Mn and CuZn superoxide dismutases (SODs) are enzymatic scavengers of superoxide free radicals. Mitochondrial MnSOD and cytosolic CuZnSOD were localized immunohistochemically in olfactory mucosa obtained at autopsy from 19 subjects, 11 males and 8 females, ranging from 24 to 98 years of age. Four patients were classified as young/middle aged (under 60 years old), 6 as old (over 60 years old), 4 (69-98 years old) as "successfully aged", and 5 (52-90 years old) had pathologically confirmed Alzheimer's disease (AD). Postmortem intervals (PMIs) ranged from 2-22 h. In young/middle aged subjects, intense immunoreactivity was observed in olfactory receptor neurons, sustentacular and basal cells in the olfactory epithelium and in Bowman's glands, olfactory nerves, and vascular endothelium in the lamina propria. Comparing young/middle aged and old, there was an age-related decrement in the overall intensity and distribution of immunoreactivity that was most pronounced in olfactory receptor neurons, basal cells, and endothelium. Old subjects often had restricted foci of intense epithelial immunoreactivity. In the "successfully aged," large regions of immunoreactivity as intense as that in young/middle aged subjects were intermingled with smaller regions of reduced intensity. Subjects with AD generally exhibited the most intense staining that was distributed like that in the "successfully aged." These differences were not related to PMI; the 3 youngest subjects had the longest PMIs, 3 old subjects had short PMIs; age- and AD-related trends were observed in subjects from the different groups matched for age and PMI. High levels of SODs in the young/middle aged and "successfully aged" may reflect the higher cellular viability of their olfactory mucosae, while high levels in the AD subjects may be related to oxidative stress associated with the disease process. Supported by NIH grants DC 01715 (MLG) and DC 00159 (TVG).

A QUANTITATIVE PCR STUDY OF GABA_A AND GLUTAMATE RECEPTOR SUBUNIT EXPRESSION IN THE RAT OLFACTORY BULB FOLLOWING PERIPHERAL DENERVATION. P. Bovolin*, I. Perroteau*, R. Ebberts*, A. Fasolo*. Dept. Animal Biology, Univ. of Torino, 10123 Torino, Italy and *Dept. Anim. Physiology, Univ. of Nijmegen, Nijmegen, 6525 The Netherlands.

The olfactory system is a remarkable model to study *in vivo* basic phenomena occurring in neuronal plasticity. Olfactory neurons, located in the olfactory mucosa, send their axons to the glomerular layer of the olfactory bulb where they make synapses with several neuronal types. An important consequence of peripheral afferent denervation of the olfactory bulb is a sharp reduction of the neurotransmitter dopamine due to loss of tyrosine hydroxylase (TH) mRNA. In the present study we began to address the question of whether the expression of subunits belonging to various GABA_A and glutamate receptor complexes is modified after unilateral chemical lesion (ZnSO₄-irrigation) of the rat olfactory mucosa. Analysis of the olfactory bulb total RNA was performed on 3 groups of male adult rats [(1) untreated, (2) saline- and (3) ZnSO₄-irrigated rats], sacrificed 12 days post-lesion. Both competitive polymerase chain reaction (PCR) assays and semiquantitative PCR experiments were employed to compare the relative abundance of mRNAs in the 3 groups. Measurements of TH mRNA were used as an indication of the effectiveness of the lesion. In ZnSO₄ irrigated rats we found a remarkable reduction of both the γ 2L and γ 2S GABA_A receptor subunit mRNAs, while we observed only a slight increase in the NMDR1b mRNA splicing form and no significant change in the NMDR1a and in the GluR1 mRNAs. Our findings suggest that the expression of at least some GABA_A receptor subunits in the olfactory bulb are under transynaptic regulation. Since it has been recently demonstrated that glutamate-immunoreactivity is present in olfactory neuron terminals (Sassoe-Pognetto et al., Neuroreport, 1993), loss of release of the neurotransmitter glutamate could be responsible of the negative modulation in the expression of GABA_A receptor genes in post-synaptic elements. MINERALOCORTICOID (TYPE I) RECEPTOR-LIKE IMMUNOREACTIVITY IS ASSOCIATED WITH BOWMAN'S GLANDS IN THE MAMMALIAN OLFACTORY MUCOSA. J.D. Foster¹, R.C. Kern², and D.Z. Pitovski¹. Depts. of Otolaryngology - Head and Neck Surgery, ¹Wayne State University, Detroit, MI 48201 and ²Northwestern University, Chicago, IL 60201.

The location of mineralocorticoid (type I) receptor-like immunoreactivity in mouse, hamster, and guinea pig olfactory mucosae was determined by the use of immunocytochemistry. Within the olfactory mucosae of all three rodent models, acinar cells (found in the glandular portion of Bowman's glands) and duct cells (found in the ductal portion of Bowman's glands) were positive for the mineralocorticoid receptor as revealed by both immunofluorescence and the ABC immunoperoxidase procedures. The distribution of mineralocorticoid receptor-like immunoreactivity was uniform throughout the cytoplasm of the acinar and duct cells of Bowman's glands. The respiratory regions of the nasal mucosa did not appear to be immunoreactive for the mineralocorticoid receptor. There was no immunocytochemical staining when the antibody to the mineralocorticoid receptor was omitted from the primary incubation medium.

There is evidence that Bowman's glands and their ducts are involved in both the secretion of glycoproteins and the secretion of electrolytes and water, processes which are apparently controlled by neurotransmitters (e.g., adrenergic and cholinergic nerve endings) and peptide hormones (e.g., VIP and LHRH). Since mineralocorticoids, such as aldosterone, have been shown to be involved in fluid and electrolyte regulation in other systems, the localization of mineralocorticoid receptor-like immunoreactivity to cells of Bowman's glands and ducts suggests that mineralocorticoids may play a similar role in the olfactory mucosa.

NMDA Blockade Partially Reverses Paired-Pulse Depression in the Turtle Olfactory Bulb

D.M. Senseman*. Div. of Life Sciences, UTSA, San Antonio, TX, 78249

In the turtle olfactory bulb, primary olfactory neurons are thought to excite mitral/tufted (M/T) cells by stimulating both NMDA and non-NMDA glutamate receptors (Berkowicz *et al.*, J. Neurophysiol. 71, 1994). It has been suggested that the non-NMDA receptors allow M/T cells to respond rapidly to incoming odor information while the NMDA receptors might provide a means for the short-term temporal integration of this information. We have examined this idea by optically monitoring electrical activity in the isolated turtle olfactory bulb stained with the voltage-sensitive dye, RH 155. The figure below shows optical responses recorded from the external plexiform layer evoked by paired-pulse stimulation (500 ms separation) of the olfactory nerve before (thin trace) and after (thick trace) addition of the NMDA antagonist, AP-5 (100 μ M), to the bathing solution. As can be seen, NMDA blockade partially reverses depression of the second (test) response but has little effect on the initial (conditioning) response.

OLFACTION AND CHEMICAL INJURY OR SENSITIVITY. Donald L. Dudley* Chemical Injury Research Foundation, Tacoma, WA 98407.

Auditory, visual and upper and lower somatosensory evoked potentials were measured in 20 patients with clinical criteria for chemical sensitivity. Measures were made before and during exposure to chemicals that volatilized and led to complete debilitation.

In general, auditory and visual P3 latencies and N19, P22, P37 and N45 latencies were significantly increased ($p = 0.0001$). In general, amplitude for the same variables was not significantly changed ($p = 0.20$). An exception was the auditory P3 amplitude which was significantly decreased ($p = 0.0001$).

Latency correlations were low or not significant prior to exposure and highly significant during exposure. On the other hand, amplitude correlations were highly significant before exposure and not significant during exposure.

Since olfactory signals are sent to nearly every part of the brain it is thought that this system's use of excitatory amino acids and their precursors for neurotransmission in association with chemicals with six or less carbon fragments that volatilize could lead to brain cell injury and subsequent neuronal changes that are experienced by the patient as the signs and symptoms of chemical sensitivity or injury.

The above will be discussed in association with agonists and antagonists of excitatory amino acids in humans.

LOCALIZATION OF HUMAN GUSTATORY AND SPEECH CENTERS USING FUNCTIONAL MAGNETIC RESONANCE IMAGING (fMRI). J. Hirsch^{*1,3}, R. DeLaPaz^{2,3}, N. Relkin¹, J. Victor², T. Li¹ and K. Kim^{1,3}. Dept of Neurology¹ and Radiology², Memorial Sloan-Kettering Cancer Center; Dept of Neurology and Neuroscience, Cornell University Medical College³, New York, NY 10021.

We present the first direct evidence that the cortical representation of human taste sensations tends to be lateralized to the dominant hemisphere. Fourteen contiguous 5mm coronal slices rostral to a plane passing through the colliculi were imaged on 1.5T GE scanner equipped for echo-planar imaging. Two right handed and two left handed normal volunteers were imaged during baseline and stimulation conditions consisting of 8cc of either water, 1 M salt or 1 M sucrose injected into the mouth. Speech tasks were either alphabetical naming or memorized rhymes and confirmed that the dominant hemispheres for language were contralateral to handedness for all 4 subjects. Tongue movements alone and water conditions served as controls for related activations. A multi-stage single voxel statistical analysis including replication criteria identified active taste regions in the insula and frontal operculum predominantly in the dominant hemisphere. These findings suggest that human cortical gustatory processing is functionally lateralized.

A 3-D FUNCTIONAL MRI DEMONSTRATION OF BRAIN STRUCTURES INVOLVED IN HUMAN OLFACTION. N.F. Ramsey, B. Rawlings, P. Van Gelderen, J. Duyn, C.T.W. Moonen, D.W. Hommer. National Institute of Alcoholism and Alcohol Abuse, NMR *In Vivo* Center, Laboratory of Diagnostic Radiology Research, NIH, Bethesda, MD 20892.

Olfactory processing selectively involves the limbic system. Imaging of limbic areas with fMRI is problematic, due to their location near the base of the skull, close to major blood vessels. We report an olfactory stimulation study involving a 3D Echo-Shifted FLASH sequence and a Gaussian random field based statistical evaluation (Worsley, K. J., Evans, A. C., Marrett, S. et al., *J. Cerebr. Blood Flow Metab.* 12, 900-918, 1992). Pleasant odors were administered to 10 subjects (Ss). After anatomical scans, 8 stimulation trials were done at 3 minute intervals. Each trial consisted of two consecutive functional scans, with 7 seconds between scans. Olfactory stimulation was switched on at the end of the first scan, and off at the end of the second scan (odor duration 27 secs.). For each subject, data were converted to difference images, obtained by subtracting the unstimulated from the stimulated 3D image within each trial. Trials were then summed, and Ss analyzed individually. Significantly activated voxels were found in structures of the olfactory system, including the amygdaloid complex (5Ss), septal nuclei (3Ss) ventromedial striatum (3Ss), posterior lateral orbitofrontal cortex (4Ss). Very few significant voxels were found outside of the olfactory system. These results indicate that the 3D Echo-Shifted Flash sequence enables *in vivo* measurement of odor-induced signal-intensity changes in human brain and that a random field model is a rigorous method for minimizing false positive results, while preserving statistical power.

IDENTIFICATION OF NOVEL PHOSPHOLIPID MEDIATORS AND LIPID SECOND MESSENGERS CAUSING GROWTH CONE COLLAPSE AND NEURITE RETRACTION IN PC12 CELLS. G. Tigyi^{*}, A. Sebökt, J. Szeberényi Dept of Physiology & Biophysics, University of Tennessee, Memphis, TN 38163; [†]Dept of Biology, Medical Univ. of Pécs, 7624, Hungary.

The endogenous phospholipid lysophosphatidic acid (1-acyl-2-lyso-sn glycerophosphate, LPA) causes the remodeling of actin cytoskeleton leading to neurite retraction in NGF-differentiated PC12 cells (Tigyi & Miledi, *J. Biol. Chem.* 267, 21360-67, 1992). We now show that several other structurally related phospholipids, including the ether-linked hexadecyl-lyso-glycerophosphate (GP), hexadecylacetly-GP, as well as palmitoylacetly-GP, palmitoyl-cyclicGP, and sphingosylphosphorylcholine, all in nanomolar concentrations, cause a rapid retraction of neurites. Interestingly, all these mediators activate oscillatory chloride currents in *Xenopus* oocytes via receptor-mediated activation of the phosphoinositide system. In contrast, PAF, DAG, and a number of other structurally similar lysophospholipids (LPC, LPE) failed to elicit a responses in either cell. LPA action is initiated at a plasma membrane receptor blocked by suramin. Retraction was not inhibited by pertussis toxin, but was sensitive to neomycin, Al^{3+} with F^{-} ions, and U73122, indicating G protein involvement. LPA-induced neurite retraction was accompanied by activation of phosphoinositide turnover, Ca^{2+} transients and inhibition of adenylylcyclase. However, activation of these very same signaling events was also found following carbachol or bradykinin stimulation, suggesting that an alternative signaling pathway is responsible for neurite retraction. Phorbol esters blocked retraction, yet staurosporine failed to inhibit it in concentrations that inhibit PKC. Although arachidonic acid and prostanoids cause neurite retraction, the action of LPA was not inhibited by indomethacin. Leukotrienes C_4 , D_4 and E_4 were also ineffective. ADP ribosylation of the small-molecular-weight GTP binding protein *rho* by C3-toxin also prevented neurite retraction. In contrast, LPA caused cell shape changes in PC12 cells expressing a dominant negative *ras*. Interestingly, the lipid second messengers sphingosine, ceramide (C2 and C8), and sphingosine-1-phosphate also caused neurite retraction. Because LPA was detected in postinjury and posthemorrhagic cerebrospinal fluid, a hypothesis is suggested that LPA-like lipid mediators may alter the regenerative sprouting of axons through a yet unidentified signaling mechanism linked to the receptor-mediated generation of ceramide and sph-1-P. CALCINEURIN FUNCTIONS IN NEURITE OUTGROWTH AND DIRECTED GROWTH CONE MOTILITY. H. Y. Chang, E. Rusnak[†], and D. G. Jay^{*}. Dept. Cell. Mol. Biol., Harvard Univ., Cambridge, MA 02138. [†]Section of Hematology Research, Mayo Clinic and Foundation, Rochester, MN 55905.

Calcineurin is a Ca^{++} -calmodulin-dependent protein phosphatase that is most abundant in the brain. Application of specific inhibitor cyclosporin A or FK506 to cultured chick dorsal root ganglia neurons delayed neuritegenesis and inhibited neurite extension, suggesting that calcineurin is involved in both of these processes. On the basis of its potential signaling function and localization in the growth cone, we hypothesized that differential calcineurin activity across the growth cone may direct growth cone motility and guide neurite extension. This idea was tested by microscale chromophore-assisted laser inactivation (micro-CALI) of calcineurin in cultured DRG neurons. Calcineurin phosphatase activity is sensitive to CALI *in vitro*. Chromophore-labeled antibodies against calcineurin were loaded into chick DRG neurons by trituration, and site-directed inactivation of calcineurin in regions of the growth cone was achieved with a laser microbeam. Micro-CALI of calcineurin caused the filopodia and lamellipodia in the irradiated region to retract; growth cone behaviors outside of the irradiated area were not affected. Micro-CALI with chromophore-labeled pre-immune serum had no effect on growth cone motility. Since the instantaneous and regional loss of calcineurin activity causes local retraction, we suggest that the spatial distribution of calcineurin activity regulates growth cone motility.

607.2

TALIN FUNCTION IS SPATIALLY INTEGRATED IN THE NEURONAL GROWTH CONE. Anne M. Szydor^{*} and Daniel G. Jay. Department of Cellular and Molecular Biology, Harvard University, Cambridge MA, 02138.

Dynamic extension and retraction of filopodia is thought to function in signal detection and force generation needed for directed motility of the neuronal growth cone. To address the role of cytoskeletal proteins in filopodial motility we have used micro-CALI (Chromophore Assisted Laser Inactivation) to functionally inactivate the cytoskeletal protein talin in growth cones of chick DRG neurons in culture. We have found that inactivation of talin in a region of the growth cone results in a loss of filopodial extension and retraction, whereas inactivation of talin over the whole growth cone has no effect on filopodial motility. Micro-CALI inactivates proteins within a 10-15 micron spot by directing the energy of a 620 nm laser beam to the protein via a dye-labeled antibody. Neurons were trituration loaded with malachite green-labeled antibodies to talin and regions of the growth cone were laser irradiated for five minutes. This caused the rate of extension and retraction of filopodia within the irradiated area to drop to zero for one to four minutes; filopodia outside this region showed no change in motility. Irradiation of whole growth cones at the same laser power did not result in any change in filopodial behavior. Laser irradiation of malachite green-BSA loaded controls showed no change in growth cone motility. This provides evidence that talin can act to couple filopodial movement to cytoskeletal dynamics. These data also suggest that the growth cone spatially integrates internal differences in protein function. We believe such spatial integration of protein function could provide the basis for directed growth cone motility and are investigating this possibility.

NERVOUS SYSTEM ABNORMALITIES RESULT FROM TARGETED MUTATION OF MAP1b. W. Edelmann, P. Costello, F. Davies, L. Roback, B.H. Wainer^{*}, R. Kucherlapati, Depts. of Molecular Genetics, Neurosurgery and Pathology, Albert Einstein College of Medicine, Bronx, NY 10461.

For proper development of the brain, an intact complement of cytoskeletal elements is required, including that of the microtubule associated proteins. The microtubule associated protein 1b (MAP1b) is a member of this microtubule network in neurons and glia. MAP1b expression is developmentally regulated and is highest during embryogenesis and the early postnatal period. This expression pattern suggests involvement in the regulation of neurite outgrowth. We targeted a mutation in the MAP1b gene which resulted in embryonic lethality in homozygous mice and a marked phenotype in some heterozygous animals. This phenotype includes blindness, an ataxic gait, a spastic tremor of the hindlimbs and an overall reduction in body weight of 25-50%. Histologically, the phenotype is pronounced in the cerebellum. The principal abnormality is in the configuration of the Purkinje cell bodies and their dendritic arborizations. Immunohistochemical studies with MAP1a and MAP1b specific antibodies show reduced staining in Purkinje cells. No decrease in staining of another cytoskeletal protein, MAP2, was observed. Western blots revealed no change in levels of neurofilament proteins, MAP2 or tau. Additional abnormalities were seen in the hippocampus, olfactory bulbs and visual system. These results demonstrate an essential role of MAP1b in the development of the brain.

607.5

EVIDENCE THAT CAMs STIMULATE NEURITE OUTGROWTH BY ACTIVATING FGF RECEPTORS IN NEURONS. P. Doherty*, E.J. Williams, J. Furness and F.S. Walsh, Department of Experimental Pathology, UMDS, Guy's Hospital, London SE1 9RT.

We have used monolayers of parental 3T3 and 3T3 cells expressing one of three transfectant cell adhesion molecules (CAMs) (NCAM, N-cadherin and L1) as a culture substrate for rat cerebellar neurons. A number of lines of evidence suggest that neurite outgrowth stimulated by the above CAMs involves activation of the FGF receptor in neurons. Affinity purified antibodies that bind to the FGF receptor in neurons inhibit neurite outgrowth stimulated by the above CAMs but have no effect on integrin dependent neurite outgrowth or neurite outgrowth stimulated by a variety of other agents. In addition we have found that a soluble L1-Fc chimera is as effective as cell associated L1 in promoting neurite outgrowth. The response to the L1-Fc chimera is fully inhibited by pre-treatment of neurons with antibodies that bind to L1 or the FGF receptor. The response is also associated with an increase in phosphotyrosine on the same set of neuronal proteins, including the FGF receptor, that are phosphorylated following activation of the FGF receptor with basic FGF. We conclude that activation of the FGF receptor, rather than changes in adhesion, underlies the neurite outgrowth response to a number of CAMs.

GAP-43 IMMUNOREACTIVITY AND AXONAL REGENERATION OF RAT RETINAL GANGLION CELLS. H. Schaden*, M. Bähr*, C.A.O. Stuermer, University of Konstanz, Germany, *MPI Tübingen, Germany.

While more than 90% of the retinal ganglion cells (RGCs) in rats die upon optic nerve section (ONS), a subfraction of those that survive is capable ("competent") of regenerating an axon into a peripheral nerve (PN) graft (Vidal-Sanz et al., 1987). To determine whether re-expression of GAP-43 and the transcription factor c-JUN is specifically found in "competent" RGCs, the relevant antibodies were applied to sections of retinae (i) in rats with ONS only and (ii) in rats which had received a PN graft. RGCs were labeled by the retrograde tracer Fluorogold (FG) applied (i) to the ON to identify surviving RGCs, (ii) to the PN graft to identify RGCs with regenerating axons.

(i) GAP-43-immunoreactivity (Ir) was seen in 22% of RGCs at 5d after ONS and in 2% and 1% at 14 and 21d, respectively, in rats without grafts. (ii) In rats with PN grafts, only those RGCs which were FG-labeled (and thus had regenerated an axon into the graft) exhibited GAP-43, and they represented 3% and 2% at 21 and 28d after surgery, respectively. c-JUN-Ir, however, was found in (i) many more RGCs than GAP-43 and in (ii) at least twice as many RGCs at 21 and 28d, than there were RGCs labeled with FG and exhibiting GAP-43-Ir.

Thus regenerating axons in PN grafts derive specifically from GAP-43 re-expressing RGCs. Appearance of GAP-43 may therefore identify those RGCs that possess the intrinsic property of axonal regeneration or sprouting.

KAINATE RECEPTOR ACTIVATION INDUCES F1/GAP-43 mRNA IN DENTATE GYRUS GRANULE CELLS AND SPROUTING OF ITS AXONS. THE MOSSY FIBERS: BLOCKADE BY MK-801 AND PENTOBARBITAL. R.K. McNamara*, P.A. Serrano & A. Routtenberg, Cresap Neuroscience Laboratory, Northwestern Univ. Evanston, IL 60208.

In the adult rat, dentate gyrus granule cells do not express F1/GAP-43 mRNA (Rosenthal et al., EMBO, 6: 3641, 1987). Kainic acid (KA), a rigid glutamate analogue, induces F1/GAP-43 mRNA in granule cells maximally at 24 hr (McNamara et al., Soc. Neurosci., 1993). KA also induces sprouting of granule cell axons, the mossy fibers, into the supragranular layer beginning ~10 d after KA (Nadler et al., Brain Res., 182: 1, 1980). To relate the induction of F1/GAP-43 mRNA in granule cells to subsequent mossy fiber sprouting, adult male Sprague-Dawley rats were injected with: 1) saline 2) KA (s.c., 10 mg/kg), 3) PENT (i.p., 50 mg/kg), 4) PENT then KA 15 min later, 5) MK-801 (i.p., 2 mg/kg), and 6) MK-801 then KA 15 min later. Rats were sacrificed either (A) 24 hr after the last injection and F1/GAP-43 gene expression assessed using quantitative *in situ* hybridization or (B) 30 d later when mossy fiber sprouting was assessed with Timm's stain.

KA alone first induced F1/GAP-43 mRNA in granule cells as well as subsequent mossy fiber sprouting into the supragranular region. Visual inspection revealed no significant cell loss in areas CA3/4 after KA alone. Pre-treatment with PENT or MK-801 significantly attenuated both F1/GAP-43 mRNA induction and supragranular sprouting but, except in one case, did not affect cell loss in CA3/4. In the one rat showing extensive cell loss in areas CA3/4, only minor mossy fiber sprouting was observed. When administered alone, PENT and MK-801 did not affect F1/GAP-43 mRNA, mossy fiber sprouting, or cell survival. It is proposed that induction of F1/GAP-43 expression in granule cells leads to mossy fiber sprouting. This sprouting appears to be independent of extensive cell loss in areas CA3/4. [supported by MH25281-21 to A.R. and Postdoctoral fellowships from NSERC to R.K.M. and NSF to P.A.S.].

PERMISSIVE ROLE OF GAP-43 IN NEURITE OUTGROWTH: PRIMARY SENSORY NEURONS AND TRANSGENIC MICE. L. Aigner, F. Botteri, and P. Caroni*, Friedrich Miescher-Institute, P.O. Box 2543, CH-4002 Basel, Switzerland.

The specific association of the growth-associated protein GAP-43 with nerve growth during development and regeneration suggests that it may play a role in this process (Skene (1989) Ann. Rev. Neurosci. 12:127). Downregulation of neuronal GAP-43 expression during development frequently coincides with the process of synapse elimination, suggesting that it may also be involved in local process outgrowth and maintenance. To define the role of GAP-43 in neurite outgrowth we have 1) analyzed neurite and growth cone (GC) activity in primary sensory neurons specifically depleted of GAP-43 by an antisense approach (Aigner and Caroni (1993) JCB 123:417), and 2) generated transgenic mice that constitutively express chick GAP-43 in adult neurons. Characteristic features of primary sensory neurons regenerating neurites on a PORN/laminin substratum in the absence of GAP-43 included: 1) poorly adhesive GC's with highly dynamic peripheral lamellae and rudimentary central domains; 2) absence of NGF-induced GC spreading or IGF1-induced GC branching; 3) high susceptibility to retraction induced by CNS myelin-derived inhibitors; 4) protection against inhibitor-induced retraction by NGF. Mice expressing GAP-43 in adult neurons (neuron-specific Thy-1 promoter construct) show extensive intramuscular nerve sprouting and a striking motor and behavioral phenotype. Several lines of mice were generated and the phenotype correlated with expression levels of the transgene. Our results indicate that GAP-43 plays an important permissive role in neurite outgrowth.

607.8

REDUCED PRESYNAPTIC ACTIVITY DURING NEUROMUSCULAR DEVELOPMENT PROMOTES FOREIGN MOTOR ENDINGS IN *DROSOPHILA*. J. Jarecki* and H. Keshishian, Genetics and Biology Depts., Yale Univ., New Haven, CT 06511.

Electrical activity plays a role in the development of *Drosophila* neuromuscular synapses. We previously showed that blocking presynaptic (but not postsynaptic) activity during embryonic synaptogenesis promoted inappropriate motoneuron contacts (JJ & HK, Neurosci Abstr, 19:645). In order to follow the development of these ectopic contacts during larval life, temperature sensitive activity mutants affecting Na channels were examined (*para^{ts}*, *nap^{ts}*, and *sei^{ts}*). Collateral sprouting increased onto muscle fibers 6&7 in the mutant embryos when reared at 34°C during stages 15 & 16. (WT: 16% sprouts, n=169 segments; *para*: 25%, n=163, p<.05; *nap*: 29%, n=91, p<.025; *sei*: 28%, n=103, p<.05). By the 3rd instar, an increase in the number of ectopic motor endings was also observed on these fibers in *nap* and *sei* but not *para* larvae. (WT: 5.6% of fibers receiving sprouts, n=89 segments; *para*: 8%, n=110, p>.10; *nap*: 17%, n=76, p<.025; *sei*: 17%, n=117, p<.01). About 60% of the ectopic endings arise from the transverse nerve, 30% from endings on the oblique muscle fibers, and less than 5% from endings on muscle fibers 13 or 8. The morphology of the native neuromuscular endings is not changed by the presence of the ectopic synapses. Temperature shifting (37°C 6 hrs/day) during larval development further increased the number of ectopic endings to 30% in *nap* (n=84) and 34% in *sei* (n=104) as opposed to shifted WT animals (6%, n=62) and shifted *para* (2.4%, n=80). Significant increases were not observed in hyperactive mutants such as *eag sh* or *sei^f*. The critical period includes both late embryogenesis and the 1st instar. We hypothesize a reduction in synaptic activity in the embryo induces filopodial sprouting, and that in the 1st instar reduced synaptic activity stabilizes them. These results show that synaptic activity contributes to the maintenance of correct neural connectivity.

607.10

INCREASED SPROUTING OF PRIMARY AFFERENTS IN THE MYELIN-FREE RAT SPINAL CORD. Josef P. Kapfhammer*, Guido Schwegler, and Martin E. Schwab, Brain Research Institute, University of Zürich, August-Forel-Str. 1, 8029 Zürich, Switzerland.

We are interested in defining physiological functions of myelin-associated neurite growth inhibitors. These molecules are involved in the prevention of axonal regeneration in the adult mammalian CNS (Schnell et al., Nature 367:170, 1994). Previous work has shown that the regional expression of GAP-43, a putative marker for fiber growth and plasticity, is inversely related to the degree of myelination in the CNS of normal rats (Kapfhammer and Schwab, JCN 340:194, 1994). Furthermore, GAP-43 expression is strongly increased in myelin-free lumbar spinal cords when myelination was suppressed by neonatal X-irradiation (Kapfhammer and Schwab, Eur.J.Neurosci. 6:403, 1994). These results suggest a role for the inhibitors in restricting sprouting and anatomical plasticity in the normal CNS.

We have now investigated whether the increased expression of GAP-43 in the myelin-free spinal cord is indeed correlated with an increased potential for sprouting of nerve fibers and terminals. Dorsal roots of lumbar segments L2-L4 were cut in myelin-free and normal cords of 8 or 15 day old rats. Sprouting of primary afferents was studied 3 weeks later using thiamine monophosphatase (TMP) histochemistry. This enzyme specifically labels a subclass of spinal cord primary afferents. We found that the sprouting of TMP positive afferents is increased in the myelin-free cords as compared to normal controls. This further supports our hypothesis that CNS myelin and its associated neurite growth inhibitors are involved in the regulation of terminal sprouting and plasticity in the normal CNS.

607.11

AN ANTENNAE-AMPLIFIER MODEL FOR REGULATION OF NEURONAL GROWTH CONE BEHAVIOR

S.B. Kater, P. Dou, L.R. Mills*, R.W. Davenport. Colorado State University, Ft. Collins, CO 80523; *Toronto Western Hospital, Toronto, Ontario M5T-2S8.

Neuronal guidance is determined, in part, by the interaction of advancing growth cones with the environmental guidance cues they encounter. Growth cone behavior may change locally at the level of individual filopodial changes, regionally in restricted subdomains of the individual growth cone or extensively with overall changes in outgrowth pattern. This spectrum of growth cone behaviors enables growth cones to guide extending axons and dendrites to their targets. At each level, such morphological changes have been associated with changes in intracellular calcium levels. How the underlying architecture of this second messenger system, i.e. the sources and sinks of calcium, interact and compartmentalize within growth cones to coordinate resultant growth cone behavior has not been directly addressed. Here, in a single system we provide evidence of how such components can be arranged in individual growth cones. In preparations consisting of both isolated filopodia and their parent growth cones, intracellular calcium signals were examined in response to application of excitatory neurotransmitters and the calcium ionophore A23187. The presence of thapsigargin or calcium-free medium revealed that intracellular calcium pools are present and functional within the growth cone proper but not in isolated filopodia. Calcium release from stores can amplify second messenger signals dependent upon calcium influx, as occur in filopodia. The spatial distribution of growth cone organelles, which could serve as morphological correlates to such calcium amplification, were examined. While the large majority of organelles are located in the central core of the growth cone proper, peripheral organelles can be present at the base of a subset of filopodia. Such peripheral organelles could subserve a regional amplification system within growth cones. A model for second messenger regulation of growth cone behavior based on highly sensitive distal antennae, limited peripheral amplifiers and a dominant central amplifier will be presented.

RULES DETERMINING THE MONOSYNAPTIC CONNECTIONS BETWEEN LGN CELLS AND SIMPLE CELLS IN CAT VISUAL CORTEX. R. Clay Reid*, Jose-Manuel Alonso and Torsten N. Wiesel. Laboratory of Neurobiology, The Rockefeller University, New York, NY.

We have studied the rules that determine whether an individual afferent from the lateral geniculate nucleus (LGN) will have a monosynaptic connection with a given cortical simple cell. Our question was: how precisely can the synaptic connections between these two cell types be predicted by their functional properties. Single units were recorded with electrodes in both LGN and cortex. Receptive field position and structure were mapped with white noise visual stimuli. Connectivity between pairs of cells (one LGN cell and one simple cell) were determined with cross-correlation analysis of the spike trains. Narrow peaks with very short latencies were taken as evidence for monosynaptic connections.

The rules of connectivity are very precise. Over 80% of cell pairs were monosynaptically connected when a receptive field was centered over a simple cell subregion of the same sign (*on* or *off*). Connections were never seen when an different sign LGN receptive field was centered over a simple subregion (*on* vs. *off*). The probability of monosynaptic connection also depended on a good match between the receptive field sizes and the time-course of the responses. In particular, fast LGN afferents were less likely to be connected to a simple cell if the overlapping simple subregion had slower dynamics than the LGN center.

The elongated distributions of the direct *on* or *off* LGN afferents to individual simple cells explains at least part of cortical orientation selectivity. It does not, however, reject an important role of intracortical processes in sharpening this tuning.

COUPLING BETWEEN NEIGHBORING LGN CELLS: POSSIBLE IMPLICATIONS FOR SIMPLE RECEPTIVE FIELDS. Jose-Manuel Alonso*, R. Clay Reid. Laboratory of Neurobiology, The Rockefeller University, New York, NY 10021.

The receptive field of simple cells is constructed largely by the convergence of the aligned input from the lateral geniculate nucleus (LGN). However, intracortical and even intrageniculate interactions could also determine part of the final shape of the receptive field. Here we are presenting evidence for excitatory connections between neighboring LGN cells recorded with the same electrode. Each receptive field was mapped with a pseudo-random dynamic checkboard stimulus (m-sequence), and the spikes were isolated with the Brainwave System. Forty percent of the LGN pairs studied showed strong and narrow peaks with cross-correlation analysis. This percentage was even larger for those pairs with good overlap of the centers (>20%), and well matched size and timing between the receptive fields of the two cells. Asymmetric narrow peaks were seen mainly when the two cells had partially overlapped *on* and *off* receptive fields. Symmetric narrow peaks were more frequent in pairs with partially overlapped either *on/on* or *off/off* receptive fields. If, as we suspect from our geniculocortical study, the connected pairs feed into the same simple cell, this could provide a means to generate a synergistic input that could drive the simple cell to threshold. VISUALLY EVOKED CALCIUM ACTION POTENTIALS IN SIMPLE AND COMPLEX CELLS IN THE CAT STRIATE CORTEX. Judith A. Hirsch*, José-Manuel Alonso, and R. Clay Reid. Laboratory of Neurobiology, The Rockefeller University, New York, NY 10021.

Synapses made by thalamic afferents compose a small minority of those made in layer 4, yet their input largely accounts for the simple receptive field. One means of enhancing excitatory synaptic input is through voltage-dependent calcium conductances in the postsynaptic membrane. We examined the role of these in the construction of visual cortical receptive fields by making whole-cell recordings *in vivo*.

We mapped receptive fields with randomly flashed bright and dark squares (Jones and Palmer, 1987, *J. Neurophysiol.* 58: 1187). Intracellular labeling showed that the simple cells we studied were either spiny stellate or pyramidal neurons. When recordings were made with a conventional internal solution, visual stimulation evoked large, fast action potentials. Intracellular blockade of these sodium spikes with QX-314 routinely revealed, on visual stimulation or current injection, smaller, slower action potentials presumably mediated by calcium. Moreover, we could map receptive fields with the visually driven calcium action potentials as we usually do with sodium spikes. Parallel results were obtained for pyramidal cells with complex receptive fields. We conclude that regenerative calcium potentials, normally eclipsed by the sodium spikes they trigger, may play a significant role in conveying synaptic excitation to the axon hillock. (Supported by NIH EY09593 and a Klingenstein Award to J.A.H., a Fulbright/MEC to J.M.A., NIH EY10115 and a Klingenstein Award to R.C.R. and NIH EY05253 to T.N.Wiesel.)

608.4

SYNAPTIC RESPONSE PROPERTIES OF COMPLEX CELLS IN THE CAT STRIATE CORTEX. María V. Sánchez-Vives*, Judith A. Hirsch, José-Manuel Alonso and R. Clay Reid. Laboratory of Neurobiology, The Rockefeller University, New York, NY 10021.

Complex cells in the superficial layers of area 17 often have more transient responses than the simple cells in layer 4 that provide much of their input. We used whole-cell recording *in vivo* to measure the relative role of synaptic excitation and inhibition in the generation of these briefer responses. The stimuli were randomly flashed bright and dark squares each lasting 40ms. Most of the cells we recorded from were pyramids, as identified by intracellular label. In these cells, the stimulus evoked EPSPs were frequently followed by marked inhibition. This inhibition seemed in large part to be mediated by chloride, as it persisted in the presence of QX-314 which suppresses the slow IPSPs mediated by potassium. The strong inhibitory component of the response observed in pyramidal cells suggests that there is a population of inhibitory interneurons driven by the rapidly flashed squares. In fact, we have recorded from a large basket cell that was vigorously excited by these stimuli. Such cells project densely to pyramidal neurons (Somogyi et al., 1983, *Neuroscience* 10: 261). We propose that the inhibition mediated by smooth cells regulates the temporal properties of their target neurons in the superficial layers of the visual cortex. (Supported by F.P.I.(M.E.C.) to M. V.S.V., NIH EY09593 and a Klingenstein Award to J.A.H., Fulbright/MEC to J.M.A., NIH EY10115 and a Klingenstein Award to R.C.R. and NIH EY05253 to T.N.Wiesel.)

608.5

THE NATURE OF INPUTS UNDERLYING SIMPLE CELL DIRECTION SELECTIVITY. D. Ferster* and L.L. Kontsevich Dept. of Neurobiology, Northwestern Univ., Evanston, IL 60208 and Smith-Kettlewell Eye Research Institute, San Francisco, CA 94115.

Direction selectivity in simple cells of cat area 17 appears to be based on variations within the receptive field of the time course of the response to visual stimulation. Response latency to flashed stimuli is longer in those parts of the receptive field first encountered by a stimulus moving in the preferred direction. We have explored whether the latency varies smoothly across the receptive field or abruptly in a small number of shifts, and we have characterized the properties of the inputs underlying these variations.

Intracellularly recorded fluctuations in membrane potential evoked by stationary sinusoidal gratings at 8 spatial phases (*Science* 257:1901) were applied to a singular valued decomposition (SVD). This analysis showed that each of the 8 responses (R_n , where n = spatial phase) could be expressed with up to 98% accuracy as a linear combination of 2 functions, $f_1(t)$ and $f_2(t)$. I.e., $R_n = A_n f_1 + B_n f_2$. The coefficients A and B varied nearly sinusoidally with spatial phase of the stimulus grating, indicating that the two types of synaptic input underlying f_1 and f_2 were linear in spatial summation. The SVD does not provide the actual input signals from the two types of synaptic input; f_1 and f_2 are instead linear combinations of those signals. To derive the input signals, a minimization procedure was applied to the even harmonics of R_n . The inputs derived from this procedure were approximately 90° out of spatial phase with one another at the optimal spatial frequency, and delayed with respect to one another by 60 to 80 ms. They were also of unequal strength, the mismatch in strength being greater for cells with lower direction selectivity.

From this analysis we conclude that 1) simple cells receive input from two cell types with different response latencies; 2) the two types are spatially linear but temporally nonlinear; 3) the simple cell sums these inputs in a highly linear fashion.

SPATIAL EXTENT OF V1 EXTRA-RF MECHANISMS IN MACAQUE K. Zipser*, T.-S. Lee, V.A.F. Lamme, and P.H. Schiller. Dpt. of Brain and Cog. Sci., MIT, E25-634, Cambridge, MA 02139

Neurons in macaque area V1 respond more strongly to texture displayed over their receptive fields when that texture appears to be part of a discrete, object-like region of the scene than when the texture appears as part of a homogenous background. Extra-receptive field mechanisms responsible for this effect thus permit V1 neurons to play a role in scene analysis at a scale larger than their receptive field area. Here we used single and multiple cell recording to study the spatial extent of extra-receptive field mechanisms in parafoveal area V1 of the awake monkey. We used texture displays in which a disc-shaped region was delineated from the background by contrast in orientation, brightness, or color of texture. As the monkey fixated, texture displays were presented with the disc region centered on the receptive field of the V1 neuron under study; texture over the receptive field was identical in all cases during recording from a cell. The diameter of the disc was varied between 1.8° and 14.4°, always larger than the receptive field region of cells under study. The resulting response profile to texture displays could be divided into two intervals: an initial burst of activity at texture onset that was similar under all conditions, and a subsequent tonic response period that showed enhanced response for disc versus homogenous texture background. Enhanced response to discs declined monotonically with increasing disc diameter, falling off for discs of diameter 12°, on average. The time course of this modulation generally did not depend on disc size. Experimental controls showed that these effects were not a result of visual attention or small eye movements.

608.9

THE RELATIONSHIP OF RECEPTIVE FIELD COVERAGE TO FUNCTIONAL MODULES IN PRIMATE V1. C. E. Landisman*, A. W. Roe, and D. Y. Ts'o. Division of Neuroscience, Baylor College of Medicine, Houston, TX. 77030. *Rockefeller University, New York, NY. 10021.

We are studying how the different functional modules in parafoveal V1 provide coverage of visual space. In particular, how do ocular dominance columns and color patches provide full representations of visual space, given their discontinuous organization in V1? Are the maps continuous or independent across the different modules? Using a combination of tangential electrode penetrations and a series of perpendicular penetrations guided by optical images of functional activity, we examined visual coverage across ocular dominance (OD) columns and across blobs.

In long tangential penetrations crossing OD columns, we have confirmed the existence of receptive field "jumps" at ocular dominance borders. Within OD columns, we have observed roughly monotonic receptive field progressions. At ocular dominance borders, we have observed jumps between left and right eye progressions, some of which are consistent with the two-steps-forward, one-step-back pattern described by Hubel and Wiesel.

We are particularly interested in coverage by color cells in V1. The occurrence of color selective cells in tangential penetrations is much lower than in perpendicular penetrations made by targeting color regions revealed by optical images. In the tangential penetrations, only about 20 percent of cells encountered were unoriented cells and approximately 15 percent were color selective cells. Only 3 to 4 percent were the classic color-opponent unoriented cells. In targeted penetrations, 50% were color-selective cells and 33% were broad band unoriented cells. Thus, by using the optical images to target a row or a region of color-selective patches, color cells can be located with much greater frequency. We are using this technique to study coverage by the color system.

Effect of Eye Misalignment on Receptive Field Formation in Realistic Visual Environments.

Harel Shouval, Nathan Intrator†, C. Charles Law, and

Leon N Cooper*, Department of Physics and Neuroscience and Institute for Brain and Neural Systems, Brown University, Providence RI 02912.

In this paper we study the ability of cortical cells to concurrently develop orientation selectivity and ocular dominance. We examine whether two proposed learning rules BCM, and a stabilized Hebbian Rule (PCA) can accomplish this aim. In addition we study how initial misalignment affects the binocularity of mature cells. We chose a realistic visual environment, composed of natural scenes that have been preprocessed by center surround filters. Each neuron is exposed to partially overlapping circular regions of the images originating from both eyes. We examine how changing the degree of the overlap, affects the properties of the mature cells. We find that for both learning rules the receptive fields from the two eyes become matched. For the PCA rule, the receptive fields from both eyes are symmetric, and are completely binocular as long as there is an overlap. For BCM neurons on the other hand the receptive fields from both eyes are non symmetric and mature neurons attain varying degree of binocularity.

CONTEXTUAL INFLUENCES ON VISUAL DISCRIMINATION IN HUMANS AND ON RF PROPERTIES OF CELLS IN STRIATE CORTEX OF ALERT MONKEYS. M.K. Kapadia, C.D. Gilbert* and G. Westheimer. The Rockefeller University, New York, NY 10021.

The context surrounding a feature influences both the perception of its attributes and the response properties of cells with receptive fields (RFs) containing the feature. We studied the context dependency of the responses of striate cortical cells in awake, behaving primates and compared these findings with psychophysical measurements of line detection in human subjects.

We compared the minimum contrast necessary to detect a light bar presented alone and in conjunction with a second, suprathreshold bar. The second bar lowered the contrast detection threshold of the first bar by 40%. The magnitude of this effect was greatest when the two bars were colinear, and was reduced as the bars were further separated along their axis of orientation, by displacing them from colinearity, and by changing their relative orientation.

The response properties of some neurons in the primary visual cortex of the alert monkey showed similar dependencies on stimulus configuration, increasing their response to a bar located within the classical RF when an iso-oriented, colinear bar was presented simultaneously in the RF surround. The second bar, when presented alone, elicited either no response or a suppression of background firing. The response facilitation often declined with bar separation and orientation contrast in a fashion similar to that observed in the psychophysical studies. The plexus of long-range horizontal connections in visual cortex provides a likely substrate of these effects by connecting cells with similar orientation preferences in disparate parts of the visual field. SPATIAL INTEGRATION AND RESPONSE CORRELATION IN THE CENTRAL VISUAL SYSTEM OF CAT AND MONKEY

A.M. Sillito*, K.L. Grieve, J. Cudeiro and J.N. Davis. Visual Science, Inst. of Ophthalmology, Bath St., London EC1V 9EL, UK. *Health Sciences, University of La Coruña, Spain.

Previously we have shown that when stimulated by moving contours layer VI cells in the visual cortex provide a feedback influence that causes correlated firing in LGN cell pairs with receptive field alignments appropriate to signalling the presence of the contour. This may serve to increase the synaptic effectiveness of their input to layer IV cells in the cortex. The layer VI cells projecting to the LGN also project to layer IV but as yet we do not know how or whether they influence the synchronisation of layer IV cells directly. With this in mind we have examined the way the spatial extent, orientation and direction of motion of a concentric bipartite grating stimulus influences the response and correlated activity of groups of cells recorded in layers II/III, IV and VI. The shuffle corrected cross-correlogram revealed highly significant synchronisation compatible with common mode input in cells with common orientation tuning and overlapping fields. This held for responses obtained throughout their orientation tuning curve. We observed that varying the orientation of the outer stimulus could profoundly modify the response to the inner stimulus in the receptive fields of cells in both cat and monkey striate cortex. This suggested that connections from orientation columns tuned to quite different orientations to those of the cell in question could influence its response. Under these circumstances we found evidence of connectivity between cells of different orientation for specific stimulus configurations only. We suggest that the input from layer VI cells may contribute to the common mode input correlation of the firing of cells with like orientation selectivity whilst other elements of the intracortical circuitry underpin the effects seen under more complex stimulus situations.

REDUCING BIOPHYSICALLY DETAILED SINGLE CELL MODELS TO SINGLE COMPARTMENT MODELS C. Koch,^{*1} Ö. Bernander,¹ R. J. Douglas,² M.A. Mahowald,² (1) Caltech, 139-74, Pasadena, CA, 91125, (2) MRC Anatomical Neuropharmacology Unit, Oxford QX1 3QT, UK.

Simulations of biophysically detailed neurons that explicitly model the dendritic tree and incorporate multiple active conductances are computationally too intensive to be feasible in the study of large networks. We therefore derive several highly simplified cell models in a two step approach. First, an intermediate model is derived that is electrically complex (using a Hodgkin-Huxley like formalism) and spatially simple in that the soma and entire dendritic tree are collapsed into a single compartment. This model preserves the response to somatic input, as described by input resistance, f-I curves, and voltage and current thresholds. In a second step, the intermediate model is reduced to three yet simpler models: Integrate and Fire (I&F), Diode, and Hopfield units. The I&F model preserves the voltage threshold and generates output spikes whenever the threshold is exceeded. The Diode model is based on the observed exponential relationship between the time-averaged somatic potential (including spikes) and the total membrane current. The Diode and Hopfield models preserve the current threshold and generate a continuous output variable that can be thought of as the mean firing rate. These models represent two extreme viewpoints: *pulse* or *temporal coding* assumes that the exact timing of inputs are relevant, while the *mean-field* viewpoint focuses on the average spike rate.

NEURAL COMPLEXITY AND THE RELATIONSHIP BETWEEN FUNCTIONAL SEGREGATION AND INTEGRATION IN THE NERVOUS SYSTEM. G. Tononi, O. Sporns^{*}, and G.M. Edelman, The Neurosciences Institute, 3377 North Torrey Pines Court, La Jolla, California 92037.

In brains of higher vertebrates, the functional segregation of local areas that differ in their anatomy and physiology contrasts sharply with their global integration during perception and behavior. We have recently (PNAS 91, 5033) introduced a measure, called neural complexity (C_N), that captures the interplay between these two fundamental aspects of brain organization. We express functional segregation within a neural system in terms of the relative statistical independence of small subsets of the system and functional integration in terms of significant deviations from independence of large subsets. C_N is then obtained from estimates of the average deviation from statistical independence for subsets of increasing size. C_N is shown to be high when functional segregation coexists with integration and to be low when the components of a system are either completely independent (segregated) or completely dependent (integrated). We apply this complexity measure in computer simulations of a primary visual area to examine how some basic principles of neuroanatomical organization constrain brain dynamics. We show that the connectivity patterns of the cerebral cortex, such as a high density of connections, strong local connectivity organizing cells into neuronal groups, patchiness in the connectivity among neuronal groups, and prevalent reciprocal connections, are associated with high values of C_N . The complexity measure has been used in an initial exploration of data from humans obtained by functional neuroimaging.

608.12

A STATISTICAL MEASURE OF COOPERATIVE INTERACTIONS WITHIN CORTICAL NEURONAL GROUPS. E.D. Lumer, G. Tononi^{*}, and G.M. Edelman. The Neurosciences Institute, 3377 North Torrey Pines Court, La Jolla, CA 92037.

The neocortex of higher vertebrates is characterized by extensive functional and anatomical compartmentalization at different scales. It has been suggested that, at the scale of a few hundred microns, the cortex is organized into dynamic and cooperative collections of strongly interconnected neurons, referred to as neuronal groups (G.M. Edelman, *Neuron*, 10:115-125, 1993). Here, we investigate a dynamic criterion for the metastable partitioning of a cortical region into neuronal groups, which is based on a statistical measure of the degree of cooperative firing within a local population of neurons. This measure is the normalized third-order moment, or skewness, of the distribution of spike counts cumulated over a local set of simultaneously recorded neurons and a short time interval. The magnitude of positive skewness of the distribution is indicative of the degree of local cooperativity. We show that this skewness is sensitive to the level of coupling among the recorded neurons by means of detailed computer simulations of cortical regions. Such a measure also discriminates local cooperative interactions from firing biases due to shared inputs and, if applied repeatedly over neighboring spatial positions, it can detect statistical borders between neuronal groups. We shall also consider the relationship of a dynamic cortical partitioning of the kind discussed above to underlying factors, such as the activity-dependent changes in the distribution of synaptic strengths and the origin of the organization of axonal terminals into segregated cortical patches.

ISCHEMIA: PROTECTION

609.1

HALOPERIDOL PREVENTS THE INDUCTION OF HSP70 BUT NOT THE ACTIVATION OF MICROGLIA IN POSTERIOR CINGULATE CORTEX FOLLOWING KETAMINE AND PHENCYCLIDINE. E.R. Sharp^{*}, J. Nickolenko, R. Nakki, and S.M. Sagar, Dept. Neurology (V127), University of California, SF, CA 94121.

Phencyclidine (PCP), ketamine (K) and MK801 are non-competitive NMDA receptor antagonists that decrease injury produced by stroke, trauma and seizures. However, these agents produce vacuoles and kill cingulate neurons. We have previously shown that the HSP70 heat shock gene is induced in the pyramidal neurons injured by PCP, K and MK801, that the HSP70 induction is age related, and that anti-psychotics like haloperidol prevent the vacuoles and HSP70 induction in injured neurons (Sharp, *J Neurosci Res*, 33:605). The present study shows that ketamine also activates microglia around injured and possibly dying neurons in posterior cingulate of adult rats. This effect is dose related, the most microglia being induced at 80-100mg/kg of ketamine. This effect was also age related, since ketamine did not induce HSP70 or activate microglia in 3, 10 and 20 day old rats, but did induce microglia in progressively older rats. Surprisingly, though haloperidol blocked hsp70 induction produced by ketamine, haloperidol did not block the activation of microglia in posterior cingulate produced by ketamine. The data is interpreted to mean that haloperidol blocks an injury pathway leading to induction of HSP70, but it does not block the injury pathway leading to microglia activation and possibly neuronal cell death produced by ketamine. The microglial activation and possibly cell death produced by ketamine, PCP and MK801 is not blocked by haloperidol alone, but may require multiple compounds.

609.2

LOCAL IMMUNE RESPONSES AFTER MIDDLE CEREBRAL ARTERY OCCLUSION IN THE RAT. G. Stoll, M. Schroeter, S. Jander, and O.W. Witte^{*} Dept. Neurology, Heinrich-Heine-Univ, Düsseldorf, Germany

This study examined infiltration of hematogenous cells after occlusion of the middle cerebral artery in rats. Cryostat sections of the infarcts were stained immunocytochemically for CD5, a pan-T cell marker, lymphocyte subsets CD4 and CD8, and ED1, a marker for macrophages. Besides granulocytes, numerous CD5+ T cells were present from days 2-7. By day 14 and 30, their number had decreased. Subtyping of lymphocytes revealed that CD4+ helper/inducer T cells were rare, while CD8+ cytotoxic/suppressor lymphocytes were abundant. Moreover, CD8+ lymphocytes greatly outnumbered CD5+ T cells indicating the presence of CD5-/CD8+ natural killer lymphocytes. ED1+ macrophages appeared on day 1 and were still present on day 30. As an early event ICAM-1 was upregulated on cerebral vessels. This study shows that ischemic lesions can lead to lymphocytic infiltration into the CNS. Blocking of lymphocyte-derived cytokines will help to elucidate the functional contribution of immune cells to stroke.

609.3

MICE DEFICIENT IN NEURONAL NITRIC OXIDE SYNTHASE GENE EXPRESSION EXHIBIT DECREASED FOCAL INFARCT VOLUME AND NEUROLOGICAL DEFICIT AFTER MIDDLE CEREBRAL ARTERY OCCLUSION. M.A. Moskowitz*, Z. Huang, P.L. Huang, N. Panahian, T. Dalkara and M. Fishman, Massachusetts General Hospital & Harvard Medical School, Boston, MA 02114

The proposal that nitric oxide and/or its reactant products mediate toxicity in brain remains controversial, in part, due to the use of agents which block NO formation in neuronal, glial and vascular compartments. In mutant mice deficient in neuronal NOS activity, we observed significantly decreased infarct volume (approximately 35%; determined by the TTC method) and neurological deficits 24 hrs after middle cerebral artery occlusion (filament method) as compared to Wild type (SV-129), which could not be accounted for by blood flow (laser-Doppler flowmetry) or vascular anatomical differences (carbon black studies) between mutant and Wild type. Elevations in brain cGMP levels present in the Wild type 30 min. after ischemia were not observed in mutant mice. These data indicate the relevance of NO to ischemic injury and the importance of developing strategies to selectively inhibit the neuronal isoform in stroke and brain injury.

609.5

DIRECT MEASURE OF NITRIC OXIDE IN RAT BRAIN SUBJECTED TO PERMANENT AND TEMPORARY ISCHEMIA. T. Matsui*, T. Nagafuji, K. Tsutsumi, S. Itoh, K. Nagata, T. Asano. Department of Neurosurgery, Saitama Medical Center/School. 1981 Kamoda, Kawagoe, Saitama 350, Japan.

Although the role of nitric oxide (NO) in the pathogenesis underlying ischemic brain damage has remained to be elucidated, our previous results conducted the conclusion that NO might mediate the ischemic cerebral damage. The present study aimed at directly measuring nitric oxide in the ischemic brain, employing middle cerebral artery occlusion (MCAO) and reperfusion in rats. The newly developed microsensor was calibrated in NO containing solution. The NO microsensor (pA), oxygenometer (mmHg) and laser CBF flowmeter (ml/100gm/min) were implanted in the lt. MCA territory. A total of 20 animals were assigned into 4 hour MCAO (saline-[N=5], LNA(N^ω-nitro-L-arginine)-treated[N=5]) or 2 hour MCAO followed by 2 hour recirculation (saline-[N=5], LNA-treated[N=5]). In this setting, the value obtained is not absolute NO concentration but relative to the baseline. The first peak (P1) of NO production, $1.73 \pm 0.19 \mu\text{M}$, was found at the period of initial 20-30 min MCAO. Three and a half hours later another peak was observed (P2, $0.53 \pm 0.08 \mu\text{M}$). Also, P3 ($0.93 \pm 0.52 \mu\text{M}$) was induced by reperfusion. LNA inhibited or abolished P1-3. The present results support the hypothesis that overproduction of nitric oxide in the brain subjected to permanent and temporary ischemia might lead to the cytotoxic effects of nitric oxide in the ischemic brain.

FRUCTOSE-1,6-BIPHOSPHATE PROTECTS ATP LEVELS IN HYPOXIC NEONATAL RAT BRAIN SLICES. L. Litt*, M.T. Espanol, J. MacDonald, L.H. Chang, G.A. Gregory, P. R. Weinstein, T.L. James, and P.-H. Chan. University of California, San Francisco, California 94143

In vivo administration of fructose-1,6-bisphosphate (FBP) provides hemodynamic and metabolic protection during ischemia and hypoxia.¹ However, mechanisms of protection have not been elucidated, and, in fact, appear to not work in certain circumstances. We applied *ex vivo* NMR spectroscopy techniques, recently developed for studies of live rat brain tissue², to examine if there is direct metabolic protection by FBP in hypoxic (PO₂<5 mm Hg) neonatal (7-day old Sprague Dawley) slices (350μ). Total acquisition time for interleaved ³¹P/¹H spectra was 5 minutes. With no pre-treatment, metabolic impairment was seen in ³¹P spectra obtained at the end of 30 min of hypoxia, at which time the Lactate/NAA ratio was increased by a factor of 3. Pre-treatment with FBP decreased ATP loss and lactate production, and increased the rate of recovery during reperfusion. Post-treatment with FBP did not produce the nearly full recovery found with pre-treatment. In this study protection comes primarily from intracellular effects in the tissue of interest, and not secondarily from physiologic response such as cardiac protection and increased blood flow. Mechanisms of FBP's protection are not understood and additional studies are needed. Hypotheses for FBP protection point to the involvement of calcium homeostasis, reduction of free-radical injury, and increased pentose phosphate pathway. Supported by NIH Grants GM34767, NS 22022, NS14543, NS25372, and RR03841. **References:** (1) Kelleher JA, Gregory GA, and Chan P-H. Neurochem. Methods 19:209-215, 1994. 609.4

EXPRESSION OF INDUCIBLE NITRIC OXIDE SYNTHASE CONTRIBUTES TO BRAIN DAMAGE IN FOCAL CEREBRAL ISCHEMIA. C. Iadecola*, X. Xu, F. Zhang, R. Casey and M. E. Ross. Dept. of Neurology, Univ. of Minnesota, Minneapolis, MN 55455.

After focal cerebral ischemia there is induction of calcium-independent nitric oxide (NO) synthase (NOS) activity in the infarct (X. Xu et al., Soc. Neurosci. Abstr., 1994). This finding may reflect expression of inducible NOS (iNOS), an enzyme that produces potentially toxic amounts of NO. We sought to determine (a) whether iNOS mRNA is expressed in the ischemic area, (b) the cell type in which iNOS is induced and, (c) whether NO production by iNOS contributes to ischemic brain damage. The middle cerebral artery (MCA) was occluded in rats and animals sacrificed at different time points (6hrs-7days). iNOS expression in the infarct was determined by iNOS mRNA amplification using RT-PCR. NOS catalytic activity was determined using the citrulline assay. In the infarcted brain, but not contralaterally, there was substantial expression of iNOS mRNA that began at 24 hrs, peaked at 36-48 hrs, and started to decline at 4-7 days. iNOS mRNA expression paralleled the time-course of induction of calcium-independent NOS activity in the infarct. iNOS immunoreactivity was seen mainly in polymorphonuclear cells. To determine whether production of NO by iNOS contributes to ischemic damage, rats were treated for 3 days with the iNOS inhibitor aminoguanidine (AG), starting 24 hrs after stroke. AG treatment attenuated the stroke-induced iNOS activity and reduced infarct volume by 33±4% (n=10), an effect reversed by co-administration of L- but not D-arginine (p>0.05; n=7/group). AG did not affect calcium-dependent brain NOS activity (p>0.05). We conclude that iNOS mRNA and enzymatic activity are expressed in the post-ischemic brain. iNOS induction occurs in polys. The finding that iNOS inhibition reduces stroke size indicates that NO synthesis by iNOS contributes to the late stages of ischemic brain damage. iNOS inhibition might be a new avenue for the treatment of ischemic stroke. HEAT SHOCK PROTECTS CULTURED CORTICAL NEURONS AGAINST DEPRIVATION OF OXYGEN OR GLUCOSE BUT NOT EXPOSURE TO EXCITOTOXINS. B.J. Snider* and D.W. Choi. Dept. of Neurology and Center for the Study of Nervous System Injury, Washington Univ. School of Medicine, St. Louis, MO 63110.

Induction of heat shock proteins protects cultured cerebellar or cortical neurons against excitotoxic death (Lowenstein et al., Neuron 7:1053, 1991 and Rordorf et al., Neuron 7:1043, 1991). Heat shock also protects astrocyte cultures from oxygen-glucose deprivation injury (Giffard et al., Soc. Neurosci. Abs. 19:1651, 1991). Hyperthermic pre-exposure reduces subsequent brain injury in a rat model of focal ischemia (Chopp et al., Neurology 39: 1396, 1989).

We studied the effects of heat shock on cultured mouse cortical cells. Cultures were exposed to 44°C for 25-30 min, a treatment sufficient to induce substantial expression of hsp72 in astrocytes as assayed immunocytochemically with a monoclonal antibody (Amersham) and by Northern blot analysis using oligonucleotide probes. These heat shocked cultures did not exhibit reduced neuronal vulnerability to subsequent exposure to either glutamate (10 min, 10 μM - 1mM) or NMDA (24 hr, 3-300 μM). However, heat shocked cultures were modestly more resistant than control cultures to injury induced by glucose or combined oxygen-glucose deprivation. This protective effect was best seen when glutamate receptors were blocked with MK-801 (10 μM) and CNQX (100 μM), and was abolished when cycloheximide was added during the heat stress. Present data support a hypothesis that expression of heat shock proteins reduces hypoxic and hypoglycemic neuronal death by attenuating non-excitotoxic components of injury. EXPRESSION OF BCL-2 FROM A DEFECTIVE HERPES SIMPLEX VIRUS 1 VECTOR LIMITS NEURONAL DEATH IN STROKE Matthew D Linnik*, Peter Zahos, Michael D Geschwind, Howard J Federoff, Marion Merrell Dow Research Institute, Cincinnati, OH 45215-6300, and Departments of Medicine and Neuroscience, Albert Einstein College of Medicine, Bronx, NY 10461

Recent evidence for programmed cell death (PCD) in stroke predicts that expression of genes that prevent PCD should protect neurons after an ischemic insult. To test the hypothesis, a candidate neuroprotective gene, *bcl-2*, previously shown to prevent PCD in other settings, was inserted into a defective HSV-1 amplicon vector under the transcriptional control of the HSV IE 4/5 early promoter (pHSVbcl-2). An identical vector expressing the *E. coli* β-galactosidase gene was used as a negative control (pHSVlac). These vectors were packaged into virus, purified, concentrated and microinjected (approx. 10⁵ infectious particles/site) into rat cerebral cortex at 2 sites (+1.7 and -3.3 anteroposterior to bregma; 3.6 mm lateral of midline). The right middle cerebral artery was occluded 24 hrs after the injection and animals were sacrificed 24 hr after the occlusion. Brains were stained with TTC to distinguish viable tissue from infarcted tissue. Protection was assessed by measuring the extent of viable tissue from the longitudinal fissure to the edge of the infarction along a line perpendicular to the midsagittal plane. The extent of viable tissue at the injection sites was 3.47±0.55 mm (pHSVbcl-2) vs 2.65±0.53 mm (pHSVlac) and 3.40±0.62 mm (pHSVbcl-2) vs 2.67±0.5 mm (pHSVlac) for the anterior and posterior injection sites, respectively (mean±S.D., p<0.05, n=6 animals per group). There was no difference in viable tissue at a site chosen equidistant between the 2 injection sites. These results suggest that viral vector mediated transfer and expression of *bcl-2* can protect neurons from dying in an acute neurodegenerative disorder.

INDUCTION OF PROTECTIVE MECHANISMS IN CEREBRAL ISCHEMIA ¹N. Kawahara, ¹C.A. Reutzel, ²S.J. Wiegand, ²S. Croll and ¹I. Klatzo*. ¹Stroke Branch, NINDS, NIH, Bethesda, MD 20892 and ²Regeneron Pharmaceuticals Inc. Tarrytown, NY 10591

Our study is based on serendipitous finding indicating protection of CA1 pyramidal neurons subjected to cardiac arrest cerebral ischemia, when the latter is preceded by the spreading depression (SD), induced 3 days earlier in the cerebral cortex of Sprague-Dawley rats, by local application of KCl. Assays on brain tissue after SD revealed: 1) intense c-Fos expression in the neurons of the cerebral cortex on the side of KCl application and bilaterally in the dentate gyri demonstrable 3 hr after SD, 2) no enhanced HSP-70 expression, 3) conspicuous increase in protein synthesis measured by ³H-leucine incorporation associated with a pronounced reduction in deoxyglucose utilization, both demonstrable in ipsilateral hemisphere 3 days after SD and 4) upregulation of mRNA for the brain-derived neurotrophic factor (BDNF), conspicuously noticeable at 4 hr and 3 days after SD.

Our studies indicate that a sublethal stress, such as SD, is capable of inducing a temporary state of resistance to cerebral ischemia, in which stimulation of protein synthesis and neurotrophic factors may play a significant role.

CHARACTERIZATION OF INDUCED ISCHEMIC TOLERANCE IN FOCAL CEREBRAL ISCHEMIA IN RATS

R.P. Simon, J. Chen, J.O. Lan, L. Zhu, R.A. Swanson* and S.H. Graham. Neurology, University of California, San Francisco, CA 94143

Background: Brief periods of non-lethal global ischemia have been reported to induce resistance against subsequent lethal ischemic injury in hippocampal neurons. To determine if this phenomenon is relevant to stroke, we developed a rat model of ischemic tolerance in focal ischemia. **Method:** Ninety-four adult rats underwent either sham operation or brief intervals of temporary focal ischemia by occluding the MCA by suture insertion. Twenty-four or 72 hrs later the MCA was occluded by the same technique for 100 min. Infarct volumes were determined 72 hrs after the 100 min ischemic insult. HSP70 protein induction was studied by immunocytochemistry at 24 or 72 hrs after the brief temporary ischemia. Alterations of glutamate receptor subunits 1-5 (GR1-GR5) were studied at these time points by *in situ* hybridization. In additional 12 rats, CBF was measured by the [¹⁴C] iodoantipyrine quantitative autoradiographic technique at 30 min of MCAO 72 hrs following either brief ischemia or sham operation. **Results:** Either 30 min of ischemia or three 10 min intervals of ischemia followed by 72 hrs but not 24 hrs of reperfusion significantly ($P < 0.05$) reduced infarct volume produced by 100 min of ischemia compared to sham-operated animals. CBF was not significantly different between sham and three 10 min ischemia-treated brain regions where tolerance was shown. HSP70 protein induction in neurons was similar in degree at 24 and 72 hrs after the three 10 min ischemia insults, but HSP70 protein was also induced in glia cells at 72 hrs. GR1-GR5 transcription was decreased at 72 hrs but not 24 hrs after three 10 min ischemia. **Conclusions:** These data indicated that the phenomenon of ischemic tolerance is relevant to focal ischemia and requires greater than 24 hrs to develop. Alterations in cellular expression in HSP or alterations in glutamate receptor subunit expression could underlie the development of ischemic tolerance, while it could not be attributed to differences in collateral blood flow. This model may be useful in studying the molecular mechanisms that determine the inducible cerebral self-defense against ischemic injury.

NEUROTROPHIC FACTORS: EXPRESSION AND REGULATION VII

610.1

NGF-HIGH-EXPRESSING TRANSGENIC MICE CONTAIN INCREASED NUMBER OF PGP 9.5-IMMUNOREACTIVE FIBERS IN THE VOMERONASAL ORGAN.

S. Takami^{1,2,3}, M.L. Getchell^{2,3}, K.M. Albers⁴, M. Yamagishi² & T.V. Getchell^{1,2,3}. ¹Dept. of Physiol., ²Sanders-Brown Ctr. on Aging, ³Div. of Otolaryngol. -- Dept. of Surgery, ⁴Dept. of Pathology, University of Kentucky College of Medicine, Lexington, KY 40536.

The expression of protein gene product (PGP) 9.5 in extrinsic nerve fibers of the vomeronasal nonsensory epithelium (VN-NE), the neighboring respiratory epithelium (RE), and the associated glands of the vomeronasal organ of the nasal mucosa, was examined immunocytochemically in nerve growth factor (NGF)-high expressing 6-week-old transgenic mice that contained the gene construct of keratin (K) 14 promoter-NGF and in age-matched controls. Increased density of extrinsic PGP 9.5-immunoreactive (IR) fibers was observed in the VN-NE, RE, and the glands of the transgenic mice. The soft palate, whisker pad skin, and tongue of the transgenic mice, which were used as positive controls, all demonstrated a marked increase in the density of PGP 9.5-IR fibers. The numbers of intraepithelial PGP 9.5-IR nerve fibers were significantly greater in the VN-NE (12.8 X control, $P < 0.01$) and RE (3.5 X control, $P < 0.01$) of the transgenic mouse. Since K14 was expressed by basal cells in the VN-NE and RE, these cells in the transgenic mice presumably contain the NGF transgene, resulting in continuous production and secretion of NGF, which induced significant hyperinnervation in the VN-NE and RE. This hypothesis is supported by the fact that basal cells in the epithelia of positive tissue controls of transgenic mice express both K14 and NGF.

CHANGES IN GENE EXPRESSION FOLLOWING MULTIPLE SPREADING DEPRESSIONS. T. L. Hoffman¹, W.B. Macklin², W.D. Lust¹, W.R. Selman¹ and R.A. Ratcheson¹. Lab. Experimental Neurological Surgery, Case Western Reserve Univ.¹, Cleveland, OH 44106 and MRRC, UCLA Medical School², Los Angeles, CA 90024

Multiple episodes of spreading depression (SD) prior to a focal ischemic insult have been shown to reduce cell loss, relative to equivalent ischemic controls. The current studies were begun to identify changes in gene expression that might be responsible for the protective effects of SD. Male Wistar rats were subjected to 2h of SD by topical application of 2 M KCl onto the dura, followed by 2, 10 and 24h of recovery time. Cerebral cortical RNA was isolated, and analyzed by Northern blots for changes in known mRNAs. c-fos mRNA was increased in 2h samples and reduced by 10 and 24h, while glial fibrillary acid protein (GFAP) mRNA was increased at 10 and 24h. Thus, these samples contained mRNA that were part of the early response and the long-term response to SD. Differential display of polymerase chain reaction (PCR) products was used to identify mRNAs in these samples that may be increased or decreased during recovery following SD. cDNA libraries of each mRNA sample were generated using T₁₂MN (M=A/T/C/G; N=C/G) primers. ³²S-dATP-labelled cDNAs were amplified by PCR, using the same set of primers and a set of arbitrary 10mers. Samples were separated on a DNA sequencing gel, and 8 differentially expressed bands were isolated for further characterization.

CONDITIONED NEUROPROTECTION FROM ISCHEMIC INFARCTION ELICITED BY ELECTRICAL STIMULATION OF THE CEREBELLAR FASTIGIAL NUCLEUS (FN) IN RAT. D.J. Reis, E.V. Golanov, S. Yamamoto, K. Kobylarz and V. Prabhakar*. Div. of Neurobiol., Dept. of Neurol. & Neurosci., Cornell Univ. Med. College, New York, NY 10021.

Electrical stimulation of the FN increases cerebral blood flow (rCBF) but not metabolism (rCGU) (Nakai et al., *Brain Res.* 260:35, 1983). Stimulation for 1h also reduces, by ~50% 24h later, the volume of the cerebral infarction produced by occlusion of the middle cerebral artery (MCA) (Reis et al., *J. Cereb. Blood Flow Metab.* 11:810, 1991). Since FN stimulation neither increases rCBF nor reduces rCGU within the salvaged area (Yamamoto et al., *Soc. Neurosci. Abstr.* 19:1056, 1993), protection cannot be due to rematching reduced rCBF with elevated rCGU in the ischemic penumbra. To assess if protection results from an enduring signal, we stimulated FN at various times before occluding MCA. Rats were anesthetized, FN stimulated for 1h (50 Hz, 1s on/1s off, 50 μ Amp), and animals returned to their cages. At different times thereafter, they were reanesthetized, MCA occluded and, 24h later, the distribution and volumes of infarctions measured. Controls were sham-stimulated. Stimulation of the FN for 1, 3, 24 or 72h prior to MCA occlusion ($n=5$ /group) decreased infarction volume by 26, 41, 44 and 42%, respectively ($p < 0.05$ for each). In 5 rats, rCBF and rCGU in the area of salvage, measured autoradiographically 2h after stimulation for 1h, did not differ between experimental and sham-stimulated controls. We conclude that: (a) stimulation of FN for 1h conditions brain so as to provide long-lasting protection from focal ischemic infarctions; (b) protection is not attributable to changes in rCBF or rCGU; (c) the neuroprotective mechanism may involve rapid transcription of "protective" genes and/or modification of constitutive molecules; (d) pathways exist in brain which function to protect the brain from ischemia.

610.2

MECHANICAL INJURY INCREASES bFGF AND CNTF EXPRESSION IN THE RAT RETINA. Rong Wen, Ying Song, Michael T. Mathews, Douglas Yasumura, George D. Yancopoulos, Matthew M. LaVail, and Roy H. Steinberg*. Depts. of Physiology, Ophthalmology, and Anatomy, UCSF, San Francisco, CA 94143, and Regeneron Pharm. Inc., Tarrytown, NY 10591.

It has been shown that mechanical injury to the retina prevents photoreceptors from degenerating in the RCS rat with an inherited retinal degeneration, and in the light-damaged rat retina. These findings indicate that mechanical injury activates intrinsic retinal mechanisms that promote photoreceptor survival. To find out if factors that show neurotrophic activity are involved in injury-induced photoreceptor rescue, we examined the expression of bFGF, CNTF, BDNF, and IGF-1 following mechanical injury. The retina was injured by making an incision through the choroid and RPE that penetrated the subretinal space of each eye of an adult Sprague-Dawley rat. Control animals were without injury. Retinas were taken 0.5, 1, 2, 4, 7, or 10 days post-injury. Northern blot analysis showed marked increases in bFGF and CNTF mRNAs following injury. Compared to controls, expression of bFGF increased by more than 6-fold at 12 hrs post-injury; peaked at 2 days post-injury (more than 7-fold); and was still at a 5-fold level at 10 days post-injury. Expression of CNTF increased more than 2-fold at 1 day post-injury; peaked at 4 days post-injury (about 3-fold); and was still at a 2-fold elevation at 10 days post-injury. *In situ* hybridization showed that both bFGF and CNTF were expressed in the inner nuclear layer and were more concentrated around the wound. BDNF and IGF-1 did not show significant changes in expression. Our results indicate that bFGF and CNTF up-regulate in the retina following mechanical injury, with the bFGF effect being earlier and greater than that of CNTF. We conclude that these two factors are likely to be involved in injury-induced photoreceptor rescue. 610.3

CDF/LIF mRNA INCREASES FOLLOWING CORTICAL INJURY. N.N. Moayeri, L.R. Banner* and P.H. Patterson. Biology Division, California Institute of Technology, Pasadena, CA 91125.

The neurotrophic cytokine cholinergic differentiation factor/leukemia inhibitory factor (CDF/LIF), can act both as a trophic factor, enhancing neuronal survival, and as a differentiation factor to alter neuronal gene expression. CDF/LIF also plays a role in the response of adult neural tissue to injury. When peripheral nerves are transected, CDF/LIF mRNA is dramatically up-regulated near the site of injury (Banner & Patterson, PNAS, in press). Moreover, the neuronal response to nerve section is much reduced in LIF knockout mice (Rao *et al.*, *Neuron* 11:1175, '93).

To test whether CDF/LIF expression is regulated in a similar manner after injury in the CNS, surgical lesions were made in adult rat cortex. Using a quantitative RNase protection assay, we find that CDF/LIF mRNA increases significantly relative to the contralateral cortex and to anesthesia-treated controls. The increase in CDF/LIF expression begins within 6 hrs after injury and reaches a peak at 24 hrs. CDF/LIF mRNA expression returns to baseline values by 7 days post-lesion. Thus, this cytokine is likely to play a role in the response to adult brain injury as it does in the periphery.

610.5

AUTOCRINE REGULATION OF NEUROTROPHIN SECRETION BY PERIPHERAL GLIAL CELLS. A. Zimmermann*, A. Sutter and U. Stephani. Institut f. Zoologie der THD, Schnittpahnstr.3, 64287 Darmstadt, FRG.

It has been shown in several vertebrate species that peripheral glial cells express receptors for nerve growth factor during development as well as following nerve injury. The functional significance of these glial receptors in the biology of NGF is not understood. Since embryonic glial cells as well as glial cells in lesioned peripheral nerves also express NGF mRNA, we have explored whether NGF would affect NGF (neurotrophin) secretion by these cells.

Glial cells purified by a rapid procedure from chicken embryonic sensory ganglia were cultured in the presence of various concentrations of NGF. After two days conditioned media (CM) were harvested and assayed for the presence of neurotrophic activity in a single neuron bioassay. Anti-NGF antibodies were employed to probe for NGF in the CM.

Glial cells cultured without NGF were found to secrete neurite growth promoting activity which was not inhibitable by antibodies against NGF. However, if the glial cultures were spiked with very low concentrations of NGF (≤ 2 pM), NGF like activity in the medium rose dramatically (up to 50 fold). This was not observed, if NGF had been added to the glial cultures at 50 times higher concentrations.

It is concluded that the availability of neurotrophins during development may not only be regulated by the target of innervation but also by glial cells which appear to have the capability to 'sense' traces of NGF and respond in an autocrine fashion, finely tuned to the NGF concentrations present extracellularly. An autocrine function of glial NGF receptors can be expected to be of critical importance for morphogenetic aspects of nerve development and in nerve regeneration.

NERVE GROWTH FACTOR INDUCTION BY OKADAIC ACID IN ASTROCYTES MAY BE MEDIATED BY INTERLEUKIN-1 AND IMMEDIATE EARLY GENE ACTIVATION. S.P. Pshenichkin* and B.C. Wise. Fidia Georgetown Institute for the Neurosciences and Department of Pharmacology, Georgetown University, Washington, D.C. 20007.

Nerve growth factor (NGF) expression in astroglial cells is regulated by growth factors and cytokines. Previous studies have shown that IL-1 and okadaic acid, a phosphoprotein phosphatase inhibitor, stimulate NGF gene transcription and NGF mRNA stabilization. The onset of okadaic acid activation of NGF gene expression was much slower than that of IL-1 requiring 6-9 h before an increase in NGF mRNA level was evident. This delay suggested that intermediary signals, such as immediate early gene (IEG) induction or increasing IL-1 synthesis may be operative. Okadaic acid treatment (20 nM) of primary cultures of astrocytes stimulated *c-fos* and *c-jun* gene transcription by 60-80%. This response peaked at about 3 h, followed by an increase in *c-fos* and *c-jun* mRNA content peaking at 4 h. The increase in *c-fos* mRNA content lasted longer than that of *c-jun* and after 24 h was about 5-fold higher than control levels. This protracted increase appears to be due to mRNA stabilization. The increase in IEG expression was followed by a 50% increase in NGF gene transcription 24 h after okadaic acid treatment. Okadaic acid also increased by 4-fold the half-life ($t_{1/2}$) of the NGF mRNA as early as 3 h of treatment. This increase was maintained for up to 24 h. Conditioned medium from okadaic acid treated (24 h) astrocytes increased NGF mRNA content following a 3 h treatment of astrocytes (okadaic acid was ineffective at this time), indicating that okadaic acid stimulated the secretion of a factor, perhaps IL-1, that induced NGF expression. Indeed, okadaic acid increased IL-1 mRNA content as early as 3 h of treatment. These results suggest that the multiple actions of okadaic acid on NGF mRNA expression are mediated, in part, through an induction of IL-1 and IEGs.

IMPLICATION OF PROHORMONE CONVERTASES PC1, FURIN AND PCS IN THE PROCESSING OF NGF AND BDNF PRECURSORS IN RATS WITH PILOCARPINE SEIZURES. M. Marcinkiewicz*, T. Nagao¹, M. Avoli¹, R. Day, NG Seidah & M. Chrétien. Clinical Research Institute of Montreal, Montreal Quebec H2W 1R7 and ¹Montreal Neurological Institute, Montreal, Quebec H3A 2B8.

Neurotrophins NGF, BDNF, NT-3 and NT-4 are synthesized as large immature prepropeptides and subsequently proteolytically processed to active neurotrophic factors. Their processing enzyme(s) have not yet been conclusively identified. However, the data on the tissue distribution and enzymatic cleavage specificity suggest that one or more of the prohormone convertases including furin, PC1, PC2, PC5 or PACE4 are involved in the maturation of proneurotrophins. To understand at the molecular and neuroanatomical levels the interrelationships between putative prohormone convertases and neurotrophic factors we studied the hippocampus of the rats in which the seizures were induced by pilocarpine. By *in situ* hybridization using ³⁵S-labeled riboprobes we compared the expression patterns of neurotrophins with that of the convertases 1,2,3,12 and 96 hrs after induction of seizures. Consistent with other groups, in the dentate gyrus both NGF and BDNF showed substantial temporary rise of mRNA levels with a peak at two hours. In the dentate gyrus, similar to NGF and BDNF the PC1 level increased strongly, while furin and PC5 displayed rather weak transient augmentation of mRNA level, and finally PC2 and PACE4 did not change much. In the CA1-CA3 regions, there was a maximal transient increase of BDNF two hours after pilocarpine administration. Interestingly, only PC1 showed a parallel pattern of mRNA expression in this region. Based on our results we propose that in the status epilepticus PC1, and to lesser extent also furin and PC5 may play a role in processing of pro-NGF and pro-BDNF.

NERVE GROWTH FACTOR REGULATES THE EXPRESSION AND KINASE ACTIVITY OF p33^{cdk2} AND p34^{cdc2}. K.J. Buchkovich* and E.B. Ziff. New York University Medical Center and Howard Hughes Medical Institute, 550 First Avenue, New York, NY 10016.

Nerve growth factor (NGF) promotes the survival and differentiation of the pheochromocytoma cell line PC12. The function of NGF as both a survival and differentiation factor may be related to its ability to regulate PC12 cell cycle progression. NGF treatment of PC12 cells leads to a decrease in the percentage of cells in the DNA synthesis phase (S phase) of the cell cycle and an accompanying increase in G2 phase cells. We have investigated the mechanism by which NGF regulates PC12 cell cycling. Specifically, we have analyzed the regulation of two cyclin-dependent kinases, p33^{cdk2} and p34^{cdc2}, which are required for progression through the G1/S and G2/M phase transitions of the cell cycle. NGF treatment lead to a decrease in the steady state levels of p33^{cdk2} and p34^{cdc2}. p33^{cdk2} and p34^{cdc2} form complexes with regulatory molecules known as cyclins. NGF treatment resulted in decreases in the kinase activity of several cyclin-p33^{cdk2} and cyclin-p34^{cdc2} complexes. The decreases in kinase activity could be attributed at least in part to the decreases in the steady state levels of p33^{cdk2} and p34^{cdc2}. The timing of the down regulation of the kinases was dependent on the level of p140^{trk} NGF receptor in the cells. A clonal cell line that overexpressed p140^{trk} and differentiated with accelerated kinetics (BL Hempstead *et al.*, 1992) also down-regulated the kinases with accelerated kinetics. This suggested that the rate of the decrease in p33^{cdk2} and p34^{cdc2} kinase activity was dependent on the level of p140^{trk} receptors and the strength of the NGF signal.

610.8

FGF-2 AND IL-1 β REGULATE S-100 β GENE EXPRESSION IN CULTURED RAT ASTROCYTES FROM MULTIPLE BRAIN REGIONS. D.A. Hinkle*, J.P. Harney#, D.C. Hilt\$, P.J. Yarowsky\$, and P.M. Wise#. Depts. of \$Physiol. and \$Pharm., Univ. of Maryland Sch. of Med., Balt., MD 21201, \$AMGEN, Thousand Oaks, CA 91320, and Dept. of #Physiology, University of Kentucky College of Medicine, Lexington, KY 40536.

The dynamic interaction between neurons and astrocytes is critical for the development and maintenance of normal physiological function in the brain. S-100 β is a neurotrophic factor which is synthesized in and released by astrocytes, and may therefore play an important role in such interactions. We examined the effects of interleukin-1 β (IL-1 β) and basic fibroblast growth factor (FGF-2) on S-100 β gene expression in enriched rat astrocyte cultures since these factors are known to regulate the expression of other neurotrophic factors in astrocytes. We report that both FGF-2 and IL-1 β regulate the S-100 β gene in astrocytes from the cerebral cortex, hippocampus, and hypothalamus. Total RNA was isolated from cultures, purified, then subjected to the solution hybridization-RNase protection assay using highly specific riboprobes for rat S-100 β and rat cyclophilin, an internal standard which is not regulated by either FGF-2 or IL-1 β . We find that S-100 β mRNA levels decrease 2- to 3-fold relative to controls in response to 24 or 48 hours of treatment with either 10 ng/ml FGF-2 or 10 U/ml IL-1 β alone, and decrease 5- to 10-fold in response to combination treatment at the same doses over the same time period. In contrast, long-term 7-day treatment with FGF-2 increases S-100 β gene expression two-fold over control levels in cerebral cortical astrocytes. Further, over a similar time-course and at the same doses, we find that only FGF-2 suppresses S-100 β mRNA levels in C6 glioma cells, whereas IL-1 β has no effect on gene expression. These data demonstrate that both FGF-2 and IL-1 β regulate astrocyte S-100 β mRNA levels, which may be an important mechanism through which these factors modulate neuron-glia interactions.

610.9

CHARACTERIZATION OF NEUROTROPHIN-3 IMMUNOREACTIVE SENSORY NEURONS IN RAT DORSAL ROOT GANGLIA

X-F. Zhou*, C. Chen and R.A. Rush. Department of Human Physiology, Flinders University of S.A., Bedford Park, S.A. 5042.

Neurotrophin-3 (NT3) is a member of the NGF family known to support survival of sensory neurons *in vitro* but its physiological roles are not known. We recently reported, using a newly generated antibody, that a subpopulation of rat sensory neurons contained NT3-like immunoreactivity [ir; Zhou & Rush, 1993, Brain Res. 621, 189-199]. In the present study, we have characterized NT3-ir neurons by size and segmental distribution, peripheral innervation, transportation and colocalization with low affinity NGF receptor (LNGFR). The size distribution indicated NT3-ir was mainly localized within larger neurons. More NT3-ir neurons were detected in cervical (36% of total) and lumbar (38%) than in thoracic dorsal root ganglia (DRG; 18%). Double-labelling experiments showed that only 12% of neurons positive for LNGFR, colocalized with NT3-ir. The combination of Fluorogold retrograde tracing with NT3 immunohistochemistry demonstrated NT3-ir sensory neurons primarily innervate muscle and cutaneous structure but not viscera. Sciatic nerve transection induced a significant reduction of NT3-ir neurons in lumbar DRG. Finally, NT3-ir accumulated distal to a ligature placed on the sciatic nerve and dorsal roots, suggesting sensory neurons require NT3 from both peripheral and central sources. Thus the characterization of NT3-ir DRG neurons in the present study suggests that large sensory neurons innervating muscle and skin require NT3 for their survival during development and for the maintenance of normal function in the adult.

610.11

BRAIN-DERIVED NEUROTROPHIC FACTOR (BDNF) AND NEUROTROPHIN-3 (NT-3) mRNA'S ARE EXPRESSED IN DIFFERENT AVIAN MOTONEURON SUBSETS. C. Kalcheim*, D. Shelton* and N. Kahane. *Dept. of Anat. and Embryol., Univ. of Jerusalem-Hadassah Med. School-Jerusalem 91120, Israel and # Dept. of Neurosciences, Genentech Inc. South San Francisco, CA 94080 USA.

NT-3 stimulates primary differentiation of cultured avian motoneurons (MN's) (Averbuch-Heller et al, PNA's, in press, 1994), whereas BDNF supports their survival *in vivo* during the period of programmed cell death (Oppenheim et al, Nature 360, 755, 1992).

We therefore studied the expression of BDNF and NT-3 transcripts in spinal MN's using *in situ* hybridization of serially sectioned chick embryos aged of 3-to-8 days (E3-8). NT-3 mRNA is present in MN subsets from E3 in brachial segments of the neural tube and from E4 onward in both brachial and lumbar regions.

Expression of BDNF mRNA is first detected on E5 in the brachial area and from E6 also in the lumbar and sacral levels of the spinal cord. No detectable mRNA coding for either of the factors was revealed by the assay in MN's localized to the remaining areas of the spinal cord.

Analysis along the rostrocaudal extent of the limb-innervating segments revealed that MN's expressing BDNF mRNA are located more rostrally than those expressing NT-3 transcripts, with an intermediate zone in which both factors appear to be synthesized. In transverse sections of these overlap zones it was observed that, in general, NT-3-positive MN's occupy the lateroventral part of the enlargements, whereas BDNF-containing MN's localize to more mediolateral areas. These results suggest that BDNF and NT-3 are synthesized in discrete levels of the spinal cord by distinct MN subsets both along the longitudinal and cross-sectional planes.

We hypothesize that these differentially expressed neurotrophins may serve various functions at different times. They may act locally within the spinal cord on the corresponding MN populations and/or be transported orthogradely to affect development of the respective target muscles. Supported by the Israeli Academy of Sciences, the Dysautonomia Foundation, and by Genentech, Inc.

610.10

REGULATION OF NEUROTROPHIN-3 BY BRAIN DERIVED NEUROTROPHIC FACTOR IN HYPOGLOSSAL MOTOR NEURONS. R. A. Rush*, X-F. Zhou and D. Greeson. Department of Physiology, Flinders University, Adelaide, SA. 5042, Australia.

Identification of the cellular location of the neurotrophins has so far proved difficult, primarily due to the lack of suitable antisera and appropriate techniques for neurotrophin immunohistochemistry. Recently we have generated antiserum to peptide sequences of neurotrophin-3 (NT3) which have proved useful for immunohistochemistry (Zhou and Rush, Brain Research, 621:189-199, 1993). Purified antibodies from this serum show no cross-reactivity with nerve growth factor (NGF) or brain derived neurotrophic factor (BDNF). Within the brain stem and spinal cord of rat, most reactivity is confined to motor neurons, consistent with *in situ* hybridization studies for mRNA^{NT3}. We now show that unilateral lesion of the hypoglossal nerve leads to the loss of NT3-immunoreactivity (ir) from the ipsilateral hypoglossal nucleus. This is accompanied by a reduction of choline acetyltransferase-ir (ChAT), but an up-regulation of both low affinity nerve growth factor receptor-ir (LNGFR) and NADPH diaphorase activity. However, application of BDNF to the lesioned nerve leads to restoration of the NT3-ir and ChAT-ir, but does not reverse the up-regulated LNGFR-ir or diaphorase activity. These findings support the view that BDNF can regulate the synthesis of NT3 via a specific intracellular pathway, thereby providing a mechanism by which neuronal connectivity can be controlled.

A HISTORY OF TRANSIENT CALCIUM ELEVATION HAS LONG LASTING EFFECTS ON THE ABILITY OF FIBROBLAST GROWTH FACTOR TO PROMOTE NEURONAL SURVIVAL. Marc F. Schmidt* and S. B. Kater. Department of Anatomy and Neurobiology, Colorado State University, Fort Collins, CO 80523

This study investigates the potential capacity of transient calcium signals to modify future cellular responsiveness to neurotrophic factors. The simultaneous presence of low levels of depolarization and basic Fibroblast Growth Factor (bFGF), which in and of themselves did not promote survival, acted synergistically to promote survival of E7 chick ciliary ganglion neurons (plated on poly-L-ornithine). This synergistic interaction was dependent on calcium influx. To test whether this synergism could be obtained when the events were temporally separated, neurons were subjected to a 3 hour pulse of elevated extracellular potassium followed by the addition of bFGF. Such treatment produced high levels of survival. In contrast, treatment with either the pulse alone or the continuous presence of bFGF failed to promote survival. This priming effect of depolarization on bFGF was mediated by intracellular calcium because it was completely abolished by the addition of calcium channel blockers and because the magnitude of the priming effect was directly proportional to the pulse induced rise in intracellular calcium. To test the time constant for the temporal summation between the calcium pulse and bFGF, we increased the time interval between the calcium pulse and the addition of bFGF. Our results are consistent with the notion that a brief calcium pulse could have long lasting effects, up to 8 hours after cessation of the depolarizing pulse, on neuronal responsiveness to bFGF. These results imply that brief pulses of increased intracellular calcium can significantly alter neuronal responsiveness to neurotrophic factors and may have significant implications for how neural activity influences neuronal survival.

OPIOID RECEPTORS

611.1

HUMAN DELTA OPIOID RECEPTOR: CLONING, EXPRESSION AND PHARMACOLOGICAL CHARACTERIZATION. R.J. Knapp, E. Malatynska, L. Fang, X. Li, E. Varga, G. Santoro, J. De Leon, Y. Wang, W. Roeske, and H.I. Yamamura*. University of Arizona Dpt. of Pharmacology, Tucson, AZ 85724.

Antinociceptive ligands selective for δ opioid receptor have fewer side effects than ligands selectively acting at μ or κ opioid receptors. Recently, we cloned a human δ opioid receptor for exclusive characterization its ligand requirements. The cloning was based on hybridization screening of several human cDNA libraries. The probe was obtained by PCR from the mouse δ opioid receptor cDNA and hybridized to a clone in a human striatum cDNA library that lacked the 5' end of the ORF. The probe obtained from this clone was used to identify the clone from human temporal cortex cDNA library that contained the missing upstream part of the ORF but ended before the termination codon. These two clones were ligated together using HincII site present in the overlapping cDNA region. It is now shown that the ligated clones encode for the same receptor using southern blot analysis of human genomic DNA. Two probes, one obtained from 5' end of human temporal cortex cDNA clone and second obtained from 3' end of human striatum cDNA clone, gave a band of the same size (about 4.6 kb) while hybridizing to human genomic DNA digested with BamHI. The reconstituted receptor encodes a 372 amino acid protein that has 93% amino acid identity to the mouse δ opioid receptor. The cDNA was expressed in COS-7 cells and its pharmacological profile was partially characterized. These cells express over 1.0 pmole receptor/mg protein when measured by saturation binding with [³H]naltrindole. The δ receptor selective ligands NBT, BNTX, [Glu⁴]deltorphin, and pCI-DPDPE all have K_i values under 10 nM while the affinities of the μ and κ opioid receptor ligands CTAP and U-69593, respectively are over 4.0 μ M. The cloned receptor is now further characterized with the newly synthesized δ receptor selective, non-peptidic ligands such as analogs of BW 373 and SNC 80 and peptidic ligands such as analogs of DPDPE and deltorphins. Supported in part by NIDA grants.

 δ -OPIOID RECEPTOR IMMUNOREACTIVITY: RELATIONSHIP TO BIOGENIC AMINES AND ENKEPHALIN IN RAT SPINAL CORD AND BRAIN STEM. MW Wessendorf¹*, U Arvidsson¹, RJ Dado¹, PY Law², HH Loh² and R Elde¹. ¹Dept. Cell Biology & Neuroanatomy, ²Dept of Pharmacology, University of Minnesota, Minneapolis, MN 55455.

Using antisera directed against the mouse δ -opioid receptor (DOR) the distribution of DOR-like immunoreactivity (-LI) was analyzed in rat spinal cord and brain stem in relation to serotonergic, noradrenergic, and enkephalinergic neurons. We found DOR-LI in varicosities distributed throughout the spinal cord gray, with highest densities in the superficial dorsal horn, in autonomic regions, around the central canal as well as in the motor nuclei. In the brain stem DOR-immunoreactive (-IR) fibers were found in several nuclei such as midline raphe nuclei, locus coeruleus, parabrachial nuclei, periaqueductal gray matter, interpeduncular nucleus and substantia nigra. A group of DOR positive cell bodies was seen in the laterodorsal tegmental nucleus. All DOR positive cells showed a punctate staining pattern at the cell body level and in primary dendrites, but no plasma membrane staining could be demonstrated. Double labeling for DOR and 5HT revealed that some 5HT-IR neurons in the raphe complex were surrounded by DOR-IR fibers. Also, TH positive neurons in the brain stem were apposed by DOR positive fibers. In the spinal cord a high degree of coexistence was found between DOR and 5HT in the neuropil around motoneurons. In autonomic regions, a low degree of colocalization was seen between DOR and 5HT whereas in the superficial dorsal horn no coexistence was found. No coexistence could be seen between DOR and TH in any part of the spinal cord. In the intermediolateral nucleus a low degree of colocalization was observed between DOR- and enkephalin-IR; however, a close relation, but no coexistence, was observed among such fibers in the spinal cord ventral horn. These data suggest that DORs may affect the activity of descending serotonergic and noradrenergic neurons by means of modulating the release of neurotransmitters from afferents to these neurons. In addition, presynaptic DORs appear poised to modulate the release of 5HT (and of coexisting peptides) from fibers in the spinal cord ventral horn. However, these receptors appear unlikely to be importantly involved in modulation of the release of catecholamines or enkephalin in the spinal cord, or in modulation of the release of 5HT in the superficial dorsal horn. Supported by NIDA.

611.3

CELLULAR LOCALIZATION OF A μ -OPIOID RECEPTOR (MOR) IN RAT BRAIN AND SPINAL CORD. U. Arvidsson¹, M. Riedl¹, J.-H. Lee¹, AH Nakano¹, R Dado¹, S Chakrabarti², HH Loh², P-Y Law², L Yu³, MW Wessendorf¹ and R Elde¹. ¹Dept. Cell Biology and Neuroanatomy and ²Dept. Pharmacology, University of Minnesota, Minneapolis, MN 55455; ³Dept. Medical and Molecular Genetics, Indiana University School of Medicine, Indianapolis 46202.

The μ -opioid receptor (MOR) was localized by immunohistochemistry using antisera raised against a synthetic peptide corresponding to the C-terminal of the predicted amino acid sequence for the μ -opioid receptor. The MOR antisera immunoprecipitated 1-125 β -endorphin cross-linked membrane proteins with mw's of 55-69 kDa that had been isolated from a cell line stably expressing μ -opioid receptor cDNA. Proteins of similar mw were labeled by MOR antisera using Western blots. In addition, the MOR antisera stained cells transfected with native and epitope-tagged μ -opioid receptors. MOR-like immunoreactivity was frequently observed in neuronal membranes, both in the somatic and dendritic domains. However, in some areas such as in the dorsal horn, axon labeling could also be demonstrated. In the brain MOR-like immunoreactivity showed an excellent correlation with the distribution of mRNA encoding MOR, and also with earlier μ -opioid receptor binding studies. The distribution of enkephalin, the putative endogenous ligand for this receptor, showed a distribution complementary to that of MOR in many areas in the brain and spinal cord. However, double-labeling was not observed. These findings suggest that the antisera to MOR recognize a CNS μ -opioid receptor on somatic and dendritic membranes, however, neurons also exist that transport MOR to the axonal compartment. Supported by NIDA.

CELLULAR DISTRIBUTION OF μ , δ and κ OPIOID RECEPTOR mRNAs IN HUMAN CNS. B. Anton^{*}, K. Miotto, M. Husain, D. Kaufman, E. Slickney, T. Maung, T. Tran, and C.J. Evans. Dept. of Psychiatry & Biobehavioral Sciences, University of California, Los Angeles CA 90024, and Dept. of Pathology, Veterans Administration Hospital, Little Rock, Arkansas.

The cloning and sequence analysis of cDNAs encoding rodent μ , δ and κ opioid receptor classes have allowed generation of specific nucleic acid probes to identify and visualize with precision by in situ hybridization the anatomical localization of cells expressing these opioid receptor classes in both mouse and rat brain. We have recently isolated genomic clones encoding the human μ , δ , and κ opioid receptors. Sequence information derived from these clones allowed us to generate specific cRNA probes targeted to exonic sequences which were used for in situ hybridization to elucidate the anatomical distribution of cells synthesizing the μ , δ and κ opioid receptor mRNAs in human tissue. Cells expressing the three opioid receptor transcripts were found in the major human cortical fields following distinct laminar and expression patterns within the 6 cortical layers. Cells containing the three opioid-receptor messages were also detected in the striatum showing distinct expression levels for each opioid receptor transcript. Additionally, in the caudate-putamen, cells expressing both δ and μ mRNAs appear somewhat diffusely distributed whereas cells containing κ mRNA seem to be localized predominantly in clusters, suggesting a possible patch-like distribution for this latter opioid receptor subtype in human caudate-putamen. Co-labelling experiments coupling opioid receptor in situ hybridization to choline acetyltransferase (CHAT) immunocytochemistry to explore preferential patch-matrix distribution of opioid receptors in human caudate-putamen are currently in progress as is the anatomical mapping of other human brain regions. CLONED KAPPA AND MU OPIOID RECEPTORS COUPLE TO AN INWARD RECTIFIER POTASSIUM CURRENT WHEN EXPRESSED IN MOUSE AtT-20 CELLS. M. Tallent^{1,2,3}, M.A. Dichter, and T. Reisine. ¹David Mahoney Institute of Neurological Sciences and ²Depts. of Pharmacology and ³Neurology, University of Pennsylvania School of Medicine and the Graduate Hospital, Philadelphia, PA 19104.

The recent cloning of the kappa, delta, and mu opioid receptors allows new techniques to be used to study cellular mechanisms of action of these receptors. Experiments focusing on endogenous opioid receptors have shown that regulation of ionic conductances is an important mechanism by which these receptors mediate cellular events. Recently, we have reported that the cloned kappa opioid receptor stably expressed in PC-12 cells is able to modulate an N-type calcium current. To further examine opioid receptor-channel coupling we have generated AtT-20 cell lines which stably express kappa and mu receptors. Whole cell patch clamp recordings demonstrate that both the kappa and mu receptor are able to modulate the activation of an inward rectifier potassium current that has previously been described in this cell line. These effects are selective as both kappa- and mu-mediated activation is blocked by selective antagonists. Having both receptors expressed separately in the same cell line will allow us to compare functional properties of the two receptors, including G protein coupling and desensitization. Supported by DA08951.

THE HUMAN μ OPIOID RECEPTOR: CLONING, PHARMACOLOGICAL CHARACTERIZATION and MODULATION of INTRACELLULAR SIGNALING by PROTEIN KINASES. A. Mestek, J.H. Hurley, L.S. Bye, A.D. Campbell¹, Y. Chen, M. Tian, J. Liu, H. Schulman² & L. Yu^{*}. Dept. of Medical & Molecular Genetics, ¹Inst. of Psychiatric Research, Indiana University School of Medicine, Indianapolis, IN 46202, and ²Dept. of Neurobiology, Stanford University School of Medicine, Stanford, CA 94305.

Three major types of opioid receptors designated δ , κ , and μ , mediate a number of physiological functions including hormone secretion, neurotransmitter release, and respiratory activity. Because opioid drugs with abuse potential such as morphine, methadone, and fentanyl act upon the μ receptor, it is considered the main cellular mediator in the development of tolerance and opioid addiction. We have isolated a human μ opioid receptor cDNA containing an open reading frame capable of encoding a protein of 400 amino acids, with 94% sequence homology to the rat μ opioid receptor. A major effect caused by activation of the μ opioid receptor in brain is the decrease in neuronal membrane excitability. One of the mechanisms for this effect is an increase in K^+ conductance, accomplished by the opening of an inward rectifier, resulting in outward K^+ currents and hyperpolarization of the cell membrane. The human μ receptor demonstrates functional coupling to a recently cloned G protein-activated K^+ channel, when both proteins are expressed in *Xenopus* oocytes. Upon repeated stimulation of the μ opioid receptor, functional desensitization is observed as a reduction in the K^+ current. Both protein kinase C and the multi-functional Ca^{2+} /calmodulin-dependent protein kinase potentiate functional desensitization, suggesting kinase modulation of intracellular signaling mediated by the μ opioid receptor.

611.6

KAPPA-OPIOID RECEPTOR AGONISTS SUPPRESS VOLTAGE-ACTIVATED POTASSIUM CURRENT IN CATH.a CELLS. S.C. Baraban^{*}, E.W. Lothman and P.G. Guyenet. Depts. of Pharmacology and Neurology, University of Virginia, Charlottesville, VA 22908.

The CATH.a cell line is derived from tyrosine hydroxylase (TH)-positive tumors in transgenic mice. CATH.a cells in culture synthesize norepinephrine (Suri et al, *J. Neurosci.* 13:1280, 1993). In this study we examined the opioid sensitivity of CATH.a cells using whole-cell voltage-clamp techniques. Depolarizing commands from the holding potential (-60 mV) produced sustained outward current (I_K). External tetraethylammonium (25 mM) reduced I_K by 40-60% ($n=10$). Depolarizing steps following a hyperpolarizing pre-pulse (-110 mV) elicited fast, transient outward current (I_A). I_A was selectively blocked by 4-aminopyridine (10 mM; $n=5$). Intracellular dialysis with TEA (25 mM) and CsCl (160 mM) blocked voltage-activated potassium currents ($n=5$).

Morphine (0.5-100 μ M) reduced I_K in a concentration-dependent manner ($EC_{50} = 3.5 \mu$ M, max. inh. = 53%, $n=30$). Naloxone (10 nM) blocked the inhibitory effect of 10 μ M morphine ($n=8$). The μ -specific agonist DAGO (2-20 μ M; $n=6$) and the δ -specific agonist DPDPE (2-20 μ M; $n=7$) produced no effect. U50,488 (0.3-50 μ M), a κ -specific agonist, reduced I_K in a concentration-dependent manner ($EC_{50} = 2.3 \mu$ M, max. inh. = 44%, $n=40$). The κ -specific receptor antagonist nor-BNI (10 nM) blocked the inhibitory effect of 10 μ M morphine ($n=6$) or 10 μ M U50,488 ($n=7$). Kappa-receptor mediated current reduction was prevented by intracellular dialysis with an inactive form of GDP (GDP- β -S 100-200 μ M, 3-5 min., $n=10$). Incubation with pertussis toxin (PTX 500 ng/ml, 24-48 hr; $n=10$) did not eliminate kappa-opioid induced suppression of I_K . These results suggest that opioid suppression of I_K in CATH.a cells is mediated by a kappa opioid receptor coupled to a PTX-insensitive G-protein.

PHYSICALLY SEPARATE EXTRACELLULAR DOMAINS OF THE KAPPA RECEPTOR ARE NECESSARY FOR AGONIST AND ANTAGONIST BINDING. H. Kong^{*}, K. Raynor and T. Reisine. Univ. of PA School of Medicine, Dept. of Pharmacology, Philadelphia, PA 19130.

The cloned κ and δ receptors display unique pharmacological profiles. Their amino acid sequences are about 60% identical. The areas of the receptors most divergent are the NH₂- and COOH-termini as well as the extracellular loops. We have hypothesized that these extracellular domains have a role in ligand recognition and/or binding. To test this hypothesis, we have constructed chimeric receptors of κ and δ in which the NH₂-termini as well as the second extracellular loops have been exchanged. The chimera containing the NH₂-terminus of the κ receptor and the remainder of the δ receptor ($\kappa\delta$) revealed that agonist and antagonist binding to the κ receptor are on separate domains. This chimera bound κ -selective agonists but not κ -selective antagonists. In contrast, binding of both δ -selective agonists and antagonists to this chimera was not dependent on the presence of the δ NH₂-terminus. δ -selective agonists could specifically inhibit cAMP accumulation via the $\kappa\delta$ chimera, but κ -selective agonists did not. These pharmacological and functional results suggest that the NH₂-terminus of the κ receptor is responsible for antagonist recognition and binding. The second extracellular loop chimeras between the two receptors have shown that this region is important for κ -selective agonist binding but not antagonist binding. The abilities of the κ -selective agonist U50,488 and dynorphin B to bind to the chimeric κ receptor containing the δ second extracellular loop ($\kappa\delta$ 2loop) were greatly reduced when compared to wild-type κ . In contrast, antagonist binding to the wild-type and chimeric receptors was similar. Furthermore, the abilities of κ -selective agonists at the $\kappa\delta$ 2loop chimera to inhibit forskolin-stimulated cAMP accumulation was lost. These results clearly demonstrate that κ -selective agonists and antagonists bind to physically distinct regions of the κ receptor. Antagonists bind to the NH₂-terminus whereas selective agonists bind to the second extracellular loop. [Supported by DA08951, MH10485 and the Scottish Rite Foundation.]

Opiate Receptor Structure/Function Relationships and Molecular Modeling Christopher K. Surrat¹, Peter S. Johnson², Akiyoshi Moriawake³, Brian K. Seidleck⁴, Carrie J. Blaschak⁵, Jia-Bei Wang⁶, Stacieann Yuhase⁷ and George R. Uhl^{1*} ¹Molecular Neurobiology Branch, ²Office of the Director, Intramural Research Program/NIDA, ³Pharmacology Research Associate Program, NIGMS; ⁴Biophysics and ⁵Depts. of Neurology and Neuroscience, Johns Hopkins School of Medicine.

μ opiate receptor cDNAs encode poorly conserved N- and C-terminal regions and conserved, charged transmembrane domain residues. Deletion of 64 N-terminal amino acids yields a receptor that binds DAMGO and mediates DAMGO and morphine inhibition of cAMP accumulation at wildtype levels. Deletion of an additional 33 C-terminal amino acids removes DAMGO's ability to inhibit cyclase, while removal of the entire C-terminal tail yields a nonfunctional receptor. Replacement of charged amino acids D114 (TM II) and D147 with alanine, asparagine or glutamic acid drastically reduces agonist binding. Naloxone binding is fully retained in D147N and D147E mutants. Each of 6 substitution mutants for H297 (TM VI) bind DAMGO poorly. Opiate inhibition of cyclase is preserved for D114E, D147E and certain H297 mutants. COS cells expressing mutant receptors can be immunostained by specific polyclonal anti- μ receptor sera. These data are reflected in molecular modeling scenarios for ion, peptide and alkaloid recognition. Charged residues in TM II, III and VI are key for full receptor function, contrasting with N- and distal C-terminal domains, while several mutant receptors revealed intriguing differences between binding and second messenger activities.

611.11

μ OPIOID RECEPTOR EXPRESSION AND DESENSITIZATION IN A STABLY TRANSFECTED CELL LINE. A.Kouvelas, M.A.Scheideler, R.L.Zastawny, J.S.Rasmussen, H.Juhl, Y.Israel¹, B.F.O'Dowd and S.R.George. Dept. of Pharmacology, University of Toronto, Addiction Research Foundation, Toronto, Canada M5S 1A8 and Novo Nordisk A/S, 2760 Malov, Denmark.

We have previously reported the cloning, characterization and mapping of the μ opioid receptor (OR) in rat brain. μ OR was transfected into BHK-570 cells using Lipofectin, and geneticin resistant clones screened for specific [³H]-bremazocine binding. A subclone (BHK-48) which stably expressed high levels of specific opioid binding was characterized. The pharmacology of the μ OR in the BHK-48 cells was compared to μ OR transiently expressed in Cos-7 cells or natively expressed in F11 cells. In BHK-48 cells, naloxone Kd for the μ OR was 3.0 ± 0.85 nM, Ki rank order for antagonists was naltrexone < naloxonazine < naltrindole. Agonist competition revealed ~80% of receptors in the high affinity state. The Ki of agonists at the high affinity state was morphine < DAMGO < DADLE < U 50488 < DPDPE. Coupling of the μ OR to adenylyl cyclase in BHK-48 cells was determined by measurement of agonist mediated decreases in cAMP synthesis. Exposure of cells to high concentrations of morphine resulted in a rapid reduction of the apparent density of μ OR by 43%, whereas low concentrations of morphine resulted in an increase in the apparent density of μ OR by 46%. These results demonstrate that our BHK-48 cell line stably expresses μ OR with appropriate pharmacology, G protein coupling and second messenger linkage. μ receptor activation and desensitization by agonist were accompanied by dose-dependent regulation of detectable receptor numbers.

611.10

CONSTRUCTION, EXPRESSION AND CHARACTERIZATION OF EPITOPE-TAGGED OPIOID RECEPTORS R.L.Zastawny, S.R.George, R.Briones-Urbina* and B.F.O'Dowd. Addiction Research Foundation and Department of Pharmacology, University of Toronto, Toronto, Ontario, CANADA, M5S 1A8.

We have previously reported the cloning, pharmacological characterization and mRNA distribution of the rat μ , κ and δ opioid receptors. These studies revealed that the receptors have unique pharmacological profile and distributions in the brain suggesting unique roles for each receptor in the CNS. To facilitate further study of these receptors, we have designed μ and κ opioid receptors with extended N-terminals incorporating six histidine residues and a 12 amino acid sequence from the T7 major capsid protein for which a monoclonal antibody is available. The cDNA constructs encoding the receptor fusion proteins were inserted into a mammalian expression vector downstream of a cytomegalovirus (CMV) promoter and transiently expressed in COS cells. Initial characterization of the pharmacological properties of the tagged κ receptors show it to be identical to the wild-type receptor suggesting the added peptide epitope does not interfere with ligand binding properties. In stable mammalian cell lines expressing these tagged receptors, the histidine-tag will be used to affinity purify the receptors using a nickel chelating affinity column. The stable expression of these tagged receptors in mammalian cells should be useful for functional analysis, biochemical characterization and immunocytochemical localization, to study the post-translational modifications and desensitization of opioid receptors.

611.12

QUANTIFICATION OF DELTA OPIOID RECEPTOR BINDING IN HUMAN BRAIN WITH N1'-([¹¹C]METHYL) NALTRINDOLE AND PET. J.S. Smith, J.K. Zubietta, J.C. Price, J. Madar, J.R. Lever, C. Kinter, H.T. Ravert, R.F. Dannals, J.J. Frost*. The Johns Hopkins Medical Institutions, Baltimore, MD.

Central opiate-mediated signaling takes place via three main receptor subtypes (μ , δ and κ). Investigations of their roles in living human subjects with PET has been limited by the lack of specific radiotracers for δ or κ subtypes. We have recently developed a radiolabelled δ subtype-selective, non-peptide opioid receptor antagonist, N1'-([¹¹C]methyl) naltrindole ([¹¹C]MeNTI); this compound was prepared at high specific activity by C-11 methylation of a naltrindole derivative. Seven healthy subjects (27 \pm 2 years old) underwent dynamic PET studies after intravenous injection with 18-20 mCi [¹¹C]MeNTI. 25 scans were obtained over 90 min, with arterial blood sampling and correction for the presence of labelled metabolites. Both graphical analysis and three compartment tracer kinetic models were applied to the data. Using the three compartment model, delivery rate constants (K1) ranged from 0.22-0.28 ml/g/min across brain regions. A constrained (k4=0) yielded values of the binding parameter k3 of 0.008 ± 0.003 in thalamus, 0.022 ± 0.007 in occipital cortex and 0.028 ± 0.005 in putamen. Regional k3 values (basal ganglia > neocortex > thalamus > cerebellum) obtained with these methods were highly correlated ($r=0.98$) with the known distribution of delta opioid receptors in human brain reported in *in vitro* binding studies. These results support the potential use of [¹¹C]MeNTI as an agent for the quantification of delta opioid receptor densities in human brain with PET.

DEGENERATIVE DISEASE: ALZHEIMER'S—BETA AMYLOID X

612.1

COMPARISON OF A BRAIN PURIFIED METALLOPROTEASE WITH HUMAN CATHEPSINS G AND D: Evaluation of Sequence Specificity Using Peptide Substrates and Regional Selectivity Using Purified Brain APP L. Sonnenberg-Reines*, A.B. Brown, D.M. Tummo, M. A. Spruyt and J.S. Jacobsen. Department of Central Nervous System Biological Research, Lederle Laboratories, Division of American Cyanamid Co., Pearl River, N.Y. 10965.

A number of proteases have been proposed as candidates for the activity that cleaves at the amino-terminus of β -amyloid peptide (β AP). No single protease has emerged as possessing all the required properties for β -secretase including sequence specificity, ability to cleave amyloid precursor protein (APP) appropriately, brain localization and correct sensitivity to sequence substitution.

We have recently purified another candidate β -secretase, a 55-60 kDa metalloprotease from rabbit and monkey brain and characterized its activity using a synthetic peptide substrate (SEVKMDAEF) which flanks the N-terminal of β AP. HPLC and amino acid analysis reveal that the major cleavage is between Met and Asp. The enzyme is inhibited by EDTA, EGTA, 1,10-phenanthroline. The pH optimum for this protease is 5.0-6.0, but activity is still retained at physiological pH.

We have compared three candidate proteases (cathepsin D, cathepsin G, and the above metalloprotease) for their ability to cleave, in addition to SEVKMDAEF, peptides which (1) incorporate the Lys-Met to Asn-Leu mutation found in a Swedish family with early onset Alzheimer's disease, (2) contain various amino acid substitutions near the M/D cleavage site, and (3) contain oxidized methionine at the M/D cleavage site. In addition, we have probed these enzymes ability to form carboxy-terminal fragments with a longer purified APP substrate or cell derived PN II. Epitope mapping of these larger substrates and their digestion products were used to localize the site of cleavage to a region near the N-terminus of β AP.

612.2

INCREASED NEURONAL CATHEPSIN D GENE EXPRESSION AND ACTIVE RELEASE OF COMPETENT PROTEASE IN ALZHEIMER DISEASE. R.A. Nixon*, A.M. Cataldo, A.L. Schwagerl, N. Kowall, L.A. Kanaley-Andrews. McLean Hospital, Harvard Medical School, Belmont, MA

We have found that activation of the lysosomal system, evidenced by increased cathepsin gene expression and accumulation of secondary and tertiary lysosomes, is an early marker of metabolic dysfunction in "at-risk" neuronal populations in Alzheimer disease. In quantitative image analyses of a series of 8 AD brains (moderate-severe neuropathology) and 8 age-matched controls immunostained with cathepsin D antibodies under identical conditions, >90% of neocortical perikarya in layers III and V of AD brains contained 2- to 8-fold elevated numbers of secondary and tertiary hydrolase-positive lysosomes in the absence of atrophic, chromatolytic or neurofibrillary changes. *In situ* hybridization analysis showed the expression of cathepsin D mRNA to be increased an average of 2-fold in these cell populations in parallel to hydrolase immunoreactivity ($p < 0.001$). Neurons exhibiting overt atrophy or neurofibrillary changes displayed massive accumulation of hydrolase-positive lysosomes and lipofuscin which were then released into the extracellular space in association with neuritic and cell degeneration. These lysosomal compartments, containing a full spectrum of enzymatically competent hydrolases, persist in the extracellular space specifically in association with deposits of β -amyloid within both neuritic and diffuse plaques. Cathepsin D content was >3-fold higher in ventricular CSF from AD patients ($n = 35$) than in samples from 26 patients with Huntington's, diffuse Lewy body or Pick's disease ($p < 0.001$), indicating that cathepsin D release from affected neurons in Alzheimer brain is an active ongoing process. Prominent extracellular accumulations of lysosomal hydrolases have thus far been observed only in the brain parenchyma of patients with Alzheimer disease or other conditions where β -amyloid accumulates. Support: NIH (AG10916).

612.3

LOCALIZATION OF A HUMAN METALLOPROTEASE CAPABLE OF GENERATING POTENTIALLY AMYLOIDGENIC FRAGMENTS FROM THE AMYLOID PRECURSOR PROTEIN. C.R. Abraham*, K. J. Conn, M. Pietropaolo, A. Amarantunga, R.E. Fine and B. Meckelein. Departments of Medicine and Biochemistry, Boston Univ. Sch. Med., Boston, MA 02118, and ENRVA Hospital, Bedford, MA 01730.

Alzheimer's disease (AD) is characterized by the deposition of β -amyloid protein (A β) in brain parenchyma and blood vessels. The formation of A β requires its proteolytic release from a larger molecule, the amyloid precursor protein (APP). Recently, we have purified and characterized a protease from human brain which is a candidate for an amyloidogenic APP processing. The enzyme is highly homologous to the rat metalloendopeptidase EC 3.4.24.15. It cleaves a synthetic peptide flanking the N-terminus of A β at the Met-Asp bond and is capable of generating a 15 kDa amyloidogenic fragment from recombinant human APP *in vitro*.

To characterize the enzyme further, we developed monoclonal antibodies against a 20 amino acid peptide derived from the sequence of the purified protease. These antibodies were used to characterize the tissue distribution and the cellular localization of the enzyme, using immunohistochemistry, immunoprecipitation and Western blots. The enzyme is present in all monkey tissues examined, with highest amounts being found in brain, testis and kidney, organs which also contain high levels of APP. In human brain, neurons were strongly stained. In human cultured cells, the metalloprotease was found in neuroblastoma and kidney cells and their conditioned media, but not in glioblastoma cells. Using a rabbit retina/optic nerve system *in vivo*, we purified by equilibrium sucrose density gradient centrifugation three fractions containing transport vesicles from the optic nerve. The protease colocalizes with APP and ApoE in the same vesicular compartments.

612.5

INTRACELLULAR AND EXTRACELLULAR ACCUMULATION OF AMYLOID A β PEPTIDE BY DIFFERENTIATED PC12 CELLS.

Debra Burdick* and Charles G. Glabe

Department of Molec. Biol. and Biochem. Univ. of Calif., Irvine, CA 92717

The mechanisms of amyloid accumulation in Alzheimer's disease are largely unknown, but may be central to the etiology of the disease. Our previous results demonstrated that A β 1-42 accumulates in late endosomes or secondary lysosomes of human fibroblasts and is resistant to degradation. We have extended these investigations to NGF-differentiated PC12 cells, and we found that while A β 1-42 also accumulates in PC12 cells, there are a number of differences from the results obtained with fibroblasts.

Immunofluorescent confocal microscopy indicates a dual localization of the accumulated A β 1-42, in intracellular, punctate granules and aggregates of peptide at the cell surface. Unlike fibroblasts, the A β 1-42 on the surface of PC12 cells is largely resistant to removal by trypsin. In contrast to fibroblasts, the shorter amyloid peptides, A β 1-28 and A β 1-40, accumulate in PC12 cells but to a lesser degree than A β 1-42. The accumulated A β 1-42 is stable for at least 3 days while A β 1-28 and A β 1-40 are degraded within 90 min after exchanging the cells into peptide free media. The intracellular A β 1-42 is located in a dense organellar compartment which overlaps the distribution of late endosomes and lysosomes and colocalizes with internalized horseradish peroxidase which is targeted to lysosomes. The internalized A β 1-42 is not sequenceable and highly aggregated, suggesting that it may be subject to modification by the cells. These results indicate the neuronal plasma membrane may nucleate amyloid assembly or otherwise stabilize amyloid aggregates and suggests that a failure to degrade A β 1-42 may be an important component of amyloid accumulation. Supported by NIH GM07311 and NS31230

MOLECULAR CHARACTERIZATION OF THE APP/APLP SUPERFAMILY. W. Wasco*, D.M. Kovacs, A. Crowley, K.M. Felsenstein and R.E. Tanzi. Laboratory of Genetics and Aging, Massachusetts General Hospital, Harvard Medical School, Boston, MA and Bristol Myers Squibb, Wallingford, CT.

The Alzheimer-associated amyloid β -protein precursor (APP), which was first identified in 1987, is now known to be a member of an evolutionarily conserved gene family. We have identified and isolated cDNAs encoding two mammalian amyloid precursor-like proteins (APLP1 and APLP2), and APP-like genes have also been identified in both *Drosophila* and *C. elegans*. All of these proteins show extensive amino acid and domain homologies, and like APP, the mammalian APLPs have a number of alternatively transcribed forms. Interestingly, the direct comparisons of the amino acid sequences of the APP-like genes and APP have demonstrated that the amyloidogenic A β domain is not conserved in the family and is found exclusively in APP.

For our current set of experiments we have established stably transfected human H4 neuroglioma cell lines that overexpress APP, APLP1 and APLP2. These lines are being used to characterize the subcellular localization of the APLPs and to compare the effects that overexpression of one member of the family may have on the expression and processing of the others. Reagents capable of indisputably distinguishing the members of the APP-like family by immunohistochemical and immunoblot analysis are currently being developed. In addition, we have compared the tissue distribution of alternatively transcribed forms of APP and the APLPs. Finally, we have examined whether the overall expression of the APLP gene transcripts and the specific expression of APLP alternatively transcribed domains (such as the APLP2 KPI and 12 amino acid domains) are developmentally regulated.

612.4

REMOVAL OF AMYLOID β PROTEIN BY CULTURED CELLS S. Gillespie*, L. Ho, and S. G. Younkin. Case Western Reserve U., Cleveland, OH 44106

There is increasing evidence that the deposition of amyloid β protein (A β) as insoluble amyloid fibrils plays a critical role in Alzheimer's disease (AD). A β is secreted by normal processing of the amyloid β protein precursor. Thus the rate of amyloid deposition will depend on (i) the rate at which A β is secreted, (ii) the rate at which secreted A β is removed, and (iii) the rate at which insoluble amyloid fibrils are formed at any prevailing concentration of soluble, extracellular A β . Fibril formation and factors influencing the rate of A β secretion are currently being intensively studied, but little is known about the mechanism(s) that remove secreted A β . To assess this issue, we added synthetic A β 1-42 or A β 1-40 to (i) unconditioned medium, (ii) medium removed from cells after 24 hours of conditioning or (iii) cultured cells when fresh medium was added. We then assayed periodically by sandwich ELISA to assess A β loss. In 24-hour conditioned but not in unconditioned medium, 95% of A β at 500 fmol/ml was lost in 4 hours. This effect of conditioning was also produced by human neuroblastoma (2C), human embryonic kidney (293), mouse fibroblast (3T3), rat glioma (C6), and mouse neuroblastoma (N2a) cells. A β loss was attenuated by protease inhibitors of several types suggesting that several different secreted proteases may be involved in the loss of A β observed in conditioned medium. We are now further characterizing the proteases involved in an effort to determine whether they are likely to be important in removing A β secreted by CNS cells *in vivo*. Medium conditioned for 24 hours by human neuroblastoma (M17) cells, unlike that conditioned by the other lines, did not cause loss of A β . Despite this, A β was rapidly lost when it was added (500 fmol/ml) to M17 cells in fresh medium. Thus this cell line, which is a BE-2 subclone with a neuronal phenotype, may be able to remove A β through a mechanism other than protease secretion. Interestingly, human 2C and 293 cells also removed A β added in fresh medium but 3T3, C6, and N2a cells did not.

DEGRADATION OF THE ALZHEIMER'S DISEASE AMYLOID A β PEPTIDE BY A SECRETED METALLOPROTEASE. J.T. Durkin*, S. Murthy, W. Biazzo, R. Siman and B.D. Greenberg. Cephalon Inc., West Chester, PA 19380-4245

The levels of soluble A β amyloid peptide in biological fluids depends both on its rate of production and its rate of removal. Human neuroblastoma cells have been shown by several groups to secrete soluble A β . Here we show that M17 human neuroblastoma cells also secrete a protease that degrades A β . Cells were metabolically labeled with [35-S]Met and the labeled conditioned medium was separated from cells by filtration. The cell-free medium was then incubated on ice or at 37°C for 24 hours, and A β levels were measured by immunoprecipitation, electrophoresis, and phosphorimaging. Media incubated at 37°C contained 60%-90% less A β than media incubated on ice. The metalloprotease inhibitors EDTA or o-phenanthroline prevented this loss of A β , suggesting that this proteolytic activity was a member of the metalloprotease class. Matrix metalloproteases are generally secreted as inactive zymogens that can be activated *in vitro* by the organomercurial compound p-aminophenylmercuric acetate (APMA). APMA addition prior to the incubation step resulted in a potentiation of A β degradation; however, degradation under these conditions was still inhibited by o-phenanthroline and EDTA. Moreover, general inhibitors of the other major protease classes (3,4-dichloroisocoumarin for serine, E-64 for cysteine, and pepstatin A for aspartic) did not inhibit A β degradation. This pharmacology demonstrates that M17 cells secrete a protease of the matrix metalloprotease family that degrades soluble A β . To the extent that cultured M17 cells reflect processes in human brain tissue, we speculate that inefficient proteolytic removal of soluble A β from brain may contribute to the etiology of Alzheimer-type amyloid formation.

TISSUE DISTRIBUTION, DEVELOPMENTAL EXPRESSION, AND PROCESSING OF APLP2 ISOFORMS IN MOUSE. G. Thinakaran*,^{1,2} H.S. Slunt*, and S.S. Sisodia*.^{1,2} ¹Department of Pathology, ²Neuropathology Laboratory, The Johns Hopkins University School of Medicine, Baltimore, MD 21205.

Amyloid precursor-like protein 2 (APLP2) is a member of a larger family of proteins that includes amyloid precursor protein and APLP1. APLP2 pre-mRNA undergoes alternative splicing to generate mature mRNAs that encode for at least four APLP2 isoforms. We have employed quantitative reverse-transcriptase polymerase chain reaction assays to analyze the expression of transcripts encoding various APLP2 isoforms in adult tissues and during mouse development. In parallel, the expression of APLP2 polypeptides is being monitored with highly specific anti-APLP2 antibodies.

We have also examined the metabolism of the APLP2-751 isoform in cultured mammalian cells. In transfected CHO, COS-1, and neuroblastoma N2A cells, APLP2 is modified by chondroitin sulfate (CS) glycosaminoglycan. Using site-directed mutagenesis strategies, we have identified the site for the CS modification of APLP2-751. We are presently characterizing the posttranslational processing of the other APLP2 isoforms.

IMMUNOCYTOCHEMICAL LOCALIZATION OF AMYLOID PRECURSOR-LIKE PROTEIN 2 (APLP2) AND AMYLOID PRECURSOR PROTEIN (APP) IN MOUSE BRAIN. CA Kitt^{1,5}, G Thinakaran^{1,5}, JC Mojekwu³, RR Reed^{2,3}, DL Price^{1,5}, and SS Sisodia^{1,5}. Departments of ¹Pathology, ²Molecular Biology & Genetics, ³Neuroscience, and ⁴Neurology, ⁵Neuropathology Laboratory, The Johns Hopkins University School of Med., Balto., MD 21205.

APLP2 belongs to a family of homologous proteins that include APP and APLP1. In earlier experiments, we provided strong evidence that several antibodies raised against APP also cross react with APLP2. We now report on the immunocytochemical distributions of APLP2 and APP in mouse brain by using antibodies that are exquisitely specific for either APLP2 or APP. We document that APLP2 and APP have overlapping distributions in cortex and hippocampus; however, the cellular localization and intensity of staining for each of these proteins in olfactory receptors, nerves, and bulbs are unique. APLP2 immunoreactivity is most pronounced in olfactory receptor cells, including cilia, cell bodies, olfactory nerve fibers, and glomeruli in the olfactory bulb. On the other hand, APP immunostaining is most pronounced in the olfactory cilia and receptor cell bodies and in granule cells that surround the glomeruli. APP immunoreactivity is conspicuously absent in olfactory nerves and glomeruli in the olfactory bulb. Notably, a distinct band of mitral cells in the olfactory bulb is intensely stained with APP antibodies. In addition, APP-immunoreactive processes course through most layers of the main olfactory bulb, and dense accumulations of large immunostained puncta are observed in the external plexiform layer. Our studies provide strong support for the view that APLP2 and APP play prominent roles in olfactory receptive processes.

SIMILAR AND DIVERGENT FEATURES OF ALTERNATIVE SPLICING OF THE AMYLOID PROTEIN PRECURSOR APP AND THE APP-RELATED PROTEIN APLP2. R. Sandbrink, U. Mönnig, R. Prior*, C. L. Masters and K. Beyreuther, Zentrum für Molekulare Biologie Heidelberg, Univ. of Heidelberg, Germany.

Among the transmembrane glycoproteins constituting the family of APP-like proteins, APLP2 is the nearest relative of the Alzheimer BA4-amyloid protein precursor (APP). We determined the complete cDNA and amino acid sequence of rat APLP2 comprising 765 residues (1), and compared its tissue-specific expression and alternative splicing to APP gene expression.

In APP, there are three alternatively spliced exons, of which, as we have previously shown, the L-APP mRNA isoforms lacking exon 15 are ubiquitously expressed in non-neuronal cells, but not in neurons (2). In APLP2, we were able to identify two alternatively spliced exons, of which the KPI-encoding exon is highly expressed in neurons and thus differs in its tissue-specific expression from the KPI-encoding APP exon. While no equivalent to exon 8 of APP was detected in APLP2, there is another alternatively spliced exon with a strikingly similarly regulated expression, that is part of that APLP2 domain most divergent to APP. L-APLP2 mRNA isoforms lacking this exon represent the major part of APLP2 transcripts in non-neuronal tissues, but are only weakly expressed in neurons (3).

Because of the similar regulation of alternative splicing of exon 15 of APP and the described APLP2 insert, and because of structural similarities of the sequences and the predicted secondary structures, a functional relatedness of alternatively spliced isoforms of APP and APLP2 is suggested. Ubiquitous expression of high levels of L-APP and L-APLP2 mRNAs except for neurons indicates an important function in non-neuronal cells, and is remarkable since neurons are the primarily affected cells in Alzheimer's disease.

GENESIS OF NEURONS AND GLIA III

613.1

20-HYDROXYECDSYONE STIMULATES GLIAL-CELL PROLIFERATION DURING A CRITICAL PERIOD IN THE DEVELOPMENT OF THE INSECT BRAIN. SR Kirschenbaum*, M Higgins and LP Tolbert. ARL Division of Neurobiology, University of Arizona, Tucson, AZ 85721.

Developmental events that shape the nervous system are often regulated by steroid hormones. During metamorphosis in the moth, *Manduca sexta*, when the larval nervous system is reshaped for adult function, the hormone 20-hydroxyecdysone (20-HE) controls diverse aspects of neuronal differentiation. Little is known, however, about hormonal effects on glial cells. In the antennal (olfactory) lobe of *Manduca*, glial cells are critically important because one type, the neuropil-associated glial cells, forms boundaries for developing olfactory glomeruli as a result of proliferation and migration during metamorphosis. The normal temporal pattern of glial proliferation is similar to the pattern of changing hormone titers, suggesting a regulatory role for hormones. We manipulated hormone titers *in vivo* by injecting 20-HE into the hemolymph at different stages of metamorphic development and monitored glial-cell proliferation, using the incorporation of BrdU as a marker. Hormone injections enhanced glial-cell proliferation during the early stages of metamorphosis when, in normal animals, the hormone titer is rapidly increasing. Later, after stage 6 (of 18 developmental stages), hormone treatment became less effective at enhancing proliferation; by stage 12, when 20-HE titers are near zero, there was no significant stimulation of proliferation. Thus, the ability of cells to respond to hormone is limited to the window of time when, normally, 20-HE circulates in the hemolymph. Two other glial classes, cell-body associated glial cells and perineurial cells also proliferate in response to 20-HE. Our results indicate that glial proliferation in the brain, like neuronal survival and growth elsewhere in the nervous system, is under the control of steroid hormones during metamorphic development.

CELL SIZE REDUCTION DURING NORMAL SPINAL CORD DEVELOPMENT. A. Chen* and R.D. Heathcote. Department of Biological Sciences, University of Wisconsin, Box 413, Milwaukee, WI, 53201

Regressive phenomena play an important role in the morphogenesis of the vertebrate nervous system. For example, cell death, pruning of neuronal arborizations and synapse elimination are frequently involved in the maturation of neuronal populations. During neural tube formation in the frog *Xenopus laevis*, average spinal cord cell body size underwent two phases of reduction. The initial phase was characterized by a corresponding increase in cell number. To determine if the reduction in cell size was caused by cell division, animals were treated with a mixture of hydroxyurea and aphidicolin (HUA) to block DNA synthesis and consequently cell division. The cells of spinal cords treated at the time of neural tube closure did not decrease in size or increase in number, showing that the first phase of reduction in cell size was the result of cell division. Subsequently, a specific population of catecholaminergic spinal cord neurons underwent a rapid decrease in size. Since catecholaminergic neurons in the peripheral nervous system can divide, we tested the possibility that this second phase of reduction might also be due to cell division. Cell division was blocked by treatment with HUA throughout this period of time, but the catecholaminergic cells continued to decrease in size, showing that the second phase of reduction in cell size was not the result of cell division. In this case cell size reduction could be caused by diversion of cytoplasm to axons and dendrites, elimination of cytoplasmic yolk droplets or cellular secretion.

Decreases in spinal cord cell size can be separated into two phases. During the one to two days following neural tube closure, cell division can account for a marked decrease in the size of spinal cord cell bodies. During the subsequent one to two days, at least some differentiating cells undergo a greater than twofold decrease in size that is independent of cell division.

NEUROGENESIS AND SYNAPTOGENESIS OF THE DEVELOPING SEPTUM AND AMYGDALA IN THE BRAZILIAN OPOSSUM BRAIN.

J. J. Swanson*, J. Iqbal, J. K. Elmquist*, and C. D. Jacobson. Department of Veterinary Anatomy and Neuroscience Program, Iowa State University, Ames, IA 50011, *Department of Neurology, Harvard Medical School, Beth Israel Hospital, Boston, MA 02115.

The Brazilian opossum, *Monodelphis domestica* is a small marsupial whose young are born in an extremely immature state with a protracted postnatal period of neurogenesis. We have previously shown that neurogenesis of the hypothalamus continues postnatally. In this study we have used postnatal injection of bromodeoxyuridine (BrdU) and immunohistochemistry to describe neurogenesis of the septum (Spt) and amygdala (Amg). A high proportion of labelled cells were found in the Amg and Spt following BrdU injections at postnatal day (PN) 7 or 8. The number of BrdU labelled cells decreased with increasing age of injection. No BrdU labelled cells were present in the Amg and Spt following injections on PN 12 and 13 respectively. However, a few cells were labelled in the lateral Spt and posterior Amg following PN 13 injection. To correlate neurogenesis with synaptogenesis, immunohistochemical analysis of proteins associated with synaptic vesicles, synaptic membranes, and microtubule-associated proteins during development in the Spt and Amg was conducted. From 1 through 9 PN the Spt and Amg are lacking immunoreactivity for the synaptic vesicle-associated proteins (SVAPs) synaptophysin and synaptotagmin. After 10 PN, there is an increase in immunoreactivity for the SVAPs. Tau-1 (associated with axons) immunoreactivity follows a similar pattern of expression, whereas synaptosomal-associated protein 25 immunoreactivity is not evident until after 11 PN. In contrast, immunoreactivity for map-2 (associated with dendrites) is present in the Spt and Amg from 7 PN on. These results indicate that synaptogenesis begins as neurogenesis is completed in the Spt and Amg of the opossum.

ULTRASTRUCTURAL AND IMMUNOHISTOCHEMICAL CHANGES OF MIDBRAIN EPENDYMAL CELLS DURING LIZARD CNS ONTOGENY. M. Monzon-Mayor¹, C. Yanes², R. Sturrock³, J. de Barry⁴ & G. Gombos^{4*}. ¹Dept. de Morfología, U. de Las Palmas de G.C., Canary Islands, Spain; ²Dept. de Biología, U. de La Laguna, Canary Islands, Spain; ³Dept. of Anatomy & Physiology, U. of Dundee, UK; ⁴Neurobiologie cellulaire, Centre de Neurochimie, Strasbourg, France.

In adult lizard, CNS repair and regeneration processes are apparently carried out by cells originating from specific areas (i.e. sulci) of the ventricular wall. Little is known on these structures and on their embryogenesis in reptiles. We have thus begun a study on the development and differentiation of ependymoglia cells in *Gallotia galloti*, a lizard indigenous to the Canary Islands.

At the earliest stage of CNS development (E31 to E34) the ventricles are lined with an undifferentiated pseudostratified columnar neuroepithelium where all cells are Vimentin positive. Between E35 and E37, Vimentin immunoreactivity decreases while GFAP and/or Glutamine synthetase immunoreactivity appear and ventricular cells begin to exhibit phenotypic differences. During this period three types of ependymoglia cells become distinguishable: columnar cells, cuboidal cells and cells rich in microtubules, glycogen granules and with an irregular shaped apical nucleus. From E38 to hatching, the regional differences in cell type proportions appear and are maintained in the adult. Columnar cells display long processes terminating subapically; some of these cells apparently mature into radial glia (which in lizard is present also in adult), others into tanycyte-like cell exhibiting microtubule rich processes. Possibly the processes of the first correspond to the GFAP rich processes while those of the latter correspond to the Glutamine synthetase rich processes.

A comparison with rat ependymal development was also carried out.

Studies are now in progress aiming at identifying the loci where neural cell multiply after CNS lesions in the adult lizard.

613.5

HISTOGENESIS OF FERRET SOMATOSENSORY CORTEX. S.C. Nector*, N. Scholnicoff, S. Pedersen, and S.L. Juliano. Departments of Neuroscience and Anatomy & Cell Biology, USUHS, Bethesda, MD.

Although it has long been established that neocortical development occurs in a rostral to caudal and medial to lateral gradient, the precise time course of events has not been elaborated in many species or regions of cortex. To this end we wished to establish when cells destined for specific layers of ferret somatosensory cortex are generated in relation to those of the well-studied visual cortex and their association to intrinsic cortical connectivity. Timed-pregnant ferrets were injected IV with bromodeoxyuridine (BrDU) on embryonic days (E) from E22-38 and on postnatal days (PND) 1 and 4. Cortical tissue was collected from ferret kits after various survival times, ranging from PND 1-60. As expected, a progressive sequence of inside-out maturation occurred in the genesis of cortical layers. Neurons labeled on E22-26 did not migrate into the cortex and were found in the subplate up to PND 14. Injections of BrDU on E33-35 labeled neurons found in layer 4 in the mature cortex; and injections on E38 labeled neurons found in layer 2. Several features of the developing somatosensory cortex differed from previous observations in the visual system. We observed very few neurons distinctly populating the cortex generated postnatally. Although occasional BrDU positive cells were seen in the cortex after injections on PNDs 1 and 4, they were highly dispersed and not definitively localized in any particular layer. In addition, by PND 1, neurons residing in all cortical layers, including layer 2, were observed in the cortical plate. Therefore, although experiments with fluorescent tracers reveal that many neurons are still migrating to the somatosensory cortex during the first week after birth, elements of the laminar scaffolding are in place at PND 1. These findings confirm the notion of a rostral to caudal gradient in neocortical development and suggest that elements of ferret somatosensory cortex development may occur up to a week prior to visual cortical development.

613.7

EFFECTS OF INTERLEUKINS ON NEURONAL AND OLIGODENDROGLIAL LINEAGES IN EGF-GENERATED CNS STEM CELL CULTURES.

R.E. Gross*, M.F. Mehler, L. Santschi, and J.A. Kessler. Depts. of Neurosurgery, Neuroscience & Neurology, Albert Einstein College of Medicine, Bronx, N.Y. 10461

Recent experiments have begun to demonstrate that various neurotrophic cytokines play an important role in survival and differentiation of neural stem and progenitor cells along the three neural cell lineages. We have previously reported that certain interleukins (IL) affect neuronal maturation of immortalized neural stem cells, and in other abstracts implicate a role for cytokines in neural development *in vivo*. Here we extend our studies of the role of ILs in neural development by investigating their effects on non-immortalized EGF-generated neural stem cells.

EGF-dependent neural stem cells were generated from embryonic or adult rodent brains as described by Reynolds & Weiss (1992). Neurospheres were dissociated, washed twice, and cultured on poly-ornithine coated coverslips in serum-free medium (SFM) with TGF α in the presence of various ILs, followed by immunocytochemistry for markers of the three neural cell lineages. Control cultures contained a large number of map1b-positive neurons and a relatively small number of myelin basic protein (MBP) - positive, highly abortive oligodendrocytes. Various ILs (including IL4, IL7, IL9, IL10 & IL12) and G-CSF had a marked stimulatory effect on both the number and length of neuritic branches of a subset of map1b-positive neurons without affecting the total number of neurons generated. Thus, certain neurotrophic cytokines may affect maturation of a set of neurons without influencing survival or proliferation. In contrast, cultures grown in the presence of these cytokines contained four- to five-fold greater numbers of MBP-positive oligodendrocytes, suggesting a role for interleukins signalling through non-gp130 receptors in proliferation, survival or differentiation of cells of the oligodendroglial lineage.

613.9

LINEAGE OF SUBPLATE (SP) AND CORTICAL PLATE NEURONS IN FERRET STUDIED WITH AN ALKALINE PHOSPHATASE (AP) RETROVIRAL LIBRARY. C. Reid^{1,2,3} and C. Walsh^{1,2,3}. ¹Neurology Department, Beth Israel Hospital, and Programs in ²Neuroscience and ³Biological/Biomedical Sciences, Harvard Medical School, Boston, MA 02115.

Since the ferret allows analysis of early cortical development, we produced an amphotropic retroviral library that encodes AP and contains up to thousands of DNA tags for cell lineage analysis. Cortical cells were labeled by injections at E27-P0, and processed for AP histochemistry and clonal analysis by polymerase chain reaction (PCR) (Walsh & Cepko, Science 255:434, 1992) at P17. As expected, early injections (E27 and E29) labeled deep layer cells, including subplate neurons, in addition to more superficial cells: 27% of neurons labeled at E29 occupied SP, layer VI, and layer V, versus 22% at E33, 9.5% at E35, and 0% at P0. Consistent with the inside-out sequence of neurogenesis, progressively later injections labeled neurons increasingly restricted to layers II and III: 43% after injections at E29 versus 61% at E33, 81% at E35 and 100% at P0. After correction for differences in cell density (Beaulieu and Collonnier, J. Comp. Neur. 279:228, 1989), E29 injections labeled remarkably similar proportions of cells in layers II-V, suggesting that retroviruses label normal cortical progenitor cells in an unbiased manner.

Since many subplate neurons are postmitotic by E27 and E29, they were labeled less frequently than cortical plate cells. Subplate neurons occurred predominantly as scattered cells, usually without associated labeling in the overlying cerebral cortex. Labeled neurons located in the cortical plate occurred as scattered cells or in small clusters after injections at E29, E33, E35, or P0.

Preliminary PCR analysis, limited to cortical plate neurons, indicates that sibling cells, both neurons and glia, occur in loose clusters (≤ 1 mm apart), or can be dispersed over large distances in both the medial-lateral and anterior-posterior axes. Thus, patterns of neuronal cell lineage for ferret cortical plate cells resemble patterns seen in rodents and are consistent with multiple modes of cell migration observed *in vitro* (O'Rourke et al, Science 258:299, 1992; Fishell et al, Nature 362:636, 1993).

613.6

LINEAGE-SPECIFIC REGULATION OF NEUROGENESIS: PACAP INHIBITS PROLIFERATION AND PROMOTES DIFFERENTIATION OF CEREBRAL CORTICAL PRECURSORS. N. Lu* and E. DiCicco-Bloom. Dept. of Neurosci. & Cell Biol., UMDNJ/Robert Wood Johnson Med. Sch., Piscataway, NJ 08854

Neurogenetic regulation has been characterized in several distinct lineages, including cerebellar granule and sympathetic precursors. In contrast, mechanisms governing the complex cerebral cortex, potentially composed of multiple neuronal lineages, remain undefined. Do common signals regulate cortical precursors? Pituitary Adenylate Cyclase Activating Peptide (PACAP), the newest member of the VIP family, was previously found to stimulate both neuroblast mitosis and survival. The expression of PACAP and receptors in embryonic cortex led us to define the peptide's role in corticogenesis.

Embryonic day 13.5 rat cerebral cortical precursors, cultured in serum-free medium, exhibited 90% and 99% MAP-2 immunoreactivity at days 1 and 2 respectively, suggesting a virtually pure neuroblast population. In contrast to other lineages, PACAP (10⁻⁹) inhibited cortical [³H]thymidine incorporation 50%, reflecting a similar decrease in the percentage of neuroblasts entering the mitotic cycle. Inhibition was observed even in the presence of mitogenic stimulation elicited by serum, insulin, EGF and FGF. Other VIP family members, including PHI, secretin and VIP, were without effects at equimolar concentration, indicating that PACAP activity is highly specific. However, since VIP was inhibitory at higher doses (10⁻⁶), the peptides apparently act via PACAP type I receptors.

To begin defining mechanisms, we examined second messenger pathways: cAMP agonists, including forskolin, DbcAMP and IBMX, reproduced PACAP's effects. Further, the peptide elicited a 5-fold increase in cAMP content.

In addition to inhibiting mitosis, the peptide increased trkB immunoreactivity by 30% and neurite outgrowth by 80%, suggesting that PACAP blockade of proliferation induced neuronal differentiation.

In sum, while the PACAP ligand-receptor-cAMP pathway regulates multiple precursors, effects are lineage-specific. Endogenous PACAP may play a critical role in regulating progress of cortical neuroblasts through the ontogenetic sequence.

CELL LINEAGE AND CELL PHENOTYPE IN RAT CEREBRAL CORTEX STUDIED WITH AN ALKALINE PHOSPHATASE (AP) RETROVIRAL LIBRARY. C. Walsh^{1,2,3}, C.L. Cepko^{2,3}, C. Reid^{1,2}, and L. Liang¹.

¹Neurology Department, Beth Israel Hospital, and Programs in ²Neuroscience and ³Biological/Biomedical Sciences, Harvard Medical School, Boston, MA 02115.

We have analyzed cell production in rat cortex with a library containing up to thousands of retroviruses distinguishable by polymerase chain reaction (PCR), and encoding AP (Fields-Berry et al, PNAS 89:693, 1992). The library was injected at E14-19, followed by histological and clonal analysis by PCR at P15 (Walsh & Cepko, Science 255:434, 1992). AP histochemistry revealed normal neuronal morphology, allowing identification of >90% of labeled cells. Earlier injections labeled progressively more neurons in deep cortical layers, consistent with the "inside-out" sequence of neurogenesis. Thus, histological analysis suggests that AP-retroviral labeling is not obviously biased, and appears to sample normal cerebral cortical progenitors.

For clonal analysis, cells from tissue sections were PCR-amplified, successful for ~45% of AP-positive cells. E15-labeled clones contained single cells (28%), clustered (≤ 1 mm) cells of similar morphology (25%) (cp. Luskin et al, J. Neurosci. 13:1730, 1993), or were widely dispersed (46%) (2.1-6.7 mm, mean=3.8mm). Widespread clones contained mostly neurons of diverse morphology and laminar location and included >75% of E15-labeled cortical neurons. Widespread clones contained 2-4 'subunits' of 1-5 neurons each, spaced at apparent intervals of 2-3 mm, with each subunit morphologically indistinguishable from a clustered clone. Neurons within subunits showed similar morphology and laminar location; distinct subunits in the same clone usually differed in laminar location, suggesting sequential formation. E17-labeled clones contained fewer neurons (mean=1.6, versus 2.2 at E15); widespread E17 clones so far contain no more than two subunits. Our data suggest that clustered clones are produced by stationary progenitors; however, progenitors of clustered clones may be produced by migratory, multipotential cells.

613.10

PROMINENT EXPRESSION OF A TUMOR SUPPRESSOR GENE, APC IN GLIAL CELLS. Ratan V. Bhat*, Karen J. Axt and Jay M. Baraban. Department of Neuroscience, Johns Hopkins University School of Medicine, Baltimore, MD 21205.

Tumor suppressor genes act as brakes to control excessive cellular proliferation and therefore could play a key role during development. *Adenomatous polyposis coli* (APC) is a tumor suppressor gene that is mutated in a familial type of colon cancer. In previous studies, we found high levels of APC mRNA during CNS development. Immunoblots of brain extracts confirmed the presence of APC protein (~310 kD). To identify the cell types expressing APC protein during development, we performed immunohistochemical studies on brain sections from E19-P30 rats. Prominent APC staining was present in oligodendrocytes as early as E19 in the brain stem. By P5, immunostaining was observed in oligodendrocytes of cerebellar white matter tracts. APC immunostaining was seen in interfascicular oligodendrocytes in white matter tracts throughout the brain from the 2nd postnatal week into adulthood. APC protein was detected in the cortex in S100 positive astrocytes starting at P7-P10. In the cerebellum, APC staining was seen in the Bergmann astroglial cells and in presumed satellite oligodendrocytes in the granule cell layer. The high levels of APC expression in astrocytes and oligodendrocytes indicate that this tumor suppressor gene may have a role in controlling glial proliferation.

