potentials near -40 mV and, if neurites had grown out, produced spikes (60 mV) spontaneously at under 1 Hz. Depolarizing current injections increased the rate of firing. Hyperpolarizing current injections revealed inward rectification with slowly decaying (1-3s) inhibition following the current step. Under voltage-clamp, five ionic currents were apparent including a rapidly-inactivating Na current, a Ca current too small to be seen except during dialysis with CsCl electrode solution, and a delayed rectifier-type K current that activates positive to -10 mV. Two other currents have kinetic properties that suggest a possible role in modulating the resting potential and spontaneous spike generation. The A-current, although transient (inactivation time constant of 250 ms at -30 mV), has overlapping activation and steady-state inactivation curves, giving rise to window current in the voltage range between -90 and -50 mV. Dialysis of the cells with low free calcium solution also induces within minutes the appearance of inward rectifier Cl current, activating negative to -30 mV. Due to the low capacitance (9.5 ± 3.3 pF, n=16, SD) and high input resistance of the cells in this voltage range (6.5 ± 6.6 Gohm), even small membrane currents exert strong influence on excitability. We thank N. Syed, K. Lukowiak and A. Bulloch for help culturing cells. Supported by AHFMR, MRC and NSF.

PUTATIVE CIRCADIAN PACEMAKER NEURONS IN APLYSIA EYE ARE IMMUNOREACTIVE TO APLYSIA NEUROPEPTIDE Y. S.M. Rajpara, D.F. Owens, V. L. Begnoche and E. Mayeri*. Dept. of Physiology, University of California, San Francisco, CA 94143-0444.

We recently identified a neuropeptide Y homolog in *Aplysia* (apNPY) that produces excitatory and prolonged inhibitory responses in neurons in the abdominal ganglion. In the present study we used an affinity purified antibody specific to the amino terminus of apNPY to investigate immunoreactivity (IR) in the *Aplysia* eye. Neurons and fibers in the outer layer of the retina were intensely IR for apNPY. The labelled neurons were secondary neurons, which correspond to the putative circadian pacemaker neurons. ApNPY IR was also present in the pacemaker neuropil, located near the initial portion of the optic nerve, and in a large bundle of fibers in the optic nerve. Staining was eliminated by antibody preadsorption with apNPY, but not by preadsorption with FMRFamide. Distribution of IR-apNPY in the eye appears to correlate well with IR previously described by Siwicki et al., 1989, for the *period* gene product. The *period* gene product has been implicated in the function of the circadian clock of *Drosophila*. Since circadian pacemaker neurons project to the central nervous system, the results raise the possibility that apNPY released from these cells may have a role in imposing a daily cycle of activity on central neurons and the animal's behavior.

EVIDENCE FOR THE DIRECT INVOLVEMENT OF TRANSCRIPTION IN THE TIMING MECHANISM OF A CIRCADIAN PACEMAKER.

S.B.S. Khalsa*, D. Whitmore, B. Bogart and G.D. Block. NSF Center for Biological Timing, Department of Biology, Gilmer Hall, University of Virginia, Charlottesville, VA 22903.

Using long pulses of translation and transcription inhibitors the *Bulla* ocular circadian pacemaker has been shown to exhibit a phase-dependent requirement for translation (PNAS, 89:10862, 1992) and transcription (Soc. Neurosci. Abstr. 16:640). Pacemaker motion is stopped with inhibitor at the sensitive phase in the late subjective night, and resumes only when the inhibitor is withdrawn.

With additional inhibitor pulses applied over a range of durations and at different phases we have determined that the transcription-sensitive phase (late subjective night / entire subjective day) is longer than the translation-sensitive phase (late subjective night / early subjective day), i.e. for the region of the circadian cycle in the mid to late subjective day the pacemaker is transcription-sensitive but not translation-sensitive. The transcription inhibitor 5,6-dichlorobenzimidazole riboside (DRB; 100 μ M) applied at ZT 6-12 yields a 7 hr phase delay, whereas 10 mM cycloheximide, which is sufficient to stop the pacemaker at the translation-sensitive phase, is ineffective at this phase.

To assess the timecourse of the DRB-induced delay, light pulses were applied at either ZT 13-16, 20-23, or 4-7 following a DRB pulse at ZT 6-12. Comparison of the resultant shifts with those to light pulses alone (no DRB pre-pulse) suggests that the delay to DRB had occurred during or immediately following the DRB treatment, i.e. the light-induced phase shifts following DRB were consistent with a pacemaker phase which was delayed by 7 hr. The observation of a transcription-sensitive phase which is translation-insensitive, together with the observation that DRB appears to stop the pacemaker at this phase, suggests that transcription is an integral component of the circadian timing loop, as opposed to simply a phase-dependent requirement. Supported by NS15264

FOS EXPRESSION IN THE RAT DIENCEPHALON DURING SLEEP (S) AND WAKEFULNESS (W) IN BASAL CONDITIONS AND EXPERIMENTAL TRYPANOSOMIASIS.

M. Bentivoglio*, G. Grassi-Zucconi*, Z.-C. Peng*, G. Bertini*, J. Harris*, A. Bassetti* and K. Kristensson*. Institutes of Anatomy, University of Verona, Cell Biology, University of Perugia, Italy, and *Clinical Research Center, Karolinska Institutes, Huddinge Hospital, Sweden.

We recently reported that expression of the Fos protein, encoded by the immediate early gene *c-fos*, occurs in different brain areas during spontaneous S and W documented by EEG monitoring and behavioral control (12h-12h light/dark cycle). The present study focuses on the diencephalon, where Fos expression occurs - consistently but not exclusively - in the paraventricular nucleus (Pv) of the thalamic midline and suprachiasmatic nucleus of the hypothalamus (SCN). Fos-immunoreactive (ir) neurons are present in Pv during both S and W, being more numerous in the W cases. On the other hand, Fos-ir neurons are mainly found in the SCN in the S animals. Given the projections of SCN to Pv, these data indicate that the link between the circadian pacemaker and the thalamic midline could play a substantial role in the sequence of gene expression underlying the S and W sequence. Pv efferents reach different limbic targets (such as the amygdala and nucleus accumbens), and we are at present verifying whether Fos expression during S and W occurs selectively in one of these cell populations. Rats infected with *Trypanosoma brucei brucei*, that produces in humans the African sleeping sickness, were matched with non-infected controls. A considerable fragmentation of the sleep pattern was observed in the infected animals. No significant differences were detected in Pv, whereas the pattern of spontaneous Fos induction in the SCN was mostly reversed in the infected animals with respect to controls: Fos-ir neurons were detected in the SCN in many of the infected W cases, but in only a few of the S infected animals. These changes in gene expression suggest that Trypanosomiasis could be underlied by selective diencephalic dysfunctions.

701.6

CIRCULATING CORTICOSTERONE (CORT) AND HYPOTHALAMIC NEUROPEPTIDE Y (NPY): ANALYSES OF GENE EXPRESSION, PEPTIDE LEVELS AND RECEPTOR BINDING SITES. S. F. Leibowitz*, A. Akabayashi*, N. Levin*, J. Roberts*, Y. Watanabe* and X. Paez*. The Rockefeller Univ., N.Y., N.Y. 10021* and Mt. Sinai School of Medicine, N.Y., N.Y. 10029*.

The present experiments support the existence of a close, positive relationship between circulating CORT, NPY gene expression in the arcuate nucleus (ARC), and NPY projections to the parvocellular paraventricular nucleus (pPVN), which is functionally expressed at the onset of the natural feeding cycle when CORT peaks to activate type II receptors. Results in intact rats demonstrate a clear light/dark rhythm of NPY gene expression (via solution hybridization/nuclease protection assay) and NPY levels (via RIA) in relation to circulating CORT, characterized by: 1) a rise in CORT, from <1.0 μ g% to 5.0 μ g%, starting at 6 hrs before dark onset; 2) an increase 2 hrs later in NPY mRNA in the mediobasal hypothalamus (MBH, containing the ARC), which returns to basal levels within 4 hrs; 3) a rise in NPY levels in the mediobasal hypothalamus (MDH, containing the PVN) at dark onset, associated with a marked decline in NPY levels within the MBH; and 4) peak levels of CORT at dark onset, which are positively correlated with NPY mRNA or peptide levels ($r = +0.90$, $p < 0.05$) in the MBH. Results in ADX rats suggest that CORT, at levels which activate type II glucocorticoid receptors, may directly contribute to this natural rise in NPY gene expression and peptide transport to the pPVN. While basal NPY gene expression in the ARC (via *in situ* hybridization) and peptide levels (via RIA) in the cell bodies and most terminal sites are unaffected by the absence of CORT, NPY levels in the pPVN, dorsomedial nucleus and preoptic area, which have high concentrations of type II receptors, are reduced by ADX and restored by CORT (>5 μ g%). In ADX rats, CORT also potentiates NPY mRNA in the ARC, as well as the locus coeruleus, and tends to raise the Bmax for ¹²⁵I-PYY receptor binding sites in whole hypothalamus, suggesting its positive action at the NPY receptor site as well.

701.8

USE OF PHOSPHOPEPTIDE-SPECIFIC ANTIBODIES AGAINST CREB AND SRF IN THE SUPRACHIASMATIC NUCLEUS. J.M. Kornhauser¹*, D.D. Ginty², K.E. Mayo¹, M.E. Greenberg² and J.S. Takahashi¹. ¹NSF Center for Biological Timing, Northwestern Univ., Evanston, IL 60208; ²Dept. of Microbiology and Molecular Genetics, Harvard Univ., Boston, MA 02115.

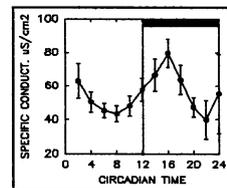

The principal mammalian circadian pacemaker is located in the hypothalamic suprachiasmatic nucleus (SCN). Light stimuli which phase shift circadian rhythms also induce the expression of a set of genes, including *c-fos*, in the SCN, suggesting a role for their gene products in photic resetting of the circadian clock. Several key molecules in signal transduction pathways regulating *c-fos* transcription undergo specific phosphorylation events concomitant with their functional activation. We are investigating the intracellular signaling pathways by which light regulates gene expression in the SCN, using antibodies specific for the phosphorylated forms of regulatory proteins. Regulation of *c-fos* transcription by both calcium and cAMP is mediated by the cAMP response element-binding protein (CREB). We have demonstrated, using immunocytochemistry with an antibody specific for the phosphorylated/activated form of CREB, that light during subjective night, but not subjective day, rapidly induces CREB phosphorylation in the hamster SCN. Another signaling pathway regulating *c-fos* utilizes the serum response element (SRE). A complex of factors binds to the SRE, including the serum response factor (SRF), which becomes newly phosphorylated on serine¹⁰³ following extracellular stimulation. We used an antibody which recognizes ser¹⁰³-phosphorylated SRF (P-SRF) to ask if light activates SRF in the SCN. P-SRF immunoreactivity is constitutively high in the SCN, and is not significantly increased by light. This may be surprising, since NMDA receptors, which are important for photic signaling to the SCN, act through the SRE to activate *c-fos* transcription in neurons *in vitro*. Thus, light may instead regulate a different protein in the SRF complex or may not signal through the *c-fos* SRE. Antibodies specific for the phosphorylated forms of transcription factors and kinases should help to elucidate further neuronal signal transduction pathways in the SCN and throughout the brain.

CIRCADIAN MODULATION OF MEMBRANE PROPERTIES OF SCN NEURONS IN RAT BRAIN SLICE. E.A. Gallman* and M.U. Gillette. Depts of Cell & Structural Biology and Physiology & Biophysics, Univ. of Illinois, Urbana, IL, 61801.

The suprachiasmatic nuclei (SCN) in rat are the neuroanatomic substrate for a pacemaker underlying circadian rhythmicity. The mechanisms responsible for circadian rhythmicity are unknown. Mean firing frequency of SCN neurons varies in a circadian pattern, with peak activity occurring near the middle of subjective day, both *in vivo* and in the *in vitro* hypothalamic brain slice. We employed whole cell recording in the rat brain slice to examine possible mechanisms for modulation of firing rate, as such mechanisms may reflect underlying organization of the circadian clock. We found statistically significant changes in membrane potential and specific membrane conductance which paralleled the changes in firing rate.

Membrane potential was more negative at CT 14-18 than at CT 6-10. Specific membrane conductance was low at CT 6-10 and high at CT 14-18 (Figure). We are investigating the ionic conductances underlying these observations. AFOSR-90-0205 & PHS NS 22155.

701.11

Morphology and distribution of retinal ganglion cells (RGC) projecting to the suprachiasmatic nucleus in the sheep.

H.M. Cooper*, A. Tessonnaud, A. Caldani, A. Locatelli, S. Richard and M.C. Viguier-Martinez. INSERM U-371, Cerveau et Vision, 69500 Bron; Lab. Neuroendocrinologie, Univ. de Tours, Fac. Sciences, 37200 Tours; INRA Lab. Neuroendocrinologie Sexuelle, 37380 Nouzilly; FRANCE.

Several lines of evidence suggest that the retinohypothalamic pathway arises from a particular class of RGC's. In the sheep, the large size of the SCN, combined with a trans-sinusal surgical approach allowing direct visual access to this structure, allowed us to accurately place single or multiple injections of retrograde fluorescent tracers (FR, FB, DY). Single injections in the SCN labels a sparse population of RGC's (< 1000), homogeneously distributed in homologous regions of each retina, above the horizontal streak. The projection of these regions into visual space covers a wide area including the entire ventral part of the visual field. Multiple, bilateral injections further show a lack of precise topographic organization. RGC's from a given sector of the retina project to all parts of the SCN, and conversely, each part of the SCN receives a projection from all regions of both retinas. RGC's were of two morphological types. One unusual class of cell had a small to medium sized elongated soma (10-15 μ m diam), and an asymmetrical organization with two or three long slender dendrites (>250 μ m). The second class, resembling W-type cells, had a small soma (<10 μ m diam) and more restricted but highly branched dendritic arborization. These results show that the spatial distribution of retinohypothalamic GC's forms a mosaic independent of thalamic and tectal projecting ganglion cells. The sparse number and widespread naso-temporal distribution of RGC's simultaneously reduces spatial resolution and increases the available sampling area. The lack of retinotopic connections (high degree of divergence and convergence) further blurs the retinal image by potentially annulling spatial contrasts, enabling whole field integration of light. Modeling this organization illustrates how retinal and optical constraints combine to increase the efficiency of this system for the detection of diffuse, ambient light levels.

SOMATOSENSORY CORTEX AND THALAMOCORTICAL RELATIONSHIPS V

Clonazepam suppresses GABA_B inhibition in relay cells through actions in the reticular nucleus J.R. Huguenard* and D.A. Prince. Dept. of Neurology & Neurological Sciences, Stanford Univ. Med. Ctr., Stanford, CA 94305.

Recurrent feedback within the intrathalamic circuit is thought to underlie various thalamocortical oscillations including those involved in absence epilepsy. Thalamocortical relay cells (TCs) excite GABAergic neurons of nucleus reticularis thalami (nRt) leading to recurrent IPSPs onto relay neurons. These hyperpolarizing IPSPs can trigger rebound low-threshold spikes (LTSs) in TCs which, in turn, lead to reexcitation of nRt and a maintained thalamic oscillation. Thus, drugs which directly (succinimides) or indirectly (GABA_B antagonists) decrease LTS generation can eliminate the pathological oscillations and absence seizures, while barbiturates, which enhance GABA_A inhibition, may exacerbate them. In this context, the beneficial actions of the GABA_A agonist, clonazepam, are difficult to explain, and were the focus of these experiments. Stimulation of nRt evoked robust biphasic (GABA_A/GABA_B) IPSPs in rat somatosensory TCs recorded in thalamic slices with patch-clamp techniques. Bath application of clonazepam (300 nM) reduced the amplitude of the GABA_B component with only slight effect on the GABA_A component. In contrast, the GABA_A antagonist bicuculline methiodide (BMI, 2-10 μ M), blocked the GABA_A component but enhanced the GABA_B component, even when excitatory amino acid receptors were blocked. Possible sites for these GABA_A modulatory actions were 1) intra-nRt inhibitory circuits or 2) presynaptic inhibition of nRt terminals impinging onto TCs. Voltage-clamp recordings coupled with local perfusion revealed that GABA_B responses were enhanced only with BMI application to nRt, thus ruling out the latter possibility. These data are consistent with the hypothesis that nRt cells are mutually inhibitory during synchronous stimuli such as those which occur with extracellular stimulation and during absence seizures. This points to a promising therapeutic target for anti-absence drugs. Supported by NIH grants NS06477 and NS12151.

CORTICAL PROJECTIONS OF THE VENTRAL PERIPHERY OF THE CAT'S THALAMIC VENTRAL POSTEROMEDIAL NUCLEUS (VPM_v). C. Vahle-Hinz* and E. Oertle. Physiologisches Institut, Univ.-Krankenhaus Eppendorf, D-20246 Hamburg and Physiologisches Institut, Univ. Würzburg, D-97070 Würzburg, Germany.

Neurons of the VPM_v in the cat are involved in processing of information about noxious events affecting the skin and the viscera. The response properties of VPM_v neurons and their location in the lateral thalamus indicate that they may subserve the sensory-discriminative aspect of nociception and pain. In order to reveal the cortical areas of projection of VPM_v neurons, the anterogradely transported neuronal tracer biotin-dextran was injected into this region and visualized by the avidin-biotin complex method using diaminobenzidine with nickel enhancement as chromogen.

The injection sites were small (100-300 μ m in diameter) lying well within the borders of VPM_v. Labeled fibers traveled rostrally in the internal capsule towards their cortical fields of termination. Terminal arbors with bouton-like endings were found in areas 1, 2, 3a, 3b, 4, 4b, 5, 6, 14 and 43. The terminals were located in layers III and IV as well as layer I. Apart from the anterograde label, a few retrogradely labeled somata of neurons in layer VI were present in the same cortical areas.

The results indicate that information about noxious stimuli, which is relayed in the thalamic VPM_v, is represented in the primary and secondary somatosensory cortices as well as in parts of the motor, the insular and orbitofrontal cortices.

SPATIAL ORGANIZATION OF INHIBITORY SYNAPTIC RESPONSES ONTO PYRAMIDAL NEURONS OF RAT NEOCORTEX A. Nicoll*, H.G. Kim & B.W. Connors. Dept. Neuroscience, Brown University, Providence, R.I. 02912.

Neocortical pyramidal cells receive GABA-mediated synaptic inputs from local inhibitory neurons, but the pattern of their postsynaptic GABA responses and the spatial extent of local inhibitory interactions is unclear. These issues were investigated with whole-cell recordings from pyramidal cells in coronal slices of rat somatosensory cortex, in the presence of bath-applied glutamate antagonists APV and DNQX. Spontaneous, picrotoxin-sensitive IPSPs were examined in 8, CsCl-loaded layer 5 pyramidal cells. They displayed a wide range of 10-90% rise times (1-34 ms), not correlated with amplitude (0.2-18 mV), suggesting that they arose over a range of dendritic locations. 'Proximal' and 'distal' IPSPs (~1 mV) were evoked in 10 CsCl-loaded layer 5 pyramidal cells using extracellular electrodes placed simultaneously in layers 5/6 and 2/3, separated by a horizontal cut made in layer 4. Evoked IPSPs were also blocked by picrotoxin. In 7 out of 10 of the averaged IPSP pairs, the distal waveform had a longer 10-90% rise time than the proximal one. The proximal IPSP could be reversed by membrane depolarization when the distal one could not (n=4/4). These results suggest that GABA-A responses can be evoked in the apical dendrites of pyramidal cells. The spatial organization of inhibitory inputs onto pyramidal neurons was mapped in layers 2/3 and 5. Cells were recorded with K⁺-filled pipettes in the presence of glutamate antagonists, and monosynaptic IPSPs were evoked by focal pressure ejections of 1-10 mM acetylcholine. Trials were made sequentially at 100 μ m intervals over horizontal distances of 100-1000 μ m from the postsynaptic cell, which was held at c. -60 mV by current injection. The frequency of IPSP occurrence declined with distance in both layers. IPSPs could be evoked from a horizontal distance of 500 μ m for 26 layer 2/3 cells, but up to 800 μ m for 30 layer 5 cells. Furthermore, within layer 5, the probability of observing IPSPs in intrinsically-bursting cells was significantly lower than in the regular-spiking cells. These results suggest that the spatial organization of inhibition varies across different layers and cell types. Supported by grants from NIH and ONR to B.W.C.

THE SEQUENCE OF ACTIVATION OF VB THALAMIC AFFERENTS, CORTICAL EFFERENT NEURONS AND PUTATIVE INTERNEURONS IN RABBIT SOMATOSENSORY CORTEX H. A. Swadlow, Dept. of Psychology, University of Connecticut, Storrs, CT 06269

Previous studies of rabbit S-1 (Swadlow, H. A., *J. Neurophysiol.*, 62, 288-308, 1989; 63, 1477-1498, 1990) examined the properties of several classes of efferent neurons and a class of suspected interneurons (SINs) which responded to VB thalamic stimulation with a high frequency (> 600 Hz) burst of very short-duration spikes. Because SINs were the first cells in S-1 to respond synaptically to thalamic stimulation, it was suggested that they were involved in feed-forward inhibition of efferent neurons. However, the above studies could not eliminate the possible synaptic activation of the SINs via the recurrent collaterals of descending corticofugal axons. The present work examines this question in the cutaneous facial representation of VB thalamus and S-1 of awake rabbits by monitoring the sequence of activation in identified elements following activation of the receptive field center with a brief (< 0.6 ms rise time) air-puff.

VB projection neurons (antidromically identified, N=27) responded at a median latency of 5.1 ms (range = 4.2 - 5.8 ms) and had a median antidromic latency of 0.94 ms (range = 0.74 - 1.3 ms) to S-1 stimulation. The estimated arrival time of air-puff generated impulses at thalamo-cortical terminals (the latency of the VB neuron to the air-puff plus the cortico-thalamic antidromic latency) was 5.98 ms (median value, range = 5.18 - 6.84). SINs were the first cells in S-1 to respond synaptically to both the thalamic stimulus (median latency = 1.45 ms, range = 1.25 - 3.1 ms) and the air-puff stimulus (median latency = 6.7 ms (range = 6.05 - 13.0, N=56)). Most SINs responded to the air-puff with several spikes. These data suggest a powerful monosynaptic activation of most SINs by VB thalamic afferents. In contrast, most cortico-cortical and descending corticofugal efferent neurons responded at considerably longer latencies to both the thalamic (median = 3.3 ms, range = 2.25 - 4.9) and air-puff (median = 10.65 ms, range = 7.55 - 22.9 ms) stimulation. THE DEVELOPMENT OF THALAMOCORTICAL AND INTRACORTICAL CONNECTIVITY IN RAT SOMATOSENSORY "BARREL" CORTEX IMAGED WITH OPTICAL RECORDING. M.C. Crair*, Z. Molnar**, S. Higashi, T. Kuratani and K. Toyama. Dept. of Physiol., Kyoto Pref. Univ. of Med., Kyoto 602 Japan and ** Univ. Lab. of Physiol., Oxford, OX1 3PT, UK.

The somatosensory (SI) cortex of rodents contains an easily identifiable functional and cytoarchitectural somatotopic map of the sensory periphery. In particular, the so called "barrels" are a classic example of a functional cortical column. This makes SI an ideal area for studying the development of laminar specific (radial) and area specific (tangential) functional connectivity patterns. We have used a new high spatial (128 X 128 pixels) and temporal (0.6 msec) resolution optical recording apparatus in conjunction with conventional electrophysiological techniques on an in-vitro thalamo-cortical slice preparation (Agmon and Connors, 1991) to study the development of barrel columns. This new device, used with a voltage sensitive dye (RH482), allows us to image the spatio-temporal pattern of signal propagation from the thalamus to SI and within SI in response to stimulation of the thalamus (VB). In newborn rats (P0-P2) the response of SI, as reflected in the optical signal and current source density analysis, has a long initial latency, slow time course, and is radially and tangentially broad. In slightly older animals (P3-P5), as layer IV neurons differentiate from the cortical plate and cytoarchitectural barrels are formed, the response is quicker and grows more patchy, presumably representing excitation of individual barrels. This barrel related response becomes more well defined as the supragranular layer matures (P6-P9), and the initial thalamocortical response in layer IV barrel hollows propagates to layer II/III and to inter-barrel regions in a column specific pattern. By the end of the second postnatal week (P10-P14), a relatively mature excitation-propagation pattern exists. In summary, we have been able to image the response of discrete barrel columns in rat SI cortex to stimulation of the VB, and study the temporal and spatial development of thalamocortical and intracortical connectivity in an in-vitro slice preparation.

PARALLEL PROCESSING OF TACTUAL INFORMATION IN THE POSTCENTRAL GYRUS OF RHESUS MONKEYS. I. Danielsson*, J. Hahm and T.P. Pons. Lab Neuropsychology, NIMH, Bethesda, MD 20892.

In Old World monkeys, including macaques, primary somatosensory cortex is comprised of four cytoarchitecturally distinct areas, 3a, 3b, 1 and 2. Each of these areas is known to receive direct inputs from the thalamic ventroposterior nuclear complex. A recent study in Marmosets (a New World monkey), however, demonstrated that cutaneous activation of area 1 was dependent upon inputs from areas 3a and 3b, rather than on a direct projection from the thalamus (Garraghty et al. 91, JCN). In the present experiment we determined whether direct inputs from the thalamus were sufficient to drive cutaneous responses in areas 1 and 2 of macaques in the absence of areas 3a and 3b.

In 4 monkeys ablations of the area 3a and 3b hand representations were made immediately prior to electrophysiological mapping of the spared hand representations in areas 1 and 2. In each case it was possible to record neuronal responses to cutaneous stimulation at numerous sites across areas 1 and 2, though a slight reduction in cutaneous inputs was noted. In an additional case we removed the hand representation in areas 3a, 3b and 1 and mapped in area 2. Again we found cutaneous activation of sites across the entire area 2 hand representation with no increase in the ratio of "deep" to cutaneous recording sites. We conclude that direct thalamic projections to areas 1 and 2 are sufficient to provide cutaneous input to these regions in macaques and that there may be fundamental differences in cortical processing of tactual information in New and Old world monkeys.

POLYSENSORY EVOKED POTENTIALS IN RAT PARIETO-TEMPORAL CORTEX: COMBINED AUDITORY AND SOMATOSENSORY RESPONSES D. S. Barth*, B. Brett and S. Di. Department of Psychology, University of Colorado, Boulder, CO 80309-0345 (U.S.A).

In a previous report from our laboratory, separate vibrissal and auditory click stimulation produced epicortical potentials centered on the granular areas of primary auditory (AI) and somatosensory (SI) cortex in the rat. However, it was noted that the auditory (AEP) and somatosensory (SEP) evoked potentials also overlapped in a region of dysgranular cortex separating these areas, suggesting a polysensory cortical site.

The present experiment was concerned with mapping epicortical potentials in this presumed polysensory cortex, evoked by combined somatosensory and auditory stimulation (ASEP). While recording from an 8x8 microelectrode array covering a 3.5 x 3.5 mm² area, the AEP, SEP and ASEP were mapped, and their areal patterns compared to cytochrome oxidase stained tangential sections of layer IV. Horse radish peroxidase (HRP) was then injected into SI, AI, or the polysensory region to trace thalamocortical projections.

Our results demonstrate a consistent response in dysgranular cortex separating AI and SI during the ASEP, that is not modeled by a simple sum of the AEP and SEP waveforms. While HRP injections into AI and SI stain the lateral divisions of the medial geniculate and ventrobasal thalamic nuclei, injections into the polysensory zone stain a more medial region at the juncture between the posterior nuclei and the medial division of the medial geniculate, suggesting that polysensory integration may occur at both the cortical and subcortical level.

STRUCTURE-FUNCTION RELATIONSHIPS EXAMINED IN RAT BARREL CORTEX USING INTRINSIC SIGNAL OPTICAL IMAGING THROUGH THE SKULL. S. A. Masino*, M. C. Kwon, Y. Dory, R. D. Frostig. Department of Psychobiology, U.C. Irvine, Irvine, CA 92717.

We used intrinsic signal optical imaging through a thinned skull to study the functional representations of the mystacial vibrissae (whiskers) in rat barrel cortex. Each whisker has a cytoarchitecturally distinct representation in cortical layer IV (Woolsey, T. A., and Van der Loos, H. 1970. *Br. Res.*, 17: 205-242), as well as a functional column spanning from the pial surface to the white matter (Welker, C. 1976. *J. Comp. Neur.*, 166: 173-190). This columnar arrangement combined with the unique cytoarchitecture provides an opportunity to investigate the relationship between structure and function within a discrete cortical representation.

We stimulated individual whiskers continuously for two seconds at theta rhythm (5Hz). In response to the stimulation of any whisker we obtained a discrete area of activity in the cortex. We verified that this activated area determined by optical imaging corresponds precisely with the response area of single units in the cortex to that whisker. Lesions placed in the center of the optical activity within cortical layer IV always corresponded with the center of the anatomical representation of that whisker within layer IV as determined by cytochrome oxidase staining.

In addition, we stimulated a 3 x 3 matrix of nine neighboring whiskers to obtain a map of their functional representations in barrel cortex. We compared this optically-determined functional map with the anatomical map of cytochrome oxidase staining of the same nine whiskers and found that the distances between the centers of the whiskers on the optical map versus the anatomical map were highly correlated (r=.99). The striking correspondence between imaging, physiology, and anatomy found in this study makes this system ideal to investigate the ongoing dynamic relationship between structure and function in the neocortex.

702.8

THE ORGANIZATION OF LATERAL SOMATOSENSORY CORTEX IN THE MACAQUE MONKEY: WHERE IS SII? L. Krubitzer*, I. Clarey, R. Tweeddale, G. Elston, and M. Calford. Vision, Touch and Hearing Research Centre, University of Queensland, Australia, 4072

The organization of somatosensory cortex lateral to SI was investigated in three macaque monkeys (*Macaca fascicularis*) using multiunit mapping procedures. Over 2,300 recording sites were obtained, and reconstruction of receptive fields, neural response properties, and stimulus preference of neurons allowed us to reconstruct comprehensive maps of this region of cortex. Cortex was flattened, cut parallel to the cortical surface and stained for myelin, and myeloarchitecture was related to electrophysiological mapping results. We found clear evidence for at least two complete representations of the body surface in the region of cortex traditionally designated as SII. We termed these fields SII and the parietal ventral area, PV, because their overall organization, relative position, and architectonic appearance were similar to SII and PV as described in other mammals. Evidence for two additional fields was also obtained. One field caudal to SII we termed 7b, because its location and architectonic appearance were similar to 7b described previously in macaque monkeys. The other field was ventral to SII and PV, and we termed this the ventral somatosensory area, VS, because the topography and relative position were similar to VS described in owl monkeys and flying foxes. Since a number of fields were demonstrated in the region of cortex traditionally defined as SII, it is logical to ask which field we should term SII. By comparing our results in the macaque monkey with those in other mammals, a clearer picture of which field is "SII" has begun to emerge. This question has important implications for the interpretation of reorganization plasticity reported in "SII" following cortical or peripheral lesions.

COMPARISON OF NEURONAL ACTIVITY IN THE PRIMARY SOMATOSENSORY CORTEX (SI) DURING ACTIVE AND PASSIVE TACTILE TEXTURE DISCRIMINATION. F. Tremblay* and C.E. Chapman. CRSN, Univ. Montréal, Canada, H3C 3J7.

While there is ample evidence from psychophysical studies that the ability to discriminate suprathreshold tactile stimuli is not affected by movement, electrophysiological experiments have clearly established that the transmission of cutaneous inputs to the SI cortex is decreased during movement, including exploratory movements (Chapman and Ageranoti, 1991). In the present study, we addressed this issue by looking at the influence of movement on 1) the ability of SI neurones to encode graded changes in surface texture and 2) the ability of monkeys to discriminate such changes in texture. Neuronal activity and performance measured during active scanning of textured surfaces (monkey scans surface with its digit tips) were compared with similar measures made during passive exploration of the same surfaces (surface displaced under digit tips). In both modes of touch, the monkey had been trained to discriminate, after a single scan, a standard surface (raised dots, 2 mm spatial period (SP) over the entire length) from 3 other surfaces in which, over the second half, SP was proportionally increased (3, 4 or 5 mm SP). In each task, the monkey indicated the presence or absence of a change in surface texture by pushing (no difference) or pulling (difference) a lever with the opposite hand. A preliminary analysis performed on a sample of 70 units with cutaneous fields on the digit tips contacting the surface, indicated that 23% of cells were texture-related (mean firing rate related with SP). Of these, the majority signalled the differences in texture during passive touch (9/16) but not during active touch. Only a few cells were texture-related in both tasks (n=4). In parallel with the unit data, analysis of the monkey's task performance indicated that it was actually better during passive, than during active, touch. The monkey made significantly fewer errors (p < 0.05) in discriminating the surface with the smallest increase in SP (3mm) during passive, as compared to active, touch (respectively, 5 and 23 % error rate). Thus, these preliminary results suggest that the gating influences associated with movement may interfere with the ability of SI neurones to signal differences in texture as well as with the ability to discriminate small differences in surface texture. DISCRIMINATION OF THE DIRECTION OF MOTION ON THE HUMAN HAND. *E.P. Gardner* and B.F. Sklar*. Dept. of Physiology and Biophysics, NYU Medical Center, New York, NY 10016

We evoke sensations of apparent motion across the skin by pulsing sequential rows on the OPTACON with independent control of spacing and timing. We previously showed that the ability of humans to discriminate direction of motion depends mainly on spatial properties. A 3-factor repeated measures ANOVA confirms that distance and spacing significantly affect discriminability d' ($P=0.0001$), yielding an increase of $0.2 d'$ /mm path length and a drop of $1.04 d'$ /row spacing. Pulse rate has a much weaker effect ($P=0.011$) characterized by higher d' at 50 Hz than at 25 or 100 Hz. The effect of spacing is not linked to stimulus proximity on the skin, but to the total number of pulses in a sweep. Greater accuracy related to path length results from increased information transmitted centrally, rather than the wider separation between start and stop points. Randomly varying the total pulses presented and their spacing confirms a linear relation between number of pulses and d' with slope=0.84 ($P=0.0001$). Total pulses account for 89% of stimulus-linked variance, while pulse spacing contributes only 5.6% of variance ($P=0.012$), and is optimal at 2.4 mm. Stimuli to two points are insufficient for accurate discrimination regardless of whether they activate overlapping or distinct populations of cutaneous afferents. Threshold discrimination occurs with three pulses; d' is only slightly lower when the stimulated fields overlap than when they are distinct. Accuracy greater than 90% requires at least 5 pulses, which shift the activated population beyond its original boundaries to a completely new group of afferents. (Supported by NIH: NS11862).

PHANTOM BREAST AS PERCEPTUAL CORRELATE OF NEUROPLASTICITY IN ADULT HUMAN BRAIN. S. Aglioti, F. Cortese, C. Franchini, S. Zamboni. Inst. of Hum. Physiology and SRRF, I-37134, Verona (SPON: European Neuroscience Association).

Upper limb amputees report sensations in the phantom limb upon tactile stimulation of other cutaneous regions (Ramachandran et al., NeuroReport, 3, 583-6, 1992). These regions (called 'reference fields') were mainly clustered on the lower face, ipsilateral to the amputation. Since hand and face are represented on contiguous zones in the somatosensory cortex, reference fields could indicate that deprived cortical and/or subcortical zones were invaded by contiguous cerebral zones. According to this interpretation, reference fields would suggest neural rearrangements on an amazing large scale in the adult human brain. Data have now been obtained from breast amputees supporting and extending this 'heretic' hypothesis. We provided evidence for such reference fields in 32.5% of an unselected population of 40 females who had undergone breast amputation for cancer treatment. Far from being randomly distributed, reference fields were located on cutaneous regions which were represented on zones of the somatosensory cortex contiguous to the zone where the amputated breast is presumably mapped. The present study reports perceptual indices of reorganization in the somatosensory system, even after breast amputation that causes only limited areas of deprivation, in comparison to limb amputation. Therefore, our data suggest that neuroplasticity in the adult human brain is potentially much higher than previously suspected, thus offering new opportunities in the field of rehabilitation.

702.12

REORGANIZATION OF SOMATOSENSORY CORTEX, AND CHANGES IN THE PERIPHERAL NERVE INNERVATION PATTERNS IN SPINAL CORD AND BRAIN STEM AFTER AMPUTATION OF THE HAND IN MONKEYS. S.L. Florence*, N.Jain, P.D. Beck, J.H. Kaas. Dept. of Psychology, Vanderbilt Univ., Nashville, TN.

To investigate plasticity mechanisms underlying cortical changes produced by long-term sensory deprivation, we mapped primary somatosensory cortex and labeled peripheral nerve inputs to the spinal cord and brain stem of 2 owl monkeys (*Aotus trivirgatus*) and 1 macaque monkey (*Macaca mulatta*) with long-standing amputations. Amputation of the hand (macaque and 1 owl monkey) or forearm (1 owl monkey) all resulted from medical treatment of injuries rather than experimental protocol. Microelectrode mapping of area 3b in the owl monkeys revealed that most of the presumptive hand representation was activated by cutaneous stimulation of the arm, forearm, and face. In the macaque, cortex normally activated by the distal digits was largely silent. However much of the region where the palm is typically represented (along the 3b/1 border) contained a new, precise representation of the forearm. Additionally, the representation of the face appeared to be somewhat enlarged. Multiple injections of HRP conjugated cholera toxin in the skin of the forearm (macaque) or arm (1 owl monkey) proximal to the amputation resulted in much more extensive labeling in both the dorsal horn of the spinal cord and the cuneate nucleus of the brain stem than matched injections in the intact arms. Based on the normal topography of inputs to these structures, the changes in the labeled peripheral nerve input patterns was coincident with the somatotopic reorganizations of area 3b. For example, in the macaque, label from the forearm which is normally lateral-most in the dorsal horn and dorsal-most in the cuneate extended medially in the spinal cord and ventrally in the cuneate nucleus where inputs from the palm normally are situated. The label did not encroach upon the regions where the distal digits are represented. Thus, somatotopic changes seen in area 3b may reflect sprouting or an increased density of previously sparse peripheral nerve inputs. Supported by NS16446 & NICHDHD15052

LONG-TERM POTENTIATION VIII

703.1

POSTSYNAPTIC EXPRESSION OF CONSTITUTIVELY ACTIVE CaMKII OCCLUDES LTP IN THE HIPPOCAMPAL SLICE. D.L. Pettit*, S. Perlman & R. Malinow. Neuroscience Program, and Pediatrics Department and Physiology & Biophysics Department, University of Iowa.

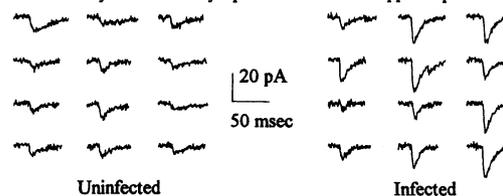

Long-term potentiation (LTP) can be prevented by postsynaptic block of calcium/calmodulin-dependent protein kinase II (CaMKII). Does increasing CaMKII activity mimic and thereby occlude LTP? To test this we have generated a recombinant vaccinia virus that produces the constitutively active CaMKII(1-290) driven by a strong early/late vaccinia promoter. A luciferase expression assay in cultured cells confirms expression of a functionally active CaMKII enzyme.

To determine the effect of increased postsynaptic CaMKII activity on LTP, we have infected CA1 pyramidal neurons in hippocampal slices. Synaptic transmission onto CA1 neurons in infected regions was elicited by stimulating electrodes placed in the stratum radiatum and recorded with whole-cell voltage clamp. After monitoring baseline transmission, LTP was attempted by pairing stimulation with postsynaptic depolarization. At depolarized potentials slow synaptic currents, indicating NMDA-receptor mediated transmission, were present in all cells. Following this pairing protocol, transmission was 101% of baseline at 5 min. ($n=10$) and 99% of baseline at 30 min. ($n=6$). LTP was observed in only 1 of 10 cells. Parallel experiments with a virus that expresses β -galactosidase showed levels of potentiation comparable to uninfected slices. These results, in conjunction with the following abstract (Shirke, et al), support the view that increased postsynaptic CaMKII activity is sufficient to mimic and occlude LTP.

703.2

MINIATURE EPSC SIZE INCREASES WITH POSTSYNAPTIC EXPRESSION OF CONSTITUTIVELY ACTIVE CaMKII. A.M. Shirke*, D.L. Pettit, S. Perlman & R. Malinow. Dept. of Physiology & Biophysics, Neuroscience Pgm., & Dept. of Pediatrics, U. of Iowa, Iowa City.

To study the effect of postsynaptic CaMKII activity on synaptic transmission, we have generated a recombinant vaccinia virus that produces constitutively active CaMKII (1-290). If CaMKII activation is sufficient to increase postsynaptic responsiveness, as suggested by recent experiments showing CaMKII-mediated regulation of kainate-elicited ion currents (Nature, 362: 640-642), then the size of miniature epsc's should be greater in cells expressing constitutive CaMKII than in uninfected cells. We measured miniature epsc's from CA1 pyramidal cells in infected and uninfected regions of a hippocampal slice. Initial results show that the mean size of miniature epsc's is larger in infected regions (11.4 ± 6.9 pA, $N=4$, compared to 8.5 ± 3.8 pA, $N=5$; $p < 0.05$). The figure shows representative miniature epsc's recorded from infected and uninfected regions of the same hippocampal slice elicited by focal application of 500 mOsm sucrose, in the presence of 1 μ M tetrodotoxin and 100 μ M picrotoxin. These results support the view that postsynaptic CaMKII activity can enhance synaptic transmission in hippocampal slices.

703.3

MECHANISM OF PROTEIN KINASE C ACTIVATION DURING INDUCTION AND MAINTENANCE OF LTP. E. Klann*, S.-J. Chen and J.D. Sweatt, Division of Neuroscience, Baylor College of Medicine, Houston, Texas, 77030.

We have previously described a persistent increase in basal (Ca^{2+} and cofactor-independent) PKC activity in the maintenance phase of LTP. Additionally, we have observed an increase in both basal and total (Ca^{2+} and cofactor-dependent) PKC activity in the induction phase of LTP. These data suggested the possibility of different mechanisms of PKC activation associated with LTP. To investigate the biochemical mechanisms underlying these phenomena, LTP of the Schaffer collateral input into area CA1 of rat hippocampal slices was studied. Slices were frozen, dissected, and homogenized either 2 min (induction) or 45 min (maintenance) after the final tetanic stimulation. Western blots for PKC with control and LTP homogenates at the 45 min time point indicated an LTP-associated decrease in PKC immunoreactivity ($69 \pm 5\%$ of control, $n=21$). Bath-applied AP5 ($50 \mu M$) inhibited the decrease in PKC immunoreactivity ($92 \pm 8\%$ of control, $n=4$). These results suggest that the maintenance of LTP is associated with a persistent modification of PKC and that NMDA receptor activation is necessary for this modification. Incubation of control and LTP homogenates with phosphatase could reverse the LTP-associated decrease in PKC immunoreactivity. A 45-min incubation resulted in a 33% reversal (minus phosphatase, $52 \pm 6\%$ of control; plus phosphatase, $68 \pm 4\%$ of control, $n=5$) and a 90-min incubation resulted in a 64% reversal (minus phosphatase, $56 \pm 5\%$ of control; plus phosphatase, $84 \pm 5\%$ of control, $n=7$). These data are consistent with a persistent increase in PKC phosphorylation and suggest this as a mechanism for the persistent PKC activation observed in the maintenance of LTP. Additional experiments indicated that the induction phase of LTP was associated with an increase in both basal and total PKC activity. This is consistent with previous reports indicating the necessity of PKC activity during LTP induction and suggest that the mechanism of PKC activation in LTP induction is distinct from that in LTP maintenance. Supported by a NIH NRSA (E.K.) and the McKnight and Klingenstein Foundations and NIH MH 48186(J.D.S.).

703.5

MAINTENANCE OF LTP IS ASSOCIATED WITH AN INCREASE IN THE PHOSPHORYLATION OF RC3/NEUROGRANIN PROTEIN. S.-J. Chen*, E. Klann, and J.D. Sweatt, Division of Neuroscience, Baylor College of Medicine, Houston, TX 77030.

We have previously observed that NMDA-receptor dependent long-term potentiation (LTP) in hippocampal area CA1 is associated with an increase in the phosphorylation of an endogenous protein, P17, using a post-hoc phosphorylation assay. The phosphorylation of P17 in vitro was greatly enhanced by the addition of calcium and lipid cofactors and was sensitive to inhibition by PKC $_{(19-36)}$, indicating that P17 is an endogenous PKC substrate protein. Two-dimensional gel analysis revealed a pI of ~ 5.5 for P17, similar to that of postsynaptic calmodulin-binding protein, RC3/neurogranin. In this abstract, we present direct evidence that P17 is identical to RC3. First, phosphorylation of P17 is attenuated by the addition of calmodulin. Second, phosphorylated P17 remained soluble in 2.5% perchloric acid. Third, an anti-RC3 antibody recognized a 17 kDa protein in hippocampal homogenates which comigrated with phosphorylated P17 and phosphorylated P17 can be immunoprecipitated with an anti-RC3 antibody. In addition, back-phosphorylation experiments were carried out to determine the *in situ* phosphorylation state of RC3 protein in the maintenance of LTP. Hippocampal homogenates were prepared from control and LTP slices 45-60 minutes after the high frequency stimulation. Samples were heat-inactivated and used as substrates for purified PKC. We observed a decrease in the back-phosphorylation of RC3 protein in homogenates from LTP samples ($n=8$). The immunoreactivity with anti-RC3 antibody showed no difference in the amount of RC3 protein between control and LTP samples. These results indicate that the maintenance phase of LTP is associated with an increase in the phosphorylation of RC3 protein *in situ*. As RC3 protein has been shown to be localized postsynaptically, our results are biochemical evidence for postsynaptic modifications in LTP. (Supported by McKnight and Klingenstein Foundations)

703.7

A NOVEL, HIGH-MOLECULAR WEIGHT PROTEIN RELATED TO PKC ζ INCREASES DURING MAINTENANCE OF CA1-LTP. E. Sublette*, P. Osten, H. Valsamis, T.C. Sacktor Dept. of Pharmacology and Neurology, SUNY-Health Sci. Ctr. Brooklyn, NY 11203.

We report the detection of higher molecular weight proteins related to the PKC ζ isoform, in rat hippocampus. On immunoblot, our antiserum against the carboxy-terminal region of PKC ζ recognizes the native isozyme (70 kD), PKM ζ (51 kD) and several higher molecular weight bands, all of which are blocked by pre-incubation of the antiserum with immunizing peptide. The most prominent of these proteins, 160 kD, is found under a variety of homogenization conditions, and by peptide mapping appears closely related structurally to PKC and PKM ζ . In CA1 of rat hippocampal slices, the 160 kD protein increases 30 min after tetanization ($27.4\% \pm 9.5$, SEM, $p < 0.05$). Like PKM ζ , which increases during LTP maintenance (see P. Osten *et al.*, these abstracts), this high-molecular weight form of ζ may also be involved in regulation of constitutive phosphotransferase activity in neurons, following synaptic activation.

703.4

ACTIVATION OF PROTEIN KINASE C IN NMDA RECEPTOR-INDEPENDENT LTP: TIME COURSE AND MECHANISM

C. M. Powell*, D. Johnston, & J. D. Sweatt, Division of Neuroscience, Baylor College of Medicine, Houston, TX 77030

We reported previously that a persistent increase in basal protein kinase C (PKC) activity is associated with the maintenance phase of NMDA-receptor-independent LTP (NMDA-R-*indep* LTP) induced by application of tetraethylammonium (TEA; LTP $_{\kappa}$). This increase in PKC activity was measured 45 min after TEA washout in area CA1 of hippocampal slices. To test whether this increase in PKC activity is specific to potentiated slices, we blocked LTP $_{\kappa}$ with the Ca^{2+} channel antagonist nifedipine. Blocking LTP $_{\kappa}$ with nifedipine prevented the increase in PKC activity after TEA washout. Low frequency stimulation alone did not alter PKC activity. If this increased PKC activity is involved in LTP maintenance, then the increase in PKC activity should persist as long as LTP is maintained. To test this we induced LTP $_{\kappa}$ and monitored potentiation for 3 hours after TEA washout. Three hours into the maintenance phase of NMDA-R-*indep* LTP, PKC activity was increased in potentiated slices. Thus the time course of the increase in basal PKC activity is consistent with the hypothesis that this increase is involved in LTP $_{\kappa}$ maintenance.

Preliminary western blot analysis suggests that proteolytic activation contributes to the persistent activation of PKC in NMDA-R-*indep* LTP. Persistent activation of PKC has been reported for NMDA-R-*dep* LTP in area CA1 of the hippocampus (Klann *et al.*, JBC 266; 24253-6) and this increase is thought to be mediated by phosphorylation of PKC (Klann *et al.*, PNAS, submitted). When compared to these studies of NMDA-R-*dep* LTP, the present studies suggest that these two forms of LTP achieve a common biochemical end via two distinct pathways. (supported by MH10338-02, MH44754, McKnight and Klingenstein Foundations).

703.6

PKM ζ , A CONSTITUTIVELY ACTIVE KINASE INCREASING IN THE MAINTENANCE OF CA1-LTP, IS SPECIFIC TO BRAIN. P. Osten*, H. Valsamis, E. Sublette, T.C. Sacktor Dept. of Pharmacology and Neurology, SUNY-Health Sci. Ctr. Brooklyn, NY 11203.

We have previously demonstrated that PKM ζ , the free catalytic domain of PKC ζ , increases in the maintenance phase of LTP in CA1. We now find that the increase in PKM ζ requires NMDA-receptor activation. The increase in PKM ζ can be demonstrated in rat hippocampal slices homogenized and fractionated into cytosol and pellet or in slices immediately boiled in SDS, indicating that *in vitro* proteolysis is unlikely to be generating the PKM form. Immunoprecipitation demonstrates that PKM ζ is the major *in vitro* autophosphorylating protein in homogenates of hippocampus. Analysis of the tissue distribution shows that while PKC ζ is ubiquitous (see M. Naik *et al.*, these abstracts), the PKM form is found in all regions of the brain tested, but not in non-neuronal tissues. These results suggest that PKM ζ may participate in long-term modifications of neuronal activity, both in hippocampus and in other neural structures.

703.8

DEFICIENCY OF HIPPOCAMPAL LONG-TERM POTENTIATION IN PKC- γ MUTANT MICE IS COMPARABLE TO THE EFFECT OF NMDA RECEPTOR ANTAGONIST. C.Chen*, A. Abeliovich, Y. Goda, C.F. Stevens and S. Tonegawa Howard Hughes Med. Inst., MIT, Cambridge, MA 02139 and Salk Institute, La Jolla, CA.

Activation of PKC is necessary for induction of hippocampal LTP (Malenka *et al.*, 1986; Malinow *et al.*, 1989). In mutant mice which lack the γ isoform of PKC, LTP in CA1 synapses is found deficient, while excitatory synaptic transmission seems to be normal (Abeliovich *et al.*, this volume). We tested with field potential and whole cell patch recording techniques whether this deficiency in mutant mice is similar to the effect of NMDA receptor antagonists. We found that the accumulative probability of long-term synaptic changes after the tetanus in the mutant mice (normal saline) is not significantly different from wild-type mice in the presence of APV, a specific NMDA receptor antagonist. In addition, approximately 10-20% of mutant slices did exhibit LTP after the tetanus, and this residual LTP could not be prevented by APV. Therefore, the deficiency of LTP in the mutant mice is comparable to the effect of NMDA receptor blockage.

We also found that these mutant mice have deficiencies in such cerebellum-dependent motor behaviors as climbing an inclined plank and hind leg reflex. We will examine synaptic transmission and plasticity in the cerebellum.

703.9

CYCLIC-AMP-MEDIATED ENHANCEMENT AND LTP AT MOSSY FIBER SYNAPSES IN THE HIPPOCAMPUS.

M. G. Weisskopf, R. A. Zalutsky and R. A. Nicoll Depts. Pharmacol. and Physiol., UCSF, San Francisco, CA 94143-0450.

In the hippocampal slice preparation it has been shown that forskolin, an activator of adenylyl cyclase, causes an enhancement of evoked responses at the mossy fiber-CA3 synapse (Hopkins and Johnston, J. Neurophysiol., 59:667, 1988). We have used field potential recordings from guinea pig hippocampal slices to investigate further this action. This enhancement, which averages 4-fold, is specific for mossy fiber-CA3 synapses as it is not seen in responses evoked by associational/commissural afferents in the same experiment. The effect is not mimicked by the inactive isomer 1,9-dideoxyforskolin, while Sp-cAMPS, a membrane permeable activator of cAMP dependent protein kinase, does produce enhancement. Both of these observations support the role of cAMP in the enhancement. This effect is likely to result, at least in part, from a presynaptic action, since it is associated with a decrease in paired-pulse facilitation and responses to iontophoretically applied glutamate are unaltered during the enhancement of the evoked mossy fiber response.

The similarity between the effects of forskolin and previously reported aspects of long-term potentiation (LTP) at mossy fiber-CA3 synapses suggested that the two mechanisms might share a common step. Therefore, the effect of forskolin was examined both before and after an LTP-inducing tetanus, and vice-versa. The forskolin-induced enhancement was reduced at synapses that had previously undergone LTP, and LTP was reduced at synapses exposed to forskolin.

Our data suggests that cAMP-mediated enhancement and LTP at mossy fiber synapses share a common step.

703.11

NITRIC OXIDE SYNTHASE INDEPENDENT LTP IN AREA CA1 OF HIPPOCAMPUS. J. David Sweatt*, Dane Chetkovich, and Eric Klann.

Division of Neuroscience, Baylor College of Medicine, Houston, TX 77030.

While the induction of LTP is dependent upon biochemical events in the postsynaptic neuron, recent evidence implicates the involvement of the presynaptic neuron in the maintenance of LTP. This implies the necessity of a retrograde messenger to carry a signal from the postsynaptic to the presynaptic neuron. The labile, membrane-permeant compound nitric oxide (NO) has been proposed to perform such a retrograde messenger function. We have previously observed that LTP-inducing stimuli elicit an increase in the activity of guanylyl cyclase, an effect blocked by inhibitors of NO synthase. We have chosen to capitalize on these data, which document the effectiveness of NO synthase inhibitors in this system, to determine if the activity of NO synthase is necessary for LTP induction under our conditions. When Schaffer collateral inputs into area CA1 were tetanized at a stimulus intensity that gave about one-half the maximal postsynaptic response (measured using extracellular field recordings, bath temp. 32 deg C), LTP was produced in 12/13 slices. Addition of the NO synthase inhibitor nitro-arginine (NO-Arg, 50 μ M) decreased the probability of LTP induction (7/13 slices) and decreased the magnitude of LTP (148 \pm 8% LTP in control slices, 114 \pm 4% LTP in NO-Arg treated slices). When tetanic stimuli were delivered under conditions eliciting the maximal EPSP, more robust LTP was observed (177 \pm 8% LTP, n=6) and no significant effect of NO-Arg was observed on the magnitude or probability of induction of LTP. These data suggest a modulatory role for NO in LTP induced using low-intensity tetanic stimulation, but demonstrate that the activity of NO synthase is not necessary for LTP induction under all conditions. (Supported by the McKnight and Klingenstein Foundations.)

703.10

CYCLIC AMP-DEPENDENT PROTEIN KINASE IS ACTIVATED DURING THE INDUCTION OF LTP. Erik D. Roberson* and J. David Sweatt.

Division of Neuroscience, Baylor College of Medicine, Houston, TX 77030.

Although the activity of protein kinases is essential for the induction of LTP, the identity of the specific enzymes involved remains unclear. We have examined the possibility of a role for the cyclic AMP-dependent protein kinase (PKA) in long-term potentiation (LTP) in area CA1 of the hippocampus. Following the induction of LTP by 100 Hz stimulation, slices were frozen and the CA1 region was dissected and homogenized. PKA activity was determined *in vitro* using the synthetic PKA substrate Kemptide. All phosphorylation was blocked by a selective inhibitor of PKA (PKI₁₋₂₀, 10 μ M). Basal PKA activity (determined in the absence of added cyclic AMP) was increased 20% above control 2 min after LTP-inducing high-frequency stimulation ($p < 0.005$). No change in total PKA activity (determined with 10 μ M exogenous cyclic AMP) was detected, consistent with activation of PKA by dissociation of the catalytic subunit. The LTP-associated increase in PKA activity was completely blocked by the *N*-methyl-D-aspartate (NMDA) receptor antagonist DL-2-amino-5-phosphonovaleric acid at concentrations which blocked the induction of LTP (50 μ M). Activation of NMDA receptors also induced activation of PKA; NMDA led to a dose-dependent increase in PKA activity with an EC₅₀ of approximately 50 μ M. These results demonstrate that activation of PKA occurs during the induction of LTP, and that stimulation of NMDA receptors is both necessary and sufficient to produce the effect. In light of the fact that PKA can enhance current flux through kainate receptors, activation of PKA may lead to potentiation of synaptic efficacy during the early stages of LTP. (Supported by the Life and Health Insurance Medical Research Fund and the McKnight and Klingenstein Foundations.)

PHOSPHATASE INHIBITORS BLOCK THE DEPRESSION OF POTENTIATED SYNAPSES BY THETA-FREQUENCY STIMULATION. T.J. O'Dell* and E.R. Kandel, HHMI, Center for Neurobiology & Behavior, Columbia University College of Physicians & Surgeons, New York, NY 10032.

We investigated the modulation of excitatory synaptic transmission in the CA1 region of hippocampal slices by theta-frequency stimulation. Three minutes of 5 Hz stimulation produced a small (13.6 \pm 2.4% above control, $\bar{x} \pm$ SEM, n = 6), persistent (> 30 minutes) potentiation of synaptic transmission. However, 15 minutes after the induction of long-term potentiation (LTP), 3 minutes of 5 Hz stimulation depressed synaptic transmission (responses were 41.7 \pm 1.4% above control (n = 7) 1 hour after inducing LTP vs. 95.5 \pm 1.3% of control (n = 7) in control experiments. 5 Hz stimulation did not inhibit potentiated synaptic transmission if delivered in the presence of 50 μ M APV (N = 9) or if delivered more than 50 minutes after inducing LTP (n = 7). This suggests that theta-frequency stimulation acts via an NMDA receptor-dependent mechanism and interferes with early processes required for the induction and stabilization of LTP.

To determine whether protein phosphatases mediate the depression of potentiated synapses, we examined the effects of the phosphatase inhibitor okadaic acid (OA). 1.0 μ M (n = 8) but not 0.5 μ M OA (n = 4) completely prevented the inhibition of LTP by 5 Hz stimulation delivered 15 minutes post-tetanus, suggesting that NMDA receptor activation during 5 Hz stimulation can activate protein phosphatases which can interfere with protein kinase activity required for normal LTP.

GENESIS OF NEURONS AND GLIA IV

704.1

A NOVEL MECHANISM FOR NEUROGENESIS IN THE ADULT BRAIN.

M.-F. Cheng* and M. Zuo. Institute of Animal Behavior, Rutgers University, Newark, NJ 07102

In a study designed to examine the kinetics of glial responses to thalamic lesion, Altman (1962) observed that intracranial injection of ³[H]thymidine not only labeled glial cells but also labeled some neurons in the adult rat. We have reexamined this long forgotten observation, using adult ring dove, a species in which we have previously shown to exhibit low level neurogenesis dispersed within the telencephalon. Two experiments were conducted. The first experiment was designed to determine the rate and distribution of cell proliferation in the ventricular zone. One year old adult ring doves were treated with a single injection of ³[H]thymidine 24 hr after the unilateral or sham lesions in the avian visual thalamus (n. Rt.). The 2nd experiment was designed to determine lesion-induced neurogenesis. The doves received the same treatment as in the 1st experiment except that they received 7 consecutive injections of ³[H]thymidine 24 hr after unilateral electrolytic or sham lesions. Lesions promoted not only cell proliferation in the normally active ventricular zone but also induced proliferation activity in the 3rd ventricle that is normally quiescent in the intact birds. Evidence of neurogenesis is subjected to a series of critical tests for verification. Supported by Hoechst-Celanese Award.

704.2

GENERATION OF NEW CELLS IN THE VENTRICULAR ZONE DECLINES DURING DEVELOPMENT IN ZEBRA FINCHES. S.D. Brown*, S.W. Botter.

Biology Dept., Univ. of Southern California, Los Angeles CA 90089-2520.

Neurogenesis continues in the songbird telencephalon into adulthood. During song learning in juvenile zebra finches, larger numbers of newly-generated neurons are incorporated into brain regions controlling song than in adulthood, when song-learning is complete (Nordeen & Nordeen, 1988). We report that the proliferative activity of stem cells located in the ventricular zone of the lateral ventricles, the source of new neurons in the telencephalon, is extremely high at 20 days of age (the beginning of song learning) but declines dramatically by adulthood when song learning is complete. Male and female zebra finches aged 20 days to adult (> 100 days) received a single injection of [³H]-thymidine and were perfused 24 hours later. We chose a short survival time in order to measure proliferation rates per se before processes such as cell death or migration could intervene. The brains were embedded in paraffin or glycol methacrylate and processed as autoradiograms. The amount of labeling found over cells within the ventricular zone, an index of the total mitotic activity of cells within this region, was compared for each age group. The amount of thymidine labeling found within the ventricular zone of the youngest birds (20 days) far exceeded that of adults. The dramatic addition of new neurons to song-control regions during song learning may be due at least in part to an overall higher level of neurogenesis at young ages. This finding makes possible the investigation of naturally occurring down-regulation of cellular proliferation in a post-hatch, adult-sized animal model.

704.3

IN VITRO NEURONAL AND GLIAL PRODUCTION AND DIFFERENTIATION BY PRECURSOR CELLS DERIVED FROM THE ADULT HUMAN BRAIN. B. Kirschenbaum, M. Nedergaard, A. Preuss, K. Bahramian, S. A. Goldman. Dept. of Neurology & Neuroscience, Cornell Univ. Medical College, NY, 10021.

A variety of subprimate vertebrates have been found to harbor neural precursor cells in adulthood, which retain the potential for neuronal production *in vitro*. We sought to determine whether the human brain might retain such precursors, by culturing adult temporal lobe under conditions permissive for neuronal differentiation. Fresh surgical samples of human temporal cortex, subcortical white matter, and periventricular zone (VZ) were either explanted or dissociated into cell suspensions, to which ^3H -thymidine was added. The cultures were incubated for 7-28 days, fixed, immunostained for one of several neuronal or glial antigens, and autoradiographed. Neuron-like cells were found in both explant cultures and single cell dissociates of the VZ; these cells expressed neuronal antigens including MAP-2, MAP-5, NF and N-CAM, and were GFA+. Such cells were only rarely found in dissociates of subcortex or cortex, and were not observed in explant cultures lacking VZ. Cultures from each region were also loaded with the calcium-sensitive dye Fluo-3, and exposed to 60 mM K^+ during confocal microscopy, so as to detect depolarization-induced calcium increments. A subpopulation of neuron-like cells responded to K^+ depolarization with rapid and reversible increases in cytosolic calcium, which were substantially greater than those observed in co-cultured astrocytes. Among MAP-2 or MAP-5 VZ-derived neurons, a small number incorporated ^3H -thymidine, suggesting their origin from precursor cell mitosis *in vitro*. Most were unlabeled by ^3H -thymidine, and may have arisen from precursors induced to differentiate by the culture conditions. Thus, the adult human forebrain may harbor precursor cells which retain the potential for neuronal and glial production, once removed from their local environment. 704.5

ALZ-50-IMMUNOREACTIVE CELLS IN HUMAN FETAL CNS. L.A. Mattiace*, K.M. Weidenheim, W.D. Lyman, W.K. Rashbaum, P. Davies. Depts. of Pathology and Ob-Gyn, Albert Einstein College of Medicine, Bronx, NY 10461

Alz-50 immunolabeled cells have been reported in the subplate region of the human fetal cortex by 36 wks of gestation. The present study was designed to determine whether Alz-50-immunoreactive cells are present in normal human fetal CNS prior to 36 wks. Serial hemisections from 16 wk to 24 wk abortuses of HIV-seronegative females were examined immunocytochemically with antibodies developed to cytoskeletal proteins including Alz-50, AP14 (MAP-2) and NP-18 (neurofilament). Cresyl violet staining on separate sections was used for anatomical localization.

In preliminary data, clusters of intensely stained Alz-50-immunoreactive cells were found in a number of subcortical cell groups at 23 wks. These areas included the corpus striatum, hypothalamus, thalamus and amygdala. Morphologically, many of these cells were bipolar and/or multipolar, depending upon the subcortical area. Scattered Alz-50-immunoreactive cells were also found in the subplate region throughout the longitudinal extent of the cortex, but in smaller numbers than previously reported in the 36 wk fetus. Scattered and sparse, but often intensely stained, Alz-50-immunoreactive beaded processes were also seen throughout the cortical layers including the marginal zone.

Because Alz-50 has been suggested to be a marker for programmed cell death, the presence of Alz-50-immunoreactive cells suggests that certain subcortical cell groups are undergoing programmed cell death in the latter part of the second trimester in the human fetus. Given that programmed cell death occurs during neuronal differentiation and maturation, this may be additional evidence that certain subcortical cell groups undergo developmental changes prior to those seen in cortical regions.

704.7

PROLIFERATION AND SURVIVAL OF RAT SENSORY NEURON PRECURSORS IN VITRO. Stacey J. Piszczkiewicz* and Alison K. Hall. Dept. Neurosciences, Case Western Reserve University School of Medicine, Cleveland, OH 44106.

The processes that regulate the development of neurons from their precursors are essentially unknown. We have developed a tissue culture system in which precursors to E12 lumbar rat dorsal root ganglion (DRG) neurons divide and subsequently differentiate. Cells were initially undifferentiated and polygonal, and after two days, numerous bipolar neurons with long processes were detected. This time period corresponds well to sensory neuron differentiation *in vivo*. The effects of specific additives on neuron precursor division and neuronal survival were assayed. Dissociated E12 DRG were labeled with the thymidine analog, BrdU, and subsequently analyzed for the presence of neuron-specific tubulin and BrdU. NGF enhanced proliferation compared with control conditions containing rat serum. BDNF potentiated the effect of NGF compared with control. LIF alone enhanced proliferation and in combination with BDNF and NGF had an additive effect compared with control. Thus, specific factors enhanced division of sensory neuron precursors. The percentage of neurons that survived 48 hr was enhanced by BDNF, NGF and LIF relative to control values. However, the addition of all three factors did not increase neuronal survival compared with BDNF alone. The lineage relationships between the neurons and glial cells that mature in these cultures is under investigation. (BDNF supplied by Regeneron; Supported by Ohio Board of Regents and Basil O' Connor Starter Scholar Research Award 5-FY92-1178)

POSTNATAL DEVELOPMENT OF THE MAGNOCELLULAR HYPOTHALAMIC NEURONS IN THE BRAZILIAN OPOSSUM. J. Iqbal, J. K. Elmquist, L. R. Ross, M. R. Ackermann* and C. D. Jacobson*. Dept. of Veterinary Anatomy and Neuroscience Program, Iowa State University, Ames, IA 50011 and *National Animal Disease Center, Ames, IA 50010.

Our laboratory has been studying the ontogeny of neuropeptide systems in the Brazilian opossum, *Monodelphis domestica*. *Monodelphis* is a small, pouchless marsupial whose young are born in an extremely immature state with a protracted postnatal period of nervous system differentiation. Presently, we are studying the development of the hypothalamic paraventricular (PVN) and supraoptic (SON) nuclei in the developing opossum. We have utilized tritiated thymidine (^3H) autoradiography and 5-bromo-2-deoxyuridine (BrdU) immunohistochemistry to study hypothalamic neurogenesis. To this end, postnatal pups were given a subcutaneous injection on one of the days between postnatal (PN) days 1 & 13 and killed on PN 60. We have found that neurogenesis of these nuclei continues to take place postnatally. Analysis of the slides revealed a high proportion of BrdU or ^3H labeled neurons in the PVN area following injection on days 6 or 7 PN. Whereas only one third of the neurons were labeled in the SON area following injection on 4 or 5 PN. The number of labeled neurons appeared to decrease with increasing age of exposure. Injection on day 10 or 11 PN resulted in no labeling in the PVN and SON areas. We have also found that arginine vasopressin-like (AVP) immunoreactivity was present as early as 1 PN in the developing hypothalamic magnocellular neurons, whereas oxytocin-like (OT) immunoreactivity first appeared at 5 PN. The early appearance of AVP and OT immunoreactivity indicate that these peptides may be playing a role in the ongoing development of the brain. Since neurogenesis and peptide expression of the magnocellular neurons occurs during the postnatal period, we believe the opossum is an excellent model for developmental and physiological studies of the magnocellular system of the hypothalamus.

704.6

PROLIFERATIVE BEHAVIOR OF PROGENITORS IN THE GANGLIONIC EMINENCE OF MICE. P. G. Bhide* and T. Takahashi. Department of Neurology, Massachusetts General Hospital, Boston, MA 02129.

Ganglionic eminence is the embryonic source of cells destined for a variety of telencephalic structures including the neostriatum. The proliferative behavior of cells in this region was studied in mice during the interval embryonic day 11 (E11; first 24 h after conception = E0) to E16 using bromodeoxyuridine as the S-phase marker. Two proliferative populations, the pseudostratified ventricular epithelium (PVE, corresponding to the ventricular zone) and the secondary proliferative population (SPP, corresponding to the subventricular zone), were distinguished based upon the spatial distribution of cells in S-phase. PVE borders the ventricular cavity and SPP is located lateral to the PVE, away from the ventricular border. Nuclei of proliferating cells in the PVE display an oscillatory movement such that nuclei in M-phase are located along the ventricular border and those in S-phase are located away from the ventricular border in the "S-phase zone". Nuclei of proliferating cells in the SPP do not display such an oscillatory movement. PVE dominates the proliferative activity during the early part of cyto genesis - until E12-13. After that time, cell proliferation in PVE begins to decrease whereas that in SPP begins to increase. By E16, PVE is virtually completely replaced by SPP. Postmitotic cells - apparently of PVE origin - accumulate lateral to the PVE as early as on E11. Those cells may be among the earliest generated cells of the telencephalon and/or the precursors of SPP which are temporarily in a resting (Go) state. The PVE and SPP of the ganglionic eminence share several characteristics with their neocortical counterparts. A marked spatio-temporal gradient of cell proliferation was apparent when the overall duration of the cell cycle and the duration of the individual phases of the cell cycle were estimated separately for rostral, middle and caudal ganglionic eminence for each of E11 to E16.

NESTIN EXPRESSION IN HUMAN FETAL BRAIN IN VIVO AND IN VITRO. P.T. Cheung†, C. Spenger*, L. Hotav†, L. Studer, N. Herschkowitz† and B.W. Sailer. Dept. of Neurosurgery and Dept. of Pediatrics†, Inselspital, CH 3010 Bern, Switzerland.

Human neural cell cultures are potential sources of neural cells for transplantation. Nestin, an intermediate neurofilament expressed by neuroepithelial stem cells, has been used as a marker to identify cells capable of proliferating and differentiating into both neurons and glial cells in embryonic and adult mouse brain cell cultures (Reynolds et al., 1992). Nestin is also expressed in human fetal neural tissues.

To define specific human fetal brain region(s) suitable for providing neuroepithelial stem cells, the expression of nestin mRNA in various brain regions was examined by Northern hybridisation using a rat nestin cDNA probe generated by RT-PCR. Nestin mRNA was detected in rhombencephalons at all ages examined [5weeks+6days (w+d) post conception (p.c.) to 9w+6d p.c.; n=9] with a decline of signal intensity after 7-8 w. p.c. It was also found in cortices [7w+4d to 9w+6d p.c.; n=4] and in cerebellum [9w+6d p.c.; n=1]. Signals in spinal cords were lower than those of rhombencephalon and cortex from the corresponding embryos [7w+4d and 8w+6d; n=2].

Rhombencephalon was then chosen to be evaluated as an *in vitro* source of human neuroepithelial stem cells using a free floating micro culture system. In these cultures cell proliferation was demonstrated by incorporation of bromodeoxyuridine and tritiated thymidine, and mitotic figures seen in histologic sections for up to 3 weeks in culture. In addition, the continual presence of neuroepithelial stem cells was suggested by the detection of nestin mRNA by Northern hybridisation. Therefore, further investigations to determine whether progenitor cells actively proliferate in these cultures are warranted. Supported by SNF-Grants No 31-36243.92 and No 3-30909.91

SERUM-FREE DERIVED MOUSE EMBRYO CELLS EXPRESS NESTIN AND SELECT NEURONAL MARKERS: REGULATION BY SERUM. D.T. Loo*, M.C. Althoen and C.W. Cotman. Irvine Research Unit in Brain Aging and Dept. of Psychobiology, University of California, Irvine, CA 92717.

We previously reported the derivation of a serum-free mouse embryo (SFME) cell line from E17 embryos using a basal medium supplemented with insulin, transferrin, epidermal growth factor, high density lipoprotein and fibronectin (D. Loo et al., *Science* 236, 200 (1987)). SFME cells have been cultured for more than 200 generations without undergoing growth crisis, have retained a diploid karyotype and are nontumorigenic *in vivo*. SFME cells are dependent on epidermal growth factor for survival and are reversibly growth inhibited by serum. Additionally, cells with properties similar to SFME cells have been isolated from adult mouse brain. Initial experiments aimed at defining the cell type represented by SFME cells showed that treatment of SFME cells with serum or transforming growth factor beta induced the expression of glial fibrillary acidic protein, suggesting that SFME cells represent an astrocyte precursor cell.

To further define the phenotypic character and explore the differentiation potential of SFME cells we are using genetic and immunocytochemical approaches to assess the expression of neuronal- and glial-specific cell markers. We found that SFME cells express the gene encoding nestin, a neuroepithelial stem cell marker. Expression of nestin is down-regulated by serum. SFME cells also express the gene encoding neuron-specific microtubule associated protein 2 (MAP2), and are immunoreactive for MAP2, MAP5 and neurofilaments. This work suggests that SFME cells represent a neural precursor cell type which retains the capacity to express markers of both neuronal and glial cells.

704.11

NEURON-SPECIFIC CLASS III BETA-TUBULIN IS EXPRESSED BY DIVIDING NEURON PRECURSORS. Alison K. Hall*, Anthony Frankfurter# and Stacey J. Piszczkiewicz, Dept. Neuroscience, Case Western Reserve Univ. School of Medicine, Cleveland, OH 44106 and #Depts. Biology and Neuroscience, University of Virginia, Charlottesville, VA, 22908.

The differentiation of precursor cells into neurons is likely to involve specific molecular and morphological changes. The expression of class III neuron-specific beta tubulin, as detected by the monoclonal antibody, TuJ1, is initiated very early in neuronal maturation (Moody et al., 1989, *J. Comp. Neurol.* 279: 567-580; Easter et al., 1993, *J. Neurosci.* 13: 285-299). We have found that the E12 rat ventral lumbar spinal cord possessed TuJ1 immunoreactive cells that, in some cases, spanned the neuroepithelium. To investigate the expression of TuJ1 in neuron precursors, embryonic rat cultures were pulsed with the thymidine analog BrdU, and assayed by double label immunocytochemistry for their expression of BrdU and TuJ1. In cultures of E14 sympathetic ganglia and E12 lumbar dorsal root ganglia or spinal cord, numerous neurons bearing long neurites and TuJ1 expression incorporated BrdU during a 24 hr pulse. These data are consistent with a precursor incorporating BrdU during division, and the postmitotic neuron subsequently elaborating TuJ1+ processes. Intense TuJ1 expression was also detected in the spindle of mitotic cells, and in pairs of cells joined at cytokinesis, indicating that TuJ1 expression is initiated before the final mitosis of a neuronal progenitor. Therefore, class III tubulin expression may represent the earliest detectable molecular event in neuronal commitment exhibited by both CNS and PNS precursors. (Supported by Basil O'Connor Starter Scholar Research Award 5-FY92-1178 to AKH).

GENE TRANSFER IN A HIGH DENSITY NEURON-ENRICHED CULTURE FROM HUMAN FETAL BRAIN. F.-C. Chiu, C. Bassallo, W. Lyman, H.J. Federoff* Albert Einstein Coll. Med., Bronx, NY 10461.

To investigate the feasibility of gene transfer into human fetal neurons that might be suitable for transplantation, we have prepared high density cultures that are enriched in neurons and transduced them with defective herpes simplex viral (HSV) vector. Fetal brains at gestation week 20-24 were dissociated within 1-2 hrs of elective termination, resuspended in a growth medium containing 10% fetal calf serum and rapidly seeded at $0.5 \times 10^6/\text{cm}^2$ on culture plates and slides previously coated with laminin and poly-ornithine. Over 60% of plated neural cells survived. At 2 days *in vitro* (DIV), cytosine arabinoside (6 μM) was added. Within 3 DIV, the culture became confluent and consisted of small cells with phase-dark cell bodies that accounted for >85% of the total population and a dense network of fine processes. These small cells and fine processes were immuno-positive for the 66 kD neurofilament (NF-66) protein that is abundant in the human fetal brain but were immuno-negative for the astrocyte-specific glial fibrillary acidic protein (GFAP). Larger cells, representing <15% of the total population, had thick processes and were GFAP+. At 7-10 DIV, cultures were transduced with HSVlac, a vector containing the *E. Coli* β -galactosidase (Lac Z) gene under the control of the HSV IE 4/5 promoter. Robust expression of Lac Z as measured by X-gal histochemistry was found in both NF-66+ and GFAP+ cells. Our data demonstrate the feasibility of gene transduction into a neuron-enriched population of cells from human fetal brain and suggest the possibility of genetically modifying these cells prior to transplantation. CONNEXIN EXPRESSION IN EMBRYONAL CARCINOMA CELLS. D.J. Belliveau* and C.C.G. Naus. Department of Anatomy, The University of Western Ontario, London, Ontario, Canada, N6A 5C1.

The P19 embryonal carcinoma cell line represents an ideal model of early neural differentiation events. We have examined the expression of connexin genes in the neural cell derivatives of differentiated P19 cells in an attempt to better understand the role gap junctions play during CNS development. P19 cells were treated for 96 hr with retinoic acid (RA; 0.3 μM) causing them to differentiate into numerous cell types including neurons and astrocytes. Untreated P19 cells expressed abundant connexin43 (cx43) and to a lesser degree connexin26 (cx26) immunoreactivity for up to 12 days in culture. Results from polymerase chain reaction experiments on reverse transcribed mRNA revealed the presence of cx26, 32, 37, and 43 gene products, although in Northern blot analysis only cx26 and cx43 mRNA were detected. In RA treated cells, neurons were the first neural cell type to develop, noticeable within 24 hours, and were maintained for as long as 8 days in culture. In 5 day cultures, cx26 immunoreactivity could be seen on processes and cell bodies in some populations of neuron-like cells. Astrocytes (positive for glial fibrillary acidic protein [GFAP]) were first detected in small numbers after 7 days in culture and by 10 days, cx43 immunoreactivity was found to be associated with the astrocytes. Not all cx43 immunoreactivity was correlated with GFAP positive cells, much of it was found in other, yet unidentified, cells in the culture. These results show that the P19 embryonal carcinoma cells express multiple connexin genes and, therefore, will prove to be a valuable tool in examining the function of specific gap junction genes in differentiation of neural cells. Supported by the Medical Research Council of Canada and the Vice President (Research) Funds from The University of Western Ontario.

PROMOTER ACTIVITY OF GLIAL FIBRILLARY ACIDIC PROTEIN GENE IN EMBRYONIC BRAIN CELLS. K. Nakahira, K. Nakajima, N. Morita, K. Mikoshiba and K. Ikenaka*. Natl. Inst. Physiol. Sci., Myodaiji, Okazaki, 444 Japan.

We developed an assay system using retroviral vector for measuring promoter activity of neural tissue-specific gene in embryonic cells. The vector, pIP200, has a cloning site followed by bacterial beta-galactosidase gene (*lacZ*) as a reporter. Promoter region of glial fibrillary acidic protein (GFA) gene (2.5kbp; it is thought to be sufficient to confer astrocyte-specific expression) was inserted in this vector, and its activity was examined in primary cultured cells from embryonic day 13 (E13) murine brain hemispheres. Infected cells were sequentially fixed and stained with X-gal and anti-GFA antibody to identify cell type. Although there were few GFA immunoreactive cells in the culture of this stage, some X-gal positive cells were observed one day after infection. After 3 - 5 days *in vitro*, increasing number of GFA immunoreactive cells appeared, however, many of X-gal positive cells were GFA-negative. After 10 days *in vitro*, all of X-gal positive cells became GFA-positive. This result suggests that GFA promoter is activated several days before GFA becomes detectable immunohistochemically, and activation of the promoter is a potent early marker for investigating astrocyte differentiation.

IDENTIFIED NEURONS FROM EMBRYONIC LEECHES CULTURED WITH AND WITHOUT POTENTIAL TARGET TISSUES. C. Pfahler, W.B. Kristan, Jr., and K.A. French*. Dept. of Biology, UCSD, La Jolla, CA 92093-0322.

Retzius (Rz) neurons in *Hirudo medicinalis* acquire certain identifying characteristics - such as the production of the neurotransmitter serotonin - as a result of early events in their development. Other characteristics are acquired relatively late in development, after their processes have grown into the periphery. These properties depend upon whether or not embryonic reproductive ducts (located in mid-body segments 5 and 6 - MS 5 and MS6) are present in the segment; the properties include certain identified synaptic inputs and how the cell responds to acetylcholine (ACh) ejected onto the soma. Experimental manipulations in embryos have shown that the final phenotype of Rz neurons depends upon association between Rz processes and reproductive ducts and that Rz neurons may become committed during a relatively brief period of time very soon after Rz processes first contact the duct mesenchyme.

To study directly this interaction between embryonic Rz neurons and the reproductive ducts, we have begun to remove individual Rz neurons from *Hirudo* embryos and to culture them in the presence or absence of potential target tissues - reproductive ducts or muscles from the body wall of hatching leeches. These embryonic neurons survive at least 3 days in culture, which allows us to compare them with adult Rz neurons cultured under the same conditions, as well as with Rz neurons *in vivo*. We should now be able to determine whether interactions between processes of embryonic Rz neurons and reproductive duct muscle *in vitro* can modify Rz neuron development as they do *in vivo*. This research was supported by funding to CP from the Education Abroad Program and NIH research grant NS25916 to WBK.

RELATIONSHIPS BETWEEN NEUROMORPHOGENESIS & CYTOCHROME OXIDASE (CO) ACTIVITY IN RAT AUDITORY AND VISUAL CORTICES, HIPPOCAMPUS & CEREBELLUM AS DEMONSTRATED WITH METAL-INTENSIFIED CO HISTOCHEMISTRY. G.H. Kageyama* and R.T. Robertson. Department of Anatomy and Neurobiology, Univ. of California, Irvine, CA 92717.

The original CO histochemical method described by Wong-Riley (79) utilizes the catalytic oxidation of DAB as the chromagen in the presence of cytochrome c. At the light microscopic level, the reaction product is typically orange to orange-brown in color. Lighter orange stained sections often require the use of a dark blue (Wratten 47B) filter for optimal B/W photography. We have used two modifications: (1) 0.05 M Tris buffer, pH 7.6 and (2) the addition of nickel ammonium sulfate, to improve the contrast and shorten the time of the reaction without loss of specificity as determined by the EM localization of reaction product within the intracristate space and outer mitochondrial compartment. In auditory and visual cortices, elevated CO was localized in the apical dendrites of cortical plate (CP) neurons and in interneurons and subplate (SP) neurons of neonatal animals. Immature neurons migrating to the CP contained few mitochondria and exhibited very little CO activity, indicating that CO becomes elevated in neurons after they reach the CP and extend apical dendrites into the marginal zone where they receive their first synaptic inputs. The dendrites of SP neurons were particularly well stained, indicating their high metabolic activity, probably resulting from convergent excitatory synaptic input from thalamocortical and other axons. Dentate granule cells and hippocampal pyramidal cells exhibited elevated CO activity in their distal dendrites where they receive their most intense excitatory synaptic input from perforant path axons (Kageyama & Wong-Riley, '82). The dendrites and somata of various interneurons were also well-stained. In the cerebellum, Purkinje cell dendritic arbors and somata were clearly delineated. This pattern clearly demonstrated that most of CO staining throughout the CNS of postnatal rats was localized predominantly in dendrites and somata of specific classes of neurons rather than in axons or terminals. Oligodendrocytes were also quite reactive compared with astrocytes. Support: NIH grants DC 00450 and NS 30109.

AXONAL AND DENDRITIC OUTGROWTH OF INFRAPYRAMIDAL GRANULE CELLS IN THE DEVELOPING DENTATE GYRUS. P. Alba, O. Rahimi, P. A. Brewer*, and B. J. Claiborne. Division of Life Sciences, University of Texas at San Antonio, San Antonio, TX 78249.

Previous results indicate that dendritic trees of granule neurons in the suprapyramidal blade of the developing dentate gyrus mature after the axons reach their target area in the CA3 region of the hippocampus (Claiborne et al., Neuro. Abstract, 17:35; personal communication). Because granule neurons in the infrapyramidal blade develop later than those in the suprapyramidal blade, we have investigated the relationship between axonal and dendritic outgrowth of infrapyramidal granule cells. Dil crystals were placed on the CA3 region in fixed 400 um thick slices of hippocampi dissected from rats ranging in age from 2 to 9 days, thereby retrogradely labeling granule neurons whose axons have reached their target area. Using a low-light camera attached to a light microscope, labeled dendritic trees were videotaped. Confocal microscopy was used to obtain three-dimensional images of representative neurons.

Results showed that granule neurons in 2 to 4 day-old rat pups displayed immature characteristics: a long primary apical dendrite, large varicosities, basal dendrites, and filamentous projections. Neurons from 5 to 6 day-old animals had a reduced number of these immature characteristics but had developed spines. In most cells from 7 to 9 day-old rats, spines became more prevalent and the number and frequency of immature characteristics decreased. These results show that the dendritic trees of infrapyramidal granule neurons mature after their axons reach area CA3, as was found previously for suprapyramidal granule neurons. 705.2

EXPRESSION OF THE CHOLECYSTOKININ GENE IN SENSORY CORTEX SLICE CULTURE OF RAT. D.K. Meyer, C. Olenik and B. Heimrich*#. Dept. of Pharmacology and #Institute of Anatomy, Freiburg University, D-7800 Freiburg, FRG.

The preprocholecystokinin gene is expressed in a subpopulation of GABAergic interneurons in rat cortex. *In vivo* experiments indicate that the expression is regulated by neuronal afferents in a complex manner. Thus, we looked for an *in vitro* model which is organotypic and allows the analysis of neuronal interactions. Slices of rat somatosensory cortex were explanted at postnatal day 1 and kept in static cultures for 12 ± 2 days (Stoppini et al., J. Neurosci. Meth. 37: 173 (1991)). In these slice cultures, two layers of neurons containing cholecystokinin-mRNA were found with *in situ* hybridization in an arrangement which paralleled the distribution pattern *in situ*. Immunocytochemistry was performed with an antiserum against cholecystokinin-8-sulfate. Examination with light- and electron-microscopy showed immunopositive cells with small round somata and a dense network of immunoreactive fibers. The immunoreactive terminals formed only symmetric synapses. All these morphological features are typical for cholecystokinin neurons *in situ*. In a first series of experiments, the GABA_A receptor antagonist bicuculline (70 µM) was applied for 90 min. Twelve hours later, the levels of cholecystokinin-mRNA were unchanged. The finding indicates the absence of GABAergic inhibition via GABA_A receptors.

Taken together, cholecystokinin neurons in slices of rat somatosensory cortex retain several biochemical and morphological properties, when cultivated *in vitro*. Organotypical slice cultures provide a model to analyze the effects of neurotransmitters on the regulation of the cholecystokinin gene in interneurons.

LIMITED MORPHOLOGICAL DEVELOPMENT OF AVIAN PURKINJE CELLS IN AN *IN VITRO* CO-CULTURE SYSTEM P.L. Jeffrey*, J. Meaney, O. Tolhurst and R.P. Weinberger, Children's Medical Research Institute, Wentworthville, N.S.W. Australia 2145.

As an approach to investigating the expression of developmentally regulated neuronal antigens and the development of neuronal polarity this laboratory has developed a unique co-culture system for the survival and differentiation of avian Purkinje cells (PC). Dissociated PC from ED chick cerebellum were plated on laminin and poly-L-lysine coated coverslips. Astrocytes from various ages were grown in Millicells and placed above the PC coated coverslips in culture dishes containing neuronal medium. Purkinje cells of purity greater than 90% were identified by calbindin-D, cyclic GMP protein kinase and NF200 immunohistochemistry. The Purkinje cells also stained positive for NSE, A2B5 and parvalbumin. After one day in culture most PC exhibit a "simple fusiform" morphology (Type I, Armengol, J.A. & Sotelo, C. Dev. Brain Res 64 (1991) 95). A generalised MAP-2 and Thy-1 staining is seen throughout processes. Following 21 days in culture the majority of the PC are arrested at the Type II complex fusiform morphology. Purkinje cells with Type III (regressive atrophic dendrites) morphology are rarely seen up to 21 days in culture. No cerebellar granule cells are present in this culture system which are necessary for the development of dendritic processes (Baptista, D.H. et al. Soc Neurosci.: 17,1991,38). A population of cells with a phenotype representing early stages of PC development has been defined which is suitable for studies of cellular interactions and effect of extracellular components on PC survival and differentiation.

EFFECTS OF ANTINEOPLASTICS ON THE DEVELOPMENT OF HIPPOCAMPAL NEURONS IN CULTURE: A MORPHOLOGICAL STUDY. J.-S. Cloix, R.L. Kenigsberg, R. Collu* and Y. Théorêt. Centre de Recherche, Hôpital Ste-Justine, Montréal, Québec, Canada, H3T 1C5.

Although remarkable advances over the last twenty years in cancer therapy have been met with higher survival rates for children, this success unfortunately has been accompanied by a high incidence of neurological disorders. It is likely that chemotherapy-induced neuronal effects are the results of alterations at the cellular level. However, ethical and methodological considerations limit severely the direct study of these structural alterations in human subjects following chemotherapeutic intervention. Consequently, the proposed study aims to determine the effects of therapeutically relevant levels of selected antineoplastics on the morphological characteristics of dendrites and axons, as well as on the time course of neurite growth. Hippocampal neurons were isolated from rat embryos (E17-18), plated at low density (1,000 to 10,000 cells/cm²) in modified multiwell dishes and co-cultured with astrocytes. These cultures were maintained in chemically defined serum-free media. At different times after plating, cells were treated with the following agents: 6-mercaptopurine (0.05-5µM), methotrexate (0.1-10µM), ara-C (1-100µM) or 4-OH-10-fluorouracil (0.02-20µM). Using an inverted microscope (Carl Zeiss) and SigmaScan (Jandel Scientific), the following parameters were measured: 1) axon length, 2) total axonal and dendritic length, 3) number of axonal and dendritic branches/neuron, 4) number of dendritic intersections, and 5) degree of branching. Our initial results indicate that the kinetics of neuronal development can be altered by antineoplastic agents. This supports the hypothesis that morphological alterations may underlie some of the neuronal deficits observed in children treated for cancer. (Supported by the National Cancer Institute of Canada and Telethon of Stars).

THE INFLUENCE OF THE NOTOCHORD ON A SPECIFIC POPULATION OF SPINAL CORD CELLS. A. Chen and R.D. Heathcote, Department of Biological Sciences, University of Wisconsin, Box 413, Milwaukee, WI, 53201.

Little is known about how spinal cord neurons become organized during development. In the frog *Xenopus laevis*, two longitudinal columns of catecholaminergic interneurons gradually form a nonrandom pattern within the floor plate region of the spinal cord. The notochord is involved in several aspects of spinal cord development. It induces the neural plate, the ventral floor plate and the longitudinal columns of motor neurons. Therefore, the role of the notochord in establishing the catecholaminergic cell pattern was examined. Ultraviolet (UV) irradiation of fertilized eggs produced a range of phenotypic abnormalities including reduction or loss of the notochord. Animals without organized notochord, had no tyrosine hydroxylase (TH) immunoreactive interneurons. Thus notochord appeared to be necessary for induction of the catecholaminergic population of cells. In other experiments, an additional notochord was transplanted next to the developing neural tube before the initial appearance of TH cells. These experiments resulted in an increased density of catecholaminergic cells whose columnar pattern was disrupted. When the size of the neural plate was reduced by inserting a cellulose filter between the neural folds, the spinal cord formed two branches. One branch was notochordless and showed signs of atrophy. The other branch, which had a greater ratio of notochord to neural plate than normal, exhibited many of the same properties as notochord transplants. Thus, manipulation of the notochord affected the density of catecholaminergic cells as well as their longitudinal columns. These experiments provide the opportunity to further test the role of the notochord in regulating the formation and organization of a specific population of spinal cord cells.

DIFFERENTIAL EXPRESSION OF β -NADPH DIAPHORASE IN SOMATIC AND AUTONOMIC MOTOR NEURONS OF DEVELOPING RAT SPINAL CORD. R. Wetts and J.E. Vaughn, Div. of Neurosci, Beckman Res. Inst. of City of Hope, Duarte, CA, 91010.

Although somatic and autonomic motor neurons (SMNs & AMNs) share certain characteristics, they differ in others. For example, the β -NADPH diaphorase histochemical reaction, which correlates with nitric oxide synthase expression, is present in AMNs, but not SMNs. Determining when this difference arises during development may provide insights into the mechanisms that control the separate fates of AMNs and SMNs.

At upper thoracic levels, AMNs stained for diaphorase activity as early as E14. These cells remained positive for the rest of development and into adulthood, whereas SMNs never stained at this spinal level. In contrast, some developing cervical SMNs were diaphorase-positive, exhibiting intense staining from E15 until E19. Subsequently, this staining gradually decreased and disappeared by birth. Thus, in one type of motor neuron (AMNs), diaphorase staining (and hence nitric oxide synthase) is continuously expressed into adulthood, whereas in a subset of another type (cervical SMNs), the staining is transient. The differential and transient nature of diaphorase expression implies that nitric oxide may have developmental roles that differ from its function(s) in the adult. SPINAL CORD MORPHOGENESIS IN A SIMPLE VERTEBRATE. J. Frey, A. Chen and R.D. Heathcote, Department of Biological Sciences, University of Wisconsin, Box 413, Milwaukee, WI, 53201.

All cells of the spinal cord originate from the germinal or ependymal layer that surrounds the central canal. In the frog *Xenopus laevis* this ependymal layer contains differentiated neurons including a cerebrospinal-fluid (CSF) contacting population that is immunoreactive for tyrosine hydroxylase. During development, the catecholaminergic population gradually formed two longitudinal columns that subsequently "converged" at the ventral midline. During this period cell bodies decreased in size and underwent changes in shape, number and position. In order to understand the mechanisms involved in these changes we began a study of the spinal cord focusing on the ependymal layer. Ultrastructural evidence of ependymal cell differentiation including cytoplasmic projections into the central canal, non-motile neuronal cilia (those lacking the two central singlet microtubules), and motile cilia were present within a few hours of neural tube closure. Thus ependymal cells began differentiating at the same time as the earliest neurons in the spinal cord. Quantitative analysis of developing spinal cords at the level of the seventh somite showed extensive remodeling early in development. Starting at neural tube closure the number of cells increased while their size decreased. Although the central canal initially increased dramatically in size, it remained roughly constant until hatching (st 35/36). The tapered spinal cord resulted from reduced spinal cord size and cell numbers in regions one millimeter caudal to the seventh somite. Unlike the more rostral region, there were no major changes in the size and number of cells throughout the developmental stages studied. Thus, cellular remodeling occurs differentially along the length of the spinal cord. In rostral regions changes in cell size, shape, number and position accompany the morphogenesis of catecholaminergic interneurons.

705.10

INFLUENCE OF NOTOCHORD AND SURROUNDING TISSUE ON OLIGODENDROCYTE DIFFERENTIATION IN XENOPUS SPINAL CORD. C.E. Maier and R.H. Miller, Dept. of Neurosciences, Case Western Reserve Univ., Cleveland OH 44106.

During the development of *Xenopus* spinal cord oligodendrocyte differentiation occurs in a ventral-dorsal sequence. Differentiated oligodendrocytes first appear in the ventral spinal cord at stage 44/45. By stage 54/55 differentiated oligodendrocytes are found in the lateral region of the spinal cord, while at stage 60/61 differentiated oligodendrocytes can be found in the dorsal spinal cord.

To determine if this distinct pattern of oligodendrocyte development in the spinal cord is influenced by extrinsic factors, the notochord was ablated and the surrounding somites and skin disrupted over a 3-5 somite distance caudal to the ear placode in embryos at stage 26/28 or stage 34/35. Operated animals were allowed to develop until stage 49. The differentiation of oligodendrocytes along the rostral-caudal axis of the CNS was then determined using Olig, a monoclonal antibody specific for myelinating frog oligodendrocytes. In control animals differentiated oligodendrocytes were found only in ventral regions of brain and spinal cord at stage 49. After ablation at stage 26/28, differentiated oligodendrocytes were absent from the area associated with notochord ablation but present in the ventral spinal cord rostral and caudal to that area. Similarly, after ablation at stage 34/35, differentiated oligodendrocytes were seen in lateral and dorsal spinal cord in the area associated with the ablation but only in ventral spinal cord rostral and caudal to the ablation site. These results imply that the notochord or surrounding tissue may play an important role in the regulating the timing and initial location of oligodendrocyte differentiation and myelination.

PROCESS OUTGROWTH, GROWTH CONES, AND SPROUTING IX

706.1

IMMEDIATE EARLY GENE EXPRESSION IN DRG NEURONS UNDERGOING STIMULATION-ENHANCED COLLATERAL SPROUTING. K.M. Mearow, Dept. of Biomedical Sciences, McMaster University Medical Centre, Hamilton, Ont. L8N 3Z5

Intact cutaneous sensory neurons will undergo collateral sprouting to reinnervate adjacent areas of denervated skin. Sprouting is NGF-dependent and electrical stimulation (in vivo) of the DRG neurons results in an acceleration of the growth response, advancing it by up to one week. In an effort to discern neuronal events which may be involved in the stimulation-induced acceleration of the sprouting response, I have examined expression of several immediate early genes, including the c-jun family, c-fos and NGFIA (KROX 24)

The following experimental paradigms were set up: 1. Normal sprouting - cutaneous nerve fields were "isolated" (by surrounding denervation); 2. Accelerated sprouting - at the time of isolation the intact nerves were electrically stimulated; 3. Stimulation only - nerves were stimulated, but not isolated. Subsequently (6 hrs, 1, 2, 4, 6, 14, and 21 days) animals were anaesthetized and the appropriate DRGs were removed and prepared for cryosectioning. Immunocytochemistry (ICC) was carried out using polyclonal antibodies against cJUN, JUNB, JUND, FOS, KROX24 (Santa Cruz Biotech), while in situ hybridization was performed using ³⁵S-labeled oligonucleotides complementary to the IEGs.

The results indicate that c-jun expression is increased in the sprouting neurons by 2d postop, peaking by 1 week and subsequently declining to control levels. While stimulation alone does not appear to influence c-jun expression, the combination of stimulation plus isolation results in increased expression apparent by 6 hrs and peaking 1-2 days earlier than in the absence of stimulation. Preliminary results suggest that neither Jun D nor NGFIA expression is significantly altered under any of these experimental conditions. Supported by NSERC.

706.2

NGF RECEPTOR mRNA EXPRESSION IN COLLATERALLY SPROUTING SENSORY NEURONS - THE INFLUENCE OF STIMULATION. Y. Kiri, J. Diamond and K. Mearow, Dept. of Biomedical Sciences, McMaster University, Hamilton, Ont. L8N 3Z5.

The collateral sprouting of intact cutaneous neurons has been shown to be NGF-dependent. Furthermore, electrical stimulation of these neurons advances the sprouting by almost one week. We have previously shown that NGF receptor (both p75 and trkA) and GAP43 mRNA expression is upregulated in the sprouting neurons, and have now extended this work to examine the influence of electrical stimulation on gene expression in sprouting neurons.

In the sprouting paradigm, alternate pairs of dorsal cutaneous nerves (DCNs) were cut in adult rats; the remaining intact DCNs then undergo collateral sprouting into the denervated areas of skin. Two further groups of animals were examined - one in which the surviving nerves were electrically stimulated, and another in which the nerves were stimulated, but denervations were not done. Subsequently (6hrs, 1, 2, 4, 6, 14, 21 days) the appropriate DRGs were removed and frozen. Cryosection of these DRGs were taken and used for in situ hybridization (ISH) with ³⁵S-labeled oligonucleotides complementary to p75, trkA and GAP43.

The results show that, as expected, the expression of NGFR (p75 and trkA) and GAP43 mRNA increases in the normal sprouting neurons, with the increases apparent by 2-4 days postop. In the stimulated sprouting neurons, however, the increase in trkA is apparent by 6 hrs, in p75 and GAP43 by 24 hrs. Stimulation in the absence of denervation resulted in an increase in only trkA expression, which was significantly less than in the combined stimulation and sprouting mode. Supported by the NCE on Neural Regeneration (JD, KM) and NSERC (KM).

706.3

PRENATAL DENDRITIC DEVELOPMENT OF RAT SYMPATHETIC PREGANGLIONIC NEURONS. K.G. Ruit* and Y.F. McKee. Dept. of Anatomy & Cell Biology, Univ. of North Dakota School of Medicine, Grand Forks, ND 58202.

We have utilized the neuroanatomical tracer DiI in fixed tissues to describe the embryonic development of the dendritic arborizations of sympathetic preganglionic neurons (SPNs) in the rat spinal cord. SPNs were labeled by placing small crystals of DiI within upper thoracic sympathetic chain ganglia or within upper thoracic ventral roots beginning in embryonic day 13 animals (E13) and continuing through the first postnatal week. SPNs were visualized by fluorescence microscopy in transverse, horizontal or sagittal sections, photoconverted using diamino benzidine, and drawn by camera lucida.

Between E13 and the day of birth, SPNs change from a bipolar to a multipolar shape and their dendritic arborizations become mediolaterally-oriented, extending laterally to the pial surface of the cord and medially across the midline; by the end of the first postnatal week, contralaterally-projecting dendritic bundles reach the opposite intermedialateral cell column. Rostrocaudally-oriented dendritic bundles develop during the first postnatal week. The development of the dendritic arborizations of SPNs may be related to the development of innervating afferent systems and/or support by centrally or peripherally-derived trophic molecules.

706.5

GROWTH CONE-TARGET CELL INTERACTIONS IN LIVE HIPPOCAMPAL SLICES: FLUORESCENCE LABELING AND TIME-LAPSE CONFOCAL IMAGING M.E. Dailey* & S.J. Smith, Dept. of Molecular & Cellular Physiology, Stanford University Medical School, Stanford, CA 94305.

We are exploring the cellular mechanisms of target cell selection and synapse formation in tissue slices of developing mammalian brain. Specifically, we are studying the formation of giant *en passant* synapses between mossy fibers (MFs) and pyramidal cell dendrites within the rat hippocampus. The ability of MFs to form new giant synapses within isolated tissue slices was previously established by a series of experiments involving Synapsin-I immunostaining, electron microscopy and intracellular recordings. In an effort to characterize the cellular dynamics related to synapse formation, the MFs and target pyramidal cells in living brain slices were stained with a fluorescent membrane dye, DiI or DiO, and imaged over time. Imaging was performed with a custom-built scanning laser confocal microscope that afforded collection of Z-axis stacks of confocal images at time intervals of a few minutes. Active filopodial protrusions were observed not only at the leading growth cone of extending MFs but also at small varicosities along the axonal shaft. Moreover, some preliminary observations suggest that target cell dendrites may likewise exhibit a dynamic morphology: filopodial-like structures were occasionally seen to emerge from dendritic shafts of some putative target cells. These studies suggest a possible dynamic interaction of axonal and dendritic processes during targeting and synapse formation.

Supported by NIH grants NS09027 & NS28587.

706.7

SYNAPSIN I GENE EXPRESSION DURING DEVELOPMENT AND IN RESPONSE TO SELECTIVE LESIONS OF THE RAT CNS. R.H. Melloni, Jr.* P.J. Apostolides, J.E. Hamos, and L.J. DeGennaro, University of Massachusetts Medical Center, Worcester, MA 01655.

Synapsin I is the best characterized member of a family of nerve terminal-specific proteins implicated in the regulation of synaptic function. To better understand the regulation of synapsin I gene expression during synapse development, we first examined the expression of the synapsin I gene in the granule cell neurons of the dentate gyrus. The results indicate a significant difference between the temporal expression of high levels of synapsin I mRNA in dentate granule somata and the appearance of protein in their mossy fiber terminals during the postnatal development of these neurons. Next, we examined the expression of synapsin I mRNA and protein following lesions of hippocampal circuitry. These studies show marked changes in the pattern and intensity of synapsin I protein staining in the dendritic field of dentate granule cell neurons following perforant path transection. In contrast, changes in synapsin I mRNA expression in target neurons, and in those neurons responsible for the reinnervation of the hippocampus, were not found to accompany new synapse formation.

On a molecular level, developmental and lesion data suggest that expression of the synapsin I gene is tightly regulated in the CNS, and that considerable changes in synapsin I protein may occur in neurons without concomitant changes in the levels of its mRNA. Finally, our results suggest that the appearance of synapsin I protein in developing and sprouting synapses coincides with the acquisition of function by those central synapses. Supported by NIH NS25050 and NS27833 to L.J.D.

706.4

CALLOSAL AXONS SHOW AN EXTENDED PERIOD OF MORPHOGENESIS IN HAMSTERS. C.Hedin-Pereira* & S.Jhaveri. Dept. Brain and Cognitive Sciences, M.I.T., Cambridge, MA 02139

We have studied the developmental changes in the morphology of callosal axons originating in the parietal cortex. Biocytin and PHA-L were used as anterograde tracers in P6, P9, P12, P20, P24 and adult hamsters. A standard immunohistochemical procedure was used to visualize labeled axons. Axons were serially reconstructed using a computerized 3D reconstruction system (Neurotrace). At P6, most fibers with homotopically projecting arbors arise from trunk axons that continue on laterally, sometimes as far as the rhinal fissure. Typically, axons have two or three sprouts along their trajectory, including in the perirhinal region. Some axons extend a collateral into the homotopic cortex and also into the striatum, a non-cortical target. Homotopic arbors have few ramifications within the gray matter. From P7 to P17, there is a dramatic increase in the number of arbor branches; these are mostly focused in the supra and infragranular layers but also send collaterals to other laminae. A heterotopic projection to the perirhinal region with arbors exhibiting a complexity similar to homotopic arbors, is consistently seen and persists to adulthood. By P25, arbors acquire two types of distribution: sharply bilaminar (layers II/III and V) or only supragranular. The lateral continuation of the trunk axon disappears. These observations document that the sculpting of callosal axons in the tangential as well as radial dimension continues at least into the fourth week of postnatal life. Support: NIH grant EY 05504; CNPq, Brazil.

ONTOGENY OF MOSSY FIBERS IN THE RAT HIPPOCAMPUS: A TIMM'S HISTOCHEMISTRY STUDY. J.P. Leite, T.L. Babb*, J.K. Pretorius and G.W. Mathern. Brain Research Institute, UCLA School of Medicine, Los Angeles, CA 90024.

The organization of the mossy fiber (MF) system which projects from granule cells of fascia dentata to the hilus, CA4, and CA3 cells was studied at postnatal (PN) days 2, 7, 14, 16, 18, 20, 22, 24, 26, 28, 30 and 42 in normal Sprague-Dawley rats. Mossy fibers and terminals (MFTs) were stained with neo-Timm histochemistry and counterstained for neurons with cresyl violet. Coronal sections at 16 "equidistant" levels covering the entire septo-temporal length of the hippocampus (HC) were examined.

At each PN age there were greater differences in the MF distribution that depended on the septal/temporal axis than the age difference within a given axis. At the septal level, MFs mostly projected to the suprapyramidal CA3 but also penetrated the neuron layer of the stratum pyramidale ("intrapyrmidal") as early as PN 7. At later ages, these intrapyramidal MFs appear to extend and form MFTs on the basilar dendrites of CA3. These intrapyramidal (stratum oriens) MFTs in CA3 were also more prevalent at the septal one-third of the HC by PN 14. In the temporal sections, intrapyramidal and infrapyramidal MFTs were sparse or absent. At PN 16, MFTs appear more highly concentrated in the suprapyramidal zone (stratum lucidum) at all septal-temporal sections, and by PN 20-22 the entire hilus, CA4 and CA3 MF distributions are virtually identical to the adult HC; although Timm staining is less intense and MFTs appear smaller. This study demonstrates that during development, MFs project diversely to several strata (PN 7-14) and later (PN 20) develop specialized MFTs on the dendritic zones, stratum lucidum (septal and temporal) and oriens (septal only). INTRAHIPPOCAMPAL COLCHICINE ADMINISTRATION INDUCES STATHMIN mRNA IN THE DENTATE GYRUS. N. Mori*, T. Himi, M. M. Dugich-Djordjevic, M. Cao, and F. Hefti. Division of Neurogerontology, Andrus Gerontology Center, University of Southern California, Los Angeles, CA 90089.

Microinjection of colchicine into the hippocampal formation selectively destroys granule cells of the dentate gyrus and their axons over several days, while sparing pyramidal cell populations. Granule cell degeneration is triggered primarily by microtubule depolymerization, however little is known about the precise mechanisms for selective granule cell death that occurs following colchicine administration. To approach this, we examined the expression of mRNAs encoding neural specific or enriched phosphoproteins, i.e. stathmin, SCG10, and synapsin I. Expression of these molecules are associated with neuronal differentiation, regeneration, and synaptic formation. Colchicine or control saline was injected unilaterally into the dentate gyrus of male Sprague-Dawley rats (2 months old), and the animals were sacrificed at 1, 3, and 7 days following injection. Quantitative *in situ* hybridization histochemistry demonstrated that SCG10 and synapsin I mRNAs expression was no longer evident in the ipsilateral dentate gyrus 3 days after the colchicine injection, suggesting that the dentate granule cells degenerate by this time. In CA3 pyramidal neurons, SCG10 and synapsin I mRNA expression declined by day 3, but recovered to control levels by day 7. In contrast, stathmin mRNA was upregulated (+35%) 1 day following colchicine administration in the ipsilateral dentate gyrus, but not in the contralateral side. By day 3, stathmin mRNA was also induced in the contralateral dentate gyrus (+20%). Stathmin mRNA was increased (+25%) in the ipsilateral CA1 and CA3 pyramidal cells, but was decreased in the contralateral side (-50%). Stathmin mRNA expression was not altered at any time in saline injected animals. Our results demonstrate that stathmin, a putative signal transduction molecule, is regulated by events associated with neurodegeneration and/or reactive synaptogenesis following the selective destruction of dentate gyrus granule cells in the adult hippocampus. It is important to determine mechanisms of the induction of p19/stathmin gene for the further understanding of synaptic reorganization process within the hippocampus.

3D RECONSTRUCTION OF INTRACELLULARLY-STAINED CA1 HIPPOCAMPAL NEURONS FROM NORMAL AND KAINIC-ACID LESIONED RATS. G.K. Pyapali*, J. Bradley and D.A. Turner. Neurosurgery and Neurobiology, Duke Univ. and Durham VAMC, Durham, NC, 27710.

Unilateral kainic acid (KA) lesions of the CA3 region of the hippocampus lead to denervation of ipsilateral CA1 neurons, particularly in the stratum radiatum. To assess these changes quantitatively, CA1 neurons were recorded *in vitro*, stained with neurobiotin and then reconstructed using a computerized 3D system (NeuroLucida).

The CA1 neurons from the lesioned animals showed an elevated input resistance but otherwise there was no difference in cell health (3 - 42 days post-lesion). Total dendritic length was slightly longer in the denervated CA1 cells: normal = 8.84 ± 0.82 mm (n = 6) versus KA = 11.0 ± 4.85 mm (n = 6), comparable to previous reconstruction estimates of 8.38 ± 2.27 mm (n = 6). However, the dendrites in the mid-stratum radiatum appeared to be increased in number in the KA-lesioned cells as compared to control neurons. Total apical dendritic length revealed that control = 5.93 ± 1.47 mm versus KA = 7.92 ± 3.38 mm (NS). Sholl analysis for density of terminals and branches in 75 μ m lamina was performed at various distances from the pyramidal cell layer in the apical dendrite: at 75-150 μ m control value = 36.3 ± 9.7 while the KA value = 38.8 ± 15.3 (NS). However, at 225-300 μ m normal = 14.3 ± 9.7 and the KA (all) = 29.8 ± 11.1 (P < 0.05 different). The KA lesions at 5 days and later showed even more significant changes in this denervated zone in the apical dendrites (34.0 ± 10.7 , P < 0.01). However, at 375-450 μ m control = 10.7 ± 5.4 while the KA cells showed 10.5 ± 9.2 (NS). Likewise, the basal dendrites showed control = 9.0 ± 6.5 and KA-lesioned cells 12.7 ± 8.0 (NS).

These findings indicate that there is a selective and specific increase in the number of terminals and dendritic branches in the denervated zone of the apical dendrite, suggestive of dendritic sprouting in the stratum radiatum following the lesion. Supported by NINDS #29482 (DAT) and VA Merit Review Award (DAT).

TRANSIENT INCREASED EXPRESSION OF CYTOSKELETON PROTEINS PRECEDES SPROUTING AND SYNAPTOGENESIS IN EPILEPTIC RATS. Repra A., Pollard H., Moreau J., Ghilini G., Khrestchatsky M., Jorquera I., Diabira D. and Ben-Ari Y., INSERM U29 123 Bd. Port Royal 75014 Paris (France).

One of the most striking changes seen in epileptic brains is the sprouting and synaptogenesis of the hippocampal mossy fibers (mf, the axons of dentate granule cells), which make ectopic synaptic contacts with hippocampal granule cells dendrites. We examined here the effects of kainate-induced seizures, upon the hippocampal expression of tubulins (α and β) and microtubule associated proteins (MAP2 and Tau). mRNAs encoding for these proteins increase in the dentate granule cell bodies 3 days after KA (MAP2 mRNA also increased in the dendrites). mRNA levels peaked on day 12. These changes were correlated with an enhanced tubulin (α and β) immunoreactivity (IR), in both granule cells dendrites and mf, already detectable 4 days after KA. 6-12 days after KA, MAP2 IR was also selectively increased in the dendrites of granule cells, whereas Tau IR was enhanced in mf and granule cell bodies. The levels of mRNA and protein IR returned to control values by 20-30 days after KA, respectively. These changes developed before and during axonal mf sprouting which starts around 12 days after KA. We suggest that the production and stabilization of tubulin polymers with Tau contribute to the axonal growing and side-branching of mf. The dendritic increase of tubulin and MAP2, which also develop during the period of synapse formation may be related to a local synthesis involved in the formation of postsynaptic specializations.

AXONAL AND GLIAL RESPONSES TO CORTICAL DEAFFERETATION OF THE STRIATUM. E.G. Szele* and M. E. Chesselet, Dept. of Pharmacology, U. of Pennsylvania, Philadelphia, PA 19104.

Whereas denervation-induced sprouting has been demonstrated in the hippocampus, less is known about this phenomenon in the striatum. Thermocoagulatory lesions of pial vessels overlying the cerebral cortex were performed in adult rats to induce a gradual loss of the massive cortical input to the striatum. Rats were sacrificed six hours to six weeks after surgery and brains processed for immunohistochemistry. Both GAP-43 and synaptophysin (indices of axonal sprouting) were transiently (1 week) increased under the corpus callosum but not in the rest of the striatum. Because astrocytes have been shown to produce molecules which can modulate sprouting, the expression of glial fibrillary acidic protein (GFAP), basic fibroblast growth factor (bFGF), tenascin, and chondroitin sulfate proteoglycan (CSPG) was examined after denervation. Despite a rapid and prolonged increase in GFAP, immunoreactivity to bFGF was not increased in the striatum, in contrast to both ipsi and contralateral cortices. Tenascin expression was increased bilaterally in the corpus callosum six hours to three weeks and in the dorsolateral striatum five to seven days after surgery. CSPG was increased to a lesser extent in the corpus callosum. Taken together these results suggest a lack of major sprouting in the striatum which may be related to the absence of bFGF induction by striatal astrocytes and the increase in adhesion molecules serving as barriers. Supp. by PHS grant NS 29230.

EMBRYONIC N-CAM IS RAPIDLY EXPRESSED IN DENERVATED DENTATE GYRUS: ULTRASTRUCTURAL ANALYSIS. P.D. Miller*^{1,2}, S.D. Styren³, C.F. Lagenaur¹, S.T. DeKosky^{1,3,4}, Depts. Neurobiology¹, Neurological Surgery², Psychiatry³, and Neurology⁴, University of Pittsburgh School of Medicine and Western Psychiatric Institute and Clinic, Pittsburgh, PA 15213

Entorhinal cortex (ERC) lesions denervate the outer two thirds of the hippocampal dentate gyrus molecular layer (ML). The denervation depletes 85% of the synapses in the outer ML, which is followed by a brisk lesion-induced synaptogenesis. The embryonic form of neural cell adhesion molecule (eN-CAM) is reexpressed in the outer ML following ERC lesion; the eN-CAM is localized on cell membranes of granule cell dendrites and occasionally axons within the denervated zone. Because eN-CAM is expressed within 2 days after ERC lesion, we were interested in the temporal sequence of expression. Denervated hippocampi (12, 18, 24, and 48 hours post ERC lesion) were stained with anti-eN-CAM (epitope: polysialic acid) prior to processing for electron microscopy. By 18 hours post lesion, cell membranes of both dendrites and axons throughout the inner and outer ML exhibited moderate eN-CAM staining; by 24 hours post lesion, staining intensity had increased significantly and labeled more profiles. eN-CAM staining disappeared from the non-denervated inner ML by 48 hours post ERC lesion, but remained intense and widely distributed in the outer ML. In the absence of cytoplasmic or Golgi staining with eN-CAM antibody in the dendrites following ERC lesion, we speculate that the rapid appearance of eN-CAM after lesion may be from modification of adult N-CAM, perhaps via membrane-associated sialyltransferases. These enzymes may glycosylate newly arriving or endogenous membrane N-CAM, aiding in afferent segregation during reinnervation.

EFFECTS OF CASTRATION AND ESTRADIOL ON GRANULE CELL DENDRITE SPINE LOSS AFTER PERFORANT PATH TRANSECTION. J.R. Day*, P.E. Schauwecker, N.J. Laping, C.E. Finch and T.H. McNeill. Andrus Gerontology Center, USC and Biology Department/Gerontology Center, Penn State University, University Park, PA 16802-5301.

