To date, two key pieces of evidence are lacking to substantiate the hypothesis that NGF may provide an effective means to treat neurodegenerative diseases: (1) better evidence that NGF enhances activity or function of basal forebrain cholinergic neurons under conditions of neurodegeneration (as opposed to atrophy); and (2) an effective and convenient means of delivering NGF to the target cells in the brain. The present studies were intended to address these issues. The neurotoxin AF64A (infused ICV, bilaterally) was used to induce degeneration of the basal forebrain cholinergic neurons. In this first study NGF was continuously infused into the lateral ventricles via an Alzet pump. The results demonstrated a reliable decrease in high affinity choline uptake (HACU) due to AF64A neurotoxicity and nearly complete protection via ICV NGF infusions. Thus, these data demonstrate that NGF is able to provide a protective and/or a compensatory response against neurotoxic-induced degeneration of the basal forebrain cholinergic system.

In a second study, we attempted to determine whether similar effects could be achieved through peripheral (IV) administration of NGF conjugated to the transferrin receptor antibody, OX26. This conjugate has been shown previously to transport NGF across the BBB. As in the first study, substantial degeneration of basal forebrain neurons was accomplished via bilateral ICV injections of AF64A. While no difference between HACU in NGF or vehicle-treated groups was observed (i.e., both showed significant decreases due to AF64A), HACU in rats administered the NGF/OX26 conjugate was increased by 50% compared to AF64A/vehicle-treated rats. However, immunocytochemistry directed against ChAT and the low affinity NGFR (p75) indicated that no increase in cell number was achieved with the NGF conjugate. Thus, under the conditions employed in this study, the NGF conjugate apparently increased HACU by enhancing the activity (and presumably the vitality and function) of surviving neurons while not necessarily protecting against the AF64A cytotoxicity, per se.

TRANSFORMING GROWTH FACTORS- β 2 AND 3 ARE POTENT SURVIVAL FACTORS FOR EMBRYONIC MIDBRAIN DOPAMINERGIC NEURONS. **K. Poulsen, M. Hynes, R. Klein, M. Armanini, H. Phillips, A. Rosenthal^{*}**. Dept. of Neuroscience, Genentech, Inc., South San Francisco, CA 94080.

The physiological factors that regulate survival of midbrain dopaminergic neurons have not yet been identified with certainty. Here we show that, transforming growth factors (TGF)- β 2 and TGF- β 3, at picomolar concentrations, prevent the death of embryonic dopaminergic neurons in culture, and that both factors are expressed in the environment of dopaminergic neurons. TGF- β 2 & 3 could therefore be physiological trophic factors for midbrain dopaminergic neurons and may be useful as therapeutic agents for Parkinson's disease.

REGULATION OF THE LOW-AFFINITY NGF RECEPTOR. **S.M. Abelleira^{1*}, R.M. Carroll¹, R.L. Dean¹, R.J. Fundekian¹, J.H. Kordower², V. Charles², R.T. Bartus¹**. ¹Alkermes, Inc., Cambridge, MA, 02139. ²Rush Presbyterian/St. Lukes Medical Center, Chicago, IL 60612.

It is known that while the cholinergic interneurons of the rat striatum express the low-affinity NGF receptor (LNGFR) during development, the immunoreactivity of these neurons to monoclonal antibody against this receptor (p75) is lost in adults. Previous findings [Gage et al., Neuron, 1989] indicate that the cholinergic neurons of the adult striatum will resume their p75 immunoreactivity in response to striatal damage and that this phenomenon is apparently modulated by endogenous NGF.

Because immunoreactivity of the LNGFR following tissue damage may provide fundamental information on the modulation and function of this receptor, we studied various parameters which might affect immunoreactivity. Injury was administered in one group by implantation of a cannula unilaterally into the striatum (AP+0.7, L-2.5, DV-5.0), and attached to an Alzet 2002 osmotic pump. In addition to injury, this group also received a 14 day continuous infusion of either NGF (300 ng/day) or ACSF. Injury was administered to a second group via injection of quinolinic acid (90 or 120 nM) into the striatum. In both cases animals were sacrificed and the tissue was processed for p75 and ChAT immunohistochemistry. Results indicate that contrary to expectations, in neither group was p75 immunoreactivity of striatal cholinergic neurons observed, despite clear immunoreactivity of septal-diagonal band cholinergic neurons in the same sections. Additionally, pronounced hypertrophy of ChAT immunoreactive striatal cholinergic neurons was seen in the NGF infusion group, demonstrating a biologically effective NGF response in these neurons.

In summary, the lack of striatal p75 immunoreactivity in either the damaged or NGF infused animals, in the face of clear p75 immunoreactivity in the septum, as well as NGF-induced ChAT(+) striatal hypertrophy, raises more questions than answers. While regulation and function of the LNGFR remains an area of interest and intrigue, these results suggest that a final analysis of this phenomenon will not likely be simple.

INTRAVENOUS ADMINISTRATION OF AN NGF CONJUGATE PREVENTS THE DEGENERATION OF CHOLINERGIC STRIATAL NEURONS IN A MODEL OF HUNTINGTON'S DISEASE. **V. Charles¹, P.M. Friden², R.T. Bartus², C. Anderson^{3*}, S. Putney², L.R. Walus², and J.H. Kordower¹**. ¹Dept. Neurological Sciences, Rush Presbyterian Med. Ctr., Chicago, IL 60612; ²Alkermes Inc., Cambridge Ma. 02139., ³Dept. Anatomy and Cell Biology, Univ. Illinois School of Medicine, Chicago Ill. 60612.

We have previously demonstrated effects on CNS cholinergic neurons following intravenous (iv) administration of an NGF-anti-transferrin receptor antibody conjugate (OX26-NGF). The present study investigated whether iv infusions of the OX26-NGF conjugate could cross the blood brain barrier and protect cholinergic striatal neurons against excitotoxicity in a manner similar to that seen previously with central NGF. All rats received an intrastriatal infusion of quinolinic acid (120 nmol). Rats received iv injections of vehicle (n=9), a nonconjugated mixture of OX26 and NGF (n=8) or the OX26-NGF conjugate (n=12). Injections were made for two consecutive days prior to the lesion, the day of the lesion, and every other day thereafter for 14 days. The dose of NGF was 20 μ g per injection for both the NGF conjugate and NGF mixture groups. Rats receiving the vehicle or the nonconjugated mixture of NGF and OX26 displayed similar reductions in striatal ChAT-immunoreactive neurons (38.7% & 42.8%). The loss was significantly attenuated in rats receiving the OX26-NGF conjugate (24%; p<.01). The protective effect was specific for cholinergic neurons since similar losses of somatostatin or diaphorase-containing striatal neurons was observed regardless of treatment. Neurochemical analyses from additional animals demonstrated that there was a dose-dependent increase in the amount of NGF delivered to the brain following a single iv injection of the OX26-NGF conjugate (1-20 μ g). These data demonstrate that systemic administration of a NGF-antibody conjugate can cross the blood-brain barrier and prevent the degeneration of central NGF responsive neurons.

NGF-TRANFERRIN FUSION PROTEIN RESCUES CHOLINERGIC MEDIAL SEPTUM NEURONS IN FIMBRIA-FORNIX TRANSECTED RATS E.-C. Park*, A.J. Schutz, P. Lynch, P. Jin, T. Lee, R.M. Starzyk, M. Percoskie, R. Dean, Y. Lee, D. Carriero, S. Abelleira, R. Carroll, R. Bartus and S. Putney. Alkermes, Inc., Cambridge, MA 02139

We have constructed plasmids that were used to express human nerve growth factor (NGF)-human transferrin fusion proteins in chinese hamster ovary (CHO) cells. To facilitate dimerization of NGF molecule, the hinge region from human IGG3 sequence was used to link the NGF moiety with the transferrin moiety in the fusion protein. The fusion protein present in tissue culture supernatant was purified using anti-NGF antibody affinity column chromatography to approximately 90% purity. When the N-terminus of the fusion protein was sequenced, it was identical to the mature human NGF protein sequence, showing that the fusion protein is processed correctly in CHO cells. The fusion protein migrated as a dimer in non-reducing condition as expected from molecules containing IGG3 hinge.

The fusion protein retained full NGF activity *in vitro* as shown by its ability to stimulate neurite formation in 6-24 cells, a derivative of PC12 cell line transfected with trkA (provided by D. Kaplan and L. Parada, NCI) and approximately 1/4-1/2 of native transferrin binding affinity as measured by its ability to compete 125I-transferrin binding to purified soluble human transferrin receptor (cell line producing soluble human transferrin receptor was provided by S. Harrison, Harvard University).

To address whether the NGF-transferrin fusion protein retains NGF activity *in vivo*, we tested the fusion molecule in fimbria fornix transected rats. Rats that received the fusion protein *in vivo* at 300 ng NGF equivalent/day show significantly higher ChAT positive neurons in medial septum than those that received vehicle alone. This result confirms the *in vitro* 6-24 cell assay results and shows that the fusion protein retains NGF function *in vivo*.

Our ability to generate biologically active NGF molecule as a part of a fusion protein opens a new way to deliver NGF to specific target tissues by selecting an appropriate carrier molecule for a given target tissue. Furthermore, the approach can be applied to other neurotrophic agents.

ADMINISTRATION OF DIFFERENT NEUROTROPHINS PRODUCES DISTINCT AS WELL AS OVERLAPPING CHANGES IN STRIATAL NEUROPEPTIDE MRNA EXPRESSION H. Sauer¹, S.J. Wiegand², V. Wong², R.M. Lindsay², and A. Björklund¹. Dept. of Medical Cell Research, Biskopsgatan 5, S-223 62 Lund, Sweden; ²Regeneron Pharmaceuticals, Inc., Tarrytown, NY 10591.

In order to determine whether administration of exogenous neurotrophins can modulate the expression of neurotransmitter-related genes in the striatum we injected the neurotrophins NGF, BDNF, NT-3 and NT-4/5, as well as vehicle alone, into the dopamine-depleted striatum of unilaterally 6-hydroxydopamine-lesioned rats at a dose of 4 µg/4µl/day for 8 consecutive days (n=5/group). The brains were processed for *in situ* hybridization histochemistry for preproenkephalin (PPT), preproenkephalin (PPE), GAP-43, choline acetyltransferase (ChAT) and glutamic acid decarboxylase (GAD) mRNA. Dissected nigral tissue samples were assayed for levels of substance P protein.

Vehicle-, NGF- and NT-3-injected animals displayed a 6-OHDA-lesioned-induced down-regulation of striatal PPT-mRNA to 56-57% of contralateral. This decrease was significantly attenuated in BDNF and NT-4/5-injected animals, which displayed on average 92% of contralateral. The lesion-induced overexpression of PPE mRNA amounted to 209% of contralateral in vehicle-, 177% in NGF-, 258% in BDNF-, 245% in NT-3-, and 251% in NT-4/5- injected animals. Injection of NT-4/5 caused a significant 94% increase in the expression of GAP-43 mRNA, while NGF, BDNF, and NT-3 caused a moderate and non-significant elevation of 39-44% of contralateral. Nigral levels of substance P, as determined by radioimmunoassay, were found to be unaffected by neurotrophin administration. Data on ChAT- and GAD-mRNA expression will be presented. These data suggest that neurotrophins can have neuromodulatory effects in the basal ganglia, and that it is possible to ameliorate some of the effects of striatal dopamine denervation in the continued absence of a dopaminergic innervation.

NGF MICROINJECTION INTO THE ROSTRO-DORSAL PONTINE RETICULAR FORMATION OF THE CAT INDUCES ACTIVE SLEEP. I. Yamuy*, F.R. Morales and M.H. Chase. Department of Physiology, Department of Anatomy and Cell Biology and the Brain Research Institute, UCLA School of Medicine, Los Angeles, CA, 90024-1746.

Neurons that produce neurotrophins and neurons which express neurotrophin receptors are present in pontine regions involved in the generation of active sleep (*Neuron*, 5: 511, 1990; *J. Neurosci.*, 8: 2312, 1986; *Neuroscience*, 34: 89, 1990). We were therefore interested in testing the hypothesis that neurotrophins enhance or induce active sleep.

Three adult cats were prepared for monitoring sleep and wakefulness and for drug microinjection into the brainstem. Microinjections of a solution of NGFβ (Sigma, 0.5-4 µg diluted in 1 µl of vehicle) or a solution of vehicle [1 µl of phosphate buffered saline (PBS) with 0.1-1% of bovine serum albumine (BSA, Sigma)] were delivered to the pontine reticular formation ([PRF] (P 3, L 2, H -3.5)).

NGF injections evoked active sleep with a mean latency of 10 min (range, 3.5 to 20 min.). The percentage of time spent in active sleep during the first hour following NGF injection was significantly greater than that following vehicle injection (44% ± 2.8, n=30 vs. 7.4% ± 2.0, n=16, respectively, means ± SEMs, p<0.0002); this increase was accompanied by a significant reduction in the percentage of time spent in wakefulness and quiet sleep.

This finding indicates that PRF neurons in areas involved in the generation of active sleep are responsive to NGF. The relatively short latency for the response to NGF indicates that the signal transduction mechanisms responsible for active sleep induction were other than the transcriptional processes that have been postulated for NGF effects, which have latencies of more than 30 minutes (*Ann. Rev. Neurosci.*, 14: 421, 1991). It is well established that injections of muscarinic agonists into the PRF induce an active sleep-like state (*Brain Res.*, 414: 245, 1987) and it has been recently reported that NGF, probably by acting on low-affinity receptors, excites putative cholinergic neurons (*Exp. Brain Res.*, 93: 226, 1993). The present data indicate that NGF induces changes in neuronal excitability and raise the intriguing possibility that neurotrophins are implicated in mechanisms of behavioral state control. This work was supported by USPHS Grants NS 23426 and MH 43362.

DIFFERENTIAL EXPRESSION OF P75 IN SEPTAL CHOLINERGIC NEURONS IN RESPONSE TO DIFFERENT TYPES OF DEGENERATIVE PERTURBATIONS. P.M. Friden*, S.M. Abelleira¹, R. Carroll¹, R.L. Dean¹, R.W. Stackman², J.H. Kordower³, T.J. Walsh² and R.T. Bartus¹. Alkermes, Inc., 64 Sidney Street, Cambridge, MA 02139¹, Dept. of Psych., Rutgers Univ., NJ² and Dept. Neurol. Sci., Rush Med. Ctr., IL³.

The regulation and function of the low affinity NGF receptor (p75) are issues of current interest and controversy. To better understand the role of this receptor in basal forebrain cholinergic neurons, we analyzed tissue for changes in immunoreactivity to the p75 protein in two different models of neurodegeneration: AF64A toxicity and fimbria-fornix (FFX) transections. In the first model, 10 days following the bilateral administration of AF64A, we detected a significant reduction in the levels of hippocampal high-affinity choline uptake, as expected. Additionally, the number of septal choline acetyltransferase (ChAT)-immunoreactive neurons was reduced. However, enlarged fibers intensely immunoreactive for p75 were observed in the septum. These fibers were most prevalent in the area dorsal to the anterior commissure, were organized in a dorsal-ventral orientation and were never associated with an obvious cell body.

Brain sections from animals subjected to FFX lesions were characterized by a loss of acetylcholinesterase activity in the target tissue and both ChAT and p75-immunoreactive neurons in the septum. In contrast to the AF64A lesion, there was no evidence of thick p75+ fibers as a result of the FFX lesion. While it remains unclear whether the presence of these p75-positive fibers represents an aborted regenerative response (i.e. sprouting) or evidence of a degenerative response (i.e. tombstoning marker), it is likely that an understanding of this phenomenon may provide insight into the regulation and/or function of the p75 low affinity NGF receptor.

EXPRESSION OF BIOLOGICALLY ACTIVE NERVE GROWTH FACTOR (NGF) MEDIATED BY RECOMBINANT HERPES SIMPLEX VIRUS TYPE 1 (HSV-1) GENE TRANSFER VECTORS.

K.A. Lee¹, W.F. Goins^{1*}, D.J. Fink², S.T. DeKosky², and J.C. Glorioso¹.

Department of Molecular Genetics & Biochemistry¹, and Western Psychiatric Institute & Clinic², University of Pittsburgh School of Medicine, Pittsburgh, PA; and Department of Neurology, University of Michigan Medical School, Ann Arbor, MI³.

In order to study the effects of neurotrophic factors in chronic neurodegenerative conditions such as Alzheimer's and Parkinson's diseases, we have constructed replication compromised and replication defective (mutant d120: DeLuca et al., 1985, *J. Virol.* 56:558) Herpes simplex virus (HSV-1) gene transfer vectors that express the beta subunit of nerve growth factor (β-NGF). A cassette containing the human cytomegalovirus immediate early promoter (HCMV-IEP) driving transcription of the murine β-NGF cDNA was incorporated into the HSV-1 thymidine kinase (tk) gene locus. Acute infection of non-neuronal cells with the NGF vectors resulted in NGF specific transcript production as detected by Northern blot analysis. *In vivo* expression of the NGF transcript was observed by *in situ* hybridization two days following stereotactic injection of the expression vectors into the hippocampus of rat brains. These results suggest that the NGF vectors are transcriptionally active *in vitro* and *in vivo*. Cell culture supernatants displayed immunoreactive NGF protein production as detected by ELISA. This same culture supernatant also induced PC-12 cells to differentiate as observed by neurite sprouting. These two results indicate that the NGF vector infected cells produce and secrete mature, biologically active β-NGF. We are currently testing the NGF vectors for the length and level of bioactive β-NGF expression in the CNS *in vivo*. Thus, we are poised to use these vectors in studies of recovery from fimbria-fornix transections and excitotoxic lesioning of striatum in rat brain as models of chronic neurodegenerative conditions.

ASPHYXIA DURING BIRTH MAY PRIME THE CNS. Induction of a long-lasting increase in bFGF gene expression concomitantly with increased number of dopamine cell bodies in the substantia nigra.

^aK. Andersson*, ^dM. Blum, ^aY. Chen, ^aP. Eneroth, ^bB. Bjelke, ^bR. Diaz and ^cM. Herrera-Marschitz.

^aDept. Internal Medicine, Karolinska Institutet, Huddinge Hospital, 141 86 Huddinge, Sweden, ^bDept. Neuroscience and ^cDept. Physiology & Pharmacology, Karolinska Institutet, ^dFishberg Research Center for Neurobiology, Mount Sinai School of Medicine, New York, U.S.A.

Asphyxia was induced during birth to male Sprague-Dawley rat pups. A quantitative analysis of the number of tyrosine hydroxylase immunoreactive (TH-IR) and thionin-stained nerve cell bodies as well as measurement of basic Fibroblast Growth Factor (bFGF) mRNA levels was carried out in the substantia nigra and the hippocampus on male rats at 3-4 weeks of age. Asphyxia produced an increase in bFGF mRNA levels and a concomitant increase in the number of dopamine nerve cell bodies of the substantia nigra. Asphyxia reduced the number of cell bodies in the CA1 and CA3 regions of the hippocampus while bFGF mRNA levels remained unchanged.

In conclusion, the asphyxia-induced long-lasting increase in bFGF gene expression may cause the increase in dopamine cell body number in the substantia nigra. The present results indicate that asphyxia during birth can prime the development of the central nervous system in a long-term perspective which may be of importance in the development of neurodegenerative disorders later in life.

455.13

EVIDENCE FOR NOVEL NERVE GROWTH FACTOR (NGF)-RESPONDING NEURONAL POPULATIONS IN THE MAMMALIAN BRAIN. MH Cayouette^{*}, RR Sukhov^{*}, MJ Radeke^{*}, DL Price^{1,4} and VE Koliatsos^{1,4}. Departments of ¹Pathology, ²Neurology, and ³Neuroscience, ⁴Neuropathology Laboratory, The Johns Hopkins University School of Medicine, Baltimore, MD 21205; ⁵Neuroscience Research Institute, University of California, Santa Barbara, CA 93106.

In the CNS, only striatal and basal forebrain cholinergic neurons have been shown to respond to NGF. Both of these populations are also known to express the high-affinity NGF receptor, trkA. This study was designed to delineate novel NGF-responsive neuronal populations in the rat brain. Using *in situ* hybridization histochemistry and RT-PCR, trkA mRNA was found in the nucleus prepositus hypoglossi and ventral cochlear nucleus. TrkA protein was also detected by immunocytochemistry in the nucleus prepositus and in the dorsal and ventral cochlear nuclei. In addition, trkA immunoreactivity was seen in the spinal vestibular nucleus, neurons within the medial longitudinal fasciculus, and the gigantocellular nucleus of the reticular formation. NGF mRNA was present throughout the vestibular and auditory systems with high levels of expression in the cerebellum. These results suggested that NGF might play a role in cerebellar afferent systems. Radiolabeled NGF injected into various sites within the cerebellar cortex was retrogradely transported to the nucleus prepositus and spinal vestibular nucleus. The trkA and NGF expression patterns and retrograde transport data together identify novel trophic targets for NGF in the brain and raise the possibility that NGF may be used as a therapeutic agent for diseases of the vestibular and auditory systems.

455.15

COORDINATE EXPRESSION OF NEUROTROPHIN-3 AND TRK C LINKED TO A MORE FAVORABLE PROGNOSIS IN MEDULLOBLASTOMA. S.L. Pomeroy^{*}, L.C. Goumnerova, Y.K. Kwon, C.D. Stiles, R.A. Segal. Depts. Neurol. and Neurosurg., Children's Hospital, Dept. Cell. and Mol. Biol., Dana-Farber Cancer Inst., Harvard Medical School, Boston, MA 02115.

We have examined the expression of neurotrophins in medulloblastoma, a malignant brain tumor believed to be derived from the external germinal layer of the cerebellum. Northern and western analyses were performed on tumor samples (n = 11) which were snap frozen in the operating room to preserve RNA and protein integrity.

All of the tumors were found to express mRNA encoding neurotrophin-3 (NT-3) and its cognate receptor, trk C. Due to limited tissue, 3 tumor samples were tested and found to have NT-3 protein and Trk immunoreactivity. Patients with tumors expressing high levels of trk C mRNA had significantly longer intervals without disease progression than those with low levels (Kaplan-Meier, P = .02). Expression of trk A, trk B, or p75 was not associated with favorable disease outcome.

Coordinate expression of ligand and receptor implies the constitutive activation of Trk C receptors in patients with a more favorable outcome. Conceivably, this activation promotes the differentiation of medulloblastoma and may be relevant to the development of new therapeutic strategies for the tumor. At minimum, our findings indicate that trk C expression is a marker of prognostic value.

455.17

NT-3 ATTENUATES REDUCTION IN H-REFLEX PRODUCED BY PYRIDOXINE TOXICITY TO LARGE PRIMARY AFFERENT NEURONS IN RATS. K.D. Cliffer^{*}, M.E. Helgren, C.C. Cavnar, P.S. DiStefano, S.J. Wiegand, and R.M. Lindsay. Regeneron Pharmaceuticals, Inc., Tarrytown, NY 10591.

High doses of pyridoxine (vitamin B6) are toxic to large primary afferent neurons, producing a peripheral neuropathy in experimental animals that can serve as a model for toxic large-fiber neuropathies in humans. Affected neurons are part of the circuitry that mediates the monosynaptic stretch reflex and a neurophysiological correlate, the H-reflex. Sprague-Dawley rats were treated with pyridoxine (800 mg/kg/d), with or without additional NT-3 treatment. When half the animals receiving either of these two treatments developed severe deficits on a precise locomotor task, all were tested electrophysiologically. Animals receiving NT-3 without pyridoxine and non-injected control animals were also tested. We recorded electromyographic activity in the plantar muscles, evoked by stimulation of the tibial nerve. Amplitudes of directly evoked motor (M-) and reflex-evoked (H-) waves were recorded. M-wave amplitudes did not differ among groups. H-reflexes (amplitudes normalized to the M-wave amplitude as H/M ratio) were absent or greatly diminished in nearly all animals receiving pyridoxine without NT-3. The reduction was significantly attenuated in animals receiving NT-3, resulting in substantial H-reflexes in nearly all animals so treated. H-reflex amplitudes were correlated with performance on the locomotor task. The results are consistent with protection by NT-3 of large sensory fibers from neurotoxic damage, potentially including damage caused by chemotherapeutic agents.

455.14

IMPLANTATION OF GENETICALLY-MODIFIED CELL LINES PRODUCING NEUROTROPHIC FACTORS REVEAL TROPHIC SUPPORT TO ADULT NORADRENERGIC NEURONS OF THE LOCUS COERULEUS IN VIVO.

Ernest Arenas^{*}, Isabelle Neveu and Miles Trupp. Lab. of Molecular Neurobiology, Karolinska Institute, S-17177 Stockholm, Sweden.

Neurotrophins and the Glial cell line-derived neurotrophic factors (GDNF) are two families of trophic factors that support neuronal survival and/or regulate their phenotype. In order to investigate the role of neurotrophic factors *in vivo*, stable cell lines secreting high levels of recombinant neurotrophins or GDNF have been produced and transplanted into the brain. We have previously reported that NT3, but not any other neurotrophin produced by the cell lines, is able to promote the survival of the noradrenergic neurons of the locus coeruleus in a 6-hydroxydopamine lesion model that resembles the pattern of cell death found in Alzheimer's disease. It is now being examined whether GDNF may promote the survival of noradrenergic neurons *in vivo* and what receptors are involved in mediating the survival-promoting effects on locus coeruleus neurons. We are also studying whether these neurotrophic factors are able to modify the phenotype of central noradrenergic neurons *in vivo*, as shown by changes in the levels of the specific marker, tyrosine hydroxylase. Finally, since NT3 supported the survival of adult central noradrenergic neurons *in vivo* and it is expressed in their target fields, we are analyzing whether NT3 could act as a target derived neurotrophic factor for the neurons of the locus coeruleus. This question is being addressed by measuring the levels of expression of neurotrophic factors in the target tissues both after selective noradrenergic lesions and after noradrenergic activation.

455.16

NERVE GROWTH FACTOR ACUTELY ENHANCES THE RESPONSIVENESS OF DORSAL HORN NEURONES TO NOXIOUS HEAT. N.Andreev^{*}, M. Inuishin, and S.B. McMahon. Dept. Physiology, UMDS, London, SE1 7EH, UK.

The responses of single convergent dorsal horn neurones to a standard heat ramp (c.1 °C/sec to 52°C) were measured before and after a s.c. dose of human recombinant NGF (0.5 µg in 50 µl) or, as a control, 50 µl saline, into the centre of the neurone's receptive field (RF), in adult anaesthetised rats.

The rapid enhancement of dorsal horn neurone responsiveness, see figure, indicates that this dose of NGF can sensitize primary afferent nociceptors. Supported by the MRC and Royal Society.

455.18

THE UPREGULATION OF NGF DURING INFLAMMATION PRODUCES PAIN HYPERSENSITIVITY AND AN INCREASED GROWTH CAPACITY IN PRIMARY SENSORY NEURONS. C.J. Woolf, B. Safieh-Garabedian, T. Leslie, J. Winter. SPON: Brain Research Association. Dept. of Anatomy, University College London, London WC1E 6BT, Sandoz Institute for Medical Research, 5 Gower Place, London WC1E 6BN

The inflammation produced by an intraplantar injection of complete Freund's adjuvant results in a significant elevation in NGF levels, first in the inflamed tissues, then in the innervating nerves. This is accompanied by the development of substantial thermal and mechanical hyperalgesia, and an upregulation in DRG neurons of the mRNA neuropeptides substance P, and CGRP and the growth associated protein GAP-43. Systemic pretreatment with a neutralizing anti-NGF antibody which does not recognize BDNF or NT3, prevents the development of the abnormal sensitivity and the changes in chemical phenotype, without reducing local edema or erythema. The production of increased levels of NGF in the periphery during inflammation may have a key role in generating inflammatory pain hypersensitivity by; increasing transduction sensitivity, amplifying the input to the dorsal horn, sensitizing dorsal horn neurons and promoting a hyperinnervation of the inflamed area by inducing collateral sprouting.

Supported by Sandoz and the Sir Jules Thorn Trust.

455.19

BRAIN DERIVED NEUROTROPHIC FACTOR (BDNF) PRODUCES AN ANTI-DEPRESSANT LIKE EFFECT IN TWO ANIMAL MODELS OF DEPRESSION. Judith A. Siuciak*, Dacie Lewis, Stanley J. Wiegand and Ronald M. Lindsay, Regeneron Pharmaceuticals, Tarrytown, NY, 10591

We have previously reported that midbrain infusion of the BDNF, a member of the NGF/neurotrophin family, produced analgesia and increased serotonergic activity within the brain and spinal cord (Siuciak et al., 1994). Alterations in serotonergic function are involved in the pathogenesis and treatment of depression. The present study examined the ability of BDNF to produce antidepressant-like effects in two animal models of depression, the forced swim test and the learned helplessness paradigm. Adult rats were infused with BDNF (24 ug/day) or PBS vehicle into the midbrain, near the PAG and dorsal raphe, as previously described (Siuciak et al., 1994). In the forced swim test, BDNF infusion (day 5) produced a 70% decrease in immobility time in the 5 min post-test as compared to vehicle-infused controls (46.6 ± 16.8 vs. 155.5 ± 27.8 sec). In the learned helplessness model, rats pre-exposed to inescapable shock showed severe impairments in escape behavior during subsequent conditioned avoidance trials (51% decrease in the number of escapes, 5 fold increase in escape latency). Midbrain BDNF infusion reversed this escape deficit to levels similar to that obtained from non-shocked control rats. No changes in locomotor activity as measured by the total number of 60° partial rotations or grid activity was seen. These data demonstrate an anti-depressant-like action of midbrain-infused BDNF. Furthermore, these results suggest a possible role for neurotrophins in the etiology and treatment of neuropsychiatric disorders.

NT-3 ATTENUATES PROPRIOCEPTIVE DEFICITS IN THE ADULT RAT WITH A LARGE FIBER NEUROPATHY. M.E. Helgren*, K. Torrento, P.S. DiStefano, B. Curtis, R.M. Lindsay and S.J. Wiegand, Regeneron Pharmaceuticals, Inc., Tarrytown, NY 10591.

The spatial and temporal pattern of expression of neurotrophins and their cognate receptors provide insight into the role of trophic factors in establishing the mammalian nervous system's structure-function relationship. For example, NT-3 and its receptor, TrkC, are prevalent in the proprioceptive system where connections of muscle and joint afferents with their central and peripheral targets are critical for feedback during movement. Early in development NT-3 and TrkC mRNA are expressed at high levels in skeletal muscle (peripheral target) and large (proprioceptive) DRG neurons, respectively. Both messages decrease in the adult suggesting that low levels are sufficient for maintaining homeostasis, but may be inadequate for providing support following injury. Pyridoxine (vitamin B6) is a selective neurotoxin for large DRG cells and at 800mg/kg/d for 8-14 days produces a distinct sensory-motor neuropathy in which axonal retrograde transport of 125 I-NT-3 to DRGs is greatly reduced, reflecting the loss of TrkC expressing sensory neurons. Using behavioral and morphometric analyses we examined the effect of NT-3 in this neuropathy model. We developed a quantitative assay to test proprioceptive function. Trained rats cross a 6' beam and a motor score is calculated based on paw placement: scale 1 (normal) - 4 (severely impaired). Rats receiving pyridoxine + NT-3 performed significantly better on this task than vehicle control rats. Taken together with cell counts and area measurements our results indicate that NT-3 can overcome the functional and anatomical deficits produced by pyridoxine neurotoxicity. These data may be relevant to the treatment of human large fiber peripheral neuropathies.

DEVELOPMENT OF THE AUDITORY AND VESTIBULAR SYSTEMS

456.1

DEVELOPMENT OF SOMATOSTATIN AND LEU-ENKEPHALIN IN THE AUDITORY BRAINSTEM OF THE RAT. M. Kungel* and E. Friauf, Univ. Tübingen, Animal Physiology, Auf der Morgenstelle 28, 72076 Tübingen, Germany.

During early ontogeny, the neuropeptides somatostatin and leu-enkephalin are prominent in several brain areas and are therefore thought to be involved in developmental events. This study was focused on the developmentally related expression of these peptides in the auditory brainstem of the rat by means of PAP-immunocytochemistry between the ages of embryonic day 17 and adulthood. During fetal development somatostatin immunoreactive (SIR) somata appeared in the nuclei of the lateral lemniscus (NLL), the cochlear nucleus complex (CN), and the inferior colliculus (IC), whereas SIR fibers were predominantly found in the superior olivary complex (SOC) and in the IC. In all these auditory brainstem nuclei, the immunoreactivity increased dramatically until postnatal day (P) 7. At this age the immunoreactivity in the brainstem was nearly restricted to auditory nuclei, which showed a heavy labeling. The most dense SIR fiber network was found in the SOC, which most probably originated from neurons of the CN, thus providing a system-immanent innervation. Subsequently SIR decreased dramatically until adulthood. In contrast to the transient expression of somatostatin, the number and labeling intensity of leu-enkephalin immunoreactive (LIR) structures increased progressively with age. LIR fibers in the fetal brain appeared in the SOC, NLL, CN and IC. LIR somata were found only after P12 in the CN and in the IC. Our results demonstrate a strong and transient expression of somatostatin and a progressive increase of the leu-enkephalin expression during development. Both neuropeptides are expressed during a period when synapse stabilization occurs in the rat auditory brainstem, suggesting that they may play a role in synaptic refinement. DEVELOPMENT OF PRIMARY VESTIBULAR AFFERENTS AND VESTIBULOSPINAL PROJECTIONS IN THE OPOSSUM, MONODELPHIS DOMESTICA. J.-F. Pflieger* and T. Cabana, Sciences Biologiques, Université de Montréal, C.P. 6128, Succ. centre-ville, Montréal, Canada, H3C 3J7.

The opossum *Monodelphis domestica* is born after only 14 gestational days. It is then very immature (eyes and ears closed, budlike hindlimbs, etc.) but has the capacity to locomote on the mother's belly with its forelimbs, from the genital aperture to a nipple where it attaches and stays until about postnatal day 28. This behavior of the newborn suggests that some sensory systems must be present to guide it. One such system may be the vestibular system, which is known to mediate sensory clues about linear and rotational head movements, and which has a strong influence on posture and balance during locomotion in adult mammals. We have looked at the development of the primary afferents to the vestibular nuclei and the vestibular projections to the spinal cord using the neuroanatomical tracing of Dil and WGA-HRP. We have found that VIIIth nerve fibers have attained the vestibular nuclear complex at birth and that some of the fibers project to the contralateral vestibular ganglion, a projection which was not found in the adult opossum. Projections from the lateral vestibular nucleus, and, to a much lesser extent, parts of the median and the inferior vestibular nuclei, to the brachial and lumbosacral enlargements of the spinal cord are also present on the day of birth. Without excluding the possibility of olfactory and/or tactile guidance for directing the "climbing" behavior of the newborn opossum, the vestibular system is likely involved.

456.3

POSTNATAL DEVELOPMENT OF THREE ISOFORMS OF PROTEIN KINASE C IN CENTRAL AUDITORY PATHWAYS OF THE RAT BRAIN. M.M. Garcia* and R.E. Harlan, Depts. of Otolaryngology and Anatomy and Neuroscience Training Program, Tulane University School of Medicine, New Orleans, LA 70112.

Although several protein kinase C (PKC) isoforms are highly expressed in brain, little is known about patterns of expression of PKC during development of the CNS. We used immunocytochemistry to study the ontogeny of PKC- β I, β II and γ in central auditory pathways of the rat brain, at postnatal (P) days 5, 11, 15, 20, and adult. With the β I antibody, labeled fibers were found in primary afferents of the VIIIth nerve in all ages. Weakly labeled terminals were found in the ventral cochlear nucleus (VCN) at P5 only; no terminals were found in the dorsal cochlear nucleus (DCN), suggesting that the labeled afferents are primarily vestibular. Labeled cells were found in the VCN at all ages, with a few labeled cells in the DCN in adults only. Labeled terminals were found in the superior olive (SO) beginning at P15. Cell body labeling was found in the SO and trapezoid body (TZ) beginning at P11. Labeled fibers were found in the lateral lemniscus (LL) at all ages, with labeled terminals on neurons of the nucleus of the LL (NLL) beginning at P20. Labeled terminals and a few labeled cells were found in the inferior colliculus (IC) at all ages, and in the medial geniculate (MG) at P20 and adult. With the β II antibody, a few labeled fibers were found in the VIIIth nerve as early as P11, corresponding to a few labeled terminals in the DCN beginning at the same age. Labeled cells were found consistently in the VCN beginning at P15. Cells decorated with labeled terminals were found in the SO beginning at P11. Cytoplasmic staining of SO cells was also noted beginning at P15. Staining of TZ cells was found beginning at P11. Decorated cells were found in the NLL and IC beginning at P11. Labeled cells and terminals were found in the IC and MG at most ages. With the γ antibody, labeled cells were first observed in the VCN and DCN at P11. Labeled terminals were found in the SO beginning at P11. Labeled terminals were found in the central core of the IC at all ages, and in the MG beginning at P15. These results suggest that these isoforms of protein kinase C may play roles in the development and function of central auditory pathways. (Supported by the Deafness Research Fnd.)

456.4

POSTNATAL DEVELOPMENT OF THREE ISOFORMS OF PROTEIN KINASE C IN CENTRAL VESTIBULAR PATHWAYS AND CEREBELLUM OF THE RAT. R.E. Harlan* and M.M. Garcia, Depts. of Anatomy and Otolaryngology and Neuroscience Training Program, Tulane Medical School, New Orleans, LA 70112.

The protein kinases C are a family of enzymes which are enriched in brain, yet little is known about their abundance during development of the CNS. We used immunocytochemistry to study the ontogeny of the β I, β II and γ isoforms of protein kinase C in the vestibular system and cerebellum of the rat brain, at postnatal (P) days 5, 11, 15, 20, and adult. With the β I antibody, immunoreactivity (ir) was visible in primary afferents of the VIIIth cranial nerve at all ages. Labeled terminals were found in the medial vestibular nucleus (MeVN) from P11 through adult. Cell bodies in all vestibular nuclei were labeled at P5, but this labeling persisted only in the MeVN. Labeled cells were found in the deep cerebellar nuclei at all ages. Strongly-ir fibers were found in the white matter layer of the cerebellum, with development in the hemispheres proceeding faster than in the vermis. Large labeled cells, possibly Golgi neurons, were found in the internal granular layer at P5-P15. At P20 and adult, many granule cells were labeled. With the β II antibody, ir was not seen in the VIIIth nerve at any age, although some punctate ir was found in all vestibular and deep cerebellar nuclei from P5 to P20. Labeled cell bodies in all vestibular and deep cerebellar nuclei were seen at P20 and adult. In the cerebellum, strongly-ir cells were found in the external granular layer at P5, and to some extent at P11. Internal granular cells were labeled at P5, P11 and adult. Apparent labeled terminals were found on Purkinje cells beginning at P11. With the γ antibody, strongly-ir fibers were found innervating the vestibular and deep cerebellar nuclei at all ages. Strong ir was found in Purkinje cells, with projections to deep nuclei, at all ages. These results suggest that these isoforms of protein kinase C, especially the γ isoform, may play roles in the development and function of the vestibular system and cerebellum. FIBER OUTGROWTH AND PATHFINDING IN THE DEVELOPING AUDITORY BRAINSTEM. M. Niblock², J.K. Bruno-Bechtold^{1,2}, and C.K. Henkel^{1,2}. Dept. of Neurobiology and Anatomy¹ and Program in Neuroscience², Bowman Gray Medical School, Wake Forest Univ., Winston-Salem, NC 27157

The trapezoid body decussation carries information that is essential to the localization of sound by the mammalian auditory system. The trapezoid body decussation consists of fibers from the ventral cochlear nucleus that terminate in the contralateral superior olivary complex. The purpose of this study was to establish the developmental time course of the decussation and to examine the relationship of the fibers and their growth cones to potential cues during pathfinding. The carbocyanine dye DiI was placed in the area of the presumptive cochlear nucleus in rats aged E13, E15, and E17 in order to label the efferent fibers and their growth cones. At E13, although cochlear nucleus neurons were just beginning to migrate away from the rhombic lip ventricular zone, they were already sending axons along the marginal edge of the hindbrain towards the midline. By E15, many fibers had entered the midline region and some appeared to contact glial cells at the midline. In addition, by this time some of the fibers had crossed the midline and had reached the vicinity of the presumptive superior olivary complex on the contralateral side. At E17, the presumptive cochlear nucleus could be clearly distinguished on the lateral surface of the hindbrain and there was a noticeable increase in the number of fibers in the trapezoid body decussation. Based on growth cone morphology and axon trajectory, it does not appear that all trapezoid body fibers depend on the basal lamina for guidance during pathfinding. In addition, growth cone complexity did not show any consistent increase in the floorplate region. Growth cone contact of glial cells at the midline is consistent with these cells playing a role in directing fibers across the midline to their targets.

FREQUENCY-DEPENDENT ADJUSTMENT OF BINAURAL TUNING PROPERTIES IN THE BARN OWL'S OPTIC TECTUM AS A RESULT OF ALTERED AUDITORY EXPERIENCE. J.L. Gold* and E.L. Knudsen. Dept. of Neurobiology, Stanford University School of Medicine, Stanford, CA 94305.

Barn owls localize sounds by combining auditory cues, including interaural differences in timing (ITD) and level (ILD), which are computed across a broad range of frequencies. The auditory space map in the optic tectum (OT) contains neurons responsive to broadband noise stimuli from restricted receptive fields. Previous studies have shown that, in the OT, neuronal tuning to ITD and ILD for narrowband noise stimuli reflects the frequency-dependence of the cues corresponding to the unit's receptive field. We examined the extent to which such frequency-dependent tuning is shaped by experience by testing the ability of neurons in the OT to adjust to novel, frequency-dependent localization cues.

An ear plug-like device ("twisted tube") was developed and shown via cochlear microphonic and probe tube microphone measurements to affect the timing and level of sounds in a frequency-dependent manner. Juvenile owls were raised for 60 d with a twisted tube in one ear. The resulting adjustments of tectal ITD and ILD tuning were assayed in two ways. First, neuronal tuning to dichotically-presented, narrowband stimuli was characterized at a variety of sites. The frequency-dependence of both ITD and ILD tuning was shown to reflect the frequency-dependent changes in acoustic cues caused by the twisted tube. Second, with the twisted tube removed, the auditory receptive fields measured with narrowband stimuli of different frequencies were shown to be misaligned in both azimuth and elevation, corresponding to the frequency-dependent changes in ITD and ILD tuning, respectively. Re-insertion of the device realigned the receptive fields, thereby demonstrating the compensatory nature of the adaptive adjustments. Thus, experience-dependent plasticity shapes the frequency-dependence of unit tuning to ITD and ILD of neurons in the barn owl's optic tectum.

RETINAL PROJECTIONS INDUCED INTO AUDITORY THALAMUS IN FERRETS: DIFFERENTIAL TERMINAL DISTRIBUTION AND EYE-SPECIFIC ZONES. A. Angelucci*, F. Clascá and M. Sur. Dept. of Brain & Cognitive Sciences, M.I.T., Cambridge, MA 02139.

Retinal axons can be induced to innervate the auditory thalamus following neonatal lesions in ferrets. We have now shown that induction of retinal projections into the medial geniculate nucleus (MGN) critically depends on extensive ablation of its ascending inputs including those from both inferior colliculi, as well as from other auditory brainstem nuclei.

To examine the pattern of retinal innervation to the MGN, adult "rewired" ferrets received binocular injections of cholera toxin B subunit (CTB). The procedure stains axons and terminals in detail, thus allowing reconstruction of single axons. Retinal fibers can invade all the subdivisions of the MGN, but consistently avoid its caudal part. The ventral and the medial divisions are the most densely innervated. In general, axons innervating the ventral division enter the MGN directly from the optic tract. These axons are thick (2-4 µm diameter), are more highly branched, and have large clustered boutons. Retinal axons innervating the medial division enter the MGN through the lateral posterior nucleus (LP), the pretectal nuclei (PT) and the lateral terminal nucleus. They are thin (0.3-0.6 µm diameter), have smaller boutons and sparser terminal arborizations. Axons entering the MGN through the LP and PT can also arborize in the dorsal division and in the posterior nucleus (Po).

By injecting WGA-HRP into one eye and CTB into the other, we find that both eyes project to the same areas of MGN and the LP, the ipsilateral projection being less dense. The patches of projections formed by one eye are adjacent to, but clearly segregated, from those formed by the other eye. In LP, the projection from each eye appears band-like. These data suggest that while the site of retinal arborization into the MGN depends on factors intrinsic to the target, retinal axons play a significant role in forming specific patterns of terminal distribution.

456.6

A TRANSIENT DEVELOPMENTAL GRADIENT OF GLYCINERGIC ENDINGS IN THE FERRET SUPERIOR OLIVARY NUCLEI. C.K. Henkel* and J. K. Bruno-Bechtold, Department of Neurobiology and Anatomy, Neuroscience Program, Wake Forest University, Bowman Gray School of Medicine, Winston-Salem, North Carolina 27157.

The development of inhibitory connections from the medial nucleus of the trapezoid body (MNTB) to the lateral (LSO) and medial (MSO) superior olivary nuclei was investigated in ferrets using immunocytochemistry with antibody for glycine (courtesy of Dr. R. Wenthold). We were particularly interested in whether or not the glycinergic inputs develop along a tonotopic gradient. Videomages of LSO and MSO in selected immunostained sections at 7 postnatal ages were digitized. Samples of the neuropil were analyzed and averaged to determine the relative density of glycine immunostaining. Only a diffuse background matrix is immunostained in the neuropil at postnatal day 7, but by the end of the second postnatal week immunostaining in the neuropil is more granular. Between the third and fourth postnatal weeks, the neuropil has the characteristic puncta of immunostained endings in the adult. A gradient is present across the tonotopic axis of both nuclei during the earliest period of diffuse immunostaining. At this time, there is nearly a two-fold increase in density of immunostaining from low to high frequency regions. By postnatal day 28 when puncta are evident, glycine immunostaining is homogeneous all along the tonotopic axis. Glycine-immunopositive cells in the MNTB appear progressively along a spatial gradient during the first postnatal month as this maturation of glycinergic terminals in LSO and MSO is taking place.

TOPOGRAPHY OF THE PROJECTION FROM THE CENTRAL TO THE EXTERNAL NUCLEUS OF THE INFERIOR COLLICULUS IN NORMAL AND PRISM-REARED BARN OWLS. DE Feldman* and EL Knudsen. Dept. of Neurobiology, Stanford University, Stanford CA 94305-5401.

The central nucleus of the inferior colliculus (ICc) contains neurons sensitive to interaural timing difference (ITD), the primary cue used by the barn owl to localize sounds in azimuth. ICc neurons are organized into a map of ITD which is relayed to the external nucleus of the inferior colliculus (ICx) via a topographic projection from ICc to ICx. Rearing owls with laterally displacing prismatic spectacles systematically alters ITD tuning in the ICx but not in the ICc, suggesting that the projection from ICc to ICx is altered by prism-rearing. This hypothesis was tested by making small injections of biotinylated dextran amine (BDA) at known locations in the ICx of normal and prism-reared owls. Retrogradely labeled ICc neurons were visualized by avidin-biotin-peroxidase histochemistry. The positions of labeled somata were measured along the rostrocaudal axis of the ICc (the axis of varying ITD), relative to calbindin immunostaining of the ICc core.

Injections (n=4) made at the representation of 0 µsec ITD in the ICx of normal owls labeled ICc neurons (n=149) in the rostral one-third of the lateral shell of the ICc, consistent with the known projection from the ICc to the ICx. Injections (n=2) made in the ICx of prism-reared owls at the same anatomical location, which in these birds was tuned to 40-50 µsec contra-ear leading ITD, labeled ICc neurons (n=243) in a significantly different distribution. About half of the labeled neurons were situated caudally in the lateral shell at locations representing ITDs corresponding to the prismatically induced shift in the auditory map. The remaining neurons were situated in the rostral third of the lateral shell, as in normal birds. These preliminary data suggest that the adaptive alteration in ITD tuning observed in the ICx of prism-reared owls results at least in part from an alteration in the projection from ICc to ICx.

CHANGES OF AUDITORY EVOKED POTENTIALS IN RESPONSE TO BEHAVIORALLY MEANINGFUL TONES INDUCED BY ACUTE ETHANOL INTAKE IN ALTRICIAL NESTLINGS AT THE STAGE OF FORMATION OF NATURAL BEHAVIOR. L.I. Alexandrov, Y.I. Alexandrov* Inst. of Higher Nervous Activity & Neurophysiology, and Inst. of Psychology, Russian Acad. of Sci. Moscow, Russia.

Acute ethanol's influence on field L auditory evoked potentials (AEP) was studied in 4-7-day-old altricial nestlings of the pied flycatcher. Nestlings were presented with behaviorally meaningful tone pips (2.0 and 5.0 kHz) and the control tone pips (3.0 kHz). Ethanol ingestion was found to reduce the N1 amplitude and maturity index (MI) of the AEP in response to "behavioral" but not to control frequencies. This effect was first observed on day 5, when the nestlings' behavior became more complex: their eyes opened and defence behavior appeared, and when previously formed feeding behavior was undergoing modifications. The MI increase during the early postembryonic ontogeny was probably due to the selective involvement of neurons with newly formed behavioral specializations into the subserving of new behavioral patterns while the decrease of MI under alcohol was due to the depression of activity in these neurones.

SYNAPTOPHYSIN EXPRESSION IN THE DEVELOPING INNER EAR OF THE CHICK. A. M. Cunningham* and B. H. A. Sokolowski. Garvan Institute of Medical Research, Sydney, NSW 2010, Australia and University of South Florida, Tampa, FL 33612.

Synaptophysin is the major integral membrane protein of presynaptic vesicles and is a useful marker for synaptic terminals. The glycoprotein may be involved in presynaptic functions such as vesicle-membrane fusion and has been implicated as having a specific role in neurotransmitter release [Adler et al., 1992]. The expression of synaptophysin was examined during synaptogenesis using a monoclonal antibody (SBI 20.10) which recognises the avian homologue of synaptophysin [Cunningham & Jeffrey, 1990, Soc. Neurosci. Abst. 16, 1291].

We examined the developing inner ear of the chick from embryonic day (ED) 6 to posthatch using an immunoperoxidase technique. In the cochlea, synaptophysin immunoreactivity was detected as early as ED 8 in the proximal region of the sensory epithelium. In this area, immunoreactivity was restricted to the regions containing the tall and intermediate hair cells. As development progressed, by ED 10, immunoreactivity also appeared in the distal regions of the cochlea, consistent with later maturation of this region. In the vestibular endorgans, the saccule, utricle and cristae ampullares, immunoreactivity was observed at ED 14, the earliest age studied to date.

Previous studies in mammals have suggested that synaptophysin is expressed primarily in the nerve fibres innervating the cochlea as well as the afferents of the peripheral vestibular system [Gil-Loyzaga & Pujol, 1988; Scafone et al., 1991; Nadol et al., 1993]. Our studies in developing cochlea show a pattern of synaptophysin immunoreactivity concentrated in areas which primarily receive afferent innervation and would be consistent with localization to the base of the hair cells. Immunocytochemistry studies are needed to verify these findings and to determine the relationship between the appearance of synaptophysin immunoreactivity and the events of synapse formation and maturation. Supported by grants from The Medical Foundation, Uni. of Syd. to AMC & NIH/NIHDCD R29 DC01923-01 to BHAS.

POSSIBLE ROLE OF VISUAL INPUTS TO THE SUPERFICIAL LAYERS OF THE SUPERIOR COLLICULUS IN THE DEVELOPMENT OF THE MAP OF AUDITORY SPACE. A.J. King*, J.W.H. Schnupp and I.D. Thompson. Laboratory of Physiology, Parks Road, Oxford OX1 3PT, UK.

Visual signals appear to play an instructive role in the development of the map of auditory space in the deeper layers of the superior colliculus (SC), although the site at which this visual-auditory interaction occurs has yet to be identified. We have examined the contribution to the development of the auditory space map of the visual representation in the overlying superficial layers of the SC in the ferret.

The caudal region of the superficial layers of the right SC was removed by aspiration on the day of birth. Recordings were made bilaterally when the animals were fully grown. On the left, unoperated side, both the visual representation in the superficial layers and the auditory representation in the deeper layers appeared to be normal. On the right side, the visual responses recorded from units in the remaining superficial layers in rostral SC had normal receptive field locations that covered a restricted region of anterior visual space. Auditory units recorded in the deeper layers of the same electrode tracks were tuned to corresponding locations, suggesting that the auditory representation in this part of the SC was unaltered. However, the preferred sound directions of auditory units recorded in more caudal regions of the SC, where the superficial layers were missing, were much more scattered, even though many of these units were also visually responsive.

These data suggest that visual responses in the superficial layers of the SC may contribute to the development of the auditory topography in the deeper layers.

456.12

DEVELOPMENTAL PLASTICITY OF THE PROJECTION FROM THE MEDIAL SUPERIOR OLIVE TO THE INFERIOR COLLICULUS IN THE RAT. S. Okoyama, T. Moriizumi, Y. Kitao, J. Kawano and M. Kudo*. Dept. of Anatomy, Sch. of Med., Kanazawa Univ., Kanazawa 920, Japan.

In one set of experiments, normal development of projection from the medial superior olive (MSO) to the inferior colliculus (IC) was examined by injecting Fluoro-Gold into the IC unilaterally at postnatal days 0 (P0), 3 (P3), 7 (P7) and adult. They were killed 1 day after injections. Retrogradely labeled neurons in the MSO appeared on the ipsilateral side only in any cases. The labeled frequency of MSO neurons was increased stepwise (from 35% to 90%) with postnatal stages, suggesting differential growth of early- and late-developing axons.

In another set of experiments, cell counting in the MSO was performed in rats, of which IC had been unilaterally ablated between P0 and maturity. Upon reaching adulthood, the rats received injections of Fluoro-Ruby into the contralateral IC so that aberrant crossed projections to the intact IC could be examined. These rats were sacrificed 2 days after injections.

1) No exuberant projections to the contralateral IC are found in the normal development. 2) When the IC is ablated unilaterally, many neurons die in the ipsilateral MSO as a result of axotomy. 3) An aberrant crossed projection occurs in a few of the survived neurons only in the P3 ablation cases. 4) Growth of late-developing axons is a major factor of plasticity in this system.

CHANGES IN OTOLITHIC FUNCTION IN INFANTS LEARNING TO WALK DEMONSTRATED WITH OFF VERTICAL AXIS ROTATION (OVAR). S. R. Wiener-Vacher*, B. Brill, A. Ledebt. Study Center of Postural and Motor Control in Children, ORL Department, Robert Debre Pediatric Hospital, Paris, 75019, France.

We applied vestibular otolith stimulation by off vertical axis rotation in normal children aged from 7 months to 3 years. Our apparatus permits rotational stimulation at variable angular accelerations as well as at constant angular velocity around the vertical axis or at an inclination up to 15 deg with respect to vertical. Children are seated on the lap of their mother and the axis of the chair is adjustable so that child's cephalic axis is in the axis of the rotation. The test is performed in total darkness. VOR is recorded with skin ENG electrodes. We recorded the horizontal and vertical components of canal and otolith VOR. We found that 13 deg of tilt for the off vertical rotation gave an optimal signal/noise ratio for otolith VOR, without altering tolerance to the test.

On a group of 30 normal children aged from 7 months to 3 y.o. we found a clear change in the characteristics of the otolith VOR at the onset of independent walking while canal VOR did not change during this same period. The modulation in amplitude of the slow phase velocity of the otolith VOR increased when the standing position and the first independent steps were obtained.

Preliminary results of a longitudinal study conducted on 5 children since the age of 7 months confirm these findings. Every month we record the canal and otolith VOR as well as the parameters of posture and locomotion by means of a 3D video system synchronized with gait data recorded with a large force plate. This study demonstrates that the evolution of the otolith VOR parallels that of the control of equilibrium during the first phase of independent walking as described by Breniere Y & Brill B (1989). The otolith information may be of greater importance than canal information at this period when the child must learn how to control disequilibrium situations in the erect position.

DEVELOPMENT OF VISUAL CORTEX III

457.1

Effect of neonatal ablation of layer 1 on the development of corticocortical projections in the cat's visual cortex. D. Caric* and D. J. Price. Dept. of Physiology, Univ. Med. Sch., Edinburgh, EH8 9AG, U.K.

We are interested in factors that control the formation of visual corticocortical connections from area 17 to area 18 and the reciprocal projections to area 17. We examined the role of layer 1 in these processes. From the earliest postnatal ages, apical dendrites of pyramidal corticocortical cells project to layer 1, where they connect with long horizontal fibres that cross several cortical areas.

We lesioned layer 1 in area 18 in newborn kittens, let them develop to 1 month of age and examined cortical projections after labelling them with carbocyanine dyes (DiI and DiA) in fixed brains. In normal kittens, by the end of the first postnatal month, fibres projecting from area 17 to area 18 terminate in patches in the cortex of area 18 and cells projecting back from area 18 are grouped in clusters, mainly in superficial layers with a few in deep layers. In lesioned animals, very few projections interconnected areas 17 and 18 although in Nissl-stained sections the cortex appeared normal below the lesions in layer 1. Thus, the lesions produced a disproportionate loss of corticocortical connections, that is not easily explained on the basis of generalised cortical damage. We postulate that intercellular signaling via layer 1 is important for the development of corticocortical connections in the visual cortex.

457.2

DEVELOPMENT OF LONG-RANGE HORIZONTAL CONNECTIONS IN FERRET PRIMARY VISUAL CORTEX Edward S. Ruthazer* and Michael P. Stryker. W.M. Keck Center for Integrative Neuroscience and Neuroscience Program, UCSF, San Francisco, CA 94143-0444.

The specificity of long-range tangential connections emerges during development from initially diffuse connections. In the cat, manipulation of visual experience influences only the late portion of this refinement. To examine the activity-dependence of the early component we have studied the ferret.

Focal injections of either the B subunit of cholera toxin (CTB) or CTB-gold conjugate were made into area 17 of ferrets ranging in age from PND 20 to adulthood. Following two to four days post-injection survival, animals were perfused and their occipital cortex flattened for sectioning parallel to the pial surface. In all but the youngest ferrets studied (PND 27 and older), small injections of CTB into superficial cortex resulted in clusters of retrogradely labeled neurons, the axons of which can be traced back to the injection site, and also in many cases to nearby sites of dense axonal arborization. These areas rich in labeled axons coincided generally, but not always, with clusters of labeled cells. At all ages studied, several clusters of labeled cells were also found in areas 18, 19, and suprasylvian cortex.

In adult animals, the clusters in area 17 were most prominent in layer III where they formed discrete groups of cells, generally within 3 mm of the injection site, separated by regions of relatively low density of labelling. In an animal injected on PND 20 a halo of labeled axons radiating from the injection site was present at all depths, however labeled somata outside of the injection site were almost exclusively found in layer VI and the underlying white matter. Supragranular labeled somata were first seen following injection on PND 24, but the earliest discrete clusters of labeled somata were observed following injection on PND 29. The degree of clustering of labeled somata appeared greater with increasing injection age studied. By PND 46 the adult-like degree of clustering was still not attained.

Activity blockade by intracortical TTX infusion from PND 23 until sacrifice two weeks later appeared to disrupt normal cluster formation in area 17.

Supported by NEI Training Grant EY07120 and NIH Grant EY09760.

457.3

DEVELOPMENT OF CLUSTERED LATERAL CONNECTIVITY IN MACAQUE VISUAL CORTEX. T. Yoshioka*, Krieger Mind/Brain Institute, Johns Hopkins University, Baltimore, MD 21218

The clustered lateral connection network in the visual cortex is thought to be a substrate for the parallel information processing underlying visual perception, and is mainly present in layers 2-3 and 5. To examine the development of this cortical wiring, and to identify whether the visual experience influences cluster formation, the anatomical organization of striate cortex (area V1) in the fetal and infant macaques was studied using Dil as a tracer. Following the placement of Dil crystals at various depths of gray matter, lateral spread of axons and densely branched dendrites of pyramidal neurons were seen in both supra- and infragranular layers at E140days, approximately 3 weeks before birth. In the supragranular layer, labeled axon terminals and somata formed clusters, whereas, in the infragranular layer, a continuous lateral spread of labeled axons was visible without noticeable clusters. These data suggest that the patches seen in layer 5 of adult V1 develop by elimination of axonal branches in later stage. Cytochrome oxidase (CO) histochemistry revealed no evidence of stained blobs despite the presence of clustered terminal patches in supragranular layers. From these observations, it was concluded that the visual experience is not necessary to form clustered horizontal connections in macaque V1, and that CO blobs do not guide axons to the proper termination site of intrinsic neurons, but rather blobs are expressed after the time of the formation of patchy connection system. (Supported by NIH grant EY06432).

457.5

SYSTEMIC YOHIMBINE PREVENTS THE EXUBERANT CALLOSAL CELL DISTRIBUTION IN THE STRIATE CORTEX OF THE RABBIT FOLLOWING MONOCULAR ENUCLEATION. A.M. Grigoris,¹ Yuechu Wang,² and E.H. Murphy.² ¹Dept. of Anatomy, Hahnemann Univ., Philadelphia, PA 19102-1192, and ²Department of Anatomy and Neurobiology, Medical College of Pennsylvania, Philadelphia, PA 19129.

We have previously shown that, following neonatal monocular enucleation (ME), the adult callosal cell (CC) distribution is exuberant, extending into areas of visual cortex which do not normally contain callosal cells, similar to the CC distribution in the neonate. We have also shown that levels of noradrenaline (NA) influence the normal development of the CC distribution. There is a decreased tangential extent of the CC distribution in the adult rabbit visual cortex following administration of an alpha-2 receptor antagonist, yohimbine, during the critical period. We presently examine the effects of yohimbine administration on the CC distribution following neonatal ME. Rabbits (N=4) were deeply anesthetized and had ME on the day of birth. Each animal received injections of yohimbine HCl (2.5 mg/kg, IP) every day from postnatal day 5 through 12. A control group (N=3) had ME and received equal volumes of IP injections of saline. Rabbits were raised until adult, at which time multiple injections of HRP (Boehringer, 20% in H₂O) were made (total volume injected: 7 µl) throughout one entire visual cortex. Animals were perfused 24 hours later and the brains were cut and reacted with TMB. ME plus saline animals had a significantly increased tangential extent of the CC distribution, similar to previous results. ME plus yohimbine animals had a restricted tangential extent of the CC distribution in area 17 similar to the normal adult pattern. Yohimbine administration during the critical period prevents ME induced CC exuberance. Results indicate that NA influences developmental plasticity of visual callosal cells. DEVELOPMENTAL CHANGES IN DENDRITIC ARBORS OF RAT VISUAL CORPUS CALLOSUM CELLS OF ORIGIN: A CONFOCAL LASER SCANNING MICROSCOPE (CLSM) ANALYSIS. A.J. Elberger* and D.L. Dodson. Dept. of Anatomy & Neurobiology, University of Tennessee, Memphis TN 38163.

The carbocyanine dye Dil placed in rat corpus callosum (CC) labels many transitory CC axons extending throughout visual cortex, which gradually disappear during postnatal month (PNM) 1 (Elberger, 1994). At least some of these transitory CC projections form synapses, providing an opportunity for the CC to influence visual cortical development (Elberger et al., 1992). To determine if other features of the callosus display transitory components, the present study examined the morphology of dendritic arbors of CC cells in rat visual cortex. Multiple crystals of either Dil or another carbocyanine dye, DiA, were placed in the corpus callosum of sagittally-bisected, aldehyde-fixed rat brains of various ages during PNM 1. Tissue was sectioned after 5 to 12 months, depending upon the age of the animal.

The cell body and dendritic arbor of individual CC cells in vibratome coronal sections were imaged using CLSM. Cells were randomly selected from all layers of cortex and cells with a partially sectioned apical dendrite were excluded. The length and complexity of the apical dendritic arbor in areas 17 and 18a were morphologically analyzed. In addition, cell body size was measured as well. The length and complexity of the dendritic arbor changed with age. Just as the CC axon was shown to undergo major changes during PNM 1, the CC apical dendritic arbor and cell body size also underwent major changes. The elimination of portions of the apical dendritic arbor with age indicates that not only the CC axon but the CC dendrite has transitory components, the function of which is as yet unknown. DEVELOPMENT OF HORIZONTAL PROJECTIONS IN LAYER 2/3 OF FERRET VISUAL CORTEX. J.C. Durack and L.C. Katz.* Department of Neurobiology, Duke University Medical Center, Durham, NC 27710.

Pyramidal cells in cat striate cortex extend long axons within layer 2/3 that form clustered projections linking iso-orientation columns (Gilbert and Wiesel, *J. Neurosci.* 1989, 9:2432). We examined the sequence of events that occur during the formation of these projections in the ferret to determine 1) whether horizontal projections exhibit similar patterns of development in the ferret and the cat; 2) whether selective axon elaboration and refinement play a role in establishing column-to-column connectivity and 3) the time course of horizontal projection formation relative to the onset of patterned visual experience and orientation selectivity. Extracellular injections of biocytin in tangential slices of layer 2/3 visual cortex were used to label axon collaterals of single neurons and small groups of cells. At the first appearance of axon collaterals in layer 2/3, around postnatal day 22 (P22) pyramidal cell axons are uniformly distributed and unbranched up to 1mm from the cell body. By P26, axons begin to form secondary branches 1-2mm from the cell body, with little evidence for clusters. The first evidence of selective elaboration of secondary branches and retraction of unbranched collaterals occurs around P28. By P34, patchy regions of axon branches emerge, although unbranched collaterals are still present. Distinct, adult-like clusters are observed by P45. Since eye opening in ferrets occurs between postnatal days 30 and 32, this system of orientation specific patches begins to develop in the absence of patterned visual input. The first signs of clustered connections are in fact apparent when most cortical cells are not yet orientation selective (Chapman and Stryker, *J. Neurosci.* 1993, 13:5251). Although the general pattern of horizontal projection formation closely resembles that seen in the cat (Callaway and Katz, *J. Neurosci.* 1990, 10:1134), the ferret circuitry matures earlier than the cat's relative to the time of eye opening. QUANTITATIVE ANALYSIS OF THE VISUAL CALLOSAL PATTERN IN NORMAL AND MONOCULARLY ENUCLEATED RATS C.A. Gilson¹, C.S. Hermit-Grant², B. Chou¹, S.A. Langer¹, K.M. Murphy³ & R.C. Van Sluyters¹. ¹School of Optometry, University of California, Berkeley, CA 94720, ²Department of Neurology, Harvard Medical School, Boston, MA 02115 and ³Department of Psychology, McGill University, Montreal PQ H3A 1B1.

Previously we reported that in neonatal rats the pattern of visual callosal cells resembles a dense, compact version of the mature pattern. The present study extends this analysis to include quantitative data on the callosal cell distribution in normally reared animals and in animals monocularly enucleated (ME) on PND 1. Pups, aged 6 to 21 days, received multiple injections of retrograde fluorescent tracer (Fluorogold or green latex beads) into the occipital cortex of one hemisphere and the density of labelled cells in the supragranular layers of the opposite hemisphere were analyzed at various survival times (2 to 17 days).

In neonatal animals, labelled cells appear to be more densely aggregated near the 17/18a border than in the body of area 17, and this difference becomes more pronounced with age. However, the present data indicate that the ratio between the callosal cell density in the body of area 17 to that in the 17/18a border region actually does not change over the first 21 postnatal days. Thus, the "sharpening" of the callosal labeling pattern with age results from a relative decrease in the intensity of labeling for callosal cells in the body of area 17, as opposed to a selective decrease in their overall number. Similarly, the density of cells in the "extra band" of callosal neurons that runs rostrocaudally through the center of area 17 in ME animals actually is no greater than that found in adjacent regions. Once again, it is the intensity with which these callosal cells are labeled, and not their overall number, that is increased. The present data indicate that postnatal maturation of the callosal cell distribution occurs over a longer time course than previously thought, and they argue against a topographically selective withdrawal of immature callosal axons as the mechanism for producing a mature visual callosal pattern.

NEUROCHEMICAL HETEROGENEITY OF DEVELOPING CORPUS CALLOSUM PROJECTIONS IN THE RAT AND CAT. S.-L. Ding* and A.J. Elberger. Dept. Anatomy & Neurobiology, Univ. of Tennessee, Memphis, TN 38163.

Corpus Callosum (CC) projections in adult mammals are often reported to be excitatory and to use glutamate and/or aspartate as their transmitters. However, neurochemicals used by developing CC projections are not well known. The present study investigates, using immunocytochemistry (ICC), several presumed neurochemicals used by developing CC axons in rats ranging in age from newborn to adult and in neonatal cats. The cells of origin of CC axons were examined using a combination method of Dil retrograde tracing and ICC with epifluorescence and confocal laser scanning microscopy.

In rats during postnatal week (PNW) 1, a large and subsequently increasing number of neuropeptide Y (NPY)-immunoreactive (ir) axons was found in the CC bundle, some of which displayed growth cones. The peak number of NPY-ir CC axons was reached during PNW 2. By the end of PNW 3, the number of NPY-ir CC axons had decreased to adult level, i.e., only a few NPY-ir CC axons were observed. During PNW 1-2 many somatostatin (SS)-ir CC axons were seen; much fewer SS-ir CC axons were present at PNW 3 - adult. Some GABA-ir and a few VIP-ir CC axons were found during PNW 1. In neonatal cat, a small number of SS-ir and GABA-ir CC axons was also observed in addition to many NPY-ir CC axons described previously (Ding and Elberger, 1992, 1994). Double labeling study in both species showed the existence of NPY-ir and SS-ir CC cell bodies in cerebral cortex. The present results indicate that multiple neurochemicals exist in developing CC projections and most of them are transiently expressed. These results also suggest that developing CC projections may be inhibitory or modulatory in nature, in addition to excitatory as generally thought. Supported by NIH grant EY08466 (AJE) and Univ. of Tennessee Neuroscience Center of Excellence.

CHANGES IN CYTOCHROME OXIDASE-RICH PATCHES IN STRIATE CORTEX OF HUMANS WITH RETINAL LESIONS.

M. Marcondes, R. Gattass*, L.F. Pary, and M.F. Farias. IBCCF/ UFRJ, Rio de Janeiro, RJ, 21941-900, Brazil.

We studied the tangential distribution of cytochrome oxidase (CytOx)-rich patches in striate cortex of two humans with retinal lesions. Patch spatial density and patch cross-sectional area were analyzed in CytOx-reacted tangential sections of flat-mounted preparations of V1. Rows of patches are more conspicuous in the cortical representation of the retinal lesions than in normal areas. The spatial density of patches remains constant in the binocular field representation in V1, although patch size changes drastically in the region of representation of the retinal lesion. In this region, patches are larger and darker above and below the ocular dominance stripes of the normal eye than in the alternate stripes. After long-term lesions, the patches corresponding to the normal eye columns appeared larger than in normal controls. In contrast, patches corresponding to the columns in the retinal lesion representation appeared smaller than in normal controls. These results suggest the existence of competitive interactions which modify the cortical intrinsic organization even in adult humans.

PLASMINOGEN ACTIVATOR AND S-100 β IN THE REGULATION OF OCULAR DOMINANCE PLASTICITY. K. Imamura^{1,2}, H. Morii^{1,3}, K. Muguruma^{1,2}, T. Shiomitsu^{1,2}, and Y. Watanabe^{1,2}. Dept. of Neurosci, Osaka Bioscience Institute¹, SFBR project JRDC², PRESTO³, Suita, Osaka 565, Japan.

Previously, we have shown that the reduction of glial functions by a gliotoxin retarded the usual process of shift in ocular dominance (OD) of cortical cells following monocular deprivation. One possibility for a glial involvement in cortical plasticity is via biochemical signals released from astrocytes. In the present study, we examined roles of plasminogen activator (PA) and S-100 β , both of which are considered to be released from astrocytes. Reactive center hexapeptide of PA inhibitor-1, (PAI-1, 10-100 μ M) was infused directly into kitten (5-7-week-old) visual cortex, concomitantly with one week of monocular deprivation. Electrophysiological recordings revealed a retardation of OD shift in the hemisphere infused with PAI-1 (binocularity, B ~50%). Next, we examined a role of S-100 β on OD plasticity by synthesizing and directly infusing *anti-sense* DNA into kitten visual cortex. The shift in OD was found to be suppressed (B ~50%) in the hemisphere infused with antisense DNA, while normal shift was consistently confirmed (B ~13%) in control cortex infused with *sense* DNA. These results suggest that proteinases and trophic factors released from astrocytes, including PA and S-100 β play roles in the regulation of ocular dominance plasticity.

ELECTROPHYSIOLOGICAL RECOVERY AFTER SPINAL CORD INJURY USING CARBON FILAMENT IMPLANTS AND ORG 2766 S. Sayers*, T. Khan, M. Dautzvardis, L. Liu, and C. Trausch. Rehabilitation R&D Center, Hines VA Hospital, Hines, IL 60141.

Our previous studies have shown that carbon filaments are capable of supporting neurite growth by providing a favorable attachment surface and directionality to regrowing axons. Melanocortins have been found to exert a trophic influence on both the central and peripheral nervous systems. The purpose of this study was to determine whether the implantation of carbon filaments and/or the administration of Org 2766 (a tri-substituted ACTH 4-9 analog) would have any beneficial effect after spinal cord injury.

Rats were anesthetized and a total transection of the spinal cord was performed at the T8-T9 level. For animals receiving carbon filament implants, a bundle of approximately 10,000 carbon filaments of 5 μ m diameter (AMOCO ThorneTM) were placed into the transection gap. For animals receiving Org 2766 (N.V. Organon, The Netherlands), a 10 μ g subcutaneous injection was given after surgery and 1 μ g subcutaneous injections at 48 h intervals for a two-week period. At the end of the eight-week survival period, the return of sensory function was evaluated by somatosensory evoked potentials (SSEPs) and the return of motor function by motor evoked potentials (MEPs) using an electromagnetic stimulator.

All of the five spinal cord transected animals, which received carbon filament implants and Org 2766, showed SSEPs recorded across the transection site, as well as MEPs. Two of the three spinal cord transected animals which received Org 2766 without carbon filament implants showed SSEPs recorded across the lesion site and one animal also exhibited MEPs. None of the four spinal cord transected animals without Org 2766 showed any SSEPs recorded across the lesion site.

This preliminary study demonstrated that Org 2766 had a beneficial effect after spinal cord injury, as evaluated by electrophysiological methods.

CARBON FILAMENT IMPLANTS ENHANCED WITH GENETICALLY MODIFIED NERVE GROWTH FACTOR SECRETING FIBROBLASTS PROMOTE REGROWTH OF INJURED SPINAL CORD FIBERS. T. Khan*, M. Dautzvardis, C. Trausch, and S. Sayers. Rehabilitation R&D Center, VA Hines Hospital, Hines, IL 60141.

Neurotrophins are proteins which are essential for the survival and maintenance of different populations of neurons. Among the neurotrophins, nerve growth factor (NGF) is the most well characterized. NGF infusion into certain types of neural tissue results in a dramatic outgrowth of nerve fibers. Recently, studies have shown that NGF has an effect on a broader spectrum of neuronal populations than was originally believed. Carbon filaments have been shown to provide a good substrate for the regrowth of injured spinal axons. The goal of this study was to determine whether the implantation of NGF-secreting fibroblasts, grown on carbon filaments and implanted into the contused spinal cord, would promote translesion growth of injured spinal cord fibers.

Fibroblasts which were genetically modified to secrete NGF were cultured on carbon filaments attached to the bottoms of petri dishes. After 24 hrs, the fibroblast-coated carbon filaments were implanted into the lesion site of spinal cord contused Fischer 344 rats. All animals were cared for according to AAALAC guidelines. After a ten-week survival period, all animals received injections of 2% WGA-HRP in the cervical spinal cord, above the lesion. Retrogradely labeled neurons were observed below the lesion, indicating that a small number of neurons were able to cross the lesion site and reach at least the mid-cervical level of the spinal cord. Immunocytochemical labeling, using anti-neurofilament antibodies showed robust growth of fibers into the lesion site. Anti-CGRP and anti-Chat-labeled fibers were found in and around the carbon filament implants. These results indicate that manipulation of the substrate with trophic factors can substantially influence the regrowth process.

NERVE GUIDES OR NERVE GRAFTS RESULT IN FASTER RECOVERY RATES OF MEDIAN NERVE FUNCTION COMPARED TO DIRECT SUTURE. S.J. Archibald*, C. Krarup, L. Wraga, and B.D. Madison.

¹Departments of Surgery (Neurosurgery) and ²Neurobiology, Duke University Med. Ctr., Durham, N.C. 27710. ³Research Service V.A. Hospital, Durham, N.C. 27710, ⁴Department of Clinical Neurophysiology, Rigshospitalet, Copenhagen, Denmark.

Adult male macaques received bi-lateral median nerve section at the wrist and removal of a 5mm nerve segment, repaired by: A) Graft (n=5), B) Collagen nerve guide (n=5), or C) Direct suture (n= 4). Serial evoked EMGs from the abductor pollicis brevis and sensory nerve conduction studies were performed up to 1400 days after repair.

The recovery rates were faster for the Compound Motor Action Potentials (CMAP) and the Compound Sensory Action Potentials (CSAP) following nerve guide or graft repair compared to direct suture (p=0.001, Tukey). The average CMAP amplitude in all cases eventually recovered to the normal range. The average CSAP amplitudes and motor and sensory conduction velocities were all lower than normal control values (P< 0.01, Scheffé) with no significant differences between the procedures. Reinnervation of digital sensory receptors was suggested by tactile evoked potentials and was confirmed by EM analysis of the Pacinian corpuscles.

A greater number of regenerated myelinated axons were maintained in the distal stump following nerve guide repair compared to normal (P< 0.05, Scheffé) and the average fiber diameter in the distal stump following graft repair was significantly smaller compared to normal (P< 0.05, Scheffé).

The measures of regeneration did not show significant differences between graft and nerve guide, whereas direct suture impeded the CMAP and CSAP recovery rates. This indicates minimal suture line tension can adversely effect the rate of regeneration.

DISSOCIATED, CULTURED SCHWANN CELLS SUPPORT AXONAL GROWTH WHEN IMPLANTED INTO THE SPINAL CORDS OF ADULT RATS. E.A. Tenaglia¹, C.T. Montgomery², G.H. Collins^{3*} and J.A. Robson⁴. ¹Dept. of Surgery, Tulane University, New Orleans, LA 70112; ²Depts. of ³Neurosurgery, ⁴Pathology and ⁵Anatomy and Cell Biology, SUNY HSC, Syracuse, NY 13210.

The ability of cultured Schwann cells to support axonal growth in the spinal cord has been investigated using adult rats. Schwann cells were cultured from the sciatic nerves of newborn rat pups. They were then harvested and injected into small tubes (>1mm diameter; 5-7mm long) made of polycarbonate film. Following a laminectomy, a lesion was made in the dorsal half of the thoracic spinal cord (total length 5-7mm) and a tube was implanted. In other animals empty tubes were implanted as controls. 1-5 weeks later the animals were perfused and longitudinal sections were cut through the tube and the adjacent spinal cord. Sections were then immunolabeled with antibodies specific for axons, astrocytes and basement membranes. After implantation of 11 days or longer the tubes are filled with cells, many of which have a spindle shape typical of cultured Schwann cells. Neovascularization is evident. Axons can be seen streaming into both ends of the tubes. With short survival times (<2 weeks) these axons extend 2-3mm toward the center. With longer survivals axons are seen throughout the full length of the tubes. Many are grouped in fascicles while others appear as single fibers. Astrocyte labeling reveals a sharp border between the host tissue and the ends of the tubes. These results provide additional evidence that cultured Schwann cells can support axonal growth in the adult central nervous system.

Cellular growth in optic nerve regeneration chambers. R.I. Podhajsky, A.R. Blight, B.B. Walters* and D.J. Bidanset. Divisions of Neurosurgery and Orthopaedic Surgery, University of North Carolina, Chapel Hill, NC 27599-7060.

Experiments in female Long-Evans rats tested the suitability of a mixed terrain of CNS and PNS components to support axon elongation. A transected optic nerve stump was inserted into the end of a silicone tube and a peripheral nerve graft (PNG) was sutured in the opposite end forming a 3-mm chamber gap. The chambers were resected after various time periods post implantation and the contents of the chambers were studied in serial cross sections to assay the growth across the gap. Early events in these chambers are similar to the analogous PNS chambers with fluid filling the chamber within one day; macrophages, erythrocytes and other vascular components exude from the stumps. A fibrin matrix forms a suspended, coaxial spindle-shaped bridge across the gap. During the second week, there was growth of fibroblasts, capillaries and glial cells into the gap. Although regenerating axons elongate readily across the gap terrain in silicone tubes implanted on peripheral nerves (Lundborg et al, Exp. Neurol. 76: 36-1, 1982), axons did not elongate into the mixed gap terrain. Numerous axons grew retrogradely through the PNG but advanced no further than the end of the graft inserted into the tube, suggesting that this mixed PNS and CNS terrain does not support axonal elongation. Supported by the Canadian Spinal Research Organization.

AXONAL OUTGROWTH FROM AN INTRASPINAL PERIPHERAL NERVE (PN) GRAFT CAN BE PROMOTED BY SUBSTRATE BOUND NEUROTROPHIC FACTORS (NTFs). J.H. Ye and J.D. Houli*, Dept. of Anatomy, University of Arkansas for Medical Sciences, Little Rock, AR 72205

One major obstacle to the use of PN grafts to repair injured central nervous system (CNS) pathways has been the reluctance of regenerated axons to extend beyond the distal end of the graft. Substrate bound NTFs (BDNF, NT-3; or CNTF; Regeneron Pharmaceuticals, Inc.) were used to test whether the CNS environment adjacent to a PN graft insertion site could be made more favorable for the ingrowth of axons. Following hemisection lesion of the mid-cervical spinal cord of adult rats, a segment of autologous PN was apposed to the rostral cavity surface. The distal end was ligated and left unapposed for 2 weeks, then apposed to a strip of NTF-treated nitrocellulose membrane implanted into the spinal cord 5 mm caudal to the lesion. Untreated nitrocellulose served as a control. Five weeks later the PN graft was cut at midpoint and the caudal end exposed to HRP and the rostral end exposed to True Blue to label neurons contributing to the graft.

CNTF-treated implants were lined by bundles of labeled axons that had grown down to the ventral edge of the implant, with some fibers extending into the adjacent intermediate gray matter. Outgrowth associated with BDNF- or NT-3-treated implants was less robust in terms of length and number of regrowing axons than with CNTF, yet was greater than with untreated nitrocellulose implants where very few axons extended beyond the PN graft. True Blue-labeled neurons were prominent in the spinal cord, raphe area, reticular formation and vestibular nuclei, the distribution of which was the same with the different NTFs used. These results indicate that regenerating axons of supraspinal neurons can be induced to extend beyond a PN graft, back into the spinal cord, by a variety of substrate bound NTFs, thereby increasing the potential for establishing contact with host neurons. Supported by NIH grant NS 26380.

HUMAN SCHWANN CELLS CAN ENHANCE AXONAL REGENERATION AND MYELINATION IN THE NUDE RAT SPINAL CORD. J.D. Guest, R.P. Bunge*, The Miami Project and Dept. of Neurological Surgery, Univ. of Miami School of Medicine, Miami, FL 33136

Human Schwann cells (HSC) can be purified from donor peripheral nerves; such human cells have been shown to enhance regeneration and to provide myelination for regenerating axons when seeded into semipermeable guidance channels in combination with Matrigel and then placed into gaps spanning sciatic nerve transections in immune-compromised rodents (Levi et al, J. Neurosci. 14:1309-1319, 1994). Furthermore it is known that syngeneic Schwann cells transplanted within semipermeable guidance channels spanning a thoracic spinal cord transection promote axonal regeneration from locally axotomized axons with cell bodies up to 9 segments rostral and provide myelination for many regenerating axons (X.M. Xu et al Soc. Neurosci. Abstr. 19:681, 1993). We have now evaluated whether human Schwann cells can have similar effects on the regeneration and myelination of CNS axons. In this series of experiments we have placed closed ended (caudal) guidance channels containing a cable of HSC (120×10^6 cells/ml) mixed with Matrigel (30:70 vol/vol) into contact with the T8 spinal segment of adult female Nude rats. We provide evidence that the HSC survive in contact with the the Nude rat spinal cord and promote regeneration of axons from several neuronal populations (including brainstem DBH positive neurons) into the cable and provide myelination to large numbers of regenerating axons within the closed ended channel when assessed at 30 days after surgery. Because numbers of HSC obtained from human donors are limited methods to expand HSCs to large numbers at high purity have been developed (Levi et al. see abstract this meeting). After 3 passages with mitogens the HSC used within guidance channels appear as competent to recruit regenerating fibres and provide myelination as non-expanded HSC. Dr. Guest is a Fellow of the American Association of Neurological Surgeons; support from NS09923

METHYLPREDNISOLONE ADMINISTRATION IMPROVES AXONAL REGENERATION INTO SCHWANN CELL (SC) GRAFTS IN THORACIC RAT SPINAL CORD. A. Chen, X.M. Xu, N. Kleitman, M.B. Bunge* The Miami Project & Depts. Neurol. Surg. & Cell Biol. & Anat., University of Miami School of Medicine, Miami, FL 33136

SCs support regeneration of axons from spinal cord neurons into guidance channels grafted into transected adult rat spinal cord (Xu et al. '92, '93). We investigated if axonal regeneration is improved if the neuroprotective agent, methylprednisolone (MP), is administered when SC grafts are implanted. SCs were purified in culture from adult rat sciatic nerves, suspended in Matrigel:DMEM (30:70), and seeded into semipermeable PAN/PVC channels at a density of 120×10^6 cell/ml. MP (30 mg/kg) or vehicle (control) was injected i.v. at 5m, 2h, and 4h after transection at T8 and removal of 1-3 caudal cord segments. Either the rostral stump was inserted 1mm into a channel capped at the caudal end, or both stumps were inserted into an open-ended channel. One mo later, the MP + SC/capped channel group, compared with controls, had larger tissue cables, improved blending of host cord and graft tissue, more myelinated axons ($n=6$; $x=1159$ vs. 500) in the graft, and labelling of more spinal cord neurons ($x=1128$ vs. 280) after injection of Fast Blue into the graft ($n=4$). Also, in contrast to the control, 5-HT+ and DBH+ axons were detected in the graft, and brainstem neurons ($x=34$) extended axons into the graft as determined by Fast Blue tracing. When the channel was open at both ends, 45-60 d later the mean of myelinated axons in the graft was 3237 ($n=5$; control, 1217). Retrograde tracing showed labelled cord (rostrally to C4 and caudally to S4) and brainstem neurons. Additional tracing is underway to assess axonal growth from graft into caudal host cord. In sum, MP improves axonal regeneration from both cord and brainstem neurons into SC grafts, possibly by reducing secondary injury of cord adjacent to graft. BDNF AND NT-3 PROMOTE AXONAL REGENERATION OF BRAINSTEM NEURONS INTO SCHWANN CELL GRAFTS IN MID-THORACIC SPINAL CORD OF ADULT RATS. X.M. Xu, V. Guénard, N. Kleitman, and M.B. Bunge. The Miami Project and Depts of Neurol. Surg. and Cell Biol., Univ. of Miami Sch. of Med., Miami, FL 33136.

We previously demonstrated that Schwann cells (SCs) in semipermeable guidance channels promote regeneration of propriospinal but not supraspinal axons in adult rat spinal cord transected at T8. Here, we tested whether exogenous brain-derived neurotrophic factor (BDNF) and neurotrophin-3 (NT-3) could stimulate supraspinal axonal regeneration in this model. SCs were purified in culture from adult rat sciatic nerves, suspended with Matrigel and seeded into PAN/PVC channels (Soc. Neurosci. Abstr., 18:1479, 1992). BDNF and NT-3 were delivered together into the capped caudal end of the channel by an Alzet mini-pump (12 μ g/day/trophi) for the first 14 of 30 days tested. Controls received vehicle solution. The spinal cord was transected at T-8 and T9-11 segments were removed. The rostral cord stump was inserted 1 mm into the channel. One month after grafting, a mean of 1523 myelinated axons was present in SC/trophin grafts, twice as many as in SC/vehicle grafts. Brainstem serotonergic axons regenerated into the SC/trophin grafts for at least 5 mm, but not into control grafts. When Fast Blue was injected at the cable midpoint, on average, 92 retrogradely labeled neurons were found in 10 specific regions of the brainstem with the highest labeling (67%) in vestibular nuclei. Labeled cells were also present throughout the rostral cord. Thus, regeneration of some neural populations distant from a spinal cord transection can be recruited by combinations of trophic factors and a favorable cellular substrate. [Regeneron Pharmaceuticals generously provided neurotrophins and Dr. P. Aebischer (Lausanne), channels; supported by NIH NS 28059 and NS 09923 and The Miami Project. EMBRYONIC CNS TRANSPLANTS ASSIST ADULT DORSAL ROOTS TO FORM SYNAPSES IN HOST SPINAL CORD.

Y. Itoh^{1,2*}, F. Mori^{1,2}, T. Sugawara¹, M. Kowada¹, and A. Tessler²

¹Dept. of Neurosurg., Akita Univ. Sch. of Med., Akita 010, Japan;

²Dept. of Anat. and Neurobiol., Med. Coll. of Pennsylvania, Philadelphia, PA 19129.

Adult dorsal root axons regenerate into embryonic spinal cord transplants and form contacts with transplant neurons that are synaptically driven in response to electrical stimulation of regenerated dorsal root axons. It is unknown whether embryonic CNS transplants also assist synapse formation by adult dorsal roots regenerated into host spinal cord. Adult Sprague-Dawley rats received intraspinal transplants of E14 spinal cord or E18 occipital cortex into left dorsal quadrant cavities in the lumbar enlargement. The severed host L4 or L5 dorsal root was sandwiched between the transplant and host spinal cord. Three to 12 months later sagittal sections were processed for calcitonin gene-related peptide (CGRP) immunohistochemistry and examined by LM and EM. CGRP-labeled axons regenerated into host spinal cord and some extended into the motoneuron pool. The area fraction occupied by regenerated axons in transplanted rats was significantly larger than in control rats without transplants. CGRP-labeled axons formed synaptic terminals within host spinal cord; most were axo-dendritic. Embryonic CNS transplants therefore mediate permanent synapse formation by adult dorsal root axons in host spinal cord and may provide a milieu that promotes reconstruction of interrupted spinal reflex arcs.

INTERSPINAL WIRING OF THE TRANSECTED RAT SPINAL COLUMN. Henrich Cheng, Fong-Lee Huang¹ and Lars Olson. Department of Neuroscience, Karolinska Institute, Stockholm, Sweden, and ¹Institute of Neuroscience, National Yang-Ming Medical College, Taipei, Taiwan.

Shortening of the spinal column has been regarded as one possible method to obtain cord-to-cord apposition after total transection of the spinal column. However, to further improve regenerative possibilities, the problems of inconsistent bony fusion and cyst formations within the junctions must be resolved. To modify the method of de Medinaceli on the rat thoracic spine, we attempted several strategies to achieve better interspinal fixation after spondylectomy and transection, including transpedicular miniscrews, wiring of the transverse processes, and wiring of the posterior spinal processes. A dynamic model, based on retracting and compressing the cut ends of the spinal cord by means of adjustable fixation devices to permit swelling and shrinkage of the stumps was also attempted to better compensate pathophysiological changes of the transected cord. Preliminary results support that the best regeneration, as indicated by regrowth of 5-HT fibers below the level of transection, was obtained following compressive wiring of posterior spinal processes. In this group, the distance between two spinal cord stumps lacking anti-GFAP immunoreactivity was also the shortest. With better approximation, the numbers of regenerated 5-HT fibers seemed to improve remarkably, suggesting that perhaps also other descending or ascending fiber systems might be able to regenerate under these conditions.

REPAIR OF PARTIAL NERVE DEFECT BY THE SILICONE CHAMBER TECHNIQUE. T. Urabe, Q. Zhao, G. Lundborg and N. Danielsen*. Dept. Hand Surg., Malmö Gen. Hosp., Univ. Lund, S-214 01 Malmö, Sweden.

Partial nerve defects are a challenging clinical problem. In this study we examined the regeneration process in partially transected rat sciatic nerve repaired with the previously established silicone chamber model. The tibial nerve fascicle was transected and a 10 mm segment was removed. The tibial proximal and distal stumps together with the intact peroneal fascicle were enwrapped into a silicone tube leaving a 10 mm defect between the two tibial stumps. Nerve regeneration was examined by immunocytochemistry and light microscopy after 7, 16, 28 or 42 days. A cellular fibrin matrix, spanning the proximal and distal stumps of the tibial fascicle and surrounding the intact peroneal fascicle, was formed within one week. This cellular matrix was then invaded by non-neuronal cells and regenerating axons. Regeneration in nerves with a partial defect was more advanced with respect to ingrowing vasculature, Schwann cells, axons and myelination as compared to a totally transected nerve with a 10 mm gap repaired with a silicone chamber. The results suggest that a partial nerve defect could be repaired using the silicone chamber technique. It opens a perspective to solve the clinical problem of repairing a partial nerve defect when neither direct suture nor nerve grafting is applicable.

CHANGES IN GAP JUNCTIONAL COMMUNICATION COORDINATE SCHWANN CELL RESPONSES TO INJURY. K. J. Chandross*, D. C. Spray, R. Dermietzel, and J. A. Kessler. Department of Neuroscience, Albert Einstein College Medicine, Bronx, NY 10461

To elucidate the mechanisms underlying coordinated, phasic Schwann cell responses to nerve injury, we examined whether the onset of de-differentiation and proliferation is temporally related to changes in the strength of intercellular communication between these cells. Previously, we have shown that cultured neonatal rat Schwann cells are weakly coupled through gap junction channels and that coupling strength is increased by conditions mimicking injury-induced de-differentiation and proliferation. To determine whether nerve injury resulted in changes in coupling *in situ*, we enzymatically (1hr, 1mg/ml type IV collagenase) separated adult rat sciatic nerve into single fibers and compared coupling strength between the Schwann cells surrounding intact and crush-injured axons. Individual Schwann cells were either microinjected with Lucifer yellow or the preparation was first loaded with acetoxystyrene esters of indicators (Fura2, Indo1) and then Ca^{+2} was microinjected into one Schwann cell. Scanning confocal imaging (Nikon RCM 8000) determined that in intact nerve, Ca^{+2} and Lucifer yellow spread longitudinally from one internodal region to the next. Spread of the dye appeared to be enhanced after nerve injury. Further, PCR analysis of gap junction expression (using primers against a conserved transmembrane region) and immunocytochemical detection (using antibody probes) showed different patterns of connexin expression between intact and crushed sciatic nerve. These observations suggest that gap junctions between Schwann cells may be important for both normal function of peripheral nerves and their responses to injury.

TUBULAR REPAIR OF ULNAR AND MEDIAN NERVES IN THE HUMAN FOREARM. CASE REPORTS. L. Dahlin*, B. Rosén, N. Danielsen and G. Lundborg. Dept. Hand Surg., Malmö Gen. Hosp., Univ. Lund, S-214 01 Malmö, Sweden.

The silicone tube technique was used to repair transected median (two cases) or ulnar nerves (one case) at the distal forearm level in three patients. In all three cases the nerve ends were enclosed in a silicone tube of such a dimension that would not cause compression of the nerve and leaving a gap of 3-5 mm between the two nerve ends. Three years after nerve repair the patients were examined including sensory evaluation and assessment of muscle contraction force. In two cases the tubes had to be removed two years (median nerve) or three years (ulnar nerve) after nerve repair because of minor local discomfort. At the time of exploration the former gap was bridged by a smooth continuous nerve structure of the same diameter as the adjacent nerve trunk. There were no signs of neuroma formation. In the median nerve cases there were excellent motor recovery of the thenar muscles. Two point discrimination (2PD) was < 6 mm (12 year old patient) and 8-10 mm (21 year old patient) respectively. In the ulnar nerve case (21 year old patient) the first dorsal interosseus muscle was almost normal in size and the strength remarkably good. 2PD was 6 mm. These three cases have demonstrated that the principle of using the tube technique in humans is feasible. The results have inspired us to conduct a randomized, prospective clinical study of the tube technique versus the conventional technique for repair of median or ulnar nerves at the distal forearm level.

REDUCTION IN AMMONIA INDUCED ASTROCYTE HYPERTROPHY BY GLUTAMINE SYNTHETASE INHIBITION. C. Willard-Mack, T. Hirata, R.C. Koehler, L.C. Cork*, R.J. Traystman and S.W. Brusilow. The Johns Hopkins Medical Institutions, Baltimore, MD 21287.

Glutamine synthetase localized in astrocytes utilizes glutamate and ammonia. We tested the hypothesis that astrocyte enlargement associated with hyperammonemia can be reduced by inhibition of glutamine synthetase with methionine sulfoximine (MSO). Pentobarbital-anesthetized rats were pretreated with either vehicle, MSO (150 mg/kg, i.p.), or bethionine sulfoximine (BSO; 888 mg/kg, i.p.), an analogue of MSO that does not inhibit glutamine synthetase. Infusion of ammonium acetate for 6 hours increased plasma ammonia levels from 58 to 533 μ M. Cortical astrocytes had marked enlargement of all cytoplasmic areas with increased numbers of mitochondria, rough and smooth endoplasmic reticulum, and glycogen. Enlargement of small astrocytic processes in neuropil and perivascular endfeet was reduced by MSO but not BSO pretreatment despite elevated ammonia levels. Nuclear diameter in hyperammonemic rats treated with vehicle ($7.98 \pm 0.73 \mu$ m; \pm SD) was greater than in those pretreated with MSO ($7.34 \pm 0.94 \mu$ m) or in controls receiving sodium acetate ($6.79 \pm 0.81 \mu$ m). We conclude that some of the astrocytic hypertrophy that occurs during acute hyperammonemia is related to glutamine accumulation and synthesis localized in astrocytes. (Supported by NS25275).

Na⁺/H⁺ EXCHANGE CHARACTERIZED AS NHE-1 IN RAT HIPPOCAMPAL ASTROCYTES. John H. Pizzonia*¹ and Christopher A. Pappas² Departments of Internal Medicine¹ and Neurology², Yale University School of Medicine, New Haven, CT 06510.

Precise regulation of intracellular pH (pH_i) in astrocytes is essential for proper function and modulation of the surrounding environment. The Na⁺/H⁺ exchanger (NHE) is an integral membrane protein which mediates 1:1 electroneutral countertransport of Na⁺ for H⁺. Four distinct isoforms (NHE's 1-4) have been reported with differing localizations and pharmacological properties. NHE-1, an amiloride sensitive (IC₅₀ ~10 μ M) isoform mediating various cell functions such as growth and proliferation, has been found to be expressed in all mammalian cell types examined. NHE's 2-4 are less well characterized with a more restricted pattern of localization, which includes brain for NHE's 2 & 4, while NHE's 2 & 3 are known to be amiloride resistant (IC₅₀ > 50 μ M). We examined Na⁺/H⁺ exchange activity in primary cultures of rat hippocampal astrocytes. pH_i recovery from an acid load in the absence of CO₂/HCO₃⁻ was assessed using BCECF. Rate of recovery from an acid load measured at a pH_i of 6.7 was 0.193 ± 0.03 pH units/min. and was completely inhibited by 50 μ M of amiloride (IC₅₀ = $3.18 \pm 0.47 \mu$ M). Northern blot performed under low stringency, using full-length NHE-1 showed expression of a single isoform (~4.8 kb) consistent with NHE-1. Interestingly, application 50 μ M EIPA, a highly potent amiloride analog, did not inhibit recovery from an acid load and caused a reversible alkalinization when applied to resting cells. (Supported by NS 15589 and CT Heart Association).

RAT HIPPOCAMPAL ASTROCYTES EXHIBIT ELECTROGENIC SODIUM-BICARBONATE COTRANSPORT

Edward R. O'Connor*, Harald Sontheimer and Bruce R. Ransom.

Dept. of Neurology, Yale School of Medicine, New Haven, CT 06510

Using whole-cell patch-clamp recordings we studied expression of electrogenic $\text{Na}^+/\text{HCO}_3^-$ cotransport in mammalian astrocytes. Primary cultures of hippocampal astrocytes derived from newborn rats were studied after 10 days in culture. Application of 25 mM HCO_3^- , at a constant pH_o , to astrocytes bathed in a nominally HCO_3^- -free solution, produced a reversible change in membrane potential ranging from +3 to -30 mV (Ave \pm S.D. = -11.8 \pm 9.34 mV). The size of the HCO_3^- -induced hyperpolarization was strongly related to the cell's initial resting membrane potential; cells with more negative resting potentials had smaller responses. The HCO_3^- induced change in membrane potential was dependent on extracellular Na^+ , blocked by the stilbene derivative DIDS, and independent of extracellular chloride. Voltage-clamp recording demonstrated that HCO_3^- -induced hyperpolarization was caused by outward currents averaging 335 \pm 104 pA (holding potential = -60 mV). The reversal potential of the HCO_3^- -induced current was between -80 to -90 mV. Based on the reversal potential of the HCO_3^- -induced response, and knowledge of the transmembrane gradients for HCO_3^- and Na^+ , it was calculated that the cotransporter has an apparent $\text{HCO}_3^-:\text{Na}^+$ stoichiometry of 2:1. These findings indicate that hippocampal astrocytes express electrogenic $\text{Na}^+/\text{HCO}_3^-$ cotransport. This transporter may play an important role in regulation of intracellular pH, depolarization-induced alkalization and intracellular Na^+ homeostasis. (Supported by NIH grants NS 09542 to ERO and 15589 to BRR).

ION CHANNELS AND GLIAL PROLIFERATION:

II. Comparison of normal and neoplastic glia.

N. Ullrich*, E. Fernandez-Marques, C.A. Pappas, and H. Sontheimer.

Interdepartmental Neuroscience Program and Dept Neurology, Yale University School of Medicine, New Haven CT 06510.

Unlike neurons, glial cells retain the ability to proliferate postnatally and can divide rapidly to form astrocytomas under neoplastic conditions. The precise control of factors involved in proliferation is poorly understood. We studied possible roles of K^+ channels in glial cell proliferation by comparing properties of spinal cord astrocytes, rat C6 glioma cells, and human astrocytoma cells in culture. To determine whether chronic exposure to ion channel blockers alters proliferation, control and sister cultures were grown in the presence or absence of channel blocking agents, and cell proliferation determined using ^3H -thymidine incorporation as a quantitative measure of DNA synthesis. Application of 4-aminopyridine (2mM), Ba^{2+} (1mM), Cs^+ (1mM), and TEA (5mM), at concentrations which block glial K^+ channels, significantly reduced ^3H -thymidine incorporation in astrocytes, but failed to alter proliferation of neoplastic cells. The phorbol ester PMA (100 μM), a known mitogen, increased proliferation in normal astrocytes by 33%, but reduced proliferation in neoplastic cells by up to 50%. As K^+ channel block should result in depolarization, we examined the potential interrelationship of resting potential and proliferation. Astrocytes in which proliferation was inhibited by cytosine arabinoside (ARA-C) exhibited 20-30 mV more hyperpolarized resting potentials than untreated, proliferating, sister cultures. Similar treatment of neoplastic cells resulted in changes in V_m of the same magnitude, but towards more depolarized potentials. These differences suggest that proliferation is regulated differently in normal and neoplastic glial cells. We are presently investigating the possibility that differences in steady-state pH_i between control and growth-inhibited cells play a role in linking ion channel expression, membrane potential, and glial proliferation.

K^+ INDUCED RELEASE OF [^3H]-D-ASPARTATE FROM ASTROCYTES BY A SWELLING MEDIATED PROCESS AND REVERSAL OF THE TRANSPORTER.

E. Rutledge* and H.K. Kimelberg.

Division of Neurosurgery and Dept. of Pharmacology/Toxicology, Albany Medical College, Albany, New York 12208

In pathological conditions astrocytes are known to swell markedly and one of the effectors thought to be responsible is an increase in $[\text{K}^+]_\text{o}$. Astrocytes are well-known, both in culture and *in vivo*, to take up the excitatory amino acids, glutamate and aspartate, on a specific transporter. Mechanisms of release involving K^+ -dependent reversal of this transporter and/or cell swelling were studied. Primary astrocyte cultures, from P 1 rat cerebral cortex, were exposed to high K^+ and the release of preloaded [^3H]-D-Aspartate was measured. A twenty min. exposure to 100mM K^+ resulted in a biphasic release of [^3H]-D-Aspartate; an initial transient release response followed by a slower sustained release. L-644,711, an anion transport blocker, blocked the slower release component but had no effect on the initial release component. The initial release component can be enhanced by increasing $[\text{Na}^+]_\text{i}$ by treating cells with ouabain; which had no effect on the second release component. The initial component seemed more sensitive to increased $[\text{K}^+]_\text{o}$, while the second component required >50mM K^+ . We propose that the initial release is caused by reversal of the uptake transporter and the second caused by a Na^+ insensitive swelling induced anion transport process. (Supported by NS 30303)

459.4

ION CHANNELS AND GLIAL PROLIFERATION: I. Role of K^+ channels, $[\text{Ca}^{2+}]_\text{i}$, and $[\text{pH}]_\text{i}$.

Harald Sontheimer* and Christopher A. Pappas

Department of Neurology, Yale University School of Medicine, New Haven CT 06510.

Astrocyte proliferation was studied in primary cultures of rat spinal cord to search for factors that might influence glial proliferation. Proliferation was assayed quantitatively by determining relative ^3H -Thymidine incorporation. Astrocyte proliferation could be largely reduced by culturing cells for 6-24 h in the presence of K^+ channel blockers, namely Cs^+ (1 mM, 43%), Ba^{2+} (1 mM, 46%), 4-AP (2 mM, 61%) and TEA (5 mM, 35%). Proliferation was also reduced by nifedipine (100 μM , 33%), but was unaltered by blocking Na^+ channels with TTX. The phorbol ester PMA (100 μM), a known mitogen, increased proliferation by 33% whereas the mitogenic inhibitor ARA-C (5 μM) completely inhibited proliferation. To address whether these effects could have been mediated by changes in resting potential, $[\text{Ca}^{2+}]_\text{i}$ or $[\text{pH}]_\text{i}$, we measured membrane potential electrophysiologically, and ratiometrically measured $[\text{Ca}^{2+}]_\text{i}$ and $[\text{pH}]_\text{i}$ using Fura-2 and BCECF respectively. While Ba^{2+} and TEA depolarized the cells by 37 and 10 mV respectively, both Cs^+ and 4-AP, which had the largest effects on proliferation did not change resting potential. $[\text{Ca}^{2+}]_\text{i}$ effects were similarly heterogeneous: Ba^{2+} increase $[\text{Ca}^{2+}]_\text{i}$ by 8%, Cs^+ and 4-AP reduced it by 3 and 17% respectively, and TEA and ARA-C had no effect. However, all drugs effective in inhibiting proliferation also resulted in an alkaline shift in $[\text{pH}]_\text{i}$ ranging from 0.05 (ARA-C) to 0.22 (4-AP) pH units. To further substantiate the role of $[\text{pH}]_\text{i}$ on cell proliferation, cells were cultured under conditions that alter $[\text{pH}]_\text{i}$ in a defined way. Proliferation showed a strong dependence on $[\text{pH}]_\text{i}$ with an optimum \sim pH 6.7. Interestingly, we observed that resting pH of proliferating astrocytes was consistently more acidic than that of sister cultures growth inhibited by ARA-C. These observations suggest that astrocyte proliferation is sensitive to changes in $[\text{pH}]_\text{i}$ and that K^+ channel blockers may have exerted their anti-proliferative effects through changes in $[\text{pH}]_\text{i}$.

EXPRESSION OF VOLTAGE-ACTIVATED Na^+ AND K^+

CHANNELS IN HUMAN ASTROCYTES N. C. de Lanerolle*, E. R.

O'Connor and H. Sontheimer

Departments of Surgery (Neurosurgery)*, and

Neurology, Yale School of Medicine New Haven, CT 06510.

Primary astrocyte cultures were derived from lateral temporal neocortex (normal cortex) and the hippocampus/parahippocampus (seizure focus) of patients with Temporal Lobe Epilepsy associated with mesial temporal sclerosis. These cultures contained primarily stellate, process-bearing, GFAP positive astrocytes. Na^+ and K^+ channel expression was studied using whole cell patch-clamp recording techniques. Astrocytes from both regions expressed Na^+ channels and up to three forms of K^+ channels. Astrocytes from the seizure focus displayed Na^+ currents at approximately 25 fold higher density (80.2 \pm 28.5 pA/pf) than normal astrocytes (3.2 \pm 1.9 pA/pf), but were indistinguishable in their biophysical features. In seizure focus astrocytes K^+ conductance equaled that of peak Na^+ conductance whereas in control cells K^+ conductance exceeded that of Na^+ by 20 fold. Biophysically, and pharmacologically K^+ channels could be classified as delayed rectifier (K_d), transient "A" type (K_A), and inward rectifier (K_ir). Interestingly, K_ir currents were only observed in normal cortical astrocytes and were absent in astrocytes from seizure foci. The resting membrane potential of seizure focus astrocytes was significantly more positive (-55 \pm 10.2 mV) than that of normal astrocytes (-80 \pm 7.8 mV). The lack of K_ir currents may be causal of the more depolarized potential of seizure focus astrocytes. Since expression of K_ir has previously been linked to cell proliferation, we hypothesize that the above observations are reflective of different proliferative states of normal and seizure focus astrocytes. This work was supported by NS 27081.

CALCIUM-DEPENDENT RELEASE OF EXCITATORY AMINO ACIDS FROM SCHWANN CELLS S. Ieftinija^{1,2}, V. Pappura², F. Liu¹, K. Ieftinija¹ and P. G. Haydon².

Signal Transduction Training Group, Neuroscience

Program, Dept. of Vet. Anatomy¹, Dept. of Zoology and Genetics², Iowa

State Univ., Ames, IA 50011.

The regulation of the extracellular levels of excitatory amino acids (EAAs) is a complex interplay between EAA release from neurons and uptake into neurons and glia. This study demonstrates an additional process in the regulation of external EAAs through the neuroglial-activated, calcium-dependent release of EAAs from Schwann cells.

The release of EAA from Schwann cell cultures derived from dorsal root ganglia (DRG) was assayed using high-performance liquid chromatography. The neuroglial bradykinin (BK) caused a receptor-mediated, dose-dependent increase in release of the EAAs (glutamate and aspartate) from Schwann cell cultures.

To ask whether calcium might play a role in BK-induced EAA release, we used fura-2 AM (4 μM) to monitor Schwann cells calcium levels. BK increased the cytoplasmic level of Schwann cells free calcium. The calcium mobilizing action of BK was impaired by thapsigargin (1 μM), but not by caffeine (10 mM), ryanodine (10 μM) nor by removal of extracellular calcium. To determine whether the BK-induced calcium mobilization stimulates EAA release, cells were loaded with BAPTA-AM (50 μM). Addition of this calcium chelator blocked BK-induced EAA release. Addition of ionomycin (5 μM) caused calcium-dependent EAA release. Taken together these data demonstrate that calcium is both necessary and sufficient for stimulating the release of EAA from Schwann cells cultures.

459.9

GLUTAMATE MEDIATES ASTROCYTE-NEURON SIGNALING IN CORTICAL CULTURES V. Pappura^{1,2}, T. A. Basarsky¹, F. Liu², K. Ieftinija², S. Ieftinija² and P. G. Haydon¹. Signal Transduction Training Group, Dept. of Zoology and Genetics¹, Dept. of Vet. Anatomy², Iowa State Univ., Ames, IA 50011.

Bradykinin (BK) caused a receptor-mediated calcium-dependent release of the excitatory amino acids (EAAs), glutamate and aspartate, from astrocyte cultures obtained from cerebral cortex together with an increase in the cytoplasmic level of astrocytic free calcium.

When applied to mixed astrocyte-neuronal cultures BK elevated calcium levels in neurons only when they contacted astrocytes. The general glutamate receptor antagonist D-glutamylglycine (DGG) and N-methyl-D-aspartate receptor antagonist D-2-amino-5-phosphonopentanoic acid (D-AP5) prevented BK-induced neuronal calcium elevation. These data indicate that BK elevates neuronal calcium levels through the action of glutamate that is released from astrocytes.

Direct photo-stimulation of astrocytes can increase their calcium levels. Exposure of a portion of an astrocyte to focal application of UV light reliably caused an elevation in internal calcium. Since elevated calcium is sufficient to stimulate the release of glutamate from astrocytes, we asked whether astrocyte photo-stimulation caused a glutamate-dependent elevation of neuronal calcium. Photo-stimulation of astrocytes led to an elevation in calcium levels of adjacent unstimulated neurons that was reduced 83 % by DGG. Thus, the mobilization of calcium in astrocytes causes the release of glutamate which signals to adjacent neurons.

459.11

RESPONSE OF ASTROCYTIC GAP JUNCTIONS FOLLOWING NEURONAL DAMAGE IN RAT BRAIN. J.L. Nagy, M.Z. Hossain*, P.A.Y. Ochalski, L.J. Murphy, E.L. Hertzberg and M.A. Sawchuk. Department of Physiology, University of Manitoba, 770 Bannatyne Avenue, Winnipeg, Manitoba, CANADA R3E 0W3

Gap junctional communication in astrocytes is postulated to be critical for metabolic homeostasis and K⁺ spatial buffering following neuronal activity. Neuronal dependence of astrocytic gap junctional regulation was investigated by examining immunohistochemically the distribution of the astrocytic gap junction protein connexin43 (Cx43) in two model systems in rat brain which cause extensive neuronal damage, namely kainic acid (KA) lesion and ischemia. With an antibody against amino acids 346-363 of Cx43, we observed (i) increased Cx43 immunolabelling at early time points after KA-treatment or ischemic insult, (ii) complete disappearance of Cx43 immunoreactivity at later time points in areas with severe neuronal damage and (iii) an increased Cx43 labelling in areas surrounding the lesion. Western blot analysis showed no detectable changes in either the normally present phosphorylated 43 kD form of Cx43 or in the post-mortem dephosphorylated 41 kD form of Cx43 at any time post-injury. Detailed analyses of KA-lesion sites with antibodies against other sequences of Cx43 revealed not only a presence but in some cases an increased density of Cx43 immunoreactivity. Ultrastructural studies in ischemic tissues, where neuronal damage was less severe than in KA-lesioned tissue, revealed increased Cx43 immunoreactivity at sites containing injured neurons. Immunoelectron microscopy of KA-lesioned tissue demonstrated a time-dependent internalization of astrocytic gap junctions and relocalization of Cx43 in multivesicular clusters which culminated in a virtual absence of astrocytic gap junctions by 7 days post-lesion. These results suggest that, depending on the degree of neuronal injury, astrocytic gap junctions undergo molecular reorganization that results in redistribution or disappearance of junctional plaques and an altered antibody recognition of Cx43.

ASTROCYTES *IN SITU* RESPOND TO GLUTAMATERGIC AND PURINERGIC NEUROLIGANDS AND DEPOLARIZATION J.T. Porter and K.D. McCarthy* Department of Pharmacology, University of North Carolina School of Medicine, Chapel Hill, NC 27599

In culture, astrocytes express many of the same receptors as neurons. *In vivo*, it is likely that these receptors are important for the modulation of astrocytic functions such as the uptake of neurotransmitters and ions. Currently, however, very little is known about the expression or stimulation of astrocytic receptors *in vivo*. Using confocal microscopy and calcium sensitive fluorescent dyes we obtained data indicating that hippocampal astrocytes *in situ* (identified by glial fibrillary acidic protein immunostaining) respond to glutamate, 1-aminocyclopentane-trans-1,3-dicarboxylic acid (t-ACPD), ATP, adenosine, and high K⁺ with increases in intracellular calcium ([Ca²⁺]_i). The responses exhibited various temporal patterns which included both oscillations and sustained increases. Increases in [Ca²⁺]_i occurred both in the cell bodies and in the processes and were unaffected by 1 μM tetrodotoxin. N-methyl-D-aspartate (NMDA) caused increases in astrocytic [Ca²⁺]_i which were sensitive to tetrodotoxin suggesting that neuronal signals were necessary for these responses. Often a single astrocyte responded to more than one neuroligand and to depolarization. These findings suggest that astrocytes *in vivo* contain receptors coupled to increases in [Ca²⁺]_i and are able to respond to neuronally released neurotransmitters. The presence of multiple pathways for increasing [Ca²⁺]_i within a single astrocyte suggests the possibility of integration of multiple stimuli.

Regional specificity in astrocyte gap junction coupling

S. H. Lee*, W. T. Kim, A. H. Cornell-Bell, and H. Sontheimer

Yale University, School of Medicine, 333 Cedar Street, New Haven, CT 06510, Departments of Cell Biology and Neurology

Astrocytes are coupled to each other via gap-junctions both *in vivo* and *in vitro*. Gap-junction coupling is essential to a number of astrocyte functions including the spatial buffering of extracellular K⁺ and the propagation of Ca²⁺ waves. Using fluorescence recovery after photo-bleach (FRAP), we quantitatively assayed and compared the coupling of astrocytes cultured from six different central nervous system (CNS) regions in the rat: spinal cord, cortex, hypothalamus, hippocampus, optic nerve and cerebellum. The degree of fluorescence recovery (%recovery) and time constant of recovery (τ) served as quantitative indicators of coupling strength. Gap-junction coupling differed markedly between CNS regions. Coupling was weakest in astrocytes derived from spinal cord (43% recovery, τ=400 s) and strongest in astrocytes from optic nerve (91% recovery, τ=226 s) and cerebellum (95% recovery, τ=100 s). As indicated by the degree of recovery, coupling strength among CNS regions could be ranked as follows: spinal cord < cortex < hypothalamus < hippocampus = optic nerve = cerebellum. Gap-junction coupling also differed between CNS regions with respect to its sensitivity to inhibition by the uncoupling agent octanol. Kd values for 50% inhibition by octanol ranged from 188 μM in spinal cord astrocytes to 654 μM in hippocampal astrocytes. Sensitivity of gap-junctions to octanol could be ranked as follows: spinal cord = cortex = hypothalamus > cerebellum > optic nerve > hippocampus. Regional differences in gap junction coupling and octanol sensitivity observed in cultured astrocytes may reflect differences in the *in vivo* rat CNS. These variations may be significant evolutionary adaptation of astrocytes to varying functional requirements in different CNS regions.

459.12

THE GAP JUNCTIONAL UNCOUPLING AGENTS OCTANOL AND HEPTANOL ALTER pH_i AND Ca²⁺_i IN RAT HIPPOCAMPAL ASTROCYTES Christopher A. Pappas* and Bruce R. Ransom. Department of Neurology, Yale University School of Medicine, New Haven, CT 06510.

Astrocytes are typically linked together by intercellular channels called gap junctions. Octanol and heptanol uncouple cells by blocking gap junction channels, but their mechanism of action is not known. Decrease in intracellular pH (pH_i) or increase in intracellular [Ca²⁺]_i ([Ca²⁺]_i) also uncouples cells. We tested the possibility that octanol and heptanol induce changes in pH_i and/or [Ca²⁺]_i, which may be relevant to their uncoupling action. We studied cultured rat hippocampal astrocytes using the ion-sensitive dyes BCECF (for pH) and Fura-2 (for Ca²⁺).

Application of 1mM octanol to confluent astrocytes in HCO₃⁻-buffered solutions resulted in a biphasic change in pH_i. pH_i initially declined by -0.14 pH units (range: -0.44 to -0.06) in 87% of cells, followed in 8-10 minutes by a rapid pH_i increase of 0.36 (98% of cells). In HEPES-buffered solutions, octanol caused a -0.16 pH_i decline (93% of the cells), followed by an increase of 0.19 pH units (90% of cells) at ~20 min. Octanol's effect on pH_i was partially reversible after brief application (2 min), but not after longer application (8 min). [Ca²⁺]_i also showed a biphasic response to octanol (HCO₃⁻ buffer), with an initial decrease of 21% followed by an increase at 9-11 minutes to 140% of initial levels. Removal of both Ca²⁺ (HEPES) caused a slight decrease in pH_i (-0.07) and blocked the late pH_i increase caused by octanol; the drug still elicited an early decrease in pH_i (-0.36) and [Ca²⁺]_i. Isolated astrocytes exposed to octanol also exhibited biphasic pH_i shifts of -0.23 and 0.18, respectively. Heptanol (1mM) had similar effects as octanol. Astrocytes from rat spinal cord responded to octanol in a similar manner as hippocampal astrocytes, but hepatocyte pH_i did not change with octanol. The changes in pH_i and [Ca²⁺]_i induced by octanol and heptanol are complex and could contribute to their actions as uncoupling agents in glia but not hepatocytes. (Supported by grant NS 15589 to B.R.R.).

NEUROTRANSMITTERS EVOKE Ca²⁺-RESPONSES IN GFAP (+) CORTICAL ASTROCYTES ACUTELY ISOLATED FROM POSTNATAL 3 TO 16 DAY (P₃₋₁₆) RATS. H.K. Kimelberg*, V. Dave and C. Charniga. Division of Neurosurgery, Albany Medical College, Albany, NY 12208.

Although many neurotransmitters evoke Ca²⁺-responses in astrocytes in primary culture it is more difficult to determine whether the same responses occur in astrocytes *in vivo*. One approach to this question is by examining cells soon after their isolation from brain tissue. In the present study, P₃, P₆₋₉ and P₁₄₋₁₆ rat cortical cells were plated onto coverslips following dissociation of enzyme treated slices, and fura-2 loaded cells were studied individually for their Ca²⁺-responses to a panel of 9 transmitters. So far, 7 GFAP(+) astrocytes have been examined within 8 hours of isolation (Grp 1), and 11 astrocytes were cultured and studied from 9-80 hours post-isolation (Grp 2). The percentages of Grp1 vs Grp 2 astrocytes that responded were 43 vs 55 to ATP, 29 vs 73 to norepinephrine, 14 vs 64 to bradykinin, 50 vs 0 to histamine and 17 vs 10 to adenosine. This could represent heterogeneity in receptor expression, receptor up- or down- regulation, or recovery from the effects of enzyme treatment. Responses to acetylcholine, glutamate and serotonin were elicited in ≤ 10% of astrocytes in both groups. Responses to endothelin-1, -2 and -3 were seen in 1/3, 3/5 and 2/7 astrocytes respectively. Almost half the astrocytes responded to any 3 of the 9 neurotransmitters tested and the remainder generally responded to less than 3 neurotransmitters. Incubation with enzyme prior to dissociation could have affected cell responsiveness, but astrocytes examined within 8 hrs of isolation using enzyme-free dissociation showed comparable patterns of responses. These results lend additional support to the idea that rat cortical astrocytes *in vivo* normally express Ca²⁺-mobilizing neurotransmitter receptors. (Supported by NINDS 19492 to H.K.K.).

"IN VITRO ISCHEMIA" INCREASES THE $[Ca^{2+}]_i$ OF ASTROCYTES WITHIN HIPPOCAMPAL SLICES. S.N. Duffy and B.A. MacVicar
Dept. of Neuroscience, University of Calgary, CANADA T2N-4N1

Increased $[Ca^{2+}]_i$ contributes to neuronal death following ischemia, but it is not known what factors trigger the concomitant transformation of astrocytes to the reactive form. Many aspects of astroglial physiology are regulated by $[Ca^{2+}]_i$, so we tested whether simultaneous hypoxia and hypoglycaemia ("in vitro ischemia") can induce $[Ca^{2+}]_i$ elevations in astrocytes within hippocampal slices. Astrocytes, identified by high resting membrane potentials ($E_m = 75 \pm 3$ mV, $n=41$) and passive responses to injected currents, were iontophoretically loaded with the Ca^{2+} -sensitive dye Calcium Orange. Hypoxia-hypoglycaemia triggered rapid elevations in the $[Ca^{2+}]_i$ of dye-coupled astrocyte networks (11 of 14 slices). The duration of hypoxia-hypoglycaemia required to elicit such increases ranged from 3 to 7 min (averaged 5.4 min). We have shown previously that depolarization (by high $[K^+]_o$) triggers Ca^{2+} influx in these cells by activating voltage-gated Ca channels. Hypoxia-hypoglycaemia for 3.5-7 min also depolarized astrocytes (range 30-70 mV, $n=7$), suggesting that the $[Ca^{2+}]_i$ increases associated with this treatment are mediated, at least in part, by voltage-dependent Ca^{2+} influx. Increased astroglial $[Ca^{2+}]_i$ may trigger many of the changes (hypertrophy, alterations in gene expression, proliferation) characteristic of reactive gliosis.

ELEVATION OF EXTRACELLULAR $[K^+]_o$ CAN TRIGGER AUTO-REGENERATIVE CALCIUM WAVES IN CULTURED MAMMALIAN BRAIN CELLS. Maiken Nedergaard, Aitken Neurosurgery Laboratory, Division of Neurosurgery, Department of Surgery, Cornell University Medical College, 1300 York Avenue, New York, NY 10021

Increases in intracellular calcium that propagate among cells ("calcium waves") have been described in a wide variety of cell types. These calcium waves may propagate from cell to cell by gap junction-mediated diffusion of a second messenger, as cell to cell propagation is dependent upon expression of the gap junction protein connexin43. In cultures of mammalian brain, calcium waves are carried by astrocytes. Neurons in contact with astrocytes participating in the wave respond to glial stimulation with increases in their cytosolic calcium levels (Science: 263, 1768-71, 1994). Signaling from astrocytes to neurons is unidirectional, since stimulated neurons are unable to evoke astrocytic calcium increases. Wave propagation is resistant to both sodium and calcium channel blockers: Glutamate receptor antagonists, L-type calcium channel blockers, and tetrodotoxin affect neither the velocity vector nor the maximal radius of propagation. Thapsigargin, on the other hand, is an effective inhibitor of wave propagation. Thus, calcium wave propagation appears to be relatively resistant to changes of the extracellular environment. The present study examined consequences of elevation of extracellular potassium $[K^+]_o$ from 5 to 60 mM on propagation of the calcium waves elicited by electrical field stimulation. High $[K^+]_o$ was an effective promoter of wave propagation. In fact, self-regenerating calcium waves, often lasting for several minutes after initiation, were regularly evoked by high potassium; these included both astrocytes and neurons. Thus, potassium-induced elevation of resting cytosolic calcium might decrease the threshold for propagation of the calcium wave among glia and neurons. (Supported by grants from the American Heart Association, the Migraine Trust, and NINDS R29 NS30007.)

CYTOSKELETON TRANSPORT AND MEMBRANE TARGETING: AXON AND DENDRITE CYTOSKELETON

MULTIPLE CALCIUM-DEPENDENT KINASES MAY REGULATE THE INTERACTION OF PEA-15 WITH MICROTUBULES IN ASTROCYTES. H. Chneiweiss, M. Kubes, M. Yokoyama, J. Cordier, A. Estelles and J. Glowinski, INSERM U114/ Collège de France, Paris, France.

Neurotransmitters, growth factors and cytokines have been shown to mediate neuron-astrocyte communication. Astrocytes are known to exhibit receptors for most of these mediators. Activation of receptors by agonists results in a cascade of intracellular events, including the stimulation of protein kinases and subsequent phosphorylation of substrate proteins. To study the regulation of astrocytic functions, we analyzed intracellular target phosphoproteins of extracellular signals, in cultured astrocytes using 2-dimensional polyacrylamide gel electrophoresis. Previously, we described a novel substrate of protein kinase C (PKC) enriched in astrocytes, PEA-15 (J. Biol. Chem. 268:5911-5920). More recently, phosphorylation studies performed both in vitro and in vivo, followed by microsequencing, suggested that PEA-15 is also a substrate for calcium-calmodulin-dependent protein kinase II (CamKII), at a seryl residue different from the PKC site. Indirect immunofluorescent studies using antibodies raised against synthetic peptides corresponding to the two phosphorylated sites, demonstrated that PEA-15 is colocalized with microtubules in cultured astrocytes. To determine which form(s) of the protein associate(s) preferentially with tubulins, polymerized tubulin was separated from unpolymerized tubulin by extracting soluble proteins using triton-X 100. Analysis of the microtubule-associated fraction suggests that both PKC and CamKII phosphorylation of PEA-15 may be involved in regulating the binding of the protein to microtubules.

REGIONAL AND FOCAL ALTERATIONS IN NEUROFILAMENT AND TUBULIN IMMUNOREACTIVITY IN INJURED RAT BRAIN K.E. Saatman and T.K. McIntosh, Dept. of Neurosurgery, Univ. of Pennsylvania, Philadelphia, PA 19104.

Axonal injury resulting from rapid deformation of the brain is often characterized by the presence of discontinuous axons with swollen club-like endings (terminal clubs) and axons with regions of enlarged diameter. These pathological changes in axonal morphology have been described clinically, in cases of diffuse axonal injury, and in animal models of acceleration and fluid percussion brain injury. We have used antibodies to tubulin, tyrosinated tubulin, and both 68 kD and 160 kD neurofilament (NF) subunits to examine axonal swelling and terminal clubbing in the rat brain following lateral fluid percussion injury. In addition, regional alterations in the immunoreactivity (IR) of these cytoskeletal proteins were investigated. Adult male Sprague-Dawley rats were anesthetized (sodium pentobarbital, 50 mg/kg) and subjected to lateral fluid percussion brain injury of moderate severity (2.4 atm). Animals were sacrificed at 2, 3, or 7 days post-injury. Cortical neurons surrounding the injury site showed decreased tubulin and NF IR and disruption of their normal radial alignment when compared to the contralateral cortex and to sham-injured animals. Decreased tubulin IR was also seen in the CA3 region at all time points. At 3 days, typical axonal swellings and terminal clubs were readily visible in injured rats, using NF antibody labelling. Populations of these damaged axons were seen in the ipsilateral subcortical white matter, cortex, and thalamus. While these focal axonal swellings could be easily located due to their intense NF IR, neither tubulin antibody used in this study showed intense labelling at the regions of axonal damage. (Supported, in part, by NS26818 and NS08803)

460.3

MEC-12 ENCODES THE ACETYLATED ALPHA TUBULIN TBA-3 WHICH MEDIATES THE 15 PROTOFILAMENT MICROTUBULE FORMATION AND TOUCH SENSITIVITY IN THE NEMATODE C. ELEGANS. Shahid S. Siddiqui and Tetsunari Fukushima, Lab. of Molecular Biology, Dept. Ecological Engg. Toyohashi Univ. of Tech. Toyohashi 441, JAPAN

In *Caenorhabditis elegans*, of the four alpha tubulin genes (*tba-1 - tba-4*), only the *tba-3* gene encodes the alpha tubulin with a lysine residue at position 40, typical of the acetylated alpha tubulins. The McAb 6-11B-1 which is specific for the acetylated alpha tubulins (Piperno and Fuller, 1985) cytochemically stains the set of 15 pf (proto filament) containing MTs in the six touch receptor neurons and the axonal processes from many other neurons in the head, tail ganglia and the ventral nerve cord. In the *mec-12(u76)* mutants that are touch insensitive and lack the 15 pf MTs in the six touch cells (Chalfie & Au, 1989), the 6-11B-1 staining is abnormal. However the *mec-12(u76)* mutants can be rescued by the *tba-3* gene in the germline transformants, regaining the staining of touch neurons and touch sensitive behavior. The *mec-12(u76)* allele also harbors a RFLP change when its genomic DNA is probed with the *tba-3* specific probe. A *tba-3::lacZ* fusion gene is expressed in the set of six touch cells, ventral cord motor neurons, and a few more neurons in the head and tail ganglia, consistent with the pattern of immunocytochemical staining with 6-11B-1 McAb.

We thank M. Hamelin and J. Culotti for cooperation and M. Chalfie for ideas and strains. This work was supported by the Ministry of Education and Science, Japan grant to SS.

460.4

A MICROTITER PLATE FORMAT FOR THE MEASUREMENT OF TAXOID-INDUCED POLYMERIZATION OF TUBULIN. E.D. Macdonald, S. Blumenthal, Z.P. Gu, K. Nyireddy and B.S. Glaeser, PHYTOpharmaceuticals, Inc., San Carlos, CA 94070 and S. Mudumba, Department of Pharmacology, University of the Pacific, Stockton, CA 95211.

We describe a 96-well plate assay for the measurement of tubulin polymerization based on the method described by Gaskin *et al.* (1974). Tubulin was purified from fresh bovine brain by two cycles of assembly and disassembly induced by heat, glycerol and GTP, followed by a third cycle with assembly induced by DMSO. For the assay (200ul), tubulin is diluted in buffer (0.1M PIPES, 1mM EGTA, 1mM $MgSO_4$). Prior to tubulin addition, each microtiter well receives 100ul of sample or reference compound in 10%DMSO/buffer. Optimal tubulin concentration is 0.75mg/ml. Polymerization is monitored kinetically at 340nm and at 37°C using a Thermomax plate reader (Molecular Devices Corp., Menlo Park, CA). The OD(340nm) correlates with compound concentration until saturation of binding sites. Compound potency is defined as the concentration of compound causing a response equal to 50% of that observed at saturation (SC_{50}). Results in the Table show good reproducibility. Compounds promoting the disassembly of tubulin (for example colchicine -10 to 200uM), inhibit taxol-induced polymerization in a dose-dependent manner. This assay may be useful for the characterization of compounds that affect tubulin assembly and disassembly such as specific MAPs and tau proteins.

COMPOUND	n	SC_{50} (uM)
Taxol	2	2.33 +/- 0.23
Cephalomannine	3	4.73 +/- 0.47
7-epi-10-deacetylataxol	3	4.67 +/- 0.39

PHOSPHORYLATION AND CONFORMATIONAL CHANGES OF MAP2 DURING CAT BRAIN DEVELOPMENT. **B.M. Riederer*, E. Dráberová, P. Dráber, V. Víklícký.** *Institute of Anatomy, University of Lausanne, Lausanne, Switzerland; Institute of Molecular Genetics, Prague, Czech Republic.

Microtubule-associated protein 2 (MAP2) is essential for the stability of microtubules and for dendritic growth. In this study five monoclonal antibodies were used to analyze MAP2 during cat brain development. Antibody AP18 was the only one directed against a phosphorylation-dependent epitope on MAP2b and c. Dephosphorylation with alkaline phosphatase abolished most immunoreactivity with AP18 and indicated that MAP2 is phosphorylated throughout postnatal development, possibly by a cAMP-dependent kinase. The AP18 epitope was less susceptible to dephosphorylation in larger apical dendrites of cortical pyramidal cells and in some neurons of the upper layers of visual cortex. It is suggested that the AP18 epitope is less accessible to alkaline phosphatase, and that MAP2 conformation must differ within parts of neurons. Three antibodies, AP14, MT01, MT02, were directed against the central region of MAP2b. An immunocytochemical comparison revealed differences in the cellular distribution during early postnatal development of cat cerebellum, while at later ages, most antibodies stained similar neuronal elements. Antibody MT02 stained at early stages cell bodies and dendrites in cerebral cortex and cerebellum. Within the first postnatal month immunoreactivity became restricted to the distal parts of apical dendrites of pyramidal cells but staining was absent from perikarya and finer basal dendrites, and no immunostaining was found in cerebellum. MT02 immunoreactivity is independent of phosphorylation. It is concluded that immunohistochemical detection of MAP2 depends on its conformation, posttranslational modifications such as phosphorylation, or masking of sites by other proteins. PROPOFOL INDUCES NO CHANGES IN ACTIN IN THE CYTOSKELETON WHEN INTRACELLULAR CALCIUM IS DEPLETED BY MAPTA/AM. **C. Eintre*, A. G. Jensen, A. Sjölander.** Departments of Anaesthesiology and Cell Biology, Faculty of Health Sciences, University Hospital, S-581 85 Linköping, Sweden.

The site of action of the intravenous anesthetic drug propofol (Diprivan®) is still uncertain. The intracellular action of propofol was studied on primary cultures of neurons from rat. Cytosolic free calcium changes in neurons were studied using Fura2 and a single-cell micro fluorometric method. Fluorescence microscopy was used to study the organisation of actin. An increase in the cytosolic free calcium concentration (ΔCa^{2+}) amounting to $244 \pm 83 \text{ nM}$ was seen shortly after addition of $3 \mu\text{g} \times \text{ml}^{-1}$ of propofol. When neurons were depleted of intracellular calcium by the presence of MAPTA/AM and stimulated by $3 \mu\text{g}$ propofol no changes were seen in the actin organisation of cytoskeleton, as revealed by a fluorescence microscopy. Only 18 of 306 cells exposed to $3 \mu\text{g} \times \text{ml}^{-1}$ of propofol exhibited changes in the morphology. Of 250 untreated cells that served as controls, 21 showed morphological changes.

Propofol in concentration exceeding or equivalent to clinical relevant concentration induces changes in the morphology of cultured neurons from the rat. These changes are a consequence of the increase in cytosolic free calcium concentration seen after stimulation with propofol. Evidence of this is that no changes in actin organisation were observed when intracellular calcium was depleted.

460.9

Vilp-a 22 kD neuronal EF-hand Ca^{2+} -binding protein from chick brain: regulation of its interaction with intracellular target molecules. **K.-H. Braunewell, S. E. Lenz and E. D. Gundelfinger*.** Federal Institute for Neurobiology (IfN), Dept. of Neurochem./Mol.biology, P.O. Box 1860, D-39008 Magdeburg, F.R.G.

Vilp (visinin-like-protein) (Lenz et al., 1992, Mol. Brain Res., 15, 133-140) is a member of a new family of neuronal Ca^{2+} -binding proteins, such as visinin, recoverin/s-modulin or frequenin. The function of these proteins remains still unclear.

Vilp is expressed by a subset of neurons in the chicken brain and retina. The molecule is localized in the cellbody, dendrites and axons and seems to be associated with the cortical cytoskeleton. At least one of the four EF-hand structures of Vilp is able to bind Ca^{2+} -ions, as revealed by mobility shift assays. The molecule is able to interact with membrane- and cytoskeletal cellular fractions in a Ca^{2+} -dependent manner. In overlay assays several potential binding partners for Vilp have been identified. One of them is actin, a main component of the cortical cytoskeleton. Several potential phosphorylation sites exist in the EF-hand structures of Vilp. This raises the possibility that the ability of Vilp to bind Ca^{2+} -ions and therefore to interact with intracellular target molecules in a Ca^{2+} -dependent manner is regulated by phosphorylation. These results suggest that Vilp may act as a Ca^{2+} -effectormolecule. It may transmit Ca^{2+} -signals to the cytoskeleton, thereby affecting processes, such as neurotransmitter release, neurite outgrowth or synaptic plasticity, which are dependent on the dynamics of the cytoskeleton. This work is supported by DFG

460.6

REGULATION OF NEURONAL CYTOSKELETAL PHOSPHORYLATION BY CATION FLUX. **M. Mata*, _____, and D.J. Fink.** Department of Neurology and GRECC, VAMC, University of Michigan, Ann Arbor, MI 48105 and University of Lausanne, Lausanne, Switzerland.

We studied the state of carboxy terminal phosphorylation of neurofilament (NF) proteins, and of the microtubule associated tau protein in fetal brain aggregates in culture. Cultures containing rat telencephalic neurons and glia in defined medium were grown for 4 weeks until myelination occurred. The cultures were then treated with $20 \mu\text{M}$ veratridine for different times in order to trigger Na^{+} influx. We used Western blot with antibodies SMI-31 (Sternberger Meyer) and N-14 (Boehringer Mannheim) to detect phosphorylated NFs, and AB 1991 (Chemicon) to determine total NF content independent of phosphorylation. Antibody tau-1 (Boehringer-Mannheim) was used to detect tau.

Beginning at 2 hrs of veratridine treatment, there was a marked decrease in phosphorylated NFs, with no change in total NF content, although a shift in mobility of total NFs detected by AB1991, consistent with dephosphorylation of NF-H. Veratridine treatment also resulted in multiple bands with more rapid electrophoretic mobility detected with the tau-1 antibody, consistent with dephosphorylation of tau.

Prolonged treatment with veratridine led to a decrease in total content of a variety of calpain substrates (NF, tau, GAP-43 and calcineurin) without affecting the level of other proteins that are not calpain substrates (membrane $\text{Na}^{+}\text{K}^{+}\text{ATPase} \alpha 1$ subunit).

These results suggest that sodium entry through voltage gated channels may regulate the dephosphorylation of cytoskeletal proteins while prolonged treatment may result in Ca^{++} entry and activation of calpains.

460.8

CORTICAL INTERNEURONS EXPRESSING CALCIUM BINDING PROTEINS HAVE AN ERYTHROCYTE-RELATED MEMBRANE CYTOSKELETON. **M. R. Celio*, B. M. Riederer*, S. Lamber*,** ¹Institute of Histology and general Embryology, University of Fribourg, CH-1705 Fribourg; ²Institute of Anatomy, University of Lausanne, Lausanne; ³Howard Hughes Medical Institute and Dept. of Biochemistry, Duke University, North Carolina USA.

Cortical interneurons have a non-pyramidal shape, receive their inputs mainly on the cell body and proximal dendrites, express a calcium-binding protein of the EF-hand family and are often surrounded by the "perineuronal net", a specialized extracellular matrix containing e.g. restrictin/janusin. We have found by immunohistochemistry that cortical interneurons immunoreactive for the calcium-binding proteins parvalbumin, calbindin D-28k and calretinin express the red blood cell isoform of spectrin and ankyrin (βR spectrin [brain spectrin 240/235 B or $\alpha\beta$ Spib] and ankyring). The immunolabelling for the two cytoskeletal proteins in each nerve cell is restricted to the cortical portion of the cytoplasm, whereas the calcium-binding proteins occur dispersed in the whole cytoplasm. Ankyring and βR spectrin can be found not only in the cell body but also underlying the membrane of the main dendrites, in decreasing concentration at least until the second dendritic ramification. In thicker sections the βR spectrin-immunolabelling is reticulated, whereas the ankyring staining is punctuated. The study of the distribution of ankyring and βR spectrin in relationship to restrictin/janusin reveals that the membrane cytoskeletal proteins are in register with the extracellular matrix protein. We suspect that calcium-binding proteins interact with the proteins of the membrane cytoskeleton, thus modulating the lateral mobility of integral membrane proteins and the adhesion of interneurons to the extracellular matrix.

SORTING SIGNALS FOR TRANSFERRIN RECEPTOR AND RETROVIRUS PROTEINS IN AXONAL AND DENDRITIC TRANSPORT:

K. Kristensson*, K. Weclawicz and H. Garoff. Karolinska Institutet, Dept. of Neuroscience, S-17177 Stockholm, Sweden, Dept. of Molecular Biology, Karolinska Institutet, Huddinge, Sweden.

Rat embryonic dorsal root ganglia, spinal cord and hippocampal neurons in culture were infected with recombinant Semliki forest virus (SFV) containing the genes for the human transferrin receptor, the envelope or nucleocapsid proteins of human immunodeficiency virus type 1 (HIV-1) or Moloney murine leukemia (Mo-MLV) virus. All nerve cell types expressed the human transferrin receptor in their cell bodies, but not in their axons. In spinal cord and hippocampal neurons the receptor also occurred in the dendrites. A mutant form of the receptor, in which the amino acids 6-53 in the cytoplasmic tail had been deleted, appeared both in axons and dendrites. HIV-1 envelope protein was also exclusively localized to the dendrites, while the gag protein appeared both in axons and in dendrites. Co-expression of the envelope and the gag proteins resulted in a dendritic localization of the latter, indicating that the envelope protein can interact with and determine the intracellular sorting of the gag protein. Similarly, the Mo-MLV gag appeared in both axons and dendrites, but only in dendrites when co-expressed with the envelope protein. Heterologous co-expression of HIV-1 envelope and Mo-MLV gag proteins and vice versa did not influence the distribution of the gag proteins.

DENDRITIC TRANSPORT OF NEURAL BC1 RNA IN SYMPATHETIC NEURONS IN CULTURE. I. Muslimov¹, S. Perini², D. Higgins², H. Tiedge¹. ¹Fishberg Center for Neurobiology, Mount Sinai School of Medicine, New York, NY 10029. ²Department of Pharmacology, SUNY at Buffalo, Buffalo, NY 14214.

Extracellular protein synthesis in postsynaptic dendritic domains may contribute significantly to long-term synaptic plasticity of nerve cells [see Steward and Banker (1992), Trends Neurosci. 15, 180-186, for review]. In this model, selected RNAs would have to be specifically sorted and targeted to dendritic microdomains. However, the mechanism of dendritic RNA targeting and transport has remained elusive.

Here we analyse the dendritic targeting competence of neural BC1 RNA. This short, non-translatable RNA has been identified in somatodendritic domains of neurons [Tiedge et al. (1991), Proc. Natl. Acad. Sci. USA 88, 2093-2097] where it may participate in transport- and/or translation-related processes. We have generated various radiolabeled BC1 sequences, including full length BC1 RNA as well as 5' and 3' segments, and microinjected them into somata of rat sympathetic neurons in primary culture. We observed a significant and specific accumulation of full length BC1 RNA in dendrites. In contrast, injected small nuclear RNAs, such as U4 and U6 RNAs, distributed to somata and nuclei. Random irrelevant RNA sequences did not exit somata to any significant extent. Transport of BC1 RNA was rapid: distal dendritic tips were reached in less than 2 h. The various structural subdomains in BC1 RNA showed significant differences in their dendritic targeting potentials. These results support the notion that BC1 RNA contains specific signaling elements that direct its sorting and targeting to dendritic domains. (Supported by NSF grant IBN-9210149 to H. T.)

SYNAPTIC STRUCTURE AND FUNCTION III

461.1

CODISTRIBUTION OF SYNTROPHIN-1 WITH DYSTROPHIN AND SYNTROPHIN-2 WITH UTPROPHIN IN SKELETAL MUSCLE. M.F. Peters, N.R. Kramarcy, R. Sealock and S.C. Froehner*. Dept. of Physiology, Univ. of North Carolina, Chapel Hill, NC 27599.

Syntrophin is associated with different members of the dystrophin family of proteins, including dystrophin, short forms of dystrophin containing only the cysteine-rich and carboxy terminal domain, and utrophin (a postsynaptic dystrophin homolog at the neuromuscular junction (NMJ)). Two forms of syntrophin which share approximately 50% amino acid identity and are encoded by separate genes have been found in mouse tissues. The tissue expression pattern of syntrophin-1 mRNA mimics that of dystrophin, while the distribution of syntrophin-2 follows that of utrophin. Thus, Adams *et al.* (Neuron 11:531) suggested that syntrophin-1 is associated with dystrophin and syntrophin-2 is associated with utrophin. To test this idea, we have prepared isoform-specific polyclonal antibodies using peptides unique to each isoform. In immunofluorescence on cryosections of rat diaphragm, anti-syntrophin-1 labeled both the NMJ and the non-junctional sarcolemma. In contrast, the anti-syntrophin-2 antibody labeled only the NMJ; labeling of the non-junctional sarcolemma was undetectable. Double labeling for syntrophins and dystrophin or utrophin revealed codistributions consistent with the predicted syntrophin-1/dystrophin and syntrophin-2/utrophin associations. We also examined the distribution of syntrophin-1 in the dystrophin-negative *mdx* mouse. Syntrophin-1 staining was absent from the sarcolemma of *mdx* muscle, presumably because its association with the membrane is dependent on the presence of dystrophin. However, the NMJ in *mdx* muscle retained syntrophin-1 staining. Thus, at the neuromuscular synapse, syntrophin-1 may be associated with some, yet to be identified member of the dystrophin family.

INTERACTIVE EFFECTS OF CILIARY NEUROTROPHIC FACTOR AND DENERVATION ON ACETYLCHOLINESTERASE GENE EXPRESSION IN RAT SOLEUS MUSCLES. R.N. Michel, H. Sveistrup*, D.J. Parry and B.J. Jasmin. Department of Physiology, Faculty of Medicine, University of Ottawa, Ottawa, Ontario, Canada.

Ciliary neurotrophic factor (CNTF) has recently been identified as a potential neurotrophic agent having an effect upon mammalian skeletal muscle fibers. For instance, daily injections of CNTF have been shown to partially counteract muscle wasting associated with denervation of the rat hindlimb musculature (Helgren *et al.*, Cell 76: 493-504, 1994). Because CNTF enhances neuronal survival, axonal regeneration, and collateral sprouting of intact nerves, the possibility also exists that this particular trophic agent may promote reinnervation of muscle fibers by acting specifically upon molecular control mechanisms localized at the neuromuscular junction. We have addressed this issue by measuring acetylcholinesterase (AChE) transcript levels in control (right) and denervated (left) soleus muscles of animals treated with daily injections of CNTF (0.3 mg/kg s.c.). CNTF treatment attenuated the relative loss in muscle mass observed 7 days post-denervation thereby confirming previous findings (Helgren *et al.*, 1994). Intra-animal comparisons of left and right soleus muscles in vehicle-treated animals showed a drastic reduction in AChE mRNA levels after denervation as also observed in untreated animals (see accompanying abstract; Vu *et al.*, 1994). In contrast, intra-animal comparisons revealed an interactive effect of CNTF and denervation. In these animals, daily CNTF injections appeared to attenuate the reduction in AChE transcripts after denervation. These results suggest that CNTF may have subtle effects on the expression of genes encoding synaptic proteins, and as such, may contribute to maintaining muscle fibers in a condition that may be less refractory to reinnervation.

461.2

NEURAL REGULATION OF ACETYLCHOLINESTERASE GENE EXPRESSION WITHIN RAT MUSCLE FIBER COMPARTMENTS. C.Q. Vu, R.N. Michel, W. Tetzlaff and B.J. Jasmin*. Department of Physiology, Faculty of Medicine, University of Ottawa, Ottawa, Ontario, Canada K1H 8M5.

Nerve electrical activity and release of trophic factors are implicated in the accumulation of mRNAs encoding AChR subunits within the postsynaptic sarcoplasm (Witzemann *et al.*, J. Cell Biol. 114: 125-141, 1991). We therefore studied the influence of these two components of neural function on the regulation of acetylcholinesterase (AChE) gene expression in mammalian skeletal muscle fibers. This was achieved by comparing the expression of AChE mRNA in adult rat muscle fibers after denervation or after selective blockage of the propagation of sciatic nerve action potentials with the sodium channel blocker tetrodotoxin (TTX). Chronic TTX superfusion of the sciatic using an osmotic pump and cuff delivery system causes a prolonged and reversible paralysis of target muscle fibers while maintaining the integrity of nerve-muscle contacts. Initially, the preferential localization of AChE mRNA within innervated versus non-innervated regions of skeletal muscle fibers was verified in microdissected fiber bundles of rat extensor digitorum longus (EDL) and diaphragm muscles using quantitative RT-PCR. In addition, *in situ* hybridization experiments using a synthetic oligonucleotide showed that AChE transcripts in innervated regions were confined to the area immediately beneath the postsynaptic membrane. These molecular procedures were then used to compare the expression of AChE mRNA in control EDL, plantaris and soleus muscles with that observed 10 days after sciatic nerve section or chronic inactivation with TTX. AChE mRNAs were substantially down-regulated after disuse in these three functionally distinct muscles. The extent of this down-regulation was similar after denervation and TTX paralysis. Our results suggest that the selective accumulation of AChE transcripts within the postsynaptic sarcoplasm is largely regulated by muscle electrical activity *per se* and not by the release of trophic factors (see abstract; Michel *et al.*, 1994).

Supported by MRC and MDA of Canada to BJJ

TROPHIC- AND ACTIVITY-DEPENDENT REGULATION OF SUCCINATE DEHYDROGENASE IN JUNCTIONAL & EXTRAJUNCTIONAL REGIONS OF RAT MUSCLE FIBERS. R.J. Campbell, B.J. Jasmin and R.N. Michel*. Laurentian University, Sudbury; and University of Ottawa, Ottawa, Canada.

Information concerning the density and biochemical composition of mitochondria located in the postsynaptic sarcoplasm of skeletal muscle fibers is still rudimentary and conflicting. We therefore studied the distribution of succinate dehydrogenase (SDH) within this specialized, as well as other distinct compartments of soleus muscle fibers. We also examined the influence of the motor nerve on the regulation of this enzyme at the endplate using two models of short-term muscle inactivity namely, tetrodotoxin (TTX)-induced neural inactivation and denervation. Using quantitative microphotometric imaging techniques, we showed that the endplate region of soleus fibers displays SDH activity that is two- and three-fold higher than in subsarcolemmal (SS) and intermyofibrillar (IM) compartments, respectively, and that essentially all endplate SDH activity is of postsynaptic origin. Both denervation and TTX paralysis reduced SDH activity to a comparable extent (30%) in SS and IM compartments suggesting that expression of this enzyme is co-regulated in these two regions. Alternatively, denervation and TTX-inactivation led to distinct alterations at the endplate level. SDH activity at denervated endplates was reduced dramatically (60%) in comparison to controls whereas at endplates of TTX-inactivated counterparts this reduction was significantly less (35%). These findings suggest that SDH activity is regulated by distinct factors in innervated vs non-innervated regions of muscle fibers. The data are coherent with the view that activity is the key factor regulating expression of SDH in non-innervated regions of muscle fibers and that accumulation of SDH within the postsynaptic sarcoplasm is also subjected to local mechanisms involving neurotrophic factors.

PSD-95, A BRAIN-SPECIFIC RAT HOMOLOGUE OF THE DROSOPHILA *DLG* PROTEIN ASSOCIATES WITH POSTSYNAPTIC DENSITIES IN FOREBRAIN SYNAPTOSOMES. M.B. Kennedy*, C.A. Hunt, L.S. Schenker, and J.L. Rawlings Div. of Biology 216-76, Caltech, Pasadena, CA 91125.

PSD-95 is a prominent, highly-enriched protein in postsynaptic density fractions prepared from rat forebrain. We recently cloned a cDNA encoding PSD-95 (Cho et al. (1992), *Neuron* 9, p.929). The deduced sequence identified it as a homologue of the Drosophila tumor suppressor protein "disc-large," (*dlg*) a component of septate junctions which bind together developing epithelial cells in insect embryos and larvae. We have used affinity-purified antiserum against PSD-95 to confirm its association with the postsynaptic density in forebrain synaptosomes examined in the electron microscope. Synaptosomes were purified from rat forebrain homogenates under non-lytic or lytic conditions to preserve or rupture the presynaptic compartment, respectively. They were lightly fixed and embedded in thin agarose slabs as previously described (DeCamilli et al. (1983), *J. Cell Biol* 96, p1355). The slabs were incubated with α -PSD-95 antiserum, followed by gold-labeled secondary Abs. Controls were incubated with non-immune IgG or with α -PSD-95 preabsorbed with recombinant PSD-95 protein. Prominent labeling of the PSD was observed in synaptosomes labeled with α -PSD-95. 92% of PSDs were labeled, with a median density of 10-15 particles per μ m PSD. In contrast, 81% of non-immune IgG-incubated synaptosomes and 88% of preabsorbed α -PSD-95-incubated synaptosomes showed no labeling of the PSD. Even in lysed synaptosomes, no labeling of the presynaptic terminal or of the cytoplasmic face of the presynaptic membrane was observed. Lysed presynaptic terminals were labeled by Abs against synapsin I, a synaptic vesicle protein, indicating that serum was able to penetrate into the terminal. These data confirm the association of PSD-95 with forebrain postsynaptic densities.

PROTEIN TYROSINE KINASES IN THE POSTSYNAPTIC DENSITY AND THE CTK-LIKE PROTEIN. S.Y. Lin^{1,2}, K. Wu^{1,2}, J.B. Bolen³, R.C. Penhallow³, Y. Huang^{4,5}, J.L. Xu¹ and J.B. Black^{1,2}, ¹Dept. Neurosci. and Cell Biol., UMDNJ/RWJ Med. Sch. and ²Grad. Program in Physiol. and Neurobiol., Rutgers Univ., Piscataway, NJ 08854; ³Dept. Mol. Biol., Bristol-Myers Squibb Pharm. Res. Inst., Princeton, NJ 08543; ⁴Div. Neurosci., NYSPI and ⁵Dept. Psych., Columbia Univ., New York, NY 10032.

Recent evidence showing high levels of protein tyrosine kinase (PTK) activity in adult rat brain suggests that these enzymes, known to regulate cell growth and differentiation, are also functionally important during maturity. Despite their potential roles, however, little is known about specific PTKs and their substrates in the CNS. Since chemical synapses play pivotal roles in brain function, and since the postsynaptic density (PSD) is crucial for synaptic function, we examined this structure for PTKs. Our pilot studies revealed that there were 4 PTKs (M.W. = 166, 90, 66, 50 kDa) present in the cortical PSD of adult rat brain. Results of phosphoamino acid analyses confirmed tyrosine phosphorylation of these kinases. Recently, Ctk, designated as Csk-type kinase, was found to be predominantly expressed in the brain. Similarity in molecular weight and unique localization in the brain suggest that Ctk and the 50 kDa PTK in the PSD may be similar or identical. Indeed, we found that the 50 kDa PTK crossreacted with antisera to Ctk, suggesting that the two proteins are related. Consequently, we termed the 50 kDa PTK in the PSD Ctk-like PTK, and have employed the antisera to Ctk to begin characterizing the enzyme in synapses. Our results, obtained by Western blot analysis, suggest that the Ctk-like PTK was selectively localized to the PSD. Further, the protein was differentially expressed in the PSD isolated from hippocampus, cerebral cortex, cerebellum and olfactory bulb, implying region-specific function. Among the 4 brain regions examined, the PTK was expressed most abundantly in the hippocampus, an area of crucial importance for learning and memory. The identity of the Ctk-like PTK remains to be determined. Nonetheless, our present findings suggest that the enzyme may play important roles in synaptic function at the postsynaptic site.

LIPASES AND PHOSPHOLIPASES IN SYNAPTONEUROSOMES FROM RAT, MOUSE, AND PIG BRAIN. L.A. Horrocks*, H.-C. Yang, and A.A. Farooqui, Dept. Med. Biochem., The Ohio State Univ., Columbus, Ohio 43210

Lipases (EC 3.1.1.34) and phospholipases (EC 3.1.1.4) are involved in signal transduction and neurodegeneration. Compared to homogenates, synaptoneurosomes from cerebral cortex of rat, mouse, and pig contain 20 to 30% of the diacylglycerol and monoacylglycerol lipase activities and 15 to 20% of the Ca^{2+} -independent phospholipase A_2 activity. Specific activities of the lipases were higher in pig and mouse brain synaptoneurosomes than in rat brain synaptoneurosomes. Ca^{2+} -independent phospholipase A_2 activities of synaptoneurosomal fractions from various animal species were similar. However, the specific activity of the Ca^{2+} -independent phospholipase A_2 acting on 1,2-diacyl-*sn*-glycero-3-phosphoethanolamine was higher than that of the Ca^{2+} -independent phospholipase A_2 acting on 1-alk-1-enyl-2-acyl-*sn*-glycero-3-phosphoethanolamine. The occurrence of lipases and phospholipases A_2 in synaptoneurosomes from rat, mouse, and pig brain suggests that these organelles provide a useful model for studying signal transduction systems.

A NEWLY-IDENTIFIED PROTEIN FROM THE RAT POSTSYNAPTIC DENSITY FRACTION, PSD-UP180, IS A MEMBER OF THE FAMILY OF LEUCINE-RICH REPEAT-CONTAINING PROTEINS. M.A. Apperson*, M.B. Kennedy, Division of Biology 216-76, Caltech, Pasadena, CA 91125.

We have identified a new protein, termed PSD-UP180, from the postsynaptic density (PSD) fraction of rat brain. PSD-UP180 has an apparent molecular weight of 180 kDa, and is enriched in the PSD fraction where it comprises about 1% of total protein. It was purified from the postsynaptic density fraction, and trypsinized. Five sequences of purified tryptic fragments were used to design degenerate oligonucleotide primers. One pair of primers amplified a brain-specific 1.1 kb PCR product from rat brain cDNA. Additional complementary clones were isolated from a rat brain cDNA library and the coding region was sequenced. It encodes a 195 kDa protein of 1495 residues. The cognate mRNA was detected only in the forebrain and not in the cerebellum or other tissues. The deduced a. a. sequence reveals a 354 residue domain with homology to the leucine-rich repeat (LRR)-containing proteins. The predicted N-terminus of PSD-UP180 contains 15 LRRs of 23 a. a.'s each. The LRR motif has been identified in a wide variety of proteins most of which are membrane-bound. PSD-UP180 also has a cysteine-rich region spanning amino acids 486-546 and mucin-like threonine/proline-rich repeats spanning amino acids 825 to 940. These three domains are also found in the LRR-containing platelet receptor, glycoprotein Ib α (GP Ib α), which is a transmembrane protein that forms a complex responsible for platelet adhesion to blood vessels. Finally, PSD-UP180 also contains a single "GLGF" repeat at the C-terminus, spanning amino acids 1403 to 1490. GLGF repeats were first identified in another PSD protein, PSD-95. Other GLGF-containing proteins include several associated with intercellular junctions. The enrichment of PSD-UP180 in the PSD fraction and its forebrain-specific expression suggest a role for this LRR-containing protein in signal transduction or adhesion at forebrain synapses.

A MULTITUDE OF SYNAPTOSOMAL PROTEINS POSSESS O-LINKED N-ACETYLGLUCOSAMINE. R.N. Cole* and G.W. Hart, Dept. of Biochem. and Molecular Genetics, Univ. of Alabama, Birmingham, AL 35294

Glycosylation of Ser/Thr residues with a single N-acetylglucosamine (O-GlcNAc) is a dynamic post-translational modification on a variety of nuclear and cytoplasmic proteins. This abundant form of glycosylation often occurs at sites of proline-directed protein kinases and appears to have a reciprocal relationship with protein phosphorylation. A current hypothesis views O-GlcNAc glycosylation as a mediator of reversible association/disassociation of multi-protein complexes.

Recent studies have demonstrated that the neuron-specific phosphoproteins, synapsins, neurofilaments, and now, tau proteins (Arnold et al., 1994 *Soc. Neurosci. Abstr.*), also possess the O-GlcNAc modification. As a first step towards elucidating a role of O-GlcNAc glycosylation in the nervous system, we assayed for the presence of O-GlcNAc in synaptosomes. Galactosyltransferase, a highly specific probe for terminal GlcNAc residues, labeled numerous synaptosomal proteins, ranging from 30-200 kD. More than 60% of the label associated with synaptosomal proteins was resistant to PNGase F (removes N-linked sugars), but sensitive to alkaline β -elimination (removes O-linked sugars). Analysis of these β -elimination products by gel filtration and Dionex HPLC confirmed that the O-linked sugars originated from single GlcNAc modifications. Taken together these data indicate that O-GlcNAc is abundantly present on synaptosomal proteins.

We also detected O-GlcNAc transferase activity in synaptosomal preparations. Thus, this dynamic form of glycosylation could play a role in the association/disassociation of multi-protein complexes regulating neurotransmitter release.

A NOVEL INTERACTION BETWEEN SYNAPTOBREVIN AND SYNAPTOPHYSIN. L. Edelmann*, E. Chapman and R. Jahn, Howard Hughes Medical Institute, Yale University School of Medicine, New Haven, CT 06510

Synaptobrevin and synaptophysin are integral membrane proteins of synaptic vesicles. It has recently been established that synaptobrevin is a key component of the exocytotic fusion complex. In contrast, the function of synaptophysin is still unclear but it has been proposed to form a channel which may play a role in transmitter release.

Here we report about a specific interaction between synaptobrevin and synaptophysin. Using a novel monoclonal antibody for synaptobrevin II, we performed immunoprecipitation experiments from synaptosomal detergent extracts. With this antibody, synaptophysin co-precipitated together with syntaxin and SNAP-25, the members of the putative fusion complex. When a monoclonal antibody for synaptophysin was used, synaptobrevin but none of the other proteins co-precipitated. The interaction between synaptobrevin and synaptophysin was further investigated using recombinant synaptobrevin-GST fusion proteins immobilized to glutathione beads. Synaptophysin bound to all isoforms of synaptobrevin, including cellubrevin. Our findings indicate that synaptobrevin participates in at least two independent sets of protein-protein interactions. Thus it is possible that the availability of the v-SNARE synaptobrevin for membrane fusion may be regulated by synaptophysin or synaptophysin-like proteins indicating that synaptophysin may function as an important regulator of exocytosis.

PROTEIN-PROTEIN INTERACTIONS BETWEEN ACTIN AND ACONITASE-LIKE PROTEINS IN THE PHOTORECEPTOR TERMINAL.

E.A. Estrella, G.W. Balkema*. Department of Biology, Boston College, Chestnut Hill, MA 02167.

Actin binding proteins are important in the dynamic role the actin molecule plays in the architecture of the cellular cytoskeleton. It is thought that many of these actin binding proteins interact with actin by mimicking certain amino acid sequences found within the actin molecule. Certain actin binding proteins are found concentrated at the presynaptic terminal of neurons. These proteins function in part in synaptic vesicle exocytosis. We have generated a monoclonal antibody, B16, that labels the ribbon structure of photoreceptors. Biochemical analysis of tissue homogenates shows that B16 also recognizes four proteins: 31, 49, 88, and 102kD on western blots. Sequencing of the 88kD protein revealed homology to aconitase. Aconitase is found in two forms; mitochondrial, a TCA cycle enzyme that catalyzes the conversion of citrate to isocitrate and cytoplasmic, an iron responsive element for translational regulation. Both forms of the enzyme have the citrate to isocitrate activity.

We decided to investigate the relationship between aconitase and actin. Amino acid sequence comparison of aconitase, actin and other actin binding proteins showed that aconitase contained two motifs implicated in the molecular mimicry of other actin binding proteins. We found that the putative actin binding sites were active by probing western blots of aconitase and aconitase containing homogenates with biotinylated actin (far-western). Next to determine if this actin-aconitase interaction was functional we found that aconitase contributes to the polymerization of actin into a filamentous network in low Ca^{2+} . Aconitase is also recognized by actin poly and monoclonal antibodies. These results suggest there maybe a functional as well as a physical similarity between aconitase and other actin binding proteins. (Supported by Boston College REG)

NEUROCHEMICAL CHARACTERISTICS OF A POSTSYNAPTIC DENSITY (PSD) FRACTION ISOLATED FROM BOVINE RETINA.
Y. Huang, J.E. Adler* and K. Wu. Div. of Neuroscience, New York State Psych. Inst. and Dept. Psych., Columbia Univ., New York, NY 10032;

Considerable evidence suggests that the PSD, a disc-shaped proteinaceous structure attached to the inner surface of postsynaptic membrane, play a crucial role in synaptic function. We have previously demonstrated that the molecular characteristics of the PSD differ among the rodent cerebral cortex (CTX), cerebellum (CBL), hippocampus (HI) and olfactory bulb (OB). To further characterize the regional differences in PSD characteristics throughout the brain, we examined the adult bovine retina, a structure richly innervated by both peripheral and central afferents. Bovine CTX-PSD was studied in parallel for comparison. Morphologically, both the CTX-PSD and retina-PSD exhibited a typical disc-like structure. On average, the retina-PSD was shorter in length than the CTX-PSD and appeared to be more sensitive to Triton X-100, the nonionic detergent employed for isolation of the PSD. SDS-PAGE profiles of the retina-PSD and CTX-PSD were similar qualitatively, but were different quantitatively. Both bovine retina- and CTX-PSD contained several intrinsic protein kinase activities, similar to those found in rodent and canine PSDs. We conclude that bovine retinal PSD may provide a useful model to study the regulation of synaptic molecular architecture in the visual system in response to environmental stimuli.

PRESYNAPTIC MECHANISMS III

462.1

DIRECT RECORDING FROM IDENTIFIED SYNAPTIC TERMINALS IN THE RAT AUDITORY PATHWAY: EXAMINATION OF A GLUTAMATE AUTORECEPTOR. L.D. Forsythe* & M. Barnes-Davies. Department of Cell Physiology & Pharmacology, Leicester University, Leicester LE1 9HN, U.K.

We are interested in the mechanism by which presynaptic glutamate receptors modulate transmission at excitatory synapses. A quantal analysis can give indirect information on changes in the probability of transmitter release, but to address the mechanism of such phenomena, direct presynaptic recording is desirable. The small size of most synaptic terminals in the mammalian CNS makes direct recording impossible, so we have developed a slice preparation of the rat brainstem, containing the superior olivary complex, within which a large synaptic terminal called the calyx of Held is localised.

Transverse slices were prepared from 6-12 day-old Lister Hooded rats. Whole-cell patch recordings were made from the principal neurones of the medial nucleus of the trapezoid body (MNTB). Dual component monosynaptic EPSCs were evoked by stimulation of the presynaptic axon. A fast component is mediated by AMPA receptors and a slow EPSC is mediated by NMDA receptors. In the presence of NMDA-receptor antagonists, perfusion of 10-50µM 1S3S ACPD or L-AP4 depressed the EPSC by up to 80% as has been observed in the hippocampus (Forsythe & Clements, J. Physiol. 429: 1-16, 1990). Analysis of the coefficient of variance for the evoked EPSCs showed that both drugs act at a presynaptic site to depress transmitter release. The putative mGluR antagonist α -methyl-4-carboxy-phenylglycine (1 mM) had no effect on the presynaptic depression.

Direct patch recordings from these presynaptic terminals have been achieved, using Lucifer yellow to confirm the identity of the recording site. Under current-clamp the action potential possessed a profound after-hyperpolarization and responded to depolarising current injection with a train of APs at up to 200 Hz (25°C). In voltage-clamp a tetrodotoxin-sensitive inward current was followed by a rapidly activating outward current which was sensitive to micromolar concentrations of 4-aminopyridine. Supported by the Wellcome Trust.

462.2

GABA_A AND METABOTROPIC RECEPTOR AGONISTS ATTENUATE EVOKED EXCITATORY POSTSYNAPTIC CURRENTS IN LATERAL PARABRACHIAL NUCLEUS (LPBN) NEURONS *IN VITRO*. J.A. Zidichouski*, J.C. Easaw and J.H. Jhamandas. Department of Medicine (Neurology), University of Alberta, Edmonton, Canada.

The LPBN is a major recipient of autonomic information from more caudal regions of the brainstem. Previously, we have reported that postsynaptic excitatory (NMDA & non-NMDA) and inhibitory (GABA_A) amino acid receptors mediate neurotransmission within the LPBN. The present study shows that excitatory postsynaptic currents observed in the LPBN are attenuated by GABA_A and metabotropic receptor agonists. These actions are independent of any apparent postsynaptic effect and suggest that the principal transmitters released in the LPBN can negatively influence transmitter liberation via a presynaptic mechanism of action.

LPBN neurons were recorded from 400 µm thick coronal brainstem slices using the whole-cell patch clamp technique. Monosynaptic excitatory postsynaptic currents (EPSC) were evoked via bipolar electrodes (@ 0.2Hz; duration 100µs; 10-50V) placed across the dorsal medial aspect of the LPBN. Bath application of the metabotropic receptor agonist, trans-1-aminocyclopentane-1,3-dicarboxylate (t-ACPD; 10 µM) reduced EPSC amplitude by $49.9 \pm 6.9\%$ (n=9). No concomitant change to the resting current ($V_{rest} = -60mV$) or the current observed during voltage ramp (-120 to -40mV; 20sec) was observed. The GABA_A agonist, baclofen (BAC; 1µM), similarly reduced the amplitude of the EPSC by $61.3 \pm 9.3\%$ (n=2). Bath application of BAC at this dose did not activate postsynaptic GABA_A receptors as no change was observed in resting current or voltage ramp-generated currents. These results provide evidence for the existence of two receptor-mediated presynaptic inhibitory mechanisms that reduce evoked transmitter release from terminals and thereby influence the excitability of LPBN neurons.

462.3

PRESYNAPTIC METABOTROPIC GLUTAMATE RECEPTORS REDUCE SYNAPTIC TRANSMISSION IN THE NEONATAL RAT HIPPOCAMPUS T.C. Dumas* and T.C. Foster. Dept. of Psychology, Univ. of Virginia, Charlottesville, VA, 22903.

Presynaptic modification of synaptic transmission occurs in the developing rat hippocampus. Developmental increases in population and unitary EPSPs are accompanied by decreased paired-pulse facilitation suggesting an increase in the probability of transmitter release. Facilitation changes may reflect developmental regulation of autoreceptors. Previous research has shown that the metabotropic glutamate receptor (mGluR) agonist, trans-ACPD, depresses CA3-CA1 EPSPs in voltage-clamped CA1 pyramidal cells from neonatal rats. This experiment investigates possible presynaptic effects of mGluR activation on synaptic function. Evoked field EPSPs (~1mV ampl.) were recorded from area CA1 in hippocampal slices taken from five week old rats. Paired-pulse stimulation (50ms ISI) was applied (0.1Hz) in order to measure changes in facilitation before and after iontophoresis (5min) of trans-ACPD. Recording was performed for 10min before and continued for at least 30min after drug application. EPSP amplitudes and paired-pulse facilitation ratios were averaged in ten minute epochs. Application of trans-ACPD (25mM) resulted in rapid decay of the EPSP to approximately 20% of baseline values and slowly recovered over the following half hour. ANOVAs revealed that the EPSP was significantly reduced ($p < 0.01$) and paired-pulse facilitation was increased relative to baseline ($p < 0.01$) suggesting a decrease in the probability of transmitter release. Post-hoc Scheffe tests showed that the reduction in the EPSP amplitude (predrug vs. 20-30min postdrug, $p < 0.05$) outlasted the increase in facilitation, suggesting either increased duration or sensitivity of the postsynaptic effects. Experiments are underway to examine possible developmental shifts in the effects of presynaptic mGluR activation on CA3-CA1 synaptic transmission. Supported by NS31830 to TCF.

462.4

PRESYNAPTIC MODULATION OF GLUTAMATERGIC NEUROTRANSMISSION BY GABA_A AND METABOTROPIC RECEPTORS IN THE HORIZONTAL LIMB OF THE DIAGONAL BAND OF BROCA (hDBB) *IN VITRO*. J.C. Easaw* and J.H. Jhamandas. Dept. of Medicine (Neurology), Univ. of Alberta, Edmonton, Alberta, Canada T6G 2B7

The DBB, a basal forebrain cholinergic nucleus, participates in central autonomic regulation, theta rhythm generation, and memory mechanisms. Previously, we reported that postsynaptic NMDA and AMPA/kainate receptors mediate excitatory transmission in hDBB neurons. In the present study, we examined the mechanism whereby GABA_A and metabotropic receptors modulate glutamatergic neurotransmission.

Whole cell patch clamp recordings were obtained from coronal slices (400µm) of the rat forebrain containing the hDBB. Bipolar stimulation electrodes (200 µs duration; 2Hz; range 10-70V) placed in the hDBB evoked excitatory postsynaptic currents (EPSCs). Bath application of baclofen (5µM), a GABA_B receptor agonist, attenuated evoked EPSCs in the hDBB with no changes in resting current or input resistance measured during voltage ramps (-140 to -40 mV; 20 sec) (n=12). NBQX (1µM), an AMPA receptor-selective antagonist, also attenuated the EPSC. The metabotropic receptor agonist trans-ACPD (10 µM) also reduced evoked EPSCs with no concomitant changes in resting current or input resistance (n=13). Furthermore, both baclofen and trans-ACPD did not alter postsynaptic AMPA-mediated inward current, thereby confirming their presynaptic locus of action. These data suggest that glutamatergic synaptic transmission, which may mediate physiologically important inputs to the hDBB, can be modulated presynaptically by GABA_B and metabotropic receptors.

Supported by the MRC of Canada and the AHFMR.

A NEW TECHNIQUE FOR COMPARING EVOKED AND SPONTANEOUS SYNAPTIC TRANSMISSION AT CORTICOSTRIATAL SYNAPSES. E.C. Tyler* and D.M. Lovinger. Dept. of Mol. Physiol. & Biophys., Vanderbilt Med. Sch., Nashville, TN 37232.

We would like to compare the effects of presynaptic receptor activation on evoked and spontaneous excitatory transmission at corticostriatal synapses. However, we have found that spontaneous EPSCs (sEPSCs) recorded in striatal slices are very small and infrequent. Thus, we have developed a new preparation in which we grow cortical explants in culture with dissociated striatal neurons. The cortical explants (~500 x 500 µm) extend processes and form synapses with the neighboring striatal cells. In this preparation we can record sEPSCs using whole-cell recordings in the striatal cells. In the presence of 200 nM TTX we can also record miniature EPSCs (mEPSCs). To record evoked EPSCs in the same striatal cells a bipolar metal electrode placed on the cortical explant is used to stimulate the tissue. 5 µM DNQX blocks mEPSCs, sEPSCs and EPSCs indicating that synaptic transmission in this system is glutamatergic. The amplitude of evoked EPSCs is inhibited by mGluR activation by *t*-ACPD and by adenosine. 5 µM *t*-ACPD produces a $9.8 \pm 3.6\%$ (n=9) potentiation, 50 µM *t*-ACPD produces a $31.3 \pm 5.2\%$ (n=7) inhibition, 75 µM *t*-ACPD, $46.9 \pm 5.2\%$ (n=3) inhibition, and 50 µM adenosine, $43.8 \pm 8.6\%$ (n=3) inhibition. Spontaneous transmission is also affected by mGluR activation with *t*-ACPD. 5 µM *t*-ACPD has no effect on the mean amplitude of sEPSCs and decreases the time between events by 21.8% (n=2), 50 µM *t*-ACPD produces a $12.3 \pm 10.0\%$ (n=7) inhibition of the mean amplitude and increases the time between events by $100.8 \pm 49.3\%$. 50 µM *t*-ACPD appears to have no effect on the mean amplitude of mEPSCs (n=3) and increases the time between events by 0 - 35%. We have successfully used this preparation to look at evoked and spontaneous transmission at the same synapse and have shown that mGluR activation affects both. (Supported by NS 30470)

462.7

PRESYNAPTIC CHARACTERISTICS OF TWO GABA_A IPSCS IN RAT HIPPOCAMPAL CA1 NEURONS. R.A. Pearce* and S.D. Grunder. Departments of Anesthesiology and Anatomy, Univ. Wisconsin, Madison, WI 53706.

Acting via a GABA_B autoreceptor, GABA limits its own release during trains of synaptic excitation, thus permitting induction of LTP and imparting a filter characteristic to the hippocampal circuit. It is not known to what extent these effects reflect modulation of the fast somatic or the slow dendritic GABA_A components, nor even whether the two components are modulated similarly. In the present study we have characterized the frequency-dependent and GABA_B-mediated depression of the two components of GABA_A-mediated inhibition.

Monosynaptic IPSCs were recorded from adult rat hippocampal CA1 cells in the presence of APV (40 µM) and CNQX (20 µM). Sharp electrodes filled with CsAcetate (3M) or CsCl (3M) and QX-314 were used to record GABA_{A,fast} and GABA_{A,slow} in response to electrical stimulation of stratum pyramidale and stratum lacunosum-moleculare, as described previously (Neuron 10:189-200, 1993). It was found that paired-pulse depression of GABA_{A,slow} follows the time course described previously for stratum radiatum responses, with a slow onset and maximal depression of 60% at approximately 160 ms. In contrast, GABA_{A,fast} was depressed maximally by 40% at 5 ms, and declined at later time points, so that only 10% depression remained at 160 ms. GABA_{A,fast} was also relatively resistant to the action of (-)baclofen, being maximally depressed by only 50% at 10-100 µM, with no effect at 1 µM, whereas GABA_{A,slow} was depressed by 50% at 0.3 µM, and completely eliminated at 1 µM. CGP 35348 only partially reversed the paired-pulse depression of GABA_{A,fast} but eliminated paired-pulse depression of GABA_{A,slow}.

These experiments demonstrate significant differences between the presynaptic characteristics of the two components of GABA_A inhibition, suggesting that different mechanisms may underlie their use-dependent depression, and further supporting distinct functional roles for the two systems.

462.9

CHARACTERIZATION OF AN ATP RECEPTOR ON A CHOLINERGIC PRESYNAPTIC NERVE TERMINAL. X.P. Sun and E.F. Stanley*. Synaptic Mechanisms Section, NINDS, Bldg 36, Rm. 5A27, NIH Bethesda, MD 20892.

ATP activates a cation channel on the presynaptic nerve terminal of the cholinergic calyx-type synapse in chick ciliary ganglion (Soc. N.S. Abst. 19:901). We have examined the pharmacology of this receptor using purinergic agonist and antagonists.

Calyx nerve terminals and their postsynaptic ciliary neurons were isolated and patch clamped (J Neurosci, 11:985). ATP induced fast-activating currents in both the calyx and neuron with reversal potentials of about 0 mV. The nerve terminal ATP current inactivated slowly whereas the neuron exhibited both fast and slow inactivating current components. The P₂-agonist, ATPγS and 2 MeS-ATP mimicked ATP while the P₁ and P_{2X}-agonists, adenosine and β,γ-methylene ATP were ineffective. The P₂-blockers, reactive blue and suramin, were ineffective on the nerve terminal and eliminated only the fast-inactivating current in the neuron.

Our results suggest that the slowly inactivating ATP conductance on this presynaptic nerve terminal is mediated by neither P_{2Y} nor P_{2X}-type receptors but by an as yet unidentified receptor type. Since ATP is stored with ACh in secretory vesicles, this presynaptic ATP receptor may play a role in the feed-back modulation of transmitter release.

462.6

RECEPTOR-EFFECTOR COUPLING MECHANISM UNDERLYING THE DESENSITIZING PRESYNAPTIC GABA_B RECEPTOR-MEDIATED INHIBITION OF EXCITATORY SYNAPTIC TRANSMISSION. K.D. Phelan*. Dept. of Anatomy, Univ. of Arkansas for Medical Sciences, Little Rock, AR 72205.

We previously proposed the existence of a desensitizing presynaptic GABA_B receptor (DS-GABA_B) mediating inhibition of glutamate release at a functionally distinct subset of excitatory terminals in which the postsynaptic membrane only expresses N-methyl-D-aspartate (NMDA) receptors (Phelan et al., Soc. Neurosci. Abstr. 18:792). In the present study, whole-cell patch clamp recordings of cultured embryonic hippocampal neurons were used to investigate and compare the receptor-effector coupling mechanisms utilized by this DS-GABA_B receptor and the non-desensitizing (NDS-GABA_B) receptor regulating transmission at conventional excitatory synapses which express postsynaptic NMDA and non-NMDA receptors.

Superfusion of Ba²⁺ (1mM) failed to block baclofen-induced activation of DS-GABA_B or NDS-GABA_B inhibition of spontaneous NMDA or non-NMDA receptor-mediated synaptic currents, respectively, indicating that neither receptor is coupled to a K⁺ channel. Pretreatment of cell cultures with pertussis toxin (1.0 µg/ml, 24-48 hrs) selectively blocked DS-GABA_B but not NDS-GABA_B inhibition in some cultures suggesting receptor coupling to separate G-proteins. Pretreatment and co-superfusion of phorbol 12,13-dibutyrate (1 µM) blocked both DS-GABA_B and NDS-GABA_B receptor-mediated inhibition. Pretreatment with diocanoylglycerol (1 µM) blocked NDS-GABA_B but not DS-GABA_B inhibition though receptor desensitization was blocked. These results suggest that presynaptic DS-GABA_B and NDS-GABA_B receptors may regulate the synaptic release of glutamate through distinct receptor-effector coupling mechanisms. This raises the possibility for selective modulation of transmission at functionally distinct glutamatergic synapses.

DOES MUSCARINE ACTIVATE K⁺ CHANNELS AT PRESYNAPTIC TERMINALS IN HIPPOCAMPAL AREA CA1?

G.J. Klapstein*, S. Wechsler and W.F. Colmers. Dept. of Pharmacology, Univ. of Alberta, Edmonton, Alberta, CANADA, T6G 2H7.

Presynaptic inhibition of glutamate release in hippocampal area CA1 can be mediated by the activation of several different receptors, including GABA_A, Adenosine A₁, Neuropeptide Y₂, and a muscarinic acetylcholine receptor. The mechanism whereby these receptors act at presynaptic terminals cannot be recorded directly. Nevertheless, if they all act via an identical mechanism, their actions should be equally affected by manipulations that affect transmitter release. 4-Aminopyridine (30 µM) reduces inhibition mediated by the Y₂, A₁, and GABA_A receptors, but not that caused by muscarine. Tetraethylammonium (1 mM) reduced the inhibition caused by muscarine. Here, we tested the hypothesis that muscarinic receptors activate presynaptic K⁺ channels, by examining its actions when some K⁺ channels are blocked by applying Ba²⁺.

Extracellular recordings were made of population EPSP's evoked in area CA1 by stimulation of stratum radiatum in hippocampal slices (400 - 500 µm, 21 - 30 d.o. S.-D. rats). Dose-response curves to muscarine were performed in the absence and presence of 100 µM Ba²⁺. Surprisingly, Ba²⁺ potentiated the inhibitory actions of muscarine throughout the dose-response curve. At the same time, in the same preparations, Ba²⁺ modestly reduced the effects of both baclofen and adenosine.

The observations are not consistent with muscarinic receptors inhibiting glutamate release by the same mechanism as A₁ or GABA_A receptors. Indeed, the observed response is consistent with the activation by muscarine of a presynaptic K⁺ channel. If this were the case, the block of presynaptic K⁺ channels by Ba²⁺ would increase the resistance of the terminal, and activation of another K⁺ channel by muscarine would bring the membrane potential closer toward E_K, thus further from threshold than under control conditions.

NICOTINE FACILITATES AND DEPRESSES GLUTAMATERGIC SYNAPTIC TRANSMISSION AT A CNS SYNAPSE *IN VITRO* D.S. McGehee* & L.W. Role. Dept of Anatomy & Cell Biology in the Center for Neurobiology and Behavior, Columbia University, 722 W 168th St, NY, NY 10032.

Although habenular neurons from both chick and rat express nicotinic ACh receptors (nAChRs). Physiological studies demonstrate that these receptors are not involved in synaptic transmission. Autoradiographic studies localize many CNS nAChRs to terminal fields, including that of the habenula-IPN projection. We tested whether habenular nAChRs could play a role in modifying synaptic transmission *in vitro*. Explants of embryonic chick habenula were cultured with dissociated IPN neurons, a principle target of habenula neurons *in vivo*. Whole cell recording from IPN neurons located near habenula explants revealed robust, spontaneous and evoked synaptic activity that is blocked by a mixture of the glutamatergic antagonists, CNQX and APV, and not by the nicotinic antagonist, mecamylamine, demonstrating glutamatergic synapses at these habenula-IPN synapses. Stimulation of the habenular neurons via an extracellular stimulating electrode evokes postsynaptic currents (EPSCs). Application of a low concentration of nicotine (0.5 µM) increases the amplitude of EPSCs, returning to baseline within 30-90sec, even in the continued presence of the nicotine. This concentration of nicotine also caused an increase in the frequency of spontaneous miniature EPSCs recorded in the presence of 5 µM TTX, without affecting the amplitude of these currents. This supports the idea that the receptors responsible for nicotine-induced synaptic facilitation are located on the presynaptic cell.

In contrast, application of nicotine at 10-20 µM increases the percent failure of the evoked EPSCs, possibly due to shunting of the invading action potential. The mechanisms and nAChR subtypes responsible for these nAChR-mediated modifications in synaptic transmission are not yet known. α -LATROTOXIN ENHANCES SYNAPTIC TRANSMISSION BUT DOES NOT PREVENT PRESYNAPTIC INHIBITION INDUCED BY ADENOSINE, BACLOFEN AND OPIOID PEPTIDES IN HIPPOCAMPUS. M. Capogna*, B. H. Gähwiler and S. M. Thompson. Brain Research Institute, University of Zurich, CH-8029 Zurich Switzerland

The black widow spider venom component α -latrotoxin (α -LTX) binds to the α -LTX receptor that is associated with presynaptic proteins, synaptotagmin, syntaxin, and Ca^{2+} channels. These proteins control the docking of synaptic vesicles at the active zones and regulate exocytosis. Spontaneous mEPSCs (in the presence of TTX and bicuculline) and mIPSCs (in the presence of TTX, CNQX, and AP5) were recorded by means of whole-cell voltage clamp in CA3 pyramidal cells of rat hippocampal slice cultures. Focal application of α -LTX ($< 1\text{ nM}$) produced a 10-100 fold increase in the frequency of both basal mEPSCs and mIPSCs which persisted for at least 1 h. The α -LTX-induced activity was characterized by intermittent high-frequency bursts, and was only slightly affected by $100\text{ }\mu\text{M}$ Cd^{2+} . Furthermore, α -LTX (with or without Cd^{2+}) did not occlude the reduction in the frequency of miniature currents induced by $50\text{ }\mu\text{M}$ adenosine, $10\text{ }\mu\text{M}$ baclofen, and by $1\text{ }\mu\text{M}$ of the μ -opioid agonist FK 33-824. Therefore, these agents inhibit transmitter release by a mechanism that does not involve the modulation of the proposed α -latrotoxin/synaptotagmin/syntaxin/ Ca^{2+} channel complex.

GENETIC EVIDENCE THAT MODULATION OF BOTH K AND Ca CURRENTS CONTRIBUTE TO α_2 -ADRENOCEPTOR-MEDIATED INHIBITION OF HORMONE SECRETION. P.P. Lakhani, D.M. Lovinger and J.E. Limbird*. Department of Pharmacology and Department of Molecular Physiology and Biophysics, Vanderbilt University, Nashville, TN 37232.

The α_2 -adrenoceptor (α_2 -AR), a member of the G-protein-coupled receptor family, inhibits neurotransmitter and hormone release in neuronal and non-neuronal systems. Point mutation of the highly conserved aspartate residue in the putative second transmembrane segment of the receptor to asparagine (D79N α_2 -AR) results in loss of coupling of the receptor to potassium (K) current without any profound effect on the receptor-mediated inhibition of adenylate cyclase (AC) and calcium (Ca) current (Science, 257:977, 1992). We have utilized this unique D79N α_2 -AR as a tool to examine the precise involvement of these effector systems in the inhibitory action of the α_2 -AR. The effect of activation of stably transfected wild-type (D79 WT) and D79N α_2 -AR on secretagogue-induced adrenocorticotrophic hormone (ACTH) secretion from mouse anterior pituitary cells (AtT20 cells) was examined. The basal ACTH secretion was not significantly different in AtT20 cells expressing D79 WT and D79N α_2 -AR. Treatment with the β -adrenoceptor agonist isoproterenol resulted in concentration-dependent stimulation of ACTH secretion which, again, was not significantly different in the two cell lines. However, activation of D79N α_2 -AR by the maximal concentration of the α_2 -AR agonist UK 14,304 resulted in significantly less inhibition of isoproterenol-stimulated ACTH secretion compared to that observed with D79 WT ($39\pm 9\%$ vs $77\pm 14\%$). Next the possible involvement of AC in the α_2 -AR-mediated inhibition was examined. When ACTH secretion was stimulated by the cAMP analogue 8-Br-cAMP, D79 WT and D79N α_2 -AR activation was still able to suppress the stimulated secretion. Together these results suggest that (1) only a part of the α_2 -AR-induced inhibition is mediated by K current activation, and (2) modulation of AC plays a minor role in the α_2 -AR-induced inhibition, implying that suppression of Ca current may be responsible for the remaining α_2 -AR inhibitory component. NORADRENALINE PRESYNAPTICALLY INHIBITS THE EPSC OF SYMPATHETIC PREGANGLIONIC NEURONS. T. MIYAZAKI, H. KOBAYASHI, S. MOCHIDA* and T. TOSAKA. Dept. of Physiol., Tokyo Medical College, Tokyo 160, Japan. Sympathetic preganglionic neurons (SPNs) in spinal cord thin slices from P7 to P12 rats were identified by DiI preinjection to the superior cervical ganglion. Under the whole-cell configuration of slice-patch method, we recorded a monosynaptic EPSC in the SPNs evoked by stimulation at the nucleus intercalatus, in the solution containing strychnine ($5\text{ }\mu\text{M}$) and bicuculline ($10\text{ }\mu\text{M}$). The EPSCs were abolished by kynurenic acid (2 mM) or CNQX ($10\text{ }\mu\text{M}$). Noradrenaline (NA) inhibited reversibly the EPSCs in about 80 % neurons tested. The inhibitory effect was dose-dependent, reaching maximum at $10\text{ }\mu\text{M}$. However, at a higher dose of NA ($500\text{ }\mu\text{M}$), about 50 % of EPSC was remaining. NA did not induce any appreciable shift of the reversal potential of the EPSCs, which was about zero mV. Glutamate current generated by pressure application to the soma was not affected by NA, though the simultaneously recorded EPSC was inhibited. NA effect completely disappeared in the phentolamine ($10\text{ }\mu\text{M}$) solution. The results suggest that NA affected the presynaptic terminal to inhibit the release of glutamate through activation of the α -adrenergic receptors.

ACETYLCHOLINE RELEASE EVOKED BY ACTION POTENTIALS IN THE ABSENCE OF CALCIUM ENTRY IN FROG MOTOR NERVE; ANTAGONISM BY ADENOSINE. M. Watanabe, E.M. Silinsky*, R.S. Redman, J.K. Hirsh, R. Qiu, J.M. Hunt, S. Alford and R.C. MacDonald. Depts of Physiol., Pharmacol. and Biolog. Chem. Northwestern U. Chicago, IL 60611 and Evanston, IL 60208.

While the essential need for Ca entry through Ca channels is indisputable for normal secretion, the importance of voltage-sensitive Ca binding proteins as mediators of secretion in vertebrate nerve endings has been a subject of considerable controversy. The target site for adenosine, which has been implicated as a presynaptic mediator of neuromuscular depression, is likewise controversial. We decided to test the possibilities that: i) a voltage-sensitive Ca binding protein promotes phasic acetylcholine (ACh) release and ii) that the action of adenosine might be to impair the functioning of Ca binding proteins associated with the secretory apparatus. We delivered Ca via Ca-containing lipid vesicles (Ca liposomes) to motor nerve terminals in frog cutaneous pectoris muscle under conditions in which Ca entry cannot occur. Neurally-evoked ACh release (recorded as multiquantal end-plate potentials) was generated by Ca liposomes suspended in solutions with no added Ca and containing either a) Mg ($1\text{-}3\text{ mM}$), b) Mg ($1\text{-}3\text{ mM}$) + Co (1 mM) or c) Mg (1 mM) + EGTA (1 mM). Adenosine ($10\text{-}100\text{ }\mu\text{M}$) inhibited ACh release generated by nerve impulses in the absence of Ca entry. Both electrophysiological controls and morphological studies using confocal laser microscopy suggest that the liposomes are interacting with the nerve terminal membrane and delivering their entrapped contents to the cytoplasmic milieu without leakage to the exterior of the cell. The results suggest that action potentials in vertebrate motor nerve endings can promote the synchronous, physiologically-functional form of ACh release in the absence of Ca entry provided the cytoplasmic Ca is elevated by Ca liposomes. Such evoked ACh release in the absence of Ca entry is antagonized by adenosine. (Supported by NIH Grants NS12782 and NS30795).

PRESYNAPTIC ENHANCEMENT OF EXCITATORY SYNAPTIC TRANSMISSION IN THE HIPPOCAMPUS BY β -ADRENERGIC RECEPTOR ACTIVATION. P.J. Conn* and R.W. Gereau IV. Department of Pharmacology and Program in Neuroscience. Emory Univ. Sch. of Med. Atlanta, GA 30322.

β -adrenergic receptor activation has effects in the hippocampus that might influence synaptic transmission, including potentiation of voltage-gated calcium channels and phosphorylation of synapsins. While direct activation of adenylate cyclase with forskolin has been shown to potentiate transmission in area CA1, it is not known if the β -adrenergic receptor-induced increase in cAMP has similar effects. We now report that application of isoproterenol to hippocampal slices potentiated evoked excitatory postsynaptic currents (EPSCs) in CA1 pyramidal cells, and this response was potentiated in the presence of a phosphodiesterase inhibitor. Isoproterenol also resulted in the appearance of a late inward current that likely represents polysynaptic EPSCs. The potentiation of EPSC in response to isoproterenol was blocked by H89, an inhibitor of cAMP-dependent protein kinase. In addition, isoproterenol induced an increase in the frequency of spontaneous miniature EPSCs, but did not affect the amplitude of mEPSCs or currents elicited by direct application of AMPA. These results suggest that presynaptic β -adrenergic receptors may act to enhance synaptic transmission in area CA1 via activation of cAMP-dependent protein kinase.

462.16

EFFECT OF PERGOLIDE ON ENDOGENOUS AND EXOGENOUS L-DOPA METABOLISM IN THE RAT STRIATUM: A MICRODIALYSIS STUDY.

S. Dethy, M.A. Laute, A. Luxen, J. Hildebrand and S. Goldman*. Service de Neurologie et PET/Biomedical Cyclotron Unit, ULB-Hôpital Erasme, Brussels, Belgium.

Previous studies have shown that dopamine (DA) receptor agonists and antagonists may modulate release and metabolism of endogenous DA. We used a model of intrastriatal microdialysis in freely moving rats to study the effect of pergolide, a D_1 and D_2 DA receptor agonist, on the biotransformation of endogenous and exogenous L-DOPA.

Levels of L-DOPA, DA, DOPAC and HVA were measured by high-performance liquid chromatography. Pergolide (50 mg/kg , i.p.) caused a 47 % decrease in basal striatal extracellular (EC) levels of DOPAC and a 65 % decrease in basal striatal EC levels of HVA, 60 minutes and 120 minutes after injection, respectively. EC DA became undetectable 60 minutes after injection of pergolide. L-DOPA (100 mg/kg , i.p.), injected 2 hours after carbidopa, produced significant increase in EC levels of L-DOPA, DOPAC, HVA and DA in rats with and without local perfusion of 10^{-4} M pergolide. The DOPAC peak value was lower and was reached 60 minutes later in the group with pergolide.

This study demonstrates inhibitory effects of pergolide on release and metabolism of endogenous DA and on biotransformation of exogenous L-DOPA. These effects, probably mediated by DA autoreceptors, might have important pharmacological implications.

Cloning and expression of the P2X receptor reveals a new class of ligand-gated ion channel

Valera, S., Hussey, N., Adams, N., Evans, R., North*, R.A., Surprenant, A.M. & Buell, G.

Glaxo IMB, CP 674, 1228 Geneva, Switzerland

A cDNA encoding an ion channel gated by extracellular ATP (P2X receptor) was isolated from the rat vas deferens by expression cloning in *Xenopus* oocytes. When expressed in oocytes or in the HEK-293 cell line, this clone produces a receptor activated by nM concentrations of ATP, which shows strong desensitization. It is non-selective for cations and highly permeable to Ca^{2+} . It exhibits a P2X-type pharmacology, being activated by 2-methyl-S-ATP > ATP > $\alpha\beta$ -methylene-ATP, and inhibited by suramin and pyridoxalphosphate-6-oxophenyl-2',4'-disulphonic acid (PPADS). In outside-out patches excised from oocytes expressing the P2X clone, single channels of about 11 pS are activated by ATP. The cDNA consists of 1837 bp with an open reading frame predicting a protein of 399 amino acids. The protein sequence bears no homology to other ligand-gated ion channels and appears to have only two hydrophobic segments long enough to span the membrane. This receptor with novel structure probably represents the first member of a new class of ligand-gated ionotropic receptors.

BIPHASIC MODULATION OF THE GLYCINE RECEPTOR BY Zn^{2+} .

A.B. Bloomenthal, E. Goldwater, D.B. Pritchett* and N.L. Harrison*.
Depts. of Anesthesia and Pharm./Phys. Sciences, Univ. of Chicago, Chicago, IL, and *Dept. of Pharm., Univ. of Pennsylvania, Philadelphia, PA.

Zn^{2+} exerts a subunit-dependent inhibitory action on the GABA_A receptor (Draguhn et al., *Neuron*, 5: 781-8). We have studied the effects of Zn^{2+} on the structurally related glycine receptor (GLY-R). In whole-cell patch clamp experiments on cultured rat spinal neurons, Zn^{2+} potentiated GLY-activated Cl^- currents at a concentration of 500 nM, but blocked the current at a concentration of 50 μM . The native GLY-R is an $\alpha_3\beta_2$ heteropentamer (Langosch et al., *PNAS*, 85:7394-8). Further experiments were conducted by transient expression of receptor in HEK 293 cells by transfection with cDNAs encoding the α_2 and β subunits of the human GLY-R. When the α_2 subunit alone was expressed, GLY-activated Cl^- currents were blocked by strychnine (100 nM) and inhibited by picrotoxin (PTX) concentrations as low as 1 μM , potentiated by Zn^{2+} concentrations between 0.2 and 2 μM , and blocked by concentrations > 5 μM . When the α_2 and β subunits were expressed together, PTX sensitivity was abolished, as in spinal neurons. However, the addition of the β subunit had little effect on Zn^{2+} sensitivity. It seems likely that Zn^{2+} acts on the α subunit, while the β subunit has little effect on the Zn^{2+} interaction. The dual action of Zn^{2+} in modulating GLY-Rs suggests that two distinct binding sites may be present. The biphasic action of Zn^{2+} on the GLY-R is interesting in view of other reports of dual Zn^{2+} modulation of ligand-gated ion channels (Hollmann et al., *Neuron*, 10:943-954). The possible conservation of Zn^{2+} modulatory sites may prove significant in the case of the NMDA receptor, which also carries a binding site for glycine as an essential co-agonist. We thank Heinrich Betz for the β subunit cDNA.

463.5

CLONING OF A cDNA FOR A GLYCINE-BINDING PROTEIN. K. N. Kumar*, K. K. Babcock, P. S. Johnson, X. Chen, A. Riegel, and E. K. Michaelis. Department of Pharmacology and Toxicology and The Higuchi Biosciences Center, Univ. of Kansas, Lawrence, KS 66045

Four proteins isolated from rat brain synaptic membranes have molecular sizes of 67-70, 53-58, 41-46, and 31-36 kDa and contain binding sites for NMDA, glutamate, 2-AP5, TCP, and glycine (Kumar et al., *Nature*, 354, 70, 1991). A 40-42 kDa glycine-binding protein has been isolated by affinity chromatography on 5,7-dichlorokynurenate (5,7-DCKA) columns (Babcock et al., *Neurosci. Abs.*, 20, 1994). Polyclonal antibodies raised against the 40-42 kDa proteins labeled a 60 kDa protein in synaptic membranes. These antibodies were used to screen a rat hippocampal cDNA library in λ ZAP vector and an ~1.9 kb clone expressing the antigenic protein was identified. The open reading frame of this clone describes a unique protein of 470 amino acids (52.8 kDa). Northern blot analyses of brain RNA revealed hybridization of the cDNA probes to transcripts of ~2.0 kb. RNA levels were expressed approximately equal in hippocampus, cerebral cortex, and cerebellum. *E. coli* transformed with the pBS vector carrying the 1.9 kb insert expressed a fusion protein that was recognized by the anti-glycine binding protein antibodies. The fusion protein was purified from IPTG induced *E. coli* extracts using a 5,7-DCKA-derivatized column. The purified protein exhibited two binding sites for [^3H]glycine with estimated K_D 's of 124 nM and 8.1 μM . The binding of glycine was displaceable by D-serine, 5,7-DCKA and HA-966. These results indicate the successful cloning of a new class of protein that may belong to a different subtype of brain NMDA receptors [Supported by grants AA 04732 and DAAL03-91-G-0167 and an unrestricted grant from Parke-Davis].

463.2

 Zn^{2+} POTENTIATES STEADY-STATE ATP ACTIVATED CURRENTS IN RAT NODOSE GANGLION NEURONS: A WHOLE-CELL AND SINGLE-CHANNEL STUDY. Jerry M. Wright* and Chaoying Li. LMCN, National Institute on Alcohol Abuse and Alcoholism, NIH, Bethesda, MD 20892

Zn^{2+} and ATP are normally present in serum at low levels and are released from some neurons during synaptic activity. In whole-cell recordings, 10 μM Zn^{2+} potentiated steady-state currents in rat nodose ganglion nerve cells by 18% in 0.5 μM ATP and 120% in 2 μM ATP. Fluctuation analysis of whole-cell currents suggested the mechanism was increased burst-duration. Single channel recording indicated the presence of several channel conductances. There was a primary conductance of 25-35 pS plus other low conductances present in the baseline noise. 10 μM Zn^{2+} did not alter the conductance of the 25-35 pS ATP-activated channel but did increase the probability of opening. Kinetics of the 25-35 pS channel were complex with fast openings and closings in addition to substate transitions and bursting. The response of the low conductance channels to Zn^{2+} was highly variable, suggesting multiple types of low conductance ATP-activated channels.

463.4

EFFECTS OF NICOTINIC ANTAGONISTS ON GLYCINE RECEPTORS. V.E. Wotring* and K.-W. Yoon. Department of Pharmacological and Physiological Sciences and Division of Neurosurgery, Saint Louis University Health Sciences Center, St. Louis, MO 63104.

Since certain nicotinic antagonists can inhibit GABA induced currents (Wotring and Yoon, *Soc. Neurosci. Abs.*, 19, 1993), we pursued the possibility that these same agents might also inhibit glycine induced currents. Measurements of glycine evoked currents were made using the whole cell patch clamp technique with rat hippocampal cells grown in culture for 10 - 15 days; drug applications were made with a U-tube. In these experiments, GABA currents and glycine currents could be distinguished with the use of bicuculline and strychnine. Strychnine (1 μM) blocked 63% ($p < 0.001$, $n = 4$) of the control glycine (100 μM) current while it did not alter a 30 μM GABA current ($p > 0.2$, $n = 4$). Correspondingly, bicuculline (1 μM) decreased the GABA current but did not affect the glycine current.

Application of the nicotinic antagonist, d-tubocurarine at a concentration of 100 μM reduced glycine currents by 57% ($p < 0.001$, $n = 5$). 100 μM trimethaphan camsylate diminished glycine currents by 63% ($p < 0.001$, $n = 8$). Nicotinic antagonists that we have previously found to not significantly affect GABA currents had unexpected effects on glycine currents. 100 μM dihydro- β -erythroidine blocked 51% ($p < 0.001$, $n = 5$) of the glycine current. Application of 1 mM mecamylamine resulted in a nearly complete blockade (89%, $p < 0.001$, $n = 6$) of glycine current. However, 1 mM hexamethonium did not alter the control glycine current ($p > 0.2$, $n = 6$).

The ability of these nicotinic antagonists to block glycine and GABA currents foreshadows structural similarities among these ligand-gated channels. However, the differential effect of mecamylamine on GABA and glycine currents suggests complex variances in the mechanisms of antagonism.

463.6

IMMUNOHISTOCHEMICAL STUDIES OF THE DISTRIBUTION IN RAT BRAIN OF A GLYCINE-BINDING PROTEIN. R. Pal*, K. T. Eggeman, K. N. Kumar, A. E. Allen, and E. K. Michaelis. Dept. Pharmacol. Toxicol. and Higuchi Biosciences Center, Univ. of Kansas, Lawrence, KS 66045

An 40-42 kDa protein that has binding sites for glycine, D-serine, HA-966, and 5,7-dichlorokynurenine acid was purified from rat brain synaptic membranes [Babcock et al., *Neuroscience Abstr.*, 20, 1994]. Polyclonal antibodies were developed against proteins of 41-43 kDa size. These antibodies reacted specifically with an 60 kDa protein in synaptic membranes (Western blot analyses). Immunohistochemical studies in rat brain were performed using the antiserum to the 41-43 kDa proteins. The results of these studies indicate that in detergent-permeabilized brain sections, the pyramidal neurons of the cerebral cortex and the hippocampus exhibit strong immune reactivity with the anti-glycine-binding protein antiserum. Most heavily labeled were the pyramidal neurons, including their proximal dendrites, in the CA2 region of the hippocampus. The granule cells of the cerebellum and the dentate gyrus were also strongly labeled. A comparison between the labelling observed with the antiserum to the 63-70 kDa glutamate-binding protein, the 53-58 kDa CPP-binding protein, and the glycine binding protein indicates that all three antibodies label some of the same populations of neurons with only small differences observed in the pattern of labeling. The antibodies raised against these three proteins may be useful probes for the determination of the distribution of a subpopulation of glutamate and NMDA-like receptors in brain. [Supported by grants AA 04732, DAAL03-91-G-0167 and HD 02528].

463.7

PURIFICATION AND IMMUNOCHEMICAL CHARACTERIZATION OF A SYNAPTIC MEMBRANE GLYCINE-BINDING PROTEIN. K. A. Babcock, K. T. Eggeman, X. Chen, and E. K. Michaelis*. Dept. Pharmacol. Toxicol. and Higuchi Biosciences Center, Univ. of Kansas, Lawrence, KS 66045

A group of synaptic membrane proteins with sizes of 67-70, 53-58, 41-46, and 31-36 kDa has recognition sites for NMDA receptor ligands, such as glutamate, NMDA, CPP, TCP and glycine. It is possible that these proteins are breakdown products of the NMDAR1/R2 proteins or that they are distinct entities. An ~40 kDa protein that has binding sites for glycine was purified from rat brain synaptic membranes by affinity chromatography first through a matrix derivatized with 5,7-dichlorokynurenate (5,7-DCKA), then through one derivatized with 8-OH-quinoline. An 40-42 kDa protein was isolated and this protein bound [³H]glycine in a strychnine-insensitive manner and with a stoichiometry of 1 mol glycine/mol protein. The glycine binding sites of the protein had a low affinity (3-8 μM) for glycine. D-Serine, 5,7-DCKA, and HA-966 inhibited glycine binding to the protein. Polyclonal antibodies developed against proteins of 41-43 kDa electroeluted from gels reacted specifically with an 60 kDa protein in synaptic membranes (Western blots). Treatment of solubilized synaptic membrane proteins with these antibodies led to the immunoprecipitation of approximately 60% of [³H]CGP 39653-binding proteins. These observations indicate that a synaptic membrane protein of ~60 kDa size may be a strychnine-insensitive glycine receptor and that this protein is a component of a form of NMDA receptors. [Supported by grants AA 04732, DAAL03-91-G-0167, and a grant from Parke-Davis].

AGONIST-INDUCED CURRENTS IN IDENTIFIED NEURONS OF THE RAT DORSAL HORN. H. U. Zeilhofer, J. T. Liebel, K. Brune* and D. Swandulla. Institute of Experimental and Clinical Pharmacology and Toxicology, University of Erlangen-Nürnberg, D-91054 Erlangen, Germany.

Neurons within the dorsal horn of the spinal cord play a critical role in sensory information processing. In the present study, we have investigated ionic currents elicited by external application of the excitatory neurotransmitter L-glutamate and of the inhibitory neurotransmitters glycine and GABA. 250 μM thick transverse slices were cut from the spinal cord of 7 to 14 day old rats. Agonist-induced currents were recorded from visually identified neurons in the dorsal horn of the rat spinal cord (lamina III to V) using the tight seal whole cell configuration of the patch clamp technique. Currents elicited by application of 100 μM L-glutamate showed a strong outward rectification in the presence of 1 mM Mg²⁺, indicating that a large portion of the current was through NMDA receptor channels. Currents induced by 100 μM glycine displayed a transient and a maintained component. Both components reversed at the chloride equilibrium potential. Neither run down nor wash out of the current could be observed with recordings that lasted up to 90 minutes. This indicates that the current was through chloride channels that are directly gated by glycine. GABA (10 μM) at a holding potential of -80 mV elicited inward currents which showed only a steady state component. Currents elicited by GABA displayed a rapid run down within 10 minutes of whole cell recording and were blocked by the GABA_A receptor antagonist CGP 35348 (200 μM). These findings indicate that GABA induced currents depended on the activation of GABA_A receptors and on a readily diffusible intracellular molecule.

Supported in part by a grant from the Hildegard Doerenkamp-Gerhard Zbinden Foundation to HUZ and DS.

CHARACTERIZATION OF A STABLE CELL-LINE EXPRESSING A RECOMBINANT GABA_A RECEPTOR SUBTYPE WITH ω₁ PHARMACOLOGY. F. Besnard, P. Granger, P. Avenet, H. Depoortere, S.Z. Langer* and D. Graham. Synthelabo Recherche, 31, ave. P.V. Couturier, 92220 Bagneux, France.

The GABA_A receptor is a pentameric protein composed of various combinations of subunits α₁, α₂, β₁, β₂, γ₁, γ₂. At least one α, one β and one γ are necessary for a fully functional GABA_A receptor exhibiting ω (benzodiazepine) pharmacology. In the present report we describe the development of a stable cell-line expressing a recombinant α₁β₂γ₂ construct of the rat GABA_A receptor. Following transfection and selection in G418 several clonal cell-lines were isolated and tested for [³H]-muscimol binding and [³H]-flumazenil binding activity. Among these cell-lines one exhibited 260 fmol of [³H]-flumazenil binding sites per mg membrane protein and was selected for further characterization. Equilibrium saturation analysis revealed a K_d value of 0.93 nM for [³H]-flumazenil in good agreement with the K_d values of [³H]-flumazenil using transiently-transfected α₁β₂γ₂ GABA_A receptor constructs and rat cerebellar membrane preparations. The K_i values of diazepam, CL 218872 and zolpidem to inhibit [³H]-flumazenil binding to this cell-line were 18 nM, 210 nM and 40 nM, respectively. The concentration-dependency of GABA-induced chloride current in this cell-line gave an EC₅₀ value of 6.3 μM as determined by the whole cell patch-clamp technique. GABA (1 μM)-induced chloride current was potentiated by diazepam and zolpidem with EC₅₀ values of 36 and 160 nM, respectively. In conclusion, these properties indicate that a functional GABA_A receptor subtype with ω₁ pharmacology has been stably expressed in this transfected cell-line.

EXPRESSION OF HETEROMERIC SUBUNITS OF NMDA RECEPTOR IN THE CV-1 CELL LINE. A.E. Allen*, O. Hong, S. Tan, and E.K. Michaelis. Dept. of Pharmacology and Toxicology, Univ. Kansas, Lawrence, KS 66045.

A group of four smaller proteins (~66,55,42, and 33 kD) was isolated from brain synaptic membranes and shown to have ligand binding sites similar to those of NMDA receptors (Kumar et al., *Nature* 354;70: 1991; Michaelis et al., *Ann NY Acad.* 654;7: 1992). A ~66 kDa glutamate-binding (GBP) and the 55 kDa CPP-binding (CBP) protein were isolated from neuronal membranes and cDNA's for the GBP and CBP were recently cloned (Kumar et al., 354;70: 1991; Johnson et al., *Molec. Pharm.* 41;750: 1992). The present studies were designed to examine whether expression of these two proteins in mammalian cells, either singly or in combination, may lead to the formation of functional receptors. The African green monkey kidney cell line CV-1 was selected as a host for stable transfections with the two cDNA's. The cDNA for GBP was subcloned into pREP4 (pOHR4GB) and that for CBP into pREP9 (pOHR950) plasmid (Invitrogen). Each vector imparts a different antibiotic resistance in successfully transfected cells and the inserts are under the control of the RSV promoter. Following selection of cells transfected with one or both vectors by means of antibiotic resistance, the CV-1 cells were grown to confluency and subjected to Western and Northern blot analyses. An ~66 kD protein was detected in Western blots of cells transfected with pOHR4GB and an ~80 kD protein in cells transfected with pOHR950. The anti-CBP antibodies recognize a protein of ~80 kD size also in synaptic membranes. Northern blots are being used to examine the size of mRNA expressed in these cell lines and to document dual expression of the proteins in cells transfected with both vectors. Finally, all cells transfected singly or doubly will be examined for the expression of glutamate and CPP binding entities and for NMDA-sensitive ion channels. [Supported by grants GM07775 and DAAL03-91-6-0167]

NEURONAL GABA AND GLYCINE RESPONSES STUDIED WITH GRAMICIDIN PERFORATED PATCH RECORDING. N. Akaike*. Dept. of Bio-Plasticity, Kyushu Univ. Fac. of Med., Fukuoka 812, Japan.

The conventional whole-cell recording of the patch-clamp technique has a great advantage over other electrical recording methods in that it could perfectly control the extra- and intracellular concentrations of ions such as Na⁺, K⁺, Ca²⁺ and Cl⁻. However, this advantage disrupts the physiological ionic environment inside cells. Thus, various Cl⁻-mediated responses, γ-aminobutyric acid (GABA) and glycine (Gly), have been recorded only under artificial conditions. Subsequently, measurement of the normal concentration of intracellular Cl⁻ ([Cl⁻]_i) has been much hampered. We have recently developed a "gramicidin perforated patch recording", a novel method of patch-clamp technique that enables analysis of membrane currents with intact [Cl⁻]_i. We here report that by applying this method to acutely dissociated CNS neurons of the rat, we could analyze the GABA- and Gly-induced membrane currents in the normal [Cl⁻]_i environment.

Bridging the Nicotinic Acetylcholine Receptor Channel: Prolonged Inhibition Associated with Use-dependent Binding of a Bi-functional Inhibitor. Roger L. Papke*, Wayne Gottlieb, Ben Horenstein, and Michael Francis. Depts. of Pharm., Chem., and Neurosci., U. of F., Gainesville, FL.

The symmetrical compound bis (2,2,6,6-tetramethyl-4-piperidinyl) sebacate (BTMPS) is a use-dependent inhibitor of nicotinic AChR. The active portions of BTMPS are the tetramethylpiperidine (TMP) rings. However, inhibition of neuronal nAChR by TMP is much more rapidly reversible than inhibition by BTMPS, suggesting that prolonged inhibition of neuronal nAChR may result from binding of the conjugated compound to multiple sites within the receptor. A compound related to BTMPS, but differing by four carbons in the length of the chain joining the piperidine rings, showed a dramatic loss of inhibitory activity.

The inhibition of muscle-type nAChR by BTMPS is rapidly reversible unless a neuronal beta subunit is substituted for the muscle beta subunit. This suggests that normal muscle-type receptors may contain a single site for BTMPS inhibition and that the expression of a neuronal beta subunit provides an additional site. The sequences of the neuronal beta subunits differ from the muscle beta subunit in the putative channel forming- and extracellular vestibule forming- domains. The muscle delta subunits are similar in sequence to the neuronal beta subunits in these regions, while the muscle gamma subunit more closely resembles the muscle beta subunits. Over-expression of the delta subunit (omitting gamma subunit RNA) has the same effect on the reversibility of BTMPS inhibition as substituting a neuronal beta subunit for the muscle beta subunit. Compared with muscle-type and delta-less, receptors these gamma-less receptors also: 1) were more sensitive to mecamylamine (p<.01), 2) showed a significant increase in divalent ion permeability (p<.05), and 3) had greater inward rectification (measured by chord conductance ratios) (p<.001). These observations suggest that the domains which control noncompetitive inhibition may also regulate ion permeation properties.

KINETICS OF ACETYLCHOLINE (ACh) RECEPTOR-CHANNEL DESENSITIZATION: RELATIONSHIP TO $[Ca^{2+}]_i$ IN FURA-2 LOADED CULTURED RAT MYOBALLS. J. F. Fiekers, Dept. Anatomy & Neurobiology, Univ. Vermont Coll. Med. Burl., VT 05405.

Cholinergic nicotinic receptor desensitization was studied in cultured rat myoballs using the whole cell configuration of the patch clamp technique. Whole cell currents were recorded following prolonged applications (40s-2min) of ACh. The current reached a peak in sec and declined to a steady state level during agonist application. The rate of onset of desensitization was voltage dependent and accelerated by an increase in extracellular $[Ca]_o$. Simultaneous measurement of $[Ca^{2+}]_i$ using dual excitation microspectrofluorometry with fura-2-loaded myoballs indicated a significant permeability of activated ACh receptor channels to calcium. Agonist-induced currents as well as increases in $[Ca^{2+}]_i$ were blocked by prior exposure of myoballs to α -bungarotoxin. Acceleration of the onset of desensitization by calcium required external calcium during receptor activation. The $[Ca^{2+}]_i$ reached a peak following ACh application and declined slowly to basal levels. An increase in $[Ca^{2+}]_i$ produced by photolysis of cytosolic DM-Nitrophen- Ca^{2+} complexes also accelerated desensitization onset in the absence of external calcium. These results suggest that Ca^{2+} entry through ACh-activated channels is an important pathway for the regulation of the ACh receptor-channel by providing Ca^{2+} required for intracellular modulatory mechanisms. The technique of photoreleased calcium will be used to determine the minimum amplitude and duration parameters of the $[Ca^{2+}]_i$ required for the modulation of the ACh receptor and desensitization kinetics (Supported by MDA).

INOSITOL (1,4,5)-TRISPHOSPHATE RECEPTOR TYPE 1: A THIRD ALTERNATIVELY SPLICED VARIANT. F.C. Nucifora Jr., S.-H. Li, S.K. Danoff, G. Pearson*, A. Ullrich, C.A. Ross. Laboratory of Molecular Neurobiology, Johns Hopkins University, School of Medicine, 720 Rutland Ave., Ross 615, Baltimore, MD 21205.

The Inositol 1,4,5-trisphosphate receptor (IP₃R) is an intracellular calcium channel involved in coupling cell membrane receptors to calcium signal transduction pathways within the cell. Several isoforms of IP₃Rs have been identified, which are expressed in many tissues with differing patterns of cellular expression. Another form of diversity that exists in the type 1 IP₃R is alternative splicing. Two alternatively spliced regions have previously been identified, one in the IP₃ binding domain (S1) and a second in the coupling domain between two consensus cAMP-dependent protein kinase (PKA) sequences (S2). We now report an additional alternatively spliced region that is 9 amino acids long, located in the coupling domain. PCR primers were synthesized to flank the alternatively spliced region and products were run on 6% polyacrylamide gels. Analysis of brain and peripheral tissues from human and rat demonstrated both the short and long S3 transcripts in all tissues. The long form predominates in most brain regions (except the cerebellum) while the short form predominates in peripheral tissues. The sequence of the long form in human appears to create a consensus protein kinase C phosphorylation site. Thus, as we have suggested in the past for S2 isoforms, the S3 isoforms may differ in their regulation by phosphorylation.

MOLECULAR LOCATION OF A CHARGED 1,4-DIHYDROPYRIDINE CALCIUM CHANNEL BLOCKER IN BRAIN LIPID BILAYERS.

P.E. Mason and R.P. Mason*. Neurosciences Research Center, Allegheny-Singer Research Institute, Medical College of PA, Pittsburgh, PA 15212.

Small angle X-ray diffraction is a powerful tool for ascertaining direct structure information concerning the interaction of small molecules with model and biological membranes. In this study, we examined the structure of oriented brain phospholipid/cholesterol lipid bilayers in the absence and presence (1% by mass) of the charged 1,4-dihydropyridine (DHP) calcium channel blocker, amlodipine. This compound has been shown to improve memory consolidation and retrieval in laboratory animals (*Behav. Neural Biol.* 1993;60:221). The chemistry of amlodipine includes an electron-dense halogen atom which serves as a strong scattering source for the X-rays. The results of these experiments demonstrated that amlodipine occupies a discrete, time-averaged location in the hydrocarbon core adjacent to the phospholipid headgroup region. This location would facilitate both ionic bonding with the phospholipid headgroups and hydrophobic interactions with phospholipid acyl chains in the hydrocarbon core. These results also support an intralayer DHP binding site on the voltage-sensitive calcium channel which is accessed from the adjacent lipid phase. The diffraction data were correlated with partition coefficient measurements for amlodipine ($K_p > 10^3$) using model membranes with a cholesterol content which reproduced neural membrane preparations from Alzheimer's disease and age-matched control cortical brain tissue. The implication of these results for the molecular pharmacology of DHP calcium channel blockers will be discussed.

ASTROGLIAL AND NEURONAL ADRENOCEPTORS LINKED TO CHANGES IN $[K^+]_i$ AND $[Ca^{2+}]_i$ EXHIBIT DIFFERENT CHARACTERISTICS. M. Nilsson¹, H. Muyderman¹, P. S. Eriksson¹, E. Hansson^{*1,3} and L. Rönnbäck^{1,2}. Institute of Neurobiology¹, Department of Neurology², University of Göteborg and Department of Cell Biology, Faculty of Health Sciences, University of Linköping³, Sweden.

Various adrenoceptor agonists were investigated for their effects on intracellular concentrations of calcium $[Ca^{2+}]_i$ and potassium $[K^+]_i$ in type 1 astrocytes and neurons. The calcium sensitive dye fura-2 and the potassium sensitive dye PBFI were used in mixed astroglial/neuronal primary cultures from newborn rat cerebral cortex. We found considerable differences in the adrenoceptor-evoked changes in $[Ca^{2+}]_i$ and $[K^+]_i$ between the two celltypes. Noradrenalin (NA), phenylephrine (phe; α_1 -agonist), clonidine (clon; α_2 -agonist) and isoproterenol (iso; β -agonist) were all able to increase calcium and decrease potassium concentrations in the astrocytes with one exception; clon could not induce potassium responses. In neurons, NA and phe evoked calcium transients while clon and iso did not. NA and clon were able to elicit potassium reductions but no responses were seen after phe and iso stimulation. The astrocytes responded in general with up to 4 different types of calcium response patterns while the neurons only exhibited 2 types. After adrenoceptor stimulation, no oscillations in intracellular calcium were seen in the neurons, but could on the contrary be observed frequently in the astrocytes. In neurons, the agonist-evoked reductions in $[K^+]_i$ always slowly (after 30-50 s) returned to baseline even in the presence of the agonists. On the other hand, in the astrocytes, the agonist-induced reductions in $[K^+]_i$ always persisted at the lower level in the presence of the agonists. The results point out the astroglial cellpopulation as potentially important receivers of adrenergic input. The results also show that astroglial and neuronal changes in $[Ca^{2+}]_i$ and $[K^+]_i$ exhibit different characteristics which might be of great importance for the understanding of the basic principles involved in the homeostasis of extracellular calcium and potassium concentrations.

463.16

A GRAPHICAL METHOD FOR USING HILL PARAMETERS TO DISTINGUISH ALTERATIONS IN THE AGONIST BINDING SITE, ALLOSTERIC COUPLING BETWEEN SITES, AND CHANNEL GATING IN MUTATED, LIGAND GATED ION CHANNELS. C.E. Spivak*. Mol. Neurobiol. Br., NIH/NIDA IRP, Box 5180, Balto., MD. 21224.

Site directed mutants of ligand gated ion channels are usually characterized empirically by parameters of the Hill equation, n_H and K_{app} , in which n_H is said to reflect "cooperativity" of the receptor, and K_{app} the affinity of an agonist for its recognition site. More realistic models of receptor occupation and transduction, however, show that these parameters are always correlated, and that this correlation can provide further insight into the effects of a mutation.

The Hill equation will best fit a log concentration response curve when the inflection of the curve corresponds to K_{app} and the slope at that point is $n_H/4$. For any model, the theoretical response function, $R(A)$, where A is agonist concentration, can be recast to correspond to a log concentration response curve by substituting $Z = \ln(A)$ for (A) . The agonist concentration at the inflection point ($d^2R/dZ^2 = 0$) is K_{app} , and the slope at this point is $n_H/4$. The computer program MLAB (Civildized Software, Bethesda, MD) symbolically found the first and second derivatives for the response functions and numerically evaluated their solutions for a range of model-dependent parameters.

A linear model, such as $2A + P \rightarrow A + AP \rightarrow A_2P$, in which P represents the receptor, is commonly assumed. When the response is current in a voltage clamped cell, and if one allows an allosteric factor to serially enhance binding of agonist, one sees graphically that, within variations on this theme, mutations that change the channel gating equilibrium have strong effects on n_H and only minor effects on K_{app} . Conversely, mutations that change the allosteric coupling strongly affect K_{app} with much smaller effects on n_H . Similar correlations occur with other models, permitting a first mechanistic interpretation of the Hill parameters.

463.18

GLYCINE RECEPTOR β -SUBUNIT BINDS TO THE PERIPHERAL MEMBRANE PROTEIN GEPHYRIN G.Meyer, J.Kirsch, M.Ramming, U.Grünert*, H.Betz, D.Langosch. Max-Planck-Institute for Brain Research, 60496 Frankfurt, Germany.

The inhibitory glycine receptor (GlyR) of rat spinal cord is composed of ligand binding α -subunits, β -subunits and an associated tubulin-binding protein termed gephyrin. Gephyrin contributes to the formation of GlyR clusters in the postsynaptic membrane of spinal neurons, as antisense oligonucleotides interfering with gephyrin synthesis drastically reduce clustering. Here we show that recombinant gephyrin expressed in 293 kidney cells binds to immobilized native GlyR depleted of native gephyrin. To determine the GlyR subunit(s) involved in binding, purified GlyR polypeptides were electrophoretically separated, transferred onto nitrocellulose membrane and overlaid with recombinant gephyrin. Gephyrin bound to the GlyR β -subunit, but not to the α -subunit. The binding region was localized to the large cytoplasmic loop of the β -subunit using bacterially expressed fusion proteins of β -polypeptide fragments. The GlyR β -subunit and gephyrin are widely expressed in rat brain and co-distribute in regions lacking ligand binding α -subunits. This raises the possibility that the β -subunit/gephyrin core complex participates in the formation of ligand-gated ion channels other than the GlyR.

POINT MUTANTS OF THE INHIBITORY GLYCINE RECEPTOR $\alpha 1$ SUBUNIT ASSOCIATED WITH HEREDITARY HYPERKPLEXIA DISPLAY REDUCED AGONIST AFFINITY AND EFFECT SINGLE CHANNEL CONDUCTANCES

B. Laube, N. Rundström, U. Emsberger*, H. Betz and D. Langosch, Department of Neurochemistry, Max-Planck-Institute for Brain Research, Deutschordenstraße 46, D-60528 Frankfurt, Germany.

Native adult inhibitory glycine receptor (GlyR) is a pentameric ligand-gated anion channel protein composed of two different subunits ($\alpha 1$ and β) in a stoichiometry of 3:2. Hyperkplexia (STHE) is a human autosomal dominant neurological disorder associated with point mutations in the gene encoding the $\alpha 1$ subunit of the GlyR (Shiang *et al.*, (1993) *Nature genetics* 3, 351-358). Accordingly, an arginine residue bordering the channel forming transmembrane region M2 at position 271 is substituted to either leucine or glutamine.

Here, we determined the functional properties of these $\alpha 1^{R271L}$ and $\alpha 1^{R271Q}$ mutants upon heterologous expression in *Xenopus* oocytes and kidney 293 cells. When analysing homooligomeric channels, glycine concentrations eliciting half-maximal responses (EC_{50}) were approximately 100-fold increased in comparison to wild-type $\alpha 1$ GlyR. Further, we observed drastic decreases in maximal whole-cell currents (up to 90%) and a reduction in single channel main conductances. In addition, the glycinergic agonists β -alanine and taurine did not elicit detectable currents but no significant change in affinity for the competitive antagonist strychnine could be observed. Coexpression of the mutants with wild-type $\alpha 1$ subunit in different ratios resulted in mixed channels with intermediate glycine affinities and maximal currents depending on the ratio of the expressed subunits. Interestingly, coexpression of the mutants with both $\alpha 1$ and β diminished the effects of the mutations in comparison to coexpression with $\alpha 1$ alone.

Our results imply that the phenotype of STHE patients is the consequence of decreased agonist affinity and efficacy of the mutant GlyRs.

463.21

MUTATIONS OF GLYCINE RECEPTOR SUBUNIT GENES IN THE MOUSE MUTANTS *SPASTIC* AND *SPASMODIC*. C.-M. Becker, C. Mülhardt, B. Saul, M. Fischer*, V. Schmieden*, C. Kling, P. Gass, D. Simon-Chazottes*, J.-L. Guénet*, H. Betz*, and J. Kuhse* (SPON: European Neuroscience Association). Neurologische Klinik und Zentrum für Molekulare Biologie, Universität Heidelberg, 69120 Heidelberg, Germany; *Max-Planck-Institut für Hirnforschung, 60528 Frankfurt/M., Germany; *Institut Pasteur, 75724 Paris, France.

The recessive mouse mutations *spastic* (*spa*, Chr 3) and *spasmodic* (*spd*, Chr 11) result in phenotypically similar motor disorders with symptoms mimicking strychnine poisoning. The adult isoform, GlyR α , of the inhibitory glycine receptor is a multi-subunit protein composed of ligand-binding $\alpha 1$ and structural β polypeptides. We mapped the β subunit gene (*Glyrb*) near the *spastic* locus on Chr 3. In the CNS of *spa/spa* mice, aberrant splicing reduced the level of full-length β subunit transcripts. However, exon skipping led to the formation of truncated β subunit mRNAs where translational frame shifts resulted in premature stop codons. In the *spastic* mutant, a nucleotide insertion was uncovered within intron 5 of the *Glyrb* gene which may be causal for the aberrant splicing.

In the *spasmodic* mouse, we identified a point mutation in the $\alpha 1$ subunit gene which predicts an amino acid exchange in the large N-terminal domain of the encoded polypeptide. Upon expression in *Xenopus* oocytes, *spasmodic* $\alpha 1$ subunit channels displayed drastically reduced agonist responses while ligand binding was only marginally affected. This indicates that agonistic amino acids possess lower intrinsic activities at *spasmodic* glycine receptor channels.

463.20

ISOLATION AND CHARACTERISATION OF THE MOUSE GLYCINE RECEPTOR β SUBUNIT GENE

M. Fischer, H. Betz* and J. Kuhse, Max-Planck-Institute for Brain Research, 60496 Frankfurt a.M., Germany.

The structure of the mouse glycine receptor β subunit gene was deduced from overlapping genomic lambda clones. Subcloning and sequencing of intron/exon boundaries led to the identification of ten exons which are spread over a distance of more than 50 kb. Comparison of the β gene with the previously characterized glycine receptor α subunit genes revealed high structural homology. However, there are some notable differences. Whereas the 5' non coding region of the α genes is encoded by the first exon, the respective region of the β gene is separated by one intron. Also, β transmembrane region 2 is encoded by two exons, a finding similar to the GABA $_A$ receptor β gene structure.

The different glycine receptor subunit genes exhibit developmental and spatial specific expression in brain and spinal cord. These expression patterns should reflect complex regulation events at the level of transcription. Therefore, we are interested in a detailed characterization of the promoter and upstream regions of the glycine receptor β gene. Transcription start points were mapped 1.6 kb upstream of the start codon. To identify regulatory elements, transient expression studies with reporter gene constructs in neuroblastoma and control cell lines are being pursued.

LIGAND-GATED ION CHANNELS: ALCOHOL MODULATION

464.1

STUDY OF ETHANOL EFFECTS ON TM II DOMAIN MUTANTS OF THE NMDA RECEPTOR-CHANNEL.

K. Masood*, C. Wu and F. F. Weight, Lab. Molecular & Cellular Neurobiology, NIAAA, NIH, Bethesda, MD 20892.

The N-methyl-D-aspartate (NMDA) receptor is one of the key neurotransmitter-gated ion channels, as it is involved in important physiological and pathophysiological aspects of nervous system function. NMDA receptors have been found to be affected by psychoactive drugs, such as ketamine, phencyclidine and ethanol, possibly contributing to the behavioral effects of these drugs. Earlier we reported differential ethanol sensitivity of NMDA receptor subunit combinations (Mol. Pharmacol. 45: 324, 1994). However, the mechanism by which ethanol exerts its effect on NMDA receptors is unknown. The transmembrane II (TM II) domain of NMDA receptor subunits is thought to constitute the pore of the channel. Single amino acid mutants in and around the TM II domain of NR1 were coexpressed with NR2A in *Xenopus* oocytes and the effect of ethanol on NMDA activated ion current was tested using the two-electrode voltage-clamp method. The NMDA activated-current of the native subunit combination was inhibited 41% by 100 mM ethanol. The ethanol inhibition for charged mutants was 43% for E598Q and 42% for D599N. The inhibition for polar mutants was 39% for T602G and 38% for S605G. The observations suggest that these charged and polar amino acid mutations did not significantly change ethanol inhibition of NMDA-activated current flow through the mutated channels.

464.2

ETHANOL SENSITIVITY OF RECOMBINANT GLUTAMATE RECEPTOR EXPRESSED IN *XENOPUS* OOCYTES IS SIMILAR TO THAT OF NEURONS B.E. Akinshola* and F.F. Weight, Lab. of Molecular and Cellular Neurobiology, NIAAA, NIH, Bethesda, MD. 20892.