A BRAIN-SPECIFIC ACTIVATOR FOR CYCLIN-DEPENDENT KINASE 5. L.-H. Tsai* and E. Harlow. Molecular Oncology, MGH Cancer Center, Charlestown, MA 02129.

Cyclin-dependent kinase 5 (cdk5) shares about 60% identity at the amino acid level with both cdc2 and cdk2, kinases that play key roles in cell cycle progression. Despite the fact that cdk5 is similar in structure to cdc2 and cdk2, it displays properties distinct from those kinases. First, cdk5 is expressed in a tissue-specific manner, being highest in adult nervous system and low or undetectable in other tissues. Second, we have detected kinase activity of cdk5 only in post-mitotic cells of neuronal origin in brain. Finally, cdk5 does not form an active kinase complex with the conventional cyclins. We observed a 35 kd protein that was associated with cdk5 from primary neuron cultures containing active cdk5 kinase activity. A cDNA for p35 has recently been cloned. Expression of p35 in human cultured cell lines activated both the endogenously as well as exogenously overexpressed cdk5. Cotransfection of p35 with a dominant negative version of cdk5 in these cells abolished the ability of p35 to activate cdk5. Cdk5 appears to be the only member of the cdk family proteins that is readily activated by p35. Therefore, p35 serves as a specific activator for cdk5. Surprisingly, p35 displays no sequence homology to any existing cyclin molecules. Northern analyses indicated that p35 is only expressed in brain. Among the central nervous system p35 is most highly expressed in the forebrain including cerebral cortex and thalamus, and it is not detectable in the hind brain or spinal cord.

TREATMENT WITH bFGF INCREASES THE EXPRESSION OF *Otx2*, *Dlx2*, AND *Dlx5* HOMEODOMAIN GENES IN PRIMARY CULTURES OF CELLS FROM EMBRYONIC DAY 13.5 RAT TELENCEPHALON. L. Robel, M. Ding, A. J. James, A. Simeone, J. F. Leckman* and E. M. Vaccarino. Child Study Center, Yale University School of Medicine, New Haven, CT 06520 USA.

The characterization of the domains of expression of homeobox genes specifically expressed in the mammalian forebrain (*Dlx1*, *Dlx2*, *Dlx5*, *Dlx6*, *Emx1*, *Emx2*, *Otx1*, *Otx2*) led to the hypothesis of its early regionalization in neuromeres. So far, the role of these homeobox genes in cell specification has not been clearly demonstrated. To address this question, we studied the effect of basic fibroblast growth factor (bFGF) on the expression of these homeobox genes in cultures of cells obtained from embryonic day 13.5 rat telencephalon. In this *in vitro* preparation, stem cells multiply and then differentiate into aspartate-, glutamate- and GABA-containing neurons, as well as in glial cells. We have previously shown that bFGF treatment leads to a 3-fold increase in the number of glutamate-containing neurons. Using an RNase protection assay, we observed an increase in the expression of *Otx2*, *Dlx2* and *Dlx5* at 3 and 5 days *in vitro*, corresponding with active neuronal differentiation in the cultures. There was no such increase at day 12, after completion of the neurogenesis. *Otx2* is expressed in the ventricular zone from E8.5, whereas the *Dlx* genes are expressed in the subventricular and mantle zones within neurons (Ding et al., Neurosci. Abstr. 1994). These results suggest that *Otx* genes mediate the effects of bFGF on neuronal differentiation through a concerted expression of downstream genes, including *Dlx2* and *Dlx5*.

ANALYSIS OF CIS-ELEMENTS IN THE α -TUBULIN PROMOTER. D. Rogers*, N. Laferriere*, A. Gloster, D. Brown*, F. Miller. Centre For Neuronal Survival, Montreal Neurological Institute, McGill University, Montreal, Canada. # Dept. Biology, University of Ottawa, Ottawa, Canada.

α -Tubulin is a neuronal specific isotype of α -tubulin which is expressed as a function of neuronal growth. We have previously utilized 1.1 kb of the 5' upstream promoter region to drive the expression of a lacZ reporter gene in transgenic mice. The pattern of expression was found to mimic the spatiotemporal expression pattern of the endogenous gene. Furthermore, we have previously demonstrated that this promoter region is capable of driving lacZ expression in P19 embryonal carcinoma cells which are induced to adopt a neuronal fate using retinoic acid. To characterize the relevant cis-elements involved in the developmental expression of α -tubulin, deletion mutants of the α -tubulin promoter were generated. Mutant promoters were assayed for their ability to drive lacZ expression in P19 embryonal carcinoma cells which were induced to adopt a neuronal fate using retinoic acid. The effects of deletion of specific cis-elements on expression of the reporter gene in P19 cells was determined.

CELLULAR DISTRIBUTION OF *Dlx2* mRNA IN THE DEVELOPING BASAL GANGLIA. M. Ding, L. Robel, A. J. James, and E. M. Vaccarino*. Child Study Center, Yale University School of Medicine, PO Box 3333, New Haven, CT 06520.

The acquisition of a morphological and functional identity of different areas of the nervous system may be regulated by specific combinations of transcription factors. In the developing mammalian forebrain, the expression of homeobox genes of the *Dlx* family is restricted to the basal telencephalon, the anlage of the basal ganglia. However, the exact cellular location of these genes is presently not known. Cells obtained from the ventricular layer of the basal telencephalon at the embryonic day 13.5 and grown in primary culture express *Dlx1*, *Dlx2*, *Dlx5* and *Dlx6*, as they do *in vivo*. In contrast, primary cultures of cells from the dorsal telencephalon do not express the *Dlx* genes. The time course of expression of *Dlx2*, *Dlx5* and *Dlx6* mRNAs peaks at 3-5 days *in vitro* and is protracted during the entire period of neuronal differentiation and maturation. *Dlx2* mRNA, identified by *in situ* hybridization, is localized in young neurons, immunoreactive for the microtubule-associated protein MAP1B, and, to a lesser extent, in more mature neurons, which contain MAP2 immunostaining. Nestin-positive stem cells and GFAP-containing astrocytes never expressed *Dlx2* mRNA. Blocking *Dlx2* gene expression by means of antisense oligonucleotides resulted in lower numbers of MAP1B- and MAP2-immunoreactive cells and in a dramatic change in the morphological characteristics of the cultures. Nestin and GFAP immunoreactivity were unchanged by the antisense *Dlx2* treatment. These data suggest that the expression of genes of the *Dlx* family may control important characteristics of the neuronal phenotype in the developing basal ganglia.

613.14

THE MOLECULAR GENETICS OF NEURONAL GROWTH: CHARACTERIZATION OF THE α -TUBULIN PROMOTER IN DEVELOPING TRANSGENIC MICE. A. Gloster*, A. Speelman, J. Toma, E. Chan, and F. D. Miller. Centre for Neuronal Survival, Montreal Neurological Institute, McGill University, Montreal, Canada.

The α -tubulin gene is regulated as a function of neuronal growth in both developing and mature mammalian neurons. We have generated transgenic mice carrying a fusion gene comprised of 1,100 nucleotides of the upstream, putative α -tubulin promoter region linked to a nuclear β -galactosidase reporter gene. Developmentally, expression of the transgene appears early during embryogenesis and is coincident with neurogenesis. Expression of the transgene is limited to the nervous system, and is first seen in the spinal cord, brain, trigeminal ganglia, facio-acoustic ganglia, and in the heart at E9.5, and in the retina at E12.0. This expression remains high during neuronal morphogenesis, at birth, and is subsequently downregulated following neural maturation, as indicated both by X-gal staining and by Western blot analysis. However, in the adult the olfactory epithelium, a region of ongoing neurogenesis, expression remains elevated. Thus, sequences exist within this promoter region which are responsible for coupling gene expression to neurogenesis and neuronal growth exist during development. We are now deleting regions within this 1.1 Kb fragment of the α -tubulin promoter, to see which regions are responsible for conferring tissue and developmental specificity upon the expression of the transgene.

BIRTHDATES AND SURVIVAL AFTER AXOTOMY OF NEUROCHEMICALLY DEFINED SUBSETS OF TRIGEMINAL GANGLION CELLS. F. A. White*, G. J. Macdonald, and R. W. Rhoades. Dept. of Anatomy, Medical College of Ohio, Toledo OH 43699.

Trigeminal (V) ganglion cells with different neurochemical phenotypes or different birthdates are affected differently by neonatal axonal transection. This study attempted to determine whether sensory ganglion cell birthdate and neurochemical phenotype were correlated and if these two variables could be related to responses to neonatal axonal transection. Immunocytochemistry, histochemistry, and [3 H]-thymidine labelling were used to determine the birthdates of V ganglion cells recognized by antibodies directed against neurofilament protein (NF), calcitonin gene-related peptide (CGRP), substance P (SP), and those that bound the lectin *Bandiera simplicifolia*-I (BS-I). The percentages (normalized to equal 100%) of NF-positive ganglion cells born on E-9.5, 10.5, 11.5, 12.5, 13.5, and 14.5 were 0.9%, 27.3%, 30.3%, 37.0%, 4.3%, and 0.3%, respectively. The respective values for CGRP-positive ganglion cells were 0%, 0.2%, 2.3%, 3.9%, 51.5%, and 42.1%. Those for SP-positive neurons were 0%, 0%, 0%, 19.6%, 65.0%, and 15.4%, and those for BS-I-positive cells were 0%, 2.4%, 10.9%, 7.2%, 70.9%, and 8.6%. NF- and BS-I-positive ganglion cells are significantly more likely to be lost after neonatal axotomy and SP-positive cells are more likely to remain. The percentage of CGRP-positive cells in the V ganglion was not altered by neonatal ION transection. These findings do not indicate a strong relationship between cell birthdate, phenotype, and survival after neonatal axonal damage.

ABLATION OF CEREBELLAR ASTROCYTES IN POSTNATAL TRANSGENIC MICE Catherine L. Delaney, Michael Brenner, and Albee Messing*. Neuroscience Training Program and Dept. of Pathobiological Sciences, Univ. of Wisconsin-Madison, Madison, Wisconsin 53706 Stroke Branch, NINDS, NIH, Bethesda, Maryland 20892

To study the role of astrocytes during CNS development, a transgene was designed to enable their ablation at selectable times. The transgene consists of the coding region for the herpes simplex virus thymidine kinase (hsv-tk) under the control of the human glial fibrillary acidic protein gene promoter. The hsv-tk is innocuous, but converts the antihelptic agent ganciclovir to a toxic product that interferes with DNA replication in proliferating cells. Treatment of transgenic mice during the first postnatal week with ganciclovir, with evaluation at 19d postnatal, revealed marked behavioral effects. The animals were ataxic, clasped their feet when suspended, and had difficulty standing upright to obtain food. Histological examination revealed disrupted astrocyte development, particularly in the cerebellum, with marked secondary effects on other cell types. Cerebellar defects included an overall reduction in size and disruption of the normally well defined cellular layers. The radial glia were disordered, and there was an apparent deficient myelination. The molecular and granule cell layers were greatly reduced in size. There was marked depletion of granule cells, and Purkinje cells were ectopically distributed in the molecular layer. These effects were more severe in animals treated 1d postnatal versus treatment at 5d. These results suggest a critical role for astrocytes in cerebellar development.

THE *meander tail* GENE HAS MULTIPLE EFFECTS ON CEREBELLAR GRANULE CELL DEVELOPMENT AND SURVIVAL. K.M. Hamre* and D. Goldowitz. Dept. of Anat. and Neurobiol., Univ. of Tennessee Memphis, Memphis, TN 38163.

The murine genetic mutation *meander tail* (gene symbol *mea*) results in the near total ablation of granule cells in the anterior lobe of the cerebellum. How the *mea* gene results in granule cell reduction remains unknown. Two approaches were used to determine whether the action of the *mea* gene is specific to anterior lobe granule cells. First, we find by estimating granule cell number in the posterior lobe (lobules VIII-X), a small (less than 20%) but statistically significant reduction in the number of granule cells in adult homozygous *mea* mice compared to heterozygous controls. Second, using two types of intraspecies murine chimeras (homozygous *mea* embryos with BALB/C or globin transgenic [GT] embryos) we find a complex effect of the *mea* gene on cerebellar granule cell survival. In *mea*→BALB/C chimeras, cells from *meander tail* embryos are labeled immunocytochemically with a strain specific nuclear antigen (Mullen and Chichocki, 1988). In *mea*→GT chimeras, GT cells are labeled using in situ hybridization with a probe for the globin transgene construct (Lo et al., 1987). The percentage of *meander tail* cells that contribute to the CNS were estimated in the cerebellar granule cell layer in anterior and posterior lobes as well as in hippocampal and olfactory bulb granule cells, and in cerebellar molecular layer interneurons. Cerebellar granule cells that are genotypically *meander tail* are found in both the anterior and posterior lobes. Additionally, the percentage of cells that are genotypically *meander tail* is equivalent in both anterior and posterior lobes. However, the percentage of *mea* cerebellar granule cells is markedly less than the percentage of *mea* cells found in other neuronal populations including the cerebellar molecular layer interneurons. These results suggest that while the *mea* gene directly affects overall granule cell survival, there are extrinsic factors that permit the successful rescue of genotypically *mea* granule cells in the anterior lobe. POSTNATAL EXPOSURE TO METHYLAZOXYMETHANOL PRODUCES HYPOPLASIA AND REACTIVE GLIOSIS IN THE CEREBELLUM OF DEVELOPING RATS. S. Barone, Jr.*¹, J.H. Freeman Jr.² and M.E. Stanton^{2,3} ¹ManTech Environmental Technology, RTP, NC 27709; ²Dept. Psychology, UNC, Chapel Hill, NC, 27599-3270; ³Neurotoxicology Div., US EPA, RTP, NC 27711.

In rats, there is dramatic cerebellar growth during the first three postnatal weeks (Altman, 1969, *J. Comp. Neurol.*, 136, 269-294). Exposure to antimitotic agents during this period produces neuronal loss and disruption of cellular structure within the cerebellum that varies depending on the day of exposure and dose (Altman & Anderson, 1973, *J. Comp. Neurol.*, 149, 123-152). In the present study, we experimentally manipulated cerebellar maturation by exposing neonatal rat pups to the antimitotic agent methylazoxymethanol (MAM) during the period of cerebellar cortical neurogenesis. Pups were given either saline or MAM (20 mg/kg) on PND4 and 7, and sacrificed on days 10, 19, 22, 26, or 33. The neuroanatomical effects of this MAM treatment were examined in sections stained for glial fibrillary acidic protein (GFAP) immunoreactivity and Nissl. Exposure to MAM greatly reduced cerebellar volume, disrupted cellular organization, and induced reactive gliosis. Cell loss within the cerebellar cortex was apparent at all ages assessed. The monolayer structure of the Purkinje cell layer was disrupted in many of the cerebellar lobules. There was also a dramatic reduction in the volume of the granule cell and molecular layers. Ectopic granule cells were seen in the molecular layer of MAM-treated animals. GFAP immunoreactivity increased as a function of age in both dosing groups. At PND26 and 33 there was an increase in GFAP immunoreactivity in the cerebellar white matter in MAM-treated animals. The dosing strategy used in this experiment produced effects that were primarily restricted to the cerebellar cortex. There was little evidence of cell loss or reactive gliosis in other postnatally developing structures such as the hippocampus or cerebellar efferents.

EPIDERMAL GROWTH FACTOR (EGF), TRANSFORMING GROWTH FACTOR- α (TGF- α) AND BASIC FIBROBLAST GROWTH FACTOR (bFGF) DIFFERENTIALLY INFLUENCE NEURAL PRECURSOR CELLS OF THE MOUSE EMBRYONIC MESENCEPHALON. J. Santa-Clalla and L. Covarrubias*. Departamento de Biología Molecular, Instituto de Biotecnología, UNAM, Apdo. Postal 510-3, Cuernavaca, Morelos 62271, México.

The molecules generally known as growth factors are key elements in the process of neural cell differentiation. In this report, we examined the effects of classical mitogens on neural precursor cells, by culturing mouse cells of the embryonic (13.5 days post coitum) mesencephalon and treating them with EGF, TGF- α , bFGF, Nerve Growth Factor (NGF) and Transforming Growth Factor- β (TGF- β). Our initial results show that EGF, TGF- α or bFGF but not NGF nor TGF- β , induced general proliferation of the cultured cells, followed by the formation of colonies. Combinations between these three growth factors suggest that an overlapping cell population is target of EGF, TGF- α or bFGF in promoting colony formation. It is noteworthy, that the number of colonies increased significantly when EGF, but not TGF- α , was used in combination with bFGF. Furthermore, a population that respond only to EGF+bFGF was detected in the dorsal mesencephalon. The colony forming activity of bFGF depended on insulin, but their cooperativity was indirect since we could not observe colony regeneration even in the presence of insulin. Cells obtained from our colonies displayed neuronal and glial morphology and expressed markers of both neurons and astrocytes; nestin, a marker of neural precursor cells, was also expressed in the majority of the colonies. Growth factors also influenced neuronal maturation; the highest neurite outgrowth was obtained from cells derived from bFGF-induced colonies cultured in the presence of EGF+bFGF. These data indicate the existence of neural precursor cells in the embryonic mesencephalon that respond to growth factors.

MODULATION OF G PROTEIN ACTIVITY AND INTRACELLULAR CALCIUM AFFECTS THE MIGRATORY BEHAVIOR OF EMBRYONIC NEURONS. A.M. Horgan* and P.F. Copenhaver. Cell Biol. & Anat. L215, Oregon Health Sciences U., Portland, OR 97201.

During embryonic development of the moth, *Manduca sexta*, a population of approximately 300 neurons (EP cells) in the enteric nervous system migrate and extend processes along eight specific muscle pathways to innervate the gut. This motile sequence is precisely regulated such that these neurons begin their migration at 55% of development (1% = 1 hour). The neurons migrate for ~5 hours, travelling up to 250 μ m. Process outgrowth then continues after neuronal migration is complete, lasting until ~80% of development. The accessibility of the EP cells and their muscle pathways during development can be used to investigate the regulatory processes that are involved in the control of neuronal motility. In previous work, we showed that one of the heterotrimeric G proteins (Go) is first expressed by the EP cells around the onset of migration. Using extracellular bath applications in semi-intact embryos and intracellular injections of individual neurons, we have examined the effects of compounds known to alter G protein activity on neuronal motility. Injections of stimulatory agents (including GTP γ S and mastoparan) caused a reduction in both neuronal migration and process outgrowth, whereas the inhibitory compound pertussis toxin resulted in exuberant filopodial extension in a number of injected cells. Transient exposure to compounds that increase intracellular Ca (including ionomycin and thapsigargin) also caused a substantial inhibition of migration. We are currently exploring the potential interactions between multiple intracellular signalling pathways in the regulation of neuronal motility during embryogenesis. Supported by NSF BNS9010538.

MIGRATION OF LHRH NEURONS IN OLFACTORY EXPLANTS: EFFECTS OF SERUM-FREE MEDIA, TETRODOTOXIN AND DEPOLARIZATION. S. M. Fueshko* and S. Wray. Lab of Neurochemistry, NINDS, NIH, Bethesda, MD 20892.

We have previously shown that embryonic mouse olfactory explants maintain large numbers of LHRH neurons which emerge and migrate away from the olfactory pit in directional tracks along a subset of peripherin positive fibers. To continue our study of the mechanisms guiding the neurophilic migration of LHRH neurons, we evaluated the migratory properties of LHRH neurons cultured in serum-free media (SFM). We also examined whether spontaneous electrical and synaptic activity and/or depolarization play a role in the movement of LHRH neurons. Olfactory explants from E11.5 mouse embryos were cultured in SFM for 1-7 days. Immunohistochemical staining indicated that compared to explants grown in the presence of serum, SFM had no significant effect on LHRH cell numbers (25-50% of the total LHRH population was typically maintained) or on LHRH cell migration as determined by emergence, directionality and distance that cells migrated away from the olfactory pits. Inhibition of spontaneous electrical and synaptic activity by continuous incubation with tetrodotoxin (10⁻⁶M) from day 2-7 in culture had no significant effect on either LHRH cell number or the ability of cells to migrate. Similarly, depolarization by incubation with potassium (20 mM) had no quantitative effect on LHRH cell migration. Therefore, we propose that interactions at the cell surface which are independent of spontaneous electrical activity and/or depolarization are instrumental in directing LHRH cell migration. Studies are now in progress to determine whether electrical activity and/or depolarization influences secretion from embryonic LHRH cells.

614.3

GABA AND NGF INDUCE CHEMOTAXIS IN CORTICAL NEUROBLASTS. T.N. Behar*, H.T. Tran, and J.L. Barker. Lab. of Neurophysiology, NINDS, NIH, Bethesda, Md. 20892

Chemotactic and chemokinetic migration of acutely dissociated embryonic cortical cells derived from 14 to 20 day-old rat embryos (E12-E15) was analyzed *in vitro* using a chemotaxis chamber. Embryonic cells migrated toward γ -amino butyric acid (GABA) beginning at E15, indicating cells generated in the ventricular zone migrate towards GABA. In contrast, NGF-induced migration was not detected until E17, suggesting cells generated in the subventricular zone respond to NGF. A modified checker-board analysis revealed that micromolar GABA exerted a chemokinetic effect on cells (increased random motility), while pM NGF and low GABA concentrations (fM) were predominantly chemotactic, inducing cells to migrate along a chemical gradient. Immunolabeling showed that the majority (>95%) of migrating cells expressed neurofilament protein (NF) and hence, were postmitotic neurons. The chemotropic effects of GABA were mimicked by muscimol and R-baclofen, suggesting GABA mediates motility via both GABA_A and GABA_B receptor proteins. These results demonstrate that both GABA and NGF are capable of directing the migration of newly generated neurons during early cortical development.

614.5

NEURONAL MIGRATION FROM THE EMBRYONIC NASAL CAVITY TO THE ROSTRAL FOREBRAIN.

S.A. Tobet*, T.W. Chickering, I. Kaddis, J.E. Crandall, and G.A. Schwarting, Program in Neuroscience, The Shriver Center, Waltham, MA 02254 and Harvard Med. Sch., Boston, MA 02115.

Following their birth in olfactory placode, gonadotropin releasing hormone (GnRH) containing neurons migrate across the developing cribriform plate and form a dispersed population in the mammalian basal forebrain. To study the migration of these neurons we are utilizing a paradigm to visualize cell migration *in vitro*, in tissue slices that maintain the structure and contact of the nasal cavity with the forebrain. On day 15 and 16 of gestation rat embryos were dissected, and the heads embedded in agarose and cut by Vibratome into 300 micron slices. Individual cells were randomly labelled by briefly immersing the slices in the carbocyanine dye, DiI. Cells were selected for video microscopic analysis based on their apparent "neuronal" morphologies and location within the known pathway for GnRH cell migration (e.g., Tobet et al., Dev. Biol. (1993) 155:471). The patterns and rates of cell movements were analyzed throughout the rostral-caudal extent of the GnRH cell migration pathway. Characteristics of cell movements differed depending upon location along the pathway. Cell movements in the nasal cavity involved fewer turns than in the basal forebrain. These studies raise the possibility that there are constraints on the ability of cells to move in selective portions of the migration pathway from the nasal cavity to the basal hypothalamus. Supported by PHS grants HD05515, MR Core Grant HD-04147, and the DMR-MA.

CALCIUM ION INFLUXES THROUGH THE PLASMA MEMBRANE TRIGGER SPONTANEOUS INTRACELLULAR CALCIUM OSCILLATION IN MIGRATING NEURONS. H. Komuro* and P. Rakic, Section of Neurobiology, Yale University School of Medicine, New Haven, CT 06510

Recently, we found that Ca^{2+} influx, regulated by a combination of voltage- and ligand-gated channels, is essential for extension of the leading process and translocation of cell soma during neuronal cell migration (Komuro & Rakic, Science 257: 806, 1992; 260: 95, 1993). Furthermore, we reported that migrating neurons exhibit transient elevation of intracellular Ca^{2+} levels (Komuro & Rakic, Soc Neurosci Abstr 19: 34, 1993). Here, we study possible cellular mechanisms underlying spontaneous intracellular Ca^{2+} oscillation in migrating neurons. Rectangular pieces (100-200 μ m) of cerebella from 3-7 day-old CD-1 mice were placed on poly-L-lysine and laminin-coated Petri dishes containing 1 ml serum-supplemented culture medium. After 2-3 day incubation, cells were bathed in serum-free, defined culture medium with 1-3 μ M Fluo-3/AM for 30-60 min at 36 °C. After rinsing and an additional 1-3 hr postincubation in defined culture medium, granule cell migration from microexplants was examined using confocal laser scanning microscopy. Changes in the rate of movement and the levels of intracellular Ca^{2+} were directly recorded in single optical sections collected at 1-60 sec intervals for up to 70 min. Migrating granule cells exhibited undulatory movement and spontaneous oscillation of intracellular Ca^{2+} levels at a frequency of 10-20 times per hour. The duration of each elevation lasted 1-2 min; the amplitude as indicated by Fluo-3 fluorescence ranged between 5-30 % of resting levels. Reduction of extracellular Ca^{2+} concentrations eliminated the spontaneous Ca^{2+} oscillation and caused cessation of cell movement. Furthermore, the addition of antagonists to either N-type Ca^{2+} channels or NMDA receptors to the culture medium reduced the amplitude of Ca^{2+} oscillations and decreased the rate of cell migration. These results suggest that spontaneous oscillation of intracellular Ca^{2+} levels may be triggered by Ca^{2+} influx through a combination of N-type Ca^{2+} channels and NMDA receptors. Furthermore, the assembly and disassembly of neuronal cytoskeletal elements associated with migration may be controlled by the periodic increase and decrease in intracellular Ca^{2+} levels. (Supported by NS22807)

ANTI-IDIOTYPIC ANTIBODIES TO GM1 PROMOTE SCHWANN CELL MIGRATION ON NORMAL AND DENERVATED SCIATIC NERVE. W.D. Matthew*, L.S. Barna and M.J. Riggott, Dept. of Neurobiology, Duke University Medical Center, Durham, NC 27710

Gangliosides are potent modulators of cell adhesion and migration. They may interact with membrane proteins that act as receptors for growth factors or extracellular matrix molecules. We have generated putative anti-idiotypic antibodies that bind the functional sites of GM1 binding proteins. These antibodies were tested for their ability to recognize Schwann cell antigens and to promote Schwann cell migration on cryostat sections of denervated or normal sciatic nerve. The antibodies recognize antigens on the cell surface of cultured primary Schwann cells and, in Western blots, these antibodies bind proteins at 66, 45 and 21 kD. Cultured primary Schwann cells treated with the antibody respond by protein tyrosine phosphorylation of proteins at 151, 134 and 107 kD. In bioassays of Schwann cell migration, the antibodies enhance migration on denervated sciatic nerve, and one antibody promotes migration on normal nerve. These results suggest that anti-idiotypic antibodies bind to cell surface receptors that are linked to protein tyrosine second messenger systems. Activation of these receptors facilitate Schwann cell migration which is crucial to peripheral nerve development and successful nerve regeneration.

THE VENTRALLY GENERATED "U-SHAPED" GROUP OF CHOLINERGIC CELLS IN EMBRYONIC RAT SPINAL CORD EXPRESS NADPH-DIAPHORASE AND MIGRATE DORSALLY *IN VIVO* AND *IN VITRO*. P.E. Phelps*, R.P. Barber, R. Wetts, and J.E. Vaughn, Division of Neurosciences, Beckman Research Institute of the City of Hope, Duarte, CA 91010.

Most neuronal migration is thought to be directed radially from the ventricular zone (VZ), but members of the "U-shaped" group of cholinergic neurons, first detected around the ventral VZ, appear to move dorsally within the spinal cord between E16-18. Some of these cells translocate relatively long distances to the dorsal horn, and others, only short distances to surround the central canal. Both dorsal horn and central canal cluster ChAT-immunoreactive cells co-express NADPH-diaphorase between E16-18, and thus either marker can label these immature neurons. As a first step in analyzing this dorsal migration experimentally, 300-400 μ m slices of E16 cervical enlargement were cultured for periods encompassing *in vivo* migration times. Preliminary data suggested that diaphorase-labeled cells of the "U-shaped" group had moved dorsally in a relatively histotypic pattern before differentiating. Thus, these *in vitro* data provide additional information that the "U-shaped" group of cells have a unique migratory pattern from the ventral VZ into the dorsal horn. Supported by NIH grant NS 18858.

Ng-CAM BLOCKADE RESULTS IN CALCIUM-SIGNALLED INHIBITION OF MIGRATION AND SURVIVAL OF NEW NEURONS IN THE ADULT AVIAN FOREBRAIN. K. Barami*, M. Nedergaard, V. Lemmon, S. Goldman, ¹Depts. of ¹Neurology and ²Neurosurgery, Cornell Univ. Med. Col. NYC, 10021, and ³Neurosciences, Case-Western Res. Sch. of Med., Cleveland, OH 44106.

The avian forebrain generates neurons throughout adulthood, from endymal/subependymal zone (SZ) precursor cells lying within the ventral surface of the lateral ventricle. New neurons migrate from the SZ along radial guide fibers, a process which permits neuronal insertion into the adult forebrain parenchyma. In the process of identifying ligands which might mediate the neuronal-radial fiber interaction in adulthood, we examined Ng-CAM/8D9 expression by new neurons in HVC, a neurogenic region of the avian neostriatum. In cryostat sections of both adult finch and canary brain, Ng-CAM/8D9 was found throughout HVC and its adjacent neostriatum, but was confined to neurites, with scant expression on neuronal cell bodies. *In vivo*, new neurons pre-labeled with ³H-thymidine expressed Ng-CAM/8D9 at all stages of their migration. In cultured explants of adult canary SZ, migrating neurons rapidly developed Ng-CAM/8D9 immunoreactivity. In contrast, the endymoglia and endymal/radial fibers upon which the neurons migrated were never found to express Ng-CAM/8D9, *in vivo* or *in vitro*. Addition of anti-8D9 Fab to these cultures yielded a dose-dependent inhibition of neuronal outgrowth from the parent explants. In addition, neurons already in the outgrowths at the time of antibody addition exhibited process retraction, cell rounding, and in some cases, late death. Migrating neurons responded to anti-8D9 with sustained increments in cytosolic calcium, as viewed by laser-activated confocal imaging of cultures pre-loaded with fluo-3. Thus, the migration of new neurons from the adult avian VZ may require their expression of Ng-CAM/8D9, and their adhesion to a heterophilic endymal/radial cell receptor. Furthermore, the viability of new neurons may be regulated, directly or indirectly, by Ng-CAM/8D9-activation dependent, calcium-mediated signaling processes.

MIGRATION OF LHRH NEURONS IN EARLY HUMAN EMBRYOS: ASSOCIATION WITH NEURAL CELL ADHESION MOLECULES. M. Schwanzel-Fukuda* and D.W. Pfaff (Rockefeller University, New York, USA); P.M.G. Bouloux (Royal Free Hospital, London, England); J.-P. Hardelin and C. Petit (Pasteur Institute, Paris, France).

Luteinizing hormone-releasing hormone (LHRH) neurons originate in the epithelium of the medial olfactory pit and migrate into the brain along a migration route formed by the vomeronasal and terminal nerves. This migration route, rich in neural cell adhesion molecule (NCAM), is formed before the LHRH neurons are first detected. In 28-31 day old embryos, NCAM-immunoreactive cells were seen in the epithelium of the medial olfactory pit and emerged to form a cellular aggregate below the rostral forebrain. Antibodies to a polysialylated form of NCAM (PSA-NCAM) showed no immunoreactivity in the nasal mesenchyme at these ages. In 41-42 day old embryos LHRH-immunoreactivity was detected in some cells among the cords of NCAM cells in the nasal mesenchyme, just outside of the epithelium of the olfactory pit. LHRH and NCAM were not co-localized. Many more LHRH cells were seen in the ganglion terminale of the terminal nerve and along the caudal margin of the cellular aggregate below the forebrain and at the basal lamina of the medial forebrain, caudal to the developing olfactory bulb. A few LHRH cells were seen in the medial basal forebrain and NCAM was present in all parts of the migration route. The PSA-NCAM, in association with LHRH cells, was seen in fascicles in the nasal mesenchyme, in the ganglion terminale, along the caudal margin of the cellular aggregate but not in the cellular aggregate below the rostral forebrain.

MIGRATION OF SPINAL CELLS INTO THE DEVELOPING MENINGES. K. Sharma*, Z. Korade and E. Frank. Department of Neurobiology, University of Pittsburgh School of Medicine. Pittsburgh, PA 15261.

Neuroepithelial cells continue to migrate from the spinal cord into the periphery after neural crest emigration is complete. Cells emigrating at st 25 differentiate into dorsal root ganglion cells and melanocytes. Do spinal cells continue to migrate away from the cord at still later stages? If so, what is the developmental fate of these cells?

Migration of neuroepithelial cells in the spinal cord was studied in st 29-30 chicken embryos. Cells were labeled with DiI injected into the central canal of cultured spinal segments. Labeled cells left the spinal cord through the dorsal and ventral spinal boundary, adjacent to the roof plate and through the floor plate, and migrated into the meningeal anlage. To determine which cells in the spinal cord were migrating, we made small injections of fluorescent dextran into the floor plate of st 29 cultured spinal segments. After 12 hours, labeled cells had migrated into the meninges. Further evidence of the fate of these cells was obtained from chimeric embryos in which quail spinal cord was transplanted into chick hosts at stage 25-26. By st 31 to P0, quail cells were present in pia, arachnoid and dura. These cells were not seen in embryos in which neuroepithelium was labeled with DiI at stage 25-27 and embryos allowed to develop for only 24 hr, suggesting that emigration of meningeal cells occurs after st 27.

These results suggest that in avian embryos, spinal cord cells emigrate through the roof plate and the floor plate and contribute to the anlage of the developing pia, arachnoid and dura surrounding the spinal cord. Supported by the NIH.

PHENOTYPE PLASTICITY AND IMMUNOCYTOCHEMICAL EVIDENCE FOR CHAT AND D β H CO-LOCALIZATION IN FETAL PIG SUPERIOR CERVICAL GANGLIA CELLS. P. Partoens*, J.M. Wang*, N. Fraeyman*, J.M. Godfraind* and W.P. De Potter¹. ¹Lab. neuropharmacol., Univ. Antwerp (UIA), Antwerp, ²Heymans Inst. Pharmacol., Ghent and ³Fac. Méd., UCL, Woluwé, Belgium

The early expression of the cholinergic phenotype in sympathetic neurons appears to be species dependent. Moreover a dual phenotype status during the noradrenergic/cholinergic transition in rodent has been electrophysiologically evaluated and recent immunohistochemical evidence indicates co-expression of tyrosine-hydroxylase and choline-acetyltransferase (CHAT) in avian sympathetic neurons. We investigated dissociated neurons from the superior cervical ganglia (SCG) of fetal piglets for the presence of dopamine- β -hydroxylase (D β H) and CHAT using immunocytochemical methods, in control conditions, continuous stimulation with high K⁺ or in co-culture with splenocytes. Four types of cells were distinguished: negative cells (non-neuronal cells), D β H⁺ or CHAT⁺ positive cells and double positive cells (D β H⁺ & CHAT⁺). After 2 days in culture the ratio of CHAT⁺/D β H⁺ single positive cells was 0.15 ± 0.01 indicating the predominance of the adrenergic phenotype. After 8 days in control medium the ratio increased to 0.30 ± 0.02 indicating a shift to the cholinergic phenotype. After 8 days in high K⁺ medium, the ratio was 0.15 ± 0.03 , while coculture of the neurons with splenocytes induced a shift in the ratio to 0.41 ± 0.03 . For the double positive cells, after 8 days in culture, the percentage of the D β H⁺ & CHAT⁺ cells in total neuronal cells was 8.4%, 7.4% and 17.5% in control, high K⁺, and co-culture with splenocytes conditions respectively. We conclude that the fetal pig neurons are predominantly adrenergic and that during a certain culture period, catecholamines and acetylcholine biosynthesis enzymes are present in the same mammal sympathetic neurons.

614.10

MUTATION OF THE SUBEPENDYMAL LAYER IN THE NCAM-180 DEFICIENT MOUSE AND ITS PHENOCOPY BY ENZYMATIC REMOVAL OF POLYSIALIC ACID. K. Ono*, H. Tomasiewicz, T. Magnuson and U. Rutishauser. Depts. of Genetics and Neurosciences, Case Western Reserve Univ., Cleveland, OH 44106.

Genetic deletion of NCAM-180 results in a smaller olfactory bulb (OB) and morphological alteration of the subependymal layer (SEL), the latter being the source and migration pathway for OB precursor cells. The mutant mice also showed a nearly complete loss of NCAM-associated polysialic acid (PSA) that is normally expressed in these tissues. The present study was intended to determine the contribution of PSA loss to the mutant phenotype in the SEL. Newborn mice received an intracranial injection of endoneuraminidase N (endo N), which completely and specifically destroys PSA, and the distribution of precursor cells was examined at P1 and P7. At P1, which is prior to appearance of the mutant phenotype in the SEL, endo N injection did not produce any morphological alterations. That is, the precursor cells tended to be positioned in caudal SEL. At P7, however both the mutant and endo N-treated animals showed the same clear perturbation: the number of OB precursor cells remaining in the caudal part of the layer increased from less than 20% to over 50%, and there was a corresponding decrease in cells that have arrived at the OB. Pulse-labeling of the SEL cells at P1 revealed an arrest in migration of cells in the caudal SEL. By contrast, there were no detectable changes in cell proliferation or death. These results provide direct evidence that the NCAM-180 mutation causes a decrease in tangential cell migration in the SEL, and that this perturbation is due to the corresponding loss of PSA.

614.12

Undifferentiated Neuroepithelial Cells In The Spinal Cord Retain The Potential To Develop Neural Crest Phenotypes. Z. Korade*, K. Sharma and E. Frank. Department of Neurobiology, University of Pittsburgh School of Medicine, Pittsburgh PA 15261.

A subpopulation of neuroepithelial cells in the spinal cord migrate to the periphery after neural crest emigration is complete to develop as DRG cells and melanocytes, formerly thought to be late neural crest derivatives. Could these spinal cells develop other crest-type phenotypes if they encountered the environment that earlier crest cells find? This was tested by placing the neuroepithelial cells into crest migratory pathways at various developmental stages.

Cells from dorsal or ventral halves of st 26 quail spinal cords were dissociated and placed into chicken hosts. Approximately 100 - 200 cells were injected under the skin at the dorsolateral margin of the neural tube in st 16-19 or st 22-24 embryos. Injected embryos were allowed to develop for 2 - 10 days and quail cells were identified using a quail-specific Mab. Cells isolated from ventral spinal cord failed to migrate from the site of injection whereas dorsal cord cells did migrate. This difference may result from the fact that more cells in the dorsal cord are undifferentiated and still dividing at st 26. The final location of the dorsal cells was dependent on the developmental stage of the host. When injected into st 16-19 hosts, dorsal spinal cells migrated into sympathetic ganglia and peripheral nerves, but in st 22-24 embryos these cells migrated to DRG, peripheral nerve and skin. The migration of spinal cells to different locations at different stages parallels the sequential developmental changes of crest phenotypes.

These results show that at least some undifferentiated neuroepithelial cells in the dorsal spinal cord retain the ability to develop a variety of neural crest-like phenotypes. Their differentiation as neural crest-like cells is dependent on the temporal environment they encounter during development. Supported by the NIH and the McKnight Foundation.

CHARACTERIZATION OF A ECTOPIC CELL TYPE FROM THE HEARTS OF α -MHC-NGF TRANSGENIC MICE. A.F. Andrade-Rozental*, R. Rozental, A. Hassankhani, D.C. Spray and H.J. Federoff. Departments of Medicine and Neuroscience, Albert Einstein College of Medicine, Bronx NY 10461.

Previously, we have demonstrated that cardiac selective expression of NGF in a transgenic mouse produced sympathetic hyperinnervation and hyperplasia of an unknown cell population within the base of the heart (Hassankhani, et al, Soc Neurosci Abst 18:1289, 1992). To further analyze the ectopic cell population, we have undertaken morphological, immunocytochemical and physiological studies. Ectopic cells prepared from the base of hearts of 3-4 week old transgenic mice were dissociated and cultured in HBSS containing 10% FCS. None of these cells showed spontaneous contractile activity and did not stain with an antibody against sarcomeric actin, ruling out a myogenic phenotype. At two days *in vitro* (DIV) a subpopulation of the cells displayed a spindle-shaped morphology. Immunocytochemical analysis indicated that this subpopulation stained positively for GFAP and vimentin. Physiological studies revealed that they were not electrically excitable that they were poorly coupled. Unitary junctional conductance of these cells were 60 pS and junctional conductances were 0.4-2 nS. After 7 DIV, a second subpopulation of cells that adopt a fiber-like morphology were detected. These cells immunostained for gp140trkA and peripherin. Overall, these results indicate that these ectopic cells are likely derived from neural crest. Experiments are being carried out to evaluate whether these cells arise by abnormal migration into the developing heart or abnormal mitogenic expansion of a normal cardiac neural crest-derived cell type.

614.15

MICROENVIRONMENTAL FACTORS IN THE DIFFERENTIATION OF ENTERIC NEURONS FROM NEURAL CREST-DERIVED PRECURSORS. J.P. Rothman*, L. Chen and M.D. Gershon, Columbia Univ. P&S New York, NY 10032

The enteric nervous system (ENS) develops from precursors that migrate to the bowel from the neural crest. Experiments involving back-transplantation of gut into younger host embryos have indicated that crest-derived cells are not committed to differentiate along enteric lineages at the time they colonize the bowel. Differentiation of these cells thus depends on signals they receive from the enteric microenvironment. Previous studies have revealed that enteric neuronal and glial development are specifically promoted by laminin, an effect that is blocked by a soluble peptide (IKVAV). This sequence is present on the Ae chain of laminin. In order to determine if laminin Ae might be one of the enteric factors that normally promotes ENS development, we examined its expression in the developing nervous system of control and congenitally aganglionic mice (*ls/ls*). mRNA encoding laminin Ae was detected in the fetal bowel (using RT-PCR) as early as day E10, was expressed through E17, but declined to trace amounts at later ages. Laminin Ae expression is therefore developmentally regulated and coincides with the period of enteric ganglion formation. *In situ* hybridization suggests that mRNA encoding laminin Ae is expressed first in the epithelium and then the mesenchyme of the bowel. Another factor that may also affect enteric neuronal development, directly or indirectly, is CNTF. Amplimers based on rat CNTF cDNA were used to clone a cDNA fragment encoding mouse CNTF, which was 94% homologous to that of rat. The mouse sequence was used to design primers (for RT-PCR) and a riboprobe (for *in situ* hybridization) to investigate CNTF expression. CNTF was expressed in the mesenchyme of the fetal mouse gut, but was not developmentally regulated. In contrast, mRNA encoding CNTF α , the component of the receptor that conveys CNTF specificity, was abundant in fetal bowel (E10-E17), but rare in adult gut. These data suggest that laminin Ae and CNTF are potentially factors that play roles in the development of the ENS. (Supported by grant HD21032).

DEVELOPMENTAL EXPRESSION OF THE MICROPHthalmia GENE IN EYE AND EAR OF WILD TYPE AND MUTANT MICE. C. Chen*, A. Nakayama, M. Tachibana, H. Arnheiter. National Institutes of Health, NINDS-LVMP, Bethesda, MD 20892. The *microphthalmia (mi)* gene encodes a novel member of the developmentally important family of basic-helix-loop-helix-zipper transcription factors. Mice with mutations in this gene may be completely white, deaf and virtually blind. These abnormalities are due to deficiencies in neural crest-derived melanocytes that populate the skin and the stria vascularis of the ear, and deficiencies in the pigment epithelium (PE) of the retina that lead to microphthalmia.

To better define the pathogenetic mechanisms leading to these abnormalities, we now study the expression of this gene during development of normal and *mi* mutant embryos via *in situ* hybridization. In wild type embryos, *mi* expression was first found at E9.5 in the PE and at E11.5 in cells surrounding the otic vesicle (OV). TRP2, a marker for melanoblasts, was expressed almost as early as *mi* and apparently in the same cells. While *mi* expression started to decrease at E12.5 in the PE and E14.5 in the OV and was barely detectable at birth, TRP2 expression remained detectable even after birth both in the PE and in the stria vascularis. In embryos homozygous for a transgenic insertion at *mi*, expression of *mi* was low in the PE and essentially non detectable in the OV. TRP2, however, could be detected in the PE, but not the OV, consistent with the observation that PE cells seem to remain intact, while neural crest-derived melanoblasts of the OV apparently do not. In embryos homozygous for a single codon deletion in *mi* that does not impair the gene's expression, both *mi* and TRP2 gave strong signals in the PE. However, in the OV, the expression of either gene remained low and became undetectable after E13.5, again suggesting absence of melanocytes. Thus, *mi* may play a role in melanoblast proliferation and differentiation but not the maintenance of the differentiated melanocyte phenotype.

CELL MIGRATION AND DIFFERENTIATION IV

615.1

DENDRITIC DIFFERENTIATION OF RETINAL GANGLION CELLS IN CHICK. R.L. SNOW, D.J. STELZNER* AND J.A. ROBSON. Dept. of Anatomy and Cell Biology, SUNY HSC, Syracuse, NY 13210.

Development of dendritic morphology of chick retinal ganglion cells was investigated using retrograde transport of Dil. Label was applied to the optic nerves of embryos fixed between E6 and E14. The embryos were stored in fixative for 6-8 weeks at 37°C. Retinal wholemounts were examined using epifluorescence and confocal microscopy. Selected retinas were photoconverted and drawings of labeled cells were made using a computerized microscope.

At E6 many ganglion cells are still migrating. These cells are bipolar in shape and lack dendrites. They have axons in the optic nerve and trailing processes attached to the scleral margin. By E8 rapid dendritic growth is prevalent and trailing processes retract. This early dendritic growth is characterized by the appearance of many short spiny projections from all sides of the soma. As the cells mature most of these spiny processes appear to retract. However, a few elongate and branch profusely giving the cells a mossy appearance. Later, many of these branches disappear. As dendrites continue to mature, distinct ganglion cell morphologies become evident. Ganglion cells with large dendritic fields differentiate first, followed by several other distinct classes. [Supported by NIH grant EY03490]

TRANSIENTLY CATECHOLAMINERGIC CELLS IN THE BOWEL OF THE FETAL RAT EXPRESS mRNA FOR THE NMDAR1 RECEPTOR. M.S. Cumming*, G.A. Burns, C. Ulibarri, and K.E. Stephens. Department of VCAPP, Washington State University, Pullman, WA 99164

Tyrosine hydroxylase-like immunoreactivity (TH-li) has been shown to be a transient marker for precursors of enteric neurons (Baetge, *Dev Biol* 141:353 '90). In this study, we sought to ascertain whether neural crest cells, destined to innervate the fetal gut, express mRNA for the NMDAR1 subtype of the glutamate receptor. Serial sections of embryonic day 12 rat tissues were initially reacted with a polyclonal TH primary antiserum (Peninsula Labs), using a standard avidin-biotin immunocytochemical protocol with DAB as the chromagen. The same sections were then hybridized with a 1.4 kb NMDAR1 riboprobe, which had been transcribed in the presence of ³⁵S-UTP. The immuno-reacted/hybridized tissues were coated with radiolabelled emulsion and incubated for 5 weeks at -70°C. Clusters of silver grains were observed over cells exhibiting TH-li in the primitive gut. The expression of NMDAR1 mRNA by TH-reactive cells suggests a possible developmental role for this receptor, such as neuronal migration.

615.2

POSTNATAL MATURATION OF THE MOUSE OPTIC PATHWAY. Zhi Ping Mi, and C. Lagenaur*. Dept. Neurobiol., Univ. Pittsburgh, Pittsburgh, PA 15261.

Although mouse optic axons reach their targets during embryonic periods, postnatal maturation of the optic pathway is critical for normal function. In the present study we describe changes in cell surface antigens that reveal the progress of maturation in both neuronal and glial compartments. Following birth, M6 and L1 antigens delineate the path of optic axons; these are lost from axonal regions that are to be myelinated during the first week. M2, Thy-1 and P84 expression rise in the optic fiber layer during the first week. P84 is ultimately lost by the end of the second week, while M2 and Thy-1 are retained. P84 does not stain the fibers that are to be myelinated, while M2 and Thy-1 become strongly expressed in the optic nerve, apparently on distinct non-neuronal membranes. O11 is a late marker for myelination. This antigen is first detectable in the myelin forming proximal to the retina at P14, and staining extends just past the chiasm by P30. O11 staining appears to delineate this optic nerve-optic tract boundary in older animals as well. One striking feature of postnatal development of the optic nerve is the series of distal to proximal maturational events occurring in both neuronal and glial components. It is not clear if these events represent a cascade of responses to a signal originating in a single cell type or if they are instead intrinsic programs of the various cells of the optic pathway.

Supported by NIH grant EY05308

615.3

NEUROBLAST MIGRATION IN THE DEVELOPING CHICK OPTIC TECTUM VIA PERIKARYAL TRANSLOCATION. J.A. Robson* and R.L. Snow. Dept. of Anatomy and Cell Biology, SUNY HSC, Syracuse, NY 13210.

Migration of neuroblasts in the optic tectum was studied using immunocytochemistry and retrograde transport of DiI. The results demonstrate that many early neuroblasts do not migrate along radial glial processes. Instead, they retain connections with both the ventricular and pial surfaces while growing axons and translocating their nuclei. Immunocytochemical studies using a monoclonal antibody specific for postmitotic neurons (TUJ1) reveal a cohort of bipolar cells spanning the neuroepithelium during the early period of cell migration (E4-E7). In older embryos the immunocytochemical label is limited to postmigratory neurons with no trailing processes extending to the ventricular surface. Migrating neuroblasts were retrogradely labeled by applying DiI to the lateral margin of the tectum in embryos fixed between E4-E10. 6-8 weeks later the tissue was sectioned using a vibratome and examined using fluorescent and confocal microscopy. Many retrogradely labeled cells have a bipolar shape with leading and trailing processes contacting the pial and ventricular surfaces. Axons grow from the leading processes before somata reach their final locations and prior to retraction of trailing processes. Several sections were photoconverted, mounted in Epon and serially sectioned at 2µm. Reconstructions of these cells show that labeling is not transcellular. These results support the hypothesis that many neuroblasts in thin tissues migrate by translocating their somata while retaining connections with the pial and/or ventricular surfaces.

615.5

INNERVATION IS REQUIRED FOR MAINTENANCE OF TWO LARVAL MUSCLES DURING METAMORPHOSIS OF THE MOTH, *MANDUCA SEXTA*. B. J. Bayline*, A. Khoo and R. Booker. Sect. of Neurobiology and Behavior, Cornell University, Ithaca, NY 14853.

During metamorphosis of the moth, the musculature of the abdomen is reorganized. While most of the larval muscles either die or are respecified during metamorphosis, several larval intersegmental muscles are maintained in a segment-specific manner; 0 in abdominal segments 1 and 2 (A1-A2) and A7-A8, 2 in A3, and 5 in A4-A6. These muscles are used to carry out pupal-specific behaviors. In segments A4-A6, denervation triggers degeneration of two maintained muscles, the ventral internal medial muscle (VIM) and the ventral internal oblique muscle (VIO). Following denervation, both the VIO and the VIM are reduced to 33% of the normal size by the end of metamorphosis. Other maintained muscles are unaffected by denervation. We compared aspects of the induced degeneration in the denervated VIO with normal degeneration in respecified muscles. Following denervation of the VIO, dying nuclei are observed between the second and the sixth day of pupal life (P+2 through P+6). In respecified muscles, dying nuclei are present from P+2 through P+4. We used the thymidine analog 5-bromodeoxyuridine (5-BrdU) to label nuclei undergoing DNA replication. No nuclei label in the innervated VIO, while some nuclei in the denervated VIO label beginning on P+4. 5-BrdU labelling also begins on P+4 in respecified muscles. The external fibers in the denervated VIO degenerate, while the internal fibers remain intact. It is the degeneration of the external fibers which leads to the reduced size of the denervated muscles. Unlike respecified muscles, no new adult fibers develop.

615.7

CHICK EMBRYO PURKINJE CELL DENDRITES ARE REDUCED IN SIZE FOLLOWING CHRONIC TREATMENT WITH A NMDA RECEPTOR ANTAGONIST, NPC 12626. B. White* and M. W. Vogel. MD Psych. Res. Center, UMAB, Baltimore, MD 21228.

The development of Purkinje cell dendrites is dependent on interactions with afferents. The role of neuronal activity in this interaction is investigated by chronically treating chick embryos with a NMDA receptor antagonist. The NMDA receptor was chosen as the target for pharmacological blockade because of its importance in synaptic stabilization, and because granule and Purkinje cells are more sensitive to NMDA early in development, suggesting that NMDA receptor activation is important for cerebellar development.

Chick embryos were given daily injections from E14 to E17 of the competitive NMDA receptor antagonist, NPC 12626 (Guilford Pharmaceuticals). The dosage was increased daily, with a low dose group starting at 25 mg/kg (end 75 mg/kg) and a high dose group starting at 50 mg/kg (end 100 mg/kg). Drug-treated (n=21) and control (n=19) embryos were killed on E18 (HH St 43 to 44) and their brains processed for Golgi-Cox staining. Purkinje cell dendritic arbors were measured using MacMeasureII (54 Purkinje cells/cerebellum).

The NPC 12626 treatment significantly reduced embryo motility after the first injections, but motility increased to control levels during the following days. The morphology of Purkinje cell dendrites in drug-treated embryos appeared to be within the range of normal variation. Morphometric analysis showed, however, that there was a 20% reduction in the average size of Purkinje cell dendritic arbors. The results suggest that NMDA receptor activation is involved in Purkinje cell dendritic growth. Research support provided by NIH grant NS29277.

615.4

DEGENERATION OF LEECH NEPHRIDIA AFTER DENERVATION AND REMOVAL OF THE URINARY BLADDER DURING EMBRYOGENESIS. A. Wenning* and B. Janisch. Fak. f. Biologie, Univ. Konstanz, 78464 Konstanz, Germany.

During formation of the leech excretory system, the ectodermal bladder contacts the mesodermal nephridium. Sensory and neurosecretory innervation of each excretory complex occurs by a single peripheral neuron (NNC). The NNCs contain, and presumably release, FMRFamide at (1) the urine-forming cells, (2) the urethral sphincter muscles and (3) central neurons (Wenning et al, J Exp Biol 182, '93). Removal of the prospective bladder cells between embryonic days 8 and 10 (E8-10) causes the nephridium to degenerate. Until E16, however, its differentiation into two types of urine-forming cells is undisturbed, whether or not the NNC has been removed as well. As seen using immunoreactivity, the NNC contacts only differentiated parts of the excretory system (Wenning et al. Roux's Arch Dev Biol 202, '93). At E16, normal nephridia contact their bladders and become functional, and the NNCs sprout extensively. The nephridia lacking bladders stop growing and degenerate. The NNC projections lose their immunoreactivity in the nephridium but not at the sphincter. Degeneration of the nephridium is not due to a missing outlet since the ectodermal urethra with its mesodermal musculature develop normally and persist. Thus, to form a functional excretory system, the nephridium must contact the bladder. Whether a special cell or subset of bladder cells (as described for *Helobdella* in Martindale & Shankland, Dev Biol 125, '88) is required is not yet known.

Supported by the Deutsche Forschungsgemeinschaft (We745/4).

615.6

DIFFERENTIAL EFFECTS OF CORTICOSTEROIDS ON NEURONAL AND GLIAL CELLS IN THE DENTATE GYRUS OF ADULT RAT HIPPOCAMPUS. B. Liao* and E.C. Azmitia. Dept. of Biology, New York Univ., Wash. SQ, New York, NY 10003.

Corticosteroids can enter the brain and regulate cell proliferation and differentiation. The hippocampus, as a central component in the limbic system, is a major target of corticosteroids. Long-term (2 mo.) adrenalectomy (LT-ADX) induces a loss of Nissl staining and 5-HT_{1A} mRNA in the hippocampal dentate gyrus. Short-term dexamethasone (ST-DEX) treatment to the LT-ADX rats for 24-72 hr produces a rapid recovery of 5-HT_{1A} mRNA, followed by a reappearance of Nissl staining. In the present study, we further explored the neuronal and glial response to the change of corticosteroid level.

Female Sprague-Dawley rats weighing 150 g were adrenalectomized and given saline to drink. Sham operated rats were given water drink. After 2 months, some of the ADX rats were given DEX (10 mg/L) in saline drink for 72 hr. Bromo-deoxyuridine (BrdU) (50 mg/kg B.W., i.p.) was injected into all three groups of rats at 24 and 48 hr later after the start of giving DEX to one group of ADX rats.

LT-ADX produced a loss of calbindin immunoreactive (CaB-IR) granule cells, which included a decrease in cell number, a swelling and pale-stained cytoplasm, a decrease in the density of dendrites, and a narrower dentate molecular layer. Double immunostaining for histone showed that small nuclei without CaB-IR were sparsely distributed within the granule cell layer. ST-DEX to LT-ADX rats reversed partly all of above consequences. No massive neurogenesis after LT-ADX or ST-DEX were observed. After LT-ADX, numerous small vimentin (Vim)-IR cells emerged in the dentate area, which corresponded to BrdU-IR area. ST-DEX did not increase the Vim-IR cell number, but promoted the elongation of the Vim-IR cell processes.

The evidences suggest a neuronal dedifferentiation and astroglial proliferation after the loss of corticosteroid support (Supported by NIA P01 AG10208 to ECA).

615.8

LOCALIZATION OF ANTI-CALBINDIN IMMUNOREACTIVE CELLS AND PROCESSES IN THE FROG CEREBELLUM DURING THYROID-INDUCED METAMORPHOSIS. N.J. Uray*, A.G. Gona* and P.S. Sexton*. Depts. of Anatomy, Kirksville Coll. of Osteo. Med., Kirksville, MO 63501* and Univ. of Med. and Dent. of N.J., New Jersey Med. Sch., Newark, N.J. 07103*.

To study the expansion of the Purkinje cell layer in the frog cerebellum during metamorphosis, tadpoles of the bullfrog, *Rana catesbeiana*, were immersed in a thyroxine solution (1 part per 100 million) to accelerate the metamorphic process, and batches of tadpoles along with control animals were anesthetized and killed at 2 day intervals up to 30 days of thyroxine exposure. The brains were fixed in Bouin's fluid for 3 hours, rinsed in buffer and embedded in paraplast. Immunocytochemistry was done on Bouin's fluid fixed, paraplast embedded sections using anti-calbindin D-28k, rabbit antiserum from SWant (Switzerland), biotin conjugated secondary antibody, and visualized with a peroxidase chromogen.

Purkinje cells were immunoreactive at all stages of development, although the pattern of distribution was not uniform. We also noted a distinct gap in the Purkinje cell layer at a site where a cone of cells forms in the external granular layer (egl). Since the gap is present prior to the formation of the egl, the cone may not be responsible for forming the gap, rather, the cone may form at the site where a gap already exists. In addition to Purkinje cells, a population of small cells in the auricular lobes and the dorsal part of the corpus cerebelli were also immunoreactive. Because these small cells remain immunoreactive past metamorphosis, our earlier contention that these may represent immature Purkinje cells may not be totally accurate. While some small cells which are immunoreactive during development may indeed be immature Purkinje cells, others appear to be cells of the interauricular granular band. Immunoreactive commissural fibers in the dorsal part of the molecular layer of the cerebellum may be processes of these cells. Supported by NIAA Grant AA97537.

MORPHODIFFERENTIATION OF SUPRAEPENDYMAL CELLS: THEIR INTERACTIONS AND DEVELOPMENT OF THE SUBCOMMISSURAL ORGAN.

I. Herrera-Vázquez*, G. Espinosa, A. Zepeda. Depto. Anatomía, Facultad de Medicina, UNAM.

The subcommissural organ (SCO) differentiates between days 10 and 16 gestational development in the rat, it is probable that supraependymal cells (SEC) participate importantly in this differentiation. In this moment the SCO's susceptibility increases to diverse factors which could produce display and induced hidrocephalus. After learning, the SEC's ontogeny with a scanning electron microscope (SEM) we identify the neural type SEC (Kolmer I) and fagocytes (Kolmer II) during their apparition in the ventricular lumen, migration and exit through the ventricles; now we are observing their interactions and superficial changes (probably laminin, fibronectin and adhesins) using SEM. The fagocytic SEC appear with vesicles and filaments in the ventricular surface, in adjacent zones to the proliferative neuroectoderm (PNE), and in the infundibular region. In the dorsal ventricular zones there appears to be less vesiculation; part of their prolongations in the (K.I) seem to be plattened other cells present an irregular discoidal shape in ventricular surface. Fibrillary elements interconnect with the PNE near the blood vessels. Interependymal cell unions with a central cilia may be prominent or in a groove like form depending on the region analyzed. SEC and ependymocytes fuse together in some cases in others, the presence of pores suggest other types of SEC communication between intra and extraventricular spaces. We will continue with immunocytochemistry identifying this interaction. Acknowledgement for review and comment to: L. Cintra and A. Carabez (supported by DEP. Anatomía and Div. Investigación y Posgrado Fac. de Medicina UNAM.)

FIRST TRIMESTER DEVELOPMENT OF THE NIGROSTRIATAL DOPAMINERGIC SYSTEM. P. Almqvist*, E. Jacobsson, H. Pschera*, A. Seiger* and E. Sundström*. Dept. of Clinical Neuroscience, Sections for Neurosurgery and Geriatric Medicine* and Dept. of Obstetrics & Gynecology*, Karolinska Institute, S-171 77 Stockholm, Sweden.

The present study emphasize to characterize the morphological and neurochemical differentiation of mesencephalic dopaminergic neurons from human embryos, derived from elective first trimester abortions. Embryonic brain tissue was taken for analyses of tyrosine hydroxylase (TH) by immunohistochemistry and Western blot, and for analyses of endogenous dopamine (DA) content using HPLC-ED. TH was first detected immunohistochemically at 4.5 weeks of gestational age. In parasagittal sections of embryonic brainstem at this developmental stage, a small, distinct population of rounded, densely packed, TH-immunoreactive perikarya was seen in the mesencephalic flexure. These cells were located in the centre of the mantle layer of the ventral basal plate, parallel to the ventricular zone. During the sixth to tenth gestational week, the number of TH-positive cells increased exponentially as did the intensity of the TH-immunoreactivity. TH-positive cells migrated ventrally and somewhat rostrally, away from the ventricular germinal layer. During this period, short primary processes developed into long axonal trajectories giving rise to the medial forebrain bundle, projecting to the neostriatum. At the tenth gestational week, varicose fibers were detected in most areas of the striatal anlage.

To confirm the identity of TH in the embryonic tissue, as recognized by the antisera used for immunohistochemistry (Pel-Freeze, USA), mesencephalic tissue of 5-10 weeks of gestation was analysed by Western blot technique. A single band with the molecular weight of 60 kDa was detected already at 5 weeks of age. The amount of TH/mg protein increased approximately ten-fold during these developmental stages. Mesencephalic tissue and forebrain/basal ganglia were taken for analyses of dopamine (DA) content using HPLC-ED. DA could be detected at 5.5 weeks of gestational age in both areas and was found to increase exponentially from 7-7.5 weeks of age to reach 4 - 5.5 ng DA/mesencephalon and 50-75 ng DA/g caudate nucleus-putamen at the end of the first trimester.

CLINICAL CORRELATES OF ABNORMAL COLUMNAR CORTICAL ORGANIZATION IN CHILDREN WITH CHRONIC FOCAL EPILEPSY. R. Goldstein, A. S. Harvey, M. Duchowny*, J. H. Bruce, P. Jayakar, T. J. Resnick, N. Altman, L. Alvarez. Miami Children's Hospital, Department of Neuroscience, Miami, FL 33155.

Developmental pathology is a well recognized cause of chronic epilepsy and mental retardation, yet there are few studies linking specific histopathologic abnormalities with postnatal outcome. We report the clinical findings of 18 children (12 females, 6 males) aged 3 months to 15 years (mean 7.2, SD 4.7) with abnormalities of cortical neurogenesis, migration, and organization. All had undergone focal cortical resection (hemispherectomy or multilobar 9, frontal 5, temporal 4) for medically resistant partial seizures. Tissue analysis revealed immaturity of cortical cytoarchitecture characterized by longitudinal rows of neurons arranged perpendicular to the cortical surface rather than the usual horizontal lamination. Ectopic white matter neurons (N=17), white matter gliosis (N=13), morphologically abnormal neurons (large ill-defined occasionally binucleated or multinucleated cells) (N=8), and variable cortical width (N=6) were also identified. Mean age at seizure onset was 1.8 years (1 month to 7 years, SD 2.0) and mean seizure duration was 5.4 years (3 months to 13 years, SD 3.6). Fourteen children experienced daily secondarily generalized motor convulsions. Eleven children were developmentally delayed and 5 functioned in the low average range of intelligence.

These findings indicate that abnormal columnar cortical organization occurs in association with other abnormalities of neurogenesis, gliosis, and neuronal ectopia in children with chronic focal epilepsy. This histopathology correlates with early onset malignant seizures, widespread epileptogenicity, and a high frequency of developmental delay.

SUBEPENDYMAL LAYER IN ADULT RATS: CHANGES IN CELL NUMBER AND ADHESION MOLECULES AFTER CORTICAL LESIONS. E.G. Szele*, M.E. Chesselet Dept. of Pharmacology, U. of Penn., Philadelphia, PA 19104

The subependymal layer (SL) is derived from the fetal subventricular zone and in the adult rat retains developmentally regulated adhesion molecules as well as immature dividing cells. This study examined the hypothesis that mitosis, growth factors, cell phenotype, and adhesion molecules in the SL change after brain injury in the adult rat. The number of Nissl-stained cells in the SL increased 2-fold after unilateral cortical lesions. However, the number of BrdU-labelled cells in the SL did not change significantly and very few BrdU-labelled cells were observed outside of the SL suggesting that mitosis and migration remained constant after lesion. Therefore the increased cell number in the SL may be due to decreases in the rate of cell death after cortical injury. The growth promoting factors fibroblast growth factor (bFGF) and epidermal growth factor (EGF) were also examined after lesion. Whereas a robust decrease in the expression of bFGF was observed in the SL following cortical lesions, EGF was undetected in the subependymal layer before and after lesion. Cells isolated from adult subependymal layer can express neuronal or glial phenotypes *in vitro*. *In vivo*, however, cells in the subependymal layer did not express mature neuronal (synaptophysin, neuron-specific enolase, MAP-2) or astrocytic (GFAP) phenotypes before or after lesion. Vimentin- (immature astrocyte protein) positive radial glia in the medial striatum also expressed GFAP after lesion. Immunoreactivity to polysialylated neural cell adhesion molecule (PSA-NCAM) increased 3-fold in the SL and medial striatum after cortical lesion. In contrast, immunoreactivity to tenascin decreased transiently in the SL and medial striatum after cortical lesions. This study demonstrates that in response to cortical lesion, the adult SL is a highly plastic area with regards to cell number and adhesion molecules. Supported by PHS grant NS29230.

S103L NEURONAL PROTEOGLYCAN IN DEVELOPMENT: ASSEMBLY AND FUNCTION. M. Domowicz, D. Mangoura, H. Li, N. Sakellariadis* and N. B. Schwartz. Depts of Peds & BMB, U. of Chicago, Chicago, IL, 60637.

We have identified two distinct chondroitin sulfate proteoglycans (CSPG) in chick brain which can be differentiated by their immunoreactivity with S103L mAb, which recognizes an epitope in the aggrecan core protein, and HNK-1 (Krueger et al., 1992). In comparative studies using cell type specific tissue culture systems, we have provided evidence that the S103L CSPG is specific to neurons and developmentally regulated, so that its transient expression coincides with late migration and establishment of cortical nuclei. Immunocytochemical studies revealed that the *in ovo* pattern of expression of S103L CSPG is reproduced in primary neuronal cultures (Hennig et al., 1993). The HNK-1 CSPG is synthesized at high levels and constitutively in neuronal cultures as compared to glial cultures. In addition, astrocytes produce an abundance of CSPG with a larger core protein (>500 kDa), probably related to versican. Our lab has recently identified a mutation in the aggrecan gene in the nanomelic chick. The mutation introduces a stop codon in the translated sequence, and as a consequence a truncated core protein is synthesized which is not glycosylated or secreted in chondrocytes (Li et al., 1993). No expression of the complete S103L CSPG was found in nanomelic brain but the expression of the other brain CSPGs was not affected. Synthesis and processing of the S103L CSPG core protein as well as the functional consequences were studied in nanomelic neuronal culture. The regular order of aggregates was dramatically interrupted, with neurons often traveling in parallel. These data further support our hypothesis that the S103L CSPG functions to halt neuronal migration and together with sequence data confirm that the neuronal S103L CSPG and the cartilage S103L CSPG, aggrecan, are products of the same gene. DEVELOPMENT OF THE NEOCORTEX OF THE MOUSE USING BRdU IMMUNOCYTOCHEMISTRY. Dr. P. Humphreys, Dr. W. Hendelman* and E. Leung. Depts. of Pediatrics (Neurology) and Anatomy & Neurobiology, University of Ottawa, Faculty of Medicine, Ottawa, ON, Canada, K1H 8M5.

Previous studies attempting to define the time of birth of neurons destined for layers II-VI of the mouse neocortex have given conflicting results, possibly due to differences in definition of embryonic day numbers, relatively long time periods (up to 12 hours) during which coitus is permitted to occur, and to inter-strain variabilities. We studied the time of generation of neocortical neurons in the Paris R-3 mouse. Animals were mated over periods varying from 1.5 to 5 hrs (average 2.5 hrs); the day of coitus was counted as embryonic day 0 (E0). Pregnant mothers were given an intraperitoneal injection of 5-bromo-deoxy-uridine (BrdU, 100 mg/kg) at one of six precise times: E14.0, E14.5, E15.0, E15.5, E16.0, E16.5. Offspring were divided into three groups and sacrificed on postnatal day 1 (P1), P9 and P22. Brains were fixed in 70% ethanol, coronally sectioned at the anterior hippocampal level, and reacted with antibody against BrdU by the peroxidase method (deFazio et al, 1987). BrdU-labeled nuclei in the dorsolateral cortical plate (P1) or neocortex (P9, P22) were counted using an image analyzer. Analysis of data from P9 and P22 animals revealed that neurons born at the 6 injection times were concentrated predominantly in specific layers as follows: E14.0-III-VI; E14.5-III-V; E15.0-III-II; E15.5-II>III; E16.0-II; E16.5-II. MICROGLIAL REACTIVITY TO N-METHYL-D-ASPARTATE (NMDA) INDUCED EXCITOTOXICITY IN THE EARLY POSTNATAL BRAIN. L. Acarín, B. González, B. Castellano and A. J. Castro*. Dept. of Cell Biology, Neurobiology and Anatomy, Loyola University Chicago, Maywood, IL 60130; and Dept. of Cell Biology and Physiology, Autonomous University of Barcelona, Barcelona, Spain.

Injections of NMDA into the early postnatal brain causes severe and rapid neuronal loss due to the high sensitivity of the developing brain to this excitotoxin. This excitotoxic process has been implicated in the neuronal damage occurring after hypoxia-ischemia. In the present study the time course of microglial reaction was examined in cortical areas receiving NMDA injections as well as in cortical projection areas such as the pontine gray. Under ether anesthesia, 6 day old rats received an injection of 50 nmols of NMDA (0.2 µl) in the right sensorimotor cortex. At various survival times ranging from 10 hours to 28 days post lesion, microglial reactivity was studied using tomato lectin histochemistry.

Microglial reaction was seen as early as 10 hours after NMDA injections. Reactive cells in the neocortex, the hippocampus and the rostral thalamus showed an ameboid and pseudopodic morphology. At 1 and 3 days after injection, microglial morphology changed to a more ramified type, and a marked increase in the number of microglial cells was seen at day 3. From day 7, the lesion became nonprogressive and microglial cells tended to accumulate in the border between neuron depleted areas and undamaged surrounding regions. A mild type of glial scar was seen from 14 days. Additionally, a microglial response was observed in association with anterogradely degenerating cortical efferents coursing through the pons. This reaction was already seen at 10 hours post injection, it peaked at day 1 and was nearly absent by day 7.

In summary, after NMDA injection in the early postnatal brain microglial reaction was restricted to areas showing apparent neuronal or axonal degeneration. This reaction was characterized by a rapid onset and followed a specific time course.

616.3

GLIAL ACTIVITY IN WILSON'S DISEASE. S.C. Page, A.N. Kolehua, A. Czlonkowska, G. Raivich* and G.W. Kreutzberg. Max Planck Institute for Psychiatry, Am Klopferplatz 18a, 82152 Martinsried, Germany, and Institute of Psychiatry and Neurology, 1/9 Sobiesko Str, 02-957 Warsaw, Poland.

Wilson's Disease (WD) is an autosomal recessive disorder characterised by the toxic accumulation of copper in a number of organs, particularly the liver and brain. The disease prevalence is approximately 3 in 100,000 live births. Recently the gene for WD has been mapped to chromosome 13q14.3. It has been suggested that the gene product is a copper transporting P-type ATPase expressed in the liver. However, little is currently known of the mechanism by which neuronal damage occurs in the brain tissue, notably in the basal ganglia, although histological techniques have shown that reactive gliosis is a feature of the disease.

This study uses *post mortem* tissue from 3 patients exhibiting neurological symptomatology. Since no data are available concerning immunocytochemical studies in WD brain tissue, screening with a variety of antibodies was performed. GFAP staining was carried out on both frozen and formalin-fixed free-floating sections as a marker for astrocytic activity. Microglial cells were visualised using either EBM11 or peroxidase-conjugated RCA for frozen and free-floating sections respectively. An antibody against the MHC-II (HLA-DR) antigen was also employed.

GFAP staining revealed a large number of reactive astrocytes in the basal ganglia tissue, notably the putamen, in addition to the thalamus and cortex. RCA labelling was also intense in the putamen. Intense EBM11 immunoreactivity was also observed in the basal ganglia, cortex and dentate nucleus. HLA-DR immunoreactivity was localised to glial cells, shown to be GFAP-positive and therefore astrocytic, in double-labelling experiments utilising DAB as the initial chromogen and BDHC as the second. HLA-DR immunoreactive cells were present with high incidence in many areas of the brain, including the basal ganglia, corpus callosum, internal capsule and the cortex. Within these tissues, HLA-DR immunoreactivity appears to be primarily, although not exclusively, located in the white matter.

To further characterise the role of reactive glial cells in neurodegeneration in WD, current work centres around potentially cytotoxic substances that may be secreted by such cells and which subsequently lead to tissue degeneration.

TOPICAL GLUCOCORTICOID MODULATE RESPONSE TO CEREBRAL CORTICAL STAB WOUNDS. M.S. Li*, S. David Centre for Research in Neuroscience, Montreal General Hospital Research Institute, Montreal, Quebec, H3G 1A4

Penetrating injury to the CNS results in the formation of an interface (glia limitans and fibrous scar) across which axons fail to regenerate. Its maturation is associated with the deposition of a basal lamina. We have examined the effects of topical steroids on the formation of this interface. Stab wounds (2 mm long and 1.5 mm deep) were made in the parietal cortex of adult rats. Immediately after lesioning animals received either 1) a topical application of halcinonide 0.1% ointment 2) placebo ointment or 3) no treatment. Animals were perfused 3 weeks later. Cryostat sections were labelled with anti-GFAP and anti-laminin antibodies and visualised by immunofluorescence. The length of laminin immunoreactivity along the lesion interface, and the number of reactive astrocytes 300 µm lateral to the lesion were quantified. Laminin deposition at the interface was diminished in the steroid treated animals by 24% compared to controls. The placebo's effect was negligible at 2%. Astrocyte reactivity was decreased in both the steroid and placebo groups by 36% and 26% respectively. This reduction in astrocyte reactivity may in part be from the barrier properties of the ointments, preventing migration of foreign material into the CNS. These results suggest that steroids could alter the formation of the interface and may have implications for axon growth across CNS lesions.

SURAMIN INHIBITS THE GLIOTIC RESPONSE FOLLOWING BRAIN INJURY. X.-R. Zhou, S. Meiners, R. Nowakowski*, and H.M. Geller. Dept. of Pharmacology, Robert Wood Johnson Medical School, Piscataway, NJ 08854.

These experiments were designed to examine the hypothesis that certain cytokines and growth factors can provide the cellular signals to initiate the process of reactive gliosis in pathological conditions such as brain trauma caused by a penetrating stab wound injury. Suramin, a polysulfated naphthylurea, has been shown to inhibit the binding of various growth factors to their cell surface receptors. We therefore investigated the effect of suramin in a stab wound model of neural trauma in rats. A stab wound injury was made through the rat's left cortex and striatum using a 22 ga. hypodermic needle. In some animals, suramin (5 µl, 75 µM) was injected directly through the needle at the time of lesioning. In control animals there was an increase in GFAP and tenascin immunoreactivity in the vicinity of the lesion at all time points tested (1, 3, 7, and 30 days post lesion). In suramin-treated animals there was an obvious reduction in GFAP and tenascin immunoreactivity as compared to control animals at 1 and 3 days after injury. There was no difference in GFAP expression in suramin-treated and control animals at 7 and 30 days after injury. The increased levels of GFAP after lesion and the reduction in GFAP levels by suramin at 1 and 3 days after lesion was confirmed by Western blot analysis in brain tissue homogenates from the lesioned area as compared to homogenates from the unlesioned contralateral side of the brain. These results demonstrate that suramin inhibits the gliotic response as reflected by upregulated GFAP and tenascin levels at early time points following injury and suggest that growth factors and cytokines may be involved in initiating reactive gliosis. TENASCIN/CSPG-RICH ASTROCYTES INHIBIT NEURONAL GROWTH: AN IN VITRO MODEL FOR GLIOTIC SCARRING. S. Meiners, E. M. Powell, and H.M. Geller*. Dept. of Pharmacology, Robert Wood Johnson Medical School, Piscataway, NJ 08854.

Astrocytes provide an optimal surface for attachment, survival, and neurite outgrowth of dissociated embryonic neurons. However, not all astrocytes are alike: previous work from this laboratory has demonstrated a heterogeneity in the ability of a monolayer of cultured astrocytes to support neuronal adhesion and neurite outgrowth. Areas of the monolayer with a fibrous, uneven surface (termed "rocky" astrocytes) were shown to be poor substrates for neuronal growth, whereas surrounding, flat areas of the monolayer ("flat" astrocytes) were permissive substrates. The current study was initiated to investigate whether the rocky and flat astrocytes represent different subtypes of cells, as opposed to, for example, different stages of astrocyte maturity. Cultures of purified astrocytes were established from the cerebral cortex of neonatal rats. As cultures with particularly pronounced, and distinct, rocky and flat areas were identified, these areas were carefully removed from the flask with a sterile spatula, trypsinized, and replated. The flat astrocytes remained flat after reaching confluency, and the rocky astrocytes remained rocky. In addition, rocky astrocytes supported reduced neuronal adhesion, neurite generation, and neurite outgrowth in comparison to flat astrocytes. Immunofluorescence analysis and Western blotting showed that the fibrous astrocytes were notably high in the production of the extracellular matrix proteins tenascin and chondroitin-6-sulfate proteoglycan. No differences were detected between rocky and flat astrocytes in the levels of laminin or fibronectin. It is our hypothesis that rocky astrocytes may represent a subtype of cells which form barriers to neuronal growth during the development of the cortex. Due to their inhibitory properties, we suggest that rocky astrocytes may also provide a cell culture model for reactive gliosis.

616.6

GLIAL REACTION IN THE RAT SEPTAL COMPLEX FOLLOWING BILATERAL FIMBRIA-FORNIX TRANSECTION. E. Hollerbach, M. Frotscher, and T. Naumann*. Institute of Anatomy, University of Freiburg, P.O. Box 111, Germany.

Transection of the fimbria-fornix leads to degenerative changes in the septal complex as well as in the hippocampal formation. In particular, mainly retrograde neuronal reactions take place in the medial septal nucleus (MS), whereas the lateral septal nucleus (LS) only contains anterogradely degenerating fibers.

Glial reaction was investigated in adult Sprague-Dawley rats 1, 3, 6 weeks and 6 months following bilateral fimbria-fornix transection (ff-t) using the following markers: GSA-I-B₄ for microglial cells, anti-GFAP for astrocytes, RIP for oligodendrocytes and anti-Fluoro-Gold (a-FG). Immunocytochemistry was carried out on vibratome sections from perfusion-fixed brains. In some animals MS neurons were prelabeled by intrahippocampal FG injections prior to axotomy in order to document both the fate of septohippocampal neurons and glial phagocytosis ultrastructurally.

At all postlesional stages only few microglial cells were detectable immunocytochemically by using a-FG. Thus, there is only limited neuronal death and glial phagocytosis following ff-t in the MS (Naumann et al., 1992). In contrast, a strong increase in GFAP and GSA-I-B₄ staining in the LS and hippocampus was observed already 1 week post lesion. Moreover, increase in glial staining was not restricted to areas affected by ff-t. The intensity of all glial markers returned to that of controls at about 6 weeks post lesion. Thus, glial reaction after ff-t is a widespread and long-lasting process.

GFAP IMMUNOREACTIVITY IN TRIGEMINAL GANGLION SATELLITE CELLS AFTER TOOTH INJURY IN RATS. J.L. Stephenson and M.R. Byers*. Dept. of Anesthesiology, University of Washington, Seattle, Washington, 98195, USA

An increase in glial fibrillary acidic protein (GFAP) immunoreactivity (IR) is often seen in astrocytes of the central nervous system in response to a wide variety of injuries. We have investigated injury induced GFAP-IR in ganglion satellite cells, in response to graded tooth injuries. We compared GFAP-IR of trigeminal ganglia (TG) after maxillary or mandibular molar injury at 1, 3, and 7 days after the injury, and for different degrees of injury. Fixed ganglia (4% formaldehyde) were cut in the horizontal plane at 50 microns, and were analyzed as a 1 in 3 series to avoid double counting of neurons encircled by reactive satellite cells. The number of neurons with satellite cell reaction in each experimental category was compared to the uninjured control TG, as well as to zones within each section that did not correspond to the site of injury. We found significant increases in the total number of GFAP-IR satellite cell profiles surrounding tooth related neuronal cell bodies in the 7 day group ($p=0.016$). The GFAP-IR at 3 days was dramatically increased, but with a larger variance in the total number of reactive cells than at seven days. The site of GFAP reaction in the TG, shifted depending on the injury site (max or mand). Satellite cell GFAP-IR corresponded to the zone labeled by retrograde labeling of neuronal cell bodies by Dil from the molars. EM confirmed the identity of the GFAP-IR cells to be satellite cells. We conclude that a GFAP-IR satellite cell reaction is induced in trigeminal ganglia by molar inflammation in a site specific manner at 3-7 days. Supported by NIH DE05159.

TYROSINE PHOSPHORYLATION IN RAT SPINAL CORD AFTER SCIATIC NERVE TRANSECTION. W.A. Eckert,¹ I.G. Valtchanoff,² C.A. Otey,³ A. Rustioni,⁴ and R.J. Weinberg.² Depts. of ¹Physiology, and ²Cell Biology & Anatomy, UNC, Chapel Hill, NC 27599, and ³Dept. of Anatomy & Cell Biology, University of Virginia, Charlottesville, VA 22908.

Nerve injury produces central changes reflecting both degeneration and regeneration of nerve fibers. Release of a growth factor, likely to act via receptor tyrosine kinases, may be an important signal associated with peripheral injury. Immunocytochemistry using antibodies for phosphotyrosine was employed to identify changes in tyrosine phosphorylation in the rat spinal cord consequent to sciatic nerve injury. Increased immunostaining in the spinal gray matter, dorsal columns and gracile nucleus on the side of the lesion became evident after three days and was more pronounced with longer survival times up to three weeks (the longest survival tested). This increase was most prominent in the fourth lumbar segment (the focus of termination of sciatic nerve afferents). Immunostaining was in astroglial cells and their processes in the dorsal horn; stained microglia was also seen. Immunopositivity also increased in glial cells surrounding motoneurons at the same levels.

These results in combination with other work from our laboratory suggest that some factor released by primary afferent fibers over a sustained period results in sustained kinase activation, either directly or via a cascade involving sustained synthesis and release of other factors. This kinase activation is likely to play an important role in the full development of the glial response to nerve damage.

INTERLEUKIN-1 β INDUCTION OF PROSTAGLANDIN G/H SYNTHASE-2 (PGHS-2) AND INDUCIBLE NITRIC OXIDE SYNTHASE (iNOS) IN CULTURED MURINE GLIAL CELLS. M.K. O'Banion*, J.C. Dusek, J.W. Chang and P.D. Coleman. Departments of Neurology and of Neurobiology and Anatomy, University of Rochester Medical Center, Rochester, NY 14642

Brain injury results in activation of glial cells, including both astrocytes and microglia, and in an increase in the expression of several endogenous pro-inflammatory cytokines such as IL-1 β and TNF- α . Increased expression of these factors has also been observed in the brains of individuals with Alzheimer's disease and AIDS. Previous studies indicate that astrocytes make both prostaglandins (PG) and nitric oxide (NO) in response to IL-1 β . To determine whether cytokines influence the expression of genes responsible for the generation of PG and NO, we performed northern blot analyses of RNA from purified primary cultures of astrocytes and microglia which had been treated with various factors. Our results indicate that PGHS-2, but not PGHS-1, mRNA is strongly induced in astrocytes exposed to recombinant IL-1 β in a dose-dependent fashion. Induction is highest at 2 h, and PGHS-2 mRNA levels return to control values by 24 h. Macrophage/Inducible NOS mRNA levels are also increased in astrocytes treated with IL-1 β but appear to peak at a later time point (4 to 8 h of exposure). TNF- α , LPS, and basic FGF also induce PGHS-2 in astrocytes, whereas dexamethasone pretreatment diminishes the level of PGHS-2 induced in response to IL-1 β . Interestingly, PGHS-2 mRNA was not detected in cultured microglia treated with IL-1 β or GM-CSF; however, PGHS-1 mRNA was present in these cells under all conditions tested. In summary, our results indicate that brain glial cells transiently increase their expression of synthetic enzymes for PG and NO in response to cytokines and suggest the elaboration of a cascade of mediators for cytokine action in the brain. 616.8

FGF RECEPTOR EXPRESSION FOLLOWING TRAUMATIC BRAIN INJURY IN RATS. L.F. Reilly and V.K. Menon*. Department of Cell Biology & Human Anatomy, School of Medicine, University of California, Davis, CA 95616.

Basic fibroblast growth factor (bFGF) is thought to play a role in astrogliosis following traumatic injury to the CNS. In the present study, trauma-induced changes in the spatial and temporal expression of FGF receptor 1 (FGFR-1, *flg*) were examined. A stereotaxic lesion through the hippocampus was placed in adult, male Fisher 344 rats. After survival times ranging from 1 to 30 days, brains were removed and processed for immunohistochemistry using a monoclonal antibody to FGFR-1. Quantitative image analysis was carried out to evaluate the magnitude of the changes. Cortical expression of FGFR-1 was increased adjacent to the wound cavity by day 2 post-lesion. Levels peaked at day 4 and decreased to control levels by day 10, except for reactive astrocytes immediately adjacent to the wound cavity. In the hippocampus, FGFR-1 immunoreactivity was increased on day 4, peaked at day 7, and remained elevated beyond day 10. By day 30, staining had returned to control levels except for reactive astrocytes immediately adjacent to the wound cavity. Double immunohistochemistry for FGFR-1 and GFAP demonstrated that astrocytes are expressing FGFR-1. bFGF colocalized with FGFR-1, suggesting that FGFR-1-expressing astrocytes are also expressing bFGF. These data demonstrate a time course for astrocyte expression of FGFR-1 which precedes and parallels the established time course for astrocyte hypertrophy. This suggests that endogenous bFGF may act directly on astrocytes to induce astrogliosis.

616.10

EXPRESSION OF A NOVEL NON-ANGIOTENSIN II [¹²⁵I]CGP 42112 BINDING SITE IN HEALING WOUNDS OF THE RAT BRAIN. M. Viswanathan*, A.M. de Oliveira, F.M.A. Correa, and J.M. Saavedra. Sec. on Pharmacology, LCS, Bldg. 10; Room 2D-45, National Institute of Mental Health, NIH, Bethesda, MD 20892

Angiotensin II (Ang II) receptor subtypes AT₁ and AT₂ seem to be involved in growth and repair processes during wound healing. Our studies using the AT₂ ligand [¹²⁵I]CGP 42112 unexpectedly revealed, in healing brain wounds of adult rats, a binding site that is recognized by CGP 42112 and not by angiotensin II. Using quantitative autoradiography, we localized and characterized this site. [¹²⁵I]CGP 42112 binding was restricted to the wound edge and the immediate periphery. Immunocytochemical localization using ED-1 monoclonal antibody raised against rat macrophages showed good correlation between the distribution of ED-1(+) cells and the binding which was saturable, reversible, and stable. Saturation studies and Scatchard analysis of the data revealed a single class of binding sites with a K_d 3.8X10⁻¹⁰ M and binding capacity (B_{max}) of 109 fmol/mg protein. The time course of injury-induced expression of the binding in the brain lesion revealed highest levels at 3 days after injury which became undetectable after 10 days. Our results suggest that activated microglia surrounding the penetrating wound express the novel binding site and that this site may have a role in mechanisms of tissue repair in the brain.

EFFECTS OF PLATINUM-RELATED CHEMICALS ON MS1 MOUSE SCHWANN CELL LINE. Y. Ogawa* and S.U. Kim. Div. of Neurology, Dept. of Medicine, Univ. of British Columbia, Vancouver, BC, Canada, V6T 2B5.

Specific toxic effects of platinum-related chemotherapeutic agents such as cisplatin and carboplatin on neurons or Schwann cells have not yet been thoroughly evaluated.

The MS1 mouse Schwann cell line (Watabe et al., J Neuropathol Exp Neurol, 49:455, 1990) was exposed to cisplatin and carboplatin, and the survival rate was measured by MTT assay. Blocking effects of NGF, ACTH₄₋₉, and α -MSH against platinum toxicity were also examined. Cisplatin displayed a marked cytotoxicity at concentrations greater than 1 μ g/ml and carboplatin at concentrations greater than 20 μ g/ml. NGF protected cell death from cytotoxic effects of cisplatin and carboplatin at the concentration of 50 ng/ml.

These results suggest that cisplatin and carboplatin can induce Schwann cell damage during platinum-induced neuropathy and that cisplatin is far more toxic to Schwann cells than carboplatin.

NEUROPROTECTION AGAINST CISPLATIN TOXICITY BY BDNF AND SCHWANN CELL CONDITIONED MEDIUM IN VITRO. E.M. Ho, D.A. Houweling, E.A.J. Joosten, W.H. Gispen and P.R. Bär. Res. Lab. Neurology, Rudolf Magnus Inst. for Neurosciences, 3584 CX Utrecht, The Netherlands.

Treatment with the anti-tumor drug cisplatin (CPT) leads to sensory neuropathy in patients, indicating that CPT affects the dorsal root ganglia (DRGs). In vitro CPT 1) inhibits neurite outgrowth from DRGs, 2) decreases the migration of DRG glia along the neurites and 3) is toxic to Schwann cells. As glial cells seem to be very sensitive to CPT treatment, we studied the role of these cells in neuroprotection. Therefore we cultured sensory neurons or satellite cells obtained from E15 rat DRGs and Schwann cells from P4 rat sciatic nerves. The sensory neurons were treated with 1 µg/ml CPT, which reduced neurite outgrowth with 37% (measured with neurofilament ELISA). After 24h the medium was replaced with conditioned medium (CM) from glial cells or medium containing 15 ng/ml BDNF. Schwann cell CM and BDNF diminished the toxic effect on outgrowth with 60%, but satellite cell CM was not effective. These results suggest that Schwann cells and not satellite cells produce a soluble factor that protects against CPT-induced neurotoxicity. BDNF also had a potent protective effect in the pure sensory neuron culture. As Schwann cells are known to produce NGF, the Schwann cell derived protective factor may be NGF.

A PRONOUNCED ASTROCYTIC AND MACROPHAGE RESPONSE TO PRENATAL METHYLAZOXYMETHANOL TREATMENT ACCOMPANIES THE ABNORMAL DEVELOPMENT OF THALAMOCORTICAL PROJECTIONS. J.R. Hoffman*, M.E. Barbe, P. Levitt. Dept. of Anat. & Neurobiol. Med. Coll. of Penn., Philadelphia, PA 19129, Dept. of Physical Therapy, Temple Univ., Philadelphia, PA 19140, Dept. of Neurosci. & Cell Biol., Robert Wood Johnson Med.School/UMDNJ, Piscataway, NJ 08854.

The development of axonal projections requires a complex series of spatially and temporally regulated cell interactions. The thalamocortical pathway is established prenatally, but grows most extensively in target cortical regions postnatally. This delay may be dependent upon target maturity, as well as nonneuronal cells. Exposure to methylazoxymethanol (MAM) kills mitotically active cells and when administered late prenatally, appears to alter thalamocortical fiber organization. We investigated the effect of MAM treatment (20mg/kg) when administered on either embryonic day 19, 20 or 21. Analysis of astroglia (anti-vimentin and GFAP), brain macrophages (anti-ED-1), and fiber connections (Dil labeling of thalamus) was performed at birth, postnatal day (P) 5 and P10. GFAP staining was more pronounced in reactive astrocyte-like cells in subcortical white matter and internal capsule at P10. Moreover, ED-1 stained macrophages accumulated in white matter at the earliest time point examined and were still evident even at P10, almost 2 weeks after the single injection of MAM. The degree of nonneuronal cell response appeared to correlate with the disruption of the Dil-labeled thalamocortical fibers. In some brains, disrupted projections, anomalous growth cone and fiber varicosities were seen at birth. The results suggest that the MAM treatment produced an abnormal gliotic and phagocyte response in the fetal brain, one which can have longlasting effects on cellular organization and developing fiber projections. β₂-ADRENERGIC RECEPTORS ARE EXPRESSED BY GLIA *IN VIVO* IN THE NORMAL AND INJURED RAT, RABBIT AND HUMAN CNS. C.A. Hodges-Savola*, S.D. Rogers, M.D. Catton, J.R. Ghilardi, C.J. Allen, S.R. Vigna, J.E. Maggio, L.A. Levin, P.W. Mantyh. Mol. Neurobiol. Lab (151), Mpls., MN 55417; Psychiatry Dept., Univ. of Minn., Mpls., MN 55455; Dept. of Biol. Chem. and Mol. Pharm., Harvard Med. School, Boston, MA 02115; Dept. Cell Biology, Duke Univ. Med. Ctr., Durham, N.C. 27710; Dept. Ophthalmol., Univ. of Wisc., Mad. WI, 53792

Glial cells in culture express several subtypes of functional adrenergic receptors. To determine if similar receptors are expressed by glia *in vivo* we examined normal, crushed, and transected optic nerves of the rabbit and rat using quantitative adrenergic receptor autoradiography. We also obtained preliminary data regarding the expression of adrenergic receptors in normal and damaged human optic nerve. High levels of α₁, α₂, β₁, and β₂ adrenergic receptors were identified in the rabbit and rat forebrain but only α₁ and β₂ receptors were observed in the normal rat and rabbit optic nerve, and these were present in low to moderate densities. Normal, as well as damaged, human optic nerves also exhibited adrenergic receptor binding limited to the α₁ and β₂ species. After unilateral optic nerve crush or transection, only β₂ adrenergic receptors were significantly increased. This increase in β₂ receptors was first significant at day 7 and 28 post-transection in the rabbit and rat, respectively. The expression of β₂ receptors in the transected optic nerve continued to increase with time so that by 90 days post-transection, the density of β₂ receptors in both the rabbit and rat optic nerve was among the highest in any area of the forebrain. Taken together with previous studies, these results suggest that *in vivo*, glial β₂ adrenergic receptors may provide a therapeutic target for regulation of human astrocyte functions including glycogen metabolism, cytokine release, and the hypertrophy and proliferation that occurs in response to neuronal injury. LEAD INDUCED DEVELOPMENTAL ALTERATIONS IN GLIAL GENE EXPRESSION. N.H. Zawia* and G.J. Harry. Environmental Immunology & Neurobiology, Laboratory of Biochemical Risk Assessment, NIEHS, P.O. Box 12233, RTP, NC 27709.

Lead is a neurotoxicant that is known to produce behavioral, biochemical and structural abnormalities in brain development. We have previously demonstrated that lead selectively disrupts developmental gene expression. The goal of this study is to examine whether these alterations in gene expression are related to regional timetables of development. To accomplish this, two brain regions with distinct prenatal (brainstem) and postnatal (cerebellum) schedules of development were chosen. Long Evans hooded rats were lactationally exposed to low levels of lead acetate (0.2 % in the drinking water of the dam begun after parturition). Tissue was then obtained from the cerebellum and brainstem on postnatal days (PND): 3, 6, 9, 12, 15, 20, 25, 30, 40, and 50. No changes in either brain structure and weight or animal body weights were observed in the pups following such exposure to lead. Total RNA was isolated and probed for myelin basic protein (MBP), glial fibrillary acidic protein (GFAP) and actin gene expression by Northern analysis. In the cerebellum, lead produced long term elevations in both MBP and GFAP gene expression that began on PND 20 and were sustained into adulthood; actin gene expression remained unchanged. No such shifts in the expression of these genes were observed in the brainstem. These results suggest that glial gene expression is more susceptible to the effects of lead in actively developing regions and that the state of gene expression may be permanently altered by lead.

AXONAL DEGENERATION CAUSES A SLIGHT INCREASE IN ASTROCYTE PROLIFERATION *IN VITRO*. V. Guénard*, G. Frisch, L.A. Gwynn, E. Cuervo, and P.M. Wood. The Miami Project and Department of Neurological Surgery, University of Miami School of Medicine, Miami, FL.

Mechanisms inducing gliosis in the CNS after injury are not well understood. Astrocytes (AS) proliferate and become hypertrophied under stimuli not yet identified. In this study, the influence of axonal injury on astrocyte proliferation was evaluated at various times post-injury and related to axonal degeneration and regrowth. Since the transplantation of Schwann cells (SC) into gliotic areas of the injured CNS is of therapeutic interest, we also assayed whether factors released in injured N-AS cultures affected SC proliferation on axons. Cultures of purified embryonic rat dorsal root ganglion neurons (N) were transplanted onto AS or SC monolayers. After the neurons extended axons on the AS or SC, a large fascicle was cut 1.5 mm from the neuronal cell bodies. Non-injured cultures were used as controls. To assess proliferation, the cultures were exposed to [³H]-thymidine 0, 1, 3 and 7 days post-injury (DPI) and processed for autoradiography. On 1 and 2 DPI AS proliferation was slightly increased and SC proliferation in sibling cultures was increased to approximately the same extent. Neurofilament staining distal to the lesion disappeared more rapidly in N-AS than N-SC cultures. Eight DPI, axonal regrowth was observed, but neither AS or SC proliferation changed. In two experiments conditioned media collected from injured and non-injured N-AS cultures decreased neurite-induced SC proliferation when compared to media from sibling N-SC cultures, as assessed by autoradiography. However, no difference was observed between media obtained from injured and non-injured N-AS cultures. Our data demonstrate that AS proliferation in gliosis may be caused partially by factors released after axonal injury. Supported by NIH grant NS28059, NMSS grant 1RG 2210-A-2 and The Miami Project.

DENERVATION-INDUCED CHANGES IN ASTROCYTIC GENE EXPRESSION ARE ALTERED IN AGING MICE. P. A. Trimmer*. University of Virginia, Departments of Neurology and Neuroscience, Charlottesville, VA 22908.

This study is designed to evaluate if the time course of changes in astrocytic gene expression associated with Wallerian degeneration is altered by normal aging. Denervation was induced in the dentate gyrus of adult (40-60 days) and aging (1-2 years) C57BL/6 mice by a unilateral lesion of the entorhinal cortex. *In situ* hybridization with a radiolabeled probe for glial fibrillary acidic protein (GFAP) was used to detect changes in levels of GFAP mRNA. In adult mice, there was a peak in GFAP mRNA levels at 2 days post-lesion (DPL). GFAP mRNA levels declined at 4 DPL but did not return to control levels until about 3 weeks post-lesion. In aging mice, the peak in GFAP mRNA levels was reduced in size and was delayed until 4 DPL. GFAP mRNA levels returned to near control in lesioned aging mice by 8-10 DPL. These results indicate that up-regulation of gene expression in reactive astrocytes is compromised in the CNS of aging mice. Compromised astrocyte function as a consequence of normal aging could limit the ability of astrocytes to provide the metabolic and functional support neurons in the CNS need to cope with the degeneration that characterizes pathological conditions such as Alzheimer's disease. Supported by the Alzheimer's and Related Diseases Research Award Fund.

617.1

CALCITONIN GENE-RELATED PEPTIDE IMMUNOREACTIVITY IN YOUNG MOTONEURONS AFTER NERVE INJURY.

K. M. Blake and R. C. Borke*. Dept. of Anatomy & Cell Biology, USUHS, Bethesda, MD 20814.

Changes in calcitonin gene-related peptide immunoreactivity (CGRP-IR) were examined in motoneurons of young rats after nerve injury to determine when during postnatal development, CGRP-IR typical of adult moto-neurons was elicited by axonal injury. Hypoglossal nerve crush or transection was performed in rats at 10, 14 or 21 days postnatal (dpn). Rats were killed by aldehyde perfusion at 1, 3, 7, 14, 20 days postoperative (dpo). Results from the 21 dpn injury cases resembled those in the adult rat. Increased CGRP-IR continued after nerve crush until regeneration was complete. After transection, a biphasic response of CGRP-IR consisted of an early increase (1-3 dpo), a decrease to basal levels (7 dpo) and a second elevation (14-20 dpo) that persisted until regeneration occurred. No consistent increase in CGRP-IR was seen after either injury at 10 dpn and regeneration was meager and nerve cell death was substantial. The same injuries in 14 dpn rats produced intermediate changes in CGRP-IR, regeneration and cell death compared to those obtained in the 10 and 21 dpn rats. The results strengthen the idea that persistent up-regulation or down-regulation of CGRP-IR can be used to predict successful regeneration or apoptosis of injured motoneurons.

617.3

ANDROGEN RECEPTOR mRNA EXPRESSION IN ADULT HAMSTER FACIAL MOTOR NEURONS (HFMN). S.M. Drengler*, R. J. Handa, K.J. Jones. Dept. of Cell Biology, Neurobiology and Anatomy, Loyola University of Chicago, Maywood, IL 60153.

We have previously demonstrated that systemic administration of exogenous testosterone propionate (TP) to adult hamsters enhances the rate of facial nerve regeneration following injury in both genders, with the effects significantly greater in males as compared to females. Further studies also indicate that these effects of TP occur via a mechanism involving androgen receptors (AR), which are present in both male and female HFMN. In this study, we tested the hypothesis that the differential effects of androgens on regeneration rate in male/female HFMN are related to gender specific differences in the levels and/or regulation of AR mRNA in these motoneurons. Four groups of hamsters were used: intact and gonadectomized males/females. *In situ* hybridization was performed using an ³⁵S-labeled antisense AR cRNA probe encoding 350 NTDs of the ligand binding region. Slides were processed for routine autoradiography and quantitative analysis was performed using a computerized image analysis system. Preliminary results indicate that AR mRNA levels are increased in male HFMN when compared to females. Gender specific regulation was also noted; gonadectomy decreases AR mRNA levels in males, but not in females. Studies are in progress to evaluate the interactive effects of hormonal/injury states on AR mRNA expression in HFMN. Supported by NIH grant NS28238.

EXPRESSION OF MICROTUBULE-ASSOCIATED PROTEINS (MAPs) IN NORMAL AND REGENERATING CAT TROCHLEAR MOTONEURONS. A.A. Book*, I. Fischer, and E.H. Murphy. Department of Anatomy and Neurobiology, Medical College of Pennsylvania, Philadelphia, PA 19129.

While previous studies have shown that the levels of actin, tubulin, and neurofilament proteins are altered in peripheral neurons following axotomy, much less is known about the role of MAPs in axonal regeneration. In this study, we examined the expression of a variety of MAPs, by immunocytochemical methods, in both normal and peripherally axotomized trochlear motoneurons (TMNs) of the cat. The left trochlear nerve of each animal (n = 4) was transected where it coursed between the cerebellum and inferior colliculus, and animals were allowed to survive 2 weeks. Three unoperated cats served as controls. Brain sections were incubated with antibodies recognizing a high molecular weight form of tau, termed HMW tau, MAP-2, MAP1B, and a phosphorylated form of MAP1B, termed MAP1B-P. In normal control TMNs, HMW tau and MAP1B were observed in cell bodies and processes. In contrast, MAP-2 was present specifically in dendrites while MAP1B-P was found only in axons. Following nerve transection, the levels of HMW tau appeared to decrease in axotomized TMNs, as compared to TMNs in the unaxotomized nucleus or in control animals. MAP 1B-P was increased in the axons of axotomized TMNs and was also observed in some cell bodies of axotomized TMNs. The levels of MAP-2 and MAP1B in axotomized TMNs appeared similar to controls. These results suggest a potential role for MAPs in the regeneration of peripheral nerve since their expression was specifically regulated following axotomy. (Supported by NIH Grant NS 24707).

617.2

INCREASED EXPRESSION OF NITRIC OXIDE SYNTHASE (NOS) AND GROWTH ASSOCIATED PROTEIN (GAP-43) IN VISCERAL NEURONS AFTER NERVE INJURY. L.-H. Tang*, S.L. Erdman, W.C. de Groat and M.A. Vizzard. Univ. of Pittsburgh, Department of Pharmacology, Pittsburgh, PA 15261.

NADPH-diaphorase (NADPH-d), a marker for NOS, is present in a large percentage of L6-S1 afferent neurons innervating the pelvic viscera in the rat; however, NOS-IR has not been detected in these neurons. The present experiments were undertaken to determine if NOS could be expressed in these neurons following axotomy. GAP-43, a substance commonly expressed in neurons after injury, was also examined. In male Wistar rats, the right major pelvic ganglion (MPG) was removed to produce axotomy. In some rats, 1 week prior to ganglionectomy, Fluorogold was injected into the left and right MPG to retrogradely label afferent neurons in the DRG. Two-four weeks later, the animals were perfused. A differential distribution of NOS-IR was detected in DRG cells at different levels of the spinal cord in control animals. Rostral lumbar (L1-L2) DRGs exhibited significantly (p<0.05) greater numbers of NOS-IR cells compared to caudal lumbar and sacral DRGs (L5-S1). L1 and L2 DRGs exhibited 15 NOS-IR cells/section (c/s) and 3 NOS-IR c/s, respectively, whereas L5-S1 DRGs had only a few cells (0.2-0.7 c/s). After axotomy, a significant increase (p<0.01) in NOS-IR c/s in the L6 and the S1 DRGs was observed ipsilaterally to nerve injury. After axotomy, NOS-IR significantly increased (p<0.05) in visceral (FG labeled) afferent neurons in the L6 DRG: 87% of visceral afferents in the L6 DRG and 91% in the S1 DRG were NOS-IR compared to 11% (L6) and 24% (S1) contralateral to nerve injury. Increased NOS-IR and GAP-43-IR were also detected in the lateral dorsal horn and in the SPN ipsilaterally to nerve injury. A significant increase (p<0.01) in NOS-IR and NADPH-d positive cells was observed in the sacral parasympathetic nucleus in L6 ipsilaterally to nerve injury. The results indicate that NOS-IR and NADPH-d activity in visceral afferent and efferent neurons are plastic and can be upregulated by peripheral nerve injury. The unmasking of NOS gene expression by axotomy in some visceral afferent neurons (L6-S1) may be due to removal of tonic inhibitory influences arising in the peripheral target organ. [Supported by NIH grants DK 37241, DK 422369, NRSA 1 F32 DK 08916-01].

617.4

CHANGES IN RETINOBLASTOMA SUSCEPTIBILITY PROTEIN (RB)- AND C-JUN-LIKE IMMUNOREACTIVITY (IR) IN HYPOGLOSSAL NEURONS FOLLOWING HYPOGLOSSAL NERVE CRUSH. H.J. Okano¹*, W.H.A. Yu², and R.B. Gibbs³. ¹The Rockefeller Univ., NY, NY 10021, ²Dept. of Cell Biol. & Anat. Sci., City Univ. of New York Med. Sch., NY, NY 10031, ³Depts. of Pharm. and Therap. and Neurobiol., Univ. of Pittsburgh, Pittsburgh, PA, 15261

RB plays an essential role in regulating cellular proliferation and differentiation by interacting with transcription factors (e.g. E2F, c-Myc) which regulate genes necessary for cell growth. We hypothesize that RB may likewise regulate growth-related molecules involved in neuronal responses to injury and/or neuronal plasticity. In the present study, we examined RB-IR in hypoglossal neurons at different times following hypoglossal nerve crush to determine if changes in RB expression occur following injury and during the course of axonal regeneration. Expression of the early response genes Fos and c-Jun were also assessed and compared with the expression of RB-IR.

Twenty-four adult, female Sprague Dawley rats received either a unilateral hypoglossal nerve crush (n=20) or sham surgery (n=4). Four animals were killed at each of 3h, 1 day, 3 days, 1 week, and 2 weeks following nerve crush. Twenty-micron thick coronal sections through the hypoglossal nucleus were cut and adjacent sections were processed for immunocytochemical detection of RB-, Fos-, or c-Jun-IR.

Intense nuclear RB-IR staining and less intense cytoplasmic staining was detected in hypoglossal neurons of sham-operated animals. Minimal c-Jun-IR and no Fos-IR was detected. Hypoglossal nerve crush resulted in a rapid induction of c-Jun-IR, but not Fos-IR, within hypoglossal neurons on the injured side. In contrast, nuclear RB-IR staining appeared to decrease 1-7 days following hypoglossal nerve crush. Optical density measurements confirmed that significantly less (p<0.05) nuclear (but not cytoplasmic) RB-IR staining was detected 1-7 days, but not 3h or 2 weeks, following nerve crush relative to the average density of staining on the uninjured side.

These data suggest that RB expression changes significantly following hypoglossal nerve crush with a time-course which correlates with the time-course for axonal regeneration. This is consistent with the hypothesis that, in neurons, RB may regulate molecules involved in neuronal response to injury and axonal regeneration.

LOCALIZATION OF INSULIN-LIKE GROWTH FACTOR II (IGF-II) PROTEIN AND mRNA DURING NERVE REGENERATION. D.J. Marsh, S.-F. Pu, B.W. Bernstein*, and D.N. Ishii. Dept. of Biochem. and Molec. Biol. and Dept. of Physiol., Colorado State Univ., Fort Collins, CO 80523.

Sensory and motor axon regeneration is dependent upon IGFs following sciatic nerve crush in rats. In the present study we examined the cellular distribution of IGF-II protein and mRNA in rat sciatic nerve and soleus muscle after nerve crush or transection by indirect immunocytochemistry and *in situ* hybridization. Immunostaining correlated with IGF-II mRNA levels, and was higher in postnatal liver and muscle than adult. Immunostaining as well as silver grain density in nerve were elevated distal to the site of crush, particularly in macrophages and Schwann cells. Immunoreactivity was also elevated on the surface of denervated muscle fibers. These results support the inter-related hypotheses that (i) IGF-dependent regeneration of axons in peripheral nerves is due to the elevation of both IGF-II protein and mRNA in nerves distal to the site of lesion, and (ii) that elevated IGF-II protein in muscle may support the sprouting of motor nerve terminals that precedes re-establishment of synapses. (Supported by grant P01 NS28323)

GALANIN EXPRESSION IN SYMPATHETIC GANGLIA AFTER PARTIAL AXOTOMY. A. M. Shadiack*, R. P. Mohny, and R. E. Zigmond. Dept of Neurosciences, Case Western Reserve University, Cleveland, OH 44106

One of the ways neurons of the sympathetic nervous system display plasticity after axotomy is by altered expression of certain neuropeptides, such as vasoactive intestinal peptide (VIP), substance P (SP), and galanin (GAL). The increase in GAL-like immunoreactivity (-IR) in the superior cervical ganglion is maximal at 3 days and declines slowly, though remaining above control levels even at 14 days (Sun et al., 1993). In the middle and inferior cervical ganglion (MIGC), the increase in GAL-IR occurs by 2 days, plateaus through 7 days, and then increases 2-3-fold further by 14 days, returning to control levels by 60 days. The further increase in GAL-IR in the MIGC between days 7 and 14 may be related to the distance between the site of axonal transection and the ganglion in this preparation.

With the use of a retrograde fluorescent marker, fast blue, we have shown that GAL-IR is mainly found in axotomized neurons of the MIGC. In order to determine whether changes in GAL mRNA are also restricted to axotomized neurons, we performed *in situ* hybridization for GAL. Using fast blue applied to the cut nerve trunk to identify axotomized neurons, we observed a high degree of coincidence between GAL mRNA- and fast blue-containing cells most of which appeared in the middle cervical ganglion region.

The functions of VIP, SP, and GAL after axotomy are yet unknown. Two possible sites of action for these peptides are within the ganglion and/or at the site of transection. We have found an increase in VIP and GAL, and perhaps a small increase in SP, in the proximal portion of the nerve trunk after transection and a further increase after ligation of that transected nerve. This suggests that VIP and GAL produced in the sympathetic neurons after axotomy are transported anterogradely within their axons.

617.9

THE CLONING AND CHARACTERIZATION OF A cDNA ASSOCIATED WITH NEURONAL INJURY AND SCIATIC NERVE REGENERATION IN THE RAT. M. De León*, R.L. Nahin§, Yi Liu, A.A. Welch¶, E. M. Shooter¶ and M. A. Ruda§. *Dept. Physiology and Pharmacology, Loma Linda Univ., CA; ¶Dept. of Neurobiol., Stanford Univ. Stanford, CA; §Neurobiol and Anesthesiol Branch, NIDR, NIH, Bethesda, MD.

We report the cloning and characterization of DA11, a full length cDNA clone isolated from a rat dorsal root ganglia (DRG) cDNA library. The sciatic nerve of Sprague Dawley rats was crushed and allowed to regenerate. At three days after the crush the ipsilateral DRG were pooled together, and the total RNA extracted. The RNA was purified through an oligo (dT) cellulose column, and 5g of mRNA was used to construct a cDNA library (DA). The DA library was screened twice by differential hybridization as described before (De León et al., J. Neurosci Res. 29:437-448, 1991) and the cDNAs found to be elevated after sciatic nerve crush were analyzed. The screening of the library resulted in the isolation of a 0.7 Kb DA11 cDNA clone whose expression was found to be induced after nerve crush. DNA sequencing and analysis of this clone revealed that the DA11 cDNA contained a single open reading frame that coded for a protein of a calculated molecular weight of about 15 kD. Northern blot analysis showed that the DA11 cDNA recognizes a single ~ 0.6kb mRNA species that showed a two-three fold induction in the DRG ipsilateral to the sciatic nerve crush, as compared to the contralateral DRG. The 0.6 Kb DA11 mRNA was detected in total RNA extracted from the lung, heart, brain, sciatic nerve and spinal cord tissue, but the highest level was found in RNA extracted from rat DRG. The relative levels of DA11 mRNA did not change in the sciatic nerve during Wallerian degeneration. The DA 11 mRNA was also higher in the cerebral cortex during the first two weeks after birth and it was significantly induced in PC12 cell lines after treatment with nerve growth factor. Our data support the hypothesis that the DA11 cDNA may play a role during sciatic nerve regeneration and cerebral cortex post-natal development.

617.11

INDUCTION OF *c-FOS-LACZ* AND *c-JUN-LACZ* TRANSGENES FOLLOWING SCIATIC NERVE TRANSECTION IN NEONATAL AND ADULT MICE. H.D. Soares*, S.-C. Chen, T. Curran, and J.L. Morgan. Roche Institute of Molecular Biology, Roche Research Center, Nutley, NJ.

The developmental stage of an animal greatly affects outcome following CNS injury. For example, peripheral nerve transection in neonates elicits profound neuronal loss whereas adult neurons survive peripheral axotomy and attempt regeneration. Paradoxically, functional recovery in neonatal animals usually surpasses recovery in adults despite severe muscular atrophy in both adults and neonates. Very little is known concerning the underlying molecular mechanisms governing recovery following peripheral nerve injury. The following study utilizes a transgenic approach to examine the transcription factors, *fos* and *jun*, in defined cell populations undergoing degeneration, regeneration, plastic reorganization, and transsynaptic activation following sciatic nerve transection. Using either *c-fos-lacZ* or *c-jun-lacZ* mouse lines, the left tibial and peroneal branches were transected and a 2mm piece removed in either PO or adult subjects. Animals were allowed to recover for 2 hrs, 1, 2, 5, 14, or 28 days post-injury. Both *fos* and *jun* were transsynaptically induced in spinal cord dorsal horn. In addition, *fos* and *jun* were both present in peripheral nerve stumps, surgically traumatized thigh and in PO denervated leg muscle. Interestingly, *fos*, but not *jun*, was present in the adult denervated leg muscle even though *jun* mRNA was substantially elevated. Axotomy elicited only a transient *fos* response in both PO and adult neurons. *Jun* was present for prolonged periods in axotomized neurons and also in adjacent neuronal cells whose axons had not been transected. These results suggest that *jun* is post-transcriptionally regulated in adult denervated leg muscle. Prolonged *jun* expression in neurons may be more associated with a sprouting phenomena rather than a pure regenerative response. Finally, our data demonstrate that developmental differences in response to peripheral nerve injury can occur on a transcriptional level.

617.8

CHANGES IN THE MACROPHAGE POPULATION IN THE RAT SUPERIOR CERVICAL GANGLION (SCG) AFTER AXOTOMY. R. C. Schreiber*, A. M. Shadiack, and R. E. Zigmond. Department of Neurosciences, Case Western Reserve University, Cleveland OH 44106

Macrophages play a role in the biochemical changes that occur in a peripheral nerve after transection. To determine whether these cells might also be involved in changes occurring in the region of axotomized sympathetic cell bodies, sections of rat SCG were examined immuno-histochemically using two monoclonal antibodies: OX6 (which recognizes macrophages and other cells expressing the Ia MHC class II antigen) and ED1 (which recognizes circulating monocytes and macrophages). SCG from normal and sham-operated animals and from animals 1, 2, 5, 8, and 14 days after nerve transection were studied, and the number of immunostained profiles, quantified by image analysis. Immunostained cells were found using both antibodies in ganglia from normal animals, and no changes were seen after sham-operation. After axotomy, OX6 staining was unchanged at 1 and 2 days, increased significantly at 5, and continued to rise at 8 and 14. ED1 immuno-fluorescence was unchanged at 1 day, increased significantly at 2, and was maintained at this level at 5, 8, and 14. The differences in the time courses of immunostaining with the two antibodies may indicate that there is differential regulation of the two antigens in a single cell population or that more than one cell population is involved. The time course of apparent invasion by circulating monocytes suggests that they do not participate in early biochemical changes after axotomy, such as the rapid increase in expression of leukemia inhibitory factor mRNA in the SCG. Whether resident macrophages participate in these early events remains to be determined. Studies using ED2 (which recognizes resident macrophages) will be reported on.

617.10

SERINE PROTEASE:SERPIN BALANCE IN MOUSE SCIATIC NERVE AFTER INJURY. J. Ma, I.V. Smirnova, E.J. Gregory and B.W. Festoff*. Neurobiology Research Lab., VA Med. Ctr, Kansas City, MO 64128; Dept. of Neurology, Univ. of Kansas Med. Ctr, Kansas City, KS 66103.

Serine proteases, such as thrombin (TH), cathepsin G (CG), plasminogen activators (uPA, tPA), tissue kallikrein (KK) and plasmin (PL) are necessary for extracellular proteolysis in various tissues. Proteolytic cascades involving these enzymes participate in the development and regeneration of nervous tissue (Festoff, 1990). Serine protease inhibitors (serpins) provide post-translational modulation of serine proteases by forming covalent complexes. Thus, the balance between serine protease and serpin may be critical in determining the tissue remodeling, particularly in synapse elimination and reinnervation. In this study we investigated the induction of a variety of serine proteases as well as the serpin protease nexin I (PNI), potent inhibitor of TH and uPA, after adult mouse sciatic nerve crush. Samples were taken from sciatic nerve distal to the crush site at day 1, 3, 6, 9 and 14. We measured the protease activities by their cleavage of several specific tripeptide chromogenic substrates. We found that TH-like activity at day 3 time point was dramatically increased, compared to other crush time points and controls, and was inhibited by addition of highly specific TH inhibitors such as PNI, hirudin and Phe-Pro-Arg-chloromethyl ketone. No significant change was observed for the other serine proteases following crush. Induction of active plasmin, either in crushed nerve or in the controls, was not detectable. Since the balance of serine proteases and their serpins in nerve was altered by nerve damage, we also estimated active PNI levels in these crush samples by means of complex formation with ¹²⁵I-labeled human uPA. The rate of active PNI in crush samples initially increased by sevenfold at day 6, peaked at tenfold by day 9 and then decreased at day 14. Thus, increase of TH after nerve crush is followed by generation of active PNI. These results suggest that shifting the balance between TH and PNI might underlie synapse retraction after injury with re-establishment of the balance facilitating repair of damage of peripheral nerve after injury. They also suggest that TH and its cognate serpin participate in axonal regeneration to a greater extent than other serine proteases studied. (Supported by the MMD Foundation/ SEP, the ADRDA and the Med. Res. Service of the Dept. of VA).

INDUCTION OF THYMOSIN B10-LACZ TRANSGENE IN REGENERATING MOTOR NEURONS FOLLOWING PERIPHERAL NERVE INJURY. S.-C. Chen, M. Butler, R. J. Wurzbarger* and J. L. Morgan. Roche Institute of Molecular Biology, Roche Research Center, Nutley, NJ.

In an attempt to identify molecular markers for neurogenesis, we found a protein named thymosin B10 that is predominantly expressed in the embryonic nervous system. Its expression levels reach a maximum around the time of axonal outgrowth and decline sharply after birth. Biochemically, thymosin B10 has been shown to be a G-actin binding protein. A rat genomic DNA of thymosin B10 was cloned and used to generate transgenic mice that carry a thymosin B10-lacZ transgene. The expression of thymosin B10-lacZ is first detected at embryonic day 8.5 in the nervous system. During late neuroembryogenesis, its expression is widely distributed in the developing nervous system, including retina, cortex, cerebellum, spinal cord, cranial motor neurons and ganglia. In the adult, high levels of thymosin B10-lacZ expression are restricted to neurons that have elevated synaptic remodeling. In addition to its cytoplasmic expression in the neuronal cell body, thymosin B10-lacZ fusion protein is also detected in dendrites and axons.

The expression of thymosin B10-lacZ was investigated following peripheral nerve injury. Five days after facial nerve transection, an induction of thymosin B10-lacZ was observed in motor neurons in the ipsilateral facial nucleus. The expression remained elevated for several weeks during regeneration. Induction of thymosin B10-lacZ in the spinal motor neurons of L4 & 5 was also detected following sciatic nerve transection. Increased blue staining in axons in the proximal stump of the injured nerve was observed and extended into dorsal root fibers supplying the secondary sensory neurons. These observations suggest that thymosin B10 plays an active role in axonal growth during development, regeneration and in synaptic reorganization.

DIFFERENTIAL DISPLAY PCR IDENTIFIES CHANGES IN GENE EXPRESSION FOLLOWING RAT FEMORAL NERVE LESION
 M.D.Aldous, M.P.Rapoza, S.J.Archibald, R.J.Rohwer, D.Rapoza, and R.D.Madison. Depts. of ¹Surgery (Neurosurgery), ²Neurobiology, Duke University Medical Center, and Research Services, ³VA Hosp., Durham, NC and ⁴VA Hosp., Baltimore, MD.

The rat femoral nerve divides into a terminal sensory branch (saphenous nerve) and a terminal motor branch to the quadriceps muscle. Motor axons preferentially regenerate into the terminal motor branch following nerve transection and repair proximal to the terminal bifurcation, even when the distal nerve branches are completely isolated from their end organs (Brushart, J. Neurosci., 13(6), 2730-2738 1993). To identify factors present in the denervated pathways which may underlie preferential motor reinnervation, we are starting to analyze lesion induced changes in mRNA expression using differential display PCR (Liang and Pardee, Science, 257, 967-971, 1992). Total RNA was extracted from terminal motor and sensory branches from control nerves or nerves which had been transected and prevented from regenerating for two weeks. Subsets of the expressed mRNAs were reverse transcribed with an anchored dTMN-primer, and amplified with PCR using end-labeled random 10-mers. PCR products were separated by PAGE. Most labeled bands representing expressed mRNAs were similar between lesioned and control motor branches or sensory branches. Several bands were present only in lesioned motor or lesioned sensory branches, representing potential mRNAs which are expressed only under denervated conditions. Differentially expressed bands will be sequenced to determine their identity. Initial results show the utility of using this approach to identify mRNAs that are up- or down-regulated following nerve transection. NS22404-09 (RDM) and VA Merit Review (RDM).

CONSTITUTIVE HEAT-SHOCK-70 mRNA IS INDUCED IN RESPONSE TO FACIAL NERVE AXOTOMY. U.E. Olazábal*, C.A. Haas¹ and G.W. Kreutzberg. Dept. of Neuromorphology, Max-Planck-Inst. for Psychiatry, Martinsried, and ¹Anatomical Inst. I, University of Freiburg, FRG.

We have shown previously that constitutive heat-shock-protein 70 (hsp70) is increased in the regenerating facial nucleus. In this study, we extended these findings and examined if hsp70 mRNA would be induced in facial nucleus following peripheral nerve lesion. Nerve transection was done in Wistar rats at the level of the stylomastoid foramen and animals were sacrificed 6h, 12h, 24h or 3d later. Facial nuclei from operated and sham-op controls were extracted and prepared for Northern blot analysis using a cDNA probe complementary to constitutive hsp70 mRNA. Autoradiograms revealed a single band (ca. 2.5 Kb) which appeared to be maximally induced in operated nuclei at 24 hours following axotomy, as compared to controls. Preliminary results at 3 days post-lesion indicate that relative levels declined but remain elevated over time. The time course of hsp70 mRNA induction is consistent to that previously reported for constitutive hsp70 protein, where maximal protein levels were observed at 3 days post-axotomy and were maintained elevated thereafter. These results indicate that peripheral nerve lesion induces hsp70 mRNA. Further, these data suggest for a role of hsp70 in the early phase and long-term maintenance of the regeneration program of motoneurons.

617.17

LONG-TERM CHANGES IN HEMOPEXIN AFTER PERIPHERAL NERVE INJURY. J.P. Swerts, N. Madore, L. Camborieux, M. J. Guinaudy, J. Smith* and P. Cocharde. Centre de Biologie du Développement, U.M.R. 9925 C.N.R.S., Univ. P. Sabatier, Toulouse, 31062 cedex, France.

Analysis of molecular environments that allow nerve repair has revealed the presence of hemopexin in adult rat peripheral nerves and the dramatic increase in the level of this glycoprotein after nerve transection (Swerts et al., J. Biol. Chem., 267, 10596-10600). Although it is a soluble protein, hemopexin is colocalized in the nerve with extracellular matrix proteins. Moreover, hemopexin synthesis has been detected within the nerve itself; thus this plasma protein can no longer be considered as a liver-specific product. In the present study, we have documented long term changes in hemopexin levels in permanently degenerated (transected) and regenerating (crushed) sciatic nerves, using western-blotting and immunohistochemical techniques. In both transected and crushed nerves, there was a 6-fold increase in hemopexin content at day 2 post-injury and a 12-fold increase at day 7 in the distal part of the nerves, compared with contralateral intact nerves. Beyond the first week, the fate of hemopexin was very different in each type of lesioned nerves: in transected nerves the level of hemopexin kept increasing, reaching over 20 times the basal level three months after injury, whereas in crushed nerves, hemopexin level declined progressively in a proximo-distal direction, returning to basal values 2 months post-injury. These results suggest that hemopexin could be regulated negatively, directly or indirectly, by growing axons and support the idea that hemopexin could be involved in the process of Wallerian degeneration and/or in nerve repair.

617.14

BDNF LEVELS INCREASE IN THE TERMINAL MOTOR BRANCH FOLLOWING LESIONS OF THE PARENT FEMORAL NERVE: A COMPETITIVE PCR STUDY
 M.P.Rapoza, M.D.Aldous, S.J.Archibald, R.J.Rohwer, and R.D.Madison. Depts. of ¹Surgery (Neurosurgery), ²Neurobiology, Duke University Medical Center, and Research Services, ³VA Hosp., Durham, NC and ⁴VA Hosp., Baltimore, MD.

A 273 bp fragment of mature BDNF (nt 2573-2846) was amplified from rat muscle RNA and cloned into the pCRII vector (Invitrogen). An unrelated Hae III digested fragment of pCRII (~100 nts) was ligated into the Ssp I site within the BDNF fragment (at position 2665). This enlarged BDNF construct was verified by DNA sequencing and used to make sense riboprobe. Increasing concentrations of riboprobe were then used to spike reverse transcriptase reactions of total RNA harvested from: muscle, sciatic nerve, lesioned and non-lesioned terminal motor branch of the rat femoral nerve. The amount of radioactive label present in each band was determined by exposing the gel to a PhosphorImager. Total counts were then used to construct a standard curve relating concentration of spiked cRNA to target RNA. In previous studies using ribonuclease protection assays (Funakoshi et. al., J. Cell Biol., 1993, 123: 455-465) levels of BDNF were barely detectable in normal sciatic nerve. In our competitive PCR assays BDNF is easily detectable in normal sciatic nerve or normal motor branch of the femoral nerve, and is present in approximately 10-fold lower concentrations compared to muscle. The amount of BDNF in two-week lesioned nerve increases 10-30 fold in the motor branch of the femoral nerve (terminal branch to the quadriceps muscle) as compared to unlesioned nerve. Experiments are currently underway to determine BDNF levels in the other terminal branch of the femoral nerve which is purely sensory. Supported by NS22404-09 (RDM) and VA Merit Review (RDM).

617.16

EXPRESSION OF NITRIC OXIDE SYNTHASE (NOS) IN MOTOR NEURONS AFTER AXOTOMY. W.H.A. Yu¹ and R.M.W. Chau². ¹Dept. of Cell Biol. & Anat. Sci., City Univ. of New York Med. Sch., NY, NY 10031 and ²Dept. of Anat., Univ. of Hong Kong, Hong Kong.

NOS, an enzyme for the synthesis of nitric oxide, becomes detectable in anterior horn cells following ventral root avulsion, and in motor neurons of cranial nerves after nerve transection. Since anterior horn cells died after root avulsion, and inhibition of NOS reduced neuron death, it was postulated that NOS expression signals the impending death of injured cells. However, extensive neuron death occurred only when cranial nerves were cut at young age, and fewer cranial neurons expressed NOS after axotomy at young age when compared with axotomy at adults. We hypothesize that expression of NOS is one of cellular events involved in neuronal response to injury. In this study, we examined the time course of NOS expression in motor neurons of cranial nerves following axotomy. Adult, female rats received either unilateral crush or transection of the vagus and hypoglossal nerves. Animals were killed at 1 and 3 days, 1, 2, 4, and 6 wks post operation (PO). Thirty-micron thick coronal sections cut through the lower brain stem were processed for NADPH-diaphorase reaction for NOS. Changes of NADPH-diaphorase reaction were observed 3 days PO in the two motor nuclei ipsilateral to axotomy. In the vagus nucleus, increases in the number of NOS positive neurons and intensity of labelling persisted 6 wks PO. In the hypoglossal nucleus, the number of NOS neurons reached maximally 3 days and 2 wks, and declined 4 and 6 wks after crush and transection, respectively. These data suggest that NOS was expressed in cranial motor neurons in a time course which could be correlated with axon regeneration, consistent with the hypothesis that expression of NOS is involved in neuronal response to injury, possibly regulated by axon regeneration.

EXPRESSION OF BETA-ACTIN mRNA IN MOTONEURONS AFTER AXOTOMY. K.M. Correia, L.M. Lund, R.L. Ruff* and I.G. McQuarrie, VA Med. Ctr. and Case Western Res. Univ., Cleveland, OH 44106.

The peripheral neuron responds to axotomy by switching from translation of proteins needed for normal function (e.g. neurotransmitter synthesizing enzymes) to proteins needed for axonal outgrowth (e.g. actin and tubulin). At 1, 4, or 14 days after unilateral sciatic nerve crush (with contralateral sham crush), the L4/5 spinal cord was excised and hemisectioned. Northern blots of mRNA showed an increase in beta-actin mRNA at one day on the crush side compared to the sham side. The increase peaked at 4 days, and was returning to constitutive levels by 14 days. We have used *in situ* hybridization to further investigate beta-actin mRNA expression after axotomy. Riboprobes were synthesized using SP6 and digoxigenin labelled nucleotides and detected immunohistochemically. Motoneurons were retrogradely labelled with Fluoro-Ruby. Preliminary *in situ* data at 4 days showed larger, darker-stained motoneurons on the axotomized side. Increases in beta-actin mRNA after axotomy correlate with known increases in beta-actin synthesis and axonal transport.

AXOTOMY OF MOTOR NEURONS ELEVATES c-JUN AND JUN D LEVELS. L.W. Lund, L.A. Campbell and I.G. McQuarrie*, VA Medical Center and Case Western Reserve University, Cleveland, OH

Stimulation of quiescent cells has been found to cause an early increase in mRNAs encoding regulatory proteins. Jun proteins regulate transcription and mediate mitogenic signal transduction. One member of this family, Jun D, is refractory to many signals that induce c-Jun. We have found that axotomizing lesions of sciatic motor neurons increase c-Jun mRNA expression in a manner similar to that described for beta-actin. Jun D also was constitutively expressed and increased during axon outgrowth. Using the L4/L5 spinal cord region, mRNA was extracted for Northern blot analysis from rats receiving bilateral axotomies (vs. bilateral sham-lesions) or unilateral axotomy (vs. contralateral sham-lesion). The cord was hemisected after unilateral lesions. Lesions were made either 20-30mm or 60-70mm from the spinal cord. Jun D and c-Jun mRNA levels increased by 24 hours after bilateral sciatic nerve crush and peaked by 4 days. Unilateral axotomy caused similar increases. By 14 days, these mRNAs had returned to near-control levels. Immunostaining reflected these changes. Jun D can mediate differentiation through homodimers or heterodimers with c-Jun, c-Fos and CREB, is nontransforming, and is a negative regulator of fibroblast growth. We are interested in Jun D as a potential negative regulator of gene expression during axonal regeneration. Supported by grants to I.G.M. from the DVA.

Trk B IN RAT SPINAL MOTONEURONS AFTER SCIATIC NERVE LESION. L.A. Campbell* and I.G. McQuarrie*, VA Medical Center and Case Western Reserve Univ., Cleveland, OH 44106.

Neurotrophins act as trophic factors for specific cell groups in the nervous system during development and regeneration. Trk proto-oncogene receptors mediate these effects. Studies that localize trk B mRNAs in specific groups of neurons have been done using *in situ* hybridization. We have used a trk B polyclonal antibody for immunohistochemistry to localize trk B receptor protein in cerebellum, cerebral cortex, and spinal cord. To study effects of axotomy, we transected the L4/5 spinal nerves (with contralateral sham lesions), and retrogradely labelled motoneurons with Fluoro-Ruby. Immunohistochemistry was performed with a biotinylated secondary antibody conjugated with horseradish peroxidase, using a methyl green counterstain. Preliminary data at 4 days post-axotomy showed an increase in the number of trk B immunoreactive motor neurons on the axotomized side, consistent with the localization of fluorescence. This increase in trk B receptor protein above basal levels corresponds to known increases of its ligand, BDNF, in target tissues. (Supported by grants from the DVA).

TAURINE PRODUCTION FROM CYSTEINE IN CEREBRAL ASTROCYTE CULTURES EXPOSED TO HYPEROSMOLALITY. J.W. Beetsch* and J.E. Olson. Dept. Emerg. Med., Wright State Univ. Sch. of Med., Dayton, OH 45435.

Hyperosmotic conditions lead to elevated astrocyte taurine content as an adaptive mechanism to altered cell volume. To investigate the mechanisms underlying this increase in taurine content, ³⁵S-taurine production from ³⁵S-cysteine was measured in rat cerebral astrocytes grown in isoosmotic and hyperosmotic conditions.

Primary astrocyte cultures were prepared from 2-4 day-old rats. Culture medium was changed twice weekly. After 2 weeks, cultures were exposed to control medium (300 mOsm) or hyperosmotic medium (450 mOsm). After 1, 8, 24, or 48 hr, culture medium was removed and replaced with PBS containing ³⁵S-cysteine together with 1 mM unlabeled cysteine and sufficient NaCl to match the osmolality of the growth medium. 1 hr later, ³⁵S-taurine was extracted from the cells, isolated by HPLC, and quantified by radioactivity counting. Intracellular taurine content also was determined by HPLC.

Taurine production from cysteine decreased 38% after 1 hr exposure to hyperosmotic medium compared to control cultures. ³⁵S-taurine production recovered to a stable level within 24 hrs and remained constant at 48 hrs; however, ³⁵S-taurine production in hyperosmotically treated cultures was less than the production in control cultures at all time points measured.

Intracellular taurine concentration decreased in both control and hyperosmotic cultures 1 and 8 hrs after the medium change when compared to untreated cells. After 24 and 48 hrs in hyperosmotic medium cellular taurine concentrations were increased 70% and 24%, respectively compared to cultures grown in 300 mOsm medium.

Thus, hyperosmotic treatment of cerebral astrocyte cultures reduces the conversion of ³⁵S-cysteine to ³⁵S-taurine despite the elevated taurine content in these cultures. These data suggest that, while taurine content of the cultures is increased by prolonged exposure to hyperosmotic medium, exogenous cysteine does not contribute to the elevated intracellular levels of taurine. Supported by NIH (NS 23218).

SYNERGISTIC ACTIVATION OF AP-1 COMPLEXES BY ATP AND bFGF IN ASTROCYTES. J.T. Neary, O. Zhu, J.H. Bruce*, A.N. Moore*, and P.K. Dash*. Lab. Neuropathol., Research Service, VA Med. Ctr., *Dept. Neurobiol. & Anat., Univ. Texas, Houston, TX, and Dept. Pathol., Univ. Miami Sch. Med., Miami, FL 33125.

Reactive gliosis that occurs following CNS injury is characterized by hypertrophy and proliferation of astrocytes. ATP and bFGF, agents that are increased after brain injury, can act synergistically to stimulate gliotic-like responses in astrocytes. c-Jun and c-Fos are also increased in response to brain injury. Therefore, we hypothesized that ATP and bFGF may enhance the expression of these transcription factors. To test this hypothesis, we examined the effect of ATP and/or bFGF on the level of AP-1 complexes, heterodimers consisting of Fos and Jun families of transcription factors. Primary rat astrocyte cultures were treated with ATP (100 μ M), bFGF (25 ng/ml), or ATP + bFGF, nuclear extracts were prepared, and DNA binding activity was measured by a gel mobility-shift assay using a ³²P-labeled AP-1 consensus oligonucleotide. Binding to AP-1 was negligible in untreated cultures. After 1 hr of treatment with ATP or 3 hr treatment with bFGF, AP-1 binding was increased. Interestingly, a synergistic effect between ATP and bFGF was observed at 3 hr. The DNA-protein interaction was sequence-specific because the shifted bands were markedly reduced when excess unlabeled AP-1 oligonucleotides were included in the binding assay. These results indicate that ATP and bFGF induce AP-1 complexes and suggest that c-Jun and c-Fos stimulate changes in gene expression that mediate the gliotic-like responses elicited by ATP and bFGF. (Supported by the Department of Veterans Affairs.)

618.2

DIFFERENTIAL EFFECTS OF BETA AND GAMMA INTERFERONS ON EXPRESSION OF MHC ANTIGENS AND ICAM-1 IN HUMAN ASTROCYTES IN CULTURE. J.-I. Satoh*, D.W. Paty and S.U. Kim. Div. of Neurology, Dept. of Medicine, Univ. of British Columbia, Vancouver, BC, Canada V6T 2B5.

Recent clinical trials have shown that recombinant human interferon beta (IFN- β) was effective in reducing exacerbations in relapsing-remitting multiple sclerosis (MS), while interferon gamma (IFN- γ) increased the frequency of relapses (Neurology 37:1097, 1987 & 43:655, 1993). To investigate mechanisms underlying the immunomodulatory effects of IFN- β and IFN- γ in MS, interferon-induced expression of class I/II major histocompatibility complex (MHC) antigens and intercellular adhesion molecule-1 (ICAM-1) was investigated in cultured fetal human astrocytes by flow cytometry and immunocytochemistry.

Under the basal condition, class I antigen and ICAM-1 were expressed in moderate numbers (23-76%) of astrocytes, whereas class II MHC antigen was expressed only in small numbers (0.3-8%). Following a 72-hour treatment with IFN- γ (10-100 U/ml), expression of all three antigens was increased greatly. However, IFN- β (10-100 IU/ml) did not induce significantly expression of class II MHC antigen or ICAM-1, while expression of class I MHC antigen was elevated. Furthermore, IFN- β significantly reduced IFN- γ -induced expression of class II MHC antigen but not of class I MHC antigen or of ICAM-1. The differential effects of IFN- β and IFN- γ on expression of class I/II MHC antigen and ICAM-1 in human astrocytes suggest that interferons act as modulators of astrocyte function in inflammatory demyelinating lesions of MS.

618.4

CYTOKINE PRODUCTION BY HUMAN ASTROCYTES. J. N. Stewart, Nalbantoglu, H. Durham* and J.P. Antel. McGill University and Montreal Neurological Institute, Montreal, PQ, Canada.

Pro- and anti-inflammatory cytokine production by astrocytes and microglia in the central nervous system (CNS) may modulate the immune response in this compartment in pathological conditions. Tumor necrosis factor (TNF) has been detected by immunocytochemical techniques in inflammatory CNS disease. TNF and IL-6 mRNA have been variably observed by Northern blotting and *in situ* hybridization in primary cultures of fetal human astrocytes maintained under basal conditions or following stimulation with IL-1, LPS or IFN- γ (Lee et al, 1993; Sebire et al, 1993; Aloisi et al, 1993). *In situ* hybridization is particularly applicable to the study of adult human astrocytes which can only be obtained in mixed cultures containing microglia. Using ³⁵S-labelled riboprobes we detected TNF and IL-6 mRNA in fetal bovine serum-containing cultures of fetal (15-20 weeks of gestation) astrocytes under basal conditions and after stimulation with LPS and IFN- γ . Signal was also detected in smears of immediately ex vivo fetal CNS tissue. In contrast to cultured fetal astrocytes, IL-6 and TNF mRNA could only be detected in a proportion of adult astrocytes under basal conditions. This proportion increased after stimulation with lipopolysaccharide and IFN- γ . Both cytokines were detected in all of the microglia in these cultures under both basal and activating conditions.

NOVEL INHIBITORS OF ASTROCYTE GLUTAMINE SYNTHETASE. K.J. Farrell,* D.K. Willis,¹ and R.A. Swanson. Dept. of Neurology, Univ. of California and VAMC, San Francisco, CA 94121, and ¹USDA/ARS, Dept. of Plant Pathology, Univ. of Wisconsin Madison

Glutamine synthetase is found in glia but not neurons. L-methionine-D,L-sulfoximine (MSO) has proven useful in the study of glial functions as an inhibitor of glutamine synthetase. However, MSO has many other effects that may be unrelated to this action. This study identified alternative compounds that can inhibit glial glutamine synthetase. Inhibition of free enzyme prepared from sheep brain (Sigma) was determined by the method of Meister. Inhibition in primary rat cortical astrocyte cultures was also assessed using a 3 hour incubation of intact cultures with these compounds, followed by washing and lysing of the cells.

Compound	IC ₅₀ (free enzyme)	IC ₅₀ (astrocyte cultures)
methionine sulfoximine	91 ± 6.1 μM	13.1 ± 18.1 μM
glufosinate	10 ± 2.9	0.007 ± 0.003
phosalone	> 2000	7.0 ± 0.88
tabtoxin lactame	400 ± 65	0.3 ± 0.032
4-N-diaminobutyric acid	212 ± 2	> 2000
oxetlin	1500 ± 250	> 2000

Inhibitor concentrations of up to 2mM did not cause astrocyte death, as assessed by lactate dehydrogenase activity of the cultures 24 hours post-incubation. Previous work with MSO has suggested a link between astrocyte glutamine and glycogen metabolism. The effect of the novel inhibitors on astrocyte glycogen accumulation was assessed by the fluorometric method of Passonneau and Lowry. Each of the agents that inhibit astrocyte glutamine synthetase were also found to increase glycogen accumulation, suggesting a causal relationship. These agents may be useful alternatives to MSO for the study of glial functions.

618.7

IDENTIFICATION OF VOLUME-SENSITIVE ORGANIC OSMOLYTE CHANNELS IN HUMAN GLIAL CELLS.

P.S. Jackson,* K. Strange, and J.R. Madsen. Depts. Neurosurgery and Medicine, Children's Hospital; Program in Neuroscience, Harvard Medical School, Boston, MA, 02115.

Regulation of cellular volume is a fundamental process critical to the survival of all cells, particularly in the central nervous system where even minor volume changes can cause severe neurological damage. Over the past several years much has been learned about the basic biology of cell volume control. It has become clear that organic osmolytes such as taurine and myo-inositol play a central role in brain volume homeostasis. During periods of cellular swelling these solutes are lost from cells through a shared transport pathway which is now known to be a relatively non-selective Volume Sensitive Organic osmolyte / Anion Channel (VSOAC; Jackson and Strange, *Am. J. Physiol.*, 465:C1489-1500, 1993). This channel requires non-hydrolytic binding of cytoplasmic ATP in order to activate in response to cell swelling. VSOAC has not been previously demonstrated in human glial cells. We report here that the channel is present in primary cultures of human cortical astrocytes and astrocytic tumors. VSOAC was activated by swelling in cells from four different patients suggesting that this channel is a consistent feature of human cortical astrocytes. The channel is outwardly rectified and inactivated at membrane potentials more positive than +60mV. Single channel measurements demonstrated a ~40 pS channel with inactivation kinetics analogous to those seen in whole cell data. These characteristics are effectively identical to those observed in model systems such as rat C6 glioma cells. Clinically available drugs (e.g., ketoconazole, clotrimazole) are capable of blocking VSOAC. Development of drugs that open or enhance the activity of this channel may provide new strategies to reduce cerebral edema and cellular swelling during brain injury and ischemia.

EXPRESSION AND CHARACTERIZATION OF ATP- AND 5'-NUCLEOTIDE-RECEPTOR(S) IN XENOPUS OOCYTES INJECTED WITH poly(A⁺) mRNA FROM RAT CORTICAL ASTROCYTES. B.F. King, ²J.T. Neary*, ²Q. Zhu, ²M.D. Norenberg, S. Wang and G. Burnstock. Dept. Anatomy & Devel. Biol., University College London, WC1E 6BT, UK, and ²VA Medical Center, Dept. Pathology, Univ. Miami, FL 33125, USA.

Burnstock, Barnard and colleagues (*FEBS Lett.*, 324, 219-225, 1993; *TIPS*, 15, 67-70, 1994) have reported cloning a G-protein coupled ATP-receptor from central neurons that has been designated a P₂_{U1}-purinoceptor (with 2-methylthio-ATP>ATP>ADP, but UTP inactive). As a corollary to the study of neuronal purinoceptors, we have investigated ATP receptors on astroglial cells. Astrocytes were harvested from rat neonatal cortices and grown to confluence on culture dishes for 21-28 days. Total RNA was extracted from primary cultures using the Guanidium method and poly(A⁺) mRNA purified with biotinylated oligo(dT) and streptavidin-coated magnetic particles. *Xenopus* oocytes (stages V/VI) were injected with mRNA (50ng) and incubated in Barth's solution for 48h at 18°C. Under voltage clamp conditions, injected oocytes responded to ATP (10⁻⁸ to 10⁻³M) with biphasic inward currents that reversed at -20mV, i.e. close to E_{CL}. Evoked inward currents were unaffected by the P₁-receptor antagonist, sulphonylthiophylline (10⁻³M), but were reduced (by 80%) by the P₂-receptor antagonist, suramin (10⁻⁴M). Expressed P₂-purinoceptors were activated equally by 2-methylthioATP and 2-chloro-ATP which were slightly more potent than ATP and ADP, α,β-methyleneATP was weakly active and adenosine inactive. However, UTP also evoked biphasic inward currents and was as potent as ATP and 2-methylthioATP; both CTP and ITP were weakly active. The results suggested either i) expressed P₂_{U1}-purinoceptors were pharmacologically atypical or ii) heterologous mRNA expressed P₂_{U1} and P₂_{U2}-purinoceptors equally. The possible combination of one or two metabotropic P₂-purinoceptors on astrocytes pharmacologically distinct from the neuronal P₂_{U1}-subtype indicates important differences in purinergic signalling at glial cells and central neurons. Supported by The Wellcome Trust and Department of Veterans Affairs.

INHIBITION OF PROTEIN SYNTHESIS PREVENTS INTERLEUKIN 1α (IL1)-INDUCED INCREASES IN PROSTAGLANDIN (PG) PRODUCTION IN OVINE ASTROGLIA. C. Thore*, M. Nam, and D. Busija. Dept. of Physiology & Pharmacology, Bowman Gray Sch. of Med., Winston-Salem, NC 27157-1083.

Little is known concerning actions and mechanisms of cytokines on prostaglandin production in astroglia. The purpose of this study was to examine short term (1-4 hour) effects of IL1 on PG production in astroglia cultured from fetal sheep. We tested the hypothesis that increased PG production is dependent upon continued or enhanced protein synthesis. Immuno-identified astroglia from second passage fetal ovine cortex were grown to confluence in 12-well (22mm) plates. PGF_{2α} levels in medium were determined using enzyme immunoassay. Cells were exposed to 10 ng/ml IL1 in medium or to medium alone. Application of IL1 did not increase PGF_{2α} levels at 1 hour but augmented the production of PGF_{2α} from 1588 ± 303 to 2868 ± 393 pg/ml at 2 hours (n=29; p<0.05) and from 1356 ± 369 to 5426 ± 1571 pg/ml at 4 hours (n=20; p<0.05). Coapplication of an inhibitor of prostaglandin H synthase (indomethacin, 10 μg/ml; n=8) or of phospholipase A₂ (quinacrine, 10⁻⁶M; n=8) prevented increases in PGF_{2α} production, as did H-7 (10⁻⁶M; n=5), an inhibitor of protein kinase C. Further, coincubation of IL1 with actinomycin D (1 μg/ml; n=9), a RNA synthesis inhibitor or cycloheximide (10 μg/ml; n=9), an inhibitor of protein synthesis, completely blocked the increase in PGF_{2α}. We conclude that IL1 increases PGF_{2α} production in ovine astroglia via a mechanism involving several steps, including activation of protein kinase C and phospholipase A₂, and continued or enhanced protein synthesis. CHARACTERIZATION OF VIP-INDUCED PROTEINS AND mRNA IN MOUSE ASTROCYTES BY 2-D GEL ELECTROPHORESIS AND BY mRNA DIFFERENTIAL DISPLAY (DD).

P.J. Magistretti¹, G. Pellegrini¹, C.L. Bolis²* and J.-R. Cardinaux¹. ¹Institut de Physiologie, Université de Lausanne, Lausanne, Switzerland. ²Department of Biology, University of Milan, Italy.