Unilateral perforant path transection removes a large percentage of presynaptic elements in the outer 2/3's of the ipsilateral dentate molecular layer. Gonadal and adrenal steroids have been shown to alter granule cell morphology in rats. The purpose of this study was to assess the effects of castration on granule cell dendritic spine density during synaptic reorganization after perforant path transection. Male Fisher 334 rats were castrated and implanted with estradiol-filled or empty silicone elastomer implants (5mm X 2mm) for 17 days prior to unilateral perforant path transection. Four days after lesion (21 days after castration) whole brains were collected for Cox-Golgi processing. The spines were counted on the distal 80-100 μ of a granule cell dendritic branch in the dorsal blade of the rostral hippocampus. In this preliminary study, 10 to 20 cells per side were counted from 2-3 rats per group. Ipsilateral dendrites of a separate group of uncastrated, lesioned males exhibited a 50% decrease in spines compared to the contralateral side (8.5 ± 3.6 vs 16 ± 1 spines/20 μ , n=3). Castrated males showed no difference in spine density between ipsilateral and contralateral granule cells 4 days after lesion (16.6 ± 1.3 vs 16.8 ± 1.3 , n=2). Perforant path lesion of E2-implanted castrates resulted in a 15% decrease in spine density in the ipsilateral hippocampus (14.7 ± 0.1 vs 17.2 ± 0.6 , n=2). The results show that the initial phases of lesion-induced synaptic reorganization in the male rat hippocampus are effected by removal of the testes, and that E2 can partially reverse this effect. The absence of a change in spine density after lesion in castrates could represent a delay in the sequence of reactive synaptogenesis and/or be evidence of plasticity in response to castration-induced atrophy. EFFECT OF FUNCTIONAL AXON SPROUTING ON OXIDATIVE METABOLISM AND SIZE OF MOTONEURON SOMA. R.N. Michel*, N. Neil, and G. Parker. Depts. of Human Movement* and Biology, Laurentian Univ., Sudbury, Ontario.

When a skeletal muscle is partially denervated, motoneurons surviving the injury respond by extending supernumerary extensions to reinnervate vacated post-synaptic sites. To accommodate this growth, the motoneuron soma must rapidly increase its proteo-synthetic drive and regulate its metabolism to meet the increased demand for transport of membrane, cytoplasmic and synaptic constituents to the new axon terminals. We measured the size and oxidative capacity of identified motoneurons at two stages of this response. Plantaris muscle fibers in one hindlimb of 10 rats were denervated by cutting radicular nerve L4. The extent of functional sprouting was assessed 10 or 28 days later by the ratio of force responses evoked via stimulation of the sprouting L5 nerve to that produced by its counterpart in the contralateral limb. L5 motoneurons on both sides were labeled with 5% Fast Blue, injected (10 μ L) into the plantaris 7 days previous to the contractile measurements. Quantitative histochemistry for succinate dehydrogenase (SDH) activity in fresh-frozen sections was used as an indicator of oxidative metabolic capacity. The progression of the SDH reaction in labelled somas from both limbs was recorded using microphotometric imaging. Motor units increased their functional size 2 to 13-fold in response to partial denervation. Sprouted motoneuron soma sizes were not different from non-sprouted counterparts (1711 vs 1658 μ m²; total n = 173). Similarly, SDH activity in 10 and 28 day sprouted motoneurons was not different from control (12.5 vs 12.1 O.D./min x 10^{-3}). Interestingly, total SDH content correlated with soma size (r from 0.542 to 0.619; P < 0.01) in all but the 28 day sprouted motoneurons. Our results suggest that the increased motoneuronal work associated with rapid terminal field expansion does not require significant modulation (i.e. up-regulation) of cell body oxidative metabolism. Indeed, as in cerebral cortex tissue, motoneurons may rely on alternate metabolic pathways (i.e. to lactate) to meet the new energy requirements associated with this growth. VOMERONASAL ORGAN TRANSPLANTATION INTO THE BRAIN CORTEX. P.F.C. Graziadei* and E.E. Morrison. Dpt. Biological Science, Florida State University, Tallahassee, FL 32306 and Dpt. Anatomy & Embryology, Auburn University, Auburn, AL 36849

Vomeranasal organs of rat pups (P1-P10) were transplanted into the parietal cortex of same age littermates. The organs developed as a series of tubules and vesicles not always interconnected. The vesicles were lined by sensory and non sensory epithelia. From the latter bundles of axons originated and penetrated the surrounding brain parenchyma. The course of the bundles appeared to be random. At variable distance from the originating sensory epithelia (from 50 microns to 1 mm) a complex plexus of sensory fibres developed. Among the bundles of the plexus we consistently observed discrete glomeruli-like structures (from 50 to 150 microns in diameter). We observed glial nuclei in the plexiform structure, however, around the glomeruli we did not observe periglomerular cells nor a special glial envelope. The occurrence of glomerular structures was also observed when the plexiform mass freely protruded into the lateral ventricle. Our study was based on histological preparations.

It is concluded that the vomeronasal organ of postnatal rats can survive and develop when transplanted into the brain parenchyma and that the axons generated by the organ are able to form a plexus and glomeruli-like structures in the absence of obvious postsynaptic neurons.

TOPOGRAPHIC SIMILARITIES BETWEEN SYMPATHETIC FIBERS AND NGF IMMUNOSTAINING IN THE HIPPOCAMPUS FOLLOWING SEPTAL LESIONS. C. Yu and K.A. Crutcher.*

Department of Neurosurgery, University of Cincinnati School of Medicine, Cincinnati OH 45267.

The ingrowth of sympathetic fibers into the hippocampus following cholinergic denervation may involve NGF-like activity (Crutcher, 1987). The suggestion that an NGF-like signal arises from dentate granule cells and their axons (mossy fibers) was originally based on the similarity in distribution between sympathetic axons, visualized with catecholamine histofluorescence, and mossy fibers, visualized with the Timm stain (Crutcher and Davis, 1982). NGF-like staining was recently reported to be localized to the dentate hilus and stratum lucidum of CA₃ (Conner et al., 1992), areas normally occupied by mossy fibers. In the present study, comparisons were made between the distribution of NGF-like staining (polyclonal antibody kindly provided by J. M. Conner and S. Varon) and the topography of sympathetic fibers [monoclonal antibody against the low-affinity NGF receptor (NGFR), generously provided by E.M. Johnson, Jr] in the hippocampus following cholinergic deafferentation.

Mature female Sprague-Dawley rats received medial septal lesions (5 mA for 30 sec) or served as sham controls. They were perfused with 0.2% parabenzquinone and 2% paraformaldehyde 4 weeks after surgery. Visualization of NGF-like immunoreactivity and NGFR-positive fibers was carried out on adjacent sections to permit topographic comparisons. As described by Conner et al. (1992), NGF-like staining was present in the dentate hilus and stratum lucidum of CA₂ and CA₃, in both normal and lesioned animals. On adjacent sections, thick, NGFR-positive fibers, arising from penetrating blood vessels, were distributed within the same areas only in animals with septal lesions. These findings support the hypothesis that the topography of sympathetic ingrowth is regulated by the distribution of an NGF-like signal associated with granule cell axons.

707.3

DOPAMINERGIC DENERVATION OF THE STRIATUM BLOCKS SCG-10 mRNA RESPONSE TO CORTICOSTRIATE LESION J.P. Cogen*, H.W. Cheng, P.E. Schauwecker, and T.H. McNeill. Andrus Gerontology Center and Department of Biological Sciences, Univ. of Southern California, Los Angeles, CA 90089.

Previous studies have shown that the growth-associated neuronal protein SCG-10 is abundant during developmental synaptogenesis, and its mRNA is upregulated during synaptic remodeling in the adult rodent after unilateral aspiration of the sensory motor cortex. On northern blot analysis, SCG-10 mRNA was increased 8-fold in contralateral cortex 3 days after the lesion and declined to near-control levels by 27 days postlesion, a time course corresponding to rapid and robust paraterminal sprouting of homologous fibers from the intact contralateral side. In contrast, there was no change in mRNA for GAP-43, a protein associated with neurite outgrowth. In addition, unilateral 6-OHDA lesions produced no change in SCG-10 or GAP-43 mRNA in the ipsilateral cortex at 3, 10, and 27 days postlesion when assessed by northern blot analysis.

In order to investigate the role of the nigrostriatal synapse in the synaptic remodeling capabilities of the striatum, 6-OHDA injections were made in the substantia nigra before or at the same time as cortical ablation. There were no changes in SCG-10 or GAP-43 mRNA in contralateral cortex after 3, 10, and 27 days on northern blot analysis. These results suggest that the maintenance of dopaminergic synapses on medium spiny striatal neurons may be critical in preserving corticostriatal synaptic plasticity. Supported by AG 09794, NS 30426 and the National Parkinson Foundation.

707.2

REGENERATING GOLDFISH CNS NEURONS CHOOSE INAPPROPRIATE PATHWAY INTO THE PNS. S.J. Zottoli* and A.P. Bentley. Dept. of Biology, Williams College, Williamstown, MA 01267.

Damaged neurons within the central nervous system of the adult goldfish are thought to regrow to appropriate target areas with resultant recovery of swimming behavior (Bernstein, Exp. Neurol., 9:161). However, after a whole spinal cord crush at the spino-medullary level (SML crush), approximately 50% of surviving goldfish do not recover all behavior. Brain neurons regenerating past a SML crush have a choice between the spinal cord and the first ventral root. To determine whether novel pathway choices were made by these regenerating CNS neurons, the normal pool of motoneurons that enters the first ventral root was defined by application of HRP to the root and compared to the pool that enters this root 70-210d after a SML crush. The experimental pool differed from the normal pool, which was exclusively ipsilateral, in three fundamental ways; 1) cell bodies were labelled on the contralateral side, 2) the rostro-caudal extent of the ipsilateral regenerated pool was greater, and 3) new classes of CNS neurons, including vestibulospinal and reticulospinal cells, were labelled on both the ipsilateral and contralateral sides. Anterograde filling of regenerated CNS neurons by application of HRP rostral to the normal pool showed that at least 60% chose the pathway into the first ventral root. We conclude that some regenerating neurons do not make the same pathway choice as they made during development, and that shunting of these fibers away from their normal target areas may limit behavioral recovery in adult goldfish. These results indicate that the goldfish PNS may present a more permissive environment to regenerating fibers than the CNS, as is the case in mammals. Therefore, we suggest that the goldfish is a better model for mammalian regeneration than previously thought. Supported by NSF grant BMS8809445.

707.4

EFFECT OF AGE ON THE EXPRESSION OF SCG-10 AND P-19 mRNA DURING REACTIVE SYNAPTOGENESIS H. W. Cheng*, T. Jiang, N. Mori and T.H. McNeill. University of Southern California, Andrus Gerontology Center, Los Angeles, CA 90089

Previous studies suggest that aging is associated with a delay in the response of surviving afferent axons to reinnervate deafferented target neurons during reactive synaptogenesis. However, whether this age-related delay is generalized to all regions of the brain or is more characteristic of specific brain areas such as the hippocampus is unclear. To address this issue we used an experimental model of striatal (ST) deafferentation and northern blot and *in situ* hybridization analysis to assess changes in mRNA prevalence for two proteins thought to be involved in neurite outgrowth (SCG-10, P-19) in young adult (3-4 mos.) and aged (24 mos.) rat brain.

We found that there is no difference in the basal expression of both SCG-10 and P-19 mRNA in the cortex and ST of young adult and aged rats and that the time course of the SCG-10 and P-19 mRNA response to the cortical lesion is the same in both age groups. However, while the time course of the response is the same, the magnitude of the response is less in aged rats. To what degree this response affects neurite outgrowth and new synapse formation in the aged ST is yet to be determined. However, these data suggest that in the ST the initiation and time course of the mRNA response to a cortical lesion is similar in the young adult and aged rats and that the age-related delay characteristic of reactive synaptogenesis in the hippocampus may not be a generalized phenomenon in the aged brain. Supported by AG 09794, NS 30426 and the National Parkinson Foundation.

707.5

MORPHOMETRIC ANALYSIS OF IPSILATERAL AND CONTRALATERAL STRIATAL NEURONS FOLLOWING A UNILATERAL CORTICAL LESION. S.A. Brown, H.-W. Cheng and T.H. McNeill* University of Southern California, Andrus Gerontology Center, Los Angeles, CA 90089

While numerous studies have examined the response of ipsilateral target neurons to a unilateral deafferentation lesion, few have addressed changes that occur in the morphology and time course of the response of target neurons ipsilateral vs contralateral to the lesion. To address this issue we used Golgi impregnation and computer assisted morphometry to investigate the bilateral effect of a unilateral cortical lesion on medium spiny I (MSI) striatal neurons in young adult Fischer 344 rats. We found that there was a significant (40%) reduction in both total dendritic length (TDL) and spine density in the ipsilateral striatum (ST) at 3 days postlesion, which reached a maximum (50%) at 10 days postlesion. In contrast, spine loss was not observed in the contralateral ST until 10 days postlesion (18%), with no change in TDL. Partial recovery of both spine density and TDL was found in the ipsilateral ST at 20 days postlesion, and spine density reached 80% and TDL 100% of intact values at 27 days postlesion. In contrast, spine loss in the contralateral ST remained decreased (20%) compared to intact values at 27 days postlesion but was equivalent to the "recovered" spine density found in the ipsilateral ST. These data suggest that the plastic response of MSI neurons to a unilateral cortical lesion differs between the ipsilateral and contralateral ST and that one possible role for a differential response is to maintain symmetry in the number of target neuron synapses following a unilateral lesion. Supported by AG 09794, NS 30426 and the National Parkinson Foundation.

707.7

REGENERATION OF CEREBROSPINAL FLUID CONTACTING NEURONS (CSFCN) IN THE REGENERATED TAIL SPINAL CORD OF THE LIZARD *ANOLIS CAROLINENSIS*. M.T. Duffy, A. Hawrych, D.R. Liebich and S.B. Simpson, Jr.* Dept. Biological Sciences, University of Illinois at Chicago, IL 60680.

Recent work in our lab has focused on the role of CSFCNs in the regenerated tail spinal cord of *Anolis* lizards. We now report results of retrograde labeling of neurons by spinal transections at either midthoracic, low lumbar or two segments rostral to regenerated spinal cord. HRP placed at thoracic levels (n=3) and lumbar levels (n=3) revealed no labeled cells in the regenerated tail spinal cord while HRP (n=2) and lucifer yellow (n=1) placed rostral to regenerates revealed an average of 16 ± 4 retrogradely labeled CSFCNs in the regenerated spinal cord. In all three positive cases, the labeled cells were clustered in the distal regenerate. However, examination of serial longitudinal sections of regenerated tail spinal cord revealed the presence of CSFCNs throughout the regenerate.

These results indicate that regeneration of ascending CNS axons is limited to a distal subset of regenerated CSFCNs. Furthermore, these ascending axons do not appear to regenerate further than the last few segments rostral to the regenerate. We have previously shown that this area of spinal cord rostral to the regenerate is the origin of the vast majority of regenerated and sprouted descending axons (Duffy et al., 1990 & 1992). While the function of CSFCNs in general remains unknown, it is possible that a subset of CSFCNs exhibiting ascending axonal regeneration might play a key role in CNS regeneration in the lizard. This might occur by extension of pioneer-type axons, secretion of neurotrophic substances or some other unstated mechanism.

707.6

ENHANCED SPROUTING OF AFFERENT AXONS AND IMPAIRED RECOVERY OF DENTATE GRANULE CELL SPINE DENSITY FOLLOWING A COMBINED ENTORHINAL CORTEX/FIMBRIA-FORNIX (EC/FF) LESION. P. Elyse Schauwecker* and T.H. McNeill, Andrus Gerontology Center and Department of Biological Sciences, University of Southern California, Los Angeles, CA 90089

This study examined the degree to which the loss of multiple synaptic input to the dentate gyrus affects the sprouting of surviving afferent axons and the recovery of dendritic spine density on dentate granule neurons. Specifically, we used a comparison of entorhinal cortex (EC), fimbria fornix (FF) and combined EC/FF lesion models to assess axonal sprouting in the commissural/associational (C/A) fiber plexus and dendritic spine density of dentate granule neurons. Based on data obtained using the Holmes fiber stain we found that similar to previous studies, there was no change in the width of the C/A fiber plexus following a FF lesion and only a transient 25-30% increase after an EC lesion. In contrast, following the EC/FF lesion there was an enhanced (40-45%) but delayed (30 days postlesion) increase in the width of the fiber plexus which remained elevated at 60 days postlesion. By comparison, data from our Golgi analysis suggests that the enhanced sprouting of C/A axons coincides with the impaired recovery of spine density on dentate granule neurons. Specifically we found that spine loss (45%) occurred as early as 4 days postlesion, was maximum at 10 days postlesion and reached 80% of intact values by 30 days post-lesion. However, in strong contrast to the EC lesion the recovery of spine density was transient and was again significantly decreased (50%) at both 45 and 60 days postlesion. L-TYPE Ca^{2+} CHANNEL IS INVOLVED IN THE REGULATION OF SPONTANEOUS TRANSMITTER RELEASE AT DEVELOPING NEUROMUSCULAR SYNAPSES. W.M. Fu* and F.L. Huang, Department of Pharmacology, College of Medicine, National Taiwan University, Taipei, Taiwan.

Involvement of L-type Ca^{2+} channel in the regulation of spontaneous transmitter release was studied in *Xenopus* nerve-muscle cultures. Spontaneous synaptic currents (SSCs) are detectable from the innervated muscle cell with the whole-cell voltage-clamp recordings. The frequency of SSCs, which reflect impulse-independent acetylcholine (ACh) release from the nerve terminals, showed marked increase in high- K^+ medium or after treatment with a phorbol ester, TPA, a drug that activates protein kinase C and depolarizes the presynaptic neuron. The potentiation effect of high K^+ and TPA requires Ca^{2+} influx through L-type Ca^{2+} channel in the plasma membrane, since it was significantly reduced by the presence of nifedipine, verapamil or diltiazem and enhanced by Bay K 8644, a L-type Ca^{2+} channel agonist. It was shown recently that adenosine 5'-triphosphate (ATP) markedly potentiates the spontaneous ACh release at these synapses through the binding of P_2 -purinoreceptors and the activation of protein kinase C. We found that potentiation effect of ATP is inhibited by L-type Ca^{2+} channel blockers, suggesting that L-type Ca^{2+} channel is responsible for the positive regulation of spontaneous ACh secretion by ATP at the developing neuromuscular synapses.

TARGET TISSUES REGULATE THE EXPRESSION OF K^+ -CURRENTS IN CHICK CILIARY GANGLION NEURONS DEVELOPING *IN SITU*. M.M. Dourado¹, C. Brumwell², M.E. Wisgirda¹, M.H. Jacob² and S.E. Dwyer¹, ¹Department of Biological Science, Florida State University, Tallahassee, FL 32306. ²Worcester Foundation for Experimental Biology, Shrewsbury, MA 01545.

Neurons of the chick ciliary ganglion are known to express a voltage-activated, transient A-type K^+ current (I_A) and Ca^{2+} -activated K^+ currents ($I_{K[Ca]}$). These currents first appear, and undergo a large increase in amplitude and density, during the developmental stages at which ciliary ganglion neurons form synapses with their target tissues in the eye. The expression of I_A and $I_{K[Ca]}$ was examined in acutely-isolated E13 chick ciliary ganglion neurons that developed *in ovo* following surgical removal of the optic vesicle at E2, prior to the formation of the ciliary ganglion. I_A was expressed at equal amplitude by neurons developing *in situ* in the absence (OV-) or presence (OV+) of target tissues. However OV-neurons expressed an I_A with activation and inactivation kinetics that were 2-4 times faster than those expressed by OV+ neurons. There were no differences in the voltage-dependence of activation or steady-state inactivation of I_A in OV+ and OV- neurons. The amplitude of macroscopic $I_{K[Ca]}$ was reduced by 75% in OV- neurons compared to OV+ controls. These results indicate that target tissues play a role in regulating the properties of voltage- and Ca^{2+} -activated ionic currents in developing vertebrate neurons.

TRANSCRIPTIONAL REGULATION OF K⁺ ION CHANNEL EXPRESSION IN DEVELOPING CEREBELLAR PURKINJE NEURONS. Y. Li Muller and Andrea J. Yool*. Dept. Physiology, AHSC, Univ. of Ariz., Tucson, AZ 85724.

During the postnatal development of the cerebellum of rat, Purkinje neurons in culture grow from immature cells (day 1-6) to large mature neurons with dendritic outgrowth (day 14-21) (1). This morphological change is associated with the activation of K⁺ ion channels that contribute to the increased complexity of the firing pattern of neurons (2). We hypothesize that the transcriptional regulation of the various channel conductances (K, Ca and Na) influences the differentiation of Purkinje cells. This hypothesis was tested using *Xenopus* oocytes to express polyA-enriched RNA isolated from postnatal rats at different ages (day 1, day 8 and 6 months) using single channel and voltage-clamp analyses. The regulation of the expression of ion channels at the transcriptional level also was analyzed by Northern blot using low stringency hybridization with randomly-primed cDNA from other cloned channels. Based on previous work (2), we predict that the delayed rectifier K⁺ channel (27pS) is expressed during the immature stage (day 1-6); this channel is not sensitive to 0.5 mM TEA. However, the developmentally delayed appearance of Ca²⁺-dependent K⁺ channel (K_{Ca}, 100pS) during differentiation (day 7-9) is hypothesized to show a different pattern of transcriptional regulation. As shown previously (2, 3), K_{Ca} currents were half-blocked at 0.5 mM TEA and sensitive to the intracellular Ca²⁺ concentration. Ongoing experiments will test the hypothesis that the developmental expression of the K_{Ca} conductance plays an essential role in the maturation of Purkinje neurons. EFFECTS OF TETRAETHYLAMMONIUM ON ONE PULSE - INDUCED RELEASE OF NOREPINEPHRINE AND [Ca²⁺]_i IN SYMPATHETIC NEURONS ALONE AND CO-CULTURED WITH TARGET CELLS V. Mashalkar, T.D. Wakade, S.V. Bhawe, D.A. Przywara, A.R. Wakade & P.E. Knapp* Dept. of Pharmacol., Wayne State Univ. Sch. of Med., 540 E. Canfield, Detroit, MI 48201.

Application of 1 pulse (1 msec, 80 mA) evoked release of ³H-norepinephrine (³H-NE) in chick sympathetic neurons (SN) which lasted up to 60 sec & increased [Ca²⁺]_i in neuritis from about 100 to 300 nM. T_{1/2} for decay of [Ca²⁺]_i was about 2 sec. Tetraethylammonium (TEA, 10 mM) prolonged duration of action potential by about 2 fold but did not significantly modify 1 pulse -induced changes in ³H-NE release & [Ca²⁺]_i. After co-culturing SN with cardiac cells or hepatocytes but not with skeletal muscle cells or sensory neurons 1 pulse did not increase either [Ca²⁺]_i or ³H-NE release. However, in presence of TEA, 1 pulse facilitated ³H-NE release & [Ca²⁺]_i over 20 fold in co-cultured SN. T_{1/2} for [Ca²⁺]_i decay in TEA treated co-cultured SN was about 10 sec. TEA prolonged action potential duration of co-cultured SN by 8 fold. We draw 2 conclusions. Target cells are essential for full expression of TEA effects on [Ca²⁺]_i mobilization & transmitter release in SN. TEA interferes with extrusion of [Ca²⁺]_i, in addition to blockade of K⁺ currents, to account for enhanced & prolonged [Ca²⁺]_i & ³H-NE responses.

MECHANISMS UNDERLYING THE DEVELOPMENT OF AFTERDISCHARGE IN THE BAG CELL NEURONS OF *APLYSIA*. L.A. Nick*, L.K. Kaczmarek and T.J. Carew. Interdept. Neurosc. Prog., Depts. of Pharm. and Psychol., Yale Univ., New Haven CT 06520.

The bag cell neurons (BCNs) of adult *Aplysia* generate a long-lasting afterdischarge which triggers egg laying. We have examined the developmental onset of the afterdischarge in the intact CNS and found that the percentage of preparations exhibiting an afterdischarge (to stimulation of the pleuro-abdominal connectives or TEA; Conn and Kaczmarek, 1988) increases systematically as a function of the weight of juvenile animals: 2-11g=2.6% (N=39); 11.1-17g=40% (N=15); 17.1-50g=80% (N=5); >50g=100% (N=11). Consistent with Leibowitz and Castellucci (1983), BCNs of preparations that failed to show an afterdischarge were normally silent but, in response to connective stimulation, exhibited single spikes of low amplitude (<40 mV) and long duration (100 msec). In juvenile BCNs that did not afterdischarge, TEA in concentrations (25-100 mM) that would stimulate a discharge in adults produced recurrent depolarizations, each ~30 mV in amplitude and 3-500 sec in duration. The onset of each depolarization was marked by a single 50-70 mV spike (0.5-1 sec duration). In low calcium (2 mM), the duration of TEA-induced recurrent depolarizations significantly increased (from \bar{x} =7.9 sec to \bar{x} =49.6 sec; p<.01; N=6) suggesting that the depolarizations may normally be terminated by a calcium-activated outward current or calcium-inactivated inward current.

We are currently investigating the development of afterdischarge capacity in cultured juvenile BCNs by measuring ionic currents with whole-cell patch clamp. Although the magnitude of net outward currents across a wide activation range is less than in adults, positive voltage steps from different holding potentials reveal at least 3 outward currents which resemble I_A, I_K(Ca), and I_{KV} described in adults. It will be of considerable interest to further characterize these and other ionic currents and determine their contribution to the development of the afterdischarge in the BCNs.

ANALYSIS OF THE ELECTROPHYSIOLOGICAL CONSEQUENCES OF AXOTOMY OF BULLFROG SYMPATHETIC B-NEURONS. B.S. Jassar*, P.S. Pennefather & P.A. Smith. Dept. Pharmacol., Univ. Alberta, Edmonton, T6G 2H7 and Fac. Pharmacy, Univ. Toronto, Ontario, M5S 2S2, CANADA.

Axotomy of B-neurons in adult bullfrog sympathetic ganglia promotes an increase in spike height and width as well as an attenuation of the amplitude and duration of the afterhyperpolarization which follows the action potential (a.p.; Gordon *et al.*, *J. Physiol.*, 392, 213, 1987). The mechanism of this effect was analyzed using whole-cell recording from dissociated control neurones and neurones dissociated from ganglia 11-13d after cutting the postganglionic nerve. After axotomy, I_{Ba} was reduced by 50%. Most of this effect was due to enhanced inactivation of N-type Ca²⁺ channels. L-type channels, which are responsible for 10-20% of the total I_{Ba} were unaffected. The kinetics of activation/deactivation of I_{Ba} and I_{Na} were little changed yet I_{Na} amplitude increased to about 170% of control. Changes in Ca²⁺-dependent K⁺ currents, I_C and I_{AHP} were the consequence of the reduction in I_{Ca}. Axotomy increased m-conductance to about 135% of control and slowed its deactivation kinetics whereas the delayed rectifier K⁺ current was reduced to about 62% of control amplitude with little change in kinetics. These data account for the axotomy-induced changes in a.p. configuration and show that i) different ion channels are affected in different ways following disruption of neuron-target contact and ii) the complement of ion channels expressed after axotomy is different from what might be expected in an immature neurone. Titmus & Faber (*Prog. Neurobiol.* 35, 1, 1990) have documented the variability of the effect of axotomy on a.p. configuration in various neuronal types. The present results will allow the formulation of a general hypothesis for the effects of axotomy on neuronal electrophysiological properties and provide a basis for investigation of the molecular mechanisms involved. TROPIC EFFECTS OF CARDIAC CELLS ON K⁺ CURRENT, [Ca²⁺]_i AND TRANSMITTER RELEASE IN CULTURED SYMPATHETIC NEURONS.

S.V. Bhawe*, D.A. Przywara, T.D. Wakade & A.R. Wakade. Dept. of Pharmacology, Wayne State University, Detroit, MI 48201.

The pharmacologic behavior of sympathetic neurons (SN) in culture is different from their counterparts growing in the body. The K⁺-channel antagonist tetraethylammonium (TEA) has little effect on evoked release of [³H]norepinephrine ([³H]NE) from cultured SN, but acts in the expected manner seen in mature neuroeffector organs when SN are co-cultured with cardiac cells (Wakade & Wakade, *Neuroscience* 27:1007, 1988). We examined this phenomenon in SN cultured from embryonic chick. TEA (10 mM) caused less than a 2 fold increase in [³H]NE release evoked by 1 Hz stimulation in SN, but caused a 6 fold increase when SN were co-cultured with cardiac cells. Stimulation-induced increase in [Ca²⁺]_i in SN was only little affected by TEA, but was facilitated more than 5 fold in SN co-cultured with cardiac cells. Action potentials (AP) of SN and co-cultured SN had similar shape and duration (3.7 ± 1 and 3.0 ± 0.4 ms at 50% repolarization). TEA caused an approximate 2 fold increase in AP duration in SN grown alone. In co-cultured SN, TEA caused up to 10 fold increase in AP duration. When [Ca²⁺]_i in SN was set to ≤ 100nM using Ca²⁺-EGTA in the patch pipette, TEA increased AP duration as in co-cultured SN. Chick SN provide a unique model to study trophism between cardiac cells and SN. The results indicate that target cells regulate transmitter release and AP repolarization via modulation of [Ca²⁺]_i.

N-TYPE CALCIUM CHANNELS IN NEURODEVELOPMENT - AN AUTORADIOGRAPHIC STUDY. I.M. McIntosh*, A. Schapper, S.R. Naisbitt, B.M. Olivera and F. Filloux. Depts. of Biology, Psychiatry, Pediatrics and Neurology, University of Utah, Salt Lake City, Utah, 84112.

Intracellular calcium ion concentration plays a critical role in nervous system function in general, and has more recently been implicated in neurodevelopmental processes. N-type calcium channels in particular appear to play a role in synaptogenesis and neuronal migration. We have used [¹²⁵I]ω-conotoxin GVIA to autoradiographically study the neurodevelopmental expression of N-type calcium channels in rat brain. In striking contrast to L-type calcium channels which are reported to gradually increase to adult levels, N-type calcium channels appear and disappear in complex temporal and spatial patterns. Developmental patterns include: gradual increase to adult levels (cortex); transient expression (pons); substructure differentiation (cerebellum); and selective depletion (medulla). These results suggest that N-type calcium channels may be important for specific neurodevelopmental sequences. In addition, ω-conotoxins may serve as useful tools for studying disorders with possible neurodevelopmental pathophysiology such as schizophrenia and Sudden Infant Death Syndrome.

SYNAPTOSOMAL $^{45}\text{Ca}^{++}$ UPTAKE PARALLELS SEIZURE SUSCEPTIBILITY IN EPILEPTIC MICE. A.F. Burroughs, J.R. Abbott, M.S. Esplin, and M.J. Litzinger* Department of Pediatrics, University of Utah, Salt Lake City, UT 84132

The N-type voltage sensitive calcium channels (VSCC) on the presynaptic neuronal membrane are involved in neurotransmitter release and action potential propagation. Evidence from ω -conotoxin binding data suggests a difference in VSCC development between genetically related audiogenic seizure mice (DBA/2J) and their non-epileptic counterpart (C57/B1). Our goal was to determine if presynaptic Ca^{++} uptake differed as did VSCC development. $^{45}\text{Ca}^{++}$ uptake into synaptosomes was monitored from postnatal days (PND) 3-60 using fresh DBA and C57 whole brains. Synaptosomes were depolarized with a 50 nM potassium solution to induce Ca^{++} flux across the membrane. The C57 mice showed an increase in Ca^{++} uptake from PND 9 through PND 17 where it peaked. The amount of Ca^{++} uptake plateaued between PND 25-60. The DBA mice also showed a Ca^{++} uptake increase beginning at PND 9 which peaked at PND 25. Preliminary data shows Ca^{++} uptake for the DBA mice between PND 17-60 to be $>50\%$ in comparison with those values obtained for the C57 Ca^{++} uptake at that age. We found that the pattern of increase in $^{45}\text{Ca}^{++}$ uptake from synaptosomes through development followed the profile for the juvenile onset of audiogenic seizure susceptibility in DBA mice. This increase in susceptibility to depolarization and potential loss of Ca^{++} homeostasis may play a critical role in the audiogenic seizure onset in DBA mice.

QUANTIFICATION AND QUALITATIVE ASSESSMENT OF DEVELOPMENTAL BRAIN Na^+ CHANNEL mRNA EXPRESSION BY RNASE PROTECTION ASSAY COMBINING A COMMON PROBE WITH SPECIFIC 3' END PROBES. J.L. Walewski, D.F. Catanzaro, J.R. Sparrow*, and E. Recio-Pinto. Cornell University Medical College, Depts. of Anesthesiology, Physiology and Ophthalmology, New York, NY 10021.

To quantify various brain mRNAs encoding voltage-dependent Na^+ channels we generated a 161b cRNA probe which recognizes a segment of high homology between the three known genes. Therefore in RNase protection assays this probe gives rise to three protected fragments, corresponding to mRNAs encoding either type I (107b); type II (71b) or type III (161b) Na^+ channels. Quantification with this common probe, when compared to the specific 3' probes for mRNA encoding Na^+ channel types I, II or III, allowed us to investigate whether there were additional Na^+ channel mRNAs. Additional mRNAs could be grouped based on their resemblance to one of the known Na^+ channel types. The combination of differential recognition of various mRNAs by using a single common cRNA probe, together with the use of specific 3' cRNA probes provides a strong tool for quantifying mRNAs encoding known Na^+ channels as well as detecting and quantifying other putative Na^+ channel mRNAs. We have begun using this approach to provide new information regarding changes in brain Na^+ channel mRNAs under different developmental conditions. J.L.W. is an Aaron Diamond Foundation Fellow and this work was supported in part by a grant from The Aaron Diamond Foundation. Additional support was provided by the Depts. of Anesthesiology and Surgery, Cornell University Medical College.

EXPRESSION OF *SHAB* TRANSCRIPTS IN THE EMBRYONIC *XENOPUS LAEVIS* NERVOUS SYSTEM. C. Burger* and A.B. Ribera. Programs in Cellular & Developmental Biology and Neuroscience, University of Colorado Health Sciences Center, Denver, CO.

Voltage-activated potassium channels belong to a multigene family that includes the *Shaker*, *Shal*, *Shaw* and *Shab* gene subfamilies. Delayed rectifier potassium currents regulate the differentiation of electrical excitability in amphibian spinal neurons. To understand the molecular basis of potassium channel gene expression in these neurons, we are identifying relevant members of the potassium channel gene family. We describe here the characterization of *Shab* genes expressed in the embryonic *Xenopus* nervous system.

Degenerate oligonucleotide primers and PCR generated *Xenopus* *Shab* products that were used as probes for the screening of a *Xenopus* tadpole brain cDNA library. We isolated three different *Xenopus* *Shab* cDNAs: XShab 6, 9 and 12. Partial sequence analysis of XShab 6, 9 and 12 confirms their identity as *Shab* homologues. Over the region spanned by the S2 and S5 transmembrane domains, XShab 6, 9 and 12 are 88%, 77%, and 95% identical, respectively, at the amino acid level to mammalian *Shab* genes. Additional sequence information indicates that although XShab 6 has its 5' end within the coding region, both the 5' and 3' ends of XShab 9 and 12 appear to contain untranslated sequences. Thus XShab 9 and 12 are likely to contain the entire coding region. Functional expression in oocytes will extend the interpretation of sequence data.

In situ hybridization studies indicate that XShab is widely expressed throughout the amphibian spinal cord during the period when the endogenous delayed rectifier current has been functionally characterized. Supported by NIH NS25217 and NS01531.

ALTERATION OF PEPTIDERGIC AND MUSCARINIC CALCIUM SIGNALING IN TRANSFECTED N1E-115 CELLS. Jay S. Coggan*, Ildikó Kovács and Stuart H. Thompson. Hopkins Marine Station, Department of Biological Sciences, Stanford University, Pacific Grove, CA 93950.

In murine N1E-115 neuroblastoma cells muscarinic and bradykinin receptors are linked to calcium (Ca^{++}) release from internal stores and Ca^{++} influx. Responses to agonists were measured with fura-2/AM fluorescence video microscopy. Undifferentiated cells respond to bradykinin but not carbachol, whereas 2% DMSO differentiated cells respond to both. N1E-115 cells were stably transfected with an antisense sequence to the binding region of the type 1 IP_3 receptor. The aminoglycoside G418 was used to select for transfected clones. After selection, if G418 was present during DMSO differentiation, greater than 90% of normal sensitivity to carbachol, but not bradykinin, was lost. Those differentiated without G418 retained normal muscarinic calcium release. Acute incubation with G418 had no effect on the muscarinic responses. In one of eight undifferentiated, antisense-transfected clones, responses to bradykinin were 99% attenuated by removing extracellular calcium. This result indicates that Ca^{++} release in this clone is significantly reduced, leaving only the Ca^{++} influx component. In differentiated clones responses to bradykinin were as in normal cells. Supported by NIH NS14519.

708.12

EXPRESSION OF CALCIUM CHANNEL TRANSCRIPTS IN THE EMBRYONIC AMPHIBIAN NERVOUS SYSTEM. M. A. Cecchini* and A. B. Ribera. Neuroscience Program and Department of Physiology C-240, University of Colorado Health Sciences Center, Denver, CO 80262.

Amphibian spinal neurons initially fire long duration calcium-dependent action potentials. Immature neurons are spontaneously active, generating transient intracellular calcium elevations which regulate aspects of neural differentiation. Impulse duration subsequently shortens due to increased voltage-dependent potassium conductance. The molecular basis for this program of electrical excitability is being analyzed using probes for voltage-dependent ion channel genes. Given the developmental requirement for calcium influx, our efforts focus on calcium channels.

A partial clone encoding a *Xenopus* calcium channel gene has been isolated by homology screening with rat neural-specific calcium channel sequences (kindly provided by Dr. T. Snutch). The 6 kb clone contains 3 kb of coding region spanning part of domain III and all of domain IV plus ~3 kb of 3' untranslated sequence. It is most related to the mammalian rCa calcium channel sequences and thus called XCaA. *In situ* hybridization assays indicate that XCaA transcripts are detectable throughout the central nervous system. In addition, the mRNA is detected in a region within the middle of each myotome. However, one day later this signal is reduced in intensity.

The temporal pattern of transcription of XCaA is consistent with a putative role in regulating excitability of developing neurons. Furthermore, these results indicate a transient pattern of expression for XCaA mRNA in peripheral structures.

EXPRESSION OF Kv3.1 mRNA ENCODING A VOLTAGE-GATED K^+ CHANNEL DURING RAT CEREBELLAR DEVELOPMENT. S. Verma* and R.H. Joho. Department of Cell Biology and Neuroscience, The University of Texas Southwestern Medical Center, Dallas, TX 75235-9111.

Kv3.1(Kv4/NGK2) is a voltage-gated K^+ channel found in different brain areas but it is particularly highly expressed in the granule and Purkinje cell layer in the cerebellum. Northern blot analyses with mRNA from postnatal days P1, P3, P7, P11, P15, and P20, and from adult rat brain showed that Kv3.1 expression started around P11 and increased steadily up to and past P20 to reach adult levels. We used *in situ* hybridization on sections of the developing cerebellum (P7, P11, P15, and P20) to study mRNA expression in the external germinal layer (EGL), the molecular layer (ML), the Purkinje cell layer, and in the granule cell layer (GCL) during postnatal cerebellar development. In particular, we addressed the question whether Kv3.1 mRNA expression can be detected in migrating granule cells, or whether its expression is confined to postmigratory cells located in the granule cell layer.

Expression levels (numbers of silver grains/area) were similar in EGL, ML, and GCL on P7. An increase of Kv3.1 mRNA expression in granule cells in GCL was first observed around P11. At P20 there was at least a five-fold increase in grains in GCL over EGL. Even during the peak of granule cell migration, the number of grains/area in EGL and ML never exceeded the number found at P7. From visual inspection, it appears that the premigratory cells in EGL and the migrating granule cells in ML do not express Kv3.1. (Supported by NS28407 to R.H.J.)

DEVELOPMENT OF Ca^{2+} ; HOMEOSTASIS MECHANISMS IN EMBRYONIC RAT CEREBRAL CORTICAL CELLS USING FLUO-3 AND FLOW CYTOMETRY. L. Maric*, D. Maric, S.V. Smith and J.L. Barker. Laboratory of Neurophysiology, NINDS, NIH, Bethesda, MD 20892.

We have previously utilized flow cytometry and a voltage-sensitive fluorescence indicator dye in order to describe the development of resting and excitable plasma membrane properties of rat cerebral cortical cells during embryonic (E) histogenesis. Here we report on the development of Ca^{2+} homeostasis of the same cell preparations isolated over E11-22 using a Ca^{2+} -sensitive fluorescence indicator dye, Fluo-3. Acutely dissociated single cell suspensions were loaded with μM Fluo-3 and their resting and stimulated cytosolic calcium (Ca^{2+}_c) levels were recorded at the rate of ~1000 cells/sec using a flow cytometer. Ca^{2+}_c levels were estimated with ionomycin, a Ca^{2+} ionophore, and $MnCl_2$. The results reveal a characteristic cellular distribution of resting Ca^{2+}_c , which we have classified into three primary subpopulations: (1) relatively low Ca^{2+}_c (80-150nM), (2) moderate Ca^{2+}_c (150nM-600nM) and (3) relatively high Ca^{2+}_c (>600nM). The percentage of cells with each of these Ca^{2+}_c levels was age-dependent with many cells exhibiting higher Ca^{2+}_c levels (>150nM) over E11-14 and >90% of cells having relatively low Ca^{2+}_c during E15-22. Ca^{2+} homeostasis in these subpopulations depended on the presence of Na^+ - Ca^{2+} exchange mechanisms, pools of sequestered Ca^{2+} ; and their voltage-sensitivity, and voltage-dependent and/or receptor-operated Ca^{2+} channels. These aspects of Ca^{2+} homeostasis were temperature dependent and could be correlated with the proliferation/differentiation status of the cells. Stimulation with veratridine, a Na^+ channel activator, γ -aminobutyric acid, glycine and glutamic acid evoked characteristic and complex Ca^{2+} responses that were highly age-dependent and cell subpopulation-specific. These results demonstrate that flow cytometric analysis of Ca^{2+} -sensitive fluorescence signals allows a relatively quick, sensitive and effective characterization of Ca^{2+} homeostasis mechanisms for entire populations of cerebral cortical cells throughout embryonic development.

708.17

REGIONAL AND SUBCELLULAR DISTRIBUTION OF N-TYPE Ca^{2+} CHANNELS IN LIVE DEVELOPING RAT HIPPOCAMPUS L.R. Mills*, C.E. Niesen, O.T. Jones, A.P. So and P.L. Carlen. Playfair Neurosc. Unit, MRC group "Nerve Cell and Synapses", Univ. of Toronto, Toronto, ON. CANADA M5T 2S8

Influx of Ca^{2+} through neuronal voltage-dependent channels (VDCC) plays a critical role in multiple cellular functions. Using fluorescein-tagged ω -conotoxin (Fl- ω -CgTx) we examined the spatial distribution of N-type VDCCs in the developing rat hippocampus. In the adult, N-type VDCCs are present on the soma, dendrites and dendritic spines of neurons in areas CA1-3 and dentate gyrus (DG). In newborn live hippocampal slices, detectable N-type VDCCs were restricted to somata of neurons in area CA3; areas CA1-2 and DG showed only scattered Fl- ω -CgTx positive cell bodies. By 4 days postnatal (dpn), cells were labelled in areas CA1-CA2. During this period, Fl- ω -CgTx positive cells were apparent in other regions of the developing hippocampus, most notably above layers CA1-3 and in the hippocampal fissure. Such cells appeared to be migrating. Areas adjacent to the hippocampus (entorhinal cortex, developing fimbria), the stria terminalis and neocortex also contained Fl- ω -CgTx labelled cells. By 1 week, labelled soma were present in all hippocampal regions. CA3 neurons showed labelling of proximal dendrites extending out 20-40 microns. By 12 dpn, further labelling of dendrites in CA3 and along initial segments of dendrites in CA1 and DG was observed.

Lucifer Yellow fills in 4 day old CA1 neurons revealed apical dendritic arborization extending 300 microns into the stratum radiatum. By 12 dpn, the dendritic tree was enlarged but spinous processes were absent. These results demonstrate the regional and time-dependent ontogeny of N-type VDCCs in the rat hippocampus. In CA1 neurons, N-type Ca^{2+} channels are not present at birth, appear on the soma during the first week of life and are exported to already formed dendritic processes over the second-third week of life.

DIFFERENTIAL REGULATION OF ASTROCYTE-DERIVED GROWTH MODULATORY PROTEOGLYCAN AND THEIR INTRINSIC PROPERTIES ARE DETERMINANTS OF REGENERATIVE NEURITE GROWTH IN AN ASTROCYTE MILIEU IN VITRO. M. Guo, K. Dow*, R. Kisilevsky and R. Riopelle. Apps Research Centre of Kingston General Hospital, Queen's University, Kingston, CAN. K7L 2V7.

Mammalian Type 1 astrocytes *in vitro* synthesize and release large quantities of proteoglycans, and heparan sulfate proteoglycans account for virtually all of the substrate-associated neurite growth-promoting activity of astrocyte-conditioned medium. Chromatographic procedures have facilitated characterization of two astrocyte PG's released to conditioned medium. A 510 kDa heparan sulfate proteoglycan (HSPG) and a 58 kDa chondroitin/dermatan sulfate hybrid PG (CS/DSPG) with similar charge densities accounted for 17% of the total released PG's. The two PG's were differentially regulated by growth phases of the astrocytes. In conditioned medium of confluent, non-proliferating cultures the molar ratio of the HSPG to the CS/DSPG was approximately 1:10. However, in subconfluent cultures where astrocytes continued to proliferate, virtually no 510 kDa HSPG was detected.

Both PG's displayed neurite growth-promoting properties when immobilized on a poly-D-lysine substrate, but on a molar basis the 510 kDa HSPG had some 40,000-fold higher specific neurite-promoting activity. By virtue of its higher avidity of binding to the poly-D-lysine substrate, the CS/DSPG inhibited the neurite-promoting activity of the HSPG by displacing it from the substrate.

POSTNATAL DEVELOPMENT OF HIGH THRESHOLD Ca^{2+} CURRENTS IN RAT HIPPOCAMPAL CA1 NEURONS. C.E. Niesen*, O.T. Jones, L.R. Mills and P.L. Carlen. Playfair Neuroscience Unit, Toronto Hosp. Research Inst., Univ. of Toronto-NCE Program, Toronto, ON. CANADA M5T 2S8

Striking developmental changes occur in the early postnatal mammalian CNS, including the genesis of many ionic currents. We studied the ontogeny of voltage-dependent Ca^{2+} currents (VDCC) in hippocampal slices from 3 day to 3 week old rats, using the whole-cell patch technique.

The high threshold L-type current was evoked from holding potentials (V_H) = -25 to -35 mV. The peak amplitude of this current "grew" as follows: 3-4 days postnatal (dpn), approx. 100 pA; 7-8 dpn, 250 pA; end of the second week, 1000 pA; end of the third week, 0.9-1.4 nA. Bath perfusion of 2-3 μM nimodipine blocked 60% of this current in the mature animal, while in the newborn of 1 week, < 30% of the L-type current is blocked. In 2 week old CA1 neurons, near adult levels of blockade were achieved by nimodipine.

A small, high threshold (HT) Ca^{2+} current was elicited only variably by large depolarizing steps from V_H = -75 mV in the 4-5 dpn CA1 neuron. In CA1 neurons at 1 week of age, the amplitude was 300-500 pA and the HT current could be evoked consistently. In 2 week old cells, the peak amplitude of this current was 1800 pA and tripled again by the end of the third week. Droplet application of 10 μM ω -conotoxin had little effect on the HT current at 1 week, blocked 20% at 2 weeks and decreased the HT current in 3 week old cells by 30-35% (adult levels).

Both L- and N-type VDCCs showed marked postnatal development, though at different rates. The L-type current tripled its amplitude during the second week, while the N-type current emerged during the second and third weeks postnatal. This confirms imaging studies with fluorescent ω -conotoxin on CA1 neurons that showed a similar, time-dependent genesis of the N-type VDCC, coincident with its spread from soma to dendrites (see L. Mills et al., Soc. for Neurosci. Abst., 1993).

CARDIAC CELLS CONTROL $[Ca^{2+}]_i$ AND TRANSMITTER RELEASE IN CULTURED SYMPATHETIC NEURONS.

D.A. Przywara*, S.V. Bhawe, T.D. Wakade, V. Mashalkar & A.R. Wakade. Dept. of Pharmacology, Wayne State University, Detroit, MI 48201.

Ca^{2+} -dependent changes in growth, survival and transmitter phenotype of developing sympathetic neurons (SN) are controlled by factors released by other cells. Here we show that postsynaptic effector cells control Ca^{2+} entry and [3H]norepinephrine ([3H]NE) release properties of developing SN. SN cultured alone exhibited maximal elevation of $[Ca^{2+}]_i$ and [3H]NE release during low frequency stimulation. Co-culturing SN with cardiac cells reduced stimulated [3H]NE release, $[Ca^{2+}]_i$ and voltage-clamped Ca^{2+} -current by 3 to 5 fold. Co-cultured SN had a positive frequency-[3H]NE release response, characteristic of mature sympathetic neuroeffector organs. This trophic maturation was produced within 24 hrs by sympathetic neuroeffector cells, but not by conditioned medium or other cell types. [3H]NE release was correlated most closely with total $[Ca^{2+}]_i$ during the stimulation period rather than with peak $[Ca^{2+}]_i$. Our studies show that SN supported by only NGF under optimal culture conditions exhibit abnormal Ca^{2+} homeostasis and transmitter release. The abnormalities are corrected by including physiological targets in culture.

Characterization and expression of insulin-like growth factor system components during optic nerve regeneration. C. M. Hall* and J. Hötner. Dept. of Anatomy and Cell Biology, University of Göteborg, S-413 90 Göteborg, Sweden

Components of the insulin like growth factor (IGF) system are produced by both neurons and glial cells in the CNS. In order to investigate the role played by IGF-I during nerve regeneration we have characterized IGF-I membrane receptors and soluble IGF binding proteins expressed in the goldfish visual system. Affinity cross-linking showed that two IGF-I receptor subunits of mw. 110 and 120 kD are synthesized in goldfish nervous tissue. Competition binding assays showed that retinal membranes contained IGF-I binding sites that displayed equal high affinity for IGF-I and IGF-II while having more than 1000-fold lower affinity for insulin. The soluble fractions of goldfish retina and brain contained at least three different IGF-binding proteins of apparent mw. 22, 27 and 31 kD. Following crush of the optic nerve, goldfish retinal ganglion cells undergo functional regeneration. Expression of IGF-I binding sites was investigated during optic nerve regeneration using 125I-IGF-I binding to fresh cryosections of regenerating retina followed by autoradiography. In the normal eye there was a prominent binding of IGF-I to all retinal layers. During the phase of axonal regrowth there was a markedly increased expression of IGF-I binding sites in the inner plexiform, retinal ganglion cell and optic nerve fiber layers. The time-course of increased IGF-I binding corresponds to the time during which the optic nerve displays accelerated growth in response to a second lesion-the conditioning lesion effect. These results support a role for IGF-I as a neurotrophic factor.

CLONING OF A NOVEL NEURONAL G PROTEIN-COUPLED RECEPTOR WITH HOMOLOGY TO THE LDL-RECEPTOR. C.P. Tensen^{1,2}, E.R. van Kesteren², R.J. Planta², E. Vreugdenhil² and H. van Heerikhuizen². ¹Department of Biology, ²Department of Biochemistry and Molecular Biology, Vrije Universiteit, De Boelelaan 1083, 1081 HV Amsterdam, The Netherlands.

In our search for G protein-coupled receptors (GPRs), we have isolated and characterized a cDNA from the central nervous system (CNS) of the mollusc, *Lymnaea stagnalis*, encoding a protein of 1115 amino acids with close sequence similarity to two different types of receptor proteins. Following a twenty residue long signal peptide, the N-terminal part of the protein contains two types of internal repeated sequences. The first type of repeat displays a high sequence similarity with the binding domains of the low density lipoprotein (LDL)-receptor, a characteristic thus far only found in the LDL receptor-related protein (LRP) and glycoprotein GP330. The second repeat and the C-terminal part of this receptor are homologous to specific regions of a set of GPRs, the mammalian glycoprotein hormone receptors. In situ hybridization experiments revealed that the mRNA encoding this receptor (designated GRL101) is predominantly located in a cluster of 15-20 neurons within the CNS. The structural resemblance of the N-terminal part of GRL101 with the binding domains of the LDL receptor and its specific expression in a small number of neurons, suggest a role for lipoprotein-like molecules in neuronal G protein-mediated signal transduction. Alternatively, GRL101 might be a receptor for ligands similar to those for LRP. This receptor was originally proposed to have a role in lipoprotein metabolism; recently it has become clear that it is a multiple ligand receptor that can recognize and internalize additional non-related ligands i.e. uPA-PAI-1 complexes. Effects of uPA-PAI-1 and a related protein, tPA, on neuronal outgrowth and plasticity were recently reported and we therefore hypothesize that GRL101 might be the first member of a novel class of GPRs that directly transduce signals carried by large extracellular (lipo)protein-complexes, into neuronal events mediated by G-proteins.

709.5

ROLE OF A FREE RADICAL SCAVENGER (Egb 761) IN THE MOUSE VISUAL SYSTEM PLASTICITY. P. Clairambault¹, R. De Guevara¹, G. Pinganaud¹, M.T. Droy-Lefaix² and Y. Christen^{2*}. Lab. Neuroembryology, University Paris VII ; IPSEN Research Lab., Paris, France.

To analyse the role of a free radical scavenger (Egb 761, IPSEN, France) on the nervous system plasticity, we studied the mouse dorso-lateral geniculate nucleus (dLGN) at 30 days post-natal (PN 30) using the autoradiographic technique after 3H proline injection (Amersham, 6 μ Ci in 6 μ l) in one eye. Morphological and quantitative data were gained at PN 30 in control animals and in unilaterally enucleated at birth. Concurrently, two similar groups were treated with Egb 761 (100 mg/kg, per os, 30 days). A comparative quantitative volumetric analysis between the 4 groups was undertaken either in the dLGN or in the geniculate visual neuropil.

After deafferentation, a significant decrease of the dLGN volume and a significant increase of the visual neuropil was observed on the side ipsilateral to the injected eye, only in the mice treated with Egb 761 suggesting a role of Egb 761 on the plasticity of the retino-geniculated connections.

709.7

REGULATION OF FGF-2 AND HIGH-AFFINITY FGF-RECEPTOR IN SPINAL GANGLIA AND PERIPHERAL NERVE AFTER LESION. Grothe C.* and Janet T., Institute of Anatomy, University of Freiburg, D-7800 Freiburg and Dept. of Anatomy and Cell Biology, University of Heidelberg, D-6900 Heidelberg, F.R.G.

The regulation of basic fibroblast growth factor (FGF-2) and FGF-receptor (R) and their mRNAs in rat dorsal root ganglia (DRG) and sciatic nerve was studied after different lesion protocols.

Sciatic nerve ligation reveals neither a distal nor a proximal accumulation of FGF-2-immunoreactivity (IR). Sciatic nerve crush leads to a decrease of FGF-2- and FGFR-IR in the distal stump; also the proliferating Schwann cells display no FGF-2 or FGFR staining. In the proximal stump no change of the staining pattern compared to control rats is found. Sciatic nerve axotomy results in an increase of the portion of FGF-2- and FGFR-IR DRG neurons. This result could suggest that i) FGF-2-ir neurons are selectively protected from axotomy-induced death or ii) an additional population of neurons is induced to express FGF-2 IR after axotomy.

Northern blot analysis shows a time-dependent regulation of FGFR-1 (*flg*) mRNA in the distal and proximal stump after nerve crush.

These regulatory changes in FGF-2 and FGFR expression suggest that the factor is involved during de-/regeneration. (Supported by DFG Gr 857/4-2)

709.4

MODAFINIL - A POTENTIAL NEUROPROTECTIVE AGENT IN THE MOUSE 1-METHYL-4-PHENYL-1,2,3,6-TETRAHYDRO-PYRIDINE (MPTP) MODEL OF PARKINSON'S DISEASE (PD).

A.M. Janson^{*}, K. Fuxe², M. Goldstein and L.F. Agnati¹. ¹Dept of Histology and Neurobiology, Karolinska Institutet, Box 60400, S-104 01 Stockholm, Sweden; ²Dept of Psychiatry, New York Univ. Med. Center, New York, NY 10016; ³Dept of Human Physiology, Univ. of Modena, Via Campi 287, I-41100 Modena, Italy.

The vigilance promoting drug Modafinil (diphenyl-methyl-sulfinyl-2-acetamide) is demonstrated to protect against MPTP (40 mg/kg sc) toxicity in the nigrostriatal dopamine (DA) system of the black mouse.

A single dose of Modafinil (30 mg/kg ip) at different time intervals before and after MPTP significantly counteracted the MPTP-induced depletion of neostriatal DA as analyzed 14 days later. Modafinil also significantly counteracted the paradoxical MPTP-induced increase in locomotion and motility as analyzed after two weeks.

Chronic administration of Modafinil (30 mg/kg ip daily for 14 days) led to a more pronounced counteraction of the MPTP-induced decrease in striatal DA and also attenuated the MPTP-induced increase in DA turnover. After a similar chronic treatment with Modafinil (10-100 mg/kg) the disappearance of tyrosine hydroxylase immunoreactive neurons in the substantia nigra appeared to be dose-dependently counteracted.

The mechanism of action has not yet been fully established, but it seems to be different from monoamine oxidase B inhibition or blockade of the DA reuptake transporter. The neuroprotective action of Modafinil could lead to new pharmacological strategies in PD.

709.6

THE EFFECTS OF α -MSH and ACTH 4-10 ON MUSCLE FIBER TYPE COMPOSITION OF FAST MUSCLE FOLLOWING NEONATAL SCIATIC CRUSH INJURY. L.A. Zuccarelli^{*} and F.L. Strand. Department of Biology and Center for Neural Science, New York University, New York, New York 10003.

Adrenocorticotrophic hormone (ACTH) has been shown to enhance the regeneration of peripheral nerve and accelerate the maturation of the developing neuromuscular system. These peptides also have potent positive effects on regeneration during development. Peptide-treated reinnervated developing motor endplates exhibit the size and complexity of interior nerve branching at the nmj comparable to uncrushed neonatal endplates. Here we report on the effects of fragments ACTH 4-10 and α -MSH on the maturation and reinnervation of the extensor digitorum longus (EDL) muscle of 2-day-old rodents which undergo sciatic nerve crush. At 60 days postnatal, the EDL muscles are excised and their weights recorded. The muscles are prepared for staining with myofibrillar ATPase at both alkaline and acid preincubation conditions. Muscle fiber cross-sections are analyzed for fiber type, distribution of fiber type groups and cell density.

The results show that the development of the EDL muscle is accelerated by peptide treatment even in the face of trauma. Neither muscle fiber type composition by percentage nor the distribution of fiber types within the muscle is altered significantly by either denervation or peptide treatment. There is some indication that fiber type grouping is occurring in α -MSH-treated muscle; these muscles also exhibit more complete reinnervation. Muscle weight comparisons and cell density measurements show that peptide-treated muscles exhibit less atrophy than saline counterparts. These results continue to support the efficacious role of ACTH/MSH peptides in PNS regeneration.

IMMUNOCYTOCHEMICAL LOCALIZATION OF ACTH 4-10 IN THE ADULT RAT BRAIN AFTER 6-OHDA LESIONING OF THE SUBSTANTIA NIGRA. F.J. Antonawich^{*}, S.J. Lee and F.L. Strand. Department of Biology and Center for Neural Science, New York University, New York, N.Y. 10003

Adrenocorticotrophic hormone (ACTH 1-39) is a naturally secreted neuropeptide possessing both neurotrophic (amino acids 1-10) and corticotrophic properties (amino acids 11-39). Administration of its neurotrophic fragments, and their synthetic analogs, has demonstrated potent effects on the central and peripheral nervous systems. Following 6-OHDA lesions of the nigrostriatal system, Org 2766 (an ACTH 4-9 analog) provides rapid neurotrophic actions by both accelerating compensatory mechanisms necessary for functional recovery and promoting cell survival by providing neuronal protection (Antonawich et al., 1993, Peptides, submitted).

Prior studies using antisera to ACTH 1-39 and ACTH 11-24 have demonstrated immunoreactivity (Ir) in various nuclei of the circumventricular organs. Recent work by Lee et al., 1992 (Society for Neuroscience Abstract #121.2) using an antiserum against the neurotrophic ACTH 4-10 fragment demonstrated Ir in the cerebral cortex, striatum, medial septal area, hippocampus, periventricular area and arcuate nucleus of neonatal brains, while in the adult brains, Ir was restricted to fibers of the arcuate and medial septal area.

Adult male Sprague Dawley rats were lesioned unilaterally with 6-hydroxydopamine (8 μ g/4 μ l) infused into the striatum. Immunocytochemical localization of anti-ACTH 4-10 was performed 6 days following surgery. It was evident in the injured nigrostriatal system with a more pronounced reactivity on the lesioned side of the brain, where both the substantia nigra and the caudate nucleus of the striatum demonstrated positive staining. Therefore, it appears that the neurotrophic fragment of ACTH reappears in adults following injury to the nigrostriatal system.

CHANGES IN EXPRESSION OF BASIC FGF INDUCED BY SPINAL CORD ISCHEMIA. D.A. Shackelford¹, D.A. Otero¹, J. Hogg², A. Baird², A.L. Miller^{1*} and J.A. Zivin¹. ¹Dept. of Neurosciences, UCSD, La Jolla, CA 92093-0624 and ²Whittier Institute, 9894 Genesee, La Jolla, CA 92037.

Ischemic injury to the brain causes an increase in bFGF and other trophic factors that can help and/or hinder functional neurological recovery. We investigated ischemia-induced changes in the endogenous expression of bFGF mRNA and protein in the rabbit spinal cord ischemia model. Northern analysis of RNA isolated from spinal cords of rabbits subjected to ischemia showed no change in the steady state level of bFGF RNA induced by 0 to 60 min of ischemia. However, an increase in bFGF RNA was seen after 18 h of reperfusion following a 60 min ischemic episode which results in permanent paraplegia in essentially all rabbits. Current studies aim to determine the time course of induction of bFGF RNA, and the cell type producing it in response to reversible versus irreversible ischemia. The protein levels of bFGF in the rabbit spinal cord homogenates were analyzed by immunoblotting. In the particulate fraction, three forms of M_r = 26k, 23k, and 18k were observed. In the cytosolic fraction mainly two forms of M_r = 24k and 18k were detected. The 23-26k Da forms are probably the result of amino-terminal extensions due to the use of alternative initiation codons as reported in other species. Spinal cord ischemia induced the transient appearance of new species of all three FGF forms with decreased electrophoretic mobility resulting in six bands of M_r = 27k, 26k, 24k, 23k, 19k, and 18k (i.e., three apparent doublets). This was observed after 3-5 min of ischemia and by 15 min the new forms were no longer detected in all animals. The slower migrating forms were also detected in homogenates from animals reperused for 18-96 h. The contribution of phosphorylation or other modification of bFGF to the shift in mobility is being investigated.

CYTOKINE GENE EXPRESSION FOLLOWING TWO MODELS OF BRAIN INJURY. R.M. Klein, R. Choudhuri, J. B. Meara, S. De, V. H. Gattone II*, and N.E.J. Berman. Department of Anatomy and Cell Biology, University of Kansas Medical Center, Kansas City, KS 66160-7400

Cytokines such as tumor necrosis factor alpha (TNF- α) are involved in cellular responses to injury. Microglia, the resident macrophages of the brain, are activated and produce cytokines in response to stimulation by bacterial lipopolysaccharides (LPS). We studied expression of TNF- α and microglial activation in two models of brain injury. To provide a model of injury alone, we injected 5 μ l PBS directly into the cerebral cortex of adult CD-1 mice. To provide a model of brain injury in which microglia are activated, we injected LPS directly into the cerebral cortex. Microglial activation was visualized by Fc receptor expression using nonspecific attachment of IgG. LPS injections activated ramified microglia throughout the brain, while PBS injections only activated amoeboid microglia in the vicinity of the damage. We studied mRNA levels for TNF- α by Northern blotting, and expression of TNF- α protein by ELISA, bioassay and immunohistochemistry. Following injection of LPS, TNF- α message levels in the brain increased at 2 hr, decreased by 4 hr, but increased again significantly 4 days later, and remained elevated for up to 7 days. TNF- α protein was not detectable in uninjured brain by ELISA or bioassay, but increased after both forms of injury. *In situ* hybridization and immunohistochemical studies indicated that the predominant source of TNF- α mRNA and protein is injured neurons rather than microglia in both injury models. Supported by MH38399 and HD02528.

709.13

EXPRESSION OF hNT3 IN RAT FIBROBLASTS: IMPLICATIONS FOR INTRACEREBRAL GRAFTING. M.C. Senut¹, N.H. Liou¹, S.T. Suhr¹, H.K. Raymon¹, K.R. Jones², L.F. Reichardt^{2*}, and F.H. Gage¹. 1. UCSD, La Jolla, CA 92093; 2. UCSF, San Francisco, CA 94143.

Neurotrophin 3 (NT3) has been shown to promote the survival of noradrenergic locus coeruleus neurons as well as other cell types. Long term goals are to assess the biological effects of NT3-producing fibroblasts in normal and lesioned rat brains. Initial studies sought to optimize conditions for NT3 mRNA expression in rat fibroblasts such as 1) promoter and enhancer, 2) culture medium, 3) cell passage number. We designed six different retroviral vectors by inserting the cDNA coding for human NT3 (hNT3) behind either a cytomegalovirus (CMV) or a Moloney murine leukemia virus long term repeat (MLV-LTR) promoter. The effects of upstream tissue-specific enhancers were also evaluated. Primary skin fibroblasts obtained from Fischer 344 rats were infected with the different retroviral vectors expressing hNT3 and a selectable neomycin resistance gene. Uninfected fibroblasts or fibroblasts infected with β -galactosidase were used as controls. NT3 mRNA expression was assessed at different confluent states using PCR and Northern blot analysis. All vectors achieved NT3 mRNA expression in rat fibroblasts, although at various levels. Fibroblasts carrying CMV promoter demonstrated NT3 mRNA levels 2 to 3 fold higher than those carrying MLV-LTR promoter. Fibroblasts with CMV and MLV-LTR promoters expressing hNT3 were selected to be transplanted in different rat brain regions. Preliminary results show that implanted cells survived well after grafting. We are currently investigating the levels of produced and secreted NT3 in the infected fibroblasts *in vivo* and *in vitro*. (Supported by NATO grant 58C91FR and by NIH grant TWO4813).

709.10

PERMANENT RESCUE OF AXOTOMIZED CLARKE'S NUCLEUS NEURONS REQUIRES MORE THAN TARGET-DERIVED NEUROTROPHIC FACTORS. B.T. Himes* and A. Tessier. Dept. of Anatomy and Neurobiology, The Medical College of PA and VA Medical Center, Philadelphia PA.

The 40% loss of Clarke's nucleus (CN) neurons that follows axotomy in neonatal rats has been attributed to loss of target derived neurotrophic factors. Axotomized CN neurons are rescued for at least 2 months by transplants of embryonic CNS (spinal cord, cerebellum and neocortex) which contain the mRNA for the neurotrophic factor neurotrophin-3 (NT-3), but not by embryonic striatum, which does not contain mRNA for NT-3. At least one peripheral organ that contains mRNA for NT-3, the renal cortex from late embryonic to early postnatal donors, also rescues axotomized CN neurons. To determine whether this rescue is permanent (4 months or longer), P2 rats received grafts of E14 spinal cord, E15 cerebellum or E18-P2 renal cortex into a T8 spinal cord hemisection cavity, and CN neurons were counted at L1 2 months or 4-6 months postoperatively. The transplants survived at all time points examined and integrated with the host spinal cord. At 2 months grafts of spinal cord, cerebellum or renal cortex prevented CN neuron death; at 4-6 months injured CN neurons were maintained only by grafts of spinal cord and cerebellum. Provision of a normal target-derived neurotrophic factor appears to be adequate for temporary survival of axotomized neurons. Grafts of appropriate CNS target tissues are required for permanent rescue of axotomized CN neurons. Supported by NIH grant NS24707 and the VA Medical Research Service.

709.12

UP-REGULATION OF BASIC FIBROBLAST GROWTH FACTOR (bFGF) AND ITS RECEPTOR mRNA EXPRESSION IN RAT BRAIN FOLLOWING TRANSIENT FOREBRAIN ISCHEMIA.

K. Takami^{1*}, Y. Kiyota², M. Iwane³, M. Miyamoto², R. Tsukuda¹, K. Igarashi³, A. Shino¹, A. Wanaka⁴, S. Shiosaka⁵, M. Tohyama⁴. ¹Drug Safety Res. Lab, Pharmaceu. Dev. Div., ²Res. Lab. I, Pharmaceu. Res. Div. and ³Res. Lab. II, Discovery Res. Div., Takeda Chemical Ind. Ltd., Osaka 569, Japan, ⁴Dept. of Anat. and Neurosci., Osaka Univ. Med. Sch., Osaka 565, Japan. ⁵Dept. of Cellular and Structural Biology, Advanced Inst. of Sci. and Technol., Nara, Nara 630-01, Japan.

We have previously shown that transient forebrain ischemia in rats leads to an early and strong induction of basic fibroblast growth factor (bFGF) synthesis in astrocytes in the injured brain regions. In this study, in order to clarify the targets and roles of such raised endogenous bFGF levels, the mRNA expression of its receptors (*flg* and *bek*) in the hippocampus following transient forebrain ischemia in rats was investigated using an *in situ* hybridization technique. The ischemia induced an increase in the number of *flg* mRNA-positive cells in the hippocampal CA1 subfield, where delayed neuronal death occurred, from an early stage (24 h after ischemia) and this increase was still evident in this area 30 days after. The time-course of the appearance and distribution pattern of *flg* mRNA-positive cells in the CA1 subfield were quite similar to those of bFGF mRNA-positive cells. On the other hand, *in situ* hybridization for *bek* mRNA showed only slight and transient (observed 72 h and 5 days after ischemia) increases in the number of mRNA-positive cells in the CA1 subfield following ischemia. These changes were less marked than those of the *flg* mRNA-positive cells. The use of *in situ* hybridization and glial fibrillary acidic protein immunohistochemistry in combination demonstrated that the cells in the CA1 subfield that exhibited ischemia-induced *flg* or *bek* mRNA expression were astrocytes. These data indicate that transient forebrain ischemia induced up-regulation of FGF receptor expression accompanied by increased bFGF expression in astrocytes and suggest that the increased astrocytic bFGF levels in injured brain regions act on the astrocytes via autocrine systems and are involved in the development and maintenance of astrocytosis.

GM1 PRODUCES MODERATE ATTENUATION OF PERSISTENT DEFICITS IN HEBB-WILLIAMS MAZE PERFORMANCE AFTER UNILATERAL ENTORHINAL CORTEX LESION. M. Glasier*, M. Goncalves, L. Janis and D. Stein. Brain Research Laboratory, I.A.B., Rutgers University, Newark, NJ 07102.

Transient deficits have been reported after unilateral entorhinal cortex (EC) lesion. To determine whether there is a more persistent deficit, adult male rats with sham (S) or electrolytic lesion (L) of the left entorhinal cortex were examined in a Hebb-Williams maze. In addition, the effect of GM1 on potential deficits was assessed. Rats received GM1 (30 mg/kg, i.p.) or saline (SAL) injections for 14 days after surgery. Starting on day 49 post-surgery, rats were tested on the Hebb-Williams Maze. Ten practice problems were followed by 12 testing problems, each problem incorporating 6 immediate retrials. Two problems/day were given, with 6 hours between problems. ANOVAs revealed that L+SAL rats were significantly ($p < .05$) impaired (vs shams) on both total errors and on repeat errors over the 12 testing problems. L+GM1 did not differ significantly from shams or L+SAL. However, L+GM1 were better than L+SAL rats in total errors on 11 out of 12 testing problems ($p < .01$, binomial and chi-square analyses), indicating that GM1 may be potentially useful as therapy after this lesion.

SINGLE INTRACEREBRAL INJECTIONS OF NGF IMPROVE BEHAVIORAL PERFORMANCE FOLLOWING DAMAGE TO THE MEDIAL SEPTUM IN RATS. L.S. Janis*, G. Martins, M.M. Glasier, D.G. Stein. Brain Research Laboratory, Institute of Animal Behavior, Rutgers University, Newark, New Jersey, 07102.

Nerve Growth Factor (NGF) has been shown to reduce lesion-induced behavioral deficits by protecting damaged cholinergic neurons in the basal forebrain from degeneration following traumatic injury. Most studies reporting beneficial results have used models of repeated or continuous infusion of NGF in the brain. However, the effects of a single intracerebral NGF injection into rats with brain injury has not been as frequently studied and has produced inconsistent results. The present study examined the effects of a single intracerebral injection of NGF into rats given electrolytic lesions of the medial septum. Rats, initially trained on a win-shift radial maze task, were given the following surgeries: sham, medial septal lesion (MSL), MSL + NGF, or MSL + vehicle, and subsequently retested on the maze. Rats treated with NGF relearned the task in fewer trials and committed less errors than rats with medial septal lesions. In order to determine whether the NGF was working to restore previously learned spatial abilities the type of learning strategy used was also assessed. Preliminary evidence indicates that while a single intracerebral injection of NGF can improve behavioral performance, it is not doing so by restoring previously learned spatial strategies.

Supported by GenRe Corp. and Sigma Xi student research grant.

TRANSFORMING GROWTH FACTOR (TGF)- β 1 REGULATES THE mRNA OF COMPLEMENT PROTEINS IN THE YOUNG ADULT MALE RAT. T.E. Morgan*, N.J. Laping, and C.E. Finch. Andrus Gerontology Center, Department of Biological Sciences, University of Southern California, Los Angeles, CA 90089-0191.

TGF- β 1 is a multifunctional peptide that plays an important role in peripheral wound healing. Recently, numerous laboratories have found TGF- β 1 in the damaged and diseased brain. This study reports on the ongoing studies investigating potential roles for TGF- β 1 in the adult rat brain (Morgan et al., 1993 Exp. Neurol. in press). Previously we showed that TGF- β 1 infused into the lateral ventricle of male F344 rats caused an increase in select astrocytic and neuronal cytoskeletal mRNAs (Laping et al., 1991 Soc. Neurosci. Abstr. 17:754; Morgan et al., 1992 Soc. Neurosci. Abstr. 18:1296). Because of TGF- β 1's important role as an inflammatory- and immunoregulator, we examined the mRNA levels for certain complement proteins in the rat brain after TGF- β 1 infusion. Twenty-four hours after infusion of vehicle into the lateral ventricle of the rat brain, C1q mRNA levels increased nearly 2-fold in cortical areas adjacent to the infusion site and in the hippocampus as compared to intact controls. TGF- β 1 (500 ng) infused into the lateral ventricle caused C1q mRNA levels to return to intact levels. The mRNA for rat brain sulfated glycoprotein-2 (SGP-2), which is the rat equivalent of the human plasma protein, complement-lysis inhibitor (CLI), also increased in these same areas in response to vehicle-infusion; however, TGF- β 1 infusion further elevated SGP-2 mRNA levels. Thus, TGF- β 1 may serve in a protective role against complement-mediated cell lysis in the adult brain by decreasing complement proteins and increasing complement inhibitors. Supported by NRSA AG-05589 (TEM) and AG-07909 (CEF).

709.16

AUTOREGULATION OF TRANSFORMING GROWTH FACTOR-BETA 1 mRNA IN THE BRAIN BY INTRAVENTRICULAR INFUSION IN ADULT MALE RATS. C.S. Young-Chan, N.J. Laping, T.E. Morgan, C.J. Huang*, C.E. Finch, N.R. Nichols. Andrus Gerontology Center, Department of Biological Sciences University of Southern California, Los Angeles, CA 90089-0191

Transforming growth factor-Beta 1 (TGF- β 1) mRNA increases in the hippocampus in response to deafferenting and neurotoxic lesions, and decreases in the hippocampus in response to glucocorticoid treatment (Morgan et al. 1993 Exp Neurol (in press), Nichols et al. 1991 J Neurosci Res). By intraventricular infusion, TGF- β 1 induces hippocampal expression of prominent astrocytic and neuronal markers that are responsive to lesions and injury in the brain (Laping et al. submitted).

We show here that intraventricular infusion of TGF- β 1 induces its own mRNA in the hippocampus ipsilateral to the infusion site in adult male Fisher 344 rats. Northern blot hybridization analysis of hippocampal total RNA showed a dose-dependent increase of TGF- β 1 mRNA, over a range of 100 - 2000 ng of infused TGF- β 1, twenty-four hours post-infusion. We observed no significant change in the mRNA level in the hippocampus contralateral to the infusion site. Apolipoprotein-E (APO-E) mRNA was also examined and shown unaffected by the infused TGF- β 1. In-situ hybridization did not show distinct cell patterns of TGF- β 1 expression after infusion.

Autoregulation of TGF- β 1 occurs in vitro in various cell types. Our observation supports an autoregulatory mechanism for TGF- β 1 in the brain. (Supported by AG-07909 to CEF, AG-05528 to NJL, AG-05589 to TEM)

709.18

TRANSFORMING GROWTH FACTOR (TGF)- β 1 AND PERFORANT PATH TRANSECTION INCREASE GLIAL FIBRILLARY ACIDIC PROTEIN (GFAP) TRANSCRIPTION. N.J. Laping*, T.E. Morgan, I.R. Rozovsky, C.E. Finch. Andrus Gerontology Center, Department of Biological Sciences, University of Southern California, Los Angeles CA, 90089-0191.

To evaluate the role of transcription in increases of GFAP mRNA after lesion or TGF- β 1, we examined GFAP transcription by nuclear run-on assay. Three GFAP probes were used for this analysis: a cDNA probe which began in exon 1 through the poly-A tail (Nichols et al., 1990); a probe for the entire intron I; and a probe for 600 bp of the 3' end of intron VIII. Perforant path transection increased nascent transcripts in the hippocampus, as detected by all GFAP probes 16 and 24 hours later. However, GFAP transcripts detected by intron VIII increased earlier, 2-3 fold by 4 hours. The signal for intron VIII was less than that for intron I or the full length cDNA probe at all times examined, which suggests that fewer active polymerases are between introns I and VIII. Apolipoprotein-E (APO-E) transcription rates did not change at 4, 16, or 24 hours after lesion.

To extend the in vivo effect of TGF- β 1 on GFAP mRNA and to identify if TGF- β 1 acts directly on astrocytes, primary astrocyte cultures were treated for 2 hours with 5 ng/ml TGF- β 1 (from porcine platelets). GFAP run-on transcripts were increased 3-fold by TGF- β 1, whereas those for APO-E were not. Again, the signals detected by the GFAP intron VIII probe were about 3 fold less than the cDNA or intron I probe; even so, the fold changes induced by TGF- β 1 were the same for all GFAP probes. These results suggest that TGF- β 1 and lesion-induced elevations of GFAP mRNA are due to transcriptional activation. (Supported by AG-07909 and J.D. and C.T. SCHWANN CELL PROLIFERATION AND INTERCELLULAR COUPLING ARE COORDINATELY REGULATED. K. J. Chandross*, M. Chanson, D. C. Spray and J. A. Kessler. Department of Neuroscience, Albert Einstein College of Medicine, Bx, NY 10461.

Following peripheral nerve injury, Schwann cells undergo a series of cellular alterations which assist in the regenerative process. Some of these changes are stimulated by the release of cytokines and mitogenic factors. Purified rat sciatic nerve Schwann cell cultures were therefore utilized to study phenotypic changes induced by tumor necrosis factor alpha (TNF α), a cytokine released after nerve injury, or forskolin with bovine pituitary extract (F-BPE), a combination known for its mitogenic effects. Treatment with TNF α inhibited proliferation, and reduced both gap junctional conductance (from 0.48 ± 0.09 nS to 0.09 ± 0.05 nS) and dye coupling between cells. However, treatment with TNF α did not alter cell morphology or expression of low affinity nerve growth factor receptor (L-NGFR). By contrast, treatment with F-BPE significantly enhanced Schwann cell proliferation, junctional conductance (1.0 ± 0.2 nS) and dye coupling. In addition, F-BPE altered cell morphology and reduced expression of L-NGFR. These data indicate that factors released after nerve injury induce a series of phenotypic changes in Schwann cells, including the coordinated regulation of proliferation and intercellular communication. Such mechanisms may underlie phasic Schwann cell responses which orchestrate recovery from nerve injury.

710.2

THE DIFFERENTIATION OF SCHWANN CELLS CULTURED ON MONOLAYERS DERIVED FROM AXOLEMMAL-ENRICHED FRACTIONS. R.O. Calderon, B. Maggio, T.J. Neuberger, and G.H. De Vries.* Dept. of Biochemistry & Molecular Biophysics, MCV/VCU Richmond, VA 23298-0614.

We have previously shown that axolemmal membrane forms a stable and reproducible monomolecular layer which can be transferred to cover slips providing a substratum on which Schwann cells (SC) are able to proliferate (J. Neurosci. Res. 34: 206, 1993). We now show that SC grown on these monolayers can respond by upregulating the major glycoprotein of peripheral myelin (P0) and galactocerebroside (GC). Primary Schwann cells were cultured on axolemmal monolayers and the content of DNA, P0 and GC was evaluated using of Hoechst dye as a marker for DNA, a rhodamine secondary antibody as a marker for P0, and a FITC labelled secondary antibody as a marker for GC. SC showed an approximate two-fold increase in P0 content when cultured on axolemmal membrane which had been spread at high lateral surface pressure (33 mN/m) or low lateral pressure (13 mN/m). SC grown axolemmal monolayers spread at 33 mN/m showed the majority of the increased P0 on the surface of the cell, while SC grown on axolemma spread at 13 mN/m showed increased P0 mostly in the cytoplasmic compartment of the cell. GC content was increased 2-3 fold when SC were grown on axolemmal monolayers spread at either condition of lateral surface pressure. However, SC grown on axolemmal monolayers spread at 33 mN/m showed the majority of the increased GC in the cytoplasmic compartment while SC grown on axolemmal monolayers spread at 13 mN/m showed the majority of the increased GC on the external surface. We conclude that lateral surface pressure of the axolemma could be an important factor but in determining the subsequent subcellular distribution of the molecules which increase during differentiation. 710.3

EPIDERMAL GROWTH FACTOR IS NOT TROPHIC FOR HYPOTHALAMIC NEURONS AND ASTROCYTES E.J. Morris* and H.M. Geller Department of Pharmacology, UMDNJ-Robert Wood Johnson Medical School, Piscataway, NJ 08854

Previous studies have demonstrated that in central nervous system cultures, epidermal growth factor (EGF) is an important neurotrophic and mitogenic agent. Furthermore, EGF binding sites have been localized to rat hypothalamus (Chabot et al, Soc Neurosci Abstr. 1988;14:1073). Therefore, we have investigated the functional role of EGF on developing and mature hypothalamic cultures. EGF did not enhance the survival of embryonic day 17 (E17) hypothalamic neurons in microwell cultures plated on a poly-L-lysine or a confluent astrocyte monolayer substrate. In contrast to the strong, dose-dependent, mitogenic effect demonstrated by basic fibroblast growth factor (bFGF), EGF did not enhance proliferation of E17 hypothalamic astrocytes. Also, EGF did not enhance the proliferation of mature (maintained 1 month *in vitro*) hypothalamic astrocytes. However, EGF, as well as bFGF, induced a morphological change in mature hypothalamic astrocytes from a characteristic polygonal to a stellate phenotype. These data demonstrate that the EGF receptor in the hypothalamus does not mediate trophic activity or glial proliferation *in vitro*, but may involve other phenotypic changes in astrocytes. INFLUENCE OF GRANULE CELLS ON THE SURVIVAL AND DIFFERENTIATION OF PURKINJE CELLS IN DISSOCIATED CEREBELLAR CULTURES. M.E. Dunn* and E. Mugnaini. Lab. of Neuromorphology, The University of Connecticut, Storrs, CT 06269-4154.

The cerebellar Purkinje cell (PC) is an excellent model for the study of neuronal development because of its stereotypical features and well known intercellular relationships. Deafferentation studies *in vivo* have suggested that the parallel fibers, which are the axons of the cerebellar granule cells (GCs), influence the PC by unknown mechanisms. We have studied PCs grown in dissociated cultures from the E14-E16 mouse cerebellar anlagen. These cultures contain a relatively small density of granule cells. We have analyzed the effects of the addition to the PC cultures of GCs derived from the postnatal cerebellum. Antibody to the calcium binding protein calbindin was used to identify the PCs. We report that the addition of GCs promotes the survival and differentiation of the dissociated PCs. Specifically, the GCs enhance the number of viable PCs, as well as the extent of the PC dendritic arbor and the degree of its dendritic branching after 3 weeks *in vitro*. Moreover, these effects tend to become more pronounced with increasing numbers of GCs. Ultrastructural examination demonstrates the presence of synaptic contacts between the PC dendrites and the GC axons. Since glutamate exerts trophic influences on receptive neurons in certain models, we are currently investigating the effect(s) of glutamate on the dissociated PCs to determine if this is the factor responsible for the influence of the glutamatergic GCs. Because glutamate has a trophic effect on dissociated GCs, we must further distinguish between direct effects of glutamate on PCs and indirect effects on PCs via the enhancement of GC survival. Supported by PHS grant NS-09904.

OSTEOGENIC PROTEIN-1 REGULATES L1 AND N-CAM GENE EXPRESSION IN NEURAL CELLS. G. Perides*, G. Hu, D. C. Rueger, M. E. Charness. Depts Pathology, Neurology (Neuroscience) Harvard Medical School, VA Medical Center, West Roxbury, MA 02132; Creative Biomolecules, Hopkinton MA 01748.

Little is known about the regulation of the immunoglobulin cell adhesion molecules (IgCAM) N-CAM and L1. Osteogenic protein-1 (OP-1) is a member of the TGF- β superfamily that is expressed in the nervous system. We recently showed that human recombinant osteogenic protein-1 (hOP-1) strongly induces the aggregation of dividing neuroblastoma x glioma hybrid NG108-15 cells, in part by inducing the major isoforms of N-CAM (Perides et al. 1992, Proc. Natl. Acad. Sci. USA, 89, 10326). Here we show that hOP-1 also induces L1 expression in NG108-15 cells without changing the levels of N-cadherin, neurofilament 200, thy-1, tau, and α_5 . The increased adhesiveness of hOP-1-treated NG108-15 cells was inhibited in part by Fab fragments of an anti-L1 polyclonal antiserum. The morphoregulatory and IgCAM-inducing effects of hOP-1 were unassociated with changes in cell proliferation and were not reproduced by cellular differentiation, TGF- β , phorbol esters, or forskolin. L1 and N-CAM expression first increased 12 to 18 hours after hOP-1 treatment, reached a maximum after 2-3 days, persisted for up to 5 days, and returned to control levels 3 days after hOP-1 withdrawal. The increases in IgCAM protein levels were preceded by large increases in the abundance of L1 and N-CAM mRNAs. Actinomycin D prevented the induction by hOP-1 of L1 and N-CAM mRNAs, suggesting that hOP-1 regulates IgCAM gene transcription. hOP-1 is the first described growth factor that regulates both N-CAM and L1 gene expression.

710.4

INTERACTION OF BASIC FIBROBLAST GROWTH FACTOR AND HEPARIN AND THEIR EFFECT ON ASTROCYTIC TENASCIN PRODUCTION S. Meiners, M. Marone, J.L. Rittenhouse, and H.M. Geller*, Dept. of Pharmacology, UMDNJ-Robert Wood Johnson Medical School, Piscataway, NJ 08876

We investigated the interaction of basic fibroblast growth factor (bFGF) and heparin on the expression of the extracellular matrix protein tenascin in cultured rat cerebral cortical astrocytes. Cultures of purified protoplasmic astrocytes were established from the cerebral cortex of neonatal rats and subcultured into tissue culture flasks for Western blotting or onto glass coverslips coated with poly-L-lysine for immunocytochemistry. Basic FGF was added to the cultures at concentrations of 0.1, 1, 2.5, 5, or 10 ng/ml. Levels of tenascin were evaluated by Western blotting techniques and by immunofluorescence analysis of living cells. Basic FGF increased tenascin production in a dose-dependent manner, with the most significant effect seen at 5 ng/ml. Basic FGF treatment also caused a concurrent change in astrocyte morphology from flat and protoplasmic to fibrous. Tenascin production was increased approximately 5-fold in serum-containing medium but only two-fold in serum-free medium. When heparin was included along with bFGF in serum-free medium, tenascin expression was further enhanced. Heparin had a smaller effect in serum-containing medium, suggesting that serum may contain heparin or heparin-like molecules with a similar ability to potentiate the effects of bFGF, thereby limiting the actions of additional heparin. Alternatively, serum may upregulate heparan sulfate proteoglycans on the surface of astrocytes, which may then present bFGF to its high affinity receptor. Previous work in this laboratory demonstrated that neuronal adhesion was reduced on bFGF-treated cultures (Petroski et al., 1991); these results, interpreted in light of the current study, suggest that a bFGF-mediated induction of astrocytic tenascin may be inhibitory to neuronal growth. It is our hypothesis that the action of bFGF during injury may invoke the induction of tenascin on astrocytes, thereby reducing regeneration in the central nervous system.

K252A INDUCES TYROSINE PHOSPHORYLATION AND DIFFERENTIATION IN SY5Y CELLS INDEPENDENTLY OF PROTEIN KINASE-C INHIBITION.

Anna M. Maroney, M. Elizabeth Forbes, Marcie A. Glicksman, Lorraine Lipfert, Nicola Neff, Robert Siman, John M. Farah*, and Craig A. Dionne Cephalon Inc., 145 Brandywine Pkwy, West Chester, PA 19380

K252a, an indolocarbazole derivative initially described as a protein kinase C inhibitor, has been shown to promote cholinergic activity in rat spinal cord cultures and survival in chick dorsal root ganglion (Glicksman, et al., J. Neurochem., in press, 1993; Borasio, Neurosci. Lett. 108:207-212, 1990). To determine the mechanism by which K252a behaves as a neurotrophic factor we examined the effects of this molecule in a human neuroblastoma cell line, SH-SY5Y. In this cell line, K252a induces neurite outgrowth in a dose-dependent manner. One mechanism by which polypeptide neurotrophic factors transmit their signal is via tyrosine phosphorylation of a variety of substrates. Similarly, K252a induced tyrosine phosphorylation of high molecular weight membrane-associated proteins in the range of 125-180 kDa in a dose and time dependent manner. Tyrosine phosphorylation of several other known proteins has also been demonstrated. These phosphorylation events are independent of protein kinase C (PKC) inhibition since down regulation of PKC by long term incubation with phorbol esters does not block the effect of K252a. In addition, the PKC inhibitors H7 and calphostin do not induce similar tyrosine phosphorylation in the SY5Y cells. K252a induces phosphorylation in responsive neuronal cells such as LAN-5 and SK-N-MC cells but does not induce neurite outgrowth or tyrosine phosphorylation in PC12 cells. We have thus identified an early K252a-induced biochemical event which is reminiscent of the early events triggered by polypeptide growth factors. The survival-promoting effects of K252a in primary cultures suggest that K252a may be a promising agent with therapeutic application to spinal cord injury. The efficacy of K252a may be mediated by activating tyrosine phosphorylation of second messengers that are similarly modified by other growth factors.

CHARACTERIZATION, TRANSFECTION, AND TRANSPLANTATION OF MITOGEN-EXPANDED SECONDARY O-2A GLIAL PROGENITOR CELLS. R.D. McKinnon*, RW Johnson Med. School, UMDNJ, Piscataway NJ08854.

The ability to expand and manipulate primary oligodendrocyte type-2 astrocyte (O-2A) glial progenitor cells *in vitro*, then transplant altered cells for analysis *in vivo*, was examined. Secondary rat cortical O-2A progenitor cells, expanded from primary cultures with mitogens from neuroblastoma B104 conditioned media (CM), responded to recombinant growth factors similar to both primary (non-passaged) O-2A cells and to an O-2A cell line, Central Glial-4 (CG-4) cells. The three populations showed: (i) continued self renewal in media supplemented with either basic Fibroblast Growth Factor (bFGF) or B104-CM, (ii) differentiation in absence of these factors; (iii) induction of a bipolar (motile) morphology in response to either Platelet-Derived Growth Factor (PDGF, AA-homodimeric form) or to B104-CM; (iv) production of Transforming Growth Factor- β (TGF- β), (v) TGF- β -mediated inhibition of mitogen-driven proliferation (PDGF, B104-CM, to a lesser extent bFGF); and (vi) production of a non-TGF- β inhibitor of proliferation, as determined by its activity on TGF- β -resistant cells. Efficient transient DNA transfection was achieved using the 'calcium technique', and infection with retroviral vectors encoding reporter genes (alkaline phosphatase, β -galactosidase) and selectable markers (G418^R) allowed the isolation of 'marked' O-2A progenitor cells. The migration and differentiation of marked cells after transplantation into neonatal brain confirmed the utility of B104-CM for preserving the phenotype of O-2A progenitors during their expansion and manipulation *in vitro*. Supported by a Pilot Research Award from the US Nat. Multiple Sclerosis Society.

NADPH-d REACTIVITY IN ADULT AND METAMORPHOSING XENOPUS LAEVIS SPINAL CORD. M.J. Crowe*, T.J. Brown, J.C. Bresnahan, M.S. Beattie. Neuroscience Program, Dept. of Cell Biology, Neurobiology, and Anatomy, The Ohio State Univ., Columbus, OH 43210

The histochemical NADPH diaphorase (NADPH-d) reaction has long been used to describe distinct populations of neurons in the CNS of several species. Recent evidence has shown that NADPH-d is actually a neuronal nitric oxide synthase (NOS). We examined the spinal cords of adult and metamorphosing (stage 51-62) *Xenopus laevis* (XL) using this procedure. In metamorphosing XL, NADPH-d reactive cells were detected throughout the spinal cord. Large primary motoneurons (MNs) in the medial ventral horn were individually labelled as well as groups of secondary MNs in the lateral motor columns (LMCs) which are present only in the lumbar and cervical enlargements. An accumulation of smaller labelled neurons were seen in the intermediate grey area between the ventral and dorsal horns. In adult XL spinal cords, no MNs or LMCs were stained, although we did observe reactive cells in the intermediate grey. In mammalian species NOS is a potent vasodilator, however we observed no reactivity in blood vessels of either adult or metamorphosing XL. All neurons in the dorsal root ganglia (DRGs) of both adult and metamorphosing XL were stained. This is in contrast with what we have seen in the rat, where only a subpopulation of small-to-medium diameter cells were labelled. The lack of NADPH-d reactivity in adult XL MNs compared to that observed in metamorphosing XL suggests that NOS may be related to processes involved in cellular differentiation in XL spinal cord. Supported by NS07291 and NS10165.

NORADRENERGIC TRANSMISSION INFLUENCES SWEAT GLAND CHOLINERGIC DIFFERENTIATION FACTOR PRODUCTION. Beth A. Habecker* and Story C. Landis. Dept. of Neurosciences, Case Western Reserve Univ. Cleveland, OH 44106

During normal development, the sympathetic innervation of rat sweat glands changes from a noradrenergic to cholinergic phenotype in response to soluble factors released from the glands. Sweat gland cells cultured from postnatal day 7-10 rats do not secrete cholinergic inducing activity, but gland cells co-cultured with sympathetic neurons induce choline acetyltransferase (ChAT) activity in the neurons. We find that extracts from cultured sweat gland cells do not induce ChAT activity in cultured sympathetic neurons, indicating that synthesis of sweat gland differentiation factor is induced by co-culture with neurons. In addition, conditioned medium from sweat gland/sensory neuron co-cultures does not induce ChAT activity, raising the possibility that noradrenergic transmission mediates the neuronal induction of a differentiation factor in gland cells. PCR and Southern analyses indicate that α_1 adrenergic receptors are present in footpads during the first two weeks of postnatal development, but their expression drops by day 21, corresponding with decreased levels of catecholamines in the sweat gland innervation. In contrast, α_2 and β_2 receptors are present in footpads from early development through adulthood. All these receptor subtypes are expressed in cultured sweat gland cells. Treatment of sweat gland/sympathetic neuron co-cultures with the β antagonists (-)propranolol or (-)alprenolol significantly blocks the induction of ChAT activity in the co-cultures, while the α antagonists prazosin (α_1) and yohimbine (α_2) inhibit ChAT induction to a lesser extent. Further, conditioned medium from propranolol treated co-cultures does not induce ChAT activity in neuron cultures, suggesting that adrenergic blockade is directly affecting sweat gland cells rather than neurons. These results suggest noradrenergic transmission stimulates production of a sweat gland differentiation factor which in turn alters neuron phenotype.

CHAT-INDUCING BIOACTIVITY FROM EARLY POSTNATAL RAT HINDQUARTERS IS PRIMARILY CNTF. S. L. Meyer*, E. Knight, Jr., M. J. Hansbury, D. M. Lang, and N. T. Neff. Cephalon, Inc., West Chester, PA 19380.

Extracts prepared from the hindquarters of 14-day-old rats contain factors that enhance ChAT activity in both E14 rat spinal cord cultures and IMR-32 neuroblastoma cells. Our primary goal was to purify and characterize the ChAT-inducing activity in these extracts, using IMR-32 cells as the assay cell. A second goal was to determine if the activity was due to known ChAT-inducing factors, particularly CNTF. CNTF enhances ChAT activity in IMR-32 cells and E14 rat spinal cord cultures at concentrations < 1 ng/ml. The ChAT-inducing activity was partially-purified 3,000-fold from a crude extract of rat hindquarters using ammonium sulfate precipitation followed by chromatography on DEAE-Sephadex, SP-Sephadex, Affi-gel blue and heparin Sepharose. During these studies, a potent neutralizing rabbit antibody was made to recombinant rat CNTF. This highly-specific antibody neutralized greater than 90% of the 3,000-fold purified ChAT-inducing activity assayed on IMR-32 cells. Furthermore, 90% of the ChAT-inducing activity in the crude extract prepared from rat hindquarters was neutralized by CNTF antibody. In addition, immunoblot analysis of the 3,000-fold purified fraction using the CNTF antibody revealed sufficient CNTF to account for all the ChAT-inducing activity. It is concluded that the majority of the ChAT-inducing activity in extracts of rat hindquarters as measured on IMR-32 cells is due to CNTF. Given the potency of CNTF and the ubiquitous contribution of peripheral nerve to postnatal muscle, muscle-derived ChAT-inducing factors would have to be isolated from either embryonic muscle or cultured muscle cells.

710.10

CDF/LIF-DEFICIENT MICE DISPLAY AN ALTERED COMPLEMENT OF NEURONAL PHENOTYPES IN THE CNS. P. H. Patterson*¹, L. Rugga¹, and C. L. Stewart². ¹Biology Division, Caltech., Pasadena, CA 91125, ²Roche Institute, Roche Research Center, Nutley, NJ 07110.

The cholinergic differentiation factor (CDF; also known as leukemia inhibitory factor, LIF) is a pleiotropic cytokine that can regulate the survival and gene expression in a variety of peripheral neurons in culture. To investigate the role of this cytokine further, we are examining the brains of mice in which this gene was deleted by homologous recombination. The mutants do not display obvious behavioral abnormalities nor do their brains express gross morphological defects. To search for differences at the cellular level, we are comparing sections from wild type and CDF/LIF-deficient brains after staining for a variety of neuronal differentiation markers. One clear difference is that staining for the neuronal calcium-binding proteins calbindin and parvalbumin is deficient in the visual cortex of the homozygous mutants. This is intriguing because we find that rat visual cortex has particularly high levels of both CDF/LIF and CDF/LIF receptor mRNAs (Banner and Patterson, Soc. Neurosci. Abstr., '93). It is not yet clear if the difference in staining is due to a loss of this subset of neurons or to a phenotypic switch. Dorsal root ganglia from the mutants also display a difference in staining for these calcium binding proteins (and are CDF/LIF⁺). This evidence supports a role for CDF/LIF in the regulation of phenotype and/or survival of selected populations of CNS neurons *in vivo*.

710.12

INTERFERON- γ (IFN- γ) TREATMENT OF CORTICAL ASTROCYTES INDUCES A FACTOR THAT PROMOTES CHOLINERGIC DIFFERENTIATION OF BASAL FOREBRAIN. G.M. Jonakait and L. Ni*. Dept. Biol.Sci., Rutgers Univ., Newark, N.J. 07102

We have shown previously that IFN- γ promotes cholinergic differentiation in cultured embryonic cells derived from the septal nucleus and adjacent basal forebrain (SN/BF; Jonakait & Ni, 1992).

Since this population of cells is well known for its responsiveness to both nerve growth factor (NGF) and fibroblast growth factor (FGF), we have sought to determine 1) whether the effect of IFN- γ is mediated by a soluble intermediate and 2) whether that intermediate is NGF or basic FGF. Since antibodies against NGF and FGF do not alter the action of IFN on cultured cholinergic neurons, these are probably not important intermediates in the IFN induction of ChAT.

However, an IFN-induced, glial-derived intermediate does exist. This molecule(s), derived from medium conditioned by IFN-treated astrocyte cultures (IFN-CM), raises ChAT activity in E16 SN/BF cultures as much as 15-fold. Its activity is not neutralized by antibodies against IFN. It is very potent, retaining activity at dilutions as low as 10%. Since bFGF, even at doses as high as 100 ng/ml, cannot mimic the action of IFN-CM and since antibodies against FGF do not neutralize its action, the active factor is probably not FGF.

Supported by the Charles and Johanna Busch Bequest.

DIFFERENTIAL EFFECTS OF PLATELET-DERIVED GROWTH FACTOR-AA AND -BB ON DOPAMINE NEURONS IN VIVO. MMI Giacobini*, S. Almström, K. Funa¹, L. Olson. Dept. of Histology & Neurobiology, Karolinska Institute, Stockholm, and ¹Ludwig Institute for Cancer Research, Biomedical Center, Uppsala, Sweden

Trophic effects of platelet-derived growth factor-AA and -BB (PDGF-AA, PDGF-BB) were followed in developing rat embryonic day 14 ventral mesencephalic grafts under chronic intermittent treatments with either PDGF-AA or PDGF-BB in the anterior eye chamber of adult rat hosts. Pieces to be grafted were incubated in either 100 ng PDGF-AA/ml buffer, 100 ng PDGF-BB/ml buffer or the buffer vehicle alone and 5 μ l of similar solutions were injected intracocularly on day 5, 10 and 15 postgrafting. Host animals were sympathetically denervated 2 weeks prior to grafting enabling evaluation of catecholaminergic fiber outgrowth onto the host iris in whole-mount preparations by use of the Falck-Hillarp technique. Morphological studies of PDGF effects on grafted brain tissue were carried out using markers for tyrosine hydroxylase- and glial fibrillary acidic protein- immunoreactivity. Growth of grafts was followed by repeated observations directly through the cornea of the host using a stereomicroscope. This revealed that there was no apparent effect on volume increase of mesencephalic grafts after the different treatments. However, PDGF-AA significantly enhanced dopaminergic fiber outgrowth from mesencephalic grafts when compared to both PDGF-BB and controls, without an accompanying rise in the number of tyrosine hydroxylase-positive neurons or astroglial elements. In contrast, a significantly greater number of tyrosine hydroxylase-positive neurons were seen in grafts treated with PDGF-BB but without an accompanying increase in outgrowth of fibers. These findings suggest that PDGF-AA may enhance formation of dopamine nerve fibers *in vivo* whereas PDGF-BB may be a maintenance factor for tyrosine hydroxylase-positive cells of the ventral mesencephalon.

710.15

TRANSFORMING GROWTH FACTOR ALPHA GENE EXPRESSION AND THYROID HORMONE REGULATION IN DEVELOPING BRAIN. K.R. Huff* and O.-X. Yuan. Harbor/UCLA Med Ctr, Dept of Pediatrics. Torrance, CA 90509.

Transforming Growth Factor alpha (TGFA) is a member of the EGF family of growth factors and is stimulatory of many nontransformed cell types. It may also be a ligand for the EGF receptor. EGF mimics and may mediate precocious maturational effects of thyroid hormone (T4) treatment in tissues outside the brain. We have examined TGFA expression and the effects of T4 treatment in the rat, an animal with relative immaturity of brain development and T4 levels at birth.

Neonatal rats were treated days 1-6 of life with T4 or vehicle control. They were sacrificed at various ages for later brain part RNA isolation. TGFA RNA (mRNA) was detected by polymerase chain reaction amplification of cDNA synthesized by reverse transcriptase. The appropriate mRNA was identified by base pair number and positive control. TGFA mRNA was made undetectable by T4 treatment at day 1 in cerebral cortex and brain stem and day 3 in cerebellum. This result correlates with T4 lowering by 60% TGFA protein by RIA to adult values at this age.

We conclude a maturational effect of T4 on TGFA at the gene transcriptional level.

710.17

EXPRESSION OF THE MYELIN TRANSCRIPTION FACTOR I IN DEVELOPING RAT NERVOUS SYSTEM. M.A.R. Dent, R. Mirsky, K.R. Jessen and L. Hudson, SPON: Brain Research Association. Department of Anatomy, UCL, Gower Street, London WC1E 6BT and NIMDS, Bethesda, Maryland 20892.

Myelin transcription factor I (MyTI) is a novel zinc finger protein that binds to a previously defined cis element of the human PLP promoter. We have studied the expression of MyTI in the rat nervous system by *in situ* hybridization. Strong expression was observed in the dorsal root ganglia and the spinal cord at embryonic day (E) 13, 14, 16, and 18. At E18 it appeared absent from Schwann cells in peripheral nerves. In the adult spinal cord MyTI is observed mainly in the neurons but there is also some expression in the cells of the white matter. In the brain low levels of MyTI are expressed at E13 and highest levels are observed in the cortical plate by E18. There is also some expression of MyTI in the adult brain.

710.19

SPECIFIC ROLES FOR RETINOIDS IN DEVELOPING AND ADULT BRAIN FUNCTION SUGGESTED BY THE TEMPORAL AND REGIONAL DISTRIBUTIONS OF THE CELLULAR RETINOID-BINDING PROTEINS CRBP I AND CRABP I AS REVEALED BY IMMUNOHISTOCHEMISTRY. Rolf Zetterström, Lars Olson*, András Simon*, MaiBritt Giacobini, Ulf Eriksson*. Department of Histology & Neurobiology, Karolinska Institute and ¹Ludwig Institute for Cancer Research, Stockholm Branch, Stockholm, Sweden.

In cells, retinol (vitamin A) and its active metabolite retinoic acid are bound to cellular retinol-binding protein (CRBP) and cellular retinoic acid-binding protein (CRABP) respectively. We have used immunohistochemistry to localize the possible presence of the two retinoid-binding proteins in the central nervous system. We find a widespread, yet distinct, presence of these two binding proteins in the adult rat central nervous system. Most of the immunoreactivity is neuronal, including somata and processes. CRBP-immunoreactivity (IR) is also found in the walls of cerebral blood vessels, the meninges, the choroid plexus, certain ependymal cells, tanocytes, and certain other glial elements. The CRBP- and CRABP-IR patterns appear to be almost exclusively non-overlapping. Very strong CRBP-IR is found in the dendritic layers of the hippocampal formation and dentate gyrus. CRBP-IR is also present in layer 5 cortical pyramidal neurons. Many subcortical areas, most notably in the hypothalamus and amygdala areas contain networks of varicose CRBP-IR nerve fibers. The medial amygdaloid nucleus contains strongly CRBP-positive neurons. CRABP-IR is more restricted in the adult brain. Strong CRABP-IR is however found in a population of neurons scattered throughout striatum. The developing CNS contains many more CRBP- and CRABP-IR structures than the adult CNS. Striatum of the newborn rat is strongly CRBP-IR in a typical patch/matrix manner, while at the same time containing evenly distributed CRABP-IR neurons. The remarkably selective patterns of CRBP- and CRABP-immunoreactivity suggest that retinol and retinoic acid have important roles in normal brain function. The high levels of CRBP-IR found in hippocampus suggests that one such role might relate to brain plasticity.

710.16

EXPRESSION OF MEMBERS OF THE NEU (ARIA) LIGAND FAMILY IN CHICK AND RAT CENTRAL NERVOUS SYSTEM Y. Kuo*, X. Yang, and L. Role. Dept. Anat. & Cell Biol. in the Ctr. Neurobiol. & Behav., Columbia Univ, P&S, 630 W 168th St, NY, NY 10032.

Innervation of muscle by motor neurons is accompanied by increased transcription of the subunits that comprise the muscle type nicotinic AChRs. AChR induction is apparently mediated by a soluble factor synthesized and released from motoneurons. Fischbach and colleagues (Cell 72, 5:801-805) have recently reported the cloning of an AChR inducing activity called ARIA which is a member of a family of growth factors homologous to the neu ligand heregulin that includes the glial growth factors and rat Neu differentiation factor. We are interested in the regulation of neurotransmitter receptor expression in cholinergic neurons induced by presynaptic input. Our previous studies demonstrate that preganglionic neurons, somatic motor neurons, or media conditioned by either of these cell types increases the magnitude of ACh evoked currents and the number of new surface AChRs in sympathetic neurons. To test the hypothesis that homologs of ARIA can increase neuronal nAChR gene transcription we must identify those homologs and test them for nAChR inducing activity in neurons. PCR screening of rat spinal cord cDNA using oligos from conserved regions of members of this family revealed a fragment whose combination of exons suggest it is a member of the neu family with strongest homology to human heregulin $\beta 1$. The fragment demonstrates 97% sequence identity in both the Ig-like and the EGF domains. Likewise, screening of a chick cDNA library with this probe at high stringency yielded several related clones. Experiments to express and test for functional effects of these heregulin/ARIA homologs are underway. (Supported by NS 29071)

DIFFERENTIAL EFFECTS OF LEAD ACETATE ON DEVELOPMENTALLY-REGULATED BRAIN GENE EXPRESSION N.H. Zawia*, T. Schmitt and G. I. Harry. Environmental Immunology & Neurobiology, NIEHS, P.O. Box 12233, RTP, NC 27709.

Lead is a neurotoxicant that is known to produce behavioral, biochemical and structural abnormalities in brain development. Exposure to high levels of lead can produce hypomyelination in the neocortex and fine structural changes in the developing hippocampus. Development and growth are marked by precise differential gene regulation. The objective of these studies was to examine whether stage-specific developmental gene expression was perturbed by lactational exposure to low levels of lead acetate (0.2 % in the drinking water of the dam begun after parturition). Hippocampal and neocortical tissue was obtained from Long Evans hooded rats on postnatal days (PND): 5, 10, 15, 20. No changes in either brain structure and weight or animal body weights were observed in the pups following such exposure to lead. Total RNA was isolated and probed for myelin basic protein (MBP), growth associated protein (GAP-43) and actin gene expression by Northern analysis. A transient repression of hippocampal GAP-43 gene expression was observed on PND 5, 10 and 15 with a return to above normal levels by PND 20. Levels of neocortical MBP gene expression peaked prematurely on PND 10 in lead-exposed animals while expression of the actin gene appeared unaltered by exposure to lead. These data suggest that low levels of lead may selectively influence developmental gene expression and may therefore contribute to lead-induced neuropathology.

EPIGENETIC IMPRINTING OF ANTI-BRAIN IMMUNITY: POSSIBLE SIGNIFICANCE IN PSYCHONEUROLOGY. A.B. Poletaev*, O.P. Selifanova. Chernobyl-Test Ctr. 10 Rimskogo-Korsakova St., 127577, Moscow, Russia.

Relationship between the presence of antibodies to brain specific proteins of S-100 family and brain development was studied in animal models and in the clinic.

Pregnant Wistar rats were injected with polyclonal antibodies to S-100 protein. Control group received equivalent amount of antibodies to bovine serum albumin. An elevated level of anti S-100 immunoreactivity was detected by ELISA in the serum of 1 month old offsprings of group treated with antibodies to S-100 compared to the control group. Ultrastructural analysis of newborn offsprings brain revealed the delay of glial cell maturation. However no signs of delay were detected in the control group.

Occurrence of antibodies to S-100 proteins was examined in the blood of children with various psychoneurological diseases and their parents. Large deviation in the serum anti S-100 immunoreactivity were detected in more than 80% of children with heavy cerebral palsy or oligophrenia and in their clinically healthy mothers, but not in their fathers.

The obtained data indicate the possibility for inborn "imprinting" of specific autoimmune reactions which may be important in the development of certain forms of diseases in the nervous system.

710.21

CHARACTERIZATION OF PROTEINS IMMUNOLOGICALLY SIMILAR TO CELLULAR RETINOIC ACID AND CELLULAR RETINOL BINDING PROTEINS (CRABP AND CRBP) IN THE CNS OF *MANDUCA SEXTA* AND *DROSOPHILA MELANOGASTER*. D. P. Muehleisen¹, R. S. Gray¹, A. L. Westbrook¹, Z. F. Wang¹, E. Chytil², D. E. Ong², and W. E. Bollenbacher^{1*}, ¹Department of Biology, University of North Carolina at Chapel Hill, Chapel Hill, NC, 27599-3280, ²Department of Biochemistry, Vanderbilt University, Nashville, TN, 27232. The highly conserved vertebrate CRABP and CRBP are believed to be cytoplasmic proteins that specifically bind retinoic acid (RA) and retinol, respectively. While their functions are not understood, they are thought to have roles in development by determining RA gradients and in modulating RA's action. Affinity purified rabbit anti-rat CRABP and rabbit anti-human CRBP were used to identify CRABP and CRBP immunoreactive embryonic and post-embryonic CNS neurons in *Manduca sexta*, and post-embryonic neurons in *Drosophila melanogaster*. Genomic southern blots of *Drosophila* and *Manduca* DNA hybridize with a fragment of a bovine CRABP cDNA and rat CRBP cDNA, revealing both insects have genes with high sequence similarity to the vertebrate CRABP and CRBP genes. The organization of the CRBP and CRABP neurons and their functions are being investigated.

710.23

EXPRESSION AND CHARACTERIZATION OF HUMAN GROWTH/DIFFERENTIATION FACTOR 1. M. Hendricks, C. Lynch, B. Happel, C. Hoban, C. Kirk, B. Sklar, L. J. Morin*, J. Isaacs, M. S. Chen and D. Gwynne. Cambridge Neuroscience, Inc., Cambridge, MA 02139

Growth/differentiation factor-1 (GDF-1) is a novel member of the transforming growth factor- β (TGF- β) superfamily and is expressed almost exclusively in the nervous system (Lee, Proc. Natl. Acad. Sci. USA 88: 4250-4254, 1991). In the present study we further resolve the expression of GDF-1 to specific cells of the nervous system and express recombinant human GDF-1 (rhGDF-1) for protein characterization and identification of biological activities.

Immunohistochemical staining of rat hippocampal cultures *in vitro* with GDF-1 polyclonal antisera showed immunoreactivity specifically with neurons. Ongoing immunostaining of rat brain and spinal cord sections coupled with *in situ* hybridization studies will further elucidate specific patterns of expression in the nervous system.

Expression of rhGDF-1 in Chinese hamster ovary (CHO) cells demonstrates that it is a secreted protein, as predicted by the presence of an N-terminal signal peptide. Western blot analysis indicates that rhGDF-1 is processed in a manner consistent with cleavage at a RPRR cleavage recognition site to give a 15 kD mature fragment and a 28 kD pro fragment. Native GDF-1 in a mouse brain extract shows a similar processing pattern. Testing of purified rhGDF-1 in various *in vitro* bioassays is in progress and will help to elucidate the role of this factor in the nervous system.

POSSIBLE ROLE OF CGRP IN THE DIFFERENTIATION OF VASCULAR SMOOTH MUSCLE CELLS. J.-J. Connat*, V. Schnüriger, A. Thiévent, A. L. Quiquerez. Lab. d'Anatomie et Physiologie Comparées, Univ. de Genève, 30 quai E. Ansermet, 1211 GENEVE 4, Switzerland.

We studied the differentiation of the wall of the rat hepatic portal vein and possible correlations with the occurrence of CGRP innervation. Electron microscopy, as well as immunocytochemistry for markers of smooth muscle cell (SMC) differentiation (desmin and α -smooth actin) demonstrated a differentiation of the muscular layers when CGRP innervation occurred at their vicinity. In order to check if this temporal correlation have a physiological meaning, we cultured SMC from rat thoracic aorta and added 10-7M CGRP in the culture medium. We examined the effects on cell proliferation and on expression of α -smooth actin 2,4,6,8 and 15 days after seeding. We noted that 2 different cases were available. (1) Certain cells which proliferated slowly had their growth rate positively influenced by CGRP, even in presence of 10% FCS in the medium. The quantity of α -smooth actin expressed by these cells was not influenced by the peptide. (2) Some other cells proliferated more rapidly, and their growth rate in 10% FCS medium was inhibited by CGRP. In certain cases, presumably in cells with highest growth rate, CGRP reduced significantly the amount of α -smooth actin expressed by the cells. We also noted an effect of the peptide on the level of mRNA for actin. We tested in the same conditions the effect of CGRP on cultured fibroblasts from the vascular adventitia. No effect was observed in the proliferation tests, neither with cells cultured with 1% FCS, nor with 10% FCS. It is the first clear demonstration of the action of a neuropeptide on the state of differentiation of a tissue, namely the vascular smooth muscle. This suggest that the autonomic nervous system could play a role in the maintenance of tissues integrity.

OTHER FACTORS AND TROPHIC AGENTS III

711.1

EFFECT OF TETRAHYDROBIOPTERIN ON THE PROLIFERATION AND DNA SYNTHESIS OF PC12 CELLS. P.Z. Anastasiadis¹, J.C. States², D.M. Kuhn³, and R.A. Levine^{1,2,4}. ¹William T. Gossett Neurology Labs, Henry Ford Hosp., Detroit, ²Cellular & Clinical Neurobiology Prgm, Psychiatry, and ³Center for Mol. Biology, Wayne State Univ., Detroit, MI, ⁴Vet. Admin. Med. Center, Allen Park, MI.