The Ethanol (EtOH) sensitive neuronal AMPA (α -amino-3-hydroxy-5-methyl-4-isoxazole propionic acid) type glutamate receptors (GluR), have multiple subunits designated as GluR1-4 (Science, 249:1033-1037, 1990.), or GluRA-D (Science, 249:556-560, 1990), which exist in two distinct "splice variant" versions known as the FLIP and FLOP (Science, 249:1580-1585, 1990). We have examined the EtOH sensitivity of the recombinant GluR1-3 FLOP receptor combinations expressed in *Xenopus* oocytes, using the two electrode voltage clamp technique. EtOH concentrations of 10-500 mM consistently inhibited currents activated in oocytes by 200 μ M kainate. The GluR1+2+3 heteromeric combination current exhibited the highest sensitivity to EtOH, with an IC_{50} value of 176 mM. The response of GluR3 homomeric receptor subunit to EtOH had an IC_{50} value of 212 mM. The sensitivity of GluR3 and GluR1+2+3 subunits to inhibition by EtOH is similar to the reported sensitivity of non-NMDA glutamate-activated current in hippocampal neurons (Ann. Med., 22:247-252, 1990). By contrast, the FLIP forms of GluR expressed in human embryonic kidney (HEK) 293 cells are reported to be more sensitive to EtOH (Neurosci. Letters, 159:83-87, 1993) than non NMDA glutamate-activated current in hippocampal neurons or the FLOP forms of GluR in our experiments.

464.3

PREGNENOLONE POTENTIATION DOES NOT ALTER ETHANOL INHIBITION OF NMDA-ACTIVATED CURRENT FOR NMDA RECEPTOR SUBUNITS ϵ_4/ζ_1 . C. Wu*, K. Masood and F. F. Weight. Lab. Molecular & Cellular Neurobiology, NIAAA, NIH, Bethesda, MD 20892.

The neurosteroid pregnenolone can modulate the activity of GABA_A, glycine and NMDA receptors. Ethanol inhibits NMDA-activated current but whether this inhibition is affected by the modulatory action of neurosteroids is not known. We investigated the effect of pregnenolone on ethanol inhibition of NMDA-activated current using the mouse NMDA receptor subunits ϵ_4/ζ_1 expressed in *Xenopus* oocytes. Membrane current was recorded using the two-electrode voltage-clamp technique at a holding potential of -70 mV. Ethanol inhibited the ion current activated by 10 μ M NMDA (in the presence of 10 μ M glycine) in a concentration-dependent manner over the range 10 to 250 mM; the IC₅₀ was 243 mM. Ethanol, 100 mM, decreased the E_{max} of the NMDA concentration-response curve but did not affect the EC₅₀ or Hill coefficient. Pregnenolone sulfate potentiated NMDA-activated current in a concentration-dependent manner over the concentration range 0.3-100 μ M. The EC₅₀ of the concentration-response curve was 4.9 μ M and the slope was 1.2; these values were not significantly changed in the presence of 100 mM ethanol. The potentiation of NMDA-activated current by pregnenolone did not affect the percentage inhibition by 100 mM ethanol of NMDA-activated current. The results suggest that the modulatory action of pregnenolone does not affect the mechanism involved in ethanol inhibition of NMDA receptor subunits ϵ_4/ζ_1 .

464.5

CHRONIC ETHANOL TREATMENT UPREGULATES NMDA RECEPTOR FUNCTION AND BINDING IN MAMMALIAN CORTICAL NEURONS. X.J. Hu¹*, M.A. Javors^{1,2}, and M.K. Ticku^{1,2}. Dept of Pharmacology¹ and Psychiatry², The University of Texas Health Science Center, San Antonio, TX 78284-7764

In the present study, we investigated the effects of chronic ethanol exposure on NMDA receptor-mediated increase in intracellular Ca²⁺ concentration (Δ [Ca²⁺]_i), and [³H]MK-801 binding in cultured cortical neurons. NMDA increased the (Δ [Ca²⁺]_i) in a dose-dependent manner with an EC₅₀ ~12 μ M. Chronic exposure of the cortical neurons to ethanol (50 mM, 5 days) did not produce any changes in the cell protein, morphological appearance and the resting [Ca²⁺]_i; however, it significantly enhanced the NMDA-mediated increase in [Ca²⁺]_i. The EC₅₀ value of NMDA was not significantly altered following chronic ethanol exposure, however its E_{max} value was increased by ~40%. This enhancement of NMDA response following chronic ethanol treatment was reversed by concomitant chronic exposure of the cortical neurons to the NMDA competitive (20 μ M CPP) and non-competitive (1 μ M MK-801) antagonists, but not by the non-NMDA receptor antagonist CNQX (10 μ M), and the L-type calcium channel blocker, nifedipine (10 μ M). In addition, chronic ethanol exposure increased the specific [³H]MK-801 binding in cortical neuron membrane by ~20%. Taken together, these results suggest that chronic ethanol exposure upregulated the NMDA receptor function in cortical cultured neurons, and this increased NMDA receptor function is a NMDA receptor mediated process. The altered NMDA receptor function may be responsible for the ethanol induced tolerance and withdrawal syndrome.

464.7

DIFFERENTIAL SENSITIVITY OF NMDA- AND GABA-ACTIVATED ION CHANNELS TO ALCOHOLS OF VARYING HYDROPHOBICITY. Robert W. Peoples* and Forrest F. Weight. Laboratory of Molecular and Cellular Neurobiology, National Institute on Alcohol Abuse and Alcoholism, National Institutes of Health, Bethesda, MD 20892.

Alcohols have been shown to inhibit responses mediated by the N-methyl-D-aspartate (NMDA) receptor-ion channel and to enhance responses mediated by the γ -aminobutyric acid_A (GABA_A) receptor-ion channel. Using whole-cell patch-clamp recording in mouse hippocampal neurons, we investigated the relationship between hydrophobicity of various alcohols and their potency for inhibition of NMDA-activated current and potentiation of GABA-activated current. We found that for alcohols with hydrophobicity equal to or less than heptanol, potency in inhibiting NMDA-activated current was correlated with hydrophobicity, as was potency in enhancing GABA-activated current. However, the slopes of the plots of potency vs. hydrophobicity differed, so that whereas the potencies for inhibiting NMDA and enhancing GABA were similar for more hydrophobic alcohols, they differed greatly for less hydrophobic alcohols such as ethanol. These results do not support a common mechanism of action of alcohols, such as disruption of the lipid membrane, on both NMDA- and GABA-activated ion channels.

464.4

POTENTIATION AND INHIBITION BY ETHANOL (ETOH) OF NMDA-EVOKED WHOLE-CELL CURRENTS IN CULTURED RAT HIPPOCAMPAL NEURONS. M. Omatsu¹, R. Sjodin^{2*} and E.X. Albuquerque^{1,3}. Depts. ¹Pharmacol. & Exp. Ther. and ²Biophysics, Univ. Maryland Sch. Med., Baltimore, MD, USA, 21201; ³Lab. Mol. Pharmacol. II, IBCCF, UFRJ, RJ, Brazil, 21944.

The effects of EtOH on whole-cell currents elicited by U-tube application of NMDA (50 μ M) plus glycine (10 μ M) were studied in cultured hippocampal neurons of the rat. NMDA-elicited whole-cell currents had distinct fast and slow decay components (*JPET* 263:859, 1992). When applied together with agonists via the U-tube, EtOH (174 μ M-174 mM) caused a decrease in the peak amplitude and in the amplitudes of the fast and slow components of the NMDA response. However, the inhibition of the NMDA response was not a monotonic function of EtOH concentration, which suggests the participation of an effect opposite to the inhibitory one. This irregular pattern was evident in concentration-response curves for individual neurons and for averaged data as well, indicating that this phenomenon was not an artifact of averaging. Additionally, an amplitude enhancement (rebound) was often evident after washing out EtOH [e.g., 2 min after washing out EtOH (522 μ M), 4 out of 6 neurons showed a rebound]. These results suggest a dual effect of EtOH, the potentiation being countered to different degrees by inhibitory effects, and are qualitatively similar to those reported earlier for single channels (*FEBS Lett.* 247:61, 1989). A later onset potentiation by EtOH of the NMDA response was also observed. When EtOH was continuously present in the bath and was simultaneously applied to the cells via the U-tube together with agonists, there was a decrease followed by a progressive enhancement of the NMDA peak current. These results suggest that in addition to the inhibitory effects of EtOH on NMDA responses, two types of potentiation, one rapidly and the other of later onset, can also be observed. EFFECTS OF CHRONIC ETHANOL TREATMENT ON GLUTAMATE RECEPTOR BINDING AND mRNA LEVELS IN THE ADULT RAT BRAIN

J.G. Rudolph¹, M.C. Rill¹, B.E. Hunter^{2*}, D.W. Walker², E.K. Michaelis³ and F.T. Crews¹. Departments of ¹Pharmacology and ²Neuroscience, University of Florida College of Medicine, Gainesville, FL 32610 and ³Departments of Pharmacology and Toxicology, University of Kansas, Lawrence, Kansas 66047.

The amino acid L-glutamate is a major excitatory neurotransmitter that is involved in many CNS functions including memory, learning, LTP, and synaptic plasticity. To determine if chronic ethanol altered glutamate receptor binding, male Sprague Dawley rats were pair fed a liquid diet for three weeks with 36% calories coming from either sucrose or ethanol. Binding studies were performed on 6 μ m brain sections using the NMDA specific ligands [³H]-MK801 and [³H]-CGP 39653 (CGP), as well as [³H]-kainate and [³H]-AMPA. Autoradiographs of the brain sections were quantitated using NIH Image software. Ethanol significantly increased MK801 binding (p<0.05) in motor (114%) and somato sensory (113%) cortex, stratum oriens of hippocampal CA1 (114%), and CA3 (112%). CGP binding was significantly increased (p<0.025) in the amygdala (110%), stratum oriens (125%) and stratum radiatum (121%) of hippocampal CA1, CA3 (124%), CA4 (123%), and dentate gyrus (117%). No significant changes were seen with either of the non-NMDA receptor specific ligands, AMPA or kainate. To determine if changes in mRNA levels corresponded to the increase in NMDA binding, total RNA was isolated from the cerebral cortex, hippocampus, cerebellum, and striatum. Northern analysis were performed using probes specific for both the NMDAR1 receptor subunit and NMDARP-71 (a glutamate binding protein). The mRNA levels for both NMDAR1 and NMDARP-71 did not change following three weeks chronic ethanol treatment. (Supported by AA06069, AA09115, and T32AA07561)

IS PHOSPHORYLATION OF THE γ 2L SUBUNIT A NECESSARY OR SUFFICIENT REQUIREMENT FOR ETHANOL SENSITIVITY OF GABA_A RECEPTORS?

J. Zhai*, C.Y. Li and F.F. Weight. Lab. Molecular & Cellular Neurobiology, National Institute on Alcohol Abuse & Alcoholism, NIH, Bethesda, MD 20892.

Recently, it has been proposed that phosphorylation of the γ 2L subunit by protein kinase C is required for ethanol sensitivity of GABA_A receptors (*FEBS Lett.* 313: 113, 1992). Neurons in rat dorsal root ganglion (DRG) have been reported to contain the γ 2L subunit of the GABA_A receptor (*Soc. Neurosci. Abst.* 11: 797, 1991). We studied the effect of ethanol on GABA-activated current in neurons freshly isolated from adult rat DRG using the whole-cell patch-clamp technique and confirmed the previous observation that GABA_A current in these neurons is insensitive to ethanol (*Brain Res.* 507: 332, 1990). We also studied the ethanol sensitivity of GABA_A current after procedures to phosphorylate the PKC phosphorylation site on this subunit. We found that GABA-activated current remained insensitive to ethanol despite: (i) the extracellular preapplication of 5-20 nM phorbol 12-myristate 13-acetate (PMA); (ii) the intracellular application of PKC (0.247 U/ml); (iii) altering the intracellular Ca²⁺/EGTA ratio to raise intracellular Ca²⁺ from 6 to 100 or 600 nM; and (iv) combining the intracellular application of 1 μ M okadaic acid and 30 μ M peptide 3 with the extracellular application of PMA. The observations raise a question of whether phosphorylation of the γ 2L subunit is a necessary or sufficient requirement for ethanol sensitivity of GABA_A receptors.

ALCOHOL INHIBITION OF ATP-ACTIVATED CURRENT IS NOT MEDIATED BY ACTIONS ON MEMBRANE LIPIDS OR INTRACELLULAR PROTEINS. Chaoying Li*, Robert W. Peoples and Forrest F. Weight. Lab. of Molecular and Cellular Neurobiology, National Institute on Alcohol Abuse & Alcoholism, NIH, Bethesda, MD 20892.

We have previously demonstrated, using whole-cell patch-clamp recording techniques in isolated bullfrog dorsal root ganglion neurons, that for alcohols with a molecular volume equal to or less than 42.2 ml/mol, potency for inhibiting ATP-activated current was correlated with lipid solubility (order of potency: 1-propanol = trifluoroethanol > monochloroethanol > ethanol > methanol). However, despite increased lipid solubility, alcohols with a molecular volume equal to or greater than 46.1 ml/mol (1-butanol, 1-pentanol, trichloroethanol and dichloroethanol) were without effect on the ATP-activated current. In the present study we found that the amplitude of the current activated by 2.5 μ M ATP was decreased by the extracellular application of 100 mM ethanol by 45 \pm 3% (n=8 cells), and the inhibition was not significantly altered by intracellular application of 100 mM ethanol in the patch pipette (n=7; P>0.05). Inclusion of GTP- γ -S (50 μ M) or GDP- β -S (100 μ M) in the pipette solution also failed to reverse the inhibitory effect of ethanol. These results suggest that alcohols inhibit the function of this neurotransmitter receptor by interacting with a small hydrophobic pocket on the receptor protein, rather than with membrane lipids or intracellular proteins.

464.10

ALCOHOLS EXHIBIT A CUTOFF EFFECT FOR THE POTENTIATION OF 5-HT₃ RECEPTOR-ACTIVATED CURRENT. P. Fan* and Forrest F. Weight. Laboratory of Molecular and Cellular Neurobiology, National Institute on Alcohol Abuse and Alcoholism, National Institutes of Health, Bethesda, Maryland 20892

The effects of several straight chain alcohols on the inward current mediated by 5-HT₃ receptors were investigated in rat nodose ganglion neurons. The whole-cell patch-clamp technique was used to record 5-HT-activated current. When applied together with 1 μ M 5-HT, propanol, butanol and pentanol potentiated the amplitude of the peak 5-HT current in all cells tested (n=19), whereas ethanol facilitated 5-HT current in 2 out of 14 cells. Potentiation of 5-HT current by propanol, butanol and pentanol was concentration-dependent and fully reversible. EC₅₀ values for propanol, butanol, and pentanol were 34.2 mM, 2.7 mM and 1.4 mM respectively. Methanol (10 to 500 mM), hexanol (0.5 to 50 mM) and octanol (0.05 to 5 mM) did not enhance 5-HT current. The data suggest that the action of straight chain alcohols on 5-HT₃ receptors exhibits a cutoff effect above 5 carbon atoms. This is consistent with a direct interaction of the alcohols with a hydrophobic pocket on the receptor protein.

ACETYLCHOLINE RECEPTORS: NICOTINIC DEVELOPMENT

465.1

CONTROL OF m1 MUSCARINIC RECEPTOR GENE EXPRESSION.

S. Pepitoni, M.C. Steel, C.A. Harrington* and N.J. Buckley. Wellcome Laboratory for Molecular Pharmacology, University College London, London WC1E 6BT, U.K

G-protein coupled receptors are encoded by one of the most diverse gene families in the nervous system. As a step towards understanding the factors controlling GPR expression, we have determined the ontogenic expression patterns and promoter structure of members of the muscarinic receptor gene family.

RT-PCR and *in situ* hybridisation reveal two waves of expression of the m1 gene in the embryonic rat brain. Around E12, there is a transient and widespread wave of m1 gene expression over wide areas of neuroepithelium of the developing forebrain, metencephalon and myelencephalon - only the forebrain expresses m1 receptors in adulthood. This transient expression is followed by a restriction of expression to those areas which express the gene in adulthood. Transcripts are detectable in cortex (E16) and hippocampus (E18) concomitant with differentiation whereas in striatum expression is not detected until E18; at this stage m1 is expressed over differentiated striatal cells but not over ventricular or intermediate zone cells. Receptor gene expression appears to precede cholinergic innervation. Thus it appears that adult patterns of expression are achieved by consecutive waves of activation and repression.

In order to identify *cis* regulatory elements directing these patterns of expression we have isolated a genomic clone from a pWE 15 rat cosmid library and mapped the upstream regions of the m1 gene. Transfection of this cosmid clone into a human neuroblastoma cells NB-OK 1 - a cell line that expresses an endogenous m1 receptor - followed by RT-PCR analysis using species specific primers demonstrated transcription of the rat m1 gene in transfected NB-OK 1 cells. 5'RACE and SLIC procedures were used to gain more 5'cDNA information. Hybridisation probes derived from RACE/SLIC sequences were then used to map the non-coding exons of the m1 gene and to characterise its promoter.

PHARMACOLOGICAL ANALYSIS OF α -BUNGAROTOXIN BINDING SITES IN THE DEVELOPING AND ADULT RAT SOMATOSENSORY CORTEX AND HIPPOCAMPUS. R.S. Broide*, D. Acevedo and F.M. Leslie. Department of Pharmacology, University of California, Irvine, CA 92717.

Past studies of the developing rat brain have demonstrated a unique, transient expression of [¹²⁵I] α -bungarotoxin (α -BTX) binding sites in the sensory regions of the cortex during early postnatal development. In our studies, we have also seen a transient expression of α -BTX binding within areas of the developing hippocampus. To examine whether this transient expression is associated with a change in the binding properties of the site with age, we have used quantitative autoradiography to characterize the pharmacological profile of [¹²⁵I] α -BTX binding sites in somatosensory cortex (SS1) and hippocampus of rats aged embryonic day 19, postnatal day 7 and adult. Animals were sacrificed and their brains removed, frozen in isopentane at -20°C and cryostat cut onto slides. Slide-mounted tissue sections were incubated with [¹²⁵I] α -BTX in the presence and absence of competing ligands, washed, dried and apposed to tritium-sensitive film. The resulting autoradiograms were analyzed by computer-assisted densitometry to quantitate radioligand binding in specific brain regions. Saturation studies revealed saturable [¹²⁵I] α -BTX binding sites in SS1 and hippocampus, with K_D values ranging from 0.5 - 1.5 nM. At all ages and in both brain regions the following order of affinity was observed: α -BTX > α -cobrotoxin > nicotine \geq cytisine. At E19 and P7, competition curves for agonist inhibition of [¹²⁵I] α -BTX binding displayed Hill slopes of \leq 1, whereas slopes of > 1 were observed in the adult. In contrast, antagonist binding curves exhibited Hill slopes of \leq 1 at all ages. These data indicate a maturation of [¹²⁵I] α -BTX binding sites during development, with the appearance of positive cooperativity of agonist binding in the adult. This change in the binding profile of agonists may be associated with the downregulation of [¹²⁵I] α -BTX binding sites in the adult.

REGULATION OF THE β 3 NICOTINIC ACETYLCHOLINE RECEPTOR GENE IN THE DEVELOPING CHICK CENTRAL NERVOUS SYSTEM

T. Roztocil, M.C. Hernandez, L. Erkman, M. Gomez, L. Matter-Sadzinski, M. Ballivet and J.M. Matter* Dept. of Biochemistry, Sciences II, Univ. of Geneva, 1211 Geneva 4, Switzerland

β 3 is a member of the neuronal nAChR gene family. Its expression has been analyzed in the chick nervous system by Northern blot, *in situ* hybridization and immunohistochemistry during development. In contrast to other subunits such as α 4 or β 2 that are widely distributed, β 3 expression is very restricted in the CNS. The β 3 mRNA and protein have only been detected in the ganglion and amacrine cells of the retina.

To identify DNA sequences responsible for the spatio-temporal specificity of its expression, 3 kb of the 5' flanking region of the β 3 gene were cloned and assayed for promoter activity by fusion to a reporter gene (CAT or lacZ) in transient transfections of primary cultures of neural cells (Matter-Sadzinski et al., 1992, EMBO J. 11, 4529-38). A 150bp fragment located just upstream from the transcription initiation site displays specific promoter activity and drives reporter gene expression in retinal ganglion cells. This suggests that the main regulatory elements are contained in this short region. Sequence analysis reveals the presence of classical promoter elements such as TATA and CAAT boxes, as well as several putative transcription factor binding sites. Disruption of one of them, an E-box (binding site for bHLH proteins), or its displacement relative to the CAAT box lead to a tenfold reduction in promoter activity, suggesting the involvement of a bHLH factor in the control of β 3 transcription.

ONTOGENY OF MUSCARINIC RECEPTORS IN A GENETIC ANIMAL MODEL OF DEPRESSION. L.C. Daws, D.H. Overstreet, and G.D. Schiller, School of Biological Sciences, Flinders University of South Australia, Adelaide, 5001 Australia.

The Flinders Sensitive Line (FSL) rat, selectively bred for increased responses to an anticholinesterase, is also more sensitive to directly acting muscarinic agonists than the Flinders Resistant Line (FRL) rat. The muscarinic supersensitivity in the FSL rats, which mimics that observed in depressed humans, occurs very early in development and seems to be regulated by recessive genes. The present study examined muscarinic receptor binding using the nonselective ligand QNB at various ages in the FSL and FRL rat to assess whether differences in muscarinic receptors could account for differences in pharmacological sensitivity. There were no differences in receptor concentration early in development (up to parturition Day 19), but by Day 32 and thereafter, the FSL rats exhibited significantly greater numbers of receptors in the hippocampus and the striatum. There were never any differences in the cerebral cortex and the differences in muscarinic receptor binding in the hypothalamus only emerged in the older adult (Day 120). Thus, these global differences in muscarinic receptors, while confirming previous reports in adult rats, are not able to account for differences in the pharmacological sensitivity between the lines; the FSL rats are more sensitive to muscarinic agonists both before and after there are receptor differences. Pirenzepine, a selective M1 muscarinic antagonist, was used to displace QNB in order to estimate the percentage of M1 and M2 binding sites. The experiment indicated that the increased muscarinic receptors seen in the FSL were for both M1 and M2 subtypes.

REGULATION OF NEURONAL NICOTINIC RECEPTORS: EFFECTS OF NICOTINE ON PRIMARY NEURONAL CELLS IN CULTURE. M.I. Dávila-García, R.A. Houghtling, S.S. Qasba and K.J. Kellar. Department of Pharmacology, Georgetown University School of Medicine, Washington, DC 20007.

The study of nicotine effects on the regulation of neuronal nicotinic acetylcholine receptors has been impeded by the lack of a suitable *in vitro* model. We have used a cell culture system from fetal rat brain to characterize the properties of neuronal nicotinic acetylcholine receptors and to begin to study the factors involved in their regulation. In the present studies we examined the effects of nicotine on [³H]cytisine binding in embryonic day 18 fetal neurons from the brainstem (which included thalamus, hypothalamus, midbrain and pons), cortex, caudate and hippocampus. We found that after 15 days in culture the brainstem neurons contain the greatest number of neuronal nicotinic receptors (≈ 50 fmol/mg protein) and that this receptor has high affinity for [³H]cytisine (0.7 nM). Binding of [³H]cytisine is competitively inhibited by nicotine ($IC_{50} \approx 20$ nM), as well as by carbachol and dihydro- β -erythroidine (IC_{50} values of < 1 μ M). Nicotine induced an increase in intracellular Ca^{2+} in cortical cells. This increase in calcium was not seen in cultures previously exposed to nicotine (100 μ M) for 7 days, suggesting that this response can be desensitized/inactivated by nicotine. Similar treatment of these cultures for 7 days with 100 μ M nicotine increased the number of [³H]cytisine binding sites. This work was supported by NIH grants DA05417 and DA06486.

ACETYLCHOLINE RECEPTORS: NICOTINIC MOLECULAR BIOLOGY

466.1

EFFECTS OF SUSTAINED NICOTINE EXPOSURE ON THE ACTIVATION OF NEURONAL NICOTINIC RECEPTORS EXPRESSED IN *XENOPUS* OOCYTES. Y.N. Hsu, J. Amin, D. Weiss and L. Wecker*. Depts. Pharmacol. and Physiol., Univ. South Florida College of Medicine, Tampa, FL 33612.

Studies suggest that nicotine induces the release of dopamine (DA) and acetylcholine (ACh) through interactions at $\alpha 3\beta 2$ and $\alpha 4\beta 2$ nicotinic receptor subtypes, respectively. The chronic administration of nicotine increases nicotine-mediated [³H]DA release, but decreases nicotine-mediated [³H]ACh release from brain slices, suggesting that chronic nicotine differentially affects these receptors. To test this hypothesis, cRNAs for $\alpha 3$ and $\beta 2$ or $\alpha 4$ and $\beta 2$ subunits were co-injected into *Xenopus* oocytes and nicotine-activated currents were measured before and after 24 hrs incubation with nicotine using the 2-electrode voltage-clamp technique. Currents in oocytes expressing $\alpha 3\beta 2$ receptors were not affected significantly by 24 hr incubation with nicotine; currents increased 6.8-fold, 5.9-fold and 5.2-fold following incubation with 0, 20 and 100 nM nicotine, respectively, due to increased receptor expression. In contrast, $\alpha 4\beta 2$ -expressing oocytes had a reduced response to nicotine; current in control oocytes increased 5.8-fold, whereas current in oocytes incubated with 20 nM nicotine increased 2.2-fold and with 100 nM incubation, no increase was noted. This reduced response to nicotine reversed after 90 min incubation in medium lacking nicotine indicating $\alpha 4\beta 2$ receptors were expressed, but desensitized. Results suggest that the differential effect of chronic nicotine on the release of DA and ACh may be due, at least in part, to differences in the desensitization of the two receptor subtypes that mediate the release of these neurotransmitters. (Supported by grants #0411 from the STRC, Inc. and #AA09212 from the NIH.)

NICOTINE-INDUCED UPREGULATION OF NEURONAL NICOTINIC RECEPTORS RESULTS FROM A DECREASE IN THE RATE OF RECEPTOR TURNOVER

X. Peng*, R. Anand, P. J. Whiting#, J. Lindstrom. Dept. of Neuroscience, Univ. of Pennsylvania, Philadelphia PA 19104-6074. #Merck Sharp and Dohme Laboratories, Terlings Park Eastwick Road, Harlow, Essex CM20 2QR, England

Chronic nicotine exposure in tobacco smokers or experimental animals is known to cause an increase in brain nicotine binding sites and to cause accumulation of chronically desensitized receptors. Acetylcholine receptors of the same ($\alpha 4$)₂($\beta 2$)₃ subunit composition as the predominant subtype of brain nicotinic receptor with high affinity for nicotine have been expressed in a permanently transfected fibroblast cell line. Chronic exposure of these cells to nicotine, other agonists, or a channel blocker is shown to result in an increase in receptor amount, indicating that nicotine induced upregulation reflects properties of the $\alpha 4\beta 2$ receptor protein which can be expressed in transfected fibroblasts, rather than an adaptive response unique to the neurons in which these receptors are normally expressed. The nicotine concentration-dependence, time course, and extent were similar to those reported for receptor in brain, suggesting that this intrinsic property could account for the upregulation observed in brain. The mechanism of nicotine-induced upregulation is shown to not require ion flow through the receptor and to involve a decreased rate of receptor turnover.

466.2

NICOTINE-INDUCED DESENSITIZATION OF RAT NEURONAL NICOTINIC ACETYLCHOLINE RECEPTOR SUBUNIT COMBINATIONS EXPRESSED IN *XENOPUS LAEVIS* OOCYTES. C.R.T. Vibat, J.A. Lasalde, M.G. McNamee, and E.L.M. Ochoa*. Section of Molecular and Cellular Biology, and Department of Pediatrics, University of California at Davis, Davis, CA 95616.

Chronic administration of nicotine up-regulates rat neuronal nicotinic acetylcholine receptors (nAChRs). A key hypothesis that explains up-regulation assumes that nicotine induces desensitization of receptor function. This is correlated to behaviorally expressed tolerance to the drug. The present experiments were conducted to obtain information on the nicotine-induced desensitization of neuronal nAChR function, a less understood phenomenon as compared to that of the muscle and *Torpedo* counterparts. *X. laevis* oocytes were injected with mRNAs encoding receptor subunits $\alpha 2$, $\alpha 3$, or $\alpha 4$ in pairwise combination with the $\beta 2$ subunit. The responses to various concentrations of ACh or nicotine were analyzed by the two electrode voltage clamp technique. $\alpha 4\beta 2$ is the predominant form in the rat brain that also undergoes up-regulation (Flores, *et al.*, 1992). We found that nicotine was more potent than ACh (EC_{50} : 0.3 μ M vs. 6 μ M) in the $\alpha 4\beta 2$ combination and we observed a depression of the maximum attained response at concentrations higher than 20 μ M nicotine, a clear indication of nicotine-induced desensitization. Inactivation of the response (calculated as a single exponential decay) was significantly faster for $\alpha 4\beta 2$ than for $\alpha 3\beta 2$. We constructed I/V curves at different concentrations of nicotine and the results suggest that blockade is not the mode of receptor inactivation at high nicotine concentration. By patch clamp analysis, $\alpha 4\beta 2$ has been shown to have three conductance states (Charnet, *et al.*, 1992). Since one or more of these states could differentially contribute to the observed desensitization, experiments are in progress to analyze desensitization kinetics at the single channel level. Taken altogether, these data suggest that the $\alpha 4\beta 2$ combination is desensitized by nicotine. This research was supported by NIH grant NS22941 and in part by funds provided by the Cigarette and Tobacco Surfactant Fund of the State of California through the Tobacco-Related Disease Research Program of the University of California, Grant Number 3RT-0098.

ANTISENSE DELETION REVEALS THAT $\alpha 5$ SUBUNITS PARTICIPATE IN NATIVE CHICK NEURONAL NICOTINIC CHANNELS

C. Yu* & L. Role. Dept. of Anat. & Cell Biol. in the Ctr for Neurobiol. & Behav. Columbia Univ. P&S, 722 W. 168th. St. New York, NY 10032

The $\alpha 5$ subunit of the chick neuronal nicotinic acetylcholine receptor (nAChR) family is present in many cholinergic neurons (Ballivet, Berg and their colleagues). Emerging evidence indicates that the $\alpha 5$ subunit can participate in functional nicotinic channels by coassembly with other α and β subunits in heterologous expression systems (see Abstract by Ramirez-Latorre *et al.* 1993). In view of these data we have examined the role of $\alpha 5$ subunits in native neuronal nAChRs.

The properties of ACh-gated macroscopic and single channel currents were assayed in embryonic chick sympathetic neurons treated with control or $\alpha 5$ antisense oligonucleotides. Two different antisense oligonucleotides against different regions of the $\alpha 5$ subunit gene were used and produced identical results: First, $\alpha 5$ deletion alters the dose response curves to ACh, cytosine and nicotine with changes in the apparent affinity for agonist. Thus $\alpha 5$ -minus neurons have a higher affinity to cytosine, (EC_{50} =24 μ M) compared with control (EC_{50} =75 μ M). These results are consistent with previous findings that inclusion of $\alpha 5$ subunits in heterologously expressed $\alpha 4\beta 2$ nAChRs decreases agonist affinity. In addition, the deletion of the $\alpha 5$ subunits changes the profile of nAChR channel subtypes. Two of the three classes of channels expressed in control neurons are deleted and new channels of 14pS and 63 pS are expressed by sympathetic neurons. These results indicate that the $\alpha 5$ subunit participates in native sympathetic neuronal nAChRs altering both agonist affinity and conductance. (supported by NIH29071 to LR)

MUTATIONAL ANALYSIS OF NOVEL RESIDUES IDENTIFIED WITHIN THE BINDING SITE OF *d*-TUBOCURARINE OF *TORPEDO* ACETYLCHOLINE RECEPTOR. Y. Xie, D.C. Chiara and J.B. Cohen Department of Neurobiology, Harvard Medical School, Boston, MA 02115

The competitive antagonist *d*-tubocurarine (dTC) binds to the two agonist binding sites of the nicotinic acetylcholine receptor (nAChR) from *Torpedo* electric organ and mouse skeletal muscle with significantly different affinities. The high-affinity and low-affinity dTC binding sites are located at the α - γ and α - δ subunit interfaces, respectively. Our photolabeling studies using [3 H]-dTC identified previously two non- α residues: γ W55 and δ W57. Here we report the identification of two additional residues photolabelled by [3 H]-dTC: γ Y111 and γ Y117. The tyrosine in the γ -subunit of mouse muscle nAChR corresponding to *Torpedo* γ Y117 has been shown to be important for the selective binding of dimethyl-TC (S. Sine, *PNAS* 90: 9346-9400, 1993). In the aligned *Torpedo* nAChR sequences, the residue which corresponds to γ Y111 in the δ -subunit is δ R113. This difference may also contribute to the difference in dTC binding affinities between the two sites. To examine the role of these two residues in dTC binding, we made γ Y111R and δ R113Y mutant receptors. When expressed in *Xenopus* oocytes, both mutant receptors show similar densities of [125 I]- α -bungarotoxin (α Bgt) binding and amplitudes of ACh-induced currents as wild type receptors. Competition studies of dTC against the initial rate of [125 I]- α Bgt binding to both whole oocytes and oocyte membranes reveal that γ Y111R mutation causes \approx 3-fold decrease of dTC affinity for the high-affinity binding site, while the δ R113Y mutation increases dTC affinity for the low-affinity binding site 2-3 fold. Functional consequences of these mutants in terms of changes of agonist/antagonist sensitivities will be assessed by using the two-electrode voltage-clamp technique.

TRANSGENE MODULATION OF NICOTINIC ACETYLCHOLINE RECEPTOR NUMBERS AND FUNCTION IN MOUSE AND HUMAN CELL LINES. Elzbieta Puchacz*, Linda Lucero and Ronald J. Lukas. Div. Neurobiol., Barrow Neuro. Inst., Phoenix, AZ 85013.

Cells of the SH-SY5Y human neuroblastoma express two types of nAChR, nicotinic α -bungarotoxin (Bgt) binding sites (nBgtS) and ganglia-type nAChR, and products of at least five human nAChR subunit genes (α 3, α 5, α 7, β 2 and β 4). Here we show that transfection of SH-SY5Y cells with rat α 7 constructs dramatically increases [125 I]-labeled Bgt (I-Bgt) binding in SH-SY5Y cells without affecting ganglia-type nAChR function. Cyclosporin sensitivity of this effect, but not of I-Bgt binding to control SH-SY5Y cells, suggests that transgenic rat α 7 subunits may assemble in a cyclophilin-dependent manner as homooligomers, whereas assembly of native α 7-containing nBgtS does not have such a dependence. Preliminary studies indicate that transfection of SH-SY5Y cells with antisense α 7 constructs produces a dramatic loss in I-Bgt binding, again without effects on ganglia-type nAChR function, suggesting that human α 7 subunits contribute to native nBgtS but not ganglia-type nAChR in SH-SY5Y cells. Other studies demonstrate that adult muscle nAChR epsilon transgene expression in BC3H-1 cells rescues nAChR from loss of function and I-Bgt binding when cells are subjected to drug treatments that mimic the motor neuronal innervation-induced loss of fetal nAChR gamma subunit expression as seen in developing muscle in vivo.

SUBUNIT COMPOSITION DISTINGUISHES MULTIPLE CLASSES OF ACETYLCHOLINE RECEPTORS IN THE SAME NEURONS. W.G. Conroy* and D.K. Berg. Dept. of Biology, UC San Diego, La Jolla, CA 92093.

The rules governing subunit assembly of neuronal acetylcholine receptors (AChRs) are only beginning to be elucidated. Chick ciliary ganglion neurons express five known neuronal AChR genes. Three of the encoded gene products (α 3, β 4, and α 5) are present in synaptic-type receptors that bind mAb 35 (mAb 35-AChRs). A fourth (α 7) is present in a second class of receptors that bind α -bungarotoxin (α Bgt-AChRs). Immunoprecipitations with subunit-specific mAbs now show that the fifth gene product (β 2) is present in about 20% of the mAb 35-AChRs while being excluded from α Bgt-AChRs. Immunoblot analysis confirms that the β 2 gene product is associated with α 3, β 4, and α 5 proteins. Immunostaining of ganglion sections demonstrates that essentially all of the neurons contain β 2 gene product. Accordingly, the same neurons apparently express both classes of mAb 35-AChRs (with and without β 2) as well as α Bgt-AChRs. All three classes have the size expected of fully-assembled AChRs and appear on the cell surface. Other experiments indicate that the ganglion also contains a novel minor population of receptors that bind both mAb 35 and α Bgt and is distinct from those described here (see abstract by Pugh et al.). The virtue of multiple AChR classes in the same neuron and the significance of β 2 subunits raise new questions. (NS12601 & 25916; TRDRP)

466.6

STABLE RECOMBINANT EXPRESSION OF HUMAN NEURONAL NICOTINIC ACETYLCHOLINE RECEPTOR α 3 β 4 SUBTYPE IN HEK293 CELLS. M. Akong, S. Mahaffy, L. Chavez-Noriega, A. Urrutia, K. Elliott, K. Berckhan, R. Reid, T.S. Rao, G.K. Lloyd, E.C. Johnson, and G. Velicelebi. SIBIA, Inc., La Jolla, CA 92037.

cDNA clones encoding full-length human neuronal nicotinic acetylcholine receptor (nAChR) α 3 β 4 subunits were subcloned into a pCMV vector and stably transfected into HEK293 cells. Functional expression of the recombinant receptor was characterized through measurements of increases in intracellular calcium ($[Ca^{2+}]_i$) and inward currents. A binding capacity of approximately 25,000 receptors/cell was estimated from measurements of [3 H]-nicotine binding. Nicotine, cytosine, and DMPP stimulated $[Ca^{2+}]_i$ levels in a concentration-dependent manner up to approximately six-fold above basal, with a potency rank order of DMPP > cytosine > nicotine, similar to that determined in *Xenopus* oocytes injected with h α 3 β 4 transcripts. The competitive antagonist, d-tubocurarine, inhibited the stimulatory effects of each agonist also in concentration-dependent manner, with IC_{50} values of $0.84 \pm 1.10 \mu M$, $1.15 \pm 1.06 \mu M$, and $0.93 \pm 0.33 \mu M$ against nicotine, cytosine, and DMPP, respectively. In whole-cell recordings from the stable α 3 β 4-transfectants, transient inward currents with magnitudes greater than 1 nA were observed at negative holding potentials following application of acetylcholine, nicotine, or DMPP. The current-voltage relationship was strongly inward rectifying, and no outward current was detected at positive potentials.

DIVERGENT EFFECTS OF CPT-cAMP ON NICOTINIC ACETYLCHOLINE RECEPTOR PROTEIN AND GENE EXPRESSION IN BC3H-1 CELLS INDUCED TO GROW OR DIFFERENTIATE. Linda Lucero, Robert S. Fisher* and Ronald J. Lukas. Division of Neurobiology, Barrow Neurological Institute, Phoenix, AZ 85013, USA.

Changes in cyclic AMP (cAMP) levels in differentiating muscle fibers are thought to influence levels of expression of muscle nicotinic acetylcholine receptors (nAChR). We assessed effects of 8-(4-chlorophenylthio)-cAMP (CPT-cAMP), a cyclic AMP analogue, on nAChR expression in BC3H-1 mouse muscle cells. CPT-cAMP treatment of cells maintained in a 'myoblast-like state' (where cells are grown in medium containing 10% horse and 5% fetal calf sera) inhibited the usual slow, time-dependent accumulation of nAChR. Conversely, for 'differentiated' BC3H-1 cells where a typical 2-fold increase in nAChR expression is rapidly induced by at least 2 days of growth in 1% fetal calf serum-supplemented medium, CPT-cAMP exposure produced an additional up-to-2-fold augmentation in nAChR expression. These divergent effects of CPT-cAMP treatment are reflected in nAChR function, numbers of nicotinic radioligand binding sites on the cell surface or in total particulate fractions, and levels of nAChR subunit mRNA. These findings suggest that effects of activation of cAMP-dependent signaling in muscle cells in vivo might also vary as a function of cellular differentiation state, acting to inhibit nAChR expression in myoblasts but to enhance the induction of nAChR expression after myotube formation.

A SUBPOPULATION OF NEURONAL ACH RECEPTORS AMONG THOSE BINDING α -BUNGAROTOXIN. P.C. Pugh*, R.A. Corriveau, and D.K. Berg. Dept. of Biology, UC San Diego, La Jolla, CA 92093.

Neuronal nicotinic acetylcholine receptors (AChRs) that bind α -bungarotoxin (α Bgt-AChRs) have previously been found to contain α 7, α 8, or both gene products. The chick ciliary ganglion at embryonic day 18 has about 30 fmol of α Bgt-AChRs containing α 7 subunits. In addition it has about 4 fmol of mAb 35-AChRs that bind mAb 35 but not α Bgt and, as a population, contain α 3, β 4, α 5 and, to a lesser extent, β 2 subunits. Using a sensitive solid phase assay we report a new population of putative receptors that bind both α Bgt and mAb 35 with high affinity, exhibit nicotinic pharmacology similar to that of α Bgt-AChRs, and constitute about 1 fmol per ganglion. The receptors sediment at 10S as expected for neuronal AChRs, are developmentally regulated, and are also found in dorsal root ganglia but not in brain or retina. Analysis with subunit-specific mAbs provides no evidence for the receptors containing any of the five neuronal AChR gene products known to be present in ciliary ganglia. The muscle AChR α 1 gene product binds both α Bgt and mAb 35, and RNase protection experiments surprisingly detect a small amount of α 1 transcript in the ganglion. Immunoblots, however, fail to detect α 1 protein in the receptors. The results raise the possibility that the receptors are composed of novel gene products yet to be described. (NS12601, NS25916, & TRDRP)

466.11

EXPRESSION OF NEURONAL ACH RECEPTOR GENES IN TRANSFECTED HEK-293 CELLS. R.C. Haselbeck, W.G. Conroy, S.J. Romano, and D.K. Berg*. Dept. of Biology, UC San Diego, La Jolla, CA 92093.

Subunit interactions and functions are poorly understood in the case of neuronal nicotinic acetylcholine receptors (AChRs). To address these issues, we have expressed three AChR genes ($\alpha 3$, $\beta 4$, and $\alpha 5$) in transfected HEK-293 cells. These subunits make up the major class of synaptic-type AChRs that binds mAb 35 on chick ciliary ganglion neurons. Immunoblots of extracts from transfected cells confirm that all three genes generate proteins that co-migrate with the subunits from native AChRs. Sucrose gradient analyses of extracts demonstrate that cells transfected with $\alpha 3/\beta 4/\alpha 5$, $\alpha 3/\beta 4$, or $\alpha 5/\beta 4$ (but not with $\alpha 3/\alpha 5$) contain large amounts of assembled components that bind mAb 35, immunoprecipitate with anti- $\alpha 3/\beta 4$ mAbs, and sediment in the 10S region as expected for neuronal AChRs. Despite the similar amounts of such components in the three kinds of transfections, $\alpha 5/\beta 4$ cells express by far the most mAb 35 binding sites on the cell surface. Surprisingly, transfections with $\alpha 5$ alone produce large amounts of surface sites for mAb 35 ($\alpha 3$ and $\beta 4$ alone do not), but immunoprecipitations indicate that the $\alpha 5$ species cannot alone account for the large number of sites on $\alpha 5/\beta 4$ cells. The results identify a new candidate neuronal AChR and suggest that $\alpha 5$ subunits may play a key role in targeting receptors to the surface. (NS12601, NS2516, AHA93-72)

DIFFERENTIAL EFFECTS ON CALCIUM LEVELS IN NEURONS CAUSED BY NICOTINIC AND MUSCARINIC RECEPTORS. M.M. Rathouz*, S. Vijayaraghavan, and D.K. Berg. Dept. Biol., UC San Diego; La Jolla, CA 92093.

Intracellular calcium levels ($[Ca]_i$) in neurons can be elevated by either nicotinic or muscarinic receptors. Chick ciliary ganglion neurons have both. The nicotinic receptors increase $[Ca]_i$ via their calcium permeability and activation of voltage-gated channels. We report M3-type muscarinic receptors on the neurons having different effects on $[Ca]_i$.

Activation of the muscarinic receptors stimulates phosphatidylinositol (PI) turnover, and the turnover is blocked by DAMP as expected for M3 receptors. Fluorescence measurements in fluo-3-loaded neurons indicate that activation of the receptors increases $[Ca]_i$ in an oscillatory manner that is blocked by DAMP, depends on extracellular calcium, but remains after emptying caffeine-sensitive calcium stores. These features are consistent with M3 receptors acting through IP_3 to produce the oscillations.

ACh at 50 μM activates both the M3 and nicotinic receptors, generating a sustained elevation of $[Ca]_i$. Selective blockade of nicotinic receptors converts the response to an oscillatory one while selective blockade of M3 receptors causes the response to decay more abruptly. The distinctive changes in $[Ca]_i$ produced by the two receptors may allow a single neurotransmitter to modulate multiple calcium-dependent events independently in a neuron. (NS12601, NS25916, & TRDRP)

ALTERATIONS IN CYCLOSPORIN-A SENSITIVITY OF $\alpha 7$ HOMOLIGOMERIC NICOTINIC RECEPTOR EXPRESSION BY MUTATIONS WITHIN TRANSMEMBRANE DOMAINS. Santosh A. Helekar*, Hong Dang and Jim Patrick. Div. of Neuroscience, Baylor College of Medicine, Houston, TX.

Synthesis of oligomeric integral membrane receptors such as the ligand-gated ion channels may depend on the activity of folding enzymes and molecular chaperones. We showed previously that blockade of a folding enzyme, the prolyl isomerase cyclophilin (CyP), with cyclosporin A (CsA) caused a dose-dependent reduction of the expression of functional rat $\alpha 7$ nicotinic receptors in *Xenopus* oocytes. We now report a second effect of CsA on the small number of residual receptors that are assembled in the presence of this compound. We observed that, in addition to a decrease in receptor expression, CsA increased the extent of run down of current responses following repeated agonist applications. We wanted to investigate whether the apparent reduction in receptor expression was caused by this increase in receptor run down induced by CsA. Using a non-desensitizing rat $\alpha 7$ receptor mutant that had a leucine to threonine substitution at position 250 in the pore forming transmembrane domain II, we were able to dissociate the two effects of CsA. We found that CsA increased the amount of receptor run down in this mutant, as well as in the wild type. However, in contrast to the wild type receptor, CsA produced a significant enhancement of the level of expression of functional mutant receptors. These data indicate that the two effects of CsA on $\alpha 7$ nicotinic receptors, namely on receptor expression and on receptor run down are distinct and unrelated. The mechanisms underlying the run down effect of CsA are currently unclear. But as regards the CsA effect on receptor expression, we now have evidence that the CsA-induced enhancement of L250T mutant receptor expression can be reversed by the substitution of a glycine residue for a highly conserved proline at position 220 in the transmembrane domain I. Supported by grants from NIH (JP) and a MDA fellowship (SAH).

POSTTRANSCRIPTIONAL REGULATION OF NEURONAL ACH RECEPTORS DESTINED FOR THE CELL SURFACE. B. Rothhut, S.J. Romano, S. Vijayaraghavan*, and D.K. Berg. Dept. of Biology, UC San Diego, La Jolla, CA 92093.

Mechanisms controlling receptor accumulation on neurons are largely unknown. M10 cells, stably transfected with the acetylcholine receptor (AChR) $\alpha 4$ and $\beta 2$ genes, permit an examination of this. We find that forskolin in 24 hours stimulates a 6-fold increase in surface AChRs and a 2-fold increase in the abundant intracellular receptors. The increases are partially blocked by H89 and mimicked by 8-bromo-cAMP, implicating protein kinase A. The intracellular increase and part of the surface increase depend on protein synthesis and correlate with increases in receptor transcripts. When protein synthesis is blocked, however, forskolin still doubles selectively the number of surface AChRs, suggesting that a cAMP-dependent process either helps target receptors to the cell surface or stabilizes them there. Okadaic acid, which inhibits protein phosphatases 1 and 2A, selectively blocks the large forskolin effect on surface receptors but not the effect on intracellular receptors. Okadaic acid does not decrease total protein synthesis or AChR transcript levels in forskolin-treated cells, but does decrease the levels of AChR protein, possibly by promoting turnover. The finding that forskolin and okadaic acid have opposite but specific effects on the accumulation of surface AChRs suggests that multiple phosphorylation events may influence receptor assembly, transport, and stability. (NS12601, NS25916, & TRDRP)

466.14

EXPRESSION OF NEURONAL ACH RECEPTOR GENES IN VERTEBRATE SKELETAL MUSCLE. R.A. Corriveau*, S.J. Romano, W.G. Conroy, L. Oliva, and D.K. Berg. Dept. of Biology, UC San Diego, La Jolla, CA 92093.

Fifteen nicotinic ACh receptor (AChR) genes have been identified; a subset of these ($\alpha 2$ -8, $\beta 2$ -4) are expressed in the nervous system and are therefore considered neuronal genes. Using RNase protection assays we demonstrate that embryonic chick skeletal muscle expresses four neuronal-type AChR genes ($\alpha 4$, $\alpha 5$, $\alpha 7$, and $\beta 4$) in developmentally regulated patterns. Of the four, $\alpha 7$ mRNA is relatively abundant and reaches a level about 20% that of $\alpha 1$ at embryonic day 8 (E8). Like $\alpha 1$, $\alpha 7$ mRNA levels increase over development, peaking at E8-E11, and fall dramatically by E17. In situ hybridizations confirm the presence of $\alpha 7$ transcripts in myotubes both in vivo and in culture. Immunoprecipitations and immunoblot analysis using subunit-specific monoclonal antibodies reveal $\alpha 7$ protein in muscle; the developmental pattern of $\alpha 7$ protein expression parallels that of $\alpha 7$ mRNA. Sucrose gradients demonstrate that the $\alpha 7$ protein is present as a 10S species, a size expected for an AChR. The $\alpha 7$ -containing component binds α -bungarotoxin but does not contain $\alpha 1$ subunits, indicating that the two α -type gene products segregate during assembly. The finding of a putative neuronal AChR in embryonic muscle indicates that the tissue-specific division of AChR gene expression is less categorical than previously recognized and raises the possibility that neuronal AChRs participate in muscle development. (NS12601 and NS25916)

ANALOGUES OF 5HT INCREASE THE RATE OF DESENSITIZATION OF NICOTINIC RECEPTORS IN OOCYTES. K.M.L. CROSS, C.H. BUYKX, J.E. CHAD AND R.C. FOREMAN. Department of Physiology and Pharmacology, University of Southampton, SO9 3TU, UK. (SPON: BRA)

We have expressed a variety of mammalian nicotinic receptors in *Xenopus laevis* oocytes. The $\alpha 4\beta 2$ combination gave a current of 580nA \pm 122nA ($n=7$) in response to 10 μM acetylcholine (ACh), with a $t_{0.5}$ of desensitization of 51.4 \pm 3.6secs. In the presence of 5HT there was a dose dependent decrease (IC_{50} 100 μM) of the peak current response. The rate of desensitization was increased by 5HT (100 μM), the $t_{0.5}$ was reduced to 17.2 \pm 2.0secs, that is to 33% of the control value. The effect was readily reversed by washout. 5HT alone did not give rise to any current. 5HT also modulated the combination $\alpha 2\beta 3\gamma 6$, the muscle subunits with a neuronal β subunit substituted. The mean peak current elicited by 10 μM ACh was 237 \pm 44nA with $t_{0.5}$ of 13.5 \pm 2.7secs. In the presence of 5HT the peak current was reduced with the same IC_{50} as for the $\alpha 4\beta 2$ combination. This dose of 5HT reduced the $t_{0.5}$ to 26% of control. In order to investigate the mechanism of modulation by 5HT we examined the effect of structurally similar molecules. The 5HT₂ receptor antagonists ketanserin and cyproheptadine increased the rate of ACh receptor desensitization. Ketanserin was found to be more potent than 5HT in reducing the peak current with the IC_{50} value being 50 μM . Cyproheptadine was less potent but still decreased the sensitivity of the nicotinic receptor to its natural ligand. These results suggest that 5HT acts on a specific site on the nicotinic receptor, which resembles the 5HT₂ receptor.

MOLECULAR REGULATION OF HUMAN $\alpha 7$ nAChR GENE EXPRESSION. L.M. Monteggia*, M. Gopalakrishnan, and T. Giordano. Neuroscience Research, D47W, Abbott Labs, Abbott Park, IL 60064-3500.

Previous reports of $\alpha 7$ nicotinic acetylcholine receptor (nAChR) gene expression have suggested extremely complex regulatory mechanisms with differences between transcriptional activity and steady state levels of the RNA reported during chicken development. We report here the regulation of $\alpha 7$ in the human neuroblastoma cell line, IMR32, in response to NGF and PMA, agents which are known to alter the expression of various genes. Three transcripts of 6.0, 3.5, and 2.4 kb were observed for $\alpha 7$ nAChR in the IMR32 cells. An approximate 2 fold increase in the steady state levels of RNA of all transcripts was detected following 24 hr treatment with either NGF or PMA. To determine the kinetics of $\alpha 7$ gene induction, IMR32 cells were treated with NGF for 0.5, 1, 2, 4, 8, 16, and 24 hr, RNA was isolated and steady state levels were determined. An increase in steady state levels of RNA can result from increased transcription, stability, or both. To assess altered transcriptional activity, cells were treated with NGF or PMA for 24 hr and the nuclei have been isolated for use in nuclear runoff experiments. The stability of the $\alpha 7$ RNA is currently being analyzed from cells treated with actinomycin D, an inhibitor of RNA synthesis. The 3'UTR region of many mRNAs contain sequences rich in A and U nucleotides, which seem to function in stability, translation, and localization of the RNA. Using RNA fold programs to analyze the 3'UTR of the human $\alpha 7$ cDNA no AUUUA sequences, a motif previously shown to regulate RNA stability, were found, however a large stem loop structure was predicted. In a 9 bp loop, ATATTCTCA, bp 2-7 are identical in rat, suggesting this may be a motif for RNA binding proteins (RNPs). Studies are underway to determine whether RNPs are present which bind to the human $\alpha 7$ 3' UTR and whether the 3' UTR from rat or other human subunits can compete for the proposed binding protein.

NEURONAL NICOTINIC ACETYLCHOLINE RECEPTOR $\alpha 4$ mRNA CONSISTS OF THREE DIFFERENT TRANSCRIPTS IN RAT BRAIN: NORTHERN DETERMINATION. Z. J. Yu, D. G. Morgan* and L. Wecker. Dept. Pharmacol. and Therap., USF College of Medicine, Tampa, FL 33612.

The initial report describing the neuronal nicotinic receptor $\alpha 4$ RNA identified 3 different messages believed to represent alternative splicing of a single transcript (Cell 48:965, 1987). Although $\alpha 4$ is the most widely expressed α subunit RNA in rat brain, the 3 species of $\alpha 4$ transcripts have not been well described with respect to their abundance ratios in different brain regions. In this study, signals of $\alpha 4$ mRNA were detected by Northern hybridization with radiolabeled plasmid DNA for $\alpha 4$ -1 or HinfI fragment of $\alpha 4$ -1. Quantification was conducted by densitometry of X-ray film. Three transcripts homologous to $\alpha 4$ -1 cDNA were found in all brain regions tested. The sizes of the $\alpha 4$ gene transcripts were approximately 2.6 kb, 4.6 kb and 6.0 kb. The ratios of the 2.6:4.6:6.0 kb transcripts were: 1.0:1.6:0.11 in basal forebrain; 1.0:1.6:0.28 in striatum; 1.0:0.41:0.14 in frontal cerebral cortex; 1.0:0.47:0.09 in midcerebral cortex; 1.0:2.6:0.10 in midbrain; 1.0:0.71:0.33 in hippocampus; and 1.0:0.65:0.34 in thalamus and hypothalamus. Further, all 3 bands diminished in parallel with increased hybridization stringency, indicating a similar degree of homology to the $\alpha 4$ -1 probe. This study demonstrates that there are 3 alternatively processed transcripts of the neuronal nicotinic acetylcholine receptor $\alpha 4$ gene, and the relative abundance of these transcripts differs in different brain regions. (DGM is an Established Investigator of the American Heart Association. Supported by grant #0411 from the STRC, Inc.)

A NOVEL *IN SITU* DOUBLE-LABELING PROCEDURE TO STUDY THE EXPRESSION OF PROTEINS AND MESSAGES. K-P. Chiu, S.A. Berman*, T. Sullivan and S. Bursztajn. Labs. of Molecular Neurosci., Harvard Medical School/McLean Hospital, Belmont, MA 02178

Nicotinic acetylcholine receptors (AChRs), the hallmark of neuromuscular junctions, express multiple receptor subunits which can be regulated by many signals. In our investigation of these phenomena, using cultured muscle cells and neurons isolated from developing embryos, it is frequently necessary to image more than one molecular response simultaneously. We devised a novel double-labeling method to detect the expression of two different signals, e.g. two different mRNA species or a protein together with its corresponding mRNA, in the same cell preparation. This method employs a separate emulsion-coated slide to detect the radioactive signal, while the other signal is detected directly in the cells on a coverslip. We have tested this method using the combination of 125 I-labeled α -bungarotoxin together with digoxigenin-labeled probe, or the combination of 35 S-labeled cDNA probe together with digoxigenin-labeled oligo probe. In either combination, the radioactive signal was detected by developing the emulsion coated on a separate slide. After exposure, the emulsion-coated slide was separated from the coverslip containing the cell sample and then developed. The cells on the coverslip were subjected to a color development procedure to detect the digoxigenin-labeled probe. After color development, the slide carrying the radioactive signal was recombined with the coverslip carrying the colored signal and the cell origin relocated. This procedure allowed us to determine the distribution of AChR protein as observed by silver grains and AChR subunit message as detected colorimetrically on the same cell. Similarly, our procedure allows for the detection of two different messages in the same cell.

ACTIVITY REGULATES $\alpha 7$ NICOTINIC ACh RECEPTOR SUBUNIT GENE EXPRESSION IN RAT SYMPATHETIC NEURONS. P. De Koninck* and E. Cooper*. Depts. of Biology* and Physiology*, McGill Univ. Montréal, Québec, Canada H3G 1Y6.

Little is known about the mechanisms by which innervation controls the expression of neurotransmitter receptors in nerve cells. Therefore, we are studying gene expression of nicotinic acetylcholine receptor (nAChR) subunits in cultured neonatal rat sympathetic neurons. These neurons express 5 nAChR transcripts: $\alpha 3$, $\alpha 5$, $\alpha 7$, $\beta 2$ and $\beta 4$. Two days after plating, mRNA levels for the $\alpha 7$ subunit decrease 3 fold while the mRNA levels for the $\alpha 3$ subunit increase and the levels of $\alpha 5$, $\beta 2$ and $\beta 4$ remain constant. These results suggest that extrinsic factors control $\alpha 7$ expression. One factor is neuronal activity: treating neurons with 40mM KCl (HK*) causes a 3 fold increase in $\alpha 7$ mRNA levels within 24-48 hours, without causing any change in the other subunit mRNA levels except for a small (10-20%) increase in $\alpha 3$ mRNA levels. Treatment of cultures with α -amanitin, an mRNA synthesis inhibitor, for 24 hours, indicated that HK* does not affect $\alpha 7$ mRNA stability, providing evidence that HK* affects $\alpha 7$ gene expression. Verapamil, an L-type Ca^{++} channel blocker, inhibits the induction by HK*, indicating that the regulation of $\alpha 7$ gene expression occurs via a Ca^{++} mediated pathway. Next, we examined whether serine/threonine protein kinases are involved in this induction pathway. Protein kinase C or A (PKC/PKA) activators do not increase $\alpha 7$ mRNA synthesis and furthermore, neither PKC nor PKA inhibitors block the induction by HK*. KN62, an inhibitor of the Ca^{++} /Calmodulin dependent protein kinase (Cam Kinase II), completely blocks the HK* induction; however, we have not yet excluded the possibility that KN62 could be having its effect by blocking the L-type Ca^{++} channels. These results show that activity can influence gene expression of neurotransmitter receptors, via a PKC and PKA independent pathway. (Support: MRC Canada)

GENE EXPRESSION OF THE NICOTINIC ACETYLCHOLINE RECEPTOR IN DIFFERENT AREAS OF THE HUMAN CORTEX. A. Wevers^{1*}, A. Jeske¹, Ch. Birtsch¹, S. Heinemann³, A. Maelicke², H. Schröder¹, ¹Inst. II für Anatomie, Univ. zu Köln, 50931 Köln, FRG, ²Inst. für Physiologische Chemie und Pathobiochemie, Univ. Mainz, 55128 Mainz, FRG, ³The Salk Institute, La Jolla, CA 92186, USA

In recent years the pharmacology of telencephalic nicotinic acetylcholine receptors (nAChRs) has become an important issue. To get some insights into the morphological basis of functional diversity we investigated the mRNA expression of different subunits of the pentameric nAChR in human brain on the cellular level.

In situ hybridization studies were carried out on autopsy samples of different cortex areas (A4, A10, and A17 according to Brodmann) from patients (n=7) with no history of neurological disease. Digoxigenin-labeled in vitro transcripts specific for the $\alpha 3$ - and $\alpha 4$ -1-subunit of the nAChR were applied and hybridization was visualized using an alkaline phosphatase conjugated digoxigenin antibody and NBT/BCIP.

We found a distinct gene expression of both nAChR subunits in neurons of different cortical areas. Whereas the $\alpha 4$ -1 mRNA expressing neurons were larger in number and distributed throughout lamina I-VI, the $\alpha 3$ ones were less abundant, especially in A17, and mainly localized in the deeper layers.

The observed differential mRNA distribution pattern of the investigated nAChR subtypes in the human cortex and the possibility to perform these studies in autopsy brains will be an important prerequisite for the evaluation of changes in nAChR expression under pathological conditions.

IDENTIFICATION OF PHOSPHOTYROSINE CONTAINING PROTEINS FROM *T. CALIFORNICA*. S. Balasubramanian, S.L. Swope* and R.L. Haganir. Dept. of Neuroscience, Howard Hughes Med. Inst., Johns Hopkins Univ. School of Med., Baltimore, MD, 21205.

Tyrosine phosphorylation has been implicated in regulation of the synthesis, distribution and gating properties of the nicotinic acetylcholine receptor (nAChR). To better understand these processes, we would like to identify proteins which are tyrosine phosphorylated at the postsynaptic membrane. The electric organ of *T. Californica* is an abundant source of nAChR and nAChR associated proteins. We have therefore purified phosphotyrosine containing proteins from the nAChR enriched membrane fraction of homogenized electric organ by immunoaffinity chromatography using antiphosphotyrosine antibodies. Polyclonal antibodies were then generated against these tyrosine phosphorylated proteins and used to screen a λ gt11 expression library made from electric organ cDNA. Both previously characterized and novel proteins have been identified by this approach. Future studies will examine the tissue distribution, subcellular localization and tyrosine phosphorylation of these proteins.

FREQUENT, LONG-LIVED SPONTANEOUS AND MONO-LIGANDED OPENINGS OF NICOTINIC ACETYLCHOLINE RECEPTORS WITH M2 MUTATIONS. W. Sigurdson and A. Auerbach*, Dept. Biophysics, SUNY, Buffalo, NY 14214.

An important functional property of muscle-cell acetylcholine receptors (AChR) is that they should remain closed in the absence of transmitter. It is well known that wt AChR open spontaneously, but such events occur at a very low frequency and have extremely brief lifetimes. When expressed in HEK293 cells and exposed to 100 nM ACh, the mutant mouse doubly-liganded AChR α L251C has an apparent single-channel lifetime (cell-attached patches, -80 mV, 5 kHz analysis bandwidth) of about 200 ms, ~20 times greater than that of the wt α β γ receptor. At 10 nM ACh, where mono-liganded openings predominate, the mutant open channel lifetime is about 2.7 ms, also about 20 times longer than the wt. Without ACh added to the pipette solution, the mutant AChR exhibit a high rate of spontaneous activity, opening at ~1.5 s⁻¹ (per patch) and having a mean open channel lifetime of ~0.5 ms. This opening rate is at least 100 times greater than that of the wt. Thus in the mutant AChR, the closing rates for vacant, mono-, and doubly-liganded receptors are slower, and the opening rate of vacant receptors is much greater than in the wt. These results suggest that in unliganded mutant receptors the energy barrier to gating is lowered, i.e. there is a destabilization of the gate. This conclusion is consistent with the notion that α 251 sidechains join with homologous residues in the M2 region of other subunits to form a structure that is the major barrier to ion permeation. The high rate of spontaneous activity is consistent with the apparent poor health of cells transfected with α L251C, as the expression of this M2 mutant would result in a steady flux of Ca²⁺ into the cell which could have cytotoxic effects. Thanks to M. Akabas and A. Karlin for generously providing the α L251C mutant, and to MDA and NIH for support.

MUTATIONS AT THE LIPID-PROTEIN INTERFACE OF THE ACETYLCHOLINE RECEPTOR AFFECT CHANNEL GATING. J.A. Lasalde, D. H. Butler, and M. G. McNamee*. Section of Molecular and Cellular Biology, Univ. of CA, Davis, CA 95616.

Previous site-directed mutagenesis studies demonstrated that the lipid-protein interface influences channel gating of the nicotinic acetylcholine receptor (nAChR). The α C418W mutant, located in the putative M4 transmembrane domain, showed a 3-fold increase in normalized macroscopic response to ACh in voltage clamped *Xenopus laevis* oocytes (Lee Y., et al., Biophys. J. 66:646-653, 1994). We have constructed mutations at the α G421 position and extended the patch clamp analysis to further characterize the role of M4 with respect to nAChR function.

At 4 μ M ACh, α G421W increased the open time constant 7-10 fold without affecting the normalized macroscopic current induced by 300 μ M ACh. Burst-oriented analysis showed a 5-fold increase in the open probability at 25 μ M ACh. Significant ACh-dependent channel block was observed. Reconstruction of macroscopic currents from an ensemble of α G421W bursts showed that the desensitization rate was 3-fold slower than wild type. In contrast, α G421A had a 2-3 fold higher desensitization rate than wild type, but the closing rate constant/opening rate constant (α/β) values were similar (86 and 75, respectively). α G421A demonstrated a 2-fold increase in the macroscopic response to ACh. The EC₅₀s of all the α G421 mutants did not differ significantly from wild type. The hybrid nAChR, α G421WA, was produced by the co-injection of α G421W and α G421A mRNA. This mutant had kinetic properties quite different than either of the pure mutants. The α/β of 184 was 2-fold higher than α G421A and 8-fold higher than α G421W. The open probability was reduced 10-fold with no change in macroscopic response as compared to α G421W. Equivalent mutations on the β -subunit, β G450F and β G450W, showed kinetic behavior similar to wild type.

466.27

CLONING OF A SECOND ALPHA ACETYLCHOLINE RECEPTOR SUBUNIT FROM CAENORHABDITIS ELEGANS. C.-M. Jen¹, P. Gamez², T. Valdez¹, T. Miranda¹, S. An¹, J. Lye², T. Barnes¹, and J. Lewis¹. ¹Division of Life Sciences, Univ. of Texas at San Antonio, San Antonio, TX 78249, ²Dept. of Genetics, Washington Univ. Medical School, St. Louis, MO 63110, and ³Dept. of Biology, McGill Univ., Montreal, PQ H3A 1B1

In a shotgun genomic sequencing effort to define the nature of *let-354*, one of us (J. Lye) found sequence fragments with high homology to nicotinic alpha acetylcholine receptor (AChR) subunits. The sequences were contained within cosmids capable of rescuing *unc-74* mutants. *unc-74* mutation is associated with loss of nicotinic acetylcholine receptor function in *C. elegans*. *unc-74* mutants are pharmacologically unresponsive to all nicotinic acetylcholine agonists effective on the wild type and are also severely deficient in binding of [³H]meta-aminolevamisole, a nicotinic agonist of nematode AChRs. A screen of a *C. elegans* cDNA library produced two positive clones at a frequency of 1 in 100,000. Sequencing of an almost full-length cDNA confirms that the cDNA encodes a nicotinic alpha subunit as shown by its high homology to the *unc-38* alpha subunit sequence of *C. elegans* and to the sequences of other known nicotinic AChR alpha subunits. Like *unc-38*, the new alpha subunit contains about 10 additional amino acids that are not found in alpha subunits of insects between the Cys loop region and the vicinal cysteines equivalent to Cys-192 - 193. RFLP mapping studies are underway utilizing transposon and γ -ray-induced mutants of *unc-74* to determine if the new alpha subunit is indeed encoded by *unc-74*. The possibility that the new alpha subunit is *unc-74* poses a mild paradox. Mutant studies show that both *unc-74* and *unc-38* are essential to produce a pharmacologically functional levamisole nicotinic AChR. If both are alpha subunits, it appears that the nematode levamisole AChR is an obligate heterodimer of alpha subunits.

MONOCLONAL ANTIBODIES PROBE STRUCTURAL TRANSITIONS OF THE ACETYLCHOLINE RECEPTOR. S. Tamamizu*, D. H. Butler, J. A. Lasalde, and M. G. McNamee. Section of Molecular and Cellular Biology, Univ. of CA, Davis, CA 95616.

We have investigated the interactions of monoclonal antibodies (mAb) with the *Torpedo californica* nicotinic acetylcholine receptor (nAChR). Using patch clamp analysis, anti-*Torpedo* monoclonal antibodies were tested to determine their effect on nAChR function. Additionally, the mAb-nAChR complexes were labeled with 3-(trifluoromethyl) 3-(m-[125I]iodophenyl diazirine) (TID) in the absence and presence of agonist. Agonist-induced desensitization of the nAChR reduces TID labeling and serves as a monitor of the resting-to-desensitized transition.

mAb 247 has previously been shown to selectively block one of the α -bungarotoxin (α -BTX) sites without altering the affinity of nAChR for acetylcholine (ACh) (Mihovilovic and Richman, J. Biol. Chem. 259: 15051-15059, 1984). Our patch clamp studies demonstrate that both mAb 247 and its respective Fab fragment completely inhibit channel opening. TID labeling determined that the mAb 247-nAChR complex undergoes the normal resting-to-desensitized transition. This supports the kinetic model which suggests that nAChR can transition from a resting state to a desensitized state without entering the active state.

mAb 387 has been previously shown to decrease α -BTX and ACh binding to nAChR (Mihovilovic and Richman, J. Biol. Chem. 262: 4978-4986, 1987). In the presence of mAb 387, we observe a 40% decrease in nAChR single-channel amplitude at -100 mV, whereas Fab 387 completely inhibits channel conductance. The labeling studies also suggest that the mAb 387-nAChR and Fab 387-nAChR complexes transition between resting and desensitized states. Interestingly, the labeling of the γ -subunit in the resting state is increased up to 2-fold in the presence of either mAb 387 or Fab 387.

Identification of Drosophila loci whose products show structural similarity to the vertebrate nicotinic acetylcholine receptor. B.A. Chase*, Dept. of Biology, Univ. of Nebraska-Omaha, 60th & Dodge Sts., Omaha, NE 68182.

The identification of multiple α - and β -like invertebrate nAChR subunits has suggested that there may be considerable heterogeneity in neuronal nAChRs. To identify potential Drosophila nAChRs or other molecules sharing structural similarity to the vertebrate nAChR, mAb probes to the vertebrate nAChR were previously used to identify cross-reacting antigens in Drosophila (Chase et al., (1987), Neurosci. 21, 959-976). One mAb specifically cross-reacted with neuropil having cholinergic function.

To isolate the genes that encode the antigen(s) recognized by this mAb (27.1A.16.42), a lambda-ZAP expression vector library has been screened and three cDNAs isolated. Southern analysis has indicated that these three cDNAs are unrelated. *In situ* hybridization to adult tissue sections has shown that the loci identified are expressed in a pattern consistent with the mAb's cross-reactivity in neuropil. Each cDNA probe detects transcripts in CNS cell bodies but not neuropil, consistent with these loci being transcribed in the cell bodies and their protein products being transported into axonal and synaptic regions. To infer the nature of the products of these loci, DNA sequence analysis has been initiated. Current data indicate that the cDNAs have little homology to known Drosophila nAChR genes. Chromosomal *in situ* hybridization has also indicated that these cDNAs do not derive from loci encoding known Drosophila nAChRs.

Thus, the cDNAs identified using mAb 27.1A.16.42 derive from loci that appear to be expressed in a pattern consistent with this mAb's cross-reactivity, but do not encode known nAChR subunits. As this mAb recognizes structural features of the β -subunit of the vertebrate nAChR that are presumably shared by the cross-reacting Drosophila antigens, the loci identified here may encode novel β -like subunits of a nAChR, or other proteins, perhaps members of the superfamily of structurally related neurotransmitter receptors including nACh, GABA-A and glycine receptors.

REGULATION OF ADULT-TYPE NICOTINIC ACETYLCHOLINE RECEPTOR GENE EXPRESSION BY PROTEIN TYROSINE PHOSPHATASES. M.K. Sapru* and D. Goldman. Dept. of Biol. Chem., Mental Health Res. Inst., Univ. of Michigan, Ann Arbor, MI 48105.

Molecular mechanism(s) regulating the postnatal switch of mammalian nicotinic acetylcholine receptors (nAChR) from embryonic type (α β γ δ) to adult-type (α β ϵ δ) at the neuromuscular junction is not well understood. Previously, we observed that calcium ionophore A23187 preferentially down-regulates ϵ -subunit gene expression (Walke et al., submitted) in rat primary myotubes. Here we report that sodium orthovanadate, a specific protein tyrosine phosphatase inhibitor, induces ϵ -subunit gene expression in rat primary myotubes. RNase protection assays and gene transfer experiments further revealed that orthovanadate blocks A23187-induced down-regulation of ϵ -subunit gene expression. In addition, gene transfer experiments showed that overexpressing protein tyrosine phosphatases in primary myotubes selectively suppresses expression from nAChR α , δ and ϵ -subunit gene promoters without affecting the embryonic-type specific γ -subunit gene promoter. Together, these results suggest that protein tyrosine phosphatases regulate mammalian adult-type nAChR gene expression and may mediate the local expression of these genes beneath the neuromuscular junction.

Transcription of neuronal nicotinic acetylcholine receptor subunit genes in thymic epithelial and thymic lymphoid cells. Mirta Mihovilovic*, Yun Mai¹, Stephen Denning², Sonia Berrih-Aknin³ and Allen D. Roses¹. ¹Division of Neurology, Duke University, Durham, NC 27710. ²Division of Cardiology, Duke University. ³Departement de Recherche Medicale, Hôpital Marie Lannelongue, Paris, France.

Normal thymus, hypertrophic thymus from Myasthenia gravis (MG) patients and thymomas from MG and non-MG patients express transcripts encoding the α -3, α -5 and β -4 subunits of nicotinic neuronal acetylcholine receptors (nAChRs). This pattern of transcriptional expression suggests that neuronal nAChRs similar to those expressed in ganglia are expressed in the thymus and that these receptors may be of importance in transducing signals delivered to the thymus through the autonomic nervous system.

To investigate the transcription of neuronal nicotinic nAChR subunit genes in thymus we have employed purified thymocyte preparations, primary cultures of epithelial cells and short term cultures of thymocytes. Our results indicate that thymocytes express transcripts at levels comparable to those of the thymic tissue as a whole, while epithelial cells expressed much lower transcript levels. Expression of these transcripts in primary cultures of thymic epithelial cells appears to be dependent on the presence of epidermal growth factor and occurs in cultures that have also shown binding of monoclonal antibodies that recognize neurofilaments. Taken together, these data reflect the neuroendocrine nature of thymic epithelia. In addition, establishment of thymocytes in culture appears to lead to lower levels of transcription for the α -3 nAChR subunit genes, indicating that the thymic endocrine/paracrine microenvironment is necessary to sustain this transcription in the thymic lymphoid cells.

CHARACTERIZATION OF TWO TIGHTLY LINKED DIVERGENT PROMOTERS AND A SILENCER ELEMENT LOCATED BETWEEN THE RAT β 4 AND α 3 NICOTINIC ACETYLCHOLINE RECEPTOR GENES. B.T. Boyd*. Department of Pharmacology and The Neuroscience Program, The Ohio State University College of Medicine, Columbus, Ohio, 43210.

In order to understand the transcriptional regulation of neuronal nicotinic acetylcholine receptors by cell contact and electrical activity, it will be first necessary to identify DNA elements that control the expression of members of this family and to identify factors required for the expression of these genes. Toward this goal we have identified two promoter regions in the β 4- α 3 intergenic region. One region is close to the β 4 gene downstream of exon 6 and has strong promoter activity in both orientations; the other is close to the start of the α 3 gene coding region. The analysis of the sense and antisense promoter constructs indicated the bidirectional promoter activity demonstrated within the β 4 gene is due to two very closely linked promoters that may share common elements. The functional role for the antisense promoter is not clear. The regulated production of antisense RNA could be involved in the regulation of the β 4 gene at the transcriptional or translational levels. Opposite strand RNAs could also affect the expression of the α 3 gene from the upstream promoter. A region with putative silencer activity was also found near the upstream promoters. DNA-binding protein interactions within this element have been studied. The level of a protein in PC12 cells that binds to an A-T rich region in the silencer was shown to be regulated by NGF. This work supported by AHA (Ohio Affiliate), Bremer Foundation (Columbus, Ohio), and NIH Grant NS29746.

EFFECT OF METHYLLYCAONITINE AND RELATED ALKALOIDS, IN VITRO AND IN VIVO, AT THE α -BUNGAROTOXIN BINDING SITE IN RODENT BRAIN. Y.D. Rollins*, M. Hall¹, K.L. Heman¹, P. Dobelis², J.P. Walrond², G.M. Rose¹, and S. Leonard¹. ¹Dept. of Pharmacology, UCHSC, and Medical Research, VAMC, Denver, Colorado 80262. ²Department of Anatomy & Neurobiology, Colorado State Univ., Fort Collins, CO.

Schizophrenia is partially characterized by an auditory gating deficit, an abnormal electrophysiological response to repeated auditory stimuli. It has recently been shown this gating deficit can be transiently reversed by nicotine. Additionally, a gating deficit can be produced in rats by the use of pharmacological agents which block a subset of the neuronal nicotinic receptors, the α -bungarotoxin binding receptor, α 7. Both α -bungarotoxin and methyllycaonitine (MLA), delivered intracerebroventricularly, induce a loss of gating of auditory evoked responses as measured by evoked potential recording in the unanesthetized animal implanted with surface and depth (CA1) electrodes. We have compared the efficacy of related nortriterpenoid alkaloids, isolated from the seed of *Delphinium brownii* by the Poisonous Plant Research Lab, Logan, UT, to compete with α -bungarotoxin binding in rat brain membranes and find one of these compounds, 14-deacetylnudicoline (14-DN), has a higher affinity for the α 7 receptor than does either α -bungarotoxin or MLA. In whole brain homogenate, 14-DN competes [¹²⁵I]- α -bungarotoxin with a K_i = 50×10^{-12} M while MLA competes with a K_i an order of magnitude higher. Another related compound, deltaine competes with a K_i = 0.6×10^{-6} M. This affinity order 14-DN > MLA > deltaine found in brain membranes is similar to the potency order of these compounds in blocking transmission at the neuromuscular junction in an *in vitro* lizard muscle preparation. These compounds will also be tested for their potency in blocking auditory gating.

UPSTREAM SEQUENCES REQUIRED FOR CONTROL OF *ard* EXPRESSION IN *DROSOPHILA*. L.C. Yang, Y. He, and T. Schmidt-Glenewinkel*. Department of Biological Sciences, Hunter College of CUNY, New York, NY 10021.

The *ard* genes encode a non- α -like subunit of one of the neuronal nicotinic acetylcholine receptors from *Drosophila*. We are interested in studying the cis-acting elements and trans-acting factors required for temporal and spatial expression of the genes encoding the acetylcholine receptor subunits. 5'-flanking sequences and intron sequences were cloned into the P-element containing vectors HZ50PL and CZ20XN generating either "enhancer fusion" or "transcriptional fusion" lacZ genes respectively. P-element-mediated germ-line transformation and establishment of balanced transformed stock was carried out by standard procedure. Frozen sections of whole flies or of heads were briefly fixed and examined for expression of lacZ fusion genes using either X-gal or an antibody against β -galactosidase. "Enhancer fusion" using about 4kb of 5'-upstream sequence show spatially correct expression in *Drosophila* heads while addition of 3kb of upstream sequence showed no expression. Spatially correct expression of "transcriptional fusion" constructs required additional downstream sequences. Constructs using a series of 5'- and 3'- deletions as well as internal fragments allowed us to define several upstream elements required for *ard* expression in *Drosophila*.

466.32

CLONING AND CHARACTERIZATION OF THE HIPPOCAMPAL α 7 NEURONAL NICOTINIC ACETYLCHOLINE RECEPTOR FROM HUMAN POSTMORTEM BRAIN. J. Logel, C. Drebing, C. Antle, C. Breese, M. Hall, C. Adams, Y. Rollins, B. Sullivan, R. Freedman and S. Leonard. VA Medical Center and University of Colorado Health Sciences Center, Denver, CO 80262.

The full length sequence of the human α 7 neuronal nicotinic receptor subunit was obtained from human hippocampus. A partial clone was obtained by screening a human hippocampal library. The amino terminus region of the cDNA was obtained with a 5' RACE clone generated from hippocampal RNA. Hippocampal α 7 appears nearly identical to that cloned from the neuroblastoma cell line SH-SY5Y (X. Peng *et al.*, 1994). Sequence obtained from PCR of cDNA suggests multiple poly-adenylation sites. Northern analysis of human cingulate and hippocampal mRNA showed variation in size compared to message in the neuroblastoma cell line and rat brain. Chemical cross-linking of α -bungarotoxin to membrane preparations of human and monkey hippocampus and whole rat brain revealed two principle protein species, only one of which was competed with nicotine and methyllycaonitine. *In situ* hybridization with a probe for the cytoplasmic loop of α 7 showed labeling of a small population of cells in the dentate hilus, consistent with the localization of α -bungarotoxin binding in control and schizophrenic brain tissue. Control and schizophrenic post-mortem brain was screened for polymorphisms by RFLP analysis and PCR.

STUDIES OF NICOTINIC ACETYLCHOLINE RECEPTOR SUBUNIT COMPOSITION IN THE SH-SY5Y HUMAN NEUROBLASTOMA. Renaldo C. Drisdell, Elzbieta Puchacz and Ronald J. Lukas*. Div. Neurobiol., Barrow Neurol. Inst., Phoenix AZ 85013.

At least five human nAChR subunit genes (α 3, α 5, α 7, β 2 and β 4) and two types of nAChR are expressed by cells of the SH-SY5Y human neuroblastoma. One class of nAChR corresponds to nicotinic α -bungarotoxin (Bgt) binding sites (nBgtS), which bind [¹²⁵I]-labeled Bgt (I-Bgt) with high affinity and appear to contain human α 7 subunits based on sense and antisense α 7 construct transfection studies. SH-SY5Y cells also express ganglia-type nAChR, which bind [³H]acetylcholine with high affinity, mediate Bgt-insensitive but neosurugatoxin-sensitive monovalent cation and ⁴⁵Ca⁺⁺ fluxes, and seem to contain human α 3 and β 4 subunits based on functional pharmacological profiles. To address questions remaining regarding the full subunit composition of ganglionic nBgtS and nAChR, we have undertaken a series of affinity purification and immunochemical studies of the nAChR subtypes in SH-SY5Y cells. Antibodies raised against unique peptide sequences of nAChR subunit cytoplasmic domains exhibit subunit specificity and interact with SH-SY5Y cell membrane proteins on Western blots. Bgt-based affinity purification yields material that specifically binds I-Bgt with high affinity and is recognized by anti- α 7 peptide-specific antibodies, consistent with the presence of α 7 subunits in nBgtS.

MAPPING NEURONAL BUNGAROTOXIN SENSITIVITY ON NEURONAL NICOTINIC RECEPTOR ALPHA SUBUNITS. C.W. Luetje*, F. Maddox and S.C. Harvey. Molecular and Cellular Pharmacology, University of Miami, Miami FL 33101.

Neuronal nicotinic acetylcholine receptors (nAChRs) can be expressed in *Xenopus* oocytes upon injection of cRNAs encoding various combinations of α and β subunits. The $\alpha 3\beta 2$ subunit combination is sensitive to neuronal bungarotoxin (NBT) blockade ($98.0 \pm 1.9\%$ block by 100nM NBT) while $\alpha 2\beta 2$ is insensitive to NBT. Previous work has shown that determinants of NBT sensitivity on $\alpha 3$ are localized to three distinct sequence segments (84-121, 121-181, 195-215), and that gln198 of $\alpha 3$ (pro in $\alpha 2$) plays a role in determining NBT sensitivity. We have made a series of mutations within these regions of $\alpha 3$, changing residues from what occurs in $\alpha 3$ to what occurs in $\alpha 2$. We assay the NBT sensitivity of mutant $\alpha 3$ subunits in combination with $\beta 2$ upon expression in *Xenopus* oocytes. Changing thr143 of $\alpha 3$, to lys as in $\alpha 2$ (T143K), results in a loss of NBT sensitivity ($7.7 \pm 4.6\%$ block by 100nM NBT). Changing amino acid residues 159-166 of $\alpha 3$ as a group (VLIGSSMN) to what occurs in $\alpha 2$ (EQMERTVD) has a modest effect on NBT sensitivity (80% block by 100nM NBT). Amino acid changes in $\alpha 3$ that had no effect on NBT sensitivity include K87I, Q101A, L109H, K111F, K129S and Y139Q. We have also made a mutant of the $\alpha 4$ subunit which forms receptors (with $\beta 2$) partially sensitive to NBT ($15.9 \pm 1.4\%$ block by 1 μ M NBT) and has a proline at position 198, as does $\alpha 2$. Changing pro198 of $\alpha 4$, to gln as in $\alpha 3$, increases NBT sensitivity ($87.4 \pm 6.8\%$ block by 1 μ M NBT). These results show thr143 to be a major determinant of NBT sensitivity and provide additional evidence for a role of gln/pro198 in determining NBT sensitivity.

466.37

MAPPING AMINO ACIDS RESPONSIBLE FOR THE PHARMACOLOGICAL DIFFERENCES OBSERVED BETWEEN $\alpha 7$ AND $\alpha 8$ HOMOMERS.

Rene Anand*, Volodymyr Gerzanich, and Jon Lindstrom. Dept. of Neuroscience, Univ. of Pennsylvania, Philadelphia PA 19104-6074

Homomers of $\alpha 7$ and $\alpha 8$ subunits of chick α Bgt-sensitive neuronal AChRs expressed from cRNAs in *Xenopus* oocytes exhibit similar channel properties but contrasting pharmacological properties (Gerzanich et al., Mol. Pharmacol. 45: 212-220, 1994). $\alpha 8$ homomers are more sensitive to agonists than $\alpha 7$ homomers (e.g. EC₅₀ (μ M): ACh 2 vs 112; nicotine 1 vs 7; cytosine 1 vs 18; tetramethylammonium 10 vs 800).

To delineate the amino acid residues responsible for these pharmacological differences, we have constructed $\alpha 7$ and $\alpha 8$ subunit chimeras as well as point mutants. A chimera ($\alpha 7(208)/\alpha 8$) consisting of the putative extracellular domain of the $\alpha 7$ subunit (residues 1-208) and the rest of the residues of the $\alpha 8$ subunit, when expressed in oocytes, forms homomers whose pharmacological properties are indistinguishable from those of $\alpha 7$ homomers. A second chimera ($\alpha 7(115)/\alpha 8$) forms homomers whose properties are indistinguishable from those of $\alpha 8$ homomers. A third chimera ($\alpha 7(179)/\alpha 8$) forms homomers whose affinity for ACh is slightly higher (EC₅₀ ~30 μ M) than that of $\alpha 7$ homomers but distinctly different from that of $\alpha 8$ homomers.

Mutating the $\alpha 7$ subunit residue F187 to the $\alpha 8$ subunit residue Y187 does not alter the pharmacology of the $\alpha 7$ mutant homomers. Thus it appears that the remaining five residues that are different between these two subunits within $\alpha 179-208$ contribute significantly to the pharmacological differences between $\alpha 7$ and $\alpha 8$ homomers. Further mutagenesis is in progress to verify this prediction.

ACETYLCHOLINE RECEPTORS: NICOTINIC PHARMACOLOGY

467.1

SYNTHESIS AND RECEPTOR BINDING OF NOVEL CHOLINERGIC CHANNEL LIGANDS AS POTENTIAL COGNITION ENHANCERS. Nan-Hong Lin,

Yun He, David J. Anderson, Dave S. Garvey*, James T. Wasicak, James P. Sullivan, Stephen P. Arneric, Neuroscience Research, D-47W, Pharmaceutical Products Division, Abbott Laboratories, Abbott Park, IL 60064-3500.

Alzheimer's disease (AD) is a progressive neurodegenerative disorder characterized by a global deterioration of cognitive function. (-)-Nicotine has reported beneficial effects in AD to improve cognitive performance. Preclinical testing (Arneric et al.; Decker et al., J. Pharmacol. Exp. Therap. in press, 1994.; Garvey et al. J. Med. Chem., in press, 1994.) has recently demonstrated that ABT-418, 1, [3-methyl-5-(1-methyl-2-(S)-pyrrolidinyl)-isoxazole] is a cognition enhancer that has fewer in vivo liabilities than (-)-nicotine. Like (-)-nicotine, however, ABT-418 possesses poor oral bioavailability. In order to assess what structural changes in ABT-418 are consistent with high affinity binding, an extensive SAR has been conducted on 1. The compounds prepared were found to have binding affinity ranging from 22 -6,000 nM (displacement of [³H](-)-cytosine from whole rat brain synaptic membrane). The SAR results indicated that a bulky alkyl group or functionality at C4' or C5' position are not well tolerated for the potent binding affinity. We report here the synthesis and receptor binding of a series of pyrrolidine modified isoxazole analogs.

466.36

MAPPING THE NEURONAL NICOTINIC RECEPTOR BETA SUBUNIT CONTRIBUTION TO BLOCKADE BY THE COMPETITIVE ANTAGONISTS DIHYDRO- β -ERYTHROIDINE AND NEURONAL BUNGAROTOXIN S.C. Harvey* and C. W. Luetje. Department of Molecular and Cellular Pharmacology, University of Miami, Miami, FL. 33101

Neuronal nicotinic acetylcholine receptors (nAChR) can be formed in *Xenopus* oocytes by injecting various combinations of cRNA encoding two classes of homologous subunits, α and β . Each subunit combination has distinct pharmacological properties, with both α and β subunits contributing to ligand sensitivity. We constructed β subunit chimeras to map determinants of sensitivity to two structurally distinct competitive antagonists, dihydro- β -erythroidine (DH β E) and neuronal bungarotoxin (NBT). Receptors formed by $\alpha 3$ and $\beta 2$ are sensitive to block by 100 nM NBT ($97 \pm 2.2\%$ block), while $\alpha 3\beta 4$ is insensitive. At ACh concentrations approximating the EC₂₀, $\alpha 3\beta 2$ is 50 fold more sensitive to DH β E (IC₅₀=400 nM) than $\alpha 3\beta 4$ (IC₅₀=20 μ M). 3 μ M DH β E effectively blocks $\alpha 3\beta 2$ ($90 \pm 4.6\%$ block) but has little effect on $\alpha 3\beta 4$ ($13.1 \pm 5.1\%$ block). Substituting the first 135 N-terminal amino acid residues of $\beta 4$ into $\beta 2$, results in a subunit which forms receptors with $\beta 4$ -like ligand sensitivity, i.e. insensitive to both 100 nM NBT and 3 μ M DH β E. Substituting the first 105 N-terminal residues had similar results. Substituting in the first 58 residues of $\beta 4$ resulted in intermediate sensitivity to NBT and DH β E ($80 \pm 1.7\%$ block by 100 nM NBT; $71 \pm 6.6\%$ block by 3 μ M DH β E). These results demonstrate that at least two distinct sections of the β subunit (1-58 and 58-105) are involved in determining receptor sensitivity to competitive antagonism.

467.2

INTERACTION OF DMXBA (GTS-21), A COGNITION-ENHANCING COMPOUND, WITH CHOLINERGIC RECEPTORS. W. R. Kem*, Vladimir M. Mahnir, and B. Lin. Dept. of Pharmacology and Therapeutics, Univ. of Florida Coll. of Med., Gainesville, FL 32610.

DMXB-Anabaseine has recently been found to enhance learning in aging rabbits (Woodruff-Pak, Li, and Kem, 1994) and rats, as well as in nucleus basalis-lesioned rats (Meyer et al., 1994). Experiments with nicotinic receptor subtypes expressed in *Xenopus* oocytes have shown that the compound acts as a very weak partial agonist upon the $\alpha 4$ - $\beta 2$ combination, but as a strong partial agonist upon homo-oligomeric $\alpha 7$ channels (Papke et al., 1993). It enhances LTP in the hippocampal slice (Hunter et al., 1994). We have indirectly investigated the interaction of DMXBA with several naturally expressed nicotinic receptors by measuring displacement of nicotinic radioligand binding to brain synaptosomes, modulation of PC12 rubidium efflux, and alteration of muscle contractility. DMXBA displaced 1 nM [³H]CYTisine specific binding to rat brain synaptosomes with an IC₅₀ of about 200 nM. Scatchard analyses of CYT binding in the presence of increasing concentrations of DMXBA showed a progressive decrease in B_{max} as well as K_d. It apparently binds to another site in addition to the ACh recognition site. Inhibition of synaptosomal α -bungarotoxin binding was primarily by alteration of binding affinity. DMXBA also displaced [³H]QNB binding to muscarinic receptors, but with an IC₅₀ about 100X higher than for displacement of CYT and BTX binding. DMXBA only inhibited nicotine-stimulated rubidium efflux from PC12 cells. Although the compound lacked nicotinic agonist action upon skeletal muscle, it did act as an antagonist at very high concentrations (>1 μ M). Further studies of the actions of this compound upon different nicotinic receptor subtypes are in progress. (Supported by Taiho Pharmaceutical Co., Ltd.)

467.3

EFFECTS OF NICOTINIC ACETYLCHOLINE RECEPTOR LIGANDS ON BEHAVIORAL VIGILANCE IN RATS. S. Ruland*, J. Turchi, L.A. Holley and M. Sarter. Dept. Psychology and Neuroscience Program, Ohio State Univ., Columbus, OH 43210.

The effects of nicotinic receptor ligands on performance in a task measuring sustained attention, or vigilance, were tested. This task required the animals to discriminate between signal and non-signal events. The sequence of signal (central panel light illumination for 500, 50 or 25 msec) and non-signal presentations was randomized over 3 blocks of 54 trials each (27 signal trials, 9 per length, and 27 non-signal trials). A left lever press following a signal was counted as a hit, and a right lever press following a non-signal event was counted as a correct rejection. Hits and correct rejections were rewarded, whereas misses and false alarms (defined as incorrect right and left lever presses, respectively) were not. Baseline performance was characterized by a signal length dependent ability of the animals to discriminate between signal and non-signal events. Administration of nicotine (0.19, 0.62, 1.9 μ mol) did not produce main effects on vigilance performance. The putative nicotinic receptor agonist lobeline (1.9, 6.2, 19 μ mol) impaired the animals' ability to discriminate between signal and non-signal events. The antagonist mecamylamine (5, 15, 50 μ mol) potentially impaired vigilance performance. While the detrimental effects of lobeline may have been related to the effects of direct cholinergic stimulation in intact animals, the reasons for the differences between the effects of nicotine and lobeline remain unsettled.

467.5

COMPARATIVE PHARMACOLOGY OF EPIBATIDINE, A POTENT SELECTIVE AGONIST FOR NEURONAL ACHRs. V. Gerzanich, X. Peng, R. Anand, F. Wang, S. Fletcher*, J. Lindstrom*. Dept. of Neuroscience, Univ. of Pennsylvania, PA 19104-6074, #Merck Sharp & Dohme Research Laboratories, Essex CM202QR, England.

Pharmacological properties of the (+)- and (-)-isomers of the synthetic analgesic epibatidine(EB), originally isolated from the skin of the frog *Epipedobates tricolor*, were tested on different chicken and human nicotinic AChRs.

In competition binding assays EB was used on immunoaffinity isolated chicken brain($\alpha 4\beta 2$, $\alpha 7$) and human neuronal nicotinic ($\alpha 3$ and $\alpha 7$)AChRs(from the SHSY-5Y cell line). Both EB isomers exhibited extremely high affinity for all neuronal AChRs tested, with IC₅₀ values ranging from 1fM(human $\alpha 3$ AChRs) to 1pM(chicken $\alpha 7$ AChRs). By contrast, no EB binding was observed on human muscle type AChRs from the cell line TE671.

EB behaved as an extremely potent full agonist on chicken ($\alpha 3\beta 2$, $\alpha 3\beta 4$, $\alpha 4\beta 2$, $\alpha 7$, and $\alpha 8$) and human ($\alpha 3\beta 2$) neuronal AChRs expressed in *Xenopus* oocytes. Currents induced by EB were effectively blocked by the nicotinic antagonists hexamethonium and mecamylamine. Apparent affinity was 100 to 1000 times higher for EB as compared to nicotine or ACh. EC₅₀ values ranged from 1nM(for homomeric chicken $\alpha 8$) to 2 μ M (for homomeric chicken $\alpha 7$). EB did not activate or block expressed *Torpedo* muscle type AChRs at concentrations up to 1mM. Currents induced by EB in oocytes expressing chicken $\alpha 4\beta 2$ and $\alpha 3\beta 2$ showed significantly slower desensitization and inactivation kinetics than did currents induced by ACh and nicotine.

467.7

FURTHER STUDIES ON THE ROLE OF CENTRAL NICOTINIC RECEPTORS IN THE ANALGETIC EFFECTS OF EPIBATIDINE.

B. Badio*, H.M. Garraffo, Dan Shi, and J.W. Daly* Laboratory of Bioorganic Chemistry, NIDDK/NIH, Bethesda, MD 20892.

Epibatidine is a potent analgesic agent, whose site of action appears to involve central nicotinic receptors. However, epibatidines elicit analgesia even in a mouse strain in which nicotine has no analgesic activity. In mice rendered tolerant to the behavioral effects of nicotine by chronic nicotine or chronic caffeine, the analgesic effects of epibatidine are reduced. Epibatidines are about 20-fold more potent than (-)-nicotine at rat brain nicotinic receptors, about 200-fold more potent at ganglionic-type receptors and about 100-fold more potent at muscle-type receptors. Responses to epibatidine are blocked like those of nicotine by both competitive and noncompetitive nicotinic antagonists. Epibatidine, like nicotine, causes desensitization of nicotinic receptors. Unlike nicotine, there is little enantioselectivity in the responses of epibatidine, either *in vivo*, in binding and functional assays with brain preparations, or in cultured cells expressing ganglionic or muscle-type nicotinic receptors. Furthermore, unlike the case for nicotine/nornicotine the presence or absence of an N-methyl group has little effect on activity of epibatidines. Molecular modeling provides a rationale for the enantioselectivity and effects of N-methylation in the nicotines and the lack of such effects in the epibatidines.

EPIBATIDINE: A PROMISING LIGAND FOR NEURONAL NICOTINIC RECEPTORS R.H.Loring*, T.McHugh, X.Zhang and J.McKay. Dept. Pharm. Sci., Northeastern U., Boston, MA 02115.

Epibatidine (EB) is reported to be a potent nicotinic analgesic (Qian et al., 1993, *Eur.J.Pharm.* 250:R14). EB agonist effects were investigated by electrophysiological recordings from perfused chick retina, and by radioligand assays for various nicotinic receptor subtypes, using anatoxin and nicotine for comparison. A 2 sec application of EB (10 μ M) caused a curare-sensitive depolarization, but subsequent depolarizations due to the nicotinic agonist dimethylphenylpiperazinium (DMPP, 300 μ M, 2 sec) were blocked by > 70%. Depolarizations due to glutamatergic agonists kainate or NMDA were not affected by EB. 10 μ M nicotine (20 min) is the minimum dose to completely desensitize DMPP responses in retina when applied continuously, but DMPP responses recover 50% from nicotine blockade within \approx 20 min. In contrast, 100 nM EB (20 min) completely blocks DMPP responses, and requires \geq 1 h for 50% recovery. Preliminary data suggest that d-tubocurarine (300 μ M) prevents long-term desensitization by EB. EB displaces ³H-cytisine binding to $\alpha 4\beta 2$ receptors (K_i=3 nM) and ¹²⁵I- α -bungarotoxin binding to $\alpha 7$ -containing receptors (K_i=22 nM) immunoprecipitated from chick brain. The corresponding K_i's for nicotine or anatoxin were 20 nM or 8 nM for ³H-cytisine and 140 nM or 22 nM for ¹²⁵I- α -bungarotoxin, respectively. In addition, EB blocked ¹²⁵I- α -bungarotoxin binding to membranes containing *Torpedo* $\alpha 1$ receptors with an IC₅₀ of 100 nM. These data suggest that EB is a strongly desensitizing nicotinic agonist that may be a useful ligand for several receptor subtypes. Supported by NIH NS22472.

FURTHER CHARACTERIZATION OF THE IN VIVO EFFECTS OF (+)EPIBATIDINE, A POTENT NICOTINIC LIGAND. A.W. Bannon, K.L. Gunther, and M.W. Decker*. Neuroscience Research, Department 47W, Pharmaceutical Discovery, Abbott Park, IL 60064-3500.

Epibatidine has been reported to be a potent nicotinic ligand that can produce analgesia (Qian et al., *Eur. J. Pharmacol.*, 250, 1993; Badio and Daly, *Mol. Pharmacol.*, in press). This study further characterized epibatidine-induced analgesia, and examined additional *in vivo* effects of epibatidine. Consistent with earlier reports, (+)epibatidine (0.1 μ mol/kg; i.p.) had antinociceptive activity in mice (n = 8/group), producing an increase in jump latency in the hot-plate paradigm. The analgesic effect of epibatidine was evident at 60 min post-injection (p < 0.05) but not at 120 min (p > 0.05). Although mecamylamine (1.5, 5, and 15 μ mol/kg; i.p.) pretreatment attenuated epibatidine-induced analgesia, mecamylamine (15 μ mol/kg) administered after epibatidine did not attenuate the analgesic response. At the analgesic dose of epibatidine (0.1 μ mol/kg) utilized in this study, significant reductions in activity and body temperature were observed. Since these effects (e.g., motor effects) possibly contributed to the apparent analgesic effect of epibatidine, additional studies were conducted with mice pretreated (i.e., 5 days prior to analgesia testing) with the nicotinic antagonist chlorisondamine (23 μ mol/kg; i.p.). In mice pretreated with chlorisondamine, the analgesic effect of epibatidine was attenuated, but there were virtually no effects on the epibatidine-induced decreases in activity or temperature. These data suggest that epibatidine produces analgesia by a central (or spinal) mechanism that can be differentiated, in part, from effects on temperature and activity.

ENANTIOMERS OF EPIBATIDINE AS POTENT NICOTINIC AGONISTS AT TWO IDENTIFIED SUBTYPES OF NICOTINIC ACETYLCHOLINE RECEPTORS (nAChRs) IN RAT HIPPOCAMPAL NEURONS. M. Alkondon^{1,*} and E.X. Albuquerque^{1,2}. ¹Dept. Pharmacol. Exp. Ther., Univ. Maryland, Sch. Medicine, Baltimore, MD 21201; ² Lab. Mol. Pharmacol. II, IBCCF, Fed. Univ. Rio de Janeiro, RJ, Brazil, 21944.

Epibatidine, a novel azabicycloheptane alkaloid isolated from the Ecuadorean frog *Epipedobates tricolor*, is a potent analgesic in mice (Spande et al., *J. Am. Chem. Soc.* 114: 3475, 1992). Synthetic enantiomers of epibatidine, which also have analgesic activity, bind with high affinity to the [³H]nicotine-binding site in rat brain membranes and are potent nicotinic agonists in PC12 cells (Badio and Daly, *Mol. Pharmacol.* 1994, in press). We have recently demonstrated that nicotinic agonists can activate at least three subtypes of nAChRs in rat hippocampal neurons (Alkondon and Albuquerque, *JPET* 265: 1455, 1993). Here, we investigated the agonist effects of enantiomers of epibatidine on two subtypes of hippocampal nAChRs using whole-cell patch-clamp technique and a U-tube agonist application system. Type IA, the α -BGT-sensitive current subserved by an $\alpha 7$ -based nAChR, was activated by epibatidine with an apparent EC₅₀ of 2 μ M and 4 μ M for the (-) and (+) enantiomers, respectively. Type II, the dihydro- β -erythroidine-sensitive current subserved by an $\alpha 4\beta 2$ nAChR, was activated by epibatidine in the low nanomolar range (apparent EC₅₀ between 2 and 10 nM), the natural (+) enantiomer being more potent than the (-) form. The results indicate that epibatidine enantiomers can distinguish between the subtypes of nAChRs present in the hippocampal neurons as i) they are about 1000-fold more potent in evoking the type II current than in eliciting the type IA current; and ii) the rank order of potency of the enantiomers of epibatidine was reversed for the two types of currents. The concentration of epibatidine necessary to activate type II current is compatible with the doses that evoke an analgesic effect in mice, and suggests the involvement of the $\alpha 4\beta 2$ nAChR subtype in such effect. ADENOSINE RECEPTOR LIGANDS AS ANTAGONISTS FOR ANATOXIN-A. Peter K. Chiang*, Dennis L. Butler, and Richard K. Gordon. Dept. of Applied Biochemistry, Walter Reed Army Institute of Research, Washington, DC 20307-5100.

(+)-Anatoxin-a (ANTX) stimulates guinea pig ileum contraction with a potency similar to acetylcholine (ACh), and this is due to the induced release of ACh from the ileum. The postulated target of ANTX is the nicotinic receptor on ganglionic interneurons of ileum, as evidenced by the inhibition of ANTX-induced contraction by muscarinic or nicotinic antagonists. When tested on the ANTX-stimulated guinea pig ileum, it was found that adenosine receptor agonists, *N*-cyclohexyl adenosine (CHA), 5'-*N*-ethylcarboxamido-adenosine (NECA), and *N*-*R*-phenylisopropyl-adenosine (PIA), all blocked the contraction with CHA being the most potent. These findings suggest that the ganglionic nicotinic receptors are under complex regulation, with possible modulation either directly or indirectly with A₁ subtype adenosine receptors.

INCREASE IN NEURONAL NICOTINIC RECEPTOR BINDING SITES FOLLOWING CHRONIC CYTISINE TREATMENT. R.D. Mellon*, R.A. Houghtling, and K.J. Kellar. Department of Pharmacology, Georgetown University, School of Medicine, Washington, D.C. 20007.

Neuronal nicotinic acetylcholine receptor (nAChR) binding sites increase following chronic administration of nicotine. Cytisine has previously been reported to increase nicotinic binding sites labeled by [³H]acetylcholine in rat frontal cortex. To investigate this further, we measured nAChR binding sites in several brain areas following chronic administration of cytisine.

Male Sprague-Dawley rats received either 1.5 mg/kg cytisine, 2 mg/kg nicotine tartrate, or saline vehicle s.c. twice daily for ten days. Following decapitation, cerebral cortex, hippocampus, striatum, thalamus, and hypothalamus were dissected and nicotinic receptor binding sites were measured by [³H]cytisine binding assays. Both chronic cytisine and nicotine treatment led to increased numbers of binding sites compared to saline treatment in cerebral cortex, striatum, and hypothalamus (*p* < 0.01). Although similar trends were observed for the hippocampus and thalamus, statistically significant increases in these brain areas were not reached in these studies. Further, no difference in [³H]cytisine binding between the nicotine and cytisine treatment was found in any brain area examined.

Recent studies in transfected oocytes found that cytisine is much less effective than acetylcholine at eliciting membrane current in receptors containing the β2 subunit, thus demonstrating properties of a partial agonist. Since chronic nicotine treatment in rats increases predominantly α4β2 nAChRs, and nicotinic antagonists such as mecamylamine and dihydro-β-erythroidine do not appear to increase nicotinic binding sites following chronic administration, our data suggest that cytisine, like nicotine, possesses enough agonist properties at α4β2 receptors to increase the number of binding sites in rat brain.

BUPIVACAINE BLOCKS NEURONAL NICOTINIC RECEPTORS IN THE CLOSED-CHANNEL STATE. Y.-P. Yu¹, D. R. Burt^{1,*}, and E.X. Albuquerque^{1,2}. Depts. ¹Pharmacol. & Exp. Ther., and ²Lab. Mol. Pharmacol., IBCCF, Fed. Univ. Rio de Janeiro, Brazil 21944.

The local anesthetic bupivacaine has been reported to be an open channel blocker of nicotinic receptors (nAChRs) in cultured rat hippocampal neurons (*Ann. Soc. Neurosci.* 19:1535, 1993) and in frog sartorius muscle (*Mol. Pharmacol.* 26:293, 1984). In the present study, we further investigated the interaction of bupivacaine with hippocampal nAChRs using patch-clamp technique. Whole-cell currents were recorded from fetal rat hippocampal neurons cultured for 10-30 days. Bupivacaine was applied by perfusion in the bath or in pulses together with ACh via a U-tube. The peak amplitude of the predominant, MLA-sensitive, fast-decaying currents, could be reduced by bupivacaine in a concentration-dependent manner. In addition, when the neurons were incubated with 50 μM bupivacaine prior to activation of nAChRs by ACh (3 mM), blockade increased with preincubation time (2-8 min). This time-dependent blockade is suggestive of a binding site for bupivacaine distinct from the site within the open channel that has been identified previously in neuronal and muscle nAChRs. Closed-channel blockade of nAChRs by bupivacaine was also evidenced by a decrease in peak amplitude of the fast decaying currents without a significant change in the decay time constants. The lack of voltage dependence of bupivacaine blockade of the fast-decaying currents also indicated that the binding site for bupivacaine on nAChRs was outside of the voltage-sensitive region of the channel itself. Competition experiments showed that the 18-20% blockade of fast decaying nicotinic currents by 100 μM bupivacaine remained unchanged over a wide range of concentrations of ACh (100 μM to 10 mM), indicating that the binding by bupivacaine to this type of receptor was noncompetitive and was not allosterically affected by the agonist. This action of bupivacaine on the closed channel, observed on neuronal nAChRs, was not reported for muscle nAChRs. (Support: USPHS Grant NS 25296)

EFFECTS OF STEROID EXPOSURE ON LIGAND BINDING AND FUNCTIONAL ACTIVITY OF NICOTINIC ACETYLCHOLINE RECEPTORS. Lei Ke* and Ronald J. Lukas. Division of Neurobiology, Barrow Neurological Institute, Phoenix, AZ 85013, USA.

To explore potential mechanisms for the differential modulation of nicotinic acetylcholine receptor (nAChR) expression and function during development and in response to environmental challenges, we tested how exposure to steroids, such as progesterone, estradiol, testosterone, corticosterone and dexamethasone, affects function and numbers of diverse nAChR subtypes. Acute steroid exposure has no effect on [³H]acetylcholine and/or [¹²⁵I]-labeled α-bungarotoxin (Bgt) binding to human muscle-type nAChR (of the TE671/RD clonal line) or on radioligand binding to human ganglia-type nAChR containing α3 and β4 subunits or to human nicotinic Bgt binding sites containing α7 subunits (of the SH-SY5Y neuroblastoma). However, steroid exposure inhibits function (assessed using ⁸⁶Rb⁺ efflux) of both muscle- and ganglia-type nAChR non-competitively with IC₅₀ values in the low-intermediate μM range, depending on the specific steroid studied, with progesterone displaying highest nAChR affinity. Assays done using steroids conjugated to albumin indicate that these functional effects are due to steroid interactions with extracellular domains of nAChR. These studies suggest that fluctuation in local steroid levels could influence nAChR function acutely, via apparently allosteric mechanisms.

LOBELINE AND CYTISINE: EVIDENCE FOR PARTIAL AGONISM IN THE NICOTINE DRUG DISCRIMINATION PROCEDURE. M.D.B. Swedberg*, K. Rinvall and P.D. Suzdak. Novo Nordisk A/S, Pharmaceuticals Division, Novo Nordisk Park, DK-2760 Måløv, Denmark.

Lobeline (1.0 - 6.0 mg/kg, s.c., 15') and cytisine (0.1 - 0.6 mg/kg, s.c., 15') produced maximal nicotine effects of 40.2% and 48.6% at 6.0 and 0.6 mg/kg in rats trained to discriminate nicotine (0.1 mg/kg, s.c., 15'; ED₅₀: 0.02 mg/kg) from no drug. Rates of responding were reduced to 23% and 86% of vehicle controls at 6.0 mg/kg of lobeline and 0.6 mg/kg of cytisine, respectively. In [³H]-methylcarbachol (MCC) receptor binding to rat hippocampal membranes, cytisine (K_i: 0.9 nM) was more potent than lobeline (K_i: 3 nM) and nicotine (K_i: 5 nM). The muscarinics RS86 and oxotremorine were not effective in the drug discrimination or [³H]-MCC assays, respectively. The apparent discrepancy between binding affinities and effects in the nicotine drug discrimination tests is consistent with previously published data, and it has been suggested that lobeline may be a partial agonist at the nicotinic receptor (Aboud et al., 1988) and that cytisine may be a partial agonist at receptors containing the α₄ and β₂ subunits (Papke and Heinemann, 1994). The effects of these compounds will be explored in other physiological systems to determine the morphological basis for the observed effects.

NICOTINIC ACETYLCHOLINE RECEPTOR ELECTROPHYSIOLOGY AND PHARMACOLOGY OF ABT-418 IN PC12 CELLS. C.A. Briggs*, M.L. Hughes, L.M. Monteggia, T. Giordano, D. Donnelly-Roberts and S.P. Ameringer. Neuroscience Research D-47W, Abbott Laboratories, Abbott Park, IL 60064-3500.

In view of the pharmacologic and physiologic diversity of nicotinic acetylcholine receptors (nAChRs), there are intriguing possibilities for developing novel nicotinic agonists that have reduced adverse effects while retaining the beneficial effects of (-)-nicotine. One example, ABT-418, is demonstrated to activate ionotropic nAChR in PC12 cells as a model for the ganglionic subtypes.

PC12 cells were maintained in DMEM containing 10% heat-inactivated fetal calf serum and 5% heat-inactivated horse serum. After 4-7 days exposure to 100 ng/ml NGF, the whole-cell patch-clamp technique was used to record ligand-gated currents activated by substances applied at defined concentrations using the U-tube flow-reversal technique (V_h = -60 mV). The extracellular solution contained 150 mM NaCl, 2.8 mM KCl, 2.0 mM CaCl₂, 1.0 mM MgCl₂, ≥ 10 mM dextrose and 10 mM Na-HEPES buffer (7.3 pH, 325 mOsm) while the intracellular (recording pipette) solution contained 140 mM KCl, 1.0 mM CaCl₂, 2.0 mM MgCl₂, 11 mM K-EGTA, and 10 mM K-HEPES buffer (7.3 pH, 315 mOsm).

ABT-418 activated inward currents with a potency 4-fold lower than (-)-nicotine (EC₅₀ = 214 μM and 52 μM, respectively), while its efficacy was not significantly different from (-)-nicotine (89%). Responses to 300 μM ABT-418, like those to 100 μM (-)-nicotine, were reversibly inhibited 81% by 10 μM mecamylamine, 38% by 10 μM dihydro-β-erythroidine, and 82% by 100 μM dihydro-β-erythroidine. Furthermore, responses to maximal concentrations of ABT-418 (3 mM) and (-)-nicotine (1 mM) were not additive. However, the Hill coefficient for ABT-418 (1.18) was smaller than that for (-)-nicotine (1.77), and high concentrations of ABT-418 appeared to elicit a more rapidly decaying response than did (-)-nicotine. Thus, ABT-418 activated ganglion-like nAChR channels in PC12 cells with a slightly lower potency than (-)-nicotine and with subtle differences in the functional dynamics.

467.15

TOLERANCE TO NICOTINE FOLLOWING CHRONIC TREATMENT: A POTENTIAL ROLE FOR CALCIUM CHANNELS. M.I. Damaj* S.P. Welch and B.R. Martin, Department of Pharmacology and Toxicology, Medical College of Virginia/Virginia Commonwealth University, Richmond, VA 23298.

Recent findings support a role for the L-type calcium channels in the pharmacological effects of nicotine. The purpose of this study was to determine whether calcium channels were involved in nicotine behavioral tolerance in mice. Male ICR mice were chronically co-administered nimodipine (5 mg/kg, i.p.) and nicotine (2 mg/kg, s.c.) twice a day for 10 days. At day 11, mice were challenged with different doses of nicotine and the effect on the tail flick test was measured. In another group of mice, nicotine (2 mg/kg, s.c.) was given chronically to the animals (twice a day for 10 days). At day 11, mice were challenged with different doses of BAYK8644 and its effect on motor coordination (rotarod test) and locomotor activity was measured after i.p. administration. The effect on the tail flick test was assessed after intrathecal (i.t.) administration of BAYK8644. Chronic co-administration of nimodipine with nicotine, significantly reduced tolerance to the antinociceptive effects of nicotine. On the other hand, BAYK8644 effects in nicotine-treated mice decreased. Indeed, the ED₅₀ for BAYK8644-induced motor impairment increased from 0.35 to 2.0 mg/kg in tolerant mice. In addition, the ED₅₀ for BAYK8644-induced antinociception after i.t. injection increased from 3.7 µg/mouse to 12 µg/mouse. These results suggest that L-type calcium channels play a role in nicotine tolerance in mice. Further experiments are needed to explain the mechanisms underlying these effects. (Supported by NIDA grant #DA-05274).

467.17

ACTIVATION AND DESENSITIZATION OF NICOTINIC RECEPTORS ON ISOLATED HISTAMINERGIC NEURONS OF THE RAT TUBEROMAMMILLARY NUCLEUS. V. Uteshev, D.R. Stevens and H.L. Haas*, Physiologisches Institut II, Heinrich-Heine-Universität, 40001 Düsseldorf, Germany

The actions of nicotinic agonists were examined on isolated neurons of the rat tuberomammillary nucleus utilizing rapid application and whole cell recording methods. Acetylcholine (ACh) and 1,1-dimethyl-4-phenyl-piperazinium (DMPP) activated rapidly rising inwardly rectifying currents with reversal potentials near 0 mV. Responses to both agonists desensitized completely. The rate of desensitization was concentration and voltage-dependent. Prolonged treatment with ACh at concentrations below the threshold for activation of inward current resulted in reduction of responses to higher concentrations of agonist. The desensitization of ACh occurred with two time constants while DMPP desensitized more rapidly with a single time course. At hyperpolarized membrane potentials there was a use-dependent reduction in responses which was long lasting and was reversed by depolarization. Projections from cholinergic regions of the basal forebrain to the tuberomammillary nucleus have been shown and rapid nicotinic neurotransmission may occur in this pathway. Supported by Human Frontier Science Program and Deutsche Forschungsgemeinschaft.

SECOND PATHWAY OF NICOTINIC RECEPTOR ACTIVATION: EFFECTS OF DESENSITIZING AGENTS AND OPEN-CHANNEL BLOCKERS. T. Tano*, C.M.S. Teixeira, M.C. Helyu-Dantas, B.S. Nascimento, Y. Aracava, and E.X. Albuquerque, Lab. Mol. Pharmacol. II, IBCCF, UF RJ, Rio de Janeiro, RJ 21944, Brazil; Dept. Pharmacol. Exp. Ther., Univ. Maryland Sch. Med., Baltimore, MD 21201, USA.

It has been demonstrated that (-)-physostigmine, certain polyamines, and 4-methylpyrazole (4-MP) can activate nicotinic receptors (nAChRs) expressed in *Torpedo* electric organ, hippocampal neurons, and muscles by binding to a nAChR site distinct from that for acetylcholine (ACh). This novel pathway of nAChR activation was shown to be insensitive to competitive nicotinic antagonists and to nAChR desensitization by high concentrations of ACh, and to be sensitive to the blockade by the nAChR-specific monoclonal antibody FK1. In this study, we evaluated whether agents known to enhance ACh-induced muscle nAChR desensitization (e.g. nortriptyline) or to produce blockade of muscle nAChR in its open conformation (e.g. atropine) also could affect the 4-MP-induced nAChR activity in *L. ocellatus* muscle fibers under cell-attached condition. Whereas nortriptyline (0.1-1 µM) reduced ACh- or anatoxin (AnTX)-induced single-channel activity, it affected neither the frequency nor the kinetic properties of 4-MP-activated single channels. In contrast, atropine (2-10 µM) blocked, in a similar manner, both ACh- and 4-MP-induced single-channel activity. Short-lived, isolated single channels and no evidence for burst activity were observed, indicating a rather slow rate of unblocking for atropine. Our results indicate that the desensitization by non-competitive blockers, similar to that induced by high concentrations of ACh, uncouples the ACh-binding site from channel gating, and does not prevent nAChR activation via another pathway. On the other hand, nAChR channels opened via either pathway are amenable to the action of an open-channel blocker. Support: Mol. Pharmacol. Train. Prog. FINEP/UMAB, FINEP and CNPq.

CALCINEURIN AND PKC REGULATE AChR FUNCTION AT SNAKE TWITCH FIBER ENDPLATES. R.L. Parsons* and J.C. Hardwick, Department of Anatomy & Neurobiology, University of Vermont, Burlington VT 05405.

Staurosporine decreases the extent of recovery of endplate sensitivity following prolonged exposure to carbachol, presumably by inhibition of protein kinase activity (Hardwick & Parsons, Br J Pharmacol 108: 741, 1993). Experiments have been done to determine which protein kinase is responsible for full recovery from agonist exposure. All experiments were done *in vitro* on garter snake costocutaneous muscles maintained in an isotonic potassium propionate solution. Following treatment with 50 µM sphingosine, an inhibitor of CaMK and PKC, the extent of MEPC amplitude recovery following a 10 min exposure to 540 µM carbachol was decreased by 33%. Conversely, KN-62 and lavendustin A, inhibitors of CaMK II and tyrosine kinase respectively, had no effect on MEPC amplitude recovery. Chronic treatment (18-20 hrs) with 200 nM PMA, which down regulates PKC, also reduced the extent of MEPC recovery by 27%. In contrast, the inactive analog 4αPMA had no effect. Following carbachol exposure in PKC-inhibited preparations, two populations of ACh-activated channels, one of ~50 pS and one of ~25 pS, were observed. In untreated preparations, only the large conductance channel was observed. Treatment of preparations with 0.5 µM deltamethrin, an inhibitor of protein phosphatase 2B (calcineurin) prevented the decrease in MEPC recovery associated with PKC inhibition and decreased the occurrence of small conductance channels. These observations suggest that AChRs or associated proteins are dephosphorylated by calcineurin during prolonged agonist exposure and this results in a population of ACh channels with a reduced conductance. Full recovery of these dephosphorylated AChR complexes requires rephosphorylation by PKC. Supported by NIH grant NS 23978.

DIFFERENTIAL MODULATION OF NEURONAL NICOTINIC ACh RECEPTOR-CHANNELS BY NEUROPEPTIDES. J. Cuevas, D.J. Adams*, Dept. Molec. & Cell. Pharmacology, Univ. of Miami Sch. of Med., Miami, FL 33101

Vasoactive intestinal polypeptide (VIP)- and substance P (SP)-immunoreactive neurons and nerve fibers have been found in the mammalian intracardiac ganglia (Weihe et al., 1984, Cell Tis. Res. 236, 527). The effects of VIP and SP on ACh-evoked currents were investigated in cultured rat parasympathetic cardiac neurons under voltage-clamp, using standard whole-cell, perforated-patch, and outside-out recording configurations of the patch clamp technique. Pressure ejection of VIP onto the soma increased the ACh-evoked current amplitude ~2-fold, with half-maximal potentiation occurring at 260 pM VIP (n = 3). VIP also potentiated the current evoked by nicotine (100 µM), but not those evoked by muscarine or ATP. Mecamylamine (3 µM) completely inhibited the currents elicited by ACh and nicotine in the presence of VIP. Pre-treatment of cultured neurons with pertussis toxin (200 ng/ml), intracellular application of GDP-β-S (100 µM), and bath application of L-8-K all blocked VIP-induced potentiation, suggesting that the effect of VIP is mediated by a G-protein coupled receptor. In outside-out membrane patches, bath application of ACh (4 µM) and VIP (4 nM) reduced the mean closed time between bursts of ACh receptor-channel activity by 36% (n = 3) compared to that observed with ACh alone. The mean closed time between clusters of bursts was reduced by 44%, whereas mean unitary current amplitude and apparent channel open time were unaffected by VIP. The open probability of ACh-activated channels in the patches increased ~1.6 fold, from 0.018 to 0.028, in the presence of VIP. Pressure ejection of SP onto the voltage-clamped soma reduced the peak amplitude of the ACh-evoked current, with half-maximal inhibition occurring at 46 µM and near complete block at 1 mM SP (n = 7). The decay rate of ACh-evoked currents was increased by SP, suggesting that SP may increase the rate of desensitization of the ACh receptor-channel. Since ACh is the primary neurotransmitter of extrinsic (vagal) innervation of the mammalian heart, VIP and SP may play an important role in modulating autonomic control of the heart.

RE-APPRAISING THE BUNGAROTOXIN-SENSITIVITY OF NICOTINIC RECEPTORS ON BULLFROG SYMPATHETIC NEURONS JP Horn*, W-X Shen and P Jobling, Department of Neurobiology, University of Pittsburgh, School of Medicine, Pittsburgh, PA 15261.

An earlier study reported that α-bungarotoxin (α-bgt) blocks synaptic transmission in bullfrog sympathetic ganglia (Marshall, PNAS, 78, 1948, 1981). This unusual finding suggests that nicotinic receptors on amphibian autonomic neurons may be fundamentally different from neuronal nicotinic receptors in other ganglia (see Libscombe and Rang, J. Neurosci 8, 3258, 1988).

We have studied the sensitivity of nicotinic synapses to α-bgt and neuronal-bungarotoxin (n-bgt) in the B and C cell systems of bullfrog sympathetic ganglia 9 & 10 by recording compound postganglionic action potentials from rami communicantes. High concentrations (10 µM) of α-bgt applied for up to 8 hours had no effect upon synaptic transmission in either the B or C cell system. Ganglia pretreated with collagenase were also insensitive to α-bgt. In control experiments on isolated sartorius muscle preparations, nerve-evoked twitches were fully blocked by 30-100 nM α-bgt. By contrast, 30-300 nM n-bgt blocked nicotinic transmission in the B and C cell systems. Block appeared within 25-45 min and reversed fully with a half-time of 40-80 min. This was indistinguishable from washout times after block by 100 µM d-tubocurarine. Based on their bungarotoxin-sensitivity the nicotinic receptors mediating ganglionic transmission in bullfrog sympathetic B & C neurons should be classified as neuronal in type.

Supported by a Grant-in-Aid and a Postdoctoral Fellowship (PJ) from the American Heart Association, PA Affiliate and NIH grant NS01427.

A COMPARISON OF NICOTINIC RECEPTORS ON SYMPATHETIC B AND C NEURONS: KINETICS, VOLTAGE-DEPENDENCE AND COMPETITIVE BLOCK BY D-TUBOCURARINE W.-X. Shen* and J.P. Horn. Department of Neurobiology, University of Pittsburgh, School of Medicine, Pittsburgh, PA 15261.

Previous studies have shown that nicotinic receptors on sympathetic B and C neurons differ in their kinetics (Marshall, J. Neurosci 6, 590, 1986) and that synaptic transmission in the C system is more sensitive to d-tubocurarine (DTC) than in the B system (Shen & Horn, Neurosci Abstr 1993). We have now used two-electrode voltage clamp recordings to analyze the voltage-dependence of receptor kinetics and DTC's actions on these 2 cell types. Consistent with earlier reports, EPSC decay follows a single time constant (τ) that is shorter in B than C cells (5.1 ± 0.6 vs 8.9 ± 1.2 ms at -50 mV). EPSCs in both cell types have similar reversal potentials (-3.9 vs -5.6 mV) and show little rectification at negative potentials. The voltage-dependence of τ is also similar in B (-0.0033 ± 0.0012 mV $^{-1}$, $n=28$) and C (-0.0039 ± 0.0011 mV $^{-1}$, $n=13$) cells. In both cell types, $3 \mu\text{M}$ DTC reduces EPSC amplitude to the same extent, independent of membrane potential (-50 mV: 41% in B cells, $n=8$ and 47% in C cells, $n=4$, $P>0.05$; -100 mV: 47% in B cells, $n=6$, and 50% in C cells, $n=3$, $P>0.05$). DTC has no effect upon the shape of the I-V relation or τ . These results provide evidence that nicotinic receptors on B and C cells are similar in every way except for τ . In both cell types DTC acts as a competitive antagonist with similar affinity. Transmission in the C system is more sensitive to DTC because of its lower synaptic conductance (B:199nS, C:154nS). MULTIPLE ACTIONS OF THE ANTICHLINESTERASE PESTICIDE ALDICARB ON MUSCLE NICOTINIC RECEPTORS. M.F.M. Braga, L.F.F. Almeida, A.L. Almeida, L.G. França, W.S. Côrtes, W.M. Cintra, Y. Aracava*, and E.X. Albuquerque. Lab. Mol. Pharmacol. II, IBCCF, UFRJ, Rio de Janeiro, RJ 21944, Brazil; Dept. Pharmacol. Exp. Ther., Univ. Maryland Sch. Medicine, Baltimore, MD 21201, USA.

Previously we demonstrated that as the concentration of the cholinesterase (ChE) inhibitor Aldicarb is increased, there is a potentiation and then a depression of nerve-elicited muscle twitch, and that these effects cannot be fully accounted for by ChE inhibition (Soc. Neurosci. Abs. 19:1526, 1993). In this study, we evaluated whether Aldicarb acts directly on muscle nAChRs by analyzing its effects on muscle contracture elicited by ACh or by ChE-resistant nicotinic agonists, and on ACh-evoked whole-cell and single-channel currents in preparations with negligible ChE activity. Aldicarb (10 – $800 \mu\text{M}$) potentiated frog rectus abdominis contracture tension elicited by ACh (0.2 – $10 \mu\text{M}$), carbamylcholine (5 – $60 \mu\text{M}$), or (+)-anatoxin-a (0.1 – $1.0 \mu\text{M}$). This effect of Aldicarb was inversely related to agonist concentration. In cultured rat myoblasts, Aldicarb ($50 \mu\text{M}$) increased the peak amplitude of ACh ($1 \mu\text{M}$)-evoked whole-cell currents, and in single interosseal muscle fibers from the hind foot of *L. ocellatus*, Aldicarb (10 – $100 \mu\text{M}$) increased the frequency of ACh ($0.4 \mu\text{M}$)-induced single-channel activity over the recording time. However, Aldicarb decreased the mean open time of ACh-activated channels and increased the number of brief closures within a burst, indicating that this carbamate-oxime can act as an open-channel blocker of muscle nAChR. Our results suggest that potentiation of nicotinic responses by Aldicarb could be due to an allosteric action of this agent on the nAChR, and that such potentiation is counteracted by its open-channel blocking activity. NICOTINIC CURRENTS IN NEURONS ACUTELY DISSOCIATED FROM RAT HIPPOCAMPUS AND INHIBITION OF THE CURRENTS BY LEAD. K. Ishihara¹, M. Alkondon¹, J.G. Montes¹, and E.X. Albuquerque^{1,2}. ¹Dept. Pharmacol. Exp. Ther., Univ. Maryland Sch. Med., Baltimore, MD 21201; ²Lab. Mol. Pharmacol., IBCCF, Fed. Univ. Rio de Janeiro, RJ 21944, Brazil.

Our previous study of nicotinic currents in cultured rat hippocampal neurons revealed the presence of four distinct types of currents, of which one, type IA, was the predominant response (JPET 265: 1455, 1993). To determine the most common type of nicotinic currents in neurons that have developed *in vivo*, we performed studies on neurons acutely dissociated from the CA1 region of the hippocampus of 4- to 20-day-old rats. The neurons were dissociated mechanically. Whole-cell currents induced by 1-sec pulses of ACh were recorded in the presence of $1 \mu\text{M}$ atropine. Most of the currents induced by 1 mM ACh decayed rapidly, and all of the rapidly decaying currents tested with 1 mM methyllycaconitine were blocked, indicating that, as in cultured neurons (JPET 265: 1455, 1993), most of the currents were type IA. As seen in type IA currents evoked in cultured hippocampal neurons (JPET 265: 1455, 1993), the peak amplitude of fast decaying currents in acutely dissociated hippocampal neurons had run down by about 60% 15 min after the initiation of whole-cell recordings. Also as in cultured neurons (J. Rec. Res. 11: 1001, 1991), the peak amplitude of currents induced by 1 mM ACh from acutely dissociated neurons increased with age of the rats ($17 \pm 2 \text{ pA}$ in 4-6 days ($n=7$) and $71 \pm 24 \text{ pA}$ in 15-20 days ($n=23$)). However, the fraction of ACh-sensitive neurons (peak amplitude $\geq 10 \text{ pA}$) was age independent (remaining at ca. 60%), while the fraction of agonist-sensitive neurons in culture varied considerably, i.e., 33–98%, increasing with neuron age. These results suggest that the majority of nicotinic currents that can be elicited from hippocampal CA1 neurons are type IA, and that the population density of nicotinic ACh receptors in these neurons increases with age. In addition, the sensitivity to Pb^{2+} of ACh-induced currents was similar to that seen in parallel studies that we performed on cultured rat hippocampal neurons (see J. G. Montes *et al.*, this issue); e.g., Pb^{2+} ($10 \mu\text{M}$) inhibited ACh-induced fast-decaying currents by 70% and 80%, respectively, in acutely dissociated and cultured rat hippocampal neurons. [³H]NICOTINE DOES NOT DETECT NICOTINIC ACETYLCHOLINE RECEPTORS (nAChRs) IN HUMAN AND BOVINE PIAL VESSELS, CORTICAL MICROVESSELS (MVs) AND CAPILLARIES (CAPs). D.G. Linville* and E. Hamel, Montreal Neurological Institute, McGill Univ., Montréal, QC, Canada, H3A 2B4.

Previous studies have implicated nAChRs, possibly located in the basal forebrain, in the regulation of cortical cerebral blood flow in the rat (Linville *et al.*, J. Pharmacol. Exp. Ther. 1993, 267:440). However, nAChRs have been reported in human and pig cerebral MVs (Homayoun *et al.* Neurosci. Abstr. 1992, 337.12). In an attempt to assess the neuronal and/or vascular localization of nAChRs involved in blood flow regulation, we measured nAChRs in post-mortem human and bovine cerebral cortex, and isolated cortical MVs and CAPs. Saturation experiments were performed in human ($n=2$) and bovine ($n=3$) cerebral cortices using [³H]nicotine as the radioligand and yielded the following respective binding parameters: K_D of 4.7 ± 1.4 and $4.3 \pm 0.6 \text{ nM}$, and B_{max} of 14.1 ± 7.9 and $49.7 \pm 2.4 \text{ fmol/mg protein}$. Specific binding in human and bovine cortices was 67 ± 4 and $92 \pm 3\%$, respectively, and Hill coefficients were 0.88 ± 0.4 and 1.0 ± 0.18 . In contrast, cortical MVs and CAPs from both human and bovine did not yield any saturable [³H]nicotine specific binding that could be analyzed with the LIGAND program. Similar results were also obtained with bovine pial vessels. In the presence of 5 nM [³H]nicotine, binding equilibrium was reached within 90 min in the bovine cerebral cortex ($n=2$) and then a time-dependent dissociation was initiated with $5 \mu\text{M}$ cold nicotine which leveled off after 60 min. In contrast, pial vessels did not display any ligand-receptor complex association/dissociation characteristics. These results suggest that [³H]nicotine-labelled nAChRs are not present, or are below detectable levels, in pial vessels and intracortical microvascular beds and thereby cannot significantly contribute to regulation of cortical cerebral blood flow. Supported by the Fonds de la Recherche en Santé du Québec and MRC of Canada.

INHIBITION BY LEAD OF NICOTINIC CURRENTS IN CULTURED RAT HIPPOCAMPAL NEURONS. J.G. Montes¹, K. Ishihara¹, M. Alkondon¹, A.T. Eldefrawi¹, and E.X. Albuquerque^{1,2}. ¹Dept. Pharmacol. Exp. Ther., Univ. Maryland Sch. Med., Baltimore, MD 21201; ²Lab. Mol. Pharmacol., IBCCF, Fed. Univ. Rio de Janeiro, RJ 21944, Brazil.

Previous studies suggested that at least some of the neurotoxic effects of Pb^{2+} are due to inhibition of NMDA receptors (FEBS Lett. 261:124, 1990; JPET 263:868, 1992). However, evidence that Pb^{2+} inhibits nicotinic currents in neuroblastoma cells (Toxicol. Appl. Pharmacol. 103:165, 1990) prompted us to investigate the effects of Pb^{2+} on ACh-induced currents in cultured hippocampal neurons. The neurons were obtained from fetal rats (2-3 days antepartum) and cultured for 13 to 34 days. Recordings were made of whole-cell currents evoked in neurons by ACh pulses (in the presence of $1 \mu\text{M}$ atropine) of 0.2 to 1 sec duration delivered via a "U" tube in the absence or presence of Pb^{2+} in the bath. Of the 4 distinct nicotinic currents that can be elicited in cultured hippocampal neurons, the most common types, IA (83%) and IB (10%), are fast decaying currents blocked entirely (IA) or partially (IB) by 10 nM α -Bgt and by 1 nM methyllycaconitine (JPET 265:1455, 1993). In this study, Pb^{2+} (1 – $30 \mu\text{M}$) reduced the peak amplitude of ACh (1 mM)-induced fast decaying currents (types IA or IB) with an IC_{50} of $3.0 \mu\text{M}$ and Hill coefficient of 1.0. In contrast, the slowly decaying (type II) currents were less sensitive to Pb^{2+} ; as $30 \mu\text{M}$ Pb^{2+} inhibited the peak amplitude of this type of current by only 50%. There was no apparent relationship between age of the neurons in culture and the sensitivity of the nicotinic currents to Pb^{2+} . Inhibition of IA currents by Pb^{2+} was noncompetitive and voltage-independent. Furthermore, Pb^{2+} did not alter the decay rate of the 2 types of currents examined. The results of our study suggest that Pb^{2+} inhibits fast decaying nicotinic currents in hippocampal neurons by binding to a single nicotinic ACh receptor (nAChR) allosteric site located outside of the electric field of the membrane. The nAChR, like the NMDA receptor (FEBS Lett. 261:124, 1990; JPET 263:868, 1992), may be involved in Pb^{2+} -induced neurotoxicity. Inhibition Of Neuronal Nicotinic Acetylcholine Receptor (nAChR) Induced Cation Efflux By Beta Amyloid Peptide Fragments-D.L. Donnelly-Roberts*, S.P. Americ, and J.P. Sullivan Neuroscience Research (D-47W), Abbott Laboratories, Abbott Park, IL, 60064-3500

Two hallmarks of Alzheimer's disease (AD) are the 39-43 amino acid peptide beta-amyloid (βA4), the primary constituent of the plaques found in the post-mortem brains, and the loss of cholinergic markers in the neocortex and hippocampus such as nAChRs. A number of studies have shown that the βA4 peptide and various peptide fragments of βA4 , i.e. $\beta\text{A4}(25-35)$ are neurotoxic *in vitro* through an as yet undefined mechanism. In the present study, the ability of several βA4 peptide fragments to directly modulate nAChR function was investigated. Specifically, the effects of these agents on nAChR-induced $^{86}\text{Rb}^{+}$ efflux in the human neuroblastoma SH-SY5Y cell line was examined. None of the βA4 peptides possessed any agonist activity at concentrations from 1 nM to $100 \mu\text{M}$. The βA4 fragments did, however, display a differential ability to inhibit (-) nicotine induced cation efflux. $\beta\text{A4}(25-35)$ was the most potent peptide evaluated with an IC_{50} value of $1.2 \pm 0.3 \mu\text{M}$ ($n=3$). Substance P, which shares the same three C-terminal residues (X-Gly-Leu-Met-NH $_2$) as $\beta\text{A4}(25-35)$ and has been shown to modulate nAChRs *in vitro*, also inhibited (-) nicotine-induced cation efflux ($\text{IC}_{50} = 0.7 \pm 0.1 \mu\text{M}$). The triad of residues is inherent to $\beta\text{A4}(1-40)$ but this peptide was 15-100 fold less potent than $\beta\text{A4}(25-35)$ depending on the aggregation state of the peptide. Thus, it may be that the conformational folding of $\beta\text{A4}(1-40)$ prevents optimal exposure of these residues especially in the aggregated state. In contrast, a control peptide, Angiotensin II, and $\beta\text{A4}(1-28)$ both of which lack these three C-terminal residues, had no effect on cation efflux at concentrations up to $100 \mu\text{M}$. These results demonstrate that the βA4 peptide fragments can modulate the function of the nAChR *in vitro* and that this modulation could be linked to loss of these receptors during the pathogenesis of AD. Whether blockade of nAChR function underlies the neurotoxicity associated with the 25-35 peptide remains to be determined.

RECTIFICATION OF ALPHA-BUNGAROTOXIN-SENSITIVE, NICOTINIC WHOLE-CELL CURRENTS EVOKED IN RAT BRAIN NEURONS IS Mg^{2+} -DEPENDENT. E.X. Albuquerque^{1,2*} and M. Alkondon¹. ¹Dept. Pharmacol. Exp. Ther., Univ. Maryland, Sch. Medicine, Baltimore, MD 21201; ²Lab. Mol. Pharmacol. II, IBCCF, Fed. Univ. Rio de Janeiro, RJ, Brazil, 21944.

Recent work from our laboratory indicated the presence of multiple subtypes of nicotinic acetylcholine receptors (nAChRs) in rat hippocampal neurons (*JPET* 265: 1455, 1993). The predominant subtype, subserved by the $\alpha 7$ subunit, gives rise to fast-desensitizing whole-cell currents (referred to as type IA) that rectify weakly and are blocked by α -bungarotoxin (α -BGT, 10 nM). A less predominant subtype, subserved by $\alpha 82$ subunits, gives rise to slowly desensitizing whole-cell currents (referred to as type II) that rectify strongly and are blocked by dihydro- β -erythroidine (100 nM). Here, we investigated the subtype/s of nAChRs present in rat olfactory bulb (OB) neurons, and studied the mechanism of rectification of α -BGT-sensitive nicotinic currents evoked from both OB and hippocampal neurons. In OB neurons grown in primary culture, acetylcholine and other nicotinic agonists evoked fast-desensitizing whole-cell currents that were blocked by both α -BGT (10 nM) and methyllycaconitine (1 nM), suggesting that IA currents were the predominant type elicited in OB neurons. In the presence of 2 mM Mg^{2+} in the internal recording solution (F^{-} -free), type IA currents in both types of neurons showed a marked nonlinearity in the current-voltage plots such that smaller outward and larger inward currents (inwardly rectifying) were recorded in the range of -100 mV to +80 mV. In contrast, in nominally Mg^{2+} -free internal recording solutions, a loss of rectification of type IA currents was evident as the whole-cell recording progressed in time, and a more linear current-voltage relationship was obtained under these conditions. However, type II currents recorded in hippocampal neurons revealed strong rectification even in Mg^{2+} -free internal recording solutions. The results suggest that the nicotinic currents elicited from α -BGT-sensitive nAChRs in both OB and hippocampal neurons differ from other types of nicotinic currents in their rectification property, being regulated (probably blocked from the inside) by intracellular Mg^{2+} rather than by a voltage-dependent, intrinsic channel-gating mechanism. CHARACTERISTICS OF NICOTINIC WHOLE-CELL CURRENTS IN PC12 CELLS. W. Randall, E.F.R. Pereira, K.A. Gregerson*, A. Storch, A. Maelicke, and E.X. Albuquerque. Depts. Pharmacol. Exp. Ther. & Pediatrics, Univ. MD Sch. Med., Baltimore, MD 21201, USA; Lab. Mol. Neurobiol., Inst. Physiol. Chem. & Pathobiochem., Johannes-Gutenberg University Med. Sch., Mainz D-600, Germany; Lab. Mol. Pharmacol. II, IBCCF, UFRJ, RJ 21944, Brazil.

The nicotinic receptors (nAChRs) that give rise to each of the three types (IA, II, and III) of nicotinic currents evoked in hippocampal neurons have been identified on the basis of the pharmacological and kinetic properties of the currents. An $\alpha 7$ -based nAChR has been assigned to type IA current, an $\alpha 82$ nAChR to type II, and an $\alpha 34$ nAChR to type III (*JPET*, 265:1474, 1993). Although the clonal rat pheochromocytoma (PC12) cells represent an established model for the study of sympathetic ganglionic transmission, and express various members of the nAChR gene family (*J. Neurosci.*, 12:4611, 1992), the nicotinic currents evoked in these cells have not been assigned to specific nAChR subtypes. In the present study, the characteristics of nicotinic whole-cell currents activated in cultured PC12 cells were compared with those of nicotinic currents elicited in hippocampal neurons. Application of ACh (3 μ M-3 mM) via a U-tube system to PC12 cells evoked whole-cell currents whose peak amplitudes increased with ACh concentration; the EC50 for ACh was $\approx 75 \mu$ M. Whereas nicotinic currents in PC12 cells were insensitive to dihydro- β -erythroidine (10 nM), they could be inhibited by methyllycaconitine (MLA, 1 nM), in this way resembling type IA nicotinic currents. In addition, a long-lasting blockade was observed when MLA was applied simultaneously via the bath perfusion and the U tube, and ACh-evoked currents in PC12 cells decayed with a slow time constant (τ_{decay} for ACh (30 nM)-activated currents was ≈ 0.250 ms in PC12 cells). Thus, whereas the sensitivity of ACh-evoked currents in PC12 cells to competitive nicotinic blockers resembled those of the $\alpha 7$ nAChR-subservated type IA currents in hippocampal neurons, the decay and the MLA-induced long-lasting blockade of nicotinic currents activated in the PC12 cells were different from those of type IA currents. It is possible that a neuronal nAChR made up of a combination of $\alpha 7$ subunit(s) and other neuronal nAChR subunit(s) subserves the nicotinic currents in the PC12 cells. EFFECTS OF DENERVATION UPON ACETYLCHOLINE RECEPTOR CLUSTERS IN AUTONOMIC NEURONS AS DETERMINED BY QUANTITATIVE LASER SCANNING CONFOCAL MICROSCOPY. H.L. Wilson and P.B. Sargent*. Depts. of Stomatology and Physiology and the Neurosciences Graduate Program, UCSF, San Francisco, CA 94143.

We previously showed that denervation altered the properties of acetylcholine receptor (AChR) clusters on the surface of frog cardiac ganglion cells (Neuron 1: 877-886, 1988). We have extended this analysis by using a laser scanning confocal microscope to optically section and reconstruct neurons dually labeled for AChR clusters and synaptic boutons. AChRs were labeled with rat anti-electric organ AChR mAb #22 (gift of Dr. Jon Lindstrom, UPenn), and cyanine 3.18-labeled goat anti-rat IgG. Synaptic boutons were labeled with mouse anti-SV2 mAb #10H (gift of Dr. Steve Carlson, UWash) and cyanine 5.18-labeled goat anti-mouse IgG. Cluster number per cell and relative AChR number per cluster were determined with image analysis software (Optimas). On normally innervated ganglion cells, AChR clusters are co-localized with synaptic boutons and are spatially clustered on the cell surface, since several may be associated with a single bouton, which are themselves clustered. On denervated neurons, by contrast, AChR clusters are spatially dispersed. Denervation also leads to a reduction in the relative number of AChRs per cluster, measured as the product of cluster size and average pixel value; this change is evident as soon as 3 days following surgery and is sustained for at least 6 weeks. Finally, denervation results in a transient change in the relative AChR number per cell, which is significantly reduced 18-20 days following denervation but which returns to normal by 40-42 days following denervation. These results indicate that synaptic AChR clusters are not stable in the absence of innervation. (Supported by NIH NS 24207.)

ELECTROPHYSIOLOGICAL EVIDENCE FOR PRE- AND POSTSYNAPTIC NICOTINIC RECEPTORS IN THE RAT INTERMEDIOLATERAL CELL NUCLEUS. A. Bordey, M.S. Ghandour*, and Feltz P. Lab. de Physiologie Générale, Univ. Louis Pasteur, 67084 Strasbourg Cedex, France.

We studied the responses of cholinergic nicotinic agonists, DMPP (Dimethyl-4-phenyl piperazinium iodide) and nicotine in thin (250 μ m) transverse slices of the thoracic and lumbar spinal cord of neonatal rats (P0-P8) using the whole-cell recording configuration of the patch-clamp technique. Recorded neurons were identified as sympathetic preganglionic neurons (SPNs) on the basis of their location (Intermediolateral cell column (IML), morphology and electrophysiological properties (resting potential of -48.6 \pm 1.5 mV (mean \pm sem, n=30), membrane resistance of 122.7 \pm 10.9 M Ω (n=43) and presence of an A current). In SPNs, DMPP and nicotine had two effects: 1) a short term effect consisting of the induction of a postsynaptic current (=12/21) and 2) a long term effect which is the induction of fast excitatory and/or inhibitory currents (respectively EPSCs and IPSCs) lasting 20-30 min after the end of the nicotinic agonist application. At -50 mV, a DMPP application either by iontophoresis or by pressure induced an inward current accompanied by an increase in conductance and characterized by two phases: a first transient peak (-181.3 \pm 100 pA, n=3) showing a fast desensitization followed by a plateau phase (-77.8 \pm 14.0 pA, n=7). This second phase diminished in amplitude after successive applications of DMPP (reduction between two successive applications of DMPP (5 sec) spaced by 3 min is 36.0 \pm 8.7%, n=3). It reversed at 0 mV and was not abolished by bath perfusion of lanthanum (200 μ M). As regards the long lasting effect, each nicotinic agonists (10-20 sec) triggered the appearance of EPSCs and/or IPSCs both in SPNs and in interneurons. These results suggest that nicotinic receptors are located postsynaptically on SPNs and presynaptically on both cholinergic interneurons that project to SPNs and on glutamate-containing terminals that project either to SPNs or to unidentified neurons of the IML.

CALCIUM PERMEABILITY OF HIPPOCAMPAL $\alpha 7$ NICOTINIC ACETYLCHOLINE RECEPTOR CHANNELS. N.G. Castro^{1,2}, N. Brookes^{1*} and E.X. Albuquerque^{1,2}. ¹Dept. Pharmacol. Exp. Ther., Univ. Maryland Sch. Medicine, Baltimore, MD 21201; ²Lab. Mol. Pharmacol. II, IBCCF/UFRJ, Rio de Janeiro, RJ, Brazil 21944.

Rat hippocampal neurons express a nicotinic receptor (nAChR) channel that is sensitive to α -bungarotoxin (α -Bgt) and presumably contains the $\alpha 7$ protein subunit (*J. Pharmacol. Exp. Ther.* 265:1455, 1993). The ion selectivity of this channel was investigated in cultured rat hippocampal neurons by measuring the reversal potentials (V_R) of acetylcholine-induced whole-cell currents in various ionic media. Dihydro- β -erythroidine (0.1 μ M), which blocks the $\alpha 82$ -type nAChR, was used to isolate the α -Bgt-sensitive currents. Permeability ratios were calculated independently of the intracellular medium, using a Goldman-Hodgkin-Katz expression for V_R shifts in the presence of Ca^{2+} . The V_R s were corrected for junction potentials, and ion activities were used instead of concentrations. When substituting extracellular Cl^- for methanesulfonate, there was a 5 mV negative shift in the V_R . This rules out a significant contribution of Cl^- to the currents. The shift was probably due to a decrease in cation activity in the presence of methanesulfonate. When switching (in the same neuron) from 1 to 10 mM Ca^{2+} in Ca^{2+} -based extracellular solutions, the V_R became more positive by 5.6 ± 0.9 mV. Considering only Ca^{2+} and Na^+ to be permeant, this shift yields a P_{Ca}/P_{Na} of 6. In identical experiments, the V_R of NMDA-gated currents shifted by 8.3 ± 1.1 mV, yielding a P_{Ca}/P_{Na} of 10. When switching from 150 mM Ca^{2+} to 150 mM Na^+ solutions, the nAChR current showed a small positive V_R shift. This could be accounted for by the higher activity of Na^+ , with a calculated P_{Na}/P_{Ca} close to 1. Thus, the native $\alpha 7$ nAChR channel in the rat hippocampus is a cation channel considerably selective for Ca^{2+} , although not as much as the NMDA channel. However, the $\alpha 7$ nAChR channel shows inward rectification, conducting linearly below -20 mV. *In vivo*, these receptors may mediate a fast, transmitter-induced rise in intracellular Ca^{2+} that would be independent of membrane depolarization and maximal at near-resting membrane potentials. Support: NIH grant NS25296; CNPq fellowship, Brazil.

468.6

ON THE ROLE OF ACETYLCHOLINESTERASE AND ACETYLCHOLINE RECEPTORS IN DENERVATION SUPERSENSITIVITY IN THE FROG CARDIAC GANGLION. E.N. Garrett*, H.L. Wilson, S.D. Matthews, and P.B. Sargent. Depts. of Stomatology and Physiology and the Neurosciences Graduate Program, UCSF, San Francisco, CA 94143.

Chronic denervation of parasympathetic neurons in the frog cardiac ganglion leads to an increase in their sensitivity to acetylcholine but does not alter sensitivity to carbamylcholine (Streichert and Sargent, *J. Physiol.*, 445:249-260, 1992). This suggests that denervation supersensitivity results from a reduced effectiveness of acetylcholinesterase (AChE). To learn whether denervation leads to an outright loss of AChE, we measured AChE in extracts of sham-operated and denervated ganglia. Denervation resulted in a significant increase in the V_{max} for AChE. Previous work (Streichert and Sargent, *J. Neurobiol.* 21: 938-949, 1990) suggested that this increase is attributable to enhancement of an intracellular pool of enzyme. When extracellular AChE was measured specifically, it was found not to be altered significantly by denervation. Quantitative histochemical studies further showed no denervation-induced change in AChE activity at the surface of ganglion cells. These studies suggest that denervation supersensitivity to ACh is not caused by a loss of AChE. Nor is it apparently explained by an increase in the number of cell surface nicotinic acetylcholine receptors (AChRs), measured as the number of binding sites for [¹²⁵I]-neuronal-bungarotoxin (α -bungarotoxin) or for [¹²⁵I]-mAb 22, a cross-reacting anti-electric organ AChR antibody (gift of Dr. Jon Lindstrom, UPenn). Finally, denervation does not appear to alter the distribution of AChRs relative to AChE, thus making it unlikely that supersensitivity to ACh results from the migration of AChRs to areas of the cell surface containing relatively little AChE. (Supported by NIH grant NS 24207.)

COGNITIVE EFFECTS OF NICOTINIC-CHOLINERGIC MANIPULATION IN A RAT STIMULUS DISCRIMINATION TASK. A.V. Terry Jr.^{1,2}, J.J. Buccafusco^{1,2}, W.J. Jackson^{1*}, M.W. Decker³, S.P. Ammer³. ¹Dept. Pharmacol. Toxicol., Medical College of Georgia, ²Dept. VA Med. Ctr. Augusta, GA 30912 and ³Neuroscience Res., Abbott Laboratories, Abbott Park, IL 60064

The purpose of this study was to determine the nature of cognitive enhancement following central nicotinic receptor stimulation in a novel version of the delayed stimulus discrimination task. In this paradigm, an animal is presented with a stimulus, which is followed by a variable length delay (retention) interval, at the end of which the animal has the opportunity to respond, and thus earn a food reward. In our model, a tone (auditory) and a light (visual) stimulus was utilized. To diminish the rat's ability to use position and spatial strategies to solve the task, we installed computer automated, retractable doors which separate the animal from the levers during the delay interval, thus preventing positioning at the lever. After stable baselines were achieved, nicotine or lobeline was administered in a randomized dose series. Each rat received two complete series of the two drugs on different occasions. Only 2 doses per week were administered. Optimal doses of both nicotine and lobeline significantly improved overall performance in the delayed stimulus discrimination paradigm by 12.5 and 8.4% respectively. A differential pattern of improvement was observed when the data was analyzed by delay, however. The most significant enhancement with nicotine appeared at the longest delays (16.5%) whereas the most significant enhancement with lobeline occurred at the shortest delays (13.7%). In addition, mecamylamine 1.0 mg/kg (a nicotinic antagonist) administered concomitantly with nicotine completely abolished the enhancement, but did not significantly reduce the enhancement stimulated by lobeline. These data suggest that lobeline's cognitive effects may be expressed through non-nicotinic mechanisms or involve a nicotinic receptor which is not responsive to mecamylamine.

INCREASED BASAL [³H]DOPAMINE RELEASE EVOKED BY NANOMOLAR NICOTINE MAY PROCEED VIA A HIGH-AFFINITY RECEPTOR CONFORMATION. P.P. Rowell*, Department of Pharmacology and Toxicology, University of Louisville School of Medicine, Louisville, Kentucky 40292.

Nicotine stimulates the release of several neurotransmitters from brain tissue by acting on presynaptic receptors. We have used an *in vitro* superfusion system to measure the nicotine-evoked release of [³H]dopamine (DA) from rat striatal synaptosomes. A 2-min exposure to micromolar nicotine produces a rapid increase in [³H]DA release. With continued exposure the response declines, apparently due to conversion of the receptors to a high-affinity desensitized conformation. In contrast, prolonged exposure to nanomolar concentrations of nicotine, while not producing an immediate response, leads to a cumulative enhancement in basal [³H]DA release. This effect is calcium-dependent and blocked by the nicotinic antagonist, dihydro- β -erythroidine. We suggest that the gradual DA release in response to low concentrations of nicotine occurs as a result of the equilibrium between the high-affinity desensitized and active states of the receptors. Therefore, nicotine may evoke neurotransmitter release by two processes; one involving a rapid and robust increase as a result of nicotine's interaction with active receptors, and a second slower and relatively weaker process brought about by prolonged exposure to low concentrations of the drug. This dual action may have important implications with respect to nicotine delivery from cigarette smoking versus patch. (Supported by N.I.H. grant DA07479-01A1.)

REGULATION OF BRAIN NICOTINIC CHOLINERGIC RECEPTORS BY CHRONIC ICV INFUSIONS OF METHYLCARBACHOL. X-H. Yang*, M.L. Hyer and J.B. Pauly. Dept. of Pharmacology and Toxicology, Medical College of Georgia, Augusta, GA 30912-2300.

Methylcarbachol (MCC) has been reported to be a selective agonist for neuronal nicotinic cholinergic receptors. However, behavioral alterations elicited by ICV infusions of MCC appear to be mediated by both nicotinic (e.g. prostration syndrome) and muscarinic (e.g. polydipsia) neurotransmission. In the present study, quantitative autoradiography was used to analyze changes in cholinergic receptor binding following chronic ICV infusions of MCC. Male Wistar rats were anesthetized and a chronic ICV guide cannula was implanted into the left lateral ventricle. Animals received two daily injections (at 0900hr and 1500hr) of saline (5 μ l) or MCC (30 μ g in 5 μ l) for 10 days. Tolerance developed for nicotinic but not muscarinic receptor mediated behaviors over the course of the chronic treatment. Following completion of behavioral testing, the brains of the animals were removed, frozen in isopentane and sectioned on a cryostat. Quantitative autoradiography was used to measure nicotinic (³H-cytisine and ¹²⁵I-bungarotoxin) as well as muscarinic (³H-QNB) receptor binding. In general, chronic MCC treatment did not alter muscarinic binding, consistent with the lack of tolerance development for MCC-induced polydipsia. However, MCC produced robust increases in nicotinic cholinergic receptor binding. Bungarotoxin binding was increased in many brain regions including the cerebral cortex, endopiriform nucleus, bed nucleus of the stria terminalis, amygdala, superior colliculus and various sites within the hippocampus. Cytisine binding was also increased following chronic MCC infusions, with the largest increases occurring in the striatum and cerebral cortex. MCC-induced changes in brain cholinergic receptor binding appear to be similar to those produced by chronic nicotine treatment and may be the result of chronic receptor desensitization. POTENTIATION OF PEPTIDERGIC TRANSMISSION IN SYMPATHETIC GANGLIA BY 1 μ M NICOTINE AND INCREASES IN TEMPERATURE. P. Jobling*, R. Thorne and J.P. Hom. Department of Neurobiology, University of Pittsburgh, School of Medicine, Pittsburgh, PA 15261.

Interaction between cotransmitters in sympathetic ganglia may have important implications for end-organ function. In bullfrog sympathetic ganglia co-release of LHRH with Ach causes asynchronous discharge of postganglionic action potentials (afterdischarge) after a stimulus train.

We have studied peptidergic afterdischarges (ADC) by recording extracellularly from rami communicantes and peripheral nerves that carry axons from ganglia 9&10. Changes in aortic tension associated with preganglionic C stimulation were also monitored. Repetitive stimulation of spinal nerves 7&8 (>40 stimuli at 20 Hz) evoked ADC's in rami that lasted up to 2 min and were blocked by glu-phe-trp-LHRH, an antagonist. Longer trains (ie 500 stimuli) evoked ADC's in cutaneous and pelvic nerves. The pelvic nerve responses suggest that C neurons must contribute to ADC. 0.5-1 μ M nicotine markedly potentiated ADC without affecting nicotinic transmission through the ganglia. This effect of nicotine persisted for several hours and was readily reversible. 250 nM α -bungarotoxin did not block the effect of nicotine. Potentiation of ADC by nicotine was not associated with an increase in the amplitude or duration of aortic contractions. Potentiation of ADC also occurred when bath temperature was warmed from 21°C to 24°C or 28°C. The duration of ADC was shorter at higher temperatures. The data reveal modulation of peptidergic transmission in sympathetic ganglia but the implications for targets remain unresolved. Supported by NS21065, NS01427 and a postdoctoral fellowship from the AHA, PA Affiliate.

THE EFFECTS OF AGING ON RAT BRAIN NICOTINIC CHOLINERGIC RECEPTOR SUBTYPES: AN AUTORADIOGRAPHIC ANALYSIS. J.B. Pauly*. Dept. of Pharmacology and Toxicology, Medical College of Georgia, Augusta, GA 30912-2300.

A reduction in the number of neuronal nicotinic receptors identified by 3H-nicotine [or 3H-cytisine] binding has been consistently demonstrated in tissue obtained from patients with Alzheimer's Disease. However, the effects of aging and Alzheimer's Disease on brain alpha-125I-bungarotoxin (BTX) receptors are not well characterized. The purpose of the present study was to compare the binding of 3H-cytisine and 125I-BTX in the brains of young and aged rodents. The brains of young (2 months) and aged (26 months) male Wistar rats were sectioned and quantitative autoradiography of 3H-cytisine and 125I-BTX binding was performed on adjacent brain sections as previously described (Pauly et al., 1991). The number of brain receptors labeled by 125I-BTX was not consistently altered by aging although region-specific increases (supraoptic nucleus, dentate gyrus) and decreases (nucleus sagulum, dorsal tegmental nucleus) in BTX binding were determined. The effects of aging on nicotinic receptors identified by 3H-cytisine binding were more consistent and of greater magnitude than those measured for BTX binding. Age-related reductions in 3H-cytisine binding were prevalent in many brain regions including most thalamic nuclei (e.g. anteroventral, anterodorsal), the medial habenula, dorsolateral geniculate nucleus, medial geniculate nucleus, subiculum, substantia nigra, ventral tegmental area and superior colliculus. It is interesting that no age-related reduction in cytosine binding was detected in such regions as the cerebral cortex, striatum, hippocampus and interpeduncular nucleus. These data suggest that the effects of aging on the nicotinic cholinergic system in rat brain are dependent on receptor subtype. Brain regions also differ substantially in the magnitude of age-related reductions in nicotinic receptor binding. Supported by DA-08443 and a grant from the Callaway Foundation.

NEURONAL NICOTINIC RECEPTORS (nAChRs) EXPRESSED IN KERATINOCYTES CONTROL CELL ADHESION AND MOTILITY AND ARE TARGETED BY PEMPHIGUS ANTIBODIES. E.F.R. Pereira, E.X. Albuquerque, P.G. George, R.M. Horton, B.M. Conti-Tronconi, and S.A. Grandt. Lab. Mol. Pharmacol. II, IBCCF, UFRJ, Rio de Janeiro, RJ 21944, Brazil; Dept. Pharmacol. Exp. Ther., Univ. Maryland Sch. Med., Baltimore, MD 21201; Depts. Dermatol. & Biochem., Univ. Minnesota, St. Paul, MN 55108.

Like cholinergic neurons, keratinocytes (KC) are capable of synthesizing, storing, releasing, and degrading ACh *in vivo* and *in vitro* (J. Invest. Dermatol. 101:32, 1993). In this study, the physiological actions of ACh in human KC were studied by means of various mutually confirmatory techniques. Application of ACh (5 mM) or nicotine (1-5 mM) to suspensions of KC induced immediate cell adhesion and spreading, and establishment of intercellular contacts. In contrast, addition of nicotinic antagonists such as α -bungarotoxin (α -BGT, 1 nM) or mecamylamine (1 μ M) to confluent KC caused cell dissociation, a phenomenon similar to acantholysis. In outside-out patches from cultured KC, ACh (10 μ M) or anatoxin-a (AnTX, 1 μ M), in the presence of atropine (1 μ M), could activate predominantly 32-pS single channels. The frequency of channel openings induced by AnTX or ACh was reduced reversibly by mecamylamine (1 μ M) and irreversibly by α -BGT (10 nM). The pharmacological properties and the conductance of these nicotinic channels suggested that a neuronal α 3 β 4 nAChR gives rise to the nicotinic responses in KC. Using specific antibodies and PCR probes for each of the nAChR α subunits, we confirmed that KC express neuronal nAChR α 3 and β 4 subunits. A high titer of antibodies that bind to the neuronal nAChR α 3 subunit was found in the serum of a patient with the skin disease pemphigus, an immunodisease characterized by acantholysis and blistering. Thus, a reduction of nAChR activity in human KC may be related to the physiopathology of pemphigus. Support: USPHS grant NS 25296; Mol. Pharmacol. Train. Prog. UMAB/FINEP.

KYNURENINE-HYDROXYLASE AND KYNURENINASE INHIBITORS: FOCUS ON THE CONTROL OF KYNURENIC ACID BIOSYNTHESIS. A. Chiarugi, R. Carpenedo, M.T. Molina[#], R. Pellicciari^{##} and F. Moroni^{*}. Dept. of Pharmacology, University of Florence, Florence, Italy and Institutes of Med. Chemistry of [#]CSIC, Madrid, Spain and of the ^{##} University of Perugia, Italy.

Kynurenic acid (KYNA) is an endogenous antagonist of the excitatory amino acid receptors. It is synthesised from kynurenine (KYN), a tryptophan metabolite, through the action of kynurenine transaminase. The availability of KYN is the rate limiting step for KYNA production. KYN is also a substrate for kynurenine hydroxylase and kynureninase two enzymes of the metabolic pathway leading to quinolinic acid and NAD biosynthesis. The inhibition of these enzymes results in an increased KYNA synthesis and in a decreased accumulation of the excitotoxic quinolinic acid, (J. Neurochem. 57; 1630;1991). A series of kynurenine hydroxylase and kynureninase inhibitors were synthesised and tested "in vitro" on the activity of the above mentioned enzymes. Two of them were pharmacologically studied. The first one was m(nitrobenzoyl)-alanine (mNBA; J.Med. Chem 37:647; 1994) selected as an inhibitor of kynurenine hydroxylase (IC50: 1 µM) and the second was α(methoxybenzoyl)-alanine (oMBA), selected as an inhibitor of kynureninase (IC50: 5 µM). When administered to rats having a microdialysis probe in their hippocampi, both mNBA and oMBA (20-400 mg/kg i.p.) significantly increased the concentration of KYNA in the dialysate (up to 10 times over basal levels). mNBA was significantly more potent than oMBA suggesting that the inhibition of kynurenine hydroxylase results in a more efficient accumulation of KYNA than the inhibition of kynureninase. The simultaneous administration of both compounds had additive effects. This increased concentration of KYNA in brain extra cellular spaces was correlated with sedation, increase of the convulsive threshold and mild analgesia. These behavioural effects are consistent with the hypothesis that the reported changes of KYNA concentration in brain extra cellular spaces cause a reduced excitatory amino acid receptor function.

CHARACTERIZATION OF ³H DICHLOROKYNURENIC ACID BINDING IN CLONED NMDA RECEPTORS EXPRESSED IN TRANSFECTED CELLS. N.J. Aneagawa, D.B. Lynch, and D.B. Pritchett^{*}. Departments of Pharmacology & Neurology, University of Pennsylvania; Children's Seashore House, Philadelphia PA, 19104

The NMDA subtype of receptors for excitatory amino acids contains a glycine recognition domain. Occupation of the glycine recognition site is required for receptor activation. Multiple NMDA receptor (NR) subunits have been recently cloned. We have transiently expressed NR1 (a-g) and NR 2A-2C in Human Embryonic Kidney 293 cells singly or in combination. Using 293 cells expressing NMDA receptor subunits, we characterized the pharmacological properties of ³H-Dichlorokynurenic Acid (³H-DCK), a proposed antagonist of the glycine recognition domain. In cells transfected with NR1 a-g, saturation analysis revealed high affinity binding with similar K_Ds of 22-37 nM in all seven NR1 splice variants. This binding in all seven subunits was inhibited by glycine and MNQX with similar IC₅₀s of 0.3-3.0 µM and 3.3-6.5 µM respectively. Interestingly, similar to results previously reported by Yoneda *et al* (J. Neurochem. 60, 634 (1993)), we observed that in brain tissue, MNQX inhibited ³H-DCK binding with a non-unity Hill coefficient. However, we did not observe this in NR 1 splice variants. In cells transfected with dimeric combination of NR 1a/2A or NR1a/2B or trimeric combination of NR 1a/2A/2B, saturation analysis revealed K_Ds of 24-30nM. In NR1a/2A and NR1a/2C, ³H-DCK binding was inhibited by glycine with similar IC₅₀s - 1.9-2.5µM. These results demonstrate that NR1 subunit is sufficient to reconstitute ³H-DCK binding. However, the observed binding displayed properties different from native NMDA receptors.

OPEN CHANNEL BLOCK OF THE NMDA-ACTIVATED CHANNEL BY STRUCTURAL ANALOGUES OF PHENCYCLIDINE. J. G. Dillmore^{*} and J. W. Johnson. Dept. of Neuroscience, University of Pittsburgh, Pittsburgh, PA 15260.

Phencyclidine (PCP) is a dissociative anesthetic that is used as a drug of abuse. It has been shown to displace [³H]MK-801 in rat brain homogenates, and to act as an open channel blocker of the ion channel activated by NMDA. In an attempt to elucidate PCP's molecular binding conformation, Kozikowski and Pang synthesized structurally constrained analogues of PCP and found that they displaced [³H]MK-801 with high affinity (Mol. Pharmacol., 37:352, 1990).

We have used patch clamp techniques to examine the electrophysiological behavior of the four PCP analogues with the highest binding affinities. All four have been found to antagonize the response to 5 µM NMDA and 10 µM glycine in cultured rat cortical neurons. Of these four, the drug with the lowest affinity (compound 5 in Kozikowski and Pang, 1990) was most thoroughly investigated and was determined to have an approximate IC₅₀ of 358 nM (n_H = 1.4) at -60 mV. This is close to the reported binding constant of 224 nM. Compound 5 can be trapped within the closed NMDA channel. The time course of block and unblock was generally multiexponential. The time to half maximal block (t_{1/2}) was weakly dependent on antagonist concentration, while the t_{1/2} for unblock showed no dependence on antagonist concentration. The drug with the next higher affinity in binding experiments was found in our experiments to have similarly high affinity but slower kinetics. The equilibrium blockade by these compounds is dependent on voltage with both displaying a much lower affinity at positive voltages. Preliminary experiments have indicated that the two compounds with highest binding affinities are active as NMDA antagonists at lower concentrations in our experiments. A discussion of structural and kinetic implications will be presented. We would like to thank Drs. Kozikowski and Pang for their donation of the compounds. Supported by NIMH.

NMDA RECEPTOR SUBTYPES ON RAT CHOLINERGIC NEURONS.

A.C. Pawley, S. Flesher, K. Jhamandas, R.J. Boegman^{*}, R.J. Benninger. Departments of Pharmacology-Toxicology and Psychology, Queen's University, Kingston, ON. K7L 3N6.

Differences in the agonist-antagonist potencies of a number of compounds at the NMDA receptor have led to the suggestion that NMDA receptor subtypes are present in the brain and spinal cord. Based on this hypothesis NMDA acts as an agonist at both NMDA-1 and NMDA-2 receptors, while quinolinic acid (QUIN) is an NMDA-2 selective agonist. The NMDA receptor is composed of several different subcomponents such as the agonist, glycine, channel/PCP, polyamine, magnesium, and zinc sites. The aim of this research was to examine the effect of different site selective antagonists on NMDA and QUIN toxicity to cholinergic neurons of the rat nucleus basalis (NB). Preliminary studies looked at the toxic effects of QUIN and NMDA to the cholinergic projections from the NB to the cortex and amygdala. QUIN was found to preferentially damage projections to the amygdala, while NMDA damaged both projections equally. Various antagonists were then coinjected with either QUIN or NMDA into the NB. It was found that a ten fold higher concentration of AP7 was needed to block QUIN than NMDA. With QUIN, the projections to the cortex were more easily protected than those to the amygdala by AP7. The antagonists at the remaining sites did not show any other differences between NMDA and QUIN. However, as with AP7, the cortical projections were more easily protected against QUIN, and in general, higher doses of antagonists were required to block QUIN than NMDA. This data indicates that there may be a difference between NMDA receptors on rat cholinergic neurons of the NB, and the difference might be expressed as differences in the agonist binding sites. Supported by MRC.

REGIONAL DISTRIBUTION AND CHARACTERIZATION OF [³H]DEXTRORPHAN BINDING SITES IN RAT BRAIN DETERMINED BY QUANTITATIVE AUTORADIOGRAPHY. J.E.Roth^{*}, T.F.Murray and P.H.Franklin. College of Pharmacy, Oregon State University, Corvallis, OR 97331.

Dextrorphan (DX), the major metabolite of the widely used antitussive dextromethorphan, is a selective noncompetitive antagonist of the NMDA subfamily of ionotropic glutamate receptors. Our previous studies in membrane homogenates (Franklin and Murray, Mol. Pharmacol. 41:131,1992) indicate that although the [³H]DX binding site is associated with an "open channel" domain of the NMDA receptor-operated cation channel, it may not coincide with the channel binding sites of either [³H]MK-801 or [³H]TCP. Using quantitative autoradiography we have further characterized [³H]DX binding sites and studied their anatomical distribution in rat brain.

[³H]DX (40nM) reached equilibrium in the CA1 region of the hippocampus by 4 hr at 20°C. The inclusion of 100 µM glycine and 1 µM glutamate in the incubation droplet increased the association rate of [³H]DX with its binding site in CA1 (t_{0.5} decreased from 46.4 min to 21.0 min) without changing maximum specific binding levels. Unlike [³H]MK-801 (Sakurai *et al.*, Neurosci. 40:533,1991), [³H]DX binding appears to be relatively insensitive to stimulation by glycine and glutamate in a manner that can not be explained by the presence of high endogenous levels of the same. [³H]DX binding was highest in the CA1 (s. radiatum) region of the hippocampus; saturation analysis indicates that [³H]DX labels a single population of binding sites (K_d=48.7 nM). High levels of binding were also seen in the outer layers of the cerebral cortex and the molecular layer of the cerebellum. (Supported by DA-07218)

RESPONSES TO EXCITATORY AMINO ACID RECEPTOR STIMULATION COUPLED TO L-ARGININE:NITRIC OXIDE PATHWAY IN RAT CEREBELLUM AND HIPPOCAMPUS. A. Balcioglu^{*} and T.J. Maher. Mass. Coll. Pharmacy, Div. Pharm. Sci. 179 Longwood Avenue, Boston, MA 02115

Differences in the responses to stimulation of the L-arginine : nitric oxide (NO) system by N-methyl-D-aspartate (NMDA) and kainic acid (KA) in the cerebellum and hippocampus have been investigated in anesthetized rats using microdialysis and a hemoglobin-trapping technique. In the cerebellum, KA stimulated NO production more robustly than NMDA, and in a dose-dependent manner between 0.1 and 1mM. This response was potentiated by L-arginine and inhibited by N-monomethyl-L-arginine (L-NMMA) and N-nitro-L-arginine (L-NNA), with L-NNA being a more potent inhibitor. In addition, the presence of K⁺ along with KA potentiated the response, which tetrodotoxin (TTX) abolished the response. In the hippocampus, however, KA did not stimulate NO production while NMDA increased NO production only at the highest dose tested (1mM). This response was potentiated by L-arginine and inhibited by L-NNA. Interestingly, K⁺ also potentiated the NMDA-induced response, which was diminished by TTX to levels of NO equal to those due to stimulation by NMDA alone. KA and NMDA-induced responses in the cerebellum and hippocampus were unaffected by pretreatment with L-citrulline, L-arginosuccinate and L-ornithine. These findings give further support for the coupling of NMDA and KA stimulation to NO production in the hippocampus and the cerebellum. Additionally, differences in their sensitivities to sodium channel blockade with TTX suggest relative differences in the underlying mechanisms mediating their NO responses to receptor stimulation.

EFFECTS OF NITRIC OXIDE (NO) ON AFFERENT EVOKED RESPONSES AND WIND-UP OF NOCICEPTIVE SPINAL DORSAL HORN NEURONS. D. Budai, G.L. Wilcox* and A.A. Larson. Departments of Veterinary Pathobiology and Pharmacology, University of Minnesota, Saint Paul, MN 55108.

Experiments were designed to determine the role of nitric oxide (NO) in sensory neurotransmission in the dorsal horn of the rat spinal cord. The lumbar enlargement was exposed by a laminectomy under urethane anesthesia. Extracellular recordings were made from wide dynamic range neurons responding to both innocuous and noxious mechanical or heat stimuli delivered to the cutaneous receptive field. Wind-up of the C-fiber-related responses evoked by electrical stimuli was analyzed by computing post-stimulus time histograms. Wind-up, the progressive potentiation of C-fiber responses during a train of stimuli, was increased by inhibition of NO synthase by $N\omega$ -nitro-L-arginine methyl ester (L-NAME) or L-N5-(1-iminoethyl)ornithine (L-NIO) but decreased after elevating the concentration of NO with S-nitroso-N-acetylpenicillamine (SNAP). The effects of NO on wind-up parallels that during nociceptive transmission as responses to noxious mechanical or heat stimuli were usually increased after L-NAME or L-NIO applications. Conversely, application of the NO donating compound, SNAP, led to a decrease in responses to noxious peripheral stimuli. While NMDA has been proposed as an important mediator of wind-up and of nociception, activity induced by iontophoretically applied NMDA was paradoxically inhibited by L-NAME. Responses to innocuous mechanical stimuli were mostly enhanced by SNAP and showed changes in either direction after inhibition of NO synthase. (Supported by USPHS grant DA04090).

REQUIREMENT FOR THE ACTIVATION OF NMDA RECEPTORS AND POSITIVE ALLOSTERIC INTERACTIONS OF GLUTAMATE, GLYCINE AND POLYAMINES. J.C. Marvizón* and M. Baudry. Neuroscience Program, University of Southern California, Los Angeles, CA 90089-2520.

Activation of NMDA receptors by glutamate, glycine and spermine was studied using non-equilibrium [3 H]dizocilpine binding to assess increases in the association kinetic of this channel blocker. Glutamate and glycine mutually increased their efficacies and affinities to stimulate [3 H]dizocilpine binding, which were further increased by spermine. Glutamate and spermine appeared initially to be sufficient to enhance [3 H]dizocilpine binding, with no need for glycine. However, in these conditions the binding was inhibited by the glycine antagonists 7-chlorokynurenate and DNQX. Enhancement curves by glycine in the presence of increasing concentration of 7-chlorokynurenate and saturating concentrations of glutamate and spermine revealed that 1) glycine is still required in the presence of glutamate and spermine, 2) spermine markedly increases the affinity for glycine, and 3) a small glycine contamination (5 nM) was enough to stimulate [3 H]dizocilpine binding in these conditions, thus explaining our initial observations. The increases in glycine affinity produced by glutamate and spermine were additive.

Spermine had a biphasic effect on [3 H]dizocilpine binding, with a stimulatory phase followed by an inhibition at higher concentrations. The potency of spermine for both phases was increased by glutamate, but not by glycine.

These observations indicate that there are positive cooperative interactions between the glutamate, the glycine and the stimulatory and inhibitory polyamine sites of the NMDA receptor, and that glutamate and glycine, but not spermine, are required to activate the NMDA receptor.

469.11

EFFECTS OF RIGID ANALOGUES OF ARCAINE ON THE POLYAMINE SITE OF THE NMDA RECEPTOR COMPLEX. J. Phillips*, V. Jubian, H. Chen, A. Hamilton and I.J. Reynolds, Dept Pharmacology and Chemistry, Univ Pittsburgh, Pittsburgh PA 15261.

The limited specificity and affinity of available ligands for the NMDA receptor-associated polyamine site has limited investigation of the role of this site in modulating NMDA receptor function. With the goal of identifying more potent and specific compounds we evaluated the effects of several rigid analogues of arcaine, the most potent competitive antagonist of the polyamine site currently available, using [3 H] dizocilpine (3 H MK801) binding to rat brain membranes.

An examination of short chain bisguanidines suggested that a chain length of 4-5 was optimal for activity while 2- and 3-carbon arcaine analogues were less potent. Conversion of the guanidine to imidazoline diminished activity by approximately 10-fold. Restriction of the flexibility of the chain also proved helpful. The compound shown had an affinity of 0.7 μ M. Replacement of the benzene ring by cyclohexane decreased the potency by about 10-fold, while substituting an acetylene into the structure of arcaine also decreased the affinity.

However, all of these compounds appeared to act at the polyamine site because they were less potent when spermidine was added to the [3 H] dizocilpine binding assay.

These studies have identified a novel, potent polyamine site antagonist that may represent a useful lead compound. Studies to evaluate the functional activity of this compound are currently in progress.

Supported by NIH grant DA07409 and ONR grant 413Y001.

COMPARISON OF DIFFERENT INHIBITORS ON THE INDUCIBLE AND CONSTITUTIVE BRAIN NITRIC OXIDE SYNTHASES. C. Demerlé-Pallardy*, A. Estival, P.E. Chabrier and P. Braquet. Institut Henri Beaufour, 1 avenue des Tropiques, 91952 LES ULIS, France.

Recently, it has been reported that aminoguanidine (AG) selectively inhibits the inducible isoform of nitric oxide (NO) synthase. The present study was designed to examine the effect of AG on the enzymatic activity of both constitutive and inducible brain NO synthases in comparison with two L-arginine analogues, N^G -nitro-L-arginine (L-NA) and 7-nitro indazole (7-NI).

Brain constitutive NO synthase inhibition was studied using neuronal cell cultures from 17-18 day old embryonic Wistar rat cortices. NO synthase was stimulated by 5 min exposure of L-glutamate (500 μ M) in the presence of the inhibitors. Inducible NO synthase inhibition was assessed using C6 glioma cells treated during 24 h with interleukin-1 (10 ng/ml). Cyclic GMP levels were used as an index of NO synthase activity and were determined by a specific radioimmunoassay.

L-NA and 7-NI inhibited with the same potency the neuronal NO synthase stimulated by L-glutamate (IC_{50} , 63 \pm 23 μ M and 39 \pm 9 μ M, respectively) while AG had no effect on the L-glutamate response. By contrast, in C6 glioma cells, AG inhibited the inducible form of NO synthase (IC_{50} , 270 \pm 5 μ M) and was approximately equipotent to 7-NI (IC_{50} , 427 \pm 90 μ M). L-NA was 3.9 more potent than 7-NI (IC_{50} , 108 \pm 17 μ M).

These results indicate that in the central nervous system, AG selectively inhibits the inducible NO synthase while 7-NI and L-NA are able to block both inducible and constitutive forms of the enzyme. Moreover, it seems to be possible to selectively modulate NO production in the brain using different inhibitors.

469.10

ACTIVATION-RELATED AND ACTIVATION-INDEPENDENT EFFECTS OF POLYAMINES ON PCP RECEPTOR BINDING WITHIN THE NMDA RECEPTOR COMPLEX. S.R. Zukin*, D.C. Javitt and M.J. Frusciante. Depts. of Psychiatry and Neuroscience and Bronx Psychiatric Center, Albert Einstein College of Medicine of Yeshiva University, Bronx, NY 10461.

The phencyclidine (PCP) receptor is located within the N -methyl-D-aspartate (NMDA) receptor-gated ion channel. The functional state of the NMDA receptor complex thus influences parameters of radioligand binding to the PCP receptor, and PCP receptor ligands can serve as *in vitro* probes for elucidation of NMDA receptor activation mechanisms. PCP receptor binding is stimulated by NMDA receptor agonists such as L-glutamate and also by distinct classes of modulatory agents such as glycine-like amino acids and polyamines such as spermidine. The present study utilizes a kinetic approach permitting differentiation of PCP receptor binding within closed and activated conformations of the NMDA receptor complex. The results demonstrate that spermidine increases radioligand binding to the PCP receptor through two distinct mechanisms. First, spermidine, like glycine, increases the percentage of time that NMDA channels remain in the open state in the presence of L-glutamate, consistent with a role as a positive allosteric modulator of NMDA receptor activation. Second, unlike glycine, spermidine increases the affinity of the PCP receptor for its ligands. The latter effect does not appear to reflect increased NMDA receptor activation. Spermidine does not induce glycine-like alteration of the EC_{50} value for stimulation of PCP receptor binding by L-glutamate, suggesting that the effects of spermidine cannot be attributed solely to augmentation of glycine binding. These findings demonstrate first, that total specific PCP receptor binding cannot, of itself, be used as an index of NMDA receptor activation and second, that glycine and polyamines differ in the mechanisms by which they potentiate PCP receptor binding. INTERACTION OF NOVEL BISTHIOUREONES WITH THE NMDA RECEPTOR. C. Cheng*, E. Aizenman, M.L. Edwards, J.E. Matt Jr. and I.J. Reynolds Dept Pharmacology and Neurobiology, Univ Pittsburgh, Pittsburgh PA 15261, and Marion Merrell Dow Res Inst Cincinnati OH 45215.

As a part of our ongoing investigations into drug interactions at the polyamine site on the NMDA receptor complex we evaluated a number of bisthioureaones of the general structure shown using [3 H] dizocilpine (3 H MK801) binding to rat brain membranes and NMDA-stimulated [Ca^{2+}] $_i$ increases and whole cell currents in cultured forebrain neurons.

BT4 inhibited [3 H] dizocilpine binding with an IC_{50} of 2.7 μ M. The effect of BT4 was reduced by spermidine in an apparently competitive fashion, consistent with an action at the polyamine site, like its bisguanidine analogue arcaine. BT8, BT10 and BT12 also inhibited [3 H] dizocilpine binding. BT10 was most potent with an affinity of 0.19 μ M, some 10-fold more potent than the bisguanidine equivalent. However these longer BT compounds were insensitive to alterations in the spermidine concentration indicating a site of action other than the polyamine site. Other modifications of the BT10 structure decreased activity in this assay.

BT8, BT10 and BT12 were also potent inhibitors of NMDA-induced increases in [Ca^{2+}] $_i$, with IC_{50} values of 0.1-0.5 μ M, while BT4 was much less potent (0.5 mM). BT10 (10 μ M) had no effect on responses produced by kainate (100 μ M), AMPA (50 μ M) or KCl (50 mM). The action of BT10 was sensitive to membrane potential, although we found no evidence for use-dependence.

Thus, bisthioureaones are a novel class of NMDA receptor ligands that exert actions on more than one site on the receptor depending on the size of the molecule.

EXTRACTS FROM *CYPERUS ARTICULATUS* (CYPERACEAE) DISPLACE [³H]CGP39653 AND [³H]GLYCINE BINDING FROM CORTICAL MEMBRANES AND SELECTIVELY ANTAGONIZE NMDA RECEPTOR-MEDIATED RESPONSES IN THE RAT CORTICAL WEDGE. E. Ngo Bum, C.L. Meier*, S. Urwyler, Y. Wang and P.L. Herrling. Sandoz Research Institute CH-3001 Bern and Sandoz Pharma Ltd., CH-4002 Basle, SWITZERLAND.

The marshland plant *Cyperus articulatus* (Cyperaceae) is commonly used in traditional medicine in Africa and Latin America, to treat a wide variety of human diseases ranging from headache to epilepsy. We tested the hypothesis that the reported anti-epileptic effect of this plant might be due to a functional inhibition of the N-methyl-D-aspartate (NMDA) receptor complex. One or several component(s) contained in the extracts inhibited the binding of [³H]CGP 39653 to the NMDA recognition site and of [³H]glycine to the strychnine-insensitive glycine site of the NMDA receptor complex from rat neocortex. Water extracts from rhizomes of *Cyperus articulatus* dose-dependently reduced spontaneous epileptiform discharges and NMDA-induced depolarizations in the rat cortical wedge preparation by a NMDA receptor-dependent mechanism. We conclude that the purported anti-epileptic effect of *Cyperus articulatus* might at least partially be due to inhibition of NMDA receptor-mediated neurotransmission.

470.3

ETHANOL INHIBITION OF HETEROMERIC NMDA CHANNELS IS NOT POTENTIATED BY THE PRESENCE OF Mg²⁺ OR AFTER REDUCTION/OXIDATION OF THE REDOX MODULATORY SITE B. Chu, V. Anantharam* and S. N. Treistman. Department of Pharmacology and Program in Neuroscience, University of Massachusetts Medical Center, Worcester, MA. 01655.

Previous reports indicate that the presence of Mg²⁺ enhances the magnitude of ethanol inhibition of NMDA channels in intact tissue preparations. To determine whether the presence of Mg²⁺ could also enhance ethanol inhibition in recombinant channels, we measured the degree of ethanol (50mM) inhibition of NR1b/2A, NR1b/2B, and NR1b/2C NMDA channels expressed in *Xenopus* oocytes in the presence of 12.5 and 3.125μM Mg²⁺. The presence or absence of Mg²⁺ had no effect upon the degree of ethanol sensitivity (0μM Mg²⁺: 19.5% inhibition; 12.5μM Mg²⁺: 16.9%; 3.125μM Mg: 13.4% for NR1b/2A). Reduction or oxidation of the NMDA channel's redox modulatory site by DTT (2mM) or DTNB (1mM) was also ineffective in changing ethanol sensitivity (control: 32% inhibition; DTT: 24%; DTNB: 29% for NR1b/2A). We have previously shown that NR1a and NR1b homomeric channels were differentially sensitive to ethanol inhibition. To determine whether this difference was also present in heteromeric assemblies, we generated dose response curves for ethanol (25-100mM) to compare the sensitivity of NR1a/NR2 and NRb/NR2 assemblies. The presence of the extra 21 amino acid cassette did not result in a consistent difference in ethanol sensitivity. NR1/NR2C assemblies, with either splice variant, were significantly less sensitive to ethanol than other combinations. These results indicate that splice variants in heteromeric combinations are not differentially ethanol-sensitive, that the presence of NR2C confers less ethanol sensitivity, and that ethanol sensitivity is independent of both the redox modulatory site and Mg²⁺ binding site. Supported by NIH grant AA05542.

THE DIHYDROPYRIDINE NITRENDIPINE REDUCES N-METHYL-D-ASPARTATE (NMDA) EVOKED SINGLE - CHANNEL ACTIVITY BY A MECHANISM CONSISTENT WITH OPEN CHANNEL BLOCK. G. A. Skeen*, R. E. Twyman, and H. S. White. Anticonvulsant Drug Development Program; Departments of Pharmacology and Toxicology and †Neurology; University of Utah; Salt Lake City, Utah.

The 1,4-dihydropyridine nitrendipine was shown by this laboratory to reduce NMDA- (5 μM) and glycine- (1 μM) evoked whole-cell and single-channel currents of cultured rodent cortical neurons in an agonist- and a voltage-dependent manner (Skeen et al., submitted to JPET, 1994). Kinetic analysis of the single-channel data (V_m = -75 mV) for the main conductance (48 pS) showed that the nitrendipine-mediated reduction of current was explained by concentration-dependent (30 - 1000 nM) reductions in the frequency of openings and bursts, the average duration of openings and bursts, and the single open duration time constant. These results suggest that nitrendipine interacts with the open state of the NMDA receptor-associated ion channel. To investigate this possibility further, kinetic models were examined by computer simulation. The simulated and experimental data were analyzed and compared for effects on the frequency and duration of NMDA- (5 μM) evoked single-channel openings, at several concentrations of nitrendipine (30 - 1000 nM). The simulated data best approximated the experimental data when generated using a model that was similar to one which described the interaction of MK-801 with the NMDA receptor-associated ion channel (Macdonald et al., J. Physiol., 410: 479-499, 1991). Consequently, the results support the hypothesis that nitrendipine interacts with NMDA receptors by an open channel mechanism similar to that described for MK-801. Supported by a grant from Miles, Inc.

GLUTAMATE AND GLUTATHIONE METABOLITES ON THE ACTIVATION OF N-METHYL-D-ASPARTATE RECEPTORS IN DISSOCIATED NEURONS: INHIBITION BY ETHANOL J.L. Morris and S.W. Leslie*, Div. of Pharmacol/Toxicol, Coll. of Pharmacy, Univ of Texas, Austin, Texas 78712-1074

Previous reports have shown that NMDA-stimulated increases in cytosolic Ca²⁺ concentration ([Ca²⁺]_i) are inhibited by ethanol while glutathione-stimulated increases in [Ca²⁺]_i at brain NMDA receptors resist ethanol inhibition. Glutamate (G), the endogenous neurotransmitter at the NMDA receptor, is also formed as a product of glutathione (GSH) metabolism by γ-glutamyl transpeptidase (γ-GT). In addition, cysteinylglycine (CG) is formed as a consequence of GSH metabolism by γ-GT. G and CG were investigated in fura-2-loaded whole brain neonatal (<24 hr) dissociated neurons to determine if CG might act at the glycine site as a coagonist. Also, studies were conducted to determine the inhibitory effects of ethanol on G-stimulated increases in [Ca²⁺]_i. Finally, the effect of CG on ethanol's inhibition of G-stimulated [Ca²⁺]_i was tested. G-stimulated increases in [Ca²⁺]_i (EC₅₀=0.7μM) were dependent on extracellular Ca²⁺, blocked by Mg²⁺, inhibited by 100 μM APV, and enhanced by glycine. Ethanol inhibited G-stimulated increases in [Ca²⁺]_i with an IC₅₀ of approximately 48 mM. CG (0-11.2μM) did not potentiate G-stimulated increases in [Ca²⁺]_i and did not reverse ethanol inhibition of G-stimulated increases in [Ca²⁺]_i. Also, glycine (0-11.2μM) was unable to reverse the ethanol inhibition. These results suggest that G-stimulated increases in [Ca²⁺]_i in dissociated neonatal whole brain neurons are highly specific for NMDA receptor-operated calcium channels under the conditions of the experiments employed. The CG product of GSH metabolism by γ-GT does not appear to act as a glycine coagonist or to change the inhibitory sensitivity of ethanol on G-stimulated increases in [Ca²⁺]_i. (Supported by NIAAA grant AA09337)

SUBUNIT-SPECIFIC INHIBITION OF CLONED NMDA RECEPTORS BY HALOPERIDOL V. Ilyin*, J. Guastella*, S. X. Cai*, E. Weber* and R. M. Woodward*. *Acce Pharmaceuticals Inc., 1003 Health Sciences Rd. West., Irvine, CA 92715. †Dept. Pharmacology, U. C. Irvine, Irvine, CA 92717.

Haloperidol, a therapeutically useful antipsychotic agent, has recently been shown to have weak inhibitory effects at neuronal NMDA receptors [Fletcher, E. J. and J. F. MacDonald, *Eu. J. Pharmacol.* 235:291 1993]. Using electrical recording techniques we assayed haloperidol on cloned rat NMDA receptors expressed in *Xenopus* oocytes, comparing effects on four heteromeric subunit combinations; NR1A co-expressed with either NR2A, 2B, 2C, or 2D. At saturating concentrations of agonists (10 μM glycine, 100 μM glutamate) only NR1A / 2B receptors were appreciably inhibited by haloperidol (IC₅₀ ~3 μM), the other subunit combinations were largely or wholly unaffected (IC₅₀'s >100 μM). Inhibition of NR1A / 2B receptors by haloperidol did not show pronounced dependence on glycine or glutamate concentrations, or upon voltage (-10 to -110 mV). Furthermore, analysis of binding kinetics, though restricted by the preparation, suggested that haloperidol does not behave like a conventional use-dependent channel blocker. Whole cell patch clamp recordings showed that NMDA receptors in cultured rat cortical neurons (E17, 4-10 days *in vitro*) have similar sensitivity to haloperidol as NR1A / 2B (IC₅₀ 1-3 μM) and, contrary to the earlier report [ibid], that inhibition was not readily surmountable by raising glycine concentrations. Our results suggest that haloperidol selectively inhibits NMDA receptors containing NR2B subunits. Inhibition does not appear to involve simple interactions at glutamate, glycine or PCP binding sites, but may be mechanistically related to the atypical antagonist ifenprodil. Haloperidol, an old drug with a promiscuous pharmacological profile, could serve as a lead for designing novel subtype-selective NMDA receptor antagonists. (Supported in part by NIDA grant DA06726 to E. Weber.)

INHIBITION BY 2,2',2"-TRIPYRIDINE OF HIPPOCAMPAL LONG-TERM POTENTIATION THROUGH BLOCKING N-METHYL-D-ASPARTATE-ACTIVATED CURRENT. K.S.Hsu*, W.M.Fu* and S.Y.Lin-Shiau*. †Dept. of Pharmacology, College of Med., National Cheng Kung Univ., Tainan, Taiwan and †Dept. of Pharmacology, College of Med., National Taiwan Univ., Taipei, Taiwan.

The effects of 2,2',2"-tripyridine on the long-term potentiation (LTP) and N-methyl-D-aspartate (NMDA) receptor-channel complex were studied in the rat hippocampal slices and the culture of hippocampal neurons. 2,2',2"-Tripyridine depressed the amplitude of evoked population spikes as well as LTP in a concentration-dependent manner. 2,2',2"-Tripyridine attenuated NMDA-evoked current recorded from rat cultured hippocampal neurons under whole-cell voltage-clamp, while neither kainate- nor quisqualate-activated whole-cell current was affected by 2,2',2"-tripyridine. The 2,2',2"-tripyridine block of NMDA-activated whole-cell current was non-competitive in nature and was not dependent on the extracellular glycine or spermine concentration. The block did, however, exhibit voltage-dependence. In single-channel recordings from outside-out patches, 2,2',2"-tripyridine greatly reduced the channel activity elicited by the application of NMDA but did not significantly affect the predominant unitary conductance. Consistent with an open-channel blocking mechanism, the mean open time and opening frequency were reduced by 2,2',2"-tripyridine. We conclude that the inhibitory effect of 2,2',2"-tripyridine on the NMDA-evoked currents could be used to explain the blocking action of 2,2',2"-tripyridine on the LTP (a long-lasting enhancement of synaptic efficacy) which appeared following repetitive electrical stimulation.

470.7

COMPARATIVE STUDIES ON NMDA RECEPTOR ANTAGONISM BY AMANTADINE (1-AMINOADAMANTANE) AND MEMANTINE (1-AMINO-3,5-DIMETHYL-ADAMANTANE). C.G. Parsons¹, O.A. Kristal², U. Misgeld³. Dept. Pharmacol., Merz + Co., 60318 Frankfurt, Germany¹; Bogomolitz Inst. Physiol., Kiev, 252024 Ukraine²; Inst. Physiology, Im Neuenheimer Feld 326, Univ. Heidelberg, Germany³.

Amantadine and memantine have similar beneficial effects to classical NMDA receptor antagonists in animal models of glutamate pathology and are used in Europe for the treatment of Morbus Parkinson and dementia respectively. Whole cell patch clamp recordings from cultured superior colliculus neurones indicate that both of these aminoadamantanes selectively block NMDA receptors with rapid use- and strong voltage-dependency (IC_{50} against NMDA 200 μ M at -70mV, memantine = 2.3 μ M, amantadine = 71 μ M). Similar uncompetitive NMDA receptor blockade was observed in whole cell recordings from freshly dissociated hippocampal neurones (IC_{50} against NMDA 1mM at -100mV, memantine = 1.0 μ M, amantadine = 18.6 μ M) whereas in freshly dissociated striatal neurones, recorded under identical conditions, memantine was less potent (IC_{50} = 2.9 μ M) and amantadine more potent (IC_{50} 12.4 μ M). A similar relative potency was apparent for the ability of amantadine (100 μ M) and memantine (30 μ M) to reduce the amplitude of NMDA receptor-mediated EPSPs in striatal slices. The increased *in vitro* potency of amantadine in striatum compared to other brain regions may underlie its beneficial effects in *Morbus Parkinson*. Whilst neither memantine (3-30 μ M) nor amantadine (10-100 μ M) affected current responses to AMPA (50-100 μ M) recorded in whole cell mode, similar concentrations of memantine, but not amantadine, weakly potentiated peak responses to AMPA 100 μ M recorded with the perforated patch technique (memantine 3 μ M, 116 \pm 8% of control, n=7) implying the involvement of secondary messengers. Although this effect was weak and of variable amplitude, similar effects were seen in a separate series of experiments with memantine 30 μ M against AMPA 50 μ M (116.3 \pm 4.6% of control, n=9). Chronic treatment of superior colliculus cultures for 2 weeks with memantine (5-10 μ M) had no discernible effect on the acute NMDA antagonistic properties of memantine but enhanced the potentiating effects of memantine 30 μ M on peak AMPA responses (127.9 \pm 15% of control, n=8). This additional effect of memantine may underlie the reported symptomatic cognitive enhancement seen with this NMDA antagonist in clinical trials of dementia.

PHARMACOLOGICAL CHARACTERIZATION OF GLUTAMATE BINDING SITE IN RECEPTORS ASSEMBLED FROM 1A, 2A AND 2B NMDA RECEPTOR SUBUNITS. S. J. Lenz, E. Greenblatt*, and D.B. Pritchett. Dept. of Pharmacology, University of Pennsylvania, Philadelphia, PA 19104

Previous studies in brain suggest pharmacological heterogeneity of the NMDA sensitive glutamate binding site. We have characterized the pharmacological properties of the glutamate binding site assembled from combinations of the 1A, 2A, and 2B NMDA receptor subunits expressed in transfected cells using ³H-glutamate and ³H-CGP 39653 binding assays. Cells transfected with 1A and 2A, 1A and 2B, and 2A alone produced saturable, specific binding of ³H-glutamate with K_D of 28 \pm 6 nM, 137 \pm 52 nM, and 123 \pm 20 nM, respectively. No binding was detected in cells transfected with 1A or 2B alone. NMDA inhibited ³H-glutamate binding in 1A2A, 1A2B, and 2A combinations with similar IC_{50} values of 23 μ M, 14 μ M, and 12 μ M, respectively. However, the antagonist inhibition profile of ³H-glutamate binding differed among the receptors assembled from 1A2A, 1A2B, and 2A with IC_{50} values of 5 \pm 2 μ M, 25 \pm 13 μ M, 57 \pm 9 μ M for APV; 0.07 \pm 0.08 μ M, 3 \pm 1 μ M, 25 \pm 3 μ M for CGS 19755, and 0.08 \pm 0.01 μ M, 0.58 \pm 0.21 μ M, 2.6 \pm 0.6 μ M for CGP 39653, respectively. Specific, saturable binding of ³H-CGP 39653 was detected in cells transfected with both 1A and 2A but not detected in cells transfected with 1A and 2B, 1A alone, 2A alone, or 2B alone in the absence of Mg⁺⁺. However, in the presence of 1mM Mg⁺⁺, the 1A2B subunit combination displayed specific, saturable ³H-CGP 39653 binding. These results suggest that the NR 2 subunits can account for heterogeneity in glutamate antagonist site.

470.11

REGIONAL VARIATIONS IN THE PHARMACOLOGY OF NMDA RECEPTOR CHANNEL BLOCKERS. R.H.P. Porter* & J.T. Greenamyre. Univ Of Rochester, Rochester, NY, 14642

Quantitative receptor autoradiography was used to examine the regional binding characteristics of a diverse group of N-methyl-D-aspartate (NMDA) receptor channel blockers that varied in potency 10⁵-fold. Full competition curves were generated in each of six brain regions for 12 different compounds. MK-801 was the most potent compound studied, with an IC_{50} of approximately 10 nM in the forebrain regions, and 24 nM in the cerebellar granule cell layer ($p < 0.05$). The binding affinities of ten and Hill slopes of five of the twelve compounds examined were significantly different in cerebellar granule cell layer than in forebrain regions. The fact that the rank order of drug potencies in cerebellum diverges from that in forebrain supports the notion that cerebellar NMDA receptor ion channels differ pharmacologically from those in forebrain. There was a general trend that drugs known to be well-tolerated in humans (remacemide and its metabolites, amantadine, bupropion and memantine) had lower affinities than compounds with severe neurobehavioral or psychotomimetic effects. Also, in contrast to MK-801, TCP, PCP and ketamine, all of these compounds had a significantly higher affinity in the cerebellum than in forebrain regions. Our results suggest that we have identified a new pharmacological classification of NMDA receptor channel blockers, and that low affinity (rapid kinetics) and, possibly, subunit specificity may be important determinants of the clinical tolerability for NMDA receptor channel blockers. (Supported by the National Parkinson Foundation Center of Excellence at the University of Rochester and Fisons Pharmaceuticals)

470.8

INCREASED POTENCY OF THE COMPETITIVE NMDA RECEPTOR ANTAGONIST D-AP5 DURING EARLY DEVELOPMENT IN HIPPOCAMPAL PYRAMIDAL CELLS. J.A. Gorter and R.J. Brady*, Wadsworth Center for Laboratories & Research, New York State Department of Health, Empire State Plaza, P. O. Box 509, Albany, NY 12201-0509.

NMDA receptor activation plays an important role in the mechanisms of developmental synaptic plasticity. This has prompted investigation of the pharmacological and biophysical properties of NMDA receptor mediated responses and has led to interesting findings, including a transient increase in receptor density and reduced voltage dependent block by Mg²⁺ during early life. The present study focused on the potency of the competitive NMDA receptor antagonist D-AP5 during development, using whole-cell patch clamp and extracellular recording techniques in rat hippocampal slices. NMDA responses were evoked by iontophoretic agonist application in the Schaffer-commissural synaptic fields. "Dose"-response curves for NMDA were constructed, and increasing doses of the antagonist were bath-applied to measure suppression of NMDA field- or whole-cell responses. The tissue response capability, as measured by the maximum field response upon NMDA iontophoresis, was larger in immature slices (PND10-16; 24.0 \pm 0.6mV) than in adult slices (PND > 40; 18.9 \pm 1.2mV). NMDA responses in whole cell mode (clamped at -40mV) revealed no differences in NMDA evoked currents between young (maximum: 1.72 \pm 0.30nA) and mature cells (maximum: 1.90 \pm 0.15nA), suggesting that NMDA receptor densities are similar in the two groups. Using Schild analysis we found however, that D-AP5 was 2-3 fold more potent in suppressing responses to NMDA in immature pyramidal cells (K_i = 3.9 μ M) in comparison with pyramidal cells in adult slices (K_i = 10 μ M). Such changes in synaptic microphysiology may be explained by age-dependent alterations in the expression of specific subunit isoforms of NMDA receptors. The finding that the competitive antagonist D-AP5 has a higher potency during early development than in adult brain has to be taken into account when competitive NMDA receptor antagonists are considered for therapeutic purposes. Supported by a HFSP grant to J.A.G. and a NIH grant (NS23071) to R.J.B.

INTERLEUKIN-1 β ANTAGONISM OF NMDA-MEDIATED INCREASES IN INTRACELLULAR CALCIUM IN CULTURED CHICK CORTICAL NEURONS. J.M. Fahey*, D.G. Lindquist and L.G. Miller. Department of Pharmacology and Experimental Therapeutics, Tufts University School of Medicine, Boston, MA 02111.

Interleukin-1 β (IL-1 β) is a proinflammatory cytokine produced in the brain which is thought to be involved in acute and chronic neurodegeneration in the CNS. Since the role of excitatory amino acids in the neurodegenerative process is well known, the present study examines the ability of this neuroactive cytokine to modulate NMDA-mediated increases in intracellular calcium of cultured chick cortical neurons using the fluorescent dye Fura2. IL-1 β alone had no effect on intracellular calcium levels except at the highest concentration used (10 ng/ml). At a concentration of 1 ng/ml, IL-1 β significantly attenuated the increase in intracellular calcium seen in the presence of NMDA/glycine. This inhibition was antagonized by 50 μ M 6-cyano-7-nitroquinoxaline-2,3-dione (CNQX), a non-NMDA glutamate receptor antagonist. CNQX also inhibited the decrease in intracellular calcium caused by IL-1 β in the presence of both NMDA/glycine and the endogenous polyamine spermine. Further experiments suggest that this modulatory effect is specific to IL-1 β , since the biologically similar cytokine interleukin-6 (IL-6) produced no changes in intracellular calcium in the presence or absence of NMDA/glycine. These data indicate that the mechanism by which IL-1 β antagonizes NMDA-mediated increases in intracellular calcium does not occur via the glycine or polyamine site on the NMDA receptor but may involve non-NMDA receptor subtypes of the glutamate receptor.

DOES ACPC DESENSITIZE THE NMDA RECEPTOR? A. Omerovic*, T. Lanthorn, and S.R. Kelso. University of Illinois at Chicago, Dept. Biological Sciences, Chicago, IL 60680.

It has been shown that chronic administration of 1-aminocyclopropanecarboxylic acid (ACPC), a specific ligand for the glycine site of NMDA receptor, results in neuroprotection from ischemic injury and reversible desensitization of behavioral responses induced by NMDA receptor activation (Skolnic et. al., Psychopharmacology, 1992, 107:489-496). The hypothesis was made that ACPC could possibly desensitize the NMDA receptor. To test this hypothesis we used *Xenopus* oocytes injected with rat brain total RNA and recorded NMDA-induced currents using two microelectrode voltage-clamp techniques. In the absence of glycine the measured NMDA current was very small or absent (6.8 \pm 2.8 nA vs. 62 \pm 1.8 nA in the presence of 10 μ M glycine). Upon addition of 1 μ M and 10 μ M ACPC the NMDA current increased to 57 \pm 1.8 nA (5 cells) and 93 \pm 2.3 nA (5 cells), respectively. However in all cells tested, the NMDA current remained stable over 5-15 minutes despite the continued presence of both NMDA and ACPC. Some cells, after initial exposure to ACPC for 5-10 minutes, were incubated overnight in 10 μ M ACPC: no significant difference was found in the size of the NMDA currents compared to previous measurements. Our results show that ACPC does not desensitize the NMDA receptors, suggesting that some other mechanisms may be involved in ACPC-induced neuroprotection.

NEW STRUCTURAL ANALOGUES OF A SELECTIVE NMDA RECEPTOR AGONIST WITH SURPRISING PHARMACOLOGICAL PROFILES. T. N. Johansen, K. Frydenvang, B. Ebert, U. Madsen and P. Krosgaard-Larsen*, Dept. Medicinal Chemistry, Royal Danish School of Pharmacy, DK-2100 Copenhagen, Denmark.

The heterocyclic acidic amino acid (RS)-2-amino-2-(3-hydroxy-5-isoxazolyl)acetic acid (AMAA) is a potent and selective N-methyl-D-aspartate (NMDA) receptor agonist. AMAA is an analogue of aspartic acid in which the 3-hydroxy-isoxazole moiety functions as a bioisostere of the distal carboxylate group of aspartic acid. In order to investigate the structural requirements for NMDA receptor interaction two analogues of AMAA, having different substituents in the 5-position of the isoxazole, the 5-hydroxymethyl (compound I) and the 5-*tert*-butyl (compound II) analogues, have been synthesized and tested *in vitro*.

Compound I is a selective NMDA receptor agonist with an electrophysiological profile in the rat cortical wedge preparation similar to that of AMAA, though slightly weaker. Surprisingly, compound II is a non-selective antagonist capable of inhibiting both NMDA and AMPA induced depolarizations in a dose dependant manner with IC₅₀-values of approx 100 μ M. Conformational analyses of the three compounds have shown that the rotational flexibility of the 4-glycyl moiety of the antagonist (compound II) is markedly reduced as compared to that of the similar glycol moieties in the two agonists (AMAA and compound I).

Compound II has been resolved using diastereomeric salt formation using (R)- and (S)-phenylethylamine and a BOC-protected derivative affording salts with a diastereomeric excess of 99.0 and 98.0 %, respectively. From the diastereomeric salts the two enantiomers have been prepared with high enantiomeric purity. The pharmacological profile of the two enantiomers is currently being investigated.

CHARACTERIZATION OF NMDA/GLYCINE RECEPTOR COMPLEX IN NEONATE RAT SYMPATHETIC PREGANGLIONIC NEURONS. S.Y. Wu* and N.J. Dun. Dept. of Anatomy, Medical College of Ohio, Toledo, OH 43614

Whole-cell patch-clamp recordings were made from sympathetic preganglionic neurons (SPNs) in transverse spinal cord slices of 10-16 day old rats. Pressure ejection of N-Methyl-D-Aspartate (NMDA) evoked in SPNs an inward current with a mean amplitude of 110 pA, rise time of 57 ± 0.66 s and decay time of 9.8 ± 2.2 s (mean \pm S.E., n=20). NMDA currents displayed a non-linear I-V relation with a region of negative slope conductance in the range of -90 to -60 mV in Krebs solution; the I-V relation was linear in Mg²⁺ free solution. The reversal potential, i.e. 0 mV, was the same in both solutions. Superfusion of glycine at low conc. (10-100 μ M) increased and at higher conc. (0.3 - 1 mM) decreased the NMDA currents; the holding current and decay time of NMDA currents were not affected by glycine. β -alanine increased and decreased NMDA currents in a dose-dependent manner similar to that of glycine. Methylmalonic acid, an inhibitor of glycine uptake, at low conc. (30-100 μ M) enhanced and at higher conc. (0.3-1 mM) depressed the amplitude without causing a significant change of the decay time of NMDA currents or the holding current. The strychnine-insensitive glycine binding site antagonists, 7-Cl-kynurenic acid (30 μ M) and HA-966 (100 μ M), depressed the NMDA currents by 71% and 56%. The enhancing or depressing effects of glycine on NMDA currents were not affected by prior superfusion of strychnine (1 μ M) in some cells. Strychnine increased the NMDA currents evoked in several SPNs and this effect could be blocked by 7-Cl-kynurenic acid and HA-966. The inward current induced by quisqualate was not affected by glycine nor by 7-Cl-kynurenic acid and HA-966. The results suggest that in SPNs the activation of strychnine-insensitive glycine binding sites is necessary for the expression of NMDA response and that the binding site is not fully saturated, probably owing to an active glycine reuptake system present in the spinal cord slices. (Supported by NS18710).

470.17

NMDA CHANNEL BLOCKADE DURING DEVELOPMENT PRODUCES AGE-SPECIFIC ALTERATIONS IN NMDA RECEPTOR DISTRIBUTION PATTERN. J. He, R. Sircar*, Laboratory for Developmental Neuroscience, Departments of Psychiatry and Neurology, Albert Einstein College of Medicine, Bronx, New York.

The NMDA receptor has been shown to play an important role in developmental plasticity. Phencyclidine (PCP) and PCP-like drugs (MK-801, ketamine) act as non-competitive antagonists at the N-methyl-D-aspartate (NMDA) receptor. We have earlier shown that postnatal PCP treatment in rats produced long-term changes in seizure susceptibility. Here we report the effects of chronic postnatal PCP treatment on the NMDA receptor distribution pattern. Pups were treated with PCP (5 mg/kg/day) for 11 days from postnatal days 5 to 15, intraperitoneally. Control pups received saline (1 ml/100 g). All rat pups were weaned on postnatal day 21. On postnatal days 21, 40, 60, and 180, separate groups of saline- and PCP-treated rats were sacrificed, their brains removed and immediately frozen in crushed dry ice. Brain sections were incubated with [³H]MK-801 in the absence and presence of excess nonradiolabeled MK-801, washed, dried and juxtaposed against tritium-sensitive film. Quantitative densitometric analyses of the autoradiographic films showed age-specific changes in [³H]MK-801 distribution patterns following postnatal PCP exposure.

CHARACTERISTICS OF GLUTAMATE RECEPTOR IN MEDIAL VESTIBULAR NUCLEUS (MVN) NEURONS. N. Sakai, N. Murakami, N. Saito¹, H. Ujihara^{*2}, M. Sasa³ and C. Tanaka¹ ¹Dept. of Pharmacology, Kobe University School of Medicine, Kobe 650, ²Dept. of Pharmacology, Yamaguchi University School of Medicine, Ube 755 and ³Dept. of Pharmacology, Hiroshima University School of Medicine, Hiroshima 734, Japan.

A patch clamp study was performed to examine pharmacological characteristics of glutamate receptors in acutely dissociated MVN neurons. In whole cell recording, a fast application of glutamate, α -amino-3-hydroxy-5-methyl-isoxazole-4-propionic acid (AMPA) and kainic acid (KA) up to 100 μ M produced dose-dependent current with reversal potentials of approximately 0 mV. These non-NMDA receptor agonists-induced currents had no desensitizing component and were completely blocked by 6-cyano-7-nitroquinoxaline-2,3-dione (CNQX) at 10 μ M. An addition of 3 μ M glycine potentiated glutamate-induced current. This potentiation was further augmented in the absence of magnesium. NMDA at 100 μ M also induced voltage-dependent current, only in the presence of glycine in the external solution. In the presence of magnesium at 1.3 mM, NMDA-induced current was not significantly inhibited under the membrane potential of -40 mV, although larger current was obtained in the absence of magnesium. The competitive NMDA receptor antagonist, 2-amino-5-phosphonopivalic acid (APV), also induced current with a same reversal potential of NMDA. MK-801 at 1 μ M, non-competitive NMDA receptor antagonist, did not significantly block NMDA-induced current. These results suggest the existence of glutamate receptors whose characteristics are different from that observed in other neurons of central nervous system.

470.16

DEVELOPMENTAL CHANGE OF THE VOLTAGE DEPENDENCY AND THE EFFECTS OF MODULATORS ON THE NMDA RESPONSE IN CENTRAL AUTONOMIC NEURONS. J. Nabekura*, H. Hamano, N. Horimoto, I. Kawamoto and T. Ogawa. Dept. of Physiology, Akita Univ. Sch. of Med., Akita, 010 Japan.

To examine the change in the characteristics of NMDA receptor mediated responses during development in the central autonomic neurons, the neurons were acutely dissociated from the nucleus tractus solitarius and ventromedial hypothalamus of the rats aged between 18 days in gestation (E18) and 21 days after birth (P21). The NMDA responses were measured by the use of a nystatin perforated patch recording configuration. Mg²⁺ block was less obvious in a number of fetal NTS neurons than in the neurons older than P9 and became rapidly apparent by P3. Protein kinase C (PKC) modulators such as staurosporine, H-7 and phorbol ester did not clearly affect the generation of the voltage-dependency of NMDA response in immature rats. In addition, the facilitatory effect of glycine on the NMDA response did not change in development. These evidences suggests that an appearance of the voltage-dependency of NMDA response in NTS neurons might be due to a developmental change in combinations of subunits composing the NMDA receptor and/or in the intracellular modulators of the NMDA other than PKC. In addition, Spermine enhanced the NMDA response in a dose-dependent manner in any age during development. However, the potentiation of NMDA response by spermine increased with age, without changing the NMDA concentrations for threshold, IC₅₀, and the maximal response. The potentiation reaches the mature level by P9.

These results indicate that NMDA receptor in the central autonomic neurons rapidly changes in function and acquires the mature characteristics by the early stage after birth.

470.18

DECREASED MAGNESIUM (Mg²⁺) BLOCK OF NMDA MEDIATED EXCITATORY POSTSYNAPTIC POTENTIALS (EPSPs) IN AGED FISCHER 344 RAT HIPPOCAMPUS. M.C. Jasek* and W.H. Griffith. Dept. of Medical Pharmacol. & Toxicol., Texas A&M Univ. Hlth Sci Center, College Station, TX 77843.

The purpose of the present study was to examine age-related changes in the Mg²⁺ sensitivity of N-methyl-D-aspartate (NMDA) synaptic potentials *in vitro* in F344 rat hippocampus. We utilized hippocampal CA1 field EPSPs in young (1-2 months) and aged (24-25 months) rats. Synaptic NMDA potentials were studied in isolation in the presence of 10 μ M DNQX. EPSP area was measured and all values were normalized to initial EPSPs prior to any drug application. In the presence of 10 μ M DNQX and no Mg²⁺, the normalized EPSP area was 1.45 ± 0.17 in young (n=6) and 1.86 ± 0.24 in aged (n=6). When 0.1 mM Mg²⁺ was added EPSP area in young decreased to 0.78 ± 0.18 while in aged, the area remained almost unchanged at 1.88 ± 0.19 . In young 0.3 mM Mg²⁺ decreased the normalized area further to 0.39 ± 0.12 while in aged 0.3 mM Mg²⁺ decreased the response to 0.88 ± 0.09 . There was a significant difference (p<0.01, independent t-test) between the two age groups at concentrations of 0.1 mM and 0.3 mM Mg²⁺ indicating an age-related decrease in the sensitivity to the Mg²⁺ block. Similar experiments testing the non-NMDA synaptic potential (using 50 μ M APV instead of DNQX) resulted in no significant difference in Mg²⁺ sensitivity between age groups. These latter results suggest that the age-related changes in NMDA synaptic potentials were due to alterations in postsynaptic sensitivity and not due to changes in neurotransmitter release. 471.1

SPECIFIC DETECTION OF NEUROTENSIN METABOLITES IN THE RAT BRAIN BY *IN VIVO* MICRODIALYSIS/ELECTROSPRAY MASS SPECTROMETRY. P.E. Andren*, M.R. Emmett and R.M. Caprioli. Analytical Chemistry Ctr., Dept. of Biochemistry & Molecular Biology, Univ. of Texas Medical School, Houston TX 77030

We have developed a highly sensitive microelectrospray mass spectrometry (uES MS)-technique in order to detect attomole levels of neuropeptides from brain microdialysis (Md) perfusates. Md samples were desalted on a nano-LC (50 μ m i.d.) C18-column at a flow rate of 800 nL/min which was then eluted directly into the mass spectrometer for ES MS analysis. In the present experiments we have studied *in vivo* neurotensin (NT) metabolism in rat striatum. NT is a putative neurotransmitter or neuromodulator in brain and several of the NT-fragments retain biological activity. The detection limit of the nano-LC/uES MS system was less than a total of 100 attomol when synthetic NT was injected.

A Md probe was stereotactically implanted into the striatum of an anesthetized rat and an infusion of 1 μ M NT through the microdialysis probe was performed at 0.3 μ L/min. NT was metabolized *in vivo* and NT-fragments were obtained in the Md perfusate and analyzed by nano-LC/uES MS. MS spectra showed that NT was metabolized to fragments 1-12, 1-11, 1-10, 1-8, 3-8 and 7-11. We will also show results of experiments which are designed to monitor endogenous NT and its metabolic fragments.

471.3

DOPAMINE D-2 REGULATION OF NEUROTENSIN RELEASE FROM STRIATUM AND NUCLEUS ACCUMBENS AS MEASURED BY MICRODIALYSIS. J.D. Wagsstaff*, J.W. Gibb, and G.R. Hanson. Dept. of Pharmacology and Toxicology, University of Utah, Salt Lake City, UT 84112.

Neurotensin (NT) is closely associated with extrapyramidal and limbic dopamine (DA) systems. It is speculated that this peptide neurotransmitter plays an important role in the regulation of these DA pathways and, in turn, NT release is controlled in part by alterations in DA activity. This has not been satisfactorily tested *in vivo* as the low levels of extracellular NT are difficult to detect consistently. Through a modification of the methods described by Maidment et al. (*Neurosci.* 45:1, 1991), we have developed a highly reliable method of measuring changes in extracellular NT in the striatum and nucleus accumbens in awake rats by *in vivo* microdialysis. Using this technique, release of NT is evoked by infusing a high concentration of potassium (100 mM) through the microdialysis probe; this potassium-evoked release is calcium-dependent. Further, we have examined the effect of stimulating the DA D-2 receptor subtype on NT release. Systemic administration of the D-2 agonist, quinpirole (5 mg/kg), induced a rapid increase of approximately 200% in extracellular NT in the striatum and 40-60% in the nucleus accumbens. This study shows that DA systems are important factors in controlling NT release in extrapyramidal and limbic DA terminal fields, and that stimulation of D2 receptors activates associated NT pathways in awake animals. (This work was supported by USPHS grants DA 04222 and DA 00869.)

ACIDIC SULFUR-CONTAINING AMINO ACIDS, γ -GLUTAMYL AND β -APARTYL PEPTIDES IN HUMAN CEREBROSPINAL FLUID

C.-M. Bergström, A. Hamberger and M. Sandberg* Dept. of Anatomy and Cellbiology, Univ. of Göteborg, S-413 90 Göteborg, SWEDEN

A method for the determination of acidic amine containing substances in human cerebrospinal fluid (CSF) is presented. The automated technique is based on precolumn derivatisation of primary amines with o-phthalaldehyde/2-mercaptoethanol, separation by reversed phase HPLC and fluorescence detection. Three different techniques with complementary selectivities were employed in order to minimize false identification. Addition of 2-mercaptoethanol to the CSF was necessary to avoid oxidation of cysteine to cysteine sulfinate. The dominant peptides were γ -glutamylglutamine and glutathione followed by β -aspartyltaurine, β -aspartylglycine and γ -glutamylcysteine. The sulfur-containing amino acids cysteine sulfinate, homocysteate, homocysteine sulfinate and sulfo-S-serine could not be detected.

471.2

STRUCTURE SPECIFIC DETECTION OF ENDOGENOUSLY RELEASED NEUROPEPTIDES BY MASS SPECTROMETRY AND *IN VIVO* MICRODIALYSIS. Mark R. Emmett*, Per Andren and Richard M. Caprioli. The Analytical Chemistry Center, Dept. of Biochemistry & Molecular Biology, University of Texas Medical School, Houston, Texas 77030.

In vivo microdialysis (Md) has been used to monitor a variety of endogenous neurotransmitters. Md has not been widely used to study endogenous neuropeptides due to low extracellular concentrations coupled with poor recoveries and salt contamination of the samples. Because of the dilute nature of the microdialysates (attomole/ μ L), previous experiments have been performed with radioimmunoassays of wide specificity which interact with all proteins/peptides containing short homologous sequences.

Micro-electrospray, an ultra-high sensitivity mass spectrometric ionization technique, has been developed that permits the detection of endogenous neuropeptides from *in vivo* microdialysates with structural (amino acid sequence) specificity. We have coupled nano-LC (C-18 packed, 50 micron i.d., 40 nL bed vol. columns) for the separation of neuropeptides. This system has been used to measure the specific release of endogenous methionine enkephalin (M-enk) from the globus pallidus/ventral pallidum area of rat brain in response to local depolarization by 100 mM KCl and the specific release of endogenous neurotensin from rat hypothalamus under similar conditions. In addition, we have demonstrated the pharmacologically stimulated release of M-enk after the systemic administration of morphine (10 mg/Kg, I.P.).

MOLECULAR HETEROGENEITY OF NEUROPEPTIDE Y IN CSF. K. Maeda*, M. Yasuda, H. Kaneda, K. Sakai and S. Maeda. Hyogo Inst. for Aging Brain Cognitive Dis., Himeji 670, Kobe Univ. Sch. of Med. Kobe 650 Japan.

We have examined the molecular heterogeneity of neuropeptide Y-like immunoreactivity (NPY-LI) and somatostatin-like immunoreactivity (SLI) in human cerebrospinal fluid (CSF). Gel chromatography, not high performance liquid chromatography (HPLC), suggested two NPY immunoreactive materials in CSF. Both gel chromatography and HPLC revealed three SLI components in CSF: somatostatin 14, somatostatin 28 and a higher molecular weight precursor. We have also measured peptide-LI in control subjects and in patients with various neurologic disorders. We observed a significant reduction in CSF SLI in control subjects over 60 years of age, compared with the younger controls. CSF SLI was significantly decreased in multiple sclerosis (MS), or Guillain-Barre syndrome, compared with that of age-matched control subjects. A reduced concentration of NPY-LI was found in CSF of patients with MS. Our results suggest that (1) the possible heterogeneity of NPY molecules occurs in human CSF, and (2) somatostatin neurons might be more susceptible than NPY neurons in various pathological conditions and aging.

SPINAL CORD DYNORPHIN NEURONS: DO DIFFERENT NOCICEPTIVE STATES ACTIVATE DIFFERENT BIOCHEMICAL ADAPTIVE MECHANISMS TO COPE WITH INCREASED DEMAND? V.M. Medina* and A.R. Gintzler. Dept. of Biochemistry, SUNY Hlth. Sci. Ctr. at Brooklyn, N.Y. 11203

Late gestation and parturition are associated with an opioid analgesia that is mediated, in part, by a maternal lumbar spinal cord dynorphin/ κ analgesic system. Recently, this laboratory demonstrated that the activation of spinal dynorphin neurons during the gestational period is accompanied by a marked decrease in dynorphin precursor content (50%). This suggests that increased rates of processing of dynorphin intermediates is a major biochemical adaptation by which spinal dynorphin neurons adjust to the increased demands of pregnancy. In order to assess the generality of this coping mechanism, spinal cord dynorphin precursor content was assessed in a rat model of arthritis, a condition in which lumbar dynorphin neurons are also activated. In these experiments, peripheral inflammatory lesions were produced by injecting Freund's adjuvant into the hind ankle. The magnitude of tryptic generation of leucine-enkephalin-arginine was used as an indicator of dynorphin precursor content. In contrast to the pregnant vs nonpregnant state, there was no significant difference in dynorphin precursor content in cervical, thoracic or lumbar spinal cord obtained from Freund's Adjuvant-treated vs vehicle-treated controls. These results suggest that different nociceptive states can activate different biochemical adaptive mechanisms that enable spinal cord dynorphin neurons to cope with increased demand.

PARATHYROID HORMONE-RELATED PEPTIDE (PTHrP) IS A CEREBELLAR GRANULE CELL NEUROPEPTIDE PRODUCED IN RESPONSE TO VOLTAGE-SENSITIVE CALCIUM CHANNEL ACTIVATION. E.H. Holt, B.E. Dreyer, A.E. Broadus, and M.L. Brines*. Departments of Cellular and Molecular Physiology and Internal Medicine, Yale University, New Haven, CT 06510.

Parathyroid hormone-related protein (PTHrP) is a secretory protein widely expressed in mammalian tissues. In the adult rat brain it is expressed in the cerebellum and hippocampus, as well as in isolated neurons in the cerebral cortex. PTHrP is encoded by a complex gene distinct from that of parathyroid hormone (PTH). Although PTHrP bears strong homology to PTH in its N-terminus, the rest of the protein is unique.

Primary cultures of neonatal (P8) rat cerebella are ideal for studying the regulation and function of PTHrP because the highly enriched granule cells possess high levels of the peptide and its receptor. On immunocytochemistry, PTHrP is seen in the cell bodies of neurons; preliminary studies on PTHrP receptor mRNA in neuron- or glia-enriched cerebellar cultures suggest the receptor is present on glia as well as neurons.

Cerebellar cultures require chronic depolarization with 25 mM potassium (K^+) for survival. Under these conditions, they produce and release high levels of PTHrP. Changing these cultures to media with physiologic (5 mM) K^+ is associated with a rapid decay of PTHrP mRNA. When these cells are again depolarized in 25 mM K^+ media, PTHrP mRNA returns to its original level within 4-6 h. Release of the peptide into culture media follows similar kinetics. PTHrP mRNA expression in response to depolarization is blocked by the L-type voltage-sensitive calcium channel (L-VSCC) antagonist nifedipine, or by omitting extracellular calcium (Ca^{2+}). The L-VSCC agonist Bay K 8644 mimics the effects of 25 mM K^+ on PTHrP mRNA expression. In contrast, the calcium ionophore A23187 does not stimulate PTHrP mRNA expression, even at high concentrations (20 μ M). These results demonstrate the fundamental importance of Ca^{2+} influx through L-VSCCs in controlling PTHrP expression.

In summary, we have described the localization and regulation of a newly identified cerebellar neuropeptide, PTHrP, whose expression requires L-VSCC activity. The presence of the peptide and its receptor in the same primary cultures makes these cultures ideal for further studies of the function of this protein.

INTRACELLULAR ROUTING AND METABOLISM OF ANGIOTENSIN II IN BOVINE ADRENAL MEDULLARY CELLS IN PRIMARY CULTURE. J.M. Wang¹, W. Annaert¹, F. Goossens², C. Van Broeckhoven^{2*} and W.P. De Potter¹. ¹Lab. Neuropharmacol., Dept. Medicine, ²Lab. Med. Biochem., Dept. Pharmacy, and ³Dept. Biochem., Univ. Antwerp (UIA), 2610 Wilrijk, Belgium.

Previous work has demonstrated that angiotensin II (AII) is internalized in bovine adrenal medullary (BAM) cells via a process of receptor mediated endocytosis. Here we report new data on the fate of the internalized ligand in cultured BAM cells. After long term incubation with [¹²⁵I]AII or pulse-chase experiments followed by sucrose density gradient centrifugation of a post-nuclear fraction, the distribution of the internalized ligand paralleled the distribution of horseradish peroxidase (HRP, 4-5 min incubation as a marker for early endosomes). The determination of subcellular organelle markers indicated that the internalized AII was not present in lysosomes. When the cells were pulsed with [¹²⁵I]AII for 5 min, followed by 0, 10, and 30 min chase, increasing amounts of radioactivity were released to the extracellular medium. At 0 min no significant radioactivity could be detected in the medium, after 10 min, 33% of the initial radioactivity was recovered and this value increased to 57% after 30 min chase. In order to investigate the nature of the released AII-related radioactivity, samples were applied to gel filtration followed by HPLC on a Vydac C₁₈ column. The elution profile revealed 3 peaks, of which the two main ones could be identified as AIII and A(1-7), two breakdown products of AII. Our results demonstrate that, after internalization, the majority of the metabolites is recycled to the extracellular medium. On the basis of these results we assume that the degradation takes place in the endosome compartment. From the physiological point of view, it is possible that the metabolized AIII and A(1-7) exert either autocrine, paracrine or both effects on the surrounding chromaffin or cortex cells.

471.11

IN VITRO AND IN VIVO EVIDENCE FOR A ROLE OF AMINOPEPTIDASE A (APA) IN CCK₈ DEGRADATION. M. Migaud, E. N. Chauvel, M.-C. Fournié-Zaluski, B. P. Roques, and C. Durieux*. Laboratoire de Pharmacochimie Moléculaire et Structurale, INSERM U266, CNRS URA D 1500, 4, Av. de l'Observatoire 75006 PARIS.