In primary cultures of mouse cerebral cortical astrocytes, a rapid glycogenolysis followed by a massive glycogen resynthesis (six- to ten-fold over basal levels after 9 hr) are induced by vasoactive intestinal peptide (VIP) or noradrenaline (NA). Both actions of the neurotransmitters are mediated by cAMP. Since the induction of glycogen resynthesis triggered by VIP or NA is abolished by inhibition of transcription and translation, we applied the 2-D gel electrophoresis and the mRNA DD techniques to search for newly synthesized astrocytic gene products induced by VIP or NA. The comparison of ³⁵S-labeled proteins from primary astrocyte cultures treated or not with VIP 1 μM or NA 100 μM reveals 8 proteins in which labeling is increased after the treatment. We focused our attention on a 23 kDa protein (pI=5.8) which seemed abundant enough for purification and microsequencing. The effect of NA is mimicked by isoproterenol, whereas methoxamine, an α₁-agonist, is inactive, thus suggesting that the induction of this protein is mediated by adrenergic receptors of the β-subtype. As a complementary approach, the identification of VIP- and NA-modulated genes has been carried out by the technique of DD (Liang and Pardee 1992, *Science* 257:967). Using this technique we have observed several differences between the patterns of amplified mRNAs from untreated cultures and from cultures exposed to VIP 1 μM or NA 100 μM. cDNA fragments differentially expressed in astrocytes can be isolated from the gel and cloned into vectors. We are presently verifying by Northern blot that astrocytes treated with VIP or NA express higher levels of the mRNAs identified by DD.

AMMONIA ENHANCES INHIBITORY EFFECTS OF BENZODIAZEPINES AND NEUROSTEROIDS ON K⁺ INFLUX IN ASTROCYTES. A.S. Bender* and M.D. Norenberg. Lab. of Neuropathology, Univ. of Miami Sch. of Med. & Vet. Adm. Med. Ctr., Miami, FL 33101.

Levels of ammonia and endogenous benzodiazepines (BZDs) (eg. DBI) are increased in hepatic encephalopathy (HE). Since astrocytes are involved in HE, and since K⁺ uptake in astrocytes plays a major role in CNS K⁺ homeostasis, we examined the effects of BZDs, as well as various neurosteroids (products of peripheral-type BZD receptor activation) on K⁺ uptake. Rat astrocytes in primary culture were incubated with 2 μCi/ml of ⁸⁶RbCl (analog of K⁺) for 1 hr in the presence of BZDs and neurosteroids with or without 5 mM NH₄Cl. Ammonia alone inhibited K⁺ uptake by 26%. Agents that interact with the peripheral-type BZD receptor (eg., Ro5-4864 and PK 11195 at 30 μM) inhibited K⁺ uptake by ~25%, whereas agents that interact with central-type BZD receptor (clonazepam and flumazenil at 30 μM) did not affect K⁺ uptake. The effect of Ro5-4864 on K⁺ uptake was significantly enhanced in the presence of 5 mM ammonia (55% inhibition). Pregnenolone sulfate (50 μM) and 5α-pregnane-3α,21-diol-20-one (5α-THDOC; 30 μM) inhibited K⁺ uptake by 30 and 20%, respectively. The effects of neurosteroids were enhanced in the presence of ammonia (41-50% inhibition). Thus, agents involved in HE are able to affect astrocyte K⁺ homeostasis which may result in altered CNS excitability. (Supported by the Veterans Administration and USPHS grants AM-38153 and NS-30291, and GRECC)

EFFECTS OF AMMONIA AND BENZODIAZEPINES ON ADENOSINE UPTAKE IN ASTROCYTES. R.S. Dombro*, A.S. Bender, and M.D. Norenberg. Lab. of Neuropathology, Univ. of Miami Sch. of Med. & Vet. Adm. Med. Ctr., Miami, FL 33101.

The mechanism of neuroinhibition in hepatic encephalopathy (HE) is not known. Benzodiazepines (BZDs) are elevated in HE and are known to reduce the uptake of adenosine, an inhibitory neuromodulator. This study was undertaken to determine whether agents acting on peripheral and central BZD receptors, products of peripheral BZD receptor activation (neurosteroids), as well as ammonia (elevated in HE), affect adenosine uptake. Rat astrocytes in primary culture were incubated with 1 μ M [3 H]-adenosine (0.2 μ Ci/ml) for 30 min in the presence or absence of the ammonia, BZDs and neurosteroids. Adenosine uptake was inhibited by 9% in the presence of 5 mM NH_4Cl ; however, 2-3 days of prior treatment with ammonia resulted in a 20-25% decrease in adenosine uptake. Agents that interact with the peripheral (Ro 5-4864 and PK 11195) and central (clonazepam and flumazenil) BZD receptors at 10 μ M, reduced adenosine uptake by ~50%. Endogenous BZDs, DBI (40 μ M) and ODN (10 μ M), inhibited adenosine uptake by ~14%. Pregnenolone sulfate (10 μ M) and 5 α -pregnane-3 α ,21-diol-20-one (5 α -THDOC; 50 μ M) also decreased adenosine uptake by 20 and 60%, respectively. Suppression of adenosine uptake by ammonia, BZDs and neurosteroids may contribute to the neuroinhibition in HE. (Supported by the Veterans Administration and USPHS grants AM-38153 and NS-30291, and GRECC)

EVIDENCE OF A LOCALIZED ABLATION OF ASTROCYTES BY INTRACEREBRAL INJECTION OF L- α -AMINOADIPATE. M. Khurgel* and G.O. Ivy. Dept. Anatomy & Cell Biology, Univ. of Toronto, Scarborough Campus, West Hill, Ont., M1C 1A4, Canada.

L- α -aminoadipate (LAA) has been proposed to be an astrocyte-specific toxin. However, the *in situ* effectiveness of this compound has not been conclusively demonstrated for adult animals. We have studied the consequences of intracerebral injections of LAA as part of our on-going inquiry into neuron-glia interactions. Adult (7 months old, 570-610 g) Long Evans hooded rats were stereotactically injected with 5 μ l of artificial cerebrospinal fluid (ACSF) or LAA (Sigma, 20 μ g/ μ l in ACSF) into basomedial amygdala/piriform cortex area. The animals were sacrificed by intracardial perfusion 48 hr following the injections. Frozen brain sections were processed for immunohistochemistry with anti-GFAP and anti-vimentin to evaluate the response of astrocytes, as well as lectin histochemistry to visualize microglia. Alternate sections were counter-stained with cresyl violet. The levels of GFAP and vimentin immunoreactivity, the morphology and distribution of astrocytes and microglia, and the density of neurons in the area of injection were compared between the LAA and ACSF rats, and surgical controls. Injections of ACSF resulted in stab wound-like pattern of morphological changes, with neuronal loss and reactive microglia confined to the needle track, and activated astrocytes within 100 μ m on either side of it. In contrast, injections of LAA resulted in a 400-800 μ m wide space devoid of GFAP-positive astrocytes, but filled with vimentin-positive cellular debris. The selective nature of the lesion was supported by the presence of activated microglia and a normal density of neurons. We conclude that LAA is an effective astroglial toxin and that this compound may be useful for addressing the functional significance of astrocytes in mammalian brain.

ELECTROPHYSIOLOGICAL AND FUNCTIONAL PROPERTIES OF *IN VITRO* BLOOD-BRAIN BARRIER CELLS. K.A. Stanness, H.R. Winn and D. Janigro. Dept. of Neurosurgery, University of Washington, Seattle, WA 98104

Brain microvascular endothelial cells are the site of the anatomical blood-brain barrier (BBB), but astrocytes (AC) interacting with non-brain endothelium (EC) can induce BBB properties. We have established a dynamic cell culture system that allows co-culturing of AC and rat brain microvascular EC (RBMEC) in a hollow fiber artificial capillary system. Bovine aortic (BAEC) or RBMEC loaded together with either C6 rat glioma or rat astrocytes formed a permeability barrier to macromolecules and membrane-impermeant dyes (HRP and Evans blue) after two weeks in culture. In addition, after replating under two dimensional tissue culture conditions, BAEC cell displayed electrophysiological properties normally found in RBMEC. In fact, ATP (1-10 μ M) caused activation of K⁺ currents in native BAEC, while after exposure to either C6 or AC, BAEC responded to ATP with activation of an inward current carried in part by Ca²⁺, a property characteristic of RBMEC. During patch clamp experiments, cells were identified based on their uptake of Ac-LDL (EC) or for GFAP positivity (AC and C6). The latter was determined on living cells permeabilized with streptolysin-O and incubated with anti-GFAP sera. GFAP-negative cells were positive for the microglial marker OX-42. We conclude that 1) co-culturing of EC and glial cells in the artificial capillary system leads to the development of barrier properties in EC 2) the cells harvested from the cartridge retain their BBB properties and can be replated in a two dimensional culture amenable for patch clamping 3) the electrophysiological properties of BAEC are altered after co-culture with AC, providing additional evidence that BBB properties can be induced by exposing non-brain EC to glial cells. Supported by NS 51614, NS30305, NS21076 and NS07144.

REVERSIBLE, *IN VIVO*, CHANGES IN ASTROCYTE MORPHOLOGY. J.B. Bobak* and A.K. Salm. Department of Anatomy, West Virginia University, Morgantown, WV, 26505

Rearrangement of astrocyte processes has been suggested to participate in CNS plasticity, for example, by influencing synapse formation or neuronal subgroupings. However, little direct evidence for such morphological changes *in vivo* has been reported. The supraoptic nucleus, which displays much plasticity, was stimulated in adult male rats by replacing drinking water with 2% saline for 2 (n=5) or 9 (n=5) days. Control (n=4) animals received free access to tap water. A rehydrated group (n=5) was given 2% saline for 9 days, then returned to tap water for 9 days. Animals were sacrificed and their brain tissue was processed for electron microscopy. Electron micrograph montages of astrocytes (3.887X) in the ventral glial limitans (VGL) and dendritic zone subjacent to the supraoptic nucleus were constructed and judged, without knowledge of grouping, as to the orientation of perinuclear cytoplasm and/or thick processes. Astrocytes in control animals were found to exhibit cytoplasm oriented mostly vertical and perpendicular to the pial surface. With dehydration, a significant reorientation ($p < .02$) of astrocyte cytoplasm to a horizontal direction, parallel to the pial surface, occurred. The changes in the vertically oriented processes were only observed in those directed ventrally towards the pial surface ($P < .01$). Within individual animals, a highly significant inverse correlation ($r = .93$, $p < .001$) was found between the proportion of cells displaying vertical vs. horizontal orientations. Upon rehydration the astrocytes in the VGL returned to a vertical orientation. From these data we conclude that astrocytes *in vivo* are capable of reversibly changing their morphology. ASTROCYTE-SPECIFIC EXPRESSION OF CD44 IN RAT BRAIN CULTURES. N.R. Bhat*, P.S. Zhang and E.L. Hogan. Neurology, Medical University of SC, Charleston, SC 29425

CD44 is a transmembrane glycoprotein that serves as an adhesion molecule in cell interactions, migration and metastasis. Although originally identified in lymphocytes as a homing receptor, CD44 variants have been found in a variety of cell types and tissues including brain. This study examines the expression of CD44 in primary cultures of developing rat brain. Immunocytochemical studies using anti-CD44 antibodies indicated the paucity of expression of this antigen in neuron-enriched cultures. Type-1 astrocytes in primary glial cultures on the other hand displayed a rather high level of expression of CD44, the immunoreactive material being present on an extensive array of thin processes. Oligodendrocytes developing in the same cultures however did not express detectable level of the antigen. In order to examine the expression of the molecule in O-2A lineage cells, the glial progenitors developing in mixed glial cultures were isolated and grown either in the presence of 10% FCS which allows type-2 astrocytic differentiation or under serum-free conditions to promote oligodendrocytic differentiation. Neither O-2A progenitors nor oligodendrocytes contained appreciable level of CD44. Type-2 astrocytes in contrast stained intensely; the staining was more extensive than that of GFAP. The differential cellular distribution of CD44 was confirmed by immunoblot analysis of the cell extracts. The results of this study indicate an astrocyte specific expression of a CD44 variant in the developing brain. Supported by NMS Society RG-2474 and RG-2481.

ACTIVATION OF POTASSIUM CHANNELS BY GLUCOSE WITHDRAWAL IN CULTURED MICROGLIA. W. Walz* and K. Datta. Dept. of Physiology, Coll. Med., Univ. of Saskatchewan, Saskatoon, S7N 0W0, Canada.

The reaction of microglia to ischemic insults is neither well studied nor well understood. First reports show that microglia are an extremely sensitive indicator of subtle and morphological nonapparent neuronal damage during early stages of ischemic injury. We investigated the question if energy deprivation has a direct effect on physiological properties of cultured mouse microglia. We used the patch clamp technique to record the whole-cell current and the membrane potential. The cells were MAC-1 positive and exhibited the inward rectifier K⁺ channel in addition to a K⁺ outward current. Glucose withdrawal resulted in the activation of a transient K⁺ inward current (130 pA), which is barium-sensitive and has a reversal potential of -65 mV. Within min the transient current disappeared and there was a decrease in the resting conductance to 44%. The membrane depolarized from -76 to -38 mV. If glucose was withdrawn in the presence of antimycin A (a blocker of oxidative metabolism) there was no transient current activation, but a decrease of the conductance to 16%. The membrane depolarized from -90 to -38 mV. It appears that glucose withdrawal alone activates an inward rectifying K⁺ channel, whereas total block of ATP production leads to a general shutdown of ion channels, with both situations leading to a large depolarization. The results suggest that microglial ion channels are directly affected by ischemic conditions and might play a role in the cell's sensitivity in early stages of ischemia.

DIFFERENTIAL INDUCTION OF NITRIC OXIDE SYNTHETASE IN PRIMARY RAT MICROGLIAL VERSUS ASTROCYTE CULTURES. L.A. Radow, T. Ryan, D. Reif and J. Blosser.* Dept. of Biology, Fisons Pharmaceuticals, Rochester, N.Y. 14623.

In culture, microglia and astrocytes can express the inducible Type II form of nitric oxide synthase (NOS). It has been suggested that glia may contribute to neuronal damage associated with cerebral ischemia and/or other neurodegenerative diseases by generating nitric oxide (NO) (Proc. Natl. Acad. Sci. 98:10945-10949;1992) via this enzyme. Since microglia and astrocytes represent two distinct populations in the brain, we investigated conditions under which these cell types maximally expressed Type II NOS and produced NO. Primary cultures of neonatal rat microglia and astrocytes were prepared (J. Neurosci. 6(8):2263-2178; 1986) and harvested after 7 days in culture. The purity of each cell population was determined using specific fluorescent probes; acetylated low-density lipoprotein for microglia and anti-GFAP for astrocytes. Microglia and astrocyte cultures were exposed to a variety of stimuli, including bacterial lipopolysaccharide (LPS), gamma interferon, tumor necrosis factor α , IL-1B or a combination of these factors. The cultures were assayed for NOS activity by measuring nitrite levels and the production of L-[³H]citrulline from L-[³H]arginine. Increases in Type II NOS mRNA and not other mRNA from other NOS isozymes showed that the observed increases in NO upon treatment were due to transcriptional upregulation of the Type II NOS gene. Quantitative differences in NOS activity was noted when both cell types responded to identical stimuli. However, microglial cultures did not respond to concentrations of LPS alone that were stimulatory for the astrocytes. These results suggest that *in vivo* microglia and astroglia NOS activation may be regulated differentially under different physiological or pathologic conditions.

EVIDENCE FOR THE PROLIFERATION OF MICROGLIA AFTER EXCITOTOXIC INJURY OF ADULT BRAIN. E. Welter*, S. Collins, J.R. Fredieu, and D.M.D. Landis. Dept. Neurology, Case Western Reserve University, Cleveland, OH 44106.

When adult mammalian brain is injured, there is a complex response of non-neuronal cells which includes cell proliferation generating astrocytes in the affected region. We are using the technique of retrovirus-mediated gene transfer to identify the lineage and characteristics of cells proliferating after injury.

Kainic acid was injected into the rat caudatoputamen to kill neurons, and 48 hours later LZ1 BAG virus was injected at the same site, to infect proliferating cells and transfer the reporter gene β -galactosidase. We have used immunocytochemical detection of β -galactosidase immunoreactivity to detect proliferating cells in the tissue at various intervals after the injection of virus. This approach circumvents the technical problem that cytochemical demonstration of β -galactosidase activity may obscure immunoreactivity detected with immunofluorescence methods.

Forty eight hours after viral injection, most of the β -galactosidase-immunoreactive cells lacked GFAP immunoreactivity. In many instances, the shape of cells with β -galactosidase immunoreactivity was similar to that of cells expressing OX-42 immunoreactivity, a marker of microglia. We are now examining the β -galactosidase-immunoreactive cells for the presence of microglial and macrophage cell markers such as OX42 and ED1 at several survival intervals after injection of the retrovirus.

REGULATION OF EXPRESSION OF MHC CLASS II ANTIGENS IN RAT ASTROCYTES AND MICROGLIA. R. P. Hellendall* and J. Ting. Lineberger Comp. Cancer Ctr., Univ. North Carolina, Chapel Hill, NC 27599.

We are studying factors regulating the expression of major histocompatibility complex (MHC) class II (Ia) antigens on rat astrocytes and microglia to better understand the role of these immune-related molecules in various non-neuronal cells in the CNS. The function of MHC class II expression in the brain is poorly understood; the induction of these molecules during a number of neurodegenerative diseases indicates a possible role in the progression of pathology. Astrocytes and microglia were isolated from neonatal rat pups and stained for surface expression of Ia or transfected with a plasmid construct containing the human MHC class II promoter (HLA-DR α) driving a chloramphenicol acetyltransferase (CAT) gene (astrocytes only) to examine promoter function. Cells were treated with interferon- γ (IFN- γ), a known inducer of class II expression, in combination with a number of effectors of intracellular signaling pathways. Preliminary data indicate induction of surface expression on astrocytes by IFN- γ can be inhibited by blocking protein kinase C activity. PKC inhibition also resulted in a reduction in microglial class II surface signal although expression remained above background. Our findings also show that selective inhibition of protein tyrosine kinase fails to inhibit IFN- γ driven class II expression in either cell phenotype. Parallel experiments with transfected cells produced similar patterns of expression from the human promoter. This work suggests MHC class II expression on astrocytes and microglia may be under similar regulatory control through PKC and some tyrosine kinases but may differ in their sensitivity to external stimuli.

ION CHANNELS AND OXYGEN RADICAL PRODUCTION IN ACTIVATED MICROGLIA. B.A. Ballyk*, D.J. Phipps, P.S. Pennefather and L.C. Schlichter. Playfair Neurosciences Unit, Toronto Western Hospital, Toronto, Canada, M5T 2S8.

The objective of the present study was to characterize ion channel expression in activated microglia and their ability to release oxygen radicals.

Primary mixed cultures from the brains of newborn Wistar rats were starved to eliminate neurons and then shaken to isolate microglia, which were plated either in 96-well plates for functional assays or on glass coverslips for patch-clamp recording. Cultures which received conditioned media containing colony stimulating factor 1 (CSF-1) showed marked proliferation, as measured by ³H-thymidine incorporation. Microglial cultures were judged to be >98% pure by staining with isolectin B₄.

Whole cell recordings showed that activated microglia expressed at least three ionic currents: an inward-rectifier K⁺ current blocked by external Ba²⁺, a delayed-rectifier K⁺ current with several features of the cloned K_v1.3 channel, including block by charybdotoxin and margatoxin, and a Cl⁻ current blocked by flufenamic acid.

In functional assays, microglia activated with opsonized zymosan produced superoxide and nitric oxide, as measured by reduction of cytochrome C and Griess reagent, respectively.

We are now using ion channel blockers in functional assays to determine what roles these channels play in the physiology of microglia.

DIFFERENTIAL EXPRESSION OF DNA CLONES CODING FOR INHERITED "HIGH" OR "LOW" HUMAN CATECHOL-O-METHYLTRANSFERASE (COMT). M.H. Grossman*, R. Weinstein and J.B. Littrell. Dept. of Pediatrics, Temple Univ. Schl. of Med., St. Christopher's Hosp. for Children, Phila., PA 19134.

Inherited variations of human catechol-O-methyltransferase (COMT) activity levels are controlled at a two allele, autosomal locus. The "low" activity enzyme is also relatively thermolabile, compared to the "high" activity form. A single nucleotide change at position #472 resulting in an adenosine in L/L individuals and a guanosine in most H/H individuals has been identified. PCR-amplified coding regions from L/L and H/H specimens were subcloned into the pGEM-3Z vector and protein was expressed using the TnT lysate coupled transcription/translation system (Promega). ³⁵S-methionine-labelled expressed proteins were analyzed by SDS-PAGE followed by autoradiography. Two major protein bands of 25.5 and 29 kd, observed in each lane corresponded to soluble and membrane-bound forms of the COMT enzyme. SDS-PAGE analysis of lysate proteins, following immunoprecipitation with antisera to soluble COMT enzyme, revealed that the relative intensities of radioactive bands from the H/H specimen were greater than those from the L/L specimen. Scanning densitometry indicated that the relative amount of radioactive immunoprecipitable protein in the 25.5 kd band from the H/H specimen was 2.3 times greater than the corresponding band from the L/L specimen. This is in excellent agreement with measured liver COMT activity levels in these two specimens. These findings are supported by results on Western blots of human liver homogenates from individuals with inherited L/L and H/H genotypes. These studies provide good evidence that the single base change in the COMT coding region influences regulation of expression of the human COMT gene either at the level of transcription, translation or degradation of protein.

MAPPING THE ACHIASMATIC MUTATION IN THE DOG: A PROGRESS REPORT. Qing Tang*, Robert W. Williams, Dan Goldowitz. Department of Anatomy & Neurobiology U.T. Memphis, 875 Monroe Ave., Memphis, TN 38163.

We have characterized a mutation in Belgian sheepdog that disrupts the formation of the optic chiasm (Williams et al, 1994). The pattern of inheritance over 6 generations indicates that the mutant allele is autosomal recessive (symbol NOX, no optic chiasm). To identify NOX we have taken complementary approaches. **Candidate gene approach:** Several mutations at the tyrosinase gene locus (TYR) are known to perturb ganglion cell projections at the chiasm. We have used primers derived from conserved sequences of human and mouse TYR to clone exon 1 of dog homolog through use of the polymerase chain reaction. The relationship between TYR and NOX will be determined through sequence comparison and linkage analysis. **Chromosome mapping:** We have begun to map canine genes that are linked on mouse chromosome 7 over a 25 cM interval. This interval, located between the *p* locus and the calcitonin gene, contains several loci that play key roles in brain development and pigmentation, including the TYR locus. To define the linkage group(s) in the dog, we outcrossed a mutant Belgian to a Siberian Husky, having first determined that the two breeds are genetically heterogeneous by using random amplified polymorphic DNA (RAPD) markers (Goldowitz et al, in progress). The F1 progeny were backcrossed to mutant Belgians. DNAs from the backcross offspring are being typed using several forms of markers, including restriction fragment length polymorphism, polymorphic microsatellites, and RAPD. This will allow us to begin constructing a molecular linkage map of the dog genome. We are also screening a dog genomic library to obtain probes that will be used to assign chromosomal position amongst linked loci via fluorescence *in situ* hybridization. Support: NEI RO1-9586

SOMATIC GENE TRANSFER IN THE ADULT CENTRAL NERVOUS SYSTEM: PRACTICAL AND THEORETICAL ISSUES. N.H. Liou, L.J. Fisher, J. Ray, S.T. Suhr, S. Thode, A. L. Miller* and F. H. Gage. Department of Neurosciences, University of California-San Diego, La Jolla, CA 92093-0627.

Somatic gene transfer has been extensively investigated using genetically modified primary fibroblasts as grafts for intracerebral transplantation in our laboratory. We used defined retroviral vector to investigate gene expression and regulation in the adult central nervous system (CNS) on a molecular and cellular basis. Our data suggest that expression from retroviral promoters/enhancers decreases with the onset of quiescence *in vitro* and in grafted fibroblasts *in vivo*. When genetically modified fibroblasts are implanted into the host CNS, the lack of tumor formation indicates that the cells reside in a quiescent status within the grafting area. As a consequence, it is necessary to enhance the capacity of engineered fibroblasts to express transgene products in a quiescent state, and the objective of this project is to examine strategies of achieving long-term stable and/or regulatable transgene expression in primary fibroblasts *in vitro* and following implantation into the adult rat CNS. To achieve this goal we use several strategies: 1) The effect of different viral, tissue-specific and housekeeping promoter/enhancer configurations in retroviral constructs is analyzed in growing and confluent cells *in vitro*. Fibroblast cultures in different serum levels have been established that may mimic conditions in the *in vivo* grafts. The effect of the size and composition of different transgenes on their expression is analyzed under the same conditions. 2) We also analyze whether potentially negative regulatory elements can be deleted from viral promoters/enhancers to direct transgene expression constitutively, and 3) The influence of exogenous factors on transgene expression is analyzed for full-length as well as truncated promoters/enhancers. In addition to *in vitro* experiments long-term stable and/or regulatable expression from various promoter/enhancer combinations is also monitored *in vivo* after grafting. Our results suggest that retroviral gene expression can be regulated by dexamethasone and retinoic acid *in vitro* and *in vivo*.

DIFFERENTIAL DISPLAY OF PCR-AMPLIFIED mRNA AS A SCREENING TECHNIQUE IN THE BRAIN. I.M. Babity*, B.J. Chiasson, and H.A. Robertson. Dept. of Pharmacology, Dalhousie Univ., Halifax, N.S., Canada, B3H 4H7.

We have adopted a technique of differential display of PCR-amplified mRNA to examine the nature and extent of changes in gene expression in mammalian brain. This technique utilizes a set of oligonucleotide primers, one anchored to the poly A⁺ tail of the message and the other located upstream of the poly A⁺ tail. While this technique has previously been used to study changes in cultured cells, little information is available on the application of this technique to heterogeneous tissues such as the brain. Currently, we are using this technique to examine changes in gene expression associated with seizure activity and focal cerebral ischemia. In the first example, we have isolated mRNA from animals that have been kindled to stage 5 seizures and left seizure free for at least 2 weeks or from animals acutely treated with kainic acid. Electrode implanted or vehicle injected animals served as a source of control mRNA. In the second example, we are studying changes in gene expression associated with a model of focal cerebral ischemia based on the photochemical induction of thrombotic stroke using the dye Rose Bengal. We have identified a number of differentially displayed messages in the brains of animals that have been kindled or have experienced kainic-acid-induced seizures. Differentially displayed messages have been isolated, PCR amplified, and subcloned into plasmid vectors. We are attempting to use both PCR-amplified material directly and subcloned material in Northern blotting experiments to further characterize gene expression associated with these differentially displayed messages in control and experimental animals. It appears that this technique is useful for studying changes in gene expression in the brain.

FACTORS AFFECTING AVAILABILITY OF ANTISENSE OLIGONUCLEOTIDES IN BRAIN. Y. Yaida, W. A. Pulsinelli* and T. S. Nowak, Jr. Dept. of Neurology, Univ. Tennessee, Memphis, TN 38163.

The use of antisense oligonucleotides (oligos) to interfere with the expression of specific proteins is of demonstrated utility *in vitro*, and several reports have indicated that this approach may also be applicable to the intact brain. Few investigations have explicitly evaluated the localization of administered oligos within brain. In the present studies we have examined the distribution and stability of oligos after intraventricular (i.c.v.) and intrahippocampal (i.h.) injection in the rat.

These studies used synthetic oligos (19-30mers) antisense to various regions of a rat hsp70 mRNA sequence. Oligos were 3' end-labeled with [³⁵S]thio-dATP, and 50 nCi (1 pmol, 2-5 µl) injected to examine distribution 1-24 h after administration. Frozen sections (15 µm) were cut and subjected to film autoradiography. Localization and stability were evaluated 6-48 h after injection of unlabeled oligos (2 nmol) by *in situ* hybridization with ³⁵S-labeled sense sequences.

After i.c.v. injection labeled oligo was largely periventricular. A more propagated signal was seen at 6 h or later, especially in white matter tracts. This likely does not represent intact oligo, since *in situ* hybridization detected only periventricular accumulation. With direct i.h. administration labeled oligo accumulated along the hippocampal fissure, probably reflecting injectate bulk flow. There was occasional prominent labeling of dentate granule cells, and limited CA1 labeling was also seen along the track of the injection. Hybridization at 6-48 h detected neuronal uptake of oligo with a similar distribution, including mossy fibers remote from the injection site. Unmodified oligos can therefore accumulate in neurons after local administration.

DEFECTIVE HSV VECTORS FOR THE STUDY OF GLUTAMATE DECARBOXYLASE EXPRESSION IN CELLS OF THE CNS

K. C. New^{1*}, R. L. Martuza², K. Gale³, S. D. Rabkin^{1,2}. Departments of Microbiology¹, Pharmacology³ and Neurosurgery², Georgetown University Medical Center, Washington, DC 20007

The plasmid-based defective herpes simplex virus (HSV) vector system offers an efficient means to deliver and express genes in cells of the central nervous system (CNS). Glutamic acid decarboxylase (GAD) is the single enzyme in the mammalian brain that converts glutamate to γ-aminobutyric acid (GABA). Mammalian GAD exists as two isoforms of 65 and 67 kD, encoded by different genes.

GAD65 or GAD67 cDNAs under control of the CMV immediate-early promoter were inserted into HSV amplicon plasmids. Double-cassette defective HSV vectors, containing separate transcription units for both GAD and E. coli lacZ, were generated with a conditional-lethal helper HSV. Because GAD is expressed throughout the brain, the presence of the lacZ marker enables us to detect and quantify vector infection *in vivo*.

These defective vectors were used to infect Vero cells and primary cultures of cerebellar granule cells (primarily glutamatergic) and cortical astrocytes. Infection resulted in the expression of both β-galactosidase and GAD in each of the cell types, as determined by immunocytochemistry. The expressed GAD protein was active and capable of GABA synthesis.

These vectors should permit us to determine the effects of GABA synthesis on glutamatergic neurons and glia *in vitro*, as well as modulate local concentrations of glutamate and GABA *in vivo*.

DEVELOPMENT OF PCREB AND FOS-LI IN SUPRAOPTIC NUCLEUS AFTER SALT LOADING. P. Shiromani*, M. Magner, S. Winston, M. E. Charness. Depts Psychiatry, Neurology, Harvard Medical School, VA Medical Center, West Roxbury, MA 02132.

Phosphorylation of the cAMP response element binding protein (CREB) precedes the induction of immediate early gene expression. Using antibodies that distinguish CREB from phosphorylated CREB (PCREB), we studied the appearance of PCREB-like immunoreactivity (PCREB-LI) and Fos-LI in the hypothalamic supraoptic nucleus (SON) in response to hyperosmolar stress in rats. Increased numbers of PCREB-LI cells were present at 15, 45, and 90 min after injection with normal or hypertonic saline. The number of PCREB-LI cells did not differ significantly between the two groups and returned to normal after 6 hrs. The SON of hypertonic saline-treated rats showed higher levels of *c-fos* mRNA than that of normal saline-treated rats, and only minimal signal was detected in the SON of uninjected rats. The number of Fos-LI cells increased dramatically at 45 and 90 min after injection of hypertonic saline and did not change at 15, 45, or 90 minutes after injection of normal saline. The discrepancy between levels of PCREB-LI and *c-fos* mRNA suggests that hyperosmolar stress may activate additional transcriptional factors besides CREB. The lack of Fos-LI in the presence of modest increases in *c-fos* mRNA in normal saline-treated rats implies that levels of *c-fos* mRNA must exceed a threshold before increases in Fos-LI cells are detectable in the SON. Such a threshold might permit neuronal cells to activate diverse cAMP or calcium-responsive genes, through phosphorylation of CREB, without inducing the constellation of Fos-responsive genes.

SOMATOSTATIN DECREASES SOMATOSTATIN MESSENGER RIBONUCLEIC ACID LEVELS IN THE RAT PERIVENTRICULAR NUCLEUS. M.C. Aguila*. Department of Physiology, UT Southwestern Med. Ctr., Dallas, TX 75235-8873.

Somatostatin (SRIF), the inhibitory hypothalamic peptide of pituitary growth hormone secretion was reported to inhibit its own release by a negative feedback mechanism. However, it is not known whether this negative regulation is exerted at the molecular level. Therefore, this study was conducted to examine the hypothesis that hypothalamic SRIF mRNA levels might be regulated by its own protein. Periventricular nucleus (PeN) from adult male rats were incubated in Waymouth's medium with SRIF or the SRIF analog RC 160 (10^{-9} to 10^{-7} M) for 6 hrs. Levels of SRIF mRNA were determined by a S_1 nuclease protection assay using a 32 P labelled rat SRIF riboprobe. SRIF (10^{-7} M) significantly ($P \leq 0.01$) decreased SRIF mRNA levels. Likewise, RC 160 (10^{-9} to 10^{-7} M) significantly ($p \leq 0.05$, $p \leq 0.01$ respectively) diminished SRIF mRNA levels. These results suggest that SRIF can regulate its own gene expression by a negative loop feedback. SRIF secreted from these neurons may be down-regulating a preceding stimulatory input. Supported by NIH grant NS26821.

REGULATION OF Na AND K CHANNEL mRNA IN CULTURED NEUROBLASTOMA CELLS. F.N. Quandt*, J.K. Hirsh, and D. Sievert. Mol. Biophys. & Physiol. & M.S. Center., Rush Univ., Chicago, IL 60612

Factors which regulate transcription of mRNA for voltage-dependent ion channels were identified using cultured N1E-115 neuroblastoma cells as a model system. Na and K channel-specific mRNA was measured using a competitive-polymerase chain reaction technique following reverse-transcription of isolated total RNA. Amplified cDNA was sequenced to confirm identity of the transcript, and the absence of genomic DNA was verified. Cell division can be arrested resulting in an enhanced differentiated phenotype during incubation of cells in medium having reduced serum and 1.5% dimethylsulphoxide. K channel (a *shaw* homolog) mRNA abundance was found to increase by approximately 100% under this condition, but there was little change in Na channel (either type II or III) mRNA. Incubation of differentiated neurons with 1 μ M A23187 or ionomycin for two days decreased Na channel mRNA to 50%, without significant reduction in K channel mRNA. Therefore, Na and K content of these neurons is differentially regulated. Mechanisms responsible for the alteration in Na channel mRNA by Ca loading were studied. Although growth of differentiated cells in high external K did not alter mRNA level by itself, it blocked the decrease in mRNA in the presence of A23187. Na channel mRNA was reduced when cells were incubated in 250 μ M chlorophenylthio-cyclic AMP (cAMP). A reduction by cAMP was not observed in cells grown in A23187. These observations suggest that the effect of Ca on transcription is mediated by cAMP, and perhaps coupled to changes in membrane potential. Supported by the National Multiple Sclerosis Society.

LOCALIZATION OF HEAT SHOCK mRNAs ENCODING HSC70 AND HSP70 IN THE RABBIT BRAIN. J.A. Foster*, S.J. Rush, and I.R. Brown. Department of Zoology, University of Toronto, Scarborough Campus, West Hill, Ontario, Canada, M1C 1A4.

In response to stresses, such as elevated temperature, cells respond by increasing synthesis of a group of highly conserved proteins known as heat shock proteins (hsp). Our laboratory studies the expression of constitutive (hsc) and hyperthermia-inducible (hsp) members of the hsp70 multigene family in the New Zealand white rabbit. Using radioactive and non-radioactive (DIG) *in situ* hybridization protocols, both hsc70 mRNA and hsp70 mRNA were localized to hippocampal neurons in control animals. The role of the stress-inducible hsp70 mRNA species in neurons of the unstressed animal is yet to be determined. Following 1 hour of hyperthermia, glial cell types (including astrocytes, oligodendrocytes, and microglia) within the hippocampal region, the overlying corpus callosum and the fimbria showed an induction of hsp70 mRNA. We performed lectin cytochemistry using GSA I-B₄ from *Griffonia simplicifolia* to identify microglia and immunocytochemistry with anti-GFAP antibody to identify astrocytes. Having previously shown that hsc70 protein is found constitutively within dendritic processes of Purkinje neurons of the cerebellum, we now analyze transport of hsc70 mRNA in neuronal processes. In addition, a time course analysis of hsp70 mRNA induction in glial cell types investigates transport of hsp70 mRNA in glial processes following hyperthermia.

THE TRANSCRIPTION FACTOR C/EBP δ IS INDUCED BY VIP, PACAP AND NORADRENALINE IN MOUSE CORTICAL ASTROCYTES.

J.-R. Cardinaux and P.J. Magistretti*. Institut de Physiologie, Université de Lausanne, Lausanne, Switzerland.

The CCAAT/enhancer binding protein (C/EBP) family of transcription factors belongs to a class of proteins, whose DNA-binding domain involves a basic region and a leucine zipper. This bZIP domain was first described for C/EBP and then for the Fos/Jun and ATF/CREB families. High C/EBP concentrations were found in the nuclei of fully differentiated hepatocytes and adipocytes. Therefore, it has been postulated that the regulation of energy balance may be channeled at least in part through C/EBP. Since we have previously described transcription dependent metabolic effects of VIP and noradrenaline (NA) in astrocytes (Sorg and Magistretti, 1992, J. Neurosci. 12:4923), we have examined the effects of these neurotransmitters on C/EBP protein levels. By Western blot analysis, we observed that C/EBP δ is rapidly induced by VIP 10 nM, by the VIP-related peptide PACAP at 10 nM or by NA 1 μ M in mouse astrocytes prepared from the cerebral cortex. The effect of NA can be mimicked by the β -agonist isoproterenol, whereas methoxamine an α 1-agonist is devoid of any effect. Moreover, the NA-induction can be antagonized by atenolol and not by prazosin, thus suggesting that the induction of C/EBP δ is mediated by β -subtype adrenergic receptors. VIP, PACAP and NA therefore probably increase the C/EBP δ expression via the cAMP second-messenger pathways. To our knowledge this is the first demonstration of the induction by neurotransmitters of a member of the C/EBP family in a mammalian brain cell type. We are currently searching putative target genes whose expression is modified in response to the C/EBP δ induction.

CONSTITUTIVE EXPRESSION OF HEAT SHOCK PROTEIN 70 (HSP70) IN THE RABBIT NERVOUS SYSTEM. P. Manzerro*, S.J. Rush, I.R. Brown, Dept. of Zoology, Univ. of Toronto, West Hill, Ont., Canada, M1C 1A4

Western blot analysis utilizing the ECL detection system has revealed the constitutive expression of stress-inducible hsp70 protein in unstressed (control) rabbit brain. This observation is not unique to rabbit brain as both rat and mouse cerebellum also constitutively express stress-inducible hsp70 protein. Two-dimensional Western blotting has identified a number of inducible hsp70 and constitutive hsc70 isoforms. A range of antibodies which specifically recognize either stress-inducible hsp70, constitutive hsc70 or both members was utilized to verify that the hsp70 family member detected in control tissue was indeed the stress-inducible hsp70 protein. Highest levels of constitutive expression of stress-inducible hsp70 were observed in control retina, brain core and cerebellum with lesser levels observed in cerebral hemispheres, spinal cord and brain stem. Constitutive expression of hsp70 was also detected in non-neural tissue, however these levels were lower than that observed in neural tissue. In response to hyperthermia, immunocytochemical studies reveal a robust induction of stress-inducible hsp70 in a pattern consistent with a strong glial response. Despite the ability of the antibodies to detect stress-inducible hsp70 by Western blotting in both control and heat shocked tissue, no hsp70 positive cells were detected by immunocytochemistry in control brain, suggesting that the immunoreactive epitope may be masked in unstressed animals. Our Western data clearly indicate that stress-inducible hsp70 is present in unstressed neural tissue. What role this protein plays in the unstressed animal has yet to be determined. Recently, we have shown that a correlation exists between levels of constitutive hsc70 protein and the magnitude of hsp70 induction, that is tissues/cells with high levels of hsc70 show a dampening in the level of hsp70 induction following hyperthermia. Constitutive levels of stress-inducible hsp70 may also exert a dampening effect on hsp70 induction.

HIPPOCAMPAL ANATOMY AND ULTRASTRUCTURAL MORPHOLOGY OF α -CALCIUM CALMODULIN KINASE II DELETION MICE. T.A. Comery*, J.A. Kleim, A. Silva and W.T. Greenough. Depts. of Psych., Biochem., Cell and Struct. Bio., Neurosc. Prog., and Beckman Inst., Univ. Illinois, Urbana, IL 61801 and Cold Spring Harbor, NY 11724.

Calcium Calmodulin Kinase II (CAMKII) regulates both pre- and post-synaptic functions. CAMKII is highly abundant in the postsynaptic densities of excitatory synapses. Transgenic mice homozygous for a null mutation for the α -subunit of CAMKII show impaired formation of hippocampal long-term potentiation, long-term depression, and abnormal short-lived plasticity. Behavioral studies reveal profound deficits in both spatial and contextual learning (Silva et al., 1992; Silva et al., unpublished results). The present study used stereological techniques to examine the ultrastructural characteristics of the CA1 region of the hippocampus in the homozygous mutant mice. Pyramidal cell density, in CA1 stratum pyramidale, was obtained using the physical disector on serial 1.5 μ m sections. Synaptic density was obtained from serial electron micrographs of stratum radiatum in CA1 using the physical disector. Preliminary results demonstrate similar neuronal and synaptic densities in the homozygous mutant (N=2) and wild-type animals (N=3). No differences were observed in the number of synapses per neuron. Initial analysis of the size of post-synaptic densities reveals no differences between the two groups. However, one mutant mouse appeared to display spontaneous seizure activity and examination of the hippocampal anatomy revealed cell loss in all CA regions of the hippocampus. Supported by NIMH 35321, NSERC, Kiwanis Nerv. Sys. Res. Fnd., Whitehall Foundation and Klingenstein Foundation.

EXPRESSION OF CALMODULIN mRNA IN THE DEVELOPING RAT BRAIN. F. Berry and I.R. Brown*. Department of Zoology, University of Toronto, Scarborough Campus, West Hill, Ontario, Canada, M1C 1A4.

In the rat, three genes have been identified which encode calmodulin (CaM). Previously in our laboratory, two cDNAs have been cloned and characterized which correspond to mRNAs of 1.8 and 4.0 kb derived from the rat calmodulin gene I. Both messages are preferentially expressed in neurons in the rat brain. We have extended our analysis to examine expression of these CaM I mRNAs during neural development in the Wistar rat. Northern blot analysis revealed that the 4.0 kb transcript increases in abundance from postnatal day 1 (P1) in the cerebral hemispheres (CH) and thalamus. In the superior colliculus (SC), the 4.0 kb mRNA demonstrates a transient increase from P1 to P10 and then declines in later ages (P15 and adult). Levels of the 1.8 kb message remain relatively constant over development, while the 4.0 kb message shows greater change. Using *in situ* hybridization, we observe that CaM I mRNA is localized to a discrete layer in the developing SC. By P5 and P10, expression is focused to neurons between the superficial gray and optic layers. In the developing CH, CaM I mRNA is localized in a punctate pattern at P1, while from P5 to P15, message is distributed in a columnar fashion in cortical layers II-V. Closer examination of cells in these layers reveals that CaM mRNA is present in the cell body and dendritic processes. The timing of CaM I mRNA expression in the developing SC coincides with the period of removal of mistargeted axons from retinal ganglion cells, while the expression pattern in the developing CH correlates to a period of synaptogenesis in the cortical layers. This work was supported by grants to I.R.B. from NSERC, Canada.

Concerted regulation of GAD and GABA_A receptor family transcripts as a model system in the molecular physiology of CNS development. R. Somogyi, X. Wen, V. Dunlap and J.L. Barker*

Laboratory of Neurophysiology, NINDS, NIH, Bethesda, MD 20892

GABA (γ -aminobutyric acid) acts as a neurotrophic signaling molecule in embryonic development of the CNS, distinct from the well-established function of GABA as a fast-acting inhibitory transmitter in the adult. Evidence for this role includes the early embryonic detection of GABA, GABA-evoked pharmacological responses involving Cl^- and Ca^{2+} ions, and promotion of neurite outgrowth. The molecular basis for the embryonic role of GABA lies in 1) its synthesis from glutamate by glutamic acid decarboxylase (GAD), and 2) the presence of GABA receptors. We have implemented a quantitative PCR strategy to enumerate GAD transcripts during development of the rat cervical spinal cord. Three GAD mRNAs, GAD65, GAD67 and EP10 were detected at E11 and steeply increased during an early embryonic period of 4 days. GAD65 and GAD67 reached maximum expression at the end of embryogenesis, at levels 1000x higher than initially detected. During the postnatal period, they gradually declined to their adult level at one third of maximum. The alternatively spliced transcript of the GAD67 gene, EP10, reached a maximum before GAD65&67 and then steeply dropped in late embryonic development. EP10 expression correlated with the transition of spinal cord tissue from proliferative to differentiating. RTPCR of 13 GABA_A receptor subunits revealed overall parallel expression to GAD. As a working model, we propose that production of GAD transcripts may involve a regenerative feedback loop, linking the product of GAD, i.e. GABA, to the induction of GAD and GABA_A receptor subunit mRNAs. We are currently testing this hypothesis using embryonic spinal cord cells grown in a serum free tissue culture on an extracellular matrix substrate; these conditions enable the continuing differentiation of cells.

POSTSYNAPTIC MECHANISMS III

620.1

THE EFFICIENCY OF CHANNEL OPENING SUMMATION AT GABA_A AND NMDA SYNAPSES: RELEVANCE TO MODULATION OF SYNAPTIC CURRENTS AND INTERPRETATION OF QUANTAL ANALYSIS. Y. De Koninck*, D.N. Lieberman and I. Mody. Depts. of Anesthesiology/Pain Mgmt. & Neurology, UT Southwestern Med. Ctr., Dallas, TX.

Stochastic simulations (Faber *et al.*, *Science* 258:1494, 1992; De Koninck & Mody, *J. Neurophysiol.* 71:1318, 1994) have demonstrated the existence of intrinsic quantal variance (σ_q^2) at the peak of miniature postsynaptic currents (mPSCs) in spite of the postulated pharmacological saturation of receptors at central synapses. The σ_q^2 depends on the relationship between activation kinetics and bursting properties of subsynaptic receptor channels. The occurrence of gaps during bursts or clusters of channel openings may cause poor or inefficient summation of channel activity.

We examined how σ_q^2 and $P_{0(\text{peak})}$, the probability that ligand-bound channels will be open at the peak of mPSCs, are affected by modulators of channel kinetics such as intracellular calcium, phosphatases and kinases. We simulated mPSCs based on cell-attached single channel data obtained in acutely isolated adult neurons. Clusters of channel openings were aligned by exponentially distributed random latencies based on the time to first opening of channels following brief agonist applications (Edmonds & Colquhoun, *Proc. Roy. Soc. Lond. B* 250:279, 1992).

For unitary currents with burst and onset kinetics such as those underlying GABA_A receptor mediated mPSCs, the $P_{0(\text{peak})}$ is high, and modulation of the intraburst kinetics has little effect on the peak mPSC amplitude. In contrast, as previously reported (Jahr, *Science* 255:470, 1992; Rosemund *et al.*, *Science* 262:754, 1993), $P_{0(\text{peak})}$ is much lower for NMDA receptor mediated mEPSCs. Thus, modulation of the intraburst kinetics will dramatically alter peak amplitude. The alteration in $P_{0(\text{peak})}$ will lead to changes in σ_q^2 . As the coefficient of variation (CV) used for quantal analysis assumes a fixed σ_q^2 , variations in σ_q^2 by modulators of channel kinetics may produce erroneous interpretations of changes in CV at certain synapses.

620.3

FUNCTIONAL CHARACTERIZATION OF THE CORTICO-NUCLEAR PROJECTION IN RAT CEREBELLUM *IN VITRO* D. Mougnot and B. H. Gähwiler* Brain Research Institute, University of Zurich, CH-8029 Zurich, Switzerland

Neurons of the deep cerebellar nuclei (DCN) constitute the major output of the cerebellum. Intracellular recordings were obtained to characterize the inhibitory synapses formed by Purkinje cells (PCs) on neurones in the DCN using organotypic cerebellar cultures. These preparations exhibit the unique property that PCs grow axons *de novo*, forming an impressive *in vitro* analog of the cortico-nuclear projection. In the presence of excitatory amino acid receptor antagonists (CNQX, 20 μM ; D-APV, 40 μM) and bicuculline (40 μM), DCN neurons spontaneously fired action potentials whose frequency depended linearly on membrane potential. Thus, DCN cells displayed a beating-type pacemaker activity under conditions of synaptic isolation. DCN neurons possess GABA_A and GABA_B receptors, as shown with bath application of muscimol (5 μM) and baclofen (10, 100 μM). In the presence of CNQX and D-APV, field stimulation of PCs evoked graded IPSPs which were completely and reversibly abolished by bicuculline. IPSP amplitudes were not markedly reduced during fast repetitive stimulation, and the resulting hyperpolarization was not affected by the GABA_B receptor antagonist CGP-35348. Trains of IPSPs (5 to 10 Hz) were able to transiently disrupt the pacemaker activity of DCN cells. In addition, experiments with bicuculline show that PCs exert a tonic hyperpolarizing tone on DCN neurones.

620.2

MONOSYNAPTIC GABAERGIC INPUTS TO RAT RUBRAL NEURONS IN SLICES G.-F. TSENG* and Y.-S. FU Department of Anatomy, College of Medicine, National Taiwan University, Taipei, Taiwan, R.O.C.

Mammalian red nucleus (RN) displayed a deafferentation induced sprouting of excitatory and inhibitory terminals, but the locations of inhibitory neurons remain enigmatic. Here we used intracellular recording and anatomical tracing methods to study the inhibitory connections of normal RN neurons in slices. In some cases, biocytin was used to reveal the morphology of recorded cells. They resembled Golgi-stained RN neurons. Recorded caudal cells were similar to identified rubrospinal neurons revealed by fixed tissue intracellular dye injection.

Stimulating electrode was placed in the mesencephalic reticular formation dorsolateral to RN (*dIMRF*), substantia nigra (SN), or ventral tegmental decussation (VTD). Stimuli in VTD evoked no postsynaptic potential (PSP) but antidromic spikes suggests the lack of a recurrent inhibition. Stimuli in *dIMRF* (11/11 caudal and 8/10 rostral neurons) and SN (16/19 caudal and 19/20 rostral neurons) evoked a short latency hyperpolarizing PSP. This PSP could temporarily delay the repetitive spiking evoked by depolarizing current injection and it was reversibly blocked by bath perfusion of 20 μM bicuculline. Blockage of this IPSP revealed no underlying depolarizing PSP indicating a direct activation of inhibitory neurons or their axons. Latencies of IPSPs evoked from both stimulus sites were around 1.1 ms consistent with the hypothesis of being monosynaptic PSPs.

Anatomically, anterograde tracer-Dextran applied in the *dIMRF* or SN of live slices labeled neurons with boutons-bearing axons extending into the RN. They were often found to oppose somata in the RN. Immunohistochemical staining shows that *dIMRF* and SN neurons contain high level of the calcium-binding protein-parvalbumin, known to present in high concentration in GABAergic neurons. Thus anatomical and physiological data suggest that *dIMRF* and SN neurons mediate a GABA_A-IPSP on rat RN neurons. (supported by NSC of Taiwan, R.O.C.)

620.4

MODELING NMDA-INDUCED BURSTING IN DOPAMINE NEURONS Y.-X. Li*, R. Bertram and J. Rinzel. Math. Res. Branch, NIDDK, NIH, BSA Bldg., Suite 350, Bethesda, MD 20892

Burst firing of dopamine neurons *in vitro* is induced by the glutamate agonist N-methyl-D aspartate (NMDA). The hyperpolarization between bursts is believed due to Na^+ extrusion by a ouabain-sensitive pump (Johnson *et al.*, *Science*, 258:665). We formulate and explore a theoretical model for this novel mechanism of burst generation. We show that interaction between the regenerative, inward NMDA-mediated current and the outward Na^+ -pump current is sufficient to generate the slow oscillation (0.5 Hz) underlying the burst. The region of negative slope in the $I-V$ relation of the NMDA channel in the presence of Mg^{2+} is indispensable for the occurrence of this slow rhythm. As suggested by Seutin *et al.* (*Neuroscience*, 58:201), we find that at least 2 spatial compartments are required: a soma where action potentials (APs) are produced and a dendrite where the slow rhythm is generated. The time scale of Na^+ -handling in the dendrite determines the burst period. In the absence of NMDA, the model shows tonic spiking ($\sim 2\text{ Hz}$) which is insensitive to Na^+ pump inhibitors. When NMDA is present, tonic spiking is replaced by repetitive bursting. Tetrodotoxin blocks the APs but leaves the slow rhythm unchanged. Na^+ pump inhibitors transform bursting back into tonic firing. When the soma is voltage-clamped, slow oscillations in current, which are generated in the dendritic compartment, are still present. These results are in good agreement with experimental observations. Insights obtained with our model may apply to other neuron types where bursting appears to involve NMDA channel activity.

620.5

NMDA CURRENT IS NEGATIVELY REGULATED BY AMPA/KAINATE AND METABOTROPIC GLUTAMATE RECEPTORS IN CULTURED HIPPOCAMPAL NEURONS. M. Yuzaki¹, L. M. Verselis, S. C. Sun, D. Forrest, T. Curran and J. A. Connor, Roche Inst. of Molecular Biol., Nutley, NJ 07110.

The major excitatory transmitter glutamate activates several subtypes of glutamate receptors. In this study, we investigated the interaction of these subtypes in single neurons. We carried out voltage-clamp recordings using the conventional whole-cell patch-clamp technique from hippocampal neurons, prepared from B6 mouse embryos (E16-E18) and cultured for 8-13 days. Glutamate (100 μ M), applied by rapid pressure ejection, induced a large inward current with prominent desensitization in Mg-free, glycine- and TTX-containing solution at -60mV. The peak current induced by glutamate was paradoxically increased to $122 \pm 5\%$ (mean \pm sem, n=9) of control by an AMPA/kainate receptor (A/K-R) antagonist, CNQX (10 μ M). The enhanced current was almost completely blocked by an NMDA receptor (NMDA-R) antagonist, D,L-APV (200 μ M). In addition, in mutant mice lacking functional NMDA-Rs, CNQX reduced the glutamate-induced current to $33 \pm 5\%$ (n=5) of control, indicating that the NMDA current was increased by about 90% in the wild-type animals by blocking A/K-Rs. The ratio of glutamate current at 3 sec to its peak amplitude was increased by CNQX, indicating that the NMDA current had been desensitized by A/K-R activation. In Ca-free solution, CNQX reduced the glutamate-induced current to $76 \pm 2\%$ (n=3) of control. In Na-free solution, with Li or Cs substitution, CNQX reduced the glutamate current to $79 \pm 4\%$ (n=3). Thus AMPA/kainate current may affect NMDA current via Na influx, which eventually increases Ca levels by the Na/Ca exchanger. Similarly, the NMDA-component of glutamate current was also increased to $120 \pm 5\%$ (n=6) by a metabotropic glutamate receptor (mGluR) antagonist, (+)-MCPG (200 μ M). These results suggest that the NMDA component of glutamate current is inhibited by A/K-R and mGluR activities.

620.7

NOVEL TIME COURSE OF TRANSMISSION AT A GIANT GLUTAMATE SYNAPSE IN RAT VESTIBULAR CEREBELLUM.

D.J. Rossi^{*}, E. Mugnaini and N.T. Slater, Department of Physiology, Northwestern University Medical School, Chicago, IL, 60611 U.S.A.

Unipolar brush cells (UBCs) of mammalian vestibulocerebellum receive innervation from a single mossy fiber in the form of an extraordinarily extensive synaptic contact (12-40 μ m²). UBCs are immunonegative for GABA and glycine (Mugnaini et al., *Synapse* 16:284, 1994), but immunopositive for glutamate. In the present study we have examined the properties of transmission at this synapse using whole-cell recording methods in thin cerebellar slices maintained *in vitro*. UBCs in the GCL of rat cerebellar nodulus and uvula were patch-clamped with Lucifer Yellow (LY)-filled pipettes, and stimulating electrodes were placed in the white matter to activate mossy fiber afferents. Confocal fluorescence imaging of their characteristic morphology was used to verify cell identity. LY filled the soma, dendritic brush, and revealed a branching axon that gave rise to 2-4 mossy-like rosettes in the GCL. In whole-cell recordings a biphasic excitatory postsynaptic current (EPSC) was observed in UBCs voltage-clamped at -80 mV in Mg-free saline. The fast initial inward current ($\tau_{on}=0.7$ ms, $\tau_{off}=3.6$ ms) was followed by an unusually slow inward current ($\tau_{on}=220$ ms, $\tau_{off}=1.4$ s), both of which were evoked in an all-or-none fashion at identical stimulus thresholds. At all postnatal ages the fast EPSC was blocked by the AMPA/KA receptor antagonist CNQX (10 μ M). In Mg²⁺-free saline both fast and slow EPSCs reversed near 0mV with linear *I-V* relations between -80 and +50 mV. The pharmacology of the slow EPSC changed with development. In young animals (6-20 days) it was preferentially blocked by the NMDA receptor antagonists D-AP5 (50 μ M) and 7-chloro-kynurenate (100 μ M) and displayed non-linear *I-V* relations in the presence of external Mg²⁺. In contrast, it was blocked by CNQX (10 μ M) and displayed no Mg²⁺ channel block in older animals (>20 days). It is proposed that the ultrastructural design of this synapse represents a specialization to prolong the lifetime of glutamate in the cleft following release, thus resulting in rebinding of glutamate to produce a long-lasting EPSC whose time course is independent of receptor type.

620.9

SATURATION OF AMPA RECEPTORS FOLLOWING QUANTAL TRANSMITTER RELEASE. C-M. Tang^{*}, M. Margulis, Dept of Neurology, Univ. of Maryland Sch. Med.

While it is generally believed that postsynaptic NMDA receptors reach saturation following the release of glutamate from a single transmitter vesicle, it remains unclear whether AMPA receptors reaches saturation. Using brief focal application of Ba²⁺ and K⁺ mEPSCs were elicited from small numbers of release sites on proximal dendrites of cultured hippocampal neurons. Closely timed mEPSCs did not follow Poisson behavior nor did they summate linearly. A minority but statistically significant number of closely timed mEPSCs were also closely matched in terms of amplitude. Addition of cyclothiazide (100 μ M) increased the non-linearity of summation and the statistical significance of "amplitude pairing". Receptor saturation best explains these observations. AMPA receptor saturation following quantal transmitter release has implications for synaptic transmission in the CNS.

620.6

WHOLE CELL RECORDINGS FROM RAT HIPPOCAMPAL CA3 NEURONS DURING STIMULATION OF DENTATE GRANULE CELLS. A.C. Greenwood^{*1} and T.H. Brown^{1,2}, Depts. of Cellular & Molecular Physiology¹ and Psychology², Yale Univ., New Haven, CT 06520.

The mossy-fiber (MF) synapse onto CA3 pyramids offers some advantages for electrophysiological study of quantal synaptic transmission and long-term potentiation (LTP). For example, the synaptic input from a MF axon onto a CA3 cell is not widely dispersed over the dendrites and is relatively proximal to the soma.

We developed a method of analyzing populations of excitatory postsynaptic currents (EPSCs) to test the applicability of different models of transmission, estimate model parameters and test hypothetical mechanisms of plasticity, with estimates of uncertainty obtained for each synapse from asymptotic theory or many simulations.

The application of these analytical methods to data collected during minimal stimulation of MF axons and to simulated data suggest that 200+ unitary EPSCs, as may be obtained by simultaneously patching CA3 pyramids and dentate granule cells, could elucidate the quantal mechanism of a MF synapse with satisfactory confidence.

Brain slices (300-400 μ m) from male Sprague Dawley rats (14-25 days) were placed in a submerged chamber on a fixed-stage upright microscope (Zeiss Axioskop) with a water immersion lens (40X, 0.75 NA) and video-DIC optics. Whole-cell electrodes were placed (under visual guidance) on "postsynaptic" pyramids in region CA3 or the hilus and on "presynaptic" dentate granule cells to obtain simultaneous recordings. During the selection of granule cells for patching, K⁺ from the presynaptic pipette in or above the dentate sometimes evoked EPSCs recorded in CA3 cells. Similarly, K⁺ from the descending postsynaptic pipette in region CA3 or the hilus sometimes evoked antidromic action potentials recorded in dentate granule cells.

Once simultaneous recordings were established (>50), granule cells were current-clamped to fire pairs of spikes separated by ~45 ms every 5 sec. Postsynaptic cells were voltage-clamped ($R_s < 10$ M Ω ; peak-to-peak noise < 5 pA; 1 kHz filtered). Spontaneous PSCs < 10 pA have been observed. Work is still in progress to record unitary MF EPSCs evoked by controlled firing of a single granule cell before and after the induction of LTP. Supported by NIH & ONR.

NMDA RECEPTOR-MEDIATED SYNAPTIC TRANSMISSION IN THE RAT MEDIAL VESTIBULAR NUCLEUS *IN VITRO*.

G.A. Kinney^{*}, B.W. Peterson and N.T. Slater, Dept. of Physiology, Northwestern Univ. Med. School, 303 E. Chicago Ave., Chicago, IL 60611.

While synaptic activation of NMDA receptors within the intrinsic circuitry of the brainstem vestibular nuclei has been proposed to contribute to plasticity of vestibular function, to date there has been no demonstration using intracellular recording methods of an NMDA receptor-mediated component of synaptic potentials within the mammalian vestibular nuclear complex. In the present study we have re-examined this issue using whole-cell recording methods in 300-450 μ m thick slices of rat medial vestibular nucleus (MVN) maintained *in vitro*. Slices were cut at the level of the vestibular nerve (nVIII), and stimulating electrodes were placed in the nVIII to evoke EPSPs. In normal saline, the nVIII-evoked EPSP was blocked by the AMPA/KA receptor antagonist DNQX (10 μ M). However, in the presence of the GABA_A receptor antagonist bicuculline (10 μ M) a late, slow component of the EPSP was observed which was blocked by the NMDA receptor antagonist D-AP5 (50 μ M). This monosynaptic NMDA-mediated component could be isolated in the presence of DNQX, and displayed the non-linear voltage relations characteristic of NMDA-mediated responses in the presence of external Mg. In some cells, DNQX also blocked a large (>50%) proportion of the D-AP5-sensitive component. Polysynaptic AMPA/KA-mediated EPSPs were observed in the presence of D-AP5. Prolonged bath application (10-20 min) of the metabotropic glutamate receptor (mGluR) agonist 1S,3R-ACPD (10-100 μ M) produced a moderate, slowly desensitizing depolarization (2-8 mV) and an acute depression of the EPSP in all cells. A long-term potentiation of the NMDA-mediated EPSP was observed in 9/13 cells following the washout of 1S,3R-ACPD. These results demonstrate that NMDA receptors contribute both to the monosynaptic nVIII-evoked EPSP and to transmission within the intrinsic circuitry of the rat MVN, and are modulated by activation of mGluRs.

DOES GLUTAMATE RELEASE SATURATE NMDA RECEPTORS AT A SYNAPSE? W.R. Holmes^{*}, Neurobiology Program, Dept. of Biological Sciences, Ohio University COM, Athens, OH 45701.

The fact that few NMDA receptor channels are ever open at a synapse and that NMDA receptors have a high affinity for glutamate suggests that a single vesicle of glutamate might saturate all NMDA receptors at a synapse. In our previous model of LTP (Holmes and Levy 1990), the first few pulses of a 400 Hz input caused the peak number of NMDA receptors bound to glutamate to increase. However, if glutamate saturates NMDA receptors, this peak number should be the same for all pulses in the train. Whether or not the peak number of bound NMDA receptors increases during a tetanus affects model predictions of the amount of calcium entry through NMDA receptor channels.

A diffusion model similar to that reported for nicotinic synapses by Wathey et al. (1979) was constructed. A single vesicle of glutamate was assumed to be released either once or 8 times at 400 Hz. The numbers of bound and open NMDA and non-NMDA receptor channels were computed. Conditions when NMDA receptors would or would not be saturated were determined.

For saturation of NMDA receptors to occur with the first pulse of a tetanus, i) the number of glutamate molecules released into the synaptic cleft must be much larger than the number of NMDA receptors and ii) the first binding constant (K_{on}) must be large. Under these conditions, a tetanus allows many more receptor channels to enter the open state even though the peak number of bound receptors never rises above that of a single input.

The first binding constant has been estimated to be 5μ M⁻¹s⁻¹ (Clements and Westbrook 1991). With this value, the number of NMDA receptors bound with glutamate increases with successive pulses of a tetanus, indicating a lack of saturation. This occurs even when the number of released glutamate molecules is 10 times the number of NMDA receptors.

SATURATING CONCENTRATIONS OF GLYCINE REVEAL UBIQUITOUS PRESENCE OF NMDA RECEPTORS AT EXCITATORY SYNAPSES IN CULTURED HIPPOCAMPAL NEURONS. K.S. Wilcox, R. Maki, ^{1,2}M.A. Dichter. Depts of ¹Neurology and ²Pharmacology, and the ³David Mahoney Institute of Neurological Sciences, University of Pennsylvania School of Medicine and the Graduate Hospital, Phila., PA 19104.

In the mammalian hippocampus, excitatory postsynaptic currents (EPSCs) are mediated by activation of both non-NMDA and NMDA receptors colocalized at the synapse. Evidence for colocalization comes from many studies in which miniature EPSCs (mEPSCs) have been shown to consist of both non-NMDA and NMDA components. An early report (Bekkers & Stevens, 1989) suggested that approximately 70% of mEPSCs recorded in cultured hippocampal neurons consisted of both components, whereas the remaining 30% could be evenly divided between synapses containing either non-NMDA or NMDA receptors exclusively. In the present study, we examined the contribution each glutamate receptor subtype makes at individual postsynaptic boutons in hippocampal neurons maintained in low density culture. Using the whole cell patch clamp technique to simultaneously record the pre- and postsynaptic neuron, it was possible to record mEPSCs arising from the same terminals that were activated during evoked responses. We found that as the concentration of glycine was increased from 0 to 10 μ M, the NMDA component of the evoked EPSC became significantly greater in both amplitude and duration. Furthermore, in 10 μ M glycine, we saw no evidence of mEPSCs comprised solely of the non-NMDA component. Therefore, in our hippocampal culture preparation, there are no postsynaptic sites comprised exclusively of non-NMDA receptors. In addition, although there were mEPSCs comprised of only the NMDA component, it is not possible to conclude that non-NMDA receptors were not present, as desensitization of those receptors, as well as a weaker affinity than the NMDA receptor for the endogenous ligand, could mask their presence. PATCH-CLAMP ANALYSIS OF SPONTANEOUS SYNAPTIC CURRENTS IN THE RAT BASOLATERAL AMYGDALA. B.N. Smith and F.E. Dudek. Dept. of Anat. and Neurobiol., Colorado State Univ., Fort Collins, CO 80523.

Alterations of local excitatory and inhibitory amino acid transmission in the CNS can lead to epileptiform activity. Amino acid transmission in the basolateral amygdala (BLA) has been demonstrated, but not extensively studied with whole-cell recordings in the slice. Because of the potential for certain substances (e.g., corticotropin-releasing hormone) to contribute to seizure activity in the amygdala, we examined spontaneous synaptic activity in the rat BLA using the whole-cell voltage-clamp technique in coronal slices (400-500 μ m) from young rats (postnatal day 6-14). Biocytin (0.2%) was used to verify the location of the recorded neurons.

Resting membrane potential for BLA neurons was -65 ± 6.3 mV (mean \pm SEM); input resistance was 293 ± 71 M Ω . At holding potentials near rest, most neurons exhibited 10 to 60 pA spontaneous inward, but usually not outward, post-synaptic currents (PSCs). At more negative potentials (-80 to -100 mV), inward PSCs of up to 300 pA were observed. Both inward and outward PSCs could usually be discerned at potentials 10 to 20 mV depolarized from rest. In some cells, Cs^+ was used in the electrode to block voltage-activated K^+ -currents. These cells usually exhibited outward PSCs of between 10 and 300 pA at depolarized potentials (-20 to 0 mV). Three Cs^+ -loaded cells also showed bursts (up to 20 Hz, 0.5 sec) of spontaneous inward and outward PSCs, suggesting that the somata of some of the cells contacting the recorded neuron were contained within the slice.

These results indicate that BLA neurons have spontaneous synaptic currents that are similar to amino acid-mediated EPSCs and IPSCs. Resolving synaptic mechanisms in the BLA may help identify how extrinsic perturbations exert epileptogenic effects. A PROMINENT ROLE FOR NMDA RECEPTORS IN FREQUENCY CODING. E. D'Angelo, P. Rossi, G. DeFilippi, V. Taglietti. Inst. General Physiol., Univ. Pavia, I-27100, Pavia, Italy.

We have investigated synaptic currents (EPSCs) and potentials (EPSPs) at the mossy fibre-granule cell synapse of the rat cerebellum using whole-cell recording techniques in a slice preparation. As in other central synapses, EPSCs and EPSPs were brought about by NMDA and non-NMDA receptors. The NMDA component, both in EPSCs and EPSPs, showed a remarkable slowing down at depolarized membrane potentials. This allowed the NMDA component to control EPSP time-course in spite of the slowing down of membrane discharge due to inward rectification, and determined a dramatic enhancement of EPSP temporal summation extending the input-output relationship of granule cells toward the low frequency range (< 50 Hz). Moreover, the NMDA component determined 30% of EPSP amplitude already at potentials as low as -80 mV. This result indicates a remarkable contribution of NMDA receptors to synaptic depolarization during low-frequency transmission and near rest, and in the process of signal coding. This result extends the functional role of NMDA receptors, which are already known to participate to the induction of LTP and LTD during high-frequency transmission.

DIFFERENCES IN INHIBITORY SYNAPTIC INPUT INFLUENCE EXCITABILITY OF CAT CORTICAL NEURONS. J.E.M. van Brederode and W. J. Spain. VA Medical Center, Seattle, WA 98108 and Depts. of Biological Structure, Neurology, and Physiology, & Biophysics, Univ. of Washington, Seattle, WA 98195.

We compared intracellularly recorded post-synaptic potentials (PSPs) evoked in regular spiking layer 2/3 (L2/3) and layer 5 (L5) neurons by stimulation of the gray matter of cat area 4y in vitro. Trains of stimuli (9 pulses; 100 Hz) caused depression and hyperpolarization in L2/3 cells, but facilitation and depolarization in L5 cells. The mechanism of this difference was investigated. 1) Single shocks evoked a stereotyped tri-phasic PSP consisting of a fast excitatory PSP (EPSP), and a fast and slow inhibitory PSP (IPSP and sIPSP, res.) in L2/3 cells. PSPs in L5 cells, in contrast, were more variable, and entirely depolarizing in 85% of neurons at rest. 2) In response to single shocks isolated γ -aminobutyric acid (GABA)-A mediated IPSPs were found in all L5 cells after blockade of glutamate receptors with 6-cyano-7-nitroquinoxaline-2,3-dione (CNQX) and D-2-amino-5-phosphonopivalic acid (AP5). They were smaller and their duration shorter compared to IPSPs in L2/3 cells and overlapped completely in time with EPSPs. 3) Large (5-15 mV) GABA-B mediated sIPSPs were always evoked in combination with IPSPs in L2/3 cells but only in 30% of L5 cells in which they were also much smaller (< 1 mV). Isolated IPSPs were able to sum during trains of shocks and caused long-lasting hyperpolarization in L2/3, but not in L5 cells due to a lack of sIPSPs. 4) After GABA-release was enhanced by 4-aminopyridine sIPSPs were evoked together with IPSPs in all layer V cells. 5) Blockade of the inward rectifier current I_h with extracellular Cs^+ lengthened and amplified isolated IPSPs in L5 cells, but not in L2/3 cells in which I_h was absent or small. 6) N-methyl-D-aspartate (NMDA) mediated responses were apparent in L2/3 cells only after GABA-A blockade, in contrast to L5 cells in which AP5-sensitive slow EPSPs were demonstrable in control perfusate. We conclude that the differences in temporal summation of PSPs in cells from deep and superficial layers is due to attenuation of GABA-A responses by I_h and weaker GABA-B mediated responses in L5 compared to L2/3 cells. Supported by a VA Merit Review and NIH EY 01208.

THE TIME COURSE OF QUANTAL SYNAPTIC CURRENTS IN RAT SUBMANDIBULAR GANGLION CELLS. R.J. Callister and B. Walmsley. The Neuroscience Group, Discipline of Medical Biochemistry, Faculty of Medicine and Health Sciences, The University of Newcastle, Callaghan, NSW 2308, Australia.

Neurons in the submandibular ganglion innervate the salivary glands. In rats, these simple spherical cells lie in a very thin connective tissue sheet and, after about 5 weeks of age, 75% of the cells receive innervation from only a single parasympathetic preganglionic fiber (Lichtman, *J. Physiol. (Lond.)* 273:155-177, 1977). We are using this preparation to study quantal synaptic transmission in order to avoid the usual problems associated with multi-fiber inputs and dendritic attenuation of synaptic potentials and currents. Ganglia from 5-10 week old rats were pinned out in a small perfusion chamber and viewed under an inverted microscope. Afferent fibers in the chorda tympani nerve were electrically stimulated using a suction electrode. Intracellular recordings of excitatory postsynaptic potentials (EPSPs) were obtained in normal Krebs' solution and in solutions containing 100 μ M cadmium chloride. Under conditions of reduced transmitter release, a large proportion of failures of release and single quantal events were evident in amplitude histograms of the evoked EPSP. Two-electrode voltage clamp recordings of excitatory postsynaptic currents (EPSCs) were then obtained to investigate previous evidence (Rang, *J. Physiol. (Lond.)* 311:23-55, 1981) that the time-course of decay of the evoked EPSC and the single quantal (spontaneous) EPSC are markedly different. In agreement with Rang, the EPSC in normal Krebs' solution exhibited a decay which could be fitted by the sum of two exponentials (with time constants of approximately 30 ms and 7 ms). However, in contrast to previous evidence, this two phase decay persisted when evoked release was reduced to the level of single quanta.

NMDA RECEPTOR-MEDIATED EPSCs MODULATED BY ENDOGENOUS pH TRANSIENTS IN RAT HIPPOCAMPUS. J.A. Gottfried and M. Chesler. Depts. of Physiol. & Neurosurgery, NYU Med. Center, New York, NY 10016.

The occurrence of extracellular alkaline shifts during excitatory synaptic transmission (1) suggests that the NMDA-receptor H^+ modulatory site (2,3) may play a functional role. We amplified these pH shifts with benzolamide (BZ), a carbonic anhydrase inhibitor, and studied the EPSCs of whole-cell clamped CA1 neurons in rat hippocampal slices. In Mg^{2+} free, $\text{CO}_2/\text{HCO}_3^-$ media, 1 μ M BZ caused an immediate increase in EPSC 50% decay time (t_{50}) at holding potentials of -80 or -40 mV (see Fig.) (mean increase $78 \pm 14\%$ at -80 mV, $p < 0.01$, $n=10$). This was time-locked to an amplification of the extracellular alkaline shift ($154 \pm 14\%$). In $\text{CO}_2/\text{HCO}_3^-$ plus APV (20-75 μ M), the EPSC t_{50} was unaltered by BZ, while the alkaline shifts were still increased ($111 \pm 23\%$, $n=8$). In HEPES, where buffering is independent of carbonic anhydrase, neither the EPSC t_{50} nor the alkaline shift was affected by BZ ($n=9$). These data demonstrate that kinetics of the NMDA receptor-mediated EPSCs depend on the buffering capacity of the extracellular fluid. The results indicate that endogenous pH shifts can modulate NMDA receptor function in a physiologically relevant time frame.

POTENT NAPHTHALENIC AGONISTS FOR MELATONIN RECEPTORS IN BRAIN. L.P. Niles*, L. Smith, J. Wang, J.J. Chen¹ and G. Firnau¹. Departments of Biomedical Sciences and ¹Nuclear Medicine, McMaster University, Hamilton, Ontario, Canada, L8N-3Z5.

In studies aimed at the identification of selective ligands for melatonin receptors in the CNS, we have assessed the binding and functional activities of a series of naphthalenic compounds bearing variable halogen substitutions on the N-acylamino group. Binding experiments were carried out with the melatonin receptor radioligand, 2-[¹²⁵I]iodomelatonin ([¹²⁵I]MEL), in either whole brain homogenates or synaptosomal (P₂) fractions. Competition experiments performed on ice, in 50 mM Tris-HCl buffer (pH 7.4 at 4°C), revealed that these compounds recognize both high (picomolar) and low (nanomolar) affinity binding sites for melatonin. In assays conducted at room temperature in the presence of Mg Cl₂ (4 mM), both binding components were also evident. More importantly, under these conditions, some naphthalenic drugs exhibited a marked increase in their competitive potency at the high-affinity sites labelled by [¹²⁵I]MEL, as indicated by affinities in the sub-picomolar range.

Preliminary functional assays, in chick brain and rat hypothalamic membranes, show that these ligands inhibit forskolin-stimulated adenylate cyclase activity. These findings indicate that compounds characterized by a naphthalene nucleus, a 7-methoxy group and halogen substituents on the N-acetyl side chain are high-affinity agonists at CNS receptors for melatonin. SUBSTRATES FOR MAP KINASE ASSOCIATED WITH SYNAPSES IN THE RAT CENTRAL NERVOUS SYSTEM. I. Suzuki¹*, K. Okumura-Noji¹, E. Nishida², ¹Dept. of Biochemistry, Nagoya City Univ. Med. Sch., Nagoya 467 and ²Dept. Genetics & Mol. Biol., Inst. for Virus Res., Kyoto Univ. 606, Japan.

Roles for MAP kinase in synaptic function have been suggested by (1) its occurrence in the brain, especially in the neuronal dendrites, and (2) excitatory neurotransmitter, glutamic acid, and electric stimulation induce MAP kinase activation. In the present study, to clarify the function of the enzyme in the synapse, we surveyed MAP kinase substrates that occur in synaptic fractions. Supernatant and synaptic fractions (P₂, synaptosome, synaptic plasma membrane [SPM], and postsynaptic density [PSD] fractions) were prepared from Wistar male rats. MAP kinases were purified from *Xenopus* oocyte or obtained from UBI (sea star p44mpk). Protein kinase activities in each fraction were heat-inactivated before phosphorylation by the MAP kinases. Western blotting showed the occurrence of both MAP kinase and MAP kinase kinase in all the fractions mentioned above. Fractions other than PSD contained two bands immunoreactive to anti-MAP kinase antiserum, these possibly corresponding to ERK1 and ERK2, respectively. ERK2 was greater than ERK1 in content in both synaptosome and SPM fractions, and only ERK2 was detected in the PSD fraction. All the fractions contained substrates for both enzymes, but each fraction showed a different substrate profile. Interestingly, sea star MAP kinase strongly phosphorylated the substrates in the supernatant and P₁ fractions, while *Xenopus* MAP kinase (ERK2 type) acted more on the substrates in the synaptic fractions, especially those in the PSD fraction. Phosphorylation of the PSD proteins by *Xenopus* MAP kinase was increased after maturation of synapses. These results indicate that part of ERK2 occurs in the synapse, especially in the postsynaptic side, and that it may play some role(s) in the synaptic function via phosphorylation of synapse-specific substrates.

STRONGLY ANISOSMOTIC SOLUTIONS SUPPRESS GABA_A CURRENTS IN FRESHLY DISSOCIATED HIPPOCAMPAL NEURONS. G.G. Somjen*, M. Vreugdenhil, W.J. Wadman. Dept. Exper. Zool., Univ. Amsterdam, the Netherlands and ¹Dept. Cell Biol. Duke Univ. Durham, NC 27710.

We have reported that sudden exposure of dissociated hippocampal neurons to strongly anisomotic or glucose deficient solutions suppressed voltage gated Na⁺, K⁺ and Ca²⁺ currents (Brain Res., 632: 180-194, 1993). We now investigated whether GABA_A-induced ion currents were similarly shut down by exposure to anisomotic solutions. Freshly dissociated rat CA1 pyramidal neurons were patch-clamped in whole-cell configuration. Voltage gated Na⁺ and K⁺ currents were pharmacologically blocked. The effect of hypo-osmotic, NaCl deficient (mannitol-substituted), or hyper-osmotic test solutions delivered from a micropipette was tested on membrane currents evoked by brief puffs of muscimol and on voltage gated Ca²⁺ currents. Hyper-osmotic solution caused cells to shrink, but hypo-osmotic solution had no effect on cell size or shape. All three test solutions depressed the muscimol-induced current and usually also the muscimol-induced increase of membrane conductance. V-gated Ca²⁺ currents were depressed by anisomotic, but not by NaCl deficient isosmotic solution. We conclude GABA_A receptor controlled membrane channels are partially shut down in a strongly anisomotic or NaCl deficient environment.

ENDOGENOUS GLUTAMATE INDUCES DEPHOSPHORYLATION OF THE NEURONAL CYTOSKELETAL PROTEIN MAP2. E.M. Quinlan and S. Halpain*. Department of Neuroscience, University of Virginia Health Sciences Center, Charlottesville, VA 22908

Cytoskeletal proteins are likely targets of glutamate transmission in the nervous system. To examine transmembrane modulation of the neuronal cytoskeleton, we have focused on the microtubule-associated phosphoprotein MAP2 in rat hippocampal slices. Changes in MAP2 phosphorylation are known to regulate its interaction with microtubules and actin. Accordingly, multiple phosphorylation sites along the primary amino acid sequence represent potential targets for synaptic regulation of MAP2 function. Previous studies suggested that NMDA receptor activation is potentially coupled to MAP2 dephosphorylation. Additionally, depolarization of slices with 40 mM KCl induced a rapid dephosphorylation of MAP2. Such dephosphorylation was blocked by the NMDA receptor antagonist MK-801, suggesting that depolarization activates NMDA receptor-induced dephosphorylation by stimulating the release of endogenous glutamate. It is well established that glia possess efficient glutamate uptake mechanisms, and that endogenous glutamate is released from slices by spontaneous neuronal activity. Application of 1 mM dihydrokainate, an inhibitor of glutamate uptake by glial cells, induced a rapid dephosphorylation of MAP2, suggesting that endogenous glutamate is a potent signal for MAP2 dephosphorylation. NMDA-induced dephosphorylation is dependent on extracellular calcium concentration. These data support a model in which glutamate transmission activates the calcium-dependent protein phosphatase 2B (PP2B or calcineurin), which targets specific proteins, such as MAP2, for dephosphorylation.

ACTIVATION OF NFκB UPON GLUTAMATE STIMULATION IN CULTURED MOUSE CEREBELLAR GRANULE CELLS. L. Guerrini, F. Blasi and S. Denis-Donini*. Genetics and Biology Departments and Center of Cytopharmacology, Milan, Italy.

NFκB (the relA/p50 heterodimer) is a pleiotropic transcription factor. It is present in an active form in the nucleus of a restricted member of cell types (lymphocytes); in most other cell types it is present in a covert cytoplasmic form and it can be induced to move to the nucleus in response to a wide variety of extracellular stimuli. The localization of relA has been studied through immunohistochemistry in brain sections and in cultures of cerebellar granule cells. In brain sections, the pattern of staining suggests a synaptic localization, as already described in the rat (Kaltuschmidt et al. *Mec.Dev.* '93). In neuronal cells in vitro, relA is mostly concentrated at the tip of processes and at contact sites. This type of spatial distribution prompted us to investigate whether physiological stimuli, such as nanomolar concentrations of neurotransmitters, could activate NFκB in such cells. Glutamate pulses induce the nuclear translocation of NFκB, as observed through band shift experiments and this induction is specifically blocked by the NMDA receptor antagonist APV. With specific antibodies, we have assessed that the activated transcription factor is the heterodimer relA/p50. We are currently investigating the potential target genes of glutamate activated NFκB.

HYPOTONIC CELL SWELLING, TISSUE ELECTRICAL RESISTANCE AND SYNAPTIC TRANSMISSION IN CA1 ST. RADIATUM OF HIPPOCAMPAL TISSUE SLICES. S.R. Chehabo¹, M.A. Hester, J. Jing, P.G. Aitken*, G.G. Somjen. Dept. Cell Biol., Duke Univ. Durham, NC

In order to determine the degree of cell swelling in brain tissue caused by lowering of osmotic pressure, hippocampal slices were exposed to bathing fluid from which varying amounts of NaCl was deleted. Interstitial volume (ISV) change was determined from the volume of dilution of marker ions. TMA⁺ or TEA⁺ administered by iontophoresis. Tissue electric resistance was measured as the voltage drop generated by subliminal constant current pulses. The decrease of ISV determined from the dilution of probe ions was dependent on the degree of hypotonicity used. In the most severe condition ISV shrank to 3.3% of the total tissue volume. Prolonged hypotonic exposure revealed regulatory volume decrease (RVD). After restoring normal osmotic pressure, the cells in the tissue underwent post-exposure shrinkage. The electric resistance of the tissue increased in part due to lowered ionic strength and in part due to the effect of restricted interstitial space. Isosmotic NaCl deficient (mannitol or fructose-substituted) solutions had either no effect or caused erratic changes of TMA⁺ space. The corrected electric resistance did not increase in low NaCl solution. Extracellular EPSPs increased much more in hypotonic than in NaCl-deficient solution, and in both cases more than could be accounted for by the increased tissue resistance, confirming increased synaptic efficacy. (On leave from Dept. Pharmacol., Feder. Univ. Rio de Janeiro, Brazil) (Support by CNPq (Brazil), the Hughes Med.Inst., & NIH grant NS17771)

The Serotonergic Inhibitory Postsynaptic Potential in Prepositus Hypoglossi is Mediated by Two Potassium Currents. D. H. Bobker* and J. T. Williams. Dept of Neurology and Vollum Institute, L226, Oregon Health Sciences University, Portland, OR 97201

Synaptic inhibition mediated by the activation of potassium channels has been reported from several types of neurons. In each case, the K⁺ conductance underlying the synaptic potential is activated by a G protein and inwardly rectifies. We report here a second K⁺ current that contributes to synaptic inhibition. Intracellular recordings were made from guinea-pig nucleus prepositus hypoglossi *in vitro*, where we have described a 5-hydroxytryptamine (5-HT)-mediated inhibitory postsynaptic potential (IPSP). Voltage-clamp analysis of the current induced by applied 5-HT revealed two separate conductances: an inwardly rectifying, rapidly-activating K⁺ current (I_{IR}) and an outwardly rectifying, slowly-activating K⁺ current (I_{OR}). I_{IR} was blocked by extracellular Ba²⁺ (200 μM) and TEA⁺ (126 mM). I_{OR} was insensitive to this concentration of Ba²⁺ and TEA⁺, but was inhibited by Cd²⁺ and intracellular BAPTA, indicating Ca-dependence.

Single focal electrical stimuli evoked a 5-HT-mediated IPSP, or under voltage-clamp, an inhibitory postsynaptic current (IPSC). Ba²⁺ blocked only a component of this IPSC, which corresponded to the current caused by I_{IR}. When multiple stimuli were applied (to prolong the release of transmitter), the time-dependent current I_{OR} was more fully activated, resulting in an augmentation of the IPSC. We conclude that the IPSC is caused by both currents and that its amplitude can be modulated by the degree to which I_{OR} is activated. This represents a mechanism by which synaptic responses can be potentiated.

METABOTROPIC GLUTAMATE RECEPTOR-MEDIATED INCREASE OF PHRENIC MOTONEURON (PMN) EXCITABILITY IN VITRO. D. Morin, X-W. Dong & J.L. Feldman*. Systems Neurobiology Laboratory, Dept. of Physiological Science, UCLA, Los Angeles, CA, 90024-1527.

The role of metabotropic glutamate receptor (mGluR) in modulation of phrenic motoneuron excitability was studied in the *in vitro* neonatal rat brainstem/spinal cord preparation. Spontaneous PMN activity was recorded from cervical ventral root (C4) or by whole-cell patch-clamp techniques. In order to activate mGluR, trans-(1S,3R)-1-aminocyclopentane-1,3-dicarboxylic acid agonist (ACPD) was applied locally via pressure ejection over the ventral spinal cord surface at the level of the phrenic nucleus. To block mGluR, (R,S)-α-methyl-4-carboxyphenylglycine (MCPG) was added to the bathing solution. Local application of ACPD (0.2 - 0.7 mM) induced up to a 30% increase of the inspiratory activity, in a dose-dependent manner. At higher concentrations (0.5, 0.7 mM), tonic activity was superimposed on the inspiratory activity. MCPG (0.6-1 mM) effectively blocked the actions of ACPD. Local application of ACPD depolarized PMN resting membrane potential (10-15 mV) and produced a concurrent 9% decrease in the inspiratory drive potential. Current pulse injection which induced one spike under control condition induced several spikes after ACPD application. Under voltage-clamp conditions, ACPD caused a tonic inward current (-150 pA) and a 32% drop in amplitude of the inspiratory synaptic current. The I-V curve exhibited a 10% increase of input membrane resistance. The ACPD-induced inward current remained after TTX was added to the bathing solution and was partially blocked by MCPG (0.4 mM).

These results show a postsynaptic action of ACPD and suggest that mGluR can modulate the excitability of PMNs. Supported by NIH Grant NS24742 and the Conseil Régional PACA.

GABA_A INHIBITOR BLOCKS THE EXPRESSION OF ANTIDROMICALLY-CONDITIONED EPSP-TO-SPIKE POTENTIATION. Lee W. Campbell* and Terrence J. Sejnowski. Howard Hughes Medical Institute, Salk Institute, PO Box 85800, San Diego, CA 92186.

EPSP-to-spike or E-S potentiation is a component of LTP which results from a shift in the excitation/inhibition balance. In the presence of bicuculline, a GABA_A antagonist, most of the E-S potentiation component of LTP is eliminated.

Pairing antidromic theta-burst stimulation in phase with 5 Hz orthodromic stimulation produces an E-S potentiation without affecting EPSP slope (Soc Neurosci Abstr 17:533.15). This associative form of E-S potentiation is not blocked by GABA_A antagonists and is mechanistically distinct from the E-S potentiation of LTP (Soc Neurosci Abstr 19:547.15). Is GABA_A involved in the induction or expression of antidromically-conditioned associative E-S potentiation?

The EPSP and population spike were recorded from the CA1 layer of rat hippocampal slices. The antidromic conditioning stimulus was 50 bursts of 5 pulses at 100 Hz with an interburst interval of 200 ms delivered to the alveus. The Schaffer collaterals were stimulated at 5 Hz. The compound 5-aminovaleic acid (5AV) was used in the bath to block GABA_A receptors.

Several results suggest GABA_A receptors are involved in the expression, but not the induction, of associative E-S potentiation. 1) In slices showing E-S potentiation following paired stimulation, adding 1 mM 5AV 10 min after pairing reduced the potentiation of the population spike to baseline; washing in normal bathing medium restored the potentiation to its former value. 2) In slices failing to potentiate following paired stimulation and in slices given the antidromic conditioning separate from the orthodromic stimulation, 5AV had no effect on the population spike. 3) Delivering paired stimulation in 5AV medium resulted* in no E-S potentiation; washing out 5AV 10 min after pairing unmasked the potentiation.

LONG-TERM POTENTIATION: PHARMACOLOGY I

A CENTRALLY ACTIVE DRUG THAT MODULATES AMPA RECEPTOR GATED CURRENTS. A. Arai, M. Kessler*, J. Ambros-Ingerson, P. Xiao, G. Rogers and G. Lynch. Center for the Neurobiology of Learning and Memory, University of California, Irvine, CA 92717-3800.

Systemic administration of the drug 1-(1,3-benzodioxol-5-ylcarbonyl)-piperidine (BDP) has been reported to enhance monosynaptic responses in the hippocampus *in vivo* and to improve spatial and olfactory memory in rats. The mechanisms of action of BDP and recently developed, more potent analogs were investigated using a receptor binding assay, ligand-gated currents in patches excised from cultured hippocampal slices, and the field EPSP in acute hippocampal slices. The results were compared with those obtained with cyclothiazide, a structurally dissimilar diuretic compound known to affect the desensitization kinetics of the AMPA receptor. BDP and some but not all of its analogs caused an increase in ³H-AMPA binding whereas cyclothiazide produced a decrease in the affinity of the AMPA receptor. BDP and analogs increased the amplitude and decay time of AMPA receptor currents in excised patches with the greater effect being on the latter variable. Cyclothiazide enhanced the steady state current mediated by the receptor, as reported by other investigators. Detailed comparisons and modelling studies indicate that BDP and analogs have substantially different effects on the kinetics of AMPA receptor currents than does cyclothiazide. Finally, the BDP drugs markedly and reversibly facilitate the field EPSP in a manner predicted from their actions on excised patches. Significant differences in potency and effects on waveform were evident across the analogs tested. In summary, the available evidence indicates that the BDP drugs—for which the name "Ampakine" has been proposed—provide tools for testing the functional consequences of pharmacologically enhancing AMPA receptor mediated transmission in behaving animals. Supported by AFOSR 92-J-0307.

AMPLIFICATION OF MONO- AND POLY-SYNAPTIC TRANSMISSION IN HIPPOCAMPUS BY A NOVEL MODULATOR OF AMPA RECEPTORS. J. Sirvio^{1,2}, G. Rogers³, G. Lynch¹, & J. Larson¹. ¹CNLM, Univ. Calif., Irvine, CA 92717, ²Univ. Kuopio, Finland, ³Neurosci. Inst., Univ. Calif., Santa Barbara, CA.

Electrophysiological studies of drug actions typically assess direct membrane effects or effects on monosynaptic responses in order to characterize cellular mechanisms of action. However the ultimate effects of drugs on behavior may depend on the compounding of their actions across serial brain circuits. Drugs that modulate the function of AMPA-type glutamate receptors are of interest since AMPA receptors mediate responses at most excitatory synapses in the brain. The present study was undertaken to compare the effects of a novel AMPA receptor modulator, CX-516, on mono- and poly-synaptic responses in hippocampus.

Hippocampal slices were prepared from adult male rats using conventional methods. Stimulation electrodes were positioned to activate perforant path (PP) fibers in the molecular layer of the dentate gyrus and Schaffer-commissural (SC) fibers in CA1. A recording electrode was placed in the CA1 apical dendritic field.

PP stimulation evoked small (0.1-0.3 mV) negative field potentials in CA1 with latency and waveform characteristics consistent with them being mediated by the trisynaptic hippocampal circuit. SC stimulation was set to elicit monosynaptic responses of the same amplitude as the trisynaptic response. CX-516 (250 μM, n=6) reversibly increased the amplitude of the monosynaptic SC-evoked field EPSP by 52% (±18, S.D.) and that of the trisynaptic response by 188% (±65).

These results indicate that it is feasible to test drug effects on a serial, polysynaptic circuit *in vitro*. The AMPA receptor modulator had much larger effects on trisynaptic than on monosynaptic responses, suggesting that its effects are amplified across serial connections. These findings should be of use in correlating physiological and behavioral effects of drugs *in vivo*.

622.3

CENTRALLY ACTIVE MODULATORS OF AMPA RECEPTORS FACILITATE THE INDUCTION OF LTP *IN VIVO*. U. Staubli¹, Y. Perez, F. Xu, G. Rogers¹, M. Ingvar², S. Stone-Elander³ and G. Lynch¹. ¹Ctr Neural Sci, New York University, New York, NY 10003; ²Neuroscience Research Inst., Univ. of Calif., Santa Barbara, CA 93106; ³Karolinska Hospital, Clinical Neurophysiol., Stockholm, Sweden S-1040; ⁴Ctr Neurobiol. Learning & Memory, Univ. Calif., Irvine, CA 92717.

Previous work has shown that an experimental drug (BDP: 1-(1,3-benzodioxol-5-ylcarbonyl)piperidine) increases the amplitude and duration of EPSPs recorded in slices of hippocampus, while having little effect on the slope of responses. Studies with outside-out patches indicate that BDP modulates AMPA receptor gated currents. After intraperitoneal (ip) injections and for 2-3 hours, BDP influences monosynaptic responses in the dentate gyrus and area CA1 *in vivo* in a manner similar to that observed in slices. Here we tested the effects of BDP on LTP in field CA1 of freely moving rats. LTP was induced using a minimal stimulation paradigm involving pairs of short high-frequency bursts (paired theta bursts) repeated 5 times at 30 seconds; this pattern produces a small and transient (24hrs) potentiation effect. Each of nine animals was tested both in absence and presence of the drug in a counterbalanced fashion. Injection of the drug prior to theta burst stimulation greatly facilitated the subsequent induction of LTP; i.e., the increase in slope and amplitude was larger in magnitude and more persistent (several days) following drug than vehicle injections. Biodistribution and pharmacokinetics were examined with positron emission tomography (PET) using BDP radiolabelled with carbon-11; the results confirmed that the drug rapidly migrates from the injection site and crosses the blood-brain barrier; time activity curves for brain, heart and liver showed that the drug reaches a maximum in the brain in less than 4 minutes. The facilitatory effects on LTP induction in freely moving animals were replicated with an analogue of BDP (BDP-5), which was also found to improve retention in a radial maze and in an odor matching problem. These results define the first tool for enhancing LTP *in vivo* and confirm an important prediction from the hypothesis that LTP is a substrate of memory.

622.5

ENHANCEMENT OF SYNAPTIC TRANSMISSION IN HIPPOCAMPUS OF AGED RATS BY NOVEL MODULATORS OF AMPA RECEPTORS. M. Coogan¹, J. Larson¹, G. Rogers², & G. Lynch¹. ¹CNLM, Univ. Calif., Irvine, CA 92717, ²Neurosci. Inst., Univ. Calif., Santa Barbara, CA 93106.

Recent studies have identified a novel class of drugs (Ampakines) that facilitates excitatory synaptic currents mediated by AMPA receptors. Since aging is accompanied by decreases in excitatory communication, it has been suggested that such drugs might offset certain types of age-related deficits. This idea rests on two unexamined assumptions about AMPA receptors in the aged brain: i) that the binding site(s) for the drugs is unchanged from that found in young brains and ii) that the channel kinetic properties affected by the drugs are also comparable in young vs. aged brains. These assumptions were tested by comparing drug effects on synaptic responses in young (1-4 months) and aged (24-28 months) rats.

Hippocampal slices were prepared using conventional methods and field EPSPs recorded in the CA1 region. Two Ampakines (CX-516 and CX-517) found to produce potent effects in pilot studies were used. Both drugs produced qualitatively similar, dose-dependent, reversible enhancements of field EPSP amplitude and prolongations of decay time in slices from young and aged rats. CX-516 had more potent effects on response amplitude whereas CX-517 was more potent in modulating the decay time. Quantitative comparisons involving several response parameters and patterns of synaptic activation will be described and shown to reinforce the conclusion that the drugs have essentially the same effects on synaptic responses in the young and aged hippocampus. Based on these findings, it appears that Ampakines can be used to test the hypothesis that facilitation of fast, excitatory transmission will have positive effects with regard to age-related changes in brain functioning.

TEA PRODUCES A PERSISTENT ENHANCEMENT OF SYNAPTIC TRANSMISSION IN RAT NEOCORTEX. Marc R. Pelletier* and John J. Hablitz. Neurobiology Research Center, University of Alabama at Birmingham, Birmingham, AL 35294.

We investigated the ability of tetraethylammonium (TEA) to induce long lasting changes in neocortical synaptic activity. Intracellular recordings were obtained from layer II/III pyramidal neurons in *in vitro* brain slices. Bath application of 25 mM TEA for 7 min produced transient effects on passive membrane properties. The resting membrane potential depolarized by 4.1 ± 0.4 mV (\pm SEM; n=9) and the input resistance increased by $16 \pm 4.2\%$. The duration of action potentials, evoked by depolarizing current, was increased dramatically; an effect consistent with the blockade by TEA of K⁺ channels. Action potential duration was not different from control after 30-40 min of wash; TEA was then considered to have been washed out. TEA produced a persistent (45 min of wash) increase of $158.7 \pm 7.6\%$ in the amplitude of EPSPs evoked by weak orthodromic stimulation (layer IV/V; 0.05 Hz). The amplitude of chloride-dependent IPSPs evoked by strong orthodromic stimulation was increased by $180 \pm 10.0\%$. These effects on synaptic transmission were APV (20 μ M)-resistant (n=4). Orthodromic stimulation during TEA application was not required for enhancement (n=5). The enhancement of EPSPs, but not IPSPs, was blocked by recording with pipets containing 200 mM BAPTA (n=4). TEA-induced enhancement of EPSPs in the neocortex is similar to that described in hippocampus. Additionally, we report an enhancement of IPSPs, which might be mediated presynaptically via an increase in GABA release.

622.4

FACILITATION OF OLFACTORY LEARNING BY A NOVEL MODULATOR OF AMPA RECEPTORS. J. Larson¹, T. Lieu¹, V. Petchpradub¹, G. Rogers², & G. Lynch¹. ¹CNLM, Univ. Calif., Irvine, CA 92717, ²Neurosci. Inst., Univ. Calif., Santa Barbara, CA 93106.

Recent studies indicate that drugs that enhance excitatory currents mediated by AMPA receptors facilitate the induction of hippocampal long-term potentiation. The present experiment tested the effects of a novel AMPA receptor modulator, CX-516, on acquisition, retention, and performance in an olfactory discrimination paradigm.

Adult rats (n=12) were trained on a series of simultaneous cue, two-odor discriminations until new problems were acquired in one session. They were then given a series of novel problems in which only 3-5 training trials were used. Prior to each problem, half the rats were given CX-516 (30 mg/kg) and the other half vehicle injections; positive and negative cues were counter-balanced across rats. Each rat was trained on 2-3 novel problems under drug and vehicle conditions. Retention was assessed 1-3 days post-training by giving 5 unrewarded probe trials.

The rats trained on odor problems after vehicle injections showed chance responding on subsequent retention trials ($51.1 \pm 6.6\%$ correct); the same rats trained after CX-516 injections showed significantly better retention ($73.4 \pm 7.0\%$ correct; $p < .01$). The animals also made more correct responses on training trials 2-5 on drug vs. vehicle days ($79.3 \pm 6.3\%$ vs. $45.8 \pm 12.4\%$; $p < .05$). There were no evident drug effects when the rats were tested on already-learned odors.

These results suggest that facilitation of AMPA receptors can enhance acquisition of novel information without causing substantial changes in performance variables (e.g., cue processing, motor responses, motivation) involved in the training paradigm. Accordingly, drugs such as CX-516 may be of use in the treatment of memory disorders.

QUANTITATIVE LOCALIZATION OF AMPA RECEPTOR mRNAs - EVIDENCE FOR REGIONALLY SPECIFIC SUBUNIT STOICHIOMETRIES S. J. Gold*², M. Hennegriff², G. Lynch², and C. M. Gall¹. ¹Dept. of Anatomy and Neurobiology, and ²Psychobiology, University of California, Irvine, CA 92717

Quantitative *in situ* hybridization and reverse-transcriptase PCR were used to determine the relative levels of AMPA receptor subunit (GluR1-3) mRNAs in rat forebrain. In all regions sampled, GluR2 cRNA hybridization was dense, being greater than or equal to the other two subtypes. Levels of GluR1 and GluR3 mRNA, however, varied markedly between hippocampus, neocortex and piriform cortex. In hippocampal neuronal layers, GluR1 cRNA hybridization density was equal to GluR2 but was 3-4 fold higher than GluR3. In contrast, piriform cortex (layers II-III) had relatively low levels of GluR1 mRNA (40% of GluR2), but high levels of GluR3 (60% of GluR2). In piriform cortex (layer II), GluR1 and GluR3 mRNA levels were both low (33% of GluR2). If relative levels of mRNA are predictive of relative levels of subunit protein, then it is likely that the stoichiometry of the AMPA receptor varies substantially between synaptic systems in cortical zones of the telencephalon. Attempts to test this using immunoprecipitation with antibodies directed at the subunits of the receptor are in progress. It will also be of interest to determine if the regional variations described here are associated with differences in plasticity of the LTP type which is reported to be dependent upon the AMPA receptor subunit composition as well as with the effects of recently developed drugs ("Ampakines") that facilitate AMPA receptor mediated responses in the hippocampus of behaving animals. Supported by AG00538.

INDUCTION OF LTP VIA VOLTAGE-DEPENDENT CALCIUM CHANNELS (VDCCs) IS NOT SYNAPSE SPECIFIC. K.M. Huber*, M.D. Mauk, and P.T. Kelly. Dept. of Neurobiology and Anatomy, Univ. of Texas Medical School-Houston, TX 77225.

Tetraethylammonium (TEA) induced potentiation (LTP_K) was used to examine the properties of LTP induced by Ca²⁺ influx through VDCCs in area CA1 of hippocampal slices. We previously showed that LTP_K in isolated CA1 slices was strictly dependent on NMDA receptor activity (Huber et al., SN abstract # 547.10, 1993). We found that delivering 80 msec pulses of 25 Hz stimulation once every 5 sec to Schaffer collaterals during TEA applications induced LTP_K ($26 \pm 4\%$, n = 12) in the presence of APV (100-200 μ M), but was blocked by APV plus nifedipine (10-50 μ M; $5 \pm 3\%$, n = 6). We utilized this protocol in two pathway experiments to determine the synapse specificity of VDCC-dependent LTP_K. Stimulation was turned off to one pathway during TEA applications, while the other independent pathway was stimulated using the 25 Hz stimulation protocol (described above). Significant potentiation was observed in the stimulation off pathway ($27 \pm 3\%$, n = 12), indicating that induction of VDCC dependent LTP_K is not synapse specific. This finding is supported by experiments in which CA1 neurons were stimulated antidromically (alveus) using the 25 Hz stimulation protocol and all synaptic (Schaffer collateral) stimulation was ceased during TEA applications. The antidromic stimulation protocol in APV (100-200 μ M) resulted in potentiation of EPSPs ($20 \pm 5\%$, n = 5) when synaptic stimulation was resumed 30 min after TEA application. This property contrasts with NMDA receptor-dependent LTP which has been shown to be specific to synapses that are active during induction and suggests that the route of Ca²⁺ entry can control the synapse specificity of LTP. These data support the hypothesis that a function of dendritic spines is to localize NMDA receptor mediated increases in postsynaptic Ca²⁺ and are responsible for synapse specificity. In contrast, VDCCs have been shown to be localized on proximal dendrites and may primarily mediate Ca²⁺ increases in dendritic shafts (Westenbroek, et al. Nature, 1990; Müller and Connor, Nature, 1991) and therefore do not contribute to the mechanisms underlying synapse specificity.

622.9

THE NMDA RECEPTOR REDOX SITE: DTNB BLOCKS INDUCTION AND EXPRESSION OF TETANIC NMDA-LTP BUT NOT AMPA-LTP P. CHINESTRA, H. GOZLAN, D. DIABIRA, B. ZALC* and Y. BEN-ARI. INSERM U-29, 123, Bld de Port-Royal, 75014 Paris, France.

In physiological conditions, the induction of LTP is mediated by NMDA receptors, whereas the expression is mediated primarily by AMPA receptors (AMPA-LTP). LTP of NMDA receptors (NMDA-LTP) can be induced however, in several conditions, notably when AMPA receptors are blocked partially or completely and (or) when (Mg^{++}) is reduced to boost NMDA responses (Asztely et al., *Europ. J. Neurosci.*, 1992, 4: 681). Since DTNB and DTT have no effect on AMPA receptor-mediated responses in rat hippocampal slices and since a redox site sensitive to these drugs has been shown to modulate NMDA receptor responses (Tang and Aizenman, *J. Physiol.* 1993, 465: 303), we have investigated the effect of DTNB (200 μ M) on the two types of tetanic LTP using extracellular recording techniques. The following results have been obtained: 1) DTNB does not affect the induction or expression of AMPA-LTP. 2) DTNB irreversibly reduced (maximally) 35-45% of control NMDA receptor-mediated responses. 3) DTNB prevented the induction of NMDA-LTP. 4) The expression of NMDA-LTP was completely reversed by DTNB. These results indicate that at least one disulfide bridge exists in NMDA but not in AMPA receptors. This S-S group is probably reduced during the tetanic stimulation and the SH groups generated in the NMDA receptor are necessary not only for the induction but also for the expression of NMDA-LTP (see Gozlan et al. this meeting). Interestingly, the induction of AMPA-LTP by NMDA receptors apparently does not require these SH groups. These observations provide the first direct evidence of a major difference between the expression of NMDA-LTP and AMPA-LTP. They cannot be readily reconciled with a presynaptic hypothesis for the maintenance of LTP.

622.11

(RS)- α -METHYL-4-CARBOXYPHENYLGLYCINE AND (RS)-4-CARBOXY-3-HYDROXYPHENYLGLYCINE BLOCK TETANUS-INDUCED LTP, BUT NOT METABOTROPIC GLUTAMATE AGONIST-INDUCED INCREASES IN ADENYLATE CYCLASE ACTIVITY. M.A. Musgrave¹, T.Y. Tomita and J.W. Goh. Department of Pharmacology and Toxicology, Queen's University, Kingston, Ontario, Canada, K7L 3N6.

Induction of long-term potentiation (LTP) in the CA₁ region of hippocampus is dependent on N-methyl-D-aspartate (NMDA) receptor activation, however, stimulation of this receptor alone is not sufficient to maintain LTP. In our previous work, we have demonstrated that coactivation of a metabotropic glutamate receptor (mGluR) coupled to postsynaptic increases in adenylyl cyclase activity and NMDA receptor is required for LTP induction (Musgrave, Ballyk and Goh, *Neuroreport*, 4, 171-174, 1993; Musgrave, Madigan, Bennett and Goh, *J. Neurochem.*, in press, 1994). In these studies we examined the ability of novel mGluR antagonists, analogues of phenylglycine, to block induction of LTP as well as the increase in cAMP induced by mGluR agonists. For LTP studies, extracellular EPSPs were recorded at the CA₁ dendritic zone of rat hippocampal slices. Bath application of either 4-carboxy-3-hydroxyphenylglycine (500 μ M) or (RS)- α -methyl-4-carboxyphenylglycine (500 μ M) both blocked tetanus-induced (100 Hz, 1s) LTP in a reversible manner. For assessment of adenylyl cyclase antagonism, rat hippocampal synaptosomes were incubated with each phenylglycine compound alone, or in combination with the mGluR agonists 1S,3R-1-aminocyclopentane-1,3-dicarboxylic acid (1S,3R ACPD; 100 μ M) or quisqualate (1mM) or L-amino-4-phosphonobutyric acid (L-AP₄; 1 mM). Neither 4-carboxy-3-hydroxyphenylglycine nor (RS)- α -methyl-4-carboxyphenylglycine had any effect on either basal levels or mGluR agonist-induced increases in adenylyl cyclase activity at any concentrations of antagonist tested (100 μ M, 500 μ M, 1 mM, 10 mM). These studies suggest that while these compounds are effective in blocking tetanus induced LTP they probably do not do so via inhibition of the mGluRs coupled to the cAMP system. (Supported by the Medical Research Council of Canada).

INOSITOL HEXAKISPHOSPHATE CAUSES DEPRESSION OF POPULATION SPIKE AMPLITUDE IN SCHAFER COLLATERAL-CA1 SYNAPSES. A.R. Parent¹, G. Massicotte², and D.J. Linden^{1*}. ¹Department of Neuroscience, Johns Hopkins University School of Medicine, Baltimore, MD 21205, and ²Département de Chimie-Biologie, Université du Québec à Trois-Rivières, Québec, Canada, G9A 5H7.

Hydrolysis of phosphatidylinositol generates various inositol phosphates including inositol hexakisphosphate (IP₆) which can reach a concentration of 25-100 μ M in mammalian cells. While the neurophysiological roles of IP₆ are not well defined, IP₆ application has been reported to cause Ca²⁺ influx and to release neurotransmitters such as aspartate and catecholamines as measured biochemically. Interestingly, IP₆ can act extracellularly by binding to AP-2, a clathrin-associated protein involved in endocytosis and synaptic vesicular recycling processes. Thus, it appears that IP₆ could play a role in the modulation of synaptic transmission. To assess this hypothesis, IP₆ was bath-applied to guinea pig hippocampal slices and the population responses evoked by Schaffer collateral stimulation were recorded in area CA1. Following 60 min of baseline recording, IP₆ (25 μ M) was applied for 30 min and synaptic transmission was monitored for another 90 min. A significant depression of the population spike amplitude (recorded in s. pyramidal) was observed 60 min after the onset of IP₆ treatment (27% decrease) and had reached a plateau after 120 min (79% decrease, n=7). However, no significant change in the population EPSP (recorded in s. radiatum) was observed over the same monitoring period (n=4). A preliminary finding indicates that pretreatment with the GABAergic antagonist bicuculline (1 μ M; n=2) blocked the depression of the population spike amplitude produced by IP₆, suggesting that this compound may exert its electrophysiological effects by potentiating GABAergic feed-forward inhibition. 622.10

THE NMDA RECEPTOR REDOX SITE: INDUCTION AND EXPRESSION OF ANOXIC LTP ARE BLOCKED BY DTNB. H. GOZLAN, D. DIABIRA, P. CHINESTRA, J. LANOIR* and Y. BEN-ARI. INSERM U-29, 123, Bld de Port-Royal, 75014 Paris, France.

A novel form of LTP induced by a brief anoxic-aglycemic episode has been recently described in this laboratory (Crepel et al., *J. Neurophysiol.*, 1993, 70: 2045). This anoxic LTP is mediated exclusively by NMDA receptors, in contrast to tetanic LTP which is primarily mediated by AMPA receptors. Since NMDA receptor responses are modulated by redox conditions (Tang and Aizenman, *J. Physiol.*, 1993, 465: 303), and since an anoxic episode induces modifications of redox equilibria, we have studied the effects of the thiol specific oxidizing reagent DTNB on the induction and the expression of anoxic LTP. In control slices anoxia generated a LTP, and this process was fully prevented by DTNB. Once potentiated, the NMDA response returned to control levels in the presence of DTNB and application of disulfide reducing agents potentiated NMDA responses reversing the inhibition induced by DTNB. In the presence of DTNB (200 μ M), 35-45% of control NMDA field epp was irreversibly reduced and the anoxic LTP could not be generated. These results indicate that anoxia induces a modification of the redox site of the NMDA receptor, probably a reduction of at least a disulfide bond and the free SH groups generated by this process are required for the induction and expression of anoxic LTP. This effect is specific to NMDA receptors: tetanic LTP of NMDA but not AMPA receptors requires a redox modification (Chinestra et al., this meeting). If such a process could be demonstrated to occur in vivo, then disulfide drugs would have some interest in the treatment of the consequences of ischemia.

622.12

1S-3R ACPD can cause long-term depression and depotentiation of synaptic transmission in the dentate gyrus of rat hippocampal slices.

S.M. O'Mara¹, M. Rowan² and R. Anwyl¹. ¹Departments of Physiology¹ and Pharmacology & Therapeutics², University of Dublin, Trinity College, Dublin 2, Ireland.

The effect of the metabotropic glutamate agonist 1S-3R ACPD (200 nM - 100 μ M) on synaptic transmission was examined in both naive (non-potentiated) and potentiated submerged rat hippocampal slices (400 μ m). A bipolar stimulating electrode and a blunt ACSF-filled recording pipette were lowered into the middle third of the perforant path of the dentate gyrus under visual control; field excitatory postsynaptic potentials (fEPSPs) were evoked at .05 Hz (stimuli were 3-15 volts, 100 μ sec). Application of 1S-3R ACPD (20 min) depressed fEPSP amplitude in a dose-dependent fashion in the dentate gyrus of 8 of 8 naive hippocampal slices. At 200 nM ACPD the average EPSP amplitude was 88% \pm 1% of baseline; at 100 μ M EPSP amplitude was 29% \pm 2% of baseline. Enhancement of synaptic transmission was observed in one slice (1 μ M, 20 mins) of 23 tested; EPSP amplitude increased by 25% \pm .05% and subsequent tetanic LTP was occluded. Long-term potentiation (LTP) was induced using 8 trains of 8 pulses at 200 Hz, inter-train interval of 2s; the average increase in fEPSP amplitude at 20 mins post-high frequency stimulation was 53% \pm 5%. When applied for 2 mins, 1S-3R ACPD (10 μ M) transiently reduced fEPSP amplitude in naive slices (94% \pm 3% of baseline) and potentiated slices (91% \pm 1% of potentiated baseline); all slices returned to baseline in 120 secs post-washoff. ACPD (100 μ M) applied for 20 minutes reduced the magnitude of potentiated EPSPs; the average decrease in EPSP amplitude 20 min post-washoff was 75% \pm 12% of baseline in 9 of 9 slices. When homosynaptic long-term depression was induced (average decrease after 20 min was to 62% \pm 5% of baseline) using low frequency stimulation (1 Hz, 10 mins), 100 μ M 1S-3R ACPD induced a further long-term depression (20 mins, decrease to 46% \pm 4% of baseline) in fEPSP amplitude which was reversible with high frequency stimulation.

We conclude that sustained activation of metabotropic glutamate receptors with 1S-3R ACPD can induce both long-term depression and depotentiation of synaptic transmission in the dentate gyrus of the hippocampal slice.

622.14

IMPAIRED LTD AND PAIRED PULSE FACILITATION IN THE CA1 REGION OF THE HIPPOCAMPUS OF COGNITIVE DEFICIENT MICROENCEPHALIC RATS.

Ramakers G.M.J.¹, Urban, I.J.A.¹, De Graan, P.N.E.¹, Cattabeni, F.², DiLuca, M.², and Gispen, W.H.¹ (SPON: European Neuroscience Association)

¹ Rudolf Magnus Institute, University of Utrecht, The Netherlands. ² Institute of Pharmacological Sciences, Faculty of Pharmacy, University of Milan, Italy.

Recently we have reported that in the CA1 region of the hippocampus of cognitive deficient microencephalic rats LTP is disturbed, and that this defect could be restored by D-Serine, an agonist for the glycine-site of the NMDA receptor (Ramakers et al., *Neuroscience* 54, 49-61, 1993). In the present study we have investigated long-term depression (LTD) and paired pulse facilitation (PPF) in slices from these rats. Microcephaly was induced by injection of methylazoxymethanol (MAM, 25 mg/kg) to pregnant rats on day 15 of gestation (G15). Field EPSPs were recorded in the radiate layer of the CA1 field by stimulating (at 0.1 Hz and 1/2 maximum intensity) orthodromically. Glass-electrodes filled with artificial cerebrospinal fluid (ACSF) were used for the recording. In slices from control rats (injected with saline on G15) 1 Hz stimulation for 15 minutes elicited LTD which lasted for at least one hour ($-52.5 \pm 3.3\%$, 60 minutes after induction). In slices from microencephalic rats identical stimulation failed to induce LTD ($+3.6 \pm 2.7\%$). D-Serine (2 mM) added to the ACSF before and during the 1 Hz stimulation did not correct the defect in induction of LTD. In addition, paired pulse stimulation with interstimulus interval (ISI) of 50, 100 and 200 ms failed to induce PPF in slices from microencephalic rats, instead a depression of the second response was observed. This depression depended on the stimulus strength, as weak stimulation showed no depression (but still no potentiation). At present the effect of D-Serine on this is investigated. The fact that D-Serine restores LTP and fails to correct LTD in slices from MAM-treated rats suggests that both forms of plasticity may require a different NMDA receptor activation. The absence of PPF and the finding of PPD suggests that the defects in plasticity of glutamatergic synapses in MAM-treated rats involve both pre- and postsynaptic mechanisms.

622.15

ENHANCED LTP PRODUCED BY EXPOSURE TO THE REDUCING AGENT DITHIOTHREITOL (DTT) IS REVERSED BY THE REDOX AGENT PYRROLOQUINOLINE QUINONE (PQQ). DL Tauck¹*, MC Stevens², E Aizenman³, PA Rosenberg², FE Jensen¹. Biology, Santa Clara Univ., Santa Clara, CA ¹; Neurol., Children's Hosp.¹, Harvard Med. Sch., Boston, MA; Neurobiol., Univ. Pittsburgh Sch. Med, Pittsburgh, PA³.

PQQ is a putative essential nutrient shown *in vitro* to diminish NMDA ionic currents and neurotoxicity by direct oxidation of the NMDA receptor redox site (*J. Neurosci.* 1992;12). Administration of PQQ prior to hypoxia/ischemia in a rodent stroke model significantly reduces infarct size (*Neuroscience*, 1994; in press). Reduction of the NMDA redox site by DTT enhances LTP (*Br. Res.* 1990; 519). In order to establish whether PQQ modulates NMDA activity via the redox site, we compared the effect of DTT and PQQ on LTP in hippocampal slices from adult rats. Extracellular synaptic potentials were recorded from s. rad. of area CA1 by stimulating CA3 Schaffer collaterals. LTP was induced by tetanic stimulation (100Hz for 1mscc, repeated once after 20 sec) at an intensity evoking 1/2 of the maximal response. In slices perfused with control medium, the tetanus increased the slope of the EPSP $52 \pm 8.5\%$ (mean \pm SE, n=12 slices, n=12 rats). DTT exposure (100 μ M for 30 min, followed by 30 min wash) significantly increased the magnitude of LTP ($88.9 \pm 16.6\%$ (n=8 slices, n=8 rats, $p < 0.04$). In contrast, following exposure to DTT, PQQ (100 μ M) significantly reduced LTP ($10.5 \pm 7.4\%$, n=7 slices, n=7 rats, $p < 0.005$). These results are consistent with *in vitro* observations from cultured cortical neurons and demonstrate that, in intact pathways in hippocampal slice, PQQ reverses the action of DTT on NMDA receptor mediated events. LONG-TERM POTENTIATION: PHARMACOLOGY II

623.1

THE INFLUENCE OF GABA_A- AND GABA_B-ANTAGONISTS ON THE MAINTENANCE OF HIPPOCAMPAL LONG-TERM POTENTIATION IN RATS. Klaus Schollmeier*, Franziska Krause and Uwe Frey. Inst. Neurobiol., Gene Regul. & Plasticity, Brennecke- Str. 6, P.O. Box 1860, 39008 Magdeburg, Germany

Hippocampal long-term potentiation (LTP) is thought to serve as an elementary model for the investigation of processes underlying learning and memory formation.

Since a possible involvement of GABAergic transmission on the prolonged maintenance of LTP (> 4 hours) has not yet been shown, we examined the influence of GABAergic antagonists on late stages of hippocampal LTP in the CA1 region *in vitro*. The method used has been described previously by Frey et. al (*Brain Res.* 452, 57 - 65, 1988).

Here we present some evidence, that bath application of the GABA_A-antagonist picrotoxin (10 μ M) and of the GABA_B-antagonist 5-aminovaleric acid (50 μ M) did not block the induction and maintenance of LTP for at least 8 hours. Even the application of 50 μ M picrotoxin and 50 μ M 5-aminovaleric acid together had no influence on the induction or maintenance of LTP. Since application of 10 μ M picrotoxin (as used in the first set of experiments) in combination with 50 μ M 5-aminovaleric acid did not cause complete inhibition of the GABAergic transmission, 50 μ M picrotoxin was used in experiments, where both substances were applied simultaneously.

Our results indicate, that the induction and prolonged maintenance of hippocampal CA1-LTP is independent of GABAergic transmission.

GABAergic AND DEVELOPMENTAL MODULATION OF HOMOSYNAPTIC LTD AND DEPOTENTIATION IN THE HIPPOCAMPUS. J.J. Wagner* and B.E. Alger. Dept. of Physiology, School of Medicine, University of Maryland, Baltimore, MD 21201

To test the hypothesis that GABA may regulate the induction of homosynaptic LTD and depotentiation (DPT), we compared the effects of GABA antagonists on hippocampal slices from young (16-22 days) and mature (5-10 weeks) rats. The slopes of extracellular CA1 field EPSPs were used to monitor synaptic transmission in s. radiatum. Low-frequency stimulation (LFS, 1 Hz/900 pulses) elicited LTD with respect to baseline synaptic transmission, or DPT from a potentiated level following LTP induction by HFS (100 Hz/1 sec). In young animals, LTD was inhibited by 1 mM CGP 35348 (a GABA_B antagonist), $-12 \pm 2\%$, n=10 vs a $-27 \pm 1\%$, n=9 decrease in EPSPs from control slices. In contrast, homosynaptic DPT was unaffected by CGP 35348. In mature animals, LFS did not induce significant LTD ($-4 \pm 2\%$, n=38, from baseline), although significant DPT could be consistently elicited by an LFS given 30 minutes after LTP induction ($24 \pm 5\%$, of potentiation remaining, n=15). Bicuculline (10 μ M, a GABA_A antagonist) had no significant effect on LTD magnitude in young animals, but significantly enhanced LTD expression in slices from mature animals. In addition, after HFS, LTD (relative to the initial baseline) was expressed in mature slices following 2-3 LFS episodes. Our results suggest that the influences of both age, and of prior synaptic activity (i.e. HFS) on LTD induction can be explained by changes in GABAergic systems in young vs mature, and naive vs tetanized slices.

623.2

Inhibitory Synaptic Transmission Modulates the Induction of Long Term Depression in CA1 Region of Hippocampus. P.M. Steele, M.D. Mauk*, Dept. of Neurobiology and Anatomy, Univ. of Texas Medical School- Houston, TX 77225.

The goal of this study was to examine the role of GABAergic input in the induction of long-term depression (LTD) at the Schaffer collateral/commissural synapses in area CA1 of hippocampus slices. The induction of LTD in the hippocampus (Yang et al., *Soc. Neurosci. Abstracts*, #183.3, 1993) and possibly in the cerebellum (Ekerot and Kano, *Brain Research*, 1985) is regulated by GABA. Therefore, we hypothesize that GABAergic input is required for LTD induction in the hippocampus. To test this hypothesis we attempted to induce LTD in the presence of 50 μ M picrotoxin (GABA_A antagonist) and again in the same slice one hour after picrotoxin washout. We find that low frequency synaptic stimulation (600 pulses at 1 or 3 Hz) in the presence of picrotoxin produces only a transient decrease of EPSP slope. This decrease returned after 25 minutes to $98\% \pm 1$ of baseline after 1 Hz stimulation and $95\% \pm 2$ after 3 Hz (n=5). In the same slice LTD could be reliably induced after picrotoxin washout; EPSPs were reduced to $86\% \pm 2$ and $80\% \pm 1$ after 1 and 3 Hz stimulation respectively. These results suggest that GABAergic synaptic transmission can influence LTD induction.

623.4

NITRIC OXIDE REGULATES THE THRESHOLD OF FREQUENCY DEPENDENT PLASTICITY IN AREA CA1 OF RAT HIPPOCAMPUS.

P.L. Malen* & P.F. Chapman. Graduate Program in Neuroscience and Department of Psychology, University of Minnesota, Minneapolis, MN 55455.

Inhibition of nitric oxide synthase (NOS) blocks the induction of certain forms of long-term potentiation (LTP) and disrupts the acquisition of several different forms of learning. We examined the effects of both nitric oxide (NO) donors and NOS inhibitors on plasticity in area CA1 of the rat hippocampal slice.

Standard techniques were used for hippocampal slice preparation. Slices were obtained from Sprague-Dawley rats (14-35 days old) and experiments were performed in a submersion-type recording chamber at 31.6°C. Stimulating and recording electrodes were placed in stratum radiatum and extracellular field potentials were elicited every 15 seconds. Drugs were washed in via a continuous perfusion system.

In the presence of an NO donor, stable LTP could be induced by a variety of tetanic stimuli that were normally below threshold for LTP induction. We were able to induce LTP at tetanus parameters as weak as 25 pulses delivered at 10 Hz in the presence of the NO donors hydroxylamine (200 μ M) or S-nitroso-N-acetylpenicillamine (200 μ M). In the presence of the NMDA receptor antagonist AP5, a subthreshold tetanus of 25 pulses delivered at 50 Hz in combination with hydroxylamine induced a slowly developing potentiation.

The frequency of synaptic activation is a critical factor in determining the resulting plasticity. While holding the absolute number of stimuli constant (900), varying the frequency of stimulation from 1 Hz to 30 Hz will shift the resulting plasticity along a curve from depression to potentiation. Inhibition of NOS at frequencies that normally induce long-term depression (1-3 Hz) does not alter the resulting plasticity. Our preliminary results indicate that although NO does appear to lower the threshold for LTP induction, it is apparently without effect on the induction of long-term depression.

Supported by a grant awarded to PFC from the Whitehall Foundation.

PLATELET ACTIVATING FACTOR (PAF) RELEASED DURING HIPPOCAMPAL LTP: ROLE AS A RETROGRADE MESSENGER.

E. Kordecki, A. Wieraszko*, G. Li, P. Dzapsatzu and V.H. Ehrlich, Dept. Anat. & Cell Biol. SUNY HSC, Brooklyn, NY 11203 and CSI/IBR Ctr. Dev. Neurosci., CUNY at Staten Island, NY 10314.

Platelet activating factor (PAF) is an alkyl-ether phospholipid with significant neuroregulatory and neuropathological actions (Science, 240:1792, 1988), including the induction of LTP in the hippocampus that could be blocked by PAF receptor antagonists, as well as by the NMDA receptor antagonists, APV and MK801 (Neuron, 10: 553, 1993). Here we have used radioimmunoassays (RIA) to measure PAF release from hippocampal slices during LTP induced by high frequency stimulation (HFS). During basal activity, before HFS, PAF levels in the medium were 0.533 ± 0.033 ng/ml. 2 min after HFS this level did not change significantly (0.605 ± 0.058 ng/ml PAF, $p = 0.37$). 15 min after HFS a significant increase to 1.33 ± 0.20 ng/ml PAF was detected ($p < 0.05$). Upon establishment of stable LTP (60 min after HFS) PAF levels increased 9 fold above basal (to 4.57 ± 0.27 ng/ml, $p < 0.001$), and remained the same up to 2 hours post stimulation (4.60 ± 0.10 ng/ml PAF). We propose that postsynaptic calcium influx stimulated by NMDA receptors increases PAF biosynthesis. The PAF released from postsynaptic membranes interacts with presynaptic receptors to increase glutamate release. Each turn of this cycle amplifies subsequent responses. These biochemical reverberations in the Hebbian synapse would create a permanent increase in synaptic efficiency.

DEVELOPMENTAL CHANGES IN CELLULAR MECHANISMS OF LONG-TERM POTENTIATION IN THE HIPPOCAMPUS: MATURATION OF A1 ADENOSINE RECEPTORS. Y. Sekino^{1,2}, Y. Saitoh², R. Ohtani-Kaneko³, H. Nakata², and Y. Kuroda², IPRESTO, Research Development Corporation of Japan, ²Dept. of Mol. & Cell. Neurobiol., Tokyo Metropolitan Inst. for Neurosci., Fuchu-shi, Tokyo 183, ³Dept. of Anatomy, St. Marianna Univ. School of Med., Kawasaki 216, Japan.

Memory processes are generally thought to change during maturation of the brain. Long-term potentiation (LTP) and post-tetanic depression (PTD) in hippocampus have been proposed as important processes underlying memory. We previously reported that endogenous adenosine is released during tetanic stimulation and plays an essential role in the induction of LTP and PTD in rat hippocampal slices (Sekino, Y., et al. B.B.R.C. 181, 1010-1014, 1991; Sekino, Y., Soc. Neurosci. Abstr. 18, 640, 1992). Here we examine how the role of adenosine in synaptic plasticity changes during brain development. We evaluated the pharmacological effects of an A1 receptor antagonist, 8-cyclopentyltheophylline (8-CPT), on synaptic transmission in slices of guinea pig hippocampus. Synaptic responses were measured in CA1 neurons in response to single stimuli and trains of stimuli applied to Schaffer/commissural fibers. In slices from adult animals, 8-CPT (1 μ M) increased synaptic responses produced by single stimuli and had no effect on LTP elicited by trains of stimuli. However, in slices from juvenile animals (3 and 4 weeks), the same treatment had quite different effects: 8-CPT had no effect on responses to single stimuli but inhibited the induction of LTP by trains of stimuli. To determine whether this change in adenosine responsiveness was associated with changes in A1 receptors, we measured adenosine binding activity in hippocampal membrane preparations obtained from rats of different ages. A1 receptor activity increased gradually during the first 2 postnatal weeks and reached a plateau by the third week. Thus, the age-dependent changes in synaptic transmission may depend upon the maturation of adenosine receptors. We speculate that such developmental changes in adenosine receptors may contribute to the cellular mechanisms underlying the development of LTP and that such changes may produce some of the alterations in memory that occur in the developing brain.

623.9

HISTAMINE AND LONG-TERM POTENTIATION. R. E. Brown¹, H. L. Haas² and K. G. Reymann¹, ¹ Fed. Inst. for Neurobiol., POB 1860, D-39008 Magdeburg, FRG, ² Physiology II, Heinrich-Heine-Universität, D-40001, Düsseldorf, FRG.

Long-term potentiation (LTP) of glutamatergic synaptic transmission in the hippocampus, a candidate mechanism for learning and memory formation, is modulated by a number of other neurotransmitters. Since histamine can increase calcium influx through the N-methyl-D-aspartate (NMDA) subtype of glutamate receptor, which is the initial trigger for LTP, we wanted to see if histamine could also modulate the induction of LTP.

We tested this possibility in the CA1 region of rat hippocampal slices, prepared according to standard procedures. A weak tetanus (0.25 s, 50 Hz) was delivered twice in the same slices with an interval of 140 min. In control experiments this tetanus led to a short-term potentiation (lasting less than one hour) of the field excitatory postsynaptic potentials on both occasions ($n = 6$, $p > 0.05$). However, when histamine (100 μ M) was washed in 20 minutes prior to the second tetanus, a long-term potentiation was observed which remained significant for up to 2 hours following the tetanus ($n = 6$, $p < 0.01$). A lower concentration of histamine (10 μ M) also gave significant potentiation at 60 min following the tetanus but by 90 min the potentiation was no longer significant ($n = 7$).

We tried to block this effect with the H1 antagonist, mepyramine (1 μ M), and the H2 antagonist, cimetidine (50 μ M), applied together before the first tetanus but were unable to do so ($n = 8$, $p < 0.01$). The antagonists did not affect the LTP produced by the combination of weak tetanus and histamine (100 μ M) application. In additional experiments we confirmed that histamine could enhance NMDA-gated responses in slices and therefore, we conclude that histamine facilitated the induction of LTP by enhancing NMDA currents.

ACTIVATION OF ADENOSINE A₂ RECEPTORS POTENTIATES SYNAPTIC TRANSMISSION IN THE HIPPOCAMPUS.

D.J. Mogul¹, L.S. Overstreet, K.M. Fleming, & B.L. Trommer, Depts. of Biomedical Engr., Neuroscience, Pediatrics, & Neurology; Northwestern University and Evanston Hospital, Evanston, IL 60208

Adenosine is released into synapses in proportion to neuronal firing rate. Adenosine agonists have been shown to decrease synaptic transmission via activation of an A₁ receptor subtype. We have previously shown that non-A₁ receptor activation significantly potentiates P-type Ca current in acutely isolated hippocampal pyramidal neurons from the CA3 region (Mogul et al., *Neuron*, 10: 1993). This effect appears to occur via activation of the A_{2b} receptor since the effect is observed with the non-selective A₂ agonist DPMA but is not seen with selective A_{2a} activation. We tested the effect of A₂ activation on synaptic transmission in young adult rat transverse hippocampal slices. Stimulation was applied to Schaffer pathway and extracellular potentials were recorded in stratum radiatum of CA1. The EPSP was potentiated in the presence of the A₁ antagonist CPT (5 μ M), presumably by the release of endogenous adenosine activating a non-A₁ receptor. In the presence of the A₂ antagonist DMPX (10 μ M), the EPSP responded to a submaximal tetanic stimulation (T_1 ; 100 Hz, 1 sec) with a post-tetanic potentiation (PTP) that returned to baseline within 10 min. LTP induced by T_1 in control solution was not affected by subsequent DMPX exposure, however no additional LTP could be induced (although PTP was observed). These results suggest that A₂ receptors may be involved in the induction of some component of LTP.

623.8

INDUCTION OF LTP IN A SYMPATHETIC GANGLION NEEDS ACTIVATION OF 5-HT₃ RECEPTORS. Karim A. Alkadhi¹, Delanthi Salgado, Subbu Apparsundaram, Samuel B. Akpaudo* and Yvonne H. Hogan* Department of Biology, Texas Southern University* and Department of Pharmacological and Pharmaceutical Sciences, College of Pharmacy, University of Houston, Houston TX 77204-5515

In the superior cervical ganglion (SCG) of rat, brief preganglionic supramaximal tetanic pulse induces LTP manifested as long-lasting enhancement of the compound action potential (population spike) of the nicotinic pathway. LTP in the SCG is independent of activation of cholinergic or adrenergic receptors during tetanic stimulation. Serotonin has been reported to be present in some of the ganglionic "interneurons"; the small intensely fluorescent (SIF) cells. We examined the role of the serotonin 5-HT₃ receptor subtype in LTP because it is widely distributed throughout the peripheral nervous system and exists at high density in peripheral neurons. Pretreatment of ganglia with the 5-HT₃ receptor antagonist MDL72222 (0.5 μ M) 1 hr before the train had no significant effect on the basal ganglionic transmission but prevented the expression of LTP. To confirm the role of endogenous serotonin in the generation of LTP we used ganglia from rats treated with reserpine (3 mg/kg) 24 hrs prior to removal of ganglia. In contrast to ganglia from untreated rats, in those from reserpinized animals tetanic stimulation resulted only in post-tetanic potentiation (PTP) with no LTP or short-term potentiation (STP). In these experiments, when the 5-HT₃ receptor agonist 1-(m-chlorophenyl) biguanide (PBG) was applied 3 min (during PTP) or one hour after tetanic stimulation no LTP was seen. However, when PBG was superfused on reserpinized ganglia 30 min before tetanic stimulation, the LTP consistently appeared. These results present evidence that activation of serotonin 5-HT₃ receptor subtype is necessary for the induction of LTP in the SCG.

623.10

PROPRANOLOL SUPPRESSES LTP INDUCTION IN BOTH THE LATERAL AND MEDIAL PERFORANT PATH INPUTS TO THE DENTATE GYRUS. J.M. Sarvey* and C.R. Bramham, Dept. of Pharm., Uniformed Services University, Bethesda, MD.

Recent evidence suggests that the lateral (LPP) and medial (MPP) perforant path inputs to the dentate gyrus can exhibit different forms of long-lasting synaptic plasticity. Norepinephrine application induces a lasting potentiation of MPP responses and a simultaneous depression of LPP responses, while LTP induction in the LPP, but not MPP, requires opioid receptor activation. β -Adrenergic receptor activation is also known to be important for LTP induction in the dentate gyrus. However, the role of β -receptors in LTP has not been assessed using selective stimulation of LPP and MPP fibers.

High-frequency stimulation (HFS; 100 Hz, 1 or 2s) applied to the dentate outer or middle molecular layer of rat hippocampal slices induced selective LTP of LPP or MPP responses, respectively, as assessed by field EPSP slope measurements obtained from the synaptic layers. The population spike was recorded by an electrode in the granule cell layer. In the MPP, the β -adrenergic receptor antagonist (-)-propranolol (1 μ M) reduced in magnitude, but did not completely block, LTP of the field EPSP and population spike. In the LPP, LTP of the field EPSP appeared to be completely blocked by propranolol. The results suggest that β -adrenergic receptor activation is required for full LTP induction of both the lateral and medial perforant path inputs to the rat dentate gyrus. Supported by NIH NS23865

623.11

DELTA AND MU OPIOID RECEPTOR ACTIVATION IS REQUIRED TO INDUCE LTP IN THE LATERAL PERFORANT PATH OF NORMAL, BUT NOT DISINHIBITED, HIPPOCAMPAL SLICES. C.R. Bramham^{*} and J.M. Sarvey^{*} Dept. of Pharm., Uniformed Services University, Bethesda, MD.

Opioid receptor-dependent LTP has been demonstrated in the lateral perforant path (LPP) input to the dentate gyrus, a system which is thought to use glutamate and opioid peptides as co-transmitters. However, the receptor pharmacology and mechanism of LTP induction have not been characterized. High-frequency stimulation (HFS; 100 Hz, 1s) applied to the dentate outer molecular layer of rat hippocampal slices induced selective LTP of LPP responses, as assessed by EPSP slope measurements obtained 40 min post-HFS. In slices maintained in standard ACSF, LTP induction was blocked or significantly reduced in magnitude when HFS was applied in the presence of the general opioid receptor antagonist, naloxone (5 μ M), the delta receptor antagonist, naltrindole (50 nM), the mu receptor antagonist, CTAP (100 nM), or the NMDA receptor antagonist, AP5 (20 μ M), while the kappa-1 opioid receptor antagonist nor-BNI (60 nM) did not affect LTP. Selective LTP of the LPP was also obtained in slices maintained in ACSF containing picrotoxin (50 μ M) which attenuates GABA-A receptor mediated inhibition. However, in disinhibited slices, HFS applied in the presence of naloxone induced LTP equivalent to control values. The results suggest that delta and mu opioid receptors regulate LTP induction in the LPP by a mechanism which depends upon GABAergic inhibition. Supported by NIH NS23865

ENDOGENOUS SUBSTRATES FOR Ca^{2+} /CALMODULIN-DEPENDENT PROTEIN KINASE II DURING THE INDUCTION OF LONG-TERM POTENTIATION IN THE HIPPOCAMPUS. Kohji Fukunaga¹, Dominique Muller² and Eishichi Miyamoto¹. ¹Department of Pharmacology, Kumamoto University School of Medicine, Kumamoto 860, Japan and ²Centre Médical Universitaire, Université de Genève, Faculté de Médecine, CH 1211 Genève 4, Switzerland.

Among the molecular mechanisms that have been proposed to contribute to long-term potentiation (LTP) in the hippocampus is the activation of Ca^{2+} /calmodulin-dependent protein kinase II (CaM kinase II) following the stimulation of the NMDA receptor. Recently, we documented long-lasting increases in the Ca^{2+} -independent and total activities of the enzyme as well as an increase in the ratio of Ca^{2+} -independent to total activity following the induction of LTP (J. Biol. Chem. **268**, 7863, 1993). It could suggest that autophosphorylation of the enzyme is responsible for the change in CaM kinase II activity. Here we demonstrate with ^{32}P -labeled hippocampal slices that high, but not low frequency stimulation applied to two groups of CA1 afferents resulted in increases in autophosphorylation of both α and β subunits of CaM kinase II 1 hr after LTP induction. In addition, significant increases in phosphorylation of endogenous CaM kinase II substrates, synapsin I and microtubule-associated protein 2 (MAP2), were observed in the same slices. The stimulations of phosphorylation of CaM kinase II and its substrates could be blocked by preincubation of slices with an NMDA receptor antagonist, D-2-amino-5-phosphonopentanoate. These results suggest that LTP is associated with increases in phosphorylation of synapsin I and MAP2 through the activation of CaM kinase II.

623.15

ACTIONS OF ALUMINUM ON SYNAPTIC TRANSMISSION AND LONG-TERM POTENTIATION OF CA1 NEURONS IN HIPPOCAMPAL SLICES. B. Platt¹, D. Büsnelberg¹, Y. Lin² and D.O. Carpenter¹. ¹Univ. Düsseldorf, Physiology II, Moorenstr. 5, 40225 Düsseldorf, FRG and ²Wadsworth Labs, NYS Dept. Health and School of Public Health, Albany, NY 12201.

Aluminum (Al) intoxication is known to induce cognitive dysfunctions and multiple forms of dementia. The precise mechanisms of the Al effects are not clear. In order to investigate the action of Al on synaptic transmission and long-term potentiation (LTP) in area CA1 of hippocampal slices, field potentials were evoked by stimulation of the Schaffer collaterals (0.2 Hz) and recorded in the stratum pyramidale of the CA1 region. After stable population spikes were recorded for 30 min in modified Ringer solution, Al was applied for 30 min by bath perfusion. Low Al concentrations (0.68 $\mu\text{g}/\text{ml}$ = 25 μM) increased the amplitude of the population spike slightly (121%) whereas 2.7 $\mu\text{g}/\text{ml}$ (100 μM) decreased the amplitude (75%) and concentrations $\geq 4 \mu\text{g}/\text{ml}$ (150 μM) blocked the population spike completely. The actions on synaptic transmission were irreversible. Induction of LTP by high-frequency stimulation in the presence of 0.68 $\mu\text{g}/\text{ml}$ Al led to a reduced level of potentiation compared to control experiments. In the presence of 2.7 $\mu\text{g}/\text{ml}$ Al potentiation was further reduced and declined to baseline level within 60 min. Subsequent washout did not lead to any recovery of the signal. For low Al concentrations (0.68 $\mu\text{g}/\text{ml}$), a rebound of the effect was found in cases of washout 15 min after tetanization. The amplitude of the population spike increased to values above those in control experiments (> 250%).

Our data suggest multiple sites of actions of Al on synaptic transmission and LTP. Both stimulating and inhibitory effects were found in a concentration dependent manner. These interactions might contribute to the neurotoxic potency of Al.

623.12

CORTICOTROPIN-LIKE INTERMEDIATE LOBE PEPTIDE [CLIP; ACTH 18-39] AND ITS N-TERMINAL FRAGMENT ACTH 18-24 BLOCK THE INDUCTION OF LONG-TERM POTENTIATION IN THE RAT DENTATE GYRUS. D. Balschun^{*}, T. Seidenbecher, D. Vogel and K. G. Reymann, Federal Institute for Neurobiology, POB 1860, D-39008 Magdeburg, Germany.

Physiological functions of the POMC-derived peptide CLIP [ACTH 18-39] are scarcely documented. Recently, we demonstrated that the intracerebroventricular administration of CLIP caused a marked enhancement of neuronal excitability in the hippocampal CA1 region as well as a selective increase of paradoxical sleep. The sleep studies led us to suggest that the active sequence is located in the N-terminal part of CLIP.

The present study was conducted to test whether CLIP can modulate neuronal transmission in the dentate gyrus and whether the full CLIP sequence is essential for such actions. Experiments were performed on freely moving male Wistar rats (8-9 weeks old), housed individually with food and water ad libitum. A monopolar recording and a bipolar stimulation electrode were implanted stereotactically in the granule cell layer of the dentate gyrus and in the perforant path, respectively, for recording of electrically evoked population spikes. Long-term potentiation (LTP) was induced by short tetanic bursts (6 bursts, each 15 stimuli at 200 Hz, at 10-second intervals) thirty minutes after intracerebroventricular administration of equimolar doses of either CLIP, ACTH, ACTH 1-24 or ACTH 18-24. Whereas none of the investigated peptides displayed significant effects on baseline recordings the infusion of 20 ng CLIP or an equimolar dose of the N-terminal CLIP-fragment ACTH 18-24 led to a blockade of the induction of LTP. In contrast, application of ACTH or ACTH 1-24 did not affect the induction of LTP. Therefore, the active sequence responsible for the blockade of LTP seems to be contained in the N-terminal segment of CLIP.

623.14

TEMPORAL DIFFERENCES IN THE PHOSPHORYLATION STATE OF PRE- AND POSTSYNAPTIC PKC SUBSTRATES B-50/GAP-43 AND NEUROGRANIN DURING LONG-TERM POTENTIATION. P.N.E. De Graan^{*}, P. Pasinelli, G.M.J. Ramakers, I. Urban, J.J.H. Hens and W.H. Gispen, Rudolf Magnus Institute for Neurosciences, Universiteitsweg 100, 3584 CG Utrecht, The Netherlands.

Pre- and postsynaptic PKC substrates have been implicated in the molecular mechanism underlying LTP. The major presynaptic PKC substrate implicated in LTP is B-50 (a.k.a. F1, GAP-43, neuromodulin). A potential postsynaptic target for PKC during LTP is neurogranin (a.k.a. BICKS, RC3), a protein which shares an 18 amino acid sequence with B-50, containing the unique PKC phosphorylation site and the calmodulin binding domain. In this study we monitored the time course of B-50 and neurogranin phosphorylation during LTP.

Rat hippocampal slices (450 μm) were labelled with ^{32}P , and were either tetanized (100 Hz, 1 sec), received low frequency stimulation or were not stimulated. After field EPSPs recordings in the CA1 region, the *in situ* B-50 and neurogranin phosphorylation state was determined in individual slices after different times by immunoprecipitation and phosphorimaging. B-50 phosphorylation was increased from 10 to 90 min, neurogranin only at 60 min after the tetanus. A high degree of correlation was found between the degree of B-50 and neurogranin phosphorylation and the degree of potentiation. Slices treated with APV, or in which tetanic stimulation failed to induce LTP, did not show increased B-50 and neurogranin phosphorylation 60 min after the tetanus.

To investigate whether phosphatases may contribute to the increase in phosphorylation, we treated slices with okadaic acid (inhibitor of PP1 and PP2a). This resulted in a dose- and time-dependent increase in B-50 and neurogranin phosphorylation and this increase was additive to the effect of PKC stimulation by phorbol esters.

Our data show that the increase in presynaptic B-50 phosphorylation during LTP precedes the increase in postsynaptic neurogranin phosphorylation. This may be due to a differential activation of pre- and postsynaptic PKC, but the contribution of phosphatases should also be considered. (supported by an ENP grant of the ESF).

623.16

MICE CARRYING A TARGETED DISRUPTION OF THE RI β REGULATORY SUBUNIT OF PKA HAVE DEFECTS IN HIPPOCAMPAL SYNAPTIC PLASTICITY. E.P. Brandon^{*}, Y.-Y. Huang, M. Zhuo, M. Qi, K.A. Gerhold, E.R. Kandel, G.S. McKnight and R.L. Idzerda. ¹Dept. of Pharmacology, Univ. of Washington, Seattle, WA 98195 and ²HHMI, Center for Neurobiology & Behavior, Columbia Univ., New York, NY 10032

RI β is the regulatory subunit of cyclic AMP-dependent protein kinase (PKA) that is expressed primarily in neurons and therefore might play a role in several types of synaptic plasticity. Mice carrying a null mutation in the gene encoding RI β were produced via homologous recombination in embryonic stem cells. These mice show a compensatory increase in RI α protein in various regions of the brain. The hippocampal slice preparation was employed to measure multiple forms of synaptic plasticity. In the CA1 region, the mutants show normal field potentials in response to Schaffer collateral stimulation, normal paired-pulse facilitation, and normal long-term potentiation (LTP), even at three hours post-tetanus. In contrast, a protocol that reliably produced long-term depression (LTD), induced by 900 pulses @ 1 Hz) in slices from control mice produced only a transient depression in mutant slices. Depotentiation following LTP showed a similar defect. In the CA3 region, a protocol that normally produced NMDA receptor-independent LTP of the field potential evoked by mossy fiber stimulation (two 100 Hz tetani of 1 second duration each, separated by 10 seconds) produced no LTP in mutant mice. Thus, the RI β isoform of PKA is necessary for at least two forms of hippocampal plasticity.

INDUCTION OF ANOXIC LTP IS PREVENTED BY PROTEIN KINASE C ANTAGONISTS. Y. BEN-ARI*, P. CONGAR, D. DIABIRA and C. HAMMOND. INSERM U29, 123 Bd Port Royal, 75014 Paris France.

We have recently described a novel form of LTP (anoxic LTP) induced in CA1 pyramidal neurons of the hippocampus by a brief anoxic-aglycemic episode in slices (Crepel et al., J. Neurophysiol., 1993, 70: 2045): i) its induction requires the activation of NMDA receptors and changes in membrane potential; ii) its expression is mediated by a persistent increase of the NMDA (but not AMPA) receptor-mediated component of the EPSP. It is due to a persistent upregulation of postsynaptic NMDA receptors and is associated with an apparent reduction of the voltage dependant Mg^{2+} block of NMDA receptor. We now report that the induction of anoxic LTP requires the activation of protein kinase C (PKC). The NMDA receptor-mediated field EPSP was recorded in isolated CA1 slices (in the presence of 10 μ M bicuculline, 10 μ M CNQX and 0.6 mM Mg^{2+}). Sphingosine (10 μ M), bath applied before, during and after the anoxic episode (2-3 min), prevented the induction of anoxic LTP in 8 out of 11 slices. At the same time, we checked that non treated slices obtained from the same rats exhibited anoxic LTP. Furthermore, intracellular recordings were performed in presence of selective PKC inhibitor (50 μ M PKCI 19-36 in 3M KCl and 50mM QX-314) in the pipette and 10 μ M bicuculline, 15 μ M CNQX and 1.3 mM Mg^{2+} in the bath. After the injection of PKCI (200 pA pulses for 15 min), anoxic LTP of the glutamatergic EPSC ($V_H = -35$ to -75 mV) was not observed ($n = 5$ cells out of 5). Interestingly, a LTD was observed instead in 4 cells out of 5. In comparison, in control experiments where injections were performed with no PKCI present in the pipette, LTP of the EPSP in 3 cells out of 5 and no LTD were observed. We conclude that the induction of anoxic LTP requires the activation of PKC.