Tetrahydrobiopterin (6R-BH₄; cofactor for tyrosine and tryptophan hydroxylases, in catecholamine and serotonin synthesis) is required for the proliferation of cultured murine erythroleukemia cells. BH₄ effects on DNA synthesis and proliferation of cultured rat pheochromocytoma (PC12) cells were tested. BH₄ inhibited (dose-dependently) PC12 cell proliferation; at high concentrations (500 μ M) BH₄ was cytotoxic. BH₄ also decreased tritiated thymidine incorporation in PC12 cell DNA; only 6R-BH₄ was active (oxidized pterins and 6S-BH₄ were not). Interferon- γ (IFN- γ) inhibits DNA synthesis in PC12 cells and induces BH₄ biosynthesis; its effects on DNA synthesis were tested under conditions modulating intracellular BH₄. Inhibition of DNA synthesis was additive when cells were incubated for 24 hours with IFN- γ (250-2000 U/ml) and sepiapterin (200 μ M; converted to BH₄ inside the cells). N-acetyl-serotonin (NAS), an inhibitor of BH₄ biosynthesis, partially reversed the sepiapterin-induced effect but did not block the IFN- γ -induced inhibition of DNA synthesis. These results suggest that BH₄ may regulate the rate of DNA synthesis in PC12 cells. The IFN- γ - and BH₄-induced effects on PC12 cell DNA synthesis may not be mediated by the same mechanism. Further studies focus on the mechanism by which BH₄ affects DNA synthesis in PC12 cells.

711.2

GROWTH FACTOR REGULATION OF NEURONAL NA CHANNEL EXPRESSION IN PC12 CELLS OVEREXPRESSING RECEPTORS FOR NGF, BDNF, AND PDGF. R.A. Maue* AND G.R. Fanger. Depts of Physiology and Biochemistry, Dartmouth Medical School, Hanover, NH 03755-3833.

The biological activity of growth factors acting through receptor tyrosine kinases can differ dramatically, resulting in growth and proliferation, or cessation of cell division and differentiation. These diverse effects appear to be determined by both the cellular environment in which the receptors are expressed and the properties of the receptor tyrosine kinase. To investigate the specificity of different receptor tyrosine kinases with regard to neuronal differentiation, we have analyzed sodium (Na) channel expression in rat pheochromocytoma (PC12) sublines stably overexpressing *trk* (6-24, 6-15; Hempstead et al., Neuron 9(1992):883), overexpressing *trkB* (PC12/*trkB*, Ip et al., Neuron 10(1993):137), and overexpressing the β -PDGFR receptor (PC-PDGFR-102, PC-PDGFR-111; Heasley and Johnson, Mol. Biol. Cell 3(1992):545). This allows the actions of a number of receptor tyrosine kinases, including those for EGF and bFGF that are already expressed in PC12 cells, to be compared in the same neuronal cell environment. Northern blot analysis of total RNA from control and NGF-treated cells revealed 3- to 5-fold increases in the steady state level of Na channel mRNA in both PC12 and the *trk*-overexpressing 6-24 and 6-15 cells. While there were no dramatic differences in the time course or extent of induction in the 6-24 and 6-15 cells when compared to the parental PC12 cells, basal levels of Na channel mRNA in the 6-24 and 6-15 cells appeared to be elevated, reminiscent of peripherin gene expression in these cells. Whole-cell patch clamp analysis of functional Na channel expression in untreated and PDGF-treated PC-PDGFR-111 cells revealed 3- to 4-fold increases in Na current density, comparable to that occurring in the parental PC12 cells, and to that occurring in the PC-PDGFR-111 cells treated with NGF. The results of studies like these will help define the degree specificity that exists among the receptor tyrosine kinases, provide a basis for identifying neuronal specific aspects of the intracellular signalling associated with their activation, and will provide the basis for mutational studies designed to investigate the mechanisms responsible for promotion of a neuronal phenotype by tyrosine kinases. TROPHIC INFLUENCES OF MELANOTROPE CELLS AND MELANOCORTINS FOR DOPAMINERGIC NEURONS IN CULTURES OF RAT HYPOTHALAMUS. **F. René¹, J.M. Félix¹, S. Varon² and J.C. Louis²**. I.P.B.C., Louis Pasteur Univ., 67000 Strasbourg, France¹ and Department of Biology 0601, University of California, San Diego, La Jolla, CA 92093².

The melanotrope cells of the intermediate lobe of the pituitary (IL) are selectively innervated by dopaminergic (DA) neurons of the rostral periventricular hypothalamus. We tested the hypothesis that IL melanotropes influence the development of DA neurons. We cultured rat IL cells together with neonatal rat hypothalamus and assessed their influence on tyrosine hydroxylase (TH) expression and on the morphology of DA neurons. We found that the number of TH-positive neurons after 7 days *in vitro* was significantly higher (~2-fold increase) in IL-hypothalamus co-cultures, as compared with hypothalamus cultured alone. Moreover, in IL-containing cultures, the TH-positive neurons displayed a more elaborate neuritic morphology. This was particularly evident for the DA neurons that were in direct contact with IL cells. We next tested whether peptides of the melanocortin family were able to influence the maturation of DA neurons in hypothalamic cultures devoid of IL cells. We found that the number and the maturation of TH-positive cells were enhanced by diacetyl- α MSH, monoacetyl- α MSH and N-acetyl(Cys⁴⁻¹⁰, D-Phe⁷)- α MSH4-13, but not by desacetyl- α MSH, ACTH1-13 and ACTH1-24. These findings indicate that the development and maturation of DA hypothalamic neurons can be modulated by their innervation target cells and suggest that this trophic influence is, at least partly, attributable to α MSH peptides, with the most acetylated forms being the most active.

711.5

ROLE OF MICROGLIAL CELLS IN EPIDERMAL GROWTH FACTOR'S (EGF) INDIRECT EFFECTS ON CHOLINERGIC CELL DIFFERENTIATION IN THE MEDIAL SEPTUM. **R.L. Kenigsberg¹ and I.E. Mazzoni²**. Centre de Recherche Pédiatrique, Hôpital Ste-Justine, Montreal, Quebec, Canada. H3T 1C5.

We have recently demonstrated that EGF decreases the activity of choline acetyltransferase (ChAT) in cholinergic neurons from the fetal rat medial septal area in culture. EGF's effects are mediated indirectly via glial cells present in our cultures (Kenigsberg et al., Neuroscience 50:85-97, 1992). We are now furthering our investigations to determine 1) which glial cell type mediates EGF's indirect action on the cholinergic neurons, and 2) what is the cell source and nature of this glial-derived cholinergic neuromodulatory activity whose expression is controlled by EGF. In this abstract we present some of the results we have obtained in reference to the first question. To assess the importance of the microglia in mediating EGF's effects on the cholinergic neurons, we have attempted to eliminate the microglia from our cultures by using the lysosomotropic agent L-leucine methyl ester (LME). A 2 hour treatment with 5 mM LME on culture days 2, 3, 4, 5 or 6 did not affect the EGF-induced decrease in ChAT activity. This single-day treatment, however, was only effective in reducing 30-40% of microglia in EGF-treated cultures. A two-day treatment of the septal cells with LME did not modify EGF's effects on ChAT but could reduce the number of microglia in EGF-treated cultures to those normally found in control sister cultures. As complete elimination of the microglia could not be attained with this treatment, in another group of experiments, various amounts of pure microglial cells were added to our septal cultures. When concentrations of exogenous microglia representing 0.5-9% of the total septal cells were added to EGF-treated cultures, we could not detect any further decrease in ChAT activity. Interestingly however, the EGF effects on cholinergic cell expression were partially antagonized by the addition of these exogenous microglia. Furthermore, the exogenous microglia increased ChAT activity in control cultures as well. As microglia may be a source of nerve growth factor (NGF), we then examined this possibility. We found that the addition of immunoneutralizing anti NGF antibodies could not block the increase in ChAT activity observed in untreated cultures supplemented with exogenous microglial cells. Therefore, this study shows that microglial cells are not implicated in the EGF-induced decrease in ChAT activity in cholinergic neurons from embryonic septal cell cultures nor do they represent a direct or indirect source of NGF in our system.

711.7

RECOMBINANT HUMAN OSTEOGENIC PROTEIN-1 (OP-1) INCREASES ADRENERGIC CELL NUMBER IN AVIAN NEURAL CREST CULTURES. **R.G. Wehby^{*}, I. E. Varley, and G.D. Maxwell**. Neuroscience Program and Dept. of Anatomy, University of Connecticut Health Center, Farmington, CT 06030.

OP-1 is a member of the TGF β superfamily of proteins (Ozkaynak et al. 1990 EMBO J 9:2085). Although originally identified by its ability to induce bone formation *in vivo*, there are indications that OP-1 and other family members may be present in and act on several tissues (Lyons et al. 1991 Trends in Genetics 7: 408). We have tested the effect of recombinant human OP-1 (Creative BioMolecules, Inc.) on quail trunk neural crest cultures. The number of adrenergic cells which were present after 7 days *in vitro* was increased in a dose-dependent manner when OP-1 (0-500 ng/ml) was added to medium containing 15% horse serum and 10% chick embryo extract. At 50 ng/ml OP-1 there was an 8-fold increase in adrenergic cell number, and a 175-fold increase at 500 ng/ml. In contrast, both melanocyte and total cell number were unaffected over this range of OP-1 concentrations. Vehicle, consisting of 60% ethanol and 0.025% TFA, showed no effect. We also tested recombinant human TGF β -1 at 50 ng/ml and, in contrast to OP-1, found a decrease in adrenergic cell number relative to controls. In the presence of TGF β -1 total cell number was unaffected, but melanocyte cell number was decreased to about half the value seen in controls. These findings indicate that OP-1 is a potent and specific stimulator of the adrenergic phenotype in avian trunk neural crest cultures. This work was supported by NIH grant NS16115 to GDM and NIH Training Grant 5 T32 DC00025 to RGW.

711.4

ROLE OF OLIGODENDROCYTES AND ASTROCYTES IN MEDIATING EPIDERMAL GROWTH FACTOR (EGF)'S EFFECTS ON FOREBRAIN MEDIAL SEPTAL CHOLINERGIC NEURONS IN VITRO. **I.E. Mazzoni¹ and R.L. Kenigsberg**, Centre de Recherche Pédiatrique, Hôpital Ste-Justine, Montreal, Quebec, Canada. H3T 1C5.

We have recently demonstrated that EGF decreases the activity of the enzyme choline acetyltransferase (ChAT) in fetal cholinergic neurons from the rat medial septum. This effect is indirectly mediated via the glial cells (Kenigsberg et al., Neuroscience 50:85-97, 1992). In our accompanying abstract, we show that microglial cells are not implicated in the EGF-induced decrease in ChAT activity. In this study we now investigate whether the oligodendrocytes (oligos) and/or the astrocytes (astros) may be implicated. Consequently, we proceeded to eliminate the oligos in our cell cultures by complement lysis using anti-galactocerebroside antibodies. Following this treatment, we monitored EGF's effects on the cholinergic neurons on these oligo-free cultures to find no significant difference in ChAT activity when compared to their appropriate EGF-treated controls. As our results to date suggest that neither the microglia nor the oligos are implicated in EGF's effects on cholinergic cell expression, we proceeded to examine the role of astros. Pure astro cultures were prepared from the medial septal region. Conditioned media (CM) from control or EGF-treated pure astro cultures were collected. The addition of EGF to astros induced their transient (48 hour) proliferation, followed by a period of apparent quiescence. We collected fractions of CM immediately following (fraction 1) and after (fraction 2) active proliferation. The effects of CM from EGF and untreated astro cultures were then tested on pure (99%) neuronal cultures from the medial septum. The addition of fraction 1 obtained EGF-treated astros did not significantly affect the activity of ChAT in pure neuronal cultures. However, fraction 2 collected from EGF-treated astros significantly decreased the activity of ChAT (40% from control levels) in pure neuronal septal cultures. The EGF-induced cholinergic neuromodulatory activity present in fraction 2 appears to have a MW>10 kD, to be heat sensitive and labile to repeated freezing and thawing. This data suggest that astros are capable of producing a soluble factor(s) that can affect forebrain cholinergic cell expression. Release of this factor(s) appears to be controlled by EGF. The characterization and identification of this astro-derived cholinergic neuromodulatory activity whose expression is controlled by EGF is currently under investigation in our laboratory.

711.6

CONSTITUTIVE AND REGULATED EXPRESSION OF MACROPHAGE INFLAMMATORY PROTEIN - 1 α (MIP-1) IN PRIMARY CEREBELLAR CULTURES. **C.B. McCullum, R.E. Smith¹, R.M. Strieter², R.I. Hume², S.L. Kunkel¹**. ¹Department of Biology, ²Department of Pathology, ³Department of Internal Medicine Pulmonary Division, University of Michigan, Ann Arbor MI 48109

The cerebellar cortex is an excellent model for the study of cellular interactions because it contains only glial cells and five types of neurons. Inflammatory cytokines have been well characterized as mediators of cell-cell interactions in the immune system but the effect of these molecules in the nervous system is poorly defined. Macrophage inflammatory protein - 1 α (MIP-1) is a chemotactic cytokine with diverse regulatory functions. We hypothesized that MIP-1 might play a role in normal neuronal and glial interactions in the cerebellum. To begin to test this hypothesis, we made primary cultures of postnatal day one through nine rat cerebella. Using a sensitive and specific ELISA, we detected constitutive expression of MIP-1 in untreated cultures. Furthermore, cultures treated for 24 hours with 0.1 through 10 ng/ml of IL-1 receptor antagonist protein (IRAP) demonstrated an increase in MIP-1 expression. These experiments are consistent with a role for MIP-1 in signalling in the rat cerebellum.

711.8

PLEIOTROPHIN (PTN) INDUCES PROCESS FORMATION IN O-2A PROGENITOR CELLS. **H.-J. Yeh¹, I. Silos-Santiago, Maria A. Gurrieri, W. D. Snider, and T. F. Deuel**. Dept. of Medicine, Biochemistry, and Neurology, Washington University and the Jewish Hospital of St. Louis, MO 63110.

Pleiotrophin (PTN) is a heparin-binding protein that functions as a weak mitogen and as a neurite outgrowth promoting activity *in vitro*. Because the PTN gene is expressed in glial cells and perhaps in ependymal cells as well as in neurons during mouse development *in vivo*, we tested PTN with primary cultures of glial progenitors of E15 rat spinal cord and neonatal rat brain to determine if PTN might have a more general influence on process outgrowth in the developing central nervous system. The cells in culture display a typical bipolar or early multipolar morphology and are recognized by the O4 antibody and thus are similar to oligodendrocyte/type-2 astrocyte (O-2A) progenitor derived from the optic nerve. PTN strikingly enhances process outgrowth of glial progenitors in a dose and time-dependent manner. Process formation is readily demonstrated at 500 pM PTN in 2 days. After 2 days with 100 ng/ml and 200 ng/ml PTN, exuberant process outgrowth and extensive branching are observed. A specific monoclonal anti-PTN antibody completely blocks the influence of PTN. In contrast to PTN, cells treated with the platelet-derived growth factor (PDGF) A-chain (50 ng/ml) for 2 days developed only a few long processes that were without branching and were only minimally different from control cells that are grown in basic media with 5 ng/ml (bFGF). Remarkably, cells exposed to PTN (100 ng/ml) and PDGF A (50 ng/ml) together for 2 days were not different from cells treated with PDGF A (50 ng/ml) alone. These results suggest that the expression of PTN in the central nervous system may have a unique role in glial differentiation and that PDGF A may serve to delay this process during development.

711.9

REGULATION OF EXPRESSION OF FGF-2 AND ITS HIGH AFFINITY RECEPTOR (FLG) IN GLIOMA CELLS BY CELL DENSITY, FGF-2, NGF, TGFs AND GDFIF. R. Westermann, C. Grothe & T. Janet. Dept. Anatomy & Cell Biology, W-3550 Marburg, Germany.

Rat C6 glioma cells synthesize FGF-2 mRNA and protein when cultured at low density and in the presence of serum. Under non-proliferative conditions, i.e. high cell density or in serum-free medium, FGF-2 synthesis drastically decreases. This decrease appears to be induced by a soluble glioma-derived FGF-inhibitory factor (GDFIF). TGFbetas overcome the GDFIF-effects and stabilize high FGF-2 mRNA expression also at high cell density, while FGF-2 and NGF have no effects. From these data we conclude that FGF-2 may act as an autocrine mitogen regulated at the transcriptional level. Binding studies of ¹²⁵I-FGF-2 on C6 cells suggest the presence of both, low and high affinity FGF receptors (FGFR). Using antibodies against FGFRs, a flg-like immunoreactive protein could be detected on the surface and in the cytoplasm of the cells. Therefore, flg may account, at least partially, for high affinity FGF-binding. Like the FGF-2 protein, flg protein is highly expressed in low density cultures and nearly absent in confluent cultures. Surprisingly, the strong flg mRNA synthesis is not influenced by cell density or growth factors. In contrast to FGF-2, flg expression appears to be negatively regulated at the translational level by GDFIF.

711.11

THE EFFECT OF SODIUM PHENYL BUTYRATE ON HUMAN GLIOMA (U373) and MEDULLOBLASTOMA (D324) CELL CULTURES. H.S. Singer*, E. Harley, T.H. Moran, A. Costello, and J. Troncoso. Depts Neurology, Psychiatry, and Pediatrics, Johns Hopkins Univ School of Medicine, Baltimore, MD 21287-8811

Sodium butyrate and associated compounds have been shown to inhibit neoplastic cell growth and induce cytodifferentiation. The mechanism(s) for this activity are being investigated using human glioma (U373) and medulloblastoma (D324) cell cultures. Incubation with sodium phenyl butyrate (NaPB), 2.5 to 10 mM, produces incremental reductions in growth rate (cell count and BUDR incorporation) and morphological changes. At 10 mM concentrations, cell counts are reduced in U373 and D324 lines by 85% and 94%, respectively, and cells assume elongated irregular shapes with increased processes. Changes are reversible when cells are allowed to recover in the absence of NaPB. The effects on cell growth were not significantly affected by the addition of basic fibroblast and transforming growth factors. In U373, NaPB induced choline acetyltransferase activity (ten-fold increase), elevated the concentration of dopamine, and enhanced [³H]-glutamate binding. NaPB reduced adenylate cyclase activity under basal conditions and following stimulation with GTP-γS and forskolin in both U373 and D324 cultures. The effects of butyrate on β-tubulin, tau, and GFAP are under investigation. These results show that NaPB induces a marked growth inhibition associated with morphological and biochemical differentiation in human glioma and medulloblastoma cell lines.

711.13

VASOACTIVE INTESTINAL PEPTIDE: A GROWTH PROMOTOR IN NEUROBLASTOMA CELLS. Y. Wollman, G. Lilling*, M.N. Goldstein, M. Fridkin D.E. Brenneman and I. Gozes. Department of Chemical Pathology, Sackler School of Medicine, Tel Aviv University, Tel Aviv, Israel; Tel Aviv Medical Center, Department of Nephrology, Tel Aviv, Israel; Department of Anatomy and Neurobiology, Barnes School of Medicine, Washington University, St. Louis MO, USA; Department of Organic Chemistry, Weizmann Institute of Science, Rehovot, Israel; LDN, NICHD, NIH, Bethesda, MD, USA.

Vasoactive intestinal peptide (VIP) is a neuromodulator and secretagogue for neuronal survival factors (Gozes and Brenneman, J. Mol. Neurosci. 4:1, 1993). Moreover, VIP has been suggested to have growth-stimulating properties on early postimplantation embryos (Gressens et al., Nature 362:155, 1993) and to act as a mitogenic factor for embryonic neurons in the sympathetic nervous system (Pincus et al., Nature 343:564, 1990). We now show that VIP had mitogenic activity on a human neuroblastoma cell line (NMB), as measured by cell number and thymidine incorporation. This mitogenic activity was dose dependent and was decreased with culture maturation. Northern blot analysis revealed VIP mRNA transcripts in this neuroblastoma suggesting an autocrine growth factor role for VIP.

711.10

EXPRESSION OF TRANSFORMING GROWTH FACTOR-β IN C6 GLIOMA CELLS TRANSFECTED WITH CONNEXIN43 CDNA. Jan J. MacPhee¹, Nelson K.S. Khoo¹, Daniel J. MacPhee², Victor K.M. Han³ and Christian C.G. Naus¹. Departments of Anatomy¹ and Zoology², University of Western Ontario, and Department of Paediatrics³, Lawson Research Institute, London, Ontario, Canada, N6A 5C1.

When C6 glioma cells are transfected with the cDNA for the gap junction protein connexin43, there is a marked decrease in cell proliferation. Furthermore, when conditioned medium from C6 cells transfected with the connexin43 cDNA is placed on normal C6 cells, the result is a decrease in proliferation. This strongly indicates that a soluble growth factor may be produced by the transfected cells. Since previous studies have shown that transforming growth factor-β (TGF-β) is a potent inhibitor of cell proliferation in a variety of cell types, an investigation into the expression of this growth factor was initiated. Utilizing a monoclonal antibody to TGF-β, immunocytochemistry revealed strong immunoreactivity of TGF-β protein in the extracellular matrix and in the cytoplasm of both the normal C6 cells and the high expressing connexin43 clone, with the greater amount identified in the latter cells. Northern blot analysis of cytoplasmic RNA showed an elevation of TGF-β mRNA level in the C6 cells that had been transfected with connexin-43 cDNA. In addition, a mink lung epithelium bioassay revealed that TGF-β was produced by both normal C6 and transfected cells, in both the active and latent forms of the protein. This suggests that an increase in intercellular coupling may directly or indirectly upregulate the expression of TGF-β as a means of controlling the proliferation of these tumor cells. Supported by the Medical Research Council of Canada.

GANGLIOSIDES SELECTIVELY ALTER THE DISTRIBUTION OF LOW MOLECULAR WEIGHT MAP-2 IN NEURO-2A NEUROBLASTOMA CELLS. L.-J. Wang, G. Yorke* and F. Roisen. Dept. of Anatomical Sciences and Neurobiology, University of Louisville, Sch. of Medicine, Louisville, KY 40292.

Our previous studies on Neuro-2a cells demonstrated that GM1: (a) enhances MT-dependent neurogenesis; (b) increases the number of MTs per neurite; and (c) alters the distribution of some MT-associated proteins (MAPs). GM1 has been reported to increase tubulin mRNA. One mechanism underlying the ganglioside-mediated neurogenesis might be MT specific. Evidence is accumulating which demonstrates that MAPs are likely intraneuronal regulators of development, morphology and plasticity. Since four major gangliosides are found in neuronal membranes, this study determined if GM1, GD1a, GD1b, GT1b or neuraminidase alter the distribution of MAP-2. Neuro-2a cells were cultured with or without ganglioside (150 ug/ml) or neuraminidase (1 unit/ml) for 24 hr prior to immunolocalization with antibodies to: (a) high and low molecular weight MAP-2 (mAb); (b) high molecular weight MAP (mAb) and (c) tubulin (mAb and pAb). Treatment with GM1, neuraminidase or GT1b produced a redistribution of MAP-2 (low molecular weight) from perinuclear cytoplasm to the distal neurites. In contrast, GD1a and GD1b, two ganglioside species with less neurotogenic potential, did not alter the intracellular distribution of MAP-2. EM post-embedding immunogold localization demonstrated that GM1 enhanced the MT cytoskeleton. Western blot analysis revealed that tubulin, but not the low molecular weight MAP-2, increased after GM1 exposure. This study demonstrated that GM1 and GT1b or conversion of endogenous gangliosides to GM1 redistributes the low molecular weight MAP-2 which alters Neuro-2a morphology. Gangliosides may not only stimulate neurogenesis but also influence the neurite's axonal or dendritic fate. Supported by Alliant Community Trust Fund, Louisville, Kentucky.

FURTHER CHARACTERIZATION OF COLLAGEN POTENTIATED NEURITE PROMOTING FACTOR. DE.Coyne*. Department of Anesthesia, University of Cincinnati College of Medicine., Cincinnati, OH 45267-0531.

As previously reported, this laboratory has identified a neurite promoting factor which is potentiated by the presence of collagen and produced by C6 glioma cells which have been adapted to serum free growth conditions. In the present study, CPNPF was examined to provide evidence that it is not an already characterized neurotrophic molecule. At its present state of purity, CPNPF appears to only support neurite outgrowth of PC12 cells for a short period of time (4 days) without the presence of a neurotrophic factor. The activity of this molecule is not dependent on the presence of intact chondroitin or heparin sulfate proteoglycan. This factor is not blocked by neutralizing antibodies directed against NGF, β-FGF, TGFβ2, TGFβ1.2, TGFβ3, TGFβ5, IL-1β, IL6, or EGF. Western blot analysis of CPNPF for the presence of fibronectin or laminin using polyclonal antisera resulted in no protein bands staining for these molecules. This result would indicate that neither the intact forms of laminin or fibronectin, nor fragments which may have resulted from proteolytic products or the production of truncated versions of these molecules by C6 cells is responsible for the neurite outgrowth activity of CPNPF. Incubation of CPNPF with mouse type IV collagen results in no loss of neurite outgrowth activity. Preincubation of CPNPF with the rat type I collagen substrate present in the assay well followed by washing to remove the soluble CPNPF results in no neurite outgrowth compared with control. These two results support the conclusion that CPNPF does not bind to collagen in order to affect its neurite promoting effect. CPNPF by indirect evidence does not appear to be glial derived protease nexin-1 since it cannot be isolated by the procedure of Guenther et al. (EMBO J 4: 1963, 1985) and does not induce neurite outgrowth from mouse neuroblastoma 2a cells. From this evidence it appears that serum free growth conditions in the presence of collagen may have induced the production of a potentially new NPF from C6 glioma cells.

JUN, FOS, KROX AND CREB PROTEIN EXPRESSION IS DIFFERENT IN ADULT DORSAL ROOT GANGLION NEURONS STUDIED IN VIVO AND IN VITRO. T. Herdegen¹, R. Bravo², S.G. Waxman, and J.D. Kocsis. Dept. of Neurol., Yale Univ. Sch. Med. and VAMC, New Haven, CT 06510; II. Institute of Physiol., Univ. Heidelberg¹, 6900 Heidelberg, Germany; Bristol-Myers Squibb Pharm. Res. Inst.², Princeton, NJ, 08543.

We compared immunoreactivity (IR) for c-Jun, JunB, JunD, c-Fos, Krox-20 and Krox-24 transcription factors in adult rat DRG neurons in culture and in vivo. In vivo lumbar DRG of the untreated rats show a selective basal expression of c-Jun and JunD which is much increased following axotomy by sciatic nerve cut whereas JunB, Fos and Krox proteins remained absent or unchanged (Herdegen et al., Mol. Brain Res. 14: 155-165). For in vitro studies, lumbar DRG were dissociated and plated on glass coverslips and maintained in culture. Expression of proteins was assessed by specific antibodies and visualized by immunocytochemistry, and double-labelling with neurofilament antibody proved the neuronal presence. Within 24 hrs after plating there was intense nuclear labelling of all Jun, Fos and Krox proteins in virtually all neurons. This was also true for Krox-20 which showed an exclusive cytoplasmic labelling in vivo. After one week, the IR decreased in large diameter neurons but fairly persisted in small and medium diameter neurons. The decrease was more pronounced for c-Fos, JunB and Krox proteins compared to c-Jun. Nuclear staining was also present for CREB protein. These data demonstrate that DRG can express a variety of transcription factors in vitro which are strictly controlled in vivo even following axotomy. Dissociation of DRG neurons for culture may remove this control indicating that DRG neurons might generate a different protein synthesis pattern as compared to axotomized DRG in vivo.

CYTOKINE INDUCED STIMULATION OF mRNA ENCODING THE RECEPTOR FOR SUBSTANCE P IN SYMPATHETIC NEURONS. W.H. Ludlam^{*}, K.E. McCarron², J.E. Krause³, and J.A. Kessler. Depts. of Neuroscience and Neurology, Albert Einstein College of Medicine, Bronx, NY 10461, and ⁴Dept. of Anatomy and Neurobiology, Washington University School of Medicine, St. Louis, MO 63110.

The mechanisms which orchestrate the temporo-spatial responses of neurons and non-neuronal cells after neural injury are not well understood. In sympathetic neurons, levels of the neuropeptide substance P (SP) are increased in response to injury, as is the receptor for substance P (SPR) in non-neuronal cells. After injury, soluble cytokines are released into the cellular milieu, and some of these factors, such as leukemia inhibitory factor (LIF), have been shown to increase neuronal levels of SP. We investigated the effects of LIF on the regulation of SPR in cultured sympathetic neurons of the neonatal rat superior cervical ganglion (SCG). In untreated SCG cultures, the level of SPR mRNA was nearly undetectable (0.022 ± 0.008 pg SPR mRNA/ug total RNA) using a solution hybridization/ nuclease protection assay. By contrast, in the presence of LIF (5 ng/ml, 14 days treatment), the SPR mRNA level rose 9.4 fold to 0.207 ± 0.047 pg/ug. SCG SPR mRNA were quantitated by comparing sample levels to a standard curve of different amounts of sense cRNA for the SPR. Conversely, levels of muscarinic receptor mRNA were decreased in LIF treated SCG cultures showing the specificity of the SPR mRNA increase. We are currently investigating cytokine induced regulation of SPR in non-neuronal cell types. These findings indicate that cytokines like LIF may play a role in the coordination of SP and SPR levels in the cells of neural tissue after injury.

The responses of the human leptomeningeal cells for thrombin, EGF, TGF- β , IL-6, aFGF, PDGF *in vitro*. O. Motohashi, M. Suzuki^{*}, A. Nishino, K. Umezawa, N. Shida, T. Yoshimoto. Div. of Neurosurg., Inst. of Brain Diseases, Tohoku Univ. Sch. of Med., Sendai, Japan 980.

Some disorders of the central nervous system result in the arachnoiditis. Thickening and adhesion of leptomeningeal membranes are reported in the disease processes or trauma and other types of meningitis. Normal pressure hydrocephalus is often recognized after subarachnoidal hemorrhage. Histopathological findings in such disease have been said to be subarachnoidal fibrosis, that is, proliferation of cells and fibers. We have first succeeded in culture of the human leptomeningeal (LM) cells in serum-free media supplemented with insulin, transferrin and dexamethasone. Using this culture system, we investigated the responses of the LM cells to several growth factors, the level of which in the cerebrospinal fluid were elevated in the patient of subarachnoidal hemorrhage. Human LM cells at confluence in the serum-free condition were trypsinized, diluted with the serum containing medium to the density of $7 \times 10^3 - 2 \times 10^4$ cells/ml and seeded in the 24-well multiplates pretreated with poly-L-lysine. 24 hours later, the medium was changed into the appropriate medium for experiment. The cells were counted triplicately every 2 or 3 day with Coulter Counter. In summary, our findings can be stated as follows: (1) We examined the proliferative responses of the LM cells to thrombin, EGF, TGF- β , IL6, aFGF and PDGF *in vitro*. (2) Thrombin might promote the LM cell proliferation dose-dependently. (3) TGF- β might enhance the proliferative effect of thrombin on the LM cells. (4) IL6 and PDGF have a little proliferative effect on the LM cells. (5) EGF and aFGF might have a considerable effect on the LM cell proliferation. These findings suggest that thrombin and TGF- β , elevated in CSF following SAH, may cause subarachnoidal fibrosis and subsequent hydrocephalus.

CYTOKINE TREATMENT CAUSES ALTERATIONS IN THE CALCIUM RESPONSES OF CULTURED CEREBELLAR GRANULE NEURONS. J. Holliday^{*}, J. Curry, S. Lee, K. Parsons and D.L. Gruol. Dept. of Neuropharmacology, The Scripps Research Inst., La Jolla, CA.

Elevated cytokine levels are associated with several human diseases (including Down syndrome and HIV infection) that result in developmental abnormalities. However, their possible role in producing abnormal development is unknown. Some cytokines are known to directly activate neuronal growth factor receptors in the CNS and are thus likely to affect CNS development. We have studied the effects of cytokine treatment upon neuronal development and function to assess the role of cytokine elevation in producing abnormal CNS function.

Cerebellar granule neurons were chosen for experimentation since they can be grown in relative isolation from other cell types that may also respond to applied cytokines. Their calcium responses to both depolarization and glutamate receptor stimulation (NMDA-type) has been well characterized during the first week of development in culture. Cells were stimulated with 1 sec. applications of either 150 mM KCl or 100 μ M glutamate (in the absence of extracellular Mg²⁺). Intracellular calcium concentration was estimated using fura-2 imaging techniques.

Treatment of granule neurons with 40 units/ml of IL-1 β on the first day in culture and supplemented again on the fourth day caused significant increases in the glutamate response but not in the depolarization response or resting level measured at the end of the first week in culture. Other cytokines, such as TNF and IL-6 produced similar results. Chronic cytokine treatment may affect the rate of neuron maturation or may directly affect responses to stimuli.

AGENTS STIMULATING cAMP FORMATION ENHANCE INTERLEUKIN 6 PRODUCTION BY RAT CORTICAL ASTROCYTES Grimaldi M., Meucci O., Ventra C., Scorziello A., Pozzoli P.L., Navarra and Schettini G.* Sez. Farmacol., Dip. Scienza Comunicazioni Umane, Univ. di Napoli, Napoli; *Ist. di Farmacol. Univ. del Sacro Cuore, Roma, ITALY.

Within the central nervous system (CNS) interleukin-6 (IL-6) is produced by astrocytes and microglia and induces neuronal differentiation and survival. The production of IL-6 by astrocytes in response to cytokines such as IL-1 or TNF or to LPS has been established. The IL-6 gene contains a multiple regulatory element region (MRE) including a cAMP responsive ones. Here we describe the effects of both forskolin (FSK), a direct activator of the catalytic sub unit of adenylate cyclase (AC) enzyme and Vasoactive Intestinal Peptide (VIP), a neurotransmitter with neurotrophic actions, known to stimulate AC activity, on IL-6 production by cortical astrocytes, assessed by means of 7TD1 bioassay. FSK stimulated IL-6 production in a dose dependent manner with plateau reached at 1 μ M concentration. Similarly, VIP stimulated, over a 24h incubation, in a dose dependent manner, IL-6 production. The effect of VIP was not affected by blocking protein kinase (PK)-C with calphostin, but was strongly reduced by blocking PK-A by using KT-5720, a specific PK-A blocker. These results suggest that the effect of VIP is achieved by activating the low affinity VIP receptor. The effect of FSK was also reduced by KT-5720. In addition the stimulatory effect of VIP and FSK was mimicked by cAMP analogues 8-Br-cAMP and dibutyryl-cAMP. Both these agents increased IL-6 production by astrocytes in a dose dependent manner being dibutyryl-cAMP more effective. FSK was able to increase, in a dose dependent manner, prostaglandins (PGs) E₂ and F_{2 α} release by astrocytes an effect not induced by VIP. In presence of 100 nM indomethacin the stimulatory effect of FSK on IL-6 production persisted, while PGs stimulation was blocked. We conclude that IL-6 release by cortical astrocytes is not only regulated by inflammation- infection-related substances such as IL-1 or LPS, but also under the tight control of cAMP-PK-A transducing system.

AUTOCRINE AND ENDOCRINE ROLES OF IGF-II SECRETION BY THE CHOROID PLEXUS. C. Nilsson^{*} and S. Gammeltoft. Wallenberg Laboratory, Div. of Molecular Neurobiology, Univ. of Lund, Box 7031, S-220 07 Lund, Sweden.

Studies by *in situ* hybridization have shown that the choroid plexus (CP) and meninges are the main sites of insulin-like growth factor-II (IGF-II) mRNA expression in the adult mammalian CNS. We have developed primary cultures of CP epithelial cells from rat and sheep to investigate the role of IGF-II in this tissue. Conditioned medium contained similar amounts of both IGF-II and IGF-binding protein-2, as shown by Western immunoblot and gel filtration, demonstrating that IGF-II mRNA is translated and secreted as mature peptide by CP epithelium. Radioreceptor assay gave an approx. amount of IGF-II of 30 and 0.8 nM in rat CP conditioned medium and CSF, respectively. Comparison with data on CP weight and CSF volume and formation shows that the CP could provide both the CSF and brain with IGF-II. The possibility of an autocrine role for IGF-II in the CP epithelium was studied by determining the number of cell divisions during two days in serumfree medium, as measured by immunohistochemical detection of bromodeoxyuridine incorporated into nuclei. Monoclonal antisera to rat IGF-II decreased the number of positive nuclei by 38% ($p < 0.01$), while IGF-I and fibroblast growth factor both stimulated mitosis ($p < 0.001$). Growth hormone, and the neuropeptides VIP and PACAP had no effect.

In conclusion, IGF-II could have both endocrine and autocrine roles in the CP, although the continuous formation of CSF by the CP would appear to favour an endocrine role.

IDENTIFICATION AND CHARACTERIZATION OF STEROID REGULATED GENES IN THE NERVOUS SYSTEM OF *MANDUCA SEXTA*. M. Mészáros and D. B. Morton. Arizona Research Laboratories Division of Neurobiology, Univ. of Arizona, Tucson, AZ, 85721

During metamorphosis the nervous system of insects undergoes dramatic changes that are regulated primarily by the ecdysteroids. 24 hr prior to the pupal molt in *Manduca sexta* steroid titers are relatively high and they fall to very low levels at 4 hr before the molt. Several physiological events accompanying metamorphosis have been shown to require the rise and then a subsequent decline of ecdysteroid levels. These events also require the expression of a new set of genes. We used subtractive hybridization to isolate the genes that are expressed 4 hr prior to the pupal molt in the nervous system of *Manduca*. These genes are expected to play a role in either ecdysis behavior or in the development of pupal/adult structures. As ecdysteroid levels peak and subsequently fall prior to the molt, these genes are expected to be turned on at very low ecdysone titers after the exposure to high steroid levels. We have isolated six cDNA clones that represent genes that are developmentally regulated prior to metamorphosis in the nervous system. Using *in situ* hybridization we have shown that three of them are expressed in neurons. Currently we are sequencing these clones, trying to identify the neurons that express the genes and looking for possible roles of these cells in metamorphosis.

SYNENKEPHALIN (PROENKEPHALIN 1-70) PROCESSING IN EMBRYONIC RAT BRAIN. M.I. Rodriguez Vida, M.C. Kleid, A. Ase, S. Finkelman, V.E. Nahmod and O.Vindrola*. Inst. Invest. Med. Fac. Med. Univ. Buenos Aires (1427) Argentina. ¹ LSU Sch. of Med. Rheumatology, New Orleans, LA 70112.

Syntenkephalin is produced and secreted as an intact molecule or as a part of precursors in adult brain and adrenal medulla respectively. However it is cleaved to low molecular weight peptides in proliferating immune cells. Considering that proenkephalin is expressed in embryonic rat brain (ERB) during cell proliferation, we studied the processing of syntenkephalin in ERB (E18) and in adult rat brain (ARB). IR-syntenkephalin was measured by RIA using a C-terminally-directed antiserum. ARB contained the highest concentration of IR-syntenkephalin (ERB: 1361±100; ARB: 2612±264) (results in fmol/mg protein, n=5). Gel filtration chromatography (Sephadex G-50) showed that in ARB most of IR-syntenkephalin eluted in the position of the authentic peptide (8.0 kDa), although partial processing to 4.5 and 3.0 kDa peptides was observed. In ERB, syntenkephalin was fully cleaved to a 1 kDa peptide, which was further characterized by affinity chromatography and HPLC. IR-Met-enkephalin (after digestion with trypsin and carboxypeptidase B) corresponded mainly to non-processed or partially processed products in ERB, but these were cleaved to free met-enkephalin in ARB. These results show that syntenkephalin was cleaved to low molecular weight peptides only in ERB, suggesting an involvement of this molecule in nervous cell proliferation.

712.5

CHARACTERIZATION OF GALANIN-LIKE IMMUNOREACTIVITY IN THE PRENATAL BRAZILIAN OPOSSUM BRAIN. J. K. Elmquist*, J. Iqbal, L. R. Ross, J. J. Swanson, and C. D. Jacobson. Department of Veterinary Anatomy and Neuroscience Program, Iowa State University, Ames, IA 50011.

Previously our laboratory has demonstrated that galanin-like immunoreactivity (GAL-IR) and GAL receptors are present as early as 1 day postnatal (PN) in the brain of the Brazilian opossum, *Monodelphis domestica*. *Monodelphis* is a small marsupial whose young are born in an extremely immature state with a protracted postnatal period of neurogenesis. We have hypothesized that the presence of GAL-IR and GAL receptors at this early stage of CNS development indicates that GAL may be playing a distinct developmental role in the CNS. Although *Monodelphis* is born in a very immature state GAL-IR was robustly expressed at birth. To further characterize a developmental role for GAL we have looked at the ontogeny and distribution of GAL-IR in the prenatal opossum. We have found GAL-IR as early as embryonic day 11 (E11) in various structures in the forming embryo. Specifically, GAL-IR was observed in the forming trigeminal ganglia and nerve, dorsal root ganglia, spinal cord, sympathetic chain, and presumed vagal fibers in the thorax and abdomen. Additionally, cell bodies containing GAL-IR were observed in the forming diencephalon. This early ontogeny of GAL-IR further indicates that GAL may play an important formative role of the mammalian nervous system. In addition we have compared the distribution of various other neuropeptides and neurotransmitters to that of GAL. At E11, 5-HT and tyrosine hydroxylase immunoreactivity is detectable in the CNS. The distribution is distinct, however from that of GAL-IR. As early as 1PN, vasopressin-like immunoreactivity (AVP-IR) is present in the forming hypothalamus. Adjacent tissue sections indicate that GAL-IR and AVP-IR may be colocalized in a subset of GAL-IR cells. The use of specific GAL antagonists may indicate potential roles for GAL.

CHANGES IN OXYTOCIN PROHORMONE PROCESSING IN HYPOTHALAMIC CULTURES. M. Morris*, L.J. Sim, and M.O. Lively. Depts of Physiology/Pharmacology and Biochemistry, Bowman Gray School of Medicine of Wake Forest University, Winston-Salem, NC 27157

There are developmental changes in oxytocin (OT) prohormone processing, with evidence for the presence of C-terminal extended OT (OT-X) in fetal brain and plasma (Altstein and Gainer, 1988, Morris et al., 1992). A hypothalamic culture model was used to further examine OT cellular development and neurosecretion. Dispersed paraventricular (PVN) cultures from 1-2 day old rats were stained for oxytocin neurophysin (NP-OT) and vasopressin neurophysin (NP-VP). Secretion studies were also performed with measurement of media and tissue levels of OT peptides under control and KCL stimulation. The predominant neurophysin cell type in the PVN cultures was NP-OT with very few cells positive for NP-VP. The use of different OT antisera, one specific for amidated OT and another which crossreacts with OT-X, revealed almost no labeling with the amidated specific antisera. Measurement of media and tissue OT supported this finding. HPLC separation with radioimmunoassay showed that the secreted form was OT-X, with a single peptide peak. The tissue contained both OT-X and OT; however, the levels of OT-X were greater (2:1 ratio of OT-X:OT). Stimulation of the cultures with KCL caused a 2-fold increase in the tissue levels of OT and OTX, while media peptides were marginally increased. These results show that cultured hypothalamic oxytocin neurons show alterations in peptide processing which is similar to that observed in the developing animal.

EARLY ONTOGENY OF MELANOTROPIN BINDING SITES IN RAT BRAIN AND SYMPATHETIC NERVOUS SYSTEM. W. Lichtensteiger*, B. Haninmann, M. Schlumpf, W. Siegrist* and A. Eberle*. Inst. of Pharmacology, Univ. of Zürich, CH-8006 Zürich, and *Research Dept., Univ. Hospital, CH-4031 Basel, Switzerland.

Developmental changes in nervous system after manipulation of α -melanotropin (α -MSH) levels suggest a role of melanotropins in ontogeny. In order to provide a basis for a detailed analysis of such effects, we studied the development of binding sites for the analog [¹²⁵I]Nle⁴,D-Phe¹- α -MSH ([¹²⁵I]-NDP). Scatchard analysis of [¹²⁵I]-NDP binding to diencephalic membranes revealed a single binding site with Kd = 0.37 nM. For *in vitro* autoradiography, cryostat sections of fetuses and offspring from time-pregnant Long Evans rats were incubated with 0.4 nM [¹²⁵I]-NDP, non-specific binding was assessed in every second section by coincubation with 200 nM cold NDP. In early fetal life, significant levels of specific binding are detected, at gestational day (GD) 14 (GD 1 - 24 hr after mating) in the sympathetic chain and in the dorsal meso-diencephalic junction, at GD 15 in spinal cord, inf. olive, solitary tract nuc., spinal trigeminal tract nuc., and ventral mesencephalon; at GD 16 i.a., in post. hypothalamus, at GD 17 in cerebellum and brainstem reticular nuclei. Perinatally, a conspicuous receptor development occurs in caudate-putamen, nuc. accumbens and olfactory tubercle where, from GD 17, receptor density rises to high levels between GD 20/22 and postnatal day (PN) 4, and subsequently decreases towards adult levels. This period is also characterized by the transient presence of binding sites in certain cortical areas, i.a., parietal cortex layers III/IV and hippocampus at PN 8. Mediobasal hypothalamic binding sites increase slowly during postnatal life. The different patterns may be linked with the type of endogenous ligand, neuron system, and receptor subtype; binding characteristics are being studied. The early presence of relatively high densities of receptors in distinct locations, marked density variations, and transient expression in regions virtually devoid of receptors in adulthood (e.g., neocortex and cerebellum) lends further support to the idea of a role in developmental processes.

712.6

ORNITHINE DECARBOXYLASE ACTIVITIES IN RESPONSE TO IN VITRO HYPOXIA AND OXIDATIVE STRESS: A NOVEL USE OF BRAIN SLICE PREPARATIONS. S. Packianathan, J. Zhao, C.D. Cain and L.D. Longo*. Div. of Perinatal Biology, Depts. of Physiology, Ob/Gyn, and Biochemistry, School of Medicine, Loma Linda Univ., and J.L. Pettis VA Hospital, Loma Linda CA 92350.

Background. Recently, we have demonstrated in fetal rats that acute hypoxia results in significantly elevated ODC activity, polyamine concentrations, and ODC mRNA (*PNAS* 90:692-696, 1993). To study and evaluate this enzyme response, as well as to avoid maternal confounding effects, we have developed an *in vitro* fetal or neonatal brain slice preparation. We have also used this procedure to study the effects of oxidative stress, i.e., free radicals on the slices. Methods. 500µm thick brain slices from 18 to 21 gestational day rat fetuses and 3 to 5 day old pups were allowed to equilibrate in artificial CSF continuously bubbled with 95% O₂/5% CO₂ for 1 hr prior to beginning hypoxic exposures. Slices were made hypoxic by replacing the gas with 40%, 21%, or 10% O₂, all with 5% CO₂ and balance N₂. Results. In brain slices ODC activity increased significantly to peak between 3 and 4 h after initiation of hypoxia. The increase varied inversely with the O₂ concentration. For instance, in slices from 4 day old pups, after 4 h of 40% O₂, ODC activity was elevated 2-fold above control, 3-fold at 21%, and 6-fold at 10% O₂. Cell viability at the end of the 4 h hypoxic exposure was assessed by ODC activity increase to fetal bovine serum (FBS) stimulation. 0, 3, 5, and 10% FBS was added at the beginning of the hypoxic exposure. At 4 h, the slices showed a serum-dose dependent increase in ODC activity at up to 5-fold, indicating their ability to respond to external mitogenic stimuli even under the hypoxic exposure. In response to 0.3% H₂O₂, slice ODC activity increased two to three-fold at 1 h, and showed a H₂O₂ dose response up to 0.5% before it decreased. Conclusions. 1) The fetal brain *in vivo* hypoxic-induced ODC increase can be replicated in a well established *in vitro* system. 2) The low but stable baseline ODC activity suggests that the cells are in a quiescent state. 3) The slice preparation may be a useful tool to study the mechanisms of free radical mediated cellular effects. 4) Apart from electrophysiological evidence, ODC activity may be an additional marker for brain slice viability. (Supported by USPHS grant HD 03807 to LDL)

712.7

THYROID HORMONES ALTER THE TIME COURSE OF CHOLINEACETYLTRANSFERASE (CHAT) EXPRESSION DURING POSTNATAL DEVELOPMENT IN THE FOREBRAIN CHOLINERGIC SYSTEM: A NONRADIOACTIVE IN-SITU HYBRIDIZATION OF CHAT mRNA. J.D. Oh*, A. Rohgani, R. Edwards, and L.L. Butcher. Laboratory of Chemical Neuroanatomy, Dept. of Psychology, University of California, Los Angeles, CA 90024-1563, U.S.A.

In the present experiment, we demonstrate that thyroid hormone manipulation can modify the time course of ChAT expression during the postnatal development of the cholinergic forebrain. Rat pups were made hyperthyroid by administering 1 mg/kg triiodothyronin (T3) i.p. daily. Other groups were made hypothyroid by providing 0.3 % propylthiouracil (PTU) in the diet of the dams. These groups were then compared with the control group who received an isovolumetric injection saline (0.9%) i.p. daily. The pups were perfused at 1, 2, 3, and 4 postnatal weeks and the tissue sections were stained for ChAT mRNA using a nonradioactive in-situ hybridization technique. As we predicted, thyroid deficient rat pups (198[±]25.20) showed markedly fewer ChAT mRNA-positive cells at postnatal 1 week than the controls (318[±]23.71) and eventually reached the adult level at postnatal week 4. On the other hand, T3-treated pups (307[±]43.30) showed an equivalent number of ChAT mRNA stained neurons as the control at postnatal 1 week. However, whereas the controls reached the adult level of ChAT mRNA neurons at postnatal week 2 and remained at this level until the postnatal 4 week, ChAT mRNA-positive cells progressively decreased in the hyperthyroid group from postnatal week 2 to week 4. At postnatal week 4, the ChAT mRNA cell number of hyperthyroid pups declined down to 70 % of the adult level (p<0.05).

NUTRITIONAL AND PRENATAL FACTORS

713.1

UNDERNUTRITION DURING EARLY LIFE DOES NOT AFFECT THE NUMBER OF NEURONS IN THE RAT CEREBRAL CORTEX. K.S. Bedi*, Department of Anatomical Sciences, University of Queensland, Australia, 4072.

Undernutrition during early life is known to cause deficits and distortions of brain structure. However, it remains uncertain whether or not this includes a diminution of the total numbers of neurons. Recent advances in stereological techniques have made it possible to obtain unbiased estimates of total numbers of cells in well-defined biological structures. Rats were undernourished from the 16 day of gestation to 30 postnatal days of age by standardised procedures. These and well-fed control rats were anaesthetised and killed at 70 days of age by intracardiac perfusion with a modified Karnovsky fixative. The left cerebral hemisphere from each animal was embedded in Paraplast and serially sectioned. The sections were analysed by the Cavalieri principle to obtain the total cortical volume, and by the 'disector' method to estimate the numerical density of neurons in the cortex. These values were later used to compute estimates of the total number of cortical neurons for each animal. Well-fed control rats had an average of 26.9 million cortical neurons whilst the perviously undernourished animals had 24.8 million. The difference between these two groups was not statistically significant. It was concluded that undernutrition of rats during early postnatal life does not affect the total numbers of neurons in the cerebral cortex.

713.3

NEONATAL MONOSODIUM GLUTAMATE (MSG) DECREASES VULNERABILITY TO THE WEIGHT-LOSS SYNDROME PRODUCED IN ADULT RATS BY VOLUNTARY EXERCISE AND FOOD RESTRICTION. I.S. Rieg*, B.A. Woynczyk, K.F. Fulton, S.N. Downing, & P.E. Aravich. Eastern Virginia Medical School, Norfolk, VA 23501; VA Medical Center, Hampton, VA 23667; Hampton University, Hampton, VA 23667.

Monosodium Glutamate (l-glutamic acid) is a neurotoxin when administered neonatally to rats. The arcuate hypothalamic nucleus, the primary source of brain beta-endorphin (BE), is among those areas damaged. A reduction in brain BE has been correlated with anorexia nervosa (AN). MSG also increases relative adiposity and an increase in relative adiposity reduces susceptibility to an animal model of AN. This experiment determined if neonatal MSG alters susceptibility to an animal model of AN produced by exercise (22.5 hr/day running wheel access) and food restriction (1.5 hr/day food access). If a reduction in brain BE causes the syndrome, MSG should increase vulnerability to it, if increased relative adiposity protects against the syndrome, MSG should reduce vulnerability. It was found in male rats, that MSG (4.0 mg/kg, sc, odd pnd 1-9) increased the number of days necessary to reach a 25% weight-loss criterion despite the fact that MSG rats were lighter at the onset and ate less compared to saline controls. There was no effect on wheel running. Finally, MSG exaggerated the effects of the syndrome on relative adrenal weight, but did not alter relative thymus weight and actually attenuated its effects on relative spleen weight. It is concluded that the weight-loss syndrome is affected by increased adiposity rather than reduced BE.

FELINE MATERNAL TAURINE DEFICIENCY: EFFECT ON VISUAL CORTEX OF OFFSPRING. H. Imaki*, Y. Xu, P. Lu and J.A. Sturman. Institute for Basic Research in Developmental Disabilities, Staten Island, NY 10314.

Cats are dependent on an adequate dietary source of taurine, without which they become taurine-deficient. This condition has an adverse effect on reproduction resulting in excessive fetal wastage and low-birth-weight live kittens, and abnormal ontogeny of the CNS. We have previously reported quantitative morphometric and immunohistochemical evidence of abnormalities in newborn visual cortex and now report similar studies of 8-week-old kittens. In contrast to newborn kittens, there were no differences in thickness of individual laminae nor in total thickness despite a persisting four-fold smaller taurine concentration and a 9% smaller total brain weight. There were no differences in number of neurons under 1mm² of surface or in numerical density of neurons. There were more astrocytes in all laminae of taurine-deficient kittens, reaching statistical significance in layers II-III.3 and IV-B.1, and fewer oligodendrocytes in layers IV-B.1 and V-2. Using antibodies raised against amino acids linked to BSA with glutaraldehyde, we examined the localization of taurine, glutamate and GABA in these kittens. There was little difference between groups except for an increased number of GABA-positive cells in taurine-deficient kittens. Thus gross morphological differences are smaller at 8 weeks than at birth, perhaps because only 40% of live-born taurine-deficient kittens survive to 8 weeks, preselecting less affected kittens.

EFFECT OF PRENATAL ALCOHOL EXPOSURE ON DEVELOPMENT IN THE SUPERFICIAL LAMINA OF THE RAT SUPERIOR COLLICULUS. K.A. Wall and D.E. Phillips*. Department of Biology and WAMI Medical Education Program, Montana State University, Bozeman, MT 59717.

Developmental alcohol exposures have been shown to cause deficits in visually oriented activities in humans and to cause structural changes in the rat optic nerve, thus changes in other areas of the visual system might be expected. Pregnant rats were fed a liquid diet containing either ethanol (6.7% v/v) or a maltose-dextrin caloric supplement. Control and ethanol exposed pups were fostered to surrogate dams after birth until sacrifice or weaning at 20 days. Brain tissues from male pups were removed at 15 and 35 days postnatal and processed for either plastic embedding or for Golgi-Cox impregnation. Standard areas of the superficial lamina (SL) were defined in 2µm plastic sections of the superior colliculus (SC) and the neurons and glial cells were counted. Golgi-Cox stained SC tissue was embedded in celloidin and 120µm sections were cut and mounted for camera lucida drawings of type II ganglion cells. There was a slight decrease in the mean number of neurons per unit area and a slight increase in the mean number of glial cells per unit area at 15 days postnatal. Neither change was statistically significant. There were significant decreases in the number of dendritic branches per neuron and the numbers of branches at specific distances from the cell soma. Dendritic changes were most apparent at 15 days postnatal (reduced 25-43% for both parameters) and were still reduced at 35 days postnatal but to a lesser degree (8-20% for both parameters). These results indicate that a prenatal exposure to ethanol can cause dramatic reductions of type II ganglion cell dendritic branches in the infant rat SC that persist, but to a lesser degree, in adolescent animals. REM-SLEEP DEPRIVATION IN NORMAL AND MALNOURISHED RATS AT 30 DAYS OF AGE. L. Cintra*, P. Durán, L. Granados, and A. Galván. Inst. Invest. Bioméd. UNAM, México, D.F. 04510.

In previous studies we reported significant decreases of REM sleep (30 and 60 days) after total sleep deprivation during the lights-on phase in malnourished rats. The objective of the present study was to evaluate the effects of protein malnutrition induced by a 6% casein diet, instituted before mating and continued during gestation and into postnatal life, using an inverted dark-light cycle on the sleep-waking cycle before and after REM sleep deprivation. A baseline-recording day was followed by one day of REM sleep deprivation by the platform technique in control and malnourished rats. This was followed by three recovery days in normal (25% casein diet) and malnourished rats of 30 days of age. We found significant decreases of waking and significant increases in SWS in malnourished rats on day 1 during the activity phase and also a significant increase of REM sleep on days 4 and 5 of the rest phase (lights-on). These data reveal a significant delay in the maturation of SWS and REM sleep in malnourished rats and in mechanisms that regulates REM sleep recovery. (Supported by DGAPA IN 202891-IIB-UNAM)

PRENATAL MALNUTRITION AND POSTNATAL NUTRITIONAL REHABILITATION ON MOSSY FIBERS AREA OF DENTATE GYRUS OF THE RAT. A. Galván*, L. Granados, S. Díaz-Cintra, L. Cintra, A. Aguilar, T. Kemper, and P.J. Morgane. UIISI-INP, SSA, C.P. 14410, and IBM, UNAM. A.P. 70228, México D.F. Neurol. Unit, Boston MA, 02118 & Worces. Found. Exp. Biol. Shrews. MA, 01545 USA.

Prenatal malnutrition produces long-term effects on the spine density in granule cells of the dentate gyrus in the hippocampal formation of rats at 220 days of age. In the present study, we analyzed this effect on the area of mossy fibers from dentate granule cells stained with Timm's technique. 64 male Sprague-Dawley rats were divided into two groups control and rehabilitated, consisting of 15, 30, 90 and 220-days-olds. The mossy fiber area was studied in five frontal levels and analyzed using an imaging digital system (BIOCOM). Results showed a significant decrease ($p < 0.05$) in the area of mossy fibers in all levels studied at 220 days of age. At 90-day-old rats showed a significant decrease ($p < 0.05$) at level 1, 15 day-old shows a reduction at levels 3-4. These findings indicate a severe long-term effect of prenatal malnutrition on mossy fibers of dentate granule cells. (Supported by DGAPA IN 202891, NIH GRANTS HD-22539-04 & HD-23338-03)

FETAL ALCOHOL EXPOSURE (FAE) ENHANCES MORPHINE BUT NOT NON-OPIOID STRESS-INDUCED ANALGESIA. M.L. Pilat and A.N. Taylor. Departments of Psychology and Anat./ Cell Biol., BRI, University of California; and Brentwood Div., West LA VAMC, Los Angeles, CA 90024.

It has been demonstrated that maternal ethanol consumption (36% ethanol-derived calories during the last two weeks of gestation) produces alterations in opioid-mediated behaviors in the offspring. In order to further explore the impact of FAE on the opioid system, adult female Sprague-Dawley FAE, pair-fed, and control rats were tested for their tail-flick latency every 30 min after a 3.5 min cold water swim (CWS) and then, a week later, after 5mg/kg morphine. This swim paradigm has been shown to produce a nonopioid analgesia (i.e. not blocked by naltrexone). No differences between the prenatal treatment groups were observed after CWS. At 2hrs after morphine administration the FAE group showed significantly more analgesia ($p < 0.01$) than both the pair-fed and controls, confirming our previous reports. At 60 and 90 min there was a significant effect of treatment due to the FAE and control rats showing more analgesia than the pair-feds. These data suggest that FAE and pair-feeding have long lasting and opposite effects on responsiveness to morphine. Currently we are attempting to determine whether these alterations in the opioid system are due to the prenatal treatments themselves or to the stress response of the dam to these diet manipulations.

713.6

EFFECT OF PRENATAL PROTEIN MALNUTRITION AND POSTNATAL NUTRITIONAL REHABILITATION ON SPINE DENSITY OF CA1 HIPPOCAMPAL PYRAMIDAL CELLS IN RATS. A. Aguilar*, S. Díaz-Cintra, A. Galván, L. Cintra, T. Kemper and P.J. Morgane. Inst. Invest. Bioméd., UNAM, México, D.F. 04510. Neurol. Unit, Boston City Hosp., Boston MA, 02118 & Worces. Found. Exp. Biol., Shrewsbury MA, 01545.

Prenatal malnutrition produces significant reductions in the dendritic spines of hippocampal CA1 pyramidal cells in strata radiatum and lacunosum moleculare. In this study, we studied 15, 30, 90 and 220-day-old rats. 288 pyramidal cells were examined using an imaging system (BIOCOM). We measured the number of spines in three 50 micron segments of perforant path (PP), Schaffer collateral (SF) and commissural fiber input systems, as well as in a 50 micron segment in the largest basal and apical dendrites. We found significant reductions ($p < 0.05$) in spine density in all segments studied in all four ages studied. Prenatal malnutrition produces severe alterations in the basal and apical dendrites where both PP and SF synapse in 30 and 220-days-old rats. 713.8

EFFECTS OF PRENATAL PROTEIN MALNUTRITION ON THE ONTOGENY OF HIPPOCAMPAL LTP. P.J. Morgane¹, R.J. Austin-LaFrance², K.S. Abu-Hasaballah³ and J.D. Bronzino². ¹The Worcester Foundation for Experimental Biology, Shrewsbury, MA 01545, ²Trinity College, Dept. of Engineering and Computer Science, Hartford, CT 06106.

Prenatally protein malnourished rats (designated 6/25 to indicate pre- and postnatal protein content of diet) were tested as freely-behaving preparations at 15, 30, and 90 days of age for their ability to establish and maintain LTP of the perforant path/dentate granule cell synapse. Tetanization in control (25/25) animals resulted in significant enhancement of both the population EPSP slope and population spike amplitude (PSA) component of the dentate field potential at all ages. This enhancement decayed earliest in adult animals (5-18 hrs. after tetanization), 18-24 hrs. in 30 day olds and was still rising in 15-day old animals at 96 hrs. Adult 6/25 animals showed initial potentiation of the EPSP slope with a corresponding decline in PSA. PSA showed minor enhancement between 3-5 hrs. but this enhancement remained significantly below control levels and decayed to baseline earlier than in controls. 30-day old 6/25 animals had a high variability of response to tetanization. A portion of these animals were similar to the 90-day 6/25 animals while nearly 50% showed declines in PSA which remained below baseline out to 96 hrs. 15-day old 6/25 animals were found to initially potentiate both EPSP slope and PSA measures in a manner similar to controls, however this enhancement decayed to baseline levels within 48 hrs. Results indicate that fetal protein malnutrition impacts both the establishment and maintenance of LTP in a manner that appears to impair the translation of enhanced synaptic activity to enhanced cellular discharge. This may reflect the existence of a tetanization-induced rise in the level of GABAergic inhibitory modulation on the granule cell population of prenatally protein malnourished animals which is not significantly ameliorated by dietary rehabilitation. 713.10

THE EFFECTS OF PRE AND POSTNATAL EXPOSURE TO AMPHETAMINE, FENCAMFAMINE AND COCAINE ON MATERNAL BEHAVIOR AND DEVELOPMENT IN RAT PUPS. W. Klupecc*, D. Lawler, S. Catlin, C. Wahling and K. Illig. Department of Psychology, Drake University, Des Moines, IA 50311

Fencamfamine (FCF) is a stimulant with a mechanism of action and behavioral effects similar to both amphetamine (AMPH) and cocaine (COC). Previous research in our laboratory has demonstrated that compared to AMPH and COC, FCF produces transient impairment of neonatal reflexes and development during the first 21 postnatal days in pups reared by dams who received daily 5.6 mg/kg doses of these drugs from mating through 21 postnatal days. The present study extends previous research to investigate growth, development and neonatal reflexes following exposure to 10 mg/kg doses of AMPH, COC and FCF compared to no injection (NI) and saline (SAL) controls. Of the eight AMPH dams to carry litters to full term, five died during labor and two cannibalized their litters. For the remaining AMPH dam, injections were discontinued for two days prior to delivery, which was normal, and gradually increased to 10 mg/kg per day after delivery. Body weight for SAL and COC pups was significantly lower than NI controls from Day 14 through 8-weeks, and FCF pups weighed less than SAL controls from Day 21 through 8-weeks. Incisors erupted by Day 10 for FCF and COC pups compared to Day 14 for both NI and SAL pups. Compared to NI controls, both SAL and FCF pups showed delayed eye opening (Day 18 or later). Unlike previous studies, no consistent effects between groups were found for righting reflex, positive geotaxis or open field activity. All AMPH and FCF, but not COC dams exhibited intense focused stereotypies and disrupted maternal behaviors for at least 4-hours after injections. While the results clearly indicate that FCF has teratogenic potential demonstrable beyond the stress induced effects for the SAL pups, the pattern of results, in the context of prior research, raises questions about the degree to which the effects of FCF are due to prenatal actions or postnatal disruption of maternal behavior.

THE EFFECTS OF EARLY MALNUTRITION FOLLOWED BY NUTRITIONAL REHABILITATION ON CENTRAL CONDUCTION VELOCITY AND CORTICAL EXCITABILITY IN RATS. G.J. Quirk*, W.R. Mejía, H. Hesse and H. Su. Dept. of Physiology, National Autonomous University of Honduras Medical School (UNAH), Tegucigalpa, Honduras.

A recent survey has indicated that over 50% of Honduran children under the age of five suffer from some degree of malnutrition. To further understand the effects of such malnutrition on the developing CNS, malnourishment was produced in rat pups from birth by restricting lactating dams to half of their normal consumption of standard laboratory chow. Following weaning (day 21) rats were housed individually and had full access to food and water. Reductions in body weight of 40% at day 21 were reduced to 20% by day 70. Total brain weight was reduced 10% relative to controls ($p < .01$). Close to day 75, male and female rats were anesthetized with urethane and the response to surface electrical stimulation of motor cortex was recorded "killed-end" from the pyramidal tract at C1. Following a single shock, direct (D-wave) and indirect (I-wave, synaptic) activation of corticospinal neurons were observed (Stewart et al. Brain Res. 508:341). Malnourishment reduced the conduction velocity of the fastest PT fibers 24% relative to controls (11 controls: 21m/s; 14 malnourished: 16m/s, $p < .001$). In addition, the size of the D-wave in malnourished rats was significantly reduced throughout a range of stimulus intensities by an average of 40%. No significant difference was observed for the I-wave. Slowed conduction velocity could be due to decreased myelination observed in rehabilitated rats (Sima et al, Acta Neuropath. 42:15). Supported by a Fulbright Grant to GJQ.

713.13

EFFECTS OF ETHANOL ON GLUTAMATE CONCENTRATION IN OVINE FETAL CEREBRAL CORTEX, DETERMINED BY MICRODIALYSIS. J.D. Reynolds, D.H. Penning, B. Atkins, J. Hrdy, D. Poduska, D.H. Chestnut & J.F. Brien*. Dept. of Pharm. & Tox., Queen's U., Kingston, Canada & Dept. of Anesthesia, U. of Iowa, Iowa 52242.

The cerebral cortex is a target site of ethanol (E) teratogenesis. L-Glutamate (GLU) is a neuroactive amino acid. For normal cerebral cortical development optimal [GLU] is required. We tested the hypothesis that E changes [GLU] in the fetal cerebral cortex. This study was conducted in the instrumented fetal sheep at 118 to 125 days of gestation (term=147 days) with a microdialysis probe in the frontal cortex. The effects of maternal IV infusion, over 5h, of 2 g E/kg body weight (n=3) or 4 g E/kg (n=3), as four equally divided doses, on fetal extracellular [GLU] were determined. [GLU] in the microdialysate and fetal blood [E] (BEC) were determined by established methods. Neither E dose produced fetal lethality during the experiment.

		Dose 1	Dose 2	Dose 3	Dose 4
2 g E/kg (SD)	[GLU]	66.82	75.60	79.11	55.72
	% Basal*	(31.12)	(31.37)	(25.93)	(12.65)
	Fetal BEC mg/ml	0.79	1.44	2.30	3.27
		(0.04)	(0.16)	(0.30)	(0.47)
4 g E/kg (SD)	[GLU]	180.06	483.38	203.89	123.14
	% Basal*	(130.81)	(573.99)	(113.86)	(83.36)
	Fetal BEC mg/ml	1.53	2.77	3.98	5.40
		(0.43)	(0.74)	(1.23)	(0.89)

* Basal [GLU] in microdialysate = 173 ± 66 (SD) ng/ml

The data demonstrate that: E produces dose-dependent changes in the extracellular fluid [GLU] in the fetal cerebral cortex with a multi-fold increase in [GLU] for 4 g E/kg; and the effects are not solely dependent on the fetal BEC. (Supported by R.J. Carver Foundation & MRC of Canada)

713.15

EFFECTS OF HYPOXIA ON THE DEVELOPING BRAIN AT MID AND LATE GESTATION IN FETAL SHEEP. S. Rees¹, Y. Just, S. Hooper, M. Wlodek & R. Harding. ¹ Department of Anatomy & Cell Biology, University of Melbourne, Parkville, Victoria 3052, Australia and Department of Physiology, Monash University, Clayton, Victoria 3168, Australia.

Recent evidence supports the view that prenatal factors, such as hypoxia, may be important antecedents of non-progressive neurological impairment. Little is known about the effects of hypoxia on the structure of the developing brain, particularly in the early preterm fetus. In this study on fetal sheep we have examined the effects of hypoxia (12hr) on the morphology of the brain at 85-95 days (n=11) and 135-140 days (n=3) of gestation (term=146d). In anaesthetized animals, an externally adjustable vascular clamp was placed on the maternal common iliac artery and vascular catheters inserted in the fetus. Five days after surgery the clamp was adjusted to reduce uterine blood flow until a 50% reduction in fetal arterial oxygen content had been achieved. One week after hypoxia, the fetal brains were perfused and tissue from the cerebral cortex, underlying white matter and hippocampus examined with light and electron microscopy. At 85-95 days, in all hypoxic animals there was evidence of neuronal degeneration predominantly in the hippocampal pyramidal cell and germinal layers but also in the cerebral cortex, particularly layers 4-6. The width of stratum oriens (hippocampus) was also significantly reduced in hypoxic animals compared with age-matched non-hypoxic control animals (n=11). There was also evidence of lesions in the cortical white matter adjacent to the lateral ventricles. By comparison the effects of hypoxia at 135-140 days were much less pronounced. Degeneration was not observed in the white matter or hippocampus and there was only sparse degeneration in the cortex. Thus in early fetal life, the brain appears to be more vulnerable to the effects of acute hypoxia than it is in late gestation when compensatory circulatory mechanisms have begun to operate.

713.12

Chronic *in utero* Microdialysis In the Ovine Fetal Brain: Effect of Maternal Hemorrhage on Extracellular Glutamate

D.H. Penning*, D.H. Chestnut, B. Atkins, P. Chatterjee, J. Hrdy & D. Poduska. Dept. of Anesthesia, U. of Iowa, Iowa City, Iowa, 52242.

Hypoxic release of glutamate may produce neurotoxicity in the developing brain. Maternal hemorrhage can produce fetal hypoxemia and acidosis. We hypothesized that maternal hemorrhage may lead to increased extracellular glutamate in the fetal brain. This was tested in 6 chronically instrumented fetal sheep (gestational age 118-125 days, term = 147) Under general anesthesia, fetal and maternal vascular catheters and an electromagnetic flow probe on the maternal uterine artery were placed. A microdialysis probe was placed in the frontal cortex of the fetus. The animals were allowed to recover from surgery for 5 days. On the day of the experiments the probe was perfused with artificial CSF @ 1µL/min. Perfusate was collected and analyzed for glutamate by HPLC. Maternal hemorrhage (5 mL/kg maternal wt.) was repeated until the fetal pH < 7.00 then the blood was re-transfused.

Experimental Period (n=6)	Peak Glutamate % Basal (SE)	Fetal pO2 mmHg (SE)	Fetal pH (SE)	Uterine Blood Flow % Basal (SE)
Control	100 (12)	19.7 (1.2)	7.34 (.01)	100 (1.5)
Hemorrhage	303 (31)	12.8 (1.3)	6.95 (.01)	11 (2)
Recovery (1 Hr)	104 (16)	22.2 (1.7)	7.09 (1.9)	87.3 (1.9)

Maternal hemorrhage in the unanesthetized ewe, producing fetal hypoxemia and acidemia, resulted in an increase in fetal brain extracellular glutamate concentration. Such glutamate release may be involved in the mechanism of fetal brain injury, (e.g., cerebral palsy), resulting from *in utero* hypoxia. (Supported by R.J. Carver Foundation)

713.14

STIMULATION OF AXONAL ELONGATION BY ALCOHOL IS REVERSED BY PROTEIN KINASE C INHIBITOR. M. Thompson and M.I. Johnson*. Dept. of Pediatr., Fan Kane Neurol. Res. Lab., Steele Mem. Childr. Res. Cntr., Ariz. Hlth. Sci. Cntr., Tucson, AZ 85724-0001.

Although fetal alcohol exposure may be the most common cause of mental retardation, little is known about the specific mechanisms by which alcohol alters central nervous system development. In an *in vitro* model of neuronal differentiation, ethanol stimulates the elongation of axons extending from explants of perinatal rat sympathetic ganglia. Because protein kinase C (PKC) is part of one pathway that may be affected by ethanol, we investigated the effect of a PKC inhibitor on alcohol-stimulated axonal growth. Sphingosine in concentrations from 50 nM to 1 µM showed a dose-dependent depression in axonal growth after 5 days in culture (control, 2392 µm ± 62; 50 nM, 2112 ± 76; 100 nM, 1972 ± 88; 500 nM, 1162 ± 57; 1 µM, 861 ± 43; µm ± SEM; $p < 0.02$ to < 0.0001). Removal of the sphingosine resulted in recovery of axonal extent to control levels at day 7 for both 50 and 100 nM sphingosine and partial recovery for cultures treated with 500 and 1000 nM. We also studied whether inhibition of alcohol-stimulated axonal elongation by sphingosine could be reversed by the phorbol ester, PDBu. At concentrations of 25 and 50 nM, PDBu reversed the effects of the 200 nM sphingosine to control values. Other PKC inhibitors acting at both the regulatory and the catalytic site of PKC are under investigation. Studies suggest that one mechanism by which alcohol may act is through a pathway involving PKC, possibly in phosphorylation of proteins important in axonal elongation. (Supported by ADC 82-2689 and USPHS-NIH R01 AA08950).

THE DEVELOPMENTAL PROFILE OF PKC ISOFORMS IN THE RAT BRAIN IS ALTERED BY GESTATIONAL EXPOSURE TO METHYL MERCURY. N. Haykal-Coates¹, E.S. Goldey², D.W. Herr², H.A. Tilson², S. Barone Jr.¹ ¹ManTech Environmental Tech. Inc., ²NTD/HERL, US EPA, RTP, NC 27711.

Protein kinase C (PKC) mediated phosphorylation has been implicated in neuronal growth and differentiation (Turner et al., Proc. Natl. Acad. Sci. USA, 1984). Using immunohistochemistry, we examined the effects of gestational exposure to the neurotoxicant, methyl mercury (CH₃Hg) on the developmental profile of immunoreactivity (IR) for the calcium-dependent, α and β, and calcium-independent, ε, PKC isoforms. Long-Evans dams were dosed on gestational days 6-15 (po) with 0, 0.1, 1, or 2 mg/kg CH₃Hg dissolved in saline. Pups were sacrificed and perfused with buffered paraformaldehyde on postnatal days (PND) 1, 4, 10, 21, 41, and 85. The brains were sectioned sagittally, stained immunohistochemically, and examined throughout the medial to lateral extent of the brain. The greatest density of immunoreactivity of neural cell bodies was seen in the olfactory bulb, hippocampus, inferior colliculus, pons, cerebral, pyriform, and cerebellar cortex, whereas axonal staining was prominent in the brainstem, internal capsule, corpus callosum, anterior commissure, fornix and olfactory tract. In controls, the IR for each isoform was highest at the earliest time-points examined (PND1-4), decreasing dramatically by PND10, and decreasing further after PND21. In all regions examined in the neonate, the locations of IR for isoforms α and ε were similar. In contrast to the neonatal α and ε, there was a different pattern for β IR in the thalamus, neocortex and olfactory bulbs. The highest dose of CH₃Hg produced a persistent increase in regional α IR, a decrease in ε IR at early time points (PND1-4), and no apparent change on β IR. These changes in PKC IR were not related to overt pathology at any of the time points examined. The present results characterize the cellular and regional ontogeny of 3 PKC isoenzymes, and suggests that developmental exposure to CH₃Hg can alter that ontogeny.

713.17

A DEVELOPMENTAL PROFILE OF TRK IMMUNOREACTIVITY IN THE RAT BRAIN IS AFFECTED BY GESTATIONAL EXPOSURE TO METHYL MERCURY. S. Barone Jr.¹, N. Haykal-Coates¹, E.S. Goldey², H.A. Tilson². ¹ManTech Environmental Tech. Inc., ²NTD/HERL, US EPA, RTP, NC 27711.

The high affinity nerve growth factor receptor, trk has been implicated in neuronal growth and differentiation. In this study we examined the effects of gestational exposure to the developmental neurotoxicant methyl mercury on the developmental profile of immunoreactivity (IR) for this receptor. Long-Evans dams were dosed on gestational days 6-15 (po) with 0, 0.1, 1, or 2 mg/kg methyl mercury dissolved in saline. Pups were sacrificed and perfused with buffered paraformaldehyde on postnatal days (PND) 1, 4, 10, and 21. The brains were sectioned sagittally, stained immunohistochemically, and examined throughout the medial to lateral extent of the brain. The greatest density of immunoreactivity of neural cell bodies was seen in the olfactory bulb, hippocampus, septum, striatum, nucleus basalis, anterior colliculus, pons, cerebral, and cerebellar cortex, and axonal staining was prominent in the brainstem, neocortex, hippocampus, cerebellum, and olfactory tract. In general the regional pattern of this IR was transient except in the olfactory bulb, hippocampus, cerebellum. In controls, trk IR appeared to peak at PND4, decreasing dramatically on PND10 and decreasing further after PND21. An adult-like pattern was apparent on PND21 with trk IR in the hippocampus and cerebellum. Methyl mercury produced a dose-related decrease which was apparent at PND1, PND10, and PND21 but not at PND4. This decrease in trk IR was not related to overt pathology at the time points examined. The present results characterize the cellular and regional ontogeny of the tyrosine kinase, trk and suggest that developmental exposure to methyl mercury can alter the ontogeny of this trophic factor receptor.

713.19

DEVELOPMENTAL EFFECTS OF VITAMIN B-6 DEFICIENCY ON THE GABA_A RECEPTOR IN THE RAT BRAIN: AN AUTORADIOGRAPHIC STUDY. J. Pilachowski and T.R. Guilarte*. The Johns Hopkins University School of Hygiene and Public Health, Baltimore, MD.

Vitamin B-6 deficiency (B6D) during development is known to result in spontaneous seizures. Seizure activity in B6D experimental animals and human infants is believed to be associated with reduced brain levels of the inhibitory neurotransmitter, GABA. There is a lack of data on the effects of B6D on the postnatal development of the GABA_A receptor in the rat brain and its potential role in the seizure susceptibility of these animals.

In the present study, [³H]-muscimol autoradiography was used to determine the effect of B6D on the postnatal development of the postsynaptic GABA_A receptor. The results indicate that in normal rats there is an increase in [³H]-muscimol binding in all brain regions analyzed from postnatal day 14 (PN14) to PN28, with a subsequent decrease in the level of binding from PN28 to PN56. Vitamin B-6 deficiency resulted in a marked increase in [³H]-muscimol binding in the granular layer of the cerebellum at PN14 and in cortical and subcortical brain regions at PN28. Deficient rats had a significantly lower level of [³H]-muscimol binding in the cerebral cortex, corpus striatum, and hippocampus at PN56 relative to controls. These results indicate that marginal intakes of dietary vitamin B-6 during development results in marked changes in GABA_A receptor binding and may be associated with the increased seizure susceptibility of these animals. (Grant # HD20939).

EFFECT OF PRENATAL MALNUTRITION AND POSTNATAL NUTRITIONAL REHABILITATION ON SPINE DENSITY OF CA3 HIPPOCAMPAL PYRAMIDAL CELLS IN RATS. M. García-Ruiz*, L. Parra, Corkidi, G., L. Cintra and S. Díaz-Cintra. Inst. de Invest. Biomédicas, UNAM, MEXICO, D.F. 04510.

The effects of prenatal malnutrition (6% casein diet) and postnatal rehabilitation (25% casein diet) were studied on synaptic spine density of CA3 hippocampal pyramidal cells in rats of 4 ages (15, 30, 90 and 220 days old). A total of 288 CA3 cells impregnated with rapid-Golgi were selected for morphometric analysis and the density of spines were counted (using a calibrated ocular reticle and 63x planapochromatic oil objective) in six 50µm segments arising from a proximal largest apical dendrite (3 segments) and middle, terminal and basal segments of the largest dendrite. Results showed that prenatal malnutrition produced significant decreases (p<0.05) in spine density. However, the only middle and terminal segments showed deficits at all ages studied. These segments represent the sites where Schaffer recurrents and perforant pathway synapse, respectively. The findings indicate that: a) the reductions on synaptic spine density due to prenatal malnutrition are not compensated by postnatal nutritional rehabilitation, b) since the reductions were found across four ages prenatal malnutrition produces a long-term effect on CA3 pyramidal cells and c) the synaptic changes found in the middle and terminal segments represent deficits in the functional integrity of field CA3. MOLECULAR AND PHARMACOLOGICAL CORRELATES OF DEVELOPMENT IV

714.1

Expression of a mitogen-inducible cyclooxygenase in brain neurons: regulation by synaptic activity and glucocorticoids W.E. Kaufmann*, K. Yamagata, K. I. Andreasson, C. A. Barnes, and P. F. Worley. Depts. of Neuroscience and Neurology, Johns Hopkins University, Baltimore, MD 21205 and ARL, Div. of Neural systems, Memory and Aging, University of Arizona, Tucson, AZ 85724.

The first step in prostaglandin synthesis involves enzymatic oxidation of arachidonic acid that is catalyzed by endoperoxidase (PGG/H) synthase, also referred to as cyclooxygenase. We have cloned an inducible form of this enzyme from rat brain that is nearly identical to a murine, mitogen-inducible cyclooxygenase identified from fibroblasts (Kujubu et al., 1991). Our studies indicate that this gene, termed COX-2, is expressed throughout the forebrain in discrete populations of neurons and is enriched in the cortex and hippocampus. Neuronal expression is rapidly and transiently induced by seizure or NMDA dependent synaptic activity. No expression is detected in glia or vascular endothelial cells. Basal expression of COX-2 appears to be regulated by natural activity in the developing and adult brain. Both basal and induced expression of COX-2 are inhibited by glucocorticoids, consistent with COX-2 regulation in peripheral tissues. Our studies indicate that COX-2 synthesis may be important in regulating prostaglandin signaling in brain. The marked inducibility in neurons by synaptic stimuli suggests a role in activity-dependent plasticity. Supported by EY08900, EY09374, HD009219, and AG09219.

DEVELOPMENTAL EXPRESSION OF GABA_A/BZ RECEPTOR SUBUNIT mRNAs IN THE MOUSE INFERIOR OLIVARY NUCLEUS. C.-C. Chang*, S. Gullapalli, A. Rotter and A. Frosthalm. Department of Pharmacology, The Ohio State University, Columbus, OH 43210.

Inferior olivary neurons receive GABAergic inputs and express GABA_A/BZ receptors. In a previous study we have reported (Frosthalm et al., 1992) that [³H]muscimol binding sites and β3 subunit mRNA are high at birth, but are considerably down-regulated during postnatal week two; α1, β1, β2, γ2 and δ mRNAs are absent, or present at low levels. In the present experiments, we have examined the developmental expression of additional α and γ subunit mRNAs in olivary neurons, which were visualized by *in situ* hybridization using subunit specific riboprobes. Unlike the β3 signal, α4 mRNA was present at moderate intensity at birth and remained stable into adulthood. However, the γ1 mRNA signal was completely absent at birth, only becoming detectable between postnatal day (P)7 and P9. Between P9 and P12, the hybridization signal increased rapidly, reaching adult levels at approximately the end of postnatal week three. Since POU domain transcription factors have been implicated in cell specific gene expression, we have also examined the developmental expression of Brn-3 mRNA, which is known to be present in the adult inferior olive. A strong signal was present in olivary neurons throughout their embryonic and early postnatal development; reduced expression was observed in older mice. These findings suggest that the subunit composition of the GABA_A/BZ receptor in inferior olivary neurons changes during development, and raise the possibility that Brn-3 may play a role in subunit expression in these cells.

PROTEIN KINASE C IN THE GOLDFISH RETINOTECTAL SYSTEM: NORMAL AND CHANGES IN REGENERATION. John T. Schmidt¹, Dept. of Biol. Sci., SUNY Albany NY 12222.

The regenerating retinotectal projection undergoes an activity-driven sharpening of its retinotopic precision. This sharpening is blocked by NMDA receptor blockers, is associated with an increased capacity for long-term potentiation (LTP), and involves the elimination of errant (nonretinotopic) branches of optic axons. Protein kinase C (PKC) is often involved in synaptic plasticity, including induction of LTP. Inhibiting or activating PKC in the regenerating projection (either intracranially or intraocularly) prevents retinotopic refinement. In this study we examined 1) what neurons in this system contain PKC, and 2) whether PKC activity levels increase during regeneration?

Sections from retina, optic nerve and tectum were immunostained with an antibody against pan PKC (UBI). Staining in retina was similar to that reported in other vertebrates. The antibody stained a subset of bipolar cells and of amacrine cells. Staining in photoreceptors was very light to nonexistent. Most if not all ganglion cell somas stained darkly, although there was much less staining in the optic fiber layer. In optic nerve, there was moderate staining, darker in glial sheath. In tectum, there was intense staining of a subset of type XIV cells, both the somas at the top of the periventricular layer and thick dendrites ascending to branch in and below stratum opticum. These cells are very similar to ones previously reported to stain for choline acetyltransferase. Staining was also somewhat darker in SO and in retinal termination bands just below.

PKC activity was measured using a substrate peptide assay (Amersham). Activity was linear with the amount of homogenate, and was eliminated with deletion of lipids or calcium. Levels in tectum were 2X and 4X higher than in retina and nerve respectively. At weekly intervals after the right nerve was crushed, PKC levels were measured in right versus left retina, tectum and nerve. Retinal levels were not significantly different except for a small increase at 3 weeks. Tectal levels decline to 85% of control in weeks 3-5. Nerve levels, however, increased by about 80% in weeks 2, 3 and 4. This may indicate either an upregulation in ganglion cells (masked in whole retina by the other cells' contribution), or upregulation in reactive glial cells. Supported by NIH grant EY-03736.

714.5

LOCAL PERFUSION OF (-)SULPIRIDE VIA MICRODIALYSIS HAS AGE-DEPENDENT EFFECTS ON SPONTANEOUS DA RELEASE IN THE NEOSTRIATUM OF DEVELOPING AND ADULT RATS. R.A. Gazzara* and S.L. Andersen. Center for Developmental Psychobiology, Dept. of Psychology, Binghamton Univ. (SUNY), Binghamton, NY 13902-6000.

A within-subject dose-response analysis of the effects of the D₂ antagonist (-)sulpiride (SULP) was conducted in urethane-anesthetized rat pups 5, 10-11, 15-16, and 21-22 days of age, and adult rats. SULP (0.1, 1, 10, and 100 μM) was administered locally via a microdialysis probe into the neostriatum. Samples were collected every 15 min and extracellular levels of dopamine (DA) and 3,4-dihydroxyphenylacetic acid (DOPAC) were measured by HPLC-EC.

Levels of DA and DOPAC increased following local perfusion of SULP in a dose-dependent manner in all age groups. The maximum effect of SULP on DA levels (as a percentage of the pre-drug spontaneous baseline levels) was greatest in the three youngest age groups (250%) and lower in both the 21-22 day group (190%) and the adult group (135%). Extracellular levels of DOPAC increased at all ages, however, the percentage increase did not differ as a function of age (160%).

These results are consistent with our previous studies that suggest that the D₂ autoreceptor in the neostriatum is functional but not mature by postnatal day 5 in the rat.

714.7

CORTICAL CELLS FROM E17 RAT EMBRYOS CONTAIN A NICOTINE-DISPLACEABLE ALPHA-BUNGAROTOXIN BINDING SITE. L.L. Jensen and F.M. Leslie*. Department of Pharmacology, U.C. Irvine, Irvine, CA 92717

The neuronal alpha-bungarotoxin (BTX) site is a pharmacologically distinct nicotinic receptor subtype that exhibits a unique, transient developmental binding pattern in rat sensory cortex. Although the physiological significance of these BTX sites remain unknown, it has been proposed that they may play a role in growth and development, and in controlling the intracellular free calcium levels in target cells. In order to identify cortical cell types which express this binding site, we have examined the binding of [125-I] BTX to fetal rat cortical cells in primary culture. Cortical cells from E17 rat embryos displayed a nicotine displaceable BTX binding site at 3 to 16 days in culture. When treated with 5-fluorodeoxyuracil on 1 to 3 DIV to inhibit glia proliferation, there was an increase in nicotine-displaceable BTX binding in the resulting neuronal enriched cultures. A similar increase in BTX binding was also observed in control cultures at 8 DIV when conditioned for 4 hours with media from the 5 fluorodeoxyuracil-treated cultures. Pure glia cells, obtained by plating cortical cells on 24-well plates not coated with polylysine, followed by daily media changes, showed a low level of BTX binding when compared to the mixed neuronal-glia cultures, and this binding was not nicotine-displaceable. Furthermore, cortical cells plated onto a pure established glia layer exhibited fewer nicotine displaceable BTX binding sites when compared to cortical cells plated onto polylysine alone. These results suggest that nicotinic BTX binding proteins are expressed on cortical neurons and not on cortical glia cells, but that this site may be regulated by glia.

Supported by PHS grant #NS 30109.

714.4

THE D₂ AGONIST QUINPIROLE MODULATES SPONTANEOUS DOPAMINE RELEASE FROM THE NEOSTRIATUM OF DEVELOPING AND ADULT RATS. S.L. Andersen* and R.A. Gazzara. Center for Developmental Psychobiology, Dept. of Psychology, Binghamton Univ. (SUNY), Binghamton, NY 13902-6000.

Results from previous studies in our laboratory examining the effects of dopamine (DA) agonists and antagonists on K⁺-evoked DA release suggest that DA autoreceptor function is apparent by postnatal day 5 and varies as a function of age. In this study we investigated the effects of local administration of the full D₂ agonist quinpirole (QUIN) on spontaneous DA release since high K⁺ is more effective in releasing DA in adults relative to younger rats and may have influenced the results.

Extracellular levels of DA in the neostriatum of urethane-anesthetized rats 5, 10-11, 15-16, 21-22 days of age, and adults were determined every 15 min by *in vivo* microdialysis coupled with HPLC-EC. Increasing concentrations of QUIN (0.01, 0.1, 1, 10, and 100 μM) were perfused successively into the neostriatum via the microdialysis probe. QUIN attenuated extracellular levels of DA (as a percentage of pre-drug baseline) in all ages (5 days, 50%; other ages, 35-40%), which is comparable to the effect of QUIN on K⁺-evoked DA release.

In addition, the results of this study will be compared with the effects of locally perfusing the partial D₂ agonist (+)-3-PPP into the neostriatum of developing and adult rats.

714.6

INITIAL CHARACTERIZATION OF PERCOLL-ENRICHED POPULATIONS OF EMBRYONIC RAT HIPPOCAMPAL CELLS. S.V. Smith, A.E. Schaffner, D. Marie, I. Marie, T.G. Smith, Jr.* and J.L. Barker. Laboratory of Neurophysiology, NINDS, NIH, Bethesda, MD 20892

We have used a multi-step discontinuous gradient of Percoll to isolate subpopulations of embryonic (E) hippocampal cells according to their buoyant density after papain dissociation. At least four distinct subpopulations of cells could be routinely isolated at E18-22. The relationship between buoyant density and cell cycle status was evaluated using *in vivo* injections of BrdU into mothers prior to sacrifice, followed by Percoll fractionation, then quantitative flow cytometric analysis of anti-BrdU immunofluorescence and propidium iodide staining. Preliminary results indicate that cells of higher density were preferentially in DNA synthesis while cells of lower density were preferentially post-mitotic. Immunocytochemical studies revealed that a number of cells in all four subpopulations expressed neuronal or glial antigens. Analysis of fractionated cells using a voltage-sensitive dye and flow cytometry revealed that the majority of cells in each fraction were well polarized, primarily according to K⁺-dependent mechanisms. Stimulation of cells with ligands to probe for electrical and chemical forms of excitability revealed that subpopulations of cells in each fraction exhibited both forms of excitability. These results indicate that fractionation of embryonic cells according to their buoyant density is an effective strategy to enrich for pre- and post-mitotic cells for quantitative analysis of antigen expression and excitability in entire populations of embryonic cells. Further characterization of the cellular properties expressed in progenitor and differentiating neurons and glia will complement this initial characterization.

NGF-INDUCED DIFFERENTIATION OF PC12 CELLS STIMULATES ACCUMULATION AND SECRETION OF A GP2-LIKE PROTEIN. S. Koshlukova, J. Roth* and J. Aletta. Dept. Pharmacol., SUNY at Buffalo, Buffalo, NY 14214. Glycoprotein 2 (GP2) is a major protein of zymogen granule membranes (ZGM) from cells of exocrine pancreas. Although it is known to possess a GPI anchor, a soluble form has been described as well. In efforts to examine the potential biological role(s) of this membrane constituent we have begun to examine several cell lines which possess distinctive secretory pathways. The present study has used the PC12 cell line. A rabbit antiserum against GP2 isolated from pancreatic juice specifically cross-reacts with a PC12 cell protein of 70 kDa on Western blots. NGF-treatment of the cells for 1-2 weeks resulted in an increased immunoreactivity. Using this GP2-specific reagent, we found that the 70 kDa protein co-localized with CA-containing vesicles obtained by differential centrifugation. Attempts to identify a GPI anchor with the use of PI-specific PLC have not been successful. It is interesting, however, that an anti-CRD antibody (which is known to recognize a carbohydrate moiety of the GPI anchor only after it is cleaved from the membrane) unexpectedly cross-reacts with the 70 kDa protein in the vesicle membrane fraction. The GP2-like molecule is also detectable in the culture medium. The apparent release, measured at 6, 12 and 24 hours was greater at each time point from cells treated with NGF for 15 days than from non-treated PC12 cells. In conclusion we report here that a GP2-like protein is (1) present in PC12 cells, (2) enriched in a crude vesicle membrane fraction and (3) can be released from cells in greater amounts after NGF-treatment. We conclude that this molecule may be developmentally regulated in neurons as well as other specialized secretory cells. Supported in part by NIH grant AM-28029 NIDDKD

NEONATAL 6-OHDA LESIONS SELECTIVELY ALTER THE EXPRESSION OF D1 RECEPTORS AND D1 mRNA IN THE STRIATUM OF ADULT RATS.

P.A. Frohna*, B.S. Neal-Beliveau and J.N. Joyce, Depts. Psychiatry and Pharmacology, Univ. of Pennsylvania Medical School, Philadelphia, PA, 19104.

Neonatal 6-OHDA lesions have allowed us to study the role of dopamine in the developmental regulation of DA receptors in the striatum. Recently (Neal and Joyce, *Synapse* 11:35, 1992), we reported a decrease in D1 DA receptors in the dorsomedial (DM), dorsolateral (DL) and ventromedial (VM) quadrants of the rostral caudate-putamen (CPu) of adult rats lesioned on postnatal day 1 (P1). In the caudal CPu only the DM quadrant continued to show a significant decrease. D2 DA receptors were unchanged in all regions of the striatum examined. To further investigate the role of DA on the development of the DA receptor systems in the striatum, we performed *in-situ* hybridization histochemistry with [35S]-labeled oligonucleotide probes for the D1 and D2 receptors in adult rats given P1 6-OHDA or saline injections.

In the rostral striatum, there was a trend towards an increase in D1 mRNA in all regions that was significant ($p < .05$) in the DM (+29%) and VM (+28%) CPu, and the core region of the nucleus accumbens (+24%). No change in D1 mRNA levels was found in the caudal striatum. With opposite changes in D1 mRNA and receptor density observed, we autoradiographically measured D1 receptors in the SNpr to determine if there was an increase in receptor transport to striatonigral terminal fields. D1 binding, measured with [3H]SCH 23390, was similar between the two groups in the rostral SNpr. In the caudal SNpr there was a significant decrease in the lesioned group (721 fmol/mg prot) compared to the controls (830 fmol/mg prot; $p < .01$). Therefore, an increase in D1 mRNA in the striatum does not lead to an increase in D1 receptors in the terminal regions of the striatonigral neurons. Like D2 receptors, there was no change in D2 mRNA levels in any region of the striatum of the lesioned animals compared to controls.

These findings further suggest that the D1 DA receptor is developmentally dependent on DA and may require DA for normal transcriptional and translational control. Funded by R29 MH 43852.

LOCAL CEREBRAL PROTEIN SYNTHESIS IN THE RAT DURING NORMAL DEVELOPMENT. Y. Sun*, G. E. Deibler, J. Jehle, J. Macedonia, I. Dumont, T. Dang, and C. Beebe Smith, LCM, NIMH, Bethesda, MD 20892.

Regional rates of cerebral protein synthesis (ICPS_{reg}) were determined with the autoradiographic L-[1-¹⁴C]leucine method (Smith et al., *PNAS* 85:9341, 1988) in 10 (n=7), 14 (n=6), 21 (n=6), 35 (n=6), and 60 (n=6) day-old rats. λ , a constant in the equation for ICPS_{reg} which corrects for recycling, was determined in whole brain at each age (Sun et al., *Soc. Neurosci. Abstr.* 18:421, 1992) and age-specific values were used in the calculation of ICPS_{reg} in all 43 brain regions. Studies were carried out on freely moving rats maintained at normal body temperature throughout the study. Values for ICPS_{reg} ranged from 5.5 to 31.6 nmol/g/min at 10 days and from 3.8 to 20.8 nmol/g/min at 60 days (adult). In brain as a whole and in most areas of cortex ICPS_{reg} were highest at 10 days gradually decreasing with age. By 60 days of age values were about 60% of those determined at 10 days. There were several noteworthy exceptions to this tendency. In the paraventricular and supraoptic nuclei, ICPS_{reg} increased during the course of development reaching peak values in adults. ICPS_{reg} in dorsomedial hypothalamic nucleus, subthalamic nucleus and pineal gland remained relatively constant at all ages examined. In white matter regions, peaks of ICPS_{reg} were reached in the cerebellum and cerebrum at 14 and 21 days, respectively, approximating the times of myelination. The decreases we found in whole brain protein synthesis with developmental age are in agreement with the work of (Dunlop et al. *J. Neurochem.* 29:939, 1977). Application of the [1-¹⁴C]leucine method in our study corrects for the effects of recycling and increases the anatomical resolution to the level of individual nuclei and cell layers.

714.13

EFFECTS OF PRENATAL COCAINE TREATMENT ON DEVELOPMENT OF ASTROGLIAL CELLS IN RAT PUPS. J. Rubinstein, H. Akbari, P.M. Whitaker-Azmitia and E.C. Azmitia. Dept. of Psychiatry, SUNY, Stony Brook, New York 11794 and Dept. of Biology, New York University, New York, New York 10003.

In previous studies, we have found that prenatal treatment with cocaine, significantly alters the growth of the serotonergic neuronal system as well as the expression of the 5-HT_{1A} receptor. Since the serotonin system and astroglial cells are highly interdependent during development, we proposed that cocaine would also cause developmental abnormalities of astroglial cells.

Pregnant Sprague Dawley rats were treated with 40 mg/kg cocaine from gestational day 10 through birth. At PD 3 and 6 pups were perfused with 20 ml of ice cold 4% paraformaldehyde in phosphate buffer (pH 7.2). The brains were sectioned at 50 micron and stained for GFAP (Sigma Immunochemicals, polyclonal, final dilution 1/2000); and S-100 (Chemicon Inc., monoclonal, final dilution 1/500).

In the cocaine-treated pups, astroglial cells were sparse in cortex and hippocampus and only lightly stained for S-100 at postnatal day 3. In addition, the subventricular zone, which supplies most of the cortical astrocytes, contained far more astroglial cells than controls - possibly cells which should have migrated out by day 3. By day six, radial glial cells were still evident in the cocaine-exposed pups, while the control pups had very few remaining radial glial cells.

714.10

EXPRESSION AND FUNCTIONAL MODULATION OF INWARD-RECTIFYING AND CALCIUM-ACTIVATED POTASSIUM CONDUCTANCES IN DIFFERENTIATING SKELETAL MUSCLE. S. J. Wieland*¹ and Q-h. Gong^{1,2}, Depts. of Anatomy¹ and Anesthesiology², Hahnemann University, Philadelphia, PA, 19102

The mouse myoblast cell line C2C12 can be controllably induced to undergo fusion into differentiated, non-dividing myotubes *in vitro*. Among the changes in functional gene expression accompanying differentiation is the induction of an inward-rectifying potassium conductance. The mean inward current of myoblasts derived from fused myotubes 7 days after induction of fusion was 1.4 nA at -140 mV. This was approximately 10-fold greater than in dividing myoblasts. The inward rectifier was subject to rapid metabolic control. Exposure of the cytoplasm to 25 μ M GTP- γ -S during whole-cell recording produced inhibition of the conductance by 75% within 20 min., while untreated cells were unchanged over this time period. Elevation of intracellular free Ca²⁺ or of intracellular IP₃ also inhibited inward rectifying currents. In contrast to the inward rectifier, a second potassium conductance which was activated by intracellular Ca²⁺ and apamin-blockable was detectable in both myoblasts and in differentiated myotubes. The sensitivity of this conductance to Ca²⁺ activation was strongly enhanced by the β -adrenergic agonist isoproterenol. Thus two potassium channels which modulate the electrical excitability of skeletal muscle, a calcium-activated, apamin-sensitive channel, and an inward-rectifying channel, are subject to separate control of expression and are separately modulated by cellular messengers.

714.12

NEUROCHEMICAL AND BEHAVIORAL ALTERATIONS IN ADULT RATS TREATED THROUGHOUT DEVELOPMENT WITH MAO INHIBITORS. X. Zhang*, C. Clarke and P.M. Whitaker-Azmitia. Dept. of Psychiatry, SUNY, Stony Brook, New York 11794.

Monoamine oxidase is a crucial enzyme in regulating the levels of the monoamine neurotransmitters dopamine and serotonin, both of which function in the immature brain as developmental signals. A number of human disease states are characterized by low levels of MAO, including Norrie's Disease, attention deficit disorders and alcoholism. As well, some drugs of abuse and environmental toxins decrease the activity of the enzyme. The current study was undertaken to determine what effect lowered MAO activity might have on brain development.

Pregnant Sprague-Dawley rats were treated once daily throughout pregnancy with 3 mg/kg IP of each of clorgyline and deprenyl and the pups treated until sacrifice. The pups were behaviorally tested up to PD 30 and assayed for serotonin and dopamine terminal density using the appropriate transporter labels. MAO-I exposed pups showed significantly increased open field activity at PD 16 ($p < .03$) and PD 30 ($p < .03$) and deficits in passive avoidance at PD 23 ($p < .01$) but no changes in a measure of anxiety or spontaneous alternation. In addition to these behavioral measures, the pups were highly stereotypic and had spontaneous seizures. There were no significant changes in dopamine innervation of caudate or cortex, but serotonin density was greatly reduced in cortex ($< 10\%$ control, $p < .01$) and greatly increased in caudate (220%, $p.01$).

714.14

FETAL AND MATERNAL DISTRIBUTION OF COCAINE FOLLOWING IV INJECTION IN RATS. I.T. Bell*, S. Milstein, A. Borella and P.M. Whitaker-Azmitia. Dept. of Psychiatry, SUNY, Stony Brook, NY, 11794.

Although many reports have appeared suggesting that cocaine is behaviorally teratogenic in humans and rats, little work has been done comparing maternal and fetal levels of the drug. Moreover, much of the animal research has been criticized on the hypothetical question of whether or not all fetuses receive equal amounts of the drug. The present study was undertaken to answer these questions.

Pregnant Sprague-Dawley rats (GD17) were injected into the jugular vein with 80 μ l ³H-cocaine (NEN 25Ci/mmol) and sacrificed five minutes following the injection by decapitation. Tissues from mother and fetuses were collected and sonicated in 500 μ l distilled water. Scintiverse was added to the samples and agitated until an emulsion formed and the samples were counted. The final results were expressed as fmoles/gm tissue.

Maternal distribution was hippocampus=caudate=lungs > heart=brainstem > eyes=liver > placenta. Fetal brain concentrations were approximately 1/7 of maternal (2492 fmoles/gm vs. 15,915 fmoles/mg for hippocampus). There were no significant differences in tissue concentration of the radiolabel among the fetuses. Fetal tissues are currently being analysed autoradiographically.

714.15

WATER DIFFUSIVITY SHOWS SIGNIFICANT MATURATIONAL CHANGES IN RAT BRAIN. T. Nakada*, H. Igarashi, H. Matsuzawa and I. L. Kwee. Neurochem. Res. Lab., VANCSC, Martinez, CA 94553 and Dept. of Neurology, Univ. of Calif., Davis, CA 95616.

Diffusivity of water molecules, the main solvent of biological multicomponent solutions (cytosol), is significantly affected by solvent composition. The maturational process of brain in various mammalian species including rats and humans involves changes in the composition of the cytosolic macromolecules, micromolecules as well as the size of the extracellular space. Macromolecular biopolymers (proteins and lipids), which form large solvational spheres (shells), affect water diffusivity by macroscopic populational changes in water molecules in shells of differential entropy, whereas charged micromolecules (Na^+ , K^+ , free amino acids) primarily contribute by affecting entropy of adjacent water molecules behaving as dipoles (rather than as subject for hydrogen bonds). Accordingly, we investigated maturational changes in water diffusivity in rat brain. In spite of a significant maturational increase in biopolymers (which increase the water population with low diffusivity), diffusivity of rat pup brain water showed an exponential increase with age. The finding strongly indicates that brain water diffusivity is more significantly affected by changes in cytosolic micromolecular levels and size of the extracellular space.

714.17

EFFECTS OF COCAINE ON NEURONS CONTAINING TYROSINE HYDROXYLASE (TH) IN FETAL RHESUS MONKEY. O.K. Rönnekleiv*, and B.R. Naylor. Oregon Regional primate Research Center, Beaverton, OR 97006, and Dept. of Physiology, OHSU, Portland, OR 97201-3098.

Pregnant monkeys were treated with cocaine 3mg/kg I.M. or saline, four times a day from day 18 of pregnancy until days 39/40 or 60. Plasma levels of cocaine were ≈ 200 ng/ml in both mother and fetus 50 min after the last dose. Body weight, crown-rump length or head circumference were not different between the two groups of fetuses. The brains from days 39/40 and day 60 fetuses were examined using immunocytochemistry and *in situ* hybridization. The early appearance of TH neurons were not different between cocaine (N=2) and control fetuses (N=2). In both groups TH neurons were present in the mesencephalic flexure and the dorsal hypothalamus by day 39, and fiber projections to the striatum by day 40. Also, in the day 60 fetuses (N=8), TH neurons were distributed similarly in both groups. However, the TH mRNA content as measured by quantitative *in situ* hybridization, was reduced in the substantia nigra and ventral tegmental area in the cocaine treated fetuses ($p < .05$; N=4). These findings suggest that fetal cocaine exposure does not affect the ontogeny of TH neurons, but, alters the expression of TH mRNA in fetal neurons perhaps by activation of D-2 autoreceptors. (Supported by DA07165).

QUANTITATIVE STUDIES OF CORRELATIONS, DNA CONTENTS (CELL NUMBERS) AND PROTEIN CONTENTS OF CEREBRAL CORTEX AND CEREBELLA OF ADOLESCENT RATS. S. Zamenhof*. Dept. of Microbiology and Immunology, and Brain Research Institute, UCLA School of Medicine, Los Angeles, CA 90024.

Previous studies (*Physiol. Behav.* 23:945, 1979) have revealed significant correlations between behavioral performances on one side, and cerebral DNA contents (total cell numbers), cerebellar DNA contents, or protein contents on the other side, in 30 days old rats (age sufficient for behavioral tests and for cerebellar studies). It is likely that higher levels (non-genetic) of these contents are indeed of importance for improvement of behavioral performance. In the present work (30 d. rats) we first determined that these contents themselves are significantly correlated: (DNA cerebral cortex - protein cerebral cortex $r = +0.502$ ($p < 0.05$); DNA cerebellum-protein cerebellum $r = +0.496$ ($p < 0.005$) (but in contrast: cerebral cortex protein - cerebellar protein $r = -0.19$, not significant). Subsequently, following previous studies with neonates (*Life Sci.* 18:1391, 1976), we determined the percentage of rats with one parameter (DNA or protein) and rats with both these parameters higher than the mean +1 standard deviation:

Parameter	Cerebral	Cerebellar	Both in the same rat
a. DNA	14%	25%	5.6%
b. Protein	14%	11%	5.6%
c. DNA and Prot.	2.8%	5.6%	<1%

Animals a and b occur as frequent as predictable from Normal Distribution Curve (15.9%); c are statistically more rare (expected 2 to 3% for two noncorrelated parameters). Conceivably, for the improvement of behavioral performance, rare occurrences (genetic or non-genetic) of exceptional values of many brain parameters in the same animal are required.

714.16

DEVELOPMENTAL DIFFERENCES IN EFFECTS OF GABA_A AGONISTS IN THE RAT SUBSTANTIA NIGRA: PRO- AND ANTICONVULSANT ACTIONS. D.S. Garant*, E.F. Sperber, and S.L. Moshé. Lab. of Developmental Epilepsy, Albert Einstein College of Med., Bronx, NY 10461.

GABA transmission in the rat substantia nigra (SN) protects against experimental flurothyl seizures. SN infusions of GVG, a metabolic GABA agonist, are anticonvulsant in both adult and 16-day-old rat pups; similar infusions of bicuculline are proconvulsant in both age groups. These data indicate that GABA_A receptor-mediated GABA transmission in SN contributes to seizure control in both mature and immature rats. Infusions of the GABA_A receptor agonists muscimol and THIP yield biphasic dose-response curves in adults: intermediate doses are anticonvulsant like GVG, but high doses are proconvulsant similar to bicuculline. In pups, only proconvulsant effects of muscimol and THIP are observed, suggesting that in both mature and immature rats, high SN concentrations of these drugs are antagonistic at GABA_A receptors. In the immature SN, therefore, these agonists lack the anticonvulsant efficacy that GABA possesses at GABA_A receptors, a profound developmental difference which may contribute to the increased susceptibility of the immature brain to generalized seizures.

REPEATED EXPOSURE OF RAT PUPS TO ISOLATION DECREASES ULTRASONIC VOCALIZATION RATES: REVERSAL WITH NALTREXONE. G. A. Goodwin*, V. A. Molina and L. P. Spear. Center for Developmental Psychobiology and Dept. of Psychology, SUNY-Binghamton, Binghamton, NY 13902-6000.

Young rat pups are dependent on the dam for their survival, thus isolation of the neonatal rat pup from the dam presents the young organism with a variety of stressors. Rat pups appear to be very sensitive to isolation as they will almost immediately emit ultrasonic vocalizations when placed in a novel environment with an ambient temperature below 35°C. The question examined in this study concerns the ability of the young rat pup to modify its response to isolation following repeated exposure to that isolation. Adult animals repeatedly exposed to the same aversive situation exhibit an opiate-dependent attenuation in several responses to that stressor. Because isolation of neonatal rat pups can elicit an endogenous opiate release (Spear, Enters, Aswad, & Louzan, 1985), the effect of opiate receptor blockade on the response to repeated isolation was also determined. In the first experiment, pups were seen to decrease vocalization rates following repeated isolations; however, administration of naloxone prior to the final isolation did not significantly reverse this effect. Altering the context in an attempt to dishabituate animals also failed to reverse the decreased vocalization rate. In experiment 2, naltrexone given following the first isolation attenuated the decrease in vocalization rates seen across repeated isolations. These results suggest that the development of this attenuated response to isolation stress in young rat pups is opiate-mediated but that once established, its expression may not be dependent on endogenous opiate release.

715.1

REGIONAL AND AGE-RELATED DIFFERENCES AMONG GLIAL CULTURES IN BETA AMYLOID INDUCED REACTIVE GLIOSIS. A. Höke*, D.B. Canning and J. Silver, Department of Neuroscience, Case Western Reserve University, Cleveland, OH 44106-4975.

Immobilized beta amyloid peptide (BAP) induces increased reactivity in cortical glial cultures and deposition of an axon growth inhibiting matrix containing chondroitin sulfate proteoglycan (CSPG). Expression of CSPG is also seen in the gliotic zone associated with dystrophic neurites around senile plaques in Alzheimer's disease (AD) (Canning et al, Soc Neurosci Abs 1993). In AD, although diffuse deposition of beta amyloid peptide is seen throughout the central nervous system, hallmarks of the disease, dystrophic neurites and senile plaques are mostly confined to hippocampus and cerebral cortices. This region specific pathology could be attributed to differences in glial reactivity in different parts of the CNS. To test this hypothesis, we investigated the expression of CSPG by glial cultures isolated from rat cortex, cerebellum and spinal cord. When these cells were exposed to immobilized BAP *in vitro* and stained with CS-56 (anti-CSPG antibody), cerebral cortical cultures showed high levels of CSPG deposition on BAP after two weeks. However, spinal cord cultures showed minimal levels of CS-56 immunoreactivity and cerebellar cultures fell in between. This reactivity required maturation of the glial cells *in vitro*. If P0 glial cells were exposed to immobilized BAP, they did not deposit CSPG onto the BAP/laminin matrix. They required a maturation period of at least two weeks, before they became capable of depositing CSPG onto BAP/laminin matrix. These findings suggest that glia are regionally heterogeneous in their reactive response to BAP. This difference in the interaction between B-AP deposits and surrounding glia may have a role in the region specific pathogenesis of Alzheimer's disease.

CYTOKINES, INFLAMMATORY CELLS AND ASTROGLIOSIS. V. Balasingam, I. Turley and V.W. Yong*, Montreal Neurological Institute, McGill University, Montreal, Quebec, Canada H3A 2B4.

Reactive astrogliosis is a characteristic response of astrocytes to injury of the adult CNS. To assess the hypothesis that cytokines from inflammatory mononuclear cells that accumulate around lesion sites have a role in modulating astrogliosis, we took the advantage of the neonatal system in which astrogliosis is reported to be minimal following injury and in which the immune system is relatively immature compared to adult animals. Unexpectedly, a nitrocellulose-membrane implant (NC-implant) into the cortex of P3 mice resulted in a tremendous astrogliotic response (GFAP IR = $1016 \pm 37 \times 10^3 \mu\text{m}^2$). In contrast, a neonatal stab wound produced limited astrogliotic response (GFAP IR = $30 \pm 2 \times 10^3 \mu\text{m}^2$) when compared to the adult stab wound (GFAP IR = $496 \pm 22 \times 10^3 \mu\text{m}^2$). Utilising the neonatal stab wound model, cytokines were micro-injected into the wound site at the time of injury. All cytokines tested resulted in a significantly increased astrogliosis (e.g., GFAP IR for γ -IFN treated animals = $634 \pm 54 \times 10^3 \mu\text{m}^2$). The NC-implant injury paradigm is currently being utilized as a suppository element to administer neutralising antibodies to cytokines in an attempt to curtail the extent of astrogliosis in both neonatal and adult animals. In addition, we are examining whether there is a spatial and temporal correlation of a particular inflammatory cell type with astrogliosis. We conclude that neonatal astrocytes can become reactive if an adequate injury stimulus is presented, and that the release of cytokines by inflammatory mononuclear cells that accumulate around lesion sites may be a mechanism that contributes to the production of gliosis.

NEURITE GROWTH INHIBITORS (NI) OF MAMMALIAN CNS MYELIN ARE PRESENT IN XENOPUS SPINAL CORD BUT NOT IN THE OPTIC NERVE. D. Lang*, B. Rubin*, M.E. Schwab*, C.A.O. Stuermer, U. Konstanz, D-7750 Konstanz, *Inst. of Brain Res., U. Zürich, CH-8029 Zürich

While mammalian CNS myelin carries neurite growth inhibiting proteins (NI) (Schwab and Caroni, 1988) which impede axonal regeneration, fish do not (Bastmeyer et al., 1991). Here we demonstrate the distribution of NI in pre- and postmetamorphic amphibians, *Xenopus* (Anurans), and the neotenic axolotl (*Urodeles*) using the antibody (AB) IN1. Cryosections were fixed and exposed to IN1 and secondary HRP coupled AB. IN1 staining was compared to the distribution of myelin markers GalC, MBP, PLP.

1. Adult *Xenopus* spinal cord exhibited IN1 staining in all myelinated tracts but IN1 was absent from optic nerve and tectum. 2. Adult Axolotl showed myelin markers in spinal cord and optic nerve but no IN1 staining. 3. *Xenopus* tadpoles were free of IN1 and myelin markers. They achieved myelin markers during metamorphosis but IN1 only in the spinal cord, and not in the optic nerve.

Axons regenerate successfully in both spinal cord and optic nerve of Axolotl and *Xenopus* tadpoles, in adult *Xenopus*, however, only in optic nerve and not in spinal cord. Thus, the presence of NI in amphibian CNS myelin correlates with the loss of axonal regeneration, and its absence with successful axonal growth.

715.2

BLOCKING OF AXON OUTGROWTH BY REACTIVE GLIOSIS INDUCED WITH β -AMYLOID PEPTIDES. D. R. Canning*, R. J. McKeon, D. A. DeWitt, G. Perry, J. R. Wujek, R. C. A. Frederickson & J. Silver, Department of Neurosciences, Case Western Reserve Univ. Sch of Med., 10900 Euclid Ave., Cleveland, OH 44106-4975.

Most axons within the adult vertebrate CNS fail to regenerate following injury and neurodegenerative disease. It has previously been shown that local reactive gliosis at the site of experimentally induced lesions in the rat cortex is accompanied by the deposition of growth inhibitory chondroitin sulfate proteoglycan(s) (CSPG), suggesting that specific molecular components of the deposition may be involved in limiting the growth of regenerating axons in the CNS. However, what triggers the conversion of glial cells to a functionally reactive state leading to this localized deposition is unknown. Here, we show that peptides of the β -amyloid molecule when presented as an insoluble substrate can induce cortical glial cells *in vitro* and *in vivo* to locally deposit CSPG containing matrices. *In vitro*, the CSPG containing matrix blocks the usual ability of the peptide to allow cortical neurons to adhere and grow to a laminin/ β -amyloid peptide substrate. Since the pathological lesions in the brains of patients with Alzheimer's disease (AD) are characterized by dense deposits of β -amyloid protein, the peptide may be inducing reactive gliosis during AD pathogenesis. We suggest that an additional effect of β -amyloid in the AD brain, which compounds the direct effects of the peptide on neurons, is mediated by the stimulation of astroglia to become reactive and deposit growth inhibitory molecules within the neuropil similar to glial scar formation following trauma. Such a process may impair neuronal process survival and regeneration leading to neurite retraction and/or dystrophy around senile plaques in AD. This idea is supported by our findings of CSPG associated with reactive astrocytes around senile plaques in human AD tissue.