Cholecystokinin octapeptide (CCK₈) is widely distributed in the mammalian brain where it may act as a neurotransmitter. Although previous studies have shown that many peptidases can cleave CCK₈ *in vitro*, the enzymatic processes responsible for its inactivation *in vivo* are not clearly established. Using the brain slices superfusion technique, a selective aminopeptidase A (APA) inhibitor, Homo-Glu-thiol, was shown to increase significantly the endogenous CCK-like immunoreactivity ($p < 0.01$) from rat hippocampal slices. Under the same conditions the serine peptidase inhibitor Ala-Ala-Pro-Val-COCH₂Cl produced a small but non significant increase and Leu-thiol, an aminopeptidase N inhibitor was ineffective. The affinity of CCK₈ alone or in association with peptidase inhibitors was determined using *in vivo* binding experiments in mice and compared with the fully enzymatic-resistant and potent agonist pBC 264. CCK₈ was 200-fold less potent than BC 264 in inhibiting the specific binding of [³H]pBC 264. Among the peptidase inhibitors tested, Homo-Glu-thiol was the most potent in protecting CCK₈ from degradation, leading to a 100-fold increase in its affinity. Taken together, these results show the critical role played by aminopeptidase A in the interruption of CCK₈ conveyed messages.

471.8

EFFECTS OF NEURONAL DIFFERENTIATION ON LUTEINIZING HORMONE-RELEASING HORMONE IN SK-N-SH HUMAN NEUROBLASTOMA CELLS. Anna Ratka*, Scott E. Mambourg, Bruce E. Torian, Becky Flores, Department of Pharmaceutical Sciences, College of Pharmacy, Idaho State University, Pocatello, ID 83209.

In our attempts to elucidate the nature of functional interactions between Luteinizing Hormone-Releasing Hormone (LHRH) and opioid receptors at the neuronal level we have employed an *in vitro* model - opioid receptors-containing SK-N-SH human neuroblastoma cells. The SK-N-SH cells differentiate into a neuronal phenotype after exposure to retinoic acid (RA). Recently we have found that the SK-N-SH cells possess the gene to express LHRH. To further characterize the LHRH system in SK-N-SH cells, the concentrations of LHRH and the LHRH mRNA levels were measured during neuronal differentiation. Cells were treated with RA (10 μ M) for 1 hr, 2, 4, and 6 days. The amount of LHRH was measured by the ELISA procedure. The longer the treatment with RA the more pronounced decrease in LHRH concentration. LHRH concentrations (μ g/mg protein) changed as follows (no RA vs RA): 3.2 \pm 0.1 vs 2.5 \pm 0.2 after 1 hr, 5.1 \pm 0.3 vs 1.9 \pm 0.1 after 2 days, 5.2 \pm 0.1 vs 3.0 \pm 0.2 after 4 days, and 7.1 \pm 0.4 vs 1.8 \pm 0.1 after 6 days. Treatment of SK-N-SH cells with RA for 6 days caused more than two-fold reduction of the LHRH mRNA level; 20.3 vs 8.7 OD \times mm². We conclude that in SK-N-SH human neuroblastoma cells the LHRH mRNA as well as LHRH concentrations decrease during the process of differentiation into a neuronal phenotype.

IMPULSE FLOW DEPENDENCY OF GALANIN RELEASE IN VIVO IN THE RAT VENTRAL HIPPOCAMPUS. S. Consolo*, G. Baldi, G. Russi, T. Bartfai*, A. Vezzani. Istituto "Mario Negri", 20157 Milan, Italy; *Dept. Neurochemistry and Neurotoxicology, Stockholm University, S-10691 Stockholm, Sweden.

Using microdialysis and a sensitive radioimmunoassay we have studied the *in vivo* release of the neuropeptide galanin (GAL) from the ventral hippocampus of freely moving rats. The spontaneous outflow of GAL-like immunoreactivity (GAL-LI) (1.8 fmol/ml/20 min) was dependent on the presence of extracellular Ca^{2+} and was inhibited by tetrodotoxin (TTX). Evoked release induced by infusion of KCl (60 mM) or veratridine (148 μ M) was also Ca^{2+} -dependent and sensitive to TTX. Electrical stimulation of the ventral limb of the diagonal band nuclei induced a frequency-dependent (50-200 Hz) and TTX-sensitive overflow of GAL-LI in the hippocampus. *In vitro* GAL-LI release, studied in slices of rat ventral hippocampus, was also Ca^{2+} dependent and increased in a concentration-dependent manner by KCl depolarization. This study provides the first demonstration of *in vivo* GAL release in the ventral hippocampus. This release is related to the activity of the cholinergic GAL-LI containing cells in the septal diagonal band nuclei.

We thank CNR, Rome, Italy, Convenzione Psicofarmacologia.

PYROGLUTAMYL PEPTIDASE II ACTIVITY IS NOT IN THE PROCESSES OF RAT BULBOSPINAL TRH-ERGIC NEURONS. P. Joseph-Bravo*, M. E. Fresán, M. Cisneros, M. A. Vargas and J.-L. Charli. Instituto de Biotecnología, Universidad Nacional Autónoma de México, A.P.510-3, Cuernavaca, Mor., México 62271.

Pyroglutamyl peptidase II (PPII) [E.C. 3.4.19.6] is a neuronal ectoenzyme enriched in synaptosomes. Various of its properties, including its narrow specificity, suggest it is involved in the inactivation of TRH released into the synaptic cleft. Because synaptosomes contain pre and postsynaptic elements, we do not know whether the enzyme is pre or postsynaptic. No specific antibodies, irreversible inhibitors or mRNA sequence information have so far been obtained. Therefore, in an attempt to define if it is present in the pre or postsynaptic membrane we induced neuronal degeneration of serotonin-TRHergic cells that project from raphe nuclei to the spinal cord. TRH levels were measured by RIA and PPII activity by a specific radiochemical assay. Two to four weeks after intracisternal injection of 200 μ g 5,7-dihydroxytryptamine to adult male Wistar rats, TRH levels decreased over 70% in the cervical, thoracic or lumbar regions of spinal cord. In contrast, PPII activity was unaffected in each region. However, 6-8 weeks after injection, a 59-66% increase in activity was detected in the lumbar region. Previous studies had demonstrated that destruction of bulbospinal TRH neurons lead to an increase in spinal cord TRH receptors. Our data suggest that PPII is not localized in the processes of bulbospinal TRHergic neurons but probably in the target cells. (Supported in part by grant IN-204791 from DGAPA-UNAM).

PURIFICATION AND CHARACTERIZATION OF RAT BRAIN TRANSGLUTAMINASE. H. Ohashi, Y. Itoh, P.J. Birckbichler and Y. Takeuchi. Tsukuba Research Institute, Banyu Pharmaceutical Co., Ltd., Tsukuba 300-33, JAPAN and Noble Center for Biomedical Research/OMRF, 825 N.E. 13th Street Oklahoma City, OK 73104

Transglutaminase (TGase) in neuronal system has been suggested to be involved in neurotransmitter release, long term potentiation, Alzheimer's disease, and so forth. In order to have molecular basis on the enzyme in the central nervous system, the enzyme was purified to apparent homogeneity from the centrifugal supernatant of male SD rat brain homogenate, using DEAE ion exchange, heparin affinity, and casein agarose affinity column chromatographies. The purified enzyme has a molecular weight of 75kDa on SDS-polyacrylamide gel electrophoresis analysis. The TGase activity was Ca^{2+} dependent ($\text{EC}_{50} = 0.38\text{mM}$), and was maximal in a pH range of 8.0 - 9.5. Km values for putrescine and N-dimethylated casein were approximately 0.3mM and 0.05mM, respectively. GTP inhibited the enzyme activity 100-fold more potently than ATP did. Iodoacetate completely inhibited the enzyme activity, suggesting the involvement of cysteine residue in brain TGase. Zn^{2+} potently inhibited the enzyme activity, while Mg^{2+} was not inhibitory at all. The rat brain TGase did not give immunoreactivity to antibodies against known types of TGase such as tissue type TGase, epidermal TGase and coagulation factor XIIIa. The results suggest a novel type of TGase in mammalian brain.

ONO-1603 INHIBITS BRAIN PROLYL OLIGOPEPTIDASE *IN VITRO*, *IN VIVO* AND *IN SITU*. N. Katsube, H. Maegawa, Y. Kagamiishi, M. Yamamoto* and H. Aishita. CNS Division, Discovery Research Laboratories, Minase Research Institute, Ono Pharmaceutical Co., Ltd., Osaka 618, Japan.

ONO-1603, (S)-1-[N-(4-chlorobenzyl)succinamoyl]pyrrolidine-2-carbaldehyde, inhibited prolyl oligopeptidase (POP) purified from bovine brain *in vitro* with competitive manner (K_i value, 12 nM). Oral administration of ONO-1603 also inhibited POP of rat brain in several regions *in vivo* for 0.25 - 4 hrs. To examine the inhibitory effects of ONO-1603 on brain POP *in situ*, we established a novel method for the evaluation of continuous POP activity in the brain of freely moving rats using the microdialysis technique. 7-(N-succinyl-Gly-Pro)-4-methylcoumarinamide, a specific substrate for POP, was continuously perfused into the hippocampus of the rat brain through the dialysis probe, and the 7-amino-4-methylcoumarin (AMC) level in the dialysate (the product by enzymatic reaction with POP) was monitored. In dialysate, the AMC was continuously and stably appeared, and was decreased by the administration of carbobenzoxy-proline-proline, a prototype inhibitor of POP, indicating that the AMC level in dialysate reflects the brain POP *in situ*. Following the oral administration of ONO-1603, the AMC levels in dialysate from the hippocampus markedly decreased in a time- and dose-related manner, and the AMC was gradually recovered to the basal level. From these observations, it is demonstrated that ONO-1603 is an orally active inhibitor of the brain POP.

471.17

CHARACTERIZATION AND PHYSIOLOGICAL FUNCTION OF LUQIN IN THE CENTRAL NERVOUS SYSTEM OF *APLYSIA CALIFORNICA*. R. S. Aloyz, A. Angers and L. DesGroseillers. Department of Biochemistry, University of Montreal, Montreal, Canada, H3C 3J7.

We are investigating the role of neuropeptides in renal physiology. Left Upper Quadrant (LUQ) neurons and neuron L10 in the central nervous system of *Aplysia* have been shown to extensively innervate the kidney and regulate renal functions. Three neuropeptide precursor genes (LUQ-1, L5-67 and L10-M), which are differentially expressed in these cells, have previously been cloned. However, the nature of the physiologically relevant peptides which they express is still unknown. In this study, metabolic labeling of the LUQ cells and RP-HPLC separation of their peptide content allowed us to identify the L5-67 precursor and the processed peptides. Cleavage of the signal peptide occurred between amino acids 23 and 24 of the prepropeptide and generated a propeptide of 89 amino acids. Further processing by endopeptidases at the twin basic residues $\text{Lys}^{12}\text{-Arg}^{13}$ of the precursor generated a peptide of 76 amino acids, as well as an amidated decapeptide, LUQIN. Immunoprecipitation of labeled LUQ peptides and RT-PCR on mRNA isolated from neurons L2-6 allowed us to identify a 4 kDa LUQ peptide which could arise by differential splicing. The sequence of LUQIN was determined by amino acid sequencing and by its comigration with the synthetic peptide Ala-Pro-Ser-Trp-Arg-Pro-Gln-Gly-Arg-Phe-amide in three different RP-HPLC systems. The amidation of LUQIN was further demonstrated by its resistance to carboxypeptidase A digestion. When applied to neuron L10, LUQIN induced a long-lasting inhibition of L10 activity. No other neurons in the abdominal ganglion, when tested at random, responded to LUQIN. Finally, LUQIN has also been purified from the kidney.

METABOLIC CONVERSION AND *IN VITRO* BLOOD-BRAIN BARRIER PERMEABILITY OF AN ENKEPHALIN ANALOG PRO-DRUG. D.L. Greene*, V.S. Hau, S.J. Weber, T.J. Abbruscato, V.J. Hruby and T.P. Davis. Dept. of Pharmacology and Chemistry, Univ. of Arizona, Tucson, AZ 85724.

To improve blood-brain barrier (BBB) penetration of the delta opioid receptor ligand [D-Pen², D-Pen⁵] Enkephalin (DPDPE), a pro-drug Phe⁰-DPDPE was synthesized to increase lipophilicity. BBB penetration studies used an *in vitro* bovine brain microvessel endothelial (BMEC) model. *In vitro* conversion was studied using mouse serum and brain resuspended at 15% protein. Phe⁰-DPDPE (100 μM) was added to samples time-course incubated at 37°C. Samples were analyzed by HPLC. To study the rate of conversion to DPDPE, specific aminopeptidase inhibitors were added. To study BBB penetration, BMECs were grown to a confluent monolayer, suspended and seeded onto membrane filters. Permeability coefficients (P.C.) were determined to give the rate of penetration in cm/min. The resultant conversion half-time for Phe⁰-DPDPE to DPDPE was 6.8 min in serum and 3.9 min in brain. After adding 6 μM amastatin (aminopeptidase M inhibitor) to the brain homogenate and 50 μM bestatin (leucine aminopeptidase inhibitor) to the serum, the half life of Phe⁰-DPDPE conversion increased to >500 min. The P.C. (cm/min) for Phe⁰-DPDPE ($62.0 \pm 4.1 \times 10^{-4}$) was 21% higher than that of its parent compound DPDPE ($49.2 \pm 2.8 \times 10^{-4}$). These results show that the pro-drug Phe⁰-DPDPE has a longer conversion time in serum than in brain. The results also show that two aminopeptidases are responsible for cleaving Phe⁰-DPDPE to DPDPE and the addition of phenylalanine to the amino terminus of DPDPE increases the BBB penetration to the brain using the BMEC model of the BBB. (Supported by N.I.D.A. #DA06284 and N.I.H. - HL7479-09)

THE ISOLATION OF FMRFamide-LIKE PEPTIDES FROM THE NEMATODE *Haemonchus contortus*. C. Keating, M. C. Thorndyke*¹, L. Holden-Dye, R. G. Williams & R. J. Walker. Dept Physiology and Pharmacology, University of Southampton, Southampton, UK, SO9 3TU and ¹ Dept Biology, Royal Holloway and Bedford New College, Egham, Surrey, UK.

Two FMRFamide (Phe-Met-Arg-Phe-NH₂) like peptides (FLPs) have been isolated from the nematode *Ascaris suum*. These are Lys-Asn-Glu-Phe-Ile-Arg-Phe-NH₂ which can be abbreviated to KNEFIRFamide or AF1 and Lys-His-Glu-Tyr-Leu-Arg-Phe-NH₂, KHEYLRamide or AF2.

We are presently attempting to purify novel FLPs from the nervous system of the parasitic nematode *Haemonchus contortus* using reverse phase high pressure liquid chromatography (rpHPLC). We are monitoring the purification steps with a radio-immunoassay, using an anti-KYSALMFamide antibody (Elphick *et al.* 1991). We have already demonstrated SALMFamide like immunoreactivity in the nervous system of this parasite (Keating *et al.* 1993). In this study we have purified a FLP from this organism and identified it as AF2. We have also purified a second immunoreactive peptide which we are presently characterizing. We have shown that AF2 potentiates the effect of acetylcholine in *Ascaris* dorsal muscle strips and that AF2 induces spontaneous activity in *Ascaris* dorsal muscle.

These findings show that AF2 has now been shown to exist in a second parasitic nematode and it may be that this peptide is ubiquitous throughout this Phylum.

CHARACTERIZATION OF cDNAs ENCODING *APLYSIA CALIFORNICA* FURIN AND PC2. G.T. NAGLE*, A.T. GARCIA, S.L. KNOCK, E. GORHAM AND A. KUROSKY. Marine Biomedical Institute and Departments of Anatomy & Neurosciences, Humanities & Basic Sciences, and Human Biological Chemistry & Genetics, University of Texas Medical Branch, Galveston, TX 77555.

The neuroendocrine bag cells and exocrine atrial gland of *Aplysia californica* express genes belonging to the egg-laying hormone (ELH) family and process the resulting precursor at mono-, di-, tri-, and tetrabasic sequences. Some of these cleavages may result from proteolysis by a furin-like or PC2-like enzyme; these enzymes have been identified in organisms as diverse as yeast and humans. The atrial gland is particularly interesting because the organ produces large (milligram) amounts of ELH-related peptides and may be a relatively rich source of prohormone processing enzymes. An atrial gland cDNA library was constructed and screened using a furin-related PCR probe and a clone encoding a furin-like protein was isolated. The insert is identical to a furin-related PCR product from the bag cells. The library was also screened using a *Lymanaea* PC2 probe (provided by A.B. Smit and W.P.M. Geraerts, Holland) and a clone encoding a PC2-like protein was isolated. Both clones have relatively long 3' untranslated regions (UTR's). The 3'-UTR's contain multiple polyadenylation sites which could be used to generate multiple mRNAs. Furthermore, the 3'-UTR's also contain relatively long microsatellite repeat sequences (CA)_n and (TG)_n. The eventual goal of these studies is to elucidate the potential role of these enzymes in prohormone processing in *Aplysia*. Supported by NIH Grant NS 29261.

PROHORMONE CONVERTASE 2 IS EXPRESSED IN PROENKEPHALIN CONTAINING NEURONS IN DEVELOPING AND ADULT RAT CEREBELLUM. Y. P. Loh, A.M. Bamberger*, W. P. Hayes, and L. P. Pu. Lab. of Devel. Neurobiol, NICHD NIH, Bethesda, MD 20892.

The enzymatic processing of peptide precursors at basic amino acids is a key step in neuropeptide biosynthesis. Prohormone convertase 2 (PC2) may participate in such processing. We have examined the distribution of PC2 mRNA in rat cerebellum during postnatal development and in adult and compared it with that of proenkephalin mRNA and enkephalin precursor. Using *in situ* hybridization, we showed that PC2 mRNA was expressed in a distinct layer pattern in adult rat cerebellum. The Purkinje cell layer expressed very high levels of PC2, while the granular cell layer showed low levels of expression. High expression of PC2 mRNA was also found in Golgi cells. Similarly, proenkephalin mRNA was detected in Purkinje cells and Golgi cells. During cerebellar development, PC2 and proenkephalin mRNAs were present as early as postnatal day 1 (P1). With age, there was a gradual increase in the expression of PC2 mRNA in Purkinje and Golgi cells through adult, which correlated well with that of proenkephalin mRNA. Interestingly, a transient expression of PC2 mRNA was observed in granule cells, which appeared as early as P1 and increased to a maximum at P28, an age corresponding to cell division and maturation. Further, by *in situ* hybridization combined with immunocytochemistry, a cellular coexistence of PC2 mRNA and proenkephalin was found in enkephalin expressing Purkinje cells and Golgi cells. These findings implicate the role of PC2 in neuronal proenkephalin processing in both developing and adult cerebellum.

472.5

IDENTIFICATION OF AT₁ LIGANDS IN THE RAT BRAIN AND DEMONSTRATION OF *in vivo* SYNTHESIS INDEPENDENT OF ANGIOTENSIN CONVERTING ENZYME ACTIVITY. B.A. Mungall*, A.E. Ball, J.W. Harding and J.W. Wright. Program in Neuroscience and Departments of Veterinary and Comparative Anatomy, Pharmacology, Physiology and Psychology, Washington State University, Pullman, WA 99163.

We have recently discovered a unique angiotensin AT₁ receptor site, assumed to bind endogenous angiotensin IV. We have provided definitive evidence regarding the identity of the naturally occurring ligand acting at this site. Utilizing acetic acid peptide extraction, High Performance Liquid Chromatography separation and Radioimmunoassay detection, we have identified and quantified angiotensin IV-like N-terminal peptides in rat cerebellum, cortex, striatum, hippocampus, thalamus and hypothalamus with high binding affinity for this AT₁ receptor. In addition, *in vivo* metabolism studies utilizing radiolabelled peptide infusion via push pull cannulation, have revealed cleavage of angiotensin I to angiotensin (2-10) and then subsequently to angiotensin IV-like peptides with high affinity for the AT₁ receptor both in control (untreated) and captopril treated rats. *In vitro* metabolism studies of cerebellum homogenates have confirmed these findings. These studies indicate the presence of high affinity endogenous AT₁ ligands, and formation of these peptides independent of the classical renin-angiotensin pathway involving angiotensin converting enzyme (ACE). ACE inhibitors are widely used in cardiovascular therapy as antihypertensive agents for treatment of congestive heart failure, myocardial infarction and stroke. The possibility of AT₁ activation playing a role in the observed effects of captopril therapy, especially on mood and cognition may provide an insight into the mechanism of ACE inhibitors.

472.2

Yeast Aspartic Protease 3 Cleaves Prohormones at Selective Paired and Mono-Basic Residues with Preference for a Lys/Arg Residue Upstream from the Cleavage site. N. X. Cawley^{1,3}, H.-C. Chen², M. C. Beinfeld⁴ and Y. Peng Loh^{1,3*}. From the ¹Lab. of Develop. Neurobio. and ²Endocrin. and Reprod. Research Branch, NICHD, NIH, Bethesda, MD 20892 and the ³Uniformed Services University of the Health Sciences, Bethesda, MD 20814 and the ⁴Dept. Pharmacological and Physiological Sciences, St. Louis University Medical Center, St. Louis, MO 63104.

The novel yeast aspartic protease 3 (YAP3) was overexpressed by induction of yeast strain BJ3501 that was transformed with a plasmid containing the YAP3 gene under the control of the galactose inducible promoter. YAP3 was secreted into the growth media and was partially purified by concanavalin A affinity chromatography. The specificity of YAP3 was studied using a number of polypeptide substrates: porcine cholecystokinin 33 (CCK33), porcine dynorphin A(1-11), porcine dynorphin B/rimorphin(1-13) and bovine proinsulin. Analysis of the products generated from each substrate demonstrated that YAP3 cleaved at selective paired and mono-basic residue sites generating CCK8 and CCK22 from CCK33; Leu-enkephalin and Leu-enkephalin-Arg from dynorphin A and dynorphin B respectively and an extended form of insulin from proinsulin. Cleavage at mono-basic residues occurred only when a Lys/Arg was present in the -4, -5 or -6 position relative to the cleavage site.

472.4

EFFECT OF NICOTINE ON PROENKEPHALIN mRNA LEVEL, SECRETION OF [MET⁵]-ENKEPHALIN, AND AP-1 DNA BINDING ACTIVITY IN BOVINE ADRENAL MEDULLARY CELLS. J.H. W. Suh*, 2P. M. Hudson, 2M. K. MaMillian, 2K. P. Das, 2B. C. Wilson, 2G. C. Wu, and 2J. S. Hong. ¹Dept. Pharmacol. Coll. Med., Hallym Univ., Chunchon, Korea, and ²LMN/NIEHS/NIH, RTP, NC U.S.A.

The effects of nicotine on the secretion of [Met⁵]-enkephalin (ME) in addition to proenkephalin A (proENK) mRNA levels, AP-1 DNA binding activity, and on the transcriptional activity of the proENK gene were studied in bovine adrenal medullary chromaffin (BAMC) cells. Nicotine (10 μM) caused a rapid secretion of ME followed by a long-term secretion into the medium. Post-treatment with hexamethonium plus atropine, nimodipine, calmidazolium or KN-62 up to 6 hr after the nicotine treatment significantly inhibited increases of proENK mRNA level, the secretion of ME, and AP-1 DNA binding activity induced by nicotine. However, nicotine-induced responses were not affected when these agents were added 9 or 12 hr after the nicotine treatment. The results of the nuclear run-on assay showed that nicotine increases the transcriptional rate for the proENK gene after 30 min and the response continues for up to 9 hr with a maximal increase of 2- to 2.5-fold. Our results suggest that the long-term stimulation (for at least 6 hr) of nicotinic receptors is required for the increases in proENK mRNA levels and the long-term secretion of ME in BAMC cells. The nicotine-induced long-term secretion of ME followed an increased biosynthesis of ME during the first 6 hr which appeared to result from increased transcription of the proENK gene followed by increased synthesis of proENK mRNA.

ANATOMICAL RELATIONSHIP BETWEEN GENES ENCODING PROHORMONE CONVERTASES AND PRO-TRH IN ADULT RAT BRAIN: IMPLICATION IN DIFFERENTIAL PROCESSING OF PRO-TRH. L. P. Pu*, W. Ma, J.L. Barker and Y. P. Loh. Labs. of LDN, NICHD and LNP, NINDS, NIH, Bethesda, MD 20892.

Pro-TRH in the CNS is differentially processed at paired-basic residues to generate several copies of TRH along with other neuropeptides. The mechanism for such differential processing is not yet known. Recently, prohormone convertases (PC1 and PC2), responsible for paired-basic residue cleavage, are found to be expressed in neuroendocrine system. We have used *in situ* hybridization histochemistry to analyse the anatomical relationship between genes encoding PC1, PC2, and pro-TRH in rat brain. PC1 and PC2 mRNA expressing cells were widely distributed throughout the brain. Expression levels of PC1 and PC2 mRNAs differed in various brain regions with PC2 showing a broader distribution. Regions with high concentrations of PC1 and PC2 cells demonstrated a good correspondence with that of pro-TRH cells. They included olfactory bulb, forebrain areas, hippocampus, hypothalamic nuclei, and several nuclei in brainstem. However, not all brain areas with high levels of pro-TRH mRNA had high levels of PC1 and PC2 mRNAs. For example, in thalamic reticular nucleus pro-TRH mRNA was expressed, but neither PC2 mRNA nor PC1 mRNA was detectable. By performing double-labeling *in situ* hybridization histochemistry, a cellular coexistence of PC1 or PC2 mRNAs with pro-TRH mRNA was found in a differential manner in several brain regions. These results suggest that the different expression patterns of PC1 and PC2 in pro-TRH neurons may be responsible for the differential processing of pro-TRH in various rat brain regions.

TISSUE DISTRIBUTION AND DEVELOPMENTAL STUDY OF APLYSIA PRO-HORMONE CONVERTASE PC2. T. Ouimet* and V.F. Castellucci. Lab. of Neurobiology and Behavior, IRCM, Univ. de Montréal, Montréal, Québec, H2W 1R7.

The nervous system of the marine mollusc *Aplysia californica* contains many neuropeptides which must undergo proteolytic cleavage at multibasic sites to release their bioactive moiety. We have recently characterized the cDNA structure of a subtilisin-like serine protease of the nervous system of *Aplysia* (aPC2) which appears to be a homolog of the vertebrate PC2, of the pro-hormone convertase family. *In-situ* hybridization shows a large distribution of aPC2 mRNA in the nervous system. Study of the tissue distribution of the aPC2 transcript by Northern blot analysis also revealed its presence in the atrial gland as well as in muscle. This last result was also confirmed by *in-situ* hybridization. Northern blot analysis of early stages of *Aplysia* development reveals the presence of a shorter transcript. Thus, aPC2 seems to have a larger distribution in *Aplysia* than in vertebrates where it seems to be restricted to neuroendocrine tissues. Furthermore, different aPC2 transcripts seem present during development. Funded by MRC of Canada (MT-12099).

GLUTAMATERGIC REGULATION OF STRIATAL PEPTIDE GENE EXPRESSION IN RATS. J. Jolkkonen*, P. Jenner and C.D. Marsden. Dept. of Neurology, Univ. of Kuopio, Kuopio, Finland, Pharmacology Group, King's College, London, U.K. and Univ. Dept. of Clinical Neurology, The National Hospital, London, U.K.

Nigrostriatal dopaminergic neurons are known to regulate enkephalin and substance P gene expression in the striatum. We studied possible modulation of striatal peptide mRNA levels by corticostriatal glutamate input following disruption of glutamate neurons, glutamate release and receptor binding.

Glutamate afferents were bilaterally lesioned by partial frontoparietal ablation of the cerebral cortex, glutamate release was inhibited by lamotrigine treatment (5 and 20 mg/kg, i.p., once a day) and NMDA receptors were blocked by intrastriatal infusion of CPP (0.12 and 1.2 µg/day). Striatal peptide mRNA levels were measured one week following the start of the experiment by using *in situ* hybridization histochemistry according to Young *et al.* (1986). Coronal brain sections (12 µm) cut at three different rostrocaudal levels of the striatum were incubated with ³⁵S-labelled oligonucleotide probes, apposed to X-ray film and average optical densities were analyzed by computerized densitometry.

Following decortication both enkephalin and substance P mRNA levels were decreased particularly in dorsolateral part of the rostral striatum (17.0-25.8%). The overall hybridization signal for striatal peptide mRNA was not affected by subchronic administration of lamotrigine. NMDA receptor blockade by CPP infusion decreased enkephalin (14.4-34.6%) and substance P mRNA levels (13.9-38.2%) in a dose-dependent manner in the striatum.

It seems that enkephalin and substance P gene expression in the rat striatum is also regulated by glutamate in addition to the well-established dopaminergic regulation.

472.11

ONTOGENY OF PROENKEPHALIN IN RAT: ITS CORRELATION WITH PROTEOLYTIC PROCESSING ENZYME GENE EXPRESSION. M. Zheng* and J.E. Pintar. Dept. of Anat. and Cell Biol., Columbia Univ. P&S, New York, NY 10032 and Dept. of Neurosci. and Cell Biol., UMDNJ Robert Wood Johnson Med. Sch., Piscataway, NJ 08854.

Proenkephalin (PE) is a proprotein which, through selective endoproteolytic cleavage, gives rise to opioid peptide enkephalins and many larger enkephalin-containing peptides (ECP). Gene transfer experiments have shown that the endoprotease PC2 is capable of performing extensive cleavage of PE, whereas PC1 and furin cleave PE only to a limited extent. It is not known which of these enzymes are coexpressed with PE and therefore may actually be involved in PE processing *in vivo*. Using *in situ* hybridization we have examined the ontogeny of PE mRNA expression and compared it with proteolytic processing enzyme gene expression. PE expression is first detected at a low level in the wall of truncus arteriosus at e10. By e12 its expression has expanded to cover the aortic sac and common ventricular chamber, which overlaps with furin expression. In the nervous system, PE expression is detected in the restricted regions of the thalamus, striatum, pons, medulla, and the spinal cord from e14 onward. At these stages, PC2 is expressed widely in the CNS and overlaps extensively with PE expression, whereas PC1 expression overlaps with PE expression only in the medulla. In mid- and late gestational stages PE expression is also detected at a high level in a variety of mesenchymal tissues, which overlaps with furin expression. Together these data suggest that PE expressed in development may be processed in a tissue-specific manner by different sets of endoproteases. In the nervous system PE may be processed extensively by PC2 and to a small extent by PC1, generating enkephalin pentapeptides or smaller ECPs. PE in the peripheral tissues, in contrast, may be processed to only a limited extent by furin, which is consistent with reported lack of detectable free enkephalins in tissues outside of nervous system. Supported by DA-08622 (JEP).

REGULATION OF CHOLECYSTOKININ mRNA BY RETINOIC ACID AND β-ADRENERGIC AGENTS IN CELL LINES. B. L. Mania-Farnell*, I.W. Botros, and T.P. Davis. Department of Pharmacology, College of Medicine, University of Arizona, Tucson, AZ 85724.

Regulation of cholecystokinin (CCK) mRNA expression was studied in two CCK expressing cell lines, the human neuroepithelioma cell line SK-N-MCIXC and a rat medullary thyroid carcinoma cell line WE 4/2. SK-N-MCIXC cells express the CCK gene at high levels and perform post-translational processing of CCK (Konings *et al.*, Neuropeptides 25, 1993; Verbeek and Burbach, FEBS 268, 1990). WE 4/2 cells contain high levels of CCK and process pro-CCK to biologically active forms (Beinfeld, Peptides 13, 1992). To examine the effect of β-adrenergic agents on CCK mRNA we used the β-adrenergic agonist isoproterenol. We also treated cells with a combination of isoproterenol and the β-adrenergic antagonist propranolol. The effect of retinoic acid on the modulation of CCK gene expression was also examined. Messenger RNA levels were quantitated using Northern blot analysis with a cRNA CCK probe. Isoproterenol significantly increased CCK mRNA levels in SK-N-MCIXC cells after 6, 12 and 24 hr treatments, the increase was blocked when isoproterenol was combined with propranolol. In WE 4/2 cells isoproterenol increased CCK mRNA levels after 6 hrs, although not significantly, the increase was no longer present after 12 hrs. Retinoic acid had no effect on CCK mRNA levels in WE 4/2 cells at 6 or 12 hr treatments; however, there were significant decreases in CCK mRNA levels in SK-N-MCIXC cells after 6, 12 and 24 hrs. Our results indicate that CCK mRNA levels may be differentially regulated in these two cell lines in response to β-adrenergic agents and retinoic acid. (Supported by N.I.H. Grant DK 36289 and MH42600 and MRC Grants MT11268 and PG2.)

472.10

ISOLATION OF THE GC-RICH, TATA-LESS PROMOTER FOR THE GENE ENCODING THE BIFUNCTIONAL ENZYME PAM. Hand, T.A., Mains, R.E., Eipper, B.A.* Dept. of Neuroscience, The Johns Hopkins University School of Medicine, Baltimore, MD 21205.

PAM (peptidylglycine α-amidating monooxygenase) is a bifunctional enzyme catalyzing the 2-step conversion of glycine extended COOH-terminal neuroendocrine peptides to α-amidated bioactive products. The 27 protein coding exons of the single copy PAM gene were isolated from rat genomic libraries and span more than 160 kb of DNA. Since the expression of PAM is tightly regulated in a tissue and developmentally specific manner, isolation of the promoter was undertaken. Exon 2 of the PAM gene contains 301 nts of 5'-UTR and the start methionine; primer extension data indicated that the longest cDNA clone isolated lacked the most 5'-end of PAM. Using RACE, products isolated from atrium and neurointermediate lobe (NIL) contained 98 nts of upstream coding sequence preceding Exon 2. Screening a genomic library yielded a clone containing 69 nts of the sequence in the RACE product (Exon 1) flanked by consensus intron/exon junction sequences. Subsequent screening of a cDNA library (made from the NILs of haloperidol-treated rats) with a 5'-specific probe revealed a clone having an additional 21 nts of upstream coding sequence. Exon 0 was identified by screening the genomic library with an oligomer complementary to the most 5'-sequence. The clone identified contained the 50 nts of Exon 0 followed at the 3' end by a consensus exon/intron junction sequence. A highly GC-rich sequence having several consensus SP1 binding sites but lacking TATA or CAAT sequences preceded Exon 0. Two kb of the upstream sequence (PAM-US) was subcloned into a reporter vector (pGL2, Promega) in the sense or antisense orientation and transiently transfected into GH3 cells, which endogenously express PAM. The PAM-US sense construct yielded levels of luciferase expression at least 150 times those of the antisense construct. Support DK 32949.

DEVELOPMENTAL EXPRESSION OF PEPTIDYLGLYCINE α-AMIDATING MONOOXYGENASE IN THE RAT. J. Zhang*, M. Zheng, B.A. Eipper, and J.E. Pintar. Dept. Neurosci. & Cell Biol., UMDNJ Robert Wood Johnson Med. Sch., Piscataway, NJ 08854 and Dept. Neurosci., Johns Hopkins Univ. Sch. of Med., Baltimore, MD 21205.

Posttranslational processing of peptide precursors frequently includes amidation of C-terminal glycine residues following proteolytic cleavage, which is performed by peptidylglycine α-amidating monooxygenase (PAM). To evaluate the contribution of this peptide modification process in development, we have begun to examine the ontogeny of PAM gene expression in the Sprague-Dawley rat by *in situ* hybridization. Using a probe that recognizes all PAM isoforms, we thus far have detected a high level of PAM expression in the heart (in both atrium and ventricle) as early as embryonic day 10 (e10). In the developing nervous system PAM mRNA is present at least as early as e14 in regions outside the ventricular layer and is particularly high in the cortical plate, hypothalamus, and spinal cord. By midgestational stages (e16-e18), PAM transcripts are also widespread in tissues outside of the nervous system and are particularly abundant in mesenchyme surrounding developing limb cartilage and are also notable in the lung, muscle, adrenal, and testis. We also have used a variety of probes that distinguish alternatively-spliced forms of PAM to determine the relative abundance of different PAM forms and whether there is cell-type specific accumulation of different PAM transcripts. Results from these studies suggest that exon-B containing PAM transcripts are the predominant PAM mRNAs at all ages examined and are found in most, if not all, tissues. In addition, rPAM-4 transcripts, which encode only the peptidylglycine α-hydroxylating monooxygenase portion of PAM, are relatively enriched in the dorsal horn of the spinal cord but are essentially absent from the ependymal region of the intermediate zone, an area rich in exon-B containing PAM transcripts. Taken together, these results provide evidence for widespread expression and alternative splicing of PAM during development. Supported by DA-08622 (JEP) and DA-00266 (BAE).

AN *IN VITRO* MODEL FOR THE STUDY OF NEUROTRANSMITTER REGULATION OF HYPOTHALAMIC GENE EXPRESSION D.M. Witt* and H. Gainer. Laboratory of Neurochemistry, NINDS, NIH Bethesda, MD 20892.

Determination of the specific neural mechanisms involved in stimulus-coupled neuropeptide gene expression is limited by the complexities of the *in vivo* environment which include a multitude of neural networks and feedback circuits. Conventional primary tissue cultures, devoid of these complexities, are usually maintained for long periods of time *in vitro* before they can be used for experiments, and often alter their normal properties during the culture period. We have developed an *in vitro* model for examining neurotransmitter / neurosteroid effects in brain slices that are acutely maintained in a controlled environment.

By combining electrophysiological preparations, organotypic slice explant technology, and immunocytochemistry we have been able to study immediate early gene (IEG) expression in acute slice explants of the paraventricular nucleus of the hypothalamus (PVN) from postnatal rats. Following *in vitro* stimulation (1.5 hrs), using either K⁺ (40 mM) depolarization or glutamate (10-100 μ M) stimulation, IEG expression was enhanced in oxytocin / vasopressin neurons, primarily in magnocellular regions of the PVN. This new approach enables the assessment of the efficacy of specific stimuli to regulate neuropeptide gene expression in the mammalian hypothalamus.

NEURONAL SPECIFIC PROCESSING OF VGF PROTEIN LEADS TO THE PRODUCTION AND REGULATED SECRETION OF PEPTIDES DERIVED FROM ITS CARBOXY-TERMINAL. R. Possenti*, A.M. Rinaldi*, N. Canu, A. Levi, G.L. FerriS, M.T. Ciotti, E. Trani. Institute of Neurobiology CNR, Via C. Marx 15, Rome, Italy; *Dept. Citomorphology, University of Cagliari; * Dept. Experimental Medicine, University of Tor Vergata, Rome.

VGF, a protein of 617 aminoacids, has a restricted expression *in vivo* in sub-populations of neuronal and endocrine cells. By the use of polyclonal antibodies directed against different domains of VGF we demonstrated that *in vivo* as well as *in vitro* neuronal cells are able to cleave this protein in smaller peptides. This processing is not observed in adrenal medulla chromaffin cells. PC12 cells, a line established from a rat pheochromocytoma, are unable to process VGF, but acquire the ability to mature this protein upon neuronal differentiation in response to NGF. In primary cultures of cerebellum granule cells the *in vitro* maturation correlates with increased processing of VGF. The major products of the VGF cleavage are a polypeptide of apparent molecular weight 20 kDa and a doublet in the 14-10 kDa range which are derived from the COOH-terminal of the protein. These products are enriched in preparation of dense core vesicles from neuronal cells and are preferentially secreted upon depolarisation in neuronal primary culture and cell lines. We suggest that these VGF-derived peptides are the biologically relevant species which may play a role in neuronal communication.

DIFFERENTIAL EFFECTS ON NEOSTRIATAL NEUROPEPTIDE mRNA ABUNDANCE BY EXCITATORY AMINO ACID RECEPTORS M. Villegas, L. Lucas*, B. McEwen* and J. Angulo*, *Lab of Neuroendocrinology, Rockefeller University and Dept. of Biological Sciences, Hunter College CUNY, New York, N.Y. 10021.

Cortical, thalamic and amygdaloid inputs to the neostriatum employ excitatory amino acids as transmitters. These inputs play a central role in excitation of neostriatal neurons most of which utilize neuropeptides as transmitters and/or modulators. The effects of NMDA and AMPA/kainate receptor blockade on the expression of preproenkephalin (PE), protachykinin (PT) and prodynorphin (PD) mRNAs in the caudate-putamen (CPU) and nucleus accumbens (NAC) were assessed with MK801 and CNQX (NMDA and AMPA/kainate antagonists, respectively). Daily systemic injections with MK801 for seven consecutive days increased the abundance of all three neuropeptide mRNAs in the caudate-putamen and accumbens. (1) PE mRNA abundance was increased in the anterior CPU (26%) dorsal and ventral CPU (46% and 39%, respectively) but was unaffected in the NAC. (2) PT mRNA was increased in the NAC (33%) as well as anterior CPU (27%), dorsal CPU (43%) and ventral CPU (67%). (3) PD mRNA was elevated in dorsal and ventral regions of the CPU (49% and 24%, respectively) and in anterior CPU (50%). In the NAC PD mRNA was increased only at the higher dose (0.1 mg/kg) of MK801. In contrast, systemic injections of CNQX for seven consecutive days decreased PE and PT mRNA abundance approximately 30% below controls in dorsal and ventral aspects of the CPU and accumbens. These observations demonstrate that NMDA and AMPA/kainate receptors differentially modulate neuropeptide expression in the neostriatum of the rat brain.

472.14

EXPRESSION OF THE PRE-PROSOMATOSTATIN GENE AND SOMATOSTATIN IMMUNOREACTIVE FORMS IN THE HUMAN NEUROBLASTOMA LA-N-2 CELL LINE.

Ronnie Folkesson*, Lena Bergström, Lars Nilsson and Bengt Winblad. Karolinska Institute Clinical Neuroscience, Geriatric Medicine, Novum KFC Huddinge, Sweden.

Initial screening of different human neuroblastoma cell lines for expression of Somatostatin immunoreactivity (SS-ir) and prepro-SS mRNA revealed only one candidate, the neuroblastoma LA-N-2 cell line. Extracted SS-ir material from LA-N-2 cells was analyzed and compared with SS-ir extracted material from rat hypothalamus after gel filtration. The SS-ir in each fraction was analyzed with RIA revealing three major peaks of SS-ir forms in the rat hypothalamus extract. The predominate peak coeluted with SS-14 the second peak coeluted with SS-28 and the third peak was found close to the void volume and corresponded to an estimated molecular weight of 15 kDa. In contrast the SS-ir extracted from the LA-N-2 cell line showed, a quite different elution pattern. Three peaks of SS-ir were measurable, one which corresponded in elution position to synthetic SS-28 and two others which corresponded to approximately 8 kDa and 15 kDa. No immunoreactivity was observed in the fractions coeluting with synthetic SS-14. Total cellular RNA from LA-N-2 cells was prepared and examined for the expression of prepro-SS mRNA by Northern blot analysis revealing the presence of a single prepro-SS mRNA of about 850 nucleotides in LA-N-2 cells. In addition this cell line is cholinergic which providing opportunities to investigate how the somatostatinergic and cholinergic systems interact. Such interactions are of interest considering the marked reduction of these two transmitters in cognitive disorders including Alzheimer's disease.

ALTERED PRODUCTION OF PROHORMONE CONVERTASE 2 (PC2) mRNA IN THE ARCuate (ARC) OF MIDDLE AGED FEMALE C57BL/6J MICE. D. Joshi*, M.M. Miller, N. G. Seidah and R. Day. Departments of Experimental Medicine, Obstetrics and Gynecology, Anatomy, and Center for Studies on Aging, McGill University; Clinical Research Institute of Montreal, Montreal, Quebec, Canada

We have previously reported a significant increase in the proportion of β -endorphin (β -endo)(1-27) and (1-26) forms in ARC of middle aged irregularly cycling female C57BL/6J mice (Joshi et al. 1993). PC2, an endoprotease of subtilisin/kexin family, mediates cleavage of β -endo(1-31) to β -endo(1-27). The objective of this study was to determine if an increase in PC2 expression is associated with the observed change in β -endo processing. PC2 mRNA was measured using an antisense cRNA probe to mouse PC2. ARC of young (4-5mo) normally cycling (n=5) and middle aged (12-13mo) irregularly cycling (n=5) female mice in diestrus of the estrous cycle were pooled for Northern blot analysis. A significant (p<0.01) increase in the PC2 mRNA was observed in ARC of middle aged animals as compared to young mice. For *in situ* hybridization, two sections each from five ARC subregions were examined in both young (n=3) and middle aged (n=3) mice. Film autoradiograms of *in situ* hybridization revealed a significant proportional increase in mid ARC PC2 mRNA (p<0.05 ANOVA) of middle aged mice vs. young females. These data suggest that there is an increase in the level of PC2 mRNA in ARC in middle aged female mice, which may account, at least in part, for altered processing of β -endo in middle aged irregularly cycling female mice. TRANSCRIPTIONAL REGULATION OF THE NPY GENE IN RESPONSE TO NGF.

D. Balbi, A. Pance, N. Holliday, J. Allen*. Physiological Laboratory, University of Cambridge, Cambridge CB2 3EG. UK.

Nerve Growth Factor has been reported to regulate the expression of the NPY gene in PC12 cells. The study of the intracellular mechanisms involved in mediating such responses may provide important clues about how neuronal cells integrate a variety of stimuli in order to produce a coordinated response. Using a CAT reporter system, we have shown that an AP-1 consensus sequence is responsible for most of the NGF-induced transcriptional activity of the NPY gene. However, a residual response to NGF was observed after the deletion of this AP-1 site, suggesting that other sequences are also involved. This residual response is mediated through both PKC and PKA dependent mechanisms. Specific inhibitors such as calphostin C (PKC) and H-89 (PKA) were shown to block only partially this residual response to NGF when applied alone, whereas combined application of both inhibitors completely blocked it. Two consensus sites for AP-2 transcription factors which are also present in the NPY promoter region, appear to be responsible for the residual activity of NGF. The deletion of these three sequences completely abolished the response to NGF. Basal levels of expression of the NPY gene in PC12 cells were also found to be mainly dependent on the two adjacent AP-2 sites.

FRAMESHIFT MUTATIONS AT HOTSPOTS IN VASOPRESSIN TRANSCRIPTS IN RAT AND HUMAN POST-MITOTIC NEURONS. F.W. van Leeuwen*, D.A.P. Evans and J.P.H. Burbach†. Neth. Inst. Brain Res., 1105 AZ Amsterdam, †Dept. Med. Pharmacol., Rudolf Magnus Inst., 3584 CG Utrecht, The Netherlands.

Mutations in DNA underlie carcinogenesis, inherited pathology and aging and are generally thought to be introduced during meiosis and mitosis. Here we report that in post-mitotic neurons specific frameshift mutations occur at high frequency. These mutations were identified in vasopressin transcripts in magnocellular neurons of the vasopressin-deficient homozygous Brattleboro rat and predominantly consist of a GA deletion at GAGAG-motifs. In homozygous Brattleboro rats substituted with vasopressin for 40 weeks and displaying a normalized water balance a 25% reduction in the number of vasopressin cells displaying a GA deletion was found. This indicates that the diseased state of the Brattleboro rat, resulting in a permanent activation of vasopressin neurons, enhanced the mutational rate. Using antibodies against peptides predicted from the +1 reading frame of vasopressin mRNA, immunocytochemical evidence was obtained for similar events in the hypothalamus of wild-type rats and human. These data have revealed hitherto unrecognized somatic mutations in non-dividing neurons. Such mutations are not restricted to the Brattleboro rat and may occur more widely in neuronal systems affecting other neuronal genes. Evidence for frameshift mutations in other genes will be presented.

CATECHOLAMINES: MEASUREMENTS, SPECT, LESIONS—IMMEDIATE EARLY GENES

VOLTAMMETRIC CHARACTERIZATION OF ELECTRICALLY-STIMULATED SOMATO-DENDRITIC DOPAMINE RELEASE IN MESENCEPHALIC SLICES. S.J. Cragg*, M.E. Rice and S.A. Greenfield. Univ. Dept. Pharmacology, Oxford OX1 3QT, UK; Dept. Physiology & Biophysics, NYU Medical Center, New York, NY 10016.

Somato-dendritic release of dopamine (DA) from the substantia nigra (SN) and ventral tegmental area (VTA) may represent a non-classical form of signaling in those regions. We have used fast-scan cyclic voltammetry (FCV) with 8 μ m carbon fiber microelectrodes to detect endogenous dopamine efflux *in situ* from tyrosine-hydroxylase (TH)-positive regions of superfused slices from guinea pig mid-brain. Release was monitored during local electrical stimulation, using a train of 100 pulses delivered at 10 Hz. Signals attributable to DA were identified on the basis of anatomical, electrochemical and pharmacological criteria. The response exhibited site-specific variation that correlated well with TH staining: release was significantly higher in VTA ($1.04 \pm 0.19 \mu$ M) than in SN pars compacta ($0.52 \pm 0.05 \mu$ M), which was in turn significantly higher than in SN pars reticulata ($0.34 \pm 0.03 \mu$ M).

The voltammogram of the released substance had oxidation and reduction peak potentials that corresponded to those of DA and the signal evoked in the DA-rich striatum, and were distinguishable from those of 5-HT. The response had apparently no contribution from DOPAC, since it was unaffected by 20 μ M pargyline. Electrically-stimulated DA release was Ca^{2+} -dependent, but TTX-independent. The selective DA uptake blocker, GBR 12909 significantly increased the response (260% of control), while desipramine, a selective inhibitor of NE uptake had no significant effect. We conclude that the direct monitoring of stimulated DA release *in situ* with carbon fiber electrodes can provide new insights in to the mechanism and function of dendritic release.

Multicomponent Analyses of Monoamines and Related Compounds in Cerebrospinal Fluid by High Performance Liquid Chromatography (HPLC) Coupled With Electrochemical Array Detectors. C.J. Hope*, P. Huettl, E. Issa, D. Kirch² and G.A. Gerhardt. Dept. of Psychiatry, Univ. of Colorado Health Sciences Center, Denver, CO, ¹NIMH, Washington D.C., and ²Medical College of Georgia, Augusta, GA.

Recent studies in our laboratory have involved the detailed analyses of monoamine neurotransmitters and related species in CSF using HPLC coupled with multichannel coulometric electrochemical array detectors. Such approaches allow for the analysis of up to 30 neurochemicals in a single sample. Frozen CSF samples (0.5 ml) are thawed, diluted to 1 ml with mobile phase, filtered and divided into two 0.5 ml fractions. An isocratic HPLC system consisting of a single pump, C18 reverse phase column (4.6 mm X 100 mm, 3 μ m particles, Hypersil; Keystone) and a dual-channel electrochemical array detector (ESA 5100A, E₁ oxidation and E₂ reduction using a 5011 cell) is used to measure low levels of dopamine, norepinephrine, DOPAC and other species using a pH 4.0 citrate-acetate mobile phase with 4-7% MeOH and 0.32-0.37 mM OS. A gradient HPLC with sixteen coulometric electrochemical detectors set at increasing potentials ranging from 0 mV to 1200 mV (CEAS; ESA Inc.) is used for the measurement of tyrosine, tryptophan, homovanillic acid and up to 20 other neurotransmitter related compounds. Separations performed with the CEAS are carried out with a combination of both phenyl (4.6 mm x 150 mm, 5 μ m particles, BDS Hypersil Phenyl; Keystone) and sulfonic acid (4.6 mm x 30 mm, 5 μ m particles, 100 SCX; Keystone) columns using a gradient elution with a pH 3.0 phosphate buffer containing 0-17.5% ethanol. The use of the electrochemical array chromatography systems for studies of monkey and human CSF samples will be presented.

473.2

REDUCTION/OXIDATION RATIOS AND NEUROTRANSMITTER IDENTITY: EFFECT OF NAFION COATING THICKNESS. R.T. Marrocco*, C.R. Harns, Collazo & M.C. Davidson. Dept. of Psychiatry, UC San Diego School of Medicine, La Jolla, CA 92093 and Institute for Neuroscience, Univ. of Oregon, Eugene, OR 97403.

Studies utilizing *in vivo* voltammetry to investigate the evoked release of catecholamines commonly use Nafion coated carbon fiber electrodes. Electrochemical signals from cations may be detected chronoamperometrically by applying a positive potential step (vs. an Ag/AgCl reference electrode) to the working electrode to oxidize electroactive molecules. The reverse current flow generated by the return of the potential to its previous value reduces the oxidized electroactive species. The ratio of the reduction to oxidation current at the maximum oxidation current is termed the reduction/oxidation (RO) ratio. It has been suggested that the RO value gives some indication of the identity of the major species measured (Gratton *et al.*, *Neurosci.* 29: 57-64, 1989).

We have recently found that the RO ratio may be related to the thickness of the electrode's Nafion coating. Nafion was applied by simple immersion or with electric current. Our results showed that as the amount of Nafion coating increased, the RO ratio also increased when the only substance added to the calibration medium was noradrenaline, dopamine, or serotonin. Moreover, increases in the duration of applied voltage also produced systematic changes in RO ratio. A three fold-increase in plating time caused a comparable increase in RO ratio for noradrenaline. While dopamine may usually exhibit a larger RO ratio than noradrenaline or serotonin, that ratio may be different for each electrode. Also, once the electrode is in the brain, the Nafion coating may begin to thin and RO ratios will change. Thus, RO ratios depend on the neurotransmitter present and the properties of the detecting electrode.

A STABLE LOW MAINTENANCE HPLC FOR THE SIMULTANEOUS ANALYSIS OF CATECHOLAMINES, INDOLES AND THEIR METABOLITES. J.D. Harvey-White and J.W. Kopin*. Clinical Neuroscience Branch, National Institute of Neurological Disorders and Stroke, 9000 Rockville Pike, Bethesda, MD 20892.

Procedures for obtaining a consistently stable, sensitive, and low maintenance HPLC with electrochemical detection for the simultaneous analysis of norepinephrine, epinephrine, dopamine, dihydroxyphenylalanine (L-DOPA), dihydroxyphenylacetic acid (DOPAC), 4-hydroxy-3-methoxyphenylalanine (3OMDOPA), 4-hydroxy-3-methoxyphenylethylamine, homovanillic acid (HVA), 5-hydroxyindoleacetic acid (5HIAA), and serotonin (5HT) are described. Conditions to meet different experimental needs for optimal selectivity, and sensitivity have been determined. 1-Heptanesulfonic acid (HSA) is used as the ion-pairing agent. The retention times (RT) for HVA, 5HIAA, and DOPAC are inversely related to the concentration of HSA (all other compounds are proportionately related). The RT of L-DOPA and 3OMDOPA (relative to other compounds) are greatly increased as pH is decreased. Resistance to complete drying of the mobile phase (MP) facilitates pump maintenance, the MP can be recycled for months, and the columns last 1 to 2 years. Addition of 1% EDTA/0.02% ethanol to dialysates stabilized all compounds of interest: with 0.1M perchloric acid tissue homogenates this addition stabilized DOPAC and 5HT, and increased the stability of 5HIAA.

COMPARISON OF TWO I-123 LABELED SPECT PROBES, FOR THE DOPAMINE TRANSPORTER IN NONHUMAN PRIMATE BRAIN. M. S. Al-Tikriti*, M. S. Gandelman, B. E. Scanley, Y. Zea-Ponce, R. M. Baldwin, S. S. Zoghbi, M. Laruelle, P. B. Hoffer, D. S. Charney, S. Wang, J. L. Neumeyer, R. B. Innis. Yale University and VA Med Ctr, West Haven, CT 06516 and Research Biochemicals Int., Natick, MA 01760.

A comparative SPECT evaluation of the regional uptake of 28-carboisopropoxy-38-(4-iodophenyl)tropane (IPCIT) and 28-carbomethoxy-38-(4-iodophenyl)tropane (8-CIT) was performed to assess the improved specificity of IPCIT over 8-CIT for the dopamine (DA) transporter. For IPCIT and 8-CIT five single bolus injection studies (n=10) ranging from 7-10 h with 6.9-15 mCi injected dose, were completed in 3 baboons (*Papio anubis*, 10 kg). Peripheral metabolism of the two ligands were similar as demonstrated by their respective clearances, 175 ± 35 l/h (mean \pm SD) for IPCIT and 134 ± 39 l/h for 8-CIT.

The SPECT images utilized ROIs over striatum (which reflect DA transporters), midbrain (previously shown for 8-CIT to reflect primarily serotonin transporters), and the cerebellar lobe (a region of nonspecific uptake). The time to peak specific striatal uptake (striatal minus cerebellar activity) was similar for IPCIT and 8-CIT (373 ± 51 and 360 ± 55 min, respectively). At time of peak specific striatal activity, striatal to cerebellar ratios were 2.9 ± 0.3 for IPCIT and 7.5 ± 0.8 for 8-CIT. However, the normalized striatal uptake values (μ Ci/cc per μ Ci injected dose per g body mass) for IPCIT (5.14 ± 0.8) were similar to those of 8-CIT (5.8 ± 1.4), whereas for the midbrain the normalized value were (3.8 ± 0.7) and (5.6 ± 1.1) for IPCIT and 8-CIT, respectively. In contrast, the normalized nonspecific uptake measured in cerebellum was higher for IPCIT (1.8 ± 0.4) than for 8-CIT (0.8 ± 0.3). In conclusion, [123 I]IPCIT demonstrated a higher DA transporter specificity and higher level of nonspecific uptake.

NIMODIPINE REVERTS THE DEPLETION OF EXTRACELLULAR DOPAMINE DURING ETHANOL WITHDRAWAL. Z.L. Rossetti, S. Carboni, R. Isola and J. DeVry*, Department of Neuroscience, University of Cagliari, Italy and *Tropon AG, Germany.

Withdrawal of chronic ethanol (EtOH) treatment in rats is associated with a profound inhibition of the mesolimbic dopamine (DA) system. DA depletion has been hypothesized to constitute a neurochemical correlate of the dysphoric and depressive state associated with withdrawal. However the cellular mechanisms underlying this phenomenon are poorly understood. Chronic EtOH treatment is known to be associated with an overactivity of L-type calcium channels. To assess whether L-type calcium channels have a role in the withdrawal-associated inhibition of the DA system, we studied the effect of the dihydropyridine calcium antagonist nimodipine on the extracellular DA in the ventral striatum of EtOH-withdrawn rats. In EtOH-dependent rats, twelve hrs following the last treatment (5g/kg every 6 h for 6 days), dialysate DA levels were about 30% of control, sucrose-treated rats. Nimodipine (2.5-10 mg/kg s.c.) dose dependently reverted the fall in DA output toward control values. At the dose of 10 mg/kg nimodipine raised DA output to about 160% of control. In contrast, the drug had no effect in control rats. Thus, overactivation of L-type calcium channels can mediate the inhibition of the mesolimbic dopaminergic system during EtOH withdrawal, presumably through inhibitory afferences to dopamine cells. In addition, our results suggest a potential use of nimodipine in the dysphoric and depressive state associated with EtOH abstinence syndrome.

FURTHER STUDIES ON THE RELATIONSHIP BETWEEN DOPAMINE CELL NUMBER AND NEUROLEPTIC RESPONSE. B. Hitzemann, K. Dains and R. Hitzemann*, Dept. of Psychiatry SUNY at Stony Brook, NY 11794 and Research Service, VAMC Northport, NY 11768.

Previous studies have shown that the genetic variability in the sensitivity to haloperidol-induced catalepsy is associated with the number of dopamine neurons in the substantia nigra zona compacta (SNZc) (JPET 266:431, 1993). To further investigate this relationship, we have used three different genetic strategies. Neuroleptic responsive (NR) and neuroleptic non-responsive lines were selected from the new heterogeneous stock/northport (HS/NP). At S_{12} , the lines differed 6-fold in their sensitivity to haloperidol-induced catalepsy. Confirming previous results, tyrosine hydroxylase (TH) cell number was significantly higher in the NNR line; the difference was most pronounced in the rostral SNZc where TH cell number was increased 23%. Fifty-two C57BL/6:DBA/2 (B6D2) F_2 hybrids were phenotyped for haloperidol response prior to determining TH cell number. Paralleling the results in the selected lines, TH cell number was significantly higher (range 10-28%) in the most non-responsive animals. TH cell number was determined in 10 inbred mouse strains that were previously phenotyped for haloperidol response. Among the inbred strains there was no significant correlation between response and cell number. The reasons for the differences between the first two and third genetic strategy are not clear but may suggest that epistatic interactions are present in the HS and F_2 animals but not the inbreds. These data bring into question the validity of using genetic correlations obtained from inbred strains.

CLINICAL APPLICATION OF A KINETIC ANALYSIS OF I-123 IBZM SPECT IN NEUROPSYCHIATRIC PATIENTS. R. Coppola*, M. B. Knable, S. S. Wolf, D. W. Jones, T. M. Hyde, D.R. Weinberger, NIMH Neuroscience Center, NIH, St. Elizabeths, Washington, D.C., 20032

I-123 IBZM, a dopamine D2 receptor antagonist, has been used for in vivo SPECT imaging to obtain measurements of dopamine receptor density. We have developed a simple kinetic analysis for time dependent IBZM uptake as an approximation of synaptic dopamine activity that emphasizes radioligand association and presumably endogenous dopamine release. We tested this approach in normals and in two neurological conditions in which alterations of striatal dopamine activity are thought to contribute to the pathophysiology. In patients with asymmetric clinical signs of Parkinson's disease (PD) (n=13) there was a nonsignificant increase in mean basal ganglia/occipital ratio of IBZM activity at 2 hrs contralateral to maximal clinical signs. Likewise, in MZ twins with Tourette's Syndrome (TS) discordant for ratings of severity (n=6 twin pairs), there was no difference between twins in bg/occ ratio. The rate of accumulation of IBZM (a parameter proportional to association and dissociation rates, receptor density and concentration of endogenous dopamine) in the basal ganglia over the 4 hr scan time revealed in the PD patients a mean slope that was significantly higher in the contralateral striatum ($p=0.02$). The more severely affected TS twins had a significantly decreased slope when compared to the less affected twins ($p=0.03$) and to normal controls ($p=0.03$). We conclude that the rate of accumulation of striatal IBZM activity reflects synaptic dopamine activity and possibly dopamine release since it is increased in the setting of decreased striatal dopamine concentration (PD) and is decreased in a disease purported to have increased striatal dopamine activity (TS). Furthermore, the rate of accumulation of IBZM activity is a more sensitive indicator of synaptic dopamine activity than single time point measurements of striatal/occipital ratio.

THE SIGMA LIGAND RIMCAZOLE ACTIVATES CATECHOLAMINERGIC NEURONS IN THE RAT HYPOTHALAMUS. M.J. Eaton, K.J. Lookingland and K.E. Moore, Dept. Pharmacology and Toxicology, Michigan State University, East Lansing, MI 48824.

The purpose of the present study was to investigate sigma receptor-mediated regulation of catecholaminergic neurons in the hypothalamus by examining the acute effects of rimcazole on concentrations of dopamine and its metabolite 3,4-dihydroxyphenylacetic acid (DOPAC) in various hypothalamic nuclei containing cell bodies or terminals of dopaminergic (DA) neurons and terminals of noradrenergic neurons. Rimcazole produced dose- and time-related increases in DOPAC concentrations in terminals of tuberoinfundibular DA neurons in the median eminence which were accompanied by decreases in plasma concentrations of prolactin. Within 15 min., rimcazole increased DOPAC concentrations without affecting concentrations of dopamine in periventricular, paraventricular, medial preoptic and dorsomedial nuclei of the hypothalamus; a neurochemical profile reflecting activation of DA neurons within these brain regions. By 30 min., concentrations of both DOPAC and dopamine within periventricular, paraventricular, medial preoptic and dorsomedial nuclei of the hypothalamus were elevated. This neurochemical profile is consistent with activation of noradrenergic neurons within these brain regions. These data suggest that rimcazole activates both DA and noradrenergic neurons within the hypothalamus. The stimulatory effects of rimcazole on tuberoinfundibular DA and noradrenergic neurons in the hypothalamus are similar to those produced by selective DA agonists such as quinolorane, therefore the ability of the D2 receptor antagonist raclopride to block the effects of rimcazole in these brain regions was assessed. Raclopride did not antagonize the effects of rimcazole indicating that its actions on catecholaminergic neurons within the hypothalamus are not mediated by D2 DA receptors. (Supported by NIH grant NS 15911)

473.10

D₂ DOPAMINE RECEPTOR DENSITY IN THE NEUROLEPTIC RESPONSIVE (NR) AND NEUROLEPTIC NON-RESPONSIVE (NNR) LINES SELECTED FROM THE HETEROGENEOUS STOCK/NORTHPORT (HS/NP). S. Kanes*, L. Cipp, K. Dains, B. Hitzemann and R. Hitzemann, Depts. Psychiatry, and Pharmacology, SUNY at Stony Brook, NY 11794 and Research Service, VAMC, Northport, NY 11768.

We have previously demonstrated (JPET 61:341, 1992 and Psychopharmacol. 103:244, 1991) that NR and NNR lines selected from HS/lbg stock differ significantly in D₂ receptor density; the NNR line has a significantly higher somatodendritic receptor density throughout the midbrain but a lower receptor density in the lateral striatum. Recently, we confirmed that among 8 inbred mouse strains (C57BL/6, DBA/2, C3H, BALB/c, LP, A, AKR and CBA), the strains least sensitive to haloperidol-induced catalepsy had the highest somatodendritic receptor density (JPET 267: 538, 1993). However, differently than the selected lines, there was a trend to higher receptor density among the non-responsive strains in the lateral striatum. These eight inbred strains were crossed to form a new HS stock. After 8 generations of random breeding, a new selection of NR and NNR lines was begun. At S_{12} the lines differed 6 fold in their ED_{50} for haloperidol-induced catalepsy. Receptor binding to the D₂ family of receptors was determined using [125 I]-epidepride and quantitative receptor autoradiography. The data obtained parallel the results obtained from the inbred strains - receptor density was higher both in the substantia nigra and striatum. Similar results have also been obtained in C57BL/6:DBA/2 F_2 animals phenotyped for haloperidol response and D₂ receptor density.

473.11

MAPPING THE GENES CONTRIBUTING TO CHOLINERGIC AND DOPAMINERGIC NEURON DENSITY USING THE BXD/TY RI STRAINS. K. Dains,* B. Hitzemann and R. Hitzemann. Departments of Neurobiology and Behavior, and Psychiatry, State University of New York at Stony Brook, Stony Brook, NY 11794 and Psychiatry Service, VAMC, Northport, NY.

Two traits associated with neuroleptic-induced catalepsy are the density of cholinergic cells in the caudate-putamen and the density of dopaminergic cells in the substantia nigra (Hitzemann, et al., 1993). By analyzing the BXD/Ty series of mice we were able to obtain significant quantitative trait loci (QTL) associated with haloperidol-induced catalepsy (Kanes, et al., 1994) and the above traits. These QTL include the microsatellites D9MIT22, D9MIT4 and D9MIT21 which map near the dopamine D₂ receptor gene (DRD2). F₂ hybrids generated from C57BL/6J and DBA/2J strains were used to confirm the associations between significant QTL by typing for haloperidol sensitivity and cholinergic and dopaminergic cell density, then genotyping for the significant QTL. This analysis has also revealed a significant QTL for cholinergic cell number at microsatellite D12MIT17, which is within proximity of the serotonin transporter gene. These markers are suitable candidates for positional cloning.

473.13

APOMORPHINE INCREASES EXTRACELLULAR GABA LEVELS IN THE PREFRONTAL CORTEX OF THE FREELY MOVING, CONSCIOUS RAT. A.C. Grobin* and A.Y. Deutch. Depts. of Psychiatry and Pharmacology, Yale Univ. Sch. Medicine, New Haven, CT 06510.

It has been hypothesized that dopamine (DA) in the prefrontal cortex (PFC) regulates GABA function. DA axons form synapses with GABA interneurons in the PFC. Furthermore, *in vitro* studies have reported that DA agonists will stimulate GABA release in the PFC. To test this hypothesis in the intact animal, the D₂/D₁ agonist apomorphine (APO) was administered to male Sprague-Dawley rats and GABA levels determined in the PFC using *in vivo* microdialysis. APO was delivered directly to the PFC through the dialysis probe, or systemically through an indwelling subcutaneous catheter. GABA levels and relative glycine amounts in dialysates were determined using pre-column derivatization with o-phthalaldehyde followed by HPLC-EC. Local administration of APO (0.01 and 1.0 μ M) produced a large increase in extracellular GABA. Systemic administration (0.5mg/kg) produced a profound increase in extracellular GABA of short duration; no increase in glycine was observed. Thus, both local and systemic administration of a DA receptor agonist increased extracellular GABA levels in the PFC. This report provides the first *in vivo* data to show that DA stimulates GABA release in the PFC. Thus, DA may inhibit pyramidal cell firing through stimulation of inhibitory GABA interneurons, as well as by directly synapsing on pyramidal cells. This arrangement has important implications for our understanding of the functional consequences of the loss of interneurons in the cortex of schizophrenics.

These studies were supported by MH-45124 and GM-07324.

3-METHOXYTYRAMINE-ACCUMULATION FOLLOWING PARGYLINE ADMINISTRATION REFLECTS THE EXTRACELLULAR DOPAMINE CONCENTRATION IN DIALYSATE FROM THE STRIATUM BUT NOT FROM THE SUBSTANTIA NIGRA. H. Nissbrandt*, A. Elverfors, J. Jonason, F. Bergquist. Department of Pharmacology, University of Göteborg, Medicinaregatan 7, S-413 90 Göteborg, Sweden.

Indirect biochemical methods, as accumulation of the dopamine (DA) metabolite 3-methoxytyramine (3-MT) after monoamine oxidase inhibition has been used as an indirect measurement of DA release. Results obtained with this indirect method are in accordance with results obtained with more direct methods, as microdialysis technique, when DA release is measured in terminal regions, as the striatum, but not when measured in somatodendritic regions, as the substantia nigra (SN). This study was undertaken to further investigate the discrepancy in the SN between the different methods to measure DA release. The DA and 3-MT concentrations were measured by microdialysis in freely moving rats in the SN and in the striatum following pargyline (75 mg/kg) treatment and d-amphetamine (3 mg/kg) plus pargyline treatment. Pargyline treatment only increased the DA concentrations to 160% of basal level in the striatum and to 300% of basal level in the SN. Combined treatment with pargyline and d-amphetamine increased the DA concentrations to 650% of basal level in the striatum and to 1600% of basal level in the SN. In the striatum, the 3-MT concentrations in dialysate increased when the animals were treated with d-amphetamine plus pargyline as compared to when treated with pargyline only. However, in the SN the 3-MT concentrations following pargyline plus d-amphetamine was equal with the concentrations following pargyline only. This suggest that pargyline-induced 3-MT accumulation in the SN does not reflect the extracellular concentrations of DA. A possible explanation for this discrepancy between the striatum and the SN could be that the metabolic enzyme COMT is located in dopaminergic neurons in the SN but not in the striatum.

473.12

LESIONING THE MEDIAL PREFRONTAL CORTEX DECREASES MIDBRAIN DOPAMINE NEURON ACTIVITY. S.S. Shim*, W.-X. Shi and B.S. Bunney. Depts of Psychiatry & Pharmacology, Yale Univ Sch of Med, New Haven, CT 06510

Lesions in the prefrontal cortex (PFC) have been shown to profoundly affect subcortical dopamine (DA) transmission in animals, and this effect is believed to be mediated by cortical projections to DA terminal areas (see reviews by Grace, *J Neural Transm* 91:111, 1993 and Deutch, *J Neural Transm* 91:197, 1993). However, since the PFC is also anatomically connected to DA neurons located in the midbrain, lesions in the PFC may directly affect the electrical activity of DA neurons which should in turn influence DA release in terminal areas. To examine this possibility, we used extracellular single unit recording techniques to record DA neurons from both A10 and A9 in control and PFC lesioned rats. To lesion the medial PFC, we either made a glass knife cut immediately caudal to the mPFC or locally injected ibotenic acid into the mPFC. One hour after mechanical lesioning the number of spontaneously active DA neurons in both the A9 and A10 areas was decreased (A9: from 1.15 \pm 0.10 to 0.57 \pm 0.07 cells/track, A10: from 1.41 \pm 0.09 to 0.77 \pm 0.09). Furthermore, the burst activity of A10 DA neurons was also reduced from 26.70 \pm 1.80% to 17.50 \pm 2.46%. However, unlike the mechanical lesion, local injection of ibotenic acid only decreased the activity of A10 neurons. Thus, four to 20 days after the injection, the number of spontaneously active DA neurons in the A10 area was significantly reduced from 1.50 \pm 0.13 to 0.56 \pm 0.11 cells/track, whereas that in A9 area were not significantly affected. Surprisingly, the basal activity of DA neurons in the A9 area was increased (control: 3.65 \pm 0.28 spikes/sec, lesioned: 4.89 \pm 0.21 spikes/sec) in these chemically lesioned rats. These results suggest that lesions in the mPFC can significantly affect DA neuron activity located in the midbrain and this effect may contribute to the change in DA transmission in subcortical areas seen after PFC lesions. CHRONIC RESERPINE ADMINISTRATION DECREASES ³H-MAZINDOL BINDING: EVIDENCE FOR RESERPINE-INDUCED NEUROTOXICITY. J.L. Neisewander* and A.N. Sussman. Dept. Psychology, Arizona State University, Box 871104, Tempe, AZ 85287-1104.

Chronic administration of reserpine produces spontaneous oral dyskinesia that persists for at least 60 days following termination of treatment. This response is also associated with persistent neurochemical changes, including a 64% depletion of dopamine and a 10-15% increase in D2 receptor density in the caudate-putamen (CPu). The increase in D2 receptor density is region-specific since it is not observed in the nucleus accumbens (NAc). In light of this long-lasting dopamine depletion and receptor up-regulation, we hypothesize that reserpine may be neurotoxic to dopamine neurons in the CPu. To test this hypothesis, we examined whether reserpine-treated animals would exhibit a decrease in dopamine transporter binding sites using ³H-mazindol. Rats were treated every other day with either vehicle (N=6) or reserpine (1.0 mg/kg, SC; N=8) for 21 days. The animals were sacrificed 24 hours after their last injection. Sections of rat brain containing the CPu and NAc were labeled with 15 nM ³H-mazindol in the presence or absence of 1 μ M GBR-12909 in buffer containing 300 nM desmethylimipramine. Quantitative autoradiographic analysis revealed a significant decrease in ³H-mazindol binding in the CPu of reserpine-treated animals relative to vehicle-treated animals. In contrast, there was no significant difference in ³H-mazindol binding in the NAc. These findings are consistent with our hypothesis that reserpine may be neurotoxic to dopamine neurons in the CPu, and may have implications for tardive dyskinesia and L-DOPA-induced dyskinesia.

PRENATAL HALDOL EXPOSURE REDUCES THE NUMBER OF SPONTANEOUSLY ACTIVE MIDBRAIN DOPAMINE NEURONS IN NEONATAL OFFSPRING. L. Wang*, J. Zhang and D.K. Pitts. Dept. of Pharmaceutical Sci., Coll. of Pharmacy & A.H.P., Wayne State Univ., Detroit, MI 48202.

The dopamine (DA) receptor antagonist, haloperidol (HAL, 5 mg/kg) or the vehicle, dimethyl sulfoxide (DMSO), was administered to pregnant Sprague-Dawley rats by s.c. injection (200 μ l/kg). Injections began on gestational day (GD) 8 and ended on GD 20. The control dams (n=2) were pair-fed and appeared to gain weight at the same rate as HAL treated dams (n=2). The average dam weights (g) were as follows: (HAL, DMSO): 234, 268 on GD 8; 296, 330 on GD 20. The body weight (g) of 2-week-old male offspring from HAL-treated dams (26.8 \pm 0.4, n=12) were significantly (P < 0.001) lower than those from DMSO-treated dams (31.2 \pm 0.8, n=8). The two-week-old male offspring were anesthetized with chloral hydrate and the number of spontaneously active midbrain DA neurons were determined in a stereotactically defined block of tissue using standard extracellular electrophysiological recording techniques. The number of spontaneously active DA neurons per electrode track in HAL-treated offspring was found to be significantly decreased in both the A9 (0.85 \pm 0.09) and A10 (0.65 \pm 0.11) regions (treatment effect, P < 0.001; cell type by treatment interaction, P > 0.50) relative to DMSO controls (A9: 1.27 \pm 0.25; A10: 1.10 \pm 0.13). There was a trend towards A10 DA neurons from HAL-treated offspring having a higher discharge rate than controls (P < 0.07; cell type by treatment interaction). Experiments examining non-injected controls, the effects of lower HAL doses and cross-fostering are underway. These preliminary results suggest that DA receptors may influence the development of both A9 and A10 midbrain DA neurons during gestation. Supported in part by MH47857 (DKP).

THE RESPONSE OF VENTRAL PALLIDAL NEURONS TO DOPAMINE AGONISTS IS NOT ALTERED BY 6-HYDROXY-DOPAMINE-INDUCED LESIONS. B.A. Heidenreich¹, I. Mitrovic², F. Rehman² & T.C. Napier¹. Dept. Pharmacol., Stritch Sch. Med., Loyola Univ. Chicago, Maywood, IL 60153.

The ventral pallidum (VP) receives a dopamine (DA) input from the substantia nigra and ventral tegmental area. Ionophoretic application of DA or the D₁ agonist SKF38393 alters the firing rate of many VP neurons (Napier and Maslowski-Cobuzzi, *Synapse*, in press). Also, systemically administered D₁ agonists increase the activity of many VP neurons (Maslowski and Napier, *EJP*, 200:103). The present study investigated the effects of chronic DA depletion on the responses of VP neurons to DA and SKF38393. Rats received infusions of 6-hydroxy-DA (6-OHDA, 8 µg/4 µl) into the medial forebrain bundle after treatment with pargyline (50 mg/kg i.p.). Desipramine (30 mg/kg i.p.) was given to protect other monoamine neurons. Seven to ten days later, rats were anesthetized with chloral hydrate and single neuron recording techniques were used to assess changes in sensitivity to microiontophoretic DA and SKF38393, and i.v. SKF38393. As observed previously, increases and decreases in activity were produced by iontophoretic DA and SKF38393. Treatment with 6-OHDA did not alter the E_{max} of DA to increase or decrease firing rate. Similarly, there was no change in the E_{max} of i.v. SKF38393 to increase neuronal activity. Because chronic removal of DA input to many brain regions produces supersensitivity to DA agonists, the present results highlight differences between the effects of DA in the VP and other DA-receptive regions. Supported by USPHS MH45180 (TCN).

WHY DO HEMIPARKINSON RATS TURN? E. I. Miklyaeva^{*} and I. Q. Whishaw^{*}, Department of Psychology, University of Lethbridge, Lethbridge, AB, Canada, T1K3M4

Hemiparkinson rats (6-OHDA in the nigrostriatal bundle) turn ipsilateral to their lesion spontaneously and under amphetamine and contralateral after apomorphine. They display sensorimotor abnormalities when eating, rearing, reaching and competing for food. Control rats move from a "diagonal" postural supporting pattern, unloading the limb opposite to the lifted one and loading the other pair of limbs, when performing most behaviors. Hemiparkinson rats are not able to use their "bad" limbs in this way. Consequently they modify their posture and movement to rely on the ipsilateral "good" limbs to actively adjust support. This change biases their behavior such that they display a variety of anomalous movements that include ipsiversive rotation spontaneously and under amphetamine, backward dodging when they protect their food from robbers, atypical sitting to eat food, and atypical standing to reach for food. Apomorphine restores more normal movements. The results show that following DA-depletions the new supporting patterns are related to the many changes in behavior typical of hemiparkinson rats. Thus, it is suggested that they turn because they have to.

PRIOR EXPOSURE TO INTRA-VTA AMPHETAMINE ENHANCES THE INDUCTION OF IMMEDIATE-EARLY GENE EXPRESSION IN THE RAT FOREBRAIN BY SYSTEMIC AMPHETAMINE. P. Vezina^{*} and G.S. Robertson^{*}. Department of Psychiatry, University of Chicago, Chicago, IL 60637 and Department of Pharmacology, University of Ottawa, Ottawa, Canada K1H 8M5.

Injections of amphetamine into the ventral tegmental area (VTA) have been shown to enhance the locomotion and the increase in extracellular nucleus accumbens (N.Acc.) dopamine (DA) produced by a subsequent systemic amphetamine challenge. The present experiment investigated whether prior exposure to such injections would also affect the subsequent induction by systemic amphetamine of immediate-early gene activation in the N.Acc., the antero-medial striatum and the medial prefrontal cortex, forebrain projection fields of A10 DA perikarya in the VTA. Rats were administered three injections of either d-amphetamine (2.5 µg/0.5 µl/side) or saline into the VTA, one injection every third day. One week following the last injection, animals were challenged with amphetamine (1.0 mg/kg, i.p.) and, 90 minutes later, brains were prepared for assessment of immediate-early gene induction by immunohistochemistry using antibodies that recognize FOS, FOS-B, JUN-B and NGFI-A. Animals preexposed to VTA amphetamine showed increased (generally two fold) expression of FOS, FOS-B and JUN-B in all A10 projection fields when compared to VTA saline preexposed animals. The two groups did not differ in amphetamine induced expression of NGFI-A in any site. This enhanced induction by amphetamine of immediate-early genes of the *fos/jun* (leucine-zipper) family in VTA amphetamine preexposed animals is consistent with the sensitized DAergic response to this drug reported in these animals in one of the DA terminal fields tested (N.Acc.). While NGFI-A (of the zinc finger immediate-early gene family) is induced by amphetamine, it does not appear to be involved in the differential expression of the behavioral and DAergic responses to amphetamine by these two groups.

473.18

WHY CAN'T HEMIPARKINSON RATS WALK NORMALLY? I. Q. Whishaw^{*} and E. I. Miklyaeva^{*}, Department of Psychology, University of Lethbridge, Lethbridge, AB, Canada, T1K3M4

The normal walking sequence of most tetrapods involves patterns of diagonal support in which one set of diagonal limbs supports weight while weight is unloaded from the others. We have examined walking in hemiparkinson rats (6-OHDA in the nigrostriatal bundle) using high speed video, kinematic, and weight support analysis. They use abnormal gaits or turn ipsilateral in tests of spontaneous locomotion rather than displaying the normal diagonal pattern of walking. An investigation of the underlying basis for this change showed that they are not able to use their "bad" limbs in to shift posture and so contribute to the normal diagonal walking pattern. To compensate for this impairment they alter their movement patterns to place more reliance on their good limbs. Thus, it is suggested that hemiparkinson rats do not walk normally because they are relying upon two limbs rather than four to shift their weight.

ADENOSINE ANTAGONISTS AND A D2 DOPAMINE AGONIST COOPERATIVELY REGULATE C-FOS INDUCTION IN THE RAT STRIATUM. A.E. Pollack^{*} and J.S. Fink^{*}. Molecular Neurobiology Laboratory, Massachusetts General Hospital and Department of Neurology, Harvard Medical School, Boston, MA 02114.

Adenosine (AD) antagonists potentiate dopamine (DA)-mediated behaviors and receptors for these neurotransmitters are abundantly expressed in striatum. The immediate early gene c-Fos is induced in the anterior dorsolateral striatum 3 hours following a single injection of reserpine (RES) (10mg/kg). Pretreatment with the D2 DA agonist quinpirole (QUIN) (0.5mg/kg) blocked c-Fos induction, indicating that this induction of c-Fos is mediated by D2 DA receptors. We tested whether co-administration of AD antagonists with a low dose of QUIN (0.05mg/kg) could block the induction of striatal c-Fos, detected by immunohistochemistry, following acute RES. Pretreatment with QUIN, theophylline (25mg/kg), or DMPX (25mg/kg) slightly attenuated c-Fos induction, while QUIN+theophylline or QUIN+DMPX completely blocked the induction of striatal c-Fos following acute RES. The A2a AD antagonist CSC (5mg/kg) did not block c-Fos induction, while QUIN+CSC attenuated c-Fos induction following RES. These results suggest that D2 DA agonists and AD antagonists cooperatively regulate c-Fos in the striatum. Since A2a AD receptors and D2 DA receptors are co-localized on the same striatal neurons these results support an functional interaction between A2a AD receptors and D2 DA receptors in a subset of striatal neurons.

Changes in cochlear tyrosine hydroxylase immunoreactivity after repeated exposure to cocaine. B.G. Shivapula, S.Y. Liu, D.Z. Pitovsky, E.P. Schoener^{*}. Dept. of Otolaryngology, Henry Ford Hospital, Detroit, MI- 48202.

The site of action of cocaine in the auditory system may include structures peripheral to the ventral cochlear nucleus, including the cochlea. Previous studies in our laboratory examined the acute and chronic effects of cocaine on cochlear function. Experiments designed to study acute effects of cocaine on the cochlea demonstrate a significant decrease in both the amplitude of the compound action potential of the auditory nerve (N_i) and cochlear blood flow. On the other hand, experiments designed to study chronic effects of cocaine on the cochlea show an enhancement of the N_i amplitude of the auditory nerve.

In order to understand the underlying mechanisms involved in chronic cocaine action in the cochlea, this experiment was designed to examine the effects of repeated administration of cocaine on the cochlear catecholaminergic systems in chinchilla using immunohistochemical techniques. Twelve chinchillas were randomly assigned to either control or experimental groups. Animals in control group were administered saline while animals in experimental group were administered 15 mg/kg cocaine IP daily for 42 days. Animals were sacrificed 24 h after the last treatment. The catecholamine system was evaluated using a polyclonal antibody to tyrosine hydroxylase (TH).

Microscopic examination of whole-mounted tissue revealed TH immunoreactive fibers that have been described previously as sympathetic. Changes in fiber density, arborization and varicosity were observed in the cocaine-treated animals. Fiber density was quantified along the organ of Corti from the apical to the basal region by counting the number of fibers below the plane of the inner sulcus cells. Statistical comparison of the total number of nerve fibers per cochlea between the two groups demonstrated a significant decrease in cocaine-treated animals. (Supported in part by NIDA/NIH grant DA07524)

INHIBITORY EFFECTS OF DOPAMINE ON SINGLE-UNIT ACTIVITY OF DORSOMEDIAL ARCUATE NEURONS ARE POTENTIATED BY COCAINE. J.T. Pan¹, S.H. Yen and C.J. Lai. Inst. Physiol., Natl. Yang-Ming Med. Coll., Taiwan R.O.C.

Whether tuberoinfundibular dopaminergic (TIDA) neurons contain dopamine (DA) autoreceptor has been a controversial issue. Earlier study from this lab using single-unit recording of dorsomedial/ventrolateral arcuate (ARC) neurons in rat brain slices found that DA only inhibited 37% of ARC neurons recorded. Recent immunohistochemical studies, however, reveal that DA neurons are localized in the dorsomedial part of the ARC only. By focusing our recording in that region, we found that DA in 50-250 nmol ranges now inhibited a significant number of ARC neurons tested (74.2% of 182 units). Apomorphine, a DA agonist, was less effective (38.1% of 21 units). Cocaine, an abusive drug whose effect is believed to increase DA concentration in synaptic clefts by inhibiting DA reuptake, also inhibited a significant number of ARC neurons by itself (51.5% of 97 units), but with a lesser efficacy. Cocaine co-administered with DA, however, potentiated the inhibitory effect of DA in 82% of DA-responsive units (n=39). The results demonstrate clearly that DA indeed had a predominantly inhibitory effect on presumed DA neurons in the dorsomedial ARC. The effects of cocaine, either by itself or with DA, further support this notion.

473.24

ACUTE AND DELAYED EFFECTS OF THE DOPAMINE DERIVATIVE BBADE ON COCAINE-INDUCED HYPERACTIVITY. H.M. Deutsch¹ and M.M. Schweri². School Chemistry and Biochemistry, Georgia Tech, Atlanta GA 30332 and ²Mercer U. School of Medicine, Macon GA 31207.

The dopamine derivative BBADE (1), a pseudoirreversible inhibitor of [³H]methylphenidate binding (unpublished data), was examined as a potential antagonist against the behavioral effects of cocaine (COC). After overnight acclimatization in separate activity monitor cages, male Sprague-Dawley rats were injected with BBADE-HCl (20 mg/kg, i.v.) or water (controls). Total (T), ambulatory (A), and nonambulatory (N) activities were recorded at 5 min intervals for 30 min thereafter. BBADE alone caused a very slight, but statistically significant increase in all activities over controls at 15-30 min after injection [two-way (time x treatment) ANOVA with repeated measures of the log-transformed activity counts (p<.03), followed by post hoc t-tests (p<.03)]. In the acute study, rats were then immediately challenged with COC (40 mg/kg, i.p.) and their activity recorded at 5 min intervals for 60 min. The BBADE treated rats continued to show significantly greater T and N activity in the first 20 min after acute COC injection, but not in the subsequent 40 min; a similar, but nonsignificant, trend was found for A activity. When the COC challenge was delayed for 24 h, opposite results were obtained: T and A activity in BBADE treated rats were decreased by approximately 30% from controls (p<.01); N activity also decreased, but nonsignificantly. The overnight activity counts of the treated rats were significantly less than controls (p<.001), suggesting that a nonspecific depressant effect may supplant the initial mild activating effect of BBADE. Supported by NIDA (DA06305).

SEROTONIN RECEPTORS: 5-HT3

474.1

DIFFERENTIAL EXPRESSION REGULATION OF THE TWO SPLICE VARIANTS OF 5-HT3 RECEPTORS BY DIFFERENTIATION IN NG108-15 CELLS. M.B. Emerit¹, E. Doucet, M.C. Miquel, M. Riad, M.P. Martres, S. El Mestikawy, and M. Hamon. INSERM U288, CHU Pitié-Salpêtrière, 91 Bd de l'Hôpital, 75634 Paris Cedex 13, France.

The 5-HT₃ receptor mRNA has recently been shown to be expressed as two forms (5-HT_{3aL} and 5-HT_{3aS}) varying by 18 base pairs in the third intracellular loop domain (Hope et al., Eur. J. Pharmacol. 245:187, 1993). As the short form of the 5-HT₃ receptor lacks a casein kinase II phosphorylation site in the region corresponding to the alternative splicing, the question of the functional roles of the two variants has been raised. We have studied the regulation of the expression of mRNAs coding for the two variants in NG108-15 clonal cells under various culture conditions. Relative abundance of the two mRNAs was determined by quantitative PCR over the linear range of the assay by using primers flanking the site of alternative splicing. Quantitation of mRNAs for both forms (L+S) was performed by competitive PCR using as an internal standard a deleted RNA corresponding to a 460 base pair fragment starting at transmembrane domain-2 and ending at TMD-4. Differentiation significantly reduced the abundance of the overall mRNA coding for 5-HT₃ receptors in different proportions depending on the inducing agent (dibutyryl cyclic AMP, with or without TPA, theophyllin + PGE₁...). In addition, the relative proportions of the two splice variants changed significantly when compared with control cells, since the ratio S/L increased with exposure time to the differentiating agents (Control: 2.75, DBcAMP 1 mM, 1 day: 3.76, 2 days: 4.29, 3 days: 4.43, 5 days: 5.36, 7 days: 6.42). As functional changes have already been described for 5-HT₃ receptors upon differentiation in these cells (Shao et al., J. Neurophysiol. 65: 630, 1991), our results suggest different functional roles for 5-HT_{3aL} and 5-HT_{3aS}. We are currently testing this hypothesis by quantifying S/L ratios during development in various central and peripheral tissues.

474.2

DEVELOPMENTAL EXPRESSION OF 5-HT₃ RECEPTOR mRNA IN RAT SYMPATHETIC AND SENSORY NEURONS. M. Rosenberg¹, P. Séguéla², and E. Cooper¹. Dept. of Physiology¹, and the Montreal Neurological Institute², McGill University, Montreal, Quebec, Canada, H3G 1Y6.

Serotonin, acting on 5-HT₃ receptors (5-HT₃Rs) on autonomic and sensory neurons, affects a variety of physiological systems, including circulation, respiration, digestion and pain. Yet little is known about the factors that influence the expression of these receptors on peripheral neurons. To learn more, we are investigating the developmental expression of 5-HT₃Rs in neonatal rat vagal sensory neurons from nodose ganglia, and in sympathetic neurons from the superior cervical ganglia (SCG). We have quantified the levels of 5-HT₃R mRNA expression in these neurons at various stages of development using RNase protection assays. Our results show that, at P₁, the level of 5-HT₃R mRNA expression is 10-15 fold higher in nodose ganglia than in SCG. We find no significant change in the level of 5-HT₃R mRNA expression in nodose ganglia during the first three weeks of postnatal development. However, in SCG, the level of 5-HT₃R mRNA increases 3-5 fold during the first postnatal week and an additional 2-3 fold during the next two weeks of development, such that, by P₂₁, the 5-HT₃R mRNA level in nodose is only 2 fold higher than in SCG. These results indicate that: (1) for the vagal sensory neurons, much of the 5-HT₃R gene expression occurs before birth; (2) for sympathetic neurons, there is a significant increase in 5-HT₃R gene expression during the first three postnatal weeks, suggesting that 5-HT₃R expression is controlled by epigenetic influences after birth. (Supported by the Canadian Heart and Stroke Foundation and the Medical Research Council of Canada.)

474.3

DEVELOPMENT AND CHARACTERIZATION OF ANTIBODIES AGAINST THE 5HT₃ RECEPTOR. M. Morales¹, E. Battenberg, L. de Lecea, P. Sanna and E. E. Bloom. The Scripps Research Institute, Neuropharmacology. 10666 N. Torrey Pines Rd., La Jolla CA 92037.

Based on the predicted amino acid sequence of the cloned rat 5-HT₃ receptor cDNA (Johnson and Heinemann. Soc. Neurosci. Abstr. 18: 249), seven different peptides of 15-19 residues that were expected to be antigenic were conjugated to bovine serum albumin and used as immunogens to develop anti-5-HT₃ receptor antibodies in rabbits. Three peptides were derived from the amino terminal, extracellular region, and four from the large intracellular loop, between transmembrane regions 3 (M3) and 4 (M4) of the receptor protein. Antibody production was evaluated by solid-phase ELISA and immunodot blot analyses. Peptides corresponding to the extracellular region of the protein gave antibodies of very low titers. Two of the peptides (P6 and P7) corresponding to the large intracellular loop produced antiserum of high titer. These antisera when tested on a dot blot analyses were able to detect 0.2 ng of synthetic peptide at dilution of 1x10³, and 2 ng at dilution of 1x10⁴.

Membranes from brain and NG 108-15 cells were solubilized with Triton X-100. By western blots, anti-5-HT₃-R antibodies recognized a single band (molecular weight close to 35 kDa) in the detergent soluble fractions. Western blot and tissue immunolabeling was abolished when antibodies were preadsorbed with the corresponding peptide. These antibodies labeled cells of different sizes and shapes on rat brain tissue: small round cells in the striatum; medium bipolar and multipolar cells in cortical areas and hippocampus. Immunolabeled neurons were also found in the olfactory bulb, olfactory tubercle and amygdala. The pattern of distribution of the immunolabeled cells is in agreement with that reported for the localization of rat 5-HT₃-R transcripts (Johnson and Heinemann. Soc. Neurosci. Abstr. 19: 632). Our data indicate that 5-HT₃R immunolabeled neurons are prominent in areas associated with the DA mesolimbic system. (Supported by AA 06420).

474.4

IMMUNOCYTOCHEMICAL CHARACTERIZATION OF NEURONS EXPRESSING THE 5-HT₃ RECEPTOR. E. Battenberg¹, M. Morales, L. de Lecea, D.S. Johnson and E. E. Bloom. The Scripps Research Institute, Neuro-pharmacology. 10666 N. Torrey Pines Rd., La Jolla CA 92037.

The type 3 serotonin receptor (5-HT₃R) is a ligand-gated ion channel present in peripheral and central neurons and in some neuronally derived cell lines (i.e. NG 108-15 cell line). Valuable information concerning the distribution of this receptor had been obtained with the use of specific radioligands and riboprobes. To better understand the role of 5-HT₃R in the CNS, we have begun to characterize the biochemical features of the rat neurons endowed with this receptor.

By immunocytochemical and *in situ* hybridization techniques, we found that some hippocampal neurons express both the 5-HT₃R and GABA. Brain sections hybridized with a radioactive antisense RNA probe for detection of 5-HT₃R transcripts and immunolabeled with antibodies against GABA, revealed double labeled neurons in several strata of the hippocampus, s. oriens, s. pyramidalis, s. lacunosum moleculare and s. lucidum. The coexistence of 5-HT₃R mRNA and GABA immunoreactivity in hippocampal interneurons supports electrophysiological data indicating that 5-HT₃R-mediated depolarization occurs in non-pyramidal GABAergic neurons (Ropert & Guy. J. Physiol. 441:21, 1991). Additionally, brain sections hybridized with the same RNA probe and immunolabeled with antibodies against somatostatin (SS) demonstrated that the hippocampal neurons containing the 5-HT₃R and GABA are a distinct subset of cells that do not belong to the previously described subclass of GABA/SS cells in the hippocampus.

Some neocortical neurons expressing the 5-HT₃R also contained GABA. Furthermore, 5-HT₃R hybridizing neurons appear to receive afferent fibers immunoreactive for tyrosine hydroxylase. These data suggest that a subset of cortical neurons containing the 5-HT₃R might be regulated by both catecholamines and serotonin. (Supported by AA 06420).

474.5

FURTHER CHARACTERIZATION OF 5-HT₃-LIKE RECEPTORS IN THE RAT MEDIAL PREFRONTAL CORTEX. J.Y. Zhang*, E. Edwards and R.Y. Wang. Dept. Psychiatry and Behav. Sci. (J.Y.Z. and R.Y.W.), SUNY at Stony Brook, Stony Brook, NY 11794-8790 and Dept. Pharmacol. (E.E.), Univ. Maryland at Baltimore, Baltimore, MD 21201-1180.

In contrast to studies indicating that applications of 5-HT₃ receptor agonists produce a fast depolarizing action, which is rapidly desensitized, on peripheral or cultured cells, we have found that iontophoresis of 2-methyl-5-HT elicits a slow depressant action with no desensitization on cells in the medial prefrontal cortex (mPFC). In addition, 5-HT₃-like receptors in the mPFC might be coupled to the phosphoinositide (PI) hydrolysis. To further characterize the pharmacological properties of 5-HT₃-like receptors in the mPFC, using the technique of single cell recording and microiontophoresis, we have compared the depressant action of various 5-HT₃ receptor agonists on the firing of mPFC cells. The rank order of effectiveness was: 5-HT > SR 57227A = 2-methyl-5-HT = mCPBG (1-(m-chlorophenyl)-biguanide) = PBG = pCPBG = oCPBG. Furthermore, in the mPFC, d-tubocurarine not only blocked the depressant action of 5-HT₃ receptor agonists but also antagonized that of dopamine and GABA. In fact, d-tubocurarine alone often accelerated the firing of mPFC cells. In another research paradigm, the effect of various 5-HT₃ receptor agonists on PI turnover were investigated and compared using the tissue of the mPFC. The rank order of potency was: 5-HT > SR 57227A = 2-methyl-5-HT > mCPBG = PBG = pCPBG = oCPBG. In summary, the following two new findings further indicate that 5-HT₃-like receptors in the mPFC are pharmacologically different from those in the periphery: 1) in the mPFC, mCPBG is not the most potent 5-HT₃ receptor agonist, and 2) d-tubocurarine is not a specific antagonist for 5-HT₃-like receptors.

474.7

EFFECT OF GRANISETRON ON ACUTE AND DELAYED CISPLATIN-INDUCED EMESIS IN THE PIGLET. L. Grélot*, S. Milano, P. Blower¹ & D. Romain², URA CNRS 1832, St Jérôme, 13397 Marseille Cedex 20, France; SmithKline Beecham Pharmaceuticals, UK (1) and France (2).

Emesis in cancer chemotherapy are classified as acute or delayed when occurring during or after the 24 hr following cytotoxic treatment, respectively. It remains unclear whether serotonin 5-HT₃ receptors are involved in delayed emesis. In 19 weaned piglets, granisetron was tested on both acute and delayed emesis. Vomiting was induced by an iv infusion of cisplatin (5.5mg/kg) and animals were observed for 60 hr. In group 1, 12 piglets received an initial (15 min prior to cisplatin) single dose (0.25mg/kg, n=2; 0.5mg/kg, n=3; 2mg/kg, n=3 or 7mg/kg, n=4) of granisetron. In group 2, 7 piglets received in addition to the initial dose (0.25mg/kg, n=2; 1mg/kg, n=3), a supplementary injection (same dose as first one) each 5 hr during 30 hr. In group 1, single doses of granisetron prevented vomiting during the first 5-18 hr in a dose dependent manner. All animals exhibited a delayed phase of vomiting, the number (13.5±8.8) of which was higher to those of animals not treated with granisetron (9.2±8.6). In group 2, repetitive administration of granisetron was beneficial in reducing both the acute and delayed phases of vomiting. Indeed, 6/7 piglets (0.25mg/kg, n=1; 1mg/kg, n=5) during the acute phase and 4/7 (1mg/kg, n=4) during the delayed phase did not vomit. These results suggest that serotonin 5-HT₃ receptors might be involved in the development of delayed emesis in this species.

474.6

THE PIGLET: AN ANIMAL MODEL FOR STUDYING CISPLATIN-INDUCED DELAYED EMESIS. S. Milano*, L. Grélot, P. Blower¹ & D. Romain², URA CNRS 1832, St Jérôme, 13397 Marseille Cedex 20, France; SmithKline Beecham Pharmaceuticals, UK (1) and France (2).

The pathogenesis of cisplatin-induced delayed emesis being obscure, we investigated the suitability of the piglet as a model for studying delayed emesis. We implanted surgically in 13 weaned piglets a cannula in the jugular vein and electrodes for recording ECG and abdominal EMG. After a 4-5 days recovery, piglets were hydrated (iv, saline+furosemide, 100ml/hr for 10hr) and then given cisplatin (5.5mg/kg, iv). Recordings were made continuously for the following 60 hr. Animals were not fed but received continuous iv infusions of glucose and polyionic solutions. All piglets responded with both acute and delayed emesis. In the acute phase of emesis, the first vomiting occurred with a latency of 131±43 min after cisplatin administration. Emetic intensity reached a peak (5 vomits/hr) within 120 min and then decreased rapidly, so that no vomiting were observed between the 15th and 16th hr. The mean number of vomits during the first 16 hr was 18.6±6. Delayed emesis started at the 17th hr and was observed to last until the 58th hr. Emetic intensity of the delayed phase reached a peak (0.8 vomits/hr) between the 19th and the 21th hr and the mean number of vomits during the whole of the delayed phase was 9.2±8.6. Cisplatin inducing delayed vomiting in the piglet without any lethality and with a weak toxicity, this animal is a suitable model in which to study the pathogenesis of delayed emesis.

5HT₃ RECEPTOR MODULATION OF FROG SPINAL CORD REFLEXES. A.M. Holohean*, J.C. Hackman and R.A. Davidoff. Neurophysiology Laboratory, Veterans Affairs Medical Center and Dept. Neurology, Univ. Miami School of Medicine, Miami, FL 33101.

Functional 5HT₃ receptors are present in spinal gray matter and are presumably involved in modulating nociception. Recently, the 5HT₃ agonist, 2-Me-5HT (2-methyl-serotonin maleate), has been shown to activate ionotropic channels in dorsal root ganglion cells. To understand the role of 5HT₃ receptors in spinal cord function, sucrose gap recordings from isolated, hemisectioned *Rana pipiens* spinal cords superfused in HCO₃⁻ Ringer's were used. Dorsal (DRPs) and ventral root (VRPs) potentials were evoked by stimulating an adjacent dorsal root.

Application of 2-Me-5HT (100 μM) did not affect either motoneuron or primary afferent terminal resting membrane potential, but the amount of spontaneous motoneuron and afferent terminal activity was substantially decreased. No significant effect on the height of evoked VRPs was produced by prolonged exposure (20-30 min) to 2-Me-5HT. However, a substantial decrease in the area of VRPs (66 ± 4%) and DRPs (71 ± 7% of control) was noted. We have previously shown that this area is sensitive to NMDA antagonists, and believe that activation of interneuronal excitatory amino acid receptors is responsible for the width of root potentials. In this regard, 2-Me-5HT decreased the depolarization (VR, 81 ± 7%; DR, 69 ± 4%) evoked by applications of NMDA (100 μM, 10 sec), but not AMPA (30 μM), KA (30 μM), or K⁺ (10 mM). This decrease was prevented by exposing the cord to TTX but was not affected by naloxone.

These results argue for a role of 5HT₃ in interneuronal firing patterns in the frog spinal cord. Supported by VAMC MRIS #1769 and 3369 and USPHS #NS17577).

SEROTONIN RECEPTORS: EFFECTOR MECHANISMS

475.1

AGONIST POTENCY AND AFFINITY AT 5-HT_{1A} RECEPTORS EXPRESSED IN CHINESE HAMSTER OVARY (CHO) CELLS. J.G. Hensler*, K.D. Burris, L.S. Cervera, H.A. Miller and P.B. Molinoff. Dept. of Pharmacology, Univ. of Texas Health Sci. Center, San Antonio, TX. 78284; Dept. of Pharmacology, Univ. of Pennsylvania School of Medicine, Philadelphia, PA. 19104.

The relationship between agonist potency and affinity was investigated in CHO cells stably expressing the 5-HT_{1A} receptor (CHO-5HT_{1A} cells). In membranes from CHO-5HT_{1A} cells, the specific binding of the radiolabeled 5-HT_{1A} receptor agonist [³H]-8-OH-DPAT (1-1.2 nM) was inhibited essentially completely (97±1.5%) by GppNhp (EC₅₀ = 2.8 ± 0.3 μM). Saturation experiments using membranes from CHO-5HT_{1A} cells indicated that the binding of [³H]-8-OH-DPAT (0.05 - 50 nM), in the absence of guanine nucleotides, was to a single site (K_d = 1.1 nM, B_{max} = 1 pmol/mg protein). Taken together, these data suggest that in CHO-5HT_{1A} cells all of the 5-HT_{1A} receptors are coupled to G proteins and exist in a high affinity state as determined by radiolabeled agonist binding. To determine whether agonist potency can be related to the high affinity state of the receptor, EC₅₀ values of agonists to inhibit forskolin-stimulated [³H]-cAMP accumulation in CHO-5HT_{1A} cells were compared with their K_i values for the inhibition of [³H]-DPAT binding. The ratio of K_i values to the EC₅₀ values were near unity: 8-OH-DPAT, 1.4/0.9 nM; 5-HT, 2/2.4 nM; gepirone, 55/37 nM; ipsapirone, 26/32 nM. Thus in CHO-5HT_{1A} cells, the potency of agonists appears to be related to their affinity at the high affinity state of the receptor. Supported by USPHS grants MH48125 and MH52369.

474.2

INTERACTION BETWEEN HUMAN 5-HT_{1A} AND 5-HT_{1C} RECEPTOR IN VITRO. J. Akiyoshi*, I. Fujii. Dept. of Neuropsychiatry, Oita Medical University, Hasama-Machi, Oita 879-55, Japan.

The 5-HT_{1A} and 5-HT_{1C} receptors were important role for depression, anxiety and schizophrenia. In vivo there was some reports of interaction between 5-HT_{1A} and 5-HT_{1C} receptor. 5-HT_{1C} receptor selective agonists induced penile erection. In contrast, selective agonists of 5-HT_{1A} receptor such as 8-OH-DPAT produced an opposite effect on penile erection. But, in vivo there is no adequate cells for studying the interaction between 5-HT_{1A} and 5-HT_{1C} receptor.

Recently, we found the cell line which had both of human 5-HT_{1A} and 5-HT_{1C} receptor. Total RNA was isolated from these cells and cDNA was synthesized. We made a primers for human 5-HT_{1A} and 5-HT_{1C} receptor. PCR amplification allowed the identification of these receptors.

We studied the interaction between human 5-HT_{1A} and 5-HT_{1C} receptor, using the Ca²⁺ sensitive dye fura-2/AM. The fluorescence of fura-2/AM was measured in a fluorescence spectrophotometer, with excitation at 340 and 360 nm. Pretreatment of 5-HT_{1A} receptor agonist 8-OH-DPAT decreased Ca²⁺ mobilization induced by DOI (5-HT_{1C} receptor agonist) in this cells.

These results show that there is interaction between human 5-HT_{1A} and 5-HT_{1C} receptor in vitro.

475.3

5-HT_{1D} AND 5-HT_{1A} RECEPTORS ARE RESPONSIBLE FOR THE MITOGENIC EFFECT OF SEROTONIN IN A HUMAN TUMOR OF NEUROENDOCRINE ORIGIN

Lucia M. Vicentini*, F. Voltolini and M.G. Cattaneo

Department of Pharmacology, University of Milano, Milano

Small cell lung carcinoma (SCLC), an aggressive human tumor often associated with tobacco smoking, possesses neuroendocrine features. These include the presence of neurosecretory granules containing hormones and neuropeptides and the expression of neuronal nicotinic receptors and voltage-dependent Ca²⁺ channels. We have found that serotonin (5-HT) is contained, is released and is mitogenic in the two SCLC cell lines GLC8 and NCI-M-592. The mitogenic effect of 5-HT is not counteracted by ketanserin, ICS 205-930 and GR 113-808 which are antagonists of the 5-HT₂, 5-HT₃ and 5-HT₄ receptors, respectively. We found that the 5-HT_{1D} agonist sumatriptan and the 5-HT_{1A} agonist 8-OH-DPAT are capable of increasing DNA synthesis in the SCLC cell lines, with lower efficacy but higher potency than 5-HT (EC₅₀ = 25 nM and 90 nM respectively). Their effects on DNA synthesis were completely additive and together they reached the maximal effect elicited by 5-HT alone. Spiperone (1 μM) and the 5-HT_{1A} antagonist SDZ 216-525 (1 μM) inhibited the 5-HT mitogenic response by about 40%.

When cells were cultivated at higher density, the two 5-HT antagonists were able to inhibit basal cell proliferation.

Taken together, our results suggest that 5-HT should be added to the list of autocrine growth factors for SCLC cells. The mitogenic effect of 5-HT is due to stimulation of both 5-HT_{1D} and 5-HT_{1A} receptor types. The design of specific antagonists might be useful for the growth control of human small cell lung carcinoma.

5-HT_{2C} RECEPTOR ACTIVATION INCREASES ARACHIDONIC ACID RELEASE.

W.P. Clarke¹, K.A. Berg² and S. Maayani^{1,2}, Departments of Pharmacology¹ and Anesthesiology², Mount Sinai School of Medicine, CUNY, New York, NY 10029.

The 5-HT_{2C} (formerly 5-HT_{1C}) receptor is a member of the 5-HT₂ receptor family which have been shown to couple to phospholipase C (PLC)-mediated phosphatidyl inositol (PI) lipid hydrolysis. Recently it has been shown that some PLC-coupled receptors can also activate phospholipase A₂ (PLA₂) to liberate arachidonic acid (AA). We have investigated the coupling of 5-HT_{2C} receptors to the PLA₂-AA pathway. CHO cells were transfected with human 5-HT_{2C} cDNA and a line stably expressing 200 fmol/mg protein was selected for study. Cells were incubated for 4 h at 37° C with 0.1 μCi/ml of [¹⁴C]-AA. After washing, 5-HT_{2C} agonist-induced release of [¹⁴C]-AA was measured at various time points (5 - 30 min). 5-HT (EC₅₀ = 28 nM), DOI (EC₅₀ = 100 nM) and quipazine (EC₅₀ = 1.2 μM) each increased AA release. DOI and quipazine were partial agonists with intrinsic activities of 0.43 and 0.32, respectively. The EC₅₀ values for each of these agonists for PI hydrolysis were similar to those for AA release (28 nM, 133 nM and 1.5 μM for 5-HT, DOI and quipazine, respectively) however, the intrinsic activities for DOI and quipazine were reversed (0.6 and 0.8 for DOI and quipazine, respectively). 5-HT-mediated AA release desensitized by 40% after 15 min treatment with 10 μM 5-HT, whereas ATP-mediated AA release was unaltered. 5-HT-mediated AA release was insensitive to treatment with pertussis toxin. Both 5-HT- and melittin-induced AA release was reduced (50%) in the absence of extracellular Ca²⁺. Inhibitors of PLC (U-73122 and ET-18-OC₃), at concentrations that reduced PI hydrolysis by greater than 90%, had little or no effect on 5-HT_{2C} agonist-mediated AA release. However the PLA₂ inhibitor mepacrine completely blocked 5-HT_{2C}-mediated AA release but did not affect 5-HT-mediated PI hydrolysis. These results suggest that 5-HT_{2C} receptors couple to the PLA₂-AA pathway in CHO cells. (Supported by UPHS grants GM 34825, DA06620, MH48125, HD26437).

475.7

2-AMINO-5-PHOSPHONOVALERATE (APV) POTENTIATES SEROTONIN-2 RECEPTOR-MEDIATED SIGNALLING IN C6BU-1 CELL AND ATT-20 CELL H.Shinno*, M.Mikuni, K.Saitoh, U.Tomita, S.Yamawaki and K.Takahashi Dep. of Mental Disorder Res., Natl. Inst. Neurosci., NCNP, Tokyo 187 and Dep. of Psychiat. Neurosci., Hiroshima Univ. Sch. of Med., Hiroshima 734, JAPAN

We investigated the effects of various N-methyl-D-aspartate (NMDA) receptor antagonists on serotonin-2 (5-HT₂) receptor-mediated Ca²⁺ mobilization and inositol 1,4,5-trisphosphate (IP₃) formation. In C6BU-1 rat glioma cell, D(-)-2-amino-5-phosphonovalerate (D-APV) potentiated 5-HT-induced Ca²⁺ mobilization and IP₃ formation, while other NMDA antagonists such as MK-801, phencyclidine and HA-966 did not. D-APV enhanced the fluoride-activated Ca²⁺ mobilization. 5-HT₂ receptor-mediated Ca²⁺ mobilization and D-APV-induced enhancement were not affected by the pretreatment with pertussis toxin. D-APV-induced potentiation of 5-HT₂ receptor-mediated signalling was also observed in AtT-20 mice pituitary tumor cell. These results suggest that enhanced GTP binding protein (G protein) function is one of the mechanisms responsible for the enhancement of 5-HT response induced by D-APV. In addition, both in C6BU-1 cell and AtT-20 cell thrombin-induced Ca²⁺ mobilization was also potentiated by D-APV suggesting that D-APV may activate G protein coupled to phosphoinositide metabolism.

CONSTITUTIVELY ACTIVE SEROTONIN 2C (5HT_{2C}) RECEPTORS STIMULATE DNA REPLICATION IN A TRANSFECTED CELL LINE. R.S. Westphal and E. Sanders-Bush*, Department of Pharmacology, Vanderbilt University School of Medicine, Nashville, TN 37232.

Agonist activation of the serotonin 2C (5HT_{2C}) receptor expressed in NIH 3T3 fibroblasts has been shown to result in the development of a transformed phenotype. In light of recent evidence demonstrating 5HT_{2C} receptor constitutive activity, the contribution of agonist independent receptor activation to transformation of NIH 3T3 fibroblasts transfected with 5HT_{2C} receptor cDNA was examined. [³H]Thymidine incorporation was used as a measure of cell growth in serum starved NIH 3T3 fibroblasts transfected with 5HT_{2C} receptor cDNA. Three classes of 5HT_{2C} receptor ligands were distinguished. In transfected, but not nontransfected, fibroblasts basal levels of [³H]thymidine incorporation were increased by agonists, decreased by inverse agonists and minimally affected by neutral antagonists. The effects of agonists and inverse agonists were blocked by a neutral antagonist. Pharmacological characterization of agonist-mediated increases in [³H]thymidine incorporation was consistent with properties of the 5HT_{2C} receptor. In addition, the rank order of potency of inverse agonists to decrease basal [³H]thymidine incorporation was consistent with the rank order to decrease basal 5HT_{2C} receptor-mediated phosphoinositide hydrolysis. Thus, in NIH 3T3 fibroblasts transfected with 5HT_{2C} receptor cDNA, the basal level of [³H]thymidine incorporation is reciprocally modulated by 5HT_{2C} receptor agonists and inverse agonists. These data suggest that constitutively active 5HT_{2C} receptors stimulate cell division and may contribute to the development of a transformed phenotype. (Supported by the National Institute of Mental Health, MH 34007).

475.6

5-HT_{2C} RECEPTORS INHIBIT 5-HT_{1B}-like RECEPTOR FUNCTION VIA ARACHIDONIC ACID METABOLISM. K.A. Berg¹, S. Maayani^{1,2}, and W.P. Clarke², Departments of Anesthesiology¹ and Pharmacology², Mount Sinai School of Medicine, CUNY, NY, NY 10029.

5-HT_{1B}-like receptor-mediated inhibition of forskolin-stimulated cAMP accumulation (FScA) is inhibited by activation of transfected human 5-HT_{2C}, but not 5-HT_{2A}, receptors in CHO cells (Berg *et al.*, Mol. Pharmacol., in press). We have investigated the role of phospholipase A₂ (PLA₂)-mediated arachidonic acid (AA) metabolism as a mediator of the effect of 5-HT_{2C} receptor activation.

In CHO cells stably expressing 5-HT_{2C} receptors (200 fmol/mg protein), 5-HT_{2C} agonists (such as DOI) increase AA release via a PLA₂-dependent mechanism (see Clarke *et al.*, this meeting). As reported previously, activation of 5-HT_{2C} receptors with DOI (1 μM) abolished 5-carboxamidotryptamine (5-CT, 5 nM)-induced inhibition of FScA. This effect of DOI was blocked following incubation with the PLA₂ inhibitor mepacrine (100 μM). The inhibition of FScA (mean % ± SE, n=5) was as follows: 55 ± 5 for 5-CT alone vs. 9 ± 7 for 5-CT + DOI; in the presence of mepacrine, 59 ± 8 for 5-CT alone vs. 61 ± 8 for 5-CT + DOI. Furthermore, the cyclooxygenase inhibitor indomethacin (2 μM) also blocked the DOI-mediated reduction of 5-CT inhibition of FScA (73% ± 5% vs 84% ± 4% for 5-CT and 5-CT + DOI, respectively, n=5). Activation of PLA₂ with melittin (2.5 μg/ml) as well as activation of naturally expressed ATP receptors abolished 5-CT-mediated inhibition of FScA and mepacrine blocked these effects. These data suggest that PLA₂-AA release mediates the 5-HT_{2C} receptor regulation of the 5-HT_{1B}-like receptor pathway in CHO cells. (Supported by UPHS grants GM 34825, DA06620, MH48125, HD26437).

475.8

INTERACTION BETWEEN INTERLEUKIN-1β AND 5-HT-2 RECEPTOR-MEDIATED SIGNALING SYSTEMS. A.Kugaya, A.Kagaya *, Y.Uchitomi, N.Motohashi and S.Yamawaki, Dept. Psychiat. Neurosci., Hiroshima Univ., Sch. Med., Hiroshima, 734, Japan.

Cytokines play an important role in the central nervous system as well as in the immune systems. In this study, we have studied the effect of several cytokines on serotonin (5-HT) -mediated signaling systems in C6 rat glioma cells. Interleukin-1β (IL-1β) inhibited 5-HT-induced Ca²⁺ mobilization (which is mediated by 5-HT-2 receptor) in a dose and time dependent manner after the cells were treated with it. However, heat-inactivated IL-1β or IFNγ did not alter the response to 5-HT. 5-HT induced cGMP generation following Ca²⁺ mobilization and this generation was inhibited by ketanserin and L-NMMA (nitric oxide synthase inhibitor), suggesting 5-HT-2 receptor and nitric oxide synthase (NOS) are responsible for the cGMP generation. IL-1β, which enhanced cGMP production mediated by NOS, attenuated 5-HT-induced cGMP response. These results suggest an interaction between IL-1β and 5-HT-2 receptor-mediated signaling systems.

475.9

PROTEIN KINASE C (PKC) INHIBITORS ENHANCE 5-HT ACTIVATION OF INTERNEURONS IN RAT PIRIFORM CORTEX MEDIATED BY THE 5-HT_{2A} RECEPTOR.

G.J. Marek* and G.K. Aghajanian. Depts. of Psychiatry and Pharmacology, Yale School of Medicine, New Haven, CT 06508.

The excitation by 5-HT of interneurons in rat piriform cortex is known to be mediated via stimulation of 5-HT_{2A} receptors. Since activation of the phosphoinositide (PI) second messenger by 5-HT acting at 5-HT_{2A} receptors leads to activation of protein kinase C (PKC), we explored the role of PKC in the 5-HT_{2A} signal transduction mechanism by testing structurally distinct PKC inhibitors. Extracellular studies were performed on interneurons excited by 5-HT near the border of layers II and III in piriform cortex slices. A specific PKC inhibitor, the benzophenanthridine alkaloid chelerythrine (25-50 μ M), increased the excitation of interneurons by 5-HT (10-100 μ M). The isoquinolinesulfonamide kinase inhibitors H7, H8 and HA 1004 (100 μ M) were also tested. H7 application robustly enhanced the excitation of interneurons by 5-HT. In contrast, H8 application only weakly enhanced the excitation of interneurons by 5-HT (10-100 μ M) and HA 1004 had no effect. None of these PKC inhibitors altered the excitation of interneurons by NE (100 μ M). The rank order potency of the isoquinolinesulfonamides is in agreement with the rank order potency of these compounds for inhibition of PKC, but not for PKA, PKG, or MLC kinase. Based on these results we propose that: 1) The activation of PKC by 5-HT rapidly desensitizes the 5-HT_{2A}-mediated excitation; 2) PKC inhibitors prevent this rapid desensitization, unmasking the full 5-HT_{2A} receptor response. Thus, activation of PKC, rather than mediating the excitatory action of 5-HT at the 5-HT_{2A} receptor, appears to have a negative feedback role.

475.11

5-HT₄ RECEPTORS MEDIATE EXCITATORY RESPONSES IN HIPPOCAMPUS THROUGH cAMP AND THE ACTIVATION OF PROTEIN KINASE A. G. Torres*, J. L. Holt and R. Andrade.

Pharmacological and Physiological Sciences, St. Louis Univ. School of Medicine, St. Louis MO 63104.

The aim of the present study was to examine the effect of serotonin (5-HT) on the calcium-activated afterhyperpolarization (AHP) in hippocampal neurons. Intracellular recordings from the CA1 region of hippocampal slices show that administration of serotonin in presence of the 5-HT_{1A} antagonist BMY 7378 produces a slow depolarization and a reduction in the AHP amplitude leading to an increase in cell excitability.

We have previously identified tentatively the serotonin receptor involved in the reduction of the AHP as belonging to the 5-HT₄ subtype. This identification was confirmed in the present study by using the selective 5-HT₄ receptor antagonists DAU 6285, SDZ 205-557 and GR 113808. All these compounds were found to act as competitive antagonists, with GR 113808 showing the highest affinity.

We also examined the signaling mechanisms involved in the 5-HT₄ receptor mediated reduction in the AHP. This effect of serotonin was mimicked by 8-Br cAMP and blocked by the protein kinase inhibitors staurosporin and Rp-cAMPS. However, it was not enhanced by IBMX at concentrations that could clearly enhance β -adrenergic responses in the same cells. The reason for this paradox is currently under investigation. In conclusion, the results of these study show that the excitatory response associated with serotonin in the hippocampus is mediated by cAMP/PKA and involves the 5-HT₄ receptor subtype. Supported by MH 43985 and the Alfred P. Sloan Foundation.

SEROTONIN RECEPTORS: MOLECULAR BIOLOGY

476.1

SITE-DIRECTED MUTAGENESIS OF THE 5-HT_{2C} RECEPTOR: IDENTIFICATION OF RESIDUES INVOLVED IN LIGAND BINDING AND RECEPTOR ACTIVATION. N.J. Stam*, P. Vanderheyden, J. Kelder, Th. de Boer, C. van Alebeek and D. Leysen. Scientific Development Group, N.V. Organon, P.O. Box 20, 5340 BH Oss, The Netherlands.

Throughout the central and peripheral nervous system multiple 5-HT receptor subtypes are expressed that belong to the family of G protein-coupled receptors. The molecular processes by which agonist and antagonists bind to 5-HT receptors are currently unknown.

In order to investigate the molecular basis for ligand binding to the 5-HT_{2C} receptor we have constructed a three-dimensional model for this receptor using the atomic coordinates of the structurally related bacteriorhodopsin as a template. Based on our model and data from other studies we have chosen six residues, proposed to be involved in 5-HT binding, for site-directed mutagenesis studies. First, we investigated the role of two aromatic residues (Phe328 and Phe329) in transmembrane domain VI, that are conserved among all G protein-coupled 5-HT receptors. To investigate the role of these aromatic residues in ligand binding and receptor activation we have substituted these residues for alanines.

Additional site-directed mutations were performed for two serine residues in transmembrane domain IV and one serine in transmembrane domain V. Both serine residues in transmembrane domain IV are conserved among all members of the 5-HT receptor family, with the exception of the 5-HT_{1A} receptor in which Ser 187 is replaced by a Gly, and in the recently cloned 5-HT_{2B} receptor in which this residue is replaced by an Ala. The Ser in transmembrane domain V is present in all members of the 5-HT₂-like (5-HT_{2A}, -2B, -2C) receptors but not in 5-HT₁-like receptors. In our model, these three Serine residues are in a position that they may interact with 5-HT. Finally, we investigated the role of an aspartic acid in transmembrane domain III, which is conserved only in cationic amine receptors and which is postulated to interact with the positively charged amine group of 5-HT. Mutant and wild-type receptors have stably been transfected into NIH3T3 cells and are currently pharmacologically characterized. Initial experiments indicate that some of the mutations affect differentially agonist binding as compared to antagonist binding.

475.10

INTERACTION OF PROTEIN KINASE C (PKC) AND PROTEIN KINASE A (PKA) IN THE MEDIATION OF 5-HT_{1P}-INDUCED SLOW DEPOLARIZATION OF TYPE 2/AH NEURONS OF THE GUINEA PIG MYENTERIC PLEXUS. H. Pan and M.D. Gershon*, Columbia Univ. P&S New York, NY 10032

5-HT evokes a slow depolarization of myenteric type 2/AH neurons by decreasing a Ca²⁺-activated K⁺ conductance (gK_{Ca}). This effect is seen in the presence of 5-HT_{1A}, 5-HT₃, and 5-HT₄ antagonists and is mediated by a novel an operationally-defined receptor (agonist = 5-hydroxyindalpine [5-OHIP]; antagonist = a dipeptide, 5-HTP-DP), called 5-HT_{1P}. Since 5-HT and 5-OHIP specifically cause immunoprecipitated G_o to become labeled by GTP-³⁵S and this labeling is blocked by 5-HTP-DP, it has been proposed that 5-HT_{1P} receptors are G_o-coupled. Experiments were done to test this hypothesis and to identify further steps in the signal transduction pathway. Responses to 5-HT were potentiated and prolonged by intracellular injection of GTP-³⁵S and inhibited by GDP- β S. Pertussis toxin (1 μ g/ml, 1.5 hrs) blocked responses to 5-HT. Responses to 5-HT were also antagonized by an inhibitor of phospholipase C (D609; 0.1mM), inhibitors of PKC (chelerythrine, 3-6 μ M; a pseudosubstrate PKC inhibitor [PKCi]₍₁₉₋₃₁₎; injected intracellularly), and down-regulation of PKC (by incubation with phorbol dibutyrate (PDBU; 10 μ M) for > 5 hrs). Activators of PKC (PDBU, (-)-7-octylindolactam V, oleoyl-acetyl-glycerol) mimicked responses to 5-HT. Responses to 5-HT, however, can also be mimicked by activators of PKA and antagonized by the PKA inhibitor, Rp-cAMPS (injected intracellularly) and by 2',5'-dideoxyadenosine (0.4-0.6 mM), an inhibitor of adenylyl cyclase. Okadaic acid (2 μ M), an inhibitor of protein phosphatases 1 and 2A, potentiated and prolonged the response to 5-HT. We propose that PKC and PKA are both activated by 5-HT and mediate the decrease in gK_{Ca}. We suggest the following pathways: 5-HT \rightarrow 5-HT_{1P} \rightarrow G_o \rightarrow \uparrow PLC \rightarrow \uparrow 1,2 diacylglycerol \rightarrow \uparrow PKC \rightarrow \uparrow adenylyl cyclase \rightarrow \uparrow cAMP \rightarrow \uparrow PKA \rightarrow \downarrow gK_{Ca}. PKC may also directly \downarrow gK_{Ca}. (Supported by NIH grant NS12969).

Mutagenesis studies of the human 5HT_{2A} and 5-HT_{2C} receptors. N. Almaula, L. Chi, B. Ebersole, S. Maavani, J.A. Ballesteros, H. Weinstein, and S.C. Sealfon*. Mount Sinai School of Medicine, New York, N.Y. 10029.

The 5-HT₂ receptor subtypes are thought to mediate the action of hallucinogenic drugs of abuse. Mutagenesis studies of human 5-HT₂ subtype receptors have been initiated in an attempt to clarify the receptor structures and the mechanism of ligand binding and activation by partial and full agonists. The targets for study have been selected based on differences between the two subtypes, interactions of transmembrane helices (TMHs) proposed in other receptors, molecular modeling, and published mutations. 9 mutations have been studied in the 5-HT_{2A} receptor at positions 120, 134, 242, 372, and 376. Corresponding mutations at 5-HT_{2C} positions 112 and 222 have also been generated. Mutation of 5-HT_{2A} S242-A causes an increase in mesulergine affinity, as reported (Kao et al. FEBS 307:324,1992) and a decrease in the affinity for the hallucinogens LSD and psilocin. Mutation or exchange of residues at two conserved loci, TMH2:D120 and TMH7:N376, residues predicted to be in proximity in the GnRH receptor (Zhou et al. Mol. Pharm. 45:165,1994) did not affect ketanserin affinity. Mutations corresponding to published mutations in the rat 5-HT_{2A} receptor yield results that differ from those reported for certain drugs. Several mutations are being evaluated to probe and refine a model of the mechanism of activation of the 5-HT_{2A} receptor (Zhang and Weinstein J.Med. Chem. 36:934,1993). (Supported by NIH-NIDA DA00620 and DA00060 and USPHS GM 34852).

476.3

AN AROMATIC RESIDUE AT POSITION 340 IS ESSENTIAL FOR ERGOT BUT NOT ERGOPEPTINE BINDING TO THE 5-HT_{2A} RECEPTOR. MS Choudhary¹, A. Uluer², RB Westkaemper¹, RA Glennon¹ and BL Roth². ¹Department of Psychiatry, Case Western Reserve University Medical School, Cleveland, OH 44106 and ²Department of Medicinal Chemistry, Medical College of Virginia, Virginia Commonwealth University, Richmond, VA.

We have investigated the molecular requirements for drug binding to serotonin_{2A} (5-hydroxytryptamine_{2A}; 5-HT_{2A}) receptors and previously discovered a single, highly conserved, aromatic residue, Phe340, which is essential for ergot binding to the 5-HT_{2A} receptor. To clarify the details of ergot-receptor interactions, an additional 8 point mutations were constructed and expressed in COS-7 cells. The effects of these point mutations on the binding of 14 different ergot and ergopeptide derivatives were then determined. Mutations at position 340 in which an aliphatic residue was substituted for an aromatic residue (e.g. F340L, F340A) greatly diminished ergot (100-1000-fold decrease in K_i) but not ergopeptide (<10 fold decrease in K_i) affinities. By contrast, mutations at position 340 in which an aromatic residue was conserved (e.g. F340Y) did not appreciably affect ergot or ergopeptide affinities. Mutations at position 339, in general, had either no effect (F339A, F339L) or modest effects (F339Y) on ergot and ergopeptide K_i's. The F125 mutations had little effect on ergot and ergopeptide binding. Two molecular models (one in which ergots and ergopeptides bind to different residues, another in which they utilize similar residues) were evaluated using three-dimensional computer-graphic models of 5-HT_{2A} receptor-ligand interactions. The results suggest that an aromatic residue at position 340, but not 339, is essential for ergot but not ergopeptide binding to the 5-HT_{2A} receptor.

MOLECULAR CLONING AND CHARACTERIZATION OF SEROTONIN AND OCTOPAMINE RECEPTORS OF APLYSIA. X.-C. Li¹, J.-F. Giot, René Hen, K.R. Weiss², X. Lo², and E.R. Kandel. Ctr. Neurobiol. & Behav., Columbia Univ., HHMI, NY, NY 10032; ²Dept. Physiol. & Biophys., Mt. Sinai School of Medicine, NY, NY 10029

Serotonin, a modulatory neurotransmitter, acts on different receptors to activate a variety of postsynaptic responses. In particular, serotonin can elicit short- and long-term facilitation of the monosynaptic connections between the sensory and motor neurons of the *Aplysia* gill-withdrawal reflex. The short-term actions of 5-HT likely involve activation of at least two types of 5-HT receptors, those coupled to cAMP and PKA and those coupled to PKC. To analyze this transduction mechanism on the molecular level, we isolated two 5-HT receptor genes from *Aplysia*, Ap5HT2A and Ap5HT2B, and one gene encoding an octopamine receptor, ApOctR. Both 5-HT receptors contain characteristic seven hydrophobic regions. The amino acid sequence in this putative transmembrane region is homologous to those of other serotonin receptors. The protein homology between the two receptors is 80%. Homology with mammalian 5-HT receptors 5HT1A, 5HT1C, 5HT2, *Drosophila* 5-HT receptors Dro1, Dro2b, *Lymanus* 5-HT receptor Lym17, are 37%, 39%, 41%, 38%, 35%, and 32% respectively. When expressed in mammalian cells both Ap5HT2A and Ap5HT2B stimulate phosphoinositide turnover by phospholipase C activation and mobilize intracellular Ca²⁺. Both are expressed in the *Aplysia* CNS. To further analyze the role of cAMP we also isolated an octopamine receptor that stimulates adenyl cyclase to increase cAMP over 500-fold in mammalian cultured cells. Since the sensory neurons of *Aplysia* lack octopamine receptors, transfection of this receptor into the sensory neurons should allow study of the short- and long-term consequences of the selective activation of the cAMP pathway.

HUMAN AND MOUSE 5-HT_{5A} AND 5-HT_{5B} RECEPTORS: CLONING AND FUNCTIONAL EXPRESSION. R. Grailhe, N. Amlaiki, A. Ghavami, S. Ramboz, F. Yocca¹, C. Mahle, C. Margouris, F. Perrot, and R. Hen. ¹Center for Neurobiology and Behavior, Columbia University, 10032 New York, NY. ²Bristol-Myers Squibb, 06492 Wallingford, CT. ³L.G.M.E CNRS, 67085 Strasbourg, France. ⁴Rhône-Poulenc Rorer, Vitry-sur-Seine, France.

We isolated from a mouse brain cDNA library and a human genomic library the genes encoding the 5-HT_{5A} and 5-HT_{5B} serotonin receptors. Amino acid sequence comparisons revealed that the human 5-HT_{5A} receptor is 85% homologous to the mouse 5-HT_{5A} receptor. We only found one human 5-HT_{5B} pseudogene raising the possibility that there is no functional human 5-HT_{5B} receptor. When expressed in Cos-7 cells, the mouse 5-HT_{5A} receptor displayed high (K_d=0.84nM) and low affinity (K_d=13nM) binding sites for the radiolabelled ligand [3H]5-CT. Both sites were insensitive to GppNHP suggesting that the 5-HT_{5A} receptor is not coupled to G proteins in Cos-7 cells. The pharmacological profile of the mouse 5-HT_{5A} receptor resembled the profile of 5-CT sensitive sites that were found in the mouse brain and that were insensitive to GppNHP. In Cos-7 and NIH 3T3 cells expressing the mouse 5-HT_{5A} receptor we did not detect any change in adenylate cyclase or phospholipase activity in response to serotonin. We are currently analyzing the possible coupling of 5-HT₅ receptors to ion channels in a variety of neuronal cell lines. In order to study the function of the 5-HT_{5A} receptor we are using gene targeting techniques to generate mutant mice lacking this receptor.

476.4

A SMALL REGION IN THE SIXTH AND SEVENTH TRANSMEMBRANE DOMAINS OF THE HUMAN 5-HT_{1Dβ} AND 5-HT_{1E} RECEPTORS DETERMINES 5-CARBOXAMIDOTRYPTAMINE AFFINITY. E.M. Parker¹, D.A. Grissel and R.A. Shapiro. Departments of Psychobiological Disorders and Inflammation, Bristol-Myers Squibb Co., Wallingford, CT and Seattle, WA

Two 5-hydroxytryptamine (5-HT) receptor subtypes, the 5-HT_{1Dβ} and 5-HT_{1E} receptors, have primary structures that are approximately 50% identical. However, the 5-HT_{1Dβ} receptor has high affinity for 5-carboxamidotryptamine (5-CT) whereas the 5-HT_{1E} receptor has low affinity for this compound. In order to ascertain the structural basis for this difference, a series of chimeric 5-HT_{1Dβ}/5-HT_{1E} receptors was constructed. Ligand binding experiments with the chimeric receptors showed that a stretch of 57 amino acids extending from the beginning of the sixth to the middle of the seventh transmembrane domain of these two 5-HT receptors was largely responsible for determining 5-CT affinity. All the chimeric receptors had high affinity for 5-HT and lysergol, suggesting that the gross three dimensional structure of the chimeric receptors was not altered. A mutant 5-HT_{1Dβ} receptor in which two residues in the sixth transmembrane domain were changed to the corresponding residues in the 5-HT_{1E} receptor (I333S334 converted to K333E334) showed markedly lower affinity for 5-CT than did the wild type 5-HT_{1Dβ} receptor but retained high affinity for 5-HT and lysergol. Neither single mutation alone (i.e. I333 converted to K333 or S334 converted to E334) was sufficient to alter 5-CT affinity. These data suggest that two amino acids in the sixth transmembrane domain are largely responsible for determining the affinity of the 5-HT_{1Dβ} and 5-HT_{1E} receptors for 5-CT.

476.6

STRUCTURE AND CHARACTERIZATION OF THE RAT 5-HT_{1C} RECEPTOR GENE. Junko Aimi¹, Hung-Teh Kao, and Roland D. Ciaranello. Nancy Pritzker Laboratory of Developmental and Molecular Neurobiology, Dept. Psychiatry, Stanford University, Stanford, CA 94305

The structure of the rat 5-HT_{1C} receptor gene has been determined by two overlapping genomic clones which span approximately 30 kb. Exon/intron junctions were defined by polymerase chain reaction (PCR) and confirmed directly by sequence analysis. Cloning the 3' region of the mRNA enabled us to determine the sequence of the entire cDNA. The 5' end of the transcript was mapped by primer extension analysis and determined to be 691 nucleotides (nt) upstream of the initiator ATG. The full length transcript is 4732 (nt). This consists of a coding sequence of 1380 nt, flanked by a long 3'UTR of 2666 nt, and 691 nt of 5'UTR.

Sequence analysis of the 5' flanking region suggests that the 5-HT_{1C} receptor gene lacks a classical TATAA box in the proximity of the transcription initiation site. However, a number of consensus binding sequences for cis-acting elements including AP1 and AP2 have been identified in this region. To characterize the regulatory sequences of the 5-HT_{1C} gene promoter, a series of promoter deletions have been constructed and engineered into a luciferase reporter system. By utilizing a transient expression assay in two neuronal cell lines, RS1 (a PC12 derivative) and Neuro 2a, regions of the 5' flanking sequences have been identified which confer positive (between nt+1 and -165) and negative (between nt-1193 and -309) gene expression in a cell-type specific manner. To examine the regulation of 5-HT_{1C} gene expression in a more physiologically relevant context, these studies are also being employed in primary rat choroid plexus cultures as well as in other rat epithelial cell lines. This will enable us to identify cis- and trans-acting element which play a functional role in 5-HT_{1C} gene expression.

476.8

CLONING AND CHROMOSOMAL LOCALIZATION OF A HUMAN 5-HT₆ SEROTONIN RECEPTOR. R. Kohen¹, M.A. Metcalf¹, T. Druck², K. Huebner², D.R. Sibley³, M.W. Hamblin¹, ¹GRECC, Seattle VAMC and the University of Washington, Seattle, WA 98108, ²Jefferson Cancer Institute, Jefferson Medical College, Philadelphia, PA 19107; ³NINDS/NIH, Bethesda, MD 20892.

The 5-HT₆ serotonin receptor, one of three known subtypes of mammalian Gs-coupled serotonin receptor, has received interest for its high affinity for the atypical neuroleptic clozapine. We previously reported the cloning of the rat 5-HT₆ receptor and now report the isolation of the corresponding human gene and its chromosomal localization.

The human 5-HT₆ receptor is a 440 amino acid polypeptide that is 96% identical to its rat homologue within the transmembrane regions. The nucleic acid sequences of the open reading frames from the two species are approximately 84% identical. Comparison of genomic and cDNA sequences reveals the presence of two introns -- a 3 kb intron occurs after base 714 and a 190 bp intron occurs after base 873.

Using hybridization to a somatic cell hybrid panel, the 5-HT₆ receptor gene was localized to 1p35-pter. This localization indicates that the 5-HT₆ and the 5-HT_{1Dα} loci may be closely linked. Such clustering has not been previously found within the serotonin receptor family. We have tentatively identified an Rsa I polymorphism within the 5-HT₆ coding region, which may be informative in linkage studies examining the role of this receptor in various human diseases.

Increased Platelet 5HT₂ Binding in Bipolar Patients Requiring Anticonvulsants. E. Risby, W. N. Morgan, M. Stipetic*, M. J. Owens, C.B. Nemeroff, Emory University School of Medicine, Atlanta, GA 30322.

The pathophysiologic abnormality responsible for bipolar mood disorders is unclear. Abnormalities in the serotonin system have been proposed based on preclinical data suggesting that lithium augments serotonin functioning. However, it is unclear why some patients respond well to lithium monotherapy, when others require the addition of an anticonvulsant to achieve optimal control of their bipolar illness. We compared serotonin receptor binding (5HT₂) in the platelets of 12 bipolar subjects whose illness was controlled on lithium monotherapy with 8 patients who required an anticonvulsant (6 on divalproex, 2 on carbamazepine) and 7 normal controls. Patients who required anticonvulsants had significantly higher mean ³H-LSD binding (mean = 123 ± 21 fmol/mg protein) than pure lithium responders (mean = 81 ± 27 fmol/mg protein) and normal controls (mean = 70 ± 21 fmol/mg protein). This preliminary data suggests there are no abnormalities in 5HT₂ receptor binding in lithium responders. However, patients requiring an anticonvulsant (either in combination with lithium or as monotherapy) tend to have higher 5HT₂ platelet receptor binding sites. It is unclear if the anticonvulsants are responsible for this elevation in binding sites or if high ³H-LSD binding predicts clinical response to anticonvulsants.

EFFECT OF DESIPRAMINE, LITHIUM AND ADINAZOLAM ON SEROTONIN RECEPTOR SUBTYPES IN RAT BRAIN. Y. Dwivedi, S.C. Pandey, X. Ren, P. Tueting*, and G.N. Pandey, Department of Psychiatry, College of Medicine, University of Illinois, Chicago, Illinois 60612.

We have examined the effect desipramine, lithium and adinazolam on 5HT receptor subtypes (5HT_{1C}, 5HT₂, 5HT₃ receptors) in rat brain. Male Sprague-Dawley rats were treated with desipramine (10 mg/Kg), lithium (2 meq/Kg twice) and adinazolam (10 mg/Kg) for 15 days and sacrificed after 24 hrs of last injection. The brain regions were used for measurement of 5HT₂, 5HT_{1C}, and 5HT₃ receptors. It was observed that treatment with desipramine decreased B_{max} of 5HT₂ receptors whereas lithium or adinazolam had no effect on 5HT₂ receptors in rat cortex. We also observed that lithium or adinazolam treatment has no effect on 5HT_{1C} and 5HT₃ receptors in rat cortex and hippocampus. The function of 5HT_{1C} receptor in rat choroid plexus was studied by measuring 5HT-stimulated inositol-1-phosphate (IP₁) formation. It was observed that treatment with adinazolam increased, whereas, desipramine treatment had no effect on 5HT-stimulated IP₁ formation in rat choroid plexus. These results suggest that modulation of 5HT-neurotransmission by lithium does not involve 5HT_{1C}, 5HT₂, 5HT₃ receptors in rat brain. Furthermore, adinazolam treatment has no effect on 5HT_{1C}, 5HT₂, and 5HT₃ receptor in rat brain but significantly increases the 5HT-stimulated inositol phosphate formation in rat choroid plexus.

Transcriptional Regulation of Hippocampal 5-HT_{1A} Receptors by Glucocorticoid Hormones. P. Zhong*, R.D. Ciaranello, Dept. of Psychiatry and Beh. Sci., Stanford Univ Med Ctr, Stanford, CA 94305.

5-HT_{1A} receptors in the hippocampus play a critical role in modulating limbic system output. The activity and level of 5-HT_{1A} receptors are modulated by glucocorticoid levels. The present study was undertaken to test the hypothesis that glucocorticoids attenuate the transcriptional activity of the 5-HT_{1A} receptor gene. Using *in situ* hybridization and RNase protection assays, we observed a substantial increase in 5-HT_{1A} mRNA expression after adrenalectomy in the same hippocampal regions in which 5-HT_{1A} binding sites are increased. This increase in 5-HT_{1A} mRNA expression occurs as early as one hour after adrenalectomy and precedes the increase in receptor binding sites. Further *in situ* hybridization analysis showed that 5-HT_{1A} mRNA is increased within individual hippocampal cells after adrenalectomy, whereas no evidence suggested recruitment of cells that do not express 5-HT_{1A} receptors normally. Nuclear run-on assays showed that the rate of transcription of 5-HT_{1A} mRNA after adrenalectomy increased from 60% to 75% above the rate from control preparations and could be reduced to basal levels by the administration of dexamethasone. These results suggest that transcription of hippocampal 5-HT_{1A} receptor mRNA is under negative regulation by corticosteroid hormones.

477.2

SEROTONIN 1A RECEPTOR BINDING IN THE ENTORHINAL CORTEX IN SCHIZOPHRENIA AND SUICIDE. D.C. Ohuoha, T.M. Hyde, M.M. Herman, C.F. Spurney, D.J. Sabourin*, and J.E. Kleinman, Clinical Brain Disorders Branch, NIMH, Neurosciences Center at St. Elizabeths Hospital, 2700 M.L.King Ave S.E., Washington, DC 20032.

Over the years, there has been a growing interest in the role of the entorhinal cortex in various neuropsychiatric disorders, such as Alzheimer's disease and schizophrenia. In this study we examined 5HT_{1A} receptor density in post-mortem entorhinal cortex, using quantitative autoradiography comparing patients with schizophrenia to normal controls, nonpsychotic suicides and non-schizophrenic neuroleptic-treated psychiatric patients. Blocked sections of fresh frozen brain containing the entorhinal region were obtained for study. Quantitative autoradiography of 5HT_{1A} receptors was performed using 2nM [³H]8-OHDPAT. Nonspecific binding was determined by incubating consecutive sections in the presence of 10uM 8-OHDPAT. Preliminary analysis of the autoradiograms using computerized image analysis did not reveal any statistically significant differences between patients with schizophrenia and other groups, confirming a prior study of schizophrenics and suicides of this brain region.

477.4

THE RELATIONSHIP BETWEEN 5-HT_{1A} RECEPTOR DENSITY AND mRNA LEVEL IN RAT BRAIN IS AGE AND REGION-DEPENDENT. L. Lu*, R.K. Raghupathi, M. Munir, M.-P. Kung, H. Kung and P. McGonigle Depts. of Pharmacology and Radiology Univ. of Pennsylvania, Philadelphia, PA 19104.

The relationship between the expression of 5-HT_{1A} receptors and the level of receptor mRNA was examined in coronal sections of brain from 3, 7, 10, 14, 21 and 60 day-old Sprague-Dawley rats. Sections were labelled with [¹²⁵I]-8-OH-PIPAT to visualize 5-HT_{1A} receptors. Adjacent sections were labelled with a 183 base ³⁵S-labelled riboprobe complementary to rat 5-HT_{1A} receptor mRNA. Preliminary experiments demonstrated that [¹²⁵I]-8-OH-PIPAT selectively labels 5-HT_{1A} receptors. In the hippocampus and cortex, the density of receptors increased significantly between days 3 and 21. After day 21, receptor density increased in CA1, plateaued in CA3 and dentate gyrus, and decreased in cortex. The pattern of mRNA expression paralleled the expression of receptors in each region between days 3 and 21. However, mRNA and receptor expression diverged in all of these regions between days 21 and 60. In contrast, the density of receptors in the thalamus increased between days 3 and 14 and then declined. The density of receptors in the cerebellar cortex declined steadily to almost undetectable levels between days 3 and 60. The pattern of mRNA expression paralleled receptor expression in both of these regions at every age. These results suggest that 5-HT_{1A} receptor expression is directly related to mRNA levels during development. However, it is likely that additional mechanisms regulate receptor expression in the mature brain. (Supported by USPHS MH 43821 and MH-48125)

477.6

THE REGULATORY ROLE OF CORTICOSTERONE ON THE 5-HT_{1A} RECEPTOR DURING ONTOGENY. H.J.J. van Oers, P. Zhong, R.D. Ciaranello and S. Levine*, Dept. of Psychiatry and Beh. Sci., Stanford Univ. Sch. of Med., Stanford, CA 94305.

Corticosterone (CORT) appears to have a role in regulating the 5-HT system. Stress, resulting in increased circulating CORT, acutely facilitates 5-HT turnover. Studies in adult rats have shown that following acute adrenalectomy (ADX) 5-HT_{1A} receptor density is elevated. CORT replacement at the time of ADX maintains the normal levels of receptor density and hippocampal 5-HT_{1A} receptor mRNA expression.

In the neonatal rat between post-natal-day (pnd) 4-14 CORT levels are normally low and non-circadian. The adrenal is hyporesponsive to endogenous and exogenous ACTH. This period is designated as the stress-hyporesponsive period (SHRP). In these experiments we studied the role of CORT on the 5-HT_{1A} receptor during development in order to determine the regulatory role of CORT on the 5-HT system. The 5-HT_{1A} receptor density in the rat hippocampus and brain stem was examined at pnd 6 (in the SHRP) and 21 by *in vitro* binding studies using the selective 5-HT_{1A} agonist [³H]8-OH-DPAT. The 6-day-old pups showed an increase in 5-HT_{1A} receptor density in the brain stem 24 hr post-ADX compared to SHAM animals. No discernable changes occurred in the hippocampus at this age. In the 21-day-old animals the reverse was found: no changes were observed in the brain stem and binding was increased in the hippocampus following ADX. The level of glucocorticoid receptors (GR) in the hippocampus at the early age (pnd 6) is about half of that seen at pnd 21. The suppressive effect of CORT on the 5-HT_{1A} receptors might be due to the low availability of GRs. These data suggest clear distinctions in the regulatory role of CORT on the 5-HT system during development.

477.7

EFFECTS OF ADRENALECTOMY AND CHRONIC GLUCOCORTICOID TREATMENT ON BRAIN 5-HT_{2C} RECEPTOR BINDING IN WISTAR RATS. Bridget A. Hulihan-Giblin*, Charanjit S. Aulakh, and Dennis L. Murphy. Lab. of Clinical Science, National Institute of Mental Health, Bethesda, MD 20892.

In a previous report from this laboratory, chronic glucocorticoid treatment was shown to attenuate m-chlorophenylpiperazine (m-CPP, a 5-HT₁ agonist)-induced increases in plasma prolactin, decreases in food intake and locomotor activity (Bagdy et al., 1989). m-CPP decreases food intake and locomotor activity (Kennett and Curzon, 1988; 1991) and increases plasma prolactin (Aulakh et al., 1992) by selective stimulation of 5-HT_{2C} receptors. In the present study, we investigated the effects of chronic glucocorticoid treatment and adrenalectomy on [³H]-mesulergine-labeled 5-HT_{2C} receptors in the frontal cortex, hippocampus, striatum and hypothalamus in male Wistar rats. The animals were divided into four different groups; sham-operated, sham-operated + corticosterone treatment, adrenalectomized (Adx) and Adx+ corticosterone treatment.

Adrenalectomy produced a significant decrease in Bmax values of 5-HT_{2C} receptors only in the striatum relative to sham-operated controls which was restored to control values by chronic corticosterone treatment. On the other hand, chronic corticosterone treatment produced a significant increase in Bmax values of 5-HT_{2C} receptors only in the hippocampus relative to sham-operated controls. There were no parallel changes in K_d values. These findings demonstrate modulation of 5-HT_{2C} receptor binding by the glucocorticoids.

477.9

CHRONIC BUSPIRONE TREATMENT DIFFERENTIALLY REGULATES 5-HT_{1A} AND 5-HT₂ RECEPTOR mRNA IN VARIOUS REGIONS OF THE RAT HIPPOCAMPUS. H. Chen*, L. Zhang, D. R. Rubinow and D.-M. Chuang. Section on Molecular Neurobiology and Section on Behavioral Endocrinology, Biological Psychiatry Branch, NIMH, NIH, Bethesda, MD 20892

Buspirone, a 5-HT_{1A} receptor agonist with antidepressant and anxiolytic efficacy, has been studied for its chronic effects on the levels of 5-HT_{1A} and 5-HT₂ receptor mRNA in the rat hippocampus. Groups of rats were treated with buspirone (1mg/kg/day) or vehicle for 21 days using osmotic minipumps implanted subcutaneously under anesthesia. Levels of 5-HT_{1A} and 5-HT₂ receptor mRNA were analyzed by *in situ* hybridization in various subhippocampal regions. In untreated hippocampus, the rank order of the abundance of 5-HT_{1A} receptor mRNA was: dentate gyrus (DG) > CA₁ > CA₂ > CA₃ > CA₄. After buspirone treatment, 5-HT_{1A} receptor mRNA levels were significantly decreased in the CA₁ and CA₂ but were markedly increased in the CA₃, CA₄ and DG. The rank order of the hippocampal 5-HT₂ receptor mRNA abundance was: DG > CA₃ > CA₄ > CA₁ > CA₂. Buspirone treatment markedly increased levels of 5-HT₂ receptor mRNA in the CA₃, CA₄, DG and CA₂, without affecting the mRNA level in the CA₁. These results demonstrate that chronic buspirone treatment differentially regulates 5-HT_{1A} and 5-HT₂ receptor mRNA in various regions of the hippocampus. Moreover, buspirone, through activation of 5-HT_{1A} receptors, appears to "cross-talk" with the 5-HT₂ receptors. Experiments are in progress to examine whether these changes in receptor mRNA result in corresponding changes in the 5-HT receptor binding sites.

477.11

EFFECTS OF LESIONS ON THE 5-HT_{1A} RECEPTOR AND 5-HT TRANSPORTER AND THEIR mRNAs IN THE RAT DORSAL RAPHE. B. Cortés*, L. Pujols, G. Mengod, and F. Artigas. Dept. Neurochemistry, Centre d'Investigació i Desenvolupament, CSIC, Barcelona E-08034, Spain.

In the present study we used receptor autoradiography and *in situ* hybridization to examine the response of dorsal raphe neurons to drug-induced lesions of the 5-HT system. We analyzed the effect of 5,7-DHT (5,7-dihydroxytryptamine) and PCPA (*p*-chlorophenylalanine) on the 5-HT transporter and the 5-HT_{1A} autoreceptor, as labeled with [³H]-citalopram and [³H]-8-OH-DPAT, respectively. Their corresponding mRNAs were visualized using [³²S]-labeled oligonucleotides. Both mRNA species were present at high densities in dorsal raphe cells. Fifteen days after *i.c.v.* administration of 5,7-DHT (200 µg/20 µl) no hybridization signal for the mRNAs encoding the 5-HT transporter and the 5-HT_{1A} receptor could be detected in the dorsal raphe. This depletion of messengers ran in parallel with a marked reduction in the density of the encoded proteins in this nucleus. The two proteins were, however, differently affected. Thus, [³H]-citalopram binding was reduced by about 40% in the ventral third of the dorsal raphe, whereas no binding could be observed in the dorsal parts of the nucleus, nor in surrounding structures of the midbrain and hippocampus. In contrast, 5-HT_{1A} receptor concentrations decreased homogeneously throughout the dorsal raphe (85% depletion), but were apparently unaffected in other brain structures. After administration of a single dose of PCPA (300 mg/kg *i.p.*) a transient but marked reduction in both 5-HT transporter and 5-HT_{1A} receptor mRNA was observed in the dorsal raphe. A similar time course profile was followed by 5-HT_{1A} receptor binding, although its recovery was slower. In the same animals [³H]-citalopram binding was not significantly affected by PCPA. The results show that damage to 5-HT neurons differentially alters presynaptic 5-HT markers.

CHRONIC ESTROGEN TREATMENT OF FEMALE RATS ENHANCES 5-HT_{1A}-MEDIATED cAMP ACCUMULATION IN HIPPOCAMPAL SLICES. Y. Chen*, K.A. Berg*, and W.P. Clarke. Departments of Pharmacology¹ and Anesthesiology², Mount Sinai School of Medicine, CUNY, New York, NY 10029.

Female sex hormones and 5-HT_{1A} receptor systems have been implicated in the etiology of affective disorders such as anxiety and depression. Recently, we showed that chronic treatment of ovariectomized (OVX) female rats with estrogen (E) enhances 5-HT_{1A}-mediated electrophysiological responses in rat hippocampal slices. E-treatment also enhances the 5-HT_{1A}-mediated inhibition of adenylyl cyclase activity in hippocampal membranes, but to a much smaller degree. To study effects of E on both responses coupled to the 5-HT_{1A} receptor in hippocampus we have developed a method to assess adenylyl cyclase activity in rat hippocampal slices that are maintained under similar conditions as those for electrophysiological studies.

OVX female rats received sc implants of either cholesterol (control) or 10% 17β-estradiol in cholesterol. Treatment of rats with E for 5 days enhanced 5-HT_{1A}-mediated inhibition of forskolin-stimulated cAMP accumulation (FSCA) in hippocampal slices. For 5-carboxamidotryptamine, values for E_{max} (% inhibition), pEC₅₀ and slope factor were 33.8±1.4, 8.27±0.06 and 1.05±0.17 for controls and 44.0±0.76, 8.44±0.04 and 0.87±0.06 for E-treated rats, n=12. For the 5-HT_{1A} partial agonist buspirone, values were 24.9±1.25, 6.34±0.06 and 1.01±0.11 for controls and 34.8±1.0*, 6.48±0.08 and 1.2±0.17, n=8. FSCA (pmol/mg protein) was higher in slices from E-treated rats (191±1.2) than in controls (167±1.2). 5-day E treatment did not alter GABA_A-mediated inhibition of FSCA. 5-HT_{1A}-mediated inhibition of FSCA was not altered after 1 day E treatment *in vivo* nor after 30 min or 2 hr treatment with 10 nM E *in vitro*. In preliminary experiments we have begun to test the hypothesis that the effect of E on 5-HT_{1A}-mediated signal transduction may be mediated by inhibition of protein kinase C (PKC), which can desensitize the 5-HT_{1A} receptor system. 5-day E treatment increased maximal PKC activity measured *in vitro* in membrane and cytosol fractions of hippocampus. Western blot analysis revealed small increases in the quantities of PKC's α and δ in hippocampal cytosol and membrane fractions and a slight decrease in PKCγ in hippocampal membranes in response to E treatment. Treatment of hippocampal slices from OVX rats with the PKC inhibitor staurosporine for 90 min did not mimic E's effect on 5-HT_{1A} receptors. More work is needed to evaluate a role for PKC as a mediator of the E effect on 5-HT_{1A}-mediated signal transduction. (Supported by HD26437 and MH48125).

MICROTUBULES ARE INVOLVED IN THE AGONIST-INDUCED UP-REGULATION OF 5-HT₂ RECEPTOR BINDING SITES IN CEREBELLAR GRANULE CELLS. D.-M. Chuang*, H. Chen, H. Li and C. Hough. Section on Molecular Neurobiology, Biological Psychiatry Branch, NIMH, NIH, Bethesda, MD 20892

We have reported that microtubules (MT) mediate the regulation of muscarinic and β-adrenergic receptor expression in cultured cells (Mol Cell Neurosci 2: 315, 1991; J. Neurochem 62: 430, 1994). Here, we examined the role of MT in the paradoxical up-regulation of 5-HT₂ receptors induced by persistent agonist stimulation (Mol Pharmacol 43: 349, 1993). Pretreatment of cerebellar granule cells with colchicine (10 µM), a MT disruptor, did not affect basal level of 5-HT₂ receptor binding sites but largely attenuated the up-regulation of 5-HT₂ receptor sites induced by a 16-hr stimulation with DOI, a 5-HT₂ receptor agonist. This effect of colchicine was dose-dependent and completely blocked by taxol, a MT stabilizer, which by itself was inactive. Nocodazole (10 µM), another MT disruptor, also attenuated DOI-induced 5-HT₂ receptor up-regulation; the nocodazole's effect was, however, not readily reversed by taxol. β-lumicolchicine, an inactive derivative of colchicine, and cytochalasin B or D, a disrupter of microfilaments, did not affect levels of basal or DOI-stimulated 5-HT₂ binding sites. These results suggest that the structural integrity of MT plays an essential role in the agonist-induced up-regulation of 5-HT₂ receptor binding sites in cerebellar granule cells.

[³H]8-OH-DPAT BINDING SITES IN RAT CEREBRAL CORTEX DURING TREMOR INDUCED BY KAINIC ACID INJECTION. E. Radja* and T.A. Reader. Centre de Recherche en Sciences Neurologiques, Département de physiologie, Faculté de médecine, Université de Montréal (Québec) CANADA

Recent investigations, carried out using membrane homogenates from rat cerebral cortex and hippocampus, have shown that [³H]8-OH-DPAT binds to two different components. The 5-HT_{1A}^{HIGH} site corresponds to the known 5-HT_{1A} receptor while the novel 5-HT_{1A}^{LOW} site requires a high range of tritiated ligand to be saturated¹. The excitatory amino acid agonist kainic acid (KA), a conformationally restricted analog of L-glutamic acid, is selective for the kainate receptor subtype and is known to cause convulsions. Here we examined cortical [³H]8-OH-DPAT binding early after an *i.p.* injection of KA (10 mg/kg). One to two hours after treatment the first seizures take place, and at that time the animals were decapitated; their brains were rapidly removed and frozen. Saturation curves were carried out with a wide range (0.02 to 160 nM) of [³H]8-OH-DPAT concentrations. The Scatchard transformations of the data showed concave curves, and their analyses using SCAFIT² revealed two different sites. Preliminary results indicate that binding to the HT_{1A}^{HIGH} receptor is unaltered by KA treatment; in contrast, the binding capacity of 5-HT_{1A}^{LOW} sites is highly (70%) increased with no major changes in the affinity. Since there were no shifts of high- to low-affinity sites, the results argue against the existence of affinity states to explain the two [³H]8-OH-DPAT binding components. These findings lend further support to the proposal that a novel 5-HT_{1A} receptor could be present in rat brain. [Supported by the Savoy Foundation for Epilepsy]. 5-HT_{1A} RECEPTOR MODIFICATION IN HIPPOCAMPUS AND CORTEX FOLLOWING 5,7-DHT LESIONS IN THE FIMBRIA-FORNIX AND CINGULUM BUNDLE. T.D. Patel* and E.C. Zhou. Program in Medical Neurobiology and Department of Anatomy, Indiana Univ. Sch. of Med., Indianapolis, IN 46202.

Microinjection of the serotonin (5-HT) neurotoxin 5,7-dihydroxytryptamine (5,7-DHT) into the cingulum bundle (CB) and fimbria-fornix (FF) denervates the hippocampus and cortex of 5-HT fiber projections and evokes denervation supersensitivity of the 5-HT_{1A} receptor on target neurons by 14 days postlesion (Patel and Zhou, 1994). This study seeks to examine early changes in the cellular distribution and expression of the 5-HT_{1A} receptor subsequent to 5-HT denervation.

Adult female Sprague-Dawley rats were pretreated with desipramine (1mg/100 g.b.w.) and microinjected with 5,7-DHT (5ug/0.5ul) into the CB and FF. At postlesion day 5, animals were perfused and brain sections were immunocytochemically stained for 5-HT and 5-HT_{1A} receptor using the antibody against peptide 170-186 of the rat 5-HT_{1A} receptor (Azmitia et al., 1992). 5-HT immunoreactivity (IM) was virtually absent in lesioned hippocampus. No qualitative difference in 5-HT_{1A}-IM staining was detectable between lesioned and nonlesioned brains on pyramidal cells of the CA fields which exhibited 5-HT_{1A} localization to the axon hillock. However, in the molecular layer of the dentate gyrus, brains with lesion exhibit a greater number of 5-HT_{1A}-IM cells as compared to non-lesion controls. Some of these appear to have a neuronal somatodendritic morphology, while others appear to be astrocyte-like. Similarly, in layer I of cortex, brains with lesion exhibit polymorphic 5-HT_{1A}-IM elements which are not detected in nonlesion controls.

These findings suggest that (1) the loss of 5-HT innervation might be involved in signaling changes in the cellular distribution and expression of the 5-HT_{1A} receptor, (2) cells which do not normally express the 5-HT_{1A} receptor can be induced to express the receptor following 5-HT denervation, and (3) these receptor changes occur as early as 5 days postlesion.

5,7-DIHYDROXYTRYPTAMINE ALTERS 5-HT_{1B} AND 5-HT_{1D} SEROTONIN RECEPTOR mRNA EXPRESSION IN THE RAT BRAIN. J. E. Neumaier*, P. Szot, D. M. Dorsa, and M. W. Hamblin. GRECC, SVAMC, and the Department of Psychiatry and Behavioral Sciences, University of Washington, Seattle, WA 98108.

The 5-HT_{1B} and 5-HT_{1D} serotonin receptors were initially described as presynaptic autoreceptors which regulate the release of serotonin. However, these receptors have also been found to regulate the release of several other neurotransmitters in various regions of the rat brain. In this study we investigated the effects of chemical lesioning of serotonergic neurons on the levels of mRNA expression of these receptors.

5,7-Dihydroxytryptamine (5,7-DHT) or vehicle was infused sequentially into the fourth and lateral ventricles using standard protocols. We used previously reported *in situ* hybridization protocols. In the olfactory bulb and subregions of the hippocampus, 5-HT_{1D} receptor mRNA levels did not appear to be altered by the 5,7-DHT lesions. In the striatum and CA1 region of the hippocampus, 5-HT_{1B} mRNA levels also appeared unchanged. However, there was a greater than two-fold increase in hybridization signal density detected for both receptor mRNAs in the dorsal raphe, a major source of serotonin projections to the forebrain. The increases in mRNA levels detected in the dorsal raphe may reflect sprouting of new axonal processes and increased synthesis of axonal proteins.

These results may suggest that these receptors are differentially regulated when expressed in presynaptic vs. postsynaptic neurons, and that the postsynaptic receptor mRNA levels may be relatively insensitive to decreases in endogenous ligand concentration.

477.17

FUNCTIONAL SUBSENSITIVITY OF 5-HT_{2A} AND 5-HT_{2C} RECEPTORS MEDIATING HYPERTHERMIA FOLLOWING LONG-TERM TREATMENT WITH 5-HT_{2A}/5-HT_{2C} RECEPTOR ANTAGONISTS IN RATS. Pascale Mazzola-Pomietto, Charanjit S. Aulakh, James Tolliver*, and Dennis L. Murphy. Lab. of Clinical Science, National Institute of Mental Health, Bethesda, MD 20892.

We have recently demonstrated that hyperthermia induced by (±) 1-(2,5-dimethoxy-4-iodophenyl)-2-aminopropane (DOI) and m-chlorophenyl-piperazine (m-CPP) is mediated by selective stimulation of 5-HT_{2A} and 5-HT_{2C} receptors, respectively (Mazzola-Pomietto et al., 1993; Murphy et al., 1993). In the present study, we investigated whether long-term administration of 5-HT_{2A}/5-HT_{2C} receptor antagonists would produce either functional supersensitivity or subsensitivity of 5-HT_{2A} and 5-HT_{2C} receptors mediating hyperthermia. Therefore, we studied the effects of daily administration of low (1.0 mg/kg/day) and high (5.0 mg/kg/day) doses of mianserin, ritanserin, metergoline or mesulergine (5-HT_{2A}/5-HT_{2C} receptor antagonists) on DOI and m-CPP-induced hyperthermia in Wistar rats.

Daily administration of high but not low doses of mianserin for 6-7 days significantly attenuated DOI-induced but not m-CPP-induced hyperthermia. Daily administration of both low and high doses of ritanserin for 13-14 days significantly attenuated m-CPP-induced hyperthermia while DOI-induced hyperthermia was attenuated only by the high dose. These findings demonstrate functional subsensitivity of both 5-HT_{2A} and 5-HT_{2C} receptors mediating hyperthermia following long-term administration of 5-HT_{2A}/5-HT_{2C} receptor antagonists. We will also present data on the effects of long-term administration of metergoline and mesulergine on DOI and m-CPP-induced hyperthermia.

477.14

QUANTITATIVE AUTORADIOGRAPHY OF 5-HYDROXY-TRYPTAMINE_{1B} BINDING SITES IN RATS WITH NEONATAL 5,7-DIHYDROXYTRYPTAMINE LESIONS. M. R. Franzatelli*, M. M. Durkin, M. Farmer. Dept. of Neurology, Pediatrics, and Pharmacology, The George Washington University, and Center for Neurosciences, Children's Research Institute, Washington, DC 20010.

We previously found different effects on behavior, 5-HT levels, and 5-HT_{1A} sites of neonatal 5,7-dihydroxytryptamine (5,7-DHT) lesions depending on the route of 5,7-DHT injection. To study the impact of early lesions on 5-HT_{1B} sites, the terminal autoreceptor and species homolog of the human 5-HT_{1D} receptor, we labelled 5-HT_{1B} sites autoradiographically with [³H]5-HT four months after intraperitoneal (ip) or intracisternal (ic) 5,7-DHT injection during the first postnatal week. Specific binding at 5-HT_{1B} sites was greatest in substantia nigra and subiculum, but 21 other areas were quantitated as well. Both routes of 5,7-DHT injection were associated with increases in specific binding in subiculum (+37% and 18%, respectively) and posterior-subiculum (+24% and +47%). In contrast, there was a 32% increase in specific binding in substantia nigra in rats with lesions made ic but not ip. No significant differences were found in nucleus accumbens, caudate-putamen, or other brain areas. In saturation homogenate binding studies using [¹²⁵I]iodocyanopindolol one month after ip injections, neonatal (5,7-DHT) lesions did not significantly alter 5-HT_{1B} maximal binding site density in cortex, striatum, diencephalon, or brainstem. These data suggest differential effects of route of neonatal 5,7-DHT injections on plasticity of 5-HT_{1B} receptor recognition sites.

SELECTIVE PROTECTION AGAINST EEDQ OF RAT CORTICAL 5-HT_{2A} RECEPTORS BY 5-HT₂ LIGANDS. K.F. Martin, S.C. Cheetham, C.J. Kettle & D.J. Heal. (SPON: Brain Research Association) Boots Pharmaceuticals Research Dept., Nottingham, NG2 3AA, U.K.

N-Ethoxycarbonyl-2-ethoxy-1,2-dihydroquinoline (EEDQ) irreversibly inactivates 5-HT_{2A} receptors (Battaglia et al., 1986, J. Neurochem., 46, 589). We have now determined the ability of selective and non-selective 5-HT receptor agonists and antagonists to protect rat brain 5-HT_{2A} receptors *in vivo*. 5-HT_{2A} receptor binding parameters were quantified using [³H]ketanserin with the functional status determined using 5-HT-stimulated phosphoinositide (PI) metabolism. EEDQ reduced the number of [³H]ketanserin binding sites in frontal cortex by 57-73% without altering affinity. Single injections of the 5-HT₂ agonist (DOI) or the antagonists (ritanserin, ketanserin, metergoline) significantly decreased the number of 5-HT_{2A} receptors by 15-44%. However, these drugs also protected 5-HT_{2A} receptors from EEDQ-induced inactivation by 49-77%. Drugs with no 5-HT_{2A} affinity (8-OH-DPAT, RU 24969, MDL 72222) were without effect. Consistent with the binding data, DOI and ketanserin decreased the PI response to 5-HT (10 µM) by 50% and also prevented the 75% EEDQ-induced decrease. These data indicate, firstly, that 5-HT_{2A} ligands down-regulate 5-HT_{2A} receptors regardless of whether they are agonists or antagonists, and secondly, that they protect against the effects of EEDQ on receptor number and function. In addition, the data show that EEDQ does not differentiate between the high and low affinity state of the 5-HT_{2A} receptor.

REGULATION OF SEROTONIN_{2A} RECEPTORS IN HETEROLOGOUS EXPRESSION SYSTEMS. M. Grotewiel, H. Canton* and E. Sanders-Bush. Department of Pharmacology, Vanderbilt University, Nashville, TN 37232-6600

The serotonin_{2A} and serotonin_{2C} receptors are unique among receptors coupled to guanine nucleotide-binding proteins in that chronic treatment *in vivo* with agonists as well as antagonists decreases receptor density. To uncover molecular events involved in down-regulation of the serotonin_{2A} receptor, the ability of agonists and antagonists to alter receptor density was examined in three heterologous expression systems: transfected NIH 3T3, transfected Madin-Darby Canine Kidney and transfected AtT-20 cells. All three transfected cell lines exhibited pharmacological properties consistent with that predicted for cells expressing the serotonin_{2A} receptor. However, the three cell lines displayed different receptor regulation properties after treatment with drugs acting at the serotonin_{2A} receptor. In transfected NIH 3T3 cells, neither agonist nor antagonist treatment altered receptor density. Treatment with agonist as well as antagonist led to up-regulation of the serotonin_{2A} receptor in transfected Madin-Darby Canine Kidney cells. In transfected AtT-20 cells, treatment with agonist led to receptor down-regulation, whereas antagonist treatment increased receptor density. Thus, the cellular background in which the serotonin_{2A} receptor is expressed appears to determine the regulation properties of the receptor. MOLECULAR MECHANISM OF AGONIST-INDUCED REGULATION OF THE RAT 5-HT₂ RECEPTOR. A.C. Chin* and R.D. Ciaranello, Nancy Pritzker Lab, Dept. of Psychiatry, Stanford University, Stanford, CA 94305

The rat serotonin 2 (5-HT₂) receptor is expressed in a wide variety of neuronal and non-neuronal tissues. Interestingly, the regulation of the 5-HT₂ receptor in response to agonist exposure differs in the various cell types. In primary cultures of rat uterine myocytes, the 5-HT₂ receptor is involved in the regulation of collagenase expression; exposure of the cultures to 5-HT₂ agonists results in the up-regulation of both the 5-HT₂ receptor and collagenase. We present data demonstrating that the agonist-induced regulation of the 5-HT₂ receptor is mediated by protein kinase C (PKC) and results in an increase in 5-HT₂ mRNA. Furthermore, this up-regulation by agonists (and PMA) is blocked in the presence of PKC inhibitors such as staurosporine and chelerythrine. Experiments addressing whether this regulation is at the transcriptional or post-transcriptional level are currently underway and the results will be presented. In addition, we have recently described the structural organization of the gene including a characterization of promoter elements required for expression of the receptor gene in different cell types. Promoter deletion plasmids will be utilized to define the *cis*-sequences required for affecting the agonist-induced increases in 5-HT₂ mRNA levels.

DOWN-REGULATED CORTICAL [³H]KETANSERIN BINDING IN ANOREXIC MUTANT MICE EXPRESSING SEROTONERGIC HYPERINNERVATION. E.S. Corp*, N. Min, T.H. Joh and J.H. Son, Burke Medical Research Institute and Bourne Laboratory, Cornell University Medical College, White Plains, NY 10605, and Neuropsychology Program, Queens College, CUNY, Flushing, NY 11367

The murine recessive autosomal mutation *anorexia (anx)* is characterized by pre-weaning weight loss resulting in death at about 21 days. Weight differences can be seen as early as post-natal day (PD) 6, and by PD 16 mutants (*anx/anx*) can weigh as little as 30% of normal littermates. *Anx/anx* mice display dysfunctions in ingestive and motor behaviors that are consistent with defects in the central serotonergic system. Previously, it was demonstrated that the *anx* mutation is associated with profound serotonergic hyperinnervation in frontal cortex and olfactory areas. We now report that in 20-day-old *anx/anx* mice, specific [³H]Ketanserin binding in the frontal cortex is reduced in comparison with normal littermates. *In vitro* autoradiographic binding methods and computerized image analysis were employed. Binding parameters were determined using nonlinear regression assuming a single-site model. Differences were assessed using t-tests (n=4 per group, *p<0.02).

	Kd (nM)	Bmax (fmol/mg)
Normal	12 ± 3.7	145 ± 15.0
Mutant	7 ± 1.5	71 ± 9.3 *

Although Kds were slightly higher than would be predicted, the location of [³H]Ketanserin binding sites in the frontal cortex strongly suggests that binding is to 5HT₂ receptors. There were 51% fewer receptors in the frontal cortex of the mutant mice compared to their normal littermates. Since serotonin hyperinnervation is a key feature of the *anx* mutation, the reduced receptor number most likely represents down-regulation of post-synaptic 5HT₂ receptors in response to high synaptic levels of serotonin.

EXPERIMENTAL HEPATIC ENCEPHALOPATHY ASSOCIATED WITH CHANGES IN 5-HT BINDING SITES IN THE RAT BRAIN. P.B.F. Bergqvist*, D. Bratanis, G. Apelqvist, M. Bugge, and F. Bengtsson, Dept. of Clinical Pharmacology, Lund University Hospital, S-221 85 Lund, Sweden.

Previous studies on rats suffering from hepatic encephalopathy (HE) have shown a profound increase in the 5-HT turnover in the brain. A recent preliminary microdialysis study by us failed, however, to show any change in the neocortical 5-HT release associated with chronic experimental HE. Further, the effects on different 5-HT receptors in the brain in HE has not been adequately investigated. We studied the brain regional 5-HT_{1A}, 1B, and 2 subreceptor types in rats with chronic experimental HE. The regional densities of these 5-HT subreceptor types were determined in 16-25 (depending on 5-HT subreceptor type studied) brain regions by the use of autoradiography. The results showed that the 5-HT_{1A} binding sites were decreased in the HE rats compared to controls only in the dorsal part of the lateral septal nucleus (p<0.05) and in the CA1 field of Ammon's horn in the hippocampus (p<0.05). The 5-HT_{1B} binding sites were unaltered in all brain regions investigated in the HE rats, but an increase (p<0.05) in the density of the 5-HT₂ binding sites in the substantia nigra was observed. We conclude that chronic experimental HE may be associated with some alterations in the density of at least two separate brain 5-HT subreceptor types. Whether or not this observation is related to an indoleamine perturbation of relevance to the pathogenesis of HE should be further addressed in future work.

DIFFERENTIAL REGULATION OF SEROTONIN 5-HT_{2A} AND 5-HT_{2C} RECEPTORS AFTER CHRONIC TREATMENT WITH CLOZAPINE, CHLORPROMAZINE AND SOME NOVEL PUTATIVE ATYPICAL ANTIPSYCHOTIC DRUGS. M. Kuoppamäki, E.-P. Pälvimäki, E. Syvälahti and J. Hietala*, Dept. of Pharmacology, University of Turku, FIN-20520 Turku, Finland.

Previous studies have suggested that 5-HT_{2A} and 5-HT_{2C} receptors may be important for the atypical effects of clozapine. We have used quantitative autoradiography to study the number of 5-HT_{2A} and 5-HT_{2C} receptor binding sites after chronic treatment (14 days, s.c. injections once a day) with saline (SAL, 1 ml/kg), clozapine (CLOZ, 25 mg/kg), chlorpromazine (CPZ, 15 mg/kg), ORG 5222 (ORG, 0.1 mg/kg), risperidone (RIS, 0.3 mg/kg), and amperozide (AMP, 5 mg/kg). Receptor binding was measured 68h after the last injections.

In the doses used, CLOZ, CPZ, and ORG decreased the frontal cortical 5-HT_{2A} receptor binding of [³H]ketanserin and [¹²⁵I]DOI by 40-60%. AMP also significantly decreased 5-HT_{2A} receptor [³H]ketanserin binding by 30%, whereas RIS did not affect 5-HT_{2A} receptor binding. In contrast to 5-HT_{2A} receptors, only CLOZ decreased significantly (by about 50%) the 5-HT_{2C} receptor [³H]mesulergine and [¹²⁵I]DOI binding in the choroid plexus. For comparison, we also determined the number of striatal D₁ and D₂ receptor binding sites with [³H]SCH 23390 and [³H]spiperone, respectively. CPZ was the only drug to significantly upregulate D₂ receptor binding sites. None of the drugs affected D₁ receptor binding to any extent. In conclusion, this study suggests that chronic treatment with CLOZ, CPZ, ORG, RIS and AMP differentially regulate 5-HT_{2A} and 5-HT_{2C} receptors.

477.22

REGULATION OF THE 5-HT₆ SEROTONIN RECEPTOR IN STABLY TRANSFECTED 293 CELLS. Steven J. Max*, Frederick J. Monsma, Jr. and David R. Sibley, Molecular Neuropharmacology Section, Experimental Therapeutics Branch, NINDS, NIH, Bethesda, MD 20892 and †F. Hoffman-LaRoche, AG, Basel, Switzerland.

We investigated the regulatory properties of the cloned rat 5-HT₆ serotonin receptor in stably transfected HEK-293 cells. The cell line was characterized using the radioligand [³H]-lysergic acid diethylamide (³H-LSD) and exhibited K_d and B_{max} values of approximately 5 nM and 1 pmol/mg protein, respectively. Exposure to 5-hydroxytryptamine (5-HT) resulted in a dose-dependent stimulation of adenylyl cyclase activity in both intact cell and membrane preparations. Stimulation of cAMP accumulation by 5-HT was maximal at 100 μM with an EC₅₀ of 1.5 μM. Pretreatment of the cells with 100 μM 5-HT for 20 hours resulted in a sixty percent decrease in the maximal response for cAMP accumulation with no appreciable change in the EC₅₀. This effect was time-dependent, reaching maximal levels at 8 hours with a t_{1/2} ≤ 1 hour. The 5-HT pretreatment appeared to have no effect on the maximum binding capacity of [³H]-LSD nor the K_d value. Treatment of the cells with various intracellular activators of protein kinases had mixed effects on 5-HT₆ receptor function. Exposure to 1 μM phorbol-12-myristate 13-acetate (PMA), an activator of protein kinase C, for 20 hours appeared to have no effect on receptor function or binding capacity. On the other hand, treatment with 1 mM 8-(4-chlorophenylthio)-cAMP (CPT-cAMP), an activator of cAMP-dependent protein kinase, resulted in a 55% reduction in the maximal 5-HT cAMP response with no apparent change in potency. In contrast, there was no effect on the B_{max} nor the K_d as measured by [³H]-LSD binding. Overall, the data suggest that agonist-induced desensitization of the 5-HT₆ serotonin receptor occurs via stimulation of cAMP-dependent protein kinase as measured by a decrease in maximal cAMP accumulation. Furthermore, there does not appear to be a concomitant agonist-induced down-regulation of the 5-HT₆ receptor as detected with [³H]-LSD.

478.1

DISTRIBUTION OF TYROSINE HYDROXYLASE IMMUNOREACTIVE AXONS IN RELATION TO MELANOTROPES AND GLIAL-LIKE CELLS OF THE RAT PITUITARY INTERMEDIATE LOBE. B.M. Chronwall¹ and K.A. Gan². ¹School of Biological Sciences, University of Missouri-Kansas City, Kansas City, MO 64108. ²Department of Psychiatry, University of Pennsylvania, Philadelphia, PA 19104.

The majority cell population in rat pituitary intermediate lobe (IL) is the melanotropes which release β -endorphin and α -MSH. Melanotrope secretion is regulated by tonic inhibition via dopaminergic axon terminals. A smaller population of glial-like cells is present in the IL, and synaptic contacts have been described between these cells and IL axon boutons in amphibian and rat. This study utilizes image analysis methods to evaluate the anatomical relationship of tyrosine hydroxylase (TH) immunoreactive axons to cellular elements in the rat IL. Pituitaries were fixed and Vibratome sectioned at 75 μ m. Sections were incubated in anti-TH serum, processed for immunohistochemistry, and embedded in Epon. One micron serial sections were toluidine blue stained. Individual melanotropes associated with TH immunoreactive axons were identified, digitally imaged, and followed through successive sections. This process was repeated with individual glial-like cells associated with immunopositive axons. Melanotropes among other melanotropes exhibited lower numbers of TH immunopositive boutons than those sharing cell membrane surface with glial-like cells. Morphometric measurement of cell membrane surface area in single sections revealed higher densities of immunopositive boutons associated glial-like cell structures than with individual melanotropes. Using Image-1 image analysis software, three dimensional reconstruction of individual melanotropes and glial-like cells indicate that TH immunopositive axons were closely apposed with glial-like cell processes and followed these processes over several microns. These observations suggest interactions between dopaminergic axons and glial-like cells of the rat IL.

COMPARISON OF GLUTAMIC ACID DECARBOXYLASE (GAD) IMMUNOREACTIVITY IN DORSOLATERAL SEPTAL (DLSN) NEURONS RESPONSIVE AND UNRESPONSIVE TO NICOTINIC AGONISTS E.M. Sorenson^{*}, W.C. McDaniel and J.P. Gallagher. Dept. of Pharm. & Tox., Univ. of Texas Med. Br., 301 University Blvd. Galveston, TX 77555-1031

Using intracellular recording, we have previously reported that nicotine and 1,1-methyl-4-phenylpiperazinium (DMPP) hyperpolarize the majority of DLSN neurons by a postsynaptic mechanism. We have now compared the morphology, electrophysiology and GAD immunoreactivity of DMPP responsive (RES) and unresponsive (UNR) neurons.

Neurobiotin (1%, Vector) was injected into neurons at the end of recording sessions. After cutting the fixed tissue into 75 μ m sections, injected neurons were visualized using the ABC method (Vector) with DAB as the chromogen. Sections containing stained neurons were processed for GAD immunohistochemistry using primary antibody at a 1:500 (Johansen et al., 1989) or 1:2000 (Chemicon) dilution. Vector* SG was the second chromogen.

Of the 26 neurons visualized, 18 were DMPP RES (69%). Neither membrane potential nor input resistance were significantly different between DMPP RES and UNR neurons. Furthermore, no other electrophysiological differences were observed, such as, the occurrence of low threshold calcium action potentials, AHPs following single action potentials or slow ADPs following a train of action potentials. DMPP RES cells were either multi- or bipolar whereas the DMPP UNR neurons were all multipolar. While no morphological differences were apparent between multipolar DMPP RES and UNR cells, all of the DMPP UNR cells tested (6/6) were GAD-negative whereas only 60% (6/10) of the DMPP RES cells were GAD-negative. In summary, DMPP UNR cells appear to be GAD-negative, multipolar neurons. Supported by DHHS 1F32 DA 05447 to EMS and The Council for Tobacco Research, USA, Inc. to JPG.

CLONING OF A NOVEL MONOAMINE OXIDASE (MAO) cDNA FROM TROUT LIVER K. Chen, H.-F. Wu, J. Grimsby and J.C. Shih^{*}. Dept. Mol. Pharm. and Tox., Sch. of Pharmacy, Univ. of Southern California, 1985 Zonal Avenue, Los Angeles, CA 90033.

A trout liver monoamine oxidase (MAO) cDNA was cloned by screening a cDNA library with a human MAOA cDNA probe. The trout MAO cDNA encodes 499 amino acids with a molecular weight of 56.6 KDa. The deduced amino acid sequences between trout MAO and human MAOA or MAOB show 70% and 71% identity respectively. Trout MAO contains the pentapeptide sequence Ser-Gly-Gly-Cys-Tyr motif in which the cofactor FAD is covalently bound. Transient expression of the cDNA in COS7 cells shows that trout MAO oxidizes both serotonin (5-HT) and β -phenylethylamine (PEA), unlike human MAOA or MAOB which oxidizes only 5-HT or PEA, respectively. The Km for 5-HT is similar for trout MAO (188.0 μ M) and human MAOA (119.3 μ M). The Km for PEA is similar for trout MAO (4.8 μ M) and human MAOB (4.6 μ M). When 5HT was used as a substrate, similar to human MAOA, trout MAO is more sensitive to clorgyline (IC₅₀ 2.0 \times 10⁻⁶ M) than deprenyl (1.1 \times 10⁻⁶ M). However, trout MAO is less sensitive to clorgyline than human MAOA (3.7 \times 10⁻¹⁰ M). Trout MAO is less sensitive to deprenyl (IC₅₀ 5.0 \times 10⁻⁷ M) than human MAOB (IC₅₀ 2.7 \times 10⁻⁹ M) when using PEA as the substrate. These results indicate that trout MAO displays substrate and inhibitor selectivities that are not identical to either MAOA or B and therefore represents a novel type of MAO. The structure of trout MAO will provide insights into the substrate and inhibitor selectivity of the MAOs. GLUTAMIC ACID DECARBOXYLASE mRNA IS EXPRESSED IN BOTH EXCITATORY AND INHIBITORY NEURONS IN CULTURED HIPPOCAMPAL NEURONS. "M.A. Dichter", "Y. Cao, "K.S. Wilcox, "J. Eberwine, Depts. of Neurology, Pharmacology, and Psychiatry, Univ. of Penn. School of Medicine and the Graduate Hospital, Phila, PA 19104

The recently developed procedure of single cell mRNA amplification, when coupled with the whole cell patch clamp technique, can be used to investigate the expression and regulation of mRNA of a variety of proteins in identified cell types. The goal of the present set of experiments was to develop specific molecular "profiles" of excitatory and inhibitory neurons. It was hypothesized that the mRNA encoding glutamic acid decarboxylase (GAD), the enzyme which catalyzes the conversion of glutamic acid to GABA, would be present in detectable quantities only in neurons which utilized GABA as a neurotransmitter. Experiments were performed in low density hippocampal cultures. The whole cell patch clamp technique was used to record from monosynaptically connected pairs of neurons. The presynaptic neurons were positively identified as either excitatory or inhibitory based on the reversal potential and waveform of the evoked postsynaptic current. Excitatory neurons release neurotransmitter which activates postsynaptic glutamate receptors, whereas inhibitory neurons use GABA as a neurotransmitter. Ten neurons were identified as inhibitory and six neurons were identified as excitatory. Inclusion of dNTPs and reverse transcriptase in the recording pipettes insured that amplification of cellular mRNA would be initiated during the recording. Messenger RNA for GAD65 was found in all sixteen neurons at a relatively high level when compared on slot blots to brain derived neurotrophic factor. However, immunocytochemistry for GABA and GAD in the cultures demonstrated that the protein was only being expressed in approximately 40% of the neurons. These results suggest that neurotransmitter phenotype may be posttranscriptionally regulated. Supported by AG9900 (JE).

LOCALIZATION OF MONOAMINE OXIDASE A (MAO-A) IN RAT BRAIN AND IN VITRO REGULATION. J.W. Jahng¹, T.C. Wessel^{1*}, K. Chen², K.S. Kim¹, and J.C. Shih². Burke Med. Res. Inst., Cornell Univ.¹, White Plains, NY 10605 and Dept. of Molec. Pharmacol. and Toxicol., USC², Los Angeles, CA 90033.

The distribution of MAO-A gene products in the adult rat brain and adrenal medulla (AM) was examined by *in situ* hybridization and by immunocytochemistry with a polyclonal antiserum. The highest levels of MAO-A mRNA and protein expression were found in the locus ceruleus; moderate levels were detected in the serotonergic dorsal raphe nucleus (DRN), habenula, and the adrenergic neurons of the medulla oblongata; low levels were found in the substantia nigra compacta (SNc), hypothalamus, hippocampus, and the cortex. Northern blot analysis of microdissected brain regions confirmed this distribution. Compared to young adult rats, aged rats showed a clear increase in MAO-A mRNA in the SNc, DRN, and AM by *in situ* hybridization. In vitro experiments using the rat PC12 cell line revealed no significant upregulation of the MAO-A gene in response to the protein kinase A (PKA) activator, forskolin. This is in contrast to the rapid increases observed in tyrosine hydroxylase (TH) and dopamine β -hydroxylase (DBH) mRNAs. PKA-deficient pheochromocytoma cell lines showed normal MAO-A mRNA levels but decreased TH and DBH levels, suggesting that the basal transcription of the MAO-A gene is not dependent on cyclic AMP. Promoter analysis of the MAO-A gene will further delineate the responding cis-acting elements in this important gene. Supported by NIMH grants 48866, 39085, 37020, 00796 and the Welin Professorship to J.C.S.

DYNAMICS OF SEROTONIN-DEGRADATIVE PATHWAYS IN THE BRAIN OF SOME FROGS. Naokuni Takeda^{*}, Department of Biotechnology, COSMO Research Institute, Satte, Saitama, 340-01, Japan

Bufotenine (BUTN) has been found in the brain of *Bufo bufo japonicus* (Soc. Neurosci. 19, 1171; Comp. Biochem. Physiol. 107C, 275, '94). The main pathways are as follows: Serotonin - N-methyl serotonin (N-MET) - BUTN and Serotonin - N,N-dimethyltryptamine (DMT). In the brain of *Rana japonica*, serotonin was degraded to N-MET, but not to BUTN. The pathway to DMT was not found. By the injection of NIALAMIDE into the body cavity, amounts of each monoamine were highly increased. Furthermore, N-MET was gradually degraded to BUTN, and the pathways to DMT were also detected. In *Bufo*, NIALAMIDE was directly injected into the brain by microdialysis. The amounts of N-MET, BUTN and DMT were highly increased. The monoamine oxidase inhibitor was shown to evoke the appearance of intrinsic metabolic pathways from Serotonin to BUTN and to DMT.

LOCALIZATION OF TRANSMITTER RECEPTORS IN THE CHICK BRAIN IN RELATION TO AUDITORY IMPRINTING. R. Schnabel and K. Braun,* Federal Institute for Neurobiology, 39118 Magdeburg, FRG

The learning process of auditory imprinting in the domestic chick is associated with a significant, regionally restricted increase in the incorporation of radioactive deoxyglucose in the rostro-medial neostriatum/hyperstriatum (MNH), the lobus parolfactorius (LPO) and a dorsal part of the caudal neostriatum (Ndc). After successful imprinting the MNH shows a marked decrease in spine density and the remaining synapses have prolonged postsynaptic densities. We assume that these synaptic changes are controlled by transmitter/receptor systems and that changes at the receptor level may occur during the learning process.

We investigated the distribution and density of the glutamatergic NMDA and kainate (KA) receptors, the dopaminergic D1 and D2 receptors, and the GABA A receptor associated benzodiazepine binding sites by ligand autoradiography.

The MNH expressed a high density of NMDA and benzodiazepine receptors homogeneously. D1 and KA receptors showed a relative low density in the neostriatal part of MNH compared to the hyperstriatal part where a significant higher density could be observed. In Ndc a high density of NMDA, benzodiazepine and D1 receptors was detected. KA showed a low binding level. The LPO expressed a high density of D1, a moderate density of KA receptors, and a low density of NMDA and benzodiazepine receptors. D2 receptors were not detectable in the MNH and Ndc but clearly visible in the LPO. Generally, an almost complementary localization of NMDA and KA receptors was found throughout the forebrain.

We have started to compare the receptor densities in imprinted, unimprinted (trained but not imprinted) and naive, isolated chicks at several time points after imprinting.

This work was supported by grant GSF 07 NBL 06 of the BMFT.

IMMUNOPURIFICATION AND CULTURE OF SEPTAL CHOLINERGIC NEURONS FROM RAT EMBRYOS. P. Taupin*, D.A. Peterson, J. Ray and F.H. Gage, Dept. Neurosciences, UCSD, La Jolla, CA 92093-0627, USA

The ability to investigate primary cholinergic neurons of the central nervous system *in vitro* is limited due to the presence of a low number of cholinergic neurons. Attempts to enrich this population *in vitro* has met with some limited success. We used antibodies to choline acetyltransferase (ChAT) to purify the cholinergic neurons of the septal area from E 17 Fischer rat embryos, by immunomagnetophoresis. At this developmental stage, these neurons may express a membrane associated form of ChAT. This form may be important for neuron-neuron and neuron-glia interaction during the neurogenesis of the cholinergic neurons. The enrichment in cholinergic neurons was assessed by ChAT enzymatic assay and by immunocytofluorescence with double and triple staining using antibodies against ChAT, neurofilament and GFAP. A highly enriched population of viable cholinergic neurons was isolated. After purification, the cells were plated at a low density, in the presence of bFGF (20 ng/ml) and cell culture conditioned medium. The cholinergic neurons grew and extended processes. These results suggest that growth factors and environmental signals influence the growth of the purified cholinergic neurons in culture. This method will allow for the purification of other types of cells (e.g. dopaminergic neurons) expressing membrane associated form of neurotransmitter synthesizing enzymes. We are presently examining antibodies against the low and high affinity NGF receptors as reagents for immunopurification of cholinergic neurons. The diversity of populations of septal cholinergic neurons and the potential of these cells to proliferate and differentiate *in vitro*, in presence of trophic factor(s), are currently under investigation. Supported by France Parkinson and NIH.

LOCALIZATION OF TAURINE AND GLUTAMATE IN PRIMARY OLFACTORY NEURONS IN THE RAT. A. Didier*(1), O.P. Ottersen(2) and J. Storm-Mathisen(2). Lab Physiologie Neurosensorielle, URA 180, UCBL, F-69622 Villeurbanne, France(1) and Anatomical Institute, University of Oslo, PO Box 1105 Blindern, N-0317, Oslo, Norway(2).

Glutamate and taurine are widely distributed aminoacids in the CNS. In the olfactory system, information on their precise cellular distribution, critical with regard to their function in this system is still lacking. EM semi-quantitative immunocytochemistry of taurine and glutamate was performed, using previously fully characterized antibodies raised in rabbits against glutaraldehyde conjugates of glutamate or taurine. Ultrathin sections of plastic-embedded olfactory bulb were incubated with the primary antibody and subsequently treated with a second antibody coupled to colloidal gold. We report here analysis of labelling in the peripheral layers of the OB (olfactory nerve layer and glomerular layer). Taurine and glutamate are co-localized in the primary olfactory terminals within glomeruli. The density of gold particles was about 50% higher in primary olfactory terminals profiles compared to dendritic profiles for glutamate ($p < 0.0001$) and taurine ($p < 0.05$). In addition, quantification of glutamate labelling of the olfactory axons running in the olfactory nerve layer revealed that the particle density in primary terminals is 40 % higher than in the axons ($p < 0.0001$). The opposite gradient was found for taurine ($p < 0.005$).

The enrichment in glutamate of the olfactory primary terminals compared to their axons is a strong argument favoring the hypothesis of a neurotransmitter role for glutamate in olfactory receptors. Further functional studies are required to resolve the role of taurine in these receptors.

NMDA RECEPTOR IMMUNOSTAINING IN MOUSE DORSAL COCHLEAR NUCLEUS AND CEREBELLUM. M. Bilak, S. Bilak, and K. Morest*. Anatomy Dept., Univ. CT Health Ctr., Farmington 06030.

With mAb to NMDAR1 (Pharmingen) light microscopic labeling (Vectastain) of cell surfaces was the same in 3 ICR adults. In cerebellum Purkinje cell body staining varied from intense to negative; dendritic staining was only on 1°/2° shafts. No labeling of 3° dendritic, synaptic, or glial structures was evident in the molecular layer. Golgi II cell bodies were only moderately stained, but more intense labeling was associated with granule cell bodies, dendrites, and rosettes. In dorsal cochlear nucleus staining of fusiform cell bodies varied; their dendritic shafts were negative. In the molecular layer there was an intense pattern resembling that of the 3° dendrites reflecting the synaptic form of parallel fibers, as seen by synaptophysin immunostaining. Granule cells were negative. There was also staining of cartwheel, corn, and giant cell bodies and dendrites. We conclude that a significant component of the NMDA receptors differs in the granule cells, inhibitory interneurons, and projection neurons of cerebellum and cochlear nucleus. This may reflect differing roles for NMDAR1 in the processing carried out in these different circuits.

IMMUNOHISTOCHEMICAL LOCALIZATION OF D-SERINE IN RAT BRAIN. M.J. Schell* and S.H. Snyder. Department of Neuroscience, Johns Hopkins University School of Medicine, Baltimore, MD 21205.

Recent biochemical evidence indicates that D-serine comprises fully 30% of the total pool of free serine in many areas of the telencephalon. Since D-serine--but not L-serine--is a potent agonist at the glycine modulatory site of the NMDA receptor, its presence in areas known to contain abundant NMDA receptors makes it a candidate neurotransmitter. To address this possibility, we have generated a highly specific antibody against glutaraldehyde conjugates of D-serine. In dot blot screens against various amino acids coupled to dialyzed rat brain protein, the antiserum diluted 1:5000 detected 2 pmoles of D-serine with a 1000-fold selectivity over L-serine, L-glutamate, glycine, and D-aspartate conjugates. The signal was blocked by glutaraldehyde/D-serine conjugates. Immunohistochemistry revealed a heterogeneous distribution of D-serine in rat brain that matched the regional distributions reported with biochemical techniques. Intense staining was observed in the gray matter of the cerebral cortex, striatum, and hippocampus. Less intense staining was seen in the olfactory bulb, and staining in the cerebellum and brainstem was undetected. Liquid phase glutaraldehyde conjugates of D-serine but not L-serine abolished staining. Stained cells were scattered throughout the striatum and hippocampus and had a morphology resembling small interneurons. Stained cell bodies were also seen isolated in certain white matter tracts, suggesting that D-serine is also present in some glia. These results show a distribution of D-serine consistent with its possible role as an endogenous ligand for the NMDA receptor.

478.12

AUTORADIOGRAPHIC DETECTION OF REDUCED SEROTONIN UPTAKE SITES IN RAT BRAIN FOLLOWING REPEATED ADMINISTRATION OF (±) 3,4-METHYLENEDIOXYMETHAMPHETAMINE (MDMA). R. Lew*, K.E. Sabol, G. Vosmer and L.S. Seiden. Dept. Pharmacology and Physiology, University of Chicago, Chicago, IL 60637.

In the present study, [¹²⁵I]RTI-55 autoradiography to serotonin uptake sites showed repeated MDMA administration to cause a long lasting reduction in serotonin uptake sites in rat brain that persisted up to 52 weeks. Age-matched Holtzman Sprague-Dawley rats (275 - 300 g) were injected i.p. with either saline (0.9% NaCl) or MDMA (20 mg/kg free base) twice daily for 4 days and allowed to recover for 2, 8, 16, 32 and 52 weeks. Following recovery, brains from saline and MDMA treated animals were histologically processed for autoradiography. Coronal brain sections (10 µm) were incubated for 120 min with [¹²⁵I]RTI-55 (40 pM) in the absence and presence of the HT uptake blocker citalopram (300 nM). Afterwards sections were washed in PBS as air dried. Autoradiograms were generated using Kodak X-ray film and quantitated using Image 1.51. Preliminary autoradiography studies showed inclusion of RTI-121 (100 nM) and propranolol (10 µM) could inhibit [¹²⁵I]-RTI-55 binding to dopamine uptake sites and lipid sites without affecting binding to serotonin uptake sites. In the experiment proper, [¹²⁵I]-RTI-55 autoradiography showed an almost complete loss of serotonin uptake sites in prefrontal, frontal and somatosensory cortex, thalamus, hypothalamus and hippocampus in brain sections from MDMA treated animals that had recovered for only 2 weeks (1.8 - 4.8 % of control). By 16 and 52 weeks after treatment, the density of serotonin uptake sites in the above regions had recovered to 52 - 65 and 65 - 79 % respectively of control, suggesting regeneration of serotonergic terminal fields. In contrast, cell body regions such as substantia nigra, ventral tegmental area and dorsal raphe were not affected by MDMA treatment. In conclusion repeated treatment with high doses of MDMA causes a reduction of serotonin uptake sites that persists up to 52 weeks following administration and that this effect is confined to terminal fields. (This work was supported by research grant DA 00085; L.S.S is supported by RSA MH-105 62)

COMPARATIVE IMMUNOCYTOCHEMISTRY OF GLYT1 and GLYT2 GLYCINE TRANSPORTERS IN MOUSE AND RAT BRAIN. E.Jursky, S.Tamura and N.Nelson*. Roche Institute of Molecular Biology, Roche Research Center, Nutley NJ 07110

Using immunocytochemistry with polyclonal antibodies raised against recombinant fusion proteins, as well as conjugated oligopeptides, we compared the distribution of the GLYT1 and GLYT2 glycine transporters in mouse and rat brain. GLYT1 consists of two almost identical subtypes GLYT1a and GLYT1b differing only in a stretch of 10 aa in the N-terminus. We raised antibodies against the common C-terminal part as well as the N-terminal region specific for the GLYT1b subtype. Both antibodies gave the same pattern in both Western blot analysis and on brain sections examined with light microscopy. This suggests that the major pattern of immunoreactivity arises in both cases from the GLYT1b subtype. GLYT2 was localized in the rat brain in the same pattern as in the mouse: it was most abundant in the gray matter of the brainstem, less in the cerebellum, midbrain, thalamus, with only traces in pallidum, cerebral cortex, hippocampus and was completely absent in the olfactory bulb. In contrast to localized presence of the strychnine matching GLYT2, GLYT1 immunoreactivity was distributed throughout the whole brain. It was most abundant in the gray and white matter of the brainstem, cerebellum, midbrain, thalamus, olfactory bulb and less present in the cerebral cortex and hippocampus. While GLYT2 immunoreactivity was localized exclusively in the varicosities and processes, GLYT1 antibody stained processes and round shaped cells distinguishable mainly in the cerebral cortex and hippocampus where the GLYT1 immunoreactivity is more scarce.

SPATIO-TEMPORAL HETEROGENEITY OF THE GENE EXPRESSION FOR THE N-METHYL-D-ASPARTATE RECEPTOR CHANNEL SUBUNITS IN THE MOUSE NERVOUS SYSTEM. M. Watanabe* and Y. Inoue. Dept. of Anatomy, Hokkaido Univ. Sch. of Med., Sapporo 060, Japan

A number of electrophysiological, pathophysiological, and pharmacological studies have shown the functional heterogeneity of the N-methyl-D-aspartate (NMDA) receptor channel in the nervous system. In order to clarify relationships between the molecular anatomical organization of the channel subunits and the functional heterogeneity, *in situ* hybridization histochemistry has applied to reveal spatio-temporal expressions in the mouse nervous system, of five NMDA receptor channel subunit mRNAs designated as the ϵ 1-4 and the ζ 1 subunit mRNAs. The ϵ 1 subunit mRNA is expressed postnatally and distributed widely in the central nervous system at mature stages. On the other hand, the ϵ 2 subunit mRNA is found throughout the fetal central nervous system, but its expression becomes restricted to the forebrain and several subregions of the brainstem and spinal cord in the postnatal maturation. The ϵ 3 subunit mRNA appears after birth and is found predominantly in the cerebellar granule cells. Although high transcript signals are detected widely in the central nervous system at fetal stages, signal levels of the ϵ 4 subunit mRNA decrease to the background level in the postnatal maturation. As a consequence of the drastic developmental changes, heterogeneous organization of the ϵ subunit mRNAs, whose distributions are consistent with the known pharmacological and electrophysiological heterogeneity of the channel, is accomplished in the central nervous system by the postnatal third week. In contrast, the ζ 1 subunit mRNA is expressed ubiquitously throughout the central and peripheral nervous system at various developmental stages. These findings suggest that the NMDA receptor channel undergoes a developmental reorganization of the ϵ subunits, through which the central nervous system would acquire the channel with functional diversity and spatial heterogeneity.

COMPARISON OF SIGMA RECEPTOR BINDING IN MOUSE BRAIN AND SPINAL CORD. K.J.Kovács, D.Budai* and A.A. Larson. Department of Veterinary Pathobiology, University of Minnesota, Saint Paul, MN 55108.

Sigma binding sites in mouse brain areas and spinal cord were characterized using labeled (+)pentazocine (PENT) and 1,3-di-(2-tolyl)guanidine (DTG). [3 H](+)-PENT, a selective ligand for sigma₁ sites, labeled a single population of binding sites (K_d =1.19-1.69 nM) with an increasing density along the neuraxis yielding B_{max} values of (in fmol/mg protein) 543 in the cortex, 725 in the cerebellum and 934 in the spinal cord. [3 H]DTG is a nondiscriminant ligand with high affinity for both sigma₁ and sigma₂ sites and with moderate affinity for a recently described low affinity site. [3 H]DTG labeled two sites in mouse cortex, cerebellum and spinal cord membranes. The K_d (8.1-9.6 nM) and B_{max} (617-687 fmol/mg protein) values calculated for the high affinity [3 H]DTG-labeled sites did not differ in these tissues. [3 H]DTG was displaced by (+)PENT and (+) N-allylnormetazocine (SKF 10047) in a clearly biphasic manner. These ligands inhibited only approximately 30% of [3 H]DTG high affinity binding in all tissues indicating the presence of [3 H]DTG-labeled high affinity sigma₂ sites throughout the CNS. Besides its high affinity sites, [3 H]DTG labeled an other, bigger receptor population with lower affinity whose K_d and B_{max} values were significantly higher in the spinal cord than in the cortex. Experiments with boiled membranes showed that a portion of those low affinity [3 H]DTG binding sites represent ligand binding to heat-resistant nonspecific sites. (Supported by USPHS DA04090).

478.14

PHARMACOLOGICAL PROPERTIES OF [3 H]3-OH-PCP BINDING SITES IN RAT BRAIN BY AUTORADIOGRAPHIC STUDIES. T.Suzuki¹⁾*, T.Yamamoto²⁾, S.Abe¹⁾, T.Hori¹⁾, T.Moroji²⁾, H.Shiraishi¹⁾, T.Ito³⁾, I.K.Ho³⁾ 1)Dept. of Psychiatry, Univ. of Tsukuba, 2)Dept. of Psychopharmacology, Tokyo Institute of Psychiatry, 3)Dept. of Pharmacology & Toxicology, Univ. Mississippi Medical Center.

[3 H]3-OH-PCP binding in rat brain was examined using an autoradiographic study. [3 H]3-OH-PCP binding reached equilibrium by 90 min at 22°C. The B_{max} and (K_d)_{app} values were determined in 11 discrete regions. [3 H]3-OH-PCP binding appeared to label a single high affinity site with (K_d)_{app} of 3.5 to 5.5 nM. The highest level of density was observed in the stratum oriens of the CA1. Relatively high amounts of binding were present in the dentate gyrus, superficial layer of cerebral cortices. In contrast, little binding was found in the globus pallidum, cerebellum and brain stem. Both MK801 and 3-OH-PCP were more potent than SKF10047 in displacing [3 H]3-OH-PCP binding sites in a monophasic manner in the different regions. D-AP5 (NMDA antagonist), 7-chlorokynurenic acid (glycine antagonist), arcaine and diethylenetriamine inhibited [3 H]3-OH-PCP binding with 1.0 of n_H . These results suggest that [3 H]3-OH-PCP binds to NMDA/PCP ionchannel complex in preference to sigma site.

478.16

SIGMA RECEPTOR LOCALIZATION IN RAT STRIATUM AND HIPPOCAMPUS. G.M. Gonzalez-Alvarez*, D. Thompson-Montgomery and L.L. Werling. Dept. Pharmacology, The George Washington University Medical Ctr., Washington, D.C. 20037.

We have previously reported that the sigma agonists (+)pentazocine and BD737 inhibited NMDA-stimulated [3 H]DA and [3 H]NE release from rat striatal and hippocampal slices, respectively, in a concentration-dependent manner. We have now investigated the effects of these sigma ligands on NMDA-stimulated catecholamine release in the presence of tetrodotoxin (TTX).

Striata or hippocampi were dissected, chopped, and washed in Mg²⁺-free modified Krebs-HEPES buffer, then incubated with 15 nM [3 H]DA or 50 nM [3 H]NE, respectively, for 30 min. Slices were loaded into a superfusion apparatus and superfused with buffer containing 1 μ M TTX. Tissue was stimulated to release [3 H]DA or [3 H]NE by a 2 min exposure to 100 μ M NMDA. After return to the non-stimulating buffer, tissue was stimulated a second time for 2 min in the presence of a sigma agonist.

Tetrodotoxin blocks the propagation of action potentials and thereby eliminates the contribution of interneuron-mediated effects. The addition of TTX to the superfusion medium had no effect on the inhibition of [3 H]DA release by (+)pentazocine (1 μ M) and BD737 (1 μ M). Both sigma agonists inhibited approximately 40% of NMDA-stimulated DA release from rat striatal slices in the presence of TTX. In addition, TTX (1 μ M) had no effect on NMDA-stimulated [3 H]DA release in the absence of a sigma agonist. In contrast, (+)pentazocine (500 nM) and BD737 (100 nM) failed to inhibit NMDA-stimulated [3 H]NE release from rat hippocampal slices in the presence of TTX. Furthermore, TTX alone had no effect on NMDA-stimulated [3 H]NE release in the absence of (+)pentazocine or BD737. Therefore, whereas it appears that sigma receptors regulating dopamine release in the striatum are located on dopaminergic nerve terminals, sigma receptor-mediated regulation of NE release in the hippocampus appears to require functional interneurons. (Supported by a grant from NIDA to LLW and by NIGMS predoctoral fellowship to GMG.)

QUANTIFICATION OF THE SEROTONIN HYPERINNERVATION IN ADULT RAT NEOSTRIATUM AFTER NEONATAL LESION OF ITS DOPAMINE INNERVATION BY INTRAVENTRICULAR 6-OHDA. A.Mrini*, J.P. Soucy, F. Lafaille, P. Lemoine and L. Descarries. Centre de recherche en sciences neurologiques and Département de pathologie, Université de Montréal, Montréal, Québec, Canada.

A previously described technique (Doucet et al., *Brain Res.* 441:233, 1988) was used to quantitate serotonin (5-HT) innervation density after the specific labeling of these axon terminals (varicosities) by uptake and storage of [3 H]5-HT, in transverse rat brain slices radioautographed as 4 μ m-thick sections of fixed and resin-embedded tissue. With the aid of an image analysis system, counts of the labeled varicosities were obtained from 3 sectors, dorsal, mediolateral and ventral, at each of 3 transverse levels, rostral (r), intermediate (i) and dorsal (d), across the neostriatum (NS). Eight 3-month-old rats, cerebroventricularly injected with 6-OHDA at 3 days (50 μ g f.b. on each side, after DMI pretreatment) and seven littermate, normal controls were sampled. After correction for incomplete radioautographic exposure and for section thickness, and based on previous electron microscopic measurements of the average diameter of these terminals, the results could be expressed in millions of axon varicosities per mm³ of tissue. Control values ranged from 4.8 in rNS to 6.3 in cNS (5.8 in iNS), for an average of 5.6, somewhat higher than previously reported (Soghomonian et al., *Brain Res.* 425:85, 1987). The corresponding values for hyperinnervated NS ranged from 9.7 rostrally to 7.7 caudally (8.8 in iNS), for an average of 8.7 and increases of 22%, 52% and 102% above control in the cNS, iNS and rNS, respectively (average increase of 55%). These results confirm the predilection of the 5-HT hyperinnervation for the rNS, but also demonstrate its presence in the cNS, as well as an inversion of the normal gradient of neostriatal 5-HT innervation density under these conditions. (MRC grant MT-3544).

AUTORADIOGRAPHIC DISTRIBUTION OF NICOTINIC RECEPTOR SITES LABELED WITH [³H]CYTISINE IN THE HUMAN BRAIN: COMPARISON WITH MUSCARINIC RECEPTORS. L. Aubert*, D. Cécry, S. Gauthier and R. Quirion. Douglas Hospital Research Center, Departments of Psychiatry, Neurology & Neurosurgery McGill University, Montreal, Quebec, Canada H4H 1R3.

The localization of nicotinic (nAChR) and muscarinic receptor sites might provide insights on the organization of the cholinergic synapse in various brain areas. Using *in vitro* receptor autoradiography, the distribution of nAChR ([³H]cytisine, 20 nM), muscarinic M₁ ([³H]pirenzepine, 15 nM) and M₂ ([³H]AF-DX 384, 2 nM) binding sites was investigated in postmortem human brains from Alzheimer's, parkinsonian and control patients. [³H]Cytisine generated high quality autoradiograms in comparison to previously used nAChR radioligands. The lateral geniculate body and the thalamus contained the highest amounts of nAChR sites. In the frontal, temporal and entorhinal cortices, the middle layers contained high amounts of nAChR sites. In the hippocampal formation, [³H]cytisine labeling is enriched in the subiculum and dentate gyrus. The molecular layer of the cerebellum is also enriched in nAChR sites. In the frontal and temporal cortices, the distributions of M₁ (superficial laminae) and M₂ (deep laminae) sites are distinct from that of nAChR, while in the entorhinal cortex, hippocampal formation, lateral geniculate body and thalamus, the localization of M₂ sites is similar to that of nAChR. However, in the cerebellum, M₂ sites are localized mostly in the granule cell layer. In addition to nAChR sites, M₁ receptors are detected in the substantia nigra. The striatum is enriched with nAChR, M₁ and M₂ sites. A detailed quantitative analysis could clarify some of the current discrepancies regarding the status of cholinergic receptors in neurodegenerative disorders. Supported by the Alzheimer Society of Canada and MRCC.

A volkensin lesion of striatonigral neurons produces a marked decrease in mRNA expression for the m4 subtype of the muscarinic acetylcholine receptor. M.B. Harrison*, M. Tissot and R.G. Wiley†. UVA, Charlottesville, VA 22908 and †DVMC and Vanderbilt Univ., Nashville, TN 37212

By *in situ* hybridization, 3 subtypes of the muscarinic acetylcholine receptor are expressed in rat striatum, the m1 subtype in the majority of striatal neurons and the m2 subtype, a probable autoreceptor, in cholinergic interneurons which also express m1 and m4. The m4 subtype is consistently expressed on striatal neurons which express PPT mRNA but only in a subgroup of neurons expressing PPE mRNA. This colocalization data suggests that m4 mRNA may be preferentially expressed by striatonigral neurons. To further define the localization of the m1 and m4 receptor, striatonigral neurons were lesioned by injection of the suicide transport agent volkensin into the left substantia nigra of adult male rats (n=5). After 10 days, alternate sections through the striatum were hybridized with ³⁵S-labelled oligonucleotide probes for m1 or m4, exposed to film and optical density (OD) determined. Expression of m4 mRNA decreased by 63% (OD 0.134 ± 0.007 vs 0.05 ± 0.006; mean ± se, p<0.01), with an 18% decrease in m1 mRNA (OD 0.311 ± 0.03 vs 0.256 ± 0.03, p<0.05). These results are consistent with the preferential localization of m4 receptors to striatonigral neurons and suggest that acetylcholine release may differentially affect the two striatal efferent projections.

REGIONAL LOCALIZATION OF RECEPTORS AND TRANSMITTERS III

479.1

DIFFERENTIAL EXPRESSION OF SOMATOSTATIN RECEPTOR SUBTYPES QUANTIFIED BY POLYMERASE CHAIN REACTION (q-PCR) IN MOUSE EMBRYONIC HYPOTHALAMIC CELL CULTURE. C. Viollet, A. Faivre-Bauman, R. Gardette*, C. Kordon, C. Llorens-Cortes, C. Loudes and J. Epelbaum U.159 and U. 36 INSERM, Paris, 75014 and 75005, France.

By whole cell patch clamp, somatostatin (SRIF) (0.1 μM) significantly decreased glutamate sensitivity by a pertussis toxin-dependent mechanism in neuronal cultures from foetal (E16) mouse hypothalamus after the onset of neuronal maturation [14 days *in vitro* (div)]. Since five subtypes of G-protein linked SRIF receptors have recently been cloned, we developed a q-PCR in order to detect which subtypes are expressed in the developing hypothalamus. At 14 div, SSTR1 mRNA levels were twice higher than those of SSTR2 and SSTR4 while SSTR3 and SSTR5 mRNAs were not detected. By ¹²⁵I-SRIF receptor radioautography, a small population of hypothalamic neurons (<10 %) was endowed with SRIF binding sites localized on both cell bodies and processes. Octreotide, a SSTR2/SSTR5 preferring agonist displaced 70 % of total ¹²⁵I-SRIF specific binding displaceable by SRIF14 while BIM 23056, a SSTR3 selective agonist, was totally inactive. These results indicate that the great majority of neuronal SRIF binding sites in primary hypothalamic cell cultures corresponds to the SSTR2 subtype and that no direct correlation occurs between the amount of mRNA expressed and the SRIF receptor protein moieties.

PLASTICITY OF ML-1 MELANIN RECEPTORS IN CHICK BRAIN VISUAL AREAS FOLLOWING INTRAOCULAR TETRODOTOXIN (TTX) M.L. Dubocovich¹, S. Jacob¹ and D.N. Krause². ¹Dept. Molec. Pharmac. Biol. Chem., Northwestern Univ. Med. Sch., Chicago, IL 60611, & ²Dept. Pharmac., Univ. CA, Irvine, CA.

This study demonstrates the recovery of melatonin receptor expression in visual areas of chick brain following suppression by intraocular TTX administration. Chicks (3 weeks old) were injected every 3 days for 7 days with either 6 μg TTX or saline/vehicle (C), and were sacrificed at day 7 (time 0) or after 1, 3 and 7 days recovery. Brain sections were labelled with [¹²⁵I]-iodomelatonin (50 pM) and specific binding defined with melatonin (1 μM). Areas ipsilateral to the TTX-injected eye served as a control. Reductions in specific 2-[¹²⁵I]-iodomelatonin binding by TTX (time 0) were observed in the contralateral optic tract, primary (optic tectum, n. basal optic root), secondary (n. trigeminal) and tertiary (ectostriatum) visual areas (also see Fig.). Binding remained depressed for 2-3 days but was completely recovered by 7 days following TTX. The extent of recovery correlated with the degree of pupillary reflex suppression. We conclude that expression of ML-1 melatonin receptors in chick brain visual areas is selectively modulated by the visual input. MH-42922.

479.2

LOCALIZATION AND CHARACTERIZATION OF ML-2 BINDING SITES WITH 2-[¹²⁵I]-MCA-NAT TO CNS AND PERIPHERAL TISSUES OF VARIOUS SPECIES. E.J. Molinari¹, P.C. North² and M.L. Dubocovich¹. ¹Dept. Mol. Pharmacol. and Biol. Chem., Northwestern Univ. Med. Sch., Chicago, IL 60611, and ²Dept. Medicinal Chemistry, Glaxo, Ware, UK.

2-[¹²⁵I]-MCA-NAT (2-[¹²⁵I]-5-methoxy-carboxylamino-N-acetyltryptamine) selectively labels ML-2 binding sites in hamster brain membranes (Dubocovich, et al., IUPHAR Abstract, 1994, in press). Here we report the pharmacological characteristics of the ML-2 binding site in hamster kidney and testis as well as the presence of specific ML-2 binding to brain membranes of various species. The binding of 2-[¹²⁵I]-MCA-NAT to whole washed hamster brain, testis and kidney membranes shows high affinity, saturable binding (K_d = 328 ± 104 pM; B_{max} = 20 ± 1.9 fmol/mg protein, n=3) and rapid kinetics of association/dissociation as demonstrated for binding of 2-[¹²⁵I]-iodomelatonin to the ML-2 receptor. In testis and kidney, melatonin analogues competed for 2-[¹²⁵I]-MCA-NAT binding with an order of pharmacological affinities [2-iodomelatonin > 6-chloro-2-methyl-melatonin > 6-chloromelatonin > prazosin > 5-MCA-NAT > N-acetylserotonin > luzindole >> serotonin] identical to that reported in hamster brain (r = 0.989, slope: 0.80, n=10, brain vs. testis; r = 0.989, slope: 1.1, n=4, brain vs. kidney). The specific binding of 2-[¹²⁵I]-MCA-NAT (55-65 pM) sites is similar (fmol/mg protein) in brain (4.6 ± 0.4, n=26), testis (6.3 ± 0.2, n=16) and kidney (5.1 ± 0.4, n=12). High affinity specific 2-[¹²⁵I]-MCA-NAT binding was also demonstrated in C3H/HeN mouse, but not in rabbit, rat, guinea pig and chick brain membranes. In conclusion, 2-[¹²⁵I]-MCA-NAT allowed detection of specific ML-2 binding sites in CNS and peripheral tissues of hamster and mouse brain. These results suggest that the distribution of ML-2 sites is widespread. Supported by a Glaxo grant and a USPHS MH-42922 grant to MLD.

MELANIN RECEPTORS IN THE CHICK OPTIC TECTUM: PRESYNAPTIC EFFECTS AND ACTIVITY-DEPENDENT REGULATION. D.N. Krause¹, J.C. Dye², S. Jacob³, H.J. Karten² and M.L. Dubocovich³. ¹Dept. Pharmacol., College of Med., U.C. Irvine, CA 92717; ²Dept. Neurosci., U.C. San Diego, La Jolla, CA 92093; and ³Dept. Molec. Pharmacol. & Biol. Chem., Northwestern Univ. Med. Sch., Chicago, IL 60611.

We previously reported a high density of 2-[¹²⁵I]-iodomelatonin binding sites in the retinorecipient layers of the chick optic tectum (*stratum griseum et fibrosum superficiale*, SGFS) and lower levels in the optic nerve (ON). Binding in both regions is decreased by ON transection (*Brain Res.* 590:325, 1992), which suggests transport of melatonin receptors in the ON from the retina to terminals in the SGFS. We have examined the electrophysiological effects of melatonin on retinotectal transmission in a brain slice preparation of the hatching chick. Bath application of 10-20 nM melatonin suppressed tectal field potentials evoked by stimulation of retinal afferents at the level of the ON or *stratum opticum*. Alterations in the presynaptic components of the field potential isolated in 0 calcium saline support the involvement of a presynaptic site of action for melatonin. We have also found that *in vivo* intraocular injections of tetrodotoxin (TTX, 6 μg), which block the electrical activity of the retinal ganglion cells, decreased 2-[¹²⁵I]-iodomelatonin binding in the ON and optic tectum to a similar extent as that seen following ON transection. TTX (in one eye of 3 week-old chicks, every 3 days for 7 days) decreased binding in the contralateral ON (31%), SGFS (outer retinorecipient layers: 58%; inner layers: 33%) and *stratum griseum centrale* (34%). Binding in these areas recovered to control levels by 3-7 days following cessation of the TTX treatment. This suggests that expression of melatonin receptors in the retinotectal pathway, including presynaptic receptors which modulate visual input, is regulated by the activity in the pathway. DOPAMINE D3 RECEPTORS ARE ELEVATED IN SCHIZOPHRENIA AND ALZHEIMER'S (AD) CASES

E. Gurevich¹, M.-P. Kung², H. Kung² and J.N. Joyce¹. Dept. Psychiatry¹, and Radiology², Univ. Penn. Sch. Medicine, Philadelphia, PA. The binding of [¹²⁵I]-7-OH-DPAT (PIPAT; 0.2 nM, or 1/2 K_d), the ligand that binds selectively to D₃ dopamine receptors, was analyzed in sections of human brain containing caudal striatal region. The binding varied from 4 to 6 fmol/mg protein in different striatal areas, which is approximately 5-7 times lower than that of D₂ receptors. The highest concentration of D₃ receptors was observed in the ventral putamen, the caudate nucleus, and the internal part of the globus pallidus (GPi) with slightly lower binding in the external globus pallidus (GPe) and ventral pallidum (VP). The nucleus basalis of Meynert exhibited relatively low PIPAT binding. The distribution of D₃ receptors in the striatal region differs from that of D₂ receptors visualized with [¹²⁵I]epidepride in the presence of 50 nM of 7-OH-DPAT. D₂ receptor density was 4-5 times higher in the dorsal caudate-putamen than in the GP and VP. The only brain regions outside the striatum that displayed D₃ receptor density comparable to that of the striatum were the SN and amygdala. We compared PIPAT binding in caudal striatum in schizophrenia cases (n=12, 76.0±1.2 yrs) with neurologically normal control (n=12; 67.3±4.7 yrs) and AD (n=11; 79±10 yrs). The binding to D₃ receptors was significantly elevated in schizophrenics in all striatal areas except for the VP. The highest increase was observed in the GPe (81%) followed by the nucleus basalis (53% average increase). There were even higher elevations in all regions for AD. The highest increase was observed in the GPe (101%) and ventral putamen (73% average increase) followed by the GPi (63%). The results suggest that alterations in the mesolimbic DA systems leads to selective elevation in D₃ dopamine receptors. Funded by MH 43860, AG 09215.

β-ADRENOCEPTOR AUTORADIOGRAPHIC LABELLING IN HUMAN BRAIN: SUBTYPE DISTRIBUTION, EFFECTS OF AGE AND POST MORTEM DELAY AND MODIFICATIONS IN ALZHEIMER'S DISEASE. A. Pazos¹, B. Grigalba¹, J. González-Gil¹ and J. Pascual^{1,2}. ¹Dept. of Physiol. & Pharmacol., ²Dept. of Medicine, Univ. of Cantabria, Santander, Spain.

The density and distribution of β-adrenergic receptor subtypes was studied by means of quantitative autoradiography in post mortem human brain, in both control and Alzheimer's disease (AD) cases. Tissue sections were incubated with [¹²⁵I]iodocyanopindolol (ICYP). ICI-89406 and ICI-118551 were used as displacers. Our results showed a clear predominance of the β₁-subtype in areas such as the basal ganglia and the neocortex. β₂-adrenoceptors were mainly distributed in cerebellum and hippocampus. There was no effect of post mortem time (4-72h) on the density of ICYP binding. In contrast, a general general tendency of β-receptors to decrease with age was found. However, this decrease was statistically significant in telencephalic areas, such as basal ganglia, frontal and visual cortex and thalamus, but not in other areas studied such as the mesencephalon and the cerebellum. This decrease was far noticeable in the β₁-subtype. Regarding β-receptors in AD, a general tendency to decrease (20%-60%) in total receptor binding was observed in neocortex, basal ganglia, hippocampus and cerebellum. While in the neostriatum the receptor loss was due to a decrease of β₁-receptor binding (42%), in the cerebellum and hippocampus the receptor loss was secondary to a decrease of β₂-receptors (39%-60%). The decrease of β-adrenoceptor density during normal aging and in AD can be explained by the neuronal loss besides the degeneration of the locus coeruleus, known to occur in these processes. (Supported by DGICYT SAF93-265)

α2C10-ADRENERGIC RECEPTOR mRNA IN THE MONKEY CEREBRAL CORTEX: NON-RADIOACTIVE IN SITU HYBRIDIZATION COMBINED WITH IMMUNOCYTOCHEMICAL LABELING OF CELL TYPE-SPECIFIC MARKERS. F. Wang^{*} and M.S. Lidow. Section of Neurobiology, Yale University School of Medicine, New Haven, CT 06510.

The noradrenergic system is involved in regulation of high order cortical functions such as learning and memory. It has also been shown that α2C10 subtype of adrenergic receptors is among the most abundant in the cerebral cortex. The present study investigates the distribution and type of cells synthesizing this receptor subtype in the prefrontal, motor, somatosensory and visual cortical regions of the adult rhesus monkey. For this purpose, animals were perfused with 4% paraformaldehyde in 0.1M PBS buffer. Brains were dissected out, postfixed in the same fixative, briefly immersed in isopentane at -30°C, and then, stored at -70°C. *In situ* hybridization was conducted on the glass slide-mounted cryostat brain sections using digoxigenin-labeled riboprobes complementary to AccI-PstI fragment of human α2C10 receptor cDNA which is within the sequence encoding the third cytoplasmic loop of the receptor. Some *in situ*-labeled sections were simultaneously processed for fluorescent immunocytochemical visualization of GABA, parvalbumin, SMI-32 and other cell markers. We found that α2C10-receptor mRNA is expressed by cells in all cortical areas and layers observed. Nevertheless, there were significant areal differences in the laminar distribution of this mRNA. For example, in the visual cortex, the labeling was particularly prominent in layers IVa and VI. In the somatosensory cortex, the strongest signal was observed in layers III and V, and in the motor cortex, the message concentrated in layer V. Finally, the prefrontal cortex had fairly homogenous laminar distribution of the message with only slight increase in layer V. The double labeling studies showed that mRNA encoding α2C10 receptors is expressed by a variety of cells including GABA and parvalbumin-containing interneurons and SMI-32 immunoreactive pyramidal cells. Such wide distribution of α2C10-adrenergic receptors suggests that they may play an important role in cortical functions.

EFFECT OF THE ANESTHETIC PROPOFOL ON 5-HT AND FOS IN THE RAT BRAIN. T. Diab, A. W. Gelb and D.F. Cechetto^{*}. Roberts Research Inst., Univ. of Western Ontario London, Ont., Canada N6A 5K8

The effects of anesthetics on neurotransmitters at specific sites in the brain are largely unknown. In this investigation, we studied immunohistochemically the effect of propofol on 5-HT and fos in the rat brain. Paired control and experimental male Wistar rats were chronically cannulated for blood pressure monitoring and anesthetic or vehicle infusion 7 days prior to the experiment. Following a 6 hour infusion of propofol (20-25 mg/kg/hr) or the intralipid vehicle, the immunoreactivity for serotonin (5-HT) and fos were studied. Changes in immunostaining levels between pairs were quantified using computerized imaging analysis. Fos activity was determined by counting the positively stained nuclei. The 5-HT signal was significantly increased by 30% in the dorsal raphe and significantly decreased by 15% in the area postrema compared to control. Numerous positively stained fos nuclei were observed in the inferior olive in the experimental animals which was not seen in the controls. The lateral parabrachial nucleus had double the number of labelled nuclei for fos compared to the control. These results suggest that an anesthetic such as propofol can initiate site specific changes in gene activity and selective changes in neurotransmitter levels which may have functional implications for the autonomic and behavioural effects of anesthetics. CELLULAR CO-LOCALIZATION OF α2A AND α2B ADRENERGIC RECEPTOR SUBTYPES IN PRIMARY CULTURES OF RAT SPINAL CORD NEURONS. Y. Huang, M.V. Langston, H.E. Laird II^{*}, P. A. St. John and J.W. Regan. Departments of Pharmacology & Toxicology, Physiology, and Anatomy, University of Arizona, Tucson, AZ 85724.

The results of molecular cloning have revealed three subtypes of the α2-adrenergic receptor. These subtypes have been defined as the α2C10 (α2A), α2C2 (α2B) and α2C4 (α2C). α2-Adrenergic receptors have been characterized in the central nervous system and spinal cord where they are involved in a number of physiological activities, including the control of blood pressure and nociception; however, the specific cellular localization and the subtypes which mediate these effects are largely unknown. For each of the α2-adrenergic receptor subtypes, polyclonal antibodies were raised in chickens using recombinant fusion proteins containing the third intracellular loops of these receptors. The antibodies were characterized in transfected COS cells expressing each of the subtypes individually and were found to be selective and did not cross-react. Primary cultures of rat spinal cord were prepared from 14 day embryos. After 9 days in culture, they were examined by immunofluorescent microscopy. Positive immunoreactivity was detected with antibodies to the α2A and α2B, but not with antibodies to the α2C. The labeling was on neuronal, but not on glial cells. It was blocked by preincubation of the antibodies with the appropriate fusion protein. The labeling in both subtypes was distributed diffusely across the cell body and neurites, and about 80% of the neurons in heterogeneous spinal cord cultures showed the labeling in both cases. Using dual-labeling techniques, positive immunofluorescence was co-localized to neurons with both anti-α2A and anti-α2B antibodies. The rat spinal cord appears to contain α2A and α2B adrenergic receptors which are present on neurons and may be co-expressed in the same cell. (Supported by the ADCRC)

AGONIST BINDING TO α2-ADRENOCEPTORS IN ROSTRAL LOCUS COERULEUS FROM DEPRESSED SUICIDE VICTIMS AND CONTROLS. V. Klimek, C.A. Stockmeier, H.Y. Meltzer, J. Overholser, A.E. Halaris^{*}, I.A. Paul, G.A. Ordway. Dpt. Psychiatry & Human Behavior, Univ. of Mississippi Med. Ctr., Jackson, MS 39216; Dpts. Psychiatry & Psychology, Case Western Reserve U., Cleveland, OH 44106

Alterations in brain norepinephrine have been implicated in depression, schizophrenia, and anxiety. The locus coeruleus (LC) is the principal source of brain norepinephrine, and release of norepinephrine is modulated by α2-adrenoceptors on LC neurons. Alterations in α2-adrenoceptors in suicide and depression have been reported previously. In this study, the binding of the α2-adrenoceptor agonist, *p*-[¹²⁵I]-clonidine, was measured at several levels of rostral LC (rostral 4.8 mm) from 8 victims of suicide and 8 age-matched control subjects. Suicide victims were retrospectively diagnosed with major depression (n=7) or bipolar depression (n=1) using DSM-III-R criteria. In all subjects, agonist binding significantly increased in a rostral to caudal gradient within the rostral LC, paralleled by a significant elevation in the number of neuromelanin-containing cells. When agonist binding was corrected for cell number at each level, no gradients were observed. Two regions of LC could be distinguished anatomically and the density of agonist binding was significantly different between these regions. There were no significant differences in agonist binding in the rostral LC between control subjects and suicide victims. [Supported by USPHS MH46692 and American Suicide Foundation.]