PHARMACOLOGY OF SYNAPTIC TRANSMISSION I

624.1

MODULATION OF EXCITATORY SYNAPTIC TRANSMISSION BY DOPAMINE AND PSYCHOSTIMULANTS IN THE NUCLEUS ACCUMBENS IN VITRO. S.B. Kumbian* and R.C. Malenka. Depts. of Psychiatry and Physiology, University of California, San Francisco, CA. 94143.

The nucleus accumbens (NA) is an important limbic-motor interface that is involved in many complex behaviors. *In vivo* evidence suggests that dopamine (DA), cocaine and amphetamine modulate these behaviors. However, the cellular actions of these substances and their underlying mechanisms are poorly defined. Using *in vitro* slices from rats and the whole cell recording technique, we examined the actions of these substances on excitatory synaptic responses recorded in cells of the "core" region of the NA evoked by stimulation of prefrontal cortical afferents in the presence of picrotoxin (25 μ M). DA consistently produced a reversible, dose-dependent decrease in EPSP/EPSC slope/amplitude with an estimated EC₅₀ of 75 μ M. DA (50 μ M) produced an inhibition of $-34 \pm 4\%$ (mean \pm SE, $n=4$) which was blocked by a D1 receptor antagonist SCH23390 (1-5 μ M; $-2 \pm 2\%$, $n=6$, $p<0.001$) but not the D2 receptor antagonist sulpiride (10 or 20 μ M; $-31 \pm 3\%$, $n=4$, $p>0.5$). Further, this effect of DA was mimicked by the D1 receptor selective agonist SKF38393 (10 μ M, $-23 \pm 3\%$, $n=10$) but not the D2 receptor selective agonist quinpirole (10 or 20 μ M; $+1 \pm 2\%$, $n=9$). The DA-induced inhibition was accompanied by an increase in paired pulse facilitation ($+19 \pm 4\%$, $n=8$) and appears to be independent of DA's postsynaptic membrane effects. Cocaine at non-anaesthetic concentrations produced a reversible dose-dependent inhibition of EPSPs (30 μ M, producing $-33 \pm 3\%$ inhibition, $n=6$) which was blocked by SCH23390 (1-5 μ M; $-6 \pm 5\%$, $n=7$, $p<0.001$) but not sulpiride (10 μ M; $-29 \pm 14\%$, $n=3$, $p>0.5$). Amphetamine (10 μ M) also induced a reversible inhibition of EPSPs ($-61 \pm 4\%$, $n=3$) which was blocked by SCH23390 (1-5 μ M; $-4 \pm 4\%$, $n=4$, $p<0.001$) but not sulpiride (10 μ M; $-54 \pm 15\%$, $n=2$, $p>0.5$). Manipulation of cAMP levels by forskolin (10 μ M) or 8-Br-cAMP (1 mM) in the presence of 10 μ M CPT (an adenosine A1 receptor antagonist) did not mimic ($+28 \pm 6\%$, $n=4$ and $+34 \pm 10\%$, $n=8$ respectively) but partially occluded (-13% , $n=1$ and $-16 \pm 3\%$, $n=3$, $p<0.02$ respectively) the actions of DA (50 μ M). These results suggest that DA and the psychostimulants reduce excitatory synaptic transmission in NA by activating presynaptic D1-like receptors which may not be linked to the cAMP second messenger pathway. SBK is supported by HFSP.

624.3

ELECTROPHYSIOLOGICAL "SENSITIZATION" OF DORSOLATERAL SEPTAL NUCLEUS (DLSN) NEURONS IN VITRO FOLLOWING CHRONIC COCAINE ADMINISTRATION IN VIVO. S. Shoji, D. Simms and J.P. Gallagher*. Dept. of Pharm. and Tox., Univ. of Texas Med. Br., Galveston, TX 77555.

We used intracellular electrophysiological recording techniques to investigate the actions of cocaine (3 μ M) applied to brain slices which contained the DLSN and were obtained from drug naive rats (NR) or rats administered cocaine (CR, 15 mg/kg, IP, 2x daily) for periods of 7, 14 or 28 days. Although cocaine did not alter the configuration or threshold levels of sodium action potentials (APs) in any of these neurons, a significant proportion of neurons recorded from CR exhibited a decrease of input resistance and an increase in the appearance of slow depolarizing after potentials following cocaine. Only 50 % of NR or 7 day-CR responded to cocaine with a hyperpolarization and inhibition of spontaneous APs. The hyperpolarization was TTX-insensitive and persisted in zero calcium media; its reversal potential varied (-70 to -90 mV). On the other hand, 100 % of neurons from 14 & 28 day-CR were hyperpolarized by cocaine. Moreover, application of bicuculline (10 μ M), which had no effect on resting membrane potential of NR, induced a TTX-insensitive depolarization of 6 mV and 10 mV in 14 day- and 28 day-CR, respectively. The same CR neurons were hyperpolarized following a combination of CNQX (10 μ M) and AP5 (25 μ M).

These results demonstrate an electrophysiological "sensitization" to cocaine in CR that involve the intrinsic cell properties of DLSN neurons and their responsiveness to excitatory and inhibitory amino acids. Supported by DA-07190.

SUBCHRONIC GLUCOCORTICOID EXPOSURE ENHANCES AMPHETAMINE-INDUCED CHANGES IN [³H]TCP INTACT CELL BINDING TO THE PRIMARY CULTURED NEURONAL CELLS. H. Yamamoto¹, X. Yang¹, T. Yamamoto^{1,2}, N. Sagi¹, A. Baba¹, E. Takamori¹, Y.L. Murashima^{1*} and T. Moroji¹. ¹Dept. of Psycho-pharmacol., Tokyo Inst. of Psychiatry, Tokyo 156, ²Lab. of Mol. Recog., Grad. Sch. of Integrated Sci., Yokohama City Univ., Yokohama 236, Japan.

We have previously demonstrated that prolonged exposure of cultured cortical cells to amphetamine (AMP) increases [³H]TCP intact cell binding in a dose- and time- dependent manner. To examine whether there are similar effects of glucocorticoids on cortical cells, the cells were exposed to corticosterone (CORT), dexamethazone (DEX) or deoxycorticosterone (DECORT) for at least 6 days. Glucocorticoids (CORT, DEX) significantly induced increases in [³H]TCP intact cell binding in a dose-dependent manner, but mineralcorticoid (DECORT) did not. Scatchard analysis revealed that subchronic exposure of CORT induced reduction of both K_d and B_{max} values of [³H]TCP intact cell binding as well as subchronic exposure of AMP. In addition, AMP-induced increases in [³H]TCP intact cell binding was enhanced by co-administration of CORT. Considering the findings that cross-sensitization occurs between stimulants and a variety of stresses, it is of interest that glucocorticoid (one of the biological indicators for stresses) affect the [³H]TCP binding and suggested that NMDA receptor/ion channel complex is involved in the cross-sensitization.

624.4

COCAINE INHIBITS SYNAPTIC RESPONSES IN RAT DORSOLATERAL SEPTAL NUCLEUS (DLSN) NEURONS THROUGH PRE- AND POST-SYNAPTIC MECHANISMS. D. Simms*, S. Shoji and J.P. Gallagher. Dept. of Pharm. and Tox., Univ. of Texas Med. Br., Galveston, TX 77555.

Focal stimulation of fimbrial fibers from the hippocampus results in the appearance of an EPSP-IPSP-LHP sequence when recording from the DLSN slice preparation. GABA_A acting at GABA_A and GABA_B receptors, mediates the inhibitory postsynaptic potential (IPSP) and the late hyperpolarizing potential (LHP), respectively. In addition to these inhibitory responses, excitatory postsynaptic potentials (EPSPs) mediated by excitatory amino acid receptor activation are also recorded from DLSN neurons. We now report that cocaine acts to inhibit synaptic transmission in the rat DLSN through pre- and postsynaptic mechanisms.

Standard intracellular current-clamp and voltage-clamp recordings were made from neurons in rat brain slices containing the DLSN. Orthodromically-induced synaptic responses were obtained before and during drug superfusion. Superfusion of cocaine (3 μ M) produced a membrane hyperpolarization due to an outward current that gradually faded during continuous superfusion. The amplitude of the IPSP and LHP were reduced during the cocaine-induced hyperpolarization even after the membrane potential was restored to its pre-cocaine value. Following the hyperpolarization and during cocaine superfusion, the depression of the LHP and IPSP persisted. Voltage-clamp experiments revealed, moreover, that the amplitude of the late hyperpolarizing current (LHC) was decreased throughout cocaine superfusion. Cocaine did not reduce a hyperpolarization produced by bath application of baclofen. In addition, cocaine was able to reduce the EPSP and LHP without producing a membrane hyperpolarization. Our results suggest that cocaine suppresses synaptic responses in DLSN neurons, not only by changing the membrane potential, but also by producing a persistent increase in membrane conductance and by presynaptically affecting neurotransmission between the hippocampus and the DLSN. Supported by DA-07190.

PROPOFOL FACILITATES SUBSTANCE P-MEDIATED INHIBITION OF CALCIUM-ACTIVATED K-CONDUCTANCE IN A GUINEA-PIG SYMPATHETIC GANGLION. W.H. Stapelfeldt, J.M. Oleszewski. Depts. of Anesthesiology & CCM, Univ. of Pittsburgh, Pittsburgh, PA 15261, and VA Medical Center, Pittsburgh, PA 15240.

The general anesthetic agent propofol (2,6-diisopropylphenol, DIPRIVAN®) specifically augments substance P (SP)- but not VIP-mediated postsynaptic responses of guinea-pig inferior mesenteric ganglion (IMG) neurons. Single-electrode current and voltage clamp recordings from isolated perfused IMGs demonstrated that propofol (1-100 µM) had no effect on the resting membrane potential or input resistance of principal ganglion cells, but augmented in a dose-dependent fashion the amplitude and duration of membrane depolarization and inward current responses evoked by exogenous SP applied via pressure microinjection from nearby pipets (Picospritzer). The increase in SP-evoked inward current responses resulted from propofol-induced inhibition of an outward current component which was also inhibited by 20mM TEA, but not 1 mM TEA. SP-evoked inward current responses augmented by 20 mM TEA were not further altered by the additional administration of propofol. During the SP response in normal Krebs solution, intermittent depolarizing voltage step (20 mV, 5 s, 0.05 Hz)-evoked calcium-activated potassium ($G_{K(Ca)}$)-tail currents were transiently reduced in amplitude. Propofol had no effect on $G_{K(Ca)}$ -tail currents in the absence of SP, but extended the time period during which $G_{K(Ca)}$ -tail currents were reduced following SP application for the duration of the prolonged SP-evoked inward current response. These findings suggest that the increase in SP-evoked inward current response by propofol is the result of an increase in SP-mediated inhibition of a $G_{K(Ca)}$ -conductance which limits the net inward current and membrane depolarization in response to SP. This action represents a novel mechanism of anesthetic action of propofol not attributable to the known facilitatory property of this compound on GABA-A receptor/anionophore complexes. EFFECTS OF THIOPENTAL AND PHORBOL ON CA1 FIELD POTENTIALS IN THE RAT HIPPOCAMPUS Y.-C. Tsai, E. Narimatsu, T. Gerhold, S. Kamath and M. Sokoll and E. Węgrzynowicz*. Dept. of Anesthesiology, Univ. of Iowa College of Medicine, Iowa City IA 52242

Thiopental (THIO) has been used primarily as an induction agent for the past 60 years. Because of its structural difference, it has been assumed that its site of action differs from that of the inhalational anesthetics in producing the anesthetic state. We studied the effects of thiopental on the field potential of the CA1 cell group of the rat hippocampal slice and its interaction with phorbol di-acetate (PDA). In previous studies we examined the interaction between halothane and PDA. Rats were anesthetized with ketamine, decapitated and 400µm thick slices of hippocampus prepared and mounted in a bath. The Schaffer pathway was stimulated using a platinum bipolar electrode and field potentials recorded with glass microelectrodes (resistance 3-8MΩ). The two negatively going potentials N1 and N2 were analyzed for amplitude, and latency. N2 was also analyzed for slope of the onset of the potential. Control observations were recorded following which THIO (400 or 800 µM) was applied for 30 minutes. Recordings were again made and then PDA 0.25, 0.5 or 1.0 µM were applied sequentially and potentials again recorded. THIO application resulted in approximately a 50% decrease in the amplitude of N2. Application of PDA 1.0µM resulted in approximately a 20% recovery of the amplitude of N2. This reversal is less than that which was seen with halothane. These results support the concept that the inhalation and intravenous anesthetics, at least to some extent, act at different sites.

624.9

INTERACTIONS OF APV, PICROTOXIN AND PHORBOL DI-ACETATE ON HALOTHANE DEPRESSED CA1 POTENTIALS IN THE HIPPOCAMPUS. E. Narimatsu, Y.-C. Tsai, S. Kamath, and M. Sokoll*. Dept. of Anesthesia, Univ. of Iowa College of Medicine, Iowa City, IA 52242

The effects of the inhalation anesthetic halothane and its interactions with protein kinase C (PKC) have been partially investigated. In this study we examined the effects of halothane and phorbol di-acetate (PDA) following the administration of APV and picrotoxin on the field potential of the CA1 layer of the hippocampus. Rats were anesthetized with ketamine and hippocampal slices 400µm thick were cut and mounted in a bath. A platinum bipolar electrode was used to stimulate the Schaffer pathway supplying the CA1 cell group. AP5 and picrotoxin were applied to block the NMDA and GABA potentials. Halothane was then applied followed by PDA. Application of AP5 produced little alteration in the amplitude of the N2 potential. Addition of picrotoxin produced a small but statistically significant increase in the amplitude of N2. The subsequent application of halothane resulted in a 52% decrease in the amplitude compared to control. The addition of PDA resulted in an increase in the amplitude of N2 to 90% of control, a value not significantly different from the control. The addition of AP5 and picrotoxin resulted in a small increase in the N2 amplitude suggesting that, in this protocol, NMDA receptors account for only a small part of the potential. The ability of PDA to produce significant reversal may be related to its stimulatory effect on the non-NMDA system.

624.6

URETHANE ANESTHESIA AFFECTS EVOKED POTENTIALS IN DENTATE GYRUS. Y. Shirasaka*, C.G. Wasterlain. Dept. of Neurology, BRL, UCLA Sch. of Med., Los Angeles, CA 90024 and Epi.Res.Lab. VAMC, Sepulveda, CA 91343.

Urethane (ethyl carbamate) is a commonly used anesthetic in animal studies. Although its mechanisms of action is not known, urethane is widely used in physiological or pharmacological studies of the nervous system. In this study, we examined the effect of urethane on the evoked potentials recorded in dentate gyrus by stimulating the perforant path.

Male adult Wistar rats (n=18) were used in this study. Evoked potentials were examined in the awake state and 30 min after the beginning of urethane anesthesia (i.v., loading dose, 1000 mg/kg, maintenance dose 50 mg/kg in saline).

Under urethane anesthesia, short interstimulus interval-dependent paired-pulse inhibition (20-60 msec) decreased significantly compared with that in the awake state. Population spike amplitude and excitatory postsynaptic potentials during input/output response examination were significantly smaller than in the awake state at low stimulus intensity. Voltage-dependent paired-pulse inhibition was weak at each stimulus intensity under urethane anesthesia, and the difference of inhibition between awake and anesthetized states increased with the stimulus intensity. Frequency-dependent paired-pulse inhibition was significantly weaker than in the awake state at 0.1 Hz and non-significantly weaker at 2 Hz.

These results clearly show that urethane affects neurotransmission in hippocampus, and indicate a possible relationship with excitatory neurotransmitter systems. Supported by EFA fellowship(YS), by the VA research service and by research grant NS13515 from NINDS.

HALOTHANE AND PROPOFOL INCREASE THE COFACTOR SENSITIVITY OF PURIFIED BRAIN PROTEIN KINASE C. H.C. Hemmings, Jr.* AIB Adamo, MM Hoffman. Departments of Anesthesiology and Pharmacology, Cornell University Medical College, NY, NY 10021.

Protein kinase C (PKC) has been implicated as a target for general anesthetics. The activation of purified brain PKC is stimulated by general anesthetics when assayed with a physiologically relevant lipid bilayer preparation *in vitro*. Here we report the further biochemical characterization of the stimulatory effects of halothane and propofol on PKC activation. PKC was purified to >80% homogeneity from rat forebrain and assayed with 0.2 mg/ml histone H1, 2 µM sn-1,2-dioctanoylglycerol (DG)/20 µM phosphatidylserine (PS)/80 µM phosphatidylcholine lipid vesicles, 50 mM HEPES (pH 7.4), 1 mM EGTA, 1.5 mM CaCl₂, 10 mM Mg-acetate, and 100 µM [γ -³²P]ATP at 30°C minus or plus 2.4 vol% halothane or 200 µM propofol.

Parameter	n	- Halothane +	- Propofol +
K_m (mg/ml histone H1)	2	0.14	0.14
V_{max} (µmol/min/mg)	2	0.46	0.73
PS EC ₅₀ (mol %)	3	18±2.5	11±0.6*
DG EC ₅₀ (mol %)	3	1.6±0.3	0.87±0.2*
Ca ²⁺ EC ₅₀ (free Ca ²⁺ , µM)	3	4.5±1.0	2.8±0.4*
			2.8±0.7
			1.9±0.2*

Values are expressed as mean±SD. *p<0.05, **p<0.01 (versus value without anesthetic). Both halothane and propofol increased the sensitivity of PKC to activation by DG, PS, and Ca²⁺, without affecting its apparent affinity for the artificial substrate histone H1. These data suggest that general anesthetics may stimulate PKC activity not by mimicking one of its regulators, but by stabilizing its active conformation. Efforts are underway to extend these observations made with purified PKC *in vitro* to endogenous neuronal PKC and PKC substrates in order to further assess the role of PKC mediated protein phosphorylation in general anesthetic action. Supported by a FAER/BOC Anesthesiology Young Investigator Award and a Cornell Scholar Award in Biomedical Science.

PHARMACOLOGY OF TRANSMITTER RELEASE IN THE DEVELOPING CHICK HEART. D. B. Gray* and C. Eielson. Department of Physiology and Neurobiology, Univ. of Connecticut, Storrs, CT 06269.

Potassium-evoked secretion of acetylcholine (ACh) and norepinephrine (NE) from cardiac parasympathetic nerve endings and cultured sympathetic cell somas respectively, is mediated by Ca influx. In this report we have examined the calcium pharmacology of ACh release from cholinergic terminals in intact excised right atria of embryonic stage 40 and hatching chick hearts. At embryonic day 14, evoked ACh release from cholinergic nerve terminals in atria can be inhibited by over 80% with 10 µM nifedipine. This sensitivity to nifedipine is gradually reduced to less than 30% at hatching. The remaining ACh release at hatching can be blocked by omega-conotoxin suggesting a switchover from L type calcium channels to N type channels involved in excitation-secretion coupling. Cultures of St. 40 sympathetic ganglia release labeled NE during a high potassium challenge (56 mM), and this evoked release is not sensitive to nifedipine. However, co-cultures of St 40 sympathetic neurons with live heart cell cultures do show sensitivity to nifedipine (>60%) suggesting that exposure to target may induce coupling of L type channels to transmitter release at least transiently, in these neurons. The effects of muscle target and developmental age resemble those in other autonomic ganglia (Gray et al., Neuron 8: 715, 1992). Additionally, embryonic sensitivity of vertebrate autonomic ganglia to nifedipine may have implications for hypertensive pregnant women. Supported by a grant to B. Gray from the Catherine and Patrick Weldon Donaghy Foundation for Medical Research.

RILUZOLE: FREQUENCY-DEPENDENT ACTIONS LINK INHIBITION OF SODIUM CHANNELS AND INHIBITION OF SYNAPTIC TRANSMISSION. G.A. Böhm, S. Le Guern, Ph. Boudeau and J.C.R. Randle. Rhône-Poulenc Rorer S.A., Central Research, 94403 Vitry-sur-Seine, France.

Riluzole (6-trifluoromethoxy-2-aminobenzothiazole) is an anti-convulsant and neuroprotectant that gave promising results in a Phase II study in amyotrophic lateral sclerosis. In cultured cerebellar granule neurons and NG108-15 hybridoma cells, riluzole (0.3-30 μ M) induced a 5-30 mV negative shift of Na^+ current steady-state inactivation, but had little effect on Na^+ current activation. Riluzole slowed the recovery of Na^+ current from inactivation ($t_{1/2}$: control = 8-20 ms, riluzole = 30-60 ms). Thus, inhibition of Na^+ currents was frequency-dependent only at high activation frequencies (≥ 20 Hz). Depolarizing current pulses evoked trains of action potentials at 20-50 Hz that were slowed by 1 and 3 μ M riluzole and reduced to a single spike by 10 μ M riluzole. Riluzole has previously been shown to inhibit the release of glutamate *in vitro* and *in vivo*. In hippocampal slices, riluzole (1-30 μ M) increased the electrical activation threshold of the Schaffer collateral-CA1 pathway evaluated as the appearance of an evoked pre-synaptic fiber volley and a post-synaptic glutamate-mediated field potential, and increased the latencies of these responses, but did not reduce the maximal response amplitudes evoked at high stimulus intensities. When trains of 10 stimuli were applied at 20-100 Hz, marked "use-dependence" of the inhibitory effects was observed that was not overcome at increased stimulus intensities. We conclude that use-dependent Na^+ current inhibition underlies riluzole's selective inhibition of high frequency electrical activity. Reduced pre-synaptic excitability would contribute to the inhibition of synaptic glutamate release and excitatory neurotransmission. This selective action of riluzole may allow it to exert anticonvulsant and neuroprotective actions while respecting lower frequency "normal" synaptic transmission.

INTRACELLULAR Cl^- DIMINISHES G-PROTEIN-ACTIVATED K^+ CONDUCTANCES IN RAT HIPPOCAMPAL NEURONS. R.A. Lenz^{1,2}, T.A. Pitler¹, P.J. Yarowsky², & B.E. Alger¹. ¹Dept. Physiol., ²Dept. Pharm. & Exp. Therapeut., Univ. MD Sch. Med., Baltimore, MD 21201.

We made whole-cell recordings from CA1 cells in rat hippocampal slices with various electrode recording solutions. We found that G-protein-mediated K^+ -dependent responses are suppressed when 160 mM KCl is in the intracellular recording solution instead of KCH_3SO_3 or potassium gluconate (KGluc). With KCl, outward current responses to applications of the GABA_A agonist, baclofen, were reduced ~60% relative to responses in cells recorded with KCH_3SO_3 or KGluc electrodes. Additionally, monosynaptic GABA_A responses in the presence of glutamate antagonists and picrotoxin, which were reliably obtained when using KCH_3SO_3 electrodes, were small or nonexistent in cells loaded with KCl.

Membrane potential and resting input resistance did not differ among cells recorded with the different solutions. When the non-hydrolyzable GTP analog, GTP γ S, was included in a KCH_3SO_3 electrode, cells were unusually hyperpolarized and input resistances were significantly reduced. However, cells recorded with KCl electrodes containing GTP γ S had membrane potentials and input resistances that were not significantly different from control. These data suggest that high $[\text{KCl}]_i$ prevents activation of a K^+ conductance by GTP γ S.

We conclude that internal Cl^- can interfere with the activation of G-protein-activated K^+ conductance. It will be important to determine if the interference occurs at the channel, the G protein or at some other step.

PROPERTIES OF POTASSIUM M-CHANNELS IN INSIDE-OUT PATCHES EXCISED FROM RAT SYMPATHETIC NEURONS. A.A.Selyanko and D.A.Brown*. Pharmacology Dept., University College, London, WC1E6BT, U.K.

M-channels in rat sympathetic neurons have previously been studied using cell-attached and excised outside-out membrane patches (Selyanko *et al.*, 1992: *Proc. Roy. Soc. Lond. B.*, 250, 119; Stansfeld *et al.*, 1993: *Neuron*, 10, 639). We have now succeeded in maintaining M-channel activity in excised inside-out patches. The most striking change on excision was a substantial and irreversible "run-up" in single channel P_o (Figure 1). This was accompanied by an increased opening frequency and decreased shut time, with a loss of the medium and long shut times observed in cell-attached patches (Selyanko & Brown, 1993: *J. Physiol.*, 472, 711). P_o retained its voltage-sensitivity, but with a shallower slope. Single channel conductances were unchanged. Run-up was not prevented by including 3 mM ATP + 1 mM GTP in the bath solution or by adjusting Ca to 50-100 nM. This suggests tonic inhibition of M-channels *in situ* by some other cytoplasmic component(s).

CHANGES IN SYNAPTIC TRANSMISSION PRODUCED BY PHOSPHOLIPASE A_2 -NEUROTOXINS IN CHOLINERGIC PAIRS OF NEURONS IN *APLYSIA CALIFORNICA*. M.L. Winfree, J.P. Aplan, T.-M. Shih* and M.G. Filbert. U.S. Army Medical Research Institute of Chemical Defense, Aberdeen Proving Ground, MD 21010.

The site of action of three snake phospholipase A_2 -neurotoxins (PLA_2), taipoxin, crotoxin, and corticotoxin I has been examined using synaptically coupled cholinergic neurons in the buccal ganglia of the marine mollusc *Aplysia californica*. Corticotoxin II was also examined because it produces neurotoxic effects similar to corticotoxin I but lacks PLA_2 enzyme activity. Toxins were either superfused over isolated ganglia or micropressure injected directly into the presynaptic neuron of an identified pair of cholinergic cells. Microinjection of toxins into presynaptic neurons produced changes consistent with inhibition of transmitter release as discerned by a decrease in the amplitude of postsynaptic responses to stimulation of the presynaptic cell. Superfusion of PLA_2 -neurotoxins into the experimental chamber resulted in depolarization of both pre- and postsynaptic cell membranes and changes in the amplitudes and decay phase of action potentials evoked by stimulation of presynaptic cells. Chamber application of toxins also resulted in spontaneous excitatory activity in postsynaptic cells. This spontaneous activity was reduced by dizocilpine, a non-competitive inhibitor of NMDA receptors. The observations reported here suggest that the above PLA_2 -neurotoxins have multiple sites of action, both external and internal.

625.2

GDP IS REQUIRED FOR ACTIVATION OF A GLYBURIDE-, ATP- AND CROMAKALIM-SENSITIVE OUTWARD CURRENT IN RAT HIPPOCAMPAL NEURONS G. Erdemli* and K. Krnjević. Anaesthesia Research Dept., McGill University, Montréal, Québec, H3G 1Y6, Canada.

There is no agreement between different groups working on cromakalim (CROM) effects on hippocampal neurons. For example, according to Politi and Rogawski (*Mol. Pharmacol.* 1991, 40:308) CROM activates a glyburide (GLYB)-sensitive K^+ current in cultured cells. However, we found that cromakalim decreases a voltage-dependent outward current - probably a delayed rectifier - in CA1 neurons in slices (Erdemli and Krnjević *Soc. Neurosci. Abst.* 1993, 19:709). The present data were obtained with whole-cell recording from CA1 pyramidal neurons in slices. In nine cells, held at -54 ± 3 mV (where membrane current was ≈ 0) and recorded with the "standard" internal solution (KMeSO_4 , HEPES, EGTA, CaCl_2 and MgCl_2), CROM (100 μ M) reduced both input conductance (G_N) (by $14 \pm 4\%$) and outward currents evoked over a wide range by brief depolarizing pulses: at -4 ± 3.0 mV, currents diminished by $30 \pm 10\%$. When the standard internal solution contained also 1 mM GDP, there was a significant outward current at ≈ -54 mV; and CROM increased outward currents at -4 ± 2.6 mV by $99 \pm 26.4\%$ ($n=10$). The enhanced outward currents were reduced by CROM washout (in 2 cells) and by 10 μ M GLYB (in 4 cells). When six other cells were recorded with electrodes containing both ATP (5 mM) and GDP (1 mM), there was no net outward current at ≈ -54 mV and CROM reduced outward currents (at ≈ 0 mV, by $38 \pm 11\%$). We conclude that, like many muscle cells, CA1 neurons have outward current channels that are both ATP- and GLYB-sensitive, and are opened by CROM - and therefore resemble classical K_{ATP} channels - but can be activated only when cytosolic GDP is present.

Supported by the Medical Research Council of Canada.

MUSCARINE-INDUCED INCREASE OF AN INWARD RECTIFIER K^+ CURRENT IS MEDIATED BY Gi_2 IN ATT-20 CELLS. T. Kozasa, T. Ohtsuka, Y. Kaziro, S. Nakajima* and Y. Nakajima. Dept. of Anat. and Cell Biol., and Dept. of Pharmacol., Univ. of Illinois at Chicago, Chicago, IL 60612, and Institute of Med. Sci., Univ. of Tokyo, Tokyo 108.

Muscarine and somatostatin induce an inward rectifier K^+ current in a pituitary tumor cell line (Att-20), and these effects are mediated by a pertussis toxin (PTX)-sensitive G protein, Gi or Go . To investigate which subtype(s) of Gi mediates these agonist effects, we constructed PTX-insensitive mutants of α -subunit cDNAs of Gi_1 , Gi_2 , and Gi_3 , and transfected them stably into Att-20 cells. PTX ADP-ribosylates the cysteine residue at the 4th from the carboxyl terminal of $\text{Gi}\alpha$ or $\text{Go}\alpha$, and uncouples those subunits from receptors. We mutated this cysteine residue of $\text{Gi}\alpha$ to serine. The function of the transfected Gi was examined after the endogenous Gi and Go of the transfected cells were inhibited by PTX. As controls, wild type $\text{Gi}\alpha$ cDNAs ($\text{Gi}_1\alpha$, $\text{Gi}_2\alpha$, or $\text{Gi}_3\alpha$, PTX-sensitive) were transfected into Att-20 cells. Muscarine (100 μ M) and somatostatin (500 nM) effects on cell lines were examined with the whole cell-clamp. Only in the cell lines into which the mutated (PTX-insensitive) $\text{Gi}_2\alpha$ cDNA was transfected, did the muscarine response become PTX-insensitive, suggesting that Gi_2 couples to the muscarinic receptors and enhances the activity of the inward rectifier K^+ channel. As for the somatostatin response, transfection of any of the mutated $\text{Gi}\alpha$ cDNAs did not alter the PTX-sensitivity of the response. Supported by NSF grant IBN-9209785.

COMPARISON OF THE INCREASE IN POTASSIUM CONDUCTANCE BY GALANIN AND OXY-M (OXOTREMORINE M) IN MUDPUDDY PARASYMPATHETIC NEURONS. J.M. Mulvaney* and R.L. Parsons, Department of Anatomy and Neurobiology, University of Vermont College of Medicine, Burlington, VT 05405.

Galanin and muscarinic agonists hyperpolarize mudpuppy parasympathetic neurons by activating a similar inwardly rectifying potassium conductance (G_K). The present experiments were done to quantitate and compare the increase in G_K produced by galanin and the muscarinic agonist Oxy-M. All experiments were done on isolated parasympathetic neurons dissociated from the cardiac ganglion of the mudpuppy, *Necturus maculosus*. Recordings were made using the perforated patch mode of the whole cell voltage clamp technique on cells bathed in physiological solution containing an elevated potassium concentration (in mM: 120 NMG, 12.5 KCl, 3.6 CaCl_2 , 10 HEPES). Both agonists produced a concentration dependent increase in G_K . At low concentrations (10^{-9} M Galanin and 10^{-8} M Oxy-M) the increase in G_K was additive. In contrast, high concentrations of either agonist occluded the response to subsequent application of the other agonist. The time course of G_K activation was very different. The increase in G_K by Oxy-M occurred rapidly, remained relatively constant in the presence of agonist, and reversed quickly following removal of the agonist. The galanin-induced G_K developed slowly and then faded. The time course of the fade was consistent whether or not galanin was removed from the bath. Previous experiments demonstrated that arachidonic acid (AA) activates an inwardly rectifying G_K with a time course similar to the galanin-induced G_K . At maximum concentrations of Oxy-M or galanin, the AA-induced G_K was occluded. Our results indicate that galanin and Oxy-M activate the same inwardly rectifying G_K but that the mechanism of activation may be different. We suggest that the galanin-induced increase in G_K may be mediated through a second messenger, possibly AA. Supported by PHS RO1 NS23978.

INVESTIGATING THE SITE OF Zn^{2+} ACTION BY SINGLE AMINO ACID SUBSTITUTION IN A VOLTAGE-GATED K^+ CHANNEL.

S.J. Gibbons¹*, G. Talukder¹, M.M. Tamkun², H. Shear² and N.L. Harrison¹
¹Anes and Crit Care & Pharm/Phys., U. of Chicago, Chicago IL 60637, ²Mol. Phys. and Biophys., Vanderbilt U. Nashville TN.

Zn^{2+} modulates the gating of a human cloned voltage-dependent potassium channel (Kv1.5) by binding to a specific site on the extracellular surface of the protein (Harrison et al. (1993) Mol. Pharm., 43 482). We have employed the techniques of site-directed mutagenesis and transient expression of mutant channels in HEK-293 cells to establish the amino acids which are important for the integrity of the Zn^{2+} binding site. Single amino acids in the S5-S6 domain ("P region") were chosen for mutation by comparing the amino acid sequence of known Zn^{2+} -sensitive (Kv1.1, 1.4 and 1.5) and insensitive (Kv1.2 and 2.1) channels. Whole cell recordings were made at 25°C, using intracellular solutions based on K gluconate and continuous extracellular perfusion with HEPES-buffered saline containing 3mM K^+ . hKv1.5 channels expressed in HEK 293 cells activated at a significantly more depolarized potential than the same channels expressed in mouse L cells. Modulation by Zn^{2+} was unaltered. Our initial approach has been to generate mutants of Kv1.5 with similar amino acids in the P region to Kv2.1, which is very weakly modulated by Zn^{2+} . Activation gating of Kv1.5 (A455K) is shifted to the right ($V_{0.5} = 25\text{mV}$) compared to the wild-type (w.t., $V_{0.5} = 11\text{mV}$) whereas activation of Kv1.5 (H461K) is not significantly changed ($V_{0.5} = 19\text{mV}$, $n=4$). Robust modulation of gating by 200 μM Zn^{2+} is still observed for both channels although the right shift (Δ) is slightly reduced (w.t. $\Delta = 25.3\text{mV}$, A455K $\Delta = 20\text{mV}$, H461K $\Delta = 17\text{mV}$, $n=3-9$). We are presently examining the affinity of these channels for Zn^{2+} . S.J.G. is supported by DHHS training grant # DA07255.

AN ATP-SENSITIVE K^+ CHANNEL IN ISOLATED RAT NEOCORTICAL NEURONS: ACTIVATION BY GANGLIOSIDES. Z.-Q. TONG* and X.-D. TANG
 Dept. of Physiol., First Military Medical Univ., Guangzhou 510515, P.R. China

Our previous studies have indicated that gangliosides (GM) protect cerebral ischemia by measuring infarcted area, contents of free radical and ECoG. The ionic mechanisms were further studied here with patch clamp technique.

Single neurons were acutely isolated from Sprague-Dawley rat neocortex at 18-23°C. The pipette and bath were all filled with TTX (1 μM) and CdCl₂ (0.3 mM) contained but glucose-lacked solutions, with potassium concentrations of 5, 5 mM (cell-attached) or 135, 135 mM (inside-out).

In 7 cell-attached patches, 2-10 μM of monosialoganglioside-GM1 (Sigma, approx. 95%) produced a class of single channel currents whose durations of the burst openings showed concentration-dependent. The values of the burst times resulted from 2, 5, 10 μM GM1 were 6 ± 2 s ($n=3$), 21 ± 4 s ($n=3$) and 42 s ($n=1$), respectively. The long-time burst-like openings would disappear after washing GM1 out. After formation of inside-out recording from the same cell-attached patch, the channel activities were depressed by either 2 mM of Na₂-ATP (Sigma) or 1 μM of glibenclamide (Sigma). The reversal potential was ~ 0 mV (pipette). So the potassium channels were of ATP-sensitive type.

In 6 inside-out patches, after applications of 5-10 μM GM1, single channel recorded often became multichannel activities which then recovered to single channel openings after GM1 was washed out. The GM-evoked multichannel currents were inhibited by applications of 4 mM ATP or 2 μM glibenclamide, with a reversal potential of ~ 0 mV and a channel conductance of ~ 90 pS.

The results demonstrate that, under the conditions of metabolism inhibition (bath without glucose and ATP), GM can activate ATP-sensitive K^+ channels in rat neocortex. The mechanism was suggested to involve protein kinase C.

CESIUM AND BARIUM BLOCKADE OF DOPAMINE-MODULATED K^+ CHANNELS IN RAT STRIATAL NEURONS. Yong-Jian Lin*, Gabriela J. Greif and Jonathan E. Freedman. Dept. Pharmaceutical Sciences, Northeastern Univ., Boston, MA 02115.

Inwardly-rectifying K^+ conductances are reported to have a prominent role in striatal (caudate-putamen) neuron firing properties, with heterogeneity at the whole-cell level in sensitivity to Cs^+ and Ba^{2+} blockade. Using cell-attached patch-clamp recording from freshly dissociated rat striatal neurons, we are studying blockade of an inwardly-rectifying 85 pS K^+ channel, which is activated by D₂-like dopamine receptors. Both Cs^+ (3 mM) and Ba^{2+} (0.5 mM) partially blocked this channel when applied to the external surface of the membrane via the patch pipette; block was rapid, flickery and voltage-sensitive. At this concentration, Ba^{2+} also produced intervening periods of stable blockade up to 1 sec. Cs^+ , but not Ba^{2+} , slightly permeated the channel at voltages near the K^+ reversal potential. These cells also express other inwardly-rectifying K^+ channels with conductances ≤ 30 pS, which are dopamine-insensitive. These channels were blocked more completely by 3 mM Cs^+ than was the 85 pS channel. Our results extend to the single channel level the finding that striatal inwardly-rectifying K^+ channels are heterogeneous in their block by these ions, and indicate that the dopamine-modulated K^+ channel is both blocked and permeated by Cs^+ . CHEMICAL INHIBITION OF SDH *IN VIVO* ALTERS TIME COURSE OF ATP CONCENTRATION AND MEMBRANE POTENTIAL UPON *IN VITRO* INHIBITION OF SDH. M. Riepe^{1,2}, W.D. Niemi^{1,3}, D. Megow², and D.O. Carpenter¹.

¹Wadsworth Labs, NYS Dept. of Health, Albany, NY 12201, ²Dept. of Neurology, Humboldt-Univ., Berlin, Germany and ³Russell Sage College, Dept. of Biology, Troy, NY 12180.

Treatment with inhibitors of succinic dehydrogenase (SDH) can induce neurodegeneration similar to that seen in Huntington's Disease. Hippocampal brain slices were prepared from rats treated with a single *in vivo* injection of 3-nitro-propionic acid (3-NPA), a suicide inhibitor of SDH which slowly alters the level of ATP. Rats were given a single injection (IP) of 20 mg/kg of 3-NPA and sacrificed by cervical dislocation at intervals of 1 to 8 h. The brains were quickly removed and placed in cold oxygenated Krebs, sliced, and then oxygenated in warm Krebs for 1.5 h. Relative to controls these slices showed a decrease in ATP and ADP concentrations within the first 2 h, an intermittent increase at 4 h, and then a second decline between 4 and 8 h, bringing the level down to that of the first 2 h. We assessed the amount of remaining SDH activity with 2,3,5-triphenyl-tetrazolium chloride (TTC) staining. We found that the intensity of staining paralleled the levels of ATP. Intracellular recordings from pyramidal neurons from control animals showed that acute perfusion of 3-NPA on isolated slices results in a hyperpolarization, while in slices taken from animals treated *in vivo* for 8 h this effect was not seen. Application of glibenclamide (10 μM), a selective antagonist at the KATP channel, reduced the hyperpolarization compared to controls. We conclude that brief periods of interruption of energy metabolism *in vivo* can be somewhat compensated, and this is reflected in such physiologic parameters as activation of ATP-regulated potassium channels. PROSTAGLANDIN E_2 REGULATES VOLTAGE-GATED POTASSIUM CHANNELS IN NEUROHYPOPHYSEAL NERVE TERMINALS. Lei ZHANG, Edward KARPINSKI and Christina BENISHIN*. Dept. of Physiology, Univ. of Alberta, Edmonton, AB Canada T6G 2H7.

A high concentration of prostaglandin E_2 (PGE_2) has been demonstrated in the neurohypophysis and may have an important role in hormone release from the posterior pituitary. In the present studies, the whole-cell version of the patch clamp technique was used to investigate the effect of PGE_2 on potassium (K^+) currents in nerve terminals which were acutely dissociated from the rat neurohypophysis. PGE_2 initially increased the delayed rectifier K^+ current (I_K). The effect of PGE_2 on I_K was transient with a return to control levels after 15 to 20 min. Additionally, 15 to 20 min after PGE_2 administration, the transient outward current (I_A) was increased. These effects were concentration dependent, within the concentration range of 50 to 500 μM PGE_2 . Forskolin, 8-bromo cyclic-AMP and dibutyryl cyclic-AMP also significantly increased I_A and simultaneously decreased I_K . These results show that cyclic-AMP modulates K^+ channels in nerve terminals, and may mediate some of the effects of PGE_2 on K^+ channels and, hence, hormone secretion from the neurohypophysis.

5-HYDROXYTRYPTAMINE MODULATION OF DELAYED-RECTIFIER-TYPE POTASSIUM CHANNELS IN ANTENNAL-LOBE NEURONS OF THE MOTH *MANDUCA SEXTA*. P. Kloppenburg^{1,2}, A.R. Mercer^{1,2} and J.G. Hildebrand¹. ¹ARL Div. of Neurobiol., Univ. of Arizona, Tucson, AZ 85721; ²Dept. of Zool., Univ. of Otago, Dunedin, NZ.

A principal goal of our studies of the olfactory system of the sphinx moth *Manduca sexta* is to determine the role(s) played by 5-hydroxytryptamine (5HT or serotonin) in the antennal lobes (ALs, the primary olfactory centers) of the brain. In *Manduca*, each of the two ALs is innervated by a single 5HT-immunoreactive neuron (J. Neurobiol. 19:451-465, 1987). Synaptic contacts between AL interneurons and the 5HT-containing cell occur within the glomerular neuropil of the AL. The majority of these contacts are output synapses from the 5HT-containing cell (J. Comp. Neurol. 338:5-16, 1993). In the brain of the adult moth, exogenously applied 5HT (100 μ M) leads to broadening of action potentials and increased excitability of AL interneurons (Soc. Neurosci. Abstr. 18:303, 1992). These effects can be mimicked by application of 5HT to AL neurons in primary-cell culture (Soc. Neurosci. Abstr. 19:126, 1993). Both *in vivo* and *in vitro*, treatment with 5HT leads to an increase in cell input resistance. Here we report that 5HT causes prolonged closure of delayed-rectifier-type K⁺ channels in these cells. Applied to AL neurons *in vitro*, in brain slices, or in semi-intact brain preparations, 5HT (5-100 μ M) decreases channel opening probability and causes reversible reduction of delayed-rectifier K⁺ current. Single-channel recordings in cell-attached mode suggest that the effects of 5HT on K⁺ channels of this type are mediated via a diffusible second messenger, the identity of which has yet to be established. Closure of delayed-rectifier-type K⁺ channels could account for the increased duration of action potentials observed in many AL interneurons in response to 5HT. TETRANDRINE: EFFECTS ON BK_{Ca} CHANNELS

R. Witka^{*}, T. Glaser, and H. Sommermeyer. Institute for Neurobiology, Tropenwerke GmbH & Co. KG, Berliner Strasse 156, 51063 Cologne, FRG

The alkaloid tetrandrine (TET) is used in traditional medicine in China because of its analgesic, antiproliferative and for its vasodilatory and antihypertensive properties. Recently, TET has been used for differentiation of certain subtypes of Ca²⁺ dependent potassium channels of high conductance (BK_{Ca}) in rat neurohypophysis nerve terminals and pars intermedia cells (Wang and Lemos, 1992). In these systems, it has been shown to block only (charybdotoxin) ChTx insensitive type II currents, whereas ChTx sensitive type I BK_{Ca} currents remained unaffected.

In the present study the effects of TET were characterized in detail in two different cell systems. In the rat glioma cell line C6-BU-1, ionomycin stimulated rubidium (Rb⁺) efflux was found to be sensitive to charybdotoxin, iberiotoxin and tetraethylammonium (TEA), while apamin and 4-aminopyridine (4-AP) were ineffective. This pharmacological profile suggests the existence of BK_{Ca} currents in these cells. Since ionomycin stimulated Rb⁺ efflux was not influenced by TET, BK_{Ca} channels in C6-BU-1 cells seem to belong to the class I BK_{Ca} channel subtype. In GH₃ (rat anterior pituitary tumor) cells BK_{Ca} currents were characterized using the patch clamp technique. In parallel with our results in the study above, external applied ChTx and TEA reversibly blocked single channel currents, whereas 4-AP had no effect. Surprisingly, also TET turned out to inhibit BK_{Ca} channel currents in GH₃ cells, suggesting the presence of a channel type not classified so far.

To get insight into the role of TET sensitive BK_{Ca} channels in the rat brain, TET effects were characterized in microdialysis experiments measuring dopamine release from the N. accumbens. Local administration of TET results in a profound and transient increase of dopamine release, while the metabolites DOPAC and HVA were hardly affected. The latter results indicate that tetrandrine sensitive processes are involved in the regulation of dopamine release in this brain area.

ETHANOL ACTIVATES LARGE CONDUCTANCE, Ca²⁺-ACTIVATED K⁺ CHANNELS IN NEUROHYPOPHYSIAL TERMINALS. A.M. Dopico, J.R. Lemos and S.N. Treistman^{*}. Department of Pharmacology, University of Massachusetts Medical Center, and Worcester Foundation for Experimental Biology, Worcester, MA 01655.

Large conductance, Ca²⁺-Activated K⁺ (maxi CAK) channels are thought to underlie interburst intervals and, thus, control hormone release from neurohypophyseal terminals. Since ethanol (EtOH) inhibits the release of vasopressin (AVP) and oxytocin (OT), we studied its effects on maxi CAK channels from these terminals using patch-clamp techniques. CAK channels show a reversal potential close to 0 mV in excised, inside-out patches in symmetric 145 mM [K⁺]. They have a unitary conductance of 250 pS, and increase activity at more positive potentials and/or when [Ca²⁺] is increased at the cytosolic side of the membrane. EtOH (25-100 mM) applied to the cytosolic surface of the patch reversibly increases CAK activity without changing the unitary conductance of the channel. This activation by EtOH may reflect a direct interaction with the channel, possibly altering the EC₅₀ for Ca²⁺-activation of I-K⁺_{Ca}, and in conjunction with the previously-reported inhibition of L-type Ca²⁺ channels, can explain the reduced release of AVP and OT after EtOH ingestion. Supported by N.I.H. grant AA-08003.

BK CHANNEL: ITS WHOLE CELL OUTSIDEOUT RECORDING AND ITS ROLE IN DETERMINING THE RESTING MEMBRANE POTENTIAL IN BASILAR ARTERY CELLS. Y. Song, K. Tewari, L.K. Liem, S. Xu^{*}, J.M. Simard. Division of Neurosurgery, Univ. of MD Sch. of Med. Baltimore, MD 21201.

We studied large-conductance, Ca²⁺-activated K⁺ (BK) channels in smooth muscle cells from the basilar artery of the guinea pig using the patch-clamp technique. In inside-out patches, the single channel slope conductance was 260 pS and in outside-out patches, the apparent dissociation constant for block by tetraethylammonium Cl (TEA) was 280 μ M. Our principal goal was to assess the contribution of BK channels to conductance at negative potentials, near the resting membrane potential. We measured N-P₀ (number of channels in the cell \times open channel probability) at physiological potentials by recording single channel currents in a whole-cell configuration, a hybrid technique designated the "outside-out-whole-cell" configuration. With physiological solutions inside and outside, including 1 μ M Ca²⁺ internally, values (mean \pm S.D.) of N-P₀ were 0.17 \pm 0.05 and 0.49 \pm 0.39 at -40 and -30 mV, respectively. Our data on the single channel properties of this current indicate that, under conditions that simulate in part those expected with active myogenic tone, including a membrane potential of -40 mV and [Ca²⁺]_i>0.1 μ M, BK channels could contribute on the order of 10-20 mV to the membrane conductance, a value that compared favorably with the amount of depolarization observed under current clamp following external application of 1 mM TEA.

625.14

SINGLE CHANNEL STUDIES OF TWO "LARGE" CONDUCTANCE Ca-ACTIVATED K CHANNELS IN SYMPATHETIC NEURONS. T. Fagaly & D. Lipscombe^{*}. Dept. of Neuroscience, Brown University, Providence, RI 02912.

It has long been recognized that multiple classes of Ca-activated K channels (K_{Ca}) are present in neurons with different pharmacological profiles. In comparison to the well studied big conductance (BK) channel, less is known of the single channel properties of other non-BK K_{Ca} channels. We have studied K_{Ca} currents in inside-out patches from sympathetic neurons of adult frogs. Using 140 mM KAsparate and 10 mM EGTA on both sides of the membrane and exposing the inside of the patch to 1-10 mM Ca, a K_{Ca} channel distinct from BK channels was observed in at least 30% of our recordings (see fig.). The single channel conductance γ_{sc} of this channel displayed strong inward rectification such that γ_{sc} increased from 80 pS to 220 pS over 120 mV (+60 mV to 0 mV and 0 mV to -60 mV, respectively). In contrast BK channel-like openings exhibited a linear conductance of about 220 pS over the same range. The inwardly rectifying K_{Ca} channel was also distinct from the BK channel in that it was only weakly voltage-dependent even at relatively low Ca concentrations (2 mM Ca/10 EGTA). We have observed this rectifying K_{Ca} channel in isolation from BK channels in at least 4 recordings and also in the presence of 500 nM Apamin in the patch pipette. Experiments are ongoing to determine whether this channel is charybdotoxin- or iberiotoxin-sensitive. Interestingly, the activity of this channel runs up in the absence of Ca with time after patch excision from the cell.

POTASSIUM CHANNELS IN THE HYPERKALEMIC RESPONSE TO SUCCINYLCHOLINE FOLLOWING DENERVATION. J.A.J. Martyn, P. Yanez, D.B. Carr^{*}, Dept. Anesthesia, Harvard Medical School, Massachusetts General Hospital, Boston, MA 02114

Denervation induces a proliferation of nicotinic acetylcholine receptors (nAChRs) at the muscle membrane. This upregulation of nAChRs is associated with supersensitivity to agonists such as succinylcholine (SCh) and is believed to be responsible for the potentially lethal hyperkalemic response to SCh observed in patients with denervation injuries. The present study uses K⁺ channel blockers, 4-aminopyridine (4-AP) and tetraethylammonium (TEA) to characterize the contributory role of K⁺ channels in this hyperkalemic response.

Rats underwent bilateral sciatic denervation. After 2 weeks, the plasma K⁺ levels to SCh (3 mg/kg I.V.) was studied. The rise in plasma K⁺ induced by SCh was significantly greater in denervated rats (2.9 \pm 0.3 Meq/L, n=6) than in controls (0.7 \pm 0.1, n=6). Pretreatment with either 4-AP (3 or 5 mg/kg) or TEA (20 or 40 mg/kg) failed to inhibit the rise in K⁺. TEA (60 mg/kg) attenuated the hyperkalemia to SCh (1.2 \pm 0.3 Meq/L, n=6, p<0.5). At this dose, however, twitch tension was decreased to 20% of control (80% muscle paralysis), suggesting that inhibition of AChR channel also occurred.

Thus, K⁺ channels alone may not play a significant role in the hyperkalemia to SCh. K⁺ channel blockers may not be clinically useful for the prevention of hyperkalemia to SCh.

625.17

ACTIN FILAMENTS REGULATE ION CHANNELS IN IDENTIFIED RETINAL NEURONS. Greg Maguire*[@], Victoria Connaughton[@], Adriana Pratt[#], George R. Jackson, and Horacio Cantiello[#], [@]Sensory Sciences Center, The University of Texas, Houston, TX 77030 and [#]Renal Unit, Massachusetts General Hospital, and Department of Medicine, Harvard Medical School, Charlestown, MA 02129.

The role of the actin-based cytoskeleton was assessed on ion channel currents of identified retinal amacrine and bipolar neurons of the tiger salamander, *Ambystoma tigrinum* both in isolation and as a functional network. Neurons were identified by fluorescence labelling and whole-cell current patterns as previously described (Maguire et al., PNAS, 86:10144, 1989). Whole-cell voltage-gated K⁺ currents increased by addition of the actin filament depolymerizing agent cytochalasin D (1-5 μ M) to the bathing medium. This regulation was time dependent with the peak current occurring 10-15 minutes after addition of the drug. Addition of phalloidin (1 μ M), an actin filament-stabilizing agent, to the whole-cell recording pipette, completely prevented the stimulatory effect of cytochalasin D on the voltage-gated K⁺ currents. Voltage-gated Na⁺ channels were similarly affected by the changes in actin filament organization. The addition of cytochalasin D to the bathing medium activated single channels under both cell-attached and inside-out conditions. Actin (1mg/ml) and/or filamin (10 nM) added to the cytosolic side of inside-out patches also increased the frequency of channel openings. The results are consistent with a dynamic role of actin filament organization on the regulation of voltage-gated ion channels in neurons.

A NOVEL Na⁺ GATED K⁺ CURRENT OF FROG TECTAL NEURONES. A. Zaykin* and A. Nistri. Biophys. Lab., Int. Sch. Adv. Studies (SISSA), 34013 Trieste, Italy.

In the frog brain the optic tectum plays an essential role in processing visual signals from the retina. The basic properties of the layer VI cells, which receive monosynaptic inputs from the optic nerve, are still largely unclear. Using a slice preparation of the adult frog optic tectum we investigated with whole cell patch clamp recording voltage-activated currents of these neurones. The recording pipette contained a K gluconate solution plus ATP, EGTA and usually 5 mM Na⁺. From holding potential of -70 mV depolarizing steps elicited a fast inward current (-50 mV threshold) peaking at 1.5-2 ms, followed by two outward currents. The first outward current was transient and invariably followed the fast inward current at all potential above inward current threshold. The second, slower current had a higher voltage threshold (-30 mV). The tail current of the fast inward current reversed at +75 mV, which was very close to E_{Na} while the tails of the outward currents reversed at values coincident with E_K. At test potentials more positive than E_{Na} the fast inward current reversed polarity but it was still followed by the transient inward current. Ca²⁺-free extracellular solution did not change any of these currents. The transient outward current was also observed when intracellular Na⁺ was changed from 0 to 15 mM. TTX (1 μ M) simultaneously blocked the fast inward and outward currents leaving the slow outward component. Replacing extracellular Na⁺ with Li⁺ selectively blocked only the fast transient current; similar results were obtained in 0.2 mM 4-AP. It is suggested that a fast inward Na⁺ current elicited a transient K⁺ current. The novel properties of this latter current include its strong sensitivity to transmembrane Na⁺ flux rather than intracellular Na⁺, and its selective block by low doses of 4-AP or by Li⁺. Supported by INFM.

FLUFENAMATE AND MEFENAMATE: EFFECTS ON NEURONAL CAN CHANNELS. L.D. Partridge*, M. Sandquist, T. Shaw. Physiol Dept, Univ of New Mexico, Albuquerque, NM 87131.

Calcium-activated non-selective (CAN) channels respond to cytoplasmic Ca²⁺, do not inactivate, and are capable of producing maintained depolarization; they thus play important roles in the physiology and pathology of neuron function. CAN channels have been studied in neurons following bursts and after Ca²⁺ injection, and in patches isolated from neuronal membranes. Although CAN channels have been shown to be modulated by a PKA mechanism, no direct drug effects on neuronal I_{CAN} have been reported.

We studied I_{CAN} in bursting neurons of *Helix aspersa* by measuring the difference in tail currents at E_K following 50 and 500 ms depolarizing pulses to 0 mV. These current tails were identified as being I_{CAN} because they had decay time constants of at least 500 ms, could be measured at E_K, were eliminated by Ca²⁺ current blockers, and were unaffected by removing extracellular Cl⁻.

Flufenamate and mefenamate have been shown to block I_{CAN} in non-neuronal cells but there are no reported blockers of neuronal CAN channels. While lower concentrations had no effect on neuronal I_{CAN} tails, 500 μ M of flufenamate or mefenamate had a biphasic effect, first increasing and then depressing I_{CAN} tails. This may represent an effect similar to that seen in non-neuronal cells where these drugs first release Ca²⁺ from intracellular stores and then block CAN channels.

INTRACELLULAR SODIUM EVOKES A SULFONYLUREA-SENSITIVE POTASSIUM CURRENT IN DOPAMINE NEURONS. S.W. Johnson*, Ke-Zhong Shen, R. Alan North and Vincent Seutin. Departments of Pharmacology and Neurology, Oregon Health Sciences University, Portland OR 97201, USA.

In Parkinson's disease, dopamine neurons may have reduced ability to synthesize the ATP needed to maintain intracellular Na⁺ homeostasis. To study the electrophysiological effects of increased intracellular [Na⁺], we used whole-cell patch pipettes to dialyze Na⁺ (40 mM) into dopamine neurons in the rat midbrain slice. We found that Na⁺-loading increased membrane conductance and evoked an outward current at -60 mV (205 \pm 22 pA; n = 36). About 70% of current evoked by Na⁺-loading was blocked by Ba²⁺ (300 μ M), glibenclamide (IC₅₀ = 4.4 nM), tolbutamide (IC₅₀ = 20 μ M), and glibenclamide (1 μ M). This current was mediated by K⁺ because it reversed direction at the expected reversal potential for K⁺ (-98 \pm 6 mV, n = 9; 100 mM K⁺ in pipette, 2.5 mM in bath), and was also blocked by extracellular TEA (30 mM) and intracellular Cs⁺ (100 mM in pipette). About 30% of current evoked by Na⁺-loading was not blocked by Ba²⁺; this current was generated by Na⁺/K⁺ ATPase because it was blocked by a reduced extracellular concentration of K⁺ (0.5 mM), and by dihydropyridine (3 μ M). We suggest that the sulfonylurea-sensitive K⁺ current evoked by Na⁺-loading may have a neuroprotective function in Parkinson's disease.

ELIMINATION OF DELAYED RECTIFIER POTASSIUM CHANNEL EXPRESSION BY ANTISENSE OLIGONUCLEOTIDES IN A RAT PITUITARY CELL LINE.

S. Chung*, D. Saal and L.K. Kaczmarek. Dept of Pharmacology, Yale Univ. Sch. of Med., New Haven, CT 06510.

A large number of different subfamilies of Shaker potassium channels have been cloned and expressed in heterologous expression systems, such as *Xenopus* oocytes. It has, however, been difficult to attribute any specific cloned K⁺ channel to a specific K⁺ current in real cells. We have now used antisense oligonucleotides against the Kv1.5 delayed rectifier K⁺ channel to show that this channel contributes to a hormone sensitive K⁺ current in the GH4C1 pituitary cell line.

Treatment with a glucocorticoid hormone, dexamethasone, rapidly increases Kv1.5 mRNA in GH4C1 cells by up to 3 fold in 4 hours. This is accompanied by an increase in the delayed rectifier K⁺ current. Using an antibody against the Kv1.5 protein, we have now observed an increase in Kv1.5 protein on hormone treatment. Pre-treatment of the cells with a 20-mer antisense phosphorothioate oligonucleotide, but not with a random nonsense oligonucleotide, blocked the increase in the expression of the protein induced by dexamethasone. The treatment of the cell with antisense oligonucleotide also specifically blocked the increase in the K⁺ current. These results indicate that the Kv1.5 channel contributes to the glucocorticoid-sensitive component of K⁺ current in GH4C1 cells.

SELECTIVE EXPRESSION OF THREE DISTINCT POTASSIUM CHANNEL ACTIVITIES IN GIANT FIBER LOBE OF SQUID. W.-S.D. Griggs, Y. Hanyu and G. Matsumoto*. Supermolecular Division, Electrotechnical Laboratory, Tsukuba, Ibaraki 305, Japan.

Cell bodies of the Giant Fiber Lobe (GFL) of squid *Loligo Bleekeri* are dissociated and cultured. Currents are recorded at 16-18°C using whole-cell patch clamp techniques. Within 24 hours of plating, the axonal bulbs (AB) and the bulb-like structures (BLS) exhibit sodium currents while the cell bodies without processes (CB) do not. Meanwhile, all CB have transient potassium currents that inactivate with time constants 50-100ms. This slow-inactivating current is totally blocked by external application of 1-2mM 4-aminopyridine (4-AP). Some CB have another fast-inactivating potassium current with time constants 10-13ms. This fast-inactivating current is less sensitive to 4-AP than the slow-inactivating one. The fast- and slow-inactivating currents reach half maximum at 4.5-8ms, depending slightly on the voltage. In some BLS, a third type of slightly inactivating current similar to the delayed-rectifier current in squid giant axon is recorded (I_h). It is tetramethylammonium-sensitive and insensitive to 4-AP. Depending on the voltage, it reaches half maximum at 9-25ms. In AB and some BLS, a slow-inactivating component similar to that in CB is present in addition to I_h. Other BLS have, in addition to I_h, a component similar to the fast-inactivating current in CB with respect to their inactivation time constants and 4-AP sensitivity. I_h and sodium current have been recorded in some CB after day 3 in culture. Our results show that each of CB, AB, and BLS in GFL expresses selective combinations of three potassium currents which are distinct in their kinetics and pharmacology. This selectivity can vary in time in culture.

626.3

A CALCIUM ACTIVATED POTASSIUM CURRENT IN X-ORGAN SOMATA. R. Godínez, B. Mendiola, R.F. Valdiosera and J. Hernández*. Depto. de Fisiología, CINVESTAV-IPN. Apartado Postal 14-740. México D.F. 07000 and Depto. de Ingeniería Biomédica, UAM-Iztapalapa. México, D.F.

Single electrode voltage clamp experiments were carried out in axotomized X-organ neurons somata of the crayfish (*Procambarus clarkii*). The outward currents recorded in response to depolarizing voltage pulses from a holding potential of -45 mV depended on $[Ca]$. These currents increased 80% when $[Ca]$ was increased from 13.5 mM to 23.5 mM. Decreased about 50% when $[Ca]$ was decreased to 2 mM from 13.5 mM and the same diminution occurred when the Ca^{++} current was blocked with 200 μ M of Ca^{++} . A diminution of the same order was observed when 1 mM TEA or 20 nM charybdotoxin were added to the bath. Apamin however, had no effect. On the other hand, a 220 pS (in 227 mM KCl) K channel was observed in inside-out patch clamp recordings of these neurons. This channel is activated when the internal $[Ca]$ is increased from 1 μ M to 50 μ M. The presence of this high conductance Ca^{++} activated K channel may be important as a burst terminating mechanism in these neurons. Supported by CONACYT 1245-N9203.

626.5

VOLTAGE ACTIVATED POTASSIUM CURRENTS IN RAT PRIMARY LACTOTROPHS AND PITUITARY CELL LINE GH3. S. Sankaranarayanan and S.M. Simasko*. Dept. of VCAPP, School of Veterinary Medicine, Washington St. Univ., Pullman, WA 99164.

How voltage activated potassium currents (K_V) influence membrane potential behavior in lactotrophs and GH3 cells was addressed by characterizing their kinetic and pharmacological properties using whole cell patch clamp techniques. Exponential fits to the decay of K_V showed that both lactotrophs and GH3 cells have 3 components, a fast inactivating component (K_{V1}), a slowly inactivating component (K_{V2}), and an offset current. Voltage at 50% activation and rate of decay of K_{V1} was similar in lactotrophs (5 mV & 15/s) and GH3 cells (4 mV & 14/s). Voltage at 50% inactivation was -52 mV in lactotrophs and -41 mV in GH3 cells. Rate of recovery from inactivation of K_{V1} fit a single exponential (9/s) in lactotrophs, while in the GH3 cells the recovery from inactivation of K_{V1} fit a double exponential [0.12/s (70%) & 6/s (30%)]. In both lactotrophs and GH3 cells, 4-aminopyridine, 300 μ M, blocks K_{V1} (~60%) and K_{V2} (~50%). Dendrotoxin (DTX), 100 nM, was found to block only the K_{V1} (41%) component in GH3 cells but had no effect on K_{V1} or K_{V2} in the lactotrophs even at a concentration of 300 nM.

These results show that although K_{V1} components in both lactotrophs and GH3 cells are similar, their differences are perhaps significant in terms of influencing membrane potential behavior. DTX will be a useful probe to investigate the role of K_{V1} in GH3 cell function.

BIOPHYSICAL AND PHARMACOLOGICAL CHARACTERIZATION OF INWARDLY RECTIFYING K^+ CURRENTS IN RAT SPINAL CORD ASTROCYTES

Christopher B. Ransom* and Harald Sontheimer

Department of Neurology, Yale School of Med., New Haven CT 06510 and *Biology, Cal. Polytechnic State University, San Luis Obispo CA 93405.

Astrocytes are known to possess a large resting K^+ conductance. We characterized the resting conductance of astrocytes derived from rat spinal cord and found that this conductance was primarily mediated by inwardly rectifying K^+ (Kir) channels. We identified two types of astrocyte Kir channels with single channel conductances of -28 pS and -80 pS respectively. Channels displayed voltage-dependent block: open probabilities were -0.8 at potentials near and negative to the cell's resting membrane potential, but were near zero at potentials positive of the resting potential. The conductance (gK) of inwardly rectifying K^+ currents (Kir) depended strongly on $[K^+]_o$, and gK was approximately proportional to the square-root of $[K^+]_o$. Kir currents inactivated in a time and voltage-dependent manner due to block by $[Na^+]_o$. Kir currents were also blocked in a dose-dependent manner by extracellular Ca^{++} (Kd=72 μ M at -160 mV), Ba^{2+} (Kd=8.5 nM) and TEA (90% block at 10 mM), but were insensitive to 4-AP (5 mM). Ba^{2+} and TEA inhibition of Kir currents caused a marked depolarization suggesting that Kir channel activity is essential to establish the negative resting potential typical for astrocytes. The biophysical features of astrocytic inwardly rectifying K^+ channels are compatible with properties required for their proposed involvement in $[K^+]_o$ clearance according to the "glial spatial buffer" hypothesis: i.) high open probability at the resting potential, ii.) increasing conductance with increasing $[K^+]_o$, iii.) and rectification, e.g. channel closure at positive potentials. It is proposed, therefore, that the dissipation of $[K^+]_o$ following neuronal activity is mediated by the activity of astrocytic Kir channels.

IDENTIFICATION OF A CALCIUM-ACTIVATED POTASSIUM CHANNEL IN PROLACTIN SECRETING CELLS OF THE TELEOST GILlichthys MIRABILIS. Lisa A. Romano and Charles R. Fournier*. Dept. of Biological Sciences, State Univ. of NY at Buffalo, Buffalo, N.Y. 14260.

Prolactin is the main freshwater adapting hormone in teleost fish. Prolactin secreting cells are located exclusively in the teleost rostral pars distalis. We have identified using patch-clamp technique a calcium-activated potassium channel in dissociated cells of the rostral pars distalis of *Gillichthys mirabilis*. In excised patches the channel has a conductance of 170 pS and is voltage dependent over the physiological range of membrane potentials, with depolarization leading to an increase in channel open probability. The channel is activated by calcium on the cytoplasmic face of the membrane in a dose-dependent manner. Application of 1mM TEA, a known K channel blocker, to outside-out patches reversibly blocks the channel, while application to inside-out patches (up to 10mM) was without effect. This channel may function to modulate action potential duration and therefore prolactin secretion in these cells.

626.6

POSTNATAL DEVELOPMENT OF HYPERPOLARIZATION-ACTIVATED INWARD CURRENTS IN RAT NEOCORTICAL NEURONS. I.J. HABLITZ* AND B. SUTOR, Neurobiology Research Center, Univ. of Alabama at Birmingham, Birmingham, AL 35294.

Neocortical neurons in vitro display inward rectification during hyperpolarizing current pulses. Voltage responses reach a peak and then "sag" back towards resting levels. We have used whole-cell patch-clamp techniques to study the postnatal development of this response in rat neocortical neurons. Slices of anterior frontal cortex were prepared from rat pups on postnatal day (PN) 2-30. Under current clamp conditions, hyperpolarizing inward rectification or "sag" was observed as early as PN2 and was prominent in neurons from PN2-10. "Sag" was observed upon hyperpolarizations to -70 mV from a rest potential of -50 mV. The difference between the peak and steady state voltages reached during long (500-800ms) current pulses increased with pulse amplitude, suggesting activation of a voltage-dependent current. Hyperpolarizations beyond approx. -130 mV were often associated with an abrupt depolarization during a sustained current pulse. Under voltage clamp conditions, using a holding potential of -50 mV, a non-inactivating, time and voltage-dependent inward current was observed during hyperpolarizing voltage steps to membrane potentials negative to -70 mV. The "sag" and inward current were sensitive to block by both Ca^{++} and Ba^{2+} . PN 10-30 neurons showed less prominent sag although IV-curves showed inward rectification. These results indicate that hyperpolarization activated inward currents are present in neocortical neurons early in development. (Supported by NS22373)

POTASSIUM CURRENTS UNDERLYING ACTION POTENTIALS OF HIPPOCAMPAL CA1 ST. ORIENS-ALVEUS INHIBITORY NEURONS. L. Zhang* and C. J. McBain. Laboratory of Cellular and Molecular Neurophysiology, NICHD, NIH, Bethesda, MD 20892

Whole-cell recordings were made from 88 CA1 st. oriens-alveus interneurons in hippocampal slices from 13-20 day-old rats to determine the complement of potassium currents underlying single action potentials (AP). AP repolarization was dependent on the transient D- and A-currents, since the spike width was broadened by 58% and 120% by 50 μ M and 2 mM 4-AP respectively. Further, a prepulse to -80 mV to deactivate the A current increased the rate of spike repolarization. A role for the Ca^{2+} -activated K current (I_C) in spike repolarization was also determined, the specific blocker ibertoxin (IBTX, 100 nM), increased the duration of APs by 36%. Ca^{2+} -free Co^{2+} -containing solution produced similar effects (38% increase) which were non-additive with IBTX. In contrast, 4-AP (2 mM) further prolonged the APs in the Ca^{2+} -free medium by 130%. APs were followed by two prominent AHPs of fast (2 ms) and "medium" (270 ms) duration. IBTX (100 nM) or Ca^{2+} -free solution completely eliminated this fast AHP, while 4-AP was without effect. The amplitude of the medium duration AHP was reduced by apamin (100 nM, 26%), Ca^{2+} -free Co^{2+} solution (63%), the muscarinic agonist carbachol (10 μ M, 20%) and histamine (10 μ M, 23%). A slow-inactivating and two transient outward currents could be elicited by membrane depolarizations in excised outside-out, or whole-cell patches. Subtraction of the currents elicited with or without conditioning prepulses to -90 or -40 mV allowed isolation of each current. The half-maximal activation of the total transient current was reached at -22 mV and the slow-inactivating at -4 mV. At -10 mV, 4-AP (2 mM) inhibited both the transient current by 66% and the slow-inactivating current by 11%. In conclusion, I_A , I_D and I_C are three of the major K currents involved in AP repolarization; while I_C , I_{AHP} and I_M mediate part of the AHP in O-A inhibitory neurons.

POTASSIUM CURRENTS IN PREVERTEBRAL AND PARAVERTEBRAL SYMPATHETIC NEURONS. Hong-Sheng Wang and David McKinnon. Dept. of Neurobiology and Behavior, State University of New York, Stony Brook, NY 11794

Intracellular recordings were made from rat sympathetic neurons in isolated superior cervical ganglia (SCG), celiac ganglia (CG), and superior mesenteric ganglia (SMG). Based on their response to a maintained depolarizing current stimulus, neurons were classified as 'phasic' or 'tonic'. All neurons in the SCG were phasic, 85% of the neurons in the SMG and 58% of the neurons in the CG were tonic and the balance were phasic. The voltage response of phasic and tonic neurons around threshold to a constant current step was markedly different. The response of phasic neurons was biphasic with an initial depolarizing response followed by significant repolarization of the membrane potential. In contrast, tonic neurons became more depolarized during a prolonged current step. The underlying currents were studied using single-electrode voltage-clamp recording. The M-current was present in all phasic neurons, but was very weak or absent in tonic neurons. An A-current was apparent in both phasic and tonic neurons. The voltage-dependent activation, steady-state inactivation, and current density of the A-current were all similar in phasic and tonic cells. A low-threshold, slowly inactivating outward current (D2 current) was observed exclusively in tonic neurons. The slow inactivation of this current appeared to underlie the slow depolarizing ramp seen in response to a maintained depolarizing current step. Computer simulations, based on the voltage-clamp data, suggested that the different firing properties of phasic and tonic neurons could be accounted for by differential expression of the M-current and the D2-current.

ROLE OF IA-DEPOL IN FREQUENCY-DEPENDENT SPIKE BROADENING OF R20 CELLS IN *APLYSIA CALIFORNICA*. M. Ma* and J. Koester. Center for Neurobiology and Behavior, Columbia University, N.Y., NY 10032.

We studied the mechanisms and consequences of frequency-dependent spike broadening in the 2 R20 neurons in the abdominal ganglion. These neurons, which activate the circuit that initiates respiratory pumping, contain the neuropeptide SCP. When fired at 4-8 Hz, the falling phase of the action potential increases 6-fold during a 6-10 sec train, from 5 to 30 msec.

Spike broadening recorded from the somata of the R20 cells was shown to affect transmitter release from nearby terminals. We tape-recorded a 7 Hz, 10 sec train of gradually broadening spikes. They were then replayed as command signals for a 2-electrode voltage clamp that controlled soma potential. The synaptic output of the R20 cell produced in this way in a postsynaptic RB cell or in the R25 cells was the same as that produced under current clamp. But when only the first (non-broadened) spike from a train was played back for 10 sec at the same (7 Hz) frequency, the synaptic output was reduced by 50 - 70%. Because the release sites are some distance from the soma, the effect of broadening on release is underestimated by this protocol.

Using pharmacological methods and 2-electrode voltage clamp, we isolated voltage-gated I_{Na} , I_{Ca} (L- and N-type), I_{K-V} , I_{Adepol} and I_{K-Ca} in the R20 cells. I_{Adepol} activates in a range more depolarized than that for traditional A currents (Pflüger et al., 1991). The contributions of different currents to spike broadening were determined by using the gradually broadening action potential train as the command for the clamp. We found that: (i) Although the peaks of I_{Ca} show 40% inactivation during the spike train, the time integral of I_{Ca} during individual spikes increases by 200%, indicating that there is more Ca^{2+} influx during broadened spikes than during the non-broadened ones. (ii) Surprisingly, I_{Adepol} is the major outward current in the non-broadened spikes. Moreover, it undergoes profound and rapid cumulative inactivation, which is the major cause of frequency-dependent spike broadening in the R20 cells.

626.13

A DENDROTOXIN-I SENSITIVE POTASSIUM CONDUCTANCE IN AUDITORY NEURONS OF THE RAT MNTB. H. M. Brew and J. D. Forsythe. SPON: Brain Research Association, Dept. of Cell Physiology and Pharmacology, Univ. of Leicester, P.O. Box 138, Leicester, LE1 9HN, UK.

Neurons of the medial nucleus of the trapezoid body (MNTB) are part of brainstem auditory pathways that underlie sound source localisation. MNTB neurons possess rapidly activating potassium currents (Forsythe & Barnes-Davies 1993, Proc. Roy. Soc. B, 251, p143-150) that are thought to contribute to their ability to follow accurately the action potentials in their single giant synaptic input. We used whole-cell patch techniques to characterize one of the conductances underlying these currents in MNTB neurons in 200µm slices of brainstem from Lister hooded rats (5-12 day old). Slices were perfused with a standard artificial CSF (aCSF) at 25°C. Drugs were applied in the perfusate. Patch pipettes contained a pseudo-intracellular solution. A modified aCSF containing 1µM tetrodotoxin, 10µM strychnine, 0.5mM calcium and 2.5mM magnesium was used for voltage clamp recordings.

One potassium conductance produced most of the outward current in MNTB neurons between -60mV and -30mV. This current, I_d , was blocked by 100nM dendrotoxin-I (DTX-I) and mostly blocked by 100µM 4-aminopyridine. I_d activated and deactivated rapidly, peaking at 5msec at -30mV, and closing with a mean time constant of 1.8msec at -100mV. I_d showed voltage-dependent inactivation, inactivating very slowly at -30mV (>10sec), and 500msec at a holding potential of -110mV gave near complete deactivation. The mean reversal potential for I_d tail currents was -72mV.

MNTB neurons respond to depolarizing current clamp steps (≥0.75nA) with a single action potential (AP). In the presence of 100nM DTX-I, current steps (≥0.25nA) produced a train of APs (140Hz in response to 1.5nA).

The I_d described here is similar to the current, I_d , described in A-type neurons of rat nodose ganglion (Stansfeld et al. 1986, Neurosci. Lett. 64, p299-304). We suggest that I_d prevents MNTB neurons from firing multiple APs in response to one giant epsc, while the other high threshold potassium conductances facilitate high frequency following of presynaptic APs. Supported by the Wellcome Trust.

A-TYPE POTASSIUM CURRENT (I_A) GATING IS ALTERED IN SYMPATHETIC NEURONS FROM HYPERTENSIVE RATS. Walter P. Robertson and Geoffrey G. Schofield*. Department of Physiology, Tulane University School of Medicine, New Orleans, LA 70112.

Increased sympathetic nerve activity has been implicated in the development and maintenance of hypertension. The cellular basis for the exaggerated sympathetic nerve activity has yet to be determined. I_A may mediate neuronal excitability via modulation of action potential duration, regulation of the interspike interval during repetitive firing, and modulation of the time course of EPSP decay. We examined I_A in the spontaneously hypertensive rat (SHR) to investigate the possibility that alterations in I_A may be involved in the hyperexcitability of sympathetic neurons. Our preliminary data shows that half inactivation voltage of I_A from SHR (n=4) is ~13 mV hyperpolarized than control Wistar rats (n=6) (Fig.). In the SHR, inactivation at such hyperpolarized potentials could reduce the availability of I_A and thus mediate the increased sympathetic activity in hypertension.

Figure. H infinity plots of peak A-current. Neurons were held at the plotted potentials for 1.0 second before stepping to +20 mV. Current is normalized to maximum. Mean $V_{1/2}$ for SHR sympathetic neurons (circles) was -78 ± 1 mV and -66 ± 2 mV for Wistar rats (squares). Solid lines are least-squares fit of the data to a Boltzmann function.

IONIC CURRENTS INVOLVED WITH AUTOMATICITY IN A CLONAL CELL LINE. H. Bryant*, V. Kowtha, K. Iwasawa, D. Stenger. Center for Bio/Molecular Science and Engineering, Naval Research Laboratory, Washington, DC 20375, Department of Physiology, Uniformed Services University of the Health Sciences, Bethesda, MD 20814, *Section on Biophysics of Sensory Processes, LCB/NIDCD/NIH, Bethesda, MD 20892.

NG108-15 (neuroblastoma x glioma) cells are capable of exhibiting stable automaticity (the spontaneous occurrence of regenerative action potentials) following transient exposure to extracellular perfusates containing 20 mM NH_4Cl . The electrical activity of NG108-15 cells was monitored using single electrode intracellular recording and whole cell patch clamp techniques after culture in serum-containing medium (SCM) or serum-free media (SFM) containing N2 or B27 supplements. Cells cultured in SCM did not exhibit automaticity. Whole cell recordings revealed a pronounced outward current component in cells cultured in SFM which was insensitive to TEA and cesium. Action potential profiles of SFM cells were characterized by prolonged after hyperpolarization (AHP) which predisposed SFM cells to fire repetitively. Cadmium blocked the AHP. K^+ channel blockers Apamin and Charybdotoxin reduced the AHP component while CTX prolonged the action potential duration. SITS, a potent anion transport inhibitor, revealed another chloride sensitive outward component that slowed the firing rate. These results suggest that the AHP and the chloride outward currents present in cells cultured in SFM modulate automaticity in NG108-15 cells.

A COMPARATIVE PROFILE OF [125I]- α -DENDROTOXIN BINDING TO VOLTAGE-DEPENDENT POTASSIUM CHANNELS IN RODENT, NONHUMAN PRIMATE AND HUMAN BRAIN. L.E. Schechter*, D.M. Pearsall, S.P. Nawoschik, N.X. Barrezuela and K.J. Rhodes. American Cyanamid Co., Med. Res. Div., CNS Biological Research, Pearl River, NY 10965.

Alpha-Dendrotoxin (α -DTX) isolated from the venom of the African Green Mamba (*Dendroaspis angusticeps*) has previously been reported to be a neurotoxic peptide that selectively labels with high affinity voltage-dependent potassium (K^+) channels. Previous investigators have extensively studied the binding profile of radiolabelled α -DTX in rodent and bovine brain. This study compared the radioligand binding profile of [125I]- α -DTX in hippocampal tissue of rat, cynomolgus monkey and human as defined by saturation analysis, competition experiments and quantitative receptor autoradiography. A rapid filtration binding assay was developed for [125I]- α -DTX using whole cell aggregates of brain tissue. The K_d and B_{max} determined by saturation analysis from hippocampal tissue of rat, cynomolgus monkey and human was 63 ± 5 pM; 723 ± 31 fmol/mg prot., 81 ± 2 pM; 553 ± 63 fmol/mg prot. and 92 ± 4 pM; 570 ± 27 fmol/mg prot., respectively. Competition studies examining the displacement of [125I]- α -DTX by peptide toxins which are known to block voltage-dependent K^+ channels indicated that the rank order of affinity constants was similar across species: α -DTX > charybdotoxin > mast cell degranulating peptide > β -bungarotoxin. This similarity of the pharmacological profile in the hippocampus among the different species was confirmed using a variety of structurally and pharmacologically diverse agents. Interestingly, the laminar distribution of α -DTX binding sites in hippocampal tissue as studied by quantitative receptor autoradiography indicated that species differences exist in localization. Taken together, these data suggest that there is significant conservation of the voltage-dependent K^+ channel subunits that bind α -DTX across species but the neuroanatomical distribution appears to be different.

626.15

DISTRIBUTION OF [125 I] α -DENDROTOXIN BINDING SITES IN THE AMYGDALA, HIPPOCAMPUS AND ENTORHINAL CORTEX OF THE MONKEY. N.X. Barrezueta*, D.M. Pearsall, L.E. Schechter and K.J. Rhodes. CNS Biological Res., American Cyanamid Co., Pearl River, NY 10965.

Voltage-gated potassium (K^+) channels play a critical role in neuronal function by controlling the resting membrane potential. In the present study we used [125 I] α -dendrotoxin ([125 I]DTX) as a radioligand for quantitative autoradiographic localization of voltage-gated K^+ channels in cynomolgous ($n=1$) and fascicularis ($n=2$) monkey brain. Twenty micron thick coronal sections were incubated for 2 hr at 4 °C in 50 mM Tris buffer (pH 7.5) containing (in mM): NaCl (140), KCl (5), $MgSO_4$ (1.3) and 40 pM [125 I]DTX. Adjacent sections were incubated in the same buffer containing unlabeled DTX (100 nM) to define non-specific binding. Sections were then washed in buffer and dH_2O , rapidly dried, and apposed to Hyperfilm- 3H along with [125 I]-plastic standards (Amersham) for 48 hr.

Quantitative analysis of the autoradiograms indicated that specific [125 I]DTX binding was 80-85% of the total and that the distribution of [125 I]DTX binding sites was qualitatively similar in cynomolgous and fascicularis brain. Analysis of binding site density within the medial temporal lobe indicated that in the amygdala there was a high density of [125 I]DTX binding sites in the lateral and lateral basal nuclei, a moderate density in the medial basal nucleus, and a low density in accessory basal nucleus. In the entorhinal cortex (area 28), there was a high density of binding sites in layers II and V, and a moderate density in layer III. There was also a higher density of [125 I]DTX binding sites in area 28S than in other entorhinal subfields. In the hippocampal formation, there was a high density of [125 I]DTX binding sites in the molecular layer of the dentate gyrus, stratum pyramidale, radiatum and molecular of CA3, and in the subiculum and presubiculum. These data suggest that DTX-sensitive voltage-gated K^+ channels may have important modulatory functions within medial temporal lobe circuits crucial for memory function.

626.17

BLOCK OF THE $Kv1.2$ K^+ CHANNEL BY AMINOPYRIDINES AND QUININE. Taco R. Werkman* and Michael A. Rogawski. Neuronal Excitability Section, Epilepsy Research Branch, NINDS, NIH, Bethesda, MD 20892.

Block of $Kv1.2$ voltage-dependent K^+ channel currents by aminopyridines and quinine was investigated in fibroblast cells stably transfected with $Kv1.2$ K^+ channel cDNA (Werkman *et al.*, *Neuroscience* 50:935-946, 1992). Voltage-clamp experiments were conducted in the whole cell mode using the switch clamp technique, and also in the cell attached and excised patch modes using conventional patch recording methods. 4-Aminopyridine, 3,4-diaminopyridine and quinine all produced a concentration-dependent, reversible block of the $Kv1.2$ K^+ current elicited with voltage steps from -60 to +30 mV ($K_{0.5}$'s = 230, 860 and 18 μ M, respectively). Aminopyridine-induced block was voltage-dependent with the fractional block diminishing at depolarized potentials. Quinine-induced block was also voltage-dependent, but with block increasing at depolarized potentials. Aminopyridine block occurs by a mechanism that doesn't require open channels, although an initial depolarization is needed to allow the aminopyridine access to its binding site. In contrast, quinine appears to block by a simple open-channel mechanism. Using intracellular perfusion, it was possible to demonstrate that the aminopyridines block the K^+ channel by binding to an intracellular site, whereas the location of the quinine binding site could not be defined with confidence. The transfected fibroblast preparation provides a useful system to characterize in detail the mechanism underlying the K^+ channel block produced by aminopyridines and quinine, compounds that are well known to act as K^+ channel antagonists, but whose mechanisms of action are incompletely understood.

NOISE FLUCTUATION ANALYSIS OF PINEAL DELAYED RECTIFIER CHANNELS AND MODIFICATION BY THE BLOCKER, DOCOSAHEXAENOIC ACID. Richard E. Frye, Jon S. Poling, and Stefano Vicini*. Department of Physiology and Biophysics, Georgetown University School of Medicine, Washington, D.C. 20007; Laboratory of Membrane Biochemistry and Biophysics, NIAAA, Rockville MD. 20852.

Docosahexaenoic acid (22:6n3) potentially inhibits the delayed rectifier current of rat pinealocytes. 22:6n3 reduces peak K^+ current amplitude and produces a dose-dependent "secondary inactivation" of macroscopic outward current. This effect is probably due to open-channel blocking ability of 22:6n3. To investigate this hypothesis we identified single channel properties through noise analysis and single channel recording techniques. A computer program to analyze current fluctuations due to ion channels was developed utilizing LabTalk™ and the user interface module of Origin™ for Windows™. The technique employs mathematical routines based on Fast Fourier Transformations (FFT's) similar to those described by Dempster (Computer Analysis of Electrophysiological Signals, Academic Press, 1993). The power spectra of whole-cell current fluctuations due to delayed rectifier K^+ channels are well described by a double Lorentian function. The slow component of the double Lorentian is shifted to a higher corner frequency when 22:6n3 is applied. To further investigate this effect, 22:6n3 was applied to outside-out patches excised from pinealocytes. In control conditions, records of single channel currents exhibit bursting behavior and a conductance of about 20 pS is observed when the membrane is depolarized from -40 mV. In the presence of 22:6n3 (6 μ M), the channel burst length is shortened and longer closed intervals become apparent. Fluctuation analysis of outside-out recordings produce parameters which correspond to the kinetics of single channel currents.

Cd^{2+} -BLOCKADE OF HYPERPOLARIZATION-ACTIVATED CURRENT I_{AB} IN CRAYFISH MUSCLE. A. Araque, D. Cattaert and W. Buño*. Instituto Cajal, CSIC, Madrid 28002, Spain.

A novel hyperpolarization-activated current mediating inward rectification in opener crayfish muscle has been recently described (Araque and Buño, *J. Neurosci.*, 1994). This voltage- and time-dependent current, called I_{AB} , is selectively mediated by K^+ , its activation curve depends on the V_m - E_K , and its underlying conductance is unaffected by $[K^+]_o$. It is insensitive to Cs^+ , Rb^+ and Ba^{2+} , but is blocked by extracellular Zn^{2+} or Cd^{2+} .

The effects of Cd^{2+} on I_{AB} were studied under two-electrode voltage-clamp in opener muscle fibres. Cd^{2+} (10 mM) totally and reversibly reduced I_{AB} , without modifying the I_{AB} equilibrium potential. Lower Cd^{2+} concentration decreased the maximal conductance of I_{AB} and shifted its activation curve towards more hyperpolarized potentials without affecting the slope of the activation curve. While the I_{AB} activation time constant increased, the I_{AB} deactivation time constant was not modified by Cd^{2+} . The effects of Cd^{2+} on I_{AB} were independent on $[K^+]_o$. Cd^{2+} effects on I_{AB} were dose-dependent, obeying the Hill equation with $IC_{50} = 0.452 \pm 0.045$ mM and a Hill coefficient of 1.

We conclude that: a) the block of I_{AB} by Cd^{2+} was exerted in a dose-dependent manner, obeying the Hill equation and suggesting that one Cd^{2+} ion binds reversibly to one receptor with a dissociation constant of 0.452 mM; b) the selective permeability of I_{AB} channels was not modified by Cd^{2+} ; c) the binding site for Cd^{2+} to block I_{AB} was different to the binding site for K^+ to permeate; d) the Cd^{2+} -blockade of I_{AB} was not voltage-dependent; e) Cd^{2+} blocked the I_{AB} channel gate interfering with its opening but not with its closing mechanism.

Supported by DGICYT (Spain) and DGXII CEC (Europe) grants to W.B. A.A. is an Arce Foundation postdoctoral fellow.

TETRAPENTYL AMMONIUM (TPA) BLOCKS THE SLOWLY-ACTIVATING, SLOWLY-INACTIVATING K^+ CURRENT ($I_{K(s)}$) OF RAT PITUITARY MELANOTROPHS. K. Wong, J.-L. Davidson and S.J. Kehl*. Dept. of Physiology, U.B.C., Vancouver, B.C., V6T 1Z3.

The $I_{K(s)}$ of the melanotroph has been shown in this and other labs to be blocked by external TEA. The aim of the work outlined here was to investigate the effects of TPA, a structural analogue of TEA, on the $I_{K(s)}$. Whole-cell currents were recorded from cultured melanotrophs by using conventional patch electrode techniques. The block of $I_{K(s)}$ by TPA was manifest as a decrease of the steady-state current amplitude and an increased rate of current decay ("inactivation"). At a given voltage, the extent and rate of the TPA-induced inactivation was proportional to the TPA concentration; and, at a given concentration of TPA, the degree and rate of inactivation increased with membrane depolarization. The K_i at 0 and 50 mV was estimated to be 2.0 and 0.8 μ M, respectively, and the Hill coefficient was near one. Tail currents recorded in TPA following a brief, intense depolarization that opened $I_{K(s)}$ channels were smaller than control responses but "deactivated" at the same rate. When TEA and TPA were applied simultaneously there was no evidence for any competitive interaction. These results are consistent with an open channel blocking mechanism for TPA.

EFFECTS OF EXTRACELLULAR PH ON MEMBRANE ELECTRICAL AND MECHANICAL PROPERTIES OF VASCULAR SMOOTH MUSCLE

Beixing Liu, P.C. Johnson and G.F. Koshland*. Department of Physiology, University of Arizona, Tucson, AZ 85724

We have investigated the effect of changing extracellular pH (pH_e) at constant level of CO_2 on the membrane electrical and mechanical properties of vascular smooth muscle in isolated guinea-pig mesenteric and femoral arteries, using intracellular microelectrode recording and force measurement. Lowering pH_e depolarizes but reduces force development of vascular smooth muscle, whereas increasing pH_e hyperpolarizes and increases force development. From measurement of the decay time constant of excitatory junction potentials, we also found that lowering pH_e from 7.4 to 6.6 decreased the total membrane conductance of vascular smooth muscle whereas increasing pH_e had the opposite effect. The relationship between membrane potential and pH_e was unchanged as we increased the $[K^+]_o$ (in mM) from 4.7 to 25 at pH 6.6, 7.4, and 7.8. The value of membrane potential measured at $[K^+]_o$ of 25 mM was close to that predicted by Nernst equation. These data indicate that the resting potential of vascular smooth muscle is predominantly determined by the membrane conductance to K^+ and that the effect of pH_e on resting potential may be mediated through altering K^+ conductance. Finally, application of cromakalim and glibenclamide did not significantly affect the resting potential at pH 6.6, 7.4, and 7.8, which suggests that changing pH_e did not affect ATP-regulated K^+ channels. The maximum effect of pH_e on membrane potential occurs within about 5 min, after which the potential tends to return toward the control level. This secondary change is blocked by 1 mM TEA, suggesting that it is due to change of intracellular pH acting on Ca-regulated K^+ channels. Supported by NIH grant HL 15390.

ANALOG VLSI MODEL NEURON: A MULTIPLE PURPOSE PROGRAMMABLE DEVICE. G. Le Masson*, S. Le Masson, Y. Deval, and M. Moulins. LNCP, Univ. Bordeaux I-CNRS Arcachon 33120 FRANCE and IXL-URA CNRS 846 Bordeaux FRANCE.

Using a BiCMOS full custom technology, we developed an analog VLSI circuit (ASIC) for modeling conductance-based neurons. Currents with voltage dependent, sigmoidally-shaped activation and inactivation are produced and summed through an external serial capacitance. The maximal gain and voltage dependence of each current are fully and easily programmable via analog inputs, as well as the slope of both activation and inactivation curves. Simple kinetics and calcium dependent currents are available, and a synaptic function allows the construction of simple networks. Assembling several circuits is possible, to model neurons with complex intrinsic properties such as burstiness, or to reproduce multicompartmental structure. We tested VLSI models in both static and dynamic range, and we successfully reproduced with the same circuit, different neuronal behavior. To further validate the models, we compared results with an identical numerical model using classical Hodgkin Huxley's conductances. Due to its analog structure, it requires no computation time, and allows a fast screening of the parameter space. We recently reported a new technique for real time interaction between model neurons and biological neurons, through artificial synapses. These VLSI models are ideally suited for such hybrid network interactions.

RECONSTRUCTION OF HIPPOCAMPAL CA1 PYRAMIDAL CELL ELECTROPHYSIOLOGY BY COMPUTER SIMULATION D.M. Durand*, E.N. Warman, and G.L.F. Yuen, Depts of Biomedical Engineering and Neurosciences, Case Western Reserve University, Cleveland, OH. 44106.

Computer models of neural activity have been very successful in simulating the neurophysiological behavior of many neurons. In the hippocampus, the electrophysiology of neurons such as the CA1 cells has been studied in great details. A large number of ionic currents have been described but previous computer models were not able to reproduce several important features of these cells. We have developed a model based on the simplest combination of ionic channels that could best reproduce CA1 electrophysiology. The model was designed using seven active ionic conductances: g_{Na} , g_{Ca} , g_{DR} , g_{CT} , g_{M} and g_{AHP} whose kinetics have been inferred from the available voltage clamp data. Particular emphasis was placed on accommodation, slow depolarization potential and spike broadening during repetitive firing. The action potential was accurately simulated and the role of the three repolarizing currents I_A , I_{CT} and I_{DR} investigated. The model also reproduces all four after-potentials recorded following activation of the cell. The fast, medium and slow AHPs were generated by I_{CT} , I_M and I_{AHP} respectively. The model accurately reproduces features observed during the injection of long current pulses such as changes in firing frequency and a gradual broadening of action potential. The role of each current in mediating these responses has been investigated. The model also suggested that I_M may be the principal outward current regulating the CA1 resting potential. Supported by NSF grant # BNS 8809504.

BURSTING, SPIKING, CHAOS, FRACTALS, AND UNIVERSALITY IN BIOLOGICAL RHYTHMS. T.R. Chay*, Y.S. Lee and Y.S. Fan. Department of Biological Sciences, University of Pittsburgh, Pittsburgh, PA 15260.

Biological systems offer many interesting examples of oscillations, chaos, and bifurcations. Oscillations in biology arise because most cellular processes contain feedbacks that are appropriate for generating rhythms. These rhythms are essential for regulating cellular function. In this tutorial review, we treat two interesting nonlinear dynamical processes in biology that give rise to bursting, spiking, chaos, and fractals: endogenous electrical activity of excitable cells and Ca^{2+} releases from the Ca^{2+} stores in non-excitable cells induced by hormones and neurotransmitters. We will first show that each of these complex processes can be described by a simple, yet elegant mathematical model. We then show how to utilize bifurcation analyses to gain a deeper insight into the mechanisms involved in the neuronal and cellular oscillations. With the bifurcating diagrams, we explain how spiking can be transformed to bursting via a complex type of dynamic structure when the key parameter in the model varies. Understanding how this parameter would affect the bifurcating structure is important in predicting and controlling abnormal biological rhythms. Although we describe two very different dynamic processes in biological rhythms, we will show that there is universality in their bifurcation structures.

MULTIPLE CONDITIONS FOR SLOW OSCILLATIONS IN THE MEMBRANE OF A BURSTING NEURON O.E. Dick, K.-D. Kniffki, C. Vahle-Hinz* Physiologische Institute, Universität Würzburg, Röntgenring 9, D-97070 Würzburg and Universität Hamburg, Martinistr. 52, D-20251 Hamburg.

We have examined the possibility of different conditions for the existence of slow oscillations underlying the bursting mode (Epstein and Marder, Biol. Cybern. 63:25,1990; Destexhe et al., Biophys. J. 65:1538,1993). The problem has been solved by searching for several nonintersecting regions in the parameter space of the model of the stomatogastric bursting neuron (Guckenheimer et al., Phil. Trans. R. Soc. 341:345,1993). Since the considered system has two slow variables: intracellular calcium concentration (Ca) and activation variable for the Ca -current (Z_{Ca}), two systems have been chosen for the analysis of the conditions of slow oscillations. The first system contains the equations for the membrane potential V and Ca , the second system involves the equations for V and Z_{Ca} . Using the methods of bifurcation theory we have obtained for each system the explicit parametric forms of the boundaries limiting the regions of slow oscillations. Analyzing these forms we have found that over the range of physiological values of the model parameters there are two nonintersecting regions on (g_{Ca} , I), (g_{Ca} , I) and (g_a , I) planes, where g_{Ca} , g_{Ca} , g_a are the maximal calcium, calcium-dependent potassium and transient potassium conductances and I is the stimulus value. These results suggest that there are multiple conditions for slow oscillations in the membrane of the stomatogastric neuron. By means of numerical integration we have tested that the frequency of slow oscillations for the parameter values belonging to the regions obtained for the V , Ca system is lower than the frequency of oscillations obtained for the V , Z_{Ca} system. The neuronal membrane is likely to display the "slow bursting mode", which has a slow component determined by intracellular Ca oscillations and a fast component caused by oscillations of the variable Z_{Ca} .

A COMPUTATIONAL MODEL OF MYELINATED AXONS IN FROG DORSAL ROOT. A.L. Padjen* & T. Hashiguchi, Dept of Pharmacology & Therapeutics, McGill University, Montreal and Dept of Physiology, Tokyo Medical College, Tokyo.

We have used a mathematical model to simulate electrophysiological characteristics of large myelinated axons (long charging and discharging processes of the electrotonic potentials, ETPs) obtained by intracellular recordings from frog dorsal roots. The simulation program (modified NEURON simulation program by M.Hines & J.W. Moore) contained parameters based on experimental data of all recognized conductances in myelinated axons based on Hodgkin-Huxley equations, including inward rectifier and fast and slow K^+ conductances. It also incorporated all known sections of myelinated axons, such as nodal, internodal, myelin, unmyelinated sections, definitions for perinodal shunt, serial and parallel internodal resistances and their measured or estimated properties.

In order to simulate ETPs the myelin leakage conductance and the ionic conductance of internodal membrane were found to be the crucial factors. In contrast to the classical estimate of $1.5 \mu S/cm^2$ a much larger value of $80 \mu S/cm^2$ is required as specific myelin conductance. The likely pathways for this conductance are Schmidt-Lantermann incisures or paranodal opening. The conductance of the internodal axolemma requires values that are $<1\%$ of the measured conductance of the node of Ranvier.

The model supports the notion that not only the ion conductances of node of Ranvier but also those of the internodal axolemma contribute to electrophysiological properties and conductance mechanism in myelinated axons. (Supported in part by MRC of Canada)

MEASUREMENT ERRORS FROM CLAMPING VOLTAGE-DEPENDENT CONDUCTANCES IN CELLS WITH ELONGATE PROCESSES Daniel K. Hartline* and Ann M. Castelfranco, Békésy Lab., Univ. of Hawaii, Honolulu, HI 96822

Voltage clamp data are often obtained from cells with attached processes. Space-clamp errors potentially invalidate such data. To assess these errors, clamp currents were simulated for somata with a single cylindrical process containing voltage-dependent Hodgkin-Huxley (HH) conductances. Leak-subtracted $I(I)$ and $I(V)$ data were fitted with HH parameters as if the cells were space clamped.

Time constants (τ 's) for m h kinetics (as opposed to m^q h) were voltage-independent. Resulting clamp currents had an activation "delay" and voltage-dependent kinetics fittable over a broad range of parameters by an m^q h form. For an outward current mechanism uniformly distributed in a compact (0.5λ) process, activation τ 's were lengthened up to several fold, with lesser effect on inactivation τ . Errors in activation τ and q increased, and in inactivation τ decreased, with increased conductance densities. Fitted kinetic parameters for both activation and inactivation displayed a spurious voltage dependence near threshold.

Parameters of the $I(V)$ curve could be well fitted up to ca 10-100x leak conductance density. Measurement errors depended strongly on the time of the measurement, well after peak current being optimal. For a uniformly distributed conductance, measurement error was most severe in conductance and activation-width and less severe for activation midpoint and reversal potential. If enough is known about the distribution of channels in processes, it may be possible to correct clamp data for some of the measurement errors.

ENTORHINAL CORTEX LAYER III NEURONS: CHARACTERIZATION AND CHOLINERGIC EXCITATION. A. Mena* and A. Alonso. Montreal Neurological Institute and McGill University, Montreal, Qc, CANADA H3A 2B4.

Layers II and III of the entorhinal cortex (EC), via the perforant path, project massively to the hippocampus, and receive input from the cholinergic neurons of the basal forebrain. By means of intracellular recordings in the *in vitro* slice preparation, we have already characterized the electrophysiology of neurons in layer II (Alonso and Klink, 1993) and studied the modulation of their excitability by carbachol (CCh) (Alonso and Klink, 1991 and this meeting). Here, we report on the extension of this study to layer III neurons. Layer III cells appear a rather homogeneous population both morphologically and electrophysiologically. Intracellular staining with biocytin revealed a typical pyramidal shape with a thick apical dendrite and a skirt of basal dendrites. Current clamp recordings showed prominent fast inward rectification in both the depolarizing and hyperpolarizing directions. Many neurons displayed rhythmic tonic firing at rest which appears primarily sustained by a persistent Na-current. In contrast to layer II neurons, no rhythmic subthreshold oscillations were observed upon DC depolarization. Pressure-pulse applications of CCh resulted in a dose-dependent depolarization which could be potentiated after eliciting firing by manual injection of current. Clamping back to the control level showed an increase in input resistance. With continued bath application (20-60 μ M) of CCh, the response displayed pronounced desensitization. These data demonstrate clear-cut differences between EC layer II and layer III neurons both in their basic electrophysiological properties and in their modulation by basal forebrain cholinergic inputs.

RELIABILITY OF SPIKE INITIATION IN NEOCORTEX. Z.F. Mainen* and T.J. Sejnowski. Howard Hughes Medical Institute, Salk Institute, La Jolla, CA 92037.

Chemical and electrical signalling in the central nervous system appear remarkably variable, yet it is not known whether this variability carries meaningful information or simply reflects the intrinsic unreliability of underlying mechanisms. We have assessed the reliability of one process critical to neural signalling, the generation of action potentials. Whole-cell recordings were made from rat neocortical pyramidal cells *in vitro* and spikes were elicited by somatic current injection in the presence of synaptic transmission blockers (DNQX, AP5, BMI). Shown below are two examples of 10 consecutive responses (superimposed) to repetitions of identical stimuli (scale bars: 50 msec, 0.5 nA, 50 mV). A constant current step (0.2 nA) produced spike trains ($f=11-12$ Hz) with individual spike times that drifted from trial to trial (top). In contrast, repetition of a stimulus with transients resembling synaptic activity (filtered gaussian white noise, $\mu=0.2$ nA, $\sigma=0.05$ nA) evoked trains ($f=12$ Hz) with highly consistent spike times (bottom). Our experiments suggest that spike generation is under some conditions an extremely reliable process able to faithfully translate an input signal into a sequence of nerve impulses, and that synaptic transients may enhance the fidelity of spike coding. 627.11

THE HYPERPOLARIZATION-ACTIVATED CATION CURRENT (I_h) IN NEOCORTEX NEURONS IS BLOCKED BY EXTERNAL PROTEOLYSIS AND INTERNAL TEA. T. Budde*, J.A. White and A.R. Kay. Dept. of Biological Sciences, Univ. of Iowa, Iowa City, IA 52242

After one day in culture neurons derived from the neonatal cerebral cortex exhibited a slowly activating current gated by hyperpolarizing voltage-clamp pulses. The current was blocked by extracellular cesium (2 mM) and unaffected by barium (1 mM), and was permeable to both Na and K ($P_{Na}/P_K = 0.29$). Its form and pharmacology are consistent with a current termed I_h in other preparations.

I_h was absent from cells acutely dissociated from both the neonatal and mature cerebral cortex, despite the use of low enzyme concentrations. The sensitivity of I_h to extracellular proteolysis was demonstrated by superfusing the cells with trypsin (1 mg/ml) while monitoring the presence of I_h in the whole-cell mode of recording. I_h was rapidly abolished ($t_{1/2} \sim 5$ min) by proteolysis and exhibited no shifts in its range of activation or changes in its activation kinetics during the course of the digestion, suggesting the abolition of the ability of the current to gate rather than a shift in its range of activation.

Intracellular TEA, at a concentration of <15 mM was shown to block I_h , while extracellular TEA and 4AP had no effect on the current. This suggests that I_h may be structurally related to potassium channels.

WHY DO CORTICAL NEURONS SPIKE IRREGULARLY? M. Tsodyks, A. Bell, Z.F. Mainen and T.J. Sejnowski*. Howard Hughes Medical Institute, Salk Institute, La Jolla, CA 92037

The spike trains of many cortical neurons *in vivo* are highly irregular during both spontaneous and driven activity. Although this variability may simply reflect large correlated fluctuations in synaptic input, an additional consideration is the balance between synaptic drive and the intrinsic conductances generating action potentials.

Using a single-compartment Hodgkin-Huxley model, we show that when excitation and inhibition are balanced to maintain the neuron in the region of optimal sensitivity, near firing threshold, then variable spike trains result even in the absence of large input fluctuations. Increased levels of balanced synaptic input increase the rate of input fluctuations, producing higher firing rates with maintained irregularity. Decreased spike repolarization (weaker K^+ rectification) increased the steepness of the input-firing curve, giving greater sensitivity to input fluctuations.

Very similar results were obtained with a simpler integrate-and-fire model, which was used to explore networks of interacting excitatory and inhibitory neurons. Despite positive feedback between the excitatory neurons, proper balance was achieved robustly through inhibitory feedback. With weak repolarization, the network was sensitive to small inputs and could be switched rapidly between stable states dominated by fluctuations. This regime is not consistent with the mean-field approximations commonly made in network models. We propose that neuromodulatory control of K^+ conductances (weakening or strengthening spike repolarization) may dynamically regulate the time-scale of information to which cortical networks are sensitive. (We are grateful to M. Shadlen for useful discussion. Supported by ONR. ZFM is an HHMI Predoctoral Fellow.)

Electropharmacological Characterization of Cryopreserved Rat Cortical Neurons. T. Weiser, J. Sabourin*, M. Wienrich*, Boehringer Ingelheim KG, Ingelheim, Germany; *Battelle Europe, Geneva, Switzerland

Primary cultures from embryonic rodent brain are widely used for neurophysiological investigations. Unfortunately, these cultures have only a limited survival time of a few days to weeks, and longer storage so far has been impossible. We therefore set out to improve the cryopreservation technique of cortical neurons from embryonic rat brain.

Cryopreserved neurons were tested using the patch-clamp technique, and their properties regarding voltage- and transmitter-activated ion channels were compared with those from unpreserved control cells.

All preserved cells had resting membrane potentials in the physiological range (-55 ± 2.8 mV S.E.M., $n=14$) and responded to voltage jump protocols with typical neuronal sodium- and potassium currents. The application of glutamate, NMDA or GABA induced currents indistinguishable from those of the control cells. The NMDA induced currents were suppressed by AP5; GABA-ergic responses were inhibited by bicuculline and amplified by the steroid 3 α -dihydroprogesterone.

We conclude that cryopreservation does not alter the properties of cortical rat neurons, and that these cells can be used for electrophysiological and neuropharmacological investigations.

FUNCTIONAL ROLE OF AXON HILLOCK AND INITIAL SEGMENT IN CORTICAL SPIKE INITIATION. J.B. Huganard*, J. Joerges, Z.F. Mainen and T.J. Sejnowski. Howard Hughes Medical Institute, Salk Inst., La Jolla, CA 92037 and *Dept. of Neurol., Stanford Univ. Sch. Med., Stanford, CA 94305.

The processes that lead from synaptic input to spike output are critical factors in information processing in cortical neurons, yet the precise mechanisms of spike initiation are not well understood. Although neocortical pyramidal cells have voltage-dependent somatic and dendritic Na^+ channels that could promote dendritic spikes, recent data [Stuart and Sakmann, Nature 367:69] support the long-standing hypothesis that spikes are initiated preferentially in the axon hillock or initial segment (AH-IS). This is consistent with our findings in acutely isolated neurons that only cells retaining a visually detectable axon segment can support robust spike generation. A biophysical model was constructed in order to explore the implications of these findings.

When reported somatic and dendritic Na^+ densities (40 pS/ μ m²) are combined with AH-IS densities at least 200-fold higher, a density comparable to measurements at nodes of Ranvier, spikes are initiated in the initial segment and then invade the soma and dendritic tree antidromically, even when the site of depolarization is in the distal dendrite. In addition to high channel density, the geometry of the AH-IS was found to be critical to this behavior. The IS achieves a lower initiation threshold by a combination of high local current density and electrical isolation from the soma, while the conical shape of the AH promotes complete invasion of spikes into the soma. Simulations of axo-axonic inhibition, as believed to occur at chandelier cell synapses on the AH-IS, demonstrate that this type of inhibition is more effective in delaying spike onset than equivalent inhibition in the somatodendritic compartment. Voltage-clamp simulations indicate that caution should be exercised in the interpretation of somatic voltage-clamp data. For example, IS spike initiation can occur after distal dendritic synaptic input, even with apparent voltage clamp in the soma. These results underscore the capacity of the AH/IS to function independently of the soma, and indicate the importance of further studies of its physiology. CAESIUM PREVENTS THE MAINTENANCE OF LONG TERM DEPRESSION IN RAT HIPPOCAMPAL CA1 NEURONS. D. DiFrancesco, D. Janigro*, E. Wanke* and G. Maccaferri. Dip. di Fisiologia e Biochimica Generali, Univ. di Milano, Italy and *Dept. of Neurosurgery, Univ. of Washington, Seattle, WA.

Hippocampal synaptic plasticity involves long-term modification of the efficiency of information processing at synaptic sites. We measured long-term depression (LTD) of field EPSP in the CA1 region of acutely isolated hippocampal slices by delivering a 15 minutes train of pulses at 1 Hz to the Schaffer-commissural-CA1 pathway. LTD was prevented by adding a NMDA receptor antagonist (AP-5, 50 μ M) to the perfusing medium. Superfusion of the slices with Cs (2 mM) during or just after the 1 Hz stimulation period could both inhibit the maintenance phase of the depression itself and elicit spontaneous rhythmic activity. Since a major effect of Cs is a block of the hyperpolarization-activated current (I_h ; *J. Neurophysiol.* 69, 2129-2136), these results suggest the possible involvement of I_h in the maintenance of long-term depression and in the regulation of hippocampal excitability.

MEMBRANE POTENTIAL OSCILLATIONS IN IMMATURE RAT HIPPOCAMPAL CA3 NEURONS IN VITRO. C. Psarropoulou* and M. Avoli². ¹Dept of Physiology & Biophysics, Sch. of Med., Sherbrooke Univ., Sherbrooke, QC, J1H 5N4 and ²Dept of Neurology & Neurosurgery, MNI, McGill Univ., Montreal QC H3A 2B4, Canada.

Sharp-electrode intracellular recordings were made from 43 CA3 pyramidal neurons *in vitro*, in hippocampal slices obtained from Sprague-Dawley rat pups taken 2-17 days postnatally (P2-P17). Membrane potential oscillations (MPOs) were recorded at resting membrane potential (RMP) or following depolarization to levels more positive than -60mV, in 31/43 neurons (72%). The RMP of oscillating neurons (-64.8 \pm 1.25 mV, n = 31) did not differ from that of non-oscillating (-63.9 \pm 1.38 mV, n = 12). MPO amplitude (3 - 5 mV measured peak to peak at -50 mV) as well as MPO frequency (ranging from 3-15 Hz, measured at -50 mV) increased upon depolarization. MPOs induced action potential firing, whose frequency increased with depolarization. The percentage of oscillating neurons increased with maturation but not significantly (P2-P10: 13/20 neurons, 65%; P11-P17: 18/22 neurons, 82%). No developmental changes in MPO amplitude or frequency were seen. Tetrodotoxin (TTX, 1 μ M) blocked MPOs in 4/4 slices (P10-P16). Tetraethylammonium (TEA, 5mM), added after TTX, revealed slower, higher amplitude MPOs (2/3 slices) that were subsequently blocked by cobalt (5 mM). Following IPSPs or afterhyperpolarizations, MPOs were transiently inhibited, an effect outlasting the return to RMP and not mimicked by negative current injection. The non-NMDA receptor antagonist CNQX (10 μ M, n = 2) reduced substantially intrinsic MPO amplitude; adenosine (50-100 μ M, n = 2) did not depress, but increased transiently during washout MPO amplitude.

These experiments indicate that intrinsic MPOs, possibly facilitating synchronization, are present in the majority of CA3 hippocampal pyramidal neurons from the early postnatal life. These MPOs are generated by the activation of Na-conductance(s) and possibly Ca-conductance(s) and are depressed by the activation of K-conductance(s); in addition their features are modified by synaptic activity.

627.17

WHOLE-CELL AND SINGLE-CHANNEL PROPERTIES OF A LINEAR MEMBRANE CONDUCTANCE IN CAT RGCs. D.W. Robinson*, S.-J. Huang, R.P. Scobey and L.M. Chalupa. Dept. of Neurology, Section of Neurobiology, Physiology and Behavior and Center for Neuroscience, University of California, Davis, CA95616.

Whole-cell recordings from isolated cat retinal ganglion cells (RGCs) revealed the presence of a previously unreported linear current, which increased with ontogeny to a mean conductance of 0.27nS/pF at postnatal ages (Robinson et al., 1993). Changing the external Cl⁻ concentration had no measurable effect on the reversal potential implicating K⁺ as the major permeant ion. When the external K⁺ concentration was increased from 5 to 35 mM the reversal potential changed from -54 to -18 mV. This change was close to the expected value of 34.5 mV calculated from the GHK voltage equation, assuming a 4% permeability to Na⁺. We also used the cell-attached and ripped-off patch variations of the patch-clamp technique to examine the single-channel basis of this linear whole-cell conductance. From -100 to +100 mV little or no voltage-dependency was observed in the isolated single-channel conductance. Changing K⁺ concentrations on both sides of the patch resulted in changes in reversal potential similar to those observed in whole-cell. This potassium channel could therefore play an important role in setting the resting membrane potential in these neurons.

TWO TYPES OF INTERNEURONS IDENTIFIED BY POTASSIUM CURRENTS IN ISOLATED HIPPOCAMPAL CELLS FROM ADULT GUINEA-PIG. Shouhui Fan* and Robert K. S. Wong. Department of Pharmacology, State University of New York Health Science Center, Brooklyn, NY 11203.

Interneurons were isolated from the CA1 lacunosum-moleculare region of adult guinea-pig hippocampal slices by a modified enzymatic and mechanical treatment. Isolated interneurons were multipolar with several dendritic processes and thereby could be distinguished from CA1 pyramidal neurons. Outward potassium currents were recorded under whole-cell voltage-clamp when the cell was depolarized following a hyperpolarizing prepulse. The holding potential was -50 mV. Since the transient potassium current (i.e. A-current) and delayed potassium currents have significantly different properties, it is possible to activate them separately and examine them independently.

It was observed that interneurons could be divided into two groups based on whether or not they had the A-current. Approximately twice as many isolated interneurons had an A-current (N=9) than those that did not (N=4). These results suggest that there are two distinctive subpopulations of interneurons which may play different inhibitory roles in this region.

THE IONIC MECHANISM OF A NONSELECTIVE CATION CONDUCTANCE INDUCED BY NEUROTENSIN IN THE VENTRAL TEGMENTAL AREA. P. Y. Chien¹, R. H. Farkas¹, S. Nakajima² and Y. Nakajima¹. Dept. of Anat. and Cell Biol.¹ and Dept. of Pharmacol.² Univ. of Illinois, College of Med. at Chicago, IL, 60612.

Neurotensin (NT) excites rat ventral tegmental area (VTA) dopaminergic neurons in culture by inducing a nonselective conductance. NT also decreases the inwardly rectifying K⁺ conductance induced by the D₂ agonist quinpirole. The I-V relation of the NT-induced current had almost a zero slope between -60 mV and -140 mV. After decreasing the external Ca²⁺ concentration, the NT-induced current increased by \approx 4 times and had a positive slope-conductance. This result suggests that in the presence of [Ca²⁺]_o, the channel is blocked by Ca²⁺. When K⁺ and K⁺ are replaced by Cs⁺, and E_{Cl} = -68 mV and E_{Na} = +13 mV, the nonselective conductance reverses at -7 \pm 2 mV, between E_{Cl} and E_{Na}. When the internal Cl⁻ concentration was reduced, shifting E_{Cl} from near 0 mV to about -80 mV, the nonselective current still reversed at -7 \pm 2 mV, suggesting that the nonselective conductance was impermeable to Cl⁻, and that it was probably a nonselective cation conductance. Neurokinin B (NKB) and ACPD also induce inward currents in VTA neurons. The I-V relations of the NKB- and ACPD-induced currents had almost a zero slope between -60 mV and -140 mV, similar to the NT-induced current. Some of the NKB- and ACPD-responding cells were found to be dopaminergic based on tyrosine-hydroxylase immunoreactivity.

TTX-RESISTANT PERSISTENT NA⁺ CURRENT UNDERLIES PACEMAKER POTENTIALS OF FISH GONADOTROPIN-RELEASING HORMONE (GNRH) NEURONS. Y. Oka*. Zoological Institute, Faculty of Science, University of Tokyo, Tokyo 113, Japan

Gonadotropin-releasing hormone (GNRH)-immunoreactive terminal nerve (TN) cells show endogenous regular beating discharges, which may be related to their putative neuromodulator functions. The ionic mechanism underlying the pacemaker potentials (PPs) was studied using intracellular and patch-pipette current clamp recordings from whole brain *in vitro* preparation of a small fish brain. Addition of 1.5-3 μ M TTX to the Krebs-Ringer solution blocked spontaneous action potentials, but small regular PPs remained. The PPs were not affected by 1 mM amiloride or 1 mM Ni²⁺ (blockers of low-voltage-activated Ca²⁺ currents), or 2 mM Co²⁺ or 0.5 mM Cd²⁺ (blockers of high-voltage-activated Ca²⁺ currents), or in Ca²⁺-free solution. Thus, Ca²⁺ currents are not essential for the generation of PPs. On the contrary, the PPs were readily blocked by substituting tetramethylammonium (TMA) or choline for Na⁺ in the perfusing solution, and the resting membrane potential became more hyperpolarized than the control level. This is probably because of the block of persistent inward current that is carried by Na⁺ and supplies the depolarizing drive during the normal beating discharge mode. The present results suggest that the TTX-resistant persistent Na⁺ current, I_{Na(slow)}, plays an important role in the generation of PPs in TN-GNRH cells.

EFFECT OF HYPOTHERMIA AND EXTRACELLULAR pH ON CORTICAL NMDA RECEPTOR ACTIVITY. A.T. Gray, L.T. Buck, J.R. Feiner, B. Hansen and P.E. Bickler*. Dept. of Anesthesia, University of California at San Francisco, S.F., CA 94143-0542

Extracellular acidity is known to inhibit N-methyl-D-aspartate (NMDA) receptor activity and may therefore protect neurons during cerebral ischemia. However, the importance of this effect during induced hypothermia is not clear. Cortical slices from rats age 10 to 11 days were loaded with fura-2 to estimate cytosolic free calcium. Baseline intracellular calcium was not different between the normothermic (37°C) and hypothermic (17°C) groups (142 ± 18 vs. 102 ± 12 nM, respectively; mean \pm S.E.M., n=8 in each group). Baseline ATP levels were 61 ± 11 nmoles/mg at 37°C (n=4). Hypothermia reduced NMDA stimulated calcium influx (156 ± 25 vs. 41 ± 6 nM, respectively, n=8 in each group). Extracellular acidity at 37°C decreased NMDA stimulated calcium influx 86% over the in vivo pH range of 6.9 to 7.4. However, no significant effect of extracellular pH on NMDA stimulated calcium influx was seen at 17°C (in vivo pH range 7.3 to 7.8). We conclude that the effect of extracellular pH on NMDA receptor activity depends on temperature. Further studies are needed to estimate these effects over similar in vivo pH ranges. Supported by the UCSF Anesthesia Research Foundation.

VISUAL TOXICITY OF ETHAMBUTOL IS MEDIATED THROUGH THE NMDA RECEPTOR OF MAMMALIAN RETINAL GANGLION CELLS. J. E. Heng*, K. Moscaritolo, & E. B. Dreyer. Harvard Medical School, Dept. of Ophthalmology, MEEI, Dept. of Neurology, Children's Hospital, Boston, MA, 02115.

Ethambutol is a mainstay in the management of tuberculosis and other mycobacterial infections. Although its ability to cause optic neuropathy and visual loss is well known, a mechanism has not heretofore been established. We have established that ethambutol is directly toxic to retinal ganglion cells *in vitro*, and that this toxicity is mediated through the NMDA receptor. In cell culture studies we have shown that the addition of 100 μ M ethambutol to retinal cultures results in the death of 50% of retinal ganglion cells within 24 hours. Ethambutol mediated retinal ganglion cell death is dose-dependent. Other cell types in these preparations are unaffected. This toxicity can be prevented in several ways: (1) the elimination of endogenous glutamate; (2) the addition of the NMDA antagonists APV (2-amino-5-phosphonovaleate), MK-801 (dizocilpine), or the calcium channel blocker nimodipine. In addition, the non-NMDA antagonist CNQX (6-cyano-7-nitroquinoxaline-2,3-dione) did not reduce toxicity.

Taken together, these experiments suggest: (1) ethambutol is directly toxic to retinal ganglion cells in culture; (2) ethambutol increases the sensitivity of retinal ganglion cells to endogenous levels of glutamate; (3) ethambutol toxicity is mediated through the NMDA receptor. These findings suggest that visual loss due to prolonged ethambutol treatment for tuberculosis may be prevented by the use of selective NMDA antagonists.

SUBLETHAL NMDA RECEPTOR ACTIVATION RAPIDLY DISRUPTS MICROTUBULES IN CULTURED NEURONS. M.P. Goldberg*, J.K. Freeman, and A.M. Rosengarten. Center for the Study of Nervous System Injury, Dept. of Neurology, Washington Univ. School of Medicine, St. Louis, MO 63110.

Brief deprivation of oxygen and glucose, or direct glutamate receptor activation, causes focal swelling in dendrites of cultured cortical neurons (Soc. Neurosci. Abstr. 18: 1583, 1992, 19: 26, 1993). We examined NMDA-induced alterations in the neuronal cytoskeleton, using immunofluorescence and laser scanning confocal microscopy. In control cultures, antibodies to the microtubule-associated protein, MAP2, revealed diffuse immunoreactivity within neuronal somata, and smooth dendritic contours. Exposure to 10-50 μ M NMDA for 10 min resulted in little neuronal death, but was sufficient to cause extensive appearance of focal swelling, or varicosities, in MAP2-labeled dendrites of most neurons. Dendritic varicosities were apparent within 3 min of NMDA exposure, and MAP2 fluorescence was substantially diminished within 1 hr. At low NMDA concentrations (10-30 μ M x 10 min), these changes were reversible within several hours. Confocal microscopy with monoclonal antibodies to α -tubulin revealed distinct microtubules arranged circumferentially in neuronal cell bodies, and in longitudinal bundles in axons and dendrites. Immediately after 10 min NMDA exposure, this pattern was replaced with diffuse immunofluorescence uniformly filling the dendritic and somatic cytoplasm. Glial microtubules were not altered. Loss of distinct microtubules was most apparent with antibodies specific for the tyrosine (dynamic) form of α -tubulin (YL1/2, Serotec; TUB1A2, Sigma). NMDA-induced varicosity formation, and loss of microtubule labeling, were blocked by pretreatment with the microtubule-stabilizing drug, taxol. Rapid disruption of dendritic microtubules may underlie early alterations in neuronal structure in cerebral ischemia, and may permit lasting changes in neuronal signaling after prolonged synaptic activation.

EFFECT OF ACIDIC pH ON EXCITATORY AMINO ACID-STIMULATED PHOSPHATIDYLINOSITOL METABOLISM IN NEURONS. D.L. Yourick* and M.A. DeCoster. Dept. Med. Neurosci., Walter Reed Army Inst. Res., Washington, DC 20307-5100.

During hypoxic brain injury, extracellular pH may drop to as low as 6.4. Most studies to date evaluating neuroprotection do so at physiological pH, 7.4. Little is understood about the role of [H⁺] on promotion/reduction of neuronal death itself. The role of excitatory amino acid (EAA)-induced phosphatidylinositol (PI) metabolism in neuronal injury is yet to be established, but, at least in young animals, agonists that specifically stimulate the metabotropic receptor can cause neuronal injury. In the present study, we investigated the effect of reduced or acidic pH on basal and EAA-stimulated PI metabolism in neuronal cultures. Basal and glutamate-stimulated PI metabolism were decreased at all concentrations tested (10-100 μ M), with maximal inhibition detected at 100 μ M, when pH was reduced from 7.4 to 6.4. Considering the multiple EAA receptor types at which glutamate acts, we expanded these studies to include the EAA receptor agonists NMDA and trans-ACPD, as well as the non-EAA receptor agonists norepinephrine and carbachol to stimulate PI metabolism. The rank ordered potencies of agonists stimulating PI metabolism (pH 7.4) were: glutamate = trans-ACPD > norepinephrine = carbachol >> NMDA. While decreasing the pH to 6.4 reduced both 100 μ M glutamate and trans-ACPD stimulation by approximately 25%, stimulation by NMDA was reduced by 77%. Preliminary results indicate that PI metabolism at pH 6.4 is slightly reduced for the non-EAA agonist norepinephrine while unaffected for carbachol. Our results indicate that PI metabolism, via direct (trans-ACPD) or indirect (NMDA) metabotropic receptor activation, is decreased by acidosis and are consistent with the known effects of pH on NMDA receptor function. Acidic pH effects on multiple EAA receptor types may be beneficial to neuronal outcome subsequent to CNS trauma.

Cyclic-AMP ANALOGUES PRODUCE EXCITOTOXICITY. J.W. McDonald* and D.D. Schoepp. Dept. Neurology, Washington Univ. Sch. Med., St. Louis, MO 63108 and Lilly Res. Labs, Indianapolis, IN 46285.

The pathologic role of cAMP in excitotoxic brain injury was assessed in a perinatal rat model. Stereotaxic intrastratial injections of 8-bromo-cAMP or dibutyryl-cAMP (600-1200 nmol, 0.5 μ l), but not cGMP analogues or vehicle, produced dose-dependent seizures and brain injury in PND 7 rats. The severity of brain injury was assessed histologically and by hemispheric weight disparities 5 days following injection (McDonald et al., 1989). Co-treatment with the NMDA antagonist MK-801 (2.5 mg/kg i.p.) abolished cAMP induced seizures and injury. Intrastratial injections of cAMP in adult rats (600 nmol) produced "wet dog shake" like limbic seizures and a pattern of local and distant injury that was prevented by MK-801 (2.5 mg/kg, i.p.). Co-injection of cAMP (600 nmol) selectively potentiated 1S,3R-ACPD (1000 nmol), but not NMDA (2 nmol) or AMPA (2 nmol) induced injury in PND 7 rats [%damage, mean \pm SEM (unpaired t-test, n=8/group)], cAMP 0.7 \pm 0.4%, 1S,3R-ACPD 2.0 \pm 0.5% vs cAMP+1S,3R-ACPD 5.4 \pm 0.4% (p<0.001), NMDA 1.1 \pm 0.3% vs cAMP+NMDA 1.9 \pm 0.4% (ns), AMPA 0.8 \pm 0.4% vs cAMP+AMPA 2.0 \pm 0.3% (ns)]. The results suggest that activation of the cAMP cascade may selectively potentiate metabotropic mediated brain injury and that cAMP injury is blocked by NMDA antagonists.

EXCITOTOXIC INTERACTION BETWEEN ACPD AND NMDA AFTER INTRAHIPPOCAMPAL ADMINISTRATION. I.P. Kesslak*, A. Theis, C.W. Cotman. Departments of Neurology, Psychobiology and I.R.U. in Brain Aging, University of California, Irvine, CA 92717.

Glutamate activates two broad categories of receptor subtypes, ionotropic (i.e., selective agonists AMPA, Kainate, or NMDA) and metabotropic (mGluRs). Maintaining the balance between plasticity and pathology may involve receptor subtype interactions. Trans-aminocyclopentane-1,3-dicarboxylic acid (ACPD), a selective mGluR agonist, can attenuate NMDA neurotoxicity (Koh et al., 1991) in cortical cultures. Although other neuroprotective actions of ACPD have been subsequently demonstrated both *in vitro* and *in vivo*, recent studies indicate neuropathological effects of mGluR activation with fairly high doses of ACPD. In the present study we examine the interaction between NMDA and ACPD to determine *in vivo* the neuroprotective or neuropathological effects of mGluR activation.

Fifteen adult male Sprague Dawley rats received intrahippocampal injections of 10 mM ACPD+100 mM NMDA, and in the contralateral side 10 mM ACPD or 100 mM NMDA. At 14 days after the injections, ACPD resulted in minor damage in the dorsal blade of the dentate gyrus, NMDA alone did not produce significant neural damage. The combination of ACPD and NMDA produced significant damage to CA3 and also involved the ventral blade of the dentate. Excitotoxic actions of the ACPD+NMDA may indirectly modify uptake or directly effect receptors. The potential neuroprotective and toxic activity of mGluRs may be an important factor in normal CNS development, disease related pathology and provide insights into the development of therapeutic interventions.

NMDA TOXICITY IN DEVELOPING CEREBELLAR GRANULE CELLS MEDIATED BY A MAGNESIUM-INSENSITIVE NMDA RECEPTOR. Y. Xia*, K.N. Kumar, R. Ragan, M. Michaelis, and E. Michaelis, Pharmacol. & Toxicol. Dept., Univ. of Kansas, Lawrence, KS. NMDA receptors play an important role in glutamate-induced neurotoxicity and are related to neurodegenerative diseases. Cerebellar granule cells in culture were used as a model system to study the NMDA-mediated neurotoxicity. Rat cerebellar granule cells were grown under depolarizing conditions (25 mM KCl) and the medium was not changed except for the addition of dH₂O to compensate for evaporation. Cells were treated with NMDA that was directly added to the culture medium in the presence of 0.8 mM Mg⁺⁺. Cell death was monitored by both the LDH and the MTT assay. The dose response curve of NMDA-induced toxicity showed that the toxicity was increased through DIV 8 to DIV 14. This increased toxicity corresponded to the increased expression of the 63-70 kDa glutamate-binding protein as determined by Western blots. The NMDA (100 μ M)-induced toxicity at DIV 14 was blocked by AP-5 (500 μ M) and MK801 (10 μ M) and it was not sensitive to CNQX (25 μ M). This indicates that the NMDA-induced neurotoxicity is mediated by NMDA receptors rather than non-NMDA receptors which might have been activated as a result of NMDA-induced glutamate release. The NMDA-activated increase in [Ca⁺⁺]_i measured by Fura-2 in the condition favoring the Mg⁺⁺-sensitive NMDA receptors (5 mM KCl, 10 μ M glycine, and Mg⁺⁺-free) did not show the developmental increase through DIV 5 to DIV 14 and did not correspond to the developmental pattern of NMDA-induced toxicity. These results may suggest a distinct role of Mg⁺⁺-insensitive NMDA receptors in NMDA toxicity of cerebellar granule cells. [Supported by a Marion Merrell Dow Fellowship and a Grant].

REDUCTION OF NMDA-INDUCED EXCITOTOXICITY IN CEREBELLAR GRANULE CELL CULTURES BY ANTISENSE OLIGONUCLEOTIDES FOR NMDA ϵ SUBUNITS. M. Didier*, S.A. Berman, and S. Bursztajn, Lab. for Molecular Neuroscience, McLean Hosp/Harvard Med. Sch. Belmont, MA 02178.

The recent molecular cloning of several NMDA ϵ subunits demonstrated the heterogeneity of NMDA receptor localizations and properties in the central nervous system. Using antisense oligonucleotides (AONs), we investigated the involvement of the NMDA ϵ 1 and the four NMDA ϵ s subunits in the formation of NMDA receptors which mediate excitotoxicity. Cerebellar granule cells displayed mRNAs for these subunits after 10 days in culture as revealed by RT-PCR. Preliminary experiments showed that a maximum amount of stable AONs was incorporated inside the cells 24-36 hr after their addition to the culture medium. Treatment of neuronal cultures with NMDA ϵ 1 AONs decreased dramatically the level of NMDA ϵ 1 protein and reduced by 60% NMDA-induced excitotoxicity. We found that AONs but not sense AONs, for NMDA ϵ s 1-2 and 3 protected also neurons from NMDA excitotoxicity when 40 to 60% of cells were damaged by NMDA. However, only AONs for NMDA ϵ s 1 and 3 displayed some protective effect when the NMDA-dependent neuronal death exceeded 70%. AONs against NMDA ϵ s 4 were much less efficient in rescuing neuronal cells whatever the level of excitotoxicity. The protective effects obtained with AONs for NMDA receptor subunits were not additive. The reduction of neuronal cell death after AON treatments was correlated with a decrease in the NMDA-stimulated calcium influx. Finally, NMDA AON treatment did not affect the toxicity induced either by activation of AMPA glutamate receptors or by MPP⁺. These results suggest that AONs for NMDA ϵ s subunits can be used to knock out the pathological roles of specific NMDA receptor subpopulations in neuronal cells.

TOXIC DOPAMINE-GLUTAMATE INTERACTIONS IN CULTURED NEURONS: EVIDENCE FOR OXIDATIVE STRESS. K.R. Hoyt*, J.J. Reynolds and T.G. Hastings, Depts. of Pharmacology and Neuroscience, Univ. of Pittsburgh, Pittsburgh, PA 15261.

Dopamine (DA) and glutamate (Glu) are neurotransmitters important for normal brain function. However, these neurotransmitters can cause neuronal damage when their extracellular concentrations are elevated, in pathological conditions such as cerebral ischemia and methamphetamine toxicity, and possibly in neurodegenerative conditions such as Parkinson's disease. We have found, using the fluorescent dyes CMFDA and monochlorobimane to measure intracellular glutathione, and dichlorofluorescein to measure intracellular oxidation, evidence for DA and Glu-induced oxidative stress. We also investigated the interaction between DA and Glu on cell death in cortical neurons cultured for 14-17 days. We used concentrations and exposure times of DA and Glu that were themselves not toxic, and we found in that combination they caused a significant loss of cell viability measured by retention of calcein-AM. Cells treated with 250 μ M DA for 2 h or cells treated with 100 μ M Glu/1 μ M glycine for 5 min showed 4% loss of viability compared to untreated controls, when measured 6 h after treatment. When these two treatments were combined, there was a 30% loss of viability ($p < 0.05$). In another experiment, 100 μ M DA for 1 h or 100 μ M Glu/1 μ M glycine for 2 min resulted in a 4% loss of viability when measured 20 h after treatment. Combining these two treatments resulted in a 36% loss of viability ($p < 0.05$). We are currently investigating the mechanisms underlying these toxic interactions. Supported by MH18273 and MH45156.

ASSESSMENT OF MEMANTINE AS A NEUROPROTECTIVE DRUG IN RATS POISONED WITH SOMAN. S.S. Deshpande, C.D. Smith, J.S. Forster, S. Phann, R.E. Sheridan* and M.G. Filbert, Neurotoxicology Branch, Pathophysiology Division, USAMRICD, APG, MD 21010-5425.

Memantine a potent noncompetitive antagonist at N-methyl D-aspartate activated receptor channels (Eu. J. Pharmacol., 166, 591, 1989) and has been shown to protect embryonic cortical neurones against glutamate-induced cell death (Eu. J. Pharmacol., 198, 215, 1991). Pretreatment of rats with memantine also has been shown to prevent seizures after soman (an irreversible cholinesterase inhibitor) injection (Toxicol. Appl. Pharmacol., 112, 95, 1992). The purpose of this study was to examine efficacy of memantine as a pretreatment drug in protecting rats from seizure-induced neuronal damage after soman. Adult male Sprague Dawley rats received pyridostigmine (0.13 mg/kg i.m.) and atropine methyl nitrate (5 mg/kg s.c.) 30 and 5 min respectively before a single injection of soman (0.1 mg/kg s.c. equivalent to a 0.9 LD₅₀ dose). Memantine (18 mg/kg s.c.) was administered 60 min prior to soman. At 24 hr rats were anesthetized with sodium pentobarbital (65 mg/kg i.p.) and transcardially perfused with buffered 10% formalin. Neuropathology of various areas of brain was examined in H&E stained coronal sections. Approximately 64% of rats receiving soman alone showed severe seizure activity and died within 24 hr. Pretreatment of rats with memantine reduced the severity of seizures and provided 100% protection from lethality. The brains of surviving rats in soman alone group showed necrotic lesions in frontal cortex, piriform cortex and hippocampus. Although memantine reduced the intensity of seizures in 66% of the pretreated rats, the drug could not protect the rats from seizure-induced neuronal degeneration in the brain areas described above. It is likely that repeated administration of memantine is needed to maintain the blockade of channels activated by excitatory amino acids in soman poisoning.

MITOCHONDRIA SEQUESTER NMDA RECEPTOR-MEDIATED CA²⁺ LOADS. G.J. Wang*, S.A. Thayer, Dept. of Pharmacology, University of Minnesota Medical School, Minneapolis, MN 55455.

Glutamate induces an intracellular acidification in cultured hippocampal neurons that results from sequestration of NMDA receptor-mediated Ca²⁺ loads by mitochondria with subsequent acceleration of cellular metabolism. Consistent with this hypothesis, pretreatment of hippocampal neurons with the mitochondrial uncoupling agent FCCP (1 μ M, 5 min), significantly increased the amplitude of glutamate-induced [Ca²⁺]_i transients as measured by indo-1 based microfluorimetry. Removal of extracellular Na⁺ (Na_o⁺) for 20 min prior to exposure to NMDA (200 μ M, 3 min), presumably reducing intracellular Na⁺ (Na_i⁺), revealed a prolonged plateau phase in the recovery of the [Ca²⁺]_i transient which resembled the mitochondrion-mediated [Ca²⁺]_i plateau previously observed in sensory neurons. Mitochondria release Ca²⁺ via Na⁺/Ca²⁺ exchange; thus, a reduction in Na_i⁺ will slow Ca²⁺ extrusion across the inner membrane consequently increasing the retention of [Ca²⁺]_i within mitochondria. Readdition of Na_o⁺ during recovery of NMDA-induced [Ca²⁺]_i transients increased the height and shortened the duration of the plateau phase. Application of FCCP during the plateau elicited a large [Ca²⁺]_i increase in the absence of extracellular Ca²⁺. When Na⁺ was maintained throughout the experiment the recovery lacked a plateau phase and FCCP failed to increase [Ca²⁺]_i. These data indicate that mitochondria sequester NMDA receptor-mediated Ca²⁺ loads and that an accompanying Na⁺ load will have profound effects on the accumulation and retention of Ca²⁺ by mitochondria.

628.12

STUDIES ON THE ROLE OF MITOCHONDRIA IN NMDA RECEPTOR-MEDIATED EXCITOTOXICITY. J.J. Reynolds*, T.G. Hastings and K.R. Hoyt, Depts Pharmacol. and Neurosci., U. Pittsburgh, Pittsburgh PA 15261.

The intracellular events that link intense NMDA receptor activation to neuronal death are not clear, although Ca²⁺ influx is essential. This series of studies in neurons cultured from fetal rat forebrain sought to identify cellular events that are correlated with neuronal death in order to characterize the lethal stimulus.

We recently reported that the fluorescent dye, 2',7'-dichlorodihydrofluorescein can be used to monitor the production of reactive oxygen species (ROS) induced by glutamate (Soc. Neuro. 19:1350, 1993). This process requires NMDA receptor activation and Ca²⁺ entry. As mitochondria are an important source of ROS we investigated a possible role for this organelle using the mitochondrial proton ionophore FCCP. FCCP (5 μ M) completely blocked glutamate (100 μ M)-induced ROS generation. As FCCP potentiates glutamate-induced [Ca²⁺]_i, changes these results suggest that elevation of [Ca²⁺]_i may not be sufficient for ROS production, and are consistent with the hypothesis that Ca²⁺ uptake by mitochondria may be the critical event that ultimately results in oxidative stress.

We also monitored the effects of glutamate receptor activation on mitochondrial membrane potential using rhodamine 123 (R123). Addition of FCCP (5 μ M) rapidly and completely disrupts the characteristic punctate staining normally seen with R123 using confocal microscopy. The addition of glutamate (100 μ M) also altered R123 staining, although to a lesser degree than FCCP. This effect was mimicked by NMDA (500 μ M) but not kainate (100 μ M). The effect of glutamate was also dependent on Ca²⁺ entry, but was not reduced by Na⁺ removal.

These studies suggest that neurotoxic stimulation of NMDA receptors results in an alteration of mitochondrial function which may contribute to cell death.

628.13

GLUTAMATERGIC RECEPTOR ACTIVATION AND EXCITATORY AMINO ACID RELEASE IN METABOLIC INHIBITION. G.S. Neal, W.J. Nicklas and G. D. Zeevalk. Dept. of Neurology, UMDNJ-Robert Wood Johnson Med. Sch., Piscataway, NJ 08854.

It has been suggested that ischemia-induced CNS damage is mediated by prolonged activation of glutamatergic receptors (excitotoxicity) which may result in whole or in part from increased extracellular glutamate ($_{\text{e}}\text{GLU}$). In these studies transverse hippocampal slices from male rats were used to investigate the effects of chemically-induced hypoglycemia (IOA-iodoacetate) or hypoxia (KCN) on temporal GLU release and associated neuronal damage mediated by glutamatergic receptor (GluR) activation. Treatment with either drug for 30 min increased extracellular aspartate (ASP) and GLU and produced lesions in the CA1, CA3, CA4 and dentate gyrus (DG) regions which were attenuated by NMDA and non-NMDA antagonists. A more severe lesion was observed in slices treated for 30 min with both IOA and KCN; this was completely attenuated by combining non-NMDA and NMDA antagonists. To investigate the temporal release of GLU and activation of GluRs, slices were treated with KCN for 2.5 to 30 min. Within 2.5 min discrete CA1 neuronal swelling was seen which coincided with decreases in tissue ATP levels. These CA1 lesions were not accompanied by increases in extracellular GLU or ASP but were completely prevented by NMDA antagonists. Within 10 min there were increases in $_{\text{e}}\text{GLU}$ which coincided with extensive lesions in the CA1, CA4 and DG. Within 20 min, all regions of the hippocampus appeared severely damaged and $_{\text{e}}\text{GLU}$ was twice that of control slices. This data supports our previous studies which suggested that excitotoxicity associated with mild metabolic stress was caused by changes in the physiological state of the NMDA receptor following compromise of energy stores rather than by increased extracellular GLU or ASP. More prolonged or more severe metabolic inhibition precipitates involvement of nonNMDA receptors perhaps mediated by increased $_{\text{e}}\text{GLU}$.

NEUROPROTECTIVE EFFECTS OF SIGMA LIGANDS: INDEPENDENCE FROM PCP-RECEPTOR RELATED NMDA RECEPTOR ANTAGONISM. J.B. Long*, D.L. Yourick, M.A. DeCoster, and M.L. Koenig. Dept. of Med. Neurosci., Div. of Neuropsych., Walter Reed Army Inst. of Res., Wash., D.C. 20307.

Several σ ligands have been shown to protect against neuronal ischemic injury in vivo. We have used primary cultures of rat spinal cord neurons to evaluate the protective effects of a variety of selective σ ligands in comparison with PCP-related noncompetitive NMDA receptor antagonists during either hypoxia or brief exposure to excitotoxic (100 μM) concentrations of NMDA or kainic acid (KA). In addition, the effects of these compounds on NMDA-induced changes in intraneuronal calcium concentration ($[\text{Ca}^{2+}]_i$) and phosphatidylinositol (PI) metabolism were compared. After 8-10 days in culture, neurons were subjected to hypoxia or brief excitatory amino acid exposure in Locke's solution from which MgCl_2 and glucose were omitted. Cell damage was quantitatively assessed on the following day using a tetrazolium salt colorimetric assay. NMDA-induced changes in $[\text{Ca}^{2+}]_i$ were measured in single identified neurons (5-20/150 μm^2 field) preloaded with the Ca^{2+} -sensitive dye indo-1 using an ACAS 570C laser cytometer. The PCP receptor ligands MK-801, dextrorphan, and ketamine, and a variety of σ ligands, including DTG, (+)-pentazocine, and caramiphen, caused significant, dose-dependent protection against hypoxia and NMDA- but not KA-induced cell injury. In contrast to the PCP receptor ligands, at neuroprotective concentrations the σ ligands failed to antagonize the sustained elevations in $[\text{Ca}^{2+}]_i$ elicited by NMDA and failed to consistently alter NMDA-stimulated PI hydrolysis (200-300% above control). These results indicate that, through mechanisms distinguishable from PCP-receptor related antagonism of the NMDA receptor, σ ligands provide an effective means of preventing excitotoxic neuronal injury.

ARACHIDONIC ACID METABOLITES INDUCE HSP70 IN CINGULATE CORTEX IN MK801 TOXICITY. J. Chen, J. Q. Lan, F. R. Sharp, S. H. Graham*. Neurology, VAMC and University of California, San Francisco.

NMDA antagonists such as MK801 and phencyclidine injure a discrete populations of neurons in the cingulate and retrosplenial cortex. These agents produce cytoplasmic vacuoles and induce production of the stress protein HSP70. Cyclopentane arachidonic acid (AA) metabolites such as P gA_2 and hepxolin A2 have been proposed to be intracellular messengers that induce HSP70 expression in tumor cells. Accordingly, we hypothesized that arachidonic acid metabolites may signal HSP70 expression due to MK801 toxicity. MK801 1mg/kg was injected i.p. in awake rats. HSP70 mRNA transcription was studied using in situ hybridization with 35-S-oligonucleotides at 8 hrs. HSP70 protein expression was studied by immunocytochemistry at 24hrs after MK801 injection. The cyclooxygenase (COX) inhibitor indomethacin, the mixed COX/lipoxygenase inhibitor BW755C and the phospholipase inhibitor mepacrine all inhibited both HSP70 mRNA and protein expression in a dose dependent manner at 5, 10, 20, 30 and 50mg/kg i.p. given 15 min prior to MK801 injection. Furthermore, the mRNA encoding the mitogen inducible cyclooxygenase (COXII) was induced in cingulate and retrosplenial cortex in regions where HSP70 was also expressed 4 hrs after MK801 injection. These data support a role for AA metabolites in the expression of HSP70 in MK801 toxicity. Further experiments will be required to determine if AA metabolism inhibitors block MK801-induced neuronal injury or if their effects are limited to HSP70 induction.

628.14

OPEN-CHANNEL BLOCKADE OF NMDA-ACTIVATED WHOLE-CELL CURRENTS BY 9-AMINOACRIDINES. M.E. Nelson*, R.F. Bullitt*, and E.X. Albuquerque^{1,2}. ¹Dept. Pharmacol. Exp. Ther., Univ. Maryland Sch. Med., Baltimore, MD, USA 21201; ²Lab. Mol. Pharmacol. II, IBCCF, UFRJ, Rio de Janeiro, RJ, Brazil 21944.

In previous studies using the single-channel patch-clamp technique we have demonstrated that the bis-9-aminoacridines are potent open-channel blockers of NMDA-activated currents in cultured rat hippocampal neurons (Nelson and Albuquerque, *Mol. Pharmacol.*, in press). Based on the acridine-induced reduction in single-channel open times at -80 mV, the forward blocking rate constants were found to be $1.1 \times 10^9 \text{ M}^{-1} \text{ s}^{-1}$ and $1.4 \times 10^9 \text{ M}^{-1} \text{ s}^{-1}$ for 1,2-propene-bis-9,9'-aminoacridine (1,2-PAA) and 1,4-butane-9,9'-aminoacridine (1,4-BAA), respectively, compared to $3.5 \times 10^7 \text{ M}^{-1} \text{ s}^{-1}$ for 1,2,3,4-tetrahydro-9-aminoacridine (THA). However, the affinities of the bis-acridines could not be easily quantitated from the single channel data because the blocked state produced by these compounds was long in duration (in the range of 200 ms) and similar to normal channel closed times. To circumvent this problem, experiments using whole-cell patch-clamp were performed with a motorized, multi-barrel, fast perfusion system to study the unbinding kinetics of these compounds. In nominally Mg^{2+} -free solutions, the recovery from blockade by THA indicated that the dissociation was from a single blocked state ($\tau_{\text{recovery}} = 48.7 \pm 0.9 \text{ ms}$, $n=3$), but the single-channel experiments clearly showed that a much briefer THA-blocked state (duration $< 200 \mu\text{s}$) exists that would not be detected by this means of drug application in the whole-cell experiments. The recoveries from blockade by the bis-acridines, on the other hand, were slower and were normally best described by a single-exponential function having time constants (τ_{recovery}) of $217.6 \pm 14.7 \text{ ms}$ ($n=5$), and $167.1 \pm 8.9 \text{ ms}$ ($n=11$) for 1,2-PAA and 1,4-BAA, respectively. The single-channel studies mentioned above also revealed that the interaction of the 9-aminoacridines with the channel of the receptor were at a site that is different from the Mg^{2+} binding site of the channel and suggested that the channel could be simultaneously occupied by Mg^{2+} and the 9-aminoacridines. This simultaneous occupation likely modifies the affinity of the receptor for the 9-aminoacridines. Indeed, preliminary results in the presence of $100 \mu\text{M} \text{Mg}^{2+}$ showed that the rates of association and dissociation of 1,2-PAA were increased. Support: USPHS Grant ES 05730.

INTERACTION OF (\pm) β -METHYL- α , β -DIAMINOPROPIONIC ACID (BMAA) WITH THE STRYCHNINE-INSENSITIVE GLYCINE SITE ON THE NMDA RECEPTOR. I. OMELCHENKO AND C. N. ALLEN*. Cntr. Res. Occup. Environ. Toxicol., Ore. Hlth. Sci. Univ., Portland, OR. 97201.