715.4

CHARACTERIZATION OF AXON-GROWTH PERMISSIVE AND INHIBITORY ASTROCYTE CELL LINES. J. Folt-Seang, J.H. Rogers, R.B. Johnson, R.J. Keynes* and J.W. Fawcett, Physiological Laboratory and Dept. of Anatomy, Downing St., Cambridge CB2 3EG, UK.

Several cell lines were generated by infecting newborn rat cortical astrocyte cultures with virus containing either the neu oncogene or the temperature-sensitive mutant form of the SV40T oncogene. Over 60 cell lines were found to be GFP-Immunoreactive, of which 3 containing the SV40 oncogene (T34-2, T27R1 and T27R2) and one containing the neu oncogene (Neu-7) were further characterized.

When newborn rat DRG neurons were grown on monolayers or in 3-dimensional cultures derived from these cell lines, T34-2, T27R1 and T27R2 were found to be permissive for axonal outgrowth to varying degrees, whereas the Neu-7 cell line appeared to be relatively non-permissive. Since all 4 astrocyte cell lines expressed the axon growth-promoting molecules laminin and N-cadherin, the failure of axons to grow on Neu-7 cells may be due to presence of an inhibitor. Neu-7 cells, however, were not immunoreactive for tenascin or chondroitin sulphate proteoglycan, molecules which have been implicated in inhibition, and furthermore, did not show growth cone collapse activity.

Taken together, our findings suggest that Neu-7 is an inhibitory astrocyte cell line and that the inhibitory molecule(s) appears to be different from the major classes of known axon outgrowth inhibitors.

715.6

INVESTIGATION OF THE NEUROPROTECTIVE EFFECTS OF HSP72 USING TRANSGENIC AND PRIMARY CELL CULTURE TRANSFECTION TECHNIQUES

J.B. Uney*, J.N.C. Kew, S. Pickering, K. Staley, M.H. Johnson & M.V. Sofroniew.

Department of Anatomy, University of Cambridge & ¹MRC Laboratory of Molecular Biology, Cambridge, U.K.

In studies using neuronal tissues a great deal of correlative but indirect evidence has been found which suggests that prior expression of hsp72 may be protective against excitotoxicity, free radical damage and ischaemic stress. Recent technical advances allow gene transfer into post-mitotic neuronal cells. In this study we have used the techniques of transgenesis and primary culture transfection to investigate the neuroprotective effects of constitutive overexpression of hsp72.

Transgenic animals have been generated and been shown to express mRNA encoding the human inducible form of hsp72. The ribonuclein gene promoter was used to drive expression and this has previously been shown to direct expression to the hippocampal CA1 and CA2 but not CA3 neurons in the adult mouse brain. We are currently utilising this precise expression pattern to assess the neuroprotective effects of hsp72 in the hippocampus by stereotactically injecting NMDA into the hippocampus of the transgenic animals and comparing the excitotoxin-induced damage of the CA1 and CA2 regions of the hippocampus with the CA3 region. Further to these experiments we have also shown that transfection of dorsal root ganglion primary cultures with an EF-1 alpha-hsp72 expression vector protects neurones and glia against exposure to heat stress.

These data support the hypothesis that overexpression of hsp72 enhances the survival of neurones following stress and suggests that the induction of a stress response in the CNS may provide an alternative form of treatment for CNS diseases.

715.7

GROWTH OF SEVERED AXONS FROM MOTOR CORTEX SUGGESTED BY ELEVATED GROWTH-ASSOCIATED EPITOPES. A.P. Foerster*. Dept. of Biomedical Science, McMaster Univ., Hamilton, ONT L8N 3Z5.

Injections of Fluoro-Ruby (FR), in adult rat medial prefrontal cortex, labeled axons confined to the medial part of the cerebral peduncle (CP). This was severed at bregma -3.5 mm with an implanted 1.5-2 mm wire cutting device [Foerster (1982) *J Comp Neurol* 210:335]. Immediately postlesion, severed FR-labeled axons faced the cut. At 8 and 20 d some labeled axons had become reoriented to pass towards, and to curve around, the ends of the lesion. At 20 d FR-labeled axons were found in at least 3 mm of the distal CP. These indications of postlesion growth were supported by the appearance at 8 d of FITC-tagged immunoreactivity (IR) (i) with a synaptophysin antibody (G-86, gift of R. Jahn) that labels growing neurites [Phelan and Gordon-Weeks (1992) *Eur J Neurosci* 4:1180] and (ii) with an antibody for a protein that binds a neurite-promoting site of laminin (LBP) [Kleinman et al. (1991) *Arch Biochem Biophys* 290:320; gift of H. Kleinman]. IR for these was elevated in labeled axons still facing the lesion, and in some which bypassed it. LBP-IR appeared at 20 d in astrocytes near the lesion with processes parallel to the line of incision, some of which were paralleled by reoriented FR-labeled axons. This suggests that such astrocytes may be involved in guiding regenerated axons around a lesion.

715.9

ACETYL-L-CARNITINE RESTORES CHOLINE ACETYLTRANSFERASE ACTIVITY IN THE HIPPOCAMPUS OF ADULT RATS AFTER PARTIAL FIMBRIA-FORNIX TRANSECTION. P. Piovesan, G. Quatrin, L. Pacifici, M.T. Ramacci, G. Tagliatela, L. Angelucci¹, M. Alderdice². Inst. for Res. on Senescence Sigma Tau, 00040 Pomezia, Italy; ¹Inst. of Pharmacology II, School of Medicine, "La Sapienza" Univ. of Rome, Italy; ²Sigma Tau Inc., Gaithersburg, Maryland 20878.

Partial transection of the septo-hippocampal pathway (fimbria-fornix) in the rat results in an impairment of cholinergic activity in the hippocampus (HIP) similar to that occurring during aging. In the present study we used cholineacetyltransferase (ChAT) and acetylcholinesterase (AChE) activities, and nerve growth factor (NGF) levels as markers of the central cholinergic function following fimbria-fornix lesion. Three-month old Fischer 344 rats bearing a unilateral partial transection of the fimbria-fornix were treated for 1 week prior and 4 weeks following the lesion with Acetyl-L-Carnitine (ALCAR; 150 mg/kg/day in drinking water), a substance known to ameliorate some morphological and functional disturbances in the aged central nervous system. Fimbria-fornix transection significantly reduced ChAT and AChE activities in the HIP ipsilateral to the lesion as compared to the contralateral one. No changes were observed in the cortex. ALCAR treatment restored ChAT activity to normal values in the HIP ipsilateral to the lesion, while AChE levels were lower as in lesioned untreated animals. Lastly, NGF levels in the septum were not affected by the lesion nor by ALCAR. Given the importance of NGF in the re-establishment of hippocampal cholinergic activity after fimbria-fornix transection, these data suggest that ALCAR may facilitate sprouting of surviving cholinergic fibers by enhancing their trophic response to hippocampal NGF.

715.11

UPREGULATION OF NITRIC OXIDE SYNTHASE (NOS) IN THE NEUROHYPOPHYSEAL SYSTEM FOLLOWING HYPOPHYSECTOMY. D.E. Scott* and W. Wu, Department of Anatomy & Neurobiology, Eastern Virginia Medical School, Norfolk, VA 23501.

Sprague-Dawley rats were used in the experiment. Animals were hypophysectomized and were divided into two groups with 12 animals in each group. Animals in the first group received daily IP injections of nitroarginine, an inhibitor of NOS. Those in the second received nothing. Following hypophysectomy rats survived 1, 2, and four weeks; 2 rats from both nitroarginine treated and non-treated groups for each survival period were prepared for NADPH diaphorase histochemistry. Another 2 rats were prepared for scanning electron microscopy (SEM). Four normal intact rats were used as controls, 2 for histochemistry and 2 for SEM. Stain intensity with NOS histochemistry of supraoptic and paraventricular (SON/PVN) neurons and their regenerating neurites in controls increased dramatically by 2 weeks and decreased to normal levels by 4 weeks following regeneration. Unlike control rats, relatively few neurites were observed on the floor of the third cerebral ventricle in nitroarginine inhibited rats following hypophysectomy. These data support the hypothesis that NO produced by NOS is directly related to the process of neurohypophyseal regeneration and may play a pivotal role in retargeting and directing regeneration of SON and PVN axons into predictable as well as novel neuroanatomical domains such as the third cerebral ventricle following the trauma of hypophysectomy.

715.8

SCHWANN CELLS PRODUCE IL-6 IN RESPONSE TO NEURONAL COCULTURE. L.M. Bolin*, A.N. Verity, J. Silver, J. Abrams and E.M. Shooter. Department of Neurobiology, Stanford University School of Medicine, Stanford, CA 94305, DNAX Research Institute, Palo Alto, CA 94304.

During peripheral nerve regeneration Schwann cells support and provide neurotrophins to regrowing axons. We have used an in vitro paradigm to examine the induction of Schwann cell trophic activities in response to neurons in coculture. We have determined that the pleiotrophic cytokine, IL-6 is a component in conditioned media from Schwann cell - neuronal cocultures. The presence of IL-6 was confirmed by a neuronal differentiation assay in rat PC12 cells and a survival assay with mouse myeloid B9 cells which are IL-6 dependent. A monoclonal antibody that neutralizes IL-6 activity in the B9 assay neutralizes the activity in coculture conditioned medium. An antibody against rat IL-6 reduces PC12 neurite extension in response to coculture conditioned medium. An induction of IL-6 message is seen in total cellular RNA isolated from Schwann cells grown in coculture which is not present in Schwann cells grown alone or in the neurons that are cocultured.

Expression of the IL-6 receptor, gp80, is being investigated in both cell types. The immortalized Schwann cell clone used in this study arose spontaneously in a primary culture of adult rat sciatic nerve Schwann cells isolated 24 hr after injury. Since these Schwann cells are transformed during their response to nerve injury, their production of IL-6 may be a contributing factor in successful regeneration.

Supported by an NIH Neonatal and Developmental Biology post-doctoral training grant (HD-07249).

GROWTH-ASSOCIATED PROTEINS IN THE SEA LAMPREY. L.D. Margolin* and N.M. Colaninno. Cambridge NeuroScience, Inc., Cambridge, MA 02139.

The lamprey spinal cord has been the focus of many studies concerned with the mechanisms of CNS regeneration. Various methods of analysis using higher vertebrates have shown that specific proteins are expressed in response to CNS injury. These proteins, called growth-associated proteins (GAP), are thought to be involved in development, plasticity and regeneration, although their specific role in each process is yet to be determined. Our efforts lie in the elucidation of regenerative processes which lead to full functional recovery in the lamprey by addressing questions pertaining to the presence and role of GAPs.

Sea lampreys (*Petromyzon marinus*) were anesthetized with 0.5g/L Tricaine (Sigma). The brain was exposed and 1-10 μ Ci of L-[³⁵S] methionine-cysteine (NEN) was pressure injected into the floor of the fourth ventricle, followed in two hours by a systemic injection of cold methionine-cysteine (Sigma). After incubation periods of 6 hours to one week, brain and spinal cord were removed and prepared for standard one-dimensional SDS-PAGE and autoradiographic analysis.

Preliminary studies have shown that radiolabeled amino acids injected into the fourth ventricle of an intact lamprey were transported anterogradely into the spinal cord. One dimensional PAGE showed the presence of many proteins, several of which have incorporated the radiolabel. Subsequent studies will include specimens that are in various stages of functional recovery following complete spinal cord transection.

THE EFFECT OF THE INCREASED ENDOGENOUS BETA-ENDORPHIN (BE) RELEASE INTO THE BLOOD ON THE REGENERATION OF DAMAGED STOMACH MUCOUS (SM)

V. Lebedev†, S. Rychkova, V. Alexandrova, A. Savchenko

Lab. of Electroanalgesia, Pavlov Institute of Physiology, St. Petersburg 199034, Russia

It is well known that some natural or synthetic opioid peptides applied exogenously accelerate the regeneration of damaged SM. In present study the influence of uninvase transcranial electrostimulation (TES) with special regime selectively activated brain opioid structures was investigated in rats on the development and repair of cold-restrained-, ethanol- and cystamine-induced SM ulcers. TES sessions elicited the increase of BE blood level from 9.18±3.17 up to 29.96±2.65 pmol/l and significantly decreased the ulcer numbers and ulcer severity in each experimental model. The TES effects was more pronounced in comparison with ones of i.m. injections of synthetic (D-Ala², Arg⁶) Leu-enkephalin (DAALE) and were reversed by naloxone. Combined effect of TES and DAAL was usually considerably lesser than separate one of each. The encephalinase inhibitor D-Leucine (nonpassed through BBB in rats) substantially potentiated TES healing effects. Conclusion was made that increased BE release into the blood elicited by TES effectively accelerates the repair of damaged SM. These experimental data were confirmed by high efficacy of usage of TES with this regime for treatment of gastric and duodenum ulcers in patients.

cDNA LIBRARIES FROM IDENTIFIED LEECH NEURONS. S.A. Korneev, S.E. Blackshaw*, J.A. Davies. Institute of Genetics, and *Department of Cell Biology, University of Glasgow, Glasgow G11 5JS, Scotland, U.K.

Our aim is to investigate synapse establishment and nerve regeneration by isolating molecules specific to regenerating neurons and to different classes of neurons in the medicinal leech *Hirudo medicinalis*. The strategy we have adopted is to use a PCR-based cloning technique to enable us to construct cDNA libraries from dissected, identified neurons. We have optimised the various steps of the procedure by producing a cDNA library from the equivalent of a single leech ganglion which consists of about 400 neurons. The library contained more than 10^6 recombinants and the average size of the inserts was approximately 600 bp. We have sequenced 6 randomly picked clones and 4 clones containing repetitive sequences and found that the library was remarkably free from cloned primer artefacts and ribosomal RNAs. The results obtained have prompted us to use the same approach for constructing a cDNA library from a few (10-15) serotonergic Retzius cells, the most prominent in the leech ganglion. By employing modifications of the reverse transcription reaction and the PCR protocol we have managed to create a cDNA library of about 10^6 recombinants, of average insert size, 700 bp.

BALLS AND BRAINS: I. IMMUNOLOGICAL PRIVILEGE FOR CNS GRAFTS. B.J. Baker and R.D. Broadwell*. Div. Neurosurg. and Neuro-path., Univ. Maryland Sch. Med., Balto. 21201.

The privilege of the CNS with respect to transplantation may be due to absence of dendritic cells and lymphatic drainage and existence of a blood-brain barrier. Despite reported immunological privilege, the testis has dendritic-like cells, lymphatic drainage, permeable vessels. Syngeneic grafts were transplanted to the testis or CNS in inbred PVG rats. Allogeneic grafts were prepared between PVG and PVG(AO) rats differing at major histocompatibility (MHC) loci and between the PVG and AO rats differing at MHC and minor HC loci. With monoclonal antibodies CNS grafts were deemed surviving if they expressed uniform Thy 1 staining, low MHC class I expression, few MHC class II+ cells, and negligible CD4+/CD8+ cells. Syngeneic grafts to the adult host CNS/testis appeared healthy/viable for 30d. All allogeneic grafts within the CNS parenchyma of adult hosts survived well. CNS allograft viability in the testis at 30d was variable. Vigorous graft rejection occurred between PVG and AO rats and less so between donor PVG and host PVG(AO) rats; graft survival without demonstrable rejection was seen between donor PVG(AO) and host PVG rats. The data suggest immune privilege of the testis is less demonstrable than that of brain. Survival of some allografts in the testis may be due to immunosuppressant factors. Existence of similar factors within the CNS may represent an additional consideration in defining CNS immune privilege.

716.3

SURVIVAL OF HUMAN NERVE GRAFTS IN NUDE RATS. N. A. Azzam*, A. A. Zalewski, M. C. Dalakas, and R. N. Azzam. Lab. of Neural Control and Medical Neurology Branch, NINDS, NIH, Bethesda, MD 20892.

Nerves from rats can be cryopreserved and stored by a technique that allows the Schwann, vascular and perineurial cells in them to survive after transplantation (J. Comp. Neurol. 331:134-147, 1993). In order to extend the cryopreservation procedure to human nerves, we first needed to find a recipient that would accept human nerves. Accordingly, we investigated whether fresh human nerves would survive in congenitally immunodeficient nude rats. Pieces of human sural nerve were placed into tissue culture medium and, within an hour, transplanted into nude rats. Some nude rats received free grafts (i.e., grafts laid alongside intact peroneal nerves) whereas other rats had their peroneal nerve cut and anastomosed to one end of the human nerve. The grafts were examined 4 and 10 weeks postoperatively by light and electron microscopy. None of the grafts were rejected. A similar pattern of Wallerian degeneration was found in 4-week-old free and anastomosed grafts. At that time, Schwann cells were present inside basement membrane tubes, a few of which contained remnants of degenerating myelin. The perineurium and a moderate number of endoneurial blood vessels also survived. In addition, thinly myelinated axons were present in the proximal portion of an anastomosed graft. At 10 weeks, the number of Schwann cells in free grafts diminished, but overall the tissue was typical of degenerating nerve. In contrast, anastomosed nerve contained numerous myelinated and unmyelinated axons throughout its length. The endothelium of endoneurial blood vessels that was present appeared normal as did the perineurium. These results demonstrate that the cellular components of human nerve grafts can survive in nude rats and that human Schwann cells can myelinate rat axons. This nude rat model may be useful for examining a variety of *in vivo* aspects of human nerve neurobiology.

716.2

BALLS AND BRAINS: II: BLOOD VESSELS IN CNS GRAFTS. R.D. Broadwell, B.J. Baker, and M. Fiandaca*. Div. Neurosurg. and Neuro-path., Univ. Maryland Sch. Med., Balto. 21201.

Graft survivability is dependent upon the graft developing a vascular network supplied with host blood. We have analyzed by immunohistochemistry and electron microscopy the origins and morphological characteristics of vessels supplying fetal CNS grafts placed into brains, testes, or beneath the kidney capsule of adult host rats. Syngeneic/allogeneic CNS grafts were performed with donor/host combinations between the inbred PVG and PVG(AO) rats. Monoclonal antibodies used were: OX-27 for MHC class I expression by PVG endothelial cells; OX-26 for the transferin receptor on blood-brain barrier endothelia; OX-18 for general MHC class I; and OX-7 for identification of healthy CNS neurons. HRP was delivered *iv* to ascertain a graft BBB to blood-borne protein. All grafts to host CNS were vascularized predominantly with host vessels and possessed a BBB with interendothelial tight junctions. Syngeneic grafts to the kidney capsule were supplied with OX-26+/BBB vessels, whereas allogeneic grafts failed to survive. Syngeneic/allogeneic grafts to the testis survived and exhibited OX-26+/BBB vessels; donor vessels predominated within these allogeneic grafts. Host testis MHC+ vessels were evident within CNS grafts and appeared OX-26 negative. The proportions of donor vs. host vessels in CNS grafts, regardless of their MHC expression and permeability characteristics, may depend on host site and/or genetic disparity between donor/host. NIH/NINDS grant #NS18030.

716.4

REJECTION OF NERVE ALLOGRAFTS AFTER STOPPING CYCLOSPORIN-A IMMUNOSUPPRESSION. A. A. Zalewski*, N. A. Azzam and R. N. Azzam. Lab. of Neural Control, NINDS, NIH, Bethesda, MD 20892.

After immunosuppressive therapy with Cyclosporin-A (Cy-A) is stopped, nerve allograft rejection occurs and host axons that had regenerated into the graft degenerate despite the fact that the axons are not foreign tissue. The present experiment was performed to correlate immune events and tissue loss in nerve allografts after terminating Cy-A treatment. Nerve grafts (4 cm long) were taken from American Cancer Institute (ACI) rats and joined to the peroneal nerve of Fischer (FR) rats that received Cy-A (10 mg/kg, intraperitoneally). After one week, Cy-A was stopped and the allografts were examined 2-6 weeks postoperatively by light and electron microscopy. No immune reaction nor destruction of allogeneic perineurial, vascular or Schwann cells was found in 2- or 3-week-old grafts. These grafts underwent Wallerian degeneration and were invaded proximally by regenerating, thinly myelinated, host axons. At 4 weeks, the perineurium of each graft became infiltrated and was destroyed by mononuclear cells. Many endoneurial blood vessels of these grafts were occluded and their endothelial cells were missing or degenerating. Despite the immune reaction, Schwann cells remained and myelinated many of the host axons that grew 3 cm into the grafts. However, at 6 weeks, most allogeneic Schwann cells were absent from all grafts, and no host axons were found. Some of the basement membrane tubes which formerly housed allogeneic Schwann cells were occupied by macrophages or were empty and fragmented. There was also evidence (i.e., masses of condensed DNA) that perineurial and Schwann cells were killed by apoptosis. These results demonstrate that there is a sequential rejection of tissue components in nerve allografts and that host axonal degeneration is related to adverse immune or metabolic effects of allogeneic Schwann cells.

PROBLEMS IN MEASURING VISUAL ACUITY IN ALBINO RATS. Susan E. Maier* & Jan Steele Russell. Texas A&M University Health Science Center, College Station, TX, 77843-1114.

Adult albino rats exposed to continuous light for 30 days show a complete loss of photoreceptors (rods) in the retina. This preparation provides a useful model for retinal transplantation research, yet the evidence regarding the extent of visual impairment following such visual loss is equivocal. To develop a behavioural procedure for testing hypotheses about visual loss, we began by generating psychophysical curves for brightness and line orientation in intact albino rats. It was evident early in testing that the rats were using nonvisual cues to solve the task, thus we double eyepatched these animals and retested them. The results show that covering the eyes had little effect on line orientation scores. We next examined the role of other cues, and preliminary data suggests that rats use various other cues including odor and vibrissa. Our data serve as a caution to researchers using albino rats that these animals are adept at solving a visual task using nonvisual cues.

716.7

RETINA REPAIR BY TRANSPLANTATION IN ORGAN-CULTURED CHICK EYES W. Halfter, Dept. of Neurobiology; University of Pittsburgh

Embryonic chick and quail eyes (E3 to E5) were organ-cultured for 1 or 2 days. Prior to culture, pieces of retina were removed. The wounds were closed by orthotopic and heterotopic transplants of retinal or brain tissue of different ages and by collagen gels. The integration of retina or brain transplants into the host retina was consistently very good, with a perfect alignment of graft and host tissue at the inner retinal surface. Transplants without basal lamina, such as tectal transplants stripped of their pial membrane, or retinal transplants facing with their ventricular surface the vitreous body, were covered with a host-derived new basal lamina. When mesenchymal tissue was grafted into the retina, no inner limiting membrane was formed, and the grafts were not integrated into the host retina. Collagen gels were only integrated when the gels were soaked with extract from retinal basal lamina. Ingrowth of optic axons into the collagen gels was observed. Our results show that wounded retinal tissue can be repaired by implantation of CNS tissue and collagen gels into the lesion site.

INFERIOR COLLICULUS LESIONS AND GRAFTS: DEFICITS AND RECOVERY OF SOUND LOCATING ABILITY. M.C. Zull* and J.R. Coleman. Depts. of Psychology, Appalachian State Univ., Boone, NC 28608, Univ. of South Carolina, Columbia, SC 29208.

The ability to detect sound in the horizontal plane is impaired by bilateral damage to the inferior colliculus (IC). Recovery from spatial hearing deficits is promoted by IC primordia grafts; rats with grafts after lesions detect sounds at random spatial loci more accurately than conspecifics with IC lesions only (Zull et al., 1991). We continued to examine behavior affected by IC lesions and tectal grafts in a sound localization task which is more complex than a spatial detection task.

Hooded rats (N=15) were trained to suppress licking when the second pulse of a noise burst pair (125 ms ea., 150 ms IBL, 50 dB SPL) came from a different location than the first pulse. After baseline sessions, anesthetized rats received IC lesions (N=5, LO), lesions plus E18 tectal tissue grafts (N=5, LG), or sham surgery (N=5, SH). By 35 days post-surgery, localization performance ratios (LRs) show LG rats (.63±.03) localize sound between levels of SH rats (.72±.03) and LO rats (.50±.03), $F(16, 65)=1.80, p<.05$. LG rats never achieve LRs of SH controls; however, SH and LG rats exhibit similar task-behavior patterns relative to rats with lesions only. Analysis of the data via item response methods allowed estimation of measurement models yielding quality of localization behavior indices. Models indicate grafts may promote recovery after IC lesions by sparing the orderliness of sound localization behavior (LG, .6 and SH, .9 vs LO, .1). Analysis of brain sections show similar lesion sites in LG and LO rats, and some evidence of viable grafts in LG rats. Relative to LO rats, soma and processes of dorsal lemniscal neurons are spared in grafted animals.

TRANSPLANTATION OF DISSOCIATED RETINAL GANGLION CELLS INTO THE SUPERIOR COLLICULUS OF POSTNATAL RATS. J.J. Miguel-Hidalgo* and L.M. Chalupa. Dept. Psychology and Center for Neuroscience, Univ. California, Davis, CA 95616.

To examine the influence of extra-retinal factors upon the morphological differentiation and survival of retinal ganglion cells (RGCs), we injected suspensions of dissociated RGCs, obtained from postnatal rats, into the superior colliculus of littermates. A 2% solution of fluorogold (FG) was injected into the retinorecipient centers of 2 to 7 days old rats to allow unequivocal identification of RGCs. Two days later the retinas of these rats were dissected, cells were enzymatically dissociated, and the resulting suspensions injected with a micropipette into the superior colliculus (SC) of littermates. After a variable survival period these animals were killed with an overdose of pentobarbital, the brains were fixed by perfusion with 2% paraformaldehyde, cryoprotected in a 30% sucrose solution overnight and sectioned with a vibratome at a thickness of 100 µm. Examination of these sections revealed that many FG-labeled ganglion cells survived for as long as three weeks. Furthermore, in some cases these neurons exhibited extensive processes demonstrating that the SC was capable of supporting the survival and growth of retinal ganglion cells. A clear laminar specificity was evident, in that, the highest proportion of surviving RGCs was found in the superficial laminae of the SC, with only a few such cells observed in the deeper layers. We are now in the process of assessing how the differentiation of RGCs surviving in the SC compares to that within the intact retina. (Supported by NEI EY03993. J.J. TRANSPLANT-MEDIATED PUPILLARY LIGHT REFLEX: EFFECT OF UNILATERAL LESIONS OF THE OLIVARY PRETECTAL NUCLEUS M. J. Young*, S.J.O. Whiteley and R.D. Lund. Dept. of Anatomy, University of Cambridge, Cambridge CB2 3DY UK

Embryonic retinæ transplanted to the surface of the midbrain of neonatal rat hosts innervate visual targets in the host brain, and when stimulated, are capable of eliciting a pupillary light reflex (PLR) in the host eye. Previous work has shown that unilateral lesions of the olivary pretectal nucleus (OPN) result in a decrease in the efficacy of the PLR in rats, but do not abolish either the direct or consensual PLR. Here we have extended this work to examine the effect of unilateral OPN lesions on a transplant-mediated PLR.

Retinæ from embryonic day 14 Long-Evans (LE) rats were transplanted to neonatal LE rats. The right eye was removed at the time of transplantation. Four-six weeks after transplantation a fiber optic light guide (4x10mm) was cemented over the transplant to allow for repeated stimulation of the grafted retinæ over time. Pupillometric analysis was performed on these animals to characterise the transplant-mediated PLR under a range of light intensities. Latency, amplitude, and the rate of pupilloconstriction were analyzed. After establishing baseline conditions, one group of animals received a unilateral OPN lesion. The right OPN was lesioned, thereby eliminating the crossed input from the host eye, as well as the transplant projection to that OPN. A control group received sham lesions. The animals were allowed to recover for one week, and were then tested again.

Unilateral OPN lesions result in an increase in the efficacy of the transplant-mediated PLR, while the host direct PLR is substantially reduced. Lesions in animals that did not possess a transplant-mediated PLR showed far less of an effect on the direct PLR. These results suggest a dynamic interaction between the transplant and the host, possibly occurring across the midline, such that when the crossed retinal input is removed, the efficacy of the transplant projection (largely to the left OPN) is substantially enhanced.

RECOVERY OF SPATIAL MEMORY FUNCTION IN FORNIX-LESIONED RATS WITH INTRA-RETROSPLENIAL AND/OR INTRA-HIPPOCAMPAL TRANSPLANTS Y.J. Li*, W.C. Low. Departments of Neurosurgery and Physiology, and Program in Neuroscience, University of Minnesota Medical School, Minneapolis, MN 55455

The retrosplenial cortex has been implicated in spatial learning and memory function. Earlier studies in our laboratory and others have demonstrated that fornix lesions destroy cholinergic inputs to the retrosplenial cortex and the hippocampus while cholinergic grafts derived from the fetal septal nucleus can reinnervate both areas in a pattern similar to that of normal afferents. In the present study we investigated the functional effects of such a reinnervation in the RSC alone, in the hippocampus alone, or a combined reinnervation in both areas. Two months after surgery the fornix-lesioned (FX) animals, fornix-lesioned animals with intra-retrosplenial grafts (RSC), fornix-lesioned animals with intra-hippocampal grafts (HIP), fornix-lesioned animals with combined RSC and hippocampal grafts (COM), and normal control (NC) animals, were tested for their performance in spatial navigation using Morris water maze. In the spatial navigation test the NC, FX, RSC, HIP, and COM groups had 9 ± 0.9 , 4.8 ± 0.8 , 6.6 ± 1.0 , 7.6 ± 0.7 , and 9.1 ± 1.2 platform crossings (mean±SEM) respectively. Statistical analysis with Mann-Whitney U test indicated that: 1) RSC performance was significantly better than FX ($p=0.015$); 2) HIP performance was also significantly better than FX ($p=0.0015$); 3) there was no significant difference between RSC and HIP groups; 4) COM performance was significantly better than RSC ($p=0.023$) but did not differ from HIP ($p=0.236$). These results demonstrate that cholinergic intra-retrosplenial graft can ameliorate spatial learning and memory impairment induced by fornix-fornix lesion. In addition, animals with combined grafts performed better than those with RSC graft alone. (This was supported in part by PHS grant NS-24464).

AMELIORATION OF BEHAVIORAL DEFICITS IN RATS WITH NUCLEUS BASALIS MAGNOCELLULARIS (NBM) LESIONS 1.5 MONTHS FOLLOWING GRAFTS OF CHROMAFFIN CELLS, BUT NOT KIDNEY CELLS, TO THE CEREBRAL CORTEX. E.S. Yuzda*, Z.C. Koty and S.A. Welner. Douglas Hospital Research Centre, Department of Psychiatry, McGill University, Montreal, Quebec, Canada H4H 1R3.

Chromaffin cell (CC) grafts to the cerebral cortex of NBM-lesioned rats have been shown to ameliorate lesion-induced deficits in performance of a task involving spatial memory at 3 months post-grafting. To test if these behavioral effects are related to the cell type grafted and not to the grafting procedure itself and whether behavioral effects occur at a time point earlier than 3 months, the effects of kidney cell (KC) grafts at 1.5 months post graft were tested. Thus, T-maze pre-trained rats were lesioned bilaterally in the NBM with 0.12M quisqualic acid and, two weeks after lesioning, were administered either no graft, KC grafts or CC grafts. Rats were retested on the T-maze 1.5 months post-graft. Results showed that, at this earlier time point, CC grafted rats also showed a clear improvement in T-maze behavior, performing as well as control animals. However, rats receiving control grafts of KC performed no better than lesioned animals. Lesions were verified by evaluating acetylcholinesterase staining in the area of the NBM; all lesioned groups, regardless of graft type or no graft, showed equally poor staining in the NBM. These results indicate that amelioration of behavioral deficits via CC grafts to the cerebral cortex are evident as early as 1.5 months post-grafting and do not occur with a control graft. Since we have previously evidenced CC grafts to contain basic fibroblast growth factor, a known neuroprotectant, at 1.5 months post-grafting (Yuzda et al., Soc. Neurosci. #473.2, 1992), it is interesting to speculate on the involvement of this growth factor in the effects of CC grafts to the cerebral cortex. (MRCC)

CHRONIC D-2 RECEPTOR ACTIVATION ENHANCES BOTH THE K⁺-INDUCED ACTIVATION OF TYROSINE-HYDROXYLASE AND THE RELEASE OF DOPAMINE FROM CULTURED FETAL RAT DOPAMINERGIC NEURONS

F.L. Van Muiswinkel, B. Drukarch¹, W.J.A.J. Smeets*, C.A.M. Jongenelen¹, H.W.M. Steinbusch and J.C. Stoof¹. Depts of Pharmacology, Neurology¹, and Anatomy², Faculty of Medicine, Free University Amsterdam, The Netherlands.

In Parkinsonian patients, previously subjected to neuronal grafting therapy, the survival and functional status of dopaminergic grafts might be impaired by the concurrent pharmacotherapy with L-DOPA and/or dopamine (DA) D-2 receptor agonists. Therefore, we studied the effects of chronic DA D-2 receptor activation on cultured fetal rat mesencephalic DA neurons using the activity of Tyrosine Hydroxylase (TH) and the uptake/release of [³H]DA as neurochemical parameters. Though the uptake capacity for [³H]DA (~survival) remained unaltered in cultures previously treated for 12 consecutive days with 1 μM of the selective DA D-2 receptor agonist LY171555, the 20 mM K⁺-evoked release of [³H]DA was significantly increased in pretreated cultures by approximately 35% (A). In our cultures, TH activity (as determined by the release of ³H₂O from ³H-[3,5]tyrosine) appeared to be tetrahydrobiopterin-, Fe²⁺-, and temperature sensitive but could not be inhibited by an acute challenge with 1 μM LY171555. However, incubation with 56 mM K⁺ for 3 min increased TH activity in a Ca²⁺-dependent manner. Whilst the basal activity of TH remained unaltered upon chronic agonist treatment for 12 days, the K⁺-induced activation of TH was significantly higher in pretreated cultures (179% vs 150% in control) (B). Since both phenomena (A/B) are Ca²⁺-dependent, it is tempting to speculate that these changes in excitability reflect alterations in the Ca²⁺ homeostasis. Thus, a change in the functional status of fetal DA neurons has occurred, due to the chronic inhibitory effect of DA D-2 autoreceptor activation.

FOOD RESTRICTION DELAYS THE AGE-RELATED INCREASE IN HYPOTHALAMIC GLIAL FIBRILLARY ACIDIC PROTEIN (GFAP) MRNA IN F344 RATS. N.R. Nichols¹, C.E. Finch¹ and J.F. Nelson². ¹Andrus Gerontology Center and Dept. of Biological Sciences, Univ. of Southern California, Los Angeles CA 90089-0191, ²Dept. of Physiology, Univ. of Texas Health Science Center, San Antonio TX 78284-7756.

Astroglisis during brain injury, disease and advancing age is characterized by increased GFAP, the intermediate filament protein of astrocytes. We have shown that GFAP mRNA also increases at later ages in rodents and humans (Nichols et al., Neurobiol. Aging, in press). Chronic food restriction (FR) in rodents delays the onset and incidence of disease, retards many aging processes and extends life span. Therefore, if GFAP mRNA expression is a marker of age-related processes, its pattern might be altered by FR. Male F344 rats were FR to 60% of ad libitum (AL) levels beginning at 6 wk of age or fed AL and were killed in the AM (lights on: 0400 h) at 3, 6, 13 (AL only), 18, 24-25, and 33 (FR only) mo of age. Total RNA was extracted by a guanidinium cesium chloride method from frozen hypothalamic (HY) tissue of individual rats. GFAP mRNA prevalence was determined by RNA blot hybridization using a ³²P-cRNA probe synthesized from a nearly full-length rat GFAP cDNA. HY GFAP mRNA increased 3-fold at 24-25 mo in AL rats (p < 0.0001) compared with 3 and 6 mo groups. There were no differences in HY GFAP mRNA between AL and FR rats from 3 to 18 mo. HY GFAP mRNA increased 2-fold at 24/25 (p < 0.05) and 3-fold at 33 mo (p < 0.0001). At 24-25 mo of age HY GFAP mRNA was 50% higher in AL than FR rats (p < 0.01). Therefore, FR delays the increase in magnitude of GFAP expression during aging, indicating that GFAP mRNA is a biomarker of brain aging and/or central effects of age-related disease. EFFECTS OF SWIMMING EXERCISE ON AGE-RELATED CHANGES IN MOTONEURONS AND PERIPHERAL NERVES IN THE RAT. K. HASHIZUME AND K. KANDA*. Departments of Kinesiology and Central Nervous System, Tokyo Metropolitan Institute of Gerontology, Itabashi-ku, Tokyo 173, Japan.

Our previous studies demonstrated that both number and soma cross-sectional area of the rat medial gastrocnemius (MG) motoneurons decreased with advanced age. The number of myelinated fibers in the MG nerve also declined, but fuscicular areas and axon diameters were increased in the aged animals. In order to study effects of long-term physical exercise on these age-related changes, male Fischer rats aged 17 months were divided into two groups, exercised and non-exercised ones. Rats of exercised group (n=15) were subjected to swim (30min, 3 days / wk) for 10 months until they were sacrificed at age of 27 months. Non-exercised, control rats (n=11) were raised under usual laboratory conditions. After the exercise period, the MG motoneurons were labeled by retrograde transport of horseradish peroxidase. Transverse semithin sections of the MG nerve were also stained with toluidine blue. The mean number of MG motoneurons in the exercised rats was significantly larger than that in the control rats. Correspondingly, fewer myelinated fibers (including both efferents and afferents) were found in the MG nerve of the control rats compared to the exercised rats, although the difference was not significant. We did not see the atrophy of motoneuronal somata in the exercised rats. The mean fuscicular areas and axon diameters in the exercised rats were significantly smaller than those in the control rats. These findings suggest that long-term, moderate endurance exercise retards the progressive changes in motoneurons and peripheral nerves in aging rats.

717.2

AGE, SEX, LIPOFUSCIN AND LIGHT DAMAGE IN THE QUAIL RETINA. K.V. Fite* and L. Bengston, University of Massachusetts, Neuroscience & Behavior Program, Amherst, MA, 01003.

Accumulation of the age related pigment lipofuscin, in the retinal pigment epithelium (RPE) was investigated in the Japanese quail at 4 and 12 months of age. Quail were exposed to 18 hours of 3200 lux, broad-spectrum, white light at 4 months of age. Half were given an identical exposure, again, at 12 months of age. Six weeks after exposure, RPE lipofuscin was quantitatively assessed as well as histopathological evaluation of photoreceptor outer segments, outer nuclear layer, and counts of rod and cone densities for all conditions compared to controls.

Major increases in lipofuscin were observed in females vs. males at 12 months of age (controls). In the double-light-exposure condition, females showed even greater lipofuscin accumulation. Histopathology effects upon outer segments and outer nuclear layer were greater in males than in females. A major (70%) loss of rods occurred only in females. A small, nonsignificant reduction in cones (12-15%) occurred in both sexes. An inverse correlation occurred between lipofuscin and rod density across age, sex and experimental condition (r = -.78), suggesting that destruction of rods by light damage contributes directly to increased RPE lipofuscin. Thus, age, sex and light exposure history appear to be critical variables influencing the amount of lipofuscin in the RPE. (Supported by grant EYO 7370).

MAST CELL ACTIVATION AND PROLIFERATION, AND OCCURRENCE OF HIGH ENDOTHELIAL VENULES IN AGING PERIPHERAL NERVE. M. G. Nunzi* and M. G. Fiori. FIDIA Res. Labs., Abano Terme and Dept. of Orthopedics, Univ. of Brescia, Italy.

In rats, age-related axonal atrophy and loss was reported to begin at 13-14 mos in the most distal parts of peripheral nerves; these phenomena are followed by vacuole formation, segmental demyelination/remyelination and proliferation of mast cells (MC): the latter has been thought to be associated with either Wallerian degeneration or demyelination. We studied the sciatic nerves of 27-mo-old rats and found that there was a 5-fold increase in the overall MC number as compared to adult (8-mo-old) rats. MC were distributed unevenly, with a much higher percentage in the endoneurial than epineurial compartment; about 40% of endoneurial MC were degranulating. Some MC were noticed encased in macrophages engulfing degenerated axons. More noteworthy was the quantitative morphological association between MC and high endothelial venules (HEV), specialized vessels subserving the passage of inflammatory cells into the tissues. The occurrence of HEV had been already described in experimental allergic neuritis, also characterized by an increase in degranulated MC. We suggest that the MC invading aged peripheral nerves are derived from both proliferation of a resident population and transluminal passage mediated by HEV. By virtue of the release of histamine and several cytokines, MC may contribute to either edema and segmental demyelination or regenerative process.

717.5

Aging-Dependent Increase in Very Long Calcium Tail Currents in Rat Hippocampal Slice CA1 Neurons. P.W. Landfield¹, O. Thibault, L.W. Campbell and E.M. Blalock. Dept. Pharmacol., Univ. Kentucky College of Medicine, Lexington, KY, 40536.

In previous current clamp studies, we have described an aging-dependent increase in the duration and amplitude of Ca²⁺-dependent afterhyperpolarizations (AHPs) and Ca²⁺ action potentials (spikes). Under voltage clamp conditions, we have also described very long (500-2000 ms) Ca²⁺ tail currents in these same slice neurons. Elsewhere in this meeting (Thibault *et al*) we present evidence that single L-type Ca²⁺ channel openings following repolarization appear to account for long-lasting whole cell Ca²⁺ tail currents. One possibility for the aging effect on the AHP and the Ca²⁺ spike, therefore, is that aging may increase the probability of repolarization openings and, thereby, increase Ca²⁺ entry following command depolarizations.

To test this hypothesis, we recorded voltage-sensitive Ca²⁺ currents from both young (3-5 months) and aged (25-27 months) rat CA1 hippocampal neurons in the *in vitro* slice preparation. Using sharp electrode voltage clamp, the Cs⁺, TTX- and TEA-treated neurons did not show significant effects of age in passive membrane properties (i.e. input resistance). However, with aging, we found a statistically significant increase in post-depolarization tail currents following a 200 ms depolarization step to -30 mV. Thus, these high voltage activated, dihydropyridine-sensitive aftercurrents appear to be enhanced in aged brain neurons, which likely accounts for the effect of aging on the AHPs under more physiological conditions. Further, larger tail currents could substantially increase overall Ca²⁺ influx into aged neurons, and contribute to Ca²⁺-mediated cytotoxicity. (Supported by AG10836, AG04542 and Miles, Inc.).

717.7

FOOD RESTRICTION-INDUCED HYPERADRENOCORTICISM IS ASSOCIATED WITH REDUCED PLASMA AND ADENOHYPOPHYSEAL ACTH AND UNCHANGED ADENOHYPOPHYSEAL POMC RNA. E.S. Han¹, N. Levin², N. Bengani², J. Roberts², Y. Suh¹, K. Karelus¹, and J.F. Nelson^{*1}. ¹Dept. of Physiology, U. of Texas Health Science Center, San Antonio, TX 78284-7756., ²Mt. Sinai Medical Center, NY, NY.

Chronic food restriction (FR), which retards many aging processes and extends life span, potentiates the diurnal elevation of plasma corticosterone (B) in rats (J Gerontol 46:B171-9, 1991). Neither the physiological significance nor the cause of increased B in FR rats is known. We therefore investigated whether FR alters plasma levels of ACTH or anterior pituitary (AP) content of ACTH, POMC mRNA or its precursors, since these molecules both regulate and can be suppressed by B. Measurements were made in 6-7 mo.-old male Fischer 344 rats that had been fed ad libitum (AL) or FR (60% of AL calories) since 6 wk of age. Tissue and plasma were collected at 0500h and 1500h (12h:12h L:D; L on at 0530h). POMC mRNA in total RNA and POMC primary transcript, processing intermediate and mature mRNA in nuclear RNA were measured by slot blot and RNase protection assays. ACTH in plasma and in AP homogenates were measured by RIA. AP content of POMC mRNA from total RNA, and AP contents of POMC primary transcript, processing intermediate, and mature mRNA from nuclear RNA did not differ in FR and AL rats. By contrast, AP ACTH content was 52% lower and plasma ACTH was 21% lower in FR than in AL rats (P<0.01). Reduced ACTH in plasma and AP of FR rats is consistent with enhanced negative feedback by the elevated B of the FR state. The absence of increased plasma ACTH in the FR rats indicates that factors other than increased immunoreactive ACTH underlie the FR-induced elevation of plasma B (e.g., altered ACTH bioactivity, adrenal sensitivity to ACTH or B metabolism). The absence of suppressed AP POMC mRNA and its precursors indicates that altered translational efficiency, post-translational processing or turnover of ACTH underlies the reduced AP ACTH content of the FR rat.

717.9

AXON DEMYELINATION AND STAINING PATTERN FOR NEUROPEPTIDES IN THE AGED RAT SPINAL CORD
B. Ulfhake (1)*, T. Hökfelt (2), H. Johnson (1), S. Kullberg (1) and X. Zhang (2), Departments of (1)Anatomy, and (2)Histology and Neurobiology, Karolinska Institutet, S-104 01 Stockholm, Sweden.

With increasing age gait and postural mechanisms become impaired. In part this may be due to demyelination and/or dystrophy of axons in afferent pathways to the motor system. In this report we present data on the occurrence of demyelination in the spinal cord white matter and the staining pattern in the dorsal horn for calcitonin gene-related peptide (CGRP), galanin (GAL), galanin message associated peptide (GMAP), neuropeptide Y (NPY), somatostatin (SOM) and substance P (SP) in the 30 months old Sprague Dawley rat.

Demyelination was studied by quantifying myelin bodies (MB) in Marchi stained sections of the spinal cord. Immunohistochemistry was used to study the distribution of neuropeptides in the dorsal horn.

Numerous MBs were encountered in all parts of the white matter. However, large local variations in the density of MBs were evident. For example, the medial dorsal column pathway disclosed a very much higher density of MBs, and there was also a clear rostro-caudal gradient with a higher density at cervical spinal cord levels compared to lumbar levels for this pathway. Thus, it seems that not only are different projecting pathways affected differently but also that the distal regions of the long projecting axons are more extensively engaged compared to the more proximal parts.

The staining pattern in the dorsal horn for CGRP, GAL, GMAP, SOM and SP was rather similar for aged and young adult rats, while NPY-LI seems to have increased in the aged rat.

717.6

INTRACORTICAL DISTRIBUTION OF SEROTONERGIC AND CATECHOLAMINERGIC TERMINALS IN THE AGED RATS. K. Iwata^{*1,2}, K. Kitajima², Y. Tsuboi¹, J. Yagi¹, K. Kanda³, N. Okado⁴ and R. Sumino^{1,2}. Depts. Physiol. and Pathophysiol², Sch. Dent., Nihon Univ., Tokyo 101, Dept. Central nervous system³, Tokyo Metropolitan Institute of Gerontology, Tokyo 173, Dept. Anat., Inst. Basic Med. Sci., Univ. Tsukuba⁴, Ibaraki 305.

Serotonergic and noradrenergic terminal distributions in the cerebral cortex of the aged (28-31 months) and young (3-9 months) rats were studied with immunohistochemical techniques. The animals were anesthetized with sodium pentobarbital (50 mg/kg, i.p.) and perfused with 4% paraformaldehyde in PB. Frontal serial sections were cut from the frontal (Fr), somatosensory (So), occipital (Oc) and visual (Vi) cortices and processed with ABC immunohistochemistry that employed polyclonal antisera to serotonin (rabbit anti 5-HT) and dopamine β-hydroxylase (rabbit anti DBH). A total of 25,408 5-HT LI and 30,088 DBH LI terminals in the cerebral cortex were drawn and counted. Distribution of 5-HT like immunoreactive (5-HT LI) and DBH like immunoreactive (DBH LI) terminals was dense in superficial (I-II) and sparse in deeper (III, IV, V and VI) laminae of both young and aged animals. The number of 5-HT LI fibers and terminals was decreased in the superficial laminae of Fr, So and Oc cortices, which was less extent in Vi cortex of the aged rats. In the deeper laminae alteration of density of 5-HT LI fibers and terminals was not found. On the other hand, DBH LI fibers and terminals were slightly decreased in the superficial laminae of Fr, So and Oc cortices, but not in the deeper laminae. However, the number of them in Vi cortex was decreased in both superficial and deep laminae of the aged rats. These findings suggest that serotonergic fibers and terminals in the superficial laminae (Fr, Oc and So cortices) and those of noradrenergic ones (Vi cortex) would be mainly involved in degeneration process of the cerebral cortex.

717.8

AGE-DEPENDENT REGULATION OF PHOSPHOINOSITIDE TRANSDUCTION SYSTEM IN THE RAT SPINAL CORD. Q.J. Lowe^{*}, Division of Pharmacology, Schools of Pharmacy & Medicine, UM-KC, Kansas City, MO 64108

Many processes associated with intracellular calcium homeostasis have been reported to change with the aging process. To determine whether the intracellular calcium-mobilizing second messenger, inositol 1,4,5-trisphosphate [Ins(1,4,5)P₃] and its receptor [Ins(1,4,5)P₃R] displays age-dependent regulation, Ins(1,4,5)P₃ contents and [³H]Ins(1,4,5)P₃ binding site density were quantified in the spinal cords of young (3 months old), adult (12 months old) and senescent (25-months old) male Fischer 344 rats. Spinal cord contents of Ins(1,4,5)P₃ were significantly increased (p ≤ 0.01) in the 25-month old rats compared to the 3- and 12-month old animals. The density of Ins(1,4,5)P₃R in particulate membranes derived from the 25-month old rats was significantly reduced (p ≤ 0.01) but with a significant increase (p ≤ 0.04) in binding affinity, compared with the 3- and 12-month old animals. No significant differences were observed in spinal cord Ins(1,4,5)P₃ accumulation and Ins(1,4,5)P₃R density in young and adult rats. A significant change in Ins(1,4,5)P₃R affinity suggests an age-dependent modification of Ins(1,4,5)P₃R protein in spinal cord neurons. The present data indicate that the spinal cord contents of Ins(1,4,5)P₃ increase with age, but with decreased efficacy and number of Ins(1,4,5)P₃-activatable Ca²⁺ channels in the spinal cord of senescent rats. These age-related changes may contribute to the attenuated responsiveness of spinal cord neurons by phosphoinositide-coupled receptors during the aging process. Supported by SEP-Marion Merrell Dow Foundation and USPHS grant AR 41606.

717.10

MOTONEURONS IN THE LUMBAR SPINAL CORD OF THE AGED RAT CONTAIN INCREASED LEVELS OF CGRP-LIKE IMMUNOREACTIVITY AND mRNAs FOR α-CGRP AND GAP-43.

H. Johnson (1)*, T. Hökfelt (2) and B. Ulfhake (1). Departments of (1)Anatomy and (2)Histology and Neurobiology, Karolinska Institutet, S-104 01 Stockholm, Sweden.

With immunohistochemistry and *in situ* hybridisation the content of CGRP-LI and mRNAs for the α-subtype of calcitonin gene-related peptide (CGRP) and the 43 kD growth associated protein (GAP-43) was studied in lumbar motoneurons (MNs) of 30 months old Sprague Dawley rats and compared with young adult rats. To quantify CGRP-LI we used photometry of 'optical' tissue-sections images recorded with a confocal microscope after removal of autofluorescence contribution. Quantification of the mRNA messages was accomplished by optical density (OD) readings of silver-grains over cell body profiles.

CGRP: Compared to young adult rats a significantly smaller number of neurons in the lateral motor nucleus stained positively for CGRP in the aged rat, while the number of positive neurons in the medial motor nucleus was similar in the two age groups. The content of CGRP-LI in positive aged rat MNs was, however, significantly higher (p<0.001). The OD of α-CGRP mRNA in aged rat MNs exceeded the level in young adult rat by about 100% (p<0.001).

GAP-43 mRNA: The OD readings for GAP-43 mRNA was 3 times higher in aged rat MNs compared to young adult MNs (p<0.001).

The possible mechanism(s) underlying these changes is discussed in relation to age-related changes in the muscles and afferent input to the MNs.

ALTERATIONS IN TARGET INNERVATION & COLLATERAL SPROUTING IN THE AGING SYMPATHETIC NERVOUS SYSTEM.

George A. Kuchel* Mt. Sinai, New York and Montreal General Hospital Research Institute, 1650 Cedar, Montreal, Quebec, Canada H3G 1A4

The ability to sustain appropriate target innervation and to undergo collateral sprouting following losses of related neural inputs may favor the maintenance of normal function. Tyrosine hydroxylase immunohistochemistry (TH IHC) was used in the rat pineal gland for quantitative morphological measurements of changes in sympathetic fiber innervation density and in homotypic collateral neuronal sprouting with aging. Rhodamine-coupled IHC was specific for sympathetic fibers, with the fluorescent image captured by a SIT camera and analyzed with an image analysis system. This target tissue receives bilateral and overlapping sympathetic innervation from the two superior cervical ganglia. Young (4 m. old) rats underwent a unilateral sympathetic denervation of the pineal gland and 1 day later exhibited an approximately 50% decrease in the area fraction represented by TH immunoreactive profiles in this target tissue ($p < .05$). Ten days after this lesion, the density of TH immunoreactivity increased to over 80% of control values ($p < .05$). In aged (25 m. old) animals, endogenous fluorescence produced by the presence of lipofuscin was subtracted from the captured image, revealing a more than 50% decrease in innervation density to this target tissue in aging. The density of TH immunoreactive profiles decreased by approximately one half in aged animals lesioned 1 day earlier ($p < .05$). However, 10 days after a unilateral denervation it was still approximately one-half of that obtained in control aged rats ($p < .05$), providing morphologic support for a failure in collateral sprouting in this system in aging.

AGE-DEPENDENT CHANGES IN GLUTAMATE AND ASPARTATE CONCENTRATIONS IN THE NON-HUMAN PRIMATE AND RODENT BRAIN.

P. Chan*, D.A. Di Monte, M.S. Sandy, L.E. DeLanney, I. Irwin and J.W. Langston, California Parkinson's Foundation, San Jose, CA 95128.

Excitatory amino acids have been proposed to play an important role in age-related neurodegenerative disorders. In this study, the concentrations of the excitatory amino acids glutamate and aspartate were determined in the frontal cortex, ventral mesencephalon, striatum, hippocampus and cerebellar cortex of 2 month old ($n=10$), 18 month old ($n=10$), and 29 month old ($n=6$) C57BL/6 mice, and in the substantia nigra, caudate, putamen, globus pallidus, accumbens and hippocampus of young ($n=6$, age=3 years old), mature ($n=6$, age=9 years old) and old ($n=6$, age >16 years old) squirrel monkeys. Glutamate was significantly decreased in 18 month old mice as compared to 2 month old mice in all areas except frontal cortex. In 29 month old mice, further decreases were observed in the ventral mesencephalon and striatum, but not in the cerebellar cortex or hippocampus. Aspartate was significantly decreased in the frontal cortex, ventral mesencephalon, striatum, and hippocampus of 18 month old vs 2 month old mice; in the oldest mouse group, a further decrease was found in the ventral mesencephalon, striatum, and hippocampus. In addition, a decrease in aspartate concentrations occurred in the cerebellar cortex in 29 month old vs 18 month old mice. In mature vs young monkeys, a significant decrease in glutamate was found in the putamen and accumbens, but no further loss was measured in the oldest animals. Aspartate levels declined with age in the substantia nigra, putamen and accumbens, reaching statistical significance in old vs young monkeys. These data indicate that decreases in excitatory amino acids occur in the ageing brain, possibly as a consequence of changes in metabolism and/or biodisposition. These changes may ultimately affect excitotoxicity.

AGE-RELATED ALTERED CALCIUM REGULATION IN SYNAPTOSOMES AND ACUTELY DISSOCIATED BRAIN CELLS: PROMINENT EFFECTS IN HIPPOCAMPUS. J. Satrustegui, A. Martínez-Serrano, J. Chowen, R. Pereira and M. Villalba. Dept. Biología Molecular. Centro de Biología Molecular. C.S.I.C.-Universidad Autónoma de Madrid. 28049-Madrid. SPAIN.

An altered regulation of neuronal cytosolic calcium levels has been suggested to play a role in the pathogenesis of neurodegeneration and Alzheimer's disease. However, evidence for an age-dependent alteration in cytosolic calcium regulation is at present controversial. Whereas we have observed a varying but consistent age dependent increase in $[Ca^{2+}]_i$ in whole rat brain synaptosomes using a variety of detectors (Martínez et al. (1988) *Neurosci. Lett.* 26, 1089-1092; Martínez-Serrano et al. (1992) *J. Biol. Chem.* 267: 4672-4679), other groups failed to confirm this using cerebrocortical preparations (Canzoniero, et al. (1992) *Biochem. Biophys. Acta.* 1107, 175-178. Farrar, et al. (1989) *Neurosci. Lett.* 100, 319-325; Giovannelli & Pepeu (1988) *J. Neurochem.* 53, 392-398). The present work was aimed at studying whether changes in synaptosomal calcium homeostasis are uniform throughout the brain or affect specific brain regions. A second question addressed in this work is whether the effect of ageing on calcium homeostasis is restricted to the nerve terminal or a more general process affecting also cell bodies. In order to study these questions, we have used synaptosomes and a preparation of acutely dissociated brain cells (Villalba et al. (1992) *Brain Res.* 570: 347-453) obtained from different brain regions of the adult rat to study in parallel the variations in calcium homeostasis in synaptosomes and dissociated neurons from 3- and 30-month old rats. The results indicate that mean resting $[Ca^{2+}]_i$ obtained at rest and after high K depolarization were unchanged in cerebral cortex synaptosomes but increased in hippocampal synaptosomes at 30 months of age. On the other hand, $[Ca^{2+}]_i$ levels increased with age in brain cells from both cerebral cortex and hippocampus. Since the altered regulation of $[Ca^{2+}]_i$ appears to affect predominantly cell bodies and synaptosomes derived from hippocampus, this can explain the discrepancies obtained earlier. An altered calcium regulation in cell bodies and synaptic terminals in the hippocampus may be involved in the development memory impairments in old age.

717.12

AGE-RELATED INCREASE IN AXONAL TORPEDOES IN CEREBELLAR PURKINJE CELLS OF TWO NORMAL MOUSE STRAINS. J. Bäurle and U. Grüsser-Cornehls*, (SPON: European Neuroscience Association), Dept. Physiology, Freie Universität Berlin, Arnimallee 22, 1000 Berlin 33, Germany.

Spindle-shaped axonal varicosities, also termed spheroids or torpedoes, are described to appear in relatively small numbers in various regions of the brain in the course of numerous neuropathological diseases but are not forcibly related to these. Torpedoes in larger amounts particularly in cerebellar Purkinje cell axons are found during the postnatal development of rats and in different cerebellar-affected mutants (*hpc, lc, nd, nr, tg^{1a}*), all of them showing massive Purkinje cell degeneration. In addition neurotoxic agents or neoplasms can also lead to axonal torpedoes. Therefore these swellings are considered to represent a relatively unspecific sign of axonal degeneration, namely 'dying-back-neuropathies' and in myelin deficiencies.

The present study systematically investigated the occurrence of torpedoes in two different mouse strains (B6CBA and C57BL/6J) during aging (up to 32 months) using Calbindin D-28k immunocytochemistry. The results show that the number of torpedoes in Purkinje cell axons increases almost linearly from a basic level of about 0.1% in 2-4-month-old mice up to 13.7% in 32-month-old animals. It is therefore suggested that torpedoes in the cerebellum of these mouse strains are age-related. While axons and terminals of affected cells undergo degeneration, the somata and dendrites are in most instances preserved and exhibit normal morphology. As a consequence, a graded degeneration of cerebellar and vestibular nuclei with age is hypothesized. Therefore even in the absence of age-related Purkinje cell degeneration, which is still a controversial point, a normal number of Purkinje cells does not guarantee for a quantitatively normal cerebello-nuclear projection.

REDUCED ADRENOCORTICOID RESPONSE TO CORTICOTROPIN SECRETAGOGUES IN THE AGED RAT. G. Cigliana, S. Scaccianoce, R. Nicolai, L.A.A. Muscolo and L. Angelucci*, Institute of Pharmacology II, "La Sapienza" Univ., 00185 Rome, Italy.

The aging process, as well as some pathological conditions (depression, dementia, Alzheimer's disease, etc.), has been shown to have a profound impact on the normal functioning of the hippocampus-hypothalamo-pituitary-adrenocortical axis system. Aged rats have been reported to have increased basal levels of circulating corticosterone (B), an impaired ability to recover from their hypothalamo-pituitary-adrenocortical stress response, an augmented plasma B response to stress (although with some stress and strain dependency) and a reduced susceptibility to dexamethasone suppression test. These alterations might arise from a reduced hippocampal negative feedback control, as suggested by the age-dependent loss of hippocampal adrenocorticoid receptors. Among the hypothalamic factors endowed with corticotropin secretagogue activity, CRF and vasopressin (AVP) are considered as the major physiological mediators of hypothalamic control of ACTH secretion. Thus, we have investigated the effect produced by the aging process on the dynamics of the response to CRF and AVP, and on the adrenocortical response to a cold stress (4 °C for 90 min). Freely-moving jugular catheterized male Sprague-Dawley rats (3- and 24-month-old) have been injected with CRF (0.01, 0.05 and 0.5 µg/kg iv), or AVP (0.05, 0.1 and 1.0 µg/kg iv) or CRF and AVP (0.05 and 0.1 µg/kg iv, respectively). Blood samples for hormones determinations (B and ACTH) have been collected 60 min before and 15, 30 and 90 min after injection. The results have: a) confirmed the increased basal levels of B in aged rats; b) indicated that with aging the response to corticotropin secretagogues is dampened but prolonged; and c) shown that the cold stress response of the 24-month-old rat was, at least with regard to the peak, not different from that of 3-month-old. (Supported by CNR grant 91.004.32.40).

MORPHOLOGICAL CHANGES AT NEUROMUSCULAR JUNCTION INDUCED BY EXERCISE DURING AGING. M.A. Fahim*, and A.S.A. Mohamed. Fac. of Med., UAE Univ., PO Box 17666, United Arab Emirates.

To evaluate exercise effect on morphological age changes, we studied the relationship between endplate parameters and muscle fiber diameter.

Male C57BL/6j mice aged 12, 18 and 24 months at sacrifice, were treadmill-exercised for 2 months for 1 h/day at velocities up to 30 m/min. The area (A) perimeter (P), nerve longitudinal extent length (E) and fiber diameter (FD) of camera lucida drawings of zinc iodide osmium-stained nerve terminals were analyzed. Non-linear regression and multivariate analysis were used to study the inter-relationships among the mentioned parameters under aging and exercise conditions.

Mathematically, any non-linear relationship can be represented successfully by polynomial representation. Application of such generalized method of analysis showed encouraging results which cannot be seen by using linear regression analysis.

At 12 months E was strongly correlated with FD, then deteriorated during aging, and exercise did not affect it. At all ages A was not correlated with FD. Exercise increased such correlation, especially at 18 months. Including the linear multivariate analysis among FD and endplate parameters shows only the influence of exercise, especially at age 18 months ($p < 0.008$). Ratio of E/FD was strongly correlated with endplate parameters, especially at age 12 months and improved with exercise ($r^2=0.721$).

The success of finding a relationship between endplate and FD with high correlation represents the ability to track the possible changes of these parameters or, to predict their new states. Estimating these relationships with low correlation implies either the stochastic variations of these parameters or non-linear multivariate analysis should be considered.

718.1

GENOMIC STRUCTURE OF DARPP-32 AND ARPP-21, MARKERS OF A DIFFERENTIATED STRIATAL PHENOTYPE. M.E. Ehrlich¹, S. Blau¹, L. Daly¹, N. Kane¹, A. Fienberg², and G. Teitelman³, New York University Medical Center¹, The Rockefeller University², and SUNY Health Sci. Ctr., Brooklyn³.

DARPP-32 and ARPP-21 are dopamine- and cyclic-AMP regulated phosphoproteins which are highly enriched in the dopaminergic medium-size spiny neurons of the striatum, thus defining a specific phenotype. Both genes are first transcribed post-migration, and the mRNA levels are not altered by surgical or pharmacologic manipulations of the dopaminergic pathway. This coordinated expression implies the existence of common transcriptional regulatory elements. The structures of the murine DARPP-32 and ARPP-21 genes have been determined. Transcription is initiated at multiples sites in each gene, and there are no TATA or CAAT boxes. Both genes contain multiple introns, but alternatively spliced products have not been identified. Constructs containing the presumptive promoters direct expression of the transgene to the striatum and other areas of endogenous gene expression in DARPP-32 and ARPP-21-*lacZ* mice.

718.3

SEPARATING GENES INDUCING NEUROPATHY AND SEIZURES IN TREMBLER MICE. M.E. Shy, G. Smith, L.D. Siracusa, S.S. Scherer, G. Alexander, A. Buchberg, Thomas Jefferson Univ. Phila, PA. Trembler¹ (*Tr*¹) is an autosomal semi-dominant mutation resulting in mice which have seizures and a severe demyelinating peripheral neuropathy. The neuropathy is associated with a point mutation in exon 1 of the Schwann cell myelin gene *Pmp-22*. *Pmp-22* mRNA is also expressed at lower levels by unidentified cells in the CNS. The relationship between *Pmp-22* expression and seizures is unknown. We have observed frequent clinical seizures in offspring from *Tr*¹ mice crossed with *Mus spratus* mice and few seizures in *Tr*¹ mice on a pure C57BL/6J background. To begin to identify genes inducing seizures, C57BL/6J-*Tr*¹ mice were crossed with C57BL/6J +/+ or *M. spratus* +/+ mice. The F1 mice were examined for seizures and for neuropathy. *Tr*¹ animals were identified by PCR with genomic DNA. *M. spratus Tr*¹ mice had morphological evidence of neuropathy and significant seizure activity detectable by EEG. C57BL/6J-*Tr*¹ animals had neuropathy but no EEG abnormalities. Therefore, gene(s) in *M. spratus* interact with -22 or a closely linked gene, inducing or exacerbating epileptic activity. Backcrossing the F1 mice to C57BL/6J will permit identification of the gene(s) responsible for the seizures.

PCR-BASED DIFFERENTIAL SCREENING TO IDENTIFY REGIONAL BRAIN SPECIFIC cDNAs. A. Dopazo, M.G. Erlender* and J.G. Sutcliffe. Dept. Molecular Biology, The Scripps Research Institute, La Jolla, CA 92037.

We are systematically surveying the expression pattern of rat mRNAs in a side-by-side comparison of cDNAs from different tissues, brain regions and physiological/behavioral paradigms using a method in which subsets of mRNAs are amplified via the polymerase chain reaction (PCR) using selected primers and picogram quantities of cDNA. For each pair of primers, 50-100 different bands ranging from 100-500 nucleotides are observed on sequencing gels and the band pattern is reproducible in duplicate runs of the same tissue and is completely changed when either primer is changed. For a given primer pair, 50-60% of the bands corresponding to amplified cDNAs derived from the brain are not detected in the liver cDNA samples. A lower percentage (1-3%) of the bands (cDNAs) differ among the cDNAs of different brain regions. Initial experiments demonstrated that known mRNAs of low to moderate prevalence give rise to bands with the expected tissue distribution using the appropriate primer pairs. So far, surveying rat hypothalamus, cortex, cerebellum and liver cDNAs has yielded the nucleotide sequences of thirty brain specific cDNAs whose heterogeneous anatomical expression pattern within the brain confirm the distribution indicated by the initial PCR surveying. By using a systematic set of primers, it should be possible to survey the expression of 10-20,000 mRNAs for a given paradigm, isolate cDNAs for those with interesting distributions and determine nucleotide sequences.

WARNING! MOLECULAR INFORMATION FROM TETRAPLOID ANIMALS MUST BE EVALUATED WITH CAUTION. Carl Risinger* and Dan Larhammar. Dept of Medical Genetics, Box 589, Uppsala University, S-751 23 Uppsala, Sweden.

Gene duplication followed by mutations is a common mode of gene evolution and has probably given rise to the many gene families in higher animals. An extreme type of gene duplication is genome doubling, i.e. tetraploidization. The tetraploid animals *Xenopus laevis*, goldfish, carp, trout and salmon are extensively used in scientific research and have recently been subjected to molecular cloning studies. Although the tetraploid condition has been known for decades, it is rarely acknowledged by molecular biologists. We have studied SNAP-25 in goldfish, *Carrasius auratus*. SNAP-25 (synaptosome-associated protein of 25 kDa) is a neuron-specific protein recently shown to be involved in synaptic vesicle docking or fusion.

Isolation and sequencing of six clones from a goldfish retina cDNA library revealed that all six clones are distinct at the nucleotide level. They correspond to two loci, SNAP-A and SNAP-B, that arose by gene duplication early in bony fish evolution prior to tetraploidization. The three SNAP-A clones have identical amino acids and are alleles of the same locus. The SNAP-B clones correspond to two loci and their divergence agrees with tetraploidization approximately 20 million years ago. This also agrees with studies of several sequences from the closely related carp, *Cyprinus carpio*, which suggest that tetraploidy arose 15-20 million years ago (Larhammar and Risinger, submitted). Surprisingly, several of the SNAP-25 clones have frameshift mutations. Furthermore, studies of amino acid sequences for goldfish SNAP-25 and carp somatotropin show that replacements seem to accumulate predominantly in one of the duplicated loci.

These findings emphasize the importance of sequencing multiple clones from tetraploid animals in order to make sure that functionally relevant loci are being studied.

DISTRIBUTION OF NEURONAL AND GLIAL mRNAs WITHIN NEURAL CELL BODIES AND PROCESSES. C.F. Landry*, J.B. Watson, V.W. Handley and A.T. Campagnoni, MRRC, UCLA School of Medicine, Los Angeles, California, 90024.

We have found that neuronal and glial mRNAs can be classified based on their selective distribution within neural cell bodies and processes. Using *in situ* hybridization with digoxigenin-labeled cRNA probes, we identified four types of neural mRNA distributions. These included: 1) mRNA species that were confined to the cell soma, i.e. mRNAs encoding the glial proteins, proteolipid protein and 2'3'-cyclic nucleotide-3'-phosphodiesterase and the neuronal enzymes, neuron-specific enolase and glutamate decarboxylase; 2) mRNA species that were found primarily in perinuclear cytoplasm but that were also observed in cell processes, i.e. those encoding the protein kinase C substrates, RC3 and GAP-43, which were identified either in the proximal (GAP-43) or proximal and distal (RC3) dendritic processes of neurons; 3) mRNA species that were abundant within the cell soma but that were also found throughout cellular processes, i.e. myelin basic protein mRNA, which was localized to the cell soma and myelin sheaths of oligodendrocytes; 4) mRNA species that were localized primarily to cell processes, i.e. MAP2 mRNA, which deeply stained dendritic fields but only lightly stained neuronal cell bodies. The distribution patterns of these mRNAs are likely to reflect the mechanisms by which the protein products of these molecules are targeted within neurons and glia. (Supported by NS23022, NS23322, HD25831 and RG223A1 from the NMSS.)

METHODS FOR ENHANCING TRANSGENE EXPRESSION IN PRIMARY RAT FIBROBLASTS. N.H. Liou, L.J. Fisher*, J. Ray, S.T. Suhr, S. Thode and E.H. Gage. Department of Neurosciences, UCSD, La Jolla, CA 92093-0627.

The Moloney murine leukemia retrovirus (MLV) is an effective vehicle for delivering transgenes to a variety of cell types. However, there is evidence that the MLV-long terminal repeat (MLV-LTR) promoter/enhancer may not sustain transgene expression after infected cells are implanted into a host animal. We are exploring several strategies for increasing transgene activity within engineered cells after grafting, including (1) developing alternate promoter/enhancer configurations for maintaining gene expression and (2) directly manipulating LTR activity. For the former approach, we have constructed vectors that express transgenes from either DNA viral (Cytomegalovirus (CMV) immediate-early promoter and the SV40 promoter) or non-viral (collagen and dihydrofolate reductase) promoters. In some constructs, cell-specific enhancers have also been inserted upstream of the promoters to potentially increase gene expression. Finally, vectors have been constructed with a variety of transgenes (sizes ranging from 0.5 kb to 3.1 kb) to assess differences in gene expression that may be linked to the transgenes. Results to date indicate that the CMV promoter sustains transgene activity within engineered fibroblasts for at least 6 months post-confluence *in vitro*. These results are consistent with work on muscle cells that suggests the CMV promoter is active for up to 6 months after intracerebral grafting. While the housekeeping promoters do not appear to be as strong as the viral promoters, they may be more effective in achieving long-term expression of the transgenes. Cells containing the various constructs are currently being characterized both *in vitro* and *in vivo*. In addition to developing new expression vectors, we have also explored the potential for regulating LTR activity directly through endogenous glucocorticoid response elements (GRE). *In vitro*, application of dexamethasone to fibroblasts that express a transgene from the LTR promoter has been found to induce a marked increase in transgene mRNA levels, protein levels and protein activity. This latter approach may offer a direct method for regulating transgene activity within engineered cells after grafting. Work supported by NIH AG10435.

INTRACELLULAR MICROINJECTION OF DNA INTO HIPPOCAMPAL PYRAMIDAL CELLS. K.E. Müller, D.J. Wigston*, K.A. Shirley and H. Joshi. Program in Neuroscience, Dept. of Physiology, and Dept. of Anatomy & Cell Biology, Emory University School of Medicine, Atlanta, GA 30322.

Hippocampal pyramidal cells are widely used to study long term potentiation and the development of neuronal morphology. However, molecular dissection of these phenomena is limited owing to the lack of procedures to introduce exogenous gene constructs into the cells. Conventional methods of DNA-mediated transfection in dividing cells, such as calcium phosphate/DNA precipitation and electroporation have not been successful because of toxicity or damage to cells, and the use of retroviral vectors is not possible in non-mitotic cells such as neurons. Because of these difficulties we examined the possibility of direct microinjection of plasmids into cultured neurons. We cultured hippocampal pyramidal neurons from embryonic day 17 mice at low density along with astrocytes plated on separate coverslips using the method of Banker and Goslin (In: Culturing Nerve Cells, Banker and Goslin Eds.; MIT Press). Four days after plating, neurons were microinjected with plasmids encoding for β -galactosidase driven by the Rous sarcoma virus (RSV) promoter, and allowed to incubate for 18 hours. Expression of the *lac Z* gene was then detected with 5-bromo-4-chloro-3-indolyl- β -D-galactoside (X-Gal), yielding a blue precipitate. In our first set of experiments in which we injected 183 cells, we found 5 cells that expressed exogenous β -galactosidase. However, since many of the injected cells died, an estimate of the success rate based on these numbers would be overly conservative. Intracellular microinjection of DNA constructs might therefore be a useful technique for dissecting the function of proteins specific to the nervous system, and it offers the advantages of single cell specificity and extremely high level, long term, production of RNAs and proteins.

DEFECTIVE HERPES SIMPLEX VIRUS VECTORS FOR THE STUDY OF PROMOTER AND GENE FUNCTION IN THE NERVOUS SYSTEM. K.C. New*¹, R.L. Martuza², K. Gale³ and S.D. Rabkin^{1,2}. Dept. of Microbiology¹, Neurosurgery² and Pharmacology³, Georgetown University Medical Center, Washington, D.C. 20007

Defective herpes simplex virus (HSV) vectors have previously been used by us and others to express foreign marker genes such as β -galactosidase in differentiated neurons both *in vitro* and *in vivo* (Mol. Cell. Neurosci. 2:320-330, 1991). This work was hindered by limited efficiency of expression for variable lengths of time. We have focused on improving the generation of defective HSV vectors and achieving greater efficiency of expression. Defective HSV genomes containing two transcription units, with two marker enzymes, β -galactosidase and human placental alkaline phosphatase, are being used to study promoter function in neuronal cell cultures and in the CNS *in vivo*. Multiple transcription units offer an easy method of comparing expression from different promoters. We have demonstrated that defective HSV vectors containing multiple transcription units lead to co-expression of both products in individual cells, although many cells express only one detectable marker. Once promoter activity is characterized by this system, the promoter may be used to drive expression of physiologically significant genes so that direct determinations may be made on their function in the CNS. Many animal models of CNS disorders, such as epilepsy, are amenable to manipulation by appropriately expressed genes. The large size available for DNA insertion is a major advantage of the defective HSV vector system over other viral vectors.

718.11

INSTANT NESTED / SECOND PCR or DIRECT GEL PCR. C. Waibel and H.M. Valjiyullah. *Biology Dept., Georgetown University, Washington D.C. 20057-1028.

Polymerase Chain Reaction (PCR) has become an important and indispensable method in neurobiology. A common problem that a research or a diagnostic laboratory encounters in a PCR reaction is unexpected PCR products. Unexpected amplified products are often observed in a PCR, especially when optimizing the conditions of the PCR to a particular set of primers and template. To verify the authenticity of the amplified product an investigator uses several methods. Sequencing the amplified product is an ideal but costly way to confirm if the amplified sequence is authentic. Often a pair of primers (nested primers) that are specific for the amplified fragment of DNA, is used to do a second or nested PCR. This is a quick way to confirm the authenticity of a PCR product from the first reaction. It is not very likely the primers in the first and second PCR will hybridize falsely to give the expected fragment length in both cases. In this study we describe a quick and easy method to perform the second or nested PCR after the first PCR. In this 'direct gel method' the gel was cut out and placed into the second PCR directly. TAE buffer over TBE buffer is preferred for electrophoresis and LMP, HGT, GTG and NuSieve 3:1 agaroses are preferred in this order mentioned. Rinsed gel pieces gave a little better results than non-rinsed gel pieces. Using this method, it is not necessary to elute and/or precipitate DNA from the gel from the first PCR to do a second PCR.

GENERATION OF CHIMERIC PROMOTERS FOR EXPRESSING FOREIGN GENES FROM HERPES SIMPLEX VIRUS VECTORS X. Wu*¹, M. Cynader², and F. Tufaro¹. Departments of Microbiology and Immunology¹ and Ophthalmology², University of British Columbia, Vancouver, B.C. Canada

We are developing a whole genome Herpes simplex virus vector to express foreign genes from chimeric promoters. Herpes simplex virus exhibits two modes of gene expression in its natural human host: the lytic phase and the latent phase. During the latent phase, viral gene expression is largely repressed, and there is abundant expression in neurons of a single transcription unit, the latency associated transcript (LAT). To test whether the LAT promoter can be regulated by other cis-acting elements, we have generated chimeric promoter constructs to test the interactions of several regulatory elements: the CMV major I/E enhancer, and the SCG10 neuronal silencer element (NRSE).

In transient assays in Vero cells, the NRSE down regulated the LAT promoter by 10% with one NRSE, and by 30% with two elements compared to control constructs. However, the CMV enhancer stimulated LAT promoter activity by at least two fold regardless of the presence of a single NRSE element. Surprisingly, when head-to-tail dimers of the silencer element was placed upstream from the CMV enhancer-LAT promoter elements, there was a ten-fold increase in transcription, indicating that we have uncovered a previously unidentified stimulatory activity of neuron specific silencer elements. It may be that the neuronal silencer dimer and CMV enhancer will be useful for upregulating a normally weak LAT promoter, thereby allowing for high expression in neurons infected with recombinant herpes vectors.

EXPRESSION OF E. COLI β -GALACTOSIDASE IN LOW-DENSITY CULTURES OF HIPPOCAMPAL NEURONS. S. Kaech, J.A. Drazba* and E. Ralston. Lab. of Neurobiology, NINDS, NIH, Bethesda MD 20892.

To study the establishment of axonal-dendritic polarity in low-density cultures of rat hippocampal neurons, a simple technique allowing expression of any foreign gene would be advantageous. We have assessed the feasibility of standard DNA transfection techniques, using the E. Coli enzyme β -galactosidase (β -gal) as a marker. We could not observe expression of β -gal after calcium precipitation or electroporation but we obtained 40-200 transfected cells per 35mm dish with the commercial transfection reagents Transfectam® and DOTAP. Best results were obtained when transfection immediately followed the trituration step in the neuron isolation protocol. The transfection efficiency was similar whether expression of β -gal was driven by a globin promoter or by a neuron-specific enolase promoter. It was also similar when cytoplasmic β -gal was compared to β -gal targeted to the nucleus. We verified that the small fraction of cells transfected (<1%) was mostly neuronal, by double-staining for β -gal and for either neuron (MAP2)- or glia (GFAP)-specific markers. Transfected neurons expressing high levels of β -gal were polar and developed normally for at least 7 days. β -gal was present in all cell processes, including the entire length of the axon. Thus DNA transfection can be used to introduce foreign genes into post-mitotic polarizing neurons.

CONSTITUTIVE AND HYPERTHERMIA-INDUCIBLE HEAT SHOCK PROTEINS IN THE RABBIT BRAIN. P. Manzerra*, S.J. Rush and I.R. Brown. Dept of Zoology, Univ of Toronto, Scarborough Campus, West Hill, Ontario, Canada, M1C 1A4

Two dimensional western blotting facilitated the resolution of constitutively expressed hsc70 protein from stress-inducible forms. High levels of hsc70 were observed in the control rabbit brain. The inducible hsp70 protein showed peak levels in the nervous system 5 to 10 hours after hyperthermic treatment. Antibodies specific to inducible hsp70 were utilized for immunocytochemistry and detected the appearance of abundant levels of hsp70 in astrocytes and oligodendrocytes in hyperthermic animals. Antibodies which detect the constitutive hsc70 revealed high levels of this protein in neuronal cell populations. In Purkinje neurons for example, hsc70 was detected at abundant levels in both the neuronal cell bodies and in dendritic processes radiating into the molecular layer of the cerebellum. The pattern of hsc and hsp70 protein in the control and hyperthermic rabbit brain supports the distribution of constitutive and stress-inducible mRNA transcripts of the hsp70 multigene family which is observed using *in situ* hybridization and Northern blotting. However, to date we have not been able to detect the inducible hsp70 protein in Purkinje neurons which show a delayed induction of hsp70 mRNA compared to the rapid response seen in glial cells. The high hsc70 protein level in these neurons may dampen hsp70 levels.

718.13

EXPRESSION OF HEAT SHOCK GENES IN THE RABBIT NERVOUS SYSTEM. J.A. Foster*, S.J. Rush and I.R. Brown. Dept. of Zoology, Univ of Toronto, Scarborough Campus, West Hill, Ontario, Canada, M1C 1A4

To aid in the identification of the types of neural cells which demonstrate expression of constitutive (hsc) or hyperthermia-inducible (hsp) members of the hsp70 multigene family, neuronal and glial-specific riboprobes have been utilized. Neuron-specific enolase was employed as a neuronal marker while proteolipid protein was used for oligodendrocyte identification. In the control rabbit brain, hsc70 mRNA was observed at abundant levels in neurons of all cerebellar layers- basket and stellate neurons, Purkinje neurons and deep cerebellar neurons. A strong induction of hsp70 mRNA was noted in 1 hr hyperthermic animals in oligodendrocytes of deep white matter fibre tracts and of the molecular layer. In the brain stem, hsc70 mRNA was localized to neuronal-enriched regions including precerebellar nuclei and was not detected in glial-rich fibre tracts. After heat shock, a strong induction of hsp70 mRNA was noted in oligodendrocytes in the brain stem including afferent and efferent fibre tracts of the cerebellum. The high level of constitutive hsc70 expression in neuronal populations may exert a feedback mechanism which dampens hsp70 induction in these neurons after heat shock. The present investigations were carried out using both radioactive and non-radioactive *in situ* hybridization procedures.

CHOLINE (Ch) AND HEMICHOLINIUM-3 (HC-3) PROTECT AGAINST AF64A-INDUCED CHANGES IN N-MYC EXPRESSION IN THE HUMAN NEUROBLASTOMA CELL LINE (LA-N-2). L.R. Santiago¹, R.A. Kroes², L.C. Erickson^{1,2} and J. Hanin^{1*}. Depts. ¹Pharmacology and ²Medicine (Section Hematology/Oncology), Loyola University Chicago Stritch School of Medicine, Maywood, IL 60153, USA.

AF64A (ethylcholine aziridinium) reduces choline acetyltransferase (ChAT) activity and steady state expression of the N-myc gene in LA-N-2 (Santiago *et al.*, 1992). To assess the specificity of AF64A's action, we studied the effect of Ch and HC-3 on steady state expression of the N-myc gene in LA-N-2, following exposure to 0, 50, 100 and 250 μ M AF64A, using the S1 nuclease protection assay. HC-3: The highest dose of AF64A (250 μ M) at t=3h produced a maximal (53%) reduction in steady state levels of N-myc message compared to control. Reductions of only 42, 32 and 8% of N-myc message levels were observed at 250 μ M AF64A at 3h, in the presence of 10^5 , 10^4 and 10^3 M HC-3, respectively. Ch: In these experiments, 250 μ M AF64A produced a 63% decrease in N-myc message levels at 3h. Reductions of 52, 37 and 9% of N-myc mRNA levels were observed at this dose of AF64A, in the presence of 10^5 , 10^4 and 10^3 M Ch at the same time point, respectively. Thus, a reduction of N-myc message induced by AF64A was significantly attenuated by agents that utilize (Ch), or inhibit (HC-3), the high affinity Ch transport system (HAcHT). These data provide additional evidence for AF64A's cholinergic specificity, by nature of its dependence on the HAcHT system for accessibility to its target of neurotoxic action. We are currently examining the possibility that AF64A also causes changes in the steady state expression of the human ChAT gene, and that Ch and HC-3 can have a modulatory action on AF64A-induced changes in ChAT expression in LA-N-2. Supported by the Earl Bane Foundation Research Trust.

INDUCTION OF NUCLEAR FACTOR- κ B IN RAT BRAIN FOLLOWING SEIZURE ACTIVITY. A.V. Prasad, N. Mohan, B. Chadrasekar, W. H. Pilcher and S. A. Joseph*. Div. of Neurosurgery, Univ. of Rochester Med. Ctr., Rochester, NY 14642.

The DNA-binding protein NF- κ B is a pleiotropic transcription factor involved in the transcriptional regulation of several specific late-response genes. We have observed and demonstrated for the first time that NF- κ B expression was induced in tetrazole-treated rats. The transcription factor NF- κ B was assayed in brains from male Sprague-Dawley rats (230-250g) treated (s.c) with 1,5-pentamethylene tetrazole at a fixed dose of 85 mg/kg (LD₅₀). Clonic-tonic seizure activity was observed 15 min post drug administration, lasting for a few minutes. Whole brains obtained at various time intervals (1-120h) post seizure activity were homogenized, and nuclear extracts were prepared. Electromobility shift assays were carried out using the NF- κ B binding protein detection system (Promega, Madison, WI). The NF- κ B subunits p50 and p65 were assayed by the Western blotting method in the same samples using respective purified rabbit polyclonal antibodies. The results of the assay emphasize that the transcriptional regulation has a role in generalized seizure activity and could lead to transcription of specific late-response genes.

Constitutive levels of the immediate early gene zif268 mRNA in skeletal muscle cells are regulated by membrane depolarization and intracellular calcium. S.Abu-Shakra*, A.J.Cole,¹ R.N.Adams,² and D.B.Drachman². Depts. of Neurology, Wayne St. Univ.,¹ Detroit MI 48201, Massachusetts Gen. Hosp.,¹ Boston MA 02114, and Johns Hopkins Univ.,² Baltimore MD 21205.

Neural synaptic activity is known to regulate several properties of skeletal muscle cells, including acetylcholine receptor synthesis and distribution, ionic channels, contractile protein composition, and enzymatic profile. One of the earliest genomic responses to neural activity in skeletal muscle is immediate early gene (IEG) induction. We previously showed that the IEG zif268, which encodes a transcription factor, is rapidly and transiently expressed in skeletal muscle in response to neural stimulation (Abu-Shakra *et al.*, *Molec. Brain Res.*, in press). Basal levels of skeletal muscle zif268 mRNA *in vivo* are low, and therefore hard to study. In the C₂ skeletal muscle cell line, which forms fused branched myotubes resembling mature noninnervated muscle cells, zif268 mRNA levels are easily detectable. We have used northern analysis to study the regulation of constitutive zif268 expression in these cells. Treatment with tetrodotoxin (10 μ M), a Na⁺ channel blocker, for 6 hours decreased zif268 mRNA levels by 28% \pm 6% (n=5, p<0.05), while a 3 hour treatment failed to decrease the basal level (n=8). Treatment with PN200-110 (1 μ M), an L-type voltage sensitive calcium channel blocker, for 3 hours (n=7) and 6 hours (n=5), failed to decrease basal zif268 mRNA levels. Treatment with Ryanodine (30 μ M), which blocks Ca²⁺ efflux from sarcoplasmic reticulum stores, decreased zif268 levels by 18% \pm 5% (n=4, p<0.05) after only 3 hours. These findings suggest that membrane excitability and intracellular Ca²⁺ levels play a role in constitutive zif268 gene expression, while Ca²⁺ influx through the L-type Ca²⁺ channels is not needed to maintain these basal levels.

CHRONIC ELECTROCONVULSIVE SEIZURES (ECS) INDUCE A LONG-LASTING AP1 COMPLEX CONTAINING NOVEL FOS-RELATED PROTEINS. B.T. Hope*, M.B. Keiz, R.S. Duman, and E.J. Nestler. Laboratory of Molecular Psychiatry, Yale Univ. Sch. of Med., New Haven, CT 06508.

To better understand changes in gene expression induced by chronic ECS, we are studying ECS regulation of c-Fos and related proteins and their AP1 DNA binding activity. Acute ECS increases AP1 binding activity in cerebral cortex and hippocampus, which is associated with the induction of c-Fos and several related proteins. These changes return to control levels within 18 hours. In contrast, chronic ECS leads to increases in AP1 binding activity which remain at peak acute levels for 2 days following the last chronic ECS, and are 50% of peak acute levels at 7 days. Supershift experiments (using an antibody from M. Iadarola, NIH) show that this chronic AP1 binding activity is formed, in part, by Fos-related antigens (Fra's). Western blots with this antibody show that acute and chronic ECS induce largely different Fra's: chronic ECS is associated with negligible levels of c-Fos and most other Fra's induced acutely, but high levels of several bands, including a doublet of 37-39 kD, which are not induced significantly by acute ECS. These apparently novel Fra's may account for the chronic AP1 binding activity. The acute and chronic AP1 binding activities show different affinities for probes containing a variety of AP1-like DNA sequences, indicating possible functional differences between these complexes.

These results provide a mechanism by which certain genes that contain AP1 sites can be selectively regulated by chronic (vs acute) ECS. As we have obtained similar results in the striatum and nucleus accumbens following chronic vs acute cocaine treatment, induction of novel AP1 binding proteins may represent a general mechanism involved in the long-term regulation of brain function.

718.18

ENHANCEMENT OF HSP70-RELATED mRNA IN HIPPOCAMPUS OF ECS TREATED-RATS. F.Passarelli*, B. Angeletti, F.Orzi, D.Orrù and E.D'Ambrosio.*Dept. of Neurosci., University "La Sapienza", I³ Neuro, V.le dell'Università and Istituto Medicina Sperimentale, C.N.R., (Rome)Italy.

The expression of heat shock proteins is largely increased by several physical and chemical stressors. The aim of the study is to evaluate the effect of electroconvulsive shock on the expression of HSP70-related mRNA of rat brain. Rats weighing 250-300 g were divided into 3 groups: first group received ECS once a day for 7 days; a second group received a single ECS; a third group of unshocked rats served as control. The animals were then sacrificed at various time intervals from treatments and the brain processed for *in situ* hybridization. Two oligonucleotides synthesized according to published rat sequence specific respectively for constitutive hsc73 and inducible hsp70 were used as [³⁵S]dATP labelled probe. The corresponding sense oligos were also utilized as hybridization control. The results shows that the mRNA expression was strongly increased mainly in the hippocampal granule cell layer of the hilus of the dentate gyrus following the treatments. The enhanced signal was detected 2hr after last seizures and persisted during 24 hr and returned to the basal values after 7 days. There is no difference between the single and repeated ECS demonstrating that the effect is observed in response to the last seizures themselves rather than the treatments "per se".

718.19

EFFECTS OF CHLORPROMAZINE ON THE INDUCTIONS OF *c-fos* AND *jun B* BY ELECTROCONVULSIVE SHOCKS IN RAT BRAIN. H. Y. Jung¹, Y. M. Ahn¹, U. G. Kang¹, J. B. Park², Y. S. Kim^{1*}. Departments of Psychiatry¹ and Biochemistry², Seoul National University College of Medicine, Seoul, Korea 110-460.

From studies with cultured cell, chlorpromazine (CPZ) has been reported to block the induction of *c-fos* by cell depolarization. However haloperidol, antipsychotics like CPZ was known to induce *c-fos* in striatum and other rat brain regions. So we examined whether CPZ itself elicited the induction of immediate early genes and blocked these genes induced by ECS *in vivo*.

Intraperitoneal injection of CPZ induced *c-fos* and *jun B* in striatum but not in cerebellum. And the induction in striatum was found to be relatively dose-dependent. When we treated rats by ECS 30 min after pretreatment with 10mg/kg of CPZ, which was clinically effective dosage, inductions of *c-fos* and *jun B* by ECS were observed in striatum and other brain regions. Above results indicated that CPZ induced *c-fos* and *jun B* and could not completely block the induction of these genes by ECS *in vivo*.

DETECTION OF CHYMOTRYPSIN mRNA EXPRESSION IN THE BRAIN BY RIBONUCLEASE PROTECTION ASSAY. X. C. Wang, K. I. Strauss, A. M. Laties* & D. M. Jacobowitz. Lab. of Clin. Sci., NIMH, Bethesda, MD 20892.

Chymotrypsin is synthesized, stored and secreted in exocrine pancreas for intestinal protein digestion. Pancreatic RNA from rat was isolated in the presence of guanidine thiocyanate. Polyadenylated RNA was isolated from total rat pancreatic RNA by binding to oligo(dT)-cellulose. A 5'-primer (27-mer), including an upstream EcoR I site, and a 3'-primer (28-mer), including a downstream Hind III site, were designed to amplify a portion of cDNA (about 500 bp) from rat pancreatic mRNA using the PCR. The sequence of the fragment was confirmed to be a portion overlapping exon-6 and exon-7 of rat chymotrypsin B gene. It was subcloned into the pGEM-4Z vector and used as a template for *in vitro* transcription of an antisense riboprobe. Using the micropunch RNase protection procedure for quantitation of mRNA in discrete brain regions we have detected chymotrypsin mRNA in rat brain. Regions such as hippocampus, striatum, thalamus and cortex contain chymotrypsin mRNA. Future work will be directed towards determining the presence in the brain of chymotrypsin in normal and neurodegenerative diseases (e.g. Alzheimer's).

ERRORS IN ESTIMATING APPARENT DIFFUSION COEFFICIENT FROM RATIO OF BOUND TO UNBOUND Ca^{2+} . J.L. Winslow (*,1,2), M.P. Charlton (2) (1)Biomedical Engineering, (2)Physiology Dept. U. of Toronto, Toronto, Ont. M5S 1A4.

Diffusion of Ca^{2+} in cytoplasm can be slowed by binding to non-diffusible sites and characterized by the apparent diffusion coefficient $D_e^* = D_e / (1 + \beta)$, where $\beta = [\text{bound } Ca^{2+}] / [\text{unbound } Ca^{2+}]$. D_e^* has been used in place of D_e in the diffusion equation $\frac{\partial C}{\partial t} = D_e \frac{\partial^2 C}{\partial x^2}$. Biologically, D_e is measured and β estimated to obtain D_e^* . This is only correct if the immobile buffer does not saturate and β is constant. We numerically solved the simultaneous reaction-diffusion equations for diffusible Ca^{2+} , non-diffusible buffer and product, A, Q, over a long cylinder with initial $[Ca^{2+}]_i = 0.1 \mu M$ and used the program as a computational preparation. The simulations start with an injection of Ca^{2+} in the cylinder's center. (1) For no buffer ($A=Q=0$), we found the best fit of the appropriate analytical solution to the numerically computed time-response to obtain \bar{D}_e , as would be done in biological experiments. This agrees with the specified D_e in the computational preparation. (2) Repeat step 1, but now $A>0$ and Q is the equilibrium value, to obtain another value of \bar{D}_e , which should agree with D_e^* , but does not, because $\beta = Q/C$ varies by 10^4 depending on location and time. To avoid errors in diffusion estimates based on constant β , simultaneous equations must be used. Measurements and models which use D_e^* must be interpreted critically.

POISSON-PROCESS ELECTRICAL STIMULATION: CIRCUIT AND AXONAL RESPONSES. K. Moradmand, T.N. Hangartner* and M.D. Goldfinger*. Dept. Physiology & Biophysics and *Dept. Biomedical & Human Factors Engineering, Wright State University, Dayton, OH 45435.

This work addresses the transformation of Poisson process electrical stimulation by GI primary afferent axons. To generate a Poisson process, amplified resistor noise was sampled by a Schmitt-trigger which drove a monostable multivibrator to elicit pulses (0.1 msec/4.2V). The pulse mean frequency was modulated by the noise envelope's amplitude. Both steady-state (Interevent Interval Distribution, IID) and real-time (Expectation Density, ED) stochastic estimators were used to characterize the temporally-stable output. The IID contained sequentially: a short (0.1 msec) dead-time (DT), a sharp rise, and a single exponential fall-off. The ED contained sequentially: a short DT and a sharp rise to a maintained noisy plateau which corresponded to the mean rate.

Poisson process electrical stimulation was applied percutaneously to the receptive field of a GI primary afferent axon in the Na-Pentobarbital anesthetized cat. The elicited trains of propagated impulses were recorded extracellularly within the cuneate fasciculus. For a given mean stimulus frequency, several stimulus amplitudes were tested. The temporally-stable axonal impulse train contained departures from the stimulus train. The impulse ED contained sequentially: a longer DT (which decreased with higher stimulus amplitude and/or mean frequency); an early peak, and a noisy plateau. The impulse ED peak delay was approximately equal to the doublet interval found separately. By filtering all doublet intervals from the axonal impulse train, the high-probability ED peak was eliminated. Thus, Poisson process stimulation elicited a Poisson-like impulse pattern which included short-interval conditioning via doublet repetitive firing.

AN INCREASE IN SPATIAL VARIANCE IN THE PROBABILITY OF NEURO-SECRETION IS ASSOCIATED WITH DRUG-INDUCED INHIBITION OF MITOCHONDRIA. S. D. Provan* and M. D. Miyamoto. Dept. of Pharmacology, East Tenn. State Univ., Johnson City, TN 37614.

Transmitter release from nerve terminals depends on an increase in $[Ca^{2+}]_i$, which normally occurs by influx of Ca^{2+} through voltage-sensitive channels. Increases in $[Ca^{2+}]_i$ may also arise from release of Ca^{2+} sequestered by mitochondria. This would be expected to produce a variation in the $[Ca^{2+}]_i$ at individual transmitter release sites, due to differing distances from the source of Ca^{2+} . This in turn should increase both mean probability of release (p) and spatial variance in p (var_p). We wished to see whether Hg²⁺, methyl Hg (MeHg) and flufenamic acid (Flu), agents known to inhibit mitochondria, produced increases in p and var_p . Miniature endplate potentials (meppps) were recorded from isolated frog cutaneous pectoris, and unbiased estimates of m (no. of quanta released), n (no. of functional release sites), p , and var_p made (Am. J. Physiol. 264: 1051-1060, 1993). $[K^+]_o$ was raised to 10 mM to increase meppp frequency, and data recorded after 10 min equilibration. HgCl₂ (1 μM) produced increases in m , n , p and var_p , all of which peaked after 15 min and returned to control values ($N = 6$ continuous recordings). Similar findings of an increase, peak and decline in m , n , p and var_p were obtained with 100 μM MeHg ($N = 6$). This effect was not abolished by 3 μM tetrodotoxin and 1.8 mM Co²⁺, which suggested that the effect was due to permeation of MeHg through the membrane rather than through voltage-sensitive Na and Ca channels. Finally, an increase, peak effect and decline in m , n , p and var_p was found with 200 μM Flu ($N = 6$). Previous studies have shown that increases in m , n and p can occur without increases in var_p , using agents not associated with mitochondrial inhibition (K^+ , Ca^{2+} , or linopirdine). The present results indicate that changes in var_p might be used as a real-time indicator of drug-induced release of Ca^{2+} from mitochondria. Whether similar effects occur with drug-induced inhibition of smooth endoplasmic reticulum remains to be determined. (Supported by NIH NS22457).

INCREASE OF TONIC AND EVOKED PRESYNAPTIC INHIBITION BY A GABA-T BLOCKER. H. Golan and Y. Grossman*. Unit of Physiology, Faculty of Health sciences, Ben-Gurion Univ., Beer-Sheva 84105, Israel.

We have previously shown that the GABA transaminase (GABA-T) blocker ethanolamine-O-sulfate (EOS), selectively increases presynaptic inhibition. In order to examine the mechanism underlying this phenomenon, action potentials (AP) and presynaptic inhibitory potentials (PIP) were recorded intracellularly at the secondary branches of the excitatory axon in the opener muscle of the crayfish walking leg. EOS (5-10 mM) had no effect on axonal R_m ($n=3$), while causing up to a 7 mV depolarization in 4 of 7 axons tested and up to 14 mV reduction in the AP amplitude. AP width was also increased, reflecting an increase of local tonic conductance in remote presynaptic sites. Applied 0.2 mM GABA generated similar effects. These findings were correlated with a 20% reduction in the excitatory transmission. Evoked inhibition was tested by delivering either a single or a short train of stimuli to the inhibitory axon 1-15 ms before evoking excitator AP. EOS enhanced the PIP amplitude (X3), but reduced the AP by only 2-5%. Considering the changes in electrotonic spread due to increased distal conductance, the predominant effect of the GABA-T blocker would appear to enhance presynaptic tonic, and evoked, GABA release,

SODIUM NITROPRUSSIDE INHIBITS NEUROTRANSMITTER RELEASE AT THE NEUROMUSCULAR JUNCTION OF THE FROG. Clark A. Lindgren¹ and Melissa V. Laird. Department of Biology, Grinnell College, Grinnell, IA 50112.

Using intracellular recording, end plate potentials (EPPs) were measured at the neuromuscular junction on the sartorius muscle of the frog, *Rana pipiens pipiens*. Sodium Nitroprusside (SNP), a compound which decomposes in the presence of light to Nitric Oxide (NO) and other miscellaneous by-products, was applied at concentrations ranging from 0.01 μ M to 1.0 mM. EPPs were reduced by an average of 57% within minutes of application of SNP. This reduction of EPPs was shown through quantal analysis (i.e. under condition of lowered extracellular calcium and elevated magnesium) to result from an inhibition of neurotransmitter release from the motor nerve endings. This inhibition was long-term; reversal of the inhibition was observed only at the lower SNP concentrations. The inhibition was also stimulus dependent. EPPs were reduced almost immediately when SNP was applied while stimulating the motor nerve; however, depression was delayed (approximately 5 minutes) if SNP was applied in the absence of nerve stimulation. In summary, these results suggest that NO inhibits the release of neurotransmitter from motor nerve endings of the frog. (Supported by NIH Grant NS-29520 and a grant from the Howard Hughes Medical Institute to Grinnell College.)

PRESYNAPTIC DEPRESSION OF GLUTAMATERGIC SYNAPTIC TRANSMISSION BY HYPOGLYCEMIA.

M. W. Fleck^{1,2}, A. M. Palmer^{2,3}, and G. Barrionuevo^{1,2}. Departments of ¹Behavioral Neuroscience, ²Psychiatry, and ³Pharmacology; University of Pittsburgh, Pittsburgh, PA 15260.

We examined the effects of hypoglycemia on glutamatergic synaptic transmission in area CA1 of rat hippocampal slices. Decreasing glucose from 10 mM to 0.2 mM depressed the calcium-dependent potassium-evoked release of glutamate by ~ 60% and depressed Schaffer collateral-evoked population excitatory postsynaptic potentials (pEPSP) and population spikes (PS) to less than 10% of their initial amplitudes. The hypoglycemic depression was complete within 1 hr at room temperature. The apparent EC₅₀ for glucose was ~ 0.6 mM. Maximal pEPSP amplitudes but not maximal PS amplitudes were significantly reduced by hypoglycemia. In addition, paired-pulse facilitations of the pEPSP and PS were enhanced from 10% to 60% and from 100% to 300%, respectively. Paired-pulse facilitation was enhanced across a 32-fold range of stimulus intensities and was most pronounced at inter-stimulus intervals less than 100 msec. The enhancement was not attenuated by the GABA_A receptor antagonists picrotoxin or bicuculline, nor by the NMDA receptor antagonist D-APV. Whole-cell recordings revealed that hypoglycemia decreased the amplitudes of evoked EPSCs and the frequency but not amplitude of spontaneous EPSCs in pyramidal cells of area CA1. Thus, hypoglycemia depresses excitatory synaptic transmission in area CA1 of the hippocampus by modulation of the release mechanism. Supported by NS24288, and an NIMH Predoctoral fellowship.

METHYLMERCURY INCREASES THE INTRATERMINAL CONCENTRATION OF AN ENDOGENOUS HEAVY METAL MF Denny¹ and WD Atchison. Dept. Pharmacol. Toxicol., Neurosci. Prgm. and Inst. Environ. Toxicol., Mich. State Univ., E. Lansing, MI, 48824.

Methylmercury (MeHg) is a neurotoxic metal known to elevate intracellular Ca²⁺ concentration upon acute exposure. We have shown previously that MeHg also causes an immediate elevation in the free intracellular concentration of an endogenous polyvalent cation within isolated nerve terminals. We postulated that this cation may be Zn²⁺. Zn²⁺ elevates fura-2 fluorescence intensity at all excitation wavelengths including the Ca²⁺-insensitive wavelength of 360 nm; MeHg itself does not interact with fura-2. Addition of MeHg to fura-2 loaded synaptosomes causes a shift in excitation spectra similar to that of Zn²⁺. Zn²⁺ also quenches quin2 fluorescence intensity at all excitation wavelengths. As such, elevations in intracellular Zn²⁺ concentration should quench quin2 fluorescence. Addition of MeHg to synaptosomes loaded with quin2 decreases intensity. The MeHg-induced alterations in both fura-2 and quin2 fluorescence intensity were reversed by the subsequent addition of the cell-permeant heavy metal chelator TPEN. These results using fluorescent indicators suggest that Zn²⁺ is the endogenous polyvalent cation responsible for these changes in intensity. Positive identification as well as quantification will require using ⁶⁷Zn-NMR. The intrasynaptosomal source of the cation(s) is unknown. Synaptic vesicles are known to contain Zn²⁺, and MeHg has been shown previously to alter vesicular release of several transmitters. Perhaps MeHg causes release of Zn²⁺ associated with synaptic vesicles. Preincubation of fura-2 loaded synaptosomes with agents known to cause mobilization of vesicles (K⁺ depolarization, 0.1 μ M veratridine or 6 nM α -latrotoxin) did not affect the elevations in fluorescence intensity induced by MeHg. Thus, either the metal is not mobilized upon release of synaptic vesicles or the vesicles are not the source of the cation(s). Supported by NIH grant ES03299. MFD is the recipient of a student fellowship from the Hazelton Co.

ARACHIDONIC ACID CONTRIBUTES TO STRIATAL SYNAPTIC DEPRESSION BY REDUCING PRE-SYNAPTIC ACTION POTENTIALS. D.D. Fraser¹, K. Hoehn, S. Weiss and B.A. MacVicar. Neuroscience Research Group, University of Calgary, Alberta, Canada. T2N 1N4.

In the striatum, both arachidonic acid (AA) release and induction of synaptic depression require co-activation of D₁ and D₂ receptors, suggesting the phenomena may be linked. We reported previously that AA depresses the peak Na⁺ current in striatal neurons and shifts the inactivation curve to hyperpolarized potentials. Since depression of the pre-synaptic spike could result in a reduction of transmitter release we have now investigated the actions of AA on Na⁺-dependent action potentials and spontaneous synaptic currents in striatal cultures. In agreement with our voltage-clamp data, action potentials evoked from the resting membrane potential (-60 mV) were depressed significantly by 10 μ M AA (36%; n=10). At a holding potential of -80 mV, single action potentials were minimally depressed (15%, n=10), whereas repetitive bursting was reduced dramatically (n=8). The spike threshold and input resistance were unaffected by AA. In voltage-clamp mode, spontaneous synaptic currents that were blocked by 1 μ M TTX or 200 μ M Cd²⁺ were depressed by 10 μ M AA (n=5). The frequency and amplitude of synaptic currents were reduced by 51% and 36%, respectively. These observations are consistent with the hypothesis that AA-induced synaptic depression involves a reduction of the pre-synaptic Na⁺-dependent action potential. Supported by the MRC (Canada) and Ciba Geigy.

GLUCOSE-DEPLETION INHIBITS SYNAPTIC TRANSMISSION IN THE CENTRAL NERVOUS SYSTEM OF THE RAT. T. Akasu¹, S. Shoji and H. Hasegawa. Dept. Physiol., Kurume Univ. Sch. Med., Kurume 830, Japan.

To study the role of glucose on synaptic transmission in the central nervous system, intracellular recordings were made from neurons in the dorsolateral septal nucleus, in vitro. Lowering the concentration of extracellular glucose resulted in a concentration-dependent hyperpolarization associated with a decreased input resistance. The spontaneous action potential was inhibited during the hyperpolarization. EPSP, IPSP and LHP evoked by stimulations of fimbria/fornix pathway were inhibited by depletion of extracellular glucose (0-2 mM). Substitution of 2-deoxy-D-glucose (11 mM) for glucose mimicked the effects of glucose-depletion. Mannoheptulose (10 mM) and dinitrophenol (50 μ M) produced the hyperpolarization and the inhibition of postsynaptic potentials even in the presence of 11 mM glucose. Sulfonylureas, glibenclamide (10 μ M) and tolbutamide (1 mM), did not antagonize the effects of glucose-depletion. Depolarizing response produced by direct application of glutamate and hyperpolarization produced by either muscimol or baclofen were almost unchanged, when glucose was reduced to 1-2 mM. These results indicate that intracellular glucose metabolism regulates the function of septal neurons not only by changing the resting membrane potential, but also by presynaptically affecting synaptic transmission from the hippocampal formation to the septum nucleus.

720.1

FREQUENCY-DEPENDENT INHIBITION OF ELECTRICALLY-EVOKED ³H-NOREPINEPHRINE (³H-NE) RELEASE FROM RAT CORTICAL SLICES BY ω -CONOTOXIN MVIIA (ω -CTM) AND ω -CONOTOXIN GVIA (ω -CTG). S. Wurster and D.J. Dooley*. Dept. of Neuroscience, Parke-Davis, Pharmaceutical Research Division, Warner-Lambert Co., Ann Arbor, MI 48106.

The extent of inhibition of K⁺-evoked ³H-NE release from rat brain slices by the N-type channel blocker ω -CTG has recently been shown to decrease with increasing [K⁺] (Biochem. Pharmacol. 45 (1993) 165). This could indicate a voltage dependence in the inhibitory action of ω -CTG, or a decreasing relative contribution of Ca²⁺ influx through N-type Ca²⁺ channels when noradrenergic nerve endings are depolarized by tetanic K⁺-depolarizations for extended periods of time. Electrically-evoked ³H-NE release is devoid of such long lasting membrane depolarization and matches the physiologically action potential-induced neurotransmitter release more closely. In the present study we have evaluated the effects of varying the frequency of electrical field stimulations on the inhibition of ³H-NE release caused by ω -CTM and ω -CTG. Rat neocortical slices preloaded with ³H-NE were superfused continuously and stimulated with 90 pulses ranging in frequencies from 0.3-100 Hz. ω -CTM or ω -CTG were added to the superfusion buffer 40 min before the stimulation. Evoked release was inhibited by the reversible blocker ω -CTM and the essentially irreversible blocker ω -CTG at all stimulation frequencies. The maximal inhibition, however, decreased with increasing frequency: 80% (0.3 Hz), 75% (3 Hz), 60% (30 Hz) and 40% (100 Hz). In contrast, the relative IC₅₀'s (2-4 nM) of ω -CTM were independent of stimulation frequency. Taken together these results seem to indicate an increasing contribution of non-N-type Ca²⁺ channels to ³H-NE release from rat neocortical slices with increasing stimulation frequency. Alternatively, this phenomenon may reflect the failing ability of Ca²⁺ extrusion systems to decrease free intracellular [Ca²⁺] during high frequency stimulations back to resting levels before the nerve endings are depolarized by the next pulse.

720.3

PHARMACOLOGY OF ION CHANNELS INVOLVED IN HIGH-K⁺-EVOKED [3H]-GLUTAMATE RELEASE. S. Katragadda*, J. B. Fischer, A. G. Knapp, K. G. Pratt, S. M. Goldin. Cambridge NeuroScience, One Kendall Sq., Bldg. 700, Cambridge, MA 02139.

High K⁺-evoked [3H]-glutamate release from rat brain nerve terminals can be resolved into three different components using a novel rapid superfusion technique. A) A Ca-independent component that is due to the reversal of glutamate transporter that lasts as long as depolarization is continued. This component can be specifically blocked by glutamate uptake blocker D,L threo- β -hydroxy aspartate. B) A transient Ca-dependent component that decays with a τ of < 0.2 sec and C) a persistent Ca-dependent component that decays in a few seconds. We are interested in understanding the nature of ion channels that are involved in Ca-dependent glutamate release. Tetrodotoxin (up to 30 μ M) did not show any effect on any component of K⁺-evoked glutamate release. This indicates that Na channels do not contribute to Ca-dep. release under our experimental conditions. ω -Aga IVA blocked 65% of Ca-dep. glutamate release indicating that most of the Ca-dependent release is governed by 'P-type' Ca channels, confirming earlier reports. ω -Cg toxin GVIA and ω -Cm toxin MVIIA exhibited only marginal block at saturating concentrations (< 20 %) suggesting that 'N-type' channels do not play major role in Ca-dependent glutamate release. Therefore among the Ca channels, P-type channels are primarily involved in this process whereas N-type channels play only a minor role.

Snail and Spider Toxins Block Action Potential-Induced Ca²⁺ Influx in Rat Dorsal Root Ganglion Neurons.

T. M. Piserl*, R.A. Lampe², R.A. Keith², S.A. Thayer¹,

¹Department of Pharmacology, University of Minnesota Medical School, Minneapolis MN, 55455. ²Department of Pharmacology, ICI Americas Inc., Wilmington, DE 19897.

Action potential-mediated transient increases in intracellular free calcium concentration were elicited by field potential stimulation of rat dorsal root ganglion neurons and measured by indo-1-based microfluorimetry. ω -Conotoxin (100 nM) and nitrendipine (1 μ M), blockers of high-threshold voltage-gated Ca²⁺ channels, inhibited action potential-mediated Ca²⁺ influx by 79 \pm 2% (n=14) and 13 \pm 3% (n=10), respectively. ω -Grammotoxin (267 nM), a novel peptide toxin purified from the venom of the tarantula spider, *Grammostola spatulata*, blocked action potential-mediated Ca²⁺ influx as effectively as ω -conotoxin (76 \pm 4%, n=6). In contrast to block by ω -conotoxin, the block produced by ω -grammotoxin was reversible. Preliminary patch clamp experiments indicate that ω -conotoxin and ω -grammotoxin block in common a component of whole cell Ca²⁺ current. These results are consistent with the conclusion that ω -grammotoxin is a novel inhibitor of N-type voltage-gated Ca²⁺ channels.

720.4

EFFECTS OF CALCIUM CHANNEL BLOCKERS ON SEIZURE ACTIVITY IN CULTURED RAT HIPPOCAMPAL NEURONS.

S.S. Lin*, R.E. Numann, and R.L. Simon. Departments of CNS and CVMD, Wyeth-Ayerst Research, CN 8000 Princeton, NJ 08543.

There are a variety of voltage dependent calcium channels found in neurons. Using specific blockers for each of the different channels, many investigators have implicated a role for the N-type calcium channel in the release of neurotransmitters. However, Horne and Kemp (Br. J. Pharmacol. 1991) found that omega-conotoxin GVIA, a specific blocker of N-type channels, did not inhibit the paroxysmal depolarization shifts (PDSs) that are characteristic of epileptic seizure activity. We have tested specific blockers of different calcium channels to determine which are involved in the generation of PDSs in a cultured rat hippocampal model of epilepsy (Furshpan and Potter, Neuron, 1989). Omega-conotoxin GVIA had little or no effects on PDS induced currents. By contrast, omega-agatoxin, a specific blocker of P-type channels (Mintz et al, Neuron, 1992) reduces PDS currents by 70-90%. Surprisingly, nimodipine, which blocks L-type channels, was the most effective antagonist, inhibiting almost all of the PDS induced currents.

720.6

PHARMACOLOGICAL CHARACTERIZATION OF THE ENDOGENOUS CALCIUM AND BETA SUBUNIT-ENHANCED CALCIUM CURRENT IN XENOPUS OOCYTES. J. D. Mills*, A. Kondo, M. E. Adams & E. Perez-Reyes. Depts. Entomology & Neuroscience, University of California, Riverside, CA 92521 & Loyola University Medical Center, Maywood, IL 60153.

The *Xenopus* oocyte, widely utilized for expression of heterologous ion channels, expresses an endogenous calcium-dependent chloride current, I_{Cl}(Ca), which is involved in the fertilization process. We found that this chloride current is 75-85% blocked by crude *Agelenopsis aperta* spider venom (n=4). Both the polyamine (1:2500 dil.; n=3) and peptide fractions (1:1250 dil.; n=3) from the venom blocked a similar percentage. ω -Aga-IIIa, a toxin isolated from the venom, inhibited 80% of I_{Cl}(Ca) (200 nM, n=30). Elevation of [Ca]_o from 5 - 40 mM increased the IC₅₀ value from 12 - 69 nM, and maximum block decreased from 80% to 55%. I_{Cl}(Ca) was insensitive to nifedipine (n=2), ω -conotoxin GVIA (n=4) and ω -Aga-IVA (n=20). Attempts to characterize the endogenous Ca channels directly were hampered by extremely low values of I_{Ba} in most oocytes. However, in a small percentage of oocytes expressing large I_{Ba}, we observed a potent blocking action by ω -Aga-IIIa (n=10), but no effect of dihydropyridines (n=3) or ω -Aga-IVA (n=3). Effects of ω -conotoxin GVIA (0.3-5 μ M) were variable between oocyte batches. In some batches, up to 68% block was observed, while no significant block was observed in others.