Functional Localization of Alpha-2 Receptors in vivo Using Idazoxan and PET. W.W. Hong, M. Schmidt, R. Risinger, G.E. Alexander, N. Azari, J.M. Maisog, D. Mangot, C.L. Grady, M.J. Mentis, M.B. Schapiro, S.I. Rapoport, J.T. Little*, U. Freo, M. Kurkjian, W.Z. Potter, J.W. VanMeeter. Laboratory of Neuroscience, National Institute on Aging, Bethesda, MD 20892.

As a prelude to studies of alpha-2 receptor function in dementia of the Alzheimer's type and normal aging, regional cerebral blood flow (rCBF) was measured using H₂O¹⁵ PET (Scanditronix PC-2048-15B, 6 mm FWHM, 15 slices) before and during infusion of the specific alpha-2 receptor antagonist idazoxan. Five screened healthy controls (aged 20-30, four male, one female, all right handed) underwent 5 scans at rest (eyes and ears occluded) and 5 during visual stimulation with isodipole textures in an alternating fashion. The first two scans (off drug) were followed by a 200 mcg/kg 30 minute infusion of idazoxan, with a maintenance drip for the remaining eight scans. All ten scans for each subject were interpolated from 15 to 43 slices, roll-yaw corrected, registered, normalized to Talairach space, and smoothed using a gaussian filter of 20 mm x 20 mm x 12 mm. Each scan for each subject was normalized to its own global mean, then multiplied by the mean of the two no drug scans for that subject. Pixel-by-pixel analysis of rCBF was performed for each subject and for the group to identify regions affected by idazoxan. In addition, changes in rCBF were measured in each subject across time in the regions with the largest drug effect. In spite of a significant decrease in global blood flow across time (p<0.0001), blood flow to visual cortex was significantly increased by idazoxan in the group in both the resting and visually stimulated conditions (p<0.05). Moreover, each subject showed an rCBF increase in visual cortex after idazoxan in the same areas identified by the group analysis. This metabolic increase is consistent with the high density of alpha-2 receptors in the human visual cortex and enhancement of neurotransmitter release. Intravenous idazoxan and PET may be a useful way to assess central alpha-2 receptor function in neuropsychiatric illnesses.

479.13

DISTRIBUTION OF NITRIC OXIDE PRODUCING NEURONS IN THE CNS OF THE AXOLOTL, *AMBYSTOMA MEXICANUM*. M. León-Olea, M. Sánchez-Alvarez, F. Pellicer*, E. Talavera, E. Sánchez-Islas, G. Martínez-Lorenzana. Lab. Histología, Div. Neurociencias, Instituto Mexicano de Psiquiatría, Av. México-Xochimilco 101, C.P. 14370, México, D. F., México.

Nitric oxide (NO) is a highly reactive and diffusible molecule which participates in a wide variety of functions such as in the cytotoxic reaction of leucocytes, as mediator of neurotransmitters in the relaxation of vascular endothelium, and as an inhibitor of platelet aggregation.

From a phylogenetic point of view, the presence of NO producing neurons has been described in vertebrates such as rat, crab, frog and fish, and in invertebrates like crayfish and snail. Thus, the aim of this study was to report the presence and localization of NO producing neurons in the CNS of the mexican amphibian axolotl, *Ambystoma mexicanum*. The axolotls (n=6) were anaesthetized with benzocaine and intracardially perfused with 4% paraformaldehyde in 0.1M phosphate buffer (pH 7.4). The brains were dissected and post-fixed for 3-12 h, and were transferred to a sucrose solution (15 %). Parasagittal and coronal sections (20 µm) were cut and mounted on gelatinized coated slides. Vincent and Kimura's histochemical reaction was done (Neurosci. 46:775, 1992). Our results show a wide distribution of positive neurons and fibers, mainly in olfactory bulb, commissures, striatum and pallio-dorsal nuclei, in striatum-amygdaline zone, cerebellum and rombencephalon, hypothalamus and fibers in median eminence. These data show the existence on NO producing neurons in *A. mexicanum*. Further studies should be carried out to elucidate the role of this molecule in this amphibian. This work was partially supported by CONACyT grants MLO 1183-N9203.

NADPH DIAPHORASE ACTIVITY IN OLFACTORY RECEPTOR NEURON AXONS CONFORMS TO A RHINOTOPICALLY-DISTINCT DORSAL PROJECTION ZONE IN THE MOB OF HAMSTERS. T. K. Knott and T. A. Schoenfeld*. Depts. of Psychology and Biology and the Neuroscience Program, Clark University, Worcester, MA 01610.

NADPH diaphorase histochemical activity is distributed widely in the CNS, where it is most commonly localized to short-projecting neurons whose axons do not collect, for the most part, in the major white matter tracts such as the corpus callosum or cerebral peduncles (Vincent and Kimura, 1992, *Neuroscience*, 46:755). By contrast, the olfactory and vomeronasal nerves show intense NADPH diaphorase activity in the main olfactory bulb (MOB) and accessory olfactory bulb (AOB), respectively. Moreover, the olfactory nerve activity patterns are also topographically restricted to the dorsal and medial MOB (Scott et al., 1987, *J. Comp. Neurol.*, 260:378; Croul-Ottman and Brunjes, 1988, *Brain Res.*, 460:323; Davis, 1991, *J. Comp. Neurol.*, 314:493). This pattern conforms almost precisely to an obliquely oriented, rhinotopically-distinct dorsal zone known to receive projections from mucosal segments that line a relatively smooth central channel within the nasal cavity (Schoenfeld et al., 1994, *Brain Res. Bull.*, 34:183; Clancy et al., 1994, *Brain Res. Bull.*, 34:211). Thus, NADPH diaphorase activity, putatively indicative of nitric oxide activity as well, may play a role in the spatial coding of odorant molecules.

(Supported by an NSF REU site grant, the Colin Research Award and the Dept. of Psychology, Clark University.)

OCTOPAMINE, DOPAMINE AND NORADRENALINE IMMUNOCYTOCHEMISTRY IN THE RAT BRAIN: THREE DISTINCT PATTERNS OF DISTRIBUTION. S. Burchett, T.P. Hicks*, J. Rapus and M. Eckert. Depts. of Biology and Psychology, UNCG, Greensboro, NC, 27412-5001.

The distributions of three amines normally present in the mammalian nervous system: octopamine (OA), dopamine (DA) and noradrenaline (NA), were compared in rat brain following immunocytochemical treatment with polyclonal antibodies. The distributions of NA and DA conformed well with previously published accounts, in that somatic NA staining was confined to the locus coeruleus (A6, A5, A2 and A1 zones) while that for somatic DA was present in the ventral tegmental area and substantia nigra. The development of a novel antibody to OA allowed us to perform the first screening study for this compound in mammalian CNS. We found somatic label to be distributed increasingly along the rostral-caudal axis; staining in more caudal regions being relatively more intense and widely distributed than rostrally. OA immunoreactivity was demonstrated best in rats perfused with fixative solutions having relatively high glutaraldehyde levels (6%), causing a high background level of stain, and using low serum dilutions (1:250). Caudally-situated structures showing the most intense reactivity included: cranial nerve nuclei (especially V and VII); throughout the central core of the long axis of the reticular formation and ventrolateral to the cerebral aqueduct; and the deep cerebellar nuclei. The distribution of label throughout CNS was heterogeneous even though immunoreactive product was dispersed very widely within somata and axons, with few areas not showing labelled cells. Background label was also quite uneven, suggesting the possibility of unequal patterns of terminal immunoreactivity. These results are not inconsistent with the view of OA as a modulator of synaptic transmission within mammalian brain.

479.14

SEROTONINERGIC BUT NOT DOPAMINERGIC FIBERS IN THE STRIATUM OF THE RAT ARE NITRIC OXIDE (NO)-RECEPTIVE. POSSIBLE CO-LOCALIZATION OF 5-HT AND cGMP.

H.W.M. Steinbusch¹*, J. Pasterkamp¹, D. Hopkins² and J. De Vente¹. ¹Department of Psychiatry and Neuropsychology, Faculty of Medicine, University of Limburg, Maastricht, The Netherlands and ²Department of Anatomy and Neurobiology, Dalhousie University, Halifax, NS, Canada.

Within the striatum several efferent and afferent transmitter systems can be demonstrated of which serotonergic and dopaminergic varicosities are most prominent. Recently the NO-system in the brain has been visualized using either antibodies to nitric oxide synthase (NOS) or NADPH-diaphorase histochemistry. Within the striatum both NOS- and NADPH-diaphorase positive cells and fibers were localized. However, it is yet not clear which proportion of these NO-producing fibers are arising from intra- or extrastriatal origin. In this study we were interested which elements are also receptive for NO, using cGMP as parameter for NO-production. We have found that the produced NO will diffuse from the cell / fiber and can activate in neighbouring neurons guanylate cyclase. This leads to the production of cGMP, and using cGMP-immunofluorescence in conjunction with a slice-procedure we have the possibility to visualize NO-receptive elements. Using 6-OHDA lesions in the ventral tegmental area and the substantia nigra complex, or 5,7-dihydroxytryptamine lesions in the medial forebrain bundle we could demonstrate that a reduction of the dopaminergic fibers does not lead to a decrease in the number of cGMP-positive fibers, while 5,7-DHT lesions induces a diminishing of the serotonergic fibers and cGMP fibers in the striatum. Further studies are in progress to show the possible co-localization between 5-HT- and cGMP-immunofluorescence, and the absence of co-localization between cGMP and NOS in the striatum. This co-localization could provide further support for a functional connection between the NO and the 5-HT system. (Supported by NWO of The Netherlands).

MAPPING OF NADPH DIAPHORASE-CONTAINING NEURONS IN THE BUDGERIGAR BRAIN: EVIDENCE FOR A SPECIFIC SYSTEM. B. Cozzi¹*, R. Massa², and G.C. Panzica³. ¹Inst. of Anat. Dom. Animals², and ³Dept. of Biol. ²Univ. of Milan 20133; and ³Dept. of Human Anat. & Physiol. ³Univ. of Turin 10126, ITALY

The presence of NADPH diaphorase activity in neurons is believed to be indicative of the presence of nitric oxide synthase in the CNS. In some avian species (quail, chicken), NADPH diaphorase is present in a series of neurons located in specific areas of the brain. This study is directed to investigate whether the presence and systemic distribution of NADPH diaphorase in the budgerigar (*Melopsittacus undulatus*) CNS show any peculiar specific segregation. To this effect, the brains of a series of *M. undulatus* have been studied for the presence of NADPH diaphorase.

In the telencephalon, the paleostriatal-paraolfactory lobe complex showed the presence of positive neurons and a diffuse network of axons. Diaphorase-containing elements were observed also in the neostriatum, in several nuclei of the archistriatum (including the nucleus tectalis) and in the hyperstriatum (accessory, dorsal and ventral). In the diencephalon, positive neurons were present both in the lateral hypothalamic and periventricular areas, and in a segregate area at the confluence of the anterior commissure and the lateral prosencephalic bundle. A group of positive perikarya was located lateral to the dorsal part of the III ventricle, and continued laterally into the thalamus. In the mesencephalon, diaphorase-containing elements were placed in the pretectal area, reticular formation (pars lateralis and pars medialis), nucleus ruber and nucleus interpeduncularis. Several positive elements were located in the nucleus tegmenti pedunculo-pontinus, and nucleus vestibularis (pars medialis and pars superior). In the cerebellum, large stained neurons were evident in the nucleus cerebellaris internus.

NADPH-containing neurons in the budgerigar brain show a specific distribution, only in part overlapping with what already observed in other avian species. In particular, NADPH-containing neurons in *Melopsittacus undulatus* are largely distributed in several striatal areas except the ectostriate. Differences with what observed in the chicken and quail are evident especially in the hypothalamus and midbrain.

NEURONAL NITRIC OXIDE SYNTHASE IN THE BRAIN OF THE SALMON. DISTRIBUTION, SUBCELLULAR LOCALIZATION AND COLOCALIZATION Bo I. Holmqvist*, Per Alm and Peter Ekström Dept. Zoology, University of Lund, Sweden. The distribution of the neuronal nitric oxide (NO) converting enzyme, NO synthase (NOS), its subcellular localization and its relation to dopaminergic neurons are being investigated in the brain of the Atlantic salmon by means of immunocytochemical, single and dual, labeling techniques. Studies include analyses with confocal laser scanning microscopy and transmission electron microscopy.

Our current results show that NOS immunoreactive (NOSir) neuronal populations are present in all major brain areas, including in the olfactory bulb, telencephalon, preoptic/hypothalamic areas, thalamus, posterior tuberculum, optic tectum, torus semicircularis, midbrain tegmental areas, cerebellum and vagus motor nuclei. The viscerosensory root of the vagus nerve is strongly labeled and scattered NOSir nerve fibers course in various parts of the brain. A distinct granular labeling is strongly associated with specific neuronal populations, among others with specific tyrosine hydroxylase immunoreactive (THir) neuronal populations and neurosecretory neurons in preoptic/hypothalamic areas. On the ultrastructural level, NOSir axons and axon terminals were detected which exhibited membrane specializations in close apposition to processes and cell bodies, indicating that the granular staining represent NOSir synaptic contacts. In several cases, NOSir neurons are located together with THir neurons, within the same area or nuclei. NOSir is colocalized with THir in a distinct population of hypophysiotrophic neurons located within the retinohypothalamic termination field.

Our data stress that NO producing neuronal systems are widespread in brain of the salmon. NO may serve multiple functions in neural mechanisms and may, via both inter- and intracellular actions, influence a variety of brain functions in teleosts. Here we show that NO may possess neuromodulatory influence on specific hypophysiotrophic dopaminergic systems.

TRANSFERRIN RECEPTOR ANALYSIS IN HYPOTRANSFERRIN-EMIC (Hp) MOUSE BRAIN. TK Dickinson* & JR Connor, Penn State Univ, Hershey Medical Center, Hershey, PA 17033

The hypotransferrinemic (Hp) mouse has a point mutation or small deletion in the transferrin (Tf) gene causing a defect in splicing of precursor Tf mRNA. This results in production of <1% of the normal circulating level of Tf. These animals are small, pale and severely anemic at birth and die within 7 days unless given supplemental i.p. injections of mouse serum or purified Tf. We have previously analyzed the brains of these animals and shown morphological alterations, especially in areas of significant postnatal development. We have also studied the cellular and regional distribution of iron, Tf and ferritin in the Hp brain. An appreciation of the cellular and regional distribution and levels of Tf receptor in these animals is critical to complete our understanding of the mechanisms of iron transport and storage in the Hp mouse brain. Polyclonal and monoclonal antibodies to Tf receptor were applied to 40µm brain sections from wild type (HH), heterozygote (Hh) and mutant (hh) Hp animals. The overall staining for Tf receptor using these antibodies is similar for all three types and staining is generally more robust using the polyclonal antibody. The predominant cell type staining positively for Tf receptor are neurons. The Tf receptor positive neurons are seen throughout the brains of all three types. White matter astrocytes stain Tf receptor-positive but white matter itself reacts poorly. Perivascular astrocytes also stain Tf receptor-positive. Blood vessels themselves, known to contain high levels of Tf receptor, stain positive in all three animals, but react more intensely with the monoclonal antibody. Oligodendrocytes, the cells responsible for myelin production in the brain and the predominant iron-positive and Tf-positive cells, do not stain positively for Tf receptor using our antibodies.

Immunohistochemical Distribution of Calretinin in the Primate Amygdala. C.H. Lam¹, A.F. Sadikot^{1*}, M. Fortin², A. Olivier¹, A. Parent² 1. Division of Neurosurgery, Montreal Neurological Institute, McGill University, Montreal, P.Q.; 2. Laboratoire de Neurobiologie, Enfant-Jésus Hospital, Laval University, Quebec City, P.Q.

The immunohistochemical distribution of the calcium binding protein calretinin was examined in the amygdala of the squirrel monkey (*Saimiri sciureus*). A complex heterogeneous pattern of cell and neuropil staining is found in the amygdala. The basal nucleus contains a light to moderate density of triangular shaped cells in its magnocellular component, with light staining of neuropil. The parvocellular part of the basal nucleus contains a moderate density of cells with light to moderate staining of neuropil. The accessory basal nucleus stains moderately for neuropil, and contains a moderate density of medium-sized multipolar cells. The lateral nucleus contains a light density of cells in its dorsomedial portion, with light to moderate cell density in its parvocellular portion. The central nucleus shows a moderate to dense population of bipolar and tripolar cells, with a higher cell density medially. Neuropil staining is moderate in the lateral part of the central nucleus as compared to dense staining medially. The periamygdaloid cortex and medial nucleus contain a moderately dense population of small to medium-sized cells, and stain moderately for neuropil. Calretinin has a distinct pattern of distribution as compared to other calcium binding proteins (calbindin, parvalbumin), suggesting the use of disparate calcium-related physiological mechanisms by distinct cell groups in the amygdala.

IMMUNOLocalization of the CEK8 RECEPTOR TYROSINE KINASE IN THE CEREBELLUM. A. Bayardo, J.A. Holash*, E.B. Pasquale*, M.E. Martone, M.H. Ellisman*. Dept. of Neurosciences, University of California, San Diego, La Jolla, CA 92093; *La Jolla Cancer Research Foundation, La Jolla, CA 92037

Cek8 is an avian member of the Eph subclass of transmembrane integral tyrosine kinases. Many tyrosine kinases, including the Eph subclass, are thought to contribute to the growth and development of the nervous system through the mediation of cell signaling. The presence of high levels of Cek8 both during neural development and in adulthood (Sajjadi and Pasquale, *Oncogene* 8:1807, 1993) suggest that it could play a role in neuronal plasticity in the adult brain.

In the present study, we examined the localization of Cek8 in adult cerebellum using a polyclonal antibody raised against a synthetic carboxyl terminal peptide. Cek8 was localized in frozen sections of adult rat cerebellum using indirect immunofluorescence and confocal microscopy. The most intense fluorescence was observed in Purkinje neurons and their processes. Other cell types in the molecular and granule cell layers were unlabeled or only lightly labeled. Within Purkinje cells, intense labeling was observed throughout the cell body, dendritic tree and dendritic spines. Labeled processes in the granule cell layer that appeared to be the axons of Purkinje neurons were also observed. Preabsorption of the primary antibody with excess peptide or omission of the primary antibody from the immunolabeling sequence resulted in no fluorescent signal in the cerebellum. This staining pattern is distinct from that of the closely related tyrosine kinase Cek5, which we have previously reported to be concentrated in axons of granule cells in the cerebellum (Pasquale et al., *J. Neurosci.* 12:3956, 1992). An ultrastructural analysis will be employed to determine the subcellular distribution of Cek8. We are currently mapping the distribution of Cek8 in the remainder of the rat brain and plan to investigate its distribution in the chicken brain as well.

SECOND MESSENGERS: KINASES AND PHOSPHATASES

METABOTROPIC GLUTAMATE RECEPTOR-MEDIATED POTENTIATION OF CYCLIC AMP RESPONSES DEPRESSES EXCITATORY SYNAPTIC TRANSMISSION BY A PROTEIN KINASE-INDEPENDENT MECHANISM. R.W. Gereau IV* and P.J. Conn. Department of Pharmacology and Program in Neuroscience, Emory Univ. Sch. of Med. Atlanta, GA 30322.

Coactivation of metabotropic glutamate receptors (mGluRs) and β -adrenergic receptors causes a synergistic increase in cAMP formation in the rat hippocampus. Increases in cAMP are known to have many actions in the hippocampus via activation of cAMP-dependent protein kinase. We now report that coactivation of mGluRs with 1S,3S-ACPD and β -adrenergic receptors with isoproterenol induces an acute depression of excitatory postsynaptic currents (EPSCs) at the Schaffer collateral-CA1 synapse. Neither 1S,3S-ACPD nor isoproterenol depresses EPSCs in area CA1 of the adult rat hippocampus when added alone. Pharmacological studies indicate that this depression of EPSCs is dependent upon increases in cAMP levels but is independent of protein kinase activity. This cAMP-mediated depression of EPSCs appears to be dependent on metabolism of cAMP and release of adenosine or 5'-AMP into the extracellular space with resultant activation of presynaptic adenosine receptors. These studies suggest that cAMP can have local hormone-like effects in the hippocampal formation that are independent of cAMP-dependent protein kinase.

480.2

METABOTROPIC GLUTAMATE RECEPTOR STIMULATED cAMP IS IMPLICATED IN VISUAL CORTEX PLASTICITY. H.J. Flavin*, N.W. Daw, D. Gregory and S. Reid. Dept. of Ophthalmology and Visual Science, Yale University School of Medicine, New Haven, CT 06520.

Metabotropic glutamate receptor (mGluR) stimulation can activate phosphoinositide (PI) hydrolysis and can increase and decrease cAMP. The mGluR's linked to PI hydrolysis have been implicated in visual cortex plasticity (Bear and Dudek, *Ann. NY Acad. Sci.* 627: 42-56, 1991). The role of the cAMP mGluR's in visual cortex plasticity has not yet been addressed, although the cAMP second messenger system has been implicated in hippocampal plasticity. This study was undertaken to examine the role of cAMP dependent mGluR's in visual cortex plasticity. The critical period in the rat begins at approximately 14 days of age and extends approximately one month. Consequently, cortical slices (400 µm) were obtained from male Long Evans rats approximately 22 and 50 days of age. After a 90 minute preincubation in a static chamber, slices were transferred and given a 10 minute experimental incubation. Basal cAMP levels were determined from slices incubated in extracellular buffer. Quisqualate (100 µM) was used to stimulate mGluR1 and mGluR5. cAMP was quantitated via RIA. Basal cAMP levels were slightly, but not significantly higher in slices from 22 versus 50 days of age rats, with 41.5 ± 25 and 20.6 ± 11 pmol cAMP / mg protein, respectively. Stimulation by quisqualate increased cAMP levels in slices from 22 days of age animals by 232.9 ± 117 pmol cAMP / mg protein. This was significantly greater ($p < 0.002$, unpaired t-test) than the corresponding values for slices from 50 days of age animals (28.1 ± 10). These results suggest that mGluR1 and mGluR5 stimulation of the cAMP second messenger system is implicated in rat visual cortex plasticity.

DIFFERENT ACTIVATION OF PKA IN CORTICAL NEURONS AND CEREBELLAR GRANULES. C. Ventra*, M. Paolillo, A. Porcellini, A. Feliciello, V.E. Avvedimento, & G. Schettini. Dept. of Neurosci., Sect. of Pharmacol.; *Dept. of Mol. and Cell. Biol. and Pathol., CEOS-CNR, II School of Medicine, University of Naples "Federico II", Italy.

Cortical neurons display a notable amount of type-II holoenzyme compared to cerebellar granules, virtually containing only type-I holoenzyme and devoid of AKAP 150, which specifically anchors type-II PKA holoenzyme. The cortical holoenzyme poorly dissociates under stimulation (5 min) by forskolin (10 μ M+IBMX 50 μ M), while completely reassociates after 15 min; nonetheless, a consistent nuclear accumulation of PKA is found. Conversely, cerebellar holoenzyme is highly sensitive to stimulation by forskolin (>60%), does not reassociate at 15 min, and the catalytic subunit does not accumulate into the nucleus. Immunofluorescence studies using a polyclonal antibody for PKA catalytic subunit and band-shift experiments using radiolabeled CRE are allowing us to further unravel this issue. In cortical neurons, the cytosolic holoenzyme is dissociated at 15 min, while the particulate counterpart dissociates between 2.5 and 5 min and fully reassociates at 15 min; negligible levels of particulate holoenzyme are found in cerebellar granules, and most of cytosolic holoenzyme dissociates under forskolin stimulation (60-70%, 1-15 min). Our results suggest that relevant functional implications could underlie the different subcellular distribution and response of PKA to cAMP, with particular regard to the cAMP-dependent modulation of gene transcription, which plays a major role in the modulation of long-term synaptic events. (Supported by TP Aging and CNR 93.00417.CT04 grants to G.S.)

PROTEIN KINASE A (PKA) INDEPENDENT EFFECTS OF IONTOPHORETICALLY APPLIED cAMP ANALOGS ON RAT SUBSTANTIA NIGRA PARS RETICULATA (SNr) NEURONS. J.-C. Liu*, L.P. Martin and B.L. Waszczak. Dept. Pharmaceutical Sciences, Northeastern Univ., Boston, MA 02115.

We have previously shown that iontophoresis of the dopamine D₁ agonist SKF 38393 acts at D₁ receptors on striatonigral terminals to increase firing rates of SNr neurons, and to enhance their inhibitory responses to applied GABA. To determine if cAMP might mediate these effects, subsequent studies examined effects of cAMP analogs using extracellular single unit recordings in male rats anesthetized with chloral hydrate. Iontophoresis of several membrane permeable analogs (8-bromo-cAMP, dibutyl- γ -cAMP and chlorophenylthio-cAMP) failed to consistently mimic the rate-increasing effect of the D₁ agonist. Moreover, these compounds, as well as the non-permeable cAMP, lessened rather than enhanced the responsiveness of SNr cells to applied GABA. The decreases in GABA potency by both permeable and non-permeable analogs prompted further studies to assess whether activation of PKA was required for the cAMP effects. Sp- and Rp-cAMPS (membrane-permeable activator and inhibitor of PKA, respectively) were next examined. Iontophoresis of Sp-cAMPS (-5 to -30 nA) caused current-related increases in firing of SNr cells to 145 \pm 12% and attenuated inhibitory responses to applied GABA to 58 \pm 10%, similar to other "active" cAMP analogs previously tested. However, Rp-cAMPS caused effects indistinguishable from Sp-cAMPS; at -30 nA, firing was increased to 138 \pm 14% and GABA potency was reduced to 68 \pm 15%. Co-iontophoresis of Rp-cAMPS (-30 nA) did not block responses to Sp-cAMPS (-5 to -30 nA). On the contrary, the effects were roughly additive. Thus, it appears that the effects of iontophoretically applied cAMP analogs in SNr involve a PKA independent action, perhaps via an extracellular site on the GABA_A receptor/Cl⁻ channel of SNr neurons. In view of this result, caution is advised in interpreting results of iontophoresis studies using cAMP analogs. Further studies are needed to elucidate the role of cAMP in mediating the D₁ agonist effects in SNr. (Supported by NS 23541.)

SARCOMA PROTO-ONCOGENE c-LYN (P-56) IS HIGHLY EXPRESSED IN THE RAT BASAL FOREBRAIN. S. Chen*, R. Bing and D. E. Hillman. Dept. of Otolaryngol. and Phys./Biophys., New York Univ. Med. Center, New York, N. Y. 10016

The sarcoma proto-oncogenes are second messengers for phosphorylation of tyrosine kinases which are essential in processes of neuronal plasticity and learning. Computer 3D mapping and reconstruction of lyn immunoreactivity (IR) revealed impressive bilateral cores of intensely labeled neurons surrounding the anterior commissure and extending along the base of the striatum from the head of nucleus accumbens caudally through the strial fundus. There was a compartmentalization of accumbens nucleus displaying multiple fascicles consisting positive cells within a negative matrix. Rostrally in this region, intensely labeled small cells were grouped along the margins of the accumbens nucleus. More caudally, these lyn-IR neurons surrounded the anterior commissure forming distinct fascicles. The dendrites of these neurons within the fascicles were oriented parallel forming discrete dorsolateral fascicles. These fascicles were also prominent in the shell of accumbens and bed strial nuclei. The fundal cells were compact dorsally with a ventral reticular extension. The lateral and medial septal nuclei were separable by intense IR somata and overlapping dendritic fields. Additionally, moderate lyn-IR cells having small to medium sizes were evenly scattered throughout the neostriatum. Double labeling revealed that a small percentage of lyn cells colocalized with parvalbumin neurons but none colocalized with large acetylcholine cells. The lyn core in the basal forebrain may represent a basic system of neurons involved in learning homeostatic functions of behavior. Supported by NS 13742 and AG 09480.

MODULATION OF PKA ACTIVITY BY PHORBOL ESTERS IN RAT CORTICAL NEURONS. M. Paolillo*, C. Ventra, A. Feliciello, A. Porcellini, V.E. Avvedimento and G. Schettini. Dept. of Neuroscience, Sect. of Pharmacology, and *Dept. of Cellular and Molecular Biology and Pathology, II Fac. of Medicine, Naples, Italy.

In cerebellar granules we found a remarkable dissociation of the PKA holoenzyme (70%) following a forskolin stimulation (10 μ M+IBMX 50 μ M). In contrast, in primary cultures of rat cortical neurons we found that 15 min activation by forskolin does not result in the dissociation of cAMP-dependent protein kinase (PKA) holoenzyme. Thus we evaluated whether the previous exposition of the cells to pharmacological agents activating PKA (forskolin) or protein kinase C (PMA) could modify the response of PKA to the next forskolin challenge. We found that a pretreatment with forskolin did not affect the PKA response to cAMP, while a 2 and 4 hr PMA pretreatment reduced the amount of particulate holoenzyme (20 %), with a consequent increase of the cytosolic holoenzyme amount. Furthermore, after 4 hr PMA, a 15 min forskolin stimulation resulted in a 25 % dissociation of the holoenzyme. We suggest that a PMA-induced phosphorylation could affect the binding of the PKA holoenzyme to the particulate fraction, either influencing the affinity of the type-II regulatory subunits or of the anchoring protein (AKAP 150). In conclusion, our data show that in cortical neurons phorbol esters determine delocalization of PKA holoenzyme and modulate its dissociation following a cAMP pulse.

Chronic Haloperidol Treatment Has No Significant Effect on Cyclic AMP Concentration in Rat Brain. W.Feng, R.Li, J.Elkes* and R.S.El-Mallakh. Mood Disorders Research Program, Department of Psychiatry and Behavioral Sciences, University of Louisville School of Medicine, Louisville, KY 40292.

It has been assumed that the therapeutic effect of haloperidol in the treatment of schizophrenia is related to its blockade of dopaminergic (D₂) receptors in the central nervous system. Our previous data has shown that chronic haloperidol treatment attenuated receptor-mediated phosphoinositide turnover in the frontal cortex, striatum and hippocampus. To investigate the influence of haloperidol treatment on another second messenger, cyclic adenosine monophosphate (cAMP), in the central nervous system, we examined the cAMP concentration in the different brain regions of rats treated with haloperidol (1.5mg/kg/day IM) for 4 or 6 weeks. The cAMP concentration was measured by dual range cAMP enzyme immunoassay kits. Our results indicates that cAMP level was slightly increased in the hypothalamus while no alteration was observed in the frontal cortex, striatum and hippocampus after 4 or 6 weeks treatment with haloperidol. However, all these changes are not significant. Chronic haloperidol treatment does not appear to be associated with the changes in cAMP that have been previously reported with acute treatments. Our results provide additional support for the notion that chronic treatment experiments are necessary to understand the mechanism of clinical action of haloperidol.

MULTIFUNCTIONAL CALCIUM/CALMODULIN-DEPENDENT PROTEIN KINASE II (CaMKII) IN BOVINE CHROMAFFIN CELLS: CHARACTERISTICS AND STIMULATION BY POTASSIUM DEPOLARIZATION. N. Verma and J. C. Waymire*. Department of Neurobiology and Anatomy, University of Texas Medical School, Houston, TX 77030.

CaMKII is a multifunctional protein kinase that has been found to exist in a variety of tissues and cell types. We examined CaMKII activity in bovine adrenomedullary chromaffin cells using a CaMKII specific substrate. After discerning its presence, we investigated the time course of CaMKII activation as determined by incubations at incremental time points with nondepolarized and high potassium depolarized (55 mM KCl) cells. We found that CaMKII activity in chromaffin cells differs both temporally and quantitatively from that in other cell types, such as PC12 cells and hippocampal slices. In chromaffin cells, the activation is almost immediate (as early as 10 seconds) and rapidly decays by 2 minutes.

CaMKII is known to activate tyrosine hydroxylase by phosphorylating serine residues 19 and 40 in chromaffin cells. The rapid phosphorylation of these residues (maximum phosphorylation within 10 seconds) correlates with the activation of CaMKII. Therefore, in chromaffin cells, the time course of CaMKII activation directly predicts the rapid phosphorylation and activation of tyrosine hydroxylase, and thereby catecholamine synthesis. Supported by NS 11061-16 JCW.

480.9

CALCIUM, BUT NOT GLUTAMATE STIMULATES THE GENERATION OF A CA-INDEPENDENT FORM OF CAM-KINASE II IN CULTURED RAT HIPPOCAMPAL PYRAMIDAL NEURONS. W.K. Scholz*, C.K. Christian and H.C. Palfrey. Univ. of Chicago, Dept. Pharmacol./Physiol. Sci., Chicago, IL 60637

Some glutamate-mediated effects on synaptic plasticity may involve the generation of a Ca-independent form of Ca/calmodulin-dependent protein kinase II (CaM-KII). Glutamate regulation of CaM-KII activity in cultured hippocampal pyramidal neurons was assessed by stimulating intact neurons and then measuring the ability of extracts to phosphorylate the selective CaM-KII substrate peptide, autocamtide-2. Ca-independent activity in neurons equilibrated in 1.26 mM Ca-buffer was about 10% of the total CaM-KII activity. Glutamate (100 μ M) and A23187 (2 μ M) had no effect on Ca-independent CaM-KII activity in pyramidal neurons equilibrated in 1.26 mM Ca-buffer. However, these agents significantly decreased total kinase activity resulting in an apparent increase in Ca-independent CaM-KII activity of 7-10% of total. Since pyramidal neurons spontaneously release glutamate in buffer containing 1.26 mM Ca it is possible that the neurons were already in a stimulated state. However, the addition of 25 μ M APV, an NMDA receptor blocker, or 1-10 mM Mg or 2 mM Co, to inhibit Ca influx, did not reduce Ca-independent CaM-KII activity. Equilibration of neurons in 50 nM Ca/0 Mg-buffer reduced the Ca-independent kinase activity to about 5% of total. When extracellular Ca was elevated from 50 nM to 1.26 mM there was a rapid increase in Ca-independent activity that peaked at 5-30sec, reaching 50-100% of the total CaM-KII activity. By 10 min, the kinase activity returned to levels observed in neurons equilibrated in 1.26 mM Ca. The addition of glutamate with the Ca did not potentiate the response and APV did not block it. The mechanism by which extracellular Ca elevation generates the Ca-independent form of CaM-KII may occur by autophosphorylation since 32 P-incorporation into CaM-KII doubled at 5 sec following the shift from 50 nM to 1.26 mM Ca, as determined by immunoprecipitation. Transient phosphate incorporation into 2 phosphopeptides of the 50 kDa subunit correlated with the burst of Ca-independent CaM-KII activity.

DEVELOPMENTAL AND REGIONAL EXPRESSION OF MULTIFUNCTIONAL CALCIUM/CALMODULIN-DEPENDENT PROTEIN KINASE ISOFORMS IN RAT BRAIN. L. Brocke, M. Srinivasan and H. Schulman*. Dept. of Neurobiology, Stanford University Medical Center, Stanford, CA 94305-5401.

Multifunctional calcium/calmodulin-dependent protein kinase (CaM kinase or CaM kinase II) is a major mediator of calcium signaling involved in diverse neuronal functions. All known subunits of CaM kinase consist of a catalytic domain at the N-terminal half of the protein followed by a regulatory domain and an association domain.

Multiple CaM kinase isoforms can be generated by putative alternative splicing at the variable domain, a region at the border of the regulatory and association domains. We have utilized the RT-PCR technique to amplify the variable domains of α - and β -CaM kinase and examine the diversity of isoforms present in rat brain.

Sequencing of a PCR fragment of α -CaM kinase from midbrain, termed $\alpha\beta$ -CaM kinase, revealed an insertion of 11 amino acids at the variable domain identical to $\alpha 33$, a PCR fragment previously obtained from monkey frontal cortex (Benson et al., J. Neurosci. 11:31-47, 1991). Interestingly, this insertion generates a nuclear localization signal (KKRK) that targets $\alpha\beta$ -CaM kinase to the nucleus in transfected neuroblastoma cells.

In addition, we isolated two new isoforms of β -CaM kinase from E18 rat brain, termed β_e - and β'_e -CaM kinase, which lack the 24 amino acids encoded by exon IX of the β -CaM kinase gene. The deletion probably involves a three base pairs shift in the position of the 3' splice site before exon VIII. In addition, β'_e -CaM kinase lacks 15 amino acids encoded by exon V. The expression of β -CaM kinase isoforms is developmentally regulated, with a pronounced switch towards the adult isoforms during the second postnatal week.

INVESTIGATIONS OF KINASE ACTIVATION IN CORTICAL SYNAPTONEUROSOMES. I.J. Weiler*, S. Ahmari, Y. Ahmed, C.F. Lee, and W.T. Greenough, Depts. Psychol and Cell & Struc. Biol., Neurosci. Prog. and Beckman Inst., Univ. Illinois, Urbana-Champaign, IL 61801.

We have shown that metabotropic agonists stimulate polyribosomal aggregation in synaptoneurosomes. We are now using this system to analyze the rapid effects of glutamate agonists on receptor-coupled substrate phosphorylation. Synaptoneurosomes suspensions are stimulated by addition of NMDA or quisqualate (with CNQX); at intervals, samples are lysed in the presence of 0.2 M EDTA and EGTA, 500 μ M pNPP, 100 μ M vanadate, 0.75 mM DTT, then flash-frozen on dry ice in 10 μ l aliquots.

The basal phosphorylation activity is high; nevertheless we observe increased activity of PKC and PKA in the presence of either NMDA or quisqualate. MAP kinase activity, measured by MBP phosphorylation seems to be stimulated preferentially by quisqualate. We observe activation of CaMKII by either NMDA or ionophore A23187, more than by quisqualate. However, there seems also to be rapid calcium activation of a phosphatase, which we are currently investigating. Supported by MH 53521.

480.10

TRANSLOCATION OF CALCIUM/CALMODULIN-DEPENDENT PROTEIN KINASE II (CaMKII) IN RAT HIPPOCAMPAL SLICES IS INDUCED BY SIMULATED ISCHEMIC INSULT. S.J. Kolb and M.N. Waxham*. Dept. of Neurobiol. and Anatomy, Univ. of Texas Med. Sch. Houston, TX 77030.

CaMKII has been shown to lose activity and to translocate from supernatant to pellet fractions of cortical and hippocampal homogenates in a global model of ischemia (Aronowski et al., 1992, J. Neurochem.).

To investigate the mechanisms underlying this translocation, a hippocampal slice model was developed. Slices were exposed to conditions that simulate an ischemic insult, and the subcellular distribution and enzymatic activity of CaMKII were monitored in homogenates prepared after increasing durations of the insult. Semi-quantitative Western Blots using a monoclonal antibody to the alpha subunit showed that there was a 70% decrease in CaMKII in the supernatant fraction and a 150% increase in CaMKII of the pellet fraction after 20 min. of ischemia. Shorter periods of ischemic insult produced a graded change in redistribution. There was little or no change detected in CaMKII in the total homogenates at any time suggesting that little proteolysis of CaMKII was evident at up to 20 min. in this model. CaMKII activity decreased in the supernatant in a parallel fashion with translocation. Activity increased by 20% in the pellet fractions at 5 and 10 min. of ischemia and then decreased back to pre-ischemic levels by 20 minutes.

We conclude that redistribution of the enzyme occurs in the hippocampal slice model and that this system may be useful in elucidating the mechanisms underlying CaMKII alterations and its impact on ischemia-induced neuronal injury.

Differential Regulation of Multiple Calcium/Calmodulin-Dependent Protein Kinase Type II Subunit mRNAs. K.D. Murray*, C.A. Rosasco, and P.J. Isackson Department of Biochemistry and Molecular Biology, Mayo Clinic, Jacksonville, FL, 32224.

Calcium/calmodulin-dependent protein kinase type II (CaMKII) is a multifunctional enzyme comprising as much as 2% of total forebrain protein and playing a critical role in excitatory neuronal processing. Originally identified as a multimeric holoenzyme composed of α and β/β' subunits, recent cloning analysis has identified two additional subunits CamKII δ and γ as well as a series of alternatively spliced isoforms deriving from these four subunits. Earlier studies have shown that hybridization to CamKII α mRNA is down-regulated throughout hippocampus and neocortex following hilus lesion induced seizures and up-regulated when afferent input is removed (Benson et al 1991, Murray et al 1993). To investigate whether the other CamKII subunits undergo a similar regulation we performed analysis using *in situ* hybridization, northern blots and S1 protection assays on tissue from adult male Sprague-Dawley rats sacrificed at various time-points following the onset of behavioral seizures induced by intraperitoneal injection of kainic acid (KA; 10mg/kg). The pattern of hybridization to CamKII α , β , γ and δ subunit mRNA in saline injected animals was consistent with previous reports in untreated control animals. One notable difference was the presence of low, but detectable hybridization of CamKII δ mRNA within the hippocampus. Consistent with hilus lesion induced seizures, KA treatment produced a stark reduction in hybridization to CamKII α mRNA (90%) throughout the hippocampus and neocortex. Hybridization to CamKII γ mRNA was also reduced within hippocampus and neocortex, but to a lesser extent. In contrast, hybridization to CamKII δ mRNA was unaffected within hippocampal subfields but dramatically increased throughout the superficial layers of neocortex (5 fold). All mRNA changes were maximal 24 hrs following KA injection. CamKII β mRNA levels were not significantly altered following KA treatment. These observations provide evidence for the regulation of CamKII at the RNA level and suggest it is more complicated than previously thought.

480.14

CARBACHOL-INDUCED PHOSPHORYLATION AND DEPHOSPHORYLATION OF PERCHLORIC ACID SOLUBLE PROTEINS IN HUMAN NEUROBLASTOMA SK-N-SH CELLS. A.M. Goldsmith and M.E. Gnegy*. Dept. Of Pharmacology, Univ. of Michigan, Ann Arbor, MI 48109.

We found that in SK-N-SH cells calmodulin (CaM) is redistributed from membrane to cytosol in response to the muscarinic agonist carbachol (CARB) or the phorbol ester TPA. This response could be due to phosphorylation of a membrane CaM-binding protein, releasing CaM to cytosol. We examined CARB-stimulated phosphorylation of proteins to correlate the time course of phosphorylation with that of CaM translocation. 32 P_i pre-equilibrated SK-N-SH cells were treated with 100 μ M CARB or 100 nM TPA. Cells were lysed in 2.5% perchloric acid (PA) as some PA-soluble proteins (i.e. GAP-43, MARCKS, and neurogranin) release CaM upon phosphorylation by protein kinase C (PKC). CARB and TPA significantly increased phosphorylation of PA-soluble proteins of approximately 86kDa (p86) and 43kDa (p43). CARB-induced phosphorylation was maximal by 30 sec and lasted 30 min. TPA-induced phosphorylation was significantly greater than that with CARB while CaM translocation was comparable. Phosphorylation of p86 and p43 may be only a part of the CaM translocation process. Pretreatment with the calcineurin inhibitor FK506 (100 nM) increased the phosphorylation of p86 and p43 at all time points including their basal phosphorylation. A 5 min pretreatment with 1 μ M OA, inhibiting PP1 and PP2A, had minimal effect on phosphorylation until 15 min after CARB. Staph. aureus V8 protease digestion and Western blotting suggested a 50kDa protein may be GAP-43. Phosphorylation of p50 was unaffected by CARB or TPA suggesting that GAP-43 is not PKC phosphorylated in these cells, that there is more than one form of GAP-43 in the cells which is not recognized by this antibody, or multiple phosphorylated proteins exist at p50. p86 may be MARCKS protein based on its M_r , phosphorylation by TPA, and solubility in PA. These results suggest that if phosphorylation is involved in the translocation of CaM multiple proteins, including p86 and/or p43, may be involved. Supported by NIMH grant MH36044.

A NOVEL NEURON-SPECIFIC MAP KINASE IN ADULT AND DEVELOPING MOUSE. J.H. Martin, A.A. Mohit and C.A. Miller*. Dept. of Pathology, Univ. Southern Calif. Sch. of Med., Los Angeles, CA 90033

In Alzheimer's disease (AD), the lack of an animal model complicates the analysis of early pathological changes. Mitogen-activated protein (MAP) kinases (also known as ERKs) have been implicated as agents of abnormal phosphorylation of microtubule-associated protein tau, the major component of AD neurofibrillary tangles (NFT). ERKs are thought to function as key regulatory molecules in the signalling pathways regulated by growth and differentiation factors. We have previously described a neuron specific human MAP kinase expressed in a subset of neurons in the human brain that undergo degeneration in AD. Here, we describe the cloning and molecular characterization of the mouse homolog. Immunocytochemically, MAb 3F12 identified a cytoplasmic antigen expressed almost exclusively in neurons. The human p49^{3F12} kinase cDNA was used to isolate a 2.5 kb mouse cDNA clone. The deduced amino acid sequence was novel and shared 99% identity with that of the human p49 kinase. Moreover, the 3' untranslated region showed 88% nucleic acid identity with the human cDNA. This suggests a conserved regulatory role for this region. Northern blot analysis showed a 2.7 kb mRNA that was exclusively expressed in the brain and a 2.4 kb mRNA expressed only in testis. All other tissues showed no expression. *In situ* hybridization showed a similar pattern of expression as that of 3F12 antigen. Developmentally, the p49^{3F12} kinase was turned on at embryonic day 11 (E11), and was expressed only in post-mitotic neurons. At E17.5, the mRNA was also present in the dorsal root ganglion as well as neurons in the CNS. These findings are in agreement with the suggested role of ERKs in neuronal differentiation. The distribution of the p49^{3F12} protein along with evidence suggesting its involvement as a pathogenic agent in AD, may lead to development of a possible model for NFT formation.

THE γ 1 ISOFORM OF PROTEIN PHOSPHATASE 1 IS CONCENTRATED IN DENDRITIC SPINES. C.C. Ouimet*, E.F. da Cruz e Silva* and P. Greengard*. Department of Psychology, Florida State University, Tallahassee, FL 32306, *Laboratory of Molecular and Cellular Neuroscience, The Rockefeller University, 1230 York Ave., New York, NY 10021.

Protein kinases and phosphatases regulate diverse neuronal processes. The subcellular localization of the γ 1 isoform of protein phosphatase 1 (PP1 γ) was examined in rat brain by immunocytochemistry using an antibody raised against a synthetic peptide derived from the PP1 γ C-terminal sequence. At the light microscopic level, immunoreactivity was present in small puncta (1 μ m or less in diameter) in the neuropil, but not in dendrites or somata. When the caudateputamen was examined at the electron microscopic level, strong immunoreactivity was observed primarily in dendritic spines. Moderate immunoreactivity was present in myelinated and unmyelinated axons, and weak immunoreactivity was present in dendrites and occasional axon terminals. The localization of PP1 γ to dendritic spines suggests its involvement in spine function, possibly in the regulation of synaptic plasticity. (Supported by USPHS grant MH40899).

CLONING OF PARTIAL cDNAs FOR THREE PROTEIN TYROSINE PHOSPHATASES FROM APLYSIA CALIFORNICA. F.C. Richardson* and L.K. Kaczmarek. Dept. of Pharmacology, Yale Univ. Sch. of Med., New Haven, CT 06518.

Patch clamp experiments of a voltage-dependent cation channel in *Aplysia* bag cell neurons have shown that the gating mode and response of this channel to protein kinase A (PKA) are determined by a PKA regulated protein-tyrosine phosphatase (PTPase)(G.F. Wilson and L.K. Kaczmarek, 1993, *Nature* vol. 366:433-438). As a first step towards a molecular characterization of this response, a PCR based cloning strategy was employed to isolate potential PTPase isoforms. cDNA was made by reverse transcribing total RNA isolated from abdominal ganglia and bag cell neurons. This cDNA was then amplified using degenerate primers designed to the conserved catalytic domain of published PTPase sequences. Products of predicted molecular weight were directly ligated into a TA vector and sequenced. Based on protein sequence homology to the catalytic domain of cytoplasmic and receptor type PTPases, three clones, named APTPa, APTPb, and APTPc, were identified as PTPases. APTPa and APTPc are 36.3% identical and are most similar to Human PTPb (48.7%) and Rat LAR(67.4%), respectively. APTPa, which is 27.9% identical to APTPb and 23.1% identical to APTPc, is the most novel of the three isoforms. Its highest similarity to any published PTPase (Human LCA) is only 34.2%. *In situ* hybridization studies and further cloning will help determine whether any of the APTP isoforms are regulated by PKA in the bag cell neurons.

TK/PTP MODULATION OF $[Ca^{2+}]_i$ RISE INDUCED BY NORADRENALINE IN PC C13 RAT THYROID CELLS. O. Meucci*, A. Scorzello, A. Avallone, T. Florio and G. Schettini Dept of Neurosci. Sect. Pharm. Univ. of Naples ITALY.

We studied the effect of genistein (an inhibitor of tyrosine-kinases, TKs) and vanadate (an inhibitor of phospho-tyrosine-phosphatases, PTPs) on noradrenergic-induced $[Ca^{2+}]_i$ rise in PC C13, a rat thyroid cell line, by means of fura 2 microfluorimetry and video imaging analysis. As previously showed in these cells, in presence of calcium in the extracellular medium, NE-stimulated $[Ca^{2+}]_i$ rise is characterized by a transient spike followed by a sustained plateau phase, mainly due to the IP₃-linked mobilization of $[Ca^{2+}]_i$ which follows the activation of $\alpha_1\beta$ adrenergic receptors. A minor component of the noradrenergic response is also due to the activation of α_1A receptor subtype which participate to the $[Ca^{2+}]_i$ increase evoked by NE through the stimulation of calcium influx from the extracellular environment. In this study we investigated the role of TK/PTP pathway in the modulation of calcium entry following noradrenaline (NE) receptor activation. Our data show that vanadate pretreatment of PC C13 cells was able to modify the plateau phase of NE-induced $[Ca^{2+}]_i$ increase keeping it higher than the control cells either in continue presence or after removal of the agonist from the perfusion medium. Similarly, genistein caused a dramatic drop of the plateau phase in presence of NE in the extracellular environment, and a complete abolishment after NE-withdrawal. To rule out the possibility that the effect of vanadate was due to the blockade of ATPase pumps, we performed the same experiments in the absence of Ca^{2+} and in presence of Ba^{2+} in the extracellular medium. Ba^{2+} enters the cells via Ca^{2+} channels and is sensed by fura-2 but, since it cannot be pumped out of the cell or into the calcium stores, the entering Ba^{2+} is trapped in the cytoplasm. In these experimental conditions NE-induced Ba^{2+} influx was still potentiated by vanadate. These results suggest that the TK/PTP pathway is involved in the modulation of noradrenergic effects on calcium mobilization (AIRC 1993 to G.S.).

THE MAJOR OKADAIC ACID- / CALYCULIN A-SENSITIVE PHOSPHATASE ACTIVITY IN LEECH CNS BELONGS TO THE TYPE I PHOSPHATASE FAMILY. A.L. Kleinhans*, S. Ding, and K.N. Lerea. Dept. of Cell Biology & Anatomy, New York Medical College, Valhalla, N.Y. 10595.

Okadaic acid (OA) and calyculin A (CalA), specific inhibitors of the protein phosphatase types I (PP-1) and 2A (PP-2A), slow the recovery of elevated $[Ca^{2+}]_i$ caused by K⁺-depolarization and prolong the divalent cation-dependent action potential in the serotonergic Retzius cells of the leech (Kleinhans & Zeman, Brain Res. 1994). These studies suggest that inhibition of PP1 and/or PP2A may directly modulate the kinetics of the voltage-dependent Ca^{2+} -conductance and/or alter other mechanisms related to Ca^{2+} movements or buffering.

To identify and quantitate the relative amounts of PP-1 and PP-2A found in these neurons protein phosphatase activity from extracts of leech segmental ganglia and isolated Retzius cells was measured using [³²P]phosphorylase-a as substrate. The major phosphatase activity in both preparations showed similarities to the mammalian form of PP-1. The dephosphorylation of phosphorylase-a by extracts from segmental ganglia, isolated Retzius cells and purified mammalian PP-1 was inhibited by okadaic acid with similar IC₅₀ values (~50 nM). In addition, enzymatic activity intrinsic to each leech neuronal preparation was inhibited 80% by addition of inhibitor 2, a heatstable inhibitor protein specific for PP-1. The enzyme was also inhibited by calyculin A, but the IC₅₀ value of 20 - 30 nM is higher than that of the purified mammalian PP-1 and PP-2A. Taken together the results indicate that phosphatase activity in leech nervous tissue is mostly due to an enzyme of the type 1 family.

Studies to characterize the subcellular distribution and composition of this PP-1-like enzyme are in progress.

CLONING AND GENE EXPRESSION OF PHOSPHATASE INHIBITOR-2 (I-2) IN THE RAT BRAIN. H. Sakagami*, and H. Kondo. Dept. of Anatomy, Tohoku Univ. Sch. of Med., Sendai, 980, Japan.

Inhibitor-2 is the regulatory subunit of the ATP-Mg-dependent protein phosphatase, a cytosolic form of type 1 protein phosphatase (PP-1). Our *in situ* hybridization study has recently demonstrated that the mRNAs for three catalytic subunits of PP-1 and inhibitor-1(I-1) were differentially distributed in the rat brain (H. Sakagami et al., Mol. Brain Res., in press). However, no information has been available concerning the distribution of the gene expression and the functional significance of I-2 in the brain. We, therefore, cloned cDNA encoding the rat I-2 and examined the distribution of the gene expression for I-2 in the rat brain by *in situ* hybridization histochemistry. The cDNA encoding I-2 was isolated from a rat brain cDNA library using ³²P-labeled cDNA probe for rabbit I-2 amplified by polymerase chain reaction (PCR). The cDNA contained a complete open reading frame of 615 nucleotides, corresponding to 205 amino acids. The deduced amino acid sequence was 86 % homologous to previously identified rabbit skeletal muscle I-2 (Park et al., 1994). By *in situ* hybridization histochemistry using oligonucleotide probes, intense expression signals were detected in the hippocampal pyramidal and dentate granule cell layers, and olfactory tubercle. Moderate expression signals were detected in the olfactory neuronal layer, caudate putamen, neocortex, and cerebellar granule cell layer. When compared this expression pattern with that of I-1-mRNA, several differences were found: the homogeneous expression of I-2 mRNA versus the laminar expression of I-1 mRNA in the neocortex; low expression of I-2 mRNA versus high expression of I-1 mRNA in the arachnoid membrane. These findings suggest that the activities of PP-1 may be differentially regulated by I-2 and I-1 in various brain regions. (Supported by grants 04404020 and 0526023 from the Ministry of Education, Science and Culture of Japan)

481.1

CHARACTERIZATION AND REGULATION OF GABAA RECEPTOR SUBUNITS ON NEURONES IN THE HYPOTHALAMIC SUPRAOPTIC (SON) AND PARAVENTRICULAR (PVN) NUCLEI. V.S. Fenelon and A.E. Herbison. (SPON: Brain Research Association) Lab. of Neuroendocrinology, Babraham Institute, Cambridge CB2 4AT, U.K.

GABA is known to regulate oxytocin (OT) and vasopressin (VP) secretion via the occupancy of GABAA receptors. As the different GABAA receptor isoforms have different pharmacodynamic properties, the present study was undertaken in order to characterize the GABAA receptor subunit types expressed by magnocellular hypothalamic neurones and determine whether changes in specific subunit mRNAs occur during pregnancy and lactation.

Double labelling studies using antisera specific for either OT or VP and antisera directed against α_1 , α_2 or $\beta_{2/3}$ subunits of the GABAA receptor showed that all OT and VP neurones located in the SON express α_1 , α_2 and $\beta_{2/3}$ subunits. However, cells in the PVN only expressed the α_2 subunit. *In situ* hybridization experiments using ³⁵S-labelled oligonucleotides complementary to α_1 , α_2 or β_3 subunits confirmed that neurones in the SON expressed α_1 , α_2 and β_3 subunit mRNAs while those in the PVN only highly expressed the α_2 subunit. Silver grain analysis for α_1 and α_2 subunits were carried out in the SON, PVN and cortex of ovariectomized (OVX), pregnant (day 10 and 19), parturient and lactating rats (day 7 and 14). α_1 mRNA expression in the SON increased during pregnancy, peaking at day 19, and fell to its lowest level on the day of parturition. α_1 mRNA expression in the cortex and α_2 mRNA expression in SON, PVN and cortex did not show such variations.

Together, these results provide a partial characterization of the GABAA receptor isoforms expressed by rat magnocellular neurones and show that the GABAA receptors synthesized by magnocellular neurones in SON and PVN are different. Furthermore, it appears that expression of an α_1 subunit-containing GABAA receptor is altered during pregnancy suggesting that GABA influences on OT and/or VP secretion at this time may be determined, in part, by receptor expression.

481.3

OVARIAN HORMONE INDUCES PLASTICITY OF OXYTOCIN NEURON ACTIVITY OF SUPRAOPTIC NUCLEUS IN THE FEMALE RAT. T. KIYOHARA*, T. NAKASHIMA and S. MIYATA. Dept. of Applied Biology, Kyoto Institute of Technology, Sakyo-ku, Kyoto 606 Japan

It has been demonstrated that oxytocin (OXT) neurons in the supraoptic nucleus of lactating rats are facilitated by exogenously applied OXT while that of virgin females are inhibited. The present study was carried out to investigate whether OXT increases the OXT neuron activity in hypothalamic slices prepared from virgin female, pregnant, delivering, lactating, and ovariectomized rat by recording extracellular single-unit activity. Most OXT neurons of virgin female and pregnant rats showed inhibitory responses to OXT. In contrast, majority of OXT neurons tested in delivering and lactating rats exhibited excitatory responses to OXT. This excitation reversed to inhibition again after the lactating period had ended. OXT neurons in ovariectomized virgin female rats showed excitatory responses to OXT. This excitation was also reversed to the inhibition by estrogen treatments. It was also founded that morphological changes of OXT neurons associated with the lactation were unaffected by ovariectomization suggesting that other stimuli such as nipple sucking may be crucial in maintaining the changes. These findings suggest that ovarian hormones might play an important role in induction of neural plasticity in rat hypothalamic OXT neurons.

HYPERTONIC SALINE-INDUCED CHANGES OF THE OXYTOCIN CONTENT OF THE THORACIC SPINAL CORD: REGULATION BY OPIOID PEPTIDES. V. Votín & J. Haldar*. Department of Biological Sciences, St. John's University, Jamaica, NY 11439.

Previously we have demonstrated that oxytocin content of the spinal cord changes in response to various stressors. For example, following immobilization stress of one minute, oxytocin content increases (Brain Res. 17:137-141, '88) whereas following hypertonic and isotonic saline injections, oxytocin content decreases (Life Sci. 53:579-584, '94). The current experiments were designed to determine what factor or factors regulate spinal cord oxytocin content. Since opioid peptides are known to regulate oxytocin release from the neurohypophysis, it was logical to investigate whether spinal cord oxytocin is also under opioid regulation. Male Sprague Dawley rats were divided into 5 groups and injected with (i) isotonic saline (0.85% ip), (ii) hypertonic saline (1M ip), (iii) Naloxone (5mg/Kg BW, sc), (iv) Naloxone + isotonic saline and (v) Naloxone + hypertonic saline. Injection volume always was 0.2 ml/100 gm body weight. For control group, rats were pin-pricked twice, once subcutaneously, matching with Naloxone injection and second time ip, matching with saline injection. Five minutes after Naloxone injection, the rats were injected with saline and were sacrificed fifteen minutes thereafter. Following decapitation, thoracic part of the spinal cord was isolated from the vertebral column and was separated into dorsal and ventral half. Oxytocin content of the spinal cord was determined by a specific oxytocin radioimmunoassay in a Sep-pak extracted sample. Our results demonstrate that (i) dorsal half of the spinal cord contains ten fold more oxytocin than that of the ventral half, (ii) both isotonic and hypertonic saline decrease oxytocin content of the spinal cord and (iii) naloxone reverses saline-induced decrease of the spinal cord oxytocin content. In conclusion, these results suggest that spinal cord oxytocin is at least partly regulated by opioid peptides.

CONOPRESSIN, A VASOPRESSIN-LIKE PEPTIDE REGULATING MALE BEHAVIOUR IN LYMNAEA STAGNALIS: CHARACTERIZATION OF THE PEPTIDE, PRECURSOR, GENE AND RECEPTORS. R.E. Van Kesteren, A.B. Smit, C.P. Tensen, J. Van Minnen, E. Van Golen and W. P. M. Geraerts*. Institute of Neuroscience, Vrije Universiteit, De Boelelaan 1087, 1081 HV Amsterdam, The Netherlands.

We used antisera raised against vasopressin to identify a vasopressin-like peptide, named conopressin, from the brain of the mollusk *Lymnaea stagnalis*. cDNA encoding conopressin was isolated using PCR and the amino acid sequence of the conopressin prohormone was deduced. The precursor is very similar to the vasopressin precursor of vertebrates, containing conopressin and a highly conserved neurophysin domain together with a less conserved copeptin domain. In *Lymnaea*, these two peptide domains probably remain uncleaved, as has been observed in lower vertebrates. The conopressin gene has also been cloned and shown to contain two introns. Expression of the conopressin gene was detected in two neurons of the pedal ganglia and in neurons of the anterior lobes of the cerebral ganglia. The neurons in the anterior lobe of the right cerebral ganglion are part of a neuronal network that regulates male copulation behaviour in *Lymnaea*. They project via the penis nerve towards the penial complex and the vas deferens. Conopressin has an excitatory effect on the vas deferens. This effect is antagonized by APGWamide, a peptide that is co-localized with conopressin. Conopressin affects also identified central neurons, indicating that it acts as a neurotransmitter. Two putative conopressin receptors were cloned from the vas deferens. These receptors have high sequence identity with the phospholipase C coupled vasopressin V1 and oxytocin receptors, which mobilize intracellular Ca^{++} upon activation. The conopressin receptors are differentially expressed in the sex organs, with one receptor being expressed in the ovotestis, the prostate and the posterior part of the vas deferens, and the other in the anterior part of the vas deferens. Both receptors are also present in the brain. The exact localization of central expression is currently under investigation.

481.4

Intracerebroventricular (icv) injection of an inhibitor of nitric oxide synthase attenuates drinking and release of vasopressin (VP) while stimulating secretion of oxytocin (OT) in conscious rats. M. Kadekaro, M.L. Terrell, E. Koehler, S. Gestl, J.Y. Summy-Long*. Div. of Neurosurgery, Univ. of Texas Medical Branch, Galveston, TX, *Dept. of Pharmacol., Penn. State Univ., Hershey, PA.

We have shown that N^G-monomethyl-L-arginine (NMMA), an inhibitor of nitric oxide (NO) synthase, attenuates water intake (Neurosci. Lett., 1994, in press) and enhances plasma levels of OT (Neurosci. Lett. 152:190, 1993) after icv injection to rats dehydrated for 24h. Because NMMA can be metabolized to L-arginine, the substrate for NO synthase, the effects of another selective inhibitor of NO synthase, N^G-nitro-L-arginine methyl ester (NAME), on water intake and plasma VP and OT was examined in conscious adult male albino rats. For drinking studies, CSF (5µl) or NAME (10µg, 250µg or 500µg) was injected icv 10 to 12 min before water was available a) to 24h dehydrated rats or b) after angiotensin II (ANG II; 250 ng/2µl, icv). Water intake (ml/60 min; $\bar{x} \pm SEM$, n=8) induced by ANG II was less ($p < 0.02$) after all but the lowest dose of NAME [CSF (9.1 \pm 0.9) & NAME 10µg (9.4 \pm 0.9) > NAME 250µg (6.0 \pm 0.6) & NAME 500µg (5.5 \pm 0.7)]. Only 500µg of NAME attenuated drinking (ml/2h) in dehydrated animals (CSF > NAME; 9.3 \pm 1.1 > 6.0 \pm 0.9; n=10). Plasma [OT] (pg/ml; $\bar{x} \pm SEM$; n=5-9) elevated after 24h of dehydration (CSF 14 \pm 2) increased ($p < 0.05$) further 15 min after 500µg of NAME (25 \pm 5), L-(46 \pm 7) or D-(67 \pm 8) arginine, whereas plasma [VP] decreased ($p < 0.05$; n=5-9) only after NAME (12 \pm 1 > 6 \pm 1). In control rats basal [OT], but not [VP], was similarly affected ($p < 0.05$) by NAME, L- and D- arginine (CSF < NAME < L- & D- arginine; 7 \pm 1 < 23 \pm 3 < 30 \pm 5 & 40 \pm 9). Thus, NO promotes positive water balance during dehydration by stimulating drinking and release of VP while attenuating secretion of OT.

INTRACEREBROVENTRICULAR ADMINISTRATION OF INTERLEUKIN-1 β SUPPRESSES REFLEX MILK EJECTION IN URETHANE-ANAESTHETIZED RATS. B.C. Wilson* and A.J.S. Summerlee. Dept. of Biomedical Sciences, University of Guelph, Guelph, Ontario, Canada N1G-2W1.

It has been shown that icv IL-1 β stimulates oxytocin release in male (Neumann et al., 1993, Soc. for Neurosci. Abst. 19(1): 97) and female (Wilson and Summerlee, unpublished data) rats and that IL-1 β excites supraoptic neurones (Li et al., 1992, Neuroreport 3: 91-93). Experiments were done using the methodology of Summerlee et al., 1984, Nature 309: 372-374 to investigate the effect of icv IL-1 β on the pattern of reflex milk ejection (RME) in rats at Day 10 of lactation. Urethane-anaesthetized rats were implanted with cannulae in the left saphenous vein and a caudal mammary gland and then placed in a stereotaxic head frame. A microsyringe was placed with its tip in a lateral cerebral ventricle for icv injection. Ten rat pups were placed to suck at the nipples of each dam to induce RME. After 6 milk ejections, rats were treated with IL-1 β (1ng/µl PBS-BSA icv) or PBS-BSA (1µl icv) and the effect on the pattern of RME observed. IL-1 β suppressed RME in 10 out of 12 (83%) rats tested compared with 0 out of 9 (0%) for those treated with the PBS-BSA vehicle. It is possible that in female rats, IL-1 β stimulates basal oxytocin release while inhibiting suckling-induced OT release involved in milk ejection. The data suggest that IL-1 β plays a role in mediating suckling-induced neuroendocrine events in the rat. Supported by NSERC Canada.

481.7

INTRACEREBROVENTRICULAR INJECTION OF RELAXIN AFFECTS THE RELEASE OF BOTH VASOPRESSIN AND OXYTOCIN IN ANESTHETIZED RATS. B.J. Geddes and A.J.S. Summerlee*. Dept. of Biomedical Sciences, University of Guelph, Guelph, Ont. CAN, N1G 2W1.

Injections of exogenous relaxin either IV or ICV produce a marked and sustained rise in systemic arterial blood pressure (Parry LJ & Summerlee AJS, 1991). Intravenous relaxin administration has also been shown to substantially affect the release of vasopressin (AVP) and oxytocin (OX) (Way & Leng, 1992; Geddes BJ, Parry LJ & Summerlee AJS, 1994). There is preliminary evidence that ICV relaxin also affects magnocellular peptide secretion (Jones, 1986) so the present study was conducted to make a more thorough examination of the influence of ICV relaxin on vasopressin and oxytocin release. Urethane-anesthetized female SD rats were cannulated such that blood samples (≤ 1 mL) and fluid replacement could take place simultaneously. Blood samples were removed before and at 1, 2.5, 5, 10 and 30 min after ICV injection of 500 ng of relaxin (in 1.0 μ L physiological saline) and the plasma assayed for AVP and OX by specific RIA (University of Bristol, Bristol, UK). Relaxin treatment caused a substantial ($\approx 250.0\%$, $p < 0.05$) elevation in plasma AVP levels above baseline 1 and 2.5 min post-treatment, and an immediate increase (110.0% at 1 min, $p < 0.05$) in plasma OX that was sustained for the duration of the experiment. The findings of the present study extend our current understanding of the central actions of relaxin by demonstrating that the effects of relaxin injected ICV and IV are ostensibly identical which supports the hypothesis that relaxin affects cardiovascular function through a central mechanism. Supported by NSERC Canada and OMAF Canada.

INCREASED VASOPRESSIN (VP) SECRETION FROM HYPOTHALAMIC CULTURES FOLLOWING EXOGENOUS VP mRNA ADMINISTRATION. J.R. Mathiasen¹, D. Maciejewski-Lenoir², F.E. Bloom², and C.D. Sladec¹.

¹Dept. of Physiology and Biophysics, Finch University of Health Sciences/Chicago Medical School, North Chicago IL 60064, ²Dept. of Neuropharmacology, Scripps Research Institute, LaJolla CA 92037

Previous studies have shown that exogenous administration of vasopressin (VP) mRNA to Brattleboro rats significantly increases serum VP and urine osmolality (Science, 1992 225:996-998). As a first step towards understanding the mechanisms by which cells take up and process exogenous mRNA, we have administered VP mRNA to long term (30 day) primary dispersed hypothalamic cell cultures from 14 day old rat (Sprague Dawley) fetuses. Hypothalamic cells were cultured either in control medium or medium containing the cAMP elevating agents 3-isobutyl-1-methyl-xanthine (IBMX 0.5 mM) and forskolin (25 μ M, together designated IF) for 23 days or 30 days in vitro to maintain the VP phenotype (VP synthesis and secretion) (Endocrinology, 1993 133:1320-1330). VP secretion into the medium of cells treated with IF for 23 days declined to baseline by 30 days in vitro, but administration of VP mRNA to these cultures on day 30 resulted in a ~ 5 -fold increase in VP content in the medium ($p = 0.005$) after 6 hrs and a ~ 2.5 -fold increase after 24 hrs ($p = 0.002$). Administration of VP mRNA to the cultures treated continuously with IF also resulted in a small increase in VP secretion which did not reach significance after 6 or 24 hrs. Autoradiography of cultures administered ³H or ³²P-VP mRNA for 24 h revealed silver grains indicating VP mRNA located in or on varicosities as well as on the perikarya and neuritic processes of rat neurophysin immunocytochemically identified neurons. These results suggest that exogenously administered mRNA has access to cell translation systems in cultured cells and that translation of exogenously applied mRNA may occur as early as 6 h after treatment.

RESTORATION OF VASOPRESSIN RELEASE FOLLOWING HYPOPHYSECTOMY IN RATS.

R.H. Melloni, Jr.*, J.A. Brewer, Y. Delville, L.J. DeGennaro[§] and C.F. Ferris. Laboratory of Behavioral Neuroscience, Dept. of Psychiatry, University of Massachusetts Medical Center, Worcester, MA 01655. [§]Wyeth Ayerst Research, Princeton, NJ 08543.

Synaptic reorganization in the median eminence (ME) following hypophysectomy has been extensively studied morphologically, although, relatively little is known regarding the molecular events that underlie the recovery of water balance. In pilot studies, male rats ($n=9$) were hypophysectomized and observed for the restoration of water balance over the next 33 days. Animals were sacrificed at weekly intervals following surgery, the blood measured for vasopressin (AVP) and the brains examined for AVP immunostaining in the ME. Urine output and water intake was variable over the first week as were the blood levels of AVP. Examination of the ME revealed an aggregation of AVP immunoreactivity with little organization. During weeks two and three the plasma levels of AVP peptide were stabilized at about 30 pg/ml while urine and water volumes remained at about 40 ml/day. The AVP immunoreactivity has increased in density and organization around multiple layers of capillaries that form a new mini neural lobe in the ME. By the fourth week urine and water volumes decline in correlation with an increase in plasma AVP levels to approximately 220 pg/ml. At this time point, the pattern of AVP immunostaining appeared to be less intense but better organized around the new capillary plexus. Studies are underway to examine the restoration of AVP function in animals maintained for longer periods, and to correlate recovery with the expression of proteins implicated in the regulation of synaptic function. Supported by NIH NS25050 and NS27833 to L.J.D.

EFFECT OF OVARIAN STEROIDS ON HYPOTHALAMIC PULSATILE OXYTOCIN RELEASE EVOKED BY SUCKLING IN THE ANAESTHETIZED RAT. Q.B. Jiang and J.B. Wakerley. (SPON: Brain Research Association). Dept. of Anatomy, Sch. of Medical Sciences, Univ. of Bristol, Bristol, BS8 1TD, U.K.

Effect of ovarian steroids on pulsatile oxytocin (OT) release during suckling was examined in late pregnancy by ovariectomy (OVX) and steroid replacement. Intramammary pressure recordings of milk-ejection responses were used to detect pulsatile OT release from the magnocellular OT neurons in the hypothalamus. OVX on day 20 of pregnancy significantly increased the frequency of milk ejection responses on day 22 of pregnancy, compared with sham-OVXed controls ($3.7 \pm 0.4/20$ min, $n=7$, versus $2.4 \pm 0.4/20$ min, $n=6$, $P < 0.05$, t-test). Replacement with either progesterone (5 mg per day, s.c.) or estradiol (5 μ g per day, s.c.) in day 20 pregnant OVXed rats each reduced milk-ejection frequency to the sham-OVXed level. However, these two different steroid regimes caused a remarkable difference in the facilitatory response to intracerebroventricular (i.c.v.) injection of OT. Milk-ejection frequency in progesterone replaced rats was decreased significantly from $2.0 \pm 0.3/20$ min before i.c.v. OT to $0.8 \pm 0.2/20$ min after i.c.v. OT ($n=8$, $P < 0.05$), whereas in estradiol replaced animals there occurred a significant increase of milk-ejection frequency from $2.0 \pm 0.5/20$ min to $3.6 \pm 0.3/20$ min ($n=9$, $P < 0.05$). In OVX ovariectomized controls, frequency of milk ejection before and after i.c.v. OT were $3.6 \pm 0.6/20$ min and $3.7 \pm 1.0/20$ min ($n=7$). These results suggest that ovarian steroids may play a role in determining the frequency of pulsatile OT release towards the end of pregnancy. Furthermore, the rising level of oestradiol and fall of progesterone towards the end of pregnancy may be a necessary prerequisite for allowing the facilitatory action of centrally-released oxytocin on the milk-ejection reflex.

TESTING THE ROLE OF NEUROHYPOPHYSEAL OXYTOCIN IN PARTURITION, LACTATION AND MATERNAL BEHAVIOR IN GOLDEN HAMSTERS. Y. Delville*, E.W. Quan, K.M. Mansour, and C.F. Ferris. Behavioral Neuroscience Lab., Psychiatry Dept., Univ. of Mass. Med. Ctr., Worcester, MA 01655.

Recent evidence have questioned the source of oxytocin in the control of parturition, as the uterus has been found to produce the peptide. We tested the presumed roles of neurohypophyseal oxytocin by destroying all neurons projecting to the neurohypophysis through micro-injection of volkensin, a neurotoxic retrograde lectin, within the gland itself. This treatment produced polydipsia and polyuria, indicating that the neurosecretory vasopressinergic system was destroyed. All animals followed regular 4-days estrus cycles, and became sexually receptive on the day of estrus. Sixteen days after mating, on the predicted day of parturition, volkensin-treated animals gave birth to their pups, producing regular size litters (7 to 16 pups). The animals were then observed for occurrences of lactation and maternal behavior. One week later, all female were sacrificed, their blood collected, and their brain fixed with acrolein. Oxytocin-immunoreactive neurons were observed and mapped in these brains, and levels of oxytocin were assayed in the blood samples. Some animals were deprived of blood levels of oxytocin and oxytocinergic neurons within neurosecretory cell groups such as the supraoptic nucleus. Interestingly, these animals did not lactate, nor show maternal behavior. These results suggest that, while neurohypophyseal oxytocin is critical for lactation, it is not necessary for parturition. IMAGING SYNAPTIC CONNECTIVITY WITH WIDEFIELD DIGITAL MICROSCOPY. C.F. Ferris*, Y. Delville, J. A. Collins and L. Lifshitz. Behav. Neurosci. Labs., Psychiatry Dept., University of Massachusetts Medical Center, Worcester, MA 01655.

We are developing the technology to visualize and quantify synaptic connections at the light microscopic level. This technology is being validated by examining the synaptic connections of glutamate decarboxylase (GAD) terminals on oxytocin (OXY) neurons in the supraoptic nucleus of rats, a system reported to be highly plastic following salt loading. OXY neurons are labeled with FITC and GAD boutons with Texas Red in 50 μ m thick sections. The sections are examined under a Nikon Diaphot inverted microscope mounted with a Photometrics CCD camera. Sections are excited for each fluorochrome, optically sectioned at 250 nm, digitized and restored. Each data set is analyzed on a Silicon Graphics Indigo Elan workstation with the interactive software DAVE. By combining immunofluorescent labeling for OXY and GAD, it is possible to examine the synaptic connections between the two systems. A synapse is identified when both fluorescence signals colocalize in a voxel ($187 \times 187 \times 250$ nm) in a set of contiguous voxels. DAVE eliminates all immunoreactive elements (e.g., spurious staining, synaptic boutons, and fibers of passage) that do not colocalize with the membrane of the OXY neuron. All putative synaptic connections that do not fall within the dimensions of a GAD synaptic bouton programmed into the computer are deleted and the remaining putative synapses are displayed on the surface of the postsynaptic membrane.

IONIC DEPENDENCE OF THE DEPOLARIZING AFTERPOTENTIAL (DAP) IN VASOPRESSIN NEURONS: ENHANCEMENT BY HISTAMINE. W.E. Armstrong* and B. N. Smith**, Depts. of Anat. Neurobiol., Univ. Tenn., Memphis, TN 38163*, and Colorado State Univ., Ft. Collins, CO 80523**.

Acting through H_1 receptors, histamine depolarizes vasopressin neurons and augments the Ca^{++} -dependent DAP to promote phasic bursting activity (Smith and Armstrong, *Neurosci.* 53: 855, 1993). The enhancement of the DAP persists when blocking the afterhyperpolarization, is independent of $[Cl^-]_i$ and is TTX-insensitive. Conventional intracellular recordings from supraoptic nucleus (SON) neurons in the rat hypothalamic explant were used to further assess the ionic dependence of histamine's effect. Neurons recorded with electrodes containing the Ca^{++} chelator BAPTA (100-500 mM) failed to exhibit a DAP and also failed to depolarize to histamine, suggesting its actions may depend upon increased $[Ca^{++}]_i$. Histamine broadened action potentials slightly in normal cells and more markedly in cells loaded with the K^+ channel blocker Cs^+ , indicating it may also promote increased Ca^{++} influx. Raising $[K^+]_o$ depolarized SON neurons and elevated proportionately the threshold for the DAP. When measured at the same membrane potential, the DAP was consistently smaller in high $[K^+]_o$, and was only weakly enhanced by histamine. The apparent conductance of the membrane is slightly but consistently decreased during the DAP when tested with small, brief current pulses which do not alter its amplitude or time course. While the conductance data could be interpreted as arising from deactivation of a voltage-dependent inward current (Bourque, *Neurosci. Lett.* 70: 204, 1986), combined with the K^+ -dependence of the DAP they are also consistent with the idea that the DAP, and histamine's effects, could be mediated in part by Ca^{++} -dependent inhibition of a slowly or non-inactivating K^+ current which is activated at depolarized potentials. Since an inward current is nevertheless likely to be involved in the DAP, experiments in progress are testing its sensitivity to altered $[Na^+]_o$. GLUTAMATE MICROSTIMULATION OF LOCAL INHIBITORY CIRCUITS IN RAT SUPRAOPTIC NUCLEUS J.-P. Wuarin* and F.E. Dudek, Dept. of Anatomy and Neurobiology, Colorado State Univ., Fort Collins, CO 80523.

GABA provides most if not all of the inhibitory synaptic input throughout the neuroendocrine hypothalamus. Half of the synaptic boutons are immunoreactive for GABA in supraoptic (SON), paraventricular, suprachiasmatic and arcuate nuclei. Neurons immunopositive for GABA and glutamic acid decarboxylase have been shown in and around SON and other hypothalamic nuclei, suggesting that inhibitory input to hypothalamic neuroendocrine cells might originate predominantly from local GABAergic neurons. Using whole-cell recordings and glutamate microdrops in hypothalamic slices, we tested the hypothesis that local GABAergic neurons provide inhibitory synaptic input to supraoptic magnocellular neuroendocrine cells. Microdrops of glutamate (20 mM, 50-150 μ m in diameter) were applied in the periphery of the SON while frequency and amplitude of synaptic currents in supraoptic magnocellular neurons were monitored ($n=23$). In 4 cells, glutamate microdrops dramatically increased frequency and average size of inhibitory postsynaptic currents (IPSCs) while no change in excitatory postsynaptic currents was detected. Glutamate microdrops increased IPSC frequency from 0.5-2 Hz to 3-20 Hz. Glutamate microstimulation also increased the average amplitude in all 4 cells by increasing the proportion of the largest IPSCs, suggesting that more IPSCs were action potential-mediated. These results support the hypothesis that GABAergic neurons located in the periphery of SON provide inhibitory input to supraoptic magnocellular neuroendocrine cells.

VASOPRESSINERGIC INNERVATION TO SUBSTANTIA NIGRA (SN) AND VENTRAL TEGMENTAL AREA (VTA) IN THE RAT. T. Yamamoto* and S.T. Kitai, Department of Anatomy and Neurobiology, University of Tennessee, College of Medicine, Memphis, TN 38163.

Vasopressin (VP) fibers are widely distributed in the brain in addition to a hypothalamo-hypophyseal system. In addition to classically known antidiuretic and vasoconstrictive actions, VP affects memory process, cardiovascular function, thermoregulation and motor behavior. SN and VTA in the midbrain are known to receive VP innervation, but the cells of origin of these VP fibers are unknown. In this study, we examined the VP innervation to SN and VTA in the rat using a retrograde fluorescence tracing technique and immunohistochemistry.

Ten to 14 days following pressure injection of Fluoro-Gold (FG) (2.5 to 4%, 25 to 45 nl) into the SN/VTA region, colchicine (120 μ g/kg) was injected into the lateral ventricle. After a 2 day survival period, the rats were transcardially perfused and sacrificed. The brains were removed, post-fixed and stored in phosphate buffer. Using a vibratome 50 μ m sections were cut for immunohistochemistry.

The neurons in the bed nucleus of the stria terminalis (BST), medial amygdaloid nucleus (MeA), locus coeruleus and paraventricular hypothalamic nucleus (PVN) were retrogradely labeled by FG. In BST there were many double labeled neurons, but there were only a few in the MeA, PVN, and hypothalamic area. These observations indicate that SN and VTA receive VP afferents mainly from BST, but some originate from the hypothalamic area, MeA and PVN.

MANNITOL AND ANGIOTENSIN II MODULATE SPONTANEOUS SYNAPTIC CURRENTS IN SUPRAOPTIC NEURONS OF RAT HYPOTHALAMUS. T. NAGATOMO, K. INENAGA*, L.-N. CUI, H. TANAKA and H. YAMASHITA, Dept. of Physiol., Univ. of Occup. and Environ. Health, Kitakyushu 807, Japan

Spontaneous synaptic currents were recorded in the supraoptic (SON) magnocellular neurosecretory cells using whole-cell patch-clamp techniques in rat hypothalamic slice preparations. Excitatory postsynaptic currents (EPSCs) were almost completely blocked by the non-NMDA receptor antagonist CNQX (10 μ M). Inhibitory postsynaptic currents were blocked by the GABA_A receptor antagonists picrotoxin (50 μ M) and bicuculline (1 μ M). Mannitol and NaCl (30-60 mOsm/kg), and angiotensin II (1 μ M) increased the number of EPSCs without changing the mean amplitude of EPSCs. The AT₁ receptor antagonist losartan potassium (10 μ M) decreased evoked postsynaptic current but little affected the spontaneous EPSCs. These results support evidence that 1) glutamate and GABA are main synaptic transmitters in *in vitro* preparations, acting through non-NMDA receptors and GABA_A receptors, respectively, and suggest that 2) hyperosmotic stimulation increases the synaptic transmission, affecting presynaptically and 3) angiotensin II modulates neurotransmission in the SON neurons of rat hypothalamic slice preparations.

NEUROENDOCRINE REGULATION: OTHER II

482.1

EXPRESSION OF THYROID HORMONE RECEPTORS (THR) IN GH3 AND B103 CELLS. C.-G. Hahn, A. Pawlyk, P.C. Whybrow* & S. M. Tejani-Butt, Dept. of Psychiatry, University of Pennsylvania School of Medicine, Phila., PA, USA.

The association of altered thyroid axis in affective illness and its modulation in treatment responsiveness is well established. Recent clinical studies suggest that the availability of thyroid hormones (TH) to the CNS is critical for the treatment responsiveness of lithium (Li), a mood stabilizer, in bipolar affective disorder. This study examined the effects of Li on THR- α 2 transcript in GH3 cells, a pituitary adenoma cell line. Cells were grown in resin stripped TH deficient media and treated with triiodothyronine (T3, 10 and 100 nM) up to 5 days, in the presence or absence of Li (1 mM). 20 μ g of total RNA from each sample was analyzed by Northern hybridization. The results indicated that the expression of THR- α 2 was decreased (75%) by T3, when compared to cells that were grown in T3 deficient media for 2 days, as has been previously reported. In cells that were analyzed at 5 days, the expression of THR- α 2 was also found to be decreased in comparison to cells grown in T3 deficient media. Addition of Li did not appear to alter the expression of THR- α 2 in GH3 cells. The present study also examined whether B103 cells, a neuroblastoma cell line, would express THRs. B103 cells were found to express both THR- α 2 and THR- α 1, suggesting that B103 cells may be a potentially useful model for the study of neuron specific regulation of THRs. (Research funds from USPHS grant MH 44210).

482.2

POSTNATAL DEVELOPMENT OF THE RAT ADRENAL MEDULLA

H. Holgeri, A. Dagerlind, H. Lagercrantz, T. Hökfelt*, Dept. Women and Child Health/Dept. Neuroscience, Karolinska Institute, S-171 77 Stockholm, Sweden.

The functional innervation of the rat adrenal medulla matures postnatally. In the present study in situ hybridization and indirect immunohistochemistry were employed in order to study this process. Neurofilament 10 (NF10)- and growth associated protein 43kD-immunoreactive (IR) nerve fibers were present in the medulla on day 2, and the gradual onset of a functional innervation correlated to increasing acetylcholinesterase (AChE) and enkephalin (ENK) (and ACh?) levels in splanchnic preganglionic fibers. The maturation of these fibers seemed to exert a suppressive effect on the expression of ENK, calcitonin gene-related peptide (CGRP) and neurotensin in chromaffin cells, while galanin (GAL) was low also in neonatal rats. The catecholamine synthesizing enzymes were little affected during this period. The large, neuropeptide tyrosine containing ganglion cells developed in parallel to the preganglionic innervation, and gradually exhibited mature properties, i.e. strong AChE- and NF10-like immunoreactivities, and expression of nerve growth factor receptor and tropomyosin receptor kinase mRNAs. In contrast, the assumed sensory CGRP- and GAL-IR innervation, and the vasoactive intestinal polypeptide-containing ganglion cells were almost fully developed on day 2. IN CONCLUSION, the postnatal development of the rat adrenal medulla is paralleled, and most likely influenced by the maturation of splanchnic preganglionic fibers, both with regard to enzyme and peptide regulation, and to maturation of the ganglion cells. However, other factors such as thyroid hormone, glucocorticoids and neurotrophins may also influence these processes.

482.3

ANTIBODY-INDUCED SYMPATHECTOMY OF THE RAT ADRENAL GLAND INCREASES PEPTIDE LEVELS MAINLY IN ADRENALINE PRODUCING CELLS. A. Dagerlind*, M. Peltö-Huikko, S. Brimijoin and T. Hökfelt. Dept. of Neuroscience, Karolinska Institute, S-171 77 Stockholm, Sweden.

Systemic administration of monoclonal acetylcholinesterase antibodies has been shown to cause selective degeneration of sympathetic preganglionic neurons. In the present study rats were subjected to a single i.v. injection of these antibodies. Exophthalmos, piloerection and ptosis were observed within 1 h after administration. Rats were sacrificed at different time-points, and the adrenal glands were analysed by means of indirect immunohistochemistry and in situ hybridization histochemistry. As soon as 3 h after the antibody treatment a marked increase in the number of chromaffin cells expressing mRNA encoding, respectively, enkephalin, calcitonin gene-related peptide, galanin, neurotensin and substance P was seen. At 12 h the peptide mRNA levels were still elevated and there was a concomitant increase in the number of peptide-immunoreactive cells. All peptide levels remained high for at least 48 h, however, seventy-seven days after the antibody treatment only enkephalin-immunoreactive cells could be encountered. A disappearance of acetylcholinesterase- and enkephalin-positive fibers was seen already 3 h after the antibody treatment, and after 24 h no fibers were encountered. In contrast, up till 48 h there was no apparent change in the number or intensity of immunofluorescent fibers expressing calcitonin gene-related peptide, galanin, neurotensin or substance P. However, 77 days after the antibody treatment the number of calcitonin gene-related peptide- and substance P-immunoreactive fibers was increased as compared to controls. In addition, reappearance of acetylcholinesterase- and enkephalin-immunoreactive fibers was seen at 77 days, although their number still was low as compared to controls. Double-labeling immunohistochemistry revealed that the cells expressing peptides preferentially were adrenaline storing cells. The majority of these cells expressed only one peptide. Both transection of the splanchnic nerve as well as treatment with acetylcholine receptor antagonists mimicked the effects seen after the AChE-antibody treatment, although changes were less pronounced.

STREPTOZOTOCIN-INDUCED DIABETES AND VITAMIN A METABOLISM.

Shahed Ziari, Andrew T.C. Ts'in, Tapan K. Basu, Elena Rodriguez, Yolanda Moreno, and Nickie Crockett. Division of Life Sciences, The University of Texas at San Antonio, San Antonio, TX 78249 and *The Department of Foods and Nutrition, The University of Alberta at Edmonton, Alberta, Canada T6G 2M8.

Purpose: To investigate the effect of streptozotocin-induced diabetes on concentration of vitamin A (retinol) and retinyl ester in the plasma, liver and ocular tissue of Wistar rats. To relate any changes in vitamin A metabolism to retinyl ester hydrolase (REH) activity in hepatic microsomal membranes. **Methods:** Twenty four animals were divided equally into experimental and control groups. Diabetes was induced by a single i.v. injection (tail vein) of streptozotocin (55 mg/kg) dissolved in acetate buffer, pH 4.5. Control group received only the vehicle. Plasma glucose concentrations were determined by glucose oxidase method. Both groups were fed *ad libitum* with a synthetic diet. Animals were sacrificed 42 days post injection. Retinoid identity and concentration was determined by normal phase HPLC. The hydrolysis of [³H]all-*trans*-retinyl palmitate by microsomal membranes of liver was measured by a radiometric assay which quantitates liberated [³H]10-³H]palmitic acid. Apparent kinetic constants (K_m and V_{max}) were determined by Lineweaver-Burk transformation of the kinetic data. **Results:** In diabetic rats the plasma retinol concentration was significantly lower than those in normal rats. Conversely, hepatic retinol concentration of diabetic rat was significantly higher than that in normal rat. The retinyl ester level in plasma and liver was not notably different between the diabetic group and control. In ocular tissues the retinyl ester of diabetic rats was significantly increased in comparison to control group while retinol level was not perturbed. The all-*trans*-REH of liver microsomes ($K_m \approx 35 \mu M$, $V_{max} \approx 102 \text{ pmol/min/mg}$) were not significantly different between the experimental and control groups. **Conclusion:** Our results show that streptozotocin-induced diabetes influenced vitamin A metabolism in the Wistar rat without alteration in storage of vitamin A. However, the transport of retinol seemed affected by diabetes. In the present study the liver REH was not affected by diabetes, suggesting that the elevation of liver retinol may be due to factors other than ester hydrolysis. Furthermore, the increase of retinyl ester storage in the eye suggests the possibility of ocular pathology(ies) whereby diabetes may be related to some form of retinopathy in the eye.

ELECTROPHYSIOLOGICAL EFFECTS OF NORADRENERGIC AGONISTS ON NEURONES OF THE BED NUCLEI OF THE STRIA TERMINALIS AND CAUDAL MEDULLARY ORIGINS OF THE CATECHOLAMINERGIC INNERVATION. M.G.Terenzi and C.D.Ingram* Department of Anatomy, School of Medical Sciences, University of Bristol, BS8 1TD, UK.

The bed nuclei of the stria terminalis (BST) are a limbic collection of neurones at the junction of the hypothalamus and septal area. The BST are important for autonomic functions and reproductive activity associated with maternal behaviour and the milk-ejection reflex. The BST are innervated by medullary noradrenergic groups (A1, A2 and A6) and high turnover of noradrenaline occurs in the BST during suckling.

We investigated the topography of the connections from the A1/A2 groups to the BST using fluorescent retrograde tracing and tyrosine hydroxylase (TH) immunocytochemistry. The results showed that the projection from the caudal medulla originates in the ventrolateral medulla and the nucleus of the tractus solitarius (NTS). Most of the input is ipsilateral and terminates in the BST ventral to the anterior commissure. Almost no labelling is observed in the caudal medulla when the injection was in the caudal BST. TH immunoreactive retrogradely labelled neurones were observed in A1/C1 and A2/C2 and a group of non-catecholaminergic neurones was observed in the NTS in the midline, dorsolateral to the central canal.

Electrophysiological studies showed that the basal firing of neurones in the BST is inhibited by iontophoresis (*in vivo*) or superfusion (*in vitro*) of clonidine and excited by phenylephrine. These neurones were also inhibited by electrical stimulation of the A2/NTS area *in vivo*. The inhibition resulting from iontophoresis of clonidine and the electrical stimulation of the dorsomedial medulla was reduced by iontophoresis of the alpha-2 antagonist yohimbine. The BST receive strong catecholaminergic innervation from the medulla which appears to exert an inhibitory effect via alpha-2 receptors and an excitatory effect via alpha-1 receptors.

ANTAGONISM OF ANGIOTENSIN TYPE₁ RECEPTORS STIMULATES PLASMA RENIN ACTIVITY IN PREWEANLING SHR AND WKY RATS.

R. F. Kirby*, K. A. Marshall and A. K. Johnson. Departments of Psychology and Pharmacology and The Cardiovascular Center, University of Iowa, Iowa City, IA 52242-1407.

Blockade of the angiotensin type 1 receptor (AT₁) with losartan potassium has been found to stimulate plasma renin activity (PRA) by interrupting negative feedback within the renin-angiotensin system. This response is largely dependent upon sympathetic innervation of renal juxtaglomerular cells, because the stimulation of PRA by losartan is abolished or severely inhibited by blockade of beta₁ adrenoceptors. In a previous study, we found the ability of sympathetic activation to stimulate PRA was minimal during early preweanling development (prior to postnatal day 10) but matured rapidly during the late preweanling period in the rat. Therefore the present study examined the developmental time course of losartan-induced PRA stimulation during the period in which functional sympathetic control of the renin-angiotensin system emerges.

Normotensive Wistar-Kyoto (WKY) and spontaneously hypertensive (SHR) pups born in our laboratory were administered losartan potassium (10 mg/kg) or vehicle on postnatal days 5, 10, 15, 20 or 35. Additional groups of 20 and 35 day old animals were tested for their response to losartan with sympathetic activity to the juxtaglomerular cells blocked by the beta₁ adrenoceptor antagonist atenolol.

Blockade of AT₁ receptors significantly increased PRA in both WKY and SHR. Pretreatment with atenolol diminished the PRA response to losartan in 20 and 35 day old animals, indicating a contribution of the sympathetic nervous system to the response. However, losartan significantly increased PRA even at the youngest ages examined. These data suggest that AT₁ receptor activity may act independently of the sympathetic nervous system during early development to regulate activity of the renin-angiotensin system.

482.6

DIFFERENCES IN PHARMACOKINETICS OF LIDOCAINE IN THE PERIPHERAL NERVE OF GRAVID RATS. FA Popitz-Berges*, GR Strichartz, JG Thalhammer, Anesth. Res. Labs. HMS, BWH, Boston MA 02030.

The mechanisms underlying the decrease in drug requirements for central and peripheral anesthesia during pregnancy in humans are not yet understood. Sex hormone effects on excitable membranes have been suggested as a possible cause. Intravenous progesterone induces sleep in man, and decreases seizure activity in experimental models of epilepsy. Furthermore, long-term progesterone exposure in rabbits enhances the effect of local anesthetics (LA) in peripheral nerve block *in vitro*.

The present study was undertaken to examine 1) if the gravid rat was a suitable model to study this phenomenon, 2) the possibility of altered pharmacokinetics of LA in the gravid rat by studying lidocaine uptake in a peripheral nerve *in vivo*.

Pregnant (P; n=3) and non pregnant female (NP; n=3) rats were briefly anesthetized with Sevoflurane. A unilateral sciatic nerve block was performed with 0.1 ml of 1% radiolabelled lidocaine (*LID). After recovery from general anesthesia (~1min), proprioception, motor function and responses to superficial (skin pinch) and deep (digit squeeze) pain were tested. As soon as deep pain sensation returned, the animal was sacrificed, the sciatic nerve rapidly removed, frozen, cut in 5 mm segments, desheathed, weighed, digested and the uptake of *LID measured by liquid scintillation counting of the different segments.

A significant difference in the time for return of deep pain sensation was observed between the 2 groups; 37, 25, 21 minutes for the NP rats and 50, 50, 47 minutes for the P rats. The fraction of the total *LID injected dose found in the nerves was $0.49 \pm 0.14\%$ for the NP rats and $0.39 \pm 0.08\%$ for the P rats. *LID distribution along the nerve was not significantly different between the 2 groups.

In summary, the duration of anesthesia was prolonged in P rats as was observed in humans, but the amount of *LID in the nerve when deep pain recovered was the same in both groups. This effect might be due to 1) an increase in uptake of LA (e.g. due to an increase in nerve sheath permeability) 2) a decrease in clearance of the LA from the nerve or 3) both.

482.8

INSULIN-LIKE GROWTH FACTOR-1 (IGF-1) PROTECTS GT1-7 CELLS FROM OXIDATIVE INJURY. M.A. Sortino*, U. Scapagnini and P.L. Canonico Institute of Pharmacology, University of Catania School of Medicine and *Chair of Pharmacology, University of Pavia School of Dentistry, Italy

The neuroprotective action of Insulin-like growth factor-1 (IGF-1) has been recently demonstrated in different experimental models of neurodegeneration. Immortalized hypothalamic, gonadotropin-releasing hormone (GnRH) secreting, GT1-7 cells display a marked sensitivity to toxicity induced by reduced glutathione (GSH) depleting agents that in these cells cause necrotic death. GT1-7 cells express IGF-1 receptors whose activation causes a bimodal modulation of GnRH secretion. On these bases we have studied the potential protective effect of IGF-1 in GT1-7 cells. Subconfluent GT1-7 neurons cultured for two days were exposed to different concentrations (50-500 μM) of buthionine sulfoximine (BSO), which reduces the intracellular levels of GSH, for 24-48 hours or to diethyl maleate (DEM; 1 mM) which binds sulfhydryl groups of GSH, for 1 to 3 hours. Both treatments produced extensive neuronal death that however was more pronounced in DEM-treated cells. Concomitant exposure of GT1-7 cells to IGF-1 (at the maximal concentration of 25 ng/ml) resulted in a remarkable reduction of neuronal death as assessed either by trypan blue exclusion or by staining with fluoresceine diacetate and propidium iodide. The neuroprotective effect of IGF-1 has been compared to that induced by the potent antioxidant idebenone that, in the low micromolar range, provided a virtually complete protection of the oxidative stress produced by either BSO or DEM. These results suggest that IGF-1, as already proposed in different cellular systems for various growth factors, may exert its neuroprotective action through antioxidant mechanisms.

FUNCTIONAL DEVELOPMENT OF NEUROENDOCRINE BAG CELLS OF *APLYSIA*. N. Wayne¹, T. Nick², T. Carew³, L.K. Kaczmarek⁴. Dept Physiol¹, UCLA Sch Medicine, Los Angeles, CA 90024, Interdept Neurosci Prgm², Depts Psychol³ and Pharm⁴, Yale Univ, New Haven, CT 06510.

Egg-laying behavior in mature *Aplysia* occurs in response to egg-laying hormone (ELH) released from neuroendocrine bag cells; ELH release is triggered by a prolonged pattern of action-potential firing (afterdischarge). Electrical stimulation of bag cells from immature *Aplysia* does not trigger afterdischarges. However, prolonged depolarization (plateau potentials) can be elicited in the presence of the K⁺ channel blocker TEA (Nick et al., Soc Neurosci, Abstr 708.7, 1993). In the present study, we sought to determine whether immature bag cells that are incapable of showing afterdischarges contain the functional mechanisms required for secretion. Suction electrodes were used for both electrical stimulation and extracellular recording from bag-cell preparations dissected from mature (avg body wt=256 g) or immature (avg body wt=10 g) *Aplysia*. Medium bathing the preparations was collected every 5 min before, during and after stimulation for a total of 125 min. Samples were frozen at -20 °C until radioimmunoassay for ELH was performed. Immature preparations (n=3) showed ~9 plateau potentials (no afterdischarges), while mature preparations (n=3) showed afterdischarges lasting ~18 min with ~650 action potentials fired during that period. Both immature and mature bag-cell preparations secreted ELH above baseline, although the total amount (~36 ng/ml vs ~2400 ng/ml) and duration (~25 min vs >105 min) of secretion was significantly lower from immature preparations. These results indicate that immature bag cells that do not show afterdischarges can nonetheless be stimulated to release ELH, and therefore must contain the necessary cellular machinery for secretion. Supported by NIH-HD 28336 (to NW), NSF-BNS 8614961 (to TC) and NIH-NS 18492 (to LKK).

EFFECTS OF STREPTOZOTOCIN-INDUCED DIABETES ON NADPH-DIAPHORASE POSITIVE NEURONES IN THE RAT PANCREAS. S.S.W. Tay* and G. Burnstock*. *Department of Anatomy, National University of Singapore, Kent Ridge, Singapore 0511 & +Department of Anatomy and Developmental Biology, University College, London, WC1E 6BT, U.K.

In saline-injected rats, NADPH-diaphorase positive neurones were dispersed in the interlobular septa, near blood vessels and ducts as well as within pancreatic lobules. NADPH-diaphorase activity was localized in the cell cytoplasm but not in the nucleus. Most of the neurones were heavily labelled while others were moderately to lightly stained. Some labelled neurones sent processes that ramified amongst the exocrine acinar cells. Numerous fine varicose NADPH-diaphorase positive nerve fibres formed networks around the individual islet cells. At 8 weeks post-diabetes, the number of NADPH-diaphorase positive neurones and nerve fibres was reduced. Labelled neurones that persisted were solitary or in small groups (2-5 cells). They were heavily labelled for NADPH-diaphorase activity, some appeared rounded and possessed few short and stubby processes. Islets of Langerhans were not easily distinguishable and their associated nerve networks seemed to have disappeared. NADPH-diaphorase positive macrophages were also found in the interlobular spaces. These results suggest that diabetes has a drastic effect on NADPH-diaphorase positive neurones and nerve fibres in the rat pancreas.

482.13

DECREASED GLUCOSE, BUT NOT FATTY ACID AVAILABILITY INCREASES FOS-LIKE IMMUNOREACTIVITY IN THE CAUDAL BRAIN STEM OF FEMALE SYRIAN HAMSTERS

B.F. Finnerty*, Y. Zhu, and J.E. Schneider. Department of Psychology, Lehigh University, Bethlehem, PA 18015

In Syrian hamsters, estrous cycles are inhibited by food deprivation or by treatment with 2-deoxy-D-glucose (2DG), a drug that inhibits glucose utilization, and methyl palmitate (MP), a drug that inhibits fatty acid oxidation. For example, hamsters become anestrus when treated with high doses of 2DG alone (1750 mg/kg), or with low doses of 2DG and MP given concurrently (750 mg/kg and 20 mg/kg respectively), but not with either drug alone at low doses. Systemic administration of 2DG at high doses (<1750 mg/kg) stimulates expression of the proto-oncogene *c-fos* in the area postrema (AP), and the nucleus of the solitary tract (NTS). These and other data suggest that the effects of 2DG on estrous cycles may occur via a glucoprivic signal detected in the AP/NTS. The present study investigated whether other metabolic treatments that induce anestrus also stimulate neural activation in the AP/NTS. Hamsters received one of the following treatments: (1) 1750 mg/kg (high dose) (2) 750 mg/kg 2DG (low dose) (3) 20 mg/kg of MP (low dose) (4) low doses of both 2DG and MP, or (5) the appropriate vehicle. Cells stained for FOS were observed in the AP/NTS only in groups that were treated with high doses of 2DG. This suggests that glucoprivation (decreased glucose availability) but not lipoprivation (decreased fatty acid availability) affects neural activation in the AP/NTS. Therefore, the signal detection for the availability of metabolic fuels necessary for reproduction may be specifically related to glucose availability. MP may have effects on estrous cycles which are independent of the metabolic effects via the AP/NTS. Supported by research grant BNS9121056 from NSF.

VARIATIONS OF MEMBRANE CURRENTS DURING SOMATOSTATIN RELEASE AS MEASURED ON IDENTIFIED *HELI*X NEURONS BY AN IMMUNOMICROELECTRODE.

MATH, F., DARBON, P., CREST, M., BRIDE, M., & GOLA, M.

Neurobiologie du développement, 25030, Besançon, France and Neurobiologie cellulaire, CNRS, 13000 Marseille, France.

Helix neurons of the visceral ganglia were studied in-situ using simultaneous current clamp and somatic somatostatin release using a micro-immunoelectrode. The results have shown it exists a somatic release of somatostatin in the extracellular spaces. This release was potential-dependent since it appears for membrane potentials higher than +20 mV. Nevertheless, the release intensity seemed to voltage-independent but was delayed when membrane potential increase. Calcium channels blockade suppressed the release. Under slow stimulations (10 Hz, +20 mV) the release became cyclic during some minutes but higher frequency increased the somatostatin release in a dependent manner. Even though a recent demonstration of a noticeable regional difference of calcium channels density, it seemed that somatic exocytosis characteristics were a good model for synaptic release. This is in good agreement with previous works which have demonstrated that exocytosis was not only related to calcium channels but also to sodium channels.

NEW EVIDENCE ON THE DIFFERENCES BETWEEN THE LEFT AND RIGHT OVARY ON THE NEURAL CONTROL OF OVULATION. R. Domínguez*, M.E. Cruz, and C. Morán. UIBR FES Zaragoza. AP9-020, CP15000 México.

There is evidence on the existence of different ovulatory ability between the right and left ovary [RO, LO] depending on ovarian innervation; which is very significant in hemiovariectomized [Hovx] animals. Present study was conducted to analyze if the blockade of ovarian innervation induced by lidocaine+adrenaline [LiA] injection into the ovarian bursa, previous to the extirpation of contralateral ovary, affects the ovulatory ability by the *in situ* ovary, performed at 13.00 h in the day of proestrus of 4-day cyclic rats. The animals were sacrificed on the next expected day of estrus. When LiA was injected to the LO and the RO extirpated 0/6 rats ovulated, while when the RO was injected and the LO extirpated 8/8 rats ovulated [p<0.01]. When Hovx by the LO or RO was performed without LiA injection, 8/8 and 9/9 rats ovulated. 6/6 rats treated at 18.00h with LiA on the LO and the RO extirpated ovulated next morning. Present results support the hypothesis that the LO is more dependent on neural information than the right one. Supported by DGAPA grant IN210893 and PUIS

Neuroendocrine control of plasma extravasation in rats.

Paul G. Green*, Frederick J-P Miao, Wilfrid Jänig and Jon D. Levine

Depts. of Medicine and Oral Surgery, and Division of Neurosciences, UCSF, Box 0452A, San Francisco, CA 94143.

Inflammation produced by complete Freund's adjuvant injection in the rat hindpaw potently inhibits plasma extravasation produced by the inflammatory mediator, bradykinin (160 nM), perfused through the knee joint. This negative feedback process is abolished in rats that have been neonatally treated with capsaicin (100 mg/kg) to deplete most of their unmyelinated primary afferent fibers, which suggests that this negative feedback process is mediated by activation of primary afferent C-fibers. Excitation of C-fibers with electrical stimulation (25mA, 3Hz) of the hindpaw also inhibited bradykinin-induced plasma extravasation in the knee joint.

Acute surgical interruptions of lumbar sympathetic afferents to the hind limb did not attenuate the depression of bradykinin-induced plasma extravasation produced by C-fiber stimulation, indicating that the depression is not mediated by the sympathetic outflow. However, transection of the spinal cord, hypophysectomy, inhibition of corticosterone synthesis, and adrenalectomy all prevented the inhibition of BK-induced plasma extravasation by electrical stimulation, indicating that the negative feedback inhibition on plasma extravasation is dependent on intact neuraxis and an intact hypothalamic-pituitary-adrenocortical axis.

Our data demonstrate a negative feedback inhibition of an inflammatory process, which is elicited by stimulation of C-fiber afferents. It is mediated by ascending pathways in the spinal cord, and probably the hypothalamic-pituitary-adrenocortical axis. Supported by NIH grant AM32634

AFFERENT PROJECTIONS TO THE ROSTRAL NUCLEUS RAPHE PALLIDUS BY IONTOPHORETIC APPLICATION OF CHOLERA TOXIN B. D.M. Hermann, P. Hinckel*, P.H. Luppi and M. Jouvet. Physiol. Institut, D-35392 Giessen, Germany; CNRS URA 1195, F-69373 Lyon, France

In order to investigate its role in thermoregulation, the afferents to the rostral nucleus raphe pallidus (rNRP) were examined by extremely restricted injection sites of cholera toxin b, which seemed necessary, since the rNRP is wrapped both dorsally and laterally by the caudal nucleus raphe magnus (cNRM).

Substantial bilateral afferents were received from the prelimbic, the medial precentral, the infralimbic, the insular and the perirhinal cortex for the rNRP. Strong afferents from the periventricular preoptic area, the paraventricular and the dorsal hypothalamic area could be confirmed in this study; additional afferents from the caudal preoptic area and the adjacent bed nucleus, the central amygdala and the perifornical lateroposterior hypothalamic area were shown. Compared with the cNRM, very few afferents were observed from the fields of Forel, the midbrain and pontine periaqueductal gray and the deep mesencephalic reticular formation. Specific afferents for rNRP, but not for cNRM, were found close to the dorsal raphe nucleus in the ventromedial pontine periaqueductal gray and laterally to the third nucleus inside the midbrain reticular formation. Afferents from the nucleus Kölliker-Fuse and the lateral medullary reticular formation were stronger for rNRP than cNRM, afferents from the subcoeruleus area, the lateral parabrachial area and the caudal pontine reticular formation less intense for rNRP than cNRM. By highly restricted injection sites, substantial afferents could be shown for rNRP from key structures of central nervous thermoregulation.

PREOPTIC PROSTAGLANDIN E₂ (PGE₂) AND CORE TEMPERATURE (T_C) RESPONSES OF GUINEA PIGS TO LPS i.v., INDOMETHACIN i.m., AND/OR PGE₂ i.a. ADMINISTRATION. E. Schic, M. Szekely, A.L. Ungar and C.M. Blautis*. Dept. of Physiology & Biophys., Univ. of TN, Memphis, TN 38163.

PGE₂ has been postulated to be a central mediator of fever. It is generally believed that PGE₂ is produced in the preoptic area (POA) because its level increases both in the third ventricle and the POA in response to i.v. pyrogen. However lately, the question has arisen whether PGE₂ may in fact be formed outside the brain substance and then diffuse into it across cerebral vessels. If produced outside the brain substance, the blockade of its synthesis should prevent LPS-induced fever, whereas the intracarotid infusion of PGE₂ should produce an increase in T_C as well as in preoptic PGE₂. To verify this hypothesis, continuous measurements of PGE₂ levels in the POA were made (sampling by microdialysis and analysis by RIA). T_C was monitored continuously during the following experiments: 1) Following a 90-min stabilization period, indomethacin (10 or 50 mg/kg) was administered i.m. 30 min before *S. enteritidis* LPS (2 µg/kg, i.v.); or 2) PGE₂ (1 and 10 µg/µl) was infused at 2 µl/min into a carotid artery for one hour. LPS induced a biphasic 1.2 °C fever which was consistently associated with an increase in the level of PGE₂ in the POA. Indomethacin at 10 mg/kg attenuated the LPS-induced fever and prevented the associated increase in PGE₂ for 90 min after fever onset; thereafter, PGE₂ was significantly reduced by comparison to controls. Indomethacin at 50 mg/kg completely abolished both the fever and the increase in preoptic PGE₂. Intracarotid infusion of PGE₂ produced a dose-dependent hypothermia without any increase in preoptic PGE₂. The blockade of fever and inhibition of the increase in preoptic PGE₂ levels further substantiate the presumptive link between preoptic PGE₂ and fever. The failure of exogenous PGE₂ intracarotid infusion to induce increases in T_C and preoptic PGE₂ excludes the possibility that PGE₂ formed outside of the brain diffuses into the POA across cerebral vessels and induces fever. BOMBESIN-INDUCED HYPOTHERMIA IN ADRENALECTOMIZED RATS. C. Barton*, D.A. York and G.A. Bray. Pennington Biomedical Research Center, Louisiana State University, Baton Rouge, LA 70808.

Bombesin (BOM) is a tetradecapeptide known to produce hypothermia when administered centrally in rats tested at normal ambient temperatures. Previous studies have demonstrated bombesin-induced hypothermia requires a state of reduced sympathetic nervous system activity. The importance of adrenal activity on this phenomenon is unknown. The present study examines the impact of bombesin injection (100ng/5µl) or vehicle (VEH) into the lateral ventricles on core body temperature of food-deprived (20hr) adrenalectomized (ADX) and sham operated (SADX) rats with peripheral corticosterone (CORT) replacement (0.1 mg/kg, ip) or vehicle injection 17 hrs prior to testing. Completeness of ADX was assessed by serum aldosterone assay at the completion of testing. This produced a between subject design with four experimental conditions: (central inj/peripheral inj/surgical treatment) VEH/VEH/SADX, BOM/VEH/SADX, BOM/VEH/ADX, & BOM/CORT/ADX (n=7/condition). Core temperatures were recorded at time of central injection and 60 min later. Central bombesin induced hypothermia in all conditions as compared to central vehicle with a significantly greater hypothermia seen in ADX + CORT (-4.13±0.19 °C) & ADX + VEH (-3.18±0.38 °C) conditions versus SADX+VEH (-1.79±0.31 °C). This data demonstrates that adrenalectomy potentiates bombesin-induced hypothermia, and suggests that corticotrophin-releasing hormone and adrenal catecholamines modulate this phenomenon.

THE EFFECTS OF IL-1β ON THE INTRACELLULAR ACTIVITY OF HYPOTHALAMIC THERMOSENSITIVE AND TEMPERATURE INSENSITIVE NEURONS. J.D. Griffin* and C.B. Saper. Department of Neurology, Beth Israel Hospital and Harvard Medical School, Boston, MA 02115

The production of endogenous cytokines within the CNS may play a role in the induction of a fever during the acute phase response. Recently, it was shown that IL-1β may have a direct effect on the inherent activity of thermosensitive neurons within the preoptic and anterior regions of the hypothalamus. These neurons are known to directly influence thermoregulatory responses. To identify the intracellular mechanisms of IL-1β induced changes in activity, tight-seal, whole-cell recordings were made of neuronal intracellular activity in rat hypothalamic tissue slices. Based on their slope of firing rate as a function of tissue temperature, neurons were classified as either warm sensitive (high slope) or temperature insensitive (low slope). Neurons were then treated with 1L-1β (0.4µg/20ml) while temperature was held at a constant level (~36°C). Temperature insensitive neurons showed no change in their spontaneous firing rates or intracellular characteristics during treatment with IL-1β. Neurons classified as warm sensitive showed a decrease in spontaneous firing rate activity during treatment with IL-1β which may be linked to specific conductance changes inherent to the neurons' activity. (Supported in part by NIH NS09466, NS07291 & AHA 91011)

SUPPRESSION OF INTERLEUKIN-1β FEVER AT PARTURITION IN RATS. S.M. Martin*, I. Neumann, T.J. Malkinson and Q.J. Pittman. Biology Department, Mt. St. Vincent University, Halifax, NS B3M 2J6 and Neuroscience Research Group, The University of Calgary, Calgary, AB T2N 4N1 Canada.

We have previously shown that pregnant rats at or near term show a significantly reduced fever to intravenous bacterial pyrogen. It is not known if pregnant rats have a decreased central sensitivity to pyrogens or if there is a change in the production of one of the cytokines, interleukin-1β (IL-1β), which is thought to mediate some of the effects of pyrogen. These experiments were undertaken to compare the effects of intravenous administration of IL-1β in pregnant rats at or near term.

Timed pregnant and virgin Sprague-Dawley rats were anesthetized for jugular vein cannulation and implantation of telemetry thermistors. Following recovery, a dose response curve for IL-1β in virgin female rats was ascertained. On the basis of this, a dose of 0.1 µg/kg iv was chosen for subsequent experiments. Pregnant rats showed an attenuated fever response as early as 72 h preparturition and the response was significant ($p \leq 0.05$) 24 h prior to ($0.6 \pm 0.11^\circ\text{C}$) and 24 h postparturition ($0.76 \pm 0.14^\circ\text{C}$) when compared to that of virgin females ($1.54 \pm 0.09^\circ\text{C}$).

The results indicate that IL-1β fever is suppressed at the time of parturition. The mechanism for this suppression remains unknown but may involve some central component of the fever response.

DISSOCIATION OF BROWN FAT SYMPATHETIC NERVOUS SYSTEM (SNS) ACTIVITY FROM BASAL HYPOTHALAMIC-PITUITARY ADRENAL (HPA) AXIS FUNCTION. A.M. Strack*, C.J. Horsley, and S.F. Akana. Dept. Physiol. UCSF, San Francisco, CA, 94143-0444

We have used the nonshivering thermogenic action of brown adipose tissue (BAT) as a measure of SNS activity. Generally SNS activity and the HPA axis, as measured by the release of the stress hormones, ACTH and corticosterone, increase in parallel (e.g. hemorrhage, cold). We tested whether a hypercaloric load (which increases BAT SNS activity, but presumably not HPA activity) would dissociate these two systems. Rats were allowed 30% sucrose to drink in addition to their chow diet for 5 or 10 days. We measured plasma ACTH and corticosterone as indices of HPA activity. As a measure of BAT SNS activity, the BAT specific thermogenic protein, uncoupling protein (UCP) was assayed. A subset of rats was instrumented with temperature probes for chronic remote measurement of BAT and core temperature (Minimitter Co.).

At 5 and 10 days, all HPA measures were the same between sucrose and control rats. As early as 5 days, UCP levels in interscapular BAT were increased. BAT temperature was elevated by the 3rd day of sucrose intake and remained elevated through all portions of the circadian rhythm throughout the remainder of the 10 day period. These results show a long term increase in SNS activity independent of that of the HPA axis. This dissociation of SNS activity from that of the HPA axis will allow differential dissection of the efferent pathways regulating these systems. NONSHIVERING THERMOGENIC RESPONSE TO COLD IS GREATER IN AGED MICE THAN IN ADULTS. S.A. Kirov* and M.L. Talan. Laboratory of Behavioral Sciences, National Institute on Aging, NIH, Gerontology Research Center, Baltimore, MD 21224.

Efferent sympathetic nervous activity (SNA) from a small branch of the intercostal nerve, which ended in the interscapular brown adipose tissue (IBAT), and metabolic heat production (MHP) were measured in C57BL/6J male adult and aged mice under urethane/ isoflurane anesthesia and vecuronium bromide myorelaxation. MHP was calculated on the basis of O_2 and CO_2 concentrations measured in expired air taken directly from the trachea through a mechanical ventilator. Nerve recording and MHP measurements were conducted before and during rapid (15-18 min) whole body cooling until colonic temperature dropped to $7^\circ C$ below control level ($37-38^\circ C$) and during rewarming.

SNA to IBAT and MHP increased during cold stress and returned to the baseline level during rewarming in both age groups. MHP and SNA responses to cold stimulation were significantly greater in aged mice than in adults. Maximal responses of aged mice exceeded those of adults by 70% for MHP and by 50% for SNA. Since all other sources of facultative thermogenesis were suppressed by anesthesia and myorelaxation, we conclude that nonshivering thermogenesis in BAT is responsible for greater MHP during cold exposure in old animals.

CARDIOVASCULAR REGULATION: MEDULLARY RETICULAR RESPONSES

NEUROTRANSMITTERS IN THE VENTROLATERAL MEDULLA MEDIATING CORTICAL AND HYPOTHALAMIC SYMPATHETIC RESPONSES. K.S. Butcher* and D.F. Cechetto. Roberts Research Institute, Univ. of Western Ontario, London, Ontario, Canada N6A 5K8. Our previous investigation demonstrated that sympathetic nerve responses to insular cortical (IC) stimulation are mediated by synapses within the lateral hypothalamic area (LHA) and ventrolateral medulla (VLM). The neurotransmitter(s) in the VLM for IC and LHA responses are unknown. Twenty male Wistar rats were instrumented for renal nerve, arterial pressure and heart rate recording. The IC or LHA were stimulated with a bipolar electrode (200-1000 μA ; 2 ms; 0.8 Hz) to elicit sympathetic nerve responses. Antagonists were then pressure-injected into the VLM (300 nl). Bilateral and unilateral kynurenate (25 mM) resulted in 100% block of IC and LHA stimulated sympathetic nerve responses. Bilateral injection of the non-NMDA receptor antagonist 6-cyano-7-nitroquinoxaline-2,3-dione (CNQX; 200 μM) also resulted in 100% block of IC and LHA sympathetic responses. Unilateral injection of CNQX in two animals resulted in 100% and 83% block of LHA sympathetic responses. Bilateral injection of the NMDA receptor antagonist D,L 2-amino-5-phosphopentanoic acid (AP5; 200 μM) did not affect the response to IC or LHA stimulation. Kynurenate produced a $363 \pm 78\%$ increase in baseline activity, while CNQX and AP5 resulted in $183 \pm 19\%$ and $191 \pm 21\%$ increases respectively. Bilateral injections of antagonists for GABA (bicuculline; 0.1 μM), acetylcholine (atropine; 0.1 μM) and catecholaminergic alpha and beta receptors (phenolamine and propranolol; 0.1 μM) had no effect on LHA sympathetic responses. These results indicate IC and LHA responses are mediated specifically by non-NMDA receptors in the VLM, although NMDA and non-NMDA receptor mediated inputs have tonic effects on RVLM neurons. (Supported by the Heart and Stroke Foundation of Ontario)

484.3

RELATIONSHIP OF THE NUCLEUS RETICULARIS PARVOCELLULARIS (NRP) TO CARDIOVASCULAR REGIONS OF LOWER BRAIN STEM AND SPINAL CORD. L.D. Mitchell and M.A. Nathan*. Depts. of Physiology and Pharmacology, CUNY Medical School, NY 10031.

Regions of the lower brain stem and spinal cord traditionally considered important in controlling resting vascular tone are the rostral ventrolateral medulla (RVLM), caudal ventrolateral medulla (CVLM), which project directly or indirectly to the intermediolateral cell column (IML) (Chalmers & Pilowsky, J. Hypertension, 9:675-694, 1991). The rostral ventromedial medulla (RVMM) also appears important in establishing vascular tone (Vamer et al., Hypertension 19:193-197, 1992). We recently showed that the NRP is another major area contributing to control of the circulation (Cochrane & Nathan, J. Auton. Nerv. Syst., 43:69-82, 1993) and that it projects to the RVLM and CVLM (Mitchell & Nathan, Soc. Neurosci. Abstr., 17:993, 1991).

Projections to the NRP from the RVLM, RVMM and CVLM and projections from the NRP to the IML were studied in male, Long-Evans rats. A micropipette (20-25 μM tip) was used to inject HRP-WGA (Sigma, 1% in 0.5 M NaCl, 10.0 nL) into the NRP. Survival times after the injections were 48-72 hrs. The tissue was processed according to the method of Gibson et al. (Brain Res., 298:235-241, 1984).

We found that the NRP receives massive ipsilateral projections from cells in the RVLM and RVMM. Lighter contralateral projections were observed as well. The CVLM also projects to the NRP. In addition, the NRP projects to the ipsilateral, lower thoracic IML.

These results, in conjunction with our earlier anatomical study, demonstrate that the NRP is reciprocally linked to other principal cardiovascular areas of the brain stem. Moreover, the NRP has a direct connection to the IML.

484.2

DECREASE IN BLOOD PRESSURE AND HEART RATE (HR) ELICITED BY INJECTIONS OF GLUTAMATE (GLU) INTO THE LOCUS COERULEUS (LC) ARE MEDIATED BY α_1 -ADRENERGIC RECEPTORS IN THE NUCLEUS AMBIGUUS/VENTROLATERAL MEDULLARY DEPRESSOR AREA (NA/VLDA). V. Malhotra* and H.N. Sapru. Depts. of Neurosurgery & Pharmacology, New Jersey Medical School, Newark, NJ 07103.

Experiments were carried out on pentobarbital-anesthetized, artificially ventilated male Wistar rats. Microinjections of L-GLU (1.77 nmol/20 nl) into the LC ($n = 5$) elicited a decrease in mean arterial pressure (MAP; 45 ± 12 mmHg) and HR (31 ± 4 bpm). An area encompassing NA/VLDA was identified by injections of L-GLU (1.77 nmol/50 nl). Muscimol (150 pmol/50 nl) was injected into the NA/VLDA ($n = 5$) to inhibit the neurons. Muscimol injections into the NA/VLDA blocked the bradycardic and depressor responses induced by injections of L-GLU into the LC. Injections of norepinephrine (NE; 0.75-6 pmol/50 nl) into the NA/VLDA elicited a decrease in MAP (15-30 mmHg) and HR (15-55 bpm). Maximum effect was elicited by a dose of 1.5 pmol/50 nl; this effect was completely blocked by prazosin (PRZ; 150 pmol/50 nl). Injections of PRZ into the NA/VLDA blocked the depressor and bradycardic effects elicited by injections of GLU into the LC. PRZ did not exert any local-anesthetic effect in the NA/VLDA because the bradycardic and depressor responses to L-GLU remained unchanged. These results indicate that: (1) the depressor and bradycardic effects elicited by stimulation of neurons in the LC are mediated by NA/VLDA, (2) α_1 -adrenergic receptors in the NA/VLDA mediate the cardiovascular effects of the stimulation of LC-neurons, and (3) norepinephrine may be the transmitter released in the NA/VLDA following the stimulation of LC-neurons which are preponderantly noradrenergic in the rat. Support: NIH: HL24377 and AHA (NJ).

484.4

CATECHOLAMINERGIC MECHANISMS INVOLVED IN THE INHIBITION OF PACEMAKER-LIKE TYPE II NEURONS IN THE ROSTRAL VENTROLATERAL MEDULLA (RVLM) *IN VITRO*. A. R. GRANATA*. Department of Pharmacology, The University of Tennessee, Memphis, College of Medicine, Memphis, TN 38163.

In previous studies we identified *in vivo* a group of bulbospinal neurons in the rat RVLM with chloride-dependent IPSP synchronized to the cardiac cycle. During constant hypotension and hence baroreceptor inactivation, the pattern of discharge of these neurons (barosensitive type II) was very regular and had pacemaker-like properties. In addition, the IPSP synchronized to the cardiac cycle vanished. Electrical stimulation of the ipsilateral aortic depressor nerve evoked IPSP on these neurons. Using an *in-vitro* slice preparation, we characterized a group of spontaneously active neurons in the RVLM with features very similar to barosensitive type II *in vivo*. These features included (1) regular pattern of discharge, (2) absence of EPSP during hyperpolarization by negative current pulses below spike threshold level, (3) resetting of neuronal activity by interrupting the spontaneous activity with pulses of hyperpolarizing current, (4) slow depolarizing and afterhyperpolarization potentials, (5) action potential < than 2.2-ms duration, (6) anomalous rectification developed by passing hyperpolarizing current pulses. Tyramine (0.5-1.0 mM) reversibly suppressed the firing of these neurons. This suppression was accompanied by an increase in membrane input resistance, abolition of anomalous rectification and a minor change in membrane potential. The α_2 -adrenergic agonist clonidine (10 μM) reversibly reduced the firing frequency in neurons with barosensitive type II characteristics. Conidine increased the firing rate of other RVLM neurons with different electrophysiological characteristics.

484.5

PRE-SYMPATHETIC NEURONS IN THE ROSTRAL VENTROLATERAL MEDULLA (RVLM) OF THE RAT 'IN VIVO': MORPHOLOGICAL PROPERTIES AND RELATIONSHIP TO C1 CATECHOLAMINERGIC NEURONS. B. Kruszezewska*, J. Lipski, R. Kanjhan and M. Smith. Dept. of Physiology, Univ. of Auckland, Auckland, New Zealand.

The activity of preganglionic sympathetic neurons is maintained by an excitatory input from neurons located in the RVLM. Previous studies conducted in tissue slices (Sun et al. *Brain Res.* 1988, 451:345; and 1991, 556:61) examined the morphology and presence of catecholamine-synthesizing enzymes in RVLM neurons. However, due to functional and anatomical heterogeneity in this medullary region, it is important to examine neurons which can be directly classified as barosensitive and reticulospinal. This was possible in the present experiments conducted *in vivo*, in pentobarbital anaesthetized adult rats (see Lipski et al., this meeting). Recordings were made with microelectrodes filled with 1% Neurobiotin or 3% Lucifer Yellow. RVLM neurons which responded with IPSPs following stimuli applied to the aortic nerve were intracellularly labeled. Some of these neurons could be excited antidromically following stimulation in T2 segment. Filled somas were found ventromedial to the compact formation of nucl. ambiguus. Dendrites extended up to 800 μ m from cell bodies. Some main axons bifurcated in the dorsomedial tegmentum, and a few had axon collaterals which displayed bouton-like varicosities in the ipsilateral RVLM. C1 adrenergic cells were revealed by immunofluorescence using antibody to tyrosine hydroxylase. Some injected neurons were shown to be double labeled.

484.7

MORPHOLOGY OF IDENTIFIED BULBOSPINAL NEURONS IN THE ROSTRAL VENTROLATERAL MEDULLA (RVLM) OF THE RAT. D. Huangfu*, W.B. Goodwin, G.F. Alheid, R.L. Stornetta and P.G. Guyenet. Depts. of Pharmacology and Psychiatric Medicine, Univ. of Virginia, Charlottesville, VA 22908.

RVLM bulbospinal neurons were identified by the presence of retrogradely transported green latex microspheres injected under anesthesia in the spinal cord at T₃, 4-7 days prior to sacrifice. Then these cells were labeled intracellularly in fixed 100 μ m slices (coronal, horizontal or parasagittal) with Neurobiotin that was visualized with an avidin-HRP reaction. Drawings and quantitative analysis of morphological features were done with the NeuroLucida software. Some of the sections were doubly labeled for tyrosine hydroxylase (TH) and Neurobiotin using fluorescent tags.

In coronal sections, 83 well-filled cells were analyzed. They had 2 to 11 dendrites (mean 5.2 ± 0.2) that extended 212 ± 10 μ m (up to 690 μ m) and branched up to five times. Their perikarya were fusiform (6%), round (16%), triangular (30%) or multipolar (48%) and had a mean cross sectional area of 417 ± 18 μ m², corresponding to a roughly computed diameter of 23 ± 1 μ m (range: 14 to 33 μ m).

Comparing parasagittal (23 cells injected), horizontal (N=21), and coronal (N=83) sections, we failed to find a predominant orientation in any plane for the extension of the dendritic tree in the whole population of the injected RVLM cells.

Forty five percent of the RVLM neurons examined in the coronal plane (37/83) had sparsely distributed spines and protuberances on their soma and dendrites. In double stained cases, TH-positive cells, which account for 67% of the injected retrogradely labeled RVLM cells, contained both neurons with and without spines. (Grant: HL 28785 to PG and NS 17743 to GFA).

484.9

GABA AND GLUTAMATE INPUTS TO BULBOSPINAL NEURONS IN RAT ROSTRAL VENTROLATERAL MEDULLA. J.J. Llewellyn-Smith*, J.B. Minson, P.M. Pilowsky, L.F. Arnold and J.P. Chalmers. Department of Medicine and Centre for Neuroscience, Flinders University, Bedford Park, SA., 5042, AUSTRALIA.

A potent vasopressor area coincides with the C1 group of catecholamine neurons in the rat rostral ventrolateral medulla (RVLM). Bulbospinal RVLM neurons participate in the baroreflex and receive an afferent inhibitory input from the caudal ventrolateral medulla and an afferent excitatory input from the nucleus tractus solitarius. Both pathways probably use amino acid neurotransmitters. To study amino acids in synapses on bulbospinal RVLM neurons, we injected cholera toxin B-gold into the intermediolateral cell column. Bulbospinal neurons were visualized with silver-intensification. Immunoreactivity for tyrosine hydroxylase (TH) was detected by pre-embedding immunocytochemistry; and GABA or glutamate, by post-embedding immunogold. Only the inputs to bulbospinal RVLM neurons forming a tight cluster ventral to the nucleus ambiguus compacta were examined. The cell bodies and dendrites of these neurons received synapses and contacts from GABA and glutamate nerve fibers. GABA occurred in 43% (23/54) and glutamate in 73% (51/70) of inputs to bulbospinal TH neurons. GABA was present in 39% (59/150) and glutamate in 54% (74/136) of inputs to non-TH bulbospinal neurons. Studies are underway to determine the origin of the amino acid synapses on bulbospinal RVLM neurons and whether GABA and glutamate are co-localized in any of these inputs.

484.6

NEURONS IN THE C1 AREA OF THE ROSTRAL VENTROLATERAL MEDULLA ARE NECESSARY FOR THE ARTERIAL CHEMORECEPTOR PRESSOR REFLEX. P.S. Clifford*, S.W. Mittelstadt, and K.J. Dormer. Medical College of Wisconsin and VA Medical Center, Milwaukee, WI 53295 and University of Oklahoma Health Sciences Center, Oklahoma City, OK 73190.

Neurons of the C1 area of the rostral ventrolateral medulla project to the intermediolateral cell column of the thoracolumbar spinal cord and contribute to the maintenance of vasomotor tone by providing tonic excitation to sympathetic preganglionic neurons. Previous studies have demonstrated that C1 area neurons are activated by stimulation of arterial chemoreceptors. The hypothesis of this study was that neurons in the C1 area are essential for the expression of the pressor response to stimulation of arterial chemoreceptors. Experiments were performed on five mongrel dogs anesthetized with alpha-chloralose/urethane and mechanically ventilated with room air. Selective stimulation of arterial chemoreceptors was accomplished by ventilation with 100% N₂ for 6 breaths and by intravenous infusion of sodium cyanide (NaCN, 50 μ g/kg). C1 area pressor sites were first identified by microinjection of l-glutamate (100nl, 150mM) and then lesions were created with bilateral microinjections of ibotenic acid (100 nl, 75mM). The following mean arterial pressures (mmHg, mean \pm SEM) were observed:

	CONTROL	100% N ₂	CONTROL	NaCN
PRELESION	120 \pm 7	141 \pm 8	119 \pm 5	147 \pm 8
POSTLESION	77 \pm 9	69 \pm 9	80 \pm 8	72 \pm 9

Stimulation of arterial chemoreceptors by brief periods of hypoxia (100% N₂) or intravenous infusion of NaCN produced marked increases in blood pressure. Following placement of lesions in the C1 pressor area, stimulation of arterial chemoreceptors resulted in depressor responses in all 5 dogs. These results indicate that, in the dog, the C1 pressor area of the rostral ventrolateral medulla is the essential brainstem site for expression of the blood pressure response to stimulation of arterial chemoreceptors.

EFFECTS OF GABA_B RECEPTOR AGONIST BACLOFEN ON NEURONS IN ROSTRAL VENTROLATERAL MEDULLA (RVLM): AN "IN VITRO" AND "IN VIVO" ELECTROPHYSIOLOGY STUDY. Yu-Wen Li* and P.G. Guyenet. Department of Pharmacology, University of Virginia Health Sciences Center, Charlottesville, VA 22908.

We studied the effects of baclofen, a GABA_B receptor agonist, on neurons in the RVLM of the rat. In 17 neurons recorded intracellularly with sharp electrodes, bath application of baclofen (1-3 μ M) produced: 1) a membrane hyperpolarization of 8 ± 2 mV (baseline 58 ± 2 mV, n=17), 2) a $15 \pm 4\%$ decrease in the membrane input resistance (baseline 138 ± 17 M Ω , n=16), 3) a decrease in firing rate (n=14) and 4) a decrease in spontaneous postsynaptic potentials (n=9). Of 83 single units recorded extracellularly in the RVLM *in vitro*, all but 2 were inhibited by baclofen (1-3 μ M). The inhibition was concentration dependent (0.1-3.0 μ M, max. inh. = $94 \pm 4\%$, n=16), and persisted in low-Ca²⁺/high-Mg²⁺ medium (n=19). The GABA_A receptor antagonists CGP54626A (1 μ M, n=19), CGP55845A (1 μ M, n=15) or 2-hydroxysaclofen (0.5 mM, n=3), attenuated the inhibitory effect of baclofen (1-3 μ M), but not that of GABA or muscimol (GABA_A receptor agonist). *In vivo*, iontophoresis of baclofen (40-120 nA) inhibited most RVLM neurons including 15 out of 16 bulbospinal barosensitive cells. This effect was attenuated by iontophoresis of the GABA_B antagonist, CGP55845A (60-80 nA, n=6), but not the GABA_A antagonist, bicuculline (40 nA, n=5). These results suggest that 1) most RVLM neurons including sympathetic premotor neurons have somatodendritic GABA_B receptors, 2) GABA_B receptors in the RVLM may play a role in central regulation of cardiovascular function.

DEVELOPMENTAL CHANGES IN EXCITATORY RESPONSES OF VENTROLATERAL MEDULLARY NEURONS TO HYPOXIA ARE NOT DUE TO DIFFERENCES IN TISSUE PO₂ LEVELS. P.C. Nolan* and T.G. Waldrop. Dept. of Physiology & Biophysics, Neuroscience Program and College of Medicine, Univ. of Illinois, Urbana, IL 61801.

Developmental differences in neuronal responses to hypoxia in several brain sites have been reported previously by other investigators. The purpose of the present study was to determine if there are developmental changes in the excitatory response to hypoxia of neurons in the ventrolateral medulla (VLM). In addition, tissue PO₂ measurements were made to quantify the hypoxic stimulus *in vivo* and *in vitro*. Whole cell recordings were made from neonatal (<16 days) and juvenile (>16 days) VLM neurons both in bottom perfused (Hatton-style) and in inclined plane (Haas-style) brain slice chambers. A platinum polarographic electrode with a 15 μ m tip was used to measure tissue oxygen tensions during control and hypoxic periods in both brain slice chambers and in the VLM of anesthetized, spontaneously breathing rats. With 95% O₂/5% CO₂ aerating the brain slice chambers, basal oxygen tensions ranged from 518 \pm 18 torr immediately below the surface of the tissue to 282 \pm 18 torr at a depth of 200 μ m. Aerating the chamber for 90 seconds with severe hypoxic (0% O₂/5% CO₂/95% N₂) or moderate hypoxic (10% O₂/5% CO₂/85% N₂) gas stimulated a higher percentage of the neurons from the older (>16 days) rats. In addition, hypoxia elicited a depolarization of 4.8 ± 0.5 mV in neonatal and 8.2 ± 1.3 mV in juvenile neurons. Oxygen tensions at a depth of 100 μ m decreased to similar levels in neonatal and juvenile VLM tissue (5.1 ± 3.4 torr and 18.0 ± 8.4 torr during moderate and severe hypoxia). No differences in the PO₂ levels during hypoxia were seen between the two types of brain slice chambers. *In vivo*, VLM tissue PO₂ was 51.7 ± 0.7 torr (room air) and 66.6 ± 7.8 torr (100% O₂) and fell to 31.5 ± 6.8 torr during a 60 sec. inhalation of 10% O₂. These findings indicate developmental changes in the responses to hypoxia of VLM neurons which cannot be explained by differences in the level of tissue PO₂. DIFFERENTIAL TIME- AND DOSE-RELATED EFFECTS OF HEMORRHAGE ON TYROSINE HYDROXYLASE (TH) AND NEUROPEPTIDE Y (NPY) mRNA LEVELS IN MEDULLARY CATECHOLAMINERGIC NEURONS. R.K.W. Chan* and P.E. Sawchenko. The Salk Institute, La Jolla, CA 92037.

Hypertensive hemorrhage induces cellular activation and up-regulation of TH mRNA in medullary catecholaminergic cell groups. To shed light on the significance of the widespread coexistence of NPY in aminergic neurons, quantitative hybridization histochemical methods were used to compare the impact of graded doses of hemorrhage (15, 20 and 25%) on the time course of changes in relative levels of TH and NPY mRNA; concurrent staining for nuclear Fos-immunoreactivity (Fos-ir) permitted comparisons between cells that ostensibly were and were not targeted by the challenge. The major results may be summarized as follows: (1) Hemorrhage induced significant up-regulation of TH mRNA in all medullary aminergic cell groups, and of NPY transcripts in all but the A2 region. At later time points (2-4 hrs) these changes were predominantly seen in Fos-ir neurons. (2) Elevated levels of hemorrhage provoked only slight increases in the total number of Fos-ir neurons and in the percentage hybridized for TH or NPY mRNA in each aminergic region, but more pronounced increases in the magnitude and duration of both mRNA responses. (3) Noradrenergic cell groups displayed more robust maximal increases in relative levels of TH mRNA, while the reverse was true of the adrenergic cell groups. (4) Hemorrhage-induced up-regulation of TH and NPY mRNAs in Fos-ir neurons displayed differential time courses, with NPY responses peaking more rapidly, particularly in the C1 and C2 adrenergic cell groups. (5) At early time points (0.5-1.0 hr), a majority cells displaying increased levels of each transcript in the aminergic regions of interest were non-Fos-ir. Sampling at early time points, however, may precede the ability of cells to mount a detectable Fos protein response. These findings indicate that hemorrhage differentially affects relative levels of TH and NPY mRNA in medullary catecholaminergic cell groups that are known to participate in central neuroendocrine and/or autonomic control mechanisms. The surprisingly robust NPY mRNA responses in adrenergic cell groups suggests a mechanism by which the peptide content of the projection fields of these cell groups is defended.

CAUDAL VENTROLATERAL MEDULLARY (CVLM) NEURONS: ELEMENTS OF THE NETWORK RESPONSIBLE FOR THE 10-HZ RHYTHM IN SYMPATHETIC NERVE DISCHARGE (SND). H.S. Oler*, S.M. Barman, and G.L. Gebber. Dept. Pharmacol. & Toxicol., Michigan State Univ., E. Lansing, MI 48824.

Spike-triggered averaging and coherence analysis were used to study the relationship between the discharges of 246 CVLM neurons and the 10-Hz rhythm in SND of 17 urethane-anesthetized cats. Spike-triggered averaging showed that the naturally occurring discharges of 66 of these neurons were correlated to the 10-Hz rhythm in SND. The interval between unit spike occurrence and the peak of the 10-Hz slow wave in inferior cardiac SND averaged 59 ± 2 ms for these CVLM neurons. Frequency domain analysis was used to characterize further the relationships between SND and the discharges of 45 of these CVLM neurons. The autospectra of the discharges of 22 of these neurons contained a sharp peak near 10 Hz (corresponding to the peak in the autospectra of SND), although the mean firing rate of these neurons was only 5.9 ± 0.5 spikes/s. The peak coherence value relating the 10-Hz discharges of these CVLM neurons and the inferior cardiac nerve was 0.42 ± 0.03 . The autospectra for the other 23 CVLM neurons did not contain a peak near 10 Hz. Their mean firing rate (2.3 ± 0.5 spikes/s) and the peak coherence value relating their discharges to the 10-Hz rhythm in SND (0.08 ± 0.01) were significantly lower than the corresponding values for the other group of CVLM neurons. In five baroreceptor-denervated cats, muscimol (1 nmol/100 nl) was slowly microinjected at four sites in the CVLM ipsilateral to the nerve recording to chemically inactivate neurons in this region. This procedure reversibly eliminated the 10-Hz rhythm in SND. Thus, we propose that CVLM neurons are elements of the network responsible for the 10-Hz rhythm in SND. (Supported by NIH grants HL-33266 and HL-13187.)

BRAIN STEM MECHANISMS ARE RESPONSIBLE FOR DIFFERENTIAL RELATIONSHIPS AMONG THE 10-HZ RHYTHMIC DISCHARGES OF SYMPATHETIC NERVES WITH DIFFERENT TARGETS. S. Zhong*, G.L. Gebber, and S.M. Barman. Dept. Pharm./Tox., Michigan State Univ., E. Lansing, MI 48824.

We previously demonstrated differential relationships among the 10-Hz rhythmic discharges of the cardiac, renal, and splenic postganglionic sympathetic nerves by using partial coherence analysis in baroreceptor-denervated, urethane-anesthetized cats (Gebber et al., Soc. Neurosci. Abstr., vol. 19, Part 2, p. 1078, 1993). Partialization mathematically removes the portion of the coherence of two signals attributable to the sources of a third signal. For example, we found that partialization using splenic sympathetic nerve discharge (SND) usually reduced the coherence of the 10-Hz discharges of the left and right cardiac nerves to a significantly greater extent than did partialization using renal SND. Such results might reflect among other things 1) nonuniform coupling of multiple brain stem oscillators, each controlling a different nerve or 2) nonuniform crosstalk among spinal circuits that control different nerves but share inputs from a common source. In the current study, we compared the ordinary and partial coherence functions relating left and right cardiac SND before and after midsagittal section of the spinal cord from the seventh cervical (C7) through the eighth thoracic (T8) segments combined with right hemisection at T8. These sections failed to change the ordinary coherence value (near one) relating the 10-Hz discharges of the two cardiac nerves or the nonuniform reductions in the coherence value after partialization using splenic SND versus left renal SND. This also was the case after midsagittal section from the C1 through C8 spinal segments. These results suggest that the differential relationships of the 10-Hz rhythmic discharges of sympathetic nerves with different targets arise in the brain stem. (Supported by NIH grants HL-13187 and HL-33266.)

DIMINISHED RESPONSES OF SPONTANEOUSLY HYPERTENSIVE RATS TO LESIONS OF THE CAUDAL VENTROLATERAL MEDULLA. H.M. Wilfahrt* and S.F. Morrison. Dept. of Physiology, Northwestern Univ. Med. Sch., Chicago, IL 60611-3008.

Elevated sympathetic nerve activity (SNA) and exaggerated sympathetic responses to posterior hypothalamic (POH) stimulation in the spontaneously hypertensive rat (SHR) suggest that central nervous system dysfunction may contribute to the pathogenesis of hypertension in this model. In the present study, we examined the hypothesis that the activity of vasodepressor neurons in the caudal ventrolateral medulla (CVLM) is diminished in SHR. Prior studies have demonstrated that excitotoxic lesions in CVLM in Sprague Dawley rats increase both SNA and mean arterial pressure (MAP). In urethane-anesthetized SHR and WKY rats (12-16 wks old), we examined the effects of kainic acid lesions in CVLM on spontaneous SNA, resting MAP and the evoked nerve responses to POH stimulation. In all rats, CVLM lesions produced significant increases in both SNA and MAP. Peak post-lesion MAP was no longer significantly different between strains (140 mmHg SHR vs. 129 mmHg WKY). However, the increase in total power (RMS) in SNA after the lesions was significantly smaller in SHRs (111%cnt) than in WKYs (302%cnt; $P < 0.01$). In both strains, post-lesion evoked responses to POH stimulation were greater than control, although this enhancement of evoked sympathetic responses was smaller in SHRs than in WKYs. We conclude that CVLM neurons may be less active in SHRs, resulting in diminished sympathoinhibition that could contribute to the pathophysiology of hypertension in the SHR. Supported by NIH HL47196.

DIFFERENT POOLS OF BRAINSTEM NEURONS GENERATE THE 10-HZ RHYTHM AND LOW FREQUENCY COMPONENTS IN SYMPATHETIC NERVE DISCHARGE (SND). S.M. Barman*, H.S. Oler, and G.L. Gebber. Dept. Pharmacol. & Toxicol., Michigan State Univ., East Lansing, MI 48824.

A 10-Hz rhythm is ubiquitous to the discharges of sympathetic nerves with different targets in urethane-anesthetized or decerebrate cats. This rhythm can coexist with a low frequency component (a cardiac-related rhythm in cats with intact baroreceptor nerves or an irregular 2- to 6-Hz oscillation after baroreceptor denervation). Spike-triggered averaging was used to study the relationship between the discharges of individual medullary neurons and SND. Data from these studies support the hypothesis that the generators of the 10-Hz rhythm and low frequency components in SND are comprised of separate pools of brainstem neurons. First, in baroreceptor-denervated cats, caudal ventrolateral medullary (CVLM) neurons with activity correlated to the 10-Hz rhythm did not have activity correlated to the irregular 2- to 6-Hz oscillations. Second, in baroreceptor-innervated cats, CVLM neurons with activity correlated to the 10-Hz rhythm did not have discharges correlated 1:1 to the cardiac-related rhythm when both rhythms were prominent in the autospectra of SND. Third, for CVLM neurons with activity correlated to the 10-Hz rhythm, the relationship between their discharges and SND was eliminated when the predominant pattern in SND was changed to a cardiac-related rhythm by raising arterial pressure. Fourth, lateral tegmental field neurons had activity correlated to the low frequency components but not to the 10-Hz rhythm in SND. Some rostral ventrolateral medullary and raphe neurons had activity correlated to both the 10-Hz rhythm and low frequency components in SND. Thus neurons in these regions receive convergent inputs from the two generators. (Supported by NIH grants HL-33266 and HL-13187.)

MATURATIONAL CHANGES IN COHERENCES OF EFFERENT SYMPATHETIC (SYMP) ACTIVITY. P.M. Gootman*, B.W. Hundley, A.L. Sica. Dept. of Physiology, SUNY-Hlth. Sci. Ctr., Brooklyn, NY 11203.

Simultaneous recordings of cervical SYMP, splanchnic and phrenic (PHR) activity along with aortic pressure, EKG and end-tidal CO_2 were obtained in Saffan-anesthetized, paralyzed and artificially ventilated (100 % O_2) 1-40 days old swine. Power spectra and coherence estimates between SYMP nerves and between SYMP and PHR discharge were obtained by a FFT routine. PHR discharge defined the inspiratory (I) and expiratory (E) epochs used for gating spectral estimates. Coherence between SYMP nerves was significant at birth in the 3-5 Hz range; the value of coherence was not age-related. In the 8-12 Hz range, coherence revealed age-related maturation attaining significance circa 2 wks. At about 16 days, higher frequencies (> 12 Hz) were present in the preganglionic SYMP power spectra. Coherence estimates of these higher frequencies were significant until about 4 wks. In both power spectra and coherence estimates, these higher frequencies disappeared after 4 wks of age. Coherence between PHR and SYMP was not significant until circa 3 wks. By 1 mo, SYMP activity resembled that observed in adult mammals (Gootman & Cohen, *Acta Physiol. Polon.* 1973, 24:97). The results suggest that there is a period of reorganization within SYMP rhythm generating circuits. (Supported by NIH grants HD-28931 and HL-20864.)

BRAIN STEM ROSTRAL DEPRESSOR AREA UNIT ACTIVITY IS CORRELATED TO THE 2- TO 6-HZ RHYTHM OF THE SYMPATHETIC NERVE DISCHARGE IN CAT. C. W. Dempsey*, D. E. Richardson, C. J. Fontana, and C. R. Burkeens. Lab. of Neurosurgery, Tulane University School of Medicine, New Orleans, LA 70112.

We have previously shown by chemical microinjection methods (Brain Research, 548:279-286, 1991) that the rostral depressor area (RDA) of the brain stem in cat contains sympathoinhibitory neurons involved in cardiovascular regulation. We now report in pentobarbital anesthetized cats a study of 55 cells in the RDA whose spontaneous activities, detected extracellularly with a metal micro-electrode, were found to be correlated with the tonically active 2- to 6-Hz sympathetic discharge of the inferior cardiac nerve. The method employed was that developed by Barman & Gebber (Progress in Brain Research, 81:117-129, 1989), in which the RDA unitary action potentials serve as triggers for averaging 1 sec segments of the sympathetic discharge envelope wave. The activities of 17 cells yielded sympathetic slow wave averages of 2- to 3-Hz (synchronized with the heart rate), while the activities of 38 cells failed to correlate with the sympathetic discharge. Baroreceptor reflex activity (induced with IV phenylephrine or balloon-inflation in the aorta) revealed that, of these 17 cells, 8 were sympathoexcitatory, 5 were sympathoinhibitory, and 4 were cardiac-unrelated. This indicates that the RDA is a heterogeneous population of cells, with cardiac-related sympathoinhibitory neuronal activity not as predominate as our previous methods suggested.

484.19

MEDULLARY NEURONS HAVING FAST SYMPATHETIC-RELATED RHYTHMS SHOW A HIGH INCIDENCE OF RESPIRATORY MODULATION. Q. P. Yu, M. I. Cohen*, W.-X. Huang. Dept. of Physiol., Albert Einstein Col. Med., Bronx NY 10461.

Sympathetic nerve discharges have both fast sympathetic-specific rhythms (2-6 Hz and 10 Hz) and respiratory rhythm. In 18 midcollicular decerebrate, paralyzed cats, we recorded phrenic and cervical sympathetic (CS) nerve discharges together with discharges of neurons in ventral medullary regions that may contain vasomotor-related systems (rostral and caudal ventrolateral medulla, lateral tegmental field, and raphe). Correlations between fast rhythms in unit and CS discharges were ascertained by coherence analyses, and respiratory rhythms in these discharges were identified by cycle triggered histograms. Of 208 recorded units, 26 had distinct and significant unit-CS coherence peaks (range 2.1-17.8 Hz). Of these, 12 had peak coherence values > 0.1 (range 0.11-0.71, mean 0.28±0.23SD). The other 14 units had peak coherence values < 0.1 (range 0.05-0.09, mean 0.07±0.01SD). Most of the neurons (21/26) had a respiratory modulated rhythm (usually tonic I or E modulated) as determined by the eta-square test (Orem & Dick, *J. Neurophysiol.* 50:1098-1107, 1983). These results suggest that the combination of fast and slow (respiratory) rhythms seen in CS discharges originates in the medulla. (Supported by N.I.H. Grant HL-27300.)

DETECTION OF LOW FREQUENCY RHYTHM IN THE DISCHARGE OF CARDIOVASCULAR MEDULLARY NEURONS IN CATS. N. Montano, S.M. Barman, A. Porta, L. Imeri*, T. Gnechchi-Ruscone, A. Malliani, G.L. Gebber. Medicina Int. II, Osp. L.Sacco & Fisio. Umana II, University of Milan, Italy; Dept. Pharmacol. & Toxicol., Michigan State University, East Lansing, MI.

Spectral analysis of heart rate (HR) and arterial pressure (AP) variabilities in man as well as in experimental animals displays two major components: a low frequency (LF; 0.04-0.15Hz) and a high frequency respiratory related (HF; 0.25 Hz) rhythm. HF is considered a marker of vagal modulation while LF is mainly a marker of sympathetic modulation. In a previous study (Montano et al, JANS, 40:21-32, 1992) spectral analysis of cardiac sympathetic efferent discharge, in the range between 0 and 0.5 Hz, showed a predominant LF oscillation, highly correlated with the LF detectable in HR and AP. This study was undertaken to evaluate whether LF rhythmicity could also be present in the variability of discharge of single medullary neurons involved in cardiovascular regulation. We analyzed, by means of autoregressive spectral analysis algorithms, AP and impulse activity of single units recorded from lateral tegmental field, medullary raphe and rostral ventrolateral medulla in decerebrate and in urethane anesthetized, baroreceptor-denervated cats. The activity of medullary neurons was correlated to higher frequency components (2- to 6-Hz or 10 Hz) in sympathetic nerve discharge. Power spectra of single neurons discharge displayed an LF oscillation, highly coherent (between 0.6 and 0.8) with the LF detectable in systolic AP. In conclusion we described for the first time that the impulse activity of single medullary neurons contains an LF rhythmicity similar to that detectable in spectral analysis of the cardiovascular variables, thus raising the possibility of an involvement of these nuclei in generating this oscillation.

RHYTHMIC DISCHARGES IN THE SYMPATHETIC SUPPLY TO THE CAUDAL VENTRAL ARTERY OF THE ANAESTHETIZED RAT. C.D. Johnson, H.A. Futuro-Neto and M.P. Gilbey*. Dept. Physiology, Royal Free Hospital School of Medicine, London NW3 2PF UK.

Recently we reported our observations regarding the rhythmic discharges of sympathetic postganglionic unit activity recorded from the caudal ventral artery of the rat tail using an extracellular focal recording technique (Johnson and Gilbey, *J. Physiol.* 476, 437-442, 1994). Units fired bursts of action potentials during normocapnia which were shown by autocorrelation analysis to have a frequency coincident with the phrenic rhythmic discharge. In the present series of experiments we examined the effects of hypocapnia and hypercapnia on this burst rhythm in chloralose anaesthetized, paralysed, vagotomized and artificially ventilated rats. Autocorrelation analysis revealed that a rhythmic discharge remained during hypocapnia when there was an absence of a regular phrenic discharge. The burst frequencies were in the range 1-1.5 Hz and were similar but different to those seen during normocapnia and hypercapnia. When the respiratory rate approached that of the burst frequency seen during phrenic silence burst frequency appeared to lock onto the phrenic rhythm. Bursts of action potentials occurred on variable levels of tonic discharge. Consequently, it appears that the generation of burst frequencies around 1 Hz may involve factors other than central respiratory drive. We hypothesize that the rhythmic burst activity seen during phrenic silence is generated by the postganglionic neurones in response to tonic drives and that phasic inputs in a similar frequency range are transmitted faithfully across the ganglion.

MEDIUM-SIZED RETINAL GANGLION CELLS PROJECTING TO THE GROUND SQUIRREL SUPERIOR COLLICULUS. N. Rivera, R.E. Blanco and N. Lugo*. Inst. of Neurobiology and Dept. of Anatomy, U.P.R., R.C.M., San Juan, P.R. 00901.

In the thirteen-lined ground squirrel (*Spermophilus tridecemlineatus*), retinal ganglion cells have been classified into 3 groups on the basis of their soma cell diameter: large (>14 µm), medium (10-14 µm) and small cells (6-10 µm; Flores, 1983). Of these, mostly small and medium-sized cells project to the superior colliculus (SC) and mostly large cells project to the dorsal lateral geniculate nucleus (Lugo-Garcia and Kicliter, 1988). In order to characterize further the ganglion cells projecting to the SC, a retrograde tracer, cholera toxin subunit B (CTB), was injected into the superficial layers of the SC. After a survival period of 5-7 days, the animal was perfused, the retina dissected and the CTB immunohistochemically detected with a goat anti-CTB antiserum (List Biologicals; 1:2,500). Labeled cells were drawn and measured with Neurolucida and ZIDAS image analysis systems. Our results confirm that retinal ganglion cells projecting to the SC are medium and small-sized. Most medium-sized cells had diameters of 10-11 µm. Their dendritic trees were extensively labeled. They differed in soma shape, number of primary dendrites, density of branching, symmetry of branching and pattern of dendritic ramification within the inner plexiform layer. This morphological diversity suggests that medium-sized cells are composed of more than one sub-population. (Supported by ONR grant N00014-89-J-3070 & NIMH Grant MH-48190).

DIFFERENTIAL EXPRESSION OF FOS-LIKE IMMUNOREACTIVITY IN BRAINSTEM PROJECTIONS OF RAT SUPERIOR COLLICULUS AFTER ELECTRICAL STIMULATION. S.M. King*, S. Shehab, P. Dean and P. Redgrave. Dept. Psychol., Oxford Uni., Oxford OX1 3UD, UK & Dept. Psychol., Sheffield Exp. Psychol., Sheffield S10 2UR, UK.

It has been proposed, in rodent, that the orienting and approach elicited by collicular stimulation is mediated by the contralateral descending pathway of superior colliculus (SC), and avoidance-type behaviour is mediated by some targets of the ipsilateral descending projections. The c-fos immediate early gene is expressed polysynaptically in neurons in response to a wide range of extracellular stimuli, and hence has been proposed as a technique for mapping functional pathways. The purpose of this study was, therefore, to investigate further the behavioural specificity of the target zones of the two main descending projections from SC by analyzing the brainstem patterns of fos-like immunoreactivity (FLI) after electrically stimulating the tectal efferents which mediate either approach or avoidance-type behaviours.

The main results of this experiment were: (i) animals in which the stimulation elicited defensive behaviour had significantly higher levels of immunostaining in specific terminal areas of the ipsilateral descending projections, for example, the ventrolateral midbrain/pontine reticular formation, the cuneiform area and rostral periaqueductal grey; (ii) there was no FLI expression in any of the terminal areas of the crossed descending projection, even in animals where the electrical stimulation elicited approach. Control studies showed that the lack of expression in the crossed descending pathway was not due to the restricted range of stimulation parameters used in the main study, or to the effects of anaesthetic. In conclusion, this experiment was able to identify likely substrates for the mediation of defensive reactions elicited by electrical stimulation of the colliculus. However, given the total lack of expression in targets of the contralateral pathway, which are known to have been activated, it also provides further evidence that c-fos cannot simply be used as a high resolution neuronal activity marker for mapping functional pathways. Supported by a Royal Society Fellowship (SK) and an SERC Research Studentship (SK).

NON-SPECIFIC EFFECTS OF ANGIOTENSIN II AND ITS AGONISTS AND ANTAGONISTS IN THE SUPERFICIAL LAYERS OF THE RAT SUPERIOR COLLICULUS. L. Merabet^{1,2*}, H. McLelland³, C. Casanova^{1,2}. Depts. of Ophthalmology¹, Physiology and Biophysics², Neurosurgery³, Faculty of Medicine, University of Sherbrooke, Sherbrooke, Quebec, Canada.

We have reported in a previous study (Merabet et al., ARVO, 1994) that activation of angiotensin II (AngII) receptors in the superficial layers of the rat superior colliculus (SC) have a profound suppressive effect on visual evoked potentials (VEP). Some of our initial observations have suggested that the "early" and "late" components of the VEP complex (likely corresponding to the "on" and "off" responses respectively) were differentially affected by the peptide. In the attempt to further characterize these effects, we investigated the impact of various concentrations of AngII and its specific receptor ligands (DUP 753, CGP 42112A). We also studied the effects of AngII on separate "on" and "off" evoked potentials. Experiments were carried out on anesthetized adult rats (13-15 weeks). A recording-injecting microelectrode filled with the peptide or selective ligand was lowered into the superficial layers of the SC to record VEP. Visual stimulation was provided by either a diffuse flash or a small flashing spot (duration of 500ms) placed in the corresponding receptive field to evoke "on" and "off" responses. The substance was injected at various concentrations (10^{-10} M to 10^{-6} M). Inhibitory effects of AngII were observed at concentrations greater than 10^{-8} M and were shown to be concentration dependent. Injection of the AT₁ agonist CGP 42112A showed differential effects depending on its concentration. At lower concentrations (10^{-10} M), there were no significant changes in the amplitude of the evoked potentials. However at 10^{-8} M, a concentration known to activate AT₁ receptors preferentially, there was a reduction in the amplitude of the potential (~35%) similar to that observed with AngII. Injection of the AT₂ antagonist DUP 753 together with AngII yielded no significant changes in the amplitude of the response. Finally, contrary to our original observation, AngII equally reduced the amplitude of both the "on" and the "off" potentials suggesting a non-specific effect for the peptide. These results contribute to earlier findings that AngII has a suppressive effect on the superficial collicular layers in the adult rat. These responses appear to be mediated by the sole activation of AT₁ receptors and tend to be nonspecific. Supported by MRC of Canada and CIBA-GEIGY Ltd.

EFFECTS OF ADRENERGIC AGENTS ON NEURONAL RESPONSES IN THE HAMSTER'S SUPERIOR COLLICULUS. Y. Zhang, R.W. Rhoades, and R.D. Mooney. Dept. of Anatomy, Medical College of Ohio, Toledo, OH 43699.

Radioligand binding experiments have demonstrated the presence of multiple adrenergic receptor subtypes in the hamster's superior colliculus (SC) and the present experiments were undertaken to assess the pharmacology of noradrenergic effects on the visual, optic chiasm (OX)-, and visual cortex (VCTX)-evoked responses of SC neurons. Of 40 neurons tested visually, 90% were suppressed by NE to $39.2 \pm 28.4\%$ of control responses and 10% were excited. Similar results were obtained during OX-stimulation (N=28 cells). Both isoproterenol (N=52 cells) and para-aminoclonidine (N=24 cells) had effects on SC cells similar to those of NE. Dobutamine (N=36 cells) had slightly weaker effects, while methoxamine suppressed 4 cells and excited 8. The effects of NE were strongly antagonized by α_2 antagonists and β -adrenergic antagonists (β_1 or β_2) generally reduced NE-evoked effects by about 50%; β_2 antagonists were ineffective in nearly all cells. The α_1 antagonist prazosin completely blocked NE-evoked excitation, but did not reduce the suppressive effects of this amine. Thus, the suppressive effects of NE upon SC responses appear to be mediated primarily by α_2 and β_1 receptors while excitation involves α_1 receptors. No noradrenergic receptor subtype was specifically associated with either the retinotectal or corticotectal pathway and experiments carried out to date have not allowed us to determine whether any of the effects of NE are exclusively pre- or postsynaptic.

ADRENERGIC MODULATION OF RETINOTECTAL INPUT TO THE HAMSTER'S SUPERIOR COLLICULUS IN VITRO. H. Tan, R.D. Mooney and R.W. Rhoades. Dept. of Anatomy, Medical College of Ohio, Toledo, OH 43699.

Previous work from our laboratory suggested that multiple adrenergic receptor subtypes may be present in the superficial layers of the hamster's superior colliculus (SC), and that substantial numbers of α_2 and β_2 receptors may be located presynaptically on retinotectal and/or corticotectal axon terminals. The functions of these receptors were tested by intracellular or whole-cell recording in a perfused SC slice that included most of the optic tract (OT) to permit stimulation of retinotectal fibers. Addition of norepinephrine (NE) to the bath or application by micropressure hyperpolarized 55.5% and depolarized 13.5% of 207 SC neurons tested; the remaining 31% showed no change >1 mV. On average the membrane potential hyperpolarized from -70.7 ± 16.5 mV to -74.3 ± 9.6 mV. When voltage clamped at their resting potentials, hyperpolarized neurons had net outward currents of 18 to 50 pA and depolarized cells had inward currents of 26 to 38 pA. The OT-evoked EPSP was reduced from 10.8 ± 3.7 mV to 6.7 ± 3.7 mV by NE, but the decrease was not correlated with any change in membrane potential. To date, tests with more selective ligands have shown that para-aminoclonidine (α_2), dobutamine (β_1), and isoproterenol (β_1 and β_2) have effects on SC cells similar to those of NE. In contrast, neither phenylephrine nor methoxamine (α_1) produced significant effects on the membrane potentials of SC neurons.

NMDA receptors and cortical influences on visual responses in cat superior colliculus (SC). K.E. Binns & T.E. Salt. Dept Visual Science, Inst. Ophthalmology, Bath St. London. EC1V 9EL. UK.

Neurons in the superficial grey layer (SGS) of the SC are innervated by the retina and visual cortex. SGS has 3 sublayers SGS_{1,2,3}. Retinal inputs dominate in SGS₁ & SGS₂, while in SGS₃ (120-500µm from the surface) cortical inputs are prevalent. The NMDA antagonist AP5 reduces visual responses in 60% of SGS neurones indicating that NMDA receptors participate in these responses¹. Many of these cells are in SGS₃. To test whether the contribution of NMDA receptors to visual responses is derived from cortical input to SGS, multibarreled pipettes were used for single-unit extracellular recording and iontophoresis of NMDA, AMPA and AP5 in cats anaesthetized with halothane/N₂O/O₂ and paralysed with gallamine.

The effects of NMDA receptor selective applications of AP5 on visual responses were studied before and during inactivation of the visual cortex with topical lignocaine. In 8 neurones where AP5 reduced the response to visual stimulation, the visual response was resistant to the effects of AP5 following cortical inactivation. Since the cortex is considered to influence the directional bias of SGS neurones, the effects of AP5 (n=17) and cortical inactivation (n=10) on directional responses were compared. Neither procedure altered the directional bias of SGS neurones.

These data imply that, considerable NMDA receptor mediated input to SGS is from the cortex. However, the cortex may not influence the directional bias of SGS neurones.

GAMMA-AMINOBUTYRIC ACID (GABA) IS EXPRESSED EARLY IN PRENATAL DEVELOPMENT IN THE CAT SUPERIOR COLLICULUS. J.P. Hewitt*, M.T. Simon, F.T. Banfro, and R.R. Mize. Dept. of Anatomy and Neuroscience Ctr., Louisiana State Univ. Med. Ctr., New Orleans, LA 70112

GABA is expressed precociously in some neurons during CNS development. GABA cells are found throughout the superior colliculus (SC) in the adult cat, but the time of expression of GABA in this structure is not known. We therefore studied the expression of GABA in kittens ranging in age from embryonic day 24 to postnatal day 60 using antibody immunocytochemistry. Labeled cell position and density were determined using a neuron tracing system. At E24, GABA-immunoreactive (ir) cells were scattered throughout the tectal plate as well as within the subventricular zone. By E28-30, GABA-ir cells and neuropil were more densely concentrated within the superficial layers of SC than deeper. Some cells in the deeper layers had bipolar morphologies with vertically oriented dendrites, reminiscent of cells in the process of migration. The number of GABA-ir cells increased roughly eight fold from E30-E46, and the adult pattern of cell distribution was clearly established during this prenatal period. There was a two-fold decrease in GABA-ir cell number between E46 and P60. Cells also increased in maturity during this period. Based upon labeling of adjacent sections with antibodies to vimentin and glial fibrillary acidic protein (GFAP), we believe that most of the GABA labeling is in neurons and not glia throughout this developmental period. In summary, GABA is expressed very early in prenatal development in the cat SC, corresponding to the early expression of the calcium binding protein calbindin in this structure. GABA is expressed in some cells before they migrate into SC and clearly precedes the formation of the adult pattern of GABA neurons. The decrease in number of GABA-ir cells may be due to loss of expression of the neurotransmitter or to cell death. Supported by NIH EY02973.

PARVALBUMIN AND CALBINDIN HAVE DIFFERENT DEVELOPMENTAL HISTORIES IN THE PRE- AND POSTNATAL CAT SUPERIOR COLLICULUS. R.R. Mize* and F.T. Banfro. Dept. of Anatomy and Neuroscience Ctr., Louisiana State Univ. Med. Ctr., New Orleans, LA 70112

Parvalbumin (PV) immunoreactive neurons in the cat superior colliculus (SC) are projection neurons that form a dense sublaminal tier in the deep superficial gray and upper optic layers. Calbindin (CB) neurons are mostly interneurons that form three sublaminal tiers, with the PV tier lying between the two upper CB tiers. We have examined kittens aged E24 to P60 to determine when these tiers develop. Sections were immunocytochemically treated with monoclonal antibodies directed against PV and CB. Labeled cell depth and number were measured from computer plots of the labeled cell distributions. PV labeled cells were first observed at E59 and were located mostly within the periaqueductal gray. A few scattered PV labeled neurons were found in the optic, intermediate, and deep gray layers by P1. By P7, the dense sublaminal tier was visible and many PV cells had mature morphologies. Dense neuropil labeling was found in the tier by P14-21. The adult pattern of labeling was complete by P35. PV neurons increased continuously in number from P1-P35. By contrast, CB was first expressed at E24. Between E28-40, CB cells migrated from the subventricular zone into the tectal plate. Sublaminal tiers were first visible at E40 and were well-established by E46-48. Cell morphology matured from E46-E59. CB cell number increased from E28-E59, then decreased three-fold by P60. In summary, PV is expressed late in development, after cells have migrated. CB is expressed early, before cells have migrated and matured. Thus, CB may play a role in afferent-target interactions while PV is more likely involved in the final stages of synaptogenesis. Supported by NIH EY02973.

CALCIUM BINDING PROTEIN CALBINDIN D-28K IN THE PRETECTUM AND ACCESSORY OPTIC SYSTEM OF THE RABBIT. B. Nunes Cardozo¹, J.J.L. van der Want¹, G. Butler² and R.R. Mize² SPON: European Neuroscience Association* ¹Dept. of Morphology, The Netherlands Ophthalmic Res. Inst., 1100AC Amsterdam and ²Dept. of Anatomy and Neuroscience Ctr., Louisiana State University Med. Ctr., New Orleans, LA 70112.

The calcium binding protein calbindin-D 28K (CB) is a highly selective marker of specific cell types in the CNS. In the cat pretectum (PT), CB cells form four cell clusters, two of which lie partially within the nucleus of the optic tract (NOT). CB cells are mostly large projection neurons that precisely overlap the retinal input to PT and cross nuclear borders. In this study, we determined whether these same cell clusters are present in the rabbit, a lateral-eyed species with a well developed PT. Sections through the NOT and accessory optic system (AOS) nuclei of three rabbits were incubated with an antibody directed against CB and visualized using silver-gold enhanced DAB. A few neurons in the rostral NOT were CB positive, while the caudal NOT was devoid of CB neurons. Unlike the cat, separate dense clusters of neurons were not observed in the PT of rabbit. However, clusters of CB neurons were observed in the caudal portion of the dorsal terminal nucleus (DTN) and in the transition zone of the DTN and interstitial nucleus of the superior fasciculus posterior fibers (inSFP). However, the medial terminal nucleus (MTN) was completely free of CB neurons. In contrast to cat, the clusters of CB neurons in the AOS fell within the established borders of these nuclei. In addition, there was no precise overlap between CB cells and retinal afferents in the rabbit PT and AOS. CB appears to label different cell classes in the two species. Supported by NIH EY02973.

CROSS-MODAL INHIBITION IN MULTISENSORY NEURONS IS BASED ON UNIMODAL RECEPTIVE FIELD ORGANIZATION. D.C. Kadunc¹, M.T. Wallace¹, G. Benedek¹ and B.E. Stein¹. Dept. Neurobiology & Anatomy, Bowman Gray School of Medicine/Wake Forest University, Winston-Salem, NC 27157

A fundamental principle of multisensory integration is that spatially coincident stimuli from different modalities enhance one another's effectiveness, whereas spatially disparate stimuli may depress one another's effectiveness. The present experiments in cat superior colliculus (SC) were designed to examine the basis for this cross-modal inhibition, and to determine whether the excitatory-inhibitory organization of multisensory RFs is significantly different from that of unimodal RFs. A total of 114 (55 unimodal; 59 multisensory) neurons were examined. Surprisingly, each multisensory RF was organized in fundamentally the same manner as its unimodal counterpart. However, the incidence of inhibitory border regions differed among modalities. The majority (81%) of auditory RFs had inhibitory regions, but far fewer visual (22%) and somatosensory (15%) RFs did. In many multisensory neurons RF inhibitory borders were not modality-specific (e.g. auditory stimuli would suppress visual excitation); in others, inhibitory regions were modality-specific and this was most common for visual inputs (e.g. visual inhibits only visual). These data indicate that while cross-modal inhibition in SC is due to the presence of nonspecific inhibitory regions, inhibitory regions themselves do not guarantee such effects. In these cases the inhibitory effect is on the input rather than on the target multisensory SC neuron. Supported by NIH grant NS22543.

SIMULTANEOUS RECORDINGS OF MULTI-SINGLE NEURONAL ENSEMBLES IN THE SUBCORTICAL VISUAL SYSTEM REVEAL PROPAGATION OF OSCILLATORY WAVES. Rowshanak Hashemiyoon^{*} and John K. Chapin, Department of Physiology & Biophysics, Hahnemann University, Philadelphia, PA

We have previously reported that dark-spontaneous oscillations (10-40Hz) are ubiquitous in the subcortical rat visual system. These oscillations are broadcast from the retina to synchronize unit activity across multiple visual pathways. These were initially investigated through the simultaneous recording of multiple single units in the visual midbrain, thalamus and optic tract. To further investigate the spatiotemporal structure of these oscillations, electrode arrays consisting of 16-microwire electrodes (1.8 x 0.5 mm) were chronically implanted across the stratum griseum superficiale (SGS) of the superior colliculus. Under anesthetized and awake conditions dark-spontaneous synchronous oscillatory discharges recorded from these electrodes exhibited variable phase angles of up to 15ms, indicating propagation of activity waves across the SGS. A small (14°) flashing light (1s ON, 1s OFF) in the contralateral visual field suppressed the oscillatory activity of the SGS neurons during LIGHT-ON. LIGHT-OFF produced a phase resetting oscillatory rebound, with response latencies varying by up to 15ms, suggesting propagation of waves away from the LIGHT-OFF point. Other studies investigated the effects of patterned vs. non-patterned stimuli. Whereas non-patterned flashing circles of light produced simple LIGHT-ON suppression, addition of a dark bar to the middle of the circle produced a more complex response, consisting of an additional oscillatory peak during the LIGHT-ON period. In conclusion, the propagating spatiotemporal pattern of these oscillations may not only integrate sensory processing across the subcortical visual system, but might also carry a distributed code for visual sensory information. POSTNATAL DEVELOPMENT OF EXCITATORY SYNAPTIC FUNCTION IN DEEP LAYERS OF SUPERIOR COLLICULUS

C.-Q. Kao¹, B.E. Stein², and D.A. Coulter¹ Department of Neurology¹ Medical College of Virginia, Richmond, Va 23298, Department of Neurobiology and Anatomy², Bowman Gray School of Medicine Winston-Salem, NC 27157

Despite the rapid maturation of neurons in superficial layers of the cat superior colliculus (SC), those in deep layers are not visually-responsive for several postnatal weeks. The present study sought to determine the ontogeny of synaptic responses in deep layer neurons using whole cell patch recordings in coronal slices. Excitatory synaptic responses were recorded in response to local electrical stimuli, and the sensitivity of postsynaptic currents/potentials (EPSC/PS) to the NMDA antagonist APV was studied at different developmental stages. Thirty percent of 1-8 DPN neurons exhibited stimulation-evoked EPSCs, compared to 73% of 31-34 DPN neurons. Not only did the proportions of activated neurons increase during maturation, but the nature of the EPSCs changed as well. APV-sensitive components of the EPSCs did not appear until 9 DPN, and their incidence gradually increased until 33 DPN when 88% of the neurons recorded were APV-sensitive. Thus, excitatory synaptic function shows a protracted postnatal development in deep SC and may contribute both to the delay in the maturation of visual responsiveness (Kao et al., 1994), and the delay in the ability to integrate information from different sensory modalities (see Wallace et al., 1993).

SENSORY REPRESENTATIONS AND THE INTEGRATION OF MULTIPLE SENSORY CUES IN MONKEY SUPERIOR COLLICULUS. M.T. Wallace¹, L.K. Wilkinson² and B.E. Stein¹. Dept. Neurobiology & Anatomy¹, Bowman Gray School of Medicine/Wake Forest University, Winston-Salem, NC 27157 and Department of Psychology², Virginia Commonwealth University, Richmond, VA 23298

A set of principles governing the neural integration of stimuli from the different senses have been found in cat superior colliculus (SC). We sought to determine the applicability of these principles to the rhesus monkey. Single unit extracellular recordings were conducted in the deep SC of anesthetized monkeys. Of the sensory responsive neurons, 73% were unimodal and 27% were multisensory. Our first question concerned the intermodal register between the visual, auditory and somatosensory representations. The second concerned the nature of the integration exhibited by multisensory SC neurons. The data suggest that, as in the cat, each modality has a well defined representation, and that these representations are in good register with one another (e.g., the rostral body surface is represented in the same areas as nasal visual space). Exceptionally good register was noted among the different receptive fields of individual multisensory neurons, and, as in the cat, dramatic response enhancements were evoked by stimuli that were spatially coincident, and response depressions were evoked by stimuli that were spatially disparate. These data are consistent with the hypothesis that many of the principles of sensory representation and multisensory integration in the SC are operative in widely divergent species, and are adaptive to a wide variety of ecological niches. GABA_A MEDIATED DISINHIBITION OF THE SUPERIOR COLLICULUS RESTORES VISUAL ORIENTING RESPONSES IN THE PREVIOUSLY HEMIANOPIC VISUAL FIELD OF THE CORTICALLY BLIND CAT

V. Ciaramitaro^{*}, J.S. Durmer, W.E. Todd & A.C. Rosenquist Dept. of Neuroscience, Univ. of Penn, Phila., PA 19104

Following unilateral removal of all known visual cortical areas, a cat is rendered hemianopic in the contralateral visual field as measured by visual perimetry and other behavioral tests. It has been shown that visual orientation behavior can be restored to the previously blind hemifield by transection of the commissure between the two colliculi, or by destruction of the contralateral substantia nigra. (Sprague, J.M., *Science* 153:1544-1547, 1966; Wallace, S. F. et al., *J. Comp. Neurol.* 296:222-252, 1990) It was hypothesized that the mechanism mediating recovery is disinhibition of the SC ipsilateral to a cortical lesion.

We directly tested this hypothesis by reversibly disinhibiting the SC ipsilateral to a cortical lesion with bicuculline, a GABA_A antagonist. In accordance with the model, disinhibition of the SC ipsilateral to the cortical lesion restored visual orienting responses in the hemianopic visual field for a period of several hours. Control injections of saline had no effect on visual orienting behavior. Conversely, inhibition of the SC with muscimol, a GABA_A agonist in a normal animal renders the animal unable to detect and orient to visual stimuli in the hemifield contralateral to the SC.

485.15

RECOVERY OF VISUAL ORIENTING IN THE HEMIANOPIC CAT AFTER SMALL SUBSTANTIA NIGRA LESIONS IS NOT ABOLISHED BY SUBSEQUENT ENLARGEMENT OF THE INITIAL LESION.

A.C. Rosenquist*, V. Ciaramitaro, S.F. Wallace
Dept. of Neuroscience, Univ. of Penn, Phila., PA 19104

Unilateral removal of all known visual cortical areas in the cat renders the animal hemianopic in the contralateral visual field as measured by visual perimetry and other behavioral tests. Visual orientation behavior can be restored in the previously blind hemifield by ibotenic acid destruction of a critical zone in the substantia nigra pars reticulata (SNpr) contralateral to the cortical lesion (Wallace, S.F. et al., *J. Comp. Neurol.* 296:222-252, 1990). Paradoxically large lesions to the SNpr which include but extend beyond this critical zone fail to restore visual orienting behavior.

In an attempt to understand this paradoxical finding, we made unilateral visual cortical lesions followed by ibotenic acid lesions of the contralateral SNpr critical zone in 5 cats. All cats recovered visual orienting behavior in the hemianopic field. In these recovered animals, the original SNpr critical zone lesion was subsequently enlarged with ibotenic acid an average of 5.4 weeks after the initial lesion. None of the 5 animals showed a loss of recovery. This finding argues strongly for the role of plasticity in nigroretinal circuitry and visual orienting behavior. The time between a critical zone lesion and an enlargement of this lesion appears to be sufficient for compensatory mechanisms to maintain recovery.

SUBSTANTIA NIGRA AFFERENTS INNERVATE THE CAT SUPERIOR COLLICULUS DURING THE SECOND HALF OF GESTATION. F. T. Banfro* and R. R. Mize, Dept. of Anatomy and Neuroscience Center, Louisiana State University Medical Center, New Orleans, LA 70112

Most afferents to the cat superior colliculus (SC) are present at birth, including those from the substantia nigra (SN). It is not known when these reach the SC during prenatal development. We have therefore studied the development of innervation of the SC by SN fibers in fetal tissue using the carbocyanine dye Dil. Dil crystals were placed within the SN in blocks of midbrain perfused at ages E40, 46, 51, 55, 57, P1 and P7. The blocks were stored in fixative in an oven at 37°C for 4-5 weeks, then sectioned and examined with an epi-fluorescence microscope. Labeled fibers were traced with a neuron tracing system. No Dil fibers were seen in SC at E40, although they were present in the mesencephalic tegmentum. By E46, Dil fibers were present in the deep layers of the caudal SC, but none were found in the superficial layers. The fibers were thin and had few varicosities. Putative growth cones were seen on some of the labeled fibers. Few fibers were found in the rostral SC. The labeled fibers were confined primarily to the ipsilateral side. By E51, the number of labeled fibers in the SC had increased. By E55, numerous labeled fibers were found in the intermediate gray layer (IGL) of the caudal SC. The fibers at this age were thicker and some had numerous varicosities. Fiber density increased at E57 and P1, but no fibers were found above the IGL even at P1. Thus, a sharp border between the superficial and deep layers is maintained at this age. No obvious fiber patches were observed at any age. The patch-like organization of SN fibers seen in the adult must therefore develop postnatally. SN fibers reach the SC about two weeks after retinal afferents have innervated SC and after SC lamination is complete. Supported by NIH EY-02973.

IBOTENIC ACID LESIONS OF THE PEDUNCULOPONTINE NUCLEUS RESTORE VISUAL ORIENTING RESPONSES IN THE PREVIOUSLY HEMIANOPIC VISUAL FIELD OF THE CORTICALLY BLIND CAT

J.S. Durmer*, V. Ciaramitaro, W.E. Todd & A.C. Rosenquist
Dept. of Neuroscience, Univ. of Penn, Phila., PA 19104

The unilateral removal of all known visual cortical areas in a cat results in an enduring hemianopia as measured by visual perimetry and other behavioral tests. By transecting the commissure of the superior colliculus (CSC) or destroying a critical zone of the contralateral substantia nigra pars reticulata (SNpr), visual orientation behavior returns in the previously hemianopic field (Sprague, JM, *Science* 153:1544-1547, 1966; Wallace, SF et al., *J. Comp. Neurol.* 296:222-252, 1990). Disinhibition by disruption of contralateral SNpr or its projections to the superior colliculus (SC) has been proposed as the mechanism for this recovery. However, large lesions of the SNpr which include but extend beyond the critical zone do not result in recovery, but transection of the CSC in these animals does. Thus, it is clear that other projections through the CSC mediate this effect. Retrograde transport studies indicate that fibers crossing in the CSC arise from the SNpr and the pedunculopontine nucleus (PPN) (Edley, S et al., *J. Comp. Neurol.* 217:187-215, 1983; Hall, W et al., *J. Comp. Neurol.* 287:495-514, 1989).

We tested the hypothesis that projections originating from the contralateral PPN mediate the recovery of visual orienting behavior by destroying this nucleus with ibotenic acid in cortically blind cats. Results indicate that recovery of the visual orienting response is mediated by the PPN. (Supported by EY02654 and 5-T32-MH-18902)

EVIDENCE THAT AREA 17 CORTICAL SYNAPSES IN THE CAT SUPERIOR COLLICULUS ARE GLUTAMATERGIC. G. D. Butler, R. H. Whitworth* and R. R. Mize, Dept. of Anatomy and the Neuroscience Center, Louisiana State Univ. Med. Ctr., New Orleans, LA 70112.

We have previously shown that antibodies to the excitatory amino acid neurotransmitter, glutamate, label at least two types of synaptic terminals in the cat superior colliculus (SC). One type contains large round synaptic vesicles and pale mitochondria and is of retinal origin (RT). The second type contains smaller round vesicles and dark mitochondria (RSD). The origin of the latter type is unknown. To determine if RSDs arise from visual cortex, we made unilateral aspiration lesions of area 17 in three cats and waited 5, 14, and 28 days before sacrifice. We then examined the distribution of glutamate in the SC of these cats using electron microscopic post-embedding immunocytochemistry and colloidal gold-conjugated antibodies. On the side contralateral to the lesion, both RT and RSD axon terminals were labeled by anti-glutamate, as in the normal SC. Some conventional dendrites and myelinated axons were also labeled. On the side ipsilateral to the lesion, morphologically normal RSD terminals were infrequently observed. However, synaptic terminals in the initial stages of electron dense degeneration that had a dark ground and irregularly shaped swollen vesicles were labeled by anti-glutamate. Axon terminals and myelinated axons undergoing neurofilamentous hypertrophic degeneration also were often labeled. By contrast, terminals in advanced stages of degeneration with no synaptic vesicles contained little or no glutamate. These results confirm that both major sets of afferents to the cat SC contain glutamate; RT terminals from the retina and RSD terminals from visual cortex. It is possible, however, that not all terminals from these sources contain glutamate because a few RT and RSD terminals were not labeled by the antibody. Supported by NIH EY-02973.

CANNABINOID AGONISTS ATTENUATE DOPAMINE-MEDIATED ROTATION IN RATS WITH UNILATERAL 6-HYDROXYDOPAMINE LESIONS. L. A. Anderson*, J. J. Anderson, J. R. Walters, and T. N. Chase, ETB, NINDS, NIH, Bethesda, MD, 20892, USA.

The presence of cannabinoid receptor mRNA in striatal neurons and dense cannabinoid receptor binding in substantia nigra pars reticulata, globus pallidus, and striatum, suggests that cannabinoids influence basal ganglia motor function by actions on the striatal output pathways. Contralateral rotation produced by dopamine D1 and D2 receptor stimulation in rats with unilateral nigrostriatal dopamine cell lesions is a behavioral measure of striatal outflow through the striatonigral and striatopallidal pathways. We have evaluated the effect of cannabinoid agonists on this rotation in rats with unilateral 6-hydroxydopamine lesions. Rotation was monitored for 4 hours following administration of the D1 agonist SKF 38393 (1.5 mg/kg s.c.) or the D2 agonist quinpirole (0.1 mg/kg i.p.), in combination with the cannabinoid agonist WIN 55,212-2 (1, 2.5, or 10 mg/kg i.p.; n = 8-11) or vehicle (60% DMSO; n = 19-20). WIN 55,212-2 produced a dose-related attenuation of D1-mediated rotation that was significant at the 2.5 and 10 mg/kg doses, decreasing rotation to 16% of control at 10 mg/kg. WIN 55,212-2 was less potent in attenuating D2-mediated rotation, producing a significant decrease at the 10 mg/kg dose only, to 57% of control. The cannabinoid agonist CP 55,940 (0.1 mg/kg i.p.) decreased both D1 and D2 rotation, although D1 rotation was suppressed to a greater extent (16% of control; n = 6) than D2 rotation (53% of control; n = 7). These results suggest that cannabinoid receptor stimulation influences both D1- and D2-mediated processes, although D1 processes may be affected to a greater degree.

EFFECT OF SUBSTANCE P (NK₁) RECEPTOR BLOCKADE ON CATALEPSY INDUCED BY DOPAMINE ANTAGONISTS. Jeffrey I. Anderson* and Thomas N. Chase, Experimental Therapeutics Branch, NINDS, NIH, Bethesda, MD 20892.

Systemic administration of dopamine D1 or D2 receptor antagonists induces catalepsy, a behavior defined as the long-term maintenance of an abnormal posture. Catalepsy is often considered an animal model of neuroleptic-induced parkinsonism. Substance P, a neuropeptide found in striatonigral neurons, acts preferentially at the NK₁ receptor. Receptor binding studies suggest that the striatum contains a moderate density of NK₁ receptors, while the substantia nigra pars reticulata contains relatively few NK₁ receptors. Hence, striatonigral substance P may act preferentially in the striatum via local axon collaterals of striatonigral neurons. In this study, the ability of NK₁ receptor blockade to influence catalepsy produced by D1 and D2 antagonists was examined. Male Sprague-Dawley rats were injected with the non-peptide NK₁ antagonist CP 99,994 (0.5, 2.5, or 10 mg/kg sc) or saline 15 min after administration of either the D1 antagonist SCH 23390 (0.5 mg/kg sc) or the D2 antagonist raclopride (2.5 mg/kg ip). Catalepsy was evaluated by the vertical grid test every 20 min for 160 min. CP 99,994 (2.5 and 10 mg/kg) decreased the catalepsy produced by raclopride by 46 and 78%, respectively. In contrast, CP 99,994 did not diminish the catalepsy induced by SCH 23390. These findings suggest that blockade of NK₁ receptors reduces catalepsy produced by D2 but not D1 antagonists and indicate that NK₁ receptors may be important in modulating behavioral responses mediated by D2 receptors. In addition, NK₁ antagonists may have therapeutic potential in alleviating motor side effects associated with neuroleptic treatment.

AN INVESTIGATION OF D₁ AND D₂ DOPAMINE AGONIST-INDUCED CHANGES IN THE ACTIVITY OF SUBSTANTIA NIGRA PARS RETICULATA NEURONS FOLLOWING LOCAL INFUSION OF SKF 38393 IN EITHER THE STRIATUM OR SUBSTANTIA NIGRA. M. J. Twery*, D. A. Bergstrom and J. R. Walters. ETB, NINDS, Bethesda, MD 20892.

Concurrent stimulation of D₁ and D₂ receptors by systemically administered dopamine agonists inhibits the activity of substantia nigra pars reticulata (SNpr) neurons in rats with 6-hydroxydopamine (6OHDA)-induced lesions of midbrain dopamine cells. In order to investigate possible sites of action, the D₁ agonist SKF 38393 was locally administered in the striatum (15 pmol-34 nmol) or the substantia nigra (9-17 nmol) of gallamine-paralyzed rats with unilateral 6OHDA lesions (6-9 wk post-lesion) while the activity of individual SNpr neurons was recorded extracellularly. Rats were tested for apomorphine (0.05mg/kg, s.c.)-induced contralateral rotation 1-2 wk prior to study. An infusion of SKF 38393 in the striatum (n=7) or the substantia nigra (n=7) produced no significant changes in the firing rate of SNpr neurons. The D₂ agonist quinpirole (0.3 mg/kg, i.v.) administered 3 or 10 min after the start of a nigral SKF 38393 infusion decreased the firing of SNpr neurons (46±5%, ANOVA, p=0.02, n=6). However, quinpirole administered after striatal infusion of SKF 38393 (n=7) or after nigral infusion of vehicle (n=6) produced no net change in the firing rate of SNpr neurons. These findings suggest that the response to intravenous quinpirole depends on whether D₁ receptors are stimulated by SKF 38393 in either the striatum or the substantia nigra. However, the stimulation of only D₁ receptors by SKF 38393 at either striatal or nigral sites is not sufficient to alter the activity of SNpr neurons. Explanations include the possibility that D₁ receptors at another site or at a combination of sites including the striatum and substantia nigra are required to produce changes in the activity of SNpr neurons.

THE MITOCHONDRIAL TOXIN 3-NITROPROPIONIC ACID INDUCED ORAL MOVEMENTS IN RATS. O.A. Andreassen¹ and H.A. Jørgensen². Depts. of Physiology¹ and Psychiatry², Univ. of Bergen, N-5009 Bergen, Norway.

Tardive dyskinesia (TD) is a serious side effect of long-term neuroleptic treatment. The mechanism of TD development is still unknown. It has been proposed that TD may be a result of neuroleptic-induced excitotoxic neuronal damage in the striatum. To investigate this hypothesis, the effect of 3-nitropropionic acid (3-NP), an inhibitor of energy metabolism which has been shown to induce striatal lesions due to glutamate receptor stimulation (indirect excitotoxicity), was studied in a rat model of TD. Three groups of rats (female Sprague-Dawley rats, n = 14-15 / group) were treated continuously for 1 month with 3 doses of 3-NP (4, 8 and 12 mg/kg/day) administered SC with osmotic minipumps. Empty plastic tubes were implanted SC to control rats. The behavior was videotaped regularly and vacuous chewing movements (VCM), a putative analogue to human TD, as well as the total behavior, were recorded.

3-NP induced a dose-dependent increase in VCM in the period from 2 to 4 weeks after start of treatment. Rats receiving the highest dose of 3-NP had significantly more VCM than controls and the rats receiving the lowest dose were at control level. 3-NP also dose-dependently decreased the general motor activity.

The effect of 3-NP on VCM suggests that striatal glutamate receptor stimulation may underlie the development of VCM in rats and maybe TD in humans.

DOPAMINE RECEPTOR AGONISTS AND FORSKOLIN SIMILARLY POTENTIATE RESPONSES EVOKED BY EXCITATORY AMINO ACID RECEPTOR AGONISTS IN RAT NEOSTRIATAL NEURONS. M. Dav, C. Colwell, N.A. Buchwald*, and M.S. Levine. Mental Retardation Research Center, UCLA School of Medicine, Los Angeles, CA 90024.

Our laboratory has studied the physiological interactions between dopamine (DA) and excitatory amino acids (EAAs) in the neostriatum. We have shown that DA potentiates responses mediated by activation of N-methyl-D-aspartate (NMDA) receptors but attenuates responses mediated by glutamate or activation of non-NMDA receptors. The present experiment was designed to examine the possibility that DA's ability to potentiate responses mediated by activation of NMDA receptors involves alterations in the adenylyl cyclase transduction cascade. Intracellular recordings were made from neostriatal neurons in brain slices using standard techniques. Similar to our previous findings, iontophoretic or bath application of the DA D₁ receptor agonist SKF 38393 potentiated NMDA-evoked responses by increasing the maximum amplitude, half amplitude duration and number of action potentials evoked. SKF 38393 also enhanced glutamate-evoked responses, but to a lesser degree. Receptor antagonists were used to evaluate the specificity of the agonist's actions. Bath application of forskolin, an activator of adenylyl cyclase which increases cAMP, mimicked the effects of D₁ DA receptor activation and enhanced responses evoked by iontophoretic application of NMDA. Forskolin also enhanced responses evoked by glutamate or AMPA. These results are consistent with a model in which DA, acting through activation of D₁ receptors, enhances EAA-evoked responses through a cAMP-dependent mechanism. Supported by USPHS HD 05958.

AP-1 DNA BINDING ACTIVITY IN STRIATUM: DOPAMINERGIC REGULATION. K.-X. Huang* and J.R. Walters. ETB, NINDS, NIH, Bethesda, MD 20892.

Stimulation of dopamine (DA) receptors in the basal ganglia affects expression of c-fos, while interruption of c-fos expression in the striatum with antisense DNA reduces behavioral response to DA agonists^{1,2}. Since Fos and Jun proteins influence cellular function by forming AP-1 which binds to DNA sites regulating gene transcription, effects of DA receptor stimulation on striatal AP-1 DNA binding activity were examined using a gel shift assay. Nuclear protein extract (10 µg), prepared from homogenized striatum, was incubated with ³²P-labeled oligonucleotides containing AP-1 or CREB consensus sequence. In normal rat striatum there was a high level of AP-1 binding. I.p. administration of (+) SKF 38393 (5 mg/kg, n = 9) or quinpirole (0.25 mg/kg, n = 8) did not significantly affect AP-1 binding 2 hr later, nor did a combination of these drugs (n = 7). In striata of rats treated with reserpine (10 mg/kg, s.c.) for 4-7 h, AP-1 binding was increased by 90% (n = 8, p < 0.01). AP-1 binding was also increased by 80% (n = 7, p < 0.01) 12 weeks after 6-OHDA-induced lesion of the nigrostriatal pathway and by 45% (n = 5, p < 0.05) 8-9 months later. In 6-OHDA-lesioned rats, a combination of (±) SKF 38393 (10 mg/kg) and quinpirole (0.25 mg/kg) further increased AP-1 binding by 76% (n = 5, p < 0.01). Striatal CREB DNA binding activity was not significantly affected in reserpinized or lesioned rats. Thus, changes in Fos synthesis critical to DA agonist behavioral effects^{1,2} are not reflected in total striatal AP-1 binding 2 hr after agonist treatment in normal rats, but are evident in 6-OHDA-lesioned rats. The observation that striatal AP-1 DNA binding is enhanced by DA depletion as well as by DA receptor stimulation after DA cell lesion suggests that different underlying mechanisms are involved. ¹Sommer et al., *Neuroreport* 5: 277, 1993; ²Dragunow et al., *Neuroreport* 5: 305, 1993.

REGULATION OF NEOSTRIATAL NEURONS BY cAMP-DEPENDENT MECHANISMS. C.S. Colwell* and M.S. Levine. Mental Retardation Research Center, UCLA School of Medicine, Los Angeles, CA 90024.

The purpose of the present study was to examine the possibility that cAMP-dependent regulation of synaptic transmission occurs in the neostriatum. Intracellular recordings were obtained from neostriatal neurons in slices using standard techniques. Depolarizing postsynaptic potentials (DPSPs) were evoked by local electrical stimulation. Bath application of forskolin (FKN), an activator of adenylyl cyclase, enhanced DPSP amplitude (155 ± 8% (mean ± se) of controls) and duration (122 ± 6%). This potentiation was dose-dependent, occurred in presence of the GABA receptor antagonist bicuculline, and was not seen with the inactive FKN analog 1,9-dideoxyforskolin. Rp-cAMPs, an inhibitor of cAMP-dependent protein kinase (PKA), was applied in addition to FKN. Rp-cAMPs (100 µM) significantly attenuated FKN's enhancement of DPSP amplitude. Moreover, the PKA activator Sp-cAMPs (100 µM, 10 min) also enhanced DPSP amplitude. These results suggest that FKN is acting through a PKA-dependent mechanism to enhance DPSP amplitude. Interestingly, in some neurons, treatment with Rp-cAMPs clearly depressed the evoked response. This inhibitory effect was also seen when the intracellularly active PKA inhibitor PKI was applied via the recording electrode. In contrast, bath application of the phosphatase inhibitor, okadaic acid (10 µM), increased DPSP amplitude. These results indicate that, at least under these experimental conditions, tonic kinase and phosphatase activity regulates DPSP amplitude. Taken together, these results suggest a role for the adenylyl cyclase cascade in the regulation of synaptic transmission in the neostriatum. Supported by USPHS HD 05958.

WHOLE CELL CURRENTS MODULATED BY DOPAMINE IN PATCH-CLAMP RECORDINGS FROM VISUALIZED NEOSTRIATAL NEURONS IN SLICES USING INFRARED VIDEO-MICROSCOPY. C. Cepeda*, O. Yu, S.H. Chandler*, N.A. Buchwald* and M.S. Levine. Mental Retardation Research Center and Department of Physiological Sciences, UCLA, Los Angeles, CA 90024.

We have shown that the direction of the neuromodulatory actions of dopamine (DA) is dependent upon the specific subtype of excitatory amino acid receptor activated. DA enhances responses evoked by N-methyl-D-aspartate (NMDA) but attenuates responses induced by glutamate or activation of non-NMDA receptors. To provide information on the ionic mechanisms and membrane currents responsible for these actions of DA, whole-cell patch-clamp recordings from visually identified neurons (Nomarski optics, infrared video-microscopy) were used. Thin (120-200 µm) or thick (up to 400 µm) slices were obtained from rats 6-20 days of age. Visualized cells (50-100 µm below the surface of the slice) had small to medium (5-15 µm) or large diameter (20-30 µm) somata. The effects of DA were examined on currents evoked by slowly depolarizing ramp commands. A persistent inward current was evident after application of the command voltage. It activated at about -45 mV and was followed by an outward current. The inward current was blocked by application of TTX (1 µM) suggesting it was mediated by Na⁺ ions. DA (20-100 µM) also reduced the current. These results indicate that the inward rectification observed in neostriatal neurons is the result of activation of a TTX-sensitive persistent Na⁺ current that is modulated by DA. It is possible that this Na⁺ current may be partly responsible for DA's ability to attenuate responses evoked by glutamate. The present findings also underscore the feasibility of using infrared videomicroscopy to identify recorded cells in thick slices in which local connectivity is intact. Supported by USPHS HD 05958.

DIZOCLIPINE MALEATE DIFFERENTIALLY INFLUENCE THE POSTSYNAPTIC EFFECTS OF NIGROSTRIATAL DOPAMINE DEAFFERENTATION AMONG SUBPOPULATIONS OF STRIATAL NEURONS.

P. Salin*, M.D. Hajji, A. Nicoullon and L. Kerkerian-Le Goff. Cellular and Functional Neurobiology Laboratory, CNRS, 13402 Marseille cx 20 (France).

This study examined the effects of systemic treatments with dizocilpine maleate (MK-801; 0.2mg/kg, i.p., twice a day for 8 days) either alone or in combination with unilateral 6-hydroxydopamine-induced lesion of the nigrostriatal dopamine neurons on neuropeptide Y(NPY) and substance P (SP) immunostaining in the rat striatum. MK-801 by itself elicited an increase in the striatal number of neuropeptide Y-immunodetectable cells, paradoxically concomitant with a decrease in the levels of intraneuronal labelling, and a decrease in SP immunostaining in both the striatum and substantia nigra. As reported previously, unilateral lesion of the nigrostriatal dopamine pathway elicited an increase in the number and staining intensity of NPY-immunoreactive neurons, out a decrease in SP immunoreactivity. MK-801 treatment of animals with unilateral nigrostriatal dopamine lesion totally reversed the changes in NPY immunoreactivity related to the dopamine lesion without modifying those in SP. These data indicate that both NPY- and SP-containing neurons in the striatum undergo tonic glutamatergic influence through NMDA receptors. They further suggest that the mechanisms underlying the effects of dopamine deafferentation may differ among the striatal neuronal populations.

NEUROTENSIN AND FOS IMMUNOREACTIVITIES IDENTIFY TWO SUBPOPULATIONS OF STRIATAL NEURONS FOLLOWING ACUTE 6-HYDROXYDOPAMINE LESIONS AND RESERPINE ADMINISTRATION. Judith S. Brog* and D. S. Zahm. Dept. of Anat. and Neurobiol., St. Louis University School of Medicine, St. Louis, MO 63104

It was previously reported that following dopamine (DA) D2 receptor blockade or DA depletion, neurotensin (NT) immunoreactivity (IR) is elicited in at least two distinct subpopulations of rat striatal neurons. Colocalized Fos-IR, interpreted as an indicator of enhanced neuronal activity, was found in only one of these subpopulations following D2 blockade (Neurosci. 57: 649-60, 1993). In this study, the degree of colocalization of Fos- and NT-IR in striatal neurons in response to acute midbrain 6-hydroxydopamine (6-OHDA) lesions and reserpine administration were studied. It was observed that a subpopulation of smaller neurons exhibiting light NT-IR and frequent colocalization with Fos-IR was predominant after reserpine administration, mainly in the dorsolateral quadrant of the striatum. Another subpopulation of larger, intensely NT-immunoreactive neurons that was rarely colocalized with Fos-IR was observed following all the drug treatments, but was present almost to the exclusion of the smaller cell type three days following 6-OHDA lesions, mainly in the dorsomedial and ventrolateral portions of the striatum. The present data are consistent with two subpopulations of striatal neurons that accumulate NT following DA depletion. The possibility is considered that one subpopulation accumulates NT in response to coordinate increases in neuronal activity and NT synthesis, and the other as a result of decreased release. ELECTROPHYSIOLOGICAL EFFECTS OF A CANNABINOID ON NEURONS IN THE SUBSTANTIA NIGRA PARS RETICULATA. A.S. Miller* and J.M. Walker. Schrier Research Laboratory, Department of Psychology, Brown University, Providence, RI 02912.

Binding studies have demonstrated that cannabinoid receptors are densely distributed in the outflow nuclei of the basal ganglia and are especially abundant in the substantia nigra pars reticulata (SNR). Cannabinoid receptors in the SNR have been localized on the striatonigral terminals. Single unit electrophysiology was used to explore the role of cannabinoid receptors in the SNR. Intravenous or intraperitoneal injection of WIN 55,212-2 in anesthetized rats produced a significant but modest increase in the basal firing rate of SNR neurons. A second set of experiments was performed in order to assess whether this increase represented a disinhibition of SNR activity. Striatal stimulation produced a brief inhibition of neural activity in the SNR. WIN 55,212-2 (up to 1 mg/kg i.v.) dose-dependently reversed the inhibition of cell firing in the SNR which was produced by striatal stimulation. These results suggest that cannabinoid receptors on the striatonigral terminals may regulate movement by disinhibiting the activity of SNR neurons, perhaps by inhibiting the release of GABA into the SNR.

GAMMA-AMINOBUTYRIC ACID (GABA) TURNOVER IN MOUSE THALAMUS FOLLOWING GABA-T INHIBITION; EFFECTS OF DOPAMINERGIC MANIPULATIONS. P. Martin*, M.L. Carlsson and A. Carlsson. Dept. of Pharmacology, Medicinareg.7, 413 90 Goteborg, Sweden.

The accumulation of gamma-aminobutyric acid (GABA) in the mouse thalamus was measured after inhibition of GABA-transaminase (GABA-T) by means of systemic administration of the irreversible inhibitors gamma-acetylenic GABA (GAG, 200 mg/kg i.p.) or gabaculine (150 mg/kg).

After treatment with reserpine and α -methyltyrosine, the accumulation of GABA in both thalamus and cerebellum was decreased to 73 % of controls. Likewise, when gabaculine was administered locally in the thalamus, the GABA turnover in thalamus was decreased to 75 % of controls.

The GABA turnover following an i.p. injection of apomorphine (0.5-1.5 mg/kg) was decreased to 82 or 67 % of control, after systemic GAG or gabaculine, respectively.

Results of ongoing microdialysis studies will be reported.

The data are discussed in relation to the proposed existence of positive and negative cortico-striato-thalamo-cortical feedback loops.

DIFFERENTIAL MODULATION OF DOPAMINE D1- AND D2-RECEPTOR BINDING IN RATS TREATED WITH A CLASSICAL NEUROLEPTIC. U. Liminga*, H. Coiroini, A.E. Johnson, L. Källström, J. Silbering, A. Hjort, L.M. Gunne, and E.-A. Wiesel. Psychiatry Department, Ulleråker Hospital, Uppsala University, S-75017 Uppsala, Sweden.

Classical neuroleptics are often employed in the treatment of schizophrenia. These compounds are known to act on the dopaminergic system primarily by blocking dopamine (DA) D2-receptors. In the following experiments, we evaluated the consequences of exposure to the classical neuroleptic, fluphenazine decanoate (FLU), on DA D1- and D2- receptor binding in several regions of the basal ganglia. Adult female Sprague-Dawley rats were treated either chronically or acutely with FLU (30mg/kg) or with vehicle. Animals were killed by decapitation and brain sections through the striatum (STR), entopeduncular n. (EP), subthalamic n. (STh) and substantia nigra (SN) were collected and processed for receptor autoradiography. D1-receptors were labelled with [¹²⁵I]-SCH23982 in the presence or absence of unlabelled SCH23390 and D2- receptors were labelled with [¹²⁵I]-NCQ298 ± Eticlopride. Analysis of autoradiograms showed that *in vivo* exposure to FLU significantly decreased specific [¹²⁵I]-NCQ298 binding by up to 70% relative to controls in all brain regions measured probably by competing with [¹²⁵I]-NCQ298 binding *in vitro*. With regard to D1-receptors however, FLU treatment decreased [¹²⁵I]-SCH23982 binding in the dorsal STR (35%), but increased binding in EP (38%) and was without effect in the SN. *In vitro* competition assays performed on sections from untreated rats showed that FLU is a potent competitor of binding at both receptor subtypes with an affinity of about 10nM for D1-receptors in the dorsal STR and EP and 2.5nM for D2-receptors in the dorsal STR and STh. These results suggest that although FLU is an effective competitor of both D1 and D2 compounds *in vitro*, it acts primarily as a D2 antagonist *in vivo*. These data suggest that even for ligands with high affinity for both D1 and D2 receptors *in vitro*, these compounds may act primarily at D2 binding sites *in vivo*. Supported by grant #8318 from the Swedish MRC.

PRE- AND POSTSYNAPTIC MEASURES OF SHORT-TERM SYNAPTIC PLASTICITY AT THE CORTICOSTRIATAL SYNAPSE OF THE AGED RAT. X. Ou* and J. P. Walsh, Andrus Gerontology Center & USC Program in Neurosciences, University of Southern California, Los Angeles, CA 90089-0191.

The corticostriatal synapse of the aged rat expresses a decrease in paired-pulse facilitation, without an associated change in short-term synaptic depression (Ou and Walsh, 1994). It is not known, however, whether age affects the kinetics of recovery from synaptic depression. Synaptic depression was induced at the corticostriatal synapse by delivering 15 stimuli (ISI of 50 msec) to the corpus callosum in an *in vitro* brain slice. Recovery from the depression was monitored by responses to a single test stimulus occurring 0.2 to 5 seconds after conditioning. Our data indicates that there is a significant difference between the two-age groups in the kinetics of recovery from synaptic depression, with aged cells showing slower recovering from depression than young cells.

We next examined the effect of age on the contribution of NMDA receptor activation to the synaptic response. Paired synaptic responses (ISI of 60 msec) were evoked before and after addition of the NMDA receptor antagonist APV (30 μ M) in Mg²⁺-free ACSF. Subtraction of synaptic responses evoked under these two conditions indicates that neurons from aged rats expressed a decrease in the NMDA component of the synaptic response. All slices were treated with 20 μ M bicuculline to block GABA_A receptor mediated inhibition.

Research was supported by a grant from the NIA (5 P01 AG0979).

EFFECTS OF 5-HT_{1A/1B} AND D₁ RECEPTOR ANTAGONISTS ON THE INDUCTION OF STRIATAL JUN B AND FOS-LIKE IMMUNOREACTIVITY BY DEXFENFLURAMINE. A.M. Gardier¹, R. Moratalla², and A.M. Graybiel². ¹Dept. Pharmacol. JE 92-372, Fac. Pharmacie, Chateau-Malabry 92296, France & ²Dept. of Brain and Cognitive Sciences, MIT, Cambridge MA 02139, USA.

The indirect serotonergic agonist fenfluramine (20 mg/kg i.p.) induces Fos-like immunoreactivity in the caudoputamen (CPu) and in other brain regions [Richard et al., *Brain Res.*, 594 (1992) 131-137]. However, fenfluramine is a racemate in which the d-isomer (d-fen) acts on the serotonergic system by increasing the extracellular levels of serotonin (5-HT) at nerve terminals (Samanin and Garattini, In *Nutrition and The Brain*, Vol.8, Raven Press, New York, 1990), whereas the l-isomer increases the turnover of dopamine (DA) in rat CPu [Invernizzi et al., *Eur.J.Pharmacol.*, 120 (1986) 9-15]. Here, the induction of c-fos and jun B protein products was studied in rats 2 hrs after administration of d-fen (0, 5, 10, 20 and 40 mg/kg, i.p.). D-fen induced a dose-dependent increase in both Fos-like and Jun B-like immunoreactivity (F-LI, Jun B-LI) in the CPu, and in other sites including the central amygdaloid nucleus and layer 4 of frontoparietal cortex. The CPu induction was most intense centrally and medially and, at caudal levels, in localized dorsal and ventral zones. The induction of F-LI and Jun B-LI by d-fen (40 mg/kg) was attenuated in CPu, but not in the cortex, by pretreatment with low doses (0.2 and 0.3 mg/kg, i.p.) of the D₁ DA receptor antagonist SCH 23390. Furthermore, the induction of F-LI and Jun B-LI by d-fen (40 mg/kg) was attenuated in the cortex, but not in CPu, by prior administration of a drug known as one of the most effective 5-HT_{1A/1B} autoreceptor antagonists, methiothepin. The latter drug was administered at a dose (10 mg/kg) that has been shown to block d-fen's effect on brain 5-HT metabolism [Gardier et al., *Brain Res.*, 588(1992)67-74]. Our results suggest that an indirect 5-HT agonist d-fen may stimulate F-LI and Jun B-LI in the rat striatum at least in part indirectly through striatal DA release, leading to an activation of postsynaptic D₁ DA receptors.

STIMULATION OF ADENOSINE A_{2a} RECEPTORS BY CGS 21680 INDUCES C-FOS EXPRESSION IN THE STRIATUM OF DOPAMINE DENERVATED RATS Morelli M.*, A. Pinna, G. Di Chiara Dpt. Toxicology Univ. of Cagliari (Italy)

The induction of the early-gene c-fos after the adenosine A_{2a} receptor agonist CGS 21680, was studied in the striatum of normal rats or after a unilateral 6-hydroxydopamine (6-OHDA) lesion of the dopaminergic nigro-striatal neurons. CGS 21680 (5 mg/kg) induced c-fos expression in the 6-OHDA lesioned striatum while in normal rats CGS 21680 failed to induce c-fos expression even at doses of 10-20 mg/kg. The dopamine D₂ agonist quinpirole reversed CGS 21680-induced c-fos expression, while blockade of muscarinic receptors by scopolamine partially prevented c-fos expression in the dorso-lateral part of the striatum. The results are consistent with the coexistence of A_{2a} and D₂ receptors on striatal neurons and with their opposite influence on adenylate cyclase. However the data also suggest that stimulation of cholinergic transmission by CGS 21680, might play a role in the induction of c-fos expression.

VESTIBULAR: VESTIBULOOCULAR REFLEX PHYSIOLOGY

VESTIBULARLY-EVOKED ACTIVITY OF SINGLE NEURONS IN THE DORSOMEDIAL CELL COLUMN OF THE INFERIOR OLIVE IN RABBIT. N.H. Barmack* and M.H. Fagerson. R.S. Dow Neurological Sciences Inst., Portland, OR 97209 and Dept. of Cell Biol., Oregon Health Sciences University.

GABAergic pathways originating from the medial and descending vestibular nuclei (DVN, MVN) as well as the nucleus prepositus hypoglossi convey vestibular information to various divisions of the inferior olive. Previously we have demonstrated a topographic representation of both the vertical semicircular canals and utricular otoliths in one of the subdivisions of the inferior olive, the β -nucleus. In the present experiment we have characterized the inputs, projections, as well as the encoding characteristics of neurons in another subdivision, the dorsal medial cell column (dmcc). We have recorded extracellularly from dmcc neurons in chloralose-urethane-anesthetized rabbits placed in a three axis rate table, permitting static and sinusoidal vestibular stimulation, as well as the determination of a vestibular null point.

All neurons were driven by static tilt or sinusoidal rotation about the longitudinal axis. These neurons responded in phase with contralateral side-down head position during sinusoidal stimulation. Measured null points did not correspond to the orientation of pairs of vertical semicircular canals. These neurons appeared to be driven primarily from the utricular otoliths. These vestibularly responsive neurons were located in the dorsal half of the dmcc. An immunohistochemical stain for glutamic acid decarboxylase demonstrates that the dmcc, as well as the β -nucleus is innervated by GABAergic fibers originating from the DVN and MVN. Injections of horseradish peroxidase (2-4 μ l, 30%) into both the nodulus-uvula and flocculus demonstrate that the dorsal half of the dmcc projects to the nodulus, whereas the ventral half projects to the flocculus. In sum, the dmcc accounts for some of the otolithic input to nodulus-uvula and may contribute to the topographic modulation of postural control about the longitudinal axis.

FOS-LIKE-IMMUNOREACTIVITY IN BASAL GANGLIA OUTPUTS FOLLOWING ADMINISTRATION OF DOPAMINE AGONISTS. David Wirtshafter* Dept. Psych., Univ. Illinois at Chicago, Chicago, IL 60680.

The pars reticulata of the substantia nigra (SNpr) and the entopeduncular nucleus (EPN) tonically inhibit cells in a number of structures including the lateral habenula, the pedunculo-pontine region and certain thalamic nuclei. Many workers have theorized that stimulation of dopamine receptors leads to inhibition of cells in the SNpr and the EPN which, in turn, results in a disinhibition of neurons in the structures listed above. Since many neurons respond to excitation by expressing the immediate-early gene c-fos, we attempted to evaluate this model of basal ganglia organization by using immunocytochemistry to examine the distribution of Fos like immunoreactivity following systemic injections of either amphetamine (5 or 10 mg/kg), amfonelic acid (2.5 or 5 mg/kg) or apomorphine (4 mg/kg). Following all of these treatments, many labeled neurons were observed in the lateral portion of the lateral habenula, in the ventromedial thalamic nucleus and the rostral pole of the ventrolateral thalamic nucleus and in the pedunculo-pontine region. In subjects with unilateral 6-OHDA lesions of the ascending dopamine pathways, injections of amphetamine resulted in labeling of all of these structures on the intact, but not the deinnervated side. Simultaneous processing of tissue for NADPH-diaphorase revealed that staining in the midbrain tegmentum was concentrated in the so called "midbrain extrapyramidal area" just medial to the cholinergic cells of the pedunculo-pontine nucleus proper.

487.2

NEURAL RESPONSES TO VESTIBULAR PARADIGMS IN THE MACAQUE NODULUS. A.F. Rosenberg* and C.A. Scudder. Dept. of Otolaryngology, Univ. of Pittsburgh, Pittsburgh PA 15213.

The goal of this study is to investigate the involvement of the nodulus in vestibular processing by characterizing its 1) input and output signals, and 2) responses during off-vertical axis rotation (OVAR). Both granular layer units (GLUs) and Purkinje cells (PCs) were recorded from the cerebellar cortex of an awake, trained, head-fixed monkey during passive vestibular stimulation in both horizontal and vertical planes, and during eye movements.

Most neurons were sensitive to vestibular stimulation. Of these neurons that were tested in three orthogonal planes, the vast majority were sensitive to movement in a vertical plane whereas few neurons responded exclusively to yaw rotation. GLUs that responded to vertical motion were sensitive to head velocity (indicating canal or dynamic otolith input) or to static tilt (indicating otolith input). Most responsive PCs were sensitive to some combination of vertical head velocity and tilt, which in some cases, depended on the particular plane of stimulation. The responses of these PCs suggest that they receive convergent signals originating from multiple types of vestibular afferents.

PCs were recorded during OVAR, which presumably invokes velocity storage. Some PCs responded with a constant change in firing rate, a modulated firing rate related to instantaneous direction of tilt, or both. The peak firing rate of units that had a modulated response component sometimes corresponded to different tilt directions for different senses of rotation.

Some neurons (GLUs and PCs) possessed eye movement sensitivity, including bursts (GLUs). Others, mostly PCs, had responses related to body movement, and appeared to be restricted to the ventral nodulus. GLUs and PCs tested with optokinetic stimulation were unmodulated.

It is concluded that the nodulus contains reflex circuitry utilizing vertical motion and static tilt information from the labyrinth. Neural signals in the nodulus may be involved in the generation of eye movements during OVAR.

487.3

FUNCTIONAL INDEPENDENCE OF NODULAR AND UVULAR MICROZONES CONTROLLING SPATIAL ORIENTATION OF VELOCITY STORAGE. B. Cohen, S. Wearne, T. Raphan, H. Reisine*. Mt Sinai School of Medicine and Brooklyn College of CUNY

Tilting the gravito-inertial acceleration (GIA) vector during yaw-axis vestibular or optokinetic nystagmus reorients the compensatory eye velocity vector toward the spatial vertical (axis reorientation). Two processes are associated with this: reduction of the horizontal time constant (dumping) and generation of vertical and/or torsional components in the eye velocity vector (cross-coupling). Axis reorientation was studied in rhesus monkeys following discrete lesions of the nodulus and uvula, and after midline medullary section to abolish velocity storage. The GIA vector was tilted in three paradigms: OKAN with static head tilts, centrifugation and dynamic head reorientation during postrotatory nystagmus. Midline medullary section abolished velocity storage, reducing the horizontal time constant from 19.1 ± 2.1 s to 5.6 ± 1.2 s, without affecting the VOR gain. This abolished eye velocity reorientation, showing that it depends upon velocity storage, not on the direct vestibular pathways. After nodulo-uvulectomy, the horizontal time constant was insensitive to static or dynamic head tilts and monkeys could generate neither vertical nor torsional components to shift the eye rotation axis. Vertical and torsional VOR time constants, tested in on-side or supine positions, fell to ≈ 2 sec. Selective ablation of the medial nodulus and uvula, sparing the most lateral nodular microzones, eliminated vertical and torsional cross-coupling but not the ability to reduce the horizontal time constant. Thus, processes associated with axis reorientation can be dissociated structurally in the nodulus and uvula. This suggests independence of the nodulo-uvular microzones controlling cross-coupling and dumping. Supported by NS00294, EY04148, EY01867.

L-ACETYL-CARNITINE TREATMENT INFLUENCES THE AGE-RELATED ADAPTATION OF BENZODIAZEPINE RECEPTORS AFTER UNILATERAL LABYRINTHECTOMY. M. Zanni, L. Giordano, M. T. Ramacci* and L. Calzà. Inst. of ORI, University of Modena and Milano, Italy; Ist. Ricerca Senescenza, Sigma Tau, Pomezia, Italy; Inst. of Human Physiol., University of Cagliari, Italy.

The functional recovery from peripheral and central nervous lesions is modified by aging. Also the vestibular compensation after hemilabyrinthectomy (HLTX) follows an age-related profile. The early phase of vestibular compensation involves a rearrangement of cerebellar GABAergic input to the lateral vestibular nucleus (LVC). In this paper, we investigated the modification of benzodiazepine binding sites in the LVC after 28 days from the HLTX in 3- and 24 months old rats (*male Sprague Dawley*). We also studied the effect of 28 days treatment with L-acetyl-carnitine (50 mg/kg/day , ip). The experiments have been performed by means of quantitative autoradiography using ^3H -flunitrazepam (^3H -FLU) as ligand. In the LVC of old unlesioned rats, a higher density of ^3H -FLU binding sites than in adult rats is found ($+14.3 \pm 2.6\%$), which is reversed by L-acetyl-carnitine treatment. The L-acetyl-carnitine treatment is ineffective in adult unlesioned rats. In adult hemilabyrinthectomized rats, ^3H -FLU binding sites in both lesioned and unlesioned sites of the LVC are not modified after 28 days from the lesion. The L-acetyl-carnitine treatment did not modify this result. The same experimental condition induces a decrease of benzodiazepine receptor density in LVC of both sides of old rats (*lesioned side*: -33.1 ± 2.5 ; *unlesioned side*: -29.8 ± 2.6). The L-acetyl-carnitine treatment performed for 28 days starting from the day of surgical hemilabyrinthectomy induces a bilateral increase in receptor density of LVC, the level of which reaches those found in old unlesioned untreated rats. These data indicate: 1. the GABAergic involvement in vestibular compensation at LVC level shows an age-dependent profile, at least for the regulatory site of GABA_A receptor labeled by ^3H -FLU; 2. the L-acetyl-carnitine treatment affects the ^3H -FLU receptor modifications observed in LVC of old rats and also those related to a rearrangement of the synaptic function during vestibular compensation.

EVIDENCE FOR A STOCHASTIC MECHANISM IN COMPENSATION FOR VIIITH NERVE SECTION IN THE VESTIBULO-OCULAR REFLEX OF THE GOLDFISH. R. Ratnam and T. J. Anastasio*. Beckman Institute, Center for Biophysics, and Department of Physiology and Biophysics, Univ. of Illinois at Urbana-Champaign, Urbana, IL 61801.

To study compensation in the period immediately following loss of vestibular input to one side in the goldfish, a preparation was developed to quickly cut the stato-acoustic (VIIIth) nerve while the animal was set-up for recording eye movements. Unilateral nerve section produces intense, nystagmic, spontaneous vestibulo-ocular reflex (VOR) eye movement, averaging in the acute stage about $35^\circ/\text{sec}$ to the ipsilateral side (from a normal of less than $1^\circ/\text{sec}$ directed nasally). VOR gain in the acute stage is harder to estimate, although it very quickly drops to values below normal. Spontaneous VOR (SVOR) is eliminated by the compensatory process within 10 minutes to 1 hour; some gain recovery also occurs in this period. This is the most rapid SVOR compensation yet reported, and greatly facilitates observation and analysis of the process. SVOR elimination appears to occur in two phases. The first phase is characterized by high variability, in which SVOR fluctuates in a random fashion with eye velocities ranging from 5 – $60^\circ/\text{sec}$ to the ipsilateral side. The second phase is marked by an abrupt decrease in SVOR to less than $5^\circ/\text{sec}$ to the ipsilateral side with an associated decrease in variability. Gain recovery in the first phase is more complex, but generally follows that of compensation for SVOR. In the second phase variability in gain is also much reduced. Gain increases to subnormal levels after about 1 hour, and continues to increase over an ensuing period of weeks. These results suggest that SVOR compensation may involve a stochastic process that results in a symmetry breaking transition to the compensated state. (This study is supported by grants from the Whitaker foundation and the Beckman Institute.)

RECOVERY OF ANTERIOR CANAL AFFERENT SPONTANEOUS ACTIVITY AND RESPONSES TO MECHANICAL STIMULATION FOLLOWING AMINOGLYCOSIDE-INDUCED HAIR CELL LOSS IN CHICKS. R. Boyle¹*, J.P. Carey², S.M. Highstein³, E.W. Rubel², and R.D. Rabbitt⁴. Depts. of Otolaryngology^{1,2,3} and Bioengineering⁴; Oregon Health Sci. Univ., Portland, OR 97201¹; Univ. Washington, Seattle, WA 98195²; Washington Univ., St. Louis, MO 63110³; Univ. Utah, Salt Lake City, UT 84112⁴.

The chicken vestibular sensory epithelium is capable of regenerating new hair cells after ototoxic drug injury; the time course of anatomical recovery is complete after 60 days (Weisleder and Rubel, *J. Comp. Neur.* 331: 97-110, 1993). To determine the events, time course, and functional status of this recovery, extra- and intracellular recordings were made from anterior canal afferents in treated (streptomycin, 1200 mg/kg/day x 5d starting at 5-7 days post-hatch) and age-matched control anesthetized White Leghorn chicks. A piezoelectric micro-actuator was used to adequately stimulate, by mechanical indentation, the exposed anterior semicircular canal. At 3 wk post-treatment, spontaneous rates of afferents are zero or low, and indentation responses are mostly absent. By 5-6 wk post-treatment, spontaneous rates increase, but on average are less than those of control chicks, and indentation responses are present in some, but not all, spontaneously active afferents. The results suggest that afferent spontaneous activity and responses to mechanosensory stimulation are progressively reestablished in the regenerating crista ampullaris. The anatomical correlates of this functional recovery is under study using a morphophysiological analysis. (Supported by PHS Grant DC00520 and 00018)

PHYSIOLOGIC CHARACTERISTICS OF REGENERATED VESTIBULAR CANAL AFFERENTS. J. Hernandez, L. Hoffman, V. Honrubia*, Victor Goodhill Ear Center, UCLA School of Medicine, Los Angeles, CA 90024.

Canalicular primary afferent neurons were investigated *in vivo* for spontaneous and evoked activity 4 months following peripheral axotomy of the anterior vestibular nerve in the bullfrog. Glass micropipettes filled with 1M KCl were used to obtain intraaxonal recordings from anterior and horizontal canal units central to the site of transection. These data were compared to data from normal afferents (Honrubia et al., *J. Neurophys.* 61:688, '89; Hoffman and Honrubia, *Abstr. Soc. Neurosci.* 15:517, '89).

Spontaneous activity recorded in the post-transected nerve exhibited normal characteristics exemplifying regularly and irregularly discharging units, as determined by the coefficient of variation (CV) of the interspike interval (ISI). CVs ranged from 0.10 to 1.20 for anterior units (mean: 0.59 ± 0.40 , $n = 18$), and from 0.07 to 1.01 for the horizontal units (mean: 0.53 ± 0.33 , $n = 19$).

Canalicular afferents responded unambiguously to sinusoidal angular accelerations of 0.05Hz and peak velocity of $15^\circ/\text{sec}$. Response gains ranged from 1.73 to 12.57 spikes $\cdot\text{s}^{-1}/^\circ\cdot\text{s}^{-2}$ for anterior units (mean: 5.51 ± 3.19 , $n = 15$) and from 0.45 to 10.45 spikes $\cdot\text{s}^{-1}/^\circ\cdot\text{s}^{-2}$ for horizontal units (mean: 3.62 ± 3.51 , $n = 16$). For horizontal and anterior units with spontaneous firing CVs < 0.5 , gains were comparable to the distribution of normal afferents with similar CVs. However, units with CVs > 0.5 exhibited lower gains compared to normal afferents (Mann-Whitney U test, $p < 0.001$). There was no difference between horizontal and anterior gains among the regenerated afferents (*t*-test, $p > 0.2$). Phase measurements (re: head acceleration) ranged from $+5.0^\circ$ to -70.2° and -11.6° to -74.3° for anterior and horizontal units, respectively. These measures were comparable to that found for normal horizontal and anterior afferents.

Thus, the appearance of spontaneous activity and responsiveness to sinusoidal rotations among horizontal and anterior afferents in the post-transected nerve indicates that the regenerated primary afferents observed morphologically in a previous study have established functional synapses. However, the reduction in response gains from normal suggests that these regenerated afferents have diminished synaptic inputs. Supported by GM08042 and DC01404.

EFFECTS OF BLOCKADE OF NMDA RECEPTORS AND UNILATERAL VESTIBULAR DAMAGE ON THE DYNAMICS OF THE VOR. D. M. Broussard* and J. K. Bhatia. Playfair Neuroscience Unit, Univ. of Toronto, Toronto, ON M5T 2S8, Canada.

Motor learning in the mammalian VOR, like compensation for vestibular lesions, may involve changes in the efficacy of the vestibular commissure. Synaptic transmission via the commissure has been shown, in frogs, to be mediated in part by N-methyl-D-aspartate (NMDA) receptors. To explore the role of commissural synapses in generating the mammalian VOR, we have compared the effects of the NMDA receptor antagonist ketamine, optically-induced VOR plasticity, and peripheral vestibular damage on the steady-state and peak responses of the VOR of young cats to a rapid horizontal rotational acceleration followed by a constant velocity. Ketamine caused a decrease in both the peak and the steady-state response of the VOR and an increase in the ratio of the peak to the steady-state eye velocity (dynamic index). We also changed the gain of the VOR using magnifying or miniaturizing spectacles, which altered both the steady-state and peak gain. After the horizontal semicircular canal was unilaterally inactivated, steady-state VOR gain for rotation in both directions recovered to near the normal value. The contraversive peak gain and dynamic index were considerably greater than ipsiversive throughout compensation. Our results are consistent with a role of the vestibular commissure in generating the low-frequency components of the VOR. The relationship between steady-state gain and dynamic index during compensation differed from the relationship during optically-induced motor learning. The relative contributions of different parts of the VOR pathway to motor learning in the VOR may, therefore, be altered by a complete unilateral lesion of the horizontal semicircular canal.

SIGNAL CONVERGENCE AND DYNAMICS RECORDED FROM VESTIBULO-OCULOMOTOR NEURONS IN THE ALERT CAT. S.C. Brettler* and J.F. Baker. Northwestern University, Chicago, IL 60611

Vestibulo-oculomotor neurons contribute to the dynamics and spatial organization of compensatory eye movements produced by the vestibulo-ocular reflex (VOR). We have recorded the responses of 96 vestibular nucleus neurons in alert cats to investigate canal convergence, eye position sensitivity, response dynamics, and otolith input. Neurons were classified according to latency of orthodromic responses to labyrinth electrical stimulation and antidromic responses to oculomotor nucleus stimulation.

Extensive spatial testing (14+ runs, 20 neurons), including several sinusoidal rotations about axes near response nulls, confirmed canal convergence on oculomotor-projecting neurons. Six of 9 neurons receiving primarily anterior canal input and 2 of 9 posterior canal neurons showed horizontal canal convergence ($>20^\circ$). Maximum activation direction vectors of anterior canal neurons (AC) varied more widely than those of posterior canal neurons (PC). Vertical and horizontal eye position sensitivity of 28 vestibular nucleus neurons (16 oculomotor-projecting) varied from 0 to 3.1 spikes/sec/ $^\circ$ and generally corresponded to vertical and/or horizontal vestibular sensitivity, with some striking exceptions. During sinusoidal rotations at low frequencies, subtraction of the eye position component from the total neuronal response advanced the response phase.