BMAA is a neurotoxic monocarboxylic amino acid which in the presence of bicarbonate is an agonist at non-NMDA-type receptors. However, BMAA has also been reported have actions mediated by NMDA-type receptors. We used whole cell voltage clamp techniques on cultured hippocampal neurons to determine whether of BMAA was an agonist at the strychnine-insensitive glycine receptor. Neither L-BMAA or (\pm)BMAA in the presence of extracellular calcium produced membrane currents. (\pm)BMAA ($\text{EC}_{50} = 300 \mu\text{M}$) but not L-BMAA coapplied with NMDA produced a reversible potentiation of the NMDA (50 μM) activated currents. Currents activated by a combination of NMDA and (\pm)BMAA showed desensitization in a majority of neurons. (\pm)BMAA increased the amplitude of NMDA-activated currents but did not change their voltage dependence. The potentiation of NMDA currents by (\pm)BMAA and glycine were antagonized by 7-chlorokynurenic acid. Concentration jump experiments were performed to determine the kinetics of the unbinding of the BMAA. The time course of BMAA unbinding was $350 \pm 60 \text{ ms}$ while that of glycine was $940 \pm 100 \text{ ms}$ suggesting that the BMAA binds with a lower affinity than glycine to the strychnine-insensitive glycine site. These data suggest that (+)BMAA is capable of binding to the strychnine insensitive glycine binding site and acting as a coagonist with NMDA to activate the NMDA receptor. This work was supported by NS 19611.

NEURON NECROTIZING PROPERTIES OF PHENCYCLIDINE. J.D. Corso*, DE Wozniak, MA Sesma and JW Olney. Washington Univ., St. Louis MO. 63110.

Antagonists of NMDA glutamate receptors, including phencyclidine (PCP) and MK-801, acutely injure neurons and induce expression of 72 Kd heat shock protein (HSP) in the posterior cingulate/retrosplenial (PC/RS) cortices when administered sc or ip to adult rats. Sharp et al. reported that a high dose of PCP (50 mg/kg ip) causes a robust HSP response not only in PC/RS neurons but in many additional neurons in several neocortical and limbic brain regions. They proposed that HSP serves a protective function and that the robustness with which an injured neuron expresses HSP may be a measure of its ability to survive the injury. Thus, the widespread injury induced by high-dose PCP may be entirely reversible. In contrast, it is known that a high dose of MK-801 (5 mg/kg ip) kills PC/RS neurons. Silver stains have been used to detect neuronal injury induced by PCP or MK-801, but it is not known what silver staining of neurons signifies regarding cell injury vs cell death. To address these questions we treated adult female rats with a single high dose of PCP (50 mg/kg ip) and examined the brains at various posttreatment intervals (4 hrs to 4 days) using H&E paraffin, de Olmos silver or HSP immunocytochemical methods. We found that high dose PCP induced HSP in PC/RS neurons in layers II to V and that it killed many neurons distributed in these same layers. Occasionally, but not consistently, it induced HSP and killed neurons in other neocortical and limbic brain regions. Our findings help to validate the de Olmos silver stain for studying PCP-induced neuronal necrosis in that in each brain only those neuronal populations showing definite signs of necrosis (intense eosinophilia) in H&E sections were impregnated by the de Olmos stain. Moreover, the de Olmos stain may be a selective marker of cell death in that PC/RS neurons did not become argyrophilic until approximately 36 hrs after PCP treatment, but PCP is well known to physically injure neurons at a much earlier interval (4-12 hrs). Our findings do not confirm the view that HSP expression by PCP-injured neurons signifies recoverability. Supported by AA 07466, AG 05681, DA 05072 and RSA MH 38894 (JWO).

RATS BECOME HYPOSENSITIVE TO MK-801 NEUROTOXICITY DURING PREGNANCY. NB Farber* and JW Olney Washington Univ., St. Louis MO, 63110.

Antagonists of NMDA glutamate receptors, including phencyclidine (PCP) and MK-801, cause vacuolar injury (low dose) or kill (high dose) neurons in the posterior cingulate/retrosplenial (PC/RS) cortices when administered sc or ip to adult rats. Non-pregnant female rats are substantially more sensitive than male rats to this neurotoxic action. We now report that female rats become hyposensitive to NMDA antagonist neurotoxicity (NAN) during pregnancy. A high dose of MK-801 (5 mg/kg sc) in E17-E19 pregnant dams (n = 4) induced a vacuole reaction affecting 88.75 ± 25.8 (SEM) neurons per section compared to 212.2 ± 18.9 (SEM) neurons per section for control non-pregnant females (n = 6). A similar phenomenon was witnessed for PCP (30 mg/kg sc), which caused 125 vacuolated neurons per section in a E18 pregnant dam compared to 268.5 ± 32.5 (SEM) neurons per section in control non-pregnant female rats (n = 2). This hyposensitivity extended into the early postpartum period in that a low dose of MK-801 (0.2 mg/kg sc) induced a vacuole reaction in 17.3 ± 15.8 (SEM) neurons per section in rats (n = 3) within the first 2 days postpartum compared to 119.25 ± 23.8 (SEM) for non-pregnant non-postpartum female controls (n = 12) or 90 ± 36 (SEM) neurons per section in 7-10 day postpartum females (n = 4). Our findings suggest that during pregnancy, and in the immediate postpartum period, sensitivity to NAN is suppressed by some factor, presumably hormonal, that is peculiar to the peripartum state. Estrogen and progesterone and/or their metabolites are likely candidates in that: 1) Concentrations of these hormones rise during pregnancy and fall shortly thereafter. 2) These hormones or their metabolites interact with CNS GABA_A and sigma receptors both of which are critically involved in the mediation of NMDA antagonist neurotoxicity. TRACING THE CIRCUITRY THAT MEDIATES NMDA ANTAGONIST NEUROTOXICITY MT Price*, NB Farber, J Labruyere, J Foster, JW Olney Washington Univ., St. Louis MO 63110.

Antagonists of NMDA glutamate receptors, including phencyclidine (PCP) and MK-801, acutely injure (low dose) or kill (high dose) pyramidal neurons in the posterior cingulate/retrosplenial (PC/RS) cortices when administered systemically to adult rats. Our prior findings suggest that a polysynaptic circuit and at least 4 transmitter receptors (NMDA, muscarinic, GABAergic, sigma) mediate this reaction. However, it is not known where in the brain the various neural components of this circuit are located. To address this question, we administered MK-801 to adult female rats in a dose (0.5 mg/kg sc) that reliably induces a full cerebrocortical neurotoxic reaction and injected various agents into the PC/RS cortex or other brain regions in an attempt to interrupt the circuit and block the PC/RS reaction. We found that the neurotoxic reaction could be prevented ipsilaterally by unilateral injection of muscimol (GABA agonist), scopolamine (muscarinic antagonist) or rimcazole (sigma antagonist) into the PC/RS cortex, or by injecting muscimol into the diagonal band (DB) region of the basal forebrain, or into the anterodorsal/anteroventral (AD/AV) nucleus of the thalamus. Our interpretation is as follows: systemic administration of MK-801 blocks NMDA receptors that tonically drive GABA inhibitory neurons in at least three separate brain regions (PC/RS, DB, AD/AV). This results in a complex disinhibition syndrome in which: 1) DB neurons release excessive ACh at muscarinic receptors on PC/RS neurons. 2) AD/AV neurons release excessive glutamate at non-NMDA receptors on PC/RS neurons. 3) local PC/RS interneurons release an endogenous agent that modulates a sigma site in PC/RS cortex. We postulate that the proximal mechanism causing PC/RS neuronal injury is simultaneous excess release of 3 endogenous transmitters/modulators from separate pathways that convergently innervate these neurons. EXCITATORY AMINO ACIDS: EXCITOTOXICITY AND NON-NMDA RECEPTORS

629.1

KAINATE FAILS TO EVOKE MITOCHONDRIAL OXYGEN RADICAL GENERATION IN A SUBPOPULATION OF CORTICAL NEURONS SELECTIVELY VULNERABLE TO AMPA/KAINATE TOXICITY. L.M.T. Canzoniero*, S.L. Sensi, L.L. Dugan, D.M. Turetsky and D.W. Choi, Dept. of Neurology and Center for the Study of Nervous System Injury, Washington Univ. School of Medicine, St. Louis, MO 63110.

We previously described a subpopulation of cortical neurons highly vulnerable to death induced by relatively brief AMPA or kainate exposure, identifiable by staining for kainate-stimulated cobalt uptake ("cobalt-positive cells"; Turetsky et al., Soc. Neurosci. Abstr. 18.81, 1992), a marker for cells expressing AMPA or kainate receptors linked to Ca²⁺ permeable channels. Elsewhere this meeting, we (Dugan et al.) report that toxic exposure to NMDA (but not kainate) elicits mitochondrial free radical production. We hypothesized that cobalt-positive cells might respond to kainate with mitochondrial oxygen radical production analogous to that produced by NMDA on most cortical neurons.

Cobalt-positive neurons were functionally identified by increased [Ca²⁺]_i (fura-2 videomicroscopy) in response to kainate in Na⁺-free medium. Mitochondrial production of oxygen radicals was detected with dihydrodihydroamine 123 (see Dugan et al.). Exposure to kainate (100 μM) for 30 min produced a marked increase in [Ca²⁺]_i in cobalt-positive cells, followed by death of >50% of the cells. The increase in [Ca²⁺]_i was comparable to that reached following neurotoxic exposure to NMDA (100 μM for 5 min) in the general neuronal population. However the same kainate exposure failed to stimulate mitochondrial oxygen radical production in cobalt-positive cells (n = 19). Failure to detect a rhodamine signal was not due to loss of the mitochondrial membrane potential as tetramethylrhodamine showed no loss of this potential in cobalt-positive cells. Present data suggest that the route of Ca²⁺ entry may be an important determinant of consequent mitochondrial oxygen radical production. Supported by NIH grants NS 30337 (DWC) and AG00599-01A1 (LLD).

629.2

IMAGING OF MITOCHONDRIAL OXYGEN RADICAL PRODUCTION IN CORTICAL NEURONS EXPOSED TO NMDA. L.L. Dugan*, S.L. Sensi, L.M.T. Canzoniero, M.P. Goldberg, S.D. Handran, S.M. Rothman and D.W. Choi, Dept. of Neurology and Center for the Study of Nervous System Injury, Washington Univ. School of Medicine, St. Louis, MO 63110.

Confocal microscopy was used to image oxygen radical generation by mitochondria in cortical neurons exposed to NMDA. The mitochondrion-specific, oxidation-sensitive dye, dihydrodihydroamine 123 (DHR; 5 μM) was added to murine cortical cell cultures for 30 min. A time- and dose-dependent increase in neuronal mitochondrial fluorescence was observed in response to toxic concentrations (50-300 μM) of NMDA. This signal, starting 3-5 min after onset of NMDA exposure, reflects oxygen radical-mediated oxidation of non-fluorescent DHR to its fluorescent derivative, rhodamine 123.

The signal was specific to NMDA in that 100 μM kainate (plus 10 μM MK-801), 50 mM potassium (plus 10 μM MK-801), 3 μM ionomycin, or 300 μM t-ACPD all failed to stimulate mitochondrial radical formation. Removal of calcium (plus 300 μM EGTA) abolished the NMDA-induced mitochondrial response. Inhibitors of mitochondrial electron transport, 10 μM rotenone or 1 μg/ml antimycin A, abolished the NMDA-stimulated mitochondrial production of radicals. An uncoupler of electron transport, FCCP (1-3 μM), mimicked the NMDA response, even in the presence of 10 μM MK-801 and 10 μM NBQX. We speculate that mitochondrial electron transport may be an important source of reactive oxygen species during excitotoxic activation of NMDA receptors (see also I. Reynolds et al., elsewhere this meeting), and that this oxygen radical generation may be due to an uncoupling of mitochondrial electron transport. Supported by NIH NS 30337 (DWC), AG0059901A1 (LLD), NS01543 (MPG).

HEK 293 CELLS EXPRESSING GLUR4 ARE VULNERABLE TO AMPA TOXICITY. D.M. Turetsky*, L.M.T. Canzoniero, S.L. Sensi, C.A. Csernansky and D.W. Choi, Dept. of Neurology and Center for the Study of Nervous System Injury, Washington Univ. School of Medicine, St. Louis, MO 63110.

Transfection of glutamate receptor subunits has been demonstrated to induce vulnerability to excitotoxicity in fibroblasts (Rogers and Heinemann, Soc. Neurosci. Abstr. 16: 544, 1990; Anegawa et al., Soc. Neurosci. Abstr. 19:1348; Bergold et al., PNAS 90:6165, 1993). We have developed a human embryonic kidney 293 cell line that is stably transfected with the AMPA receptor GLUR4, and have begun to characterize its responses to receptor stimulation. Immunocytochemistry using a polyclonal antibody to GluR4 revealed moderate levels of receptor expression in 80-90% of cells. Fura-2 microfluorimetry demonstrated that either AMPA (100 μM) or kainate (500 μM) could increase [Ca²⁺]_i approximately 2 fold over basal in this transfected line. Addition of 100 μM cyclothiazide, which blocks AMPA receptor desensitization, to the exposure medium increased the AMPA-induced elevation in [Ca²⁺]_i to about 10-fold; further increases could be achieved by raising the extracellular Ca²⁺ concentration from 1.8 mM to 10 mM.

Continuous exposure to 500 μM AMPA, 100 μM cyclothiazide, and 10 mM Ca²⁺ resulted in the death of 50-60% of transfected cells by 24 hrs, and about 90% of cells by 48 hrs. Death was dependent on AMPA concentration (30-1000 μM), and could be blocked by 50 μM NBQX. Death could also be induced by 24 hr exposure to 500 μM kainate, but not by 48 hr exposure to 500 μM NMDA. Supported by NIH grant NS 30337 (DWC).

SMI-32 ANTIBODY LABELS SUBSETS OF CORTICAL AND SPINAL CORD NEURONS WITH UNUSUAL, Ca²⁺-DEPENDENT VULNERABILITY TO KAINATE TOXICITY. S.J. Burke, S.G. Carriedo, R. Lamberia, H. Yin and J.H. Weiss*, Depts. of Neurology and Psychobiology, U.C. Irvine, Irvine CA 92717

SMI-32 is a monoclonal antibody (Sternberger-Meyer Immunocytochemicals) that recognizes non-phosphorylated neurofilament epitopes, and has been reported to label subsets of CNS neurons, including populations of pyramidal neurons that degenerate in Alzheimer's disease (J Comp Neurol 301:44). We found SMI-32 immunostaining to label small subsets (2-4%) of neurons in dissociated cultures of murine cortex and spinal cord. Cortical SMI-32 (+) neurons were larger than average, frequently multipolar and sometimes of pyramidal morphology. Double staining in cortex revealed the majority (75-90%) of SMI-32 (+) neurons to be immunoreactive for GABA. In spinal cord, SMI-32 labeled some small neurons, as well as a set of darkly staining neurons with features characteristic of motor neurons (large soma, extensive dendritic tree and frequently a prominent axon).

In both cortex and spinal cord, most SMI-32 (+) neurons appeared to be selectively damaged by a brief kainate exposure (100 μM, 10-40 min); removal of Ca²⁺ during the exposure significantly enhanced survival. Also, a large majority (> 80%) of both cortical and spinal cord SMI-32 (+) neurons were subject to kainate-activated cobalt uptake, a histochemical procedure that marks cells with Ca²⁺ permeable AMPA/kainate channels. While further studies are necessary to identify the full range of neurons identified by SMI-32 staining in intact brain and in culture, these results suggest that unusual vulnerability to Ca²⁺-dependent, AMPA/kainate receptor-mediated injury may be a feature of SMI-32(+) neurons in diverse CNS regions. If, as seems likely, certain cortical pyramidal neurons and spinal motor neurons are among those stained, these results could bear upon factors contributing to preferential degeneration of those neuronal populations in diseases like Alzheimer's disease and ALS. Supported by a grant from the Alzheimer's Assoc.

AMPA-INDUCED DELAYED NEURONAL INJURY IN THE HIPPOCAMPAL SLICE, WITH PROTECTION WITH POST-TREATMENT DNQX. K.L. Panizzon* and R.A. Wallis, Dept. of Neurology UCLA, Los Angeles, CA 90024 and Sepulveda VAMC, Sepulveda, CA 91343.

Prevention of delayed neuronal injury is a prime objective in the acute treatment of stroke and head trauma. To investigate potential non-NMDA excitotoxic mechanisms of delayed neuronal injury, we examined the effect of sub-lethal AMPA exposure upon CA1 neurons in hippocampal slices. In these studies, paired rat hippocampal slices taken from the same dissection were placed in recording chambers perfused with ACSF containing 2.4 mM Ca^{2+} , 1.3 mM Mg^{2+} and 4 mM glucose. One slice of each pair was exposed to 25 μM AMPA until disappearance of the orthodromic CA1 population spike (PS). In three paired trials, the AMPA exposure averaged 3.7 ± 0.9 mins. in duration. AMPA treated slices regained an average of $98\% \pm 2$ of their original orthodromic PS within a mean of 30 ± 0 min. After initial recovery, AMPA-treated slices maintained generally stable recordings for several hours and then abruptly collapsed. Control slices maintained PS significantly longer. A 3mV CA1 PS amplitude was used as the criterion for slice viability. AMPA treated slices maintained a PS of greater than 3 mV for an average of 6.3 ± 1.4 hrs while paired control slices maintained an PS greater than 3 mV for 16.5 ± 1.1 hrs. Post-AMPA treatment of 100 μM DNQX extended the duration of CA1 PS recordings from 7.7 ± 0.4 hrs to 18.6 ± 1.4 hrs. These findings suggest that activation of non-NMDA receptors can induce delayed neuronal dysfunction, and that protection from this injury can be afforded by DNQX treatment given after that receptor activation.

NON-NMDA RECEPTOR ANTAGONIST ACTIVITY AGAINST EXCITOTOXIC INJURY IN IMMATURE RAT BRAIN. W.H. Trescher* and M.V. Johnston. Kennedy Krieger Institute, Johns Hopkins Medical Institutions, Baltimore, MD 21205.

Antagonists of non-N-methyl-D-aspartate (NMDA) receptors have been shown to be protective against cerebral hypoxic-ischemic injury in the adult brain. Therefore, we investigated the non-NMDA receptor antagonist GYKI 52466, activity in two models of injury in the immature rat brain. In a model of cerebral hypoxic-ischemic injury, postnatal day (PND) 7 rats underwent a unilateral carotid ligation followed by 2 hours of hypoxia. In a model of selective excitatory amino acid (EAA)-induced injury, PND 7 rats received an intrahippocampal injections of specific EAA analogues. Damage was assessed one week after the injury. Intraperitoneal GYKI 52466 provided only minimal protection against injury in the model of cerebral hypoxic-ischemic injury in the immature rat brain. Against excitotoxic injury, GYKI 52466 failed to protect against AMPA- or kainate-induced injury to the hippocampus in the neonatal rat brain. In preliminary experiments, however, GYKI 52466 provided partial protection against NMDA-induced hippocampal injury. The data suggest that GYKI 52466 neuroprotection may be partially through an NMDA dependent mechanism.

L- α -AMINOADIPIC ACID-INDUCED ASTROGLIAL LESIONS ENHANCE GLUTAMATE EXCITOTOXICITY IN STRIATUM. M. Garcia-Osuna, C. Davolio & J.T. Greenamyre*. Dept of Neurology, University of Rochester, Rochester, NY, 14642

Excitotoxicity has been implicated in the pathogenesis of Huntington's disease (HD). There is reason to believe that normal astroglial function may be essential for resistance against glutamate (GLU) toxicity, but the role of astroglia in excitotoxicity *in vivo* has not been studied. The selective glial toxin, L- α -amino adipic acid (L-AAA), was used to ablate striatal astrocytes and the effect of this treatment on GLU excitotoxicity was examined. Rats received stereotaxic injections of buffer or L-AAA into striatum on day 1, and injections of GLU or buffer into the same site on day 2. On day 5, animals were killed and the brains were processed for histology. Rats that received buffer/glutamate injections had a lesion volume of 1.65 ± 0.40 mm³, and those injected with L-AAA/buffer had a lesion volume of 1.24 ± 0.08 mm³. In contrast, rats that received L-AAA/GLU had a lesion volume of 5.50 ± 0.47 mm³, which was significantly larger than the other treatments alone ($p < 0.0001$) or summed ($p < 0.002$). GLU toxicity was mediated by both NMDA and non-NMDA receptors: MK-801 reduced lesion volume by 43%, NBQX (a non-NMDA antagonist) by 71%, and MK-801 + NBQX by 87%. NBQX and NBQX + MK-801 provided significantly greater protection than MK-801 alone ($p < 0.05$), suggesting that most of the toxicity is mediated by non-NMDA receptors. The results suggest that astroglial cells protect against glutamate toxicity, which is particularly intriguing in light of reports of glial cell loss in HD. (Supported by an unrestricted grant-in-aid from Fisons Pharmaceuticals).

629.6

DOMOIC ACID ACTION ON HIPPOCAMPAL NEURONS OF THE NEONATAL RAT. D. Xi, T.B. Taylor, L. Matsuda* and J.S. Ramsdell. Marine Biotoxins Program, U.S. National Marine Fisheries Service and Marine Biomedical and Environmental Sciences, Medical University of South Carolina, Charleston, SC 29412.

Domoic acid (DOM) is a rigid analog of glutamate demonstrated to be an agonist on non-NMDA receptors. We previously determined that DOM given i.p. to mice induces the c-fos immediate response gene and causes degeneration in hippocampal CA1 and CA2 pyramidal cells. We have now investigated the acute effects of DOM on neonates, using rats aged postnatal (P) day 1, 5, & 10. DOM-induced behavioral changes include immobility and ataxia, repetitive scratching and finally generalized clonic or tonic/clonic seizures. P1-P5 rats were more sensitive than P10 ($\text{EC}_{50}=0.3$ vs 0.7 mg/kg). Scratching occurred within 20 min and seizures within 30 min at 0.2 mg/kg, twice as long at 0.1 mg/kg and did not occur at 0.02 mg/kg. We next localized the *in vivo* action of DOM to hippocampal pyramidal cells of CA2 and CA3 using c-Fos immunohistochemistry. Primary hippocampal cultures were then used to evaluate the ionic effects of DOM. 30 μM DOM elevated $[\text{Ca}^{2+}]_i$ and caused membrane depolarization measured using FURA-2 and bisoxinol. The NMDA antagonist AP-5 (100 μM) totally prevented DOM elevated $[\text{Ca}^{2+}]_i$ and depolarization. Pretreatment of P5 rats with 1 mg/kg AP-5 also prevented the induction of c-Fos by DOM, but failed to prevent DOM-induced symptoms. These results indicate that neonatal rats are highly sensitive to the toxic effects of DOM. The ionic and neuroexcitatory actions of DOM on pyramidal cells appear to require involvement of NMDA receptors, yet the behavioral changes appear to occur independently of the NMDA receptor subtype.

629.8

MELATONIN PROTECTS PRIMARY CULTURES OF CEREBELLAR GRANULE NEURONS FROM KAINATE BUT NOT FROM NMDA EXCITOTOXICITY. M. Gusella*, M. Lipariti, D. Milani, P. Giusti, and H. Manev*. Dept. Pharmacology, Univ. Padova, Italy¹; ASRI, Medical College of Pennsylvania, Pittsburgh, PA 15212²

We and others have shown that in primary neuronal cultures, neuroprotective agents which do not block glutamate receptors protect from excitotoxicity by selectively affecting mechanisms associated with either N-methyl-D-aspartate (NMDA) receptors or non-NMDA receptors (*Brain Res* 1993, 624: 331). Thus, non-NMDA, but not the NMDA, excitotoxicity can be attenuated with an analog of vitamin E, suggesting that free radical formation plays a role in the latter type of toxicity (*Brain Res* 1994, 639: 102). Recently, it was proposed that melatonin might be a potent endogenous hydroxyl radical scavenger (*Endocrine J* 1993, 1: 57). In addition, melatonin has been shown to protect neurons from photochemically induced oxidative stress (Manev et al., this meeting). In this study, we used 7-9-day-old primary cultures of rat cerebellar granule neurons. Cultures were exposed to kainate (30 min), glutamate (15 min), or NMDA (without magnesium; 60 min) and then returned to the culture-conditioned medium. Viability was measured with the MTT technique (*Neuropharmacology* 1990, 29: 1103) 16-18 hrs later. Co-treatment with melatonin (500 μM) protected neurons completely from the toxicity of kainate (up to 1 mM), and shifted the LD₅₀ for glutamate from 55 ± 2.6 to 97 ± 3.6 μM . It was ineffective in protecting from NMDA toxicity. When melatonin was added to cultures only before or after kainate treatment, there was no resultant protection from kainate toxicity. The neuroprotective effect of melatonin does not appear to be related to the direct action of melatonin on non-NMDA glutamate receptors. That is, the kainate-stimulated increase in free cytosolic calcium (measured at the single-cell level with a digital imaging fluorescent microscopy with fura-2) was not affected by melatonin; the binding of 3H-glutamate to rat cerebellar membranes was likewise not affected. Further studies are needed to evaluate the pharmacological relevance of the neuroprotective action of melatonin.

629.10

SYSTEMIC ADMINISTRATION OF KAINIC ACID SELECTIVELY DECREASES GLUCOCORTICOID RECEPTOR mRNA EXPRESSION IN THE DENTATE GYRUS OF THE RAT HIPPOCAMPUS.

D. O'Donnell*, S. Kar*, J.R. Seckl², and M.J. Meaney¹. ¹Develop. Neuroendo. Lab., Douglas Hosp. Res. Ctr.; McGill University, Montreal, Canada. ²Dept. Medicine, Western General Hosp., University of Edinburgh, Edinburgh, Scotland.

Kainic acid is a glutamate analogue which possesses potent excitotoxic properties. Systemic administration of kainic acid causes severe pyramidal neuron loss in the CA1 and CA3 cell fields, but with no apparent detrimental effects to the granule cells of the dentate gyrus. Glucocorticoids have been shown to exacerbate neuronal cell loss in excitatory amino acid mediated insults. The present study examined the effects kainic acid treatment on glucocorticoid receptor (GR) mRNA expression. Male Sprague Dawley rats were intraperitoneally administered kainic acid (12 mg/kg body weight) or vehicle (0.9% sodium chloride) and sacrificed 12 hours following the injection. Brains were snap-frozen and processed for *in situ* hybridization using a ³⁵S-labeled GR cRNA probe. Saline treated controls exhibited the classical hippocampal distribution pattern of GR mRNA expression. In contrast, animals injected with kainic acid showed a 30-35% decrease in GR mRNA levels in the dentate gyrus with no significant changes observed in either CA1 or CA3 regions. This selective decline in GR expression in the granule cells of the dentate gyrus may account for their sparing following exposure to an excitotoxin.

629.11

DOWN-REGULATION OF A CALCIUM-PERMEABLE NON-NMDA RECEPTOR BY KAINATE. S. Allcorn and P. Mobbs. Dept. of Physiology, University College London, Gower St., London, WC1E 6BT, England.

Kainate, a non-NMDA receptor agonist, acts as a potent neurotoxin in the adult retina. Consistent with this, acute exposure (12 hours) of primary cultures of chick embryonic day 8 retinal cells to 100 μ M kainate caused 59.6 \pm 0.3% of the cells to die when applied at 6 days *in vitro* (DIV). In contrast the number of cells in cultures grown in the presence of 10, 100 and 500 μ M kainate from 1 DIV did not differ significantly from those grown in the absence of kainate. This lack of effect of kainate on cell survival does not appear to result from receptor desensitization since whole-cell patch clamp recording showed that cells grown in the presence of kainate for 6 days continue to exhibit a current which is suppressed by the non-NMDA receptor antagonist CNQX. We have utilised the cobalt staining technique of Pruss et al. (1991, *Neuron* 7, 509) to determine the number of cells that express the calcium permeable form of the AMPA/kainate receptor in retinal cultures. We found that the number of cells expressing this receptor in control cultures rose from 5% at 2 DIV to a maximum of 50% at 5 DIV. However, in cultures grown in the presence of 10-500 μ M kainate the number of cells stained by cobalt was reduced by as much as 90% at 5 DIV. The effects of kainate on the expression of the receptor could be prevented by the addition of 20 μ M CNQX, but not by 20 μ M AP5 or 20 μ M diltiazem and nifedipine. When kainate was removed from the culture medium at 4 DIV the number of cells expressing the receptor at 7 DIV was restored to normal. A down-regulation of the Ca^{2+} -permeable non-NMDA receptor will decrease Ca^{2+} influx into the cells and this may account for their survival when grown in the presence of excitotoxic concentrations of kainate.

INTRINSIC OPTICAL SIGNALLING IN THE HIPPOCAMPAL SLICE EVOKED BY THE EXCITOTOXIN DOMOIC ACID. Trevor M. Polischuk* & R. David Andrew. Dept. of Anatomy & Cell Biology, Queen's Univ., Kingston, Ontario, K7L 3N6.

As cells swell, light transmittance increases across brain slices (Lipton, *J. Physiol.* 231, 365; Andrew and MacVicar, *Neuroscience* in press). Also, as shown by Adams and Andrew (this meeting), increases in light transmittance induced by glutamate agonists can be imaged in real time in the entire hippocampal slice. Here we studied the effects of the potent neurotoxin and glutamate analogue, domoic acid (DOM), in the rat hippocampal slice. We attempted to characterize 1) which hippocampal regions were affected, 2) which sub-class of receptors were involved, and 3) if cell swelling played a role in the response. A 1 min exposure of 10 μ M DOM (22°C) elevated light transmittance by up to 58% in the dendritic regions of CA1 and of upper dentate gyrus. The response slowly reversed during a 30 min wash ($n=10$). No significant changes were observed in the CA3 region nor in the lower blade of the dentate gyrus. The response to DOM was reversibly blocked by the non-NMDA receptor antagonist kynurenic acid (1 mM; $n=5$), CNQX (50 μ M; $n=5$) or DNQX (50 μ M; $n=7$) but not by the NMDA receptor antagonist AP-5 (50 μ M; $n=5$) nor the kainate receptor antagonist GAMS (100 μ M; $n=5$). Tetrodotoxin (1 μ M) blocked action potentials and the evoked CA1 population spike but light transmittance increases were maintained and therefore were not associated with neuronal discharge. Extracellular tissue resistance measured across CA1 stratum radiatum increased rapidly in response to DOM and slowly fell over 30 min, which paralleled the light transmittance response. We conclude that brief DOM exposure elicits a prolonged, post-synaptic swelling in the CA1 dendritic region primarily mediated by AMPA receptors. This imaging technique allows a real-time view of events preceding neuronal death and so may prove useful in assessing potentially therapeutic glutamate antagonists that combat excitotoxicity.

DELAYED ANTAGONISM OF AMPA/KAINATE RECEPTORS REDUCES LONG-TERM FUNCTIONAL DEFICITS RESULTING FROM SPINAL CORD TRAUMA. Jean R. Wrathall* and Yang Dong Teng, Neurobiology Division, Dept. of Cell Biology, Georgetown Univ., Washington, DC 20007.

Ionotropic glutamate receptors appear to play a significant role in secondary injury processes after spinal cord trauma. We previously reported that NBQX, a potent and highly selective antagonist of the AMPA/kainate subtypes of glutamate receptors, focally administered at 15 min after a standardized traumatic spinal cord injury (SCI), results in a dose-dependent increase in the speed of recovery and reduction in long-term hindlimb deficits. There was a correlated, dose-related, sparing of gray and white matter at the injury site, and increased serotonergic innervation below the level of the injury. We have now examined the effects of delaying administration of NBQX. A weight-drop device was used to produce a standardized incomplete thoracic SCI in rats, and NBQX (15 nmoles), or vehicle alone, administered focally at the injury site at 4 hrs post-injury (p.i.). Behavioral tests of hindlimb functional deficits were performed at 1 day and weekly thereafter for 8 weeks. The group treated with NBQX demonstrated a reduction in long-term functional deficits that was significant from 4 through 8 weeks. There was improved performance in tests of a number of hindlimb reflexes, and, most importantly, in use of the hindlimbs in locomotion. However, administration of NBQX at 4 hrs p.i. did not increase the speed of recovery, as had been observed when the same dose was given at 15 min p.i.. The results indicate that this antagonist of AMPA/kainate receptors may be effective in a clinically-relevant time frame. They confirm the importance of long-term analyses of functional deficits in evaluating the potential of drugs that may mitigate the effects of SCI. In addition, they suggest that NBQX can act differently, perhaps due to alterations in the presence or sensitivity of cellular targets, when administered at different times after SCI. NON-NMDA RECEPTOR ANTAGONISTS PROTECT AGAINST NEUROTOXIC SPINAL CORD INJURY IN THE RAT. S. Liu, G.L. Ruenes, H.A. Dancus*, R.P. Yezierski, Dept. of Neurological Surgery and The Miami Project, University of Miami, Miami, FL 33136.

The effects of the non-NMDA receptor antagonists NBQX and MCPG on quisqualate (QUIS), AMPA or ACPD induced spinal cord injury were evaluated. Twenty-eight male rats were divided into seven groups: 1) QUIS; 2) QUIS+MK-801; 3) QUIS+NBQX; 4) AMPA; 5) AMPA+NBQX; 6) ACPD; and 7) ACPD+MCPG. Drugs were intraspinally injected between spinal segments T13-L5. Animals were perfused transcardially with 10% formalin 1-10 days after injection. Spinal segments with injection sites were blocked and cut (75 μ m) on a freezing microtome. Cross-sections were stained with cresyl violet and evaluated with light microscopy. The rostrocaudal extent of cell loss in the gray matter and the area of gray matter damage at the epicenter of injection sites were evaluated.

The longitudinal extent of cell loss in AMPA+NBQX or ACPD+MCPG injected animals was significantly less than animals injected with AMPA or ACPD alone ($P<0.05$). The area of gray matter damage in AMPA+NBQX animals ($1,922.38 \pm 782.45 \mu\text{m}^2$) was significantly less than AMPA animals ($11,058.13 \pm 1,445.45 \mu\text{m}^2$; $P<0.001$). The difference in gray matter damage between ACPD animals ($15,474.17 \pm 1,742.01 \mu\text{m}^2$) and ACPD+MCPG animals ($1,963.17 \pm 1,176.35 \mu\text{m}^2$) was also significant ($P<0.001$). Although there was no significant difference between QUIS and QUIS+NBQX animals, NBQX showed some blockage of QUIS effects. MK-801 produced no protective effects on non-NMDA induced spinal cord damage. The results suggest that non-NMDA (including metabotropic) receptors may have an important role in mediating the excitotoxic effects of excitatory amino acids in spinal cord injury. IN VITRO AND IN VIVO EFFECTS OF β -OXALYLAMINO-L-ALANINE (BOAA) ON NADH-DEHYDROGENASE ACTIVITY IN MOUSE BRAIN. M.L. Sahbi*, D. N. Roy, B. Lystrup, C. N. Allen, and P. S. Spencer, Center for Research on Occupational and Environmental Toxicology, Oregon Health Sciences University, Portland OR 97201.

Experimental primate studies have shown that chronic ingestion of the excitatory and neurotoxic amino acid BOAA, disrupts motor neuron function in a manner similar to that seen in the human neurodegenerative disease, lathyrism. BOAA is known to exert its neurotoxic effects at μ M concentrations by over-stimulation of non-NMDA receptors, especially the AMPA receptor. A recent study (Brain Res., 621:215, 1993) has reported that a very low (0.1 pM) concentration of BOAA selectively inhibits the activity of the mitochondrial enzyme NADH-dehydrogenase (NADH-DH; Complex I), while 1 pM BOAA promotes LDH release into the incubation media indicating neuronal cell death. This study investigates the effect of pure BOAA on mouse brain NADH-DH both *in vitro* and *in vivo*. For *in vitro* studies, transverse brain slices (500 μ m) from adult male CD-1 mice (25-34 g) were incubated in Krebs Ringer (3.0 ml/slice) bubbled with 95% O_2 + 5% CO_2 with and without BOAA for 1h at 37°C. The specific activity of NADH-DH in control slices after 1h incubation was 12.1 ± 0.85 nmoles NADH oxidized/min/mg protein ($n=15$). Treatment of slices with BOAA showed a concentration-dependent inhibition of NADH-DH, but only at μ M concentrations (16, 24, 33, and 37% inhibition at 10, 100, 500 and 1000 μ M BOAA, respectively). Release of LDH into the incubation media was observed only in slices treated with 500 μ M and 1000 μ M BOAA. Young (8-day old) and adult (4-month) mice treated ip with 500 and 700 mg/kg BOAA, respectively, showed behavioral signs of BOAA toxicity. Young mice had severe convulsive seizures while adult animals exhibited drowsiness and lethargic movement. The NADH-DH activity in brain homogenates and mitochondria from BOAA-treated animals did not differ with that in age-matched animals treated ip with an equivalent volume of saline. These findings are in contrast to the reported suggestion that BOAA is a highly potent inhibitor of mitochondrial energy metabolism. Supported by NIH grant NS 19611 and MRF of Oregon.

CYCLOTHIAZIDE POTENTIATES INTRACELLULAR CALCIUM INCREASE IN RESPONSE TO AMPA IN CULTURED RAT HIPPOCAMPAL NEURONS. M. Okada, K. Ohno, M. Shimizu-Sasamata* and T. Yamaguchi. Neuroscience/Gastrointestinal Research Lab., Institute for Drug Discovery Research, Yamanouchi Pharmaceutical Co. Ltd., 21 Miyukigaoka, Tsukuba, Ibaraki 305, Japan.

AMPA receptors are characterized by a fast desensitization which is considered to be a possible mechanism for the termination of excitatory synaptic transmission. The present experiments are aimed to evaluate the ability of cyclothiazide (CYT), a drug which reduces desensitization of AMPA responses, to alter the intraneuronal Ca^{2+} concentration ($[Ca^{2+}]_i$) after exposure to AMPA.

Experiments were performed in primary rat hippocampal neurons grown for 10-16 days in cultures. Changes in $[Ca^{2+}]_i$ were measured by microfluorometric monitoring of the fluorescence intensities from individual neurons loaded with fura-2. In most neurons, application of AMPA induced a very small increase of $[Ca^{2+}]_i$. CYT markedly potentiated the responses to 30 μ M AMPA in a dose-dependent manner ($EC_{50}=3.2 \mu$ M). In the presence of 10 μ M CYT the EC_{50} for AMPA was 12.5 μ M. The AMPA-CYT-induced $[Ca^{2+}]_i$ increase was inhibited by competitive AMPA receptor antagonists, NBQX and YM90K(6-(1H-imidazol-1-yl)-7-nitro-2,3(1H,4H)-quinoxalinedione monohydrochloride), and by a non-competitive antagonist, GYKI52466. Under the condition of 10 μ M CYT and 20 μ M AMPA, IC_{50} values for NBQX, YM90K and GYKI52466 were 0.19, 0.30 and 9.9 μ M, respectively. From these results, it is demonstrated that CYT potentiates the action of AMPA in terms of intraneuronal calcium mobilization as well.

CONCAVALIN A RECRUITS CEREBELLAR NEURONS RESPONDING TO GLUTAMATE, OVERCOMES THE QUISQUALATE ANTAGONISM OF THE KAINATE RECEPTOR AND PRODUCES A GLIA-LIKE EFFECT, by P. McCaslin* and A. R. Arora. Ochsner Medical Foundation, Division of Research, 1516 Jefferson Highway, New Orleans, LA 70121

Glutamate is the predominant excitatory neurotransmitter in the CNS, and when directly applied on neural tissue, it excites most central neurons. The effects of Concanavalin A (Con A) on the pharmacology of glutamate were examined in cultures of cerebellar granule cells using digital and ratio Ca^{2+} imaging. In Mg^{2+} buffer, glutamate, quisqualate, and α -amino-3-hydroxy-5-methyl-4-isoxazolepropionic acid (AMPA) activate the same neuronal subpopulation (10-15% of the neurons), whereas kainate activates all neurons and NMDA activates none. Glutamate, AMPA and quisqualate reverse the kainate-induced elevations of $[Ca^{2+}]_i$ in cells unresponsive to glutamate (85-90%). The treatment of cells with Con A (1) reverses the quisqualate inhibition of the kainate response, (2) recruits the percentage of neurons responding to glutamate, AMPA and quisqualate without effecting kainate and decreasing NMDA responses, (3) and results in the pharmacologic expression of a specific population of receptors. Finally, Con A-like effects are seen in co-cultures of neurons and glia. Contrary the assumption that glutamate is universally excitatory to neurons, these results indicate that the neuronal response to glutamate is not apparent in most neurons in cerebellar neuronal cultures and that glia, like Con A, can change the glutamate pharmacology.

UNIQUE PROPERTIES OF AMPA RECEPTOR AGONISTS ACTING AT GLUR1-FLOP RECEPTORS EXPRESSED IN *XENOPUS* OOCYTES.

P. Wahl, U. Madsen, Banke T., Krogsgaard-Larsen P., and A. Schousboe. PharmaBiotec Res. Center, The Royal Danish School of Pharmacy, DK-2100 Copenhagen, Denmark.

A series of AMPA derivatives were evaluated for activity at homo-oligomeric GluR1-flop receptors expressed in *Xenopus* oocytes, using two electrode voltage clamp. (RS)-2-Amino-3-(3-carboxy-5-methyl-4-isoxazolyl)propionic acid (ACPA) (EC_{50} , 2.4 μ M) a homologue of AMPA with a carboxylate group as the terminal acidic functionality was five times more potent than (RS)-2-amino-3-(3-hydroxy-5-methyl-4-isoxazolyl)propionate (AMPA) (EC_{50} , 12 μ M) and 20 times more potent than kainate (KA) (EC_{50} , 48 μ M). (RS)-2-Amino-3-(3-hydroxy-5-trifluoromethyl-4-isoxazolyl)propionic acid (Trif-A-AMPA) in which an electrophilic trifluoromethyl group has been substituted for the methyl group on the isoxazole ring in the AMPA structure was three times more potent than AMPA, whereas (RS)-3-hydroxy-4,5,6,7-tetrahydroisoxazolo 5,4-c pyridine-5-carboxylic acid (5-HPCA), a homologue of AMPA with highly restricted structural mobility was 10 times less potent than AMPA. Responses evoked by near saturating concentrations of the agonists varied in amplitude by greater than 7-fold. The sequence of efficacy was ACPA = KA > Trif-A-AMPA > AMPA > 5-HPCA. Moreover, when a saturating concentration of Trif-A-AMPA and KA was co-applied the response was significantly larger than if the agonists were applied separately. The potency of the antagonist 2,3-dihydroxy-6-nitro-7-sulfamoylbenzo(f)quinoxaline (NBQX) (estimated K_D , ~ 0.2 μ M) at blocking currents mediated by GluR1-flop receptors was similar for all the agonists tested in this study. These results indicate that simple changes in the molecular structure of AMPA are associated with marked effects on potency and efficacy. In particular, it is suggested that the acidity of the terminal group plays a major role in determining the degree of receptor activation in the steady-state state.

INTERACTIONS OF GYKI 52466 AND CYCLOTHIAZIDE: PATCH CLAMP STUDIES. G. Rammesl, W. Müller, D. Swandulla, C.G. Parsons*, and G.L. Collingridge*³ Dept. Molecular Pharmacol., Univ. Erlangen, Germany¹, Dept. Pharmacol., Metz + Co., Frankfurt, Germany², Dept. Pharmacol., Univ. of Birmingham, England³.

The effects of GYKI 52466 and cyclothiazide on isolated AMPA receptor-mediated EPSCs and AMPA-induced inward currents were investigated with whole cell patch clamp recordings from the CA₁ region of hippocampal slices and cultured superior colliculus neurones respectively. Cyclothiazide concentration-dependently slowed the decay of AMPA-EPSCs (10 μ M, 157%; 30 μ M, 198%; 100 μ M, 291%; 330 μ M, 306% of control $\tau=23$ ms) with an EC_{50} of 31 μ M and produced a variable increase in the amplitude of AMPA-EPSCs (up to 133% of control). GYKI 52466 (10-30 μ M) concentration-dependently reduced the amplitude of AMPA-EPSCs without affecting response kinetics, both in the absence and the presence of cyclothiazide (330 μ M). Control inward currents to AMPA 100 μ M rose rapidly ($\tau=4.8$ ms) to a peak of 973 pA and then desensitized ($\tau=21$ ms) to a plateau of 187 pA. Cyclothiazide concentration-dependently potentiated the plateau component to a greater degree than the peak component (10 μ M, peak 195%, plateau 698%; 30 μ M, peak 223%, plateau 926%; 100 μ M, peak 252%, plateau 1114% of control). This effect was accompanied by a reduction in the rate of desensitization (10 μ M, $\tau=593$ ms) with little effect on the rate of onset ($\tau=7$ ms) or offset ($\tau=162$ ms cf. 167 ms control) of AMPA responses. GYKI 52466 antagonized both peak and plateau components of control AMPA response (IC_{50} Peak=12.9 μ M, plateau=10.9 μ M) whilst having little effect on response kinetics. Cyclothiazide 10 μ M shifted the GYKI 52466 concentration-response curve to the right in a manner suggestive of a common site of action for the two substances (GYKI 52466 Plateau $IC_{50}=57.9 \mu$ M). However, in the presence of cyclothiazide 10 μ M, GYKI 52466 was unable to reintroduce desensitization and concentration-dependently slowed the onset kinetics and enhanced the offset kinetics of AMPA responses (GYKI 52466 30 μ M, τ onset 19 ms, τ desensitization 966 ms, τ offset 83 ms). In conclusion, cyclothiazide may be an agonist and GYKI 52466 an antagonist at a common regulatory site on AMPA receptors but the two compounds mediate very divergent effects on receptor activation kinetics. Furthermore, these data provide supportive evidence that the offset kinetics of AMPA receptor-mediated EPSCs are partially governed by desensitization.

630.4

STABLE EXPRESSION OF GLUR6 AND GLUR2(Q) IN BHK CELLS. C. K. Tygesen, J. S. Rasmussen, O. Thastrup, M. Jørgensen and P. H. Andersen*. Departments of Molecular Pharmacology, Molecular Biology II and BioImage Satellite, Bioscience, Novo Nordisk, DK-2880 Bagsvaerd, Denmark.

Rat GluR6 was cloned by PCR using rat hippocampal derived 1. strand cDNA as template and sequence specific oligonucleotides as primers. Rat GluR2flip(Q) was constructed from previously cloned rat GluR2flip(R) using PCR. Each cDNA was transfected into BHK cells under control of a constitutively active metallothioneine promoter. Following addition of selection agent, subclones were isolated showing binding of either ³H-kainate (GluR6) or ³H-AMPA (GluR2). Western blots using antibodies specific to either GluR6 or GluR2 revealed bands of approximately 100 kd each. The pharmacological profiles of the receptors were studied by binding of either ³H-kainate (GluR6) or ³H-AMPA (GluR2). For GluR6 the rank order of potency was: domoate>kainate>quisqualate>L-glutamate>AMPA and for GluR2(Q): quisqualate>AMPA>L-glutamate>kainate. Functional properties of the receptors were studied by Ca^{2+} -imaging using Fura-2. With both GluR6 and GluR2(Q), application of kainate resulted in a marked increase in intracellular Ca^{2+} .

630.6

UTILIZATION OF QUISQUALIC ACID ANALOGUES TO DEFINE THE SPECIFICITY OF THE QUIS SENSITIZATION SITE IN RAT HIPPOCAMPUS. M.K. Schulte, R.J. Roon*, S.

Venkatraman, R.L. Johnson and J.F. Koerner. Depts. of Biochemistry and Medicinal Chemistry, Univ. of Minnesota, Minneapolis, MN 55455-0347.

Quisqualate sensitization is a highly specific process in which exposure to quisqualate enhances sensitivity of neuronal pathways to depolarization by α -amino- α -phosphonate analogues of excitatory amino acids. To analyze the structural specificity of this sensitization process, we have synthesized a series of quisqualate (1) analogues (2-7).

Compounds 2, 3, 6, and 7 produced no sensitization at the highest levels tested whereas compounds 4 and 5 were 1/10 and 1/1000, respectively, as active as 1 in sensitization of hippocampal CA1 neurons to depolarization by L-AP6. Since cellular uptake has been implicated in QUIS-sensitization, we compared the uptake of 1 and 4 into hippocampal slices and found that the rate of uptake of 4 is ~50% of that of 1. (Supported by NIH NS 17944).

630.7

2,3-BUTANEDIONE MONOXIME SUPPRESSES KAINATE-INDUCED CURRENTS OF MURINE VENTROMEDIAL HYPOTHALAMIC NEURONES. J.H.Ye* and J.J. McArdle. Dept. Pharmacology/Toxicology and Anesthesiology, New Jersey Medical School (UMDNJ), Newark, NJ 07103-2714.

The effects of the "chemical phosphatase" 2,3-butanedione monoxime (BDM) on kainate-induced current were studied in hypothalamic neurones acutely dissociated from young mice. Drug containing solutions were rapidly applied to activate current in neurons subjected to the nystatin perforated patch or conventional whole cell recording techniques. When applied simultaneously with kainate, BDM produced a rapid, reversible and dose-dependent (IC_{50} 25 mM) suppression of agonist-induced current. This acute blocking effect of BDM was neither voltage- nor use-dependent. Including 500 μ M ATP- γ -S in the recording pipette did not prevent the acute effect of BDM. Furthermore, H-7 (200 μ M), a non specific protein kinase inhibitor, did not prevent the rapid recovery of the kainate response following washout of BDM. These findings suggest that the acute blocking action of BDM on the kainate response of hypothalamic neurone does not require a "chemical phosphatase" action. The most likely mechanism of action is a direct block of channels from the outside surface of the neurolemma. However, preincubating neurons with 30 mM BDM reversibly reduced the current recorded with the perforated patch technique when neurons were subsequently exposed to kainate alone. This persistent effect of BDM was not seen for neurons dialyzed with a solution containing ATP- γ -S during conventional whole cell recording. Furthermore, exposure to H-7 prevented recovery of the kainate response suppressed by preincubation in BDM. These findings suggest that BDM causes sustained suppression of the kainate response of hypothalamic neurones via a "chemical phosphatase" action. Support from the NIH (NS31040) and the NIAAA (AA08025) made this work possible.

KAINATE-INDUCED Ca^{2+} SIGNALING IN ASTROCYTES REQUIRES Na^{+} AND Ca^{2+} FLUX VIA THE Na^{+}/Ca^{2+} EXCHANGER. W. T. Kim, M. G. Rioult, and A. H. Cornell-Bell*. Dept. of Cell Biology, Yale Univ. Sch. of Med., New Haven, CT 06510.

In primary cultures of rat hippocampal astrocytes, the binding of ionotropic glutamate receptors with kainate (KA, 100 μ M) induces a rise and sustained elevation of $[Ca^{2+}]_{in}$ as well as regenerative intercellular Ca^{2+} waves. Using time-lapse confocal scanning laser microscopy and Fluo-3 we found that the removal of Na^{+} or Ca^{2+} from the bath abolished these $[Ca^{2+}]_{in}$ changes; therefore, external Na^{+} and Ca^{2+} are both necessary for the KA-induced response ($N = 7$ experiments). The involvement of Na^{+} and Ca^{2+} in the ionotropic response is not via influx through voltage-dependent channels. Blocking Na^{+} channels with TTX (10 μ M) did not affect the incidence, latency, or spatio-temporal characteristics of KA-induced $[Ca^{2+}]_{in}$ changes ($N = 3$ experiments). Similarly, blocking L-type Ca^{2+} channels with Nifedipine (10 μ M) and Nimodipine (1 μ M) did not affect the $[Ca^{2+}]_{in}$ elevation or waves ($N = 4$ experiments). However, inhibiting the Na^{+}/Ca^{2+} exchanger with Benzamil (100 μ M) completely abolished the $[Ca^{2+}]_{in}$ elevation and intercellular Ca^{2+} waves ($N = 7$ experiments). The inhibition of Ca^{2+} signaling by Benzamil appears to result from its effects on the Na^{+}/Ca^{2+} exchanger in particular rather than to its non-specific effects on Na^{+} and Ca^{2+} channels and the Na^{+}/H^{+} antiporter. The more selective Na^{+}/H^{+} antiporter inhibitor 5-(N,N-dimethyl)-amiloride (100 μ M) did not affect KA-induced $[Ca^{2+}]_{in}$ changes ($N = 3$ experiments).

630.11

MK-801-INDUCED HYPERMETABOLISM IN THE POSTERIOR CINGULATE CORTEX IS ATTENUATED BY AN AMPA RECEPTOR ANTAGONIST. T.R. Patel & J. McCulloch*, Wellcome Surgical Institute, University of Glasgow, G61 1QH, U.K.

MK-801 induces marked increases in glucose utilisation in the posterior cingulate cortex. We have examined if pretreatment with the AMPA receptor antagonist NBQX alters the pattern of glucose use seen with the administration of MK-801. Local cerebral glucose use was measured in male SD rats using ^{14}C -2-deoxyglucose autoradiography. NBQX (7mg/kg i.v.) was administered 2 min prior to the administration of MK-801 (0.2 mg/kg i.v.). The effects of NBQX and MK-801 alone (with vehicle administration at appropriate times) was also examined.

At the dose used, NBQX (7mg/kg) had no significant effect on glucose use in any area examined. MK-801 (0.2mg/kg) increased glucose use in some components of the limbic system. In the posterior cingulate gyrus, MK-801 caused a marked increase in local cerebral glucose use from 67 ± 2 with vehicle to 101 ± 9 μ moles/100g/min after MK-801. Pretreatment with NBQX attenuated the MK-801 induced increase in glucose use in the posterior cingulate cortex (69 ± 3 μ moles/100g/min after NBQX + MK-801). Pre-treatment with NBQX did not attenuate the MK-801-induced decreases in glucose use in the neocortex.

The attenuation of the MK-801 hypermetabolism in the posterior cingulate cortex indicates that there may be some interaction *in vivo* between NBQX and MK-801. The combination of these drugs may be useful in counteracting the potential adverse effects of the non-competitive NMDA receptor antagonists.

630.8

PARADOXICAL EFFECT OF A NON-NMDA ANTAGONIST ON THE KAINATE-INDUCED ELEVATION OF CYCLIC GMP (cGMP). S. Oh* and P. McCaslin¹. Dept. Pharmacol. & Toxicol., University of Miss. Med. Ctr, Jackson, MS 39216, and ¹Alton Ochsner Medical Foundation, Div. Res., 1615 Jefferson Hwy., New Orleans, LA 70121

It is well known that N-methyl-D-aspartate (NMDA) and kainate (KA) result in the elevation of cGMP. These studies were designed to examine the long-term effects of NMDA and KA on cGMP elevation in primary cultures of cerebellar granule cells, and also to determine if this elevation has functional significance. Both NMDA and KA result in a concentration-dependent elevation of cGMP with maximal elevations of cGMP occurring at 200 μ M NMDA and 50 μ M kainate after a 3 min exposure. The cGMP concentration-response to kainate or NMDA is markedly blunted and shifted to the left if cells are incubated for an hr when compared to the above 3 min exposure. As expected, an NMDA antagonist blocked the elevation of cyclic GMP and the release of glutamate induced by NMDA with both short-term and long-term exposures. However, a non-NMDA antagonist produced paradoxical results by augmenting the kainate-induced elevation of cGMP. While 6,7-dinitroquinoxaline-2,3-dione blocked the kainate-induced elevations of cGMP with short-term incubations, it augmented the response with long-term incubations; moreover, in both cases it blocked the kainate-induced release of glutamate. These results suggest a more complex agonist-antagonist receptor interaction with the kainate receptor than is seen with the NMDA receptor.

630.10

Excitatory amino acid responses in acutely isolated cerebellar Purkinje neurons

D. Bleakman, A. McCormack, S.R. Baker* and J. Tarnawa. Lilly Research Centre Ltd., Erl Wood Manor, Windlesham, Surrey GU20 6PH, U.K. and Institute of Drug Research, Budapest, Hungary.

We have examined the effects of agonists and antagonists of excitatory amino acid receptors in acutely isolated cerebellar Purkinje cells from 6-9 day old rats. Neurons were whole cell voltage clamped at -70mV with a KCl based pipette solution and compounds applied by bath perfusion. Kainate (KA, 10-300 μ M) AMPA (10-50 μ M), domoate (10-100 μ M) and L-glutamate (10-100 μ M) induced inward currents in a concentration-dependent manner. Applications of NMDA (100 μ M in Mg free/10 μ M glycine solutions) failed to evoke inward currents at either -70 or -40mV ($n=4$). Kainate (100mM)-induced currents were antagonized by NBQX (IC_{50} value approx. 0.2 μ M) and 2,3-benzodiazepines, GYKI 52466 and 53655 with IC_{50} values of 5.1 ± 1.1 μ M ($n=3$) and 1.5 ± 0.2 μ M ($n=3$) respectively. Peak KA (100 μ M)-induced currents were potentiated in the presence of cyclothiazide (30 μ M) by $43 \pm 11\%$ ($n=5$) and AMPA (50 μ M)-induced currents by $450 \pm 40\%$ ($n=4$). Concanavilin A (10 μ M) had no significant effect on either KA- or AMPA-induced currents. Cobalt uptake into isolated neurons was stimulated by KA (100 μ M). KA-evoked cobalt uptake was prevented by NBQX (10 μ M) and 2,3-benzodiazepines suggesting the presence of divalent permeable AMPA/KA receptors.

AN AUTORADIOGRAPHIC STUDY OF THE LOW-AFFINITY [3H]KAINATE BINDING SITE IN RAT BRAIN

T.H. Johansen^{1,2} and E.O. Nielsen¹

¹NeuroSearch A/S, 26B Smedeland, DK-2600 Glostrup, Denmark;

²Vanderbilt University School of Medicine, Nashville, TN 37212-6600, USA.

[3H]Kainate binding to rat cortical membranes can be separated into high- and low-affinity binding sites with K_d -values of 2 and 24 nM, respectively. The low-affinity binding site can be studied separately in the presence of Ca^{2+} . Saturation of [3H]kainate binding to rat brain sections was examined in 10 regions in the absence or presence of 30 mM $CaCl_2$. In the absence of $CaCl_2$, both high and low-affinity [3H]kainate binding sites could be detected in all the investigated regions, whereas only binding to a single receptor population ($K_d = 40-90$ nM) could be detected in the presence of 30 mM $CaCl_2$. Comparison of the regional distribution of the low-affinity [3H]kainate binding site and the [3H]AMPA binding site did not indicate that calcium insensitive [3H]kainate binding represents binding to the AMPA receptor.

The non-NMDA antagonist 5-nitro-6,7,8,9-tetrahydrobenzo[*g*]indole-2,3-dione-3-oxime (NS-102), which selectively blocks the low-affinity [3H]kainate binding site in rat brain and which has high affinity for the recombinant GluR-6 receptor, has been used to examine regional differences in [3H]kainate binding. In the absence of $CaCl_2$, where both high and low-affinity binding sites were labelled, NS-102 only partially inhibited the binding and showed regional differences in IC_{50} values (hippocampus, CA3: 75 μ M - cerebellum: 2 μ M) indicating a relatively higher proportion of low-affinity binding sites in cerebellum compared to the rest of the brain. In the presence of $CaCl_2$, where only the low-affinity [3H]kainate binding site is labelled, NS-102 showed an increased affinity in all regions. However, regional differences in the IC_{50} -values of NS-102 for the low-affinity [3H]kainate binding site were obtained (hippocampus, CA3: 12 μ M - cerebellum: 0.7 μ M), indicating that the low-affinity [3H]kainate binding site may not represent a homogenous receptor population.

STRUCTURAL ANALOGS OF THE NON-NMDA RECEPTOR ANTAGONIST GYKI 52466 DEPRESS K⁺ CURRENTS IN HIPPOCAMPAL NEURONS. W. Li, D. L. Czilli and L. K. Simmons.* CNS Research, Lilly Research Laboratories, Indianapolis, IN 46285.

The 2,3-benzodiazepine GYKI compounds have been characterized as potent, selective antagonists of neuronal responses mediated by non-NMDA receptors. In this study we used whole-cell voltage-clamp protocols to investigate the K⁺ channel actions of structural analogs of the parent compound GYKI 52466 in embryonic rat hippocampal neurons.

Three of the four compounds evaluated blocked voltage-gated K⁺ currents with a rank order potency and stereoselectivity comparable with their reported antagonist activities at non-NMDA receptors. In contrast, the most potent K⁺ channel blocker of the compounds tested was GYKI 53391, a 4',3-di-N-acetyl derivative of GYKI 52466 known to be inactive at non-NMDA receptors. Kynurenate, CNQX and Ro-15-1788 failed to elicit similar responses, therefore the GYKI analogs do not appear to be modulating K⁺ channel function indirectly via interactions with ionotropic EAA or benzodiazepine receptors. The results described here suggest that the K⁺ channel and non-NMDA receptor actions of the 2,3-benzodiazepine GYKI compounds can be isolated so that further evaluation of structural analogs within this series may lead to the identification of more potent K⁺ channel blockers.

PEPTIDES: BIOSYNTHESIS, METABOLISM, AND BIOCHEMICAL CHARACTERIZATION II

631.1

BOMBESIN EXISTS IN BOTH A LEU AND PHE FORM: IMPLICATIONS FOR THE CLASSIFICATION OF THE BOMBESIN-LIKE PEPTIDES. E.B. Spindel*, J. Taylor, B.J. Barry and S.R. Nagalla. Div. Neuroscience, Oregon Rgl. Primate Research Ctr., Beaverton OR 97006 and Biomeasure Inc., Milford MA 01757.

The bombesin-like peptides are a diverse family of peptides initially characterized in frog skin and later found to be widely distributed in mammals. The bombesin-like peptides have been classically divided into the bombesin/GRP subfamily, the ranatensin/NMB subfamily and the phyllolitorin subfamily. Distinguishing the bombesin subfamily from the ranatensin subfamily is the presence of a Leu or Phe as the penultimate C-terminal amino acid. We now show that this separation is incorrect as bombesin occurs in both a Phe and Leu form. Multiple cDNAs encoding bombesin from brain of *Bombina orientalis*, *Xenopus laevis* and phyllolitorin from *Phyllomedusa Sauvagei* were characterized. In all three species, two forms of peptide were encoded, one containing Leu and one containing Phe - and the Phe form strongly predominated in brain. cDNAs were highly homologous differing by only a few nucleotides. In *Xenopus* and *Bombina*, Phe and Leu bombesin appear to arise from separate genes. In *Phyllomedusa*, Phe and Leu phyllolitorin appear to arise by RNA editing (*Mol. Endocrinol.*, In Press). Phylogenetic analysis showed that the GRP and bombesin prohormones strongly diverge; that the NMB and ranatensin prohormones strongly diverge; but that there is strong homology between the bombesin, ranatensin and phyllolitorin prohormones. This suggests that the bombesin-like peptides should be reclassified into the GRP subfamily, the NMB subfamily and the bombesin subfamily. Consistent with this, Nagalla et al., have found 3 classes of receptors in frogs that correspond to these 3 peptide subfamilies (Abstract, Soc. Neurosci., 1994). These findings predict that mammals also have a (as yet uncharacterized) member of the bombesin subfamily and that it will exist in both a Phe and Leu form.

631.3

COMPARATIVE POTENCIES OF MID-PORTION CALCITONIN GENE-RELATED PEPTIDE ANALOGUES IN PROTOTYPICAL CGRP₁ AND CGRP₂ IN VITRO BIOASSAYS. D. Lavalée², Y. Dumont¹, D. Jacques¹, S. St-Pierre², A. Fournier² and R. Quirion¹ (1) Douglas Hosp. Res. Ctr., Dept. Psychiatry, McGill Univ., Verdun, P.Q., Canada, H4H 1R3. (2) INRS-Santé, Pointe-Claire, P.Q., Canada, H9R 1G6.

Alanine substituted analogues and fragments of hCGRP α , hCGRP₈₋₃₇ (a potent antagonist) and its linear-analogue [Cys(ACM)^{2,7}]hCGRP α (a CGRP₂ preferential agonist) were synthesized in order to investigate the respective role of amino acid residues between positions 14 to 23 for their abilities to induce an inotropic effect in the guinea pig atria and to inhibit contraction of the electrically-stimulated rat vas deferens, two prototypical CGRP₁ and CGRP₂ receptor bioassays, respectively (Dennis et al., J. Pharmacol. Expt. Ther. 254: 123-128, 1990). Results demonstrated that Leu¹⁶ and Arg¹⁸ are critical for the activation of CGRP receptors in both tissues; [Ala¹⁶]hCGRP α being inactive. Interestingly, Ala substitutions of Gly²⁰ and Gly²¹ residues generated analogues having similar or greater potencies than hCGRP α itself in the CGRP₂ assay, while being less potent than the native peptide in the CGRP₁ bioassay. [Ala²¹]hCGRP α was found to be 2.5 fold more potent than hCGRP α in the CGRP₂ preparation while being somewhat less potent (63%) than the endogenous peptide in the guinea pig atria. The two analogues [Cys(ACM)^{2,7},Ala¹⁷]hCGRP α and [Cys(ACM)^{2,7},Ala²¹]hCGRP α were slightly more potent than the unmodified analogue on CGRP₂ receptors while being inactive on the CGRP₁ receptors. Additionally, Ala substitutions of the peptide antagonist hCGRP₈₋₃₇ demonstrated that [Ala¹⁷]hCGRP₈₋₃₇ and [Ala²⁰]hCGRP₈₋₃₇ had slightly higher potencies than hCGRP₈₋₃₇ in blocking hCGRP α in the guinea pig atria while being ineffective in the rat vas deferens. Taken together, these results demonstrate the importance of the amino acid residues in positions 16, 17, 18 and 20 for adequate CGRP recognition and activation, and should be helpful toward the development of full selective analogues.

630.14

DIFFERENTIAL RESPONSES TO PHOSPHONATE ANALOGS OF GLUTAMATE DISTINGUISH TWO SUBCLASSES OF L-AP4-SENSITIVE SITES. J.F. Koerner*, R.D. Randall and R.J. Roon. Dept. of Biochemistry, Univ. of Minnesota, Minneapolis, MN 55455.

In previous studies of hippocampal neural pathways, it has been shown that L-2-amino-4-phosphonobutanoic acid (L-AP4) is a potent inhibitor of excitatory glutamatergic projection pathways of the lateral perforant pathway (LPP) of the rat, the mossy fiber-CA3 pathway (MF) of the guinea pig, and a partial inhibitor (10-40%) of the medial perforant pathway (MPP) of the rat hippocampus. It is also a potent inhibitor of the Schaffer collateral-CA1 pyramidal pathway after (but not before) sensitization by exposure to quisqualic acid (QUIS). It was also demonstrated that the QUIS-sensitized site is pharmacologically distinct from the L-AP4 receptor of the rat LPP and the guinea pig MF. Specifically, the QUIS-sensitized site also shows high sensitivity to L-AP6 and *E*-cyclopentyl-AP4. We now wish to report that the partial sensitivity of the rat MPP also shows the pharmacological profile of the QUIS-sensitized site, not of the classical L-AP4 receptors which have low sensitivity for L-AP6 and *E*-cyclopentyl-AP4. Exposure of a slice to QUIS sensitizes the MPP for 100% inhibition by L-AP4, L-AP6, and *E*-cyclopentyl-AP4 with IC₅₀ values indistinguishable from the partial inhibition observed with these compounds before QUIS. The high sensitivity of the rat LPP and guinea pig MF to L-AP4 previously made it impossible to demonstrate QUIS-sensitization of these pathways. However, using L-AP6 and *E*-cyclopentyl-AP4, QUIS-sensitization can be readily demonstrated. (Supported by NIH NS 17944).

CONVERSION OF MET-ENKEPHALIN-ARG-PHE TO MET-ENKEPHALIN IN HUMAN SERUM. M.K. Leung*, K. Oscar, D. Dieudonne and N. Dowell. Neuroscience Research Institute and Department of Chemistry, SUNY/Old Westbury, Old Westbury, NY 11568-0210.

Both Met-enkephalin (YGGFM) and the opioid heptapeptide, Met-enkephalin-Arg-Phe (YGGFMRF), are reported to be capable of activating the same population of immune cells in the human circulatory system. Earlier study also showed [¹²⁵I]-YGGFMRF is converted by human serum to a product with the same HPLC retention time (Rt) as [¹²⁵I]-YGGFM. The aim of this study was to verify the conversion of YGGFMRF to YGGFM in human serum. Time-course study with pooled human serum (Pel-Freez, WI) showed YGGFMRF (50 uM) was processed rapidly to three major products with HPLC Rt's corresponding to that of GGFM, YGGFM and GGFMRF. The material with the Rt of YGGFM rose to its highest level in 1 min and remained at over 70% of this level after 5 min. The identity of the peptide material in this peak was verified with three procedures. 1) It was reactive against YGGFM antibody in RIA. 2) When derivatized with PITC the peptide derivative migrated with the same Rt as the derivatized YGGFM standard. 3) Amino acid analysis of the peptide with PTC technique showed the presence of Y, G, F and M in the ratio of 1:2:1:1 as with YGGFM. Serum protease inhibitors studies showed the conversion of YGGFMRF to YGGFM is mediated by ACE and GGFMRF and GGFM are products of the action of aminopeptidase on YGGFMRF and YGGFM. Unlike YGGFMRF, the opioid octapeptide, Met-enkephalin-Arg-Gly-Leu, is not converted to YGGFM by human serum. Our results showed YGGFMRF is converted to YGGFM in human serum and it may be serving as a part of a mechanism for sustaining YGGFM concentration in the circulatory fluid.

PITUITARY ADENYLATE CYCLASE ACTIVATING PEPTIDE (PACAP) IS UP-REGULATED IN THE RAT DORSAL ROOT GANGLIA AFTER PERIPHERAL NERVE INJURIES. Y-Z. Zhang*, J. Hannibal, Q. Zhao, N. Danielsen, K. Moller, H. Mulder, E. Ekblad, J. Fahrenkrug and F. Sundler. Depts. Anesth., and Hand Surg., Malmö Gen. Hosp., Univ. Lund, S-21401 Malmö, Dept. Med. Cell Res., Univ. Lund, S-22362 Lund, Sweden and the Dept. Clin. Biochem., Bispebjerg Hosp., D-12345 Copenhagen, Denmark.

The effects of sciatic nerve injuries on the levels of PACAP and its mRNA in the dorsal root ganglia (DRG) and the spinal cord were investigated in rats. The sciatic nerve on the left side was either transected or crushed in anesthetized rats. The sciatic nerve on the right side was intact. The animals were killed 14 days postoperatively. The spinal cord L4-S1 and the DRG related to the sciatic nerve were dissected and processed for immunocytochemistry, immunochemistry, in situ hybridization and northern blot. Immunostaining of PACAP was seen in a population of mainly small nerve cells in the DRG of the control side, confirming our previous observations in normal DRG. PACAP was more intense in the DRG on the injured sides where PACAP was also seen in many large cells. In the dorsal horn of the spinal cord, transection reduced PACAP intensity whereas crush injury revealed no overt difference as compared to the control. The results from northern blot and in situ hybridization supported the immunocytochemical observations. The PACAP-mRNA in the DRG increased significantly after nerve crush or transection injury.

NEUROPEPTIDE-LIKE IMMUNOREACTIVITIES IN BOVINE BRAIN CLATHRIN COATED VESICLES. W.L. Silva*, L. Martinez, and N. Rosario. Department of Pharmacology, Universidad Central del Caribe, School of Medicine, Call Box 60-327, Bayamón, Puerto Rico 00621-6032.

Clathrin coated vesicles (CCV) participate in the proteolytic maturation of neuropeptides (NP) in the trans Golgi network (TGN), and potentially in the internalization of neuropeptides and their receptors. In this study CCV from bovine brain gray matter were purified after chromatography over Sephacryl S-1000 columns. Fractions (15-25ml) were collected and analyzed for their adaptor protein profile via SDS-PAGE, for their carboxypeptidase H (CPH) activity via radioenzymatic assays, and for their NP (NPY₁₋₃₆, CCK-8 and SS-14) content by means of radioimmunoassays. The results reveal the expression of CPH and neuropeptide-like immunoreactivities (NP-Li: NPY-Li, CCK-Li and SS-Li) associated with clathrin coated vesicles. The NP-Li and CPH were mainly associated with the ascending portion of the CCV peak suggesting that these molecules pertain to the expectedly larger diameter CCV subpopulation associated with the TGN, recycling and/or endocytic CCV. Analysis of the adaptor protein profile of the material eluting from the Sephacryl S-1000 column demonstrates a wide distribution of the Golgi-associated AP-1 (HA-1) molecules (AP47 and AP19) in relation to the CCV peak, spanning both the ascending and descending portions of the CCV peak. This adaptor protein pattern is consistent with the inherent size microheterogeneity of TGN CCV, large diameter CCV of the regulated secretory pathway and smaller diameter CCV of the lysosomal pathway. Analysis of NP and NP processing enzymes in brain CCV will yield valuable information about the factors and conditions that influence the post-translational maturation and activation of NP. (This work was supported by NIH grants NS27259 and RR03035 awarded to WIS).

SUBCORTICAL LESIONS REDUCE CORTICAL GALANIN. S.M. Gabriel, V. Haroutunian, P.J. Knott.* Departments of Psychiatry, Mount Sinai School of Medicine, New York, NY 10029 and Bronx VA Hospital, Bronx, NY 10468.

GAL is associated with multiple long tract neurons, such as the cholinergic neurons of the nucleus basalis of Meynert [NBM], the noradrenergic neurons of the locus coeruleus and the serotonergic neurons of the dorsal raphe nucleus [DRN]. Lesions of each of these systems in the rat produce significant alterations in GAL concentrations in the frontal cerebral cortex. Following NBM lesions, decreases in cortical GAL depend on the magnitude of cholinergic depletion and lesion survival time. Lesions of the anterior noradrenergic bundle result in immediate reductions in cortical GAL concentrations which are comparable to the considerable depletion in norepinephrine. In contrast, biphasic effects of DRN lesions occur with increased GAL and serotonin 1 hour after DRN lesion and decreased GAL and serotonin 7 days after injury. Six weeks after a DRN lesion, GAL concentrations recover in the cortex despite, continued depletion of serotonin. These studies suggest a complex pattern for GAL regulation within the cerebral cortex, in which a large portion of the peptide is derived from multiple classical neurotransmitter efferents.

EXPRESSION OF ANTISENSE PC1 OR PC2 IN STABLY TRANSFECTED RIN 5F CELLS SIGNIFICANTLY REDUCES CELLULAR CONTENT AND SECRETION OF CCK 8. J.Y. Yoon* and M.C. Beinfeld. Dept. Pharm. Phys. Sci. St. Louis U. Sch. Med., St. Louis, Mo. 63104

The subtilisin-like enzymes PC1 and PC2 have been implicated in the processing of a number of pro neuropeptides. Northern analysis of total RNA from several cell lines, including RIN 5F, which express CCK mRNA and process pro CCK to CCK 8 indicates that both PC1 and PC2 transcripts are present. In order to evaluate whether PC1 or PC2 is involved in pro CCK processing, stable cell lines derived from Rin 5F cells were created which express either anti PC1 or anti PC2 mRNA. Cellular extracts and media were assayed for CCK 8 by radioimmunoassay. Individual clones that express anti PC1 or anti PC2 were identified that displayed a significant reduction of CCK 8 cell content and secretion. These results suggest an important role of both PC1 and PC2 in the processing of pro CCK to CCK 8. This work supported by NS 18667 and NS 31602.

631.6

AN OXYTOCIN (OXT) ANTISENSE OLIGONUCLEOTIDE (AS) INFUSED INTO THE SUPRAOPTIC NUCLEUS (SON) RAPIDLY ALTERS THE EXCITABILITY OF OXT NEURONS IN LACTATING RATS. I. Neumann and Q.J. Pittman*. Neuroscience, Med. Physiol., Univ. of Calgary, Calgary, T2N 4N1, Canada.

We, recently, described a rapid effect (within 4 hours) on suckling after infusion of OXT AS into the SON. In this study we asked, if this was due to reduced excitability of OXT neurons. The femoral vein and artery and an abdominal mammary gland of urethane anesthetized, lactating rats were cannulated. Phosphorothioated OXT AS (2.5 µg/0.5 µl, n=8), mixed bases (MB, n=8) or saline (SAL, n=6) were infused into both SON. A stimulation electrode was placed into the neurohypophyseal stalk. Injection of synthetic OXT increased mammary pressure in an identical fashion in all groups. Electrical stimulation of the stalk (50Hz, 4sec) increased mammary pressure due to stimulated OXT secretion from the neurohypophysis, but the threshold was higher in OXT AS treated rats (34.0±3.78 V versus 14.1±2.57 V [MB] and 10.0±2.23 V [SAL]; p<0.001) within 1.5 - 2 hours after treatment. Extracellular recordings from OXT neurons (identified by antidromic invasion from stalk, response to CCK-8 and non-response to nitroprusside) revealed threshold for antidromic stimulation higher in OXT AS rats (29.1±2.56 V) than in MB (18.5±3.08 V) or SAL rats (14.8±1.79 V, p<0.001). Furthermore, in OXT AS treated rats, the antidromic threshold was higher in OXT cells than in cells identified as vasopressinergic neurons (29.1±2.56 vs. 19.1±2.28 V).

These results demonstrate a rapid, local and selective effect of OXT AS on the excitability of OXT neurons. Supported by HFSP, MRC and AHFMR.

631.8

DISTRIBUTION OF DEAMIDASE ACTIVITY IN BOVINE BRAIN H. L. Jackman*, C. H. Anderson, and E. G. Erdős. Lab. of Peptide Research, Depts. of Pharmacol., Anesthesiol., and Anat. and Cell Biol., Univ. of IL Coll. of Med., Chicago IL 60612.

Deamidase is a lysosomal serine carboxypeptidase which has deamidase and esterase activities as well. It is identical with the lysosomal protective protein and probably with cathepsin A. The lack of this protein causes genetically determined galactosialidosis with involvement of the CNS. The enzyme inactivates peptides or modulates their actions (e.g., bradykinin, endothelin, and enkephalin hexapeptides, Jackman et al., J. Biol. Chem. 265:11265, '90; 267:2872, '92). We measured the specific activity of deamidase, with Dansyl-Phe-Leu-Arg as substrate, to study its distribution in the bovine brain. Areas that had the highest specific activity (nmol/h/mg) are the choroid plexus (288), the pineal body (155), and the pituitary (131). Areas with the lowest activity are the corpus callosum (65), the fornix (64), and the caudate (50). The activity in other regions of the brain (hippocampus, occipital cortex, frontal cortex, thalamus, hypothalamus, putamen, and amygdala) is between the high and low values given above. As deamidase cleaves a number of precursors and active peptides, and the lack of it causes a degenerative brain disease, the high activity found in some areas suggests a functional importance for this enzyme. (Supported by NIH grants HL36473, HL36081).

ISOLATION OF A CANDIDATE cDNA CLONE FOR RAT BRAIN CCK 8 GENERATING ENZYME (CGE) BY EXPRESSION CLONING. M.C. BEINFELD*, L.R. ALLARD, AND T.B. USDIN. Dept. Pharm. Phys. Sci., St. Louis University Medical Center, St. Louis MO, 63104 and Laboratory of Cell Biology, NIMH, Bethesda, MD.

An enzyme capable of generating CCK 8 from CCK 33 was isolated and partially purified from rat brain synaptosomes in 1992 (Viereck and Beinfeld, J. Biol. Chem. 267:19475-19481). Using the hybrid vaccinia T7 infection/transfection system and a highly sensitive assay system using batchwise ion exchange and CCK RIA, we identified a single cDNA clone from a rat cerebral cortex library which when expressed in CV1 cells displayed enzymatic activity which was identical to the isolated enzyme including pH optimum, inhibitor sensitivity, and product formation. The clone is not present in the Gene Bank. Northern Analysis of the distribution of its mRNA in a variety of endocrine tumor cells which express CCK mRNA and which process it to CCK 8 is consistent with a role in the processing of pro CCK. Additional clones were isolated which differ in inhibitor specificity or product formation. Supported by NIH grants NS 18667 and NS 31602 (to M.C.B.).

FACTORS PREDICTING AMINO ACID INCORPORATION IN THERMAL PROTEINS.
LeDuc, R.L., D.C. Smith and S.W. Fox. Dept. of Psychology, Southern Illinois University,
Carbondale IL 62901 and University of South Alabama.

Studies of the minimum excitable biological membrane depend on an understanding of the self-organizing abilities of amino acids (AA). Thermal proteins (TP) are the leading model of self-organization of amino acids. Here multiple linear regression is used to determine correlations between individual AA and their concentration in TP polymers.

The multiple regression analysis used a previously published series of 11 TP reactions using 11 AA each, from which crude hydrolysis data were available. Data consisted of paired values of the mole percent of each of 11 AA in the reaction mixture and the resulting polymer. A stepwise multiple linear regression was performed on the reaction concentration of all AA in the mixture to predict the concentration for each AA in the crude product. Additionally, 11 multiple linear regression analyses were performed to predict the concentration of each AA using the concentrations of all the other AA in the crude TP. In each of these cases the AA in question was excluded from the regression analysis. All equations were cross-validated. Eight equations predicting AA concentration in the polymer from the reaction conditions cross-validated. In each case the reaction concentration of the given AA was the best predictor of the concentration of the AA in the polymer. Only three equations predicting AA concentration in the TP polymer from all other AA in the polymer cross-validated. Aspartic acid (Asp) and glutamic acid (Glu) covaried (Multiple R=.975) and isoleucine was predicted from valine (Multiple R=.988). Thus the best predictors of TP polymer composition are the properties of the specific AA and not the presence or absence of other AA (except for Asp and Glu). Supported by NSF-IBN-9223377 to D.C. Smith and S.W. Fox.

SEROTONIN RECEPTORS: PHYSIOLOGY

5-HT_{1D} RECEPTORS REGULATE SOMATODENDRITIC RELEASE OF 5-HT: NEUROCHEMICAL STUDIES IN THE RAT RAPHE NUCLEI.
G. Piñeyro*, C. de Montigny and P. Blier. Neurobiological Psychiatry Unit,
McGill University, Montréal, Québec, Canada, H3A 1A1.

Classically, 5-HT_{1A} receptors which modulate the firing activity of 5-HT neurons have also been suggested to control the somatodendritic release of 5-HT. We have recently shown that the somatodendritic 5-HT release is regulated independently of firing frequency via 5-HT_{1D} receptors (*Neurosci. Abst.* 93.4, 1993). The present study further assessed the regulation of somatodendritic release of 5-HT. In a first series of experiments, voltammetry studies using nafion-coated carbon fiber electrodes showed that the non-selective 5-HT₁ agonist TFMP (0.5 mg/kg, i.v.) gradually reduced extracellular 5-hydroxyindoles in the dorsal raphe over a two-hour period. This effect was prevented by mianserin (2 mg/kg, i.v.), which blocks rat 5-HT_{1D} but not 5-HT_{1B} receptors, but not by the selective 5-HT_{1A} antagonist (+)WAY 100135 which effectively blocked the reducing effect of 8-OH-DPAT (30 µg/kg, i.v.) on the voltammetric signal. The receptor subtype(s) mediating inhibitory control of somatodendritic release of 5-HT was then assessed with electrically evoked release of [³H]5-HT from slices of the mesencephalon containing the dorsal and median raphe nuclei. The evoked release of [³H]5-HT was Ca²⁺ dependent. Neither TFMP (1 nM - 1 mM) nor the selective 5-HT_{1B} agonist CP 93,129 (1 nM - 10 µM) affected the evoked release of [³H]5-HT. However, the non-specific 5-HT₁ agonist 5-CT and the 5-HT_{1D} agonist sumatriptan, dose-dependently reduced electrically the evoked release of [³H]5-HT, attaining maximal inhibitions of 80% and 100% respectively, at 1 µM. Mianserin (1 µM) blocked the effects of both agonists. The present results suggest that 5-HT_{1D} receptors locally control extracellular 5-HT concentration in the raphe nuclei and may thus consequently play an important role in controlling 5-HT release in widespread projection areas.

632.2

MODULATORY EFFECT OF 5-HYDROXYTRYPTAMINE (5-HT) ON CRAYFISH NEUROSECRETORY CELLS. F. Sáenz, U. García and H. Aréchiga*. Dept. Fisiología, Biofísica y Neurociencias, CINVESTAV, IPN México and *División de Estudios de Postgrado e Investigación, Facultad de Medicina, UNAM, México

5-Hydroxytryptamine (5-HT) has been shown to influence the release of neurohormones from the crustacean eyestalk (see Fingerman and Nagabushanam, *Comp. Biochem. Physiol.* 71C:195, 1992). Its possible mechanism of action on neurosecretory cells, is largely unexplored. In the present work, 5-HT was applied onto neurosecretory cells in the X-organ of the crayfish eyestalk. The effects were tested in the same population of neurons, both *in situ*, in isolated eyestalks and in cultured cells, taken from the same population. Two effects were found: a) a long-lasting (up to 15 min) dose-dependent (within a range of 1-100 µM) depolarizing response, which could result in the firing of action potentials in previously silent neurons, or in the enhancement of ongoing activity. There was a strong desensitization. This response was blocked by methysergide. b) a long-lasting hyperpolarization, with similar temporal and pharmacological properties to the depolarizing response. Under voltage-clamp, these effects are associated to an outward current with a reversal potential around -90 mV, thus suggesting a potassium channel as the target of 5-HT effects. No differences were found in the responses of X organ cells to 5-HT when tested *in situ* as compared with isolated neurons in culture.

This work was supported by CONACYT grant number 0804-10110.

THE 5-HYDROXYTRYPTAMINE (5-HT)₄ MEDIATED DECREASE IN THE SLOW AFTERHYPERPOLARIZATION IS MODIFIED BY CORTICOSTERONE. S. Bimstiel* and S.G. Beck. Dept. of Pharmacology, Loyola Univ. Med. Ctr., Maywood, IL 60153.

In response to stressful stimuli, corticosterone (CT) production is increased by the hypothalamic-pituitary-adrenal (HPA) axis. One site of feedback regulation is the hippocampus, which contains high densities of both mineralocorticoid (MR) and glucocorticoid (GR) receptors. Basal plasma CT levels occupy the MR; high concentrations of CT activate the MR and the GR, both of which are implicated in the feedback control of the HPA. Activation of 5-HT₄ receptors decreases the slow afterhyperpolarization (sAHP) elicited by a train of action potentials or a calcium spike. To investigate if CT modifies the 5-HT₄ receptor mediated decrease of the sAHP, intracellular recordings of the sAHP following a calcium spike were obtained from the CA1 pyramidal cell layer of transversal hippocampal slices. Male Sprague-Dawley rats were adrenalectomized (ADX) 14 days prior to recording. One ADX group was chronically treated with a CT pellet (12.5 mg) to mimic basal plasma CT levels. Another ADX group was implanted with 300 mg CT to induce chronic stress. Data for concentration-response curves were generated by addition of 5-HT in half log unit decrements (0.1-100 µM). Preliminary results suggest that the EC₅₀ of the 5-HT induced decrease in sAHP amplitude is higher in stressed animals than in ADX animals. When 1 nM CT was added to the superfusion medium of slices from ADX animals, the decrease in AHP amplitude was significantly more pronounced, indicating a short term modulatory role of the MR. The modulatory effects of CT on the 5-HT mediated response may underlie feedback control of the HPA and may influence pyramidal cell excitability. Supported by NS28512 and MH00880.

RECEPTOR RESERVE FOR 5-HT_{1A} RECEPTORS IN RAT BRAIN AS ASSESSED BY NEUROENDOCRINE RESPONSES TO 8-OH-DPAT STIMULATION. W. Pinto*, T. Cabrera, Q. Li, L. Van de Kar and G. Battaglia. Neuroscience Graduate Program and Dept. of Pharmacology, Loyola University of Chicago, Stritch School of Medicine, Maywood, IL 60153.

The present study investigates receptor reserve in female rats with respect to 5-HT_{1A} mediated neuroendocrine responses. While previous studies have reported a large reserve for pre- and postsynaptic 5-HT_{1A} receptors in male rats, 5-HT_{1A} receptor reserve in female rats has yet to be determined. The stimulation of postsynaptic, hypothalamic 5-HT_{1A} receptors with the full agonist 8-OH-DPAT, elicits an increase in several plasma hormones including ACTH and corticosterone. Therefore, neuroendocrine responses to 5-HT_{1A} stimulation can be used as a functional end-point to assess receptor reserve. Female, adult rats (350-400 gms) were administered a single s.c. injection of vehicle (1:1 v/v EtOH/H₂O) or 1 mg/kg EEDQ (N-ethoxycarbonyl-2-ethoxy-1,2-dihydroquinoline), an irreversible receptor inactivator. 24 hours post-treatment, rats were challenged with either vehicle (0.9% saline) or increasing doses (0.05, 0.2 and 0.5 mg/kg s.c.) of 8-OH-DPAT and sacrificed 30 mins later. There was a significant (p < 0.001) reduction (53%) in the Bmax of [³H]-8-OH-DPAT labeled hypothalamic 5-HT_{1A} receptors in EEDQ-treated rats, with no alteration in K_D. In non-EEDQ treated rats, 8-OH-DPAT elicited a significant (p < 0.001) dose-dependent elevation of plasma ACTH (8.4 fold at highest dose) and corticosterone (3.7 fold at highest dose). Following receptor inactivation by EEDQ, there was no significant difference in the maximal ACTH (868.3 ± 148 vs 1025 ± 188 pg/ml) or corticosterone (43.4 ± 6.3 vs 50.5 ± 8.8 µg/dl) elevation elicited by 8-OH-DPAT. These data provide evidence for a large receptor reserve (at least 53%) for hypothalamic 5-HT_{1A} receptors mediating the elevation of plasma ACTH and corticosterone levels in female rats. MODULATION OF RAT NEOCORTICAL HIGH-VOLTAGE SPINDLE ACTIVITY BY SEROTONIN RECEPTOR SUBTYPE SPECIFIC DRUGS. P. Jäkälä, J. Sirviö, J. Kaukua, E. Koivisto, M. Björklund, L. Yavich, P. Riekkinen Sr. and P. Riekkinen Jr. Dept. of Neurology, Univ. of Kuopio, P.O.B. 1627, SF-70211 Kuopio, Finland. Fax: 358-71-162048.

The present experiments investigated the role of serotonergic (5-hydroxytryptamine, 5-HT) receptors in the modulation of rat neocortical high-voltage spindle activity. We administered different 5-HT₁/5-HT₂ receptor subtype specific drugs singly or in combination either systemically or via cannulae that were implanted unilaterally to the ventromedial thalamus, and measured neocortical high-voltage spindle activity of adult rats by IBM software. A mixed 5-HT₁/5-HT₂ receptor antagonist, methiothepine (i.p.), significantly increased neocortical high-voltage spindle activity, whereas another mixed 5-HT₁/5-HT₂ receptor antagonist, methysergide (i.p.), had no effect. A 5-HT_{2A}/5-HT_{2C} receptor agonist, 1-(2,5-dimethoxy-4-iodophenyl)-2-aminopropane (DOI) (s.c.), significantly decreased neocortical high-voltage spindle activity, and systemic methiothepine and specific 5-HT_{2A}/5-HT_{2C} receptor antagonists ketanserin (s.c.) and ritanserin (s.c.) blocked this effect. Furthermore, intrathalamic infusions of DOI dose-dependently decreased neocortical high-voltage spindle activity and systemic ketanserin completely blocked this effect. The results suggest that 1) the serotonergic system may via 5-HT_{2A}/5-HT_{2C} receptors modulate rat thalamocortical arousal as assessed by neocortical high-voltage spindle activity, 2) 5-HT_{2A}/5-HT_{2C} receptor agonists may decrease neocortical high-voltage spindle activity, and 5-HT_{2A}/5-HT_{2C} receptor antagonists may block this effect, 3) the effects of 5-HT_{2A}/5-HT_{2C} receptor subtype specific drugs on rat neocortical high-voltage spindle activity may be at least partly mediated at the thalamic level, suggesting that activation of thalamic 5-HT_{2A}/5-HT_{2C} receptors may increase the efficacy of transfer of information through the thalamus to the cortex.

632.7

TOLERANCE AND CROSS-TOLERANCE OF HALLUCINOGENS: ELECTROPHYSIOLOGICAL AND BIOCHEMICAL STUDIES. R.Y. Wang*, E. Edwards and J.Y. Zhang. Dept. Psychiatry (R.Y.W. and J.Y.Z.), SUNY at Stony Brook, Stony Brook, NY 11794-8790 and Dept. Pharmacol. (E.E.), Univ. Maryland at Baltimore, Baltimore, MD 21201-1180.

We have previously shown that local bilateral injection of hallucinogens d-LSD and (-)-DOB, but not non-hallucinogenic congeners lisuride and BL 3912A, into the medial prefrontal cortex (mPFC) elicited the head twitching response (HTR). This HTR was prevented by the selective 5-HT_{2A} receptor antagonists. It was proposed that 5-HT_{2A} receptors in the mPFC could play an important role in mediating the action of hallucinogens. Ionophoresis of low currents of (-)-DOB, and to a lesser extent d-LSD, markedly potentiated glutamate-induced activation of the firing of mPFC cells. The aim of the present study was to decide whether pretreatment with mianserin or subacute treatment of d-LSD, which is known to down-regulate the 5-HT_{2A} receptors in the frontal cortex, would induce the development desensitization of mPFC cells to d-LSD and (-)-DOB. Groups of rats were treated with d-LSD (2 mg/kg/day, i.p. for 5 days; experiments began 24 hr after the last injection), mianserin (10 mg/kg, i.p. 48 - 72 hr prior to experiment), and saline (1 µl/kg, i.p. either for 1 or 5 days), respectively. Compared to cells in the saline group, mPFC cells in rats pretreated with either d-LSD or mianserin became subsensitive to both d-LSD and (-)-DOB. Furthermore, in these drug pretreated rats, both d-LSD and (-)-DOB became less effective in stimulating the phosphoinositide hydrolysis in the mPFC. In conclusion, our results suggest that hallucinogen-induced tolerance and cross-tolerance may be accounted for, at least partly, by the functional desensitization of mPFC 5-HT_{2A} receptors at the cellular level. (Supported by USPHS grants MH-41440 and DA-07193).

FUNCTIONAL EVIDENCE FOR THE DIFFERENTIAL RESPONSIVENESS OF PRE- AND POSTSYNAPTIC 5-HT_{1A} RECEPTORS IN THE RAT BRAIN. P. Blier*, B. Seletti, C. Bouchard, F. Artigas and C. de Montigny. Neurobiological Psychiatry Unit, McGill Univ., Montreal, Canada H3A 1A1.

Several groups have documented the capacity of (±)pindolol to antagonize the hypothermic effect of 5-HT_{1A} agonists, including that of 8-OH-DPAT, whereas the increase in prolactin produced by the latter 5-HT_{1A} agonist is not blocked by similar doses of (±)pindolol (*Eur. J. Pharmacol.* 146: 253, 1988). In a first series of experiments, the effectiveness of pindolol to block presynaptic 5-HT_{1A} autoreceptors was examined by assessing the firing activity of dorsal raphe 5-HT neurons in rats treated for 2 days with the 5-HT reuptake blocker paroxetine (10 mg/kg/day, s.c.) alone or together with (±)pindolol (10 mg/kg/day, s.c.), both drugs being delivered by an osmotic minipump. The firing rate of 5-HT neurons under chloral hydrate anesthesia was decreased by about 75% in both groups. However, the firing rate of 5-HT neurons was within the control range in rats treated with paroxetine and 15 mg/kg/day of (-)pindolol (which is the enantiomer with 5-HT_{1A} affinity) for 2 days. In keeping with the latter observations, the suppressant effect of the 5-HT autoreceptor agonist LSD on the firing of 5-HT neurons was markedly attenuated. In a second series, the prolactin increase produced by 8-OH-DPAT (100 µg/kg, s.c.) was also prevented by (-)pindolol (15 mg/kg, i.p.) given 30 min prior to 8-OH-DPAT. The inhibitory effect of iontophoretic applications of 5-HT and 8-OH-DPAT on the firing rate of hippocampal CA₃ pyramidal neurons was however unaltered in rats treated with (-)pindolol (15 mg/kg/day X 2 days). These data indicate that a high dose of (-)pindolol can block the presynaptic 5-HT_{1A} receptor modulating 5-HT neuronal firing activity and the postsynaptic 5-HT_{1A} receptor controlling prolactin release, but not the postsynaptic 5-HT_{1A} receptor coupled to K⁺ channels in the hippocampus.

632.6

EFFECTS OF 5-HT ON NMDA AND NON-NMDA RECEPTOR-MEDIATED RESPONSES IN TRIGEMINAL MOTONEURONS. P.R. Trueblood*, S.H. Chandler, M.S. Levine. Department of Physiological Science and Mental Retardation Research Center, UCLA, Los Angeles, CA 90024.

Previously, we demonstrated that 5-HT potentiated both the NMDA and non-NMDA mediated EPSP evoked by Mesencephalic V stimulation in trigeminal motoneurons using an in-vitro preparation of the brainstem from guinea pigs. To further examine the mechanism by which 5-HT facilitates excitatory amino acid responses in trigeminal motoneurons, we tested the effects of .5-20 µM bath application of 5-HT to NMDA (200mM) and AMPA (5 mM) iontophoretic responses. In current clamp mode, 5-HT significantly potentiated both the NMDA and AMPA response in a dose-dependent manner. Selective agonists and antagonists were used to show that this potentiation resulted from activation of 5-HT_{2/1C} receptors. Furthermore, using voltage clamp technique, 5-HT enhanced both the NMDA and AMPA current, suggesting that 5-HT has a direct modulatory role to these receptors, in addition to a potentiating effect to the intrinsic properties of trigeminal motoneurons. Therefore, 5-HT may function to facilitate the afferent input to trigeminal motoneurons by potentiation of both NMDA and non-NMDA receptor-mediated synaptic processes. Supported by NIH grants DE06193 and DE07212.

632.8

A POSSIBLE ROLE OF 5-HT₂ RECEPTORS FOR SYNAPSE FORMATION. N. Okado*, Y. Niitsu, and S. Hamada. Lab. of Neurobiol., Dept. Anat., Inst. Basic Med. Sci., Univ. Tsukuba, Tsukuba, Ibaraki 305, Japan.

Serotonin appears to enhance formation and maintenance of synapses in developing as well as adult brain and spinal cord (*J. Neurobiol.* Vol. 24; *Neurosci. Res.* Vol. 19). The present study was undertaken to clarify the specific receptor subtype involved in synapse formation. One of serotonin antagonists specific to each serotonin receptor subtype was daily injected in eggs between embryonic day (E)11 and E17. Embryos were deeply anesthetized and perfused on E18. The density of axosomatic synapses on motoneurons in the lateral motor column of lumbar spinal cord was calculated from electron micrographs. Following injections of 5 mg (N=4) and 50 mg (N=4)/kg weight of ketanserin the synaptic density decreased by 15 % (P<0.03) and 40 % (P<0.0002) compared to that of control animals (N=4), respectively. Although further studies are necessary to conclude 5-HT₂ receptors are involved in facilitation of formation and maintenance of synapses, the result of present study may explain synaptic loss and reduction of 5-HT₂ receptors in the aged and Alzheimer brain.

632.10

REGULATION OF BASAL FOREBRAIN MONOAMINE SYNTHESIS BY 5-HT RECEPTORS IN THE RAT SUBSTANTIA NIGRA PARS RETICULATA (SNr) AND VENTRAL TEGMENTAL AREA (VTA). S.Ahlenius¹*, V.Hillegaars¹ and O.Magnusson². Departments of Behavioral Pharmacology¹ and Neuropsychopharmacology², Astra Arcus AB, S-151 85 Södertälje, Sweden.

The 5-HT_{1A} receptor agonist 8-OH-DPAT (0.5 µg), or 5-HT (0.40 µg), was infused into the SNr or into the VTA in awake, gently hand-restrained male Wistar rats, at a rate of 0.33 µL min⁻¹ to a final volume of 0.5 µL. Upon completion of the infusion, the animals received an injection of the cerebral decarboxylase inhibitor NSD-1015 (100 mg kg⁻¹ IP) and were decapitated for brain dissections 30 min later (medial prefrontal cortex, d-l neostriatum, nucleus accumbens, olfactory tubercle and amygdala). The *in vivo* rate of forebrain 5-HT and DA synthesis was estimated by measuring the accumulation of 5-HTP and DOPA (n=3-5). Stimulation of 5-HT_{1A} receptors by 8-OH-DPAT in either SNr or the VTA produced a dose-dependent, and statistically significant, decrease in forebrain 5-HT synthesis, whereas DA synthesis was only decreased in the prefrontal cortex and amygdala and only after a VTA infusion. In sharp contrast, a 5-HT infusion into the SNr or the VTA did not affect forebrain 5-HT synthesis. However, there was a marked increase in the DA synthesis of the neostriatum after SNr application, and to a lesser extent also after VTA infusion. It is suggested that 5-HT_{1B} receptors on midbrain DA somata and/or dendrites exert an inhibitory control of firing and release in dopaminergic neurons. The effects of 8-OH-DPAT demonstrate an important role of 5-HT_{1A} receptors in the SNr and VTA for the regulation of forebrain 5-HT synthesis. 5-HT_{1A} receptors in the VTA were also found to selectively affect DA synthesis in meso-cortical dopaminergic projections.

EFFECTS OF BUSPIRONE ON 5-HT TURNOVER IN DIABETIC AND NONDIABETIC RATS L.L. Bellush* and A.M. Wright. Dept. of Psychology, Ohio University, Athens, OH 45701.

Diabetic (D) rats have reduced 5-HT turnover throughout the brain. They also show attenuated hypothermia to the 5-HT_{1A} agonist 8-OHDPAT, as well as enhanced response to stress and greater anxiety, both of which could reflect altered 5-HT functioning. However, anxiolytic effects of the 5-HT_{1A} partial agonist buspirone (BUSP) did not differ in D and nondiabetic (N) rats, and anxiolysis was greater after chronic BUSP. Here we measured 5-HT turnover in brainstem, midbrain, hippocampus and hypothalamus after single BUSP injections or after two weeks of daily treatment. BUSP had no effect on 5-HT turnover 20 min after acute treatment BUSP (0.1 mg/kg) in either D or N. BUSP did not affect light/dark emergence either, although D were more anxious than N, as well as having lower 5-HT turnover. BUSP (0.1, 0.6 and 1.2 mg/kg) reduced 5-HT turnover in all 4 regions of N rats 30 min after drug treatment. Here, the lower doses tended to reduce anxiety, while the high dose was anxiolytic. Assessment of 5-HT turnover after chronic BUSP 0.1 and 0.6 mg/kg in D and N is now being completed.

632.13

5-HT_{1A} ANTAGONISTS AND TERMINAL 5-HT RELEASE. EFFECTS OF THE COMBINED TREATMENT WITH 5-HT UPTAKE INHIBITORS. E. Artigas*, L. Romero, P. Celada and N. Bel. Dept. of Neurochemistry, C.S.I.C. Barcelona, Spain

Antidepressant drugs of different types increase extracellular 5-HT in the raphe nuclei of the midbrain. As a result, somatodendritic autoreceptors are activated and terminal release decreases. Thus, the local infusion of 50 μ M citalopram (CIT, a 5-HT uptake inhibitor) into the dorsal raphe nucleus (DRN) reduced *in vivo* release of 5-HT in striatum of the same animals by ~47%. Pretreatment with (-) pindolol (15 mg/kg i.p.) or (-) tertatolol (10 mg/kg i.p.) totally abolished intra-DRN effects of CIT, indicating that these reductions were mediated by 5-HT_{1A} autoreceptors. Lower doses of (-) pindolol (5 and 10 mg/kg, i.p.) induced a partial antagonism. In contrast, (+) WAY 100135 at a dose (10 mg/kg, i.p.) that antagonized the effects of 8-OH-DPAT (0.1 mg/kg, s.c.) on striatal release, was unable to prevent the CIT-induced reduction. These results indicate that the effects of 5-HT on somatodendritic 5-HT_{1A} autoreceptors are antagonized by (-) pindolol and (-) tertatolol, but not by (+) WAY 100135. The previous (1-3 days before) intra-DRN injection of pertussis toxin also prevented the effects of CIT on striatal 5-HT release. This further supports the role of 5-HT_{1A} autoreceptors in the attenuation of terminal 5-HT release elicited by 5-HT uptake inhibitors. In agreement, the combined treatment with (-) pindolol and 5-HT uptake inhibitors (paroxetine, citalopram, fluoxetine) increased terminal 5-HT release to a greater extent than the 5-HT uptake inhibitors alone (e.g., (-) pindolol + 1 mg/kg CIT elevated striatal 5-HT release by +600% whereas the increase produced by 1 mg/kg CIT was +150%). Thus, blockade of somatodendritic 5-HT_{1A} receptors may be a new way to potentiate the effects of low doses of 5-HT uptake inhibitors, in agreement with recent clinical data (Artigas et al., *Arch. Gen. Psychiatry* 51:248-251, 1994) (Supported by FIS grant 92/268)

632.15

ESTRADIOL ENHANCES THE BRADYCARDIA ELICITED BY THE CENTRAL ADMINISTRATION OF THE 5-HT_{1A} AGONIST 8-OH-DPAT. R.H. Alper* and T.M. Schmitz. Department of Pharmacology, The University of Kansas Medical Center, Kansas City, KS 66160-7417.

Activation of central 5-HT_{1A} receptors by the selective agonist 8-OH-DPAT decreases blood pressure (BP) and heart rate (HR). This study was to determine if the steroid hormone estradiol (E₂) modulates the cardiovascular responses elicited by 8-OH-DPAT when administered into the lateral cerebral ventricle (icv). Experiments were performed in conscious, freely-moving rats implanted chronically with a guide cannula for icv drug infusions and an arterial catheter to monitor BP and HR. 8-OH-DPAT (100 nmoles, icv) decreased BP similarly in male and ovariectomized female (OVX) rats. There was a tendency for a greater bradycardia in the OVX rats, but this did not attain statistical significance. The experiment was repeated to include OVX rats implanted subcutaneously with time-release pellets containing E₂ (0.1 mg/21 day pellet). The BP response to 8-OH-DPAT was the same in all 3 groups: male, OVX and OVX + E₂. By contrast, 8-OH-DPAT produced a greater bradycardia in the OVX + E₂ group when compared to either male or OVX rats; OVX again tended to be greater than male. In the final experiment, graded doses of 8-OH-DPAT (3 - 100 nmoles, icv) were administered to OVX and OVX + E₂ rats. The hypotensive effect produced by 8-OH-DPAT was not altered by hormone treatment, but the bradycardia was greater across doses in the E₂-treated rats. In summary, the cardiovascular responses elicited by 8-OH-DPAT were not significantly different between male and OVX rats. However, E₂ enhanced the bradycardia, but not the hypotension, elicited by 8-OH-DPAT, suggesting that estrogen modulates some, but not all, functional responses produced by central 5-HT_{1A} receptor activation. [Supported by NIH Grant NS 29765]

632.12

SEROTONERGIC FIBERS ARE NOT DEVELOPED IN THE TRANSPLANTED HIPPOCAMPAL TISSUE OF THE S-100 β RETARDED MUTANT MOUSE.

S.Ueda*, P.M. Whitaker-Azmitia, E.C. Azmitia and M. Kawata. Dep. of Anatomy, Kyoto Pref. Univ. of Med., Kyoto 602, Japan, Dep. of Psychiatry, SUNY at Stony Brook, NY 11794, and Dep. of Biology, NYU, NY 10003, USA.

Our previous study (Ueda et al. 1994 Brain Res. 633:275-283) has demonstrated that the hippocampus of the homozygote of polydactyly mutant mouse (Polydactyly Nagoya, Pdn/Pdn) was markedly reduced in both S-100 β positive astrocytes and serotonergic fibers as compared to the heterozygote (Pdn/+) and wild type (+/+). Since the Pdn/Pdn mice die within 2 days after birth, it is impossible to examine postnatal changes in development. To demonstrate the developmental change of Pdn/Pdn hippocampal tissue, hippocampal pieces of neonatal Pdn/Pdn and +/+ mice were transplanted into the right and left sides hippocampus of the same adult ICR mice, respectively, and immunocytochemistry was performed. Two weeks after transplantation, +/+ hippocampal tissue contained a large number of GFAP and S-100 β positive astrocytes and a small number of serotonergic fibers. Pdn/Pdn hippocampal tissue contained numerous GFAP positive astrocytes, while S-100 β positive astrocytes and serotonergic fibers were not observed. Two months after transplantation, GFAP and S-100 β were expressed in the Pdn/Pdn hippocampal tissue similar to the +/+ tissue. Serotonergic fibers were distributed in the +/+ tissue, whereas few serotonergic fibers were observed in the Pdn/Pdn transplant tissue. On the contrary no difference was observed in the tyrosine hydroxylase positive fibers between Pdn/Pdn and +/+ graft.

632.14

5-HT₄ RECEPTOR STIMULATION FACILITATES THE *IN VIVO* RELEASE OF ACETYLCHOLINE IN RAT FRONTAL CORTEX. H. Ladinsky*, S. Arnaboldi¹, G. Russi¹, G.B. Schiavi and S. Consolo¹. Department of Biochemistry and Molecular Pharmacology, Boehringer Ingelheim Italia, Milan 20139 and ¹Laboratory of Neuropharmacology, Istituto di Ricerche Farmacologiche "Mario Negri", Milan 20157 Italy.

The effect of the serotonergic 5-HT₄ receptor agonists BIMU 1 and BIMU 8 on the *in vivo* release of ACh in brain hemispheric regions of freely moving rats was investigated using the microdialysis technique. Both agonists, applied intracerebroventricularly, facilitated ACh release selectively in the frontal cortex at doses of 30-100 nmol. The agonists were ineffective in striatum, despite the high density of 5-HT₄ receptors in this region. BIMU 1, 60 nmol i.c.v., produced a significant decrease in ACh release in the dorsal hippocampus. The facilitatory effect of BIMU 1 (40 nmol, i.c.v.) in frontal cortex was prevented by the highly selective and potent 5-HT₄ receptor antagonists GR 125487 (10 and 20 nmol, i.c.v.) and GR 113808 (15 nmol, i.c.v.), which by themselves did not alter basal ACh release. The results provide evidence that serotonin facilitates ACh release in frontal cortex through stimulation of 5-HT₄ receptors that are not tonically activated. Assuming that ACh plays a role in cognitive processes, this facilitation supports the theory that 5-HT₄ sites are important in the control of learning and memory. 5-HT₄ receptor activation might thus offer a novel means of boosting central cholinergic function to overcome the cholinergic deficit in memory disorders. Financed in part by CNR, Rome, Convenzione Psicofarmacologia (S.C.).

633.1

CHARACTERIZATION OF [³H]8-OH-DPAT BINDING TO HUMAN CEREBRAL CORTEX. E.K. Nénonéné* and T.A. Reader. Centre de Recherche en Sciences Neurologiques, Département de physiologie, Faculté de médecine, Université de Montréal (Québec) CANADA H3C 3J7.

A series of saturation and competition experiments were conducted with the selective serotonin (5-HT) agonist [³H]8-OH-DPAT to investigate the properties of the 5-HT_{1A} receptors from the temporal region of human cerebral cortex. The binding parameters of the saturation curves were best fitted to a two-site model, thus giving two dissociation constants, i.e.: K_H and K_L of 1.22 nM ± 0.30 and of 12.63 ± 1.54 for the high- and the low-affinity binding sites, respectively. Using a 1 nM concentration of the radioligand, the pharmacological profile of the 5-HT_{1A} receptors from human cerebral cortex was studied by competitions with 5-HT and the specific agonists 8-OH-DPAT and buspirone, as well as with the antagonists pindolol, NAN-190, and WAY 100148. In all cases, both the agonists and the antagonists competed with [³H]8-OH-DPAT binding in a biphasic manner, revealing high- and a low-affinity sites. The competition curves with these drugs gave two inhibition constants (K_i) of nanomolar and micromolar values, respectively. Furthermore, kinetic experiments carried out at 1 or 10 nM concentrations of [³H]8-OH-DPAT showed that the equilibrium was reached after 30-45 min incubation at 25°C. Even though the association curves were best fitted to a one-site model, two dissociation rate constants could be documented. It can be concluded from these observations that, as was the case for the rat cortex (Nénonéné et al. 1994; *J. Neurochem.* 62, N° 5), human cerebral cortex also contains two different and heterogeneous populations of 5HT_{1A} receptors. [Supported by the Réseau de Recherche en Santé Mentale FRSQ / Université de Montréal].

633.3

CHARACTERIZATION OF AGONIST AND ANTAGONIST RADIO-LIGANDS AT 5-HT_{1A} RECEPTORS. K.D. Burris*, H.A. Miller, J.G. Hensler, M.-P. Kung, H.F. Kung and P.B. Molinoff. Depts. of Pharmacology and Radiology, Univ. of Pennsylvania, Phila., PA 19104.

CHO cells expressing transfected 5-HT_{1A} receptors (CHO-5HT_{1A} cells) were used to characterize iodinated radioligands. An iodinated derivative of 8-OH-DPAT, 8-hydroxy-2-[N-propyl-N-(3'-iodo-2'-propenyl)amino]tetralin (8-OH-PIPAT), inhibited forskolin-stimulated cAMP accumulation in CHO-5HT_{1A} cells. Furthermore, [¹²⁵I]R(+)-8-OH-PIPAT bound with high affinity (K_d = 0.1 nM) to 5-HT_{1A} receptors on membranes prepared from CHO-5HT_{1A} cells. An iodinated derivative of the putative 5-HT_{1A} receptor antagonist, WAY100635, was examined for its ability to block 5-HT_{1A} receptor activation. 4-(2'-Methoxy-phenyl)-1-[2'-(n-2"-pyridinyl)-p-iodobenzamido]-ethyl-piperazine (p-MPPI) blocked the decrease in forskolin-stimulated cAMP accumulation produced by 8-OH-DPAT in CHO-5HT_{1A} cells. [¹²⁵I]p-MPPI bound with high affinity (K_d = 0.4 nM) to 5-HT_{1A} receptors. [¹²⁵I]R(+)-8-OH-PIPAT labeled approximately 70% as many receptors as were labeled with [¹²⁵I]p-MPPI. Specific binding of [¹²⁵I]R(+)-8-OH-PIPAT was inhibited by Gpp[NH]p, whereas the binding of [¹²⁵I]p-MPPI was not affected by the addition of Gpp[NH]p. The agonists 8-OH-DPAT and 5-HT bound with approximately 40-fold greater affinity to receptors labeled with [¹²⁵I]R(+)-8-OH-PIPAT than to receptors labeled with [¹²⁵I]p-MPPI (in the presence of Gpp[NH]p). In contrast, spiperone, an antagonist at 5-HT_{1A} receptors, bound with nearly 10-fold lower affinity to receptors labeled with [¹²⁵I]R(+)-8-OH-PIPAT than to receptors labeled with [¹²⁵I]p-MPPI. [¹²⁵I]R(+)-8-OH-PIPAT and [¹²⁵I]p-MPPI should prove useful in further studies of the properties and regulation of 5-HT_{1A} receptors. (Supported by USPHS grants NS18591, NS09245, NS24538, MH48125)

THE 5-HT_{1A} ANTAGONIST 4-(2'-METHOXY)-PHENYL-1-[2'-(N-2"-PYRIDINYL)-p-IODOBENZAMIDO]-ETHYL-PIPERAZINE (p-MPPI) COMPETITIVELY ANTAGONIZES 5-HT_{1A} RECEPTOR ACTIVATION IN VIVO. R.J. Thielen* & A. Frazer. Dept. of Pharmacol., UTHSCSA and Vet. Affairs Med. Ctr., San Antonio, TX 78284.

Until recently, selective 5-HT_{1A} receptor antagonists were unavailable, in that the available antagonists either lacked selectivity for the 5-HT_{1A} receptor or were shown to have partial agonist activity. We report that p-MPPI (Zhuang et al., *J. Med. Chem.*, in press), competitively antagonizes 5-HT_{1A} receptor activation in the rat, as measured by hypothermia and forepaw treading. Further, on these parameters, p-MPPI exhibits no partial agonist activity. p-MPPI (1-10 mg/kg, ip) dose-dependently antagonized the hypothermia induced by a fixed dose of 8-hydroxy-2-(di-n-propylamino)tetralin (8-OH-DPAT) (0.5 mg/kg, sc), with an IC₅₀ of 5.7 mg/kg. Further, the inhibitory effect caused by a fixed dose of p-MPPI (6 mg/kg) was competitively antagonized by higher doses of 8-OH-DPAT. p-MPPI (10 mg/kg, ip) also attenuated the hypothermia induced by gepirone (10 mg/kg, sc). Forepaw treading caused by 8-OH-DPAT (2 mg/kg, sc) in reserpine-pretreated rats (1 mg/kg, sc, 18-24 hours prior to the experiment) was dose-dependently antagonized by p-MPPI (2.5-10 mg/kg, ip), with an IC₅₀ of 3.3 mg/kg. p-MPPI also antagonized forepaw treading induced by 5-methoxy-N,N-dimethyltryptamine (5-MeODMT) (5 mg/kg, sc) in reserpine-pretreated rats, and this antagonism was competitively overcome by higher doses of 5-MeODMT. These results suggest that p-MPPI is a competitive antagonist at 5-HT_{1A} receptors mediating these responses and does not have intrinsic activity at these receptors; however, these data do not rule out the possibility that p-MPPI may show intrinsic activity in other tests of 5-HT_{1A} receptor activation. (Supported by Research Funds from the VA and USPHS Grant MH48125).

633.2

A NEW 5-HT_{1A} RECEPTOR ANTAGONIST: MPPI. M.-P. Kung*, Z.-P. Zhuang, D. Frederick, M. Mu and H.F. Kung. Departments of Radiology and Pharmacology, University of Pennsylvania, Philadelphia, PA 19104.

Previously, a new radiiodinated agonist, [I-125]8-OH-PIPAT, for 5-HT_{1A} receptors, was reported (Kung et al., *Neuroscience Abs.*, 1993). In developing antagonists for 5-HT_{1A} receptors, we have recently prepared several iodinated derivatives of the phenylpiperazine (Zhuang et al., *J. Med. Chem.*, in press). Among them, MPPI (4-(2'-methoxy-phenyl)-1-[2'-(n-2"-pyridinyl)-p-iodobenzamido]-ethyl-piperazine) displayed high binding affinity for 5-HT_{1A} receptors (K_i=1.0 nM, rat hippocampal homogenates). Low to moderate binding affinity of MPPI to D₂, α₁, α₂, β and 5-HT₂ was observed with K_i values of 19, 35, 181, 740 and 270 nM, respectively. Saturation binding studies in rat hippocampal homogenates revealed that [I-125]MPPI bound to a single population of affinity sites with a K_d of 0.18 nM (no MgCl₂) and a B_{max} of 320 fmol/mg protein. In parallel studies, the density of sites labeled with [I-125]MPPI was 30-40% higher than that with [I-125]8-OH-PIPAT. Guanylyl nucleotides did not affect the specific binding of [I-125]MPPI, but significantly inhibited the specific binding of the radiiodinated agonist, [I-125]8-OH-PIPAT. In addition, Mg²⁺ ion showed an inhibitory effect on MPPI binding, in contrast to the stimulatory effect observed for the agonist ligand, 8-OH-PIPAT. Both agonists and antagonists inhibited [I-125]MPPI binding with K_i values consistent with pharmacological profile of binding to 5-HT_{1A} receptors. Autoradiographic studies with [I-125]MPPI in rat brain sections further illustrated the anatomical distribution of 5-HT_{1A} sites. In summary, [I-125]MPPI displayed antagonist-like binding properties with high affinity and selectivity for 5-HT_{1A} receptors. In combination with the potential radiiodinated agonist, [I-125]8-OH-PIPAT, they may provide powerful tools for studies of the pharmacology of the 5-HT_{1A} receptor system. Acknowledgment: support from PHS (NS-24538 and MH-48125).

633.4

EVALUATION OF 4-(2'-methoxy-phenyl)-1-[2'-(n-2"-pyridinyl)-p-iodobenzamido]-ethyl-piperazine (p-MPPI) FOR ANTAGONIST ACTIVITY AT 5-HT_{1A} RECEPTORS. A.R. Allen*, A. Singh, H.F. Kung, M. Kung and I. Lucki. Departments of Psychiatry, Pharmacology and Radiology, University of Pennsylvania, Philadelphia, PA 19104.

The lack of selective 5-HT_{1A} receptor antagonists has hampered study of the functional role of these receptors. A candidate for such an antagonist, p-MPPI, is a structural analog of WAY-100,135 that binds with high affinity to 5-HT_{1A} receptors (K_d=0.3 nM). p-MPPI was tested for its ability to antagonize the effects of the 5-HT_{1A} receptor agonist 8-OH-DPAT on two responses mediated by postsynaptic 5-HT_{1A} receptors, the 5-HT syndrome and hypothermia. Male Sprague-Dawley rats were pretreated with p-MPPI (3-30 mg/kg, s.c.) 15 min prior to 8-OH-DPAT injection (1 or 2 mg/kg in the hypothermia and 5-HT syndrome studies, respectively). p-MPPI dose-dependently prevented the full 5-HT syndrome (ie, the production of four out of the six component behaviors) induced by 8-OH-DPAT. However, p-MPPI did not prevent two of these behaviors, flat body posture or hindlimb abduction. p-MPPI did not produce any of the behavioral symptoms when given alone. In rats pretreated with reserpine (1 mg/kg, 18 hours), p-MPPI (30 mg/kg) also blocked the 5-HT syndrome without producing any symptoms when given alone. p-MPPI did not produce changes in body temperature when given alone, but may only partially antagonize the hypothermic effect produced by 8-OH-DPAT. These results demonstrate that p-MPPI has antagonist properties and is devoid of any intrinsic efficacy at 5-HT_{1A} postsynaptic receptors. Studies are currently underway to examine whether p-MPPI is an effective antagonist at presynaptic 5-HT_{1A} receptors by examining the effects of p-MPPI, given alone and in combination with 8-OH-DPAT, on extracellular levels of 5-HT using *in vivo* microdialysis. This research was supported by USPHS grants MH 14654, MH 36262 and MH 48125.

633.6

LY206130, A CYCLOHEXYL ANALOG OF PINDOLOL, AN ANTAGONIST OF 5-HT_{1A} RECEPTOR. D. T. Wong*, D. N. Mayle, N. W. Delapp, D. O. Calligaro, D. W. Robertson, Lilly Research Laboratories, Eli Lilly and Co., Indianapolis, IN 46286;

The beta-adrenergic blocking drug, pindolol, is also an antagonist to 5-HT_{1A} receptor. Replacement of the N-iso-propyl in pindolol by a N-cyclohexyl as in LY206130, increases the affinity for 5-HT_{1A} receptor 5 times and decreases affinity for beta-adrenergic receptor 6 times as indicated by the concentrations to inhibit 50% binding of ³H-8-OHDPAT (IC₅₀ of 17.4 and 3.4 nM) and ³H-dihydroalprenolol (IC₅₀ of 3.8 and 23 nM), respectively. LY206130 has near micromolar affinities for other receptors. At 1-1000 nM, LY206130 antagonized the agonist, 8-OHDPAT (1 μM), induced inhibition of the forskolin stimulated adenylate cyclase of rat hippocampus, while up to 10 μM LY206130 alone had no effect. 8-OHDPAT at 1 mg/kg s.c. significantly lowered 5-hydroxyindoleacetic acid (5-HIAA) levels in hypothalamus, hippocampus and cerebral cortex. LY206130 at 1 and 3 mg/kg s.c. antagonized the decrease of 5-HIAA in hypothalamus and cortex and at 1 mg/kg s.c. attenuated the hyperphagia induced by 8-OHDPAT. Thus, LY206130 has a pharmacological profile of an antagonist of the postsynaptic 5-HT_{1A} receptor in projected areas and the 5-HT_{1A} autoreceptors in cell bodies of 5-HT neurons.

633.7

THE 5-HT₂ ANTAGONISTS, KETANSERIN AND RITANSERIN, DISCRIMINATE BETWEEN RECOMBINANT HUMAN 5-HT_{1D} AND 5-HT_{1D} RECEPTOR SUBTYPES: IDENTIFICATION OF "SELECTIVE" 5-HT_{1D} ANTAGONISTS. J.M. Zgombick*, L.E. Schechter, S. Kucharewicz, R.L. Weinshank, P.R. Hartig and T.A. Branchek. Synaptic Pharmaceutical Corporation, 215 College Road, Paramus, NJ 07652.

Molecular cloning has demonstrated that the 5-HT_{1D} subfamily is comprised of two closely related subtypes termed 5-HT_{1D} and 5-HT_{1D}. These receptors display a high transmembrane homology (~75%) which contribute to their similar pharmacological profiles. The classical 5-HT₂ antagonists, ketanserin and ritanserin, displayed moderate affinity (K_i = 50-75 nM) and marked selectivity (25-70-fold) for the cloned human 5-HT_{1D} subtype relative to the 5-HT_{1D} receptor. In contrast, the nonselective 5-HT_{1/2} antagonist, methiothepin, exhibited similar affinities (K_i = 10-20 nM) for both 5-HT_{1D} subtypes. These three compounds were evaluated for their ability to antagonize sumatriptan-induced inhibition of forskolin-stimulated cAMP accumulation in stable cell lines expressing the 5-HT_{1D} or 5-HT_{1D} gene. All three compounds behaved as competitive antagonists devoid of intrinsic activity in the functional assays. The apparent K_i values measured in the functional assays closely matched their K_i values obtained in binding assays. The development of selective 5-HT_{1D} antagonists, devoid of crossreactivities at other biogenic amine subtypes (i.e. 5-HT₂, α_1 -adrenergic), will allow for evaluation of 5-HT_{1D} receptor function in intact animals and isolated tissue preparations.

633.9

[³H]BMS-181101: A NOVEL HIGH AFFINITY 5-HT_{1D} AGONIST RADIOLIGAND. H.P. Nowak*, D.D. Dischino, L.G. Jben, E.D. Yocca and C.D. Mahle. CNS Drug Discovery and Central Chemistry, Bristol-Myers Squibb Co., Wallingford, CT 06492.

Binding sites displaying high (5-HT_{1D}) and low (5-HT_{1E}) affinity for 5-carboxamidotryptamine have been described using [³H]5-HT and selectively masking 5-HT_{1A} and 5-HT_{1C} receptors. Utilizing [³H]5-HT (0.5 nM) as the radioligand eliminated binding to the 5-HT_{1E} sites. However, potent 5-HT_{1D} agonist compounds such as sumatriptan and BMS-181101 (a novel antidepressant candidate) continued to produce a regionally distinct biphasic displacement (K_H=20 nM, 2 nM and K_L=1 μ M, 10 μ M, sumatriptan and BMS-181101, respectively), suggesting a heterogeneous population of 5-HT_{1D}-like sites radiolabeled by [³H]5-HT in certain mammalian brain regions. In bovine substantia nigra, both sumatriptan and BMS-181101 produced monophasic displacement of [³H]5-HT binding. Therefore, this tissue was utilized initially to characterize the binding of [³H]BMS-181101 to 5-HT_{1D} binding sites. In bovine substantia nigra membrane homogenates, [³H]BMS-181101 binding was rapid, reversible and saturable, displaying high affinity (K_d=1 nM) and low non-specific binding. Pharmacologically, affinity values revealed the following rank order of potency: 5-CT>5-HT>LSD>DHE>sumatriptan>methiothepin>GTI>8-OH-DPAT. CP-93,129, mesulergine, buspirone and spiperone all displayed negligible affinity. Gpp(NH)p induced a concentration-dependent decrease in high affinity [³H]BMS-181101 binding, suggesting an agonist interaction with the binding site. Given these properties, we suggest that [³H]BMS-181101 will be a useful pharmacological tool in the characterization and regional localization of pre and post-synaptic 5-HT_{1D} receptors. (Supported in part by NIH Grant RR01237, National Center for Research Resources).

GR127935: *IN VITRO* AND *IN VIVO* CHARACTERIZATION OF A PUTATIVE 5-HT_{1D} ANTAGONIST. F.D. Tingley*, A.W. Schmidt, H.R. Howard, and D.W. Schulz. Central Research Division, Pfizer Inc., Groton, CT. 06340.

Functional studies of 5-HT_{1D} receptors have been hampered by the limited receptor selectivity of available antagonists (e.g. methiothepin). Recently it was reported that the biphenyl carboxamide GR127935 has high affinity for the cloned human 5-HT_{1D} and 5-HT_{1D} receptors, displays >100-fold selectivity vs other receptor subtypes, and behaves as an antagonist based on its reversal of contralateral rotation in guinea pigs caused by intranigral administration of a 5-HT₁ agonist (Br. J. Pharmacol. 110:9P, 1993). We have further characterized the functional activity of GR127935 at 5-HT_{1D} receptors in guinea pig brain by 1) measuring its effects on forskolin-stimulated adenylate cyclase activity in substantia nigra and 2) examining changes in 5-HT turnover in guinea pig hypothalamus following peripheral administration.

Adenylate cyclase studies revealed that GR127935 is a full agonist at 5-HT_{1A} receptors and a partial agonist at 5-HT_{1D} receptors (50-60% efficacy, relative to 5-HT). EC₅₀ values (>1 μ M at 5-HT_{1A} receptors, 2 nM at 5-HT_{1D} receptors) are consistent with the reported receptor selectivity profile of GR127935.

In vivo, s.c. treatment with GR127935 reversed the decrease in 5-HT turnover (5-HIAA:5-HT ratio) caused by the 5-HT_{1D} agonist CP-135,807 (see Schmidt et al., Soc. Neurosci. Abstr., 1994). When administered alone, GR127935 dose-dependently increased 5-HT turnover in guinea pig brain, suggesting an antagonism of endogenous 5-HT acting at inhibitory 5-HT_{1D} terminal autoreceptors.

633.8

KINETIC CHARACTERIZATION OF THE RESPONSES TO SUMATRIPTAN AND SEROTONIN IN CEREBRAL BLOOD VESSELS. G.P. Thalody, F.D. Yocca and H.L. Wiener*. CNS Drug Discovery, Bristol-Myers Squibb Co., Wallingford, CT 06492.

Although traditional pharmacological evaluations in isolated blood vessels have applied steady-state methods to study the responses to selective agents, and have provided a wealth of information, they fail to consider the time-dependent aspects of response generation. It is for this reason that kinetic models supersede studies performed under steady-state conditions, for they extend our knowledge of the manner by which the steady-state is achieved and allow for a quantitative analysis of the time-dependent changes which should assist in elucidating the biochemical basis of the observed physiological response (Wiener et al., EJP 220: 131, 1992). The bovine middle cerebral artery was chosen as a model system to study the responses to serotonin (5-hydroxytryptamine; 5-HT) and sumatriptan, a clinically efficacious antimigraine agent, by steady-state and kinetic models. While both 5-HT and sumatriptan evoked concentration-dependent and saturable contractile responses, sumatriptan was a weak partial agonist whose intrinsic activity was approximately 20% that of 5-HT. The kinetic model described by Clancy et al. (JPET 242: 108, 1987) was, therefore, chosen to characterize the kinetics of competitive drug action between 5-HT and sumatriptan, and to estimate the association and dissociation rate constants for both agents. The association rate constants for 5-HT and sumatriptan were 0.55±0.08 and 2.9±1.1 (μ M min)⁻¹, the dissociation rate constants were 0.19±0.01 and 0.0064±0.0010 min⁻¹, and the pK_A and pK_D values were 6.42±0.04 and 8.50±0.11, respectively. To the best of our knowledge, this is the first report of the association and dissociation kinetics for sumatriptan in isolated cerebral blood vessels.

633.10

THE ATYPICAL NEUROLEPTIC, SERTINDOLE, IS A 5-HT_{2C} RECEPTOR ANTAGONIST. E. Meier and K. Frederiksen*. Pharmacological Research, H. Lundbeck A/S, Ottilavej 9, DK-2500 Copenhagen-Valby, Denmark.

An important new advance in the pharmacotherapy of schizophrenia has been the introduction of drugs which have antipsychotic activity without extrapyramidal side effects (e.g., dystonia, parkinsonism, and akathisia) usually seen with classical neuroleptic drugs. The exact molecular mechanism of action of atypical neuroleptics is still unknown, however, binding studies with a new atypical neuroleptic, sertindole (Skarsfeldt & Perregaard, Eur. J. Pharmacol. 182, 1990, 613), have indicated that 5-HT₂ and α_1 receptors may be involved (Sanchez et al., Drug Devel. Res. 22, 1991, 239).

In the present study the effect of sertindole on the 5-HT_{2C} receptor has been characterized in binding and functional studies utilizing a NIH-3T3 cell line transfected with cloned rat 5-HT_{2C} receptors. Both sertindole (K_i = 0.51 nM) and clozapine (K_i = 5.1 nM) display high affinity in receptor binding assays utilizing homogenates of 5-HT_{2C} transfected NIH-3T3 cells while the classical neuroleptic, haloperidol (K_i = 1500 nM), displays very low affinity for this 5-HT receptor subtype. The same rank order of potencies of sertindole, clozapine and haloperidol is obtained utilizing living 5-HT_{2C} cells although the binding affinities is about 100 fold lower. In functional studies of 5-HT mediated phosphoinositid turnover in 5-HT_{2C} transfected NIH-3T3 cells, sertindole (IC₅₀ = 140 nM) and clozapine (IC₅₀ = 720 nM) act as antagonists while haloperidol (IC₅₀ > 100,000 nM) has no effect in this functional assay.

These data indicate that functional inhibition of 5-HT_{2C} receptors may be involved in the antipsychotic effect of atypical neuroleptics.

633.12

CP-135,807: A SELECTIVE 5-HT_{1D} AGONIST WITH CENTRAL ACTIVITY. A.W. Schmidt*, F.D. Tingley, H. Rollema, J.E. Macor, and D.W. Schulz. Central Research Division, Pfizer Inc., Groton, CT. 06340-1596.

The use of sumatriptan to study central 5-HT_{1D} receptors is limited by its poor brain penetration. Here we describe the functional properties of CP-135,807 (3-[pyrrolidin-2-ylmethyl]indole), a novel 5-HT_{1D} agonist with improved potency and CNS penetration.

CP-135,807 (3-[pyrrolidin-2-ylmethyl]indole) binds with high affinity (K_i = 1.3 nM) to brain 5-HT_{1D} receptors (Koe et al., Soc. Neurosci. Abstr., 1994). Like sumatriptan, CP-135,807 behaves as an agonist by inhibiting adenylate cyclase activity at both 5-HT_{1D} (guinea pig substantia nigra, EC₅₀=1.0 nM) and 5-HT_{1A} receptors (guinea pig hippocampus, EC₅₀=41 nM). Sumatriptan has a similar receptor selectivity profile, but is much less potent (5-HT_{1D} EC₅₀=97 nM).

Using *ex vivo* binding, it was determined that CP-135,807 readily crosses the blood-brain barrier, while sumatriptan was undetectable in brain after a subcutaneous (s.c.) dose of 5.6 mg/kg. As expected of a compound that activates 5-HT_{1D} terminal autoreceptors, s.c. CP-135,807 dose-dependently inhibited 5-HT turnover in guinea pig brain, decreasing 5-HIAA:5-HT ratios by up to 50%. Consistent with this mechanism of action, *in vivo* studies demonstrated that perfusions with 0.2-10 μ M CP-135,807 through a microdialysis probe in the hypothalamus caused a dose-dependent decrease in extracellular 5-HT. The centrally-mediated effect of CP-135,807 on 5-HT turnover is consistent with its ability to cause hypothermia in guinea pigs (Seymour et al., Soc. Neurosci. Abstr., 1994).

633.13

CP-135,807, A NOVEL 5-HT_{1D} AGONIST INDUCES HYPOTHERMIA IN THE GUINEA PIG. P.A. Seymour*, D.W. Schulz, F.D. Tingley and J.E. Macor. Departments of Neuroscience and Medicinal Chemistry, Central Research Division, Pfizer Inc, Groton, CT 06340.

Central serotonergic systems have long been implicated in thermoregulation. The 3-(pyrrolidin-2-ylmethyl)indole, CP-135,807, has recently been characterized as a novel 5-HT_{1D} agonist *in vitro* with greater than 30-fold functional selectivity vs. 5-HT_{1A} receptors as measured by inhibition of adenylate cyclase activity (Schmidt *et al.*, Soc. Neurosci. Abstracts, 1994). To investigate the functional correlates of 5-HT_{1D} receptor activation *in vivo*, the effect of CP-135,807 on body temperature was evaluated in guinea pigs, a species known to have central 5-HT_{1D} receptors. Rectal temperatures were measured prior to and 30, 60, 120 and 240 min after either s.c. or p.o. administration. It was found that CP-135,807 profoundly and dose-dependently lowers body temperature after either route of administration, with greater potency obtained after the s.c. route. This effect appears to be centrally mediated since sumatriptan and CP-123,803, an analog with a similar binding profile that does not readily enter the CNS, failed to produce this response. In addition, the putative 5-HT_{1D} antagonist, GR-127935, antagonizes this effect when given 60 min prior to agonist administration. These data suggest that 5-HT_{1D} receptors play a thermoregulatory role in guinea pig, and that this response may be useful in the characterization of drugs that act at 5-HT_{1D} receptors.

633.14

NOVEL TRYPTAMINE DERIVATIVES WITH A 5-(3-NITRO-2-PYRIDYLAMINO) MOIETY BIND PREFERENTIALLY TO 5-HT_{1D} RECEPTORS. B.K. Koe*, L.A. Lebel, C.B. Fox, and J.E. Macor. Central Research Division, Pfizer Inc, Groton, CT 06340

The recent introduction of serotonergic drugs (5-HT reuptake inhibitors as antidepressants; 5-HT_{1A} agonists as anxiolytics and antidepressants; a 5-HT_{1D} agonist as antimigraine agent) as well as the chemical description of new and distinct 5-HT receptors have spurred interest in finding selective agonists for these receptors. Our approach is based on modifying the serotonin molecule by introducing novel substituents at the indole C5 and C3 positions. Examples from our laboratories include a selective 5-HT_{1B} agonist, CP-93,129 (Macor *et al.*, 1990), and a potent ligand at 5-HT_{1A}, 5-HT_{1B}, 5-HT_{1D} receptors and the DA transporter, CP-110,330 (Koe *et al.*, 1992; Nowakowski *et al.*, 1993). We now report that the 5-(3-nitro-2-pyridylamino) moiety (R) confers 5-HT_{1D} binding selectivity to tryptamine derivatives (IC₅₀ nM):

Compound	C5 Moiety	C3 Moiety	5HT _{1D}	5HT _{1A}
Serotonin	HO	CH ₂ CH ₂ NH ₂	3.0	5.2
Sumatriptan	MeNH ₂ SO ₂ CH ₂	CH ₂ CH ₂ NH ₂	61	640
CP-113,113	R	CH ₂ CH ₂ NMe ₂	10	73
CP-135,807	R	N-Me-2-pyrrolidinylmethyl(r)	3.1	33
CP-123,803	R	2-pyrrolidinylmethyl(r)	6.2	120
CP-124,439	R	N-Me-3-pyrrolidinyl	15	320

SEROTONIN RECEPTORS: BEHAVIOR

634.1

WAY-100635, A POTENT AND SELECTIVE 5-HT_{1A} RECEPTOR ANTAGONIST, INCREASES SEROTONERGIC NEURONAL ACTIVITY AND BLOCKS THE ACTION OF 8-OH DPAT IN BEHAVING CATS. C. A. Fornal*, C. W. Metzler, R. A. Gallegos, S. C. Veasey, A. C. McCreary and B. L. Jacobs. Prog. Neurosci., Princeton Univ., Princeton, NJ 08544.

We have recently demonstrated that pharmacological blockade of somatodendritic 5-HT_{1A} autoreceptors increases the basal firing rate of central serotonergic neurons in awake cats. These results were obtained using spiperone, a non-selective 5-HT_{1A} autoreceptor antagonist. The present study examined the effects of WAY-100635, a selective 5-HT_{1A} receptor antagonist (Fletcher *et al.*, Br. J. Pharmacol. 112: 91P, 1994), on spontaneous serotonergic neuronal activity and 8-OH DPAT-induced neuronal suppression. Serotonergic neurons in the dorsal raphe nucleus (DRN) were recorded and identified using methods previously described (Fornal *et al.*, Am. J. Physiol. 259: R963-R972, 1990). Systemic administration of WAY-100635 (25-500 µg/kg, i.v.) significantly increased the basal firing rate of serotonergic DRN neurons, while producing no appreciable effects on behavior or polygraphic parameters. The stimulatory action of WAY-100635, like that of spiperone, was apparent during wakefulness (when neurons display a relatively high level of activity) but not during sleep (when neurons display little or no spontaneous activity). Pretreatment with WAY-100635 at doses as low as 100 µg/kg i.v. completely blocked the inhibitory action of 8-OH DPAT, indicating that WAY-100635 has a strong antagonist action at 5-HT_{1A} autoreceptors. These results confirm the general findings obtained with spiperone, and further support the hypothesis that 5-HT_{1A} autoreceptor-mediated feedback inhibition operates under physiological conditions when cells are firing at a relatively high rate. Supported by grants from the AFOSR (90-0294) and the NIMH (MH 23433).

634.2

EFFECTS OF 5-HT_{1A} AUTORECEPTOR BLOCKADE WITH WAY-100635 ON SENSORY-EVOKED ACTIVITY OF SEROTONERGIC NEURONS IN BEHAVING CATS. R. A. Gallegos*, C. A. Fornal, C. W. Metzler, J. C. Horvitz, and B. L. Jacobs. Program in Neurosci., Princeton University, Princeton, NJ 08544.

Somatodendritic 5-HT_{1A} autoreceptors are thought to be part of a local negative feedback mechanism and may modulate the responsiveness of central serotonergic neurons to sensory stimulation. The present study examined the effects of autoreceptor blockade with systemic WAY-100635 (Fletcher *et al.*, Br. J. Pharmacol. 112: 91P, 1994) on sensory-evoked responses of serotonergic dorsal raphe neurons. Single-unit responses to repeated presentation of a simple auditory stimulus (click: 100 dB, 1 msec; 100 trials) and to complex arousing stimuli (e.g. door opening) were obtained both before (baseline) and after administration of WAY 100635 (100 µg/kg, i.v.). This dose has been shown to block 5-HT_{1A} autoreceptors in cats (see Fornal *et al.*, preceding abstract). Unit activity was stored on a computer and used to construct peri-stimulus time histograms (PSTH). Of the 15 cells studied, 11 (73%) showed excitation and 4 (27%) showed inhibition in response to phasic auditory stimulation. Onset of excitatory and inhibitory responses occurred approximately 40-60 msec and 20-40 msec, respectively, after the stimulus and lasted for about 100 msec. WAY-100635 increased basal serotonergic unit activity and attenuated excitatory responses (8 of 11 cells), but had no appreciable effect on inhibitory responses. In contrast, WAY-100635 potentiated the increase in unit activity produced by arousing stimuli. These results provide preliminary evidence that 5-HT_{1A} autoreceptors exert an inhibitory influence on neuronal responses to arousing stimuli. Supported by grants from the AFOSR (90-0294) and the NIMH (MH 23433).

634.3

After acute and repeated treatment with the 5-HT_{1A} receptor antagonists (-)UH-301 and WAY100135, tolerance develops to a 5-HT_{1A} receptor-mediated functional response. L. Rényi* and P. Jimenez. CNS Preclinical R & D, Department of Behavioural Pharmacology, Astra Arcus AB, S-151 85 Södertälje, Sweden.

After acute treatment with the 5-HT_{1A} agonist 8-OH-DPAT tolerance develops to several 5-HT_{1A} receptor-mediated responses. These include the inhibition of the cage-leaving response (ICLR) induced 24 h later by a subsequent dose of this agonist (Ross *et al.* Naunyn-Schmiedeberg's Arch Pharmacol 1992;346:138). A similar result was obtained following acute treatment with the 5-HT_{1A} antagonists (-)UH-301 and WAY100135 (3.0 mg/kg s.c.). These compounds (1.0 mg/kg s.c.), when administered 30 min before 8-OH-DPAT (0.1 mg/kg s.c.), blocked the 8-OH-DPAT-induced ICLR, but tolerance was evident when the rats were challenged 24 h later with the same dose of 8-OH-DPAT. The development of tolerance was blocked by the non-competitive NMDA receptor antagonist, dizocilpine. Furthermore, the rats did not leave their cages after 10.0 mg/kg of (-)UH-301. This response could not be blocked by any receptor antagonist investigated in the study. However, (-)UH-301 induced tolerance to itself already after the second administration when given every third day, and after the third administration when given once a week. Simultaneously, wet-dog shakes induced by the 5-HT₂ receptor agonist DOI (0.3 mg/kg s.c.) were strongly potentiated.

Further studies are in progress to establish whether the effects of (-)UH-301 are pre- or postsynaptically mediated.

S 15535, A NOVEL AND SELECTIVE ANTAGONIST AT POSTSYNAPTIC 5-HT_{1A} RECEPTORS AND AGONIST AT 5-HT_{1A} AUTORECEPTORS: ACTIONS IN MODELS OF ANTIDEPRESSIVE, ANXIOLYTIC AND PROMNESCIC ACTIVITY. M.J. Millan, M. Brocco, R. Schreiber, J.-M. Rivet, S. Hjorth, P. Lacroix, R. Samanin, R. Jaffard, S. File, M. Spedding and J.-L. Peglion*. Institut de Recherches Servier, 125 Chemin de Ronde, 78290 Croissy, France.

S 15535 is a novel, potent antagonist at postsynaptic 5-HT_{1A} receptors which retains agonist actions at 5-HT_{1A} autoreceptors. Here, we evaluate its potential therapeutic utility. Doses are in mg/kg. All animals were male. In the learned helplessness paradigm in rats, S 15535 (0.63 - 40.0, p.o.) abolished escape failures from the first day of treatment whereas, in the forced-swimming test, S 15535 was inactive. In the pigeon conflict test, S 15535 (0.04 - 0.63, i.m.) selectively augmented punished responses, an action prevented by the 5-HT_{1A} antagonist, (-)alprenolol (10.0, i.m.). Similarly, S 15535 (0.3 - 3.0, s.c.) increased punished responding in a Geller-Seifter test in rats. Further, S 15535 (0.63 - 10.0, s.c. and 2.5 - 40.0, p.o.) reduced aggression in isolated mice and, though it did not show anxiolytic activity in the elevated plus-maze, WAY 100,135 and buspirone were also inactive under these conditions. Consistent with potential antidepressant and anxiolytic activity, S 15535 (0.16 - 10.0, s.c.) reduced release of 5-HT in dialysates of hippocampus and blocked the firing of raphe nuclei in rats. Microinjection of S 15535 (1 µg) into the hippocampus of rats attenuated the inhibitory influence of hippocampal 8-OH-DPAT (5 µg) upon working memory in a water maze. Further, S 15535 (0.16 and 0.63, s.c.) significantly improved the working memory of mice in a radial maze. Up to 40.0, s.c. and p.o., S 15535 did not elicit a serotonin syndrome or ataxia, did not modify spontaneous or amphetamine-induced locomotion and did not alter the release of dopamine in dialysates of the accumbens and striatum. In conclusion, S 15535 possesses a distinctive profile of antidepressant, anxiolytic and promnesic properties in rodents.

EFFECTS OF PSYCHOSOCIAL STRESS ON 5HT_{1A} RECEPTORS IN THE BRAIN. G. Flügge* and E. Fuchs. German Primate Center, 37077 Göttingen.

Normal neurotransmission in the brain requires normal numbers of receptors. Perturbing situations such as sustained psychosocial stress (PSS) may disturb the functional balance of the transmitter systems. In the present study, we investigated the effects of PSS on 5HT_{1A} receptors in the brains of tree shrews (*Tupaia belangeri*). Using quantitative in vitro autoradiography with ³H-8-hydroxy-2-(di-n-propylamino)tetralin (³H-DPAT), high numbers of 5HT_{1A} receptors were detected in the dorsal raphe nucleus, the dorsal tegmental nucleus, in the hippocampal CA1 region, the basal nucleus of the amygdala, and the claustrum. In the frontal cortex, the moderate number of ³H-DPAT binding sites can differ by up to 30% between the left and right hemisphere. In subordinate male tree shrews, whose physiology is characterized by a constantly elevated activity of the HPA-axis, the hippocampal ³H-DPAT binding sites are diminished in number after 21 days of social conflict. In other brain areas, the number of binding sites increases with the duration of PSS. After 30 days of perpetual social confrontation, subordination is accompanied by an elevation of low affinity ³H-DPAT binding sites in the dorsolateral frontal cortex, in the dorsal raphe, and the dorsal tegmental nucleus. These data indicate that prolonged PSS induces an up-regulation of 5HT_{1A} recognition sites in the raphe nuclei and some raphe projection fields.

5-HT_{1A} RECEPTOR ANTISENSE OLIGONUCLEOTIDE, MDMA AND 8-OH-DPAT TREATMENT EFFECTS ON COCAINE INHIBITION OF DORSAL RAPHE 5-HT CELLS. R.T. Windh*, R. De La Garza II, E.J. Mah, M.L. Thomas and K.A. Cunningham. Dept. Pharmacol., Univ. Texas Med. Branch, Galveston, TX 77555.

We have reported that cocaine inhibits dorsal raphe nucleus (DR) serotonin (5-HT) neuronal activity through 5-HT_{1A} and D₁ receptor mechanisms. In order to further investigate 5-HT_{1A} involvement in cocaine-induced inhibition of DR 5-HT activity, the sensitivity of DR 5-HT cells to cocaine was determined after chronic 8-OH-DPAT (DPAT, 1 mg/kg, sc, qd, 7 days), 5-HT_{1A} antisense nucleotide (ASN, 5 ug, iv, bid, 7 days), or (+)MDMA (10 mg/kg, sc, bid, 4 days) treatment. In addition, the presence and severity of flat body posture (FBP), forepaw treading (FPT), forward locomotor activity (FLA) and lower lip retraction (LLR) in response to DPAT (0.5 mg/kg, sc) were used as an independent assay of 5-HT_{1A} function. Drug naive, male Sprague-Dawley rats (200-300 g) were scored for DPAT behavior, treated with one of the 3 chronic regimens, and then re-scored for DPAT behaviors or used for single barrel extracellular recording. Chronic DPAT treatment (n=6) nearly eliminated FPT and reduced FBP and FLA, whereas 5-HT_{1A} ASN treatment (n=4) prevented FBP and FLA and reduced FPT and LLR. MDMA treatment had no effect on any DPAT-induced behaviors (n=5). The ED₅₀ for cocaine-induced inhibition of DR 5-HT cell firing was 0.6 mg/kg in drug-naive, chloral hydrate-anesthetized rats (n=6), as determined by intravenous cumulative dose-response analysis. MDMA (n=3) and 5-HT_{1A} ASN (n=3), but not DPAT (n=9), treatment significantly reduced the potency of cocaine to inhibit DR 5-HT cells compared to untreated controls (ED₅₀s = 1.3, 1.2 and 0.8 mg/kg, respectively). Thus chronic ASN and DPAT treatments differentially alter DPAT-induced behaviors and cocaine inhibition of DR 5-HT firing, suggesting that 5-HT_{1A}-induced FBP and FLA may be more closely associated with cocaine mechanisms of DR 5-HT cell inhibition and less easily desensitized than others. Additionally, the integrity of DR 5-HT forebrain projections may be important in mediating cocaine inhibition of these cells. These results are currently being replicated and extended. Supported by DA 06511.