Injection of cloned β 2 and β 4 subunits enhanced the endogenous current by 11- and 3-fold, respectively. ω -Agatoxins affected the β -enhanced currents in a similar manner as the endogenous currents. ω -Aga-IVA had no effect on β -enhanced I_{Cl}(Ca) showing that the channel was not P-type. β -enhanced barium currents were up to 60% blocked and β -enhanced chloride currents up to 85% blocked by 200 nM ω -Aga-IIIa. (Supported by NIH grants NS24472 and HL46702).

720.7

INHIBITION OF NEURONAL VOLTAGE-SENSITIVE CALCIUM CHANNEL (VSCC) RESPONSES: EFFECTS OF SYNTHETIC ω -Aga-IVA AND SYNTHETIC ω -GRAMMOTOXIN SIA. R. A. Lampe*, T. J. Mangano, P. A. DeFoa, M. B. Horn, and R. A. Keith. Dept. of Pharmacology, Zeneca Pharmaceuticals Group., Wilmington, DE 19897.

ω -Aga-IVA and ω -grammotxin SIA (ω -GsTx) are naturally occurring spider venom peptides that have been isolated from *Agelenopsis aperta* and *Grammostola spatulata*, respectively. ω -Aga-IVA is reported to be a selective inhibitor of P-type VSCC (Mintz *et al.*, Nature, 355:827, 1992) whereas ω -GsTx inhibits P- and N-type VSCC responses, but does not displace 125 I- ω -conotoxin GVIA in binding studies (Lampe *et al.*, J. Mol. Pharmacol., in press). Studies using purified preparations are subject to the possibility that trace impurities may contribute to the observed pharmacology. In an attempt to address this possibility, synthetic samples of ω -Aga-IVA and ω -GsTx were obtained and tested in functional assays of neuronal VSCC activity. Synthetic ω -Aga-IVA (commercially available from Peptides International) and ω -GsTx (custom synthesis by Bachem, California) were tested against K⁺-evoked synaptosomal (rat brain) 45 Ca⁺⁺ influx and release of 3 H-D-aspartate from rat hippocampal slices. ω -Aga-IVA and ω -GsTx caused a concentration-dependent inhibition of synaptosomal 45 Ca⁺⁺ influx with IC₅₀ values of approximately 80 nM and 50 nM, respectively. These potency values are similar to those previously reported for the natural peptides, with the exception that synthetic ω -GsTx is approximately 3 times more potent than the natural peptide. At 200 nM, both peptides inhibited 3 H-D-aspartate release by approximately 50%, again agreeing well with values previously reported for the natural peptides. The results suggest that trace impurities were not substantially contributing to the pharmacology of the purified preparations.

BLOCK OF INSECT NEURONAL CALCIUM CHANNELS BY PEPTIDE SPIDER TOXINS. E.A. Ertel, M.M. Smith, T.A. Bale, V.A. Warren & C.J. Cohen* Merck Res Labs, Rahway, NJ. 07065.

Previous voltage-clamp studies of insect neuronal Ca channels were hampered by preparations with small currents and poor voltage control. Using freshly dispersed neurons from locust (*Schistocerca americana*) thoracic ganglia and cockroach (*Periplaneta americana*) A6 ganglia, we are able to record robust well-controlled Ba currents. Locust Ca channels have kinetics similar to those of high-voltage-activated Ca channels in mammalian neurons, but they activate at more negative voltages (\approx -50 mV). We have isolated peptide toxins from the spider *Agelenopsis aperta* by HPLC. We used insecticidal activity against blowfly larvae as the bioassay for ω -Aga-IA and inhibition of binding of 125 I- ω -conotoxin GVIA to rat brain synaptosomal membranes for ω -Aga-IIB and ω -Aga-III. Identification was confirmed by N-terminal sequence analysis. We observe potent Ca channel block by all 3 toxins, in contrast to earlier studies with housefly neuromuscular junction, where only toxin types I and II are inhibitory (Bindokas, J. Neurophysiol, 66:590). Percent block by each toxin varies widely among cells, but each toxin-sensitive component is generally affected with IC₅₀ = 20 nM. These results indicate neuronal heterogeneity and multiple types of Ca channels. We also evaluated Ca channel block by ω -Aga-IA in guinea pig atrial myocytes and find no effect of 100 nM toxin on L- or T-type Ca channels. This contrasts with earlier reports using rat DRG neurons [Scott, Mol Pharm. 38:711]. ω -Aga-IIB and ω -Aga-III inhibit binding of 125 I- ω -conotoxin GVIA to rat brain synaptosomal membranes (IC₅₀ = 20 pM), but 100 nM ω -Aga-IA does not. This suggests that N-type Ca channels are also not blocked by ω -Aga-IA.

720.11

SMALL PLECTREURYS TOXINS. W.D. Branton* and Zhou Yi.

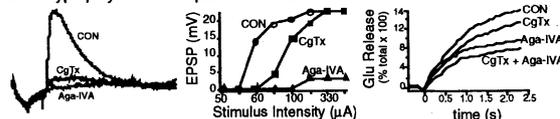

Department of Physiology, University of Minnesota, Minneapolis MN 55455.

The venom of the spider *Plectrueris tristes* contains a family of peptide calcium channel blockers with members specific for insect and vertebrate calcium channels. Both insect and vertebrate toxins are present in at least two apparent molecular weight (MW) ranges. The most abundant toxins have a MW of about 5-6 kDa. Previously, we structurally characterized one of the insect toxins (PLTXII) in the 5-6 kDa range. PLTXII is a 44 amino acid peptide with a unique O-Palmitoyl Threonine amide as the final residue. All of the peptide calcium channel blockers in the venom probably share a similar C-terminal structure. The lipid is apparently a requirement for activity, and we have speculated that the unique structure may be associated with a unique mechanism of action. Although synthesis or expression of toxins like PLTXII are potentially feasible, toxins with smaller peptide components would be easier to synthesize. To this end we are investigating toxins with apparent MW of 2.5 kDa or smaller. We have identified both insect and vertebrate selective activities and have partially purified an insect toxin. These toxins are likely to be fatty acylated like PLTXII. They elute even later than PLTXII on C18 reverse phase, as would be expected of a toxin similar to PLTXII but with a smaller hydrophilic peptide component; and the small toxins (like PLTXII and others in the higher MW range) shift to a much more hydrophilic retention time after saponification to remove ester linked lipids. The apparent size of 2.5 kDa suggests that the peptide component is approximately 20 amino acids. If this estimate proves accurate, it may be possible to efficiently synthesize the structure once it is established.

MULTIPLE CALCIUM CHANNEL TYPES REGULATE GLUTAMATE RELEASE IN THE HIPPOCAMPUS. J.L. Luebke*, K. Dunlap, and T.J. Turner Physiology & Neuroscience, Tufts University School of Medicine, Boston, MA 02111

We have employed peptide toxins that specifically block N-type (ω -CgTx) or P-type (ω -Aga-IVA) calcium channels to determine which channel types control evoked synaptic transmission between Schaffer collaterals and CA1 pyramidal neurons in rat hippocampal slices. In parallel experiments, rapid superfusion techniques allowed a direct measure of calcium-dependent [3 H]-glutamate release from hippocampal synaptosomes. ω -Aga-IVA (100 nM) and ω -CgTx (1 μ M) both reduced the amplitude of glutamatergic excitatory postsynaptic potentials in CA1 neurons. ω -Aga-IVA was much more efficacious than ω -CgTx, however, producing 100% block in \approx 15 min. (as compared to 75% block by ω -CgTx in \approx 30 min.) for a given stimulus amplitude. Furthermore, the inhibitory effects of both toxins could be overcome through an increase in stimulus intensity (presumably by recruiting additional synaptic inputs), but much smaller increases were required to overcome the effects of ω -CgTx. These electrophysiological results were corroborated by the biochemical studies of [3 H]-glutamate release. When synaptosomes were stimulated with 30 mM KCl, 100 nM ω -Aga-IVA inhibited [3 H]-glutamate release by 40%, compared to the 16% inhibition produced by 1 μ M ω -CgTx. Taken together, these data suggest that both P-type and N-type calcium channels trigger glutamate release from hippocampal neurons, but P-type plays the more prominent role.

720.10

PHARMACOLOGICAL CHARACTERIZATION OF THE P-TYPE CALCIUM CHANNEL IN ISOLATED RAT NEOCORTICAL NEURONS. A.M. Brown, P.C. Schwindt* and W.E. Crill Dept. of Physiology & Biophysics, University of Washington School of Medicine, Seattle, WA 98195.

High voltage activated (HVA) calcium currents were recorded in pyramidal neurons acutely isolated from sensorimotor cortex of 7 - 20 day old rats using the whole cell patch clamp configuration. Application of 100 nM and 200 nM ω -Aga-IVA reduced the HVA current by 31.5%. The reduction of the HVA current by ω -Aga-IVA was less when 10 μ M nifedipine was added first. ω -Aga-IVA did not affect calcium tail currents lengthened by Bay K 8644 suggesting that ω -Aga-IVA does not inhibit the dihydropyridine-sensitive HVA component. The reduction of the HVA current by 10 μ M ω -CgTx was not affected by the order of its application. A dilution of 1:1000 FTX reduced the HVA current by 81.4% and occluded the inhibitory effects of ω -Aga-IVA. We conclude that about 30% of the HVA current in acutely isolated rat neocortical neurons is specifically inhibited by ω -Aga-IVA and is carried by P channels. ω -CgTx specifically inhibits the N channel component but nifedipine at 10 μ M partially inhibits the ω -Aga-IVA sensitive component. FTX is not a specific inhibitor of the P channel in these neurons. Supported by ONR N0014-90-5-1627, NS 16792, and W.M.Keck Foundation.

720.12

MULTIPLE SUBTYPES OF VOLTAGE-GATED CALCIUM CURRENTS IN NEURONS OF THE CHICK EDINGER WESTPHAL NUCLEUS. Z. Lucaj and J.T. Fujii* Dept. of Anatomy and Cell Biology, Wayne State U. Sch. of Med., Detroit, MI 48201.

Calyciform terminals, formed by axons projecting from the neurons of the Edinger Westphal (EW) nucleus and terminating in the chick ciliary ganglion, express N-type calcium channels (Stanley and Goping *et al.*, 1991). Whole cell voltage clamp techniques were used to record from the cell bodies of EW neurons in slices obtained from embryonic day 16 chicks. Depolarizing step commands of 10mV from a holding potential of -70mV were used to study the voltage-current relationship of calcium currents. A voltage step from a prepulse of -40mV to 0mV was used to isolate high-voltage activated (HVA) from low-voltage activated (LVA) calcium currents. These commands indicated the presence of both LVA and HVA calcium currents.

Pharmacological agents that were bath applied yielded the following results: (i) 10mM nickel chloride caused a reversible decrease in the amplitude of the calcium current, (ii) cadmium chloride (100 μ M) produced a reversible decrease in the amplitude of the calcium current, and (iii) omega-conotoxin (2 μ M) caused an irreversible decrease in the amplitude of the calcium current. There was also an omega-conotoxin resistant component of the whole cell current. This data suggests that currents similar to N-type and T-type calcium currents are expressed in EW neurons of E16 chicks. This work was supported by NSF BNS-8719391, NEI R01EY09768 and an award from The Michigan Eye Bank and Transplantation Center.

CHARACTERIZATION OF L-TYPE CALCIUM CHANNELS IN MUSSEL OOCYTE PLASMA MEMBRANES. S. Krantic*, M. Tomkowiak and P. Guerrier. Lab. of Mol. and Cell. Biol., UMR 49 CNRS-ENS, Lyon 69000, France.

Membrane depolarization induced by an excess KCl (53mM) triggers an intracellular Ca^{2+} surge and activates metaphase I-arrested oocytes of the mussel (*Mytilus galloprovincialis*). This response is inhibited by the dihydropyridine (DHP) analog, nitrendipine, thus suggesting the involvement of L-type voltage-gated calcium channels in KCl-dependent oocyte activation. We therefore performed binding assay on semi-purified membrane preparations of metaphase-arrested oocytes, using a radioactive DHP analog, [3H]-PN 200-110. Saturation data suggest the existence of a single class of DHP binding sites with an apparent affinity of $1.82 \pm 0.38 \mu M$ and a maximal binding capacity of 998 ± 115 pmol/mg protein. Only DHP-related compounds could inhibit [3H]-PN 200-110 specific binding with following order of potencies: nitrendipine > PN 200-110 > fluspirilene > nifedipine = bepridil > flunarizine = diltiazem. These data point to the existence of an original form of L-type calcium channels in mussel oocyte plasma membranes.

720.15

DIFFERENT ROLES OF N- AND L-TYPE CALCIUM CHANNELS IN DEPOLARIZATION-INDUCED CALCIUM TRANSIENTS IN CA3 PYRAMIDAL NEURONS. E.M. Elliott¹, A.T. Malouf², and W.A. Catterall¹. Depts. of ¹Pharmacology and ²Neurological Surgery, University of Washington, Seattle, WA 98195.

N- and L-type calcium channels have a complementary distribution in hippocampal pyramidal neurons: N-type are predominantly dendritic and presynaptic while L-type are primarily somatic (Westenbroek et al., *Nature* (1990) 347, 281; *Neuron* (1992) 9, 1099). The roles of each of these channels in mediating the somatic calcium increase in response to depolarization may also differ. Individual CA3 neurons in cultured hippocampal slices were intracellularly injected with fura-2 and stimulated with a 20 Hz pulse train for 10 sec via an electrode placed at the soma or 200 μm along the apical dendrite. With somal stimulation, antagonists of L channels (1 μM nimodipine or isradipine) inhibited the somatic calcium increase by 56% while an antagonist of N channels (5 μM ω -conotoxin GVIA) had no effect. In contrast, with dendritic stimulation, both N and L channel antagonists inhibited the stimulus-induced somatic calcium increase by 35% and 47% respectively. Inhibitors of glutamate-mediated synaptic transmission via NMDA and non-NMDA receptors (100 μM AP-5 and 20 μM CNQX, respectively) inhibit the somatic calcium increase by 37% following dendritic but not direct somatic stimulation. L channel antagonists inhibited the somatic calcium transient remaining after AP-5 and CNQX by 40% while ω -conotoxin had only small effects. Our results indicate that L-type calcium channels play an essential role in somatic calcium transients in response to either direct somal or indirect dendritic stimulation consistent with their preferential localization in cell bodies, while N-type calcium channels only participate in calcium transients in response to dendritic stimulation consistent with their preferential localization in dendrites and presynaptic terminals.

720.17

THE EFFECTS OF VERAPAMIL AND EMOPAMIL QUATERNARY AMMONIUM SALTS ON EVOKED NEURONAL CALCIUM INFLUX AND 3H -D-ASPARTATE RELEASE. R.A. Keith*, T.J. Mangano, P.A. DeFoa, G.E. Ernst and E.J. Warawa. Depts. of Pharmacology and Medicinal Chemistry, Zeneca Pharmaceuticals Group., Wilmington, DE 19897.

Verapamil and emopamil are structurally related calcium channel/5-HT₂ receptor antagonists that differ in their ability to provide neuroprotection in experimental studies. The quaternary ammonium salts (QAS) of these compounds were prepared and tested in assays of neuronal calcium channel function to determine whether the compounds act at intra- or extracellular sites. The compounds were tested in K^+ -evoked: 1) rat brain synaptosomal $^{45}Ca^{++}$ influx, 2) release of 3H -D-aspartate from rat hippocampal brain slices, and 3) increase in intracellular calcium in neocortical neurons in primary culture. Verapamil, emopamil and the emopamil QAS caused concentration-dependent and comparable (IC_{50} values ~ 30-40 μM) inhibition of synaptosomal $^{45}Ca^{++}$ influx and 3H -D-aspartate release. The verapamil QAS was considerably less active in these assays (IC_{50} > 100 μM). The evoked increase of intracellular calcium in neocortical neurons was inhibited with the following rank order of potency (approximate IC_{50} value, μM): emopamil (5) > verapamil (15) > emopamil QAS (30) > verapamil QAS (>100). The results suggest that verapamil and emopamil inhibit nerve terminal calcium channel function (synaptosomal $^{45}Ca^{++}$ influx and 3H -D-aspartate release) by acting at distinct intracellular and extracellular sites, respectively. Verapamil may inhibit cell body calcium influx (evoked increase of intracellular calcium in neocortical neurons) by acting predominantly at intracellular sites, whereas emopamil may act at both intra- and extracellular sites.

720.14

DISTRIBUTION OF N-TYPE VOLTAGE-SENSITIVE CALCIUM CHANNELS IN DEVELOPING AND ADULT RAT BRAIN. B.D. Shivers*, J.M. Hopkins and P.D. Doyle. Neuroscience Pharmacology, Parke-Davis Pharmaceutical Research Division, Warner-Lambert Co., Ann Arbor, MI 48105.

Using the iodinated snail neurotoxin ω -Conotoxin MVIIA and the method of *in vitro* autoradiography, we localized N-type voltage-sensitive calcium channels (VSCCs) in developing and adult rat brain. In adult brain, N-type VSCCs were most abundant in olfactory bulb glomeruli, olfactory tubercle, cerebral cortex, caudate-putamen, CA1 hippocampal region, lateral septum and substantia gelatinosa in the spinal cord. N-type VSCCs were moderately abundant in the hypothalamus, superior colliculus, cerebellar molecular layer, midbrain, substantia nigra reticulata, medial geniculate and posterior lobe of the pituitary. A low density of N-type VSCCs was observed in the adrenal medulla. Removal of retinal projections eliminated most of the N-type VSCCs in the contralateral superior colliculus. N-type VSCCs were more widely expressed in perinatal than adult brain. These results suggest that N-type VSCCs are distributed throughout the neuroaxis existing on some neurons presynaptically where they regulate neurotransmitter release. In developing brain, the N-type VSCC may participate in activity-dependent changes in synaptic connectivity.

720.16

INHIBITION OF CALCIUM CURRENTS BY ZINC: PREFERENTIAL EFFECTS ON LOW VOLTAGE-ACTIVATED T CURRENTS AND ALLEVIATION OF ACTIONS BY ALBUMIN. S. Huck*, I. Steffan, M. Razavi and S. Boehm. Departments of Neuropharmacology and Analytical Chemistry, University of Vienna, A-1090 Vienna, Austria.

Interference of zinc with various ligand- and voltage-gated ion channels has attracted considerable attention in the recent past. We now report effects of zinc on the low voltage-activated (LVA) component which significantly exceeded the inhibition of high voltage-activated (HVA) Ca^{2+} currents. The effects of zinc were attenuated by albumin in a concentration-dependent manner. Whole cell Ca^{2+} currents were recorded in embryonic chick sensory neurons using the patch clamp technique. LVA Ca^{2+} currents were dissected from HVA components by step depolarizations to -30mV from a holding potential of -80mV and/or pretreatment of cells with ω -conotoxin GVIA. Zinc, applied in concentrations ranging from 0.8 μM to 800 μM readily and reversibly inhibited the LVA current with an IC_{50} of 30 μM . HVA components, induced by test pulses to +20mV, were inhibited by only 7% at a concentration of 50 μM Zn^{2+} . Effects of 100 μM Zn^{2+} on LVA Ca^{2+} currents were antagonized by bovine serum albumin (BSA) in a concentration-dependent manner. These experiments were conducted in order to reevaluate our previous observation that BSA selectively enhanced the LVA Ca^{2+} component (Huck et al., Soc. Neurosci. Abstr. Vol. 17, p.1158, 1991) and after having detected Zn^{2+} as a major contaminant in our previous perfusion system. The attenuation of Zn^{2+} effects is explained by its strong binding to albumin. We have measured free Zn^{2+} using inductively-coupled plasma atomic emission spectrometry (ICP-AES) in a quasi steady-state ultrafiltration assay with a Centrprep 30 (Amicon, M_r -cutoff 30kDa) concentrator. In the presence of 2mg/ml BSA, Zn^{2+} binding showed little saturation with concentrations ranging from 6.25 μM to 200 μM . High concentrations of Zn^{2+} ($\geq 1mM$) caused apparent denaturation of BSA. More than 95% were bound when 50 μM zinc were incubated with 2mg/ml BSA. Since Zn^{2+} is released at synaptic sites in the hippocampus, the effects on LVA Ca^{2+} currents may add to its range of physiological actions previously described. The binding of zinc (and other divalent cations) by albumin must be taken into consideration when albumin effects are observed in *in vitro* assay systems.

720.18

DUAL Na^+/Ca^{++} CHANNEL BLOCKERS INHIBIT 3H -NOREPINEPHRINE (3H -NE) RELEASE EVOKED BY K^+ -DEPOLARIZATION BUT NOT BY ELECTRICAL FIELD STIMULATION IN RAT NEOCORTICAL SLICES.

J.J. Geer*, S. Wurster and D.J. Dooley. Dept. of Neuroscience, Parke-Davis Pharmaceutical Research, Division of Warner-Lambert Co., Ann Arbor, MI 48106.

Both Na^+ and Ca^{2+} channels are important for synaptic neurotransmitter release. Na^+ channels propagate action potentials which activate voltage-sensitive Ca^{2+} channels in nerve endings, triggering exocytosis. *In vitro*, neurotransmitter release can be evoked by several methods. Electrical field stimulation closely mimics action potentials in time resolution and channel involvement. K^+ -depolarization clamps the membrane potential for an extended period of time and only partially depends on Na^+ channels. Using both stimulation protocols, we examined the effects of several lipophilic dual Na^+/Ca^{++} channel blockers on 3H -NE release. Rat neocortical slices preloaded with 3H -NE were stimulated either electrically with 90 pulses at 3 Hz or by increasing $[K^+]$ in the superfusion buffer from 3 mM to 25 mM for 2 min. The superfusion buffer contained the NE re-uptake blocker (+)-oxaprotiline (1 μM) and the α_2 -antagonist idazoxan (1 μM) to prevent autoinhibition. The amount of 3H -NE released by each stimulus was comparable, averaging 12% of tissue tritium. Lidoflazine (10 μM), R 58735 (10 μM), RS 87476 (3 μM), and flunarizine (10 μM), added to the superfusion buffer 30 min before the stimulation, did not affect electrically-evoked 3H -NE release, but inhibited K^+ -stimulated release by 45-65%. Furthermore, inhibition of K^+ -evoked 3H -NE release was concentration dependent.

A possible explanation for the stimulus-dependent effects of these drugs on 3H -NE release could be that they preferentially affect a Ca^{2+} channel state that is accessible only during the long-lasting membrane depolarization of a K^+ -stimulation but not during the shorter lifetimes of channel states during an electrical stimulation.

720.19

MULTIPLE COMPONENTS OF VOLTAGE-GATED CALCIUM CHANNEL CURRENTS IN ACUTELY ISOLATED GRANULE CELLS FROM THE RAT HIPPOCAMPUS. E.Viana* and B. Hille. Univ. of Washington, Dept. of Physiology & Biophysics, Seattle, WA 98195.

In the hippocampus, induction of some forms of LTP is calcium-dependent but independent of NMDA receptor activation suggesting a possible role for voltage-gated Ca^{2+} channels in the modulation of synaptic transmission. We used the whole-cell configuration of the patch-clamp technique to investigate properties of calcium channels in the soma and proximal dendrites of acutely isolated rat granule cells. From -90 mV, depolarizations to -30 mV revealed a small (<100 pA) inward current that inactivated rapidly and almost completely within 100 ms. From the same potential, steps to 0 mV activated a larger (200-1000 pA) inward current. This high-voltage activated (HVA) current peaked near -10 mV (5 mM Ba^{2+}) and had transient and sustained components with different steady-state inactivation properties. All of the HVA current was highly sensitive to Cd^{2+} (50% block at ~1 μ M), compared with ~20 μ M for the LVA current. The dihydropyridine Ca^{2+} channel agonist (+)-S-202-791 enhanced the peak HVA current and slowed the inward tail current at -40 mV. These effects were readily reversed by application of nifedipine (NIF), implicating L-type channels. 10 μ M NIF inhibited the peak current by 32±4% (mean±SE). Application of the N-type channel blocker ω -conotoxin GVIA (CTX) caused a further 15±1% reduction of the barium current. In addition, a large fraction (~50%) of the HVA current was blocked irreversibly by application of 500 nM synthetic ω -agatoxin IVA (AGA), suggesting the presence of P-type channels. The combined application of NIF, AGA and CTX spared ~20% of the peak HVA current. In contrast, the low-threshold current was insensitive to all three agents.

In summary, we present evidence for multiple pharmacological components of transient and sustained barium currents in granule cells. (Supported by USPHS grant #NS08174 and the W.M.Keck and McKnight Foundations.)

CALCIUM CHANNEL PHARMACOLOGY AND MODULATION IV

721.1

BIOLOGICAL CHARACTERIZATION OF A P-TYPE CALCIUM CHANNEL BLOCKER, ω -Aga-K, FROM AGELENOPSIS APERTA SPIDER VENOM. L.D. Hirning^{*1}, A.L. Mueller¹, N. Alasti¹, L.D. Artman¹, E.G. Delmar¹, E.F. Nemeth¹, T.N. Parks², W.R. Gray², B.C. Albensi² and H. Jackson¹. ¹NPS Pharmaceuticals, 420 Chipeta Way, Salt Lake City, UT 84108 and ²University of Utah, Salt Lake City, UT 84132.

The venom of the funnel-web spider *Agelenopsis aperta* contains a number of peptides which block voltage-sensitive Ca^{2+} channels (VSCC) (*Ann. Rev. Neurosci.* 12:405, 1989). One such peptide was shown previously to block synaptic transmission in the chick cochlear nucleus by a presynaptic mechanism involving VSCC blockade (*Soc. Neurosci. Abstr.* 12:730, 1986). The amino acid sequence of this peptide, ω -Agatoxin-K (ω -Aga-K), was determined in 1986 (48 amino acid residues, 4 disulfide bonds, 5.3 kD) and disclosed in U.S. Patent #5,122,596. Recently, ω -Aga-K was identified independently by M. Adams as ω -Aga-IVB.

P-type Ca^{2+} channel current recorded in cerebellar Purkinje cells is blocked potently (IC_{50} = 30 nM) by ω -Aga-K. N-type and L-type VSCC in a variety of cell types (N1E-115 cells, cerebellar granule neurons, sympathetic neurons) are less sensitive to ω -Aga-K. ω -Aga-K blocks DHP/ ω -CgTx-resistant cerebellar Ca^{2+} spikes, but is less effective against hippocampal Ca^{2+} spikes. ω -Aga-K is a more efficacious blocker of glutamatergic EPSPs (83% block, IC_{50} = 252 nM) than monosynaptic GABAergic IPSPs (46% block, IC_{50} = 199 nM) in rat hippocampal slices; ω -CgTx displays the reverse efficacy. ω -Aga-K inhibits the Ca^{2+} -dependent release of tritiated neurotransmitters, being more effective than ω -CgTx at blocking the release of DA from the striatum (55% block, IC_{50} = 100 nM), and GABA from the striatum (100% block, IC_{50} ~ 100 nM) or hippocampus (45% block, IC_{50} ~ 100 nM). The release of ACh from either striatum or hippocampus is relatively unaffected by ω -Aga-K. These data together identify ω -Aga-K as a unique probe with which to identify and characterize VSCC in the mammalian CNS.

PRODUCTION AND BIOLOGICAL CHARACTERIZATION OF SYNTHETIC ω -Aga-IVA. M.K. Ahljianian*, G. Andrews, B. Guarino, N.A. Saccomano, L.D. Hirning#, A.L. Mueller#, N. Alasti# C.J. Siok, M.J. Welch, A.H. Ganong, R.A. Volkman, Pfizer Inc., Central Research Division, Groton, CT 06340 and #NPS Pharmaceuticals, Salt Lake City, UT 84108. ω -Aga-IVA, a 48-amino acid peptide toxin isolated from the spider *Agelenopsis aperta*, selectively blocks P-type voltage-dependent calcium channels. Using solid phase methods, we synthesized ω -Aga-IVA and characterized its calcium channel antagonist activity in a variety of functional assays. In rat cerebellar Purkinje cells, synthetic (s) ω -Aga-IVA inhibits whole cell calcium current by greater than 90% at a concentration of 100 nM. The IC_{50} is 5 nM and relief of block was voltage-dependent. In rat brain synaptosomes, s ω -Aga-IVA inhibits up to 85% of potassium-stimulated ^{45}Ca flux with an IC_{50} of 30 nM. In the latter two assays, ω -conotoxin GVIA (CgTx) (1 μ M) and nimodipine (10 μ M) are only marginally effective. s ω -Aga-IVA inhibits calcium-dependent 3H -GABA release from rat striatal and hippocampal slices. s ω -Aga-IVA (3 μ M) also completely blocks Schaeffer-CA1 field potentials. CgTx maximally blocks this response by 39% at a concentration of 3 μ M. In no experiment could the actions of ω -Aga-IVA be distinguished from those of native ω -Aga-IVA. The biological activity of s ω -Aga-IVA unequivocally identifies this molecule as a selective antagonist of P-type calcium channels. s ω -Aga-IVA will serve as an important tool for probing the function of P-type calcium channels.

720.20

EFFECTS OF Ca^{2+} CHANNEL BLOCKERS ON THE K^{+} - or 4-AMINOPYRIDINE EVOKED $[Ca^{2+}]_i$ INCREASE AND DOPAMINE RELEASE IN RAT STRIATUM SYNAPTOSOMES. C.M. Carvalho, C.B. Duarte, I.L. Ferreira and A.P. Carvalho*. Center for Neurosciences of Coimbra, Dep. of Zoology, Univ. of Coimbra, 3049 Coimbra Codex, Portugal

Depolarization of striatum synaptosomes with 20 mM KCl transiently increases the $[Ca^{2+}]_i$ by about 300 nM, and evokes the release of 18.8±1.4% of the total $[^3H]$ dopamine ($[^3H]$ DA). 4-aminopyridine (4-AP) at 1 mM rises the $[Ca^{2+}]_i$ by about 200 nM and releases 20.4±3.4% of the total $[^3H]$ DA. Nitrendipine (1 μ M) decreases the change in $[Ca^{2+}]_i$ evoked by K^{+} and 4-AP by, respectively, 7% and 13%, whereas it decreases $[^3H]$ DA release by 20% and 23%, respectively. ω -Conotoxin GVIA (ω -CgTx) at 0.5 μ M more effectively blocked the effect of 4-AP on the $[Ca^{2+}]_i$ than on the release of $[^3H]$ DA. Neomycin (0.35 mM) blocked by, respectively, 32% and 50% the $[Ca^{2+}]_i$ increase stimulated by K^{+} or 4-AP depolarization. Similarly, neomycin inhibits potently the release of $[^3H]$ DA evoked by the two agents. Neomycin and ω -CgTx together further inhibited the effects of K^{+} and 4-AP on the $[Ca^{2+}]_i$ and $[^3H]$ DA release. Our results indicate that striatal synaptosomes are endowed with ω -CgTx-sensitive (N-type) and nitrendipine-sensitive (L-type) calcium channels, both coupled to the release of $[^3H]$ DA. The neomycin-sensitive and ω -CgTx- and nitrendipine-insensitive channels may be P-type channels (Supported by INIC and JNICT).

721.2

TWO NEW AGELENOPSIS SPIDER PEPTIDE P-TYPE CALCIUM CHANNEL BLOCKERS ARE FOLDING ISOMERS. A.H. Ganong*, N.A. Saccomano, L.D. Hirning*, A.L. Mueller*, C.J. Siok, D. Phillips, S.D. Heck, M.K. Ahljianian, and R.A. Volkman. Pfizer Inc, Central Research Division, Groton, CT 06340 and †NPS Pharmaceuticals, Salt Lake City, UT 84108.

The venom from the funnel web spider *Agelenopsis aperta* has been a rich source of neuroactive peptides, including ω -Aga-IVA which is a selective P-channel blocker (Mintz *et al.*, *Nature*, 1992, 355, 827; Hirning *et al.*, *Neurosci. Abstr.*, 1992, 18, 970). We report here two new P-channel antagonist peptides from *Agelenopsis* venom. These 48 amino acid peptides, termed ω -Aga-K and ω -Aga-K2, have identical amino acid sequences, but are chromatographically distinct on RP-HPLC. Their primary structure (including 8 cysteines) is similar to that of ω -Aga-IVA. The current data suggest that ω -Aga-K and ω -Aga-K2 can interconvert, and therefore, may differ in disulfide bonding pattern.

ω -Aga-K and ω -Aga-K2 are potent (IC_{50} < 100 nM) and fully efficacious blockers of P-channels as evidenced by their inhibition of barium currents in whole-cell recordings from rat Purkinje neurons. These peptides do not block ω -conotoxin GVIA-sensitive barium currents in IMR32 cells. ω -Aga-K does not block fast Na^{+} currents or TEA-sensitive K^{+} currents recorded in IMR32 cells at 10 μ M.

Both peptides inhibit ω -conotoxin GVIA/nifedipine-resistant $^{45}Ca^{2+}$ uptake into rat brain synaptosomes and show efficacious inhibition of synaptic transmission of the Schaeffer-CA1 synapse in rat hippocampal slices. These new peptides will be useful in defining the functional role of P-channels in central neurons. (see Hirning *et al.*, this volume.)

P-LIKE Ca^{2+} CHANNELS IN HUMAN CEREBELLUM AND SMALL CELL LUNG CARCINOMA BIND ω -CONOTOXIN-MVVIC AND ARE IMMUNOPRECIPITABLE BY LAMBERT-EATON MYASTHENIC SYNDROME (LES) IgGs THAT REACT HIGHLY WITH N-TYPE Ca^{2+} CHANNELS. VA Lennon, T Kryzer, GE Griesmann, NA Pinsky, G Miljanich¹, J Ramachandran¹, EH Lambert^{2*}. Mayo Clinic, Rochester, MN 55905; ¹Neurex Corp., Menlo Park, CA 94025; ²University of Minnesota, Minneapolis, MN 55455.

RNA transcripts encoding a human neuronal class A (P-like) voltage-gated Ca^{2+} channel (VGCC) were recently identified in a small cell lung carcinoma (SCLC) cell line (*Mayo Clin Proc* 67:1150, 1992). This suggested that a tumor-associated P-like VGCC might be the antigen that induces certain autoimmune paraneoplastic neurologic disorders in patients with SCLC. We therefore investigated in 3 SCLC lines (2 from patients with neurologic autoimmunity, 1 without) the effect of the synthetic P-like VGCC antagonist ω -CTX-MVIC (SNX-230; *Neuron* 9:69, 1992) on depolarization-dependent $^{45}Ca^{2+}$ influx. All 3 were inhibited, to a maximum of 73±4.5% (mean±SE) compared with 23±4.7% for ω -CTX-GVIA (Peninsula Labs, at 1×10^{-4} M). The IC_{50} for MVIC inhibition of Ca^{2+} influx was $\sim 1 \times 10^{-7}$ M. A specific binding site for ^{125}I -labelled MVIC was found in digitonin-solubilized membranes of SCLC (~2 fmol/mg protein) and cerebellum (~1300 fmol/mg). Solubilized cerebellar MVIC receptors (K_d ~300 pM) were immunoprecipitated by IgG from 0 of 7 patients with SCLC-related autoimmune CNS disorders and 0 of 5 normal subjects, but were precipitated by IgG in 3 of 4 LES patients' sera that were highly reactive with GVIA receptors. The data suggest that neuronal P-like and N-type VGCC may be related antigenically. (Supported by NCI grant CA-37343).

721.5

CALCIUM CHANNEL SENSITIVITY TO *AGELIENOPSIS APERTA* VENOM MEASURED BY STOPPED-FLOW FLUORIMETRY IN RAT BRAIN SYNAPTOSOMES. M.M.Thomas* and S.M.J.Dunn Dept. of Pharmacology, U. of Alberta, Edmonton, Canada T6G 2H7

The sensitivity of voltage-dependent calcium channels to crude venom and isolated venom components from the funnel web spider, *Agelenopsis aperta*, has been measured in synaptosomal preparations from rat brain. Synaptosomes were loaded with the calcium chelating dye, Fura 2-AM and depolarization-dependent changes in intra-synaptosomal free calcium concentration were measured in stopped-flow experiments by following the fluorescence quench of the entrapped dye. Rapid mixing with a high potassium (30mM_{final}) buffer resulted in an increase in intrasynaptosomal calcium concentration. Crude spider venom blocked 50% of the observed response. The dose dependency was apparently biphasic with IC₅₀ values of 100ng/mL and 16µg/mL. FTX, a polyamine fraction from the venom effectively blocked 40% of the quench (IC₅₀=4nL/mL) and synthetic FTX blocked the response at millimolar concentrations. ω-Aga IVA, a polypeptide toxin purified from *A. aperta* blocked the effect at micromolar concentrations. In the same preparations, dihydropyridine antagonists and ω-conotoxin GVIA had little effect on the observed responses. Calcium channels in mammalian nerve terminals are thus sensitive to spider venom components but not other calcium channel ligands. Supported by AHFMR and Toupin Foundation.

FTX-INDUCED P-TYPE CALCIUM CHANNEL BLOCKADE (P-CCB) INHIBITS SYNAPTIC TRANSMISSION IN THE CANINE STELLATE GANGLION (SG). HK Schedewie, N Boban and JP Kampine* Department of Anesthesia, Medical College of Wisconsin, Milwaukee, WI 53226

We have previously shown that N-type calcium channel blockade (N-CCB) inhibits synaptic transmission in the SG by about 50%, whereas L-type CCB had insignificant effects. The present study was designed to investigate the *in vitro* effects on synaptic transmission of FTX spider toxin (courtesy Dr. Llinas), the prototype of a new class of potent CCB that inhibit high-threshold voltage-gated P-channel calcium conductance. Six SG were isolated from adult mongrel dogs, desheathed and superfused with Krebs' buffer at pH 7.4 and 37°C. Compound action potentials (CAP) were generated by supramaximal stimulation of the pre-ganglionic T₃-ramus and were recorded from the ventral *ansa subclaviae*. The percent CAP change from control was measured after SG superfusion for 1 hour, each, with dilutions of 2, 4 and 6 x 10⁻⁵ of partially purified FTX. Superfusate Ca²⁺ concentrations were then doubled from 1.25 to 2.5 mM and finally SG were exposed to dexmedetomidine (DMT) and atipamezole (ATI) to assess the effect of combined P- and N-type CCB. **Results:** 1. P-CCB caused profound inhibition of synaptic transmission in the SG in a dose-dependent fashion (p <0.01); 2. Increasing extracellular calcium concentrations were only partially able to overcome P-CCB; 3. DMT-induced N-CCB was additive with P-CCB (p <0.01); 4. ATI failed to reverse the effects of DMT, suggesting possible interference by FTX at the N-type calcium channel. **Conclusion:** P-type channel calcium transport seems to play an essential role in the process of synaptic transmission in the peripheral sympathetic nervous system. Mode and site of action appear to be distinct from N-channel calcium conductance.

PHARMACOLOGICAL PROPERTIES AND LOCALIZATION OF CALCIUM CHANNEL TYPES IN THE CEREBELLAR CORTEX. P. A. Doroshenko, A. Woppmann, G. Miljanich, G.J. Augustine*. Dept. Neurobiol., Duke Univ. Medical Center, NC 27710 and Neurex Corp., Menlo Park, CA 94025.

We have used whole-cell patch clamp recordings from Purkinje cells in thin slices of cerebellum to examine the ability of a variety of synthetic peptide toxins to block Ca channels. We first screened the activity of three peptide toxins: (1) SNX-111, (MVIIA) which blocks N-type Ca channels with higher affinity than the "classical" conotoxin (GVIA); (2) SNX-230 (MVIIC), which blocks a class of Ca channels that are not sensitive to blockers of N- or L-type Ca channels (Neuron 9: 69, 1992); and (3) SNX-260, an analog of SNX-230 which exhibits higher affinity and specificity for SNX-230-sensitive channels. Excitatory PSCs evoked by stimulation of either climbing fiber (CF) or parallel fiber (PF) inputs, as well as Purkinje cell Ca currents, were blocked by SNX-230 and SNX-260 (1-10 µM), but not SNX-111. Interestingly, inhibitory PSCs spontaneously produced by electrical activity of interneurons were not eliminated by any of these compounds. We next used confocal laser-scanning microscopy to visualize the binding of a biotinylated derivative of SNX-260 associated with streptavidin-Texas Red. Punctate high-affinity toxin labeling was found throughout the molecular layer and may correspond to the presynaptic terminals of the parallel fibers. Other high-affinity sites were found in the granule cell layer, perhaps staining presynaptic terminals that innervate granule cells. Lower affinity binding sites were visualized on Purkinje cell dendrites, where SNX-260-sensitive Ca channels are known to reside, as well as on the cell bodies of granule cells. We conclude that the Purkinje cell Ca channels cannot as yet be distinguished from those of the PF or CF presynaptic terminals. However, the excitatory and inhibitory presynaptic terminals of the cerebellar cortex clearly possess different types of voltage-gated Ca channels. This presumably imparts different regulatory properties on transmission at the two types of synapses. Partially supported by a HFSP grant to GJA.

FTX SELECTIVELY BLOCKS P-TYPE CALCIUM CURRENT IN HIPPOCAMPAL AND OLIVARY NEURONS.

A. Manfredi*, S. Charpak, B. Cherksey, M. Sugimori and R. Llinas. Department of Physiology & Biophysics, New York University Medical Center 10016 N.Y.

Funnel web spider toxin (FTX) blocks the high-threshold calcium spikes in adult cerebellar Purkinje cells by acting on P-type calcium channels (Llinas et al. PNAS 86, 1689,1989). These channels cannot be distinguished from N- and L-types channels on the basis of their single-channel conductances (Usowicz et al. Neuron 9, 1185, 1992). Since FTX could in principle interact with more than one channel subtype, we addressed the issue of its selectivity in inferior olive neurons and in hippocampal dentate gyrus granule cells, by performing whole-cell recordings in adult guinea pig brain slices. Olivary neurons exhibit a low-voltage transient T-current and a slowly inactivating high-voltage current that underlie, respectively, the low-threshold and high-threshold calcium spikes. Purified FTX did not affect the former while it almost entirely blocked the latter. L- and N-type channel blockers (nifedipine 20 µM, ω-conotoxin GVIA 4 µM) were ineffective. In contrast, the P-type current contributed in the range of 40% of the high-voltage current in hippocampal granule neurons, the remaining being blocked by ω-conotoxin (~ 15%) and nifedipine (~ 40%). Our results suggest that P-channels are differently distributed in the CNS and that they can be selectively discriminated on the basis of their sensitivity to FTX.

721.8

N Channel Inhibitory Activity of the Polyamine Funnel Web Spider Toxin, FTX, synthetic FTX and Spermine. M. G. Hamilton, R. Frew and P. M. Lundy* Pharmacology and Therapeutics, Defence Research Establishment Suffield, Box 4000, Medicine Hat, AB T1A 8K6

The P channel inhibitor isolated from the funnel-web spider *Agelenopsis aperta*, known as funnel-web toxin (FTX), its synthetic analogue sFTX, and their structural analogue spermine were examined for effects on K⁺ stimulated Ca²⁺ influx and ωCgTx binding. In chicken brain synaptosomes, which contain exclusively N type VSCCs, FTX (1 µL/mL), sFTX (1-5 mM) and spermine (1-5 mM) all caused concentration dependant inhibition of K⁺ stimulated Ca²⁺ influx. The N channel blocker ωCgTx (1 µM) reduced influx by 97%, while Cd²⁺, very dilute *Hololena curta* venom and a partially purified fraction from this venom, all also markedly reduced K⁺ stimulated Ca²⁺ influx. In comparable studies using rat brain synaptosomes, spermine and sFTX reduced Ca²⁺ influx in a concentration related fashion while FTX (1µL/ml) totally abolished influx. Maximal inhibition of influx by ωCgTx was 25% while *Hololena curta* venom (1:2,500 dilution) and Cd²⁺ (50µM) reduced influx by >80%. Spermine and sFTX both inhibited [¹²⁵I]ωCgTx binding to rat and chicken synaptosomal membranes. These results strongly suggest that sFTX and FTX in addition to their blocking activity at the P channel, have major inhibitory effects on pharmacologically defined N type Ca²⁺ channels.

RADIOAUTOGRAPHIC COMPARISON OF THE DISTRIBUTION OF HIGH AND LOW AFFINITY BINDING SITES FOR [¹²⁵I]ω-CONOTOXIN GVIA IN RAT BRAIN: INFLUENCE OF CALCIUM. S. Vandaele⁽¹⁾ and T. Reader⁽²⁾. ⁽¹⁾Unité de neurocytologie moléculaire, Département de pathologie, and ⁽²⁾Département de physiologie, Université de Montréal, Montréal, Québec, Canada.

The N-type calcium channel ligand [¹²⁵I]ω-Conotoxin GVIA (ω-CgTx) was used at low (30 pM) and high concentrations (300-500 pM) to compare in rat brain the distribution of high and low affinity binding sites (apparent K_d in the 15 pM and 500 pM range respectively). Sections were incubated with *ω-CgTx (2000 Ci/mmol) according to Maeda et al. (*Brain Res.* 489:21, 1989) in the absence or in the presence of Ca⁺⁺. Without Ca⁺⁺, the high affinity binding sites appeared uniformly distributed throughout brain, except for higher densities in the granular and pyramidal layers of hippocampus, the layer II of piriform cortex, the layer IV of cerebral cortex, and the granular layer of cerebellum. The low affinity binding sites were similarly distributed, except that the molecular layer of cerebellum was now more densely labeled than the granular layer. The presence of 30mM Ca⁺⁺ greatly diminished *ω-CgTx binding in most brain regions, and lead to identical distribution patterns for low and high affinity sites. Some regions were more densely labeled than others. The highest density of *ω-CgTx binding sites was found in cerebral cortex, basal ganglia, neuropil layers of hippocampus, substantia nigra, and the molecular layer of cerebellum, while lower densities of *ω-CgTx binding sites were found in the other brain regions. Almost no labeling was found in densely cellular layers, such as the granular and pyramidal layers of hippocampus, the layer II of piriform cortex, the Purkinje cell layer of cerebellum. These results are consistent with the existence of several families of ω-CgTx binding sites in the central nervous system, some of which may be characterized by their sensitivity to Ca⁺⁺. If associated to presynaptic calcium channels, these Ca⁺⁺-sensitive *ω-CgTx binding sites could be preferentially located on inhibitory terminals contacting nerve cell bodies. Supported by the Savoy Foundation (S.V.)

721.11

N-TYPE (CLASS B) NEURONAL Ca^{2+} CHANNELS EXPRESSED IN SMALL CELL LUNG CARCINOMAS OF PATIENTS WITH AND WITHOUT LAMBERT-EATON MYASTHENIC SYNDROME (LES). M Oguro-Okano, GE Griesmann, T Kryzer, ED Wieben[†], VA Lennon*, Depts. of Immunology, Neurology, Laboratory Medicine & Pathology, and [†]Biochemistry & Molecular Biology, Mayo Clinic, Rochester, MN 55905.

We previously reported cloning from a prototypic small cell lung carcinoma (SCLC) line two cDNA fragments encoding a P-type (class A) voltage-gated Ca^{2+} channel (VGCC) and a neuroendocrine form (class D) of L-type VGCC (*Mayo Clin Proc* 67:1150, 1992). By reverse transcription of RNA and PCR amplification of cDNA, we have now identified transcripts for the ω -conotoxin-GVIA-sensitive class B VGCC in all of 9 SCLC cell lines, 4 derived from patients with the paraneoplastic neuromuscular disorder LES, and 5 from patients without LES. Oligonucleotide primers encompassing the class B α_1 subunit sequence encoding domain II, S2 through S5, yielded a PCR product of 488 base pairs. Sequencing of several clones revealed a cDNA fragment predicted to encode a VGCC of N-type. No PCR product was obtained using RNA from a colonic carcinoma line derived from a patient with LES, nor using RNA from a human B lymphoma. A protein in digitonin-solubilized SCLC membranes bound ¹²⁵I- ω -CgTx-GVIA with high affinity ($K_d = 3$ pM), and was immunoprecipitable by LES IgG. Production of pathogenic autoantibodies that impair the stimulated release of neurotransmitter in peripheral cholinergic synapses presumably reflects a genetically determined immune response initiated by an immunogenic form of class B VGCC expressed in SCLC. (Supported by National Cancer Institute grant CA-37343).

ω -Conotoxin-Sensitive and Insensitive Calcium Channel Subtypes in the Soma and Nerve Terminals of a Mammalian Central Neuron. T.E. Fisher^{*} and C.W. Bourque. Centre for Research in Neuroscience, Montreal General Hospital and McGill University, Montreal, Canada, H3G 1A4.

Calcium channel subtypes are likely to be selectively distributed within the neuron in order to execute specific functions. We have therefore undertaken a comparative study of calcium channels in isolated somata and nerve endings of the magnocellular neurosecretory cells (MNCs) of the rat supraoptic nucleus. Standard whole-cell patch clamp techniques have shown previously that while only the somata express a "T-like" calcium current ($\tau = 30$ ms), both preparations express a more slowly inactivating calcium current component(s) ($\tau = 200$ ms). In the present work we have used the "N-type" specific blocker ω -conotoxin GVIA (ω -CgTx) to further characterize this slowly inactivating current in the two preparations. In the terminals, ω -CgTx blocks over 80% of the total inactivating current with a IC 50 of about 50 nM. In the somata however, μ M concentrations of ω -CgTx block only about 35% of the slowly inactivating current. These data suggest that there is a distinct component of slowly inactivating calcium current that is insensitive to block by ω -CgTx and that is expressed predominantly in the somata of the MNCs.

PHARMACOLOGY OF WHOLE-CELL CALCIUM CURRENTS IN HIPPOCAMPAL DENTATE GRANULE NEURONS. L.S. Eliot^{*} and D. Johnston, Div. Neuroscience, Baylor Coll. Medicine, Houston, TX 77030

Hippocampal granule cells contain at least 3 different types of voltage-gated Ca^{2+} channels (Fisher et al., *J. Neurophys.* 64:91), raising the possibility that distinct channel types underlie different Ca^{2+} -dependent functions of the neuron, particularly, synaptic transmission from their mossy fiber terminals. As a first step in testing this hypothesis, we are identifying antagonists for the various channel types using whole-cell voltage clamp in acutely dissociated granule cells. Whole-cell Ba^{2+} currents activate around -30 mV, peak at +5 to +10 mV, reverse around +50 mV, and are completely blocked by 200 μ M Cd^{2+} when elicited either with step or ramp (2.2 mV/ms) commands from -70 mV. The dihydropyridine antagonist, nimodipine (5 μ M), blocks just under 40% of peak Ba^{2+} current whether elicited by steps (39.0 \pm 3.1%, n=5) or ramps (38.1% \pm 3.9%, n=11). Nimodipine blocks in a dose as low as 100 nM (20.3 \pm 0.3%, n=3) and saturates between 2 μ M and 5 μ M, with 10 μ M blocking 39.5 \pm 1.4% of peak current (n=3). The snail toxin, ω -conotoxin GVIA (CgTx, 3-6 μ M), blocks 22.7 \pm 2.7% of peak current (n=7). CgTx is effective at lower doses, but 3 μ M acts rapidly and appears saturating since subsequent application of 6 μ M produces no additional block. Applied together, saturating doses of nimodipine and CgTx block 58.9 \pm 1.1% of peak current (n=5), indicating that the two antagonists do not occlude each other and that they act specifically in granule cells at L-type and N-type channels, respectively. Both blockers inhibit larger fractions of total current from -40 mV holding potentials, suggesting that the remaining, nimodipine- and CgTx-resistant current is inactivated at depolarized potentials. We are currently investigating whether components of this residual current are blocked by putative T-channel blockers and by the P-channel blocker, ω -agatoxin IVA. (NS09255, MH44754, and MH48432.)

PHARMACOLOGICAL PROPERTIES OF LOW-VOLTAGE-ACTIVATED CA CHANNELS IN UNDIFFERENTIATED HUMAN RETINOBLASTOMA CELLS. A. Juhasz, L.W. Haynes and S. Barnes, Neuroscience Research Group, University of Calgary, Alberta, Canada T2N 4N1.

Undifferentiated human retinoblastoma cells (Y-79 and WERI) produce oscillations and action potentials under current clamp due to transient Ca channel activation. These channels appear similar to other T-type channels on the basis of gating kinetics and single channel conductance (Barnes & Haynes, *Brain Res.* 598:19-22), but they have been considered unique due to both a reported requirement for Ca to gate and a relatively high sodium/calcium permeability ratio (Gomez et al., *Invest. Ophthalmol. Vis. Sci.* 29:243, 1988). The aim of the present work was to characterize these channels pharmacologically to allow further comparison with existing Ca channel descriptions.

In contrast to the previous study (which used TMA), equimolar replacement of sodium with N-methyl-D-glucamine in the bathing medium had no effect on the magnitude of macroscopic barium current. Furthermore, in the presence of 10 mM barium, addition of extracellular calcium at 0, 0.1, 1 and 5 mM had no effect on channel gating, but did reduce the transient current in a manner consistent with the mole fraction effect. Comparative blocking efficacies of cadmium ($K_{1/2} = 110 \pm 26$ μ M, n=5, SE) and nickel ($K_{1/2} = 75 \pm 14$ μ M, n=6) are in the range expected for T-type Ca channels. Nifedipine (10 μ M) had almost no effect on the transient barium current, but completely (n=3) or partially (n=1) blocked it at 100 μ M. ω -conotoxin GVIA (3 μ M) had no effect, ruling out characterization as N-type, but the failure of ethosuximide (5 mM) to block and the weak block (5%) by amiloride (100 μ M) suggest that this retinoblastoma Ca channel falls loosely within a T-type classification.

Supported by the Medical Research Council of Canada and the Alberta Heritage Foundation for Medical Research.

CHARACTERIZATION OF ω -CONOTOXIN RECEPTOR / N-TYPE CALCIUM CHANNEL IN IMR32 AND PC12 CELLS H. Liu, D. R. Witcher, M. Pragnell, J. D. Coulter*, K. P. Campbell, HHMI, Neuroscience Program and Dept. of Physiology and Biophysics, University of Iowa College of Medicine, Iowa City, IA 52242

In order to characterize calcium channels in human neuroblastoma IMR32 cells and rat pheochromocytoma PC12 cells, various antibodies were tested for their ability to recognize ω -conotoxin (ω -CgTx) receptor / N-type calcium channel from these two cell lines. Both cell lines express the ω -CgTx receptor ($K_d = 0.8 \pm 0.2$ nM, $B_{max} \sim 500$ fmol/mg for PC12 and $B_{max} = 240 \pm 70$ fmol/mg for IMR32) as shown by ¹²⁵I- ω -CgTx binding. A monoclonal antibody VD21 which is directed against a common region on all β subunits and polyclonal antibody sheep-46 which recognizes the rabbit brain ω -CgTx receptor complex, immunoprecipitate ω -CgTx receptor from both cell lines as well as from rabbit brain. This suggests that N-type calcium channel has epitopes in human and rat which are similar to that of rabbit brain. Polyclonal antibodies affinity-purified from a rabbit brain β C-terminal fusion protein which is specific to the rabbit brain β subunit of ω -CgTx receptor, also immunoprecipitates ω -CgTx receptor from these two cell lines as well as from the rabbit brain, suggesting that the receptor in all three species may be the same β gene product in the ω -CgTx receptor. Polyclonal antibodies affinity-purified from fusion proteins, one recognizing rabbit brain α_{1B} specific loop region between the second and third repeats of α_1 subunit, the second recognizing α_{1B} specific C-terminal region, immunoprecipitate ω -CgTx receptor from these two cell lines as well as from rabbit brain, suggesting that ω -CgTx receptor in all three species consist of an α_{1B} subunit as well as a β subunit. We are currently studying biosynthesis, phosphorylation regulation and subunit composition of calcium channels in these cell lines.

721.16

AUTORADIOGRAPHIC LOCALIZATION OF [¹²⁵I] ω -CONOTOXIN GVIA BINDING SITES IN HUMAN HIPPOCAMPUS AND CEREBELLUM. B.C. Albensi¹, K.T. Rvujin^{2,3}, J.M. McIntosh^{4,5}, S.R. Naisbitt⁵, B.M. Olivera⁵ and F. Filloux^{2,3,4}. Neurosci. Prog. 1 and Depts. of Neurol.², Pediatr.³, Psychiat.⁴, and Biol.⁵, Univ. Utah, Salt Lake City, UT 84132.

Only limited studies of ω -conotoxin GVIA (ω -CgTx) binding to human nervous tissue have been performed to date. We describe the labeling of human hippocampus and cerebellum with [¹²⁵I] ω -CgTx in order to characterize the distribution of N-type Ca^{++} channels. A pattern similar to that present in rodent brain is described. Human tissue was obtained at autopsy from three individuals dying of non-neurological causes. Slide-mounted tissue sections (10 μ M) of hippocampal formation and lateral cerebellar hemisphere were labeled with 200 pM [¹²⁵I] ω -CgTx for association/dissociation and "mapping" experiments, and with varying concentrations (5 pM to 5 nM) for saturation analysis. Autoradiograms were quantitated using image analysis. The binding of [¹²⁵I] ω -CgTx to human brain is primarily irreversible and saturable under these conditions with an estimated K_D of 910 pM and B_{max} of 11.5 fmole/mg tissue. The distribution of binding sites is heterogeneous. Densest binding within hippocampus is seen within the hilus of the dentate gyrus (2.65 fm/mg tiss), the pyramidal layer (2.45 fm/mg tiss CA1) and in the adjacent str. radiatum (1.87 fm/mg tiss CA3). Within the cerebellum, binding is denser in the molecular layer (2.17 fm/mg tiss) than in the granule cell layer (1.54 fm/mg tiss). Binding within white matter tracks is lowest overall. These findings suggest that ω -CgTx may serve as a valuable tool for future studies of N-type Ca^{++} channels in human brain.

SPECIFIC LOCALIZATION OF OMEGA-CONOPEPTIDE SNX-230 (MVIIC) BINDING SITES IN THE MOUSE NEUROMUSCULAR JUNCTION. Y. Sugiura*, C-P. Ko, A. Wopmann and G. Miljanich. Dept. Biol. Sci., Univ. Southern California, Los Angeles, CA 90089. NEUREX Corp., Menlo Park, CA 94025.

SNX-230 (MVIIC) and its analog, SNX-260, inhibit transmitter release at the mouse neuromuscular junctions (NMJ) by blocking non-N type voltage-sensitive Ca^{++} channels (see abstract by Bowersox, et al). The present study aimed to examine if SNX-260 can be used as a specific probe for the localization of voltage-sensitive Ca^{++} channels in the mammalian NMJ. Mouse diaphragm muscles were incubated with biotinylated SNX-260 (3 μ M) which, like native SNX-260, blocked transmitter release. The muscles were then stained with FITC-ultra-avidin and double-labeled with rhodamine conjugated α -bungarotoxin (BTX). The fluorescence microscopic observations revealed that SNX-260 recognized NMJs which were identified with BTX staining. Control muscles pretreated with native SNX-260 and followed by the above procedures showed no labeling at the NMJ. The structure labeled by SNX-260 was thinner than and outlined by acetylcholine receptor clusters. In addition, spots of labeling with SNX-260, which might be indicative of active zones, could sometimes be seen. SNX-260 also stained some nerve fibers leading to the NMJ. The labeling with SNX-260 disappeared after muscles were treated enzymatically to remove the nerve terminal. Furthermore, SNX-260 labeling was not observed in denervated muscles. These findings suggest that SNX-260 binding sites are located in the nerve terminal and are consistent with the physiological data that SNX-260 blocks voltage-sensitive Ca^{++} channels in the mammalian NMJ. (Supported in part by NIH grant NS 30051 to CPK)

721.19

INTERACTION OF PRESYNAPTIC CALCIUM CHANNELS WITH SYNAPTOTAGMIN AND SYNTAXIN. M.J. Seagar*, A. Yoshida, C. Leveque, N. Martin-Moutot, O. El Far, P. David, B. Lang, J. Newsom-Davis and M. Takahashi. INSERM U374, Faculté de Médecine Nord, 13916 Marseille 20, France; Mitsubishi Kasei Institute of Life Sciences, Tokyo, Japan; Institute of Molecular Medicine, John Radcliffe Hospital, Headington, Oxford, UK.

The synaptic vesicle protein synaptotagmin (p65) associates with ω -conotoxin GVIA (wCgTx) sensitive calcium channels and is thought to be a target for autoantibodies from patients with Lambert-Eaton myasthenic syndrome (LEMS), an autoimmune disease which affects neurotransmitter release. The specificity of LEMS IgG has been examined using proteolytic cleavage and a panel of sequence-directed anti-synaptotagmin antibodies.

The synaptotagmin/calcium channel interaction involves syntaxin (HPC-1), a 35kDa synaptotagmin binding protein localized in the presynaptic plasma membrane. Monoclonal antibodies directed against syntaxin immunoprecipitate approximately 50% of CHAPS solubilized wCgTx receptors and immunoaffinity methods are being used to identify calcium channel associated proteins which may play a role in docking synaptic vesicles near sites of calcium entry prior to exocytosis.

ω -AGATOXIN-IVA ABOLISHES EXCITATORY AND INHIBITORY SYNAPTIC TRANSMISSION BETWEEN CEREBELLAR NEURONS IN TISSUE CULTURE. W. Raabe*, R.D. Randall and M.E. Adams. Depts. Neurology and Physiology, VA Med Ctr. and U. of Minnesota, Minneapolis, MN 55417, Depts. Entomology and Neuroscience, UC, Riverside, CA 92307.

The characteristics of the calcium channel responsible for transmitter release from excitatory and inhibitory cerebellar neurons were investigated in cerebellar neurons grown in primary tissue culture. Whole cell patch voltage clamp recordings were obtained from large ($\geq 15 \mu$ m \varnothing) cerebellar neurons presumed to be Purkinje cells. Excitatory postsynaptic currents (EPSCs) were elicited by stimulation of a nearby granule cell ($\leq 8 \mu$ m \varnothing) with an unpolished patch pipette. Inhibitory postsynaptic currents (IPSCs) were elicited by stimulation of medium size and large cerebellar neurons ($\geq 8 \mu$ m \varnothing), basket, stellate, Golgi or Purkinje cells.

Addition of Cd^{2+} (20-50 μ M) to the extracellular solution abolished evoked but not spontaneous miniature EPSCs and IPSCs. This demonstrated the Ca^{2+} dependence of evoked EPSCs and IPSCs. ω -Agatoxin-IVA (100 nM solution containing 0.1 mg/ml cytochrome C) abolished evoked EPSCs and IPSCs 10-35 min after application by perfusion or direct addition to the bath. Spontaneous miniature EPSCs were not affected by ω -Agatoxin-IVA. Large depolarizations applied through the stimulus electrode could partially restore evoked EPSCs and IPSCs. These observations indicate that the presynaptic Ca^{2+} channel responsible for excitatory transmitter release from cerebellar granule cells and inhibitory transmitter release from basket, stellate, Golgi or Purkinje cells is a high voltage activated Ca^{2+} channel of the P-type.

INHIBITORY EFFECT OF INTRACELLULAR Mg^{2+} ON ω -CONOTOXIN-SENSITIVE Ca^{2+} CHANNEL CURRENTS. H.A. Pearson* and A.C. Dolphin. Dept. Pharmacology, Royal Free Hospital Sch. of Med., London NW3 2PF, U.K.

We have previously observed that the presence of functional ω -conotoxin-sensitive Ca^{2+} channel currents (I_{Ba}) in cerebellar granule neurones is dependent on the solution used to fill pipettes during whole-cell patch-clamp experiments(1). This has led to the present study in which we have investigated the effect of free intracellular magnesium ion concentration ($[Mg^{2+}]_i$) on I_{Ba} in these cells.

I_{Ba} was recorded from the soma of cerebellar granule neurones (-80mV holding potential) using internal solutions containing varying concentrations of free Mg^{2+} and Mg-bound ATP (Mg.ATP). Values for $[Mg^{2+}]_i$ and $[Mg.ATP]_i$ in each solution were calculated from the concentrations of $MgCl_2$ and K_2ATP added to the solution, using a computer program. In the presence of a constant $[Mg^{2+}]_i$, increasing $[Mg.ATP]_i$ from 0.3mM to 2.0mM was found to increase I_{Ba} from -102 \pm 11pA (n=12) to -195 \pm 20pA (n=9). This change was not associated with an increase in any particular component of I_{Ba} since the proportion of current inhibited by ω -conotoxin (ω -CgTX) was unchanged (29.3 \pm 5.7% at 0.3mM, n=5, and 39.0 \pm 11.3% at 2.0mM Mg.ATP, n=4). In contrast to this, increasing $[Mg^{2+}]_i$ in the presence of constant $[Mg.ATP]_i$ led to a decline in I_{Ba} from -123 \pm 11pA (n=12, 0.13mM $[Mg^{2+}]_i$) to 66.8 \pm 8.4pA (n=9, 1.0mM $[Mg^{2+}]_i$). This decline in current was associated with a loss of ω -CgTX sensitivity (from 26.0 \pm 5.1% inhibition at 0.13mM $[Mg^{2+}]_i$ to 7.1 \pm 2.4% at 1.0mM $[Mg^{2+}]_i$, n=8 and 4 respectively).

Inhibition of I_{Ba} by Mg^{2+} had no effect on the inactivation kinetics of the current, or on the proportion of current that inactivated during the activating voltage step. These data suggest that internal Mg^{2+} selectively inhibits ω -CgTX-sensitive Ca^{2+} channel currents in these cells. Preliminary evidence suggests that a rapid block of the open channel is not the mechanism of action.

ION CHANNEL MODULATION AND REGULATION IV

722.1

ACTIVITY-DEPENDENT CHANGES IN VOLTAGE-SENSITIVE CALCIUM CURRENTS. S.J. Hong* and G.A. Lnenicka. Dept. of Biol. Sci., State Univ. of New York, Albany, NY 12222.

Previous experiments demonstrated that Ca^{2+} influx produced a long-term reduction in initial transmitter release from the motor terminals of a crayfish abdominal phasic motoneuron, F3 (Hong & Lnenicka, *Brain Res.* 605:121-127, 1992). To investigate possible mechanisms by which Ca^{2+} influx produces this synaptic change, we have examined the effect of Ca^{2+} influx on voltage-activated Ca^{2+} channels using two-electrode voltage-clamp techniques. To measure the Ca^{2+} current in the cell body of F3, Na^+ and K^+ currents were blocked with 1 μ M TTX, 50 mM TEA, 1 mM 4-AP, and Cs^+ . The Ca^{2+} current (I_{Ca}) was activated at approximately -50 mV and peaked near 0 mV. I_{Ca} was blocked by 10 mM Co^{2+} or 6 mM Mn^{2+} . To examine the effects of Ca^{2+} influx on the voltage-activated Ca^{2+} conductance, the cell was conditioned with 50 msec voltage steps to 0 mV delivered at 1 Hz for 10 min. I_{Ca} declined dramatically during conditioning. After conditioning I_{Ca} slowly recovered and reached an asymptote. One hour after conditioning, there was a 6% (n=3) decrease in peak I_{Ca} when the cell was conditioned in normal Ca^{2+} saline (13.5 mM), whereas there was a 26% (n=3) decrease when conditioned in higher Ca^{2+} (27 mM). To verify that Ca^{2+} influx was responsible for the reduction in I_{Ca} , we performed double-pulse experiments in normal Ca^{2+} and $0Ca^{2+} + Ba^{2+}$ saline. The conditioning pulse (P1) was varied, whereas the subsequent test pulse (P2) was set to 0 mV. The amplitude of I_{Ca} during P2 was inversely correlated to Ca^{2+} entry during P1. The peak I_{Ca} during P2 depressed significantly less than I_{Ca} at corresponding voltage steps of P1. These results suggest that long-term Ca^{2+} -dependent inactivation of Ca^{2+} influx may play a role in activity-dependent changes in transmitter release. (Supported by NSF grant IBN-9121757.)

722.2

P CHANNELS ARE RESPONSIBLE FOR SPIKE DEPENDENT RELEASE, BUT SUSTAINED RELEASE INVOLVED OTHER VARIETIES OF CALCIUM CHANNELS. G.R. Gonzalez Burgos, F.I. Bjalil, B.D. Cherksey, M. Sugimori, R. Llinás and O.D. Uchitel*. Fac. de Medicina Univ. Bs As Paraguay, 2155 Buenos Aires (11211) Argentina and Dept. of Physiology/Biophysics, NYU Medical Center, NY, NY 10016.

Transmitter release at the nerve terminals is mediated by the influx of Ca^{2+} through voltage-dependent calcium channels (VDCC). Many types of VDCC have been found in neurons (T_L,N and P) but uncertainty remains about which ones are involved in neuronal excitation-secretion coupling. We have studied the effect of VDCC blockers on the release of tritium labelled acetylcholine (3H-ACh) and on synaptic transmission in the rat superior cervical ganglion (SCG). Potassium-evoked 3H-ACh release was markedly reduced in the absence of Ca^{2+} or the presence of Cd^{2+} . The release was also inhibited by the toxin purified from the funnel-web spider venom (FTX, a P-type channel blocker) and by ω -conotoxin (ω -CgTx, a N-type channel blocker), but was unaffected by the L-type channel blocker nifedipine. In contrast, postsynaptic action potentials recorded in the postganglionic nerve and triggered by preganglionic stimulation were blocked by FTX, but not affected by ω -CgTx or nifedipine. Thus, P-type calcium channels play a dominant role in synaptic transmission at the SCG, but other not well defined types of VDCC mediate transmitter release evoked by K^+ stimulation. Support by CONICET, Argentina, NIH-NINCDS13742, NIH-NIAAG09480.

722.3

INHIBITORY COUPLING OF μ -OPIOID RECEPTORS TO P-TYPE CALCIUM CHANNELS IN RAT SENSORY NEURONS. K.I. Rusin* and H.C. Moises. Dept. of Physiology, Univ. of Michigan, Ann Arbor, MI 48109.

We previously showed that μ -opioid receptor activation decreases omega-CgTx-sensitive (N-type) high threshold calcium current in rat DRG neurons. In addition, we found that in many neurons, μ -agonists reduce a fraction of omega-CgTx-resistant current even in the presence of saturating concentrations of dihydropyridines. To characterize channel types that might contribute the latter current component we recorded whole cell barium currents through calcium channels in DRG neurons acutely dissociated from 19-30 day old rats. The effects of application of the μ -selective agonist PLO17 (0.3-3 μ M) were examined on high threshold current components, isolated on the basis of their voltage dependency of inactivation and sensitivity to omega-CgTx (N-type), nifedipine (L-type) and Aga IVA (P-type). PLO17 reduced N- and P-type high threshold current components, whereas a nifedipine-sensitive, sustained (L-type) component was unaffected. However, in one third of the cells PLO17 continued to inhibit a slowly inactivating component even in the presence of saturating concentrations of all three calcium channel antagonists. These data suggest that μ -opioid receptors are negatively coupled to at least three types of high threshold calcium channels in DRG neurons, including an omega-CgTx-sensitive (N-type) channel, an Aga IVA-sensitive (P-type) channel and a channel that is insensitive to omega-CgTx, Aga IVA and nifedipine (presumably O-type). (Supported by DA03365 to H.C.M.)

ETHANOL INHIBITION OF CA CHANNELS IS CONSISTENT WITH THE INTERACTION OF A SINGLE DRUG MOLECULE WITH A SINGLE TARGET SITE. X. Wang, J. Lemos, G. Wang, S.N. Treisman*, Dept. of Pharmacol., Univ. Mass. Med. Sch., Worcester, MA 01655 and Worcester Fdn. Exper. Biol., Shrewsbury, MA 01545.

Ingestion of ethanol results in a decreased level of plasma vasopressin, which appears to be caused by inhibition of arginine vasopressin (AVP) release from the neurohypophysis. Ethanol, at concentrations below that constituting legal intoxication, blocks dihydropyridine-sensitive 'L-type' Ca^{2+} channels in isolated nerve terminals of the rat neurohypophysis. Ethanol reduced the channel open probability in a concentration-dependent manner. To allow finer resolution of channel openings and to better characterize the mechanisms of ethanol action, Bay K 8644 was used to prolong the openings of L-type Ca^{2+} channels. In the presence of this dihydropyridine (DHP), the reduction of the channel open probability could be determined to be due primarily, although not completely, to a shortening of the open duration of this L-channel. Channel conductance was unaffected by ethanol, even at high concentrations. These results are consistent with previous macroscopic data indicating that calcium channels in these peptidergic terminals are targets for ethanol action, and indicate that ethanol acts directly on the gating characteristics of the L-type channel. The results of a Hill plot analysis of ethanol's effects on the channel open probability, as well as analysis of the distributions of open and closed times are consistent with the interaction of a single drug molecule with a single target site, following first order kinetics. (Supported by NIH grant AA08003).

722.7

A BIPHASIC DOPAMINERGIC MODULATION OF THE HIGH VOLTAGE-ACTIVATED Ca^{2+} CURRENT (HVA- I_{Ca}) OF IDENTIFIED SNAIL NEURONS. J. Golowash, J. Pastor, and D. Paupardin-Tritsch*. Lab. Neurobiology, Ecole Normale Supérieure, 75005 Paris, France.

Identified neurons of the snail *Helix aspersa*, either *in situ* or dissociated from the ganglia, were respectively voltage-clamped with two microelectrodes or using the whole cell patch clamp configuration. Dopamine (DA) induced a biphasic modulation of HVA- I_{Ca} consisting of an initial fast decrease of HVA- I_{Ca} followed by a slower enhancement of this current. DA reduced HVA- I_{Ca} by $33.9 \pm 18.8\%$ in the *in situ* neurons ($n=22$) and by $38.0 \pm 11.6\%$ in the dissociated cells ($n=26$). The augmentation of HVA- I_{Ca} was significantly larger in the *in situ* neurons than in the dissociated ones ($25.6 + 20.8\%$ increase versus $8.4 + 3.5\%$). In addition, the DA enhancing effect showed a marked desensitization in the *in situ* cells which did not appear in the dissociated ones.

None of the classical intracellular mechanisms (PKA, PKG, PKC, arachidonic acid, intracellular Ca^{2+} , Ser-Thr phosphatases) appear to be involved in any of the two successive DA-induced modulations of HVA- I_{Ca} . Intracellular application of the protomer A of *Bordetella pertussis* depressed in parallel and with the same intensity both the decrease and the enhancement of HVA- I_{Ca} by DA. As previously shown for other identified snail neurons by Harris-Warrick et al. (Neuron, 1988, 1, 27-32), the inhibitory action of DA very likely involves the α subunit of a G_o protein, immunologically related to mammalian brain α_o subunit. A possible role of the β subunits of the snail G_o in the enhancement of HVA- I_{Ca} by DA will be discussed.

722.4

ANANDAMIDE, AN ENDOGENOUS CANNABINOID, INHIBITS CALCIUM CURRENTS (I_{Ca}) AS A PARTIAL AGONIST IN N18 NEUROBLASTOMA CELLS. K. Mackie*, W.A. Devane¹, and B. Hille. Physiology and Biophysics, University of Washington, Seattle, WA 98194 and ¹NIMH/LCB, Bethesda, MD 20892.

Anandamide (arachidonyl ethanolamide) (AND) has been identified as an endogenous ligand of cannabinoid receptors on the basis of its ability to displace ³H-synthetic cannabinoid in a binding assay. Previously we showed that synthetic cannabinoid agonists inhibit N-type I_{Ca} via a PTX-sensitive mechanism in NG108-15 cells. Here we used N18 cells and whole-cell voltage clamp to show that AND also potentially inhibits N-type I_{Ca} in a PTX-sensitive fashion. As for the cannabinomimetic aminoalkylindole, WIN 55,212-2, inhibition by AND is voltage-dependent and NEM-sensitive. However, AND is less efficacious than either WIN 55,212-2 or the non-classical cannabinoid, CP 55,940. Indeed, AND appears to act as a partial agonist at cannabinoid receptors. Application of WIN 55,212-2 always caused further inhibition of I_{Ca} in cells exposed to a maximally effective concentration of AND, and application of AND caused a partial recovery of I_{Ca} in cells exposed to a maximally effective concentration of WIN 55,212-2. The AND analogs, dihomoy-linolenyl ethanolamide and arachidonyl propanolamide, both of which bind to the cannabinoid receptor and inhibit adenylyl cyclase, inhibited I_{Ca} in a fashion similar to AND. This partial agonist property of AND in I_{Ca} inhibition suggests, that while it inhibits N-type I_{Ca} , its actions as a neuromodulator in the intact animal may be more complex than would be inferred by extrapolating the results of *in vivo* studies with (-)- Δ^9 -THC or potent synthetic cannabinoids. (Supported by NS01588, NS08174 and the McKnight and W.M. Keck Foundations.)

GALANIN DECREASES BARIUM CURRENTS IN DISSOCIATED MUDPUPPY PARASYMPATHETIC NEURONS. L.A. Merriam* and R.L. Parsons. Department of Anatomy and Neurobiology, University of Vermont, Burlington, VT 05405

Barium currents (I_{Ba}) were recorded from neurons dissociated from the mudpuppy cardiac ganglion using the perforated patch technique. The extracellular solution contained in mM: 110 NMGC1, 10 TEA, 5 HEPES, 3×10^{-7} M TTX, 3.6 BaCl₂. In addition to nystatin (1720 units/ml), the patch solution contained in mM: 90 Cs-aspartate, 20 CsCl, 5 MgCl₂, 10 HEPES. With cells held at -90 mV, inward currents were first seen with steps to -20 mV and peak currents occurred at +10 mV. ω -conotoxin (1 μ M) decreased I_{Ba} by 85% whereas 10 μ M nifedipine decreased I_{Ba} by 10-15% suggesting that most of the current was due to the activation of N-type channels. With bath application, galanin produced a concentration-dependent (10^{-10} - 10^{-6} M), slowly developing, longlasting decrease in I_{Ba} (maximum decrease ~60%). Galanin decreased I_{Ba} after treatment with 10 μ M nifedipine, but not after exposure to 1 μ M ω -conotoxin indicating that galanin preferentially inhibited N-type channels. Galanin reduced the peak current without producing a consistent shift in the I-V relationship. Depolarizing steps to +70 or +100 mV did not reverse the galanin-induced decrease in I_{Ba} . The results suggest that galanin produces a decrease in I_{Ba} in mudpuppy parasympathetic neurons that does not appear to be voltage-dependent. Supported by NIH grant NS 23978.

722.8

MODULATION OF CALCIUM CURRENTS IN INSULIN-SECRETING CELLS BY STIMULANTS OF THE CYCLIC AMP PATHWAY. J.A. Love*, C. Owyang, and D.C. Dawson. Departments of Internal Medicine and Physiology, University of Michigan Medical Center, Ann Arbor, MI 48109

Stimulation of adenylate cyclase and elevation of intracellular cyclic AMP levels potentiate glucose-stimulated Ca^{++} influx and insulin secretion by pancreatic β cells. The mechanisms of this effect remain to be defined. We have previously demonstrated that high-threshold, voltage-dependent Ca^{++} currents in insulin-secreting HIT-T15 cells are modulated by other second messengers (Neurosci. Abstr 18:798, 1992). We used stimulants of cyclic AMP production to determine whether this second messenger system also modulated Ca^{++} currents. Acute exposure to the adenylate cyclase activator forskolin (5-10 μ M; 5-15 minutes) resulted in an increased fractional open-time (.026 vs. .054) of single Ca^{++} channel currents from cell-attached patches in 2/3 cells tested. Exposure to forskolin (5-10 μ M) in the presence of the phosphodiesterase inhibitor IBMX (100 μ M) resulted in an increase in fractional open-time (.037 vs. .095) in 5/8 patches. Finally, the membrane permeable cyclic AMP analog 8-bromo-cyclic AMP (2mM) increased fractional open-time (.048 vs. .092) in 2/4 patches. These results suggest that voltage-dependent Ca^{++} channels are one site where the cyclic AMP pathway can act to elevate intracellular Ca^{++} and potentiate insulin secretion. Supported by the NIH.

CELL $[Ca^{2+}]_i$ REGULATION AND THE ACTIVATION OF A CALCIUM-ACTIVATED CURRENT. L.D. Partridge*. Dept. of Physiol., Univ. of New Mexico, Albuquerque, NM 87131.

Intracellular Ca^{2+} is an important messenger in a number of cellular processes including the gating of ion channels. Activity of calcium-activated non-selective (CAN) channels underlies neuronal burst firing, neurosecretory activity, and perhaps excitotoxicity.

Our fura-2 measurements in *Helix* neurons indicate that $[Ca]_i$ decays with a $\tau \approx 5$ sec following intracellular Ca^{2+} injection. CAN currents measured under similar conditions relax with a $\tau \approx 2$ sec. In modelling studies, we have shown that CAN currents are activated by Ca^{2+} in a very local sub-membrane domain. Our inside-out patch records indicate that CAN channels do not inactivate in the presence of cytoplasmic Ca^{2+} . Current through CAN channels should thus be a good indicator of sub-membrane Ca^{2+} activity.

In this study I assessed the role of cellular Ca^{2+} sequestering mechanisms in regulating the pool of Ca^{2+} available to activate CAN channels. Bursting neurons from *Helix aspersa* were single electrode voltage clamped and quantitative pressure injections of Ca^{2+} were used to activate CAN currents. Thapsigargin, ruthenium red, and NaN₃ were used to block respectively uptake by ER and mitochondria, and all ATP-coupled Ca^{2+} transport. There was no significant change in CAN current decay constant ($\tau = 2.10$ s.d. = 1.56) with any of these treatments. Thapsigargin caused about a 10 fold reduction (from about 5 nA/fmol Ca^{2+}) in the activation of CAN current. Neither Ca-ATPases in the plasma membrane and ER nor Ca-H exchange in mitochondria are major factors in reducing Ca^{2+} that activates CAN channels. Maintained increased sub-membrane $[Ca^{2+}]_i$ following block of ER uptake has an inhibitory effect on CAN channel activation.

722.11

MODULATION OF CALCIUM-DEPENDENT POTASSIUM CHANNELS BY CALMODULIN. A. J. Boileau* and C. Kung. Neuroscience Training Program and Dept. of Genetics, University of Wisconsin, Madison, WI 53706.

Paramecium tetraurelia is a model system for the study of ion channels and their modulation in governing a behaviorally relevant action potential. Our laboratory has several behavioral mutants, many of which have point mutations in the calmodulin gene. One set of such "cam" mutants shows defects in macroscopic calcium-dependent potassium currents in whole-cell voltage clamp.

The present study shows that the connection between calmodulin and the channel may be direct. Calmodulin (CaM) application to excised inside-out patches of *Paramecium* membranes containing a previously described 72 pS gK(Ca) causes an increase in P_o and the number of opening events. Either *Paramecium* CaM or bovine CaM modulate the channel, but troponin C application has no effect. The effect is calcium-dependent and can be seen at 200nM CaM.

722.13

NOREPINEPHRINE, BUT NOT ACETYLCHOLINE, INHIBITS IAHP IN RAT HIPPOCAMPAL SLICES BY ACTIVATING PROTEIN KINASE A. R. Nouranifar, T. Wong, E. M. Landau, and R. D. Blitzer*. Depts. of Psychiatry and Pharmacology, Bronx VAMC and Mt. Sinai Medical Center, New York, NY 10029.

The coupling of transmitter receptors to the Ca^{2+} -dependent K^+ current, IAHP, was studied in the whole cell configuration in CA1 pyramidal cells. The time-course, voltage-dependence, and pharmacological characteristics of the current were similar to those obtained using sharp electrodes. It was inhibited by acetylcholine, norepinephrine, and by tetraethylammonium only at a high concentration (10 mM, but not 1 mM). The effect of norepinephrine on IAHP was enhanced in the presence of baclofen, as seen with sharp electrode recording (Andrade, Neuron 10:83, 1993). Rundown of IAHP was greatly delayed by inclusion of an ATP-regenerating system in the pipet solution, permitting long-term (>2 h) recordings of agonist-sensitive IAHP. Prior dialysis of cells with the protein kinase A inhibitor Rp-cAMPS blocked the effect of norepinephrine on IAHP, but did not alter the effect of acetylcholine. The sensitivity of the noradrenergic effect to Rp-cAMPS confirms and extends work implicating cAMP in the effect of norepinephrine (Madison & Nicoll, J. Physiol. 372:245, 1986). The block of IAHP by acetylcholine does not proceed through protein kinase A, and the transduction of the cholinergic effect remains unknown. (Supported by NARSAD and a VA Merit grant)

722.10

Ca^{2+} INFLUX THROUGH L-TYPE, BUT NOT N-TYPE, Ca^{2+} CHANNELS ACTIVATES Ca^{2+} -DEPENDENT K^+ CURRENT IN ACUTELY ISOLATED CHICK CILIARY GANGLION NEURONS. M. E. Wisgirda* and S. E. Dryer. Program in Neuroscience, Florida State University, Tallahassee, FL 32306.

Neurons of the chick ciliary ganglion are known to express Ca^{2+} -activated K^+ currents ($I_{K(Ca)}$) and two types of Ca^{2+} currents, the so-called "N-type" that is sensitive to blockade by omega-conotoxin, and the "L-type" that is sensitive to blockade by dihydropyridines. The interactions between $I_{K(Ca)}$ and the two Ca^{2+} channel subtypes were examined in ciliary ganglion neurons obtained from E11-E13 chick embryos. Standard whole-cell and perforated patch recording methods were used. Application of omega-conotoxin, either in the bath saline (2 μ M) or by pressure ejection onto the cell (20 μ M), produced a substantial blockade of Ca^{2+} current but had little or no effect on $I_{K(Ca)}$. By contrast, bath application of 10 μ M nifedipine produced a substantial blockade of $I_{K(Ca)}$. The L-type Ca^{2+} channel agonist S(-) Bay K 8644 caused an increase in $I_{K(Ca)}$. These results suggest that L-type Ca^{2+} channels are the sole source of Ca^{2+} for activation of Ca^{2+} -dependent K^+ current in ciliary ganglion neurons. Supported by NIH Grant NS-27013.

722.12

WHOLE-CELL RECORDING OF THE SLOW CALCIUM-DEPENDENT I_{AHP} IN RAT HIPPOCAMPAL CA1 NEURONS. P. Watson*, L. Zhang, J. L. Weiner, T. A. Valiante, A. Velumian, S. S. Jahromi, S. Schertzer, P. Pennefather, P. L. Carlen. Playfair Neurosci. Unit, MRC group "Nerve Cell and Synapse", Bloorview Epilepsy Prog., Univ. of Toronto, Canada M5T 2S8.

In mammalian brain neurons, a train of action potentials is followed by a slow afterhyperpolarization (AHP) lasting seconds, which is generated by a K^+ current (I_{AHP}) highly sensitive to intracellular Ca^{2+} . In the past decade, the I_{AHP} has been extensively studied using sharp electrodes. However, it has not been well demonstrated in the whole-cell recording mode, suggesting that internal dialysis with conventional whole-cell recordings may interfere with normal intracellular Ca^{2+} homeostasis.

To address this issue, we studied the slow I_{AHP} current in mature rat hippocampal neurons in brain slices using patch pipette solutions containing 2 mM K-ATP and different potassium salts including KMethylsulfate, KCl, KGlucuronate, KGlutamate or KCitrate. Only KMethylsulfate-loaded neurons showed stable AHP (I_{AHP}) and strong firing adaptation as observed with sharp electrodes. In neurons dialysed with other potassium salts, the AHP (or I_{AHP}) was small and unstable. The magnitudes of the AHP in neurons dialysed with different potassium salts were ranked as follows: KMethylsulfate > KCl > KGlucuronate > KGlutamate > KCitrate. Likewise, sustained voltage-activated Ca^{2+} -currents were stable in neurons dialysed with cesium methanesulfonate, but not with cesium gluconate or cesium chloride. The mechanisms underlying the interactions between internally applied anions and cytoplasmic Ca^{2+} handling are under investigation. We suggest that the KMethylsulfate-containing internal medium is favourable for whole-cell recording of ionic currents sensitive to, or modulated by intracellular Ca^{2+} .

POSSIBLE MODULATION BY PKC OF THE *trans*-ACPD INHIBITION OF THE SLOW I_{AHP} IN DENTATE GRANULE NEURONS OF THE HIPPOCAMPUS

M. A. Abdul-Ghani*, T. A. Valiante, P. S. Pennefather, P. L. Carlen. MRC Nerve Cell and Synapse Group, Playfair Neuroscience Unit, University of Toronto, Canada.

Glutamate is the major excitatory transmitter in the brain, acting through ionotropic and metabotropic receptors. Activation of metabotropic glutamate receptors has been shown to inhibit several calcium and potassium currents in hippocampal neurons. Using the whole cell configuration of the patch clamp technique, we have studied the mechanism underlying the inhibition of the post spike-train afterhyperpolarization current (I_{AHP}) by mGluR receptor activation in dentate granule neurons in the hippocampal slice preparation. *Trans*-ACPD (10 μ M) completely inhibited I_{AHP} . After 15 min dialysis of the cell with GDP- β -S (1.2 mM), *trans*-ACPD still inhibited I_{AHP} while the serotonin inhibition of I_{AHP} was completely blocked. Furthermore, unlike serotonin, the inhibitory effect of *trans*-ACPD on I_{AHP} was observed when the slices were preincubated for three hours with two non-specific kinase inhibitors, either H-7 (300 μ M), or staurosporine (1 μ M). However, application of the phorbol ester PMA (5 μ M) (which by itself reduced I_{AHP} by approximately 30%) slightly reduced the inhibition of I_{AHP} by activation of the mGluR. Our results show that the transduction mechanism that mediates the inhibition of the AHP by activation of the mGluR is different from that which mediates the regulation of the AHP by other neurotransmitters.

SEROTONIN INHIBITS THE SLOW AHP IN DENTATE GRANULE NEURONS VIA A G-PROTEIN MEDIATED MECHANISM. P.L. Carlen, T. A. Valiante, M. A. Abdul-Ghani, P. S. Pennefather, S. S. Jahromi*. MRC Nerve Cell and Synapse Group, Playfair Neuroscience Unit, University of Toronto, Canada.

The post-spike train afterhyperpolarization current (I_{AHP}) is an intrinsic inhibitory ionic mechanism that contributes to neuronal excitability. Serotonin has been shown to block I_{AHP} through the 5-HT₄ receptor subtype, however little is known about the signal transduction pathway responsible for this effect. To elucidate this transduction pathway we have used the whole cell configuration of the patch clamp technique to record from dentate granule neurons in the hippocampal slice preparation. Intracellular dialysis with 1.2 mM GDP- β -S for 15 minutes blocked the inhibitory effect of 5-HT (10 μ M) on I_{AHP} indicating mediation through G-proteins. Preincubation of the brain slice with a potent non-specific protein kinase inhibitor, staurosporin (1 μ M for three hours) profoundly reduced the inhibition of I_{AHP} by 5-HT. These results indicate that 5-HT inhibits the AHP through protein kinase(s) linked to serotonin receptors via G-proteins.

INTERNAL PERFUSION OF RAT HIPPOCAMPAL NEURONES IN BRAIN SLICES: EFFECTS ON NEURONAL EXCITABILITY. A.Velumian*, L.Zhang, P.Pennefather, M.P.Charlton, P.L.Carlen. Playfair Neurosci. Unit, MRC Nerve Cell and Synapse Group, Department of Physiology, Bloorview Epilepsy Program, Addiction Research Foundation, University of Toronto, Toronto Ont., Canada M5T 2S8

We have developed a simple method of multiple and fast replacements of solutions in the patch pipette tip and thereby inside the recorded cell, which allows the study of various aspects of internal modulation of neuronal membrane ion currents in brain slices. This method allows more than 10 effective replacements of different internal solutions within one hour during recording from a single neuron. The blockade of voltage-activated K⁺ channels by replacement of internal 150 mM K⁺ by 150 mM Cs⁺ ions occurred within 2-3 minutes, including the one minute "flow latency" due to solution flow through the perfusing tube. The recovery on return to 150 mM K⁺ occurred at nearly the same speed. GABA_A receptor-mediated IPSCs were reversed due to replacement of internal gluconate by chloride ions within 1.5-2 minutes. Internally perfused Cs⁺ and TEA⁺ resulted in the blockade of K⁺ channels and the appearance of a plateau on the falling phase of the action potential. The changing main anions in the internal solution, including gluconate, methylsulphate and chloride, produced sharp changes in the spike adaptation pattern and in the slow afterhyperpolarization following depolarizing pulse-evoked spike train. The effects of Ca buffers with different K_s on spike adaptation, AHPs and underlying currents are being studied.

cAMP-DEPENDENT PROTEIN KINASE (PKA) MEDIATES THE MODULATION OF THE HIPPOCAMPAL Ca²⁺-ACTIVATED K⁺ CURRENT I_{AHP} AND ACCOMMODATION BY NOREPINEPHRINE, SEROTONIN AND HISTAMINE, BUT NOT BY ACETYL CHOLINE OR GLUTAMATE.

P.Pedarzani* & J.F.Storm, *Inst. of Neurophysiol., Univ. of Oslo, Norway.*

The slow Ca²⁺-activated K⁺ current I_{AHP} underlying accommodation in hippocampal pyramidal neurons is regulated by multiple transmitters. It has been postulated, but not proven that protein phosphorylation underlies some of these effects (Nicoll, *Science* 241, 545-551, 1988). By intracellular application of kinase- and phosphatase inhibitors and catalytic subunit of protein kinase A (PKA-C), we have now obtained compelling evidence that PKA mediates the suppression of I_{AHP} and accommodation by three transmitters.

Whole-cell recordings were obtained from 125 CA1 pyramidal cells in slices from young rats. I_{AHP} was seen as a slow tail current following depolarizing steps which elicited Ca²⁺ influx. I_{AHP} was reversibly suppressed by norepinephrine (NE), isoproterenol, serotonin (5-HT), histamine (HA), carbachol, muscarine, the metabotropic glutamate receptor (mGluR) agonist t-ACPD, or a cAMP analog (CPT-cAMP). When the selective PKA-inhibitor Rp-cAMPS was applied intracellularly, it blocked the effects on I_{AHP} by isoproterenol, HA, 5-HT, and CPT-cAMP but not by carbachol or t-ACPD. The pseudo-substrate PKA peptide inhibitor Walsh PKI also prevented suppression of I_{AHP} by isoproterenol or CPT-cAMP, while the protein phosphatase inhibitor microcystin or PKA-C both caused run-down of I_{AHP} in the absence of applied agonists. Rp-cAMPS also blocked the effects on spike accommodation by NE, 5-HT or HA, but not by carbachol. These results indicate that protein kinase A mediates the effects of NE, 5-HT or HA on I_{AHP} and accommodation. [Thanks to S.Døskeland for PKA-C and A.Czernik, A.Nairn & P.Greenard for PKI.]

ION CHANNELS: CELL FUNCTION

NEURON, A COMPUTER PROGRAM SPECIALIZED FOR SIMULATING NERVE FUNCTION. Michael Hines & John W. Moore*. Dept. Neurobiology, Duke Univ. Med. Cntr. Durham NC 27710

NEURON was designed to solve two especially difficult kinds of problems: 1) complex membrane properties involving many ion-specific channels and ion accumulation and 2) where cable properties of cells play an important role, possibly including extracellular potentials close to the membrane.

NEURON provides **continuous cable sections** which may be connected together to form any type of branched cable and which are endowed with properties which may vary continuously with position along the section. This innovation allows one to keep the physical properties of the neuron entirely separate from the numerical issue of size of spatial compartments.

User defined channels may be entered conveniently by expressing models in terms of kinetic schemes and sets of simultaneous equations. Fast and efficient computation is carried out by compiling these model descriptions and using an implicit integration method optimized for branched structures.

We will demonstrate the great flexibility which results from using an object oriented interpreter to setup the physical properties of the cables, control the simulation, and plot the results. Furthermore, the interpreter provides a **highly convenient graphical interface** for setting parameters, managing either voltage clamp or current injection, and graphing variables as a function of time and position.

ACTIVITY-DEPENDENT CONDUCTANCES PRODUCE NONUNIFORM CURRENT DISTRIBUTIONS IN MODEL NEURONS. M. S. Siegel, E. Marder*, and J. F. Abbott. Departments of Biology and Physics and Center for Complex Systems, Brandeis Univ., Waltham, MA 02254.

We study biophysically realistic model neurons in which membrane current maximal conductances are slowly varying dynamic variables regulated by intracellular calcium. This allows us to model activity-dependent effects arising from processes that develop and modify membrane channels. Starting with no conductances (a passive cell), the multi-compartmental model neurons develop a heterogeneous and realistic distribution of membrane conductances: strong inward currents in the soma tapering to a constant intermediate level along the axon and weak inward and strong outward currents in the dendrite. Thus an initially passive and electrically homogeneous cell differentiates into several active substructures: an axon hillock/soma region capable of initiating action potentials, a mature axon capable of sustaining action potentials and a dendritic arbor that adapts locally to synaptic input. Different dendritic regions can specialize to define separate "computational units," forming "hot" and "cold" spots in the active dendritic membrane. The morphology of the neuron and the intracellular calcium concentration determine the final spatial distribution of currents. Supported by MH46742.

A QUANTITATIVE MODEL OF CILIARY NEURONS OF THE CHICK CILIARY GANGLION. *Richard Bertram & Stuart E. Driver**¹ *Supercomputer Computations Research Institute and Program in Neuroscience¹, Florida State University, Tallahassee, FL 32306.*

The chick ciliary ganglion contains two populations of neurons. One of these, the ciliary neurons, receive dual electrical-chemical synaptic inputs from preganglionic fibers, and innervate striated muscle in the iris and ciliary body. Ciliary neurons are unusual amongst autonomic neurons in being able to maintain sustained firing rates of greater than 200 Hz during injection of depolarizing current pulses. We have developed a mathematical model of these cells that includes the following ionic currents, with amplitudes and kinetic parameters based on voltage-clamp data from these neurons: a rapidly-inactivating Na⁺ current (I_{Na}); a sustained high-threshold Ca²⁺ current (I_{Ca}); a slowly-inactivating delayed rectifier (I_{DR}); a transient rapidly-inactivating K⁺ current (I_A); a mixed-cationic inward rectifier activated by hyperpolarization (I_{IR}); a large voltage-dependent Ca²⁺-activated K⁺ current (I_{KCa}); a smaller voltage-independent Ca²⁺-activated K⁺ current (I_{KHP}); and an ohmic leak (I_L). The model also includes first-order mechanisms for the influx and elimination of cytoplasmic free Ca²⁺. The model exhibits sustained firing rates of 250 Hz during injection of depolarizing current pulses, with very little change in interspike interval during the course of the train. The model also predicts a gradual decrease in spike amplitude during the course of the train. Each of these are features observed in current-clamp recordings from ciliary neurons. Supported by NS-27013.

ACTIVITY-RELATED CALCIUM DYNAMICS IN LAMPREY MOTONEURONS AS REVEALED BY VIDEO-RATE CONFOCAL FLUORESCENCE MICROSCOPY. *B.J. Bacskai^{1,2}, P. Wallén³, V. Lev-Ram³, S. Grillner³, and R.Y. Tsien^{1,2*}.* ¹Howard Hughes Medical Institute and ²Dept. of Pharm., Univ. of Cal. San Diego, La Jolla, CA 92093, ³Nobel Institute for Neurophysiology, Karolinska Institute, Stockholm, Sweden

Calcium influx plays a key role in various mechanisms regulating neuronal activity in the segmental network for locomotion in the lamprey. A Ca-dependent K-conductance underlies the late afterhyperpolarization and thereby regulates the firing behavior of motoneurons and interneurons, including the termination of the burst during locomotor activity. Similarly, during endogenous pacemaker-like oscillations induced by NMDA-receptor activation, calcium entry gives rise to the hyperpolarizing phase, also through activation of Ca-dependent K-channels. However, the localization and time course of calcium fluxes in neurons of the locomotor network have not been previously investigated. Therefore, measurements of [Ca²⁺]_i in motoneurons of the isolated spinal cord of *Ichthyomyzon unicuspis* were obtained with a high-speed laser scanning confocal microscope. Intracellular iontophoresis of the calcium indicator fluo-3 allowed visualization of free Ca²⁺ changes in cell bodies (as deep as 150 μm into the preparation), dendrites, and the axon at up to video frame rates (30/s) with high spatial resolution. Extracellular stimulation of descending reticulospinal axons gave rise to a rapid and localized [Ca²⁺]_i increase in ventromedial, distal dendrites, concomitant with the compound EPSP. Intracellular current injections to elicit single or trains of action potentials produced rapid increases in [Ca²⁺]_i throughout the cell, with the smallest changes observed in the cell body, possibly due to its small surface to volume ratio. The increase in calcium persisted for a few seconds after single spikes and tens of seconds after trains of 50 spikes. Fluo-3/AM loading revealed fast, dynamic changes in [Ca²⁺]_i in motoneuron axons near the ventral roots during NMDA-induced fictive swimming, suggesting the presence of a calcium component in the action potential. Antidromic stimulation of ventral roots while observing [Ca²⁺]_i in motoneuron axons indicated that the calcium increase required external Ca²⁺, was dihydropyridine and verapamil-insensitive, and could be blocked by nickel.

Ca²⁺ HOMEOSTASIS IN CULTURED RAT MYENTERIC NEURONS: THE EFFECTS OF CHRONIC DEPOLARIZATION ON [Ca²⁺]_i TRANSIENT DECAY RATES. *D.J. Fickbohm^{*1} and A.L. Willard^{1,2*}* ¹Neurobiology Curriculum¹ and Dept. of Physiology², Univ. of North Carolina, Chapel Hill, N.C. 27599.

Chronic depolarization affects the development of rat myenteric neurons in cell culture. Growth in depolarizing medium containing 25 mM K⁺ decreases the density of voltage-dependent I_{Ca}'s and causes sustained elevation of [Ca²⁺]_i (Franklin et al., J. Neurosci., 1992). The decreased I_{Ca} density (i.e., decreased Ca²⁺ influx) in chronically depolarized neurons leads to a decrease in AP-evoked [Ca²⁺]_i transient amplitudes (Fickbohm & Willard, Neurosci. Abstr., 1992). Here we report that [Ca²⁺]_i transients decay faster in chronically depolarized neurons than in control neurons. These findings support the hypothesis that Ca²⁺ homeostatic mechanisms are enhanced in chronically depolarized neurons.

Myenteric neurons dissociated from intestines of 2-3 d old rat pups were grown in cell culture for 3-10 d in medium containing control (5 mM) or elevated (25 mM) KCl. [Ca²⁺]_i was monitored in fura-2-loaded cells, using a video-based system. Neurons were stimulated with a pair of Pt wires. Brief trains of pulses (1-16 pulses) elicited [Ca²⁺]_i transients with a rapid rise (<3 s to peak) and a slower decay (τ, range = 2.1-73.9 s). The decay rates were faster for a chronically depolarized population than for a control population at almost every [Ca²⁺]_i transient amplitude. The mean τ of [Ca²⁺]_i transients in chronically depolarized neurons is significantly lower than in control cells (14.3 s vs 18.0 s). Interestingly, the maximum decay rates occur at the same [Ca²⁺]_i transient amplitude (≈12 nM) for both populations, indicating that the relationship between decay rate and amplitude is unchanged. In conclusion, chronically depolarized myenteric neurons restore [Ca²⁺]_i to basal levels faster than do control cells. This suggests that the Ca²⁺ handling abilities of rat myenteric neurons are upregulated by chronic depolarization. Supported by NIH grant NS24362.

COMPUTATIONAL ANALYSIS OF THE SENSITIVITY OF NEURONAL BEHAVIOR TO CHANNEL DENSITY DISTRIBUTIONS IN HIPPOCAMPAL CA3 NEURONS. *R.M. Eichler West^{*}, L.R. Petzold, and G.L. Wilcox,* Army High Performance Computing Research Center, Grad. Program in Neuroscience, Depts. of Computer Science and Pharmacology, U of Minnesota, Minneapolis, MN, 55415.

Previous computational models of single neurons have focused primarily on the passive electrical properties of branched dendritic tree structures. Evidence from patch clamp recordings and immunohistochemical studies suggest that voltage-gated channels are more prevalent in the soma and dendrites than had been previously suspected and that these channels mediate non-linear behavior. This experimental evidence suggests an explanation for the observed shortcomings of the passive models. The present study applied combinatorial analysis to simulations of multi-compartment neural models incorporating six types of voltage-activated channels.

Determining non-linear signaling behavior of realistic neural models using finite-element representations requires knowledge of the probable density of active and passive conductances on the cell surface that is not completely described in the experimental literature. Exploration of all possible combinations would be computationally intractable. We have explored several classes of channel density distributions in an attempt to match simulation data with experimental findings. We have superimposed these distributions on morphometric data (generated by the Eutectic Neuron Tracing System) from hippocampal CA3 neurons using six classes of channels with appropriate kinetics adapted from Traub. We performed the calculations on a CM-5 (Thinking Machines Corporation) using the integration package DASPK and displayed the results on an IRIS VGX workstation. We analyzed the electrical and ionic responses of the soma and dendritic compartments to intracellular current injections. The analysis examined the sensitivity of observed behavior to random noise and to dendritic morphological resolution. The results indicate that inclusion of voltage-gated conductances in neuronal simulations strongly affects the behavior of the model. NON-LINEAR PROPAGATION OF AGONIST-INDUCED CALCIUM WAVES IN ASTROGLIA. *S. Yagodin, L.A. Holtzclaw, and J. T. Russell*¹ LCMN, NICHD.

In rat cortical astrocytes, neurotransmitters such as norepinephrine and glutamate induce intracellular calcium signals by release from cellular stores following IP₃ formation. We have studied these agonist-induced calcium signals with high temporal (0.25s) and spatial (0.8 - 5 μm) resolutions. Calcium signals consistently originated from a single locus within an astrocyte, and this locus remained invariant for subsequent challenges with agonists that are coupled to IP₃. In these loci the resting Ca²⁺ concentration is elevated with respect to the rest of the cytoplasm. From the locus of origin, wave propagation is achieved by a process of diffusion and regenerative Ca²⁺ release in multiple cellular loci provoked by the advancing wave front; in this way, wave propagation is non-linear and saltatory. The regenerative loci appear as discrete focal areas of 7 μm to 15 μm in diameter, have different Ca²⁺ activation thresholds, and possess intrinsic oscillatory properties capable of initiating local Ca²⁺ waves which collide and annihilate. The data show that multiple sites exist within astroglia with different thresholds of activation for calcium release in a hierarchical manner, such that the low threshold centers initiate waves, and the higher threshold centers provide for regenerative amplification. In this way, since diffusion of IP₃ in the cytoplasm is rapid, wave propagation could proceed with IP₃ channel openings alone. The spatio-temporal organization of Ca²⁺ waves in astrocytes could provide a cellular mechanism for transduction of the strength of agonist action to discrete cytoplasmic sites as well as to the cell nucleus.

723.8

DISRUPTION OF CALCIUM HOMEOSTASIS LEADS TO CALCIUM INFLUX IN NEURONAL CELLS. *Chris Mathes^{##} and Stuart H. Thompson[#],* [#]Hopkins Marine Station, Stanford University, Pacific Grove, CA 93950 and [#]Neurosciences Ph.D. Program, BRI, UCLA, LA, CA 90024.

Muscarinic receptor agonists (1 mM carbachol; 1 min.), EGTA/AM (10 μM; 30 min. load), and thapsigargin (1 μM; 15 min.) disrupt calcium homeostasis in N1E-115 mouse neuroblastoma cells. In nystatin perforated-patch voltage clamp experiments, these manipulations activate a voltage-independent calcium current that is reduced by bath application of Mn²⁺ and Ba²⁺. During the calcium current, addition of Mn²⁺ or Ba²⁺ causes a biphasic response: an initial block followed by an increase of inward current. The blockable component is the calcium current turned-on by carbachol, EGTA/AM, and thapsigargin. The Mn²⁺ and Ba²⁺ influx component occurs through hyperpolarization activated non-selective cation channels (I_h). Carbachol, EGTA/AM and thapsigargin activate the same calcium current, but they differentially affect calcium stores. Using fura-2/AM to monitor calcium concentration changes in single cells, we observe that intracellular stores are emptied by thapsigargin, but not by muscarinic receptor activation or EGTA/AM loading. These results suggest that global changes in calcium homeostasis, including store depletion, lead to voltage-independent calcium influx. (supported by NIH NS14519 to SHT and NIH MH10425 to CM)

723.9

SPECIFIC Ca CHANNEL-SECRETION COUPLING IN ADRENAL CHROMAFFIN CELLS. C. R. Artalejo⁺ and M. E. Adams⁺, ⁺Dept. Neurobiology & Physiology, Northwestern Univ., Evanston, IL 60208 ^{*}Dept. Entomology & Neuroscience, Univ. of California, Riverside, CA 92521

The chromaffin cells of the adrenal medulla secrete catecholamines and several neuropeptide hormones in response to neuronal stimulation. Secretion is a Ca²⁺-dependent process that is triggered by the entry of Ca²⁺ through voltage-gated Ca channels in the plasma membrane. We have found that chromaffin cells contain three distinct types of Ca currents carried by "non classical" N-type channels, P-type Ca channels and a novel class of L-type channel known as "facilitation" Ca channels. These channels can be distinguished by their sensitivity to three selective toxins: ω -conotoxin-GVIA (N-type), ω -agatoxin-IVA (P-type) and dihydropyridines (L-type). Together these channels comprise >99% of the total Ca current present in these cells.

In the present work we have analyzed the contribution of different Ca channel types to the secretory process using capacitance measurements as an assay of catecholamine release. Although all three Ca channel types can contribute to secretion, the coupling between facilitation Ca channels and exocytosis is far more efficient than for the other two channels. That is, for the same magnitude of Ca current mediated by each of the three channels, more secretion (5 fold larger) is elicited when Ca enters through the facilitation pathway. Thus it appears likely that the facilitation Ca channel is most closely coupled to exocytotic sites. These results support the hypothesis that these channels may be the underlying regulatory system in the "fight or flight" response.

A MECHANISM FOR ECTOPIC BURSTS OF IMPULSES IN CENTRAL, DEMYELINATED AXONS. R. Kapoor¹, P.A. Felts² and K.J. Smith². ¹Inst. Neurol., Queen Sq., London, UK, and ²Depts. of Neurol. and Anatomy, UMDS, Guy's Campus, London, UK.

The mechanisms by which ectopic discharges and positive symptoms are produced in diseases of myelinated axons remain poorly understood. We have recently shown (Soc. Neurosci. 41.1, 1992) that bursts of impulses can be induced in normal myelinated fibres by a raised periaxonal, internodal [K⁺]_o; the locally elevated extracellular [K⁺]_o results in inward, and thereby excitatory, K⁺ currents. When recorded periaxonally the K⁺ currents produce prolonged negative voltage shifts and bursts of impulses. Using *in vitro* techniques we have now obtained intraxonal recordings of ectopic bursts of impulses occurring spontaneously in rat dorsal column axons passing through experimental demyelinating lesions. In some recordings, judged to be at or near the site of generation of the bursts, the discharges were associated with periodic, slow depolarisations of the axonal membrane. Bursting could be induced in demyelinated axons by high frequency stimulation, consistent with a rise in [K⁺]_o. Upon movement of the recording micropipette from an intraxonal to a periaxonal position, the depolarisations underlying the bursts changed to negative shifts similar in appearance to those described above in normal fibres with high periaxonal [K⁺]_o. In addition, periodic hyperpolarization and conduction block occurred during tetanic stimulation, suggesting activity of the Na⁺-K⁺ ATPase. We suggest that ectopic discharges in demyelinated axons may result from an elevated [K⁺]_o (arising either as a result of K⁺ accumulation during periods of intense axonal firing, and/or because of impaired K⁺ buffering), and that the discharges may be interrupted periodically by hyperpolarisation resulting from Na⁺-K⁺ ATPase activity.

SYNAPTIC ACTIVATION TRIGGERS SODIUM SPIKES IN THE APICAL DENDRITES OF LAYER V CORTICAL PYRAMIDAL CELLS. W.G. Regehr^{1,2}, J. Kehoe², P. Ascher², C.M. Armstrong¹. ¹Dept. of Physiology, University of Pennsylvania, Philadelphia, PA 19104; ²Ecole Normale Supérieure, Paris, France.

We have recorded from layer V pyramidal cells in thin slices of rat motor cortex. The soma was voltage-clamped by means of a low resistance patch pipette. Depolarizations were induced in distant, unclamped regions of the neuron by activating synapses far out on the apical dendrite. This caused small, slowly rising synaptic currents as recorded at the soma. The synaptic current in the unclamped regions sometimes elicited regenerative responses, which were seen at the soma as a complex, multicomponent current spike. The later components of the spike complex could be blocked by hyperpolarization, leaving only the synaptic current and the first component. Local application of TTX to the soma and basal dendrites eliminated the later spike components but spared the first spike, which apparently was synaptically triggered far out in the apical dendrite. Extracellular stimulation sometimes caused a short latency response that we identified as a directly stimulated dendritic sodium spike. Step depolarizations applied to the soma also caused multiple TTX-sensitive spikes, which merged into a single spike for large depolarizing steps. TTX applied to the apical dendrite significantly reduced the amplitude of the merged spike. The major conclusion from our work is that sodium action potentials are generated in the apical dendrite in response to synaptic input.

Characterization of Sodium-Dependent Oscillations Induced by Calcium Channel Blockers in Leech Neurons. J.D. Angstadt^{*}, A.M. Suran, and D.S. Wolfe. Dept. of Biology, Siena College, Loudonville, NY 12211.

Superfusion of leech ganglia with Co²⁺ or Ni²⁺ saline (Ca²⁺ replaced with an equimolar concentration of Co²⁺ or Ni²⁺, respectively) evokes synchronized, Na⁺-dependent membrane potential oscillations (Angstadt and Friesen, 1991, J. Neurophysiol. 66:1858-1872). Our working hypothesis is that the depolarizing segment of these oscillations is generated by Na⁺ influx through non-inactivating Na⁺ channels and that repolarization depends on activation of an electrogenic Na⁺/K⁺ pump. Based on this hypothesis, we predicted that other effective Ca²⁺ channel blockers would also evoke oscillations. To test this prediction, we superfused isolated leech ganglia with La³⁺ and Cd²⁺ salines. Consistent with our hypothesis, both salines evoked slow membrane potential oscillations in Retzius cells. However, evoked oscillations occurred only transiently in most preparations, with rhythmic activity ceasing after a 3-6 min. This is similar to oscillations induced by Mn²⁺ saline, but in contrast to oscillations evoked by Co²⁺ saline, which persist for hours. The explanation for the variable stability of oscillations evoked by different Ca²⁺ channel blockers is not yet clear.

Previous studies showed that the Na⁺/K⁺ pump inhibitor ouabain disrupts oscillations by causing prolonged depolarization (Angstadt and Friesen, 1991). To assess further the role of the Na⁺/K⁺ pump in the repolarizing segment of oscillations, we superfused ganglia with K⁺-free Co²⁺ saline (K⁺ replaced with an equimolar concentration of Na⁺). Removal of extracellular K⁺ also would be expected to suppress pump activity. As expected, K⁺-free saline increased the duration of oscillations by prolonging the duration of the depolarizing plateau, providing further evidence that the Na⁺/K⁺ pump contributes to repolarization of the oscillations.

723.12

SPONTANEOUS "BURST" AND "REGULAR" FIRING IN DISSOCIATED NEURONS FROM RAT NEOCORTEX. E. Guatteo, A. Bacci, S. Franceschetti, G. Avanzini and E. Wanke (SPON: European Neuroscience Association) Dip. di Fisiologia e Biochimica Generali and Istituto Neurologico "C. Besta", Milano I-20133, Italy.

Intracellular recording in the *in vitro* slice preparation and whole-cell, patch-clamp recording of acutely dissociated neurons from the rat (postnatal days 14-16) sensorimotor cortex were combined to study the pattern of firing. The classical "regular firing" and "intrinsically bursting" behaviour was found to be present in both preparations suggesting the idea that intrinsic membrane properties underlie the excitable properties. Dissociated neurons showed resting potentials around -65 mV and very high input resistance R_i (1 G Ω , n=9). The high fluctuations of the resting potential in the region -60/-80 mV caused frequently spontaneous firing. In 5 out of 9 neurons spontaneous repetitive firing was observed for more than 30-40 min. Various shapes of the action potentials (AP) were observed: brief (1-2 ms) and high (110 mV) APs, spikes with shoulder, broad and small spikes. Reversible pharmacological treatments with TTX, QX-314, Cd²⁺, Ni²⁺, DHPs and omega-CgTx suggested the cooperation of various Na⁺ conductances and T, N, L and P Ca²⁺ channels in the excitable behaviour even around the resting potential region. Voltage clamp analysis of the ionic conductances are in progress also on neurons from older animals in order to study the ion channels ontogenesis in the neocortex.

A PERSISTENT SODIUM CURRENT UNDERLYING SUBTHRESHOLD MEMBRANE POTENTIAL OSCILLATIONS IN MESOPONTINE CHOLINERGIC NEURONS *IN VITRO*. C.S. Leonard^{*} & Prashanth Kumar A.K. Center for Neural Science, New York University, 6 Wash. Pl., NY, NY 10003.

Brainstem cholinergic neurons are believed to play a pivotal role in triggering rapid eye movement sleep through a sustained increase in their action potential firing rate. The repetitive firing of these cells is controlled, in part, by an intrinsic, subthreshold membrane potential oscillation that is TTX sensitive (Leonard & Linas, *Soc. Neurosci. Abstr.* 15: 1144, 1989). Here we report that a persistent Na current which activates at membrane potentials negative to the inactivating Na current, contributes to these membrane potential oscillations. Current and voltage clamp experiments were conducted in guinea pig brain slices of the laterodorsal tegmental nucleus (LDT) using both intracellular and whole-cell recording methods. Intrinsic oscillations were observed at membrane potentials between -60mV and spike threshold. In this range, brief depolarizing current pulses produced plateau potentials that were enhanced in Ringer containing 0.1mM Ca, Cd (0.4mM), TEA (15mM) and Cs (2mM) and were blocked by TTX (0.5 μ M). Steady-state I-V curves indicated the presence of TTX-sensitive inward rectification and the subtraction currents from before and after TTX revealed a distinct inward current. This current fully activated within 20mS and showed no inactivation for the duration of the voltage steps (>100mS). Since this current activates at membrane potentials positive to -65mV, it contributes to the TTX-sensitive plateau potentials and provides depolarizing drive for the membrane potential oscillations as well as enhancing subthreshold synaptic input. Supported by NS27881.

PLASTICITY OF SODIUM AND POTASSIUM CHANNELS IN RAT BLADDER AFFERENT NEURONS FOLLOWING SPINAL CORD INJURY OR PARTIAL URETHRAL OBSTRUCTION. Naoki Yoshimura* and William C. de Groat. Dept. of Pharmacology, Univ. of Pittsburgh, Pittsburgh, PA 15261.