Responses of 26 neurons to sinusoidal rotations were nearly in phase with velocity ($89^\circ \pm 18^\circ$ s.d. at 0.5 Hz) with advanced phases at high ($129^\circ \pm 10^\circ$ at 4 Hz) and low (horizontal canal, $104^\circ \pm 21^\circ$; PC, $114^\circ \pm 19^\circ$; AC, $78^\circ \pm 16^\circ$ at 0.05 Hz) frequency extremes. Comparison of responses to horizontal and vertical axis pitch rotations at 0.05 Hz revealed modest phase changes for some neurons (-13° to $+27^\circ$) while others had large phase shifts ($+91^\circ$ to $+98^\circ$) indicating otolith input. CONNECTIONS BETWEEN THE SACCULAR NERVE AND NECK EXTENSOR AND FLEXOR MOTONEURONS IN THE DECEREBRATE CAT. H. Sato²*, M. Imagawa¹, M. Sasaki¹, H. Ikegami¹ and Y. Uchino¹. ¹Dept. of Physiol., Tokyo Medical College, Tokyo 160; ²Dept. of Anat., Nippon Medical School, Tokyo 113.

The saccular (SAC) receptors in the otolith organs are sensitive to vertical linear acceleration of the head. We studied the sacculo-neck connectivities by means of intracellular recording from the extensor and flexor motoneurons in C2-C3 segments. Bipolar tungsten electrodes (inter-electrode distance, 0.8 mm) were fixed in place on the SAC nerve; the other branches of the vestibular nerve were transected. Dorsal rami (DR; extensor) and longus capitis (LC; flexor) motoneurons in C2-C3 were identified antidromically. Stimulation of the SAC nerve evoked excitatory postsynaptic potentials (EPSPs) in bilateral DR motoneurons. The latencies of EPSPs in ipsi- and contralateral motoneurons ranged from 1.8 to 2.6 ms (2.2 ± 0.2 ms; mean \pm SD, $n=26$) and from 1.8 to 4.0 ms (2.9 ± 0.7 ms; mean \pm SD, $n=17$), respectively. The SAC nerve stimulation evoked inhibitory postsynaptic potentials (IPSPs) in almost all bilateral LC motoneurons. The latencies of IPSPs ranged from 2.1 to 3.6 ms (2.5 ± 0.4 ms; mean \pm SD, $n=18$) ipsilaterally and from 2.7 to 4.0 ms (3.1 ± 0.4 ms; mean \pm SD, $n=13$) contralaterally. The results demonstrate the presence of reciprocal connections from SAC to extensor and flexor muscles which may play a role in fixing the head and to the body under resting condition and during vertical linear acceleration.

LINEAR AND ANGULAR MOTION MAPPED INTO THE VESTIBULAR NUCLEI. J.E. Holly*, R. Boyle, and G. McCollum, R.S. Dow Neurological Sciences Institute, Portland, OR 97209 and Oregon Health Sciences Univ., Portland, OR 97201.

Cells in the vestibular nuclei discharge in relation to motion factors including angular head velocity, linear head velocity or acceleration, the position and/or velocity of the eyes in orbit during ocular tracking and gaze holding, and events associated with rapid eye movements. Each responding cell discharges either in relation to a single factor or to a certain combination of two or more factors. The number of possible combinations of converging factors grows exponentially with the number of factors considered. The ensemble response across the vestibular nuclei during head and/or eye movement reflects the multitude of combinations of convergence.

We have developed a formal framework that identifies patterns of convergence within the vestibular nuclei and relates these patterns to ensemble response during movement. Each movement of the head maps formally to a certain status of the sensors, one relevant set of sensors being the hairs of the semicircular canals and otolith organs. Deflection of the vestibular hairs evokes a range of primary afferent responses, reflected in the afferents' sensitivity to velocity and/or acceleration. Convergence within the vestibular nuclei determines the ensemble response of secondary vestibular neurons. In the framework, we relate the identified patterns of convergence with the full map from head movement to cell discharge in the vestibular nuclei, thus identifying patterns available to the nervous system for responses such as the vestibuloocular reflex, the vestibulocollic reflex, and self-motion perception.

PVP CELLS RECORDED DURING VERTICAL VISUAL-VESTIBULAR INTERACTION, IN THE ALERT SQUIRREL MONKEY J.D. Dimarogonas*, Y. Zhang, and S.M. Highstein, Dept. of Otolaryngology and Program in Neurosciences, Washington Univ. Sch. of Med., St. Louis, MO 63110.

Extra cellular records were taken from the region of the medial (MVN) and ventro-lateral (VLVN) vestibular nuclei in the alert squirrel monkey. Responses were recorded during (i) visual following (of a full-field optokinetic drum), (ii) VOR in the dark, (iii) VOR in the light, and (iv) VOR suppression. Two types of neurons were identified, namely those that had up-eye position and down head velocity sensitivity, and those that had down eye position and up head velocity sensitivity. Both types paused for saccades and are thus classified as classic position-vestibular pause (PVP) neurons, previously reported. We conclude that some MVN & VLVN PVP cells receive input from the anterior canal (AC) and others from the posterior canal (PC). Therefore it appears that there are two components of the 3 neuron arc from the AC to the third nucleus: 1 via the superior vestibular nucleus that conveys head and eye velocity information and a second via the MVN & VLVN conveying PVP type of information to the IIIrd nucleus. The extent of flocculus control of each of these two pathways is under investigation.

487.12

VESTIBULAR INPUTS TO THE DORSAL Y GROUP NUCLEUS, IN THE SQUIRREL MONKEY P.M. Blazquez, A.M. Partalis and S.M. Highstein* Dept. of Otolaryngology, Washington University, St. Louis, MO 63110.

Dorsal Y group (Y) neurons in the squirrel monkey carry visual following and vestibular signals, and the nucleus has been implicated in adaptation of the vertical VOR (Partalis et al 1993). Y neurons are monosynaptically inhibited by the flocculus; pharmacological inactivation of flocculus removes the visual following signal but spares a head velocity signal on Y cells. To examine the origin of this signal, we studied responses of Y cells to electrical stimulation of the labyrinths in alert squirrel monkeys.

Stimulating electrodes were implanted in the labyrinth bilaterally in two animals. Y cells were recorded extracellularly in the alert animal and identified by their characteristic response patterns during visual following and visual-vestibular interaction paradigms, as previously described (Partalis et al 1993). The responses of cells to electrical pulse stimulation of the labyrinths were examined. Peristimulus time histograms revealed that the vast majority of Y cells were activated at disynaptic latencies following stimulation of either (both) labyrinths.

Taken together with previous evidence, our results suggest that the Y group, an immediate premotoneuronal center, is a site of interaction between vestibular signals from both labyrinths and flocculus output signals. The interneuron between the primary afferent and the Y group probably lies in the vestibular nucleus. Preliminary anatomical data indicate that the Y group receives a projection from the superior vestibular nucleus.

A COMPARISON OF THE RESPONSES OF RAT AFFERENT VESTIBULAR NEURONS AND VESTIBULAR NUCLEI NERVE CELLS EVOKED BY SINEWAVE POLARIZATION OF THE LABYRINTH. O.-J. Grüsser* and J. Kleins, Department of Physiology, Freie Universität, 14195 Berlin, Germany

Sinewave galvanic stimulation (0.1-100 Hz, 2-200 uA amplitude) was applied in pentobarbital-anaesthetized pigmented Norwegian rats. The responses of Ggl. Scarpa nerve cells were uniform and independent of their peripheral origin (semicircular canals-SC, otoliths-O). Within the vestibular nuclei complex (VNC) there was differentiation:

(a) Negative ipsilateral labyrinth polarization led to an activation of units driven by one or two SC-inputs or by SC- and O-inputs.

(b) Some VNC neurons were activated by contralateral negative labyrinth polarization.

(c) Some neurons responded with a slow delayed activation to ipsilateral, some to contralateral negative polarization.

The neurons of category (a) exhibited similar response characteristics as Ggl. Scarpa nerve cells and followed up to a frequency range between 60 and 100 Hz. Owing to the lower spontaneous discharge rates of VNC neurons, however, non-linear response components that consisted of a "silencing" during the positive phase of ipsilateral labyrinth polarization tended to emerge at lower stimulus frequencies. The lowest thresholds at 1-2 Hz galvanization did not differ significantly from those of the afferent fibers (~5 uA). The convergence of many fairly uniformly responding afferent vestibular fibers seems to determine the response characteristics of this subgroup of VNC cells. Sinewave galvanic stimulation of the labyrinth is a powerful tool to synchronize vestibular input. (Supported in part by a BMFT-grant).

OFFSET OF HUMAN SMOOTH PURSUIT: EFFECTS OF TARGET VELOCITY, POSITION, AND PRESENCE. J. Pola* and H. J. Wyatt, SUNY College of Optometry, New York, NY 10010.

We have been studying the offset response of the pursuit system as part of an effort to determine some of the system's dynamic features. **Methods.** Subjects observed a target moving horizontally at 15 deg/sec. When pursuit velocity became steady, the target either: (1) suddenly disappeared; (2) jumped to the fovea with target velocity and feedback becoming 0 (target stabilized at the fovea); or (3) stepped to a retinal location 3 deg ahead of the fovea with target velocity of 0 and feedback of either 0 (target stabilized 3 deg from fovea), -0.2, -0.4, or -1 (target fixed in space). **Results.** When the target disappeared, the eye decelerated rapidly (time constant $T = 0.1s$), but with the target stabilized at the fovea, deceleration was slower ($T = 0.6s$). With the target stabilized 3 deg ahead of the fovea, the eye continued at moderate velocity, a response to target position (since target retinal velocity was zero). As feedback increased from 0 to -1.0, eye deceleration systematically increased. **Modelling and Conclusions.** All of the experimental results can be simulated by a model with target velocity and position inputs, and an internal positive feedback loop. A key feature of the model is that the positive feedback loop is enabled by the presence of a visual target. Thus, long-time-constant offset reflects the action of the positive feedback loop, whereas short-time-constant offset is a result of a loss of positive feedback following target disappearance. The model also suggests that the systematic change in deceleration with increasing feedback depends on the effects of a pursuit position mechanism — the same mechanism that drives the eye when the target is stabilized 3 deg ahead of the fovea.

Craniotopic smooth pursuit deficits in humans. MJ Morrow*, Olive View-UCLA Department of Neurology, Sylmar, CA 91342

Neural circuits arranged in a head-centered (craniotopic) framework influence smooth pursuit eye movements. Craniotopic ocular motor organization is demonstrated in patients with acute cerebral hemispheric damage causing ipsilateral gaze deviation. These patients typically cannot generate pursuit movements across the orbital midline, away from the side of the lesion. Smooth pursuit was recorded in 5 patients with acute frontal or parietal lobe infarction. By comparing responses to target motion within the right and left gaze fields, craniotopic pursuit deficits were quantified. Responses were also compared in rightward and leftward directions to identify directional pursuit asymmetry.

One patient had left hemispheric infarction with right spatial neglect and left gaze deviation. He could not make any eye movements across the orbital midline to the right, but smooth pursuit had lower velocities to the left within the left gaze field. Three patients without gaze deviation or limited ocular motor range generated worse smooth pursuit in the gaze field contralateral to cerebral damage; each of these patients had lower velocities of pursuit for targets moving in the ipsilateral direction. Craniotopic pursuit defects are distinct from pursuit impairment based on the direction or retinal locus of motion. These defects comprise a spectrum in which the most severe examples are associated with complete inability to generate smooth pursuit in the contralateral field of gaze. The craniotopic pattern of impairment implies that orbital position is taken into account by cerebral mechanisms that govern smooth pursuit in humans.

TWO DIMENSIONAL SMOOTH PURSUIT EYE MOVEMENTS DURING TRACKING OF DOUBLE SINE WAVES IN MONKEY RE Kethner, H-C Leung, ME Giszold & BW Peterson. Dept of Physiology, Northwestern University Medical School, Chicago, IL 60611

We examined smooth pursuit in the rhesus monkey along simple 2D trajectories by moving a back-projected laser spot sinusoidally along horizontal and vertical axes. Component waveforms had a frequency ratio of 2:3 and were equated for velocity. Single-sine and sum-of-two-sine tracking along the single axes were studied at the same frequencies. A computer rewarded correct eye position via a scleral search coil. Gain and phase were computed by comparing sine regression fits to saccade-edited velocity components.

Above about 0.6 Hz, the gain of all components decreased with increasing frequency. Phase differences were always less than $\pm 20^\circ$ indicating good predictive pursuit. There were several consistent trends in the interactions between components on both the same axis and on opposite axes. (1) The addition of a higher frequency component reduced the gain of a component presented alone. (2) Reductions were greater for components added to the same axis versus the opposite axis. (3) Horizontal gains were larger than vertical gains for comparable stimuli. (4) For combination stimuli, the high frequency component had a higher gain and a phase lag, while the low frequency component had a lower gain and a phase lead. Analogous results were obtained for stimuli generated from three sinusoids presented along the same and different axes. These findings indicate nonlinear interactions between components both within and across axes, and suggest distinct roles for high and low frequency components during pursuit. Others have reported similar data for 1D pursuit in humans. We also studied correlations between kinematic variables and tracking performance. Corrective saccades were most commonly clustered around points of peak velocity. Pursuit gain was correlated with measures of peak velocity, acceleration and jerk. This explains why pursuit was better for cross-axis combinations that appeared subjectively smoother than the same components acting along the same axis. (Supported by grant MH 48185)

ATTENTION AND TARGET SELECTION IN SMOOTH PURSUIT. Vincent P. Ferrera* and Stephen G. Lisberger, UCSF Dept. of Physiology and Keck Center for Integrative Neuroscience, San Francisco, CA 94143

The selection of appropriate sensory inputs to guide movement is a major issue in sensory-motor integration. We have developed a behavioral paradigm for studying the representations and cognitive decisions involved in input selection for smooth pursuit eye movements. When multiple inputs (targets) are present, selection may be achieved by shifting attention to a particular feature or spatial location. We investigated the role of attention in initiating smooth pursuit in monkeys trained to track moving targets presented on a CRT display. In the first experiment, we adapted a familiar attention paradigm (Posner) by preceding the target with a valid cue indicating the location or direction of the target, or an invalid cue indicating a different location or direction. A single target then appeared randomly in one of four positions around a central fixation mark and moved either towards or away from the fovea. When the target was preceded by a location or direction cue there was no difference in performance (pursuit latency or initial eye acceleration) for valid vs. invalid cues. In contrast, saccade latencies may be up to 50 ms shorter with valid location cues as compared to invalid cues. In the second experiment, two targets (red and green, equated for luminance) were presented and the monkey was instructed which one to track by the color of the fixation mark. If the two targets moved in the same direction, pursuit latencies were as short or shorter than latencies for single targets. If they moved in opposite directions, monkeys were able to choose the correct target >90% of the time, but latencies were 20-40 ms longer than for single targets. Latencies were reduced only slightly (~5 ms) if a cue was given that anticipated the position of the correct target. These observations are consistent with the hypothesis that pursuit initiation uses a velocity-space representation that preserves motion, but not position information. Supported by the McDonnell-Pew Program in Cognitive Neuroscience Fellowship JSMF 92-38.

ADAPTATION OF OPEN-LOOP SMOOTH PURSUIT RESPONSES IN THE RHESUS MONKEY. Maninder Kahlon and Stephen G. Lisberger*, Dept. of Physiology and Keck Center for Integrative Neuroscience, UCSF, San Francisco, CA 94143.

During the initiation of smooth pursuit eye movements, there is a clear relationship between eye acceleration in the first 100 ms (the open-loop period) and target velocity. We have developed an adaptation paradigm for changing the eye acceleration response to a particular velocity. Adapting trials required an animal to track a target that began to move at an adapting velocity, but accelerated or decelerated, after 100 ms, to a higher or lower velocity. Thirty minutes of adaptation caused as much as two-fold changes in the eye acceleration evoked either by the adapting stimulus or by test stimuli consisting of prolonged target motion at the adapting velocity. The largest change in eye acceleration occurred in the interval 50-80 ms after the onset of pursuit, with less change occurring in the initial 0-30 ms interval. The adaptation did not transfer to the opposite direction, but did transfer in an unexpected way to other target velocities. With a stimulus that started at 10 deg/sec and accelerated to 30 deg/sec, the greatest changes in eye acceleration responses occurred at the adapting velocity. However, with a stimulus that started at 25 deg/sec and decelerated to 5 deg/sec, the greatest changes occurred at test velocities lower than the adapting velocity.

This paradigm will allow us to study neuronal changes that underlie adaptation of a relatively well-defined voluntary behavior that requires the cerebral cortex. Supported by NIH grant EY03878.

TWO DIMENSIONAL SMOOTH PURSUIT EYE MOVEMENTS DURING CIRCULAR TRACKING AND PERTURBATIONS IN MONKEY H-C Leung*, RE Kethner, ME Giszold & BW Peterson. Dept. Physiology, Northwestern Univ. Med. School, Chicago, IL 60611

We studied smooth pursuit along three trajectories: circles, circles with occasional perturbations along horizontal or vertical midlines, and horizontal and vertical sinusoids. Reliable behavior developed after repeated sessions with reward delivered contingent upon correct fixation. Horizontal and vertical eye and target velocity curves were estimated using a least square error fit after removing all the saccades. Eye velocity gain was defined as eye velocity divided by target velocity.

Eye velocity gain and phase response to a 5° circular trajectory with a frequency range of 0.2 to 1.8 Hz was examined. Gain and phase curves of horizontal and vertical components initially showed unity gain and zero phase below 0.6 Hz, followed by decreasing gain and increasing phase lag at higher frequencies. Comparison analyses of horizontal and vertical sinusoidal pursuit showed similar trends. In both cases, corrective saccades were preferentially clustered near high vertical and horizontal velocity points, especially for the sinusoids. Because a number of kinematic variables including peak velocity and acceleration vary systematically during these tracking behaviors, this result suggests that there are preferred parameters controlling saccade initiation during pursuit. Collewijn and Tamminga (1984) have obtained similar gain and phase results in humans.

Horizontal and vertical perturbations produced consistent corrective saccades after a delay of 120-180 ms. After perturbations and before corrective saccades, pursuit followed the curved trajectory of the non-perturbed waveform. This continuation of pursuit is caused by the prediction of the circular waveform instead of the maintenance of velocity in a single direction. Tracking along the perturbed axis showed attenuation in amplitude at all frequencies. However, pursuit along the non-perturbed axis only showed attenuation at higher frequencies. This indicates cross-axis interactions under these conditions. (Supported by grant MH48185).

VISUAL TRACKING OF ILLUSORY MOTION IS AFFECTED BY TARGET WAVEFORM. A.Z. Zivotofsky, L. Averbuch-Heller, C.W. Thomas, V.E. Das, A.O. DiScenna, and R.J. Leigh. Ocular Motor Lab., VA Medical Center and Case Western Reserve University, Cleveland OH 44106

We studied ocular motor responses to a variant of the Duncker illusion, in which the perception of motion of an object is induced by moving its frame of reference. Using the magnetic search coil technique, we measured head-fixed and head-free tracking responses of 10 normal subjects to vertical movement of a target (laser spot). Movement of the target was synchronized to horizontal movement of a background Amsler grid subtending 20 X 20 deg, producing a strong illusion of diagonal motion, the horizontal component being opposite to the direction of the grid. Both visual stimuli moved ± 9.2 deg at 0.35 Hz, either sinusoidally or in square-waves. In response to sinusoidal target movement, gaze always followed the target vertically, with a small horizontal component (mean gain 0.05) that was phase lagged compared with grid movement by a mean of 37 deg. When the head was free to move, it usually (85%) showed a diagonal trajectory with a horizontal component (mean gain 0.32) that was phase lagged compared with grid movement by a mean of 156 deg. In response to stepping target movement, inappropriate horizontal saccades were made for 71% of steps. When these saccades were anticipatory (58%), they were always (100%) in the direction of the illusion; when not (latency >90 msec), 49% of saccades were still in the direction of the illusion. The head tracking movements in response to stepping targets were also (100%) in the direction of the illusion. Thus, ocular tracking was programmed differently for sinusoidal and stepping target waveforms, the former response being to actual target motion, the latter to illusory target motion. Head tracking, however, was always of illusory movement of the target, irrespective of its waveform.

OTOLITH DETECTION OF ANGULAR VELOCITY IN THE VOR. B.J.M. Hess*, D.E. Angelaki and J.-I. Suzuki. Dept. of Neurology, Univ. of Zurich, Switzerland; Dept. of Surgery (Otolaryn.), Univ. of Mississippi, Jackson MS; Dept. of Otolaryn., Teikyo Univ, Tokyo Japan.

It has been shown previously that in the presence of simultaneous dynamic otolith input the vestibulo-ocular reflex (VOR) represents more faithfully head angular velocity in the low frequency range (Rude and Baker 1988; Tomko et al. 1988). These observations have raised two yet unresolved questions. First, do these results reflect the sensitivity of the otolith system to head position or to centrally computed otolith-born angular velocity? Second, what is the functional significance of such a property? We have addressed these questions by examining the horizontal, vertical and torsional VOR in rhesus monkeys before and after plugging of either the lateral or one pair of coplanar vertical canals, using sinusoidal low frequency oscillations (0.1-0.01 Hz, $\pm 58^\circ/s$) and constant velocity off-vertical axis rotations ($\pm 58^\circ/s$).

Our results in the intact animals indicate that the low frequency VOR enhancement during simultaneous dynamic otolith stimulation reflects the sensitivity of the otolith system to head angular velocity. A surprising observation was made in canal plugged animals: Acutely after canal plugging, the otolith contribution to the VOR was unchanged, however, it progressively decreased thereafter. Two months after the surgery, the low frequency and steady-state responses to sinusoidal and constant velocity off-vertical axis rotations were completely abolished in the plane of the plugged canals. Our findings in canal plugged animals do not support the current belief that the main function of canal/otolith interactions through the velocity storage mechanism is to improve the low frequency VOR dynamics. Rather the low frequency dynamic otolith contribution to the VOR could reflect the inertial representation of vestibular angular motion signals in the velocity storage network (Angelaki and Hess 1994).

TEMPORAL CONSTRAINTS ON THE MECHANISM OF LEARNING IN THE VOR. Jennifer L. Raymond* and Stephen G. Lisberger. UCSF Dept. of Physiology and Keck Center for Integrative Neuroscience, San Francisco, CA 94143.

Changes in the amplitude and dynamics of the vestibulo-ocular reflex (VOR) can be induced by the association of vestibular and visual (image motion) stimuli. We examined the dependence of these learned changes in the VOR on the temporal properties of the sensory signals used to induce learning. First, rhesus monkeys were adapted for 3 hours with sinusoidal vestibular and visual stimuli at a single frequency from 0.5 to 10 Hz ($\pm 10^\circ/s$). The stimuli for adaptation were provided by passive head turns either with magnifying or miniaturizing spectacles or with optokinetic stimuli that mimicked the effects of magnifying or miniaturizing spectacles. Adaptation with stimuli at frequencies up to 5 Hz induced large, adaptive changes in the VOR. Adaptation with frequencies of 8 or 10 Hz resulted in smaller and less consistent changes in the VOR. A second set of experiments examined the changes in the VOR induced by short (300-ms) pulses of vestibular and optokinetic stimuli, presented either simultaneously or at some constant relative delay during a 3-hour adaptation period. When the visual and vestibular stimuli were presented simultaneously during adaptation, large adaptive changes in the amplitude of the VOR occurred. The adaptive changes were not specific to the vestibular stimulus used during adaptation, but generalized to vestibular stimuli of different amplitudes and durations and to sinusoidal vestibular stimuli. When the onset of the visual stimulus was delayed relative to the vestibular stimulus during adaptation, striking changes in the dynamics as well as the amplitude of the VOR occurred. When the onset of the visual stimulus preceded the vestibular stimulus during adaptation, the changes in the VOR were small relative to the case of simultaneous onset or delayed visual stimulus onset. These temporal constraints on the stimuli that induce learning can guide efforts to identify the neural mechanism(s) of plasticity in VOR pathways. SPATIOTEMPORAL VOR ADAPTATION AFTER SEMICIRCULAR CANAL INACTIVATION. D.E. Angelaki*, B.J.M. Hess and J.-I. Suzuki. Dept. of Surgery (Otolaryn.), Univ. of Mississippi, Jackson MS 39216; Dept. of Neurology, Univ. of Zurich, Switzerland; Dept. of Otolaryn., Teikyo Univ, Tokyo Japan.

Selective semicircular canal inactivation by plugging and three-dimensional eye movement recordings were used in rhesus monkeys to address the following questions: 1) What is the 3d structure of the VOR matrix which relates semicircular canal inputs to oculomotor output? 2) How is the VOR matrix modified during recovery from inactivation of either both lateral or a coplanar pair of vertical canals? To address these questions, horizontal, vertical and torsional eye movements were recorded during sinusoidal oscillations at different frequencies (0.01-1.1 Hz) and head orientations. The VOR matrix was computed based on data acquired before and acutely after canal plugging. Similarly, the evolution of the VOR matrix elements during recovery was computed from data acquired two weeks, as well as one, three and eight months after canal plugging.

The VOR matrix elements were frequency dependent. At mid and high stimulus frequencies, inputs from the lateral and vertical canals contribute to torsional and horizontal eye movements. At low frequencies, however, the VOR matrix was diagonal. After semicircular canal inactivation, the VOR matrix in the mid and high frequency range changed continuously while gain and phase in the plugged canal plane progressively recovered. No recovery was ever observed at frequencies below approximately 0.05-0.1 Hz. These results suggest a frequency-selective central reorganization of vestibulo-ocular connectivity after selective semicircular canal inactivation. In addition, the data strongly suggest that the spatio-temporal organization of the VOR in the mid and high frequency range differs distinctly from that in the low frequency range. This observation raises the possibility that the "velocity storage mechanism" is not simply a parallel loop in the VOR circuitry but that it might represent a distinct entity with different organization and function.

DIFFERENTIAL EFFECTS ON COMPENSATORY GAZE OF INTERAURAL (IA) LINEAR ACCELERATION IN MONKEY AND MAN. S. Wearne, T. Raphan, B. Cohen*. Brooklyn College of CUNY, Mt. Sinai School Medicine

Contributions of linear and angular vestibulo-ocular reflexes (LVOR & AVOR) to gaze stabilization were determined in macaque monkeys during centrifugation, off-vertical axis rotation (OVAR) and optokinetic after-nystagmus (OKAN). Animals were centrifuged either facing or back to motion with velocity trapezoids (10-40°/s² to 400°/s) producing peak IA linear accelerations of 1.24g. Peak horizontal eye velocity (\dot{E}_H) was invariant for the two orientations and beating fields remained close to the midline. Horizontal time constants (Tc) fell faster with GIA tilt when facing than back to motion (.13s° vs. 0.7s°). This corresponded to Tc asymmetries during yaw axis OKAN for head tilts associated with upward or downward cross-coupling. Dynamic parameter modification as a function of tilt was incorporated into our velocity storage model, using the OKAN Tc's from each monkey. These simulations accounted for all asymmetries in \dot{E}_H during centrifugation. Despite this, these monkeys had a direct horizontal translational LVOR during OVAR at velocities of 5°/s to 360°/s (≈ 0.01 -1Hz). Plugging the 6 semicircular canals moreover abolished \dot{E}_H during eccentric rotation, leaving ocular torsion and the response to OVAR intact. Thus, in macaque monkeys, the translational LVOR does not contribute significantly during sustained linear acceleration. In contrast, humans had large facing/back beating field asymmetries and differences in peak \dot{E}_H during centrifugation with similar GIA magnitudes (Wearne, 1993). A direct contribution from the translational LVOR and consequent shift in the beating field was necessary to model the human response. Thus, LVORs both modify the Tc's of velocity storage, reorienting AVOR coordinates, and generate direct compensatory responses to translation. Differentially weighting these two mechanisms accounts for different effects of linear acceleration on compensatory gaze in man and monkey during centrifugation. MODELLING THREE DIMENSIONAL VELOCITY-POSITION INTEGRATION IN THE VESTIBULO-OCULAR REFLEX (VOR). C. Schnabolk* and T. Raphan. Institute of Neural & Intelligent Systems, Dept. of CIS, Brooklyn College of CUNY, 2900 Bedford Ave, Brooklyn New York, 11210

A recent model of velocity-position transformation has focused on the torque-orientation properties of the eye, and the dynamical system representing the eye dynamics (Schnabolk & Raphan, 1994). The final common velocity-position integrator is represented as a dynamical system with a matrix feedback which is an extension of the one dimensional integrator. Because of the nonlinear dynamics of the torque-orientation equations associated with the plant, it was of interest to utilize this three dimensional model to examine the predicted behavior of the canal mediated rotational VOR. When the eye was initially in the primary position, changes in head orientation about an axis in Listing's plane induced both eye velocity and position compensation which was maintained along the axis of rotation. If the head was first moved about a yaw axis, held for a second, and then rotated about a pitch axis, eye velocity compensated accurately. Eye orientation compensated accurately for this sequence for 1-2 seconds following the second movement. If the head was first pitched and then rotated about a yaw axis, eye velocity and orientation behaved similarly. In both instances, the eye slowly rotated to an orientation aligned with the torque axis of the velocity-position integrator which was in Listing's plane. Additional compensatory components generated from the otoliths would enhance the compensation over time. Thus, the model is consistent with the compensatory function of the VOR. It generates appropriate roll components for 1-2 seconds despite the fact that the torque is in Listing's plane and has no roll component. It supports the idea that velocity-position integration in three dimensions is an additive feedback system which is a three dimensional extension of the one dimensional integrator model. MODULATION AND BIAS OF THE VESTIBULO-OCULAR REFLEX (VOR) DURING LOW VELOCITY HORIZONTAL AXIS PITCH ROTATIONS. S.A. Rude* and J.F. Baker. Northwestern University, Chicago, IL 60611.

We used electromagnetic search coil techniques in darkness to assess at equilibrium the sinusoidally varying eye velocity (modulation) and average eye velocity (bias) of the VOR in cats during ± 2 -32°/s constant velocity horizontal axis pitch rotations.

Modulation of vertical VOR eye velocity increased with head velocity, and was greater at all velocities for backward (nose up) than forward (nose down) rotations. Minimum modulation responses shifted toward forward rotations, occurring at +4°/s forward pitch. Slow phase eye velocity bias increased nonlinearly with head velocity and was greater for forward than backward rotations at all velocities. Minimum average eye velocity shifted toward backward rotations, occurring at -2°/s (backward).

We propose that three mechanisms are responsible for this behavior. (1) A central velocity estimate, generated from otolith signals as proposed by others, which produces an eye velocity bias that increases with head velocity in the range tested. (2) An afferent or central "jerk" signal, generated from the rate of change of an anterior-posterior otolith stimulus, which produces modulation of eye velocity increasing with head velocity. (3) A gravity-dependent downbeat nystagmus (GDDN), as we reported in cats (NS '91), generated by a saccular response to tilt, summing with the central velocity estimate to affect bias while also summing with the jerk signal to affect modulation of vertical eye velocity. The static position GDDN is near zero in the upright position and peaks with an upward slow phase at 180° tilt. During rotation the upward slow phase velocity of GDDN adds to the central velocity estimate, subtracting during backward rotation when the velocity bias is downward. Analogously the peak upward slow phase velocity of the GDDN signal at 180° tilt subtracts from the peak modulation signal only during forward rotations when, at 180° tilt, the eye velocity is downward. Thus the GDDN signal is of the correct direction and magnitude to account for the observed shifts in minimum slow phase eye velocity modulation and bias at low rotation velocities. CEREBELLAR β -NORADRENERGIC RECEPTOR ANTAGONISM BY PROPRANOLOL INHIBITS THE VESTIBULO-OCULAR REFLEX ADAPTATION IN GOLDFISH. L. Williams* and J.G. McElligott. Dept. of Pharmacology, Temple University School of Medicine, Phila., PA 19140.

Adaptation of the vestibulo-ocular reflex (VOR) in cats has been shown to be inhibited after norepinephrine (NE) depletion by the neurotoxin 6-hydroxydopamine (6-OHDA) within the central nervous system. Cerebellar NE blockade in rabbits by sotalol (a β -adrenergic antagonist) has also been shown to inhibit an adaptive VOR gain increase. In this study cerebellar β -adrenergic antagonism in the goldfish using propranolol was investigated to confirm and extend these findings. After the initial calibration of the VOR in light and dark, goldfish received a bilateral vestibulo-cerebellar injection (0.25 ml/side @ 0.025 ml/min) of either artificial cerebral spinal fluid or propranolol. VOR measurements were taken after the injections to assure that the pre-adapted VOR was unchanged. VOR gain modification began approximately 30 minutes after the injection and continued for 3 hours. Training towards a gain increase (or decrease) was accomplished by presenting visual stimuli 180 degrees out of phase (or in phase) with the vestibular table rotating about the vertical axis (1/8 Hz @ ± 20 degrees). Our results showed a dose-dependent (14, 108 and 270 mM) reduction of adaptive VOR gain increase in the light and dark without any effect on pre-adapted VOR gain. For VOR gain adaptation towards 0X, propranolol exhibited no effect. Vestibulo-cerebellar injection of propranolol after the completion of 3 hours of VOR adaptive increase showed an initial rapid decay of the VOR adaptation toward pre-adapted levels compared to controls. The present study agrees with previous studies conducted in the cat and rabbit implicating goldfish cerebellar β noradrenergic receptors in VOR adaptation and post-adaptational processes. STATIC AND DYNAMIC EFFECTS OF GRAVITO-INERTIAL ACCELERATION (GIA) ON SPATIAL ORIENTATION OF VELOCITY STORAGE T. Raphan*, S. Wearne, B. Cohen. Brooklyn College of CUNY, Mt. Sinai School of Medicine

We compared axis orientation during off-axis rotation and dynamic head tilt during post-rotatory nystagmus (PRN), i.e., tilt dumping, to that during OKAN. We tested reorientation from pitch to roll/yaw and roll to pitch/yaw. Absence of the latter was a key aspect in model-based studies of OKAN axis reorientation (Raphan & Sturm, 1991). Monkeys were rotated off-axis at $10^\circ/\text{s}^2$ & $40^\circ/\text{s}^2$ to velocities of 200-400°/s, tilting the GIA vector from 17° - 52° . Orientation vectors were computed using a model-based approach. During acceleration, the GIA vector had pitch and roll components and both pitch and roll cross-coupled eye velocities were generated. At constant velocity, the GIA pitch component remained, inducing continued pitch eye velocity that decayed with a 5-8s Tc. This was close to the yaw Tc. The roll component of the GIA dropped rapidly and roll velocity decayed with a short time constant (Tc = 1 s). Off-axis rotations of monkeys such that the GIA vector was solely in the yaw plane elicited no pitch-roll or roll-pitch axis reorientation. Yaw tilt dumping during pitch/roll PRN with peak tilt velocities < 60°/s elicited no significant horizontal velocity and no pitch-roll or roll-pitch cross-coupling. Thus, the reported 'pitch-yaw' and 'pitch-roll' cross-coupling (Angelaki & Hess 1994) is likely due to high velocity pulses along the yaw axis that charged the roll state with a small time constant which then discharged with a longer time constant when the animal was supine/prone. It is not due to additional off-diagonal terms in the system matrix. The reorientation of eye velocity trajectories was the same during dynamic head movements and centrifugation as during OKAN ($\approx 10^\circ$ from the spatial vertical), and was predicted by dynamic parameter changes in the system matrix of velocity storage. We conclude that the yaw axis vector codes the spatial orientation of velocity storage during vestibular activation as during OKAN. Only the yaw axis reorients toward the spatial vertical when the GIA vector is shifted; the pitch and roll axes move with the head. EY04148, NS00294, EY01867, CUNY-PSC 664230

OCULOMOTOR: CLINICAL STUDIES

CHANGES IN OCULOMOTOR CONTROL WITH AGE IN HUMANS. H. Cohen*, L. Heaton, S.L. Congdon, H.A. Jenkins. Dept. of Otorhinolaryngology, Baylor College of Medicine, Houston, TX 77030.

We examined oculomotor responses in elderly people and compared them to responses in younger adults. Twenty-two asymptomatic, community-dwelling subjects aged 70-79 and 11 subjects aged 80-89 were tested on a standard battery of sinusoidal vestibular, optokinetic, saccadic and pursuit eye movements, in a servo-controlled rotatory chair, while eye movements were recorded with electrooculography. Their data were compared to those from 137 subjects aged 18 to 44 and 44 subjects aged 45 to 69 years.

As reported previously, vestibuloocular reflex (VOR) gain and phase in darkness changed significantly with age. Also, the gain of optokinetic responses was significantly higher in the younger subjects, and they had shorter phase lags than elderly subjects. On VOR tests in light, young and middle-aged subjects had higher gains than elderly subjects, and shorter phase lags, but younger subjects had only minimal differences in gain from older subjects on VOR fixation/suppression in light. Subjects in their 70s had less variability than subjects in their 80s in response times and accuracy in making saccades to randomized stimuli. Young adults had significantly higher pursuit gains and shorter phase lags than other subjects.

REDUCTION OF VOR TIME CONSTANT WITH MAINTAINED VOR GAIN IN A GROUP OF ELDERLY SUBJECTS. M. Dai*, B. Cohen, T. Raphan. Mount Sinai School of Medicine, Brooklyn College of CUNY

Some elderly patients have short bilateral vestibulo-ocular reflex (VOR) time constants (Tc) but normal or high VOR gains. They generally complain of imbalance rather than vertigo. The anatomic basis for these findings is unknown. We studied 14 subjects, ages 75-93, with short VOR Tc and with no history of ototoxicity. VOR gains, determined from the initial jump of slow phase velocity elicited with velocity steps ($60^\circ/\text{s}$, $200^\circ/\text{s}$), ranged from 0.5-1.0 (mean 0.74 ± 0.15). VOR Tc ranged from 3-5 s (mean 4.2 ± 0.6 s), compared to Tc of ≈ 15 -25 s in normals. The gains of optokinetic nystagmus (OKN) induced by full field motion were normal (gain 0.9 for 20 & 40°/s), and there was no optokinetic after-nystagmus (OKAN). Subjects were rotated in a lighted earth-fixed surround for 15 sec and stopped in darkness. The post-rotatory VOR gain was the same as after they had been rotated in darkness, showing that velocity storage was not activated during OKN. This is in contrast to the normal reduction of post-rotatory eye velocity by 40-100% after rotation in light. The short VOR Tc and the absence of OKAN as well as the inability to reduce post-rotatory eye velocity could be modelled by a reduced canal Tc and a deactivated velocity storage integrator. Aging is associated with degeneration of hair cells and a loss of fibers in the vestibular nerve. The selective impairment of the VOR Tc with preservation of gain may be secondary to selective hair cell or nerve fiber loss. The imbalance noted by these elderly people may be related to inactivation of velocity storage, which is important for coding spatial orientation and stabilizing gaze and posture during movement. HIGH FREQUENCY, PITCH AND YAW VESTIBULO-OCULAR REFLEX (VOR) IN VERY ELDERLY PEOPLE. I. L. ^{1,2}Demer* and Robert W. ²Baloh. ¹Jules Stein Eye Institute & ²Department of Neurology, University of California, Los Angeles, 90024.

Advanced age is known to result in a shortening of the time constant of the yaw VOR at high velocities, resulting in reduced low frequency gain and increased phase lead. Since these conditions are not representative of physiologic head rotations during everyday life, we investigated the VOR of very elderly subjects during high frequency rotations in both pitch and yaw.

Eye movements were recorded using magnetic search coils for pitch and electro-oculography for yaw in groups (N ≥ 9) of young subjects (mean age 30 yrs) and very elderly subjects (mean age 80 yrs). Subjects underwent passive, sinusoidal whole-body rotations (peak velocity 20-30°/sec) in yaw at 0.8 and 1.25 Hz, and in pitch at multiple frequencies from 0.8-3.2 Hz. Gain (eye velocity/stimulus velocity) of the VOR was obtained from digitally sampled signals following saccade removal.

For both young and very elderly subjects, VOR gain was greater for pitch than for yaw, and gain increased with increasing frequency. Gain in the very elderly was never significantly less than that in the young. The pitch VOR gain of the elderly was actually significantly greater than that of the young at 0.8 Hz (0.94±0.04 vs. 0.83±0.11, mean ± standard deviation, P < 0.05).

Very elderly people have no functionally significant deterioration of pitch and roll VOR at velocities ≤ 30°/sec. Possible velocity saturation in the high frequency VOR of the elderly, such as occurs at low frequencies, cannot yet be excluded and is being studied in our ongoing experiments. However, these data suggest that the rotational VOR of elderly people is normal in the important functional range of frequencies and velocities.

THE EFFECT OF HEAD PITCH ON HORIZONTAL GAIN IN PATIENTS WITH UNILATERAL VESTIBULAR ABLATION. R.J. Tusa, M.P. Grant, D.S. Zee, S.H. Herdman*, U. Buettner, J.K. Niparko. The Johns Hopkins Univ School of Medicine, Baltimore MD, 21287.

Following unilateral vestibular loss, high speed rotation towards the intact ear results in a higher gain than rotation towards the defective ear, resulting in a directional preponderance (DP) ((GainR-GainL)/(GainR+GainL)X100)). This occurs because of the inability of inhibitory stimuli to decrease vestibular nerve firing rates to < 0. We examined the DP in 4 patients following unilateral vestibular nerve section, and in 2 patients with partial labyrinthectomy with absent caloric but spared vertical SCC on CT scan and compared it to 6 normal subjects. The horizontal VOR was measured by EOG during constant-velocity step rotations (300°/s) while the head was pitched 30° up, kept level or pitched 30° down.

The DP in the controls was less than 5% regardless of head pitch. The DP in patients with unilateral nerve section varies according to pitch in a manner expected by the degree in which the H and V SCC sense head acceleration. When the head is pitched down, head acceleration is maximally sensed by the H SCC and DP is maximum (23%). When the head is pitched up only 61% of the head acceleration is sensed by the H SCC, 25% is sensed by the V SCC, and there is little DP (4.2%). In the patients with spared V SCC, there is little to no DP when the head is level or pitched up.

These results suggest that rotary chair with the head pitched up and down may be a useful technique for assessing V SCC function.

DIFFERENCES BETWEEN NORMALS AND PATIENTS WITH UNILATERAL VESTIBULAR DEAFFERENTATION DURING ON-CENTER ROTATION AND CENTRIFUGATION. T. Haslwanter¹, I.S. Curthoys^{1*}, R.A. Black², A.N. Topple¹, G.M. Halmagyi². ¹Dept. of Psychology, University of Sydney, NSW, 2006. ²Royal Prince Alfred Hospital, Camperdown, NSW 2050, Australia.

Using dual search coils we have recorded 3-dimensional eye position in normal subjects and in patients after unilateral vestibular deafferentation on the right (RUV) or left (LUV) side. We used two different paradigms. In a first set of experiments, subjects were exactly aligned with the axis of rotation, and then accelerated at 20°/s² about an earth vertical axis to a steady state velocity of 250°/s. These experiments produced two interesting results: first, even in normals, rotation about an earth vertical axis elicits torsional eye movements; and second, the torsional eye velocity components in LUVs, normal subjects, and RUVs are clearly different. In a second set of experiments, subjects were placed 1m out on the arm of the centrifuge, facing either towards the center of the rotation or away from it. Then they were accelerated at 10°/s² to 200°/s. The results from eccentric rotation show the relative contributions of the semicircular canals and the otoliths, and an analysis of these experiments is presented.

489.4

THE EFFECT OF HEAD PITCH ON HORIZONTAL VOR GAIN DURING ROTATION AT HIGH SPEEDS M.P. Grant, R.J. Tusa*, and D.S. Zee. The Johns Hopkins University School of Medicine, Baltimore, MD 21287

The VOR serves to maintain a stable retinal image during rapid changes in head position by producing slow-phase eye movements to offset the change in head position. Previous studies suggest that at low velocities (< 100 °/s) head pitch does not influence the gain of the horizontal VOR. We recorded horizontal VOR gain using EOG in 7 normal subjects during constant velocity chair rotations (60-300 °/s accl 80 °/s²) in yaw with the head pitched up or down 30°. The mean VOR gain with the head pitched down was 0.56, independent of speed. With the head pitched up, the gain decreased from 0.58 at 60 °/s to 0.40 at 300 °/s.

During the normal VOR at high velocities, central mechanisms must compensate for the nonlinear behavior of the primary vestibular afferents since the vestibular afferents are driven into inhibitory cutoff. This study demonstrates an unexplained decrease in the gain of the horizontal VOR in the head up position, suggesting the central mechanisms are not completely compensating for the nonlinear behavior. Two hypothesis which could explain our observations are:

1) Otolithic afferents may modulate the "antinonlinearity" mechanism. 2) The inputs from the horizontal and vertical semicircular canals may effect the "antinonlinearity" mechanism in different ways.

489.6

FRactal ANALYSIS OF READING EYE MOVEMENTS. A.D.Epstein*, E.T.Schmeisser, J.M.McDonough, Q.Dai. Depts of Ophthalmology, Mechanical Engineering, and Computer Science; Univ of Kentucky, Lexington KY 40536-0284.

We recorded eye position during free text reading in a 48 year old man with clinically undiagnosable reading discomfort. Position traces were digitized at 200 Hz with a resolution of 1.52 arc min. Nonlinear dynamical systems analysis by the Grassberger-Procaccia algorithm demonstrated a correlation dimension (Dc) less than 3.0. In this patient, gross inspection of position and delay map traces during sinusoidal pursuit testing showed satisfactory pursuit right of the midline and saccadic pursuit left of it. This asymmetry persisted at all velocities tested.

Previous analysis of reading eye movements showed a Dc near 3.3 for 2 normal subjects, near 2.1 for a slow reader and a dyslexic, and indeterminate for a patient with acquired nystagmus. All non-dyslexic subject data showed evidence of multifractal behavior.

These findings suggest that fractal analysis of unconstrained eye movements alone cannot explain the differences between normal and abnormal reading eye movements. Experiments using a forcing function and more sophisticated multifractal analysis may be more sensitive.

ANALYSIS OF EYE TRACKING DYSFUNCTIONS IN SCHIZOPHRENIA

A. Mackert, K.-M. Flechtner, R. Sauer, B. Steinacher, S.Traversi, J. Kasper*. Dept. Psychiatry, Free University of Berlin, 14050 Berlin, Germany

Although many studies exist on smooth pursuit eye movement (SPM) dysfunctions in schizophrenic patients, the specificity of the defect remains unclear.

We examined SPM performance of 39 schizophrenic in-patients and compared them with 39 healthy volunteers. Eye movements were recorded with a high resolution infrared scleral reflection technique. We counted the number and amplitudes of saccades during SPM and determined the average gain.

Mean number of saccades was significantly increased and mean gain was reduced in schizophrenic patients. There were no significant correlations to psychopathology or previous doses of neuroleptic medication. We found strong negative correlations between frequency of saccades and gain and between gain and amplitude of saccades. The reduced mean gain in the schizophrenic group could indicate a dysfunction of the smooth pursuit system or could be an effect of anticipatory saccades with large amplitudes and following reduction of gain. Since anticipatory saccades are rather infrequent, we think that our results rather indicate a functional impairment of the smooth pursuit system.

489.9

FAST SACCADIC RESPONSES IN PARKINSON'S DISEASE

A. Erben¹, M. M. Wierzbicka^{*2}, W. Wolf¹¹Bundeswehr University, Munich, Germany, ²West Roxbury VA Medical Center & Harvard Medical School, Boston MA 02132.

Saccadic reaction times of 14 patients with mild to moderate Parkinson's Disease (PD) were compared to those of 9 elderly control subjects (CS). The target appeared 8° left or right from the central fixation point at the time when the fixation point was switched off (gap 0) or 200 ms later (gap 200). An experimental session consisted of 200 trials in which directions and gap intervals were randomized. Only primary saccades were considered. We found no significant differences in the mean saccadic reaction time between the PD and control group in either gap condition. The mean saccadic reaction time was shorter for gap 200 (PD 166 ms; CS 179 ms) than for gap 0 (PD 221 ms; CS 246 ms); this difference (gap-effect) was not statistically different in between groups. There was a tendency toward shorter reaction times and a higher proportion of anticipatory saccades in the PD group. Express saccades were present in some gap 200 trials of several subjects in both groups. Therefore, we conclude that express saccades may be mediated by pathways which do not involve the basal ganglia.

In some subjects anticipatory responses, identified by directional error, extended to longer reaction times and the entire saccadic reaction time distribution was shifted along the time axis. To allow for these effects we proposed 1) correction of the bin value in the saccadic reaction time distribution based on the statistical estimation of the proportion of anticipatory saccades; 2) flexible boundaries for visually guided saccade types (express, fast regular, slow regular) by introducing an adaptive classification schema.

CONTROL OF POSTURE AND MOVEMENT VII

490.1

THE INFLUENCE OF TARGET MOVEMENT ON REACHING AND GRASPING IN LEUKOTOMIZED AND UNLEUKOTOMIZED ADULTS WITH SCHIZOPHRENIA. H. Carnahan¹, D. Elliott², & V.R. Velamoor³. Dept. of Kinesiology Univ. of Waterloo¹, Waterloo, Ont., Dept. of Kinesiology, McMaster Univ.², Hamilton, Ont., & Victoria Hospital³, London, Ont. Canada.

Seven leukotomized adults with schizophrenia (LS), eight unleukotomized adults with schizophrenia (ULS), and eight healthy control (C) individuals were required to reach toward and grasp a small object that was either stationary or moving. Reflective markers were placed on the subject's index finger, thumb and wrist, and movements were videotaped. As expected the LS and ULS groups moved more slowly than the C group when the target was stationary. However, when the target was moving, all three groups moved faster, with the LS and C groups having the same movement times, and the ULS group having the fastest movement time. When the timing of the reaching trajectory was assessed, the LS group spent less time decelerating toward the object, indicating their movements were controlled with less precision. When grasp formation was analyzed, for the stationary condition, the maximum apertures of the LS and ULS groups were not different, and both were larger than those of the C group. For the moving target condition, aperture increased for all groups but was smallest for the C group, intermediate for the LS group and largest for the S group. There was actually less within subject variability in peak aperture for the LS and ULS groups in comparison to the C group, perhaps indicating a limited repertoire of potential motor responses. These results are discussed in terms of the role of the frontal lobes in reaching and grasping, and the ability of schizophrenic individuals to use redundant information. (Supported by NSERC).

UPPER EXTREMITY RHYTHMIC MOVEMENTS: EFFECTS OF ARM POSITION AND FATIGUE ON DYNAMICAL PATTERN SWITCHING AND MUSCLE COACTIVATION. S.M. Tuel^{*}, W.B. McKay, D.N. Surber, and A.M. Sherwood, Department of Physical Medicine and Rehabilitation and Division of Restorative Neurology and Human Neurobiology, Baylor College of Medicine, Houston, TX, 77030.

Dynamical analysis of coordinated movements of the fingers have shown evidence of multistability and nonlinearity. As rate of cycling increases, loss of stability and pattern switching occur. We examined how these effects occur in whole arm movements during two different forearm positions, pronated and supinated, and in the rested and fatigued states.

Subjects were asked to trace a figure-8 on a digitizing tablet using a writing cuff to stabilize pen position. Surface EMG was obtained from the pectoralis, infraspinatus, biceps, triceps, wrist flexors and extensors. Subjects smoothly increased the rate of tracing until pattern switching occurred.

The critical frequencies for pattern switching depended on the position of the forearm, the orientation of the figure-8, and the direction of movement. EMG analysis indicated that the majority of control occurred in the proximal muscles at slow speeds, but distal activity increased with speed. Coactivation reached a maximum just before the pattern switch, followed by a change of EMG activity from tonic to more phasic. Fatigue decreased the critical frequencies and shortened the latency of coactivation, but does not appear to alter the relationship between those characteristics.

IMAGE PROCESSING MEASUREMENT OF EYE MOVEMENTS IN HUMANS AS A VIABLE ALTERNATIVE TO SCLERAL SEARCH COILS. S.T. Moore², T. Haslwanter¹, I.S. Curthoys¹, G.M. Halmagyi^{2*}. ¹Dept. of Psychology, University of Sydney, NSW, 2006.

²Royal Prince Alfred Hospital, Camperdown, NSW 2050. Australia.

Up to now, scleral search coils have been the only way to measure 3-dimensional eye position in human subjects accurately. The main disadvantages of search coils are the need to wear a contact lens, and the cost of the coils. To overcome these disadvantages, our group has developed an image processing technique for measuring 3-dimensional eye position "VTM", which is based on commercially available video cameras and personal computers. Horizontal and vertical eye position are determined by tracking the center of the pupil; torsion is obtained by measuring the amount of rotation of a segment of the iris about the pupil center. We found that it is possible to express eye position accurately in a manner analogous to coils, i.e. in rotation vectors or Euler angles, if we take into account the geometric distortion of the video image of the eye when calculating eye position. Neglecting this image distortion leads to large errors in measured ocular torsion. We present a summary of the techniques used, the effects of the correction algorithms, and show experimental data, for example Listing's Plane, obtained with this video system.

THE INFLUENCE OF GRASPING SURFACE CONTOUR ON PREHENSION. P.L. Weir^{*}, & S. Desjardins-Denault, Dept. of Kinesiology, University of Windsor, Canada, N9B 3P4.

Altering the size of the grasping surface has shown that smaller contact surfaces require greater precision (Weir, Desjardins-Denault, & Gyurcsik; 1993). However, kinetic measures remain unchanged with the exception of peak load force over the transport phase which decreased with surface size. Weir (1991) reported that changing the contour of the grasping surface from flat to curved effectively reduced the surface area contacted. This decrease in surface area produced kinematic differences, but the forces associated with the movement were not examined. The question then becomes: Does changing the contour of the grasping surface alter the forces associated with the reach to grasp movement?

Subjects were required to reach over a 20 cm distance to contact and grasp a force transducer dowel, and transport it an additional 20 cm to place it centred over a target. The contact plates were 2.5 cm² and 2 cm apart with one set of the plates being flat and the other curved. The movement was divided into four phases: free motion, dowel acquisition, dowel transport and release (Weir, 1991).

The contour of the grasping surface had no effect on the free motion phase. However, over the dowel acquisition phase, the rate of both load and grip force application was lower for the curved plate than the flat plate. This paralleled the finding that subjects contacted a smaller surface area on the curved plate. Peak velocity and deceleration were lower for the curved plate over the dowel transport phase, suggesting that a less stable grasp had been effected. The findings during the dowel release phase paralleled those of the acquisition phase. Subjects released the curved plate over a longer period of time, with a lower rate of grip and load force release. These results suggest that altering the contour more profoundly influences the performance of the movement in the phases that occur after contact. (Supported by NSERC)

A METHOD OF ANALYSIS TO DETECT AND CHARACTERIZE UPPER LIMB CONTROL DEFICITS IN SUBJECTS WITH STROKE. PA Genova, CA Giuliani^{*}, KE Light. Motion Analysis Laboratory, UNC CH, Chapel Hill, NC 27499-7153

The purposes of this study were to develop measurements based upon dynamic systems analysis and nonlinear dynamics for quantifying trajectory dynamics of rapid reciprocal limb movements and to characterize limb control deficits in subjects with stroke. Twenty five subjects with CVA (12 left, 13 right) and 25 age and gender matched non-disabled (ND) subjects were tested performing a vertical tapping task. All subjects were videotaped for 2-D analysis tapping as fast as possible with a stylus on a 3 inch target for 10 seconds. The trajectory of the stylus was digitized at 60 Hz and the data were 4 times upsampled through Fourier interpolation. Variables included: cycle period, peak vertical position, up and down velocities, the ratio of amplitude/velocity slopes, the ratio of acceleration to deceleration duration for upstroke and downstroke, the ratio of maximum to average velocity for upstroke and downstroke, Pearson's r coefficient for return maps of cycle period and peak amplitude, and harmonic magnitude ratio (HMR). Subjects with CVA had lower tapping frequencies ($p < 0.003$) than ND subjects and exhibited spatial and temporal asymmetries between upstroke and downstroke that were markedly different than those of the ND subjects. Return maps of peak position showed significant ($p < 0.003$) differences in the control of successive peak vertical positions due to dominance, and to the presence of right and left brain lesions. Significantly higher values for HMR were seen for dominant limbs of ND subjects, and for ND subjects compared to subjects with CVA. High values for HMR may represent minimum jerk movements. The results of this study suggest that these analyses captured the movement dynamics of the stylus trajectory and are sensitive to subtle differences in upper limb control between dominant and non-dominant limbs in ND subjects and between involved and uninvolved limbs of subjects with CVA.

FRICTION, NOT TEXTURE, DICTATES GRASP FORCE USED IN OBJECT MANIPULATION. Geneviève Cadoret* and Allan M. Smith. Centre de Recherche en Science Neurologique, Université de Montréal, Québec, Canada, H3C 3J7

A study of grasping and lifting in 10 subjects indicated a capacity to detect the friction of surfaces of a grasped object against the skin and adjust dynamic and static grip forces accordingly. Test surfaces, were composed of smooth or 1.0 mm raised beads spaced at 2.0 or 3.0 mm intervals etched in polyamide plastic. In addition, the surfaces were treated with lubricant (e.g. talc) or adhesive (e.g. water or sucrose) coatings which either increased or decreased the coefficient of friction. Changes in friction were associated with appropriate and inversely scaled changes in grip force. Both the dynamic grip force used to lift an object, as well as the static force used to hold it against gravity were negatively correlated ($r = -0.70$) with the coefficient of friction. Surface texture was only effective in changing grip force insofar as it altered the surface friction. Lubricants had less effect on the coefficient of friction of textured surfaces because of the smaller area in contact with the skin. Conversely, adhesives increased the friction of the smooth surface more than the beaded surfaces. The grip forces for all subjects reflected changes in the coefficients of friction and ignored the changes in surface texture. When coatings were used to equate different textures to the same coefficient of friction, the grip force profiles were nearly identical. This research was supported by the Medical Research Council of Canada and a fellowship from FCAR groupe de recherche sur le système nerveux central.

DISCRETE POINTING MOVEMENTS IN ALZHEIMER'S DISEASE: EVIDENCE OF PRESERVED AND IMPAIRED MOTOR CONTROL J.D. Fisk*, K. Rockwood, C.E. Maxner, K. Stadnyk, and D. Tripp. Dalhousie University and Camp Hill Medical Centre, Halifax, N.S., Canada

This study employed a kinematic analysis of visually directed upper limb movements in an unconstrained pointing task, to see if characteristic deficiencies in the performance of Alzheimer's disease (AD) patients could be identified. Groups of young controls, elderly controls, and patients with clinically probable AD were asked to point to small or large light targets, that were presented randomly in one of 4 locations, and that were illuminated either for 300 ms or until the target screen was contacted. For some blocks of trials the subjects were asked to point 'as quickly as you can' while for others, they were asked to point 'as accurately as you can'. All groups showed the same pattern of changes in their motor behaviour in response to the trial-by-trial changes in target characteristics. Although both control groups demonstrated changes in peak velocity, duration of deceleration, and accuracy with changes in the instructions, the AD group failed to modify their performance in accordance with the changes in the objectives of the task. This study illustrates that impairments analogous to those revealed on cognitive neuropsychological tasks may be evident in the motor planning and execution of relatively simple reaching tasks.

SYNCHRONIZATION AMONG MOTONEURON POOLS DURING DIFFERENT PHASES OF CAT REACHING. M. L. McCurdy*, T. M. Hamm, and K. M. Horn. Division of Neurobiology, Barrow Neurological Institute, Phoenix, AZ 85015.

Coherence spectra reveal the strength of synchronization between coactive neurons or nerves and are used as evidence of common synaptic input (Christakos et al., 1991; Farmer et al., 1993). Coherence analysis of electromyographic records collected from elbow, wrist and digit muscles during a reaching task from one cat was used to determine synchronization during reach, grasp, hold and stance phases. Significant coherence was observed at lower (<20Hz) and higher frequencies. Stronger coherence at high frequencies was present between proximal and distal muscles during the reach phase than during the grasp phase. Coherence at high frequencies was also found in comparisons among digit muscles or digit and wrist muscles during reach, grasp and hold phases, but not the stance phase. These findings suggest that there are common inputs to motor pools involved in the reaching task. In addition, inputs may differ during various phases of movement. Direct descending projections from the red nucleus to digit pools (McCurdy et al., 1987) may account for coherence among distal limb pools while interneuronal pools projecting to both proximal and distal pools may be important during the reach phase. THE EFFECTS OF GRADED TACTILE ANESTHESIA ON THE CONTROL OF GRIP FORCE. K.J. Cole*. The University of Iowa, Iowa City, IA 52242.

Tactile sensory information from the hand appears to provide information about discrete mechanical events during manipulation of objects (Johansson, R.S. In Humphrey, D.R., Freund, H.J. *Motor Control: concepts and issues*. Wiley, New York, pp. 331-355, 1991). One prediction from this theory is that altered fingertip forces are unlikely at mild levels of tactile anesthesia. A sufficient population of afferents should remain to encode the necessary mechanical information. Tactile anesthesia of the hand was induced by variably compressing the median nerve at the palm in three subjects. Median nerve function was monitored by recording the compound sensory nerve action potential (SNAP) at the finger from electrical stimulation of the nerve at the wrist. The forces at the fingertips (normal and tangential, corresponding the grip and lift forces) were recorded as subjects lifted an object using the thumb and index finger. Reductions in SNAP amplitude of 20-30% yielded small but significant decreases in tactile sensibility. Fingertip forces were normal in their size and timing in all subjects. Substantial increases in grip force occurred when SNAP amplitudes were reduced by 50% or more. No subject could detect cotton stroked on the fingertips and all reported that their hand felt 'thick'. Grip forces returned to precompression levels when SNAP amplitudes returned to 70% of normal. These observations are consistent with the theory of discrete event sensory-driven control of grasp.

DETERMINING CONSISTENCY OF ELBOW JOINT THRESHOLD ANGLE IN SPASTIC MUSCLES. S.L. Wolf*, P.A. Catlin, R.L. Segal, P. Pate, T. Raleigh, J. Tschorn, and H. Watson. Div. Physical Therapy, Emory Univ. Sch. of Med., Atlanta, GA 30322.

Valid measurements of spasticity are needed to evaluate effectiveness of therapeutic interventions. The angle at which EMG onset to passive muscle lengthening (threshold angle) occurs has been suggested as a measure of spasticity. However the conditions under which consistency in threshold angle responses within subjects occur must be determined. This study determined the effect of starting joint position and velocity of stretch (provided from a torque motor) on threshold angle within and between subject. Two starting angles and 2 stretch velocities (the conditions) were randomly assigned at each of three testing sessions among 5 patients with spastic hypertonia. Threshold angle was determined from biceps and brachioradialis EMG responses. Starting angle, subject, and session produced a significant effect on threshold angle ($p < .05$). A 90° starting angle and a 1.0 rad/s velocity stretch yielded the most consistent threshold angles between sessions within subjects. If data from these subjects can be extended to more patients with spastic hypertonia, then ability to use threshold angle to measure spasticity consistently should depend on: comparison within individuals, use of a consistent starting angle, and use of condition 90° and 1.0 rad/s across sessions.

IS ACCURACY IN POINTING INFLUENCED BY DISTURBANCES TO POSTURAL KINESTHESIS?

S. Prentice and J.S. Frank*. Dept. of Kinesiology, Univ. of Waterloo, Waterloo, Ontario, Canada, N2L 3G1.

Vibration of the posterior postural muscles is known to cause illusions of falling forward. In a previous study, we demonstrated that this illusion affects one's ability to locate a target in space: the arm's position became elevated in the presence of Achilles tendon vibration. This study further investigates the relationship between postural kinesthesia and the performance of a goal-directed arm movement. Subjects ($N=7$) stood in the dark and pointed to a 5x5 matrix of diodes. Only those diodes located in the vertical midline were analysed. Bilateral vibration of the Achilles tendon was initiated after the target diode had been extinguished. In the previous study, vibration was present during target illumination. All movements were initiated with the arm at the subject's side, and targets were located 20° and 5° above and below a shoulder angle of 90°. Trials were randomized with respect to presentation of target diode and vibration, with each combination being presented only once. Joint angles (Optotrak) and center of pressure data confirmed that subjects tended to lean backwards in response to the illusion of falling forward, which was induced by the vibration. The trunk orientation remained unchanged in the presence of vibration. Vibration also had no effect on the final position of the arm or on the accuracy of the pointing movement. The absence of any arm adjustments may be attributed to the effects of vibration on the perceived target location rather than postural orientation. Since vibration was not on during target illumination, there was not a false impression of target location and an accurate pointing movement was achieved. Thus, it appears that postural kinesthesia has a limited contribution to pointing movements when gravitational cues are present, and perception of target location dictates the pointing movement.

RELATIONSHIP BETWEEN THE SITE OF LESION AND THE REGULATION OF STANDING POSTURE DURING REACHING MOVEMENTS IN STROKE PATIENTS. M.C. Verrier*, D.R. Fogal Smith, C.D. MacKinnon, S.H. Dick, J.A. Howe, and C. Diep. Departments of Physical Therapy and Physiology and the Queen Elizabeth Hospital, University of Toronto, Toronto, Ontario, Canada M5T 1W5.

Previous work in our lab has shown a predictable pattern of ground reaction forces (GRFs), center of pressure (CP) and postural muscle activity (EMG) during visually cued fast-paced focal reaching movements in normal subjects. Following stroke, GRFs were prolonged and decreased in amplitude, CP excursions were both decreased and abnormal and postural muscle activation was delayed and had increased variance. In contrast to the literature, we found that patterns of muscle activation were variable and subject-specific in stroke. Moreover, muscle activation patterns were not related to pre-established clinical postural measures, but appeared to relate to the site of lesion (cortical (C) versus basal ganglia (BG)). We postulated that C lesions would have decreased reaction time/movement time ratios (RT/MTs) compared to normals indicative of disordered movement execution whereas BG lesions would have increased RT/MTs indicative of disordered movement preparation.

Current studies show that RT/MTs are 14% lower for the C's and 11% higher for the BG's in comparison to controls. C's are unable to activate contralateral distal postural muscles whereas BG's are able to activate bilateral postural muscles but with inappropriate temporal sequencing. These findings support lesion specific sensorimotor processing deficits in postural regulation associated with goal-directed movements. Subject specific 3-D lesion reconstructions using MRI and differences in postural muscle activation strategies are presented for subjects with C and BG lesions during both cued and self-initiated fast reaching movements.

EFFECT OF SURFACE TEXTURE ON THE PERCEPTION OF WEIGHT WHEN LIFTING WITH A PRECISION GRIP. J. R. Flanagan*, A. M. Wing. Teachers College, Columbia University, New York, NY 10027 and MRC Applied Psychology Unit, Cambridge, UK

We investigated the effects of surface texture (satin and sandpaper) on perceived weight in a task in which subjects lifted a reference object and then a test object with the same hand using a precision grip with the tips of the thumb and index finger at the sides. Subjects judged objects covered in satin to be heavier than objects of equal weight covered in sandpaper. Because the grip force required to lift the more slippery satin objects is greater than that required to lift the sandpaper objects, these results suggest that the effect of texture on perceived weight may be due to grip force; the greater the grip force, the heavier the perceived weight. This conclusion was supported by a control study in which subjects grasped objects with the index finger and thumb above and below the object so that different grip forces for the two textures would not be required. In this case, there was no effect of texture on perceived weight. The implications of these results with respect to sensorimotor memory are considered.

CONTROL OF MULTIJOINT ARM MOVEMENTS IN HUNTINGTON'S DISEASE. L.A. Quinn, V. Hamel, J.R. Flanagan, T.R. Kaminski*. Teachers College, Columbia University, NY, NY 10027.

Multijoint arm movements of individuals with Huntington's Disease (HD) were examined using 3D kinematic analysis. Six HD subjects with moderate chorea and 4 age-matched healthy subjects performed rapid pointing movements to 1" target located at 3 distances, 2 of which required trunk motion. HD subjects were divided into high and low functioning groups (HF and LF) based on the Barthel index. Movement times of HD subjects were longer than healthy subjects ($p=.005$). All HD subjects had similar curvilinear hand paths, which were not reflective of an inability to move shoulder and elbow joints simultaneously. However, LF subjects showed greater variability in the hand paths and shoulder/elbow coordination, particularly in the farthest target which required substantial trunk movement. Whereas the movements of healthy subjects featured unimodal hand tangential velocity profiles, the movements of HD subjects were multimodal. For the HF subjects, a large initial movement was followed by smaller submovements (SM's) as the subject honed in on the target. Moreover, the peak velocity and amplitude of the initial movement scaled with target distance. The velocity profiles of the LF subjects were more variable, especially for the farthest distance, where they exhibited a higher number of SM's than the HF subjects. Additionally, the LF subjects did not scale peak velocity to displacement. Presence of SM's in all HD subjects could be due to impaired force modulation, or to factors such as slowness of movement and greater accuracy constraints, as previously observed in healthy subjects (Milner & Ijz, *Neuroscience*, 1990).

EFFECTS OF PRACTICE ON THE CONTROL OF RECIPROCAL AIMING MOVEMENTS POST-STROKE. P.S. Pohl* and C.J. Winstein.

Univ. of S. Calif, Dept. Biokinesiology & Physical Therapy, L.A., CA 90033.

Changes in control of aiming movements as a function of practice have been characterized in healthy, young adults (e.g., Proteau & Cournoyer, 1990), but the literature is silent about practice effects on these movements in adults with brain damage. Subjects with unilateral cerebral lesions have demonstrated differences in performance and control of aiming movements dependent on the side of the lesion, suggesting that each hemisphere has a specialized role in motor control (Haaland et al., 1987). The purpose of this study was to investigate the differential roles of the hemispheres in the control of aiming movements over practice. Two groups of right-handed adults with unilateral stroke (right-RS and left-LS) practiced a reciprocal aiming task in two conditions of task difficulty. Using the ipsilesional arm, subjects performed 10 s trials until they accumulated 500 target hits in each condition. Compared with the LS group, the RS group required more trials due to a higher error rate. Movement time group differences were largest early in practice. Kinematic analyses revealed differences in control strategies over practice. Overall, subjects increased horizontal velocity, especially in the less difficult condition. Control of the vertical dimension revealed group differences which increased over practice. In contrast to the persistent low vertical target impact of the LS group, over practice the RS group appeared to use impact to minimize reversal time. The inability of the LS subjects to optimize the reversal despite practice is consistent with the role of the left hemisphere in the sequencing of actions (Winstein & Pohl, 1994). To address the effect of handedness, healthy controls were tested and their performance was compared to that of those post-stroke.

AUTOMATIC ADJUSTMENTS OF REACHING MOVEMENTS TO A TARGET THAT MOVES UNPREDICTABLY. B.L. Day* & I.N. Lyon. MRC HMBU, Institute of Neurology, Queen Square, London WC1N 3BG, UK.

We have investigated the limb adjustments that occur when reaching for a target that moves and how these responses are modified by the subject's intent.

Subjects ($n=8$) reached out to touch a disc of light projected on to a screen in front of them. In a third of the trials, approximately 25ms after movement onset, the disc moved either to the left or the right. Subjects were required either to continue trying to point to the disc (P+) or to point in the opposite direction as soon as they perceived it to move (P-). This was contrasted with a reaction task in which subjects held their right index finger stationary in front of them. When the disc moved, they had either to follow it (R+) or move in the opposite direction (R-). The position of the finger tip in space was recorded at 5ms intervals (SelspotII).

In all conditions, when the disc moved, the finger tip began to move in the same direction approximately 130ms later. However, in the P- and R- conditions, this was followed by a second response in the opposite direction, at approximately 200ms. The magnitude of the early response was measured by calculating the lateral deviation of the finger during the period 130-190ms and finding the difference between target left and target right trials. These magnitudes were (mean \pm SEM): P+ 18.1 ± 4.4 mm; P- 9.3 ± 2.5 mm; R+ 2.3 ± 0.8 mm; R- 0.7 ± 0.2 mm.

The results show that arm movements can be adjusted at short latency by a moving visual stimulus. The fact that the early response was not suppressible by voluntary intent may suggest that it is an automatic or reflex component. The early response was much larger during a reaching movement than in the reaction task which indicates that the mechanism is task-dependent.

490.16

ADAPTATION TO CORIOLIS FORCE PERTURBATIONS OF REACHING MOVEMENTS IN THE BLIND. J.R. Lackner*, R. Easton*, E. Bentzen*, P. DiZio*, Ashton Graybiel Spatial Orientation Laboratory, Brandeis University, Waltham, MA 02254 and *Psychology Department and *School of Education, Boston College, Chestnut Hill, MA 01267.

Forward reaching movements during passive, constant velocity, counterclockwise body rotation (10rpm) generate Coriolis forces that deviate the arm to the right. As a movement slows down the Coriolis force abates and the arm trajectory bends back toward the intended path but still ends significantly to the right of pre-rotation endpoints. Normal subjects regain straight line trajectories and accurate endpoints, without tactile feedback about target location, within ~20 reaches in darkness and 6 with sight of the arm. We exposed five congenitally blind subjects to Coriolis forces as they attempted to reach forward along their perceived body midline (distance, 32cm; peak velocity, 620mm/s). Relative to pre-rotation their movement trajectories were deviated rightward 55mm, peak, and ended 47mm right. After 20 reaches their endpoints were again accurate and movement trajectories straight. Thus, blind subjects adapted to Coriolis force perturbations of their arm movements as well as sighted subjects denied vision. Vision is clearly not essential for motor adaptation to altered inertial characteristics of arm movements. Brachial proprioceptors, cutaneous receptors and efferent commands must be providing the information used to tune arm trajectory and endpoint.

INEQUIVALENCE OF DIRECTION AND EXTENT PRECUE EFFECTS ON REACTION TIME. J.G. Anson,¹ J.R. Wickens,² B.I. Hyland,³ & R. Köster.⁴ ¹Schl. of Physical Education, ²Dept. of Anatomy & Structural Biology, ³Dept. of Physiology & ⁴The Neuroscience Res. Centre, U. Otago, New Zealand, ⁴Inst. f. Hirnforschung, U. Düsseldorf, Germany.

In a reaction time task with two possible directions and two possible extents in each direction, direction and extent cues would be considered equivalent in information-theoretic terms: Precue information about direction should have the same effect on reaction time (RT) as information about extent. Eight subjects performed a wrist pronation/supination RT task to one of two possible extents in each direction. One, two or four targets were lit prior to the GO signal to give five different conditions: (i) a single target lit specifying direction and extent; two targets lit specifying (ii) direction only, (iii) extent only, or (iv) a choice of two direction-extent combinations; and (v) four targets lit. Subjects performed 320 trials per condition in four sessions of four blocks (100 trials each, 20 in each condition, randomly mixed) recorded on different days. Results showed that direction precueing was associated with significantly greater RT benefit (shortening) than extent. Precueing extent but not direction was no more beneficial than giving a choice of two different yet completely specified targets, but did offer an advantage compared to conditions in which no precue information was available. These results indicate an inequivalence in the way that information about direction and extent are represented in the brain. They are consistent with a model of motor programming in which movements involving antagonist groups of muscles are represented by different cell assemblies while level of activation within an assembly encodes movement extent.

CHORNOBYL VERTIGO: DIAGNOSTICS AND TREATMENT. K. Trinius,*G. Meshcheriakov. BCA, Kiev.

We have examined 167 patients. Almost all the patients have complained of vertigo episodes which lasted more than 1 minute and have appeared more frequently than once per week. The episodes have resulted or been augmented with the head movements and body position changes. Vertigo is accompanied with headaches, sweating, vascular disorders, cardiac symptoms. Among frequent complaints there have been nausea with vomiting up to consciousness losses (40%), which might be the index of the seriousness of illness. Specific vestibular tests have shown the sign of alteration: Uemura up to 2.9, Fucuda stepping-1.3, Fucuda writing-1.3, Tracking-1.5, Indication-1.7 and Complaints-2.7. Vestibular evoked potentials have shown the increase of all the peaks latencies up to: P1-44.6 ms, N1-95.6 ms, P2-154.6 ms. We have not found the differences in the symptoms between former inhabitants of Pripiat (41 persons), clean-uppers living now in Donetsk (29 persons) and inhabitants of Kiev (32 persons). The treatment with the specific vestibular drugs (Arlevert; EGE-761-Rokan, Tanakan; Vertigoneel) has the positive effect in up to 80% of cases.

BIMANUAL COUPLING IN DIRECTION IS EXHIBITED WHEN AN AMPUTEE PRODUCES CONCURRENT MOVEMENT WITH THE INTACT LIMB AND THE PHANTOM LIMB. E.A. Franz,* R.B. Ivry, and V.S. Ramachandran. University of California, Berkeley, CA 94720.

Normal subjects exhibit spatial coupling in movement trajectories when movements of different directions are combined in a bimanual task. We investigated whether subjects with an amputated limb experience similar coupling in the movement trajectories of their intact limb when making simultaneous imagined movements with the missing limb. Two subjects with amputation of the proximal third of the right humerus were tested. One of the amputees experiences a vivid phantom limb experience, whereas the other has no sensation attributed to the missing limb. The subjects were asked to produce lines in the vertical direction by drawing on a digitizing tablet with the intact limb flexing and extending at the wrist. These lines were produced in single-limb conditions and in combination with an imagined movement which was in the same direction as the intact limb movement, or in the horizontal direction (pronation-supination movements at the wrist). For the amputee with a phantom limb experience, the vertical trajectory of the intact limb deviated from its intended path when the phantom limb produced a horizontal trajectory. In contrast, the amputee without a phantom limb produced no such spatial interference. The results suggest that imagined movements of a phantom limb interact with central pathways in planning the spatial trajectory of the intact limb movement. This coupling can not be explained by interference due to imaging two tasks at once. Phantom limb sensation appears to be necessary for spatial coupling to occur.

OPTICAL RECORDING OF THE TRITONIA SWIM NEURAL NETWORK. G.D. Brown*, S. Yamada, M. Nakashima, A. Watanabe, and S. Shiono. Central Research Laboratory, Mitsubishi Electric Corporation, Amagasaki 661, Japan.

The escape swim response of the nudibranch mollusc *Tritonia* and the underlying swim neural network (SNN) have been used to study the neural bases of rhythmic movement and of behavioral plasticity. However, some elements of the SNN are still hypothetical (Gettings, 1983). We have undertaken a study of the SNN using optical recording to determine if the current model of the SNN is correct and to find missing elements. Previously, the gastropod *Aplysia* has been used in optical recording studies by L. Cohen and coworkers and by us. In general, signals from neurons in the isolated brain of *Tritonia* are bigger and have a better signal to noise ratio than signals from the *Aplysia* abdominal ganglion when using the voltage sensitive dye RH155.

Many *Tritonia* SNN neurons fire periodic bursts of action potentials in the isolated brain preparation and their optical signals are easily recognized. Based on their swim-like bursting patterns, we have identified a set of candidate SNN neurons including most previously identified neuron types. Although the data analysis is ongoing, it is clear that flexion neuron motor pools are bigger than previously reported (Hume et al. 1982). We have also located a neuron which bursts in phase with the swim neural program and which may be an unidentified part of the SNN, perhaps part of the central pattern generator (CPG) for swimming. Another group of neurons bursts strongly at the beginning of the swim program but does not fire in phase with the CPG, a pattern predicted for a group of cells which produce the ramp depolarization in CPG interneurons. We are currently using conventional electrophysiological techniques to determine if these candidates are actually part of the SNN.

491.2

THE EFFECTS OF NEUROMODULATORS ON THE DYNAMIC INTERACTIONS BETWEEN VOLTAGE AND Ca^{++} DEPENDENT SYSTEMS IN A MODELED BURSTING NEURON. R. J. Butera, J. W. Clark, C.C. Canavier*¹ and J. H. Byrne¹. Dept. of Elec. & Comp. Eng., Rice U., Houston, TX 77251 and ¹Dept. of Neurobiology & Anat., U. of Tex. Med. Sch., Houston, TX 77225.

A major action of second messenger systems is the modulation of the electrical properties of neurons. The effects can be complex, however. A single second messenger can directly modulate several types of ionic currents in a cell and these currents may indirectly affect other currents via voltage-dependent or Ca^{++} -dependent mechanisms. Thus, in order to understand these global actions of modulatory agents, it is necessary to have a detailed understanding of all of the membrane currents and their modulatory influences. One neuron which meets these criteria is the endogenously bursting neuron R15 in *Aplysia*.

We have implemented proposed mechanisms for the modulation of two ionic currents (I_R and I_{SR}) associated with a model of R15. The model is sufficient to simulate a wide range of endogenous behavior in the presence of various concentrations of serotonin (5-HT) or dopamine (DA). Additional insights into the consequences of modulation of multiple currents were obtained by placing the model into a silent or beating mode by various methods and examining the model's response to extrinsic stimuli. Some of these insights were obtained by examining the Ca^{++} -dependency of I-V plots. Also, by selectively "clamping" specific variables within the model we were able to elucidate mechanisms through which depolarizing and hyperpolarizing pulses can terminate beating and elicit a sustained (8-10 sec) poststimulus hyperpolarization. The results suggest that the actions of modulatory agents and second messengers cannot be understood on the basis of their direct effects alone. It is also necessary to take into account their indirect effects on other unmodulated ion channels which occur through the dynamic interactions of voltage-dependent and Ca^{++} -dependent processes.

SEROTONIN REGULATES THE ELIGIBILITY FOR MULTIMODAL ACTIVITY IN THE BURSTING NEURON R15 IN *APLYSIA* H.A. Lechner, D.A. Baxter, J.W. Clark and J.H. Byrne*. Dept. of Neurobiol. and Anatomy, Univ. of Texas Medical School at Houston, TX 77030, Dept. of Electrical and Computer Engineering, Rice University, Houston, TX 77251-1892.

Simulations of a mathematical model of the bursting neuron R15 in *Aplysia*, revealed that multiple stable modes of oscillatory electrical activity can coexist at a given set of parameters, that transient synaptic inputs can induce a persistent shift from one mode to another and that modulatory transmitters can regulate multimodal activity (Canavier, 1993).

Intracellular recordings from R15 revealed that long lasting changes in spike activity can be induced by brief (0.5 - 1.5 s), depolarizing (5 - 10 nA) or hyperpolarizing (-10 to -20 nA) current pulses, as predicted by the model. Under certain conditions such perturbations were able to switch the electrical activity of R15 between bursting and beating. The beating persisted for varying durations ranging from ~30 sec seconds up to ~40 min. The effect of perturbations was dependent on two factors, steady-state bias current and the presence of serotonin (5-HT). Perturbations were ineffective for bias currents of <0.5 nA, whereas 30 - 40 % of the perturbations triggered transitions from bursting to beating with bias currents >1 nA. In the presence of 5-HT (2.5 μ M), multistability was observed at lower levels of bias current. With a bias current of -0.5 nA transitions to beating were triggered in 60 % of the cases, and with bias currents >1 nA 40 - 50 % of the perturbations induced transitions.

We conclude that both 5-HT and depolarizing bias currents can regulate the eligibility of R15 for mode shifts, and thus may alter its sensitivity to synaptic input.

EVIDENCE THAT SEROTONERGIC NEUROMODULATION INTRINSIC TO THE *TRITONIA* SWIM CPG IS DUE TO PRESYNAPTIC ENHANCEMENT OF RELEASE. P.S. Katz* and W.N. Frost. Department of Neurobiology & Anatomy, University of Texas Medical School, Houston, TX 77030.

One of the neurons in the central pattern generator (CPG) for escape swimming in the mollusc *Tritonia diomedea* evokes neuromodulatory effects upon other members of the CPG. We previously reported that stimulation of one dorsal swim interneuron (DSI) enhances the size of synaptic potentials evoked by neuron C2 onto two followers: the dorsal flexion neurons (DFN) and other DSIs (Katz et al., *Nature* 367:729-731, 1994). Our evidence now suggests that this neuromodulation is mediated by effects on the presynaptic neuron (C2) rather than on its followers. 1) DSI enhanced the chemical synapses (both excitatory and inhibitory) of C2 onto each of its followers which have been tested, including the ventral swim interneurons (VSI), DSI, DFN, and pedal cells not directly postsynaptic to DSI. 2) DSI evoked little or no change in R_m recorded in the somata of C2 followers. 3) DSI-evoked modulation did not affect the E_{rev} of the synapses. 4) If the effect were postsynaptic then inputs from other neurons onto the follower might be enhanced, yet DSI stimulation did not enhance the synapses from other DSIs onto the same C2 follower, but instead caused them to decrease.

Although the mechanism producing the presynaptic enhancement is not known, possible mechanisms are suggested by the following observations. Stimulation of the serotonergic DSIs decreased the after-hyperpolarization (AHP) following C2 spikes. Likewise, exogenous serotonin also caused the C2 AHP to decrease. The decrement in AHP may be related to presynaptic currents involved in transmitter release. Preliminary results indicate that DSI stimulation also may interact with the homosynaptic facilitation of transmitter release from C2. (This work was supported by NIH grant MH49563.)

CALCIUM PLATEAUS AND GRADED SYNAPTIC TRANSMISSION IN LEECH HEART INTERNEURONS. Ø.H. Olsen, F. Nadim, and R.L. Calabrese*. Dept. of Biology, Emory University, Atlanta, GA 30322.

Pairs of reciprocally inhibitory neurons in the leech CNS form the oscillator that controls the frequency of the heart rhythm. These pairs oscillate in antiphase, generating bursts with underlying plateaus and both graded and spike-mediated postsynaptic transmission. To find the extent to which low-threshold Ca currents contribute to plateaus and determine the duty cycle of the graded synaptic transmission, we voltage-clamped such a neuron with a voltage waveform that was obtained by removing the spikes from real waveforms. Its post-synaptic cell was simultaneously voltage-clamped at -35 mV and showed the graded postsynaptic current associated with these presynaptic oscillations. The same experiments were also performed in a detailed conductance-based model of the two cells. The results confirmed the predictions of the model: the rise of the plateau cannot be completely accounted for by the Ca currents only. Thus other inward currents like the persistent Na current and the hyperpolarization-activated inward current (h) contribute in the process of building the plateau. The duty cycle of the graded synaptic transmission proves to be smaller than 0.5, thus suggesting that the spike-mediated transmission is necessary to produce the observed prolonged inhibition.

These results are supported by further experiments in Na -free saline where the persistent Na current and h -current were reintroduced through dynamic-clamp (Sharp et al., *TINS* 16: 389, 1993). To obtain non-spiking oscillations, it was necessary to add these currents, thus demonstrating their role in triggering the plateau. The period of these oscillations is shorter than that observed in normal saline where the graded synaptic transmission is supplemented with spike-mediated transmission.

DETERMINATION OF SYNAPTIC POLARITIES USING A COMPUTATIONAL CELLULAR MODEL OF THE NEMATODE TAP WITHDRAWAL REFLEX. C.J. Roehrig,*¹ S.R. Wicks*, and C.H. Rankin³. ¹Dept. of Computer Science, ²Program in Neuroscience, and ³Dept. of Psychology, University of British Columbia, Vancouver, B.C., CANADA V6T 1Z4.

The nematode *C. elegans* is a tiny soil-dwelling worm which exhibits many behaviours found in higher vertebrates, such as reflex hierarchies, learning, and memory. Its genetics, neuroanatomy, and physiology are well understood to the point where it is possible to construct a model of a complete behaviour that includes every individual neuron and synapse.

We have previously constructed a computational model of the *C. elegans* tap withdrawal reflex. The model circuit consists of all 7 sensory cells and 6 pairs of interneurons which were found to play a role in the tap withdrawal reflex (Wicks and Rankin, 1992), together with a "gearbox" which models the motoneuron circuitry and mechanics which transduce the interneuron activity into locomotion. Based on biological evidence, we used a non-spiking, isopotential model of the neuron membrane potential and a tonic and graded model of synaptic transmission. Synaptic efficacy was inferred from anatomical data (White et al., 1986).

The polarities of the synaptic connections are as yet unknown and we have developed a strategy to use our model to predict these polarities. We computed the probabilities of different polarity combinations by testing the model's predictions against the behaviour of the living animal when several different neurons were ablated using laser microsurgery. In addition, we used a modified factorial design to determine interaction effects between connection polarities and other physiological parameters that describe membrane properties and synaptic activation kinetics.

491.6

IDENTIFICATION OF *TRITONIA* "RAMP" INTERNEURON: DRI NEURON RELAYS SENSORY INPUT TO THE ESCAPE SWIM CPG AND ALSO PARTICIPATES IN RHYTHM GENERATION. W.N. Frost* and P.S. Katz. Dept. of Neurobiol. & Anat., Univ. Texas Medical Sch., Houston, TX 77030.

Work by Getting and colleagues concluded that the key driving force for the oscillatory escape swim motor program in the marine mollusc *Tritonia* is a long-lasting declining ramp depolarization in the dorsal swim interneurons (DSIs) of the swim central pattern generator (CPG). A significant component of this depolarization was hypothesized to originate from unidentified "ramp" cells presynaptic to the CPG. Here we describe a neuron which is the source of the ramp depolarization in the DSIs. The dorsal ramp interneuron (DRI) elicited strong, fast epsps onto the DSIs ($n=11$). In response to a swim-inducing nerve stimulus, DRI fired intensely at the onset, and then at a lower, steadily declining rate throughout the swim motor program ($n=8$). Hyperpolarization of DRI during the nerve stimulus prevented both the swim motor program and the ramp depolarization in the DSIs ($n=5$). Tonic DRI depolarization elicited the swim motor program, which then continued for as long as DRI was active ($n=6$). These observations identify DRI as a "ramp" interneuron, and indicate that this single neuron has a key role in relaying sensory input to the *Tritonia* CPG.

DRI also had features not predicted by previous work. DRI: 1) fired in phase with the DSIs during the dorsal portion of the oscillatory swim motor program; 2) was excited by C2, and in fact appeared responsible for much of C2's polysynaptic excitatory synaptic connection to DSI in normal saline ($n=4$); 3) could reset the phase of an ongoing motor program ($n=1$); and 4) quickly halted an ongoing rhythm when hyperpolarized ($n=2$). These features indicate that DRI not only produces the ramp input to the CPG, it is also a component of the central pattern generator itself.

MODULATION OF OSCILLATIONS IN A MODEL OF LEECH HEART INTERNEURONS. F. Nadim*, Ø.H. Olsen and R.L. Calabrese. Dept. of Biology, Emory University, Atlanta, GA 30322.

The bursting oscillations underlying the heartbeat of the medicinal leech are generated by pairs of reciprocally inhibitory heart interneurons (HN cells). We have built a conductance-based Hodgkin-Huxley type model of a pair of HN cells using experimentally measured ionic and synaptic currents. The synaptic current in the HN cells has a graded component, which, in our model, is dependent on presynaptic Ca^{++} , as well as a spike-mediated component. Our Lab has previously shown that FMRFamide has neuromodulatory effects on the heartbeat rhythm by changing the shape and amplitude of spike-mediated IPSP's, and by shifting steady-state activation and inactivation curves of the K^+ currents. The effect of changing the shape and amplitude of the IPSP's in the model on modulating the period of oscillations is similar to the modulatory effects observed in the biological cells. We are in the process of analyzing the effect of shifting the activation curves of the K^+ currents in the model.

Even though the model cells are capable of oscillation merely with the graded component of synaptic transmission, the simulated oscillations closest to oscillations of the biological cells are dominated by the spike-mediated component. This suggests that spike-mediated transfer can play a dominant local role in a network of neurons that has large graded synaptic currents. The dominant role of spike-mediated transfer is significant in light of the fact that neuromodulation of the heartbeat cycle rate is directed, towards spike-mediated ipsp's and towards K^+ currents that affect spiking.

A HIGHER ORDER LOCOMOTOR INTERNEURON CAUSES DIRECT INHIBITION OF RESPIRATORY CENTRAL PATTERN GENERATING NEURONS OF *LYMNAEA*. T. Inoue, G. Spencer, N.J. Syed, K. Lukowiak, W. Wildering, S.U. Hassan*, and M. Takasaki#. Departments of Anatomy and Medical Physiology, University of Calgary, Calgary, Alberta, Canada, T2N 4N1. # Department of Anaesthesiology, Miyazaki Medical College, Miyazaki, Miyazaki, Japan, 889-16.

A pair of electrically coupled interneurons termed Left and Right Pedal Dorsal 11(L/RPeD11) was previously shown to control locomotor and/or whole body withdrawal behaviors of *Limnaea* (Syed and Winlow, 1991, JEB 158, 37-62). Since respiration and locomotion or whole animal withdrawal in *Limnaea* are antagonistic motor functions, reciprocal inhibitory connections must exist between the CPG neurons controlling these behaviors. This study demonstrates that the electrical stimulation of RPeD11 in an isolated brain preparation causes direct inhibition of respiratory interneurons RPeD1 and IP3L. Whereas, its effects on a third respiratory interneuron VD4, known to be involved in the termination of respiratory episodes, were biphasic. When cell VD4 was hyperpolarized to -70 to -80mV, the electrical stimulation of RPeD11 caused a strong depolarization of its membrane potential (10-20 mV). However, when VD4 was depolarized to its spiking threshold, RPeD11 stimulation induced spiking in this cell following a brief period of inhibition. The respiratory interneurons IP3L and VD4 on the other hand, inhibited the activities of neuron RPeD11. These connections persisted in salines containing high divalent ions. Furthermore, RPeD11 reestablished its specific synaptic connections with a number of cardio-respiratory neurons in culture, demonstrating further that they are monosynaptic in nature. This study provides first direct evidence for mutual inhibitory connections between respiratory and locomotor or withdrawal CPG neurons of *Limnaea*.

EFFECTS OF TEMPERATURE ON PROPERTIES OF LOCUST FLIGHT NEURONS: IMPLICATIONS FOR MOTOR PATTERN GENERATION. H. Xu* and R. M. Robertson. Dept. of Biology, Queen's University, Kingston, Ontario, Canada K7L 3N6.

Elevated temperature causes a mild increase in wing-beat frequency of flying locusts. This is mainly due to the global effects of temperature on neuronal properties of flight neurons in CPG circuits. Our previous investigation of flight motoneurons showed that an increase in conduction velocity ($Q_{10}=1.53$) and a decrease of membrane time constant ($Q_{10}=0.62$) were the major factors which might account for the increase of the central rhythm ($Q_{10}=1.28$). Hyperpolarization of the resting membrane potential ($Q_{10}=1.18$) and reduction in input resistance ($Q_{10}=0.54$) might be involved in automatic compensation for the effects of increased temperature. Also increases in temperature above room temperature decreased the amplitude of postsynaptic potentials (PSPs).

We have investigated how the change of resting membrane potential and the PSP amplitude contribute to the observed temperature effects on the frequency of the central rhythm. The temperature dependent hyperpolarization of flight neurons was mimicked by changing the K^+ concentration of the saline from 10 mM to 2 mM. After 5 mins low- K^+ superfusion, the resting membrane potential of flight motoneurons hyperpolarized from an average of -39.1 mV to -47.8 mV, while the frequency of the central rhythm decreased from an average of 10.1 Hz to 8.8 Hz. The temperature dependent change of PSPs recorded from flight neurons was mimicked by replacing normal saline with zero Ca^{++} /high Mg^{++} saline. Although the amplitude of PSPs was more than halved after 10 mins zero Ca^{++} /high Mg^{++} treatment, the frequency of the central rhythm changed minimally (<1 Hz). These results support the hypotheses that resting membrane potential directly affects the central rhythm, whereas synaptic strength could serve simply to trigger endogenous mechanisms of burst generation.

pH SENSITIVITY OF SPONTANEOUS NETWORK ACTIVITY OF MAMMALIAN NEURONAL CULTURES. S. R. Lauffer* and G. W. Gross. Dept. of Biological Sciences, University of North Texas, Denton, TX 76203.

The association of pH changes with normal and pathological neural activity, as well as the influence of pH on major ligand-gated ion channels, has been established in studies using single cell, slice, and animal models. However, pH effects on the activity of small networks in well controlled culture environments have received less attention. We investigated the effects of pH, close to and within the physiological range, on monolayer networks derived from embryonic mouse spinal tissue. Neurons were cultured on multimicroelectrode plates to permit extensive spatio-temporal monitoring of network activity. The pH was shifted by altering the CO_2 flow to bicarbonate buffered medium in the recording chamber and was continuously monitored. Spike data was stored on 14 channel analog tapes and integrated for chart recorder display. Preliminary observations indicate that spontaneous network activity is highly sensitive to pH over the explored range of 7.0 to 8.0. Using activity at pH 7.3 as reference, total spike production, as reflected by integrated burst area, fell as low as 1% at pH 7.2 and increased as much as 65% at pH 7.7. With increasing pH, burst frequencies increased as did the appearance of large complex bursts. This pattern reversed as pH was lowered, with large bursts disappearing below pH 7.2. Under bicuculline disinhibition (producing coordinated, regular bursting) a pH decrease from 7.4 to 7.2 caused both burst frequency and duration decreases of up to 40%. pH increases from 7.4 to 7.7 caused frequency decreases of up to 30%, but duration increases of up to 40%. This degree of pH sensitivity necessitates that quantitative studies of network dynamics be performed in a well controlled pH environment. In addition, pH may be a useful variable in determining burst initiation and burst maintenance mechanisms.

INTERACTIONS BETWEEN SEGMENTAL LEG CENTRAL PATTERN GENERATORS IN ISOLATED LOCUST THORACIC NERVE CORDS.

S. Ryckebusch* and G. Laurent. Biology Division, Computation and Neural Systems Program, Mail Code 139-74, California Institute of Technology, Pasadena, CA 91125.

Rhythmic motor patterns can be induced in leg motor neurons of isolated thoracic ganglia of the locust, *Schistocerca americana*, by bath application of the muscarinic agonist pilocarpine (Ryckebusch and Laurent, *J. Neurophysiol.*, 69(5), 1993). We have recorded the rhythmic motor patterns evoked in preparations of thoracic ganglia in which the connectives between ganglia remained intact. Cross-correlation analysis of the activities of different motor pools in the three thoracic ganglia revealed that the rhythmic motor patterns in different ganglia are centrally coupled. In particular, trochanteral levator motor neurons were coactive with trochanteral depressor motor neurons in adjacent hemiganglia. Trochanteral levators also tended to be active within a short latency of levator bursts in an ipsilateral adjacent hemiganglion. The coupling we observed, while not sufficient to account for the coordination of the legs during walking, demonstrates that central mechanisms exist which may contribute to leg coordination and the maintenance of stability and posture during walking.

QUANTIFICATION OF SYNCHRONY IN NEURAL POPULATIONS BY COHERENCE ANALYSIS. C.N. Christakos*, Med. School, Univ. of Crete, Greece, and Ctr. Neurobiol., Columbia Univ., New York, U.S.A.

A recent study (C.N. Christakos, *Neurosci.* 58, 43-57, 1994) indicated that for a neural population comprising uncorrelated units and units that are correlated around some frequency F_s , the unit-to-aggregate (UTA) coherence function is near zero for the uncorrelated subset but has a nonzero value at F_s for members of the correlated subset. This value reflects the numerical size of the population and the characteristics of synchrony (extent and strengths of unitary correlations, and phase concentration for the correlated units); and as indicated by simulations of a uniform population, it is substantial for wide ranges of values of these parameters. Thus, UTA coherence computations on a sample of units allow the estimation of the extent of population synchrony, as well as inferences on correlation strengths, i.e., a quantification of neural synchrony. Current mathematical analysis using the same model of synchrony verifies these results for the UTA coherence. It further reveals that the value of the aggregate-to-aggregate (ATA) coherence at F_s between unit (sub)populations reflects the same four parameters, and is also substantial in a wide range of conditions. However, from this value the characteristics of synchrony cannot be separately estimated. Therefore, the ATA coherence at F_s only provides a general measure of synchrony, on the condition that the sizes of the two (sub)populations stay relatively fixed. Finally, the analysis shows that the UTA and particularly the ATA coherence are very sensitive indicators of population synchrony, especially when synchrony is weak (unit-to-unit coherences < 0.3).

COMPUTATIONAL MODELS OF THE RESPIRATORY OSCILLATOR IN MAMMALS. J.C. SMITH* Laboratory of Neural Control, NINDS, NIH, Bethesda, MD 20892.

Computational models for the respiratory oscillator in both the neonatal and adult nervous systems have been developed and used to explore interactions of intrinsic cellular and synaptic properties in the generation of respiratory rhythm and pattern. The model for the neonatal nervous system is an extension of our previous hybrid pacemaker-network model (Smith et al., 1992) which includes voltage-dependent pacemaker neurons as the kernel of the oscillator. The model for the adult is an extension of previous network models (Ogilvie et al., 1992; Balis et al., 1994) and now incorporates intrinsic membrane currents which give the model neurons voltage-dependent bursting and spiking behavior. Modeled membrane currents and synaptic connections are inferred from available intracellular recording and connectivity data from neonatal rat brainstem in vitro and the anesthetized adult cat in vivo. The models incorporate all major classes of neurons currently known in the neonatal and adult ventral respiratory group, including the preBötzinger Complex—the proposed locus for rhythm generation (Smith et al., 1991). Membrane currents are modeled with Hodgkin-Huxley equations and synaptic conductances mimicked fast excitatory and inhibitory interactions. The simulations reproduce spike discharge patterns and membrane potential trajectories of the main classes of respiratory neurons in the neonate and adult. Possible transformations of the oscillator during development were investigated. The oscillatory behavior and discharge patterns in the neonatal model transform into the adult patterns when synaptic inhibition in the network is increased, indicating that the neonatal and adult models are compatible. These models provide tools for investigating the dynamic properties of the respiratory oscillator, including developmental transformations. (Supported in part by HL40959).

THE USE OF SYNAPTIC POTENTIALS AS THE CHARGE ON PARTICLES IN THE GRAVITATIONAL REPRESENTATION OF NEURONAL ASSEMBLIES: RESULTS FROM SIMULATIONS
J. A. Jacques*, K. F. Morris, G. L. Gerstein, and B. G. Lindsey
Dept. Physiology & Biophysics, Univ. S. Florida Med. Ctr. Tampa, FL 33612 and Dept. Neuroscience, Univ. Pennsylvania, Philadelphia, PA. 19104

The gravitational representation of simultaneously recorded spike trains (Gerstein et al. 1985) provides a conceptual framework for the analysis of the dynamic organization of neuronal assemblies (Lindsey et al. 1992). Each neuron is represented as a particle carrying a time varying charge that is a filtered version of spike activity. The charged particles exert force on each other; aggregation of particles indicates non-random temporal relationships (effective connectivity) among the spike trains. We have enhanced the gravity method so that fluctuations in membrane potential can be mapped to particles as well, allowing correlation of intracellular and spike train data. Simulated uncorrelated spike trains and an analog signal representing the membrane potential of a target cell were used to evaluate the enhanced gravity algorithm. All of the simulated neurons exhibited similar firing rates but only one in each trial induced inhibitory synaptic potentials in the target cell, resulting in IPSPs with amplitudes and time constants approximating *in vivo* values. The algorithm correctly distinguished the spike train producing the hyperpolarizations. Subsequent tests introduced synaptic noise in the intracellular trace from up to 512 discrete inhibitory synapses unrelated to the analyzed spike trains. The algorithm detected the interaction in the presence of this synaptic noise. These results 1) show that the advantages of the gravity method can be extended to intracellular recordings, and 2) support the idea that other analog signals related to neuronal activity may be used to define the charge on particles in the gravitational representation. Supported by NS19814.

A NEW HIGHER-ORDER INTERSPIKE INTERVAL ANALYSIS FOR DETECTING SEQUENTIAL FIRING TRENDS IN NEURONS. D. C. Tam.*
Center for Network Neuroscience, Dept. of Biological Sciences, University of North Texas, Denton, TX 76203.

A new spike train analysis method is developed to detect how transitions of firing intervals in neurons are dependent on higher-order interspike intervals (ISIs). A set of "firing trend indices" is introduced to detect trends in firing independent of time scales. The firing trend index h_1 is defined as the ratio between the first-order ISI and the second-order ISI relative to any reference spike. Since the value of h_1 is bounded by 0 and 1, (i.e., $0 < h_1 < 1$) comparison between how firing intervals are changed can be made independent of the absolute time scale of the underlying intervals. The asymptotic value of $h_1 \rightarrow 0$ represent the extreme change from short to long ISIs, and vice versa, for $h_1 \rightarrow 1$, and $h_1 = 0.5$ represents no change. Similarly, h_2 is defined as the ratio between the second first-order ISI and the second-order ISI relative to a reference spike, with the relationships: $h_1 = 1 - h_2$ and ($0 < h_2 < 1$). In addition, another firing trend index k can be defined as the ratio of the difference between the two adjacent ISIs to the second-order ISI. The value of k is bounded by -1 and 1, ($-1 < k < 1$), with the relationship: $k = h_2 - h_1$, where $k = 0$ indicating no change in firing consecutive intervals, $k \rightarrow 1$ indicating extreme lengthening in ISI, and $k \rightarrow -1$ indicating extreme shortening in ISI. Plotting these indices against the sequential spike number provides clear indication of the evolution of serial trends in firing. Thus, the transition into and out of burst firing, for instance, can be detected easily. Furthermore, plotting these indices against the first-order ISI will provide an estimate of the transitional probability of spike firings. Using these new state transition analyses, the underlying state transition processes, such as Markov processes or other processes, may be revealed in neurons. (Supported by ONR N00014-93-1-0135)

LEVEL OF ACTIVITY AND INHIBITION EFFECTS IN A SPINAL MOTOR CIRCUIT SIMULATION. D. P. Bashor* and D. M. McDermott.
Dept. of Biology, University of North Carolina at Charlotte, NC 28223.

A computer simulation based on R. J. MacGregor's (1987) SYSTM series was used to investigate the importance of level of network activity on flexor and extensor motoneuron (fMn, eMn) activity in a segmental motor circuit. The spatial distribution of Renshaw cell (Ren) excitation by Mn was also studied. Single fMn and eMn populations (169 cells each) were interconnected with 5 pairs of interneuron populations in a network composed of about 2300 cells. The network was driven by 5 pairs of fibers representing IA and IB afferents, and tonic descending excitation. At low levels of network activity, fIA and fIB input initiated fMn firing which continued following termination of input. At intermediate levels of network background firing, fMn activity was quenched immediately after termination of input. At high levels of background, afferent input made only small differences in frequency and number of active Mn cells, as well as providing little reciprocal inhibition of the antagonist population. The effects of focal activation of Ren by Mn compared with widespread activation demonstrated complex effects in the network. Changing from widespread to focal activation of fRens by fMns had little effect on fMn activity, but a rather large effect on eMn frequency. However, both mean frequency and number of cells active changed in fRen and eRen populations.

GRAPHICAL MEASURES OF SPIKE TRAIN SIMILARITY AND COUPLING BASED ON RECURRENCE TIME HISTORY MATCHING (RTHM).
B.K. Rhoades*, J.M. Kowalski, H.J. Mackey and G.W. Cross, Depts. of Biological Sciences and Physics, Univ. of North Texas, Denton, TX 76203.

We have applied the Hausdorff metric and related similarity functions as cumulative and running time estimators of similarity or coupling between two spike trains, based on the local auto-recurrence time history associated with each spike. These new methods have been tested with biological spike trains from cultured mouse spinal cord networks, as well as artificial spike trains from a class of stochastic models. The central algorithm operates on two spike trains and a particular cross pair of spikes A and B, and begins by finding the best match for each of N sequential auto-recurrence times of spike A in the auto-recurrence time history of spike B. This constitutes a set of N minimal A->B distances. A set of N minimal B->A distances is similarly determined. The maxima from each of these sets are then summed to produce the local Hausdorff distance (DH) between the two spike trains, associated with the cross recurrence time L (lag or lead) between A and B. Accumulating DH and associated L values across spikes provides a metric for graphical assessment of local spike train similarity and temporal relationships. Alternatively, the minimum distance (Dm) from the A->B and B->A sets provides a very sensitive measure of local spike train coupling. By comparing Dm to a predetermined threshold Θ , we can find the set of associated L values corresponding to cross pairs of spikes with criterion matches in their auto-recurrence time histories. The histogram of this "RTHMm" set reflects defined coupling relationships between artificial spike trains more accurately than does the standard cross-correlogram, which is shown to be a special case of the RTHMm histogram, where Θ or N is large. RTHMm is also appropriate as a running-time measure of coupling latencies and strengths, for detecting coupling state transitions in non-stationary data sets. By graphically combining this similarity function with the ranked mean local interspike interval we have produced a clear demonstration that networks can become functionally decoupled during paroxysmal bursts, as a manifestation of nonlinear, activity-dependent gain. Supported by the State of Texas Advanced Technology Program.

A FUZZY-CLUSTERING APPROACH TO THE RECOGNITION OF MULTINEURON ACTIVITY. G. Zouridakis* and D. C. Tam.*
*Dept. of Electrical & Computer Engineering, University of Houston, Houston, TX 77204-4793 and *Center for Network Neuroscience, Dept. of Biological Sciences, University of North Texas, Denton, TX 76203.

Typically, spike discrimination techniques can be used to extract separate spike trains from many neurons in multi-unit extracellular recordings. The performance of these methods often depends critically on the availability of reliable spike templates. The presence of overlapping spikes may introduce misidentification of spikes when conventional template-creation approaches are used. To overcome this problem, we use a fuzzy clustering approach to extract multi-unit activity.

Our procedure employs fuzzy K-means clustering on a data segment containing multi-unit activity (1) to identify the number of neurons contributing to the recorded signal, and (2) to create reliable spike templates for each neuron. For this purpose, a performance index is used as an optimization criterion.

Comparison of performance between the conventional crisp K-means and our fuzzy K-means clustering approaches is done with synthetic spike trains generated using real spikes and segments of background noise recorded from crayfish neurons. Extensive simulations clearly demonstrate the advantage of the fuzzy procedures in identifying the exact number of neurons in the recording and the exact templates over a wide range of signal-to-noise ratios and several "fuzziness indices". They also allow us to determine the optimum "amount of fuzziness" for real-time processing. This method can be applied to other electrophysiological signal analyses, such as EEG and evoked potentials. (Supported by ONR N00014-93-1-0135)

CORRELATION RASTER DISPLAYS OF SPIKE TRAINS: A NEW METHOD OF ANALYSIS OF OSCILLATIONS IN EXPERIMENTAL AND SIMULATED DATA. A.B. Kirillov and D.J. Woodward.
Department of Physiology and Pharmacology, Bowman Gray School of Medicine, Wake Forest University, Winston-Salem, NC 27157.

Standard tools for analysis of spike trains are usually based on averaging techniques. Thus, auto-correlation histogram represents a time-averaged measure of internal structure of a spike train. This and other time-averaged histograms cannot specify, however, the onset and termination of coherent oscillating modes within groups of spike trains. Raster displays of spike trains, that are able to show the patterns in neuronal firing times, are usually used only to demonstrate changes in neuronal activity around a stimulus presentation. We routinely use similar raster displays but with a reference point being a spike instead of a stimulus. This simple generalization of stimulus-related raster displays gives the investigator a powerful tool to analyze detailed pattern structure of spike trains. It is not unusual to display thousands of raster dot lines using this technique and therefore a high resolution monitor and printer as well as some restructuring of the computational routines are required. Auto- and cross-correlation raster displays are especially useful when analyzing spike trains with an oscillatory components. Auto-correlation raster displays allow one to visualize and identify the instances of oscillatory behavior and their structure. Cross-correlation raster displays reveal the time course of synchronization and phase lag changes. We demonstrate typical patterns that emerge in correlation rasters and present several examples of using this technique to study ensemble neuron data recorded from hypothalamus, cortex and neostriatum of rats as well as from neural network models. FROG HINDLIMB MUSCLE FORCE FIELDS *Loeb, E.P.*; Bizzi, E.; Saltiel, P.; Giszter, S.F.; Schottland, J.* Dept. of Brain and Cognitive Sciences, MIT, Cambridge, MA 02139

Using microstimulation, we have previously described a few hindlimb postures encoded in the spinal interneuronal grey. These postures can be described as convergent force fields. We have also previously measured force fields from the major muscles in the frog hindlimb. In order to clarify the relation between muscle force fields and spinal force fields we measured force fields over a large portion of the workspace by electrically stimulating each muscle in the hindlimbs of 10 frogs.

All of the muscles had divergent force fields (because the force never reversed direction. It should be mechanically impossible for a muscle to produce a stable force field). There were three primary directions in which those divergent force fields pointed. Radially away from the body (Pyriformis, Quadratus Femoris, Peroneus, Vastus Externus, Tibialis, and Semimembranosus), Contralaterally behind the body (Semitendinosus, Adductor Magnus, Rectus Internus (major and minor), and toward flexion (Biceps, Ilio-Psoas, Pectinius, Rectus Anticus, Adductor Longus, Gastrocnemius, and Sartorius). Thus there is redundancy in the muscle force fields. In addition, some of the muscles had zero-valued force fields throughout some part of the workspace. The muscles Rectus Anticus, Rectus Internus (major and minor), Gastrocnemius, Adductor Longus, Vastus Internus, and Sartorius all showed a complete or near complete loss of force throughout some portion of the workspace. The utility of this type of muscle force field may lie in its ability to provide position-dependent force field modulation without requiring position (afferent)-dependent EMG modulation.

Because none of the muscle force fields was stable, we conclude that limb stability can only be achieved through appropriate combinations of muscle activations. A primary function of the spinal cord may be to insure stability by serving as a locus for implementing the co-activation of muscles. INFLUENCES OF DAILY SHORTENING OR LENGTHENING CONTRACTIONS OF THE FUNCTIONAL PROPERTIES OF CHRONICALLY INACTIVATED SOLEUS. *S. J. Harkema, R.R. Roy*, J.A. Hodgson, V. H. Zhong and V.R. Edgerton.* BRI and Physiological Science Dept., UCLA, L.A., CA. 90024.

Spinal isolation (SI, transection of the spinal cord at T12-T13 and at L7-S1 and deafferentation between the two transection sites) was used to produce inactivation of the cat soleus for 4 months. We examined the effects of cyclical activity (1 Hz) mimicking the step cycle with electrical stimulation (40 Hz, 300ms, 30 min/d) during either lengthening (SI-L) or shortening (SI-S) on the functional deficits associated with chronic inactivation: MWt, muscle wet weight; TPT, isometric twitch time to peak tension; Po, maximum tetanic tension; Vmax, maximum rate of shortening; FI, fatigue index (% difference from control).

Group	MWt	Po	TPT	Vmax	FI
SI	-64	-81	-33	+57	-15
SI-S	-45	-68	-41	+29	-12
SI-L	-47	-60	-38	+58	-5

The force frequency curve was shifted towards that of a faster type muscle after SI. This effect was attenuated by programmed activity. The in vivo soleus tendon force was ~7 and 9 times more during active than passive manipulation in the SI-L and SI-S cats, respectively. SI resulted in a smaller and faster muscle with general daily programmed activity ameliorating the adaptations in MWt, Po, and FI. SI-L had a greater effect than SI-S in Po and FI. The relative nonfatigability of the soleus was maintained in all groups. Thus, as little as 30 min/day of activity had a positive effect in maintaining the mechanical properties of a chronically inactivated muscle. Further, stimulation during lengthening was more effective than during shortening probably reflecting the larger force integrals during lengthening. (Supported by NIH Grants NS16333 and NRSR HD 7416).

DOUBLET POTENTIATION IS DIMINISHED DURING SHORTENING MOVEMENTS OF CAT SOLEUS MUSCLE. *T.G. Sandercock* and C.J. Heckman.* Department of Physiology, Northwestern University School of Medicine, Chicago, IL 60611

When motor units are stimulated with low frequency trains, the addition of a single extra pulse, or doublet, at the beginning of the train can dramatically increase tension during an isometric contraction (Burke et al., Science 168:122-124, 1970). This study investigated the effects of muscle movement, using either isovelocity ramps or simulated locomotor patterns, on doublet potentiation in whole muscle or single motor units in cat soleus. The light line in Fig. A shows the isometric force produced by stimulating a portion of the soleus with a 10Hz train. The heavy line depicts the addition of a doublet (pulse added 10ms after the first pulse). In B, using identical stimulus patterns, the same muscle was shortened at 20mm/s from 0.2 to 0.7s, and then allowed to contract isometrically. Shortening movements diminished the effects of the doublets in whole muscle and motor units. Less dramatic results were seen with slower or shorter isovelocity ramps, or with locomotor type movements. Moderate isovelocity stretches of similar speed and distance had little effect on doublet potentiation.

492.2

EFFECT OF DOUBLE PULSE ACTIVATION ON FORCE ENHANCEMENT IN THE HUMAN PARALYZED SOLEUS MUSCLE. *R.K. Shields* and K.C. Shields.* Physical Therapy Graduate Program, University of Iowa, Iowa City, IA 52242.

Doublets, or two repetitive stimuli delivered with a short interpulse interval, have been shown to produce a force output that is greater than the linear sum of force produced from one stimulus (Burke et al. Science 1970). In addition, this effect may be motor unit or muscle fiber type specific. We previously showed that the human chronically paralyzed soleus muscle histochemically and physiologically responds as a predominantly fast muscle while the acutely paralyzed soleus muscle (less than 6 weeks) responds as a slow muscle. This study examined the effects of the repetitive doublet on the human chronically and acutely paralyzed soleus muscle both before and after a standard fatigue regimen.

Ten chronic (one year) and two acute (6 weeks) completely paralyzed individuals had their lower leg positioned in a torque measuring device with the knee in 90° of flexion. The soleus muscle m-wave was monitored during all stimulations to ensure supramaximal activation. Three interpulse intervals (6 msec, 12 msec, 18 msec) for the doublet were delivered in six possible combinations via the tibial nerve. Each doublet was preceded by a single twitch. Next, a fatigue protocol consisting of a 20 Hz frequency delivered each second for 330 msec was delivered for two minutes. This protocol lead to significant fatigue. Immediately after the fatigue protocol the same doublet protocol was administered. Dependent measures included peak force, force-time integral, and the rate of force production both before and after the fatigue protocol. Following the fatigue protocol, the doublet lead to approximately 3 times the peak force and force-time integral than that of a single stimulus in the chronically paralyzed soleus muscle. Conversely, the acutely paralyzed soleus muscle showed no significant change in the output from the doublet. This study suggests that increased force production from the doublet was muscle fatigue dependent. Mechanisms and implications of these findings will be discussed.

COMPARISON OF FORCE-FREQUENCY RELATIONS IN HUMAN VOLUNTARY AND STIMULATED CONTRACTIONS. *C. L. Rice* and B. Bigland-Ritchie.* Dept. of Pediatrics, Yale University School of Medicine, New Haven, CT 06510 and The School of Physical and Occupational Therapy, McGill University, Montreal, Canada H3G 1Y5

In voluntary contractions muscle force is modulated by a combination of motor unit recruitment and rate-coding. When either whole muscle or single motor units are stimulated at different rates, a sigmoid force-frequency relation results. In contrast, during voluntary contractions, mean spike frequencies increase linearly with force up to 100% MVC (Bigland-Ritchie, et al. 1991; Thomas et al. 1991); a force which usually matches that from supramaximal stimulation. The purpose of this study was to compare, in the same muscle, forces generated by electrical stimulation with those generated by motor units recorded during voluntary contractions of various intensities.

Muscle force and motor unit firing rates were recorded from the quadriceps muscles of 16 subjects during voluntary contractions varying from 25% to 100% MVC. In separate experiments, quadriceps muscles were stimulated electrically at rates from 1 to 100 Hz. The two force-frequency relationships were compared. For forces up to about 60% of MVC, there was little discrepancy between voluntary and stimulated excitation rates. However, for higher forces the stimulated force increments per Hz became progressively smaller, while this non-linearity was largely avoided during voluntary contractions. Possible explanations for this discrepancy include: 1) the progressive recruitment of larger units at higher forces; 2) that forces from different units add non-linearly when their territories overlap (Clamann & Schellhorn, 1988); and 3) whether or not the CNS can excite all units to respond at maximal rates.

EFFECTS OF TRAIN FREQUENCY AND FATIGUE STATE ON THE CATCHLIKE PROPERTY IN THE RAT GASTROCNEMIUS MUSCLE. *S.A. Binder-Macleod* and L.J. Landis.* Dept. of Phys. Therapy, Univ. of Delaware, Newark, DE, 19716

The catchlike property of skeletal muscle is the tension enhancement seen when an initial, brief interpulse interval (IPI) is added to the beginning of a subtetanic train of pulses. Though the train frequency and fatigue state have been reported to affect the catchlike property of a muscle these factors have never been simultaneously investigated. This study compared the force produced by trains with all pulses within the train separated by the same IPI (CFTs) to trains with the initial IPI = 10 ms and the remaining IPIs equal to the IPIs of the CFTs. These later trains were the catch-inducing trains. The IPIs of the CFTs ranged from 20 to 60 ms. Data were collected prior to fatigue, during repetitive fatiguing contractions, and during recovery from fatigue.

The CFTs with the 25 ms IPIs produced greater integrated forces (impulses) than any of the other CFTs during all fatigue states. This IPI was consistently slightly less than the twitch contraction times (TwCTs) of the muscles. In the nonfatigued state, the catch-inducing trains only augmented forces when the IPI of the trains were ~ 2 times the TwCT of the muscle. However, when the muscle was fatigued, the catch-inducing trains showed marked force augmentation for all trains with IPIs greater than or equal to the TwCT of the muscle. As the muscle recovered from fatigue, this augmentation gradually diminished. These data show for the first time that when a muscle is fatigued catch-inducing trains can produce greater impulses than even the optimal CFT. (Supported by NIH Grant AR41264)

MODELING ISOMETRIC FES MUSCLE FATIGUE BY ARTIFICIAL NEURAL NETWORKS. M. Dornay*, O. Yadid Pecht, J. Mizrahi, E. Isakov and Z. Susak. Dept. of Biomed. Eng., Technion, Haifa 32000, Israel and Loewenstein Rehabilitation Hospital, Ra'anana, Israel.

This study investigates the relation between the input electrical current applied to the paralyzed human quadriceps muscle in vivo during Functional Electrical Stimulation (FES) and the output muscle force. The electric current is applied by surface electrodes to the muscle, and the force is measured in isometric conditions. The instantaneous input to the muscle during FES consists of the following parameters: 1: Muscle length, described by the knee angle θ (60°); 2: Current frequency, f (20 Hz); 3: Current pulse width, D (0.25 msec) and 4: Current amplitude, A (0 to 130 mA). The output is muscle tension T (N). T at time t is the function of the input history to the muscle. We model T using a sampling rate of 1 Hz to represent the current amplitude A . The output force is very non-linear and it is difficult to estimate its magnitude in advance. We use 2-layer feedforward artificial neural networks simulations to learn the forward dynamics model of the force produced in the muscle. The training stage is done by supervised learning with the backpropagation algorithm. Following the training stage with muscle fatigue data of $A = 50$ or 70 mA FES, the neural networks predict the output force for the unknown case of muscle fatigue induced by 60 mA FES. The network can also extrapolate the output muscle force during a 50-60 seconds period, after learning the forward dynamics model of muscle force production during the first 50 seconds of FES stimulation. We propose that by using appropriate neural network architectures one can represent knowledge of FES experiments by training the weights of the networks. The network weights could be eventually stored on VLSI chips and help in the design of appropriate controllers aimed to replace the motor brain in activating paralyzed muscles. This study was supported by the Segal Foundation and the Sandra and Walter Kaye fund.

CHANGES IN MUSCLE MEMBRANE EXCITABILITY FOLLOWING FATIGUE. L. McFadden, V. Galea and A. J. McComas*. Dept. Biomed. Sci., McMaster Univ., Hamilton, ON, Canada L8N 3Z5.

Following either supramaximal electrical stimulation or maximal voluntary contractions sufficient to induce fatigue, a full or near full recovery of the muscle compound action potential (M-wave) has been observed within 3 minutes of cessation of the fatiguing process. (Galea and McComas, J. Physiol. 438:212P, 1991). Little attention has been given to the excitability during recovery, and we have found evidence of a late depression.

Fatigue was induced by 20 Hz supramaximal stimulation of the motor nerve of the biceps brachii muscle in healthy men of varying activity levels, and the recovery period was examined for up to 8 hours post fatigue. Immediately after cessation of the fatiguing stimulus the amplitude and area of the M-wave had returned to control values, whereas the isometric twitch force was significantly reduced in all subjects. The M-waves declined throughout the recovery period, with one group ($n=9$) reaching a maximum M-wave depression (DEP) between 7 to 30 minutes post fatigue ($60.4 \pm 9.0\%$ control); whereas another group showed maximum M-wave depression much later in the recovery period, between 13 minutes and 4 hours post fatigue (DEP = $42.4 \pm 6.2\%$ control). The isometric twitch force recovered gradually, returning to control values by the end of the 8 hour recovery period. The depression of M-wave activity may be explained by a reduction in $\text{Na}^+\text{-K}^+$ pump activity or by increased open times of the sodium channels.

A RODENT NAVIGATION MODEL THAT COMBINES PLACE CODE, HEAD DIRECTION, AND PATH INTEGRATION INFORMATION. H.S. Wan, D.S. Touretzky*, and A.D. Redish. Computer Science Dept., Carnegie Mellon, Pittsburgh PA 15213.

This model, utilizing coupled mechanisms for place recognition, maintenance of head direction, and path integration, replicates a variety of rodent behavioral and neurophysiological data. We simulated experiments by Collett, Cartwright, and Smith on gerbils performing a family of open-field landmark-based search tasks, and experiments by Cheng on rats navigating to a goal location in a rectangular arena.

Experiments by Mittelstaedt & Mittelstaedt have shown that gerbils possess a path integration faculty allowing them to follow a direct trajectory back to the nest after performing a random search. Presumably the animal's position in some internal coordinate system is being updated with each motor action. Although the neural basis of this ability is unknown, it clearly requires an accurate sense of head direction. Head direction cells have been found in several areas of the rat brain.

In addition to a path integrator and units coding for head direction, our model contains units with place fields controlled by visual landmarks, reflecting properties of hippocampal pyramidal cells. However, unlike other models of place cells, our model also accounts for the persistence of place fields in the absence of any visual input, by allowing place units to be driven by the path integrator. Thus, in our theory, the role of the hippocampal formation is to learn associations between external state (views of landmarks) and internal state (path integrator coordinates). Visual cues, when available, drive the place units, which can then correct for drift in the path integrator or reset it to a known value when the animal is first placed in a familiar apparatus, such as a radial maze.

Our model shows how allocentric bearings derived from head direction can be used to disambiguate visually identical landmarks, replicating the gerbil and rat data. Conversely, local view information can be used to correct for drift in the head direction estimate. Parallel relaxation among place units produces a consistent place code even when the model is presented with a distorted landmark array, emulating the robustness that animals show in novel situations. Parts of the model have been implemented on a mobile robot.

ELBOW-JOINT IMMOBILIZATION DECREASES FATIGABILITY AND ALTERS THE PATTERN OF ACTIVATION IN HUMANS. G.H. Yue*, M. Bilodeau, and R.M. Enoka. Dept. Biomedical Engineering, The Cleveland Clinic Foundation, Cleveland, OH 44195

The left arm of 8 subjects was immobilized in a fiber-glass cast and a sling for 4 weeks at an elbow joint angle of 90 degrees. Twenty-four-hour chronic EMG recordings indicated that the activity of the biceps brachii muscle was significantly reduced during immobilization. Before and after immobilization, the following variables were measured: (1) elbow-flexion force, and EMG signals from the biceps brachii and brachioradialis muscles during maximal voluntary contractions (MVCs); (2) fatigability of the elbow-flexor muscles when force was sustained at 20 and 65% of the MVC force; (3) cross-sectional areas and volume of the biceps and triceps brachii, and brachioradialis muscles measured with magnetic resonance imaging (MRI); and (4) the degree of muscle (biceps brachii and brachioradialis) activation during an elbow-flexion MVC as evaluated with MRI T2 relaxation time. The immobilization induced a significant decrease in the elbow-flexion MVC force and cross-sectional areas and volume of the elbow flexor muscles, but the reduction in muscle size was less than the decline in MVC force. After immobilization, the fatigability of the elbow flexors was decreased (more resistant to fatigue) at both force levels (20 and 65% MVC). There were also significant changes in the EMG activity and T2-indicated degree of activation during the MVC. The neuromuscular adaptations were diverse and had different effects on the various physiological processes.

Supported by NIH grant NS 20544 (RME).

493.2

AROUSAL DEPENDENT ACTIVATION OF FD MOLECULAR LAYER GLYCOGEN PHOSPHORYLASE-A. A. Uecker*, G. Rao, B.L. McNaughton, C.A. Barnes, T.A. Foley and E.M. Reiman. ARL Division of Neural Systems, Memory and Aging, University of Arizona, Tucson, AZ 85724.

"Patches" of glycogen phosphorylase-a activity observed in the fascia dentata (FD) molecular layer (Harley & O'Keefe, 1992; Wallace, 1982) occur following microinjections of glutamate into the entorhinal cortex (Harley & O'Keefe, 1986) and are correlated with the depletion of glycogen stores in the nervous system during metabolic work (e.g. Wallace, 1983). In addition, reduced phosphorylase-a activity in the FD molecular layer after exploration (Uecker et al, 1994) concurs with single cell recording studies (Ranck, 1973; Thompson & Best, 1989) showing that most hippocampal neurons are least active during behaviors typically associated with hippocampal theta rhythm, i.e. active exploration and paradoxical sleep. Place cell activity is maintained when an animal explores or is manually transported to an identified place field, but dramatically reduced after it has been snugly restrained (Foster, et al., Science, 244:1580, 1989), although the theta rhythm is only marginally reduced. We hypothesized that phosphorylase activity would be minimized under restraint, relative to animals either freely exploring, manually moved, or anesthetized with sodium pentobarbital. FD molecular layer glycogen phosphorylase-a activity was measured in 12, 6 month old female Long-Evans rats. Contrary to the firing-rate based expectation, phosphorylase-a activity was least during exploration, higher during passive-movement, higher yet during restrained movement, and highest under anesthesia. The omnibus F was significant ($p < .05$). Phosphorylase-a expression may thus be more correlated (inversely) with hippocampal theta rhythm and/or septohippocampal activity than with principal cell firing-rates *per se*. 493.3

TOWARDS A COMPUTATIONAL MODEL OF THE HIPPOCAMPAL FORMATION INCORPORATING REALISTIC ANATOMICAL CONNECTIVITY: AMMON'S HORN AREA CA3. P. Patton* and B.L. McNaughton. ARL Division of Neural Systems, Memory and Aging, University of Arizona, Tucson, AZ 85724.

A computational model of the rat hippocampal formation incorporating realistic anatomical connectivity is being developed. This report focuses on Ammon's horn area CA3. Points representing neurons were distributed through a rectangular sheet representing this structure. 250,000 pyramidal cells were assumed (West et al., *Anat. Rec.* 231:482-497). Major extrinsic inputs to CA3 derive from the entorhinal cortex and FD granule cells. Entorhinal input possesses a rough topographic organization, and is divergent, with individual arbors extending up to 2 mm septotemporally (Tamamaki and Nojyo, *Hippocampus* 3:471-480). Entorhinal arbors are represented as rectangles extending across CA3. Each entorhinal neuron makes about 4700 synaptic contacts onto pyramidal cells (Amaral et al., *Prog. Brain Res.* 83:1-11). Each granule cell makes about 15 mossy fiber contacts onto pyramidal cells (Claiborne et al., *JCN* 246:435-458). CA3 pyramidal cells possess a network of recurrent collaterals, represented in the model as diagonal swaths like those described by Ishizuka et al. (*JCN* 295:580-623), with each cell receiving 6,000 ipsilateral synaptic contacts. These cells also provide a significant input to the inner molecular layer of FD (Li et al., *JCN* 339:181-208). 5 groups of CA3 non-principal cells were represented: vertical and horizontal basket cells, chandelier cells, spiny non-principal cells, stratum oriens cells, and superficial cells. CA3 contains an estimated 67,000 non-principal cells (Dietz et al., *Verh. Anat. Ges.* 81:883-884). This anatomical representation will serve as a basis for models of postulated hippocampal operations such as associative memory. Supported by MH46823.

SPARSE VS. DISTRIBUTED POPULATION CODING IN SUPERFICIAL AND DEEP LAYERS OF RAT NEOCORTEX. W.E. Skaggs*, B.L. McNaughton, C.A. Barnes, K. Moore, C. Duffield, L. Frank and R. D'Monte. ARL Division of Neural Systems, Memory and Aging, University of Arizona, Tucson, AZ 85724.

324 cells were recorded extracellularly from two areas of the rat neocortex (Zilles's areas HL and OC2ml), using a parallel recording method that permitted monitoring of up to 40 individual neurons at the same time. Excluding a small group with distinctive properties (putative interneurons), during sleep, all superficial cells fired at mean rates of 0.1-0.5 Hz, with little variance across the population. While the rat ran for food reward on a triangle-maze, the population mean rate was not much different, but the population variance was much higher, with many cells shutting off almost completely, while others exhibited behavioral correlates, and fired at instantaneous rates of up to 30 Hz for brief periods of time. In contrast, most cells in the deeper layers fired at mean rates an order of magnitude higher, during both sleep and performance of the task. The depth of modulation varied considerably, but it was very unusual for deep-layer cells to be silent for extended periods of time. Thus the overall pattern of activity appears much more sparse in the superficial neocortical layers than in the deep layers. These findings are of interest in light of the fact that the superficial layers are the predominant source of the cortico-cortical association system. A role in memory has been proposed for this system by theorists including Marr (1970) and Eccles (1978, etc.); and it has been shown mathematically that sparse activity patterns confer special benefits on associative memory networks by reducing interference between jointly stored patterns. Moreover, the majority of neocortical NMDA receptors are located in the superficial layers (Monaghan and Cotman, 1989). Supported by MH46823 and MH00897.

493.7

PRESERVATION OF TEMPORAL ORDER IN HIPPOCAMPAL MEMORY REACTIVATION DURING SLOW WAVE SLEEP. M.A. Wilson*, and B.L. McNaughton. ARL Division of Neural Systems, Memory and Aging, University of Arizona, Tucson AZ 85724.

In a previous study, it was found that coactivity of cells during behavior produced an increase in discharge correlation between these cells during subsequent slow wave sleep (Wilson and McNaughton, 1994). This suggested that hippocampal memories for recent experience were recapitulated during these sleep periods. A question which remained unanswered was whether the temporal structure of experience was also preserved and was present during sleep activity. To address this question, 50-100 cells in area CA1 of the hippocampus were recorded simultaneously during spatial behavioral tasks. Individual pairwise correlation histograms taken during these tasks were classified based on their direction of skew. In each pair, if firing of cell 1 (master cell) tended to precede the firing of cell 2, this pair was assigned a positive skew. The converse relationship was assigned a negative skew. During behavior, this skew resulted from the relative spatial locations of the "place fields" for each cell, and the specific pattern of behavior the animal would follow during each task. It was found that the direction of skew of the cross correlation function for pairs examined during behavior (peak shift 1-2 sec) determined the direction of skew of the same pairs during the immediately following slow wave sleep period (peak shift 5-10 msec). This indicates that both the structure and temporally compressed order of recently experienced states are recapitulated in the hippocampus during slow wave sleep. The preservation of both coordinated states and their temporal order suggests a mechanism within the hippocampus which is capable of storage and reactivation of temporally sequenced information. Supported by MH46823 and McDonnell-Pew.

493.4

SIMULATION OF THE SPONTANEOUS REACTIVATION OF EXPERIENCE-SPECIFIC HIPPOCAMPAL CELL ASSEMBLIES DURING SLEEP. B. Shen and B.L. McNaughton*. ARL Division of Neural Systems, Memory and Aging, University of Arizona, Tucson, AZ 85724.

During slow-wave sleep (SWS) following periods of spatial activity, CA1 "place-cells" that were temporally correlated, by virtue of the overlap of their place fields, exhibit enhanced temporal correlations, even though the animal sleeps in a different location (Wilson and McNaughton, *Neurosci. Abs.*, '93, '94). The discharge of cells with overlapped place fields was more correlated in subsequent sleep, particularly during sharp-waves, than in sleep episodes prior to the behavior, or than cell-pairs with non-overlapped place fields. To explore the plausibility that this reflects spontaneous reactivation of cell assemblies in the CA3 recurrent association system, we constructed a simple model in which place fields are represented as 2-D gaussians, and connection weights between cells with place fields in the environment are proportional to the spatial overlap of their firing probability density functions (a Hebbian learning rule), which falls off exponentially with the square of the distance between place field centers. The network was presented with random input patterns to simulate the presumed condition during SWS. Consistent with results of Pavlides and Winson (1989), simulated cells with place fields exhibited higher firing during "SWS" than cells without place fields, and, as observed by Wilson and McNaughton, cells with overlapped fields were highly positively correlated, whereas those with non-overlapped fields were weakly negatively correlated. Moreover, during correlated states, coherent patterns (cell assemblies) corresponding to specific locations were reactivated. The random inputs resulted in all-or-nothing network reactivations of place representations, irregularly distributed in time in a manner reminiscent of hippocampal sharp-wave activity during SWS. Supported by MH46823.

493.6

POPULATION ACTIVITY PATTERNS IN HIPPOCAMPUS AND NEOCORTEX PERSIST MUCH LONGER DURING WAKING AND REM SLEEP THAN DURING SLOW-WAVE SLEEP. K. M. Moore, W. E. Skaggs, B. L. McNaughton, C. A. Barnes, R. D'monte, C. Duffield. ARL Division of Neural Systems, Memory and Aging, University of Arizona, Tucson, AZ 85724.

To gain insight into the possible role of sleep in memory consolidation, we quantified the structure of population dynamics during different brain states. Using a parallel recording method (Wilson and McNaughton, 1992), populations of up to 40 neocortical cells or up to 70 hippocampal cells were recorded simultaneously in the neocortex or area CA1 of rats, during behavioral states of REM sleep, slow wave sleep (SWS), or performance of a spatial task. The persistence of population activity patterns in each state was quantified by calculating the correlations between population firing rate vectors at different times, with care to exclude high-rate cells (putative interneurons) from the populations. In each behavioral state, the mean correlations decayed more or less exponentially as a function of time interval, and the time constant of decay was taken as a measure of the average persistence of an activity pattern. The approximate time constants observed, both in neocortex and hippocampus, were: SWS, 100-200 msec; REM sleep, 1-2 sec; active locomotion, 400 msec-2 sec. As might be expected, the persistence of correlated states during behavior appears to be a function of the behavior itself. During SWS, correlations persist on a timescale similar to hippocampal sharp-waves, consistent with a possible hippocampal origin of the correlated states. During REM, the persistence is not correlated with any obvious neocortical or hippocampal EEG phenomenon. These findings add to the extensive evidence for similarities between REM sleep and the waking state. Supported by MH46823 and MH00897.

VARIATIONS IN PLACE-SPECIFIC FIRING OF HIPPOCAMPAL NEURONS ALONG THE SEPTOTEMPORAL AXIS. M.W. Jung*, S.I. Wiener, K. Moore, S. Kipen, and B.L. McNaughton. ARL Division of Neural Systems, Memory and Aging, University of Arizona, Tucson, AZ 85724.

The anatomical and neurochemical organization of hippocampal circuitry exhibit a substantial septo-temporal gradient. Although it is well established that place-specific firing is a fundamental characteristic of hippocampal neurons, almost all unit recording studies in freely behaving animals have come from the septal one third, largely for technical reasons. In the present study, therefore, single units were recorded in the dorsal and ventral hippocampi of opposite hemispheres in the same rats, in many cases simultaneously. Units were first identified as the rats entered slow wave sleep. The rats then performed a food reinforced, random search task in a square chamber containing simple visual landmarks. As in dorsal hippocampus, ventral CA1 units could be classified as "complex spike" (CS-pyramidal) cells or "theta" interneurons. Both dorsal and ventral theta cells fired at relatively high rates with low spatial selectivity in the arena. As previously reported (*Soc. Neurosci. Abs.*, 19:796), "place cells" were found among the CS cells in the ventral hippocampus; however, significantly fewer ventral units had "place fields" than dorsal units, and the spatial selectivity of ventral units was significantly lower than that of dorsal units. Thus a septotemporal gradient of spatial selectivity was found in the CA1 field of the hippocampus, complementing many other anatomical and neuropharmacological studies. A number of possible functional interpretations can be suggested from these results, including a computational advantage of representing space at different scales or a preeminence of essentially non-spatial information processing in the ventral hippocampus. HIPPOCAMPAL PLACE FIELDS CHANGE WITH NAVIGATIONAL CONTEXT. Y. Qin, E.I. Markus*, B.L. McNaughton and C.A. Barnes. ARL Division of Neural Systems, Memory and Aging, University of Arizona, Tucson, AZ 85724.

When general behavioral requirements are held constant, rat hippocampal complex spike cells fire selectively with respect to the animal's location. The locations of "place fields" of individual cells are generally quite robust against manipulations such as additions or deletions of visual stimuli, darkness, or allowing the rat to explore previously unexplored adjacent regions of space. Although firing rates are modulated by behavioral variables such as running velocity or direction of turning, the location of firing is relatively unaffected by the specific behavior. In the present study, the effects of the navigational requirements of the task were assessed in fixed environments. Hippocampal place cells were recorded in adult male rats (n=15) as they searched for chocolate either on a radial arm maze or a circular platform. The rats would first retrieve randomly scattered chocolate; then the task was altered by placing the food sequentially and repeatedly in 4 specific locations. This resulted in a switch from a random to a directed search pattern by the rats, typically over the course of 1-2 minutes. On the circular platform, this also involved a change in the trajectories and distribution of locations visited. The switch from random to directed search was accompanied by a pronounced change in the location of the place field in approximately 1/3 of the cells on the circular platform. There was a smaller, but significant effect when the recordings were conducted on the radial arm maze. In 2 rats the directed search was routinely followed by a second random search episode. In these cases, the place fields returned to their original location. We conclude that, if hippocampal cells encode location *per se*, the representation changes in different behavioral or navigational contexts. Supported by MH00897 & ONR.

DYNAMICS OF VISUAL CUE CONTROL OVER HEAD DIRECTION CELLS AND PLACE CELLS. J.I. Knierim*, H.S. Kudrimoti and B.L. McNaughton. ARL Division of Neural Systems, Memory and Aging, University of Arizona, Tucson, AZ 85724.

Thalamic head direction (H) cells and hippocampal place cells comprise a tightly coupled system. We investigated the dynamics of visual cue control over these cells by introducing conflicting direction information between visual cues and internal cues. Rats foraged for food in a high-walled apparatus with a single salient cue card. In some experiments, we disoriented the rats before each session. This weakens visual cue control over place and H cells (Knierim et al., Soc. Nsci. Abst., 1993), although most cells have a preferred firing direction or location relative to the cue card over multiple sessions. In 30% of 119 sessions, however, firing orientation rotated 30°-130° within the session, usually in the first few min. In 25/34 cases, rotation was from an "incorrect" orientation to the "correct" one. In 6 cases, cells rotated from one incorrect orientation to another. In 3 cases, cells started at the correct orientation, rotated away, but then returned. In no cases did cells permanently rotate away from the correct orientation. In other experiments, we abruptly rotated both apparatus and rat by 180°. Typically, cells either immediately rotated 180° with the cue, or remained at the same orientation relative to the external world. In other sessions, however, cells initially maintained their external orientations, but then rotated 180° smoothly over a few min until they returned to the original orientation relative to the cue card. Thus, visual cues can correct for large errors in spatial orientation with a slow, steady rotation of both the H cell system and the hippocampal spatial map until they realign with the cue. The progressive shift suggests that transitions between neighboring network states are preferred over transitions among less similar states. Supported by ONR and NS09052.

AGE-RELATED DECREASE IN THE NMDA-MEDIATED EPSP IN FD. G. Rao*, C.A. Barnes, B.L. McNaughton and J. Shen. ARL Division of Neural Systems, Memory and Aging, University of Arizona, Tucson, AZ 85724.

Previously we demonstrated a decline in both the non-NMDA and NMDA-mediated Schaffer collateral EPSP in senescent CA1. Here, we characterize the NMDA response in senescent fascia dentata (FD), where, although there is a smaller presynaptic fiber potential for a given stimulus intensity, indicating loss of perforant path fibers, the non-NMDA EPSP is actually larger for a given fiber volley amplitude (Barnes and McNaughton, 1980), indicating that individual perforant path synapses of old animals are more powerful (Foster et al., 1991). F344 rats (n=18, 26-35 days; n=18, 9 mo; n=18, 24-27 mo) showed an age-related deficit in spatial learning ability in the spatial version of the Morris water task, (% time in target quadrant: yng = 45.3 ± 5.2; adult = 39.8 ± 6.7; old = 24.9 ± 7.3) with no impairment in visual discrimination ability. Hippocampal slices were then prepared and incubated in low Mg⁺⁺ ACSF. Recording and stimulating electrodes were placed in FD. Input-output curves of the relation between the presynaptic fiber volley and EPSP were constructed before and after local application of CNQX, a non-NMDA (AMPA) antagonist. Abolition of the residual response by AP5 confirmed that it was NMDA-mediated. As found previously, prior to CNQX application the EPSP-to-fiber volley ratio was significantly larger in the old rats. After CNQX application, the NMDA component for a given fiber volley amplitude was significantly reduced (p<.005) in the old rats relative to the younger age groups. This result demonstrates that components of excitatory synaptic transmission within the same hippocampal subregion are differentially affected by the aging process, even when the receptor subtypes may be colocalized. BEHAVIORAL CORRELATES OF HIPPOCAMPAL CA1 CELLS IN A LANDMARK NAVIGATION TASK. K.M. Gothard*, W.E. Skaggs, K.M. Moore and B.L. McNaughton. ARL Division of Neural Systems, Memory and Aging, University of Arizona, Tucson, AZ 85724.

To address the nature of hippocampal representation in a landmark navigation task modeled after Collett et al. (J. Comp. Physiol., 1986), three rats were trained to find food at a location predicted by two movable landmarks in a 3.5 m diameter circular arena surrounded by static background cues. On each trial the rat was released from a box to which it returned (at a different location) for reward after finding the goal. CA1 cells were recorded using a microdrive with 12 movable tetrodes (Wilson and McNaughton, Science 261:1055-1058, 1993) which enabled monitoring the simultaneous activity of up to 43 cells. Of 463 recorded cells, 199 had clear behavioral correlates during the task. Four major categories of cells were observed: 111 were place cells with single or double place fields that were stable with respect to the static background cues; 51 were box-related cells that fired either when the rat was inside the box, or as it was leaving or entering the box, regardless of the position of the box relative to the static cues; 8 were landmark/goal related cells that fired in the vicinity of the goal, but only for certain conjunctions of the location of the landmarks and the static cues; and 23 were cells related to more than one variable of the task. In some cases, the goal-related or box-related cells could be shown to fire simultaneously (± 50 msec) with place cells, suggesting that in the hippocampus multiple representations are processed simultaneously and that the hippocampus can transmit a distributed representation of specific objects and/or events within the spatial context in which they occur. Supported by NS20331 and ONR.

A DELAYED CONDITIONAL SPATIAL DISCRIMINATION TASK FOR RATS. T.M. Abdulaziz, C.A. Barnes, B.L. McNaughton, C. Duffield*, L.T. Church. ARL Division of Neural Systems, Memory and Aging, University of Arizona, Tucson, AZ 85724.

In preparation for a study of the neural correlates of route planning and short-term memory, rats were trained to perform a delayed conditional spatial discrimination task on an alternating T-maze on which the two opposite arms (reward arms) were always in the same position in space, and the orthogonal start arm alternated pseudorandomly from one side to the other. The animals were pretrained that specific food items (S1 and S2) could be found only at the associated reward arms and thus at specific locations in space. For conditional trials, animals were placed on a randomly selected start arm, and presented with a small sample of either S1 or S2, which served as a cue to guide the rat's subsequent spatial response. Only the food item presented in the start arm was made available on its appropriate reward arm. The other arm contained no reward. Thus, animals had to match the food sample given in the start arm with the correct location in space. Trials were counterbalanced to counteract response biases of individual animals or the development of a response strategy. Animals were trained to a criterion of 85%. Once animals reached this criterion, delays were imposed after presentation of the food cue, before the animal was allowed to respond. Delays ranged from 10 to 60 seconds in 10 second increments. These delays were grouped either as short (10 and 20 seconds), intermediate (30 and 40 seconds), or long (50 and 60 seconds). Percentage of correct response decreased with increasing length of delay, approaching chance by the longest delays. The effects of lesions to hippocampus and medial prefrontal cortex, as well as neuronal correlates in these areas during the delay phase are under investigation. Supported by NS20331, AG03376 and MH00897.

AGE-RELATED DECREASE IN CHOLINERGIC SYNAPTIC TRANSMISSION IN FD, CA3, AND CA1 OF RAT HIPPOCAMPUS. J. Shen*, G. Rao and C.A. Barnes. ARL Division of Neural Systems, Memory and Aging, University of Arizona, Tucson, AZ 85724.

The electrophysiological consequence of neurochemical cholinergic deficits in normal aging has been examined in area CA1 of hippocampus where the cholinergic slow epsp has been found to be reduced in aged rats (Potier et al., 1992; Taylor and Griffith, 1993). Whether this change occurs in all three hippocampal subregions and whether it covaries with age-related behavioral deficits has been studied here. F-344 rats (n=31, 3 wk; n=33, 9 mo; n=35, 24-27 mo) were tested in the Morris water task. There was an age-related deficit in spatial learning ability. Hippocampal slices were subsequently prepared, and the atropine-sensitive, cholinergic slow epsp was recorded intracellularly in CA1 and CA3 pyramidal cells and FD granule cells. The responses were induced by stimulation (40-50 Hz, 0.5 sec) at each of two intensities of either stratum oriens (CA1, CA3) or stratum granulosum (FD). Within each age group, the cholinergic slow epsp was larger in CA3 than in either CA1 or FD. There were no age differences in intrinsic biophysical properties of principal cells within each subregion; however, the amplitude of the cholinergic slow epsp was significantly reduced in old rats in all areas (CA1-59%; CA3-55% and FD-56%, p<.001). The 3 wk and 9 mo rats did not differ. The amplitude of the slow epsp in CA1 was correlated with spatial learning on the Morris water task in old rats (p<.01). In conclusion, our data suggest that cholinergic synaptic transmission in all three subregions of the hippocampus is compromised in normal aging. The possible pre- and post-synaptic loci of these changes are under investigation. Supported by AG03376 and MH00897.

ALTERED IEG INDUCTION AFTER LTP IN MEMORY-DEFICIENT AGED RATS. A. Lanahan, P.F. Worley, G. Lyford, G.S. Stevenson*, G. Rao, L. Church, and C.A. Barnes. ARL Division of Neural Systems, Memory and Aging, University of Arizona, Tucson, AZ 85724 and Dept. of Neuroscience and Neurology, Johns Hopkins Univ., Baltimore, MD 21205.

Aged rats show deficits in the maintenance of hippocampal LTP and in spatial memory. To identify possible molecular mechanisms of these changes, we examined the regulation of a panel of immediate early genes induced in association with LTP. Seven young (9-10 mo) and 7 old (26-28 mo) F344 rats were bilaterally implanted with electrodes for evoking and monitoring perforant path field potentials in fascia dentata (FD). Recording commenced approximately 2 weeks after surgical recovery, at which time rats were given 50 mg/kg cycloheximide (i.p.), followed by 1 hour of low-frequency test stimulation (0.1 Hz). Five young and 5 old rats received bilateral repeated 100 pulse bursts of high-frequency stimulation every 7.5 min, and 2 rats in each age group were used as implanted controls. Poly (A+) RNA (Fasttrack, Invitrogen) was prepared from FD that was microdissected from the rest of the hippocampus, and used to prepare cDNA by reverse transcription (Superscript, BRL). The cDNAs were [32P] labeled by random priming and used to screen a panel of IEGs with the "Reverse Northern" technique. Hybridization to each of the IEGs was quantified (phosphorimager, Molecular Dynamics) and normalized to a non-inducible mRNA, glutaraldehyde phosphate dehydrogenase (GAPD). Most IEGs were similarly induced in the young and aged animals, however the induction of *c-fos* was much more robust in the old than the young animals and this difference was significant at $p = 0.034$. These observations indicate that mechanisms controlling the induction or turnover of *c-fos* are selectively altered in aged, behaviorally impaired animals. Support: AG09219, MH00897.

CEREBELLAR MECHANISMS OF EYELID CONDITIONING: MATHEMATICAL ANALYSIS OF PLASTICITY AT TWO COMPETING SITES. G.T. Kenyon* and M.D. Mauk. Department of Neurobiology and Anatomy, University of Texas Medical School, Houston, TX 77225.

Empirical evidence suggests the involvement of two sites of synaptic plasticity in simple forms of motor learning: one in the cerebellar cortex and another in the cerebellar nucleus. A mathematical model based on the synaptic organization of the cerebellar-olivary system is used to analyze the relative contributions from these two sites. Based on experimental data, we assume that plasticity at synapses from granule to Purkinje (Gr→Pjk) cells display generalized long term depression: synaptic weights decrease when active during elevated calcium induced by climbing fiber input and increase when active in the absence of climbing fiber input (during which calcium levels should be reduced). We find that incorporating standard generalized Hebbian plasticity at synapses from mossy fibers to cerebellar nucleus cells (mf→nuc) leads to runaway changes in synaptic strength. However, when a generalized Hebbian rule is modified such that mf→nuc synaptic weights only decrease when active during tonic Purkinje cell inhibition, synaptic weights become stable. Furthermore, the system is self-regulating such that neural activity is always driven to equilibrium levels at which synaptic weights remain constant. We next simulate idealized conditioning trials. An unconditioned stimulus, which increases the excitatory drive to climbing fibers, induces adaptive changes in the subsets of Gr→Pjk and mf→nuc synaptic weights encoding the conditioned stimulus (CS). We assume that Gr→Pjk synapses provide greater temporal discrimination such that a single subset of mf→nuc synapses but many different subsets of Gr→Pjk synapses are activated throughout the CS. We show that each subset of Gr→Pjk synapses active during the CS attempts to transfer plasticity to the nucleus. Thus, the relative contribution to conditioned responses made by plasticity at mf→nuc synapses is related to the weighted average across all subsets of Gr→Pjk synapses active during the CS.

NEURAL NETWORK MODEL FOR CONDITIONED AMYGDALOID NEURAL RESPONSES. K. Muramoto*, T. Ono*, and H. Nishijo*. *Dept. Elec. & Computer Eng., Fac. Tech., Kanazawa Univ., Kanazawa 920, *Dept. Physiol., Fac. Med., Toyama Med. & Pharmaceut. Univ., Toyama 930-01, Japan.

The amygdaloid neuron model was constructed from single neuron activity data [1]. Significant features were the acquisition to conditioned stimuli and extinction after acquisition. A mathematical model of the amygdaloid neural network is presented to quantitatively produce the elemental physiological mechanisms of learning. General model for single neuron is proposed by McCulloch-Pitts. Main functions of the McCulloch-Pitts model are all-or-none response, potential summation and synaptic delay. Added features to the model were the acquisition and extinction to conditioned stimuli. These features were described by connection weight between neurons. When the conditioned response is followed by the unconditioned response after short delay, connection weight increases. The connection weight is always decreased by small value. Detailed temporal firing activities of the model were examined under various conditions. Results show that neurons acquired responses to conditioned stimuli associated with unconditioned ones and these responses were extinguished by extinction.

UNILATERAL NMDA LESIONS OF THE HIPPOCAMPUS DO NOT AFFECT WORKING MEMORY IN AGED RATS. A.H.J. Herremans, A. Van Hest*, T.H. Hijzen, J.L. Slanzen. Dept. of psychopharmacology, Faculty of Pharmacy, Rudolf Magnus Institute for Neuroscience, Utrecht University, Sorbonnelaan 16, 3584 CA, Utrecht, The Netherlands.

The NMDA receptor in the hippocampal CA1 area is suggested a role in memory function. Delayed Conditional Discrimination (DCD) tasks are used to investigate working memory (WM). In the task effects on WM can be separated from other effects by examining delay dependency of an effect. Recently a DCD task was developed that is not sensitive to mediating behavior based on spatial cues (Herremans et al. 1994, *phys & beh.*). Involvement of NMDA receptors in the CA1 in the DCD task was examined in 23 aged rats. 16 trained rats were equipped with a guide cannulae unilateral in the hippocampal CA1 area. Ten days after operation performance in the DCD task was impaired in the operated animals ($F(1,21)=5.56$) and not in 7 unoperated controls. No interaction with delay was found. After retraining for 12 sessions operated animals relearned the DCD task to preoperation levels. Next, eight animals were infused with NMDA (120 mMol, 0.5 μ L) and eight animals received phosphate buffer. Four days after the NMDA lesion performance of lesioned animals never differed from controls during four days measured. Histological examination showed mechanical lesions of the CA1 in all operated animals. It is concluded that mechanical lesions in the CA1 temporarily impaired performance in the DCD task in old rats (recovery within 12 days) but did not affect WM. Subsequent NMDA lesions had no effect.

CLASSICAL CONDITIONING AND VALUE-DEPENDENT LEARNING IN NOMAD, A REAL WORLD ARTIFACT. P.E.M.J. Verschure, J. Wray and G.M. Edelman*. The Neurosciences Institute, 3377 North Torrey Pines Court, La Jolla, CA 92037.

In previous work, it was demonstrated how adaptive behavior can occur in a real world artifact, NOMAD, carrying out a tracking and a block-sorting task (1). NOMAD is a mobile automaton with visual and auditory sensors and a magnetic snout that allows it to "taste" the conductivity of colored objects and pick them up. The behavior of NOMAD is controlled by a simulated neuron-based nervous system containing circuitry for the execution of reflexes and fixed or sensory-driven action patterns (avoidance, approach, exploration). States of the sensors are projected onto mapped and non-mapped neural areas. Initially, the value system is fixed and innate (e.g. "light is better than no light"). It is modeled in terms of the properties of a diffuse ascending system that can modulate synaptic plasticity. Recently, the modeling of value has been expanded to include the experience-dependent modification of value itself (acquired value) (2). In the present work, acquired value was incorporated into the nervous system of NOMAD. Our goal was to show how behavioral regularities resulting from classical conditioning can be understood in terms of value-dependent learning. A convergence of sensory and motor components takes place in a neural region that is an analog of the amygdala. Acquired value is achieved by synaptic modification of projections from the sensory areas to the diffuse ascending value system. As a result, discrimination of color preferences associated with value became more rapid and the responses became more marked. To test this anatomical and dynamical arrangement NOMAD is being subjected to classical conditioning paradigms emphasizing blocking and secondary conditioning with auditory stimuli. We analyze the conditioned behavior of NOMAD in terms of the success of avoidance and approach responses, the correlated states of its nervous system, and the effect of modifications in the stimulus environment. 1. MODELING BIOLOGICAL NEURONS WITH SPATIOTEMPORAL EVENT MAPPING (STEM) CELLS. S.D. Murphy* and E.W. Kairiss. Interdepartmental Neuroscience Program, Department of Psychology, Center for Theoretical and Applied Neuroscience (CTAN), Yale University, New Haven CT 06511.

A biological neuron can be viewed as a match-filter that instantiates a mapping, \mathcal{M} , from multidimensional spatio-temporal (synaptic) events to unidimensional temporal events (action potentials). A computational abstraction of a biological neuron called a Spatio-Temporal Event Mapping (STEM) cell has been designed to perform this mapping in a general way. The three major components of the STEM architecture are (1) an input time-to-space mapping layer (2) a nonlinear spatial mapping layer (3) a recurrent time-to-space mapping layer. A STEM cell implementation of a biophysical model is developed by training on input-output mappings generated from random activation patterns applied to the biophysical model. We show that the STEM cell is capable of learning \mathcal{M} for biophysical models of cortical pyramidal cells of varying complexity, and that it offers advantages over biophysical models in terms of computational efficiency, analytical tractability, and as an avenue towards comparative complexity parameterization of different biophysical models. Because STEM cells are computationally cheaper than conventional differential-equation-based biophysical models, networks of STEM cells can be used to investigate the dynamics of biological neural networks at a scale that is not practical with conventional biophysical models.

SEQUENTIAL INFORMATION PROCESSING: THE NECESSITY FOR MAPPING TIME INTO SPACE. K. Schill, C. Zetzsche and E. Pöppel * Inst. for Med. Psychology, Univ. of Munich, 80336 Munich, Germany

Problems in modeling the perception of dynamic scenes have casted doubts upon the concept of "iconic memory". Analysing current concepts of visual temporal information processing reveals that some basic inconsistencies regarding the temporal properties have not yet been resolved. We have developed a model for the representation of spatio-temporal information in early vision [1]. Its key feature is the mapping of temporal structure into *simultaneously accessible locally distributed activities*. Although the model is aimed at the description of spatio-temporal information processing, application to tachistoscopic presentations also predicts basic results obtained in this field. Furthermore, the model resolves inconsistencies of processing rates obtained with partial report and backward masking paradigms. The standard view on neural information processing, that information is represented by the spatio-temporal activity of discrete elements (neurons), is shown to *necessarily* imply a *discrete* internal representation of time. We believe that the need for the proposed mapping is so fundamental as to be expected to appear in a distributed fashion on various parallel and hierarchical levels in the nervous system. However, since on subsequent levels, sequences with larger temporal extension have to be represented, information reduction has to be applied to avoid combinatorial explosion of connections. Future theories and investigations should concentrate on the syntactical and semantical aspects of suitable integration mechanisms and how they are represented. [1] Schill K., Zetzsche C. (1994): A model of visual spatio-temporal memory: the icon revisited, *Psych. Res.*, in press.

HIPPOCAMPUS AS A THREE-DIMENSIONAL NEURAL NETWORK FOR ASSOCIATIVE MEMORY. Y. Shigematsu and G. Matsumoto * Electrotech. Lab., Tsukuba, 305 Japan.

A neural network model of associative memory is proposed for information processing in the hippocampus. Recent morphological and physiological findings of three-dimensional neural network structure in the hippocampus are considered for the modelling. We have adopted an assumption that each lamellar network accepts its respective category of information. In this model, the networks between granule cells and CA3 cells are constructed within each lamella, in which the information is processed according to their respective categories. The granule cells competitively select particular signals by negative self-feedback for each category. Further, the recurrent paths in the CA3 cells strengthen the associative learning within a category. Both granule and CA3 cells fire sparsely. Association among different categories of information is made by the following inter-lamellar connections of the CA1 and subiculum areas. This associative interaction has a general tendency to induce excessive correlation among the signals. Therefore, sparse firing inputs to the CA1 cells are quite reasonable to protect from the excessive interaction. The other direct input paths from the entorhinal cortex to these areas are very important. These looped circuits can lead the associated output signals to the appropriate input parts of the entorhinal cortex. We can understand the three-dimensional structure and the functions of the hippocampus by this model, and the importance of the hippocampus for associative memory as well.

PATTERN DISCRIMINATION IN AN IMPEDANCE MATCHING MODEL OF DENDRITES K.T. Blackwell*, T.P. Vogl¹, D.L. Alkon². ¹Environmental Research Institute of Michigan, Arlington, VA 22209; ²Laboratory of Adaptive Systems, National Institute of Neurological Disorders and Stroke, NIH, Bethesda, MD

Associative learning in Dystal (Blackwell et al., *Pattern Recognition*, 1992), an artificial neural network, is based on associative learning in *Hermisenda* (Alkon, *Memory Traces in the Brain* 1987). A crucial aspect of associative learning is the ability of a dendritic patch, consisting of a spatially contiguous group of synapses, to recognize previously learned patterns (pattern matching) (Olds et al., *Science*, 1989; Alkon, *Science*, 1984). To investigate the details of this aspect of associative learning, we developed a model of pattern matching in a group of synapses. The model is based on the finding that classical conditioning causes an increase in membrane resistance, and employs an impedance matching paradigm: when the dendritic membrane impedance equals the synaptic resistance, voltage across the dendritic membrane is maximized. The model consists of a small piece of dendritic membrane with a number of synaptic spines, each of which is modeled as an RC circuit (Koch and Zador, *J. Neuroscience*, 1993). The model's resistive elements have the following properties: (1) spine neck resistance increases quickly when calcium concentration exceeds its normal resting value; (2) spine neck resistance slowly adapts to the increased calcium concentration so that after repeated stimulus presentations, spine neck resistance increases only when calcium concentration exceeds the learned value. (3) During repeated stimulus presentations, dendrite membrane resistance increases slowly to match spine neck resistance. Simulations show that this model discriminates patterns that differ solely by biologically reasonable variations in signal strength across synaptic inputs.

INFORMATION TRANSFER IN NETWORKS WITH HEBBIAN CONNECTIONS. E. Salinas, E. Marder* and L.F. Abbott. Biology Department and Center for Complex Systems, Brandeis University, Waltham, MA 02254.

In many systems the firing rates of a population of neurons code for the value of an external variable. We investigate how information about the coded quantity can be communicated from one population (or topographic map) to another. We also explore how nervous systems might combine these representations in order to carry out coordinate transformations. These problems are analysed using computer simulations of the responses of cells that are broadly tuned to an external quantity. We have implemented methods to decode the information in such ensembles of neuronal activities (Salinas and Abbott, *J. Comput. Neurosci.*, in press). This allows us to closely monitor changes in the coded quantity as information is transmitted between or combined in networks. We find that a value coded by one population can be faithfully reproduced in another one if the connections between them are established through a correlation based, or Hebbian type of learning mechanism. This corresponds, for example, to the generation of a motor command in the same direction as a given sensory input. Furthermore, the same algorithm can be used to couple two maps, so that the resulting set of activities codes for a linear combination of the original coded quantities. In this case a coordinate transformation is being carried out. These results demonstrate how networks can perform important computational tasks using biologically plausible learning mechanisms, such as the Hebb rule.

NEURON EXCITABILITY AND ASSOCIATIVE MEMORY FUNCTION. E. P. Cook¹, M. Migliore², & D. Johnston¹. ¹Div. of Neuroscience, Baylor College of Medicine, Houston, TX 77030 & ²Inst. of Interdisc. Applic. of Physics, Natl. Res. Council, Palermo, Italy.

In previous work we showed that the ability of three different biophysical models of a hippocampal pyramidal neuron to use synaptic potentiation as a mechanism of memory storage is dependent on a match between the magnitude of the synaptic input and cell excitability (Cook et al. *Soc. Neurosci. Abs.*, 660.4, 1993). This previous work, however, only explored memory function in model neurons that were initially at rest and in a steady state. In the present report we have compared how previous synaptic activity reduces excitability of the three different neuron models and tested whether this affects subsequent associative memory function.

Our three models were reconstructed hippocampal pyramidal neurons with the following different channel distributions and types: 1) passive dendrites with H&H-like Na⁺ and K⁺ channels in the soma, 2) passive dendrites with a full complement of voltage-gated channels in the soma, and 3) a complete biophysical model that included active dendrites (Migliore et al. *Soc. Neurosci. Abs.*, 295.13, 1993). Activation curves were computed for each model at various time points after four different stimulus paradigms: a) Somatic current injection, and b) low (subthreshold), c) medium, and d) strong synaptic inputs. The program NEURON by Michael Hines was used in all computer simulations.

Comparisons between associative networks constructed from all models show that correct recall of stored patterns is affected by previous synaptic activity in models 2 and 3 but not 1. Simulations demonstrate that the two most realistic models (2 and 3) have increased thresholds to firing after experiencing all four types of stimulus paradigms. As synaptic input is increased (c and d), however, model 3 shows even greater reductions in excitability. This is a direct result of residual [Ca²⁺], activating AHP K⁺ channels. Model 3, which contains dendritic Ca²⁺ channels, was affected the most by all three types of synaptic activity. (Keck Center and MH10475, MH44754, MH48432, and NS11535.)

PARIETAL NEURAL ACTIVITY IS DISTINCT FROM HIPPOCAMPUS DURING AUDITORY DIRECTIONAL DELAYED NONMATCHING-TO-SAMPLE IN AWAKE RATS. K. Nakamura*, T. Ono, H. Nishijo, T. Hirota and R. Nagura. Dept. Electronics and Informatics, Toyama Prefectural Univ., Toyama 939-03, and Dept. Physiol., Fac. Med., Toyama Med. & Pharmaceu. Univ., Toyama 930-01, Japan.

The neural network from parietal cortex (PG) to hippocampus (HF) is important for spatial recognition memory. In the present study, Sprague-Dawley rats were trained to perform a spatial working memory task, directional delayed nonmatching-to-sample (DNMS). Single unit activity was recorded from the PG and HF of an awake rat. While unit recording, the rat could be rotated in some direction or moved within a 63 cm X 63 cm horizontal field. Six speakers surrounded the field at the same height in a hexagonal arrangement. In the directional DNMS, two tones (1s in duration, identical in frequency, and separated by 2 s) were directed at the rat from either the same location (matched pair) or different locations (non-matched pair). To receive an award, the rat needed to lick the spout immediately for a non-matched pair or postpone licking for a matched pair. There were 12 of 57 neurons in the PG and 10 of 30 neurons in the HF that responded to auditory directional stimuli. Ten neurons in the PG also had significant activity during the delay period that sometimes became enhanced after the rat was rotated to an unfamiliar direction. None of the HF-neurons responded during the delay period, but occasionally activity would emerge after the rat was rotated. These results suggest that spatial working memory in the PG is persistent, whereas that in the HF is transient.

Retrograde amnesia for spatial discrimination following entorhinal cortex or parietal cortex lesions in rats. Y. H. CHO* 1,2, R.P. KESNER 1 and R. JAFFARD 2, 1. Department of Psychology, University of Utah, Salt Lake City, 84112 Utah, USA; 2. Lab. Neurosciences Comportementales & cognitives, CNRS URA 339, Avenue des Facultés, 33405 Talence Cedex, France.

Our previous study has demonstrated that lesions of entorhinal cortex (EC) produced a temporally graded retrograde amnesia for spatial discrimination in mice. The present research was conducted to study further retrograde amnesia using rats as subjects as well as to extend to parietal cortex (PC), another brain region involved in processing of spatial memory.

Rats learned successively, one at a time, and every two weeks, 6 single-pair discriminations in two radial mazes (2 pairs in an 8-arm maze and 4 pairs in a 12-arm maze). Either electrolytic lesions of the EC or aspiration of the PC or sham-operation was performed on the day after subjects had attained learning criterion on the 6th discrimination. Postoperative retention performance assessed only for the last 4 discriminations indicated that the PC-lesions impaired overall performance as compared to control rats. The EC-lesions produced a more severe impairment than the PC lesions in addition to an extended temporal gradient of retrograde amnesia. The EC-lesioned rats were significantly impaired in retention of the 3 recent discriminations acquired immediately and up to 4 weeks prior to surgery, but were not different from controls for the first discrimination learned 6 weeks before surgery.

These results are consistent with previous findings obtained in mice with ibotenate lesions of the EC and suggest that the EC as well as the PC might be differentially involved in long-term storage/retrieval of spatial discrimination memory in rodents.

CHARACTERIZATION OF A PREFRONTAL CORTEX AREA INVOLVED IN AUDITORY EVOKED ASSOCIATIVE LEARNING OF THE DEGU (OCTODON DEGUS). M. Müller and G. Poegegel*, Institute for Neurobiology, Brenneckestr.6, 39118 Magdeburg, FRG

Imprinting is one form of early filial learning. Most of the studies dealing with imprinting mechanisms were carried out on birds. However, there is a gap in our knowledge concerning imprinting behaviour in mammals. The degu (*Octodon degus*) provides a good experimental model for studies of auditory filial imprinting in mammals. The mothers use individual calls to attract their pups and to stimulate and probably also to reinforce suckling. Based on earlier studies, we developed a behavioural discrimination test using a Y-shaped test arena equipped with loudspeakers presenting alternatively either the mother call or various control sounds. As controls, pups of surgically muted mothers were tested. Pups from normal mothers showed a significantly higher preference for the mother call compared to pups from muted mothers. In another subset of experiments using 2-deoxyglucose (2-DG), we exposed pups from normal and muted mothers either to the mother call or control sound, respectively. In pups of normal mothers the exposure to the familiar mother call provokes an autoradiographically detectable activation of the medial prefrontal cortex (PFC) and the premotor cortex. Pups of muted mothers and pups exposed to control sounds failed to show such an activation. These areas were immunohistochemically investigated using different techniques. Antibodies against calcium-binding proteins label distinct subsets of neurons in the prefrontal cortex; particularly calretinin is abundantly present in this brain area. With the use of c-fos/c-jun-immunohistochemistry in an identical test setup as in the 2-DG experiments we were able to identify the neurons responsible for the 2-DG staining pattern. These cells were scattered over the PFC with lack of any layering. At present, efforts are made to characterize these neurons and to look for possible alterations at the cellular and subcellular level. (Supported by grant GSF 07 NBL 06 of the BMFT)

THE EFFECTS OF PARIETAL CORTEX AND HIPPOCAMPAL LESIONS ON MEMORY FOR ALLOCENTRIC DISTANCE, EGOCENTRIC DISTANCE, AND SPATIAL LOCATION IN RATS. J.M. Long* R.P. Kesner, Dept. of Psychology, University of Utah, Salt Lake City, UT 84112.

Deficits in finding a hidden platform in the Morris swim maze (a task thought to require a "cognitive map") after lesions to the hippocampal formation or the parietal cortex have been interpreted as evidence for their role in processing spatial cues and their relationships. What has not been explored is which spatial cues or relationships are mediated by these structures. The present study explicitly assessed the effect of post-training lesions of the hippocampus or the parietal cortex on the memory for three such cues: allocentric distance, egocentric distance, and spatial location. In three separate experiments in the same apparatus, Long-Evans rats were trained on a delayed match-to-sample, go/no-go task in which the rats had to remember the distance between two identical objects (allocentric distance), the distance between the rat and an object (egocentric distance), or the spatial location of an object (spatial location). Hippocampal lesions resulted in deficits in all three tasks, whereas parietal cortex lesions did not significantly impair performance in any task. In separate experiments both hippocampal and parietal cortex lesioned rats retained the ability to discriminate allocentric and egocentric distance information, thus providing evidence against the possibility that deficits in the memory tasks could be attributed to deficits in the perception of spatial information. It is postulated that spatial information can be reduced to spatial features (i.e. distance, direction), which are processed primarily by the hippocampal formation.

FUNCTIONAL DIVERSITY IN THE RAT MEDIAL PREFRONTAL CORTEX. J.K. Seamans*, S.B. Floresco, A.G. Phillips. Dept. of Psychology, University of British Columbia, Vancouver, B.C. Canada, V6T 1Z4.

The rat medial prefrontal cortex (mPFC) consists of two distinct subregions, the prelimbic cortex (PL) and the anterior cingulate cortex (AC). Most behavioral investigations have treated these subregions as homogeneous, therefore their individual contribution to the numerous cognitive functions ascribed to the mPFC remains unclear. The present study examined the effects of transient lidocaine-induced lesions of the PL or AC on delayed spatial win-shift (DSWSH) behavior on a radial-arm maze. The DSWSH task consists of a training phase where 4 of 8 arms are baited randomly and the remaining 4 arms are blocked, and a test phase where all 8 arms are open but the previously blocked arms are baited.

Lidocaine microinjections (2%, 1ul/2min) into the PL prior to training had no effect on: 1) training phase performance or 2) subsequent test phase performance as assessed when the anesthetic effects of lidocaine had dissipated. Similar injections into the AC had no effect on training phase performance, however lesioned animals made significantly more entries into previously baited arms during the test phase. Transient lidocaine lesions of the PL delivered prior to the test phase disrupted test phase performance as lesioned animals foraged randomly. Similar microinjections to the AC also impaired test phase performance, but in this case the errors were predominately revisits to previously baited arms. During the random foraging task in which 4 of 8 arms were baited transient lesions of the AC were again accompanied by significantly more revisits to baited arms. PL lesions had no effect on this task. Given that PL lesions disrupted foraging for 4 pellets on the DSWSH but not during the random foraging task, the PL may play a role in complex rule guided behaviors that utilize previously acquired information. Alternatively, the perseverative pattern of responding observed following transient lesions of the AC suggest that the AC is involved in situations which require newly acquired information to be used in a flexible manner.

494.6

EFFECTS OF HIPPOCAMPAL AND MEDIAL PREFRONTAL LESIONS ON DISCRIMINATION OF DURATION IN RATS.

P. Jackson-Smith*, R.P. Kesner, and K. Amann. Depts. of Psychology, Radford Univ., Radford, VA 24142* and Univ. of Utah, SLC, UT 84112.

We examined the effect of hippocampal and medial prefrontal cortex (MPF) lesions on discrimination of temporal duration and on memory for duration in rats. One short duration (2 sec) and one long duration (8 sec) was used and involved visual presentation of a 3-dimensional object. In the discrimination experiment, the door separating the rat from the stimulus was opened at the end of the time period, and latency to approach and move the stimulus was measured. For half of the rats, the stimulus covered a piece of food on the short duration presentations, but not the long durations, and the other half had the opposite contingency. In the second experiment, memory for duration was measured by presenting a study phase (short or long duration) followed one second later by a test phase. The test phase involved presentation of one of two different 3-D stimuli. One object was always correct following a short duration and the other was always correct (food underneath) following a long duration. Half of the trials involved correct pairings of duration and object and half involved incorrect pairings. Latency to approach and move the stimulus during the test phase was measured. Rats in both experiments received control, hippocampal, or MPF lesions following acquisition (significantly greater latencies on nonreinforced trials as compared to reinforced trials). Hippocampal and MPF lesioned groups showed performance deficits following surgery as compared to the control-operated groups on both tasks. Performance on the duration discrimination task returned to normal as compared to controls and pre-surgery performance, whereas both the hippocampal and MPF groups continued to perform at chance levels on the memory for duration task. Both the hippocampus and the medial prefrontal cortex appear to be involved in data-based memory for temporal information.

494.7

LESIONS OF POSTERIOR CINGULATE CORTEX AND VERTICAL LIMB OF THE DIAGONAL BAND OF BROCA IMPAIR THE LATE STAGES OF LEARNING IN A CONDITIONAL VISUAL DISCRIMINATION TASK.

B.J. Everitt*, T.W. Robbins, T.J. Bussey and J.L. Muir. Department of Experimental Psychology, University of Cambridge, Cambridge, CB2 3EB, U.K.

It has recently been shown that excitotoxic lesions of the anterior cingulate cortex facilitate early learning, and posterior lesions impair late learning, on a conditional visual discrimination task (Bussey et al., Soc. Neurosci. Abstr. 19: 1233, 1993). Furthermore, excitotoxic lesions of the vertical limb of the diagonal band of Broca (VDB), which result in cholinergic denervation of both these cortical areas, produce both of these effects on the same task (Muir et al., Soc. Neurosci. Abstr. 19: 1233, 1993). These results are concordant with those of others, who suggest that the anterior cingulate cortex is involved in mechanisms operative during the early stages of learning, while posterior cingulate activity predominates during later stages (Gabriel et al., Exp. Brain Res. 86: 585-600, 1991).

The aim of the present study was to determine whether the late-learning effects observed in our previous experiments were independent of the fact that animals were required to learn the task under the influence of the lesion. Accordingly, rats were trained to a criterion of 70% correct responding on two consecutive days, at which time animals received either quinolinic acid lesion of the anterior or posterior cingulate cortex, or excitotoxic AMPA lesions of the VDB. Following recovery, the animals were returned to the task and trained until they had achieved 85% correct responding on two consecutive days. The results reveal that effects on late learning observed in our previous studies were indeed reproduced: both VDB and posterior cingulate lesioned animals showed an impairment in the ability to progress through the later stages of learning the task. In addition, the effects of the lesions on a post-acquisition retention test and on extinction were examined.

THE EFFECT OF CINGULATE CORTEX LESIONS ON ACQUISITION OF A SIMPLE VISUAL DISCRIMINATION AND REVERSAL, AND AN 8-PAIR CONCURRENT DISCRIMINATION TASK IN RATS: THE USE OF A NOVEL TOUCHSCREEN APPROACH. **J.L. Muir*, T.J. Bussey, B.J. Everitt and T.W. Robbins.** Department of Experimental Psychology, University of Cambridge, Cambridge, CB2 3EB, U.K.

Cingulate cortex - the division of midline limbic cortex overlying the full rostrocaudal extent of the corpus callosum - has received little attention relative to other limbic structures such as the hippocampus. Recently it has become apparent that the cingulate cortex can be anatomically dissociated into anterior and posterior components. However, the characteristic behavioural functions of these structures remain to be elucidated. Results obtained using an active avoidance paradigm suggested that the anterior cingulate cortex mediates mechanisms operative during early learning, while posterior cingulate cortex is involved predominantly in late learning (Gabriel et al., Exp. Brain Res. 86: 585-600, 1991). More recently, it has been demonstrated that lesions of the anterior cingulate cortex facilitate early learning, and posterior cingulate cortex lesions produce a deficit in late learning, of a visual conditional discrimination task which requires the acquisition of a stimulus-response rule (Bussey et al., Soc. Neurosci. Abstr. 19: 1233, 1993).

These results have led us to investigate the role of anterior and posterior cingulate cortices in the learning of stimulus-reward associations. We have recently developed a new computer automated touchscreen testing procedure which enables the testing of rats on various tasks involving the presentation of computer graphic stimuli. The present study employed this technique to examine the effects of anterior and posterior cingulate cortex lesions on simple visual discrimination and reversal and the acquisition of an 8-pair concurrent visual discrimination task. The results show that neither anterior or posterior cingulate lesions affected acquisition of a simple discrimination. However, lesions of the anterior cingulate cortex impaired the early but not the late stages of acquisition of the 8-pair concurrent discrimination task.

INSULAR CORTEX GRAFTS RESTORE REMEMBRANCE OF PREVIOUSLY LEARNED TASTE AVERSIONS.

C.E. Ormsby, V. Ramírez-Amaya and F. Bermúdez-Rattoni* Instituto de Fisiol. Celular, UNAM, México, D.F., México 04510.

Previous studies in our laboratory have shown that cortical grafts are able to induce recovery in the ability to acquire a conditioned taste aversion (CTA) in insular cortex (IC) lesioned rats. Furthermore, tissue specificity has been shown since only homotopic grafts induce recovery whereas occipital cortex (OC) tissue does not. Further studies have shown that IC lesions interfere with short and long term memory for CTA. The aim of the present study is to evaluate the effects that cortical grafts have on the recovery of memory aspects of CTA.

Twenty-nine male Wistar rats were trained for CTA by pairing a saccharin solution (0.1%) with a gastric malaise induced by an ip injection of LiCl solution (0.15M). After 4 days to allow consolidation, all animals except a control (Con) group were lesioned by microinjections of NMDA and 10 days later the lesioned animals were randomly divided in 3 groups: one received IC grafts from 15-day-old fetuses (TxIC), one received OC grafts (TxOC), and one remained lesioned. Sixty days after grafting, all animals were tested for the CTA to saccharin and then retrained for a CTA to saline taste. The animals that remained lesioned did not recall the saccharin CTA nor were able to acquire the new CTA to saline. Both grafted groups showed a recall of the CTA for saccharin similar to the control, but only the TxIC group showed values similar to the control for the acquisition of the new CTA for saline. It is noteworthy that the TxOC group was able to recall previously learned CTA but unable to learn a new one. This data suggests that the graft-induced recovery of recall is less tissue specific than recovery of acquisition of CTA, and that the IC is highly involved in the evocation aspects of CTA. INTRODUCING A NEW COMPUTER AUTOMATED TOUCHSCREEN TESTING PROCEDURE FOR THE RAT USING COMPUTER-GRAPHIC STIMULI: OBJECT DISCRIMINATION AND RECOGNITION TASKS.

T.J. Bussey*, J.L. Muir and T.W. Robbins. Department of Experimental Psychology, University of Cambridge, Cambridge, CB2 3EB, U.K.

The comparative neuropsychological approach involves the comparison of brain-damaged human patients with animal models of the same disorders, using tasks designed to assess specific psychological functions. This enterprise is greatly facilitated when the tasks are as similar as possible for both species, and very difficult when they are not. Many researchers have succeeded in devising such tasks involving, for example, the use of "junk objects" in the Wisconsin General Test Apparatus or, more recently, the presentation of computer graphic stimuli on a VDU/touchscreen apparatus in primates and patient groups. Unfortunately, few tasks have been designed for the rat with this approach in mind. This is perhaps surprising given that the rat is, in psychology at least, by far the most popular and convenient laboratory animal.

Thus, we have recently developed a touchscreen procedure for the rat using computer generated visual stimuli. In addition to inter-species comparability, other advantages of this technique include the nature of the response, the rat being able to interact directly with the stimulus by nose-pokes to the VDU screen; the ease with which rats can be trained to respond in this manner; and the ability to collect data on a wide range of performance measures. These points will be discussed and data will be presented to illustrate the use of a touch-sensitive screen for rats on various tasks, including object discrimination and serial reversal learning, 8-pair concurrent visual discrimination learning, spatial and non-spatial delayed non-matching to sample and visuospatial conditional rule learning.

RATS' VISUAL MEMORY IN A COMPUTER-CONTROLLED TESTING ENVIRONMENT. **E.A. GAFFAN***, Department of Psychology, Reading University, Reading RG6 2AL, UK and **M.J. Eacott**, Department of Psychology, Durham University, Durham DH1 3LE, UK.

Rats, of the Hooded Lister and Dark Agouti strains, were trained in a fully automated setting; a Y-maze each of whose arms terminates in a pair of adjacent monochromatic VGA screens, with a food dispenser between them. The abstract stimuli include internally complex, wide-angle displays - "scenes" analogous to those whose processing is disrupted by hippocampal system lesions in primates - and more localised, homogeneous "objects". Displays can incorporate movement and brightness fluctuation to enhance their salience. We report rats' performance in tests of associative reference memory (concurrent discrimination among pairs of displays) and working memory (matching or non-matching).

MEMORY FOR FOOD REWARD MAGNITUDE: THE ROLE OF THE AGRANULAR INSULAR CORTEX. **W.E. DeCoteau, R.P. Kesner* and J.M. Williams.** Department of Psychology, University of Utah, Salt Lake City, UT 84112.

Memory for magnitude of reinforcement was assessed in rats using a go, no-go task. During the task's study phase rats were given a piece of cereal comprised of either 25% or 50% sugar. For all trials, one of the cereal types was designated positive, the other negative. On the ensuing test phase the rat was presented with an object which covered a food well. If a positive food reward was given during the study phase, a second food reward was placed beneath the object. No food reward was placed under the object if the study phase consisted of a negative food reward. Latency to object displacement was used as the measure of performance. Following the establishment of a significant difference between latency to approach the object with reward compared to latency to approach the object without reward, rats were given either medial prefrontal cortex, agranular insular cortex, infra-limbic/pre-limbic cortex or sham control lesions. Sham controls excepted, all lesion groups showed post-surgery impairment followed by recovery of performance. Furthermore, all animals transferred to a new set of cereals containing 25% and 50% sugar. Thus, independent of lesion type, all post-surgery animals were able to perceive differences between magnitudes of reward. Trials consisting of 10 and 20 second delays between the study and test phases were then introduced. Only agranular insular lesioned animals showed significant impairment at each delay. These results demonstrate that lesions to the agranular insular cortex in rats produce accelerated forgetting of reward magnitude and suggest that this structure plays a significant role in memory for affect.

494.13

NEGATIVE PATTERNING DISCRIMINATION PERFORMANCE IS IMPAIRED IN RATS WITH BILATERAL QUISQUALIC ACID LESIONS OF THE NUCLEUS BASALIS MAGNOCELLULARIS. A.E. Sutt* and G.K. Hodge. Dept. of Psychology, University of New Mexico, Albuquerque, NM 87131.

It was hypothesized that NBM lesions would selectively impair the ability to learn conditional, or configural, associations while sparing the ability to learn simple, or elemental, associations (see Sutherland & Rudy, 1989). To test this hypothesis, rats received bilateral quisqualic acid or sham lesions of the NBM and were subsequently tested in a negative patterning operant discrimination task. In this task, animals are food-reinforced (+) for pressing an operant chamber lever in the presence of either a light (L) or tone (T), but are not reinforced (-) in the presence of a compound stimulus comprised of the light and tone presented together (LT). Animals must learn that the reinforcement values of the elements L and T are determined by whether these stimuli occur separately (L+, T+) or simultaneously (LT-). Thus, learning to withhold responses to LT- requires the formation of a configural representation of the compound cue that is discriminable from the representations of its constituent elements. Based on evidence suggesting that simple associative learning remains intact in NBM-lesioned animals, it was hypothesized that these animals would learn to respond normally to the elements L+ and T+. It was further hypothesized, however, that NBM-lesioned animals would be unable to form the configural representation of LT- and would continue to respond in the presence of this nonreinforced compound stimulus. Data support these hypotheses. All animals were able to discriminate between the presence and absence of the reinforced elements L+ and T+, suggesting that the ability to solve simple associative discriminations is unimpaired in NBM-lesioned animals. In contrast, negative patterning discrimination performance was impaired in NBM-lesioned animals; lesioned animals made significantly more LT- responses across training sessions than controls ($p < .05$), although behavioral recovery eventually ensued. Results suggest a selective involvement of the NBM in the acquisition of configural but not simple associative tasks. (Supported by UNM RAC #93-33)

494.15

EFFECTS OF MEDIAL SEPTAL LESIONS ON DELAYED GO/NO-GO RESPONSE ALTERNATION IN RATS. R. Numan* Psychology Department, Santa Clara University, Santa Clara, CA 95053.

In an earlier study (Numan and Quaranta, 1990) we found that medial septal lesions impaired a two-lever (left-right) operant delayed alternation task in rats. We concluded that the impairment was due to a disruption of working memory. However, a 'spatial' interpretation of the data could not be ruled out. Subsequently (Numan and Klis, 1992), we found that medial septal lesions facilitated performance on a cued go/no-go discrimination task with a delay between the cue and the required response. This task was not spatial (only 1 lever was used), but did require working-memory. Hence, the lesion could not have produced a general working-memory impairment.

These findings, taken together, suggested to us that the medial septal lesions impaired 'response' working memory which in turn led to a compensatory enhancement of 'stimulus' working memory. If this were true, then the lesions should impair a go/no-go task based on response working-memory. The current experiment tested this hypothesis.

Rats (12 with medial septal lesions and 12 with sham operations) were tested on a discrete trial operant go/no-go response alternation task without cues. The rats were first tested for 20 days without a delay contingency, followed by 30 days of testing with a 15-sec delay between 'go' and 'no-go' trials.

The septal lesions did not impair performance at the 0-sec delay ($p > 0.05$). Both groups achieved about 85% correct and acquired the basic requirements of the task. However, when the delay contingency was added, the medial septal lesions impaired performance ($p < 0.025$). By the end of testing, the controls averaged about 75% correct while the septal lesioned rats averaged about 68% correct.

As the go/no-go task does not require spatial processing, the best explanation for all of these findings (impairment on L-R delayed alternation and delayed go/no-go response alternation, but facilitation on a delayed but cued go/no-go discrimination) is that the medial septal lesions produce an impairment in 'response' working memory. Such an impairment may result in a compensatory enhancement in the processing of salient environmental cues to guide behavior and improve performance on cued tasks.

494.17

LATERAL DORSAL NUCLEUS OF THE THALAMUS CONTRIBUTES TO SPATIAL LEARNING. M. Palmer* & R. J. Sutherland. Dept. of Psychology, University of New Mexico, Albuquerque, NM 87131.

The lateral dorsal nucleus (LD) of the thalamus has reciprocal connections with retrohippocampal areas. Recent electrophysiological work implicates LD as playing an important role in the spatial navigation process, especially in encoding head direction (Mizumori & Williams, 1992). The present experiment was designed to investigate LD's role in spatial learning.

Eight rats received electrolytic lesions of LD (coordinates: -2.6, +2.6, -2.6, 5.7) of 15mA for 15s. Sixteen rats served as sham controls. All rats were naive to the Morris water task. We used a moving platform version of the water task in which the submerged platform was moved to a new position on each subsequent day, but remains in the same position over the day's trials.

The LD rats displayed a significant deficit in learning relative to the sham controls.

We will also report on acquisition of a negative patterning discrimination and a light-tone discrimination in an operant task.

494.14

CHANGES IN ATTENTION AND NORADRENERGIC REUPTAKE SITES IN FRONTAL CORTEX OF BASAL FOREBRAIN-LESIONED RATS. C.L. Wellman* and M.A. Pellemounter. Department of Neurobiology, Amgen, Thousand Oaks, CA 91320.

The nucleus basalis magnocellularis (NBM) is the major cholinergic projection to frontal cortex in the rat and appears to modulate cortical neuronal activity. Lesions of the NBM produce deficits in radial arm maze performance and morphological alterations in frontoparietal cortex. In the present study, we have assessed selective attention and noradrenergic receptor binding in frontal cortex of rats with bilateral lesions of the NBM. Nineteen rats received either ibotenic acid or sham lesions of the NBM. Two months after surgery, rats were trained in a blocking task. While sham-lesioned rats showed blocking, suppressing significantly more to a meaningful cue than to a redundant cue, NBM-lesioned rats did not show blocking, suppressing less to both cues. The groups performed comparably on a passive avoidance task, suggesting that deficits on the blocking task were due to attentional changes rather than a learning deficit. Three months after surgery, rats were killed and their brains removed. Sections were incubated with either [3H]hemicholinium-3 (HC-3) to assess extent of cholinergic denervation or [3H]desmethylinipramine (DMI) to assess noradrenergic function and processed for autoradiography. Quantitative densitometry revealed a 28% decrease in HC-3 binding and a 24% decrease in DMI binding in frontal cortex of lesioned rats. Thus, the NBM appears to modulate noradrenergic function in frontal cortex, and alterations in NBM function may influence behavior and cortical morphology through the noradrenergic system.

RETROGRADE AND ANTEROGRADE SPATIAL MEMORY IMPAIRMENTS FOLLOWING RADIO-FREQUENCY LESIONS TO THE LATERAL INTERNAL MEDULLARY LAMINA. L.M. Savage*, A. Sweet, A. Bassett, & P.J. Langlais

VA Medical Center San Diego, CA. 92169, & Department of Psychology, SDSU, San Diego, CA. 92182.

Rats were pre-trained on a Non-Matching-To-Position (NMT) task in the T-maze. After initial acquisition (90% correct for 2 sessions) subjects were randomly assigned to two treatment conditions: (A) radio-frequency lesions to the lateral Internal Medullary Lamina (IML-lesioned), or (B) probe placement in the same location (sham). Following recovery from surgery, the IML-lesioned rats took significantly more trials than shams to re-acquire the criterion. This suggests that lesions to the lateral IML region produce retrograde deficits. Once subjects re-mastered the NMT task, delays intervals were introduced to access working memory. Although the performance of IML-lesioned rats at the shortest delay (4 s) was equivalent to shams, their accuracy at longer delays (30, 60 and 90 s) had a steeper decline. Anterograde learning and memory was subsequently assessed using the Morris water maze. Again, IML-lesioned rats demonstrated impaired spatial abilities-their latency to find the location of the hidden platform was significantly longer than shams. However, they were able to decrease their latency to find the location of a visual platform. IML-lesioned rats, relative to shams, demonstrated no deficits in learning a single trial passive avoidance task. These results suggest that lesions to the IML region produce a range of spatial deficits that parallel the pyriminamine-induced thiamine deficiency model of Wernicke-Korsakoff syndrome. Funded by a VA Merit Award to P.J.L.

494.18

IBOTENATE LESIONS OF RAT NUCLEUS REUNIENS THALAMI FAIL TO IMPAIR SPATIAL LEARNING AND MEMORY. M.J. Dolleman-van der Weel*, R.G.M. Morris, and M.P. Witter. Graduate School of Neurosciences, Dept. Anatomy and Embryology, Vrije Universiteit, Amsterdam, The Netherlands, 'Centre for Neuroscience, Univ Edinburgh, Scotland.

Monosynaptic projections from nucleus reuniens may enable it to modulate activity in the entorhinal-hippocampal circuit and, hence, play a role in learning and memory. We explored this idea using the watermaze (fixed hidden platform, 18 spatial training trials, transfer test, 4 cue trials). The reuniens (RE, n=12) was lesioned with ibotenic acid and the behavioural effects were compared to Unoperated (Unop, n=6) and sham-lesioned controls (SH, n=11), mediadorsal nucleus (MD, n=6) and hippocampal-dentate gyrus lesioned rats (HDG, n=6). ANOVAS revealed overall Groups effects in both training and the transfer test ($p < 0.001$), but, despite a trend towards poor performance by the RE group, pairwise comparisons (Dunn's test) revealed that only the MD and HDG groups were impaired relative to the SH group during training ($p < 0.01$ and 0.025 respectively) and only the HDG group was impaired during the transfer test ($p < 0.025$). The cue test revealed a trend towards poorer performance in the MD group ($0.10 > p > 0.05$). Our protocol was, therefore, sufficiently sensitive to detect hippocampal dysfunction in spatial learning and memory, but showed only a nonsignificant trend towards impairment following damage to the reuniens.

In summary, the presumed modulatory input from the reuniens to the entorhinal-hippocampal circuit has only a subtle effect on spatial learning. Its function may be better revealed using other learning and memory paradigms.

494.19

ASSESSING THE PERFORMANCE OF RATS WITH LESIONS TO THE MEDIODORSAL THALAMUS ON A BATTERY OF NONSPATIAL MEMORY TASKS. T.J. Kornecook and J.P.J. Pinel*. Dept. of Psychology, University of British Columbia, Vancouver, B.C. Canada. V6T 1Z4.

Rats with bilateral electrolytic or sham lesions of the mediodorsal thalamic nucleus (MD) were tested on a battery of six object-memory tasks, which resemble those which have been used in the study of amnesia in humans and monkeys: (1) simple two-choice object discrimination, (2) discrimination reversal, (3) 8-pair concurrent object discrimination, (4) nonrecurring-items delayed nonmatching-to-sample (DNMS) with retention delays of 4, 15, 30, 60, 120 s, (5) DNMS with lists of 3, 5, and 7 samples, and (6) order discrimination. Each task made use of the same apparatus and, like the monkey versions of these tasks, each one used objects as test stimuli. All testing was conducted postsurgery.

Relative to control rats, the rats with mediodorsal thalamic lesions were unimpaired at learning the simple object discrimination, but they took significantly more trials to master both the object reversal and the concurrent object discrimination tasks. The DNMS testing revealed that the rats with MD lesions were impaired at all delays of 15s or longer, and there was an overall group impairment across the three list lengths. There was no significant difference between the controls and MD-lesioned rats on the temporal-order discrimination task. The results from this battery of memory tasks will help in fully characterizing the nature of the memory deficits associated with medial diencephalic lesions in the rat and allow for direct comparisons to similar experiments in monkeys.

494.21

LESIONS OF THE TUBEROMAMMILLARY NUCLEUS FACILITATE REWARD AND LEARNING. J.P. Huston, K. Klapdor, U. Wagner, P. Zimmermann and R.U. Hasenöhrl*. Inst. Physiological Psychology, University of Düsseldorf, D-40225 Düsseldorf, Germany.

The tuberomammillary nucleus (TM) is located in the posterior part of the hypothalamus and provides the only source of neural histamine in the CNS. Our experiments performed with unilateral lesions of the TM region provide evidence for an involvement of the TM system in reinforcement mechanisms. Unilateral destruction of the TM with DC or ibotenic acid was found to increase the rate of lateral hypothalamic self-stimulation ipsilateral to the lesion site, suggesting that the TM may function as a reinforcement inhibiting neural substrate. Experiments performed with bilateral lesions of the TM region provide evidence for a role of the TM in learning and memory processes. Adult (3-month-old) and aged (31-month-old) rats with bilateral DC lesions in the TM region were tested along with sham-lesioned controls on the one-trial step-through inhibitory avoidance task and on a spatial discrimination test in a water-filled T-maze. Bilateral lesions of the TM led to significantly longer retention latencies in the step-through task and improved long-term retention in the water maze test in both adult and aged rats, indicative of superior learning. Thus, lesions of the TM may have a facilitatory effect on learning and mnemonic functioning, which is possibly related to a lesion-induced disinhibition or facilitation of reinforcement ("stamping-in") processes. *Supported by DFG.*

DIFFERENT SUBCORTICAL AREAS SUBSERVE SPATIAL BUT NOT VISUAL DISCRIMINATION PERFORMANCE IN INBRED MICE. M. Ammassari-Teule* and C. Rossi-Arnaud*. Inst. of Psychobiology and Psychopharmacology and * Dept of Psychology, University of Rome "La Sapienza", Rome, Italy.

C57BL/6 (C57) and DBA/2 (DBA) inbred mice differently perform spatial tasks with C57 doing better than DBA at such learning. Hippocampal lesions have been shown to impair performance in both strains while amygdaloid and frontal cortex lesions have a deleterious effect only in the "high learner" strain C57. The aim of the present study was to examine whether the genotype-dependent involvement of limbic structures remains the same across tasks which make either the spatial or the visual modality relevant for discriminating the set of baited arms. C57 and DBA mice were tested in the standard (experiment 1) or in the visually-cued (experiment 2) version of the four-baited path task in a radial eight-arm maze.

Results show that, when the spatial modality was relevant for identifying the correct arms, both hippocampal and amygdaloid lesions impaired performance in C57 while hippocampal but not amygdaloid lesions impaired performance in DBA. Conversely, when the visual modality was relevant, the two strains performed the task in the same fashion and their performance was impaired by hippocampal lesions only. Spatial but not visual discriminative learning is therefore selectively based upon the involvement of different subcortical areas in the two strains considered.

MEMORY IMPAIRMENT FOLLOWING LESIONS TO THE ANTERIOR NUCLEI OF THE THALAMUS. V. Sziklas*, F. Leri, and M. Petrides. McGill University, Montreal, Quebec, Canada.

In the present study, rats with lesions to the anterior thalamic nuclei (ATN), the fornix (FX) or a control operation (OC) were trained on an eight-arm radial maze under two conditions. In the first condition, there was a 20 sec delay between choices; in the second, there was no intratrial delay. Animals with lesions to the FX improved significantly when there were no delays between choices but the performance of this group was significantly impaired in comparison with the OC animals under both conditions. The overall performance of the ATN group was significantly worse than that of the OC group and, in addition, did not improve significantly with the removal of the intratrial delay. An analysis of the distribution of errors made in the delay condition suggests that the nature of the memory deficit following lesions to the ATN and the FX might be different. Taken together, these findings suggest that restricted lesions to the ATN are sufficient to produce a working memory deficit on the radial maze under the conditions used in this study.

INVESTIGATION OF NEURAL AREAS CONTROLLING CONDITIONED TASTE AVERSIONS IN RATS: EFFECTS OF COOLING THE AREA POSTREMA. Y. Wang, D. G. Lavond, & K.C. Chambers*. Department of Psychology USC, Los Angeles, CA 90089

Four studies were designed to determine the feasibility of using cooling to investigate neural mechanisms of conditioned taste aversions (CTAs). Study 1 was designed to determine whether cooling the area postrema (AP) can induce a CTA. After 13 rats were given access to a sucrose solution, the AP of 7 of the rats was cooled for 1 hour and the AP of 6 was not cooled. Starting 2 days later, all rats were given daily extinction trials until their acquisition day consumption levels were restored. Cooling the AP induced a CTA; the rats whose AP was cooled showed a decrease in sucrose consumption but the non-cooled group did not. Study 2 was designed to determine whether preexposure to cooling of the AP could attenuate the CTA induced by cooling the AP. In 7 rats, the AP was cooled daily for 7 days and in another 7 rats the AP was not cooled. On acquisition day, the AP of all rats was cooled after consumption of sucrose solution. Preexposure to cooling attenuated the aversion induced by cooling; the non-preexposed group showed a decrease in sucrose consumption but the preexposed group did not. Study 3 was designed to determine whether cooling the AP could be used to block a CTA induced by LiCl. All rats were preexposed to cooling. After sucrose consumption, the AP of 6 rats was cooled just prior to injection of LiCl and was kept cooled for 1 hour. Another 7 rats received LiCl only. Cooling the AP attenuated the aversion induced by LiCl; rats exposed to cooling during LiCl stimulation acquired a weaker aversion than those not exposed. Study 4 was designed to determine whether cooling the AP could block a CTA induced by apomorphine (Apo). After sucrose consumption the AP of 8 rats was cooled just prior to injection of Apo and was kept cooled for 1 hour. Another 8 rats received Apo only. Cooling had no effect on the aversion induced by Apo. The results of these studies, attenuated aversion induced by LiCl but not apomorphine, replicate those of studies that have used permanent lesion techniques. *Supported by USC FRIF.*

ASYMMETRICAL EFFECTS OF LESIONS IN FR2 ON LEFT-RIGHT RESPONSE DIFFERENTIATION IN THE RAT. M. Noonan*, D. Chmiel, Jr., and S. Axelrod*. 1 Canisius College, Buffalo, NY 14208; 2 SUNY at Buffalo, Buffalo, NY 14214.

We compared rats with left or right lesions in supplementary motor area Fr2 (Zilles), and sham operates, on a left-right response differentiation (LRRD) water-maze task given after prior experience with a control task in the same apparatus. We found that (1) rats exhibited an overall left-turning bias during acquisition; (2) the bias was particularly pronounced on the LRRD task; and (3) right-lesioned rats performed better than left-lesioned rats.

Overall, our results provide evidence of a consistent cerebral asymmetry in the rat. The left-turning bias replicates earlier findings in our laboratory and points to an asymmetrical motor activation favoring the right hemisphere during these water escape tasks. Nonetheless, a lesion in the right Fr2 left our rats better able to acquire an LRRD task than a lesion in the left Fr2. We have previously shown that extensive right hemidecortication, compared to left decortication, improves performance on the LRRD task when it was similarly presented as a second learning experience. The present finding appears to localize the relevant asymmetry to area Fr2, and suggests that it is motor/attentional in nature.

DIFFERENTIAL INVOLVEMENT OF HIPPOCAMPAL SUBFIELDS CA1 AND CA3 IN ODOR DISCRIMINATION. U.S. Hess*, G. Lynch, and C.M. Gall. Dept. of Psychology, Univ. of CA, Irvine 92717.

Expression of the protooncogene *c-fos* is a useful marker of neuronal activity. In the present study, levels of *c-fos* mRNA were evaluated in order to define functional brain circuitries that underlie odor discrimination. Rats were trained on one odor pair in a familiar chamber with six odor alleys. Odors were emitted from any random two odor ports on a given trial and rats had to nosepoke at the positive port to receive water reward and to avoid the negative port (response to which resulted in a strobe flash). Control rats (i.e. *nosepoker controls*) performed a practiced nosepoking behavior for water reward in the same apparatus with no odor presentation. *c-fos* mRNA was quantified using in-situ hybridization of ³⁵S-cRNA probes. Hybridization to *c-fos* mRNA was substantially lower in rats performing the task (*learners*) as compared to *nosepoker controls*. Levels of *c-fos* mRNA in *learners* were lower by 30 to 40 % in i) medial glomerular and granule cell layers of main olfactory bulb, ii) medial superficial superior colliculus, iii) rostral occipital cortex, iv) dorso-lateral caudate/putamen, and v) hippocampal CA1 stratum pyramidale. Other regions measured showed no difference in *c-fos* mRNA content between *learners* and *nosepokers*. In no region were *c-fos* mRNA levels greater in *learners* than controls. These selective differences in *c-fos* mRNA content resulted in differential regional labeling suggesting primary sensory and limbic structure involvement in task performance. In olfactory bulb, the increased lateral/ medial *c-fos* ratio seen in *learners* appears functionally relevant since it is the lateral portion of the bulb which maps the positive, most frequently sampled odor (i.e., peppermint). Sustained *c-fos* expression in area CA3 of *learners*, and notably suppressed *c-fos* mRNA content in area CA1 of these rats in relation to controls, indicates a differential involvement of these two hippocampal subfields in odor discrimination. This is especially interesting in light of the postulated role of the hippocampus in memory consolidation. Supported by 1 F31 MH10510-01 and HD24236.

FACILITATION OF PLACE LEARNING AND DEFICIT OF RELATIONAL REPRESENTATIONS INDUCED BY HIPPOCAMPAL INJECTIONS OF SOMATOSTATIN. J.-L. Guillou*, L. Lamirault, J. Micheau and R. Jaffard. Lab. Neurosciences Comportementales et Cognitives URA CNRS 339 Univ. Bordeaux 1 Av des facultés 33405 Talence Cedex France.

Previous studies with rodents showing alterations in both spatial learning and LTP following injections of either somatostatin (SS-14) or its depletor cysteamine have generated the hypothesis that hippocampal SS-14 could play a role in spatial mapping processes. However we reported that, although intra-hippocampal SS-14 injections facilitated the acquisition (regular trials) of spatial discriminations (two overlapping pairs (A-B+) vs. (B+C-) in a 8-arm radial maze, SS-14 also impaired performance during probe trials (A-B+C) aimed at taxing relational representations, (Guillou et al., Psychobiology 21-4, 1993). In the present study the aim was to determine whether this latter impairment was due to a deficit of relational encoding during the acquisition of the task or, alternatively, to a retrieval deficit (fragment fitting) occurring only when testing was shifted on probe trials. Accordingly, SS-14 or artificial CSF was injected either before regular or probe trials, or both. As in the previous study, injections of SS-14 before both regular and probe trials facilitated regular trials and significantly impaired probe trials. Injections of SS-14 before only regular trials produced the same pattern of results. In contrast, injections of SS-14 before only probe trials did not yield any behavioral effect. Thus, injections of SS-14 into the hippocampus appear to disrupt relational representations that, in normal mice, would occur during the acquisition of the task. This SS14-induced deficit of relational representations could account for the facilitation of acquisition (by use of individual representations of each pair). However, other results along with the observation that cysteamine produces a large impairment on regular trials seem difficult to explain by the relational theory alone. Taken together, these results suggest that both spatial mapping and the formation of relational representations are two separate HPC-dependent functions.

BEHAVIORAL AND ANATOMICAL EFFECTS OF 192-SAPORIN & ANTI-DβH-SAPORIN: PASSIVE AVOIDANCE, CONDITIONED FREEZING AND OPEN FIELD ACTIVITY. R.G. Wiley*, T.G. Berbos, D.A. Lappi, M.J. Picklo & D. Robertson. VAMC & Vanderbilt University, Nashville, TN 37212 & The Whittier Institute, La Jolla, CA 92037.

Analysis of the behavioral function of the cholinergic basal forebrain (CBF) has benefited from the development of the immunotoxin, 192-sap, that selectively destroys neurons expressing the low affinity NGF receptor (p75). Animals with high grade CBF lesions are profoundly impaired in a variety of behaviors including passive avoidance. Since the ascending noradrenergic projections innervate both the CBF and many of its targets (hippocampus, neocortex), we sought to compare rats injected intraventricularly with 192-sap (N=8) to controls (N=8) and to rats treated with another immunotoxin, anti-DβH-sap (N=8), that selectively destroys neurons (adrenergic & noradrenergic) expressing the enzyme, dopamine β-hydroxylase. Rats injected with anti-DβH-sap were slower to regain weight after surgery than rats injected with 192-saporin (p<0.002). Anti-DβH-sap rats also showed less of an increase in immobility in a conditioned fear paradigm than 192-sap treated rats (p<0.003). In a step-through passive avoidance task, anti-DβH-sap treated rats behaved similar to controls showing none of the impairment seen in the 192-sap treated rats (p<0.001). In the open field, there was a nonsignificant trend for increased activity among 192-sap treated rats compared to the controls and anti-DβH-sap treated rats. Immunocytochemical staining for p75 and choline acetyltransferase (ChAT) showed near complete (>90%) loss of p75+/ChAT+ neurons from the CBF in 192-sap treated rats compared to controls. Anti-DβH-sap treated rats showed about 50% decrease in p75+/ChAT+ neurons in the CBF and near complete (>90%) loss of tyrosine hydroxylase (TH)-positive neurons from the noradrenergic and adrenergic brainstem nuclei. Dopaminergic TH+ neurons were unaffected in the substantia nigra and ventral tegmental area. These results confirm that 192-sap and anti-DβH-sap produce the expected selective lesions and that animals prepared with these agents are useful in analysis of the behavioral function of CNS cholinergic and noradrenergic neural systems.

GLUCOSE FACILITATES ACQUISITION AND REDUCES HIPPOCAMPAL DEFICIT IN THE MORRIS WATER MAZE IN RATS. R.W. Skelton* & S.P. Ross. Psychology, U. Victoria, Box 3050, Victoria, B.C. V8W 3P5 CANADA

Post-trial glucose has well-known facilitatory effects on retention of inhibitory conditioning. Increases in blood glucose levels have been proposed to underlie the mnemonic facilitation produced by epinephrine, norepinephrine and nootropics. The present study examined the effects of pre- and post-trial glucose on acquisition in the Morris water maze, an aversively motivated escape-learning task which requires spatial navigation and a functioning hippocampus. The present study also examined the effects of pre-trial glucose on performance of rats recovering from bilateral transections of the perforant path (a major cortico-hippocampal-cortical pathway).

During initial acquisition, glucose (100 mg/kg) was administered for 10 days 15 min before or after 2-trial daily sessions with a submerged platform in a fixed location. Probe trials were given as the second trials of Days 5 and 10, and an undrugged probe trial was given after a 5 day undrugged retention interval. After such pretraining, rats were given bilateral knife cuts to the perforant path and allowed 5 days to recover. They were then tested for 7 days with the platform in the original location and 7 days with the platform in the opposite quadrant. Glucose (100 mg/kg) was injected 15 min prior to each daily session of 4 submerged platform trials, 1 probe trial, and (for the 1st 5 days) 1 visible platform trial.

Both pre- and post-trial glucose increased the rate of acquisition and enhanced retention. Pre-trial glucose reduced the lesion-induced deficit in navigating to the previously learned platform location, but had little effect on the smaller deficit in reversal learning.

These results extend previous reports that glucose facilitates learning and retention, and indicate that glucose can also ameliorate cognitive deficits after hippocampal damage. (Supported by grants from NSERC Canada and BC Health Research Foundation.)

DENTATE GYRUS DESTRUCTION AND SPATIAL LEARNING IMPAIRMENT AFTER CORTICOSTEROID REMOVAL IN YOUNG AND MIDDLE-AGED RATS. C.D. Conrad* and E.J. Roy. Neurosci., Univ. Ill., Champaign, IL 61820.

We investigated the functional and behavioral implications of chronic corticosteroid removal in young and middle-aged rats. Pre-pubertal rats were placed in these groups: adrenalectomized (ADX) with no hormone replacement; ADX given corticosterone chronically, **chCORT**; ADX given corticosterone acutely at time of Morris water maze testing, **acCORT**; and **SHAM**. 13 month old rats were ADX or SHAM operated only. All rats were run on the Morris water maze 12 weeks after surgery for 11 days after which, they were sacrificed and brains saved for histological analysis.

The results showed that prolonged corticosteroid absence caused major damage to the dentate gyrus and impairment on the Morris water maze. The **chCORT** rats had little dentate gyrus cell loss and were as efficient as the **SHAMs** in the Morris water maze performance whereas the **acCORT** rats had dentate gyrus cell loss and were impaired in the spatial acquisition task. Middle-aged ADX rats lost cells only in the dorsal blade of the dentate gyrus but they did not show a greater learning impairment in the Morris water maze relative to the middle-aged **SHAMs**. These results indicate that corticosteroids are trophic for the dentate gyrus and that **substantial** dentate gyrus damage impairs spatial learning.

EFFECTS OF 192 IgG-SAPORIN-INDUCED LESIONS OF THE CHOLINERGIC BASAL FOREBRAIN ON BEHAVIORAL VIGILANCE. J. McGaughy*, T. Kaiser, D. Wendelin and M. Sarter. Dept. Psychology, Ohio State Univ., Columbus, OH 43210.

The available evidence supports the hypothesis that the immunotoxin 192 IgG-saporin selectively destroys the cholinergic neurons bearing p75 NGF receptors. Heckers et al. (1994) showed that infusions into the basal forebrain destroyed the cholinergic projections to the cortex and spared the cholinergic neurons projecting to the amygdala and rhinal cortex (which do not bear NGF receptors). As cortical cholinergic afferents have been assumed to mediate the subjects' ability to detect and process behaviorally significant stimuli, the effects of 192 IgG-saporin-induced lesions of the cholinergic basal forebrain on behavioral vigilance were examined. Rats received infusions of 192 IgG-saporin (0.20 µg/0.5 µl/hemisphere) after they were trained to criterion in an operant vigilance task. This task requires the animals to discriminate between signal (central panel light presented for 25, 50 or 500 msec) or non-signal events. Hits and correct rejections were rewarded, while misses and false alarms were not. Following the post-lesion retraining period, animals were treated with a benzodiazepine receptor agonist (chlordiazepoxide; 1, 3, 5 mg/kg; i.p.), and partial inverse agonist (FG 7142; 0.5, 1, 2 mg/kg; i.p.) to test the hypothesis that, in lesioned animals, the detrimental effects of the agonist are more potent than in control animals, and that the partial inverse agonist attenuates the lesion-induced impairments in vigilance performance.

192 IgG-SAPORIN LESIONS OF BASAL FOREBRAIN CHOLINERGIC CELLS: EFFECTS ON LEARNING AND MEMORY IN RATS. M. G. Baxter¹, D. J. Buccì¹, A. A. Chiba², L. Thai¹, R. G. Wiley³, and M. Gallagher^{1,2}. ¹Curriculum in Neurobiology and ²Department of Psychology, University of North Carolina at Chapel Hill, Chapel Hill, NC, 27599; ³DVAMC and Vanderbilt University, Nashville, TN 37232.

The development of 192 IgG-saporin, which acts as a specific cholinergic neurotoxin when infused directly into basal forebrain nuclei, permits direct assessment of the role of basal forebrain cholinergic cells in cognitive function. Male Long-Evans rats, 2-3 months old, received infusions of 192 IgG-saporin (LES) or vehicle (CON) into either the medial septal area (MSA) or substantia innominata (SI). Place discrimination in the Morris water maze assessed spatial reference memory, and a 2-trial delayed matching-to-place task in the Morris water maze assessed spatial working memory. MSA-CON and SI-CON rats did not differ in behavioral performance and were pooled for statistical analysis. MSA-LES and SI-LES rats were not impaired relative to CON rats in acquisition of the place discrimination. MSA-LES and SI-LES rats were impaired relative to CON rats in performance of the working memory task; however there was no obvious delay-dependence of the deficit at the delays tested (delays ranged from 30 seconds to 3 hours), suggesting that this deficit may not be purely mnemonic in nature. This pattern of results calls into question the central role postulated for cholinergic neurons of the MSA in learning and memory. (Supported by NIA Grant PO1-AD09973-03 to MG and an NSF Predoctoral Fellowship to MGB.)

c-FOS EXPRESSION FOLLOWING PAIRED OF UNPAIRED CUTANEOUS NERVE STIMULI: SPECIFICITY RELATED TO LTP OF SPINAL REFLEXES. R. G. Durkovic*, Dept. of Physiology, SUNY Health Sci. Ctr., Syracuse, NY 13210

In order to help define the neural circuits involved in two forms of associative reflex potentiation, spinal neurons expressing *c-fos* were examined following various sequences of cutaneous nerve stimuli. Previous work from his laboratory has shown that in the spinal cat preparation when two cutaneous nerves are stimulated in specific "paired" sequences, flexion reflexes evoked by stimulating one of the nerves exhibit LTP (Long-Term Potentiation) that lasts for hours. These reflex changes obey the general rules established for learning and memory behavior in intact animals (*J. Neuroscience* 6:2921, 1986). Thus, these spinal reflex changes represent a simplified model for investigating neural mechanisms of elementary forms of learning and memory behavior. The experiments reported here compare the numbers and locations of *fos* labeled neurons in the spinal cords of operative control animals (no nerve stimuli), animals given 30 "unpaired" cutaneous nerve stimuli, and animals given 30 "paired" cutaneous nerve stimulus presentations. *fos* label was differentially expressed among these groups with few neurons labeled in operative control animals and the greatest numbers of labeled neurons in "paired" animals. Furthermore, two methods of "pairing" resulted in concentrations of labeled neurons in different spinal cord regions. The paradigm that preferentially potentiates spinal circuits activated by large myelinated saphenous cutaneous nerve fibers labeled neurons principally in deeper laminae (V-VII) of spinal cord. The paradigm that preferentially potentiates spinal circuits activated by small myelinated saphenous cutaneous nerve fibers labeled neurons primarily in more dorsal laminae (I-V). The results are consistent with the hypothesis that learning and memory result from alterations in the synaptic strengths of specific sets of synapses. Supported by NSF grant IBN 9220206.

495.11

INHIBITION OF NITRIC OXIDE REDUCES HIPPOCAMPAL MEDIATION OF PLACE LEARNING IN THE RAT. G. Wörtwein, B. Gustafson, P. Ermens and J. Mogensen*, Laboratory of Neuropsychiatry, University Hospital-6102, Copenhagen, Denmark.

In Experiment 1 the behavioural consequences of transection of the fimbria-fornix were investigated in animals that had acquired a place learning task after a control pretreatment or a pretreatment period during which near-total inhibition of NOS (the nitric oxide synthesizing enzyme) had been accomplished. While the lesion significantly impaired task performance in normals, the rats which had acquired the task during NOS inhibition did not reveal a lesion associated impairment. In Experiment 2 four groups of rats were studied: two groups received transection of the fimbria-fornix while the two others were subjected to sham surgery. Subsequently, one of the lesioned and one of the sham groups received a period of L-nitro-arginine (L-N-ARG) injections. During the final 5 days of injections the four groups were subjected to training on place learning. While NOS inhibition impaired task acquisition in the sham operated animals, L-N-ARG administration in fimbria-fornix transected rats failed to impair task acquisition. Conclusions: (1) Normal place learning acquisition involves hippocampus associated mechanisms that depend on NOS, and (2) Under NOS inhibition the task can be acquired by a system that differs from the one mediating task acquisition in normals by receiving reduced contributions from the hippocampus.

495.8

SUBSTANTIA INNOMINATA LESIONS IMPAIR INCREMENTAL ATTENTIONAL PROCESSING IN A PAVLOVIAN CONDITIONING PARADIGM. A. A. Chiba^{1*}, I. S. Han¹, P. C. Holland², and M. Gallagher¹, Department of Psychology, Univ. of North Carolina, Chapel Hill, NC 27599; Department of Psychology, Duke University, Durham, NC 27706.

Holland and Gallagher (1993) proposed a role for the central nucleus of the amygdala (CN) in incrementing attention based on associations formed during appetitive conditioning. Furthermore, recent evidence indicates that regulation of attentional processes by CN may be mediated through the corticopetal system located in the substantia innominata (SI), a component of the basal forebrain system in the rat brain.

An associative learning paradigm was used to examine the role of the SI in modulating attention. Each rat was exposed to conditioned stimuli (CS) that were either consistent or inconsistent predictors of subsequent CSs. Intact control rats maintained higher levels of attention to a CS when it was an inconsistent predictor of subsequent CSs, whereas SI-lesioned rats failed to show this enhanced attention. Thus, SI-lesioned rats displayed an impairment in incrementing attention equivalent to that previously demonstrated by CN-lesioned rats. These data support the notion that CN attentional modulation is dependent on the projections of the CN to the SI corticopetal cholinergic system. Based on this hypothesis, further experimentation using selective cholinergic lesions of the SI corticopetal system is being pursued within the identical behavioral paradigm. (Supported by an award from the Human Frontier Science Research Program.)

LONG TERM POTENTIATION (LTP) OF PYRAMIDAL NEURONS IN LAYER FIVE OF THE CAT MOTOR CORTEX. Akihisa Kimura*, Francesco Melis, Marcello A. Caria and Hiroshi Asanuma. The Rockefeller University, New York, N.Y. 10021.

Long term potentiation is supposed to play a crucial role in learning new skilled movements (Asanuma and Keller, 1991). A series of experiments revealed ubiquitous existence of LTP in various structures involved in execution of skilled movements. In this study, generation of LTP within the motor cortex was studied using intracellular recording and labeling (biocytin) techniques under Nembutal anesthesia. Intracortical microstimulation (ICMS) was delivered in the superficial layers and recordings were obtained from cells in layer V of the motor cortex. Of 20 labeled cells in layer V, 6 cells showed short lasting potentiation (1-4 min, 160-240% of control EPSP) immediately after tetanic ICMS (100-200 Hz, 10-30 sec) which was followed by steady potentiation (130-150% of the control) lasting until the electrode went out of the cell (7-28 min). In 12 labeled cells, only PTP (120-270% of the control) was observed. The duration of the PTP was from one to 4 minutes. All the labeled cells were pyramidal neurons. The effective stimulating sites inducing LTP were located immediately superficial to the labeled neurons. These results suggest that plasticity exists within the intracortical connections of the motor cortex that may be involved in learning of new motor skills.

Stress Effects on Memory and AMPA Receptors are Abolished by Adrenalectomy. D.M. Diamond*, B.J. Branch, G.M. Rose and G. Tocco. Dept. of Pharmacology, Univ Colo Health Sci Ctr, & VA Med. Ctr., Denver, CO and Neurosciences Program, USC, Los Angeles, CA

We have reported that exposure of a rat to an unfamiliar environment (psychological stress) blocked LTP (*Psychobiology*, 18:273, 1990; *Beh. Brn. Res.*, in press) and selectively impaired hippocampal-dependent memory (*Neurosci. Abst.*, 19:366, 1993). The present work is a test of the hypothesis that the effects of stress on hippocampal function will be eliminated by adrenalectomy (ADX).

Male rats were trained on a 14-arm radial maze incorporating hippocampal-dependent (working memory) and hippocampal-independent (reference memory) components (see *Neurosci. Abst.*, 19:366, 1993 for details). Stress impaired working, but not reference, memory in intact rats. In contrast, stress had no effect on memory in ADX rats. The ADX rats did exhibit other behavioral manifestations of stress (e.g., fecal boli production). Therefore, the effects of stress on emotionality and cognition (memory) can be dissociated. We have also found that stress produces a hippocampal-specific reduction in AMPA receptor binding in intact, but not in ADX, rats. These findings indicate that stress produces adrenal-dependent effects on hippocampal plasticity, memory and glutamate receptor binding dynamics.

INFLUENCE OF ENVIRONMENTAL STIMULATION AND BEHAVIOURAL TESTING ON SOMATOSTATINERGIC NEUROTRANSMISSION IN THE RAT BRAIN. L. Nilsson*, A.K. Mohammed, B.G. Henriksson, B. Winblad and L. Bergström, Department of Clinical Neuroscience and Family Medicine, Huddinge University Hospital, Karolinska Institutet, S-141 86 Huddinge, Sweden.

Housing rats in an enriched environment has been shown to induce morphological changes in the cerebral cortex, such as synaptogenesis and dendritic branching. In this study adult Sprague-Dawley rats (n=28) were housed for 30 days in either enriched or impoverished environments. Subsequently half of the groups were tested for spontaneous motor activity for 1 day followed by 2 days of spatial learning test. The rats housed in "enriched conditions" were characterized by superior learning ability and more rapid habituation to novel environment, when compared to their impoverished counter-parts. The relation of cortical somatostatinergic neurotransmission to learning was studied by quantification of somatostatin levels and gene expression. Somatostatin levels were significantly elevated following enriched environment, compared to impoverished conditions. Impoverished but not enriched rats also demonstrated increased cortical somatostatin levels after behavioural testing. The immunoreactivity detected was furthermore characterized by gel filtration in two of the groups. The relative proportion of proSS (14kD) was significantly lower in the impoverished tested group compared to the non-tested group, suggesting activation of somatostatin neurotransmission occurs at the post-transcriptional level in association with learning stimulation.

IMPAIRED LEARNING AND MEMORY IN MATURE AND OLD SPONTANEOUSLY HYPERTENSIVE AND WISTAR KYOTO RATS. J.M. Wyss, J.A. Franklin and T. van Groen, Dept. of Cell Biology, University of Alabama, Birmingham, AL 35294-0019

Recent studies in our laboratory indicate that in very old, normotensive rats, a selective breakdown occurs in the limbic cortex and that a similar disorganization occurs in spontaneously hypertensive rats (SHR), but at a much earlier age (12 compared to 30 months). The breakdown leads to a deficit in learning and memory in the 12 month old SHR. In the present study we employed a water maze task to test the hypothesis that learning and memory are disturbed in old (24 month) SHR and in old normotensive Wistar Kyoto (WKY) rats, and we examined the ability of long-term, antihypertensive therapy with captopril to attenuate the deterioration of learning and memory in old SHR and WKY. At the end of the 5 day training period, young SHR display the best performance and have the shortest escape latency, i.e., 7 ± 2 sec, 12 month old SHR are slower to find the platform, i.e., 38 ± 16 sec, and 24 month old SHR are still slower, i.e., 98 ± 22 sec. In comparison, young WKY are slower than age-matched SHR, i.e., an escape latency of 25 ± 3 sec, but 24 month old WKY are similar to 24 month old SHR and perform much worse than 3 month old SHR or WKY. SHR that were made normotensive by long-term captopril treatment were significantly better in the task than the age-matched SHR. The captopril treated WKY also showed an improved performance. It should be noted that swim speeds were similar for all groups. These data indicate that 24 month old SHR and WKY have impaired memory function, and that treatment with captopril partially improves this function in hypertensive and non-hypertensive rats.

AGE OBSCURES THE IMPAIRMENT OF LEARNING PERFORMANCE IN S100B TRANSGENIC MICE. R. Gerlai¹, M.D. Kawaia² & J. Roder^{*1}. 1. Mount Sinai Hospital, Samuel Lunenfeld Research Institute, and University of Toronto, CANADA; 2. Queen's University, Department of Anatomy, Kingston, CANADA

S100B is a brain protein whose levels are elevated in Down's Syndrome (DS) and Alzheimer Disease (AD). S100B has neurotrophic properties *in vitro* and has also been implicated in long-term potentiation (LTP), a neurophysiological correlate of memory. We have shown an LTP/synaptic depression deficiency in transgenic mice overexpressing S100B. Here we investigate the learning abilities and neurohistology of mice from two independent transgenic lines carrying 8 and 70 copies of the human S100B gene along with normal, non-transgenic, mice of the same background genotype (CD1). In order to reveal possible age dependent effects we analyzed mice ranging from 3 to 24 months of age. The distribution of neuronal (e.g. neurofilament, calretinin) and glial (e.g. GFAP, S100) markers among animals from each experimental group showed comparable age-dependent changes in both control and transgenic mice. The learning performance of mice was tested in various tasks of the Morris water maze. Young (3-mo-old) transgenic mice exhibited a significant spatial task dependent impairment but normal non-spatial task performance. Although a similar trend was observed in the old mice (16-mo-old), no significant difference was found between transgenic and normal mice in either of the tasks. Comparison of the age-groups showed a significant age effect: old age impaired the learning performance of mice of all genotypes in both the spatial and non-spatial tasks. Unlike the observations in DS and AD, where the neurological impairments are age dependent, our results suggest that aging in the mouse obscures the effects of overexpressing the gene for S100B. BICUCULLINE ADMINISTERED POST-TRAINING INTO THE AMYGDALOID COMPLEX BLOCKS BENZODIAZEPINE-INDUCED AMNESIA. H. Dickinson-Anson* & J.L. McGaugh, *Center Neurobiology Learning & Memory, Dept. Psychobiol., UC, Irvine, CA 92717.

It is well known that benzodiazepines (BZD) produce anterograde amnesia. Recent evidence suggests the amygdaloid complex (AC) GABAergic system mediates BZD-induced amnesia. Lesions of the AC block the impairing effects of a BZD on retention of inhibitory avoidance (IA) training. Additionally IA retention is impaired by pre-training intra-AC infusion of the BZD midazolam (MDZ) and enhanced by intra-AC infusion of a BZD antagonist. We recently reported that pre-training infusion of the GABAergic antagonist bicuculline methiodide (BMI) into the AC blocks the memory impairing effects of systemically administered midazolam on IA behavior. In general, BZDs impair memory when administered before, but not after, aversively motivated learning takes place, whereas GABAergic drugs affect retention when administered post-training. Consequently, it is not clear whether these drugs modulate pre- or post-training memory processes. Because BZD-induced behavioral effects are mediated by the GABA_A receptor complex, it is likely that BZD-induced memory deficits are also due to post-training influences on memory processes. The present experiment examined this implication. Before training in a multiple trial IA task, male Sprague-Dawley rats (250-300g) were injected (ip) with either midazolam (MDZ, 2.0 mg/kg) or vehicle (1.0 ml/kg). Immediately following IA training BMI (2.0, 5.6, 56.0, or 197.0 pmol/0.5µl) or vehicle (0.5 µl) was infused bilaterally into the AC. On a 48 hr retention test the performance of the MDZ treated animals was significantly poorer than that of controls. The retention of MDZ-treated animals given intra-AC injections of the lowest dose of BMI (2.0 pmol) was comparable to that of controls, whereas higher doses of BMI impaired retention. The present results are consistent with other findings indicating that the amygdaloid complex mediates the amnesic effects of BZDs on aversive learning. Furthermore, these data suggest that BZDs impair memory by disrupting post-training processes underlying memory consolidation. Supported by PHS MH12526, NIMH & NIDA (JLM).

GABAERGIC-CHOLINERGIC INTERACTION IN THE SEPTAL REGION MEDIATES BOTH ANXIETY AND SPATIAL WORKING MEMORY IN MICE. M.P. Mano, M. Belotti and D. Galey*, Lab. Neurosci. Comportementales et Cognitives, CNRS URA 339, Université de Bordeaux I, 33405 Talence France.

Convergent data suggest that the septal region may constitute an interface between anxiety and spatial working memory (SWM). Using C57BL/6 mice, we have examined the role of cholinergic and gabaergic septal neurons interaction in these two processes. The anxiety level was evaluated by comparison between exploratory activities measured in an elevated plus-maze and in a four hole-board. The SWM was assessed using a sequential alternation procedure achieved in a T-maze.

Results indicated that intraseptal infusion of scopolamine (2.5µg/0.2µl) combined with i.p. injection of diazepam (0.5 mg/kg) in same animals produced an "anxiolytic"-like effect. Furthermore, SWM was differentially affected by this treatment. Indeed, performance was unaffected when a 30 sec intertrial interval was used whereas for a 5 sec intertrial interval alternation scores were reduced below the chance level. In addition, the application of either scopolamine or diazepam alone did not induce any changes whatever the behavioral testing situation. These results suggest that a cholinergic/gabaergic septal mechanism mediates both the anxiety phenomenon and SWM. This interpretation is consistent with hypothesis that the cholinergic septo-hippocampal pathway produces anxiety (GRAY, J., Oxford University Press, Oxford, 1982). Thus, decrease in SWM abilities observed after modulating activity of these structures seems to be the consequence of release from an anxious response, which will induce increasing vulnerability to proactive interference rather than an accelerating forgetting.

IMPAIRED LEARNING RESULTS FROM A PERSISTENT VIRAL INFECTION IN MICE. M.D. Broit*, L.H. Gold, A. Tishon, M.B.A. Oldstone and G.F. Koob, Dept. of Neuropharmacology, The Scripps Research Institute, La Jolla, CA 92037.

Lymphocytic choriomeningitis virus (LCMV) is a nonlytic murine virus that forms a model system for studying the behavioral correlates of central nervous system virus infections. Newborn mice infected with LCMV develop a persistent infection that is characterized by high viral titers in all tissues including the brain. In this model, virus persists in neurons throughout the animals' life. Previous work has demonstrated learning and locomotor deficiencies in mice infected with LCMV. The present study focuses on learning impairment in a mouse strain in which immunologic parameters of persistent viral infection in neurons, and neurons from which virus has been cleared by immunotherapy, can be directly correlated with behavioral learning procedures.

Neonatal Balb/cByJ mice were infected with LCMV or vehicle and then tested behaviorally as adults for their ability to learn a Y-maze spatial avoidance discrimination task. In this task, the mouse learns to avoid a shock by running into the non-shocked maze arm prior to the onset of the shock. The number of avoidance responses and errors were used as an index of learning. The virus-infected mice performed more poorly on this discrimination task than sham-infected controls, although they eventually reached control levels by the end of the 6 day testing period. Thus, functional deficits in Balb/c mice result from this persistent virus, which replicates previous experiments in other strains and will enable future studies to examine learning behavior of this strain following viral clearance from the brain.