Hallucinogenic drug interactions with recombinant cells expressing 5HT_{2A} or 5HT_{2C} receptors: evidence further implicating the 5HT_{2A} receptor as the brain site-of-action. C. Casey*, K. Herrick-Davis, K.J. Miller*, B.J. Hoffman*, R.A. Glennon*, and M. Teitler. Dept. of Pharmacology and Toxicology (C.C., K.H.D., M.T.), Albany Medical College, Albany, N.Y. 12208; Lab. Cell Biol., NIH, Bethesda, MD 20892; *Dept. Med. Chem., Virginia Commonwealth University, Richmond, VA 23298

Evidence from radioligand binding, animal drug-discrimination, and human trials have been presented as implicating the 5HT_{2A} receptor as the "LSD receptor" in brain; i.e. that LSD and related hallucinogenic phenylisopropylamines stimulate this receptor in initiating the cascade of events producing the hallucinogenic experience (1). Recently evidence has been presented indicating that lisuride, a purported non-hallucinogenic congener of LSD, stimulates 5HT_{2A} receptors and not 5HT_{2C} receptors (2). Thus it has been proposed that the 5HT_{2C} receptor is more likely to be the "LSD receptor". In order to further investigate the interaction of lisuride with 5HT_{2A} and 5HT_{2C} receptors we tested the ability of lisuride and LSD to stimulate PI metabolism in recombinant cells stably expressing 5HT_{2A} or 5HT_{2C} receptors. We have found lisuride potently stimulates IP₃ production in cells expressing 5HT_{2C} receptors, as well as stimulating IP₃ production in cells expressing 5HT_{2A} receptors. These data indicate that lisuride is a non-specific 5HT₂ receptor agonist and is consistent with reports that lisuride does have hallucinogenic activity. Data concerning the effects of other hallucinogens in stimulating PI metabolism in these recombinant cells will be presented.

EFFECTS OF 5-HT AND 8-OH-DPAT ON SPONTANEOUS OPEN-FIELD MOTOR ACTIVITY AFTER LOCAL APPLICATION INTO THE SUBSTANTIA NIGRA PARS RETICULATA (SNr) AND VENTRAL TEGMENTAL AREA (VTA) IN THE RAT. V. Hillegaart* and S. Ahlenius. Department of Behavioral Pharmacology, Astra Arcus AB, S-161 85 Södertälje, Sweden.

The 5-HT_{1A} receptor agonist 8-OH-DPAT (0.5 µg), or 5-HT (0.40 µg), was infused into the SNr or into the VTA in awake, gently hand-restrained male Wistar rats, at a rate of 0.33 µL min⁻¹ to a final volume of 0.5 µL. Ten minutes upon completion of the injection, the animals were transferred to the open-field arena (0.5 m²) for 30 min photocell monitoring of patterns of movement [locomotor activity (LMA), rearing (R), forward locomotion (FL) and peripheral activity (PA)]. Repeated measurements were made on four groups (n=13-15) given the different doses of 8-OH-DPAT or 5-HT in the SNr or VTA, respectively, in a change-over design. 5-HT, locally applied into the SNr produced a decreased LMA, FL and R with a shift to the periphery of the arena. A more stereotyped pattern of activity was obtained after the VTA infusion of 5-HT, primarily characterized by an increased LMA and loss of habituation. The local application of 8-OH-DPAT into the SNr produced the characteristic pattern of spontaneous motor activity seen after its systemic administration i.e. a decrease in LMA and R, and an increased proportion of FL and PA. A similar, but less conspicuous, pattern of effects was obtained after 8-OH-DPAT infusion into the VTA.

In conclusion, serotonin receptors in the SNr and VTA are important targets for effects on spontaneous motor activity by serotonergic drugs, and 8-OH-DPAT in particular, after their systemic administration in the rat.

634.8

5-HT_{1A} RECEPTOR MODULATION OF THE HYPERACTIVITY INDUCED BY ACUTE COCAINE ADMINISTRATION. R. De La Garza II* and K. A. Cunningham. University of Texas Medical Branch, Department of Pharmacology and Toxicology, Galveston, Texas 77555-1031.

Important interactions between 5-HT and DA systems occur in brain regions known to be critically involved in drug abuse. Moreover, specific manipulations of 5-HT_{1A} receptors may modulate the output of cocaine-induced behaviors (i.e., pretreatment with the partial 5-HT_{1A} agonist gepirone enhanced the locomotor activation induced by cocaine). To more definitively clarify the potential role of 5-HT_{1A} receptors in this behavior we sought to study the full dose-response relationship for cocaine in the presence of multiple doses of the selective and full agonist 8-OH-DPAT (DPAT). To this end, experimentally naive rats (n=32) were pretreated with DPAT (0, 0.1 or 0.2 mg/kg) 15 min prior to an injection of cocaine (0, 10 or 20 mg/kg). Similar levels of horizontal activity were observed in animals pretreated with DPAT (0.1 or 0.2 mg/kg) or saline, although vertical activity was reduced by DPAT. Pretreatment with DPAT (0.1 mg/kg) had no effect on cocaine-induced horizontal activity but significantly decreased rearing elicited by cocaine (10 and 20 mg/kg). At a higher dose (0.2 mg/kg), DPAT significantly increased horizontal, and decreased vertical, activity induced by cocaine (10 and 20 mg/kg). Thus, a similarity in the ability of the full (DPAT) and partial (gepirone) 5-HT_{1A} agonists to enhance cocaine-induced locomotor activity is observed. If 5-HT inhibits DA function, it is possible that stimulation of somatodendritic 5-HT_{1A} autoreceptors by DPAT or gepirone and a subsequent reduction in terminal 5-HT release might diminish this inhibitory 5-HT role, thereby enhancing the DA-mediated behavioral effects of cocaine.

USE OF SEVERAL 5-HT_{2AC} ANTAGONISTS TO DIFFERENTIALLY SEPARATE THE DOI-INDUCED 5-HT_{2A}- AND 5-HT_{2C} RECEPTOR FUNCTION IN MICE. N.A. Darmani* and C.F. Gerdes. Dept. of Pharmacol., Kirksville Col. of Osteo. Med., Kirksville, MO 63501.

The serotonergic 5-HT_{2A} receptor subtypes consist of 5-HT_{2A} (classical 5-HT₂), 5-HT_{2B} (5-HT_{2B}) and 5-HT_{2C} (5-HT_{2C}) sites. The 5-HT_{2A} and 5-HT_{2C} receptors have similar structures and use inositol phosphate hydrolysis as their signal transduction mechanism. Relative to the classical 5-HT_{2AC} antagonists, the new 5-HT_{2A} antagonists (SR-46349B and AMI-193) are reported to bind more selectively to 5-HT_{2A} versus 5-HT_{2C} as well as other monoamine receptors. The purpose of this investigation was to compare the effects of the new antagonists with the classical 5-HT_{2AC} antagonists (e.g. ketanserin, ritanserin and spiperone) on the DOI-induced behaviors such as the 5-HT_{2A}-mediated head-twitch response (HTR) and the 5-HT_{2C}-mediated ear-scratch response (ESR) in mice. Different groups of mice were treated with either vehicle (n=12) or the cited antagonists (0.001 - 0.5 mg/kg, n=5-8, i.p.) 30 min prior to DOI (1.0 mg/kg, i.p.) administration. The DOI-induced HTR and ESR frequencies were counted for 20 min following its injection. The antagonists reduced the HTR frequency with similar ID₅₀ values (mg/kg) in following order: SR-46349B (0.12); ketanserin (0.14); spiperone (0.15); ritanserin (0.17) and AMI-193 (0.27). They were more potent (2-12 times) in reducing the ESR frequency relative to the HTR score with the following respective ID₅₀ values: 0.021; 0.012; 0.037; 0.035 and 0.115. Thus, the potency order of the cited antagonists to differentiate between the DOI-induced HTR and ESR is ketanserin > SR-46349 > ritanserin > spiperone > AMI-193. None of the cited antagonists appear to be selective for the 5-HT_{2A}- versus 5-HT_{2C}-mediated behaviors.

634.11

CLOZAPINE AND THE PUTATIVE, ATYPICAL ANTIPSYCHOTICS, RISPERIDONE, SERTINDOLE AND MDL 100,907, BLOCK DOI-INDUCED DISCRIMINATIVE STIMULUS EFFECTS AND HEAD-TWITCHES IN MALE RATS. M. Brocco, R. Schreiber, V. Audinot* and M.J. Millan, Institut de Recherches Servier, 125, Chemin de Ronde, 78920 Croissy, France.

The present study evaluated the contribution of serotonin (5-HT)_{2A} receptors to the *in vivo* actions of clozapine and several, putative atypical antipsychotics. In a drug discrimination paradigm employing animals trained to discriminate the 5-HT_{2A/2C} agonist, DOI (0.63 mg/kg i.p.), from saline, the discriminative stimulus (DS) effects of DOI were dose-dependently and completely blocked by the 5-HT_{2A/2C} receptor antagonists, ritanserin, ICI 169,369 and mianserin (ID₅₀s: 0.32, 0.26 and 0.15 mg/kg, s.c., respectively), the preferential 5-HT_{2A} antagonist, ketanserin (0.06) and the novel, highly selective 5-HT_{2A} receptor antagonist, MDL 100,907 (0.001). Like MDL 100,907, both clozapine and two putative, atypical antipsychotics possessing marked affinity at 5-HT_{2A} receptors, risperidone and sertindole, blocked the DS effects of DOI (0.05, 0.03 and 0.32, respectively). All compounds abolished the head-twitches (HTWs) evoked by DOI (2.5 mg/kg, s.c.): ID₅₀s: 0.28, 12.1, 0.02, 0.06, 0.005, 0.04, 0.025 and 1.0, respectively. The dopamine D₂ antagonist, haloperidol, failed to block the DS effects of DOI (dose-range tested: 0.01 - 0.16), but abolished DOI-induced HTWs (ID₅₀: 0.07). In conclusion, these data demonstrate the role of 5-HT_{2A} receptors in mediating both the DS effects and the HTWs elicited by DOI, though the latter response is also modulated by D₂ receptors indicating the superior selectivity of the drug discrimination paradigm. The marked activity of clozapine, risperidone, sertindole and MDL 100,907 in these models supports the concept that 5-HT_{2A} receptor antagonism contributes to the *in vivo* actions of atypical antipsychotics.

634.13

TREATMENT WITH 5-HT_{2A/2C} RECEPTOR AGONIST DISRUPTS INITIAL DEVELOPMENT OF SPATIAL NAVIGATION STRATEGIES IN RATS. M. Riekkinen*, J. Sirviö and P. Riekkinen Jr., Dept. of Neurology, Univ. of Kuopio, P.O.B. 1627, FIN-70211, Kuopio, Finland. Fax: 358-71-162048.

The present study investigates the effects of 5-HT_{2A/2C} receptor stimulation on spatial and cue navigation, and visual discrimination. Daily s.c. pre-training treatment with 1-(2,5-dimethoxy-4-iodophenyl)-2-aminopropane (DOI) at 3 mg/kg, but not at 1 mg/kg, impaired initial development of water maze (WM) spatial navigation strategies (hidden platform), but had no effect on the development of non-spatial navigation strategies (visible platform). Pre-training injections of ketanserin (0.1, 0.4 and 2 mg/kg, i.p.), a 5-HT_{2A/2C} receptor antagonist, had no effect on WM performance, but blocked the impairing effect of DOI 3 mg/kg on WM spatial navigation. Spatial reference and working memory were not disrupted by pre-training DOI (1 and 3 mg/kg) treatment if the rats had learned the reference memory rule before drug treatment. 5-HT_{2A/2C} receptor stimulation did not impair consolidation as post-training DOI at 1 and 3 mg/kg had no effect on the development of spatial navigation strategies. Visual discrimination learning was not impaired by pre-training DOI 1 and 3 mg/kg. The present results suggest that 5-HT_{2A/2C} receptor stimulation impairs initial development of spatial navigation strategies in rats.

634.12

ANTISENSE KNOCKOUT OF THE 5-HT_{2A} RECEPTOR *IN VIVO*: ANXIOLYTIC EFFECTS AND INCREASED 5-HT_{2C}-MEDIATED RESPONSES. D. BENJAMIN*, M. TOTH, K.R. GOLDSTEIN, E.I. SAHFF, AND L.A. POHORECKY. Center of Alcohol Studies, Rutgers University, Piscataway, NJ 08855, Cornell University Medical College, New York, NY 10021, Ramapo College of New Jersey, Mahwah, NJ 07430.

Antisense (A) phosphorothioate oligonucleotides complimentary to 5-HT_{2A} receptor mRNA were administered in media to cultured C6 glioma cells and ICV (intracerebroventricular) to rats. In C6 cells, significant decreases in 5-HT_{2A} mRNA and spiperone-sensitive [²⁵I]-LSD binding were evident after 3d treatment with A but not control (C) sequences (20-200 nM). In male Long-Evans rats, treatment with A (50 ug ICV twice daily x 4d; tests were 24 h after final dose), but not C, resulted in a significant decrease in 5-HT_{2A} receptor mediated headshakes induced by the 5-HT_{2A/C} agonist DOI ((±)-1-(2,5-dimethoxy-4-iodophenyl)-2-aminopropane hydrochloride); conversely, a significant increase in DOI-induced, 5-HT_{2C}-mediated, skin crawls was observed. A significant anxiolytic-like effect was observed in A but not in C-treated rats tested in the elevated plus-maze. Autoradiographic and saturation analysis of 5-HT_{2A} and 5-HT_{2C} binding from the rats in the behavioral studies indicated significant, 50-72% decreases in 5-HT_{2A} binding, and no change in 5-HT_{2C} binding. These results demonstrate that 5-HT_{2A} receptor expression and function can be selectively attenuated using A sequences, and suggest that the 5-HT_{2A} receptor inhibits agonist-induced 5-HT_{2C} receptor-mediated responses. (Supported by the Smithers Foundation and the Charles and Johanna Busch Foundation).

Acute and Chronic Effects of M-Chlorophenylpiperazine on Food Intake and Brain 5-HT₂ and 5-HT_{1b} Binding Sites, M.A. Blackshear*, Department of Biological Sciences, Tennessee State University, Nashville, TN 37209-1561.

The acute and chronic effects of m-chlorophenylpiperazine (m-CPP) on serotonin (5-HT) induced decreased food intake on brain 5-HT₂ and 5-HT_{1b} binding sites were investigated. Male Sprague-Dawley rats received a single dose of 10 mg/kg of m-CPP or 5 mg/kg twice daily for seven days. Given acutely, 10 mg/kg of m-CPP produced a marked decrease in food consumption at 1-hour and at 4-hours. Maximal inhibition occurred at 1-hour with a significant reduction in eating behavior still present at 4-hours. Acute m-CPP administration had no effect on the affinity (K_D) or maximal number of binding sites (B_{max}) of 5-HT_{1b} or 5-HT₂ binding sites in the striatum and frontal cortex, respectively. In contrast to the acute effects on eating behavior, chronic injections of m-CPP failed to modify food intake when compared to saline controls. Unlike acute m-CPP, repeated m-CPP injections caused a marked decrease in [³H]-ketanserin binding to 5-HT₂ sites in the frontal cortex. A small, but significant increase in the K_D was observed also. However, chronic m-CPP treatment had no effect on the binding of [³H]-5-HT to 5-HT_{1b} sites in the striatum. These findings confirm previous reports that adaptive mechanisms in 5-HT receptor systems following repeated agonist treatment may be different for 5-HT receptors and 5-HT binding sites. Further, considering that m-CPP has been widely used as a probe in various psychiatric disorders to evaluate central 5-HT function, this study provides additional information on the chronic effects of m-CPP on brain 5-HT function.

SEROTONIN RECEPTORS: LOCALIZATION

635.1

IN VIVO STUDIES OF 5-HT₂ RECEPTORS IN MONKEYS USING F-18-ALTANSERIN. C.A. Mathis*, Y. Choi, N.R. Simpson, M.A. Mintun, PET Facility, University of Pittsburgh Medical Center, Pittsburgh, PA 15213

Altanserin is a closely related structural analogue of ketanserin and has a high *in vitro* affinity and selectivity for 5-HT₂ receptors. We examined the *in vivo* properties of this radioligand in monkeys as a candidate for imaging brain 5-HT₂ receptors using positron emission tomography (PET). Three rhesus monkeys received 8-10 mCi of high specific activity (1100-2500 Ci/mmol) F-18-altanserin. In addition, one monkey received a second 10 mCi injection of low specific activity (13 Ci/mmol) F-18-altanserin. Twenty scans of increasing duration were acquired over a 120 min time period. Arterial blood samples were obtained and the plasma radioactivity was corrected for the presence of radiolabeled metabolites. In two monkeys, ketanserin and altanserin (1 mg/kg) were injected 2 h after the injection of F-18-altanserin to displace specifically bound radioactivity.

At times greater than about 30 min, regionally selective retention of radioactivity was observed in cortical areas while cerebellum, caudate, and thalamus had low radioactivity levels. The ratio of frontal cortex-to-cerebellum was 2.5±0.3 in the high specific activity studies and decreased to 1.5 at 2 hours after the tracer injection in the low specific activity study. A two compartment fit to the dynamic PET data yielded kinetic rate constants K₁, k₂, and distribution volume (DV). Estimates of DV, which is proportional to the B_{max}/K_d, were 3.4±1.2 for frontal cortex, 2.1±0.8 for caudate, and 1.7±0.5 for cerebellum. The DV's varied regionally in a manner consistent with the known distribution of 5-HT₂ receptors. Both ketanserin and altanserin displaced specifically bound radioactivity in cortical areas with displacement half-times of 23 and 37 min, respectively. Unmetabolized altanserin comprised 58±1% of the total plasma activity at 2 h post injection. These results indicate that F-18-altanserin is a useful agent to image and quantitate 5-HT₂ receptors *in vivo* using PET.

635.2

LOCALIZATION OF 5-HT_{2A} RECEPTOR mRNA IN NEURONS OF THE HUMAN BRAINSTEM. M.C. Austin*, J.A. Weikel and J.J. Mann, Labs of Neuropharmacology, Dept. of Psychiatry, Univ. of Pittsburgh, Pittsburgh, PA 15213.

A previous receptor autoradiography study, using [³H] LSD as a ligand, reported the anatomical localization of serotonin receptors in the human brainstem (Palacios et al. 1983). This study found that the highest levels of binding occurred predominantly in the raphe nuclei, thus revealing the localization of serotonin receptors of the 5-HT₂-like subtype. Given the recent cloning of the human 5-HT_{2A} receptor (Chen et al. 1992), the present study was designed to examine the distribution of neurons expressing 5-HT_{2A} receptor mRNA in the human brainstem using *in situ* hybridization histochemistry (ISHH). Postmortem human brainstem tissue was obtained at autopsy, dissected and frozen. All cases (N=4) had negative toxicological results and no known neurologic or psychiatric disorders. Coronal tissue sections (20 µm) of the brainstems were cut, thaw-mounted on gelatin-coated slides and processed for ISHH. At the level of the medulla, neurons in the hypoglossal nucleus, the dorsal motor nucleus of vagus and the gigantocellular reticular nucleus all contained abundant levels of 5-HT_{2A} receptor mRNA. In the pons, dense silver grains corresponding to 5-HT_{2A} receptor mRNA were localized in neurons in the motor trigeminal nucleus and in pigmented and small, non-pigmented locus coeruleus neurons. A small, discrete population of neurons in the caudal dorsal raphe, bordering the fourth ventricle, expressed hybridization signal. Scattered mRNA-positive cells were also found in the oral pontine nucleus. A large population of neurons expressing 5-HT_{2A} receptor mRNA was found in the diffuse sector of the pedunculopontine tegmental nucleus, and several mRNA-positive neurons were located in the caudal portion of the substantia nigra. These findings provide important information regarding the postsynaptic localization of 5-HT_{2A} receptors and the relevant nuclei in the human brainstem that receive a putative serotonergic innervation. (Supported by MH30915, MH46745)

635.3

5-HT_{1A} RECEPTOR LOCALIZATION IN THE RAT, CAT AND PRIMATE SPINAL CORD. ¹N.M. Khech, ²P.J. Gannon, ³B.L. Jacobs and ⁴E.C. Azmitia. ¹Dept Biology, New York Univ, NY, NY10003; ²Dept Otolaryngology, Mt Sinai Sch Med., NY, NY10029; ³Neuroscience, Princeton Univ, Princeton, NJ 08544

The anatomic distribution of 5-HT_{1A} receptors in rat brain and spinal cord has been defined by radioligand binding studies and quantitative autoradiography using the specific, high affinity radioligand, ³H-8-OH-DPAT. We are currently using a synthetic antipeptide antibody to characterize the localization of the 5-HT_{1A} receptor protein in the mammalian spinal cord. This polyclonal antibody was raised in rabbit against amino acid sequence 170-186, a transmembrane region of the 5-HT_{1A} receptor that is structurally linked to the ligand binding site, and has no sequence homology with other known proteins.

In the spinal cords of rats, cats and macaques we observed the highest density of 5-HT_{1A}-IR in the superficial layers of the dorsal horn on primary afferent sensory fibers, and in nerve fibers surrounding the central canal. This pattern of 5-HT_{1A} receptor-IR corresponds precisely to the autoradiographic localization of ³H-8-OH-DPAT described in the rat spinal cord. The most notable pattern of 5-HT_{1A} receptor-IR that we observed was on the axon hillocks of motoneurons throughout the ventral horn. This novel site of 5-HT_{1A} receptor localization is not detected with ³H-8-OH-DPAT, suggesting possible heterogeneity of 5-HT_{1A} receptor signal transduction mechanisms. A dense population of 5-HT_{1A} receptors on the motoneuron axon hillock indicates an important role in the regulation of motor output. Species differences in 5-HT_{1A} receptor-IR were noted: for example, variation in density of fiber labeling in the dorsal horn, the pattern of 5-HT_{1A}-IR around the central canal, and the intense somatodendritic labeling of spinal serotonergic (raphe) cells in the primate cervical spinal cord. DISTRIBUTION OF 5-HT_{1A} RECEPTOR mRNA IN THE HUMAN HIPPOCAMPUS J.F. López, D.T. Chalmers, A.A.F. Sima, and S.J. Watson. University of Michigan-MHRI, Ann Arbor, MI 48109-0720

The present study examined the comparative distribution of 5-HT_{1A} receptor mRNA and 5-HT_{1A} binding in human hippocampus using *in situ* hybridization with a specific human cRNA probe and receptor autoradiography with the selective ligand [³H]8-OH-DPAT. In agreement with previous binding studies, the highest levels of 5-HT_{1A} binding in the human hippocampus were observed in the CA1 subfield and in the subiculum. High levels of binding were also observed in the granular and molecular layers of the dentate gyrus. Intermediate levels were present in the pyramidal and molecular layers of CA2 and CA3 subfields. In contrast to 5-HT_{1A} binding, the highest concentration of 5-HT_{1A} mRNA expression was observed in the granular layer of the dentate gyrus. A positive signal was also detected in the pyramidal cell layer of CA1, CA2 and CA3 subfields, although the mRNA levels were lower than in the dentate gyrus. No 5-HT_{1A} mRNA was detected in the stratum oriens, radiatum or moleculare. The subiculum and the external layers of the parahippocampal gyrus also expressed 5-HT_{1A} mRNA at concentrations similar to the CA subfields. In conclusion, there is a concordance between the areas expressing 5-HT_{1A} mRNA with the areas showing specific 5-HT_{1A} binding in human hippocampus. However, there are differences in distribution and concentration between mRNA and receptor sites within specific anatomical regions. These differences are probably due to the cytoarchitectural distribution of the neuronal cell bodies, where the 5-HT_{1A} mRNA is transcribed, versus the apical and basal dendrites, where the 5-HT_{1A} receptors are localized. Supported in part by a grant from the American Suicide Foundation.

EXPRESSION OF 5-HT_{1A}, 5-HT_{2A} AND 5-HT_{2C} RECEPTORS ON ASTROCYTES. W.D. Hirst, M.A.N. Ratnay, G.W. Price and G.P. Wilkin. (SPON: Brain Research Association), Department of Biochemistry, Imperial College of Science, Technology and Medicine, London SW7 2AZ, England.

The evidence to date for the presence of serotonin receptors on astrocytes *in vitro* has mainly been dependent on ligand binding and second messenger assays. We have demonstrated the expression of serotonin receptor subtype mRNAs using *in situ* hybridisation. cDNA clones of 5-HT_{1A}, 5-HT_{2A} and 5-HT_{2C} subcloned into suitable vectors were used to generate specific ³⁵S-labelled riboprobes. These were hybridised to neonatal rat cortical astrocyte cultures. Results show that the astrocytes *in vitro* express mRNAs for the above three receptor subtypes. Data from binding experiments with receptor specific ligands and second messenger assays complement the *in situ* hybridisation results, showing that the astrocytes express the receptor protein and that it is functional.

We have also addressed the question of serotonin receptor subtype expression on astrocytes in adult rat brain sections using a combination of *in situ* hybridisation of receptor subtype specific cRNAs and immunohistochemical localisation of the astrocyte specific marker GFAP. We found little evidence of co-localisation of receptor message with GFAP positive astrocytes, suggesting that few astrocytes express these serotonin receptors in the adult brain. We are currently investigating the possibility of *in vivo* receptor expression during development or following brain damage to interpret our *in vitro* findings.

635.4

DISTRIBUTION OF 5-HT_{1A} RECEPTORS IN THE PRIMATE BRAINSTEM ¹P.J. Gannon, ²N.M. Khech, and ³E.C. Azmitia. ¹Dept Otolaryngology, Mt Sinai Sch Med, NY NY10029; ²Dept. Biology, New York Univ. NY NY10003.

We used an 5-HT_{1A} receptor antipeptide (aa170-186) antibody to investigate the distribution of this serotonin receptor subtype in the brainstem of the Old World monkey *Macaca fascicularis*.

Three adult monkeys were fixed by transcardiac perfusion, then 40µm brainstem sections incubated in primary antibody at 1:2000 for 72 hours at 5°C followed by visualization using an ABC-peroxidase kit (Vector).

Three main types of cell labelling patterns were apparent throughout the brainstem: 1) on neurons of both the serotonergic raphe nuclei and the noradrenergic locus ceruleus, dense labelling was distributed diffusely throughout the soma and dendritic tree. Similarly labelled large neurons were scattered throughout the reticular formation; 2) Most neurons in the brainstem motor nuclei showed a dense label localized specifically to the axon hillock. This axon hillock pattern was also seen throughout the brainstem on some neurons of both sensory and reticular groups. Sub-populations of vestibular nuclei neurons were also labelled; 3) A diffuse general label was present on astrocytes throughout the brainstem.

The somatodendritic label we observed may represent receptor populations acting as autoreceptors. The dense axon hillock label may represent populations of 5-HT_{1A} receptors involved in temporally dynamic regulation of motor output at this critical cellular location. During primate evolution, basal mammalian motor systems evolved and changed to subserve the more sophisticated communicative repertoire present in primates. These evolutionary advances in brain function involved incorporation of the 5-HT_{1A} receptor as a key player.

DISTRIBUTION OF THE SEROTONIN-1A RECEPTOR, SEROTONIN UPTAKE SITE AND TRYPTOPHAN HYDROXYLASE-LIKE IMMUNOREACTIVITY (TpH-LI) IN THE HUMAN DORSAL RAPHE. L.A. Shapiro, C.A. Stockmeier*, M.T. Lowy and J.F. Singer. Department of Psychiatry, Case Western Reserve University, Cleveland, OH 44106.

The anatomical distribution of serotonin-1A (5HT-1A) receptor binding and 5HT uptake sites, in relation to TpH-LI, was measured in serial sections in subnuclei of the human dorsal raphe nucleus. Midbrains from 7 male subjects dying of natural causes were collected at autopsy, frozen, and 10 µm thick sections were cut. The ranges in ages and postmortem intervals were 46-67 years and 11-24 hr., respectively. Quantitative receptor autoradiography was used to measure the binding of [³H]8-hydroxy-DPAT to 5HT-1A receptors and [³H]paroxetine to the 5HT uptake site in serial sections. Immunohistochemical localization of TpH-LI was also done in post-fixed sections to localize 5HT-synthesizing neurons in relation to radioligand binding. Subnuclei within the DR were identified according to Baker et al. (1990, 1991). 5HT-1A receptor binding was significantly greater in the ventrolateral (VL) subnucleus than the ventral (V), interfascicular (IF) or dorsal (D) subnuclei. 5HT-1A receptor binding closely paralleled cell bodies stained for TpH-LI. In contrast, [³H]paroxetine binding was homogeneously distributed among the subnuclei. Age was negatively correlated with 5HT-1A receptor binding in only the VL, and postmortem interval was negatively correlated with 5HT-1A receptor binding in only the V subnucleus. Immunohistochemical localization of TpH-LI is an important tool for identifying 5HT-1A receptor binding and 5HT uptake sites within subnuclei of the human dorsal raphe nucleus. MH45488 and MH41684.

TWO POPULATIONS OF [³H]8-OH-DPAT BINDING SITES IN BRAIN: REGIONAL DIFFERENCES IN BINDING PARAMETERS AND RESPONSE TO GTP. A.Y. Korneyev*, O.B. Belonogoff and S.B. Seredenin. Institute of Pharmacology, 8 Baltiyskaya Str. Moscow, Russia.

The heterogeneity of [³H]8-OH-DPAT binding is attributed to an independent population of binding sites, 5-HT transporter, or to the multiple affinity states of a 5-HT_{1A} receptors. The situation is complicated by the high tendency of 8-OH-DPAT and 5-HT to artefactual, nonreceptor binding, when incubation medium is not supplemented with ascorbic acid.

In the present study the profiles of [³H]8-OH-DPAT binding to 5-HT_{1A} receptors in rat brain cortex and brain stem were compared in the presence of ascorbic acid. In both brain regions [³H]8-OH-DPAT specific binding was stimulated by a number of divalent cations (most potent Mn²⁺) and inhibited by Cu²⁺ and GTP. The high affinity binding component (K_d = 0.2 - 0.3 nM) represents 62 ± 14% of the binding capacity in the brain cortex membranes, whereas the low affinity component (K_d = 8 - 12 nM) predominates in brain stem (79 ± 13% of binding capacity). In the presence of GTP the fraction of the high affinity component decreases to 24 ± 6% in brain cortex membranes and to less than 6% in brain stem membranes. GTP-insensitive [³H]8-OH-DPAT binding may occur as a result of oxidation of -SH groups on the 5-HT_{1A} receptor/G protein complex or other posttranslational modifications. Since the membranes from the two tissues were isolated and incubated in identical conditions and in the presence of ascorbic acid, the detected regional differences have apparently preexisted in the rat brain. These data indicate that the fraction of high affinity [³H]8-OH-DPAT binding sites, not sensitive to GTP negative modulation, is about 4 times higher in brain cortex, than in brain stem.

LOCALIZATION OF 5-HT₆ RECEPTOR mRNA IN THE RAT BRAIN BY IN SITU HYBRIDIZATION HISTOCHEMISTRY. R.P. Ward¹, M.W. Hamblin², B.J. Hoffman³, J.E. Lachowicz⁴, D.R. Sibley^{4*}, and D.M. Dorsa¹. ¹Dept. of Pharmacology, Dept. of Psychiatry and Behavioral Sciences, Univ. of Washington, Seattle, WA 98195; ²GRECC, Seattle VAMC, Seattle, WA 98108; ³Molecular Neuropharmacology Section, Experimental Therapeutics Branch, NINDS, NIH Bethesda, MD 20892; ⁴Laboratory of Cell Biology, NIMH, NIH Bethesda, MD 20892.

The Serotonin receptor subtype 5-HT₆, which raises intracellular cAMP via stimulatory G-proteins, has been recently cloned and characterized. To determine the CNS distribution of 5-HT₆ mRNA, *in situ* hybridization was performed in coronal sections of rat brain. An ³⁵S labeled riboprobe, complementary to the 5 prime noncoding region of the 5-HT₆ RNA, and a ³³P labeled riboprobe complementary to its 3 prime noncoding region were used for hybridization.

5HT-6 receptor message was found in serotonin projection fields, rather than regions of serotonin containing cell bodies, suggesting that the receptor is mainly postsynaptic. Hybridization signal was highest in olfactory tubercle, as well as prominent in the striatum, nucleus accumbens, dentate gyrus, and CA1, 2, and 3 of the hippocampus. Less intense hybridization was observed in cerebellum, some diencephalic nuclei, the amygdala, and layers two, three, four, and six of the cortex, including prefrontal cortex. This pattern of hybridization was observed with both probes, but not when sense transcripts were used.

Given the 5-HT₆ receptor has a high affinity for the atypical antipsychotic clozapine, and the importance of striatum and nucleus accumbens as proposed sites of antipsychotic drug effects, the data suggests that this receptor may play an important role in mediating the effects of the atypical antipsychotic agents.

PHARMACOLOGICAL CHARACTERIZATION OF THE EFFECT OF EXTRACELLULAR ADENOSINE 5'-TRIPHOSPHATE ON THE CONCENTRATION OF FREE CYTOPLASMIC CALCIUM IN RAT PHEOCHROMOCYTOMA PC12 CELLS. E. Adamec^{*} and G. Koski. Dept. of Anesthesia, Massachusetts General Hospital, Boston, MA 02114.

In PC12 cells, ATP causes substantial elevation of [Ca²⁺]_i ([Ca²⁺]_imax = 1400 nM, EC₅₀ = 30 μM). Administration of ATP in Ca²⁺-free buffer caused a [Ca²⁺]_i rise of approximately 10% of the total response indicating a small contribution of Ca²⁺ release from internal stores to the total [Ca²⁺]_i rise. The majority of ATP-induced [Ca²⁺]_i rise was therefore caused by Ca²⁺ influx. Increasing [Ca²⁺]_e increased peak [Ca²⁺]_i response to ATP with half-saturation at 3.5 mM reflecting high permeability of ATP-activated ion channels to Ca²⁺. ATP-induced [Ca²⁺]_i increase positively correlated with the concentration of free, uncomplexed, ATP (ATP⁴⁻) suggesting that ATP⁴⁻ is the agonist at the ATP receptor in this cell type. Administration of UTP also increased [Ca²⁺]_i ([Ca²⁺]_imax = 322 nM, EC₅₀ = 36 μM). This elevation again consisted of a combination of Ca²⁺ influx and Ca²⁺ release from internal stores. The [Ca²⁺]_i response to ATP and UTP administered together was not additive and pre-exposure to one nucleotide decreased the response to the other indicating that, in PC12 cells, ATP and UTP share a common receptor (P_{2N}). Since the EC₅₀ values for the ATP- and UTP-induced [Ca²⁺]_i rise were not significantly different, but ATP caused much larger maximal [Ca²⁺]_i rise, it appears that ATP acts as a full agonist and UTP as a partial agonist on the P_{2N} receptor in PC12 cells.

Facilitation by zink of ATP-activated currents and dopamine release in PC12 cells. K. Inoue^{*}, K. Nakazawa, K. Koizumi, M. Ikeda and K. Inoue. Div. Pharmacology, NIH, 1-18-1 Kamiyoga, Setagaya, Tokyo 158, Japan

We reported that ATP stimulates P₂ purinoceptor, activates Ca-permeable cation channels, stimulates Ca influx and dopamine (DA) release in PC12 cells (a review in NIPS, April, 1992). We have also reported that endogenous transmitters, dopamine (Eur.J. Pharmacol., 215, 321-324, 1992; Pflügers Arch., 422, 458-464, 1993), 5-HT (Pflügers Arch., in press, 1994), and adenosine (Br.J.Pharmacol., in press, 1994; Eur.J.Pharmacol., in press, 1994) regulate the ATP-evoked responses. We report here that zink also regulates ATP-activated currents and DA release from PC12 cells.

Zink (3 to 300 μM) potentiated ATP(30 μM)-evoked inward current in a concentration dependent manner without change the maximal response. The mechanism of the facilitation by zink was different from that by dopamine and high dose of adenosine. Zink also potentiated ATP(30 μM)-evoked dopamine release in the same manner as that of the currents. Zink (10 μM) shifted the concentration-response curve of ATP-evoked release to the left without affecting the maximal response. It is suggested that the facilitation is dependent on the calcium influx through ATP-activated cation channels since it was dependent on external calcium, was blocked by an ATP-receptor blocker suramin, and was parallel to the increase of intracellular free calcium concentration.

635.10

SEXUAL DIFFERENCES IN mRNA EXPRESSION AND BINDING DISTRIBUTION OF 5-HT_{1A} AND 5-HT₂ RECEPTORS IN RAT HIPPOCAMPUS. L. Zhang^{*}, W. Ma^{*}, J.L. Barker^{*} and D.R. Rubinow. BPB, NIMH, Lab. of Neurophysiology, NINDS, NIH, Bethesda, MD 20892

Sexual differences in the expression of mRNA and concentration of 5-HT_{1A} and 5-HT₂ receptors were studied by *in situ* hybridization and autoradiography ([³H]DPAT and [³H]ketanserin binding) in rat hippocampus. 5-HT_{1A} receptor mRNA showed distinct expression patterns in female and male rats. In males little 5-HT_{1A} receptor mRNA was detected in CA3 and CA4, while in females the receptor expression was relatively uniform throughout the hippocampal formation. However, there were no significant sexual differences in the distribution of 5-HT_{1A} receptor binding sites. Unlike 5-HT_{1A}, 5-HT₂ receptor mRNA was expressed in CA3 and CA4 with little expression detected in CA1 and CA2. However, the concentration of the 5-HT₂ receptor measured with [³H]ketanserin was significantly higher in females than in males. To our knowledge, this is the first report of the sexual differences in the transcript and receptor levels of hippocampal 5-HT receptors. The data complement a growing literature demonstrating functional and anatomical difference in the 5-HT system in males and females.

636.2

Distinct cellular responses are evoked by ATP and UTP in PC12 cells.

L. de Souza¹, H. Moore², J. K. Reed^{1,2} and J. Fullard^{3*}. Depts. of Biochemistry¹, Chemistry² and Zoology³, University of Toronto, Erindale College, Mississauga, ONT. L5L 1C6, Canada.

Extracellular ATP is a modulator in many cell types including those of neuronal origin. The intracellular responses of ATP are mediated by purinergic P₂ receptors, of which several sub-types have been identified based on the ATP analogue efficacy profiles. We and others have identified a P_{2N} sub-type in PC12 cells that recognizes both ATP and the pyrimidine, UTP and mediates the increase in [Ca²⁺]_i and IP₃ (Raha et al., J. Cell. Physiol., 154: 623-630, 1993).

We have now identified additional signalling pathways in PC12 cells that are mediated by ATP but not by UTP. Specifically, ATP but not UTP depolarizes PC12 cells (measured with bisoxonol and [³H]TTP⁺). The ATP-mediated depolarization is not desensitized by preincubation with UTP.

The effect of extracellular nucleotides on pH_i in PC12 cells was measured using BCECF. 100 μM ATP induces a rapid initial acidification from an basal pH_i of 7.0, followed by a gradual amiloride-sensitive alkalinization; 100 μM UTP evokes only a delayed alkalinization. The degree of ATP-mediated acidification is concentration dependent.

In addition, ATP but not UTP (up to 400 μM) induces secretion of endogenous dopamine. Taken together, these observations support the view that purine and pyrimidine nucleotide triphosphates activate distinct signalling pathways in PC12 cells. This research was supported by NSERC.

UPREGULATION OF A₁ ADENOSINE RECEPTORS IN CEREBELLAR GRANULE CELLS IN RESPONSE TO CHRONIC CAFFEINE EXPOSURE. B.D. Hettinger-Smith, M. Leid and T.F. Murray*. College of Pharmacy, Oregon State University, Corvallis, OR 97331.

Adenosine is a ubiquitous neuromodulator acting in the central nervous system at A₁, A₂ and A₃ adenosine receptors. Caffeine and related methylxanthines act as nonspecific antagonists at A₁ and A₂ adenosine receptors. Chronic antagonism of these G-protein coupled receptors results in tolerance to the stimulatory effects of caffeine which may, in part, be due to A₁ adenosine receptor upregulation. The effect of chronic caffeine exposure in cerebellar granule cell cultures was examined.

Cerebella were obtained from eight day old Sprague Dawley rat pups and primary cultures of the granule cell neurons were established. Binding in membranes derived from granule cell neurons was examined using the A₁ adenosine receptor antagonist [³H] 8-cyclopentyl-1,3-dipropylxanthine (DPCPX). Nonspecific binding was determined in the presence of 100 μM N⁶-cyclopentyladenosine (CPA). Receptor expression was analyzed at day 5, 7, 9, 11 and 13 post culture. Maximum [³H]DPCPX binding was present at day 13. In order to determine the caffeine concentration needed to obtain maximal upregulation, cells were incubated with final concentrations of 10⁻⁴ to 10⁻⁹ caffeine and [³H]DPCPX binding was analyzed. Maximal upregulation of [³H]DPCPX binding was obtained with 100 μM caffeine. Time course studies revealed that incubation with 100 μM caffeine for 7 days produced the greatest upregulation of [³H]DPCPX binding. Cerebellar granule cells in primary culture appear to afford a useful model system for the study of A₁ adenosine receptor regulation.

CHARACTERIZATION AND EXPRESSION OF THE HUMAN A2a ADENOSINE RECEPTOR GENE. RA Peterfreund*, MM MacCollin, J Gusella, JS Fink, Depts. Anesthesia and Neurology, Massachusetts General Hospital, Boston, MA 02114.

Adenosine A2a receptors (A2aRs) mediate vasodepressor actions of adenosine in the CNS and periphery and behavioral actions of adenosine in the basal ganglia. To begin to define mechanisms controlling the expression of A2aRs, we isolated and characterized genomic clones from a human chromosome 22-only cosmid library which contain the A2aR sequence. Southern blot and PCR analysis confirm the location of this gene on chromosome 22. A single intron (~6 kb) interrupts the coding sequence between transmembrane domains III and IV of the cDNA. Northern blot analysis reveals that the gene encodes a principle ~2.6 kb transcript as well as a secondary ~1.4-1.8 kb transcript in some tissues. Abundant expression is observed in caudate but little or no expression is detected by Northern blot in other brain regions sampled. Heart, lung and hematopoietic tissues express significant amounts of A2aR mRNA. We conclude that the human A2aR gene is a member of the intron-containing class of G protein-linked receptor genes with regionalized expression in discrete brain and peripheral tissues. The findings support roles for A2aRs in basal ganglia, cardiopulmonary and immune function.

ACETATE DOES NOT INDUCE ADENOSINE-MEDIATED INHIBITION IN THE DENTATE GYRUS OR HIPPOCAMPAL CA1 REGION. J.M. Brundage and T.V. Dunwiddie*. Dept. of Pharmacology, University of Colorado Health Sciences Center, and Veterans Admin. Medical Res. Service, Denver, CO.

Acetate is the primary breakdown product of ethanol metabolism and can accumulate in the brain following ethanol consumption. It has been suggested that acetate can be metabolized to adenosine within cells in the CNS and release of this adenosine may cause neuronal inhibition. In order to determine the effects of extracellular acetate on neurons, we applied exogenous sodium acetate (0.5 to 2 mM) to hippocampal slices from adult male rats. The acetate caused no significant effect on the resting membrane potential, input resistance, or EPSP amplitude in CA1 pyramidal neurons and had no effect on extracellular field EPSPs in either the CA1 region or the dentate gyrus. To determine the effects of intracellular acetate, we compared the effects of the adenosine receptor antagonist theophylline on cells impaled with intracellular microelectrodes containing 2.5M K⁺-acetate, 1M KCl, or 2M K⁺-methylsulfate. With all three intracellular filling solutions, theophylline produced small but statistically significant increases in input resistance, consistent with the presence of low concentrations of extracellular adenosine. However, the response to theophylline with acetate-filled electrodes was not different from the other filling solutions. These results suggest that the presence of acetate, either in the extracellular solution or within the intracellular electrode, does not induce a significant adenosine response in the hippocampus. ADENOSINE RECEPTOR-MEDIATED MODULATION OF CHOLINERGIC NEURONES OF THE LATERODORSAL TEGMENTAL NUCLEUS OF THE RAT, IN VITRO. D.G. Rainnie, H.C.R. Grunze, R.W. McCarley, and R.W. Greene, Dept. of Psychiatry, Harvard Medical School and VAMC, Brockton, MA 02401.

Increased discharge activity of mesopontine cholinergic neurones plays a key role in the production of electroencephalographic (EEG) arousal. We recently reported that mesopontine cholinergic neurones are under the tonic inhibitory control of endogenous adenosine (AD; Rainnie et al., Science 1994). Here we extend this study to examine factors regulating the multiphasic response of laterodorsal tegmental nucleus (LDT) neurones to exogenous adenosine application.

Whole cell patch-clamp recordings were made from LDT neurones using a standard *in vitro* brainstem slice preparation. Application of AD (5-100 μ M) resulted in a dose-dependent hyperpolarization-depolarization-hyperpolarization, in 76% of all neurones tested (n=67). The hyperpolarization was associated with a decrease in membrane input resistance that was mediated by activation of an inwardly rectifying potassium conductance. The hyperpolarization was mimicked by the A₁ agonist N⁶-cyclohexyladenosine (CHA, 1 μ M) and blocked by the A₁ antagonist 8-cyclopentyl-1,3-dimethylxanthine (CPX, 500nM) suggesting that A₁ purinergic receptors mediate this response. In the presence of 500 nM CPX, no response was observed following application of the specific A₂ receptor agonist CGS-21860, suggesting that activation of A₂ receptors does not mediate the intervening depolarization. Pressure ejection of AD (1 mM, 300 ms) during the depolarization evoked an equivalent hyperpolarization to that obtained before AD application, suggesting that the depolarization does not result from a desensitization and subsequent resensitization of A₂ receptors. The depolarization persists in the presence of specific AD uptake inhibitors, NBTT (10 μ M) and dipyridamole (1 μ M). This data also suggests that activation and subsequent saturation of the AD uptake pump cannot account for the membrane depolarization. Additional experiments are being conducted to determine the mechanism underlying the depolarizing response.

INTERACTIONS BETWEEN ETHANOL AND ADENOSINE IN HIPPOCAMPAL BRAIN SLICES. L. Diaz* and T.V. Dunwiddie. Dept. Pharmacology, UCHSC & VA Med. Res. Service, Denver, CO 80262.

A number of studies have strongly suggested that adenosine may be an important mediator of the effects of ethanol (EtOH) both in isolated systems as well as intact animals. These adenosine-mediated effects of EtOH might result from increases in extracellular adenosine which occur as a result of the inhibition by EtOH of adenosine uptake via the nucleoside transporter. Although this effect has been demonstrated biochemically, there have been few functional studies of EtOH-adenosine interactions. In the present study, we tested whether EtOH inhibits the uptake of adenosine *in vitro* by measuring the extracellularly recorded fEPSP response in the rat hippocampal slice preparation. When tested alone, EtOH (20mM and 100mM) produced variable effects on the fEPSP response. In about one third of slices, EtOH had a biphasic effect with an initial excitation followed by inhibition. In the remainder of the slices, EtOH had no effect or produced a slow decline the response, but the overall effect was not statistically significant. However, on the one hand, when slices were pretreated with competitive adenosine receptor antagonists such as theophylline (250 μ M) and 8-cyclopentyltheophylline (1 μ M), both types of responses to EtOH were blocked, and there was a 2 to 6-fold reduction in the standard deviation of responses to EtOH. On the other hand, when slices were pretreated with the adenosine uptake inhibitor dipyridamole (5 μ M), exogenous adenosine (10 μ M and 30 μ M), and the selective A₁ adenosine receptor agonist N⁶-cyclohexyladenosine (1 μ M), ethanol caused significant decreases in fEPSP amplitudes that were reversible upon washout or application of theophylline (250 μ M-1mM). However, when slices were pretreated with EtOH, this had no effect upon subsequent responses to either dipyridamole (5 μ M) or adenosine (10 μ M and 30 μ M). These results suggest that the ability of EtOH to modulate synaptic transmission at these synapses is dependent on the prior activation of adenosine receptors, but this does not appear to involve an inhibition of adenosine uptake by EtOH.

ADENOSINE REDUCES ACCOMMODATION AND A TRANSIENT OUTWARD CURRENT IN RAT SPINAL DORSAL HORN NEURONS IN CULTURE. Y.S. Pak* and M.W. Salter, Div. Neurosci., Hosp. for Sick Children, Dept. Physiol., Univ. Toronto, Toronto, Ont. Canada M5G 1X8.

Studies *in vivo* have indicated that adenosine may be a chemical mediator in the spinal dorsal horn (Salter et al. Prog. Neurobiol. 41:125-156, 1993). To investigate the effects of adenosine further we made recordings from dorsal horn neurons *in vitro* using perforated patch and whole-cell techniques. Recording electrodes contained the following (in mM): for perforated patch - K₂SO₄ 90, KCl 35, EGTA 11, Ca²⁺ 1, HEPES 10; for whole-cell - KCl 140, HEPES 10, EGTA 11, MgCl₂ 2, \pm ATP 4, \pm GTP 0.5. Adenosine (100-500 μ M; 30-120 s) had no effect on the resting membrane potential or resting conductance during current clamp recordings (n=9 cells). However, adenosine caused a 50-100% increase in the rate of action potential discharge evoked by depolarizing intracellular current pulses. This effect was reversible and reproducible. To investigate the underlying mechanism we examined the effect of adenosine on voltage-activated K currents. Tetrodotoxin (1 μ M) was included in the extracellular medium for these experiments. Currents were evoked by voltage steps from -110 to +30 mV; a hyperpolarizing pulse (-120 mV; 100 ms) was given prior to each step. Typically, a rapidly-activating transient outward current was elicited beginning near -60 mV and a sustained outward current was recruited at -20 mV. With 34 of 38 cells adenosine reduced the amplitude of the transient outward current but had no effect on the sustained current; neither current was affected in the remaining cells. The transient outward current appeared to be an A-type current because it was blocked by 4-AP (6 mM) but was insensitive to TEA (10 mM). Our results suggest a novel effect of adenosine to reduce accommodation by depressing an A current in dorsal horn neurons. (Supported by Canadian MRC).

636.10

PROTOCOL FOR IN VIVO MICRODIALYSIS OF ADENOSINE IN THE BRAINSTEM AND BASAL FOREBRAIN OF FREELY MOVING CATS. C.M. Portas*, M. Thakkar, D. Rainnie, R. Greene and R.W. McCarley Lab. Neurosci., Dept. Psychiatry, Harvard Med. School/ VAMC, Brockton, MA 02401.

Considerable evidence implicates mesopontine and basal forebrain cholinergic neurons in control of EEG and behavioral arousal. Our recent *in vitro* work indicates these neurons are under tonic inhibitory control of adenosine (Rainnie et al., Science, 1993). This raises the question of whether increased brain metabolism during prolonged wakefulness might increase extracellular adenosine concentration, thereby promoting sleep. This abstract describes the methodology for *in vivo* microdialysis detection of adenosine levels, and preliminary data on effects of adenosine perfusion. Following a two week postoperative recovery period, a 2 mm tip probe (CMA 10) was inserted into the target area 20-24 hours before starting perfusion with artificial CSF at a flow rate of 1 μ L/min (CMA 100 microdialysis pump). Perfusate was collected via a dual channel microdialysis swivel (Insteach Laboratories PA) incorporated in a 24 channel electrical swivel (Airflyte Electronics Company N.J.) used for the polygraphic recordings. Analysis of 20 μ L samples was via a HPLC system (Waters Pump 501), coupled to a UV detector (Waters 486). The column used was a Waters ODS bonded phase and the mobile phase consisted of Na phosphate buffer 8mM, methanol 9%, pH ~5. Chromatographic data were recorded and concentrations determined by a Shimadzu (CR3A, Japan) integrator using an external standard calibration curve. RESULTS: The detection limit for adenosine was 100 f-moles/sample. The baseline waking level in the mesopontine LDT was about 15 nM (0.3 pmoles/sample), while in basal forebrain it was about 50nM (1 pmoles/sample). Since *in vitro* tests have shown probe recovery to be about 8%, this implies extracellular concentration levels of about 120nM in the LDT and 400nM in basal forebrain. Measurements of state-related adenosine alterations are incomplete. However, preliminary data show dramatic changes from baseline state values during 2 h of adenosine (1mM) perfusion via the microdialysis probe into the basal forebrain: there were marked increases in SWS (140%) and REM sleep (290%) and a 70% decrease in waking.

TRH ANALOGUES AND ADENOSINE AGONISTS ELICIT VOMITING IN THE CAT. James B. Lucot⁺. Dept. Pharmacol., Wright State Univ., Dayton, OH 45435

During the testing of novel receptor actions which theoretically could decrease motion sickness, some receptor selective drugs unexpectedly elicit vomiting. Describing novel emetics has value in (1) offering new tools for research into emetic mechanisms, (2) having potential for new insights into the emetic pathways and (3) identifying possible clinical side effects missed by studies with anesthetized subjects or in species which do not vomit. All drugs were administered SC in a volume of 0.1 ml/kg. Tests lasted 30 min or 15 min after the last vomit, whichever occurred later. The disubstituted stable TRH analogue MK 771 elicited vomiting with an ED₅₀ of 3.1 µg/kg and the monosubstituted analogue CG 3703 did so with an ED₅₀ of 1.9 µg/kg. The adenosine A₁ agonist CHA elicited vomiting with a steep dose-response curve. Vomiting elicited by 10 µg/kg was blocked by 300 µg/kg of the A₁ antagonist CPT, reduced by 100 µg/kg of the nonselective antagonist PD 115199 and not affected by up to 300 µg/kg of the A_{2a} antagonist CGS 15943. The adenosine A_{2a} agonist CV 1808 elicited vomiting with a shallow dose-response curve. The vomiting elicited by 300 µg/kg was not altered by the above doses of CPT, CGS 15943 or up to 100 µg/kg of the A₂ antagonist DPMX, leaving questionable the emetic site of action.

GENOMIC CLONING AND CHARACTERISATION OF A RECOMBINANT HUMAN HISTAMINE H₁-RECEPTOR. W.H.M.L. Luyten⁺, M.D. De Backer, P. Van Gompel, K. De Loore, W. Gommeren and J.E. Leysen. Department of Biochemical Pharmacology, Janssen Research Foundation, Beerse, B2340 Belgium.

A human histamine H₁-receptor (H₁-R) gene lacking introns was isolated by screening a human genomic library with a bovine H₁-R probe (BBRC 197: 1601-1608 (1993)). The coding region of the human H₁-R was sequenced and subcloned into the pSVL expression vector (Pharmacia) yielding pSVL/H₁-R. Membranes from COS-cells transiently transfected with pSVL/H₁-R showed saturable specific binding of [³H]pyrilamine with a K_D of 1.2 nM and a B_{max} of 3400 fmol/mg protein (compared to a K_D of 0.30 nM and B_{max} of 480 fmol/mg protein for guinea-pig cerebellum membranes). Radioligand binding was inhibited by histamine and by several H₁-R antagonists at comparable concentrations for membranes of pSVL/H₁-R-transfected COS-cells and of guinea-pig cerebellum. Untransfected COS-cells or COS-cells transfected with pSVL showed very little specific [³H]pyrilamine binding (< 50 fmol/mg protein). However, histamine (10⁻⁶M-10⁻⁴M) concentration-dependently induced inositol phosphate (IP) formation to a similar extent in transfected and untransfected COS-cells, and this effect could be progressively inhibited by increasing pyrilamine concentrations. This suggests that an endogenous H₁-R in COS-cells couples much more efficiently to the IP signal transduction cascade than the transfected H₁-R.

CHO-K1 cells were permanently transfected with a H₁-R construct in pRC/CMV (Invitrogen). Membranes prepared from transfectants showed specific [³H]pyrilamine binding ranging from 100 to over 2000 fmol/mg protein. Histamine concentration-dependently induced IP formation more than ten-fold over background in transfected but not in untransfected CHO-cells, and this effect could be progressively inhibited by increasing pyrilamine concentrations.

Sequencing of the genomic human H₁-R clone upstream of the start-codon revealed several sequence motifs with known regulatory function. Their functional relevance is being assessed by cloning 5'-flanking regions of various size into pGL2 luciferase reporter vectors (Promega) and measuring luciferase activity after transfection.

HISTAMINE H₃ RECEPTOR SUBTYPE CHARACTERIZATION IN ISOLATED GUINEA PIG TISSUES. C.A. Rizzo, S. Tozzi, M.E. Monahan, D. Krobatsch and J.A. Hey⁺. Schering-Plough Research Institute, Kenilworth, NJ 07033.

The histamine H₃ receptor subtypes involved in the H₃ modulation of electrical field stimulated (EFS) neurogenic responses in pulmonary artery sympathetic and ileum parasympathetic preparations were characterized to determine whether H_{3A} or H_{3B} receptors are present in these tissues. Simultaneous measures of EFS-evoked [³H] overflow and tension in [³H]-norepinephrine-loaded pulmonary artery were sensitive to tetrodotoxin (300 nM) and insensitive to hexamethonium (100 µM), with only evoked tension significantly antagonized by prazosin (100 nM). R-α-methylhistamine's inhibition of evoked tension and [³H] overflow were both dose-dependently antagonized by thioperamide (30 - 100 nM). In the pulmonary artery the rank order potency of the H₃ antagonists thioperamide (pA₂ = 8.1 ± 0.1), burimamide (pA₂ = 7.1 ± 0.2), and impromidine (pA₂ = 6.7 ± 0.1) vs R-α-methylhistamine (pD₂ = 7.1) suggests a predominant H_{3A}-like receptor population on postganglionic sympathetic neurons. In the ileum H₃ receptor assay, the rank order potency of the H₃ antagonists thioperamide, burimamide, and impromidine, with pA₂ estimates of 8.7 ± 0.1, 7.3 ± 0.1 and 7.1 ± 0.1, respectively, vs R-α-methylhistamine (pD₂ = 8.2), also suggests a predominantly H_{3A}-like receptor population.

THE HISTAMINE ACTION ON ACUTELY DISSOCIATED NEURONS OF THE RAT NEOSTRIATUM. M. Munakata⁺ and N. Akaike. Dept. of Bio-Plasticity, Kyushu Univ. Fac. of Med., Fukuoka 812, Japan

The neostriatum is innervated by histamine fibers. Histamine receptors have been detected in this region by the radioligand binding study and also involved in pathological conditions such as acathisia and catalepsy. However, the functional role of histamine receptors in the neostriatum remains unknown. We investigated, therefore, the effects of histamine in neurons acutely dissociated from the neostriatum of 2-week-old Wistar rats, using *perforated patch clamp technique*. In current-clamp mode 10⁻⁵M histamine slowly depolarized the membrane with increased firing activities, and in voltage-clamp mode it evoked a net inward current accompanied by decreased conductance at a V_H of -44 mV. This response may be restricted in interneurons. We clarified pharmacologically that this histamine-induced response was mediated by both the H₁ and H₂ receptors. H₁-mediated response arose with a threshold concentration of 10⁻⁸ M and reached the maximal response at 10⁻⁶ M, whereas H₂-mediated response was in the range between 10⁻⁶ and 10⁻⁵ M. Both H₁ and H₂ receptor-mediated currents resulted from a decreased K⁺ conductance, which may increase neuronal excitability. The co-existence of H₁ and H₂ receptors with a wide concentration range may result in extensive modulation of the functional activities in the neostriatum.

MOLECULAR MODELLING OF THE H₂ HISTAMINE RECEPTOR

C. Olea-Azar, M. Ortells and G. Lunt⁺. Biochemistry Department, University of Bath, Bath, BA2 7AY, UK

A 3-D model of the canine H₂ receptor (1) was constructed and analysed. This model was defined using primary sequence comparisons and three-dimensional homology building, using bacteriorhodopsin as a template. Experimental data from a variety of sources were used to localise the ligand binding site and to identify residues likely to be responsible for receptor affinity, selectivity and efficacy.

Molecular mechanics of the receptor model with tautomeric forms and folded and extended conformations of histamine were studied.

The potential energies of this model are consistent with the binding data obtained from mutagenesis studies (2) On the basis of our results we have postulated that Glu-270 in transmembrane VII would be an important residue to target in future mutagenesis studies.

Finally, we have studied a potent H₂ antagonist receptor, famotidine. The complex energy for this antagonist was 50 Kcal/mol more stable than for the histamine complex. The principal interactions were the cation guanidine chain, that corresponds to the protonated amine in histamine, with Asp-98, the amino group of the sulphonamide chain with Asp-186 and a weak interaction between the oxygen sulphonamide and Thr 190.

CLOZAPINE-SENSITIVE BINDING TO HISTAMINE H₃ RECEPTOR IN RAT FRONTAL CORTEX. A. Rodrigues, J. Goldfarb and GD Prell⁺. Dept Pharmacology, Mount Sinai Medical Center, New York, NY 10029

There is evidence suggesting that histaminergic activity is elevated in brains of schizophrenic patients (Soc. Neurosci. Abstr. 18: 446; Lancet 335: 1351; Biol Psychiat. 30: 349). For example, in patients refractory to conventional neuroleptic drugs, CSF levels of histamine's primary metabolite were higher than in controls and correlated with severity of symptoms. In cortex of patients with chronic schizophrenia, H₁ receptors were downregulated, consistent with overstimulation by histamine. H₃ autoreceptors regulate synthesis and release of histamine; H₃ heteroreceptors influence release of dopamine and 5-HT. Neuroleptics bind to H₁ and H₂ receptors. We examined their interactions with H₃ receptors. The latter, in rat cortical membranes prepared in Na/K-phosphate buffer (50 mM, pH 7.4), were labeled with [³H]-N-α-methylhistamine. Saturation binding (non-specific binding defined with either 1 µM thioperamide or R(-)-α-methylhistamine) yielded a K_D of approx 0.5 nM and a B_{MAX} of 150-170 fmol mg⁻¹ protein. In competition studies using 0.8 nM [³H]-N-α-MeHA (spec. binding =90% of total) typical neuroleptics of many chemical classes (e.g. haloperidol, chlorpromazine, thiothixene, pimozide, spiperone) showed low affinity binding (IC₅₀s 3-50 µM). The atypical neuroleptic clozapine displayed much higher affinity, producing shallow competition curves consistent with more than one binding site. Preliminary data suggest a high affinity component (approx 30% of total specific binding) with a K_i (assuming competitive inhibition) in the 3-10 nM range, consonant with the range of plasma levels seen clinically. Clozapine's interactions with H₃ receptors may have therapeutic relevance. (NS-28012)

HISTAMINERGIC NEURONS MEDIATE RESTRAINT STRESS-INDUCED CHANGES IN ACTIVITY OF SELECTED CENTRAL CATECHOLAMINERGIC AND 5-HYDROXYTRYPTAMINERGIC NEURONS IN THE RAT A.E. Fleckenstein¹, K.J. Lookingland¹ and K.E. Moore², Dept. Pharm./Tox., Michigan State Univ., E. Lansing, MI 48824

The role of histaminergic (HA) neurons in mediating stress-induced changes in activity of selected catecholaminergic and 5-hydroxytryptaminergic (5HT) neuronal systems was examined in male rats. Dopaminergic (DA), noradrenergic (NE) and 5HT neuronal activity was estimated by measuring concentrations of neurotransmitters and metabolites in brain regions containing terminals of these neurons. Placement of rats within restraining tubes increased dopamine metabolism in the nucleus accumbens, decreased dopamine metabolism in the intermediate lobe of the pituitary, and was without effect in the striatum and median eminence. These data indicate that restraint stress increases mesolimbic, decreases periventricular-hypophyseal, and is without effect on nigrostriatal and tuberoinfundibular DA neuronal activity. Neither depletion of neuronal histamine by α -fluoromethylhistidine (α FMH), blockade of H_1 receptors by mepyramine, nor blockade of H_2 receptors by zolantidine prevented stress-induced increases in dopamine metabolism in the nucleus accumbens suggesting that HA neurons are not major contributors to stress-increased mesolimbic DA neuronal activity. In contrast, treatment with both α FMH and mepyramine, but not zolantidine, prevented stress-induced decreases in dopamine metabolism in the intermediate lobe indicating that HA neurons mediate stress-induced decreases in periventricular-hypophyseal DA neuronal activity through an action at H_1 receptors. Stress increased norepinephrine and 5-hydroxytryptamine metabolism in the hypothalamus, and 5-hydroxytryptamine metabolism in the nucleus accumbens. Both α FMH and mepyramine antagonized, whereas zolantidine did not prevent these increases suggesting that HA neurons contribute to stress-induced increases in 5HT and NE neuronal activity through an action at H_1 receptors. MELATONIN MODULATES CHOLINERGIC SYNAPTIC TRANSMISSION IN ENTERIC NEURONS. B. Prieto-Gómez¹, R. Espinosa-Luna² and C. Barajas-López². ¹Department of Physiology, Faculty of Medicine, UNAM, México ²Department of Biomedical Sciences, McMaster University, Ontario, Canada.

Melatonin, a hormone produced and released by the pineal gland, is also synthesized by cells of the gastrointestinal wall, where it might be a local regulator of gut functions. In this study, we investigate the actions of melatonin as a modulator of synaptic transmission in the submucosal plexus from the guinea-pig ileum. Intracellular recordings were made in submucosal neurons to measure the amplitude of nicotinic excitatory postsynaptic potentials (EPSPs). Melatonin (0.03-3 mM) reversibly decreased the amplitude of nicotinic EPSPs in a concentration dependent manner ($EC_{50}=332 \mu M$). Maximal effects were observed within 4 min after the arrival of the melatonin-containing solution and they persisted for as long as melatonin was present (up to 15 min). Melatonin actions were not modified by the presence of idazoxan and atropine (1 μM) indicating that they are not mediated by endogenous release of ACh or noradrenaline or by direct activation of α_2 -adrenergic or muscarinic receptors by melatonin. The superfusion of melatonin (1 μM) also blocked the nicotinic depolarizations induced by locally applied ACh. These observations indicate that melatonin might be a local modulator of synaptic transmission in the enteric nervous system and that at least part of its effects are postsynaptic. This work was supported by the MRC, OMH and CONACYT.

SIGMA RECEPTOR LIGANDS REGULATE MELATONIN SYNTHESIS IN RAT PINEAL GLAND. L. Steardo¹, P. Monteleone², M.R. Carratù¹, A. Tortorella², M. Persichella¹, M. Mai² and V. Cuomo¹. Dept. Pharmacology Medical School Univ. of Bari¹, Dept. of Psychiatry Medical School Univ. of Naples² (Italy)

Into rat pineal gland blood-derived tryptophan is sequentially converted to serotonin (5HT), N-acetyl-serotonin and finally to melatonin. N-acetyltransferase (NAT), the enzyme catalyzing the acetylation of 5HT, is believed to be the rate limiting factor in this biosynthetic pathway. Recently sigma receptors have been reported to be highly concentrated in rat pineal gland, but at moment, their physiological role remains to be understood. Therefore the effects of sigma receptor ligands on NAT activity and melatonin content in rat pineal gland were investigated. In a first set of experiments, +N-allylnormetazocine (+SKF 10047), the prototype agonist of sigma binding sites, at doses of 0.5; 2.5 and 5.0 mg/kg i.p. was able to induce clear-cut increases in both pineal NAT activity ($F_{3,16} = 3.864$ $p < 0.03$ two way ANOVA) and melatonin content ($F_{3,16} = 9.229$ $p < 0.001$ two way ANOVA) at night, but not during the day. In a second set of experiments 1,3 - di (2tolyl) guanidine (DTG), a potent and selective sigma agonist, at doses of 5; 10 and 20 mg/kg i.p., markedly enhanced NAT activity and melatonin synthesis stimulated by beta 1 adrenoreceptor activation induced by 0.3 and 1 mg/kg of i.p. isoproterenol ($F_{3,48} = 2.478$ $p < 0.03$ two way ANOVA) ($F_{3,48} = 3.551$ $p < 0.007$ two way ANOVA), respectively. The present results suggest that sigma receptor stimulation is involved in the regulation of melatonin production in rat pineal gland.

ADENOSINE INCREASES THE SIGNAL TO NOISE RATIO IN FASCIA DENTATA BY A PRE-SYNAPTIC MECHANISM.

T.H. Swanson^{*}. Departments of Neurology and Neurosciences, Research Institute, Cleveland Clinic Foundation, Cleveland, OH 44195.

Adenosine analogs increase or decrease perforant path stimulation evoked dentate granule cell action potential firing depending on concentration. We have previously reported that 1.0 nanomolar of the stable A1 adenosine analog cyclopentyladenosine (CPA) increases granule cell action potential firing for a given population PSP amplitude. To explore the mechanism of this novel finding, we performed whole-cell current clamp recordings of rat dentate granule cells were performed in 400 μM thick hippocampal slices. Resting membrane potential (-65 ± 4 mV), input resistance (136 ± 32 M Ω), and action potential threshold (-33 ± 7 mV) during perforant path stimulation were compared in the presence and absence of 1.0 nanomolar CPA in seven experiments. No significant change in any of the measured variables could be detected during CPA application. In other experiments, we measured glutamate release from perforant path stimulated granule cells using a sensitive HPLC assay with PTC derivatization (resolution limit 10 picomoles). Average basal glutamate release was 170 ± 65 pM / ml, rising to 450 ± 50 pM / ml during one Hz perforant path stimulation. No change in glutamate release was detected during CPA application. We conclude that low concentrations of adenosine analogs increase perforant path / granule cell synaptic efficiency without affecting intrinsic post-synaptic membrane properties or altering glutamate release. These data support a pre-synaptic mechanism for this novel action in accord with the documented ability of adenosine to inhibit polysynaptic but not monosynaptic IPSP's in similar preparations.

NEUROTRANSMITTER INTERACTIONS: SEROTONIN

637.1

EVIDENCE FOR INVOLVEMENT OF MEDIAN, BUT NOT DORSAL, RAPHE NEURONAL 5-HT_{1A} AUTORECEPTORS IN THE MEDIATION OF THE ANTICATALEPTIC EFFECTS OF 8-OH-DPAT IN THE RAT. M-L Wadenberg^{*} and V. Hillegaart. Dept. of Behavioral Pharmacology, Astra Arcus AB, S-15185 Södertälje, Sweden.

The systemic administration of the 5-HT_{1A} receptor agonist 8-OH-DPAT has been shown to counteract the catalepsy induced by DA D₂/D₃ receptor blocking agents like raclopride or haloperidol. 8-OH-DPAT also produces this effect after icv, but not intrathecal, administration, suggesting a supraspinal mediation of the effect. The dorsal and median raphe nuclei have both been implicated as the target for effects by 8-OH-DPAT, but there are divergent opinions on the relative importance of these nuclei in this regard.

The present study was designed to clarify the functional role of median versus dorsal raphe 5-HT nuclei in the mediation of the anticataleptic effect of 8-OH-DPAT. Animals were observed for catalepsy on an inclined (60°) grid at different time intervals. Degree of catalepsy was scored according to a square root transformation of raw data. It was found that 8-OH-DPAT (0.5 or 2.5 μg , -10 min) locally injected into the median raphe nuclei produced a dose-dependent and statistically significant antagonism of raclopride-(16 mg kg⁻¹ sc, -1h) induced catalepsy. 8-OH-DPAT (0.5 or 2.5 μg) locally injected into the dorsal raphe nuclei, however, had no effect on raclopride-(16 mg kg⁻¹ sc) induced catalepsy.

In conclusion: The results provide evidence for a specific involvement of 5-HT_{1A} autoreceptors of the median raphe in the mediation of the antagonism by 8-OH-DPAT of catalepsy induced by dopamine receptor blocking drugs.

637.2

STRIATAL C-FOS INDUCTION BY CONCOMITANT STIMULATION OF 5-HT_{1A}-5-HT₂, D₁-5-HT_{1A} AND D₁-5-HT₂ RECEPTORS. J. Gervais¹, S. Boyette², D. Richard³ and C. Rouillard^{1,2}. ¹Lab. of Neurobiology, ²Dept. of Pharmacology and ³Physiology, Laval University, Québec, Canada G1J 1Z4.

We have previously demonstrated that the release of 5-HT by fenfluramine (FEN) induces Fos-like immunoreactivity (Fos-LI) in the dorso-medial part of the striatum (STR) as well as in other brain structures receiving a dense 5-HT innervation. The immediate-early gene response is under the control of both DA and 5-HT. However, we were unable to reproduce the effects of FEN in the STR with the administration of selective 5-HT receptor subtypes agonists. This markedly contrasted with c-fos expression in cortex where 8-OH-DPAT (5-HT_{1A}) and DOI (5-HT₂) reproduced the effects of FEN. Therefore, the main objective of the present study was to investigate the possibility of interaction between different 5-HT receptor subtypes or between 5-HT and DA receptor subtypes. To investigate this possibility, seven groups of animals, each consisting of at least 3 rats were used in this study. Agonists were administered i.p. and animals were sacrificed 120 min later. Brains were removed, sliced and processed for Fos-LI. Treatments were a) Saline+Saline, b) Saline+8-OH-DPAT (2.5 mg/kg), c) Saline+DOI (2.5 mg/kg), d) Saline+SKF38393 (2.0 mg/kg), e) SKF38393+DOI, f) SKF38393+8-OH-DPAT and g) 8-OH-DPAT+DOI. Our results show that all three agonist combinations induce Fos-LI expression in the medial part of the STR, the nucleus accumbens and the cortex. The 8-OH-DPAT+DOI combination was the most effective, followed by SKF 38393+DOI and SKF38393+8-OH-DPAT combinations. No Fos-LI was found in the lateral part of STR. This study strongly suggest the possibility of interaction and synergism between 5-HT receptor subtypes and between DA and 5-HT receptors in the STR. The immediate-early gene expression is restricted to a striatal territory related to associative functions while the striatal territory related to motor functions did not show any Fos-LI. (Supported by NSERC and FRSQ)

637.3

THE EFFECT OF SEROTONIN ON TYROSINE HYDROXYLASE ACTIVITY: AN *IN VIVO* MICRODIALYSIS STUDY. Richard S.J. Nassar¹ and Matthew P. Galloway², Cellular & Clinical Neurobiology Program, Dept Psychiatry & Behavioral Neurosciences, Wayne State Univ Sch Med, Detroit, MI 48202.

We have shown previously that striatal perfusion of 5-HT agonists increases extracellular levels of DA. As an extension of these studies, the potential role of serotonin (5-HT) in modulating tyrosine hydroxylase (TH) activity in striatal DA nerve terminals was monitored by *in vivo* microdialysis. To ascertain TH activity extracellular DOPA levels were measured during the continual perfusion of the decarboxylase inhibitor, difluoromethylpapa (100 μ M, DFMD, MDL 71,801), in artificial CSF (2 μ L/min). Once a baseline of DOPA was established, pharmacological manipulation of TH activity was evaluated. To test the responsiveness of TH under these experimental conditions either the D₂ antagonist haloperidol or the D₃ preferring agonist 7-OHDPAT was administered systemically. 7-OHDPAT (0.5 mg/kg, i.v.) decreased DOPA levels by 40% and haloperidol (1 mg/kg, i.v.) increased DOPA levels 82% over baseline levels. Further, haloperidol reversed the decrease in DOPA levels brought on by 7-OHDPAT. Co-perfusion of DFMD and 5-HT (100 μ M, 10 min) induced a 79% increase in DOPA levels with a return to baseline levels after removal of 5-HT. Moreover, when the 5-HT agonist m-chlorophenylpiperazine (mCPP, 100 μ M, 10 min) was co-perfused with DFMD, DOPA levels increased 80% \pm 4% (n=6) with a return to baseline after mCPP was removed. In summary, the local application of 5-HT or a 5-HT agonist caused a reversible increase in DOPA levels indicating that 5-HT may modulate TH activity. Supported by NIDA-04120 and the Joe Young Sr. research Fund.

637.5

5-HT₂ RECEPTORS ARE NOT INVOLVED IN THE 5-HT INDUCED INCREASE OF EXTRACELLULAR DOPAMINE IN THE PREFRONTAL CORTEX OF AWAKE RATS. R.N. Iyer¹ and C.W. Bradberry², Department of Psychiatry, Yale Univ. Sch. of Med. and Veterans Administration Medical Center, Box 116/A2, 950 Campbell Avenue, West Haven, CT 06516.

Interactions between central DA and 5-HT pathways have been proposed to play a role in either the pathophysiology of schizophrenia or its amelioration by antipsychotics and there is increasing interest in the prefrontal cortex (PFC) as a site of dysfunction in schizophrenia. We have previously shown that the local application of 1-10 μ M 5-HT through a microdialysis probe facilitates DA release in a dose-dependent manner in the PFC. Because previous work suggested that a 5-HT₂ receptor sub-type partially mediated a 5-HT induced DA release in the nucleus accumbens, we determined if there is 5-HT₂ mediation of DA release in the PFC. Infusion of the selective 5-HT₂ agonist DOI through a microdialysis probe at a concentration of 500 μ M did not cause any increase in extracellular DA and co-perfusion of the selective 5-HT₂ antagonist MDL-907 (100 nM) with 3 μ M 5-HT failed to significantly attenuate the 5-HT induced enhancement of extracellular DA. These results demonstrate the absence of 5-HT₂ receptor involvement in 5-HT induced DA release in the prefrontal cortex of the rat. Supported by DA 08073, MH 44866, DA 08227, the West Haven Veterans Administration Center Grant for the study of PTSD, and a NARSAD Young Investigator Award to CWB.

637.7

5-HT₄ RECEPTORS ARE INVOLVED IN THE ENHANCEMENT OF STRIATAL DOPAMINE RELEASE INDUCED BY SEROTONIN *IN VIVO*. U. Spampinato, N. Bonhomme, M. Le Moal and P. De Deurwaerdère, Université de Bordeaux II, INSERM U. 259, Domaine de Carrière, 33077 Bordeaux Cedex, France. (SPON: European Brain and Behaviour Society).

The role of different serotonin receptor subtypes (5-HT₁, 5-HT₂, 5-HT₃, 5-HT₄) in the control of striatal dopamine (DA) release exerted by serotonin (5-HT) was studied by using *in vivo* intracerebral microdialysis. A microdialysis probe (CMA 11/3 mm) was implanted in the striatum of rats anesthetized under a mixture of halothane-NO₂/O₂ and perfused with an artificial CSF (NaCl 145, KCl 2.7, CaCl₂ 1.2, MgCl₂ 1 mM, pH = 7.4) at a constant flow rate of 2 μ L/min. Two hours after the onset of perfusion, 15 min fractions were collected over 150 min period of time and analysed by HPLC coupled with electrochemical detection. In control animals the resting DA release was stable during the experience.

Drugs used were locally applied by means of the microdialysis probe. One, 2.5 and 5 μ M 5-HT significantly enhanced DA release in a dose-dependent manner up to 157, 253 and 446% of basal value respectively. The effect induced by 1 μ M 5-HT was not blocked in the presence of 10 μ M (-)-pindolol, a 5-HT₁ receptor antagonist; 1 μ M ketanserin or 10 μ M cinanserin, both 5-HT₂ antagonists, as well as 1 or 10 μ M ondansetron (GR 38032F), a selective 5-HT₃ antagonist, were also ineffective. In contrast, 10 or 100 μ M DAU 6285, a 5-HT₄ antagonist, significantly reduced the effect of 5-HT on DA release (-20% and -60% respectively). Moreover, 100 μ M BIMU8, a selective 5-HT₄ agonist, enhanced DA release (+ 85%) and this effect was reduced by 100 μ M DAU6285 (-40%).

These results demonstrate that *in vivo* 5-HT exerts a facilitatory influence on striatal DA release and that 5-HT₄, but not 5-HT₁, 5-HT₂ or 5-HT₃ receptor subtypes are implicated in this effect.

637.4

ENDOGENOUS SEROTONIN MODULATES HISTAMINE RELEASE IN THE RAT HYPOTHALAMUS MEASURED BY *IN VIVO* MICRODIALYSIS. K.S.M. Laitinen¹, J.T. Laitinen and L. Tuomisto², Departments of Pharmacology & Toxicology and Physiology, University of Kuopio, POB 1627, FIN-70211 Kuopio, Finland.

Histamine (HA) acts as a neurotransmitter/modulator in the mammalian brain. HA is thought to modulate circadian functions, including food intake, arousal, body temperature and hormone secretion. In the anterior hypothalamus (AHy), HA content is high in the suprachiasmatic nuclei (SCN). A major non-photic input to the SCN is the serotonergic projection from the midbrain raphe nuclei. Hypothalamic serotonin (5-HT) is also implicated in the regulation of circadian rhythms, including feeding behavior. We used *in vivo* microdialysis to study possible interactions of HA and 5-HT in the AHy. Male Wistar rats were anesthetized and a microdialysis probe was implanted into the AHy (aimed at the SCN). The probe was perfused with aCSF (2 μ L/min) and samples were collected every 30 min. The dialysate concentration of HA was analyzed by HPLC with fluorescence detection and that of 5-HT by HPLC-EC. Local perfusion with 5-HT (10 or 100 μ M) increased HA release significantly and dose-dependently. Methysergide (10 mg/kg ip.), a 5-HT₂ blocker, suppressed basal HA release by 30%. Dexfenfluramine, a 5-HT releaser and reuptake inhibitor, via the probe (10 μ M), increased HA release up to 160%. With the same dose of dexfenfluramine, 5-HT release increased 10-fold in the same brain area. These data suggest that endogenous serotonin modulates histamine release in the AHy and histamine may participate in the anorexic effect of dexfenfluramine.

PET AND *IN VIVO* MICRODIALYSIS STUDIES OF SR 46349B, A NEW AND SELECTIVE 5-HT₂ ANTAGONIST. S.L. Dewey¹, P. Tan, G.S. Smith, P. King, N. Pappas, R. MacGregor, Y.-S. Ding, C. Shea, D. Alexoff, T. Martin, S. J. Gatley, J.S. Fowler, and A.P. Wolf², Chem. and Med. Dep't, BNL, Upton, NY 11973.

Our previous PET studies with labeled raclopride have demonstrated 5-HT's inhibition of striatal DA, using altanserin (5-HT₂ antagonist) and citalopram (5-HT₂ reuptake inhibitor), and we have replicated these findings with *in vivo* microdialysis studies. To measure the ability of DA to modulate 5-HT in cortical, striatal and limbic areas, we sought to develop a selective radiotracer for the 5-HT₂ receptor. The utility of the new and highly selective antagonist, SR 46349B was investigated as a potential PET radiotracer and microdialysis studies were performed to measure the effects of SR 46349B on extracellular dopamine. Serial PET studies using 11C-SR 46349B (11C-SR) were carried out in baboons for 90 minutes with a two hour time interval between studies. Test/retest variability was excellent (<10%). Radioactivity peaked at 20 mins in all cortical areas. Cerebellum, thalamus, and striatum peaked at 10 mins. At 60 mins the frontal cortex to cerebellum ratio was 1.5. Pretreatment with altanserin reduced this ratio to 1.0. Citalopram administration reduced 11C-SR binding both cortically and subcortically suggesting its sensitivity to changes in endogenous 5-HT. HPLC of mouse brain homogenate after 11C-SR showed >94% of the C-11 was parent compound. Microdialysis in freely moving rats after injection of SR 46349B showed an average peak increase in striatal DA of 375% which is higher than the 150% effect noted with altanserin. Supported by NARSAD award to SLD and GSS, USDOE/OHER, NIH Grants MH-49165, NS-15638, NS-15380.

SEROTONIN RECEPTOR STIMULATION MODULATES BASAL GANGLIA NEUROPEPTIDE mRNAs FOLLOWING 6-HYDROXYDOPAMINE LESIONS. J.G. Capodilupo¹, W.A. Wolf & P.D. Walker², Departments of Anatomy & Cell Biology and Psychiatry, Wayne State University School of Medicine, Detroit, MI 48201 and VA Medical Center, Allen Park, MI 48101.

Inhibition of dopamine (DA) neurotransmission lowers preprotachykinin (PPT) and raises preproenkephalin (PPE) mRNAs within the rodent striatum. Since serotonin (5-HT) is also a potential trans-synaptic regulator of striatal neuropeptide gene expression, we sought to determine the effects of 5-HT receptor stimulation on PPT and PPE mRNA levels following lesions of the nigrostriatal pathway. Adult male Sprague-Dawley rats (175-200g) received unilateral injections of vehicle or 6-hydroxydopamine (6HD; 10 μ g) into the left ventral midbrain. After 3 weeks, each vehicle or 6HD-lesioned animal received daily intraperitoneal injections of saline, DOI (5-HT₂ agonist; 1 mg/kg), or 8-OH-DPAT (5-HT₁ agonist; 1 mg/kg) for 7 days followed by sacrifice on the day of the last injection. Within the saline or DPAT-treated 6HD groups, nigral DA levels ipsilateral to the DA lesion were only depleted by approximately 50% compared to contralateral controls. Not surprisingly, these two 6HD groups containing mild lesions exhibited no change in striatal PPT or PPE mRNAs. However, 6HD-lesioned rats treated with DOI had significantly lower nigral DA levels (below 10% of controls) and expressed the "classic" striatal neuropeptide pattern (decreased PPT, increased PPE) signifying complete DA depletion. These results suggest that 5-HT₂ receptor stimulation may contribute to the development of neuropeptide transcriptional abnormalities within the striatum following removal of dopamine. Supported by the Michigan Parkinson's Foundation and a 1993 WSU Research Grant.

SEROTONIN ENHANCES DOPAMINE-INDUCED INHIBITION OF VENTRAL TEGMENTAL AREA (VTA) NEURONS RECORDED *IN VITRO*. M.S. Brodie and E.B. Bunney, Dept. Physiology and Biophysics and Program in Emergency Medicine, University of Illinois at Chicago, Chicago, IL 60612.

Dopaminergic neurons of the ventral tegmental area (VTA) have been implicated in a number of pathological processes, including drug abuse and schizophrenia. The VTA receives serotonergic innervation from the median and dorsal raphe nuclei, and recent studies have demonstrated that serotonin has both excitatory and inhibitory effects on VTA neurons. We have recently reported that serotonin potentiates ethanol-induced excitation of VTA neurons; our objective in the present study was to determine whether serotonin alters dopamine-induced inhibition of VTA neurons.

Coronal brain slices containing the VTA were prepared from young adult F344 rats. Dopamine (1 μ M - 5 μ M) inhibited all neurons tested, and was administered in the absence and presence of serotonin (5 - 25 μ M). Serotonin alone produced small increases or decreases in the baseline firing rate. The mean percent inhibition of firing produced by 2 μ M dopamine was increased from 38.8% to 48.3% by 5 μ M serotonin, and was increased to 53.4% in 10 μ M serotonin. Similar effects were seen on the inhibitory potency of 1 and 5 μ M dopamine; 5-HT enhancement was statistically significant as determined by ANOVA ($P < 0.05$). This increase in potency was not explained by an additive effect of serotonin and dopamine, since 1) potentiation of dopamine effects was seen regardless of whether serotonin alone increased or decreased the firing rate, and 2) when serotonin did cause a slight decrease in firing rate, the effect of dopamine was superadditive with that of serotonin. These data suggest that serotonergic neurotransmission in the VTA may serve to enhance the inhibitory action of dopamine in the VTA. Grant Support: PHS AA-09125; Ulf Helen M. Thomsen Research Fund.

SEROTONIN INHIBITS GABA_A RECEPTOR-MEDIATED CURRENT VIA ACTIVATION OF 5-HT₁ RECEPTOR IN CULTURED SUPRACHIASMATIC NEURONS. H. Katsuki*, F. Kawahara and H. Saito, Dept. Chemical Pharmacol. Fac. Pharmaceutical Sci., The Univ. of Tokyo, Tokyo 113, Japan.

The suprachiasmatic nucleus (SCN) neurons receive extrinsic and intrinsic neural inputs, the majority of which utilizes GABA as a neurotransmitter. They also receive serotonergic input from midbrain raphe nuclei, which is known to influence SCN neuronal activity through as yet unidentified mechanisms. In the present study, whole-cell voltage-clamp recordings were made from postnatal rat SCN neurons in dissociated cell culture, in order to test possible modulation by 5-HT of GABA-activated current (I_{GABA}). With $[Cl^-]_o$ and $[Cl^-]_i$ of 149 and 133 mM respectively, and at a holding potential of -60 mV, GABA activated bicuculline-sensitive inward current in the SCN neurons, with the EC_{50} value of 6.6 μ M. 5-HT reversibly inhibited I_{GABA} in a concentration-dependent manner (100 nM to 1 μ M), without changing the reversal potential of I_{GABA} , which was almost equal to the Cl^- equilibrium potential. 8-OH-DPAT, a 5-HT_{1A/7} agonist, mimicked the effect of 5-HT at concentrations of 100 nM to 10 μ M. 5-CT (5-HT_{1D} agonist, 1 μ M) also inhibited I_{GABA} , whereas a 5-HT₂ agonist DOI (1 μ M) had no significant effect. The effect of 100 nM 8-OH-DPAT on I_{GABA} was virtually abolished by co-application of ritanserin (5-HT_{2D} antagonist, 100 nM) but not by pindolol (5-HT_{1A} antagonist, 100 nM). The effect of 100 nM 5-HT was also suppressed by co-application of ritanserin, but not by pindolol or ketanserin (5-HT₂ antagonist, 100 nM). External application of 8-bromo-cAMP (1 mM) or forskolin (50 μ M) suppressed I_{GABA} , the magnitude of which was similar to that of 5-HT. Furthermore, the effect of 100 nM 5-HT on I_{GABA} was significantly suppressed by a protein kinase A inhibitor H-8 (1 μ M). These results suggest that 5-HT inhibits I_{GABA} in the SCN neurons, which involves the activation of 5-HT₁ receptor and its coupled cAMP-dependent system. This inhibition of GABA_A receptor function may be involved in the regulation by 5-HT of SCN neuronal activity.

SEROTONIN INTERACTIONS WITH SUBSTANCE P AND ENKEPHALIN IN THE HYPOGLOSSAL NUCLEUS AND THE SPINAL CORD VENTRAL HORN OF THE RAT. D.A. Jackson*, K.M. Imel and S.R. White, Dept. of Pharmacol., Univ. of Washington, Seattle, WA 98195 and Dept. of Vet. & Comp. Anat., Pharm. & Physiol., Washington State Univ., Pullman, WA 99164.

Many serotonin-containing fibers that terminate on or near motoneurons in the ventral horn of the spinal cord and in the hypoglossal nucleus contain colocalized substance P. A smaller population of fibers in the same regions appear to contain colocalized serotonin and enkephalin. Rapidly firing serotonin cells appear to corelease both serotonin and neuropeptides but little is known about how these substances interact to affect postsynaptic cells. The present study used electrophysiological techniques to examine how serotonin may interact with these neuropeptides to alter motoneuron excitability in the lumbar spinal cord and in the hypoglossal nucleus. Microiontophoretic application of serotonin or substance P enhanced glutamate-evoked firing of all motoneurons that were tested in the spinal cord and the hypoglossal motor nucleus. Application of serotonin and substance P together had additive effects on motoneuron excitability until a maximum firing rate was reached. In contrast, microiontophoretic application of enkephalin inhibited glutamate-evoked firing of the same cells that were facilitated by serotonin. Concurrent application of enkephalin and serotonin diminished the facilitatory effects of serotonin alone. Therefore, it appears that cells which contain colocalized serotonin and enkephalin may either enhance or inhibit motoneuronal excitability depending upon the firing rate of the cell.

THE EFFECT OF SEROTONERGIC AGENTS ON THE EXPRESSION OF D₁ AGONIST MEDIATED REPETITIVE JAW MOVEMENTS (RJM). Helen Rosengarten* and Arnold J. Friedhoff, Department of Psychiatry, Millhauser Labs. NYU School of Medicine, New York, N.Y. 10016 USA.

Selective D₁ receptor agonists are capable of inducing repetitive jaw movements (RJM) in rats. SKF 38393 appears to be selective for the D₁ receptor, however, at higher concentrations it is capable of interacting with 5HT_{1C} and 5HT₂ receptors. To explore a possible interaction between serotonergic and dopaminergic systems in the mediation of RJM, we studied the effect of a series of 5HT agonists and antagonists on SKF 38393 inducible behavior. It was demonstrated that the mixed 5HT_{1C} and 5HT₂ receptor agonist, mCPP, and 5HT₂ antagonists, ritanserin and cyproheptadine, are capable of enhancing SKF 38393-induced RJM by 180%, 240% and 217%, respectively, while the 5HT_{1A} agonist, 8OH-DPAT, the 5HT_{1B} agonist, CGS 120066, and the 5HT₂ agonist, DOI, had no effect. The results of this study demonstrate that there is an interaction between DA and 5HT systems in the expression of RJM. This study was supported by NIMH Grants 06818 and 35976.

REGULATION OF SEROTONIN RELEASE IN THE INTERMEDIATE AREA OF THE RAT THORACIC SPINAL CORD BY COEXISTING NEUROCHEMICALS: SUBSTANCE P AND THYROTROPIN-RELEASING HORMONE. L. Yang* and C.J. Helke, Dept. of Pharmacology, Uniformed Services University of the Health Sciences, Bethesda, MD 20814.

Serotonin (5-HT), substance P (SP) and thyrotropin-releasing hormone (TRH) coexist in ventral medullary neurons which project to the intermediolateral cell column (IML) of the thoracic spinal cord (Sasek *et al.*, Neuroscience, 35:105, 1990) and are involved in the spinal regulation of sympathetic nervous system. [³H]5-HT is released from the intermediate area (which includes the IML) and the release of [³H]5-HT is regulated by presynaptic inhibitory 5-HT_{1B} autoreceptors (Yang *et al.*, Synapse, in press, 1994). We used *in vitro* superfusion of the microdissected intermediate area of the rat thoracic spinal cord to study the effects of SP and TRH on the release of [³H]5-HT. A neurokinin 1 (NK₁, the preferred receptor for SP) selective agonist, GR 73632 (1 μ M), significantly increased the basal release of [³H]5-HT. The increased release of [³H]5-HT induced by GR 73632 was blocked by a selective NK₁ antagonist, GR 82334 (1 μ M). GR 82334 (1 μ M) did not change the basal release of [³H]5-HT itself. SP (1 μ M) also increased the basal release of [³H]5-HT. A TRH agonist, MK-771 (1 μ M), had no effect on the basal or K⁺-stimulated release of [³H]5-HT. The present study suggests that the release of [³H]5-HT at the intermediate area could be regulated by SP, but not by TRH. The excitatory effect of SP on the release of 5-HT appears to be mediated by NK₁ receptor. These findings will be helpful in understanding the complex roles of coexisting neurochemicals in the spinal regulation of the sympathetic nervous system. (Supported by NIH grant R01 NS24876).

EFFECT OF THE α_2 -ADRENOCEPTOR ANTAGONIST REMERON ON RAT 5-HT NEUROTRANSMISSION. N. Haddjeri*, P. Blier and C. de Montigny, Neurobiological Psychiatry Unit, McGill Univ., Montréal, Canada H3A 1A1.

Remeron (ORG 3770) is a mianserin derivative having antidepressant activity in humans. Using an *in vivo* electrophysiological paradigm in male Sprague-Dawley rats, the aim of the present study was to assess the effect of racemic remeron [(±)RM] and of its (-)-isomer on pre- and postsynaptic α_2 -adrenoceptors and to characterize their putative modulation of 5-HT neurotransmission in the hippocampus. Previous studies in our laboratory have shown that the activation of α_2 -autoreceptors on norepinephrine (NE) terminals by a low dose of clonidine (10 μ g/kg, i.v.) enhances the effectiveness of the electrical stimulation (200 pulses: 0.5 ms, 300 μ A, 1 Hz) of the ascending 5-HT pathway in suppressing the firing activity of dorsal hippocampus CA₃ pyramidal neurons, whereas a high dose (100 or 400 μ g/kg, i.v.) activates the α_2 -heteroreceptors on 5-HT terminals thereby reducing the effectiveness of the stimulation. The injection of (±)RM (25 μ g/kg, i.v.) significantly enhanced the effectiveness of the stimulation and prevented the effects of subsequent i.v. administration of both low and high doses of clonidine. (-)RM (25 μ g/kg, i.v.) did not prevent the enhancing effect of the stimulation induced by the low dose of clonidine, but antagonized the reducing effect of the high dose of clonidine. Furthermore, (±) and (-)RM (500 μ g/kg, i.v.) blocked the suppressant effect of microiontophoretically-applied NE on the firing activity of CA₃ hippocampus pyramidal neurons. In the dorsal raphe, only (±)RM dose-dependently (10 to 250 μ g/kg, i.v.) enhanced the firing activity of the 5-HT neurons, and only (±)RM (100 μ g/kg, i.v.) antagonized the suppressant effect of clonidine (10 μ g/kg, i.v.) on 5-HT neuron firing activity. In conclusion, these results suggest that (±)RM is an antagonist of both α_2 -adrenergic auto- and heteroreceptors, whereas (-)RM is selective for the α_2 -heteroreceptors.

IS TRYPTAMINE SYNTHETIZED BY SEROTONERGIC NEURONS?

Brusco A., Tagliaferro P., Canessa O. and Pecci Saavedra J. Instituto de Biología Celular, Facultad de Medicina, U.B.A. Cât. Biol. Cel. e Histol., Fac. Farmacia y Bioquímica U.B.A. Paraguay 2155, 3° Piso, (1121) Buenos Aires, Argentina.

Tryptamine (T) is present in the Central Nervous System (CNS) in very low concentration. T is synthesized from Tryptophane (Trp) by the aminoacid aromatic decarboxylase (AADC), enzyme that is present in all monoaminergic neurons and also in glial cells. Localization of T in serotonergic neurons is not yet clear. An immunocytochemical technique (ICT) was applied to CNS of adult rat, using specific anti-T or anti-serotonin as primary antibody. To increase the concentration of both indoleamines in the CNS, pretreatment of rats with Trp and pargiline was performed 2 hr prior to fixation. T immunoreactivity was restricted to soma and processes of neuronal cells of raphe nucleus, substantia nigra (pars reticulata), and pons gigantocellularis nuclei. We discarded, therefore, that T be synthesized by glial and other cells in the CNS.

Distribution of serotonergic cells does not lay on top of tryptaminergic cells in the CNS, detected by ICT, so not all serotonergic neurons are able to synthesize T. Immunoreactivity for both indoleamines was strongly reduced by inhibition of serotonin synthesis with parachlorophenylalanine pre-treatment. We postulate that synthesis of T is not an alternative route for Trp utilization when Trp-hydroxylase (limitant enzyme of serotonin synthesis) is inhibited.

(Supported by grants of CONICET and UBACYT, Argentina).

ANTI-PSYCHOTIC-INDUCED CHANGES IN MONOAMINE SYNTHESIS AND TURNOVER: DIFFERENCES BETWEEN CLOZAPINE AND HALOPERIDOL.

R.E. Arthur, Jr. and W.A. Wolf, V.A. Medical Center, Allen Park, MI 48101 and Cellular and Clinical Neurobiology Program, Dept. of Psychiatry, Wayne State University, Detroit, MI 48201.

Haloperidol and clozapine differ in their clinical profile and propensity for inducing extrapyramidal side effects. One reason for this may be their effects on the activity of serotonin (5-HT) and dopamine (DA) neurons subserving behavior and motor control. To assess 5-HT and DA synthesis and turnover *in vivo*, animals were administered haloperidol (0.5 mg/kg, i.p.) or clozapine (5-20 mg/kg, i.p.) followed by the decarboxylase inhibitor, m-hydroxybenzylhydrazine (100 mg/kg, i.p.). Animals were killed and brain regions were dissected and processed for HPLC analysis. Clozapine-treated animals had higher levels of the 5-HT metabolite, 5-hydroxyindoleacetic acid (5-HIAA), in the midbrain raphe than vehicle-treated animals (6.28 ± 0.41 and 4.06 ± 0.11 pmoles/mg wet wt, clozapine and vehicle, respectively). This effect was evident at the lowest dose of clozapine (5 mg/kg). Raphe 5-HIAA levels in haloperidol-treated animals were similar to control. 5-HIAA in substantia nigra was also higher with clozapine, but not haloperidol, treatment (3.96 ± 0.19 and 2.53 ± 0.13 pmoles/mg wet wt, clozapine and vehicle, respectively). 3,4-dihydroxyphenylalanine (DOPA) accumulation was elevated in substantia nigra only in haloperidol-treated animals (4.76 ± 0.31 , 2.79 ± 0.19 and 3.06 ± 0.10 pmoles/mg wet wt, haloperidol, clozapine and vehicle, respectively). In caudate and nucleus accumbens, low dose clozapine (5 mg/kg) increased DA turnover 2-4 fold, but not DOPA accumulation. High dose clozapine (20 mg/kg), like haloperidol, increased both DA synthesis and turnover. Additional data will be presented. The present results suggest that clozapine affects 5-HT and DA synthesis and turnover in a manner different from haloperidol.

NEUROTRANSMITTER INTERACTIONS: CHOLINERGIC/GABA

DIHYDREXIDINE RELEASES ACETYLCHOLINE AND IMPROVES COGNITIVE PERFORMANCE IN RATS. T.D. Steele, D.B. Hodges, Jr., T.R. Levesque and K.W. Locke.

Interneuron Pharmaceuticals Inc., Lexington, MA 02173.

Neurochemical and behavioral studies have elucidated extensive interactions between dopaminergic and cholinergic systems in brain areas associated with movement and cognition. The initial goal of these studies was to evaluate the effect of the anti-Parkinson drug dihydrexdine (DHX), a full D_1 agonist, on brain acetylcholine (ACh) release using *in vivo* microdialysis techniques. Moderate doses (3 & 10 mg/kg) of DHX produced an approximate 50% increase in striatal ACh release that was blocked by the D_1 antagonist SCH23390 (0.3 mg/kg). A higher dose (17.5 mg/kg) was less effective in raising striatal ACh, possibly due to D_2 receptor activation. In frontal cortex, DHX (10 mg/kg) evoked a more robust increase (200%) in ACh release that was blocked by SCH23390 (0.3 mg/kg). Since elevations in brain ACh are associated with cognitive improvement, the effectiveness of DHX in a passive avoidance model of learning and memory was evaluated. These studies revealed a significant improvement in performance by 0.3 mg/kg DHX in scopolamine-amnesic rats. These results provide support for the hypothesis that DHX improves cognitive performance as a consequence of ACh release in relevant brain regions. Further, D_1 agonists may have novel therapeutic potential in the treatment of dementia.

RELEASE OF [3 H]ACETYLCHOLINE FROM SLICES OF RAT STRIATUM AND CEREBRAL CORTEX BY 5-HT $_3$ RECEPTOR ANTAGONISTS. J. Del Río, B. Lasheras and M.J. Ramírez, Dept. of Pharmacology, Schools of Medicine and Pharmacy, University of Navarra, 31080-Pamplona, Spain.

Controversial results have been reported on the ability of 5-HT $_3$ receptor ligands to modulate acetylcholine (ACh) release from rat entorhinal cortex and also from other brain regions. We have studied the effect of 5-HT $_3$ receptor stimulation and blockade on basal and K^+ -evoked [3 H]ACh release from superfused slices of rat striatum and cerebral cortex. K^+ -evoked release consisted of two stimulations (S_1 and S_2 , 30 min apart) with KCl (20 mM, 6 min) with drugs added 15-20 min before S_2 and calculation of changes in S_2/S_1 . The 5-HT $_3$ antagonist ondansetron (0.01-10 μ M) increased in a concentration-dependent manner both basal and K^+ -evoked [3 H]ACh release from striatal slices, the latter effect being more marked. A lower though significant [3 H]ACh release by ondansetron was also found in superfused cortical slices. However, basal rather than K^+ -evoked [3 H]ACh release was influenced by this 5-HT $_3$ antagonist in the cerebral cortex. Similar effects were observed with higher concentrations of granisetron in both brain regions. The 5-HT $_3$ agonist 2-Me-5-HT (1 μ M) did not modify by itself [3 H]ACh release and a moderate decrease was only observed in the presence of the 5-HT $_2$ antagonist ritanserin. Interestingly, 2-Me-5-HT blocked the increase in both basal and K^+ -evoked [3 H]ACh release induced by ondansetron. The results suggest that 5-HT $_3$ receptor antagonists may influence acetylcholine release from specific brain regions.

PRETREATMENT WITH THE NORADRENERGIC NEUROTOXIN DSP-4 *IN VIVO* REDUCES ACETYLCHOLINE (ACh) RELEASE IN THE RAT PREFRONTAL CORTEX *IN VITRO*. Stéphane Tellez, Francis Colpaert and Marc Marien*, Centre de Recherche Pierre Fabre, 17 avenue Jean Moulin, Castres 81100, France.

A deficiency in the locus coeruleus-noradrenergic system (LC-NA) has been proposed to be an important contributory factor in the pathogenesis and progression of central neurodegenerative disorders including Alzheimer's disease (Colpaert 1994, in *Noradrenergic Mechanisms in Parkinson's Disease*, CRC Press, Boca Raton, pp. 225-254). To examine the influence of the LC-NA on cortical ACh release, male SD rats were injected with DSP-4 (40 mg/kg i.p.) preceded 30 min by an injection of citalopram (10 mg/kg). Three days later, slices of the prefrontal cortex (PFC) were prepared, incubated with [3 H]choline, superfused and stimulated by exposure to increasing concentrations of K^+ . The DSP-4 treatment reduced endogenous noradrenaline levels in cortical tissue by 71-94%. In slices of PFC from DSP-4 treated rats, the [3 H] overflows which were stimulated by 20, 35 and 45 mM K^+ were reduced by 18%, 21% and 42%, respectively, compared to slices prepared from vehicle treated animals. These results indicate that disruption of the LC-NA reduces a facilitative input to the cortical cholinergic system, and suggests that injury to or loss of LC-NA neurons might contribute to the cortical cholinergic dysfunction in Alzheimer's disease.

638.4

CHRONIC EFFECTS OF CAFFEINE, NICOTINE AND ETHANOL ON CENTRAL ADENOSINE AND CHOLINERGIC RECEPTORS AND CALCIUM CHANNELS: BEHAVIORAL CORRELATES IN MICE. Dan Shi, O. Nikodijevic, B. Radio, K. Jacobson and I.W. Daly, Laboratory of Bioorganic Chemistry, NIDDK, NIH, Bethesda, MD 20892.

Chronic caffeine increases density of central A_1 -adenosine (cortex, striatum), nicotinic, muscarinic, serotonin and $GABA_A$ receptors. Central A_{2A} -Adenosine, α -adrenergic, dopaminergic, and NMDA-glutamatergic receptors are unchanged and the densities of β -adrenergic receptors are decreased. Theophylline and theobromine also increase density of A_1 -receptors. The changes in A_1 , β_1 - and muscarinic receptors occur after 3-4 days of chronic caffeine and are reversed after 4-7 days of withdrawal. Chronic nicotine increases density of nicotine receptors, but has no effect on adenosine receptors or muscarinic receptors. Chronic ethanol increases density of A_1 -receptors. Both caffeine and ethanol, but not nicotine, increase density of L-type calcium channels. Behavioral sensitivity (open field locomotor) to adenosine agonists increases after caffeine. Behavioral sensitivity to nicotine decreases after either chronic nicotine and caffeine, in spite of upregulation of receptors. Behavioral sensitivity to the muscarinic antagonist scopolamine is enhanced after chronic caffeine. Adenosine and cholinergic systems appear interrelated behaviorally as are L-type calcium channels.

638.5

INFLUENCE OF VENTRAL PALLIDAL DOPAMINE ON FOREBRAIN AND MIDBRAIN CHOLINERGIC SYSTEMS. T.C. Napier*, F. Rehman and L.K. Gorman. Dept. Pharmacol., Loyola Univ. Chicago, Sch. Med., Maywood, IL 60153; and Dept. Anesth., The Johns Hopkins Univ., Baltimore, MD 21218.

Ventral pallidal regions of the basal forebrain (VP) contain cholinergic neurons that project to the prefrontal cortex (pFC), frontal cortex (FC) and amygdala (AMG) and are involved in cognition. Cholinergic neurons of the midbrain pedunculopontine nucleus (PPN) are directly innervated by non-cholinergic neurons of the VP that mediate motoric function. Our previous work demonstrated that intra-VP injections of dopamine (DA) and its receptor-subtype selective agonists alter motor function, but do not effect working memory (i.e., choice accuracy on the radial arm maze). It is not known whether cholinergic neurons within the VP, or cholinergic neurons impinged upon by VP efferents, are affected by these treatments. In the present study, changes in hemicholinium (HC-3) binding, a marker for high affinity choline uptake, were measured in pFC, FC, AMG and PPN tissue homogenates as an indicator of cholinergic neuronal activity. Intra-VP microinjection of DAergic agonists was performed in rats previously implanted with guide cannulae, and the cholinergic regions were dissected 30 min post-treatment. DA, SKF82958 (D1 agonist), and quinpirole (D2/D3 agonist) injected in doses that change motor behavior (i.e., 0.05 μ mole/0.5 μ l per VP) did not alter HC-3 binding. Larger doses of DA (0.5 μ mole/0.5 μ l per VP) increased binding by 230% in the PPN. In contrast, 6OHDA-induced lesions of the ascending DA projection increased HC-3 binding in the pFC and AMG 300% and 240%, respectively. These data indicate that the various cholinergic systems influenced by the VP are differentially sensitive to 1) DA receptor stimulation within the VP, and 2) the compensatory mechanisms evoked upon removal of endogenous DA. Work supported by MH45180 to TCN.

ADRENOCEPTOR ANTAGONIST TREATMENT ALTERS MUSCARINIC ACETYLCHOLINE RECEPTOR (mAChR) AFFINITY AND DENSITY FOLLOWING CHOLINERGIC DENERVATION OF THE RAT HIPPOCAMPUS. L.E. Harrell*, D.S. Parsons, K. Kolasa. Alzheimer's Disease Center, Dept. Neurology, V.A. & Univ. Alabama Med. Ctr., Birmingham, AL 35294

After medial septum lesions (MSL), peripheral sympathetic adrenergic fibers, originating from superior cervical ganglia, appear in the hippocampus (hippocampal sympathetic ingrowth, HSI). We have previously reported that HSI is detrimental to learning in rats and that treatment with phentolamine (PHENT), α -adrenergic antagonist, ameliorated this deficit. However, biochemical studies of HSI have revealed changes in the hippocampal cholinergic system. To determine whether PHENT treatment might mediate its effects through muscarinic cholinergic (mAChR) receptors, we assessed the effect of PHENT treatment on hippocampal mAChR. Animals underwent 1 of 4 surgeries: control [sham MSL + sham ganglionectomy (Gx)]; HSI(+) [MSL + sham Gx]; HSI(-) [MSL + Gx]; Gx [sham MSL + Gx]. Half of the animals in each group were treated with either phentolamine (20 mg/kg; IP) or vehicle daily for 5 weeks. After completion of treatment, the hippocampi were dissected into the dorsal and ventral regions and membrane binding of [³H]-QNB, a non-selective mAChR antagonist, was assessed. PHENT treatment was found to 1) decrease the binding affinity of mAChR in HSI(+) animals in both hippocampal regions (K_d: 1.06 + 0.52; 1.08 + 0.31 nM) in comparison to controls (K_d: 0.48 + 0.06; 0.54 + 0.05) and 2) increase the number of mAChR in dorsal hippocampus of HSI(+) animals (B_{max}: 1111 + 416 fmol/mgP) in comparison to control (B_{max}: 409 + 50.7). These results suggest that PHENT treatment may mediate its effect through the mAChR perhaps by altering the release of acetylcholine from intrinsic cholinergic neurons and indicate that balance between noradrenergic and cholinergic system may be important for mediating the behavioral effects of HSI.

INTERACTION OF SOMATOSTATIN AND CARBACHOL ON HIPPOCAMPAL M-CURRENTS. P. Schweitzer*, S. Madamba and G.R. Siggins. Department of Neuropharmacology, The Scripps Research Institute, LA JOLLA CA 92037.

The M-current (I_M) is a non-inactivating potassium current that persists at slightly depolarized potentials. In CA1 hippocampal pyramidal neurons, somatostatin (SS) increases I_M whereas carbachol (CCh) decreases it. To further study the ionic mechanisms of I_M, we investigated the interaction of these two substances on I_M using intracellular voltage-clamp recordings in the rat hippocampal slice preparation. We recorded from 26 neurons with a mean resting membrane potential of -68 ± 1 mV. Superfusion of CCh 1 μ M decreased I_M to 25-45% of control, an effect greater than previously reported. We attempted to reverse the CCh inhibition of I_M by adding SS 1 μ M together with CCh: SS had no effect and I_M remained inhibited. Reversing the order of agonist application gave different results. When SS 1 μ M was superfused first, I_M was increased by 55-75%, as previously reported. Then adding CCh 1 μ M to the SS-augmented I_M returned its amplitude back to 85-95% of control. As CCh did not decrease I_M below control in the presence of SS as compared to CCh alone, SS thus provides a protective effect. However, when we applied a high concentration (30 μ M) of CCh in the presence of SS, the I_M amplitude greatly decreased (15-25% of control), an effect identical to the effect of CCh 30 μ M alone. Thus, in rat hippocampus CCh prevails over SS for the control of I_M. However, SS can protect some of the M-channel pool against low (1 μ M) but not high (30 μ M) concentrations of CCh. Since CCh concentration and sequence of superfusion determines the end-effect, the interaction between these two agonists could take place at the second messenger level.

SYNAPTIC INTERACTIONS INVOLVING ACETYLCHOLINE, GLUTAMATE AND GABA IN RAT NEOCORTEX. Raju Metherate* and John H. Ashe. Depts. of Neuroscience and Psychology, Univ. of California, Riverside, CA 92521.

Prior studies of cholinergic modulation of cortical activity have generally used exogenously applied cholinergic agonists. We have extended these studies utilizing extracellular and whole-cell intracellular recordings *in vitro* to examine how endogenous ACh modifies cortical synaptic activity mediated by glutamate and GABA. Recordings were from layer III of rat auditory cortex brain slices maintained *in vitro*. Single stimulus pulses to deep layer VI elicited a highly consistent sequence of four field potentials (A, B, C, D) that resembled four intracellular potentials, an early-EPSP (nonNMDA), early-IPSP (GABA-A), late-EPSP (NMDA), and late-IPSP (GABA-B), respectively, in terms of latency, time course, recruitment with stimulus intensity, and sensitivity to receptor antagonists. Bath application of the anticholinesterase eserine (1-50 μ M) reduced the amplitude of A and B by about 10-30%; this effect was mimicked by the cholinergic agonist carbachol (25 μ M) and antagonized by the muscarinic antagonist atropine (0.3-1.0 μ M). The degree of component A reduction was greater at low stimulus intensities (that elicited A alone) than at higher intensities (that elicited B as well). This differential suppression was not seen in the presence of the GABA-A antagonist picrotoxin (1 μ M), suggesting that normally muscarinic suppression of B disinhibits A and limits net suppression of A. To examine cholinergic actions on responses mediated by nonNMDA vs NMDA glutamate receptors, eserine was applied in the presence of APV (50 μ M) or CNQX (10-20 μ M), respectively. Eserine-induced suppression of responses occurred in the presence of APV, but not in the presence of CNQX.

Cholinergic suppression of excitatory synaptic transmission that varies inversely with the strength of afferent drive and the degree of NMDA receptor activity may be an important facet of cortical information-processing. Supported by NSF (IBN 9008818, IBN 9118872).

CALRETININ IMMUNOREACTIVITY IN THE ADULT RAT SEPTO-HABENULAR PATHWAY. J.A. Wilson and M.D. Kawaja*. Department of Anatomy and Cell Biology, Queen's University, Kingston, Ontario, Canada, K7L 3N6.

The medial habenula (MHb) consists of a densely packed population of neurons, the majority of which stain immunohistochemically for choline acetyltransferase (ChAT). The cholinergic MHb is innervated by axons that originate from posterior septal neurons; these axons course caudally via the stria medullaris (sm). To date, one of the few neurochemicals to be identified within the sm is calretinin, a calcium-binding protein. The purpose of this investigation is to determine the normal patterns of connectivity of calretinin-positive fibers in the MHb, as a prelude to our examination of sm innervation of fetal habenular grafts placed within the adult habenula. A dense plexus of calretinin-immunoreactive axons was evident throughout the rostro-caudal extent of the normal MHb. Following a unilateral lesion of the sm, calretinin immunostaining of fibers was completely abolished in the ipsilateral MHb; a small population of calretinin-positive neurons situated between the medial and lateral habenulae was revealed. At the electron microscope level, calretinin immunoreactivity was associated with myelinated and unmyelinated axons, as well as with numerous terminals containing spherical vesicles. These immunoreactive terminals formed asymmetric synaptic contacts with dendritic processes of MHb neurons. Double immunohistochemical staining was used to simultaneously demonstrate calretinin-positive fibers among ChAT-positive neurons within the ventral two-thirds of the MHb. Data will be presented concerning the ultrastructural organization of ChAT and calretinin immunoreactivities within the normal adult rat MHb and within implants of fetal rat habenula grafted into the mature rat brain. IMIDAZENIL AND ABECARNIL, TWO ANXIOSELECTIVE GABA_A RECEPTOR MODULATORS REDUCE STRESS-INDUCED RELEASE OF ACETYLCHOLINE AND DOPAMINE IN THE RAT BRAIN. L. Dazzi, C. Molto, A. Imperato, M. Serra and G. Biggio*. Departments of Experimental Biology and Neuroscience, University of Cagliari, 09123 Cagliari, Italy

The effect of the partial agonist imidazenil (IM) and the selective agonist abecarnil (AB), was studied on the basal and stress-stimulated release of acetylcholine and dopamine in the rat hippocampus and cerebral cortex using the microdialysis technique on freely moving rats. The effect of these drugs was compared with that of diazepam (DZ) and alprazolam (AZ), two benzodiazepines full agonists. AB (0.05 - 1 mg/kg i.p.), IM (0.05 - 1 mg/kg i.p.), DZ (2.5 - 10 mg/kg i.p.) and AZ (1 - 10 mg/kg i.p.) produced a dose-dependent decrease of basal acetylcholine release in the hippocampus. On the other hand only DZ and AZ significantly decreased dopamine release in the c. cortex. These effects were antagonized by flumazenil. Foot-shock (0.2 mA/500 ms per s.) produced a sudden and marked (+ 75%) increase of hippocampal acetylcholine output. This effect lasted for 30 min and returned to basal values in about 60 min. Foot shock enhanced also dopamine release in the c. cortex. The maximal effect (90%) was obtained in 20 min and in 30-40 min dopamine release returned to control values. The previous administration of AB or IM in a dose unable to modify the basal release of acetylcholine and dopamine prevented the effect of stress. An effect mimicked by much higher doses of DZ and AZ. The differential efficacy of IM and AB on acetylcholine and dopamine release is consistent with the existence of multiple GABA_A receptor subtypes with different sensitivity to these drugs.

ADENOSINE A_{2A} RECEPTOR STIMULATION BLOCKS DOPAMINE D_2 RECEPTOR-MEDIATED INHIBITION OF GABA RELEASE IN SLICES OF RAT GLOBUS PALLIDUS. R.D. Mayfield*, R.A. Orona, and N.R. Zahniser. Dept. Pharmacol., Univ. Colorado Hlth. Sci. Ctr., Denver, CO 80262.

Behavioral and biochemical studies suggest that a negative interaction exists between adenosine (ADO) A_2 and dopamine (DA) D_2 receptors in the brain and that this interaction underlies the opposing effects of ADO and DA receptor agonists *in vivo*. ADO A_{2A} receptors are localized to GABAergic striato-pallidal neurons, and we have shown that activation of these receptors increases electrically-evoked endogenous GABA release in micropunches of rat globus pallidus (GP). We examined the functional significance of A_{2A} and D_2 receptor subtypes in modulating electrically-evoked GABA release and whether agonist stimulation of these receptors produces opposing actions on pallidal GABA release. Consistent with previous findings, GABA release was increased 35-40% by the selective A_{2A} receptor agonist CGS 21680 (10 nM). The selective D_2 receptor agonist N-0437 (1-100 nM) resulted in a concentration-dependent decrease in evoked GABA release in micropunches of GP as well as in striatal slices (containing GP). Maximum inhibition of release was approximately 35% in both tissue preparations. However, in the presence of 10 nM CGS 21680, N-0437 (1-100 nM) had no effect on evoked GABA release. These results demonstrate that agonist stimulation of ADO and DA receptor subtypes has opposing actions on pallidal GABA release and that the stimulation of A_{2A} receptors abolishes the effects of D_2 receptor stimulation. It is suggested that this functional interaction between A_{2A} and D_2 receptor subtypes represents an important mechanism by which GABAergic striato-pallidal output is differentially modulated by ADO and DA. Zn⁺⁺ MODULATES GABAERGIC TRANSMISSION IN ORGANOTYPIC SLICE CULTURES OF RAT HIPPOCAMPUS. T.N. Ricciardi* and A.T. Malouf. Neurological Surgery, RI-20, University of Washington, Seattle, WA 98195.

Intracellular recordings of CA3 pyramidal cells (PCs) were used to study the actions of Zn⁺⁺ in slice cultures of hippocampus. Zn⁺⁺ (100-300 μ M) caused spontaneous and stimulus-evoked giant depolarizing potentials (GDPs) consisting of a burst of action potentials riding on top of a prolonged depolarization (see Xie and Smart (1993) J. Physiol. 460:503). Paired recordings of neighboring PCs showed simultaneous GDPs, suggesting synchronous synaptic drive. Blockade of synaptic transmission using either 1 μ M TTX or 300 μ M cadmium prevented the appearance of GDPs. Glutamate and GABA receptor antagonists were used to examine the contribution of these neurotransmitters to GDP initiation and topography. The glutamate receptor antagonists CNQX or kynurenic acid did not abolish the bursts of action potentials but partly attenuated the late depolarizing phase of spontaneous GDPs, indicating that glutamate plays a role in GDP topography. The NMDA receptor antagonist APV had no effect on the appearance of evoked or spontaneous GDPs. Application of Zn⁺⁺ in the presence of APV, CNQX, and the GABA_A antagonist CGP-35348, resulted in the appearance of spontaneous and evoked depolarizations. The depolarizing potentials appear to be GABA_A mediated, since they were reversible near resting membrane potential. Application of Zn⁺⁺ in the presence of APV, CNQX, and the GABA_A antagonist bicuculline methiodide, resulted in the appearance of large spontaneous and evoked hyperpolarizations. These large hyperpolarizations were blocked by CGP-35348, suggesting they were GABA_A receptor-mediated IPSPs. These data suggest that Zn⁺⁺ enhances GABA_A and GABA_B mediated neurotransmission in organotypic cultures of hippocampus. The appearance of GDPs appears to result primarily from the enhancement of GABA_A transmission. (Supported by NIH-NS28650 and NIH-T32NS-07144-15.)

COLOCALIZATION OF GABA AND GLYCINE IN RAT CUNEATE NUCLEUS. A. Popratiloff*, I.G. Valtchanoff, P.S. Bernardi, R.J. Weinberg and A. Rustioni. ¹Dept. of Cell Biology & Anatomy, UNC, Chapel Hill, NC 27599, USA, and ²Dept. Fisiologia Bioch., Univer. di Milano, Milano 20133, Italy.

Recent evidence suggests that GABA and glycine are released by the same local circuit neuron in the spinal cord (Todd and Sullivan, *J. Comp. Neurol.* 296:496-505, 1990). Among the relevant questions raised by this possibility is whether all GABAergic neurons may also release glycine, and what role these two amino acids may play in mechanisms of pre- and post-synaptic inhibition, respectively. We have approached these questions in the dorsal column nuclei of the rat because: i) projecting neurons, and local circuit neurons are easily distinguishable, ii) local circuit neurons in these nuclei are mainly GABAergic, iii) they contain a large number of axo-axonic synapses thought to mediate presynaptic inhibition. We employed post-embedding immunocytochemistry and found that of all neurons that stain for GABA and/or glycine in the cuneate nucleus, 29% stain for GABA, 29% stain for glycine, and 42% stain for both.

Electron microscopy showed that GABA colocalizes with glycine at both axodendritic and axoaxonic synapses, supporting a role for glycine in pre-synaptic as well as in post-synaptic inhibition. Most GABAergic terminals were also glycinergic but some terminals were clearly enriched in GABA and not glycine, and vice versa. We are now studying quantitative differences in the enrichment of GABA and glycine in various classes of terminals in the cuneate nucleus.

DIFFERENTIAL MODULATION OF STRIATAL GABA EFFLUX *IN VIVO* BY DOPAMINE AND GLUTAMATE SELECTIVE AGONISTS. E.M. Byrnes* and J.P. Bruno. Dept. of Psychology and Neuroscience Program, Ohio State Univ., Columbus, OH 43210

There are two known sources of neuronal GABA within the striatum, interneurons and recurrent collaterals of medium spiny projections. Electrophysiological data suggest that corticostriatal glutamatergic neurons converge on these neurons, increasing firing rates. The effects of nigrostriatal DA afferents on these GABAergic neurons are more complex, interacting with the DA receptor subtype involved. Activation of D1 receptors hyperpolarize these neurons. The effects of glu and DA ligands on GABA release have been largely confined to *in vitro* slices. Increases in extracellular K⁺ enhance striatal GABA release and this effect is potentiated by activation of D1 receptors. We have recently begun to characterize the *in vivo* modulation of striatal GABA efflux by glu- and DA-containing afferents. Striatal GABA efflux was measured using *in vivo* microdialysis in awake rats. All drugs were perfused into the striatum via the dialysis probe. Under these conditions, basal GABA efflux was decreased by 52% following TTX (10 μ M) and increased by 1000% following the GABA-uptake blocker nipecotic acid (0.5 μ M). The glu agonist AMPA (100 μ M) produced a significant (100%), transient increase in GABA efflux and a long-lasting behavioral activation. The full D1 agonist SKF 81297 (10 μ M) decreased basal GABA and only modestly reduced the stimulating effects of AMPA.

COLOCALIZATION OF GLUTAMATE DECARBOXYLASE (GAD), SEROTONIN (5HT) AND TYROSINE HYDROXYLASE (TH) IN RAT MEDIAL PREFRONTAL CORTEX (mPFC). J.B. Taylor* and F.M. Benes. Department of Psychiatry and Program in Neuroscience, Harvard Medical School and Lab for Structural Neuroscience, McLean Hospital, Belmont, MA 02178.

Recent evidence has suggested that GABAergic cell bodies in rat pyriform cortex receive a convergence of monoaminergic inputs (Gellman and Aghajanian, 1993). To obtain corroborative microscopic support for this idea, a fluorescent immunocytochemical technique has been developed for the colocalization of GAD, TH and 5HT in single sections of rat mPFC. The primary antisera included a polyclonal antibody raised in rabbit against GAD₆₇, a monoclonal antibody raised in mouse against TH and a polyclonal antibody raised in goat against 5HT. Secondary antibodies were raised in donkey against rabbit (FITC), mouse (TRITC), and goat (AMCA), respectively. A digital confocal microscopic system equipped with appropriate filters was used to visualize the three fluorescent emissions. For a given cell of interest, serial Z axis planes were corrected for background flare using a deconvolve subroutine followed by co-registration of the three images. While TH and 5HT varicosities were found in apposition with GAD immunoreactive (IR) cell bodies, ghosts of pyramidal neurons also showed a "trivergence" of TH-, 5HT- and GAD-IR varicosities/boutons. Interactions of TH-, 5HT- and GAD-IR elements with one another were also commonly observed pre-synaptic to pyramidal cell bodies. These findings are consistent with the idea that monoaminergic afferents converge on GABAergic and pyramidal cell bodies. Moreover, pre-synaptic interactions of monoaminergic varicosities with GABAergic elements may play a significant role in the inhibitory modulation of pyramidal cell output from mPFC. Supported by MH42261, MH00423, MH31154 and the Stanley Foundation.

INCREASED INTERACTION OF DOPAMINE (DA) VARICOSITIES WITH GABA CELLS OCCURS PROGRESSIVELY IN RAT MEDIAL PREFRONTAL CORTEX (mPFC) FROM BIRTH TO ADULTHOOD. F.M. Benes*, S.L. Vincent, R. Molloy. Dept. of Psychiatry and Program in Neuroscience, Harvard Medical School and Lab for Structural Neuroscience, McLean Hospital, Belmont, MA 02178.

A recent study has demonstrated non-random interactions between DA-immunoreactive (IR) varicosities and GABA-IR cell bodies in rat mPFC (Benes et al., 1993). Because both the DA and GABA systems of cortex have been shown to undergo progressive postnatal development, the current study has explored the possibility that increases in the interaction of these neural elements might also occur postnatally. In the present study, a progressive linear increment in the percentage of GABA cell bodies having DA-IR varicosities in apposition has been observed to occur between birth and postnatal day 60 ($r = 0.75$, $N = 19$, $p < 0.0005$). The number of DA-IR varicosities in contact with each GABA cell also shows a curvilinear increase during the post-weaning period ($r = 0.81$, $N = 19$, $p < 0.0005$). When these latter two parameters are multiplied to generate an index of interaction, a 2.5 fold increase is observed in post-weanling rats when compared to similar data for the pre-weanling period. Overall, these findings are consistent with the idea that late postnatal changes in the interaction of DA and GABA cells progressively occur. Such changes could potentially play a role in the onset of a neuropsychiatric disorder, such as schizophrenia, in which there is a defect of GABA neurotransmission and a typical onset during late adolescence and early adulthood. Supported by MH00423, MH31154 and the Stanley Foundation.

638.17

COLOCALIZATION OF GABA-, GLYCINE-, AND GLUTAMATE-LIKE IMMUNOREACTIVITY IN THE INNER NUCLEAR LAYER OF THE POSTHATCH CHICKEN RETINA. H. Sun and W.J. Crossland*, Dept. Anat. & Cell Biol., Wayne State Univ. Schl. Med., Detroit MI 48201

We previously reported the localization of immunoreactivity to the amino acid transmitters GABA, glutamate (GLU), and glycine (GLY) in the chicken retina. We report here on the colocalization of these transmitters in the chicken retina inner nuclear layer.

Posthatch chicks were deeply anesthetized (halothane), decapitated, and their retinas fixed by immersion in mixed aldehydes. Small strips of central retina were embedded in epon and sectioned transversely at 1.5 μ m. Adjacent serial sections were mounted on different slides to compare sections through the same cell immunoreactive to primary antibodies; (Chemicon) GLU, GABA, or GLY; visualized using an ABC kit (Vector).

Horizontal cells were GLU+. Most GLU+ cells were also GABA+. A few GABA+ cells were GLY+. Bipolar cells were virtually all GLU+ and those which were both GLU+ and GLY+ were often adjacent to horizontal cells. Amacrine cells stained heterogeneously. GLU+ cells were most numerous followed by GLY+. Fewer of the GLU+ cells were GABA+, but most GABA+ cells were also GLU+ or GLY+, suggesting that at least some of these cells may contain all 3 transmitters.

The colocalization of GABA and GLY in some horizontal cells, the colocalization of GLU in GLY+ bipolar cells, and the probable colocalization of all 3 among some amacrine cells raises the question of possible functional and morphological differences among these cells.

THE EFFECTS OF SUBSTANCE P (SP) AND SEROTONIN (5-HT) ON DOPAMINE (DA) RELEASE IN THE STRIATUM: MICRODIALYSIS STUDIES IN VIVO. Camille S. Suchowski* and Matthew P. Galloway, CCN Program, Dept. of Psych & Behav Neurosciences, Wayne State Univ Sch of Med, Detroit, MI 48202.

Several studies have demonstrated that 5-HT facilitates DA release in vivo, however the 5-HT receptor subtype and the synaptic organization remain to be determined. Using microdialysis, we analyzed the potential involvement of 5-HT_{1b} receptors and the effects of the neurokinins, SP and senktide (a NK3 agonist) on extraneuronal striatal DA levels. Local perfusion with 100 μ M 5-HT significantly increased DA levels approximately 7-fold above baseline (65 \pm 71%, n=6). After perfusion with 100 μ M cyanopindolol (CYP), a 5-HT_{1b} antagonist, baseline DA levels increased 91%. In the presence of CYP, 100 μ M 5-HT no longer had a significant effect on DA levels (n=5). Perfusion of 100 μ M SP did not significantly alter extracellular striatal DA levels (n=7) nor did local perfusion of 100 μ M senktide (n=6). To determine whether SP interacted with the effect of 5-HT, tissues were perfused with 100 μ M SP or senktide followed by a 10 μ M pulse of 5-HT. SP or senktide pretreatment did not alter 5-HT's effect on extracellular DA levels (n=11). Preliminary microdialysis experiments measuring extracellular DOPA after perfusion of difluoromethyltyrosine, a decarboxylase inhibitor, indicated that 100 μ M senktide increased DOPA levels by 89% (n=3). In summary, 5-HT induced DA release was blocked by CYP. Perfusion of SP and senktide did not significantly alter DA release or alter the 5-HT facilitation of DA release. Supported by NIDA 04120 and the Joe Young Sr. Research Fund.

EXCITATORY AMINO ACID MODULATION OF DOPAMINE RELEASE IN THE RAT PREFRONTAL CORTEX: A MICRODIALYSIS STUDY. H. P. Jedema and B. Moghaddam*, Dept. of Psychiatry, Yale Univ. Sch. Med. and VA Med. Ctr. 116A/2, West Haven, CT 06516.

In the present study, we have investigated the effects of various classes of excitatory amino acid agonists on the release of dopamine in the medial prefrontal cortex of conscious rats. Bilateral microdialysis probes were used to assess extracellular levels of dopamine and to infuse excitatory amino acid agonists locally. Infusion of 20 μ M kainate resulted in behavioral stimulation (e.g., sniffing) and a sustained, robust, nearly 7-fold increase of in the extracellular levels of dopamine. Local application of 20 μ M AMPA had a less profound effect, causing an increase of 2- to 3-fold in extracellular levels of dopamine. Higher concentrations of AMPA (100 μ M) increased dopamine levels by nearly 10-fold. However, this increase was associated with convulsions in most animals tested. Local infusion of 20 μ M NMDA did not affect extracellular dopamine levels. A much higher concentration of NMDA (200 μ M) led to a 3- to 5-fold increase in dopamine levels. In contrast to AMPA or kainate, higher concentrations of NMDA did not cause convulsions. These results indicate that excitatory amino acid agonists facilitate the release of dopamine in the prefrontal cortex *in vivo*, and that non-NMDA receptor agonists are more potent than NMDA receptor agonists in so doing. This finding is in agreement with our previous studies showing that non-NMDA receptor antagonists can attenuate the release of dopamine in the prefrontal cortex during stress. Supported in part by MH48404 and MH44866 and the Scottish Rite Foundation.

639.2

EFFECTS OF CCK-4, CCK-8S AND PENTAGASTRIN ON DOPAMINE RELEASE IN THE STRIATUM: STUDIES WITH MICRODIALYSIS IN VIVO Mark D. Barsamian* and Matthew P. Galloway, Cellular and Clinical Neurobiology Program, Dept. of Psychiatry and Behavioral Neurosciences, Wayne State University Sch of Med, Detroit, MI 48202.

Clinical studies have demonstrated that both Cholecystokinin (CCK) fragment 30-33 unsulfated (CCK-4) and pentagastrin (PG) induce panic attacks in panic disorder patients. Since dopamine (DA) neurons are exquisitely activated by mild stress, we investigated the effects of CCK-4, CCK-8S (CCK 26-33) or PG on DA release in the striatum. Microdialysis techniques and HPLC-EC were employed to measure extracellular levels of striatal DA in male Sprague Dawley rats anesthetized with chloral hydrate. Perfusion of artificial CSF (2 μ L/min) with 100 μ M CCK-4 (1, 20-min pulse, n=4) or 100 μ M CCK-8S (3 successive pulses, n=4) had no significant effect on levels of extracellular striatal DA. Similarly, intravenous administration of CCK-4 (0.6 mg/kg and 2.10 mg/kg, n=2), CCK-8S (1 mg/kg, n=4), or pentagastrin (0.5 mg/kg, n=2) had no significant effect on striatal DA release. Pentagastrin could not be reliably examined via perfusion studies due to its solubility properties; further studies are in progress. Taken together, these results indicate that CCK does not have a robust influence on DA release from the striatum. However, the diffusion efficiency of peptides through the dialysis membrane may influence the bioavailability of CCK or PG. Supported by NIDA and the Joe Young Sr. Research Fund.

639.4

DOPAMINE RELEASE IN ANTERIOR MEDIAL STRIATUM IS CONTROLLED BY THE PREFRONTAL CORTEX: EVIDENCE FOR TONIC AND PHASIC MODULATION. M. Karreman* and B. Moghaddam, Dept. of Psychiatry, Yale University School of Medicine and West Haven VA Med. Ctr. 116A/2, West Haven, CT 06516.

In the present study, we have investigated whether the prefrontal cortex exerts a modulatory effect on dopamine release in the anterior medial striatum of conscious rats. Two concentric microdialysis probes were used in each animal: one placed in the medial prefrontal cortex, used primarily for drug infusion, and the other placed in the contralateral anteromedial striatum, used to measure extracellular levels of dopamine. Infusion of TTX (5 μ M) into the prefrontal cortex caused a decrease in extracellular dopamine levels in the anterior medial striatum, indicating that neuronal events in the prefrontal cortex exert a tonic excitatory effect on striatal dopamine release. Infusion of bicuculline (100 μ M) into the prefrontal cortex resulted in an increase in the release of dopamine in the striatum, while application of amphetamine (50 μ M) in the prefrontal cortex attenuated dopamine release in the striatum. These data suggest that GABAergic, as well as monoaminergic, systems in the prefrontal cortex control striatal release of dopamine. Further pharmacological characterization of tonic and phasic cortical mechanisms that modulate the release of dopamine in the striatal complex are currently underway.

THE 5-HT₂ ANTAGONIST AMPEROZIDE POTENTIATES AMPHETAMINE-STIMULATED DOPAMINE RELEASE IN THE RAT PREFRONTAL CORTEX. E.A. Pehek* and H.Y. Meltzer. Department of Psychiatry, Case Western Reserve University School of Medicine, Cleveland, OH 44106.

The pharmacological profile of the putative atypical antipsychotic drug amperozide includes 5-HT₂ antagonism coupled with the ability to block dopamine (DA) uptake. One or both of these properties may be the basis for the reported ability of amperozide to attenuate amphetamine (AMPH)-stimulated DA release in the dorsal and ventral striatum. Since previous research has demonstrated significant differences between the mesostriatal and mesocortical DA pathways, it is important to compare the regulation of DA release between these systems. The present study thus examined the effects of amperozide administration on AMPH-induced DA release in the prefrontal cortex (PFC). Male rats were implanted with chronic indwelling guide cannulae above the medial PFC. 2-3 days later, microdialysis probes were lowered through these cannulae into the PFC of awake rats. Following collection of baseline samples, amperozide (1.0, 5.0 or 10.0 mg/kg i.p.) or saline were administered 30 min before d-AMPH (5.0 mg/kg i.p.). AMPH increased basal extracellular DA levels from 0.68 pg/20 μ l to 4.35 pg/20 μ l 30 min following injection. Amperozide administration did not attenuate this increase. Rather, injections of amperozide potentiated AMPH-stimulated DA release in a dose-dependent manner. Relative to AMPH alone, administration of 1.0, 5.0 and 10.0 mg/kg amperozide produced additional increases in DA efflux of 1.06, 2.44 and 4.05 pg/20 μ l, respectively. These results may be due to actions of amperozide on the cortical 5-HT₂ receptor coupled with effects of AMPH on the DA transporter. Furthermore, these data add to previous work demonstrating differences between the mesocortical and mesostriatal systems in the regulation of DA release.

FLUOXETINE AND (+)-MDMA-INDUCED DOPAMINE RELEASE *IN VIVO*: THE ROLE OF ENDOGENOUS SEROTONIN

Susanne Koch* and Matthew P. Galloway. CCN Program, Dept. Psych. and Behav. Neuroscience, Wayne State Univ Sch Med, Detroit, MI 48202

(+)-MDMA (3,4-methylenedioxymethamphetamine, "Ecstasy"), an amphetamine related drug of abuse, is a potent releaser of serotonin (5-HT) and causes toxicity to 5-HT neurons after repeated exposure. (+)-MDMA also releases dopamine (DA), although with less potency. Since we have shown previously that the intrastriatal application of 5-HT facilitates DA release via an axo-axonic mechanism, we hypothesized that increased release of striatal 5-HT after (+)-MDMA may influence extracellular levels of DA. To elucidate the effect of (+)-MDMA on 5-HT and DA release, both *in vitro* (striatal slices) and *in vivo* (microdialysis) studies were used. *In vitro*, (+)-MDMA (4.7 μ Mol/kg, i.v.) increased extracellular DA levels 401% ($p < 0.01$, $n = 12$). In the presence of fluoxetine (FLX, 14.4 μ Mol/kg, s.c.), which prevents (+)-MDMA effects on 5-HT release, the (+)-MDMA-induced increase in DA was significantly less (27%, $p < 0.05$, vs no FLX, $n = 8$). *In vitro* studies with striatal slices, to test drug selectivity, showed that (+)-MDMA (0.3-3 μ M) increased extracellular levels of both DA and 5-HT in a dose-dependent manner. FLX (3 μ M) completely blocked the effects of (+)-MDMA on 5-HT release, but did not alter (+)-MDMA-induced DA release *in vitro*. The selective DA transport inhibitor GBR-12909 (1 μ M), blocked (+)-MDMA's effect on DA release. Surprisingly, the 5-HT₂ antagonist ketanserin (1 μ M) greatly attenuated (+)-MDMA's effect on 5-HT release *in vitro*. It is concluded that 5-HT release after (+)-MDMA treatment partially contributes to (+)-MDMA's effect on DA release *in vivo*. Further, the DA transporter appears to be essential in mediating the direct effect of (+)-MDMA on DA release. Supported by NIDA-04120 and the Joe Young Sr. Research Fund.

EXTRACELLULAR DOPAMINE IN NUCLEUS ACCUMBENS SHELL IS ALTERED BY 6-OHDA LESIONS OF MEDIAL PREFRONTAL CORTEX. D. King*, M.J. Zigmond, and J.M. Finlay. Department of Neuroscience, University of Pittsburgh, Pittsburgh, PA 15260.

We previously reported that neither basal nor evoked extracellular dopamine (DA) in neostriatum is altered by medial prefrontal cortex (mPFC) DA depletion (King et al., Soc. Neurosci. Abst. 19:1829). In the present study, the impact of such lesions on extracellular DA in nucleus accumbens subregions, shell and core, were examined using *in vivo* microdialysis. Bilateral 6-OHDA infusions (1 μ g/2 μ l/side) into mPFC were performed 30 min after treatment with desipramine (25 mg/kg). Two weeks later, a microdialysis probe (150 μ m O.D., 1.5-2 mm active length) was placed into shell or core. Approximately 18 hours after implantation of the dialysis probe, basal extracellular DA levels were determined at 15 min intervals (all data expressed as pg per 20 μ l). In rats sustaining lesions of mPFC (60 \pm 5 % DA and 24 \pm 7 % NE loss), basal levels of DA in shell were increased relative to control rats (7.2 \pm 0.6 ($n = 11$) and 5.0 \pm 0.7 ($n = 8$), respectively). In contrast, basal DA levels were not different in core of lesioned and control rats (9.0 \pm 1.0 ($n = 5$) and 8.4 \pm 0.7 ($n = 6$), respectively). Systemic d-amphetamine (1.5 mg/kg, i.p.) produced a similar increase of extracellular DA in shell of both lesioned and control rats (28.6 \pm 3.1 and 29.0 \pm 4.0, respectively). In contrast, mPFC lesions attenuated the effects of d-amphetamine in core relative to controls (33.0 \pm 1.0 and 44.8 \pm 5.8, respectively). Tail pressure (30 min) produced a similar increase of extracellular DA in core of lesioned and control rats (10.4 \pm 1.4 and 9.4 \pm 0.9, respectively). In contrast, 6-OHDA lesions of mPFC potentiated the tail pressure-induced increase of extracellular DA in shell compared to controls (8.5 \pm 0.8 and 5.9 \pm 0.8, respectively). These data suggest that the mesoaccumbens DA neurons terminating in shell but not core may be regulated by mesocortical DA neurons especially under conditions of stress. BASAL GANGLIA SUBSTRATES OF MK-801-INDUCED STIMULATION OF STRIATAL DOPAMINE RELEASE. D.W. Miller* and E.D. Abercrombie. Center for Molecular and Behavioral Neuroscience, Rutgers University, Newark, NJ 07102.

Glutamate and dopamine (DA) interactions are important in regulating the behavioral outputs of the basal ganglia. Previously, we have reported that systemic administration of the non-competitive NMDA antagonist MK-801 significantly increases extracellular DA in striatum, measured with *in vivo* microdialysis in awake rats. MK-801 (0.5 mg/kg) increased extracellular DA from 5.1 pg/20 μ l sample to 7.3 pg ($n = 7$). This increase was TTX-sensitive. These data support electrophysiological studies from other laboratories showing that systemic MK-801 increases activity of nigrostriatal DA neurons. We hypothesize that blockade of excitatory glutamatergic drive to striatum could increase DA cell firing by decreasing the activity of GABAergic projections to the SNC (direct striatonigral path) and/or via disinhibition of globus pallidus (GP) projections (indirect striatonigral path) to SNR neurons which in turn inhibit the SNC. The present experiments analyzed the effects of intrastriatal application of kainic acid (KA; 2 μ g/ μ l) on MK-801-induced striatal DA release. Two weeks following the administration of KA, striatal DA levels were significantly lower in KA-lesioned ($n = 6$) vs non-lesioned ($n = 7$) animals. Although MK-801 increased extracellular DA from 1.8 pg to 2.4 pg in KA-lesioned animals, this increase was significantly less than in non-lesioned animals. To control for the likelihood that GP was damaged by an intrastriatal injection of KA as well as to differentiate the role of both the direct and indirect striatonigral paths in MK-801's stimulatory effects on striatal DA release, selective lesions of GP were carried out using ibotenic acid (IBO; 10 μ g/ μ l, 0.1 μ l/injection, 3 injections in the same dorsal/ventral plane) two weeks prior to the dialysis experiment. Preliminary data suggest that basal striatal DA levels are unaltered in IBO-lesioned animals ($n = 2$). The role of GP in MK-801-induced striatal DA release has yet to be determined, but preliminary data also suggest that GP-lesions may decrease MK-801's stimulatory effects on striatal DA release. Thus, the efferents of striatum and GP may have differential roles in regulating both basal and MK-801-induced striatal DA release. [Supported by USPHS Grant NS 19608]

STRIATAL EXTRACELLULAR DOPAMINE IS REGULATED BY EFFERENT PROJECTIONS OF MEDIAL PREFRONTAL CORTEX.

J.M. Finlay*, M.J. Zigmond and A.F. Sved. Department of Neuroscience, University of Pittsburgh, Pittsburgh, PA, 15260

Excitatory amino acid containing projections from the medial prefrontal cortex (mPFC) may regulate the activity of nigrostriatal dopamine (DA) neurons and disruption of this interaction has been proposed to play a role in schizophrenia and Tourette's syndrome. We have examined the impact of ibotenic acid lesions of mPFC on DA efflux in the striatum (STR) using *in vivo* microdialysis. Lesions of neurons intrinsic to the mPFC were produced by local application of ibotenic acid (5 μ g/0.5 μ l/side). Following a 2 week recovery period, microdialysis probes (2.5 mm length, 250 μ m O.D.) were implanted in the STR and approximately 18 h later, basal extracellular DA levels were determined in freely moving rats. Basal DA levels (determined as pg/20 μ l in 15 min samples) were not affected by ibotenic acid lesions of mPFC [control: 11.7 \pm 0.8 ($n = 17$); lesion: 11.7 \pm 1.0 ($n = 13$)]. The effect of amphetamine (1.5 mg/kg, i.p.) on extracellular DA was attenuated in lesioned rats relative to control rats (+462 \pm 70% and +603 \pm 82% from baseline, respectively) whereas 30 min of tail pressure elicited a greater increase in extracellular DA in lesioned than control rats (+32 \pm 3% and +12 \pm 3% from baseline, respectively). These data support the hypothesis that efferent projects of mPFC regulate the activity of nigrostriatal DA neurons. GLUTAMATE POTENTIATES THE STRESS-EVOKED INCREASE IN STRIATAL DOPAMINE SYNTHESIS. S.L. Castro*, A.F. Sved, and M.J. Zigmond. Departments of Neuroscience and Psychiatry, University of Pittsburgh, Pittsburgh, PA 15260

The present study examined the role of glutamate in the regulation of stress-evoked changes in tyrosine hydroxylation (TH) in neostriatum. Adult male rats were exposed to 30 min of intermittent tail shock in the presence of an aromatic amino acid decarboxylase (AADC) inhibitor, NSD-1015 (100 μ M), administered locally through a dialysis probe implanted into the striatum, and the concentration of DOPA in the dialysate was measured. Stress was applied beginning either 15 min or 75 min after the onset of NSD treatment, corresponding to the initial rate or steady-state phase of the DOPA accumulation curve, respectively. Stress significantly increased the steady-state levels of extracellular DOPA (+40%). However, no change was observed in the initial rate of DOPA accumulation unless animals also received the D₂ antagonist, eticlopride (50 nM). The impact of stress on the steady-state level of DOPA could be attenuated by the D₂ agonist quinpirole (100 μ M). Similar results were obtained using APV (100 μ M) or CNQX (100 μ M), glutamate antagonists acting at NMDA or AMPA receptors, respectively. These results suggest that acute stress normally has little effect on TH in striatum due to the inhibitory influence of DA present in the extracellular fluid. However, when that influence is absent (e.g., during long-term inhibition of AADC or DA receptor blockade) stress does increase TH, an effect that is mediated by glutamate. Thus, glutamate released from corticostriatal projections may serve to stimulate DA synthesis and thereby restore dopaminergic activity under conditions in which the availability of DA for release has temporarily been compromised. DOPAMINE-SOMATOSTATIN INTERACTIONS IN THE RAT STRIATUM: AN IN VIVO MICRODIALYSIS STUDY. A. Kastellakis¹, J. Radke, Y. Anagnostakis, K. Thermos and C. Spyrali². Lab of Pharmacology, Dept. of Basic Sciences, Sch. of Medicine and ²Dept. of Psychology, Sch. of Social Sciences, Univ. of Crete, Crete, Greece.

The neuropeptide somatostatin is found throughout the central nervous system where it is believed to act as a neurotransmitter. Pharmacological and behavioural studies have provided evidence suggesting a role for somatostatin in dopamine mediated behaviours. To assess such an interaction between the two systems, our first attempts focused on the elucidation of the effect of dopaminergic agents on somatostatin release, using *in vivo* microdialysis. Apomorphine administered subcutaneously, and directly infused in the striatum, as well as the selective dopamine antagonists SCH 23390 and sulpiride, failed to elicit somatostatin release (1). In the present work we examined the effect of different concentrations (10-4M, 10-5M, 10-6M) of somatostatin-14 and somatostatin-28 on dopamine release in the striatum. Vertical designed probes were implanted bilaterally in the striatum and used for the infusion of somatostatin, as well as the collection of the dialysate at 15 min intervals (1 µl/min). Dopamine and metabolites were measured prior to and 120 min after administration of somatostatin. A net dose-dependent increase of dopamine was observed, without significant alterations in the levels of the metabolites, HVA and DOPAC. Rats exhibited signs of stereotypy and grooming.

These results, taken together, show that although the induced alterations in dopamine transmission failed to influence somatostatin levels, somatostatin did modulate dopamine release. This suggests that a unidirectional interaction exists between somatostatin and dopamine in the striatum, at the neurochemical level.

NEUROKININ-1 TACHYKININ RECEPTOR-DOPAMINE INTERACTIONS IN THE RAT. M. Brackstone, C. J. Gibson^{*} & A. J. Stoessl. Clinical Neurological Sciences, University of Western Ontario, London, ON, Canada, N6A 5A5.

There is anatomical evidence for a dense substance P (SP) projection from the striatum to the substantia nigra (SN). Electrophysiological, neurochemical and behavioural studies all suggest a functionally significant interaction between tachykinins and dopamine (DA) neurons of the SN, but this structure is devoid of SP receptors. Pharmacological and molecular studies have demonstrated that SP and related compounds act through a family of tachykinin receptors, termed neurokinin (NK) 1-3. Autoradiographic studies have demonstrated the presence of NK-3 receptors on nigral DA neurons and stimulation of nigral NK-3 receptors leads to classical DA-mediated behavioural responses of locomotion and rearing. In contrast, stimulation of nigral NK-1 receptors elicits grooming in the absence of locomotion and rearing. We explored the possibility that NK-1-induced grooming might reflect *dendritic* release of DA which could then stimulate local DA D1 receptors. Nigral infusion of the selective NK-1 agonist [AcArg⁸,Sar⁹,Met(O₂)¹¹]SP₆₋₁₁ (0.1 nmol) elicited dose-dependent stereotypic grooming. This response was significantly attenuated by peripheral administration of the DA D1 antagonist SCH 23390 (100 µg/kg s.c.), but not by the DA D2 antagonist sulpiride (30 mg/kg i.p.). Grooming induced by nigral infusion of the NK-1 agonist was unaffected by either nigral or striatal SCH 23390 (0.1-5 µg), but was blocked by bilateral 6-hydroxydopamine lesions. Our findings indicate that stimulation of nigral NK-1 receptors elicit grooming which is dependent upon release of DA and stimulation of D1 receptors in an as yet unidentified site.