Spinal cord injury (SCI) or partial urethral obstruction (UO) in rats enhance the spinal micturition reflex pathway and induce hypertrophy of the urinary bladder (UB) and bladder afferent neurons (B-AN) in dorsal root ganglia. This study examined the functional changes in B-AN following SCI and UO. Whole-cell patch-clamp recordings were performed on acutely dissociated B-AN labeled by axonal transport of a fluorescent dye (Fast Blue) injected into the bladder wall. Transection of the spinal cord (T8-T9) or partial ligation of the urethra performed 4 and 6 weeks, respectively, prior to the experiment resulted in 4- and 7-fold increases in UB weight and hypertrophy of B-AN. After SCI, the following functional changes were observed: (1) a reduction ($p < 0.01$) in thresholds for action potential and Na^+ current activation from -20.4 ± 0.9 (mean \pm s.e., $n=20$) and -26.5 ± 1.7 mV ($n=15$) to -27.9 ± 0.9 ($n=25$) and -38.9 ± 1.1 mV ($n=11$), respectively. (2) an increase ($p < 0.01$) in TTX-sensitive Na^+ current densities from 17.9 ± 9.2 ($n=13$) to 80.6 ± 16.1 pA/pF ($n=11$) in association with a decrease ($p < 0.05$) in TTX-resistant Na^+ current densities from 60.1 ± 5.5 ($n=13$) to 32.1 ± 9.5 pA/pF ($n=11$). (3) a shift ($p < 0.05$) toward negative membrane potentials in the voltage dependence of steady-state inactivation of A-type K^+ current: 1/2 maximal inactivation voltages changed from -79 ± 3.6 ($n=9$) to -89 ± 4.9 mV ($n=11$). However, after UO, these properties of B-AN did not differ significantly from those in normal rats except for a moderate increase ($p < 0.05$) in TTX-sensitive Na^+ current densities to 51.2 ± 10.3 pA/pF ($n=16$). These results indicate that SCI in comparison to UO produces more prominent functional changes in B-AN, although both conditions produce similar hypertrophy of UB and B-AN. This suggests that changes within the spinal cord as well as in the hypertrophied bladder muscle may be required to induce functional plasticity in B-AN following SCI.

IONIC CURRENT IN NEURONS ACUTELY DISSOCIATED FROM ADULT COCKROACH'S PROTOCEREBRUM

X.-S. Zhang¹, J. Inouchi¹, J. Chen¹, T. Inoue¹ and M. Ichinose*². ¹Lab. of Neurophysiology, Nat. Ins. Ser. and Entom. Sci., Tsukuba, Ibaraki 305 and ²Dept. of Physiology, Shimane Medical Univ., Izumo 693, Japan

Neurons were acutely dissociated from the protocerebrum of adult cockroach (*Periplaneta americana*) by both enzymatic and mechanical isolation. Collagenase 1mg/mL and hyaluronidase 1mg/mL were used for enzyme treatment. Isolated neurons with neurites survived for more than 4 hr after the isolation. The electrical properties of the dissociated neurons with a diameters in the range of 10-15 μm were studied with whole-cell patch clamp recording. Voltage dependent currents could be separated into two ionic components: an inward calcium current and an outward potassium current. The calcium current was recorded in the external saline without Ba^{2+} and was blocked by Cd^{2+} . Maximum activation occurred near 0 mV. The magnitude of potassium current increased with depolarization and decreased by TEA and 4-AP. No sodium current was recorded. The result demonstrated that acutely dissociated protocerebrum neurons from adult cockroach with neurites can be used for electrophysiological and pharmacological studies on ionic channel current.

ELECTROPHYSIOLOGICAL AND IMMUNOLOGICAL EFFECTS OF LEUKOTRIENE B_4 COMPARED TO LIPOPOLYSACCHARIDES ON CULTURED ASTROCYTES.

H. Köller, W. Däubener[#], M. Siebler, K. Pitz[#].

Spon: European Neuroscience Association

Dept. of Neurology and [#]Dept. of Microbiology, Heinrich - Heine University, Moorenstraße 5, D 4000 Düsseldorf, Germany

After stimulation with immunologically active substances like Leukotriene B_4 (LTB_4) and lipopolysaccharides (LPS) electrophysiological properties of cultured astrocytes from new-born rats were tested in order to investigate a coupling between immunological activation and putative functional impairment. Both substances lead to a marked depolarization which in case of LTB_4 ($1\mu\text{M}$) was mediated by a reduction of K^+ conductance. In contrast, LPS ($5\mu\text{g/ml}$) seemed to stimulate a Na^+ dependent uptake system and by this way induce a depolarization. Dexamethasone ($1\mu\text{M}$) inhibited the depolarization induced by LTB_4 in contrast to that induced by LPS. As a marker for immunological activation the production of IL-6 was tested after stimulating the astrocytes either by LTB_4 or LPS. LTB_4 in contrast to LPS did not induce a marked production of IL-6.

Our results indicate that both substances lead to a marked alteration of electrophysiological properties by specific intracellular mechanisms and the depolarization is not a stimulus for the production of IL-6. The marked depolarization, which e.g. impairs the glial capacity for maintaining ionic homeostasis, may contribute to neuronal and glial dysfunction during inflammatory CNS diseases.

DIVERSITY OF Na AND Ca CURRENTS IN CHOLINERGIC NUCLEUS BASALIS NEURONS. R. Klink*, M.P. Faure, A. R. KayY and A. Alonso. Dept. Neurology & Neurosurgery, McGill University, MNI, Montreal, Canada H3A 2B4; and YDept. of Biol. Sci., Univ of Iowa, Iowa City, IA 52242.

Magnocellular basal forebrain (BF) cholinergic neurons are characterized electrophysiologically by transient outward rectification and prominent low-threshold rhythmic bursting. In order to investigate the voltage-gated ionic currents underlying this rhythmicity, neurons from the guinea pig substantia innominata and magnocellular preoptic nucleus were acutely dissociated. Choline acetyl transferase immunostaining demonstrated that 75% of the dissociated neurons and all those with a large rounded soma with 2-3 dendritic processes were cholinergic. Moreover, only the cholinergic cells bound and internalized fluoro-neurotensin and hence could be used as a marker. Whole-cell patch-clamp recordings demonstrated in all magnocellular cholinergic neurons a transient outward K current and at least two components in both the Ca and Na currents. With 500ms step depolarizations from a V_h of -90mV a transient (T-type) Ca current activated at a threshold of ~ -60 mV and inactivated rather slowly with a τ of $\sim 90\text{ms}$ at -50 mV. A second, persistent Ca-current component activated at a threshold of $\sim -45\text{mV}$. With respect to the Na currents, inactivation kinetics analysis revealed the existence of two distinct components. At -50mV the Na-current decayed as a single exponential with a τ of $\sim 30\text{ms}$ while positive to -30mV both a fast and slowly decaying component were required to obtain a good fit. While the T-type Ca-current is the main current responsible for the bursting behavior, the low-threshold slowly inactivating Na-current can also provide pacemaker drive and may be involved in sustaining the oscillatory behavior of the BF cholinergic neurons.

DIABETES MELLITUS IS ASSOCIATED WITH ALTERED CALCIUM CURRENTS BUT NOT POTASSIUM CURRENTS IN CAPSAICIN-SENSITIVE PRIMARY AFFERENT NEURONS. J. Wiley*, K. Hall, D. Mann. Dept. of Internal Medicine, University of Michigan, Ann Arbor, MI. 48109

Little is known about abnormalities in neural function that underlie diabetic autonomic neuropathy. We examined the possibility that DM is associated with functional changes in voltage-activated calcium and potassium currents present in capsaicin-sensitive dorsal root ganglion (DRG) neurons. Wistar bio-bred (BB) rats were used in these studies: i) adult male non-diabetic controls (C) and matched diabetics (D), DM duration 12-32 wks treated with insulin to maintain serum glucose between 350-450 mg%. These animals demonstrate histopathological criteria for diabetic peripheral neuropathy. Currents were recorded using the whole-cell variation of the patch clamp technique. I_{Ca} were recorded in media that blocked Na^+ and K^+ currents. I_{K} were recorded separately in the presence of tetrodotoxin. Capsaicin-sensitive DRG's demonstrated several I_{Ca} and I_{K} current components that differed in their voltage ranges for activation, inactivation and responses to nifedipine (NF; antagonizes L-type calcium currents evoked from a holding potential (V_h) = -40mV at clamp potential (V_c) = $+10\text{mV}$, ω -conotoxin (ω -CTx; antagonizes N-type calcium currents evoked from V_h = -80mV at V_c = $+10\text{mV}$), cadmium (Cd, 0.5mM; blocks I_{Ca}), TEA (1mM; inhibits I_{K} (Ca)) and charybdotoxin (Cbtx, 20nM; antagonizes I_{K} (Ca)). In C the mean peak I_{Ca} evoked from -40mV was 3.42 ± 28 nA and from -80mV was 4.30 ± 31 nA. The D group demonstrated a significant increase in the peak of the I_{Ca} evoked from -40 mV (5.85 ± 35 nA) and from -80 mV (7.89 ± 50 nA) ($p < .001$). The C and DM groups did not show any shift in the peak of the I_{Ca} current-voltage relation or the voltage-dependence of steady-state inactivation. In C, NF ($10\mu\text{M}$) reduced I_{Ca} evoked from -40mV by 32% and ω -CTx ($1\mu\text{M}$) reduced I_{Ca} evoked from -80mV by 28% supporting the presence of additional (NF- and ω -CTx-insensitive) I_{Ca} in DRGs. The effects of NF and ω -CTx were similar in the C and D groups. Outward currents were evoked from V_h = -80mV at V_c = $+20\text{mV}$. The mean peak amplitude of outward currents in C were 17.5 ± 95 and in D 16.1 ± 1.1 nA ($p = .31$). The peak of the outward currents were reduced similarly in C and D by Cd, TEA and Cbtx. In conclusion, DM was associated with an increase in high voltage-activated I_{Ca} in DRG neurons but outward I_{K} currents were not affected. Altered regulation of $[\text{Ca}]_i$ reportedly contributes to cellular injury and the increase in I_{Ca} may, thereby, participate in the mechanisms that underlie DM autonomic neuropathy.

DIFFERENTIAL DOPAMINERGIC REGULATION OF STRIATAL AND HIPPOCAMPAL ACETYLCHOLINE RELEASE *IN VIVO*. A. Imperato*, M.C. Obinu, L. Dazzi and G.L. Gessa. Department of Neuroscience Bernard B. Brodie, University of Cagliari, via Porcell, 4 09124 Italy.

The existence of dopaminergic afferents to the main cholinergic brain areas has been well established, suggesting a possible functional interaction between these two systems. However, the mechanism through which this interaction takes place *in vivo* is still under investigation.

We have studied by means of brain microdialysis and by the use of selective D₁ and D₂ dopaminergic drugs, the dopaminergic control over the cholinergic transmission in the striatum, where cholinergic neurons appear to be interneurons, and in the hippocampus, which is site of termination of cholinergic neurons originating mainly from the septum. SKF 38393 (10 mg/kg i.p.) increased (50%), while LY 171555 (0.2 mg/kg i.p.) decreased (30%) acetylcholine release in the striatum. In contrast, both compounds enhanced acetylcholine release in the hippocampus (82 and 95%, respectively), and also caused an additive effect when injected together (182%). Moreover, cocaine (10 mg/kg) and amphetamine (2 mg/kg) induced a much greater enhancement of acetylcholine release in the hippocampus compared to the striatum.

These results suggest that dopaminergic mechanisms regulating acetylcholine release in the hippocampus are different from those in the striatum. Moreover, while D₁ and D₂ receptors appear to exert an opposite control on striatal acetylcholine release, they only show a facilitatory and synergistic effect on hippocampal acetylcholine release.

RECEPTOR-MEDIATED EFFECTS OF INTERLEUKIN-2 ON HIPPOCAMPAL ACETYLCHOLINE RELEASE. D.Seto* & R.Quirion. Douglas Hospital Research Centre & Dept of Pharmacology & Therapeutics, McGill University, Montréal, Québec H4H 1R3

Previous studies have suggested: 1) the presence of IL-2 immunoreactivity in brain (Luber-Narod & Rogers 1988; Araujo et al., 1989; Lapchak et al., 1991); 2) the existence of one of the highest densities of [125I]-IL-2 binding sites in the hippocampus, a region of enriched ChAT immunoreactivity (Araujo et al., 1989); 3) that IL-2 and IL-2R immunoreactivities are present in, respectively injured rat brain and Alzheimer-lesioned brains (Nieto-Sampedro & Chandry 1987; Luber-Narod & Rogers 1988); 4) that IL-2 plays a possible modulatory role in acetylcholine (ACh) release from the hippocampus (Araujo et al., 1989); 5) that chemically lesioned hippocampi exhibit more [125I]-IL-2 binding sites and are more sensitive to IL-2 inhibition of ACh release (Araujo et al., 1989). Since it is believed that deficits in cholinergic transmission underlie some of the cognitive hallmarks of Alzheimer's disease and given the observations that point to the normal and diseased hippocampus as a target for IL-2 modulation, it is of importance to define the spectrum of effects of IL-2 on cholinergic neurotransmission in the hippocampus. Recently, using *in vitro* brain-slice superfusion, we established that IL-2 modulates K(+)-evoked hippocampal ACh release in a biphasic dose-dependent (IM-potential; nM-inhibition, time-dependent, stimulation-dependent manner and displays a reversible profile (Hänisch et al., J Neurosci., in press). To test whether these effects are receptor-mediated, the anti-TAC antibody against the IL-2 receptor α subunit was used. Our results suggest that the inhibition by IL-2 of ACh release requires binding to low-affinity receptor subunit, demonstrating the specificity and the type of IL-2 receptor involved. Furthermore, profiles of IL-2 effects on ACh release were similar using either K(+) or veratridine as depolarising agents. It thus provides further evidence for the relevance of IL-2 as a modulator of ACh release in the hippocampus. (Supported by FRSQ & MRC)

SEROTONIN-3 RECEPTORS CONTROL INHIBITION OF ACETYLCHOLINE RELEASE FROM FRONTAL CORTEX AND FACILITATION FROM DORSAL HIPPOCAMPUS: A MICRODIALYSIS STUDY WITH 2-METHYL-SEROTONIN AND DAU 6215. H. Ladinsky*¹, F. Borsini¹, R. Cortes², J. M. Palacios², S. Giorgi³, G. Russi³ and S. Consolo³. ¹Boehringer Ingelheim Italia, Milan 20139, ²Consejo Superior Investigaciones Científicas, Barcelona 08034 Spain and ³Istituto di Ricerche Farmacologiche "Mario Negri" Milan 20157 Italy.

We investigated whether 5-HT₃ receptors modulate *in vivo* ACh release from rat frontal cortex (FC) and dorsal hippocampus (DH), ACh-rich brain areas showing significant amounts of specific 5-HT₃ binding sites. In FC, the selective 5-HT₃ agonist 2-methyl-5-HT (125-1000 μ g, i.c.v.) reduced ACh output in a dose-dependent manner. The inhibitory effect was slow in onset (reaching its nadir of 40% at 120 min), and was long lasting (>240 min). By contrast, in DH, 2-methyl-5-HT raised ACh output, giving a bell shaped dose response curve. The facilitatory effect (25% and 50%; 125 and 250 μ g, i.c.v.) was rapid in onset and transient, while 500 μ g and 1000 μ g, i.c.v. doses were ineffective. The potent, selective 5-HT₃ antagonist DAU 6215 (30 μ g/kg, i.p.) blocked the effects of 2-methyl-5-HT. Autoradiographic analysis of the regional localization of [³H]DAU 6215 showed concentrations of these binding sites in the external layers of the FC, and in the hippocampus. Thus, the data show that 5-HT₃ receptors oppositely control ACh output from FC and DH and suggest differences in neuronal circuitry involved.

724.2

GLUCOSE ATTENUATES MORPHINE-INDUCED DECREASES IN HIPPOCAMPAL ACETYLCHOLINE OUTPUT. M.E. Ragozzino*, G.L. Wenk¹ & P.E. Gold. Dept. Psychology, U. Virginia, Charlottesville, VA 22903 and ²Div. Neural Systems, Memory and Aging, U. Arizona, Tucson, AZ 85721.

Glucose attenuates the effects of both systemic and intraseptal morphine injections on memory and other measures. One hypothesis is that the morphine-induced behavioral impairments may be the result, in part, of a decrease in acetylcholine (ACh) release which can be reversed by administration of glucose. In the present experiment, we employed *in vivo* microdialysis procedures in freely moving rats to measure ACh release in the hippocampus after morphine and glucose injections. Dialysate samples were collected every 12 min. From 20-40 min after morphine (IP, 10 mg/kg) injections, ACh output was reduced by 30% compared to baseline levels. Concomitant treatment with glucose (100 mg/kg) blocked this effect, with ACh output remaining at baseline. Glucose and saline injections alone produced a transient increase in ACh output evident only during the first 12 min after injection, apparently in response to handling during injection. Thus, glucose attenuates morphine-induced decreases in ACh release in the hippocampus under pharmacological conditions similar to those employed in studies in which glucose attenuated morphine-induced behavioral deficits. These findings are consistent with the view that regulation of acetylcholine release contributes to pharmacological regulation of memory and other measures. [Supported by NSF BNS90-12239, NSF BNS 89-14941, NIA AG07648, ONR N0001489-J-1216, and NIMH 5-T-32-MH18411].

724.4

ENDOGENOUS SEROTONIN FACILITATES ACETYLCHOLINE RELEASE *IN VIVO* FROM RAT DORSAL HIPPOCAMPUS VIA 5-HT-3 RECEPTORS.

S.Consolo*, G. Russi, M.Zambelli and R.Bortorelli. Istituto di Ricerche Farmacologiche "Mario Negri", 20157 Milan, Italy.

The role of serotonin (5-HT) in regulating *in vivo* acetylcholine (ACh) release from the rat dorsal hippocampus was investigated using the microdialysis technique. The two 5-HT releasers d-fenfluramine and its active metabolite d-norfenfluramine or the 5-HT uptake inhibitor citalopram facilitated *in vivo* ACh output from dorsal hippocampi. The cholinergic effects of d-norfenfluramine (7.5 mg/kg, i.p.) and citalopram (10 μ M, applied by reverse dialysis) were completely prevented by a 14-day chemical lesion of the raphe nuclei. The increase in ACh output induced by d-norfenfluramine (5 mg/kg, i.p.) was antagonized by the 5-HT-3 antagonists tropisetron (0.5 mg/kg, i.p.) and DAU 6215 (60 μ g/kg, i.p.) but not by the mixed 5-HT-1 and 5-HT-2 antagonist metergoline (2 mg/kg, s.c.). The selective 5-HT-3 receptor agonist, 2-methyl-5HT (10 μ M), applied by reverse dialysis, induced a rise in ACh release; this effect was abolished by concurrent infusion of tropisetron (10 μ M). Thus, the overall control exerted by endogenous 5-HT on hippocampal ACh release *in vivo* is primarily facilitatory in nature.

724.6

EFFECTS OF ACUTE AND CHRONIC MORPHINE ON EXTRACELLULAR ACETYLCHOLINE IN THE NUCLEUS ACCUMBENS AND PREFRONTAL CORTEX OF FREELY MOVING RATS. P. Rada*, G.P. Mark and B.G. Hoebel. Dept of Psychology, Princeton University, Princeton, NJ 08544.

We have previously reported a decrease in extracellular acetylcholine (ACh) in the nucleus accumbens (NAC) during acute morphine treatment; after 7 daily injection, this decrease in ACh was no longer apparent, and a dose of naloxone caused a large increase in ACh¹. In the present microdialysis study basal recovery of ACh was significantly and chronically lowered by an escalating dose of morphine (from 20 raised to 80 mg/kg in 1 wk). In the NAC, ACh decreased from 600 \pm 60 fmol in naive rats down to 370 \pm 75 fmol in morphine dependent rats (T=2.36; Df=33; p<.05). No basal chronic effect was observed in the PFC. Superimposed on these basal levels, acute morphine (20 mg/kg; ip) significantly increased extracellular ACh levels in the PFC (F(1,8)=3.7; p<.001) while decreasing it in the NAC. Following chronic exposure, morphine (80 mg/kg; ip) still produced an increase in ACh in the PFC (F(1,8)=5.6; p<.001) and a decrease in the NAC (F(1,8)=8.5; p<.001). Naloxone (5 mg/kg; ip) caused an exaggerated increase in ACh in both PFC and NAC. These results confirm and extend evidence that cholinergic systems are involved in opiate dependence and withdrawal. Supported by USPHS grant 30697.

724.7

INCREASES IN STRIATAL ACETYLCHOLINE BY SKF-38393 ARE MEDIATED THROUGH D1 DOPAMINE RECEPTORS IN STRIATUM AND NOT THE FRONTAL CORTEX. A. Zocchi* and A. Pert BPB, NIMH, Bethesda MD 20892

There is considerable evidence to suggest that D1 and D2 dopamine receptor agonists exert differential effects on striatal cholinergic function. D2 receptor agonists appear to inhibit striatal acetylcholine (ACh) release while D1 agonists increase release. While D2 receptor agonists seem to modulate ACh release through D2 receptors located directly on the cholinergic interneurons, the mechanism underlying the actions of D1 receptor agonists on cholinergic function remain controversial. It has been proposed by some that the D1 receptor effects are mediated through striatal actions, while others have suggested that they are determined indirectly through the frontal cortex. The experiments reported here represent a further attempt to resolve this controversy. It was found that focal applications of the inactive and active enantiomers of SKF-38393 (A D1 dopamine receptor agonist) to the rat striatum via reverse dialysis increased extracellular ACh in a stereoselective manner. Infusions of SKF-38393 into the frontal cortex, on the other hand, were ineffective in altering striatal ACh. Furthermore, partial hemisections caudal to the frontal cortex did not alter the ability of systemically administered SKF-38393 to increase striatal ACh. Taken together, these results suggest that at least some of the effects of D1 receptor agonists on striatal cholinergic function are mediated through actions in the striatum and not the frontal cortex.

724.9

BOTULINUM TOXIN A ENHANCED PROTEIN PHOSPHORYLATION AND INHIBITION OF ACETYLCHOLINE RELEASE. G.H. Sterling*, K.E. Asermely, M.R. McCafferty and J.J. O'Neill. Dept. of Pharmacology, Temple Univ. Sch. of Med., Phila., PA 19140

Considerable evidence supports the role of phosphorylation of neuron specific proteins, e.g., synapsin and synaptophysin, in regulation of neurotransmission. In this study concerning factors regulating presynaptic cholinergic function, the effect of Botulinum toxin A (BoNT A), a potent inhibitor of ACh release, on protein phosphorylation was examined. Synaptosomes from rat cerebral cortex were preincubated with BoNT A (0-100 nM) followed by 45 mins with 32 P-orthophosphate. Proteins were separated by SDS-PAGE gels with radioactivity identified by autoradiography and liquid scintillation counting. BoNT A increased, in a dose dependent manner, the steady state phosphorylation of several neuron specific proteins: e.g., the vesicle specific 38 kDa protein, synaptophysin, identified by Western blot; a 43 kDa protein (possibly B50), thought to be associated with neurotransmitter release; an unidentified 28 kDa component and a doublet of 80-86 kDa, resembling the synapsins which depend on cAMP dependent kinase for phosphorylation. 4-Aminopyridine, known to reverse BoNT-induced inhibition of ACh release, restored steady state phosphorylation toward control levels. These effects of BoNT A on protein phosphorylation may provide important insights into presynaptic factors regulating cholinergic neurotransmission and lead to sites for drug intervention in BoNT-induced toxicity.

724.11

EFFECT OF NITRIC OXIDE ON ACETYLCHOLINE RELEASE IN THE STRIATUM: A MICRODIALYSIS STUDY. R. Guevara-Guzman†, K.M. Kendrick, R. Senaris and P.C. Emson. Dept Neurobiology, AFRC Babraham Institute, Babraham, Cambridge, U.K., †Dept Physiology, Faculty of Medicine, Natl. Univ. Mexico, Mexico 04510, D.F.

Nitric oxide (NO) has recently been shown to function as a neuronal messenger in the brain. Furthermore it has been reported that activation of NMDA receptors leads to the formation and release of NO. The aim of this paper was to study the effect of different NO releasers on acetylcholine (ACh) release *in vivo*. The experiments were conducted in male wistar rats anaesthetized with urethane. Microdialysis probes (CM-12, 3 mm membrane length, CMA microdialysis) were placed in the striatum. Ringer (pH 6.0) containing 10 μ M neostigmine was pumped through the probes at 1.5 μ l/min using a CMA 100 pump. A liquid switch was used to introduce different substances into the system. Sampling was at 15 min intervals and ACh was measured using HPLC with electrochemical detection. NMDA (50 μ M) stimulated ACh release and this was blocked by the NMDA receptor antagonist APV. The NO releasers, sodium nitroprusside (SNP) isosorbide (ISO), S-nitroacetyl penicillamine (SNAP) and S-nitrosoglutathione (SNOG) all increased ACh release at 10³. Potassium ferrocyanide, penicillin and glutathione, which do not produce NO, did not alter ACh release. When NO gas was bubbled through buffered Ringer to provide a pure NO stimulus via the microdialysis probe, the results showed that NO administered in this manner also stimulated ACh release. This NO effect was Ca⁺⁺ dependent and could be blocked by the NO scavenger haemoglobin or by the NO synthase inhibitor, nitroarginine. The effect of NO was not mediated via the NMDA receptor since SNAP still increase ACh release in the presence of APV concentrations that blocked its release in response to NMDA. The cGMP agonist, 8-bromo-cyclic GMP and dibutyl-cyclic GMP at 10³ also increased ACh release suggesting that the effect of NO on ACh release might be mediated via cGMP. This data proved that NO may play a significant role in ACh release in the striatum.

NICOTINIC RECEPTOR AGONISTS INCREASE ACETYLCHOLINE AND NOREPINEPHRINE LEVELS IN RAT CORTEX: A MICRODIALYSIS STUDY. K.L. Summers* and E. Giacobini. Dept. Pharmacology, Southern Illinois University School of Medicine, Springfield, IL 62794-9230.

Patients suffering from Alzheimer's disease (AD) may benefit from treatment with nicotinic agents as nicotine has been shown to improve memory. Transverse microdialysis was employed to compare the effects of several nicotinic receptor agonists on the simultaneous release of acetylcholine (ACh), norepinephrine (NE), dopamine (DA), and serotonin (5-HT) in rat cortex *in vivo*. No cholinesterase inhibitor (ChEi) was added to the perfusate. L-nicotine (3.6 μ mol/kg, s.c.) significantly increased ACh levels (100%) in the dialysate for 2 hrs and significantly increased NE levels (85%) for 1 hr. D-nicotine (3.6 μ mol/kg, s.c.) increased ACh and NE (30%) for 1 hr, indicating stereoselectivity. Metanicothine (3.6 μ mol/kg, s.c.) elevated ACh (110%) and NE (80%) for less than 2 hrs. Anabaseine (3.6 μ mol/kg, s.c.) appears to be more potent than nicotine at elevating levels of both ACh (150%) and NE (100%) while fluoronicotine (3.6 μ mol/kg, s.c.) appears to be less potent at elevating ACh (70%) and NE (20%). No significant effects of these compounds have been observed on DA or 5-HT levels. (Supported by R.J. Reynolds Tobacco Co.)

724.10

EFFECTS OF PHYSOSTIGMINE AND SOME NITRIC OXIDE-CYCLIC GMP RELATED COMPOUNDS ON MUSCARINIC RECEPTOR-MEDIATED AUTOINHIBITION OF HIPPOCAMPAL ACETYLCHOLINE RELEASE. T. Suzuki and K. Kawashima* Department of Pharmacology, Kyoritsu College of Pharmacy, Tokyo 105, JAPAN.

We have investigated the effects of 1) the cholinesterase inhibitor physostigmine and 2) drugs which are known to change intracellular cGMP levels, on the autoinhibition of acetylcholine release from rat hippocampal slices. Autoinhibition was triggered by submaximal electrical stimulation in both the absence and presence of physostigmine. The results obtained indicate that an unusual increase in the extracellular acetylcholine content, such as that induced by cholinesterase inhibition, is not essential for autoinhibition triggering. Dibutyl cGMP reduced significantly the stimulation-evoked acetylcholine release in the presence, but not in the absence, of atropine. Neither sodium nitroprusside nor glyceryl trinitrate exerted a dibutyl cGMP-like effect. NG-Nitro-L-arginine did not lessen the autoinhibition. These results indicate that an increase in the intracellular cGMP level reduces acetylcholine release, and that the muscarinic receptor stimulation-nitric oxide synthesis-(soluble) guanylyl cyclase activation pathway is not involved in the cholinergic autoinhibition processes.

724.12

EFFECTS OF CONCUSSIVE BRAIN INJURY ON NEUROTRANSMITTER MONOAMINES AND ACETYLCHOLINE IN THE RAT BRAIN. K. Shima, S. Okuyama¹, Y. Imagawa¹ and S. Ogawa¹. Dept. of Neurosurgery, National Defense Medical College, Tokorozawa, 359; †Dept. of Pharmacology, Research Center, Taisho Pharmaceutical Co. LTD, Omiya, 330

Previous studies have demonstrated a transient release of acetylcholine (ACh) after moderate fluid-percussion injury. The objective of the present study is to investigate whether there is a similar release of ACh in the rat brain after closed head injury (CHI) and to determine whether there are accompanying changes in other aminergic neurotransmitters following CHI. Male Wistar rats were divided into a CHI group and a sham control group. CHI was induced by dropping a 400 g weight from 70 cm on the vertex. The tissue concentrations of the neurotransmitter monoamines dopamine (DA), norepinephrine (NE), serotonin (5-HT), and acetylcholine (ACh) and of their major metabolites (dihydroxyphenyl acetic acid (DOPAC), homovanillic acid (HVA) and 5-hydroxyindole acetic acid (5-HIAA)) were measured using HPLC in 9 brain areas. Measurements were determined at 15 min, 30 min, 2 h, 4h and 24 h after CHI. Compared to sham controls, the concentrations of DA, NE, 5-HT and ACh up to 30 min after CHI were decreased or unchanged in the many brain areas, whereas DOPAC and HVA levels were significantly increased in the amygdala, pons and cerebellum. 5-HIAA level was increased in the amygdala, hippocampus and cortices 2-24 h after CHI. At 24 h after CHI ACh level was significantly (p<0.001) increased in 7 of 9 areas. These results demonstrate that concussive brain injury in the intact skull model, as well as fluid-percussion injury through a vertical craniectomy, causes a transient increase in cholinergic neuronal activity in the pontine area. Moreover, monoaminergic neuronal derangements may be related to the pathophysiology of concussive CHI.

EXTRACELLULAR RELEASE OF ACETHYLCHOLINE, NORADRENALINE AND SEROTONIN IN THE CEREBRAL CORTEX INCREASES IN RESPONSE TO WALKING IN RATS. M. Kurosawa, Y. Sakiyama and A. Sato, Department of Autonomic Nervous System, Tokyo Metropolitan Institute of Gerontology, 35-2 Sakaecho, Itabashi-ku, Tokyo-173, Japan.

Cerebral cortical blood flow (CBF) increases during exercise. We have demonstrated that CBF increases via cholinergic nerve fibers originating in the nucleus basalis of Meynert in rats. In the present experiments, we examined whether release of acetylcholine (ACh) in the cerebral cortex increased during walking in rats. Release of noradrenaline (NA) and serotonin (5-HT) in the cerebral cortex which contribute to the vasoconstrictive regulation of the CBF was also investigated. Extracellular release of ACh, NA and 5-HT in the parietal lobe of the cerebral cortex was measured using a combination of microdialysis and high-performance liquid chromatography. Walking at the speed of 2.3 m/min for 5 min produced significant increases in ACh, NA and 5-HT release in the cerebral cortical extracellular space. The mean increase in ACh release (205 % of control) was much greater than that of NA (131 %) or 5-HT (133 %). It is suggested that the vasodilative effect of ACh on CBF during walking is more influential than vasoconstrictive effect of NA and 5-HT, and that the increased release of ACh in the cerebral cortex may contribute at least partly to the increase in CBF during walking.

PHORBOL DIACETATE INCREASES TRANSMITTER RELEASE AND REVERSES THE EFFECT OF HALOTHANE AT THE NEUROMUSCULAR JUNCTION: M. Sokoll, S.-I. Lee, S. Kamath, T. Gerhold, Department of Anesthesia, University of Iowa College of Medicine, Iowa City, IA 52242.

Previously we have demonstrated the ability of halothane (HAL) to decrease transmitter release from the motor nerve terminal. In this study we investigated the ability of phorbol diacetate (PDA) to reverse this effect of HAL.

METHODS: We studied the effect of PDA (0.25, 0.5 and 1.0 μ M) alone and combined with HAL (1.0%) on the miniature endplate current (MEPC) and endplate current (EPC) of the rat diaphragm preparation. The diaphragm was rapidly removed from a halothane anesthetized rat and mounted in a plexiglass bath. The tissue was perfused with control, PDA or PDA-HAL containing solutions sequentially. Transmembrane currents were recorded using the two microelectrode voltage clamp. MEPC's were analysed for amplitude and time constant of decay. EPC's were elicited at 0.4 and 40 Hz and analysed for amplitude and quantum content (m) (direct method).

RESULTS AND DISCUSSION: Addition of halothane 1% caused a 15% decrease in MEPC amplitude which was not altered by PDA. Halothane produced a 32% decrease in m of EPC #1 and a 40% decrease in m of the plateau phase of the tetanic train. These results indicate that PDA has the ability to reverse the halothane induced decrease of m of the indirectly stimulated motor nerve terminal and that probability of release and mobilization of transmitter are both involved.

HALOTHANE ANESTHESIA DIMINISHES ACETYLCHOLINE (ACh) RELEASE IN THE MEDIA PONTINE RETICULAR FORMATION (mPRF). J. C. Keifer, L. Becker, R. Lydic, Department of Anesthesia, Pennsylvania State University, College of Medicine, Hershey, Pa 17033.

Anesthesia and sleep are distinctly different, but both states have features in common including: 1) altered EEG activity, 2) eye movements, 3) hypotonia, and 4) altered regulation of breathing. Since the mPRF is a cholinergic brainstem area known to be involved in REM sleep generation, we are testing the hypothesis that ACh release in the mPRF is altered during exposure to inhalational anesthesia. Cats were implanted with electrodes for measuring cortical EEG, EOG, and EMG. Following induction of anesthesia with 1.2% Halothane (measured by Raman Spectroscopy), a microdialysis probe was inserted into the mPRF. Microdialysis samples were collected at 10 minute intervals for measuring ACh. Replicate samples were collected at 1.2, 0.6 and 0% expired halothane. Analysis of variance for anesthetic effect on ACh release was significant ($F=18.155$, $p<.001$). ACh release was significantly reduced following exposure to 1.2% (-33%) and 0.6% (-31%) halothane when compared to the awake state. These observations are consistent with the hypothesis that mPRF levels of ACh contribute to generating some of the physiologic traits comprising the anesthetic state induced by halothane. *Support: Department of Anesthesia, FAER Grant (JCK), HL-40881(RL).*

NEUROMUSCULAR TRANSMISSION AND MUSCARINIC ACETYLCHOLINE RECEPTORS. R.J. Storella and T.S. Ackerman, Dept. of Anesthesiology, Hahnemann Univ., Philadelphia, PA 19102.

Measurements of Ca^{++} currents from motor nerve endings and tritiated acetylcholine (ACh) release indicate that muscarinic antagonists can alter ACh release at the neuromuscular junction. We investigated the effect of atropine on train-of-four (TOF) fade, which is used clinically to monitor neuromuscular transmission. TOF fade is due to a decrease in ACh release caused by d-tubocurarine (dTC). Isometric twitch tension (TT) was measured from a standard mouse phrenic nerve-diaphragm preparation at 37°C. TOF stimulation consisted of 4 pulses at 2 Hz every 11.5 seconds. Preparations were exposed to 0.75 μ M dTC during a control period and then treated by adding either saline or 20 μ M atropine ($n=4$ for each treatment). Block (first TT in the TOF to pre-dTC TT) and fade (fourth to first TT in the TOF train) were determined for both the control and treatments periods. There were no differences in the effect of treatment (expressed as percent of the control period) between the saline and atropine groups for either block (92.5 ± 14 vs. 92.5 ± 9.6) or fade (119 ± 49.8 vs. 102 ± 30). Additionally, for both treatment groups, there were no changes in the amount of fade between control and treated periods (paired t-tests). Thus, we could not find support for the implication from other studies that atropine might alter ACh release (and thus TT) under these clinically relevant conditions. Supported by NIH NS28165.

ACETYLCHOLINE RECEPTORS: MUSCARINIC

725.1

CHOLINERGIC REGULATION OF INTRACELLULAR CALCIUM LEVELS IN AN IMMORTALIZED HIPPOCAMPAL CELL LINE. J. P. Sullivan, T. Giordano, L. M. Monteggia, M. Downen, B.H. Wainer, and S.P. Americ, Neuroscience Research, Pharmaceutical Products Division, Abbott Laboratories, Abbott Park, IL, 60064 and ¹Dept. of Pathology, Albert Einstein University, New York, NY 10461

HN33 cells, derived via somatic cell fusion of hippocampal cells from postnatal day 21 mice to N18TG2 neuroblastoma cells exhibit morphological and cytoskeletal features which are typical of their neuronal parents but which are not expressed by the N18TG2 cells (Lee et al., J. Neurosci., 10; 1779, 1990). Furthermore, these cells display electrophysiological properties typical of primary hippocampal neurons when differentiated with retinoic acid. HN33 cells have not, however, been extensively studied with respect to neurotransmitter-associated properties. In the present study, the cholinergic regulation of intracellular calcium levels in undifferentiated and differentiated HN33 cells was investigated.

In the presence of physiological (1 mM) extracellular Ca^{2+} , carbachol ($ED_{max} = 500 \mu$ M) and acetylcholine ($ED_{max} = 50 \mu$ M) caused a dose-related increase in intracellular Ca^{2+} levels in fura-2-loaded undifferentiated ($n=3$) and differentiated HN33 cells ($n=3$). The elevation of $[Ca^{2+}]_i$ was biphasic, consisting of a transient initial peak followed by a decline to a plateau that was 40% higher than the basal level. EC_{50} values for the peak and plateau carbachol-induced response in undifferentiated cells were 5 μ M and 3 μ M, respectively. (-) Nicotine (10-500 μ M) had no effect on calcium levels. The M3 muscarinic receptor antagonist, 4-DAMP, was a more potent inhibitor ($IC_{50} = 4.5\pm 1.2$ nM, $n=3$) of carbachol-induced increases in Ca^{2+} levels than pirenzepine ($IC_{50} = 180\pm 16$ nM, $n=3$).

These results demonstrate the existence of mAChRs in both differentiated and undifferentiated HN33 cells that are coupled to changes in intracellular levels of calcium via activation of M3 receptors.

725.2

EFFECTS OF METAL CATIONS ON MUSCARINIC RECEPTOR MEDIATED CHANGES IN FREE INTRACELLULAR CALCIUM IN HUMAN SH-SY5Y NEUROBLASTOMA CELLS. J. Naarala, M. Tuomala and K. Savolainen, Natl. Publ. Hlth. Inst., Dept. Toxicol., Kuopio, Finland.

The effects of aluminum (Al), magnesium (Mg), potassium (K), zinc (Zn), cupric (Cu), lead (Pb) and sodium (Na) acetate on free intracellular calcium ($[Ca^{2+}]_i$) were studied in human SH-SY5Y neuroblastoma cells. The cells were first incubated for 60 min with each one of the metal acetates at a concentration of 30 μ M and then the cells were stimulated with 10 μ M of acetylcholine (ACh), and the changes in $[Ca^{2+}]_i$ measured, applying a fluorometric method using a fluorescent calcium probe fura-2. All metal acetates inhibited the ACh-induced elevations of $[Ca^{2+}]_i$ in human SH-SY5Y neuroblastoma cells. Zinc was the most potent one of the acetates causing a 90 % attenuation in ACh-induced elevation of $[Ca^{2+}]_i$. The suspected neurotoxin, aluminum, produced a 40 % reduction, as did also the cupric acetate. These results shed new light on these metallic neurotoxins, because calcium in excess is also neurotoxic. Pb, Mg, and Na acetates produced similar effects with a 20-30 % reduction in the ACh-induced elevation of $[Ca^{2+}]_i$. The potassium acetate had the most striking and unexpected effect on $[Ca^{2+}]_i$. The inhibition of ACh-induced $[Ca^{2+}]_i$ elevation by K-acetate was 50 % at low doses even though it alone, by depolarizing the neurones, remarkably elevates $[Ca^{2+}]_i$ at high doses. Thus, K-acetate may have opposite effects on $[Ca^{2+}]_i$ at low and high doses, respectively. The effects of metal cations on $[Ca^{2+}]_i$ may be due to modification of the binding of ACh to the muscarinic receptors in neuroblastoma cells. Supported by The Academy of Finland.

COUPLING OF m2 AND m4 MUSCARINIC RECEPTOR SUBTYPES TO Ca²⁺-DEPENDENT K⁺ CHANNELS IN TRANSFORMED NL308 NEUROBLASTOMA X FIBROBLAST HYBRID CELLS. M. Noda¹, M. Katayama², D. A. Brown³, J. Robbins³, S. Marsh³, N. Ishizaka¹, K. Fukuda², N. Hoshi¹, S. Yokoyama¹ and H. Higashida^{1*}. ¹Kanazawa Univ. Sch. Med., Kanazawa 920, Japan, ²Kyoto Univ. Facul. Med., Kyoto 606, Japan and ³Univ. College London, London WC1E 6BT, UK.

The muscarinic acetylcholine receptor (mAChR) subtype (m1-m4)-specific DNAs were transfected in NL308 neuroblastoma-fibroblast hybrid cells and clones expressing each of the individual mAChR subtypes m1, m2, m3 and m4 were obtained. ACh increased phosphoinositide (PI) turnover in m1- and m3-transformed cells, but little or no production of it was detected in m2- and m4-transformed cells. In cells expressing m1- and m3-subtypes, ACh produced an initial outward K⁺ current, followed by an inward current due to the activation of Ca²⁺-dependent cationic channels. No M-current inhibition evoked by ACh was recorded in m1- and m3-transformed NL308 cells, because they are M-current deficient mutant cells. In m2- and m4-transformed cells, only the initial K⁺ current was detected. The outward currents were associated with a rise in intracellular Ca²⁺ as measured with Fura-2 or Indo-1, and were inhibited by chelating intracellular Ca²⁺ with external BAPTA-AM, or by external charybdotoxin or Ba²⁺, hence they were attributed to the activation of a Ca²⁺-dependent K⁺ current. However, the outward current produced in m2- and m4-transformed cells was blocked by pretreatment with 5 ng/ml Pertussis toxin (PTX), whereas that in m1- and m3-transformed cells was not. These results indicate that m2- and m4-receptors in transformed NL308 cells couple to a PTX-sensitive G protein which is capable of mobilizing intracellular Ca²⁺ and activates I_K(Ca), whereas m1- and m3-receptors activate a similar process through a different, PTX-insensitive G-protein.

PERTUSSIS TOXIN BLOCKS M₂ MUSCARINIC RECEPTOR-MEDIATED CONTRACTIONS OF THE GUINEA PIG ILEUM WITHOUT INHIBITING M₃-MEDIATED-CONTRACTIONS. E. A. Thomas* and F. J. Ehlerl. Department of Pharmacology, University of California at Irvine, College of Medicine, Irvine, CA 92717.

We have previously demonstrated, by pharmacological characterization with AF-DX 116, that contractions of the guinea pig ileum can be elicited by M₂ muscarinic receptors when measured in the presence of histamine and forskolin or isoproterenol. (Thomas et al. Mol. Pharmacol. in press). We have further characterized the M₂ nature of the contractile response by examining the effects of pertussis toxin on oxotremorine-M (oxo-M) induced contractions. Under basal conditions, pertussis toxin treatment (18 hr; 32 °C) had no effect on the EC₅₀ value of the concentration-response curve to oxo-M, an M₃-mediated event. In contrast, when ilea were pre-contracted with histamine (1 μM) and then relaxed back to baseline with forskolin (2 μM) before oxo-M induced contractions were measured, pertussis toxin shifted the concentration-effect curve to oxo-M by a 6.1-fold increase in EC₅₀. Ilea were then incubated with 4-DAMP mustard (40 nM; 1 hr) in the presence of AF-DX 116 (1 μM) to selectively inactivate the M₃ muscarinic receptors, and contractions to oxo-M were repeated in the presence of histamine (1 μM) and forskolin (1 μM). Under these conditions, pertussis toxin blocked the concentration-effect curve to oxo-M by a 30-fold increase in the EC₅₀ value. In addition, 4-DAMP mustard treatment caused only a 4.6-fold increase in the EC₅₀ value for oxo-M in the control tissues, and a 22-fold increase in EC₅₀ in the pertussis toxin-treated tissues. These results demonstrate the importance of M₂ muscarinic receptors in the contraction of the guinea pig ileum. Supported by N.I.H. Grants NS 26511 & 30882.

CHARACTERIZATION OF THE MUSCARINIC RESPONSE OF WT3 CELLS TO CARBACHOL USING THE CYTOSENSOR™ MICROPHYSIOMETER. K. De Moor, S. Pitchford, M.A. Hirst, & B.S. Glaeser*, Molecular Devices Corporation, Menlo Park, CA 94025.

The Cytosensor Microphysiometer has been used to monitor the responses of M1 muscarinic receptors transfected into CHO cells (WT3). This instrument directly measures changes in cellular acidification rates by monitoring the extracellular acidification of a low-buffered F12 medium bathing the cells. We have investigated serum starvation, exposure/washout times and medium modifications to determine the effect on receptor-mediated activation of WT3 cells by the agonist, carbachol. Cells were exposed for 30 seconds to increasing concentrations of carbachol (0.01-100 μM) followed by a 30-minute washout. Prior to carbachol exposure, WT3 cells typically required 2-3 hours to reach stable baseline acidification rates. This occurred both with non-starved or 18-hour serum-starved cells. This equilibration time was greatly reduced, however, by the addition of 1% serum to the low-buffered F12 medium. WT3 cells responded to carbachol treatment with a transient increase in acidification rates. These responses increased in a dose-dependent fashion (EC₅₀ ≈ 2 μM). Rapidly repeated stimulation with carbachol (<15 minutes between doses) resulted in attenuated responses and a shift in the dose response curve. Serum starvation resulted in a reduction in the peak response (increase above basal acidification rate) but no alteration in the EC₅₀ value. In other studies, atropine inhibited the carbachol response.

CARBACHOL - PHORBOL ESTER INTERACTIONS AT MUSCARINIC RECEPTORS IN RABBIT STRIATUM.

L. X. Cubeddu*, I. S. Hoffmann and R. K. Talmaciu. Dept. of Pharmacology, School of Pharmacy, Central University of Venezuela, Caracas, Venezuela.

In rabbit striatal slices, both 4-beta-12,13-dibutyrate phorbol-ester (PDBu) (EC₅₀ = 82 ± 12 nM) and carbachol (EC₅₀ = 2.3 ± 0.35 μM) enhanced the release of dopamine (DA) evoked by electrical stimulation. No additivity was observed when slices were treated simultaneously with 0.1 μM PDBu and 10 μM carbachol. Pretreatment with PDBu (0.01-0.1 μM) abolished carbachol-induced facilitation of DA release and pretreatment with carbachol (3-100 μM) antagonized the enhancement in DA release produced by PDBu. The effect of carbachol was blocked by atropine (0.1 μM) but not by hexamethonium (10 μM); whereas, the enhancement in the evoked-release of DA produced by PDBu was not modified by either antagonist. If receptors are blocked with atropine (0.1 μM), carbachol failed to antagonize PDBu-induced facilitation of DA release. PDBu, but not carbachol, antagonized the inhibition of ACh release induced by DA D₂-receptor and by MACHR agonists on ACh release.

This is the first report to indicate that activation of MACHR by an agonist prevents the effects of an active phorbol-ester. We suggest that activation of MACHR (probably M1) enhances DA release possibly through activation of PKC. It also appears that the PKC linked to MACHR (activated both by carbachol and PDBu) mediates increases in DA release; whereas the activation of the "other" PKCs (activated by PDBu) exerts no effect on DA release, but may have other actions, for example inducing receptor internalization in ACh neurons.

AN ASSAY FOR m4 RECEPTORS IN RAT STRIATAL MEMBRANES USING DOPAMINE-FORSKOLIN STIMULATION OF ADENYLATE CYCLASE AND cAMP DETERMINATION BY AUTOMATED ELISA. Kris Eckols and Neil DeLapp*, Lilly Research Laboratories, Eli Lilly & Co., Indianapolis, IN 46285

The m₂ and m₄ subtypes of muscarinic receptors are negatively coupled to adenylate cyclase. In rat striatum, m₄ receptors are present at considerably higher density than m₂ receptors as shown by analysis of mRNA (Brann et al., J. Neurosci. 8: 4646, 1988), binding studies (Potter et al., Life Sci. 52: 433, 1993), and immunoprecipitation of receptor proteins (Wolfe et al., Mol. Pharm. in press, 1993). Analysis of mRNA has shown a heavy colocalization of m₄ and dopamine D₁ receptors (Bloch et al., J. Neurosci. 12: 2591, 1992). Adenylate cyclase was assayed by a modification of the method of Olanas and Onali (Mol. Pharm. 23: 393, 1983) using a combination of 100 μM dopamine and 50 nM forskolin (D+F) to stimulate enzyme activity. cAMP was determined with a commercial ELISA (Cayman Chemical) using a BioMek workstation with side loading arm to automate plate preparation, addition of samples, and plate development.

The D+F combination stimulated adenylate cyclase activity 3.5 - 5.5 fold above basal. Stimulated activity was inhibited 45-55% and 40-50% by 1 mM carbachol and 1 nM oxotremorine M respectively. By comparing the response due to carbachol, SCH23390 (a D₁ antagonist), and a combination of the two, it was estimated that 60% of the carbachol effect on D+F stimulated activity results from inhibition of dopamine-stimulated cyclase. Agonist potencies in the assay were oxotremorine M = McNA343 > pilocarpine > carbachol > arecoline > bethanecol. McNA343 and pilocarpine were partial agonists. Rank order of antagonist potencies was 4DAMP > atropine > methoctramine > pirenzepine > AFDX116. Agonists and antagonists potencies were similar to those reported by Olanas and Onali for inhibition of striatal membrane basal activity. Inhibition of D+F stimulated activity was greater than that reported by Onali et al. for inhibition of basal activity, and addition of dopamine to the assay may reduce the contribution of m₂ receptors due to co-localization of D₁ and m₄. The use of a commercially available cAMP ELISA has allowed partial automation of the assay thereby increasing productivity and eliminating the necessity for use of radioisotopes.

Effects of cAMP on Muscarinic Receptor-Mediated IP₃ and IP₂ Accumulation in the Rat Parotid Gland. E. H. Gerstin, Jr* and F. J. Ehlerl, Department of Pharmacology, College of Medicine, University of California, Irvine, CA 92717.

We have demonstrated that the adenylate cyclase activator, forskolin (75 μM) can dampen the accumulation of inositol monophosphates (IP₁) elicited by the muscarinic agonists oxotremorine-M (OXO-M) and pilocarpine (PILO) in a slice preparation of the rat parotid gland. (Soc. Neurosci. Abs. 18:481.17, 1992) The active second messenger, inositol triphosphate (IP₃), is similarly affected by forskolin. OXO-M (10 μM) increased production of IP₃ 3.1-fold in the absence of lithium. Forskolin (75 μM) dampened this response, decreasing the IP₃ accumulation to 2.1-fold (P > 0.02). In the presence of Li⁺ (10 mM), the OXO-M effect was 7.8-fold, and was reduced to 2.6-fold by the addition of forskolin (75 μM). The reductions in IP₃ correlate with those seen in measurement of IP₁, indicating that the measured effects of forskolin on IP₁ accumulation accurately reflect effects on IP₃ production. To investigate whether receptors coupled to activation of adenylate cyclase had similar effects on the accumulation of inositol monophosphates, we first determined the abilities of various agonists to increase cAMP levels. Isoproterenol (0.1 mM), 2-chloroadenosine (0.1 mM), and prostaglandin E₂ (10 μM) all demonstrated ability to elevate cAMP levels in the parotid slice prep, by 24-, 4-, and 3-fold, respectively, in the presence of IBMX (1 mM). Collectively, our data indicate that β-adrenergic, adenosine A₂, and PGE₂ receptors may dampen the phosphoinositide hydrolysis response to muscarinic agonists in the rat parotid gland. Studies are underway to test this hypothesis. Supported by NIH Grants NS 26511 and 30882.

725.9

MUSCARINIC RECEPTORS STIMULATE c'AMP ACCUMULATION IN THE RAT PERIPHERAL LUNG.

E. Esqueda, E. H. Gerstin Jr., and F. I. Ehler*. Department of Pharmacology, College of Medicine, University of California, Irvine, Ca 92717.

Muscarinic receptors in the rat peripheral lung were investigated using radioligand binding and second messenger assays. When measured by the displacement of [³H]N-methylscopolamine binding, the competition curve of the M₁ selective antagonist pirenzepine was consistent with a two-site model. The proportion of high affinity sites was 9%, and the observed K_D's of the high and low affinity sites were .069 and 1.4 μM, respectively. Adenylyl cyclase activity was then tested in a slice preparation by assaying for c'AMP accumulation in the presence of the muscarinic agonist oxotremorine M (OXO-M) and forskolin (FSK). Cyclic AMP levels were increased 1.6 fold over basal by OXO-M (10 μM) alone, and 4.3 fold by FSK (37 μM) alone. When added together, OXO-M potentiated FSK and caused a 9.6 fold increase in c'AMP levels. This response was inhibited by pirenzepine with an observed K_i value of 0.8 μM, indicating that a muscarinic receptor with low affinity for pirenzepine is causing the accumulation of c'AMP. In preliminary experiments, prostaglandin E₂ (10 μM) alone stimulated the accumulation of c'AMP by 1.5 fold; with the addition of OXO-M (10 μM), the accumulation was potentiated by ~20%, to 1.9 fold. The potentiation of FSK by OXO-M was unaffected by treatment with tetrodotoxin, confirming that it was not elicited by release of neurotransmitters. Supported by NIH Grants NS 26511 and 30882.

NEUROTROPHIC-LIKE EFFECTS MEDIATED BY AF102B, AN M1-SELECTIVE MUSCARINIC AGONIST, IN PC12M1 TRANSFECTED CELLS. D. Gurwitz*, R. Haring, R. Pinkas-Kramarski*, R. Stein* and A. Fisher. Israel Inst. Biol. Res., Ness-Ziona 70450, and *Dept. Biochem., Tel-Aviv University, Tel-Aviv 69978, Israel.

Rat pheochromocytoma (PC12) cells stably transfected with the cloned rat m1 muscarinic acetylcholine receptor (PC12M1 cells) were shown to undergo phenotypic change upon treatment with oxotremorine (Pinkas-Kramarski et al., J. Neurochem. 59:2158, 1992). This was manifested by neurite outgrowth, which synergized with NGR-mediated neurites. We now report that similar neurotrophic-like effects are mediated by AF102B, an M1-selective muscarinic agonist, and a candidate Alzheimer's disease (AD) drug (Fisher et al., JPET 257:392, 1991). However, unlike the neurotrophic-like effects of non-selective muscarinic agonists such as oxotremorine or carbachol, which were evident in the absence of NGF, AF102B (up to 100 μM) did not induce neurite outgrowth by itself, but synergized strongly (ED₅₀ = 5 μM) with 2 nM NGF, which by itself mediated only a mild response. This synergized response was not observed in non-transfected PC12 cells, and was completely blocked in PC12M1 cells by 10 μM atropine, indicating involvement of m1 receptors. In addition, atropine retracted neurites which were previously extended by co-incubation of PC12M1 cells with AF102B and NGF. AF102B (100 μM) mediated a robust (> 10-fold) stimulation of phosphoinositide hydrolysis in PC12M1 cells. Neurites extended by a combined treatment with NGF and AF102B were stable for long periods in culture (> 10 days), indicating that the signaling mechanism(s) responsible for maintenance of neurites were not desensitizing in the continued presence of AF102B. Since neuronal cell-death in AD probably involves decreased production and/or availability of neurotrophins, which in turn compromises survival of cholinergic neurons, our observations imply that AF102B may, under certain conditions, compensate for such deficiencies and thus may constitute a novel treatment for AD. Supported by Snow Brand, Japan.

M-1 MUSCARINIC RECEPTOR MEDIATED FACILITATION OF ACETYLCHOLINE RELEASE IN THE RAT URINARY BLADDER BUT NOT IN THE HEART. G.T. Somogyi, M. Tanowitz and W.C. de Groat, Department of Pharmacology, University of Pittsburgh, Pittsburgh, PA 15261.

The contribution of presynaptic muscarinic receptors to frequency dependent facilitation of ³H-acetylcholine (ACh) release was studied in isolated muscle strips from the body of the urinary bladder (UB) and cardiac atrial tissue of the rat. In strips prelabelled with ³H-choline electrical field stimulation increased ³H-ACh outflow during superfusion. The quantity of ³H-ACh release was influenced by the pattern and duration of stimulation. Continuous stimulation (CS) with trains of 20-100 shocks released ten times larger amounts of ACh than the same number of shocks presented as short trains (10 shocks per train) with 5 sec inter-train intervals (IS). The volley output of ³H-ACh release during CS was facilitated as the number of shocks was increased between 5 and 70. ACh release decreased with longer train durations (100-360 shocks). Facilitation was not detected with IS using 20-360 shocks. The facilitation of transmitter release was antagonized completely by the administration of atropine (1 μM) or pirenzepine (0.05 μM) a selective M1 antagonist. Administration of the anticholinesterase agent, eserine (5 μM), markedly facilitated ACh release induced by CS and IS. Atropine blocked the facilitation. Release of ACh from atrial strips did not exhibit CS-induced facilitation. Eserine decreased IS and CS-evoked ACh release in the atrium. It is concluded that continuous stimulation of postganglionic cholinergic nerves in the rat urinary bladder leads to activation of M1 muscarinic facilitatory presynaptic receptors which enhance the release of ACh. These receptors were not detected in the atrium. Presynaptic facilitation may be an important mechanism for modulating neural input to bladder during micturition. Supported by NSF Grant BNS-890-8934.

COMPARATIVE ALTERATIONS OF CORTICAL CHOLINERGIC MARKERS FOLLOWING LONG TERM BILATERAL LESIONS OF THE SUBSTANTIA INNOMINATA IN THE RAT. D. Cécyre*, J. Aubert, J.-C. Martel and R. Quirion, Douglas Hosp. Res. Ctr and McGill Univ., Depts of Psychiatry and Neurology & Neurosurgery, Montreal, QC, Canada H4H 1R3.

In rats, lesions of the substantia innominata (SI), an area enriched with cholinergic perikarya, have been shown to produce cholinergic deficits in the cortex. However, most of these studies were performed following short term SI lesions. In this study, we were particularly interested in the effect of SI lesions combined with aging. Therefore, bilateral ibotenic acid (two infusions of 0.5 ul each; 5 mg/ml) lesions of the SI and sham operations were performed in 2 months old rats which were sacrificed only at 21 months. Brain sections were then processed for either [³H]pirenzepine (5 nM) M1 sites, [³H]AF-DX 384 (0.2 nM) putative M2 sites, [³H]N-methylcarbamylcholine (20 nM) nicotinic sites and [³H]hemicholinium-3 (10 nM) high affinity choline reuptake site (HACU) receptor autoradiography. Cortical choline acetyltransferase (ChAT) activity was also measured. The density of HACU binding sites was significantly reduced (45%) in the frontal and parietal cortices of long term SI lesioned rats. No changes in HACU binding was observed in the occipital and entorhinal cortices. ChAT activity was decreased (20%) in the cortex (all cortices included) of lesioned rats. The density of other cholinergic markers was not decreased in cortical areas of lesioned rats.

AF150(S) AND AF151(S): NEW M1 AGONISTS MEDIATE m1-SELECTIVE SIGNALING, NEUROTROPHIC-LIKE EFFECTS AND RESTORE AF64A-COGNITIVE DEFICITS IN RATS. A. Fisher*, E. Heldman, D. Gurwitz, R. Haring, H. Meshulam, R. Brandeis, M. Sapir, D. Marcianno, D. Barak, Z. Vogel* and Y. Karton. Israel Institute for Biological Research, Ness-Ziona, & # The Weizmann Institute, Rehovot, ISRAEL.

Using computer-assisted molecular modeling we designed two new rigid thiazoline-piperidine analogs, AF150(S) and AF151(S) [US. Pat. Appl., April, 1990]. These compounds are selective and efficacious agonists for M1AChRs in rat cortex (CT) vs cerebellum (CER) (binding of ³H-pirenzepine ± GppNHp (Gp) vs ³H-QNB, respectively; e.g., for AF150(S) in CT: K_{i,CT} = 0.39 μM (42%), K_{L,CT} = 14 μM; K_{L,CT} = 8.9 μM (100%); in CER: K_i = 22 μM). In CHO cells stably transfected with cloned m1 muscarinic receptor (m1AChR), AF150(S) and AF151(S) are full agonists in elevating [Ca²⁺]_i, but partial (30-50% vs. carbachol, CCh) and full agonists, respectively, in stimulating phosphoinositides hydrolysis (in CHO and PC12M1 cells). In CHO cells transfected with m1AChR, these compounds are inactive when compared with CCh in elevating cAMP levels. In epithelial cells derived from human salivary gland rich in m3AChR, AF150(S) is an antagonist to CCh, whilst AF151(S) is a partial agonist in elevating [Ca²⁺]_i. Both compounds synergized (EC₅₀ ~ 1 μM) with NGF (2 nM) in mediating neurotrophic-like effects in PC12M1 cells, being about 5-folds more potent than AF102B, an M1 selective agonist. In AF64A (3nmole/2μl/site, icv)-treated rats, AF150(S) (1 mg/kg, po) restored cognitive impairments in a passive avoidance test, in Morris water maze and in a radial-arm maze (0.5, 1 mg/kg, po), without producing adverse effects up to 100 folds higher doses. Due to their profile at m1AChRs and activation of only distinct G-protein subset(s), their neurotrophic-like activity *in vitro*, and beneficial effects *in vivo*, such agonists can be unique candidates for the treatment of Alzheimer's disease.

MUSCARINIC ACETYLCHOLINE RECEPTORS IN URINARY BLADDER. T.A. Cawley, Jr.,* P. Wang, M.R. Ruggieri, and G.R. Luthin. Departments of Pharmacology and Urology, Temple University School of Medicine and Department of Physiology & Biophysics and Institute for Neuroscience, Hahnemann University, Philadelphia, PA 19102.

In rat myocardium the m2 subtype of muscarinic acetylcholine receptor (mAChR) inhibits contractility, while in urinary bladder mAChR activation produces a contractile response. To investigate the possible differences in mAChRs that mediate these opposite contractile responses, subtype levels were determined in the rat bladder. Receptors were labelled using [³H]QNB, solubilized, and immunoprecipitated using subtype-specific anti-peptide and anti-fusion protein antisera. The m2 subtype of mAChR was found to comprise ~ 90% of the total mAChRs in bladder, the remainder being the m3 mAChR subtype. Using immunocytochemistry (see Shickley, et al. accompanying abstract), the m2 mAChRs were localized to cells discrete from those labelled using anti-m3 mAChR antisera. When activated by carbachol, the m2 mAChR and G proteins could be solubilized and co-precipitated using anti-mAChR or anti-G protein antisera. Thus, it is likely that mAChR-effector coupling differences seen in bladder and heart are not due to differences in mAChR subtype or to differences in mAChR-G protein interactions but may be reflective of the type of G protein activated. Supported by NIH DK43333.

STABLE ASSOCIATION OF m3 MUSCARINIC RECEPTORS AND G PROTEINS. P. Wang and G.R. Luthin.* Department of Physiology & Biophysics and Institute for Neuroscience, Hahnemann University, Philadelphia, PA 19102.

Rat parotid gland contains predominantly the m3 subtype of muscarinic acetylcholine receptor (mAChR). We studied interactions of this mAChR with guanine nucleotide binding proteins (G proteins). When carbachol was used to inhibit [³H]NMS binding to parotid membranes, only low-affinity binding was observed, and this was not altered in the presence of GTP or GTP analogues. Direct labelling of parotid membranes by [³H]joxotremorine-M was also not possible, in contrast to m2 mAChR containing tissues. In spite of the lack of high affinity agonist binding to this tissue, we could co-purify the m3 mAChR with G proteins following agonist labelling, solubilization, and immunoprecipitation. An interaction with Gi but not Go was established using this protocol. Together, these results suggest that a stable association of the m3 receptor with G proteins requires the presence of agonist, but does not require high affinity agonist binding. Supported by NIH NS23006.

PROSTATE GLAND CONTAINS HIGH LEVELS OF THE m1 SUBTYPE OF MUSCARINIC RECEPTOR. R.J. Smyth, M.R. Ruggieri, M.D. Colton, P.Wang, T. Shickley and G.R. Luthin. Department of Physiology & Biophysics and Institute for Neuroscience, Hahnemann University and Departments of Pharmacology, Anatomy & Cell Biology and Urology, Temple University School of Medicine, Philadelphia, PA 19140.

The prostate glandular epithelium secretes and the capsular smooth muscle contracts in response to activation by cholinergic neurons. Muscarinic acetylcholine receptor (mAChR) subtypes were analyzed in adenoma specimens from the human prostate gland, to determine the subtypes present in prostate that might be responsible for the secretory component of the muscarinic response. Immunohistochemical studies with antibodies to the m1 mAChR demonstrated immunoreactivity on the secretory epithelium of the prostate. Contractile studies demonstrated that the adenoma tissue did not contract in response to carbachol stimulation whereas the prostatic capsule did. Pharmacological studies were performed using selective drugs to inhibit [³H]QNB binding to membrane homogenate. Pirenzepine and hexahydrostiladifenidol, both selective for the m1 mAChR, were more potent than methoctramine (m2 selective) in binding studies. Immunoprecipitation was performed on [³H]QNB labelled mAChRs following solubilization from prostate membranes, using anti-peptide or anti-fusion protein antibodies. The m1 subtype of mAChR comprised > 80% of the total mAChRs, with m2 and m3 subtypes each ~5% of the total. No m4 or m5 mAChRs could be found in this tissue using the precipitation assay. The human prostate adenoma thus becomes the first mammalian tissue shown to contain predominately the m1 subtype of mAChR, and the first tissue shown to contain significant levels of this subtype outside of the brain. This should allow examination of the role of the m1 mAChR in excitation-secretion coupling. Supported by NIH DK43333 and NS23006.

IDENTIFICATION AND CHARACTERIZATION OF A HIGH-AFFINITY PERIPHERAL-TYPE BENZODIAZEPINE RECEPTOR IN RABBIT URINARY BLADDER SMOOTH MUSCLE. M.R. Ruggieri, E.J. Uhlman and R.J. Smyth. Departments of Pharmacology & Urology, Temple University School of Medicine, Philadelphia PA 19140.

The existence of the peripheral-type benzodiazepine receptor (PBR) has been demonstrated in several types of smooth muscle as well as in steroidogenic tissues. The present study utilized radioligand binding and in-vitro contractility experiments to identify and characterize a PBR in rabbit urinary bladder smooth muscle. [³H]PK11195 bound to bladder membranes with high-affinity and density ($K_d = 310$ pM, $B_{max} = 6.4$ pmol/mg protein) indicating the presence of a PBR, whereas [³H]flunitrazepam bound with moderate affinity and density ($K_d = 30$ nM, $B_{max} = 372$ fmol/mg protein). There was no significant difference in [³H]PK11195 or [³H]flunitrazepam binding between bladder base and dome. The rank order potency of various benzodiazepines and isoquinoline carboxamides in displacing the binding of [³H]PK11195 was Ro5-4864 > diazepam = flunitrazepam >> Ro15-1788 = clonazepam. No significant binding of [³H]Ro15-1788 was detected in bladder base or dome, denoting the absence of a central-type benzodiazepine receptor. Ro5-4864 and PK11195 inhibited nerve-evoked contractions in a concentration-dependent manner ($IC_{50} = 42$ μ M and 56 μ M, respectively). Carbachol- and KCl-induced contractions were also inhibited by Ro5-4864 and PK11195. KCl-induced contractions were inhibited to a greater extent than carbachol-induced or field-stimulated contractions with all the drugs tested. Both Ro5-4864 and PK11195 significantly increased the ED_{50} for calcium-induced contractions following a cholinergic stimulus compared to control. This data demonstrates the presence of a PBR in urinary bladder smooth muscle, capable of altering contractility in-vitro through modulation of calcium activity. This study was supported by National Institutes of Health grants DK43333 and DK40579 to MRR.

ACETYLCHOLINE RECEPTORS: MUTAGENESIS OF MUSCARINIC AND NICOTINIC RECEPTORS

726.1

MUTATION OF CONSERVED ASPARTATE AND ARGININE RESIDUES IN TRANSMEMBRANE HELIX 3 OF THE MUSCARINIC ACETYLCHOLINE RECEPTORS. E.C. Hulme, K.M. Page, P. Jones, C.A.M. Curtis and R. Morris. MRC National Institute for Medical Research, Mill Hill, London, NW7 1AA, UK.

We have studied the contribution of conserved Asp and Arg residues in transmembrane helix 3 of the m1 and m2 muscarinic receptors to agonist binding and receptor activation. To do this, we have used conservative mutations (Asp105Glu, m1 mAChR; Asp103Glu, m2 mAChR; Arg123Lys, m1 mAChR) which perturb, but do not destroy, receptor function and ligand binding. The results are consistent with the hypothesis that the positively-charged headgroups of muscarinic agonists dock with a region of the receptor which is relatively remote from the conserved Asp. The establishment of a tight ionic bond with the Asp carboxylate group is coordinated with the formation of productive interactions between the receptor and the ligand side-chain. This may be contingent on the induction of a conformational change in the receptor. The side-chain of Arg123 may participate in an intramolecular bond, which constrains the agonist-induced conformational change. We are investigating the hypothesis that this bond may be broken as a result of agonist binding, allowing the Arg side-chain to participate in binding and activation of the GTP binding protein.

726.2

MUTATION OF ASPARTATE 103 TO ASPARAGINE OR GLUTAMATE IN HUMAN MUSCARINIC RECEPTOR SUBTYPE Hm2: EFFECT OF SUBTYPE SELECTIVITY VERSUS pK_a ON RECEPTOR BINDING. C.J. Spencer, R.D. Schwarz, D.W. Moreland, A.J. Thomas and H. Teclé. Parke-Davis Pharm. Res. Div. of Warner-Lambert Co., Ann Arbor, MI 48105

Previous work in our laboratory has shown that mutation of Asp 103 to Asn (D103N) in the Hm2 subtype transiently expressed in COS-7 cells decreased the affinity of ³H-NMS for the receptor by 29 fold. This mutation preserves the relative size of the target residue but eliminates the negative charge of the amino acid. Examination of a small group of reference muscarinic agonists and antagonists suggested that this mutation could be a tool to refine the selection of compound specificity for m2 vs. m1. Those compounds displaying m2 selectivity showed a more dramatic reduction of affinity in the mutant compared to wild type (WT) than did those with m1 selectivity. These studies were expanded to ask whether the pK_a of a compound or its subtype selectivity in m1 vs. m2 WT receptors correlated with the affinity change seen with the mutation. Results from additional reference agonists and antagonists showed there was little relationship between pK_a and the affinity shift; however, the selectivity for m2 did parallel the shift. Examination of six novel muscarinic agonists with no appreciable subtype selectivity also showed a minimal relationship between pK_a and the change in affinity between WT and D103N. These results suggest that the affinity shifts observed in the D103N mutated Hm2 receptor are a consequence of more than the charge of the ligand in the environment of the receptor. These studies will be extended to the mutation of Asp 103 to Glu.

726.3

SITE-DIRECTED MUTAGENESIS OF ASPARTATE 103 IN THE Hm2 MUSCARINIC RECEPTOR: EFFECT ON RECEPTOR BINDING OF 1-AZABICYCLO[2.2.1]HEPTAN-3-ONE OXIMES. R.D. Schwarz*, C.J. Spencer, J. Jaen, T. Mirzadegan, D. Moreland, H. Teele, A. Thomas, and R. Davis. Parke-Davis Pharmaceutical Res., Div. of Warner-Lambert Co., Ann Arbor, MI.

Like other G-protein coupled receptors, key aspartate residues appear to be involved in ligand binding at muscarinic receptors. In our laboratory, mutation of asp 103 to asn (D103N) in Hm2 receptors produced a 29-fold reduction in affinity for [³H]-NMS while mutation to ala resulted in a loss of specific binding. Using the D103N mutant, selected muscarinic agonists and antagonists were examined for changes in affinity compared to wild type receptors. Subtype selectivity (m1 vs. m2) appeared to correlate better with affinity changes rather than pKa values; the more m2, the greater the loss in affinity (Spencer, et al., this meeting). Recently, Teele, et al. (Life Sci. 52:505, 1993) described a novel series of 1-azabicyclo[2.2.1]heptan-3-one oxime agonists with increased length and bulk relative to traditional muscarinic ligands. In the present study, compounds from this group were studied for changes in affinity between D103N mutants and wild type receptors. While some compounds showed no change, others showed up to 40-fold decreases in affinity. The relationships between structural modifications and affinity changes observed in the binding experiments will be discussed.

726.5

EFFECTS OF SITE-DIRECTED MUTAGENESIS OF A HIGHLY CONSERVED ARGININE RESIDUE ON THE FUNCTION OF THE M1 MUSCARINIC RECEPTOR. S.Z. Zhu, S.Z. Wang, J. Hu and E.E. El-Fakahany*. Div. of Neuroscience Research in Psychiatry, University of Minnesota Medical School, Minneapolis, MN 55455.

Point mutation of the arginine residue at position 123 of the m1 muscarinic receptor sequence into asparagine (Asn¹²³) was induced and the mutant gene was stably transfected into Chinese hamster ovary cells. This residue is conserved in all G-protein-coupled receptors in an invariant fashion at the beginning of the second cytoplasmic loop. This mutation almost abolished agonist-induced increase in phosphoinositide hydrolysis, even though wild and mutant receptors were expressed at similar numbers. There was no significant effect on antagonist binding. In marked contrast, while the binding of carbachol to wild receptors exhibited high and low-affinity components, this binding in Asn¹²³ mutant cells was to a single low-affinity state. There was also a disappearance of agonist-induced enhancement of the specific binding of [³⁵S]GTP-gamma-S in membranes. Taken together, our data suggest that this highly conserved arginine residue plays an important role in coupling of m1 muscarinic receptors to G-proteins.

726.7

SINGLE AA SUBSTITUTIONS IN I3 OF THE PORCINE MUSCARINIC RECEPTOR ALTER G-PROTEIN COUPLING CHARACTERISTICS. D.A. Bulsech and M.L. Schimerlik. Biochemistry and Biophysics, Oregon State University, Corvallis, OR 97331.

The N-terminal region of the third intracellular loop (i3) plays an important role in G-protein coupling of the muscarinic acetylcholine receptor. Site directed mutagenesis was used to introduce single amino acid substitutions in i3 of the porcine atrial muscarinic receptor (pm2) followed by stable expression in Chinese hamster ovary (CHO) cells. Substitution of Ala with Glu at amino acid position 212 (A212E) or Lys with Ala in position 214 (K214A) resulted in binding characteristics similar to wildtype. The K_d for [³H]-QNB binding is 21±5 pM for wildtype receptor while A212E and K214A have dissociation constants of 40±11 pM and 26±2 pM respectively. Agonist competition binding experiments show that both possess high affinity binding sites for carbachol and oxo-M. Stimulation of phosphatidylinositol (PI) metabolism for A212E and K214A resembled wildtype receptor for carbachol, acetylcholine and pilocarpine in both fold stimulation and EC₅₀, while oxo-M appeared normal for K214A. In A212E, oxo-M does not promote coupling to PI metabolism and has about half the maximal percent inhibition of adenylyl cyclase. The coupling of K214A to PI metabolism is similar to wildtype but appears to be mediated by a different G-protein. In CHO cells, wildtype receptor is coupled to both inhibition of adenylyl cyclase and stimulation of PI metabolism by a PTX sensitive G-protein(s). K214A on the other hand couples to PI metabolism through a G-protein with lowered PTX sensitivity. 100 ng/ml PTX failed to inhibit PI metabolism in K214A while wildtype receptor was completely uncoupled. Although 1 μg/ml PTX did reduce the PI response seen in K214A, it failed to completely abolish it. K214A inhibits adenylyl cyclase with reduced efficacy with PTX sensitivity similar to wildtype. Thus, single amino acid substitutions superficially result in an unchanged receptor but more detailed examination indicates that the G-protein coupling properties are altered. Oxo-M appears to become a partial agonist for the mutant A212E, while K214A appears to couple to PI metabolism either through a different G-protein or through both PTX sensitive and PTX insensitive G-proteins. (Supported by NIH grant # HL23632 to M.L.S.)

726.4

THE STRUCTURE OF THE LIGAND BINDING DOMAINS OF A MUSCARINIC RECEPTOR INVESTIGATED BY RANDOM-SATURATION MUTAGENESIS. Tracy A Spalding*, David Hill-Eubanks and Mark R Brann. Molecular Neuropharmacology, Department of Psychiatry and Vermont Cancer Center, University of Vermont, Burlington, VT 05405.

Ligand binding to the muscarinic receptor involves the third, fifth and sixth transmembrane domains, (TM 3, 5 and 6). To define the amino acid residues involved in ligand binding, TM3 and TM5 were subjected to random saturation mutagenesis which was carried out using PCR in conjunction with a randomly mutated primer. Recombinant receptors were amplified in *E. coli* to produce a library of 3000 mutants, which was transfected into NIH 3T3 cells and screened for functional receptors using 0.1mM carbachol. Since m5 muscarinic activity transforms NIH 3T3 cells, cells expressing active receptors grow into foci. Around 5-15% of the recombinant receptors formed foci, and mRNA purified from these has been sequenced by RT-PCR. Using random-saturation mutagenesis, every possible substitution of every amino acid in each transmembrane domain of the receptor can be tested to show whether or not that mutation is tolerated. It is also possible to screen for constitutively-activating mutations. The pattern of tolerated and activating mutations should provide information on the residues involved in the binding of carbachol to the receptor, the residues which play key roles in the activating mechanism of the receptor, and the orientation of the seven transmembrane helices.

726.6

SITE DIRECTED MUTAGENESIS IN THE CHANNEL DOMAIN M2 OF THE NEURONAL NICOTINIC ACETYLCHOLINE RECEPTOR REVEALS A FUNCTIONAL STRATIFICATION. D. Bertrand*, J.-L. Galzi, A. Devillers-Thiéry, S. Bertrand and J.-P. Changeux Dpt of Physiology, CMU, 1211 Geneva, Switzerland

Investigation at the amino acid level of the functional properties of the residue lining the ionic pore was done in the chick α7 receptor. We found that the wild type receptor displays a rather high selectivity for calcium, with a pCa/pNa of about 10, that can be abolished by single point mutations at two distinct sites within M2. The first site is the intermediate anionic ring, where substitution of glutamates by alanines abolishes the calcium permeability without significantly affecting the other physiological properties of the receptor. The second site is composed of two adjacent leucine rings (positions 254 and 255), where replacement by threonines or asparagines reduces calcium permeability by at least 1000 fold. These mutations also cause significant modifications of response time courses, apparent agonist sensitivity and Hill numbers of agonist dose-response relationships. Together with previous findings (Devillers-Thiéry et al., 1992; Galzi et al. 1992) these mutagenesis experiments reveal a functional stratification of the channel domain M2.

726.8

STRUCTURE/FUNCTION OF MUSCARINIC RECEPTOR/G-PROTEIN COUPLING Molecular Neuropharmacology Division, Department of Psychiatry and Vermont Comprehensive Cancer Center, Univ. of Vermont, Burlington, VT 05405. E. S. Burstein*, D. H. Eubanks, H. B. Jørgensen, & M. R. Brann.

The N- and C-terminal regions of the third cytoplasmic loop of several G protein coupled receptors play pivotal roles in G-protein coupling. To define structural requirements for receptor/G-protein coupling, we subjected these regions of the m5 muscarinic receptor to random-saturation mutagenesis, and identified mutant receptors that retain function. The positions and frequency of conservative versus nonconservative substitutions within N-i3 displayed periodicity, providing compelling evidence for an α-helix. All the amino acids on one side of the helix only tolerate certain highly conserved substitutions, while all the amino acids on the opposite face tolerate multiple nonconservative substitutions. The conserved face is comprised of hydrophobic residues surrounding an invariant arginine. A library of receptors mutated in C-i3 was constructed, and is being similarly analyzed.

726.9

IDENTIFICATION OF AN INTRACELLULAR TYROSINE RESIDUE CRITICAL FOR MUSCARINIC RECEPTOR-MEDIATED STIMULATION OF PHOSPHATIDYL INOSITOL HYDROLYSIS. K. Blüml*, E. Mutschler* and J. Wess. Natl. Inst. of Diabetes and Digestive and Kidney Diseases, Lab. of Bioorganic Chemistry, Bethesda, MD 20892, and *Dept. of Pharmacology, Univ. of Frankfurt, Germany.

Several lines of evidence suggest that the N-terminal portion of the third cytoplasmic loop (i3) of muscarinic (m1-m5) and other G protein-coupled receptors is of pivotal importance for G protein recognition and activation. It has been shown (Wess et al., Mol. Pharmacol. 38, 517, 1990) that replacement of the first 16 amino acids of the i3 loop of the rat m3 muscarinic receptor (primary biochemical response: stimulation of PI hydrolysis) with the corresponding segment of the human m2 receptor (primary biochemical response: inhibition of adenylyl cyclase) resulted in a mutant receptor that was no longer able to activate the PI pathway. Based on this observation, the present study was designed to identify specific amino acids within the N-terminal portion of the i3 region of the m3 receptor (rat) which are required for efficient G protein coupling. Functional analysis of several chimeric m2/m3 muscarinic receptors (transiently expressed in COS-7) showed that the first 4 amino acids of the i3 domain of the m3 receptor (Arg252-Ile253-Tyr254-Lys255) are of primary importance for receptor-mediated stimulation of PI hydrolysis. Further mutational analysis of this 4-amino-acid segment by single amino acid substitutions demonstrated that Tyr254 is essential for efficient activation of the PI pathway. This Tyr residue (or its aromatic character) is conserved among most biogenic amine and glycoprotein hormone receptors, suggesting that it may also play an important functional role in other G protein-coupled receptors.

EXCITATORY AMINO ACIDS: EXCITOTOXICITY VII

727.1

GLUTAMATE-INDUCED INTRACELLULAR pH CHANGES IN HIPPOCAMPAL NEURONS DEMONSTRATE ALTERED ENERGY METABOLISM RESULTING FROM Ca²⁺ AND Na⁺ LOADS. G. J. Wang*, B. D. Randall and S. A. Thayer. Dept. of Pharmacology, Univ. of Minnesota Medical School, Minneapolis, MN 55455.

Glutamate(Glu)-evoked increases in the free intracellular H⁺ concentration, [H⁺]_i, in single rat hippocampal neurons grown in primary culture were studied with carboxy SNARF-based dual emission microfluorimetry. The response was blocked by the NMDA receptor antagonist CGS19755 and required extracellular Ca²⁺; Ba²⁺ substituted for Ca²⁺. Pretreatment with 2-deoxy-D-glucose completely blocked the Glu-induced [H⁺]_i increase but did not block Glu-induced Ca²⁺ influx. We hypothesize that the Glu-induced Ca²⁺ load uncouples mitochondrial respiration. Consistent with this hypothesis, the mitochondrial uncoupler FCCP mimicked and occluded the Glu-induced [H⁺]_i increase. Maximally effective concentrations of FCCP (1 μM) not only blocked the Glu-induced [H⁺]_i increase but also reversed the effect of Glu on [H⁺]_i. Thus, following treatment with FCCP the same Glu challenge that produced a [H⁺]_i increase now decreased the FCCP-induced [H⁺]_i elevation. The Glu-induced [H⁺]_i decrease did not require extracellular Ca²⁺, was blocked by 100 μM CNQX, required extracellular Na⁺, and was mimicked by veratridine. Arachidonic acid (10 μM) uncoupled mitochondria and produced pH changes similar to those elicited by FCCP. Thus, depending on the state of the mitochondria Glu produced either a Ca²⁺ dependent acidification or a Na⁺ dependent alkalization. We postulate that exposure to both an uncoupling agent, such as arachidonic acid, and a large Na⁺ load shuts down glucose metabolism.

727.3

MK-801 INDUCES EXTENSIVE NEURONAL NECROSIS IN POSTERIOR CINGULATE/RETROSPLENIAL CORTICES. D. F. Wozniak, M. McEwen, M. A. Sesma*, J. W. Olney, A. S. Fix. Washington University, St. Louis, MO 63110 and Eli Lilly & Co., Greenfield IN 46140.

We have previously shown that phencyclidine (PCP), or various PCP receptor ligands (PRL), cause pathomorphological changes in pyramidal neurons of the rat cerebral cortex. A single systemic (sc or ip) injection of dizocilpine (MK-801), the most selective and potent PRL known, causes this neurotoxic reaction to occur in rats, with females being more sensitive (ED₅₀ = 0.18 mg/kg, sc) than males (ED₅₀ = 0.32 mg/kg, sc). The neurotoxic reaction is restricted to pyramidal neurons in layers III and IV of the posterior cingulate/retrosplenial (PC/RS) cortices, and consists of vacuole formation and dissolution of mitochondria. Although we initially considered this reaction reversible, Allen and Iversen (Science, 1990, 247: 221) reported that MK-801, at a high dose (5 mg/kg, ip), killed a small number of cingulate neurons (5 necrotic neurons per section) in adult male rats. In the present study, we treated adult female rats (5 - 7 months old) with a very high dose of MK-801 (10 mg/kg, ip) and counted the number of necrotic neurons in hematoxylin and eosin-stained sections of PC/RS cortices 4 days later. Since preliminary data indicated that the acute vacuole reaction induced by MK-801 was less severe in the rostral and more severe in the caudal portions of the PC/RS cortical area, we counted necrotic neurons at both rostral and caudal levels. At a rostral level (1.6 to 3.5 mm posterior to bregma), the number of necrotic neurons ranged from 29 to 107 per section and at a more caudal level (6.1 to 8.3 mm posterior to bregma) the counts ranged from 64 to 191 necrotic neurons per section. It appears from these findings that the neuron-necrotizing effects of MK-801 can involve a much larger number of neurons than was previously described. Supported by RSA MH 38894 (JWO), AG 05681 (DFW/JWO).

NMDA INDUCES A RAPID, CONCENTRATION AND Ca²⁺ DEPENDENT ACIDOSIS IN CULTURED FETAL RAT HIPPOCAMPAL NEURONS. R.P. Irwin*, S-Z. Lin, R.T. Long and S.M. Paul. Section on Molecular Pharmacology, Clinical Neuroscience Branch, National Institute of Mental Health, NIH, Bethesda, Maryland 20892

Using the pH sensitive fluorescent indicator 2',7'-bis-(2-carboxyethyl)-5-(and-6)-carboxyfluorescein (BCECF) and the Ca²⁺ sensitive indicator fura 2 we studied the ability of NMDA to alter intracellular pH (pH_i) and intracellular calcium [Ca²⁺]_i in fetal rat hippocampal neurons and glia. NMDA (2.5-250 μM) applied for 60 sec to hippocampal neurons resulted in a rapid, usually reversible (with recovery of pH_i taking several minutes) and concentration-dependent reduction in pH_i with an EC₅₀ of 39 μM and E_{max} (ΔpH) of -0.53. By contrast, glial cells showed little or no change in pH_i following exposure to NMDA. The NMDA-receptor induced intracellular acidification of hippocampal neurons was blocked by the NMDA receptor antagonist [3-(±)-2-carboxypiperazine-4-yl]-propyl-1-phosphonic acid (CPP). Removal of extracellular Ca²⁺ eliminated both the NMDA-induced elevation in [Ca²⁺]_i and the reduction in pH_i suggesting that the NMDA-induced acidification is mediated by Ca²⁺ influx. Increasing extracellular pH from 7.4 to 8.0 (thereby reducing extracellular [H⁺] by ~75%) did not significantly attenuate the NMDA-induced reduction in pH_i suggesting an intracellular source of H⁺. Finally, exposure of neurons to neurotoxic concentrations of NMDA for more prolonged periods of time (≥10 min) resulted in a more prolonged reduction in pH_i. We postulate that the NMDA-induced reduction in pH_i may mediate some of the actions of glutamate. For example, a prolonged reduction in pH_i induced by excitotoxins may result in an inhibition of important metabolic enzymes (e.g. phosphofructokinase) leading to ATP depletion and cell death. The ability (or inability) of neurons to rectify pH_i following exposure to NMDA/glutamate may therefore determine their susceptibility to excitotoxins.

727.4

RETINAL TOXICITY INDUCED BY D,L-2-AMINO-3-PHOSPHONOPROPIONIC ACID (D,L-AP3) IN THE RAT: A LIGHT AND ELECTRON MICROSCOPIC EVALUATION. A.S. Fix*, J.W. Horn, J.A. Johnson, C.A. Johnson, R.L. Hall, and J.P. Tizzano. Toxicology Research Laboratories, Lilly Research Laboratories, Eli Lilly and Co., Greenfield, IN 46140.

Metabotropic glutamate receptors are thought to have a role in the development and plasticity of the nervous system. D,L-AP3, a phosphono-substituted analog of aspartic acid, has mixed agonist/antagonist activity at metabotropic glutamate receptors. After treatment of neonatal rats, D,L-AP3 produced neurobehavioral deficits (Tizzano et al., NS Abstr., 1990, 1991) and severe atrophy of the retina and optic nerve (Fix et al., NS Abstr., 1992). The present study examined the evolving retinal lesion induced by D,L-AP3. Neonatal rats were treated intraperitoneally with vehicle or 400 mg/kg/day D,L-AP3 on postnatal days (PND) 3 through 6. On PND 5, 7, 10, 15, and 20, retinas were examined by light and electron microscopy. At PND 5 and 7, cells injured by D,L-AP3 were evident in two developing retinal layers; the middle of the outer neuroblastic layer and the more differentiated inner nuclear layer. Injured cells had swollen, pale cytoplasm or remained as dense, pyknotic debris. Retinal damage progressed at PND 10 and 15, since more cells were injured and necrosis of additional retinal layers was observed. By 20 PND, retinal atrophy was severe, although ganglion cells remained. This study indicates that affecting metabotropic glutamate receptors during postnatal development can severely alter normal retinal development in the rat.

EFFECT OF AGE, SEX, AND STRAIN OF RAT ON MK(+)-801-INDUCED BEHAVIORAL RESPONSES AND RETROSPLENIAL CORTICAL NEURONAL NECROSIS. L.L. Truex*, E. Gomez, C.A. Johnson, R.A. Smith, K.A. Wightman, and A.S. Fix. Toxicology Research Laboratories, Lilly Research Laboratories, A Division of Eli Lilly and Company, Greenfield, IN 46140.

Early investigations in our laboratory suggested that after single doses of MK(+)-801, behavioral responses and retrosplenial neuronal necrosis might vary with age, sex, and strain of rat. To examine this, male and female (70±4 or 127±2 days of age) Fischer 344 (F344) and Sprague Dawley (SD) rats were given a single subcutaneous dose of 0, 0.5, 1.0 or 5.0 mg/kg MK(+)-801. The severity of behavioral responses and the degree of neuronal necrosis in the retrosplenial cortex were determined. Within 30 minutes of treatment, all rats given 5.0 mg/kg MK(+)-801 developed ataxia, twitching, and lateral recumbency; rats given lower doses exhibited the same behavioral responses but to a lesser degree and duration. Differences in the character of behavioral responses were not noted when comparing age, sex and strain. However, male rats recovered within 24 hours but female rats were still moderate to severely ataxic 2 days after treatment. Also, ataxia was more severe for all older rats in the 5.0 mg/kg group. In female rats, necrosis of retrosplenial neurons occurred in all treatment groups and was extensive in the 5.0 mg/kg group. However in male rats, limited necrosis was detected only in the 5.0 mg/kg group. Although there was a suggestion of increased neuronal necrosis in SD rats, obvious differences were not evident when comparing strain and age. These behavioral and histologic data indicate that female F344 and SD rats are more sensitive than male rats to the effects of MK(+)-801.

DISSOCIATION OF SEIZURES AND CA1 HIPPOCAMPAL DAMAGE INDUCED BY THE CYANIDE METABOLITE 2-IMINOTHIAZOLIDINE-4-CARBOXYLIC ACID (2-ICA) ‡. R.S. Bitner, G.E. Isom and G.K.W. Yim. Department of Pharmacology and Toxicology, Purdue University, West Lafayette, IN 47907.

The cyanide metabolite 2-ICA produces MK-801 and CNQX-sensitive seizures in mice and selective CA1 hippocampal damage following 7-day icv infusion at a subconvulsive dose in rats. In the present study, seizure activity was observed in all mice receiving a single i.c.v. injection of 2-ICA (3.2 μ mol). When sacrificed 5 days later, 7 out of 10 mice displayed CA1 hippocampal damage. As expected, 2-ICA induced seizures were seen only in 3 out of 10 mice pretreated with MK-801 (1 mg/kg i.p.). However, CA1 damage was seen in 60 % of these animals. Consistent with our earlier findings in rats, these studies in mice indicate that 2-ICA-induced CA1 hippocampal damage is independent of seizure activity. Moreover, the inability of MK-801 to prevent 2-ICA damage suggests that NMDA receptor activation may not be required for 2-ICA neurotoxicity. (Supported in part by NIH grants ES4140 & RR0586.)

NMDA RECEPTOR ACTIVATION SELECTIVELY DESTABILIZES LIGATIN mRNA IN HIPPOCAMPAL NEURONS. D.M. Panchision, C.M. Gerwin, R.J. DeLorenzo*, and E.R. Jakoi. Department of Neurology, Medical College of Virginia, Richmond, VA 23298.

Acute activation of N-methyl-D-aspartate (NMDA) receptors in hippocampal neurons results in the down-regulation of ligatin, a receptor for phosphoglycoproteins present on dendritic and somal surfaces (Jakoi et al., *Brain Res* 582:282-290, 1992). This change in ligatin protein is accompanied by a selective reduction (40-80%) in steady state levels of mRNA coding for ligatin, whereas mRNAs encoding neuron-specific enolase and glucose-6-phosphate dehydrogenase are not decreased. Using nuclear run-on assays, *in situ* hybridization, and transcriptional inhibition studies with α -amanitin, we found that the NMDA receptor-mediated effect on cytosolic ligatin mRNAs occurs post-transcriptionally via an accelerated degradation of the RNA transcripts. Furthermore, steady state levels of ligatin mRNAs are altered by inhibition of protein synthesis in either the presence or absence of NMDA receptor activation, suggesting that ligatin mRNA stability is coupled to translation. The data support the hypothesis that modulation of mRNA stability is an early consequence of NMDA receptor activation leading to long-term changes in neuronal function.

GLUTAMATE ENHANCES ZINC TOXICITY IN XENOPUS OOCYTES EXPRESSING EXCITATORY AMINO ACID RECEPTORS. J.M. Nave* and J.D. Connor. Department of Pharmacology, The Pennsylvania State University College of Medicine, Hershey, PA 17033

Glutamate receptor agonists and zinc are known to be neurotoxic independently of each other. We have recently shown that exogenous zinc administration enhances kainic acid-mediated CA1 and CA3 pyramidal cell toxicity *in vivo* (*Brain Res.*, 604: 298-303 (1993)). We wanted to test whether the reverse is true: i.e. can excitatory amino acid receptor activation enhance cytotoxicity caused by zinc. The effects of glutamate on toxicity produced by zinc were studied using the *Xenopus* oocyte expression system. Oocytes were injected with total (cerebrum) rat brain poly(A)⁺ mRNA or distilled water. Zinc (50 mM-400 mM) toxicity in incubated oocytes before and after glutamate was measured two ways: by persistent depolarization of the membrane potential and by dye (trypan blue) exclusion. In oocytes injected with mRNA, subtoxic doses of glutamate (1mM) significantly enhanced the toxicity caused by zinc compared to water-injected controls. Moreover, toxic responses elicited by zinc alone and zinc with glutamate were significantly augmented when calcium was depleted from the medium. These findings (in concordance with previous *in vivo* findings from our laboratory) suggest that glutamate and zinc may act synergistically to cause cytotoxicity and that calcium may protect cells from the toxic effects of zinc.

ONTOGENY OF IBOTENIC ACID LESION IN RAT BRAIN REVEALED BY COMBINED MRI AND HISTOLOGY. N. Ben-Horin¹, R. Schul¹, S. Hazvi¹, P. Bendel² and Y. Dudai¹. Depts. of ¹Neurobiology and ²Chemical Physics, Weizmann Institute, Rehovot, Israel.

We have analyzed the ontogeny of a neurotoxic lesion in rat brain. Rats were each unilaterally microinjected with ibotenic acid at 5 sites aiming at the piriform cortex (PC). The brains were imaged at 8 time points during 60 days post-lesioning, using *in vivo* magnetic resonance imaging (MRI). The MR spin-echo, T₂-weighted images were taken at 4.7 T. Following MRI at each time point, the brain of some of the animals was sectioned and stained for cytoarchitecture (Nissl), myeloarchitecture (modified Heidenhain) and cytochrome oxidase. The MR images taken 2 days post-lesioning revealed a high intensity signal, indicating edema, in extended areas in and around the PC and around the injection needle penetration sites in the neocortex. Similar but smaller affected areas were detected by the histological stainings. All the techniques revealed additional damage, including increased size of the contralateral ventricle relative to the ipsilateral one, and deformation of structures lining the edematous area in the neocortex (e.g. corpus callosum and hippocampus). With time, a dramatic decrease was detected in the size of the affected area surrounding the PC. The appearance of the other affected areas essentially returned to normal. Each of the techniques gave unique information about the lesion, with MRI being the most reliable in determining the extent of edema and structural deformation. Our data emphasize the need to take into account the post-lesion interval and the multiple and often distributed consequences of the lesion. The data also indicate that ca. 2 weeks elapse before transient acute effects of the trauma and the lesion subside. (N.B.H. is a recipient of a Stone Post-Doctoral Fellowship).

ROLE OF PROTO-ONCOGENE *c-fos* ACTIVATION IN GLUTAMATE-MEDIATED NEUROTOXICITY. J.R. Dave*, M.A. DeCoster, E. Knight, T. Dang, B.P. Doctor, F.C. Tortella and H.S. Ved. Division of Neuropsychiatry and Biochemistry, Walter Reed Army Institute of Research, Washington, DC 20307-5100.

Earlier *in vivo* and *in vitro* studies have reported that activation of the glutamate/NMDA receptor complex results in stimulation of *c-fos* oncogene. However, the effect of glutamate-mediated *c-fos* activation in various anatomical regions of the brain and the functional importance of *c-fos* activation are poorly defined. The objectives of the present study were to determine if 1) glutamate produced differential effects in neuronal cultures derived from cerebral cortex, hippocampus and cerebellum and 2) treatment with *c-fos* antisense (AS) oligonucleotide prevented glutamate toxicity. Primary cultures enriched in neurons dissociated from embryonic rat cerebral cortex, hippocampus and cerebellum were treated in a serum-free media with either vehicle or glutamate (100 μ M) for 15, 30 or 60 min and *c-fos* mRNA levels were determined. Treatment of cells with glutamate produced a transient increase in *c-fos* mRNA levels. The increase in *c-fos* mRNA was highest in neuronal cells obtained from cerebellum and lowest in those from cerebral cortex; hippocampus exhibited intermediate stimulation. Similar changes in glutamate-induced calcium flux, as measured by fluo-3, were observed in cells obtained from these brain regions. Addition of 5 μ M *c-fos* AS oligonucleotide along with 100 μ M glutamate produced a minimal (5-15%) neuroprotective effect in neurons obtained from cerebellum, an intermediate (40-50%) effect in hippocampus and a maximal (60-70%) effect in cortex. These results demonstrate that glutamate has differential specificity for anatomical regions of the brain and suggest a causative role of *c-fos* proto-oncogene in glutamate-mediated neuronal toxicity.

REDUCTION OF GLUTAMATE-LIKE IMMUNOREACTIVITY IN THE LOCUS COERULEUS FOLLOWING REPETITIVE INJECTIONS OF β -AMYLOID PEPTIDE INTO THE HIPPOCAMPUS OF THE RAT. Z. Wang, R.-H. Liu, V.K. Reddy and C.D. Barnes*. Department of VCAPP, Washington State University, Pullman, WA 99164-6520.

The neurotoxic effect of β -amyloid protein (β -AP) has been reported to be associated with excitotoxicity of glutamate (Glu). Recently, the presence of Glu in the locus coeruleus (LC) has been demonstrated in the mouse, rat and cat. In this study we injected β -AP (25-35 fragments) into the rat hippocampus to examine its effect on Glu- and tyrosine hydroxylase (TH)-like immunoreactive (LI) neurons in the LC. β -AP injections were made repetitively once every five days (two or three injections; 3 nmol in 2 μ l of distilled water). Fluorescent microspheres (either alone or with β -AP) were also injected into the hippocampus in some rats to show the Glu- and TH-LI coeruleo-hippocampal neurons. Control experiments were conducted by injecting the vehicle (distilled water) into the hippocampus.

The results from this study revealed a significant cell loss in the hippocampus at the site of β -AP injection as well as a reduction of Glu- and TH-LI neurons in the LC. Furthermore, in β -AP/microsphere injected animals, only 34% and 50% of hippocampal projection neurons contained Glu and TH respectively, compared to 93% and 92% in animals that received microspheres alone. The reduction of Glu- and TH-like immunoreactivity was more prominent in the dorsal division of the LC, correlating with the predominant concentration of coeruleo-hippocampal neurons in this area. These results suggest that β -AP not only has a neurotoxic effect on hippocampal cells but also on noradrenergic cells whose axons project to this area. In addition, β -AP is known to cause severe damage to noradrenergic terminals (Emre, M. et al., *Neurobiology of Aging*, 13:553, 1992) and this in turn may lead to increased firing of LC cells resulting in depletion of Glu.

D-ASPARTATE EFFLUX FROM ASTROCYTES OCCURS DURING GLUCOSE BUT NOT OXYGEN DEPRIVATION AND IS PREVENTED BY THREO-B-HYDROXY-ASPARTIC ACID. M.C. Longuemare* and R.A. Swanson, Dept. of Neurology, Univ. of California and VAMC, San Francisco, CA 94121.

Controversy exists as to whether astrocytes are a major source of excitatory amino acid release during cerebral ischemia. To address this issue, primary rat cortical astrocytes were preloaded with [3 H]-D-aspartate (D-ASP) and subjected to substrate deprivation. Glycolytic blockade caused an 85% reduction in intracellular D-ASP ([D-ASP]_i) in one hour. Preloading the cells with the transport inhibitor threo-B-hydroxy-aspartic acid (TBHA) completely prevented this efflux, suggesting reversal of uptake as the route of efflux. To investigate the mechanism of uptake reversal, D-ASP-loaded astrocytes were depolarized (4mM Na, 142mM K) in the presence of ouabain. Depolarization produced an 80% reduction in [D-ASP]_i which was largely prevented by preloading cells with TBHA. These results support the hypothesis that glucose deprivation causes disruption of ion homeostasis and reversal of glutamate uptake. In contrast to glycolytic inhibition, blockade of oxidative metabolism with sodium azide failed to induce efflux of D-ASP. These results suggest that continued glycolytic metabolism is an important determinant of whether excitatory amino acids will be released from astrocytes during ischemia.

NEUROBEHAVIORAL EFFECTS OF PERINATAL INTRACRANIAL ADMINISTRATION OF EXCITOTOXINS. B.A. Pappas*, K. Hewitt, J.N. Armstrong, W. McCleod and D.C. McIntyre. Dept. of Psychology, Carleton Univ., Ottawa, Canada K1S 5B6.

The neonatal rat brain is most sensitive to the glutamate receptor agonist N-methyl-D-aspartate (NMDA) at around 7 days of age (McDonald and Johnston, *Brain Res. Rev.*, 1990). We have observed that medial septal injections of NMDA but not ibotenic (IBO) or quisqualic (QUIS) acid at this age severely impairs behavior and causes marked ventricular hypertrophy and periventricular tissue loss. The brain damage was evident ten days after injection and persisted into adulthood. The NMDA-injected rats also developed spontaneous recurrent seizures. NMDA and IBO but not QUIS caused transient reductions of hippocampal and cortical choline acetyltransferase activity. IBO caused minimal ventricular hypertrophy ten days later but substantial hypertrophy in adulthood. The neural and behavioral effects of NMDA were prevented by systemic administration of MK-801 thirty minutes beforehand. Administration of MK-801 thirty minutes after afforded lesser but significant protection.

GP120, AN HIV-1 DERIVED PEPTIDE, SELECTIVELY AUGMENTS NMDA-MEDIATED HIPPOCAMPAL INJURY IN PERINATAL RODENTS. Faye S Silverstein, John DE Barks*, Rong Sun University of Michigan, Ann Arbor, MI 48109

Recent data suggest that gp120, a glycoprotein secreted by HIV infected macrophages, is neurotoxic, and that toxicity is mediated, in part, by activation of NMDA-type excitatory amino acid (EAA) receptors. Since susceptibility to NMDA-mediated injury peaks in immature rodents, we examined the neurotoxicity of gp120 alone, and co-injected with NMDA in 7 day old (P7) rats using stereotaxic coordinates targeted to right dorsal hippocampus (HIP) or striatum. Our previous studies suggested that HIP neuropil was most susceptible and that loss of tissue mass was a sensitive index of injury. Injury was assessed on P12, by histopathology and estimates of bilateral HIP volumes (from serial cross-sectional areas). GP120 elicited subtle, dose-dependent HIP injury (1 ng, n=3, no injury; 50 ng, n=7, subtle cell loss close to injection site, 7/7, mild HIP atrophy, 1/7; 200 ng, n=5, focal cell loss 4/5, mild HIP atrophy, 3/5). Co-injection of 50 ng gp120 with 5 nmol NMDA (n=22) produced much greater HIP atrophy than 5 nmol NMDA alone (n=23) (gp120+NMDA, -43 \pm 3.3%, NMDA, -21 \pm 2.6%, p<0.001, t-test). In striatum, gp120 did not influence the severity of NMDA-mediated injury. In contrast, co-injection of 50 ng gp120 with 25 or 50 nmol quisqualate did not increase HIP injury. Thus, gp120 increased EAA-induced neuropathology in a region and agonist-specific fashion. These data provide strong support for the hypothesis that locally secreted gp120 may potentiate the neurotoxicity of endogenous EAA neurotransmitters, acting at NMDA-type receptors, in HIV-infected brain.

MK-801 ATTENUATES INCOMPLETE BUT NOT COMPLETE INFARCTION IN PHOTOTHROMBOTIC DISTAL MIDDLE CEREBRAL ARTERY OCCLUSION (MCAO) IN RATS. H.Yao, C.G.Markgraf, W.D.Dietrich, R.Prado, B.D.Watson and M.D.Ginsberg*. Cerebral Vascular Research Center, Department of Neurology, University of Miami School of Medicine, Miami, FL 33101

Despite its published success, the non-competitive NMDA antagonist, MK-801, failed to reduce infarct volume in a stroke model of Sprague-Dawley rats (Yao et al., *Stroke* 1993). In this study, we studied the effects of MK-801 on incomplete (selective neuronal injury) as well as complete infarction in the same model mentioned above, using Wistar rats. MK-801 (1mg/kg, i.p.), administered 30 min before distal MCAO, failed to affect the volume of complete infarction (n=5-6, mean \pm S.D., 95 \pm 16 mm³ and 92 \pm 14 mm³ in untreated and treated groups, respectively). By contrast, the volume of incomplete infarction was reduced by 44% with MK-801 treatment. Nonetheless, the potentially treatable zone of incomplete infarction, which consisted of 7% of total injury volume (complete+incomplete infarct), was small. Thus, therapeutic efficacy with MK-801 would be small in this model of thrombotic distal MCAO.

727.16

QUANTITATIVE EVALUATION OF THE PROTECTIVE EFFECTS OF GLUTAMATE RECEPTOR ANTAGONISTS IN A PHOTOTHROMBOTIC MODEL OF RETINAL ISCHEMIA. F. Moroni Jr., G. Lombardi, S. Faussone-Pellegrini and F. Moroni*. Depts. Pharmacology, Ophthalmology and Histology, Univ. of Florence, 50134 Firenze, Italy.

We previously described a quantitative "in vivo" model to study ischemic neuronal damage in the rat retina. Neuronal damage was quantified by measuring the activity of the marker enzymes choline acetyl-transferase and glutamic acid decarboxylase (*Vision Res.*, 1993, in press). Retinal ischemia was induced by injecting rats i.v. with the photosensitive dye rose bengal (80 mg/kg) and by exposing one of their eyes to cold light filtered at 560 nm. This results in profound damage of retinal tissue. The inner nuclear and the inner plexiform layers had a diffused swelling and numerous neurons had the chromatin densely packed forming clumps distributed all along nuclear contours. Blood vessels were enlarged and had thrombotic material. With the aim of investigating whether excitatory amino acid antagonists were able to reduce this neuronal damage we intravitreally administered to the rats, immediately after the photochemical reaction, the following compounds: 1) aminophosphonovaleric acid; MK801 (competitive and non competitive NMDA antagonists); 2) NBQX and GYKY 52466 (competitive and non competitive AMPA antagonists); 3) 7-Cl-thiokynurenic acid (glycine antagonist and free radical scavenger) and 4) thiokynurenic acid (nonselective glutamate antagonist and radical scavenger). A significant degree of protection was obtained when large doses of these antagonists (50-200 nmoles) were injected intravitreally. However, a maximum degree of protection (a reduction of 80% of the damage found in saline injected eyes) was obtained when both AMPA and NMDA receptor antagonists were simultaneously injected. This was also obtained by administering 20-50 nmoles of thiokynurenic acid. In conclusion, antagonism of both AMPA and NMDA receptors results in better protection than selective antagonism of only one receptor type.

727.17

INTRACELLULAR CALCIUM DEPOSIT FORMATION AFTER EXCITOTOXIC LESIONS OF THE RAT GLOBUS PALLIDUS. N. Mahy^{1*}, J. Rivero^{3,5}, F. Bernal¹, M. Lorente², R. Sainz¹, N. Andres, X. Llovet³, K. Fuxe^{1,4} and A. Prats². U. Biochemistry¹ and Dept. Anatomy², Sch. Medicine, Scient. Tech Serv.³ Univ. Barcelona, Spain, Dept. Histol. Neurobiol. Karolinska Inst. Stockholm, Sweden⁴ and CONICET, Argentina⁵.

Microinjections of ibotenic acid (25 mM) into the globus pallidus of adult male Sprague-Dawley rats led to the progressive appearance of intracellular calcium deposits related to a progressive neurodegenerative process. In the present study electron microprobe showed the existence of two different groups of deposits, one of which contained phosphorus and the other one silicon and aluminium. A concomitant rise in potassium was associated with the lesion. Transmission electron microscopy revealed a strong astro and microglial activation and the presence of thin fibrous material in the calcium deposits linked with mitochondria and other intracellular organelles. The pattern of distribution of these deposits excludes their possible capillary origin. In summary, our data show the diversity of intracellular calcium deposits and establish a close relationship between their progressive formation and the neurodegenerative processes. (Supported by FISs 90E0593-2E; N.A is a fellow of CIRIT)

727.19

GLUTAMATE-INDUCED ENERGETIC STRESS IN HIPPOCAMPAL SLICES. D.H. Pennington, A. J. Douglas, W.D. Lust and T.S. Whittingham. Department of Neurosurgery, Case Western Reserve University, Cleveland, OH 44106.

We previously reported that exposure of hippocampal slices to 1 mM glutamate for 30 minutes produced a marked decrease in ATP and PCr, and elevation of tissue lactate. This metabolic stress did not appear to be mediated by NMDA receptor stimulation or enhanced glutamate uptake. We have now investigated the possible roles of the kainate, AMPA and metabotropic receptors in triggering these alterations. Transverse hippocampal slices from male mongolian gerbils were equilibrated for 2 hr before exposure to artificial cerebrospinal fluid (ACSF) containing an experimental condition. Slices were frozen after 30 min, assayed for ATP and PCr, and metabolite values expressed as nmoles per mg protein.

1 mM glutamate produced a 13% fall in ATP (from 10.21 to 8.88; $p < 0.05$) and a 30% drop in PCr (from 19.59 to 13.79; $p < 0.05$). Kainate exposure produced a dose-dependent fall in both ATP and PCr, with 10 μ M producing a maximal effect (ATP fell to 8.99 and PCr to 13.87). Another kainate agonist, 1 μ M domoic acid, produced a similar fall in ATP and PCr. AMPA also caused a substantial fall in the high energy phosphates, but was maximally effective at 100 μ M (ATP = 5.65; PCr = 10.11). However, two other AMPA agonists, quisqualate and aniracetam, were relatively ineffective. Finally, the metabotropic agonist ACPD (1 μ M) was the most potent agonist tested, dropping ATP to 4.95 and PCr to 8.34. The agonist experiments suggest that all three glutamate receptor subtypes which were tested could produce the metabolic effects. Three receptor antagonists were tested at concentrations of 100 μ M. CNQX blocked the kainate- and AMPA- and ACPD-induced metabolic stress. The kainate antagonist GAMS also blocked the metabolic effects of kainate, AMPA and ACPD. The metabotropic antagonist, AP3, was effective in blocking the ACPD effects. Finally, CNQX was the only antagonist which prevented the metabolic changes during exposure to 1 mM glutamate. The results suggest there are multiple mechanisms by which glutamate can elicit an energetic stress *in vitro*, involving kainate, AMPA and metabotropic receptor subtypes, but not involving the NMDA receptor. CNQX appears to be the only compound capable of blocking all aspects of the metabolic stress.

727.18

MODULATION OF GLUCOCORTICOID RECEPTOR BINDING IN PRIMARY CULTURES OF-DISPERSED HIPPOCAMPAL CELLS FOLLOWING NMDA TREATMENT. D. O'Donnell*, R. Alonso, J. Diorio, and M.J. Meaney. Develop. Neuroendocrinology Lab., Douglas Hosp. Res. Ctr., Depts. of Psychiatry and Neurology & Neurosurgery, McGill Univ., Montreal, Canada H4H 1R3.

Glucocorticoids have been shown to exacerbate neuronal cell loss in cases of excitatory amino acid mediated insults. The present study examined the effects of NMDA treatment on glucocorticoid receptor (GR) binding capacity in a model of delayed excitotoxicity in primary cultures of dispersed hippocampal cells. Two hours following a 10 min. exposure to a lethal dose of NMDA (500 μ M), a 30-40% decrease in GR binding capacity was detected in comparison to vehicle-treated cultures. Examination of cell viability indicated no cell loss at this early time point. Western blot analysis from total cell culture homogenates revealed no change in the 97 kDa immunoreactive GR protein thus ruling out degradation of the receptor as a likely cause for the decrease in GR binding. Elevation of intracellular calcium (Ca^{2+}) is the hallmark NMDA neurotoxicity. *In vitro* manipulations of Ca^{2+} concentrations in cell culture homogenates successfully mimicked the NMDA-induced decrease in GR binding capacity. These findings suggest that during the initial stages of NMDA toxicity, which are associated with a massive influx of Ca^{2+} , effects of glucocorticoids may be dampened. This study strengthens the hypothesis that intracellular Ca^{2+} may act as a physiological modulator of GC hormone action at the receptor level.

727.20

COMPARISON OF NON-CHOLINERGIC NEUROTRANSMITTER EFFECTS FOLLOWING INTRACRANIAL INFUSIONS OF COLCHICINE AND IBOTENIC ACID INTO THE BASAL FOREBRAIN. L.W. Shaughnessy¹, S. Barone Jr.², W.R. Mundy², D.W. Herr³ & H.A. Tilson³. ¹Curriculum in Neurobiology, UNC, Chapel Hill ²ManTech Environmental Tech. Inc. ³NTD/HERL RTP, NC 27711

Intracranial infusion of various toxicants has been used to experimentally produce an animal model of basal forebrain neurodegeneration. The goal of the present experiment was to make direct comparisons of the effects of ibotenic acid and colchicine infusions on several non-cholinergic neurotransmitter systems. Bilateral infusions of either vehicle (0.5 μ l 0.1 M phosphate buffer, pH 7.4/site) colchicine (3.0 μ g/0.5 μ l/site) or ibotenic acid (6.0 μ g/0.5 μ l/site) were made in the nucleus basalis magnocellularis (NBM) of male Long-Evans rats. Four weeks post-lesion, behavioral assessments were made, and one week later, the rats were sacrificed for neurochemistry or histochemistry. Previous data showed that basal forebrain cholinergic and cognitive effects were similar following infusion of either neurotoxicant (Shaughnessy *et al.*, *Soc. Neurosci. Abst.* 1992). Analysis of several non-cholinergic measures revealed differences between the two neurotoxicants. Both neurotoxicants produced decrements in glutamic acid decarboxylase (GAD) staining in regions surrounding the NBM as determined by computerized image analysis. GAD immunoreactivity was significantly decreased in the reticular nucleus of the thalamus and the globus pallidus following ibotenic acid (41%) and colchicine infusions (21%), with a greater decrease in both area and density of stain for ibotenic acid. Catecholamine and indoleamine levels were measured in frontal and parietal cortex, striatum, and hippocampus using HPLC. No effects were observed in cortical or hippocampal catechol- or indoleamines. However, colchicine infusion decreased striatal dopamine and 3,4-dihydroxyphenylacetic acid (DOPAC) 21 and 24%, respectively, while ibotenic acid infusion had no effect on neurotransmitter levels. These results are discussed in relation to the cholinergic hypothesis of cognitive function.

EXCITATORY AMINO ACIDS: EXCITOTOXICITY VIII

728.1

NMDA-RECEPTOR MEDIATED NEUROTOXICITY IN CULTURED CEREBELLAR NEURONS IS ENHANCED AT LOW TEMPERATURES. A. Novelli* and A. Marini. Dept. Functional Biol., Biochem., Oviedo Univ., Sch. of Med., 33006 Oviedo, Spain; and Dept. of Neurology, Veterans Medical Center, Washington D.C. 20422, USA.