HIGH DOSE MK-801 KILLS NEURONS IN A SINGLE BRAIN REGION AND CHRONICALLY IMPAIRS MEMORY. G. Brosnan-Watters, D. F. Wozniak*, A. Nardi, J. W. Olney, A. S. Fix, Washington Univ., St. Louis, MO 63110 and Eli Lilly & Co., Greenfield IN 46140.

Previously we reported that a high dose (10 mg/kg sc) of MK-801 produced chronic memory impairment in adult male mice (Brosnan-Watters et al., 1993). Here we confirm in Harlan ICR adult male mice that MK-801 (10 mg/kg sc) chronically impairs acquisition performance on a spatial learning task and, in addition, produces neuronal necrosis confined to the posterior cingulate/retrosplenial (PC/RS) cortices. In Exp. I, mice were injected sc with either 10 mg/kg MK-801 (n = 10) or saline (n = 6), and perfused 4 days later. Brains were comprehensively screened histologically (H&E stained paraffin sections) for the presence of necrotic neurons. None were found in the controls nor in any brain region of the MK-801-treated mice except for the PC/RS cortices where the number of necrotic neurons ranged from 1 to 12 per section. In Exp. II, adult male mice were trained on a hole board food search task (4-corner version) using a massed trials protocol and were required to learn in a single day which 1 of the 4 holes was baited on every trial. Mice were assigned to two groups matched according to acquisition performance and then placed back on ad lib food for 4 days before being dosed with either 10 mg/kg MK-801 (n = 7) or saline (n = 8). Two weeks later they were retested on acquisition using a different baited hole. On the posttreatment test, the controls significantly improved their own acquisition scores (fewer trials to criterion), whereas the MK-801-treated mice showed no improvement. In addition, the controls performed significantly better than MK-801 treated mice on the posttreatment test. Ten weeks posttreatment, MK-801-treated mice still showed memory impairment relative to controls, this time on a newly configured hole board task. The results suggest that a high dose of MK-801 induces chronic memory acquisition impairment and raise the question of whether PC/RS neurons play a role in this deficit. WORKING AND REFERENCE MEMORY IN CXB RECOMBINANT INBRED MICE. D. F. Peeler*, Department of Neurosurgery, University of Mississippi Medical School, Jackson, MS 39216

Two types of memory which have been described - reference and working - appear able to function essentially independently. This implies not only separate CNS mechanisms, but also possibly different genetic influences. This was investigated in the CXB set of recombinant inbred (RI) strains. Association between genotype and performance in an 8-arm radial maze was assessed. Adult male mice (N=103) representing the 9 strains of the CXB set were familiarized with the maze for two consecutive days, 5 min per day, with all arms baited. For sessions 3 - 12, four arms were consistently baited. A dim lamp illuminated one corner of the room, with equipment and walls providing different shapes and textures as distant orientation cues. Each arm of the maze was dimly illuminated at its distal end. The mice were placed directly in the maze center, facing the lighted corner in sessions 1 - 7, and away from the lighted corner for sessions 8 - 12. Session duration was 5 min. Analyses utilized ANOVA and multiple range tests.

Strains show similar rates and levels of acquisition. There are significant differences among the strains for working memory (number of arm re-entries; number of baited arms entered before re-entry) and reference memory (number of non-baited arm entries), but the strain distribution patterns are different. Orientation change at the beginning of session 8 disrupted performance, presumably reflecting the contradiction of reference memory. The strain distribution pattern for reference memory indicated a possible major single gene effect. For some measures of working memory, the progenitor strains were statistically similar but the strain distribution pattern was different, implying some genetic determinants different from reference memory with no major single gene effect.

MORRIS WATER MAZE IN THE NAPLES HIGH AND LOW-EXCITABILITY RAT LINES. A. Gallo¹, H. Welzl²*, M. P. Pellicano¹ and A. G. Sadile¹. ¹Lab. Neurophysiol. Behav. & Neural Networks, Dept. Human Physiol. "F. Bottazzi"; Second Univ. of Naples, 80138 Naples, I; ²Inst. Behav. Biol., ETH, 8092 Zürich, CH.

Behavioral, histochemical, neurochemical and electrophysiological evidence supports the hypothesis that the Naples High (NHE) and Low-Excitability (NLE) rat lines may be genetic model to study hippocampal functions (Cerbone et al., *Neurosci. Biobehav. Rev.* 17: 295-303, 1993). To further challenge this proposal, adult male rats of the NLE, NHE and random-bred controls (NRB) were tested in a Morris water maze. A video camera system was used to monitor and record the rat behavior. In the place-learning task, one block of four trials per day was given for 5 days. Every day a rat had to find the hidden platform starting to swim from all four locations (N, S, E, W) in a random order. For each trial the escape latency and the swim distance were measured. On day 6, the platform was removed from the pool and a 30-s trial was given. The time spent in each of the four quadrants, and the total swim distance were recorded. During session 1, both NLE/NHE, but not NRB-rats, decreased the time and the distance travelled to find the platform. During the acquisition phase, both NLE/NHE spent more time to find the hidden platform, but the NHE on session 5 were not different from NRB-rats. The distance travelled was higher in the NHE than in the NLE/NRB-rats. In the platform removal test, NLE/NHE rats spent less time than NRB-rats in the quadrant where the platform had been. The results indicate that both NLE/NHE rats are coherent with a non linear model of the inverted-U type with both extremes leading to impaired spatial processing. EVIDENCE SHOWING THAT HIPPOCAMPAL PROTEIN KINASE C ACTIVITY APPEARS TO BE MORE LINKED TO LEARNING ABILITY THAN TO LEVEL OF TRAINING. X. Nogués, J. Micheau* and R. Jaffard Lab. Neurosciences Comportementales et Cognitives, URA CNRS 339, Univ. Bordeaux I, Av. des facultés, 33405 Talence Cedex, France

We have previously shown a decrease in hippocampal cytosolic PKC activity following partial learning of a reference memory task in a radial maze (Nogués et al., *Hippocampus*, in press). Conversely, membrane bound PKC activity remained unchanged, but was negatively correlated with performance level. Since this result did not fit with the translocation hypothesis, this study was designed to examine the effects of an increased level of training on PKC activity in the hippocampus.

Mice were trained in a spatial concurrent discrimination task performed in an 8-arm radial maze for 2, 5 or 12 sessions. Then, PKC activity was measured in membrane and cytosolic compartments of the hippocampus.

Behavioral results showed a slower rate of acquisition as compared to our previous studies. Biochemical results did not show any significant decrease in cytosolic PKC activity for any group. Nevertheless, membrane bound PKC activity was correlated with the number of reference memory errors at the third day of training ($r=0.74$; $p<0.001$). Firstly, these data show that the decrease in cytosolic PKC activity is not cumulative across sessions. Secondly, they confirm the correlation between membrane-bound activity and performance accuracy. Further statistical analysis on all animals tested in our previous experiments ($n=77$), shows that the amplitude of the PKC cytosolic decrease is correlated with performance accuracy on the second day of training ($r=0.247$; $p<0.02$; one-tail test).

Taken together, these observations support the idea that the membrane-bound PKC activity derives from a pre-existing pool that plays a significant role in the rate of acquisition. Moreover, they suggest that learning abilities at the early stages of training are linked to a decrease in cytosolic PKC activity.

MOUSE STRAIN DIFFERENCES IN MORRIS WATER MAZE PLACE TASK PERFORMANCE

B.F. Petrie* Dept of Psychology, New Mexico Tech, Socorro, NM, USA 87801

AJ; DBA; and C57 mice were tested for acquisition and retention of place task in the Morris water maze. All animals were swum for 14 days (4 trials per day; 60 seconds maximum per trial), with the platform being moved from the NW to the SE quadrant on day 8. AJ mice were unable to reliably find the platform, while the time taken by DBA animals in escaping the pool declined gradually during the study. C57 mice reached asymptote performance in 4 days, and found the platform significantly faster than either the DBA or AJ mice, while the DBA animals were significantly faster than the AJ mice in escaping the pool. Swim paths used by the 3 strains indicated that C57 mice selected the most efficient strategy for the solution of the task, while DBA animals did not acquire the same elegance in performance. AJ mice were never able to devise an appropriate strategy for solution of the task. Neuroanatomic differences between the 3 strains are also described, and the implications discussed.

DIFFERENTIAL EXPRESSION OF NADPH-DIAPHORASE IN THE BRAIN OF THE NAPLES HIGH AND LOW-EXCITABILITY RAT LINES FOLLOWING AROUSAL AND HABITUATION TO NOVELTY. M. Papa¹, and A. G. Sadile². ¹Inst. Anatomy, and ²Lab. Neurophysiol. Behav. & Neural Networks, Dept. Human Physiol. "F. Bottazzi", Second Univ. Naples, 80138 Naples, Italy.

The effects of exposure to spatial novelty on the expression of nitric oxide synthase were mapped in the brain of the Naples High (NHE) and Low-Excitability (NLE) rat lines by NADPH-diaphorase (NDP-d) histochemistry. Adult male rats of the NLE, NHE and control rats (NRB) were tested for 10 min in a L&T-maze and sacrificed at different time intervals thereafter (0, 2, or 24 h). Handled unexposed rats served as controls. The brains were perfused with paraformaldehyde, cryoprotected with sucrose and processed for histochemistry for NDP-d reaction. Sections were processed for densitometric evaluation by digital image analysis. In unexposed control rats the number of NDP-d positive cells and total optical density values were low and scattered. In contrast, following exposure to novelty, all rats showed an increased NDP-d staining in the hippocampus (granule cells, few hilar neurons and some CA1 pyramidal cells), the caudate-putamen complex, the cerebellum, and all layers of somatosensory cortex. However, NLE/NHE-rats were less positive than NRB-rats. The positivity was not due to activity per se, since immediately after exposure did not differ from baseline. In contrast, it peaked at 2h to fade out 24h later. In addition, a strong neuronal discharge induced by pentylenetetrazol did not induce NDP-d 2 h afterwards. The widespread induction of NDP-d suggests that exposure to novelty activates overlapping neural networks across different organizational levels of the CNS, whereas the impaired expression in the NHE-rats provides a tool for studying the neural substrates of spatial and non spatial information processing. (Supported by CNR 92.01092.CT04, and MURST 40% grants).

GABAergic reticular thalamic neurons project to the contralateral mediodorsal nucleus of the thalamus in the cat. I. Gritti*, M. Mariotti and M. Mancina. Institute of Human Physiology II, University of Milan, I-20133 Milano, Italy.

In order to investigate the topographical and chemical organization of the pathway involved in the regulation of the EEG synchronization at a thalamic level horseradish peroxidase conjugated with wheat germ agglutinin (WGA-HRP) was injected into the intermediate part of the Mediodorsal nucleus (MD) of the thalamus. Retrograde transport was also combined with glutamic acid decarboxylase (GAD)-immunohistochemistry to provide additional criteria for the identification of retrograde labelled neurons. In cats under pentobarbital anaesthesia WGA-HRP was stereotactically injected into the intermediate part of MD. After a survival time of 24-48 hrs, the animals were perfused through the ascending aorta with mixed aldehydes; 25 μ m frozen sections were horizontally cut. Alternate sections were reacted for WGA-HRP visualization using tetramethylbenzidine as a chromogen with cobalt intensification, and the peroxidase anti-peroxidase technique on immunohistochemistry for GAD. In the same sections GAD-immunohistochemistry, combined with the retrograde transport of WGA-HRP, revealed that the intermediate part of MD nucleus receives an important input from GABA synthesizing neurons located in the ipsi and contralateral rostral-pole of the RE nucleus. Although the distribution of GAD-immunoreactive retrogradely labelled neurons was similar both in the ipsilateral and contralateral RE nucleus, their number was much smaller in the latter. The findings suggest that through both GABAergic ipsilateral and contralateral projections the RE contribute to a GABA mediated inhibition within the intermediate MD neurons population and to a thalamo-cortical synchronization.

496.3

GABA release in the locus coeruleus as a function of sleep/wake state. D.A. Nitz and J.M. Siegel* UCLA Dept. of Neuroscience and UCLA Dept. of Psychiatry, Los Angeles, CA 90024 and Sepulveda VAMC, Sepulveda CA 91343

Noradrenergic neurons of the nucleus locus coeruleus fire tonically throughout waking, decrease discharge in non-REM sleep, and cease discharging in REM sleep. Only serotonergic nuclei of the raphe system and histaminergic nuclei of the posterior hypothalamus display similar firing patterns. The locus coeruleus is densely innervated by GABAergic neurons. In vitro studies have shown that application of GABA onto noradrenergic neurons potently inhibits their activity. Based on this evidence, we hypothesized that GABA mediates the inhibition of noradrenergic locus coeruleus neurons during sleep.

GABA release in the locus coeruleus was measured as a function of sleep/wake state using microdialysis and HPLC techniques. Histological analysis confirmed the placement of two dialysis probes in the locus coeruleus and peri-locus coeruleus areas. GABA release in the more caudal site was increased during both non-REM and REM sleep as compared with wake. Data from the more rostral locus coeruleus including the peri-locus coeruleus area indicated a selective increase in GABA release during REM sleep as compared to wake and non-REM sleep. We have previously reported a similar selective increase of GABA release in the dorsal raphe nucleus during REM sleep (Soc. Neurosci. Abstr., 19:1815, 1993). These data suggest that GABA mediates the inhibition of noradrenergic locus coeruleus neurons during non-REM and REM sleep.

Effects of muscimol on non-cholinergic neurones of the nucleus basalis in guinea-pig brain slices. A. Khateb*, P. Fort, B.E. Jones* and M. Mühlethaler Dept. of Physiology, CMU, 1211 Geneva 4, Switzerland and *Montreal Neurological Inst., McGill University, Canada H3A 2B4

The nucleus basalis contains both cholinergic and non-cholinergic magnocellular neurones which respectively display distinct electrophysiological properties when recorded in guinea pig brain slices. Non-cholinergic cells demonstrate high frequency (30-60 Hz) subthreshold oscillations and have the ability to discharge in clusters of action potentials (recurring at 2-6 Hz). In order to assess the potential modulation of their activity by GABA, the effect of muscimol, a selective GABA_A agonist, was tested on the non-cholinergic cells. Out of 31 cells tested, 23 were depolarized by high concentrations of muscimol (10^{-4} M), yet concomitantly inhibited due to a marked decrease of their membrane resistance. With smaller concentrations of muscimol (10^{-6} M), tested on 8 cells, 5 were still depolarized, but in addition their ability to fire in clusters was greatly facilitated. This effect persisted throughout the duration of the agonist's application and was perfectly reversible. Furthermore, the effect was antagonized by bicuculline, a GABA_A blocker. These results suggest that locally released GABA could serve to facilitate the cluster firing pattern of non-cholinergic neurones and thus the rhythmic activity of these cells could participate in the generation and/or maintenance of theta rhythms in the forebrain (Swiss NSF, Canadian MRC, Fondation Fyssen and Lyonnaise des Banques).

496.2

NOVEL SLEEP STATE ORGANIZATION IN THE ECHIDNA: IMPLICATIONS FOR THE EVOLUTION OF REM AND NON-REM SLEEP J.M. Siegel, P. Manger, R. Nienhuis, H.M. Fahringer and J. Pettigrew* VAMC, Sepulveda CA 91343, UCLA, Los Angeles, CA 90024 and U. of Queensland, Brisbane, Australia

We have examined brainstem neuronal activity in the primitive monotreme mammal, the echidna (*Tachyglossus aculeatus*) across the sleep cycle. While no periods of REM sleep were seen, unit activity patterns differed from those seen in placental mammals during nonREM sleep.

Twenty-two brainstem units were recorded from the midbrain and subcoeruleus region. Unit discharge rates were significantly lower in sleep than in quiet waking ($F=3.8$, $p<.05$). However, both midbrain and pontine regions had substantially increased discharge variability (burst firing) throughout sleep ($p<.001$).

Therefore, neuronal activity during sleep in the echidna does not resemble that seen in nonREM sleep in placental mammals. While the discharge rate of the neuronal population decreases, as in placental nonREM sleep, discharge variability increases, as in REM sleep. We hypothesize that both REM and nonREM evolved from this primitive "mixed" sleep state.

Simultaneous application of serotonin or carbachol facilitates NMDA-dependent bursts of nucleus basalis cholinergic neurones in guinea-pig brain slices. P. Fort, A. Khateb, B.E. Jones* and M. Mühlethaler* Dept. of Physiology, CMU, 1211 Geneva 4, Switzerland and *Montreal Neurological Inst., McGill University, Canada H3A 2B4

Cholinergic neurones of the nucleus basalis provide the major cholinergic input towards the cerebral cortex. In a recent study we have demonstrated that these cells, which are endowed with a potent low threshold calcium spike (LTS), responded to the continuous application of NMDA by rhythmic bursts. However, in the majority of cases (85%), this effect became apparent only when the cells were artificially hyperpolarized. In parallel studies we found that both serotonin and carbachol were able to hyperpolarize cholinergic neurones. Our goal in this study was thus to identify the possible interactions in between these substances. When NMDA was applied alone, it depolarized these cells and led them to fire tonically. However, when serotonin was added concomitantly, the neurones started to slightly hyperpolarize and then discharged rhythmically in bursts (21 out of 26 experiments). This effect persisted in TTX ($n=4$). Interestingly the duration of the LTS was greatly increased in presence of NMDA+ serotonin, as compared to the situation of NMDA alone (tested at different levels of membrane hyperpolarization). Almost similar results were obtained for the simultaneous applications of NMDA and carbachol (9 out of 19 experiments). These interactions might be the means by which cholinergic neurones could discharge rhythmically in bursts in vivo. (Swiss NSF, Canadian MRC, Fondation Fyssen and Lyonnaise des Banques).

HYPERPOLARIZING POTENTIALS IN MASSETER MOTONEURONS ARE ELICITED BY AN AUDITORY STARTLE REFLEX AFTER CARBACHOL INJECTIONS IN THE NUCLEUS PONTIS ORALIS. K.A. Kohlmeier, F. López-Rodríguez*, R.-H. Liu, F. Morales, M.H. Chase. Dept. of Physiology, Dept. of Anatomy and Cell Biology, and the Brain Research Institute. UCLA School of Medicine, Los Angeles, CA 90024.

One striking phenomenon of active sleep is the occurrence of ponto-geniculo-occipital (PGO) waves. Morrison and Bowker (Acta Neurobiol. Exp. 35:821-840, 1975) proposed that these waves are neuronal signatures of a startle response produced by internally generated signals. We have found that PGO waves are accompanied by large amplitude IPSP's recorded in lumbar and trigeminal motoneurons (Pedroarena et al., Sleep Res., 20A:58, 1991). We therefore decided to investigate whether startle responses induced by auditory stimulation are also accompanied by the inhibition of motoneurons. For this purpose we microinjected carbachol (20mM) into the nucleus pontis oralis of five α -chloralose anesthetized cats (40mg/kg, i.v.) because carbachol-induced muscle atonia is comparable to that which occurs during active sleep (Morales et al., J. Neurophys., 57A:1118-1129, 1987). Responses to an acoustic stimulus (95 dB; duration=1.5ms) were recorded intracellularly (KCl-filled glass electrodes) from antidromically identified masseter motoneurons both before and after the injection of carbachol. In 19 of the 20 masseter motoneurons recorded before the injection of carbachol, the auditory stimulus elicited no response. In one neuron there was a long latency depolarizing potential. After the injection of carbachol the auditory stimulus elicited a distinct hyperpolarizing potential in 20 of 21 masseter motoneurons (latency to onset=31.2 \pm 1.3ms; latency to peak=45.6 \pm 1.5ms; rise time=14.4 \pm 1.5ms; half-width=25.5 \pm 5.8ms; amplitude=-2.6 \pm 0.4mV). In two of the neurons the effect of hyperpolarizing and depolarizing current injection was examined; the amplitude of the stimulus-induced hyperpolarizing potentials decreased and increased, respectively, suggesting that they are inhibitory postsynaptic potentials. These findings indicate that the carbachol-activated motor inhibitory system is responsive to a startle stimulus in the α -chloralose anesthetized animal and that the processing of this sensory input includes the production of a hyperpolarizing potential in motoneurons. The physiological significance of this hyperpolarizing potential during active sleep may be to aid in insuring the maintenance of muscle atonia that otherwise might be disrupted by auditory sensory stimuli. Supported by NS 23426 and NS 09999.

CIRCADIAN MODULATION OF THE RAT ACOUSTIC STARTLE REFLEX. P. W. Frankland¹ and M.R. Ralph^{1,2}, Dept. of Psychology¹ and Zoology², University of Toronto, Toronto, Canada M5S 1A1.

The acoustic startle reflex (ASR) in rats exhibits robust circadian modulation, with ASR amplitudes greater in subjective night. Because the ASR is mediated by a serial circuit with few synapses, it provides a simple system in which to study the circadian modulation of behavior. We sought to identify the location of modulation by recording amplitudes of startle reactions evoked either acoustically or electrically via electrodes implanted in the primary startle circuit. Responses were measured at four hour intervals over 48 hours in constant dark conditions. Startle amplitudes were greater in subjective night for acoustically evoked and electrically evoked responses from both the ventral lateral lemniscus and medial longitudinal fasciculus. These results show that circadian modulation of startle occurs at some point in the circuit after the last brainstem synapse in the caudal pontine reticular formation, at the level of spinal interneurons, motoneurons or at the neuromuscular junction.

In a second experiment, animals with electrolytic lesions of the hypothalamic suprachiasmatic nucleus (SCN) exhibited no circadian variation in ASR amplitudes. Mean startle amplitudes were similar to pre-lesion basal (subjective day) levels. These results suggest that circadian rhythm of ASR is driven by the SCN, and that the SCN may enhance startle amplitudes during subjective night.

INDUCTION OF FOS PROTEIN IN THE RAT CIRCADIAN SYSTEM BY NON-PHOTIC STIMULI. S. Amir*, K. Edelstein, B. Robinson and B. Woodside, Center for Studies in Behavioral Neurobiology, Concordia University, Montreal, Canada.

Immunohistochemistry of Fos proteins in the hypothalamic suprachiasmatic nucleus (SCN) and intergeniculate leaflet (IGL) of the lateral geniculate complex is often used as a tool in studies on the neural mechanisms and cellular processes involved in photic regulation of circadian rhythms of rodents. Photic stimuli that induce phase shifts of circadian rhythms in mice, rats and hamsters also induce the expression of Fos in the SCN and IGL; photic stimuli that fail to induce phase shifts appear to be without effect on Fos expression in these structures. The effect of non-photoc stimuli on Fos expression in the SCN and IGL is less well defined. Here we report that in rats, cortical injury (induced under pentobarbital anaesthesia, 50 mg/kg, by lowering a 28 gauge needle 3 mm below the surface of the skull) or immobilization stress (60 min) induce the expression of Fos in the SCN and IGL. Stimuli such as i.p. saline injection (1 ml/kg) and cage transfer induce Fos expression in the IGL. Expression of Fos in the SCN and/or IGL in response to each of these stimuli is independent of the time of treatment, and is associated with expression in other brain regions, including many cortical, subcortical and hypothalamic areas such as the paraventricular nucleus, anterior hypothalamic nucleus and preoptic nucleus. SCN cells which express Fos in response to cortical injury or immobilization are located in subregions of the nucleus that also express Fos in response to photic stimuli. Results indicate that neural components of the rat circadian system respond to diverse types of non-photoc stimuli and that Fos expression in SCN and IGL should not be regarded as light-specific.

CIRCADIAN RHYTHMS IN A GENETIC MODEL OF OBESITY. R.E. Mistlberger*, H. Lukman, and B.G. Nadeau, Department of Psychology, Simon Fraser University, Burnaby, BC V5A 1S6, Canada.

The Zucker (fa/fa) rat is a widely used model of genetic obesity characterized by a variety of metabolic and endocrine abnormalities, and by low amplitude and/or phase advanced circadian rhythms. The nature of the circadian disturbance, and its possible role in obesity, are unclear. Body temperature rhythms (Tr) were recorded by telemetry in 7 obese and 5 lean Zucker rats under a 12:12 light-dark (LD) cycle and in constant dark (DD) and light (LL). Obese rats exhibited a phase advanced Tr in LD; the acrophase of the best fitting cosine function occurred 6.7 h early by comparison with lean rats ($p < .05$). The amplitude of the cosine function did not differ between groups. The phase advance was retained in DD, indicating that it is not due to differential masking effects of light. In LL, all rats exhibited free-running Tr's with periods > 24 h (no group difference). This suggests that phase advances in LD are independent of pacemaker period and may reflect altered phase responses to light or changes downstream from the clock, in homeostatic processes or coupling to slave oscillators. Obese rats also exhibited an advanced feeding rhythm, with more intake during the light period. The role of advanced rhythms in the development of obesity was examined by measuring body weight and food intake for 60 days in 2 additional fa/fa groups (6 weeks age); one group received food ad-lib, the other only during the dark period, i.e., phase advanced feeding was prevented. Daily food intake did not differ between groups, but the nocturnal-fed rats exhibited a lower average daily weight gain ($p < .05$), suggesting that circadian abnormalities may contribute to obesity.

RETICULAR THALAMIC NUCLEUS AND NEOCORTICAL PAROXYSMS IN THE RAT. G. Marini*, R. Giglio, G. Macchi* and M. Mancina (SPON: European Neuroscience Association). Ist. Fisiologia Umana II, Univ. degli Studi; * INB-CNR, Milano; °Ist. Neurologia, Univ. Cattolica, Roma (Italy).

The reticular thalamic nucleus (NRT) has been involved in mechanisms for the induction of normal thalamocortical rhythmicity in cats. The goal of the present study was to test the hypothesis that in rats the abolition of NRT unique influence (due to absence of intrinsic GABAergic interneurons) has a more crucial role on synchronization processes than in cats.

Unilateral chemical lesions were stereotactically placed in the anterolateral sectors of NRT of 5 ketamine-sedated rats, chronically implanted to monitor frontoparietal EEG and nuchal EMG. Ibotenic acid (20 µg/µl in 1M phosphate buffer) was used. In all animals in which lesion of anterolateral NRT sectors were histologically confirmed, after 1.5-2.5h post-injection, an EEG epileptic activity (high-voltage polyspikes and spike-wave complexes) emerged abruptly from a background of delta activity primarily in the contralateral hemisphere. The number of episodes peaked at 2-3h post-injection and decreased gradually. The epileptic activity declined within 2 days. Bilateral NRT lesions failed to trigger the phenomenon and abolished EEG synchronization. The results further confirm the role of anterolateral NRT sectors in both physiological and pathological synchronization processes.

ABNORMAL EXPRESSION OF CIRCADIAN ACTIVITY RHYTHMS IN MICE LACKING THE GENE FOR THE TYROSINE KINASE *lyn*. T.S. Kilduff*, B.F. O'Hara, H.C. Heller, W.C. Dement, and D.M. Edgar. Center for Sleep and Circadian Neurobiology, Depts. of Psychiatry and Biological Sciences, Stanford University, Stanford, CA 94305.

Protein tyrosine kinases (PTKs) phosphorylate substrates involved in a variety of cellular regulatory processes and play an important role in signal transduction. We have begun to characterize the circadian system of a strain of mice in which the gene for a particular nonreceptor PTK known as *Fyn* has been eliminated by homologous recombination. In contrast to wildtype 129 Sv mice which entrain adequately to an LD cycle, *fyn* mutants exhibit phase control abnormalities under LD. In mutants in which the endogenous rhythm is relatively strong (2/8 animals), this abnormality was manifest as an altered phase relationship with the LD cycle: even though $\tau_{DD} > 24$ hr, activity onset preceded light offset by as much as 8 hours. The net result in these mutants is that the majority of activity occurred in the lights on period. In cases in which the endogenous rhythm was relatively weak, LD masking of the activity rhythm occurred (5/8 animals). Under DD conditions, a progressive dampening of the activity rhythm was evident over the course of 8 months as confirmed by both chi-square and Schuster periodogram analyses; chi-square periodogram analysis was eventually unable to detect significant rhythmicity in the circadian range in 6 of 8 *fyn* mice. One *fyn* mutant was periodic in DD at 6 months of age, exhibited an abnormal phase relationship under LD at 10 months of age, and circadian rhythmicity was undetectable at 14-15 months of age. These results suggest that the tyrosine kinase *fyn* may be involved in the expression of the activity rhythm, if not the intrinsic timing mechanism of the circadian pacemaker and/or its processing of photic input (Supported in part by AG06490 and AG11084).

PROGRESSIVE CIRCADIAN RHYTHM DECLINE IN ALZHEIMER'S DISEASE. William Fishbein*, Steven Ferris and Barry Reisberg. Dept. of Psychology, The City College & Graduate School, CUNY, New York 10031 and NYU Medical Center, Alzheimers Disease Center, New York 10016.

This research is concerned with developing an early behavioral marker for AD. We have accumulated circadian rest-activity data (12 days per subject) from six healthy elderly subjects and fifteen very reliably diagnosed, community residing, AD patients (mild to severe), employing a miniature ambulatory wrist monitor.

The present report describes the detection and decline of the generator(s) of the circadian process by non-linear curve fitting, an iterative process that reduces noise and detects peaks that otherwise might be missed by direct examination of circadian rhythm data. Precise measures of amplitude, area, center and width of peaks, and overall area of a single circadian cycle are determined.

In normal elderly (Global Deterioration Score (GDS) = 1, Mini-Mental State (MMS) = 30), four activity peaks are detected accounting for 92% to 94% of the variance of the 24 hour circadian rhythm. Qualitatively, the circadian rhythm looks like a square wave with small perturbations throughout the 24 hour cycle. At night, subjects' sleep periods are relatively free of waking movement activity.

In Alzheimer's Disease, advancing from mild to severe, (GDS = 4 to 6; MMS = 24 to 3) five to eight activity peaks are necessary to account for 92% to 94% of the variance of the 24 hour circadian rhythm. Most notable as dementia advances: (1) progressive increase in the number of peaks, (2) phase shift of peaks to earlier clock time hours, (3) increasing variance between peaks and troughs, and (4) progressive increase in level of activity during the nighttime. Ultimately, in subjects with severely advanced dementia the circadian rhythm disappears completely.

Although the research is in an early stage, the accumulated data indicate that with decline in cognitive and functional competence, a concurrent and profound degeneration of the circadian time keeping system occurs in Alzheimer's disease.

INVESTIGATION OF THE EFFECTS OF PHASE-SHIFTING TREATMENTS ON THE REGULATION OF PUTATIVE OSCILLATOR PROTEINS IN *APLYSIA*. C. Koumenis, M. Sloan, T. Liu, M. Nunez-Regueiro, and A. Eskin*, Dept. of Biochem. & Biophys. Sci., Univ. of Houston, TX 77204.

A circadian pacemaker located in the isolated eye of *Aplysia* is responsible for generating a rhythm of spontaneous nerve impulses. A model of this system predicts that light and 5-HT will phase shift the oscillator by modifying the synthesis of oscillator proteins at the level of translation and perhaps transcription as well. Using 2-D gel electrophoresis, we previously searched for putative oscillator proteins (POPs) in the eye whose synthesis was modified by treatments of light.

To extend these studies, proteins were labeled with ^3H -leucine during the last 4h of a 6h 5-HT treatment, as well as 1h and 3h after the end of the 5-HT treatment. 5-HT increased incorporation of label into POP-1, POP-2, and POP-3, while it decreased incorporation into POP-4 and POP-5. Interestingly, the effects of 5-HT on the synthesis of POP-1, POP-2, POP-4 and POP-5 are opposite to those of light. 2h pulses of DRB (a transcription inhibitor) also altered ^3H -leucine incorporation into all five POPs during, or shortly after, DRB exposure.

These experiments focused our attention on several POPs which we have identified using microsequencing techniques: POP-1 — lipocortin, POP-2 — porin, POP-3 — GRP78/BiP, and POP-4 — "multiple stimulus response" protein. POP-5 was identified as HSP70 by heat shock experiments.

To measure mRNA levels and other aspects of gene expression, we have selected two of these putative oscillator proteins for study. Riboprobes for BiP (a molecular chaperone in the endoplasmic reticulum) and porin (a large conductance channel protein found in the outer mitochondrial and other membranes) have been made. *Aplysia* BiP clones were obtained from the Kandel lab. *Aplysia* libraries were screened with human porin clones and a clone containing the full-length cDNA porin coding sequence has been obtained. A 199-bp sequence from the 5'-end of this clone was found to have a 60% identity with human porin. We are currently using these probes in ribonuclease protection assays to examine the effects of light and 5-HT on the mRNA levels of these two proteins.

498.3

EXPRESSION OF GROWTH HORMONE-RELEASING HORMONE (GHRH) AND SOMATOSTATIN (SRIF) GENES DURING REM SLEEP DEPRIVATION IN THE RAT. T. Porkka-Heiskanen*, J. Toppila, M. Asikainen, F.W. Turek, D. Stenberg. University of Helsinki, Helsinki, Finland and Northwestern University, Evanston, IL 60208.

GHRH increases both SWS and REM sleep, while SRIF increases REM sleep. Antiserum to GHRH decreases sleep and inhibits sleep rebound after deprivation. We tested the hypothesis that REM sleep deprivation affects the expression of GHRH and SRIF genes. Male rats were deprived of REM sleep on small platforms for 24 or 72 h, and one group was allowed a rebound sleep of 24 h after 72 h deprivation. Large platforms and animals taken directly from their home cages served as controls to sleep deprived groups. In situ hybridization was made from 20 μm cryosections through the periventricular and arcuate nuclei using specific oligonucleotide probes for GHRH and SRIF. Number of cells expressing SRIF and GHRH was counted, as well as the area of silver grains over the labeled cells; serum GH was measured. Number of cells expressing GHRH in the arcuate nucleus was lower after 24 hours of REM sleep deprivation than in home controls, and stayed low through 72 h of deprivation. Number of cells expressing SRIF was elevated on small platforms after 24 h of deprivation but had returned to home control level at 72 h. Serum GH levels were decreased through the deprivation. We conclude that both elevated SRIF gene expression in the beginning of the deprivation and decreased GHRH gene expression through the deprivation may contribute to the low serum GH levels during the deprivation.

498.5

CENTRAL THYROTROPIN-RELEASING HORMONE ADMINISTRATION PRODUCES PHASE SHIFTS IN THE CIRCADIAN RHYTHM OF HAMSTER WHEEL RUNNING BEHAVIOR. Keith A. Gary*, Patricia J. Sollars, Nedra Lexow, Andrew Winokur, and Gary E. Pickard. Department of Psychiatry, School of Medicine, University of Pennsylvania, Philadelphia, PA 19104.

Several lines of evidence suggest that thyrotropin-releasing hormone (TRH) plays a primary role in the regulation of arousal in mammals. Analeptic effects of this tripeptide have been established by numerous studies, and endogenous levels of TRH vary in response to increased and/or decreased CNS activity states. Modulation of arousal state would require integration and coordination of autonomic, neuroendocrine, and circadian functions. TRH and its receptors have been localized in the retina, suprachiasmatic nucleus (SCN), and pineal gland; anatomical structures associated with circadian function. This study evaluates the effects of TRH microinjection into the suprachiasmatic nucleus (SCN) of the hamster on 24 hour wheel running behavior. The precision displayed by the hamster in wheel-running activity prompted our use of this species in these studies. TRH or saline was administered both by intracerebral ventricular (icv) injection and site specifically via chronic indwelling cannulae stereotactically placed in the SCN. Drug administration was performed at circadian times (CT) 6 and 18, times corresponding to subjective day and night, respectively. At CT 6, both phase advances and delays in wheel running activity were observed in hamsters receiving 10nM and 100nM TRH icv, whereas phase advances were observed following the same doses delivered directly in the SCN. The magnitude of the phase advance was dose dependent, with 10 nM and 100 nM TRH administration resulting in 35 and 50 minute advances in wheel running activity, respectively. No changes in wheel running activity was observed following icv TRH administration at CT 18. These data support the hypothesis that TRH influences circadian rhythmicity.

498.2

ESTROGEN RECEPTORS ARE NOT PRESENT IN THE CIRCADIAN SYSTEM OF THE OCTODON DEGUS, A DIURNAL RODENT. N. Goel¹, L. Smale and T.M. Lee, Depts. Psychology, ¹University of Michigan, Ann Arbor, MI 48104, and ²Michigan State University, East Lansing, MI 48824.

Steroid hormones, in particular estrogen, influence circadian rhythms in various rodents, but the site of action for estrogen's effects is not yet known. *Octodon degus* are hystricomorph rodents that exhibit diurnal temperature and activity rhythms (Labyak, 1993). In the degu, elevated estrogen levels during estrus lead to phase advances in the wheel-running rhythm and increased levels of activity (Labyak and Lee, in press). Because lesions of the intergeniculate leaflet (IGL) of the thalamus in hamsters, a major afferent projection to the SCN, result in changes in the phase angle of activity onset, the IGL has been suggested as a candidate for estrogen's site of action. Estrogen receptors have been located in the IGL of guinea pigs (DonCarlos, pers. comm.), but not in hamsters (Smale, unpub.). No steroid receptors have been identified in the suprachiasmatic nucleus (SCN), the primary circadian clock. The goal of this study was to identify the distribution of estrogen receptors throughout the degu brain. Three adult degu brains (one male, two female) were processed for immunohistochemical identification of estrogen receptors using the H222 antibody. ER-immunoreactive (IR) cells were found in the medial preoptic area (mPOA), bed nucleus of the stria terminalis (BNST), supraoptic nucleus (SON), arcuate nucleus, paraventricular nucleus (PVN), infundibulum, ventral posterior medial nucleus (VPM) and amygdala. No ER-IR cells were found in the SCN or IGL. Thus, it appears that estrogen cannot directly influence the circadian system via the SCN or IGL in the degu.

498.4

DIURNAL RHYTHMS OF MONOAMINES AND THEIR METABOLITES IN CORTEX, HIPPOCAMPUS AND HYPOTHALAMUS OF MALE WISTAR RATS. D. Stenberg*, M. Asikainen, J. Toppila and T. Porkka-Heiskanen. University of Helsinki, Helsinki, Finland.

Normal values for the diurnal variation of monoamine and metabolite concentrations in brain tissue of male Wistar rats were needed for studies on effects of sleep deprivation. Rats aged 3 months and adapted to LD 12:12 (lights on 0600) were decapitated (six rats with 2 h intervals for 24 h) and brain regions dissected, frozen, and subsequently analysed by HPLC-ED. Analysis of variance and cosinor analysis were used. 5-HT levels tended to decrease after onset of dark in frontal cortex (CX) and hippocampus (HC) while 5-HIAA levels showed no variation. In posterior hypothalamus (PH) both 5-HT and 5-HIAA had a 12 h rhythm with acrophase at 1210 h, while in rostral hypothalamus (MH) no diurnal variation was found. Dopamine levels in all regions tended to increase between 0600 and 1400 h, with a 24 h rhythm in PH with acrophase at 1330 h. The ratio DOPAC/DA varied greatly with 12 h rhythm in CX and HC peaking around 1500 and 0300 h. HVA had a 24 h rhythm with acrophase at 1210 h in PH, but not in CX or MH. Noradrenaline had no significant diurnal variation in any of the regions. Rat strains differ from each other in drug responsiveness and in brain chemistry. The diurnal pattern is also dependent on brain region. The measured descriptors thus form a useful basis for evaluating experimental manipulations in this rat strain.

IN VIVO ANALYSIS OF ADENOSINE LEVELS IN HIPPOCAMPUS AND NEOSTRIATUM DURING REST AND ACTIVITY PERIODS. M. Pfister, J.P. Huston*, R. Schwarting, U. Decking#, J. Schrader# and H.L. Haas#. Inst. Physiol. Psychol. and Physiol.#, Univ. Düsseldorf, 40225 Düsseldorf, Germany.

Adenosine occurs in the extracellular space of the central nervous system where it exerts tonic inhibitory effects at pre- and postsynaptic levels, including reduction of excitatory transmitter release, induction of a potassium current and increase of the Ca^{++} -dependent potassium current I_{AHP} . The sedative properties of this metabolite have long been known but the question remains whether endogenous adenosine is responsible for fatigue after intense neuronal activity and/or whether it increases propensity for sleep by global or even site-specific accumulation during periods of activity. We used the in vivo microdialysis technique combined with RIA to monitor extracellular levels of adenosine in hippocampus and neostriatum of freely moving rats, kept in a normal day-night cycle (lights on from 7:00 to 19:00) for 24 hours. In some animals, adenosine increased slowly and gradually in the hippocampus but not in the neostriatum over the course of the active period. During this light-off period extracellular adenosine levels in the hippocampus were about 60% higher than the mean values of the preceding light-on phase. The maximal increase (260%) occurred at the end of the period of activity. These results are the first obtained by in vivo microdialysis showing progressive accumulation of hippocampal adenosine during nocturnal activity in rodents, supporting its hypothesized involvement in fatigue and/or induction of sleep propensity.

CHARACTERIZATION OF FOOD INTAKE REDUCING EFFECT OF METFORMIN IN GENETICALLY OBESE ZUCKER RATS: LACK OF EVIDENCE FOR THE INVOLVEMENT OF NEUROPEPTIDE Y. J. Roux*, U. Pesonen*, E. Santi*, T. Rouvari*, R. Huuopponen*, M. Koulou** and M. Jhanwar-Unival*. *Dept. of Pharmacology, Univ. of Turku, FIN-20520 Finland. **Dept. of Clinical Pharmacology, Turku Univ. Hospital, Finland and *Lab. of Neuroendocrinology, The Rockefeller Univ., New York, USA

Metformin is an antihyperglycaemic agent widely used for treatment of obese type 2 diabetic patients particularly because of its weight reducing effect. The hypothalamic neuropeptide Y (NPY) content was measured by radioimmunoassay and preproNPY mRNA expression was studied by quantitative *in situ* hybridization procedure in metformin treated (300 mg/kg orally for 12 days), in pair-fed and in *ad libitum* fed obese Zucker rats in order to elucidate possible mechanisms involved in the anorectic and body weight reducing effect of metformin treatment in genetically obese Zucker rats. The concentration of NPY in the hypothalamic paraventricular nucleus (PVN) was significantly higher in the metformin-treated and pair-fed rats when compared to the control animals. The expression of preproNPY mRNA in the arcuate nucleus (ARC) was similar in all three treatment groups. Both chronic metformin treatment and pair-feeding markedly lowered hyperinsulinaemia in these animals. It is concluded that the treatment with metformin and pair-feeding, which result in comparable reductions in food intake, body weight gain and hyperinsulinaemia, similarly increase NPY concentrations in the PVN while not affecting preproNPY mRNA expression in the ARC. The increase in hypothalamic NPY content may be secondary to reduction of hyperinsulinaemia during metformin treatment and pair-feeding. Thus, the anorectic effect of chronic metformin treatment cannot be explained by changes in content or expression of hypothalamic NPY.

499.3

NALOXONE DECREASES BOTH CARBOHYDRATE AND FAT INTAKE INDUCED BY NEUROPEPTIDE Y (NPY). A.S. Levine*, M. K. Grace, and C.J. Billington. VA Medical Center and University of Minnesota, Minneapolis, MN 55417

Central administration of NPY markedly enhances food intake in rats and appears to selectively stimulate intake of high carbohydrate diets. Naloxone has been reported to decrease intake of high fat (HF) diets much more effectively than high carbohydrate (HC) diets. In the current studies we examined whether naloxone would decrease NPY-induced intake of HC and HF diets, given individually or concurrently. In our first study we presented rats with a choice of a high carbohydrate (HC) or a high fat (HF) diet and stimulated feeding by intracerebroventricular (icv) injection of NPY. In this group of carbohydrate preferring rats (n=16), NPY induced HC intake (4.4 g/5 hr), but failed to increase HF intake (0.3 g/5 hr). Naloxone potentially decreased intake of the HC diet at doses ranging from 0.1-3 mg/kg (.1mg/kg: 2.7 g; 0.3mg/kg: 2.5 g; 1mg/kg: 1.7 g; 3mg/kg: 1.5 g). In the second study the same rats were injected icv with NPY and presented with either the HC or the HF diet (no choice). NPY stimulated both HC (3.9 g/0.5 hr) and HF (2.9 g/0.5 hr) intake, and naloxone decreased intake of both the HC (0.3 mg/kg: 1.9 g; 3mg/kg: 1.2 g) and HF (0.3 mg/kg: 1 g; 3mg/kg: 0.4 g) diets. Thus, we found that naloxone potentially decreased NPY stimulated intake of HC and HF diets. This is in contrast to the published observation that naloxone has little or no effect on HC intake in food deprived rats offered a choice between HC and HF diets. Our data lend support to the idea that an NPY-opioidergic feeding system exists in the central nervous system.

499.5

RAPID LOSS OF FEEDING DURING CONTINUOUS HYPOTHALAMIC INFUSION OF NPY. W.T. Chance*, X. Zhang, B. Mohapatra & A. Balasubramaniam. Dept. Surgery, Univ. Cincinnati Med. Ctr. and VA Med. Ctr., Cincinnati, OH 45267.

Anorectic tumor-bearing (TB) rats exhibit a refractory feeding response to neuropeptide Y (NPY) and decreased hypothalamic NPY concentrations. Therefore, we hypothesized that constant hypothalamic infusion of NPY would correct the anorexia exhibited by these TB rats. Following anesthetization, 24 ga. infusion cannulae were implanted into the perifornical hypothalamic area of 32 male Fischer 344 rats, 18 days after sc. MCA sarcoma or sham inoculations. These cannulae were connected to sc. Alzet minipumps (Model 2002) that infused NPY (125 ng/hr) or artificial CSF (0.5 μ l/hr). Although food intake by both NPY-infused groups was increased immediately following surgery, 3 days later food intake by these groups was not different from that of the CSF-infused rats. Food intake by the TB rats continued to decline, with significant anorexia being noted 21 days after tumor inoculation. These results suggest a rapid desensitization of hypothalamic NPY receptors in both TB and control rats in the continuous presence of exogenous NPY.

499.2

PERIPHERAL NALTREXONE INDUCES NEUROPEPTIDE Y GENE EXPRESSION IN THE ARCULATE NUCLEUS. C. M. Kotz*, M. K. Grace, J. Briggs, C.J. Billington and A.S. Levine. University of Minnesota, St. Paul MN 55108 & VA Medical Center, Mpls MN 55417

Neuropeptide Y (NPY) induces feeding and deprivation results in increased NPY mRNA in the arcuate nucleus (ARC). Naltrexone (NTX), an opioid receptor antagonist decreases NPY-induced feeding. We thought NTX would also block deprivation-induced increases in ARC NPY mRNA. To test this, osmotic minipumps pre-filled with either 0.9% saline (SAL) or NTX (70 μ g/ μ l/hr) were implanted subcutaneously in 32 male Sprague Dawley rats weighing 275-300 g. Half these rats were food-deprived and half were allowed food *ad lib* for 48 h. At study's end, NPY levels in the paraventricular nucleus (PVN) and ARC NPY mRNA levels were determined using an NPY radioimmunoassay and an NPY cDNA probe respectively. The data were analyzed by a 2 factor ANOVA (NTX level x deprivation level):

Treatment	48 h Food Intake (g)	PVN NPY levels (ng/mg PRO)	ARC NPY mRNA levels (O.D. units)
SAL <i>ad lib</i>	43.9 ^a	36.8 \pm 5.8	1.13 \pm .16 ^a
SAL dep	0	36.9 \pm 2.4	2.18 \pm .16 ^{bc}
NTX <i>ad lib</i>	32.1 ^b	42.0 \pm 5.5	2.10 \pm .28 ^{ce}
NTX dep	0	46.5 \pm 6.9	3.80 \pm .37 ^d

Food intake was decreased 26% by NTX, PVN NPY levels were not different, and there were significant positive main effects of deprivation and NTX but no interaction among the 2 factors on ARC NPY mRNA. Thus NTX decreases normal feeding and increases deprivation-induced NPY gene expression, suggesting a complex interaction between NPY and endogenous opioids in the regulation of feeding.

499.4

DISSOCIATIVE EFFECTS OF NEUROPEPTIDE Y ON FEEDING AND BODY TEMPERATURE AFTER INJECTION INTO DIFFERENT HYPOTHALAMIC SITES. P.J. Currie* and D.V. Coscina. Section of Biopsychology, Clarke Institute of Psychiatry, 250 College St., Toronto, ON, M5T 1R8 Canada.

Recent research has shown the perifornical hypothalamus to be a particularly sensitive brain site in eliciting feeding after local injection of neuropeptide Y (NPY). Since other work has demonstrated that NPY injected into the paraventricular nucleus of the hypothalamus (PVN) evokes both feeding-stimulatory and metabolic effects, the current study examined the simultaneous impact of this peptide on food intake and body temperature (T_{bo}) of unrestrained rats following injection into the PFH, and contrasted it with similar measures after injection into the PVN. NPY (0-235 pmol) was infused in a volume of 0.4 μ l using a 28-ga. microinjection assembly. Food intake and T_{bo} were measured every 30 min for 3 h postinjection. Both PVN and PFH injections of NPY increased food intake dose-dependently in the first 30 min test interval, with the PFH showing a stronger response than the PVN. In PVN treated rats, the increased eating was associated with a significant decline in T_{bo} which was also evident 30 min after NPY injection and lasted 2 h. A mean maximal T_{bo} decline of $0.97 \pm 0.20^\circ\text{C}$ occurred within 90 min following PVN treatment of 235 pmol NPY. In contrast, NPY had no apparent effect on T_{bo} when injected into the PFH. These findings support previous suggestions that while PFH NPY acts to stimulate a robust and relatively specific ingestive response, PVN NPY may participate in the integrative mechanisms responsible for the simultaneous regulation of feeding, heat conservation, and energy metabolism. (Supported by NSERC and NIN of Canada).

CHANGES IN NEUROPEPTIDE Y GENE EXPRESSION CORRELATE WITH ALTERATIONS IN MACRONUTRIENT PREFERENCE IN THE RAT DURING ZINC DEFICIENCY-INDUCED ANOREXIA. N.F. Shay*, T.M. Rains and G. Li. Department of Food Science and Division of Nutritional Sciences, University of Illinois, Urbana, IL 61801.

Zinc deficiency is known to cause anorexia among other physiological symptoms. The cause of this anorexia is poorly understood. We are currently investigating the role of Neuropeptide Y in the development of zinc deficiency-induced anorexia. Sprague-Dawley rats were fed modified AIN-76 diets containing either adequate or deficient levels of dietary zinc (Zn+: 30 mg/kg; Zn-: 1 mg/kg). Alterations in body zinc content were confirmed by measuring bone zinc content via atomic absorption spectrophotometry. Within 9 days of administration of a zinc deficient diet, reductions in the mRNA for preproNPY could be detected in the hypothalamus and intestine. After 28 days of diet administration, preproNPY levels were 4-fold higher in the intestine (Zn+/Zn-) and nearly 2-fold higher in the hypothalamus. In another set of studies, rats were allowed to self-select a diet from pure macronutrient diets containing fat, carbohydrate, and protein. Each diet was supplemented with complete vitamin and mineral mixes except for Zn- rats, in which Zn- mineral mix was used (Harlan). During a 28 day feeding period, the reduction in intake for Zn- was 20% (1710 \pm 47 vs. 1360 \pm 17 kcal). This reduction was due in total to a reduced intake of carbohydrates ($p < .01$); protein and fat intakes were statistically the same between the Zn+ and Zn- conditions. Upon repletion with zinc, normal carbohydrate intake was restored in 24-48 h, and a 50% surge in protein intake was noted for the first 5 days of repletion. This reduction in carbohydrate preference correlates with our observation of reduced NPY levels in zinc deficiency, as NPY is known to be a potent stimulator of carbohydrate intake.

499.7

EFFERENT PROJECTIONS FROM THE PERIFORNICAL AREA OF THE HYPOTHALAMUS IN THE RAT. E.M. Tomkins*, H.A. Akmal, A. Polzin, B.G. Stanley. Depts. Neurosci. & Psych., Univ. Calif., Riverside, CA 92521.

Neuropeptide Y (NPY) injected into various regions of the hypothalamus elicits robust eating responses. A recent cannula-mapping study employing nanoliter volume injections of NPY identified the medial perifornical area of the hypothalamus (mPFH), at the level of the posterior paraventricular nucleus, as the most sensitive site for NPY's eating stimulatory effect (Stanley et al., Brain Res. 1993, 604, 304-317).

To identify the neural projections from this area, 30 nanoliters of the anterograde tracer, biotinylated dextran amine (10%), was pressure injected into the mPFH of adult male Sprague-Dawley rats through glass micropipettes with 40-60 μ m O.D. tips. Following survival times of 7-10 days, the animals were perfused, 60 μ m frozen sections were collected, incubated in avidin-HRP, and visualized with a nickel-intensified diaminobenzidine reaction.

Dense projections of labelled fibers extended from the site of injection to the central gray, bed nucleus of the stria terminalis, medial and lateral preoptic areas, posterior hypothalamus, and median preoptic nucleus. Moderate projections were visible in the dorsal premammillary nucleus, parabrachial nucleus, lateral septum, paraventricular thalamic nucleus, precommissural nucleus, and locus coeruleus. Terminal labeling was also evident in the accumbens, amygdala, lateral parabrachial nucleus, and nucleus tractus solitarius. Although the roles of these projections remains to be established, by acting on PFH neurons NPY could directly influence activity in multiple intra- and extra-hypothalamic structures.

499.9

ALTERATIONS IN NUTRIENT METABOLISM HAVE DIFFERENTIAL EFFECTS ON GALANIN (GAL) AND NEUROPEPTIDE Y (NPY) IMMUNOREACTIVITY IN HYPOTHALAMIC NUCLEI. J. Wang, A. Akabayashi, C.T.B.V. Zaia*, I. Silva, and S. F. Leibowitz. The Rockefeller University, New York, N.Y. 10021.

Hypothalamic injections of GAL and NPY have differential effects on nutrient ingestion, with NPY preferentially enhancing carbohydrate intake and GAL preferentially stimulating fat intake. The question is whether endogenous production of these peptides in hypothalamic neurons is differentially responsive to signals related to the metabolism of these nutrients. To test this, two compounds that alter carbohydrate and fat metabolism were examined in albino rats: 2-deoxy-D-glucose (2-DG, 200 mg/kg), which inhibits glucose utilization, and mercaptoacetate (MA, 600 μ moles/kg), an inhibitor of fatty acid oxidation. Intraperitoneal injection of 2-DG, compared to vehicle, caused a significant increase in NPY levels (measured via RIA), specifically in the paraventricular (PVN) and supraoptic nuclei but not other areas. However, no change in GAL levels was detected. While MA, in contrast to 2-DG, produced no change in NPY levels, this metabolic inhibitor significantly reduced GAL levels, only in the lateral division of the PVN (-35%, $p < 0.05$). Since cAMP production is inversely related to intracellular glucose, the impact of ventricular injections of dibutyl cAMP (25 μ g) on NPY and GAL levels was also examined. This agent caused a significant increase in NPY levels specifically in the medial PVN and arcuate nucleus, while having no impact on GAL in any area. Thus, intracellular regulatory signals for NPY and GAL production appear to differ, consistent with the differential impact of these peptides on nutrient ingestion.

VAGOTOMY REDUCES FOOD INTAKE IN LEAN BUT NOT OBESE ZUCKER RATS. D. Greenberg*, D.L. Lewis, and A.J. Strohmayr. Bourne Laboratory and Departments of Psychiatry and Neurology, Cornell University Medical College, White Plains, NY, 10605.

The genetically obese Zucker rat (fa/fa) is hyperphagic compared to lean controls (Fa/Fa). This hyperphagia is characterized by increased meal size. The abdominal vagus has been implicated in the mediation of satiety signals and severing the abdominal vagus reverses the hyperphagia of hypothalamic obesity (Powley & Opsahl, 1974). We investigated the effects of total subdiaphragmatic vagotomy on the food intake and body weight of obese and lean male and female Zucker rats.

Male and female obese and lean Zucker rats received bilateral subdiaphragmatic vagotomies or sham operations (n=4-9 each group). Rats were placed on a low fat diet (< 1% fat) for 2 weeks and then placed on a high fat diet (30% fat) for an additional 2 weeks. Food intake and body weight was measured daily.

Vagotomy reduced the food intake (28% $p < .001$) and body weight (23% $p < .0003$) of male and female lean rats in both diet conditions. Vagotomy failed to reduce the food intake of male or female obese rats fed the low fat diet, but did reduce the food intake (22% $p < .03$) and body weight (16% $p < .02$) of obese rats fed the high fat diet.

The fact that vagotomy reduces low fat intake in lean but not obese rats indicates that intact vagal function is required for the expression of hyperphagia and obesity in obese Zucker rats under these conditions.

EFFECT OF FOOD DEPRIVATION ON NEUROPEPTIDE Y (NPY) MESSENGER RNA IN HYPOTHALAMUS OF SYRIAN AND DJUNGARIAN HAMSTERS. J.G. Mercer, C.B. Lawrence and P.J. Morgan. The Rowett Research Institute, Bucksburn, Aberdeen, U.K. AB2 9SB.

Imposed manipulations of energy balance that increase food intake in rats often have no effect or elicit an attenuated response in various hamster species. Thus, Syrian, Turkish and Siberian hamsters either fail to express, or exhibit only limited post-fast hyperphagia, and are unresponsive to glucoprivation or inhibition of fatty acid oxidation (Bartness, Int.J. Obesity 14 Suppl. 3:115, 1990). Syrian hamsters are, however, sensitive to the appetite-stimulating effect of Neuropeptide Y (NPY) injected intracerebroventricularly (Kulkosky et al., Peptides 9:1389, 1989). To assess whether endogenous NPY in hamsters is sensitive to alterations in energy balance we have examined the effect of food deprivation on preproNPY mRNA in the hypothalamus of two species of hamster, the Syrian hamster, *Mesocricetus auratus*, and the Djungarian hamster, *Phodopus sungorus campbelli*. PreproNPY mRNA was studied by *in situ* hybridisation using the cloned rat gene to synthesise antisense and sense ³⁵S-riboprobes. Autoradiographic images were quantified by computerised image analysis, providing measures of integrated intensity (OD x mm²). In the Hooded Lister rat, which was employed as a control species, 48 h food deprivation induced a 2.2-fold increase in total hybridisation in the hypothalamic arcuate nucleus (ARC), relative to fed controls. The same manipulation resulted in a 1.5-fold increase in total hybridisation in the ARC of the Djungarian hamster. In contrast, preliminary studies of the Syrian hamster indicated that NPY expression in this species may not be regulated by food deprivation.

THE IMMUNOLOGICAL TARGETING OF TOXINS TO NPY NEURONS OF THE ARCULATE NUCLEI DECREASES FOOD INTAKE FOR SEVERAL DAYS AND DISTURBS NPY mRNA EXPRESSION. A. Burlet*, H. Rafai, E. Grouzmann, B. Fumette, E. Angel, J.P. Nicolas and C. Burlet. INSERM U308, 38, rue Lionnois - F-54000-Nancy (France).

Cellular toxins (Tox., ricin A chain and monensin) centrally injected with a monoclonal antibody (MAb) to a neuropeptide may specifically penetrate the peptidergic neurons and induce long-lasting disturbances of neuronal functions. Presently, the toxins were injected with a MAb to the Neuropeptide Y precursor molecule (MAB to C-flanking peptide, C-PON) near the hypothalamic arcuate (ARC) or paraventricular (PVN) nuclei; by itself, the injected C-PON-MAB was devoid of biological activity. The effects of one injection of C-PON-MAB or non specific IgG with toxins on spontaneous food intake and mRNA expression of NPY by *in situ* hybridization were studied.

In rats injected with the C-PON-MAB mixture into ARC, the daily food intake significantly decreased (26%, $p < 0.001$) during the week after the injection. This was due to a decrease of the nocturnal food intake (30%, $p < 0.001$) since the diurnal food intake was unchanged. On the day of injection, the diurnal food intake acutely increased (75%, $p < 0.001$) whereas the following nocturnal food intake decreased (30%, $p < 0.01$). The food intake was not modified by the injection of the non specific mixture into ARC or PVN, and by the injection of C-PON-MAB/Tox. mixture into PVN. The injection of C-PON-MAB/Tox. mixture into ARC increased the mRNA expression of arcuate NPY which decreased after the same injection performed into PVN.

The long-lasting decrease of food intake was due to an efficient immunological impairment of the arcuate NPY neurons in which the damages likely up-regulated the mRNA expression of NPY.

ICV ADMINISTRATION OF ANTI-GALANIN ANTISENSE OLIGONUCLEOTIDE: EFFECT ON FEEDING BEHAVIOR AND BODY WEIGHT. M.G. Hulsey*, C. M. Pless and R. J. Martin. Department of Foods and Nutrition, University of Georgia, Athens, Georgia 30602

The neuropeptide Galanin has been reported to potentiate the consumption of high-fat diet in a macronutrient selection paradigm. This study investigated the effects of an ICV-administered antisense phosphorothioate oligonucleotide, directed against the Galanin mRNA, on feeding behavior and body weight in rats. Sixteen male HSD rats were cannulated in the lateral ventricle, and cannula placement was confirmed using Angiotensin II. Rats were given *ad libitum* access to tap water and a high-fat (60% w/w corn oil) semipurified diet. Feeding behavior was recorded by computer. Rats were given 7.5 μ g of an anti-Galanin oligonucleotide (5'-cctggccattctgagcag, N = 8) or a missense control oligo (5'-tcgccgtatcagatgcc, N = 8) in the hour before the onset of the nocturnal cycle (1200-2400 h) for six consecutive days. Cumulative food intake was assessed at 12 and 24 h after each injection as well as over the six day injection period, and was subjected to one-way ANOVA. Body weight change was assessed daily, and subjected to one way ANOVA. Compared to missense controls, rats receiving the antisense oligonucleotide ate significantly more of the high fat diet ($p = .0025$) during the six day injection period. There was no effect on cumulative food intake at 12 h or 24 h after injection ($p > .05$). There was no effect on body weight change ($p > .05$). These data are incongruent with previous data from macronutrient selection paradigms where the peptide was administered, and may suggest that Galanin's role in the regulation of body energy balance may be less pivotal than previously thought.

499.13

MODULATION OF GENE EXPRESSION IN HYPOTHALAMUS OF OBESE ZUCKER (fa/fa) RATS IN RELATION TO AGE AND GENDER. M. Jhanwar-Unival* and A. Burlet. The Rockefeller Univ. New York, New York 10021 and INSERM U308 Nancy, France.

Obesity in genetically predispose Zucker rats is inherited as an autosomal recessive trait. Associated with this gene are various metabolic, endocrine and behavior disturbances, such as hyperinsulinemia, hypothermia, enhanced lipogenesis, low energy expenditure, increased hypothalamo-pituitary axis, and hyperphagia. These phenotypic and metabolic abnormalities are observed relatively early in life of obese rats and are gender specific. Certain peptides and hormone receptors, by virtue of their early abnormal status in fa/fa rats or their role in primary metabolic systems show response to the changes associated with the obesity. This study examines the hypothalamic gene expression (messenger RNA; mRNA) of corticotropin-releasing factor (CRF) and glucocorticoid receptor (GR) by using the Northern blot analysis in male and female, lean and obese Zucker rats of 2, 5, and 9 wk old. The results demonstrate that: 1) higher gene expression of CRF in obese rats as compared to lean at 2, 5 and 9 wk age; 2) gene expression was significantly altered with age in both lean and obese rats; 3) gene expression of GR was significantly different in female vs. male, in lean and obese rats. Thus, result of this study show that the gene expression of the CRF and GR is associated with development/maintenance of obesity.

499.15

CENTRAL AND PERIPHERAL 2-DG: EFFECT ON NEUROPEPTIDE Y GENE EXPRESSION AND PEPTIDE LEVEL. S.O. Giraudo*, M. K. Grace, A.S. Levine and C.J. Billington. University of Minnesota, St. Paul MN 55108 & VA Medical Center, Mpls MN 55417

Neuropeptide Y (NPY) induces feeding and has been associated with carbohydrate selection. 2-deoxyglucose (2-DG) blocks glucose utilization and it potentiates appetite for carbohydrates. Thus, blockade of glucose utilization could affect NPY gene expression in the arcuate nucleus (ARC) and NPY levels in the paraventricular nucleus (PVN). To test this, 2 studies were set up as follows: 1) 32 male rats were injected intraventricularly (icv) with 18.3 μ mol/10 μ l of 2-DG and 2) 30 male rats were injected i.p 200 mg/kg of body weight. Both studies had a control (0.9% saline), a 2-DG with ad libitum food or 2-DG food deprived group. Two hours after treatment animals were sacrificed and NPY levels in the PVN and ARC NPY mRNA levels were determined using an NPY radioimmunoassay and an NPY cDNA probe respectively.

Treatment	2 h Food Intake (g)	PVN NPY levels (ng/mg PRO)	ARC NPY mRNA levels (O.D. units)
Saline icv	0.7 \pm 0.2 ^a	20.3 \pm 2.4	4.59 \pm 0.18
2-DG/food icv	2.9 \pm 0.7 ^b	19.3 \pm 1.5	5.05 \pm 0.34
2-DG/dep icv	0 ^a	19.7 \pm 2.1	4.28 \pm 0.25
Saline ip	1.5 \pm 0.2 ^a	15.4 \pm 1.5	5.17 \pm 0.28
2-DG/food ip	5.8 \pm 0.5 ^b	13.6 \pm 2.0	4.90 \pm 0.19
2-DG/dep ip	0 ^a	18.7 \pm 1.5	5.10 \pm 0.29

2-DG increased food intake 4-fold, but did not affect NPY mRNA nor peptide levels. These data suggest that 2-DG-induced feeding, through decrease glucose availability, does not involve changes in NPY activity.

IS THE ATP-SENSITIVE POTASSIUM CHANNEL (K_{ATP}) THE NEURONAL GLUCOSENSOR? B.E. Levin* Neurology Serv. VA Med. Ctr., E. Orange, NJ 07019 and Dept. Neurosciences, NJ Med. Sch., Newark, NJ 07103.

Sulfonylureas binding sites (SBS) are associated with the K_{ATP} which is responsible for glucose-induced insulin release in pancreatic β -cells. Neurons in the ventrobasal hypothalamus and other sites are also glucosensitive, altering their firing rates when ambient glucose or sulfonylurea concentrations change. These neurons contain K_{ATP} which are similar to those on pancreatic β -cells. But the high affinity SBS (SBS_H) is not concentrated in areas with large populations of glucosensor neurons. Here, SBS_H and low affinity (SBS_L) were mapped by quantitative receptor autoradiography in rat brain using 20mM 3H glyburide (GLYB). Subtraction of images in the presence (SBS_H) or absence of Gpp(NH)p to block SBS_L ($SBS_H + SBS_L$) were used to define the anatomical location of these binding sites. Unlabelled 1 μ M GLYB was used to define non-specific binding. Initial studies show SBS_H to be concentrated in areas in which sulfonylureas evoke GABA release, presumably from axon terminals. SBS_L were relatively diffuse but showed a propensity for brain sites in which glucosensor neurons are concentrated with less binding in areas containing the highest concentrations of SBS_H . These results are compatible with the hypothesis that SBS_L are linked to the K_{ATP} which serves as a glucosensor on neurons. It provides a potential site for pharmacologic intervention to modulate energy intake and body weight.

c-FOS INDUCTION IN THE PONS AND FOREBRAIN BY LITHIUM CHLORIDE AND SUCROSE AFTER CONDITIONED TASTE AVERSION FORMATION.

T.A. Houpt*, J.M. Philopena, J.W. Jahng, T.H. Joh. and G.P. Smith. Bourne Lab., Dept. Psychiatry, and Lab. Molec. Neurobiol., Burke Med. Res. Inst., Dept. Neurol. Neurosci., Cornell Univ. Med. Coll., White Plains, NY 10605.

We have previously reported that intraorally infused sucrose does not induce c-Fos-like immunoreactivity (c-FLI) in the rat NTS unless a CTA has been formed to sucrose. Lesion studies indicate that brain areas rostral to the NTS are necessary for CTA acquisition and expression. Thus, we qualitatively surveyed c-FLI as a marker of neuronal activity in the pons and forebrain at the level of the hypothalamus 1 hour after 4 treatments: intraoral sucrose infusion alone (5%, 6ml/6min), LiCl alone (0.15 M, 12ml/kg i.p.), intraoral sucrose paired with LiCl for the first time, and intraoral sucrose in rats with a CTA formed by 3 previous pairings of sucrose and LiCl.

LiCl alone induced robust c-FLI in the dorsolateral PBN, dorsal tegmental gray, olfactory CTX, thalamic PVN, central and medial amygdala, hypothalamic PVN, VMH, LH, DH, SON, AH, and BNST. c-FLI in rats receiving intraoral sucrose paired with LiCl appeared qualitatively similar to the c-FLI observed after LiCl alone. Sucrose alone induced robust c-FLI in the thal. PVN, olfactory CTX, PVN, LH, and AH. Sucrose induced some but less c-FLI than LiCl in the amygdala and PBN, and little or no c-FLI in the VMH and SON. Sucrose, however, did induce more c-FLI than LiCl in LC and striatum. In rats with an established sucrose CTA, sucrose induced more c-FLI in medial PBN and VMH than unconditioned sucrose; striatal c-FLI appeared reduced. Thus c-FLI was observed after LiCl and sucrose in many areas implicated in CTA formation by lesion studies, e.g. amygdala, LH, and PBN. Extension of the survey to other brain regions and quantitation by cell-counting may reveal patterns of neuronal activity underlying CTA formation and expression.

EFFECTS OF LITHIUM CHLORIDE PRE-EXPOSURE ON CONDITIONED PALATABILITY SHIFTS IN RATS. L. A. Eckel* and K.-P. Ossenkopp. Neuroscience Program, University of Western Ontario, London, Ontario, Canada, N6A 5C2.

Conditioned taste aversions can be produced by pairing a novel tasting substance with exposure to an emetic agent such as lithium chloride (LiCl). Using a rapid conditioning paradigm, the effects of LiCl pre-exposure on conditioned changes in taste reactivity responses were examined. Rats were pre-exposed to LiCl or NaCl (3.0 meq/kg, ip, N=12 per group) and placed in an observation box for 30 min. Conditioning occurred 2 days later when LiCl/NaCl injection was paired with intraoral sucrose infusions. Half of each pre-exposed group received LiCl injection while half were injected with NaCl. The rats were then placed in the observation box and 7 brief (30 sec) intraoral infusions of 0.3 M sucrose were administered at 5 min intervals. Both groups conditioned with LiCl produced fewer ingestive and more aversive responses than NaCl conditioned rats ($p < .05$). Comparison between the two LiCl conditioned groups revealed that LiCl pre-exposure had no effect on ingestive responses and passive drip, but did reduce aversive responding relative to NaCl pre-exposed rats ($p < .05$). These results suggest that LiCl pre-exposure attenuates conditioning by selectively reducing aversive responses. (Supported by an NSERC to KPO).

β -ESTRADIOL-INDUCED CONDITIONED SHIFTS IN SUCROSE PALATABILITY IN MALE RATS. K.-P. Ossenkopp*, Y. J. Rabi, and L. A. Eckel. Neuroscience Program, University of Western Ontario, London, Ontario, Canada, N6A 5C2.

Conditioned taste aversions (CTA) can be produced by pairing a novel taste with exposure to a toxin. Previous studies have shown that estradiol is effective in producing a CTA. The present experiment examined the ability of estradiol to produce conditioned shifts in taste reactivity responses to sucrose in male rats. Rats were fitted with intraoral cannulae and adjusted to a 23 hr/day water deprivation schedule. On two conditioning days the animals received 1 hr access to a 0.30 M sucrose solution followed by s.c. injection of 17 β -estradiol (100 μ g/kg) or vehicle (polyethylene glycol). All rats were then given free access to water and 3 days later tested for their taste reactivity to 0.30 M sucrose. The rats were placed in an observation box and three 30 sec intraoral infusions of sucrose were administered at 5 min intervals. The orofacial and somatic responses to the sucrose taste were videotaped to assess palatability. The estradiol group exhibited significantly reduced ingestive behaviors and increased aversive behaviors ($p < 0.01$), relative to the control group. When the two groups were subsequently given a 24 hr two-bottle choice test between sucrose and water, the estradiol group displayed a significant ($p < 0.01$) CTA to the sucrose. Thus, estradiol-induced CTAs seem to be based on conditioned shifts in palatability.

FOOD DEPRIVATION REDUCES STIMULUS DISCRIMINABILITY IN THE NUCLEUS TRACTUS SOLITARIUS OF THE RAT. L. J. Nolan* and T. R. Scott. Department of Psychology, University of Delaware, Newark, DE 19716

The results of human psychophysical and animal behavioral studies suggest that a state of food deprivation alters hedonic perception of taste stimuli and broadens the range of substances an animal will accept as food. We recorded from the NTS of 72-hour deprived rats to determine whether these hedonic and behavioral changes resulted from alterations in the sensitivity of the taste system. The deprivation resulted in a 10% decrease in body weight at the time of recording. The evoked activity of 45 units from food deprived rats and 40 units from calorically replete rats to an array of 13 taste stimuli was recorded and analyzed. Food deprivation significantly reduced the spontaneous firing rate of NTS gustatory neurons and attenuates the response to the sodium and lithium salts. In addition, the breadth of tuning of salt-sensitive neurons was greater in food deprived rats than in controls. We then analyzed for differences in the code for taste quality. Activity profiles evoked by the salts (NaCl, LiCl, MSG) and carbohydrates (Polycose, glucose, fructose, sucrose) across neurons were significantly more similar in deprived rats. Temporal patterns of activity in the firing rate of NTS neurons for the acids (HCl and citric) and sugars were also significantly more similar in these rats. The willingness of 72-hour food-deprived rats with a conditioned taste aversion to glucose to ingest an array of taste stimuli was tested. Results indicated a reduced ability in 72-hour food-deprived animals to discriminate between acid and sugar stimuli. The implication is that deprived rats are able to make fewer discriminations among tastants, an effect that could underlie their wider acceptance of potential foods.

SIMULTANEOUS CONTRAST EFFECTS IN CHRONIC DECEREBRATE RATS. P. S. Grigson*, M. F. Roitman*, J. M. Kaplan¹, H. J. Grill¹, and R. Norgren. Dept. Behavioral Science, College of Medicine, Penn State Univ., Hershey, PA 17033¹ and Dept. of Psychology, Univ. of Penn, Phila, PA 19104.

Seven rats received full supracollicular decerebrations in two hemi-transections spaced one week apart. These rats, along with 7 control subjects, were then implanted with two intraoral cannulae and one anterior digastric EMG electrode. On the first day following recovery from surgery, the rats received forty 10 sec infusions of 0.1 M sucrose. On a second day, they received identical infusions of 1.0 M sucrose. On two other days, the 2 concentrations were alternated for a total of forty infusions/day. All stimuli were delivered at a rate of 1.2 ml/min and the interstimulus interval was 30 sec. The rhythmic activity of the anterior digastric, which closely follows spout-licking, was evaluated during both the 10 sec infusion period and the 20 sec offset period. The results showed that during the offset period (1) both the intact and the decerebrate rats demonstrated a reliable concentration effect by generating more motor movements for the high than for the low concentration of sucrose. (2) While intact rats demonstrate contrast using other parameters, they failed to do so under these circumstances. (3) Regardless, chronic decerebrate rats did express simultaneous negative contrast. That is, they made fewer responses for the low concentration of sucrose when alternated with the high concentration than when the low concentration was presented alone ($p < .004$). Thus, an intact brain stem is sufficient for the occurrence of simultaneous negative contrast. Supported by DC-02216, DC-00240, MH-00653, DK-42284, and DK-21497.

THE RESPONSIVENESS OF GUSTATORY NEURONS IN THE AMYGDALA OF THE MACAQUE MONKEY IS INDEPENDENT OF HUNGER. T. R. Scott* and J. Yan. Department of Psychology, University of Delaware, Newark DE 19716

Taste cells in the macaque code for quality and intensity, but may be sensitive to the motivational state of the subject as well. The dichotomy between neurons that are influenced by hunger and those that are not appears to be total: cells in OFC and hypothalamus respond to a chemical only when the monkey is motivated to consume it, while those in NTS and primary taste cortex are independent of motivational state. The amygdala receives afferents from primary taste cortex, yet has close reciprocal connections with the hypothalamus. Its functions have been associated with motivation and reward, particularly as these relate to feeding. We recorded from amygdaloid taste neurons to determine whether they were influenced by the monkey's motivational state. Subjects were two male cynomolgus macaques. Tastants were applied to the tongue, and single neuron records taken from the central nucleus of the amygdala during 15 separate experiments. Monkeys were fed to satiety using 50-cc aliquots of glucose, sucrose or fruit juice, and evoked activity was measured after each aliquot. Inhibition was nearly as common a response option as excitation. Whether inhibitory or excitatory, however, the response was unaltered as the monkey progressed from acceptance to rejection of the satiating stimulus. Thus, the decreased pleasure and acceptance of foods as satiety develops does not result from changes in gustatory activity in the amygdala.

TASTE PREFERENCES FOR AMINO ACIDS AND NaCl AFTER SECTION OF CHORDA TYMPANI AND/OR GLOSSOPHARYNGEAL NERVES. E. Tabuchi¹, T. Kondoh¹, T. Vovnikov¹, T. Yokawa¹, T. Ono², J. H. Teeter³, and K. Torii^{1,4}. ¹ERATO, R&D Corp. of Japan, Yokohama 221, Japan; ²Dept. Physiol., Toyama Med. & Pharmaceut. Univ., Toyama 930-01, Japan; ³Monell Chemical Senses Center, Philadelphia, PA 19104-3308, USA; ⁴Ajinomoto Co., Inc., Central Res. Lab., Yokohama 224, Japan.

Preferences for amino acids and NaCl change with the nutritional status of the animal. To learn how the gustatory nerves convey information about nutritionally dependent taste preferences, the taste preferences in rats with bilateral chorda tympani (CTX) and/or glossopharyngeal (GPX) neurotomy were determined when animals were fed a control diet or a diet deficient in L-lysine (Lys). The group receiving CTX did not select nor ingest Lys during feeding of the Lys deficient diet, and, while being fed the control diet, their intake of L-arginine was low, whereas intake of monosodium L-glutamate (MSG) was normal. The GPX group did not substantially alter its preference for Lys, L-arginine or MSG under either diet when compared with intakes of the intact group, yet it did show altered intakes of L-histidine, saline and water, along with an increase in total fluid intake. The preferences of the group receiving both CTX and GPX evidenced themselves as a combined effect of those observed when each nerve was cut. The present data suggest that primarily the chorda tympani nerve conveys taste information for some amino acids, such as Lys and arginine, that are related to a nutritionally dependent preference. The glossopharyngeal nerve may convey other tastes, such as aversive tastes, and may be involved in sensory aspects of osmotic regulation. It is concluded that preferences seen in the selection of nutrients depend on the nutritional state of the animal. This conclusion is likely true for humans as well.

EFFECTS OF HEPATIC-CELIAC BRANCH VAGOTOMY AND SITE OF POLYCOSE INFUSION ON CONDITIONED FLAVOR PREFERENCES IN RATS. E. A. Simons, F. A. Martinson, E. A. Watson, C. C. Horn, and J. C. Mitchell. * Department of Psychology, Kansas State University, Manhattan, KS 66506.

We have shown (Horn & Mitchell, *Soc. Neurosci. Abs.*, 1993) that conditioned flavor preferences using intragastric polycose infusions are not blocked by hepatic branch vagotomy. The present study extended this research using a discrete trial procedure and a hepatic-celiac branch vagotomy. A normal control (n=7) and a hepatic-celiac vagotomized group (n=8) were both implanted with gastric fistulas and a duodenal group (n=8) was implanted with duodenal fistulas. While 22 hours food deprived, rats were trained for a total of 12 days. During training, rats received a flavor (CS+) paired with intragastric or intraduodenal infusion of 5 ml of 16% w/v polycose (US) and on alternate days, received a different flavor (CS-) paired with intragastric or intraduodenal infusion of 5 ml distilled water. The flavors used were grape and cherry Kool-Aid. After training, rats were given two-bottle extinction preference testing for four days. Results showed that the combined hepatic-celiac vagotomy failed to interfere with conditioned flavor preferences. Furthermore, flavor preferences appeared to be greater in the vagotomized animals. The results showed that polycose infused into the duodenum is as effective as intragastric infusion in conditioning preferences.

500.9

HIGH FAT-MODERATE CARBOHYDRATE DIET INCREASES FLAVOR PREFERENCES CONDITIONED WITH INTRAGASTRIC FAT INFUSION IN RATS. E.A. Watson*, E.A. Simons, F.A. Martinson, C.C. Horn, and J.C. Mitchell. Department of Psychology, Kansas State University, Manhattan, KS 66506-5302.

Using a discrete trial procedure, Lucas and Sclafani (*Physio. & Behav.*, 1989) found that conditioning flavor preferences using intragastric fat infusion was difficult and produced only a 60% preference. We modified their study using three groups of food deprived rats on special diets: a high fat-low carbohydrate group, a low fat-normal carbohydrate group, and a high fat-moderate carbohydrate group. Three cycles were completed each consisting of four days of 1-bottle training and two days of 2-bottle testing. During training, a CS+ flavor was paired with a 2-minute intragastric infusion of a variable amount of 7.1% corn oil emulsion and a CS- flavor with water. Rats maintained on the high fat-moderate carbohydrate diet had a mean preference as high as 80% for the flavor paired with the fat infusion (individual preferences reached as high as 98%). Rats in the high fat-low carbohydrate, and the low fat-normal carbohydrate groups showed no preference.

ANALYSIS OF CENTRAL OPIOID RECEPTOR SUBTYPE ANTAGONISM OF HYPOTONIC AND HYPERTONIC SALINE INTAKE IN WATER-DEPRIVED RATS. R.J. Bodnar*, M.J. Glass and J.E. Koch. Dept. of Psychology and Neuropsychology Doctoral Program, Queens Coll., CUNY, Flushing, NY 11367.

Intake of either hypotonic or hypertonic saline solutions is modulated in part by the endogenous opioid system. Morphine and selective mu and delta opioid agonists increase saline intake, while general opioid antagonists reduce saline intake in rats. The present study evaluated whether intracerebroventricular administration of general (naltrexone) and selective mu (beta-funaltrexamine, 5-20 ug), mu, (naloxonazine, 50 ug), kappa (nor-binaltorphamine, 5-20 ug), delta (naltrindole, 20 ug) or delta, (DALCE, 40 ug) opioid receptor subtype antagonists altered water intake and either hypotonic (0.6%) or hypertonic (1.7%) saline intake in water-deprived (24 h) rats over a 3 h time course in a two-bottle choice test. Water intake was significantly reduced by both peripheral naltrexone (0.5-2.5 mg/kg) in the hypotonic (-56%) and hypertonic (-57%) saline paradigms and central naltrexone (1-50 ug) in the hypotonic (-56%) and hypertonic (-31%) saline paradigms. Peripheral naltrexone significantly reduced hypertonic saline intake (-48%), but not hypotonic saline intake, while central naltrexone significantly reduced hypotonic saline (-44%) intake, but not hypertonic saline intake. Water intake was significantly reduced following mu (-53%) and kappa (-51%) receptor antagonism, but not following mu, delta or delta, receptor antagonism. In contrast, neither hypotonic nor hypertonic saline intake was significantly altered by any selective antagonist. These data are discussed in terms of opioid receptor subtype control over saline intake relative to the animal's hydration state and the roles of palatability and/or salt appetite. Supported by NIDA DA 04194.

CENTRAL KAPPA AND MU OPIOID ANTAGONISTS DECREASE SUCROSE INTAKE IN SHAM-FEEDING RATS. L. Leventhal*, T.C. Kirkham, J.L. Cole and R.J. Bodnar. Dept. of Psychology, Queens Coll., CUNY, Flushing, NY 11367 and Bourne Labs, Cornell Univ. Med. Ctr., White Plains, NY 10605.

Opioid antagonists decrease food intake in rats, especially palatable intake. While sucrose intake is significantly increased by mu, kappa and delta agonists, it is decreased by general, mu and kappa antagonists, but not by mu, delta or delta, antagonists. Since sucrose intake acts postingestively, studies with intact rats cannot distinguish between opioid modulation of hedonic orosensory or postingestive factors. In sham-feeding rats in which postingestive factors are eliminated, peripheral naloxone stereospecifically decreased sucrose intake by shifting its concentration-dependent effects. To assess whether central kappa and mu opioid receptor subtypes alter sucrose intake through orosensory mechanisms, the present study evaluated whether selective kappa (nor-binaltorphamine: NBNI) or mu (beta-funaltrexamine: BFNA) opioid antagonists reduced sucrose intake in sham-feeding rats in a manner similar to peripheral naltrexone. Naltrexone (0.01-1 mg/kg, sc) dose-dependently reduced sucrose (20%) intake in sham-feeding rats with its peak inhibitory effects occurring after 15-30 min. This corresponds with the premise of interference with the maintenance and not initiation of intake. NBNI (20 ug) and BFNA (20 ug) significantly decreased sucrose intake in sham-feeding rats in a manner both similar to their respective effects in intact rats, and to peripheral naltrexone's effects in sham-feeding rats. Thus, kappa and mu receptors appear to reduce sucrose intake by acting on the hedonic orosensory characteristics of the ingestate. Supported by NIDA DA 04194.

OPIOID SUBTYPE ANTAGONISTS IN MEDIAL HYPOTHALAMUS ALTER DEPRIVATION, GLUCOPRIVIC AND PALATABLE FOOD INTAKE IN RATS. J.E. Koch*, M.J. Glass, M.L. Cooper and R.J. Bodnar. Dept. of Psychology & Neuropsychology Doctoral Program, Queens Coll., CUNY, Flushing, NY 11367.

Intraventricular injections of selective mu and kappa opioid subtype antagonists decrease intake after food deprivation (FD), 2-deoxy-D-glucose (2DG) hyperphagia and sucrose intake in rats. Opioid agonist injections into the medial hypothalamus (MH), particularly the paraventricular nucleus, stimulate food intake. The present study compared the abilities of naltrexone (NTX), the mu-selective antagonist beta-funaltrexamine (BFNA) and the kappa-selective antagonist norbinaltorphamine (NBNI) microinjected into MH to alter deprivation (24h) intake, 2DG (500 mg/kg i.p.) hyperphagia, or sucrose (10%) intake.

Deprivation intake was significantly reduced by NTX (10 ug: 26%), BFNA (5 ug: 26%) or NBNI (5 ug: 31%) in MH. 2DG hyperphagia was significantly reduced by NTX (10 ug: 69%), BFNA (20 ug: 83%) or NBNI (20 ug: 69%) in MH only after 2h. Neither NTX, BFNA nor NBNI in MH altered sucrose intake. The MH effects are compared with ventricular effects to infer MH mediation of opioid antagonist actions on different forms of intake. Supported by NIDA DA 04194.

BLOCKADE OF DIETARY OBESITY DEVELOPMENT BY CENTRAL SELECTIVE OPIOID ANTAGONISTS IN RATS. J.L. Cole*, L. Leventhal, G.W. Pasternak, W.D. Bowen and R.J. Bodnar. Neuropsychology Doctoral Program, Queens Coll., CUNY, Flushing, NY 11367; Dept. of Neurology, Memorial Sloan-Kettering Cancer Ctr., New York, NY 10021; Div. of Medicinal Chemistry, NIH, Bethesda, MD 20892.

Chronic injections of naloxone or naltrexone transiently reduce food intake and body weight, probably due to a limited duration of action. The irreversible mu, antagonist, naloxonazine, reduced body weight and food intake over 2 weeks in normal rats, but failed to affect these variables in dietary-obese rats. Since acute administration of opioid antagonists reduce palatable intake, the present study examined whether body weight and intake of a high-fat, sweetened condensed milk and chow diet would be altered by daily (11 days) central microinjections of long-acting mu (beta-funaltrexamine: BFNA, 20 ug), mu, (naloxonazine: NAZ, 50 ug), kappa (nor-binaltorphamine: NBNI, 20 ug), delta, (DALCE, 40 ug) or delta, (naltrindole 5'-isothiocyanate: NTII, 20 ug) opioid subtype antagonists. Rats exposed to the palatable diet gained significantly more weight (+9% vs. +5%) than chow-fed controls. Significant reductions in body weight occurred immediately and progressed thereafter for each antagonist: BFNA (-9%), NAZ (-11%), NBNI (-6%), DALCE (-7%) and NTII (-7%). Corresponding decreases in milk, fat and chow intakes were also observed following antagonist treatments. These data implicate each opioid receptor subtype in maintenance of body weight under palatable conditions. Supported by NIDA DA 04194.

EEG RESPONSES TO ICE CREAM AND PAIN: OPIOID AND PREFERENCE EFFECTS. D.D. Krahn*, B.A. Gosnell, R.J. Davidson, J. Williams, L. Redmond, L. Vitte. University of WI Dept of Psychiatry, Madison, WI 53792.

Research by our group and others has demonstrated that (1) treatment with opioid agonists increases and treatment with opioid antagonists decreases intake of and preferences for highly preferred foods and fluids in animals and humans; (2) intake of highly palatable foods affects the endogenous opioid system and alters responses to painful stimuli; and (3) states associated with positive affect and approach behaviors are associated with relative activation of the left frontal cerebral hemisphere (RAL) as measured by EEG in humans. In order to determine whether the eating of a highly preferred food resulted in altered response to pain, changes in mood, and RAL due to effects on the endogenous opioid system, we are conducting an experiment in which the hedonic, EEG, and analgesic responses of young female subjects (classified as ice cream likers or non-likers on the basis of their answers to a questionnaire) to ingesting ice cream (750 cal in 10 minutes) followed by either naloxone or saline are measured. The same responses are also measured in likers and nonlikers during a no eating, saline trial. Initial results in three ice cream likers and two nonlikers are available; additional data are being collected. After ice cream ingestion, naloxone treatment resulted in a large shift to relative right activation on the EEG in likers; this effect was not seen in nonlikers. Also, the three likers showed a relative increase in right-sided EEG activation on the no eating day in response to repeated painful stimuli, but on days on which they received ice cream and saline, they demonstrated relative left-sided activation. These preliminary data support the hypothesis that subjects who highly prefer ice cream differ from those subjects who do not prefer ice cream in their affective and analgesic responses to palatable food ingestion. This research was supported by NIDA grant DA05471.

NITROUS OXIDE STIMULATES FOOD INTAKE IN NON-DEPRIVED RATS. D.A. Czech* and C.T. Kazel. Department of Psychology, Marquette University, Milwaukee, WI 53233.

Previous research suggests that nitrous oxide (N₂O) exerts one or more of its effects through a benzodiazepine (BZP) receptor system. Further, BZP's are known to influence ingestive behaviors in several animal species. This study examines a possible N₂O effect on food intake in the non-deprived rat.

In expt. 1, male Long-Evans hooded rats were exposed to one of four concentrations of a N₂O and O₂ mixture (10-40% N₂O) or to room air circulated through an enclosed environment. Following an initial acclimation to gases, ground chow and tap water were provided *ad lib* in the same environment for a 60 min test. Intakes at 30 and 60 min were corrected for body weight and evaluated (here and in other expts.) with ANOVA procedures and, as appropriate, Dunnett's or adjusted Student's *t* tests; alpha level was set at *P* < 0.05. Food intake increased in a dose-related manner with increasing concentration of N₂O, differing significantly from room air controls at 20% N₂O.

In expt. 2, pretreatment with 10 or 20 mg/kg (ip) of the BZP receptor blocker, flumazenil, failed to attenuate the hyperphagia induced by a challenge concentration (30%) of N₂O.

In expt. 3, pretreatment with the opioid antagonist, naltrexone (0.1-10.0 mg/kg, sc), attenuated 30% N₂O-induced hyperphagia in a dose-related manner; all doses were significant relative to vehicle control. These data fail to support an hypothesis that N₂O-induced hyperphagia in the rat is mediated by a BZP receptor. The data do, however, implicate an opioid mechanism.

500.17

HEPATIC PORTAL AND VENA CAVA GLUCOSE AND AMINO ACID INFUSIONS DECREASE DAILY FOOD INTAKE IN RATS. A. E. Willing & H. S. Koopmans*. Dept. of Medical Physiology, Univ. of Calgary, Calgary, Canada, T2N 4N1.

Intravenous infusions of glucose and/or amino acids into the vena cava cause daily food intake to decrease by 50% to 100% of the kilocalories (kcal) infused (Walls & Koopmans, 1992). Since glucose and amino acids are normally absorbed from the gut into portal circulation before they are taken up or metabolized in the liver or passed on to the rest of the body, we examined whether glucose and amino acid infusions into the hepatic portal vein (HP) of male Lewis rats would lead to better caloric compensation than vena cava (VC) administration. A 10 kcal glucose infusion decreased daily food intake to a similar degree in the HP (3.3 ± 1.5 kcal) and VC groups (2.5 ± 4.9 kcal, *p* > .90). Daily food intake was significantly decreased (*p* < .01) during the 20 kcal infusion by 12.8 ± 4.8 (HP) and 14.7 ± 3.1 kcal (VC). There was no significant difference between the two routes of infusion (*p* > .75). With the 20 kcal amino acid infusion food intake was significantly reduced (*p* < .005) by 17.4 ± 4.9 kcal in the HP group and 17.7 ± 2.7 kcal in the VC group. Again there was no difference in route of infusion (*p* > .90). There was no significant effect of treatment or route of infusion on the rate of body weight gain. These results show once again that infused nutrients can provide part of a signal that controls daily food intake. Furthermore, the liver is not likely to be the site where this signal is generated even though it plays a central role in nutrient metabolism. The infusion of glucose or amino acids into the portal vein would generate high hepatic plasma values of these nutrients but produced reductions in daily food intake that were similar to those found after vena cava infusion.

HORMONAL CONTROL OF REPRODUCTIVE BEHAVIOR: MATING

501.1

DIFFERENTIAL MATING STIMULATION EFFECTS FOS EXPRESSION IN BRAIN AND SPINAL CORD OF THE FEMALE RAT. E. Komberg, J.-W. Lee and M.S. Erskine*. Department of Biology, Boston University, Boston, MA 02215 USA

Threshold amounts of cervical stimulation (CS) received during mating are essential for the initiation of the prolactin (PRL) surges of early pregnancy in the rat. The expression of FOS in brain and spinal cord in response to amounts of CS which are sufficient or insufficient to induce PRL surges was examined. Ovariectomized rats primed with estrogen (EB, 40µg/kg) and progesterone (2mg/kg) received subthreshold (mounts-without-intromission; MO), perithreshold (5 or 10 intromissions, I), suprathreshold (15 I) mating stimulation from males or were taken directly from the home cage (HC). Animals were sacrificed 1 hr post mating, and brain and spinal cord sections were stained for FOS protein using standard techniques. Numbers of FOS-immunoreactive (FOS-IR) cells increased in proportion to the number of I in the medial amygdala (mAMYG) and bed nucleus of the stria terminalis (BNST) and in response to I compared to MO and HC in the preoptic area (POA) and ventromedial nucleus of the hypothalamus (VMN). The L6 segment of the cord showed graded numbers of FOS-IR cells following 5 or 15 I; this effect was restricted to laminae II and X. At thoracic (T13), lumbar (L1-L3) and sacral (S1-S2) levels, I stimulation did not increase FOS above HC levels. MO animals at all spinal levels examined had significantly higher FOS-IR than HC and I animals, suggesting an analgesic effect of CS on neural activity in the cord. Since the mAMYG, BNST and L6 showed graded responses to CS, these areas may be involved in acquisition of information relevant to initiation of PRL surges. Supported by HD21802 to MSE.

EVIDENCE FOR INNERVATION OF THE HEPATIC PARENCHYMA IN THE RAT. M.I. Friedman, M. Ketchum, P. Ulrich, P.A.S. Breslin and C. DellaCorte. Monell Chemical Senses Center, Philadelphia, PA 19104.

Although innervation of the hepatic parenchyma has been demonstrated in many species, its existence in the rat has been controversial. The intralobular innervation of human liver has been characterized using immunocytochemical staining for a variety of neural markers. To determine whether the hepatic parenchyma of rats is innervated, we examined liver tissue immunohistochemically for the presence of neurofilament protein 200 (NF 200) using a monoclonal antibody to NF 200. Reaction product indicative of fine neuronal processes was observed in close association with hepatocytes in certain areas of the liver. The processes were seen transversing several hepatocytes and often had a beaded appearance indicative of varicosities. NF 200-like immunoreactivity was also found in association with the hepatic vasculature suggesting a vascular innervation as well. Western blot analysis of liver tissue confirmed the presence of NF 200. These observations provide evidence for intralobular innervation of the rat liver.

ALTERNATIVE MALE TYPES IN TREE LIZARDS HAVE DIFFERENT DELAYED STEROID HORMONE RESPONSES TO AGONISTIC ENCOUNTERS. R. Knapp* and M.C. Moore. Dept. of Zoology, Arizona State Univ., Tempe, AZ 85287-1501.

Steroid hormones are known to mediate agonistic behavior in a variety of species. We are examining the role of testosterone (T) and corticosterone (B) in agonistic behavior in a species where a male can be one of two permanent types with respect to aggressiveness. Previously, we reported finding a delayed (1-day) increase in plasma B levels, but no changes in T, in aggressive-morph male tree lizards (*Urosaurus ornatus*) who won short encounters in the laboratory (*Amer. Zool.*, 32(5):24A, 1992). We have now repeated the experiment to determine whether this delayed effect of winning occurs under more natural conditions, and if it also occurs in the less aggressive morph. Staged encounters were run using a tethered intruder male presented to marked lizards in the field. The two types of males differed in their hormonal response to the encounter. Winning staged encounters had no significant effect on plasma T or B levels in the territorial, more aggressive morph one day following the encounter. However, males of the less aggressive, satellite/nomadic morph exhibited decreased T (ANCOVA, *p* = 0.02) and increased B levels (*p* = 0.003) relative to controls. A contributor to morph-specific levels of aggression documented earlier (*Horm. Behav.*, 26:568, 1992) may be a morph-specific response of T and B levels following male-male encounters. However, morph differences in aggressiveness may not be mediated by differential sensitivity of plasma T to increases in B, as i.p. injections of 0-600 ng B revealed no difference in T levels for the two types of males. The results do, however, suggest a hormonal mechanism whereby frequency of male-male encounters may influence whether a male of the less aggressive morph is a satellite or nomad.

501.3

EFFECTS OF TESTOSTERONE (T) AND PROGESTERONE (P) ON CCK-INDUCED LORDOSIS IN THE ESTRADIOL BENZOATE (EB)-PRIMED MALE RAT. P. Butler, J.G. Kohlert and G.J. Bloch*. Dept. of Psychology, BYU, Provo, UT 84602. Sulfated CCK octapeptide (sCCK-8) increases lordosis behavior when microinjected into the medial preoptic nucleus (MPN) of the EB-primed male rat (Bloch et al, Physiol Behav 46, '89). The male does not normally express high levels of lordosis, however, even though MPN levels of CCK and CCK mRNA are high. To test whether T inhibits the lordosis response to CCK, saline (SAL) or 50ng sCCK-8 were microinjected into the MPN of adult-gonadectomized EB-primed male rats implanted with blank (Bk) or T-filled Silastic capsules. 3 behavioral tests were spaced 1 week apart. Males received a P-filled capsule immediately after the 2nd test. sCCK-8 increased lordosis in Bk- and T-treated males. (Bk: LQ=25.6±4.8(SAL) vs 52.2±7.6(CCK) p<0.02, paired t test; T:LQ=35.5±7.8(SAL) vs 67.5±7.4(CCK), p<0.01). Interestingly, with P treatment, lordosis was very low in T- vs Bk-treated males (LQ= 21.7±16 vs 71.1±10.2, p<0.025); sCCK-8 abolished this effect: LQ's=72.5,78.0 for Bk- and T-treated males. Although T is reported to inhibit lordosis in EB-primed females, T was not inhibitory in males. Thus, CCK injected into the MPN stimulated lordosis in the EB-primed male with or without T, administered alone or in combination with P. Low levels of lordosis in the male do not therefore result from a suppression by gonadal steroids of neural mechanisms mediating the lordosis-stimulating effects of CCK. (NIH HD27334)

501.5

LHRH MICROINJECTED INTO THE MEDIAL PREOPTIC NUCLEUS (MPN) INCREASES SEXUAL BEHAVIOR IN THE MALE RAT. G.J. Bloch, J.G. Kohlert, P. Butler, J. Stowell, S. Huber, W. Johnson, J. Sovereign, N. Kuemmerle, M. Walden, & D. Fleming*. Psychology Dept., BYU, Provo, UT 84602. Galanin (GAL) microinjected into the MPN facilitates male-typical sexual behavior in the rat (Bloch et al, Physiol Behav 54, '93). GAL stimulates LHRH and is found within LHRH cells located within the medial preoptic area (MPOA). Others have reported that subcutaneous LHRH facilitates male sexual behavior. I.c.v. LHRH also is stimulatory, but this result is not site-specific. No effect was noted with LHRH in the MPOA, but gonadally intact males behave maximally and thus may have been insensitive. We determined the behavioral response of .3ul saline (SAL) or 20,50,100,200,500ng LHRH microinjected into the MPN of gonadectomized male rats implanted with 2mm testosterone-filled Silastic capsules; these produce low levels of behavior, allowing for measurement of facilitatory effects. The percentage of males that mounted (M), intromitted (I), or ejaculated (Ejac) increased with higher doses of LHRH. M and I latencies (ML, IL) decreased dose-responsively. ML and IL scores in 500ng LHRH males, for example, were 144±50 and 211±61 sec, respectively, vs 372±96 and 593±109 sec for SAL controls. M and I frequencies, Ejac latencies, and post-ejaculatory intervals were not affected. Thus, as with GAL, LHRH microinjected into the MPN appears to increase sexual arousal. GAL and LHRH may interact to regulate sexual behavior. (Supported by NIH HD 27334)

501.7

SPECIES DIFFERENCES IN ESTROGEN SENSITIVITY IN WHIPTAIL LIZARDS L.J. Young* and D. Crews, Dept. of Zoology, Univ. of Texas, Austin TX 78712

C. uniparens is a unisexual species of whiptail lizard whereas *C. inornatus* is a sexual species and the maternal ancestor of *C. uniparens*. Together they represent an excellent model for investigating the evolution of hormone-brain-behavior relationships. Plasma levels of estradiol in *C. uniparens* are approximately 5-fold lower than those of female *C. inornatus* in a similar reproductive state. This translates into species differences in dose-response curves for estradiol benzoate (EB)-induced female sexual behavior (receptivity) (p<0.01). Ten-fold smaller dosages of EB are capable of stimulating receptivity in *C. uniparens* compared to female *C. inornatus*. *In situ* hybridization analysis indicates that estrogen induction of progesterone receptor (PR) expression in the ventromedial nucleus of the hypothalamus (VMH) also differs between the species. EB was significantly more potent in ovariectomized *C. uniparens* than in ovariectomized female *C. inornatus* at inducing PR gene expression within the VMH (p<0.01). Preliminary results indicate that species difference in estrogen receptor expression in the VMH may account for the differences in behavioral and molecular sensitivities to EB. These results indicate that the differences in behavioral sensitivity to estrogen lies in the estrogen target neurons in the brain area (VMH) controlling receptive behavior. Furthermore, these differences in sensitivity to estrogen may provide insight into the evolution of species differences in circulating hormone levels and of hormone sensitivity of steroid dependent behaviors in general. Supported by NSF Pre-doctoral Fellowship (LJY) and NIMH 41770 (DC).

501.4

PREPUBERTAL TESTOSTERONE (T) DEFEMINIZES OR MASCULINIZES MEDIAL PREOPTIC AREA (MPOA) STRUCTURES IN THE RAT. R. Mills*, J.K. Graham and G.J. Bloch. Dept. of Psychology, BYU, Provo, UT 84602.

Gonadotropin secretion and sexual behaviors are defeminized or masculinized in adulthood by prepubertal T treatment of female and NeoGx male rats (Bloch et al, Neurosci Biobehav Rev, in press). The periventricular preoptic (PvPO), anteroventral periventricular (AVPv), and medial preoptic nucleus (MPN) and its central and medial divisions (MPNC, MPNm) were measured in adult-sacrificed females and NeoGx males that received blank (Bk-) or 7mm T-filled Silastic capsules during days 15-30 of age. The width of the PvPO in T-treated, constant-estrus females and NeoGx males decreased 19% and 18%, respectively, vs Bk controls (P<0.06, <0.03); the volume of the AVPv decreased by 35% and 29% (p's<0.03). Cell number and density decreased significantly within the PvPO of T-treated NeoGx males but not T-treated females. Similarly, the T treatment increased the size of the MPNm by 26% in NeoGx males but not females. There were no effects on the size of the MPNC and MPN, although the MPNC of gonadally intact males was 45% larger than in NeoGx males. Interestingly, the morphology of the MPNm and PvPO was affected more by T in NeoGx males than in females, similar to results with sexual behavior and gonadotropin secretion. Thus, a prepubertal T treatment that defeminizes or masculinizes reproductive function in females and NeoGx males has analogous effects on sexually dimorphic structures of the MPOA.

501.6

INHIBITION OF TESTOSTERONE AROMATIZATION IN THE INTACT MALE RAT PREOPTIC AREA ENHANCES ESTROGEN RECEPTOR-LIKE IMMUNOREACTIVITY AND REDUCES MATING. A. N. Clancy, D. Zumpke and R. P. Michael*. Department of Psychiatry and Behavioral Sciences, Emory University School of Medicine, GMHI, 1256 Briarcliff Rd., Atlanta, GA 30306.

Copulatory behavior was studied in 5 groups of sexually experienced, intact male rats in which: (i) the nonsteroidal aromatase inhibitor Fadrozole (CIBA-Geigy CGS 16949A) was delivered bilaterally into the medial preoptic area (POM) together with normal saline given s.c. via osmotic minipumps, (ii) normal saline was delivered bilaterally into POM together with the same Fadrozole dose given s.c., (iii) Fadrozole was delivered bilaterally into the cerebral cortex together with saline given s.c., (iv) Fadrozole was delivered bilaterally into the lateral preoptic area together with saline given s.c., and (v) unoperated controls. Mounting and ejaculation were significantly decreased in rats receiving Fadrozole in POM compared with the behavior of rats in the other 4 groups. Few differences occurred between rats in the latter 4 groups, all of which continued to mate. The H222 (Abbott Laboratories) and ER-715 anti-estrogen receptor (ER) antibodies were used to examine the distributions of ER immunoreactive (ERir) neurons in gonadectomized controls and some of the rats in groups i, ii and v. Since labeling of ERir neurons with the H222 antibody, but not the ER-715 antibody, is inhibited by estrogen, areas labeled by both antibodies presumably were sites where the conversion of testosterone (T) into estradiol (E₂) was blocked. Intense H222 ERir neuronal labeling was confined to the POM of males in group i, and significantly more labeled neurons were found in the POM of males in group i than were found in the POM of males in group ii. The ER-715 antibody labeled neurons in the brains of all rats. Results show that conversion of T into E₂ in POM is important for copulatory behavior in male rats and that H222 ERir can be used to identify the neurons in POM affected by Fadrozole. (Funded by USPHS grant MH 19506 and the Emory University Research Committee).

FOS EXPRESSION FOLLOWING ELECTRICAL STIMULATION OF THE VOMERONASAL ORGAN. M. Meredith* and G. Fernandez-Fewell. Program in Neuroscience, Florida State University, Tallahassee FL 32306.

c-fos expression in the forebrain following electrical stimulation of the vomeronasal organ (VNO) was compared with Fos patterns obtained previously after mating and pheromonal stimulation in male golden hamsters. Electrodes were implanted unilaterally via a midline incision in the palate. Two 125 um teflon coated wires were bared 0.5 mm at the tip and inserted one near the anterior end, one midway along the vomeronasal capsule. The wires were sealed in place with cyanoacrylate tissue adhesive and their free ends passed under the skin around the nose then along the dorsal skull surface to a connector mounted on the parietal bone. The palate was sutured and the animals allowed 3 days to recover. Via a flexible cable connected with a constant current stimulator, animals were stimulated for 45 min intermittently with low current in their home cages, or were connected but not stimulated for 45 min. Typical stimulation currents were 120-175 uA (0.5-1 ms pulses) and produced no stimulus driven movements in the awake animal. Low level Fos activation occurred in accessory olfactory bulb, medial preoptic area and medial amygdala (both anterior (MeA) and posterior (MeP)). The activation in the MeA on the side ipsilateral to the stimulation was similar to activation previously seen in mated and pheromonally stimulated animals. Fos expression was also seen in the anterior medial preoptic/diagonal band region, including a few LHRH immunoreactive (ir) cells; a colocalization never seen in male hamsters following mating behavior or stimulation with female chemical stimuli. This may reflect activation of the LHRH system by vomeronasal input, but could also reflect activation of the Nervus terminalis system. Supported by NIH grant DC 00406.

501.9

FOS PATTERNS IN MALE HAMSTER VOMERONASAL PATHWAYS: PHEROMONE STIMULATION AND EFFECT OF EXPERIENCE Gwen Fernandez-Fewell* and Michael Meredith Neuroscience Program, Florida State University, Tallahassee, FL 32306

Removal of vomeronasal organs (VNX) from sexually naive, but not from sexually experienced male hamsters results in severe deficits in mating behavior. Previous studies of Fos patterns in VNX and intact inexperienced males indicate a preferential activation of VN pathways (Accessory olfactory bulb, Medial amygdala; Me) during mating behavior and pheromonal stimulation. Activation in the medial preoptic area (MPOA) mainly reflected copulatory performance. Here, c-fos expression was used to analyze patterns of neural activity in sexually experienced intact and VNX males exposed to pheromonal stimulation either alone or during mating. Males from each group were placed in clean boxes with fresh bedding and each exposed to female hamster vaginal fluid (HVF) or a sexually receptive female for 45 mins. After an additional 45 mins they were perfused with 4% paraformaldehyde. Control animals were put into clean boxes with fresh bedding and perfused 90 mins later. Fifty μ m vibratome sections were processed for immunocytochemistry using a polyclonal Fos antibody. (Cambridge Research). When exposed to HVF, experienced males had higher levels of Fos expression in the MPOA than did inexperienced males, whether intact or VNX. Mated animals all had extensive Fos expression in MPOA but here there appeared to be a denser expression in intact than VNX animals. Fos expression in Me, among HVF exposed males, was highest in intact experienced animals with lower levels in inexperienced animals and in VNX animals. Mated animals had a higher overall level but similar relative levels of expression. Supported by NIH Grant DC00906.

ESTROUS FEMALE ELICITS DOPAMINE RELEASE IN MPOA OF INTACT, BUT NOT CASTRATE, MALE RATS. J. Du, D. S. Lorrain, L. Matyszewicz, and E. M. Hull* Department of Psychology, SUNY at Buffalo, Buffalo, NY 14260.

Extracellular levels of dopamine (DA) metabolites DOPAC and HVA increased in the medial preoptic area (MPOA) of male rats during copulation; DA was below the sensitivity of the assay (Hull et al., 1993). The presence of an estrous female increased the catecholamine amperometric signal in MPOA, but the contribution of DA could not be determined (Blackburn & Pfau, 1992). This experiment tested whether extracellular DA, serotonin (5-HT) and their metabolites in the MPOA of male rats were affected by exposure to an estrous female behind a barrier or by copulation. We also tested if testosterone (T) facilitates the DA response to the female. Microdialysis samples were assayed using an LC Packings capillary column and Antec electrochemical detector. In intact males, DA, DOPAC and HVA increased in the presence of the female and during copulation; 5-HT and 5-HIAA were not affected. In castrates with T replacement DOPAC and HVA increased significantly in the presence of the female and during copulation; DA increased slightly. In castrates without T, DA fell throughout the experiment, and DOPAC and HVA did not rise in the presence of the female; these animals did not copulate. Since DA in MPOA enhances male sex behavior (Hull et al., 1986), T may influence copulation in part by increasing DA release in MPOA in response to an estrous female. (NIMH grant #40826 to EMH)

501.13

AXOTOMY AND TESTOSTERONE SENSITIVITY OF THE RAT BULBOSPONGIOSUS MOTOR SYSTEM. W.F. Collins, III,* W. Hu and M. Gonzalez. Dept. of Neurobiology and Behavior, SUNY, Stony Brook, NY 11794.

Rat bulbospinosus (BS) motoneurons exhibit androgen dependence in adulthood. However, it is not clear whether androgens act directly on BS motoneurons or indirectly via the BS muscle. To address this question, we have examined the effect of axotomy on the androgen sensitivity of the rat BS motor system.

The BS muscle nerve was sectioned unilaterally in 180 gm male rats anesthetized with ketamine and xylazine. The rats were then castrated (with or without testosterone pellet implants) or sham-castrated (sham). After 28 days survival, the rats were sacrificed, and the left and right BS muscles were removed and weighed. Transverse sections from L5-L6 spinal cords were counterstained with cresyl violet, and the somal cross sectional areas of 20 randomly selected motoneurons in both the left and right dorsomedial nuclei from each rat were measured. The data were analyzed using ANOVAs.

As expected, castration produced decreases in mean BS muscle weight and motoneuron somal cross sectional area (73% and 17% of sham controls; respectively) on the axonally intact control side. Chronic denervation of the BS muscle resulted in a 53% decrease in weight (compared to contralateral control), and the BS muscle exhibited a further loss in weight (59% decrease compared to denervated sham) following castration. Chronic axotomy produced a 23% decrease in BS motoneuron somal cross sectional area (compared to contralateral control). Furthermore, somal cross sectional area of axotomized BS motoneurons was 12% smaller in castrated rats compared to axotomized sham controls. All castration effects were reversed by testosterone administration and are significant to $p < 0.01$.

Thus, both denervated BS muscles and axotomized BS motoneurons are sensitive to androgen. However, the effect of castration on axotomized BS motoneurons is attenuated compared to that observed in axonally intact BS motoneurons.

STEROID-INDUCED REPRODUCTIVE BEHAVIOR IN OBESE ZUCKER FEMALE RATS. C.L.M. Bivens* and D.H. Olster. Department of Psychology & Neuroscience Research Institute, University of California, Santa Barbara, CA 93106.

Obese Zucker female rats are infertile. Anecdotal evidence suggests ovary-intact obese Zucker females display less reproductive behavior than their lean counterparts. The present study was designed to compare reproductive behavior induced by exogenous steroid hormones in ovariectomized (OVX) lean and obese Zucker rats. OVX adults were given estradiol benzoate (EB, 15-100 μ g/kg) or EB plus progesterone (P, 2-10 mg/kg), and tested for sexual receptivity. At the highest EB dose obese Zucker females displayed lordosis less frequently than lean rats (Lordosis Quotient, LQ = $8 \pm 6\%$, vs. $32 \pm 13\%$ respectively, $p < 0.01$). At the lowest doses of EB plus P lean females were maximally responsive (LQ = $93 \pm 4\%$); Zucker obese females, in contrast, were only slightly receptive (LQ = $26 \pm 11\%$, $p < 0.00003$). Increasing the dose of either EB or P, administered in combination with the lowest dose of the other hormone, produced responses in obese Zucker females that were comparable to those observed in lean rats. These data suggest that considerably higher doses of EB and/or P are required to elicit robust lordosis responses in OVX obese Zucker, as compared to lean rats. This behavioral hyporesponsiveness may contribute to infertility in the obese Zucker female rat. (This work was supported by NIH HD 23483 and the American Psychological Association.)

SEXUAL EXPERIENCE INCREASES COPULATION INDUCED FOS-LIKE IMMUNOREACTIVITY IN THE MPOA. L.A. Lumley* and E.M. Hull. Department of Psychology, SUNY at Buffalo, Buffalo, NY 14260.

Male sexual behavior increases the induction of the immediate early gene c-fos in the medial preoptic area (MPOA) (Robertson et al., 1991), a brain area important in the regulation of male sex behavior. We recently reported that a D1 antagonist lowered the number of copulation induced Fos-like immunoreactive cells in the MPOA (SN, 1993). Male rats improve their copulatory efficiency with sexual experience. We hypothesized that sexual experience may affect copulation induced Fos in the MPOA. In the current study, we compared copulation induced Fos-like immunoreactivity in sexually experienced relative to sexually inexperienced male rats. One group of male rats received sexual experience every five days for seven weeks, at which time they were able to achieve three ejaculations in a 30 minute interval. Another group of male rats of equal age received no sexual experience prior to the test day. On the test day, all males were allowed to achieve one ejaculation, and brains were subsequently assayed for Fos-like immunoreactivity. A noncopulatory control group was also included. After one ejaculation, an increase in Fos-like immunoreactivity in the MPOA was observed in sexually experienced relative to sexually inexperienced males. Since dopamine in the MPOA is released during copulation and is important in the regulation of male sexual behavior, increased Fos-like immunoreactivity may reflect a more sensitive dopamine system in sexually experienced male rats. DISCRIMINATION LEARNING WITH INJECTIONS OF MORPHINE INTO THE PARABRACHIAL NUCLEUS, BUT NOT INTO THE VENTRAL TEGMENTAL AREA (VTA) T.V. Jagger* and D. van der Kooy, Dept. of Anatomy, Univ. of Toronto, Toronto, Canada M5S 1A8.

In a previous study, we demonstrated a dissociation between the neuroanatomical sites which mediate the motivational effects of morphine and its discriminative effects. Morphine was found to have both aversive and rewarding motivational effects in the VTA, but not in the parabrachial nucleus (PBN). Conversely, morphine produced discriminative effects in the PBN, but not in the VTA. To extend these studies, we use a taste aversion model of discrimination to show that 1) the discriminative effects of morphine within the PBN are specific to the activation of opiate receptors and 2) injections of morphine into the PBN, but not into the VTA, may serve as a stimulus for discrimination learning. Rats were injected with morphine (5 mg/kg, i.p.) 15 min prior to the presentation of a 0.1% saccharin solution. Lithium chloride (130 mg/kg) was injected immediately after 20 min of exposure to the flavour. On alternate days, an injection of 0.9% saline both preceded and followed the presentation of saccharin. Unilateral guide cannulae were then implanted into the PBN and generalization to central routes of administration was evaluated following the microinjection of 2.5 and 5 µg of morphine and 2.5 and 5.0 µg of (+)-morphine. Stimulus generalization was observed with 2.5 and 5.0 µg of morphine, while the inactive (+)-isomer of morphine failed to produce responses reliably different from the saline training condition.

Separate groups of rats received bilateral cannulae implants into either the PBN or the VTA and were trained in the discrimination task using either 2.5 or 5.0 µg of intracerebral morphine as the training stimulus. Rats with implants into the VTA did not demonstrate differential responding under either dose of morphine tested. Rats with implants in the PBN, however, quickly learned the task, consuming significantly less saccharin after morphine than after saline injections. The data demonstrate that injections of morphine into the PBN are sufficient to support discrimination learning.

FUNCTIONAL MAGNETIC RESONANCE IMAGING OF NICOTINE EFFECTS ON BRAIN ACTIVATION BY A VISUAL SPATIAL WORKING MEMORY TASK IN HUMANS. E.A. Stein*, A.S. Bloom, J. Pankiewicz, J.-K. Cho, S.A. Fuller, D.C. Osmont, Y. Suchy, and J.R. Zigun. Medical College of Wisconsin and University of Wisconsin+, Milwaukee, WI 53226.

Nicotine facilitates human attention, memory and sensorimotor function. A visual spatial working memory (VSWM) task that utilizes these functions activates several frontal and parietal cortical regions as measured by functional magnetic resonance imaging (fMRI). Since evidence exists for the involvement of forebrain dopamine (DA) systems in VSWM as well as the effects of nicotine on DA systems, we examined the effects of nicotine on task-induced fMRI activation. Single shot echo planar imaging was obtained on a 1.5 Tesla GE Signa scanner using an insertable, balanced torque, 3-axis head gradient coil designed for rapid gradient switching. To obtain images throughout the entire brain volume, a shielded quadrature elliptical endcapped transmit/receive birdcage radio frequency coil was used. Four experienced smokers performed the VSWM task while fMR data were acquired (TR=5 sec; TE=40 msec; 8 mm slice thickness). A trial consisted of 7 cycles of task repetition (30 sec rest, 45 sec task). Nicotine (0.75, 1.5 or 3.0 mg) or saline was injected iv over a 15 sec period after the third task cycle. The most common nicotine effect observed (defined as appearing in 4 contiguous pixels) was an increase in the magnitude of the task-induced activation response in both frontal and parietal regions with doses as low as 0.75 mg. In each case, an increase in activation magnitude was seen within 1 minute of drug (but not saline) administration. The average injection-induced increase in signal was 5.3% after saline, 53.5% after the low (0.75 mg) nicotine dose, and 86.3% after the medium (1.5 mg) nicotine injection. The present data suggest that nicotine enhances regional neuronal activation induced when performing a VSWM task.

IBOGAINE ANTAGONISM OF MORPHINE-INDUCED HYPERACTIVITY: ENHANCEMENT BY PRIOR MORPHINE EXPOSURE AND ROLE OF KAPPA OPIOID RECEPTORS. S.M. Keefner* and S.D. Glick, Dept. of Pharmacology and Toxicology, Albany Medical College, Albany, NY 12208

Ibogaïne, an indole alkaloid, is currently being investigated as a potential anti-addictive therapy. It has been shown to decrease morphine self-administration and to inhibit both morphine-induced locomotor stimulation and morphine-induced dopamine release in the nucleus accumbens and striatum of rats. However, in both rats and humans, the effects of ibogaïne appear to be quite variable; the present study sought to determine if prior morphine history might account for individual differences in sensitivity to ibogaïne. Female Sprague-Dawley rats, pretreated for 2 days with morphine (30 mg/kg, i.p.) before receiving ibogaïne (40 mg/kg, i.p.), showed significantly less locomotor activity in response to morphine (2.5-30 mg/kg, i.p.) than controls pretreated with saline prior to ibogaïne. Thus, prior morphine exposure enhanced ibogaïne antagonism of morphine-induced locomotor activity. To study whether ibogaïne's effects may be related to activation of the kappa opioid receptor, for which ibogaïne has affinity, two kappa agonists were administered using the same treatment parameters. The selective kappa agonists, U50488 (10 mg/kg, i.p.) and U62066 (1 mg/kg, i.p.), when administered in place of ibogaïne, mimicked ibogaïne's effects. Furthermore, in preliminary studies, the selective kappa antagonist nor-binaltorphimine (10 mg/kg, s.c.) appeared to reverse the ibogaïne-induced antagonism of morphine. These results suggest that the long-lasting effects of ibogaïne may be due to persisting levels of ibogaïne and/or an ibogaïne metabolite interacting at kappa opioid receptors to yield anti-addictive effects. AVERSIVE EFFECTS OF THE SYNTHETIC CANNABINOID CP 55,940 IN RATS J.S. McGregor* and C. Issakidis, Dept. Psychology, University of Sydney, NSW, 2006, Australia.

Despite the widespread use of cannabis, questions relating to the addictive potential of this drug are a matter of considerable controversy both scientifically and politically. The recent development of highly selective and potent synthetic cannabinoids, such as CP 55,940, have allowed new avenues of research into cannabinoid effects. The present study investigated the hedonic properties of CP 55,940 in rats across a variety of paradigms. An initial experiment showed that a low dose of CP 55,940 (10 µg/kg) increased locomotor activity, indicating behavioural excitement, but that a higher dose (100 µg/kg) caused a sedative effect. A second experiment using the conditioned place preference paradigm showed that rats developed a powerful aversion to an environment in which they received CP 55,940 (100 µg/kg). A lower dose (10 µg/kg) produced a weaker aversion. In a third experiment using the conditioned taste aversion paradigm it was shown that rats developed a strong aversion to a fluid (saccharin) that was ingested just prior to administration of 100 µg/kg CP 55,940. In a final experiment it was shown that rats under the influence of CP 55,940 (10 or 100 µg/kg) displayed a higher rate of anxiety-related ultrasonic vocalisation in an environment in which they had previously received mild footshock. This suggests that the aversive effects of CP 55,940 summated with the aversive effects of the environment to magnify anxiety. It is concluded that CP 55,940 is aversive to rats, probably due to an anxiogenic effect. The utility of animal models for increasing understanding of human cannabis use is therefore open to question.

MICRODIALYSIS ASSESSMENT OF NUCLEUS ACCUMBENS GLUTAMATE DURING IV HEROIN SELF-ADMINISTRATION K. Bonter*,^{1,2} K. Leeb,^{1,3} D. Pocock,^{1,2} R. A. Wise,^{1,3} Ctr Stud Behav Neurobiol¹ and Depts Chem Biochem² and Psychol,³ Concordia Univ., Montréal, Que, CANADA H3G 1M8

Nucleus accumbens septi (NAS) is identified as a critical structure for the habit-forming actions of opiates, and glutamatergic afferents from the frontal cortex have been suggested to regulate NAS activity. Accordingly, the present study was designed to determine fluctuations in NAS glutamate levels during intravenous heroin self-administration. Rats with NAS dialysis probes were allowed to self-administer heroin. Extracellular fluid from NAS was sampled at 4min intervals by micro-dialysis and glutamate was assayed using HPLC with electrochemical detection of OPA amino acid derivatives. Glutamate concentrations in the dialysate increased during heroin self-administration stabilizing at 200% to 400% above baseline. Glutamate concentrations appeared to increase further during extinction conditions that followed the self-administration period. The glutamate elevation during self-administration coincides with reported elevations in dopamine; the elevation in glutamate during extinction occurs at a time when dopamine levels are falling. Thus behavioral states appear capable of dissociating fluctuations in extracellular levels of the two transmitters, suggesting a more complex glutamate-dopamine interaction than has been recently hypothesized.

502.6

HEROIN SELF-ADMINISTRATION PRODUCES BIOCHEMICAL ADAPTATIONS SIMILAR TO CHRONIC MORPHINE TREATMENT IN BRAIN REWARD REGIONS. A.W. McClenahan, D.W. Self, D. Beliner-Johnson, R.Z. Terwilliger, and E.J. Nestler*, Dept. of Pharmacology and Psychiatry, Yale Univ. Sch. of Med., New Haven, CT 06508

The mesolimbic dopamine system, specifically the ventral tegmental area (VTA) and its projection to target neurons in the nucleus accumbens (NAc), mediates some of the reinforcing effects of drugs of abuse. Previous results from rats forcibly treated with chronic morphine found several biochemical adaptations in the VTA and NAc (see Neuron 11:995, 1993). This experiment validates the previous findings by using the animal model of drug self-administration (SA), which better approximates human drug addiction. In these studies, rats self-administered heroin in limited, daily 6-hr test sessions for three weeks. A yoked-heroin and a yoked-saline control group were used for comparison. The findings show that opiate SA produces similar biochemical adaptations, when compared to animals receiving yoked injections of saline, as produced by chronic, forced opiate treatments. These include an increase in tyrosine hydroxylase (TH) and glial fibrillary acidic protein, and a trend toward a decrease in neurofilaments, in the VTA, and an increase in cAMP-dependent protein kinase activity and a trend toward a decrease in Gi proteins, in the NAc. Interestingly, heroin SA produces one important adaptation in the NAc, a decrease in TH levels, not seen in animals treated chronically with morphine. There were no differences between heroin SA rats and rats receiving yoked heroin injections.

Although the heroin self-administering rats failed to show signs of physical dependence, biochemical adaptations in the mesolimbic dopamine system of these rats suggest that these changes could contribute to the motivational aspects of drug addiction.

502.7

REINSTATEMENT OF HEROIN SELF-ADMINISTRATION BEHAVIOR BY EXPOSURE TO STRESS AFTER PROLONGED EXTINCTION. Y. Shaham*, J. Stewart. Center for Studies in Behavioral Neurobiology, Department of Psychology, Concordia University, Montreal, Quebec, Canada, H3G 1M8.

We have shown previously that non-contingent IV priming injections of heroin, or intracranial injections of morphine into VTA reinstate heroin self-administration behavior in rats following a period of extinction. Naltrexone blocks these effects, and given alone reduces baseline responding. Here we report that first-time exposure to 10 min of intermittent footshock reinstates previously extinguished heroin self-administration behavior.

Male and female rats were trained to self-administer heroin (6.125-50 µg/kg/injection, IV) during four 3-h sessions/day over a 2-week period. The drug-reinforced behavior was extinguished by at least 16 sessions (lever presses resulted in saline infusions). Reinstatement was studied following non-contingent infusions of saline, 50 µg/kg heroin, naltrexone-precipitated opioid withdrawal (5 mg/kg naltrexone, SC, 40 min after 10 mg/kg morphine, SC) and by 10-min of footshock (1 mA; 0.5 sec on, mean off period of 40 sec).

Reinstatement was observed following footshock stress and priming injections of heroin, but not following saline or naltrexone-precipitated withdrawal. Most importantly, footshock stress reinstated self-administration behavior upon first exposure, and again more than one month after the termination of heroin self-administration. These findings suggest that exposure to some stressors can precipitate relapse, possibly by mimicking the neurochemical effects of a heroin priming injection and not by inducing opioid-like withdrawal symptoms.

502.9

THE DEVELOPMENT OF A CONDITIONED PLACE PREFERENCE (CPP) TO MORPHINE. I. EFFECTS OF LESIONS OF VARIOUS CNS SITES. M.C. Olmstead* and K.B.J. Franklin. Department of Psychology, McGill University, Montreal, Quebec, Canada.

The CPP paradigm is used to assess the reinforcing effects of incentive stimuli in that animals spend more time in the presence of cues previously associated with rewarding stimuli than those associated with neutral stimuli. In order to determine the neural substrates mediating the reinforcing effects of morphine, separate groups of male Long-Evans rats received neurotoxic lesions of various CNS sites and were tested for the development of a CPP to morphine (2 mg/kg X 3 pairings). Lesions of the hippocampus, periaqueductal gray, or pedunculopontine nucleus disrupted the CPP. Lesions of the entire ventral striatum reduced the CPP whereas selective lesions of anterior or medial portions were ineffective. Lesions of the dorsal striatum, lateral amygdala, or mesolimbic dopamine system changed the pattern of CPP behaviour but did not reduce the CPP. It appears that the development of a CPP to morphine is a complex phenomenon which depends on interactions between a number of brain structures.

502.11

EFFECT OF IBOGAINE ON MORPHINE AND NALOXONE-INDUCED PLACE CONDITIONING. T.L. Luxton, L.A. Parker* and S. Siegel. Department of Psychology, Wilfrid Laurier University, Waterloo, Ontario and McMaster University, Hamilton, Ontario, Canada.

Ibogaïne has been proposed to serve as an agent to reduce craving for addictive agents. A series of experiments were conducted to determine the effects of ibogaïne (40 mg/kg, ip) on place preference conditioning produced by morphine (5 mg/kg, ip) and on place aversion conditioning produced by naloxone (1-2 mg/kg, ip). Ibogaïne alone was found to be ineffective in producing either a place preference or a place aversion; however, it did interfere with the establishment of a morphine-induced place preference after 1, but not after 4 conditioning trials. These results are contrasted with the effects of ibogaïne on naloxone-induced place aversion conditioning. In addition, the ability of ibogaïne to attenuate the expression of a previously learned morphine-induced place preference was assessed.

502.8

OVARIAN HORMONES DO NOT ALTER SELF-ADMINISTRATION OF HEROIN IN OVARECTOMIZED FEMALE RATS. J. Stewart*, B.C. Woodside and Y. Shaham. Center for Studies in Behavioral Neurobiology, Department of Psychology, Concordia University, Montreal, Quebec, Canada, H3G 1M8.

We studied the effect of ovarian hormones on the initiation and maintenance of heroin self-administration in ovariectomized female rats. In Experiment 1, the effects of 10 µg estradiol benzoate (EB) and 0.5 mg progesterone (P) on the reinforcing efficacy of heroin were studied. Animals were trained to self-administer heroin (50 µg/kg per infusion, IV) on a progressive ratio schedule, 4 sessions per day, 4-h each. Animals were tested with descending doses of heroin (50, 25, and 12.5 µg/kg) in 5-day blocks. Neither EB, given on the third, nor P, given on the fifth day of each block, affected number of heroin infusions taken.

In Experiment 2, we studied the initiation of IV self-administration of heroin on an FR1 schedule using an ascending series of doses (6.125 - 50 µg/kg per infusion). Following ovariectomy, 8 of 16 animals were injected with 10 µg EB on 3 occasions every 3 days before self-administration training and every 3 days throughout training. Twelve 3-h sessions per dose, 4 session per day, were given. No differences in rate of responding between groups were observed at any of the heroin doses; most animals achieved stable responding at the 25 µg/kg dose. Finally, no group differences were found when animals were tested again using a descending series of doses.

These results suggest that circulating ovarian hormones do not affect the sensitivity of female rats to the reinforcing effects of heroin.

502.10

INTRAVENOUS MORPHINE SELF-ADMINISTRATION BY RATS WITH LOW VS. HIGH SACCHARIN PREFERENCES.

B.A. Gosnell*, D.D. Krahn, K.E. Lane and S.M. Bell. Department of Psychiatry, University of Wisconsin-Madison, Madison, WI 53792.

An experiment was performed to determine the relationship between saccharin preference and morphine self-administration. On the basis of voluntary intake of a 0.1% saccharin solution in 1 hr daily sessions, low and high preference groups (n=8/group) of male Sprague-Dawley rats were selected from a larger group. Oral morphine consumption (0.5 mg/ml) was then measured in the selected rats in 1 hr daily sessions. The groups did not differ in either water-deprived or non-deprived conditions. Jugular catheters were then implanted in all rats. Five days after surgery, daily 1 hr sessions in operant chambers began, during which rats were allowed to self-administer morphine sulfate (i.v.) at unit doses beginning at 0.04 mg/kg/injection; over the course of the experiment, the dose was raised to 0.08 and then to 0.16 mg/kg/injection. Fourteen rats completed the study through the end of the sessions at 0.08 mg/kg/injection; 10 completed the entire study. The groups did not differ in the number of infusions obtained at 0.04 mg/kg/injection. Over the course of the 0.08 mg/kg sessions, saccharin-preferring rats began to self-administer significantly more morphine than rats with a low saccharin preference. For example, averaged over sessions 16-20 at this dose, the high saccharin rats obtained 10.5 ± 2.3 infusions per session, whereas the low saccharin rats obtained 4.1 ± 0.8 ($p < 0.05$). Increasing the unit dose from 0.08 to 0.16 mg/kg/injection caused an increase in self-administration in the low saccharin group and a decrease in self-administration in the high saccharin group. The positive relationship between saccharin intake and morphine self-administration may be due to their mediation by a common reward mechanism. Supported by NIDA DA05471 and DA06827.

502.12

TASTE- AND ODOR-SPECIFIC LOCOMOTOR SENSITIZATION USING MORPHINE. R. A. Bevins*, K. Shammugham, & M. T. Bardo. Dept of Psychology, Univ of Kentucky, Lexington, KY 40506.

Context-specific locomotor sensitization occurs when a distinct environment (context) previously paired with morphine elicits an increase in activity relative to a context that was explicitly unpaired. Given that this work has typically used a context conditioned stimulus (CS), it is unclear whether a context CS is necessary for locomotor sensitization, or whether other CS types would work. A context can be viewed as a polymodal stimulus composed of many elements (eg, auditory, olfactory, and tactile). The present work examined the ability of these more unimodal cues (odor and taste) to serve as CSs in a conditioned sensitization paradigm. Adult male Sprague-Dawley rats were used in both the taste and the odor studies. Rats received 8 conditioning trials in which a morphine injection (2 mg/kg, SC) was immediately followed by 15-min exposure to the CS (eg, saccharine taste or banana odor) in a chamber. Using a CS-alone test to assess locomotor sensitization, we found greater activity in morphine-paired rats than in unpaired control rats (see Fig below). Thus, olfactory and gustatory elements of a context are capable of controlling Pavlovian conditioned increases in locomotor activity.

502.13

ORAL DISCRIMINATIVE AND REINFORCING EFFECTS OF ETONITAZENE IN RHESUS MONKEYS. E.D. Pakarinen and J.H. Woods. Dept. of Pharmacology, University of Michigan, Ann Arbor, MI 48109-0626.

To induce drinking of drug, rhesus monkeys were provided with prandial etonitazene (ETZ, 2.5 ug/ml) drinking opportunities (e.g., Carroll and Meisch, 1978, *Psychopharmacol.*, 59: 225-229). In the Carroll and Meisch study, it was reported that all subjects orally self-administered more ETZ relative to water. The purposes of the present study were to replicate the oral reinforcing effect of ETZ and to extend the observations with ETZ (0.019 - 5 ug/ml) to a situation in which ETZ was provided concurrently with water in rhesus monkeys. Fluid deliveries were provided following contact responses on solenoid-operated drinking spouts. After the induction procedure, less than the majority of a set of monkeys reliably self-administered more ETZ than water when presented concurrently. The intake of ETZ increased in a concentration-related manner across monkeys. The oral discriminative effects of ETZ were also studied in monkeys trained to discriminate fentanyl (0.0032 mg/kg, s.c.) from vehicle. As expected, ETZ generalized in the fentanyl-trained monkeys, however, ETZ had a slow onset of discriminative effect when delivered orally. ETZ may not be as efficacious as an oral reinforcer among rhesus monkeys as originally reported; large individual differences across monkeys were evident. Significant individual differences have not been noted in studies of intravenous etonitazene reinforcement in primates. (Supported by USPHS Grants DA 00254, DA 05325, DA 07268, and DA 08568).

502.15

EFFECTS OF ADENOSINE AGONISTS AND ANTAGONISTS ON MORPHINE WITHDRAWAL SYNDROME. G.B. Kaplan*, M.T. Sears. Dept. of Psychiatry and Human Behavior, Brown University and Veterans Affairs Medical Center, Providence, RI 02908.

Central opiate actions depend, in part, on the involvement of adenosine. We examined the effects of selective adenosine agonists and antagonists in opiate withdrawal. Male CD-1 mice were implanted with morphine (75 mg) or placebo pellets and a withdrawal syndrome was precipitated by injecting opiate antagonist, naloxone (5 mg/kg, i.p.) 72 hours later. Animals (N=3-8 per dose) were injected i.p. with either vehicle, A₁ agonist R-N⁶-(2-phenylisopropyl)adenosine (0.05 mg/kg), A_{2a} agonist, CGS 21680 (0.05 mg/kg) or A₁ antagonist, 1,3-dipropyl-8-cyclopentylxanthine (1 mg/kg) or A₂ antagonist, 3,7-dimethyl-1-propargylxanthine (1 mg/kg) and placed in a plexiglass cylinder. The following behaviors were counted over a 20 minute period: jumps, wet dog shakes, weight loss and diarrhea while teeth chattering, forepaw treads and tremors were checked for their presence during each 1 min interval. In naloxone-precipitated withdrawal groups, A₁ agonist R-PIA decreased jumps and diarrhea by 49 and 58%, respectively, while A₂ agonist decreased jumps by 68% but increased wet dog shakes by 81%. A₁ antagonist increased jumps and tremors by 67 and 30%, respectively, and A₂ antagonist increased wet dog shakes by 68%. In conclusion, adenosine A₁ agonist inhibited, and both adenosine antagonists enhanced withdrawal behaviors, providing support for the role of adenosine receptors in opiate dependence. Follow-up studies will examine acute and chronic agonist and antagonist effects on opiate withdrawal at other doses.

502.14

THE DEVELOPMENT OF A CONDITIONED PLACE PREFERENCE TO MORPHINE. II. EFFECTS OF MICROINJECTIONS INTO VARIOUS CNS SITES. K.B.J. Franklin* and M.C. Olmstead. Dept. Psychology, McGill University, Montreal, Quebec, Canada.

In the CPP paradigm, animals will approach and maintain contact with an environment previously paired with morphine administration. The present study investigated the neural sites where morphine may produce its reinforcing effect. Bilateral infusions of morphine (1 ug in 0.5 ul over 1 min X 2 pairings) into the lateral ventricles, periaqueductal gray (PAG), or ventral tegmental area (VTA) produced a CPP. Injections into the dorsal striatum, frontal cortex, hippocampus, lateral amygdala, lateral hypothalamus, pedunculopontine nucleus, posterior hypothalamus, ventral pallidum, or ventral striatum did not produce a CPP. Injections 1 mm dorsal to the PAG or VTA were also ineffective. Naloxone methiodide injections (5 nmole in 0.5 ul over 1 min) into the PAG or VTA blocked the CPP induced by systemic morphine (4 mg/kg X 1 pairing). Activation of either PAG or VTA opioid receptors is sufficient to produce morphine reinforcement but the effect may involve an interaction between the two sites.

DRUGS OF ABUSE: BEHAVIOR II

503.1

MK-801 Non-differentially Attenuates Both Associative and Non-Associative Morphine Tolerance

J.E. Grisel*¹, S.F. Maier² & L.R. Watkins²

¹Department of Veterans Affairs Medical Center, Oregon Health Sciences University, Portland OR 97201, ²Department of Psychology, University of Colorado, Boulder, CO 80309

Morphine tolerance is mediated by both associative and non-associative factors. Animals tested in a context which has been repeatedly paired with drug are more tolerant in that context than in others, indicating situationally-specific or associative tolerance. Non-associative tolerance simply results from physiological changes following drug exposure, and does not depend upon contextual cues. Previous experiments have shown that spinal neurotensin mediates associative morphine tolerance. The present experiments examined the role of NMDA receptors in both situationally-specific and non-situationally specific morphine tolerance. Two groups of rats were administered morphine (5mg/kg) once a day for 4 consecutive days and then tested for morphine analgesia (tailflick): one group was tested in the same context in which they had received all prior morphine and the second group was tested in an equally familiar context which had been associated with prior saline injections. A third group of drug naive but similarly handled rats were also tested for morphine analgesia. Before testing, subjects were intrathecally injected with either MK-801 (2.5, 5.0 or 10 nmol in 5 µl) or vehicle. Both 2.5 and 5 nmol of MK-801 attenuate morphine tolerance. This reversal of tolerance occurred independently of the rats' prior experience in the testing context indicating that unlike neurotensin, NMDA receptors in the spinal cord play a general role in the expression of morphine analgesic tolerance.

503.2

UNIQUE PATTERNS OF MORPHINE AND NICOTINE EFFECTS ON EVOKED RESPONSES IN THE NUCLEUS ACCUMBENS (NAS). C. Eyl and R. Hakan* Dept. of Psychology, Univ. of North Carolina at Wilmington, Wilmington, N.C. 28403

Behavioral studies have indicated that the nucleus accumbens septi (NAS) is critically involved in drug reward. The purpose of studies in our lab is to elucidate the neuropharmacological nature of NAS related brain circuits and to determine their role in the mediation of psychoactive drug effects. The present study examined the effects of morphine and nicotine on the amygdala-NAS afferent pathway. Electrical stimulation of the amygdala was used to evoke single-unit responses in the NAS of anesthetized rats. Baseline parameters of extracellularly recorded evoked responses were established and then the effects of systemic morphine and nicotine were examined. Both morphine and nicotine consistently inhibited these evoked responses (15/15 and 7/8 respectively). Also, morphine inhibited spontaneously active single-units in the NAS while nicotine did not. These results are meaningful when compared to the previously established effects of morphine and nicotine on NAS unit responses evoked by fimbria and ventral pallidum (VP) stimulation (Hakan and Eyl, 1993; Hakan et al., 1994). Fimbria evoked responses are inhibited by nicotine but not by morphine whereas both morphine and nicotine have mixed effects on NAS unit responses evoked by electrical stimulation of the VP. Thus, the pattern of effects of these drugs on different NAS circuits are unique. Further analysis of drug effects on NAS circuitry should help explain both the common and distinct reinforcing properties of different psychoactive compounds.

503.3

EFFECT OF NITRIC OXIDE SYNTHASE INHIBITION ON MORPHINE TOLERANCE, PHYSICAL DEPENDENCE AND ABSTINENCE SYNDROME IN THE RAT. George A. Matwyszyn, N.P. Plotnikoff* and Hemendra N. Bhargava, Dept. Pharmacetics and Pharmacodynamics, Univ. Ill. at Chicago, IL 60612.

The effects of L-N^G-monomethyl-arginine (NMMA) on the development of tolerance to and dependence on morphine as well as on the naltrexone-induced abstinence symptoms were determined. Male Sprague-Dawley rats were made tolerant to and dependent on morphine by s.c. implantation of 4 morphine pellets during a 3-day period with 2 pellets on am of day 1 and 2 pellets on pm of day 2. NMMA (2, 4 or 8 mg/kg, s.c.) was administered twice a day for 3 days. The pellets were removed on day 4 and tolerance and dependence were assessed 6 hr after the pellet removal. The development of tolerance to the analgesic but not to the hyperthermic action of morphine was inhibited by 4 and 8 mg/kg doses of NMMA. Physical dependence development was also inhibited as evidenced by the decrease in jumping behavior induced by naltrexone (5 mg/kg, i.p.) but the other symptoms were not affected. The doses of NMMA which inhibited the tolerance and dependence development were unable to inhibit the naltrexone-induced withdrawal symptoms in morphine-dependent rats. It is possible that much higher doses of NMMA are required to inhibit antagonist-induced withdrawal in morphine-dependent rats (Supported by a Research Scientist Development Award K02-DA-00130 from the National Institute on Drug Abuse).

ETHOANALYSIS OF THE OPIATE WITHDRAWAL SYNDROME IN RATS E. F. Espejo¹, L. Stinus^{2*} and M. Cador², (1) Esc. Ciencias de la Salud, Univ. de Sevilla, Sevilla, Spain, (2) INSERM U.259, Univ. de Bordeaux II, Bordeaux, France

Physical signs during the rat's opiate withdrawal syndrome are usually evaluated by the Gellert-Holtzman score (J. Pharmacol. Exp. Ther. 205: 536-546, 1978). However, this score was not elaborated according to a modern behavioral criterion, and it appears to be somewhat arbitrary. The objectives of this study were thus: i) to analyse the overall rat's behavior during the opiate withdrawal syndrome, and ii) to evaluate the validity of the classic score. Rats were implanted with morphine pellets (75 mg x 2, s.c.), and assigned to six groups (n = 10), receiving naloxone (0, 0.01, 0.05, 0.1, 0.5, 1 mg/kg i.p.) to precipitate the withdrawal syndrome. Behavior was videotaped and analysed by an ethogram and ethological techniques. Score value as well as frequency, duration and latency of each pattern were quantified. A cluster analysis allowed to discern the behavior structure. Ethogram was composed of: sniff, walk-sniff, rearing, leaning posture, wet dog shake, autogroom, face-washing, genital-groom, abnormal posture, swallowing, intermittent walking, jumping, teeth-chattering, freezing, elongation, yawn, and lying. Number of ejaculations, defecations and micturitions, as well as other physical signs (diarrhea, irritability, weight loss, etc.) were also evaluated. Results revealed that abnormal posture and intermittent walking, core patterns, changed in a dose-related fashion. Wet dog shakes and jumping, main behavioral signs included in the classic score, were only enhanced in a dose-related manner with intermediate doses. Significant changes in weight loss and irritability were found to be dose-dependent. Score values were gradually enhanced after naloxone injection, except for the highest dose (1 mg/kg). In conclusion: i) the Gellert-Holtzman score is useful, but it appears not to be very accurate for high naloxone doses, and ii) abnormal reactions, weight loss and irritability are the best indicators of the opiate withdrawal syndrome "level", and they might be the basis of a simpler "ethological" score.

503.7

SUBCUTANEOUS INJECTION OF AN ANALOG OF NEUROPEPTIDE FF PREVENTS NALOXONE-PRECIPIATED MORPHINE ABSTINENCE SYNDROME.

J.R. Lake^{*}, D.A. Smith, J.A. Jgnes, J. Morel, A.E. Claunch, P.A. Stevens, K.K. Ho¹, J. Liu¹, K. Burgess¹ and D.H. Mallin Univ. of Houston-Clear Lake, Houston, TX 77058, and ¹Texas A&M Univ., Dept. of Chemistry, College Station, TX 77843.

Neuropeptide FF (NPFF) has antioptive activity and may play a role in opiate dependence and abstinence syndrome. Previously, the C-terminal tetrapeptide of NPFF was danylated to increase lipophilicity and penetration of the blood-brain barrier. This compound, danyl-PQRFamide, precipitated morphine abstinence following s.c. administration. In the present study, the C-terminal -Phe was removed from danyl-PQRFamide in an effort to convert it to a NPFF-antagonist. In Expt. 1, 12 opiate-naive rats were injected in the 3rd ventricle with either 1 µg danyl-PQRFamide (n=6) or 20% ETOH:water vehicle alone (n=6) 6 mins prior to receiving 10 µg NPFF. Rats pretreated with danyl-PQRFamide had a significant, p<.001, 67% decrease in morphine abstinence-like signs compared with rats pretreated with vehicle alone. In Expt. 2, 12 morphine-dependent rats were injected subcutaneously with 13 mg/kg danyl-PQRFamide (n=6) or 20% ETOH:water vehicle alone (n=6) 5.5 mins prior to receiving 0.125 mg/kg naloxone. Rats pretreated with danyl-PQRFamide exhibited a significant, p<.001, 76% reduction in overall abstinence signs as compared with rats receiving vehicle alone. NEUROCHEMICAL SUBSTRATES IN THE EXPRESSION OF THE OPIATE WITHDRAWAL SYNDROME: ROLE OF SPINAL NITRIC OXIDE. J.J. Buccafusco, A.V. Terry*, Dept. Pharmacology and Toxicology Medical College of Georgia and Dept. VA Med. Ctr., Augusta, GA 30912.

In the morphine-dependent rat, the expression of autonomic symptoms of naloxone-precipitated withdrawal are mediated to a large extent by an ascending spinal cholinergic muscarinic pathway. The purpose of this study was to determine which neurotransmitter systems participated in the efferent, bulbo-spinal component of this pathway. Our recent studies in non-dependent rats indicated that the pressor response to intrathecal (I.T.) injection of the muscarinic agonist carbachol was mediated by a spinal NMDA-glutamatergic pathway linked to a NO generating system. Rats were made dependent on morphine by a continuous yoked i.a. infusion of increasing doses over 5 days. Withdrawal was precipitated by the i.a. injection of 0.5 mg/kg of naloxone. Mean arterial pressure (MAP), heart rate and several behavioral symptoms of withdrawal were measured over a 60 min observation period. In control dependent rats, i.a. injection of naloxone produced a rapid increase in MAP up to about 30 mmHg over the first 5 min after injection; thereafter, MAP slowly decreased to pre-withdrawal levels. Signs of opiate withdrawal, including body shakes, escape behavior, etc. accompanied the MAP changes. I.T. pretreatment with 100 or 200 nmol of the NMDA antagonist MK801 produced a dose-dependent inhibition of the opiate withdrawal response up to about 60%. I.T. injection of 100 or 200 nmol of the NO synthase inhibitor, L-NAME also significantly inhibited the expression of the withdrawal response. This inhibition was reversed in the presence of 100 nmol L-arginine. Also, L-NAME demonstrated essentially no affinity for spinal muscarinic receptors as assessed using a competition assay with [³H]methylscopolamine. These results are consistent with a role for an NMDA-NO system in the expression of spinal opiate withdrawal. Supported by the Div. Res Svc. Dept. Vet. Affairs.

OPIOID RECEPTOR SUBTYPES MODULATE PONTINE EXCITATORY AMINO ACID (EAA) LEVELS DIFFERENTLY IN BUTORPHANOL AND MORPHINE DEPENDENCE. Yangzheng Feng, Tianshu Zhang, Robin W. Rockhold* and Ing K. Ho, Dept. of Pharmacol. & Toxicol., Univ. of Miss. Med. Ctr., Jackson, MS 39216-4505

To clarify the involvement of different opioid receptor subtypes in regulation of brain glutamate (Glu)/aspartate (Asp) levels during opiate withdrawal, extracellular fluid (ECF) levels of Glu/Asp were examined with *in vivo* microdialysis of the locus coeruleus (LC) following precipitation of withdrawal using antagonists selective for µ (CTOP; D-Phe-Cys-Tyr-D-Trp-Orn-Thr-Pen-Thr-NH₂), κ (Nor-BNI; nor-binaltorphimine) or δ (NTI, naltrindole) opioid receptors in conscious morphine or butorphanol dependent SD rats. Dependence was induced by intracerebroventricular (i.c.v.) infusion of morphine (26 nmol/1 µl/hr), butorphanol (26 nmol/1 µl/hr), or saline (1 µl/hr) for 3 days. Microdialysis probes (2 mm tip) were inserted into the LC 24 hr before precipitation of withdrawal by i.c.v. injection of 48 nmol/5 µl of CTOP, Nor-BNI, or NTI. Behavioral evidence of withdrawal was detected following CTOP challenge in morphine and butorphanol infused rats, and following Nor-BNI challenge in butorphanol infused rats, but not in other groups. Levels of Glu in the LC increased to 409% and 258%, respectively, above basal values in the first 15 min sample following CTOP injection in morphine (n=5) and butorphanol dependent (n=5) rats, while Asp increased to 258% (n=5) and 183% (n=5) of basal levels in the same groups. Withdrawal precipitated by Nor-BNI produced significant increases in LC levels of Glu (200% of basal; n=6) and Asp (132% of basal; n=6) only in butorphanol dependent rats. No changes in EAA levels were noted following NTI injection, in any group. Opioid withdrawal is associated with increased levels of EAAs, within the LC. These increases are mediated primarily through µ opioid receptors in morphine dependent rats. In contrast, both κ and δ receptor subtypes regulate EAA levels during withdrawal from butorphanol. (Supported by DA 05828).

503.8

INHIBITION OF MORPHINE TOLERANCE AND DEPENDENCE BY DIAZEPAM AND ITS RELATION TO CYCLIC AMP LEVELS IN THE RAT BRAIN. M.-J. Shew, P. Sribanditmongkol, D. Santosa and G.A. Tejwani*, Dept. of Pharmacology, College of Medicine, Ohio State University, Columbus, OH 43210

We have recently observed that met-enkephalin may be involved in the inhibition of morphine tolerance and dependence by diazepam (Sribanditmongkol et al. *Brain Res.* in press). We now propose that cyclic AMP may also play an important role in this phenomenon. Male Sprague-Dawley rats were made tolerant-dependent by s.c. implantation of six morphine pellets. Diazepam (0.25 mg/kg body wt.) was injected i.p. in some rats. Control rats were implanted with placebo pellets and injected daily with saline or diazepam. Morphine tolerant rats were sacrificed 1 h. after injections. Abstinence was induced by injecting s.c. naloxone (10 mg/kg) and withdrawal effects were observed for 30 min. There was no change in cyclic AMP levels in hypothalamus, striatum or cortex of morphine-tolerant animals compared to rats given placebo. Diazepam had no effect on cyclic AMP levels in these animals. Morphine abstinent rats showed a significant increase in cyclic AMP levels in striatum (71%), cortex (126%) compared to placebo treated rats. This increase in cyclic AMP levels was attenuated in morphine abstinent rats injected with diazepam. It is concluded that cyclic AMP may be involved in the inhibition of morphine dependence by diazepam.

CENTRAL ADMINISTRATION OF NITRIC OXIDE SYNTHASE INHIBITOR ATTENUATES NALTREXONE-INDUCED WITHDRAWAL IN MORPHINE-DEPENDENT MICE. Sanjay N. Thorat* and Hemendra N. Bhargava, Dept. Pharmacutics and Pharmacodynamics, Univ. Ill. at Chicago, Chicago, IL 60612.

The effects of N^G-monomethyl-L-arginine (L-NMMA) an inhibitor of nitric oxide synthase (NOS) on naltrexone-induced abstinence symptoms in morphine-dependent mice were determined. Male Swiss-Webster mice were rendered dependent on morphine by subcutaneous implantation of a morphine pellet for 3 days. Mice which served as controls were implanted with placebo pellets. Six h after pellet removal, mice were injected intracerebroventricularly (i.c.v.) with either vehicle or L-NMMA (0.1, 1.0 and 10 µg/mouse). Five minutes later, the animals were injected with 50 µg/kg, s.c. of naltrexone and the intensity of withdrawal symptoms was determined. Naltrexone-induced stereotyped jumping response was used as an index. Mice were put individually on a platform following the naltrexone injection and the number of mice jumping off the platform or the total number of jumps within a 15-min observation period were noted. I.c.v. administration of L-NMMA (0.1, 1.0 and 10 µg/mouse) 5 min prior to the injection of naltrexone attenuated the stereotyped jumping response in a dose-dependent manner. These results confirm our earlier report (Brain Res., 642: 153-159, 1994) and strongly suggest a role for CNS nitric oxide in opioid withdrawal phenomenon. In addition, these studies suggest that NOS inhibitors may be clinically beneficial in managing the symptoms of morphine withdrawal (Supported by a Research Scientist Development Award K02-DA-00130 from the National Institute on Drug Abuse).

ABSTINENCE PRECIPITATED BY NALOXONE FOLLOWING A SINGLE DOSE OF MORPHINE: POTENTIATION FOLLOWING A SECOND EXPOSURE. C.J. Heyser*, G.F. Koob, and G. Schulteis. Dept of Neuropharmacology, The Scripps Research Institute, La Jolla, CA 92037.

Recent studies in humans with no prior history of opiate abuse reported naloxone-precipitated withdrawal signs following a single exposure to morphine, and this effect was markedly enhanced following a second morphine exposure (Azorlosa et al., *Psychopharmacology*, 114:71, 1994). In a recent report using an established animal model of this acute dependence-like phenomenon, the response disruptive effects of naltrexone on operant responding in rats were enhanced 4 hrs after a single injection of morphine, with a further potentiation of this effect following weekly exposures to morphine and naltrexone for 2 months (Adams & Holtzman, *J Pharmacol Exp Ther*, 253:483, 1990). Using a similar operant measure, the present study sought to determine if this increase in sensitivity to an opiate antagonist could be observed following only 2 morphine exposures, as was seen with humans. Rats were trained to lever press for food on an FR-15 schedule of reinforcement. Rats were pretreated with morphine (2, 5, or 10 mg/kg s.c.) followed 4 hours later by an injection of naloxone (0 - 3.0 mg/kg s.c.). Prior morphine administration dose-dependently increased naloxone's response disruptive effects relative to morphine-naïve baseline, and this effect was markedly potentiated following a second morphine/naloxone exposure 7 days later. The current results confirm previous reports in humans and rats that withdrawal-like signs may be elicited following acute exposure to opiates, and demonstrate a potentiation of this effect with a second exposure. These findings suggest that the development of dependence on opiates as defined by the manifestation of precipitated withdrawal is a progressive phenomenon that may begin with a single dosing. Clonidine Antagonizes The Rewarding Effects Of Morphine Only In Opiate Withdrawn Rats As Well As The Aversive Effects Of Opiate Withdrawal Itself. K. Nader* and D. van der Kooy, Neurobiology Research Group, Dept. of Anatomy, Univ. of Toronto, Toronto, Ontario, M5S 1A8.

Lesions of the brainstem tegmental pedunculopontine nucleus block morphine's rewarding effects only in drug naïve animals. Conversely, dopamine antagonists block the rewarding effects of morphine only in opiate deprived rats, as well as the aversive effects of morphine withdrawal itself. As clonidine, an α_2 -noradrenergic receptor agonist, has been reported to antagonize the somatic signs of opiate withdrawal, we asked if clonidine would block the motivational effects of opiate withdrawal as well as respect the boundary between nondeprived and deprived motivational states. In a place conditioning paradigm, clonidine (0.05 mg/kg ip) blocked the rewarding effects of morphine in opiate withdrawn rats (as well as the aversive properties of withdrawal itself), but did not affect morphine place preferences (2 and 20 mg/kg) in previously drug naïve rats. These results suggest that the motivational system activated in opiate deprived animals includes dopaminergic and noradrenergic components that are in series with each other. Furthermore, clonidine blocked the acquisition of morphine (15 mg/kg), but not LiCl (15 mg/kg), conditioned taste aversions. Given that dopamine antagonists also block morphine, but not LiCl, conditioned taste aversions, we suggest that the aversive effects of both opiate withdrawal and morphine conditioned taste aversions are mediated by the same neurobiological substrates.

503.10

PRECIPITATED MORPHINE WITHDRAWAL FROM THE NEONATE THROUGH THE ADOLESCENT RAT. K. Jones* and G. A. Barr. Dept. of Psychology, Hunter College, NY, NY 10021 and New York State Psychiatric Institute, 722 W. 168th Street, NY, NY 10032.

There are few reports on the morphine withdrawal syndrome in the developing animal. In this study, we examine the behavioral effects of precipitated withdrawal in morphine dependent 7, 14, 21, and 42 day old rats. On the first treatment day (which differs for each age group), the litter was removed from the dam (except for postweaning rats which were housed separately) and individual rats were injected with morphine sulfate (10 mg/kg, i.p., b.i.d., 7 day-old pups also received a dose of 3 mg/kg, i.p.) for 6.5 days. Controls included saline injected groups. The last injection was on the morning of the 7th day. For preweaning rats, two hours after the last morphine treatment a single pup was injected with one of several doses of naltrexone (0, 0.3, 1.0, 3.0, 10.0, mg/kg) and observed in a blind manner with the remainder of the litter for a total of 20 minutes. Ongoing behaviors were recorded every 15 seconds. When the observation period ended, the pup was anesthetized and placed back into the observation chamber with the remainder of the litter. Postweaning rats were tested individually on fresh bedding in the same manner as were preweaning pups. Naltrexone injected pups that had been chronically treated with morphine displayed greatly increased specific behaviors and were activated. The results also show that morphine abstinent animals demonstrate withdrawal behaviors that were appropriate to the age group examined. For example, morphine abstinent 7 day-old pups show increased head movements, rolling, wall climbing, and paw movements. Morphine treated 42 day-old animals displayed the classic adult-like behaviors. These results clearly show that a morphine withdrawal-like syndrome can be described in the very young rat and that this syndrome is reflective of the specific behavioral repertoire appropriate to the age of the animal. CLOCCINAMOX STUDIES IN MORPHINE-TOLERANT AND NONTOLERANT RATS TRAINED TO DISCRIMINATE MORPHINE. E.A. Walker*, T.M. Richardson, Y. Wu and A.M. Young. Dept. of Psychology, Wayne State Univ., Detroit, MI 48202.

The effects of irreversible opioid antagonist clocinnamox (C-CAM) on morphine (MS) and fentanyl (FT) were compared in rats before and after repeated injections of MS to determine the role of agonist efficacy in tolerance. Male, Sprague-Dawley rats (n=20) were trained to discriminate 3.2 mg/kg MS from saline under a FR 15 schedule of food reinforcement. Cumulative doses of MS (0.32-10 mg/kg) or FT (0.0032-0.056 mg/kg) produced MS-appropriate responding and decreased response rates. In nontolerant rats, 10 mg/kg C-CAM decreased MS potency by 7-fold, but failed to significantly alter FT potency to produce MS-like stimulus effects. Repeated treatment with 20 mg/kg/day MS for 7-14 days decreased MS and FT potency to produce MS-like stimulus effects by approximately 4-fold. In these MS-tolerant rats, 10 mg/kg C-CAM further decreased MS and FT potency to produce MS-like stimulus effects by an additional 8-fold. No withdrawal signs were observed after C-CAM administration. Quantitative analysis of these data suggest that chronic opioid treatment may increase the apparent efficacy required for an agonist to exert MS-like discriminative stimulus effects. (Supported by DA03796 and KO2 DA00132).

SHORT-TERM TOLERANCE DEVELOPS BEFORE LONG-TERM TOLERANCE IN RATS. Heather L. Burton and Catherine P. Cramer. Dept. of Psychology, Dartmouth College, Hanover, NH 03755.

The development of tolerance to morphine analgesia was investigated in three separate experiments with the purpose of comparing "short-term" and "long-term" mechanisms. "Short-term" tolerance occurs with closely spaced injections of high doses, whereas, "long-term" tolerance is characterized by low to moderate doses at widely-spaced intervals (Tiffany & Baker, 1985).

In the first two experiments Long-Evans hooded rats received i.p. injections beginning on Day 1 and continuing through Day 6. Twenty minutes following the injection, pups were tested for latency to retract a hindpaw from a 52°C hotplate. On Day 7 the litters were each divided into 6 test conditions. In four of the conditions pups received either 0, 1.0, 3.0, or 10.0 mg/kg morphine and were tested for analgesia 20 min. following injection. The two other conditions were 10 mg/kg naloxone and a saline control. These groups were then tested for hyperalgesia, weight changes (1 and 4 hours postinjection) and locomotor behavior.

In Experiment 1, pups received 0, 1.0, 2.0, 5.0 or 10.0 mg/kg of morphine sulfate once a day on Days 1-6. Experiment 2 followed the same format, with the exception that dosages were 0, 0.6, 3.0, 15.0 mg/kg, twice daily, 8 hours apart. In Experiment 3, the pups also received two daily injections of either 0, 0.6, 3.0, or 15.0 mg/kg of morphine but were tested on Day 3.

In Experiment 1, the results of Fanselow & Cramer (1988) were confirmed. Under long-term parameters tolerance was not observed at Day 7. The results of Experiment 2 show shifts in the dose-response curve at Day 7 indicative of tolerance. Withdrawal was not observed in either of the first two experiments. In Experiment 3, a shift in the dose-response curve was observed on Day 3 and withdrawal was indicated by both hyperalgesia and behavioral effects.

In sum, neonatal rats seem capable of short-term, but not long-term, tolerance during the first week, perhaps due to the nonassociative properties of the short-term paradigm.

503.15

MORPHINE WITHDRAWAL IMPAIRS ACQUISITION OF A MORRIS WATER MAZE TASK: POTENTIAL INVOLVEMENT OF PROCEDURAL MEMORY. K.D. Opello¹, T.J. Walsh¹, K. Grasing², S. Bailey², S. Schlusman². ¹Rutgers University, New Brunswick, NJ 08903; ²UMDNJ, Piscataway, NJ, 08854.

Behavioral and neurochemical changes in rats during early and longterm morphine withdrawal were investigated. Experimental subjects (M) were implanted with osmotic pumps (8.75 mg/240 µl/day over 7 days). Controls (C) received sham implants of similar size and weight. One or 21 days following pump removal, subjects were tested in for 8 days in a Morris water maze (MWM) task. Rats were sacrificed and high affinity choline transport was assessed in the hippocampus (HPC) and striatum (STR). M subjects exhibited a significant decrease in bodyweight during withdrawal that recovered by 21 days after pump removal. M subjects trained during early withdrawal exhibited significantly longer escape latencies due to a possible failure of procedural memory. However, during sequential probe trials these subjects exhibited a significant preference for the target area and accurate search strategies suggesting intact declarative memory. Nine days after removal of the osmotic pumps, HAcHT in M subjects was elevated in the STR but not in the HPC. M rats trained during longterm withdrawal exhibited no deficits in any measure of MWM performance. HAcHT in these rats was comparable to C levels in both the HPC and STR. Early morphine withdrawal was accompanied by increased striatal HAcHT and impaired MWM acquisition.

503.17

TOLERANCE AND CROSS-TOLERANCE TO CANNABINOID LIGANDS AFTER CHRONIC ADMINISTRATION OF ANANDAMIDES. E. Fridé^{*} and B. Mechoulam. Dept. of Natural Products, Hebrew University of Jerusalem, Israel

The development of tolerance to cannabinoid receptor ligands has been well established. However, it is not known whether repeated injections of the recently discovered "anandamides", a family of endogenous cannabinoid ligands, also induce tolerance to subsequent administration of anandamides or cannabinoid drugs. Ten daily injections (*i.p.*) of anandamide (20:4, n-6 [ANA] or 20:6, n-6, 20 mg/kg) were administered to adult female C57/BL mice. Twenty four h after the last injection, animals were challenged with 20 mg/kg of ANA or Δ^9 -tetrahydrocannabinol (THC) and tested for a tetrad of responses, typically seen after administration of cannabinoid drugs.

After chronic injection of the anandamides, full tolerance to ANA was seen for catalepsy in the "ring test", while partial but significant tolerance was seen in the open field test for motor activity, for hypothermia and for analgesia on a hot plate. Under these conditions, cross-tolerance was also displayed to a challenge dose (10 mg/kg) of Δ^9 -THC. Full responsiveness to ANA was restored 1 week after cessation of the chronic injections. Ten daily injections of a lower dose (1 mg/kg) of ANA did not induce tolerance. In contrast, 10 daily injections of a very low dose (0.001 mg/kg) of ANA, which has been shown to attenuate the response to Δ^9 -THC (Fridé et al., *submitted*), induced a slight increase in the response to ANA for some parameters.

These results indicate that repeated administration of anandamides induces tolerance to cannabinoid receptor ligands. Further, the tendency for increased sensitivity to ANA after chronic administration of a very low dose of ANA, support our previous suggestion that a Gs protein mediated signalling pathway may be involved in the receptor activation by the anandamides (Fridé et al., *submitted*).

ELEVATIONS AND PHASIC FLUCTUATIONS IN NUCLEUS ACCUMBENS DOPAMINE (DA) DURING IV HEROIN SELF-ADMINISTRATION. D. Pocock^{*}, K. Leeb and R. A. Wise. Ctr Stud Behav Neurobiol, Concordia Univ., Montréal, PQ, Canada H3G 1M8

Fluctuations in extracellular nucleus accumbens DA and DOPAC levels were monitored in 4-min microdialysis samples from rats engaged in IV heroin self-administration. DA levels were elevated to 200-400% of baseline during self-administration, fluctuating phasically between responses. Each injection caused a short-latency increase in DA levels; a subsequent decrease preceded the next lever-press. Drug requests (lever-presses) normally occurred well before DA levels fell to near-normal levels. DOPAC levels increased in the first minutes and remained elevated through the period of drug availability, showing no significant fluctuations that were time-locked to the response cycle. These observations confirm that self-administered IV doses of heroin are sufficient to activate the mesolimbic DA system; independent evidence implicates ventral tegmental mu and delta receptors in the mechanisms of this opiate action. The patterns of elevation and phasic fluctuation were similar to those seen in cocaine and amphetamine self-administration; this is consistent with the suggestion of a common mechanism for the habit-forming actions of these otherwise disparate agents. These and other microdialysis data taken during self-administration studies remain difficult to reconcile with earlier interpretations of *in vivo* voltammetry data.

503.16

EFFECT OF MORPHINE TOLERANCE AND ABSTINENCE ON NITRIC OXIDE SYNTHASE ACTIVITY IN BRAIN REGIONS AND SPINAL CORD OF THE MOUSE. Marc J. Barja and Hemendra N. Bhargava^{*}, Dept. Pharmaceutics and Pharmacodynamics, Univ. Ill. at Chicago, Chicago, IL 60612.

Male Swiss Webster mice were rendered tolerant to and dependent on morphine by subcutaneous implantation of a pellet containing 75 mg of morphine base, for 3 days. Nitric oxide synthase (NOS) activity was determined in the brain regions (cortex, striatum, pons-medulla and hypothalamus) and spinal cord of morphine tolerant and abstinent mice. NOS activity was measured by the conversion of [³H]arginine to [³H]citrulline. In tolerant mice, the pellets were left intact, whereas in abstinent mice the pellets were removed 6-8 hr prior to sacrificing. NOS activity was found to be significantly increased (16%) in cortex of morphine-tolerant mice, but in striatum, hypothalamus, pons-medulla and spinal cord it was unchanged. In morphine-abstinent mice, the activity of NOS was not altered in spinal cord, hypothalamus, pons-medulla cortex and spinal cord but was increased by 32% in the striatum. *In vitro*, morphine did not modify the NOS activity. It is concluded morphine tolerance and abstinence increases the activity of NOS in certain brain regions (Supported by a Research Scientist Development Award K02-DA-00130 from the National Institute on Drug Abuse).

DIPOLE SOURCE LOCALIZATION OF THE P300 DURING OPIATE/COCAINE WITHDRAWAL AND BUPRENORPHINE TREATMENT IN HEROIN AND COCAINE ABUSERS.

E. M. Kouri^{*}, S. E. Lukas and J. H. Mendelson. Clinical Neuropsychopharmacology Laboratory, Alcohol and Drug Abuse Research Center, McLean Hospital, Belmont, MA 02178.

The present study was conducted to determine the utility of using novel dipole localization algorithms to identify the origin of the auditory P300 ERP during a cycle of withdrawal from opiate/cocaine use and buprenorphine or placebo treatment. Fifteen male volunteers between the ages of 25-40 who met DSM-III-R criteria for concurrent opiate and cocaine dependence provided informed consent to participate in this study. Subjects were admitted to an inpatient treatment unit and were tested before, after 12 days of detoxification and then on the 15th day of either buprenorphine (12 mg/day, s.l.) or placebo treatment. P300 ERPs were elicited with an auditory oddball task. To estimate the dipole solution, we assumed a 3 shell model (brain, skull and scalp) and a single source model. Treatment with placebo resulted in an apparent P300 source that was ventral but of larger magnitude than during buprenorphine treatment. These results suggest that P300 source localization may be a sensitive indicator of CNS function during drug withdrawal. (Supported by NIDA Grants DA03994, 06116, 00115, and 00064)

SELF-ADMINISTRATION OF HEROIN, COCAINE, AND HEROIN PLUS COCAINE IS REDUCED BY THE CO-ADMINISTRATION OF THE D3 SELECTIVE COMPOUND 7-OHDPAT. C. Duvauchelle^{*}, J. Francher, T. Sapoznik and C. Kornetsky. Lab. Behavioral Pharmacology, Boston University School of Medicine, Boston, MA 02118.

Because of the recently postulated role of the D3 dopamine receptor in mediating the rewarding effects of cocaine (COC) (Caine & Koob, 1993), the D3 selective compound 7-hydroxy-N,N-di-n-propyl-2-aminotetralin (7-OHDPAT) was co-administered *i.v.* to male Wistar rats self-administering heroin (H), COC, or a combination of H+COC (speedball) on a progressive ratio schedule (PR). 7-OHDPAT (1.0, 2.0, or 4.0 µg/kg/infusion) reliably decreased the PR breakpoint of H (.009, .018, or .036 mg/kg/infusion), COC (.15 mg/kg/infusion), and low doses of H+COC (.009+ .15 mg/kg, respectively). The decrease in PR was characterized by periods of complete cessation of lever pressing accompanied by an increased incidence of catalepsy, oral stereotypy and hypomotility in most subjects. These results suggest that there are multiple effects of 7-OHDPAT that interfere with the self-administration of H, COC and H+COC. (Supported by Grants DA02326 and DA00099 to CK).

DIFFERENTIAL EFFECTS OF DOI ON COCAINE (COC) AND MORPHINE (MOR)-INDUCED EXTRACELLULAR DOPAMINE (DA) RELEASE IN THE NUCLEUS ACCUMBENS (NA) D.L. Willins*, J. Ichikawa, J.A. Garcia, J. Dai and H.Y. Meltzer, Department of Psychiatry, Case Western Reserve University, Cleveland, Ohio 44106

There is previous evidence that blockade of 5-HT₃ receptors can inhibit the effect of COC and MOR to increase extracellular DA in the NA. The purpose of this study was to determine if DOI, a direct acting 5-HT_{2A/2C} agonist, can influence the effect of COC and MOR on extracellular DA in the NA in awake rats using microdialysis. The systemic administration of DOI (2.5 mg/kg, sc) alone had no effect on basal extracellular NA DA levels. COC (10 mg/kg, i.p.) produced an increase in extracellular DA in the NA of 323% over baseline. Pretreatment of rats with DOI 30 min. prior to the administration of COC did not significantly alter the increase in extracellular DA produced by COC. MOR (5mg/kg, s.c.) produced an increase in extracellular DA in the NA of 206% over baseline. DOI pretreatment 30 min. prior to MOR inhibited the MOR-induced increase in extracellular DA. These findings suggest that MOR and COC-induced increases in extracellular DA in the NA are regulated differently by the activation of 5HT_{2A/2C} receptors. The ability of DOI to suppress MOR-induced DA release in the NA suggests that non-hallucinogenic 5-HT₂ agonists may have a role in the treatment of addiction.

EVIDENCE FOR A WITHDRAWAL SYNDROME FOLLOWING CHRONIC ADMINISTRATION OF AN ANABOLIC STEROID TO RATS. Katherine R. Bonson, Nancy A. Garrick* and Dennis L. Murphy, Laboratory of Clinical Science, National Institute of Mental Health, Building 10, Room 3D41, 9000 Rockville Pike, Bethesda, MD 20892.

In the past decade, anabolic steroids have been recognized as drugs of abuse, especially among athletes and body builders. Chronic administration of testosterone and other androgens has been shown to induce behavioral changes in rats and in humans which includes increases in aggression and alterations in mood. A putative withdrawal syndrome following chronic self-administration of anabolic steroids has been described in humans but has not been demonstrated experimentally in either humans or in rats. The present study shows that distinct behavioral effects emerge in two strains of rats following withdrawal from long-term but not short term administration of testosterone propionate (TP) (30 mg/kg/day). In both Wistar and Fawn-Hooded rats, withdrawal from TP following ten weeks of daily administration induced a behavioral syndrome characterized by facial tremor, head-weaving, full-body lurches and ptosis. This syndrome appeared to be of a greater intensity in the Fawn-Hooded strain. These behaviors subsided within two weeks of withdrawal from the androgen. There were no significant changes in temperature, food intake or body weight over the same period. In comparison, three weeks of daily TP administration did not produce a consistent behavioral syndrome following withdrawal in either Wistar or Fawn-Hooded rats, although there was a significant increase in yawning behavior. These results show evidence for the first time of a withdrawal syndrome in rats following chronic administration of high-dose anabolic steroids.

503.22

NICOTINE INCREASES MET-ENKEPHALIN CONTENT AND PREPROENKEPHALIN mRNA IN MOUSE STRIATUM. N.H. Neff*, R.K. Dhatt, T.A. Wemlinger, G.A. Tejwani and M. Hadjiconstantinou, Depts. of Pharmacology, Psychiatry and The Neuroscience Program, Ohio State University College of Medicine, Columbus, Ohio 43210

Behavioral evidence suggests that opioids play a role in nicotine addiction. Indeed, naloxone reportedly can precipitate withdrawal behavior in animals treated with nicotine chronically. We now present evidence that acute or chronic administration of nicotine increases met-enkephalin immunoreactivity (Met-Enkl) in the mouse striatum. The response to a single dose of nicotine is time-dependent, with Met-Enkl content reaching a maximum 30-60 min post-injection and returning to near normal by 6 hr. The nicotine-induced increase of Met-Enkl is blocked by pretreatment with the nicotinic antagonist mecamylamine, but not by the muscarinic antagonist atropine. Daily administration of nicotine for 2 weeks also increases striatal Met-Enkl. In addition to increasing Met-Enkl content, chronic nicotine increases preproenkephalin mRNA in the striatum when assayed after 7 or 14 days of treatment. We postulate that nicotine addiction is associated with enhanced brain content of opioids which could explain withdrawal behavior when nicotine addicted animals are treated with naloxone.

DRUGS OF ABUSE: METABOLISM—PHARMACOLOGY

504.1

THE LOCAL CEREBRAL METABOLIC EFFECTS OF MORPHINE SENSITIZATION IN THE RAT. M.A. Kraus*, J.M. Piper, R.T. Livezey and C. Kornetsky, Lab. Behavioral Pharmacology, Boston University School of Medicine, Boston, MA, 02118.

Repeated administration of morphine sulfate (MS) will sensitize a rat to oral stereotypic effects. The effects of this sensitization on local cerebral metabolic rate of glucose (LCMR_{glu}) was determined in male F-344 rats. Rats were sensitized by four 10 mg/kg MS (sc) injections at 12 hr intervals. Two control groups were administered saline. One week later, the sensitized animals and one control group, morphine-control, were administered a 0.5 mg/kg challenge of MS 10 min prior to the 2-[C¹⁴]deoxyglucose bolus. The second control group received saline in place of MS. LCMR_{glu} in 49 brain sites was significantly greater in the sensitized rats than the morphine-control rats after the MS challenge. There also were increases in LCMR_{glu} in the sensitized animals compared to the saline-controls in a number of structures. These results suggest that MS sensitization involves increased metabolic activity in multiple brain systems including mesolimbic and motor structures. (Supported by Grants DA02326 and DA00099 to CK)

504.2

THE EFFECT OF NALOXONE, MORPHINE, AND THEIR COMBINATION ON LOCAL CEREBRAL METABOLIC RATES FOR GLUCOSE IN THE RAT. C. Kornetsky*, M.A. Kraus and J.M. Piper, Laboratory of Behavioral Pharmacology, Boston University School of Medicine, Boston, MA 02118.

The present experiment used 2-deoxy-D-[¹⁴C]glucose (2-DG) to determine the effects of naloxone (NX), morphine sulfate (MS), and the combined treatment of NX+MS on local cerebral metabolic rates for glucose (LCMR_{glu}) in rats. Four groups were studied (N = 18): saline, NX, MS, and NX+MS. On test day, NX (1 mg/kg s.c.) was administered 20 minutes prior to and MS (4 mg/kg s.c.) 10 minutes prior to the 2-DG bolus. NX, by itself, significantly decreased LCMR_{glu} in the locus coeruleus, a structure believed to be involved in the expression of opiate withdrawal, suggesting a role of endogenous opioids in the regulation of central noradrenergic activity. Also, NX significantly increased LCMR_{glu} in the mediodorsal thalamic nucleus which has extensive reciprocal connections with the limbic system and prefrontal cortex, suggesting an impact on the integration of limbic and cortical activity. Finally, NX blocked the inhibitory effects of MS on LCMR_{glu}. (Supported by Grants DA02326 and DA00099 to CK).

MOLECULAR MODELING OF ANANDAMIDE V.M. Showalter and M.E. Abood*. Dept. of Pharmacology/Toxicology, Virginia Commonwealth University, Richmond, VA 23298.

Other investigators have utilized molecular modeling to gain more insight into how cannabinoid ligands bind to their receptor. Anandamide (arachidonyl ethanolamide) is thought to be the endogenous ligand at cannabinoid receptors. The purpose of this study was to extend the cannabinoid pharmacophore to include anandamide. The structures of cannabinoid ligands were modeled using SYBYL. The structure of Δ^9 -tetrahydrocannabinol (Δ^9 -THC) was constructed based on x-ray crystal data for Δ^9 -THC. The structure of anandamide was generated by adding ethanolamine to the crystal structure of arachidonic acid; a systematic search was performed about the rotatable bonds and each conformer was extensively energy minimized. The minimum energy conformation of Δ^9 -THC then served as a template for the alignment of anandamide conformers. Preliminary superimpositions suggest that anandamide conformers can mimic the portions of Δ^9 -THC thought to be involved in receptor recognition and activation. (Supported by DA-07027 and DA-05274)

504.5

CHARACTERIZATION OF A CANNABINOID RECEPTOR IN THE ROUGH-SKIN NEWT. K.Soderstrom¹, F.L.Moore², P.H.Franklin^{1*} and T.F.Murray¹. ¹College of Pharmacy, and ²Department of Zoology, Oregon State University, Corvallis OR 97331.

Binding of the synthetic cannabinoid [³H]CP-55940 to membranes prepared from brains of rough-skin newts (*Taricha granulosa*) was investigated using a rapid filtration assay. Binding equilibrium was reached by 480 min at 15°. Specific binding was saturable whereas non-specific binding (determined in presence of 10 μ M levanantradol) was linearly related to [³H]CP-55940 concentration. Saturation isotherms provided a K_d value of 10.5 nM and B_{max} of 1.64 pmol/mg protein. Estimates of K_d obtained by kinetic analyses agreed with equilibrium saturation results. Competition experiments using unlabeled CP-55940 and levanantradol yielded K_i values of 8.6 nM and 5.9 nM respectively. Affinity differences between the amphibian receptor and values previously reported for the rat (0.2 - 4.0 nM) may be explained by differences in incubation temperatures; 15° for the newt vs. 30° for the rat. Using a rat brain membrane preparation we found that K_d varied inversely with temperature: K_d = 12.5, 6.5, and 3.9 nM at 5°, 15°, and 30°C. Behavioral experiments suggest that the cannabinoid binding site has physiological relevance. Newts treated with 5 μ g of levanantradol IP displayed significantly decreased locomotor activity (measured in crossings of lines painted on a testing-arena floor during a three minute period): Treated animals averaged 4.1 line crossings vs. 11.4 in vehicle controls (p = 0.01, 2-tailed t-test). The same dosage significantly decreased the incidence of male clasping behavior (a characteristic mating behavior): clasping was seen in 20% of treated animals vs. 68% of vehicle controls (p < 0.001, Rank Sum Test). These behavioral correlates render the rough-skinned newt a useful system for the study of cannabinoid pharmacology.

504.7

BINDING OF [³H]MK-801 TO BRAIN REGIONS AND SPINAL CORD OF MICE AND RATS TREATED CHRONICALLY WITH MORPHINE. Krishnamurthy P. Gudechithlu*, Poluru L. Reddy and Hemendra N. Bhargava. Dept. Pharmaceutics and Pharmacodynamics, Univ. Ill at Chicago, Chicago, IL 60612.

The effect of morphine tolerance-dependence and abstinence on the binding of [³H]MK-801 to brain regions and spinal cord of mice and rats was determined. Male Swiss-Webster mice and Sprague-Dawley rats were rendered tolerant-dependent by implanting a pellet (mice) containing 75 mg of morphine base for 3 days and 6 pellets during a 7-day period (rats), respectively. In tolerant-dependent animals, the pellets were left intact where in abstinent animals pellets were removed 6 hr (mice) and 16 hr (rats), respectively before sacrificing. In the absence of glutamate and glycine, the binding (B_{max}) of [³H]MK-801 was decreased by 10% in the cerebral cortex of morphine tolerant but not in the abstinent rats. In the presence of glycine and glutamate, the binding was decreased in midbrain and spinal cord of tolerant rats, and in hypothalamus, midbrain and spinal cord of morphine abstinent rats. In morphine tolerant mice, the binding of [³H]MK-801 was decreased in pons-medulla and hypothalamus but was increased in spinal cord. In morphine abstinent mice, the binding of [³H]MK-801 was increased in hippocampus. It is concluded that chronic treatment of mice and rats with morphine produces differential effects on central NMDA receptors. Additionally, different changes are seen when the binding is done in the absence or presence of glycine and glutamate (Supported by a Research Scientist Development Award K02-DA-00130 from the National Institute on Drug Abuse).

DOSE DEPENDENCE OF IBOGAINE NEUROTOXICITY. H.H. Molinari*, I.M. Maisonneuve, and S.D. Glick. Dept. of Pharmacology and Toxicology, Albany Medical College, Albany, N.Y. 12208

Ibogaine is claimed to be an effective treatment for opiate and stimulant addiction. O'Hearn and Molliver (1993), however, showed that in rats ibogaine can cause degeneration of cerebellar Purkinje cells. The present study extended their observations using female Sprague Dawley (Charles River) rats given IP injections of ibogaine and allowed to survive seven days after the last injection. Purkinje cell degeneration was evaluated with a Fink Heimer II stain; enhanced glial cell activity, with a GFAP antibody stain.

One set of animals received an ibogaine dose tested by O'Hearn and Molliver: 100 mg/kg per day for three consecutive days. All of these animals displayed bilaterally symmetric, parasagittal strips of Purkinje cell degeneration. The degeneration was more extensive than suggested by O'Hearn and Molliver, consistently occurring in the medial simple lobule and Crus 1 as well as the vermis and intermediate regions of lobules 5, 6, and 7.

A second set of animals received a dose of ibogaine capable of reducing morphine self administration (Glick et al., 1991): a single injection of 40 mg/kg. No evidence of Purkinje cell degeneration was found in these animals. Thus, ibogaine in sufficient quantities can cause neurotoxicity but the toxicity may not occur with doses that have anti-addictive effects. (Supported by NS29771 and DA03817.)

504.6

ANANDAMIDE AND Δ^9 -THC DILATION OF IN VIVO CEREBRAL ARTERIOLES IS BLOCKED BY INDOMETHACIN. S.F. Moore, K.A. Willoughby and E.F. Ellis*. Department of Pharmacology and Toxicology, Medical College of Virginia, Richmond, VA 23298-0613.

An endogenous ligand of the Δ^9 -THC receptor, arachidonyl ethanolamide (anandamide, AN) has been shown to cause some behavioral and physiological alterations similar to those induced by Δ^9 -THC. We investigated the effect of increasing, topically applied doses (10^{-12} - 10^{-3} M) of AN and Δ^9 -THC on in vivo cerebral arteriolar diameter using the acute cranial window technique in anesthetized rabbits. Both AN and Δ^9 -THC induced a dose-dependent dilation, with a maximal dilation of 22%. AN and THC were active at doses as low as 10^{-11} M. Dilation by both agents was completely blocked by topical co-application of the cyclooxygenase inhibitor indomethacin. Superoxide dismutase plus catalase, which block cyclooxygenase-dependent dilation induced by bradykinin and arachidonic acid, were inactive on AN- and Δ^9 -THC-induced dilation, implying dilation is not via vasoactive, dilator oxygen radicals. HPLC analysis of ³H-AN passed under the cranial window showed approximately 20% metabolism to ³H-arachidonic acid (AA). Following IV injection of ³H-AN in mice both ³H-AN and ³H-AA were found in brain. Reported increases in cerebral blood flow caused by marijuana may be related to formation of brain eicosanoids. Endogenous AN may modulate cerebral blood flow. Supported by DA 07027 and a Javits Neuroscience Investigator Award.

504.8

PRENATAL EXPOSURE TO MORPHINE ALTERS BRAIN μ OPIOID RECEPTOR CHARACTERISTICS IN ADULT FEMALE RATS. Agnes Rimanóczy* and Ilona Vathy*. Dept. Psychiatry, Albert Einstein College of Medicine, Bronx, NY 10461. *Dept. Psychiatry, A. Sz-Gyorgyi Medical School, Szeged, Hungary.

The present study investigated the opioid binding characteristics of membranes of different brain regions of adult female rats exposed to morphine *in utero* (10 mg/kg/twice daily on days 11-18 of gestation). Females were ovariectomized (OVX) at least one week prior to sacrifice, and some females were injected with 3 μ g of estradiol benzoate (EB) 48 hours before sacrifice. Saturation binding assays were carried out using the ³H labeled, highly selective ligand D-Ala-Gly-N-Methyl-Phe-Gly-ol (DAMGO) to label μ opioid receptors. The maximal binding capacity (B_{max}) and affinity (K_d) were estimated in the hypothalamus (HYP), preoptic area (POA), frontal cortex (CX), striatum (STR), ventral tegmental area (VTA) and cerebellum (CER). Prenatal exposure to morphine reduced the B_{max} and the K_d about 25% in the HYP of OVX females when compared to OVX, saline-treated females. A 3 μ g EB injection increased the B_{max} and the K_d about 25% in the HYP of morphine-exposed females without affecting saline-treated females. These effects of prenatal morphine were not apparent in either the B_{max} or the K_d in the POA, CX, STR, VTA or CER. The increase in hypothalamic μ receptor binding capacity in prenatally morphine-exposed females in response to estrogen treatment may be related to the deficit seen in adult sexual behavior of prenatally morphine-exposed females in a previous study (Vathy and Katay, Dev. Brain Res., 68:125-131, 1992). Supported by DA 05833 awarded to IV.

504.9

INTERACTION OF TOLUENE WITH GABA AND GLUTAMATE (GLU) IN THE HIPPOCAMPAL SLICE PREPARATION. N. Shinsky* and G. T. Pryor. Neuroscience Department, SRI International, Menlo Park, CA 94025.

Toluene (T) is inhaled for its euphoric effects. We reported that T markedly enhanced electrically evoked responses elicited by single pulses in the hippocampal slice preparation (*Neurosci. Abst.* 19(2), 1461, 1993). This effect was antagonized by GABA and muscimol. To explore further its neuropharmacology, we also examined the effect of T on responses elicited by paired-pulses and its interaction with compounds affecting the GABA and GLU neurotransmitter systems. Responses evoked by single-pulse stimulation (0.1 Hz) of Schaffer collaterals in the stratum radiatum were recorded from pyramidal cells of area CA1 in transverse hippocampal slices from mice. Paired stimuli, separated by 20 msec, were periodically interspersed with the single-pulse train. In this paradigm, there was an increase in the response to the second relative to the first pulse (facilitation). T enhanced paired-pulse facilitation. This enhancement by T was antagonized by GABA and muscimol, but not by baclofen. The competitive NMDA antagonist CGS-19755 was without effect on T-enhanced facilitation; however, after T was washed out, it markedly enhanced paired-pulse facilitation, suggesting a residual effect of T. CNQX, an antagonist at the quisqualate site, blocked the response to single- and paired-pulses, alone and with T. After washout of CNQX and T, the response to single pulses only partially recovered, whereas paired-pulse facilitation was markedly enhanced. These results further characterize the interactions of T with specific neurotransmitter systems in the brain, possibly related to its psychoactive effects.

CATECHOLAMINE METABOLITES IN THE CEREBROSPINAL FLUID OF HYDROCEPHALIC RABBITS. Ch.E.Olmstead, M.C. Wehby-Grant, W.C. Peacock, J.A. Lazareff, R.S. Fisher, A. Fluharty, K.F. Faull and E.N. Orlino. Division of Neurosurgery and Dept. of Anatomy, U.C.L.A. Sch. of Med., Los Angeles, CA 90024.

We have been using the rabbit with chronic kaolin-induced hydrocephalus to assess the factors determining the success of ventriculoperitoneal shunting for infantile hydrocephalus. To that end we have been developing a battery of neurological, behavioral, radiological and anatomical tools to describe the progress of the untreated disease and to evaluate the efficacy of treatment.

In the current study the effects of hydrocephalus on the levels of tyrosine, tryptophan and 5HIAA were determined by HPLC with fluorimetric detection in 6 day old normal (N=14) and in 26 to 69 day old hydrocephalic (N=11) rabbits. Samples of cerebrospinal fluid (50 - 100 μ l) were obtained either by puncture of the *cisterna magna* or directly from the lateral ventricle at the time of shunt insertion. Samples were stored at -80°C until processed.

The hydrocephalic rabbits showed significant decreases in both tyrosine and tryptophan levels and a highly significant increase in the serotonin metabolite 5HIAA. There was a significant positive correlation between the intracranial pressure (ICP) and the increase in 5HIAA, but not with the two precursor amino acids.

These data suggest that the increased ICP adversely affects the mechanism of removal of the serotonin metabolite from the cerebrospinal fluid.

505.2

STRUCTURAL AND FUNCTIONAL ASSESSMENT OF CHRONIC KAOLIN-INDUCED HYDROCEPHALUS IN THE RABBIT. M.C. Wehby-Grant, Ch.E. Olmstead, W.C. Peacock, T.H. Hsu, G. Olavarria, D. Hovda, R.S. Fisher. Depts Neurosurgery and Anat., U.C.L.A. Sch. of Med., Los Angeles, CA 90024.

Rabbits with chronic kaolin-induced hydrocephalus have few neurological deficits despite profound ventriculo-megaly. We report here both structural and metabolic sparing in the somatosensory cortex in chronic untreated animals. Hydrocephalus was induced at 4-6 days of age. Control (N=15), untreated hydrocephalic (N=18) and shunted (N=5) animals were sacrificed at survival periods between 10 and 366 days. The brains were either processed for quantitative 2-deoxy-D-glucose autoradiography and cytochrome oxidase (N=19), stained with cresyl violet for somatosensory cortex barrel fields (N=16), or silver impregnated for quantitative neuronal golgi (N=6).

Glucose utilization and oxidative metabolism were significantly higher in the chronic hydrocephalics than in normal, with the highest metabolic activity in the outer cortical layers in both groups, while the lowest activity was seen in the white matter. The organization of the barrel fields in the facial portion of cortex was preserved. The areas of the individual fields were significantly larger in the hydrocephalic than in the normal littermates. Shunted animals showed intermediate sized fields. In the hydrocephalics the apical dendrites of the layer IV neurons remained perpendicular to the cortical surface, but the dendritic shafts are thickened and the spines much more prominent.

These data show that even with profound ventriculomegaly, the structural organization of the cortex is maintained, and there is considerable functional activity in the cortical mantle of the chronic hydrocephalic rabbit.

505.3

ELECTRON MICROSCOPY OF THE CEREBRAL CORTEX IN YOUNG HYDROCEPHALIC AND SHUNT-TREATED H-TX RATS. H.C. Jones, C.A. Boilat, N.G. Harris, G.L. Kaiser. 1. Dept of Pediatric Surgery, Univ. of Bern, Switzerland. 2. Dept of Pharmacology, Univ. of Florida, Gainesville, FL 32610.

Shunt-treatment in hydrocephalic infants results in marked clinical improvement but little is known about the cellular effects of hydrocephalus and the response to shunting. The H-Tx rat has inherited hydrocephalus with onset in late gestation and is a useful model in which to study these effects. Rats were shunt-treated at two ages: 4-5 days after birth (before the CSF pressure increases) or at 10 days (after the pressure starts to increase). Cortical tissue was prepared from these rats (n=7) at 21 days of age and from age-matched control (n=6) and hydrocephalic rats (n=8). The ultrastructure of the pyramidal cells and surrounding neuropil from layers V and VI was examined in a Phillips 200 transmission electron microscope. In hydrocephalic rats the cortex was frequently edematous with swollen irregularly-shaped neurites. The neurones had watery cytoplasm, swollen mitochondria, multivesicular bodies, expanded endoplasmic reticulum and dispersed nuclear chromatin. Synaptic contacts were few. Tissue from rats shunted at both ages showed a dramatic recovery of neuronal organization and contained neurones with increased metabolic activity, with frequent Golgi complexes, centrioles, mitochondria and ribosomes. Some neurites showed remaining injury and synaptic contacts were only partly restored. The abnormalities seen in hydrocephalic rats were prevented more effectively in the rats shunted soon after birth at 4-5 days. It is concluded that shunt treatment, if carried out early enough, has the potential for normalizing cortical ultrastructure.

505.4

HIGH RESOLUTION $^1\text{H-NMR}$ ANALYSIS OF CEREBRAL CORTEX FROM CONTROL AND HYDROCEPHALIC H-TX RATS.

N.G. Harris, B.A. Inglis, H.C. Jones, R.W. Briggs. Depts of $^1\text{H-NMR}$ Biochemistry and $^2\text{Radiology}$, University of Florida, Gainesville, FL 32610 USA.

The H-Tx rat develops hydrocephalus in late gestation due to an obstruction of the cerebral aqueduct and if left untreated, affected animals die within 4-6 weeks after birth. By 21 days there is gross lateral ventricular expansion and severe cortical thinning with abnormal cell morphology. Cerebral glucose metabolism and blood flow (CBF) are greatly reduced so that in some areas CBF is below the ischemic threshold. Although many of these gross pathophysiological changes are reversible by the placement of a ventriculosubcutaneous shunt soon after birth, it is not known to what extent the shunted brain is able to function normally. Therefore in an attempt to provide baseline information on the more discrete, biochemical changes that occur in the unshunted hydrocephalic rat cortex, we have used high resolution 1-dimensional $^1\text{H-NMR}$ spectroscopy to analyse perchloric acid extracts of cortex prepared by the freeze-funnel technique using spontaneously-breathing control and hydrocephalic rats at 21 days after birth (n=4&4). Many cerebral metabolite concentrations in the hydrocephalic cortex were significantly reduced from control. N-acetyl aspartate (NAA) at 2.02ppm was $3.1 \pm 0.54 \mu\text{mol/g}$ wet weight (means \pm sem) in the hydrocephalic cortex compared to 5.9 ± 0.51 in the control ($P < 0.01$), creatine/phosphocreatine at 3.04ppm was 2.0 ± 0.33 and 3.9 ± 0.32 ($P < 0.01$) in hydrocephalic and control cortex respectively and taurine at 3.44ppm was 3.6 ± 0.51 and 7.6 ± 0.79 ($P < 0.01$). The following metabolites were also significantly reduced: alanine, glutamate, aspartate, glycerophosphocholine /phosphocholine, inositol. These results confirm our previous measurements of a disrupted cortical metabolism and further indicate that the biochemistry of the hydrocephalic cortex is severely disturbed. This data establishes a good baseline from which subtle differences in the biochemistry of the shunted hydrocephalic cortex can be investigated.

505.5

QUANTITATIVE ULTRASTRUCTURAL BASIS OF GERMINAL MATRIX MICROVASCULAR MATURATION. L.R.Ment*, W.B.Stewart, C.C.Duncan, and J.A.Madri. Yale Univ. School of Med., New Haven, CT 06510

The risk period for intraventricular hemorrhage (IVH) of the preterm neonate is the first 3 - 4 days and is independent of gestational age. We hypothesized that the risk period is attributable to perinatal induction of maturation of the germinal matrix (GM) microvessels.

Newborn beagle pups (N = 6) were anesthetized and systemically perfused and the brains were prepared for electron microscopic examination. Examination of electron micrographs from the GM of animals on the first, fourth and tenth postnatal days demonstrated no difference in perimeter lengths and capillary and endothelial cell areas; in contrast, luminal areas decreased across postnatal age ($p = 0.05$). Increases were found in basement membrane area between days 1 & 4 ($p = 0.01$) and tight junction length ($p = 0.02$). No such changes were noted in the periventricular white matter. On day 1, 19% of GM capillary perimeter was not covered by glial endfeet. By day 10, only 5% was bare. The microvessels of the white matter had approximately 5% bare perimeter regions at all three ages examined. These data suggest that the risk period for IVH in the preterm infant represents the interval of development of the blood brain barrier in the GM microvasculature. (supported by NS 32578)

ABSENCE OF BRAIN ELASTIN IMMUNOSTAINING IN WILLIAMS SYNDROME. A.M. Galaburda, P.P. Wang, M. Rossen, and U. Bellugi. Beth Israel Hospital and Harvard Medical School, Boston, MA, 02215 and The Salk Institute for Biological Studies, La Jolla, CA 92037.

Williams syndrome (WS) is a rare genetic disorder resulting in characteristic facies, heart defect, and a unique neurobehavioral profile. Cytoarchitectonic neocortical anomalies include exaggerated horizontal laminar organization, increased cell packing density, abnormally clustered and oriented neurons. Posterior forebrain areas are markedly diminished in volume. We have suggested that the increased cell packing density is in part the result of infantile hypercalcemia. (Galaburda, A.M. *et al.*, *NeuroReport*, 5:753-757, 1994).

The recent report that WS is associated with hemizygous deletion including the elastin locus (at chromosome 7q11.23) and contiguous genes (Ewart, A.K. *et al.*, *Nature Genetics* 5:11-16, 1993) suggests that the brain symptomatology of WS may be due to abnormal expression of elastin, laminin B1, and/or acetylcholinesterase.

In one brain from a WS patient aged 8 months we were able to immunostain normally for laminin B1 but not for elastin compared to controls. Another WS brain stained normally for acetylcholinesterase.

Although little is known about elastin's brain distribution and function, there is ample evidence that other extracellular matrix proteins are neurodevelopmentally active. Abnormal elastin activity may contribute to the developmental malformation in WS. This work was supported by NIH grants HD20806, HD26022, NS22343, DC01289, and a grant from the Oak Tree Philanthropic Foundation.

THE DISTRIBUTION OF DYSTROPHIC AXONS PREDICTS CLINICAL FEATURES OF NEUROAXONAL DYSTROPHY: A CASE STUDY. L.A. Goodman*, I. Rapin, and D.W. Dickson. Departments of Pathology and Neurology, Albert Einstein College of Medicine, Bronx, New York 10461.

Neuroaxonal dystrophies are neurodegenerative disorders characterized clinically by dementia and motor abnormalities, and pathologically by dystrophic axons that appear as spherical eosinophilic granular structures called spheroids. In immunocytochemical and electron microscopic studies of a case of late infantile neuroaxonal dystrophy, the distribution of spheroids correlated with the patient's clinical signs. This 11 year old girl had markedly delayed motor and language development, ataxia, severe behavioral disturbances, sleep abnormalities and autonomic dysfunction. At autopsy, the brain was grossly normal. Routine sections revealed numerous spheroids in many gray matter regions. Immunocytochemical studies showed them to be positive for ubiquitin and amyloid precursor protein (APP), weakly positive for parvalbumin and synaptophysin, and negative for neurofilament, A β , tau and PHF-tau. Additional markers demonstrated an intense microglial and astrocytic reaction associated with the spheroids. Ultrastructural studies revealed the spheroids to be filled with membrane-bound organelles containing electron-dense granular material and membranous lamellae. Adjacent neuronal perikarya were normal. Spheroids occurred at axon terminals as shown by their localization to target regions of major fiber tracts, positive staining for synaptophysin and APP, and juxtaposition to neuronal perikarya. They were most numerous in the hippocampal endplate, septal nuclei, nucleus accumbens, hypothalamus, certain cranial nerve nuclei, dorsal column nuclei, and dorsal horns of spinal cord, but virtually absent from cerebral cortex and white matter. The selective distribution of spheroids within limbic, sensory, autonomic and reticular activating systems thus corresponded closely to the patient's clinical manifestations. CONJUNCTIVE EYE MOVEMENTS IN CEREBRAL PALSY. M.LeGare*, S.Lee and H.Zhang. Dept. of Psychology and Biomedical Engineering Program, California State University, Sacramento, CA 95819.

Do the conjunctive movements of the eyes in cerebral palsy (CP) differ from the norm? If so, this deficit would affect spatial vision in CP. The right and left eye positions of 6 CP and 6 normal (N) adults were measured by the binocular 7000S (Micromasurements, Inc., Farmington CT). Square, sine and triangle waveforms in the time domain were stimuli for 24, 10sec tests of horizontal and vertical saccadic and pursuit movements ($0.3, 0.5$ Hz; $\pm 4, \pm 8$ degrees). The pooled mean coefficients of determination (r^2) for right and left eye positions across all tests for N ranged from 0.96 ± 0.03 to 0.98 ± 0.006 and for CP from 0.80 ± 0.24 to 0.90 ± 0.08 . The mean r^2 was significantly lower for CP than N on all tests (Mann-Whitney U; $p < .02$) except for horizontal saccades. The degree of binocularity across CP subjects did not coincide with the severity of the disorder. While the final common path for coupling the two eyes' positions may be in the tegmentum and pons, these results indicate that this visuomotor feature is not necessarily conserved in CP and its contribution to poor aimed movement control in CP may not be trivial. (Supported by NSF-BCS9107276 and a CSU-S/CA Award to ML.)

SELECTIVE INCREASE IN NEURON SIZE IN AGING MICRENECEPHALIC RATS WITH NEOCORTICAL TRANSPLANTS. M. H. Lee*, A. Heaney, A. Disenhouse and A. Rabe. NYS Institute for Basic Research in Developmental Disabilities, Staten Island, NY 10314

The rat with prenatally induced micrencephaly, a model of congenital brain defects, displays life-long cognitive deficits, and a premature aging-related deterioration of spatial learning competence. We recently demonstrated that a neocortical transplant grafted in the hypoplastic cerebrum during the second postnatal week ameliorated the premature aging-associated decline in learning.

To determine whether a life-long presence of a neural transplant would protect the micrencephalic brain from aging-related deterioration, the cerebral cortex and hippocampus were examined in old (19-26 months) rats with methylazoxymethanol-induced micrencephaly that had received a solid transplant of normal E18 neocortex at 10 days of age. The cortical pyramidal neurons were larger in transplant-bearing rats (T) than in micrencephalic rats without transplants (M), while there was no significant difference between the T group and normal controls (C). No group difference was observed in the size of cortical granular cells. In the hippocampus, neuron size in subfields CA2 and CA3 did not differ between T and C rats, while in the M rats neurons were smaller than in T and C rats. On the other hand, no group difference in size was seen in CA1 and CA4. It needs to be determined whether these selective transplant-induced differences in neuron size are responsible for cognitive improvement in the old micrencephalic rat.

505.10

HEATED WATER-INDUCED CONVULSIONS: A MODEL FOR STUDYING THE EFFECTS OF EARLY FEBRILE CONVULSIONS AND PERINATAL EXPOSURE OR WITHDRAWAL FROM DRUGS UPON THE SENSITIVITY OF THE CNS. S.B. Sparber*, B.J. Klauenberg and L.W. Thomas. Department of Pharmacology, Univ. of Minnesota, Minneapolis, MN 55455.

Exposure to heated water for not more than 4 minutes caused convulsions in rats during postnatal development. Following exposure to water of 45°C , rats in each age group (24, 32, 36 and 56 days) had more convulsions compared to rats exposed to water of 44°C ($N=12-26/\text{group}$). The occurrence of a convulsion was inversely related to age. The younger rats experienced more convulsions, reached greater maximum colonic temperatures, higher convulsion temperatures and had more rapid increases in temperature. Overall, the results suggest that the rate of temperature change (i.e. heat transfer in the case of an external source) may be the most salient factor. The rates at which temperature increased in rats that convulsed were significantly greater than those that didn't convulse at each age. The maximum body temperature reached at each age was generally not different for convulsing and nonconvulsing rats following exposure to the heated water bath. The younger rats were able to withstand greater temperature changes (e.g. slope of rise; peak temperature, etc.) than older rats without experiencing a convulsion. Although fewer of the older rats convulsed, their convulsion temperatures were lower, their slopes were shallower and, in the case of the oldest rats, these parameters were significantly different from the other age groups, suggesting that older rats are actually more susceptible to hyperthermia-induced convulsions if their thermoregulatory capacity is exceeded. This procedure may be a useful developmental model for inducing febrile seizures, since convulsions were induced during the first exposure (i.e. no kindling; (1)) without causing mortality. It may also be a sensitive procedure for unmasking altered sensitivity of the CNS of subjects exposed to or withdrawn from drugs during development. Supported by USPHS grants DA 01880, DA 04979 and HD 07279.

BEHAVIORAL CONSEQUENCES OF NEONATAL INJURY OF THE NEOCORTEX. G.D. Rosen,* N.S. Waters, A.M. Galaburda, and V.H. Denenberg. Beth Israel Hospital and Harvard Med. School, Boston, MA, 02215 and Univ. of Connecticut, Storrs, CT 06268.

Focal developmental neocortical anomalies, including molecular layer ectopias and microgyria, are associated with developmental dyslexia. Some autoimmune mice spontaneously develop ectopias that are similar in appearance to those seen in dyslexic brains. In addition, these mice have behavioral anomalies, some of which are associated with ectopias, others with the immunological disorder. In an attempt to further test the dissociation of the behavioral effects of autoimmunity and of cortical malformation we induced ectopias (with puncture wounds) and microgyria (with freezing lesions) in the neocortex of one-day old mice without immune disorders.

DBA mice received either a puncture wound or freezing lesion of either the left or right hemisphere. Some mice received sham surgery. Compared to sham-operated animals, mice with either puncture wounds or freezing lesions performed poorly in discrimination learning, in a spatial Match-to-Sample task, and in a Lashley Type III maze. In shuttlebox avoidance conditioning, in which immunological disorder diminishes performance, there was no difference between lesioned and sham animals. These results (1) support the dissociation between the effects on behavior of developmental neocortical anomalies and autoimmune disease, (2) point out similarities between spontaneous and induced neocortical malformations, and (3) fail to support behavioral differences between ectopias and microgyria.

DIFFERENCES IN NEURONAL AND GLIAL MORPHOLOGY IN HUMAN SUBSTANTIA NIGRA IN INTRA-UTERINE GROWTH RETARDATION (IUGR) AND COT DEATH CASES. E. Markova,* C.V. Howard* & D. van Velzen. Moscow Brain Research Institute, 5 Obukha, 103064 Moscow, Russia & *Dept. of Fetal and Infant Pathology, University of Liverpool, L69 3BX, UK

Free-floating sections of the mid-brains of 4 control, IUGR and cot death cases for each of three postnatal ages, i.e. 1 week, 1 and 4 months, were prepared for Golgi staining, Braitenberg modification. In addition the 1 week group was immuno-histochemically stained for GFAP and TH.

Qualitatively abnormal changes in Golgi stained dendrites, including varicosities, enlarged shafts of dendrites and aneurysm-like changes, were noted in the IUGR and cot death groups, which were similarly affected. Many neurons showed growth-cone like dendritic endings and also filopodium-like very thin dendrites arising from the soma or proximal dendrites.

60 neurons from each case were measured, using a Leitz Orthoplan 3-D system. In both pathological groups a significant reduction in lengths of total dendritic tree, unbranched dendrites and terminal dendritic segments was revealed. In addition there was a reduction in the maximal radius of the dendritic trees in the IUGR and cot death groups compared to control.

A significant reduction in soma size of TH positive neurons with a concomitant increase in soma size of GFAP positive astrocytes was measured in IUGR and cot death groups compared to control.

The data suggests the presence of delayed maturation and pathological changes in SN neurons and a hypertrophic astrocytic reaction, possibly associated with chronic hypoxic conditions during prenatal development. These results support the known clinical association between IUGR and cot death. It also may be relevant to findings of behavioural changes and impairment of cognitive function in groups of low birth weight infants.

EPILEPSY: ANTICONVULSANT DRUGS—AMPA AND NMDA RECEPTOR

506.1

THE EFFECTS OF VALPROIC ACID ON PKC ACTIVITY IN THE RAT HIPPOCAMPUS.

G.Y.-P. Lee*, T.J. Teyler and L.M. Brown. Depts. Neuro. and Pharm., NE Ohio Uni. Coll. of Med., Rootstown, OH 44272-0095

Valproic acid can suppress the NMDA induced [3H]-NE efflux in rat cortical slices (Eup. J. Pharm. 254 (1994) 307-309), the NMDA receptor mediated synaptic responses (Brain Res. Bull. 33 (1994) 333-336), and PKC activity in cultured cells (Soc. Neurosci. Abstr. 19 (1993) 750). Enhanced PKC activity may underlie the central role of the NMDA receptor in neuronal plasticity (TINS 15 (1992) 333-339). Valproic acid induced alterations in PKC may serve as a mechanism underlying the ability of valproic acid to suppress NMDA activity.

Brain slices (350 μ m) from the hippocampus of Long-Evans hooded rats were used. The control slices were incubated in ACSF, and experimental slices were incubated in ACSF containing 100 μ g/ml valproic acid for 20 mins. After the treatment, slices were washed in Tris-HCl buffer, and prepared for PKC phosphorylation assay (Brain Res. 524 (1990) 144-148). Under the treatment of valproic acid, the cytosol PKC activity was 279 μ g/pmol/min (decreased about 35%); and the membrane PKC activity was 44 μ g/pmol/min (decreased about 27%). Valproic acid had a tendency to suppress PKC activity in both membrane and cytosol components.

THE BROAD SPECTRUM ANTICONVULSANT ADCI BLOCKS TTX SENSITIVE VOLTAGE-ACTIVATED Na CHANNEL CURRENTS IN NE1-115 MOUSE NEUROBLASTOMA CELLS. G. White*, Neurogen Corp. Branford, CT 06405.

ADCI is a novel anticonvulsant drug that is efficacious in a wide variety of seizure models. ADCI is a hybrid analog of both carbamazepine (a Na channel blocker) and MK-801 (an NMDA receptor un-competitive antagonist) and appears to have anticonvulsant activity consistent with both antagonist activities. While the NMDA antagonist activities of this compound have been characterized electrophysiologically (Rogawski et al, J. Pharm. Exp. Ther., 1991) little direct evidence is available concerning ADCI's activity as a Na channel blocker. In the present series of experiments, the sodium channel activity of \pm ADCI and its enantiomers were evaluated using the whole-cell patch-clamp technique in a cell line (NE1-115) in which TTX sensitive Na currents were isolated using the following recording solutions: external (in mM): 100 NaCl, 25 TEA, 1.8 CaCl₂, 5 CsCl₂, 1 MgCl₂, 1 CoCl₂, 25 glucose, 5 HEPES, pH 7.35; internal (in mM): 115 CsCl₂, 4 MgATP, 0.6 GTP, 5 EGTA, 10 HEPES, pH 7.35. ADCI was found to block Na currents in a manner similar to that of carbamazepine. Both drugs were ~5 fold more potent as blockers at -65 mV than at -85 mV. Similar to carbamazepine, ADCI shifted the I_{Na} curve of the Na channels in a hyperpolarizing direction and showed a use dependent block of current amplitude. No differences were observed in block of Na channel activity among racemic (\pm)ADCI and its two (+ and -) enantiomers. 100 nM of the NMDA antagonist, +MK-801, had no detectable effect on Na currents. These findings suggest that the spectrum of anticonvulsant activity of ADCI results from its blocking action at TTX-sensitive Na channels in addition to its NMDA antagonistic activity.

506.2

SUPPRESSION OF REFRACTORY STATUS EPILEPTICUS BY U54494A AND DIAZEPAM IN THE LITHIUM-PILLOCARPINE MODEL IN RAT.

A. Handforth*, VAMC West Los Angeles, Los Angeles, California 90073.

Treatment of clinical status epilepticus (SE) is frequently unsatisfactory; many cases are refractory to treatment or develop serious adverse events. We have utilized the lithium-pilocarpine SE model to investigate potential new therapies. In this model rats pretreated with LiCl (3 mM/kg ip) develop SE after pilocarpine is injected (30 mgs/kg ip). Once EEG-recorded continuous fast spiking is attained the SE is highly refractory to all conventional SE therapies.

U54494A has been shown to antagonize seizures in several models, but does not possess the sedative properties of the related kappa opioid agonist U50488H. We found that U54494A, 24-30 mgs/kg, infused iv over 1 to 15 minutes (n=12) converted fast continuous spiking to periodic epileptiform discharges (PEDs). Higher doses that stopped all epileptiform activity caused subsequent mortality. Diazepam 20-30 mgs/kg iv as monotherapy did not slow or stop continuous fast spiking (n=6). Diazepam 2-10 mgs/kg iv given 10 min after U54494A-induced PEDs stopped all epileptiform activity with subsequent recovery of the rat (n=7). Diazepam administration after lower doses of U54494A that did not cause PEDs did not stop SE (n=6). The combination of U54494A and diazepam thus is effective in stopping SE in this model of refractory SE. Supported by Upjohn.

506.4

BEHAVIORAL CHARACTERIZATION OF A NOVEL COMPETITIVE AMPA RECEPTOR ANTAGONIST (LY293558). D.R. Helton*, P.L. Ornstein, M.J. Kalman and J.P. Tizzano. Lilly Research Laboratories, Eli Lilly and Company, Indianapolis, IN 4613

Competitive AMPA receptor antagonists protect against convulsions and neuronal injury in animal models. LY293558 is a parentally active, selective, competitive AMPA (2-amino-3-(3-hydroxy-5-methylisoxazol-4-yl) propionic acid) receptor antagonist. In this study, the anticonvulsant and behavioral effects of LY293558 were evaluated following intravenous administration (0, 1, 3, or 10 mg/kg) in CD-1 mice. Convulsive thresholds for intracerebral administration of S-AMPA, electroshock and pentylenetetrazol were dose-dependently increased. Clinical observations at higher doses included labored breathing (3 and 10 mg/kg), ataxia, hyperreactivity or hypoactivity (10 mg/kg). No overt clinical observations were noted at 1 mg/kg. LY293558 produced quantitative reductions in spontaneous ambulatory and nonambulatory activity levels at 10 mg/kg. In addition, sensorimotor reactivity was decreased at the high dose of 10 mg/kg. Muscle tone and pain thresholds (writhing and tail flick) were not affected by LY293558 treatment. These data suggest that LY293558 has anticonvulsant activity in several animal models.

506.5

EFFECTS OF DEXTROMETHORPHAN (DM) ON KAINIC ACID (KA)- INDUCED SEIZURE IN RAT. H. Kim¹, K. R. Pennypacker, G. Bing and J. S. Hong. LMIN-NIEHS, Research Triangle Park, NC 27709.

Several studies showed that DM exerts both anticonvulsant and proconvulsant effects depending on the experimental conditions. In this study, we examined the effects of DM on KA- induced cell loss in the hippocampus and changes in AP-1 DNA binding activity which are associated with seizure activities. KA (8mg/kg, i.p) administration produced robust behavioral convulsions lasting 4- 6 hours. Pretreatment with DM (12.5- 75 mg/kg, p. o) 15 minutes before KA injections reduced the seizure activities as well as lethality in a dose dependent manner. Histochemical studies revealed a severe loss of cells in CA1 and CA3 fields of the hippocampus in KA- treated rats. DM pretreatment also reduced the degree of cell loss in a dose depend fashion. Biochemical studies also showed that DM pretreatment attenuated the KA-induced increase of AP-1 DNA binding activity in hippocampus. These results indicate that DM is an effective anticonvulsant to antagonize KA- induced seizures and its related changes.

MK-801 DISRUPTS THE NETWORK OF BRAIN REGIONS AFFECTED BY KAINIC ACID AND PREVENTS THE MANIFESTATION OF LIMBIC CONVULSIONS. A.M. Planas¹*, M.A. Soriano^{1,2}, L. Ferrer² and E. Rodríguez-Farré¹. ¹Dep. Pharmacol. & Toxicol., CID, CSIC, 08034 Barcelona, and ²Unitat de Neuropatologia, Hospital Prínceps d'Espanya, Universitat de Barcelona, Spain.

MK-801 reduces the convulsant and excitotoxic effects of kainic acid administration. This study examined the effect of MK-801 on the regional expression of heat-shock protein-70 (HSP70), HSP70 mRNA and neuropathological outcome following systemic kainic acid. HSP70 is a marker of cellular stress that does not invariably precede cell death (Sloviter and Lowenstein., 1992). Rats received either kainic acid (9 mg/kg), MK-801 (1 mg/kg), or MK-801 one hour prior to kainic acid. Kainic acid alone caused convulsions in 74% of treated rats. Convulsing rats expressed HSP70 mRNA and HSP70, predominantly in limbic regions. Necrosis was also seen in select limbic areas. Pre-treatment with MK-801 reduced the percentage of convulsing rats to 4% and inhibited HSP70 mRNA and HSP70 expression mainly in thalamus and cortex. HSP70 mRNA and protein was maintained in CA3, subiculum and the amygdala. Rats pre-treated with MK-801 and not convulsing showed no histopathological changes. These data identify brain regions putatively involved in the manifestation of limbic convulsions and through which the anticonvulsant effect of MK-801 might be mediated.

506.9

THE ANTI-CONVULSANT AND ANTINOCICEPTIVE EFFECT OF 5-NITRO-6-METHYL-7-CHLORO-2,3-QUINOXALINEDIONE (NMCQX) AND 5-NITRO-6,7-DIMETHYL-2,3-QUINOXALINEDIONE (NDMQX), TWO NOVEL NMDA RECEPTOR/GLYCINE SITE ANTAGONISTS IN THE MES AND FORMALIN TESTS. M. Tran¹, K. Lutfy², L. Kwon², S.X. Cai¹, J.F.W. Keana³ and E. Webster^{1,2}. ¹Acacia Pharmaceuticals, Inc., 1003 Health Sciences Road West, Irvine, CA 92715; ²Dept. of Pharmacology, UC Irvine, Irvine, CA 92717; ³Dept. of Chemistry, University of Oregon, Eugene, OR 97403.

Recent studies have suggested a modulatory role for the N-methyl-D-aspartate (NMDA) receptor in several physiological as well as pathological states, e.g., LTP, epilepsy, ischemia, pain etc. In the present study we, respectively, evaluated the anticonvulsant and antinociceptive effect of NMCQX and NDMQX in the maximal electroshock (MES) model and in the formalin test in Swiss Webster mice. In the MES test, mice were injected i.p. with NMCQX (1.25-7.50 mg/kg; N=15 mice/dose) or NDMQX (5.0-15.0 mg/kg; N=15 mice/dose). Control mice were injected with Tris (0.05 M) or Arginine (0.1 M), respectively. Seizures were then induced by applying a rectangular pulse, 50mA, 60 pulses/sec, 0.8msec pulse width and 0.2 sec train length at the time of drugs' peak effect. Both compounds dose-dependently protected mice from generalized clonic-tonic seizures induced by electroshock. In the formalin test, following a 1 hr accommodation period mice were injected i.p. with NMCQX (1.0-10.0 mg/kg, N=7-13 mice/dose) or NDMQX (0.5-20.0 mg/kg, N=8-9 mice/dose). Control mice were injected with Tris (0.05 M) or Bis-Tris (0.2 M), respectively. Mice were then injected with formalin and the amount of time that each mouse spent licking and/or biting the injected paw was recorded for 1 hr. A s.c. injection of formalin produced a biphasic nociceptive response, i.e., a transient early phase (0-5 min) followed by a tonic late phase (15-50 min). Both compounds produced a dose-dependent antinociceptive effect in both phases of the formalin test. These data suggest a modulatory role for the NMDA receptor in MES-induced seizures and in formalin-induced nociception. (Supported by Acacia Pharmaceuticals, Inc. and NIDA Grant DA 06726)

506.6

VALPROIC ACID, PHENOBARBITAL AND PHENYTOIN DO NOT DISPLACE [³H]MK-801 BINDING L.M. Brown*, Dept. of Pharmacology, Northeastern Ohio Universities College of Medicine, Rootstown, Ohio 44272.

NMDA antagonists have anticonvulsant properties and are capable of enhancing the effects of other anticonvulsant agents (Urbanska et al., Eur. J. Pcol. 200; 1991; 277-282). Previous studies have demonstrated that the antiepileptics; valproic acid, phenobarbital and phenytoin inhibit NMDA-stimulated [³H] norepinephrine efflux in rat cortical slices (Brown et al., Eur. J. Pcol. 254; 1994; 307-309). The ability of the antiepileptics to inhibit [³H]MK-801 binding in rat cortical homogenates was examined to determine if these drugs have the ability to interact with the NMDA channel site.

[³H]MK-801 binding was performed using the method of Javitt and Zukin (PNAS. 86; 1989; 740-744). Well washed rat cortical homogenates were incubated in the presence of [³H]MK-801 (5 nM), glutamate (10 μ M), D-serine (10 μ M) and varying concentrations of antiepileptic drug in a 5 mM Tris acetate buffer. The binding reaction was carried out for 4 hrs at 37°C. The binding reaction was terminated by vacuum filtration and radioactivity determined using liquid scintillation counting.

PCP competed for [³H]MK-801 binding with an IC₅₀ of 6.2 μ M \pm 3.2 μ M. Valproic acid (1 μ M to 10 mM) did not displace [³H]MK-801 binding. Phenobarbital and phenytoin in concentrations of 0.1 μ M to 3 mM also failed to displace [³H]MK-801 binding. These results indicate that the ability of antiepileptics to inhibit NMDA stimulated efflux of [³H]norepinephrine does not involve an interaction at the NMDA channel site.

506.8

THE ANTICONVULSANT REMACEMIDE ALLOSTERICALLY BLOCKS THE NMDA RECEPTOR: INTERACTION WITH THE POLYAMINE SITE. Swaminathan Subramaniam, Sean D. Donevan and Michael A. Rogawski*, Epilepsy Research Branch, NINDS, Bethesda, MD 20892.

Remacemide [2-amino-N-(1-methyl-1,2-diphenylethyl)acetamide] is a novel anticonvulsant drug that is metabolized to an open channel blocker of the NMDA receptor. Remacemide itself is also a weak NMDA receptor antagonist, but it appears to act, at least in part, by a mechanism distinct from that of the metabolite. We used voltage-clamp recordings from cultured rat hippocampal neurons and [³H]dizocilpine binding to rat forebrain membranes to investigate the mechanism of the remacemide block. Remacemide inhibited NMDA induced currents and displaced [³H]dizocilpine binding to rat forebrain membranes at a concentration of ~50 μ M. The block of NMDA induced currents at -60 mV was weakly voltage-dependent and was reduced by ~15% at +60 mV. To eliminate the voltage-dependent component of block, subsequent experiments were carried out at +60 mV. Concentration-response curves for remacemide were obtained in the presence and absence of the polyamine spermine. Spermine (1 mM) shifted the remacemide isotherm to the right (IC₅₀ increased from 95 to 198 μ M), whereas the purported polyamine site antagonist diethylenetriamine (1 mM) produced a comparatively smaller shift (IC₅₀ increased to 139 μ M). Using the rate of dissociation of [³H]dizocilpine as a measure channel activity, spermine (0.3-100 μ M) was observed to markedly increase the rate of unbinding, whereas remacemide (10-100 μ M) slowed unbinding. The concentration-response relationship for remacemide in the presence of different concentrations of spermine indicated a competitive interaction between the anticonvulsant and the polyamine. We conclude that remacemide allosterically inhibits NMDA receptor channel opening via an action at the polyamine site.

506.10

FELBAMATE, A NOVEL ANTIEPILEPTIC, REVERSES NMDA/GLYCINE STIMULATED CALCIUM ION INFLUX IN CULTURED RAT HIPPOCAMPAL NEURONS. L.A. TAYLOR*, R.D. McQUADE AND M.A.B. TICE, Schering Plough Research Institute, Kenilworth, NJ 07033.

Felbamate, 2-phenyl-1,3-propanediol dicarbamate, is a novel, orally active anticonvulsant that is reported to exhibit neuroprotectant properties. Felbamate has recently been approved for the treatment of Lennox-Gastaut syndrome and partial onset seizures in the United States and Europe. Although its mechanism of action has yet to be fully elucidated, felbamate appears to inhibit the spread of seizures and to elevate seizure threshold in animal models.

A proposed mechanism of action for felbamate is via the N-methyl-D-aspartate (NMDA) receptor complex. Neurotransmission mediated by the NMDA receptor complex has been shown to be associated with seizures, ischemic neuronal injury, and other neurological disorders. The neutral amino acid glycine, which acts as a co-agonist for the activation of the NMDA receptor channel, is postulated to be involved with seizure disorders and neuroprotection. Previous studies demonstrate the ability of felbamate to inhibit binding at the glycine site on the NMDA receptor.

The present study examined the effects of felbamate on NMDA/glycine-stimulated calcium ion influx in cultured rat hippocampal neurons. The results of these experiments demonstrate that felbamate inhibits NMDA / glycine-stimulated calcium ion influx with a minimal effective concentration of 100 μ M. Dose response studies suggest a concentration-dependent relationship between felbamate and the reversal of calcium ion influx. However, due to limited solubility, an extensive range of concentrations of felbamate could not be studied.

506.11

SELECTIVE ANTAGONISM OF THE ANTICONVULSANT EFFECTS OF FELBAMATE BY GLYCINE. M. Cohen-Williams, D. T. McHugh, A. Barnett and V. L. Coffin*, Schering - Plough Research Institute, Kenilworth, NJ 07033.

Felbamate (2-phenyl-1,3-propanediol dicarbamate) is a novel antiepileptic with a unique structure; however, its mechanism of action is unknown. Felbamate has been shown to bind to strychnine-insensitive glycine sites (McCabe et al., 1993) but thus far, this action has not been linked to its anticonvulsant effects. In the present study the effects of glycine on felbamate's ability to block convulsions was studied in two rodent models: N-methyl-D-aspartate (NMDA)-induced and electroshock-induced convulsions. Briefly, NMDA (0.5nmol/mouse) was injected i.c.v. and mice (CF-1) were observed for 0-30 min for clonic and myoclonic seizures. Electroshock-induced seizures (50 mA, 60 Hz, 0.2 s through corneal electrodes) produced tonic seizures in at least 95% of the mice. The ED50 for felbamate was shifted from 59 mg/kg to 705 mg/kg by pretreatment with glycine (800 mg/kg i.p.), with a potency ratio of 0.08 ($p < 0.05$). An even greater shift was observed for blocking NMDA-induced convulsions. This interaction appears to be unique to felbamate since the ED50's for phenytoin, valproate, carbamazepine and phenobarbital were not increased by glycine. Plans to study newer anticonvulsants are under way. These findings suggest that felbamate blocks the actions of glycine and thus is the first anticonvulsant clinically available that acts by this novel mechanism.

DEGENERATIVE DISEASE: ALZHEIMER'S—BETA AMYLOID VII

507.1

FUNCTIONAL CHARACTERIZATION OF A TRANSCRIPTIONAL REGULATOR OF AMYLOID PRECURSOR PROTEIN GENE M. Grilli*, M. Ribola, B. Bossini, M. Memo and P.F. Spano, Pharmacology Sec., Dept. of Biomed. Sci. & Biotech., University of Brescia, Medical School, Brescia, Italy.

Since several observations underscore the potential contribution of APP gene overexpression or dysregulated expression to Alzheimer's Disease pathogenesis we judged important to elucidate molecular mechanisms of APP gene regulation at the transcriptional level and, as reported previously (Grilli et al. Society for Neuroscience, 1993, 421.8), we have identified a nucleotide sequence we refer to as APPkB in the APP gene regulatory region which specifically binds a protein complex belonging to the NFkB/Rel family of transcription factors. We now report that in transfection studies with constructs in which the APPkB sequence has been linked to a heterologous eukaryotic promoter (herpes simplex virus tk promoter) governing expression of the bacterial CAT reporter gene, this nucleotide region behaves as a transcriptional repressor. The complex able to bind the APPkB sequence, unlike most of the NFkB/Rel family members, is constitutively present in nuclear extracts from various rat brain areas and cell lines we examined. It is feasible that this repressor protein may contribute to maintain low levels of APP gene expression also *in vivo* and that an alteration at any step in this regulatory pathway may result in deregulated expression of the APP gene. Future experiments will be directed to investigate alterations of this pathway in patients affected by Alzheimer's Disease.

AMYLOID PRECURSOR PROTEIN: LOCALIZATION OF mRNA AND PROTEIN ISOFORMS IN RAT OLFACTORY EPITHELIUM AND ALTERATIONS IN EXPRESSION DURING NEURONAL DEGENERATION AND REGENERATION. N. Zaidi and B. Talamo*, Tufts Medical School, Boston, MA 02111.

The major component of the senile plaques in Alzheimer's disease (AD) is β A4 or amyloid protein, which is derived from a larger integral membrane protein, Amyloid Precursor Protein (APP). β A4 is toxic to neurons in culture and may contribute to neurodegeneration in AD. APP is widely distributed in neurons and other cell types, but the role of APP under normal physiological conditions and in AD is not understood. A single APP gene generates various transcripts by alternative splicing in both humans and rodents. APP 695 is the predominant form in rat central nervous system, while APP 751 and 770 forms (containing a Kunitz protease inhibitor (KPI) domain) are abundant in peripheral tissues. Recent studies suggest a role for APP 695 in neuronal differentiation; KPI-containing isoforms have been implicated in neuronal repair, regeneration and synaptogenesis. Olfactory neurons in nasal mucosa turn over throughout life at a slow rate, but accelerated turnover can be achieved by olfactory bulbectomy, thus providing an excellent model for examining the role of APP in neuronal differentiation and repair in adult animals *in vivo*. We have previously used RT-PCR to show that three major APP isoforms are expressed in nasal olfactory tissue at ratios different from those in brain. Western blots confirm that these APP protein isoforms are present in nasal olfactory tissue. *In situ* hybridization with digoxigenin-labeled riboprobes shows that APP mRNA is localized primarily in the neuronal layer of the olfactory epithelium. Immunocytochemical studies using a C-terminally directed APP antibody that recognizes all full length isoforms show that APP is localized both in the neuronal layer of olfactory epithelium, and in nerve bundles. Experiments are in progress to localize APP isoforms by using isoform specific oligonucleotide probes in control olfactory epithelium and during neuronal degeneration and recovery following bulbectomy.

TWO NUCLEAR FACTOR BINDING DOMAINS ACTIVATE TRANSCRIPTION FROM THE HUMAN AMYLOID β -PROTEIN PRECURSOR (APP) PROMOTER. Wolfgang W. Quitschke* and James P. Matthews Department of Psychiatry and Behavioral Science, State University of New York at Stony Brook, Stony Brook, NY 11794-8101.

The promoter of the APP gene was analyzed for its ability to activate transcription in selected cell lines that showed variant levels of endogenous APP transcripts. Transient transfection assays showed that 94 base pairs 5' to the main transcriptional start site are sufficient for high levels of cell-type specific promoter activity.

Two nuclear factors that bind to this region in a sequence specific manner were identified by mobility shift electrophoresis, DNase footprinting, and methylation interference. One of the factors binds to the recognition sequence GGATCAGCTGAC, here designated as APB α . The other binding domain APB β contains the recognition sequence GCCGCTAGGGGT.