STRIATAL DOPAMINE LEVELS INCREASE FOLLOWING PERIPHERAL SCOPOLAMINE INJECTIONS AND FOLLOWING APPLICATION OF SCOPOLAMINE TO THE TEGMENTAL PEDUNCULOPONTINE NUCLEUS. J.R. Blackburn¹*, C.A. Chapman¹, C.D. Blaha² and J.S. Yeomans³. Depts. of Psychology, ¹McMaster University, Hamilton, Ontario; ²University of British Columbia, Vancouver, B.C.; and ³University of Toronto, Toronto, Ontario, Canada.

The cholinergic cells of the tegmental pedunculopontine nucleus (PPT) monosynaptically excite dopaminergic (DA) neurons of the substantia nigra. Further, DA-dependent behaviours are enhanced following peripheral or central PPT injections of antimuscarinic drugs, consistent with a disinhibition of PPT cholinergic cells via blockade of their inhibitory autoreceptors. Rat dorsal striatal DA levels were monitored chronoamperometrically (1 sec 350mV pulses) with bilateral, chronically implanted, stearate-modified graphite paste electrodes. I.p. injections of scopolamine (1, 3, 10 mg/kg) resulted in bilateral dose-related increases in DA oxidation currents in the striatum. Unilateral microinjections of scopolamine into the PPT (10, 50, 100 µg/5 µl) also resulted in short-latency, bilateral dose-related increases in striatal DA oxidation currents which usually peaked 50-80 min post-injection. Carbachol (4 µg/5 µl) injected in the PPT 20 min prior to 100 µg PPT scopolamine attenuated these increases. These results indicate that elevated striatal DA levels following the systemic scopolamine treatments may be mediated by the PPT. This study further demonstrates a powerful excitatory effect of Ch5 PPT cells on the nigrostriatal DA system.

BEHAVIORAL EVIDENCE FOR CHOLECYSTOKININ-D1 INTERACTIONS. J. M. VanKampen, H. Frydvszak & A. J. Stoessl^{*}. Clinical Neurological Sciences, University of Western Ontario, London, ON, Canada, N6A 5A5.

The neuropeptide cholecystokinin (CCK) has been shown to have modulatory effects on dopaminergic activity in several areas of the central nervous system, including the striatum. In light of this, it has been proposed that abnormalities of CCK may play a significant role in the development of dyskinesias. We examined the effects of CCK on the behavioral responses to a dopamine D1 agonist in the rat. Peripheral administration of the selective D1 agonist SKF 38393 (5 mg/kg s.c.) resulted in significant increases in vacuous chewing movements (VCMs) and stereotypic grooming, which were significantly attenuated by the peripheral administration of CCK-8S (50 µg/kg i.p.). Elucidation of the specific CCK receptor subtype involved in this effect was approached in two ways. The preferential CCK-B agonist CCK-4 (10-50 µg/kg i.p.) failed to suppress SKF-induced VCMs. Suppression of SKF-induced VCMs and stereotypic grooming by CCK-8S (50 µg/kg i.p.) was significantly attenuated by the CCK-A antagonist devazepide (0.1-0.3 mg/kg i.p.) but not by the CCK-B antagonist L-365,260 (0.1-0.3 mg/kg i.p.). CCK-8S appears to suppress some dopamine-mediated behaviors via post-synaptic mechanisms linked to the D1 receptor, via stimulation of CCK-A receptors. CCK agonists may prove useful in alleviating dyskinesias in humans.

CHRONIC L-DOPA TREATMENT ALTERS LIGAND BINDING TO STRIATAL NMDA RECEPTORS AND DOPAMINE UPTAKE SITES IN RATS WITH NIGROSTRIATAL INJURY. S.J. O'Dell^{*}, F.B. Weihmuller, and J.F. Marshall. Dept. of Psychobiology, University of California, Irvine, CA 92717.

Growing evidence suggests that alterations of brain dopamine (DA) activity can change corticostriatal transmission and striatal glutamate (GLU) receptors. We previously found large decreases (75-80%) in [3H]mazindol binding to DA transporters and substantial increases (22-46%) in [3H]GLU binding to NMDA receptors in postmortem striatal tissue sections from Parkinsonian patients. However, it was not certain whether these changes resulted from the disease process or long-term dopamine replacement therapy. To investigate this, rats were given unilateral 6-OHDA injections along the nigrostriatal DA projections. One month later, these lesioned rats and unlesioned control rats were given 2 daily injections of Sinemet (100 mg L-DOPA + 25 mg carbidopa/kg, ip) or vehicle for 21 days. Three days after the last injection, their brains were processed for *in vitro* autoradiography. The nigrostriatal 6-OHDA injection alone reduced ipsilateral striatal [3H]mazindol binding by 90% but failed to increase striatal [3H]GLU binding to NMDA receptors. In contrast, 6-OHDA-lesioned rats treated chronically with Sinemet showed a 30% increase in NMDA receptor binding ipsilaterally. Unexpectedly, chronic Sinemet also altered striatal [3H]mazindol binding in both lesioned and control animals. Thus, the receptor changes measured in postmortem Parkinsonian striatum may be strongly influenced by DOPA therapy.

CHRONIC BLOCKADE OF DOPAMINE RECEPTORS AFFECTS BINDING TO NMDA RECEPTORS IN RAT CORTEX AND BASAL GANGLIA. J. Ulas^{*}, F.B. Weihmuller¹, S.J. O'Dell¹, J.F. Marshall¹ and C.W. Cotman. *IRU in Brain Aging and* ¹Dept. of Psychobiology, University of California, Irvine, CA 92717, USA.

We have previously shown that chronic haloperidol treatment increases binding to NMDA receptors in the outer layers of parietal cortex. To further elucidate this phenomenon, we investigated the effect of long-term (3 weeks) blockade of dopamine receptors (D1, D2 or both) on binding to NMDA receptors in rat cortex, hippocampus and striatum. SCH23390 (0.5 mg/kg/day, s.c.), eticlopride (0.5 mg/kg/day, i.p.), or combination of both drugs was used to block D1, D2, or both subtypes of dopamine receptors, respectively. As revealed by quantitative autoradiography, eticlopride treatment significantly increased L-[³H]glutamate binding to NMDA receptors in the outer layers of frontal cortex, and the pyramidal layer of CA3 hippocampal region, while significantly attenuated binding to NMDA receptors in the lateral and ventral caudate-putamen, and nucleus accumbens. SCH23390 alone generally had no effect on NMDA receptor binding. On the other hand, simultaneous blockade of D1 and D2 receptors resulted in a slightly smaller increase (than that evoked by eticlopride alone) in binding to NMDA receptors in the frontal cortex, an increased binding in the deep layers of parietal cortex and CA3 region, and further reduced binding to NMDA receptors in the striatum. These results suggest that i) dopamine modulates NMDA receptor function differently in basal ganglia vs various cortical regions, ii) although SCH23390 alone does not affect binding to NMDA receptors, chronic blockade of D1 receptor may modify the effects of D2 receptor inhibition, and iii) the effect of haloperidol on NMDA receptors cannot be completely explained by blockade of D2 receptors.

DOPAMINE NEURONS MAKE TWO KINDS OF TERMINALS. D. Sulzer and S. Rayport*. Depts Psychiatry, Neurology, Anatomy & Cell Biology, and Ctr Neurobiology & Behavior, Columbia Univ; Dept Neuropathology, NYS Psychiatric Institute, NY 10032.

Morphological studies suggest that ventral midbrain dopamine neurons form dopaminergic as well as non-dopaminergic synaptic terminals in target areas at which glutamate may be the cotransmitter (Hattori, *Neurosci Res*, 1993); similarly, serotonergic raphe neurons appear to release glutamate (Johnson, *Neuron*, 1994). Electrophysiological studies of single identified dopamine neurons show that the cells frequently make glutamatergic autaptic EPSPs (Sulzer and Rayport, *Soc Neurosci Abstr*, 1993). We now report that individual dopamine neurons immunostained for tyrosine hydroxylase show significant variation in neurite staining. In single neuron microcultures, where all processes arise from a single dopamine neuron, some thin neurites — which are most likely axonal — have varicosities that stain darkly and others have varicosities that stain lightly or are unstained. Double staining for synaptophysin shows putative release sites that do not stain for tyrosine hydroxylase. Double immunostaining with a polyclonal antiserum directed against glutamate (the glutaraldehyde-conjugate) shows that dopamine neurons are often glutamate-positive, while GABA neurons are rarely glutamate-positive. Taken together, these observations are consistent with the possibility that dopamine neurons release glutamate as a cotransmitter and may do so at separate terminals from where they release dopamine. If so, this may account in part for glutamate dependence of dopamine synaptic plasticity and neurotoxicity.

NEUROPEPTIDE Y RELEASE FROM PC12 CELLS IS REGULATED BY DOPAMINE X. Chen*, S.P. Han and T.C. Westfall. Department of Pharmacological and Physiological Science, St. Louis University Health Science Center, St. Louis, MO 63104.

We have previously demonstrated that NPY is co-localized and co-released with dopamine from pheochromocytoma PC12 cells by potassium-induced depolarization (*J. Neurochem.* Vol. 61, suppl., 1993). This study was designed to further investigate the mechanisms regulating NPY release from the peripheral sympathetic nervous system using PC12 cell line as a model system. PC12 cells grown in cell culture inserts were differentiated with nerve growth factor for 5 days. NPY content in the cell and in the releasing buffer was determined by radioimmunoassay as described previously (DiMaggio, 1992). KCl (50 mM) induced a 1-2 fold increase in NPY release over basal levels. KCl-stimulated NPY release was greatly attenuated by the activation of dopamine receptors on PC12 cells with apomorphine, a non selective D₁ and D₂ dopamine receptor agonist. The inhibitory effect of apomorphine on NPY release was dose dependent and could be partially reversed by eticlopride, a D₂ dopamine receptor selective antagonist.

These results suggest that NPY release from PC12 cells is regulated by dopamine which acts as a cotransmitter of NPY in this model of a peripheral sympathetic neuron. This work is supported by HL26319; HL35202 and NS02254.

NEUROPEPTIDE Y INCREASES CHOW INTAKE AND DOPAMINE CONCENTRATIONS IN MICRODIALYSATE FROM THE NUCLEUS ACCUMBENS OF RATS IN A FOOD CHOICE PARADIGM. R. L. Corwin* and J.N. Crawley. SBN, ETB, NIMH, NIH, Building 10, Room 4N212, Bethesda, MD 20892.

Neuropeptide Y (NPY) stimulates food intake when injected centrally (1). This effect of NPY on feeding may be direct or may be mediated by other neurotransmitters. Previous reports have demonstrated a high density of NPY neurons in the nucleus accumbens (NA) of the rat (2,3), some of which are in synaptic contact with tyrosine hydroxylase-like immunoreactive terminals (4). In the present study, rats were provided continuous access to rat chow and water, and limited access to a wet cookie mash, during *in vivo* microdialysis in the anterior NA. NPY (5 µg/5 µl) or vehicle (Ringer's, 5 µl) was administered intraventricularly. Food intake and dopamine (DA) concentration in microdialysate samples were measured every 20 min for 3 hours. DA concentration was quantitated using HPLC-EC. NPY increased chow intake and DA concentration, while having no effect on cookie mash intake in most of the rats tested. No increase in DA was seen in rats who did not consume chow but did consume cookie mash. These results suggest that NPY may play a role in food choice and that this effect may involve mesolimbic DA. 1. Clark, et al., 1984, *Endocrinology* 115:427. 2. EFFECTS OF HALOPERIDOL AND CLOZAPINE ON AMPHETAMINE INDUCED DOPAMINE RELEASE MEASURED WITH *IN VIVO* MICRODIALYSIS IN FREELY MOVING RATS. M.R. Kastan, M.A. Clinton, A.M. Ulrich, D.L. Alexoff, G.S. Smith, C.R. Ashby, Jr*, and S.L. Dewey. Chem. and Med. Dep't, BNL, Psych. Dep't, NYU, Upton, NY 11973.

Using PET we have demonstrated that clozapine altered the ability of 5-HT or GABA to modulate cortical and subcortical ACh while haldol altered the ability of 5-HT and GABA to modulate striatal DA in the primate brain (Dewey, et al., 1993). More importantly, these alterations appeared dependent upon the duration of neuroleptic exposure. To investigate the mechanisms underlying this altered responsiveness, we performed studies in rats using *in vivo* microdialysis and a similar drug treatment protocol. Consistent with our PET findings, rats exposed to haldol (1.0 mg/kg) for 1 week demonstrated a potentiated responsiveness of the DA system to an amphetamine challenge when compared to saline controls. Unlike our PET findings this potentiated response was evident in rats exposed to haldol for 5 weeks. Similar findings were observed in rats exposed to clozapine. Taken with our previous PET studies, these data suggest that alterations in the ability of 5-HT to modulate DA following *acute* exposure, may result primarily from changes in the DA system while alterations observed in animals exposed *chronically* may be linked primarily to changes in 5-HT or its ability to interact with DA. These data suggest that drug induced alterations may occur with different temporal profiles in specific neurotransmitter systems resulting from either direct or trans-synaptic alterations. NEUROTRANSMITTERS: GLUTAMATE/NITRIC OXIDE

640.1

THE MESOPONTINE NADPH-DIAPHORASE SYSTEM IN THE JAPANESE QUAIL G.C. Panzica*, A. Garzino. Dept. Human. Anatomy & Physiology, Univ. of Torino, I-10126 Torino, Italy

The distribution of NADPH-diaphorase activity (ND), an enzyme recently identified as the nitric oxide synthase, was histochemically investigated in the Japanese quail brainstem. A large number of ND-positive neurons were observed at all levels of the brainstem. In particular, they were located within the substantia nigra (SN), the area ventralis tegmentalis (AVT), the substantia grisea centralis, the nucleus interpeduncularis (IP), the locus coeruleus (LoC) and the subcoerulean nuclei (SCon). Scattered elements were present in other regions such as the vestibular nuclei or the nucleus of the solitary tract (S). This distribution partly overlaps with catecholamine (CA) neurons evidenced both with histochemical and immunohistochemical techniques. In most mammalian species, ND-positive neurons also show immunoreactivity for cholineacetyltransferase (ChAT) and they are intermingled but distinct from the CA-synthesizing elements. In the present study, we performed a double staining for ND, and ChAT (antiserum provided by M.Epstein), or tyrosine hydroxylase (TH), or serotonin (5HT) in order to analyze the degree of coexistence of these systems in the quail brainstem. At the level of LoC and SCon, the large majority of the ND positive neurons is also expressing ChAT, but the ND and TH systems are almost totally segregated in different parts of the nuclei. On the contrary, in the more rostral areas, at the level of SN, AVT and IP, ND positive neurons are essentially distinct from the ChAT immunopositive neuron and a large majority of them is expressing TH immunoreactivity. In contrast with the findings reported in rodents, there is only a rare or no coexpression of both ND and 5HT along the entire brainstem. In conclusion these data demonstrate that, within the mesopontine ND systems, it is possible to identify neuronal populations containing different neurotransmitters (CA, acetylcholine, 5HT). Moreover, the demonstration that the TH immunopositive neurons of SN and AVT are largely positive for ND suggests that the nitric oxide could have an important role in regulating the target areas connected to these regions. Supported by grants of CNR and MURST 60%.

SIMULTANEOUS VOLTAMMETRIC DETECTION OF STIMULATED DOPAMINE AND NITRIC OXIDE RELEASE IN RAT BRAIN SLICES M. Iravani, J. Millar & Z.L. Kruk*, Departments of Pharmacology and Physiology (JM), Queen Mary & Westfield College, Mile End Rd, London E1 4NS UK.

We have recently described a voltammetric method which uses a carbon fibre electrode for real time detection of nitric oxide (NO; Iravani et al 1993, *J. Physiol.*, 496: 48p), and we have used this to examine a NO like signal in rat striatum. Pressure ejection of NMDA, or electrical stimulation with trains of pulses in a 350µM rat striatum slice, gave rise to complex voltammetric signals which could be resolved into components attributable to the presence of dopamine (DA) and NO. The time courses of the DA and NO signals were different. The signal attributed to NO could be reduced by addition of the NOS inhibitor L-NMMA to the perfusion fluid. In the presence of the endogenous NO like substance, release of DA by electrical stimulation was attenuated, indicating that NO may have a role in local regulation of dopamine release.

SIMULTANEOUS MEASUREMENT OF ENDOGENOUS GLUTAMATE RELEASE AND NITRIC OXIDE PRODUCTION *IN VIVO* IN THE RAT HIPPOCAMPUS. K.M. Mitchell¹, G.S. Wilson² and E.K. Michaelis¹. Depts. of Pharmacology & Toxicology¹ and Chemistry², Univ. of Kansas, Lawrence, KS 66045.

Glutamate activation of NMDA receptor ion channels and the subsequent influx of Ca^{2+} is known to result in the activation of nitric oxide synthase (NOS) and enhancement of nitric oxide (NO) production. While glutamate and NO are known to be involved in the excitotoxic process of neuronal degeneration the exact mechanisms of this process are still unclear. The objective of this research was a first step towards the goal of further elucidation of the role of these transmitters in the excitotoxic process. This initial step entails the application of electrochemical detection methods to the measurement of evoked glutamate and NO overflow in the extracellular fluid (ECF) of the rat hippocampus. Evoked glutamate overflow was monitored using a dual enzyme biosensor developed in our laboratories. NO was measured using a nickel porphyrin based sensor developed by Malinski and colleagues (Nature 358:676-678, 1993). Glutamate and NO overflow were evoked by the focal injection of depolarizing levels of K^+ into the hippocampus. Potassium evoked glutamate release was correlated with local NO production. Local administration of nitro-L-arginine methyl ester (L-NMAE), an inhibitor of NOS, resulted in a decrease in NO production as well as a decrease in glutamate overflow. Furthermore, application of L-arginine in addition to L-NMAE reversed this effect. Our results indicate that NO and glutamate in the ECF can be detected simultaneously *in vivo* using electrochemical methods. In addition, NO production appears to result in the enhanced overflow of glutamate in confirmation of similar findings reported previously (Buisson, et al., J. Neurochem. 61:690-696, 1993).

NITRIC OXIDE DEPOLARIZES PARAVENTRICULAR NUCLEUS NEURONS *IN VITRO*. J.S. Bains* and A.V. Ferguson. Department of Physiology, Queen's University, Kingston Ontario, Canada K7L 3N6.

The presence of nitric oxide synthase, the enzyme necessary for the production of nitric oxide (NO), within neurons in the paraventricular nucleus of the hypothalamus (PVN) has led to the suggestion that NO may play a role in neurotransmission within this structure. Recent *in vivo* experiments have demonstrated that microdialysis of NO directly into PVN elicits decreases in blood pressure. This physiological change is accompanied by an increase in the release of excitatory amino acids such as glutamate within this nucleus (Horn et al., AJP, 1994). In this study, we have used whole-cell patch clamp recording techniques to investigate the potential effects of NO on PVN neurons. Using patch electrodes filled with potassium-gluconate, recordings were made from PVN neurons in coronal brain slices (400 μ m thickness) of adult, male Sprague-Dawley rats. Bath application of NO (5×10^{-10} - 5×10^{-8} M for 1-3 min.) induced a variable (8.2 mV to 17.9 mV) membrane depolarization in 6 of the 7 cells tested (mean depolarization \pm SEM: 10.6 ± 4.1 mV). This NO induced depolarization was also accompanied by a mean decrease in membrane resistance of 28 ± 17 %. These results indicate that NO, either itself, or through influencing the release of other neuronal mediators acts to excite PVN neurons.

640.7

HEPATIC ENCEPHALOPATHY: INTERACTIONS OF NMDA RECEPTORS AND DOPAMINE RELEASE IN THE STRIATUM AND FRONTAL CORTEX. S.S. Oja*, H.D. Borkowska, J. Albrecht and P. Saransaari. Tampere Brain Res. Ctr., Univ. Tampere, Finland, and Med. Res. Ctr., Polish Acad. Sci., Warsaw, Poland.

Hepatic encephalopathy (HE) is often accompanied by motor abnormalities which are thought to reflect dysfunction of the striatal dopaminergic system. The release of dopamine (DA) from nigrostriatal neurons is presynaptically regulated by glutamate receptors. We studied now the effects of HE on the interactions of the N-methyl-D-aspartate (NMDA) subtype of glutamate receptor with DA release in the striatum and frontal cortex of male Wistar rats. The precoma stage of HE was induced with intraperitoneal injections of hepatotoxin, thioacetamide. NMDA (0.1 mM) potentiated the release of newly-loaded [3H]DA from slices from both brain regions studied, the effects being similarly abolished by the non-competitive receptor antagonist dizocilpine (MK-801). HE diminished the stimulation of NMDA by 46 % in striatal slices but had no significant effect in frontal cortical slices. In membranes prepared from the cerebral cortex of HE rats the maximal binding capacity B_{max} of dizocilpine was decreased when compared to controls. The binding constant K_d of dizocilpine to striatal membranes was not altered but B_{max} was decreased in rats with HE. B_{max} for N-[1-(2-thienyl)cyclohexyl]-piperidine (TCP) binding was not markedly altered by HE in the cerebral cortex but was significantly diminished in the striatum. The function of NMDA receptors seems thus to be attenuated in HE, which apparently diminishes DA release in the striatum. This phenomenon may be a factor causative of the motor disturbances of HE *in vivo*.

NITRIC OXIDE INHIBITS NEUROGENIC NON-ADRENERGIC, NON-CHOLINERGIC CONTRACTIONS BUT NOT CHOLINERGIC CONTRACTIONS OF CIRCULAR MUSCLE FROM GUINEA PIG ILEUM. J.J. Galligan* and A.M. Yunker. Dept. Pharmacology and Toxicology and Neuroscience Program, Michigan State University, E. Lansing, MI 48824

Nitric oxide (NO) is released from enteric neurons resulting in relaxation of gastrointestinal (GI) smooth muscle. NO may also inhibit release of excitatory neurotransmitters such as substance P (SP) and acetylcholine (ACh) from enteric nerves. This hypothesis was tested using circular muscle-myenteric plexus preparations (CMMPs) from guinea pig ileum. In the presence of scopolamine and guanethidine, stimulation (1-50 Hz, 0.01 TPS) of CMMPs produced non-adrenergic, non-cholinergic (NANC) contractions. These contractions were blocked by tetrodotoxin and were attenuated in a concentration-dependent manner by CP96345-1, a neurokinin-1 receptor antagonist. The nitric oxide synthase (NOS) antagonists N^G -nitro-L-arginine, N^G -nitro-L-arginine methyl ester, and N^G -methyl-L-arginine potentiated the amplitude of the NANC contractions in a concentration-dependent manner. The D-stereoisomers of these NOS antagonists did not alter the NANC contractions. Oxyhemoglobin binds extracellular NO and caused a concentration-dependent increase in the amplitude of NANC contractions. Neither the NOS antagonists nor oxyhemoglobin altered the concentration-response curve for substance P methyl ester, suggesting that GI smooth muscle was not the site of action for these drugs. Finally, sodium nitroprusside attenuated NANC contractions in a concentration-dependent manner. Neither the NOS antagonists nor oxyhemoglobin affected cholinergic contractions generated in the presence of guanethidine and CP96345-1. These data suggest that NO inhibits SP but not ACh release, thus providing a second mechanism by which NO can inhibit motility of GI smooth muscle. (Supported by DK 40210 and NS 07279)

EFFECTS OF NMDA ON NITRIC OXIDE AND NEUROTRANSMITTER RELEASE IN THE RAT STRIATUM. R. Guevara-Guzman¹, P.C. Emson and K.M. Kendrick. Dept. Neurobiology, BBSRC Babraham Institute, Cambridge CB2 4AT, U.K. ¹Dept. Physiology, Faculty of Medicine, Mexico University, Mexico 04510, DF.

We have shown previously that nitric oxide (NO) stimulates *in vivo* release of acetylcholine (ACh), 5-HT, glutamate (GLU), taurine (TAU) and GABA in the rat striatum and that these effects are mimicked by cGMP. Dopamine (DA) release is inhibited by NO and increased by cGMP suggesting that this NO effect is mediated indirectly. The present study has investigated the effects of NMDA on NO and classical transmitter release in the presence and absence of the NO synthase inhibitor nitroarginine (NARG) using *in vivo* microdialysis.

The experiments were conducted in urethane anaesthetised rats and microdialysis probes were placed in the medial striatum. Krebs Ringer, with 2 μ M neostigmine, was passed through the probes at 1.5 μ l/min and a liquid switch was used to deliver different substances into the probe. ACh, DA, 5-HT, GLU, TAU and GABA were measured by HPLC. Nitrite (NO_2) and citrulline (CIT) were used as indicators of NO. NO_2 was measured using the Greiss reaction and a microplate reader (550nm) and CIT using HPLC. Results showed that a 15 min infusion of NMDA (150 μ M), GLU (1mM) or KCl (100mM) evoked simultaneous release of NO_2 and CIT. NMDA (1-100 μ M) evoked a dose-dependent release of CIT and all the transmitters measured, although for the transmitters a clear dose-response relationship was mainly seen with the lowest NMDA concentrations (1-10 μ M). With a 50 μ M NMDA dose, when a second application (S2) was given 3h after the first (S1) then evoked release of transmitters was reduced in S2 compared to S1, with the exception of DA which was increased in S2. If NARG (100 μ M) was applied for 2h before S2 by retrodialysis, or given peripherally, then the transmitter response to NMDA after S2 was significantly increased, except in the case of DA where it was decreased.

Our results indicate that NO is released in response to doses of GLU and NMDA which are not toxic. NMDA also evokes transmitter release in the striatum, although inhibiting NO-release with NARG potentiates this release. This provides further support for a neuroprotective role for NO. The fact that effects of NMDA on DA release either in the presence or absence of NARG are opposite to those on the other transmitters measured probably reflects differential levels of inhibition of DA release produced by NMDA activation of ACh and GABA.

640.8

GLUTAMATE - SOMATOSTATIN INTERACTIONS IN THE RAT STRIATUM: AN *IN VIVO* MICRODIALYSIS STUDY. J.M. Radke, C. Suvraki and K. Thermos*. Lab of Pharmacology, Dept. of Basic Sciences, Sch. of Med., Univ. of Crete, Iraklion, Crete, Greece.

In the rat striatum, somatostatin is contained within a specific population of medium sized aspiny interneurons, where it is believed to act as a neurotransmitter. The corticostriatal (glutamatergic) pathway may play an important role in somatostatin's function. To improve our understanding of somatostatin's role in the striatum, we investigated the interactions of this peptide with the excitatory amino acid system.

Using the technique of *in vivo* microdialysis we have successfully measured neuronally released somatostatin in the striatum. Administration of N-methyl-D-aspartate (NMDA) at doses of 10-4M and 10-5M significantly increased the release of somatostatin. This increase was blocked by the administration of the NMDA antagonists 2-APV and MK801, but was unaffected by the administration of the sodium channel blocker tetrodotoxin (TTX). Administration of kainic acid also increased somatostatin release, in a dose dependent manner (10-5M to 10-7M). This increase was attenuated by the kainic acid receptor antagonist 6,7 DNQA but only partially blocked by the administration of TTX. Kainic acid at the dose of 10-4M resulted in a decrease in somatostatin release. This effect is believed to be due to the lesioning effects of high doses of the drug. Quisqualate (10-4M) had no effect on the release of somatostatin.

These results indicate that excitatory amino acids interacting with NMDA and kainate receptors, but not quisqualate receptors, regulate the release of somatostatin in the striatum.

REGULATION OF THE PHOSPHORYLATION STATE OF DARPP-32 IN THE HALOTHANE-ANAESTHETIZED RAT. J. Ingum¹, J. Sefland² and S.J. Walaas^{1,2}. ¹Natl. Inst. of Forensic Toxicology, Oslo, Norway. ²Neurochemical Laboratory, University of Oslo, Norway.

Results obtained *in vitro* indicate that the phosphorylation state of DARPP-32, a cytosolic protein that is highly enriched in the medium-sized spiny neurons of the striatum, is regulated by several neurotransmitters. The present study determined the phosphorylation state of DARPP-32 obtained *in vivo* by injection of drugs i.p. or by perfusing microdialysis probes inserted into the striatum of halothane anaesthetized rats with various neuroactive substances. Dopamine levels in the microdialysates were determined by HPLC, and the phosphorylation state of DARPP-32 was measured by Western blotting with phosphorylation state specific monoclonal antibodies.

Injection of amphetamine (1-10 mg/kg) i.p. significantly increased the state of phosphorylation of DARPP-32, as did intrastriatal perfusion with carbachol (2.5 mM). In contrast, perfusion with NMDA (0.5 mM) for 1 h dephosphorylated DARPP-32 significantly. Forskolin (0.1 mM) (an activator of adenylate cyclase) and Rp-cAMP (0.1 mM) (an inhibitor of protein kinase A) only moderately influenced the phosphorylation state of DARPP-32. Despite their differential effects on DARPP-32 phosphorylation, carbachol and forskolin both increased the extracellular levels of dopamine 8-10 fold. These results suggest that, under the experimental conditions employed, DARPP-32 phosphorylation is regulated in the intact brain by both muscarinic and NMDA receptor-regulated mechanisms, in addition to previously the described D1 receptor-cAMP-PKA signal pathway.

MUSCARINIC MODULATION OF NMDA RESPONSES IN NEOCORTEX. V.B. Aramakis¹, J.H. Ashe and A.E. Bandrowski. Depts. of Neuroscience and Psychology, Univ. of California, Riverside, CA 92521.

Muscarinic actions of acetylcholine facilitate the amplitude of glutamate-induced membrane depolarizations (DPs) in rat auditory cortex (Cox et al, Synapse, 16:123, 1994). To assess the contribution of NMDA receptors to this facilitation, the actions of the cholinergic agonist, methacholine (MCh) were tested upon glutamate-induced DPs elicited in the presence of the AMPA/kainate antagonists CNQX or NBQX (20 μ M). The actions of MCh upon the late-EPSP (NMDA-mediated) were also examined. Whole-cell recordings were obtained from layer III cortical neurons of the *in vitro* auditory cortex. Ionophoretic application of MCh (1M, 50-150 nA, 1-3 min) or glutamate (1M, 5-60 nA, 20 sec) was also to layer III within 50 μ m of the recording electrode. During MCh, the amplitudes of glutamate DPs were consistently suppressed in either the presence or absence of CN/NBQX. On the other hand, following MCh the amplitudes of glutamate DPs were largely facilitated; about 75% in the absence of CN/NBQX, and about 300% in the presence of CN/NBQX. Durations of facilitation could last up to 35 min. MCh was also tested upon the isolated late-EPSP, i.e., elicited in the presence of CN/NBQX at 10-20 μ M to block AMPA/kainate receptors, and to also minimize the contribution of the IPSPs (Metherate & Ashe, in press). Under these conditions, the isolated late-EPSP was consistently suppressed by MCh. Moreover, the isolated late-EPSP amplitude was usually enhanced above pre-MCh levels, following the initial suppression. Thus, the actions of MCh on glutamate-induced DPs and the isolated late-EPSP suggests an involvement of NMDA receptors in cholinergic modulation of glutamatergic transmission. MECHANISM OF THE SYNERGISTIC ENHANCEMENT OF GLUTAMATE INDUCED CALCIUM INCREASE BY NORADRENALINE IN CULTURED VISUAL CORTICAL NEURONS. B. Yang*, Y.H. Wang and M.S. Cynader. Department of Ophthalmology, University of British Columbia, 2550 Willow St., Vancouver B.C., Canada V5Z 3N9.

In our previous studies, noradrenaline was found to be able to synergistically enhance glutamate induced intracellular free calcium ($[Ca^{2+}]_i$) increases in cultured visual cortical neurons (Neurosci. Abst. 205.13, 1993). To further address the mechanism underlying this interaction, we employed antagonists of a variety of receptor subtypes to investigate the cellular pathways responsible for the modifying effect. We found that the dose dependent glutamate induced calcium increase was blocked by 25 μ M APV. It was interesting to find that this NMDA receptor antagonist also completely blocked the synergistic increase in $[Ca^{2+}]_i$ observed when both glutamate and noradrenaline were coapplied. This result indicates that the noradrenaline enhanced increase in calcium require at least an initial activation of NMDA receptor channels. Further possible sources of calcium mobilization include facilitated NMDA receptor channels, voltage gated calcium channels, internal calcium stores or any combination of these potential routes. We also tested three major subtypes of adrenoceptors with respective antagonists, propranolol (β), prazosin (α_1) and rauwolfine (α_2). Since we were dealing with a mixed culture of cortical neurons, these antagonists showed varying effectiveness in blocking the synergistic enhancement induced by noradrenaline in different individual neurons. Analyses of data obtained thus far indicate that propranolol is capable of blocking the synergism more completely on more cells than rauwolfine. Prazosin showed relatively weak effects. This implies that both cAMP and PI turnover pathways may be involved in the synergistic interaction between these transmitters. This result is being further studied by manipulating intracellular cascades that may be involved.

THE μ OPIOID AGONIST DAMGO DIFFERENTIALLY MODULATES THE NMDA COMPONENT OF EPSPs IN NUCLEUS ACCUMBENS (NAcc) NEURONS VIA PRE- AND POSTSYNAPTIC MECHANISMS. G. Martin, Z. Nie and G.R. Siggins*. Dept. of Neuropharmacology, The Scripps Research Institute, La Jolla, CA 92037.

We previously showed that DAMGO decreases evoked EPSP amplitude in the NAcc slice (Yuan et al., Neurosci. Lett. 134: 223, 1992). However, the mechanism of this effect was unclear. In the present study, we investigated the action of DAMGO on pharmacologically-isolated NMDA components of evoked EPSPs. We recorded from a total of 44 NAcc cells in a slice preparation. In current-clamp, their mean resting membrane potential was -84 mV; mean input resistance was 43 M Ω and spike amplitude, 124 mV. In addition, these cells showed a strong inward rectification with a small sag in the hyperpolarized direction and a depolarizing ramp in response to positive currents. DAMGO 1 μ M did not alter membrane potentials or input resistance in any cell tested (n = 34). In the presence of CNQX (10 μ M) and bicuculline (15 μ M), EPSPs evoked by local stimulation displayed the characteristics of an NMDA component: 1) long duration; 2) increase in amplitude with membrane depolarization; 3) total block by the NMDA receptor antagonist d-APV (60 μ M; 9 of 9 cells). DAMGO 1 μ M significantly decreased NMDA-EPSP amplitude by up to 50% of control (ANOVA: p < 0.001; 12 of 12 cells), with reversal of this effect by the opiate antagonist naloxone (1 μ M; 9 of 9 cells). To assess a possible postsynaptic DAMGO action, we superfused the slices with TTX (1 μ M) and evoked NMDA currents by pressure application from pipettes. Under these conditions, DAMGO 1 μ M markedly enhanced (by 75%) the NMDA currents (4 of 5 cells). These results suggest that DAMGO modulation of the NMDA components of glutamatergic synaptic transmission is complex: DAMGO may decrease the NMDA-EPSP amplitude through a reduction of glutamate release, yet increase it via a direct postsynaptic action.

EFFECT OF NMDA RECEPTOR BLOCKADE ON REGIONAL DOPAMINERGIC ACTIVITY. Gina M. Fadavel, Vicki L. Taylor, Geoffrey Metcalf* and Christopher J. Schmidt. Marion Merrell Dow Research Institute, 2110 E. Galbraith Road, Cincinnati, OH 45215

A dopaminergic bias within the glutamate/dopamine (DA) balance of the basal ganglia is believed to contribute to the symptoms of schizophrenia. The psychotomimetic MK-801, a channel blocker at the NMDA-glutamate receptor complex, is used to model this imbalance by reducing glutamate activation of NMDA receptors. Although MK-801 can produce its behavioral effects in monoamine-depleted animals, this occurs at higher doses than are necessary to elicit behavior in intact animals. MK-801 is also reported to increase the firing rate and bursting pattern of midbrain DA neurons. These observations suggest that increases in DA activity as well as decreased glutamatergic activity may contribute to the behavioral effects of MK-801. To further explore this question, the effect of MK-801 on DA release was determined in several brain regions using microdialysis in awake, freely moving rats. High doses of MK-801 (2 mg/kg, s.c.) caused a rapid increase in extracellular concentrations of DA in both the medial prefrontal cortex (mPFC) and the nucleus accumbens (NAS). DA concentrations reached 360% of basal levels in the mPFC and increased to approximately 150% in the NAS. Transmitter levels remained elevated for 3 h. Concentrations of the DA metabolites DOPAC and HVA rose in delayed sequence. MK-801 also increased dopamine synthesis in both regions as assessed by DOPA accumulation following decarboxylase inhibition. In contrast to the results in the mPFC and NAS, striatal DA and its metabolites decreased following MK-801 administration. These observations are consistent with the hypothesis that alterations in DA activity contribute to the behavioral effects of MK-801. The results also suggest that the mesolimbic and mesostriatal DA systems differ significantly in their interaction with the NMDA-glutamate system.

LOCALIZATION OF MYOMODULIN-LIKE IMMUNOREACTIVITY IN THE LEECH CNS.

H. H. Keating and C. L. Sahley*. Dept. of Biological Sci., Purdue University, West Lafayette, IN 47907.

The distribution of myomodulin-like peptides in the leech CNS was determined using an antiserum raised against Aplysia myomodulin (Miller et al., 1991). Numerous immunoreactive neurons were found in the nervous system. Also, immunoreactive varicosities were found throughout the neuropil. Two types of immunoreactive fiber staining were observed in the connectives between ganglia and in the nerve roots, 1) fibers with smooth contours and 2) fibers with periodic swellings. Double-labeling experiments are in progress to identify the labeled neurons. Preliminary results suggest that myomodulin-like peptides are present in the Anterior pagodas, AE motoneurons and the Leydig cells; components of the shortening reflex which can be modified by learning. Kuhlman et al., (1985) have previously demonstrated FMRF-amide immunoreactivity in these cell types as well. Specific staining was abolished by preabsorption of antiserum with synthetic myomodulin but not with FMRF-amide. It is likely, therefore, that these cells contain multiple neuromodulatory peptides. HPLC elution profile data are consistent with the presence of myomodulin in the leech CNS.

HYPOTHYROIDISM IMPROVES THE STRESS RESPONSE AND MODIFIES ANXIETY BEHAVIOR IN RATS.

S. L. Abend¹, J. A. Lindwall², D. Bitran², J. A. King¹, L. Pellerin¹, C. Eccles², and E. Edwards². Dept. Psychiatry, Univ Massachusetts Med. Ctr., Worcester, MA, 01655, Dept. Psychology, College of the Holy Cross², Worcester, MA 01610, Dept. Pharmacology, Univ. Maryland¹, Baltimore, MD 21201

Learned Helplessness (LH), an animal model that determines the response of rats to footshock stress, has been used to screen pharmacologic agents for use in depression. In addition to tricyclic antidepressants, low dose T3 administration and GABA-mimetic agents have been useful in improving performance in this paradigm. Low doses of T3 may actually cause brain hypothyroidism by decreasing pituitary secretion of thyrotropin, thereby inhibiting endogenous thyroid hormone secretion. We tested this hypothesis by studying hypothyroid rats for LH. Hypothyroid rats had a 25% lower incidence of LH and a 20% increase in LH-resistant behavior compared to euthyroid controls ($p < 0.05$). There were no differences in activity level by open field testing between hypothyroid and euthyroid rats. Hypothyroid rats also displayed anxiolytic behavior relative to euthyroid rats in the elevated plus maze, a behavioral assessment of GABAergic activity, although on retesting 1 month later, hypothyroid LH rats displayed anxiogenic activity. Hypothyroid rats did not display differences in GABA_A receptor sensitivity compared to euthyroid controls, as assessed by GABA_A receptor-mediated chloride ion influx. Euthyroid LH-resistant rats did manifest an increase in GABA_A receptor sensitivity compared to euthyroid LH controls. We conclude from these studies that hypothyroidism decreases the incidence of LH behavior, and the antidepressant activity of T3 may actually be due to its induction of secondary brain hypothyroidism. This effect may be mediated in part by a hypothyroidism-induced enhancement of GABAergic transmission by a mechanism other than GABA_A receptor sensitivity.

DOES SEASONAL VARIATION AFFECT RESULTS OF THE MIRROR CHAMBER BEHAVIORAL ASSAY? S. J. Ciric and N. L. Katz*. Dept. Pharmaceuticals and Pharmacodynamics, U. Ill. at Chicago, Chicago, IL 60612.

We fashioned several mirrored chambers described by Toubas et al. (Pharmacol. Biochem. Behav. 35: 121, 1990). The mirrored chamber test is a behavioral assay based on an approach-avoidance response when a mirror is placed into a mouse's environment. The sight of an animal reflected in the mirror is a source of anxiety presumably preventing entry into the chamber. In the present studies, male Balb/cByJ mice were used. Their ages, at the onset of the studies, were 7-8 weeks. Each mouse was allowed to explore the chamber for 5 min. The time to first entry into the mirrored chamber (T), total time spent in the chamber (TT), and number of entries (NE) were quantitated. Control studies were run during the first 2 weeks of October (1993), first 2 weeks of December, first 2 weeks of February (1994), and last week of April. Latencies to entry were 182 (N=30), 102 (N=47), 101 (N=17), and 236 sec (N=10), respectively. In the winter months, results seemed heterogeneous and inconsistent, and base line (percent of animals entering the chamber) ranged from 50-75%. During this season, cholecystokinin tetrapeptide (CCK₄), in doses ranging from 3-30 µg/kg, produced a dose-dependent increase in T, and decreased both TT and NE. The CCK₄ antagonist PD135158, 1 mg/kg, reversed CCK₄-induced changes in T and TT. PD135158 alone was without effect. Results obtained in April were most similar to those reported by Toubas et al. (1990). Diazepam, 1 mg/kg, decreased T, and increased TT and NE. PD135158 had no effect.

ESTABLISHMENT OF MELATONIN DISCRIMINATION IN PIGEONS. J. A. Stanley* and A. A. Ortiz. CNS Psychobiological Disorders, Bristol-Myers Squibb Company, Wallingford CT 06492.

Melatonin (5-methoxy-N-acetyltryptamine) is a pineal neurohormone that controls circadian patterns of behavior (e.g., sleeping, eating, drinking, and reproduction) in many species by modulating the "biologic clock," a cluster of cells found in the suprachiasmatic nuclei (SCN). In order to permit exploration of the functional effects of melatonin, pigeons were trained to use the interoceptive cue produced by peripheral administration of this hormone as the discriminative stimulus for differential responding using a drug discrimination procedure.

Ten minutes before daily fifteen-minute sessions, White Carneaux pigeons were given melatonin (0.3 or 0.56 mg/kg, i.m.) or vehicle (0.5% DMSO in normal saline) and placed in a darkened, two-key operant chamber. Responding on the appropriate key was reinforced (FR-30); whereas, responding on the incorrect key had no consequence other than resetting the FR value.

Pigeons learn to discriminate a systemically administered dose of melatonin from its vehicle at doses that have no effect on response rate. When doses of melatonin from 0.01 and 3.0 mg/kg, i.m., are substituted for the training dose (0.3 or 0.56 mg/kg, i.m.), the drug-key is selected demonstrating complete stimulus generalization.

In rats melatonin discrimination has been demonstrated only at doses which are sedative and more than 100 times those used in circadian rhythm studies. Our results, demonstrating the exquisite sensitivity of the pigeon to melatonin, suggest the bird may be the subject of choice in discrimination studies investigating the effects of melatonin at doses comparable to those used in circadian rhythm studies.

641.2

EFFECTS OF THE CARBAMATE PESTICIDE CARBARYL ON THE REPEATED ACQUISITION OF RESPONSE SEQUENCES IN RATS. J. Cohn¹ and R.C. MacPhail². ¹Curriculum in Toxicology, UNC, Chapel Hill, NC; ²US EPA, Research Triangle Park, NC.

Carbaryl is a commonly used carbamate pesticide that inhibits acetylcholinesterase. Cholinergic neurotransmission is known to play an important role in cognitive function. This experiment was therefore undertaken to determine the effects of acute carbaryl administration on the repeated acquisition of response sequences in rats. Repeated acquisition is a method by which learning can be continuously assessed in single subjects. Adult male Long-Evans rats, maintained at 300 g, performed under a multiple schedule of RA and performance (P) in a standard operant chamber equipped with three response levers. The RA component required rats to learn a new 4-member sequence of responses during each experimental session (Center Right Left Right, RLCL, RCRL, etc.); the correct sequence of responses for the P component remained constant across sessions. Components alternated twice during a session. After baseline training, rats were given vehicle (5% Emulfor, 5% ethanol in saline), 3, 6.5, 7.9, 10 and 17.4 mg/kg carbaryl. Injections were given i.p. (1 ml/kg) 20-min pre-session, and no more than twice weekly. Significant decreases in both accuracy and response rate were produced by doses of 6.5 mg/kg and greater. Generally, results indicated that carbaryl's effects on RA were non-specific in that both the RA and P components were equally affected. Some rats, however, exhibited specific effects of carbaryl on RA. Microanalysis of response patterning indicated that errors consisted primarily of pseudorandom lever presses ("skipping" errors) rather than perseverative responses on single levers.

NCS-382 REVERSES HYPERTHERMIA, NOT HYPOTHERMIA, INDUCED BY GAMMA-HYDROXYBUTYRATE IN THE RAT. R. Godbout,¹ P.-P. Rompré,¹ M. Schmitt² and J.-J. Bourguignon.²

¹Dép. psychiatrie, U. de Montréal, Montréal (Québec) H4J 1C5; ²Labo. pharmacochim. molécul., CNRS 421, Strasbourg France

Gamma-hydroxybutyrate (GHB) is an endogenous fatty acid recognized for its sedative-hypnotic effect. Since thermoregulatory mechanisms are bound to be involved in this effect, we measured central temperature before and after administration of GHB at various doses and we tested the newly synthesized GHB receptor antagonist, NCS-382. Body temperature was monitored by mean of a rectal probe; baseline readings were first taken, then each 15 min for the 1st hour following an i.p. injection of saline or GHB, and each hour thereafter. When NCS-382 was used, it was co-administered with GHB, at the same dose. Low GHB doses (10 mg/kg) were associated with increased temperature (max = +0.67°C, 45 min post injection) whereas hypothermia was observed from 20 to 250 mg/kg (max at 250 mg/kg = -0.95°C, 30 min post injection). NCS-382 blocked the hyperthermic effect of GHB 10mg/kg but not the hypothermia induced by GHB 250mg/kg. These results suggest that the pyrogenic effect of GHB is mediated by high affinity specific GHB receptors and that GHB-induced hypothermia involves a more complex mechanism. RESTORATIVE EFFECTS OF FIBROBLAST GROWTH FACTOR, GIVEN TEN DAYS AFTER FIMBRIA-FORNIX SEVERANCE, ON SPATIAL MEMORY IMPAIRMENT IN RATS H.Amino*, N.Nishiyama and H.Saito. Department of Chemical Pharmacology, Faculty of Pharmaceutical Sciences, The University of Tokyo, Tokyo 113, Japan.

Fimbria-fornix (F-F) is a major cholinergic afferent from medial septum to hippocampus, which is suggested to play a critical role in spatial learning. We have previously reported that both acidic and basic fibroblast growth factor (a, bFGF) accelerated the acquisition of position discrimination reversal learning in Y-maze test in naive rats. In the present study, we studied the effects of FGFs on spatial memory deficits induced by F-F lesion. Rats with a normal spatial learning ability had been selected, based on the results of Y-maze test training. Guide cannulas were planted into bilateral cerebroventricle, and F-F was severed with a blade at the same time. From 10 days after the operation, spatial learning performances of the rats were observed in Y-maze test, and subsequently in water maze test. FGFs (100-400 ng/rat, i.c.v.) were daily injected 30 min prior to each learning session. F-F lesion induced severe and long-lasting spatial memory deficits in Y-maze test (correct response: intact 89.6 ± 8.2 %, lesioned 37.5 ± 8.5 %) and in water maze test (escape latency: intact 9.4 ± 1.5 sec, lesioned 69.5 ± 15.1 sec). Both aFGF and bFGF significantly ameliorated the spatial memory deficits induced by F-F lesion in dose dependent manners (correct response: 400 ng of aFGF 85.4 ± 6.0 %, 400 ng of bFGF 75.0 ± 6.9 % escape latency: 400 ng of aFGF 11.0 ± 1.2 sec, 400 ng of bFGF 12.8 ± 1.2 sec). Reduction of hippocampal choline acetyltransferase activity caused by F-F lesion was not affected by the injection of aFGF and bFGF. In conclusion, we suggest that delayed application of aFGF and bFGF improve the surgically induced spatial memory disorders without affecting the hippocampal cholinergic transmission. Further investigations would differentiate the long-term (neurotrophic) and short-term (neuromodulatory) actions of FGFs on learning and memory.

EFFECTS OF CHRONIC ddC ADMINISTRATION ON LOCOMOTOR ACTIVITY IN RATS. H.D. Davis¹, D.E. Morse¹ and N.E. Grunberg². ¹FDA, Antiviral Research Laboratory, Rockville, MD 20857. ²Uniformed Services University of the Health Sciences, Medical Psychology Department, Bethesda MD 20814. Dideoxycytidine (ddC) is a nucleoside analogue used in the treatment of HIV infection. Unfortunately, the long-term use of ddC has been associated with an apparent peripheral neuropathy and debilitating pain in a subset of HIV patients. Recently, we reported on the value of a behavioral paradigm in rats to study the neurotoxicity of the anti-HIV nucleosides. We found that locomotor activity was altered in a U-shaped dose-effect relationship following increasing doses of ddC (IG) to rats. The present experiment examined the effects of chronic ddC administration (PO, 0.1-10.0 mg/ml in the drinking water) on the locomotor activity of female Sprague-Dawley rats. Activity was monitored for one hour each day for eight consecutive days during a period of continuous drug administration. Body weight, food and water consumption were also monitored. Exposure to ddC at 3.0-10.0 mg/ml concentrations resulted in a significant decrement in locomotor activity beginning with day 5 of exposure. While water consumption was reduced somewhat among animals in the high drug concentration group, this occurred during days 2-3 of dosing and was not correlated with the observed locomotor decrement. Body weight, food and water consumption among all other dose groups was indistinguishable from that of the control group. Chronic dosing thus revealed a pattern of behavioral toxicity that an acute paradigm could not detect. Implications of these findings for the neurotoxicity testing of drugs used in AIDS therapy will be discussed.

EVALUATION OF DOSE-RELATED EFFECTS OF D-CYCLOSERINE IN UNMEDICATED OBSESSIVE COMPULSIVE DISORDER PATIENTS. Barr LC^{*}, Bennett A, D'Souza DC, Price LH, Krystal JH. Yale Univ Sch of Med, New Haven, CT 06519

Functional neuroimaging studies implicate orbital frontal cortex and caudate in the mediation of obsessive compulsive symptoms. As excitatory transmission within the frontal cortex and from frontal cortex to striatum is prominent, the effects of D-cycloserine, a partial agonist at the glycine site of the NMDA receptor, on obsessive compulsive symptoms was assessed. **Method:** 11 unmedicated Obsessive Compulsive Disorder (OCD) patients (mean \pm SD age = 39.6 \pm 11.2; 7 male, 5 female) received either a placebo, a 50 mg or 500 mg oral dose of D-cycloserine on three test days each separated by 7 days. A 15 point scale was used to assess obsessions and compulsions. Possible effects of D-cycloserine on frontal and memory function were assessed using the following: Hopkins Verbal Learning Test, Nonverbal Selective Reminding Test, Rey Taylor Complex Figure Test and a test of verbal fluency. As 50 mg D-cycloserine has been shown to increase cortisol in healthy subjects, cortisol was measured at baseline and following D-cycloserine. Data were analyzed using RM-ANOVA. **Results:** No dose or dose X time effects were identified for clinician or patient-rated obsessions and compulsions and no clinically apparent changes in symptom severity were observed. Neuropsychological testing also did not identify medication effects. Data comparing the hormonal response of these patients with healthy subjects will be presented. **Conclusions:** Putative facilitation of excitatory transmission produced by D-cycloserine may not markedly effect OC symptoms or neuropsychological deficits sometimes observed in these patients.

TYROSINE REVERSES COLD-STRESS INDUCED IMPAIRMENT OF DRL PERFORMANCE IN RATS. J.R. Thomas^{*}, D. Shurtleff, J. Schrot, and R. Moran. Naval Medical Research Institute, Bethesda, MD 20889-5607.

Acute exposure to cold stress has been reported to impair performance on a variety of tasks, including an increase in the speed with which behavioral and neural operations occur. Exposure to a temperature of 2°C increases rate of responding on a time-based differential-reinforcement-of-low-rate (DRL) reinforcement schedule, without affecting attentional, sensory, or motor aspects. Administration of the amino acid, L-tyrosine, has been shown to improve behavioral impairments induced by exposure to cold. The present study examined the effects of tyrosine in rats performing on a DRL schedule that were exposed to a temperature of 2°C for one hour. Consistent with previous research and relative to 22°C exposure sessions, during the 2°C exposure response rates on the DRL schedule increased markedly. Administration of tyrosine (50, 100, 200 mg/kg i.p.) returned DRL response rates during cold to within control values. Pretreatment with valine (100 mg/kg), an amino acid that competes with the transport system for tyrosine, prevented the DRL response rate-reversing effects of tyrosine during cold exposures, suggesting a rather direct effect of tyrosine on cold-stress impairment of DRL performance.

THE ROLE OF THE ADENOSINE SYSTEM IN MITIGATING THE LOCOMOTOR DEFICITS PRODUCED BY THE RADIOPROTECTOR WR-151327. J.B. Hogan, C.A. Castro, K.A. Benson, T.W. Shehata, J.F. Weiss, H.M. Jacobs^{*}, and M.R. Landauer. Department of Behavioral Sciences, Armed Forces Radiobiology Research Inst., Bethesda, MD 20889.

The methylxanthine caffeine has been shown to mitigate the locomotor deficit that follows administration of aminothiol radioprotective compounds. A likely mechanism of action for this effect is caffeine's antagonism of the adenosine (A) system. This study compared the effects of nonselective adenosine antagonists (theophylline and caffeine) with those of selective A₁ (8-Cyclopentyl-1,3-dimethylxanthine, CPT) and A₂ (3,7-Dimethyl-1-propylargylxanthine, DMPX) receptor antagonists in attenuating locomotor decrements induced by WR-151327 [S-3-(3-methylamino-propyl-amino)-propylphosphorothioic acid]. Locomotor activity (total distance travelled) was examined in male CD2F1 mice in an automated activity monitor for 12 hr postinjection. The effects of WR-151327 alone and in combination with adenosine antagonists on locomotor activity were examined. WR-151327 (200 mg/kg, i.p.) alone significantly reduced activity from 30 min to 3 hr postinjection. The adenosine antagonists (20 mg/kg, i.p.) were each administered 30 min prior to WR-151327 (200 mg/kg, i.p.) at which time locomotor activity monitoring began. Compared with vehicle controls, theophylline alone significantly increased activity for 1 hr, and caffeine alone for 2 hr. CPT alone increased activity for 0.5 hr, and DMPX alone increased activity for 2 hr. When combined with WR-151327, theophylline reversed the WR-151327-induced motor deficit for 1 hr, and caffeine for 2 hr. DMPX reversed the deficit for 1 hr, while CPT failed to mitigate the deficit. These results provide evidence that the A₂ adenosine receptor is important in mitigating WR-151327-induced locomotor activity decrements.

DISULFIRAM CAUSES SUSTAINED BEHAVIORAL AND BIOCHEMICAL EFFECTS IN RATS. M.A. Rahman, N.E. Grunberg^{*} and G.P. Mueller. Neuroscience Program, Uniformed Services University of the Health Sciences, Bethesda, MD 20814-4799.

Disulfiram is the most commonly used pharmacologic treatment for alcoholism. Despite its established use, the research literature is sparse regarding the central neurochemical or behavioral toxicology effects of this important medication. We recently observed (Mueller, Husten, Mains, & Elipper, 1994) that disulfiram causes a marked inhibition in the biosynthesis of α -amidated peptides which persists for weeks after the cessation of treatment. More than half of the peptides used in intercellular communication are α -amidated and in nearly all cases this modification is required for receptor binding and biologic activity. The present experiment was designed to evaluate the effects of disulfiram administration on behavioral measures of nociception (hot plate and tail flick), peripheral muscular performance (grip strength), motivated performance, balance, and coordination (rotorod); body weight; and peptidylglycine α -hydroxylating monooxygenase (PHM) activity in the hypothalamus, neuro-intermediate lobe of the pituitary (NIL), adenohypophysis, and atrium; and α -MSH levels in the neurohypophysis. Adult, male, Sprague-Dawley rats were treated daily for one week with disulfiram (0, 50, or 150 mg/kg, s.c.) and were evaluated for two weeks after cessation of treatment. Disulfiram significantly increased hot plate response latencies, decreased grip strength, decreased rotorod performance, and decreased body weight in a dose-response manner. These effects persisted through the two week post-treatment period and paralleled the time course of the inhibition of PHM previously reported. In addition, disulfiram significantly altered PHM activity in tissue samples from the NIL and atrium, and significantly decreased amounts of α -MSH. These findings indicate that disulfiram may have several untoward effects that are relevant to therapeutic use and warrant further investigation.

A TEST OF THE CLASSICAL CONDITIONING MODEL OF THE PLACEBO EFFECT WITH CARISOPRODOL AS UNCONDITIONED STIMULUS. M.A. Flaten, T. Simonsen, K.K. Waterloo and H. Olsen, Dept. Psychology, Univ. Tromsø, N-9037 Tromsø, Norway.

Two groups (N=10) received pairings of a distinct environment, the laboratory, and administrations of 700 mg of the muscle relaxant carisoprodol (Carisoprodol group), or pairings of the same environment with administrations of an inactive agent (Control group) for a total of three sessions, each spaced one week apart. The laboratory was hypothesized to constitute a conditioned stimulus (CS) for the drug unconditioned stimulus (US) in the Carisoprodol group. In the fourth session the Carisoprodol group received the inactive agent in the laboratory, and the Control group received carisoprodol in the laboratory. Dependent variables were blink reflexes and carisoprodol serum concentration. Results showed facilitated blink reflex amplitudes in the Carisoprodol group when an inactive agent was administered in the laboratory, which is opposite to the effects of carisoprodol. This indicates that a conditioned drug antagonistic response was elicited by the CS in this group. Moreover, blink reflex amplitudes were inhibited in the Control group when it received carisoprodol, indicating that an antagonistic response was not elicited in this group.

DISCRIMINATIVE-STIMULUS EFFECTS OF THE POTASSIUM CHANNEL BLOCKER 4-AMINOPYRIDINE IN RATS. R. Brandsgaard*, S. Rosenzweig-Lipson, J. Willets and J. E. Barrett. American Cyanamid, Lederle Laboratories, CNS-Biology, Pearl River, NY 10965.

In the present study, rats (N=12) were trained to discriminate the voltage-gated potassium channel blocker 4-aminopyridine (4-AP) (1.0 mg/kg, n=9 or 1.7 mg/kg, n=3, s.c., 30 minute pretreatment) from saline in a two-lever drug discrimination procedure. Rats responded differentially on the left and right levers under a 30 response fixed-ratio schedule of food presentation depending on whether 4-AP or saline was administered. 4-AP served as a discriminative-stimulus in all the rats, showing dose-dependent (0.1-1.7 mg/kg) increases in drug lever responding up to the training dose. Administration of saline resulted in <1% drug lever responding. There was no effect on response rate for the rats with a training dose of 1.0 mg/kg, and a moderate dose-related decrease in response rate for rats with a training dose of 1.7 mg/kg. Once the discrimination was established, the discriminative-stimulus effects of 4-AP were compared to several known potassium channel blockers, a calcium channel opener and an acetylcholinesterase inhibitor. The structurally related potassium channel blocker, 3,4-diaminopyridine (0.3 - 17.8 mg/kg) fully substituted at doses which moderately decreased response rate in 4 out of 4 rats trained at 1.0 mg/kg. 3,4-diaminopyridine did not substitute in 2 rats that were trained at 1.7 mg/kg. Other potassium channel blockers, including quinine (30.0 - 100.0 mg/kg) and amodiaquin (30.0 - 56.0 mg/kg), a Ca²⁺ channel opener, Bay K 8644 (0.3 - 1.0 mg/kg), and an acetylcholinesterase inhibitor, 9-amino-1,2,3,4-tetrahydroacridine hydrochloride (THA) (1.0 - 5.6 mg/kg), generally did not substitute up to doses that decreased response rate. The present results demonstrate that 4-AP can serve as a discriminative-stimulus in rats. In view of the substitution of 3,4-diaminopyridine, but not quinine or amodiaquin, the present results suggest that the discriminative-stimulus effects of 4-AP are mediated by a subset of voltage-gated potassium channels.

NEUROPEPTIDE-Y ALTERS THE ACQUISITION OF RESPONSE SEQUENCES IN RATS. J. Schrot* and J.R. Thomas. Naval Medical Research Institute, Bethesda, MD 20889-5607.

Administration of neuropeptide-Y (NPY) has been shown to both improve and impair working memory as measured with a delayed matching-to-sample (DMTS) procedure. The present study used a repeated acquisition (RA) procedure to investigate the effect of NPY (2.0 to 34.0 ug/kg, icv) on the acquisition of three-member response sequences in rats. Each incorrect response in this procedure results in a brief timeout from reinforcement. Sessions were divided into a learning and a performance phase by imposing a five-minute delay at the mid point. A biphasic response pattern of acquisition, followed by performance, was observed during control sessions. The average number of error responses was 296 during the 1st half and 155 during the 2nd half of each session. Administration of NPY slightly improved performance at a dose of 8.6 ug/kg and markedly disrupted performance at a dose of 34.0 ug/kg. The 1st half vs 2nd half incorrect responses at the 8.6 ug/kg dose were 208 and 116, while the same measures with the 34.0 ug/kg dose were 502 and 214, respectively. A dose of 2.0 ug/kg had no effect on performance. The RA procedure contains elements of both working and reference memory. Working memory is requisite for acquiring the novel sequence of lever presses each day, while reference memory is invoked by the timeout stimulus. NPY administration altered both working and reference memory aspects of the procedure. These results are consistent with and extend the finding that NPY altered working memory in a DMTS procedure.

641.14

HORSE SERUM BUTYRYLCHOLINESTERASE PROTECTS AGAINST MEPQ-INDUCED RESPONSE SUPPRESSION IN RATS. R.F. Genovese*, R. Larrison and B.P. Doctor. Divisions of Neuropsychiatry and Biochemistry, Walter Reed Army Institute of Research, Washington, DC 20307-5100.

New therapies against organophosphorus (OP) toxicity have focussed on the administration of enzyme "scavengers", in order to prevent deleterious effects by neutralizing the OP before target areas are affected. We examined the ability of horse serum butyrylcholinesterase (HS-BChE) to attenuate the effects of the OP, MEPQ, in rats trained to lever press under a variable interval 56" schedule of food reinforcement. Under baseline conditions, the schedule produced constant and relatively fast rates of responding throughout the 60 min sessions. MEPQ (32ug/kg, IP) (n=5) produced complete or nearly complete response suppression in rats pretreated with vehicle. Rats treated with 7500 U HS-BChE (IP) (n=5) approximately 18 h before MEPQ injection, however, responded at nearly 70% of control rates. Blood BChE activity was elevated in rats receiving HS-BChE (34-68 U/ml) as compared to rats receiving vehicle (0.8-1.6 U/ml), but decreased when measured 1 h following MEPQ administration.

These results demonstrate that administration of HS-BChE can attenuate the toxic effects of MEPQ, and merits consideration as a prophylactic therapy against OP exposure. These results also confirm and extend previous reports demonstrating that protection against OP toxicity can be conferred by a number of cholinesterases.

OSMOTIC REGULATION

642.1

PERSISTENT ELEVATION OF VASOPRESSIN MRNA AFTER SALT-LOADING. M.D. Fitzsimmons*, M.M. Roberts, A.G. Robinson. Department of Endocrinology, University of Pittsburgh, PA 15261

Based on computer modeling, we have suggested that pituitary vasopressin (AVP) levels depleted after chronic salt-loading recover to age-matched control simply by translating mRNA that accumulates during the period of salt-loading (AmJPhysiol 262: R1121, Endocrinology 134:1874). The amount of mRNA needed for such recovery depends on the assumptions in the model, but the smallest reasonable estimate would require a 4-fold increase over baseline. Experimental measurements in our lab with RNase protection assay of whole hypothalamus show that salt-loading increases AVP mRNA expression by only 1.5-2.5 times, a range consistent with other recent reports. These results might be interpreted to indicate that translational regulation plays a role in the regeneration of posterior pituitary vasopressin levels. Alternatively, mRNA may remain elevated after the stimulus is removed. Evidence from Zingg et al (JBiolChem 261:12956) and Arnauld et al (NeurosciLetters 149:177) supports the latter. We tested the impact of stimulus duration on vasopressin mRNA levels after salt-loading. Both 3 days and 5 days of salt-loading result in a significant increase in mRNA versus control (1.6-fold and 2.0-fold respectively, p<0.001), with 5 days being significantly greater (p<0.01). AVP mRNA showed no detectable decrease after two days of recovery in both the 3 day and the 5 day groups; the 3 day group remains elevated even 4 days after recovery (p<0.01). Plasma sodium levels in the salt-loaded groups increased significantly (p<0.001), but were not different from baseline in the recovered groups. These results demonstrate that the length of salt-loading affects the magnitude of AVP mRNA increases and that the post-stimulus elevation of mRNA is independent of stimulus duration. Whether the persistence of AVP mRNA is due to "momentum" in the transcriptional regulation of the gene or to increased mRNA stability will be determined with intronic *in situ* hybridization. In either case, the unexpectedly prolonged mRNA elevation probably contributes to the recovery of pituitary vasopressin content to age-matched levels after salt-loading.

642.2

OXYTOCIN (OT) AND VASOPRESSIN (AVP) EXPRESSION IN THE HYPOTHALAMUS OF THE HYPOTHYROID OSMOTICALLY-STIMULATED RAT. J.A. Amico, A. Thomas, M.M. Roberts*. Dept. of Med., Univ. of Pittsburgh, Sch. of Med. and Oakland VA Med. Ctr., Pittsburgh, PA 15261.

Sustained hyperosmolality enhances the abundance of OT and AVP mRNAs in the rat hypothalamus. Gonadal steroids modify this response. Gonadectomy prevents, and gonadal steroids restore, OT and AVP expression to osmotic challenge. The OT gene is influenced by other hormones, including thyroid hormone (T4). We questioned whether T4 deficiency would also alter OT and AVP mRNA abundance in the paraventricular nucleus (PVN) of the osmotically-challenged rat. Male Sprague-Dawley rats (7 wks of age) were sham thyroidectomized (sham TX) or TX, implanted 3 wks later with empty (TX+sham) or T4-filled (TX+T4) capsules, randomized to 2% NaCl solution or tap H₂O for 5-10 days and sacrificed at the end of the NaCl challenge. Serum T4 levels were significantly lower in the TX vs. sham TX and TX+T4 groups (P<0.001). All NaCl groups developed hypernatremia and depleted pituitary stores of AVP. Northern blot hybridization showed that salt loading increased PVN OT and AVP mRNAs in all groups compared to their respective tap H₂O cohorts. In contrast to the effect of gonadectomy, hypothyroidism does not alter osmotically stimulated-accumulation of OT and AVP mRNAs in the rat PVN.

642.3

BC1 RNA IN THE RAT POSTERIOR PITUITARY: AXONAL LOCALIZATION AND REGULATION UPON DEHYDRATION AND REHYDRATION. A. Trembleau* and F. E. Bloom. Department of Neuropharmacology, The Scripps Research Institute, La Jolla, CA 92037.

Brain cytoplasmic 1 (BC1) RNA, a small non-translated RNA-polymerase III transcript, has recently been detected in the posterior pituitary (PP) using a low resolution radioactive *in situ* hybridization (ISH) approach, and it has been hypothesized that this RNA might be axonally compartmentalized (Tiedge et al., J. Neurosci., 13:4214-4219, 1993). In the present study, we aimed to determine whether BC1 was truly located within axons, rather than in the glial cells of the PP, and further to analyse the possible regulation of this RNA upon dehydration (chronic salt-loading, providing 2% of NaCl as exclusive source of water for 3, 5 and 7 days) and rehydration (return to regular water beginning after day 7 of salt-loading, for 1, 2, 3, 4 and 7 days). Using a Northern blot assay, we were able to detect BC1 RNA in both the anterior and neurointermediate lobes of the pituitary. Non-radioactive ISH of BC1 RNA performed on PP at both the light and electron microscopic levels revealed that BC1 RNA was axonally compartmentalized. Using a semi-quantitative ISH approach, we have measured and compared the changes in BC1 RNA and vasopressin (AVP) mRNA during dehydration and rehydration. During dehydration, BC1 RNA was significantly increased, but it already reached a maximum at day 3 of salt-loading, while AVP mRNA was more progressively increased during the full period of salt-loading, peaking at day 7. The increase in BC1 RNA labeling (2.5-fold) was however modest compared to the increase in AVP mRNA labeling (around 11-fold). Upon the rehydration, the BC1 RNA content in the PP was reversed to control value as early as 1 day after the onset of rehydration, while AVP mRNA slowly decreased to reach the control value at day 7. In conclusion, like AVP mRNA, BC1 RNA is transported in axons of the hypothalamo-neurohypophyseal system, and its axonal transport is similarly regulated. Therefore, we propose that BC1 RNA might be involved in either the axonal targeting and/or transport of AVP or other axonal mRNAs.

Testosterone (T) Enhances Vasopressin Messenger Ribonucleic Acid (AVP mRNA) Abundance in the Hypothalamus of Osmotically-Stimulated Female Rats. J.A. O'Keefe*, N.B. Kim, J.A. Amico. Dept. of Medicine, University of Pittsburgh School of Medicine and VA Medical Center, Pittsburgh, PA 15261

Gonadectomy (gdx) prevents enhanced accumulation of AVP mRNA in the hypothalamic supraoptic nucleus (SON) of osmotically-challenged male and female rats and T and dihydrotestosterone (DHT) restore this response in the male rat (Soc N.S. Abs. 530.2:1280, 1993). We questioned whether AVP neurons in the SON of osmotically-stimulated rats display a sexually dimorphic response to gonadal steroid replacement. We examined the effects of various gonadal steroid replacement regimens upon AVP mRNA accumulation in the SON of osmotically-stimulated female rats. Female rats were gdx or sham gdx (intact) and implanted with sham, T or estradiol(E₂) capsules and randomized one week later to 2% NaCl solution or tap H₂O x 5 days. NaCl groups lost weight, developed hypernatremia and depleted their pituitary stores of AVP compared to tap H₂O groups (p<.05, Fisher's PLSD). Gdx-T and gdx-E₂ treated animals had mean T and E₂ concentrations of 1.5 ng/ml and 60 pg/ml, respectively. Intact and gdx-T-replaced rats, but not gdx or gdx-E₂ rats, receiving 2% NaCl increased hypothalamic AVP mRNA accumulation compared to respective tap H₂O controls (p<.05, Scheffe F-test). The data suggest that similar to male rats, T, but not E₂, modulates AVP mRNA accumulation in the SON of osmotically-challenged female rats.

642.7

DIFFERENTIAL DISPLAY PCR TO IDENTIFY REGIONAL SPECIFIC GENES IN RAT HYPOTHALAMUS. X. WANG* and W. S. YOUNG, III. Lab. Cell Biology, NIMH, NIH, Bethesda, MD 20892

Hyperosmolality induced by drinking 2% saline has long been known to induce expression of many genes in the supraoptic (SON) and paraventricular (PVN) nuclei of the hypothalamus. We used a PCR technique ("differential display") to screen differentially expressed genes there. The mRNAs isolated from various brain regions from animals after drinking 2% saline or water were reverse transcribed using a TTTTITTTTITTTG (T12GC) primer. The PCR products amplified by pairing the T12GC primer with several 10-base primers were displayed on a 6% polyacrylamide gel. About 50 distinct bands ranging from 100-400bp were seen for each pair of primers. This technique provided a sensitive way to detect differentially expressed genes, and both up- or down-regulated genes could be compared side-by-side on the gel. Several clones that appeared to be preferentially expressed in SON/PVN were isolated. The regional specific expressions were examined by hybridization histochemistry using ³⁵S-UTP labeled riboprobes. Differential display still suffers from a lack of specificity that we are still addressing. However, one of the clones was highly expressed in the SON and PVN and was used to screen a rat hypothalamic library. A cDNA of 2.1 kb was sequenced and analyzed.

642.4

DOES GLUTAMATE REGULATE VASOPRESSIN CONTENT IN HYPOTHALAMIC NEUROENDOCRINE CELLS? R.B. Meeker, R.S. Greenwood*, J. Stewart, Y.-H. Shih and J.N. Hayward. Dept. Neurology, University of North Carolina, Chapel Hill, NC 27599.

Although many lines of data indicate that glutamate receptors play a prominent role in the excitatory control of vasopressin neuroendocrine cells, little is known about how these excitatory events might translate into control of vasopressin synthesis. To evaluate the effects of glutamate receptor activation on vasopressin regulation, we measured VP content and VP mRNA in cultured neuroendocrine cells stimulated *in vitro* with glutamate, AMPA, kainate or NMDA. VP content was measured by radioimmunoassay and mRNA levels by agarose gel electrophoresis of a 179bp or 437bp PCR product spanning Exon B and Exon C (179bp) or Exon A through Exon C (437bp) of the vasopressin gene. Glutamate stimulation resulted in a small decrease in cellular VP content and a corresponding small suppression of VP mRNA levels. AMPA stimulation gave results similar to glutamate. NMDA stimulation resulted in less VP mRNA than controls or glutamate-stimulated cultures while kainate caused an almost complete loss of detectable VP mRNA. Thus, each subtype of ionotropic glutamate receptor appears to be coupled to a mechanism which down regulates VP mRNA levels and VP production. These changes may reflect a greater turnover of VP and VP mRNA in response to increased release but also indicate that excitatory drive alone may not be sufficient to support the increased mRNA levels observed with physiological stimuli. Thus, independent, parallel mechanisms are likely to be present to insure the activation of new synthesis in response to VP secretion. Supported by NIH Grants NS30923 and NS13411.

642.6

DISTRIBUTION OF ARGININE-VASOTOCIN (AVT) mRNA AND AVT-CONTAINING NEURONS IN THE BRAIN OF JAPANESE QUAIL. N. Aste*, E. Mühlbauer*, G.C. Panzica*, and R. Grossmann*. *Dept Human. Anatomy & Physiology, Univ. of Torino, I-10126 Torino, Italy and *Inst. for Small Animal Res., 3100 Celle, Germany.

The distribution of AVT containing neurons in quail brain has been studied in detail by immunocytochemistry (ICC). However no data are available for this species on the gene level. Up to now the chicken represents the only avian species in which chicken AVT gene expression has been investigated by specific cDNA probes. Thus we have used a gene probe directed to the 5' part of the AVT mRNA in order to detect the distribution of AVT expressing neurons in chicken and quail brain. Northern and Southern analysis demonstrated the specificity of this probe for quail AVT mRNA. 20µm thick cryostat sections from chicken and quail brain were collected on different slides to obtain adjacent slices. Consecutive series were fixed by 4% paraformaldehyde and processed for *in situ* hybridization (IH) and ICC respectively. The results indicate a common pattern in the distribution of AVT neurons containing mRNA and the peptide. In particular a wide population of perikarya was observed close to the pial surface of the preoptic region (lateral or supraoptic division), in the periventricular hypothalamic region (paraventricular nucleus) and scattered along the lateral forebrain bundle. Few neurons were observed by IH and ICC in extrahypothalamic areas. Quail and chicken AVT mRNA expressing neurons showed a common pattern of distribution, confirming the suitability of the probe. Considerably more AVT expressing neurons were detected in the hypothalamus of the chicken if compared to the quail. Furthermore the hybridization signal was more intense in the brain of chicken than in quail. In conclusion our studies show that 1) the probe we used is suitable to investigate AVT gene expression in quail, 2) the localization of AVT neurons is comparable between chicken and quail, 3) the basal activity of the AVT system in chicken is higher than in quail.

AP-1 DNA BINDING ACTIVITY INDUCED BY HYPEROSMOLALITY IN THE RAT HYPOTHALAMIC SUPRAOPTIC AND PARAVENTRICULAR NUCLEI. Z. Ying*, D. Reisman, and J. Buggy. Depts. of Physiology and Biological Science, University of South Carolina, Columbia, SC 29208

The immediate early gene (IEG) c-fos is induced after hyperosmotic stimulation in the paraventricular (PVN) and supraoptic (SON) hypothalamic magnocellular nuclei. AP-1 DNA binding activity was examined in these brain regions since Fos acts as a transcription factor in other systems by binding to the AP-1 site on DNA to influence gene transcription. Rats were given hypertonic saline injection (i.p.) and nuclear proteins were extracted from PVN and SON tissue punches 2 hrs later to assess AP-1 binding activity using an electrophoretic mobility-shift assay and a labeled oligonucleotide containing the AP-1 consensus sequence. Hyperosmolality induced AP-1 DNA binding in both PVN and SON; this binding was competitively displaced by excess unlabeled AP-1. The binding of proteins to the AP-1 element was shown to be specific in gel shift assays utilizing competitor DNAs such as SP-1. Thus, AP-1 binding activity in nuclear extracts from the SON and PVN was induced after hyperosmolality suggesting that dehydration-induced IEG expression results in protein products that may function in the regulation of target gene expression.

EVIDENCE FOR A FUNCTIONAL PROJECTION TO THE LATERAL HYPOTHALAMUS FROM THE MEDIAN PREOPTIC NUCLEUS AND SUBFORNICAL ORGAN IN THE RAT. **A.B. Kelly*** & **A.G. Watts**. NIBS Program and Department of Biological Sciences, USC, Los Angeles, CA 90089-2520.

We have previously reported increased levels of CRH mRNA in the lateral hypothalamic area (LHA) in response to cellular dehydration caused by increased plasma osmolality. Here, we have combined tract-tracing techniques with *in situ* hybridization in an attempt to identify those neurons responsible for this response. Following iontophoresis of fluorogold (FG) into the LHA we identified retrogradely labeled soma in a number of cell groups, including the subfornical organ (SFO), median preoptic nucleus (MePO), bed nucleus of the stria terminalis, preoptic area, and other forebrain regions. We then combined FG retrograde tracing from the LHA with *c-fos* *in situ* hybridization in male rats that had been given intraperitoneal injections of 1.5M saline 30 minutes before anesthesia and perfusion; these injections rapidly increase plasma osmolality, and increase *c-fos* mRNA accumulation in the MePO & SFO. In the MePO and SFO we found a number of FG-labeled cells which also contained *c-fos* mRNA, in addition to singly-labeled cells of each type.

In a second study, anesthetized male rats were given coronal unilateral knife cut lesions at the level of the suprachiasmatic nucleus, separating the LHA from more rostral inputs, including the MePO & SFO. Two weeks after surgery rats were salt-loaded for 5 days to induce cellular dehydration, then anesthetized, perfused, and processed for CRH mRNA *in situ* hybridization. Frontal deafferentation significantly attenuated the CRH mRNA response to cellular dehydration in the ipsilateral LHA.

Taken together, these studies show that cells in the MePO and SFO send direct projections to the LHA, and that a subset of these cells are osmosensitive. This input may be implemental in the LHA response to cellular dehydration. (Supported by NS 29728).

FOS AND JUN EXPRESSION IN RAT SUPRAOPTIC NUCLEUS [SON] NEURONS AFTER ACUTE vs. REPEATED OSMOTIC STIMULATION. **K. Wang and J.T. McCabe***. Anatomy & Cell Biology, Uniformed Services University of the Health Sciences, Bethesda, MD 20814-4799

Fos and Jun, protein products of the immediate early genes *c-fos* and *c-jun*, form a heterodimeric complex that affects the transcription of genes containing AP-1 and CRE DNA-binding sites. Using a double-label immunofluorescence method (CELL & TISSUE RESEARCH, 1994, 276:1-6), we find that intraperitoneal injection of hypertonic saline results in the appearance Fos and Jun in the nuclei of SON neurons. Cell counts of immunostained sections demonstrate the co-existent appearance of Fos and Jun occurred within 30 min (20%), peaked at 90-120 min (80%) and gradually disappeared by 4 hr (13%) after injection. At 4 hr post-saline injection, 5 rats each received a second injection of normal or hypertonic saline. A second injection of normal saline resulted in no Fos/Jun immunostaining 90 min later, while hypertonic saline induced Fos/Jun staining in only 17% of SON neurons. Of the remaining SON cells, 23% had staining to Fos alone and 4% of the cells stained for Jun. These results indicate SON neurons, after a second hypertonic saline injection, exhibit decreased *colocalized* Fos/Jun immunostaining, dramatically decreased Jun expression, and substantial, but attenuated, immunostaining for Fos. Supported by grants NIH NS25913 and USUHS R070AL to JTM.

VENTRAL FOREBRAIN RELAYS SALT INPUT FROM GUT TO VASOPRESSIN NEURONS. **Y. Shan, M. King and A.J. Baertschi***. Physiology Dept., Univ. of Virginia, Charlottesville, VA 22908, and Stetson College, FLA.

Gastric hypertonic saline infusions (600 mOsm/kg, 2.5ml) elicit vasopressin (AVP) release in conscious rats via noradrenergic pathways ascending from A1/A2 (Brain Res. 580:81-91, 1992). Microinjections of 6-OHDA (4µg/400nl) into magnocellular hypothalamic nuclei, caudal MPA or MnPO does not affect this AVP response, but 6-OHDA lesion of the ventral vertical limb of the diagonal band of Broca (DB) reduces it by 60.9% ($p < 0.05$; total $n=21$). The 6-OHDA lesions were then applied in 20 rats at various ventral sites from anterior 8.5 to 11 mm/ear bar, and characterized following the AVP study by immunocytochemistry for tyrosine hydroxylase (TH) and DBH. Partial or total depletion of TH/DBH from OVLT, MnPO, caudal DB, BNST or periventricular areas does not affect mean Δ AVP (over 30 min) = 5.63 ± 0.40 pg/ml, whereas depletion extending to anterior 11 mm reduces mean Δ AVP to 2.02 ± 0.45 pg/ml ($p < 0.01$). Electrolytic lesions in ventral forebrain from anterior 9.5-11 mm (± 0.5 mm/midline) also strongly reduce the AVP response. These results suggest that salt signaling by the gut is mediated by noradrenergic projections ascending probably via MFB to ventral forebrain, and via non-catecholaminergic fibres descending to the vasopressinergic nuclei (support: NIH R01 NS27644).

SEPTAL VASOPRESSIN AND OSMOTIC REGULATION

L. Zhou*, C. Hopkins*, G. J. De Vries. Dept. of Psychology; Prog. in Neurosci. & Behav.; Univ. of Massachusetts, Amherst, MA. 01003; ψ , Dept. of Psychology; Smith College, Northampton, MA 01007

Septal areas have been found to play an important role in the regulation of water intake and vasopressin (AVP) neurosecretion. Several studies have suggested that the AVP innervation of the septum may play a role in this regulation. In dogs, intraventricular injections of AVP lowered the hyperosmotic thirst threshold whereas injections of AVP antagonist raised it. In rats, hyperosmotic and hypovolemic stimuli decreased AVP content in the lateral septum, and increased AVP release from this area. AVP-immunoreactive fibers in the lateral septum (LS) arise from the bed nucleus of the stria terminalis and medial amygdaloid nucleus. AVP expression in these nuclei depends on the presence of gonadal steroids. If the AVP innervation of the lateral septum is indeed involved in water intake, one would predict that this function is influenced by gonadal steroids. Here we showed that this is the case. We found that when challenged with the same amount of hypertonic saline, injected intraperitoneally, castrated male rats drank less than intact rats and castrated rats treated with testosterone did. AVP injections into the lateral septum of castrated rats partly restored the amount of water intake. AVP injections into the lateral septum of intact rats increased, and V_{1a} antagonist injections decreased, water intake in response to hypertonic saline. We also found that hypertonic saline injections increased *c-fos* and *egr-1* expression in lateral septum neurons as well as in neurosecretory AVP neurons in the paraventricular and supraoptic nucleus. This increase was more pronounced in intact than in castrated rats suggesting that the septum may also mediate steroid effects on AVP neurosecretion.

ADAPTATION OF THE BRAIN TO HYPONATREMIA IN TWO DIFFERENT SPECIES: EFFECTS OF GENDER. **Z. Vexler, T. Roberts, N. Derugin, J. Kucharczyk, A. Arleff***. Dept. of Neuroradiology and Medicine, UCSF & VAMC, San Francisco, CA 94121

This study was to evaluate adaptation of the brain to hyponatremia as a function of gender. Brain adaptation to vasopressin (AVP)-induced hyponatremia was studied in adult male and female cats and rabbits during 3 hours or 4 days of hyponatremia, which was induced by subcutaneous AVP and 140 mM glucose/H₂O. Changes in cerebral perfusion were evaluated using contrast-enhanced high speed echo-planar MRI, using bolus IV administration of a magnetic susceptibility contrast agent (DyDTPA-BMA). An Index of cerebral perfusion (CPI) was obtained as a reciprocal of the width of the contrast transit curve. Water, sodium and potassium content were assessed in brain gray matter of both cats and rabbits. Acute hyponatremia (2 - 4.5 hrs; serum sodium fell from 155 ± 3 to 127 ± 3 mmol/L) resulted in a significant prolongation of contrast transit time through the brains of both male and female cats: CPI decreased from 0.28 ± 0.02 sec⁻¹ to 0.14 ± 0.02 sec⁻¹ in males and 0.16 ± 0.02 sec⁻¹ in females. Adaptation was gender dependent: brain (gray matter) water content increased from 391 ± 8 ml/100 gm dry wt to 434 ± 5 in females and 415 ± 3 in males ($p < 0.001$ vs control), and hyponatremic females greater than males ($p < 0.02$). A gender dependent decrease of brain sodium was found, from 271 ± 13 mmol/kg dry tissue to 222 ± 2 in males ($p < 0.005$) and to 233 ± 5 in females ($p < 0.035$). In rabbits, serum sodium was decreased from 142 ± 1 to 122 ± 2 mmol/L over 4 days. Brain water increased from 426 ± 13 ml/100 gm dry wt to 498 ± 27 in females ($p < 0.01$) and 432 ± 27 in males ($p = ns$). Brain sodium fell from 318 ± 6 to 294 ± 8 mmol/kg dry wt in males ($p < 0.01$) but was unaffected in females. Brain potassium did not change. Brain swelling, however, was significantly less in hyponatremic males than in females in both species. Better adaptation of brain to hyponatremia in males of 2 species, and decreased cerebral perfusion, appears to be related to interaction between AVP and sex steroid hormones.

OSMOTIC ACTIVATION OF NEURONS DISSOCIATED FROM THE OVLT AND MEDIAN PREOPTIC NUCLEUS (MnPO). **D. Richard* and C. W. Bourque**. Montreal General Hospital and McGill University, Montreal, P.Q. Canada.

Neurons within the OVLT and MnPO have been implicated to play a key role in osmoregulation. To determine whether they are intrinsically sensitive to hypertonicity, patch clamp recordings were obtained from cells acutely dissociated from these regions as described by Oliet & Bourque (J. Physiol. 445, 1992). Neurons were plated on petri dishes and superfused with a HEPES-buffered medium. Recordings were obtained from phase-bright somata with a mean cross-sectional diameter ranging from 12 to 22 µm. Hyperosmotic stimuli (+10 to +30 mM Mannitol) caused a reversible and reproducible increase in the mean firing rate in 2 of 5 MnPO and 9 of 14 OVLT cells tested. These effects were associated with a membrane depolarization and a 32 ± 7 % decrease in input resistance ($n=14$). Analysis of voltage-current relationships obtained before and during the osmotically-evoked depolarization revealed a reversal potential near -45 mV. Furthermore, the E_{Cl} was -108 mV, suggesting the possible involvement of cationic conductance. These results demonstrate that some neurons within the OVLT and MnPO are intrinsically sensitive to hypertonicity. Supported by the MRC and the Heart & Stroke Foundation of Canada.

GADOLINIUM-INDUCED BLOCK OF OSMOSENSITIVITY AND MECHANOSENSITIVE CHANNELS IN RAT SUPRAOPTIC NEURONS. Stéphane H. R. Oliet* and Charles W. Bourque. *Centre for Research in Neuroscience, Montreal General Hospital and McGill University, Montreal, P.Q. Canada H3G 1A4.*

The release of neurohypophysial hormones from supraoptic neuron terminals is regulated by plasma osmolality. Recent biophysical studies in our laboratory have suggested a role for mechanosensitive cationic channels in the sensitivity of supraoptic neurons to changes in external osmotic pressure. The involvement of such channels in osmoreception was assessed by the use of gadolinium (Gd^{3+}), a trivalent cation known to block different types of stretch-sensitive cationic channels. Whole-cell recordings obtained from isolated rat supraoptic neurons revealed a marked reduction of hyperosmotically-mediated membrane depolarization and firing rate increase in presence of Gd^{3+} (100 μM ; $n=4$). In voltage-clamp mode ($n=10$), bath-applied Gd^{3+} induced a reversible and dose-dependent inhibition ($IC_{50}=20 \mu M$) of the inward current elicited at -60mV by hypertonic stimulations. This inhibition resulted from specific suppression of the cationic conductance which was previously shown to be associated with osmotic responses ($E_{rev} \approx -40mV$). In cell-attached experiments ($n=15$), Gd^{3+} was also able to block mechanosensitive cationic channels when included or perfused in the recording pipette. These results confirm a role for mechanically-gated channels in the endogenous osmosensitivity of rat supraoptic neurons. Supported by the MRC and Heart & Stroke Foundation of Canada.

ENHANCED VASOPRESSIN AND BEHAVIORAL RESPONSE TO METHYLPHENIDATE IN SCHIZOPHRENICS WITH WATER INTOXICATION M.B. Goldman, D.J. Luchins and G.L. Robertson. *Illinois State Psychiatric Institute, University of Chicago Pritzker School of Medicine, Chicago IL. 60637.*

Water intoxication accounts for about 20 % of deaths in non-geriatric schizophrenics. This episodic disorder is associated with transient impairments in water excretion which often occur during exacerbations of psychosis. Many other schizophrenics remain normonatremic during such exacerbations, even if they are polydipsic. We administered the psychotomimetic, methylphenidate (0.5 mg/Kg intravenously), to matched polydipsic schizophrenics with and without a previous history of water intoxication, in order to further examine the relationship of psychosis to water imbalance.

Basal AVP was maximally suppressed in both groups, but peak post-methylphenidate levels were greater in test (time = + 15 min.: $Mn \pm SD$) 1.9 ± 0.7 pg/ml) than control (1.0 ± 0.7 , $t = 2.21$ $df = 12$ $p < .05$) subjects, despite lower plasma osmolality in the former ($T = 278 \pm 5.0$ mOsm/Kg, $C = 288 \pm 5.0$). AVP stimuli (e.g. nausea, abdominal discomfort, hypotension) were not present in any subjects, and parameters influencing AVP release were similar in both groups over the two hours post-methylphenidate. Desire for water was also similar and did not change. 'Positive' symptoms of psychosis increased, and negative symptoms diminished, equivalently in the two groups. Test subjects, however, were more psychotic and showed a greater increase in other psychiatric symptoms.

Methylphenidate causes greater AVP secretion and behavioral activation in schizophrenics with episodic water intoxication. These findings strengthen the link between psychotic exacerbations and vasopressin secretion, and suggest the former is not necessarily a consequence of hyponatremia, per se. Differences in limbic pathology between schizophrenics could account for the findings.

FEMALE SEX HORMONES INHIBIT VOLUME REGULATION IN RAT BRAIN ASTROCYTE CULTURE. C.L. Fraser* and R.A. Swanson. *University of California San Francisco, V. A. Medical Center, San Francisco, CA 94121.*

To determine if sex steroids play any role in the increased morbidity associated with acute symptomatic hyponatremia in menstruant females, we studied the actions of estradiol, progesterone and testosterone on regulatory volume decrease (RVD) of brain astrocytes in culture. Using 3H -3-O-D-methylglucose to determine intracellular space, cells cultured in media containing either estradiol or progesterone and those treated with ouabain were unable to volume regulate normally, whereas testosterone treated cells displayed normal RVD. After 15 seconds of hypotonic exposure, control and testosterone (100nM) treated cell volume increased by 26% and 31% respectively. Cell volume in control cells went from 1.74 ± 0.24 to 2.41 ± 0.28 ul/mg protein. At the same time, cells treated with either 10 nM estradiol or 10 nM progesterone significantly ($p < 0.01$) increased their volume by 129% and 90% respectively. Both the antiestrogen agent tamoxifen, and the antiprogesterone agent RU486 blocked the effects of estradiol and progesterone. The Na-K ATPase pump, which plays an important role in cell RVD was significantly ($p < 0.03$) inhibited by 32% and 21% in estradiol and progesterone treated cells, but significantly ($p < 0.001$) stimulated (49%) by testosterone treatment. Taken together, these results provide a possible explanation for the increased morbidity associated with acute symptomatic hyponatremia in menstruant females.

NON-MYELIN-FORMING SCHWANN CELLS EXPRESS ENDOTHELIN-B RECEPTORS *IN VIVO* S.D. Rogers, J.R. Ghilardi, C.J. Allen, S.R. Vigna, J.E. Maggio, M.W. Dysken*, P.W. Mantyh. *Mol. Neurobio. Lab (151) and GRECC, Mpls., MN 55417; Psychiatry Dept. Univ. of Minn., Mpls., MN 55455; Dept. of Biol. Chem. and Mol. Pharm., Harvard Med. School, Boston, MA 02115; Dept. Cell Biology, Duke Univ. Med. Ctr., Durham, N.C. 27710*

In contrast to myelin-forming Schwann cells, little is known about the factors regulating Schwann cells that do not elaborate myelin sheaths. These non-myelin-forming Schwann cells co-express several surface proteins and intermediate filaments, including glial fibrillary acidic protein (GFAP), not found in myelin-forming Schwann cells. These non-myelin-forming Schwann cells are physiologically important in that they ensheath the peptide-containing sensory C-fibers, and thus may indirectly regulate the transmission of nociceptive information and the inflammatory response in which that unmyelinated C-fibers are involved. In the present study we have used combined receptor autoradiography and immunohistochemistry to demonstrate that the same non-myelin-forming Schwann cells that are GFAP+ also express high concentrations of ^{125}I -Endothelin receptor binding sites. Pharmacological analysis suggests that these binding sites correspond to Endothelin-B receptors. These results suggest a mechanism by which a circulating factor such as endothelin may specifically, yet indirectly, affect the population of non-myelinated primary afferents that are hypothesized to be involved in transmitting chronic pain and in regulating the inflammatory response in peripheral tissues. (Supported by the NIH and VA).

TRIGEMINAL AND DORSAL ROOT GANGLION NEURONS EXPRESS $\alpha_1, \alpha_2, \beta_1, \beta_2$ ADRENERGIC RECEPTOR BINDING SITES IN THE RAT, RABBIT AND MONKEY J.R. Ghilardi, C.J. Allen, S.D. Rogers, S.R. Vigna, J.E. Maggio, L. Kruger, W.A. Raabe*, P.W. Mantyh. *Mol. Neurobio. Lab (151), Mpls., MN 55417; Psychiatry and Neurology Dept, Univ of Minn., Mpls., MN 55455; Dept. of Biol. Chem. and Mol. Pharm., Harvard Med. School, Boston, MA 02115; Dept. Cell Biology, Duke Univ. Med. Ctr., Durham, N.C. 27710, Dept. of Anatomy and Cell Biology, UCLA, LA, CA 90024.*

Noradrenaline has been shown to modulate some trigeminal and dorsal root ganglia (DRG) neurons, but the site of noradrenergic actions and the adrenergic receptor subtype(s) mediating these effects have not been explored fully. Quantitative receptor autoradiography and homogenate receptor binding was used to localize and characterize the adrenergic receptor binding sites expressed by the cells comprising the trigeminal and dorsal root ganglia in the rat, rabbit and monkey. ^{125}I -HEAT was used to label the α_1 binding sites, p - ^{125}I -iodoclonidine was used to label the α_2 sites and ^{125}I -cyanopindolol was used to label the β_1 and β_2 sites. In the rat, rabbit, and monkey DRGs a high concentration of β_2 adrenergic receptor binding sites were observed, with moderate concentrations of α_2 binding sites and low but detectable concentrations of α_1 and β_1 receptor binding sites. Within the DRG, specific binding sites corresponding to all 4 subtypes of adrenergic receptors were associated with neurons and not the supporting cells, fibroblasts or endothelial cells. That all four adrenergic receptors are expressed primarily by neurons is supported by the observation that after double ligation of the sciatic nerve, build up of all four adrenergic receptors was observed proximal to the ligation. These results suggest that at least in the rabbit and monkey, the vast majority of sensory neurons, including the large mechanoreceptive cells, express $\alpha_1, \alpha_2, \beta_1$ and β_2 adrenergic receptors and that these adrenergic receptors are appropriately positioned to presynaptically modulate primary afferent neurons. (Supported by the NIH and VA)

643.3

Role of a Slow Ca^{2+} -dependent Afterhyperpolarization in Prostaglandin E_2 -Induced Sensitization of Cultured Rat Sensory Neurons. Michael S. Gold*, Michael J. Shuster, Shahram Dastmalchi, and Jon D. Levine. Depts. of Medicine and Oral Surgery, and Division of Neurosciences, UCSF, Box 0452A, San Francisco, CA 94143. To determine if inhibition of a slow (> 1 sec) Ca^{2+} -dependent afterhyperpolarization (sAHP) contributes to prostaglandin E_2 (PGE_2)-induced sensitization of dorsal root ganglion (DRG) neurons, we have used patch-clamp electrophysiological techniques on cultured DRG neurons from the adult rat. In support of a role for the sAHP in sensitization of DRG neurons, we demonstrate that: 1) sAHP expression is restricted to a subpopulation of DRG neurons (21% of all cells studied) which also express properties associated with nociceptors, including small cell body size, a shoulder on the falling phase of the action potential (AP), and a rapid depolarization in response to capsaicin; 2) burst duration is controlled by a sAHP in these neurons; and 3) in some neurons, PGE_2 blocks the sAHP, and produces a concomitant increase in the number of APs generated in response to depolarizing current injection. However, our results also demonstrate that sAHP modulation is not sufficient to explain PGE_2 -induced sensitization in the majority of DRG neurons because: 1) PGE_2 sensitized 59% of the neurons tested; 2) in many of these neurons, PGE_2 produces a decrease in AP threshold as well as an increase in the number of APs in response to current injection; and 3) the sensitizing effects of PGE_2 are dissociated from its effects on the sAHP in more than half of neurons tested. Thus, PGE_2 -induced sensitization must involve the modulation of ionic currents in addition to that underlying the sAHP. Supported by NIH grant NS21647

643.5

MORPHOLOGICAL AND PHYSIOLOGICAL CHANGES IN ISOLATED DORSAL ROOT GANGLION CELLS AFTER NERVE INJURY. M. Petersen* and R.H. LaMotte¹. Dept. of Physiology Univ. Würzburg, D-97070 Würzburg and Dept. of Anesthesiology, Yale Univ. School of Medicine¹, New Haven, CT 06510

We have studied the changes in membrane properties of freshly dissociated dorsal root ganglion (DRG) cells following a unilateral chronic constriction injury to their peripheral axons (Bennett and Xie 1988). An injury of the sciatic nerve was produced by 4 tight or 4 loose ligatures. After a survival time of 12 to 20 days, cells from L4 and L5 ganglia were recorded electrophysiologically by the whole-cell patch clamp technique.

In a subpopulation of cells, spontaneous activity could be recorded in cells of small to medium size. These cells exhibited either discharges with regular interspike intervals with a frequency of 1 to 3 Hz, or bursting discharge patterns. In a subpopulation of cells there was also a de novo sensitivity to norepinephrine. Most of the cells responded with action potentials and a few with a slow membrane depolarization. The threshold concentration was about $300 \mu\text{M}$. Most of the cells were small to medium in size and responded also to capsaicin (300 nM).

Phenotypically, there was a difference in the onset of outgrowth of processes from somata whose peripheral axons were injured by a tight ligation vs. from somata of uninjured cells. Seven hours after plating, 1.3% of the cells with uninjured axons developed processes vs. 19% of cells whose axons were injured 13 to 15 days earlier.

The results show the plasticity of isolated somata after nerve injury. Supported by DFG Pe 299/3-1 and by P.H.S. grants NS 14624 and PS 09871.

INTRADERMAL INJECTION OF COMPOUND 48/80, SUBSTANCE P AND SEROTONIN BUT NOT HISTAMINE PRODUCES HINDLIMB SCRATCHING IN MICE. Y. Kuraishi¹, T. Nagasawa¹, K. Hayashi¹ and M. Satoh². ¹Dept. of Applied Biochem., Res. Inst. for Traditional Medicines, Toyama Med. & Pharm. Univ., Toyama 930-01, ²Dept. of Mol. Pharmacol., Fac. of Pharm. Sci., Kyoto Univ., Kyoto 606-01, Japan.

As a step in investigating the peripheral mechanisms of itch sensation, we examined behavioral effects of peripheral injection of agents that are known to produce itch or pain in humans. Male ddY mice (5-6 weeks old) were given intradermal (i.d.) or subcutaneous (s.c.) injection into the rostral part of the back and scratching was observed using a video camera. An i.d. injection of compound 48/80 ($10\text{-}100 \mu\text{g}$) or substance P ($100 \mu\text{g}$), which produces itch sensation in humans and mast cell degranulation, induced scratching towards the injected site by the hindlimbs. The number of scratching was 41.8 ± 9.5 ($n=8$) for 10 min after $100 \mu\text{g}$ of compound 48/80. No significant behavioral effects, except transient vocalization during injection, were observed after s.c. injection of pain-producing substances such as capsaicin (30 and $100 \mu\text{g}$) and 5% formaldehyde. As histamine and serotonin are contained in the rodent mast cells, behavioral effects of these amines were examined. Serotonin ($0.3\text{-}30 \mu\text{g}$, i.d.) produced dose-dependent scratching, the number of which was 38.4 ± 7.6 ($n=8$) for initial 10 min at $30 \mu\text{g}$, but histamine ($1\text{-}100 \mu\text{g}$, i.d.) was without such effect. Scratching induced by serotonin at doses of 141 nmol ($30 \mu\text{g}$) and 100 nmol was significantly suppressed by 15-min pretreatment with the 5-HT₃ antagonist KB6933 (0.1 mg/kg) and by simultaneous injection of this antagonist (0.01 nmol), respectively. The results suggest that scratching towards the injected site by the hindlimb is due to itch rather than pain and that serotonin, but not histamine, produces scratching towards affected skin, probably at least partly through 5-HT₃ receptors in the periphery.

CATEGORIZATION OF ACUTELY ISOLATED RAT SENSORY NEURONS BASED ON ION CHANNEL EXPRESSION AND SENSITIVITY TO CAPSAICIN. C. G. Cardenas*, L.P. Del Mar, and R.S. Scroggs. University of Tennessee, College of Medicine, Department of Anatomy and Neurobiology, Memphis, TN 38163.

Rat dorsal root ganglion cell bodies (neurons) were screened according to action potential (AP) shape, capsaicin sensitivity, and expression of several ion currents. The data for individual neurons often conformed to one of four patterns, named Type 1, 2, 3, and 4.

Type 1 neurons ($N=15$) had long duration APs (average = 12.6 ms), and were capsaicin sensitive. High-threshold Ca^{2+} current averaged 29.2% ω -conotoxin GVIA sensitive (N-type), 48% nimodipine sensitive (L-type), and 22.8% was resistant to both blockers (resistant). T-type Ca^{2+} currents averaged 260 pA . I_H current and I_IR current were not expressed. Soma diameter averaged $23.5 \pm 3.4 \text{ SD}$.

Type 2 neurons ($N=7$) differed from Type 1 in having shorter APs (average = 4.8 ms), negligible T-type currents (average = 46 pA), and an I_A -like current. Similar to Type 1, Type 2 neurons were capsaicin sensitive, lacked significant I_H and I_IR current, and had high threshold Ca^{2+} currents composed of 33.3% N-type, 30% L-type, and 36.7% resistant-type. Soma diameter averaged $20.1 \pm 1.7 \text{ SD}$.

Type 3 neurons ($N=9$) differed from Types 1 and 2 in having brief APs (average = 1.8 ms), I_H current (average = 111.3 pA), I_IR current, and were capsaicin insensitive. Type 3 high threshold Ca^{2+} current resembled that of Types 1 and 2, i.e., 22.8% N-type, 47.4% L-type, and 29.8% resistant. Similar to Type 1 neurons, T-type Ca^{2+} currents in Type 3 neurons averaged 260.7 pA . Soma diameter averaged $16.1 \pm 2.1 \text{ SD}$.

Type 4 neurons ($N=7$) differed markedly from Types 1, 2, and 3 regarding Ca^{2+} current expression. Little high threshold Ca^{2+} current was N- or L-type (11.7% and 7% , respectively), most being the resistant type (average = 81.2%). Also Type 4 cells had huge T-type Ca^{2+} currents averaging 4082 pA . Otherwise they were similar to Type 3 cells in having brief APs (average = 1.1 ms), I_H current (average = 1035 pA), I_IR current, and were capsaicin insensitive. Soma diameter averaged $34.6 \pm 1.6 \text{ SD}$.

These different phenotypes may transmit different kinds of sensory information.

NOCICEPTOR EXCITATION BY PLATELETS IS NOT DUE TO 5-HT OR PROSTANOIDS RELEASED. M. Ringkamp¹, M. Schmelz¹, M. Allwag², A. Ogilvie², P. W. Reeh^{1*}. ¹Dept. Physiol. & Biocyber., ²Dept. Biochem, Univ. Erlangen-Nürnberg, D-91054 Erlangen, Germany

Accumulation of platelets is an early event in inflammation. Activated platelets release potentially algogenic chemicals, e.g. serotonin. In the rat skin-nerve preparation, ADP-activated human thrombocytes in plasma (PRP) excited 14/18 polymodal C-fiber endings (Ringkamp et al., Neurosci. Lett., in press, 1994). In a recent psychophysiological study, intradermal injection of autologous concentrated platelets in plasma induced burning pain, flare, as well as mechanical and heat hyperalgesia. In contrast, platelet poor plasma, with ADP added, was ineffective as well in rat as in human skin. To test the hypotheses that the effects of activated PRP are due to platelet derived 5-HT or prostanooids, as thromboxane A_2 , in vitro experiments on identified C-fiber terminals were performed. A combination of 5-HT antagonists (methiopepin $1 \mu\text{M}$, ketanserin $1 \mu\text{M}$, ICS 205-930 $0.1 \mu\text{M}$) was added to ADP-activated PRP, or PRP was gained from a donor treated with 500 mg lysine-acetylsalicylate i.v. 12 hours before blood sampling. In both protocols no significant difference to previous results in percentage of polymodal C-fibers excited (9/11 and 13/17, respectively) and in magnitude of the response was found, while the onset of nociceptor excitation was clearly delayed in both conditions. Thus, nociceptor excitation by activated platelets should not be due to 5-HT or prostanooids, but seems to be accelerated by these agents. In a further study on polymodal nociceptors, it turned out that platelets suspended in a plasma free solution had lost their ability to excite nociceptors, while they were still able to aggregate (in a photometric assay). When such platelets were re-suspended in plasma, their excitatory potency was regained, which is evidence for a necessary interaction between plasma and platelets in nociceptor excitation.

PROSPHOLIPASE A₂ INDUCED ELECTROPHYSIOLOGICAL CHANGES IN RABBIT LUMBAR FACET JOINT CAPSULE. JC OZAKTAY¹, S KALLAKURI¹, S VAIDYANATHAN¹, OH LI¹, DC BLAGOEV¹, JM CAVANAUGH¹, AI KING¹. Bioengineering Center, Wayne State University, Detroit, MI 48202.

The aim of this study was to investigate the histological and electrophysiological effects of phospholipase A_2 (PLA_2) injected in the lumbar facet joint capsule. **METHODS:** 12 male rabbits were anesthetized, an L5-L6 laminectomy and ventral ramus rhizotomy were performed. The dual bipolar electrode recordings were made from split L6 dorsal roots. The L6-L7 facet joint capsule was mechanically searched for receptive fields. The units were characterized by their conduction velocities and mechanical thresholds. 750 or 1500 U of PLA_2 (naja naja venom, Sigma) in the buffered carrier solution ($100 \mu\text{l}$, pH 7.5) was then injected into the receptive field. The threshold and unit activity were recorded for later computer analysis. At the end of the experiment the tissue was histologically examined with H&E staining. **RESULTS:** 1500 U PLA_2 injections ($n=4$): a) At 30 min, a significant decrease was observed in multi-unit spontaneous discharge rate (SDR) and the units were no longer mechanically responsive. b) Group II units ($n=3$): SDR was significantly decreased and all units disappeared before 15 min. c) A previously silent unit reached a discharge rate of $20/\text{s}$ and disappeared at 7 min. 750 U PLA_2 injections ($n=4$): a) Multi-unit SDR was decreased at 30 min. After 30 min, the SDR rate increased in response to probing in 2 experiments. b) Group II units ($n=3$): SDR decreased after the injection. c) Group III units ($n=8$): SDR reached a higher level after the mechanical probing at 30 and 45 min. d) Silent units ($n=2$) were mechanically evoked after 30 min. Control injections ($n=4$) did not show any significant changes. There were also no histological changes observed in any type of injections. Supported by NIH Grant NS-28994.

DIFFERENTIAL CONTRIBUTIONS OF 5HT, BRADYKININ AND PGEs TO NOCICEPTOR SENSITIZATION. B.Y. Cooper, Dept. of Oral Surgery, University of Florida, Gainesville, FL, 32610.

Substantial mechanical sensitization can be observed in A-delta mechanical nociceptors following injection of carrageenan (Cooper et al., 1991). This includes changes in both reactive range and mean discharge rate. It is unclear whether pro-inflammatory (PI) mediators make distinct contributions to sensitization. These studies examined the qualitative and temporal features of sensitization that follow bradykinin (BK), serotonin (5HT), and prostaglandins (PGE₁ or PGE₂). Using a force-servo stimulator, nociceptor reactivity was assessed at 5, 30, and 60 minute intervals after injection of PI agents.

Significant decreases in discharge range were observed following BK or 5HT. Changes in range were complementary, with BK producing effects within the first 5 minutes while significant effects of 5HT were delayed to the 30 and 60 minute test intervals. Neither BK or 5HT produced changes in mean discharge rate. In contrast, injections of PGEs produced delayed changes in rate of discharge (60 min) but no significant changes in reactive range. It was concluded that 5HT, BK, and PGEs made qualitatively and temporally distinct contributions to mechanical sensitization. Supported by NIH DE08701.

AMPA AND NMDA RECEPTOR-IMMUNOREACTIVITY POST-SYNAPTIC TO PRIMARY AFFERENT TERMINALS IN THE SUPERFICIAL DORSAL HORN OF THE CAT SPINAL CORD. E.J. Alvarez*, D. Harrington and R.E.W. Wyffe. Dept of Anatomy, Wright State University, Dayton, OH, 45435.

Primary afferent synapses are believed to use excitatory amino acids (EAA) as their principal "fast" neurotransmitters. There is potential for great functional variability at EAA-synapses because of the diversity of EAA-receptor subtypes that can be expressed, but details of this diversity are largely unknown for individual synapses. A promising approach is to use antibodies (Abs) against different subunits to detect their presence at primary afferent synapses using electron microscopy immunocytochemical techniques. Here, we used Abs directed against epitopes found in the GLUR2 and 3 subunits of the AMPA receptor (Chernicon) and in the NMDAR1 subunit of the NMDA receptor (Pharmingen) to detect these subunits in the superficial laminae of the cat spinal cord. The Abs labeled many postsynaptic sites and also the cytoplasm of cell somas and dendrites. All three kinds of known central glomerular types (presumed primary afferent origin) were associated with postsynaptic immunoreactivity (ir) to GLUR2/3 and NMDAR1. Interestingly, within a single glomerular terminal less than half of the synapses were immunolabeled, although many of the postsynaptic profiles displayed cytoplasmic ir. Our results provide immunocytochemical proof supporting the assertion that most classes of primary afferents arborizing throughout laminae I to III use AMPA and NMDA receptors to elicit postsynaptic effects, but intriguingly the Abs did not universally label all primary afferent synapses despite our efforts to increase detection sensitivity to a maximum. It remains to be determined if these results are due to the presence of different subunit types, subtype isoforms, variable conformations, or posttranslational epitope masking (either in vivo or during fixation) at different synapses established by a single primary afferent terminal.

CAPSAICIN PRODUCES SECONDARY HYPERALGESIA TO MECHANICAL BUT NOT HEAT STIMULI. Z. Ali, R.A. Meyer*, S.M. Meleka, and J.N. Campbell. Dept. Neurosurgery, School of Medicine; and Applied Physics Lab., Johns Hopkins Univ., Balto., MD 21287.

Hyperalgesia to mechanical but not heat stimuli occurs in the uninjured skin surrounding a burn to the glabrous hand (Raja et al., Brain, 1984). In the present study, we investigated whether a similar dichotomy occurs when secondary hyperalgesia is produced by capsaicin injected into the hairy skin. Heat and mechanical testing was done twice before, and 20 and 60 min after an intradermal injection of capsaicin (50 µg in 10 µl) to the volar forearm of 12 volunteers. A 9 bar Von Frey filament was used to map the zone of hyperalgesia to punctate mechanical stimuli after the capsaicin injection. Our laser thermal stimulator was used for heat testing at multiple sites inside and outside the mechanical hyperalgesic zone plus the site of capsaicin injection. Subjects pressed a key to indicate heat pain threshold to a ramped (1°C/s) heat stimulus (39 to 49°C). Subjects used a visual analog scale to rate pain to intense heat (44, 46 & 48°C; 1 or 2 s duration). Sixty minutes after the capsaicin injection, pronounced secondary hyperalgesia to mechanical stimuli was present, but heat pain thresholds (44.7 ± 0.4°C inside; 44.5 ± 0.3°C outside; ± SEM) and normalized suprathreshold pain ratings (85 ± 10 inside; 79 ± 11 outside) were not significantly altered. However, in all subjects, heat pain threshold was significantly higher (P < 0.01) and suprathreshold ratings were significantly lower (30 ± 9) at the capsaicin injection site. Similar results were obtained in 5 other subjects tested with contact heat. These results suggest that secondary hyperalgesia in the hairy skin is characterized by hyperalgesia to mechanical but not to heat stimuli. Supported by NIH (NS-14447).

INTERLEUKIN-2 AND CUTANEOUS C POLYMODAL NOCICEPTORS: DOSE-RESPONSE RELATION, TACHYPHYLAXIS AND LACK OF SYNERGY WITH PROSTAGLANDIN E₂. H.A. Martin*, Division of Neurobiology, Medical School, The University of Newcastle upon Tyne, NE2 4HH, U.K.

In a previous study, we have shown that interleukin-2 (IL-2; 0.06 U/3 µl) activates broadly a third of cutaneous C polymodal nociceptors and, more rarely, other classes of nociceptors. In the present study, we have investigated whether (i) the percentage and the response characteristics (i.e., latency, intensity, duration and pattern of discharge) of activated units are dose dependent, (ii) PGE₂ induces a sensitization to IL-2.

Activity of single nociceptive fibers was recorded in *in vivo* saphenous nerve preparations, in nembutal anesthetized rats.

(i) Increasing doses of IL-2 (0; 4.10⁻³; 4.10⁻²; 4.10⁻¹ U/µl) were injected (3 µl) in the receptive field of 28 C-polymodal nociceptors and 6 mechanonociceptors (4 C and 2 Aδ). Only 8 polymodal nociceptors were activated (28.5%). This activation appeared at 4.10⁻³ U/µl and became stronger with higher doses.

(ii) 14 C-polymodal nociceptors and 5 C-mechanonociceptors were initially treated with PGE₂ (100 ng/3 µl). Only 4 C-polymodal (28.5%) were activated by IL-2 (0.06 U/3 µl) and their response characteristics were unchanged, compared to control. Also, tachyphylaxis to subsequent injections of IL-2 (0.06 U/3 µl) was unaffected by PGE₂.

In conclusion, pruritus produced by high doses of IL-2 in the treatment of advanced cancer may result from the selective activation of a fraction of C-polymodal nociceptors, chemosensitive to this cytokine. The failure for PGE₂ to enhance the chemoresponsiveness to IL-2 may explain the inefficiency of steroids in the treatment of such pruritus.

SUPPRESSION OF RESPONSE OF CUTANEOUS C- AND A-FIBER NOCICEPTORS IN THE MONKEY TO REPEATED MECHANICAL STIMULI DIFFERS. R.M. Slugg*, R.A. Meyer, and J.N. Campbell. Dept. of Neurosurgery and The Applied Physics Lab, Johns Hopkins University, Baltimore, MD 21205.

A pronounced decrease in response has been reported for C-fiber nociceptors when identical heat stimuli are repeated at interstimulus intervals less than 5 min. In this study, we investigated whether a similar decrement in response occurs following repeated presentations of a mechanical stimulus. Standard teased fiber techniques were used to record from single primary afferent nociceptors innervating hairy skin in the anesthetized monkey. Force-controlled mechanical stimuli (10, 20, or 40 gm; 3 s) were delivered via a 400 µm diameter cylindrical probe to the receptive field using a recently developed mechanical stimulator (Slugg et al., Soc. Neurosci. Abstr. 18:326). The conditioning and test stimuli were identical and were delivered at interstimulus intervals (ISIs) of 300, 150, 60, 30 and 15 s. A 10 min stimulus free interval separated every conditioning-test pair. For ISI less than 30 s, the response of the C-fiber nociceptors to the test stimulus was significantly lower than the response to the conditioning stimulus, ranging from 81 ± 3% at the 150 s ISI to 57 ± 4% at the 15 s ISI (n=23). In contrast, significant suppression of the A-fiber response was only observed for ISIs of 30 s or less (77 ± 4% at 15 s; n=11). These results indicate that stimulus interaction effects are prominent in the response of C-fiber nociceptors to mechanical and heat stimuli, and suggest that C- and A-fiber nociceptors differ with regard to transduction of mechanical stimuli. NOCICEPTOR ACTIVATION IS ESSENTIAL FOR AXON-REFLEX FLARE FOLLOWING MILD HEAT STIMULI. R.-D. Treede, W. Magerl (SPON:ENA*) Inst. Physiol. & Pathophysiol., Johannes-Gutenberg University, D-55099 Mainz, FRG.

Noxious stimulation induces a spreading erythema (flare) in human skin, which is supposed to depend on an axon reflex of cutaneous nociceptors.

To investigate the concordance of flare response and pain perception we applied stepped heat stimuli of different base temperatures (30 or 35°C) to the forearms of human volunteers using a peltier thermode (TSA 2001). Flare responses were measured with a laser Doppler flowmeter at 8, 19 and 30 mm distance. The pain magnitude was rated on a visual analogue scale.

With stimulus duration of 2s, the probability curves for pain and flare were nearly identical, with an average threshold of 40°C. Using different base temperatures, the magnitude of flare was related to the final temperature, not the size of the temperature step (see Fig.). A pure warm-fiber stimulus (5°C step from 30 to 35°C) was ineffective.

Flare thresholds in human skin thus coincide with the activation thresholds of heat-sensitive C-nociceptors in monkey hairy skin (Treede et al., Soc Neurosci Abstr 16, 1990, 416).

CUTANEOUS COLD STIMULI IN THE RAT: DETERMINATION OF BEHAVIOURAL NOCICEPTIVE THRESHOLDS. H. Bester, A. Dugray and J.-P. Rivolt. (Spon: European Neuroscience Association*), INSERM U.161, 2 rue d'Alésia, 75014 Paris, France.

After habituating rats (mean weight 230g, n=60) to the experimental conditions (2 sessions per week for 3 weeks), a thermal stimulus was applied to their right hind paw by immersion in a thermostated bath (30% alcohol). Ten different temperatures (T^*) were used from -20 to +25°C (5°C step). On each 5 subsequent test-days (9h00 to 13h00) 12 rats were randomly selected and exposed to one T^* also chosen at random from the ten, each rat being stimulated only once (6 rats/ T^*). Latencies of paw withdrawal (PWL) were measured and immersion prolonged to 30s, unless vocalization occurred, in which case the stimulation ended, and vocalization latency (VL) was noted. In addition, during a 12 min post-stimulation observation period, the occurrence of nociceptive behaviours (NB: licking, shaking, guarding, lameness) and their duration (ND) were noted.

The relationship between PWL and T^* appeared to be an exponential function: $PWL = 5.00504 \times (1.07049)^{T^*}$. For $T^* > 0^\circ\text{C}$, PWL encoded the applied T^* , the threshold being situated between 20°C (1/6 rats over the cut-off) and 25°C (3/6 over the cut-off). For $T^* \leq 0^\circ\text{C}$, PWLs did not differ from one another (mean $PWL = 2.7\text{s}$). Only for these T^* , some of the rats displayed NB and/or vocalization. VL and NB thresholds were -10°C and -15°C respectively. At -20°C, VL was 8.5s; (n=4/6), 19s at -15°C (n=4/6) and 20s at -10°C (n=3/6). All rats displaying NB did not vocalize, and reciprocally. Rats which vocalized displayed a longer ND (mean 75s, 8 rats) than those which did not (mean 9s, 7 rats), although the duration of the stimulation in vocalizing rats was much shorter than the 30s cut-off. This suggests that NB is likely to be related to the sensation of pain, rather than to the duration of the stimulation, even when intense.

In conclusion, behavioral responses to cold innocuous and noxious stimulation in the awake rat can be described with at least 4 parameters: the PWL for $0^\circ\text{C} < T^* \leq 25^\circ\text{C}$; the VL (threshold -10°C), NB and ND for $T^* \leq 0^\circ\text{C}$. In view of the lack of literature on this subject, our results have implications for studies using nociceptive cold stimulation paradigms.

TEMPORAL CHARACTERISTICS OF ORAL TRIGEMINAL ACID SENSITIVITY. Bruce P. Bryant* and Paul A. Moore, Monell Chemical Senses Center, 3500 Market St., Philadelphia, PA 19104

Single unit studies of oral trigeminal neurons have been conducted to ascertain what types of trigeminal neurons are likely to contribute to acid irritation and pain. Acid sensitive neurons were found that were solely sensitive to acid although most also responded to cooling. Conduction velocities of acid sensitive neurons were found to be distributed bimodally, corresponding to C- and A-delta fiber types, which functionally corresponded to polymodal, and cold/cool/acid sensitive neurons. Responses of acid-sensitive neurons could be classified into three basic types 1) simple excitation, followed by rapid adaptation, 2) excitation followed by adaptation to sub-spontaneous activity, and 3) non-adapting excitatory responses of long onset latency (5-10 secs). These three types of responses correspond to thermal/acid (response type #1 and 2) and acid only (response type #3) type neurons. To examine whether acid stimulation exhibited the same phenomena of sensitization and desensitization as capsaicin, neural recordings were obtained from fibers during repetitive lingual exposure to 150 mM pentanoic acid. Responses to both acid and cool/cold stimuli were suppressed in most classes of neurons that were initially sensitive to acid. However, hot-sensitivity was induced in a previously cold/cool/acid sensitive neuron and acid sensitivity was reversibly induced in 2 previously silent neurons. Earlier studies of plasma extravasation implicated vascular processes in capsaicin-induced suppression of responses to acid. Under the same conditions that produced adaptation of responses to acid, no evidence of plasma extravasation was observed. Multiple lines of evidence suggest that acid stimuli cause modulation of sensitivity directly at transduction processes and by conduction block. The sustained noxious sensations of acidic stimuli may result from non-adapting acid sensitive neurons as well as by input from relatively fast adapting acid sensitive neurons that is sustained by central or spinal processes.

CENTRAL PROJECTIONS OF NERVES INNERVATING THE RABBIT MAXILLARY SINUS LOCALIZED USING WHEAT GERM AGGLUTININ-HORSE RADISH PEROXIDASE (WGA-HRP). A.K. Roche* and K.C. Kajander. Depts. of Pharmacology, Oral Science, and Cell Biology and Neuroanatomy, and Graduate Program in Neuroscience, University of Minnesota, Minneapolis, MN 55455.

The purpose of this study was to localize the central projections of nerves innervating the rabbit maxillary sinus.

We used adult, male, New-Zealand White rabbits (2.5-3.5 kgs). After the onset of anesthesia, the left maxillary sinus was opened by drilling through the bony wall of the nasal dorsum. To prevent spread of the WGA-HRP to adjacent nasal areas, the maxillary ostium was closed using a cotton plug and cyanoacrylate ester. Crystals of WGA-HRP (2 mgs) were placed into the sinus, and the sinus was left open for two hours. The opening in the nasal dorsum was then closed using dental resin; the skin incision was sutured, and the animal was allowed to recover. Animals were sacrificed five days later for histochemical localization of retrogradely and transganglionically transported WGA-HRP. Tetramethylbenzidine was used as the chromogen.

More than 50 labeled cell bodies were seen in the ipsilateral trigeminal ganglion. Only 1-3 labeled cell bodies were observed in the contralateral trigeminal ganglion. Dense, particulate, terminal-like labeling was observed only in the ipsilateral spinal trigeminal nucleus. No labeling was present at other levels of the neuraxis (C2-caudal midbrain).

This study appears to be the first to trace the central terminals of nerves innervating the maxillary sinus. We believe these results will help us perform future studies, which will evaluate alterations that occur in the central nervous system following sinus inflammation.

643.16

RESPONSES OF RAT C-FIBER NOCICEPTORS TO NOXIOUS COLD. K.C. Kajander*, B.J. Allen*, B.L. Allard*, C. Courteix* and D.A. Simone*. Depts. of 'Oral Science & Cell Biology & Neuroanatomy and 'Neurosci. Res. in Psychiatry, Univ. of Minnesota, Minneapolis, MN 55455.

Most C-fiber cutaneous nociceptors are polymodal and are excited by mechanical, heat and chemical stimuli. Few studies, however, have quantitatively examined responses of these nociceptors to noxious cold. It has been reported, using stimuli above 0°C , that a relatively small proportion of nociceptors are excited by noxious cold. We have reported that all Aδ nociceptors in rats are excited by noxious cold and most had response thresholds below 0°C . In the present study, cold stimuli were used to characterize responses of C-fiber nociceptors to a wide range of stimulus temperatures. Electrophysiological recordings were made from the saphenous nerve of anesthetized rats. Nociceptors were searched for by mildly pinching the skin. Once a nociceptor was identified and its receptive field mapped, conduction velocity, mechanical threshold and responses to thermal stimuli were determined. A total of 12 C nociceptors were studied. Mechanical thresholds (von Frey monofilaments) ranged from 0.63-43.2 mN. 8 of 12 nociceptors were excited by noxious heat and had a mean threshold of $44.3^\circ \pm 1.73^\circ\text{C}$. All nociceptors were excited by noxious cold. The mean response threshold was $2.8^\circ \pm 4.01^\circ\text{C}$, and thresholds ranged from 30° to -14°C . Approximately 50% of the nociceptors studied (5 of 12) had response thresholds at or above 0°C , while 7 of 12 were excited with stimulus temperatures below 0°C . Responses evoked by cold stimuli usually increased with stimulus intensity (lower stimulus temperatures).

It is concluded that like Aδ "mechanonociceptors", C-fiber "mechanonociceptors" are excited by noxious cold stimuli. Responses of Aδ and C nociceptors to cold differ in that a greater proportion of C nociceptors are excited by stimulus temperatures above 0°C (approximately 50% of C nociceptors; 10% of Aδ nociceptors). Supported by NIH grants NS29567 and NS31223.

ACTIVITY-DEPENDENT VARIATIONS IN CONDUCTION VELOCITY OF C-FIBERS OF RAT SCIATIC NERVE H.C. Shin*, Y.L. Lee, H.Y. Kwon, H.J. Park & S.A. Raymond. Dept. Physiol., Coll. Med., Hallym Univ., Chunchon, Korea, #200-702. Dept. of Anesthesia, Brigham & Women's Hospital, Harvard Med. Sch., MA 02115, USA.

Activity-dependent changes in fiber excitability and conduction velocity are ubiquitous following both natural or electrical stimulation of myelinated axons of peripheral and central nervous system. Activity-dependent changes in excitability are strong and long-lasting and have been implicated in the encoding of discharge trains, and modulation of impulse conduction at regions of low conduction safety such as axonal branches. C-fibers are the most numerous axons in the sciatic nerve, and are highly heterogeneous, biochemically as well as physiologically. Previously, we have demonstrated different profiles of the activity-dependent threshold changes in sciatic C-fibers (Shin & Raymond, 1991, Neurosci. Letts. 129: 242-246). In this study, changes of the conduction velocity (CV) and subsequent conduction block were characterized following impulse activity (0.5, 1, 5, 10, 25, 50 Hz, 1 min) in single C-fibers (n=49, range of resting CVs: 0.25-1.72 m/sec, at 0.5 Hz, 0.12-0.8 mA, 150-570 μA) of rat sciatic nerves. C-fibers which had same resting conduction velocities often exhibited quite different profiles of the activity-dependent latency change and/or conduction block following impulses. Although C-fibers showed only small ($4.19 \pm 0.6\%$) decrease of CV at the lowest activity rate (1 Hz), they exhibited much extensive decrease of CV at higher activity rates (5 Hz: $26.61 \pm 2.4\%$, 10 Hz: $36.09 \pm 3.8\%$, 25 Hz: $39.34 \pm 10.0\%$, 1 Hz vs. others: $p < 0.01$). The frequency of conduction block also increased dramatically as the activity rate rose (5 Hz: 16.3%, 10 Hz: 51.0%, 25 Hz: 89.8%) and most of the fibers were blocked at 50 Hz (95.9%). Eleven of 49 C-fibers showed intermittent conduction block before the occurrence of the complete block, whereas 38 of 49 fibers exhibited direct conduction block without showing intermittent firing activities. These results imply underlying variation among C-fibers in the activity-dependent excitability changes, especially in the buildup and recovery of the hyporecitable phases. (This study has been supported by KOSEF grant 931-0700-026-2).

RESPONSES OF VENTRAL POSTEROMEDIAL THALAMIC NUCLEUS NEURONS AFTER CHRONIC CONSTRICTION INJURY TO THE RAT'S INFRAORBITAL NERVE. B.P.Vos, M.Gautron, J.M.Benoist, G.Guilbaud*, INSERM U161, 2 rue d'Alésia 75014 Paris.

Chronic constriction injury to the infraorbital nerve (IoN-CCI) produces behavioral changes which suggest the presence of trigeminal neuropathic pain (Vos et al., '94, J. Neurosci.). In the present study, single unit recordings were made in the Ventral Posteromedial Thalamic Nucleus (VPM) of rats (n=30) with a unilateral IoN-CCI, once they showed hyperresponsiveness to mechanical stimulation of the affected IoN territory (PO12-15). Extracellular recordings (glass micropipettes filled with NaCl and pontamine) were made under moderate gaseous anesthesia. To date, 125 VPM-units have been recorded: 87 in the VPM contralateral to the nerve injury (VPMc), 43 in the ipsilateral VPM (VPMi). All 43 VPMi-units had identifiable receptive fields (RFs): 26 (60%) had IoN RFs, 4 (9%) mandibular RFs, 2 (4%) intraoral RFs and 11 (25%) non-facial RFs. Of those with IoN RFs, 15 (57%) responded to stimulation of a single vibrissae (60% rapidly adapting, 26% slowly adapting, 13% follicle pinch), 7 (27%) to guard hair deflection, 3 (11%) to gentle skin indentation and 1 (4%) to noxious pinch. Of 87 VPMc-units, 60 (69%) had IoN RFs, 1 (1%) an intraoral RF, 15 (17%) non-facial RFs and for 11 (13%) no RF could be found. Of those with IoN RFs, 10 (17%) responded to vibrissal stimulation, 28 (46%) to mechanical skin stimulation, and 22 (36%) to deep pressure at the level of the Io-foremen, zygomatic arch or rostral eye corner. The 10 VPMc vibrissal units responded only to follicle pinch and were all multi-vibrissal. Of 28 VPMc skin units, 3 (11%) had small RFs, 13 (46%) wide or discontinuous RFs, and 12 (28%) combined RFs (skin, multiple vibrissae and/or guard hair); of these units 11 (39%) were activated by gentle skin indentation, 17 (61%) by pin prick, pinch or deep pressure. Spontaneous discharge rates of IoN-units in VPMc ($X=3.7\text{Hz}$) were not different from those in VPMi ($X=2.9\text{Hz}$). In the majority of VPMc units, responses to mechanical stimulation (10-15sec) outlasted the stimulus; with repeated stimuli (ISI:150sec) VPMc cells showed periods of sustained discharges (30-924sec).

These data suggest that IoN-CCI has important functional consequences at the level of the VPM which may be involved in the behavioral changes that were used as parameters of trigeminal neuropathic pain.

BILATERAL VB THALAMOTOMY DOES NOT REDUCE PAIN IN THE FORMALIN TEST

J.E. McKenna* and R. Melzack, Dept. of Psychology, McGill University, 1205 Dr. Penfield Ave., Montreal, Quebec, Canada H3A 1B1.

It has long been proposed that ventrobasal (VB) thalamic neurons are primarily responsible for mediating central responses to noxious peripheral stimulation. Although this may be true for brief noxious stimulation, it is not the case for persistent supra-threshold stimulation. Previous studies in our laboratory have indicated that while lidocaine blockade of intralaminar thalamic nuclei significantly attenuates formalin-induced pain behavior, it does not diminish formalin pain responses when injected into VB nuclei. In the present experiment, Long-Evans rats received large bilateral electrolytic lesions 10 days prior to testing. Each animal was injected with 20 μl of 2.5% formalin acetate (1% formaldehyde) in the plantar surface of one hindpaw and was rated for pain behaviors for 50 min. The behavioral responses of thalamotomized rats were not significantly different from the responses of unoperated control animals. Implications of these results are discussed. Supported by NSERC grant A7896.

SII HAS THE MOST ROBUST RESPONSE OF THE MULTIPLE CORTICAL AREAS ACTIVATED DURING PAINFUL THERMAL STIMULI IN HUMANS. USING MULTI-SLICE FUNCTIONAL MRI, P.A. Gelinar¹, N.M. Szeveneni², A.V. Apkarian^{1*}, Depts. Neurosurgery¹ and Radiology², SUNY HSC, Syracuse, NY.

Cortical areas involved in human pain perception remain controversial in spite of a number of imaging studies performed on the topic. We studied cortical responses to an experimentally induced painful stimulus in normal subjects utilizing functional magnetic resonance imaging (fMRI).

A 1.5 Tesla MRI system with a within slice pixel size of 1.6 X 1.6 mm, a single surface coil, and an echo planar acquisition sequence were used to image changes in activity in the middle third of the cerebral cortex contralateral to experimentally applied stimuli. In a single imaging session multiple repetitions of noxious heat (45-48°C for 50 s, control = 40°C), motor (sequential apposition of D2-4 to D1, control = rest), and mechanical vibratory stimuli (attached to D1, control = rest) were presented to the subject. Eight 6.0 mm slices were imaged during 6 stimulus-control cycles in each session. Five images/slice were obtained during stimulus or control. T-maps were superimposed on high resolution MR images.

Noxious heat stimulation resulted in significant (t-map clusters greater than 5 pixels with $p<0.05$) activation in the primary (SI) and secondary (SII) somatosensory cortices, primary motor (MI) cortex, and posterior area 24. The largest increase in activity occurred in SII where 3.5% increases in intensity over baseline were noted. The activity in MI was larger than that in SI. For the motor task, significant activation was noted in MI (6% increases), premotor cortex, posterior area 24, SI, and SII. Mechanical vibratory stimulation resulted in increases in activity in SI and SII (2.5% increase).

These results show that multiple cortical areas are activated in response to thermal painful stimulation, including the motor cortex. In addition, the somatotopy of pain perception corresponds with those observed for mechanoreception and motor tasks.

IMMUNOHISTOCHEMICAL IDENTIFICATION OF A PUTATIVE SPECIFIC PAIN AND TEMPERATURE RELAY IN HUMAN THALAMUS. A.D. (Bud) Craig¹, E.-T. Zhang, and A. Blomqvist, Div. of Neurobiol., Barrow Neurol. Inst., Phoenix, AZ, and Dept. of Cell Biol., Fac. of Health Sci., Linköping, Sweden.

Anatomical work using PHA-L in the macaque demonstrated that dense, topographic lamina I spino- and trigemino-thalamic terminations are located in a cytoarchitecturally distinguishable region termed the posterior part of the ventral medial n. (VMpo) (SN 18:385, '92). Physiological examination showed that VMpo contains a topographically organized concentration of nociceptive-specific and thermoreceptive-specific neurons (SN 19:1073, '93). Since VMpo is coextensive with a zone of dense calbindin-positive fibers (SN 18:385, '92), we have used calbindin immunoreactivity to examine the human thalamus.

Blocks of diencephalic tissue, obtained with appropriate permissions from normal autopsy material, were fixed by immersion in 4% paraformaldehyde for 2-3 wks. Serial 50 μm frozen sections were cut in the frontal, transverse, sagittal or horizontal plane and separate 1-in-3 series were processed for calbindin 28kD immunoreactivity (Sigma monoclonal antibody; DAB rxn) or stained with thionin. Endogenous peroxidase activity was suppressed in some cases by pre-incubation in methanol/peroxide.

A dense, compact region of fibers with strong calbindin immunoreactivity is located in the posterior, inferior lateral thalamus in the region previously called the supragenulate/posterior complex. It has nearly identical neighborhood relationships with other calbindin-positive structures as VMpo in the macaque, and it has similar cytoarchitectonic characteristics.

We propose that this structure is homologous to VMpo in the macaque and is the specific pain and temperature relay first postulated by Head and Holmes in 1911. Its location is consistent with clinical lesion, stimulation and recording findings relevant to pain and temperature sensibility. (Supported by NS 25616 and the Swedish Medical Research Council)

NEURONS IN THE HUMAN THALAMIC PRINCIPAL SENSORY NUCLEUS RESPOND TO PAINFUL MECHANICAL STIMULI.

F.A. Lenz¹, R.H. Gracely¹, L.H. Rowland¹, P.M. Dougherty, Depts. of Neurosurg. & Neurosci., Johns Hopkins, Baltimore, MD, 21287-7713 and NAB-NIDR-NIH¹.

The human thalamic substrate of mechanical pain and hyperalgesia has been uncertain since cells responsive to painful mechanical stimuli have not been described previously. We now report results of microelectrode recording prior to thalamic procedures for treatment of chronic neuropathic pain (n=3) or movement disorders (n=9). Thermal stimuli were probes at room temperature, 43°C and 51°C or 53°C while mechanical stimuli included a camel hair brush, a large arterial clip and a small arterial clip. The small clip and the highest temperature stimuli evoked pain sensations rated at 3-8/10 on a visual analog scale; the other stimuli were non-painful. The area of Vc was divided into the region where the majority of cells responded to innocuous somatic stimuli (core region) and the region posterior and inferior to the core region (posteroinferior region). Testing with the series of somatic stimuli was carried out on 21 of 87 cells recorded in the core region and 21 of 54 cells in the posteroinferior region. Seven cells demonstrated a clear increase in firing across the mechanical series from brush to small clip but not across the thermal series. All of these cells were located in the core of Vc. The graded response of these cells to mechanical stimuli extending into the painful range suggests that they may signal acute pain evoked by mechanical stimuli and may participate in mechanical hyperalgesia. Support: Lilly Corp, NIH (NS28598, K08-NS1384).

USING PSYCHOPHYSICAL RATINGS TO MAP THE HUMAN BRAIN: REGRESSION OF REGIONAL CEREBRAL BLOOD FLOW (rCBF) TO TONIC PAIN PERCEPTION. G.H. Duncan, C. Morin, R.C. Coghill, A. Evans, K.J. Worsley, M.C. Bushnell*, Univ. Montréal and Montreal Neurol. Inst., Montréal, Canada.

Functional imaging studies in man show that phasic noxious stimuli reliably evoke increased CBF in several brain regions. However, studies using tonic noxious stimuli show less consistent results for reasons which remain unclear. In the present study we tried to maximize detection of tonic-pain-related rCBF changes by using a regression analysis which weights experimental conditions according to subjects' perceptions, rather than to the physical characteristics of the stimuli.

Positron emission tomography (PET) was used to measure rCBF following bolus injections of H_2^{15}O in 11 normal males during 6 conditions (70-s immersion of the index finger in 35°, 39°, 45°, 46°, 48°, or 49°C circulating water). A regression analysis was performed across conditions using subjects' psychophysical ratings to model a monotonic function between perceived pain and rCBF. A directed search of cerebral regions of interest, predicted from studies of phasic pain, revealed significant trends of increasing rCBF with pain perception in the contralateral sensorimotor cortex (SM), secondary somatosensory cortex (SII), rostral insula (RI), anterior cingulate (AC) and thalamus ($t's>3.0$). Ipsilateral SM, SII and RI showed no trend towards activation. A global search of the entire intracerebral volume revealed additional regions of high correlation in areas involved in motor processing such as red nucleus, basal ganglia and cerebellum ($t's>4.0$, significance threshold adjusted for the larger search area.) These data suggest that although tonic pain may be less robust in evoking rCBF changes, more sensitive analysis techniques can reveal effects of such stimuli in regions activated by phasic pain stimuli.

SPATIAL DISTRIBUTION OF CHRONIC PAIN-INDUCED BLOOD FLOW CHANGES IN THE HUMAN BRAIN. B.C. Coghill¹, K.F. Berman², R.H. Gracely, M. Max, M. Byas-Smith, G.J. Bennett, and M.J. Iadarola. Neurobiology & Anesthesiology Branch, NIDR, and ²Clinical Brain Disorders Branch, NIMH, NIH, Bethesda, MD 20892

Functional brain imaging may provide one tool by which chronic pain syndromes may be accurately evaluated, yet little data exist on the spatial distribution of brain activity during chronic pain. In order to better characterize possible functional changes during chronic pain, five patients were recruited for functional brain imaging studies. Four patients suffered from post-traumatic chronic pain and secondary hyperalgesia affecting one of their limbs and one patient suffered from post-herpetic neuralgia in the trigeminal distribution. All subjects exhibited ongoing pain in the absence of overt somatic stimulation. Cerebral blood flow (CBF) was used as an index of functional activity and was measured by 60 s positron emission tomography (PET) scans following bolus intravenous injection of ¹⁵O H₂O. Subjects underwent multiple PET scans during rest and during allodynia elicited by low intensity mechanical stimulation. Preliminary analyses reveal that these patients demonstrate statistically reliable and robust asymmetries in thalamic blood flow during both rest and allodynia (ANOVA, $p < 0.0005$). During both conditions, thalamic CBF contralateral to the afflicted side was consistently lower than that of the ipsilateral thalamus. At this point, the neural correlate of this asymmetric blood flow remains unclear. These findings, however, are consistent with similar results obtained from cancer patients with unilateral pain (Di Piero, et al., *Pain*, 46:9, 1991) and indicate that asymmetry in thalamic blood flow is a salient feature of different types of chronic pain.

CENTRAL REPRESENTATION OF CHRONIC NEUROPATHIC PAIN STUDIED BY POSITRON EMISSION TOMOGRAPHY (PET). I.C. Hsieh^{1,4}, M. Beltrage², P. Hansson³, S. Stone-Elander¹, E. Kinnman^{3*} and M. Ingvar¹. ¹Dept. Clin. Neurosci., ²Pain Unit, Dept. Anesthesiol. and Intensive Care, ³Neurogenic Pain Unit, Dept. Rehabil. Med., Karolinska, Hospital/ Karolinska Institute, 17176, Stockholm, Sweden; ⁴Pain Unit, Dept. Anesthesiol., Veterans General Hospital-Taipei, 11217 Taipei, Taiwan, Republic of China.

PET studies of phasic and tonic experimental pain using regional cerebral blood flow (rCBF) as the index for neuronal activity have demonstrated activation of primary and secondary somatosensory areas (SI, SII), anterior cingulate cortex (ACA) and thalamus. We investigated the cerebral representation of chronic ongoing pain in patients with mononeuropathy (MNP). Seven patients (42-53 yrs) with MNP in the lower extremity (4 in the right, 3 in the left) were recruited. Three PET image sets were obtained with intravenous injection of [¹⁵O]butanol (35-40 mCi) in the patient's habitual painful state and following a successful regional lidocaine block (3 mg/kg) in the painfree state, respectively. Pain intensity was assessed before each measurement of rCBF. The images were reformatted to a common anatomical representation and subsequently normalized to the global mean. The images of the painful and painfree states were subtracted pairwise within the subject and averaged according to the side of MNP. The determination of significant change was based on the local Z-maximum. Significant increase in rCBF was observed, in the painful state, in the right ACA (Brodmann 24) regardless of the side of MNP. Other activated regions included insula, association cortices and cerebellum. Reduced rCBF was recorded in the contralateral thalamus. Unaltered rCBF was observed in the SI and SII. The present results suggest a right hemispheric lateralization of ACA (Brodmann 24) as well as a reduced thalamic activity in chronic pain perception. Experimentally induced pain may contain a more expressed component in the cerebral response (SI, SII) pertaining to the localization of the painful event as well as intensity coding. CHEMICAL LESION IN THE NEOSTRIATUM INHIBITS AUTOTOMY BEHAVIOR IN RATS. N.E. Saadé*, S.A. Shbeir, S.F. Atweh and S.J. Jabbur. Fac. of Med., American University of Beirut, Beirut, Lebanon.

Recent studies have shown that the basal ganglia receive a nociceptive input (J. Neurophysiol., 1993, 69:1890) and play a role in pain relief produced by electroanalgesia (Pain, 1985, 23:83). The aim of this work is to investigate the possible role of the neostriatum in the modulation of deafferentation pain in rats.

The latency and frequency of autotomy (AT) following leg denervation were compared between a control group (n=6), a basal ganglia lesioned group, in which kainic acid (0.5 µl, 0.01M) was stereotactically injected in the neostriatum one week prior to the leg denervation (n=14), and sham group in which scalp overlying the skull was sectioned and sutured one week prior to the leg denervation (n=6).

All rats in the control and sham groups exhibited autotomy (AT) with a time onsets of 7.8±2.8 days and 10.3±3.0 days, respectively. Only 5 out of the 14 (35.7%) neostriatum-lesioned rats exhibited AT which was also significantly delayed in onset to 24.4±6.7 days. These results suggest that the neostriatum may play a role either in processing sensory input or in the ability to locate and orient the AT towards the part of the body originating the pain sensation.

TEMPORO-SPATIAL DYNAMICS OF HUMAN FOREBRAIN ACTIVITY DURING NOXIOUS HEAT STIMULATION. K.L. Casey*, S. Minoshima, R.A. Koeppe, J. Weeder, and T.J. Morrow. Depts. of Neurology and Div. of Nuclear Medicine, Univ. Michigan, and VAMC, Ann Arbor, MI. 48105.

Positron emission tomography (PET) with intravenous injection of H₂¹⁵O was used to detect changes in regional cerebral blood flow (rCBF) while normal, right-handed, awake humans (N=14, ages 18-42) received repetitive 5sec heat pulses to the left forearm. Stimulus intensity was 40°C (rated warm) or 50°C (rated painful) on alternate scans and was constant throughout the 1 min duration of each of 8 scans. Four scans began at the onset of stimulation (early phase) and 4 began 15sec after stimulation onset (late phase). After normalizing each subject's image set to global CBF, stereotactically standardized subtraction PET images were analyzed statistically voxel-by-voxel and by volumes of a priori interest ($p < 0.05$ adjusted for multiple comparisons). An ANOVA showed a significant ($p=0.002$) effect of phase. In the early phase, significant pain-specific increases in rCBF were seen in the contralateral thalamus, ponto-mesencephalic junction, and S1, anterior cingulate, and supplementary motor cortices. In the late phase, activity appeared in the contralateral lenticular nucleus, S1, S2, anterior cingulate, insula, and premotor cortices. Ipsilateral activity appeared in the insula, thalamus, and cerebellum. A magnitude estimation study of 8 additional subjects showed a significant ($p<0.009$) increase in perceived intensity during identical repetitive 50°C stimuli. A graphical reconstruction method also showed an increase of perceived unpleasantness ($p<0.024$). These results suggest an underlying perceptual correlate of the changes in the temporo-spatial pattern of forebrain rCBF during repetitive noxious heat stimulation.

REGIONAL CEREBRAL BLOOD FLOW (rCBF) CHANGES DURING PAIN: AN ANIMAL MODEL. T.J. Morrow^{1,2,3}, P.J. Danneman³, K.A. Frey^{1,4} and K.L. Casey^{1,2,3}. Depts. of Neurology¹, Physiology², Lab. Animal Medicine³, Nuclear Medicine⁴, University of Michigan and VAMC⁵, Ann Arbor, MI 48105.

BACKGROUND: Recent studies of regional cerebral blood flow (rCBF) in humans using positron emission tomography (PET) have suggested new ideas regarding which CNS structures participate in the perception of pain in man. To examine the effects of CNS lesions and pharmacological manipulations on rCBF during pain, an animal model analogous to PET must be developed. The goal of this study was to evaluate the use of a positron emitting radiopharmaceutical, ^{99m}Tc-HMPAO combined with standard autoradiographic methods as a potential tool for in vivo imaging of CNS structures that participate in the perception and/or modulation of pain. **METHODS:** Under halothane a 24ga catheters were placed in the tail veins of Sprague Dawley rats. Subjects were placed in a soft restraint jacket and recovered from anesthesia for 45 minutes. 2.5% formalin (0.05 ml) injected into the hindfoot served as the noxious stimulus. After 2 minutes stimulation, 10 mCi of ^{99m}Tc-HMPAO was injected through the catheter. Five minutes later the rats were sacrificed and the brain removed. Twenty micron frozen sections were cut and mounted. Standard autoradiographic images of the brain sections were then analyzed for relative optical density. Ipsi- and contralateral ROI's (regions of interest) were sampled separately from several brain regions, and statistically analyzed (t-test) for differences. **RESULTS:** This technique showed similar rCBF changes as seen in human PET studies, e.g. side to side differences in sensorimotor cortex (31.48% diff, $p<0.001$) and cingulate cortex. (17.58% diff, $p<0.05$). **CONCLUSION:** Measurement of rCBF promises to be an exciting new tool for examining changes in CNS activation patterns during pain perception in the awake animal brain.

POSTNATAL TUNING OF CUTANEOUS NOCICEPTIVE INPUT TO A SPINAL MOTOR SYSTEM

HOLMBERG*, H. AND SCHOUENBORG, J.

Department of Physiology and Biophysics, Lund University, Solvegatan 19, S-223 62 Lund, Sweden
Detailed information about the development of nociceptive systems is necessary for understanding the mechanisms by which the adult organization of these systems is accomplished. Also, such information is needed for adequate interpretation of children's responses to potentially noxious stimuli. We have now examined the postnatal development of the hind limb withdrawal reflex (HWR) evoked by noxious thermal stimulation (CO₂-laser pulses) in decerebrated, spinalized rats. Behavioral studies in neonatal rats showed stereotyped, often misdirected reflex withdrawals, indicating immature properties of the HWR system at this age. EMG-recordings in rats examined at postnatal day (PND) 0-3 revealed chaotic receptive fields (RFs), typically covering the whole plantar surface, small response amplitudes and great response variability. With increasing age a decrease in RF size and an increase of response amplitudes were observed in mm. extensor digitorum longus, peronei and biceps posterior, whereas responses evoked in gastrocnemius-soleus decreased with age and were absent after PND 21. At PND 21-25 the RFs of the muscles studied were similar to their counterparts in adult rats, although the detailed distribution of sensitivity still differed somewhat from the adult. According to our data the final tuning of cutaneous RFs of the nociceptive withdrawal reflexes occurs after the third week of life. We suggest that an experience dependent process is involved in this tuning.