We have previously shown that 24 h exposure of cultured cerebellar neurons to glutamate (GLU) into the growth medium at 37°C, produces a concentration-dependent neurotoxicity, which is entirely blocked by NMDA-receptor antagonists (Novelli *et al.* Brain Res. 1992, 577, 41), and that GLU neurotoxicity increases with days in culture (DIC), being negligible at 5 DIC (Fernández *et al.* 1993, Mech. Neur. Injury and Degen., in press). We now report that the concentration of GLU producing signs of excitotoxicity such as darkening and swelling of the cell bodies in virtually all the neurons at 5-6 DIC, was reduced from >1000 μ M to ~20 μ M by lowering the incubation temperature to 25°C for 30 min before and 60 min after the addition of GLU to the growth medium. 24 h after returning the culture to 37°C, 50% of the neurons were dead following exposure to 25 μ M GLU. Maximum toxicity by GLU (500 μ M) was limited to ~65% of the neurons. GLU (1000 μ M) failed to produce any neurotoxicity in cultures continuously kept at 37°C. At 24 DIC, the concentration of GLU producing 50% neurotoxicity (NTC50) shifted from ~15 μ M at 37°C to ~5 μ M at 25°C, while 90% neurotoxicity was observed at ~25 μ M at 37°C, and ~10 μ M at 25°C. The neurotoxic effect of GLU was blocked by the NMDA receptor antagonist MK-801 (1 μ M) at any DIC. The neurotoxicity elicited via stimulation of the ionotropic NON-NMDA receptor by domoate (DOM), was not significantly enhanced by temperature changes in 5-6 DIC cultures. At 24 DIC, a modest shift in DOM NTC50 was observed (~5 μ M at 25°C vs. ~7.5 μ M at 37°C). Nevertheless, such shift was abolished in the presence of MK-801, indicating a role for DOM-induced release of endogenous GLU in the enhancement of neurotoxicity. Our results suggest that cerebellar neurons at early DIC already possess NMDA receptors that may mediate neurotoxicity, although they appear to be protected by other mechanisms which are temporarily impaired by short exposures to lower than physiological temperatures. COMPUTER SIMULATION OF N-METHYL D-ASPARTATE-RECEPTOR-DEPENDENT CHANGES IN A MAMMALIAN SPINAL NEURON. P. Saxena, R. Goldstein[†], T. Marczynski[†], L. Isaac Dept. Pharmacol. and Computer Ctr[†], Univ. of Ill. at Chicago, 60612.

Previously, we showed that dynorphin-induced neuron toxicity was mediated by N-methyl-D-aspartate (NMDA) sites in rat spinal cord. To study this excitotoxic process we developed a computer neuron model to simulate membrane effects of NMDA-receptor activation. This is a compartmental model based on Hodgkin-Huxley type equations. Parameter values are within the range typically observed in mammalian neurons. We included voltage-dependent Mg^{2+} blockade of NMDA-associated ion channels and the kinetics of Ca^{2+} influx through these channels. Synaptic input may be placed at varying distances from the axon and the model is designed to minimize computing time.

The output of our model is in harmony with observations of potential changes following application of NMDA to neurons. Also, it responds to simulated changes in extracellular Na^+ and K^+ in a manner characteristic of neurons. We are currently working to incorporate our neuron model into a larger simulation of a spinal reflex pathway. Our goal is to use the model to explore mechanisms of dynorphin-induced neuron toxicity.

NMDA ANTAGONISTS AND MPP⁺-RELATED DOPAMINERGIC TOXICITY IN MESENCEPHALIC CULTURES. W.J. Nicklas, E. Derr-Yellin and G.D. Zeevalk, Dept. Neurology, UMDNJ-Robert Wood Johnson Med. Sch., Piscataway NJ 08854.

Excitatory amino acid (EAA) receptor activation has been implicated in neurodegeneration associated with various modes of metabolic stress. The dopaminergic (DAergic) neurotoxin, MPP⁺, is thought to cause cell death by mitochondrial inhibition but whether excitotoxicity is involved has been controversial. Rat mesencephalic cultures incubated with MPP⁺ for 24 h evinced a dose-dependent decrease in DA cell viability as measured by DA uptake immediately after the 24 h incubation or 2 to 3 d later. However, at < 1 μM MPP⁺ the DA uptake 2 to 3 d after treatment was no longer depressed and was actually increased over controls. At > 5 μM MPP⁺, there was no recovery or augmentation of uptake. Thus there was a clear dose relationship for irreversible DAergic damage. In all cases, GABA uptake, as a measure of non-specific damage, was unaffected. The decrease in DA uptake observed 2-3 days after treatment, but not the acute decrease at 24 h was prevented by incubation during the 24 h insult period with NMDA antagonists (MK-801 or CGS-19755). The KA/AMPA antagonist, CNQX, had no effect. At present, it is not completely clear whether the NMDA antagonists are directly protecting against MPP⁺ toxicity or if the antagonists themselves are exerting a trophic-like action on the survivability of stressed neurons.

TGF-β1 ATTENUATES NMDA-INDUCED [Ca²⁺]_i ELEVATIONS AND NEUROTOXICITY IN CULTURED RAT HIPPOCAMPAL NEURONS J.H.M. Prehn^{1*}, C.L. Marcuccilli & R.J. Miller, Dept. Pharmacol. and Physiol. Sciences, Univ. of Chicago, Chicago, IL. 60637.

Transforming growth factor-β1 (TGF-β1), a multifunctional cytokine, is virtually absent in the CNS of humans and other mammalian species. In contrast, TGF-β1 expression increases strongly under a variety of pathophysiological conditions, such as cerebral ischemia, Alzheimer's disease and AIDS neuropathology. Previous studies have demonstrated that TGF-β1 has neuroprotective properties (Prehn et al., 1993), but its mechanism of action is poorly understood. In cultured rat hippocampal neurons we found that bath application of TGF-β1 (3 and 10 ng/ml) did not change the basal free [Ca²⁺]_i as determined by fura-2 based microfluorimetry. However, perfusion with TGF-β1 (3 ng/ml) for 10 or 30 min was able to reduce the increase in [Ca²⁺]_i produced by fast application of the glutamate receptor agonist NMDA (30 μM) by 18 and 20 %, respectively. In contrast, kainate (10 μM)-induced [Ca²⁺]_i elevations were enhanced by 24 - 30 % in approx. 70 % of the neurons perfused with TGF-β1 (3 ng/ml). In the same culture system, TGF-β1 (1 - 10 ng/ml) dose dependently reduced neuronal injury induced by exposure of the cultures to 100 μM NMDA for 20 minutes. Neuronal injury caused by exposure to 100 μM kainate for 18 h was reduced by treatment with 1 ng/ml TGF-β1, but potentiated at higher concentrations of TGF-β1. In further experiments, cultured rat astrocytes were heat stressed for 60 minutes at a temperature of 42.5 °C. Treatment with TGF-β1 (10 ng/ml) led to an increased expression of the 70 kD heat shock protein (HSP70) compared with controls as demonstrated by Western blot analysis and immunocytochemistry. The present study suggests that TGF-β1 acts on both neurons and astrocytes to induce a variety of responses that could modulate neuronal survival.

DELAYED IMMEDIATE-EARLY GENE ACTIVATION AND THE EXCITOTOXIC CASCADE Y. Shan¹, L.R. Carlock & P.D. Walker, Departments of Anatomy/Cell Biology & Molecular Biology/Genetics, Wayne State University School of Medicine, Detroit, MI 48201.

Excitatory amino acid receptor overstimulation produces a rapid cascade of neuronal death and glial/immune activation. Previously, we had demonstrated that intrastratial injection of the NMDA agonist, quinolinic acid (QA), triggers an extended phase of immediate-early gene (IEG; c-fos, c-jun, jun-B, zif/268) activation that overlaps with the induction of glial transcripts (GFAP, IL-1B) and the decline of neurotransmitter mRNAs (Shan et al., Soc. Neurosci. Abstr. 18 [1992] 167). Since it is possible that glial IEG activation may contribute to the spread of the excitotoxic cascade, the following experiments represent further characterization of the delayed IEG transcriptional phase.

Adult male rats received unilateral intrastratial injections of QA followed by sacrifice at acute time periods throughout the first day of the lesion. Northern analysis revealed normal neurotransmitter mRNA levels up to 6 hours following QA injection with a rapid decline thereafter. Interestingly, the delayed phase of IEG activation exhibited peak levels at 6 hours. Additional studies that attempt to determine if the delayed IEG transcriptional phase only occurs in relationship to excitotoxicity will be discussed. DEVELOPMENT OF NEURODEGENERATION INDUCED BY 3-NITROPROPIONIC ACID (3-NPA) INTOXICATION. C.N. Allen^{1,2}, J. Marino¹, and C.K. Meshui^{3,4}. Cntr for Res on Occup and Environ Toxicol¹, Dept Physiol² and Dept Med Psychol³, OR Hth Sci Univ and V.A. Med Cntr⁴, Portland, Oregon 97201.

3-NPA, a naturally occurring neurotoxin, is a suicide inhibitor of succinate dehydrogenase (SDH), a component of the mitochondrial electron transport chain complex II. 3-NPA is proposed to produce neurodegeneration by reducing neuronal energy levels, making neurons more vulnerable to glutamate excitotoxicity. We used a silver impregnation procedure to study the development of neurodegeneration in rats continuously receiving 3-NPA via osmotic minipumps. Two days of continuous 3-NPA intoxication (6.7 mg/day) produced a significant loss of weight which continued for up to 7 days. In contrast, rats receiving chronic 0.9% saline had a significant weight gain by 5 days. During the 3-NPA intoxication behavioral signs progressed from a wobbly gait to complete ataxia. The silver staining showed no evidence of degeneration at 1, 2 or 3 days of chronic 3-NPA intoxication. Degenerating fibers were observed within the diencephalon after 5 days with increasing fiber degeneration at 7 days. Removal of the 3-NPA after 5 days caused a reversal of the weight loss but degenerating fibers were still present in the diencephalon at day 10. Severely affected animals showed complete deterioration of the striatum and were ataxic. 3-NPA is a useful tool to study the effects of chronic exposure to metabolic toxins. ANDROGEN ALTERS NMDA-MEDIATED RESPONSES IN HIPPOCAMPAL CA1 PYRAMIDAL CELLS. W.A. Pouliot, R.J. Handa and S.G. Beck* Departments of Pharmacology, and Cell Biology, Neurobiology and Anatomy, Loyola University Medical Center, Maywood, IL 60153.

Anabolic/androgenic steroid abuse is a silent epidemic among athletes at all levels of competition. The psychological side effects associated with steroid abuse implicate the limbic system. Androgen receptor protein and mRNA are high in the CA1 region of the hippocampus. Our goal was to determine if the androgen 5-α-dihydrotestosterone propionate (5-DHTP) modulates the physiology of CA1 hippocampal pyramidal neurons and/or glutamate receptor mediated responses. Standard intracellular recording techniques in hippocampal slices *in vitro* were used. Male Sprague-Dawley rats, age 6-8 weeks, were either sham operated (SHAM), gonadectomized (GDX), or gonadectomized with two Silastic capsules of 5-DHTP surgically implanted (GDX+DHTP) to generate supraphysiological plasma levels of DHTP. Rats were sacrificed 3 weeks after surgery. Hippocampal slices from GDX+DHTP treated rats were perfused with buffer containing a high concentration of 5-DHTP (10 nM) to mimic the *in vivo* environment. High concentrations of DHTP altered active membrane properties of CA1 pyramidal neurons. The fast afterhyperpolarization was decreased in cells from GDX+DHTP treated rats. To test 5-DHTP's effects on glutamate receptor mediated actions, slices were exposed to 1 μM, 10 μM, and 30 μM concentrations of N-methyl-D-aspartate (NMDA), a synthetic glutamate agonist. In cells from SHAM and GDX treated rats, NMDA led to irreversible depolarization; however the GDX+DHTP cells were protected from the excitotoxicity. We conclude that DHTP altered hippocampal CA1 neuronal membrane properties and protected the pyramidal neuron from NMDA induced excitotoxicity.

DEVELOPMENTAL ALTERATIONS IN THE VULNERABILITY TO NMDA RECEPTOR ACTIVATION DETECTED WITH DIFFUSION-WEIGHTED NUCLEAR MAGNETIC RESONANCE IMAGING. M. van Lookeren Campagne¹, H.B. Verbeul², K. Nicolay² and R. Balázs* (spon:ENA), ¹Neth. Inst. Brain Res., Amsterdam, ²Dep. Neurosurg., Univ. Hosp. Utrecht, ³Bijvoet Center for Biomol. Res., Utrecht Univ., The Netherlands.

Contrast in diffusion-weighted images (DwIs) reflects differences in molecular translational movement (Brownian motion) of water molecules. We observed that an increase in signal intensity in DwIs taken from CNS of rat pups after intracerebral injection with NMDA parallels an increase in the intracellular volume fraction, measured with electrical impedance and confirmed by histology. Diffusion-weighted imaging therefore offers a possibility to detect, *in vivo*, local changes in cell volume as an early consequence of excitotoxic injury. In postnatal day (PND) 7 rat pups, intracerebral injection of NMDA shows a rapid increase in cell volume over a large area, encompassing the ipsilateral dorsal striatum, parietal cortex and the rostral part of the hippocampus. The degree of cell swelling, as well as the number of areas in which cells acutely respond to NMDA, peak between PND4-10 and decline rapidly at older ages. The ontogenetic peak of enhanced vulnerability to NMDA coincides with an enhanced diffusion of injected extracellular tracer molecules in the normal brain, detectable with magnetic resonance imaging techniques. We suggest that developmental changes in diffusion of NMDA together with changes in NMDA receptor properties contribute to the peak in vulnerability of the neonatal brain to intracerebrally injected NMDA.

HIV COAT PROTEIN GP160 EVOKES POTENTIATION OF NMDA-INDUCED RESPONSE OF CULTURED HUMAN EMBRYONIC NEURONS. P.-M. LLEDO¹, A. LANISELLE², M. TARDIEU² & J.-D. VINCENT¹; ¹CNRS, I.A.F., 91198 Gif-sur-Yvette, France; ²INSERM, Lab. Neurobiol., U. 56, Hôpital Bicêtre, 94275 Le Kremlin-Bicêtre, France.

The envelope protein of the human immunodeficiency virus (gp 120) has been proposed to cause neuronal death in developing murine hippocampal cultures or rat retinal ganglion cells. In HIV-infected individuals, gp120, released after cleavage of gp160 from HIV-infected macrophages or other cells in the brain, has been proposed as the etiology for the pathophysiology of AIDS central nervous system (CNS) disease. In this study, we have used cultured human embryonic cerebral cortical and spinal neurons to test whether gp160 is itself neurotoxic. Neuronal cultures of 10-30 days from 8 to 12-week old foetuses were exposed for various times (1-45 min) to a buffered Locke's solution containing up to 500 pM gp160 (Transgene) without any effect on voltage-gated Ca²⁺ currents or on intracellular free Ca²⁺ concentration ([Ca²⁺]_i). By contrast, the large rises in [Ca²⁺]_i induced by 50 μM NMDA were potentiated by acute (15 min) exposure to 50-250 pM gp160. This potentiation, which was not mimicked by other glycoproteins such as IgG, provides a mechanism by which HIV infection may cause neuronal death through Ca²⁺-mediated excitotoxicity induced by NMDA and, therefore, may be relevant to the pathophysiology of HIV-related CNS disease.

NEURODEGENERATION INDUCED BY ISCHEMIA OR GLYCOLYSIS INHIBITORS IS PREVENTED BY LACTATE INFUSION IN HIPPOCAMPAL SLICES. AM. Benz, Y. Izumi, CF. Zorumski, DB. Clifford*, MT. Price & JW. Olney, Depts of Psychiatry and Neurology, Washington Univ, St Louis, MO

Using rat hippocampal slices, we have shown participation of nitric oxide (NO) in NMDA excitotoxicity, and it has been proposed that NO may play a role in ischemic neurodegeneration. Although the mechanism by which NO damages neurons is not understood, it is known that NO induces ADP-ribosylation which may inhibit glyceraldehyde-3-phosphate dehydrogenase (GAPDH), an enzyme required for glycolysis. As a first step toward investigating the potential role of GAPDH inhibition in excitotoxic phenomena, we have begun examining the effects on rat hippocampal slices of blocking glycolysis by GAPDH inhibitors. Consistent with findings of Schurr et al., blocking glycolysis with the GAPDH inhibitors, iodoacetate (IA) or iodosobenzate (IB), caused a loss of extracellularly recorded EPSPs, whereas addition of lactate or pyruvate to the medium conserved EPSPs. Histologically, inhibition of glycolysis by IA or IB caused severe degenerative changes in CA1 neurons resembling changes induced by NMDA (edematous swelling and nuclear pyknosis). These changes were prevented by including lactate in the incubation. Exposure of the hippocampal slice to simulated ischemia (O₂/glucose deprivation) also caused severe NMDA-like degeneration which was prevented by inclusion of lactate. These findings suggest that either glycolysis inhibition or simulated ischemia causes neurotoxic changes in CA1 neurons which can be prevented by supplementing with an end product of the glycolytic pathway. Further pursuit of these findings may shed new light on mechanisms underlying the role of NO in NMDA excitotoxicity and on methods of protecting against ischemic neuronal degeneration. PURKINJE CELL DEGENERATION AFTER IBOGAIN TREATMENT: ULTRASTRUCTURAL EVIDENCE. M.A. Wilson* and M.E. Molliver, Johns Hopkins University School of Medicine, Baltimore, MD 21205

The indole alkaloid ibogaine has been proposed for use in the treatment of drug addiction. However, in rats ibogaine induces glial activation in the cerebellar vermis¹ and signs of Purkinje cell (PC) degeneration including loss of Nissl staining, MAP2 and calbindin, and staining of PC's with the Gallyas reduced silver method for degenerating neurons². We now present ultrastructural evidence that ibogaine treatment produces Purkinje cell degeneration.

In untreated controls, PC's exhibit finely granular chromatin, infoldings of nuclear membrane filled with polysomal ribosomes, prominent rough ER and Golgi apparatus, mitochondria, few lysosomes, and hypolemmal cisternae of smooth ER. Twenty-four hours after ibogaine treatment (100 mg/kg, i.p.) profoundly abnormal PC's are seen in small zones of the vermis; intervening PC's exhibit normal morphology. Most abnormal cells appear to have undergone edematous necrosis, leaving a large void in the PC layer containing vacuolar and granular debris. While fragments of the nuclear membrane may remain, few organelles are identifiable. Other PC's exhibit cytopathologic features of dark cell degeneration: they are extremely electron-dense and have aggregated chromatin, an extremely irregular nuclear membrane, clusters of clear vacuoles, swollen mitochondria and remnants of ER. Extremely dark, abnormal PC dendrites are present in the molecular layer directly above degenerating PC bodies. Further studies will attempt to determine whether these two types of cytopathology reflect distinct neurotoxic mechanisms or different stages in a single pathologic process. ¹O'Hearn et al. CHARACTERIZATION OF THE ACUTE NEUROTOXICITY OF GLUTAMATE IN PRIMARY CULTURES OF CEREBELLAR GRANULE CELLS. F.W. Berman, T.F. Murray*, College of Pharmacy and Toxicology Program, Oregon State University, Corvallis, Oregon, U.S.A.

The objective of the current study was to develop and characterize an excitotoxicity assay in the presence of a normal physiologic milieu. Cerebellar granule neurons derived from 8 day old rat pups were grown in primary culture. Neurotoxicological assays were performed at 12 days in culture in normal physiologic medium at 25°C. Under these conditions, N-methyl-D-aspartate (NMDA) was shown to be non-toxic at concentrations as high as 800 μM. The neurotransmitter glutamate was toxic with an EC50 of 94 μM. Several non-competitive antagonists at the NMDA receptor were tested against a 300 μM glutamate challenge. These compounds afforded neuroprotection with the following rank order of potency: (+)-5-methyl-10,11-dihydro-5H-dibenzo[a,d]cyclohepten-5,10-iminodrogen maleate (MK-801) > 1-[2-(2-thienyl)cyclohexyl]piperidinehydrochloride (TCP) > dextropropofol > ketamine > dextromethorphan. The competitive NMDA receptor antagonist D-2-amino-5-phosphonopentanoic acid (D-AP5), demonstrated neuroprotection as well. The strychnine-insensitive glycine site antagonist, 3-amino-1-hydroxypyrrolidin-2-one (HA-966), was also effective in preventing glutamate neurotoxicity. Interestingly, the quinoxaline derivative 6-cyano-7-nitroquinoxaline-2,3-dione (CNQX), which acts at the AMPA/kainate receptors, also potently prevented neurotoxicity at concentrations less than those expected for significant occupancy of the strychnine-insensitive glycine binding site. These results suggest that glutamate is excitotoxic in the presence of Mg²⁺ and that this effect is first triggered by an action at the AMPA/kainate receptors, whereby neuronal depolarization via sodium influx effects release of the voltage dependent magnesium blockade of the NMDA receptor ion channel. CLIMBING FIBERS MEDIATE IBOGAIN-INDUCED PURKINJE CELL DEGENERATION. E. O'Hearn and M.E. Molliver*, Johns Hopkins University School of Medicine, Baltimore, MD 21205.

Ibogaine, a plant indolealkylamine proposed for treatment of drug addiction, leads to degeneration of parasagittal bands of Purkinje cells (PKCs) in the vermis. This toxicity is demonstrated by loss of PKC MAP-2, calbindin, and Nissl-stain with positive silver staining of PKC bodies and processes¹. Markedly activated astrocytes and microglia are co-extensive with the degenerating PKCs². Harmaline, a structurally related indole alkaloid which also induces PKC degeneration¹, is known to excite inferior olivary neurons and causes sustained PKC activation via climbing fibers³.

In order to determine whether climbing fibers mediate ibogaine-induced PKC degeneration, we lesioned the inferior olive with the neurotoxic regimen of 3-acetylpyridine followed by harmaline and nicotinic acid⁴. Ibogaine (100 mg/kg i.p.) administered one week later had a markedly reduced neurotoxic effect on PKCs compared to the loss of PKC MAP-2, calbindin, calcium-calmodulin kinase II, and Nissl-stain seen after ibogaine was given to rats with inferior olives intact. Activation of astrocytes and microglia was also significantly reduced. These results demonstrate that ibogaine-induced PKC degeneration requires an intact olivocerebellar projection. We propose that the toxicity is due to excessive release of an excitatory amino acid from climbing fiber axons and that ibogaine-induced PKC degeneration is a new model of experimentally induced endogenous excitotoxicity.

IGF-I confers glutamate-sensitivity to glutamate-resistant cerebellar granule cells.

P. Calissano, M.T. Ciotti, D. Mercanti, C. Volonté*, D. Merlo, S. Giannetti, A. Angelini.

Institute of Neurobiology, C.N.R. via C. Marx 00162 Roma, Italy.

We have previously reported that 8 days old rat cerebellar granule cells cultured in vitro in the presence of a neurite outgrowth adhesion complex (NOAC) differentiate but are resistant to the otherwise lethal action of glutamate. NOAC-cultured neurons grown also in the presence of human recombinant IGF-I become fully sensitive to the toxic action of this excitatory amino acid. The effect of this somatomedin is not mimicked by other growth factors such as NGF, EGF, PDGF, b-FGF, a-FGF, alpha-TGF. The glutamate-sensitizing action of IGF-I is concentration dependent (half maximum effect at 2-4 ng/ml), occurs within 1-3 days and is accompanied by the appearance of functionally active, glutamate-operated Ca⁺⁺ channels and of voltage-gated Na⁺ and late K⁺ channels. Removal of IGF-I from the culture medium restores the glutamate resistant phenotype of NOAC-cultured neurons with a t 1/2 of 30 min. We postulate that the constitutive phenotype of cerebellar granule is glutamate-resistant and becomes glutamate-sensitive under the action of IGF-I and possibly of other epigenetic cues.

THE GANGLIOSIDE GM1 ATTENUATES THE DEVELOPMENT OF HALOPERIDOL-INDUCED ORAL MOVEMENTS IN RATS. O. A. Andreassen¹ and H. A. Jørgensen². (SPON: European Neuro-science Association). Dept. of Physiology¹ and Psychiatry², Univ. of Bergen, N-5009 Bergen, Norway.

Tardive dyskinesia (TD) is a serious side effect of long-term neuroleptic treatment. The mechanism of TD development is still unknown. It has been proposed that TD may be a result of neuroleptic-induced glutamate neurotoxicity in the striatum. To investigate this hypothesis, the effect of the anti-excitotoxic ganglioside GM1 (Fidia, Italy) was studied in a rat model of TD (female Sprague-Dawley rats). Four groups of rats (n = 10) were treated for 14 weeks with combinations of haloperidol decanoate 38 mg/kg IM every fourth week, GM1 20 mg/kg SC daily or placebo (sesam oil and saline). In an initial acute experiment a similar regimen was used, but ordinary haloperidol 1.2 mg/kg was injected IP. Haloperidol-induced behaviour was videotaped and vacuous chewing movements (VCM), an analogue to human TD, were scored.

Haloperidol induced a significant increase in VCM both in the acute and in the chronic experiment. Co-administration of GM1 did not attenuate the acute haloperidol effect. In the chronic experiment the co-administration group showed significant less VCM compared to animals receiving only haloperidol. GM1 administration in the placebo group did not affect the number of VCM.

These results may indicate that neuroleptic-induced excitotoxic neurodegeneration is a mechanism for the development of chronic VCM in rats and possibly for TD in humans.

DEXAMETHASONE ENHANCES NMDA RECEPTOR-MEDIATED INJURY IN THE POSTNATAL RAT. D.E. Supko^{*} and M.V. Johnston. Kennedy Krieger Research Institute and Johns Hopkins University School of Medicine, Baltimore, MD 21205.

Pretreatment with glucocorticoids can worsen brain injury resulting from hypoxia-ischemia or kainic acid injections in adult rats. Conversely, in postnatal rats, glucocorticoid pretreatment affords protection against hypoxic-ischemic brain damage. In the present study, we investigated the effect of a glucocorticoid on excitatory amino acid-induced neurotoxicity in postnatal rats. The synthetic glucocorticoid, dexamethasone (0.7 mg/kg, ip) was administered to 7 day old rats one hour prior to unilateral intrastriatal injection of either NMDA (20 nmol), AMPA (20 nmol) or kainic acid (35 nmol). One week later, damage was assessed both histologically and by measurement of striatal cytochrome oxidase activity. Dexamethasone enhanced NMDA receptor-mediated striatal damage by 56% (p<0.01) but had no effect on either AMPA or kainic acid receptor-mediated injury. Pretreatment with the phospholipase A₂ inhibitor, mepacrine (20 mg/kg, ip) or the adrenal mineralocorticoid, aldosterone (5 mg/kg, ip) did not affect NMDA-induced striatal damage. The effect of dexamethasone on NMDA sensitive [³H]glutamate binding was assessed autoradiographically but no differences in binding were apparent in the striatum. Although these results do not suggest a mechanism, they indicate glucocorticoids may enhance neurotoxicity resulting from excessive NMDA receptor activation.

728.16

EFFECT OF OPIOID AGONISTS ON EXCITOTOXIC DAMAGE TO THE STRIATOPALLIDAL GABAERGIC NEURONS. K. Jhamandas^{*}, S. Beare, R.J. Boegman. Department of Pharmacology and Toxicology, Queen's University, Kingston, Ontario, Canada K7L 3N6.

The enhancement of methionine-enkephalin levels, observed in striatum and globus pallidus post excitotoxin injury to the striatum (Ruzicka and Jhamandas, Brain Res. 536: 227-239, 1990), may represent an adaptive response by which endogenous opioids modulate injury to other neurons. To determine if opioids have this potential, the present study evaluated the ability of μ , δ and κ receptor agonists to influence excitotoxic injury to the striatopallidal gabaergic neurons. Intrastriatal infusion of quinolinic acid (QUIN) (36, 72, 108 and 144 nmol, 1 μ l volume) in the rat produced a dose-related depletion of glutamate acid decarboxylase activity (GAD), a biochemical marker for gabaergic neurons, in both the striatum and globus pallidus. This effect of QUIN was fully blocked by kynurenic acid. Co-injection of a kappa receptor agonist, U50,488H (50, 100 150 nmol), with QUIN (108 nmol) partially prevented the depletion of GAD activity. This effect, however, was not shared by DAGO or DPDPE, agonists which activate μ and δ receptors, respectively. The results suggest that certain opioids have the potential to modulate excitotoxin-induced injury to striatopallidal gabaergic neurons.

EXCITATORY AMINO ACIDS: EXCITOTOXICITY IX

729.1

Comparison of hippocampal injury caused by endogenous and exogenous glutamate in organotypic cultures. R. C. Tasker^{*}, J. K. Park and J. J. Vornov. Dept. Intensive Care, HSC, Great Ormond St., London, England and Dept. of Neurology The Johns Hopkins School of Medicine, Baltimore, MD 21205

The characteristic regional vulnerability of the hippocampus to ischemic injury can be reproduced in organotypic cultures of hippocampal slices. While injury can be prevented by NMDA receptor antagonists, the regional vulnerability to ischemia or direct glutamate exposure are distinct from the distribution of NMDA receptors. The time course of glutamate and ischemic injury are slower than injury caused by direct exposure to NMDA itself.

We have now examined the injury caused by inhibition of sodium-dependent glutamate uptake to investigate the toxicity of endogenous glutamate. Blockade of uptake elevates extracellular glutamate to toxic concentrations. A 30 min exposure to either of the specific antagonists of glutamate transport, *threo*-3-hydroxyaspartate (THA) or *L-trans*-PDC caused selective neuronal injury. PDC is a more potent inhibitor of uptake and was more toxic than THA. The injury caused by endogenous glutamate was partially blocked by TTX or MK-801, as we previously observed for exogenous glutamate or simulated ischemia. The histologic appearance of glutamate-mediated injury was distinct from that caused by NMDA. Ultrastructurally, glutamate exposure caused a slow, edematous degeneration of dendrites and neuronal cell bodies. While glutamate toxicity is dependent upon the NMDA receptor, other mechanisms seem to create a pathologic process distinct from direct NMDA toxicity.

729.2

TWO COMPONENTS IN NEUROTOXICITY BY THE METABOTROPIC RECEPTOR ANTAGONIST AP3 IN CULTURED CEREBELLAR NEURONS. M. T. Fernández^{*}, A. Torreblanca and A. Novelli. Dept. Functional Biol., Biochem. and Mol. Biol. Section, Oviedo Univ. Sch. of Med., 33006 Oviedo, Spain.

Metabotropic glutamate receptor (GLURm) activation by glutamate (GLU) or trans-ACPD appears to stimulate phosphatidyl inositol hydrolysis, intracellular calcium mobilization, protein kinase C activation, changes in cAMP levels, and excitatory amino acid release. Several authors have recently reported that the GLURm antagonist 2-amino-3-phosphonopropionate (AP3) may lead to neuronal degeneration. Using cerebellar neurons at 15-19 days in culture we have found that exposure to AP3 (50 μ M) in the culture growth medium for 24 h did produce 95 % neuronal death, which was completely prevented by the addition of the NMDA receptor antagonist MK-801 (1 μ M). Longer exposures (72 h) to AP3, did produce a neurotoxic effect which could not be blocked by MK-801, nor by the combined addition of MK-801 and the ionotropic NON-NMDA antagonist CNQX. Neurotoxicity by AP3 was completely prevented by the addition of GLU (1mM) in the presence of MK-801. Trans-ACPD (1mM), which per se did not produce neurotoxicity, failed to protect from neurotoxicity by AP3. Depolarizing conditions, such as increasing KCl to final 50 mM in the growth medium, significantly reduced AP3 neurotoxicity both at 24 h and 72 hours. The possibility that endogenous GLU release may account for KCl effect appears unlikely since in the absence of MK-801, KCl produced only 30% neurotoxicity, as compared to 95 % neurotoxicity produced by 50 μ M GLU, which in the presence of MK-801, was insufficient to antagonize to any extent AP3 neurotoxicity. We suggest that inhibition of tonic GLURm stimulation may affect mechanisms of control of NMDA receptor-mediated neurotoxicity. Other mechanisms, independent of NMDA receptors, involved in neuronal survival appear also to be under the control of GLURm. Both, NMDA-dependent and independent type of mechanisms share a common sensitivity to depolarizing conditions.

POSSIBLE ROLE OF EXCITOTOXICITY-INDUCED INHIBITION OF CAM KINASE II ACTIVITY IN DELAYED NEURONAL DEATH. S. B. Chum*, D. Limbrick, and R. J. Delorenzo, Dept. of Neurology, Med. Coll. of VA, Richmond, VA 23298.

Excitotoxic activation of glutamate receptors results in a delayed, calcium-dependent neuronal necrosis (*J Neurosci* 1987;7:39). The same excitotoxic paradigm also results in significant inhibition of CaM kinase II activity in neuronal cultures (*Stroke* 1993;24:271). The present study was undertaken to characterize the pharmacology and relationship of excitotoxic glutamate receptor activation-induced inhibition of CaM kinase II and delayed neuronal death in primary neuronal cultures. Hippocampal cultures (16 days in culture) from D-2 neonatal rat pups were exposed to glutamate + 10 μ M glycine for 10 minutes. After glutamate exposure, the cultures were evaluated for neuronal survival or harvested and studied for CaM kinase II activity under standard conditions. Excitotoxic glutamate exposure resulted in significant inhibition of CaM kinase II activity. Both cell death and inhibition of kinase activity were blocked by co-incubation with 20 μ M MK-801, but were not blocked with co-incubation with 200 μ M CNQX. In addition, 100 μ M NMDA treatment resulted in significant inhibition of CaM kinase II activity and significant cell death. Thus, excitotoxic activation of NMDA receptor channels resulted in both delayed neuronal cell death and significant inhibition of CaM kinase II. Significant inhibition of CaM kinase II activity was observed immediately following excitotoxic glutamate treatment and persisted at all time points measured. In parallel experiments, both cell death and the glutamate-induced inhibition of CaM kinase II were blocked by removal of calcium in the extracellular medium. In addition, the inhibition of kinase activity was not reversible with phosphatase treatment. The rapid decrease in CaM kinase II activity could have significant effects on neuronal calcium/calmodulin-dependent effector systems and may be an important initial molecular change that triggers a cascade of events that culminate in delayed cell death.

INCREASED $[K^+]_o$ AND CELL SWELLING AFFECTS UPTAKE AND RELEASE OF GLUTAMATE AND ASPARTATE BY PRIMARY ASTROCYTE CULTURES

H.K. Kimelberg*, C. Charniga, E. Rutledge and S.K. Goderie
Division of Neurosurgery, and Department of Pharmacology/Toxicology, Albany Medical College, Albany, NY 12208

Astrocytes are considered to be important in the uptake of the excitatory amino acids (EAAs) glutamate and aspartate and thus play an important role in the control of their extracellular EAA levels. Reversal of uptake and swelling-induced release have both been proposed as mechanisms whereby net astrocytic uptake can be reduced. In this study we have examined how high $[K^+]_o$ (to induce both reversal of EAA uptake and slow swelling) and hypotonic media (to induce rapid swelling), affect both uptake and release of [3 H]-glutamate and [3 H]-D-aspartate in primary astrocyte cultures, prepared from the cerebral cortices of 1 day old rat pups. Uptake of [3 H]-glutamate is reduced both by exposure to hypotonic and high $[K^+]_o$ media. One reason for the hypotonic swelling-induced reduction of uptake is possibly due to increased release, thus short-circuiting the uptake process. Hypotonic swelling-induced release appears to be a mechanism separate from reversal of the uptake system. It occurs to the same extent in cells that have been incubated in Na^+ -free media to deplete them of $[Na^+]_i$ as in cells not depleted of Na^+ . Part of the high K^+ -induced release also appears to be due to swelling. We have found that lowered temperature (37° to 26° C) reduces high K^+ , but not hypotonic media-induced release, but has much less effect on uptake of EAAs. This inhibition by temperature of high K^+ medium-induced release of EAAs from astrocytes may contribute to the protection against ischemic damage seen due to lowered temperature. Increased $[K^+]_o$ and astrocytic swelling are known to occur in stroke and trauma and diminished uptake and increased release of EAAs from astrocytes may well contribute to the increased levels of EAAs seen under such conditions. LARGE RETINAL GANGLION CELLS ARE MORE SENSITIVE TO GLUTAMATE TOXICITY.

E.B. Dreyer*, S. K. Storm, and S.A. Lipton, Harvard Medical School and Dept. of Neurology, Children's Hospital, Boston, MA, 02115

Previous work in our laboratory (Hahn et al., 1988, PNAS, 85:6556) has demonstrated that glutamate toxicity to retinal ganglion cells is predominately mediated through the NMDA subtype of glutamate receptor. Other work has suggested that glutamate toxicity may play a role in the retinal ganglion cell loss seen in glaucoma (Dreyer et al., 1992, Soc Neurosci Abstr 190.1). In this disease, selective loss is seen of large retinal ganglion cells (Quigley, et al., 1981 Arch Ophthalmol, 99:635). Accordingly, we sought to explore whether glutamate preferentially killed large retinal ganglion cells in culture.

Using a toxicity assay previously described (Hahn et al., 1988, PNAS, 85:6556), postnatal day 7-10 rat retinal ganglion cells were exposed to 0.8 mM Mg^{2+} , and 3 mM Ca^{2+} (the normal vitreal concentration), with or without 100 μ M glutamate. After one day in culture, retinal ganglion cells were scored based on viability and size. Glutamate had little or no effect on the viability of retinal ganglion cells smaller than 10 microns. However, this concentration of glutamate was toxic to 79% of the larger retinal ganglion cells ($p < 0.05$, Student's paired t test). This suggests that larger retinal ganglion cells are more sensitive to NMDA-receptor mediated toxicity. If glutamate does indeed play a role in glaucomatous visual loss, our findings may explain in part why larger retinal ganglion cells are lost in this disease.

NMDA RECEPTOR STIMULATION BLOCKS NEURONAL VOLUME REGULATION. K. B. Churchwell*, P. A. Rosenberg and K. Strange, Depts. of Anesthesia, Neurology, and Medicine (Div. of Nephrology), Children's Hospital, Boston, MA 02115.

Excitotoxic neuronal injury consists of at least two components: (1) isotonic cell swelling due to salt and water entry, and (2) a delayed phase associated with Ca^{2+} influx. We have been studying isotonic swelling-induced neuronal injury and subsequent recovery using real-time, video microscopy measurements of cell volume. Exposure of neuron-enriched, astrocyte-poor, cortical cultures to 100 μ M veratridine (VT) for 10-15 minutes caused a 1.8 ± 0.1 fold increase in neuronal somal volume that persisted for at least 90 min. This volume increase was blocked by both Na^+ removal or by addition of 5 μ M tetrodotoxin, indicating that swelling was due to entry of Na^+ through Na^+ channels. Treatment of cells with VT together with an NMDA antagonist (0.1-10 μ M MK801, 5 mM AP5, or 100 μ M 7-chlorokynureate) had no effect on the magnitude of cell swelling. NMDA receptor antagonist-treated cells, however, underwent nearly complete volume recovery within 50-70 min after VT exposure. For example, cells treated with 10 μ M MK801 or 100 μ M 7-chlorokynureate had mean relative volumes of 1.06 ± 0.1 and 1.09 ± 0.1 , respectively, 90 min after exposure to VT. In contrast, cells treated with the non-NMDA receptor antagonist CNQX (100 μ M plus 1 mM glycine) remained swollen following VT exposure (relative volume = 1.9 ± 0.15). Our results demonstrate: (1) cortical neurons possess powerful volume regulatory mechanisms that protect them from swelling induced by increased solute influx, and (2) NMDA receptor stimulation appears to inhibit these mechanisms. These findings suggest that excitotoxic injury may be caused, at least in part, by disruption of neuronal osmoregulatory capabilities. Elucidation of the mechanisms and control of neuronal volume regulation may provide insight into the prevention and treatment of ischemic brain injury. AN INHIBITOR OF Na^+ -DEPENDENT GLUTAMATE (Glu) UPTAKE, L-trans-PYRROLIDINE-2,4-DICARBOXYLATE (L-trans-PDC), SLOWS THE CLEARANCE OF Glu AND POTENTIATES Glu TOXICITY IN VIVO. A.K. Butler*, S. Djali, B.A. McLaughlin, and M.B. Robinson, Children's Seashore House; Depts of Ped., Pharm., and Neuro., U. PA., Phila., PA, 19104.

Accumulation of extracellular Glu may contribute to the neurotoxicity observed in acute insults to the CNS. Although Glu kills neurons in cell cultures, and this toxicity is attenuated by uptake, there are several conflicting reports regarding the toxicity of Glu *in vivo*. Last year, we reported that co-injection of 5 μ mol Glu and 2 μ mol of L-trans-PDC into the striatum did not cause significant neuronal loss. The goal of the present studies was to determine if L-trans-PDC slows the clearance of Glu *in vivo* and potentiates Glu toxicity. 2 μ l of Glu (4 μ mol) \pm L-trans-PDC (4 μ mol) was injected into rat striatum (AP -0.6, ML -3.5, DV -5.7 from bregma at 20 $^\circ$) while the extracellular fluid was continuously sampled with a microdialysis probe (CMA 10) 1.5 mm from the injection site (AP +2.6, ML +2.5, DV -5.1 from bregma). Body temperature was maintained between 37 $^\circ$ and 38 $^\circ$ C. Thionin staining was used to evaluate damage and stereotaxic placement. Several amino acids were measured by HPLC. Although the injection of Glu by itself caused a small increase in Glu (0- to 10-fold, n=6), co-injection with L-trans-PDC caused a dramatic increase (approx. 200-fold, n=8). L-trans-PDC alone did not alter the extracellular concentration of Glu. Glu or L-trans-PDC alone did not cause significant damage at the site of probe placement, but co-injection caused extensive gliosis that extended to the probe. These studies suggest that Glu toxicity is potentiated by co-injection with L-trans-PDC. (NS29868, P30-HD-26979)

NEURONAL CELL DEATH IN ORGANOTYPIC CULTURES OF RAT HIPPOCAMPUS AFTER THE REMOVAL OF BLOCKERS OF GLUTAMATERGIC SYNAPTIC TRANSMISSION. D. M. D. Landis*, L. D. Pozzo Miller*, N.K. Mahanty* and J.A. Connor*, ¹Depts of Neurology and Neurosciences, Case Western Reserve University, Cleveland, OH 44106; ²Roche Institute of Molecular Biology, Roche Research Center, Nutley, NJ 07110.

The neuronal death that occurs in organotypic cultures of neonatal rat hippocampus during the first 21 days *in vitro* (div) is largely prevented by culture in the presence of agents that reduce glutamatergic synaptic transmission (Pozzo Miller & Landis, Soc. Neurosci. Abstr. 18:440, 1992). In dissociated hippocampal cell cultures, culture in such agents and subsequent removal of them results in seizure-like activity and neuron degeneration (Furshpan & Potter, Neuron 3: 199-207, 1989). We have carried out parallel experiments with organotypic cultures. Starting at 7div, slice cultures were exposed to 10.4mM Mg^{2+} , 3mM kynurenic acid, or 100 μ M D,L-APV for three weeks (medium was changed every 48 hours). Sequential examination by confocal microscopy of propidium iodide (PI) fluorescence in these "blocked" cultures confirmed the prevention of spontaneous cell death. At 28div, the cultures were placed in normal medium (no glutamate receptor antagonists, 1.07mM Ca^{2+} , 1mM Mg^{2+}), and PI fluorescence was imaged after 6, 24 and 96 hours. Removal of high Mg^{2+} was followed by widespread degeneration of neurons in cell layers CA1, CA3, CA4 and the dentate gyrus, evident at 6 hours after return to normal medium and maximal at 24 hours. Removal of kynurenic acid or of D,L-APV was followed by extensive degeneration of neurons in CA1, CA3 and CA4, detected 24 hours after return to normal medium. These results are additional evidence that glutamate receptors are involved in the spontaneous cell death in these slice cultures.

MONITORING OF EXTRACELLULAR ASPARTATE AND GLUTAMATE LEVELS IN PATIENTS WITH TRAUMATIC HEAD INJURY USING IN VIVO MICRODIALYSIS. J.J. Woodward*, A.K. Stout, J. Myseros, H. Young, and R. Bullock. Depts. of Neurosurgery and Pharmacology, Medical College of Virginia, Richmond, VA 23298.

Intracerebral microdialysis was used to monitor the levels of the excitatory amino acids glutamate and aspartate in the extracellular fluid of several human subjects who had suffered severe head injury. The amino acids present in the dialysate were derivatized with o-phthalaldehyde in the presence of thiol, and aspartate and glutamate levels were quantitated using high performance liquid chromatography. Patients with diffusely-damaged brains (as determined by CAT scan) had normal concentrations of aspartate and glutamate in their extracellular fluid (~1 and ~2 μM respectively). Patients with microdialysis probes placed in an area of focally-contused tissue demonstrated a near tenfold increase in glutamate and aspartate levels throughout the monitoring period (eight hours). One patient with diffuse injury but uncontrollable intracranial pressure had glutamate levels almost one hundred times that of patients with diffuse injury and normal intracranial pressure, and the levels remained elevated for several days. These results indicate that focal injury is associated with elevated glutamate and aspartate levels, while diffuse injury is not. However, intracranial pressure may be a more important determinant of extracellular glutamate and aspartate levels. ADRENALECTOMY ATTENUATES KAINIC ACID-INDUCED SPECTRIN PROTEOLYSIS AND HEAT SHOCK PROTEIN 70 INDUCTION IN HIPPOCAMPUS AND CORTEX. M.T. Lowy*, L. Wittenberg and S. Novotny. Dept. of Psychiatry, Case Western Reserve University, Cleveland, OH 44106

Glucocorticoids have been shown to augment the damaging effects of a variety of neurotoxic insults in the hippocampus and other brain areas. Evidence suggests that the endangering effects of glucocorticoids may be due to augmenting the cascade of events due to excitatory amino acid (EAA) receptor stimulation. A potential mechanism responsible for EAA-induced neuronal damage is activation of calcium-sensitive proteases, such as calpain, which then proteolytically degrades cytoskeleton structural proteins, such as spectrin. The present study was designed to determine if glucocorticoids can regulate the spectrin proteolysis produced by the excitatory amino acid agonist, kainic acid (KA). Rats were adrenalectomized (ADX) or sham operated and 7 days later injected with KA (10 mg/kg). Twenty four hrs later rats were sacrificed and tissues obtained for Western blot analyses of the intact spectrin molecule and the proteolytically derived breakdown products. KA produced an approximate 7-10 fold increase in the 145-155 kDa spectrin breakdown products in the hippocampus and frontal cortex relative to ADX or sham rats injected with vehicle. ADX attenuated the KA-induced increase in breakdown products by 43-80%. Induction of heat shock protein 70 (hsp70) has been suggested to be a sensitive indicator of cellular stress and is induced by neurotoxic insults. KA induced large amounts of hsp70 in both hippocampus and frontal cortex of sham-operated rats which was markedly attenuated (85-95%) by ADX. These results suggest that part of the endangering effects of glucocorticoids on hippocampal and cortical neurons may be due to augmentation of calpain-induced spectrin proteolysis. Supported by a grant from Alzheimer's Disease and Related Disorders Assoc.

EXCITOTOXICITY MAY INVOLVE RECRUITMENT OF OTHER RECEPTORS, NEURONAL LOSS, THEN A GRADED IMMUNE RESPONSE. Linda M. Pullan*, Maryann Britt, Pauline G. Dargis, Kathy A. Paschetto, and Robert J. Stumpo. Department of Pharmacology, ZENECA Pharmaceuticals Group, ZENECA, Inc., Wilmington, DE 19897 USA

Excitotoxic damage in focal ischemia can be explored with NMDA or kainate lesions. NMDA or kainate injected into the right striatum of Sprague Dawley rats gave a consistent reduction of choline acetyltransferase activity and a substantial increase in [^3H]PK 11195 binding to the macrophage or microglia $\alpha 3$ benzodiazepine site at 5 days after the agonist injection. The loss of choline acetyltransferase activity after NMDA injections was largely complete after 2 days while the $\alpha 3$ binding increased over 5 days. Protection of against NMDA lesions by delayed intraperitoneal NMDA competitive antagonist CGP 37849 or by the non-competitive antagonist MK-801 was essentially complete for the loss of choline acetyltransferase but only partial for the increase in $\alpha 3$ binding. The glycine antagonist (R)-HA-966 was as efficacious as competitive or non-competitive antagonists. The protection against NMDA lesions demonstrated some stereoselectivity; the sedative (S)-enantiomer was not protective of the choline acetyltransferase activity. Interestingly, the non-NMDA antagonist NBQX also offered similar protection against NMDA lesions. The results suggest that excitotoxicity mediated by glutamate receptors involves not only the neuronal loss seen as decreases in choline acetyltransferase activity but also a delayed immune response seen with $\alpha 3$ binding. The protection of the immune response may be graded even when the neuronal loss is completely protected. Initiation through either the NMDA or kainate/AMPA receptors may recruit both receptor populations.

729.10

INHIBITION OF SUCCINATE DEHYDROGENASE BY MALONIC ACID PRODUCES AN "EXCITOTOXIC" LESION IN RAT STRIATUM. James G. Greene*, Richard H. P. Porter, Robert V. Eller, and J. Timothy Greenamyre. University of Rochester, Rochester, NY 14642

We report that reversible inhibition of succinate dehydrogenase (SDH), an enzyme central to both the tricarboxylic acid (TCA) cycle and the electron transport chain, produces an "excitotoxic" lesion in rat striatum which can be blocked by the NMDA antagonist, MK-801. Male Sprague-Dawley rats received intrastriatal stereotaxic injections of the SDH inhibitor malonic acid (1 or 2 μmoles) in combination with i.p. injections of vehicle or MK-801 (5 mg/kg) 30 minutes before and 210 minutes after malonic acid. Animals were sacrificed 72 hours after surgery, and brains processed for histology, cytochrome oxidase activity, and [^3H]MK-801 and [^3H]AMPA autoradiography. The higher dose of malonic acid (2 μmoles) produced large lesions that were markedly attenuated by treatment with MK-801 ($28.1 \pm 3.6 \text{ mm}^3$ vs. $4.7 \pm 2.6 \text{ mm}^3$; $p < 0.001$). [^3H]MK-801 and [^3H]AMPA binding were reduced in the lesions by 60% and 63%, respectively. One micromole of malonic acid produced smaller lesions ($9.7 \pm 2.2 \text{ mm}^3$) that were completely blocked by MK-801 treatment. The toxic effects of malonic acid were due to specific inhibition of SDH since co-injection of a 3-fold excess of succinate with the malonic acid blocked the striatal lesions. We conclude that inhibition of SDH can lead to NMDA receptor-mediated excitotoxic neuronal death. These results have implications for the pathogenesis and therapy of neurodegenerative diseases. (NS01487 & T32 GM08427 and Fisons Pharmaceuticals)

EFFECT OF METHAMPHETAMINE ON DOPAMINE AND GLUTAMATE RELEASE IN RAT STRIATUM AND NUCLEUS ACCUMBENS. T. Abekawa*, T. Ohmori, T. Koyama. Dept. of Psychiatry, Hokkaido Univ. Sapporo 060 Japan

To investigate a potential role of glutamatergic and dopaminergic neural transmissions in the methamphetamine(MA) neurotoxicity, we examined effects of a high dose of MA (5mg/kg,sc,at 2h intervals,4 injections) on extracellular concentrations of amino acids such as glutamate,glutamine,homoserine,glycine,taurine,alanine and those of monoamines such as DA,DOPAC,HVA and 5-HIAA in nucleus accumbens (NA) and striatum (ST) using in vivo microdialysis. Five days after the microdialysis ,the rats were decapitated and tissue concentrations of monoamines were measured. The toxic dose of MA markedly increased extracellular concentrations of DA, and decreased those of DOPAC,HVA and 5-HIAA in both NA and ST. Magnitude of these changes was not different between NA and ST. Extracellular concentrations of glutamate were increased in ST,but not in NA,while other amino acids showed no changes in both NA and ST. Tissue concentrations of 5-HT and 5-HIAA were decreased to 43-58% of control values in both NA and ST, whereas those of DA,DOPAC and HVA showed 43-54% decrease in ST, but no changes in NA. These data suggest that the marked increase of DA release was not directly related to MA-induced dopaminergic neurotoxicity. The increase in glutamate release found only in ST may be related to the dopaminergic damage in ST. However,interrelationship between MA-induced serotonergic damage and dopaminergic or glutamate neural transmissions remains to be elucidated.

PREGNENOLONE SULFATE POTENTIATES NMDA-INDUCED CELL DEATH IN CULTURED NEURONS. C. E. Weaver, JR.*, F. S. Wu and D. H. Farb. Department of Pharmacology and Experimental Therapeutics, Boston University School of Medicine, Boston, MA 02118.

We have shown previously that the neurosteroid pregnenolone sulfate (PS) enhances the current induced by N-methyl-D-aspartate (NMDA) in voltage-clamped neurons. Here we report that PS potentiates NMDA-induced excitotoxicity in primary cultures of rat hippocampal neurons. Cultures (17-19 days *in vitro*) were exposed to 16 hr treatments of drugs. Assessment of cell survival was performed using the trypan blue exclusion method. NMDA (0.25-100 μM) dose-dependently induced neuronal cell death with an EC_{50} of 14 μM and maximal cell death of 79%. MK-801 (10 μM) completely blocked NMDA-induced neurotoxicity. PS (50-200 μM) when applied together with 12.5 μM NMDA potentiated NMDA-induced neurotoxicity in a dose-dependent manner. In addition, PS (100 μM) reduced the NMDA EC_{50} to 5 μM with little effect on the maximum NMDA-induced cell death, consistent with positive allosteric modulation of the NMDA receptor by PS. PS (100 μM) alone produced little cell death. The immediate precursor of PS, pregnenolone (20 μM), had little or no effect on NMDA-induced cell death. Over stimulation of the NMDA receptor has been proposed to play a role in many neurodegenerative diseases. Our present findings not only confirm our previous observation that PS acts as a positive modulator of the NMDA receptor but also demonstrate that PS may potentiate the physiological consequence of NMDA receptor over activation.

729.15

PLATELET-ACTIVATING FACTOR (PAF) STIMULATES GLUTAMIC ACID RELEASE FROM HIPPOCAMPAL SYNAPTOSOMES. V.L. Marcheselli and N.G. Bazan. LSU Eye Center and LSU Neuroscience Center, LSU Med. Ctr. Sch. Med., New Orleans, LA 70112

During brain ischemia, platelet-activating factor (PAF) is generated. A massive release of excitatory amino acid neurotransmitter also takes place and may be involved in neuronal damage. The PAF antagonist BN-52021 is neuroprotective in ischemia-reperfusion (Panetta et al., *BBRC* 149, 580-587, 1987), and competes with a specific PAF receptor of synaptic membranes (Marcheselli et al., *JBC* 265, 9140-9145, 1990). Moreover, PAF enhances excitatory neurotransmission (Clark et al., *Neuron*, 9, 1211-1216, 1992). A perfusion cell was used in the present study to show the mechanism of PAF-induced glutamic acid release from [³H]-glutamic-acid-loaded rat hippocampal synaptosomes. PAF, at concentrations of 10 and 100 nM, produced a 25% release from the total [³H]-glutamic acid taken up, which is antagonized by 1 μM BN-52021. 40 mM KCl induced a 30% [³H]-glutamic acid release, which cannot be blocked by the PAF antagonist. Lower PAF concentrations, such as 100 pM or 1 nM, were incapable of inducing glutamic acid release, which is in agreement with binding data on synaptosomal membranes indicating a K_d of 1.2 nM. We conclude that the protection in ischemia reperfusion demonstrated by BN-52021 resides mainly in blocking the control mechanism of glutamic acid release at the presynaptic level. Supported by NIH grant NS23002.

PROTECTION AGAINST THE TERATOGENICITY OF COCAINE BY CLOZAPINE.

E. Yablonsky-Alter*, T. I. Lidsky, S.P. Banerjee.
City College of New York, Medical School, N.Y. and
Inst. of Brain Research, Staten Island, N.Y.

Administration of Cocaine (10 mg/kg, IP) to pregnant mice decreased the striatal dopamine levels by 28%, 34%, 29% and 33% in 3, 7, 11 and 21 day old pups respectively. Co-administration of clozapine (3 mg/kg, IP) prevented the changes in the concentration of striatal dopamine. In contrast, co-administration of haloperidol failed to provide similar protection. Since clozapine blocks the electrophysiological effects of glutamate release on striatal neurons, its antigitamate actions may contribute in the protection of cocaine induced damages to the striatal dopaminergic neurons. Thus, cocaine induced teratogenicity may involve excitotoxicity.

EXCITATORY AMINO ACIDS: PHARMACOLOGY VI

730.1

L-GLUTAMATE EXCITATION OF VTA DOPAMINE NEURONS IS PREFERENTIALLY MEDIATED BY ACTIVATION OF NMDA RECEPTORS: EXTRA- AND INTRACELLULAR ELECTROPHYSIOLOGY IN BRAIN SLICES. T. Wang* and E. D. French. Dept. Pharmacol., Univ. of Arizona, Tucson, AZ 85724.

The present study assessed the effects of L-glutamate (L-GLU) on the neurophysiology of VTA dopamine neurons in midbrain slices using extra- and intracellular recording methods. L-GLU perfusion at 10-100 μM produced dose-dependent increases in firing rate, with no changes in pattern of firing, while higher concentrations led to a loss of activity reminiscent of depolarization inactivation. These effects were reflected by the pronounced membrane depolarizations observed in intracellular recordings. The effects of low doses (≤30 μM) of L-GLU on firing rate and membrane potential were completely antagonized by co-perfusion with the non-competitive NMDA blocker, phencyclidine, or the selective competitive NMDA receptor antagonist, CGS 19755, but not by the selective non-NMDA blocker NBQX. However, at ≥300 μM L-GLU's effects could not be completely blocked without the presence of both CGS 19755 and NBQX. These results suggest that in physiological-like conditions that low extracellular levels of glutamate excite dopamine neurons via a preferential activation of NMDA receptors, and that only at higher concentrations of L-GLU are non-NMDA receptors brought into play.

730.3

AN *IN VITRO* STUDY OF EXCITATORY AMINO ACID (EAA)-MEDIATED SYNAPTIC TRANSMISSION IN THE DIAGONAL BAND OF BROCA.

J.C. Fasaw* and J.H. Jhamandas, Dept. of Medicine (Neurology), Univ. of Alberta, Edmonton, Alberta, Canada T6G 2B7.

Anatomical studies suggest that afferents to the diagonal band of Broca (DBB), a basal forebrain region, contain the EAAs glutamate and aspartate. We therefore examined the actions of specific EAA receptor agonists on DBB neurons *in vitro* utilizing the whole cell patch clamp technique. We further assessed a role for EAAs in mediating synaptic transmission within the DBB.

Coronal slices (400 μm), including the DBB, were taken from male Sprague Dawley rats, placed in a small recording chamber, and superfused with artificial cerebrospinal fluid. Exogenous application of N-methyl-D-aspartate (NMDA, 10 μM), α-amino-3-hydroxy-ethyl-4-isoxazolepropionic acid (AMPA, 10 μM), and kainate (5 μM) evoked an excitation in 31 DBB neurons (resting membrane potential 69.5 ± 11.5 mV). Bipolar electrodes were placed adjacent to the horizontal limb and single stimuli (200 μs duration @ 2 Hz, range 10-70 volts) evoked graded excitatory post-synaptic potentials (EPSPs) or currents (EPSCs) in 32 neurons. Voltage and current clamp recordings revealed the following responses: 1) a fast AMPA/kainate receptor-mediated EPSP(C)s, 2) an NMDA-sensitive slower component of the fast EPSP(C)s, and 3) the metabotropic receptor agonist trans-1-amino-cyclopentyl-1,3-dicarboxylate (t-ACPD, 10 μM) reduced EPSP(C) amplitude without changing membrane conductance. This action of t-ACPD may be indicative of a presynaptic effect.

These data indicate that both NMDA and non-NMDA receptors mediate excitatory synaptic transmission within the DBB.

Supported by the MRC and the AHFMR.

730.2

GLUTAMATE AGONISTS PRODUCE RECEPTOR-SPECIFIC INCREASES IN THE FREQUENCY OF SPONTANEOUS EPILEPTIFORM DISCHARGES (SEDs) IN THE RAT CORTICAL WEDGE. L.J. Robichaud*, R.J. Chang, W.L. Vaalburg, and P.A. Boxer, Neuroscience Pharmacology, Parke-Davis Pharmaceutical Research, Division of Warner-Lambert Co. Ann Arbor, MI 48105.

In the cortical wedge model, SEDs result when extracellular Mg⁺⁺ is removed. Since Mg⁺⁺ blocks the NMDA ion channel in a voltage dependent manner, discharges appear to depend on activation of NMDA receptors. Various types of NMDA antagonists block SEDs; the non-NMDA antagonist NBQX has no effect. NMDA, AMPA, and kainate at ≥10 μM caused depolarizations and blocked SEDs. Several drugs including polyamines increase SED frequency, possibly by increasing glutamate release. The present experiments attempted to mimic increased glutamate release by adding low concentrations of glutamate agonists. At concentrations ≤10 μM each agonist caused little or no depolarization but increased SED frequency in a sustained (90 min), dose-related manner. For example, 1 and 3 μM NMDA increased SED frequency by 35% and 200%, respectively. Continuous treatment with 1 μM and 10 μM of the competitive NMDA antagonist CPP caused a -3 and 10-fold respective shift of the concentrations of NMDA increasing or blocking SED frequency. The AMPA and kainate concentration-response curves were right-shifted by NBQX but not by CPP. In summary, low concentrations of glutamate agonists produce sustained receptor-specific increases in SED frequency. Agents that increase glutamate release have the potential to increase SED frequency, although the mechanism of action is not understood.

730.4

NMDA-RECEPTOR ACTIVATION STIMULATES DENDRITIC RELEASE OF DOPAMINE IN THE PARS RETICULATA OF THE RAT BRAIN. M.G.

Rosales, G. Flores, S. Hernández and J. Aceves, Dept. of Physiology, Biophysics and Neurosciences, CINVESTAV-IPN. Apartado Postal 14-740. 07000 México, D.F. México.

As is well known, the dopaminergic cells of the pars compacta of the rat substantia nigra release DA not only from their presynaptic terminals in the striatum but also from their dendrites in the pars reticulata. By microdialysis, we have recently shown (Martinez-Fong et al., *Brain Res.* 595, 309, 1992) that presynaptic NMDA receptors modulate the release of DA from nigrostriatal terminals in the unanesthetized rat. Here we have explored if the glutamatergic input to the pars reticulata could modulate not only the firing frequency of the nigral cells (Robledo and Féger, *Brain Res.* 518, 47, 1990), but also the release of DA from dopaminergic dendrites. As a first approximation, we have studied if the activation of the NMDA receptors stimulated, as in striatum, the release of DA. The experiments were done in anesthetized (chloral hydrate) rats. A microdialysis probe was stereotaxically implanted into the right pars reticulata. DA was measured in the perfusate by HPLC with electrochemical detection. N-Methyl-D-Aspartate (NMDA) (1 mM) (corrected concentration 100 μM) added to the perfusion medium caused an increment of 130 ± 25% (n=6) in the release of DA. The selective antagonist of NMDA receptors, 2-amino-phosphonovalerate (1 mM), totally blocked the effect of NMDA (n=5). These results suggest that the glutamatergic innervation of the pars reticulata may modulate via NMDA receptors the release of DA from the dendrites projecting from the pars compacta into the pars reticulata.

PROPERTIES OF EXCITATORY POSTSYNAPTIC CURRENTS IN NEONATAL RAT SYMPATHETIC PREGANGLIONIC NEURONES. Krupp, J., Gombos, G.* & Feltz, P.; Laboratoire de Physiologie (URA CNRS 1446); 21, rue René Descartes; 67084 Strasbourg Cedex; France.

The objective of our investigation was to characterize electrically evoked excitatory postsynaptic currents (EPSCs) in sympathetic preganglionic neurones (SPNs) by means of the patch-clamp technique in thin (200-300 μm) spinal cord slices of neonatal rats (P0-P14). SPNs were identified after Lucifer Yellow injection on the basis of morphological criteria. Except for two cases the evoked EPSCs of all SPNs recorded ($n=36$) had two components. The entire EPSCs reversed at 1.2 ± 4.6 mV ($n=12$). After blockade of the NMDA component by APV (10-40 μM ; $n=11$), the EPSC had a linear peak I/V relation with a reversal potential of -0.3 ± 3.9 mV ($n=9$). The kinetics of this component depended critically on the stimulation site: accordingly, the rise time (10-90%) could be as fast as 0.4 ms and the monoexponential decay had a time constant of less than 2 ms. When blocking the non-NMDA-component by CNQX (5 μM ; $n=10$), the peak I/V relation of the EPSC reversed at 2.1 ± 1.3 mV ($n=6$). It had a region of negative slope conductance at holding potentials more negative than -30 mV. This region of negative slope conductance was abolished in Mg^{2+} -free saline. The rise times (10-90%) for this component ranged from 3.3 to 9.5 ms. At a V_h of +50 mV the time constants of the biexponential decay were $\tau_1 = 62.0 \pm 14.9$ ms and $\tau_2 = 401.9 \pm 64.9$ ms ($n=4$). Both time constants decreased with hyperpolarization. Our results show, that SPNs receive fast excitatory synaptic inputs using L-glutamate or an analogue to act on glutamate receptors of the NMDA- and non-NMDA-type.

MECHANISM UNDERLYING FACILITATION OF NMDA DEPOLARIZATION BY THAPSIGARGIN (TG), CYCLOPIAZONIC ACID (CPA) AND A23187 AT CORTICAL PYRAMIDAL NEURONS. R.S. Neuman* and S. Rahman, Fac. of Med. Memorial University, St. John's, Nfld. Canada A1B 3V6.

TG, CPA and A23187, agents which raise intracellular Ca^{2+} concentration, are similar to serotonergic, muscarinic and noradrenergic agonists (Rahman and Neuman, Eur. J. Pharmacol. 231(1993) 347) and 1S,3R ACPD (submitted) in that they selectively facilitate NMDA induced depolarization of cortical neurons (Rahman and Neuman, this meeting). This could result from an indirect effect (presynaptic) or a direct (postsynaptic) action. We have tested TG, CPA and A23187 on cortical wedges perfused with a cocktail consisting of 0.1 μM TTX, 1 μM prazosin, 10 nM scopolamine, 10 nM ritanserin, and 50 μM AP3. This cocktail reduced, but did not abolish the facilitation. Moreover, facilitation by these agents was present in Mg^{2+} free medium, which eliminates serotonin and phenylephrine induced facilitation. Nifedipine (1-2 μM) reduced, but did not block the facilitation to TG, CPA and A23187. Finally, 1 μM calmidazolium and 1 μM chlorpromazine, which inhibit calmodulin, did not block the facilitation by these agents, but instead prevented the loss of facilitation which occurs at high concentrations.

In conclusion, we suggest: 1) TG, CPA and A23187 act directly on pyramidal neurons to facilitate the NMDA response; 2) a rise in intracellular Ca^{2+} is responsible for the facilitation and 3) the facilitation does not result from an action on calmodulin or involve alteration in the voltage dependence of the NMDA receptor channel. Supported by the Canadian MRC.

QUISQUALATE (QA), GLUTAMATE (GLU) AND AMPA BUT NOT ACPD ACTIVATE THE SAME SUBPOPULATION OF NEURONS AND BLOCK KAINATE (KA)-INDUCED ELEVATIONS OF CALCIUM IN PRIMARY TISSUE CULTURE J. D. Sherrod & P. P. McCaslin*, Dept. Pharmacol. & Toxicol., Univ. Miss. Med. Ctr., 2500 N. State Str., Jackson, MS 39216-4505

We examined the ability of GLU to activate different excitatory amino acid (EAA) receptors in cerebellar granule cells in tissue culture using cell imaging with the fluorescent dye, fluo 3. In the presence of 1.2 mM Mg^{2+} , GLU did not activate either the N-methyl-D-aspartate (NMDA) or the KA receptors. However, GLU consistently activated about 15% of the neurons in the presence of Mg^{2+} which was the same population of neurons activated by both QA and α -amino-3-hydroxy-5-methyl-4-isoxazolepropionic acid (AMPA); the metabotropic GLU receptor agonist, aminocyclopentane-1,3-dicarboxylic acid (ACPD), did not activate these neurons. QA was the most potent compound tested in activating this subpopulation of neurons with 0.5 μM QA consistently elevating intracellular Ca^{2+} . If Mg^{2+} was removed from the medium, GLU resulted in elevations of Ca^{2+} in all the neurons, and this increase was blocked by the NMDA receptor antagonist, AP7, but not by the KA receptor antagonist, GAMS, thus indicating that GLU will only activate the NMDA and QA but not the KA receptors. We tested several endogenous EAAs for their ability to activate the KA receptor; homocysteate, aspartate, cysteate, cysteine sulfinate, homocysteine sulfinate and guinoline were unable to activate the KA receptor in the presence of Mg^{2+} ; a number of amino acids were tested in conjunction with GLU for their ability to activate the KA receptor but none were found to do so. Collectively, these results show that QA, AMPA and GLU activate a subpopulation of cerebellar granule neurons, and that no endogenous amino acid tested was able to activate the KA receptor. Supported by NIDA grant DA 64843.

NMDA ANTAGONISTS CGS19755 AND MK801 DIFFERENTIALLY BLOCK STRIATAL FOS-LIKE IMMUNOREACTIVITY INDUCED BY THE D_1 -DOPAMINE AGONIST SKF-38393 IN NEONATALLY 6-HYDROXYDOPAMINE LESIONED RATS. Kevin B. Johnson*, James P. O'Callaghan, Robert A. Mueller and George R. Breeze, Curriculum in Neurobiology and Brain and Development Research Center, Univ. of North Carolina School of Medicine, Chapel Hill, N.C., 27599

Previous studies from this laboratory have shown that administration of the D_1 -dopamine agonist SKF-38393 induces a dose-dependent increase in striatal c-fos-like immunoreactivity in neonatally 6-OHDA-lesioned rats. Repeated, intermittent administration of D_1 -dopamine agonists can sensitize neonatally lesioned rats to the behavioral effects of dopaminergic agonists, and this behavioral sensitization has been shown to be blocked by administration of the NMDA antagonists MK801 and CGS-19755. In the present study, we sought to determine the ability of NMDA antagonists, at doses known to block the behavioral sensitization of D_1 -dopamine receptor-mediated responses, to block this striatal c-fos response. In neonatally lesioned rats, pretreatment with the competitive NMDA antagonist CGS-19755 (10 mg/kg, i.p.) produced a 71% decrease in the number of fos-positive striatal cells induced by SKF-38393 (1.5 mg/kg, i.p.) alone. In contrast, pretreatment with a high dose of the noncompetitive NMDA antagonist MK801 (1 mg/kg, i.p.) did not reduce the number of striatal fos-positive cells induced by the same dose of SKF-38393. Further studies will explore the nature of these antagonistic effects, and seek to determine whether the differential effects of these two NMDA antagonists may reflect the delineation of regionally-selective NMDA receptor subtypes. Supported by HD-23042 and HD-03110.

THAPSIGARGIN (TG), CYCLOPIAZONIC ACID (CPA), AND A23187 FACILITATE NMDA RECEPTOR MEDIATED DEPOLARIZATION OF RAT CORTICAL NEURONS. S. Rahman* and R. S. Neuman, Fac. of Med. Memorial University, St. John's, Nfld. Canada A1B 3V6.

Using grease gap recording from cortical wedges we have shown that activation of 5-HT₂ receptors facilitates NMDA depolarization of pyramidal neurons (Rahman and Neuman, Eur. J. Pharmacol. 231 (1993) 347). Employing similar methods, we now report that agents which raise intracellular Ca^{2+} mimic this facilitation.

TG, an inhibitor of Ca^{2+} -ATPase, applied concurrently with 50 μM NMDA for 2 min, reversibly facilitated the NMDA depolarization. The facilitation increased in magnitude over the range of 10 to 100 nM, but was not significantly different from control at 300 nM. Perfusing wedges with nominally Ca^{2+} free medium or buffering internal Ca^{2+} , using 50 μM BAPTA AM, prevented the TG induced facilitation. These treatments also blocked the 5-HT facilitation. CPA (5 to 30 μM), another Ca^{2+} -ATPase inhibitor, as well as A23187 (0.25 to 3 μM), a Ca^{2+} ionophore, dose-dependently facilitated the NMDA depolarization. Magnitude of the CPA facilitation was similar to that induced by TG, whereas the response to A23187 was significantly larger. When quisqualate and kainate were substituted for NMDA, no enhancement was observed with CPA.

In conclusion, facilitation of the NMDA depolarization induced by TG, CPA and A23187 is similar to that found with 5-HT. The facilitation is selective for NMDA receptor activation and requires both external and internal Ca^{2+} . (see also Neuman and Rahman, this meeting). Supported by the Canadian MRC.

PREGNENOLONE SULFATE-MEDIATED INCREASES IN INTRACELLULAR CALCIUM IN CULTURED CHICK CORTICAL NEURONS. J.M. Fahey*, G.A. Pritchard, D.G. Lindquist and L.G. Miller, Department of Pharmacology and Experimental Therapeutics, Tufts University School of Medicine, Boston, MA 02111.

Pregnenolone sulfate has been reported to selectively augment glutamate-induced depolarizations mediated by the N-methyl-D-aspartate (NMDA) subtype of the glutamate receptor. The present study examines the ability of this neuroactive steroid to potentiate NMDA-mediated increases in intracellular calcium of cultured chick cortical neurons using the fluorescent dye Fura2. Pregnenolone sulfate alone elevated intracellular calcium in a dose-dependent manner (1-500 μM). These increases in intracellular calcium were attenuated by 1 μM nimodipine, a voltage-sensitive calcium antagonist, and 50 μM 6-cyano-7-nitroquinoxaline-2,3-dione (CNQX), a non-NMDA glutamate receptor antagonist. Dizocilpine, an NMDA receptor antagonist, did not inhibit the elevations in intracellular calcium caused by pregnenolone sulfate. In the presence of NMDA, pregnenolone sulfate increases in intracellular calcium were also inhibited by nimodipine and CNQX but not dizocilpine. These data indicate that the mechanism by which pregnenolone sulfate increases intracellular calcium may be mediated either through non-NMDA receptor subtypes of the glutamate receptor or voltage-gated calcium channels.

FORSKOLIN INHIBITS GLUTAMATE-INDUCED $[Ca^{2+}]_i$ INCREASES IN CULTURED RAT STRIATAL NEURONS. K.R. Hoyt* and L.J. Reynolds. Department of Pharmacology, Univ. of Pittsburgh School of Medicine, Pittsburgh, PA 15261.

In a single neuron, interactions between neurotransmitter receptors may occur via second messengers. We are studying the modulation of glutamate receptor-mediated increases in $[Ca^{2+}]_i$ by neurotransmitters. Because some neurotransmitters (e.g. dopamine) activate adenylate cyclase, we investigated the effects of cAMP on glutamate responses. Forskolin (5 μ M) was used to increase [cAMP], by activating adenylate cyclase. Glutamate-induced $[Ca^{2+}]_i$ increases were measured in single cultured striatal neurons loaded with fura-2. Glutamate responses were elicited by applying 3 μ M glutamate for 20 sec. We found that a 1 min exposure to forskolin significantly inhibited glutamate responses compared to solvent (0.05% DMSO) controls. This forskolin-induced inhibition developed slowly and got progressively greater with time, reaching a limit of about 36% inhibition within 1 hour of forskolin exposure. For example, the first glutamate response after forskolin was $92 \pm 9\%$ (n=5) of untreated control responses compared to $99 \pm 7\%$ (n=4) in cells treated with DMSO in place of forskolin (mean \pm s.d.; $p > 0.05$, not significant). By the fifth glutamate response (approximately 35 min) after forskolin the response had decreased to $73 \pm 5\%$ of control compared to $88 \pm 7\%$ of control in the DMSO controls ($p < 0.05$). However, forskolin did not consistently or significantly inhibit NMDA/glycine, kainate or AMPA responses in similar experiments. The mechanism underlying the selective effect of forskolin on glutamate responses is currently under study. Supported by NIMH (MH18273).

GLYCINE SITE INVOLVEMENT IN GLUTATHIONE STIMULATION OF N-METHYL-D-ASPARTATE RECEPTOR-MEDIATED NEURONAL CALCIUM ENTRY. R.D. Trent*, L.A. Randall and S.W. Leslie. Div. Pharmacol. and Toxicol., Univ. Texas at Austin, Austin, TX 78712.

Glutathione (γ -glutamylcysteinylglycine) stimulates the entry of calcium into dissociated neurons from newborn rats (< 24 hr old). This influx of calcium can be blocked by the N-methyl-D-aspartate (NMDA) receptor antagonists APV, Mg^{2+} and MK801. This study investigated the effects of glycine, the NMDA receptor co-agonist, and 5,7-dichlorokynurenic acid (5,7-DCKA), a glycine site antagonist, on glutathione-mediated neuronal calcium entry into fura-2 loaded neurons isolated from newborn rats.

Reduced or oxidized glutathione (GSH or GSSG, 2 mM) was added to a cuvette containing 3.5×10^6 fura-2 loaded cells 50 sec after the addition of glycine (0, 1, 10 or 100 μ M). Although these concentrations of glycine markedly enhance the response to NMDA in this preparation, there was no effect on glutathione stimulation measured as nM change in intracellular calcium.

In a second set of experiments NMDA, GSH and GSSG concentration response curves were generated in the presence and absence of 5,7-DCKA (185nM and 370nM). The NMDA curves showed significant overall effect for both concentrations of 5,7-DCKA as well as significant NMDA \times 5,7-DCKA interaction characteristic of a noncompetitive antagonist. The GSH and GSSG curves, while showing a slight but significant overall effect for 5,7-DCKA, did not show significant glutathione \times 5,7-DCKA interaction. This parallel shift in concentration response curves is characteristic of a competitive antagonist.

These experiments provide evidence for involvement of the NMDA receptor glycine site in glutathione stimulation of calcium influx. (Supported by NIAAA grants R01 AA09337 and R37 AA05809)

CALCIMYCIN EXHIBITS A PERMISSIVE EFFECT ON NMDA STIMULATION OF PHOSPHATIDYLINOSITOL HYDROLYSIS IN NEONATAL RAT CEREBELLUM L.L. and S.S. Smith. Anat. Dept, Neuro. Ins, Hahnemann U., Phila.

The calcium ionophore calcimycin (A23187) can enhance NMDA-induced responses (Markram and Segal, 1991), an effect which may be important for development and plasticity. The products of phosphatidylinositol (PI) hydrolysis have also been implicated in developmental processes in the CNS. Therefore, in the present study, the effect of calcimycin on NMDA stimulation of PI turnover was investigated. PI turnover was assessed by using $[H^3]$ -inositol in 160 μ M cross chopped slices of cerebellar tissue from rats at postnatal day 7-10. Following a 5 min preincubation of the slices with calcimycin (100 μ M) and a 20 min incubation with NMDA (10 μ M) or other stimulants, chloroform extraction and anion exchange chromatography were used to isolate total inositol phosphates. Preloading with calcimycin increased NMDA-stimulated PI turnover up to 44% above control levels ($P < 0.05$) (The control level represents an elevated basal level in the presence of calcimycin alone). NMDA alone did not alter PI turnover in neonatal cerebellum. Calcimycin potentiation of NMDA-induced PI hydrolysis was not blocked by the nitric oxide synthase blocker, nitroarginine (100 μ M), suggesting that this gaseous second messenger does not mediate this NMDA-associated effect. In addition, calcimycin failed to significantly elevate levels of quisqualate (10 μ M)-induced PI turnover. These data suggest that this permissive effect of calcimycin is specific for the NMDA receptor. One of the important conclusions drawn from the above data is that the ability of NMDA receptor activation to stimulate PI turnover is dependent upon an adequate level of $[Ca^{2+}]_i$, an effect which may be required for maximal activation of phospholipase C, a Ca^{2+} -dependent enzyme. NMDA-induced activation of PI hydrolysis under these conditions may be important for developmental processes in the cerebellum. (Supported by USAFOSR #F49620-93-1-0136 DEF)

CARBAMAZEPINE INHIBITION OF NMDA-STIMULATED CALCIUM INFLUX IN CEREBELLAR GRANULE CELLS.

C. Hough*¹, R.P. Irwin², X.-M. Gao¹, M.A. Rogawski³ and D.-M. Chuang¹.

¹Biological Psychiatry Branch and ²Clinical Neuroscience Branch, NIMH, and ³Neuronal Excitability Section, Epilepsy Research Branch, NINDS, Bethesda, MD 20892

The most common toxic effects of carbamazepine (CBZ) are ataxia, nystagmus and vertigo, which suggests that the drug specifically impairs cerebellar function at high doses. Since the cerebellum expresses unique NMDA receptor subunits, we wondered whether the cerebellar impairment produced by CBZ could be due to a particular sensitivity of cerebellar NMDA receptors to the drug. Here we investigated the effects of CBZ on NMDA receptor responses in cultured rat cerebellar granule cells using fura-2 fluorometry. CBZ blocked Ca^{2+} influx induced by 100 μ M NMDA (+10 μ M glycine) in a dose-dependent manner. At a concentration of 100 μ M, CBZ produced a $27 \pm 3\%$ block of the Ca^{2+} signal, whereas the Ca^{2+} responses to 120 mM KCl or 100 μ M carbachol were unaffected. In contrast, NMDA responses in cultured hippocampal neurons were less sensitive to the drug. We conclude that this sensitivity of cerebellar neurons to supratherapeutic concentrations of carbamazepine could account for the clinical observation that the major CNS side effects of CBZ are referable to the cerebellum. Moreover, these data may provide insight into the finding (Gao and Chuang, *Neuroscience Lett.* 135: 159, 1992) that NMDA can completely block delayed toxicity of 100 μ M CBZ in cerebellar granule cells.

730.14

N-METHYL-D-ASPARTATE RECEPTOR-LIKE COMPLEX IS COUPLED TO PERTUSSIS TOXIN-SENSITIVE G-PROTEIN AND PHOSPHOLIPASE C IN C6 CELL. H. Shinno, M. Mikuni*, K. Saitoh, S. Yamawaki and K. Takahashi. Div. Mental Disorder Res., Natl. Inst. Neurosci., NCNP, Tokyo, 187 and Dep. Neurol. Psychiat., Hiroshima Univ., Sch. Med., Hiroshima, 734, Japan.

We have studied pharmacological property of glutamate receptors in C6 glioma cell. Glutamate and N-methyl-D-aspartate (NMDA) but not kainate caused the increase in the intracellular Ca^{2+} concentration ($[Ca^{2+}]_i$) and in inositol 1,4,5-trisphosphate (IP_3) level in the absence of extracellular Mg^{2+} and Ca^{2+} . D-APV, HA-966, MK-801 and Mg^{2+} inhibited the increase in $[Ca^{2+}]_i$ induced by glutamate. Glutamate-induced increase in $[Ca^{2+}]_i$ was abolished by pertussis toxin (PT).

We also found that there was an interaction between NMDA receptor and serotonin-2(5-HT₂) receptor in the presence of Mg^{2+} . Glutamate inhibited 5-HT₂ receptor-mediated intracellular Ca^{2+} mobilization and IP_3 formation in a concentration dependent manner. D-APV, PCP, MK-801 and HA-966 reversed the inhibitory effect, while L-APV did not. The same result was obtained in the absence of extracellular Ca^{2+} . Treatment with PT abolished the inhibitory effect. These pharmacological results suggest that the inhibitory effect is mediated via NMDA receptor-like complex coupled to PT-sensitive G protein and phospholipase C.

730.16

NMDA RECEPTORS EXPRESSED IN OOCYTES: EFFECTS OF LIGANDS RELATED TO HIV INFECTION Prado de Carvalho L*, Bochet P., Rossier J. Institut Alfred Fessard, CNRS, 91198 Gif sur Yvette, Cedex, France.

NMDA receptors in *Xenopus* oocytes injected with in vitro transcripts of cloned subunits (NMDAR1a or 1b + NMDAR1c, gift from Dr. Nakanishi), or with rat cortex mRNA were studied under voltage clamp. In oocytes injected with in vitro transcripts, glutamate with glycine (Glu + Gly) was always a better agonist than NMDA, with higher affinity (10^{-6} M, and 10^{-5} M for NMDA) and higher efficacy (maximal response up to 2 times the maximal response with NMDA). Glu and NMDA responses were voltage dependently blocked by Mg^{2+} ($EC_{50} \sim 60 \mu$ M at -100 mV). Quinolinic acid (QN) had little or no effect (up to mM concentrations, with or without Gly). QN had also little or no effect in mRNA injected oocytes expressing NMDA, AMPA, GABA_A and serotonin receptors. However, homoquinolinic acid (HQN) with Gly was a potent NMDA agonist, with affinity and efficacy comparable to those of NMDA. Incubation with GP 160 (330 pM, 15 min), had no effect on Glu induced responses. Memantine (gift of Dr. Quack, Merz and Co), a recently described NMDA open channel blocker, inhibits responses induced by Glu, NMDA and HQN. Current-voltage curves show that memantine blockage, unlike that of Mg^{2+} , was not voltage dependent. Under these conditions submaximal doses of memantine and Mg^{2+} do not seem to interfere with each other. The effect of memantine was reversible, with washout time of 1-2 min. Dose response curves of memantine, tested on saturating concentrations of Glu + Gly, show an EC_{50} of $\sim 10^{-7}$ M.

N-ACETYL-L-ASPARTYLGLUTAMATE (NAAG) DOES NOT MODULATE NMDA-STIMULATED $[^3\text{H}]$ NE RELEASE THROUGH THE GLYCINE RECEPTOR OR VIA THE L- OR N-TYPE VOLTAGE-DEPENDENT CALCIUM CHANNEL (VDCC). P.S. Puttfarcken* J.S. Handen, J.T. Coyle, and L.L. Werling, Dept. of Psychiatry, Harvard/MGH, Boston, MA 02129, and Dept. of Pharmacology and Program in Neuroscience, The GWU Med. Cr., Washington, DC 20032.

The release of preloaded radiolabeled norepinephrine ($[^3\text{H}]$ NE) from slices of rat hippocampus can be stimulated by excitatory amino acids (EAAs) that interact with the N-methyl-D-aspartate (NMDA) receptor. The dipeptide NAAG is colocalized with NE in projections of the locus coeruleus. Under conditions in which the activity of NAALADase, the enzyme responsible for the degradation of NAAG, was inhibited, studies have demonstrated that NAAG serves as a neuromodulator of EAAs-stimulated NE release by acting at least partially through the NMDA receptor/channel complex. NAAG ($>250\mu\text{M}$) directly stimulated release of $[^3\text{H}]$ NE albeit by a small percent. Additionally, NAAG inhibited the release evoked by NMDA and L-glutamate in a concentration-related manner. However the mechanism by which NAAG exerts this action does not appear to be solely competitive. Experiments were performed to identify potential sites of action for NAAG. Both 7-chlorokynurenate or 1-hydroxy-3-aminopyrrolidone-2 (HA966) decreased $[^3\text{H}]$ NE release in a concentration-dependent manner. Glycine did not reverse inhibition by NAAG, and the inhibition produced by NAAG in the presence of glycine antagonists was greater than that produced by NAAG alone. Similarly, the addition of NAAG in combination with either the L-type voltage-VDCC blocker nitrendipine, or the N-type channel blocker ω -conotoxin, produced an additional inhibition. These data suggest that NAAG does not elicit its actions through the strychnine-insensitive glycine recognition site nor via the L- or N-type VDCC.

N-METHYL-D-ASPARTATE RECEPTORS AND SPINAL NOCICEPTIVE PROCESSING. M.J. Cumberbatch and P.M. Headley, SPON: Brain Research Association, Dept. of Physiology, University of Bristol, BS8 1TD, England.

NMDA can enhance nociceptive responses in spinal neurones, NMDA antagonists can reduce such responses and NMDA receptor activation may trigger long-term nociceptive processes. However it remains unclear to what extent these changes are effected exclusively by NMDA receptors.

Recordings were made from single dorsal and ventral horn neurones in *chloralose* anaesthetized, spinalized rats. Iontophoretic NMDA enhanced responses to noxious heat ($146 \pm 33\%$ (S.E.M) of control, after subtracting background activity of 25 spikes/s) which returned to control immediately after NMDA ejection ceased. (RS)-alpha-amino-3-hydroxy-5-methyl-4-isoxazole-propionic acid (AMPA) and kainate were only slightly less effective ($115 \pm 8\%$ and $123 \pm 20\%$ control respectively). The NMDA antagonist D-2-amino-5-phosphonopentanoate (AP5) reduced not only responses to noxious heat and pinch ($69 \pm 7\%$) but also spontaneous activity ($43 \pm 12\%$). When this fall in spontaneous was compensated by maintaining a constant background discharge with AMPA, AP5 no longer significantly decreased the responses ($87 \pm 4\%$). Equivalent effects were seen with the non-NMDA receptor antagonist 6-cyano-7-nitroquinoline dione (CNQX; $56 \pm 8\%$ without, versus $85 \pm 5\%$ with compensation).

If activation of synaptic NMDA receptors triggers long-term enhancement of nociception, then exogenous NMDA should cause a maintained increase of phasic nociceptive responses. It did not do so. NMDA receptors do however mediate background synaptic input under these conditions, but not phasic thermal or mechanical nociceptive responses. These results show that caution is required in interpreting the role of NMDA receptors in nociception.

MODULATION OF SPERMINE-INDUCED $[^3\text{H}]$ TCP BINDING BY GUANINE NUCLEOTIDES ON THE NMDA RECEPTOR COMPLEX. T. Yamamoto*^{1,2}

H. Yamamoto² and T. Moroji². ¹Lab. of Molecular Recognition Yokohama City Univ., Yokohama 236, Japan and ²Dept. of Psychopharmacol., Tokyo Inst. of Psychiatry, Tokyo 156, Japan.

The N-methyl-D-aspartate (NMDA) receptor complex consists of several modulatory site, i.e., strychnine-insensitive glycine-site, high-affinity Mg^{2+} -site (stimulatory), low-affinity Mg^{2+} -site (inhibitory), polyamine-site and phencyclidine (PCP)-site. We have previously demonstrated that the high-affinity Mg^{2+} -site and glycine-site may be coupled to a GTP/GDP binding site using $[^3\text{H}]$ TCP binding to rat cortical membranes. In this study, we further examined the effect of guanine nucleotides on the spermine-induced $[^3\text{H}]$ TCP binding to well washed rat cortical membranes comparing with glutamate- and glycine-induced binding. Guanine nucleotides strongly inhibited spermine-induced $[^3\text{H}]$ TCP binding while showing a lesser effect on Mg^{2+} , glycine- and glutamate-induced binding. GDP was most potent compound. GDP inhibited spermine-induced $[^3\text{H}]$ TCP binding with an IC_{50} of $11.2\mu\text{M}$. Stimulation of $[^3\text{H}]$ TCP binding with either glycine or Mg^{2+} , nor glutamate, was also inhibited by GDP (IC_{50} = 181 and $96.3\mu\text{M}$, respectively). Scatchard analysis indicates that the GDP inhibition of spermine-induced $[^3\text{H}]$ TCP binding results from a decrease in the number of binding site. These results suggest that spermine-site is more closely coupled to GDP/GTP site than the other modulatory sites.

731.2

CHARACTERIZATION OF PHENCYCLIDINE (PCP) BINDING IN MOUSE BRAIN AND SPINAL CORD MEMBRANES. A.A. Larson* and K. Kovacs, Department of Veterinary Pathobiology, University of Minnesota, St Paul, MN 55108, U.S.A.

Our behavioral studies suggest the presence of a PCP site in the mouse spinal cord that is not linked to NMDA activity. To test this hypothesis more directly, we examined PCP binding in mouse brain and spinal cord using $[^3\text{H}]$ 1-[1-(2-thienylcyclohexyl)piperidine] ($[^3\text{H}]$ TCP). Whole brain and spinal cord tissues each resulted in a two-site model having high ($K_d = 5.5$ and 9.3 nM respectively) and low ($K_d = 155$ and 149 nM respectively) affinity binding. Brain homogenates yielded a high density ($B_{\text{max}} = 680\text{ fmol/mg protein}$) of high affinity sites, which constitute a much smaller population ($B_{\text{max}} = 231\text{ fmol/mg protein}$) in the spinal cord. The number of low affinity sites was about the same in both tissues ($B_{\text{max}} = 2993$ and $2881\text{ fmol/mg protein}$ in the brain and spinal cord). Competition studies with (+)MK-801 clearly resolved two sites with distinct K_i values of 1.4 and 3827 nM in the brain, 1.2 and 3845 nM in the spinal cord. The abilities of haloperidol, DTG and (+)3-PPP to compete with high affinity for $[^3\text{H}]$ TCP binding in the spinal cord suggest that the low affinity site labeled by $[^3\text{H}]$ TCP has characteristics of a *sigma* receptor. Inclusion of GBR12909, a dopamine transport inhibitor at concentrations up to $1\mu\text{M}$, had no effect on either high or low affinity $[^3\text{H}]$ TCP binding. These data suggest that the majority of PCP binding in the spinal cord is not linked to the NMDA receptor complex. (USPHS grants DA04090, 04190 and 00124).

TIME DEPENDENT EFFECTS OF PHENCYCLIDINE ON NMDA RECEPTOR BINDING IN RAT HIPPOCAMPUS. M. Gottschalk*, X.-M. Gao, C.A. Tamminga, Maryland Psychiatric Research Center, University of Maryland, Baltimore, MD 21228

Phencyclidine (PCP) is a psychotomimetic drug which produces both acute and delayed psychotic effects in humans and psychosis exacerbation in schizophrenia. Hence it has been used in animals as a model of psychosis. We have previously demonstrated that a single administration of PCP in rats produces a dose-responsive increase in NMDA-sensitive $[^3\text{H}]$ glutamate binding in hippocampal CA_1 24 hours after a dose. In this study, we analyzed the time course of NMDA receptor binding changes following PCP treatment at 3, 6, 12, 24 and 48 hours after a single dose (8.6 mg/kg). Our results show that NMDA receptor binding in CA_1 shows no change at 3 hours; however binding is increased by 21% at 6 hours ($p < 0.25$), and by 24% at 12 hours ($p < 0.05$). The effect reaches its maximum at 24 hours with a 34% increase ($p < 0.05$). By 48 hours, the NMDA binding has returned to control levels.

This report shows that the alterations in NMDA receptor binding after a single PCP administration are time related, extended, and transient. We have previously reported a similar extended time course for changes in $[^{14}\text{C}]$ -2-deoxyglucose metabolism following PCP treatment (Gao et al. Eur. J. Pharmacol. in press, 1993). These data, taken together with the known clinical time course of PCP-induced psychosis in humans which includes delayed psychotomimetic effects, may have implications for the underlying mechanism of the psychotomimetic action of PCP.

DELAYED ALTERATIONS IN NMDA RECEPTOR BINDING AFTER MK801 TREATMENT IN RATS. X.-M. Gao*, C.A. Tamminga, Maryland Psychiatric Research Center, University of Maryland, Baltimore, MD 21228

We have previously demonstrated that a single dose of PCP in rat produces a dose-related increase in NMDA-sensitive ^3H -glutamate binding in hippocampus CA_1 region at 24 hours. Because clinical psychotomimetic effects of PCP can also show this delayed property, this neurochemical finding could be informative about the mechanism of PCP-induced psychosis. MK801 is a non-competitive NMDA receptor antagonist, which acts at the level of the NMDA receptor operated ion channel as an open channel blocker, a site of action shared by PCP. Here, we report the effect of MK801 at 24 hours (1 mg/kg) on NMDA sensitive ^3H -glutamate binding, and on ^3H -kainate (KA) binding. NMDA and KA glutamate receptors were quantified according to standard technique, using ^3H -glutamate and ^3H -KA, respectively (Gao et al. Neurosci. Abstr. 18:377, 1992). MK801 produced an increase of 22% in NMDA receptor binding in CA_1 pyramidal cells (MK801 = 211.5 ± 17.6 , Control = 173.0 ± 21.2 , mean \pm SD, $n = 6$, $p < 0.01$), 24 hours after the dose, and also an increase in the same receptor in posterior cingulate cortex and thalamus. MK801 also increased ^3H -kainate binding sites in dentate gyrus at 24 hours (MK801 = 151.3 ± 10.1 , Control = 134.5 ± 12.4 , $p < 0.05$). Thus, MK801 shows the same delayed effect on NMDA receptor binding as previously demonstrates for PCP. This delayed effect may be mediated at the NMDA-PCP receptor on the Schaffer collaterals extending from CA_3 to CA_1 . These late NMDA receptor alterations may be related to the psychotomimetic actions of PCP.

ALTERED EXCITATORY AMINO ACID RECEPTOR EXPRESSION AFTER HYPOTHERMIC CIRCULATORY ARREST IN THE DOG. M.E. Blue*, J.M. Redmond, K. Zehr, M.S. Lange, M. Gillinov, M.V. Johnston and W.A. Baumgartner, The Kennedy Krieger Institute and Depts. of Neurology and Surgery, The Johns Hopkins Medical Institutions, Baltimore, MD 21205.

Hypothermic circulatory arrest (HCA) is used clinically to provide a bloodless field for repair of congenital heart defects and other surgical procedures. HCA is accompanied by a characteristic pattern of ischemia and neurological injury which resembles that produced by the excitatory amino acid (EAA) transmitter, glutamate. In the present study, we examined the role of glutamate neurotoxicity in a canine model of HCA. Using quantitative receptor autoradiography, ³H-glutamate binding to NMDA receptors and ³H-AMPA binding was characterized in hippocampus 3 days after HCA. Both NMDA and AMPA receptors declined in density after HCA, with the greatest decreases in a zone spanning the cell bodies, basal dendrites and proximal apical dendrites of pyramidal cells in CA1 and CA 3 and in the molecular layer of the dentate gyrus. The decrease in EAA receptors was most marked in these regions, which have enhanced binding site density, whereas zones with fewer EAA receptors were less affected by HCA. The distribution of diminished receptor expression also correlated with the selective pattern of necrosis in the hippocampus and dentate gyrus.

Additional experiments determined whether administration of the EAA antagonists, MK-801 and NBQX and GM1-ganglioside would reverse the decline in EAA receptors after HCA. All three compounds preserved AMPA and NMDA receptors and afforded neuronal protection in regions of the hippocampus and dentate gyrus where receptor density was highest. These results suggest a role for excitotoxicity in HCA and some possible therapeutic approaches for ameliorating the associated neuronal deficits.

NMDA AND NON-NMDA RECEPTOR BINDING IN THE BRAIN OF THE NAPLES HIGH AND LOW-EXCITABILITY RATS: AN AUTORADIOGRAPHIC STUDY. M.P. Pellicano and A.G. Sadile. (SPON: European Brain and Behaviour Society). Dipt. Fisiologia Umana "F. Bottazzi", 2nd Univ. Naples (SUN), Naples, Italy.

The Naples High- (NHE) and Low-Excitability (NLE) rats, selectively bred for high and low activity in a Låt-maze, have been proposed as animal model to study hippocampal functions. The anatomical distribution of NMDA and non-NMDA receptors has been studied in the brain of these rats by quantitative autoradiography using ³H-L-glutamate as ligand. Twenty µm thick cryostat sections were incubated for 45 min at 4 °C with 150nM ³H-L-glutamate (56 Ci/mmol) in 50 mM Tris-HCl buffer (pH 7.2) containing 2.5 mM CaCl₂ alone or in presence of 100µM NMDA or 2.5µM quisqualate (QA). Non specific binding was determined in presence of 1mM unlabelled glutamate. The sections were exposed to tritium-sensitive films for 3 weeks at 4 °C. Quantitative analysis revealed (i) higher levels of total binding in NHE than in NRB and NLE-rats in all areas but cerebellum; (ii) a positive correlation in hippocampal CA1 and dentate gyrus between binding sites and activity level with NLE < NRB < NHE; (iii) a higher displacement by QA than NMDA across brain areas (but not cerebellum) in NHE compared to NRB and NLE-rats; (iv) the displacement by NMDA was lower in the hippocampus of NLE than NRB and NHE-rats; (v) a negative correlation between QA binding and activity level with NLE > NRB > NHE in all areas but cerebellum. In the hippocampus, NLE-rats have lower binding sites for both NMDA and QA-receptors, whereas NHE-rats have higher binding sites for QA-receptors. Thus, the hippocampus and neocortex of the NHE and NLE rats appear to be differentially modelled by an unbalance between NMDA and non-NMDA receptors.

DEVELOPMENTAL CHANGES IN [³H]-KAINATE BINDING IN HUMAN BRAINSTEM SITES VULNERABLE TO PERINATAL HYPOXIA-ISCHEMIA A Panigrahy*# and HC Kinney†, Dept of Neurology# and Pathology*, Children's Hospital, Boston MA 02115

While the pathogenesis of CNS neuronal death secondary to hypoxia-ischemia (H-I) is complex and multifactorial, the distribution and ontogeny of excitatory amino acid receptors likely contribute to the regional and developmental patterns of selective vulnerability. In humans the brainstem is more susceptible to H-I in the fetal, perinatal, and early infant periods than in childhood and adulthood, with specific regions of vulnerability in the inferior olive (IO), basis pontis (BP), inferior colliculus (IC), and reticular core. We postulated that the selective vulnerability of these brainstem regions in early development coincides with a transient elevation in binding to the kainate (KA) receptor, a nonNMDA receptor implicated in glutamate-induced neuronal death complicating H-I. To test this idea, we compared the quantitative distribution of [³H]KA binding in multiple nuclei between human fetuses (n=4; 19-25 gestational weeks), young infants (n=4; 1-9 postnatal mos), and "mature" individuals (n=3; 1 child and 2 adults) without neurological disease or H-I. Quantitative receptor autoradiography was used, with 4nM [³H]KA for total binding and 4nM [³H]KA and 100µM KA for nonspecific binding. The highest brainstem binding (>20 fmole/mg tissue) at any age occurred in the fetal IC, fetal and infant BP, and infant IO. Binding in the IC decreased significantly between the fetal and infant groups and was negligible in the mature group. Binding in the IO increased from the fetal to infant period and was significantly lower in the mature group. Binding in the mature BP was significantly lower than the fetal and infant BP. In the reticular core, binding was intermediate (10-20 fmole/mg) in the fetal group, compared to negligible levels in the mature group. In contrast, binding was intermediate in cranial nerve and other nuclei, with no significant differences among the fetal, infant, and mature group. Quench did not fully account for decreased [³H]KA binding. These data support the hypothesis that the vulnerability of certain nuclei in the immature human brainstem to H-I coincides with a developmentally-regulated, transient elevation in KA receptor binding. ETHANOL EFFECT ON THE NMDA RECEPTOR COMPLEX: ALTERATION IN BINDING OF THE LIGAND MK-801 IN CORTEX/HIPPOCAMPUS IN VITRO. K.S. Phillips, J. Gonzalez, P.K. Randall and S.W. Leslie*, Div. of Pharmacol. and Toxicol., The Univ. Texas at Austin, Austin, TX 78712.

Ethanol has been demonstrated to inhibit NMDA receptor-mediated functions. We investigated this phenomenon in more detail by examining ethanol action on MK-801 binding to the internal PCP receptor site as an index of the functional status of the NMDA-associated ionophore.

Membrane preparations of adult rat cortex/hippocampus were assayed according to the method of Javitt and Zukin (PNAS 86:740-744, 1989). Briefly, homogenates (0.2-0.4 mg protein) were incubated with 12 concentrations of [³H]MK-801 from 1.2 - 150 nM, each under conditions of basal, 10 µM glutamate or 10 µM glutamate/30 µM D-serine, and ethanol (0, 50, or 100 mM) for 4 hrs at 37 °C. Non-specific binding was determined by displacement with 50 µM PCP. Kd and Bmax were estimated by Scatchard analysis initially with Program Ligand, followed by nonlinear regression with MACSPSS 4.0, coupled to iterative computation of equilibrium free and bound concentrations.

For each assay all concentration curves for the different conditions were fit simultaneously to a two-site model with high and low Kd's shared across sites. These analyses generated estimates of high and low affinity constants (Kd) and receptor densities (Bmax), compatible with a definition of open and closed states of the ion channel, respectively. Ethanol (50 and 100 mM) did not alter the apparent dissociation constants of MK-801 binding; however, it decreased the % high affinity receptors in basal and agonist/(+/-)coagonist conditions. This finding is due, at least in part, to an apparent increase in the low affinity receptor density. Association experiments further explained this conclusion, in that ethanol diminished fast component binding (MK-801 rapid diffusion in open channel state) in the presence of glutamate. Slow component binding, however, was increased by ethanol, suggesting that ethanol does not simply prevent activation of the channel by the agonist. 731.8

NE-100, A NOVEL SELECTIVE σ RECEPTOR ANTAGONIST, MODULATES [³H]TCP INTACT CELL BINDING POSSIBLY THROUGH INTRACELLULAR CROSS-TALK BETWEEN σ-1 SITE AND NMDA/PCP RECEPTOR/ION CHANNEL COMPLEX. H. Yamamoto¹, T. Yamamoto¹, N. Sagi¹, V. Klenerová², F. Mizobe², S. Okuyama², T. Moroji¹. ¹Dept. of Psychopharmacol., Tokyo Inst. of Psychiatry, Tokyo 156, ²Dept. of Pharmacol., Res. Center, Taisho Pharmaceutical Co., Ltd., Saitama 330, Japan.

N,N-dipropyl-2-[4-methoxy-3-(2-phenylethoxy)phenyl]-ethylamine monohydrochloride (NE-100), a highly selective σ ligand, is effective in behavioral tests of phencyclidine. More precise pharmacological profile of NE-100 will be also presented by Okuyama et al. at this meeting. NE-100 was tested of an ability to modify muscarinic acetylcholinergic phosphatidylinositol turnover and [³H]TCP binding in primary cultured neuronal cells derived from fetal rat telencephalon. NE-100 inhibited IP₃ production induced by 1mM carbachol, suggesting that NE-100 acts at σ-1 site. Haloperidol, NE-100, DuP 734 and XJ 448 decreased [³H]TCP intact cell binding under physiological condition. The order of potency is NE-100 > haloperidol > DuP 734 > XJ 448. Considering the finding which NE-100 has no affinity for NMDA/PCP receptor/ion channel complex, inhibitory action of NE-100 on [³H]TCP intact cell binding would be explained by a cross-talk between σ-1 site and NMDA/PCP receptor/ion channel complex.

ETHANOL SENSITIVITY OF GLUTAMATE RECEPTORS EXPRESSED IN XENOPUS OOCYTES DOES NOT DIFFER AFTER INTERNAL PERFUSION. S.N. Treistman, H. Bayley*, V. Anantharam, A. Wilson, Dept. Pharmacol., Univ. Mass. Med. Sch., Worcester, MA 01655, and Worcester Fnd. Exp. Biol., Shrewsbury, MA 01545.

We have shown previously that homomeric assemblies of the NMDAR1 subunit expressed in Xenopus oocytes are sensitive to ethanol at pharmacologically relevant concentrations. We wished to assess the importance of cytoplasmic elements for this ethanol response. To perfect the necessary technique, we examined oocytes injected with GluR1 and GluR2. The experimental protocol was modified from protocols previously described (Dascal, et al., J. Neurosci. Meth., 39:29-38, 1991; Tagliatela, et al., Biophys. J., 61:78-82, 1992). Briefly, the oocyte was allowed to seal to the lumen of a fire-polished pipette, and was then pierced with the perfusion pipette, and the inside of the oocyte was perfused with 30 µl of "internal medium" containing K-MeS and K-ATP. The exterior of the oocyte was perfused with control medium containing 10 µM glutamate either with or without ethanol. Glutamate-induced currents in the internally-perfused oocyte were 67 ± 7% of the currents elicited by 2-electrode voltage clamp in the same oocytes. Glutamate current was reduced 32 ± 7% by 100 mM ethanol in the intact oocyte, and 28 ± 2% in the internally-perfused oocyte. Thus, inhibition of the glutamate receptors was likely to result from direct interaction of ethanol with the receptor, and did not require the involvement of cytoplasmic elements. (Supported by NIH grant AA05542).

IN VITRO ETHANOL EFFECT ON BINDING OF THE NMDA RECEPTOR ANTAGONIST, CGP 39653, DURING POSTNATAL DEVELOPMENT. R. Robichon, P.K. Randall, K.S. Phillips, M. Weaver* and S.W. Leslie, Div. of Pharmacol. and Toxicol., The Univ. Texas at Austin, Austin, TX 78712.

Previous studies have shown that ethanol inhibits NMDA receptor-mediated functions. To investigate further the mechanism of these actions, we examined acute ethanol exposure on properties of antagonist binding at the NMDA receptor site during postnatal (PN) development in the rat.

Membrane preparations of whole brain from animals, ages 7-14-21-28 and 90 days (PN) were assayed according to the method of Sills et al. (Euro. J. Pharmacol. 192:19-24, 1991). Briefly, tissue (0.2-0.4 mg protein) was incubated with 12 concentrations of [³H]CGP 39653 from 0.29 - 60 nM and ethanol (0, 24, 48, or 96 mM) for 2 hrs at 4 C. Non-specific binding was determined by displacement with the agonist, 10 μ M glutamate. Binding parameters, K_d and B_{max}, were estimated by Scatchard analysis using Program Ligand.

The affinity (K_d) of CGP 39653 was found to vary significantly among PN ages with affinity increasing from 7 day to adult. Ethanol exposure (>25 mM) lowered the affinity of antagonist binding in 7-day and 14-day whole brain homogenates. The affinity of 7-14 day tissue remained lower than older ages in the presence of ethanol (25 to 100 mM). Receptor density (B_{max}) was lower in 7-day and adult tissue compared to 14 to 28-day whole brain homogenates. Ethanol exposure (> 25 mM) significantly increased B_{max} in tissue of all ages, analyzed jointly. This increase was maximal at 25 mM ethanol, and was highest in 21-day and lowest in 7-day whole brain homogenates (25 to 100 mM). These results suggest the hypothesis that ethanol may alter the confirmation of the NMDA receptor site to a more antagonist-conferring state; and that this configuration is synonymous with an inactivated form of the receptor. This response to ethanol appears more sensitive at certain stages of postnatal development than others. (Supported by NIAAA grants R01 AA09337 and R37 AA05809)

ENFLURANE INHIBITION OF GLUTAMATE-STIMULATED [³H]MK-801 BINDING IS ATTENUATED BY SPERMIDINE. D.C. Martin*, R.L. Dennison, and R.S. Aronstam. Departments of Anesthesiology and Pharmacology & Toxicology, Medical College of GA, Augusta, GA, 30912

N-methyl-D-aspartate (NMDA) receptors are a class of glutamate receptors that mediate excitatory transmission in the mammalian nervous system. We have previously demonstrated that the inhibition of glutamate-dependent [³H]MK-801 binding to the NMDA ionophore by the volatile anesthetic, enflurane, is attenuated by the positive NMDA allosteric modulator, glycine. The present study examined the influence of the NMDA receptor allosteric agonist, spermidine, on the disruption of glutamate-dependent [³H]MK-801 binding by enflurane. Membranes for radioligand binding assays were prepared from rat forebrains by homogenization followed by differential centrifugation. Following treatment with Triton X-100 (0.04%), the membranes were extensively washed. Enflurane (0.15-1.0 mM) inhibited glutamate-stimulated [³H]MK-801 binding by as much as 50% with an IC₅₀ value of 0.4 mM. The presence of 100 μ M spermidine reduced the inhibition of glutamate-dependent [³H]MK-801 binding by enflurane from 50% to 12%. In the presence of 100 μ M glutamate, spermidine stimulated glutamate-dependent [³H]MK-801 binding by 150% (10 μ M spermidine) and mitigated the disruption of [³H]MK-801 binding by enflurane in a concentration-dependent manner with an EC₅₀ of approximately 3 μ M. In the absence of glutamate, enflurane had little influence on [³H]MK-801 binding stimulated by spermidine. These results suggest interactions between general volatile anesthetics and polyamine allosteric modulatory sites on NMDA receptors. Supported by GM 46408 and the Medical Research Service of the Veterans Administration.

EVIDENCE FOR TWO GLUTAMATE, TWO GLYCINE, AND THREE MAGNESIUM/CALCIUM BINDING SITES ON THE NMDA CHANNEL. G. von Euler* and Y. Liu. Dept. of Histology and Neurobiology, Karolinska Institutet, Box 60400, S-10401 Stockholm, Sweden

In order to elucidate the complex effects of glutamate and glycine on the NMDA receptor-coupled ion channel, we have investigated the effects of these amino acids on equilibrium [³H]MK-801 binding in cerebrocortical membrane preparations from male rats, in the presence of various concentrations of Mg²⁺, Ca²⁺ and H⁺.

1: The potency of glutamate and glycine to synergistically increase specific [³H]MK-801 binding was strongly enhanced by low concentrations of Mg²⁺ and Ca²⁺ (<30 μ M) and inhibited by H⁺.

2: In the presence of Mg²⁺ (>0.1 mM) glutamate and glycine synergistically decreased the affinity of [³H]MK-801 binding. Ca²⁺ and H⁺ partly antagonized the decrease, whereas the competitive glutamate and glycine antagonists D-CPP and 7-CI-KYNA completely reversed the decrease in [³H]MK-801 binding affinity.

3: High concentrations of Mg²⁺, Ca²⁺, and H⁺ inhibited [³H]MK-801 binding, probably by a direct competition at a common binding site. Thus, acidic conditions counteracted the blocking effect of Mg²⁺.

Based on these results we have developed a mathematical model which closely mimics experimental data. The model indicates the presence of at least two glutamate, two glycine, and three magnesium/calcium binding sites on the NMDA channel. Our results suggest that glutamate and glycine synergistically decrease the binding affinity of Mg²⁺ to its voltage-dependent site within the channel pore, in addition to the opening of the NMDA channel.

731.12

ANTIDEPRESSANT-INDUCED ADAPTATION OF THE NMDA RECEPTOR COMPLEX. R.T. Laver*, G. Nowak, P. Popik, P. Skolnick and I.A. Paul. Lab. Neuroscience, NIH, NIDDK, Bethesda, MD 20892.

Chronic treatment with either antidepressant drugs (tricyclics, MAOIs, and atypicals) or electroconvulsive shock (ECS), reduces the affinity of glycine to inhibit [³H]5,7-DCKA binding to the strychnine-insensitive glycine modulatory site of the NMDA receptor complex (Nowak et al., PNAS, submitted; Paul et al., Eur. J. Pharmacol. - Mol. Pharmacol. Sect., in press). We examined the time course and dose-response relationships after treatment with imipramine (IMI), citalopram (CIT) and ECS. The first significant increases in the IC₅₀ of glycine to inhibit [³H]5,7-DCKA binding were observed after treatment for 7 d with ECS; 14 d with IMI and; 10 d with CIT. These effects disappeared by the 10th d after withdrawal from treatment. The E_{max} for ECS (350% > control) was twice that of IMI. The ED₅₀ values for IMI and CIT were 5 mg/kg, however the E_{max} for IMI was twice that of CIT. These characteristics indicate that antidepressant-induced decreases in the affinity of glycine to inhibit [³H]5,7-DCKA binding are: 1) slowly developing (7-14 d) adaptive phenomena and; 2) remarkably persistent after antidepressant withdrawal. Moreover, these data are in good agreement with the clinical differences observed among these treatments. These findings lend further support to the hypothesis that the NMDA receptor complex plays a critical role in the neural adaptation presumed to underlie the therapeutic response to antidepressant treatment.

731.14

CONANTOKINS: PEPTIDE LIGANDS OF THE NMDA RECEPTOR

R. A. Myers*, J.-F. Hernandez, J. L. Torres, J. Rivier and B. M. Olivera. Dept. of Biology, University of Utah, Salt Lake City, UT 84112 and Clayton Laboratories for Peptide Biology, Salk Institute, La Jolla, CA 92138.

The conantokins are peptides isolated from the venom of fish-hunting marine snails of the genus *Conus*, which target to the N-methyl-D-aspartate (NMDA) receptor (Olivera et al. (1990) *Science* 249, 257). These peptides have 17-27 amino acids, at least four of which are the modified amino acid γ -carboxyglutamate, which confers an α -helical conformation onto these peptides (Myers et al. (1990) *J. Toxicol.-Toxin Reviews* 9, 179). Electrophysiological studies with conantokins suggest that these peptides discriminate between different NMDA receptor subtypes (Hammerland et al., (1992) *Eur. J. Pharmacol.* 226, 239; Haack et al., manuscript submitted). Structure/function studies, both with the naturally occurring peptides and the numerous chemically-synthesized analogs, have allowed identification of which amino acids are necessary for activity. Radiolabeled analogs have also been prepared and employed in a crosslinking assay which was used to follow the purification of complexes of >300 kd from whole rat brain membranes. With a purification strategy including affinity chromatography with an immobilized NMDA ligand, SDS-PAGE reveals that the complexes are glycoproteins composed of subunits with M_rs of 100-170 kd; one such protein (160 kd) has been purified to homogeneity. Preliminary evidence suggests that the SDS-PAGE banding pattern varies according to brain tissue type, thus supporting the existence of multiple NMDA receptor subtypes. (Supported by GM48677.)

EFFECT OF MONO-, DI- AND POLYVALENT CATIONS ON NMDA SENSITIVE [³H]CGP-39653 BINDING IN RAT BRAIN MEMBRANES. A. Mukhin*, E. Kovaleva* and E.D. Londont. §§ Neuroimaging and Drug Action Section, Addiction Research Center, NIDA, NIH, Baltimore, MD 21224; §Dept. Pharmacol. Exp. Ther., School of Medicine, University of Maryland, Baltimore, MD 21201; and ¶Dept. Radiology, The Johns Hopkins School of Medicine, Baltimore, MD 21205.

It has been shown previously that divalent cations can enhance the binding of [³H]MK 801 ([³H]dizocipine) in preparations of well-washed membranes from rat brain. This effect is demonstrable in the presence of low, but not saturating concentrations of L-glutamic acid (GLU). One might suggest that this stimulation is due to an enhancement by divalent cations of the affinity of the NMDA receptor for GLU.

Using [³H]CGP-39653 (CGP) as a radioligand probe for GLU recognition sites on the NMDA receptor, we observed that MgCl₂ or CaCl₂ (EC₅₀ 0.8 mM) can enhance CGP binding up to five-fold in well-washed membranes from rat brain. Monovalent cations (Li⁺, Na⁺, K⁺, and Cs⁺), added to incubations as chloride salts, produced similar stimulation of CGP binding, but with lower potencies (2.5-fold stimulation with EC₅₀ values about 8 mM). Of the cations studied, the most potent ones were the polyamines spermine and spermidine, which enhanced CGP binding up to six times, with EC₅₀ values of 6 μ M and 20 μ M, respectively. Effects of the cations on CGP binding were not additive, suggesting that all of the cations acted through the same mechanism and the same binding sites.