The contributions of the binding domains APB α and APB β to the activity of the APP promoter were assessed by introducing block mutations into the respective recognition sequences, which were analyzed by transient transfection. The results suggested that APB β contributes approximately 70-90% and APB α 10-30% to the transcriptional activity from the APP promoter in all cell lines analyzed.

CHANGES IN AMYLOID PRECURSOR PROTEIN AND RNA IN PRIMARY CULTURES OF EMBRYONIC CORTICAL NEURONS UNDERGOING GLUTAMATE-INDUCED NEURODEGENERATION. D. Willoughby*, J. Rozovsky, and C. E. Finch, Andrus Gerontology Center and Department of Biological Sciences, University of Southern California, Los Angeles, CA 90089.

Extracellular deposits of β -amyloid (A β) in disease-affected regions of the brain are a diagnostic feature of Alzheimer's disease (AD). A β is a 39-43 amino acid peptide derived from the amyloid precursor protein (APP). A Kunitz protease inhibitor (KPI) domain is encoded by an alternatively spliced exon of the APP gene. KPI-mRNA may be related to A β deposition or neuronal cell death in the AD brain.

To examine possible relationships between APP RNA alternative splicing and neuronal cell death, we measured alternatively spliced APP-mRNAs in primary cultures of rat embryonic cortical neurons treated with 250 μ M glutamate. By LDH release assay, glutamate-induced cell death was $\leq 20\%$ after 4 hours of glutamate treatment, with variable cell death after 9 hours. Cell death was 45%, after 24 hours of glutamate treatment. KPI-mRNA was increased 2-fold after 6 hours of glutamate treatment, while APP-mRNA lacking KPI was unchanged. Aminophosphovalerate, a NMDA receptor antagonist blocked glutamate-induced increases in KPI-mRNA. Thus, induction of KPI-mRNA was dependent on NMDA-receptor activation.

Recently, it was shown by M. P. Mattson and co-workers that APP protected cultured rat hippocampal neurons from excitotoxin-induced cell death. We measured APP in cell lysates and conditioned media of neurons treated with 250 μ M glutamate. APP was decreased in cell lysates of glutamate treated neurons within 1 hour of glutamate treatment. Cellular APP remained depleted for at least 20 hours following glutamate addition to the cultures. APP was also reduced in conditioned media 4 hours after glutamate addition. These results suggest that sustained glutamate receptor activation results in rapid degradation of APP. Induction of KPI-mRNA may be a compensatory response to glutamate-induced APP depletion in the neuronal cell, supported by AG00093 and AG7909.

ACIDOSIS, NOT HYPOGLYCEMIA, STIMULATES PROCESSING OF BETA-AMYLOID IN CULTURED HIPPOCAMPAL NEURONS, G.J. Brewer* Southern Illinois Univ. Sch. Med., Springfield, IL 62794.

Reductions in cerebral glucose or increases in lactic acid in Alzheimer disease (AD) may signal pathogenic metabolism of the β -amyloid precursor protein (APP). We tested these stressors of cell metabolism on cultured rat embryonic hippocampal neurons. After 4 days of growth in serum-free medium, either lactic acid was added to the medium or the medium was exchanged with a medium containing lower glucose. After 24 hr., whole cells and cell extracts were tested for immunoreactivity with antibodies specific for residues 17-24 of β A4 (4G8) or residues 645-694 near the C-terminus of APP₆₉₅ (369W). Hypoglycemia was found to have no effect on APP synthesis or processing. In contrast, lactic acid stimulated processing of APP. Less APP was secreted into the medium and more was found in the cytoplasm, processed to forms of apparent 21 and 25 kD. These forms were reactive with the antibodies directed against sequences for β A4 and the C-terminus of APP. Acidosis in the brains of the elderly may contribute to processing of APP that is potentially amyloidogenic. Supported by the Illinois Dept. Public Health.

MICROGLIAL PHAGOCYTOSIS OF PRE-AGGREGATED A β 1-42 AFTER INTRA-HIPPOCAMPAL INJECTION IN RATS. S.A. Johnson*, R.L. Bethel and C.E. Finch. Andrus Gerontology Center and Dept. of Biological Sciences, University of Southern California, Los Angeles, CA 90089-0191.

Mature plaques in Alzheimer's disease brain are intimately associated with amoeboid microglia that express surface markers consistent with antigen presentation and phagocytosis. EM studies showed intracellular amyloid fibrils in plaque-associated microglia, yet it is unclear if such intracellular amyloid was phagocytosed or synthesized. Microglia in culture contain detectable APP mRNA, but in situ hybridization of AD cortex or hippocampus did not detect APP mRNA in plaque-associated amoeboid microglia.

Since cultured microglia and fibroblasts accumulate exogenous A β 1-42, we examined the fate of A β 1-42 after intra-hippocampal injection in rats. Synthetic A β 1-42 was aggregated in PBS (1 mg/ml, pH 7.0, 48 h, 25°C) with N-terminal biotinylated A β 1-42 (bio-A β ; gift of Dr. C. Glabe) prior to stereotaxic injection (1 μ l). In pilot experiments, rats were sacrificed at 1 and 5d post-injection. Injected amyloid was visualized by avidin-biotin complex (ABC-HRP/DAB) histochemistry without antibodies, or by double-label histochemistry using nickel/DAB to detect cell-specific antibodies.

We detected intra-cellular bio-A β by ABC only at 5d post-injection. Double-label histochemistry showed bio-A β in Griffonia simplicifolia isolectin B4 positive macrophage/microglia. Combination ICC with anti-GFAP showed no intracellular accumulation of A β in astrocytes, but showed direct contact of astrocyte endfeet on extracellular A β . Numerous bio-A β -containing microglia (macrophage) surrounded the injection site. Some bio-A β -microglia were distant from the main A β 1-42 depot, occasionally surrounding, or even within, blood vessels, suggesting a route for clearance from the brain. This demonstrates microglial phagocytosis of extracellular, aggregated A β 1-42 in rat brain and suggests that microglia also phagocytose extracellular amyloid in the AD brain. Supported by AG10673 (SAJ) and AG07909 (CEF).

AN IN VIVO STUDY ON FACTORS AFFECTING AMINO ACID AND APP RELEASE FROM CORTICOSTRIATAL NEURONES, USING PUSH-PULL AND MICRODIALYSIS TECHNOLOGY.

S. Dijk, P.T. Francis, G.C. Stratmann, M.A. Smith and D.M. Bowen. (SPON: Brain Research Association). Institute of Neurology, Dept. Neurochemistry, 1 Wakefield street, London WC1N 1PJ, U.K.

A maintained inhibition on cortical pyramidal neurones through the 5-HT_{1A}-receptor may contribute to the cognitive symptoms of Alzheimer's disease. In this study in the rat it was investigated whether a selective 5-HT_{1A}-receptor antagonist would enhance the activity of cortical pyramidal neurones, and whether an increased neuronal activity would stimulate secretion of APP. Striatal microdialysis and HPLC was used to assess aspartate and glutamate release as a marker of activity. APP in striatal push pull perfusate was measured with Western blotting, using the N-terminal antibody 22C11. Topical application of the selective 5-HT_{1A}-antagonist (+) WAY 100135 (50 μ M) on the surface of the frontal cortex increased significantly basal glutamate release in the striatum, and potentiated NMDA induced aspartate and glutamate release. Depolarisation of striatal neurones with a potassium challenge through the push pull probe induced an increase in 22C11 immunoreactivity. These results indicate that a selective 5-HT_{1A}-antagonist may be useful in attenuating the cognitive symptoms of Alzheimer's disease. In addition, as an increased secretion of APP may result in less amyloidogenic fragments being produced, an increased neuronal activity may also slow down the progression of the disease. Supported by the Brain Research Trust.

TIME COURSE OF AMYLOID PROTEIN PRECURSOR, APOLIPOPROTEIN E, GLIAL FIBRILLARY ACIDIC PROTEIN, β -AMYLOID ACCUMULATION, AND MICROGLIAL ACTIVATION FOLLOWING A BILATERAL CAROTID OCCLUSION IN THE GERBIL. J.A. Oostveen*, D.B. Carter, E. Dunn and E.D. Hall. CNS Diseases Research, The Upjohn Company, Kalamazoo, MI 49001.

The post-ischemic time course of the expression of amyloid protein precursor (APP), apolipoprotein E (APO-E), glial fibrillary acidic protein (GFAP), and β -amyloid (β -AP), as well as the activation of microglia were examined immunocytochemically in the selectively vulnerable CA1 region of the hippocampus of gerbils subjected to 10 min of bilateral carotid occlusion-induced forebrain ischemia. These markers were compared to the time course of CA1 neuronal necrosis. Loss of 90% of the CA1 neurons occurred between 24 and 72 hrs after ischemia, after which no further neuronal necrosis was observed. At 24 hrs postischemia, there was a decrease in APP, β -AP, APO-E, and GFAP in the CA1 region. Although there was no microglia activation at 24 hrs, by 2 days, activated microglia were observed throughout the hippocampus. This coincided with a dramatic increase in the expression of APP, APO-E and β -amyloid between days 2 and 7. GFAP expression paralleled this increase, which is indicative of an activation of astrocytic protein synthesis. Reactive microglia were also observed in the CA1 region from days 4 to 7. It has been shown that the E₄ isoform of APO-E, when oxidized, avidly binds to β -AP and, thus, increases the likelihood of β -AP deposition. Therefore, it is postulated that the increased expression of amyloid proteins coincident with an increased production of APO-E in response to ischemic neuronal necrosis provides conditions that are favorable for the post-ischemic formation of amyloid deposits. Production of oxygen radicals by activated microglia may enhance the binding of β -amyloid to APO-E.

MICROGLIAL REMOVAL OF AMYLOID β PEPTIDE (A β) IS PREVENTED BY PROTEOGLYCANS. L. M. Shaffer*, M.D. Dority, S.G. Younkin and K.R. Brunden. GliaTech, Inc., Cleveland, OH 44122, and Case Western Reserve Univ., Dept. of Pathology, Cleveland, OH 44106.

In the Alzheimer's Disease (AD) brain, activated microglia are found closely associated with the cores of mature senile plaques. A major constituent of the plaque is A β , a 40-43 amino acid peptide which aggregates to form fibrillar extracellular deposits. We have previously demonstrated that primary cultures of rat microglia and a human monocyte cell line are capable of removing A β under conditions where the fibrillar peptide was in solution or immobilized on a substrate, mimicking a plaque-like structure. There is thus a question of why plaques in the AD brain persist in close proximity to activated microglia. This persistence could result from the association of A β with other plaque components, resulting in inhibition of the microglial removal mechanism. Since proteoglycans are an invariable feature of all amyloidoses and are known to bind A β , they may contribute to plaque formation and persistence by altering microglial processing of A β . We therefore examined whether proteoglycans could prevent removal of A β by rat microglia and the human monocyte line, THP-1. Using thioflavin-T staining to detect immobilized A β before and after treatment, it was found that both cell types showed good adhesion to the peptide substrate and removed the A β in approximately one week. Because astrocytes are a likely source of brain proteoglycans, primary rat astrocytes were grown in culture dishes containing immobilized A β to allow secreted molecules to associate with the peptide. Upon hypo-osmotic removal of the astrocytes and subsequent seeding of microglia or THP-1 cells, the conditioned A β was found to be resistant to breakdown. Direct application of proteoglycan purified from astrocytes onto the A β substrate also resulted in inhibition of microglial processing of the peptide. These data suggest that astrocyte-derived proteoglycans may play a role in the persistence of A β .

507.10

MUSCARINIC CONTROL OF AMYLOID PRECURSOR PROTEIN (APP) PROCESSING IN CULTURED HUMAN NEURONS DERIVED FROM A TERATOCARCINOMA CELL LINE (NT2N). A. M. Werkin¹, B. A. Wolf¹, B. B. Wolfe², Y. M.-Y. Lee¹ * ¹Dept. of Path. and Lab. Med., Univ. of Pennsylvania Med. School, Philadelphia, PA 19104. ²Dept. of Pharmacology, Georgetown Univ. School Med., Washington, D.C. 20007.

It is established in the literature that carbachol, a muscarinic agonist stimulates increased APP secretion in a variety of neural and non-neuronal cell lines transfected to express the M1 and M3 muscarinic receptors. Occupancy of M1 and M3 receptors results in phospholipase C activation via a G-protein. These data have led to the theory that APP metabolism is controlled, at least in part by neurotransmitters, i.e., acetylcholine. We aim to provide evidence for the muscarinic control of APP processing in NT2N cells, which may provide a unique model system for understanding the contributions of neurons to amyloidogenesis. Previously, we have provided evidence that the NT2N cells solely express the 695 amino acid APP isoform and secrete intracellularly produced A β peptides. We now demonstrate that: NT2N cells express similar levels of endogenous M2 and M3 receptors as well as the GTP-binding protein, Gq. Carbachol, an M1 and M3 agonist, induces the activation of phospholipase C in NT2N cells as evidenced by a time-dependent increase in the levels of the second messenger end-products diacylglycerol and inositol triphosphate (IP₃) which peaked at two min. Subsequently, as would be expected from the increased IP₃ levels, carbachol increased intracellular Ca²⁺ levels measured fluorometrically in single NT2N neurons. Carbachol treatment of 30 min causes at least a two-fold increase in the release of APP_s into the conditioned media. Furthermore, preliminary experiments suggest that the level of A β peptides secreted into the conditioned media may be reduced with extended carbachol treatment. We conclude that APP processing in the NT2N human neurons is regulated by the muscarinic receptor / phospholipase C signal transduction pathway.

PKC STIMULATION BUT NOT CHOLINERGIC RECEPTOR STIMULATION INCREASES SECRETION OF THE β -AMYLOID PRECURSOR PROTEIN IN CULTURED RAT CORTICAL NEURONS. J. Mills and P.B. Reiner, Kinsmen Laboratory of Neurological Research, University of British Columbia, Vancouver, B.C., Canada V6T 1Z3

The progressive deposition of the amyloid β -peptide (A β) is an early and invariant feature of Alzheimer's disease pathology. The A β sequence is contained within a much larger membrane-spanning glycoprotein, the β -amyloid precursor protein (BAPP) which can be processed by multiple proteolytic pathways. Conventional secretory processing of BAPP is thought to be nonamyloidogenic, since cleavage occurs within the A β sequence, releasing the soluble ectodomain of BAPP (APP_s). Alternative processing routes are potentially amyloidogenic yielding the A β segment intact.

PKC signal transduction pathways have been implicated in the regulation of APP_s secretion. These data are derived from studies in continuous cell lines. It is not known whether or not this same mechanism of control occurs in central neurons. In the present investigation, we examined whether direct or indirect stimulation of PKC increases the secretion of APP_s in primary cultures of rat cortical neurons. Activation of PKC by the phorbol ester phorbol 12,13-dibutyrate (PDBu) or phorbol 12-myristate 13-acetate (PMA) significantly increased the release of APP_s. In contrast, activation of the PLC/PKC-coupled muscarinic m₁ receptor by oxotremorine-M did not significantly increase basal release of APP_s. Similarly, chemically induced depolarization using 35 mM KCl did not alter APP_s secretion. Our data indicate that although PKC stimulation can alter β -APP processing in central neurons, neuronal activity and cholinergic neurotransmission does not.

507.13

PROCESSING OF THE AMYLOID PRECURSOR PROTEIN WITH THE CODON 670/671 MUTATION IS ALTERED IN THE SECRETORY PATHWAY. R.G. Perez* and E.H. Koo, Brigham and Women's Hospital and Harvard Medical School, Boston, MA 02115.

A mutation at codon 670/671 of BPP (KM \rightarrow NL) from one form of familial Alzheimer's disease results in significantly elevated A β release by an undefined mechanism. Because we have recently demonstrated that A β production and release involves the internalization and recycling of cell surface BPP, we asked whether the codon 670/671 mutation alters BPP processing in this pathway. As expected, A β release was significantly elevated in CHO cells transfected with KM \rightarrow NL mutation (δ NL) as compared to BPP751 (WT) cells. However, the kinetics of A β release was different in δ NL as compared to WT cells such that A β release occurred earlier in δ NL cells. The enhanced release of A β in δ NL cells was correlated with an increase in an intracellular 12 kDa C-terminal BPP fragment. In addition, a lower molecular weight BPP_s species was present intracellularly and released into medium of δ NL cells. By epitope mapping, this shorter BPP_s from δ NL cells is consistent with a "B-secretase" cleaved product. The premature intracellular cleavage of BPP by B-secretase resulted in a 50% reduction of full length BPP sorted to the cell surface. Moreover, A β release was not significantly elevated in δ NL cells after cell surface iodination, demonstrating that although A β generation also occurred after internalization in δ NL cells, processing of BPP was not altered in this pathway. In sum, our studies demonstrated that the KM \rightarrow NL mutation resulted in a selective alteration of BPP processing by B-secretase. More importantly, our results suggest that the early cleavage of BPP at the B-secretase site occurs in a different compartment within the secretory pathway in δ NL cells.

EXPRESSION AND PURIFICATION OF RECOMBINANT SUBSTRATES FOR APP SECRETASES. J.K. Kawooya, T.L. Emmons, D. Zitkus, S. Trusko, D. Lang, R. Scott, R. Siman* and B.D. Greenberg, Cephalon, Inc. 145 Brandywine Pkwy. West Chester, PA 19380

The growing interest in the identification, isolation and inhibition of secretases which generate A β peptides from Alzheimer's amyloid precursor protein (APP) calls for the production of highly purified enzyme substrates. The purified substrates must be soluble, and free of proteolytic contaminants. In this report we describe the recombinant expression and purification of soluble full length APP from the baculovirus insect cell system, and the COOH-terminal 100 amino acid APP segment (C100) from *E. coli* inclusion bodies. Full length APP was extracted from the insect cell membranes with 6M urea, purified by a combination of anion exchange and immobilized nickel affinity chromatography, then refolded in physiological buffer by dialysis. Cells seeded in one liter of conditioned medium yielded 2 mg product at ~98% purity. C100 was extracted from *E. coli* cells that were pre-washed with a mixture of formic acid/acetic acid, solubilized in 8M Guanidine-HCl, and purified by size exclusion chromatography using Guanidine-HCl as the mobile phase. The protein was refolded by dialysis against physiological buffer in the presence of polyethylene glycol. Fifteen mg purified soluble C100 was recovered from one liter of fermentation beer at ~95% purity. Both purified substrates were shown to be devoid of contaminating proteolytic activity, as neither was degraded during extended incubation (4 hours to 7 days) under conditions optimal for activation of the four common classes of mammalian proteases. These purified soluble proteins will be useful tools for studying physiological and pathological functions of APP, and for the identification and characterization of proteases involved in A β peptide formation.

507.12

INVOLVEMENT OF PROTEIN TYROSINE PHOSPHORYLATION IN SECRETORY PROCESSING OF THE AMYLOID PRECURSOR PROTEIN OF ALZHEIMER'S DISEASE. B.E. Slack*, M. A. Petryniak, J. Breu, K. Srivastava, and R.J. Wurtman, Department of Brain and Cognitive Sciences, MIT, Cambridge MA 02139.

Secretory cleavage of the amyloid precursor protein (APP) of Alzheimer's disease (AD) is stimulated by the muscarinic agonist carbachol in human embryonic kidney (HEK) cells expressing human muscarinic m1 or m3 receptor subtypes, but not in cells expressing m2 or m4 receptors (Nitsch et al., Science 258:304,1992). The m1 and m3 subtypes are coupled to phosphatidylinositol (PI) hydrolysis; the m2 and m4 subtypes are not. The effect of carbachol was blocked by the protein kinase inhibitor staurosporine, and mimicked by phorbol esters, which directly activate protein kinase C (PKC), suggesting that PKC regulates APP processing. However, a more selective PKC inhibitor, GF 109203X, completely blocked the response to phorbol esters, but only partially inhibited (by 30%) the increase in the release of soluble derivatives of APP (APP_s) elicited by carbachol. Since staurosporine also inhibits protein tyrosine kinases, we investigated the involvement of tyrosine phosphorylation in the regulation of APP_s release. Carbachol increased tyrosine phosphorylation of a number of proteins in HEK cells, and this effect, like APP_s release and PI turnover, was preferentially coupled to m1 and m3 receptors. Moreover, an inhibitor of protein tyrosine phosphatase (vanadyl hydroperoxide) stimulated APP_s release, while tyrosine kinase inhibitors reduced the effects of carbachol and vanadyl hydroperoxide on APP_s release. The results suggest that both PKC and protein tyrosine phosphorylation contribute to the stimulation of APP processing by muscarinic receptor activation. (Grant #MH-28783 of NIMH)

CATHEPSIN S: AN A β GENERATING/ DEGRADING ENZYME ? S. Petanceska and L. A. Devi*, Dept. of Pharmacology, NYU Medical Center, NY 10016

Cathepsin S is a cysteine lysosomal protease resistant to neutral pH. Our studies in rat brain as well as peripheral tissues have shown that it is preferentially expressed in cells from the mononuclear phagocytic lineage. Of all cell lines tested so far cathepsin S transcript could be detected only in monocytic leukemia cell lines.

Studies of entorhinal cortex lesions in rat brain have shown an upregulated expression of cathepsin S in activated versus resting microglia, suggestive of an important role for this protease in processes of neuronal degeneration and regeneration.

We have studied the changes in the level of cathepsin S transcripts that occur upon differentiation of the HL 60 leukemia cell line. The possibility of cathepsin S to be secreted in the media of normal leukemia cells, differentiated leukemia cells as well as macrophages challenged with inflammatory agents was also assessed.

Cysteine lysosomal proteases have been implicated to take part in the metabolism of the Amyloid Precursor Protein (APP). The fact that cathepsin S is expressed in microglia in brain, a cell type pertinent to the pathology of Alzheimer's and other neurodegenerative diseases, its resistance to neutral pH and its substrate specificity (preference for small neutral amino acids N-terminal to the cleavage bond), make cathepsin S a strong candidate for a protease involved in the generation of the A β peptide from the APP. On the other hand, other research groups have shown that secreted media from microglia are able to cleave soluble and aggregated A β peptide.

Here we present the processing pattern obtained by *in vitro* proteolysis of the wild type and mutant variants (Swedish and Dutch) of the holo APP by cathepsin S. The ability of cathepsin S to degrade soluble and/or aggregated A β peptide is also addressed. Supported by NS26880 (L. D.)

THE LOCALIZATION AND INTERNALIZATION OF CELL SURFACE BAPP IN CULTURED NEURONS. T. Yamazaki, D.J. Selkoe and E.H. Koo*, Brigham and Women's Hospital and Harvard Medical School, Boston MA 02115.

At the cell surface, the β -amyloid precursor protein (BAPP) may be released after cleavage by α -secretase or internalized without cleavage. Recent evidence suggests that the latter pathway may be important in the constitutive production and release of amyloid β -protein. Using monoclonal antibodies that recognize the extracellular domain of BAPP, we previously demonstrated that cell surface BAPP in CHO cells is internalized via coated pits and targeted to lysosomes. In this study, we demonstrate that in primary rat hippocampal neurons, a population of full length BAPP is similarly located on the cell surface and subsequently endocytosed. BAPP was present on the cell surface of neurons cultured at low density shortly after plating (Banker Stage 1). Immature neurons (Stage 3) showed punctate BAPP immunostaining on the soma. On axons and minor neurites, BAPP staining was distributed in a distinctly segmental pattern. In mature neurons (Stage 5), the pattern remained discontinuous and was located principally on axons. BAPP immunoreactivity was colocalized with α 1, α 5, and B1 integrins, but not with NCAM, synaptophysin, transferrin receptor or clathrin. In immature neurons, internalized BAPP was located in a compartment which contained fluid-phase endocytic markers. This staining pattern was coarsely granular and was located both in the perikaryon and neuritic processes. In mature neurons, internalized BAPP was located principally in axons and soma. To demonstrate endocytosis of BAPP from axonal surface, dissociated sympathetic neurons were grown in compartment (Campenot) cultures. Using this system, BAPP was clearly internalized from the cell surface of distal axonal sites and retrogradely transported to the neuronal soma. In summary, these studies in primary neuronal cultures show that 1) in early stages, cell surface BAPP was not distributed in a polarized manner, 2) in mature cultures, surface BAPP was localized predominantly in the axonal rather than somatodendritic compartment (Haass, 1994), 3) BAPP showed a tight association with integrins, a result consistent with its putative role in adhesion, and 4) full-length BAPP is retrogradely transported from the surface of distal axonal sites to the cell body.

PROCESSING OF ALZHEIMER'S β -AMYLOID PRECURSOR PROTEIN IN C6 GLIOMA CELLS. E. Morato², L. López-Mascaraque¹ and E. Mayor², Jr. ¹Instituto Cajal, 28002 Madrid and ²Centro de Biología Molecular "Severo Ochoa" (CSIC-UAM). Universidad Autónoma, 28049 Madrid, Spain.

The major neuropathological characteristic of Alzheimer's disease is the deposition in the brain of insoluble aggregates of β -amyloid peptide (β A4), a small (39-43 residues) fragment contained within a family of large glycoproteins, the β -amyloid precursor proteins (BAPP). The understanding of the intracellular processing of BAPP in nervous cells and of the pathways leading to β A4 generation are essential issues to be addressed. In this context, we have investigated the subcellular location and processing of BAPP in an experimental model of glial cells in culture (C6 rat glioma cells), by using several affinity-purified antipeptide antibodies raised in our laboratory against different domains of both the β A4 peptide and BAPP. Antibodies raised against the N and C-terminal regions of the β A4 peptide can detect the presence of a soluble 4 kDa peptide in the conditioned medium of C6 glioma cells (Morato & Mayor, (1993) FEBS Letters 336, 275-278), in line with recent reports in other cell types. Consistent with this observation, normal α -secretase activity appears to be low in C6 glioma cells, whereas large soluble BAPP derivatives containing the C-terminal portion of the β A4 molecule are detected in the conditioned medium. Immunofluorescence studies show a preferential intracellular location of BAPP antigens, and a rapid reinternalization of plasma membrane BAPP, which accumulates in endosomes/lysosomes in the presence of inhibitors of lysosomal proteases. Our results confirm a distinct processing of BAPP in glial cells, and further suggest that glial cells may prove a major source of β -amyloid production in the nervous tissue. Cultured glial cells may be an important experimental tool in investigating the modulation of the cellular pathways involved in β A4 generation and its possible alteration in pathological circumstances. Supported by CAM C105/91, Boehringer Ingelheim and Fundación Ramon Areces.

BACTERIAL EXPRESSION, PURIFICATION OF FULL LENGTH AND CARBOXYL TERMINAL FRAGMENT OF ALZHEIMER AMYLOID PRECURSOR PROTEIN AND THEIR PROTEOLYTIC PROCESSING BY THROMBIN. Y.H. Chong, W. Choi, S.H. Kim, K.S. Min, Lyhna Hong, C.W. Park, and Y.H. Suh^{*}. Dept. of Pharmacology, Coll. of Med. and Neurosci. Res. Center, Seoul National Univ., Seoul 110-799, Korea.

Human amyloid protein precursor (APP770) and its carboxyl terminal portion (CT105) including β A4 domain were highly expressed using strong expression systems in *E. coli*. These recombinant APP peptides were purified with a combination of urea solubilization and ion-exchange chromatography and used for proteolytic processing by thrombin. Three thrombin cleavage sites were predicted by the decrease of APP770 and the appearance of Mr 56, 27 and 18 kDa fragments containing β A4 domain on SDS-PAGE gel and on the immunoblot. A similar but limited proteolysis of platelet APPs exposed to thrombin resulted in the stimulated production of 60 and 27 kDa carboxyl terminal peptides containing the intact β A4. This thrombin mediated proteolysis was completely blocked by hirudin, the specific thrombin inhibitor. These results suggest that thrombin may play a role in altered processing of APP to generate potentially amyloidogenic intermediates *in vivo* leading to amyloid deposition.

APP EXPRESSION IN THE CELL LINE NTERA2. R.E.B. Watson, P.R. Heath, P.W. Andrews and R.C.A. Pearson^{*}. Department of Biomedical Science, The University of Sheffield, Western Bank, Sheffield S10 2TN, UK.

The cell line NTERA 2 is a useful tool for studying the mechanisms of protein processing with relevance to human neurodegenerative disease (Andrews, 1984; Wertkin *et al.*, 1993) particularly the differential expression of the mRNAs encoding for Amyloid Precursor Protein (APP) isoforms. Previous work (Ackerman *et al.*, Mol. Brain Res., in press) has shown using cDNA libraries that APP₆₉₅ and APP₇₇₀ are present in undifferentiated and differentiated cell libraries. APP₇₅₁ was observed in libraries from differentiated, neuron-like cells only.

The study used *in situ* hybridization histochemistry to examine the occurrence of APP mRNA transcripts and Western blotting to examine the protein isoforms produced. Oligonucleotide probes were produced corresponding to regions encoding the β A4 sequence (β A4; 30mer), to a sequence specific to APP₆₉₅ (APP₆₉₅; 30mer), to exon 8 (APP₇₇₀; 57mer) and to 30 bases on each side of this region (APP₇₅₁; 60mer). Cell lysates from undifferentiated (NT2D1), 14 day treatment with Retinoic Acid (RA; 14dRA), 28 day treatment with RA (28dRA) and mature neurons were separated on a 7.5% acrylamide gel, transferred to nitrocellulose and probed with the antibody 22C11 (Boehringer Mannheim).

APP₆₉₅ mRNA was shown to increase through differentiation with RA. Expression of APP₇₇₀ decreased with time in RA whilst expression of APP₇₅₁ increased to be maximal in the differentiated neuron-like cells. β A4-containing mRNA was observable throughout differentiation. On Western analysis, one band of molecular weight (mw) 117kDa was present at all times, although the density of immunostaining increased with neuronal differentiation; this band probably represents APP₆₉₅. A second band of mw 132kDa was present in protein extracted from mature neurons and also visible from extracts of 28dRA. It was not present in NT2D1. Stem cells and 14dRA showed an immunostained band at 112kDa. This was present but faint in 28dRA and was not seen in extracts from mature neurons. Both the 112 and 132kDa band probably represent KPI-containing isoforms of APP. By correlation with the *in situ* data we propose that the 112kDa product represents APP₇₇₀ and the 132kDa product APP₇₅₁. This study confirms the value of this culture system in the understanding of the processing of APP.

NEURONS DERIVED FROM A HUMAN TERATOCARCINOMA CELL LINE GENERATE INTRACELLULAR β PRIOR TO ITS SECRETION INTO CONDITIONED MEDIUM. R.S. Turner¹ and V.M.-Y. Lee², Depts. of ¹Neurology and ²Pathology and Laboratory Medicine, Univ. of Pennsylvania School of Medicine, Philadelphia, PA 19104-4283.

Alzheimer's disease (AD) brain is characterized pathologically by neuronal and synaptic loss, neurofibrillary tangles which consist primarily of the microtubule-associated protein tau, and amyloid plaques which consist primarily of a 4-kDa peptide (β) derived from one or more of at least three alternatively spliced amyloid precursor proteins (APP). We examined the kinetics and intracellular localization of APP metabolism in cultured neurons derived from a human teratocarcinoma cell line (NT2). These neurons constitutively secrete a 95-kDa secretase fragment of APP (APPs) and β . Metabolic labeling of NT2 neurons with [³⁵S]methionine followed by immunoprecipitation of APP, APPs and β from cell lysates and conditioned medium revealed that β was first recovered from cell lysates and, after an approximate 2 hour delay, from conditioned medium. In addition, cellular β plateaued after 8 hours while β in conditioned medium continued to increase. This suggests that β is first generated intracellularly soon after APP synthesis and then secreted into medium. In the presence of 10 μ g/ml Brefeldin A, cellular APP accumulated with no evidence of its metabolism, thus precluding the secretion of APP fragments into medium. Ammonium chloride (10 mM) decreased the recovery of β in medium, suggesting that an acidic intracellular compartment is required for its generation and secretion. Collectively, these data suggest that β is synthesized within the distal Golgi or endosomal/lysosomal compartment of NT2 neurons. Since a considerable fraction of APP is metabolized to β and secreted, NT2 neurons may serve as a unique model system of APP metabolism and β synthesis, thus providing insights into the molecular basis of amyloid formation in AD brain.

EXPERIMENTAL CHLOROQUINE MYOPATHY IN RATS -MODEL FOR APP PROCESSING-

K. Tsuzuki,¹ R. Fukatsu,^{2*} Y. Takamaru,³ K. Kimura,¹ N. Fujii,¹ and N. Takahata².

¹Dept. of Microbiology, ²Dept. of Neuropsychiatry, Sapporo Medical University, ³Dept. of Psychiatry, Hokkaido University, Sapporo 060, Japan.

Deposition of β A4 protein is most characteristic pathological change in Alzheimer's disease. There have been no good models for studying β A4 production. Chloroquine, a potent lysosomotropic agent, induces muscle pathology in experimental animals similar to human rimmed vacuole (RV) myopathy, in which β A4 deposition was observed. In this study, we present morphological, immunopathological, and biochemical data in regard to APP processing in this experimental model.

Innervated and denervated soleus muscle from chloroquine treated and untreated WKA rats were studied. Atrophy of muscle fibers, numerous dense granule bodies, and vacuoles were seen in denervated soleus muscle of chloroquine treated rats. Progressive destruction of muscle, and proliferation of connective tissue were present. Dense granular bodies, or cytoplasm were stained with anti cathepsin D, and several anti APP antibodies. Western blot analysis showed that 49, 50 kDa bands and 20 kDa band were detected in buffer soluble, and detergent soluble fractions with anti β 9-25, and anti C terminus antibodies respectively in chloroquine treated rats.

This experimental model seems to be useful for study of APP processing. And present data suggests lysosomal pathway is involved in β protein production.

507.22

IRON LEVELS MODULATE α -SECRETASE CLEAVAGE OF AMYLOID PRECURSOR PROTEIN. S. Bodovitz^{*}, M. Falduto, D.E. Frail, and W.L. Klein. Dept. of Neurobiology and Physiology, Northwestern University, Evanston, IL 60208

The amyloid precursor protein (APP) is a membrane-spanning glycoprotein that is the source of β A4 peptides which aggregate in Alzheimer's disease to form senile plaques. APP is cleaved within the β A4 sequence to release a soluble N-terminal derivative (APP_N) which has a wide range of trophic and protective functions. In the current paper, we have examined the hypothesis that iron availability may modulate expression or processing of APP, whose mRNA contains, based on sequence homology, a consensus Iron Response Element (IRE). Radiolabeled APP and its catabolites were precipitated from lysates and conditioned medium of stably transfected HEK 293 cells using antibodies selective for C-terminal, β A4, and N-terminal domains. Relative abundance of the different APP catabolites under different conditions of iron availability was determined by quantitative densitometry after separation by SDS-PAGE. Data show a specific effect on the production of APP_N. Using standard conditions previously established for IRE studies, it was found that iron chelation reduces APP_N production, while iron elevation augments it. No changes were observed in levels of immature and mature APP holoprotein, nor in C83, β A4, and p3 peptides. The specificity for modulatory changes in APP_N suggests that iron acts at the level of secretase activity. In addition to its modulatory effects, iron at very high levels was found to inhibit maturation of APP and production of its down-stream catabolites without blocking formation of immature APP. The data establish a potential physiological role for iron in controlling the processing of APP. If APP_N were to function trophically, as suggested by other studies, the current conclusion would suggest that changes in iron and iron-regulating proteins in Alzheimer's disease could contribute to neuronal degeneration by decreasing the production of APP_N.

507.23

IRON AND ALUMINUM EFFECT AMYLOID EXPRESSION. J. Hu and J. R. Connor². Dept. of Neuroscience & Anatomy, Penn State University, College of Medicine Hershey PA 17033

Iron is consistently found in abundance in cells surrounding neuritic plaques. The robust expression of transferrin receptors on these cells suggests that iron uptake is high and on-going in the plaque vicinity raising the possibility that iron is involved in plaque formation. Aluminum is also a consistent component of neuritic plaques. This study was undertaken to test the hypothesis that iron and aluminum exposure will affect amyloid accumulation by cells. Two human cell lines were studied: SK-N-SH (neuroblastoma) and SW-1088 (astrocytoma). The cells were grown to subconfluence in DMEM medium supplemented with 10% FCS. For experimental manipulation, the cells were exposed to serum free DMEM containing 100uM FeCl₃ or 100uM AlCl₃ for 2,3 or 4d. The experimental medium was changed after 2 days. Both iron and aluminum increase intracellular and secreted APP. In addition, following iron exposure, an increase in a truncated form of APP was seen using Western blot analysis. These observations were specific to the astrocytoma cell line. No change was observed in the neuroblastoma. The metals had minimal somewhat transient effects on expression of APP mRNA in the astrocytoma. A modest decrease in expression within the first two days of exposure was followed by a return to normal. In the neuroblastoma, APP mRNA levels are initially very low and these increase in response to metal exposure after 3 days. These data demonstrate that APP levels in cells are affected following exposure to metals but that cell response is specific. The data further suggest that the effect of metals on APP is at the level of posttranslation.

DEGENERATIVE DISEASE: ALZHEIMER'S—BETA AMYLOID VIII

508.1

CEREBRAL AMYLOID ANGIOPATHY IS ASSOCIATED WITH CORTICAL NEURONAL LOSS. C. Zarow¹, S.A. Lyness, H. Chui. Department of Neurology, University of Southern California, Rancho Los Amigos Medical Center, Downey, CA 90242. The deposition of β -amyloid in cerebral blood vessels (so-called cerebral amyloid angiopathy (CAA)) is a frequent finding in Alzheimer disease (AD). An association between CAA and cerebral hemorrhage and infarction is well-recognized, but potential ongoing effects of CAA on neuronal survival are unknown. We examined the relationship between the severity of CAA and numbers of neurons in five neocortical areas and entorhinal cortex in 103 neuropathologically-confirmed cases of AD. CAA was rated on a semi-quantitative scale (0 to 3) in thioflavin S-stained leptomeningeal and cortical vessels. Neurons, neurofibrillary tangles, and senile plaques were counted in complete cortical columns in semi-adjacent sections stained with cresyl-violet or Bielschowsky silver method. Some degree of CAA was found in at least one region in 82% (84/103) of cases. Severe CAA (grade 3 in at least one region) was found in 29% (30/103) of cases. Severity ratings for leptomeningeal and cortical CAA were highly correlated. Furthermore, inverse correlations were found between the severity of cortical CAA and neuronal number in area 22 ($r = -0.22$, $p = .045$) and the severity of leptomeningeal CAA and neurons in area 9 ($r = -0.21$, $p = .006$). The relationship between CAA, neurofibrillary tangles, senile plaques, and age at symptom onset and neuronal number was further examined using multiple regression analyses in each anatomical region. Again, cortical CAA in area 22 ($p = 0.007$) and leptomeningeal CAA in area 9 ($p = 0.02$) were significant predictors of neuronal loss. We hypothesize that CAA may compromise blood flow and the delivery of essential nutrients to neurons; alternatively, β -amyloid may exert a direct neurotoxic effect. (NIH 2P50AG05142 and AG07624)

HISTOLOGICAL AND BEHAVIORAL EFFECTS OF INTRAHIPPOCAMPAL INJECTIONS OF A β (1-42) IN THE MALE RAT. T. Giordano^{2*}, W.A. Dorman¹, A. W. Bannon², N.W. Kowall², A.R.V. McCampbell¹, A.R. Peterson¹, G.P. Tinkler¹. ¹Dept. of Psychology, Illinois Wesleyan Univ, Bloomington, IL 61701, ²Neuroscience Dept., Abbott Laboratories, Abbott Park, IL 60064, ³Geriatric Res Educ Clin Ctr, Veterans Admin Med Ctr, Bedford MA 01730.

Alzheimer's disease is characterized by the extracellular deposition in the brain of insoluble aggregates of the amyloid β peptide (A β). Evidence from several laboratories have demonstrated the neurotoxicity of A β *in vitro*, and *in vivo*. Very few studies, however, have examined the behavioral effects of A β when injected into the rat brain. In a series of experiments, a comparative histological and behavioral assessment were conducted following injections of A β (1-42) into the hippocampus and medial septum of male rats. Experiment 1: animals received bilateral injections into the hippocampus of 3.5 nmol/.5 μ L of either A β (1-42), A β (1-42) in a scrambled form, or DMSO. In experiment 2, animals were injected bilaterally into the medial septum with 3.5 nmol with A β (1-42), the scrambled sequence or DMSO. In experiment 1, animals were tested on a radial arm maze. In experiment 2 animals were tested following intra septal injections of A β (1-42) using the Morris Water Maze. Following the behavioral tests, animals were sacrificed and analyzed for ChAT activity in the hippocampus either 7 or 14 days following injections. In experiment 3, another group of animals were injected with 3.5 nmol A β (1-42) into the medial septum or hippocampus. Following a two week survival period, animals were sacrificed and their brains were processed for immunocytochemistry using the ALZ-50 antibody. Our preliminary results indicate that bilateral injections of A β (1-42) into the hippocampus or medial septum had no significant effect on spatial learning in the male rat. Additionally, no significant differences were found in ChAT activity in the hippocampus following injections of A β into the septum at 7d (controls = 15.877 ± 0.371 pmol/min/ μ g ptn; A β = 15.65 ± 0.78 pmol/min/ μ g ptn) or at 14 d. The histological study is in progress, and the results of this study will be also presented at this conference.

IN VIVO EFFECTS OF THE AMYLOID β PROTEIN IN THE RAT BRAIN. T. Duong^{*}, P.J. Acton and B. Ghetti. Indiana Univ. Sch. of Med., Terre Haute Center, Terre Haute, IN 47809 and Indiana Alzheimer Disease Center, Indianapolis, IN 46202.

The specific aim of this study was to compare the long-term *in vivo* effects of senile plaque cores (SPC) or synthetic amyloid β peptide (A β) in the rodent brain at 2 different ages. SPC-enriched pellets were isolated from the temporal cortex of Alzheimer brains. Synthetic A β (1-40) was purchased from Bachem, Philadelphia, PA., dissolved in phosphate buffered saline at a concentration of 50 μ M and incubated at 37°C for 48 hrs prior to use. Pressure injections were performed in the cortex of young (6 months) and old (20 months) male Fischer 344 rats and the animals were allowed to survive 1 or 3 months. At the end of the survival periods, the rats were euthanized and perfused. The brains were removed and processed for histology and immunohistochemistry. Hyperplasia and hypertrophy of astrocytes surrounding the injection site were observed at up to 3 months in all cases. The injection sites were clearly seen at 1 and 3 months due to cavitation and deposition of the injected SPC or A β . These deposits were strongly immunoreactive to A β antiserum at 1 month but were less so at 3 months. ALZ50 immunoreactivity, which is indicative of abnormal cytoskeletal changes, was seen at and around the injection site at 1 month but was substantially decreased at 3 months. No major difference was seen between the use of SPC or A β , or between young or old animals. Thus, over a long survival period, acute *in vivo* injection of SPC or A β in the rat brain results in clearance of the injected deposits and attenuation of abnormal cytoskeletal changes. Supported by grant #P30AG10133.

COMPARISON OF THE EFFECTS OF INTRAHIPPOCAMPAL INJECTIONS OF A β (1-42) IN COMBINATION WITH GLUCOCORTICOIDS AND IBOTENIC ACID ON THE ACQUISITION AND RETENTION OF A SPATIAL TASK IN MALE RATS. W.A. Dorman^{1*}, T. Giordano², A.R.V. McCampbell¹, H.K. Wijeweera¹, J.S. Pequette¹, L.L. Chapman¹, S.M. Bond¹, A.R. Peterson¹, L.J. Hickman¹. ¹Dept. of Psychology, Illinois Wesleyan Univ, Bloomington, IL 61701, ²Neuroscience Research, Abbott Laboratories, Abbott Park, IL 60064.

Alzheimer's disease is characterized by the extracellular deposition in the brain of insoluble aggregates of the amyloid β peptide (A β), a 39-43 amino acid peptide. Although the cause of neuronal degeneration in AD remains unclear, one major focus is on the role of A β . Evidence from several laboratories have repeatedly demonstrated the neurotoxicity of A β *in vitro*, however, other investigators have reported little direct neurotoxicity, but rather an increase in the vulnerability of neurons to EAAs. Furthermore, very few studies have examined the behavioral effects of A β when injected into the rat brain. In a series of experiments, we assessed the effects of bilateral injections of A β (1-42) 3.5nmol/.5 μ L into the hippocampus on both acquisition and retention of a spatial task in the male rat. In experiment 1, intact or adrenalectomized animals were injected with either A β (1-42) or a scrambled sequence of A β with either daily injections of 7mg/1mL corticosterone at a concentration previously reported to induce artificial stress levels or sesame oil (controls). In experiment 2, animals were injected with either ibotenic acid (3nmol/ μ L), ibotenic acid and A β (1-42) in a scrambled sequence; or IBO in combination with A β (1-42). Animals in experiments 1 and 2 all animals were pre-trained on a radial arm maze task with 5 of 8 arms baited. In group 1, half of the animals were pre-trained, the other half were tested for acquisition. After surgery the animals were tested for two weeks with the configuration conserved. Animals were tested for another week with the new configuration. A variety of behavioral parameters were measured using the radial arm maze. Our preliminary results indicate that there is a clear disruption of learning performance in animals that received A β (1-42) in combination with corticosterone.

508.5

INTRAHIPPOCAMPAL BETA-AMYLOID 25-35 ATTENUATES RETENTION OF ONE-TRIAL/DAY REWARD LEARNING 4 WEEKS LATER. D.H. Malin, P.G. Negrete, B.J. Tomic, R.E. Plotner, M.K. Crothers, S.A. Garcia, R.M. Greenwood, S. Jordan and J.R. Lake. University of Houston-Clear Lake, Houston, TX 77058.

It has been suggested that the complete neurotoxic activity of BAP 1-40 may be contained in the fragment BAP 25-35. In a previous study from this laboratory, multiple intrahippocampal injections of BAP 25-35 impaired retention of one-trial reward learning 2 weeks later. The present study investigated whether similar injections would cause such severe, long-lasting degenerative changes that the task could not be retained, even if training began 4 weeks afterward. The task employed is sensitive to aging and to modulation of cholinergic mechanisms. The subjects were 39 male rats, 3-4 months old. They received 7 hippocampal injections of 6 nmol BAP 25-35 (n=21) or distilled water alone (n=18), bilaterally. After recovery and deprivation to 82% of initial weight, they received an initial training trial 28 days post-injection, and 3 subsequent daily retention trials. The apparatus was a sunburst maze with 4 level alleys and 1 baited ascending alley with a grid floor. Rats were scored for errors (entrances into unbaited alleys). Each rat's retention score was its decrease in errors relative to the baseline trial. The control rats steadily reduced their errors from day to day, while the BAP-treated rats showed little improvement. Tukey's HSD procedure revealed significant, $p < .01$, differences between treatment groups on the last 2 retention trials.

508.7

EVALUATION OF SPATIAL LEARNING IN RATS RECEIVING β -AMYLOID INFUSION. B.A. Tate, M. Rojas, R.E. Majocha and C.A. Marotta. Dept. of Psychiatry and Human Behavior, Miriam Hospital and Dept. of Neuroscience, Brown University, Providence, RI 02906.

A chronic intraventricular β -amyloid infusion paradigm was used to induce cognitive and memory deficits. During infusions of either β -amyloid peptide (1-40) or glucose vehicle, adult male rats were tested in a spatial memory task. Animals were required to locate a hidden platform to escape from a pool of water. Early in testing, the amyloid infused rats had significantly longer latencies to escape than glucose infused rats, but eventually reached latencies equal to control animals. After four days of testing, the platform was removed and the amount of time spent in each quadrant of the pool was measured. Only the glucose-infused animals spent significantly more time in the quadrant that previously contained the platform. Therefore, amyloid-infused rats showed subtle memory deficits. When animals were sacrificed, immunostaining of the brains revealed β -amyloid-positive deposits and significant gliosis in the brains of amyloid-infused rats.

CHARACTERIZATION OF IMMEDIATE EARLY GENE INDUCTION BY $A\beta$ IN CULTURED NEURONS. A.J. Anderson, C.J. Pike and C.W. Cotman. IRU in Brain Aging, Department of Psychobiology, University of California Irvine, Irvine, CA 92717-4550.

The protein products of the Jun and Fos immediate early gene (IEG) families are cooperative transcriptional regulatory factors which act as cellular 'third messengers' and have been implicated in regulating the expression of many genes, including the amyloid precursor protein (APP). We have previously demonstrated that immunoreactivity for Jun- and Fos-related proteins is increased in AD tissue and associated with neuronal pathology (Exp. Neurol. 125: 286-295), that these proteins are induced by $A\beta$ in cultured hippocampal neurons, and that Jun proteins are not induced in cells that are resistant to $A\beta$ -mediated cell death (submitted). Several of these genes have been implicated in the control of apoptosis in other systems. As a result, we have suggested that the expression of some IEGs (e.g. one or more of the Jun proteins) may be related to or participate in $A\beta$ -induced apoptosis, and that the expression of these genes may be an early event in AD pathology. Immunostaining with an antibody that recognizes a variety of Jun proteins indicates that $A\beta$ induces a sustained increase in Jun proteins in culture, whereas other agents which induce IEGs such as phorbol esters produce a more typical and transient elevation in Jun protein expression. More specific antibodies reveal a similar pattern of $A\beta$ -induced c-Jun immunoreactivity, but do not provide evidence for the induction of JunB in response to $A\beta$. These data suggest some specificity in the cellular response to $A\beta$, which should be apparent in the regulation of these genes at the mRNA level.

508.6

EFFECTS OF INCUBATED AND NON-INCUBATED INTRAHIPPOCAMPAL BETA-AMYLOID 25-35 ON RETENTION OF ONE-TRIAL/DAY REWARD LEARNING. P.G. Negrete, M.K. Crothers, J.R. Lake, R.E. Plotner, B.J. Tomic, S.A. Garcia, S.H. Spell, K.K. Roberts and D.H. Malin. Univ. of Houston-Clear Lake, Houston TX 77058.

It has been suggested that the complete neurotoxic activity of BAP 1-40 may be contained in the fragment BAP 25-35 and that pre-incubation of amyloid peptides may increase their aggregation and neurotoxicity. Previously, multiple intrahippocampal injection of BAP 1-40 impaired retention of learning that occurred 2 weeks later. In this study, 3-4 month-old rats received 7 hippocampal injections per side of 6 nmol BAP 25-35 (n=14) incubated for 24 hrs at 37°C or non-incubated BAP 25-35 (n=14) or distilled water alone (n=33). After deprivation to 82% of initial weight, they received an initial training trial 14 days post-injection, and 3 subsequent daily retention trials. The apparatus was a sunburst maze with 4 level alleys and 1 baited ascending alley with a grid floor. Each rat's retention score was its decrease in errors (unbaited alleys entered) from the baseline trial. Retention scores, averaged across 3 trials were 5.4±1.4 (S±SEM) for the control group, 1.7±0.6 for the incubated BAP group and -1.4±1.8 for the non-incubated BAP group. ANOVA indicated a significant, $p < .05$, drug effect and post-hoc analysis (Tukey's HSD) indicated that only the non-incubated BAP group was significantly different, $p < .01$, from controls. One-sample t-tests indicated significant retention in all groups except non-incubated BAP.

508.8

INFLUENCE OF AMYLOID PRECURSOR PROTEIN ON TROPHIC RESPONSE OF PC12 CELLS TO NERVE GROWTH FACTOR. R.E. Majocha, S. Agrawal, E. Humke, J. Tang and C.A. Marotta. Depts. of Psychiatry & Human Behavior and Neuroscience, Brown U. and Miriam Hospital, Providence, RI, 02912; and, Hybridon, Inc., Worcester, MA, 01605.

The relationship between NGF and the amyloid precursor protein (APP) is of interest with respect to the therapeutic potential of growth factors applied to Alzheimer's Disease. Changes in APP levels and distribution in PC12 cells treated with NGF have been reported. To explore the relationship between APP and NGF we applied antisense oligonucleotides (AO), containing a phosphorothioate backbone, complementary to the 5' end region of APP mRNA, to stimulated and unstimulated PC12 cells. APP AO significantly reduced the level of APP compared to an unrelated AO. Maintaining APP AO in cultures (2 μ M, 48hr.) both prior to and during NGF addition inhibited stimulation of cell size and neurite extension, as compared with controls. Since reduction of APP levels by AO reduced the response of PC12 cells to NGF, APP may be a modulating element of the trophic factor cascade.

508.10

EFFECTS OF α_1 -ANTICHYMOTRYPSIN ON THE TOXICITY OF β -AMYLOID FRAGMENT 25-40 IN RAT PRIMARY CULTURED NEURONS. N. NISHIYAMA, T. KOBAYASHI AND H. SAITO. Dept. of Chem. Pharmacol., Fac. of Pharmaceut. Sci., The Univ. of Tokyo, Tokyo 113, JAPAN.

β -Amyloid is the main component of senile plaques. Neurotoxic effects of β -amyloid peptide has been suggested to be involved in the pathogenesis of Alzheimer's disease (AD). We used a novel synthetic peptide β_{25-40} , corresponding to β -amyloid residues 25-40 which contained presumable toxic domain, to test its effect on neuronal cells. α_1 -Antichymotrypsin (ACT), a serine protease inhibitor, colocalizes with amyloid deposits. ACT might contribute to the development of amyloid deposits and pathogenesis of AD through its protease inhibitory activity. We investigated the combination effects of ACT and a novel β_{25-40} on rat primary cultured neurons. Single cell suspensions of hippocampus and cerebral cortex were prepared from fetal rat brain, and plated at either high (1×10^5 cells/cm²) or low (5×10^3 cells/cm²) cell density. Desired concentrations of drugs were applied in chemically defined medium. The cells were visualized by cresyl violet staining or MAP2 immunohistochemistry. In some cases, cell viability was evaluated by MTT assay. Although ACT (0.1-10 μ g/ml) did not affect the neuronal survival in high density culture, it decreased the number of surviving neurons concentration dependently. β_{25-40} (0.3-30 μ M) significantly reduced cell viability in both high and low density cultures. Combination of ACT (10 μ g/ml) with β_{25-40} did not alter the toxicity of β_{25-40} in high and low density culture (F-value = 2.22 and 0.61, respectively). These results suggested that both ACT and β_{25-40} were neurotoxic but that there was no synergistic interaction between them.

508.11

HEPARAN SULFATE GLYCOSAMINOGLYCAN ATTENUATES NEURODEGENERATION INDUCED BY β -AMYLOID 25-35 BUT NOT β -AMYLOID 1-42 A.G. Woods*, D.H. Cribbs, E.R. Whittemore & C.W. Cotman. IRU in Brain Aging, University of California, Irvine, Irvine, CA 92717.

β -amyloid and heparan sulfate are found in neuritic senile plaques in Alzheimer's disease (AD). The co-localization of heparan sulfate and amyloidogenic proteins is a common feature of amyloidoses. β -amyloid 1-42 has been previously reported to be toxic to neurons *in vitro*, and the aggregation and toxic activities have been associated with amino acids 25-35. The role of heparan sulfate in the pathogenesis of amyloidoses however, is unknown. To investigate the interaction of β -amyloid and heparan sulfate in a cell culture model, rat hippocampal neurons were exposed simultaneously to heparan sulfate glycosaminoglycan and either 25 μ M β 25-35 or β 1-42. We observed that heparan sulfate attenuated β 25-35-induced process degeneration and neuronal death in a dose-dependent manner with an optimal effective dose at 15 μ g/ml. Concentrations as low as 0.5 μ g/ml were observed to have some protective influence. Heparan sulfate alone at these concentrations did not significantly increase cell survival. Heparan sulfate had no significant influence on β 1-42 induced toxicity, even at concentrations as high as 50 μ g/ml. These data suggest that the neurotoxic effects of β 25-35 may not be identical to those of the full-length peptide. It is further suggested that β 1-42 retains its biological effect even when associated with heparan sulfate, however the activity of smaller fragments of β 1-42 may be modified by heparan sulfate.

508.13

PATHOGENIC INTERACTIONS BETWEEN C1q AND AMYLOID β PEPTIDE IN ALZHEIMER'S DISEASE. Scott Webster* and Joseph Rogers. Sun Health Research Institute, Sun City, AZ 85372.

Soluble amyloid β peptide (A β) is present in CSF of normal individuals. This finding (and others) has made it increasingly important to identify mechanisms by which A β becomes aggregated into its pathogenic fibrillar, cross β -pleated form in the Alzheimer's disease (AD) brain. We have previously shown that C1q, the first component of the classical complement pathway, binds to synthetic A β peptides. Such binding activates the classical complement cascade and potentiates A β aggregation *in vitro*.

The present studies had two objectives. First, we modified a previously reported fluorimetric assay so as to demonstrate dramatic enhancement of A β aggregation by C1q at physiologically relevant, nanomolar concentrations. Second, we employed enzymatically generated C1q fragments to characterize the C1q binding site for A β . The latter appears to be within the globular head region (GHR) of C1q, a finding that may clarify not only the mechanism by which C1q augments A β aggregation and β structure, but also the mechanism by which A β activates C1q. The GHR provides multiple binding sites for the Fc region of Ig. By analogy, it must also provide multiple binding sites for A β , an optimal quality for nucleating A β aggregation. Likewise, A β and Ig share a similar target for binding and activating C1q, the GHR. Thus, complement activation in the AD brain is interactive with and may even be a consequence of A β aggregation into its pathogenic form.

(Supported by NIA AGO 7367).

β -AMYLOID STEREOISOMERS EXHIBIT SIMILAR STRUCTURAL AND BIOLOGICAL PROPERTIES: IMPLICATIONS FOR MECHANISM OF TOXICITY. S.L. Weinstein*, D.H. Cribbs, C.J. Pike, and C.W. Cotman. Dept. of Psychobiology, IRU, in Brain Aging, Univ. of California, Irvine, CA 92717 USA

Neurodegenerative changes in Alzheimer's disease (AD) have been hypothesized to be mediated by β -amyloid protein (A β), an amphipathic peptide composed of a 42-residue fragment of the β -amyloid precursor protein. Previous studies have shown that the assembled form of A β is toxic to cultured neurons, and that the A β (25-35) fragment may be the active region mediating this toxicity. To determine if A β binds to neurons via a stereospecific ligand-receptor interaction, we synthesized (D) and (L) stereoisomers of A β (25-35). Purified peptides were shown to comigrate on HPLC. Phase-contrast microscopy, electron microscopy and sedimentation analysis revealed that the two peptides exhibit nearly identical structural characteristics and aggregation levels. In addition, both isomers induced similar levels of toxicity in cultured hippocampal neurons. These data suggest that the neurotoxic actions of A β do not result from classic stereoisomer-specific ligand-receptor interactions. Rather, A β neurotoxicity may result from adsorption to surface proteins, perturbation of cellular membranes, or other processes in which fibril features of the amyloidogenic peptide are important. This possibility is consistent with recent reports of similar neurotoxic actions by amylin and prion, amyloidogenic proteins which share structural similarities with A β but lack amino-acid homology. Further investigation of the mechanism of A β -induced toxicity will likely benefit attempts to understand the neurodegeneration that occurs in AD and perhaps other amyloid-related disorders.

CLUSTERIN (APO J) FROM A STABLY TRANSFECTED MAMMALIAN CELL LINE PROTECTS AGAINST AMYLOID β (A β) NEUROTOXICITY. K. S. Fuson*, L. N. Boggs, M. Baez, D. McClure, J. Convalan, D. Hepburn, G. Becker, L. Churgay and P. C. May. Lilly Research Laboratories, CNS and Biotechnology Divisions, Eli Lilly and Company, Indianapolis, IN 46285.

Clusterin (Apo J, SGP-2, ADHC-9, SP-40,40) was recently found bound to A β in cerebrospinal fluid and proposed to be a chaperone for A β [Ghisso *et al* (1993) *Biochem J* 293:27]. Since the aggregation/conformation state of A β is important for its neurotoxicity, interactions with clusterin may affect A β toxicity. To test the hypothesis that clusterin may modulate A β neurotoxicity, we expressed human clusterin (80 kD) by cloning the pADHC-9 (~1.6 kb) cDNA into the expression vector pGT-d and stably transfecting the hamster cell line AV-12. Clusterin was purified from conditioned medium to ~95% homogeneity by anion exchange and size exclusion chromatography. To study the putative relationship between clusterin and A β , we evaluated A β neurotoxicity in the presence and absence of clusterin using primary hippocampal cultures from fetal (E18) rats. Clusterin activity was assessed against 50 μ M A β (Bachem lot ZK840), a well-characterized lot of A β that shows prominent neurotoxicity over a four-day timecourse. Co-treatment for four days with 50 μ M A β and 31.25 nM to 500 nM clusterin, but not BSA or PBS controls, resulted in A β neuroprotection in a dose-dependent manner. These results suggest that clusterin may interfere with the adoption of a neurotoxic conformation/aggregation state of A β *in vitro* and may have a similar function *in vivo*.

AGGREGATED β -AMYLOID INDUCES REACTIVE ASTROCYTOSIS BOTH *IN VITRO* AND IN ALZHEIMER'S BRAIN. C.J. Pike*, B.J. Cummings, and C.W. Cotman. Irvine Research Unit in Brain Aging, University of California, Irvine, CA 92717 USA.

The senile plaques characteristic of Alzheimer's disease (AD) are often associated with astrocytes expressing a reactive phenotype. Since β -amyloid (A β) is the primary component of plaques, reactive astrocytosis in AD may result in part from direct effects of A β on astrocytes. To investigate this possibility, we first examined the effects of A β peptides on cultured astrocytes. A β did not induce significant cell loss in these cultures. However, upon exposure to aggregated but not soluble A β , astrocytes rapidly and stably adopted a stellate, process-bearing morphology consistent with the reactive phenotype. This altered morphology was accompanied by increased immunoreactivities for two markers of reactivity, basic fibroblast growth factor (bFGF) and glial fibrillary acidic protein (GFAP). In addition, similar to their interaction with senile plaques, astrocytic processes *in vitro* were observed to envelop A β aggregates. To investigate whether A β may induce similar effects on astrocytes in the AD brain, we triple-labeled sections of hippocampal formation from six AD subjects with thioflavine-S and antibodies raised against GFAP and either A β or bFGF. Upon scoring the intensity of each label within individual plaques, we found that reactive astrocytes were co-localized specifically with plaques exhibiting positive but not negative thioflavine staining, a marker of β -sheet structure characteristic of aggregated A β . Similar to the *in vitro* findings, we observed increased immunoreactivity for bFGF in reactive, plaque-associated astrocytes. These data suggest that A β , in an aggregation-dependent manner, can induce a reactive astrocyte phenotype. Thus, in addition to its hypothesized direct neurodegenerative effects, A β may indirectly affect the progression of AD via reactive astrocytosis.

AN ANALYSIS OF THE SEQUENCE REQUIREMENTS OF THE AMYLOID β -PEPTIDE FRAGMENT (25-35) FOR ITS FIBRILLISATION AND CYTOTOXIC PROPERTIES. J.B. Davis*, S. Wood[§], M.S. Clark, G.W. Roberts, R.B. Wezel[§]. Dept. Molecular Neuropathology, SmithKline Beecham Pharmaceuticals, Harlow, CM19 5AD, UK; [§]Dept. Biopharmaceuticals, SmithKline Beecham Pharmaceuticals, King of Prussia, PA19406, USA.

The fibrillisation and cytotoxicity of peptide analogues of the amyloid β -peptide (25-35) fragment are being studied in order to determine the sequence and conformational requirements for these properties. Previous reports have demonstrated the neurotoxicity of the β -peptide (1-40) and the (25-35) fragment (Behl *et al.* 1992 BBRC 186, 944) a correlation between fibrillisation and cytotoxicity (Pike *et al.* 1993 J. Neurosci. 13, 1676) and also a cell surface binding requirement (JBD unpublished observation) but have not related them to sequence.

The fibrillisation and cytotoxic properties of analogues of the amyloid β -peptide (25-35) fragment, containing proline, alanine or D-amino acid substitutions, were tested. Peptides which did not fibrillise were found to be non-toxic, confirming a requirement for peptide aggregation. Loss of activity might be attributed to (i) loss of non-specific peptide aggregation, (ii) loss of quaternary structure, (iii) an additional loss of sequence specificity, due to the substitution. Chemical aggregation of the peptide to BSA failed to rescue activity, suggesting that the tertiary structure of the aggregate is important for toxicity. Future substitutions will further define β -peptide's determinants for cell surface binding.

AGGREGATION OF ALZHEIMER'S AMYLOID β -PROTEIN AND ITS NEUROTOXICITY: ENHANCEMENT BY ALUMINUM. M. KAWAHARA*, M. KATO, K. MURAMOTO, K. KOBAYASHI, H. MORI*, and Y. KURODA. Department of Molecular & Cellular Neurobiology, Tokyo Metropolitan Institute for Neuroscience, Fuchu-shi, Tokyo 183, #Department of Molecular Biology, Tokyo Institute for Psychiatry, Setagaya-ku, Tokyo 156, Japan.

It has been suggested that the aggregation of amyloid β -protein enhances its neurotoxicity, and may play a key role in the deposition of senile plaques. We revealed that aluminum, an epidemiologic risk factor for Alzheimer's disease, promoted the aggregation of synthetic amyloid β -protein (B1-40) using immunoblotting and centrifugation (KAWAHARA *et al.*, B.B.R.C., 198:531-535(1994)). Here, we report that such significantly aggregated B1-40 has neurotoxic effects on cultured rat hippocampal neurons.

After incubation at 37°C for 24 h in 25 mM HEPES buffer (pH 7.0), B1-40 (obtained from BACHEM) was separated by SDS-PAGE and immunostained by antibody to amyloid β -protein (α B42). In the presence of 500 μ M of $AlCl_3$, B1-40 formed aggregates from higher molecular weight up to the gel top. The aggregation was inhibited by the presence of deferoxamine, a chelator of aluminum. Other metals including Zn^{2+} , Cu^{2+} , Fe^{3+} caused only a small degree of aggregation compared to Al. Pre-treated solutions of B1-40 (aged- β), pre-treated solutions with Al (aged (+Al)- β), and B1-40 without pre-treatment (new- β) were applied to cultured hippocampal neurons obtained from 18-day embryo after 8-10 days in culture. After 7 days, cells were fixed and stained by antibodies to MAP2 and α B42. Neurons treated with aged (+Al)- β showed a remarkable degeneration compared to aged- β or new- β . The neurites of the neurons were also damaged. Widespread, fibrous deposits of B1-40 appeared on cells treated with aged- β and aged (+Al)- β , but not with new- β . More condensed and characteristic deposits were observed in aged (+Al)- β . These results suggested that the degeneration of neurons and the deposition of amyloid β -protein are enhanced by Al.

$A\beta$ -EVOKED DEGENERATION OF DIFFERENTIATED SH-SY5Y HUMAN NEUROBLASTOMA CELLS. G. Stevens*, M. P. Lambert, S. Sabo, K. Barber, and W. L. Klein. Dept. of Neurobiology and Physiology, Northwestern University, Evanston, IL 60208.

$A\beta$ peptides are known to induce neurodegeneration in cultures of rat brain cells and rat neural cell lines (Yankner, *et al.*, 1990, *Science*, 250: 279-282; Behl, *et al.*, 1992, *Biochem Biophys. Res. Comm.* 186: 944-950). The current data show that these peptides induce similar neurodegeneration in SH-SY5Y neuroblastoma cells, extending characterization of $A\beta$ toxicity to a human nerve cell line. Human SH-SY5Y cells respond to aggregated $A\beta$ with changes in cell shape, membrane blebbing, antigenic modification, loss of attachment to the substrate, and cell death. $A\beta$ peptides require aggregation for maximum toxic effects, as cellular degeneration is evoked by aggregated $A\beta$ 1-42 and aggregated $A\beta$ 4-41 (Ile to Cys) but not by monomeric $A\beta$ 1-40. Aged (pre-aggregated) $A\beta$ 1-40 also evoked neurodegeneration.

Antigenic changes comprise upregulation of Alzheimer's-type tau epitopes, recognized by the PHF-1 and Alz-50 monoclonals. These particular changes in tau support the connectivity between this *in vitro* model and mechanisms leading to neurodegeneration in Alzheimer's disease. A significant feature of the SH-SY5Y response is that cells must be differentiated before they become sensitive to the degeneration evoked by $A\beta$. Signaling pathways leading to $A\beta$ -evoked neurodegeneration thus are under experimental control, becoming complete only when proliferating cells withdraw from the cell cycle and develop a postmitotic phenotype.

THE ROLE OF FIBRIL FORMATION IN THE MECHANISM OF BETA AMYLOID TOXICITY. A. Lorenzo and B.A. Yankner*. Department of Neurology, Harvard Medical School and the Children's Hospital, Boston, MA 02115.

Recent studies suggest that the physical state of beta amyloid (βA) is an important determinant of its neurotoxic property. To determine whether a specific aggregated form of βA is required for toxicity, we have established defined conditions where βA predominantly forms either fibrillar or amorphous aggregates, as determined by Congo red staining and electron microscopy. Rat hippocampal cultures were treated with 20 μ M of the different preparations for 4 days. After treatment there was significant cellular βA deposition in both preparations as determined by βA immunocytochemistry. Cultures treated with the fibrillar preparation showed a large proportion of Congo red-positive aggregates, accompanied by typical morphological changes of βA toxicity (shrinkage and clumping of neuronal cell bodies, dendritic retraction and axonal tortuosity), and by significant neuronal loss (viable neurons: $54 \pm 3\%$). Cultures treated with the amorphous preparation showed only occasional Congo red-positive aggregates, some neuronal clumping, few morphological abnormalities and slight neuronal loss (viable neurons: $84 \pm 5\%$). These results suggest that fibril formation may be necessary for βA neurotoxicity. We have recently reported that pancreatic islet cell toxicity of amylin is mediated by the fibrillar form of the peptide. Taken together, these findings suggest that amyloid fibril formation may be the pathogenic mechanism underlying cellular degeneration in different amyloidoses.

POTENTIAL ROLE OF TGF- β 1 IN ALZHEIMER'S DISEASE: REGULATION OF APP EXPRESSION AND INHIBITION OF β AP NEUROTOXICITY. M. F. Galindo, J. H. M. Prehn*, V. P. Bindokas and R. J. Miller. Dept. Pharmacol. and Physiol. Sciences, Univ. of Chicago, Chicago, IL 60637.

Transforming growth factor β 1 (TGF- β 1) is found in plaques of patients with Alzheimer's disease. The β -amyloid peptide (β AP), the major component of these plaques, has been shown to be directly toxic to neurons and has thus been linked to the pathogenesis of Alzheimer's disease. In the present study we determined whether TGF- β 1 is able to modulate β AP neurotoxicity and the synthesis of its precursor protein (APP).

Cultured rat hippocampal neurons were exposed to 0.1 - 10 μ M of the β AP fragment 25-35 (β AP25-35) for a period of 5 days. Exposure to β AP25-35 led to a significant decrease in neuronal viability, which was maximal at 1 μ M. Terminal deoxynucleotidyl transferase-based immunodetection demonstrated that neuronal injury was accompanied by extensive DNA fragmentation, an indication of "apoptotic" cell death. A single addition of TGF- β 1 (10 ng/ml) inhibited both β AP25-35 neurotoxicity and reduced the extent of DNA fragmentation. Repeated treatments with TGF- β 1 (4 x 10 ng/ml) completely prevented the death of the hippocampal neurons. In contrast to β AP, its precursor protein (APP) is thought to actually have neurotrophic and neuroprotective properties. We next determined the effects of TGF- β 1 on APP expression both in cultured rat hippocampal neurons and in secondary cultures of astrocytes. Treatment with TGF- β 1 (0.1 - 10 ng/ml) led to an increased neuronal and glial production of APP, as determined by Western blotting and immunocytochemistry with a monoclonal antibody specific for APP.

We conclude that, in addition to its effect on Ca^{2+} homeostasis and bcl-2 expression, an increase in APP expression could underlie the protective effects of TGF- β 1 against β AP neurotoxicity.

PHOSPHOINOSITIDE HYDROLYSIS IN HUMAN POSTMORTEM BRAIN MEMBRANES: ALTERATIONS IN ALZHEIMER'S DISEASE. A.F. Greenwood*, L. Song, R. Powers and R.S. Jope. Dept. of Psychiatry, Univ. of Alabama, Birmingham, AL 35294.

Membranes prepared from postmortem human prefrontal cortex hydrolyzed exogenous [3H]phosphatidylinositol (PI) when (i) phospholipase C (PLC) was stimulated with Ca^{2+} ; (ii) GTP γ S or NaF was added to stimulate G-proteins coupled to PLC, or (iii) carbachol, ACPD, histamine, ATP, or serotonin plus GTP γ S were added with GTP γ S. Only the response to ATP was influenced significantly by the duration of the postmortem interval (measured between 5 and 21 hr, $n = 16$). There was a decline in responses to several stimulants correlated with increased age (measured between 18 and 100 yr, $n = 23$). Utilization of antibodies to block responses indicated that Gq and PLC- β were the active subtypes mediating human membrane PI hydrolysis. ATP induced the greatest responses of the agonists tested and results indicate that it acts through P_2 -purinergic receptors. Comparisons of membranes from Alzheimer's disease and age-matched controls indicated that Ca^{2+} -stimulated PLC activity was unaltered but the responses to GTP γ S and carbachol were reduced. Further comparisons between AD and controls with other agonists and comparisons of G-protein levels are also measured.

PERIPHERAL BENZODIAZEPINE RECEPTORS IN LYMPHOCYTES OF PATIENTS WITH ALZHEIMER'S DISEASE AND MULTI-INFARCTUAL DEMENTIA. C. Ferrarese*, A. Scuratti¹, G. Bianchi, R. Cavarretta, R. Riva, G. Bianchetti¹ and L. Frattola. Dept. of Neurology, University of Milan, Monza and (1) Alzheimer's Unit, Sacro Cuore Institute, Brescia, Italy.

Peripheral benzodiazepine receptors (PBR) are modified in brain areas in animal models of stress and in Alzheimer's disease (AD) patients. Since PBR are present also in circulating lymphocytes, where appear to modulate immunologic functions, we presently investigated possible modifications of PBR in lymphocytes of patients with dementia, to investigate their role as putative peripheral markers of neurochemical alterations in degenerative disorders. 15 AD, 11 multi-infarctual dementia (MID) patients (NINDS-ADRDA and DSM-III-R criteria) and 10 age and sex matched controls were selected for peripheral blood withdrawal and lymphocyte preparation. Frozen lymphocyte pellets were resuspended and incubated with various concentrations of [3H]PK-11195, specific ligand of PBR, to analyze receptor density (Bmax) and affinity (Kd). PBR Bmax in aged controls was similar to Bmax of young volunteers; a high variability of Bmax was observed in AD, although the mean was unchanged respect to controls. On the contrary, MID patients presented PBR densities significantly reduced respect to controls. No change of Kd was observed in any patient population. These findings may indicate a biochemical heterogeneity in different AD patients and a possible role of PBR in neurochemical modifications observed in degenerative disorders.

AMELIORATIVE EFFECTS OF MCI-225, A NOVEL PSYCHO-ACTIVE COMPOUND, ON AMNESIA AND ATTENTION DEFICIT IN RODENTS. J. Eguchi, T. Yuasa, A. Tobe#, M. Egawa# and K.-I. Saito*. Pharmaceuticals Lab. I, Research Center, Mitsubishi Kasei Corporation, 1000 Kamoshida-cho, Midori-ku, Yokohama 227, JAPAN. #Clinical Research Center, MKC.

Effects of a new compound MCI-225, [4-(2-fluorophenyl)-6-methyl-2-(1-piperazinyl)thieno [2,3-d]pyrimidine monohydrate hydrochloride], on memory and attention were examined. In water maze task in rats, MCI-225 (1-10 mg/kg, p.o.) ameliorated scopolamine-induced amnesia. Consecutive administration of MCI-225 (0.3 and 1 mg/kg, p.o.) reversed the passive avoidance failure in the basal forebrain-lesioned rats. MCI-225 at 1-10 or 10 and 30 mg/kg, p.o. reversed the attention deficits in mongolian gerbils or rats, whose cortical noradrenergic neurons were destroyed by N-(2-chloroethyl)-N-ethyl-2-bromobenzylamine or 6-hydroxydopamine, respectively. In the range of doses used, MCI-225 showed no abnormal behavior. Neurochemical studies showed that MCI-225 potentiated noradrenergic neuron pre- and post-synaptically, by inhibition of noradrenaline uptake ($IC_{50} = 69nM$) and by increasing the c-AMP formation via modification of α receptor-mediated potentiation to β receptor stimulation.

509.5

EXPRESSION OF D2 RECEPTOR "COLUMNS" IN TEMPORAL CORTEX OF ALZHEIMER'S IS REDUCED

A.J. Myers and J.N. Joyce*. Dept. Psychiatry, Lab. Chemical Neuroanatomy, Univ. Penn. Sch. Medicine, Philadelphia, PA 19104-6141

We have previously described the autoradiographic mapping of D2-like receptors with [^{125}I]epidepride in human brain (Joyce et al., JPET, 253:1253, 1991), showing high expression in limbic regions. Reductions in the number of D2-like receptors in the DG, CA3, subiculum and perirhinal regions are observed in Alzheimer's disease (AD) (Joyce et al., 1993; Neurosci. Lett. Ryoo and Joyce, J. comp. Neurol., 1994). Multimodal regions of the temporal cortex that provide afferents to parahippocampus show a very different pattern of D2 receptor expression than other cortical regions. Dense columns of D2 receptors are observed in temporal association cortex that are bracketed by regions of very low numbers of receptors. The bands either cross all cortical layers, or show a paucity of binding in the mid-layers (Goldsmith et al., 1991 Soc Neurosci. Abstr). They have a mean width of 2.75mm (± 0.62), and are continuous for an anterior-posterior distance of at least 1500 μm . The majority of bands are observed in the lateral and inferior aspects of the superior temporal gyrus, with occasional bands observed on the lateral surface of the middle temporal gyrus and on the parahippocampal cortices. No bands of D2 binding are observed in anterior Heschl's gyrus or in the posterior primary auditory cortex. Hence, these columns form modular bands that travel in the rostral-caudal axis of these multimodal association areas of the temporal lobe. We compared AD cases ($n = 11$; 79 ± 10 yrs; PMI = 7.8 ± 6 hrs) with controls ($n = 8$; 64 ± 14 yrs; PMI = 10 ± 7 hrs) for frequency of these columns. Whether expressed as an absolute number of columns or relative frequency for each of four rostral-caudal levels of the temporal cortex, there was a significant difference (ANCOVA, $p = 0.0001$) between groups (Control = 2.5 ± 2 columns/level vs AD = 0.2 ± 1) Funded by MH 43880, AG 09215.

THE C-TERMINAL AMYLOID PRECURSOR PROTEIN FRAGMENT His 657-Lys 676 REVERSES NORADRENALINE- AND ENKEPHALIN-INDUCED INHIBITION OF VOLTAGE SENSITIVE CALCIUM CURRENTS IN NG108-15 HYBRID CELLS. H.W.G.M. Boddeke*, I. Meigel, P. Boeijsing and R. Swoboda, Sandoz Pharma Ltd., Preclinical Research, CH 4002 Basle, Switzerland.

Recently it has been reported that the cytoplasmic C-terminal amyloid precursor protein (APP) sequence, His 657-Lys 676, forms a complex with isolated G_o , a major GTP-binding protein in the brain (Nishimoto et al., 1993). In this study we have investigated the effect of the APP fragment His 657-Lys 676 (APP 657-676), its reverse sequence and the smaller APP fragment Gly 659-Lys 676 upon calcium currents in NG108-15 neuroblastoma x glioma hybrid cells. In addition, we have investigated the interaction of these peptides with calcium current suppression mediated by adrenergic α_{2A} and opioid δ receptors.

APP 657-676 (10^{-6} - $10^{-4}M$) did not affect calcium currents per se but clearly blocked calcium current suppression mediated by both adrenergic α_{2A} - and opioid δ receptors in a concentration-dependent manner. The reverse APP fragment 676-657 and the shorter APP fragment Gly 659-Lys 676 did not affect calcium current suppression by adrenergic α_{2A} - and opioid δ receptors.

Our results show an interaction of C-terminal APP with adrenergic α_{2A} - and opioid δ receptor-mediated calcium current suppression downstream of the receptor, possibly via the GTP binding protein G_o .

STATUS OF SEROTONIN TRANSPORTER SITES (5-HTT) IN THE AGING HIPPOCAMPUS AND DORSAL RAPHE NUCLEUS (DRN) IN ALZHEIMER'S DISEASE. S. M. Tejani-Butt, J. Yang, I. Halasz* & G. A. Ordway¹. Dept. of Psychiatry, Univ. of Penn. School of Medicine, Phila., PA 19104 and ¹Dept. of Psychiatry & Human Behavior, Univ. of Mississippi Medical Center, Jackson, MI 39216.

There is increasing evidence that the functional integrity of the 5-HT system is compromised in age-related cognitive disorders. Several reports have indicated neuropathological changes in the DRN, including modest to severe losses of DRN neurons in Alzheimer's Disease (AD). Since ~40% of DRN neurons are considered to be 5-HT immunoreactive, this study measured 5-HTT binding sites to obtain a quantitative assessment of the status of 5-HT innervation in the DRN in AD and in the aging hippocampus. Sections were taken from the mid-region of the DRN from 8 subjects who had died of AD and 5 controls, and from the mid-region of the hippocampus from 18 subjects who had died of natural causes, ranging in ages from 19-80 years. A significant decrease in 3H -cyanoimipramine binding to 5-HTT sites was seen in the DRN in AD cases versus controls, with the most significant reductions (~30%) occurring in the lateral wings ($p < 0.01$) of the DRN complex. In contrast, regression analysis revealed no significant effect of age on 5-HTT binding sites in the hippocampus (dentate gyrus, CA1, CA2, CA3,4) and entorhinal cortex. The results indicate that the integrity of 5-HT neurons in the DRN, as measured by 5-HTT binding, may be compromised in AD, whereas the integrity of 5-HT terminals in the hippocampus may be unaffected by age. (Research funds from USPHS grant NS 31699).

Differential regulation of RNA editing for an AMPA receptor subunit gene in the prefrontal cortex of Alzheimer's patients, schizophrenics and controls. S. Akbarian*, M.A. Smith and E.G. Jones.

Dept. of Anatomy and Neurobiology, University of California Irvine, CA 92717.

Studies in rat brain have demonstrated that the RNA for the GluR-B (2) subunit of the AMPA receptor is subject to RNA editing, by which a selected glutamine codon (CAG) is changed to an arginine codon (CGG). AMPA receptors containing GluR-B (2) polypeptides derived from edited RNA show upon stimulation much less Ca^{2+} permeability in comparison to AMPA receptors containing GluR-B (2) polypeptides derived from unedited RNA (Sommer et al., 1991, Cell 67:11). In the rat, the ratio of unedited vs. edited GluR-B (2) RNA changes from 1:99 during early brain development to 0.01:99.99 in the adult brain (Burnashev et al., 1992, Neuron 8:189).

Dysregulation of GluR-B (2) editing could potentially cause AMPA and Ca^{2+} mediated neurotoxicity. In the present study, the ratio and percentages of unedited and edited GluR-B (2) mRNA was analysed in the prefrontal cortex of Alzheimer's patients, schizophrenics and controls, using polymerase chain reaction with radiolabeled oligonucleotides, restriction enzyme analysis and scintillation radiography. In the Alzheimer's brains the relative abundance of unedited RNA was tenfold higher in comparison to age-matched controls (1.60% and 0.06%, $p < 0.05$) while in age-matched schizophrenics it was 0.39%. The abnormally high proportion of unedited GluR-B (2) mRNA in the Alzheimer's brains indicates that RNA editing for GluR-B (2) subunit is compromised and could potentially be involved in mechanisms that underlie chronic neurodegeneration. It will be of interest to study possible dysfunction of AMPA/Ka receptor RNA editing in other neurodegenerative diseases such as Amyotrophic lateral sclerosis or Huntington's disease. Supported by NIMH grant MH44188 and by NARSAD and Stanley Grants.

REGULATION OF THE OLFACTORY BULB ALZHEIMER'S PRECURSOR PROTEIN (APP) BY LESIONING OF THE OLFACTORY BULB. M.C. Wilson, V. Ramkumar, R. Wang, D.N. Dhanraj, R. Struble*. Dept. of Pharmacology, Southern Illinois University School of Medicine, P.O. Box 19230, Springfield, IL 62794-9230 USA

Recent evidence suggest that APP modulates the activity of the guanine nucleotide regulatory protein, G_o , a major growth cone protein. Growth cone associated protein (GAP-43) stimulates the binding of GTP to G_o and thereby promotes its activation. Olfactory nerve deafferentation of the olfactory nerve led to an approximately 2-fold increase in GAP-43 in 3 to 4 weeks which is associated with regeneration of the olfactory nerve (Verhaagen et al., J. Neurosci. Res. 26, 31-44). This study determined whether other components of this signalling pathway were regulated by olfactory nerve lesioning. Lesioning was performed by administering a single injection of diethylthiocarbamate (DDTC) to Wistar rats (200-250 g). Vehicle-injected animals were used as controls. The levels of APP, G_o and GAP-43 were determined by Western blotting. Olfactory nerve lesioning produced a transient increase in expression of APP (2-3 fold) by 6 weeks that recovered to control levels by 12 weeks. The levels of GAP-43 were also transiently increased (~2 fold) by 6 weeks and recovered by 12 weeks. In contrast, G_o was decreased (~3 fold) over this time period and showed partial recovery (70-80% of control level) by 12 weeks. This upregulation of APP and GAP-43 might represent an attempt by the cell to compensate for the decrease in G_o . Olfactory nerve lesioning might provide a useful *in vivo* model to study.

Regulation of the β -APP promoter activity through a Ras-dependent pathway. T. Massamiri*, T.L. Deng and J.H. Brown. Dept. of Pharmacology, Univ. of Calif. San Diego, CA 92093-0636.

We have previously shown that the β -amyloid precursor protein (β -APP) gene promoter is activated by the transcription factor c-Jun via a functional distal AP-1 site. We propose that stimuli that lead to activation of Ras-dependent pathways would also regulate AP-1 activity to induce β -APP expression. Human astroglial cells (1321N1) were transiently co-transfected with a β -APP promoter luciferase reporter gene (a 593bp *HindIII/BamHI* proximal promoter fragment of a human β -APP genomic clone) along with an expression vector for constitutively activated Ras. Our results show that expression of activated Ras increases β -APP-luc promoter activity approximately 6 fold, suggesting that stimulation of the Ras pathway can activate the β -APP promoter. Further experiments were carried out with a mutated form of the β -APP promoter containing a dysfunctional distal AP-1 site (Mut- β -APP-luc) which did not respond to co-expression of c-Jun or c-Fos. The mut- β -APP-luc promoter was not inducible by activated Ras. We conclude that stimulation of the ras pathway leads to transactivation of β -APP expression via its distal AP-1 site. Studies are currently under way using a dominant negative Ras expression construct to establish a requirement for Ras in the regulation of the β -APP promoter activity by cellular mediators.

IDENTIFICATION OF AN 8-HYDROXYGUANOSINE NUCLEOTIDE IN CSF THAT BLOCKS GTP BINDING TO β -TUBULIN. B.E. Haley*, E. Duhr and S. S. M. David, College of Pharmacy and Center on Aging, Univ. of Kentucky, Lexington, KY 40536-0082.

In comparison to control brain samples it has previously been shown that approximately 80% of Alzheimer's Disease (AD) brains have the GTP binding site on β -tubulin substantially blocked and unable to be photolabeled with [32 P]8N₃GTP. Also, addition of the cytosolic fraction of AD brain homogenates was able to decrease this photoinsertion in control brain tubulin (Khatoun et al., Ann. Neurol. 26, 210, 1989). Now we report that CSF from AD patients contains a very selective inhibitor of [32 P]8N₃GTP photoinsertion into β -tubulin of control brain. This inhibitor is in the flow through of centricon filtration and is stable to heat treatments of 90°C for 10 min. Treatment of CSF with cation binding resins enhanced inhibitory activity whereas treatment with anion binding resins or with alkaline phosphatase totally abolished inhibitory activity. Ion exchange HPLC of centricon filtered CSF and testing of the fractions for ability to reduce [32 P]8N₃GTP photoinsertion into β -tubulin identified one UV absorbing compound with an absorbance max of 291nm that blocked β -tubulin photolabeling. This compound was tentatively identified as a phosphorylated form of 8-hydroxyguanosine or 8-hydroxydeoxyguanosine. It is proposed that levels of this compound in the CSF may be a measure of the levels of hydroxy radical (OH \cdot) or singlet oxygen (1 O₂) in the brain. Also, these results imply that the radicals or endoperoxides formed by OH \cdot or 1 O₂, leading to 8-hydroxyguanosine nucleotides, may interact with various GTP binding proteins permanently modifying their biochemical properties. Supported by NIH grant GM-35766 and the Lexington Clinic Foundation.

STAGE-SPECIFIC INCREASES IN CSF EXCITATORY AMINO ACIDS IN ALZHEIMER'S DISEASE. J.G. Csernansky*, M.E. Bardgett, Y.L. Sheline, and J. Olney. Department of Psychiatry, Washington University School of Medicine, St. Louis, MO 63110

Increased release of excitatory amino acids (EAA) has been proposed to be involved in the pathogenesis of degenerative brain diseases, such as Alzheimer's disease (AD). However, inconsistent changes in cerebrospinal fluid (CSF) concentrations of EAA have been reported in patients with AD compared to controls, perhaps because the patients studied had illnesses of mixed severity. To determine whether there are stage-specific changes in CSF concentrations of EAA in patients with AD, we measured the CSF concentrations of glutamate, aspartate, and taurine (a comparison neutral amino acid) using high pressure liquid chromatography in 32 AD patients and 11 controls, recruited from the Alzheimer's Disease Research Center. Twenty patients had early AD (CDR stage 0.5 - 1.0) and 12 patients had advanced AD (CDR stage 2.0 - 3.0).

ANOVA revealed a significant increase in aspartate concentrations in advanced patients compared to early patients and controls ($F=5.15$, $p=.010$, post-hoc Fisher's PLSD - normals = early AD < advanced AD). A similar trend was observed for CSF glutamate concentrations ($F=2.49$, $p=.095$). No significant differences in CSF taurine concentrations were observed among the groups. CSF aspartate concentrations were highly correlated with glutamate concentrations ($r=.84$, $p<.0001$), but not with taurine concentrations. These results indicate that CSF EAA concentrations are abnormally increased in patients with advanced but not early AD, and suggest that increased EAA release may play a pathophysiological role late in the disease. This project was supported by the Alzheimer's Disease Research Center Grant P50 AG05681.

IMPAIRMENTS OF G α FUNCTION IN HUMAN BRAIN CORTEX OF ALZHEIMER'S DISEASE: COMPARISON WITH NORMAL AGING. H. Ozawa*, E. Hashimoto, S. Hatta*, T. Saito, L. Frölich*, H. Ohshika*, N. Takahata, and P. Riederer*. Dept. of Neuropsychiatry and ¹Pharmacology, School of Medicine, Sapporo Medical University, Sapporo 060, Japan. ²Dept. of Psychiatry, Würzburg University, D-97080 Würzburg, Germany.

GTP binding (G) proteins are believed to be key elements on the downstream of intracellular signal transduction from many receptors. In this study, we examined the quantity and quality of G proteins in membrane preparations from normal adult human cerebral cortex (17-89 years old) and subjects with dementia of the Alzheimer type (DAT). The immunoreactivities by immunoblotting with polyclonal antibody of G α and G β subunits were correlated inversely with normal age in parietal, temporal and occipital cortex regions. The G β subunit immunoreactivities showed a negative correlation with age in temporal and occipital cortex areas. The function of G proteins was examined by photoaffinity GTP analog [azidoanilido GTP (AAGTP)] binding. AAGTP labeling to G α and G β and the ratio of G α to G β AAGTP binding showed no age-dependent changes. There are no significant differences in the amount level of G α , G β , G γ , G δ , G ϵ , G ζ , G η , G θ , G ι , G κ , G λ , G μ , G ν , G ξ subunits by immunoblotting between DAT and matched controls in these cerebral cortex regions. In contrast, photoaffinity GTP labeling of G α but not G β was decreased in DAT compared to controls in parietal and temporal cortex but not occipital cortex regions. These results suggest that disturbances of post-receptor trans-signaling in DAT are attribute to functional changes of stimulatory G proteins (Gs) independent of alterations in the gross level and normal aging process on those proteins.

ALTERATIONS IN THE NEURONAL CYTOSKELETON FOLLOWING METABOLIC INHIBITION AND EXCITOTOXIC INSULT. Z. Pang and J.W. Geddes*. Sanders-Brown Center on Aging and Dept. Anatomy & Neurobiology, Univ. Kentucky, Lexington, KY 40536.

Impaired energy metabolism can induce 'excitotoxic' neuronal death and may contribute to the pathogenesis of late-onset neurodegenerative disorders such as Alzheimer's disease. To determine if impaired energy metabolism could play a causal role in the formation of neurofibrillary tangles, we administered the mitochondrial inhibitor malonate (a reversible inhibitor of succinate dehydrogenase) to rats via intra-hippocampal injection. Immunocytochemistry was used to examine cytoskeletal changes at different postinjection time points. Within six hours after injection, malonate (2 μ moles) resulted in neuronal cell death, loss of MAP2 and MAP1B, and relative sparing of tau in the hippocampus. At the drug injection site, damage was widespread and involved most cell types in the hippocampal formation. Distal to the injection site CA1 neurons were most vulnerable, although CA3 neurons were also affected. Intrahippocampal injection of the excitotoxin quinolinic acid resulted in a similar pattern of cell loss and cytoskeletal disruption. These results support the hypothesis that metabolic inhibition and excitotoxic insult may contribute to the sparing of tau and loss of other cytoskeletal proteins in tangle-bearing neurons in Alzheimer's disease. REDUCTION IN NON-NMDA GLUTAMATE RECEPTOR SUBUNIT IMMUNOREACTIVITY IN THE ENTORHINAL CORTEX OF PATIENTS WITH ALZHEIMER'S DISEASE PATHOLOGY. B. Sheffield, M.D. Ikonomic, R.P. Yasuda*, B.B. Wolfe*, and D.M. Armstrong*. Allegheny-Singer Research Institute, Medical College of Pennsylvania, Pittsburgh, PA 15212; ¹Dept. Pharmacology, Georgetown University.

In a previous study (Brain Research 632 (1994) 207-216) we employed immunohistochemical techniques and demonstrated a reduction in GluR2/3 and GluR1 immunoreactivity in the entorhinal cortex (EC) of patients with Alzheimer's disease. In the current study, Western blot analysis is employed in order to determine the extent to which selected GluR subunits are reduced in the EC. Moreover, we seek to determine whether the decrease in GluR2/3 immunoreactivity within layer II pyramidal neurons in the EC parallels alterations in the expression of various cytoskeletal markers. Throughout these studies we examined normal control subjects and subjects displaying variable degrees of AD pathology. In patients with clinical and pathological verification of AD, GluR2/3 protein was reduced by nearly 50% of controls while GluR1 was decreased by 40%. Cell counts of GluR2/3 immunoreactive neurons demonstrated that the reduction of GluR2/3 could be attributed largely to a loss of layer II-labeled cells. In contrast, labeled cells were abundant in layers V and VI even in those cases with severe AD pathology. Examination of subjects with relatively mild AD pathology in the EC revealed a number of findings applicable to layer II neurons: (1) the decrease in GluR2/3 appears to precede the actual loss of these neurons as determined in Nissl-stained tissue sections; (2) the reduction in GluR2/3 immunolabeling is observed prior to a decrease in MAP2 or neurofilament protein; (3) in some but not all cases, GluR2/3 immunolabeling is reduced prior to the appearance of PHFs. These data suggest that the reduction in GluR2/3 within the EC occurs early in the disease process and may be contributing to cytoskeletal pathology. This work is supported by NIH grant AG08206 and The American Health Assistance Foundation.

NON-NMDA GLUTAMATE RECEPTOR SUBUNIT IMMUNOREACTIVITY IN THE HIPPOCAMPUS OF NORMAL CONTROLS AND PATIENTS WITH ALZHEIMER'S DISEASE PATHOLOGY. M.D. Ikonovic*, B. Sheffield and D.M. Armstrong. Allegheny-Singer Research Institute, Medical College of Pennsylvania, Pittsburgh, PA 15212.

In a companion work, we report a decrease in GluR2/3 immunoreactivity in the entorhinal cortex of patients with AD. That study prompted us to investigate the immunolabeling of this receptor subunit within the projection fields of the perforant pathway (i.e., the hippocampus). Throughout our studies anterior and posterior aspects of the hippocampus were examined. Within the anterior hippocampus of normal control patients, we observed numerous labeled neurons within the stratum pyramidale. In addition, intense peroxidase reaction product was observed within the stratum moleculare. Examination of more posterior sections revealed a distinctive and highly consistent pattern of GluR2/3 immunolabeling. Within the dentate gyrus, granule cells were labeled as was the molecular layer. Throughout the CA subfields, numerous pyramidal neurons were GluR2/3 positive. These labeled neurons were particularly abundant in the CA3/CA2 subfields. In many instances, labeled cells within the stratum pyramidale extended their dendrites through the stratum radiatum and into the stratum moleculare. In AD subjects, the anterior hippocampus was characterized by a marked reduction of GluR2/3-labeled cells within the stratum pyramidale and nearly a complete absence of labeling within the stratum moleculare. In most instances, within those regions where we observed a marked reduction in GluR2/3 labeling we also observed numerous neurofibrillary tangles. In contrast to the anterior hippocampus, studies of the posterior hippocampus of subjects with AD demonstrated that the extent and intensity of immunolabeling was comparable if not greater than that observed in controls. Moreover, in regions of intense GluR2/3 labeling, neurofibrillary tangles were relatively sparse. At present, studies are underway which seek to determine the precise relationship between GluR2/3 expression and neurofibrillary pathology. This work is supported by NIH grant AG08206 and the American Health Assistance Foundation.

DEGENERATIVE DISEASE: ALZHEIMER'S—CELLULAR MECHANISMS OF DEGENERATION

510.1

SYNAPTOPHYSIN AND ELECTRON MICROSCOPIC ASSESSMENT OF REACTIVE SYNAPTOGENESIS. S.W. Scheff*, J. Tewes, S.A. Baldwin, and J.W. Geddes. Center On Aging, Dept. Anatomy & Neurobiology, University of Kentucky, Lexington, KY 40536-0230

The entorhinal cortex provides a major input to the ipsilateral hippocampal dentate gyrus. A unilateral entorhinal cortex lesion denervates the outer molecular layer triggering synaptogenesis and the replacement of lost synaptic connections. This reactive replacement of synaptic connections was originally studied with quantitative electron microscopy (EM). More recent experiments have employed synaptophysin immunoreactivity (SI) to quantitatively assess synapse numbers utilizing light microscopy. No one has directly compared actual numbers of synapses observed with EM to values obtained with SI.

Adult Fisher 344 rats were subjected to a unilateral entorhinal cortex lesion and killed at 2, 4, 10, 15, 30 and 60 days after the injury. Tissue was processed for both immunoreactivity utilizing an antibody directed against synaptophysin, and for EM employing standard techniques. For the EM prepared tissue, the number of synapses per 100 μ^2 was ascertained. An image analysis device was used to obtain the corrected optical density for the SI prepared tissue.

Both techniques demonstrated a loss of synaptic contacts immediately following the lesion, although the magnitude was significantly less for the SI material. A time dependent change in staining could be observed in the SI material which, mimicked but did not parallel the rate and magnitude of synapse replacement observed with EM. The present results call into question the use of SI for the accurate quantitative assessment of synaptic number. Supported by AG05144.

SYNAPTIC ANTIGEN REACTIVITY WITH A SERIES OF MONOCLONAL ANTIBODIES. A. Pruchnicki*, R. Bowser, W.G. Honer¹ and P. Davies. Dept. of Pathology, Albert Einstein College of Medicine, Bronx, NY, and (1) Dept. of Psychiatry, Univ. of British Columbia, Vancouver, BC (Canada).

In a previous report, a series of 16 monoclonal antibodies (the SP series) to presumed synaptic antigens were produced. (W.G. Honer, et al, Brain Research 609:9-20 (1993)). This report is to verify that these antibodies do, in fact, react with synaptic antigens. The antibodies were produced by injecting mice with protein from whole brain homogenates which was partially purified by eluting from an affinity column of the monoclonal antibody EP10, which reacts with a synaptophysin-like antigen, attached to agarose. Antigens presumably associated with synaptophysin in synaptic vesicles or membrane fractions would also be enriched by this method.

Normal brain homogenates were prepared and fractionated to produce a synaptic vesicle rich fraction. Electrophoresis on a 12% acrylamide gel was performed and immunoblotting was done with each of the 16 SP series antibodies, along with EP10 and a commercial anti-synaptophysin antibody. When equal amounts of protein from each of the fractions was examined this way, there was a pattern of enrichment of the antigens in the synaptic vesicle fraction. These antibodies, therefore, are reacting with antigens associated with a synaptic vesicle fraction, as predicted. We have confirmed that the SP monoclonals are reactive with five different proteins of this fraction. Further work with synaptic vesicles fractions isolated from Alzheimer's disease brains is ongoing.

510.2

SYNAPTIC DENSITY IN THE HIPPOCAMPAL DENTATE GYRUS INNER MOLECULAR LAYER IN PATIENTS WITH ALZHEIMER'S DISEASE. D.A. Price, D.L. Sparks* and S.W. Scheff. Center On Aging, University of Kentucky, Lexington, KY 40536-0230

Substantial synapse loss occurs in many cortical areas associated with Alzheimer's disease (AD). These brain regions are primary association cortex which normally receive significant inputs from many other association regions known to have AD pathology. The hippocampal formation is one of the primary areas affected in AD, and responsible in part for some of the impaired memory and dementia characteristic of the disease. We previously reported a substantial loss of synaptic numbers in the outer molecular layer of the hippocampal dentate gyrus. This area normally receives a direct input from the ipsilateral entorhinal cortex which has significant neuronal loss in AD. The inner molecular layer of the dentate gyrus receives most of its input from within the ipsilateral and contralateral hippocampus, and may not be affected by the disease process. The present study determined whether or not this area of the hippocampus is capable of maintaining synaptic numbers in AD patients as compared to neurologically normal controls.

Human brains were obtained at postmortem examination from patients who met the NINCDS-NIA criteria for AD and from age-matched controls. All tissues were obtained within 10 hours postmortem. The tissue was coded and prepared for ultrastructural examination. The density of synapses and the synaptic apposition length was determined for each subject. Because of ongoing research with these tissues the group designation remains coded at this time but will be discussed in full at the meetings. Correlations with synaptic density in the outer molecular layer will be presented. Supported by AG05144.

TWO-DIMENSIONAL GEL ELECTROPHORETIC ANALYSIS OF CORTICAL PROTEINS FROM ALZHEIMER AND AGE-MATCHED CONTROL: INITIAL CHARACTERIZATION OF AN UNIDENTIFIED PROTEIN IN ALZHEIMER BRAIN. M.L. CHOUINARD*, H. MARUSAWA, M. MCKINNEY AND K. SUGAYA. MAYO CLINIC, JACKSONVILLE, FLORIDA, 32224, AND FUJISAWA PHARMACEUTICALS, TOKYO, JAPAN

Fibrillary tangles and amyloid plaques, the traditional markers of Alzheimer's disease (AD), are identified only post-mortem, and are present to a varying degree in nondemented aged brain as well. In addition, a definitive causative role in AD, for either of these complexes and their associated protein components, has not yet been shown. Here, we have attempted to identify proteins in cortex of AD brain as potential markers of the disease using high resolution two-dimensional electrophoresis in an effort to provide immuno-reactive targets more specific for AD and perhaps more indicative of AD etiology.

Protein from prefrontal cortex of AD and age-matched control brain was extracted, solubilized and separated first by isoelectric point, followed by molecular weight using the Millipore 2D-gel electrophoresis system. The region between 25 and 70 kD and pH 6-8 contained at least one or more spots as identified by silver and coomassie stain in AD samples that were not present in controls. One of these spots (30 kD) was targeted for further analysis by electrophoretically blotting onto PVDF membrane. The target spot was cut out of the membrane after being revealed by coomassie stain and sequenced using an automated amino acid sequencer. Two sequences were obtained and used to synthesize peptide decamers, both beginning five residues from the N-terminus. These peptides were identical, except for a single amino acid residue (A/W) at position nine in the peptide or position 14 from the N-terminus of the protein. These peptides were injected into rabbits and antisera for each peptide was recovered and used to identify the target spot. However, immunoblots using the A-peptide revealed three or more spots in control and five or more spots in AD samples within the same pH region but with a much larger molecular weight and possibly greater abundance than the target spot. Furthermore, the A to W amino acid substitution completely changed the specificity of the antibody, revealing a single spot within the same molecular weight region detectable in AD as well as normal brain. Results obtained in this study suggest, assuming the accessibility of antibody to the antigenic site of the proteins, the possibility of an alternative processing of proteins observed in AD relative to controls.

510.5

CHARACTERIZATION OF *apl-1*, AN AMYLOID PRECURSOR-LIKE GENE IN THE NEMATODE *CAENORHABDITIS ELEGANS*. L. Daigle*, and C. Li. Dept. of Biology, Boston University, Boston, MA 02215

Alzheimer's disease is a neurodegenerative disease for which the cause is still unknown. Accumulation of a β -amyloid peptide in the brain of patients has been associated with the disease. This β -peptide is derived from a larger amyloid protein precursor (APP), for which the normal function and processing remain to be understood. Recently, a family of APP-related proteins have been identified in different organisms. We are interested in elucidating the function of APP by looking at APP-related genes in the nematode *Caenorhabditis elegans*.

We have previously reported the isolation and characterization of an APP-related cDNA from *C. elegans*, *apl-1*, and have shown that the predicted APL-1 protein is a member of the APP family of proteins. The genomic region corresponding to *apl-1* has been identified and characterized; *apl-1* spans 4 kbp and contains 12 exons and 11 introns. It has been positioned to the left arm of the X chromosome of *C. elegans*.

We are interested in studying the function of *apl-1* by generating "knockout" worms, using a transposon insertional inactivation strategy. A mutant strain containing a transposon inserted in *apl-1* has been isolated by Ron Plasterk and kindly provided to us. The transposon insertion has been located to exon 12, prior to the transmembrane domain coding sequence. Further characterization of the mutant phenotype is underway. To determine the expression pattern of APL-1, antibodies against different parts of APL-1 are being generated and will be used to perform immunocytochemistry.

510.7

CHARACTERISTICS OF SECRETASE CLEAVAGE OF APP FROM PC12 CELL MEMBRANES. J.A. Ripellino*, Y. Chen*, S.B. Roberts*, K.M. Felsenstein*, and N.K. Robakis*. Dept. of Psychiatry and Fishberg Center for Neurobiology, Mount Sinai Medical Center, New York, NY 10029, and Bristol-Myers Squibb, Wallingford, CT 06492

The primary component of amyloid plaques, the hallmark of pathology in Alzheimer's Disease, is a 39-43 amino acid long peptide known as the amyloid- β -peptide. β -peptide is derived by proteolytic processing of a larger precursor protein known as Amyloid Precursor Protein (APP). One pathway for APP processing which results in cleavage within the β -peptide domain prevents the production of amyloidogenic products and occurs via an enzyme known as "a-secretase". In this report we show that a subcellular fraction of PC12 cells is enriched in "a-secretase" activity. After incubation at 37°C of membranes devoid of peripherally-associated molecules, a soluble 120kD fragment of APP is produced which on 7% SDS-PAGE has the same mobility as purified, secreted APP. This APP species is recognized by N-terminal specific antibodies but is not recognized by C-terminal specific antibodies. The enzymatic activity resulting in the release of the Nexin II form of APP has a pH range of 7.5 to 10.0, is differentially regulated by divalent cations, and is inhibited by two serine protease inhibitors. Moreover, the activity appears to be tightly membrane associated since extraction with 0.5M NaCl or sodium carbonate did not reduce the production of Nexin II.

510.9

EFFECTS OF ETHANOLAMINE (Etn) ADMINISTRATION ON THE LEVELS OF Etn AND CHOLINE IN PLASMA, BRAIN EXTRACELLULAR FLUID (ECF) AND BRAIN TISSUE, AND ON THE LEVELS OF BRAIN PHOSPHOLIPIDS IN RATS: AN *IN VIVO* AND *IN VITRO* STUDY. E. De Micheli* and R. J. Wurtman. Department of Brain and Cognitive Sciences, Massachusetts Institute of Technology, Cambridge, MA 02139

The sources and fates of brain ethanolamine (Etn) are poorly known and the effects of its administration have not been investigated, even though the cortical levels of this base are shown to be reduced in neurodegenerative pathologies with cholinergic function like Alzheimer's disease and Huntington's disease. We studied the effect of i.p. different Etn doses (10^{-3} , 5×10^{-3} and 10^{-2} mol/L/kg) on its and choline's (Ch) levels in arterial plasma and brain extracellular fluid (ECF) of awake rats. We also studied its effects on brain levels of Etn, Ch, and their respective major phospholipids. Etn administration caused dose dependent increases in Etn levels within plasma ($p < 0.05$) and brain ECF ($p < 0.05$), and also in brain Etn ($p < 0.05$) and phosphatidylethanolamine ($p < 0.05$). Systemic Etn also increased Ch levels in plasma (not completely dose dependently), brain ECF (dose dependently) ($p < 0.05$), and in brain tissue ($p < 0.05$); brain levels of phosphatidylcholine also increased. Possible metabolic pathways relating these increased Etn are discussed, as well as possible mechanisms of the decrease brain Etn in Alzheimer's disease.

510.6

STRUCTURE OF APP PROTEOGLYCAN AND DETECTION OF A NOVEL APP PROTEIN. M.N. Pangalos, J. Shioi, S. Efthimiopoulos, J. Ripellino, L.M. Refolo*, N.K. Robakis. Dept. Psychiatry and Fishberg Ctr. Neurobiol., Mt. Sinai. Med. Ctr., NY, NY 10029.

We have previously reported a novel chondroitin sulphate proteoglycan form of the Amyloid Precursor Protein (CSPG-APP) produced in C6 cells (Shioi et al, J. Biol. Chem. 1992; 267:13819). Further work has shown that other cell types produce CSPG-APP including human kidney 293 cells transfected with APP₅₅.

In an effort to characterize the glycosaminoglycan chain attachment sites on the APP core protein, CSPG-APP was purified from [³⁵S]- sulphate labelled media collected from transfected 293 cells. Media was passed through a dextran sulphate Sepharose column and APP and CSPG-APP containing fractions were then passed through an FPLC ion-exchange column. The resulting CSPG-APP fractions were digested overnight with Endoproteinase lysine-C and the peptide products separated by ion-exchange chromatography. CSPG containing peptide fractions, as determined by sulphate label, DMMB dye binding assay and chondroitinase ABC digestion, were immobilized onto membranes and subjected to protein sequence analysis.

Sequencing data indicated one predominant peptide. The first 10 amino acids corresponded to known APP sequences, however these were followed by 10 amino acids which have not been previously identified with any published APP sequence. Molecular biology techniques are now being used to identify and clone this unique APP cDNA.

510.8

THE PRION PROTEIN FRAGMENT PrP106-126 INDUCES CORTICAL TYPE I ASTROCYTES PROLIFERATION *IN VITRO*: CHARACTERIZATION OF THE MOLECULAR MECHANISMS INVOLVED. T. Florio*, M. Grimaldi, M. Salmons*, O. Bugiani*, F. Tagliavini*, G. Forloni* and G. Schettini. Dept. of Neuroscience, Sect. of Pharmacology, Univ. of Naples Federico II, Naples; Inst. of Pharmacological Research Mario Negri and Neurological Inst. Carlo Besta, Milan Italy.

The cellular prion protein (PrP^C) is a sialoglycoprotein of unknown function, highly expressed in neurons. In transmissible and genetic neurodegenerative diseases such as scrapie of the sheep and Creutzfeldt-Jacobs encephalopathy of the humans, PrP^C is converted in an altered form (PrP^{Sc}), identical in its primary structure but distinguishable from the normal protein for its resistance to protease digestion. In fact PrP^{Sc} accumulates in the brain of affected individuals in protease-resistant, amyloid-like aggregates. Recently, it was reported that a fragment of PrP (PrP106-126) was able to induce neuronal apoptotic death *in vitro*, and that this peptide can polymerize in amyloid fibrils. Since all the PrP-related neurodegenerative diseases are characterized by both neuronal death and astrogliosis, our study was aimed to identify a direct proliferative effect on primary cultures of cortical astrocytes of the PrP106-126 fragment and which intracellular mechanisms were involved. PrP106-126 induced a remarkable increase in quiescent (growth in absence of serum) rat cortical astrocytes assayed as both tritiated thymidine incorporation and exosaminidase proliferation assay. Specific antagonists for different intracellular pathways were used to identify the molecular mechanism of action of PrP106-126. (MURST 40% 1992, 1993 to G.S.)

510.10

DISTRIBUTION AND SEMI-QUANTITATIVE ANALYSIS OF TYROSINE HYDROXYLASE mRNA IN THE NORMAL HUMAN AND ALZHEIMER'S DISEASE LOCUS CERULEUS. J. Leverenz*, M.A. Miller, P.E. Kolb, E.R. Peskind and M.A. Raskind. Departments of Medicine (Neurology) and Psychiatry and Behavioral Sciences, University of Washington, Seattle, WA, 98195.

Locus ceruleus neuronal loss is well documented in Alzheimer's disease, though concomitant decline of noradrenergic function has not been convincingly demonstrated. We have, therefore, become interested in the regulation and function of locus ceruleus neurons in both the normal state and in Alzheimer's disease. Brainstems with the complete locus ceruleus from both normal elderly patients and those with Alzheimer's disease were collected and snap frozen. The entire locus ceruleus was serially sectioned from rostral to caudal extent and prepared for anatomic, immunohistochemical, receptor binding and *in situ* hybridization studies. We have developed *in situ* techniques for use in human brain tissue to examine the presence and level of expression of tyrosine hydroxylase message using a 153 bp riboprobe (cDNA generously provided by Karen O'Malley, Washington Univ.). Our initial studies have demonstrated message for tyrosine hydroxylase in the locus ceruleus in both the normal and Alzheimer's disease brain. The findings are consistent with previous reports in other primate and rat brain. We will describe the distribution and level of expression of tyrosine hydroxylase message. We believe these studies will help elucidate the influence of Alzheimer's disease on locus ceruleus function and explain some of the paradoxes seen in the noradrenergic system in this disease.

510.11

LOCALIZATION OF THE DEFICIT IN CYTOCHROME OXIDASE (COX) ACTIVITY AND COX SUBUNIT mRNA WITHIN THE CEREBRAL CORTEX IN ALZHEIMER'S DISEASE (AD).

K. Hatanpää, D.R. Brady, L. Stoll, S.I. Rapoport, K. Chandrasekaran*. Laboratory of Neurosciences, NIA, Bethesda, MD 20892.

Quantitative COX histochemistry was used to measure COX activity in tissue sections from motor and temporal cortices of 12 AD and 7 control brains. The method was calibrated with tissue sections from homogenates of known COX activity. We also used *in situ* hybridization to localize mRNA of COX subunit III (COX III) and 16S rRNA, a marker of total mitochondrial RNA levels. To ensure identical hybridization conditions, slides containing sections from the temporal and motor cortex of the same patient were paired and hybridized with the sections facing each other, with the probe between them.

Within the AD brain, COX activity in temporal cortex, a region typically affected in AD, was 29% lower than in motor cortex ($p < 0.01$), a region typically spared in AD. The levels of COX III mRNA in temporal cortex relative to motor cortex were 35% lower ($p < 0.01$), while 16S rRNA showed no difference. Control cases showed no differences between the two brain regions in COX activity or COX III mRNA levels. There were no significant correlations between the decreases in levels of COX activity or COX III mRNA and the numbers of neurofibrillary tangles or senile plaques in the AD brains.

The levels of COX activity and mRNA were plotted as a function of distance from the pial surface. The AD cases showed the most pronounced decrease in layers I-III. Studies are under way to relate these deficits to the *pre mortem* clinical state of the disease, to loss of neurons and synapses, and to altered regulation of mitochondrial gene expression.

510.13

ACCUMULATION OF UBIQUITIN-PROTEIN CONJUGATES IN A NEURONAL CELL LINE FOLLOWING TREATMENT WITH AN INHIBITOR OF THE MULTICATALYTIC PROTEINASE COMPLEX (20S PROTEASOME). M.E. Figueiredo-Pereira*, K.A. Berot & S. Wilk. Depts of Pharmacology and Anesthesiology, Mount Sinai School of Medicine, CUNY, New York, New York 10029, USA.

Accumulation of ubiquitin-protein conjugates is common in abnormal brain inclusions of patients with idiopathic chronic neurodegenerative diseases. Covalent binding of ubiquitin to proteins is viewed as a means by which proteins are marked for subsequent degradation. We report that exposure of HT4 cells (a mouse neuronal cell line) to a potent permeable inhibitor of the multicatalytic proteinase complex (MPC) causes accumulation of ubiquitinated proteins. In contrast, incubations with a calpain inhibitor or with a lysosomotropic agent failed to produce detectable ubiquitin-protein conjugates. These results suggest that a malfunction in the ubiquitin/ATP-dependent protein degrading system, of which MPC is the "catalytic core", could be a factor in the accumulation of ubiquitin protein conjugates identified in neurodegenerating brains. The MPC-inhibitor may therefore be a useful tool for developing a model for the study of neurodegenerative diseases. (Supported by NIH grants NS-29936, MH-00350, GM-34852 and MH-48125).

510.15

AN INFORMATIVE MICROSATELLITE [GT] REPEAT ON A CHROMOSOME 14 COSMID ALSO CONTAINING E2K. Ghazala Ali, Wilma Wasco, Rudolph Tanzi, and John Blass. Burke Medical Research Institute, Cornell Medical College, White Plains, NY 10605 and *Laboratory of Genetics & Aging, Massachusetts General Hospital, Charlestown, MA 02129.

Previous studies have indicated that the activity of the α -ketoglutarate dehydrogenase complex (E2k) is reduced in Alzheimer (AD) brain (Gibson et al, *Arch Neurol* 45:836,1988; Mastrogiovanni et al, *J Neurochem* 61:2007,1994) and fibroblasts (Cooper et al, *Ann Neurol* 35:312, 1994). KGDHC consists of 3 proteins, E1k, E2k, and E3. We have localized E1k to chromosome 7 (Szabo et al, in press) and E2k to chromosome 14q24.3 (Ali et al, in press); E3 had previously been localized to chromosome 7. In order to test for association of the E2k gene with Alzheimer's disease, we have identified a microsatellite repeat region on a chromosome 14 cosmid which also binds the full-length E2k probe which we have isolated and sequenced previously (Tanzi et al, in press).

Ten cosmids derived from a human chromosome 14 library were tested for cohybridization with E2k and with a GT repeat 30-mer. The one cosmid which was found to bind both probes was subcloned and sequenced. The sequence flanking the GT₂₁ microsatellite region was used to design PCR primers amplifying a 401 bp fragment. This is an informative polymorphism giving rise to at least 10 separate common alleles. This polymorphism is being tested for association with familial and apparently sporadic AD.

PROPERTIES OF A POTENT AND CELL PERMEABLE INHIBITOR OF THE CHYMOTRYPSIN-LIKE ACTIVITY OF THE MULTICATALYTIC PROTEINASE COMPLEX. S. Wilk* and M.E. Figueiredo-Pereira. Dept. of Pharmacology, Mount Sinai School of Medicine, CUNY, New York, New York 10029, USA.

The multicatalytic proteinase complex (proteasome; MPC) is a high molecular weight enzyme found in all eukaryotic cells. There is mounting evidence that MPC participates in several fundamental cellular processes including the degradation of ubiquitin-protein conjugates. To explore its physiological role, N-benzoyloxycarbonyl-Ile-Glu(OtBu)-Ala-Leucinal [Z-IE(OtBu)AL-CHO], a peptide aldehyde inhibitor of the chymotrypsin-like activity of MPC, was synthesized. This compound potentially inhibits hydrolysis of succinyl-LLVY-methylcoumarinylamide (IC₅₀=0.25 μ M) by purified bovine pituitary MPC. Other catalytic activities of MPC were much less affected. Furthermore, this hydrophobic aldehyde is cell permeable. Due to its discriminating inhibitory effects Z-IE(OtBu)AL-CHO may be a powerful tool to investigate the mechanisms leading to accumulation of ubiquitin-protein conjugates in neurodegenerative diseases. IMMUNOREACTIVE CERULOPLASMIN IN NORMAL AND ALZHEIMER'S DISEASE BRAIN. D. Loeffler*, L. Vaysman*, H. Nguyen*, K. Leone*, P. Lewitt*, P. Juneau*, L. Kanaley*, and A. Sima*. Sinai Hospital, Detroit, MI 48235, Warner Lambert Co., Ann Arbor, MI 48106, Brain Tissue Resource Center, McLean Hospital, Belmont, MA 02178, and *University of Michigan, Ann Arbor, MI 48109.

Ceruloplasmin (CP) provides the majority of anti-oxidant activity in plasma due to its ferroxidase activity. This study examined cellular distribution of CP in normal and AD brain (n = 5/group). Immunoperoxidase staining of formalin-fixed normal brain showed faint neuronal staining in frontal cortex, parietal cortex, and caudate, with variable staining in hippocampus, putamen, substantia nigra (SN), and cerebellum. Neuronal staining was more widespread and of greater intensity in AD (vs. normal) brain in frontal and parietal cortex, caudate, and hippocampus, and immunoreactive astrocytes were present. Differences between AD and normal brain were not seen for putamen, SN, and cerebellum. These results suggest that neuronal production of CP may be increased in some regions of AD brain. (Tissue provided by Dr. E. Bird, Brain Tissue Resource Center.)

MOLECULAR CHARACTERIZATION OF BRAIN ANTIGENS AND THEIR INVOLVEMENT IN NEUROPATHOLOGY OF ALZHEIMER DISEASE. R. Fukuyama, K. Hatanpää, C.R. Jones, S.I. Rapoport and D.R. Brady*.

Laboratory of Neurosciences, National Institute on Aging, NIH, Bethesda, MD 20892

We have hypothesized that the selective vulnerability found in Alzheimer disease (AD) brain is based on differential expression of unknown molecules in target brain regions. To test this hypothesis, we employed a conventional and a new monoclonal hybridoma technique, SOFISTIC (Fukuyama et al. *Neurosci. Abstr.* 1993), to raise monoclonal antibodies (MAbs) against antigens extracted from selected human and rat brain areas, hippocampus, entorhinal cortex and amygdala. We characterized molecular sizes and subcellular localization of antigens that are recognized by our MAbs and examined their distribution in rat, monkey and human brain. The immunohistochemical staining pattern of MAbs on brain sections fell into 6 categories: neuronal, dendritic, axonal, synaptic, astroglial and nuclear. Some of the MAbs showed region-specific staining. Five MAbs showed distinct immunoreactive bands on Western blots of cultured cell and brain extracts. Molecular sizes of antigens ranged from 14 to 230 kDa. BG5 antigen was localized to the mitochondria, and AE2 antigen to the cytosolic fraction. We screened 1gt11 rat hippocampal and human amygdala cDNA libraries by MAbs to isolate cDNA clones that could encode epitopes of these antigens. We isolated 5 distinct cDNA clones. Except for clone BG5, partial sequence data obtained from 2-3 clones for each gene showed no obvious similarity to known sequences reported in GenEMBL database (released in Dec. '93). One of BG5 clones, BG5i-2, detected a single mRNA band about 10 kb in size. Among tissues tested, the BG5 gene showed the highest expression in human brain. It also weakly cross-hybridized to rat brain mRNA under stringent conditions. We further hybridized BG5i-2 clone to the human-mouse hybrid panel and assigned the BG5 gene to human chromosome 15. Its partial cDNA sequence showed a homology to rat microtubule associated protein (MAP) 1A. Western blot and immunohistochemical staining with our MAbs and with SY38, a Mab to synaptophysin, showed a marked decrease of BG5 and AH9 antigens, and synaptophysin, in temporal cortex of AD brains. We suggest that our MAbs are useful tool for analyses of AD and brain structure.

APOPTOSIS IS INDUCED BY HYDROGEN PEROXIDE IN CULTURED CENTRAL NERVOUS SYSTEM NEURONS E.R. Whittemore*, D.T. Loo, and C.W. Cotman. IRU in Brain Aging, Univ. of Calif., Irvine, CA 92717.

The accumulation of β -amyloid peptides (A β P) in senile plaques is a principal event in the neuropathology of Alzheimer disease. We previously reported that CNS neurons undergo apoptosis following exposure to A β P in vitro. A link between A β P-mediated apoptosis and oxidative damage has been suggested by studies reporting that antioxidant agents protect neurons from A β P-induced cell death. We have pursued this possibility and demonstrated that exposure of neurons to 100 μ M hydrogen peroxide for 24h induced apoptosis as assessed by toxicity assays, nuclear staining, and assessment of internucleosomal DNA fragmentation.

We have begun to examine in more detail the mechanism of induction of apoptosis in neurons by hydrogen peroxide. We report that a reduction in cell viability and mitochondrial function occurs within 3h following hydrogen peroxide exposure, and parallels the induction of DNA fragmentation. In other models of apoptosis, increases in $[Ca^{2+}]_i$ have been linked with the activation of endonucleases responsible for DNA fragmentation. Measurement of $[Ca^{2+}]_i$ using fura-2 imaging following exposure of neurons to hydrogen peroxide indicates that the $[Ca^{2+}]_i$ increases steadily over time, consistent with the idea of activation of a Ca^{2+} -dependent endonuclease. Vulnerability to hydrogen peroxide is cell type specific within the CNS, with neurons being most sensitive, followed by microglia, then astrocytes. These results suggest that direct oxidative injury may serve as a general trigger for neuronal apoptosis in the CNS, and that apoptotic cell death may be induced by oxidative injury and/or stress that accompanies many neurodegenerative diseases.

MEMBRANOUS LIPODYSTROPHY WITH ALZHEIMER'S SENILE PATHOLOGY. Y. Takamaru¹, R. Fukatsu³, K. Tsuzuki⁴

T. Yokoo⁵, H. Takahashi², N. Itoh⁵, N. Fujii⁴, I. Kusumi¹, T. Koyama¹, K. Nagashima² and N. Takahata³ Depts of ¹Psychiatry and ²Pathology, Hokkaido Univ., Depts of ³Neuropsychiatry and ⁴Microbiology Sapporo Medical Univ., ⁵Nakamura Memorial Hospital, Sapporo 060, Japan.

Membranous leucodystrophy (ML) is a rare disease characterized by multiple bone lesions with repetitive fractures and progressive neuropsychiatric deterioration. We had an opportunity to examine two cases of the disease with Alzheimer's senile change. In present study, we compare the senile changes in ML with those in Alzheimer's disease.

case 1. 50 yro female. Brain weight 740 g. Severe generalized atrophy diffuse and profound demyelination and gliosis, sudanophilic granules, axonal swelling and spheroids were present. Wide spreaded senile plaques (SPs) and neurofibrillary tangles (NFTs) in the cortex.

case 2. 53 yro female. Brain weight 1030 g. Marked cerebral atrophy, severe demyelination and gliosis, numerous SPs and NFTs were found.

SPs were distributed in cerebral cortices, predominantly in parietal and occipital lobes. The classical or compact plaques were predominant, but diffuse or subpial plaques were rare. Amyloid angiopathy were not recognized SPs were stained with anti β antibodies, and anti amyloid associated proteins Western blot analysis of brain extracts showed similar results.

In conclusion, the differences in senile alteration suggest that there are differences in pathogenesis of these senile changes between two cases extremely unusual cases and Alzheimer's disease.

DEGENERATIVE DISEASE: OTHER—NEUROTOXIC EFFECTS AND HUNTINGTON'S

511.1

MAGNETIC RESONANCE IMAGING OF IBOTENIC ACID LESIONS IN THE PRIMATE CAUDATE NUCLEUS. E.C. Gower* and R.N. Samaraweera. Boston VAMC, Boston, MA 02130.

Monkeys (*Macaca fascicularis*) with ibotenic acid (IA) lesions of the head of the caudate nucleus are characterized by anterograde and retrograde memory defects, and *in vivo* evidence of atrophy of the injected nucleus and ventricular enlargement on MRI. As in Huntington's disease, overt signal change in regions of presumptive hypocellularity is elusive on visual inspection. In this study, we mapped the distribution of signal intensity on proton density images (TR = 2000-2500, TE_{eff} = 42; in plane resolution = 0.47 mm). The region containing the caudate nucleus was located by identifying pixel intensity transitions at the border of the caudate in the lateral ventricle, corpus callosum, corona radiata and internal capsule. Dorso-ventral columns of pixels were averaged after subtracting boundary-adjacent pixels to reduce the weighting of the means by heavily myelinated areas, CSF and edge enhancement artifacts. In the normal caudate, signal intensity rose moderately from lateral to medial. In contrast, a local zone of hypointensity caused each IA injected caudate to depart from the linearity of the normal distribution. Regional deviations were approximately in register with the planned coordinates of the lesions. Loss of signal intensity may reflect neuronal depletion and gliosis, and thus the distribution of signal across the caudate nucleus appears to be sensitive to the local anatomic and neurochemical consequences of neurotoxic tissue injury. However, hemosiderin deposits associated with microhemorrhage may also contribute. The findings may have relevance in assessing early state neuropathology in HD with structural imaging.

510.18

ABNORMAL LYSOSOMAL HYDROLASE mRNA EXPRESSION IN NEURONS FROM ALZHEIMER DISEASE BRAIN. A.M. Cataldo*, D.J. Hamilton, S.A. Berman, C. Lippa, R.A. Nixon, McLean Hospital, Harvard Med. Sch., Belmont, MA and Dept. Neurol., U. Mass. Med. Ctr. Worcester, MA.

Our cytochemical studies demonstrate progressive disturbances of endosomal-lysosomal function in Alzheimer Disease (AD) pathogenesis. Lysosomal alterations were identified in normal-appearing, at-risk AD neurons and progress with advanced degeneration. Following cell lysis, lysosomal hydrolases are present extracellularly in amyloid-containing senile plaques (SP). To establish whether cytochemical alterations could be explained by changes at the molecular level, we examined the gene expression of cathepsin D (CD) in flash frozen, AD and control brains (PMI \leq 6.5 hrs). Serial sections of the prefrontal cortex were analyzed with CD antiserum and by *in situ* hybridization (ISH). Changes in the levels of CD expression were evaluated by semiquantitative densitometric and Northern blot analyses. SP were identified by silver stain and thioflavin S. In AD brains, \geq 75% of neocortical perikarya in layers III and V displayed 2 fold higher levels of CD mRNA by ISH compared to control brains ($p < 0.001$). The same neuronal populations contained increased CD immunoreactivity. Elevated levels of CD mRNA were confirmed by Northern blot. CD mRNA signal was localized in the soma and dendrites, but not in SP immunoreactive with CD antiserum. Our results indicate that lysosomal system alterations occur early in AD pathogenesis. Activation of the lysosomal system is manifested by increased CD gene expression and immunoreactivity in "at-risk" AD neurons. Changes in hydrolase expression may be one of the earliest indicators of selective cell vulnerability in certain AD neurons preceding other histological and cytochemical evidence of degeneration and may relate to the formation of amyloid-containing SP.

511.2

3-NITROPROPIONIC ACID NEUROTOXICITY IN STRIATAL AND NON-STRATIAT CULTURES IS MODULATED BY ENERGY SUBSTRATE AVAILABILITY BUT NOT SIGNIFICANTLY BY GLUTAMATE RECEPTOR ANTAGONISTS. S.L. Fink, D.Y. Ho*, and R.M. Sapolsky. Depts. of Neurosciences and Biological Sciences, Stanford Univ., Stanford, CA 94305-5020.

3-Nitropropionic acid irreversibly inhibits the activity of the mitochondrial enzyme succinate dehydrogenase. When administered systemically to rats or ingested accidentally by humans or livestock, it causes selective striatal lesions. All reports thus far on 3-NP's neuronal effects have used whole animals or cortical explants. We studied the effects of 3-NP on dissociated cultures of neurons and glia. We found that, despite its selective toxicity *in vivo*, incubation with 3-NP leads to comparable dose-dependent neuron death in cultured striatal, hippocampal, cerebellar and hypothalamic neurons. In addition, 3-NP's effects were remarkable energy substrate-dependent, with its toxicity being potentiated by low glucose conditions to a greater extent than was the case for glutamate. Furthermore, infection of the cultured neurons with a herpes simplex virus vector carrying GLUT-1 glucose transporter significantly protected them against toxicity caused by moderately damaging doses of 3-NP in low glucose media.

Finally, the striatal damage caused by 3-NP administration has been theorized to be partially mediated by excitotoxins. This is supported by one report in which glutamate receptor antagonists attenuated 3-NP-induced damage in cortical explants [A. C. Ludolph, *et al.*, *Neurodegen* 1, 155-161 (1992)]. We found that incubation with the non-specific glutamate receptor antagonist, kynurenic acid, increased neuronal survival from 15% to 61% of control in low glucose conditions, but did not significantly increase survival of neurons exposed to 3-NP. We are currently studying whether 3-NP toxicity can be decreased by co-incubation of the cultures with kynurenic acid and DL-2-amino-7-phosphonoheptanoic acid (APV), an NMDA-selective glutamate receptor antagonist. If so, this would support a role for excitotoxin-induced cellular cascades in neuron death caused by this energetic toxin; however, pilot experiments indicate that most of the toxicity is caused by other cellular processes.

511.3

NEURONAL DEGENERATION INDUCED BY 3-NITROPROPIONIC ACID IN THE FOREBRAIN: ANALYSIS WITH A SILVER METHOD. P.J. Miller* and L. Zaborszky. Center for Molecular & Behavioral Neuroscience, Rutgers, The State University of NJ, Newark, NJ 07102

3-Nitropropionic acid (3-NP) is a mitochondrial toxin which has been suggested (Beal et al., 1993) to replicate many of the histological and neurochemical characteristics of Huntington's disease upon systemic or local striatal application. The subsequent neuronal loss in other brain areas is less well understood. 3-NP was injected stereotactically (500nmol, 0.1-0.5ul) into various forebrain areas (striatum, internal capsule, thalamus, lateral hypothalamus). Animals were perfused 5-15 days after the lesion and brain sections were impregnated according to a sensitive silver method (Gallyas et al., 1990). This method produces selective, Golgi-like staining of cells whose cytoskeletal system is damaged by various pathological events. While injections of 3-NP into the striatum resulted in local neuronal degeneration, an equally large number of medium-sized spiny striatal neurons degenerated if their axons in the forebrain were exposed to this toxin. Injections of 3-NP also resulted in topographically organized neuronal degeneration in various thalamic nuclei, corresponding to the damage of their axons and/or terminals. Thalamostriatal neurons were always heavily affected. Moderate neuronal degeneration was also observed in the pars compacta and in some cases in the pars reticulata of the substantia nigra. In spite of the fact that corticofugal axons were exposed to the toxin, little cell death was observed in the cortex. These studies suggest that intracerebral injection of 3-NP can cause substantial retrograde degeneration in basal ganglia circuits, with different projections showing different vulnerability. This data should be taken into consideration when using 3-NP in an animal model of Huntington's disease.

511.5

HISTOLOGICAL AND BEHAVIORAL EFFECTS OF CHRONIC 3-NITROPROPIONIC ACID TREATMENT IN OLD RATS. E. Brouillet*, M.-C. Guyot, R. Dolan, M. Mazière and P. Hanlyave. Service Hospitalier Frédéric Joliot, CNRS URA1285, CEA, 4 place du Général Leclerc, 91401 Cedex Orsay, FRANCE

Chronic administration of 3-nitropropionic acid (3NP) in rats has been shown recently to produce bilateral striatal lesions, closely replicating the neuropathology of Huntington's disease (HD) (Beal et al. 1993, J. Neurosci. 13:4181-92). In the present report, we studied the behavioral and anatomical effects of a chronic 3NP treatment (10 mg/kg/day s.c. for 4 weeks). Four months post-lesion, 60-70 % of 3NP-treated animals showed mild motor symptoms including a wobbling gait, an apparent decrease in the length of their steps and an abnormal paw placement during locomotion. Quantitative analysis of the locomotor behavior (under spontaneous and after methamphetamine administration) using video recording showed significant changes in several parameters as compared to saline-treated animals, consistent with stable impairment of locomotion. Histological evaluation of the animals showed small lesions (30-60 % neuronal loss based on Nissl with NADPH-diaphorase interneurons sparing). These lesions were located consistently in the dorso-lateral part of the striatum in 70 % of the 3NP-treated group. These data confirm that chronic 3NP treatment leads to NMDA receptor-mediated like-lesions which are associated with stable motor symptoms.

511.7

DIFFERENTIAL RESPONSE OF EXTRACELLULAR GABA IN THE STRIATUM AND NUCLEUS ACCUMBENS IN THE QUINOLINIC ACID RAT MODEL FOR HUNTINGTON'S DISEASE. W. LIN, D.L. Roegig and N.C. REYNOLDS*. Neurology Dept., Med. College of WI and VA Med. Center, Milwaukee, WI 53295.

This study examines the changes in extracellular GABA in the nucleus accumbens (NA) following quinolinic acid (QA) infusions into the striatum to determine whether striatal degenerative change can effect the NA to provide a physical basis for behavioral changes in Huntington's disease (HD). The NA constitutes a major functional interface between the limbic and motor systems in locomotor processes but has also been implicated in positive reinforcement and psychiatric disorders. Although Huntington's disease (HD) is a neurodegenerative disorder with severe effects on striatal neurons, post-mortem GABA content in the NA is significantly decreased in HD patients with psychotic features. Despite the common use of "dementia" as an explanation for behavioral problems in HD in clinical practice, cortical atrophy is a late finding and mental status changes are quite dissimilar to changes seen in classical dementia (i.e., Alzheimer's disease) and often involve psychotic features or emotional lability with violent outbursts.

30 min. after intrastriatal perfusion of QA (0.24M, at 2ul/min for 10 min.) laboratory rats displayed overt hypermotility with contralateral rolling movements and rigidity in the neck and forelimbs for 90 to 120 min. Over the next three days increased stereotypic grooming behavior was observed. Irritability to touch and piloerection was apparent from the second day through sacrifice on day 8.

On the 1st day after QA perfusion, extracellular GABA was decreased in striatum (67% of baseline) and increased in NA (156% of baseline). On day 2, GABA returned to baseline in the NA and then declined gradually to 40% of baseline by day 7. Striatal GABA slowly declined to this same level by day 7. These results show that QA perfusion of the striatum causes a slow decline in extracellular GABA in both nuclei but early transient increases in the NA. An extrapolation of such changes to the more protracted time course in HD may help to explain several locomotor and behavioral changes in humans with HD.

511.4

PROGRESSIVE BEHAVIORAL CHANGES DURING ONE-MONTH LOW DOSE ADMINISTRATION OF 3-NITROPROPIONIC ACID. T.K. Koutouzis, C.V. Borlongan, T.B. Freeman, D.W. Cahill* and P.R. Sanberg. Div. of Neurological Surgery, Depts. of Surgery, Neurology, Psychiatry and Pharmacology, Univ. of South Florida Coll. of Med., Tampa, FL 33612.

Excitotoxic animal models have been widely utilized to define the mechanisms involved in the abnormalities observed in Huntington's disease (HD). Recently, 3-Nitropropionic acid (3-NP) has been proposed as an excitotoxic model that closely mimics the anatomical pathology associated with HD based on the striatal atrophy following mitochondrial impairment induced by 3-NP. Since impaired oxidative energy metabolism has been implicated in HD patients, 3-NP seems to reflect a similar mechanism leading to striatal pathology. Very few studies have investigated the consequent behavioral pathology following 3-NP injections in animals. In our previous studies with low dose systemic 3-NP-injected animals (Koutouzis et al. Brain Res., in press), we observed significant hypoactivity, and accordingly suggested that this reflected advanced or juvenile onset HD cases. In the present study, the previous dosing regimen of 3-NP (15 mg/kg, i.p., once every 4 days for 28 consecutive days), was administered but instead of testing only after 28 days, the animals were tested following each day of injection. The present results were very interesting; initially, the 3-NP-injected animals exhibited significant hyperactivity, reaching a plateau after the third injection (day 12), then showing significant hypoactivity from the fourth injection (day 16) onwards. The close resemblance between systemic 3-NP's behavioral effects in rodents and the ongoing behavioral pathology of HD in humans supports the suitability of 3-NP as an animal model of HD. (Supported, in part, by STRC, USF President's Council, and T. Larsen and friends.)

511.6

CHRONIC BILATERAL INTRASTRIATAL DIALYTIC ADMINISTRATION OF QUINOLINIC ACID PRODUCES ABNORMAL MOTOR BEHAVIOR IN RATS. T. Bazzett*, C. Trahey, S. Ugarte, J. Becker and R. Albin. Depts. of Neurology and Biopsychology, University of Michigan, Ann Arbor, MI 48104-1687

We have previously reported that chronic intrastriatal dialytic administration of quinolinic acid (QA) in the rat produces selective neurodegeneration similar to that seen in Huntington's disease (HD). In addition to neuronal loss, we have reported that chronic QA administration induces reversible changes in some areas of the striatum. The present results show that bilateral administration of QA using this technique, produces behavioral changes that may be analogous to motor abnormalities associated with HD. QA treated rats showed increased rearing behavior, oral movements, and nocturnal activity compared to vehicle treated animals. Unlike rats receiving acute injections of QA, animals exposed to chronic QA show a more progressive development of abnormal behaviors.

Additional behavioral measures will be presented including changes in motor behavior following acute stress. Results will also show if any QA induced changes in behavior improve after cessation of QUIN infusion correlating with transient changes in striatal anatomy.

511.8

TIMING THE TRANSCRIPTIONAL RESPONSE OF THE IT15 GENE (HUNTINGTIN) DURING THE EARLY STAGES OF THE NMDA RECEPTOR-MEDIATED EXCITOTOXIC CASCADE. L.R. Carlock, K. Gutridge, Y. Shan & P.D. Walker*. Departments of Molecular Biology/Genetics and Anatomy/Cell Biology, Wayne State University School of Medicine, Detroit, MI 48201.

NMDA receptor overstimulation produces a pattern of neuronal death within the rodent striatum similar to Huntington's disease (HD). However, does the excitotoxic rodent model provide information that can elucidate the function of the IT15 (Huntingtin) gene in the chronic HD process? We sought to examine the transcriptional response of the rodent IT15 gene during the initial stages (1-72 hours) of the excitotoxic cascade and compare it to changes in immediate-early, neurotransmitter-specific, and glial genes. Adult male Sprague-Dawley rats (175-200g) received unilateral intrastriatal injections of quinolinic acid (QA; 1ul of a 240mM concentration) and were sacrificed at various times from 1 to 72 hours later. Following QA injection, striatal induction of immediate early genes (IEGs; c-fos, jun-B, c-jun, and zif/268) extended from 1-12 hours while neurotransmitter mRNAs for GABA, tachykinin and enkephalin synthesis began to decline within the lesion site after 6 hours and were maximally reduced by 24 hours suggestive of neuronal death. Glial transcripts were increased after 3-6 hours and remained high within the lesioned striatum at 72 hours. Interestingly, the transcriptional response of the IT15 gene temporally mimicked the IEGs and also followed the decline of neurotransmitter mRNAs from 6-24 hours. These results suggest that the rodent IT15 gene is transcriptionally responsive to NMDA receptor overstimulation and is mostly expressed by neurons that degenerate during the excitotoxic cascade. Supported by NS24236 (LRC) and WSU Office of Neuroscience Programs.

511.9

MITOCHONDRIAL ENZYME ACTIVITIES IN HUNTINGTON'S DISEASE. S.E. Browne*, Allen C. Bowling and M.F. Beal. Neurology Research, Massachusetts General Hospital and Harvard Medical School, Boston, MA 02114.

An attractive hypothesis of how the gene defect in Huntington's disease (HD) leads to neuronal degeneration is that a defect in mitochondrial energy metabolism may render cells more vulnerable to endogenous levels of glutamate, resulting in slow excitotoxic neuronal death. In support of this hypothesis, PET studies have shown reduced glucose utilization in the basal ganglia of HD patients, while a recent NMR spectroscopy study found increased lactate concentrations in the occipital cortex and basal ganglia of HD patients (Jenkins *et al.*, *Neurology* 1993, 43, 2689-2695). In addition, chronic systemic administration of mitochondrial toxins to rodents have been found to produce striatal lesions exhibiting close neurochemical and histological similarities to HD lesions (Beal, *Ann. Neurol.* 1992, 31, 119-130).

The aim of the present study was to investigate whether activities of electron transport chain enzymes are altered in HD patients, relative to levels in control subjects. Activities of citrate synthase and the oxidative phosphorylation enzyme complexes I, II-III and IV, were measured in mitochondrial preparations by spectrophotometric assay procedures. Citrate synthase-corrected complex I activity was found to be significantly increased in frontal cortex of HD patients (+28%, $p < 0.05$), and showed a trend towards an increase in HD caudate. A trend towards decreased complex II-III activity was also evident in caudate. This study is presently being expanded to other brain regions.

(Supported by the Huntington's Disease Society of America).

511.11

PURIFICATION AND CHARACTERIZATION OF THE HUNTINGTON'S DISEASE PROTEIN FROM RAT BRAIN SYNAPTIC VESICLES. J.P. Steiner*, T.M. Dawson, A.H. Sharp, R.K. Barrow, C.A. Ross and S.H. Snyder. Depts. Neurosci., Neurol. and Psych., The Johns Hopkins Univ. Sch. of Med., Baltimore, MD 21205.

The identification and cloning of the IT15 gene and the subsequent development of high affinity antibodies raised against two peptide sequences contained within the open reading frame of IT15 has provided us with the necessary reagent to attempt to isolate and purify the Huntington's Disease protein (HDP). Using the affinity-purified antibodies raised against amino acid residues 1-17 of HDP, we probed various membrane and soluble protein subfractions isolated from rat forebrain. HDP is enriched in the synaptic vesicle-containing subfraction, but is readily dissociated from the vesicles by increasing ionic strength. The extracted HDP was fractionated by gel filtration, ion exchange chromatography and differential centrifugation on sucrose gradients and revealed two high molecular weight proteins of 300 and 350 KDa, which cross-react with our anti-HDP Ig. We are obtaining primary amino acid sequence of both proteins in order to identify them. Preliminary sequence analysis indicates that the 350 KDa protein is rat brain HDP. The 300 KDa protein may be a structural homolog of HDP as indicated by the cross-reactivity to HDP antibodies. Both proteins reassociate specifically with synaptic vesicles as well as cytoskeletal elements, suggesting that HDP may play a role in neurosecretion and vesicle recycling.

511.13

A CONTROLLED TRIAL OF THE GLUTAMATE ANTAGONIST REMACEMIDE HYDROCHLORIDE IN HUNTINGTON'S DISEASE. K. Kiebert, M. McDermott, A. Feigin, P. Como, D. Abwender, C. Zimmerman, C. Hickey, C. Orme, K. Bordwell, J. Sotack, C. Dunn, J.T. Greenamyre, I. Shoulson* Dept of Neurology, Univ of Rochester, and Fisons Pharmaceuticals, Rochester, NY 14642

The neuropathology of Huntington's disease (HD) is characterized by selective degeneration of striatal medium-sized spiny GABA-ergic neurons, a pattern of neuronal loss which can be reproduced in experimental animals by striatal injections of glutamate or NMDA agonists, suggesting that excitotoxic neurotransmission may play a role in the neurodegenerative process. Glutamate receptor antagonists may therefore ameliorate or slow HD, but such drugs (e.g. MK-801) in humans have been associated with intolerable side effects. We conducted a randomized, double-blind, placebo-controlled tolerability trial of remacemide hydrochloride, a non-competitive NMDA channel blocking agent. Subjects were randomized to receive remacemide 200 mg/d, 600 mg/d or placebo and were assessed by standardized neurological and cognitive tests for 6 weeks, including a 1-2 week blinded staggered withdrawal of drug. The primary outcome measure was the proportion of subjects able to complete the study on the assigned treatment regimen. Thirty-one HD patients in early to moderate stages of illness (18 men, 13 women) were enrolled in the study; and twenty-nine completed treatment. One subject was terminated for non-compliance and one subject elected to discontinue drug because of nausea and vomiting (both in 600 mg/d group). There were no significant differences in the primary measure of tolerability between treatment arms. No severe adverse experiences or adverse cognitive effects were reported. Remacemide appears to be safe and well tolerated in patients with HD at dosages up to 600 mg/day. Larger long-term study of the impact of remacemide on HD is warranted. (Supported by Fisons Pharmaceuticals and the University of Rochester Clinical Research Center RR00044.)

EXPRESSION OF THE ALPHA ISOFORM OF PROTEIN KINASE C (PKC α) IS INCREASED IN CAUDATE NEURONS IN PRESYMPTOMATIC HUNTINGTON'S DISEASE. G. Figueredo-Cardenas and A. Reiner. Dept. Anat. & Neurobiol., UT-Memphis, Memphis, TN 38163.

Protein kinase C (PKC) is a calcium/phospholipid dependent kinase and numerous isoforms have been found in nervous tissue. We have found that the PKC α isoform, a cytosolic isoform normally found in very low levels in striatal projection neurons, is upregulated to immunohistochemically detectable levels in surviving rat striatal neurons subjected to an excitotoxic or ischemic insult. We therefore immunohistochemically examined fixed striatum from a presymptomatic Huntington's disease (HD) victim to determine if PKC α expression was increased and might reveal the early expression of the HD disease process. We found high expression of PKC α in the presymptomatic HD caudate and low expression in the presymptomatic HD putamen. Normal striatum was largely devoid of PKC α labeling. In presymptomatic HD caudate, double-label studies showed that PKC α was expressed by 80% of the Calbindin (Calb) neurons (i.e. projection neurons), a small number of glial cells, but no somatostatin- neuropeptide Y containing interneurons. Using Calb-immunolabeling to distinguish the patch and matrix compartments of caudate (low Calb neuropil = patch) in one section and examining an adjacent PKC α -labeled section, we found that a higher percentage of neurons in patch labeled for PKC α than in matrix. Our results show that enhanced PKC α expression specifically occurs in neurons destined to die in HD, seemingly much before they actually die. This expression occurs first in the neurons that will die first (i.e. caudate neurons). The slightly greater expression in patch than matrix suggests that patch neurons may be affected earlier than matrix neurons in HD. Since the functions of PKC α are diverse, it is uncertain if the enhanced PKC α expression serves to promote or combat the HD process. CELLULAR LOCALIZATION OF HUNTINGTON'S DISEASE (HD) GENE PRODUCT: ENRICHMENT IN NERVE TERMINALS. A.H. Sharp*, S. Loev, G. Schilling, J. Steiner, A. Lo, I. Hedreen, S. Sisodia, T. Dawson, S.H. Snyder, C.A. Ross. Laboratory of Molecular Neurobiology, Johns Hopkins University, School of Medicine, 720 Rutland Ave., Ross 615, Baltimore, MD 21205.

Huntington's disease (HD) is an inherited neurodegenerative disorder with autosomal dominance and nearly complete age dependent penetrance. The causative gene contains an expanding CAG repeat presumably coding for glutamine in a long open reading frame yielding a 348 kDa predicted protein (HD Collaborative Group, 1993). The disease is notable for selective neuronal loss in the basal ganglia and deep layers of the cerebral cortex which has been proposed to result from excitotoxicity. However, the mRNA for the gene causing HD is widely expressed in both the brain and periphery, with no enrichment in the basal ganglia (Li *et al.*, 1993; Strong *et al.*, 1993). To examine the expression of the protein product, we have now developed affinity-purified polyclonal antibodies against peptides corresponding to amino acids 1-17 and 650-663 of the deduced sequence of the human HD gene product which react specifically with a 350 kDa band on Western blots. Using immunochemical and immunohistochemical methods, we find that the HD protein product, like the mRNA, is widely expressed and enriched in brain. Within the brain, it is more highly expressed in neurons than glia and present in cytoplasm, dendrites, and axons. Within several brain regions, particularly the striatum, it is enriched in nerve terminals and loosely associated with synaptic vesicles and other membranes. These results are compatible with a role for the HD gene product in regulation of neurotransmitter release or reuptake and, perhaps, involvement in excitotoxicity.

511.14

HUNTINGTON'S DISEASE AND CRANIAL DYSTONIA DIFFERENTIALLY AFFECTS JAW MOTOR CONTROL. L.T. Robertson* and J.P. Hammerstad, Dept. of Biol. Structure & Function & Dept. of Neurology, OR Health Sci. Univ., Portland, OR 97201.

Parkinson's disease (PD) and Huntington's disease (HD) are frequently cited as examples of hypokinetic and hyperkinetic disorders of the basal ganglia, respectively (DeLong, 1990). The present study examines the effects of HD and cranial dystonia, another hyperkinetic basal ganglia disorder, on a series of jaw motor tasks and then compares the deficits with those of previously studied PD subjects. We expected subjects with HD and dystonia to have jaw motor deficits reciprocal to those with PD. The patients and matched control subjects were tested on a series of jaw motor tasks including simple voluntary movement, isometric clenching, and natural and paced rhythmic movements. Jaw movements were measured by changes in electromagnetic fields and electromyographic activity of the masseter and temporalis muscles.

HD markedly affected most voluntary and rhythmic jaw movements. HD resulted in a decrease in vertical jaw opening and in velocity during opening and closing and produced low force levels during clenching. Particularly striking was the large trial-to-trial variability that occurred on every task. Both normal and paced chewing were abnormal and included large fluctuations in the cycle frequency, vertical amplitude, and occlusal duration. The performance abnormalities for subjects with cranial dystonia were usually the opposite of those of HD. The subjects with dystonia typically had increased muscle activity, involving increased vertical amplitudes during voluntary jaw opening and high levels of force during clenching. Although no abnormalities occurred during normal chewing, vertical amplitudes were increased during paced chewing. The jaw clenching and paced chewing tasks were also associated with fatigue and intermittent spasms.

The jaw motor deficits for HD were similar to the deficits produced by PD subjects, although HD subjects had greater variability than did the PD subjects. Although HD is associated with chorea, HD is best characterized as a hypokinetic disorder for jaw movements whereas cranial dystonia is best characterized as a hyperkinetic disorder.

Posteroventral Pallidotomy for the Treatment of Dystonia.

T. Kondoh, J.P. Blount, E.P. McDaniels, T.J. Ebner, W.C. Low, and R.E. Maxwell.* Department of Neurosurgery, University of Minnesota Medical School, Minneapolis, MN 55455.

Recent advances in the understanding of the functional anatomy of the basal ganglia have led to the development of new approaches for the surgical treatment of movement disorders. The neural circuitry in the basal ganglia generates excitatory and inhibitory outputs to the pallidum via direct and indirect striatopallidal pathways. Under various pathological conditions, the balance between these excitatory and inhibitory projections can be disrupted, thus resulting in motor dysfunction. Lesions of the pallidum have therefore been proposed to eliminate the outflow of abnormal motor/sensory information. Such lesions in parkinsonian patients have been shown to ameliorate bradykinesia, rigidity, and tremor. In the present study, we have examined the effects of pallidotomies for the treatment of dystonia. Four cases of secondary dystonia resulting from different causes were treated by posteroventral pallidotomy. Dystonia resulted from either intracerebral hemorrhage, cerebral palsy, head injury or viral encephalitis. Each patient had a long history of spasticity and uncontrolled dystonic movements of the extremities (3 - 18 years). In addition, preoperative MRIs revealed lesions extending to the basal ganglia in each patient. MRI guided stereotactic surgeries were performed using the BRW MRI stereotactic frame. The posteroventral pallidum contralateral to the affected extremity was chosen as the target site. Several radiofrequency lesions were made in the targeted pallidum after stimulation to verify the appropriate target area. Following surgery all patients exhibited marked reduction in spasticity. Postoperative MRI showed that the surgical lesions were confined to the posteroventral pallidum. These results suggest that surgical lesions of the pallidum can ameliorate dystonia induced by damage to the basal ganglia, and further support the notion of ablative cancellation therapy for the treatment of basal ganglia-mediated movement disorders.

EVIDENCE FOR APOPTOSIS IN THE CENTRAL NERVOUS SYSTEM IN PATIENTS WITH AIDS. *F.J. Denaro**. Department of Neurology, Texas Tech University Health Sciences Center, Lubbock, TX 79430.

The precise mechanism for the neuropathology which has been observed in HIV-infected individuals is now believed to be due to a complex mechanism involving HIV-infected lymphocytes and the neuronal tissue. An indirect mechanism involving viral peptides and/or other cellular agents is believed to be causative in producing cell death in the CNS. Recent studies of the HIV-infected immune system suggests that HIV can induce apoptosis in lymphocytes, and this mechanism is in part responsible for cell death. In the present study, a commercial marker for apoptosis has been used to identify this process in postmortem CNS tissue. With this marker, it has been possible to identify cells histologically in the nervous system which are undergoing apoptosis. Most of these cells are lymphocytes, but some glial cells were also labeled. However, it was not possible to identify them as microglia, astrocytes, or oligodendrocytes at this time. The present observations suggest that the mechanisms which cause cell death in the CNS may be underscored by use of a marker for apoptosis. Whether this involves HIV and/or other agents is to be determined together with the cell types. Supported by NIH Grant R29NS31857-02.

512.3

APOPTOSIS, VACUOLATION AND INFECTIVITY IN A NOVEL CELL LINE PRODUCING SCRAPIE PRIONS

H.M. Schätzl, R. I. Weiner, L. Laszlo, D. M. Holtzman, W. C. Mobley and S. B. Prusiner.* Dept. of Neurology and Reproductive Endocrinology Center*, UCSF Medical School, San Francisco, CA 94143-0518

Currently available scrapie-infected cell lines do not show distinct morphological changes related to spongiform degeneration. We infected the GT1-1-trk9 neuronal hypothalamic cell line, which secretes GnRH in a synchronized manner and is transfected with the trk-A gene (NGF-R), with mouse RML prions (ScGT1-1-trk9). Subclones have been in culture for over 9 months and were passaged more than 40 times without any decrease in PrP^{Sc} production. Interestingly, there is a pronounced morphological difference between the ScGT1-1-trk-9 and the parental GT1-1-trk9 cells. EM studies showed two characteristic and very prominent ultrastructural changes in ScGT1-1-trk9 cells, which were not detectable in GT1-1-trk9 cells: a) huge vacuoles, and b) the apoptotic features of nuclear condensation and fragmentation and autophagocytosis. Extraction of Triton X 100 soluble DNA from ScGT1-1-trk9 cells revealed a DNA fragmentation pattern typical for apoptosis (not detected in GT1-1-trk9 cells). Although showing these very pronounced apoptotic features, over 80% of ScGT1-1-trk9 cells are viable. Notably, after NGF treatment of ScGT1-1-trk9 cells the DNA fragmentation was reduced. For the first time it was possible to infect GT1-1-trk9 as well as mouse neuroblastoma cells (N2a) with conditioned media from ScGT1-1-trk9 cells, permitting transfer of prions between mouse cell lines. Our findings present a cell culture model for the study of prion pathogenesis. The ScGT1-1-trk9 cells exhibiting intracellular vacuolation and apoptotic cell death maybe an useful model for neurodegeneration in humans and animals dying of prion diseases.

TNF α -MEDIATED APOPTOSIS IN SK-N-MC NEUROBLASTOMA CELLS: A MODEL FOR NEURONAL CELL LOSS IN HIV-1 INFECTION OF THE CNS. *H. A. Gelbard*, A. Talley, S. Perry, K. A. Dzenko, and L. G. Epstein.* Div. of Ped. Neurology, University of Rochester Medical Center, Rochester, NY 14642.

An important feature of the neuropathogenesis of HIV-1 associated dementia is neuronal loss in discrete areas of the cortex and subcortical regions. Evidence for HIV-1 infection of neurons is controversial, but soluble neurotoxic factors, including tumor necrosis factor alpha (TNF α), produced by activated HIV-1 macrophages, may mediate neuronal death. We have demonstrated that TNF α is neurotoxic to cultures of human fetal cortical neurons in a dose-dependent fashion (Gelbard et al., Dev. Neurosci., in press). Because TNF α has been implicated in apoptotic cell death of non-neural cells, we tested the hypothesis that TNF α could induce programmed cell death (apoptosis) in a neuroblastoma cell line (SK-N-MC) differentiated to a neuronal phenotype with 5 μ M retinoic acid. TNF α , at a dose of 2 ng/ml, induces formation of DNA laddering in gel electrophoresis studies. Apoptotic nuclei in SK-N-MC cells were identified by an *in situ* method to label free 3'-OH ends of newly cleaved nuclear DNA. Apoptotic nuclei in SK-N-MC cultures can be identified 6 hours after exposure to 0.2 ng/ml of TNF α , and reach a maximum by 48 hours. At a dose of 0.05 ng/ml TNF α , ~10% of SK-N-MC cells/culture well have apoptotic nuclei. At a dose of 25 ng/ml TNF α ~66% of SK-N-MC cells/culture well have apoptotic nuclei. This dose-dependent increase in apoptotic nuclei is inversely proportional to a dose-dependent (same dose range) decrease in cell viability as measured by trypan blue exclusion and enzymatic conversion of 3-(4,5-dimethylthiazol-2-yl)-2,5-diphenyl tetrazolium bromide (MTT). Studies are in progress to prevent TNF α -mediated neuronal apoptosis by infection of SK-N-MC cells with a recombinant adenoviral vector that expresses a portion of the extracellular domain of the TNF α receptor. BIOCHEMICAL CHARACTERIZATION AND TISSUE LOCALIZATION OF PRION PROTEIN LIGANDS. *B. Oesch, F. Coufal, E. Gubler, C. Bandlow*, S. B. Prusiner, and S. J. DeArmond.* Brain Research Institute, University of Zürich, 8029 Zürich, Switzerland and Dept. of Neurology and Pathology, University of California, San Francisco, CA 94143.

Interaction of the prion protein with other cellular components may be an important step for the function of cellular PrP (PrP^C) in the normal animal or for the infection with prions which contain an isoform of the prion protein (PrP^{Sc}). We have investigated the biochemical characteristics of PrP binding proteins resulting in the purification of a PrP ligand of 110'000 kDa (Pli 110). We have used ligand blots as an assay for purification¹. The sedimentation properties of PrP ligands were analyzed by sucrose density centrifugation. Pli 110 in postnuclear supernatants was found to sediment with high density particles suggesting that it may be associated with macromolecular complexes. Purification to homogeneity was achieved by a combination of subcellular fractionation, ion exchange chromatography and SDS polyacrylamide gel electrophoreses.

As a second, independent line of investigation we have characterized binding sites for the prion protein in normal and scrapie-infected brain. Binding of radiolabeled PrP 27-30 was strongest to granule and pyramidal cells of the hippocampal formation. Competition with unlabeled PrP 27-30 revealed a K_d of 2 nM. A synthetic peptide (designated P5) corresponding to the central portion of the prion was able to reproduce the binding pattern observed with PrP 27-30. Peptide P5 bound with a similar affinity and to the same sites as intact PrP 27-30. Binding sites seem to be mostly localized over cell bodies or proximal dendrites. From previous work it is known that PrP is axonally transported and located at the synapse leading to the conclusion that PrP may serve a signaling function at the synapse.

ASTROCYTOSIS AND PROLIFERATING CELL NUCLEAR ANTIGEN (PCNA) EXPRESSION IN BRAIN OF SCRAPIE-INFECTED ANIMALS. X. Ye* and R.L. Carp. New York State Institute for Basic Research in Developmental Disabilities, Staten Island, New York, U.S.A.

Scrapie is the archetype unconventional slow infection disease. PCNA is a 36-kd, acidic, non-histone, delta accessory protein of the DNA polymerase associated with cell proliferation. One issue is whether the astrogliosis seen in scrapie is a function of an increase in reactivity, or, if there is actual replication of astrocytes. In the current study, we used antibody to PCNA as a determinant of cell replication. Female, weanling Syrian hamsters, strain LVG/LAK, were injected intracerebrally with scrapie strain 139H or 263K or with normal hamster brain homogenates. Paraffin sections from scrapie and control brains were examined with PCNA immunostaining (ir-PCNA). We observed that the intensity of ir-PCNA in hippocampus, thalamus, hypothalamus and cortex of 139H- and 263K-infected hamsters was greater than in controls. Furthermore, by using double-staining analysis, we found that PCNA and glial fibrillary acidic protein were co-localized in brain cells. Our results suggest that the astrogliosis seen in scrapie-infected animals is, at least in part, due to actual replication of astrocytes in these animals.

ANTI-MYELIN BASIC PROTEIN ANTIBODY IN PEDIATRIC AIDS PATIENTS. K.M. Weidenheim*, M. Tricoche, A. Rubinstein and W.D. Lyman. Department of Pathology (Neuropathology) and Pediatrics (Immunology), Albert Einstein College of Medicine, Bronx, NY 10461.

Infection with human immunodeficiency virus type 1 (HIV-1) is associated with progressive neurologic impairment. Characteristic white matter changes which are thought to contribute to the neurological problems include a generalized decrease in myelin, leukoencephalopathy, vacuolar myelopathy and corticospinal tract degeneration. Corticospinal tract degeneration is important in pediatric AIDS because it correlates with the progressive motor dysfunction observed clinically, and the clinically observed cognitive dysfunction may correlate with injury to hemispheric white matter during HIV-1 infection. Anti-myelin antibodies have been shown to damage white matter in other disease states, and antibodies to myelin basic protein (MBP) have been identified in adult patients with AIDS. However, anti-myelin antibodies have not yet been identified in children with HIV-1 infection. We have developed an ELISA technique which can detect anti-MBP antibody in microliter quantities of human serum. Serum samples from 4 pediatric AIDS patients with neurologic symptoms were analyzed using this system. ELISA plates coated with human MBP were incubated with test sera from 4 pediatric AIDS patients with neurologic disease. Antibody binding was detected using an ABC technique. Anti-MBP-antibodies were identified in 2 patients. Pre-absorption of sera with MBP decreased antibody reactivity. This suggests that the antibody was MBP-specific. Both children with anti-MBP antibodies had motor dysfunction, and one had neuropsychologic impairment. These results suggest that anti-MBP antibodies are present in the serum of some HIV-infected children neurologic symptoms. These antibodies may contribute, in part, to the white matter pathology observed in pediatric AIDS. Support: USPHS MH47667, MH46815.

IN VIVO DEVELOPMENT OF HIV INFECTED HUMAN BRAIN GRAFTS. C.L. Achim, P. Sarnacki, E. Bonaroti, G. Wang, R. Hammond and C.A. Wiley*. Div. of Neuropathology, Univ. of Pittsburgh, Pittsburgh, PA 15213.

Approximately one quarter of AIDS patients develop severe HIV encephalitis with abundant macrophage infiltration and diffuse neuronal damage. Immune factors secreted by activated/infected CNS macrophages may be mediators of HIV associated neurologic damage. To test this hypothesis we developed an experimental model based on grafting HIV infected human neural cells into the brain of SCID mice. In this model, fetal brain cell aggregates grown in vitro are co-cultured with human macrophages infected with the neurotropic HIV strain YU-2. Neural cell aggregates infiltrated by infected macrophages are transplanted into the brain of SCID mice. In this in vivo environment synaptic formation can be studied and the perturbations caused by addition of HIV infected macrophages can then be temporally monitored. By immunolabeling and laser confocal imaging, in vitro cultures of human brain cells show abundant neuronal survival and differentiation. By EM, neuritic and synaptic formation can be detected in long term cultures. In vivo pilot studies suggest that brain microspheres injected into the fat pad of SCID mice survive for several months. Study of these grafts shows presence of functional neural cells and vascular organization suggesting a blood brain barrier. Grafts with HIV infected macrophages contained multinucleated giant cells and virus. Based on these findings we conclude that transplantation of developing human fetal brain grafts into SCID mice is a feasible model of HIV associated neurologic damage. CORTICAL NEURONAL LOSS IN ASYMPTOMATIC CATS INFECTED WITH FELINE IMMUNODEFICIENCY VIRUS (FIV). B.A. Thiede, R.B. Meeker* and C. Hall. Dept. Neurology, Univ. North Carolina, Chapel Hill, NC 27599 and R. English and M. Tompkins, Dept. of Microbiology, Parasitology and Pathology, School of Veterinary Medicine, North Carolina State University, Raleigh, NC 27606.

In post mortem studies of humans infected with human immunodeficiency virus (HIV), loss of large cortical neurons has been described which may, in part, explain the cognitive deficits of AIDS dementia. Feline immunodeficiency virus (FIV) produces an HIV-like pattern of disease in cats and has recently been shown to contribute to neuronal excitotoxicity in vitro. To evaluate if adult cats infected with (FIV) show early neurodegenerative changes which mimic the neurodegenerative changes seen in humans, we examined cortical cell densities in seven asymptomatic specific pathogen free cats three years after inoculation with FIV. Cell density in cortical layers II-V, was evaluated for small, medium and large cells and compared to cell densities measured from the brains of six cats infected with FeLV. A 15-44% decrease in the number of large neurons in the frontal cortex was found. The largest decreases in neuron density correlated with low CD4:CD8 ratios. Neuronal loss was also evaluated in two FIV-infected random source cats and compared to two random source controls. A 30-34% decrease in large cell density was found. This pattern indicates that FIV induces similar neurodegenerative changes as HIV and that these changes may begin to appear in relatively early stages of infection, before the appearance of overt behavioral or neurological symptoms. Sponsored in part by USPHS Grants N01 AI35515, 1R01 AI32310 and SP01 NS26680.

512.8

FETAL BRAIN ACCUMULATES GP120 SYSTEMICALLY ADMINISTERED TO PREGNANT MICE. J.Y. Wu*, T.W. Moody, D.E. Brenneman and J.M. Hill. Lab. of Dev. Neurobiol., NICHD, NIH, Bethesda, MD 20892; BPRB, NCI, NIH, Rockville, MD 20850.

Pediatric AIDS is often perinatally acquired and frequently accompanied by extensive neurological damage despite low levels of HIV-infected cells. The HIV envelope protein, gp120, has been shown to be toxic to neurons in culture (*Nature* 335:639,1988) and to induce neuronal dystrophy and behavioral retardation (*Brain Res.* 603:222,1993). The present study was designed to determine if gp120 could be transmitted from the maternal circulation to the fetal brain during pregnancy. ¹²⁵I-gp120 was injected into the tail vein of mice during the 16th day of pregnancy, and fetuses were examined after 1, 24, 48 and 72 hours. The extracts of fetal brain and body were analyzed with gel filtration chromatography. The fraction co-eluting with stock gp120 is shown below in % of total CPM ± S.E.M. eluted:

	1 hr	24 hrs	48 hrs	72 hrs
Brain	1.79±0.36	17.34±4.07	46.97±11.41	27.20±3.58
Body	0.56±0.11	2.29±0.56	4.48± 0.48	4.71

Small amounts of radiolabelled material were found in fractions corresponding to the neurotoxic gp120 fragments (*Brain Res.* 603:222,1993). After 2 days, approximately 0.01% of the radioactive gp120 injected into a mother appeared in the brain of one fetus. This study has shown that: 1) gp120 crossed the placental barrier; and 2) although gp120 levels increased in both the fetal brain and body with time, gp120 was preferentially sequestered in the brain. These data suggest that the neurological damage occurring in pediatric AIDS may be due, in part, to maternal to fetal transmission of gp120.

512.10

HIPPOCAMPAL PATHOPHYSIOLOGY DUE TO LYMPHOCYTIC CHORIOMENINGITIS VIRAL INFECTION Pearce, B.D.*, Baldrige, J.R., Steffensen, S.C., Henriksen, S.J. and Buchmeier, M.J., Scripps Research Institute, La Jolla, CA 92037

Lymphocytic choriomeningitis virus (LCMV)-infected rats develop ataxia and distinct retinal, hippocampal and cerebellar neuropathology. We evaluated the pathophysiology of LCMV hippocampal tropism by immunohistochemical staining for viral antigen and by electrophysiological examination of evoked potentials and electroencephalographic (EEG) recordings from the dentate gyrus and CA1 hippocampus of halothane-anesthetized Lewis rats. Animals were inoculated intracerebrally with LCMV at postnatal day 4. Although cleared of infectious virus by post-inoculation day 21, viral antigen was detected in the dentate granule cell layer and hilus through day 41 but was usually absent at 80-90 days. In the dentate gyrus, granule cell loss was extensive (approximately 50%). In Ammon's horn, no viral antigen nor cell loss was observed in any subfield. Hippocampal evoked potentials were elicited by stimulation of corresponding monosynaptic afferents to the dentate and CA1. While there were no differences in the temporo-spatial properties of the hippocampal field potential waveforms between groups, there was a site-specific suppression of GABA-mediated recurrent inhibition in the dentate gyrus of LCMV-infected rats. CA1 paired-pulse responses did not differ between groups. Hippocampal EEG activity was recorded by microelectrodes oriented in the dentate hilus and CA1 hippocampus and frequency spectra were generated from 4 sec EEG epochs. Age-matched uninfected rat EEG was characterized by episodes of high voltage spontaneous theta (4-6 Hz) alternating with low voltage mixed activity while LCMV-infected rat EEG was dominated by continuous theta. These findings demonstrate ongoing pathophysiology in LCMV-infected rats that persists long after clearance of infectious virus from the CNS. Early mediators of the immune response, excitotoxic factors and/or GABA dysfunction may contribute to the observed post-infection abnormalities in synaptic function.

512.11

PROTECTIVE EFFECT OF THYMOSIN PEPTIDES AND PHENOTHIAZINE NEUROLEPTICS ON SURVIVAL OF MICE TREATED WITH LETHAL DOSES OF ENDOTOXIN. M. Fagarasan*, M. Badamchian, and A. Goldstein, Department of Biochemistry and Molecular Biology, The George Washington University, Washington, DC. 20037

Pretreatment with phenothiazine neuroleptics (chlorpromazine, thioridazine, trifluoperazine), thymosin α_1 and thymosin β_4 protected the mice against the lethality induced by endotoxin. Endotoxin and protective compounds were administered i.p. in Swiss-Webster mice. We investigated the molecular mechanism involved in this effect. We determined that phenothiazine neuroleptics and thymosin peptides inhibit a cascade of pathological mediators: free radicals, cytokines (interleukin-1 and tumor necrosis factor) platelet activating factor and arachidonic acid metabolites (6-keto-PGF $_{1\alpha}$ and TXB $_2$). The effect on free radical formation was determined by measuring blood lipid peroxidation and red blood cell glutathione levels. Serum cytokine levels were measured by ELISA and plasma concentrations of arachidonic and metabolites and platelet activating factor by RIA. Pretreatment of the mice with vitamin E, which is an antioxidant also increased survival against lethal doses of endotoxin. We concluded that free radicals are the first step in the cascade of toxic mediators induced by endotoxin. Phenothiazine neuroleptics and thymosin peptides by inhibiting free radical formation, inhibit this whole cascade which induces lethality.

512.13

HERPES SIMPLEX VIRUS (HSV) INFECTION INCREASES NERVE GROWTH-ASSOCIATED PROTEIN (GAP-43/B-50) IMMUNOREACTIVITY IN RABBIT CORNEA AND TRIGEMINAL GANGLION (TG). R.E. Martin*¹, D.B. Henken², J.M. Hill³. ¹Univ. Oklahoma College of Medicine; ²NIH, NINDS Lab. of Exp. Neuro-pathology; ³Louisiana State Univ. Eye Center.

HSV type-1 infection (McKrae strain) is correlated with increased GAP-43 immunoreactivity in rabbit cornea during latency, 52 days post-inoculation (52 dpi). Here we determine GAP-43 immunoreactivity in cornea and TG during the acute stages of HSV-1 infection (5 dpi), in latency (84 and 154 dpi) and after reactivation by iv injections of cyclophosphamide and dexamethasone (Cx/Dx). Tissues were evaluated biochemically and histologically. Preliminary results indicated that, for all conditions, GAP-43 immunoreactivity was greater in cornea than in TG. During acute infection, immunoreactivity in cornea was 48% higher than in non-infected controls and no significant difference was seen in TG. During latency (84 dpi), increases were found in cornea (59%) and TG (119%). This effect was maintained at 154 dpi when cornea and TG demonstrated increased immunoreactivity over controls (36% and 104%, respectively). Reactivating latent virus with Cx/Dx at 152-153 dpi revealed higher GAP-43 in cornea and TG compared to controls (134% and 55%, respectively). The data suggest that establishing and maintaining HSV-1 latency are not silent events in these neurons. Supported by OU College of Medicine and NIH EYO6311.

MURINE NEUROPATHOGENIC ts₁ - RETROVIRUS REPLICATION IN MYOBLASTS AND ASTROCYTES IN VITRO T. Powers, P. Stanko, A.J. Goldman, J. Vann, P. Szurek, A. Wacławik, B.R. Brooks*. Dept. of Neurology, UW Medical School, Madison, WI 53792 and Neuromuscular Research Laboratory VAMC Madison, WI 53705

The pathogenesis of the neurodegenerative disease caused by ts₁ retrovirus is not fully understood. This virus can only cause spinal cord degeneration during postnatal development and not in adult mice. ts₁ retrovirus replication in affected animals occurs to very high levels in spleen, CNS and muscle tissue. It is unknown what the role of the replication of ts₁ retrovirus in muscle tissue is in the spinal cord degeneration caused by this virus. We are characterizing this model to determine whether both muscle and CNS infection are required to produce disease. Integrated and unintegrated viral specific DNA forms are present in various tissues post infection. A novel low molecular weight, unintegrated virus specific DNA is seen in CNS tissues but not spleen or muscle.

We studied the replication of ts₁ retrovirus in differentiated astrocytes and muscle cells (CRL 1772) from C3H mice. Virus titers in supernatants from infected myoblasts (2x10⁷/ml) were of the same magnitude as seen following infection of astrocytes (1-10 x 10⁶/ml).

Virus specific DNA species in infected cells were characterized by Southern blot hybridization techniques at various times after infection. Cellular specific gene (actin, glut-1) expression was compared with virus specific gene (env) expression. No new low molecular weight virus specific DNA species have been identified following ts₁ retrovirus infection in vitro. [Neurology 1994;44(Suppl 2):A396]

512.12

ICAM-1 BLOCKADE ATTENUATES THE INCREASE OF REGIONAL CEREBRAL BLOODFLOW (rCBF) DURING THE EARLY PHASE OF EXPERIMENTAL BACTERIAL MENINGITIS. J.R. Weber, K. Angswurm, K.M. Einhäupl, W. Bürger, G. Ransmayr*, U. Dirnagl. Dep. of Neurology, §Inst. of Microbiology Charité, Humboldt University, 10098 Berlin, Germany, #Dep. of Neurology, University of Innsbruck, Austria.

Intercellular adhesion molecule-1 (ICAM-1), a cell surface receptor plays an important role in leucocyte endothel interaction in inflammatory disease. High levels of ICAM-1 can be measured in the CSF of patients with bacterial meningitis and provide evidence for a strong immune response, which may cause severe complications in spite of effective antibiotic treatment. We investigated the effect of systemic treatment with ICAM-1 antibodies on rCBF in male wistar rats. Meningitis was induced by intracisternal injection of pneumococcal cell wall components (equivalent of 10⁷ cfu *Streptococcus pneumoniae* PnR-527, Jena). rCBF was measured continuously over 6 hours with laser Doppler flowmetry. Rat ICAM-1 antibodies (TM8, Athena Neurosciences, Inc. San Francisco) were injected i.v. (1.5mg/kg) in three animals (n=3). In control animals saline was injected (n=4). There was an increase of rCBF in untreated animals 3 hours (mean=187% of baseline \pm 47%SD) and a dramatic increase 6 hours after the induction of meningitis (mean=266% \pm 59%). In the ICAM-1 antibody treated group the increase of rCBF was lower 3 hours (mean= 127% \pm 15%) and significantly attenuated (mean=134% \pm 19, t-test p=0.015) 6 hours after induction. The results demonstrate that ICAM-1 is involved in mediating rCBF changes associated with bacterial meningitis.

512.14

HERPES SIMPLEX VIRUS (HSV) INOCULATION BY A FOOTPAD ROUTE RESULTS IN INCREASED GROWTH-ASSOCIATED PROTEIN (GAP-43) IN MOUSE DORSAL ROOT GANGLIA (DRG) AND DORSAL ROOTS Henken, D.B.¹, Martin, J.R.¹, Goldstein, M.E.², and Curtis, R.³ ¹LENP, ²LNC, NINDS, NIH, Bethesda, MD, and ³Regeneron Pharmaceuticals, Tarrytown, NY, USA.

To obtain evidence on neuronal sprouting following HSV infection in sensory ganglia, GAP-43, a protein induced by growing neurons, was examined. The hind footpads of mice were unilaterally inoculated with HSV type-2 strain MS (9.3x10⁵ pfu/ml) or medium. At 0 (control), 5, 14 and 28 days post-inoculation (dpi), mice were fixed. Sections of decalcified spinal columns and DRGs, were immunoreacted for GAP-43. Reaction product was quantified in ipsilateral (infected) and contralateral (uninfected) lumbar 4th and 5th DRG and proximal dorsal roots using image analysis. At 14 dpi, there was a 4-fold increase in GAP-43 immunoreactivity in the ipsilateral DRG and 8-fold increase in dorsal root. Both cell bodies and fibers were GAP-43-positive. At 28 dpi, GAP-43 was decreased in DRG, but sustained in dorsal roots. Contralateral tissues showed no increase in GAP-43, nor did ganglia or dorsal roots of mock-inoculated mice. Western analysis also showed induction of GAP-43 in dorsal roots. This result, together with selective neuropeptide alterations that we have previously shown, indicate that a sprouting response may be mounted in ganglia in reaction to herpesvirus infection.

512.16

A PCR-BASED ANALYSIS OF HSV-1 LATENCY IN THE TRIGEMINAL GANGLION OF THE RAT. D.J. Fink*, R. Ramakrishnan and M. Levine. Departments of Neurology and Human Genetics, and GRECC, VAMC, University of Michigan, Ann Arbor, MI 48105.

Competitive quantitative PCR and RT-PCR was used to quantitate DNA and RNA from an attenuated ribonucleotide reductase (RR)-deleted herpes simplex virus type 1 (HSV-1) mutant in the rat trigeminal ganglion after peripheral inoculation following corneal scarification. Amplification of ganglionic DNA with oligonucleotide primers specific for the HSV gB gene and for the LAT gene indicated that there were approximately 2 x 10⁵ genome equivalents per ganglion at 2, 7 and 56 days after inoculation. Amplification of ganglionic RNA with primers specific for HSV LAT indicated that there were approximately 1 x 10⁷ LAT molecules per ganglion at 2 and 7 days post inoculation, and 1.4 x 10⁷ LAT molecules per ganglion at 56 days. *In situ* hybridization with a digoxigenin-labeled riboprobe specific for LAT detected an average of 1-2 LAT positive cells in each positive 6 micron section of trigeminal ganglion. *In situ* PCR detection of HSV genomes in similar sections, using digoxigenin-labeled nucleotides with primers specific for HSV gB, identified 27-150 genome-positive cells per section.

These results indicate that there are approximately 50 LAT molecules per latent HSV genome in the trigeminal ganglion, compared to 15 LAT molecules per latent HSV genome in the CNS (Ramakrishnan *et al.*, *J. Virol.*, 1994), but that cells with detectable LATs by *in situ* hybridization represent only a small proportion of those ganglionic neurons containing HSV genomes. The presence of latent HSV genomes in a large number of neurons suggests that HSV may be more efficient in establishing the latent state than would be anticipated from previous reports.

IMPROVED BRAIN DELIVERY AND IN VITRO EFFICACY OF ZIDOVUDINE (AZT) USING A REDOX CHEMICAL DELIVERY SYSTEM. Y. Mizrahi, A. Rubinstein, Z. Harish, A. Biegon¹, W. Anderson² and M. Brewster³. Div. of Allergy and Immunol., Albert Einstein College of Med., Bronx, NY 10461, ¹Pharmos, Corp. Alachua, FL 36215 and ²Pharmos, Corp. Rehovot, ISRAEL.

Improved therapy for AIDS dementia and related encephalopathies may be achieved through enhanced delivery of effective anti-retroviral agents to the brain and CNS. One approach for attaining this goal is the chemical delivery system (CDS) which has been applied to a number of drugs including zidovudine (AZT). The current evaluations were aimed at further defining the pharmacokinetic profile of the AZT-CDS as well as establishing its in vitro antiviral efficacy against HIV in both lymphocytes and a neural cell line. AZT or AZT-CDS at a dose of 130 $\mu\text{mol/Kg}$ was administered to Spague Dawley rats (i.v., tail vein) using a cyclodextrin-based vehicle. The AZT-CDS produced significantly higher brain levels of AZT ($\text{AUC} = 425 \mu\text{g}\cdot\text{min/g}$) than did equimolar AZT dosing ($\text{AUC} = 13.5 \mu\text{g}\cdot\text{min/g}$). In addition, blood levels were reduced (AZT from AZT-CDS, $\text{AUC} = 583 \mu\text{g}\cdot\text{min/mL}$; AZT from AZT, $\text{AUC} = 1580 \mu\text{g}\cdot\text{min/mL}$). In culture systems (CEM lymphocytes and a SKNMC neuroblastoma cell line), AZT uptake after co-incubation of cells with AZT for 1.0 hour was minimal. By contrast, addition of the AZT-CDS to tissue cultures resulted in large increases in the uptake of the AZT-CDS followed by biochemical conversion of the CDS to its main metabolites (the AZT-CDS quaternary salt, AZT-Q⁺, as well as AZT itself). These improved uptake profiles were associated with greater in vitro efficacy. Thus, AZT-CDS at 0.5 μM was 80% more effective than AZT in suppressing p24 production (at day 3) in a lymphocyte culture infected with 6000 TCID₅₀'s of the N1T strain of HIV and 50% more effective at 0.05 μM . Furthermore, syncytia formation was completely suppressed at an AZT-CDS dose of 0.5 μM (600 TCID₅₀'s) while AZT at the same dose was ineffective. Finally, while AZT (at 0.5 μM) is not active in reducing viral replication in an SKNMC neural cell line, the AZT-CDS provided for significant reductions in p24 expression.

MENTAL ILLNESS: SCHIZOPHRENIA II

513.1

KINDLING WITH CLOZAPINE. J.R. Stevens* and D.D. Denney, Depts of Neurology & Psychiatry, Oregon Health Sciences University, Portland OR 97201,

The atypical neuroleptic clozapine improves symptoms and behaviors of many patients with schizophrenia who have failed to respond to other neuroleptics. In addition to blockade of central nervous system monoamine, muscarinic and other receptors, clozapine often causes bilateral spike-wave activity in the EEG and generalized seizures occur in 3-5% of patients treated with the drug. Acute administration of clozapine in rats induces dose related myoclonic jerks. Although considered an undesirable side effect of clozapine, this evidence for epileptogenicity could relate to the therapeutic effect of this drug. The experiments reported here demonstrate that repeated fixed sub-convulsive doses of clozapine (1 mg/kg) that initially caused no behavior change, caused seizure-like activity manifest as myoclonic jerks (MJs) after the third injection of clozapine, and reached 150 MJs/hour by the 15th injection. These results are consistent with *kindling*, i.e., a progressive sustained increase of brain excitability following repeated administration of a fixed subconvulsive dose of a proconvulsive agent. If excitation of neurons in critical brain areas is an important aspect of the therapeutic effect of clozapine and other neuroleptics, *kindling* with repeated fixed low dose administration of clozapine and related drugs might be effective clinically and should decrease undesirable side effects associated with conventional high dose treatment regimens.

D2/D3 AND D4 RECEPTOR DENSITIES ARE NOT ALTERED IN RATS WITH NEONATAL HIPPOCAMPAL DAMAGE. Michael B. Knable, Angela M. Murray, Barbara K. Lipska, Farouk Karoum*, Daniel R. Weinberger. Clinical Brain Disorders Branch, IRP, NIMH, Neuroscience Center, Washington, DC 20032.

Previous studies demonstrated that rats with excitotoxic ventral hippocampal (VH) lesions postpubertally develop DA-related behavioral changes. These effects were similar to some aspects of schizophrenia. We sought to determine if these behavioral effects were associated with changes in the distribution or number of striatal DA receptors. On postnatal day 7 (PD7), rats received infusions of ibotenic acid or vehicle into the VH. They were sacrificed on PD35 and PD56. Brain sections (20 μm) were incubated with 1.0nM [³H]YM-09151-2 (containing 50nM 8-OH-DPAT). Adjacent sections were preincubated with 200 μM Gpp(NH)p and incubated with 6.0nM [³H]raclopride. Butaclamol (10 μM) was used to define non-specific binding in both assays. Mean optical density in the dorsolateral (DLS) and ventromedial (VMS) striatum, and nucleus accumbens (NAC) were converted to fm/mg of tissue. Specific raclopride binding was subtracted from specific YM-09151-2 binding to estimate D4 receptor density. There was decreased binding of YM-09151-2 and raclopride in both control and lesioned rats in DLS and VMS on PD56 compared with PD35. In contrast, D4 analysis did not show an age effect in DLS or VMS. There were no effects of lesion for either ligand or for the calculated D4 receptor density in any region. These results suggest that delayed hyperdopaminergic behaviors in rats with neonatal VH lesions are not mediated by abnormalities in density of striatal D2/D3 or D4 receptors.

513.2

FRONTAL DYSFUNCTION IN SCHIZOPHRENIA. J. Gold, B. Hermann, C. Randolph*, G. Chelune, M. Trenerry, D. Loring, T. Goldberg, D. Weinberger. NIMH Neuroscience Center at Saint Elizabeths, Washington, D.C. 20032

Prior neuropsychological and neuroimaging studies had implicated dysfunction of the frontal cortex in schizophrenia (SC). However, this hypothesis has not been examined directly using a between-patient group design. In this study, we contrasted the neuropsychological performance of 66 SC patients with that of 91 patients with frontal lobe epilepsy (36 with a left frontal seizure focus, 51 with a right frontal focus) who were drawn from 4 epilepsy surgery programs. The epilepsy patients had a mean age of onset of chronic seizures at age 12 and were refractory to conventional pharmacotherapy. All test data was obtained prior to any eventual surgical treatment. The three patient groups did not differ in age, education, or Full Scale IQ. The SC group performed significantly better than either frontal group on measures of semantic memory such as single word reading and vocabulary. The SC patients did not differ from either frontal group on measures of attention and motor speed, which we have previously found to distinguish SC from temporal lobe epileptic patients. SC patients performed significantly better than either frontal group on phonemic fluency, a task which does distinguish frontal from temporal lobe epilepsy patients, but significantly worse than the right frontal group on the Wisconsin Card Sorting Test. The data suggest the limitations of focal lesion models of schizophrenic cognitive impairment, and demonstrate differential impairment of frontal function in schizophrenia with maximal impairment in attention and working memory and a relative sparing of frontally mediated verbal fluency.

513.4

C-FOS EXPRESSION IN RATS WITH A NEONATAL HIPPOCAMPAL LESION IS ALTERED AFTER AMPHETAMINE CHALLENGE. Sonia M. Lillrank, Barbara K. Lipska*, Susan E. Bachus, Daniel R. Weinberger. Clinical Brain Disorders Branch, NIMH, Neuroscience Center at St. Elizabeths, Washington, DC 20032.

A neonatal (day 7 after birth, PD7) ibotenic acid lesion (large size) in the ventral hippocampus results in postpubertal (PD56) onset of a variety of abnormal behaviors that have been related to corticolimbic and striatal dopaminergic dysfunction. A more restricted lesion (small) does not induce behavioral hyperactivity on PD56. To further characterize this potential animal model of schizophrenia, we studied the expression of c-fos mRNA in rats with two sizes of hippocampal lesions. C-fos has been shown to be induced by catecholaminergic stimuli. Rats were previously given amphetamine (AMP) (1.5 mg/kg) twice (on PD35 and PD56) and their motor activity was tested. C-fos mRNA expression using an oligonucleotide probe was assessed six weeks later 30 and 90 minutes after AMP (10 mg/kg) or saline. A significant effect of drug treatment was seen in the ventromedial (VMS) and dorsolateral striatum (DLS), in superficial and deeper bands of parietal cortex (SPC and DPC, respectively) as well as the medial prefrontal cortex (MPFC). C-fos expression was decreased in MPFC in rats with a large lesion 30 min after AMP, but not in the striatum. AMP produced a significant time effect in the DPC in rats with both lesions and in DLS after a large lesion. These preliminary results demonstrate that an early hippocampal damage alters the cortical c-fos response to AMP in adult rats.

513.5

NEONATAL EXCITOTOXIC HIPPOCAMPAL DAMAGE ALTERS DOPAMINE RESPONSE TO MILD CHRONIC STRESS AND CHRONIC HALOPERIDOL. Barbara K. Lipska, Stanislaw J. Chrapusta, Michael F. Egan, Richard J. Wyatt, Daniel R. Weinberger, Clinical Brain Disorders Branch and Neuropsychiatry Branch, IRP, NIMH, Neuroscience Center at St. Elizabeths, Washington, DC 20032.

The effects of neonatal (day 7 after birth, PD7) ibotenic acid lesions of the ventral hippocampus (VH) on dopamine release in response to chronic stress (saline injections for 21 days) and haloperidol treatment (0.4 mg/kg for 21 days, i.p.) were investigated in adult (PD56) Sprague-Dawley rats. Tissue 3-methoxytyramine (3-MT) accumulation after MAO inhibition with pargyline measured by GC/MS was used as an index of dopamine release. At baseline (no injection), 3-MT was reduced in striatum (STR) of lesioned rats. Repeated saline injections resulted in a further 3-MT reduction in STR, nucleus accumbens (NAC) and frontal cortex (FC) in lesioned rats, and had no effect in controls. Chronic haloperidol, compared with vehicle, increased 3-MT accumulation in STR, NAC and FC in control and lesioned rats. The 3-MT increase was enhanced in FC and NAC of haloperidol-treated lesioned rats vs controls. These data show that a developmental lesion of VH alters dopamine responsivity to environmental (chronic mild stress) and pharmacological (chronic haloperidol) challenge.

QUANTIFICATION OF MESOPONTINE CHOLINERGIC NEURONS IN THE HUMAN BRAIN. K.F. Manaye, D. Wu, S. de Lacalle, C.B. Saper, and D.C. German, Dept. of Psychiat., UT Southwestern Med. Cntr., Dallas TX 75235, Dept. of Biochem., Univ. of Kentucky, Lexington KY 40536, and Dept. of Neurol., Beth Israel Hosp., Harvard Med. Sch., Boston MA 02115.

Karson et al. (1991) reported that schizophrenics have significantly more NADPH-diaphorase-containing, putative cholinergic, pedunculopontine nucleus neurons than controls (*Psychiat. Res.: Neuroimaging*, 40:31-48). The purpose of the present study was to use a specific marker for cholinergic neurons, an affinity purified human antibody against choline acetyltransferase (ChAT), and computer imaging techniques to map the locations of cholinergic mesopontine neurons in the human brain. Four cases were collected from the Medical Examiners Office, 22-47 years of age. Cells were mapped on one side of the brain, in 50 μ m thick horizontal sections, sampled from 0.5-0.8 mm intervals (n=7-10 sections/case), and stained with 1:200-2,000 antibody concentration. The cell counts were corrected for split-cell counting error. There was an average of $14,986 \pm 1,593$ neurons (mean \pm SEM) (11,661-17,933) within the compact and diffuse sectors of the Ch5 region, and the Ch6 region (nomenclature of Mesulam et al. [*J. Comp. Neurol.*, 281:611-633, 1989]). Future studies will determine whether differences in mesopontine cholinergic neuron numbers exist in schizophrenic cases.

513.9

"PERINEURONAL NETS OF EXTRACELLULAR MATRIX" AROUND NERVE CELLS IN VARIOUS NEUROPSYCHIATRIC DISORDERS. C. Bouras^{1,4}, P.R. Hof^{4*}, J. Miklóssy² and M.R. Celio³. ¹Dept of Psychiatry, Univ. of Geneva, ²Division of Neuropathology, ³Institute of Histology, Univ. of Fribourg, Univ. of Lausanne, Switzerland; ⁴Dept of Neurobiology, Mount Sinai Med Ctr, New York, NY 10029.

"Perineuronal nets of extracellular matrix" (PNs) are observed around subpopulations of nerve cells in the adult brain and may control their interactions with surrounding cells. In the cerebral cortex, PNs are associated with interneurons containing the calcium-binding protein parvalbumin (Celio and Blümlcke, *Brain Res. Rev.* 1994;19:128-145). In the present study, the distribution of PNs was analyzed in several areas of the cerebral cortex in the normal human brains and compared to cases affected by psychiatric (Alzheimer's disease, Pick's disease, Down syndrome and schizophrenia) and neurologic disease (multiple sclerosis, epilepsy). Brains were obtained at autopsy (4-24 hours postmortem delay). PNs were visualized using *Vicia villosa* lectin and chondroitin sulfate proteoglycan immunohistochemistry. No obvious changes in distribution and staining intensity of PNs were observed in Alzheimer's disease, Pick's disease, Down syndrome, epilepsy, and multiple sclerosis cases. However, a decrease of PNs around neurons was found in the cerebral cortex of schizophrenic cases. This finding may reflect the fact that disruption of the extracellular matrix or loss of certain components of PNs occur in schizophrenia. Such changes in PNs around select interneuronal cell classes such as parvalbumin-containing cells may cause functional alterations in this population of inhibitory neurons in schizophrenia.

513.6

STRAIN DIFFERENCES IN BEHAVIORAL ABNORMALITIES ASSOCIATED WITH NEONATAL EXCITOTOXIC HIPPOCAMPAL DAMAGE IN THE RAT. Ingrid Phillips, Barbara K. Lipska, Llewellyn B. Bigelow*, Daniel R. Weinberger, Clinical Brain Disorders Branch, IRP, NIMH, Neuroscience Center at St. Elizabeths, Washington, DC 20032.

Neonatal ventral hippocampal (VH) lesions in male Sprague-Dawley (SD) rats do not affect dopamine related behaviors before puberty (35 days of age, PD35). After puberty (PD56), lesioned rats express a variety of behavioral disturbances indicative of increased mesolimbic/nigro-striatal dopamine function. In the present study, we compared the effects of VH damage in two genetically inbred strains of rats - Fisher 344 (F) and Lewis (LEW) with outbred SD rats. It was shown previously that LEW and F rats differ genetically in a number of ways, including stress responsiveness and preference for drugs of abuse, suggestive of different functional states of the mesolimbic dopamine systems. We demonstrate that the patterns of behavioral abnormalities following neonatal VH lesions differ markedly between the strains in terms of severity of disturbances and the age at which they appear. In SD VH lesioned rats, spontaneous and amphetamine-induced locomotion are enhanced at PD56, but not at PD35. In F and LEW VH lesioned rats, exaggerated hyperlocomotion appears early (PD35). More restricted lesions of VH result in the delayed onset of hyperlocomotion (PD56) in F rats, while in SD rats they do not affect locomotor behaviors on PD35 or PD56. These data suggest that the developmental lesion may interact with genetic factors involved in dopaminergic function. They may have implications for studying pathophysiology of schizophrenia in which structural hippocampal defects and genetic liability have been indicated.

513.8

EXPRESSION OF SYNTROPHIN IN THE BRAIN POSTSYNAPTIC DENSITY OF THE RAT, MDX MOUSE AND A DUCHENNE MUSCULAR DYSTROPHY PATIENT. Kim, T.W.^{1,2}, K. Wu^{1,2}, Y. Huang^{3,4} and I.B. Black^{1,2}. ¹Dept. Neurosci. and Cell Biol., UMDNJ/RWJ Med. Sch. and ²Program in Physiol. and Neurobiol., Rutgers-The State Univ. of NJ, Piscataway, NJ 08854; ³Div. Neurosci., NYSPI and ⁴Dept. Physchi., Columbia Univ., New York, NY 10032.

Duchenne muscular dystrophy (DMD) is an inherited fatal disease affecting one in 3500 boys with progressive muscle degeneration. Although cognitive impairment is a common feature of DMD, mechanisms underlying mental changes are unknown. DMD is characterized by a defect in dystrophin, a 427 kDa protein that is located predominantly in muscle, and that has recently been detected in brain. We have previously found that brain dystrophin is a component of the postsynaptic density (PSD) and is absent in the *mdx* mouse, an animal model of human DMD. Recently, syntrophin, a 58 kDa dystrophin-associated protein, was reportedly concentrated at postsynaptic sites at mouse neuromuscular junction. One postulated function of syntrophin is involvement in clustering of acetylcholine receptors. Colocalization of syntrophin with dystrophin in muscle prompted us to examine the protein in the rat brain by focusing on the PSD. Our results, obtained by Western blot analysis using a specific antibody against syntrophin, revealed that brain syntrophin is an intrinsic component of PSD. Moreover, it is differentially expressed during cortical development and is expressed in a region-specific manner. Despite complete deficiency of the 427 kDa dystrophin in *mdx* mouse and dystrophic human brain, syntrophin was detectable but decreased in cortical PSDs from the *mdx* mouse and from one case of human DMD. Our results indicate that dystrophin and syntrophin are colocalized in the PSD, but are differentially expressed in the diseased state.

513.10

PHARMACOLOGICAL CHARACTERIZATION OF THE BINDING OF [3H]YM09151-2 TO D4 DOPAMINE RECEPTOR SUBTYPES IN BASAL GANGLIA AND CORTEX OF SCHIZOPHRENICS AND CONTROLS.

A. M. Murray*, T. M. Hyde, M. B. Knable, M. M. Herman, L.B. Bigelow and J.E. Kleinman, Clinical Brain Disorders Branch, IRP, NIMH, St. Elizabeths Hospital, Washington, DC 20032.

The identification of 5 distinct dopamine (DA) receptor sub-types has important implications for the DA hypothesis of schizophrenia. The D4 receptor is particularly intriguing because it binds clozapine with high affinity. Seeman (1993), subtracting the binding of [³H]Raclopride (labels D2 and D3 receptors) from that of [³H]YM 09151-2 (labels D2, D3 and D4 receptors) for identification of D4 receptors, demonstrated a six fold increase in D4 binding in schizophrenic putamen compared to the controls. We characterized the pharmacology of [³H]YM 09151-2 binding and the density and distribution of D4 receptors using quantitative receptor autoradiography in the striatum, entorhinal and prefrontal cortex, in schizophrenic brains compared to normal controls. Adjacent sections were incubated with 1 nM [³H]YM 09151-2, 1 nM [³H]YM 09151-2 in the presence of 50 nM 8-OH DPAT (to block 5-HT₁ receptors) or 6.0 nM [³H]Raclopride. Butaclamol (10 μ M) was used to define non-specific binding. In the basal ganglia, schizophrenics had significant increases in D4 receptors in all regions (60-80%) labeled with [³H]YM 09151-2 alone compared to controls. A similar trend was observed in the presence of 8-OH-DPAT, although the variability in binding was increased. No significant changes were observed in entorhinal cortex in schizophrenics. However, 8-OH-DPAT significantly decreased [³H]YM 09151-2 binding (>50%) in the subiculum and entorhinal cortex compared to [³H]YM 09151-2 alone. This suggests that [³H]YM 09151-2 binds to 5-HT₁ receptors in cortical regions.

513.11

RESPONSE OF NEUROTENSIN SYSTEMS SUGGESTS THAT THE 5HT-2 ANTAGONIST, MDL 100,907, HAS CLOZAPINE-LIKE ANTIPSYCHOTIC EFFECTS. G.R. Hanson*, L.G. Bush, J.W. Gibb, and C.J. Schmidt. Dept. Pharmacol. and Tox., University of Utah, Salt Lake City, UT 84112 and Marion Merrell Dow Inc., Cincinnati, OH 45215.

Drugs such as haloperidol (HA) are classified as *typical* antipsychotics because of their prominent extrapyramidal side effects and their lack of effectiveness against the negative symptomatology of schizophrenia. In contrast, drugs like clozapine (Cloz) are considered *atypical* antipsychotics because of their lack of extrapyramidal effects and their ability to relieve schizophrenia-related negative symptoms. Although the difference between typical and atypical antipsychotics is not known, the antagonistic effects of Cloz on 5HT-2 receptors, an effect not shared by HA, suggests that a serotonergic mechanism may be important. Based on this hypothesis, the highly selective Marion Merrell Dow 5HT-2 antagonist, MDL 100,907 (MDL), may have atypical antipsychotic effects. This was tested by comparing the responses of caudate and nucleus accumbens neurotensin (NT) systems (a neuropeptide dramatically altered by antipsychotic drugs) to 1, 2 and 4 doses of HA, Cloz and MDL. These studies revealed that the pattern of changes caused by MDL in neurotensin-like immunoreactivity in 6 caudate regions was much more like the effects of Cloz than HA. In contrast, the responses of the NT systems in the anterior and posterior nucleus accumbens were very similar for all three drugs. We conclude from these findings that (1) antagonism of 5HT-2 receptors plays a critical role in the mechanism of atypical antipsychotics, (2) the MDL compound has atypical antipsychotic effects like Cloz and (3) 5HT-2 receptors contribute to the regulation of both caudate and accumbens NT systems. (This work was supported by Marion Merrell Dow Inc. and USPHS grants DA 04222 and DA 00869.)

513.13

Effects of D1 antagonist SCH23390 on vacuous chewing movements and striatal neuropeptide mRNA following long term haloperidol decanoate M.F. Egan, S.E. Bachus, T.M. Hyde, J.N. Ferguson, B.J. Wyatt, J.T. Noga*, J.E. Kleinman, NIMH at St. Elizabeths, 2700 M.L. King Ave. S.E., Wash., D.C., 20032.

Long term haloperidol treatment produces a syndrome of vacuous chewing movements (VCMs) in rats, a putative model of tardive dyskinesia. Increased striatal dynorphin and enkephalin mRNA levels in rats with VCMs suggest overactivity of both D1 mediated striatonigral and D2 mediated striatopallidal pathways. We attempted to reduce VCMs using the D1 antagonist SCH 23390 (0.5 mg/kg s.c. twice daily for three weeks) in rats treated previously with haloperidol decanoate (n=34) or vehicle (n=13) for 7 months and withdrawn for 5 months. Paradoxically, SCH 23390 markedly increased VCMs in both haloperidol (12.5 vs. 22.5 VCMs/2min) and vehicle (0.5 vs. 6.3 VCMs/2min) treated groups. Activation of striatonigral and striatopallidal pathways was assessed using *in situ* hybridization for enkephalin, dynorphin, and substance P mRNA. Increased VCMs from SCH 23390 treatment were associated with elevated enkephalin, dynorphin and substance P mRNA in the dorsolateral and/or ventromedial striatum. These results demonstrate that SCH 23390 increases D1 mediated striatonigral and D2 mediated striatopallidal neuropeptide gene expression during long term neuroleptic treatment. Furthermore, they suggest that increased activation of both pathways underlies increased frequency of VCMs.

513.15

SMOOTH PURSUIT EYE MOVEMENTS IN PARENTS OF PROBANDS WITH SCHIZOPHRENIA: AN OBLIGATE CARRIER APPROACH. R.G. Ross*, J. Harris, C.M. Cullum, L.M. Rilling, A.D. Radant, L.E. Adler, and B.F. Freedman. Schizophrenia Research Center, Univ. of Colorado Health Sci. Center, Denver, Colorado, 80262.

Smooth pursuit eye movement (SPEM) abnormalities have been found in patients with schizophrenia and in a large percentage of their nonschizophrenic relatives, suggesting that SPEM abnormalities may be an inherited marker of a biologic risk for schizophrenia. This study used infrared oculography and computerized pattern recognition software to study SPEM during a 16.7°/second constant velocity task. Subjects were 7 families with (a) schizophrenic probands, (b) both biological parents available for study, and (c) where only one of the biologic parents had a positive family history for schizophrenia (making that parent the "obligate carrier" for any inherited risk for schizophrenia).

Although 7/14 (50%) of parents had abnormal SPEM (smooth pursuit gain less than 0.85), parents with and without positive family histories did not differ in smooth pursuit gain (t=0.26, n.s.). Sources of error in SPEM include (1) deficiency at accurately tracking the target (requiring "catchup" saccades as compensation) and (2) problems with anticipating target movement (and having an "anticipatory" saccade intrude upon accurate tracking). Comparison of parents with and without a positive family history for schizophrenia demonstrated no difference in SPEM error due to catchup saccades (t=0.40, n.s.), but a significant difference in SPEM error due to anticipatory saccades (t=2.35, p<.04).

Although SPEM abnormalities are common in parents of schizophrenic probands, examination of the sources of error may be necessary to define the biologic marker of schizophrenic risk.

513.12

Reduced striatonigral activity related to vacuous chewing movements induced by acute haloperidol treatment: a possible model for dystonia. J.N. Ferguson, M.F. Egan, S.E. Bachus, T.M. Hyde, R.J. Wyatt, D. Grega*, J.E. Kleinman, NIMH at St. Elizabeths, 2700 M.L. King Ave. S.E., Wash., D.C., 20032 and Boehringer Mannheim, Indianapolis, IN, 46250.

Long term haloperidol treatment produces a syndrome of vacuous chewing movements (VCMs), a putative model of tardive dyskinesia. Increased striatal dynorphin and enkephalin mRNA levels in rats with VCMs suggest overactivity of both D1 mediated striatonigral and D2 mediated striatopallidal pathways. Several studies have indicated that short term intraperitoneal (i.p.) injections of haloperidol can also produce VCMs, raising doubts about the validity of the VCM model. To investigate this issue, we measured mRNA for dynorphin and substance P co-localized in D1-mediated striatonigral neurons. Rats received i.p. haloperidol or vehicle (0.4 mg/kg/d) for three weeks. Significant increases in VCMs were seen shortly after the initiation of treatment. Using *in situ* hybridization, we found reduced dynorphin and substance P mRNA levels in the dorsolateral and ventromedial striatum in haloperidol treated rats compared to the control group. Substance P mRNA was also reduced in the nucleus accumbens. These findings indicate that "acute VCMs" induced by short term i.p. haloperidol are related to reduced D1-mediated striatonigral activity. "Acute VCMs" appear to be neurochemically distinct from VCMs induced by long term haloperidol treatment, and may be a model for acute neuroleptic-induced dystonia.

513.14

IMAGING CEREBRAL BLOOD FLOW IN SCHIZOPHRENICS BY SINGLE-PHOTON EMISSION COMPUTED TOMOGRAPHY WITH TECHNETIUM-99m-HMPAO.

Jin-Sook Cheon*, Department of Neuropsychiatry, Kosin University, School of Medicine, Pusan 602-702, South Korea.

The single-photon emission computed tomography (SPECT) is an unique method to monitor the regional cerebral blood flow three dimensionally in clinical field. In psychiatry, it has a limited value to be applied to the research field rather than the clinical purpose. This is the first study of regional cerebral blood flow mapping in twelve schizophrenic patients using 99mTc as a radiotracer in Korea. Most of the SPECT results except one revealed hypoperfusion pattern (91.7%). The most prevalent loci of the lowest perfusion were bilateral parietal areas (P<0.05), next, left parietal, left temporal and bilateral frontal, and then cerebellum, and the last basal ganglia and thalamus. Comparing a spectrum produced by enlisting eight cases of a neurosis, a major depression with psychotic features, a schizotypal personality disorder, a residual schizophrenia, subchronic paranoid schizophrenia with acute exacerbation, subchronic paranoid schizophrenia without acute exacerbation, chronic undifferentiated schizophrenia with acute exacerbation, chronic undifferentiated schizophrenia without acute exacerbation in decrease order of perfusion, the cerebral blood flow changes tended to be related with the intensity of psychotic symptoms and duration of illness.

RAPID SMOOTH PURSUIT EYE MOVEMENTS AND THE ACOUSTIC STARTLE RESPONSE M.D. Brady, A.A. Freeman, E.L.F. Ho, T.L. Rawls and K.A. Young* Neuroscience Laboratory, Waco Veterans Administration Medical Center, 4800 Memorial Dr., Waco, Texas 76711

In eye movement desensitization therapy (EDT) for the treatment of post-traumatic stress disorder (PTSD), patients are instructed to concentrate on mental images which are associated with their stress response while making rapid smooth pursuit eye movements (rSPEM). Patients often report that after sessions of this therapy, they no longer experience the intense psychophysiological and pseudopsychiatric responses previously generated by the target mental image. One psychophysiological response that is abnormal in many PTSD patients is the startle response. We investigated the possible relationship between rSPEM and the startle response in normal controls. Subjects made 30 rSPEM movements in a 60 sec period followed by 3 startle stimuli in the next 60 seconds. The pattern was repeated 6 times for a block (SPEM). A corresponding block had the same startle stimuli, but the SPEM target moved very slowly in the center of the subjects visual field (NoSPEM). Each subject was exposed to one of 2 treatment orders (NoSPEM-SPEM, SPEM-NoSPEM). Startle response amplitude, prepulse inhibition and within-session habituation was not significantly influenced by rSPEM movements. However, there was a significant interaction of block treatment order with startle amplitude changes between blocks, suggesting that rSPEM may have had a relatively subtle effect to suppress startle amplitude when the SPEM block preceded the NoSPEM block. This experiment suggests that the mechanism of EMD therapy may be related to influences of rSPEM on basic neural processes responsible for abnormal psychophysiological responses in PTSD patients.

QUANTITATIVE MEASUREMENT OF SPEM IN SCHIZOPHRENIA USING THE SEARCH COIL TECHNIQUE. H.P. Goldstein and R.C. Alexander*

Thomas Jefferson University, Philadelphia, PA 19107

Impaired smooth pursuit eye movement (SPEM) in schizophrenia appears to be one of the most consistent biological correlates of schizophrenia. Most previous studies, however, have used non-quantitative methods which do not allow specification of the defects involved. In our study, 9 schizophrenic and 5 normal subjects underwent measurement of initiation and maintenance of smooth pursuit using the search coil technique. Eye movement targets were small spots of light projected onto a tangent screen 1 m in front of the subject and attention was maintained by asking subjects to detect periodic brightening of the target. For some trials involving horizontal target motion, the target was stabilized on the retina for 300 ms (open loop condition) so that the target would follow eye movements. Detailed quantification of eye movements showed considerable overlap between the gain and variability scores of the schizophrenic subjects relative to controls. Further, schizophrenic subjects successfully predicted changes in target direction in the open loop condition, indicating that they were able to construct an "internal model" of target movements.

NEUROANATOMICAL CORRELATES OF AN EVENT-RELATED POTENTIAL (ERP) INDEX OF AUDITORY SENSORY MEMORY IN SCHIZOPHRENIA. P.B. Ward, C. Loneragan, B. Liebert, S. V. Catts, P. T. Michie, S. Andrews, G. Dixon*, & N. McConaghy. Schools of Psychiatry and Psychology, University of New South Wales, Sydney, NSW 2052 & School of Behavioural Sciences, Macquarie University, NSW 2109 AUSTRALIA.

To investigate the functional significance of subtle neuroanatomical changes in temporal lobe neuroanatomy frequently reported in post-mortem and neuroimaging studies of schizophrenic patients, we recorded an ERP index of auditory sensory memory, termed mismatch negativity (MMN), from 15 DSM-III-R schizophrenic patients and age-, sex- and handedness-matched healthy controls. Patients were aged between 21 and 49 years (mean age 34.3 ± 8.2 years), and included 9 females and 6 males. MMN was elicited by infrequent 100ms tone pips interspersed among 50 ms standard tones during a visual distraction task. 3D volumetric MRI scans were obtained from all subjects, and Heschl's gyrus (HG) and planum temporale (PT) areas were measured on coronal slices using the BRAINS package (Andreasen et al, 1993). MMN amplitude at the Fz electrode was significantly reduced in schizophrenic patients, as was HG area, particularly in the left hemisphere. PT asymmetry (L>R) was significantly greater in male compared to female subjects, and there was a significant diagnosis by sex by side interaction for PT areas, reflecting significantly reduced right hemisphere PT areas in male schizophrenics. MMN amplitudes were significantly correlated with HG areas ($\rho = .43$ to $.67$) in both controls and schizophrenics. Supported by the NH&MRC (Australia) and the Rebecca L Cooper Medical Research Foundation.

IMPROVED REVERSAL LEARNING FOLLOWING L-NAME INHIBITION OF NOS ACTIVITY IN AN ANIMAL MODEL OF SCHIZOPHRENIA. M. Lyon*, C. N. Karson, B. L. Freeman. Center for Brain and Behavioral Research, University of Arkansas for Medical Sciences, Little Rock, AR 72205.

One animal model of schizophrenia (Lyon and McClure, 1994) includes abnormal behavioral effects as well as increased numbers of nitric oxide synthase (NOS)-containing cells in the brainstem (Nielsen et al., 1992), as also reported in schizophrenia (Karson et al., 1991). Such animals, exposed to maternal treatment with d-amphetamine during mid-pregnancy, are behaviorally more sensitive to increased NOS activity produced by nitroglycerin or to inhibition of NOS by NG-nitro-L-arginine methyl ester (L-NAME) (Lyon et al., 1994).

Offspring of Sprague-Dawley dams treated in mid-pregnancy with either 5.0 mg/kg d-amphetamine s.c. (AM), or saline s.c. plus the reduced food intake of AM dams (US), were used. N=19 AM, and N=18 US, young received either 20 mg/kg L-NAME or saline s.c. 5 minutes before holeboard foraging trials. Each animal was given 4 baits only in the right-side, or only in the left-side, holes in the field. Three training trials were followed by a right/left reversal trial, and then by extinction. RESULTS: Under saline, right/left lateral turning preference was significantly greater in AM animals than in US controls, and AM animals spent more time in far-field exploration. L-NAME reduced rearing and locomotion, but sharpened correct holepoking in both AM and US rats. L-NAME produced significant improvement in reversal learning in AM rats, which was not found in US animals nor under saline conditions. NOS inhibition by L-NAME may have significant therapeutic value for cognitive dysfunctions, including deficient reversal learning, which are found in schizophrenia.

Regional Cerebral Blood Flow in Schizophrenia: Classification Using Pixel-Wise Discriminant Analysis. J.D. Van Horn*, K.F. Berman, and D.R. Weinberger. Unit on PET, Neurosciences Center at St. Elizabeth's, 2700 Martin Luther King Jr. Ave. SE, Washington DC 20032

Regional cerebral blood flow (rCBF) differences between patients and controls have been widely reported as between-subject comparisons of normalized mean values derived from cognitive activation paradigms. Differences in activation between groups are often used to identify affected regions in the pathological subject sample. More recently, multivariate approaches have been applied to region of interest as well as pixel-based data (e.g. principle component analysis). Here we employed a pixel-based discriminant analysis approach to the comparison of schizophrenics and control subject rCBF that enables one to analyze two or more groups of subjects performing two or more tasks, maximizing the statistical difference between the groups and displaying the results as images. The advantages of this method include the ability to localize brain areas most responsible for variation between groups, while partitioning these differences into orthogonal images to reflect potential functional network differences. Additionally, the posterior probability of an individual subject's group classification may be measured to determine, in this case, whether or not he/she demonstrates a pattern of rCBF similar to controls or to schizophrenics.

THURSDAY AM

SYMPOSIA

515

SYMPOSIUM. STRUCTURE, FUNCTION, AND REGULATION OF GLUTAMATE RECEPTORS. R.L. Haganir, HHMI, Johns Hopkins Univ., (Chairperson); P.H. Seeburg, Univ. of Heidelberg; M.L. Mayer, NIH-NICHHD; S. Tonegawa, HHMI, Mass. Inst. of Technology.

Glutamate receptors mediate excitatory synaptic transmission in the central nervous system and play critical roles in synaptic plasticity, neuronal development and neurological disorders. These receptors can be divided into two major classes: metabotropic receptors, which are coupled through G-proteins to intracellular second messengers; and ionotropic receptors, which are ligand-gated ion channels. The ionotropic receptors can be further subdivided based on their pharmacological and physiological properties into AMPA, kainate, and NMDA receptors. This symposium will review the recent advances in our understanding of the structure, function and regulation of these receptors and their role in brain function. Peter Seeburg will discuss studies on the molecular cloning of subunits for the AMPA, kainate, and NMDA glutamate receptors including recent studies on the role of RNA editing in the regulation of glutamate receptor function. Mark Mayer will present data comparing the physiological properties and allosteric regulation of native and recombinant AMPA and kainate receptors. Richard Haganir will discuss the role of protein phosphorylation of glutamate receptors in the regulation of their function and in certain forms of synaptic plasticity such as LTP and LTD. Finally, Susumu Tonegawa will present studies using homologous recombination to generate mutant mice to analyze glutamatergic synaptic function. Mutant mice that are deficient in models of synaptic plasticity such as LTP and LTD will be discussed.

516

SYMPOSIUM. GENERAL ANESTHETIC EFFECTS ON SOMATOMOTOR PROCESSING. P. Mason, Univ. of Chicago (Chairperson); J.G. Collins, Yale Univ.; J. Kendig, Stanford Univ.; E. Puil, Univ. of British Columbia.

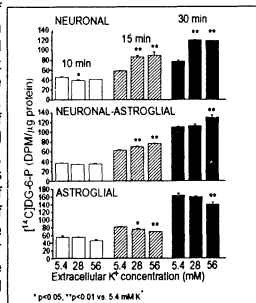

This symposium will highlight our current understanding of how general anesthetics affect excitatory and inhibitory neurotransmission in specific neuroanatomical sites important in somatomotor processing. The relative contributions of actions within the spinal cord, brainstem and thalamus to the somatic unresponsiveness observed during general anesthesia will be outlined. The symposium's aim is to increase our understanding of how anesthetics produce surgical immobility while stimulating further investigations that address this important question. Collins will describe the effects of diverse general anesthetics on the evoked responses and receptive field characteristics of spinal dorsal horn cells. These findings will be discussed with reference to the loss of sensation associated with general anesthesia. Kendig will review the effects of a variety of anesthetic agents on receptor-specific spinal reflex pathways. Particular attention will be paid to variations in the importance of GABA_A effects among agents and to the extent to which actions on a single receptor can account for somatic unresponsiveness. Mason will describe the effect of general anesthetics on pain modulatory neurons, and propose mechanisms that may account for the observed changes in neuronal firing. Predictions will be made of how these brainstem actions may affect somatomotor processing within the spinal cord. Puil will discuss the effect of inhalational anesthetics on neurons in the rat ventrobasal thalamus. Anesthetic blockade of the transitions to the thalamic firing modes characteristic of specific behavioral states may serve to interrupt somatosensory perception.

518.1

EFFECTS OF EXTRACELLULAR POTASSIUM ION CONCENTRATION ON RATES OF PHOSPHORYLATION OF DEOXYGLUCOSE IN CULTURED ASTROGLIA AND NEURONS.

S. Takahashi, B.F. Driscoll, M.J. Law and L. Sokoloff*, Lab. of Cerebral Metabolism, National Institute of Mental Health, Bethesda, MD 20892.

The effects of increasing extracellular K⁺ concentration on glucose metabolism in primary cultures of rat astroglia and neurons were examined. Cells were incubated with bicarbonate buffer containing 2 mM glucose, tracer amounts of 2-deoxy-D-[¹⁴C]glucose ([¹⁴C]DG), and various concentrations (5.4, 28, 56 mM) of K⁺ for 10, 15, or 30 min followed by a 5 min incubation in [¹⁴C]DG-free buffer for an efflux of unphosphorylated [¹⁴C]DG. Cells were digested and assayed for labeled metabolites. K⁺ caused significant elevations in rates of phosphorylation of [¹⁴C]DG in both neuronal and neuronal-astroglial mixed cultures at 15 and 30 minutes, but not in astroglial cultures (Fig.). Veratridine (75 μ M), which opens Na⁺ channels, significantly raised rates of phosphorylation in astroglial and neuronal cultures (132 and 116%, respectively), and these elevations were completely blocked by 1 mM of ouabain, a specific inhibitor of Na⁺,K⁺-ATPase. These results indicate that elevated extracellular K⁺ concentration does not stimulate energy metabolism in cultured astroglia.

MECHANISMS UNDERLYING THE INTRINSIC SIGNAL DURING OPTICAL IMAGING OF RAT SOMATOSENSORY CORTEX. M. M. Haglund*, D. W. Hochman, J. R. MENO, A. G. NGAI, AND H. R. WINN. Department of Neurological Surgery, University of Washington, Seattle, WA 98195.

Optical imaging of intrinsic signals has been accomplished *in vitro* in hippocampal slices (MacVicar & Hochman, 1991) and *in vivo* in monkey visual cortex (Frostig et al., 1990). The source of the *in vitro* signal is primarily due to postsynaptic activation and cellular swelling, while the *in vivo* signal from monkey visual cortex is dominated by blood volume changes and oxygen delivery from capillaries.

In rat sensory cortex, sciatic nerve stimulation elicited localized cortical potentials (N1-20 msec; P2-35 msec) that correlated with a 25-50% dilation of the pial arterioles feeding the hindlimb cortex. Optical imaging of intrinsic signals showed changes in areas fed by pial arterioles that dilated. Cerebral blood flow/volume was uncoupled from increases in cortical activity by topically applying theophylline (10uM; A1/A2 adenosine antagonist), decreasing pial arteriole dilation by 70-90% and eliminating the P2 wave. Even though blood volume changes are highly sensitive to changes in arteriole diameter, the intrinsic signals from areas activated in controls increased in its spatial extent and magnitude in the presence of theophylline. Topical application of CPX (1uM; 8-cyclopentyl-1,3-dipropylxanthine; A1 antagonist) blocked the P2 wave and potentiated arteriole dilation, while intrinsic signals changes were similar to that found with theophylline.

Uncoupling the increases in blood flow/volume from increases in cortical activity did not effect the intrinsic signal changes. These findings suggest that changes related to blood flow/volume are not the main contributors of the intrinsic signal changes in our preparation.

THE ROLE OF NEURONAL NITRIC OXIDE SYNTHASE (nNOS) IN THE CEREBRAL HYPEREMIC RESPONSE TO HYPERCAPNIA (HC) IN RATS. Q. Wang*, D.A. Pelligrino, V.L. Baughman and R.F. Albrecht. Dept. of Anesthesiol., Univ. of Ill.-Chicago, Chicago, IL 60612

NO has been shown to play a role in the cerebral vasodilatory responses (CVDRs) to a wide variety of stimuli, including HC. NO is produced by the action of NOS. There are 2 constitutive NOS isoforms in the brain, the endothelial (eNOS) and nNOS. Previous studies have used non-specific NOS inhibitors (e.g., nitro-L-arginine) to reveal NO influences, and found, in rats, that such agents attenuated the CVDR to HC (PaCO₂ = 60-80 mmHg) by 40-80%. However, the cellular source of that NO is not known. 7-nitroindazole (7-NI) is reported to be a selective inhibitor of the nNOS. In the present study, we monitored cortical cerebral blood flow (CBF) in rats, under normo- and hypercapnic conditions, using laser-Doppler flowmetry (LDF), in the presence and absence of 7-NI. To confirm that eNOS was unaffected by 7-NI, we assessed the CBF responses to the muscarinic acetylcholine agonist, oxotremorine (OXO), which activates eNOS exclusively. The experiments were performed on male Sprague-Dawley rats (~400g, n=9), anesthetized with fentanyl/70% N₂O and mechanically ventilated. Cortical CBF was measured via LDF. In all experiments, an initial CBF response to 5 min HC was obtained prior to 7-NI or vehicle (corn oil) injection. Three ml of the 7-NI solution (at 80 mg/kg) or vehicle were injected i.p. CBF responses to 5 min HC were repeated at 30 and 60 min post-injection. After an additional 15 min, the CBF response to a 7 min iv infusion of OXO (1 μ g/kg/min) was measured. At the end of the study, the brains were rapidly removed and the cortical tissue was frozen and subsequently analyzed for NOS activity. 7-NI inhibited brain NOS activity by 60% and reduced baseline CBF by 19%, but did not affect MAP or the CBF response to OXO. This confirmed that eNOS is unaffected by 7-NI. The CBF responses to HC at 30 and 60 min were identically attenuated (~50%) by 7-NI, when compared to controls. That reduction is within the range observed by us and others using non-specific NOS inhibitors. The results imply that a major portion of the NO released during HC is nNOS-derived. This presumably neuronally-released NO also contributes to the maintenance of basal CBF.

518.2

DIRECT MEASUREMENT OF INTERSTITIAL GLUCOSE AND LACTATE IN THE CONSCIOUS HUMAN BRAIN. E. Wallace, D. Mages, S.S. Spencer, D. Spencer, C.C. Duncan*, R.S. Sherwin and M.J. During. Departments of Medicine and Surgery, Yale School of Medicine, 330 Cedar St., New Haven CT 06510.

Estimates of brain glucose and lactate can be made by NMR spectroscopy. However, the actual concentrations of these metabolites in human extracellular fluid (ECF), and their relationship to fluctuations in the vascular compartment are unknown. To address this issue, we used microdialysis to monitor glucose and lactate concentrations in human brain ECF, while manipulating plasma glucose (glucose-insulin clamp technique). **Methods:** Microdialysis catheters were placed bilaterally in the hippocampi of subjects (n=4) undergoing intracerebral depth electrode monitoring for intractable epilepsy. Studies were carried out 3 days after surgical placement, subjects had been seizure free at least 3 days. Measurements were made from both epileptogenic and non-epileptogenic hippocampi. Arterialized plasma and dialysate, glucose and lactate levels were measured sequentially under plasma glucose conditions of fasting (5.5 \pm 0.5 mmol/l), hyperglycemia (11.5 \pm 0.5 mmol/l) and hypoglycemia (3.0 \pm 0.5 mmol/l). Absolute glucose ECF concentrations were measured by net flux calculation. **Results:** At each level of plasma glucose, brain ECF glucose concentrations were substantially lower than concurrent plasma levels (~30%). In addition ECF glucose reached equilibrium 30-40 mins after plasma glucose. In comparison fasting brain ECF dialysate lactate levels were higher than fasting plasma lactate measurements (~x2), and did not change with plasma glucose. **Conclusions:** 1. Neurons and glia are consistently exposed to glucose concentrations that are substantially lower than those of arterial blood. 2. Brain ECF glucose shows a delayed response to changes in plasma glucose. 3. The marked glucose gradient, from blood to brain ECF, implies that neuronal metabolism may be unexpectedly vulnerable to even small decrements in glucose levels, and that, in this context lactate might serve as an alternative fuel source.

518.4

EXPLORING THE TEMPORAL BOUNDARIES OF FMRI: MEASURING RESPONSES TO VERY BRIEF VISUAL STIMULI. R.L. Savoy*, K.M. O'Craven, B.M. Weisskoff, T.L. Davis, J. Baker, B. Rosen. The Rowland Institute for Science, 100 Edwin H. Land Blvd, Cambridge, MA 02142; MGH-NMR Center, 149 13th St., Charlestown, MA 02129

There is little doubt that fMRI will improve the *spatial* resolution of functional brain imaging; but can fMRI, on its own, yield sufficient *temporal* resolution to be of value in studying the timecourse of perceptual and cognitive processes? In the present study, we begin to address this question by looking at the response to very brief visual stimuli...stimuli of much shorter duration than the hemodynamic response to which fMRI is sensitive. The goals were two-fold. First, to see if such brief temporal stimuli would elicit measurable fMRI responses. Second, to examine the variability of response to temporally precise stimuli, especially the latency of response.

Three normal subjects participated in the experiment. We imaged a single 7mm oblique slice through the calcarine fissure of each individual using Gradient Echo imaging with a 1.5 T GE Signa modified by Advanced NMR, Inc. (Surface coil, TR=400, TE=50, Flip Angle=53°)

In a given run, we presented a full-field circular checkerboard for 1000ms, 100ms, or approximately 17ms. Stimulus onset was synchronized with the scanner. A bite bar minimized subjects' head movements both within and between runs. This combination permitted us to average 10 runs for each subject in each condition.

The stimuli of 1000msec duration yielded clear fMRI responses even on single runs. The responses to the briefer stimuli were apparent in the averaged data. In all three conditions, the response latency was consistent. An increase in the averaged fMRI signal occurred 2 seconds after stimulus onset. These experiments (and other experiments with TR=100) suggest a variability of the averaged response latency of not more than 300msec.

518.6

THE LOWER LIMIT OF CEREBRAL BLOOD FLOW AUTOREGULATION WITH NITRIC OXIDE SYNTHASE INHIBITION. S.C. Jones* and C.R. Radinsky. Cerebrovascular Res. Lab., Cleveland Clinic Found., Cleveland, OH 44195.

Current evidence indicates that nitric oxide is not involved in CBF pressure autoregulation in spite of other evidence that endothelium influences autoregulation. Because systemic NOS inhibition raises MABP, we investigated cortical NOS inhibition with superfusion.

Four Sprague-Dawley rats (345 \pm 15 g, SEM) were anesthetized with 0.5-1% halothane and 70% N₂O in O₂ with body temperature maintained at 37°C. The first day a cranial window was placed over a 6 mm diameter craniotomy (no dura matter) and the animal was allowed to recover. The second day, under anesthesia, a tracheotomy was performed, permitting artificial ventilation, and femoral arterial and venous catheters were placed. Physiological variables (MABP, PaCO₂, PaO₂, and pH) were stabilized. CBF was determined using laser Doppler flowmetry through the window. Animals with low CO₂ reactivity were excluded. After superfusion with artificial CSF (aCSF), MABP was sequentially lowered by exsanguination to 100, 85, 70, 55, and 40 mm Hg, followed by reinfusion. After cortical superfusion with 10⁻³ M N^G-nitro-L-arginine (NNLA) for 103 \pm 2 m, the sequential pressure drops were repeated. The lower limit (LL) of autoregulation was identified visually as a change in the slope of the CBF vs MABP plot or as the maximum pressure if the plot was linear. The LL was 59 \pm 7 during aCSF and 81 \pm 10 mm Hg during NNLA superfusion (p<0.05). In one of these animals, a 3rd withdrawal sequence with NNLA plus 10⁻² M L-arginine did not decrease the LL.

Thus, NNLA superfusion raises the LL of autoregulation, but the increase is not reversed by L-arginine. Although our finding is in contrast to those of previous workers, these data suggest 1) that there is a local autoregulatory response that is undetectable with the global CBF techniques of others, 2) that the length of NNLA exposure allowed inhibition of a NOS source that mediates autoregulation, or 3) that the effects of systemically administered NOS inhibitors somehow override their effect on the LL of autoregulation. (Supported by NSF IBN 90-22190)

NITRIC OXIDE MODULATES LOCAL INCREASES OF BLOOD FLOW IN RAT CEREBELLUM. M. Lauritzen*, N. Akgören, and M. Fabricius. Dept. Medical Physiology & Clin. Neurophysiology, Univ. Copenhagen, DK-2200 Copenhagen, Denmark.

We explored the possibility that NO was of importance for increases of cerebral blood flow (CBF) associated with activity of the well-defined neuronal circuits of rat cerebellar cortex. Laser-Doppler flowmetry was used to measure increases of CBF evoked by trains of electrical stimulations of the dorsal surface. The evoked increases of CBF were frequency-dependent, being larger on than off parallel fiber tracts, suggesting that conduction along parallel fibers, and synaptic activation of target cells were important for the increased CBF. This was verified experimentally since the evoked CBF increases were abolished by TTX, and reduced by 10 mM Mg^{2+} and NBQX and CNQX, antagonists for non-NMDA receptors. The cerebellar cortex contains high levels of NO synthase. This raised the possibility that NO was involved in increases of CBF associated with neuronal activation. NO synthase inhibition by topical application of N^G -nitro-L-arginine, attenuated evoked CBF increases by about 50%. This effect was partially reversed by pretreatment with L-arginine, the natural substrate for the enzyme, while N^G -nitro-D-arginine, the inactive enantiomer, had no effect on the evoked CBF increases. Simultaneous blockade of non-NMDA receptors and NO synthase had no further suppressing effect on the CBF rise than either substance alone, suggesting that the NO-dependent flow rise was dependent on postsynaptic mechanisms. The findings are consistent with the idea that local synthesis of NO is involved in the transduction mechanism between neuronal activity and increased CBF.