Our preliminary results indicate that CGP binding sites in well-washed membranes are present in two affinity states, and that cations convert low affinity binding sites to high affinity sites. The findings have implications regarding at least part of the mechanism by which polyamines modulate the function of the NMDA receptor.

ACUTE INTRAVENOUS INFUSION VS. MULTIPLE INFUSIONS OF FENTANYL DERIVATIVES IN A RAT EEG MODEL.

S. La Marca, R.J. Lozito, M.H. Ossipov, R.W. Dunn, and T. Jerussi*, Anaquest, Inc., 100 Mountain Ave., Murray Hill, NJ 07974

Administration of anesthetic agents to rats produces a loss of righting (LOR) which is predictive of clinical anesthesia. Following bolus i.v. administration of fentanyl, sufentanil, alfentanil, and remifentanil, the ED₁₀₀ doses for LOR were 0.035, 0.003, 0.05, and 0.020 mg/kg, respectively. For the EEG infusion studies, rats were implanted with jugular catheters and 5 cortical electrodes just below the dura mater. Each agent was infused at a rate of 0.02 ml/min such that each animal received the ED₁₀₀ dose every 60 seconds until LOR was observed and the infusion was stopped. Following acute infusion to LOR, the difference in time from return of the righting reflex (RRR) to baseline EEG for fentanyl, sufentanil, alfentanil, and remifentanil was 30.9, 35.3, 14.9, and 1.3 minutes, respectively. Following a three hour washout period, multiple infusions (three successive infusions to LOR) were administered. Following RRR (after the third LOR) the return to baseline EEG for fentanyl, sufentanil, alfentanil, and remifentanil was 56.1, 57.1, 13.6, and 2.9 minutes, respectively. There were no statistically significant differences between the acute and multiple infusions for the return to baseline EEG for alfentanil and remifentanil, but there was significant increases in time to return to baseline following multiple infusions of fentanyl and sufentanil. These results show that there was no cumulation of alfentanil and remifentanil with respect to EEG effects but cumulation was observed for fentanyl and sufentanil.

ACUTE & CHRONIC NALTREXONE DECREASES THE HYPERACTIVITY OF AUTISM B.H. Herman*, G. Asleson, E. Lukens, J. Borghese, L. Anselmi, R.P. Allen, M.B. Benoit, J. Chatoor, & P. Papero, Med Dev Div, NIDA, NIH, Rockville, MD 20857, Brain Res Cen & Dept Psychiat, Children's Natl Med Cen & Dept Pediatrics, GWUSM, Washington, DC 20010, & Dept Psychiat, JHUSM, Baltimore, MD 21214

Hyperactivity is a common and severe symptom of autism (Asleson et al. *Soc Neurosci* 17: 1346, 1991). Here the effects of the opioid receptor antagonist, naltrexone, were investigated after both acute (1x week) and chronic (3x week) administration (0.5, 1.0, 1.5, 2.0 mg/kg) versus placebo on the motor/attentional behavior of 20 autistic children. Measures included a subjective scale (parents' ratings, Conners' 10 Item Parent Teacher Rating Scale (CPTRS)) and two objective tests (# quadrants entered (Qs), activity monitor (AAM) counts during a playroom test (BRCSTP)). The CPTRS revealed that naltrexone induced highly significant decreases for acute (N=14) and chronic drug (N=12) (p's < 0.001). Acute naltrexone also significantly decreased Qs entered during the BRCSTP (N=20; p<0.05) but this effect was not significant for chronic drug. Results for the AAM measure were inconclusive due to a small N for acute (N=9) and chronic naltrexone (N=7) although for both drug trials there were overall decreases in AAM counts under naltrexone versus placebo (p's > 0.10). These data suggest that hypermobilization of opioid peptides and possibly dopamine (Herman et al. *Soc Neurosci*, 18: 657, 1992) underlies the hyperactivity/inattention of autism (Supported by FDA, NICHD, DuPont, Janusz Korczak Foundation).

732.5

EFFECTS OF ACUTELY AND CHRONICALLY ADMINISTERED NALTREXONE ON SOCIAL BEHAVIOR AND LANGUAGE OF CHILDREN WITH AUTISM. J.F. Borghese*, B.H. Herman, L.S. Anselmi, G. Asleson, E. Lukens, M.B. Benoit, J. Chatoor, & P. Papero, Med Dev Div, NIDA, NIH, Rockville, MD 20857, Brain Res Cen & Dept Psychiat, Children's Nat Med Cen, Dept Pediatrics, George Washington USM, Washington DC, 20010.

Hypermobilization of brain opioids appear to play a role in autism (Herman, In J.J. Ratey (Ed.), *Mental Retardation: Developing Pharmacotherapies*, 1991). Here we examined the effects of naltrexone (0.5, 1.0, 1.5, 2.0 mg/kg)-acute (1X per week) and chronic (3X per week) administration-versus placebo (P1, P2) in 20 autistic children. Dose-dependent decreases in the severity of autistic symptoms as measured by the Childhood Autism Rating Scale were produced by acute (N=11/20) and chronic (N=18/20) naltrexone (p's < 0.0001).

Language was assessed in three playroom tests (BRCSTP) where ~~Se~~ were evaluated for 10 min. in the presence of a volunteer (V) or mother (M): no toys NT/V, toys T/V, and NT/M. Acute naltrexone significantly decreased nonmeaningful vocalizations (NMV), but it had no significant effects on the frequency of words and talking in the 3 conditions. In contrast, chronic naltrexone did not produce any significant effects on either NMV or words and talking. Sponsored by FDA, NICHD, DuPont, & Janusz Korczak Foundation.

732.2

COGNITIVE AND EEG RECOVERY FOLLOWING BOLUS INTRAVENOUS ADMINISTRATION OF ANESTHETIC AGENTS.

R.W. Dunn*, R.J. Lozito, and S. La Marca.

Anaquest, Inc., 100 Mountain Ave., Murray Hill, NJ 07974

Bolus intravenous administration of fentanyl and the fentanyl derivatives, alfentanil, remifentanil, and sufentanil, as well as the intravenous anesthetic agents etomidate and propofol, produce anesthesia in rats as measured by the loss of righting (LOR) with calculated ED₅₀ doses (derived from linear regression analysis) determined to be 0.06, 0.09, 0.037, 0.007, 2.51, and 6.12 mg/kg, respectively. Immediately, 15 minutes, and 30 minutes following intravenous administration of the ED₁₀₀ dose of each of these agents and subsequent return of the righting reflex, trained animals were assessed for cognitive recovery in an eight-arm radial arm maze. Performance during each session was scored by visual observation in terms of efficiency of responding (percentage of correct arm entries within 10 minutes). Animals administered fentanyl or sufentanil were unable to successfully complete the maze throughout the testing periods. Animals receiving remifentanil showed cognitive recovery within the first testing interval (immediately following return of righting reflex), while animals receiving alfentanil, etomidate, or propofol showed recovery at the 15 minute testing interval following return of the righting reflex. In a separate experiment, bolus intravenous administration of the ED₁₀₀ dose of these agents was evaluated in an acute EEG model. Rats implanted with 5 frontal cortical electrodes were assessed for the return to baseline control EEG levels following return of righting reflex. Return to baseline EEG levels were 0.3, 2.88, 5.06, 16.25, 31.29, and 43.98 minutes for remifentanil, propofol, alfentanil, etomidate, fentanyl, and sufentanil, respectively. These data show that the return to efficient cognitive functioning corresponds to the return to normal baseline EEG levels.

732.4

COMPARISON OF CARDIOVASCULAR AND OTHER PHYSICAL SIDE EFFECTS OF ACUTE AND CHRONIC ADMINISTRATION OF NALTREXONE IN AUTISTIC CHILDREN. G.S. Asleson*, B.H. Herman, J.A. Lewis, A. Powell, R. Ruckman, J.F. Borghese, E. Lukens, L.S. Anselmi, Med Dev Div, NIDA, NIH, Rockville, MD 20857, Brain Res. Cen., Depts Psychiat. & Cardiology, Children's Natl. Med. Cen. & Dept. Peds., George Washington USM, Washington DC, USA 20010

The physical side effects of acute and chronic naltrexone (0.5, 1.0, 1.5, 2.0 mg/kg) versus placebo (P1, P2) were investigated in 20 autistic children. Measures obtained before and 55 min after placebo/drug included: auscultated heart rate (HR), pulse rate, systolic and diastolic blood pressure (BP), mean arterial blood pressure (MAP) and axillary body temperature (BT). Serum concentrations of the liver enzymes SGOT and SGPT were obtained by venipuncture 60 min after drug. EKG parameters (Axis, PR, QRS, QT, QTc) were obtained 3h after drug/placebo. Acute naltrexone had no significant (NS) effects on any of these measures in comparison with placebo (p's > 0.10). Chronic naltrexone had NS effects on pulse, MAP, systolic and diastolic BP, SGOT and SGPT (p's > 0.10). There was a small decrease in AHR (maximum=7bpm) under naltrexone, however this effect was NS (p>0.10). Chronic naltrexone produced a small decrease in axillary body temperature (0.15-0.32°C), but this effect just failed to attain statistical significance (p=0.051). Therefore, these data provide further support for the clinical safety of naltrexone on cardiovascular, BT and liver function in children. Supported by FDA, NICHD, DuPont, Janusz Korczak.

732.6

EVALUATION OF ACUTE VERSUS CHRONIC NALTREXONE ON PAIN SENSITIVITY IN AUTISTIC CHILDREN. E. Lukens, B.H. Herman, G. Asleson, J. Borghese, M. Benoit, J. Chatoor, P. Papero, & A. Arthur-Smith* Med Dev Div, NIDA, NIH, Rockville, MD 20857, Brain Res Cen & Dept Psychiat, Children's Natl Med Cen & Dept Pediatrics, George Washington USM, Washington, DC 20010

Opiate antagonists fail to produce hyperalgesia in normal normotensive nonstressed adults (e.g., Grevert & Goldstein, *Science* 199:1093, 1978). In contrast, in schizophrenia where brain opioids may be hypermobilized, naltrexone significantly decreases evoked response to pain stimuli (Davis & Buchsbaum, *Mod Probl Pharmacopsychiat* 17:97, 1991). Here we show that a subgroup of "pain-insensitive" autistic children show significant evidence of a hyperalgesic response to acute but not chronic naltrexone.

The effects of naltrexone (0.5, 1.0, 1.5, 2.0 mg/kg) versus placebo administered acutely (1X per week) and chronically (3 X's week) on the distress responses of autistic children to venipuncture blood draw were investigated. Collapsed across all 20 ~~Se~~, both acute and chronic naltrexone failed to significantly effect the number of autistic children demonstrating either distress vocalization (DV) or lacrimation in response to venipuncture. In a subgroup of "pain-insensitive" (baseline, no lacrimation response to venipuncture) autistic children (N=13/20), acutely administered naltrexone significantly increased the % showing lacrimation (p<.05) while similar effects were not obtained with chronic naltrexone. Supported by FDA, NICHD, DuPont and Janusz Korczak Foundation.

732.7

OPIOIDS AND TIMEOUT FROM AVOIDANCE: EFFECTS OF FENTANYL, METHADONE, AND U50,488.

M. Galizio* and C. Ordroneau, Department of Psychology, University of North Carolina at Wilmington, Wilmington, NC 28403

The effects of μ - and κ -opioid drugs on rat behavior maintained under negative reinforcement schedules were studied. Rats were trained on concurrent schedules in which responses on one lever postponed shock on a free-operant (Sidman) avoidance schedule, and responses on another lever produced brief (2-min) periods of signaled timeout from avoidance on a variable-ratio schedule. μ -agonists fentanyl (.003-.1 mg/kg) morphine (1-10 mg/kg) and methadone (1-10 mg/kg) all decreased timeout lever responding at doses that increased or had no effect on avoidance. These effects were reversed by naltrexone. However, the κ -agonist U50,488 (1-20 mg/kg) did not show comparable actions. U50,488 produced variable effects at low doses, and non-selectively decreased responding at higher doses. These findings suggest the possibility that selective reduction of timeout responding is mediated by the μ receptor system.

732.9

ANXIOLYTIC EFFECTS AND A PUTATIVE SITE OF ACTION FOR THE KAPPA OPIOID AGONIST U-50,488H. T.H. Privette* and D.M. Terrian. Department of Anatomy and Cell Biology, East Carolina University School of Medicine, Greenville, North Carolina 27858.

Prodynorphin-derived peptides and other kappa(κ)-selective opioid agonists produce a spectrum of physiological and behavioral effects including enhancement of analgesia, a lowered reward threshold, and changes in measures of motivation. Collectively, these and other effects suggest prodynorphin-derived peptides may act to ameliorate the integrated response of an animal to physical and psychological stress. Although anxiety is a prominent psychological component of the stress response, the ability of κ opioid agonists to suppress anxiety-related behaviors has not been examined.

The objective of the present study was to investigate the effects of the κ_1 opioid agonist, U-50,488H, on anxiety-related behavior using the elevated plus-maze. Male Sprague-Dawley rats were injected i.p. 20 minutes before testing with either PBS vehicle or U-50,488H at doses of 0.01, 0.1 and 1.0 mg/kg. Each rat was placed in an open field for 5 minutes to measure spontaneous locomotor activity and then immediately placed on the elevated plus-maze for 5 minutes. Our results showed that: (1) U-50,488H had no sedative effects on spontaneous locomotor activity, (2) U-50,488H dose-dependently reduced measures of anxiety on the elevated plus-maze, (3) intrahippocampal microinjections of the selective κ_1 antagonist nor-binaltorphimine completely reversed the anxiolytic effect of U-50,488H, and (4) i.p. administration of U-50,488H attenuated the recovery of glutamate in the hippocampus by push-pull perfusion.

These data indicate that U-50,488H is endowed with potent anxiolytic properties and suggest that prodynorphin-derived peptides may act as endogenous anxiolytics within the hippocampus, possibly through a mechanism involving the κ_1 -mediated inhibition of glutamate release, to reduce this psychological component of stress. INVERSE GENETIC CORRELATION BETWEEN MORPHINE ANALGESIA AND HYPERLOCOMOTION IN MICE SELECTIVELY BRED FOR STRESS-INDUCED ANALGESIA. J.S. Mogil*, M. Shomer, W.-C. Chang, B. Kao, and J.C. Liebeskind. Dept. of Psychology and Brain Research Institute, UCLA, Los Angeles, CA 90024.

Studies using inbred mice, especially the divergent DBA/2 and C57BL/6 strains, have uncovered an inverse genetic relationship between opiate mechanisms of analgesia and reward. Strains exhibiting high analgesia display low morphine-induced hyperlocomotion (MIH), morphine preference, addiction potential, and withdrawal severity, and vice versa. We have previously demonstrated that mice selectively bred for high (HA) and low (LA) swim stress-induced analgesia also display high and low morphine analgesia, respectively, a difference apparently mediated by a single genetic locus. In the present study, 29th generation HA and LA mice, as well as their F₁ hybrids (HAXLA and LAXHA), were tested for MIH in the open field 20 min after morphine (10 mg/kg, i.p.). LA mice displayed significantly more line crosses than HA mice. F₁ hybrids also were significantly more hyperlocomotive than HA mice, and did not differ significantly from LA mice. Thus, the LA phenotype (high locomotion) is fully dominant over the HA phenotype. Preliminary data from our laboratory indicate that LA mice also exhibit a higher conditioned place preference to morphine, supporting the hypothesis that LA mice display up-regulated opiate reward systems simultaneously with down-regulated opiate analgesia systems. Supported by NIH Grant NS07628 and an Unrestricted Pain Research Grant from the Bristol-Myers Squibb Company.

CUES ASSOCIATED WITH SOCIAL STRESS INDUCE CFOS ONCOGENE EXPRESSION. C.A. Cohen*, K.A. Miczek, and R.M. Kream. Department of Psychology, Tufts University, Research Building, 490 Boston Ave., Medford, MA 02155, Department of Anesthesiology, Tufts University School of Medicine, 136 Harrison Ave., Boston MA 02111.

Socially stressed animals show marked potentiation of the analgesic effect of morphine, as demonstrated by a shift in the dose response curve to the left, during the social stress experience. Within 24 hours after social confrontation, there is also evidence for emerging tolerance to opiate analgesia, and tolerance continues to develop as a function of time. Previously, we have reported that the threats by an aggressive opponent are sufficient to significantly increase cFos expression one hour after stress in the periaqueductal gray of the brainstem, followed by a significant increase in the density of met-enkephalin stained fibers at three hours. Surprisingly there was also a significant increase in cFos at 18 hours even though the subjects remained undisturbed in their home cage prior to perfusion. This suggests that there were a set of cues previously associated with the stressful encounter that evoked this biochemical change. In the current experiment, an intruder male rat was placed into the home cage of a resident and subsequently exposed to attack and threat. Once the animal showed unambiguous signs of submission, the intruder was placed into a protective cage for one hour while being exposed to the threat of attack. The intruder was then placed into its home cage and perfused at 18 hours or was returned to the resident's cage in the absence of the resident for one hour and then perfused at 18 hours. In comparison with subjects with the same history of stress, the re-exposed intruders showed a significant increase in cFos expression. Studies are now underway to determine whether administration of an opiate antagonist, such as naloxone, can reverse the expression of cFos.

732.10

EFFECTS OF ICV AND IT NALOXONE AND MORPHINE ON THE ACQUISITION AND EXPRESSION OF CONDITIONED HYPOALGESIA. H. Foo* and R.F. Westbrook. School of Psychology, University of New South Wales, Sydney, Australia.

The study examined the involvement of supraspinal and spinal opioid mechanisms in mediating the acquisition and expression of the conditioned hypoalgesia associated with exposure to a heat stressor. The results showed that acquisition of conditioned hypoalgesia was enhanced by an ICV administration of naloxone and attenuated by an ICV administration of morphine. However, acquisition of the hypoalgesia was unaffected by IT administration of either drug. The results also showed that expression of the conditioned hypoalgesia was enhanced by an ICV administration of naloxone, but was unaffected by an IT administration of the opioid antagonist. Thus, these results suggest a role for supraspinal opioids in mediating the acquisition and expression of the conditioned hypoalgesia associated with exposure to a heat stressor.

732.12

A SPECIFIC PERIAQUEDUCTAL GRAY REGION MEDIATES INTRASPECIFIC DEFENSIVE REACTIONS EVOKED BY PRECIPITATED MORPHINE WITHDRAWAL. A. Depaulis, D. Eichenlaub, C. Lazarus and R. Bandler* LNBC, Centre de Neurochimie du CNRS, 5 rue Blaise Pascal, 67084 Strasbourg Cedex, France and Department of Anatomy and Histology, University of Sydney, NSW 2006, Australia.

Opiate withdrawal is known to evoke emotional reactions including defensive behavior in rodents. We have shown recently in the rat and the mouse that distinct populations of neurons within the midbrain periaqueductal gray matter (PAG) are responsible for the coordination of different defensive strategies. The present study investigated in the rat the kind of defensive reactions evoked by morphine withdrawal and whether PAG neurons are involved in these effects. Rats were made tolerant to morphine by subcutaneous implantations of 75-mg morphine pellets (NIDA, Rockville). Precipitated withdrawal was induced either by systemic injection of naloxone hydrochloride (1 mg/kg, i.p.) or intra-PAG injection of naloxone methyl bromide (2 nmol in 0.2 μ l). When tested for 8 min with a non-aggressive partner in a neutral test cage, rats experiencing systemic precipitated morphine withdrawal displayed confrontational defensive reactions (i.e., upright postures, backward movements) and immobility as compared to controls. Similar confrontational defensive reactions were evoked, along with 22-28 kHz ultrasonic vocalizations, by intracerebral injections of naloxone methyl bromide made in the intermediate third of the lateral PAG of morphine tolerant rats. No effects were evoked, however, when these injections were made in the caudal third of the lateral PAG, an area which has been shown to coordinate flight and avoidance reactions. This study suggests that morphine withdrawal evokes a specific defensive strategy in the rat and indicates that neurons in the intermediate third of the lateral PAG are implicated in these effects.

732.13

MODULATION OF OPIATE TOLERANCE ON SOCIAL BEHAVIORS BY MK-801. G. Bernatzky*, J. Panksepp, E. Nelson and A. Saba. Dept. of Zoology, Univ. of Salzburg, Salzburg, Austria and Dept. of Psychology, Bowling Green State University, Bowling Green, OH 43403.

Low doses of opiates have powerful effects on the social behaviors of young animals, including strong reductions in separation distress vocalizations (DVs) and both increases (low dose) and decreases (high dose) in rough-and-tumble play. This work evaluated whether NMDA receptor blockade with MK-801 would inhibit the development of tolerance to opiate effects in these animal models of emotions as reported for models of pain in adult rats (Trujillo & Akil, *Science*, 1991, 251, 85-87). DVs were measured in young chickens and play in juvenile rats.

Tolerance to opiates was weak in both models. Morphine at 5 to 10 mg/kg exhibited sustained inhibition of both DVs and play for up to 10 days of once daily drug administration. Some opiate tolerance could be demonstrated in both models after 10 days using reduced morphine challenges (e.g., 1 - 2.5 mg/kg). This tolerance was apparently partially blocked by co-administration of 0.2 mg/kg of MK-801, while the mere administration of the NMDA antagonist for the ten day pre-treatment period did not itself modify sensitivity to opiates. MK-801 alone (0.5 - 2 mg/kg) induced a weak suppression of DVs, and a powerful inhibitory effect on social play.

These results highlight the fact that opiate tolerance to the emotional effects of morphine is rather weak in young animals, suggesting the presence of endogenous anti-tolerance factor during youth and/or gradual developmental insensitivity to opiates. Some apparent inhibition of the tolerance could be produced by concurrent treatment with MK-801, suggesting the existence of neurochemical controls over opiate tolerance in social control networks of young rats and chickens which resemble those reported for pain in adult rats. However, the possibility that MK-801 induced inhibition of opiate tolerance is merely an artifact of the behavioral and cognitive disrupting effects of MK-801 needs further experimental attention.

732.15

BEHAVIORAL RESPONSES TO AN ARTIFICIAL NIPPLE IN THE DEVELOPING RAT FETUS: EFFECTS OF μ AND κ OPIOID ACTIVITY. S. R. Robinson*, T. C. M. Hoeltzel, and W. P. Smotherman. Laboratory of Perinatal Neuroethology, Center for Developmental Psychobiology, Binghamton University, Binghamton, NY 13902-6000.

Newborn mammals have the capacity to recognize and express specific behavioral responses to the nipples of the lactating mother within hours or minutes of birth. Experimental study of the rat fetus in vivo has confirmed that organized action patterns can be elicited by an artificial nipple fashioned from soft vinyl on the last three days of gestation. Other aspects of neonatal suckling behavior are affected by endogenous opioid activity, but little is known about the influence of opioids on nipple-evoked behavior. In the present study, rat fetuses were prepared for direct observation on E19, E20 or E21 and were pretreated by ip injection of the selective κ opioid agonist U50,488, the μ opioid agonist DAMGO ([D-Ala², NMe-Phe⁴, Gly⁵-ol]-enkephalin), or the isotonic saline vehicle. Behavioral responses to the artificial nipple were videotaped for frame-by-frame analysis of fetal movements. Perioral contact with the nipple elicited a suite of appetitive behavioral responses, including mouthing activity, licking, oral grasping of the nipple, and forelimb treadling. Fetuses also expressed aversive reactions, including facial wiping and head avoidance. U50,488 reduced appetitive responses and increased avoidance of the nipple, resulting in shorter periods of attachment. In contrast, DAMGO promoted certain appetitive responses to the nipple and facilitated longer attachment on E21. In addition to documenting the prenatal ontogeny of this important neonatal behavior, these findings imply a role for endogenous opioids in modulating behavior during the newborn rat's first suckling episode.

This research is supported by Grant HD 28231 to WPS and SRR.

732.17

OPIATE MODULATION OF PALATABILITY BY THE SECOND GUSTATORY RELAY: IMPLICATION OF LATERAL HYPOTHALAMIC NEURONES. S. Moufid-Bellancourt, R. Razafimanalina and L. Velley*. Lab. Neurosci. Comportementales et Cognitives, URA CNRS 339, Université de Bordeaux I, 33405 Talence France.

Lesions of lateral hypothalamic (LH) neurones modify the taste preference of rats for saccharin and also modulate the well-known effects of morphine on palatability (Touzani and Velley, 1990, *Pharmacol. Biochem. Behav.* 36:585). We later showed, by local injections, that the second gustatory relay station, the medial parabrachial area (Pbm) is, concomitantly, one of the central sites where morphine effects on palatability are mediated and also the site of LH-mediation of morphine effects (Moufid-Bellancourt and Velley, 1993, submitted).

Here we attempt to determine if LH lesions modify sensitivity to the different subtypes of opiate receptors present in Pbm. We tested, by local injections into the Pbm, a μ agonist, DAGO (0.01-0.1 μ g / 0.2 μ l) and a κ agonist, DynA 1-13 (0.1-3 μ g / 0.2 μ l). Finally, we tested a mixture of two inactive doses of DAGO and DynA 1-13 (respectively, 0.01 and 0.1 μ g).

Results show that: 1) at the highest doses used, μ and κ agonists exert opposite effects on saccharin ingestion: the μ agonist increasing while the κ agonist decreases this measure; 2) LH lesions induce marked changes in reactivity towards these opiate agonists: the μ agonist decreasing global liquid intake while the κ agonist selectively decreases water consumption. In sham-lesioned rats, both μ and κ agonists significantly depressed water intake, this effect not being observed in LH lesioned subjects; 3) reactivity to Pbm injections of morphine is not significantly modified by previous injections of μ or κ agonists and 4) the profile of the morphine effect is reproduced by combined injection of μ + κ agonists at doses at which neither is active alone.

732.14

OPIATE REGULATION OF AFFILIATION BETWEEN PRIMATE MOTHERS AND INFANTS. S.E. Shelton* and N.H. Kalin. Dept. of Psychiatry, Univ. of Wisconsin Sch. of Med., Madison, WI 53792-2475

For the primate infant, affiliation with its mother is imperative to survive. Because affiliation is an interactive process between mother and infant, we separately examined the importance of mothers' and infants' opiate systems in regulating affiliative behaviors within the dyad. On different occasions, opiate agonists and antagonists were administered to rhesus mothers and infants immediately preceding reunion. In the first series of experiments infants were administered either morphine or naltrexone. Results demonstrated that morphine (0.1 mg/kg) decreased clinging between infant and mother ($p < .020$). This was associated with significant increases in locomotion and environmental exploration. In contrast, naltrexone (5 mg/kg) increased clinging ($p < .03$) and as a result infants engaged in less locomotion and exploratory behavior. When mothers received morphine or naltrexone similar effects on affiliative behaviors were observed. These results demonstrate, in primates, the importance of opiate systems in regulating the level of affiliation between a mother and her infant. Of particular interest is the demonstration that alterations in opiate systems in either the mother or her infant have similar effects on affiliation. This suggests that complementary affiliative behaviors occurring between a mother and her infant are modulated by parallel changes in brain opiate systems. These findings may have important implications for the development of attachment bonds as well as in understanding conditions associated with abnormal affiliative responses.

SUCKLING-INDUCED CHANGES IN RESPONSIVENESS TO THE HYPOALGESIC EFFECT OF MORPHINE. B. C. Woods*¹ and J. Rochford². ¹Center for Studies in Behavioral Neurobiology and Department of Psychology, Concordia University, ²Douglas Hospital Research Centre, Department of Psychiatry, McGill University, Montreal.

There is growing evidence that there are fluctuations both in endogenous opiate systems and responsiveness to exogenously administered opiates across reproductive states in rats. In the first study responsiveness to the analgesic effect of morphine was compared among independent groups of rats that were at different stages of lactation, cycling, or ovariectomized. Animals were placed on a hot plate (52° C) prior to (baseline) and 30 minutes after a subcutaneous injection of morphine (5mg/kg) and latency to lick the hindpaw was measured. Dams tested on Day 12 or 18 postpartum had shorter paw lick latencies after morphine administration than either the ovariectomized or cycling females. The latencies of dams tested on Day 6 or 24 of lactation did not differ from the ovariectomized or cycling groups. There were no differences among the groups on the baseline measure. Subsequent studies showed that both the time course and the dose response curves to morphine-induced hypoalgesia were reduced in dams on day 12 of lactation in comparison to cycling controls. Data obtained in the final study showed that the reduced response to the hypoalgesic effect of morphine in postpartum dams was not dependent on the delivery of milk but was dependent on suckling stimulation. These data add further to the suggestion that reproductive state modulates opiate sensitivity. (Supported by NSERC).

EXCITATORY AMINO ACID (EAA) ANTAGONISTS ATTENUATE SEIZURES INDUCED BY ICV MORPHINE-3-GLUCURONIDE (M3G). M.E. Fundytus*, S. Norris and T.J. Codere. Pain Mechanisms Laboratory, Clinical Research Institute of Montreal and Dept. of Psychology, McGill University, Montreal, Quebec, Canada.

High-dose morphine and low-dose M3G administered intrathecally or intracerebroventricularly (icv) produce a "toxic activation syndrome" and seizure activity. EAA antagonists selective to the NMDA receptor decrease the activation associated with administration of high doses of morphine (Jacquet, Y. and Squires, R.F., *Behav. Brain Res.* 31, 85-88, 1988). Besides the NMDA receptor, there are two other ionotropic EAA receptor subtypes (AMPA and kainate) and a family of metabotropic EAA receptor subtypes. The purpose of the present investigation was to determine whether icv pretreatment with receptor subtype selective EAA antagonists could attenuate seizure activity induced by icv injection of M3G.

Rats were injected icv with one of the following: saline; a competitive NMDA receptor antagonist (CPP); a non-competitive NMDA receptor antagonist (MK-801); an AMPA/kainate receptor antagonist (CNQX); a metabotropic receptor antagonist (L-AP3); or an opioid antagonist (naloxone). Behaviour was observed for a ten minute baseline period, then rats were injected icv with 5 μ g M3G and behaviour was observed for an additional 20 minutes. Recorded behaviours included writhing (seizure activity), ambulating, grooming, resting and rearing. Each of the EAA antagonists decreased seizure activity, whereas the opioid antagonist naloxone was without effect. The activity measures (ambulating, grooming, resting and rearing) did not differ between groups, indicating that all rats were equally active.

The present results suggest that activity at EAA receptors may play a significant role in the toxic effects of low doses of the morphine metabolite morphine-3-glucuronide, and perhaps, therefore, of high doses of morphine. These toxic effects do not appear to involve opioid receptors, as the opioid antagonist naloxone was unable to decrease seizure activity in the present study.

732.19

NEUROADAPTATION OF RATS TO U-50,488 (U-50) REVEALED BY I.C.V. ADMINISTRATION OF NOR-BINALTORPHIMINE (norBNI). A. Cowan* and C.W. Murray, Dept. of Pharmacology, Temple Univ. Sch. of Medicine, Philadelphia, PA 19140

When U-50 is given to rats over 5 days by twice-daily peripheral injection, s.c. challenge with one of several opioid antagonists causes a qualitatively distinct behavioral syndrome. Here, we examined the ability of norBNI, a selective antagonist at kappa receptors, to uncover the behavioral consequences of persistent agonism at these sites. NorBNI was given i.c.v. since this antagonist, per se, elicits confounding behavioral effects after s.c. administration (Prog. Clin. Biol. Res. 328: 303, 1990). Male S.D. rats (200-220 g) were each implanted i.c.v. with a cannula. They were then injected s.c. with U-50 (10-40 mg/kg) or saline at 8.30 a.m. and 8.30 p.m. over 5 days. The rats (n=5-8) were housed individually (at 20°C) and, 4 hr after the 9th injection, were challenged i.c.v. with either norBNI (0.3, 1, 10 and 25 nmol) or saline. Increasingly pronounced behavioral syndromes were associated with higher doses of norBNI (1-25 nmol). At 25 nmol, norBNI provoked head and body shakes, yawning, licking penis, scratching and hyperthermia (over 1 hr).

CATECHOLAMINE RECEPTORS: α - AND β -ADRENERGIC

733.1

MULTIPLE ALPHA-ADRENOCEPTOR SUBTYPES: MODULATION OF PALPEBRAL APERTURE AS AN *IN VIVO* MODEL OF α_{1A} -ADRENOCEPTOR-MEDIATED ACTIVITY IN THE RAT. K. Bervoets* and M.J. Millan, I.D.R.S., 7 rue Ampère, 92800 Puteaux - France.

Evidence from binding and cloning studies has demonstrated the existence of multiple subtypes of α_1 -adrenoceptor: these have been provisionally termed α_{1A} , α_{1B} , α_{1C} and α_{1D} . Of these, the α_{1A} and the α_{1B} sites are present in the CNS of man and rats. Currently, no simple *in vivo* paradigms of α_1 -adrenoceptor-mediated activity are available. Thus, as a potential model for the characterization of actions at α_1 -adrenoceptors, we have examined the role of α_1 -adrenoceptor subtypes in the modulation of palpebral aperture in rats. Drugs were given s.c., 30 min before verification. Aperture was scored as follows: 4, normal; 5, exophthalmia; 3-2-1-0, one-quarter, one-half, three-quarters and fully-closed, respectively. The subtype-non-selective α_1 -antagonist (ANT), prazosin and the subtype-non selective α_1 -agonist (AGO), cirazoline, provoked pronounced ptosis and exophthalmia, respectively. The preferential α_{1A} -AGOs, oxymetazoline and methoxamine (which do not pass the blood-brain-barrier) also elicited exophthalmia. Further, the structurally-diverse, preferential α_{1A} -ANTs, 5-methylurapidil, WB 4101 and benoxathian (of which the latter does not pass the blood-brain-barrier) all elicited ptosis. In distinction, chloroethylclonidine, which irreversibly inactivates α_{1B} - (and α_{1C} -) adrenoceptors failed to modify palpebral aperture. Chlorpromazine and spiperone, which show some preference for α_{1B} -adrenoceptors, were only weakly active. In contrast to α_1 -adrenoceptor ligands, the selective α_2 -AGO, UK 14,304 and the selective α_2 -ANT, L 657,743, did not modify palpebral aperture. Further, selective AGOs and ANT's at particular serotonin and dopamine receptor subtypes were also inactive. In conclusion, these data suggest that peripheral α_{1A} -adrenoceptors are involved in the modulation of palpebral aperture in the rat. This parameter offers a simple, rapid and robust model for the characterization of drug actions at α_{1A} -adrenoceptors *in vivo*.

α_{2A} -ADRENERGIC RECEPTORS: PRE- OR POST-SYNAPTIC? C-G. Go¹, C. J. Aoki¹, C. Venkatesan¹ & H. Kurose², ¹Center for Neural Science, New York University, NY, NY 10003 & ²Duke Univ. Med. Ctr, Durham, NC 27710.

Are all catecholaminergic transmissions synaptic? To address this question, we used a polyclonal rabbit antiserum directed specifically against the third intracellular loop region of the A-subtype α_2 -adrenoceptors (α_{2A} -AR) (Kurose et al., 1993) to determine whether these receptors are restricted to morphologically identifiable synaptic junctions in adult rat brains. We examined the locus coeruleus (LC), a major noradrenergic cell group, and the neocortex, a major noradrenergic terminal field, since both regions exhibit intense immunoreactivity (ir) for α_{2A} -AR by light microscopy (Aoki et al., submitted). Electron microscopic analysis of the LC revealed α_{2A} -AR-ir within dendrites, axons and glia. Within axonal terminals, it was associated with the plasma membrane and small clear vesicles. Within dendrites, it was predominantly associated with the plasma membrane. Interestingly, ir within axons and dendrites were rarely associated with identifiable synaptic specializations. In the neocortex, labeling was most prevalent within axonal terminals but was also detectable near postsynaptic densities of distal dendrites. Ir within cortical somata was often associated with plasma membranes and mitochondria. Examination of tissue dually labeled for α_{2A} -AR and a catecholamine-synthesizing enzyme showed that: (1) synaptic associations between profiles labeled for the two markers exist but are rare; (2) catecholaminergic profiles rarely exhibit receptor ir; but (3) the two types of labeled profiles are in close proximity to one another. These results demonstrate that a large portion of α_{2A} -AR ir is non-synaptic, thus suggesting that catecholamines mediate their effects through volume transmission. CA is supported by NIH EY08055 (FIRST), NS30944 & NSF RCD9253750 (Presidential Faculty Fellowship).

CLONED RAT HOMOLOG OF THE BOVINE α_{1C} -ADRENERGIC RECEPTOR EXHIBITS AN α_{1A} -LIKE RECEPTOR PHARMACOLOGY. T.M. Laz, C. Forray*, K.E. Smith, P.J.J. Vayssé, P.R. Hartig, C. Gluchowski, T.A. Branchek, and R.L. Weinshank, Synaptic Pharmaceutical Corp., Paramus, NJ 07652.

Oligonucleotide probes based on the bovine α_{1C} -adrenoceptor sequence were used to screen a rat brain cDNA library at reduced stringency. We isolated a 2.3 kb cDNA whose deduced amino acid sequence contained seven putative transmembrane helices characteristic of G protein-coupled receptors. The rat cDNA exhibited ~88% amino acid identity with the bovine α_{1C} receptor but only ~45% amino acid identity with the rat α_{1A} and α_{1B} adrenoceptor receptors, suggesting that the rat clone is the species homologue of the bovine α_{1C} receptor. Transient transfection of the cDNA in COS-7 cells resulted in specific and saturable binding of [³H]prazosin (K_d = 0.33 ± 0.01 nM; B_{max} = 5 pmol/mg prot). In competition binding assays the rank order of potencies for α_1 -agonists and antagonists was WB-4101 ≥ prazosin ≥ 5-methyl urapidil > indoramin > oxymetazoline (Oxy) > norepinephrine (NE). Treatment of intact cells with chloroethylclonidine at 10 or 100 μM for 30 minutes, inactivated 25% of the [³H]prazosin binding sites. In transiently transfected COS-7 cells the agonists NE, epinephrine, phenylephrine, Oxy, and methoxamine stimulated the formation of [³H]inositol phosphates between 9- and 23-fold. The expressed rat α_1 receptor has many of the features of the pharmacologically defined α_{1A} receptor-subtype, yet the pharmacology is distinct from those of the cloned rat $\alpha_{1A/D}$, rat α_{1B} and bovine α_{1C} receptors.

733.4

THE CLONING AND EXPRESSION OF THE OPOSSUM KIDNEY (OK) CELL LINE ALPHA-2C ADRENERGIC RECEPTOR. H.S. Blaxall*, D.R. Cerutis, N.A. Hass and D.B. Bylund, Dept. of Pharmacol., Univ. Neb. Coll. Med., Omaha, Nebraska 68198-6260.

Pharmacologically four subtypes of alpha-2 adrenoceptors have been defined: A, B, C, and D. Previous studies from our laboratory have characterized the alpha-2 adrenoceptor in the OK cell and opossum kidney to be of the alpha-2C subtype. The human homologue of the OK alpha-2C adrenoceptor is designated C4. We have performed radioligand binding with OK cell membranes and COS-C4 cell membranes. The correlation coefficient between the pK_i values was found to be 0.95. To further characterize the OK alpha-2C adrenoceptor, RT-PCR was performed on RNA isolated from OK cells using oligonucleotides to the second and seventh transmembrane regions. 3' and 5' RACE procedures were used to obtain a full length clone OKc2. This was directionally cloned into the expression vector pRc/CMV (Invitrogen) sequenced and transiently expressed in COS-1 cells. The sequence obtained for the OK alpha-2C had only 68% sequence similarity at the amino acid level to C4 whereas C4 and the rat homologue RG10 were 90% similar. Radioligand binding was performed on membranes from these cells using [³H]rauwolscine which bound with high affinity characteristic of alpha-2C pharmacology. (Supported by NIH grant GM40784).

ALPHA-AGONIST INTRACELLULARLY MODULATES INHIBITORY AMINO ACID RESPONSES IN RAT SUBSTANTIA NIGRA NEURON. J. Nabekura*, T. Oomura, M. Munakata and N. Akaike. Dept. Neurophysiol., Tohoku Univ. Sch. Med., Sendai 980, Japan

Taurine (Tau) is enriched in substantia nigra (SN). The SN receives the afferent nerve terminals containing Tau from striatum, suggesting that Tau may play a functional role in this region. Recently, we reported that, in SN neuron, Tau elicited Cl^- current by activating glycine receptor and that an intracellular cAMP modulated the Tau response via the activation of PKA. It is known that there are noradrenaline (NA) receptors in SN, especially in the pars reticulata. The NA receptors couple with various G proteins and regulate the production of cAMP and other intracellular second messenger systems. Here, we studied the effect of NA on Tau-induced current (I_{Tau}) in acutely dissociated rat SN neurons using a nystatin perforated patch clamp technique. NA itself did not elicit any current. When either alpha 1 or 2 adrenoceptor was activated, I_{Tau} increased gradually over 5 min whereas the activation of beta adrenoceptor had no effect on I_{Tau} . The treatment with pertussis toxin blocked the enhancement of I_{Tau} by NA. Either IBMX or forskolin inhibited the facilitatory effect on I_{Tau} . The results suggest that alpha 2 adrenoceptor activates Gi protein, resulting a decrease of intracellular cAMP which reduces an activity of PKA kinase A, and finally disinhibits the I_{Tau} . However, the intracellular mechanism about the facilitatory effect of alpha 1 adrenoceptor on I_{Tau} is unclear at this moment.

MECHANISM OF ACTION OF JUDAS GUT EXTRACT ON AORTIC RINGS FROM THE GUINEA PIG. E. Gijón*, M. Lorenzana, L. Cartas, and X. Garcia. Dep. of Physiol and Dep. Pharmacol. Sch. Med. UNAM. Ap. P. 70-250, México, D.F. 04510, MEXICO. FAX (525) 550-2920.

Judas gut (JG) infusion is used in traditional medicine for relieving pain and inflammation. Hydroalcoholic extract of JG studied in male guinea pig vascular smooth muscle prepared for in vitro isometric recording contracts relaxed vascular smooth muscle, contractions were similar to that induced by catecholamines. JG contractions were not calcium dependent or endothelium-dependent (1). Further experiments explored the mechanisms of action of JG extract as an adrenergic agonist. Propranolol did not block JG contraction. Phentolamine partially blocked JG contraction. Zolertine and yohimbine blocked JG contraction in dose dependent form, and prazosine partially blocked JG contraction. These results suggest an alpha-adrenergic synergism, and membrane effects on calcium movement and/or receptor interaction will be explored.

LARGE SCALE PRODUCTION OF MEMBRANE EMBEDDED α_2 -RECEPTORS IN MAMMALIAN CELLS. S. Ala-Uotila, M.-T. Matikainen, M. Koulu* and M. Jalkanen. Dept. of Pharmacology and Centre for Biotechnology, Univ. of Turku, PO Box 123, SF-20521 Turku, Finland.

We have generated and characterized stable recombinant cell lines of adherent Shionogi 115 mouse mammary tumor cells (S115) expressing the α_2 -AR subtypes α_2 -C2, α_2 -C4 and α_2 -C10.

In order to obtain large amounts of homologous material for pharmacological studies and for studies on receptor structure and function, we studied three different cell culture techniques: culture bottles, roller bottles and bioreactor (hollow fiber, 0.8m³). Nude mice were also injected with S115 tumor cells expressing receptor subtypes α_2 -C4 and α_2 -C10. Bioreactor was by far the most efficient and least money and time consuming way of producing large quantities of cells expressing α_2 -adrenergic receptors.

Scatchard analysis of [³H]rauwolscine binding assayed on the hollow fiber material revealed B_{max} values of 6 and 0.7 pmol/mg protein and K_{d} s 3 and 4.5nM for the recombinant C2 and C10 receptors. Total amount of protein in the batch varied from 0.8 to 1.4g, but it is possible to optimize this type of production system to reach the level of 2-3g total protein.

733.6

CNS AND PERIPHERAL TISSUE EXPRESSION OF MULTIPLE ALPHA ADRENERGIC RECEPTOR SUBTYPES IN NEWBORN RATS EXPOSED TO MATERNAL COCAINE. S. K. McCune*, M. M. Voigt and J. M. Hill. Lab. of Developmental Neurobiology, NICHD, NIH, Bethesda, MD and Dept. of Neonatology, Children's National Medical Center, George Washington Univ. Med. Center, Washington, D.C. 20892.

Catecholamine levels are known to be elevated in the off-spring of mothers exposed to cocaine. We examined the behavioral characteristics of rat pups exposed *in utero* to cocaine and then investigated the expression of multiple alpha adrenergic receptor subtypes by *in situ* hybridization in the brains, hearts, lungs and kidneys of the pups.

Three pregnant rats were treated with daily injections of cocaine from E8-E20 while 2 mothers were injected with saline. Equal numbers of pups from each litter were maintained for behavioral testing while the remainder of the animals were sacrificed at birth. Statistically significant differences between the two groups were observed for righting on day 0 and startle responses.

The expression of multiple alpha adrenergic receptor subtypes (1A, 1B, 1C, 2A and 2C) was studied by *in situ* hybridization in newborn and three week old animals. The alpha-1B receptor subtype is found in the globus pallidus of the normal newborn but not in the 3 week old. There was a statistically significant increase in the expression of the alpha-1B receptor subtype in the globus pallidus of the cocaine treated pups versus the saline treated. Expression in the globus pallidus was not detected in the 3 week old animals of either group. There were no other differences detected in any of the other subtypes in any of the tissues examined.

The globus pallidus is an area responsible for initiating motor behavior and also has connections with the limbic system. The behavioral differences seen between the two groups of animals may be related to the increased adrenergic receptor expression in this area. Transiently expressed receptor subtypes in the perinatal period may play a significant role in pharmacologic responses during the newborn period.

TSH REGULATES ALPHA 1 ADRENERGIC RECEPTORS WHICH MEDIATE $[Ca^{++}]_i$ RISE IN PC CL3, VIA A cAMP-DEPENDENT PATHWAY. O. Menoci*, A. Scorzello, *M.T. Bertinieri, A. Avallone, *A. Fusco, M. Grimalki, C. Verstra, and G. Schettini. Dept. Pharmacology, and ^Dept. Biol. Patol. Cell. Mol., School of Medicine, Univ. of Naples and *Univ. of Catanzaro, Via S. Pansini 5, 80131 Napoli, ITALY.

We studied the effect of TSH on norepinephrine (NE)-induced cytosolic calcium rise in PC C3 rat thyroid cells. The cells were grown both in presence (PC 6H) and in absence (PC 5H) of TSH and intracellular calcium levels were measured by fura-2. In PC 6H the cytosolic calcium rise induced by NE was characterized by an early transient spike followed by a second phase of sustained calcium levels, while in PC 5H we observed only a slower monophasic response. The acute addition of TSH to PC 6H caused a modest increase of basal calcium and a 50% enhancement of the calcium rise induced by NE. This latter effect was abolished in a calcium free medium and not observed in PC 5H. Both NE and TSH stimulated inositol phosphates production in PC 6H and by a lesser extent in 5H. The reintroduction of TSH in the culture medium of PC 5H induced the recovery of NE-stimulated intracellular calcium rise similarly to the native PC 6H, an effect abolished by the simultaneous treatment of cells with cycloymide. Also the treatment of PC 5H with forskolin restored the effect of NE on calcium level, while the treatment with FMA was ineffective. To characterize the α_1 adrenergic receptor subtypes mediating the effect of NE in PC C3 cells, we used antagonists of α_1A and B receptors (WB4101 and CEC respectively). In these experimental conditions we found that 1) CEC caused a marked inhibition of NE-induced calcium increase in PC 6H, while slightly affected NE response in PC 5H; 2) WB4101 at a concentration specific for α_1A receptors (0.01 μ M) reduced the effect of NE in PC 6H and 5H; 3) CEC+WB4101 0.01 μ M completely abolished the noradrenergic response in both groups of cells. These results show that, in PC C3, TSH modulates NE-induced calcium rise through a kinase A-dependent pathway, and that α_1B receptors expression are the main target of this regulation. Binding studies with 3H-prazosin confirmed this hypothesis since we observed in PC 5H a lower B_{max} than in PC 6H. (Supported by A.I.R.C. 1992 grant to Genaro Schettini)

COMPARISON OF RECOMBINANT α_2 -C2-ADRENERGIC RECEPTORS PRODUCED IN MAMMALIAN, INSECT AND YEAST CELLS. K. Pohjanoksa, A. Marjamäki, S. Ala-Uotila, C. Oker-Blom, D. Sizmann, H. Kurose and M. Scheinin. Dept. of Pharmacology and Centre for Biotechnology, Univ. of Turku, and Dept. of Biochemistry, Åbo Akademi, SF-20520 Turku; VTT Technical Research Centre of Finland, SF-02151 Espoo, Finland; and Duke University, Durham, NC 27710, USA.

We have compared ligand binding properties of the human α_2 -adrenoceptor subtype α_2 -C2 in three cell lines expressing recombinant α_2 -C2-AR: Shionogi S115 mouse mammary tumour cells, *Spodoptera frugiperda* Sf9 insect cells and *S. cerevisiae* yeast cells. [³H]rauwolscine binding in cell homogenates was inhibited by prazosin, oxymetazoline, RX821002, chlorpromazine and (-)-noradrenaline with and without the GTP-analogue Gpp(NH)p. The K_i -values of each agent were in close agreement between the different cell lines. This indicates that α_2 -C2-AR retains its binding characteristics irrespective of the host cell system. The expected 43 kDa α_2 -C2 protein from each cell line was visualized with immunoblotting using a polyclonal α_2 -C2-AR-antibody.

733.11

USE OF RECOMBINANT HUMAN α_2 -ADRENOCEPTORS TO CHARACTERIZE SUBTYPE SELECTIVITY OF ANTAGONIST BINDING. **A. Marjamäki*, K. Luomala, S. Ala-Uotila and M. Scheinin.** Dept. of Pharmacology and Centre for Biotechnology, Univ. of Turku, SF-20520 Turku, Finland.

We have generated stably transfected Shionogi S115 mouse mammary tumour cell lines expressing separately the human α_2 -AR subtypes α_2 -C10, α_2 -C2, and α_2 -C4. Binding of [³H]-rauwolscine was inhibited by co-incubation of S115 cell homogenates with ten α_2 -adrenergic antagonists and oxymetazoline, a weak partial agonist known to discriminate the receptor subtypes. Other useful agents for discrimination of subtypes were prazosin, chlorpromazine, phentolamine and yohimbine. The most sensitive indices for differences between subtypes were Ki ratios chlorpromazine/oxymetazoline, prazosin/oxymetazoline and chlorpromazine/atipamezole. Correlation analysis between our results for human-type receptors and published data for their rat α_2 -adrenoceptor homologues demonstrated good general agreement, with some interspecies differences in the affinity of rauwolscine, phentolamine and oxymetazoline.

733.13

A TIME-COURSE OF ALTERED THYROID STATES ON THE NORADRENERGIC SYSTEM IN RAT BRAIN. **A. Yu*, J. Yang & S. M. Tejani-Butt.** Department of Psychiatry, University of Pennsylvania School of Medicine, Philadelphia, PA 19104.

Thyroid hormone (TH) dysfunction has been linked with abnormalities in noradrenergic (NA) neurotransmission. Low TH levels and dysfunction of NA receptors have been postulated in depression. The present study was aimed at investigating the time-course of thyroidectomy (TXT) and T₄ replacement on β_1 and β_2 -adrenoceptors (β -ARs), α_2 -adrenoceptors and presynaptic transporter sites for norepinephrine (NET) in the adult rat brain. Using selective radioligands for each of these systems, measurements in discrete brain regions were made by the technique of quantitative autoradiography. Statistical comparisons were made by ANOVA followed by post-hoc analyses using Newman-Keuls test ($p < 0.05$). A significant decrease in [¹²⁵I]-iodopindolol binding to β_1 -ARs in the cortex and hippocampus, and to β_2 -ARs in the hypothalamus was seen following TXT (7, 14 or 35 days). A decrease in [³H]-idazoxan binding to α_2 -adrenoceptors was observed selectively in the amygdala, and [³H]-nisoxetine binding to NET sites was found to be decreased in the hypothalamus following TXT. T₄ replacement (for 7 or 28 days) caused radioligand binding to recover to control levels in brain regions where alterations were observed after TXT. These results indicate that a neuromodulatory link between TH and the NA system exists in the rat brain, that is both region and receptor specific. (Research funds from USPHS grants MH 44210 and MH 45472).

CIS-ACTING ELEMENTS OF THE RAT β_1 -ADRENERGIC RECEPTOR GENE. **R. P. Searles¹, V. J. Nipper¹, and C. A. Machida^{1,2}.** ¹Div. of Neuroscience, Oregon Regional Primate Research Center, Beaverton, OR 97006, and ²Dept. of Biochemistry and Molecular Biology, Oregon Health Sciences University, Portland, OR 97201.

Cis-acting components important for basal expression of the rat β_1 -adrenoceptor (β_1 AR) gene have been localized by using a series of deletion mutants of the 5' flanking sequences to control expression of the reporter gene luciferase in rat C6 glioma cells. Maximum expression of luciferase is achieved using β_1 AR sequences between -479 and -1 ([-479,-1]) relative to the translation initiation codon. Successive deletions from -479 to positions -369, -329, and -299 reduces expression by 42%, 71%, and 78%, respectively. Expression from [-479,-299] is equivalent to the expression of the deletion mutant [-1252,-479], which lacks the region between -479 and -1. These data suggest that primary determinants of expression are present within the region from -479 to -299. Within this region is an inverted CCAAT box (-359 to -355) positioned similarly to the inverted CCAAT sequence which has been designated to be part of the human β_2 AR promoter. A mutant which substitutes a 6 base linker for 11 bases of β_1 AR sequence, including this CCAAT box, expresses only slightly less than the intact [-479,-1] construct. It is therefore unlikely that this inverted CCAAT box is important for expression of the rat β_1 AR. Deletions from the 3' end of the region [-479,-1] also affect expression; the construct [-479,-258] expresses 48% less than [-479,-1]. Within the deleted region are an SP1 site and an AP3 site, either of which may be responsible for the decline in activity. Further deletion mutants are being examined to carefully map the region from -479 to -1 for specific sequences important for basal level expression.

733.12

CENTRALLY-INDUCED OCULAR HYPOTENSION IN THE RABBIT: INVOLVEMENT OF ALPHA-2 AND IMIDAZOLINE RECEPTOR SUBTYPES. **W. R. Campbell*, S. Long, R. Strothers and D. E. Potter.** Department of Pharmacology and Toxicology, Morehouse School of Medicine, Atlanta, Georgia 30310-1495.

Glaucoma, a leading cause of blindness particularly in African-Americans, results in irreversible neuronal damage within the optic nerve head. One focus of research efforts is to understand the mechanisms of aqueous humor dynamics and how it relates to pressure within the eye. The purpose of this study was to examine the effects of alpha-2 and imidazoline receptor subtypes on centrally mediated changes in intraocular pressure. New Zealand White rabbits were fitted with indwelling stainless-steel guide cannulae for injections into the CNS. After 5 days recovery the centrally applied (icvt) and topically applied effects of UK-14,304-18 (brimonidine), oxymetazoline, and moxonidine were examined with and without the antagonists rauwolscine, idazoxan, and efaroxan. Efaroxan and idazoxan (3.0 ug vs icvt, 10.0 ug vs topical) were more active in inhibiting the ocular hypotensive actions of oxymetazoline (0.9 ug, icvt; 50.0 & 500 ug, top) and moxonidine (0.3 ug, icvt; 25.0 ug, top), but were ineffective on the actions of UK (0.9 ug, icvt; 50.0 ug, top). Conversely, rauwolscine (3.0 ug, icvt; 10.0 ug top) inhibited the ocular hypotension induced by both icvt and topically applied UK, but was much less active on the actions of OXY and MOX. These data show that ocular hydrodynamics are mediated by sites in the CNS, and that both alpha-2 and imidazoline receptor subtypes play an important role in the central mediation of intraocular pressure. Supported, in part, by EYO6338.

733.14

HYPOTHYROIDISM-INDUCED SHIFTS IN HIPPOCAMPAL ADRENERGIC RECEPTOR BINDING: IMPLICATIONS TO ISCHEMIA-INDUCED HIPPOCAMPAL DAMAGE. **Susan Hemmings** Dept. of Physiology and Ashfaq Shuaib*, Sask. Stroke Research Center, Univ. of Saskatchewan, Saskatoon, Canada, S7N 0W0.

Hypothyroidism was induced in male Fischer 344 rats by administration of propylthiouracil (0.05%) for six weeks. Plasma levels of thyroid hormones confirmed hypothyroidism: control rats (CON): Total T₃ - 67.14 ± 3.93 ng/dl, Total T₄ - 3.37 ± 0.14 µg/dl; Hypothyroid rats (HYPO): Total T₃ - 30.54 ± 1.68 ng/dl, Total T₄ - 1.56 ± 0.14 µg/dl. Functional hypothyroidism was demonstrated by: i) a decrease in hepatic plasma membrane α_1 -adrenoceptor binding: CON - 998.10 ± 57.59 fmol/mg; HYPO - 508.50 ± 15.49 fmol/mg; and ii) an increase in hepatic plasma membrane γ -glutamyl-transpeptidase activity: CON - 6.20 ± 0.18 nmol/mg/min; HYPO - 69.37 ± 7.09 nmol/mg/min. Membranes were isolated from hippocampi and specific α_1 and β_2 adrenoceptor binding determined by [³H] Prazosin and [¹²⁵I] Iodocyanopindol binding. Hypothyroidism effected a shift in the balance of α_1 and β_2 adrenoceptor binding: CON - α_1 : 88.59 ± 10.22 fmol/mg, β_2 : 1191.28 ± 82.47 fmol/mg; HYPO - α_1 : 139.31 ± 20.15 fmol/mg; β_2 : 934.32 ± 50.29 fmol/mg. This receptor shift may explain the protective effect of hypothyroidism on ischemia-induced hippocampal damage by favoring inhibitory input and limiting excitotoxic input by catecholamines. Funded: Cosmo. Fndn. Can. (Inc).

THE 5' FLANKING REGION OF THE RAT β_3 -ADRENERGIC RECEPTOR GENE: DIVERGENCE WITH THE HUMAN GENE AND IMPLICATIONS FOR SPECIES-SPECIFIC GENE EXPRESSION. **J.A. Brown^{1*} and C.A. Machida^{1,2}.** ¹Div. Neuroscience, Oregon Regional Primate Research Center, Beaverton, OR 97006, and ²Department of Biochemistry and Molecular Biology, Oregon Health Sciences University, Portland, OR 97201.

β_3 -adrenoceptor receptors (β_3 -ARs) were the first "atypical" β -adrenoceptor receptors to be molecularly cloned. β_3 -AR mRNAs exhibit species-specific expression (human vs. rodent) in distinct anatomical regions and appear to be expressed abundantly within rodent adipose tissue, but only at low levels within corresponding human tissues. In order to determine the genetic basis of the differential expression of the rat and human β_3 -AR genes, we cloned and sequenced the rat gene and compared the 5' flanking regions of the two genes to identify potential discriminators in transcriptional regulation. We have found that the rat and human β_3 -AR flanking regions are only 58% similar, unlike the close sequence similarity observed between the coding blocks (>90%) and also observed between species for the 5' flanking regions of other β -AR subtype genes (>90%). In addition, the rat β_3 -AR gene lacks the four potential cAMP responsive elements identified within the 5' flanking region of the human receptor gene. The striking divergence in regulatory sequences between the rat and human β_3 -adrenoceptor receptor genes may potentially explain the differences in species-specific expression and tissue localization of the rat and human receptor mRNAs.

733.17

LACK OF ECS INDUCED BETA RECEPTOR CHANGE IN ANESTHETIZED, VENTILATED RATS. S.K. Brannan*, A.L. Miller, A.M. Biedeger, D.J. Jones. Dept. of Psychiatry and Anesthesiology, The Univ. of Texas Health Science Center at San Antonio, TX 78284.

The purpose of this study is to explore electroconvulsive shock (ECS) induced noradrenergic receptor regulation in anesthetized and ventilated (A&V) rats. Previous studies have established that chronic ECS induces a reduction in beta receptor density in rat cerebral cortex. One limitation of these studies is that they did not control for the effects of oligemia and hypoxia on CNS receptors during ECS. The present study addresses this concern by measuring beta receptor density in rat cerebral cortex according to the following groups: ECS+A&V (A), Sham+A&V (B), ECS alone (C), and Sham alone (D). Anesthesia is induced with methohexital (15mg/kg) via a femoral vein catheter followed by administration of succinylcholine (2mg/kg). Rats are then intubated and kept on 97% O₂. ECS is administered via ear clips (40mA, 150 pulses/sec, 1 millisecond/pulse, 1sec duration) on a M-W-F schedule until a total of 6 sessions ECS or Sham is reached. 24 hrs after their last session the rats are sacrificed and their brains dissected out and frozen. Receptor density was determined by scatchard analysis of saturating isotherms of [¹²⁵I]CYP (20-600nM). The maximal binding density (Bmax) of group C (122.2 fm/mg protein) was less than that of group D (136.7 fm/mg protein), but there were no significant differences between Groups A and B (132.6 and 132.5 fm/mg protein respectively). There were no significant differences in Kd between the groups. Although cortical beta receptor density is felt to indicate antidepressant response, this may be an epiphenomena. If so, our interpretation of previous experiments will be profoundly altered.

GLUCOSE DETECTORS IN THE CAUDAL BRAIN STEM CONTROL ESTROUS CYCLES IN SYRIAN HAMSTERS. J.E. Schneider*, Y. Zhu, J.M. Swann and J.M. Gabriel. Department of Psychology, Lehigh University, Bethlehem, PA 18015 and Department of Biology, Rutgers University, Newark, NJ 07102.

Fertility and ovulatory cycles are inhibited by decreased food intake or increased energy expenditure in a variety of mammals including human beings. In Syrian hamsters, the signals that mediate these effects appear to be related to the availability of oxidizable glucose. For example, estrous cycles are inhibited by treatment with high doses of 2-deoxy-D-glucose (2DG) a drug that inhibits cellular glucose utilization. To examine the role of glucose detectors in the central nervous system, hamsters fed *ad libitum* were treated with a variety of doses of 2DG injected intracerebroventricularly (ICV) every six hours on days 1 and 2 of the estrous cycle. Estrous cycles were inhibited by 75mg/10 μ l ICV injections of 2DG, but not by intraperitoneal (IP) injections at the same dose. Next, we compared the effects of IP injections of 2DG (1750 mg/kg) in hamsters with or without lesions of the area postrema (AP). Both sham and lesioned hamsters showed at least two consecutive four-day estrous cycles prior to the start of 2DG injections. 2DG treatment blocked estrous cycles in 89% of the hamsters with sham lesions, but failed to block cycles in any of the 10 hamsters with confirmed lesions of the AP. Finally, we examined the effects of 2DG on neuronal activity in the AP using immunocytochemistry for FOS. We observed cells stained for FOS in the AP and nucleus of the solitary tract (NTS) in hamsters perfused three hours after 2DG treatment (1750mg/kg). No FOS staining was observed in the AP/NTS in vehicle-treated hamsters. These results are consistent with the idea that estrous cycles are controlled by glucose detectors located in the AP and/or NTS. Supported by research grants BNS9121056 from NSF (J.E.S.) and HD28467 from NICHD (J.M.S.).

AREA POSTREMA LESIONS ABOLISH METABOLIC INHIBITORS-INDUCED SUPPRESSION OF ESTROUS BEHAVIOR IN SYRIAN HAMSTERS. H.-Y. Li* and G. N. Wade. Neuroscience and Behavior Program and Department of Psychology, University of Massachusetts, Amherst, MA 01003.

Previous studies in our laboratory showed that treatment with metabolic inhibitors which block glycolysis (2-deoxy-D-glucose, 2DG) and fatty acid oxidation (methyl palmoxirate, MP) suppresses steroid-induced estrous behavior in ovariectomized Syrian hamsters. Although it is known that the ventromedial hypothalamus (VMH) is involved in facilitation of estrous behavior, very little is known about the pathway(s) conveying visceral information into the VMH and thus leads to changes in lordosis. Since area postrema (AP) is anatomically located for transmission of information related to metabolic fuel availability and it projects to the VMH directly or indirectly via lateral parabrachial nucleus, we investigated the hypothesis that lesions of the AP can prevent the attenuation of estrous behavior caused by metabolic challenges.

Ovariectomized Syrian hamsters were either sham-operated or were given aspiration lesions of the AP. Each group of animals was further divided into two groups that were treated with 2DG (750 mg/kg) + MP (25 mg/kg) or vehicles for 48 h. Estrous behavior was induced by sequential injections of 5 μ g of estradiol benzoate and 200 μ g of progesterone. Duration of lordosis (DL) was measured out of 180 sec. Our results showed that there was significant difference in DL between lesioned and sham groups treated with metabolic inhibitors (124 \pm 13 vs. 76 \pm 20), but there was no significant difference between 2DG + MP and vehicle-treated groups in AP-lesioned animals (124 \pm 13 vs. 118 \pm 15). This suggests that the VMH receives at least part of visceral information via the AP; moreover, AP lesions can block the metabolic signal generated by glucoiprivation and lipoprivation which suppress estrous behavior in intact animals. The Effect of Propranolol on Bone Remodeling in Rats During Simulated Weightlessness. H. W. Burden*, G. T. Price, C. A. Hodson, A. T. Davenport, C. M. Manning, and D. M. Terrian. Dept of Anatomy and Cell Biology and Obstetrics and Gynecology, East Carolina University School of Medicine, Greenville, NC 27858.

Propranolol administration has been reported to significantly affect bone properties in rats (Minkowitz et al., J. Orthop. Res., 9: 869, 1991). In the present study, the effects of this drug on remodeling in the tibia during simulated weightlessness were evaluated. Two groups of adult female Sprague Dawley rats were fitted in a back harness and the animals suspended for 14 days at an angle of approximately 30° head down tilt. One group served as a suspension control and the other group received propranolol (100 μ g daily, ip). A gravity control group of rats was allowed to ambulate normally. On day 14, tibias were removed, weighed and subsequently processed for histomorphometric analysis. The areas of metaphyseal trabeculae and osteoid were determined using a point counting method with a Merz grid. There was no difference in tibial weights (mg/100g bw) in the three groups. The area of metaphyseal trabeculae and osteoid was significantly (p<0.05) reduced in suspension control animals vs gravity controls. Propranolol significantly (p<0.05) reversed the effect of simulated weightlessness on metaphyseal osteoid area but not total trabecular area. These data indicate that propranolol stimulates bone formation in this model of simulated weightlessness. Supported by NASA Grant No. NAGW-2927.

734.2

THE FASTING-INDUCED SUPPRESSION OF LH SECRETION IN MALE RHESUS MONKEYS IS DECREASED BY CASTRATION.

J.L. Cameron*, D.L. Berger, and C.M. Zeigler. Departments of Behavioral Neuroscience, Psychiatry, and Cell Biology & Physiology, University of Pittsburgh, Pittsburgh, PA 15260.

Brief periods of fasting (i.e., 1-2 days) significantly suppress LH secretion in several species, including rats, monkeys and men. In male rhesus monkeys, we have previously shown that LH secretion is suppressed within the first 4-6 h after the daily meal is missed and becomes progressively more suppressed with continued fasting (fed: 4.57 \pm 0.53 LH pulses/12 h; 1 day fasting: 1.86 \pm 0.46 LH pulses/12 h). In a number of nonprimate species, fasting has been shown to be more effective in suppressing LH secretion in gonad-intact versus castrate animals. To address this issue in primates, we examined whether the sensitivity of the gonadal axis to brief periods of fasting in male monkeys is influenced by castration. Five castrate male rhesus monkeys with indwelling venous catheters were maintained on jacks/tether/swivel systems. Blood samples were collected on two days, a day of normal feeding (1 meal at 1100 h), and after 2 days of fasting (samples collected at 7.5 min intervals from 1600-2400 h on each day), for measurement of pulsatile LH secretion. Two days of fasting caused no significant change in mean plasma LH concentrations (fed: 109.2 \pm 23.3 ng/ml; fasted: 114.5 \pm 30.1 ng/ml) or in LH pulse frequency (fed: 9.2 \pm 0.6 pulses/8 h; fasted: 9.4 \pm 0.3 pulses/8 h). These results suggest that either the inhibitory signal provided to the gonadal axis by fasting is mediated via a gonadal steroid dependent mechanism, or that the inhibitory signal provided by short-term fasting is not great enough to significantly suppress the elevated central drive to the gonadal axis in the castrate state. Studies examining the effects of fasting on LH secretion in castrate monkeys maintained on steroid hormone replacement regimens are currently being performed to explore these two possibilities.

PREGNANCY-ASSOCIATED OPIOID RESTRAINT OF OXYTOCIN NEURONES INVOLVES A PRESYNAPTIC ACTION ON BRAINSTEM CATECHOLAMINERGIC AFFERENTS. R.J. Bicknell*, T. Onaka, G. Leng, S.M. Luckman & A.J. Douglas†, Department of Neurobiology, AFRC Babraham Institute, Babraham Hall, Cambridge CB2 4AT, U.K. and †Department of Physiology, University Medical School, Edinburgh EH8 9AG, U.K.

Endogenous opioid inputs inhibitory to oxytocin (OXT) neurones become activated during pregnancy in the rat, probably as a consequence of elevated circulating sex steroids. This central opioid action does not involve κ -active opioid peptides co-expressed in the neurohypophysial neurones (J. Neuroendocr., in press). We have shown that morphine, a μ -opioid, inhibits the electrical activity of OXT neurones, decreasing OXT release and suspending parturition. We have examined the cellular site of opioid action following systemic administration of cholecystokinin (CCK) which activates OXT neurones via brainstem catecholaminergic cells (1).

We now report: (i) CCK (20 μ g/kg) induces expression of Fos-immunoreactivity (Fos-IR) in the supraoptic nuclei (SON) and in 45% of tyrosine hydroxylase (TH)-IR cells in both C2/A2 and C1/A1 regions of the rat brainstem. Morphine (1mg/kg) pretreatment prevents CCK-induced expression of Fos-IR cells in SON, but does not affect the percentage of TH-IR cells expressing Fos-IR in the brainstem, (ii) Electrically-evoked release *in vitro* of [³H] noradrenaline from preloaded SON explants from virgin rats was inhibited 41% by morphine, (iii) Under anaesthesia, the electrical activity of SON OXT neurones was excited by systemic CCK. In virgin rats this response was not influenced by blocking endogenous opioid actions with naloxone (2mg/kg) but in late pregnant rats CCK excitation was enhanced by 260%.

Thus morphine actions to reduce OXT cell activity are likely to involve presynaptic rather than cell body inhibition of brainstem catecholaminergic inputs and pregnancy induces endogenous opioid systems to act on this mechanism.

DEVELOPMENT OF METABOLIC RESPONSE IN MALE QUAIL BRAIN DURING SEXUAL MATURATION. R. Teruyama, M. M. Beck*, J.H. Douglas, N.J. Gonzalez and T.M. Brown. Dept. of Animal Sci., Univ. of Nebraska-Lincoln, Lincoln, NE 68583.

The eyes have been strongly implicated as a significant component in the photosexual response of Japanese quail, but the mechanism is not clear. A neural retino-hypothalamic (via SCN) connection has been proposed as one possibility. This study addresses the metabolic response (2-deoxyglucose, 2DG) of male quail during sexual maturation. Quail raised to 10 wk of age from hatching on 8h L:16h D received .0125 mCi of 2DG/100g body wt on day 0 and +3, +6, +9, +12 and +18 days after onset of 16 h L:8h D. Brains were processed for autoradiography; testis wt, cloacal gland size and serum testosterone were used as indicators of reproductive response to photoperiod. Reproductive responses were curvilinear, reaching maximum levels at d +18. Heavily labeled nuclei were identified in four discrete neural pathways: thalamofugal, tectofugal, ascending auditory, and efferent vocalization. It is hypothesized that the auditory and vocalization pathways responded to increased crowing as the birds matured, perhaps influenced by increasing T. No accumulation of label was found in SCN at any time. In addition, the hypothalamic nuclei involved in copulatory behavior did not show evidence of metabolic activity, perhaps because males were raised without females. In this study evidence for a metabolic response to photoperiod was not found in SCN, though it should be noted that all birds were sacrificed during the daylight period.

734.7

EFFECT OF ANTERIOR HYPOTHALAMIC AREA (AHA) LESIONS ON PHOTOPERIOD-INDUCED SHIFTS IN REPRODUCTIVE ACTIVITY OF THE EWE. S.M. Hileman, D.E. Kuehl, G.L. Jackson. Department of Veterinary Biosciences, University of Illinois, Urbana, IL 61801.

Areas of the brain involved in photoperiodic control of reproduction are not well defined. Our objective was to determine the effect of AHA lesions on responses of the sheep reproductive system to shifts in length of the daily photoperiod. Eleven intact Suffolk ewes received bilateral radiofrequency lesions of the AHA (AHAX) and 5 received sham lesions (SHAM). Ewes were then placed in photoperiod chambers and exposed to alternating periods of long (16L:8D) and short (10L:14D) days of about 90 days for approximately 1 year. Blood samples were collected twice weekly to monitor progesterone and prolactin release and, on one occasion, hourly for 24 h to assess melatonin release. Lesions increased ($P < 0.001$) the interval between start of long days and cessation of estrous cycles during both long-day periods but did not affect ($P > 0.10$) the interval between start of short days to onset of estrous cycles for either short-day period. Duration of both anestrus periods was shorter ($p < 0.001$) for AHAX than for SHAM ewes. No effects of lesions were evident on serum patterns of either prolactin or melatonin. These results suggest that AHA lesions disrupt neuronal pathways mediating the effects of shifts in photoperiod on reproductive activity in this species. Furthermore, these lesions appear to mainly affect response to long-day-induced suppression of reproductive activity.

SEASONAL PROLACTIN SECRETION IN FEMALE SIBERIAN HAMSTERS IS MODULATED BY VASOACTIVE INTESTINAL PEPTIDE. Andrew M. Snyder* and Lori L. Badura. University of Connecticut Health Center, Farmington, CT 06032, and Behavioral Neuroscience, University of Connecticut, Storrs, CT 06264.

The role of central VIP in the photoperiodic modulation of basal PRL release was investigated by employing chronic infusion of VIP or a VIP antagonist (AVIP) via microdialysis probes implanted within the hypothalamus. In a first experiment, female hamsters housed under a 16L:8D photoperiod were fitted with probes and received constant daily infusions of 800 ng VIP, 1.2 ug AVIP, or the vehicle, for 7 weeks. For the VIP infusions, animals with probes located in the PVN region showed a significant rise in circulating PRL as early as one week post-surgery. In contrast, neither vehicle infusions, nor VIP infusions located in other neural regions, induced changes in basal PRL. Similarly, AVIP induced a decline in circulating PRL when infused in the PVN region, but not when the probes were located in other neural sites.

The role of VIP in the short-day induced decline in PRL release was investigated in a second experiment. Animals were again fitted with dialysis probes and then transferred to a 10L:14D photoperiod where they received VIP or vehicle infusions for 9 weeks. VIP infused into the PVN region prevented the short-day induced decline in basal PRL that was shown by both the vehicle-treated animals and animals receiving VIP in other neural regions. These findings taken together suggest that hypothalamic VIP may act at the level of the PVN to stimulate anterior pituitary release of prolactin, and that the activity of this peptide may be under photoperiodic control.

EVIDENCE FOR A DIRECT PATHWAY FROM THE SCN TO THE GNRH SYSTEM IN THE FEMALE RAT HYPOTHALAMUS. EM van der Beek¹, VM Wiegant^{2*}, and RM Buijs³ ¹Dept of Cell Biol; ² Dept of Med Pharmacol, Med Fac, Utrecht Univ, Utrecht, and Dept of Human & Animal Physiol, Agricult Univ, Wageningen, The Netherlands; ³Netherlands Inst for Brain Res, Amsterdam, The Netherlands, and Loeb Res Inst, Ottawa Civic Hosp, Ottawa, Canada.

The influence of the suprachiasmatic nucleus (SCN) on the regulation of the reproductive cycle is most evident in the female. Timing of the preovulatory luteinizing hormone (LH) surge is determined by the SCN. Destruction of the SCN leads to a cessation of the ovarian cycle, while implantation of estrogen in ovariectomized rats results in daily LH surges. The anatomical substrate for these effects is not known. Studies involving lesions of the SCN have demonstrated a direct vasoactive intestinal polypeptide (VIP) containing pathway to gonadotropin releasing hormone (GnRH) neurons (VanderBeek et al., J. Neuroendocrin. 5:137). To further investigate the existence of a direct connection between the SCN and the GnRH system we have combined tract-tracing using the anterograde tracer Phaseolus Vulgaris Leu-agglutinin (Pha-L) with double labelling immunocytochemistry in LM and EM studies. In addition, VIP input on GnRH neurons was studied at the EM level. Small unilateral Pha-L deposits in the rostral ventrolateral portion of the SCN revealed a partially bilateral projection to the preoptic area, and Pha-L immunoreactive fibers were in close apposition to a number of GnRH neurons. EM studies showed contacts between Pha-L containing fibers and GnRH immunoreactive structures. In addition, synaptic interactions of VIP containing fibers with GnRH neurons were observed. The present study provides substantial evidence for a monosynaptic pathway from the SCN to the GnRH system in the hypothalamus of the female rat. This pathway may be the anatomical substrate for the circadian regulation of the ovarian reproductive cycle.

734.8

EFFECTS OF PROLACTIN ON EXPRESSION OF THE mRNAs ENCODING THE IMMEDIATE EARLY GENES ZIF/268, NUR/77, C-FOS AND C-JUN IN THE HYPOTHALAMUS. C.A. Sagrillo* and M. Selmanoff. Department of Physiology, University of Maryland, School of Medicine, Baltimore, MD 21201-1559.

Prolactin (PRL) exerts a short-loop negative feedback effect on hypothalamic neurons which control its secretion from the anterior pituitary gland. The purpose of this study was to identify particular hypothalamic neurons which respond to acute PRL exposure. Quantitative *in situ* hybridization histochemistry was used to visualize the induction of mRNAs for four different immediate early genes (IEGs): zif/268 (NGF1-A), nur/77 (NGF1-B), c-fos and c-jun. Increasing evidence indicates that excitation of neurons often results in the rapid transcription of IEGs. Three groups of male rats were studied: unmanipulated controls, rats injected sc with 2.4 mg ovine PRL suspended in polyvinylpyrrolidone (PVP) and PVP-injected controls. Animals were decapitated 0, 0.5, 1, 2, 3 or 4 h following the injection. Brains were immediately frozen at -70°C and 12 µm sections were prepared. Sections were hybridized with ³⁵S-dATP-labeled specific oligonucleotide probes 45 to 60 nucleotides in length. In all rats, all probes labelled cells in the cortex (particularly the cingulate and piriform), the hippocampus and the striatum. In the arcuate region, a greater number of cells were labeled with the zif/268 and nur/77 probes in PRL-treated compared with PVP-treated control rats. The labeled neurons are co-extensive with, but are not necessarily the tuberoinfundibular dopaminergic neurons. The data suggest that cells located in the arcuate region may be involved in mediating PRL autorefeedback effects. (Supported by NIH grant HD21351).

AGE DEPENDENCE ON THE EFFECTS OF LESIONING THE DORSAL RAPHE NUCLEUS (DRN) IN PREPUBERTAL RATS ON FIRST OVULATION. M.E. Ayala and R. Dominguez*. B.R.R.U. FES-Zaragoza UNAM. AP 9-020, México DF

The serotonergic denervation induced by p-chloroamphetamine administration to prepubertal rats, affected first ovulation in an age-dependent way. Because the role of the serotonergic innervation of the hypothalamus arising from the DRN is controversial, to analyze if its participation in the regulation of ovulation varies with the age of the animal, the effects of an electrolytic lesion of the DRN at different ages of the juvenile period on ovulation at the first day of vaginal estrus, were studied. The results obtained were:

GROUP	Age of lesion	Ovulation rate	Ova shed
Control	-----	26/34	7.9±0.3
Lesion	21 day	3/7	7.3±0.9
	24 day	6/8	10.0±0.7*
	27 day	8/8	9.6±0.6*
	30 day	0/8*	0*

* $p < 0.05$ vs control group.

Present results suggest that the role of the innervation arising from the DRN is inhibitory at the beginning of the juvenile period and excitatory at the end. Supported by DGAPA and PUIS, UNAM.

734.11

ENDOCRINE PULSATILITY AND MUSCLE SPASM ACTIVITY IN SPINAL CORD INJURED (SCI) MEN BEFORE AND DURING NALOXONE INFUSION. N.L. BRACKETT^{1,2*}, C.M. LYNNE³, M. WEIZMAN¹, M. AMADOR¹, M. ABAE⁴. The Miami Project to Cure Paralysis¹, Dept. of Neurological Surgery², Dept. of Urology³, Dept. of OB/GYN⁴, Univ. of Miami Sch. of Med., Miami, FL 33136.

The present study sought to determine: (1) if the pulse release of luteinizing hormone (LH), follicle-stimulating-hormone (FSH) and cortisol (C) were different in SCI men compared to non-injured men (controls), and (2) if infusion of naloxone would alter the pulse release of LH, FSH and C in either group. SCI (n=3) and control (n=3) subjects were placed in a research wing of Jackson Memorial Hospital, (Miami, FL) for 48 consecutive hours. Following an overnight adaptation period, blood (3 cc) was drawn every 15 minutes for 30 hours. Physiologic saline was infused during hours 2-7 and naloxone (bolus of 8 mg followed by 4 mg/hr) was infused during hours 24-30 of blood draws. Serum was separated and stored (-80^o) for 1-3 months prior to assay. Serum levels of LH, FSH, and C were determined by chemiluminescence assay (Amerlite System, Amersham). Pulse analysis was performed using PULSEFIT.

There was no difference between the two groups in the frequency or amplitude of LH and FSH peaks before naloxone infusion. During naloxone infusion, LH and FSH pulse frequency increased above saline baseline in 2 SCI subjects. Frequency of C pulses in the two groups were similar, but diurnal variation in C was flattened in SCI subjects. During naloxone infusion, an unexpected side effect occurred in SCI subjects. There was an increase in frequency, duration and intensity of muscle spasm activity. Spasms occurred throughout the body, but primarily below the level of injury.

These results indicate that the pulse release of gonadotropins may not be different in SCI men, but that the neuromodulatory role of endogenous opioids may be different in SCI men.

NEUROENDOCRINE REGULATION: OXYTOCIN, VASOPRESSIN, FLUID BALANCE, AND THE PINEAL

735.1

INTRACELLULAR CALCIUM CHANGE OF CELLS IN HYPOTHALAMIC SUPRAOPTIC REGION. H. Yamashita*, K. Inenaga, L.-N. Cui, T. Nagatomo and H. Tanaka. Dept. of Physiology, Univ. Occupational & Environmental Health, Sch. of Med., Kitakyushu 807, Japan.

Neurotransmitters or neuromodulators modify neural activities in the central nervous system. Accumulating evidence suggests that such modification is accompanied with intracellular calcium change. To know the intracellular calcium change in cells located in supraoptic regions, thin slice preparations from young rats and Fura-2 image technique were used in this experiment. Some cells showed spontaneous change of $[Ca^{2+}]_i$. $[Ca^{2+}]_i$ in the cells was decreased by TTX or TTX/ Ca^{2+} free medium. Angiotensin II (All), endothelin (ET), kainic acid (KA) and NMDA increased $[Ca^{2+}]_i$. The fast component of $[Ca^{2+}]_i$ induced by All and ET was maintained with TTX/ Ca^{2+} free medium but not the slow component. The increase of $[Ca^{2+}]_i$ induced by KA and NMDA was abolished with TTX/ Ca^{2+} free medium. These data suggest that the fast component of intracellular calcium increase induced by All and ET is due to calcium release from the calcium store in cells of hypothalamic supraoptic region.

735.3

ROLE OF THE NUCLEUS MEDIANUS IN THE RELAXIN-INDUCED SECRETION OF VASOPRESSIN AND OXYTOCIN IN ANAESTHETIZED RATS. B.J. Geddes and A.J.S. Summerlee*. Dept. of Biomedical Sciences, University of Guelph, Guelph, Ont., Canada N1G 2W1.

Injection of relaxin (iv) causes the release of both vasopressin and oxytocin as well as a rise in systemic arterial blood pressure (Parry, L.J. & Summerlee, A.J.S. (1991); *Endocrinology* 129: 47). It has been shown that central angiotensin II within the forebrain angiotensin pathway mediates the central effects of relaxin. The present experiments were done to investigate the role of the nucleus medianus in this action. Urethane anaesthetized female (SD) rats received an electrolytic lesion of the nucleus medianus. Blood samples were then taken at five intervals following an iv injection of either relaxin (5µg in 0.01mL) or physiological saline (0.01mL). Plasma vasopressin and oxytocin levels were determined by specific radioimmunoassay and analyzed by ANOVA. Lesion of the nucleus medianus but not control or sham-lesion significantly attenuated ($p < 0.05$) the relaxin-induced secretion of both vasopressin and oxytocin. These results implicate the nucleus medianus in the central action of relaxin.

735.2

ALTERED EXPRESSION OF GLUT1 & GLUT3 GLUCOSE TRANSPORTERS IN THE NEUROHYPOPHYSIS OF DIABETIC RATS. S.J. Vannucci*, E. Maher, I.A. Simpson, M.S. Hershey Medical Center, Hershey, PA 17033 and NIH/NIDDK/DB, Bethesda, MD 20892

The neurohypophysis (NH) is an extension of the central nervous system which contains axon terminals of vasopressin- and oxytocin-secreting neurons of the hypothalamus and glial-like pituicytes, but lacks a blood-brain barrier. The transport of glucose into these cells is mediated by the glucose transporter proteins, GLUT1 and GLUT3. In rat brain GLUT1 (55kDa) is concentrated in the blood-brain barrier, 45 kDa-GLUT1 is widely distributed in the neuropil; GLUT3 is the major neuronal transporter. Both GLUT3 and 45 kDa-GLUT1 are detected in the NH. In streptozotocin (STZ)-diabetic rats the hypothalamo-NH complex shows anatomic evidence of increased synthetic/secretory activity. The purpose of this study was to determine whether STZ-diabetes alters the expression of NH GLUT1 or GLUT3. Adult male rats were injected i.p. with STZ, 65 mg/kg. Blood glucose was elevated (> 500 mg/dl) by 3d after STZ, demonstrating onset of diabetes. Animals were studied daily through 1 week, then at 2 and 4 wks. GLUT1 & GLUT3 were studied in individual NH by Western blot analysis with specific anti-C-terminal antisera; autoradiograms were quantitated by phosphorimage analysis. By day 3, NH GLUT3, per mg protein, increased by 20% and stayed at this level through 4 weeks; NH GLUT1 decreased by 20% at 3d, remained there through 2 wks and was 53% of age-matched control at 4 wks. The decrease in NH GLUT1 is similar to the peripheral cellular response to high glucose. However, the increase in NH GLUT3 (presumably axon terminal) in STZ-diabetes is the first demonstration of an up-regulation of GLUT3 in response to metabolic stress.

735.4

BRAIN ANGIOTENSIN MECHANISMS MEDIATE SEROTONIN (5HT)-INDUCED STIMULATION OF VASOPRESSIN (VP), BUT NOT OXYTOCIN (OT) SECRETION IN CONSCIOUS MALE RATS. M.S. Brownfield^{1*}, P.A. Rittenhouse², L.D. Van de Kar², and J.A. Saydoff¹ Departments of Comparative Biosciences, Univ. of Wisconsin Sch. Vet. Med., Madison, WI 53706¹ and Pharmacology, Loyola Univ. Sch. Med., Maywood, IL 60153².

We have previously shown that brain 5HT depletion blocks osmotically stimulated VP release and intraventricular (iv) administration of 5HT to conscious male rats stimulates the secretion of both vasopressin and oxytocin, via a 5HT_{1c/2} mechanism. We questioned whether the serotonergic influence on VP cells was direct since immunocytochemical (ICC) studies have reported that 5HT terminals on VP cells are very scarce and on OT cells are only moderate. We hypothesized that the serotonergic effect on VP was indirect, possibly acting via an intermediate pathway, possibly angiotensinergic in nature.

In a preliminary study we administered rats the angiotensin converting enzyme antagonist enalapril (60 mg/l) for 4 days in their drinking water prior to administration of the serotonin releaser d-fenfluramine (2 mg/kg ip) 30 and 60 minutes before sacrifice. Enalapril administration significantly blocked the VP, but not the OT response to fenfluramine. This suggests that inhibition of angiotensin II formation inhibits the normal VP response to 5HT release via fenfluramine.

We also tested the effect of selective brain angiotensin II receptor blockade by the AT₁ antagonist losartan (10 µg icv.) 30 minutes prior to 5HT stimulated (10 µg icv.) VP and OT secretion in serial blood samples of chronically cannulated conscious rats. Results showed that losartan administration significantly blocked the vasopressin, but not the oxytocin response to serotonin. Correlative ICC for cfs showed overlapping distributions of 5HT and angiotensin activated nuclei.

These studies suggest that 5HT stimulates both VP and OT secretion, and that VP secretion is activated by a brain angiotensinergic intermediate pathway.

735.5

RELEASE OF OXYTOCIN FROM SPINAL CORD SYNAPTOSOMES -- A MODULATORY ROLE BY MITOCHONDRIA. M. Daddar & J. Haldar*. Biological Sciences, St. John's Univ., Jamaica, NY 11439.

Previously we have shown that 56 mM KCl-induced oxytocin (OT) release from spinal cord (SC) synaptosomes (SP) is Ca^{++} dependent but differs in 3,100g (p2) and 12,000g (p3) pellets. Since SP contain mitochondria (Mit), an organelle which stores Ca^{++} , we have investigated if the difference in release pattern with p2 and p3 is related to the presence of Mit. SC of male Sprague Dawley rats was separated into cervical, thoracic and lumbosacral regions. Tissues were homogenized in 270 mM sucrose and p2, p3 pellets were separated. The presence of Mit in p2 & p3 pellets were determined morphologically by electron microscopic (EM) studies and biochemically by N-ethylmaleimide insensitive glycerophosphate acyltransferase (GAT). EM studies showed that in p2, Mit were located inside the SP while in p3 Mit were outside the SP. The GAT content of the p2 pellet was much higher than that of the p3 pellet. To determine whether the presence of Mit reduced SP Ca^{++} concentration by a Ca^{++} uptake process, ruthenium red, a mitochondrial Ca^{++} uptake inhibitor was used. Addition of 3 μ M ruthenium red, 1 min prior to the addition of high KCl solution, reversed the OT release pattern in p2 pellet. The results suggest that mitochondria exert a modulatory role in OT release from spinal cord synaptosomes.

735.7

IS BASIC FGF A NEUROENDOCRINE MODULATOR OF FLUID BALANCE? A.M. Gonzalez¹, E. Stopa², A. Logan³, and A. Baird¹. ¹Dept. Molecular and Cellular Growth Biology, The Whittier Institute for Diabetes and Endocrinology, La Jolla, CA 92037; ²Dept. Pathology, Rhode Island Hospital, Providence, RI 02903; ³Wolfson Research Labs, Birmingham, UK B15 2TT.

Although the brain and pituitary are the richest sources of basic FGF, its exact physiological functions in these tissues are still unknown. Its localization in ependyma, subfornical organ, and magnocellular neurons from paraventricular and supraoptic nuclei suggests that it may be involved in water balance. In order to investigate the potential role of pituitary basic FGF as a neuroendocrine modulator of water balance, we studied the presence and distribution of basic FGF, its high affinity receptor (FGFR1), and their corresponding mRNAs in the neurohypophysis of normal rats. Extraction and Western blotting of the normal rat neurohypophysis show the presence of the three expected molecular forms of basic FGF. Similar analysis of this extract for FGFRs reveals proteins of the expected molecular weight (150kDa) as well as an immunoreactive protein of 80kDa. In the normal rat, basic FGF and FGFR localize to both the neurohypophysis and pars distalis, but not in the pars intermedia. In the neurohypophysis, basic FGF is detected in basement membranes, pituitocytes and associated with Herring bodies. Pituitocytes and Herring bodies also show intense immunostaining for FGFR. As expected from Northern analysis, *in situ* hybridization studies with a cRNA for rat basic FGF show that the pars distalis, pars intermedia and neurohypophysis all have non detectable to very low levels of basic FGF mRNA. In contrast, there is an intense positive signal for FGFR1 mRNA in the neurohypophysis that appears even more intense at the border between the adenohypophysis and neurohypophysis. The cells containing the FGFR mRNA were identified as pituitocytes. Preliminary studies of the human pituitary gland reveal a distribution of basic FGF within the neurohypophysis which is similar to that seen in the rat. Classical models of fluid balance are currently being evaluated in order to identify the source of basic FGF (*i.e.*, SON and PVN nuclei) and test its potential role as a neuromodulator of posterior pituitary function. (Supported by NIH DK18811 and AG10682).

INHIBITORY EFFECTS OF ATRIAL NATRIURETIC FACTOR (ANF) ON SUPRAOPTIC NEURONS ISOLATED FROM THE RAT. Stéphane H.R. Oliet* and Charles W. Bourque. Centre for Research in Neuroscience, Montreal General Hospital and McGill University, Montreal, P.Q. Canada H3G 1A4.

ANF-like immunoreactivity has been recently found within brain areas involved in the control of fluid and electrolyte homeostasis including the supraoptic nucleus (SON). In order to investigate possible post-synaptic effects of ANF, we have used a preparation of acutely isolated rat SON neurons devoid of synaptic inputs. Bath-application of ANF (1-20nM) inhibited spontaneous spiking activity recorded in the on-cell mode in 17 of 23 cells tested. Whole-cell voltage-clamp recordings indicated that ANF increased membrane conductance due to the activation of a current reversing at -97 ± 2 mV ($n=12$). When the extracellular $[K^+]$ was raised ($n=6$), the reversal potential of the current shifted in strict correspondence with the K^+ equilibrium potential, suggesting that ANF was activating a current highly selective for K^+ . Similar effects were evoked in 5 of 7 cells when dibutyl-*c*-GMP (0.5-1mM) was added to the perfusate.

Our results suggest that endogenously released ANF may modulate the electrical activity of rat supraoptic neurons via the activation of post-synaptic K^+ channels, possibly involving the production of *c*GMP.

EFFECTS OF THE LESION OF THE NUCLEUS OF THE TRACTUS SOLITARIUS ON LABOR OF RATS. J.G. Ninomiya and I. Zarco de Coronado*. Fac. de Med., UNAM. A. Postal 70-250, C.P. 04510 and Esc. Médico Militar, U.D.E.F.A., México, D.F., México.

It has been described that approximately 85% of the afferent fibers of the vagus nerve have their first central synapses at the nucleus of the tractus solitarius (NTS). This study was made, in order to know about the role of these connections on the integrative function of paraventricular nucleus (NP) during parturition. Unilateral or bilateral DC current 0.5 nAmp during 20 sec was injected 24 to 48 hrs before parturition, at NTS of anesthetized pregnant rats. Bilateral lesions produced a delayed labor (12-15 hrs) and all the fetuses were born dead. The unilateral lesions of NTS caused a delayed labor (5-30 hrs) and most of the fetuses were born dead. Our results indicate that the connection between the uterus and NTS is part of the complex neuroendocrine circuit involving NP, which plays an important integrative role for parturition.

NEUROTENSIN-EVOKED EXCITATION OF RAT MAGNOCELLULAR NEUROSECRETORY CELLS (MNCs) INVOLVES INTRACELLULAR Ca^{++} MOBILIZATION. K. Kirkpatrick and C.W. Bourque. Centre for Research in Neuroscience, Montreal Gen. Hosp. & McGill University.

We have previously shown that neurotensin (NT) excites rat supraoptic MNCs via postsynaptic receptors (Kirkpatrick and Bourque, *Neurosci. Abst.*, 1991). In this study we examined a possible role for intracellular $[Ca^{++}]$ in NT-evoked responses using superfused rat hypothalamic explants and acutely isolated MNCs. As previously reported, application of NT (0.1-10 μ M) during intracellular recordings from MNCs in explants excited 29 of 31 cells tested. In contrast, 4 of 5 MNCs impaled with electrodes containing 0.8M BAPTA failed to respond to NT application, suggesting that Ca^{++} may play a role in transducing NT-evoked excitation.

This possibility was further examined by incubating isolated MNCs in a medium containing 1-5 μ M of the $[Ca^{++}]$ indicator Fluo3-AM (45 minutes; 32°C). These cells were later perfused (≈ 1 ml/min) at 30-34°C and changes in fluorescence (emission at 525 nm; excitation at 490) were monitored using a Leitz confocal scanning laser microscope. Bath application of NT (1-10 μ M; 1 min) produced increases in cytoplasmic fluorescence in 9 of 12 cells bathed in the presence of Ca^{++} (1 mM). NT-evoked intracellular $[Ca^{++}]$ increases were also observed from 8 of 10 cells perfused with media containing 0 Ca^{++} and 0.5 mM EGTA. These results suggest that the NT-evoked excitation of MNCs involves the mobilization of Ca^{++} from internal stores. Supported by FCAR and the MRC of Canada.

PASSIVE ELECTRICAL PROPERTIES OF SUPRAOPTIC NUCLEUS (SON) NEURONS OBSERVED WITH WHOLE CELL RECORDINGS *IN VITRO*. W.E. Armstrong*, Dept. of Anat. Neurobiol., Univ. Tenn., Memphis, TN 38163.

The electrical properties of neurons should be estimated more accurately with whole cell recordings by reducing current leak at the electrode-membrane interface and by reducing electrode noise. Whole cell voltage recordings were obtained from intact neurons in the SON of the rat hypothalamo-neurohypophysial explant. With an internal solution containing (in mM) 135 K-gluconate, 5 KCl, 2 MgCl₂, 4 KOH, 2 ATP, 0.2 GTP and 10 HEPES, properties commonly observed with sharp electrodes, including transient outward rectification, a prominent afterhyperpolarization, spike-frequency adaptation and in some cells, a depolarizing afterpotential, were observed.

Neurons recorded with the whole cell method exhibited input resistances at least twice that of those seen with sharp electrodes (400-500 vs 200 M Ω). With hyperpolarizing pulses, a linear steady state I/V range from about -60 to -90 mV was present, but this range was not strictly passive as indicated by asymmetries between the discharging and charging limbs of voltage transients, and between the responses to depolarizing and hyperpolarizing current injection. In addition, a voltage related change in the estimated membrane time constant (τ_0) was present in some neurons in the linear steady state range. The passive range was more narrow and covered only a 5-10 mV region at least 10-15 mV beneath spike threshold. Analysis of voltage transients in this passive region revealed a membrane time constant 2-4 times longer than that seen in sharp electrode recordings, with τ_0 ranging from 25-54 ms across neurons. Taking advantage of the lack of a somatic shunt, an equivalent cylinder analysis of some neurons revealed a dendritic electronic length of ≈ 1.0 calculated from transients exhibiting an equalizing time constant, a value similar to that estimated previously with sharp electrodes (*Neurosci.* 38: 485, 1990). Transients from other cells were monoexponential. Supported by NIH NS23941 (WEA).

NEURAL MODULATION OF OXYTOCIN (OT) RELEASE DURING SUCKLING. E. Koehler*, S. Mantz, and J. Summy-Long. Dept. of Pharmacol., MS Hershey Med. Ctr., Penn. State Univ., Hershey, PA, 17033

During lactation new GABAergic synapses form on oxytocinergic neurons which may modulate release of OT by suckling. Moreover, pharmacologic evidence documents that nitric oxide (NO) attenuates release of OT during dehydration (Summy-Long et al, Neurosci. Lett. 1993, in press). We therefore examined in conscious lactating rats whether GABA or NO modulates suckling-induced release of OT. Stretch reflexes (SR) in the pups, associated with milk let-down during nursing, were timed and used as indices of OT release. In study #1, CSF (5 ul) with or without GABA (25ug) or bicuculline (BIC; 50ng), was infused intracerebroventricularly (icv) following the 3rd SR and the dam was decapitated after the 4th SR. Study #2 was similar except an inhibitor of NO synthase (N^G-nitro-L-arginine methyl ester, NAME; 1000 or 500ug) or CSF was infused icv at the onset of nursing and the mother was killed at the 3rd SR. OT was quantified by RIA. Plasma levels of OT (pg/ml; \bar{x} ±SEM; n=5-11) elevated by suckling (CSF, study #1: 22±4; study #2: 29±5) were unchanged after GABA (18±4), BIC (19±2) or NAME (1000ug: 30±6; 500ug: 30±4). Both BIC and NAME (1000ug) disrupted nursing behavior such that the last SR was delayed (min; $p < 0.05$, Tukey's t) only by BIC (CSF vs BIC; 6±1 vs 14±3). Suckling-induced release of OT was therefore unaffected by low doses of GABA and NAME that did not disrupt nursing behavior. (Supported by RO1HD25498)

ATYPICAL PLASMA VASOPRESSIN RESPONSES TO NON-OSMOTIC STRESS IN ADRENAL DEMEDULLATED RATS. D. Jezova, A. Kiss and G. Aquilera*, DEB, NICHD, NIH, Bethesda, MD and SAS, Bratislava, Slovakia.

We have recently shown unexpected increases in hypothalamic vasopressin (VP) mRNA and plasma VP responses to acute immobilization (IMMO) in 2-month adrenal demedullated (MDX) rats with normal adrenocortical function. The role of adrenal catecholamine deficiency on the VP responses was studied in rats with splanchnic nerve section or β -adrenergic or dopaminergic blockade. Injection of propranolol (5 mg/kg) or domperidone (2 mg/kg), 45 min prior acute IMMO in intact rats, did not affect ACTH and corticosterone responses and failed to increase plasma VP. Similarly, 10 days after splanchnic nerve section, IMMO did not increase plasma VP, despite near absent plasma epinephrine responses. In contrast to chronic MDX, after short term (12 days) enucleation of the inner adrenal zones, there was no increase in plasma VP after acute IMMO, with or without corticosterone replacement. The data show that neither the lack of acute epinephrine release during stress, nor short term absence of the medulla causes magnocellular activation. Thus, long term adaptation to MDX may suppress an inhibitory pathway which normally prevents increases in plasma VP to non-osmotic stress.

PHOTOPERIOD REGULATES THE MELATONIN RECEPTOR DENSITY IN THE QUAIL OPTIC TECTUM. B. Stankov¹, N. Aste², V. Lucini¹, S. Capsoni¹, C. Viglietti-Panzica², R. Nonno², F. Fraschini¹, G.C. Panzica², and B. Cozzi^{1*}. ¹University of Milan, 20129 Milano and ²University of Turin, 10128 Torino, ITALY

Male quails (*Coturnix japonica*) were kept under short (LD 8:16, n=6) or long photoperiod (LD 16:8, n=6) for 8 weeks, their brains collected around the middle of the light phase, and processed for quantitative melatonin receptor autoradiography. In both experimental groups, melatonin receptors were identified in several nuclei involved in the entrainment of circadian rhythms and processing of visual inputs (GLV, nDSV, ROT, nBOR, PPC, PT, TeO), and in the nuclei of cranial nerves responsible for the control of eye movements (nVI, EW, OM), as recently reported (Cozzi et al., 1993, Neurosci. Lett. 150:149). The apparent receptor density was approximately two times higher in the optic tectum of the short-day group. A similar difference in the optic density was evident also in the pars tuberalis. Melatonin receptors have already been described in the GLV, nDSV, and other brain nuclei in birds. Although differences in melatonin receptor density during the day have been demonstrated in the chicken brain (Brooks and Cassone, 1992, Endocrinology 131:1297), changes in the receptor density related to the photoperiod are reported here for the first time. The quail responds to increments in the dark phase of the photocycle with a dramatic alteration of its reproductive competence. These changes might be mediated through the action of melatonin on its high-affinity receptors in the brain, where their apparent density is inversely proportional to daylength.

LACK OF RESPONSE TO NMDA IN RAT SUPRAOPTIC OXYTOCIN NEURONS IN VIVO. R. Nissen*, B. Hu, L.P. Renaud. Loeb Research Institute, Ottawa Civic Hospital, Ottawa, Ontario, Canada, K1Y 4E9.

We previously reported that NMDA receptor blockade by a non-competitive open channel blocker, ketamine, depresses spontaneous activity of supraoptic vasopressin (VP) but not oxytocin (OT) neurons (Nissen et al., 1992). The latter suggests a lack of functional NMDA receptors in supraoptic OT neurons. In the present study, the effects of specific glutamate receptor agonists were evaluated *in vivo* to determine whether OT neurons are responsive to NMDA application. Extracellular recordings were obtained from identified VP and OT neurons in pentobarbital anesthetized Long-Evans rats. Local pressure application of NMDA (100 μ M) evoked activity in a dose dependent manner when applied during periods of spontaneous quiescence in 27/28 phasic VP neurons and significantly increased spontaneous firing when applied during periods of activity in 5/5 of these cells. By comparison, identical application of NMDA was associated with an increase in firing of only 1/9 OT neurons. The selective non-NMDA receptor agonists AMPA (100 μ M) and kainate (100 μ M) elevated spontaneous activity in 4/5 and 7/9 oxytocin neurons, respectively; similar excitatory responses were also observed in the majority of vasopressin neurons (21/21 and 14/15 respectively). Our results suggest that both VP and OT neurons are sensitive to non-NMDA receptor activation, while OT neurons appear to lack a response to NMDA. (Supported by MRC).

VASOPRESSIN NEURON ACTIVATION AND FOS EXPRESSION: ELECTRICAL STIMULATION OF THE CAUDAL MEDULLA OBLONGATA. S. Shioda, Y. Nakai, M. Iwase, I. Homma and M. Kawatani*. Dept. of Anatomy and Physiology, Showa Univ. Sch. of Med., Tokyo 142, Japan.

The expression of Fos, the protein product of the primary response gene c-fos, was used metabolically to map the effects of unilateral electrical stimulation (150 μ A at 50 Hz for 10 min) of A1 or A2 cell group in the caudal medulla oblongata. Electrical stimulation of the A1 cell group in rats anesthetized with urethane led to increase in mean arterial pressure and to bilateral increase of Fos-like immunoreactivity (FLI) in the ventral part of the supraoptic nucleus (SON) and posterior magnocellular part of the paraventricular nucleus (PVN). FLI was visible only in the vasopressin neurons but rarely in oxytocin neurons after stimulation of A1 cell group. However, electrical stimulation of A2 cell group led to increase heart rate but blood pressure was unchanged, and to bilateral increase of FLI in the SON and PVN, especially abundant in the parvocellular parts of the PVN. FLI was visible both in vasopressin and oxytocin neurons in the SON and PVN after stimulation of A2 cell group.

735.16

TEMPORALLY DISTINCT RELEASE OF SEROTONIN AND MELATONIN FROM SUPERFUSED RAT PINEALOCYTES. J. Olcese*, M. Schumacher, M. Munker and C. McArdle. Institute for Hormone and Fertility Research, University of Hamburg, 2000 Hamburg 54, Federal Republic of Germany.

The present studies examined the adrenergic regulation of serotonin (5HT) and melatonin (MEL) secretion from superfused pinealocytes grown on microcarrier beads for 48h before stimulation. Indoleamine release was measured in 10 min fractions by two specific radioimmunoassays. Whereas MEL release following 1 μ M norepinephrine or isoproterenol was robust but relatively sluggish (rising not until 1.5 - 2 hours after stimulation), the molar release of 5HT was considerably greater and much more rapid, occurring within 30 minutes after adrenergic stimulation. The α -agonist phenylephrine was without effect on either indoleamine. Using a 15 minute stimulation paradigm individual 5HT pulses could be elicited repetitively without similar MEL release profiles. These data support the hypothesis that different secretory mechanisms are involved for pineal 5HT and MEL. This new cell culture system should allow for a finer analysis of serotonergic function in the mammalian pineal gland.

735.17

REGULATION OF PINEALOCYTE SYNAPTIC RIBBONS (SR) BY NORADRENALINE (NE) AND SYMPATHETIC NEURONS IN A CO-CULTURE MODEL. J.A. McNulty*, T. Meldgaard, L.M. Fox, S-Y. Tsai, N. Tander. Dept. Cell Biology, Neurobiology, Anatomy, Loyola Univ. Med. Ctr., Maywood, IL 60153, and PharmaBiotec, Inst. Neurobiol., Univ. Aarhus, Denmark.

The mammalian pineal gland (PG) is characterized by SR, which reflect the PG's phylogenetic derivation from photoreceptors. More importantly, numerous studies have demonstrated numerical changes in SR related to PG melatonin production. To test the hypothesis that SR frequency is regulated by innervation from the superior cervical ganglia (SCG), a PG-SCG co-culture model was developed. PG and SCG from neonatal (5 day old) Wistar rats were mounted on glass coverslips in a clot of reconstituted chicken plasma coagulated by a drop of thrombin and cultured by the roller-tube technique (Gähwiler, BH, Neurosci. Meth. 4: 329-342, 1981). The groups included: 1) PG cultured alone, 2) PG co-cultured with SCG, and 3) PG treated with NE (10^{-5} M) added every 3 days. After 30 days, cultures were fixed, processed for routine transmission electron microscopy and SR counted by a "blind" observer. SR frequency (number/unit area of PG) was significantly higher in PG cultured alone compared to PG+SCG and PG+NE (ANOVA; $p < 0.01$). SR fields (2-8 SR) were common in the PG group. Pinealocytes were highly differentiated and displayed an ultrastructure typical of that seen *in situ*, except that pinealocytes in the PG+NE group tended to have enlarged mitochondria and expanded Golgi saccules and endoplasmic reticulum. These findings are consistent with the hypothesis that SCG innervation regulates PG SR. Ultrastructural changes in NE-treated cultures suggest that NE effects on SR are mediated by other mechanisms. Supported by NSF (BNS 8801726), the Danish MRC, and the Lundbeck Foundation, DK.

PAIN MODULATION: PHARMACOLOGY V

736.1

THE DEVELOPMENT OF MORPHINE TOLERANCE IS ASSOCIATED WITH INCREASES IN MEMBRANE-BOUND PROTEIN KINASE C: PREVENTION BY GMI GANGLIOSIDE D.J. Mayer, J. Mao and D.D. Price, Dept. Anesthesiology, Medical College of Virginia, Richmond, VA 23298

In a rat model of morphine tolerance and dependence, we examined the hypotheses that the development of morphine tolerance is associated with the translocation of protein kinase C (PKC) and that agents blocking PKC translocation will prevent both the development of morphine tolerance and dependence. The translocation of PKC was measured by using an established [3 H]phorbol-12,13-dibutyrate binding assay ([3 H]PDBu), which measures primarily membrane-bound (translocated) PKC. The development of morphine tolerance was examined utilizing the tail-flick test. Once daily intrathecal (i.t.) treatment with 10 μ g morphine sulfate for 8 days produced morphine tolerance and, at the same time, reliable increases in [3 H]PDBu binding within laminae I-II of the spinal cord dorsal horn of these same rats when examined on Day 8 as compared to saline controls ($P < 0.05$). Both the development of morphine tolerance and the increase in [3 H]PDBu binding were potently prevented by i.t. co-treatment of morphine with 160 nmol GM1 ganglioside (an inhibitor of PKC translocation) when tested on Day 8 as compared to saline plus morphine controls (each $P < 0.05$). GM1 ganglioside (10, 30, 60 mg/kg) given intraperitoneally at 30 min before each subcutaneous (s.c.) morphine injection (10 mg/kg) for 9 days also prevented the development of morphine dependence as indicated by reliably less naloxone (2mg/kg) precipitated jumping at 24 hr after the last morphine treatment as compared to saline controls ($P < 0.05$). The results indicate a critical role of PKC in the development of morphine tolerance and dependence and suggest that the development of morphine tolerance and dependence may be mediated through central nervous system neuroplasticity initiated by PKC translocation following neuronal excitatory amino acid receptor activation. Supported by NS 24009 and VCU Grant-in-Aid.

BEHAVIORAL TESTING MAY PRODUCE TAIL-FLICK HYPERALGESIA IN RATS ACUTELY TREATED WITH MORPHINE. A.E. Baldwin, K.P. Myers, J.P. Willis, K.K. Newman, M.R. Dilley, & J.T. Cannon*. Department of Psychology & Neuroscience Program, University of Scranton, Scranton, PA 18510-4596.

Recently, Kaplan and Fields (1991) demonstrated hyperalgesia following naloxone injections in rats that had previously received a single morphine injection. They concluded that this was evidence for the development of acute tolerance and withdrawal.

Baldwin et al. (1992) found that simply exposing rats to a prolonged tail-flick stimulus can produce long lasting reductions of flick latencies. In the Kaplan and Fields study, all morphine-treated animals were behaviorally tested under the influence of morphine and were therefore exposed to repeated prolonged tail-flick trials. The present study examined the possibility that such testing contributes to the post-morphine hyperalgesia observed by Kaplan and Fields.

Male albino rats were tested 40 min after injection with pentobarbital (50 mg/kg i.p.). Baseline tail-flick latencies ($M = 4.22$ sec) were obtained at 1 min intervals. Animals (8/group) received either morphine (5 or 15 mg/kg s.c.) or saline injections. One saline and one 5 mg/kg morphine group were then tested for 40 min. The remaining 3 groups (saline, 5, and 15 mg/kg morphine) were handled at each test interval, but not exposed to the heat stimulus. All groups then received naloxone (5 mg/kg s.c.), and were then tested for 30 min. Surface tail temperatures were obtained following each test interval for all groups.

Post-naloxone latencies of the 5 mg/kg morphine group that was not tested while analgesia did not differ significantly from those of either saline group. Post-naloxone latencies of the 5 mg/kg morphine group that was tested were significantly lower than all other groups. This difference was not dependent on changes in tail temperature.

These data suggest that hyperalgesia following a single morphine injection may be dependent upon behavioral testing under the influence of morphine. In light of Kaplan and Fields' demonstration that the rostral ventromedial medulla is involved in the hyperalgesia they examined, this region of the brain may also mediate the hyperalgesia observed here and in our previous work, which did not involve the administration of opiates.

735.18

MULTIPLE INJECTIONS OF ISOPROTERENOL DELAY THE RAPID DECLINE OF ENDOGENOUS MELATONIN PEAK IN TURKISH HAMSTERS. S.M.Hong* and M.H.Stetson. Univ. of Delaware, Newark, DE 19716.

In a preliminary study, we found that multiple injections of isoproterenol (ISO) generate an overall stimulatory effect on induction of pineal melatonin synthesis in Turkish hamsters (*Mesocricetus brandti*) and that the effect is not as potent as in Syrian hamsters (*Mesocricetus auratus*). In order to further examine the role of beta-adrenergic components in generating the endogenous melatonin peak, Turkish hamsters were subjected to 4 injections of ISO (1 mg/kg B.W.) beginning at 0600 h with the room light off until the end of experiment (normal light onset, 0800 h). ISO or saline injections were given s.c. every two hours from 0600 h to 1200 h and pineal glands were collected under dim red light every hour from 0700 h to 1000 h and every other hour from 1000 h to 1400 h. Uninjected animals were also sacrificed every other hour from 2000 h to 0800 h. ISO injected animals showed a significantly higher content of pineal melatonin than in saline groups at 0800, 0900 and 1000 h ($p = 0.0006, 0.0225, \text{ or } 0.0006$, respectively, LSMeans). These results suggest that the beta-adrenergic receptors play a critical role in maintaining the endogenous melatonin peak in Turkish hamsters. (supported by NSF Research Grant DCB87-14638)

736.2

THERMAL HYPERALGESIA ASSOCIATED WITH THE DEVELOPMENT OF MORPHINE TOLERANCE IN RATS: ROLE OF EXCITATORY AMINO ACID RECEPTORS AND PROTEIN KINASE C J. Mao, D.D. Price, J. Lu and D.J. Mayer, Dept. Anesthesiology, Medical College of Virginia, Richmond, VA 23298

In a rat model of morphine tolerance and dependence induced by repeated intrathecal (i.t.) morphine treatment, we examined whether thermal hyperalgesia develops in association with the development of morphine tolerance. Once daily i.t. treatment with 10 μ g morphine sulfate for 8 consecutive days reliably induced tolerance to the analgesic effect of morphine (tail-flick test) as compared to saline controls ($P < 0.05$) when examined on Day 8. In association with the development of morphine tolerance, foot-withdrawal latencies to radiant heat were significantly reduced ($P < 0.05$), i.e., thermal hyperalgesia, in these same rats when tested on Day 8 before morphine treatment or Day 10 (48 hr after the last morphine treatment). Both the development of morphine tolerance and thermal hyperalgesia were reliably prevented by co-treatment of morphine with MK 801 (an NMDA receptor antagonist, 10 nmol, $P < 0.05$) or GM1 ganglioside (a protein kinase C inhibitor, 160 nmol, $P < 0.05$). In addition, a single treatment with MK 801 (10, 5, not 2.5 nmol) or CNQX (a non-NMDA receptor antagonist, 160, 80, not 40 nmol), but not GM1 (160 nmol), reliably reversed thermal hyperalgesia that had developed following repeated morphine administration on Day 10 when tested 30 min after each drug treatment (each $P < 0.05$). These results indicate that thermal hyperalgesia develops in association with the development of morphine tolerance and that NMDA/non-NMDA receptors and protein kinase C may mediate the thermal hyperalgesia. The data suggest that repeated morphine treatment may exacerbate some clinical pain states such as neuropathic pain and post-operative pain. Supported by PHS grant NS 24009 and Virginia Commonwealth University Grant-in-Aid.

DOSE-DEPENDENT DIMINISHED SENSITIVITY TO MORPHINE PLACE PREFERENCE IN RATS WITH PERSISTENT INFLAMMATORY PAIN. K. J. Sufka*. Department of Psychology, University of Mississippi, Oxford, MS 38677.

Rats display preferences to environments that have been previously paired with positively reinforcing drugs. Morphine possesses both positively (reward) and negatively (analgesic) reinforcing effects. The present research sought to determine whether animals experiencing chronic pain would display an enhanced place preference to morphine. Persistent inflammatory pain was induced by unilateral injections of complete Freund's adjuvant (0.1 ml) into the rat hindpaw. Rats received 8 counterbalanced conditioning trials (4 drug, 4 no-drug) of 60 min. each to various morphine doses (Exp. 1: 0.0, 0.1, & 1.0 mg/kg; Exp. 2: 0.0, 3.0, & 10.0 mg/kg) in a 3 compartment (2 stimulus, 1 neutral) place-preference apparatus. Significant place preference, as indexed by time spent in drug-paired chamber during a 15 min. test period, was observed in non-inflamed rats at all morphine doses tested. However, inflamed rats exhibited significant place preference only at the 3.0 and 10.0 mg/kg morphine doses. This diminished sensitivity to morphine's reinforcing effects in inflamed animals may reflect the development of tolerance resulting from activation of the endogenous opioid system during persistent inflammatory states.