518.9

A NOVEL SET-UP TO STUDY CEREBROVASCULAR RESPONSES UNDER WELL-CONTROLLED PHYSIOLOGICAL CONDITIONS IN THE MOUSE. T. Dalkara, K. Irikura, Z. Huang, N. Panahian*, M.A. Moskowitz. Stroke Research Lab., M.G.H., Harvard Medical School, Boston, MA, USA.

Control of physiological parameters such as respiration, blood pressure and gases has proven difficult due to the lack of microtechnology required to monitor these parameters. Here we report that mice can successfully be maintained under anesthesia for 5-6 hours without deterioration in physiological parameters and with normal cerebrovascular reactivity. This can be achieved by a ventilator having an inspiration time below 0.1 second, which appears to be critical to maintain adequate cardiac output and blood pressure. Monitoring end-tidal CO_2 is also indispensable because several manipulations require frequent readjustment of the respiratory parameters.

SV-129 mice were anesthetized with urethane (750 mg/kg, i.p.) and alpha-chloralose (50 mg/kg, i.p.), intubated, paralyzed and ventilated. Body temperature was kept at 36.5-37.5°C. End-tidal CO_2 was maintained to give a p_aCO_2 of 35±4 mm Hg (mean±s.d.). Mean arterial pressure was 95±8 mm Hg, heart rate was 545±77/min and arterial pH was 7.27±0.15. SV-129 maintained a normal cerebral perfusion between 40-120 mm Hg of systemic arterial pressure. Hypercapnia led to a 38±15 (5% CO_2) and 77±34% (10% CO_2) increase in rCBF (laser-Doppler flowmetry). Mechanical stimulation of contralateral vibrissae increased rCBF by 14±3%. After placement of a closed cranial-window, normal rCBF and pial vessel responses to hypercapnia and whisker stimulation could be maintained.

CEREBRAL CORTICAL ACTIVATION STUDIES WITH [^{99m}Tc]-BICISATE (ECD) SPECT. E. Matthew* and T. Hill. Deaconess Hospital and Harvard Medical School, Boston, MA 02215.

This study investigates the feasibility of using [^{99m}Tc]-Bicisate (ECD; NeuroLite®), a new perfusion agent, to demonstrate changes in regional cerebral blood flow (rCBF) in cortical activation studies.

Normal volunteers (n=25) were studied under baseline conditions (resting in a darkened room), and during activation by either full-field (n=10; mean [SD] age, 32.8 [8.0] years; male, 6; handedness, 7 right), or right hemi-field (n=10; age, 30.4 [5.7] years; male, 5; handedness, all right) visual stimulation with a flashing checkerboard, or repetitive right hand finger movements (n=5; age, 33.2 [9.4] years; female, 4; all right handed). These paired scans were realigned and co-registered with an automated program. Baseline and activation studies were compared in each subject. Regions of interest normalized to whole-slice activity were used to determine differences between resting and activated states, as well as left-right differences.

Right hemi-field stimulation caused significant rCBF change only in the left occipital cortex (mean [SD] % change from baseline: left, 4.9 [3.9]; right -0.6 [7.5], $p < 0.05$, t-test, 2-tail), while full-field visual stimulation produced bilateral activation in the occipital cortex. During repetitive right hand finger movements, rCBF was significantly higher in the left precentral area compared to the right (mean % left-right difference [SD], 9.0 [2.1], $p < 0.001$, t test, 2-tail). No other significant regional changes were demonstrated under baseline conditions or during activation.

These data demonstrate that [^{99m}Tc]-Bicisate SPECT scans can be used for cortical activation studies.

Stimulation of endothelial α_2 adrenoreceptors relaxes the rat middle cerebral artery by a mechanism involving endothelium-derived nitric oxide and a pertussis toxin-sensitive G protein. R.M. Bryan*, Jr., M.Y. Eichler, and T.D. Johnson. Department of Anesthesiology, Baylor College of Medicine, Houston, TX 77030

Changes in the diameter of rat middle cerebral arteries (MCAs) were studied after stimulation of α_2 adrenergic receptors with UK14304. Rat MCAs were isolated, cannulated at each end with a glass micropipet, and pressurized to 85 mm Hg. The MCAs were immersed in a bath (37°C) containing physiological saline solution (PSS), and luminally perfused with PSS (100 μ l/min). Changes in the vessel diameter were measured after magnification of the MCAs. Resting diameter for the MCAs was $250 \pm 4 \mu$ m. When UK14304 was added extraluminally to the solution bathing the MCAs, a dose-response dilation was produced with a 13 ± 2 % increase in diameter occurring at a concentration of 10^{-4} M. Luminal administration of UK14304 had no effect on the vessels. The dilations produced by UK14304 were blocked with phentolamine (10^{-6} M), a combined α_1 and α_2 antagonist, and idazoxan (10^{-6} M), a selective α_2 antagonist, but were not blocked by prazosin (10^{-6} M), an α_1 antagonist. The dilations could be blocked by removal of the endothelium, or the nitric oxide synthase inhibitor N-nitro-L-arginine methyl ester (L-NAME, 10^{-5} M). The inhibitory effects of L-NAME were reversed with the addition of 10^{-3} M L-arginine, but not 10^{-3} M D-arginine. Furthermore, the dilation produced by UK14304 was completely abolished with pertussis toxin (100 ng/ml). We conclude that the stimulation of α_2 adrenergic receptors with UK14304 produces a relaxation in the rat middle cerebral artery which (a) is endothelium dependent, (b) involves endothelium-derived nitric oxide, and (c) stimulates nitric oxide synthase via a pertussis toxin-sensitive G protein. (Supported by PHS grant PO1 NS 27616.)

518.10

GENE KNOCKOUTS FOR THE NEURONAL FORM OF NITRIC OXIDE SYNTHASE HAVE A NORMAL rCBF RESPONSE TO CO_2 INHALATION. K. Irikura, T. Dalkara, Z. Huang, P.L. Huang, W.S. Lee*, M. Fishman, M.A. Moskowitz. Stroke Research Lab., M.G.H., Harvard Medical School, Boston, MA, USA.

The vasodilator, nitric oxide has been proposed as an important mediator in the regulation of cerebral circulation. We compared rCBF responses to hypercapnia in wild-type and mutant SV-129 mice which lack the neuronal form of nitric oxide synthase. Mice were anesthetized with urethane (750 mg/kg, i.p.) and alpha-chloralose (50 mg/kg, i.p.), intubated, paralyzed and ventilated. Respiratory end-tidal CO_2 was monitored and maintained to give a p_aCO_2 of 35±4 mm Hg (mean±s.d.). Baseline mean arterial pressure, blood gases and pH were not significantly different in wild (19) and mutant (12) animals. Hypercapnia was induced by inhalation of 5 or 10 % CO_2 balanced with O_2 and N_2 and led to a 38±15 and 77±34% increase in rCBF (laser-Doppler flowmetry) in both the mutant and wild-type. A robust increase in whole brain cGMP was observed in 5 wild mice sacrificed at the end of a 10-min 5% CO_2 inhalation. Mutants (5) had a lower basal level of cGMP and did not show any change after hypercapnia. Topical application of L-nitro-arginine (1 mM) by closed cranial window diminished the hypercapnic response in an hour in both wild and mutant mice. These data suggest that neuronal NO is not the principle mediator of hypercapnic hyperemia. However, the cGMP data implicate that there is an increased production of parenchymal NO in response to hypercapnia in the wild-type.

SEROTONERGIC ACTIVITY CONTRIBUTES TO RESTING CEREBRAL BLOOD FLOW BUT NOT THE RESPONSE TO DORSAL RAPHE NUCLEUS STIMULATION IN RAT. M.D. Underwood*, M.J. Bakalian, V. Arango, A.V. Gubbi and J.J. Mann. Laboratories of Neuropharmacology, University of Pittsburgh, Pittsburgh, PA 15213.

Electrical stimulation of the caudal dorsal raphe nucleus (DRN) elicits an increase in cerebral blood flow (CBF). Paradoxically, stimulation of rostral DRN decreases CBF. Because serotonin (5-HT) has both vasoconstrictory and vasodilatory effects on the cerebral vasculature, we sought to determine whether 5-HT contributes to the maintenance of resting CBF and mediates the decreased CBF response to DRN stimulation.

Adult male Sprague-Dawley rats were anesthetized (α -chloralose, 40 mg/kg), paralyzed and ventilated. Arterial pressure (AP), heart rate and blood gases were monitored and controlled and did not differ between groups ($p > 0.05$, ANOVA). 5-HT neurons were lesioned by microinjection of 5,7-DHT (25 μ g/0.5 μ L) into the DRN. Three weeks later the DRN was stimulated (100 μ A) and CBF was measured autoradiographically in 32 regions using [^{14}C]-iodoantipyrine. 5-HT and 5-HIAA in frontal cortex were determined by HPLC.

In unstimulated, unlesioned controls (n=14) CBF ranged from 48±4 ml/min/100g in corpus callosum to 152±12 ml/min/100g in the nucleus tractus solitarius. DRN stimulation in unlesioned animals (n=12) increased 5-HT (20%) and 5-HIAA (29%) in frontal cortex and reduced CBF globally from 3-24% ($p < 0.05$). In lesioned controls (n=6), 5-HT and 5-HIAA were reduced 48% and 52%, respectively and resting CBF was less than in unlesioned controls in 30 of 32 regions by 14±1% ($p < 0.05$). In unstimulated animals, resting CBF positively correlated with 5-HIAA ($r = 0.61$, $p < 0.01$), but not 5-HT ($r = 0.24$, $p > 0.05$). DRN stimulation in lesioned animals (5HT: 18% of control; 5-HIAA: 17% of control; n=5) resulted in a proportionally similar decrease in CBF as in unlesioned animals ($p < 0.05$).

We conclude: 1) intrinsic serotonergic activity contributes a vasodilatory action on CBF and 2) rostral DRN stimulation elicits widespread CBF decreases which are not mediated by 5-HT. (Supported by NARSAD and MH46745.)

519.1

POLYMORPHISM AND GENETIC MAPPING OF SIX HUMAN SEROTONIN RECEPTOR GENES. D. Goldman*, J. Lappalainen, N. Ozaki, B. Nakhai, U. Pesonen, M. Koulu, B. Giblin, D. A. Nielsen, M. Linnoila and M. Dean. Lab. of Neurogenetics, National Institute on Alcohol Abuse and Alcoholism, Rockville, MD 20852.

Polymorphisms were identified within coding sequences of six 5HT receptor genes. Variants were detected using single strand conformational polymorphism (SSCP) analysis and then converted to PCR-RFLPs. Synonymous substitutions were identified at 5HT_{1A}, 5HT_{1E}, 5HT_{1D α} , 5HT_{1D β} , and 5HT₂. A relatively abundant Cys → Ser substitution was identified at 5HT_{2C}. The 5HT receptor genes (some previously localized by *in situ* hybridization or in somatic cell hybrids) were then genetically mapped on a fine-scale basis by linkage analysis in CEPH/NIH pedigrees, as follows:

5HT _{1A}	Chromosome 5	Previously linkage mapped.
5HT _{1Dα}	Chromosome 1p35	
5HT _{1Dβ}	Chromosome 6q13	
5HT _{1E}	Chromosome 6q13	
5HT ₂	Chromosome 13	
5HT _{2C}	Chromosome Xq21	

The 5HT_{1D β} and 5HT_{1E} genes are genetically linked on 6q13, providing the first example of physical clustering of two members of the 5HT receptor gene family. The 5HT_{2C} Ser/5HT_{2C} Cys amino acid substitution is being evaluated for functional significance and for association to serotonin-influenced traits.

519.3

THE 5-HT₄ RECEPTOR: MOLECULAR CLONING AND PHARMACOLOGICAL CHARACTERIZATION OF THE HUMAN 5-HT_{4L} RECEPTOR. C. Gerald, N. Adham, P.J.-J. Vaysse*, T.A. Branchek and R.L. Weinschank. Synaptic Pharmaceutical Corporation, 215 College Road, Paramus, NJ 07652.

Recently, we described the molecular cloning and pharmacological characterization of two splice variants (5-HT_{4S} and 5-HT_{4L}) of the rat 5-HT₄ receptor. We now report the identification of a human 5-HT_{4L} cDNA clone from a human hippocampal cDNA library. The amino acid sequence deduced from the longest open reading frame is 91.8% identical to the rat sequence, revealing 31 amino acid changes of which 11 are non conservative, including 2 in TMI, 1 in TMII and 1 in TMIV. Interestingly, the human cDNA contains one deoxynucleotide insertion at the 3' end of the coding region, creating a reading frame shift and introducing a stop codon 16 deoxynucleotides downstream in the reading frame. Due to this nucleotide insertion, the carboxy terminal tail of the human 5-HT_{4L} receptor is 16 amino acids shorter than its rat counterpart. The human clone displays 5 fold higher affinity than the rat clone for the 5-HT₄ antagonist [³H]GR113808. Benzamide derivatives like cisapride, BRL-24924 and zacopride, partial agonists at the 5-HT₄ receptor, all potently inhibited binding. The biggest differences between the human and the rat clones were observed with α -Me-5-HT and zacopride which exhibited at least 5 to 10 fold higher affinity for the human 5-HT_{4L} receptor.

SUDDEN DEATH IN 5-HT_{1C} RECEPTOR "KNOCKOUT" MICE. L.H. Tecott*, L. Sun and D. Julius. Depts. of Pharmacology and Psychiatry, University of California, San Francisco, CA 94143-0450.

The 5-HT_{1C} receptor is an abundant serotonin receptor subtype that is restricted to the central nervous system. It has been implicated in many of the physiological effects of serotonin and psychotherapeutic drugs, however, the lack of specific agonists and antagonists of this receptor hinders analysis of its functional significance. To study the roles of this receptor, we have generated, through homologous recombination, mutant mice lacking a functional 5-HT_{1C} receptor gene. To verify the loss of functional receptor protein, brain polyA⁺ RNA from mutant and wild type mice were injected into *Xenopus* oocytes. A loss of serotonin-induced depolarization was noted in oocytes injected with RNA from the mutant animals. In addition, 5-HT_{1C} receptor immunocytochemistry revealed a loss of immunoreactivity in brain sections from mutant animals. Most mutant mice appear healthy and evidence no reproductive abnormalities. However, approximately 25% of males hemizygous for this X-linked mutation display an apparent sudden death syndrome. Death is preceded by no apparent signs of illness such as loss of weight or reduced levels of activity. The age range of animals at death is from 3 to 13 weeks, with a peak incidence at 6-8 weeks of age. Studies are underway to determine the cause of death in these animals. In particular, the possibilities that deaths of mutant mice are due to seizures or cardiac arrhythmias are under examination.

519.2

PHARMACOLOGICAL CHARACTERIZATION OF TWO SPLICE VARIANTS OF THE CLONED RAT 5-HT₄ RECEPTOR COUPLED TO STIMULATION OF ADENYLATE CYCLASE. N. Adham*, C. Gerald, P.J.-J. Vaysse, R.L. Weinschank and T.A. Branchek. Synaptic Pharmaceutical Corporation, 215 College Road, Paramus, NJ 07652.

We have isolated two splice variants of the pharmacologically-defined 5-HT₄ receptor, 5-HT_{4L} and 5-HT_{4S}, differing in the length and sequence of their carboxy termini. In rat brain, the 5-HT_{4S} transcripts are restricted to the striatum, but the 5-HT_{4L} transcripts are expressed throughout the brain, except in cerebellum. When either receptor is transiently expressed in COS-7 cells, each of them stimulates adenylate cyclase activity and is sensitive to the benzamide derivative cisapride. Although 5-HT_{4S} and 5-HT_{4L} clones exhibit very similar pharmacological profiles, some differences were noted: The expression levels of 5-HT_{4S} were approximately 2-fold greater than the 5-HT_{4L} clone when transiently transfected in COS-7 cells and compared in parallel experiments. Despite the lower expression levels, 5-HT_{4L} clone produced significantly greater stimulation of adenylate cyclase relative to 5-HT_{4S} clone. These data indicate that although 5-HT_{4S} and 5-HT_{4L} are splice variants and differ only at their C-terminal tails, they may nevertheless possess different coupling efficiencies to elicit functional responses. Whether 5-HT_{4S} and 5-HT_{4L} couple to different isoforms of G_s and/or adenylate cyclase remains to be investigated. Interestingly, 5-HT_{4L} clone has 4 protein kinase C phosphorylation sites, whereas 5-HT_{4S} clone has only 3. This additional phosphorylation site could lead to differences in the regulation of these two receptors. Alternative splicing may provide a mechanism by which functional diversity is established for 5-HT₄ receptors.

MICE LACKING 5-HYDROXYTRYPTAMINE 1B RECEPTORS DISPLAY AGGRESSIVE BEHAVIOR. ¹R. Hen*, ²F. Saudou, ³D. Ait Amara, ⁴C. Belzung, ²A. Dierich, ²M. LeMeur, ¹S. Ramboz, ³L. Segu, ⁴R. Misslin, ³M.C. Buhot. ¹Center for Neurobiology and Behavior, Columbia University, 10032 New York, ²CNRS, INSERM, 11 rue Humann, 67085 Strasbourg, ³Lab. de Neurobiologie du CNRS, 13402 Marseille; ⁴Lab. de Psychophysiologie, U.L.P., 67000 Strasbourg.

The 5-HT_{1B} receptor, which is the rodent homologue of the human 5-HT_{1D β} receptor, has been suggested to be involved in a number of physiological states such as appetite, locomotor activity and aggressiveness, as well as in certain pathological states such as migraines.

In order to study the functions of the 5-HT_{1B} receptor in the mouse, we have generated by homologous recombination, mutant mice lacking the gene encoding the 5-HT_{1B} receptor. Such homozygous mutant mice develop, move, feed and breed apparently normally. When analyzed in a light-dark choice test and in an open field, the 5-HT_{1B}-minus mice displayed the same behavior as their wild type littermates, suggesting that this mutation does not affect base-line levels of locomotion and anxiety. However, the hyperlocomotor and anorectic effects of the 5-HT₁ agonist RU24969 (5mg/kg, i.p.) were absent in mice lacking the 5-HT_{1B} receptors.

In the resident-intruder aggression test where isolated test mice are faced with a wild-type intruder, the mutants attacked the intruder faster and more intensely than wild type mice. This increased aggressiveness of 5-HT_{1B}-minus mice might be related to the fact that a class of 5-HT₁ agonists termed serenics (eltopazine) have antiaggressive properties, and with the finding that certain impulsive aggressive behaviors are associated with deficits in central serotonin.

519.6

TARGETED DISRUPTION OF THE 5HT₂ RECEPTOR GENE RESULTS IN DEVELOPMENTAL ABNORMALITIES IN MICE. M. Toth*^{1,3}, T. Robinson², D. Benjamin³ and T. Shenk². ¹Dept. of Pharmacology, Cornell Univ. Med. Coll., New York, NY 10021; ²Dept. of Mol. Biol., Princeton University, NJ 08544; ³Center of Alcohol Studies, Rutgers Univ. Piscataway, NJ 08855.

Although 5HT is considered as a neurotransmitter, recent findings indicate that it is also a developmental and mitogenic signal. In order to study the developmental function of the receptor directly, we have disrupted the 5HT₂ receptor gene by homologous recombination in D3 embryonic stem (ES) cells. These ES cells express the 5HT₂ receptor, thus it was possible to determine the extent of receptor loss as the result of the gene knock-out. Interestingly, inactivation of one allele of the 5HT₂ receptor gene resulted in a more than 50% loss in receptor binding. In parallel, transcripts encoded by the intact receptor were also reduced more than twofold, upto 20% of the level measured in normal ES cells. In contrast, large amount of transcripts encoded by the truncated receptor allele was produced in the knock-out cells (8-10 fold of the expected 50% level). We speculate that the truncated mRNA is more stable than the intact receptor RNA, and the high steady state level of the truncated RNA may suppress the expression of the wild type allele, a phenomenon resembling to allelic exclusion. Alternatively, the receptor allele which remained intact in the knock-out cells may have been parentally imprinted. Presently, we are performing experiments to distinguish between these two possibilities. Suppression of the intact allele was observed not only in ES cells. Chimeras with high extent ES cell contribution displayed negligible receptor binding in tissues derived from ES cells demonstrating that suppression is maintained through development. Chimeras showed disturbances in postnatal development, probably as the result of low receptor expression. A reduction in weight gain was evident starting at postnatal day 5-10. Feeding was also reduced, particularly at the age of 3-5 weeks resulting in cachexy and eventually death.

CHARACTERIZATION OF HUMAN 5-HT₂ RECEPTOR GENE PROMOTER Q.S. Zhu*, K. Chen and J.C. Shih, Dept. Mol. Pharm. and Tox., Sch. of Pharmacy, Univ. of Southern California, 1985 Zonal Avenue, Los Angeles, CA 90033.

The 5' flanking sequence of human 5-HT₂ receptor gene has been characterized. Anchor PCR mapped multiple transcription initiation sites between nucleotide -1157 to -1127 in human brain and two cell lines SHSY-5Y (neuroblastoma) and HeLa (cervix carcinoma). Promoter activity was detected in a 0.35 kb HaeIII/BamHI fragment which encompasses these initiation sites in a transient transfection assay in the two cell lines. Sequence analysis revealed Sp1 and PEA3 binding sequences in this fragment. Gel retardation assay detected Sp1 and two other protein factors. DNaseI footprinting analysis detected a 30 bp protected region which contained a Sp1 binding sequence and a novel protein binding sequence, possibly for the new factor found in gel retardation assay. A 0.39 kb BamHI/PvuII fragment, 3' of the 0.35 kb fragment, exhibited the highest promoter activity. It contains a cyclic AMP response element (CRE)-like sequence, a PEA3 sequence and E-boxes. DNaseI footprinting assay found a protected E-box and a new protein binding sequence next to the CRE element. In addition, a transcription initiation site was found downstream of this fragment (at -496) in brain, suggesting that the 0.39 kb fragment could be an additional promoter. A 0.45 kb PvuII/Sma fragment, 3' of the 0.39 kb fragment, strongly down regulated the promoter activity. This new data is essential for further studying the regulation of 5-HT₂ receptor gene expression. A BRAIN-SPECIFIC PROTEIN THAT BINDS TO 5-HT_{1C} AND 5-HT₂ mRNA. H.T. Kao* and R.D. Ciaranello, Nancy Pritzker Laboratory of Molecular and Developmental Neurobiology, Stanford University Medical Center, Stanford, CA 94305.

The 5-HT_{1C} and 5-HT₂ receptors are members of the serotonin 5-HT₂ family of receptors, sharing similar pharmacology, signal transduction pathways, and sequence homology. The RNAs for both receptors contain untranslated regions more than twice the length of the coding region, suggesting that post-transcriptional regulation may be an important mechanism for regulating these receptors.

Many post-transcriptional processes, such as the control of RNA stability or translation, are exerted by the action of RNA binding proteins. We thus began our investigations by searching for brain proteins that bind to RNAs encoding 5-HT_{1C} and 5-HT₂ receptors.

We observed several proteins capable of binding to both 5-HT_{1C} and 5-HT₂ receptor RNAs, when binding was detected by crosslinking radioactive RNA to rat brain cortical extracts. Most of the binding is confined to the 3' UTR and coding region of the RNA. Of all these proteins, we have focused on one, a 60 kd protein, that binds in a sequence-dependent manner and recognizes AU rich domains. 5-HT_{1C} RNA sequences can compete against binding of this protein from 5-HT₂ RNA, suggesting that the same protein is capable of binding to both RNAs. Kinetic studies also suggest that the affinity of the interaction is high (K_d = 3 nM).

The 60 kd protein is expressed specifically in the central nervous system, with highest levels in the cortex and hippocampus. The protein is also expressed in a cell line of neuroectodermal origin, Neuro2A cells. We hypothesize that this protein is an important post-transcriptional regulator of a class of brain RNAs, including RNAs encoding neurotransmitter receptors. The Neuro2A cell line will facilitate studies aimed at examining the function of this protein.

519.11

MOLECULAR REQUIREMENTS FOR HALLUCINOGEN ACTIONS AT 5-HT_{2A} RECEPTORS. BL Roth*, A. Uluer and MS Choudhary, Department of Psychiatry, Case Western Reserve University School of Medicine, Cleveland, OH 44106.

There is now considerable evidence that 5-HT_{2A} receptors are a major site of action for hallucinogens in the central nervous system. We investigated the molecular details responsible for hallucinogen-induced regulation of 5-HT_{2A} receptor distribution and activity using native and mutant 5-HT_{2A} receptors. Chronic (14 hr) DOI exposure (10 µM) caused a desensitization of 5-HT and quipazine stimulated phosphoinositide (PI) hydrolysis. Chronic exposure to DOI (1-10 µM) also induced a redistribution of immunolabeled 5-HT_{2A} receptors to intracellular organelles; this change in subcellular receptor distribution was abolished by the 5-HT_{2A} antagonist clozapine. By contrast, overnight exposure to clozapine alone shifted the overall distribution of immunolabel to the cell surface with minimal intracellular staining evident; an apparent decrease in cell surface staining was also evident after clozapine treatment. Point mutations (F340L, F340A) greatly diminished the affinities of several phenethylamine and tryptamine hallucinogens at the 5-HT_{2A} receptor, but did not alter the intrinsic efficacy of the phenethylamine hallucinogens DOI and DOB. Despite DOI's ability to maximally activate PI hydrolysis (>20-fold), DOI was unable to induce down-regulation of [³H]-ketanserin binding sites or to desensitize PI hydrolysis after chronic exposure in cells expressing the F340L mutation. These results suggest that DOI causes an intracellular redistribution of 5-HT_{2A} receptors and that desensitization of 5-HT_{2A} receptor activity after long-term agonist exposure occurs via a process independent of second messenger production.

519.8

TRANSCRIPTIONAL CONTROL OF THE SEROTONIN-2 RECEPTOR GENE. S.J. Garlow*, R.D. Ciaranello, Dept. of Psychiatry and Beh. Sci., Stanford Univ Med Ctr, Stanford, CA 94305.

Analysis of the DNA sequence in the promoter region of the rat serotonin-2 (5-HT₂) receptor gene reveals a variety of consensus and near consensus response elements for known transcription factors. There are potential response elements for NF-1, AP-1, AP-2, SP-1, EGR-1, and two very degenerate versions of the glucocorticoid response element (GRE). We have been testing the functionality of these elements in a co-transfection assay system. In this system a promoter-reporter plasmid, with the 5-HT₂ promoter driving the firefly luciferase gene, is transfected into cells along with the cDNA for the particular transcription factor carried on the CMV5 expression vector.

There are three potential EGR-1 sites in the 5-HT₂ promoter, which overlap the major site of transcription initiation. The effect of EGR-1 on the 5-HT₂ promoter has been tested in three different cell lines including CCL-39, A7r5, and Neuro2A. In all three cell types the EGR-1 factor seems to inhibit transcription from the 5-HT₂ promoter.

There are four potential AP-1 sites in the 5-HT₂ promoter, with two located 5' to the site of transcription initiation, and two located 3' to the site of transcription initiation. The AP-1 complex is introduced into the cells by transfecting in equal amounts of the Fos and Jun cDNAs on the CMV5 expression vector. The AP-1 factor seems to have a cell specific effect on transcription of the 5-HT₂ promoter. In the CCL-39 cell line, the AP-1 factor inhibits expression from the 5-HT₂ promoter. In the Neuro2A line, the AP-1 factor stimulates expression from the 5-HT₂ promoter.

The potential GREs have been tested in two different paradigms. In the first, the cDNA for the GR is co-transfected into CCL-39 cells along with the luciferase reporter plasmid, then challenged with dexamethasone. In the second paradigm, the luciferase reporter plasmids are transfected into RS-1 cells which are a steroid responsive sub-line of PC12 cells, then challenged with dexamethasone. In both paradigms, there is a dexamethasone mediated inhibition of expression of the 5-HT₂ promoter.

519.10

STRUCTURAL AND MECHANISTIC BASIS OF ALLOSTERIC REGULATION IN THE 5-HT₂ RECEPTOR. H. Weinstein, D. Zhang and B.J. Ebersole*, Mount Sinai School of Medicine, NY, NY 10029

A structural model of the 5-HT₂ receptor we described recently [J. Med. Chem. 36:934, 1993] was used to explore the mechanism of allosteric regulation of G-protein coupled receptors (GPCRs) by cations. Ligand binding and effector coupling had been shown to be subject to such regulation. Mutations in α₂-adrenergic and dopamine-D₂ receptors have implicated a conserved Asp in transmembrane helix (TMH) 2 in this process, but the mechanism remained unclear. The 5HT₂ receptor model in which we studied the mechanistic relation between the TMH2-Asp and the ligand binding site, had been shown to be similar to the structure of rhodopsin, and to behave in computational simulations of ligand binding in a manner consistent with the known pharmacological properties of the ligands. In this model, the conserved Asp98 in TMH2 (TMH2:Asp98) directly interacts with two other conserved residues TMH7:Tyr380 and TMH7:Asn376 which, in turn, create with TMH7:Ser372 a hydrogen-bond network connecting TMH2:Asp98 to the ligand binding pocket. Structural insights from the model, amplified by mechanistic conclusions from the computational simulation of receptor activation by agonist binding, led to a hypothesis for the mechanism of allosteric regulation, and to a quantitative assessment of the interaction between various ligands and the 5-HT₂ receptor model. A significant correlation emerged between the experimentally determined ligand affinities and computed interaction energy terms. The nature of this correlation connects ligand binding to the conformational changes induced in the 5HT₂ receptor, and suggest specific interactions between TMH2 and other TMHs involved in the allosteric regulations. Supported by NIH DA-06620 and DA-00060.

519.12

ACTIVATION OF TWO DISTINCT CLASSES OF PROTEIN KINASE REGULATES EXPRESSION OF 5-HT_{2A} RECEPTOR mRNA IN P11 CELLS. R. C. Ferry*, L. Cass, and P. B. Molinoff, Dept. of Pharmacology, University of Pennsylvania School of Medicine, Philadelphia, PA 19104-6084.

Exposure of P11 cells to 5-HT leads to down-regulation of 5-HT_{2A} receptors and to a transient increase in levels of mRNA encoding the receptors. The increase in receptor mRNA appears to represent a counter-regulatory mechanism since the increase was associated with attenuation of agonist-induced receptor down-regulation and acceleration of receptor recovery following chemical inactivation of receptors with N-ethoxycarbonyl-2-ethoxy-1,2-dihydroquinoline (EEDQ). The roles of protein kinase C (PKC) and tyrosine kinase(s) (TK) in regulating levels of 5-HT_{2A} receptor mRNA were investigated. Exposure of P11 cells to 5-HT (10 µM; 90 min) or phorbol 12-myristate 13-acetate (PMA; 100 nM; 105 min), an activator of PKC, caused a two-fold increase in receptor mRNA levels. Preincubation with 100 nM PMA for 24 h, which down-regulated PKC activity, or with the selective PKC inhibitor bisindolylmaleimide (5 µM; 15 min) antagonized the effects of both 5-HT and PMA. These findings suggest that activation of PKC is sufficient to increase levels of 5-HT_{2A} receptor mRNA and indicate that the effects of 5-HT on receptor mRNA levels require activation of PKC. Exposure of P11 cells to genistein (150 µM; 15 min), a nonselective inhibitor of cellular TK, prevented 5-HT and PMA from increasing receptor mRNA levels, whereas the inactive analog daidzein (150 µM; 15 min) did not. The cell membrane-impermeable TK inhibitor lavendustin A (10 µM; 15 min) had no effect on basal, 5-HT-, or PMA-stimulated increases in receptor mRNA levels. The finding that genistein specifically blocked 5-HT- as well as PMA-induced increases in receptor mRNA indicates that 1) a TK lies downstream from PKC in the transduction pathway that regulates 5-HT_{2A} receptor mRNA expression, and/or 2) PKC- and TK-dependent phosphorylation of a common intermediate protein is required to increase receptor mRNA levels. Incubation with the tyrosine phosphatase inhibitor orthovanadate (1 mM; 15 min) prior to exposure to 5-HT prolonged the time that receptor mRNA levels were elevated. Collectively, these data suggest that activation of PKC and modulation of cellular phosphotyrosine levels are involved in regulating levels of 5-HT_{2A} receptor mRNA in P11 cells. (Supported by USPHS grants MH 48125 and NS 18591.)

519.13

EXPRESSION OF 5-HT₂ RECEPTOR IMMUNOREACTIVITY ON GABA-ERGIC INTERNEURONS IN RAT CORTEX. D. A. Morlak*, R. Lujan-Miras, P. Somogyi and R. D. Ciaranello, Nancy Pritzker Lab, Dept. Psychiatry, Stanford Univ., Stanford, CA 94305 and MRC Anatomical Neuropharmacology Unit, Oxford University, Mansfield Road, Oxford OX1 3TH, UK

We have previously demonstrated 5-HT₂ receptor immunoreactivity in the rat brain using a polyclonal antibody raised against the rat 5-HT₂ receptor. The distribution and morphology of labelled neurons in cortex, hippocampus, basal forebrain and other regions led us to speculate that they may be GABAergic interneurons. In the present study, we addressed this question using *in situ* hybridization histochemistry for GAD67 mRNA, and post-embedding immunocytochemistry for GABA. We observed a substantial overlap in distribution of neurons expressing GAD67 mRNA and 5-HT₂ immunoreactivity. This correlated distribution was seen in cortex, hippocampus and basal forebrain, supporting the hypothesis that 5-HT₂ expressing cells in these regions synthesize GABA. To test this hypothesis directly, we employed a double-immunoperoxidase approach. Animals were perfused with 4% para-formaldehyde/0.1% glutaraldehyde. This fixation protocol represented a compromise between the requirement for glutaraldehyde for GABA processing, and the sensitivity of 5-HT₂ immunoreactivity to over-fixation. Following 5-HT₂ immunoprocessing on 50 µm sections, serial 0.5 µm semithin sections were cut through identified 5-HT₂-positive cells in cortex, and subjected to post-embedding GABA immunoprocessing. Even though the fixation protocol resulted in a severely attenuated GABA labelling, we still observed a small number of double-labelled, 5-HT₂ positive GABAergic interneurons. From these data, together with the distribution and morphology of 5-HT₂ positive cells, we conclude that 5-HT₂ expressing neurons in cortex, and perhaps also in hippocampus and other forebrain regions, represent subpopulations of GABAergic interneurons.

REGENERATION

520.1

NEURONAL REGENERATION IN HOLOTHURIA GLABERRIMA J. E. García-Arrarás*, J. Torres, E. Arroyo, W. Cruz, L. Jiménez, L. Estrada, K. Rivera and L. Díaz-Miranda, Biology Dept., Univ. of Puerto Rico, Río Piedras, P.R. 00931.

Among higher metazoans, echinoderms exhibit the most impressive capacity for regeneration. Holothurians, or sea cucumbers, respond to adverse stimuli by autotomizing and spewing out their visceral organs which are then replaced by a regeneration process. Neuronal fibers and cell bodies are known to be present within the viscera, however, previous regeneration studies do not account for the nervous component. We have used immunocytochemistry at the light microscope level (antibodies to acetylated α -tubulin, to the neuropeptides GFS, galanin and CCK and novel monoclonal antibodies) and the electron microscope to describe the enteric nervous system of holothurians. We show here, that the enteric nervous system of the sea cucumber, *Holothuria glaberrima*, regenerates following evisceration and in 3-5 weeks is virtually identical to that of non-eviscerated animals. The regeneration of the enteric nervous system occurs parallel to the regeneration of other organ components, fibers are observed prior to the formation of the mucosal layer and the first neurons appear shortly after. The regeneration of the nervous system commands high interest in view that members of the closely related phylum, Chordata, either lack or have a very limited capacity to regenerate their nervous system. Thus, holothurians provide a model system to study nervous system regeneration in deuterostomes. [Supported by grants from EPSCoR, the Whitehall Foundation, and the University of Puerto Rico.]

DIRECT INVOLVEMENT OF p53 IN PROGRAMMED CELL DEATH OF OLIGODENDROCYTES. O. Eizenberg, A. Faber-Elman, E. Gottlieb, M. Oren, V. Rotter, V. Lavie* and M. Schwartz, Department of Neurobiology, Weizmann Institute of Science, 76100 Rehovot, Israel.

Recent studies have shown that dimeric interleukin 2 produced enzymatically *in vitro* by nerve-derived transglutaminase is cytotoxic *in vitro* to mature oligodendrocytes, known to inhibit axonal growth. The cytotoxic effect operates via apoptosis. Cells showed commitment to apoptosis after 3-4 h of treatment with dimeric interleukin 2. This interval could reflect a necessary rate limiting process of activation or suppression of specific genes, or modification of specific regulatory proteins. A protein that appears to act as a positive regulator of apoptotic cell death in a number of cell types is the p53 tumor-suppressor gene product. The aim of the present study was to determine whether p53 is involved in the death of mature rat brain oligodendrocytes in response to dimeric interleukin 2. We demonstrate here that the dimeric interleukin 2 induces in oligodendrocytes translocation of endogenous wild-type p53 from the cytoplasm to the nucleus, as early as 15 min after exposure. Moreover, oligodendrocytes infected with a retroviral vector encoding a p53 miniprotein expressing the dimerization site of p53 and by that acts as a negative dominant inhibitor of endogenous wild-type p53 activity, are effectively protected from apoptosis induced by dimeric interleukin 2. These findings led to the conclusion that p53 is directly involved in the apoptotic mechanism induced by dimeric interleukin 2.

STIMULATION OF REGENERATIVE SPROUTING ENHANCES PREFERENTIAL MOTOR REINNERVATION (PMR)

T.M. Brushart*, Depts of Orthopaedics and Neurology, Johns Hopkins Hosp., Baltimore Maryland 21287

Motor axons regenerating after transection of mixed nerve preferentially reinnervate distal motor branches. Collaterals of a single motor axon often enter both sensory and motor Schwann cells of the distal stump; specificity is generated by pruning collaterals from sensory pathways while maintaining those in motor pathways (J. NSci. 13:2730). Stimulation of collateral formation should therefore allow increased pathway sampling and greater regeneration specificity. Experiments were performed on the proximal femoral nerves of 250gm female SD rats. Forty nerves were sharply transected and sutured; 40 others were crushed with jewellers forceps proximal to the repair site both 2 and 4 weeks before suture to stimulate collateral sprouting. Twenty nerves in each group were evaluated at 3 weeks, and 20 at 3 mos., by applying HRP to one terminal branch and Fluoro Gold to the other. The mean number of motoneurons projecting axons into the femoral sensory and motor branches at 3 weeks was similar after routine suture (M=149, S=170), but was significantly different after crush/crush/suture (M=244, S=103, p=.001). Specificity was apparent 3 mos after routine suture (M=242, S=130, p=.001), but was greatly augmented 3 mos after crush/crush/suture (M=263, S=81, p=.001). The number of motoneurons projecting collaterals to both branches at 3 wks, the substrate for specificity generation by collateral pruning, was significantly greater after crush/crush/repair (72 vs 53, p=.01). Nerve crush before suture thus increases the number of motoneurons projecting collaterals to both sensory and motor branches, and also results in substantial augmentation of PMR. This finding mandates a search for non-invasive techniques of stimulating collateral sprouting to enhance regeneration specificity.

THE EFFECTS OF MACROPHAGES ON PERIPHERAL NERVE REGENERATION IN NERVE GRAFTS IN THE ABSENCE OF LAMININ, FIBRONECTIN OR COLLAGEN IV. G. Wang, Y. Xin*, Y. Hu, J. Qin, S. Zhong and K. Hirai, Dept. of Anatomy, First Military Med. University, Guangzhou, China, Ctr. for Neurobiology and Behavior, Columbia University, 722 W. 168 St. New York, NY 10032 and Dept. of Anatomy, Kanazawa Medical University, Ishikawa, 920-02, Japan.

We previously studied the effects of laminin (LN), fibronectin (FN) and collagen IV (Col.IV) on peripheral nerve regeneration. To investigate the effects of macrophages (MPHs) on peripheral nerve regeneration in the absence of LN, FN or Col.IV, nerve transplantation experiments were done by using 151 male adult Wistar rats. Donor sciatic nerve grafts (N=98) were obtained from 49 rats and denatured by repetitive freezing and thawing. After treatment with anti-rat LN (N=24), FN (N=20), Col.IV (N=30) serum or control serum (N=24), the nerve grafts were implanted into the recipient rats to bridge sectioned sciatic nerves. The grafts were excised and examined under light and electron-microscope at different postoperative days. The results showed that MPHs were recruited from blood and appeared earlier than Schwann cells. The number of MPHs in the anti-FN, anti-Col.IV and control groups increased sharply from postoperative day 2 and peaked at day 7, then quickly decreased. In the anti-LN group, increase of MPHs was delayed to postoperative day 7, peaking at day 10. The number of MPHs then decreased slowly. Rate of axon growth and myelination was fast in the control group, followed in turn by anti-Col.IV, anti-FN and anti-LN groups. Our results indicate that in the early stage of nerve regeneration, increased MPHs eliminate degenerated tissues effectively and thereby promote nerve regeneration. In the absence of LN, however, both increase and decrease of MPHs are delayed, resulting in delayed axon growth and myelination.

CREATION OF A NEURON INHIBITORY ENVIRONMENT MEDIATED BY A SPECIFIC ASTROCYTIC PROTEOGLYCAN. DR. Canning*, A. Hoke & J. Silver. Dept of Neurosciences, Case Western Reserve University, 10900 Euclid Ave., Cleveland, OH 44106-4975.

CNS astrocytes normally support the growth and maintenance of axons. One aspect of this tropic behavior is the supplying of favorable substrates which allow axons to grow on their surfaces and the extracellular matrix. We have recently discovered an *in vitro* method of converting the behavior of astrocytes from supplying neuronal growth promotory environments into those which are inhibitory. This change in behavior can be activated by exposure of the astrocytes to small peptide sequences of the beta-amyloid protein in an insoluble form. This activation results in the localized deposition of a matrix containing chondroitin sulfate, similar to that seen at sites of reactive gliosis after trauma *in vivo*.

Amongst the various proteoglycans manufactured by astrocytes, we have found that the experimentally induced inhibitory environment is mediated by the upregulation and deposition of a specific chondroitin/heparan sulfate proteoglycan. This proteoglycan has properties inhibitory to axonal outgrowth when combined with other molecules of the extracellular matrix. These inhibitory properties can be experimentally reversed by removal of chondroitin sulfate glycosaminoglycans from the matrix created by activated astrocytes, but not by enzymatic removal of other glycosaminoglycans. Affinity purification of this proteoglycan has revealed that it is lightly glycosylated and carries the carbohydrate epitopes 7D4, CS-56 and 3B3. Data from molecular weight estimations, preliminary peptide analysis and amino acid composition determinations suggest that this may be a novel proteoglycan to the CNS, which is upregulated in areas of reactive gliosis.

SHORT- AND LONG-TERM DEGENERATIVE CHANGES IN PERIPHERAL NERVE AND THEIR ABILITY TO SUPPORT AXONAL REGENERATION. A. K. Gulati* Department of Cellular Biology and Anatomy, Medical College of Georgia, Augusta, GA 30912.

The present study was designed to define acute and chronic changes in peripheral nerve undergoing *in situ* degeneration and their ability to support axonal regeneration after transplantation. Peripheral nerves were degenerated *in situ* for a period of 2, 4, 8 and 48 weeks for analysis and transplantation in a surgically created gap of the host rat peroneal nerve. During early phase of degeneration the injured axons and associated myelin is broken down and absorbed by proliferating Schwann cells and infiltrating macrophages. The Schwann cell basal laminae persisted throughout degeneration, however were progressively reduced in size and at 12 months were occluded. Such long-term degenerated nerves were reduced in diameter as compared to short-term degenerated nerves (2 and 4 weeks) that exhibited increased diameter. In order to study axonal regeneration through predamaged nerves, 2 cm long segment was transplanted in host rats. Grafts and distal host nerves were analyzed to determine axonal regeneration. Axonal regeneration was rapid and by 12-weeks many myelinated axons were observed in distal nerve with establishment of innervation of target muscle. Although many regenerated axons were observed in the 48-week degenerated transplant group, the nerves remained small in diameter and the axons were thinly myelinated. In addition buildup of connective tissue was observed in such grafts. The results show that, short-term degeneration is beneficial as compared to long-term degeneration in supporting axonal regeneration (supported by NIH grant NS-24834).

RECOVERY FROM SPINAL CORD INJURY IN NEONATAL S.AMERICAN OPOSSUMS. N.R. Saunders, L.Weller*, A. Deal and G.W. Knott. Depts of Physiology & Anatomy, University of Tasmania, GPO Box 252C, Hobart, Tasmania 7001.

Recovery from spinal cord crush has been studied in neonatal (P5-7) and postnatal (P14-20) S.American opossums (*Monodelphis domestica*). Mothers were anaesthetized with intraperitoneal pentobarbitone; the young, still attached to the mother received additional inhaled Metofane anaesthesia. Spinal cords were crushed at the upper thoracic level via a skin incision using fine forceps. Completeness of the lesion was assessed by application of a minor nociceptive stimulus to the hind limbs below the lesion both at the time of lesion and on the day following; absence of a forelimb response was taken as indicating a complete lesion. Control littermates were unoperated. Video recordings were made of operated and control animals at different intervals after surgery up to and beyond weaning (P60). Spinal cords were removed under terminal anaesthesia at different times after operation and in controls. Conduction across the crush was tested *in vitro* by electrical stimulation of the central end of the cord and recording caudally. In 12 neonates the spinal cord was isolated 24-48h after crushing. Ten out of 12 showed complete block of conduction. In the other 2 the amplitude of the mass action potential was less than 1% of controls. Conduction across the crush by recovered 5 to 10 days post crushing (n=14). Bouin's fixed spinal cords were examined morphologically using silver staining and examination of thick (30-50µm) sections using an Edge Scientific Stereomicroscope. Complete crush at P5-7 was followed by fibre growth across the crush by 5 to 10 days after operation. Substantially normal locomotor function was present towards the time of weaning (P50-60). In neonates operated at P14-20 recovery of conduction did not occur.

ESTABLISHMENT OF A NEURON-GLIAL CO-CULTURE SYSTEM IN CHEMICALLY DEFINED MEDIUM; A TOOL FOR STUDIES ON CNS REGENERATION. C. Johansson, K. Fried, M. Risling, S. Cullheim*, and J. Frisén. Department of Neuroscience, Karolinska Institutet, S-171 77 Stockholm, Sweden.

The lack of axonal regrowth after injury in the brain and spinal cord is not primarily a result of weak intrinsic neuronal regenerative capacity. Rather, it is a result of an unfavourable environment for neurite extension in the CNS. It is known that astrocytes as well as oligodendrocytes may inhibit axon growth. CNS glial cells are however known to support axonal growth and guidance during embryogenesis. Moreover, after CNS injury, reactive glial cells can support axonal sprouting in the lesion area. This demonstrates that CNS glial cells can support axonal growth in the adult under certain circumstances. If the signals which induce a switch in glial phenotype to one which supports axonal growth were known, strategies to induce such properties *in vivo* after nervous system injury could be developed. In order to search for factors which may determine glial phenotype, we have developed an assay to measure the effect of different molecules on the ability of astrocytes to support neurite growth.

Mixed glial cultures were obtained from new-born rat brain and grown in DMEM with 10% fetal calf serum. Pure astrocytes were isolated by shaking confluent cultures. Sensory neurons were prepared from new-born rat dorsal root ganglia. The astrocyte medium was changed to L15 with essential supplements 0, 1, 3, 5, 7, 9, or 11 days before the neurons were plated on astrocyte monolayers. Serum-free medium may provide an environment which is close to physiological, since astrocytes *in vivo* are separated from serum by the blood-brain barrier. A vast number of neurons adhered and grew elaborate neurites on astrocytes which had been in serum containing medium short before the neurons were plated. In contrast, significantly less neurons attached to astrocyte cultures which had been grown for longer time in serum-free medium, and many of the neurons had no or only very short processes.

The data show that serum can induce axon-growth permissive features in astrocytes. Since astrocytes give poor support for adhesion and neurite out-growth under serum-free conditions, the co-culture system presented here can be used to assay the capacity of different molecules to induce an axon-growth promoting astrocytic phenotype.

INJURY INDUCED PROTEOGLYCANS INHIBIT THE POTENTIAL FOR LAMININ MEDIATED AXON GROWTH THROUGH AN ASTROCYTIC SCAR. Robert J. McKeon*, Ahmet Hoke, and Jerry Silver. Department of Neurosciences, Case Western Reserve University, Cleveland, OH 44106.

Following injury to the adult CNS, a number of extracellular matrix molecules are upregulated in areas of glial scarring. These molecules include laminin and a chondroitin sulfate proteoglycan (CS-PG) which, when used individually as substrates in *in vitro* assays, can promote or inhibit neurite outgrowth, respectively. We have hypothesized that the balance of the expression of these molecules ultimately determines the potential for neuronal regeneration *in vivo*. In order to test this hypothesis, we have begun to characterize the expression of CS-PG's after cortical injury. Using Western analysis, we have identified a 3B3-positive CS-PG with an apparent molecular weight of 180-400 kd that is specifically upregulated in gliotic tissue after injury to adult, but not neonatal animals. This CS-PG inhibits the ability of astrocyte produced laminin to promote neurite outgrowth. Following digestion with chondroitinase ABC, neurite outgrowth on glial scars formed *in vivo* on nitrocellulose implants is significantly increased. However, treatment of chondroitinase treated glial scars with antibodies to the B1,B2 chains of laminin dramatically reduces neurite outgrowth compared to tissue treated with chondroitinase alone. These data suggest that the timing and relative amount of different ECM molecules produced by reactive astrocytes is a critical factor in determining the amount of axonal outgrowth which takes place after CNS injury. Experiments designed to purify, and further characterize this injury induced CS-PG, and analyze the mechanism of its interaction with laminin are currently in progress. Supported by a grant from the Paralyzed Veterans of America Spinal Cord Research Foundation and NS 25713.

CORRELATION OF THE FINE STRUCTURE OF LESIONS WITH NEURAL REPAIR IN ISOLATED SPINAL CORDS OF NEONATAL OPOSSUMS AGED 5 DAYS AND 12 DAYS. Z.Varga, J.Fernandez and J. Nicholls*, Biozentrum, Univ. of Basel, Basel Switzerland, 4056.

Profuse outgrowth of neurites has been shown to occur into and beyond the site of a crush in the spinal cord isolated from a 5 day old opossum. We have now analyzed repair at various stages after injury, by light and electron microscopy. During the first 1-3 days, the site of the lesion as well as rostral and caudal segments were totally disrupted, containing no identifiable elements. After 5 days in culture axons and growth cones unaccompanied by glia entered the lesion. Growth occurred along the basal lamina of the pia mater on which synaptoid structures were made. By contrast in lesioned spinal cords in culture isolated from older animals aged 12 days, no repair occurred. The lesion produced by a crush was restricted in its length to the actual site of damage and involved neighboring segments to a lesser extent. Axons and growth cones approached the edge of the crush but did not grow through it. Antibodies against glial fibrillary acidic protein labeled material in these lesions of cords from 12 day old animals which contained only debris and no astrocytes or oligodendrocytes. Our results confirm the existence of a critical period for repair in the neonatal opossum. As yet, no cellular or molecular component has emerged as being responsible on its own for the failure of repair in older animals.

PATTERNS OF NEURITE OUTGROWTH ACROSS TRANSECTED SPINAL CORD OF NEONATAL OPOSSUM IN CULTURE
H.A. Vischer¹, Biozentrum, Univ. of Basel, Switzerland

Profuse neurite outgrowth occurs across a lesion made by a crush in the isolated spinal cord of neonatal opossum. Such lesions break axons while the pia mater remains intact (Woodward et al., J. exp. Biol., 1993, 176: 77-88). In this study entire central nervous systems (CNS) of 3-6 day old animals were placed into sylgard molds and completely transected at C5-C7 levels. The two parts were tightly fit together and held in place by Matrigel. To visualize growing fibers, the rostral parts of the preparations were labeled with the lipophilic marker Dil and incubated for up to 6 days in BME. In 27 out of 35 preparations, fibers in the ventrolateral segment of spinal cords grew up to 500 µm beyond the cut. To determine whether the local environment might influence axonal pathfinding, the spinal cord were cut and the caudal parts were rotated by 180°. In 13 out of 17 experiments ventrolateral fibers turned rostrally on the site of the cut. In 4 out of those 13 experiments fibers grew across the cut into the caudal part at its organotypic ventral segment and thus entered the "correct" area of the spinal cord. This behavior suggests that they use local cues for guidance. We now are using molecular biological approaches to learn more about the nature, distribution and temporal expression of factors that might be involved in axonal guidance.

EVIDENCE FOR GROWTH OF SUPRASPINAL AXONS THROUGH HEMISECTED AND TRANSECTED SPINAL CORD IN THE DEVELOPING OPOSSUM, DIDELPHIS VIRGINIANA. G.F. Martin¹, J.R. Terman and X.M. Wang, Depart. Cell Biology, Neurobiology and Anatomy, The Ohio State Univ. Coll. of Med., Columbus, Ohio 43210.

We have shown previously that at least some supraspinal axons grow around a hemisection of the thoracic cord in developing opossums and that a critical period exists for that plasticity. In such experiments, normal spinal cord was left and axons used it to circumvent the lesion. More recently, we hemisected the thoracic cord at earlier stages of development (postnatal day 5). When the animals were sacrificed as adults, normal-appearing spinal cord was present at the lesion site and orthograde transport methods showed that brainstem axons grew through the lesion, not around it. In a second series of animals operated at the same age, the spinal cord was transected at the same level and approximately 30 days later, Fast Blue was injected several segments caudal to the lesion. In such cases, relatively normal appearing spinal cord was present at the lesion site and supraspinal neurons were labeled in all of the areas expected from controls. Our results suggest that the mammalian spinal cord regenerates after lesions at early stages of development and that descending spinal axons grow through the lesion site to more caudal levels. (Supported by NS-25095 and 10165).

COGNITION: HUMAN I

HUMAN OSCILLATORY BRAIN ACTIVITY NEAR 40-HZ COVARIES WITH COGNITIVE TEMPORAL BINDING.

M. Joliot¹, U. Ribary² and R. Llinás. Center for Neuromagnetism, Dept. of Physiology and Biophysics, New York University Medical Center, New York, N.Y. 10016, USA, ¹SHFJ, DRIPP-CEA, Orsay, France.

The minimal time interval required to identify auditory stimuli as separate was correlated with the reset of the 40-Hz magnetic signal in the human brain, in order to test the hypothesis that 40-Hz activity may relate to temporal binding by the C.N.S.

Neuromagnetic recordings of coherent oscillatory activity near 40-Hz were obtained over auditory areas of the right hemisphere from nine healthy adults, using a 37-channel Magnetoencephalography (MEG) system (BTi). Subjects attended to auditory stimuli organized in ten blocks consisting of one or two clicks (10 kHz, 60dB SPL) presented binaurally at varying interstimulus intervals (3, 6, 9, 12, 15, 18, 24 or 30 ms). 1000 epochs were recorded for each block with inter-pair intervals of 130 ± 10 ms, the transient responses were averaged and filtered between 20-50 Hz. The average response to a single stimulus consisted of a 2.5 oscillatory cycle 40-Hz response. A set of two stimuli were then presented and the perceptual threshold for identifying the stimuli as two events was established. Experimental and modeling results indicate a stimulus-interval dependent response with a critical time interval of 12-15 ms. At shorter intervals, at which the subjects reported the perception of only one auditory event, only one 40-Hz response was observed. As the interval increased a second 40-Hz wave appeared, abruptly. This second 40-Hz correlated significantly with the recognition by the subjects that two distinct auditory stimuli had been delivered.

These results indicate that oscillatory activity near 40-Hz represents a neurophysiological correlate to auditory temporal processing. It also supports the view that 40-Hz activity relates not only to primary sensory processing, but also to the temporal binding underlying cognition.

521.3

ELECTROPHYSIOLOGICAL AND BEHAVIORAL SIGNS OF HEMISPHERIC ASYMMETRIES OF ATTENTION IN A "SPLIT-BRAIN" PATIENT. A. M. Proverbio¹, A. Zani², G. R. Mangun¹, M. S. Gazzaniga¹. ¹Center for Neuroscience, University of California, Davis, CA 95616, ²Istituto di Psicologia del CNR, 00137 Rome, Italy.

Neuropsychological data have shown that the two cerebral hemispheres differ in the control of spatial attention. The present study investigated hemispheric asymmetries and visuomotor integration in a patient who has undergone complete resection of the corpus callosum, thereby disconnecting the cerebral hemispheres at the cortical level. Simple reaction times (RTs) and Event-related potentials (ERPs) were recorded to lateralized visual stimuli in the patient J.W. and in an age-matched normal control subject (both right-handed). The ERPs were recorded from 61 scalp sites referred to a balanced non-cephalic sterno-vertebral reference. The subject's eyes were monitored by means of an infrared video-camera and horizontal and vertical electro-oculogram. Stimuli were randomly presented at 6° and 10° of eccentricity to the left or right of a centrally located fixation point. The ISI varied between 1400 and 2800 msec. A response to all stimuli was required. The control subject showed no asymmetries in RTs or P3 amplitude. In contrast, in the split-brain patient RTs were 20 msec slower for more eccentric stimuli in the LVF, but no effect of eccentricity was evident for RVF stimuli. P3 amplitude measures showed that both hemispheres produced a strong response to RVF stimuli, while LVF stimuli elicited a much greater response over the contralateral, right hemisphere. The results support previous theories (e.g., Kinsbourne, 1987) proposing that the right hemisphere allocates attention broadly over left and right hemispace, while the left hemisphere is strongly biased toward the right.

521.2

EVENT-RELATED POTENTIAL CORRELATES OF WORKING MEMORY PROCESSES. I. Kiss¹, C. Pisio¹, A. Francois¹ & D. Schopflocke². ¹Toupin Psychophysiology Lab., Edmonton General Hospital, University of Alberta, Edmonton, AB, Canada T5K 0L4.

In an initial study of event-related potentials (ERPs) associated with operationally defined working memory processes, subjects viewed randomly arranged series of 2 to 5 single digits (fixed 1.5 sec inter-stimulus interval). Digit pairs were interposed between series. ERPs were recorded from the scalp (Fz, Cz, Pz, Oz). In the Control condition, subjects were instructed to detect digit pairs. The Update condition used the same stimuli and motor requirements but subjects were asked to indicate whether digit pairs matched the preceding two single digits. Success in the Update task requires retention of the first two single digits and their order of presentation. Beyond two, this representation must be successively "updated". ERPs to single digits in the Control condition were digitally subtracted from Update condition ERPs for corresponding serial positions, resulting in Difference waveforms for single digit positions 1 to 5. Subtraction was intended to remove perceptual, response-related and other processes common to the two conditions, thereby isolating the ERP's attributable to cognitive processes required for "updating". ERPs for positions 1 & 2 were relatively small and did not differ. A large positive potential was observed at position 3 which became significantly larger in the Difference traces for positions 4 and 5. These data are consistent with Baddeley's model of working memory, which postulates distinct mechanisms for short term information storage and on-line processing. Two supplementary studies support the ability of this novel ERP paradigm to distinguish between storage and processing, as well as processing types.

521.4

WORDS AND PSEUDOWORDS EVOKE DIFFERENT PATTERNS OF GAMMA-BAND (30 HZ) RESPONSES. F. Pulvermüller¹, C. Eulitz¹, H. Preißl¹, C. Pantev², W. Lutzenberger¹, T. Elbert¹ & N. Birbaumer¹. Department of Medical Psychology and Behavioral Neurobiology, University of Tübingen, 72074 Tübingen, Germany

Words and pronounceable pseudowords are physically similar, but invoke different cognitive processes. If gamma-band responses of the brain are related to cognitive processing, these stimuli may induce distinct patterns of gamma-band responses in humans. Words and pseudowords were presented in lexical decision and memory tasks. EEG and MEG signals were recorded from both hemispheres. Analysis of spectral responses around 30 Hz revealed differences between stimulus classes. Over the left, language-dominant hemisphere words evoked stronger 30 Hz responses compared to pseudowords. While word-evoked responses did not significantly deviate from the baseline, pseudowords elicited a reduction of spectral power.

A tentative explanation of this effect is the following: Word presentation invokes ignition of a cortical cell assembly corresponding to the word. The ignition process includes fast periodic and coordinated activation of large numbers of neurons which is visible in the EEG and MEG. After pseudoword presentation, a variety of assemblies are (pre-) activated leading to uncorrelated activity in numerous assemblies. This results in a reduction of spectral power in the EEG or MEG.

521.5

LOCALIZATION OF SPONTANEOUS OSCILLATORY CORTICAL ACTIVITY FROM MAGNETOENCEPHALOGRAPHIC DATA RECORDED DURING THE IMAGINATION OF MOVEMENT AND SILENT SPEECH. Claudia D. Tesche*, Mikko A. Uusitalo, and Matti J. Kajola. Low Temperature Laboratory, Helsinki University of Technology, 02150 Espoo, Finland. Risto J. Ilmoniemi BioMag Laboratory, Helsinki University Central Hospital, 00290 Helsinki, Finland

Does mental imagery in the absence of external stimuli alter the spectral characteristics of spontaneous oscillatory activity in humans? We measured spontaneous activity in six subjects with a 122-channel whole-scalp magnetoencephalographic (MEG) array. The subjects performed two contrasting tasks: the imagination of the self-performance of a motor activity and the silent generation of a chain of words. We developed a novel analysis method, frequency-domain signal-space projection (FDSSP), to compute components of ongoing spontaneous activity at specific cortical sites from this data. Although intersubject differences were significant, highly reproducible spectra of oscillatory activity were obtained within subjects in the primary somatomotor and parietal association areas which showed variability in the spectral features with task including variations in amplitude and, in some subjects, task-dependent changes in the frequency of sharply defined spectral peaks.

FDSSP analysis may also be applied to electroencephalographic (EEG) data. Objective evidence of the constancy of the state of a subject obtained from FDSSP may facilitate the interpretation of psychophysical measurements. FDSSP analysis of rhythmic EEG and/or MEG data recorded during epileptic activity and sleep may lead to the localization of sources of activity in specific neuronal populations.

521.7

DISCORDANCE FOR PLANUM TEMPORALE ASYMMETRY IN HANDEDNESS-DISCORDANT MONOZYGOTIC (MZ) TWINS. H. Steinmetz*, A. Herzog, G. Schlaug, Y. Huang and L. Jäncke†. Departments of Neurology and †General Psychology I, Heinrich-Heine-University, PO Box 101007, D-40001 Düsseldorf, F.R.G.

Studies comparing biological with adoptive families have shown that handedness is influenced by prenatal factors. It is unclear whether these factors are genetic or non-genetic. Using *in vivo* magnetic resonance (MR) morphometry we measured the degree of planum temporale (PT) asymmetry $\delta PT = (R-L)/[0.5(R+L)]$ in 20 MZ twin pairs concordant (10 right-handed pairs) or discordant (10 pairs) for handedness reporting no birth complication, neuropsychiatric illness, learning disability or failure in elementary school (3 MR observers blind for twins vs. 60 controls, and right vs. left hemisphere). As previously described for singletons, right-handed twins showed leftward PT asymmetry ($P < .05$) whereas the left-handed co-twins, as a group, lacked asymmetry ($P > .10$). Intraclass correlations were low ($R < .25$). This discordance for structural asymmetry can be accounted for by models assuming cleavage of an intrinsically asymmetric blastomere or differential action of other non-genetic factors within MZ twin pairs *in utero*. The findings confirm a coupling of lateralized brain structure and function. At least in MZ twins, early epigenetic factors must play a role in laterality development. [Support: DFG, H. & L. Schilling Foundation]

521.9

PET ACTIVATION IN ALZHEIMER'S DISEASE DEMONSTRATE THE ROLE OF LEFT ANGULAR GYRUS IN SEMANTIC MEMORY. M. Grossman*, E. Hughes, K. Onishi, N. Biassou, M. D'Esposito, K.M. Robinson, X.-S. Ding, A. Alavi, M. Reivich. Cognitive Neurology Section, University of Pennsylvania School of Medicine, Philadelphia, PA 19104

We sought to define the cognitive and physiologic basis for semantic memory. Cognitive assessments were used to characterize semantic memory deficits in patients with probable Alzheimer's disease (pAD) during comprehension and expression of words and pictures. An equilibrium technique used the constant infusion of ^{15}O -H $_2$ O to quantify regional cerebral blood flow (rCBF) in individual patients and controls during a semantic category membership recognition task (identifying exemplars of a familiar superordinate category). An individualized anatomic atlas based on each subject's MRI localized rCBF activation. Cognitive assessments revealed that several pAD patients had a supramodal semantic memory deficit. These patients demonstrated characteristic difficulty understanding and expressing word and picture information about a target concept that could not be attributed to a memory deficit or non-specific cognitive limitations. PET assessment revealed that individual control subjects consistently recruited left angular gyrus during the PET semantic challenge. By comparison, pAD patients failed to recruit left angular gyrus during a semantic challenge while PET monitored rCBF. Instead, pAD patients recruited right inferior parietal structures. pAD patients without supramodal semantic memory deficits were able to recruit left angular gyrus during a PET semantic challenge. We hypothesize that left angular gyrus contributes importantly to semantic memory by integrating information from multiple, material-specific and modality-specific sources.

521.6

THE EFFECTS OF BROMOCRIPTINE, A D-2 DOPAMINE RECEPTOR AGONIST, ON THE COGNITIVE ABILITIES OF HUMAN SUBJECTS WITH DIFFERENT WORKING MEMORY CAPACITIES. D. Y. Kimberg, M. D'Esposito and M. J. Farah*. Dept. of Psychology, Carnegie Mellon Univ., Pittsburgh, PA 15213; Depts. of Neurology and Psychology, Univ. of Pennsylvania, Philadelphia, PA 19104.

Recent research in monkeys and humans has suggested that the prefrontal cortex (PFC) subserves working memory (WM), and that dopamine plays an important role in the PFC WM system. In order to provide a new test of this hypothesis, and to investigate the role of dopamine and WM in a variety of cognitive tasks, we administered a battery of tasks to normal human subjects twice, on and off bromocriptine, a D2 dopamine receptor agonist, in a double blind procedure. The battery of tasks included: working memory tasks (spatial working memory, verbal working memory, and the fan effect paradigm), other tasks thought to depend on PFC (The Wisconsin Card Sorting Test, Stroop Task, a context memory task, and a dual task paradigm), and a control task (visual search) not hypothesized to depend on WM or PFC. Although there was no significant main effect of bromocriptine over all subjects, those with lower verbal WM capacity benefitted from the drug on both WM tasks and other PFC tasks and, more surprisingly, those with higher WM capacity were reliably impaired by it on these same tasks. No effects of bromocriptine were observed for the visual search control task. These results demonstrate a selective effect of bromocriptine on PFC tasks, which depends on subjects' WM capacity. Of course, the precise nature of the relations among individual differences in WM, PFC function and cognition remains to be understood. Nevertheless, these results strengthen the evidence for the role of dopamine in WM and PFC function, and also suggest a possible mode of therapy for PFC-related cognitive impairment.

PET STUDIES OF COGNITIVELY RELATED CEREBRAL BLOOD FLOW IN MENSTRUAL-RELATED MOOD DISORDER PATIENTS AND CONTROLS: EFFECTS OF GONADAL STEROIDS. K. F. Berman*, P.J. Schmidt, J.L. Ostrem, M.A. Danaceau, G. Esposito, J.D. Van Horn, D.R. Rubinow, D.R. Weinberger. NIMH/IRP, Clinical Brain Disorders and Biological Psychiatry Branches, Bethesda, MD 20892.

Despite inferential evidence from cognitive and other behavioral studies and from animal experiments, there is little direct information about the effects of hormones on human neurophysiology during cognition. We used the oxygen-15 water PET method to measure regional cerebral blood flow (rCBF) in four women with menstrual-related mood disorder (MRMD) and four controls during three pharmacological conditions: 1) ovarian suppression induced by gonadotropin releasing hormone agonist (Lupron), 2) Lupron plus estrogen (E), and 3) Lupron plus progesterone (P). During each drug condition subjects were scanned at rest and while performing the Wisconsin Card Sorting Test and a simple matching task. Absolute CBF (ml/min/100g) was determined pixel-by-pixel, and the three PET data sets were each registered to a single MRI scan on which regions were drawn.

Global CBF was lower in the patients than the controls during the resting Lupron baseline (45 vs. 55, $p = 0.04$) and tended to increase with P and decrease with E for the group as a whole. The region most affected by hormone treatment was the superior left anterior cingulate (ANOVA drug effect $F = 4$, $p < 0.05$), which was increased by P and decreased by E during the tasks despite unaltered performance scores. These data provide direct insight into the effects of gonadal steroids on brain function during cognition and may also suggest a neurophysiologic characteristic of patients with MRMD.

521.10

IMPAIRED RECOGNITION MEMORY IN AGING IS ASSOCIATED WITH REDUCED ACTIVATION OF HIPPOCAMPUS AND FRONTAL CORTEX. Cl. Grady*, AR McIntosh, B Horwitz, JG Ungerleider, P Pietrini, MI Mentis, JV Haxby. Lab. of Neuroscience, NIA, Lab. of Neuropsychology, NIMH, and Lab. of Psychology and Psychopathology, NIMH, Bethesda, MD 20892.

We measured rCBF in 10 young (25 ± 2 yrs) and 10 old (69 ± 6 yrs) healthy subjects using positron emission tomography and $[15-O]$ water during learning of and recognition memory for faces. Three tasks were carried out by all subjects in the following order: learning, face matching, and recognition. Old subjects performed significantly worse than young subjects during the recognition condition (66% v. 80% correct, $p < 0.001$). During learning, compared to face matching, young subjects showed increased rCBF ($p < 0.001$) in the right hippocampal region, left inferior frontal and medial frontal cortex. Old subjects did not show significant activation of the hippocampus during learning. They did show activation in left frontal cortex ($p < 0.001$), but in a location different from the one seen in young subjects. During recognition, compared to face matching, the young subjects had rCBF increases in right frontal and parietal cortex, and anterior cingulate ($p < 0.001$), and the old subjects had rCBF increases in right frontal cortex (again, in a different location). These results support earlier PET studies that found right frontal activation during recognition memory, and provide evidence for the role of the hippocampus in stimulus encoding. In addition, they suggest that reduced recognition in older subjects is due, at least in part, to a failure to adequately activate the hippocampal area during learning, and thus to adequately learn the list of faces. Alterations of rCBF in prefrontal cortex also appear to play a role in age-related memory impairment.

521.11

LOCALIZATION OF LANGUAGE OPERATIONS WITH $H_2^{15}O$ PET: INDIVIDUAL DIFFERENCES IN FUNCTIONAL ANATOMY AND THEIR RELATION TO IMAGE SMOOTHING. S.Y. Bookheimer* and T.A. Zeffiro. Brain Mapping Division UCLA, Los Angeles, CA 90024 and National Institute on Aging, NIH, Bethesda, MD.

Sixteen normal volunteers underwent positron emission tomography while performing simple language tasks (reading words and naming objects). Images were stereo-tactically normalized and smoothed using Statistical Parametric Mapping (MRC Cyclotron Unit) to an effective FWHM of 12 or 21 mm. Although the same critical threshold was used in both analyses, the results differed markedly: activation in left inferior frontal (IFG) cortex (Broca's area) was identified only with the broad-filter while significance in cerebellum, striatum and extrastriate cortices were detected with both filters. However, spatially separate maxima were identified in these regions only with the narrow filter. A second experiment with left handers—who are known to have greater spatial variability in language organization—confirmed the difficulty in obtaining reliable anterior but not posterior results. High between-subject variability in the structural and functional anatomy should favor broad band filters, which are more sensitive to changes occurring over a wider spatial extent; Inferior frontal language areas are among the most variable cortical structures. Our data suggest that the optimum smoothing kernels will differ as a function of the known anatomic variability. Interpretation of PET language data is critically dependent on how this variability is treated in image analysis.

DEGENERATIVE DISEASE: ALZHEIMER'S—MECHANISMS OF DEGENERATION

522.1

NONLINEAR EEG DYNAMICS IN AGING AND DEMENTIA. KL Coburn*, WS Pritchard, DW Duke, NC Moore, RM Hostetler, MW Jann. Mercer Univ. Sch. of Med., Macon, GA 31207.

A series of 5 studies investigate topographic aspects of nonlinear EEG dynamics and their changes with information load, aging, and dementia. Major findings are that dimensional complexity (DCx; estimated correlation dimension) topography corresponds to EEG patterns of different cortical areas; some areas are more "chaotic" than others. Topographic patterns change in response to stimulation, and DCx offers a single-variable approximation of information load. Increasing visual information load increases DCx, especially over occipital areas in young subjects, but this effect is reduced in aging and nearly lost in dementia. Addition of nonlinear measures to traditional linear (FFT) measures improves the discrimination of demented patients from controls. For both types of measures, nonlinear neural net prediction offers significant advantages over linear analysis methods. Thus, nonlinear EEG measures and analysis methods offer unique perspectives for understanding both normal and pathological aging.

522.3

ANALYSIS OF STAGED AUTOPSY CASES UNCOVERS PACE OF ALZHEIMER'S DISEASE-RELATED NEUROFIBRILLARY CHANGES. J. Bohl (1), H. Müller (2), H. Braak (2)* T.G. Ohm (2). (1) Abt. Neuropathologie, J. Gutenberg Universität, 55131 Mainz, (2) ZMorph., J.W. Goethe Universität, 60590 Frankfurt; Germany.

The speed of progression of Alzheimer's disease (AD)-related neurofibrillary changes is unknown. This is because of the impossibility to histopathologically follow-up one and the same individual over decades of its life. The present approach is based on a recently introduced staging system which differentiates between six stages of AD-related neurofibrillary changes and analyzes a staged sample of 887 autopsy brains. The time needed to attain respective stages of pathology for 5% of a given cumulative sample is determined. The resulting 5%-percentiles are a measure for the average pace by which the disease-related changes progress assuming that the underlying stages represent a sequence of events and do not independently "pop-out". Advancing age and the prevalence of AD-related changes of a given stage show a nonlinear positive correlation with only slight acceleration above the age of 65. Statistically, it takes at least 16 years to shift from stage I to stage II, 14 years from stage II to III, 13 years from stage III to IV and 5 years from stage IV to V (=AD) for 5% of a given cumulative sample. Obviously, the deep roots of AD-related neurofibrillary changes can be traced about 50 years back and may thus even extend into adolescence. The unveiling of the duration of the shift between selected stages provides a powerful tool for epidemiological studies. A possible risk factor should shorten this period whereas beneficial influences would result in a delayed shift even if the considered cohort dies "too early" for the full development of AD.

522.2

INITIAL CLINICAL APPLICATIONS OF "BURST" fMRI IMAGING. DR. Weinberger*, V.S. Mattay, K.J. Kozlra, J.H. Duyn, C.T. Moonen, R. Sexton, T. Sunderland, F.A. Barrios, J.A. Frank. Clinical Brain Disorders Branch, National Institute of Mental Health, Washington, D.C. 20032.

Functional neuroimaging using MRI techniques (fMRI) have unique capabilities for mapping the physiological correlates of behavior; their potential clinical applications are less clear. In this study, we evaluated the utility of a fast 3-dimensional T2* sensitive method, called Frequency Shifted BURST (FS-BURST) in various neurologic disorders. This novel method has the capability to scan the whole brain on a conventional 1.5 T MR scanner in only two seconds. Nine normal volunteers, three patients with mild to moderately severe dementia of the Alzheimer's type (DSM-III-R diagnosis), one patient with a subacute cortical infarct in the left middle cerebral artery distribution and one patient with a high grade lymphoma were studied in the resting condition. Scans were performed on a conventional 1.5T GE/SIGNA MR scanner. Modified (FS) BURST MRI was performed during intravenous bolus administration of Gd-DTPA (0.13 mmol/kg). 3D datasets were acquired with an effective spatial resolution of 4.3x4.3x6.4mm within 2.2 seconds. 3D maps of relative cerebral blood volume (rCBV) and bolus arrival time were created by fitting a synthetic curve to the intensity time course on a pixel by pixel basis. The rCBV maps of the Alzheimer's patients revealed focal areas of hypoperfusion in a frontotemporo-parietal distribution identical to their SPECT perfusion scans. In the patient with the subacute infarct, the transit time maps showed arrival time delays of 5-7 seconds within and around the infarct clearly confirming the diagnosis of left middle cerebral artery occlusion. In the patient with CNS lymphoma decreased CBV around the tumor correlated with a mass effect. No focal defects were identified in the normal controls. These results illustrate the technique's potential as a clinical tool in the diagnosis and management of various brain disorders. This technique can be added to routine clinical MR scanning, requiring additional imaging time of only 3 - 5 minutes.

522.4

LAYER-SPECIFIC DENDRITIC ALTERATIONS OF HIPPOCAMPAL GABAergic NEURONS SUGGEST TRANSNEURONAL CHANGES IN ALZHEIMER'S DISEASE. S. Münch, R. Nitsch* and T. G. Ohm Center of Morphology, University Clinic Frankfurt, F.R.G.

Neurons in layer II and III of the entorhinal cortex are the first to exhibit neurofibrillary changes in Alzheimer's disease (AD). In this early stage of the disease, the target area of axons arising from these neurons, i.e., the hippocampus, remains devoid of these changes. Experimental studies have demonstrated layer-specific transneuronal changes on dendrites in the termination zone of entorhinal fibers, e.g., the outer zones of the dentate molecular layer. The present study was designed to unravel whether similar transneuronal dendritic changes occur during the spread of neurofibrillary tangles from the entorhinal cortex to the hippocampus as shown in a staging analysis by Braak and Braak (Acta Neuropathol. 82:239, 1991). We analyzed the hippocampal formation of 33 staged Alzheimer cases obtained from autopsy. The entire dendritic tree of parvalbumin-immunostained hippocampal GABAergic neurons was monitored using an interactive neuron tracing system. This cell population is known to remain devoid of neurofibrillary tangles even in severe AD. The quantitative analysis revealed a statistically significant reduction of the mean dendritic length, the segment number and branch order of dendrites in the course of AD. These changes were confined to the apical dendritic tree which extends into the termination zone of entorhinal fibers. In contrast, basal dendrites extending into the hilus remained unchanged in their morphology. Our data demonstrate that layer-specific dendritic alterations in hippocampal GABAergic neurons appear together with the spread of histopathological changes in AD. This suggests the occurrence of transneuronal changes on the hippocampal targets of entorhinal neurons. (Supported by the DFG: Ni 344/1-1, Ni 344/5-1, and Oh 48/4-1).

DYSTROPHIC PERIKARYA AND NEURITES INTERSPERSED WITH NORMAL NADPH DIAPHORASE/NITROGEN MONOXIDE SYNTHASE (NOS)-CONTAINING NEURONS (NOSN) IN THE CEREBRAL CORTEX OF PATIENTS WITH NONALZHEIMER DEMENTIA AND MOTOR NEURON DISEASE (MND), BUT NOT WITH MND WITHOUT DEMENTIA. R.O. Kuljis* and R.L. Schelper. Depts. Neurology and Pathology, The University of Iowa and VAMC, Iowa City, IA 52242.

Many adult patients with MND develop cognitive impairment, which may antedate motor manifestations, and that is most frequently not attributable to superimposed conditions such as Alzheimer's disease. The precise basis for such cognitive deterioration in patients presumed to have an insult selective to motor neurons remains elusive. In the course of a series of studies on the role of NOSN in neurodegenerative disorders, we discovered that these neurons exhibit clearly dystrophic features in MND. Five patients with sporadic MND were studied, two with neuropsychologically verified dementia (MND+d; both 65 years old; 1-23 hours of postmortem autolysis) and three without dementia (64-68 years old; 4-18 hours of autolysis). Tissue blocks from nine primary sensory, motor, association and limbic areas of the neocortex were sectioned frozen and reacted for NADPH diaphorase histochemistry, which reveals NOSN and their neurites. A conventional histopathologic analysis failed to show a cause for the cognitive symptoms in MND+d, but verified the clinical diagnosis of MND in all cases. Cases with MND+d, but not those without dementia, exhibit numerous markedly dystrophic NOSN perikarya and neurites, interspersed with normal NOSN in all areas examined. An additional series of control tissue sections from four age-matched and two younger patients -- with a wide range of autolysis intervals and fixation parameters -- failed to reveal similar dystrophic changes, indicating that they may be selective to MND+d. These observations suggest that cognitive impairment in MND+d may be related to a pancortical deterioration of the ubiquitous NOSN network, indicating a novel role for these neurons in neurodegenerative disorders. Supported by PHS grant NS29856.

DISTRIBUTION OF NGF IN THE NORMAL AGED HUMAN BRAIN AND IN ALZHEIMER'S DISEASE.

SA Scott*, J Weingartner, and KA Crutcher. Department of Neurosurgery, University of Cincinnati School of Medicine, Cincinnati OH 45267-0515.

Using the two-site ELISA, both the rodent and monkey brain have been examined for NGF content with high levels found in the hippocampus and neocortex. Recent data from our laboratory suggest a similar distribution in the aged human brain (mean 74 yr) and, moreover, that the levels are comparable to those observed in other species. The highest levels of human NGF are within the dentate gyrus (1200 pg/g) whereas the lowest are found in cerebellum (80 pg/g), brainstem (40 pg/g) and spinal cord (0 pg/g). Between these extremes, neocortical areas contain 300-500 pg/g NGF with little variation among the principal gyri, although the temporal and insular regions generally contain the highest levels. The basolateral amygdala and the nucleus basalis of Meynert are rich sources of NGF (~700-800 pg/g). Other areas with notably high levels include the choroid plexus (>1000 pg/g), entorhinal cortex (750 pg/g), medial thalamus (600 pg/g), and neostriatum (450 pg/g), whereas the pineal gland, olfactory bulb/tract, hypothalamus/mammillary bodies, and globus pallidus contain generally lower levels (<350 pg/g). This broad spectrum of NGF localization in brain, together with the known distribution of high-affinity trkA receptors, suggests that brain NGF is not localized simply in relation to the basal forebrain cholinergic system.

NGF levels were at least moderately higher with Alzheimer's disease in all regions examined (frontal and occipital poles, amygdala, putamen, hippocampus, cerebellum, superior temporal gyrus, and inferior parietal lobule), although the distribution was similar to that in aged controls.

ALZHEIMER'S DISEASE PATHOGENESIS: EVIDENCE OF INCREASED PROOXIDANT ACTIVITY IN THE INFERIOR TEMPORAL LOBE. A.M. Palmer* and M.A. Burns. Departments of Psychiatry and Pharmacology, University of Pittsburgh School of Medicine, Pittsburgh, PA 15213.

The concentration of a product of lipid peroxidation (malondialdehyde) was determined in six areas of neocortex of 8 subjects with Alzheimer's disease and 8 control subjects, matched for age (74 ± 7 and 73 ± 8 years, respectively) and postmortem delay (10 ± 6 and 11 ± 7 hours, respectively). Malondialdehyde (MDA) concentration was significantly increased by incubation with iron and ascorbate in all samples. Basal and iron/ascorbate-stimulated malondialdehyde concentration were 19-40% higher in the inferior temporal cortex of Alzheimer subjects than corresponding controls; other regions were unaffected. In order to assess antioxidant capacity, we determined the activities of glutathione peroxidase and glutathione reductase in addition to two enzymes of the pentose phosphate pathway (glucose-6-phosphate dehydrogenase and 6-phosphogluconate dehydrogenase) in three areas of neocortex. The only difference was an increase in the activities of glucose-6-phosphate dehydrogenase (to 126% of controls) and 6-phosphogluconate dehydrogenase (to 162% of controls) in the inferior temporal cortex of Alzheimer subjects. Together these data indicate that lipid peroxidation is increased in Alzheimer's disease because of increased prooxidant activity rather than diminished antioxidant defenses. Moreover, it appears that the activity of pentose phosphate pathway is increased in response to increased prooxidant activity since 6-phosphogluconate dehydrogenase activity significantly correlated ($R_s = -0.89$, $p < 0.01$) with the stimulated formation of MDA. This inverse relationship suggests that elevations in the activity of pentose phosphate enzymes reflect a compensatory change in response to increased prooxidant activity. Although it is not clear if increased prooxidant activity is a cause or a consequence of early pathological change, it is consistent with the involvement of oxidative stress in the maintenance and progression of the cascade. Antioxidant therapy can therefore be expected to stop, or at least slow, the progress of this debilitating disease of late life.

522.6

A DECREASE OF GROWTH INHIBITORY FACTOR (GIF) IN THE TEMPORAL CORTEX OF ALZHEIMER'S DISEASED (AD) BRAIN IS INVERSELY RELATED TO GLIAL FIBRILLARY ACIDIC PROTEIN (GFAP) EXPRESSION AND GLIOSIS. N.J. Cartel*, W.H. Yu, C.A. Mizzen, E.T. Jaikaran, D.R. McLachlan. Centre for Research in Neurodegenerative Diseases, Tanz Neuroscience Building, 6 Queen's Park Crescent West, University of Toronto, Toronto, Ontario, Canada, M5S 1A8.

GIF, or metallothionein-3 (MT-3), a member of the metallothionein family, is localized predominantly in astrocytes of the molecular layer of the dentate gyrus, the pyramidal cell layer of the hippocampus, and layers 2-6 of the neocortex. GIF is expressed in mature astrocytes but is down-regulated during fetal development and in AD brain.

Western blots for GFAP, GIF, and total metallothionein (MT-1, MT-2 and GIF; MT_{TOT}) were performed to quantitate these proteins in temporal lobe of adult human control and AD brains. Levels of MT_{TOT} in control and AD temporal cortex were indistinguishable. However, GIF in AD brain was decreased by 84.1% when compared to control. Conversely, there was an 83.4% increase of GFAP expression in AD brain when compared with control.

Immunocytochemical detection of the same proteins was performed on sections of control and AD from the middle temporal gyrus. Double immunostaining suggested that GIF is down-regulated in the cytoplasm, nucleus and processes of astrocytes even though reactive gliosis was found in AD brains. This was reflected in heavy GFAP staining of astrocytes in AD sections. Furthermore, even though no differences in MT_{TOT} expression were apparent when assessed by blotting, immunostaining suggested diminished staining per glial cell. Presumably, absolute levels determined by blotting were unaltered due to increases in cell number concomitant with gliosis. Thus, it seems that basal MT_{TOT} expression is not altered in large regions of temporal lobe in AD. GIF is the first astrocytic protein found to be down-regulated during gliosis in AD.

522.8

SELECTIVE ABNORMALITIES IN MULTIPLE NEUROTRANSMITTER RECEPTOR DENSITIES IN NEURODEGENERATIVE DISEASES.

L. R. Murthy*, VA Med Ctr /Mt. Sinai Sch of Med, NYC, NY.

This study investigates the densities of multiple neurotransmitter receptors, in ten different cortical regions of human brain, obtained from patients: Normal, Schizophrenia (Sch), Alzheimer's disease (AD) and Multi Infarct Dementia (MID).

Aliquots of membrane suspension obtained from each cortical region were analyzed simultaneously for the binding of radiolabeled nicotine, ketanserin and SCH 23390 to nicotine, serotonin 5HT₂ and dopamine D1 receptors respectively. The receptor binding assays were done in the absence and presence of cold ligands to obtain specific and non-specific binding respectively of radiolabeled ligands. Important differences in the densities of the three different neurotransmitter receptors were noted in the ten cortical regions of Sch, AD, MID brains as compared to normal.

-5HT₂ receptor showed a significant increase in Sch brains and a remarkable decrease in AD and MID brains.

-Nicotinic receptor underwent significant reduction in AD and MID brains, and in 9 out of 10 cortical regions in Sch brains.

-D1 receptor was enhanced in the cortical regions studied in Sch brains.

Selective alterations in the densities of the above multiple neurotransmitter receptors in brain, appear to be present in aforementioned Neurodegenerative diseases.

522.10

NEUROTOXIC EXTRACTS OF ALZHEIMER'S DISEASE BRAIN ARE ASSOCIATED WITH REACTIVE MICROGLIA. L.J. Haverkamp* and J.B. Kirkpatrick. Depts. of Neurology and Pathology, Baylor College of Medicine, Houston, TX 77030.

We have adopted a triple stain for plaques (thioflavine-S), cell nuclei (bisbenzimidazole), and reactive microglia (immunohistochemistry for HLA-DR) in tissue obtained after relatively short post-mortem intervals (<6 hr.), lightly fixed in paraformaldehyde. Using this technique, we note as especially prominent in Alzheimer's disease (AD), clusters of three or more reactive microglia, invariably in association with all (99%) core senile plaques, a majority (40-85%) of neuritic plaques, and none of the diffuse plaques which are often found in the brains of non-demented elderly. Confocal scanning laser microscopy comparisons of the microglia at a distance from plaques and those associated with core plaques, show the latter to exhibit up to three times the level of HLA-DR immunoreactivity, six times the cell body volume, and 70-fold decreases in process length. In vitro, microglia stimulated with β -amyloid assume a reactive morphology and produce a potent neurotoxin whose effects can be blocked by NMDA receptor antagonists. A neurotoxin, apparently identical in properties to this poison produced by microglia in vitro (Giullian et al., 1993, J. Neurosci. 13:29), can be extracted from AD brain autopsy material. Extracts of normal (N=5) and neurological control (ALS; N=6) brains (matched for age and post-mortem interval) lacked toxic effect. Toxic activity was regionally distributed within AD brains (N=7), with hippocampus invariably containing high levels of toxin while cerebellum and white matter had very little. Correlations of histopathology and toxicity of adjacent tissue, from 8 regions in each of the control and AD brains, showed a close relationship between neuron-killing activity and the density of microglial clusters. Lesser degrees of association were found between toxicity and neuritic or diffuse plaques. These findings suggest participation of activated microglia-derived neuronal poisons in the neuron death which occurs in AD.

APOE4 GENE-DOSE DEPENDENT DEVELOPMENT OF ALZHEIMER-TYPE NEUROFIBRILLARY TANGLES - A PCR-AIDED AUTOPSY ANALYSIS. T.G. Ohm* (1), M. Kirca (2), J. Bohl (3), H. Scharnagl (2) and W. März (2,4); (1) ZMorph. & (2) ZBioChem J.W. Goethe-Universität, 60590 Frankfurt/M., (3) Neuropath. J. Gutenberg-Universität, 55131 Mainz, (4) Klin. Chemie, Albert Ludwigs-Universität, 79106 Freiburg, Germany.

The final diagnosis of Alzheimer's disease rests on the presence of a sufficiently high number of neurofibrillary tangles and neuritic plaques. We based our study on a staging system (Braak and Braak, Acta Neuropathol 82: 239, 1991) which considers the gradual development of AD-related changes over time and correlates highly with the cognitive decline assessed ante mortem. Our analysis revealed that the mean stages for NFTs as well as for A β /amyloid deposition get significantly shifted upwards in ϵ 4-carriers. A NFT-stage shift represents an earlier onset of the pathological process of about one decade. The fact that both NFT and extraneuronal amyloid formation coincidentally correlate positively with the genotype for apoE suggests a metabolic link to apoE-metabolism associated with apoE isoform-specific alterations.

ApoE genotype	Observed Means		Age-adjusted means	
	NFT	A4/B	NFT	A4/B
ϵ 2/2	2.00	1.00	3.23	1.80
ϵ 3/2	3.89	2.54	3.33	2.18

CELL LINEAGE AND DETERMINATION III

523.1

An identified neuron necessary for induction of segment-specific neurons in the leech CNS. G. W. M. Bothe*, T. Becker and E. R. Macagno. Dept. Biol. Sci., Columbia Univ., New York NY 10027

Whereas a set of 400 neurons is found in most ganglia in the leech, *Hirudo medicinalis*, ventral nerve cord, each of the two ganglia innervating the sex organs contains an additional 350 small neurons. The birth of these neurons is induced by the male organ during a critical period from day 13 to 16 of embryogenesis. They were therefore named "Peripherally Induced Central" (PIC) neurons. The inductive signal leading to the birth of these cells is conveyed via the nerves that connect the CNS to the male organ (the sex nerves). In the absence of these nerves, induction does not take place. The sex nerves contain the axons of 10 - 11 identified neurons in each sex ganglion.

To test whether any of these neurons are involved in the induction process, we used single and pairwise cell ablations. One pair of cells, the mediolateral (ML) neurons, were found to play a key role in the induction process. Ablation of a single ML neuron resulted in a 50% reduction of dividing PIC precursors on the side of the ganglion where the neuron was killed. Ablations of other neurons had no significant effect. Ablation of both ML neurons in one ganglion did not totally abolish cell divisions, suggesting that other neurons can partly substitute for the ML neurons in inducing PIC neurons.

The effect of the ML neuron on proliferation in the sex ganglia is consistent with the idea that their axons convey the inductive signal from the target to the CNS. We are currently investigating the spatial relationship of the ML neuron and the PIC neuron precursors at the time of induction.

523.3

NEURONAL PHENOTYPE DETERMINATION IN THE HINDBRAIN: CONSECUTIVE ASSIGNMENT OF AXIAL POSITIONAL VALUES. A.Lumsden*, A.Hornbruch and H.Simon. (SPON: Brain Research Association) MRC Brain Development Programme, UMDS, Guy's Hospital, London SE1 9RT, England.

A working hypothesis is that cell pattern in the neural tube is controlled by a coordinate system of positional information, set up along the anteroposterior (AP) and dorsoventral (DV) axes. During development, the AP axis of the chick hindbrain becomes subdivided into a series of compartments (rhombomeres) that underlie its segmented architecture. Coincident with delineation by interfaces where cell mixing is transiently restricted, the rhombomeres become determined for expression of a specific combination of selector genes (Hox genes) that may encode rhombomere identity. Rhombomere phenotype is determined at this stage. Thus, when presumptive rhombomere 4 (r4) is transposed for r2 (at 6 somites), the graft expresses an r4-specific gene (Hoxb-1) and develops r4-specific neurons. We now find that only the AP and not the DV positional value of the rhombomere is determined at this time. Thus, when r4 is grafted to the r2 position with its DV polarity inverted (the alar plate positioned ventrally, abutting the floor plate) r4-specific motor neurons appear medially, within the original alar plate. Cells are committed to their fates according to position on a Cartesian grid whose coordinates are set sequentially; DV positional values are labile when AP values are already fixed.

523.2

MESOTOCINERGIC NEURONS ARISE FROM A REGION PREDICTED BY A NEURAL PLATE FATE MAP FOR *XENOPUS* FROG EMBRYOS. K.M. Conway* and C. Thaler. Dept. Biol., The American Univ., Wash., D.C. 20016

We used Eagleson and Harris' fate map (*J. Neurobiol.* 21, 427) to identify a region comprising left anterior medial neural plate and adjacent medial anterior neural ridge likely to contain all precursors of left side mesotocinergic neurons. Reciprocal grafts of this region were exchanged among embryos of the *Xenopus* species *laevis* and *borealis*. The experimental design included sham operated and unoperated controls. Early limb bud stage animals were processed for immunocytochemistry (ICC) using a primary anti-mesotocin antibody reagent (VA-10: Conway and Gainer, *J. Comp. Neurol.* 264, 494), and ultimately labelled with the fluorochrome Texas Red (TR). Detergent treatment then permitted nuclei to be stained with 4'-6-diamino-3-phenylindole (DAPI).

Borealis host embryos subject to surgery had poor survival rates, statistically fewer mesotocinergic cells, and fuzzy DAPI staining, and were thus not further considered. Slides with tissue from *laevis* hosts and unoperated *borealis* controls were examined using a 40x oil immersion objective lens. They clearly showed mesotocinergic neurons labelled by TR and, where appropriate, regions of speckled DAPI stained nuclei characteristic of *borealis* tissue.

Resolution of DAPI stained speckles in individual *borealis* nuclei using a 100x oil immersion objective lens was obtained by digital contrast enhancement of video images. A few known *borealis* nuclei were artifactually scored as *laevis* as their nuclear speckles were not resolved. However, analysis of mesotocinergic cells on the operated side of chimeric *laevis* hosts showed statistically significant numbers of *borealis* cells and statistically insignificant numbers of *laevis* cells.

Thus, the grafted region contains the precursors of all mesotocinergic neurons on the operated side in early limb bud stage *Xenopus* tadpoles. We thank NICHD and TAU for support and Tom Miele (Opelco) for equipment demonstrations.

523.4

PHYLOGENETIC DIVERSIFICATION WITHIN EMBRYONIC HINDBRAIN RHOMBOMERES AND THE NEURONAL ORGANIZATION UNDERLYING POSTURAL CONTROL. E. Gilland and R. Baker*. Department of Physiology and Biophysics, New York University Medical Center, New York, NY 10016

Comparative ontogenetic models have great potential for establishing how gene expression confers positional identity to cells, an identity that in turn largely predetermines early embryonic axonal pathways and innervation patterns. Despite the diversity of adult brainstem organization, recent data suggest that the overall segmental, rhombomeric (Rh) blueprint of the hindbrain has been genetically conserved in vertebrates. The phylogenetic diversification of cellular identity related to derived sensory-motor circuits responsible for vertebrate posture can now be addressed within this Rh framework. Dye labeling demonstrates that cranial and spinal somatomotor neurons arise as largely non-overlapping segmental populations arrayed rostral to caudal along the Rh neural axis with homeotic-like shifting of cranial nerve efferents occurring in different species. Surprisingly, the hindbrain areas identified as afferent to eye, head and spinal cord limb/axial motor nuclei are ordered posterior to anterior in the medulla of diverse vertebrates. In particular, we have documented the morphology and physiology of individual, non-overlapping nuclei extending through regions arising from Rh 8 to 4 in teleosts. Notably, the two most evolutionarily derived oculomotor centers, the horizontal eye position and velocity integrators, are located just rostral to the spinal cord and are presumed to originate from Rh 8. Two other gaze-related nuclei are located further rostral, likely arising from Rh 7. Comparison of homologous postural circuitry between taxa suggests that gene expression within a given embryonic hindbrain compartment must coordinate the developmental plans of diverse neuronal types that were acquired and combined through stepwise phylogenetic elaboration. We propose that the need to insert novel, derived circuitry (e.g. the integrators) into established, more primitive, hindbrain sensory-motor blueprints constrains the functional organization of downstream targets of homeotic selector genes. As a result, gene deletion/ectopic expression experiments involving high level selector genes can be expected to produce a mosaic pattern of variation affecting both ancient and recently acquired species-specific neuronal circuitry. We conclude therefore that to incisively address the molecular correlates of neuronal development, experimental analyses will require consideration of the phylogenetic diversity of neuronal structure and function observed in embryonic rhombomeres.

CELL LINEAGE IN THE FORMATION AND REGENERATION OF THE OLFACTORY PLACODES. G.D. Burd*, A. Collazo, and S.E. Fraser. Dept. of Molecular and Cellular Biology, Univ. of Arizona, Tucson, AZ 85721 and Div. of Biology, California Institute of Technology, Pasadena, CA 91125.

Previous studies in *Xenopus* demonstrated that the olfactory placodes are derived from cells in the anterior neural ridge (Eagleson and Harris, 1990). We and other laboratories have also observed that the olfactory placodes can regenerate (Byrd and Burd, 1993). The goals of the current study were to demonstrate the origin of the olfactory receptor neurons during normal development and to determine the origin of olfactory receptor neurons in regenerated olfactory placodes. The lineage of cells was determined by labeling small groups of cells with Dil(5)C18 or single cells with lysinated rhodamine dextran (Molecular Probes), and the fate of these cells was followed *in vivo* using low light level video microscopy. Cells in the anterior-lateral region of the anterior neural ridge (labeled at stages 14-16) give rise to olfactory placodes and form the olfactory and vomeronasal epithelia in tadpoles (stage 48). At later stages (stages 22-24), cells in the sense plate prior to and during olfactory placode formation give rise to olfactory receptor neurons and supporting cells. Following removal of the olfactory placodes (stages 33-34), we found that undifferentiated cells surrounding the olfactory placodes in the sense plate form new olfactory placodes and give rise to new olfactory receptor neurons. In summary, undifferentiated cells in the sense plate retain the potential to form olfactory receptor neurons well after olfactory placodes have formed. The molecular signals and genes involved in this process remain an exciting avenue for future investigation. Support: NSF, MDA, and NIMH.

NOTCH IS A DETERMINANT OF RETINAL GANGLION CELL FATE IN THE CHICK. C.P. Austin*, D. Feldman, J. Ida, S. Fields-Berry, and C.L. Cepko. Dept. of Genetics, Harvard Medical School, Boston, MA 02115.

The factors affecting cell type determination and differentiation in the vertebrate retina are largely unknown. Ganglion cells (GC) are the first cell type to be produced in the chicken retina, and we have used an *in vitro* system to study the factors influencing their development. The presence of an inhibitor of GC differentiation was suggested by the finding that when E4 chick retinal cells were dissociated and cultured at low density, the percentage of cells expressing GC-specific markers increased 5-fold over 24 hours (Austin and Cepko, Soc. Neurosci. Abstr. 519.13, 1993). The *Notch* gene family has been hypothesized to code for cell surface receptors that mediate inhibitory signals influencing cell fate in a number of organisms. We have now found that *Notch* plays a similar role in the chick retina, as an inhibitor of GC differentiation. When antisense oligonucleotides directed against any of 3 regions of the *Notch* sequence are added to retinal explant cultures, the number of GC's in the explant increases by 50% over 24 hours relative to explants incubated with sense oligo controls. To test the specificity of the oligo sequences in bringing about GC overproduction, we have used antisense oligonucleotides mismatched at 1, 3, or 5 bases, and found that the extent of GC overproduction decreases with increasing mismatch. Western blots showed that *Notch* protein level is greatly diminished in the explants treated with antisense oligonucleotides, relative to sense oligonucleotide, or non-oligo-treated explants. Expression of a truncated form of the human *Notch* homologue (*TAN-1*), corresponding to the intracellular portion of the protein, via retroviral transduction reduced the number of GC produced *in vivo* and prevented the overproduction of GC previously seen in dissociated culture. These findings suggest that *Notch* is an inhibitor of ganglion cell differentiation in the early chick retina, and supports the emerging hypothesis that this gene family may play a central role in neuronal determination in vertebrates. Supported by K11 EY 00321 (C.P.A.) and RO1 EY 09676 (C.L.C.) from the National Eye Institute.

ORIGIN OF SUBVENTRICULAR ZONE CELLS M. C. Mione* and J. G. Parnavelas. Department of Anatomy, University College London, Gower Street, London WC1E 6BT, U.K.

In the late stages of cortical neurogenesis, the subventricular zone (SVZ) is a prominent layer containing numerous mitotically active cells. It is believed that these cells give rise to the astrocytes and oligodendrocytes of the cerebral cortex and the subcortical white matter. In order to investigate whether SVZ cells originate from ventricular zone (VZ) cells, we made intraventricular injections of a recombinant retrovirus carrying the reporter gene for *E. Coli* β -galactosidase at different embryonic ages. Rats were killed after 3 days or at birth, and at postnatal days (P) 3, 7 and 14. All animals, irrespective of the age of injection, showed β -gal+ SVZ cells when examined at birth or later. Therefore, we concluded that cells present in the VZ between E15 and E19 give rise to some, if not all, SVZ cells. β -gal+ cells were present in the SVZ at least until P14, although their number was greatly reduced by this age. In order to ascertain whether SVZ cells originate from a dormant population of neuroepithelial cells or if they are stem cells left behind by their migrating progeny, we used bromodeoxyuridine (BrdU) to distinguish between mitotically active or quiescent cells. BrdU was given every two hours over a period of 24 hours starting 2 days after retroviral injection. Animals were killed shortly after the last injection or at birth. It was found that the majority of β -gal+ SVZ cells had incorporated BrdU, thus indicating that they were mitotically active during the period of BrdU injection. This finding suggests that stem cells in the VZ give rise to the glial progenitors present in the SVZ. Supported by the Wellcome Trust.

GENESIS OF OLFACTORY RECEPTOR NEURONS PROCEEDS THROUGH DISTINCT PROGENITOR CELL STAGES AND IS REGULATED BY FIBROBLAST GROWTH FACTORS. A.L. Calof*, J.L. Guevara, K. Hannont, B.B. Olwin†, and M.K. DeHamer. Department of Biological Sciences, University of Iowa, Iowa City, IA 52242, and †Department of Biochemistry, Purdue University, West Lafayette, IN 47907.

In vivo, neurogenesis in the olfactory epithelium (OE) proceeds continually, but *in vitro*, in minimally supplemented defined medium, Immediate Neuronal Precursors (INPs) of olfactory receptor neurons (ORNs) divide only once. We found that Fibroblast Growth Factors (FGFs) promote extended proliferation of INPs in OE cultured from E14-15 mouse embryos, while other polypeptide growth factors tested do not. Expression of FGF receptors, detected by RT-PCR in RNA isolated from E14-15 OE, suggests that FGFs may stimulate INP proliferation *in vivo* as well. Labeling INPs through successive S phases with bromodeoxyuridine (BrdU) and ³H-thymidine (³H-TdR) demonstrated that FGF allows INPs to undergo a second division before differentiating into ORNs. Varying the interval between BrdU and ³H-TdR pulses allowed length of the INP cell cycle to be estimated as 17 hr with an S phase of ~8 hr; this finding enabled us to estimate that FGF exerts its effects in late G2/M or early G1. Neurogenesis usually ceases by 48 hr in culture, even in FGF, because >90% of INP progeny differentiate into postmitotic ORNs. However, in rare explants grown in FGF, large groups of proliferating INPs are seen after this time, suggesting that a progenitor cell—possibly a stem cell—is producing new INPs in these explants. Genetic experiments suggest that the transcription factor Mammalian Achaete Scute Homolog 1 (MASH1) may be required at an early stage of genesis of ORNs (Guillemot et al., Cell 75:463-476 [1993]). We find that a subpopulation of proliferating migratory cells in early (t=6 hr) OE cultures expresses MASH1, but expression declines rapidly; this decline is not due to cell death. MASH1+ cells are immunologically and morphologically distinct from basal cells and ORNs, and their high ³H-TdR labeling index suggests that they are not stem cells. The data are consistent with a model of olfactory neurogenesis in which the MASH1-expressing cell is an early stage of, or progenitor to, the INP, which functions as a neuronal transit amplifying cell.

523.8

PROLIFERATION AND CELL TYPE CHOICE ARE MODULATED IN RAT RETINAL CELLS EXPRESSING VIRALLY TRANSDUCED EGF RECEPTORS. L.E. Lillie†, Dept. of Anatomy and Neurobiology, Medical College of Pennsylvania, Philadelphia, PA 19129.

TGF α is expressed in the developing retina and affects several aspects of retinal development *in vitro*. These effects are age- and dose-dependent: low levels of TGF α (0.01–0.1 ng/ml) stimulate the proliferation of late embryonic and early post-natal retinal cells, but not younger retinal cells; higher concentrations of TGF α (1–10 ng/ml) affect cell type choice, inhibiting rod development and enhancing bipolar, Muller, and amacrine cell development. To study the contribution of limitations in EGF receptor (EGF-R) expression to the age- and dose-dependence of retinal cell responses to TGF α , a retroviral vector was used to introduce additional copies of wild-type human EGF-Rs into rat retinal progenitor cells (human EGF-Rs are immunohistochemically distinct from endogenous EGF-Rs). The vector also contains an IRES sequence, which allows a second gene encoding the marker B-gal to be co-expressed at high levels in infected cells. For example, 98–100% of retinal cells that express virally transduced EGF-Rs also express B-gal. The co-expression of B-gal facilitates analysis of the proliferation, survival, and differentiation of infected cells. Explants of E18 rat retina were infected with virus expressing EGF-Rs and B-gal, or with virus expressing B-gal alone. Proliferation (measured by BrdU incorporation) was analyzed 6–7 d after infection, and differentiation into rods (determined by opsin expression) was analyzed 11–16 d after infection, using rabbit anti-B-gal together with either mouse anti-BrdU or mouse anti-opsin (Ret-P1) antibodies. Proliferation of retinal cells infected with EGF-R virus was enhanced by 30–300% in response to endogenous ligand (no TGF α added) or exogenous TGF α (0.1 ng/ml). Development of retinal cells infected with EGF-R virus into rods was reduced by 50–75%. These observations suggest that limited levels of EGF-R expression contribute to the regulation of proliferation and differentiation in the retina, and that these restrictions can be overcome by manipulating levels of receptor expression.

523.10

A DEVELOPMENTALLY REGULATED, NEURAL SPECIFIC PROTEIN EXPRESSED BY EARLY POST-MITOTIC NEURONS IN THE EMBRYONIC RAT CORTEX J.E. Minturn*, H.J.L. Fryer, D.H. Geschwind, and S. Hockfield. Section of Neurobiology, Yale Univ. Sch. of Med., New Haven, CT 06510

Using two-dimensional gel electrophoresis we previously identified a 64 kD protein (protein 310) that is neural specific, abundantly expressed in the embryonic cerebral cortex, and down-regulated in the adult (J. Neurosci. 9:4304). Antibodies to synthetic peptide fragments from protein 310 label cells in the developing rat brain as early as embryonic day 12 (E12) when only a few neurons have been born. In double immunofluorescent labeling experiments all cells in the developing cortex that express class the neuronal marker class III β -tubulin also express protein 310 at all ages examined. Double label studies with protein 310 and an antibody to proliferating cell nuclear antigen, a nuclear protein expressed by dividing cells, demonstrate that protein 310 is only expressed by non-mitotic cells. These data indicate that protein 310 is expressed by early postmitotic neurons.

Further support for the expression of protein 310 by cells as they make a commitment to a neuronal phenotype was obtained by examination of two cell lines. PC12 cells exposed to NGF differentiate into cells with neuronal properties, including neurite extension and membrane polarization. Western blot analysis shows that protein 310 levels are markedly increased in PC12 cells induced into a neuronal phenotype by NGF addition. Similarly, in the P19 embryonal carcinoma cell, different concentrations of retinoic acid (RA) cause cells to assume different phenotypes (either muscle or neural). Northern analysis shows that the mRNA for protein 310 is present only when P19 cells are induced into a neural phenotype.

The expression of protein 310 in early post-mitotic neurons and in cell lines that are induced to express neural properties, make protein 310 one of the earliest proteins expressed after cells have undergone the commitment to a neuronal phenotype. (Supported by NS22807 and the HHMI).

REGULATION OF THE RADIAL GLIA-ASTROCYTE TRANSFORMATION PATHWAY IN THE DEVELOPING FOREBRAIN K.E. Hunter* and M.E. Hatten, Laboratory of Developmental Neurobiology, The Rockefeller University, 1230 York Avenue, New York, New York 10021.

Two classes of astroglial cells underlie establishment of structure in the developing cerebral cortex. In the embryonic period, a system of radial glial cells serves to support neuronal migration: these cells are process-bearing and specifically express the RC2 antigen. In the late embryonic and perinatal period, radial glia are believed to transform irreversibly into astrocytes, which are stellate in form and express GFAP but not RC2. Astrocytes are not supportive of neuronal migration, instead providing neurotrophic and metabolic support for maturing neurons and contributing to the maintenance of the mature cortical cytoarchitecture.

We previously showed that expression of radial glial cell identity *in vitro* requires extrinsic soluble signals which are present in embryonic neocortex, and that these signals can induce mature astrocytes to assume a radial glial-like form and express RC2 antigen *in vitro* in the presence of embryonic signals, and *in vivo*, following transplantation into embryonic neocortex (Soc. Neurosci. Abs. 256.12, 1993). These observations suggest that, when provided with appropriate inducing signals, astrocytes can express some of the features of radial glia, their precursors, and that this developmental pathway is therefore reversible and regulated at least in part by availability of these inducing signals. The inducing signals are absent from mature forebrain, suggesting that the progression from radial glia to astrocyte is a bidirectional pathway, which is extrinsically regulated by these signals. Preliminary characterization indicates that the inducing signals are protein in nature, and represent either a previously unidentified role for a known peptide, or a potentially novel neural growth factor.

CO-LOCALIZATION OF CDK-5, MUNC-18 AND SYNTAXIN DURING DEVELOPMENT OF THE RAT CEREBELLUM. P. Grant*, Veeranna K.T. Shetty and H.C. Pant, LNC, NINDS, National Institutes of Health, Bethesda, Md. 20892.

Neuronal cdk-5 phosphorylates the high molecular weight neurofilament protein (NF-H). During the purification of this kinase, we identified a molecule of 67 kd (P67) which is associated with and activates cdk-5 activity (Shetty, et al, 1993 Abst. Soc. Neurosci. 19: 62). A molecule, called Munc 18, with a sequence identical to P67, was shown to be associated with syntaxin, one of the key molecules of the synaptic vesicle fusion protein complex (Hata et al, 1993, Nature 366,347). To further explore the function of Munc 18, either as a regulator of cdk-5, or as a component of the synaptic vesicle complex, (or both), we investigated the immunohistochemical expression of cdk-5, Munc 18, syntaxin and NF-H during development of the rat cerebellum from P2 to the adult. We assumed that if these molecules were functionally related, then they should: (1) co-localize within the same cells and tissues, and (2) undergo similar patterns of developmental regulation. Using antibodies to cdk-5, NF-H, syntaxin and Munc-18, we could show that at all stages, the epitopes for cdk-5, Munc-18 and syntaxin were co-localized in the developing molecular layer (parallel fibers), the synaptic glomeruli in the inner granule cell layer, and in afferent and efferent fibers (climbing fibers, mossy fibers and Purkinje cell axons) within each folium. Only cdk-5 and Munc-18 antigens were detected within the Purkinje cell bodies. The pattern of NF-H expression, however, showed differences since it was absent from the molecular layer through most of development, but was primarily restricted to axons and fiber bundles within each folium. At late developmental stages, NF-H stained fibers were seen within the dendritic and surrounding soma regions of Purkinje cells. The expression patterns of CDK-5 and Munc-18 during development, as seen immunohistochemically and in immunoblots, are similar, which is consistent with the hypothesis that they are functionally related.

EVIDENCE FOR A ROLE OF STRIATAL GABA IN THE ANTAGONISTIC DOPAMINE - GLUTAMATE REGULATION OF LOCOMOTION. AN *IN VIVO* MICRODIALYSIS STUDY IN THE AWAKE FREELY MOVING RAT. W.T. O'Connor*, M. Morari, U. Ungerstedt and K. Fuxe, Departments of Pharmacology and Neuroscience, Karolinska Institute, Stockholm, Sweden.

The effect of local perfusion with tetrodotoxin (TTX) in the substantia nigra pars reticulata (SNr) on behavior and basal dopamine (DA), GABA, and glutamate (GLU) levels in the dorsolateral striatum was monitored using *in vivo* microdialysis in the awake rat. Basal striatal DA, GABA and GLU levels (nM) were 1.7 ± 0.9 , 10.4 ± 0.7 and 307 ± 40 respectively. Nigral perfusion (70min) with TTX (10uM) produced a strong contralateral rotation (8.5 ± 4 per min after 30 min); a decrease in ipsilateral striatal DA release (-70% of control) and an increase in striatal GABA (+40%) and GLU (+80%) release. Intrastriatal perfusion with MK-801 (10uM) alone did not affect behavior or striatal neurotransmitter release but counteracted the contralateral rotation (1.3 ± 0.5 per min after 30 min); abolished the increase in striatal GABA release and delayed the increase in striatal GLU release associated with perfusion with TTX in the ipsilateral SNr. The reduction in striatal DA release associated with nigral TTX was not affected by intrastriatal MK-801. Thus, the counteraction of the nigral TTX induced increase in both rotational behavior and striatal GABA release following intrastriatal perfusion with MK-801 strengthens the evidence for the striatal GABA neuron as a major target for the antagonistic DA-GLU interaction in the regulation of locomotion.

SEIZURE PROTECTION WITH IB-MECA, A SELECTIVE AGONIST OF THE NOVEL ADENOSINE A3 RECEPTOR. D.K.J.E. von Lubitz^a, M.F. Carter^a, R.C.-S. Lin^b, K.A. Jacobson^{a*}.

^aNIDDK/NIH/Molecular Recognition Section, Bethesda, MD 20892;

^bDept. of Physiology and Biophysics, Hahnemann University, Philadelphia, PA, 19102.

The biological function of adenosine A3 receptors is virtually unknown. We have, therefore, investigated the effect of acute and chronic preischemic stimulation of these receptors on the outcome of NMDA or pentylenetetrazole (PT) induced seizures in C57Bl/15 mice (N=10/group). Animals were injected I.P. with N6-(3-iodobenzyl)-adenosine-5'-N-methylcarboxamide [IB-MECA (10, 50, 100 µg/kg)] 15 min prior to either NMDA (60 or 125 mg/kg) or PT (75 mg/kg). In the chronic regimen, IB-MECA (100 µg/kg/day) was injected I.P. for 4 weeks followed by NMDA (60 mg/kg) administered 24 h after the last administration of IB-MECA. The onset of neurological symptoms following injection of NMDA (60 and 125 mg/kg) was significantly delayed by acute and chronic IB-MECA at doses >50 µg/kg. At 100 µg/kg both acute and chronic IB-MECA significantly reduced postictal mortality in both NMDA and PT groups. Acute injection of 120 µg/kg IB-MECA improved survival of PT induced seizures even further. Our results indicate that, contrary to its effect in cerebral ischemia, acutely injected IB-MECA is highly protective against seizures elicited by different epileptogenic drug classes and that, as in stroke, chronic treatment with IB-MECA offers an equally significant seizure protection. In view of our results, further exploration of the therapeutic value of adenosine A3 receptor stimulation is highly warranted.

524.2

ADENOSINE ANTAGONIST DELAYS THE SUPPRESSION OF SYNAPTIC FUNCTION INDUCED BY CYANIDE (CN) IN RAT HIPPOCAMPAL SLICES. P.J. Zhu* and K. Krnjević, Anaesthesia Research and Physiology Departments, McGill University, Montréal, PQ, H3G 1Y6, Canada.

Acute exposure to cyanide causes a variety of CNS symptoms. The exact mechanisms are not understood. In the present experiments, evoked population spikes were recorded in the CA1 region. CN rapidly, but reversibly inhibited population spikes: with 5 µM CN and 10 µM CN (for 5 min, in the bath), population spikes were reduced by $19 \pm 2.9\%$ (\pm S.E., n=3) and $29 \pm 2.5\%$ (n=9), respectively; with 50 µM and 100 µM CN, they were fully blocked in 5 out of 9 slices and 9 out of 9 slices, respectively; and the respective 50% reduction times were 138 ± 6.9 s and 115 ± 6.4 s. Though field EPSPs were also decreased, they were more resistant to CN. The adenosine receptor antagonist 8-sulphophenyl theophylline (8-SPT) strongly delayed the CN-induced suppression of population spikes: the 50% reduction times being 119 ± 6.7 s before, and 189 ± 14.3 s during the application of 1 µM 8-SPT (n=7); in 10 µM 8-SPT, 5 min of CN reduced population spikes by a maximum of only $41 \pm 4.4\%$ (n=8). 8-SPT's effects could be washed out. Conversely, the action of CN was potentiated by the adenosine transport blocker dipyrindamole (1 µM, n=5). The ATP-sensitive K-channel blocker gliburide did not alter the CN-induced suppression of population spikes (n=8). The present results indicate that adenosine release contributes to the suppression of synaptic transmission induced by cyanide.

K⁺-INDUCED ATP RELEASE FROM ORGAN OF CORTI OF THE INNER EAR MEASURED BY LUCIFERIN/LUCIFERASE BIOLUMINESCENCE ASSAY IN VITRO. P. Wangemann* and D.C. Marcus, Cell Physiology Lab and Biophysics Lab, Boys Town National Research Hospital, Omaha, NE 68131

Purinergic receptors for ATP have been identified in several cell types within the organ of Corti including outer and inner hair cells, Deiter's and Hensen's cells. The presence of purinergic receptors suggested that there is a source of ATP within the organ of Corti. However, stimulus-induced release of ATP from the organ of Corti has never been demonstrated. In the present study, we measured ATP as rate of photons released by a luciferin/luciferase bioluminescence assay. Organ of Corti was microdissected from the inner ear of the gerbil and placed into a perfusion chamber on the stage of an inverted microscope. Addition of luciferin/luciferase bioluminescence assay caused virtually no increase of the baseline photon count. However, substitution of 40 mM K⁺ for an equimolar amount of Na⁺ caused a rapid increase in the rate of photons counted. These data suggest that the organ of Corti contains a source of ATP which can be released upon depolarization with K⁺. Even though it has been speculated, based on analogy to other cholinergic systems, that ATP is coreleased with acetylcholine from cholinergic efferent nerve terminals, the source of ATP within the organ of Corti remains to be determined.

CHARACTERIZATION OF MAMMALIAN ARGININE DECARBOXYLASE (ADC) AND ITS DISTRIBUTION IN BRAIN. G. Li*, S. Regunathan & D.J. Reis. Div. of Neurobiol., Dept. of Neurol. and Neurosci., Cornell Univ. Med. Coll., New York, NY 10021.

The amine agmatine (Agm) (decarboxylated arginine), is an endogenous ligand for imidazoline (I-) and α_2 -adrenergic receptors present, with its biosynthetic enzyme ADC, in bovine and rat brain (Li et al., *Science* 263:968, 1994). While prevalent in bacteria, neither Agm nor ADC have previously been found in mammalian tissue. We investigated whether mammalian ADC has unique properties. ADC was assayed by measuring conversion of ^3H -arginine to $^3\text{CO}_2$. Unlike bacterial ADC, which is cytosolic, brain ADC is membrane associated, synaptosomal, enriched in the inner membranes of mitochondria and unevenly distributed with activity greatest in cerebral cortex and hippocampus, in agreement with immunocytochemical distribution of Agm (see Wang et al., *Soc. Neurosci. Abstr.*, 1994). To partially purify ADC, rat liver mitochondria were isolated by differential centrifugation and Percoll gradients. Mitochondrial enzymes were solubilized by detergent and further purified by chromatography. Rat hepatic ADC is also mitochondrial, utilizes arginine and ornithine as substrates (K_m s of 0.75 and 0.25 mM), has pH and thermal optima of 8.23 and 25°C, respectively, and is facilitated by Mg^{2+} and inhibited by Ca^{2+} , with other ions ineffective. In contrast to most decarboxylases, ADC does not require pyridoxal phosphate (PLP) as co-factor. Difluoromethylarginine (DFMA) or -ornithine (DFMO), selective inhibitors of ADC or ornithine decarboxylase, or inhibitors of nitric oxide synthase (NMA, NMMA), an enzyme also utilizing arginine as substrate, were ineffective. We conclude: mammalian ADC is a mitochondrial-associated enzyme which differs in many characteristics from cytosolic forms of ADC in bacteria. Since many I-receptors are mitochondrial, the findings indicate that Agm interacts with receptors close to its site of biosynthesis.

SITE-DIRECTED MUTAGENESIS OF THE HISTAMINE H_1 -RECEPTOR INDICATES A SELECTIVE INTERACTION OF Asn^{207} WITH SUBCLASSES OF H_1 -RECEPTOR AGONISTS. R. Leurs*, M. J. Smit, C. P. Tensen*, A. M. Ter Laak and H. Timmerman. Leiden/Amsterdam Center for Drug Research, Department of Pharmacology and Graduate School for Neurosciences, Department of Biochemistry and Molecular Biology*, Vrije Universiteit, De Boelelaan 1083, 1081 HV Amsterdam, The Netherlands

The cloning of gene encoding the H_1 -receptor made it possible to study the interaction of subtype specific ligands with the receptor protein. In this study we investigated the role of the Asn^{207} and the Thr^{203} residues in TM5 of the guinea-pig histamine H_1 -receptor by site-directed mutagenesis to non-functional alanines.

After stable expression of the receptor mutants in Chinese Hamster Ovary cells the pharmacological properties of the receptor proteins were investigated by [^3H]mepyramine binding studies and [^3H]inositol phosphate accumulation. Whereas the Thr^{203} is not important for the action of histamine, the Asn^{207} residue appears to be involved in the binding of the N^{ϵ} -nitrogen atom of histamine and its 2-methyl analogue. For the 2-(3-bromophenyl)-analogue and the non-imidazole H_1 -receptor agonists 2-pyridylethylamine and 2-thiazolylethylamine the Asn^{207} residue is not essential for binding. On the basis of this study we conclude that different histamine H_1 -receptor agonists interact in different ways with the receptor proteins. Moreover, we speculate that the interaction with the N^{ϵ} -nitrogen atom is essential for receptor activation.

524.9

HISTAMINE DYSFUNCTION IN THE RED NUCLEUS CAN PRODUCE TORSIONAL DYSTONIA WHICH IS RELIEVED BY DIPHENHYDRAMINE, PYRILAMINE, OR CIMETIDINE. M.R. Stone, J.L. Vant Groenewout, V. Vo, D.D. Truong*, R.R. Matsumoto. Department of Neurology, Univ. of California Irvine, Irvine, CA 92717.

It has previously been shown that diphenhydramine hydrochloride (Benadryl) eliminates or reduces symptoms of dystonia in human patients with acute dystonic reactions and idiopathic torsion dystonia. This study demonstrates that beneficial effects of diphenhydramine in the treatment of idiopathic torsion dystonia are related to the H_1 -selective antihistaminergic actions of the drug. In addition, the H_1 antagonist pyrilamine and the H_2 antagonist cimetidine effectively reduce the symptoms of idiopathic torsion dystonia. Our data also provides support to previous research which has implicated the red nucleus in the pathophysiology of dystonia. The effects of drugs injected into the red nucleus of rats were observed by measuring the angle of deviation of the head from the horizontal plane. A significant rotation of the head is indicative of dystonia. Histamine (dose range 0-10 nmol) produced dose dependent dystonia in rats ($P < 0.002$). The dystonia produced by a high dose of histamine (10 nmol) could be antagonized by coadministration of diphenhydramine ($P < 0.01$), pyrilamine ($P < 0.05$), and cimetidine ($P < 0.04$). Significantly more dystonia was observed when histamine was injected into the red nucleus rather than midbrain areas surrounding the structure ($P < 0.002$). These results indicate that the beneficial effects of diphenhydramine, pyrilamine, and cimetidine in reducing symptoms of idiopathic torsion dystonia occur via a histaminergic pathway involving the red nucleus.

FLUOXETINE AND MOUSE BRAIN NOREPINEPHRINE TURNOVER: A PRELIMINARY STUDY RELEVANT TO THE MECHANISM OF DRUG-INDUCED AKATHISIA. L.M. Hall*, G.M. Anderson, and D.J. Cohen. Child Study Center, Yale Univ. School of Medicine, New Haven, CT 06520.

Akathisia, or restlessness, can be a debilitating side effect in patients treated with neuroleptics, tricyclics, and serotonin selective reuptake inhibitors. The amelioration of akathisia by propranolol or clonidine, and the development of akathisia-like symptoms after administration of β -agonists, suggest that the noradrenergic system may play a critical role in the pathophysiology of akathisia. Reports of fluoxetine (FL)-induced akathisia, and a possible relationship between drug-induced akathisia and suicidality, make the study of FL's effects on the noradrenergic system of particular interest.

In limited previous neurochemical research, acute FL has been reported to increase the norepinephrine (NE) metabolite MHPG-SO, in rat hypothalamus by 50-60% (Perry and Fuller, *Neurosci. Abstr.*, 1991, p. 1178), while G.A. Smythe et al. (1988) have reported increased hypothalamic NE turnover after combined treatment with FL and 5-hydroxytryptophan. There are also several recent reports of increased extracellular fluid NE after acute FL.

We have examined FL's acute (2 hr) and subacute (4 day) effects on mouse fore-brain, hindbrain, and hypothalamic NE turnover. No significant changes in regional MHPG levels or MHPG/NE ratios were observed after 2 hr or 4 day treatment with either 1 or 10 mg/kg ip FL. The noradrenergic agents clonidine (1 mg/kg) and yohimbine (5 mg/kg) were observed to markedly and significantly alter MHPG levels and MHPG/NE ratios in the expected manner. Additional data will be presented regarding the effects of acute and chronic haloperidol and imipramine, and chronic FL, in mice, as well as the acute effects of FL in rats. The preliminary results do not provide support for the idea that acute and subacute FL may produce akathisia through increases in central NE functioning.

THE GUINEA PIG HISTAMINE H_2 RECEPTOR: GENE CLONING, TISSUE EXPRESSION, AUTORADIOGRAPHIC MAPPING AND CHROMOSOMAL LOCALIZATION OF ITS HUMAN COUNTERPART. E.Traiffort, M.L.Vizuete, M. Ruat, J. Tardivel-Lacombe, V. Dimitriadou*, M.L. Bouthenet and J.C. Schwartz. U.109 de l'INSERM, Centre Paul Broca, 75014 Paris.

The screening of a guinea pig genomic library, using DNA probes derived from the sequence of the rat histamine H_2 receptor, allowed us to isolate an intronless gene encoding a protein of 359 amino acids displaying all major features of G protein-coupled receptors and a 84% homology with the rat histamine H_2 receptor. Northern blot analysis, performed with a specific C-terminal tail DNA probe derived from the guinea pig sequence revealed a 4.6 kb transcript in various guinea pig tissues. In brain, a high expression was found in striatum, brainstem, olfactory tubercles and bulb. A signal was also present in hippocampus, cerebellum, hypothalamus, thalamus, substantia nigra. In peripheral tissues, the expression was detected in stomach, lung and heart, where the labelling was very high in ventricles but hardly detectable in atrium. *In situ* hybridization studies showed the highly contrasted guinea pig cerebral expression of the H_2 -receptor gene transcripts which was compared to a detailed autoradiographic mapping of the receptor using [^{125}I]iodoaminopotentidine. There was a rather good agreement between the distribution of the two markers. A high labelling was detected in striatum, Calleja islands, olfactory tubercles, cortex, hippocampus, pontine nuclei, inferior olive. Amygdaloid complex, lateral geniculate nucleus, superior colliculi and median thalamus were also labelled. An interesting discrepancy exists, however, in the hippocampal complex where the binding sites were high in the molecular layer, whereas the mRNA were localized in the pyramidal or granular cell layers. Finally, using a chromosome mapping panel constructed from somatic cell hybrids, we assigned the human histamine H_2 -receptor gene to chromosome 5 showing that the genes encoding the H_1 - and the H_2 -receptor are not clustered.

ADENOSINE-DOPAMINE INTERACTION IN THE VENTRAL STRIOPALLIDAL SYSTEM: A NEW FOCUS FOR THE TREATMENT OF SCHIZOPHRENIA. S. Ferré*, W.T. O'Connor*, P. Snaprud*, U. Ungerstedt* and K. Fuxe*. Dept. of Neurochemistry, C.S.I.C., 08034 Barcelona, Spain. *Department of Neuroscience and *Department of Physiology and Pharmacology, Karolinska Institute, S171 77 Stockholm, Sweden.

Recent studies have shown the existence of a specific antagonistic interaction between adenosine A_{2A} receptors and dopamine D_2 receptors in the brain. This A_{2A} - D_2 interaction seems to be essential for the behavioural effects of adenosine agonists and antagonists, like caffeine. In the present study quantitative receptor autoradiography and brain microdialysis were combined to demonstrate a powerful antagonistic A_{2A} - D_2 interaction in the ventral striopallidal system. In the presence of the A_{2A} agonist CGS 21680, dopamine exhibited a lower efficacy in displacing the radiolabelled D_2 receptor antagonist [^{125}I]iodosulpride from the rat ventral striatum, specially in the nucleus accumbens. A tonic dopaminergic modulation of the striopallidal neurons from the ventral striopallidal system was demonstrated by a dual-probe approach, by infusing selective dopamine agonists and antagonists in the nucleus accumbens and by measuring dopamine extracellular levels in the nucleus accumbens and GABA extracellular levels in the nucleus accumbens and in the ipsilateral ventral pallidum. The infusion of CGS 21680 in the nucleus accumbens induced the same postsynaptic changes as the D_2 antagonist raclopride, i.e., an increase in pallidal GABA extracellular levels, without changing those levels in the nucleus accumbens. Furthermore, the coinfusion in the nucleus accumbens of low concentrations of CGS 21680 and raclopride, which were ineffective when administered alone, induced a significant increase in pallidal GABA extracellular levels. These results suggest that A_{2A} agonists, alone or in combination with D_2 antagonists, could be advantageous antischizophrenic drugs, as blockade of D_2 receptors in the ventral striopallidal system appears to be associated with the antipsychotic activity of neuroleptics but not with their extrapyramidal motor-side effects.

EFFECT OF CHRONIC NEUROLEPTIC ADMINISTRATION ON RAT STRIATAL ADENOSINE-2 (A-2) RECEPTOR DENSITY. B. Parsons, D. Togasaki*, S. Kassir, S. Przedborski. Depts. of Psychiatry and Neurology, Columbia University, New York, NY 10032.

We have demonstrated synergistic interactions between adenosine-2 (A-2) and dopamine-2 (D-2) receptors in a behavioral rat model. Because A-2 and D-2 receptors are co-localized on the same type of striatal neuron, we studied the effects of chronic neuroleptic administration (typical and atypical) on striatal A-2 and D-2 receptors in rat brain. Rats received 21 daily injections (i.p.) of haloperidol (1.5 mg/kg), fluphenazine (1.5 mg/kg), sulpiride (100 mg/kg), clozapine (20 mg/kg), or saline. Striatal receptor density (B_{max}) and affinity (K_d) values for [3H]CGS21680-labeled A-2 receptors and [3H]sulpiride-labeled D₂ receptors were measured using homogenate binding. Haloperidol and fluphenazine significantly increased (>30%) striatal A-2 and D-2 receptor density, whereas sulpiride and clozapine had no significant effect. K_d values for [3H]CGS21680 were unchanged in all groups. Thus, we observed significant increases in the density of A-2 receptors in rats striatum following chronic administration of typical, but not atypical, neuroleptics. The findings may be relevant to the mechanisms by which typical neuroleptics produce tardive dyskinesia, and may be of relevance to other neurologic and psychiatric disorders.

STIMULATORY EFFECTS OF SUB-ANESTHETIC DOSES OF KETAMINE, A PSYCHOTROPIC NMDA RECEPTOR ANTAGONIST, ON THE OUTFLOW OF DOPAMINE AND GLUTAMATE IN THE PREFRONTAL CORTEX. B. Moghaddam and M.L. Bolinao*, Dept. of Psychiatry, Yale Univ. Sch. Med. and VA Med. Ctr. 116A/2, West Haven, CT 06516.

Sub-anesthetic doses of ketamine, a non competitive NMDA-receptor antagonist, cause several schizophrenia-like symptoms in non-schizophrenics including impaired performance on frontal lobe sensitive tests (Krystal et al., Arch. Gen. Psychiat. 1994). In this study, intracerebral microdialysis in conscious rats was used to assess the effect of ketamine on the extracellular levels of dopamine and glutamate in the prefrontal cortex. A thorough dose-response study indicated that sub-anesthetic doses (10, 20, and 30 mg/kg, i.p.) of ketamine increase glutamate levels while the anesthetic dose of 100 mg/kg decreases these levels. An intermediate dose of 50 mg/kg was without an effect. This finding is similar to our previous data with other types of NMDA receptor antagonist, and may be attributed to activation of an NMDA-type autoreceptor on glutamatergic terminals. Administration of 30 mg/kg ketamine, and not 100 mg/kg ketamine, also increased the release of dopamine in the prefrontal cortex. Local infusion of the non-NMDA receptor antagonist, CNQX, blocked the stimulatory effect of ketamine on dopamine release. Although the behavioral effects of the sub-anesthetic doses of ketamine have been attributed to post-synaptic inhibition of the NMDA receptor, this study indicates that ketamine may exert some of its effect by increasing the levels of endogenous excitatory amino acids, thus, causing a stimulation of post synaptic (non-NMDA) excitatory amino acid receptors. EXTRASTRIATE VISUAL CORTEX: PARIETAL AREAS II

525.1

EFFECTS OF VESTIBULAR AND NECK PROPRIOCEPTIVE SIGNALS ON VISUAL RESPONSES IN POSTERIOR PARIETAL CORTEX.

L.H. Snyder*, R.A. Andersen, Division of Biology, Caltech, Pasadena CA, 91125.

Eye, head and body position modulate the discharge of retinotopically tuned units in posterior parietal cortex (PPC). The conjunction of retinal and extraretinal signals may aid coordinate transformations from visual to body- or world-centered reference frames. We investigated the sensory modalities responsible for extraretinal signals in areas 7a and LIP of macaque monkeys.

Vestibular signals mediated effects of body position in space on single units in PPC. Animals were seated on a vestibular turntable in a light-proof room. Saccades to retinotopically identical locations were elicited after whole-body displacement in the dark. The discharge of single units was influenced following rapid (10 d/s/s) but not gradual (0.04 d/s/s) rotations (7/8 cells), ruling out unintentional auditory, visual or other cues to body position in space.

Neck proprioceptive signals mediated effects of head-on-body position. Proprioceptive, vestibular and visual signals may all be affected by head displacement. To show that changes in proprioceptive signals alone were sufficient, whole-body rotation in the light was followed by counter-rotation of the head back to the starting position in the dark, resulting in body but not head displacement. Identical saccades subsequently elicited in the dark revealed single unit modulation identical to that obtained by merely rotating the head on a stationary body (11 units).

Vision influenced the effect of position in space on single units. Following whole body rotation in the light, responses to identical saccades elicited in the dark were often modulated by body position (8/22 units). In contrast, body position was much less likely to effect saccadic responses following whole body rotation in the dark (7/58 units). Our results suggest that in the absence of vision, the PPC boosts its reliance on vestibular signals.

525.2

MAPPING VISUAL SPACE AROUND THE ARM WITH BIMODAL VISUAL-TACTILE NEURONS. Michael S. A. Graziano* and Charles G. Gross. Department of Psychology, Princeton University, Princeton, NJ 08544.

Neurons in the ventral portion of area 6, in the frontal lobe, may help to encode the locations of objects in nearby, extrapersonal space. In monkeys, these neurons often respond to both visual and tactile stimuli. They have tactile receptive fields (RFs) on the face or limbs, and corresponding visual RFs, which extend outward from the tactile RFs about 20 cm into the space surrounding the body.

We recorded from neurons in the arm representation of area 6 in awake fixating macaques, and studied the effect of placing the animal's arm in different locations. For most cells with tactile RFs on the arm or hand, when we moved the arm, the corresponding visual RF moved with it. However, when we moved the fixation point, the visual RF remained stationary, "attached" to the arm. Thus, these neurons appear to code the location of visual stimuli with respect to the arm, independent of eye position. These "arm centered" neurons may be useful for hand-eye coordination.

525.3

EGOCENTRIC MOTION FROM OPTIC FLOW AND EYE POSITION IN AREA 7A OF THE BEHAVING MACAQUE. R.M. Siegel* and H.L. Read, Center for Molecular and Behavioral Neuroscience, Rutgers University, Newark, NJ 07102.

Eye position and optic flow can be combined to determine heading in head-centered coordinates. Recordings were made from area 7a while the monkey was performing a reaction time visual perceptual task. The random dot motion stimuli elicited percepts of translation, planar rotation, radial expansion or compression, or three-dimensional shape. No neurons were found to be selective for the three-dimensional shape from motion stimulus. The absence of neurons in area 7a selective for three-dimensional shape is in accordance with the proposed division of visual processing into a what and where pathway (Ungerleider and Mishkin, 1983).

Area 7a neurons were found with translation, radial, and planar rotational selectivity or various combinations (Read et al., 1994). For example single neurons could be selective to both clockwise rotation and radial expansion. This suggested that there might be cells selective to spiral motion as predicted earlier on psychophysical grounds (Anderson and Siegel, 1993). Neurons were found with selectivity to particular spiral motions (e.g. clockwise compression). Thus there seems to be a coarse coding for the type of structured motion in area 7a which could in principle be used to determine heading.

The dependence of the response of these optic flow selective neurons on the retinal locus of the stimulus was examined. The 20° diameter patterns were moved to different locations on a 10° by 10° grid. Area 7a neurons did not respond with equal activity at all locations. This retinotopic tuning is dissimilar to the spatial invariance for position reported in some MST neurons (Tanaka et al., 1986; Duffy & Wurtz, 1991; Lagae et al., 1994).

Combination of these retinotopic position dependent signals with eye position signals could be used to determine egocentric motion in body coordinates. To test this, a particular optic flow was presented while eye position was systematically varied; the retinal locus of the center of the pattern remained constant under these conditions. Although the relative motion selectivity of area 7a neurons did not change with eye position, the strength of the responses was modulated by eye position. Using multi-variate linear regression it was found that about half of the cells exhibited a linear dependence on the horizontal and/or vertical eye position at the p<0.05 level. In summary, using carefully controlled psychophysical stimuli, neurons in area 7a were shown to be selective to many different optic flow patterns. These visual responses were dependent on eye position providing signals needed to compute egocentric heading. Support: NIH EY09223 and ONR N00014-93-1-0334.

SPACE CELLS IN THE DORSAL STREAM: OPTIC FLOW SELECTIVITY IN AREA 7A. H.L. Read*, C.A.M. Nogueira, K.C. Anderson and R.M. Siegel, Center for Molecular and Behavioral Neuroscience, Rutgers University, Newark, NJ 07102.

The opponent vector selectivity and angle of gaze sensitivity of area 7a neurons lead to the hypothesis that these cells are involved in the construction of an egocentric space (Anderson et al., 1985; Motter et al., 1987). We have examined the response properties of area 7a neurons in three hemispheres of two monkeys to a host of egocentric motion patterns to further test this hypothesis. Single unit recordings of neurons in area 7a were obtained from monkeys performing a reaction time task. Trials were initiated when the monkey pulled a lever and fixated a 3° square. A visual stimulus appeared 2000 msec after trial initiation; 1500 to 4000 msec later a change in visual stimulus or fixation point was the cue to release a lever and end the trial. Visual receptive fields were mapped with a 10° bar of light in a 40° x 40° grid. Light sensitive neurons responded to a bar of light with a brief increase in firing rate following stimulus onset and offset. RFs covered from 100 to 1600 deg² of the test area and often included the central region of fixation. The response selectivity to radial, rotation and spiral motion was assessed at one position within a neuron's RF. Test displays were presented in a structured motion to unstructured motion sequence or vice versa. Neurons were selective for stimulus type if the change in firing rate in the 500 msec interval following stimulus onset varied with stimulus type (ANOVA; p<0.05). Selectivity for both structure (translation, radial, rotation) and direction of motion (e.g. expansion vs. compression) were observed. When the initial stimulus was a structured motion of the preferred type, tonic responses often lasted for the 1500 to 4000 msec period prior to unstructuring of the display. In contrast, the response following onset of non-preferred or unstructured motion was phasic as seen with a stationary bar of light. The transition from unstructured motion to structured motion evoked a phasic response that occurred either before or on the key release. The selectivity at this transition was the same as that selectivity associated with the structured motion onset. For the majority of neurons, the RF for optic flow stimuli overlapped with that of the classical RF. The magnitude of response varied with retinotopic position, but the selectivity did not. These findings suggest that the structure and/or direction of optic flow is indeed a salient feature for area 7a neurons. Supported by NIH EY09223 and ONR N00014-93-1-0334.

OPTIC FLOW RESPONSES OF MST NEURONS DURING PURSUIT EYE MOVEMENTS. C. J. Duffy¹ and R. H. Wurtz. Dept. of Neurology, Univ. of Rochester Med. Ctr., Rochester, NY 14642, and Lab. of Sensorimotor Research, National Eye Inst., NIH, Bethesda, MD 20892.

The retinal image of an optic flow field is altered by concurrent smooth pursuit eye movements, complicating the task of interpreting that image. Information about pursuit, if available to the visual system, might simplify that interpretation. We recorded the responses of 117 MST neurons to optic flow stimuli, during fixation and smooth pursuit, to determine whether the response of these cells is altered by smooth pursuit.

We recorded from 117 single neurons in area MST in two monkeys. We first determined which optic flow pattern (radial or circular) evoked the strongest response when the center of motion (COM) was centered on the screen. We then presented the preferred pattern, with 8 other stimuli created by combining it with 8 directions of planar motion, shifting the COM to 8 different positions in the stimulus. Ninety-four percent of the neurons responded differently to the centered and shifted COMs. Each neuron was then tested with the centered COM during smooth pursuit in 8 different directions. Eighty-five percent of the neurons showed different responses to different pursuit directions. We compared the shifted COM response with those to pursuit across the centered COM, and found that most neurons (61%) had the same response to the retinal image, whether it was created by optic flow, or optic flow with pursuit. However, 39% responded differently when pursuit effects contributed to the retinal image. In addition, over half of the neurons (56%) responded during smooth pursuit across a blank screen.

These studies suggest that some MST neurons access both optic flow and smooth pursuit signals, potentially contributing to optic flow analysis during smooth pursuit eye movements.

525.7

RELIABLE TEMPORAL MODULATION IN CORTICAL SPIKE TRAINS IN AWAKE MONKEY W Bair¹, C Koch¹, WT Newsome², KH Britten³. ¹Computation and Neural Systems, Caltech, Pasadena, CA 91125; ²Dept. of Neurobiology, Stanford Univ., Stanford, CA 94305; ³Center for Neuroscience, UC Davis, Davis, CA 95616.

We analyzed the repeatability and precision of temporal structure in spike trains recorded from area MT in behaving rhesus monkeys which viewed a dynamic random dot stimulus that did not vary from trial to trial (no-var data; Newsome, Britten, and Movshon, 1989). We find a surprising degree of regularity in the temporal modulation of the response of many cells—the most reliable cells will fire a few isolated action potentials or show a period of elevated firing which begins and ends fixed in time relative to stimulus onset with a standard deviation of less than 4 msec in recording periods which may last many minutes to hours. Spike count during these short periods of elevated firing rate is more reliable, i.e. has a lower variance to mean ratio, on average than the spike count taken over the entire 2 sec stimulus. Onset and offset of high firing periods can occur with very similar and fast time constants. Autocorrelation analysis reveals that deviations from the mean response are rarely substantially correlated beyond 100 msec, and in half of cells no correlation exists between consecutive interspike intervals beyond that predicted from the time-varying mean firing rate. Reliable temporal modulation disappears or diminishes for completely coherent motion stimuli, and we propose an experiment to determine whether this is due to saturation in firing rate or due to a qualitative change in the way MT cells respond to the stimulus.

525.9

SINGLE NEURONS IN POSTERIOR PARIETAL CORTEX MAY REPRESENT BASIS FUNCTIONS FOR SPATIAL TRANSFORMATIONS. A. Pouget^{*} and T. J. Sejnowski. Howard Hughes Medical Institute, Salk Institute, La Jolla, CA 92037

Many neurons in the monkey posterior parietal cortex have gaussian visual receptive fields that are modulated by a monotonic function of eye position, called the gain field. Similar gain fields have been observed in neural networks that compute the head-centered position of objects (Zipser and Andersen, Nature, 1988), suggesting that populations of parietal neurons may form a distributed representation of the egocentric position of objects.

There is an alternative interpretation for these gain fields in the context of sensori-motor transformations. Motor commands generated from the retinal location of an object and the current eye position are nonlinear functions of these inputs. Such transformations can be approximated by using a single intermediate representation in which neurons compute basis functions of the sensory inputs. We propose that the parietal cortex contains such an intermediate representation. A gain field can be modeled as a gaussian function of retinal location multiplied by a sigmoidal function of eye position, which is known to form a basis function. This raises the possibility that the parietal cortex does not attempt to compute the positions of objects in a particular frame of reference but instead computes a general purpose representation of the retinal and eye position from which any transformation can be synthesized by direct projection. This representation predicts that hemineglect, a neurological syndrome produced by parietal lesions, should not be confined to egocentric coordinates but should be observed in multiple frames of reference in single patients, a prediction supported by several experiments.

525.6

RESPONSES OF LIP NEURONS DURING A MOTION DISCRIMINATION TASK: A DECISION PROCESS IN ACTION?

MN Shadlen^{*}, JM Groh, CD Salzman & WT Newsome. Depts. of Neurobiology and Neurology, Stanford University, Stanford, CA 94305

Visually guided behavior requires selection or decision processes that identify one among many possible objects as the target of a movement. We investigated one such decision mechanism in a rhesus monkey trained to discriminate the direction of motion in a visual display and to indicate its decision by executing a saccade to one of two possible targets. During performance of the task, we recorded from neurons in LIP, a parietal area that receives projections from MT and MST and participates in the planning of saccades.

In each experiment, we placed one potential saccade target within, and the other outside, the movement field of the neuron under study. Each trial contained a 2 sec stimulus presentation followed by a 0.5-1 sec delay period prior to the saccade. Not surprisingly, delay period activity of LIP neurons reliably predicted the monkey's eye movement: activity was stronger on trials in which the monkey chose the direction of motion toward the movement field. More interestingly, LIP neurons also signaled the monkey's impending choice during the stimulus presentation interval, well before the saccade. This predictive activity built up earlier and was more reliable for easy than for hard discriminations (strong vs. weak motion signals). In other words, LIP neurons appeared to accumulate evidence regarding the direction of motion in the stimulus and to maintain a response suitable for guiding the appropriate saccade. Little evidence for this kind of activity was observed in control blocks of trials in which the same stimuli were presented, but the animal was not required to perform the direction discrimination. Thus the activity of LIP neurons may reflect an active decision process in which sensory signals are evaluated to inform target selection. Supported by NEI (EY05603), training grant NS 07158-14, and HHMI.

525.8

INTEGRATION OF MOTION AND STEREO CUES IN MACAQUE VISUAL AREA MT. D.C. Bradley¹ and R. A. Andersen. Division of Biology, California Institute of Technology, Pasadena CA 91125.

Most neurons in primate middle temporal cortex (MT) are highly sensitive to motion in a particular direction, but are inhibited when an opposing movement occurs simultaneously in their receptive field. An important benefit of this "motion opponency" is that random motion signals created by non-motion stimuli (e.g. flicker) tend to cancel each other out. However, motion opponency may also lead to impaired MT responses under conditions of transparent motion, where motion direction signals are often locally opposed and as such tend to negate each other in MT. We hypothesized that this problem might be overcome if opponency between signals from different visual depths (and thus different surfaces) did not occur. To test this idea, we stimulated 146 MT neurons with a random dot pattern moving in the preferred direction and at the optimal disparity (i.e. depth) for a given cell. A second pattern moving in the antipreferred direction was introduced, and the suppression due to this pattern was measured as a function of its disparity. In ~40% of the cells, suppression was greatest when the antipreferred disparity was similar to the disparity of the preferred pattern and decreased substantially as the patterns became separated in depth. Further studies in which the disparity of the preferred pattern was altered showed that the maximally-suppressive antipreferred disparity tended to coincide with the cell's optimal disparity (as defined for preferred motion) regardless of the actual disparity of the preferred pattern. Our findings thus suggest that motion opponency in MT occurs mainly within a given disparity channel. This disparity-specific opponency favors the cancellation of random motion signals from a given depth, while allowing independent representation of surface movements at different depths.

525.10

EXPLICIT SPATIAL REPRESENTATION IN PARIETAL CORTEX IS NECESSARY FOR PROPER CONJOINING OF VISUAL FEATURES

S.R. Friedman-Hill^{1,2}, L.C. Robertson^{1,2} and A. Treisman³. ¹Center For Neuroscience, UC-Davis, Davis, CA 95616; ²Veterans Administration, Martinez, CA; ³Princeton University, Princeton, NJ

Research with human and non-human primates implicates parietal cortex in spatial attention. Our studies of a patient with remarkably symmetrical, bilateral parietal lesions due to embolic infarcts suggest that spatial deficits may also contribute to impaired object perception.

The patient, RM, is frequently unable to make explicit spatial judgments. When asked to judge the position of a single object (left, right, or center, in one condition; up, down, or center in another), RM was incorrect for 30% of the trials. This deficit in judging the location of one item was not further increased by the presence of an irrelevant distractor. However, if asked to judge the location of the first item relative to the second item, RM's performance fell completely to chance.

Concomitant with these spatial deficits, RM has a tendency to misjoin features of objects. Errors of this type are referred to as "illusory conjunctions." For example, when presented with a red X and a blue O, he may report seeing a red O, even with free viewing (display times up to 5 sec) and undivided attention. Neurologically normal subjects produce illusory conjunction errors only under divided attention conditions with very short exposures. RM makes fewer illusory conjunction errors with sequential presentation of stimuli than with simultaneous presentation. In the absence of reliable spatial information, temporal information can be used to organize which features should be conjoined.

The data suggest that there are important interactions between the "what" and the "where" pathways. Spatial information plays an integral role in the construction of our percepts of objects from neurally distributed features.

A MODEL FOR COMBINED EYE-HEAD TRACKING INCORPORATING THE PROPERTIES OF MSTI VT-NEURONS. P.W. Dicke and P. Thier. Dept. of Neurology, University of Tübingen, 72076 Tübingen, Germany

Combined smooth eye-head-tracking (CEHT) is carried out by primates in order to stabilize the retinal image of a moving object on or close to the fovea. We have tested the idea that the generation of CEHT is based on a signal related to target velocity in space, reconstructed in a spatially distributed manner at the level of parietal area MSTl. Two 3-layered connectionist networks were used in order to represent area MSTl on the left and on the right side of the brain respectively. The input layer of each of the two "MSTl" networks was made up of units, sensitive to retinal image slip, eye velocity and head velocity with identical directionalities. Further experimental findings build into the networks were the speed-tuning of VT-neurons and the distribution of their preferred directions, characterized by the fact that every direction between 0 and 360 deg may be found on either side of the brain with a possible bias for ipsiversive directions. Using error backpropagation the "MSTl" networks could be trained successfully so that the sum of the outputs of the two networks equalled target velocity in space. Assuming a fully activated VOR and furthermore taking into account the established properties of the eye and head motor systems, this signal was then used to generate coordinated eye and head movements. The overall model has proven able to fit measured combined smooth eye and head movements under a wide variety of conditions. Furthermore it is able to predict the effects of experimental lesions of MSTl in monkeys: Unilateral MSTl lesions were mimicked by removing one of the two connectionist networks involved. This manipulation resulted in an ipsiversive eye-head tracking deficit, which, with respect to the eye movement part, is in full accordance with reported experimental findings. EIGHT NOVEL FMRFamide-LIKE PEPTIDES (FLPs) FROM ASCARIS SUUM. C. Cowden* and A.O.W. Stretton. Zoology Dept., Univ. of Wisconsin-Madison, 53706.

We are investigating the role of FLPs in the control of locomotion in *Ascaris*. AF1 and AF2 were isolated from extracts of 10,000 heads. Confirmation of additional sequences has been limited by the low yield of purified peptide (2-10 pmol).

We are now isolating FLPs from an acid methanol extract of 62,000 heads and male tails. After 7 HPLC steps, 8 FLPs have been isolated and their sequences confirmed by MALDI-MS. The yield of purified peptide was 70-500 pmol. Peptides AF1-AF12 range from 4-14 amino acids and have six C-terminal tetrapeptides: FIRF-, YLRF-, YMRF-, FLRF-, VLRF-, and PLRFamide. On the basis of their effects on muscle tension, 3 classes of bioactivity have been found.

This is the most heterogeneous family of FLPs reported from one species. Additional active peaks from this purification are being isolated at this time.

NEUROPEPTIDE PRODUCTS OF THE FMRFamide GENE MODULATE THE DROSOPHILA NEUROMUSCULAR JUNCTION. R.S. Hewes* and P.H. Taghert. Department of Anatomy and Neurobiology, Washington University Medical School, St. Louis, MO 63110.

The *Drosophila* FMRFamide gene encodes a complex, neuropeptide precursor protein encoding many diverse FMRFamide-related sequences. In the larval CNS, this gene is expressed in a small, stereotyped pattern of neurons, including 6 that project to the thoracic dorsal neurohemal organs. From there, FMRFamide-related peptides may be released to act on peripheral targets via the circulation. Three synthetic peptides—with sequences deduced from the FMRFamide precursor (DPKQDFMRamide, MDSNFIRamide, SVQDNFMHamide)—enhanced nerve-stimulated contractions of internal and external abdominal muscle fibers by increasing peak tension, contraction rate, and relaxation rate. These peptide effects began within 1-2 min of the onset of peptide application, reached peak strength after 3-7 min, and ceased after 10-30 min. The threshold concentrations were 10 nM for DPKQDFMRamide and MDSNFIRamide and were 10-100 nM for SVQDNFMHamide. These results suggest that 1) receptors with high affinity for FMRFamide-related peptides are located on several skeletal muscles and/or on motoneuron terminals, and 2) multiple sequences contained in the FMRFamide precursor may be functionally equivalent at the neuromuscular junction. The design of labeled peptides will be important for receptor localization and for cloning of FMRFamide receptors by functional expression. Towards this end, we found that biotinSGSGDPKQDFMRamide, an N-terminally extended form of DPKQDFMRamide, also enhanced nerve-stimulated contractions at a threshold of about 10 nM. (Supported by NIH Grants #NS21749 and #NS07071).

PHYSIOLOGICAL ACTIONS OF NINE MEMBERS OF THE MYOMODULIN FAMILY OF PEPTIDE COTRANSMITTERS AT THE B16-ARC NEUROMUSCULAR JUNCTION OF APLYSIA. V. Brezina*, B. Bank, E.C. Cropper and K.R. Weiss. Dept. of Physiology & Biophysics, Mt. Sinai School of Medicine, New York, NY 10029.

Neuromodulation by multiple related peptides with different spectra of physiological effects appears an effective way to integrate complex physiological functions. A good opportunity to study this issue is provided by the intrinsic network of modulatory peptides that regulates output of the simple ARC neuromuscular circuit of *Aplysia*. Under appropriate behavioral circumstances, ACh-induced contractions of the ARC muscle are modulated in several ways by members of at least three families of peptide cotransmitters released from the ARC's own motoneurons. In this work we have focused on the myomodulins (MMs), released from motoneuron B16. Nine MMs have now been identified, either purified from the ARC system, found encoded by a MM gene, or both (Cropper et al., *PNAS* 84:5483; *Peptides* 12:683; Miller et al., *Soc. Neurosci. Abstr.* 16:307; *J. Neurosci.* 13:3358). Previous work with MM₄ and MM₉ has shown that they both potentiate the size as well as the relaxation rate of ARC-muscle contractions at low concentrations, but only MM₄ depresses the contractions again at higher concentrations. We have proposed that the potentiation is due to enhancement of the L-type Ca current in the muscle, and the depression to activation of a K current (Brezina et al., *J. Neurosci.*, in press). We have now extended this analysis to all nine MMs. All similarly enhance the Ca current and potentiate the size, as well as the relaxation rate, of ARC-muscle contractions. In contrast, their ability to activate the K current varies greatly, and their ability to depress the contractions varies correspondingly. These results further support the modulation of the Ca and K currents as the mechanisms of the potentiation and depression, and suggest differential modulation of the size and relaxation rate of the contractions as one possible important role of the MMs at the B16-ARC neuromuscular junction.

cAMP DEPENDENT PHOSPHORYLATION OF APLYSIA TWITCHIN MAY MEDIATE MODULATION OF MUSCLE CONTRACTIONS BY NEUROPEPTIDE COTRANSMITTERS. W.C. Probst, E.C. Cropper*, J. Heierhorst, S.L. Hooper, H. Jaffe, F. Vilim, S. Baushausen, I. Kupfermann, and K.R. Weiss. Dept. Physiol. & Biophys., Mt. Sinai Med. Schl., NY, NY 10029; Ctr. Neurobio., Columbia Univ., NY, NY 10032, LNC-NINDS Protein/Peptide Sequencing Facility, and the Laboratory of Neurobiology, NINDS, Bethesda, MD 20892.

Acting via a cAMP-cAPK cascade, members of two neuropeptide families, the small cardioactive peptides and myomodulins, modulate contraction amplitude and relaxation rate in the accessory radula closer muscle of the marine mollusc *Aplysia californica*. A ~750 kDa phosphoprotein was identified in the ARC muscle as the major substrate for cAMP-dependent protein kinase activated either by application of neuropeptides or by peptides released by motor neuron stimulation at physiological frequencies. Immunoblot and immuno-electronmicroscopy experiments revealed the widespread presence of this protein in *Aplysia* muscles, and its colocalization with contractile filaments in the ARC muscle. Sequence analysis of proteolytic peptide fragments derived from the protein indicated that it is structurally related to the muscle protein twitchin. Finally, the level of neuropeptide-induced phosphorylation of the protein correlated well with peptidergic modulation of the relaxation rate of the muscle. We propose that twitchin in *Aplysia*, and perhaps in other species, may mediate the modulation of the relaxation rate of muscle contractions.

NITRIC OXIDE MEDIATES CHEMOSENSORY ACTIVATION OF FEEDING IN *LYMNAEA STAGNALIS* M.R. Elphick, G. Kemenes, K. Staras and M. O'Shea* Sussex Centre for Neuroscience, Sch. of Biol. Sci., Sussex Univ., Brighton, BN1 9QG, U.K.

We have used NADPH diaphorase histochemistry to establish the distribution of NO synthase in the CNS of the mollusc *Lymanaea stagnalis*. A dense population of stained fibers are present in the lip nerves and these are derived from a band of sub-epithelial bipolar cells located at the margins of the lips. These could be chemosensory neurons and NO may be involved in activating feeding. To test this hypothesis we used a semi-intact lip-CNS preparation where a sucrose stimulus can be applied to the lips while recording from identified neurons that control feeding. Sucrose activation of the feeding network was inhibited when the CNS was pre-incubated with the NO scavenger haemoglobin (Hb), the NO synthase inhibitor N^ω-Nitro-L-arginine or the guanylyl cyclase inhibitor methylene blue (MB). Central activation of the feeding network by current injection into the slow oscillator (SO) interneuron was not affected by Hb. Application of NO donors or 8-bromo-cGMP to the CNS also activated the feeding network. We tested the behavioural significance of these physiological experiments by injecting animals with Hb or MB before placing them in a sucrose-rich environment and monitoring feeding behaviour. Both Hb and MB delayed the onset of feeding compared to met-Hb (which should not bind NO) and distilled water, respectively. Our results indicate that NO is released in the *Lymanaea* CNS by sucrose-activated chemosensory neurons and causes cGMP-mediated activation of feeding behaviour. This is the first description of a specific behavioural role for NO in the CNS. [Supported by BBSRC grant no. GR/J3234]

SEROTONIN STIMULATION OF CILIA BEAT FREQUENCY IS MEDIATED BY AN INCREASE IN INTRACELLULAR CALCIUM IN EMBRYOS OF *HELISOMA TRIVOLVIS*. J.J. Goldberg*, K.J. Christopher, C. Neumann and J.P. Chang. Department of Biological Sciences, University of Alberta, Edmonton, Alberta, Canada T6G 2E9.

Prior to the development of crawling, *Helisoma trivolvis* embryos display a cilia-driven rotational behavior within the egg capsule. One component of this behavior, rotational surges, results from the transient stimulation of pedal ciliated cells by serotonin that is released from the identified embryonic neurons, ENCI. In order to examine the signal transduction mechanism underlying the serotonin-induced stimulation, ciliated cells were isolated from *Helisoma* embryos, plated under cell culture conditions and monitored in slow motion using time-lapse videomicroscopy. In the absence of serotonin, cilia beat spontaneously and regularly at frequencies ranging from 5-9 cycles per second. Serotonin induced a sustained, dose-dependent increase in cilia beat frequency with an EC₅₀ around 1 μM. This stimulation was not mimicked by either potassium-induced depolarization or addition of 100 μM forskolin and 200 μM isobutylmethylxanthine, a treatment that elevates the level of intracellular cyclic AMP. In contrast, addition of thapsigargin (1 μM) or A23187 (10 μM), treatments that increase the concentration of cytosolic free calcium, caused an increase in cilia beat frequency similar to that produced by 100 μM serotonin. Furthermore, the response to serotonin was prevented when cells were exposed to calcium-free medium or the voltage sensitive calcium channel blockers, nifedipine or verapamil (1 μM). These data suggest that serotonin stimulates cilia beating by causing a calcium influx in a depolarization-independent manner. Supported by NSERC of Canada.

AGE RELATED CHANGES IN SEROTONIN AND DOPAMINE NEUROTRANSMITTERS AND RECEPTORS IN *APLYSIA CALIFORNICA*. M.D. Southall, S. Shirazi, V. Chandhoke*, P.W. Royt and J.M. Flinn. George Mason University, Fairfax, VA 22030

The age associated changes in dopaminergic and serotonergic receptors were examined in *Aplysia californica*. In earlier studies (Hong, 1994) it has been shown that the levels of serotonin (5-HT), dopamine (DA) and their ratio vary with age. In this study the levels of neurotransmitter receptors were examined in the ganglia obtained from 4, 5, 6, 10 and 12 month old animals. Receptor analysis was performed using radiolabeled bound ligands specific for the receptor of interest. ³H-LSD was used to determine the saturation binding for total 5-HT and DA receptors. We report here the results for the 5 month (young) and 10 month (old) animals. Specific binding in the 5 month animals was found to be 9.9 fmol/mg of total protein for 5-HT and 8.4 fmol/mg protein for DA. For the 10 month animals, the specific binding for 5-HT was 20.9 fmol/mg protein and 16.4 fmol/mg protein for DA. This represents a two fold increase in specific binding for both 5-HT and DA in the 10 month as compared to the 5 month animals.

526.6

NITRIC OXIDE AS A PUTATIVE TRANSMITTER AT SYNAPSES BETWEEN IDENTIFIED CENTRAL NEURONS OF *APLYSIA*. J.W. Jacklet* Dept. Biol., SUNY Albany, NY 12222.

NADPH-diaphorase staining of the CNS of *Aplysia* was used to identify neurons that may contain nitric oxide synthase (NOS) and produce nitric oxide (NO). There are a few densely stained neurons in all ganglia and ca 30 bilaterally paired neurons in the cerebral ganglion, including 2 in each E-cluster. Their axons and neurites are stained and form well defined fiber tracts and synaptic glomeruli, including the lateral terminus, which is also stained by antiserum to myomodulin, a neurotransmitter / modulator. NADPH-diaphorase stains terminal processes on cell bodies of some unstained E-cluster neurons, suggestive of axo-somatic synapses. NO generated using 1 mM SIN-1 (3 morpholino-sydnonimine) and S-NC (S-Nitrosocysteine) depolarizes these neurons, induces action potentials and increases input resistance. Degassed SIN-1 and S-NC solutions have no effect. A membrane permeant cGMP analogue, 8-bromo-cGMP mimics the effect of SIN-1 and S-NC. E-cluster neurons stained by NADPH-diaphorase, and marked by dye injection, synaptically depolarize neurons that receive NADPH-diaphorase stained terminals. Consistent with NO effects, the response is calcium dependent and blocked by nitro-arginine. These results suggest that NO released from NADPH-diaphorase stained neurons acts like a neurotransmitter and depolarizes postsynaptic neurons by activating guanylate cyclase and increasing cGMP, which alters ionic conductance.

526.8

NEUROTRANSMITTER 5-HT AND DA LEVELS AND THEIR SYNTHESIS ACROSS THE LIFE SPAN OF *APLYSIA*.

C. Hong*, J.M. Flinn, R. Holt, V. Chandhoke and Tom Capo.† George Mason University, Fairfax, VA 22030, † Univ. of Miami, FL 33149.

The levels of serotonin (5-HT) and dopamine (DA) in ganglion tissue were examined for animals ranging in age from 3 to 13 months post-hatch, the tissue tryptophan and tyrosine levels were also measured using HPLC. The results indicated that 5-HT increased slowly in the ganglion from 3 to 4 months and from 7 to 13 months, however it increased rapidly in the 4 to 6 month age range. In contrast, the increase in DA was predominantly constant across the age span. The ratio of 5-HT to DA showed a strong age dependency, with the lowest values at 3, 4, 12, and 13 months and the highest ratio at 6 months. 5-HT/DA represents the excitatory to inhibitory neurotransmitter ratio. These results suggest that DA may dominate 5-HT in very young and very old animals where previous studies have shown behavioral sensitization of the Gill-siphon withdrawal reflex to be weaker. The analysis of the ratios of neurotransmitter to its precursor in the ganglion (5-HT/TRP and DA/TYR) suggests that the synthesis of neurotransmitters may be one of the factors contributing to the changes in the net neurotransmitter levels. The 5-HT/TRP ratio increased at the 6 to 8 months period and then leveled off, while the synthesis of DA/TYR ratio had a slight increase after 7 months. Further studies on the metabolic enzymes and degradation courses are underway.

EVIDENCE FOR INSULIN-LIKE PEPTIDES IN *APLYSIA* AND POSSIBLE LOCALIZATION IN THE CEREBRAL GANGLIA. L. Stadtmayer, J. Koester, N. M. McKay, D.H. Solomon, and J.H. Schwartz*. Departments of OB-GYN and Pharmacology and the Center for Neurobiology & Behavior, Columbia University College of Physicians & Surgeons, New York, NY 10032.

Vertebrate insulin can stimulate tyrosine autophosphorylation of a vertebrate insulin-like receptor in *Aplysia* bag cell neurons. We have therefore searched for peptides in *Aplysia* similar to vertebrate insulin using HPLC purification and a placental insulin-receptor autophosphorylation assay. Fractions from *Aplysia* embryos and total nervous system were purified by HPLC. One fraction both stimulates placental insulin-receptor kinase activity and competes with insulin in receptor-binding assays and in radioimmunoassays at nanomolar concentrations of the vertebrate peptide. The material in this fraction has been purified and its amino acid sequence is being determined. Input to the bag cells originates in the cerebral ganglion (Ferguson et al, *J. Comp. Physiol. A* 164: 849), which contains cells that we find may be homologous to the light green cells (LGCs) of *Lymanaea* (LGCs produce molluscan insulin-like peptides -- MIPs -- which control growth and reproduction): We find that an antiserum against R15α2 peptide cross-reacts with vertebrate insulin as well as with the material that purifies as insulin. Immunocytochemical studies with this antiserum stain two bilateral clusters of neurons in the cerebral ganglion that appear homologous to the LGC clusters in *Lymanaea*. Since these cells do not express R15α2, this antiserum may be recognizing another peptide. As in *Lymanaea*, the neurons in *Aplysia* that exhibit this insulin-like immunoreactivity send processes to neurohaemal organs at the base of the lip nerves. Further studies are in progress to determine whether these LGC-like clusters are the source of the insulin that acts on bag cell neurons.

ASSAY FOR CYCLIC AMP LEVELS, SYNTHESIS AND DEGRADATION AT THE MEMBRANE OF LIVE MOLLUSCAN NEURONS. Sudlow, L.* and Gillette, R. Dept. of Physiology and Biophysics, Univ. of Ill, Urbana, IL 61801

Neurons exhibiting cyclic AMP-gated current ($I_{(Na,cAMP)}$) allow *in vivo* assay of cyclic AMP levels, synthesis and degradation (Huang and Gillette, '91, J.Gen.Physiol. 98:835, '93, J.Physiol.462:307; Sudlow, et al., in prep.). We have estimated 1) the concentration of cAMP due to stimulation by 5-HT; 2) 5-HT stimulated adenylate cyclase activity; and 3) phosphodiesterase rate constants. Occlusion of $I_{(Na,cAMP)}$ by 5-HT-induced current, and the voltage-dependent inactivation associated with both cAMP injection and neuromodulators, indicate common modes of action. The procedure requires establishing: 1) the dose response relationship for $I_{(Na,cAMP)}$ with steady-state cAMP iontophoretic current; 2) occlusion assay of $I_{(Na,cAMP)}$ with neuromodulator; 3) analysis of phosphodiesterase rate constants; and 4) measurement of cell diameter. Calculations yield an estimate of adenylate cyclase activity per sec per unit membrane area. We have estimated the adenylate cyclase activity in pedal ganglion G neurons in *Pleurobranchaea* during 10 μ M 5-HT stimulation to range from 0.98 to 2.77 pmol \cdot cm $^{-2}$ sec $^{-1}$, averaging 1.59 \pm 0.31 (n=5). 5-HT-induced cAMP concentrations at the membrane ranged from 4.94 to 12.14 μ M, averaging 7.68 \pm 1.22 μ M (n=5). Supported by NIH grant RO1 NS26838-01 to R.G.

A SUBDIVISION OF OCTOPAMINE NEUROSECRETORY CELLS IN THE LOBSTER. P. Bräunig, I. Walter, H. Schneider* & E.A. Kravitz. Neurobiol. Dept., Harvard Med School, Boston, MA 02115.

Octopamine (OA) and serotonin (5HT) appear to participate in the regulation of aggressive behavior in lobsters (*Homarus americanus*). Injections of OA generate extended postures resembling those seen in submissive lobsters, while 5HT injections trigger flexed postures typical of dominant lobsters. We have mapped OA- and 5HT-immunoreactive neurons in the lobster CNS and identified 4 5HT and 28 OA neurosecretory cells likely to be important in this postural regulation. Within the OA group, immunostaining appears gradually throughout embryonic and larval development. This suggests that the OA system might be divided into subsets showing coincidental appearance of immunostaining and function. Here we describe one such subset. It includes 3 pairs of cell bodies located in the 3rd and 4th thoracic ganglia that selectively innervate the claws. Projections of these cells were traced through the paramedian nerves that run parallel to the nerve cord into the 1st roots of 1st thoracic ganglia, supplying the claws. The identity of the cells as octopaminergic was confirmed by combining iontophoretic injections of Lucifer Yellow with immunostaining. Large overshooting action potentials are recorded from their somata. These are characteristic of arthropod neurosecretory cells, and suggest that the claw octopamine cells (CLOCs) might form neurosecretory endings in claw muscles. During development OA-immunostaining appears in CLOCs at the 2nd larval stage, shortly before functional claws first appear. We are exploring the role served by the CLOCs in fighting behavior in lobsters. Supported by NIH, DFG, and Gottlieb-Daimler and Karl-Benz Stiftung.

AXON GUIDANCE II

527.1

OUTGROWING RETINAL AXONS GUIDED BY RADIAL (GLIA) CELLS. B. Schlosshauer* and H. Stier. Naturwissenschaftliches und Medizinisches Institut an der Universität Tübingen (NMI), 72762 Reutlingen, FRG.

In order to analyse the cellular mechanisms that govern oriented axonal outgrowth within the retina, we employed cryocultures of the embryonic chicken. Viable retina strips were explanted onto cryosections of retina and axonal outgrowth was monitored. *In vivo* only ganglion cell axons and neuroepithelial/radial glia endfeet form the optic fiber layer; radial Müller glia is the only nonneuronal cell type in the chicken retina. 1) Ganglion cell axons are directed by a dual mechanism: the retina tissue is composed of an inhibitory zone (all outer layers) and a permissive zone (optic fiber layer). a) *In vitro*, axons grow preferentially on the innermost layer of retinal cryosections even after coating sections with laminin. b) Axons approaching outer retina layers respond partially with a growth cone collapse (time lapse video recording). c) In contrast, prior heat inactivation of cryosections allows axonal outgrowth even in outer retina layers. 2) The permissive zone is formed by endfeet of neuroepithelial/radial glia. a) After elimination of ganglion cells and their axons due to prior optic nerve transection, explant axons still prefer the innermost retina layer of *in vivo* pretreated cryosections. b) Isolated glia endfeet provide an excellent growth substrate. 3) The inhibitory zone is formed by somata of radial glia. a) Axonal outgrowth is inhibited on radial glia somata purified from retina cell cultures by complement mediated neuronal cytolysis. b) The restricted number of outgrowing axons on glia somata are highly fasciculated therefore avoiding contact with glia somata (scanning electron microscopy). c) Heat inactivation of purified glia somata converts glia cells into a permissive substrate. The data suggest that ganglion cells axons are guided into the innermost retina layer by polarized neuroepithelial/radial glia cells with their endfeet being permissive and their somata being inhibitory for outgrowing axons. Supported by DFG.

NEURONAL ORGANIZATION OF THE EMBRYONIC FORE- AND MIDBRAIN IN WILDTYPE AND MUTANT MICE. G.S. Mastick* and S.S. Easter, Jr., Dept of Biology, U of Michigan, Ann Arbor, MI 48109

The fluorescent axon tracers diI and diO were used on fixed E10.5 embryos to map groups of early neurons and pioneer axons with respect to interneuromeric boundaries. The spatial and temporal relationship between central neurons, tracts, and cranial nerves defines the coordinates of the rostral embryonic brain, revealing several general features: a) Groups of neurons can straddle major transverse interneuromeric boundaries. dmesV and mlf somata were found in both mesencephalon and synencephalon, implying that these neuronal types are not simply defined by neuromere boundaries. In contrast, oculomotor (nIII) somata were confined to the ventral mesencephalon, abutting but not crossing the synemes border. b) Position and timing may specify neuronal identity, at least in terms of axon projections. A double-labelling strategy showed that mlf and nIII somata were both in ventral mesencephalon, but in non-overlapping nuclei. In contrast, the late-appearing tectobulbar neurons were interspersed with the very early dmesV neurons in dorsal mesencephalon. c) Two major axon systems develop, marking the dorsal and ventral halves of the rostral brain. dmesV (dorsal) and mlf (ventral) appeared first, projecting caudally into the rhombencephalon. Axons of the tract of the postoptic commissure (tpoc) extend from the base of the optic stalk into dmesV, suggesting that the tpoc is dorsal, and the "front" end of the brain is ventral to the optic stalk. d) The pioneer axons do not follow interneuromeric borders. Instead, broad zones of the neural tube are filled with axons sharing trajectories.

We examined the altered organization of the embryonic brain in *Wnt-1* mutant mice using neuronal landmarks at E9.5. The loss of this secreted growth factor causes deletion of mesencephalon and rhombomere 1, loss of nIII and nIV, and creates a new boundary between the forebrain and rhombomere 2. Surprisingly, pioneer axons navigate accurately across the new boundary.

527.2

RETINOIC ACID AND PEPTIDE GROWTH FACTORS INFLUENCE OLFACTORY NEURITE OUTGROWTH. J.G. Whitesides* and A-S. LaMantia. Department of Neurobiology, Duke University, Durham, NC 27710.

We have evaluated the role of retinoic acid and various peptide growth factors in the initial formation of the olfactory nerve in the mouse. Immunohistochemical and *in situ* localization has shown that several retinoic acid receptors (RAR α and RXR γ) as well as trk-B and FGF receptors are present in olfactory epithelial cells and/or axons at embryonic day 10-11. Furthermore, local sources of retinoic acid, FGF, and other peptide hormones are available in the fronto-nasal mesenchyme (where olfactory axons grow toward the brain) and the anterior neural tube (their ultimate target). Thus, it is possible that retinoic acid and various growth factors may influence the outgrowth of developing olfactory axons as well as their initial trajectory to the ventrolateral forebrain.

To assess the effects of these signaling molecules on olfactory axon outgrowth, we used a neurite outgrowth assay in which explants of the early olfactory epithelium are placed on a laminin substrate in serum-free media. We then added all-*trans* retinoic acid (10^{-7} M) and allowed the explants to extend neurites for 48 hours. Retinoic acid significantly increased both the number and length of neurites that grew out from these explants compared to those grown on the laminin substrate alone. The effects of peptide growth factors whose receptors are found on olfactory epithelial neurons (BDNF, b-FGF, and NT-4) have also been examined. Apparently, a variety of signaling molecules and their receptors that are normally found in and around the developing olfactory epithelium and nerve can influence aspects of olfactory neurite outgrowth *in vitro*. These factors may similarly contribute to the growth and guidance of olfactory axons to their telencephalic targets *in vivo*. Supported by HD29178 to A-S. L.

ARREST OF AXONAL GROWTH *IN VITRO* BY LIVING, SECTIONED OR FIXED TARGET NEURONS. D.H. Baird* and B. Kruk. Department of Anatomy and Neurobiology, Medical College of Pennsylvania and Hahnemann University, Philadelphia, PA 19129.

The regulation of axonal growth by CNS targets was examined using an *in vitro* system in which the extension of cerebellar mossy fibers from explants of basilar pontine nuclei is interrupted by their targets, granule neurons. This "stop-growing signal" is both target- and axon-specific, and its regulation involves NMDA receptors. In the presence of NMDA antagonists, mossy fibers are not arrested by granule neurons, and the growth of long (>300 μ m) neurites is 3-4 times that of controls. NMDA has an opposing effect; it enhances the stop signal provided by granule neurons, resulting in shorter mossy fibers. Neither NMDA nor its antagonists alter the growth of mossy fibers in the absence of granule neurons.

To determine if functional, pre- or postsynaptic NMDA receptors are involved in the stop-growing signal, mossy fibers were cultured on granule neuron monolayers that had previously been fixed in 4% paraformaldehyde, and on unfixed, frozen sections of cerebellum. In both cases, mossy fibers extended less than 100 μ m from their explant of origin, while mossy fibers extended more than 500 μ m on fixed laminin or on sections of brainstem. These results suggest that molecules which directly mediate the stop-growing signal are insensitive to fixation, and are located on the granule cell plasma membrane, or are part of a matrix produced by granule neurons. In addition, the results suggest that functional granule neuron NMDA receptors are not strictly required for the arrest of axons by target neurons, and if they are involved at all, they must regulate this process indirectly.

527.5

EVIDENCE FOR GUIDEPOST CELLS IN AXON OUTGROWTH DURING DEVELOPMENT OF *DROSOPHILA*. L.S. Wang* and H. Keshishian. Department of Biology, Yale University, New Haven, CT 06511

The characteristic pattern of the bodywall innervation in *Drosophila* embryos provides an ideal system to study axon guidance and synapse formation. Segmental nerve branch A (SNa) grows out laterally in the anterior half of the segment and makes a stereotypical posterior turn at mid-bodywall to innervate muscle fibers 5 and 8. Cash et al. (J. Neurosci. 12:2051, 1992) showed that in the absence of these target muscle fibers, SNa still turns posteriorly. Therefore, cues other than the targets are present to guide SNa growth. Although the SNa trajectory can be altered by laser ablation of the muscle fibers in its path, it always makes the posterior turn to innervate its target muscle fibers (Wang and Keshishian, Neurosci. Abst. 18:1273, 1992). We observed the presence of 2 cells (possibly glial) at the corner of muscle fibers 12 and 5. Their locations correspond to the site at which SNa usually makes endings on muscle fiber 5. In mutants of the *spitz* family, such as *pointed*, which affect ventrolateral patterning, 20% of the SNa nerves fail to turn (Wang et al., Neurosci. Abst. 19:235, 1993). Examination of *pointed* mutants showed: (A) In 6 out of 8 cases SNa failed to turn when the 2 glial cells were missing. (B) In 20 out of 22 cases SNa turned normally when these cells were present. To test whether these cells are in fact guidepost cells, we are surgically removing them in filleted embryos at late stage 15, when SNa has not yet turned. The embryos are then cultured until late stage 16, when SNa normally has reached its targets. These experiments will critically define the role of these putative guidepost cells in inducing the posterior turn of SNa.

527.7

SPECIFICITY OF SYMPATHETIC PREGANGLIONIC PROJECTIONS IN THE CHICK IS INFLUENCED BY THE MATURATION STATE OF THE SOMITIC MESODERM. L.W. Yip*. Dept. of Neurobiology, University of Pittsburgh, Sch. of Med., Pittsburgh, PA 15261

The spatio-temporal patterns of sympathetic preganglionic projections in the chick are segmentally specific. For example, T1 preganglionic neurons enter the sympathetic trunk at stage 27 and project rostrally. In contrast, T4 preganglionic neurons enter the sympathetic trunk at stage 28 and project caudally. Previous studies from this laboratory have shown that the somitic mesoderm influences these patterns. This study examines whether the maturation state of the somitic mesoderm is responsible for that influence.

Two series of experiments were designed to confront preganglionic neurons with somitic mesoderm of an older maturation state. In one, the T1-T4 neural tube segments of a stage 14 embryo were transplanted to the upper cervical (more mature) region of the same embryo. Orthograde HRP labeling showed that outgrowth of T1 preganglionic neurons translocated to the cervical region occurred much earlier than normal, such that by stage 26 the translocated T1 preganglionic neurons have already projected extensively into the sympathetic trunk. This indicates that preganglionic neurons will send their axons out earlier when they encounter a more mature somitic mesoderm. In another series of experiments, the T1-T4 neural tube segments from a stage 13 donor were transplanted homotopically to a stage 18 host. In the resultant embryo, the T1 preganglionic neurons projected in both rostral and caudal directions, instead of in their normal, predominantly rostral direction. This result indicates that the direction of preganglionic projections can be altered by the maturation state of the somitic mesoderm.

The maturation of the somitic mesoderm may therefore relate to the formation of the specific pattern of preganglionic projections.

527.9

TESTING THE ROLE OF TARGETS IN MOTONEURONAL SPECIFICITY. C.E. Beattie* and J.S. Eisen. Institute of Neuroscience, University of Oregon, Eugene, OR, 97403

We are investigating mechanisms underlying neuromuscular specificity in vertebrates using embryonic zebrafish. During zebrafish development, identified motoneurons with specific soma positions in the spinal cord become committed to innervate particular regions of myotome. Motor growth cones may be guided by myotomal cues. Alternatively, they may grow in a specific direction regardless of myotomal cues, suggesting that guidance cues originate from some other source. To differentiate between these mechanisms, we analyzed motor axonal outgrowth after altering the orientation of the myotome. Labeled donor myotomes were isolated, rotated along the dorsal-ventral axis and transplanted into unlabeled host embryos from which native myotomes had been removed. Following dorsal-ventral reorientation of the myotome and isochronic transplantation at 16h, an identified motoneuron, CaP, extended its growth cone ventrally as it does normally. This result suggests either that dorsal and ventral myotomal regions have become respecified or that CaP extends its axon ventrally independently of myotomal cues. To resolve this issue, heterochronic transplants were performed. Following dorsal-ventral reorientation and transplantation of 19h myotomes into 16h hosts, CaP extended an axon which often grew laterally and appeared to avoid the ventral myotomal region which now contained dorsal muscle. This result supports the idea that younger myotomes respecify their dorsal and ventral regions while older myotomes retain their original polarity after transplantation. Motor axons, therefore, appear to be guided by cues originating from myotome. Supported by ACS PF-3982 and NS23915.

THE *DROSOPHILA* *DERAILED* GENE ENCODES A PUTATIVE RECEPTOR TYROSINE KINASE REQUIRED FOR BOTH AXONAL FASCICULATION AND MUSCLE INSERTION SITE SELECTION. C.A. Callahan^{1,2} and J.B. Thomas^{*1}. ¹The Salk Institute, La Jolla, CA 92037, ²Dept. of Neurosciences, Univ. of California, San Diego, CA.

In order to establish synaptic connections with their appropriate targets, neurons must choose specific axon pathways during development. Similarly, developing somatic muscles choose stereotyped insertion sites within the epidermis. To begin understanding the molecular mechanisms underlying these recognition events, we have carried out an enhancer-trap screen using a novel fusion reporter, tau-b-gal, which effectively labels the projections of expressing neurons (PNAS, in press). From 2500 enhancer-trap lines, we have isolated approximately 40 that express tau-b-gal in subsets of interacting embryonic CNS neurons and/or in somatic muscle subsets.

The *derailed* (*drl*) gene was isolated from one line by plasmid rescue and shows the same pattern of expression as tau-b-gal. *drl* is expressed in a subset of approximately 20 interneurons that fasciculate into 2 major axon bundles, as well as in somatic muscles 21-23. From sequence analysis, the *drl* gene product is a member of the receptor tyrosine kinase (RTK) family, and shows the highest similarity to the vertebrate *RYK* RTK. Individuals homozygous for the P element insertion, which severely reduces CNS *drl* transcription, show defasciculation of the *drl* expressing interneurons. Transcriptional nulls for *drl* were generated by P element excision. In embryos lacking *drl* expression, the muscles that normally express *drl* fail to insert at their appropriate locations within the epidermis. These results suggest that mutations in *drl* disrupt specific recognition events both between neurons and their axonal pathways and between muscles and their insertion sites. They also implicate the RTK gene family in these developmental processes.

MUTATIONS IN *sidestep* LEAD TO DEFECTS IN PATHFINDING AND SYNAPTIC SPECIFICITY DURING THE DEVELOPMENT OF NEUROMUSCULAR CONNECTIVITY IN *DROSOPHILA*. H. Sink and C.S. Goodman*, HHMI, Neurobiol. Div., Dept. of Mol. and Cell Biol., U. C., Berkeley, CA 94720

We screened over 5000 heavily mutagenized 3rd chromosome lines in *Drosophila*, and identified 140 mutations that disrupt the embryonic projection of motor axons. Here we focus on mutations in the *sidestep* gene which disrupt specific aspects of motor axon pathfinding, while the muscles appear normal. In the periphery of wild-type embryos, motor axons defasciculate to generate 5 characteristic branches or motor nerves. In *sidestep* mutant embryos, the motor projection frequently has 2 instead of 5 branches, with a resultant lack of innervation of the most ventral muscles.

Several deficiencies delete the chromosomal region containing the *sidestep* gene. The phenotype of *sidestep* deficiency embryos is the same as homozygous *sidestep* embryos (4 independent alleles), suggesting that this phenotype may represent the null condition. The *sidestep* mutants are semi-viable as transheterozygotes and over deficiency. Despite the lack of innervation of many of the ventral muscles, and inappropriate innervation of certain dorsal muscles (see below), larval responses to touch appear relatively normal.

Motor axons that innervate the most distal muscles (e.g., #12,13) of the ventral muscle group often diverge from the inappropriate pathway and innervate their correct muscle targets. In contrast, other misrouted motor axons continue to extend dorsally. Instead of innervating their normal ventral muscle targets (e.g., #7,6), these axons synapse on dorsal muscle 4. Interestingly, muscle 4 has the same relative orientation within its muscle group as do several of the uninnervated ventral muscles (7,6) within their group. The *sidestep* mutant phenotype suggests that targeting cues may be similar or even duplicated in different regions of the embryonic musculature. Work in progress is aimed at cloning the *sidestep* gene.

SCHWANN CELL PROCESSES GUIDE REGENERATING AXONS. Y.-J. Son* and W.J. Thompson. Dept. of Zoology, Univ. of Texas, Austin, TX 78712.

Terminal Schwann cells (TSCs) at the adult rat neuromuscular junction sprout extensive processes following denervation (J. Neurocytol. 21: 50). We have used an antibody which marks denervated TSCs and an antibody against neurofilament to examine the relationship between TSC processes and regenerating axons in the soleus muscle. Prior to any reinnervation, some TSC processes grow to contact adjacent endplates or fasciculate with the TSC processes emanating from adjacent endplates. Thus, TSC processes come to interconnect many endplates prior to the return of regenerating axons. Most axons arrive at denervated endplates by growing down the old Schwann cell tubes. After re-occupying the endplate, axons extend processes onto the TSC processes, and, in many cases, navigate along these TSC processes to innervate adjacent endplates. Consequently, many endplates come to be polynuronally innervated, by an axon in the old Schwann cell tube and one or more sprouts guided from adjacent endplates by TSC processes.

To determine whether this guidance of axons is a general property of Schwann cells (SCs), we examined SC outgrowth from the cut end of a denervated nerve stump transplanted to the surface of soleus. SCs and their processes grew out over the muscle in the absence of axons. When a nerve with axons was transplanted, axons and SCs both grew from the nerve and each axon was associated with SC processes. In several cases we found axons navigating along SCs with the SCs apparently leading the axons. The rate at which axons and SCs extended from a transplanted nerve was the same as that at which SCs extended in the absence of axons. On the other hand, when axons were confronted with existing SC processes their growth rate was at least 7 fold faster. Our results suggest that SC processes guide axonal growth during regeneration in the peripheral nervous system.

MOTOR AXON SPROUTS ARE INDUCED AND GUIDED BY PROCESSES EXTENDED FROM SCHWANN CELLS. W.J. Thompson* and Y.-J. Son. Dept. of Zoology, Univ. of Texas, Austin, TX 78712.

In view of the guidance that terminal Schwann cells and Schwann cells (SCs) in the nerve give regenerating axons (Son and Thompson, this meeting), we have examined the possibility these cells play a role in the sprouting of motor nerves in adult muscles.

We first examined nerve sprouting induced by partial denervation (PD). Within 3 days of PD, use of an anti-neurofilament antibody showed that nerve sprouts were extended from about 28% of the terminals remaining in the muscle. Staining with a general SC marker (anti-S-100) showed that all of these sprouts were associated with SC processes. Staining with the antibody 4E2, which marks SCs at denervated endplates and the processes they extend, showed that a large fraction of the terminal sprouts were extended from junctions which had been contacted by processes of SCs from denervated junctions. In these cases the nerve sprouts grew along the SC process to the adjacent denervated endplate. Additional examples were found of nodal sprouts which were growing along SC processes.

We next examined sprouting induced by botulinum toxin-induced paralysis. In all cases, nerve terminal sprouts were associated with Schwann cell processes extended from the endplate. In several cases, SC processes were longer than axonal processes.

Finally, we examined the ability of SCs and their processes growing from the end of a denervated, nerve stump implanted on the surface of the soleus muscle near the endplate band to induce sprouting from intact junctions. Schwann cells growing into intact junctions induced sprouts which then followed the Schwann cell processes. On the other hand, passage of a Schwann cell process near a junction seemed insufficient to induce sprouting.

Our experiments demonstrate a clear association between the extension of Schwann cell processes and the induction and guidance of nerve terminal sprouts in muscle.

EFFECT OF CELL-ELIMINATION IN THE DISTAL PART OF CRUSHED TIBIAL NERVES STUDIED BY IMPLANTED NERVE CUFF ELECTRODES IN THE CAT. K. Fugleholm*, J. Sørensen, H. Schmalbruch, C. Krarup. Inst. of Med. Physiology, Univ. of Copenhagen, and Dep. of Clinical Neurophysiology, Rigshospitalet, Denmark, DK 2200 N.

The importance of Schwann and other cells for nerve regeneration after a crush lesion was studied in the cat tibial nerve. Segments of the distal nerve adjacent to the crush were made cell-free by freezing and thawing. Regeneration was followed by a series of cuff electrodes implanted around the tibial and sciatic nerve. Twice weekly, action potentials were elicited distally and recorded proximally; this allowed to continuously follow axonal elongation. The elongation rate was about 3 mm/day; it was unchanged whether the distal nerve was not frozen or frozen for 20 (Fugleholm et al., 1994, *J. Neurosci.* in press) or 30 mm. Freezing the nerve for 40 mm, however, slowed the elongation to almost stand-still about 35 mm distal to the crush lesion, i.e. inside the frozen segment. The electrophysiological findings were confirmed by morphometric evaluation at four levels distal to the lesion. Removal of myelin debris was delayed in 40- as compared to 30-mm-long frozen segments. The results indicate that axonal regeneration is limited by the length of a cell-free nerve segment distal to the lesion and suggest that invading macrophages may play a critical role for the repopulation of the nerve segments by Schwann cells.

527.12

DYNAMICS OF TERMINAL SCHWANN CELL PROCESSES AT NEUROMUSCULAR JUNCTIONS IN LIVING MICE. R. J. Balice-Gordon* Dept. Biology & Inst. for Neurol. Sci., Univ. of Pennsylvania, Phila., PA 19010-6018.

Presynaptic motor nerve terminals at neuromuscular junctions are covered by non-myelinating terminal Schwann cells whose function is poorly understood. In living animals, terminal Schwann cells can be selectively labeled using Calcein Blue (CB; an ester, Molecular Probes, Eugene, OR). CB labels Schwann cell bodies and processes at junctions but does not label nerve terminals, muscle fibers, myelinating Schwann or other cells. In adult mice, CB stained Schwann cell processes were observed to be confined to the endplate region and were often precisely aligned with motor nerve terminal branches. Such alignment was not observed in neonatal mice. Following denervation, terminal Schwann cells rapidly extended processes well beyond the endplate region, often joining with processes of cells from adjacent endplates, consistent with observations made using S-100 immunohistochemistry (Reynolds & Woolf, 1992). Recently, Thompson et al. have shown that following denervation, regenerating axons are closely associated with Schwann cell processes and suggest that these cells may play a role in axon guidance back to the endplate (Son & Thompson, this vol.). Observations of terminal Schwann cells *in vivo* will allow the dynamics of the response of these cells to denervation and their role in synaptic regeneration and maintenance to be studied.

527.14

GROWTH OF AXONS IN ADULT FIBRE TRACTS. G. Raisman*, M. Suzuki, S.J.A. Davies, G.A. Brook, Y. Li and P.M. Field. Norman and Sadie Lee Research Centre, Lab of Neurobiology, NIMR, MRC, London NW7 1AA, UK.

Adult fibre tracts (fimbria, corpus callosum, spinal dorsal columns) have a regular, rectilinear arrangement of astro- and oligodendroglial cells and processes. Embryonic neurons microtransplanted by minimally traumatic injections into otherwise unlesioned tracts grow profuse axons which rapidly elongate along the planes determined by the longitudinal glial and axonal structure of the host tracts. Both specific and also incorrectly matched neurons (e.g. superior collicular cells in the fimbria, hippocampal cells in the spinal cord) grow equally rapidly, profusely, and with the same topographic distribution. Axons enter terminal fields, but their ultimate fate has not yet been determined. Cultured Schwann cells injected as a suspension rapidly migrate along blood vessels, and become transformed into elongated, thread-like cells which also migrate and become dispersed along the longitudinal axis of adult host tracts. Cultured Schwann cells microtransplanted into otherwise unlesioned adult spinal dorsal columns induce sprouts from both cut and uncut axons. Both motor axons (of the corticospinal tract) and sensory axons (of the dorsal columns) respond. These sprouts arise either from the cut ends of the axons, or as branches of axonal stems (probably from myelin internodes). In contrast to the sprouting from cut axons in the absence of Schwann cells (when profuse sprouts persist for long periods after lesion, but do not elongate), the Schwann cell induced sprouts branch and elongate along the long axis of the host tract, and form local terminal field-like arborisations with varicosities, but their ultimate fate is still not known.

INGESTIVE BEHAVIORS VI

CORTICOTROPIN-RELEASING FACTOR (CRF) ANTAGONIST BLOCKS THE AUTONOMIC, ENDOCRINE, INGESTIVE & BEHAVIORAL EFFECTS OF CENTRAL BOMBESIN (BN).

Z. Meralli*, H. Plamondon, P. Kent and K. Banks¹. ¹Psychology & *Pharmacology, Univ. of Ottawa, Ottawa, Ont. Canada, K1N 9A9.

Bombesin (BN)-like peptides and their receptors are widely distributed within the mammalian CNS. Central administration of BN has a number of biologically significant actions including elevation of blood catecholamines, glucose and corticosterone, elicitation of grooming and locomotor activity, and suppression of food intake. It is of interest to note that the autonomic and behavioral syndrome elicited by CRF strongly resembles that of BN, and that there is a significant anatomical overlap in the localization of these two neuropeptides. In the present study, we attempted to elucidate the potential role of CRF in the mediation and/or modulation of the BN effects, by utilizing a specific CRF receptor antagonist α -helical CRF₉₋₄₁ (α -hCRF). In male Sprague-Dawley rats, BN (0.1-0.5 μ g; i.c.v.) caused a dose- and time-dependent increase in the circulating levels of glucose and ACTH. Although α -hCRF (5-10 μ g; i.c.v.) by itself was without significant effect, it blocked the BN-induced increase in ACTH and markedly attenuated BN-induced hyperglycemia. BN increased grooming and locomotor activity, both of which were markedly attenuated by α -hCRF. Finally, in rats trained to ingest daily food ration during a 4 hr access period, BN markedly suppressed ingestive behavior for up to 4 hr. This suppression was completely blocked by pretreatment with both doses of α -hCRF (5 or 10 μ g). These data indicate that central CRF system may play a significant role in the mediation of behavioral and autonomic effects of BN.

528.2

EXOGENOUS CCK ANALOG AND INTRAGASTRIC GLUCOSE PRELOADS PRODUCE SIMILAR MICROSTRUCTURAL CHANGES IN MEAL PATTERNS. T.H. Moran*, A.R. Baldessarini, and G.J. Schwartz. Department of Psychiatry and Behavioral Sciences, Johns Hopkins Univ. Sch. of Med., Baltimore, MD 21205.

Ingested food elicits a variety of peripheral and central signals that can determine the pattern and magnitude of food intake within a meal. While the magnitude of intake suppression resulting from two different signals may be identical, the pattern of intake producing those suppressions may not be. If the intake patterns underlying two identical suppressions are similar, it seems likely that the signals produced by the two stimuli are processed in similar ways. Using automated lick detectors, we examined the patterns of glucose intake (0.125 g/ml) over a 30 min test period following an overnight food deprivation in male Sprague-Dawley rats following: 1) 5 ml intragastric glucose preloads (0.125 - 0.25 g/ml), and 2) a dose range of the a norleucine substituted CCK analog. Both intragastric glucose and the CCK analog reduced intake to similar degree and the patterns of intake for similar suppressions did not differ. Analyses of the ongoing behavior revealed: 1) that neither class of stimuli affected the peak interlick interval or the lick rates within a burst, and 2) overall lick rates were slower and the number of bursts were significantly reduced to a similar degree by both classes of stimuli. These similar patterns suggest that the signals arising from exogenous administration of the CCK analog are processed in a similar fashion to those arising from a nutrient preload. Supported by DK19302.

EFFECTS OF CONTINUOUS NEAR-CELIAC CCK-8 INFUSIONS ON SUCROSE INTAKE AND FEEDING BEHAVIOR. J.E. Cox*, G.S. Perdue, and W.J. Tyler. Dept. Psychology, Univ. Alabama at Birmingham, Birmingham, AL 35294.

Bolus injections of cholecystokinin octapeptide (CCK-8) are more potent for reducing sucrose intake when injected through an aortal catheter with its tip near the celiac artery than when given intravenously (Calingasan et al., *Am. J. Physiol.* 263:R572-R577). We compared suppression of intake of 30% sucrose produced by continuous near-celiac and intravenous infusions of 100 - 1600 ng CCK-8. Adult, male Spague-Dawley rats received infusions throughout 20 min feeding tests. Significant reductions in intake were produced by 400, 800, and 1600 ng near-celiac CCK-8. Only the two highest doses reduced intake when administered intravenously. Behavioral observations indicated [1] that CCK-8 had no effect on feeding during the first several minutes but accelerated the decline in incidence of feeding later in the test and [2] that near-celiac CCK-8 had more pronounced effects on feeding behavior than did intravenous CCK-8. Thus during slow infusions, greater potency of near-celiac CCK-8 was accompanied by temporal intake patterns indicative of enhancement of satiety. These data provide further evidence that cholecystokinin acts within the upper gastrointestinal tract to inhibit food intake.

DEPLETION IN HYPOTHALAMIC NEUROPEPTIDE Y AND DIETARY PREFERENCES IN MSG-TREATED RATS. B. Beck*, A. Stricker-Krongrad, A. Burlet, J.P. Nicolas and C. Burlet. INSERM U.308 - MRCA - 38, rue Lionnois - 54000 Nancy (France).

Neonatal treatment with monosodium glutamate (MSG) induces neuronal degeneration in the arcuate nucleus (ARC). This nucleus is the main hypothalamic site of neuropeptide Y (NPY) synthesis. Hypothalamic NPY preferentially stimulates carbohydrate intake and is influenced by diet composition. In this experiment, we measured the effects of a MSG treatment on NPY levels and dietary preferences. Newborn Long-Evans rats were injected I.P. with either MSG (4 mg/g BW) or saline on the 3rd, 5th and 7th days of life. Rats were fed on a control (C) diet until adulthood. Then, they could choose between a high carbohydrate (HC) diet and a high fat (HF) diet. NPY concentrations were measured in several microdissected hypothalamic nuclei. They were significantly smaller in the MSG rats than in the control rats in the ARC (-52 %; $p < 0.001$) and in the parvocellular part of the paraventricular nucleus (pPVN) (-57 %; $p < 0.004$). Energy intake in the food choice situation was greater in the control than in the MSG rats (81.3 ± 5.3 vs 62.2 ± 3.7 Kcal/day; $p < 0.01$). This augmentation was due to a greater intake of HF diet (+60 %; $p < 0.001$) and a smaller intake of HC diet in the control rats (-25 %; $p < 0.01$). These results confirm some of our previous findings showing that rats with a carbohydrate preference are characterized by lower NPY levels in the pPVN. Supported by Fondation B. Delessert (Paris).

NPY IMMUNONEUTRALIZATION SUPPRESSES FEEDING IN VMH-LESIONED HYPERPHAGIC RATS. Sarva P. Kalra, M.G. Dube* and Pushpa S. Kalra. Departments of Neuroscience and Physiology, Univ. of Fla. College of Medicine, Gainesville, FL 32610

It has been known for a long time that destruction of the ventromedial hypothalamus (VMH) induces hyperphagia and increase in body weight. The neural signal(s) responsible for the hyperphagic response have not been identified. Neuropeptide Y (NPY) is the most potent orexigenic signal known and the evidence that passive immunization of rats against NPY suppresses daily food intake implies that NPY may be a physiological appetite transducer. Therefore, we hypothesized that hyperphagia in VMH-lesioned rats may be NPY-dependent. Female rats received electrolytic or sham lesions in the VMH and permanent cannulae in the third ventricle of the brain. The VMH-lesioned rats displayed robust hyperphagia (5.5 ± 1.1 g/2h) as compared to sham-lesioned rats (1.6 ± 0.3 g/2h) 12-26 days post-surgery. These rats were passively immunized against NPY by intraventricular injections (3 μ l) of purified IgG containing a specific NPY-antibody (NPY-Ab) at 0900, 1100 and 1300 h, and food consumption was evaluated between 1300-1500 h. The results showed that food intake was suppressed by greater than 93% in the NPY-Ab injected, VMH-lesioned rats. Similar central injections of purified IgG from normal rabbit serum (control) had no effect on food intake in these VMH-lesioned or sham-lesioned rats. These results implicate for the first time a locally-produced neural signal in the VMH-lesioned syndrome and support the hypothesis that the potent orexigenic effects of hypothalamic NPY may participate in induction of hyperphagia and the attendant body weight gain in VMH-lesioned rats. (Supported NIH, DK 37273).

ROLE OF CCK IN MEDIATING THE SATIETY RESPONSE TO DUODENAL PEPTONE IN RATS. T.A. Woltman and R.D. Reidelberger*. VA Medical Center, Omaha, NE 68105 and Department of Biomedical Sciences, Creighton University School of Medicine, Omaha, NE 68178.

An important role for CCK in mediating the satiety response to duodenal nutrients is supported by data showing that CCK receptor blockade reverses the anorexic effects of duodenal nutrient infusions in *sham* feeding rats. In the present study, we used the CCK-A receptor antagonist devazepide (DEV) to examine the role of CCK in mediating the anorexic effects of peptone infusion into the duodenum of non-food deprived *real* feeding rats at the start of the dark period. Rats ($n=15$) with duodenal and jugular vein cannulae, received 2-h duodenal infusions of peptone (0, 1.7, 3.5, 7, 14, 28%); meal patterns were measured for 4 h. Peptone suppressed feeding dose-dependently primarily by decreasing meal size. The minimal effective dose was 3.5%: 14% peptone decreased caloric intake by about 50%. Rats ($n=15$) then received IV injections of DEV (0, .03, .1, .3, 1 mg/kg) 15 min before 2-h duodenal infusions of vehicle or 14% peptone. Data were analyzed by repeated measures ANOVA. When given alone, peptone suppressed feeding and DEV stimulated feeding. There was a significant interaction of peptone and DEV at low but not high doses of DEV. DEV (.03 and .1 mg/kg) had no effect on feeding when given alone, yet reversed the anorexic effect of peptone. In contrast, DEV (.3 and 1 mg/kg) was equally effective in stimulating feeding whether or not peptone was infused and peptone was equally effective in suppressing feeding whether or not DEV (.3 and 1 mg/kg) was injected. These results do not support the hypothesis that CCK mediates the satiety response to duodenal peptone in *real* feeding subjects.

HYPOTHALAMIC NEUROPEPTIDE Y (NPY) UPREGULATION PRECEDES THE ONSET OF DIABETIC HYPERPHAGIA. A. Sahu*, C.A. Shinsky*, and S.P. Kalra. Depts. Neuroscience and *Medicine., Univ. Fla., Gainesville, FL 32610

Recent evidence shows that *in vivo* and *in vitro* NPY release in the paraventricular nucleus (PVN) and NPY gene expression in the arcuate nucleus (ARC) increase in association with hyperphagia in longterm diabetic rats. In the present study we sought the timing of the onset of NPY upregulation and hyperphagia in streptozotocin (STZ)-treated diabetic rats. Adult male SD rats were injected with either STZ (65 mg/kg) or vehicle via tail vein on day 0. Rats were killed on days 2, 3 and 4. PreproNPY mRNA levels in the medial basal hypothalamus which includes the ARC, were determined by solution hybridization/RNase protection assay using a cRNA probe. NPY levels in the microdissected hypothalamic sites were also estimated by RIA in STZ-treated rats. As expected, STZ treatment induced marked hyperglycemia and hypoinsulinemia along with loss in body weight after STZ treatment. Analysis of NPY gene expression, peptide levels and food intake showed a remarkable temporal sequence of events. PreproNPY mRNA levels were significantly increased (4.5 fold, $p < 0.001$) within 48 hours of STZ treatment. Similarly, of the 7 hypothalamic sites examined, NPY peptide levels were increased only in the PVN 2 days after STZ injection. In contrast, food intake was decreased for 3 days and thereafter, a significant hyperphagia was evident on day 4. Collectively, these results show that the enhanced NPY synthesis and release in the ARC-PVN axis precedes hyperphagia in diabetic rats. Since very low levels of insulin can inhibit NPY release from the PVN nerve terminals (Soc. Neurosci. Abst. 19:1821, 1993), we propose that the regulation of food intake by insulin is mediated by PVN NPY innervations of a subpopulation of neurons in the ARC. 528.8

THE BENZODIAZEPINE AGONIST MIDAZOLAM MICROINJECTED INTO THE RAT PARABRACHIAL NUCLEUS PRODUCES HYPERPHAGIA. S.J. Cooper* and S. Higgs. Sch. of Psychology, Univ. Birmingham, Birmingham B15 2TT, U.K.

Benzodiazepine (BZ) receptor agonists cause a substantial hyperphagia in rats and numerous other mammalian species, and produce striking enhancements of taste preferences and positive taste reactivity measures. We have located a population of BZ receptors in the rat parabrachial nucleus (PBN) (unpublished data), and have therefore investigated the possible role of the PBN in relation to BZ-induced hyperphagia. Nondeprived male rats were trained to consume either a sweetened palatable mash or a 3% sucrose solution. The water-soluble BZ, midazolam, was microinjected bilaterally into the PBN (3, 10 or 30 μ g/ μ l in 0.5 μ l) and compared with a saline-vehicle condition. Microinjection of midazolam (30 μ g/ μ l) into the PBN significantly increased the intake of either mash ($N=6$) or sucrose solution ($N=5$) ($p < 0.01$). The hyperphagic response was blocked by the selective BZ receptor antagonist, flumazenil. Intra-PBN injections of midazolam (3, 10 or 30 μ g/ μ l in 0.5 μ l) did not affect locomotor activity as determined by an activity monitor. These data are consistent with the view that BZ receptors in the PBN may constitute the receptors at which BZs induce their considerable hyperphagic effect.

528.9

TAMOXIFEN PREVENTS NEUROLEPTIC-INDUCED WEIGHT GAIN AND HYPERPHAGIA IN FEMALE RATS. T. Baptista*, E. de Baptista, M. Altamirano, and S.R.B. Weiss Biological Psychiatry Branch and Clinical Neuroendocrinology Branch, NIMH, Bethesda, Md. 20892

Elsewhere, we have suggested that the weight gain and hyperphagia induced by chronic administration of neuroleptics in female rats is related to a neuroleptic-induced hyperprolactinemia, which causes a decrease in gonadal estrogen synthesis, ultimately resulting in decreased activity of hypothalamic neurons involved in satiety (Parada et al., 1989). This mechanism has been investigated using the D₂ selective dopamine antagonist sulpiride, and the weight gain was prevented by concomitant administration of either estrogen or bromocriptine. Recent evidence suggests that the antiestrogen tamoxifen may act as an estrogen agonist on food intake regulation because, in the short term, it prevents weight gain and hyperphagia in ovariectomized rats. In addition, tamoxifen and neuroleptics compete for the same receptor in hypothalamic neurons (Gray et al., 1993), which further suggests that tamoxifen might prevent neuroleptic-induced weight gain. To assess this hypothesis, female rats were divided into groups of 10 animals each, and were treated for 21 days with either vehicle, sulpiride (20 mg/kg, i.p.), or sulpiride plus one of the following doses of tamoxifen citrate: 2.5, 5, 10, 20, 50, or 100 mg/kg, i.p. Sulpiride-induced weight gain and hyperphagia were completely prevented by tamoxifen at doses of 5 or more mg/kg. A trend was observed between the dose of tamoxifen and inhibition of weight gain under sulpiride: $r = 0.68$, $F(1,6) = 4.4$, $p < 0.08$. Tamoxifen may be useful to prevent weight gain in obesity-prone women under neuroleptic treatment.

CAFETERIA-DIET OBESITY DAMPENS THE MESOACCUMBENS DOPAMINE SYSTEM AND ALTERS ITS RESPONSE TO AMPHETAMINE AND FOOD INTAKE. E. Poethos*, A. C. Krain and B. G. Hoebel, Dept. of Psych., Princeton Univ., Princeton, NJ 08544.

Feeding can increase extracellular dopamine (DA) levels in the nucleus accumbens (NAc) of freely moving rats (Hernandez & Hoebel, *Physiol. & Beh.* 44, 599), but little is known about the effects of obesity on basal DA release in the NAc. In the present study, female albino rats (n=16) developed cafeteria-diet obesity and body weight averaging 23% above controls (n=16). *In vivo* microdialysis showed that basal DA levels in the NAc of the obese rats were 70% lower than in controls ($p < .01$), but *d*-amphetamine (1.5 mg/kg i.p.) increased NAc DA to 759% of baseline in the obese group and only to 285% in the control group ($p < .05$). When both control and obese rats were food deprived for 24-36 hrs, there was no longer any measurable depression of basal NAc DA in the obese group. After a Purina pellet meal, NAc DA increased significantly in the food deprived controls ($p < .01$), but not in the food deprived obese; however, a cafeteria-diet meal did increase DA ($p < .01$). The results suggest that cafeteria-diet obesity (a) dampens basal activity of the mesoaccumbens DA system, but mild food deprivation and highly palatable food restore it, and (b) increases the amount of DA available for release by amphetamine.

CONDITIONED PREFERENCES AFFECT THE TEMPORAL PROPERTIES OF THE TASTE CODE. B. K. Giza¹, K. Ackroff², A. Scialani^{2*}, S. A. McCaughy¹ and T. R. Scott¹ (¹Dept Psychol, Univ Delaware, Newark DE 19716; ²Dept Psychol, Brooklyn Col, Brooklyn NY 11210)

Conditioned taste preferences (CTPs) may be created by pairing a novel taste (CS) with intragastric infusion of nutrients (US). We recorded taste-evoked activity in the NTS of rats with CTPs to either 0.1 M MgCl₂ (Mg⁺) or 0.01 M citric acid (Ci⁺) to determine whether the afferent code was modified by this procedure. Forty-seven rats trained in Brooklyn were transported to Delaware for electrophysiological recording. Behavioral tests were conducted before recording to exclude rats that did not show >75% preference for the CS⁺ over both the CS⁻ and water. The two neural data sets were composed of single unit responses from 15 Mg⁺ (N=61) and 12 Ci⁺ (N=68) rats. Three neural subgroups—oriented toward NaCl, HCl and glucose—were identified by cluster analysis in each data set. There was no significant change in mean evoked activity to either CS⁺, either across all neurons or within any subgroup. The positions of Mg⁺ and Ci⁺ in taste spaces generated from each data set were unaltered by conditioning. Therefore, the gustatory neural code across neurons was not affected by development of a CTP. Temporal aspects of the evoked activity were then examined. The phasic burst that characterizes responses to non-sweet stimuli was suppressed to citric acid in Ci⁺ rats rendering the temporal profile less like that of HCl ($p < 0.01$) and more like that of glucose ($p < 0.01$). Thus, in the temporal taste space, citric acid abandoned the sour-bitter stimuli and joined the sugars. The time course of activity to MgCl₂, however, was unmodified in Mg⁺ rats. A phasic burst of activity is generated as the temporal signature of a conditioned aversion (Chang & Scott, 1984). Here the phasic response is selectively reduced for a stimulus to which a preference has been conditioned. The effect was limited to citric acid, which occurs in the natural environment of rats and has been associated with health consequences. Supported by grant DK30964 from the NIDDKD.

CARBOHYDRATE OXIDATION PREDICTS FOOD DEPRIVATION-INDUCED FOOD INTAKE. C.R. Park*, R. Seeley, and S.C. Woods, Depts. of Behavioral Neuroscience and Psychology, University of Washington, Seattle, WA 98195

Hyperphagia following fasting is a robust phenomenon. However, the actual signal used by a fasted animal to detect the necessity to ingest calories is still not known. Theories have focused upon glucose or lipid oxidation and cellular energy generation. We conducted the following study to investigate the relationship between several whole-body metabolic parameters and hyperphagia following food deprivation.

Naive, Long-Evans rats (14) were food deprived for periods ranging from 3 to 16 hours. Two hours before refeeding, they were placed in an indirect calorimeter for 2 hours. The rats were then returned to their home cages, food was restored, and food intake was recorded for 3 hours. Multiple regression analysis of several parameters, including respiratory quotient, carbohydrate and fat oxidation rates, energy expenditure, body weight, VO₂, and VCO₂ was performed. Of all the variables considered, only carbohydrate oxidation rate reliably predicted the amount of food consumed when access to food was restored. Importantly, using linear regression line fitting, a function was derived which predicted 0 grams of intake at a carbohydrate oxidation rate identical to that observed in the post-prandial state. These data indicate that fasting carbohydrate utilization rate may be an important determinant of refeeding hyperphagia.

ANTISENSE OLIGODEOXYNUCLEOTIDES TO G-PROTEIN SUBUNIT SUBCLASSES: CHRONIC INTRACEREBROVENTRICULAR (ICV) INFUSION IDENTIFIES A TRANSDUCTIONAL REQUIREMENT FOR THE MODULATION OF FEEDING. C.R. Plata-Salamán¹, C.D. Wilson² and J.M.H. French-Mullen³, ¹SLHS, Univ. Delaware, Newark, DE 19716 and ²Dept. Pharmacology, Zeneca Pharmaceuticals Group, Wilmington, DE 19897.

Heterotrimeric guanine nucleotide-binding (G) proteins transduce signals from the membrane G-protein-coupled receptors to cellular effectors. We studied in rats the effects of the chronic ICV (into the third ventricle) infusion for 72 h (through osmotic minipumps) with antisense phosphothio-oligodeoxynucleotides (15 µg/24 h) corresponding to G-protein subunit subclasses (α, β, and γ). The results for nighttime food intake (mean±SE, g) at the 48-60 h period after initiation of the vehicle, antisense or sense infusion were: vehicle, 20.2±1, n=10; Gαs antisense, 20.5±1, n=12; Gαi common antisense (to Gαi1, i2 and i3), 20.0±1, n=8; GαO common antisense (to GαOA and GαOB), 15.8±1, $p < 0.01$, n=11 (water intake increased 9% from control); GαOA antisense, 15.4±1, $p < 0.01$, n=11; GαOB antisense, 19.2±1, n=10; Gαq antisense, 19.5±1, n=7; Gα11 antisense, 21.3±1, n=7; Gβ common antisense, 20.3±1, n=5; Gγ common antisense, 15.8±0.5, $p < 0.02$, n=8. (Gγ1.1, 2.1, 3.1 and 4.1 antisense also decreased feeding, n=6-7/group). Infusion with 15 µg/24 h of GαO common sense or GαOA sense had no effect on nighttime food intake (19.4±1, n=8; and 20.7±1, n=9). Computerized analyses of behavioral patterns demonstrated that the GαOA antisense depresses nighttime feeding by reducing meal frequency (to 4.9±0.3 meals, n=11, $p = 0.001$ from control: 7.5±0.6 meals, n=8) without decreasing meal size or meal duration. Immunoblots of hypothalamic ventromedial nucleus from normal rats (n=12) show that the levels of GαO protein subunit are >30-fold higher relative to those of Gαi1-i3 and Gαs subunits. The results suggest that the G-protein subunit subclasses GαOA and Gγ are required for the modulation of normal feeding behavior, and that changes in their activity may be associated with the chemical regulation of feeding.

CROSS-TOLERANCE TO D₂ BUT NOT D₁ DOPAMINE RECEPTOR AGONISTS IN RATS TOLERANT TO CAFFEINE-INDUCED ROTATIONAL BEHAVIOR. B.E. Garrett* and S.G. Holtzman. Dept. of Pharmacology, Emory University School of Medicine, Atlanta, GA 30322.

Caffeine produces contralateral turning in rats with unilateral 6-OHDA (8 µg/4µl)-induced lesions of the nigrostriatal pathway. The present study a) determined if tolerance develops to this effect of caffeine and b) examined the role of dopamine receptors. Male Sprague-Dawley rats with 6-OHDA lesions received scheduled access to either a 0.1 % caffeine solution (average drug intake = 70 mg/kg/day) or to drug-free tap water (controls). Drugs were administered SC to groups of 8 rats and turning was recorded for 3 hr. Caffeine (10-100 mg/kg) and theophylline (3.0-100 mg/kg) produced biphasic increases in contralateral turning in control rats, with the peak increase occurring at 30 and 56 mg/kg, respectively. Rats receiving caffeine chronically were tolerant to this effect of both drugs. The selective D₂ agonists quinpirole (0.01-1.0 mg/kg) and R(-)-propylorapomorphine (NPA, 0.003-0.1 mg/kg) and the selective D₁ agonists SKF-38393 (0.3-10 mg/kg) and SKF-77434 (0.3-10 mg/kg) also produced dose-dependent increases in contralateral turning in control rats. This effect of the D₂ agonists was reduced significantly in rats receiving caffeine chronically, whereas the effect of the D₁ agonists was unchanged. Therefore, tolerance develops to caffeine-induced rotational behavior and there is cross-tolerance to the methylxanthine derivative theophylline. The differential cross-tolerance among dopamine receptor-selective agonists suggests that tolerance to caffeine-induced rotational behavior is mediated by the D₂ but not the D₁ dopamine receptor. BEHAVIOURAL AND NEUROCHEMICAL STUDIES OF A PHENTERMINE AND FENFLURAMINE DRUG MIXTURE IN RATS. Shoaib M*, Baumann MH*, Rothman RB*, Goldberg SR*, Schindler CW* ¹Preclinical Pharmacology Branch, ²Clinical Pharmacology Branch, Addiction Research Center, National Institute on Drug Abuse, Baltimore MD 21224, USA.

Clinical case studies suggest that combined administration of phentermine (PHEN) and fenfluramine (FEN) may be useful in the treatment of alcohol and cocaine addictions (Hitzig, *Maryland Med J* 42, 1993). The present experiments examined the nature of interaction between the two aminergic agonists using the drug discrimination paradigm to examine subjective effects and the *in vivo* microdialysis technique to assess the neurochemical effects in the nucleus accumbens. Three groups of Sprague-Dawley rats were trained to discriminate saline from (1) FEN (1.0 mg/kg i.p.), (2) PHEN (1.0 mg/kg i.p.) and the mixture (3) PHEN+FEN (1:1 ratio) under a fixed ratio (FR10) schedule of food reinforcement. The majority of rats trained on the mixture acquired the discrimination after 32 ± 4 sessions. In comparison the majority of rats trained to discriminate the individual compounds failed to meet criteria in 60 sessions. The individual compounds (1 mg/kg i.p.) generalized partially to the mixture, and complete generalization was observed following 3.0 mg/kg of FEN or PHEN. In conscious rats, local infusions of FEN (1 µM) or PHEN (1 µM) into the nucleus accumbens selectively increased serotonin and dopamine respectively. The mixture (1:1 ratio) increased both amines to a similar degree. Therefore, this dual stimulation of the amines by the mixture may be the basis for the cueing effects of the FEN+PHEN drug mixture. Furthermore, these aminergics appear to interact additively at both behavioural and neurochemical levels.

CLORGYLINE POTENTIATES THE TOXICITY OF SUBSTITUTED AMPHETAMINES IN CULTURED FETAL RAPHE NEURONS. E.T. Kokotos Leonardi*, X.P. Hou and E.C. Azmitia. Dept. of Biology, New York University, NY 10003.

MDMA and FEN are substituted amphetamines that bind to the serotonin transporter, promote the release and inhibit the re-uptake of, serotonin in pre-synaptic terminals. The release of serotonin and inhibition of its reuptake and catabolism may work synergistically to raise extracellular levels of serotonin in the brain. A consequence of increased extracellular serotonin is PKC activation (see abstract by Kramer and Azmitia) and the stimulation of glycogenolysis (see abstract by Poblete and Azmitia) which may contribute to the neurotoxic mechanism of substituted amphetamines. We now report that MDMA and FEN toxicity at concentrations ranging from 1-10 µM is potentiated by the addition of clorgyline at concentrations ranging from 0.1 to 10 nM. For example, uptake of ³H-5-HT in 10 µM FEN treated cells= 50% of control; 10 µM FEN+ 0.1 nM clorgyline=32% of control (p<0.001); ³H-5-HT uptake in 5 µM treated MDMA cells=63% of control, 5 µM MDMA+0.1 nM clorgyline=57% of control (p<0.001). Furthermore, the addition of serotonin at concentrations ranging from 10 nM-10 µM produced inhibition of serotonin uptake in a dose-dependent manner.

Serotonergic cells were obtained from E14 rat pups. A rostral rhombencephalic and caudal mesencephalic slice was dissected from each embryo. Following mincing and trituration, cells were plated on poly-D-lysine coated 96 well plates (1.2x10⁵ cells/mL) and were incubated at 37°C. FuDR was added on day 2, and was removed followed by the addition of serum free media on day 3. Drugs were added on day 8 and uptake assay of ³H-5-HT was performed on day 12. Samples were counted by liquid scintillation counting at a counting efficiency of 58%. These results suggest that serotonin may be a component in the neurotoxic mechanism of MDMA and FEN. Neurobiological bases of methamphetamine action in the hippocampus. E. S. Onaivi*¹, K. A. Parker¹, A. Chakrabarti¹, G. Chaudhuri³, E. D. Motley², C. Bishop-Robinson¹ and S. S. Chirwa² Depts of ¹Pharmacology, ²Physiology and ³Division of Biomedical Sciences, Meharry Medical College, Nashville, TN 37208.

The effect of psychoactive drugs such as psychomotor agitation, attentional disturbances and memory dysfunctions suggests the involvement of the hippocampus and temporal lobe. However, the exact mechanisms by which the above effects are mediated are not known. A multidisciplinary approach is being used to investigate the neurobiological bases of membrane bound (DA) receptor function following activation by methamphetamine in the hippocampus of a rodent model. Groups of rats (N=10 per group) were chronically treated with vehicle, 1.0 and 10.0 mg/kg methamphetamine (ip) for about 3 months. The locomotor activities, stereotype behavior and performance in the elevated plus-maze tests were evaluated weekly. A reduction in aversion to the open arms was produced by the 1 mg/kg dose. The animals treated with the 10 mg/kg, also displayed a reduced aversion which reverted to an intense aversiveness towards the open arms of the maze after six weeks of treatment. Locomotor activity and stereotype behavior were significantly increased following treatment with the low and high doses of methamphetamine, the magnitude being greater at the 10 mg/kg dose. The tolerance which developed was more pronounced with the locomotor activity and stereotype behavior than with the performance on the plus-maze test. The neurochemical, molecular and electrophysiological bases underlying these neurobehavioral changes induced by methamphetamine are currently being studied in the hippocampal slices. IS METHYLPHENIDATE LIKE COCAINE? STUDIES ON THEIR PHARMACOKINETICS AND DISTRIBUTION IN HUMAN BRAIN. N.D. Volkow*, Y.-S. Ding, J.S. Fowler, G.-J. Wang, J. Logan, J.S. Gatley, S. Dewey, C. Ashby, J. Lieberman, R. Hitzemann, A.P. Wolf. Medical Department and Chemistry Department, Brookhaven National Laboratory, Upton, New York 11973; Department of Psychiatry SUNY-Stony Brook, Stony Brook, New York 11794; Hillside Hospital, Glen Oaks, New York 11004.

Cocaine and methylphenidate (MP) have very similar pharmacological properties. Yet cocaine is considered one of the most reinforcing and addictive drugs while MP is widely used to treat attention deficit disorder in children. PET was used in conjunction with [¹¹C]methylphenidate to measure the pharmacokinetics and regional brain distribution of methylphenidate in normal volunteers. The relationship between MP's pharmacokinetics and MP-induced "high" were also evaluated. The results were compared with those previously obtained for cocaine as assessed with [¹¹C]cocaine. MP's absolute uptake in brain (7-10%) as well as its regional distribution, was identical to that of cocaine. MP pretreatment (0.5 mg/kg iv) inhibited binding only in striatum suggesting, that as for cocaine, specific binding was limited to striatum. The pharmacokinetics of MP and of cocaine in brain were significantly different. Clearance of MP from striatum (90 minutes) was significantly slower than that of cocaine (20 minutes). For both drugs their fast uptake in striatum paralleled the experience of the "high". For MP the "high" decreased very rapidly despite significant binding of the drug in brain. In contrast for cocaine, the decline in the high paralleled its fast rate of clearance from brain. Because the experience of the "high" correlated only with the initial fast uptake of the drug in brain, the slow clearance of MP from brain may serve as a limiting factor in promoting its frequent self-administration and may explain the much lower abuse of MP than of cocaine.

THE ACTIVATION OF PKC BY MDMA IS DEPENDENT ON THE RELEASE OF 5-HT FROM VIABLE NERVE TERMINALS. H.K. Kramer* and E.C. Azmitia. Dept. of Biology, New York Univ., NY, NY 10003.

Substituted amphetamines, such as 3,4-methylenedioxymethamphetamine (MDMA), have been shown to bind with high-affinity to and inhibit the serotonin (5-HT) uptake transporter, promote the release of 5-HT, increase the uptake of extracellular Ca²⁺, and inhibit the activity of monoamine oxidase-A. Additional studies have shown that many of MDMA's acute and neurotoxic effects arise from an interaction with the central 5-HT₂ receptor. This receptor is coupled to the breakdown of membrane-bound phospholipids and the activation of protein kinase C (PKC). These effects, occurring in concert, appear to underlie MDMA's neurotoxic properties. Our laboratory has previously reported that MDMA induces a prolonged translocation of soluble PKC to the plasma membrane when administered *in vivo*, and this persists up to 5 days after the cessation of treatment. We now report that this metabolic effect is dependent on the release of 5-HT and the stimulation of postsynaptic serotonin receptors.

Male Sprague-Dawley rats were exposed to MDMA (8 x 20 mg/kg, s.c.) and assayed for PKC translocation. A subset of animals were pretreated (21 days earlier) with the 5-HT neurotoxin, p-chloroamphetamine (PCA), to reduce cortical 5-HT content. 72 hrs. following the last MDMA injection, rat cortices from both groups were assessed for PKC translocation and 5-HT terminal density via high affinity ³H-PDBu and ³H-paroxetine binding, respectively.

MDMA induced a lasting translocation of PKC in animals exposed for four days (saline: 7.32 ± 0.25 pmol/mg prot vs. MDMA: 10.78 ± 0.37 pmol/mg prot; p < 0.05). Rats pretreated with PCA showed a significant (94.5%) decrease in the density of cortical 5-HT uptake sites, and in those groups, MDMA was unable to elicit an activation of PKC. We believe that the prior loss of cortical 5-HT nerve terminals prevents the cytosolic release of 5-HT by MDMA and the concomitant activation of PKC. These results show that the presynaptic release of 5-HT mediates this metabolic effect of MDMA, and that the activation of PKC and subsequent phosphorylation of its membrane-bound substrates may contribute to amphetamine-induced neuronal death. (NIDA # 271-90-7403 to ECA)

ACTIVATION OF GLYCOGEN PHOSPHORYLASE BY MDMA(+) IN ASTROGLIAL-RICH PRIMARY CULTURES. J.C. Poblete* and E.C. Azmitia. Dept. of Biology, New York Univ., NY, NY 10003.

Glycogen is the single largest energy reserve in the brain. Neurotransmitters, neuropeptides, and ions regulate glycogen levels in the brain by modulating the activity of glycogen synthase (GSase) and glycogen phosphorylase (GPase). GPase has recently been shown to be co-localized with glial fibrillary acidic protein (GFAP), an astroglia-specific marker, suggesting that glycogen is localized in astroglial cells. Additionally, serotonin (5-HT) has been shown to stimulate glycogenolysis and functional receptors are found in neurons and in glia. It has been reported that 3,4-methylenedioxymethamphetamine (MDMA), a drug of abuse, stimulates the release of, inhibits the reuptake of 5-HT, and selectively inhibits the activity of MAO-A. These biochemical consequences of MDMA lead to a prolonged 5-HT activity. This study investigates the effects of MDMA and 5-HT on glycogen metabolism in the CNS. A histochemical method was designed to visualize active GPase in an astroglial-rich primary culture. The number of GPase reactive sites were measured using computer-aided densitometric software (OPTIMAS; Bioscan, Inc).

5-HT activates GPase in a concentration-dependent manner. Maximal activation by 5-HT was achieved at 10 μ M and resulted in a 126% increase in the number of reactive sites. Interestingly, MDMA(+) directly stimulated GPase activity with maximal activation induced by 5 μ M and which caused a 70% increase in the number of reactive sites. The effects of 5-HT and MDMA(+) were attenuated by 10 μ M mianserin, a 5-HT₂ (S₂) receptor antagonist. Our results indicate that these effects may be mediated by S₂ receptor, and that MDMA leads to increased synaptic 5-HT activity (see abstracts by Kramer and Azmitia, and Kokotos-Leonardi and Azmitia), and consequently, GPase activity. Extended GPase activity can lead to depletion of synaptic energy stores. Thus, compromising the energy state of the synapse will lead to synaptic dyshomeostasis and may contribute to terminal degeneration induced by substituted amphetamines. An astrocyte-neuron metabolic link may be vital for synaptic homeostasis. (NIDA # 271-90-7403)

529.9

ATTENUATION OF METHYLENEDIOXYAMPHETAMINE (MDA)-INDUCED NEUROTOXICITY IN TRANSGENIC MICE WITH INCREASED CU/ZN-SUPEROXIDE DISMUTASE ACTIVITY (SOD): EVIDENCE FOR INVOLVEMENT OF FREE RADICALS. J.L. Cadet*, B. Ladenheim, R.B. Rothman, E. Carlson, C. J. Epstein. NIH/NIDA, ARC, Baltimore, MD 21224; and Department of Pediatrics, UCSF, San Francisco, CA 94143.

Administration of methylenedioxymethamphetamine (MDA) to rodents causes loss of monoaminergic terminals. The mechanism by which MDA causes its neurotoxicity is not known. MDA might kill these terminals by producing oxyradicals due to the increased release of dopamine in the synaptic space (Nash and Nichols, 1991). In order to further evaluate the role of oxyradicals in MDA-induced neurotoxicity, we have tested its effects in transgenic mice (SOD-Tg) which overexpress the human SOD gene. In nontransgenic mice, MDA administration causes a significant loss of DA terminals in the caudate-putamen measured by receptor autoradiography of [¹²⁵I]RTI-55-labeled dopamine uptake sites. In contrast, there were no significant changes in heterozygous SOD-Tg mice. Homozygous SOD-Tg mice show small decrements in striatal DA terminals which were of much smaller magnitude than those observed in the Non-Tg mice. These results suggest that MDA-induced toxicity in rodents may be secondary to the increased production of superoxide radicals after administration of MDA.