CHOLINERGIC INPUTS ONTO DIRECTIONAL GANGLION CELLS. C. Brandon*, Dept. Cell Biology and Anatomy, Chicago Medical School, North Chicago, IL 60064.

In the rabbit retina, ON-Center, Directionally-Selective neurons (ON-DSGC's) project to the accessory optic system of the midbrain. The directional component of their receptive fields appears to be generated via GABAergic input, and modulated by cholinergic input. The dendrites of ON-DSGC's intermingled with the processes of starburst amacrine cells (Brandon, SN '93); the present work examines the synaptic connections between these two cell types.

ON-DSGC's were labeled by retrograde transport from the medial terminal nucleus, and individual labeled cells were injected with Lucifer Yellow *in vitro*. The tissue was stained immunocytochemically for both Lucifer and choline acetyltransferase (CHAT), and tangential sections through the inner plexiform layer were examined by EM.

By light microscopy, ON-DSGC dendrites were completely embedded within the plexus of starburst amacrine dendrites. By EM, ON-DSGC dendrites were surrounded by an extremely dense plexus of ChAT-IR processes; they received many direct synaptic inputs from these processes, which covered virtually their entire surface area. The bulk of the remaining input was from very long, *en passant* synapses from non-CHAT-IR amacrine processes; these had a very low electron density.

Identified ON-DSGC's therefore receive dense, monosynaptic cholinergic input. The large, non-cholinergic synapses, because of their size and placement, seem ideally placed to veto the massive, excitatory, cholinergic input that impinges on large dendritic branches of the ON-DSGC.

REGULATION OF GLUTAMATERGIC TERMINALS IN THE INNER PLEXIFORM LAYER OF THE TIGER SALAMANDER RETINA. D. Henderson*, W. Yu, and R. F. Miller. Department of Physiology, Graduate Program in Neuroscience, University of Minnesota, Minneapolis, MN 55455.

Using a retinal slice preparation, we examined the effects of different neurotransmitter agonists/antagonists on evoked synaptic currents in inner retinal neurons of the tiger salamander. Synaptic currents were evoked by light or by a pulse of hyperosmotic sucrose applied to the IPL. Synaptic currents were monitored through whole cell voltage clamp recordings from neurons in the ganglion cell layer. In the presence of picrotoxin and strychnine, GABA_A agonists reduced sucrose evoked glutamatergic synaptic transmission in approximately half of the cells studied, and in some cases rendered the synaptic currents more transient. In almost all cells studied GABA_A agonists inhibited light evoked synaptic transmission. The results of this study are consistent with the idea that GABA_A receptors inhibit transmitter release from glutamatergic terminals in the IPL. The results of this study also suggest that local hyperosmotic stimulation of transmitter release from terminals in the IPL can be used to study presynaptic regulation of transmitter release.

MODULATION OF HIGH-THRESHOLD CALCIUM CURRENT BY METABOTROPIC GLUTAMATE RECEPTOR IN GANGLION CELLS OF XENOPUS RETINA. A. Akopian* and P. Witkovsky^{1,2}. Depts. Ophthalmology¹ and Physiology & Biophysics,² New York University Medical Center, New York, N.Y. 10016

Presumed ganglion cells of the *Xenopus* retina were studied in short term culture by the whole-cell version of the patch clamp technique. The studied neurons were identified by their characteristic current-voltage relation. In a cocktail of TEA (20 mM); 4AP (5 mM); TTX (1 μ M) and Ba (20 mM) as a charge carrier, we observed both low voltage-activated (LVA) transient and high voltage-activated (HVA) Ca currents. The HVA current was blocked by nifedipine (10 μ M) and enhanced by dopamine (50 μ M). LVA current was blocked by Ni (20 μ M) but was not affected by nifedipine. The metabotropic glutamate receptor agonist t-ACPD (200 μ M) reduced the amplitude of the HVA Ca current by 46 \pm 6% (n=7). The inhibition by ACPD increased to peak within 20 s and was completely reversed within 15 s by a Ringer wash.

The involvement of G-protein in the inhibitory effect of ACPD was studied by including GDP β S (300 μ M) in the patch pipette, resulting in a significant reduction in ACPD-induced inhibition. In contrast, the inhibitory effect of ACPD on Ba current was irreversible when GTP γ S (200 μ M) was added to the patch pipette. In addition, internal application of GTP γ S by itself reduced only the HVA component of the Ba current. These results indicate that activation of G-protein-coupled metabotropic receptors on ganglion cells by glutamate can lead to the modulation of voltage-gated Ca current. Supported by NIH grant EY03570 to P.W..

THE EFFICACY OF SEROTONINERGIC AGENTS VARIES WITH ADAPTATIONAL STATE IN RABBIT RETINA.

X.T. Jin, and W.J. Brunken*. Department of Biology, Boston College, Chestnut Hill, MA 02167

We have been studying the role of the serotonergic amacrine cells in the rabbit's retina. Our approach integrates electrophysiological, anatomical and molecular techniques. Previously, we have shown that antagonists at both 5HT₂ and 5HT₃ receptors inhibit On responses and enhance Off responses in all classes of ganglion cell in dark adapted retinae. Agonists for 5HT₃ receptors have the opposite effect: they enhance On responses and depress Off responses.

We report here on our most recent studies. We have compared the effects of 5HT₃ drugs on the light-evoked responses of single ganglion cells under both light- and dark-adapted conditions. During light-adapted states, neither 5HT₃ agonists nor antagonists significantly affected light-evoked ganglion cell responses. In clear contradistinction, under scotopic conditions 5HT₃ drugs had the same effects as described previously (summarized above).

Thus, these data exclude the possibility that serotonergic drug effects are pharmacological artifacts. Specifically, since the effectiveness of these agents is dependent on the adaptational state of the retina, it is highly unlikely that: 1, the serotonergic agents are acting directly on ganglion cells; 2, spare or "vestigial" serotonin receptors can account for the physiological results; 3, blood borne contamination of exogenous serotonin contributes to our observations. On the other hand, these data strongly support the hypothesis that the serotonergic system specifically modulates signals in the rod pathway and that serotonergic function plays a role in the network processes of dark-adaptation.

VOLTAGE-CLAMP AND CURRENT-CLAMP RECORDING FROM RETINAL GANGLION CELLS. G.M. Ratto*, L. Lambardi, S. Bisit, L. Cervetto and L.M. Chalupa*. Ist. di Neurofisiologia CNR Pisa, Italy and @Center for Neuroscience, University of California, Davis CA.

The electrical properties of retinal ganglion cells (GCs) were analysed in rat retinal slices using the patch clamp technique in the whole cell configuration. The cells were identified morphologically by filling them with diffusible dyes.

Two classes of GCs were identified on the basis of the characteristics of their potassium current. In one class, the K⁺ current had two components: a transient rapidly activating current and a slowly inactivating current. In some cells the slow component lasted for several hundred ms. without appreciable inactivation. In the second class of cells the transient current was absent.

Current clamp recordings also provided evidence for two distinct classes of cells. In one group of GCs the onset of a steady depolarisation caused by outwardly injected current evoked a single large spike, occasionally followed by a few spikes of decreasing amplitude. In these cells no sustained discharge was observed upon injection of constant current. In the second group of GCs current injection evoked a sustained discharge whose frequency and amplitude increased with the extent of depolarisation. At the largest levels of depolarisation these cells produced transient discharges superimposed on a gradually increasing depolarisation which followed a time course similar to the closure of the slowly inactivating potassium current. The sustained cells displayed spontaneous activity, with spike frequency varying with relation to the baseline potential.

MICROGLIAL AND MACROPHAGIC RESPONSE IN RAT RETINA FOLLOWING OPTIC NERVE SECTION. S.C. Sharma*, E. Garcia-Valenzuela. Dept. of Cell Biology, New York Medical College, Valhalla, NY 10595.

Cellular debris, following retrograde degeneration of retinal ganglion cells (RGC), has been shown to be cleared by resident microglial cells in the retina (Thanos, 1992). Here we show that blood derived macrophages also have a distinct role in the removal of RGC's debris. The phagocytic process was studied using double labeling with antibodies against macrophages and phagocytic cells (ED-1 and OX-42) together with retrograde tracing of RGCs after application of either a hydrosoluble dye (Fast blue) or a membrane bound dye (Di I). It was found that while resident microglia from different retinal layers take care of most of the debris, macrophages invade the retina primarily in the nerve fiber layer and upper RGC layer. Macrophages are probably dedicated to engulf axonal debris since unlike microglia, they stain only with di I and not fast blue. Temporal and topographic aspects of these phenomena were also studied.

BLOCKAGE OF VOLTAGE DEPENDENT SODIUM CHANNELS PREVENTS DENDRITIC COMPETITION IN THE CAT RETINA. S. Deplano², C. Gargini¹, G.M. Ratto¹ and S. Bisti¹. ¹Istituto di Neurofisiologia C.N.R., Pisa, I-56127 and ²Istituto di Anatomia Comparata, Università di Genova, Genova, I-16100.

A small lesion at the vitreal surface of the retina produces degeneration of ganglion cells whose axons are severed and leaves a small region in the retina depleted of ganglion cells. When the lesion is performed at an early stage during postnatal development the ganglion cells at the border of the depleted area show an abnormal elongation of the dendritic trees toward the bare area. A possible explanation for this is that dendrites compete either for synaptic space or chemical factors. Alternatively one may suppose that the electrical activity plays a role in the regulation of dendritic arborization as it happens in the segregation of retinal afferents at the LGN level. In the present study we combined a small retinal lesion with the block of the regenerative electrical activity by intraocular administration of TTX. The treatment was continued for the whole critical period. The LGNs were then injected with HRP and the retinae were wholemounted and reacted. The ganglion cell population at the border of the depleted zone was then analyzed. It is seen that neurons near the border present a symmetrical dendritic arborization with few exceptions located in correspondence with the lesion. These results suggest that the electrical activity plays a role in shaping the dendritic arborization during the development of ganglion cells.

IN VIVO TRANSFECTION OF RETINAL GANGLION CELLS IN THE RAT. E. Garcia-Valenzuela, S.C. Sharma, A.B. Drakontides*. Dept. of Cell Biology, New York Medical College, Valhalla, NY 10595.

Following injury, most central neurons in mammals are unable to regenerate, even after the manipulations of their cellular and molecular microenvironment. Modifying their intracellular functions through gene transfer might be necessary for complete restoration of their anatomy. Here we describe successful transfection of axotomized retinal ganglion cells by immediate administration of plasmid at their cut ends. Two different plasmids were used, containing either the SV40 promoter linked to the luciferase gene, or the CMV promoter linked to the lacZ gene. Assays for the expression of both reporter genes demonstrated that a significant proportion of ganglion cells express them successfully 3 and 6 days after retrograde transport. Such an approach might be useful in studies of neuronal molecular functions in vivo, and as an experimental therapeutic strategy.

645.11

CHARACTERIZATION OF RETINAL GANGLION CELL TYPES BY QUANTITATIVE ANALYSIS OF DENDRITIC MORPHOLOGY IN THE RAT. A. Aschoff, B.A. Sabel*. Inst. Med. Psychol., Univ. Magdeburg, Germany.

Soma and dendritic field size of retinal ganglion cells (RGC) are not sufficient criteria to separate clearly the cell types described by Perry (1979) and Dreher et al (1985). We therefore quantified dendritic morphology of RGC to allow unequivocal classification of different RGC types. 50 RGC, identified by retrograde labelling, were injected intracellularly with lucifer yellow and morphometrically analyzed. As previously described, we were able to classify three cell types by soma and dendritic field size. These criteria are not sufficient because many cells cannot be identified as a particular cell type. For example, type I neurons, with soma area ranging from 200-500 μm^2 , can clearly be distinguished from type II neurons (50 and 150 μm^2). Type III neurons however, have similar soma sizes than type II neurons. We therefore tried to find additional criteria for RGC classification using quantitative analysis of dendritic morphology. These include: dendritic spread, dendritic complexity at growing distance from the soma, or segment length and segment ordering. Three cell types can be clearly characterized by average segment length (ASL), which is shortest in type II cells, intermediate in type I cells, and longest in type III cells. In type II dendrites the ASL is similar in all segment orders (15-20 μm), regardless of centrifugal or centripetal order. In type III dendrites the ASL is 32 μm in all branching orders up to the 13th centrifugal order, thereafter shorter. Especially in type III dendrites, the 1. and 2. order segments of the centripetal order (end segments) are very long (40-50 μm). In type I dendrites the segments of the 1. centrifugal order are relatively short (25 μm), the segments of the 2. to the 7. order very long (40 μm) and thereafter extremely short (10-20 μm). By combining ASL, segment order, dendritic field size and soma size all three cell types can be classified unequivocally. There is indication of further subgroups of cells types in all three cell groups.

SELECTIVE BLOCKADE OF MÜLLER CELL GLUTAMINE IN CAT RETINA CAUSES OCULAR DOMINANCE SHIFTS IN VISUAL CORTEX. S.R. Robinson, K.M. Lee, M.G.P. Rosa, L.M. Schmid and D.J. Vaney*, Vision, Touch, and Hearing Research Centre, Department of Physiology and Pharmacology, University of Queensland, St. Lucia, Australia, 4072.

Inhibition of the enzyme glutamine synthetase in Müller cells by methionine sulfoximine (MSO), causes a complete loss of glutamate immunoreactivity in retinal ganglion and bipolar cells¹. The present study investigates changes in response properties of neurons in cat visual cortex following intraocular MSO injection. Four adult cats were anaesthetised with thiopentone sodium (4mg/kg.hr IV) and $\text{N}_2\text{O}/\text{O}_2$ (70:30), while pancuronium bromide (Pavulon 0.15mg/kg.hr IV) was administered to minimise eye movements. The right eye was injected with 0.1ml of MSO at a dosage equivalent to 2mM. Multiple electrophysiological responses were recorded from visual cortical areas V1 and V2 over a period of 24 hours. Within eight hours of MSO administration, histograms for ocular dominance exhibited a shift towards the uninjected eye. This shift was statistically significant (Mann-Whitney U; $p < 0.01$) in both hemispheres, and in both V1 and V2; the shift being greatest in V2. The cats were subsequently euthanased with sodium pentobarbital (60mg/kg; IV) and their retinae processed for immunocytochemistry. The retinae were found to be devoid of glutamine, while the ganglion cells and bipolar cells were depleted of glutamate. These data lead us to conclude that Müller glial cells are an essential component of glutamatergic neurotransmission in the primary visual pathway.

DEMONSTRATION OF SUBLASSES OF RAT RETINAL GANGLION CELLS EXPRESSING MESSENGER RNAs OF γ -AMINOBUTYRIC ACID_A RECEPTOR $\alpha 1$ SUBUNIT AND L-GLUTAMATE DECARBOXYLASE

I. Kosaka, E. Mori†, S. Nomura† and Y. Fukuda*

Dept. of Physiology and Dept. of Pathology†, Osaka Univ. Med. Sch., Suita, Osaka 565, Japan.

We investigated the localization of the mRNAs of γ -Aminobutyric Acid_A receptor $\alpha 1$ subunit (GABA_A $\alpha 1$) and L-Glutamate Decarboxylase (GAD) among subclasses of RGCs by non-radioactive *in situ* hybridization.

Adult male Wistar rats were used after overdose injection of pentobarbital. cRNA probes of GABA_A $\alpha 1$ and GAD were labeled with Digoxigenin-11-UDP (Boehringer) and hybridized with vertical sections of retina. Soma diameter measurement was performed for all cells with positive signals in the ganglion cell layer (GCL).

GABA_A $\alpha 1$ and GAD mRNAs were detected in the inner nuclear layer and the GCL. In this work, we classified the cells with soma diameter larger than 13 μm as RGCs (Perry, 1981, Beale and Osborne, 1982). Since signal positive cells for GABA_A $\alpha 1$ mRNA distributed within 5-22 μm in diameter, RGCs including α -cells ($\geq 17 \mu\text{m}$) expressed GABA_A $\alpha 1$ mRNA. Soma diameter of cells expressing GAD mRNA distributed within 6-16 μm in diameter. We interpreted to indicate that small (S) and medium-sized (M) RGCs but no α -cells expressed GAD mRNA.

CHARACTERIZATION OF THE RABBIT RETINAL GANGLION CELLS THAT PROJECT TO THE SUPRACHIASMATIC NUCLEI. D.S. Tjepkes, F.R. Amthor and D.C. Tucker*, Dept. of Psychology and NRC, Univ. of Alabama at Birmingham, Birmingham, Alabama 35294.

The retina has previously been shown to have a projection to the suprachiasmatic nuclei (SCN). SCN neurons have been shown to have a maintained firing rate that either has a sustained increase or decrease in its firing rate in response to increased illumination (Groos and Mason, *J. Comp. Phys.*, 1980; Meijer *et al.*, *Brain Res.*, 1986). The goal of this research is to characterize the retinal ganglion cells that mediate these responses, which are likely to play a role in the photic entrainment of circadian rhythms.

Fluorescently labelled latex beads were stereotactically injected into the SCN of rabbits. After a recovery period the retinas containing retrogradely labelled ganglion cells were isolated and mounted in a fluorescence microscope and superfused with oxygenated Ames medium. The activity of the labelled cells was examined with extracellular electrodes while visual stimuli were projected through the microscope condenser. The cell was then intracellularly impaled with a pipette electrode and injected with HRP and processed to allow morphological examination.

The first cells labelled exhibit a sustained rate of firing that tonically increases with an increase in general illumination, with no sign of an antagonistic surround. These cells responded poorly to small flashing spots. These responses are consistent with a role of luminance coding. The cell's morphology is characterized by small somata and very fine dendrites that are bistratified. Labelled cells were located in the inferior and superior retina with the densest labelling among the bundles of fibers just inferior to the myelinated fiber band.

This research was supported by NEI grant EY05070.

DISTRIBUTION AND COVERAGE OF BETA CELLS IN THE CAT RETINA. J.J. Stein, S.A. Johnson and D.M. Berson*. Dept. Neuroscience, Brown University, Providence, RI 02912.

We have estimated the distribution of beta cells in the cat retina by mapping the densities of medium sized (non-alpha) cells labeled by retrograde tracer deposits largely or completely confined to the geniculate A-layers. We visualized the dendritic fields of selected cells by intracellular staining *in vitro*. In the nasal retina, beta cells exhibited a well-developed visual streak and, except centrally, accounted for about 40-50% of ganglion cells. However, the incidence of beta cells increased substantially in the central retina (to about 60-70% of all ganglion cells; see Neurosci. Abstr. 19:529, '93) and throughout much of the temporal retina (to about 70%). Though beta-cell densities were lower temporally than nasally, the distribution was far more symmetrical about the line of nasotemporal division than the distribution of all ganglion cells. These results are consistent with our evidence that colliculopetal W-cells (which account for the vast majority of non-beta cells) exhibit a complementary distribution: they make up about half of the ganglion cells in the mid- and far-peripheral nasal retina, including the visual streak, but are underrepresented in the area centralis and temporal retina (where they make up, respectively, about 33% and 25% of all ganglion cells). Dendritic-field areas of beta cells systematically reflected local beta-cell density. For example, in the nasal retina (eccentricity: 30°), areas were 4-fold smaller within than outside the visual streak. Coverage factor (beta-cell density X dendritic-field area) remained constant everywhere, whether central or peripheral, nasal or temporal, on or off the visual streak (mean = 3.9; SD = 0.76; N=203). We suggest that the beta-cell system shows greater binocular balance and is more specialized for fine sampling of central visual fields than other cell classes, and has enhanced functional capacity along the horizon.

TWO REMARKS ON CODING IN THE OPTIC NERVE OF THE FROG. A.C. Grant*, G.A. Pratt and J.Y. Lettvin. Dept. of Biomedical Engineering, Rutgers Univ., Piscataway, NJ 08855, and Lab for Computer Science, MIT, Cambridge, MA 02139.

We studied pulse interval coding on two types of retinal ganglion cell (RGC) in the frog, *Rana pipiens*, by recording extracellularly from single optic nerve fibers with metal-filled microelectrodes. Records were taken from color sensitive fibers (RGC Class V) and "dimming detectors" (RGC Class IV).

With regard to the color fibers, we noted strikingly different pulse interval patterns on a single fiber in response to light stimuli of two different wavelengths, despite approximately equal average firing frequencies in each response. These data are consistent with a pulse pattern rather than pulse frequency coding for color.

The dimming detectors had a sensitivity to step changes in light intensity of less than 0.01 decade, and a sensitivity to continuous changes in intensity of less than 6 decades per hour. The evoked response to step decrements in light intensity was logarithmically related to the magnitude of the step, and was independent of background illumination over a range of at least two decades.

645.14

THE SPECTRAL SENSITIVITY OF GANGLION CELLS IN THE MOUSE RETINA VARIES ALONG THE INFERIOR-SUPERIOR AXIS. E. R. Soucy, E. Wu and M. Meister*. Dept. of Cellular and Molecular Biology, Harvard University, Cambridge, MA 02138.

We are interested in the nature of the information encoded in the spike trains of ganglion cells. Using a multi-electrode array, we recorded visual responses from the population of mouse retinal ganglion cells. The response properties of each cell were determined by computing the reverse-correlation function of its spike train to a pseudo-random stimulus. This allowed us to measure the spatial, temporal, and spectral components of an individual ganglion cell's receptive field. Initial characterization of mouse retinal ganglion cells revealed a relationship between spectral sensitivity and retinal location, with cells in the inferior region displaying greater sensitivity to short wavelengths relative to cells in the superior region of the retina. Szel et al. (J. Comp. Neurol., 325, 327-342) report a topographic separation of two classes of photoreceptors in the mouse retina: short wavelength cones localized predominantly to the inferior retina and medium wavelength cones localized exclusively to the superior retina. It appears that this distribution of cone densities results in a gradient of spectral sensitivity among ganglion cells. By comparing the ganglion cell response spectra to the photoreceptor absorption spectra, we are currently evaluating the respective contribution of each photoreceptor class.

INITIAL PHASE OF ROD RESPONSES, GANGLION CELL FIRING AND BRIGHTNESS SENSATIONS CORRESPOND UNDER DIFFERENT BACKGROUND CONDITIONS.

K. Djupsund*, K. Donner¹, N. Fyhrqvist¹ and T. Hariyama^{1,2}, ¹Dept Zoology, FIN-00014 Univ Helsinki, Finland and ²GSIS, Tohoku Univ, Sendai 980, Japan.

The rods are the first filter in the visual sensory chain and ganglion cells (GC) the last retinal processing step before visual information enters the optic nerve and higher processing. Therefore one might in these nerve cells find common constraints and guidelines for processes mainly studied in psychophysics.

We have compared on one hand brightness sensation and adaptation data and on the other hand the timescale of the rise of intracellularly recorded rod responses and extracellularly recorded GC response frequencies in the frog *Rana temporaria* to flash/step stimuli.

We show that if brightness sensations are determined by the initial rise of the photoreceptor signal, this can account for the intensity-brightness sensation relationship under different backgrounds. The rise of rod responses accelerated with a power of -0.14--0.2 over saturating background and stimulus ranges, which corresponded to the rate of GC responses.

VISUAL CORTEX: STRIATE VI

CHOLINERGIC DEAFFERENTATION OF THE VISUAL CORTEX BY INTRACORTICAL INFUSIONS OF 192 IgG-SAPORIN IN RATS: EFFECTS ON VISUAL DISCRIMINATION AND VISUAL ATTENTION. M. Sarter*, L.A. Holley and M. Matell. Dept. Psychology, Ohio State Univ., Columbus, OH 43210.

The visual cortex, as all cortex, is innervated by the cholinergic neurons situated in the basal forebrain. The functions of the cholinergic afferents of this cortex have remained unclear. Furthermore, the role of the cholinergic cell loss in the visual dysfunctions of patients with senile dementia is unknown. Rats were trained to discriminate between simultaneously presented pairs of visual stimuli flashing at 5 Hz versus 4.17, 3.75, 2.5, 1.67, or 1.25 Hz. Cholinergic inputs to the visual cortex were selectively lesioned by infusions of the immunotoxin 192 IgG-saporin into this area (0.01 µg/0.8 µl/hemisphere). Control animals received either infusions of the immunotoxin into the frontoparietal cortex or infusions of vehicle into the visual cortex. Lesions performed after the animals learned the task did not robustly affect performance. Lesions placed before the acquisition of the task resulted in a transient impairment in the rate of acquisition. The role of cholinergic afferents of the visual cortex in the animals' ability to detect visual signals presented for 25, 50, or 500 msec and to discriminate these signals from non-signal events was also examined. These experiments represent a first step toward the determination of the functions of cholinergic inputs to the visual cortex.

STRUCTURE-FUNCTION CORRELATION OF SINGLE NEURONS IN THE MONKEY VISUAL CORTEX, *IN VITRO*. J. Zhu* and D. J. Uhlrich. Neuroscience Training Program and Department of Anatomy, University of Wisconsin Medical School, Madison, WI 53706.

In rodents, distinct physiological characteristics of cortical cells, *in vitro*, are correlated with morphological features (Connors and Gutnick, TINS, 13:99, 1990). We used the whole-cell recording technique with biocytin-filled electrodes to examine this relationship in the macaque primary visual cortex. Cells were grouped based on their intrinsic response properties. Regular-spiking cells were correlated with pyramidal (n=20) or stellate cell (n=3) morphology. The duration of the action potentials of stellate cells was shorter than that of pyramidal cells. An intrinsically bursting cell, found in layer V, was a spiny, pyramidal-like cell. Fast-spiking neurons (n=4) had smooth and beaded dendrites and exhibited less spike-frequency adaptation than regular-spiking cells. Transient-spiking neurons (n=3), which responded to long duration, depolarizing current injections with only 1 or 2 spikes, were correlated to another cell type with beaded, smooth dendrites. The cell types also differed in their axonal projection pattern. Other properties were similar across cell types: the mean resting potential of all neurons was -73 mV (after adjustment of the junction potential), the median input resistance was roughly 200 mega-ohm, and most cells showed a strong non-linear I-V relationship. These results indicate that the interaction of distinct intrinsic membrane properties and synaptic organization underlies the sculpting of sensory responses in the visual cortex.

NEUROCHEMICAL EFFECTS OF MONOCULAR APHAKIA IN SUPRAGRANULAR LAYERS OF V1 OF THE ADULT MACAQUE. S.S. Leclerc* and R.K. Carder. Zanvyl Krieger Mind/Brain Institute, Johns Hopkins Univ., Baltimore, MD 21218. Unlike monocular enucleation or intravitreal TTX injections, monocular aphakia results in a chronic defocusing without eliminating retinal output. Loss of neural activity in one retina, as with these other forms of monocular deprivation, leads to chemical changes in V1. In the present study, cytochrome oxidase (CO) histochemistry and calbindin immunocytochemistry were used to determine if chronic defocusing without elimination of retinal input can lead to similar neurochemical changes in the supragranular layers of V1. CO and calbindin staining are normally complementary, with CO staining occupying puffs along the centers of both sets of ocular dominance columns, and calbindin staining occupying the surrounding CO-poor interpuffs. After 3-12 weeks of monocular aphakia, changes in CO histochemistry and calbindin immunocytochemistry are apparent. CO-rich puffs at the centers of normal-eye columns fuse to form stripes while CO-rich puffs at the centers of deprived-eye columns become pale and shrunken. Calbindin immunostaining, normally intense in the CO-poor interpuffs and weak in the CO-rich puffs, is similarly affected. Alternating dark and lightly stained stripes are centered respectively on the stripes of CO-rich puffs of the normal-eye columns and on the shrunken CO puffs of the deprived-eye columns, suggesting a novel induction of calbindin immunostaining in the CO-rich puffs of the normal-eye columns. These results are similar to those found in TTX-injected monkeys indicating that aphakic amblyopia also produces neurochemical changes across compartments and ocular dominance columns. Supported by EY06344 and FRSQ.

ONCOGENE EXPRESSION REVEALS OCULAR DOMINANCE COLUMNS IN ADULT CAT VISUAL CORTEX. L. Arckens^{1,2}, G. Wouters^{1,2}, W. Vanduffel², E. Vandenbussche², G. A. Orban² and F. Vandesande¹. ¹Lab. Neuroendocr. & Immunol. Biotechnol., Zoological Institute, KULeuven, ²Lab. Neuro- and Psychophysiol., KULeuven, B-3000 Leuven, Belgium.

Immunocytochemical methods were employed to determine whether manipulation of visual input can induce changes at the protein level of two oncogenes, *c-fos* and *zif-268*, in the primary visual cortex of the adult cat. Under normal visual conditions *zif-268* was expressed at high basal levels in layers II, III, IVB and VI of area 17 and 18, while *c-fos* was hardly detectable. Monocular deprivation drastically influenced the expression of both oncogenes. Already after one hour of monocular visual stimulation, *Fos* and *zif-268* positive nuclei were distributed in a columnar fashion. Using longer monocular deprived cats and cytochrome oxidase histochemistry, we demonstrated that the immunocytochemically detected columns are ocular dominance columns corresponding to the stimulated eye. From immunocytochemical double stainings we know that both oncogenes are expressed in the nuclei of non-GABA-ergic neurons.

EFFECTS OF LONG-RANGE CONNECTIONS ON GAIN CONTROL IN AN EMERGENT MODEL OF VISUAL CORTICAL ORIENTATION SELECTIVITY. D. Somers*, S.B. Nelson, and M. Sur. Dept. of Brain and Cognitive Sciences, MIT, Cambridge, MA 02139.

We previously constructed a model visual cortical circuit with short-range (< 300 μ) intracortical excitatory and inhibitory connections which yielded emergently sharp orientation selectivity (Somers et al '93). The model predicts a small contribution to orientation tuning from direct inhibitory inputs to single cells, but a substantial contribution from the distributed inhibitory inputs to a cortical column. Intracortical excitation selectively amplifies responses to preferred stimuli, and inhibition primarily regulates the gain of excitatory feedback. Here we demonstrate that cortical gain also depends on stimulus contrast: the gain rises to boost mild suprathreshold stimuli and drops off as stimulus strength increases. This mechanism yields cortical contrast response functions that rise more rapidly and saturate more quickly than do their geniculate inputs.

We have added to our model two forms of longer range cortical connections: very sparse inhibitory inputs from oblique or cross orientations (300 – 600 μ) and more extensive excitatory inputs from iso-orientations (≥ 1 mm). Long range inhibitory connections comprise less than 20% of inhibitory and less than 5% of all model synapses. Although long-range inhibitory connections are not required to achieve sharp orientation tuning, these connections permit the circuit to maintain sharp orientation selectivity and contrast gain control across the full range of suprathreshold stimulus contrasts (Skottun et al. '87). As in the short-range model, inhibition is strongest at the preferred orientation and has predominately distributed rather than direct effects on tuning. Adding long-range excitatory connections produces biphasic effects that depend on stimulus context. Strong iso-orientation surround stimuli can up- or down-modulate the responses to stimuli within the classical receptive field; responses to subthreshold or weak center stimuli are amplified, while those to strong center stimuli are reduced. INTEGRATIVE PHYSIOLOGY OF PYRAMIDAL CELLS IN TURTLE VISUAL CORTEX: I. GENICULOCORTICAL SYNAPSES. P.S. Ulinski*, M. Calef and M. Fowler. Depts. of Organismal Biology and Anatomy and of Psychology, University of Chicago, Chicago, IL 60637.

Attempts at understanding the functional relationships between cortical microcircuitry and receptive field generation have been hampered by the technical difficulty of studying the biophysics and synaptic physiology of cortical neurons with *in vivo* preparations. We have circumvented this difficulty by using an *in vitro* preparation of the eyes and brain of freshwater turtles, allowing us to record intracellularly from cortical neurons while presenting natural visual stimuli to the eye cup. Results from intracellular recordings have been combined with anatomic data and with compartmental models of cortical neurons and of neural circuits implemented with the *Nodus* software package. We investigated the responses of pyramidal cells in the visual cortex to 1 sec, 660 nm light flashes with intensities varying from 0 to 1500 photons/cm²/sec, finding that threshold light intensities produced monosynaptic EPSPs. Shape parameter analysis indicated that EPSPs recorded at the soma are usually composite EPSPs. Simulations showed these composite EPSPs could result from asynchronous activation of geniculate boutons on several dendrites of the cell, consistent with earlier results from our lab using electrical stimulation of geniculate afferents. Supported by PHS Grant EY-3852.

RESIDUAL VISION AFTER STRIATE CORTEX DAMAGE IN MONKEYS: STUDIES OF MOTION SENSITIVITY. T. Moore*, H.R. Rodman, A.B. Repp, C.G. Gross. Department of Psychology, Princeton University, Princeton, NJ 08544.

Residual visual capacity in humans with damage to striate cortex has been reported to include sensitivity to presence and direction of motion (e.g., Perenin, 1991, *NeuroRep.* 2:397). We investigated the ability of three monkeys with large unilateral striate lesions to process motion in the affected portion of the contralateral visual field. Lesions were made at 5 weeks of age in two animals and in adulthood in the third. Stimuli were small (5 deg. diameter) gaussian-filtered fields of dynamic random dots (dot size 0.1-0.5 deg.) presented on a video monitor. Moving stimuli contained 98% correlated motion. A go/no-go paradigm employing a saccadic eye movement response was used to test the ability of each monkey to discriminate 1) upward from downward motion at speeds of 4 and 20 deg./sec., 2) upward motion from motion noise (0% correlated motion) and 3) upward motion from a static field of random dots. All animals quickly learned all discriminations in the intact hemifield. In the impaired hemifield, however, they failed to perform above chance on all tasks except the discrimination of moving vs. static dots. The results indicate that preserved visual capacity after striate cortex damage in monkeys does not include at least some types of motion sensitivity, i.e., the integration of local motion signals present in dynamic random dot displays.

STUDIES OF HUMAN VISION COMBINING MEG AND ANATOMICAL AND FUNCTIONAL MRI. I.S. George*, C.J. Aine, I.C. Mosher, H.A. Schlitt, C.C. Wood¹, J.D. Lewine and J.A. Sanders². ¹ Los Alamos National Laboratory, 2 Albuquerque Federal Regional Medical Center.

Integrated analyses of human anatomical and functional measurements offer a powerful paradigm for human brain mapping. MEG and EEG provide excellent temporal resolution of neural population dynamics. MRI provides excellent spatial resolution of head and brain anatomy and an alternative measure of functional activation. These methodologies constrain and complement each other and can thereby improve our interpretation of functional neural organization. In these experiments, MEG data (3x37 channels) and fMRI data (6 slices, 8 or 10mm thick, with 2 mm in-plane resolution) were elicited by a patterned stimulus in the lower right visual field. T1 weighted 3-D volumetric MRI data (128 slices 1.5 or 2mm thick, with 1mm in-plane resolution) were acquired during the same session. The geometry of cortex and of major conductivity interfaces within the head was defined by segmentation of MRI data using semiautomatic image analysis procedures in *MRView*, a software package developed in our laboratory. Cortical edge voxels were identified and cortical normal vectors were calculated for edge voxels using a 3-D convolution over the 26 nearest neighbors. 35-50,000 voxels were required to define the cortical surface at 2 mm isotropic resolution. Conductivity boundaries were defined by shrink-wrapping an icosahedron-based mesh over the surfaces. Electric potential was evaluated at node points using a boundary integral calculation. Magnetic fields at sensors were calculated by evaluating an integral over all node potential values. As a first estimate of MEG sources, the MUSIC metric was evaluated for voxels under the sensor array, assuming locations and orientations derived from anatomical MRI. In agreement with previous dipole-based analyses of MEG data and with fMRI data, at least three sources are evident in these images, a primary response (V1/V2) and bilateral sources near the parietal/occipital border. As a second step, distributed current sources were defined based on clusters of active voxels identified in fMRI maps. Component dipole sources were assigned locations and strength based on fMRI and orientations based on anatomical MRI. Such geometrically complex composite sources can be treated as single sources for temporal analyses based on MEG.

646.9

PAN II: A TWO LAYER NEURAL NETWORK MODEL OF LAYER IV IN PRIMARY VISUAL CORTEX F.W.Grasso* BUMP, MBL Woods Hole, MA 02543

Previous simulation results demonstrated that Primitive Acquisition Networks (PANs) were capable of self-organizing distinct representations of both experienced and novel input sets by storing repeated features contained in the training set in their plastic connections. In the earlier studies model network elements in the PAN layer shared properties of spatial and temporal summation as well as orientation selectivity with 'simple' cells in primary visual cortex. In the model, orientation selectivity developed in a systematic 'columnar' arrangement across the layer when the net was trained with digitized images of natural forest scenes. In recent simulations a new layer of processing elements has been added which receives as input the output of the PAN layer and a parallel copy of the PAN layer input. The elements in this second layer share properties with 'complex' cells in the primary visual cortex: they are not significantly activated by points of light smaller than their receptive fields but are activated by and selective in their responses to larger patterned inputs presented within their receptive fields. Elements in the second layer preserve the orientation selectivity and spatial frequency selectivity of their corresponding PAN elements together the two layers form a 'column' with a depth of two cells. In both model layers the various selectivities of the elements arise from the joint effects of excitatory afferent input and intrinsic lateral inhibitory connections. In the first (PAN) layer there is greater dependence on the afferent input while in the second layer evolved selectivities depend more on intrinsic connections. These results suggest the model embodies a plausible mechanism by which useful representations of the visual environment may be constructed from experience of that environment while providing an explanation for origin of major observable properties of neural networks and neurons in primary visual cortex.

646.11

LAMINAR SPECIFICITY IN THE RELAY OF MAGNOCELLULAR AND PARVOCELLULAR STREAMS TO THE SUPERFICIAL AND DEEP LAYERS OF MACAQUE STRIATE CORTEX.

W.M. Usrey* and D. Fitzpatrick. Dept. of Neurobiology, Duke University Medical Center, Durham, NC 27710.

Magnocellular and parvocellular neurons in the lateral geniculate nucleus terminate primarily in layers 4C α and 4C β of striate cortex respectively. In order to examine the relay of information from these layers to the more superficial and deep layers, we made *in vivo*, intracellular injections of biocytin into spiny neurons in layers 4C β , 4C α and 4B of macaque striate cortex. Our results show that spiny stellate neurons in layer 4C β give rise to axons that arborize in layers 4A and 3B. In contrast, spiny stellate neurons in layer 4C α only occasionally send axons above layer 4A. Rather, layer 4C α neurons extend long distance, horizontal axons that arborize almost exclusively within layers 4C α and 4B. The relay of activity in the magnocellular stream to the superficial layers appears to depend primarily on neurons in layer 4B: Both spiny stellate and pyramidal neurons in 4B give rise to axons that terminate in the superficial cortical layers. However, unlike the neurons in 4C β , those in 4B have axons that pass through 4A and 3B to terminate in layers 3A, 2 and 1. These results suggest that laminar stratification may play an important role in the integration of magnocellular and parvocellular information within layers 2 and 3.

The projections of neurons in layers 4C β , 4C α and 4B are also selective with respect to their targets within the deep layers of striate cortex. Layer 4B neurons give rise to axons that terminate primarily in layer 5, while layer 4C β and 4C α neurons give rise to axons that terminate almost exclusively in layer 6. Within layer 6, the terminals from 4C β and 4C α neurons are restricted to different sublamina divisions of the layer. Terminals from 4C β neurons are found restricted to the upper half of layer 6 while terminals from 4C α neurons are found restricted to the lower half of layer 6. These divisions of layer 6 correspond to those previously identified as receiving restricted inputs from the parvocellular and magnocellular layers of the LGN respectively. Supported by EYO6821 and EYO6661.

DIFFERENTIAL DISTRIBUTION OF GLUTAMATERGIC SYNAPSES BETWEEN CYTOCHROME OXIDASE (CO)-RICH PUFFS AND CO-POOR INTERPUFFS IN PRIMARY VISUAL CORTEX OF MONKEYS. E.Nie, R.Curtis* and M.Wong-Riley. Dept of Cellular Biology & Anatomy, Medical College of Wisconsin, Milwaukee, WI 53226

Glutamate is a major excitatory neurotransmitter in many regions of the brain. Our previous study indicated that puffs contained more asymmetric synapses (presumed excitatory) than interpuffs. In the present study, a double labeling technique combining cytochrome oxidase with glutamate was used to determine whether the distribution of glutamate-positive synapses is correlated with a difference of CO activity between puffs and interpuffs at the EM level. Our results showed that almost all glutamate-positive synapses originated from asymmetric axonal terminals. Quantitative analysis demonstrated that there were more glutamate-positive synapses in puffs than in interpuffs: 21.33 ± 1.5 in puffs versus 14.53 ± 1.2 in interpuffs within $100 \mu\text{m}^2$ of neuropil ($P < 0.005$). Furthermore, glutamate-positive axonal terminals in puffs contained a higher proportion of darkly CO-reactive mitochondria than those in interpuffs, indicating that they might be more active in puffs. In addition, glutamate-positive axosomatic synapses selectively targeted GABAergic neurons, which contained more darkly reactive mitochondria. Thus, the present study suggest that glutamatergic synapses play an important role in excitatory transmission within puffs and interpuffs. Glutamate may be the neurochemical basis for higher metabolic demands related to greater depolarizing activity in puffs than in interpuffs. (Supported by NIH grants EY05439 and NS18122).

INTERMODULATION COMPONENTS IN THE STEADY-STATE VEP AS INDICES OF FIRST HARMONIC BINOCULAR PROCESSING. S. Suter*, P.S. Suter, D.T. Perrier, and I.A. Fox. Vision Laboratory, Psychology Dept., California State Univ., Bakersfield, CA 93311.

The steady-state visual-evoked potential (VEP) to an ordinary pattern-reversal grating contains a robust second harmonic (2H), but little or no fundamental (1H) activity. Cortical 1H processing is of considerable importance, however, because only 1H is clearly linked to neural substrates carrying spatial phase information, which is necessary for the binocular processes of fusion and stereopsis. A stimulus incorporating several simultaneous modulation rates (e.g. F1, F2) enables inferences about cortical processing of 1Hs from nonlinear intermodulation (IM) components--the sum and difference of the 1Hs (e.g. F1-F2, F1+F2). Steady-state VEPs were recorded (Oz to right ear) from 17 stereonormal (Randot E) adults. Stimuli were 0.86 c/deg gratings subtending 10 deg presented for 60-sec trials. Stimuli contained up to three simultaneous modulation rates (F1=6.1, F2=8.5, F3=12.8 Hz) with monocular, binocular or dichoptic conditions achieved using liquid crystal lenses synched to the 256/sec monitor frame rate. Fourier analysis extracted amplitudes at frequencies of interest. Monocular IM components, but not monocular 2Hs, were significantly reduced when a different temporal frequency was added to the other eye. Therefore, in these conditions, 1Hs, but not 2Hs, seem to index binocular processing. Nonlinear models of visual processing are discussed in relation to these findings. The Dorothea Haus Ross Foundation.

646.12

EXPANDED REPRESENTATION OF THE FOVEA IN BOTH THE MAGNOCELLULAR AND PARVOCELLULAR SUBDIVISIONS OF THE RETINOCORTICAL PROJECTION OF THE MACAQUE. P. Azzopardi & A. Cowey (SPON: European Brain and Behaviour Society), Dept. of Exptl. Psychology, University of Oxford, Oxford OX1 3UD, UK.

A well known feature of the retinocortical projection is that in angular terms the fovea is overrepresented in the striate cortex. Recent evidence suggests that more cortex is allocated to the representation of the most central retina than expected from the distribution of retinal ganglion cells alone (Azzopardi & Cowey 1993 *Nature*, 361, 719-721). We have now extended these findings to the parvocellular and magnocellular subdivisions of the retinocortical projection.

A retrograde, transneuronal tracer (WGA-HRP) from cortex to retina was used to relate precisely regions of the striate cortex with corresponding regions of the retina in three macaque monkeys. This enabled us to evaluate the amount of cortex per ganglion cell projecting in the central few degrees of the visual field (mean 8.6° , range $5.7^\circ - 11.9^\circ$) and the amount of cortex per ganglion cell in the whole of the projection. The ratio of these two quantities is called the expansion ratio (ER). Overall, ERs ranged between 2.13 and 3.02 (mean 2.71), and the fact they are greater than 1.0 shows that the representation of the central field is expanded between retina and cortex. In the magnocellular subdivision, ERs ranged from 2.6 to 3.62 (mean 3.11), and in the parvocellular subdivision they ranged from 2.09 to 3.00 (mean 2.67). Thus, the central fields of both subdivisions are expanded.

This result eliminates the most trivial explanation of central expansion in the retinocortical projection, which is that it could arise simply because the two (parvocellular and magnocellular) retinal maps, represented by populations of ganglion cells with different distributions, are expanded to different extents in order to preserve the topographic co-registration of the inputs to the striate cortex. It suggests that the expansion subserves some visual function.

ANATOMICALLY BASED NEURAL NETWORK MODEL FOR GENERATION OF ORIENTATION SPECIFICITY IN MONKEY PRIMARY VISUAL CORTEX (V1). Q. Wu*, J.S. Lund and P. Hadingham. Inst. of Ophthalmology, Univ. of London, London EC1V 9EL and Dept. of Computer Science, Univ. of Western Australia

To understand the correlation between structure and function in primary visual cortex (V1) of primates, we are attempting to develop neural network models which are closely based on anatomical observations and able to simulate physiological results. Our previous modeling study of the primary thalamic recipient layer 4C in V1 suggests that spiny stellate neurons in layer 4C accomplish weighted summation of distinct input sets from LGN through dendritic overlap to produce a physiological gradient of contrast sensitivity and receptive field size. We hypothesize that the strategy of combining distinct input sets to produce a gradient is quite ubiquitous in cortical information processing and may also apply to the issue of generation of orientation specificity in V1. Human psychophysical studies demonstrate that there is a meridional anisotropy (or oblique effect) for discriminating horizontal and vertical orientations versus oblique ones, and that the latency associated with horizontal and vertical orientations is shorter than for other orientations. Based on this evidence, we propose that orientation specificity in primate V1 is generated in two stages: the first stage (in mid 4C) is the generation of two tuning functions centered around horizontal and vertical orientations, and the second stage uses these functions to produce a continuum of all possible orientations. In our model we incorporate the lateral spread of axon collaterals from spiny stellate neurons in mid 4C as the anatomical substrate for producing the two orthogonal orientations in the first stage, and lateral dendritic overlap of spiny stellate and pyramidal cells in layers upper 4C α and 2/3 for combining these two orthogonal orientations to produce a full continuum of orientation specificities in the second stage. Compared to the Hubel and Wiesel model of generation of orientation specificity, our model is more economical in terms of neuronal wiring and has anatomical, physiological and psychophysical support. MONOCLONAL ANTIBODY CAT-305 LABELS GENICULOCORTICAL RECIPIENT LAYERS IN PRIMARY VISUAL CORTEX OF CAT, MONKEY AND FERRET. S. Hockfield*, C. Blakemore† and P.C. Kind, Section of Neurobiology, Yale Univ. Sch. of Med., New Haven, CT 06510 and †Univ. Lab. of Phys., Oxford, UK

Monoclonal antibody Cat-305 labels cortical layer IV of areas 17 and 18 in the cat (Cerebral Cortex, 1994). This restricted localization suggested that the Cat-305 protein may be associated with the presynaptic terminals of axons originating in the dorsal lateral geniculate nucleus (dLGN). To address this possibility we have now examined Cat-305 staining in the cerebral cortex of macaque monkey and ferret, and in the cortex of cats following lesions in the dLGN.

As in the cat, Cat-305 staining is also restricted to primary visual cortex in the adult ferret and monkey. In the ferret, immunoreactivity appears as a dense band of label through layer IV in areas 17 and 18. In macaques, Cat-305 labels two bands, both of which are restricted to striate cortex. Laminar analysis demonstrates that the more superficial band of staining demarcates layer IVa and the deeper band layer IVc, corresponding to the laminar termination of geniculocortical afferents.

To determine whether the Cat-305 antigen is associated with or dependent on presynaptic elements in layer IV, unilateral ibotenic acid lesions were made in the dLGN of adult cats. Three weeks following the lesion, Cat-305 immunoreactivity was markedly reduced in the cortex ipsilateral to the lesion compared to the contralateral, non-lesioned hemisphere and to normal controls. Staining for monoclonal antibody Cat-301 and GFAP in layer IV were not affected by the lesion, indicating that there was little or no degeneration of cortical neurons. The decrease in Cat-305 immunoreactivity in cortical layer IV after dLGN lesions suggests that the loss of the Cat-305 antigen is a result of degeneration of the presynaptic terminals of geniculocortical afferents. ASSESSMENT OF VISUAL ABILITIES IN ALZHEIMER'S DISEASE AND MENTAL RETARDATION. S.A. Shimp* & S. Gross III. Dept. of Psychology, Vanderbilt University, Nashville, TN 37240.

Alzheimer's patients exhibit visual losses including elevated contrast sensitivity thresholds, blue-yellow color deficiencies, and elevated thresholds for detecting coherent motion in kinematograms. To assess the degree to which profiles of visual losses may differentiate between clinical populations, we have begun comparing the performance of Alzheimer's patients to three groups of adults with mental retardation: unspecified etiology, young (<35 years) Down Syndrome, and old (>35 years) Down syndrome. Measurements of visual acuity, contrast sensitivity, color perception, and detection of motion coherence were obtained. Detection of motion coherence was assessed using a 2AFC task in which subjects had to determine which one of two simultaneously presented kinematograms contained coherent motion (signal strength varied between 1 to 100%). The other kinematogram contained only random noise. Relative to standards obtained with control subjects, all groups exhibited elevated visual acuity, contrast sensitivity and motion coherence detection thresholds. Variations in these threshold elevations suggest that profiles of visual losses may differentiate between the groups. Discussion concerning the construction and use of a battery of visual tasks for assessing the neurological status of various clinical populations will be advanced.

SPATIAL SUMMATION ACROSS THE VERTICAL MERIDIAN AFTER COMPLETE OR PARTIAL HEMISPHERECTOMY. F. Tomaiuolo*, A. Pito*, T. Paus and M. Pito. Istituto di Fisiologia Umana, Universita' di Verona, Verona, Italy. Montreal Neurological Institute, McGill University, Montreal H3A 2B4, Canada.

Three patients with right hemispherectomy, one with right-sided removal of the temporo-parietal-occipital cortex and four normal control subjects were tested for spatial summation in the visual field across the vertical meridian. The double stimulus paradigm described by Tassinari et. al (1984) and Marzi et al (1986) was used. Monocular eye fixation was monitored with a pupil/corneal reflection tracking system and all subjects used their right eye. Single or pairs of flashes (LEDs) were randomly presented during 10 msec at 10° or 30° to the left or to the right of the fixation point, either within or across hemifields. Subjects had to respond as fast as possible to the stimuli by a keypress. As expected, control subjects reacted more quickly to double stimuli than to single ones. Although the patients never responded to stimuli in the blind field, they were significantly faster when two flashes were displayed in both hemifield rather than when a single flash was presented in the intact hemifield only. This summation effect across hemifields in subjects in whom a whole cerebral hemisphere has been removed or deafferented supports the possibility that alternate visual structures (e.g. superior colliculi) contribute to residual vision in the blind field. PROCESSING PROFILES AT THE RETINAL VERTICAL MIDLINE OF A CALLOSOTOMY PATIENT. R Fendrich*, CM Wessinger, MS Gazzaniga. Center. for Neuroscience, UC, Davis 95616.

Previously, we reported that a callosotomy patient could not compare small outline shapes presented 15° from the retinal vertical midline with comparison shapes in the opposing visual field. This foveal splitting argued against the attribution of macular sparing to a zone of nasotemporal overlap. We now report evidence that a narrow zone of overlap does occur at the human retinal vertical midline, but is limited in its ability to convey visual information to the cerebral hemisphere contralateral to each hemiretina. Pairs of 2° x 2° square wave gratings ranging from 1 to 8 cpd were displayed to a callosotomy patient with one grating in each visual field. The subject judged whether the gratings had the same orientation. Retinal stabilization insured the grating patches remained properly lateralized. When the gratings were presented for 200 msec or their medial edges were 2° from the retinal vertical midline, the subject performed at or near chance. When presentations lasted 2 seconds and the grating medial edges were 1° from the midline, above chance performance was obtained with the 1, 2 and 4 cpd gratings. Performance degraded when both gratings were displaced 2° upward from the horizontal meridian, but was unaffected or improved by a like downward displacement. Remarkably, accuracy rates improved when the gratings were offset vertically away from each other (one 2° up, one 2° down). Supported by NIH/NINDS P01 NS17778-12 & PHS NS31443-01

Residual Vision in The Blind Field after Partial or Complete Hemispherectomy. C.M. Wessinger*¹, R. Fendrich¹, A. Pito², and M.S. Gazzaniga¹

¹Center. for Neuroscience, Univ. of California, Davis 95616, U.S.A.

²Montreal Neurological Institute, Montreal H3A 2B4, Canada.

One patient with left functional hemispherectomy (JB) and one with right-sided removal of the temporo-parietal-occipital cortex (SE) were tested for residual vision in their blind field. Using image stabilization procedures, we identified a zone of residual vision along the vertical meridian in each patient. The lateral edge of this zone was generally within 3.5° of the vertical meridian, although in both patients we found a local area of detection beyond 3.5°. The region of residual vision was not identical in the two patients. In JB it was confined to the superior quadrant; in SE it was present in both superior and inferior quadrants. Each patient could detect stimuli and correctly perform shape discriminations within the zone of residual vision, but not outside of it. In contrast, neither patient was able to name complex line drawings presented within the zone.

Acuity profile assessments in each patient's seeing field argue against the attribution of these abilities to eccentric fixation. Given the reported complete absence or deafferentation of a hemisphere contralateral to the residual vision, alternate structures would be mediating this residual vision. The superior colliculi and/or the remaining cerebral hemisphere could be candidate structures.

FURTHER RESULTS FROM A TRAINING OF BRIGHTNESS PERCEPTION AND REACTION TIMES IN HOMONYMOUS HEMIANOPIA. L. Dornheim, F. Schmielau*. Inst. for Medical Psychology, Med. Univ. of Luebeck, Luebeck Germany, GER 23538.

Visual field (VF) defects in patients with lesions of the post-chiasmatic visual system demonstrate a reduction of perceived brightness at the border of the residual VF. Dornheim and Schmielau (1994) showed that visual functions can be improved by a rehabilitation training using a magnitude estimation technique of apparent brightness. Now further results are demonstrated for a female patient (age 73 yrs.) who suffered from an incomplete homonymous hemianopia of the right VF caused by stroke. Monocular scaling of threshold and super threshold stimuli and a specific training of light-dark discrimination (70 therapy sessions of 45 min. each) by a computerized perimeter within the lower right quadrant caused a VF enlargement, a reduction of reaction times and threshold as well as an increase of perceived brightness within the trained area and an increase of visual acuity. The authors explain the improvements by recovery of visual cortex neurons due to repetitive stimulation during selective attention.

DYSPHONEIDETIC DYSLIXICS DEMONSTRATE A MAGNOCELLULAR PATHWAY DEFECT. W.H. Ridder, III, E. Borsting, M. Cooper, B. McNeel, and P. Simmons*. Southern California College of Optometry, Fullerton, CA., 92631.

A review of the literature reveals that approximately 75% of dyslexics have a processing deficit in the magnocellular pathway (Lovegrove et al., 1990). In addition, a recent report demonstrated that the dyslexic subtype, which comprises 10 to 30% of the dyslexic population, does not have an abnormal magnocellular pathway (Ridder et al., 1993). These results suggest that the other two subtypes of dyslexia (dysphonetic and dysphonetic) should have a magnocellular pathway deficit. The purpose of this study was to determine if dysphonetic dyslexics exhibit a magnocellular pathway defect. Five dysphonetic dyslexics and five age and sex matched, normal controls were examined. All subjects had normal intelligence and educational opportunities, no ocular disease, sensory impairments, overt psychological problems, or systemic pathology. The presence of dyslexia was determined with the Adult Dyslexia Test. Contrast sensitivity functions were determined with vertically oriented sine wave gratings (0.5, 1.0, 2.0, 4.0, 8.0, and 12.0 c/deg drifting at 1.0 and 10.0 Hz) and for a full field flickering stimulus (5, 10, 15, 20 and 25 Hz) by employing a temporal, 2 alternative, forced-choice technique. Unpaired t-tests demonstrated significant differences existed between the dysphonetic dyslexics and the normal controls for the data obtained at low spatial and high temporal frequencies. These results suggest that dysphonetic dyslexics have a magnocellular pathway defect.

THE EFFECT OF RETINAL ECCENTRICITY ON IMPLICIT AND EXPLICIT JUDGEMENTS OF OBJECT WIDTH. K.J. Murphy* and M.A. Goodale. University of Western Ontario, London, Ontario, Canada N6A 5C2.

We report here evidence to suggest visual sensitivity in normal subjects can vary as a function of response mode. Subjects estimated the width of five different rectangular objects presented at various retinal eccentricities. Three different modes of responding were used. In one block of trials, subjects were asked to indicate the width of the object by stating which of the five different blocks (numbered 1 to 5) it was. In another block of trials, subjects indicated how wide they thought the block was by opening their forefinger and thumb to the same width. In addition to these two explicit judgements of object width, another more implicit judgement was obtained by simply requiring subjects to reach out and grasp the object using a precision grip (with forefinger and thumb). Based on previous work, it was expected that grip aperture would be strongly correlated with object width. In this case and in the previous manual estimation condition, the opening between the finger and thumb was measured using standard opto-electronic recording (WATSMART). The effect of retinal eccentricity on size estimation varied as a function of the response used. When verbal responses were required, size estimates decreased as a function of retinal eccentricity; when manual estimates were required, there was little change. When subjects were required to grasp the object, their grip aperture increased with eccentricity. In short, increasing retinal eccentricity had different effects on judgements of object width, depending upon the response mode. This finding lends further support to the proposal that visual perception and the visual control of action depend on different transformations of visual information (Goodale, *Curr Opin Neurobiol* 3: 1993). This research was supported by a grant from MRCC to MAG.

VISUAL EVOKED POTENTIALS (VEP) TO MOVING SINE-WAVE GRATING AT EQUILUMINANCE. Doris Braun* Sect. Visual Science, University Eye Clinic, Röntgenweg 11, D-72076 Tübingen, Germany

Cavanagh et al. (1984) reported that at equiluminance perceived slowing of sine-wave gratings with low spatial frequency is proportional greatest for slow drift rates (at or below 1 deg/sec).

The effect of chromatic contrast was investigated with motion-onset VEPs recorded in three subjects in response to chromatic and luminance sine-wave gratings moving at 1 and 8 deg/sec across a 19 in colour monitor screen. For each subject the point of equiluminance was defined by equalizing the red and green luminance of a checkerboard pattern flickering at 12 Hz. Chromatic gratings (1.6 cpd) were generated by superimposing red and green sinusoidal gratings 180 deg out of phase. While mean luminance was held constant (24 and 15 cd/m²), luminance of red and green was modulated around equiluminance. For comparison gratings with different luminance contrasts were also tested.

4 channel EEG-recording equipment amplified cortical potentials recorded bipolarly against the ear lobe by gold plated cup electrodes placed over the occipital skull, 3 cm above, and 3 and 5 cm left or right of the mid-sagittal. Potentials of 100 sweeps were separately band-pass filtered (1-80 Hz) for each channel and digitized at 250 Hz. To avoid motion adaptation a 8% duty cycle (200 msec motion & 2500 msec stationary phase) was used.

A motion-related negative component as described by Kuba & Kubova (1992) was found in the VEPs of all subjects even at equiluminance. It had with a negative peak latency of about 180 msec for 8 deg/sec and over 200 msec for 1 deg/sec. At equiluminance the duration of the negative component increased and the peak latency shifted by about 10 msec for 8 deg/sec and up to 40 msec for 1 deg/sec compared to gratings with higher chromatic or luminance contrast.

SPATIAL FREQUENCY TUNED MECHANISMS OF THE RED-GREEN CHANNEL ESTIMATED BY OBLIQUE MASKING. R.L.P. VIMAL¹ and R. PANDEY^{1,2}, New England College of Optometry, Boston, MA 02115

Purpose. Last year, we reported that threshold elevation (TE) curves for the Red-Green (R-G) Channel fell into 5 empirical groups (ARVO '93). The curves were broader at 11 years of age (OSA '93) than were those of adults. Our purpose was to (i) measure the TE curves at 12 years of age with the same subject, and (ii) to extract the spatial frequency (SF) tuned mechanisms for all 3 observers. **Methods.** Threshold contrasts were measured with oblique masking and the method of constant stimuli using a color monitor system. We used the STEPT optimization procedure (Chandler, QCPE, 1976) to estimate the mechanisms. **Results.** We found that (i) TE curves of the boy were narrower at 12 years of age than those at 11 years, and were closer to those of the adults, (ii) his contrast sensitivities were still lower than those of adults, (iii) as the number of SF tuned mechanisms was increased from 1 to 8, the correlations between the data and the best fit and the multiple-R² increased and the sum of the square of the relative error [(data-fit)/max (data, fit)] per data point decreased, (iv) a minimum of 6 SF tuned mechanisms [one lowpass to satisfy the chromatic contrast sensitivity function (CCSF), and 5 bandpass (peak SFs: 0.125, 0.5, 2, 4 and 8 cpd) to satisfy the 5 groups of the bandpass TE curves] appeared to achieve a reasonable fit, and (v) a large number of mechanisms helped to bring the best fit amplitude and bandwidth of the TE curves closer to the data by a small amount. **Conclusions.** We conclude that (i) TE curves of the R-G channel for the 12 year old boy were close to adult levels but, the amplitude of his CCSF was still developing, (ii) a minimum of 6 SF tuned mechanisms for the R-G channel were necessary to simultaneously satisfy the CCSF and TE data. INFLUENCE OF NON VISUAL CUES ON BILATERAL SYMMETRY DETECTION: THE EFFECT OF PROLONGED WEIGHTLESSNESS.

G. Leone¹, M. Lipshits², V. Gurfrinkel² and J. R. Duhamel¹. 1 Laboratoire de Physiologie de la Perception et de l'Action, CNRS Collège de France, Paris, France; 2 Institute for Problems of Information Transmission, Russian Academy of Sciences, Moscow, Russia;

One of the most striking properties of bilateral symmetry detection is the spatial anisotropy in the performance of the visual system. Thus, the shapes of error rates or response times (RT) as a function of symmetry axis orientation show a clear oblique effect, i.e. there is superior performance for a retinally vertical/horizontal orientation of symmetry axis than for oblique orientations. This oblique effect is assumed to be a basic property of the visual system. We investigated, with eight cosmonauts, if performance in symmetry detection could be altered by a prolonged exposure to weightlessness (between 4 days to 7 months). The cosmonauts were maintained in a body restraint system, facing a computer screen where 2D polygons were displayed during 50 ms. The subjects were asked to press the right button if shape was symmetrical or the left one if asymmetrical. We compared RTs and error rates for in-flight versus ground tests.

The results indicate an overall increase in RT (and a decrease in accuracy) in weightlessness that can be related to an increase in computational load associated specifically with the visual symmetry detection task. We found also that the significant advantage of a vertical symmetry axis over an horizontal one vanished in microgravity. Nevertheless, some individual differences appeared. In a ground control experiment, naive subjects performed the experiment in an upright posture and in a horizontal supine posture. The results again indicated a trend towards a decreasing vertical orientation advantage in the latter condition. Our results suggest that the processing of low level visual information integrates also non-visual information. We suggest that otoliths inputs could dynamically modify the properties of some orientation selective cells in the visual cortex.

VISUAL REPRESENTATIONS FOR CLASSIFYING 3D OBJECTS.

Hiroshi Ando* and Satoshi Suzuki,
ATR Human Information Processing Research Labs., Kyoto, Japan.

There have been increasing interests in how the brain represents visual information for object recognition. Physiological experiments have shown that IT neurons may represent local features or prototypes of learned objects (Fujita et al., *Nature*, 360, 343, 1992; Logothetis, et al., *Neurosci. Abstr.*, 1993). Psychophysical studies have indicated that the visual system may extract view-specific prototypes of 3D objects in identification tasks where human subjects differentiate the target object from distractors (Edelman & Bülthoff, *Vision Research*, 32, 2385, 1992). This research examines through psychophysical and computational investigations whether the visual system may extract global prototypes or local distinctive information in 3D object classification tasks.

In the psychophysical experiments, subjects were trained to classify 2D views of a fixed set of wire-frame 3D objects. The results show that some views yield higher error rates. To investigate what representations are extracted, we examined three network models, i.e., the MLP (multi-layer perceptron) network which can extract local linear features, the GRBF (generalized radial basis function) network which extracts global prototypes, and an extension of HBF (hyper basis function) network that allows to emphasize various local templates. The simulations on the same objects used for the psychophysics show that with a small number of hidden units the MLP and HBF networks perform better than the GRBF network. The results suggest that it is useful to extract local distinctive information that is stable over different view directions, such as acute angles formed by successive segments. Analyses of errors reveal that some subjects made errors at particular views similar to the views these networks fail, suggesting that the visual system may extract local distinctive information for classifying 3D objects.

DYSOXIA AND DYSPBARIC CONDITIONS AFFECTS RED/GREEN COLOR VISION. Nico Schellart^{1,3} and Ad van der Kley² (SPON: Europ. Neurosci. Ass.). ¹Lab. Med. Physics, ²Dept. Surg., Univ. Amsterdam, ³Dutch Found. Diving Res., Amsterdam. The Netherlands NL 1105-AZ.

It is known that acute and semi-acute hypobaric conditions reduce the (relative) sensitivity to green light, which lasts for at least 3 days. To what extent red/green color vision is affected under acute normobaric hyperoxia and hypoxia, hyperbaric conditions, and chronically increasing hypobaric conditions has not been reported before. The red-green balance-flicker (16 Hz) fusion point was measured psychophysically for normal subjects with the portable OSCAR color vision tester.

The red/green (R/G) modulation sensitivity ratio is enhanced by normobaric acute hypoxia (10-13 kPa O₂, 0-11% increase, 3 subjects, Sa_{O₂} 58-83%) and reduced by normobaric hyperoxia (60-100 kPa O₂, 2-10% decrease, 6 subjects). The effects are maximal after 20 min of exposure. Exertion (>30 min 150 W) also results in an enhanced (2-9%) R/G ratio. Hyperbaric air pressures, examined up to 520 kPa, reduce less the ratio. An hypothetical explanation of this lesser reduction is an opposite effect of N₂ narcosis (and hypercapnia) at air pressures ≥ 300 kPa. Above 100 kPa O₂ the effect of O₂ saturates (5 subjects). This may partly be due to hypercapnia since normobaric CO₂ mixtures (2 and 4 kPa) resulted in an increased sensitivity ratio (2 subjects). Color discrimination, except for acute hypoxia, was hardly affected. Surprisingly, long-term hypobaric conditions (2 weeks trekking from 800 and 5400 m altitude with altitude adaptation, 2 subjects) resulted in a 4% decrease of the R/G ratio superimposed at the diurnal rhythm.

647.12

MAGNETIC AND ELECTRIC OSCILLATORY RESPONSES TO FLASH STIMULATION: EFFECTS OF LUMINANCE AND ECCENTRICITY. L. Lopez¹, M. Peresson¹, A. Pasquarelli², G.L. Romani¹, W.G. Sannita^{3,4}, ¹ITAB, University of Chieti, Italy, ²IESS-CNR, Rome Italy, ³DISM, Center for Cerebral Neurophysiology University of Genova, Italy, ⁴Dept. Psychiatry SUNY, Stony Brook, NY USA, .

Flash stimulation elicits fast frequency (100-120 Hz) oscillatory responses, that can be recorded electrically from retinal and scalp locations. Magnetic recordings in the occipital regions have suggested that oscillatory responses recorded electrically at scalp locations are originated in the cortex. In this study we wanted to further characterize the origin and possible functional role of these responses.

We measured electric and magnetic responses to full-field and to various spots that progressively varied in area and eccentricity from point of fixation (from 5° to 30°), alternatively in the upper left and right quadrants of visual field. Eight healthy volunteers were studied. Stimulation was delivered monocularly, to the left eye with a Grass PS22 (10 s duration, 0.5 Hz, 3.5 cd/m² (at full-field) 90 dB masking white noise) The stimuli could be delivered without moving the subject. One position, covering an area of 250 mm² over the left occipital lobe, was chosen as a standard for magnetic recording.

Electric and magnetic oscillatory responses during full-field stimulation, were obtained. When changing the stimulus to eccentric and smaller spots, the retinal oscillatory potentials tended to disappear, together with ERG, while the cortical oscillatory responses could still be detected with features that varied as a function of eccentricity and luminance. Such findings would indicate that the mechanisms underlying the generation of oscillatory responses in the cortex are partly independent of the retinal oscillatory potentials and that a magnification occurs in the visual system.

Color Sensations in Honeybees? Werner Backhaus*, Institut für Neurobiologie, c/o Institut für Biophysik, Freie Universität Berlin, Thielallee 63, 14195 Berlin, Federal Republic of Germany.

Neuronal color coding and color choice behavior of honeybees is very well described by the color theory for the bee (Backhaus, 1991, Vis. Res. 31, 1381; 1992, 32, 1425). The results of ordinary color training experiments are described by the color theory on the basis of electrical excitations of two color opponent coding neurons. The results of double color training experiments, in which two color stimuli were trained simultaneously, cannot be explained exclusively on the basis of the electrical properties of neurons. The choices rather appear to be related to color sensations (Backhaus & Kratzsch, 1993, Proc. 21st Göttingen Neurobiol. Conf., 39, New York: Thieme).

A quantitative model is presented which describes color sensations in bees to consist of unique-colors, as in humans (Hering, 1905, Leipzig). Since bees ignore brightness differences in color training experiments, only five unique colors are needed. The amounts of unique-colors are assumed to be linearly related to the electrical excitation values of the two color opponent coding neurons. In double color training experiments, honeybees appear indeed to learn the unique-colors which the two trained colors have in common and to choose the stimuli in the tests according to the amounts of these unique-colors. Quantitative predictions for further experiments are derived from the model for further testing the hypothesis about the existence of unique-color sensations in the honeybee.

MOTOR SYSTEMS AND SENSORIMOTOR INTEGRATION: REFLEX FUNCTION I

648.1

A STUDY OF CUTANEOUS INHIBITORY INPUT TO A SPINAL NOCICEPTIVE MOTOR SYSTEM
H.-R. Weng* and J. Schouenborg. Department of Physiology and Biophysics, University of Lund, Sölvegatan 19, S-22362, Lund, Sweden.

The nociceptive withdrawal reflex system has been extensively studied from both motor and sensory aspects. A "modular" organization of this system has recently been described, each "module" acting on a single or a few synergistic muscles (Schouenborg et al., *News in Physiological Sciences*, in press, 1994). Each "module" receives excitatory input from the skin area withdrawn by its effector muscle(s). We have now studied the cutaneous inhibitory input to this motor system in the decerebrate spinal rat (N=15).

Reflex responses in single hindlimb muscles evoked by sustained noxious pinch (2N, 1mm²) were recorded using electromyographic techniques. Inhibitory receptive fields of mm. peroneus longus and brevis, extensor digitorum longus, tibialis anterior and biceps posterior were mapped using mechanical pinch (up to 2.5N, 1 mm²) and CO₂-laser thermal stimulation (50-300 mJ, 3 mm diameter).

For each muscle, the reflex responses could be inhibited by mechanical and thermal stimulation of the skin area which is moved towards the cutaneous stimulation on contraction of the muscle. Noxious stimuli produced stronger inhibitory effects than innocuous stimuli, indicating a nociceptive inhibitory input.

In conclusion, the spatial organization of the excitatory and inhibitory receptive fields of withdrawal reflexes to single muscles reflects the movement pattern caused by the muscles. Both the excitatory and inhibitory actions on this system protect the body from injury.

648.2

ESTIMATED NET SYNAPTIC POTENTIAL IN HUMAN MOTONEURONES.
K.S. Türker* and H.B. Cheng. Department of Physiology, University of Adelaide, S.A. 5005, Australia

Although recording single motor unit activity from human muscles is technically simple, quantifying reflex responses has not been easy. The most commonly used method for quantifying the reflex response has been the peri-stimulus time histogram (PSTH) and its cumulative sum (CUSUM) which illustrates the change in the firing probability of the single motor unit in response to a stimulus. According to this method, an increase in the firing probability relative to the pre-stimulus period indicates excitation and a reduction represents inhibition. However, it has been demonstrated that the stimulus may induce synchronous activity of the unit and this may induce several peaks in the histogram many of which are not due to the stimulus-induced extra activity in the motoneurone. These peaks are, in fact, due to resumption of normal discharge activity from a fixed point of time "the autocorrelation effect". The frequency of firing of motor units, however, avoids these synchronous activity-induced false peaks and troughs. Furthermore, the frequency of firing of a motoneurone integrates the excitatory and inhibitory effects and represents the net effect of the stimulus on the membrane potential. An increase in the frequency of discharge of a motoneurone indicates that the stimulation has a net excitatory effect, and vice versa. Therefore, in order to estimate the net synaptic potential induced by the low-threshold stimulation of a mixed nerve and the oral mucosa the raw frequency values that belong to individual trials of a reflex experiment are superimposed, averaged and normalized to the afterhyperpolarization of 10 mV. This procedure brings out the estimated net synaptic potential (ENSP) that is initiated in the motoneurone by the activation of the afferent system. Normalization procedure allows the comparison of such responses between experiments.

REFLEX RESPONSES TO LOW-INTENSITY STIMULATION OF THE SURAL, TIBIAL AND PERONEAL NERVES DURING HUMAN WALKING. B.M.H. Van Wezel, F.A.M. Ottenhoff and J. Duysens*. Dept of Medical Physics & Biophysics, University of Nijmegen, 6500 HB Nijmegen, The Netherlands.

The skin of the foot is innervated by 3 nerves, namely the sural, tibial and peroneal nerve. Most studies on the reflex responses to stimulation of these nerves during human locomotion have concentrated on only one of these nerves. The question arises whether the reflexes, and their phase-dependent modulation during locomotion, show differences for these different nerves. The purpose of the present study was to compare the reflex responses to stimulation of these 3 nerves in the same subjects, while walking on a treadmill.

Both facilitatory and suppressive reflex responses with a latency of about 80 ms were observed following stimulation at 2 times perception threshold of all 3 nerves. In general, the responses for the 3 nerves are of the same order of magnitude. The pattern of the responses can be different, however. For example, the responses in biceps femoris (BF) were generally facilitatory during the whole step cycle, whereas responses in BF to tibial nerve stimulation at end swing were often suppressive. In tibialis anterior suppressions at end swing were observed in the response pattern for all three nerves. During the stance phase, however, a clear difference was found: generally no responses were found for sural and peroneal nerve stimulation, but large facilitatory responses were often found during mid to end stance for tibial nerve stimulation.

In conclusion, the low-threshold afferents from the 3 nerves, innervating the skin of the foot, have both excitatory and inhibitory pathways to various leg muscles. The phase-dependent reflex modulation can be different, presumably by adjusting the balance of activity in these opposite paths. This suggests the existence of differences in the reflex pathways for the different nerves, which can be controlled separately during the course of the step cycle.

EFFECTS OF THE SEROTONIN-2 AGONIST DOI ON S VS. F MOTONEURONS *IN VIVO*. R.H. Lee, J.F. Miller, W.Z. Rymer and C.J. Heckman*. Physiology, Northwestern Univ. Med. Sch. and VA, Lakeside Hospital, Chicago IL, 60611.

The orderly recruitment of motor units is largely due to systematic differences in the threshold currents (rheobases) of slow twitch (S) vs. fast twitch (F) motoneurons (MNs). Serotonin (5HT) agonists can greatly reduce rheobases and our goal was to investigate the relative amount of this decrease in rheobase in S vs. F MNs.

DOI, a 5HT-2 agonist, has long lasting actions *in vivo* (>2 hrs; see the companion poster by Miller et al.). The intrinsic properties of two populations of triceps surae MNs in the decerebrate cat were compared, one in control conditions and one following i.v. administration of DOI (0.5-1 mg/kg). The preparation was spinalized at T10 to eliminate the effects of descending 5HT tracts.

The average rheobase of the DOI population (8.2 nA; range: -8 to 21 nA; n=62) was significantly less (t-test, $p < 0.005$) than that of the control population (12.8 nA; range: 0 to 32 nA, n=42). DOI MNs with negative rheobases (n=12) had sustained rhythmic firing in the absence of any injected current. Negative rheobase MNs had slow conduction velocities (CVs) and were probably type S. However, the slopes of the regression lines for the rheobase-CV relations were not significantly different in the two populations, indicating that the effect of DOI was approximately the same in both S and F MNs. These data suggest that 5HT input can enhance the excitability of the motoneuron pool without altering its recruitment order.

DISYNAPTIC AUTOGENIC AND HETEROGENIC EXCITATION FROM GROUP I AFFERENTS IN HINDLIMB EXTENSOR MOTONEURONS DURING FICTIVE LOCOMOTION. M.J. Angel, P. Guertin, I. Jiménez¹ & D.A. McCrea. Dept. of Physiology, U. of Manitoba, Winnipeg, CANADA, R3E 0W3 and CIEA-IPN¹, MEXICO.

Stimulation of plantaris group I afferents during the extensor phase of fictive locomotion evokes disynaptic EPSPs in medial gastrocnemius motoneurons, thus replacing the inhibitory potentials evoked at rest (McCrea et al., Congr. Int. Union Physiol. Sci. 1993). The present investigation examines the distribution of disynaptic EPSPs from ankle extensor group I afferents to hindlimb extensor motoneurons during MLR-evoked fictive locomotion in the cat. During extension but not flexion, stimulation of ankle extensor nerves (single shocks, 1.5 times threshold) produced EPSPs in ankle and hip extensor motoneurons and in the bifunctional PBSt motoneurons (hip extensor + knee flexor). Autogenic excitation was also observed in ankle and hip extensor motoneurons during extension. The latencies of the EPSPs (1.1 - 1.9ms) suggest the opening of a disynaptic pathway from group I afferents to extensors during extension. The presence of group I autogenic and heterogenic, non-monosynaptic excitation is a functional reorganization of ankle extensor group I reflexes during locomotion. The switch from inhibition at rest to excitation during locomotion indicates recruitment of a previously undisclosed population of excitatory group I interneurons. Activation of these interneurons by group I afferents during overground locomotion would excite hindlimb extensor motoneurons and act as a positive feedback system enhancing centrally programmed extension. Supported by MRC & The Rick Hansen Legacy Fund.

DOES THE NERVE BRANCH PATTERN REFLECT A RE-MODELING WITHIN THE MOTONEURON POOL - MUSCLE COMPLEX OF OLDER RATS? S. Vanden Noyen*, N.K. Latham and M.H. Partidas. Sch. of Physical & Occupational Therapy, McGill Univ., Montreal, QC H3G 1Y5.

In this laboratory, the medial gastrocnemius (MG) motoneuron pool-muscle complex in rat (Sprague-Dawley; Fischer 344) is being used in various morphological and electrophysiological studies in order to further our understanding of the mechanisms underlying the function of aged motoneurons. The two extra-muscular nerve branches innervating the MG muscle in the Sprague-Dawley rat subserve a physiological and histochemical compartmentalization (Vanden Noyen et al., 1994). The afferent contribution to the two MG nerve branches has also been found to differ between rats of different ages (Vanden Noyen, 1993). In this study, dorsal root volleys (Group I stimulus strength) and the MG muscle nerve branch pattern was compared between young adult (n=5) and older animals (19-23 mo; n=5). Neural potentials, evoked by stimulation of the L4-L6 dorsal roots, were recorded from each of the two nerve branches. The MG muscle nerve branch pattern was more complex and the topographic distribution of DR afferents entering the spinal cord was disrupted in the older age group. Taken together with other data on motoneuron and muscle properties, results suggest that the MG complex undergoes a re-organization with age. (Supported by NSERC Canada).

EFFECTS OF THE SEROTONIN AGONIST DOI ON FORCES AND STRETCH REFLEXES OF THE DECEREbrate CAT. J.F. Miller*, K.D. Paul, W.Z. Rymer and C.J. Heckman. Physiology, Northwestern Univ. Med. Sch. and VA, Lakeside Hospital, Chicago IL, 60611.

5-HT-2 agonists produce subthreshold depolarizations of spinal motoneurons. Such actions should substantially increase the input-output gain of the motoneuron pool. We therefore investigated the effect of the 5HT 2A/2C agonist DOI on the reflex output of the triceps surae muscles in the precollular decerebrate cat preparation.

The stretch reflex and background force of extensors are greatly enhanced in the decerebrate cat. Intrathecal administration of DOI (1-5 μ mol, cumulative) further increased stretch reflex amplitude by 30-50%. Even more striking changes in background tension generation were observed. For example, soleus background force typically increased 2-4 fold after DOI, and in one experiment exceeded 20 N, which is near the maximal tetanic force for this muscle. Similar results were seen following i.v. administration of DOI (0.5-1 mg/kg).

The duration of DOI's actions by either route typically exceeded 120 min. Ketanserin (0.5-1 mg/kg i.v.) transiently reversed the effects of DOI for 30-45 min. In one experiment, the spinal cord was transected at T10, resulting in a great reduction in background force and stretch reflex amplitude. DOI (1 mg/kg i.v.) restored force and reflexes to their pre-spinalized level. These results show that serotonergic synaptic input can greatly enhance the output of the motoneuron pool.

BOTH DISYNAPTIC AND LONGER LATENCY INTERNEURONAL PATHWAYS MEDIATE EXTENSION ENHANCEMENT EVOKED BY GROUP I MUSCLE AFFERENTS DURING FICTIVE LOCOMOTION. P. Guertin*, M.J. Angel, I. Jiménez¹ and D.A. McCrea. Depts of Physiology, U. of Manitoba, Canada and CIEA-IPN¹, Mexico.

Trains of group I stimuli to ankle extensor nerves increase the amplitude and duration of extensor electroneurogram locomotor bursts (Guertin et al. Soc. Neurosci. 19:61.15, 1993). The present study examined the synaptic effects of group I stimulation intracellularly in motoneurons during MLR-evoked fictive locomotion. Plantaris nerve stimulation (1.5 times threshold; 20 pulses; 200Hz) during extension increased the amplitude and duration of hindlimb extensor motoneuron locomotor drive potentials (LDPs). The increase in LDP amplitude began within 10 ms after the first shock in the train and often continued well beyond the duration of the stimulus train. Accompanying the LDP enhancement, and depending on the preparation, were distinct disynaptic excitatory or other post-synaptic potentials following each stimulus pulse. In most cases, the depolarization produced by the LDP enhancement was larger than the disynaptic depolarizations. Since LDP enhancement occurred in the presence or absence of short latency EPSPs, multiple interneuronal pathways mediate group I reflex effects during fictive locomotion. Both disynaptic and longer latency group I excitation would increase motoneuron recruitment and enhance locomotor extensor bursts. These studies further support the hypothesis that ankle extensor group I afferents are part of a positive feedback system during locomotion that shapes the amplitude and duration of centrally programmed extensor bursts. Supported by the MRC and the Rick Hansen Legacy Fund.

STIMULATION OF THE GROUP I EXTENSOR AFFERENTS CAN PROLONG THE STANCE PHASE IN WALKING CATS. P.J. Whelan*, G.W. Hiebert, & K.G. Pearson. Dept. of Physiol., Univ. of Alberta, CANADA.

Group Ib afferents from extensor muscles exhibit a reflex reversal during locomotion that leads to excitation of the extensor motoneuronal pool. This excitation can prolong and enhance the extensor bursts during fictive locomotion. A question that arises is whether these excitatory actions are functionally relevant in a moving animal that is receiving phasic afferent inflow from many sources.

To address this issue, extensor nerves in the hindlimbs of decerebrate cats were stimulated, while the animals walked spontaneously on a treadmill. The ankle (Lg-Sol & Pl) and knee (Vi & Vi) extensor nerves were dissected, cut, and enclosed in stimulation cuffs. Stimulation of each nerve with trains (400-1500 ms duration, 200 Hz, 1.8 X T) during the extensor portion of the step cycle resulted in a prolongation of the extensor burst. Flexor burst initiation was delayed during stimulation but not always to the end of the stimulus volley. Stimulation during early flexion resulted in premature termination of the flexor burst and a delayed excitation of the extensors, followed by a reinitiation of flexion coincident with stimulus offset. When the stimulation intensity was reduced to sub threshold levels for each nerve, it was possible to stimulate two nerves simultaneously and elicit an increase in the extensor duration. This nonlinear summation suggests that regulation of the stance phase be partly regulated by group I afferents from many extensor muscles converging onto a common interneuronal pool.

Since the observed effects are similar to those attributed to group Ib afferents in reduced preparations, it is concluded that a reduction in force feedback from Ib extensor afferents is necessary for the initiation of the swing phase in a walking animal.

AUTOGENIC (IB) INHIBITION IN SITTING AND WALKING IN HUMANS. M.J. Stephens*, & J.F. Yang. Dept. of Physical Therapy and Div. of Neuroscience, University of Alberta, Edmonton, Canada, T6G 2G4

Recently, it has been shown that autogenic inhibition arising from group Ib afferents in extensor muscles is largely eliminated during walking in reduced cat preparations (Conway et al. 1987 Exp Brain Res 68:643, Pearson & Collins 1993 J Neurophysiol 70:1009). Instead, a longer latency autogenic excitation is seen. The purpose of this study was to determine whether this change is also apparent in humans. Putative Ib responses can be elicited by conditioning the soleus H-reflex with a stimulus to the medial gastrocnemius nerve at or just below motor threshold (e.g., Pierrot-Deseilligny et al. 1979 Brain Res 166:176). The response was observed both in quiet sitting and in the stance phase of walking. The inhibition during sitting, observed by others, was reproduced. Preliminary results indicate this inhibition was either reduced or eliminated in walking. Sometimes, this was replaced by excitation. Hence, qualitatively, the results support those obtained from the cat, but quantitatively, the effect was considerably more modest in the normal human.

THE EFFECTS OF A TONIC INCREASE OF PRESYNAPTIC INHIBITION OF MUSCLE SPINDLE AFFERENTS ON THE STRETCH REFLEX PARAMETERS OF THE CAT. C. CAPADAY* Centre de Recherche en Neurobiologie, Université Laval, Québec City, (Qué), Canada, G1J 1Z4.

Experiments were done in cats decerebrate at the precollular postmammillary level, or intercollicularly, to determine how a tonic increase of presynaptic inhibition of the intraspinal terminals of muscle spindle afferents changes the mechanical properties of the soleus stretch reflex (s.r.). Baclofen, a specific GABA_B receptor agonist, was injected i.v. (1mg/kg) so as to induce a tonic increase of presynaptic inhibition. The effects of Baclofen on the stiffness and threshold of the s.r. were determined from plots of stiffness vs. background force and force vs. length (length-tension plot), respectively. Baclofen, at these doses, had no effect on the excitation-contraction coupling properties of muscle, or on the intrinsic stiffness-force relation. Changes of the soleus background force, required to obtain the stiffness vs. force plots, were produced by stimulation of the contralateral common peroneal nerve or the posterior tibial nerve and occasionally by electrical stimulation in the area of the red nucleus. The stiffness of the s.r. as a function of the background force level was determined by stretching the muscle with a square pulse of 1-2mm amplitude and 200-300ms duration. The length-tension relation of the soleus stretch reflex was determined by stretching the muscle 12-17 mm at a constant rate of 1-2mm/s. Baclofen produced a significant decrease (40% or more) of the s.r. stiffness within 10-15 mins of injection as determined from the stiffness-force plots. The length-tension plots revealed that the decrease of s.r. stiffness was always accompanied by an increase of the s.r. threshold (typically 3-4mm). Therefore, the s.r. threshold is not an independent variable, it depends on the level of presynaptic inhibition on the muscle spindle afferent terminals. It is concluded that it may be possible for the CNS to adaptively modify the s.r. stiffness via presynaptic inhibition of the intraspinal terminals of muscle afferents. However, any such change of s.r. stiffness will be accompanied by a change of the s.r. threshold. Supported by MRC of Canada.

POSITIVE FEEDBACK OF MUSCLE CONTRACTION IN CAT PERONEAL MOTONEURONS J.-F. Perrier, N. Kouchir, D. Zytynicki and L. Jami* URA CNRS 1448, UFR des Saints-Pères, 75270 Paris, France.

Motoneurons supplying peroneal muscles were recorded in anesthetized cats during sustained isometric contractions of peroneus brevis (PB) produced by stimulation of cut ventral root filaments. In contrast with the declining inhibition previously observed in triceps surae motoneurons during contractions of gastrocnemius medialis (1) the afferent input generated by PB contractions elicited excitatory potentials (EPSPs) in peroneal motoneurons. These EPSPs were ascribed to spindle afferents because 1) their amplitudes increased when ventral root stimulation strength was raised to recruit γ axons; 2) with stimulation under γ threshold, PB contraction still excited peroneal motoneurons and evidence was obtained that activation of spindles by B-axons accounted for this excitation. The lack of contraction-induced inhibition in peroneal motoneurons and the prevalence of contraction-induced excitation raise the possibility that, in contrast to the usual effects of tendon organ afferents, Ib fibers from PB might excite peroneal motoneurons. The fact that electrical stimulation of group I afferents in PB nerve only exceptionally evoked inhibition in peroneal motoneurons would appear compatible with this hypothesis. Further, stimulation of cutaneous afferents, known to facilitate transmission in Ib pathways, only exceptionally revealed a contraction-induced inhibition. The functional significance of a positive feedback of PB contraction on peroneal motoneurons is probably related to the complex biomechanical operations of peroneal muscles in preservation of foot contact with support.

WALKING AND TONIC CONTRACTIONS WITHOUT ACTIVITY IN γ -MOTONEURONS IN CLONIDINE AND NALOXONE TREATED CATS. D.J. Bennett*, S.J. De Serres & R.B. Stein. Div. of Neuroscience, Univ. of Alberta, Edmonton, Canada, T6G 2S2.

Recordings in both awake chronic cats and acute cats show that activity of γ -motoneurons can occur without α -motoneuron activity (Prochazka, 1989, Prog. Neurobiol. 33:281-307). The γ -motoneurons have a lower threshold for recruitment, so γ -motoneurons are often activated tonically with only phasic α activity. We present evidence here that just the opposite recruitment can occur in the soleus muscle of decerebrate cats treated with the noradrenergic agonist clonidine (50 μ g/kg) and the opioid antagonist naloxone (25 μ g/kg). In this preparation α -motoneurons are often recruited without apparent activation of γ -motoneurons. The γ drive was inferred from recordings of muscle spindle group Ia and II afferents. The rate of firing in these afferents dropped markedly during a contraction elicited by a crossed-extensor stimulus, indicating that the extrafusal muscle contraction had unloaded muscle spindles. When evidence for γ drive was seen, it was weak and of a γ static type, as indicated by the slight increase in Ia firing and decrease in sensitivity to stretch (4 Hz sinusoid, 0.25 mm). A similar finding of unloading of muscle spindles due to lack of γ drive was found in the same cats during locomotion produced after spinalization. Thus, both phasic and tonic contractions can occur without corresponding activity in γ -motoneurons.

This research was supported by MRC and AHFMR of Canada.

HETEROGENEOUS REFLEXES AMONG MUSCLES OF THE CAT'S FORELIMB. D.A. Backus, B.J. Silverstein, and T.R. Nichols*. Dept. of Physiology, Emory University, Atlanta, Ga 30322.

Previous results have shown that muscles that provide weight-bearing and postural stabilization in the cat hindlimb are linked by powerful force-dependent and inhibitory reflexes, including reciprocal inhibition, Ib inhibition, and long latency inhibition (Nichols, 1989, J. Physiol.: 463-477). Initial studies in decerebrate cats show that all 3 types are also observed in the muscles of the elbow and wrist of the cat forelimb. In addition, the forelimb musculature demonstrates similar reflex organization whether activated via peripheral stimulation or brainstem stimulation. Elbow flexor muscles appear to be linked by mutual inhibition, with latencies ranging from 20 to 70 ms. In addition, Extensor Digitorum Communis receives excitatory input from Extensor Digitorum Longus, which is consistent with findings regarding Ia afferents between these muscles. These findings suggest that reflex patterns exhibited in cat hindlimb muscles may also exist in forelimb muscles. Supported by NS20855 to TRN.

THE INNERVATION OF THE DORSAL AND VENTRAL HORNS OF THE RAT SPINAL CORD BY AXONS DESCENDING FROM THE LOCUS COERULEUS/SUBCOERULEUS COMPLEX AND A5 CELL GROUP. M. Antal*, E. Polgár and A. Cs. Berki. Department of Anatomy, University Medical School, Debrecen, H-4012 Hungary.

The spinal projections of noradrenergic brainstem nuclei that influence complex sensory and motor activities in the spinal cord were studied in the rat by using the anterograde neural tracer Phaseolus vulgaris leucoagglutinin (PHA-L). After injecting PHA-L unilaterally into the nucleus coeruleus, nucleus subcoeruleus and A5 cell group, labelled fibers and terminals were detected at cervical, thoracic as well as lumbar segments of the spinal cord. Most of the terminals (60-80%) from all three nuclei were found in the ventral horn (laminae VII-IX). The superficial dorsal horn (laminae I-IV) received a relatively sparse innervation from the locus coeruleus and A5 cell group. The subcoeruleus complex, however, projected more intensively to the dorsal horn. More than 30% of the terminals arising from the subcoeruleus complex were revealed in laminae I-II at the level of thoracic and lumbar segments on both sides of the spinal cord.

To study the postsynaptic targets of these descending fibers sections were stained for both PHA-L and calbindin-D28k (CaB), a calcium-binding protein that have been reported to be markers of certain subsets of spinal neurons including stalked cells and supraspinally projecting neurons in the dorsal horn and Renshaw-cells in the ventral horn. All of the aforementioned types of CaB-immunoreactive neurons were found to receive contacts from fibers descending from the investigated noradrenergic brainstem nuclei. Synaptic contacts of terminals in laminae I-II and laminae VII-IX as well as GABA and glycine immunoreactivities of their postsynaptic targets were also investigated in a correlative electron microscopic study.

649.3

DORSAL BORDER PERIAQUEDUCTAL GRAY NEURONS PROJECT TO THE SPINAL CORD IN THE CAT. L. J. Mouton*, L. Kerstens and G. Holstege. Dept. Anatomy and Embryology, Faculty of Medicine, Rijksuniversiteit Groningen, The Netherlands.

The mesencephalic periaqueductal gray (PAG) plays an important role in many different functions, such as the regulation of pain, cardiovascular control, vocalization and micturition. In the previous tracing study in the cat (Mouton and Holstege, 1994) HRP injections in the upper thoracic and cervical spinal cord resulted in many strongly labeled neurons in the ventrolateral PAG, but also a few faintly labeled small neurons were found at the border between the dorsal PAG and the adjacent intercollicular zone. Nothing is known about the pathway or the function of these small dorsal border PAG-spinal neurons. The purpose of the present retrograde and anterograde tracing study was to exactly describe this dorsal border PAG-spinal pathway.

In nine cats WGA-HRP was injected in the spinal cord, each at a different spinal level. Prior to the injection a hemisection was made rostral to the injection site. In order to identify and count the retrogradely labeled PAG neurons every fourth 40 µm transverse section of the brainstem was incubated using the TMB method. In an anterograde tracing study WGA-HRP injections were made in the area which contained the small dorsal PAG-spinal neurons.

Results show that there exist several hundreds of relatively small neurons at the dorsal border of the subpretectal PAG projecting to the cervical and thoracic spinal cord. Only a few dorsal border PAG neurons seem to project to the lower lumbar cord, while almost one hundred neurons project to the sacral spinal cord. The neurons project ipsilaterally to the area immediately surrounding the central canal, but not corresponding to lamina X. Further electronmicroscopic studies are needed to more precisely reveal the nature of this pathway.

649.5

EFFERENT CONNECTIONS OF THE DEEP MESENCEPHALIC NUCLEUS: A PHA-L STUDY IN THE RAT. M. GOTO, M. COSTA, A. PERACOLI AND S.J. SHAMMAH-LAGNADO*. Dept. of Physiol. & Biophys., Inst. Biomed. Sci., Univ. of São Paulo, SP, 05508-900, Brazil.

The deep mesencephalic nucleus (DP) is an extensive territory included in the mesencephalic reticular formation. In 32 rats small deposits of *Phaseolus vulgaris* leucoagglutinin (PHA-L) were placed in the DP. Striking differences were noted in the projections of different DP regions to the thalamus, zona incerta, superior colliculus, accessory oculomotor nuclei, periaqueductal gray substance, reticular formation, precerebellar and cranial motor nuclei. Thus, the reticular and central lateral thalamic nuclei, ventrolateral geniculate, intergeniculate and subgeniculate nuclei, zona incerta, anterior pretectal nucleus and superior colliculus (superficial layers) are targeted mainly by ventral DP districts (Olszewski and Baxter's ('54) nucleus subcuneiformis); the central medial, paracentral and mediodorsal (ventrolateral sector) thalamic nuclei, superior colliculus (intermediate and deep layers) and periaqueductal gray, chiefly by dorsal DP districts; the rostral interstitial nucleus of the medial longitudinal fascicle, medial accessory oculomotor nucleus and inferior olive, primarily by medial DP districts; and whereas the rostradorsal DP innervates the parvocellular reticular formation, the remaining DP districts terminate mainly in the magnocellular ventromedial reticular formation.

These hodological data stress the heterogeneous character of the DP and provide an anatomical foundation for its participation in arousal, visuomotor functions and rhythmic jaw movements. (Supported by FAPESP grant 91/0450-5)

649.2

PUDENDAL MOTONEURON AXON COLLATERALS AS REVEALED BY INTRACELLULAR INJECTION OF TETRAMETHYL RHODAMINE-DEXTRAN. S.J. Shefchyk*¹, P.A. Carr¹, M.-C. Perreault¹, J. Jimenez² & B. Segura³. Depts. Physiol., Univ. of Manitoba¹, Canada, R3E 0W3, CIEA-IPN², and Iztacala, UNAM³, Mexico.

Previous reports have described some of the anatomical characteristics of sacral motoneurons innervating the external urethral and anal sphincters in cat (Beattie & Bresnahan, Neurosci. Lett. 1990, 111:69; Thor et al., J. Comp. Neurol. 1989, 288:263). The present study uses intracellular injection of the fluorescent dye tetramethylrhodamine-dextran (TMR-D) into individual external urethral or anal sphincter motoneurons in the cat to determine if these motoneurons have axon collaterals. In chloralose anaesthetized male cats, single pudendal motoneurons were impaled with glass microelectrodes containing 2% TMR-D (3000 MW) in 0.9% saline. The cells were then injected with dye using 27 to 69 nA x min. of depolarizing current. Following a minimal post-injection interval of two hours, cats were perfused with an aldehyde-based fixative and the lumbosacral spinal cord removed for post-fixation and subsequent cryoprotection. The tissue was then sectioned at 30 µm and examined using standard epifluorescence microscopy. Five of the eight urethral and anal pudendal motoneurons examined had axon collaterals which branched from the primary axon near the ventral spinal white matter. This anatomical evidence suggests that some type of recurrent system from these motoneurons exists in cat, perhaps similar to those observed in rat (W. Collins III, pers. comm.). No physiological evidence has been found for the presence of recurrent inhibitory connections to cat pudendal motoneurons (Jankowska et al., J. Physiol. 1978, 285:425; Mackel, J. Physiol. 1979, 294:105) such as described for hindlimb motoneurons. Both the target neurons and the functional significance of these collaterals have yet to be determined. Funded by the Medical Research Council of Canada.

649.4

DIRECT PROJECTIONS FROM THE NUCLEUS RETROAMBIGUUS TO HINDLIMB MOTONEURONS: A COMBINED ELECTRON- AND LIGHTMICROSCOPIC STUDY IN THE CAT. Veronique G.J.M. VanderHorst*, Henk DeWeerd and Gert Holstege. Department of Anatomy, University of Groningen, The Netherlands

The nucleus retroambiguus (NRA) is a compact group of interneurons in the caudal medullary lateral tegmental field. It receives a strong and specific projection from the periaqueductal gray (PAG). NRA interneurons are known to project to motoneurons innervating the pharynx, larynx, intercostal, and abdominal wall muscles. These PAG-NRA-motoneuron projections are involved in vocalization, an example of specific emotional behavior. Apart from the projections related to sound production, the NRA also appears to project directly to specific groups of L4-S2 motoneurons innervating iliopectors, adductor, hamstring, and proximal tail muscles. This combined light- and electronmicroscopic study was done to obtain direct evidence for monosynaptic projections from the NRA to the lumbosacral motoneurons. To anterogradely label NRA axons, in four cases injections of wheat germ agglutinin horseradish peroxidase (WGA-HRP) were made in the NRA. In two of these cases plain HRP was injected in hamstring muscles to retrogradely label motoneurons receiving projections from the NRA. After a three day survival time, the animals were perfused and lumbosacral segments were cut on a vibratome into 60 µm sections. All sections were processed for either electron- or lightmicroscopy using TMB as chromagen. The results show that NRA terminals form asymmetrical contacts on proximal dendrites of lumbosacral hamstring motoneurons. The terminals contain mainly spherical vesicles, which implicates the direct NRA-motoneuron projections to be excitatory. The direct NRA-hamstring motoneuron projection might be part of a PAG-NRA-lumbosacral motoneuronal pathway, possibly involved in mating behavior (called lordosis in females).

PHA-L ANALYSIS OF ASCENDING PROJECTIONS FROM THE MEDIAN RAPHE NUCLEUS IN THE RAT. William J. Fortin* and Robert P. Vertes. Center for Complex Systems, Florida Atlantic University, Boca Raton, FL 33431.

The median raphe nucleus (MR) is directly involved in the desynchronization of the hippocampal EEG. The present study was carried out primarily to examine MR projections to the hippocampus (HP) and associated structures as well as to the neocortex. The projections of the MR have not previously been examined with the PHA-L technique. Detailed analysis was carried out on 16 rats with single injections correctly placed in the MR.

At the level of the brainstem, MR was shown to project heavily to the lateral dorsal tegmental n., pedunculopontine tegmental n. (PPT), central gray, interpeduncular n., ventral part of n. pontis oralis/B9 area and the ventral tegmental n. Light terminal labeling was seen in the substantia nigra, pars compacta. Within the forebrain, the supramammillary n. (SUM), medial mammillary body, lateral habenula, posterior hypothalamus, central lateral n. of the thalamus, vertical limb of the diagonal band and the medial septum (MS/DB) were densely labeled. There was also light labeling in the dorso-lateral septum. The MR also projected heavily to the HP, mainly to the stratum lacunosum-moleculare of Ammon's horn and to the granule cell layer of the dentate gyrus. Light to moderate labeling was observed in the entorhinal cortex, n. accumbens, cingulate cortex and frontal cortex.

These findings indicate that MR influences the HP directly as well as indirectly through intervening nuclei including the PPT, SUM and MS/DB complex, each of which is known to influence the hippocampal EEG.

Supported by grants to WJF (Bryan W. Robinson Neurological Foundation, Tallahassee FL and Sigma Xi, The Scientific Research Society) and to RPV (NIMH grant MH45075).

ANATOMICAL AND IMMUNOCYTOCHEMICAL CHARACTERIZATION OF MASSETERIC EFFERENT NEURONS OF CELL GROUP K IN THE RABBIT. M. Saad, C.G. Widmer*, S. Lepage, D. Umbriaco, K.G. Westberg, R. Dubuc and J.P. Lund. Centre de recherche en sciences neurologiques, Univ. de Montréal, Montréal, Canada H3C 3J7; Dept. of Oral Surgery, Univ. of Florida, Gainesville, Dep. de Kinanthropologie, Univ. du Québec à Montréal.

It has been shown that efferent neurons supplying the masseter and digastric muscles of the rabbit are located in two brain stem nuclei: the trigeminal motor nucleus (mot V) and Cell group k (group k), a series of three cell columns ventrolateral to mot V. We have now conducted two series of experiments to characterize the masseteric efferent neurons of group k. In the first, retrograde labelling with fluorescent dyes (fluorogold and fastblue) was used. The dyes were applied to the central ends of cut branches of the masseteric nerve and animals were killed after 8 days. We found that the nerve branches to superficial, intermediate and deep layers of the muscle are all represented in group k, and that the efferent neurons to these branches are intermingled. As a first step towards understanding the function of group k neurons, their immunoreactivity to choline acetyltransferase (ChAT), a specific marker for cholinergic neurons was tested. Animals were anesthetized and perfused. After fixation, serial vibratome coronal sections of the brain tissue were cut at 50µm. Free floating sections were treated with a ChAT monoclonal antibody (Code AB8), using the avidin-biotin peroxidase method. Like mot V, the vast majority of cells in group k were immunostained and were of the same size and shape as retrogradely labelled neurons. This suggests that neurons of group k are cholinergic and are likely to be motoneurons. However, group k neurons are fusiform and smaller in size (mean diameter=31µm) than mot V cells, which are round or ovoid (mean diameter=44µm). This suggests that Cell group k neurons supplying the masseter muscle could be gamma motoneurons; but this is contradicted by the fact that the digastric muscle, which contains no muscle spindles in the rabbit, is also innervated by this nucleus.

POPULATIONS OF MYELINATED NERVE FIBRES IN THE DORSAL AND VENTRAL ROOTS OF THE LUMBOSACRAL ENLARGEMENT IN THE OPOSSUM, *MONODELPHIS DOMESTICA*. H. Leblond and T. Cabana*. Sciences Biologiques, Université de Montréal, C.P. 6128, Succ. Centre-Ville, Montréal, Canada, H3C 3J7.

A light microscopic study of the dorsal and ventral roots at the lumbosacral enlargement of the spinal cord was made in the opossum in order to establish the total number of myelinated fibres and their size distribution. Dorsal and ventral roots were removed from deeply anesthetized animals and were immersed overnight in 2% glutaraldehyde - 2.5% paraformaldehyde in cacodylate buffer (pH 7.3). The tissue was rinsed, postfixed for 4 hours with 1% osmium, rinsed again, dehydrated in graded ethanol and embedded in Spurr Mixture. Semithin (1µm) sections were cut from the proximal part of the roots, stained with toluidine blue and dried. They were photographed so as to obtain a montage of the whole root section. An average of 809 ventral root fibres are myelinated. They can be divided in two populations: small fibres having a mean diameter of 6±2µm (42%), and large fibres having a mean diameter of 18±4µm (58%), myelin sheaths included. An average of 2450 dorsal root fibres are myelinated. They are distributed in three populations: a population of small and poorly myelinated fibres with a mean diameter of 4±2µm (38%), a second population of fibres with mean diameter of 12±4µm (51%), and a third population of large caliber fibres with a mean diameter of 20±3µm (11%). These data will serve as an endpoint to a developmental study of myelogenesis of the spinal cord in the *Monodelphis* opossum. (Supported by NSERC.)

ENCODING OF LIMB GEOMETRY BY SPINOCEREBELLAR NEURONS. G. Bosco and R.E. Poppele*. Dept. of Physiology, University of Minnesota, Minneapolis, MN 55455.

Only in the recent past has attention been devoted to the integrative features of second order sensory neurons. The dorsal spinocerebellar tract (DSCT) represents a good model to investigate this process in a sensory-motor system because recent evidence suggests that it may convey to the cerebellum a complex signal related to parameters of movement for the whole limb, in particular, the direction of limb displacement (Bosco & Poppele, J. Neurophysiol., 1993, 70: 863). It has also been suggested that a directional coding by this population of cells, constitutes a reference frame which may relate to limb geometry, namely its length and the orientation of the limb axis.

We explored this possibility by recording from DSCT neurons following perturbations of the hindlimb in four directions (up, down, forward and back) from two initial positions characterized by different limb geometries. The result was that directional preferences were more closely related to the orientation of the limb axis than to the extrinsic vertical. In fact, the mean population vectors, computed by applying Raleigh statistics to the distribution of the cells' preferred directions, differed in the two experimental conditions by 15.75°±5.88 SD, which corresponded to the difference in limb axis orientations. This finding suggested a rotation of the mean population vectors consistent with the tilting of the limb axis. Indeed translating the mean vectors' directions from extrinsic cartesian coordinates to limb axis coordinates reduced the phase difference to 5°±6.2 SD. (Supported by N.I.H. grant NS 21143).

THE BRAINSTEM IMAGE OF A PRIMATE HAND NERVE. X-F Wu*, S.K. Rasey, and J.T. Wall. Department of Anatomy, Medical College of Ohio, Toledo, OH 43699.

The primate hand is innervated by the ulnar, median, and radial nerves. Inputs from each nerve dominantly activate band or patch-like aggregates of neurons in the cortical area 3b map of the hand. The shapes and extents of these aggregates are similar in different normal monkeys. To begin study of the ascending anatomical substrates that underlie these aggregates, horseradish peroxidase conjugates were injected into the ulnar nerve near the wrist, and three dimensional reconstructions of labeled terminations were made from serial sections through the brainstem. Brainstem label was restricted to divisions of the cuneate nuclei. Dense label was distributed in a continuous manner across the rostral, central (pars rotunda and triangularis), and caudal divisions of the main cuneate nucleus. Sparse label sometimes extended to the border region between the main and external cuneate nuclei. Within the pars rotunda, labeled terminations were consistently dense in medial and mediodorsal locations, with less dense fringes extending laterally and ventrally. The observed pattern of label was similar in different monkeys. The peripheral receptors of ulnar nerve sensory fibers innervate a continuous territory on the ulnar side of the hand. The central terminals of ulnar nerve fibers, in turn, are consistently shaped as a continuous, rostrocaudally elongated substrate in the main cuneate nucleus. It is suggested that the shape and extent of this substrate contributes to the shape and extent of the handlike ulnar nerve dominance aggregate in the hand cortex. Supported by NS21105.

THE PROJECTION OF PHYSIOLOGICALLY IDENTIFIED JAW-MUSCLE SPINDLE AFFERENTS TO THE CAUDAL BRAINSTEM USING INTRACELLULAR BIOTINAMIDE. R. Wong*, P. Luo and D. Dessem*. Dept. Physiol., U. Maryland Dental Sch., Baltimore, 21201

Jaw-muscle spindle afferents were physiologically identified and intracellularly stained with biotinamide in rats. Rostrally, these axons projected to the trigeminal motor nucleus, supratrigeminal region, mesencephalic trigeminal nucleus and dorsomedial part of the principal sensory nucleus as reported in previous studies. Additional, previously undescribed jaw-muscle spindle projections to the caudal brainstem were also found. Axon collaterals with boutons emerged from the tract of Probst and projected to the dorsomedial part of spinal subnuclei oralis (Vodm) and interpolaris (Vidm), the parvocellular reticular formation (PCRF) of the caudal brainstem, laminae IV and V of the spinal trigeminal subnucleus caudalis (Vc) and the dorsal division of the medullary reticular nucleus (Mdd). Labeled axon collaterals in the caudal Vodm formed a dense reticular distribution. Labeled spindle boutons in Vodm formed predominately axo-dendritic synapses. Some of these boutons received presynaptic inputs from unlabeled boutons containing type 'S' and 'F' vesicles. In Vidm, labeled collaterals and boutons were densely clustered into glomerular-like structures which surrounded individual or small groups of neurons. Labeled boutons in Vi made axo-dendritic, axo-somatic and axo-axonic synapses and received synaptic contacts from unlabeled boutons containing either type 'S', 'F' or dense core vesicles. Axon collaterals in Vc were much sparser and simpler than in Vidm. Labeled boutons mainly formed synaptic contacts with large diameter dendrites in the neuropil of Vc. Synaptic convergences between labeled boutons and multiple unlabeled boutons were often encountered contacting the same dendrite in Vc. Supported by NIH DE10132.

BRAINSTEM DISTRIBUTION OF C-FOS IMMUNOREACTIVITY FOLLOWING REPETITIVE COUGHING IN DECEREBRATE CATS. C. Gestreau, F. Portillo, M. Yousfi, J.J. Puizillout, A.L. Bianchi* & L. Grélot. URA CNRS 1832, St Jérôme, 13397 Marseille Cedex 20; (1) CNRS-LNB, 13402 Marseille Cedex 20, France (Spon: ENA)

Using the expression of the immediate early gene *c-fos* as a marker of neuronal activation, we compared in the brainstem of cats the pattern of distribution of cells exhibiting a *Fos*-like immunoreactivity (FLI) in response to repetitive coughing (i.e. stimulated animals) to that observed in sham operated animals. In decerebrate, paralyzed and ventilated cats, 100 to 250 coughing episodes were elicited by stimulation (1-3 V, 0.4 ms, 2-4 Hz, 45 min) of superior laryngeal nerves (SLN), applied 4 hours after surgery was completed. Coughing was monitored on the phrenic and ilio-hypogastric neurograms. Brainstem tissues were immunoprocessed using an antibody recognizing both the *fos* and *fos*-related nuclear antigens, and the avidin-biotin peroxidase complex. In the brainstem of stimulated cats, intense FLI was observed in various subnuclei (i.e. commissural, lateral, ventrolateral, medial and dorso-medial) of the nucleus tractus solitarius, the ambiguous and retrofacial nuclei, the ventral aspect of the medial accessory inferior olive, the retrotrapezoid nucleus, the inferior central (raphe) nucleus and the locus caeruleus. In these regions only very weak or none FLI was evidenced in control cats. FLI in the medullary reticular formation and in the pontine lateral and medial parabrachial nuclei was only augmented in experimental cats.

RETICULOSPINAL NEURONS AND THEIR SPINAL PROJECTIONS IN LAMPREYS: A STUDY USING RETROGRADE TRACERS. N. Bussi  res* and R. Dubuc. D  p. de kinanthropologie, UQAM H3C 3P8 and Centre de recherche en sciences neurologiques, Universit   de Montr  al H3C 3J7 Canada.

As in other vertebrates, lamprey reticulospinal (RS) neurons play an important role in the supraspinal control of locomotion. In the present study, retrograde tracers were used to study the organization of RS lamprey neurons within the different reticular nuclei and to characterize their spinal projections in adult *Ichthyomyzon unicuspis*. Cobalt-lysine was applied *in vitro* to the rostral end of the spinal cord (n=30), or applied iontophoretically to label descending cells projecting to specific spinal cord tracts (n=10). Another tracer, horseradish peroxidase (HRP), was applied at the 12th, 40th, 57th and 88th spinal cord segments and transported *in vivo* in order to determine the length of the axonal projections of RS cells (n=28). Retrogradely labelled cells were counted from serial sections on the best specimen for each injection site and their soma was measured. 3-D computer reconstructions were made of each reticular nucleus. A total of 1299 RS neurons were counted on one side. The posterior rhombencephalic reticular nucleus (PRRN) contains the largest number of RS cells (845), 21% (177) of which project to the contralateral spinal cord and are located mainly in the caudal end of the nucleus. The middle rhombencephalic reticular nucleus (MRRN) contains fewer RS neurons (339), 18% (60) of which project contralaterally and are found predominantly in the lateral basal plate. Of the 90 RS neurons counted in the anterior rhombencephalic reticular nucleus (ARRN), 27% (24) project to the contralateral spinal cord. They are intermingled with cells projecting to the ipsilateral side. Finally, the mesencephalic reticular nucleus (MRN) contains 102 neurons, projecting their axon exclusively to the ipsilateral spinal cord. Iontophoretic application of cobalt-lysine to the lateral tract on one side labelled, on both sides, a higher proportion of cells in the PRRN (63%) than in the other nuclei (MRRN=91, ARRN=1, MRN=1). Spinal cord injections at the 12th segment labelled 716 RS cells, with a steep (63%) decrease in the number of small (less than 20 μ m) RS cells counted as compared to injections in the 2nd spinal segment. Injections at the 40th (first dorsal fin), 57th (second dorsal fin) and 88th segments (tail) labelled a gradually decreasing number of neurons with only 10% (138) of all RS cells projecting to the level of the tail and distributed predominantly in the PRRN (96) and the MRRN (33). Results from this study reveal a higher number of RS cells than previously reported, with a noticeable (20%) component of contralaterally projecting cells. (Supported by MRC, FCAR, FRSQ and NCE for neural regeneration and recovery).

PROJECTIONS FROM THE RAT SPINAL TRIGEMINAL SUBNUCLEUS ORALIS TO THE SPINAL CORD STUDIED WITH THE PHA-L METHOD.

R. Dallei, P. Raboisson, J. Pajot, C. Aigouy, and A. Woda. (SPON: European Neuroscience Association*). Lab. de Physiologie Oro-faciale, Faculty of Dentistry 63000 Clermont-Ferrand (France).

Subnucleus oralis (Sp5O), the rostral subdivision of the spinal trigeminal nucleus has been reported to project to the spinal cord in the rat, but the precise locus of termination of this descending pathway is unknown. This location was examined using the anterogradely transported Phaseolus Vulgaris Leucoagglutinin (PHA-L).

Male Sprague-Dawley rats were anaesthetized with chloral hydrate and PHA-L was electrophoretically injected into either the ventrolateral or the dorsomedial region of the Sp5O. Two weeks later, the rats were perfused transcardially, the brain and the spinal cord were removed and cut in serial sections which were reacted with PHA-L antibody and ABC complex.

Spinal projections from the ventrolateral part of Sp5O were found in the ventral horn (lamina IX) of the whole cervical cord, bilaterally but with a clear contralateral dominance. The highest density of labelling was at the C2-C4 level. Projections to the dorsal horn were only ipsilateral. The labelling (lamina V) was of medium density at the C1 level and progressively decreased up to the C4 level. Projections from the dorso-medial part of Sp5O to the ventral horn (lamina IX especially) were of lower density than after injection into the ventrolateral part of Sp5O. Labelling was bilateral with ipsilateral dominance and only observed from C1 to C4 level. Labelled terminals were also noted in the ipsilateral dorsal horn (lamina III-V) especially at the C1 level. No labelled terminal was observed in the lower thoracic and lumbar cord.

Our findings are consistent with the hypothesis that Sp5O is involved in the integration of head and neck motor functions. However, observation that Sp5O projects to the dorsal horn suggest that this nucleus could also contribute to modulation of incoming sensory information at the spinal level.

GAP JUNCTIONS ON SOMATA, DENDRITES AND CHEMICAL SYNAPSES OF MAPPED NEURONS IN RAT SPINAL CORD

J. E. Rash*, R. K. Dillman, L. R. Whalen, P. B. Guthrie, D. W. Wheeler, and H. S. Duffy. Dept. of Anatomy and Neurobiology, Colorado State University, Fort Collins, CO 80523

"Grid-mapped" freeze-fracture was modified to allow mapping of gap junctions (GJs) to individual neurons in histological slices of adult rat spinal cord. After freeze-fracture replication, each sample was immobilized in a Lexan film on a gold "Finder" grid, thawed, and the replica plus attached tissue was mapped in three dimensions by confocal microscopy. To date, we have used this technique to identify a total of thirty-six neuronal GJs on twelve mapped motor neurons and interneurons in Rexed Laminae VI, VII, VIII, and IX. GJs were found on neuron somata, on basal, proximal, and distal dendrites, and on "synaptic plateaus" of chemical synapses. Most neuronal GJs contained fewer than 50 connexons (range = 6-800 connexons). GJs were present at an overall density of approximately 1/30 μ m² of neuronal plasma membrane, implying that the average neuron in rat ventral horn contains several hundred to several thousand GJs. Since most neuronal GJs are less than 0.06 μ m in diameter, they were too small to be detected by previous thin section TEM methods. Likewise, because most GJs on spinal cord neurons are small, they contain few antibody binding sites, and thus, would not be detectable by conventional immunocytochemical staining techniques. Grid-mapped freeze fracture has permitted identification and precise mapping of GJs on neurons in adult rat spinal cord.

Supported by NIH Grant # NS-39503.

THREE-DIMENSIONAL DENDRITIC ANALYSIS OF RAT PHRENIC MOTONEURONS DURING POSTNATAL GROWTH.

K.G. Smithson*, Y.S. Prakash and G.C. Sieck. Departments of Anesthesiology and Physiology, Mayo Foundation, Rochester, MN 55905.

The rapid growth of diaphragm muscle fibers between postnatal day 21 (D21) and adulthood may also be reflected by growth of phrenic motoneurons and their dendritic arborization. Concurrent growth of the spinal cord may also induce changes at the dendritic level, in order to properly integrate descending synaptic input. In the present study, qualitative and quantitative features of rat phrenic motoneuron dendritic morphology were examined in D21 and adult animals. Cholera toxin B-fragment was used to retrogradely label phrenic motoneurons. Computer-assisted three-dimensional neuromorphometry was used to statistically summarize dendritic branching patterns. While these analyses broadly confirmed previous qualitative observations on rat phrenic motoneurons, several new features were highlighted. For example, contralateral projections of dendrites were more frequent in D21 animals than in adults. Dendritic diameter was smaller in D21 compared to adults. Total dendritic lengths were shorter at D21, and showed less variability compared to adults. Branching angles of D21 dendrites were also greater compared to adults, suggesting a re-orientation of dendrites during growth. This was also reflected by smaller receptive areas of motoneurons at D21. Receptive areas at D21 also showed smaller variance compared to adults, indicating a differential growth of motoneurons. However, when normalized for spinal cord growth, receptive areas were not different between the two ages. We conclude that these morphological changes may contribute to changes in motoneuron recruitment during growth. (Supported by NIH grants HL37680, HL34817 and GM08288.)

BRAINSTEM PROJECTIONS TO THE SUPRAMAMMILLARY NUCLEUS AND MEDIAL MAMMILLARY BODY: A WGA-HRP TRACING STUDY.

J.S. Thinschmidt, A.M. Crane, K.S. Panicker* and R.P. Vertes. (1) Dept. of Neuroscience, Univ. of Florida College of Medicine, Gainesville, FL 32610 and (2) Ctr. for Complex Systems, Florida Atlantic Univ., Boca Raton, FL 33431.

We have recently shown that a subset of cells of the supramammillary nucleus (SUM) and mammillary body (MB) discharge synchronously with the hippocampal theta rhythm (Kocsis and Vertes, *J. Neurosci.*, in press). Recent findings indicate that the theta-related cells of SUM may control the frequency of the theta rhythm (Kirk and McNaughton, *Hippocampus* 3:517, 1993). With the exception of a single recent report by Hayakawa et al. (*Anat. Embryol.* 188:139, 1993), afferents to SUM have not been examined. The present report examined brainstem afferents to the SUM as well as to the medial MB in the rat.

Under sodium pentobarbital anesthesia, single pressure injections of WGA-HRP (25-30 nl of 3% WGA-HRP) were made into the SUM (10 rats) and MB (5 rats). The HRP reaction procedure was the same as described previously (Vertes, *Neuroscience* 24:907, 1988). Injections in either site gave rise to labeled cells that were essentially restricted to the upper brainstem (pons and midbrain). In the caudal pons, labeled cells (with SUM or MB injections) were mainly seen within nuclei imbedded in the pontine gray including nucleus incertus, the laterodorsal tegmental nucleus, Barrington's nucleus and the locus coeruleus. At the rostral pons-caudal midbrain, labeled cells were present in the dorsal and median raphe nuclei, pontomesencephalic gray, and the dorsolateral pons (lateral parabrachial-pedunculopontine region). The MB cases, but not the SUM cases, gave rise to labeled cells in the ventral tegmental nucleus and anterior tegmental nucleus (of Gudden). The results indicate some common brainstem inputs to SUM and medial MB. Some of the brainstem inputs to SUM may regulate SUM in its modulation of the hippocampal EEG. Supported by NIMH grant MH45075.

649.18

THE PROJECTION OF BULBOSPONGIOSUS MOTONEURON AXON COLLATERALS IN THE RAT. M. Gonzalez* and W.E. Collins, III.

Dept. of Neurobiology and Behavior, SUNY, Stony Brook, NY 11794.

Bulbospongiosus (BS) motoneurons (MNs) are bilaterally activated during penile reflexes (e.g., penile cup formation). To investigate the possible involvement of axon collaterals, we have examined the projection of BS MN axon collaterals and their relationship to dendritic processes from ipsilateral and contralateral BS MNs.

In male Sprague-Dawley rats (300-450 g), anesthetized with ketamine + xylazine and prepared for *in vivo* intracellular recording, BS MNs were penetrated with glass micropipettes filled with biocytin (2% in 1.75M KCl) and identified by antidromic activation. Biocytin was then injected intracellularly using brief pulses of pressure (10-60 psi). In each rat 1-4 BS MNs were filled, or biocytin was dumped into the dorsomedial (DM) nucleus. The rats were allowed to survive 1-2 hr after the last injection. The biocytin was visualized in transverse spinal cord sections using standard ABC and nickel-enhanced diaminobenzidine (DAB) reactions. In a number of experiments, BS MNs were retrogradely labeled with subunit B of cholera toxin (CTB; 1 μ l; 0.5% in H₂O) injected into the BS muscles 2-3 d prior to the electrophysiological experiment and visualized immunohistochemically using DAB.

BS MN axons coursed 300-400 μ m from the DM nucleus in the medial dendritic bundle before making a ventral turn to exit the spinal cord. Of 21 BS MNs labeled with biocytin, 3 (14%) were found to possess a single axon collateral. In each case, the axon collateral emerged at the point where the axon began its ventral turn and projected dorsally 10-50 μ m before exhibiting a limited arborization (10-30 boutons) in the region of the ipsilateral medial BS MN dendritic bundle.

Since the medial dendritic bundle contains dendrites from both ipsilateral and contralateral BS MNs, axon collaterals terminating within the medial dendritic bundle could provide excitatory inputs to both ipsilateral and contralateral BS MNs. However, the limited frequency and projection of BS MN axon collaterals suggest that they play a minimal role, if any, in the bilateral activation of BS MNs.

IDENTIFICATION OF FACIAL MUSCLE INTERNEURONS USING PSEUDORABIES VIRUS. R. Fay* & R. Norgren, Neuroscience Program & Department of Behavioral Science, College of Medicine, The Pennsylvania State University, Hershey, PA 17033.

The facial, lingual, and masticatory muscles all participate in a variety of functions including ingestion, respiration, swallowing, and communication. We previously identified the interneurons that are involved in the control of the masticatory and tongue musculature. The present experiments complete the series by identifying the sources of brainstem afferent input to the facial motor nucleus (Mo 7) in Sprague-Dawley rats. The facial muscles are of particular interest because of their role in emotional expression. The posterior digastric was exposed and the virus injected directly into the belly of the muscle. The buccinator, platysma, and zygomatic muscles are arranged in thin sheets just beneath the skin. In order to label them, the virus was injected subcutaneously. The animals were allowed to survive for up to 90 hours. Prior to viral injection, the superior cervical ganglia were removed bilaterally. Injection volumes ranged from 1 to 12 μ l at an average titre of 5×10^8 pfu/ml. Primary infections were restricted to the Mo 7 in a predictable myotopic pattern. Virally infected neurons appeared in nuclei known to project monosynaptically to Mo 7, including the central tegmental field, supratrigeminal, Kolliker-Fuse, parvocellular reticular formation, and the dorsal region of the spinal trigeminal nucleus caudalis. At 90 hours post-infection, tertiary (and possibly higher) infections were present in neurons in the pedunculopontine, laterodorsal tegmental, gigantocellular, lateral paraventricular, rostromedial, and paratrigeminal nuclei. Labeled neurons also were found surrounding the nucleus ambiguus and primarily within the ipsilateral nucleus of the solitary tract. The trigeminal ganglia and trigeminal motor nucleus were devoid of PrV infected cells in all animals. Supported by PHS grants DC 00240 and MH 00653.

VESTIBULAR AND CEREBELLAR PROJECTIONS TO THE GRACILE AND CUNEATE NUCLEI IN RATS AND CATS. S.J. Jabbur*, H. Jourdi, W. Takash, M.Z.M. Ibrahim, S.F. Atweh, and N.E. Saade. Fac. of Med., Am. University of Beirut, Beirut, Lebanon.

The roles of the vestibular nuclei (VN) and the cerebellum in motor functions including muscle tone and activities in 3-dimensional space are well established. During the past 25 years, various motor functions have also been ascribed to the dorsal column nuclei (DCN). These include serial motor acts (Exp. Brain Res., 1973, 18:165) and anticipatory motor behavior (Exp. Neurol., 1974, 42:274). In the present study, we searched for direct projections from the VN and the cerebellum to the DCN.

The DCN of anesthetized cats (n=6) and rats (n=7) were injected with horseradish peroxidase (which was strictly limited to the nuclei), either free or coupled with wheat-germ agglutinin. After 24-48 hr, the animals were reanesthetized and transcardially perfused. The brainstem and cerebellum were then removed and sectioned. In addition to other well known projecting areas to the DCN, labeled neurons were also observed bilaterally in the inferior and medial VN and the fastigial nuclei of the cerebellum. Such projections could be part of reciprocal loops between the VN, cerebellum and DCN and could serve as neuroanatomical substrate for the motor functions ascribed to the DCN. (Supported by grants from the Diana Tamari Sabbagh Fund the Lebanese Nat. Res. Council and the University Research Board).

SPINAL CORD AND BRAINSTEM: TRANSMITTER LOCALIZATION

SUPRASPINAL CONTROL OF CERVICAL SPINAL CORD MOTONEURONAL DENDRITE BUNDLES IN THE RAT. W.J. Anderson* and G. Bennett, Neurobiology Lab, Indiana Univ. Medical center, Terre Haute, IN 47809

Our laboratory has previously described motoneuronal columns in the cervical spinal cord of the rat into discrete dendrite bundles with continuity with the brain stem and thoracic cord. This organization identified a midline, medial (which included the phrenic nucleus) and a lateral column (internal and external). These dendrite bundles in the rat have electrotonic junctions that are dendrodendritic, dendrosomatic, and somatosomatic. There are interconnections between these columns which are referred to as microbundles. This study will present data that this organization of dendrites acts as a substrate for descending supraspinal axons which include serotonin, norepinephrine and thyrotrophic hormone. Utilizing double immunocytochemical techniques, utilizing choline acetyltransferase, tyrosine hydroxylase, thyrotrophic releasing factor, and serotonin with different substrates from Chemicon Corporation, we have demonstrated that specific supraspinal axons specifically innervate motoneuronal columns with pericellular contacts, distribute along dendrite bundles in the longitudinal plane in a specific manner, and finally interact with microbundles which interact with the different columns. The distribution of each transmitter varies in its distribution to the various bundles. We hypothesize that this supraspinal control has specific control over different columns, and yet can influence all to varying degrees through their microbundle distribution.

650.3

COLOCALIZATION OF SUBSTANCE P IN SEROTONERGIC AFFERENTS TO THE HYPOGLOSSAL NUCLEUS. S. Manaker* and J.N. Henry, Center for Sleep and Respiratory Neurobiology and Pulmonary and Critical Care Division, Department of Medicine, University of Pennsylvania, Philadelphia, PA 19104.

The serotonergic (5HT) innervation of the hypoglossal nucleus (Mo12) originates from the caudal raphe nuclei (CRN). Non-5HT neurons in these nuclei also project to the Mo12. Substance P (SP) neurons are present in the CRN, often colocalized with 5HT. We sought to determine the presence of SP in non-5HT afferents to the Mo12. Rhodamine microspheres (Rh; 100nm) were injected into the Mo12 of anesthetized rats, who survived 6-9 days. Two days before sacrifice, rats were reanesthetized and injected intravenously with 100 μ g colchicine. Following perfusion and fixation, sections (32 μ m) were cut through the entire brainstem. In cases with the Rh injection site restricted to the Mo12, every seventh or tenth section was processed for dual immunofluorescence for 5HT (rabbit anti-5HT, 1:2000; AMCA-conjugated goat anti-rabbit, 1:50) and SP (rat monoclonal anti-SP, 1:200; FITC-conjugated goat anti-rat, 1:100). Retrograde labeling by Rh was observed in all sources of Mo12 afferents, while 5HT or SP immunofluorescence was present in all major groupings of 5HT or SP somata, respectively. Within the medial tegmental field, most SP neurons also contained 5HT. Of the neuronal afferents projecting to the Mo12, most (>75%) of the SP immunoreactive neurons also contained 5HT, and these triple-labeled cells were present mainly within the CRN. Very few (<10%) of the non-5HT afferents to the Mo12 contained SP alone. These observations suggest that the SP projections to the Mo12 are a subset of the 5HT projections to the Mo12, and that SP neurons account for a very small proportion of the non-5HT afferents to the Mo12. CO-LOCALIZATION OF ACETYLCHOLINE AND GLUTAMATE IN NEURONS AT THE FELINE MESOPONTINE JUNCTION. J.-P. Wu, Y.Y. Lai*, J.S. Kuo, C.Y. Chai, and J.M. Siegel. Dept Med Res, Taichung Vet Gen Hosp, Taiwan; Dept Psychiat, UCLA and VAMC, Sepulveda, CA 91343.

Both cholinergic and glutamatergic neurons have been identified in the laterodorsal tegmental (LDT) and pedunculopontine (PPN) nuclei. Both cholinergic and glutamatergic neurons in LDT and PPN project to the pontine inhibitory area, an area that is involved in the control of REM sleep atonia. The present study was designed to clarify if neurons in LDT and PPN co-contain Ach and glutamate, using choline acetyltransferase (ChAT) and glutamate immunohistochemical techniques. Three cats were perfused with saline followed with 3% paraformaldehyde and 0.25% glutaraldehyde in phosphate buffer solution, pH 7.4. The tissue was cut at 50 μ m and alternate sections were processed with the following 1) ChAT 2) glutamate and 3) ChAT and glutamate. We found that neurons in both LDT and PPN co-contain glutamate and acetylcholine. However, the percentage of cholinergic neurons co-containing both transmitters was higher in PPN than in LDT. 78% of cholinergic neurons in PPN were double labeled with glutamate, while only 44% of neurons in LDT contained both transmitters. We suggest that the neurons in LDT and PPN that co-contain Ach and glutamate may play an important role in REM sleep control.

A STUDY OF THE TRANSMITTER SYSTEMS MEDIATING TECTORETICULAR INPUTS IN LAMPREYS. J.C. Zompa* and R. Dubuc. D  p. de kinanthropologie, Universit   du Qu  bec    Montr  al, H3C 3P8 and CRSN, Universit   de Montr  al, H3C 3J7, Canada.

It has been shown by Ull  n et al. (Behav. Brain Res. 54:107-110, 1993) that illumination of a lateral eye in lampreys induced a turning movement away from the light source. Anatomical studies revealed that the retina projects to the contralateral tectum (Kennedy & Rubenson, J. Comp. Neurol. 171:465-480, 1977). However, little is known on the interactions between visual inputs and motor systems in lampreys. In a previous study, we identified populations of neurones on either side of mesencephalic tectum, that project to the middle (MRRN) and to the posterior (PRRN) rhombencephalic reticular nuclei of lampreys. These nuclei contain reticulospinal (RS) neurones which are known to play a key role in descending motor control. We have also shown that microstimulation of the tectal cell populations, in the *in vitro* isolated brainstem-spinal cord preparation, evoked mixed excitatory and inhibitory responses in RS neurones. This study was aimed at characterizing these tectoreticular inputs further. Large M  ller cells of the MRRN received strong excitatory inputs, while some RS neurones in the caudal PRRN received predominantly inhibitory inputs. To identify the transmitter systems involved, CNQX (10 μ M) was added to the perfusate, and both the excitatory and inhibitory inputs were abolished, suggesting that AMPA receptors were involved in mediating these responses and that inhibition is di- or oligosynaptic. Strychnine (5 μ M) completely abolished the inhibitory responses, indicating that glycine is the inhibitory transmitter. Perfusing the preparation with Mg^{2+} -free Ringer's, increased the duration of the excitation and this was suppressed by 100 μ M AP5 or when normal Mg^{2+} concentrations were restored. NMDA receptors are thus present in this pathway. In conclusion, we have shown that excitatory and inhibitory inputs from tectum to reticulospinal neurones, are similar to those reported in cats (Peterson et al., Exp. Brain Res. 21:19-44, 1974). Moreover, this study indicates that, within tectoreticular pathways of lampreys, excitation is mediated by excitatory amino acids and inhibition by glycine. Funded by MRC Canada, FCAR and FRQS Qu  bec.

SYNAPTIC INTERACTIONS OF SUBSTANCE P IMMUNOREACTIVE (SP) NERVE TERMINALS WITH HYPOGLOSSAL (N.XII) MOTONEURONS WHICH INNERVATE THE INTRINSIC MUSCLES OF THE TONGUE: AN ELECTRON MICROSCOPIC DUAL LABELING STUDY. P.J. Gatti¹, T.A. Johnson², M. Shirahata³ and V.J. Massari¹, Depts. of Pharmacology¹ and Veterinary Services², Howard Univ. Coll. Med., Washington, D.C. 20059, and ³ Div. Physiology, School of Hygiene and Public Health, Johns Hopkins University, Baltimore, MD 21205.

The intrinsic muscles of the tongue play important roles in speech and respiration. Little is known of the central mechanisms regulating N.XII motoneurons. To elucidate which afferent neurotransmitters modulate functionally associated subgroups of N.XII motoneurons, we have employed an electron microscopic dual labeling technique. Cholera toxin-horseradish peroxidase (CTB-HRP) or unconjugated HRP was injected into the intrinsic tongue muscles of the cat. The animals were sacrificed 48 hr later and sections were processed histochemically for the visualization of HRP using tetramethylbenzidine as the chromogen. Retrogradely labeled neurons were found predominantly ipsilaterally in the intermediate and ventromedial subdivisions of N.XII particularly at the level of the rostral pole of the area postrema. These motoneurons showed abundant cytoplasm and organelles, and round nuclei. Sections were processed for the simultaneous immunocytochemical localization of SP using diaminobenzidine as the chromogen. SP immunoreactivity was found in nerve terminals primarily associated with large dense core vesicles. Some of these terminals made synaptic contact with proximal dendrites and perikarya of labeled N.XII motoneurons. These data indicate that SP afferents modulate the activity of N.XII motoneurons which control the function of intrinsic tongue muscles. Supported by NHLBI 44922, & Howard Univ. Grad. Sch. Collab. DIRECT SEROTONERGIC INPUT TO DORSAL SPINOCEREBELLAR TRACT NEURONS IN THE CAT. J.C. Pearson, D.E. Dewey, F.J. Alvarez, D. Harrington, M.J. Sedivec* and R.E.W. Fyffe, Dept of Anatomy, Wright State Univ, Dayton, Ohio 45435, and * Dept of Biology, Appalachian State Univ, Boone, N.C. 28608

Serotonergic systems exert important modulatory effects on sensory neurons and motoneurons in the mammalian spinal cord. These effects, which may be inhibitory or facilitatory, are mediated by synapses and receptors distributed over the surface of the target neurons. We were interested to determine if an important sensory feedback pathway providing proprioceptive information to the cerebellum, the dorsal spinocerebellar tract (DSCT), received direct serotonergic input and to what extent such input was distributed over the proximal versus distal dendrites of DSCT cells. Identified DSCT cells were intracellularly stained with horseradish peroxidase, and 5-HT immunoreactive varicosities in contact with the cells were revealed by immunohistochemistry using an antibody raised in guinea pigs against keyhole limpet hemocyanin-conjugated 5-HT. At the light microscopic level, 5-HT contacts were observed on the soma and all regions of the extensive dendrites of stained DSCT cells. However, the density of 5-HT contacts was much lower than previously observed on spinal motoneurons, suggesting that the DSCT is not subject to particularly powerful descending serotonergic influences, thereby allowing the system to faithfully and rapidly relay its information regardless of activity in other systems. Supported by NIH grant NS25547.

SOMATIC MEMBRANE COVERING BY GLYCINERGIC TERMINALS AND GLYCINE RECEPTORS OF α -MOTONEURONS AND RENSHAW CELLS IN CAT SPINAL CORD. D. A. Harrington, F. J. Alvarez, and R.E.W. Fyffe*, Department of Anatomy, Wright State University, Dayton OH 45435.

Glycine is a major inhibitory neurotransmitter in the ventral horn of the spinal cord, exerting powerful effects over neural elements involved in motor behavior. Here we evaluated quantitatively various synaptic parameters related to glycinergic terminals over the cell somas of α -motoneurons (α -MN) and Renshaw cells (RC). We assessed glycine receptor presence using electron microscopy pre-embedding immunocytochemistry with antibodies directed against gephyrin, a protein associated with postsynaptic glycine receptor clusters. α -MNs were identified by their size, location and characteristic synaptology. RCs were identified by their location in ventral lamina VII and their distinctive gephyrin-immunoreactivity (geph-ir). Overall synaptic covering was similar in α -MN and RCs (45-65% of the available somatic membrane), with geph-ir terminals being the most abundant type on both RCs and α -MNs. But, while terminals with geph-ir synapses constitute about 90% of the synaptic covering in RCs, they constitute only 40-45% in α -MNs. An average of 87% of all terminals that contacted RC somas displayed geph-ir while this value was 49% for α -MNs. All geph-ir terminals were of the F type, and had similar ultrastructural features on RCs and α -MNs. The percentage of apposition area occupied by postsynaptic geph-ir was larger in RC somas: 36-40%, compared to 15-20% on α -MNs. The extension of postsynaptic geph-ir was almost identical to the extension of the opposed presynaptic active zone. In conclusion, while glycinergic control is very substantial over both neuronal types, it is much more abundant over the cell somas of RCs. Individual glycinergic synapses on RC somas have the potential to elicit larger postsynaptic effects since their active zones are larger and the postsynaptic receptor regions are usually more intensely immunoreactive than those on α -MN somas. Supported by NIH grant NS25547.

DESCRIPTION AND ANATOMICAL TRACING OF PROJECTIONS OF THE B9 SEROTONIN-CONTAINING NUCLEUS: 5-HT IMMUNOSTAINING AND PHA-L ANTEROGRADE TRACING. R.P. Vertes* and A.M. Crane, Center for Complex Systems, Florida Atlantic Univ., Boca Raton, FL 33431.

The present study examined the distribution of 5-HT containing cells in the ventral pontomesencephalic tegmentum (commonly referred to as the B9 area) as well as the projections of this cell group. The brains of 15 rats were immunohistochemically reacted for the presence of 5-HT in cells and fibers according to a modified procedure of Arita et al. (Exp. Brain Res. 95:100, 1993). The projections of B9 were examined in a separate group of 20 rats using PHA-L (Vertes, J. Comp. Neurol. 326:595, 1992). 5-HT-containing cells of B9 distribute over a widespread region of the pontomesencephalic tegmentum from the level of the mid-pons rostrally to approximately the level of the red nucleus. They are most densely concentrated directly above the medial lemniscus and further rostrally immediately lateral to the interpeduncular nucleus. As in the cat (Wiklund et al., J. Comp. Neurol. 203:613, 1981), there are more 5-HT-containing cells in B9 than in any other raphe group, with the possible exception of the dorsal raphe. In the brainstem, B9 was found to project heavily throughout the extent of the reticular formation (medulla through midbrain), the pontomesencephalic central gray, the parabrachial-pedunculopontine region, midline raphe groups, the laterodorsal tegmental nucleus, and parts of the tectum and pretectum. In the forebrain, B9 projects densely to the lateral hypothalamus, the zona incerta, and the substantia nigra, as well as lightly to moderately to the striatum, amygdala, and prefrontal cortex. Few labeled fibers were seen in the septum or hippocampus. Overall, B9 sends considerably stronger projections to the brainstem than to the forebrain. The present results indicate that B9 is an overlooked source of relatively prominent 5-HT projections to several structures of the brainstem and forebrain. Supported by NIMH grant MH45075.

IMMUNOHISTOCHEMICAL ANALYSIS OF SPINAL NEUROTRANSMITTER SYSTEMS AND RECEPTORS IN CATS WITH SPINAL CORD TRANSECTION. R.E.W. Fyffe, F.J. Alvarez, J.A. Hodgson, R.R. Roy, V.R. Edgerton, J.C. Pearson*, D.E. Dewey, D.A. Harrington and J.V. Priestley, Dept of Anatomy, Wright State Univ. Dayton, OH 45435, Dept of Physiological Sciences, UCLA, CA 90024, and Dept of Physiology, UMDS, St Thomas's Campus, London SE1 7EH, UK.

Spinalized cats exhibit variable degrees of weight bearing and locomotor ability in their hindlimbs, and these parameters can be differentially affected by training and certain pharmacological manipulations. To determine if the variability between animals is correlated with different patterns of neurochemical reorganization we studied the distribution of immunocytochemical markers for a variety of neurotransmitters and receptors involved in descending and segmental control of motor function, in cats that had undergone different training paradigms and exhibited different types of motor behavior following transection at T12-T13. Unlike controls, immunoreactivity for serotonin, tyrosine hydroxylase, and thyrotropin releasing hormone was completely absent in all cats in segments below the lesion site, indicating that the transections were complete in all cases. Interestingly, CGRP immunoreactivity was decreased in the ventral horn, suggesting some direct or indirect supraspinal influence. A similar result was observed for substance P labelling. There was no obvious rearrangement or expansion of markers for likely segmental transmitters (e.g. GAD, glycine receptors) to occupy sites vacated by the descending systems. It appears that the difference in locomotor capability among cats is the result of more subtle changes in circuitry or transmitter/receptor expression in spinal neurons. Supported in part by NIH grants NS16333 and NS25547.

SEROTONIN (5-HT) REDUCES AN AFTERHYPERPOLARIZATION IN NEONATAL RAT MOTONEURONS THROUGH INHIBITION OF N- AND P-TYPE CALCIUM CHANNELS. D.A. Bayliss*, M. Umekiya and A.J. Berger. Dept. of Physiology and Biophysics, University of Washington, Seattle, WA 98195

We have shown that 5-HT increases input-output gain of neonatal rat hypoglossal motoneurons (HMs) via decreased amplitude of Ca^{2+} -dependent afterhyperpolarization (AHP) (*Neurosci. Lett.* 143: 164, 1992). To determine if the decreased AHP is mediated by decreased Ca^{2+} influx, we tested the effect of 5-HT on Ca^{2+} currents in visualized HMs using a thin-slice preparation of rat brainstem. 5-HT inhibited high-voltage-activated (HVA) Ca^{2+} currents (measured at 0 mV from a holding potential of -70 mV), by >10% in ~70% of HMs tested (n=99); in responsive neurons, 5-HT decreased HVA current by 22%. Low-voltage-activated currents, evoked during steps to between -30 and -40 mV from hyperpolarized potentials, were unaffected by 5-HT (n=7). The 5-HT_{1A} receptor mediated inhibition of both the AHP and HVA current. Thus the effect of 5-HT on the AHP was mimicked by 8-OH-DPAT; HVA current inhibition by 5-HT was mimicked by 5-CT and 8-OH-DPAT, but not by TFMPP, and was blocked by the 5-HT_{1A} antagonist, NAN-190, but not by ketanserin, a 5-HT₂ antagonist. 5-HT inhibited both N-type (ω -Conotoxin GVIA-sensitive; 3 μM) and P-type (ω -Aga IVA-sensitive; 0.2 μM) Ca^{2+} channels in neonatal HMs; 5-HT had no effect on the residual current remaining after application of both toxins. Effects of 5-HT on HVA current were irreversible, and subsequent applications of 5-HT were occluded when GTPyS was substituted for GTP in the pipette solution. In addition, inhibition of Ca^{2+} current was partially relieved following large depolarizing prepulses, indicating that inhibition of Ca^{2+} channels by 5-HT is mediated by G proteins, perhaps directly. Therefore, inhibition of Ca^{2+} current by 5-HT is responsible, at least in part, for the 5-HT-induced decrease in AHP in neonatal HMs and, in this way, 5-HT enhances the excitability of HMs. (Supported by NS14857 and Francis Families Foundation).

ADENOSINE MODULATES EXCITATORY SYNAPTIC TRANSMISSION TO RAT HYPOGLOSSAL MOTONEURONS. M.C. Bellingham* and A.J. Berger. Dept. Physiol. & Biophys., Univ. Washington, Seattle, WA 98195.

Adenosine modulation of excitatory inputs may be especially significant in hypoxic responses of HMs, as extracellular CNS adenosine levels rise many-fold under these circumstances. To investigate this modulation, intracellular recordings were made from adult rat hypoglossal motoneurons (HMs; n = 25) in brainstem slices. Electrical stimulation lateral to the hypoglossal motor nucleus evoked short-latency (0.6-1.4 ms) excitatory postsynaptic potentials (EPSPs). These EPSPs were markedly suppressed or abolished by bath application of kynurenic acid (1 mM; n = 7), showing that they were glutamatergic. Bath application of adenosine receptor agonists 2-chloro-N⁶-cyclopentyladenosine (CCPA, 100 nM) or 2-chloroadenosine (2-CA, 1 μM) significantly reduced EPSP amplitude to 42 \pm 5% (n = 6) and 76 \pm 7% (n = 6) of control, respectively. The adenosine receptor antagonist 8-cyclopentyl-1,3-dipropylxanthine (DPCPX, 0.1-1 μM) significantly increased the EPSP amplitude to 124 \pm 14% of control (n = 9), and blocked EPSP reduction by bath or local application of CCPA or 2-CA (n = 7). CCPA, 2-CA and DPCPX did not significantly alter HM input resistance or membrane potential. Repeated local application of ω -conotoxin (ω -CgTx, 1 μM), which caused maximal reduction of the medium afterhyperpolarization that followed action potentials evoked by brief current pulses, also reduced EPSP amplitude to 68% of control (n = 2), but failed to occlude EPSP amplitude decrease in response to bath application of 2-CA (10 μM ; reduction to 50% of the remaining EPSP after ω -CgTx, cf. reduction to 61% of control values before ω -CgTx). These data indicate that excitatory glutamatergic inputs to rat HMs are modulated by adenosine A₁ receptors, most probably at a presynaptic site. Modulation of presynaptic N-type calcium channels does not appear to be essential for the mechanisms by which presynaptic A₁ receptors reduce excitatory synaptic transmission to HMs. (Supported by NS 14857, HL 49657).

THYROTROPIN-RELEASING HORMONE (TRH) DEPOLARIZES RESPIRATORY RELATED NEURONS IN A THICK SLICE PREPARATION OF THE NEWBORN MOUSE BRAINSTEM. J.C. Reikling*, J. Champagnat and M. Denavit-Saubié. C.N.R.S., Institut Alfred Fessard, 91198 Gif-sur-Yvette, France.

A thick (1.5-2.0 mm) slice preparation of the 1-6 day old mouse brainstem was developed. TRH (1-5 μM) increased the frequency of respiratory related discharges recorded from hypoglossal roots by a factor of three. Whole cell patch recordings from anatomically identified hypoglossal motoneurons showed that the neurons were depolarized by TRH and the respiratory bursts of EPSPs were increased in duration, as were the discharges on the hypoglossal nerve. In the ventrolateral part of the preparation a subset of inspiratory related neurons were depolarized by TRH, others were unaffected. Expiratory related neurons (hyperpolarized during the nerve discharge) were also depolarized by TRH.

It is concluded that TRH increases the respiratory rhythm of the newborn mouse by an action at the level of the brainstem caudal to the facial nucleus. The results suggest that the increase in respiratory frequency induced by TRH may result from depolarization of a subset of ventral respiratory neurons, either by a direct postsynaptic action or by excitation of other modulatory neurons present in the preparation. (Supported by an EEC grant and The Augustinus Foundation)

651.2

AT LEAST TWO DISTINCT IONIC MECHANISMS UNDERLIE THE RESPONSE OF HYPOGLOSSAL MOTONEURONS (HMs) TO NOREPINEPHRINE. M.A. Parkis*, D.A. Bayliss, and A.J. Berger. Department of Physiology and Biophysics, University of Washington, Seattle, WA 98195

The *in vitro* response of HMs to norepinephrine (NE) mimics their response to thyrotropin releasing hormone (TRH), i.e. depolarization accompanied by increased input resistance (R_N) recorded in current-clamp, or development of an inward current with decreased input conductance in voltage-clamp (*J. Neurophys.* 68:1733, 1992, *Soc. Neurosci. Abstr.* 18:512, 1992). The NE current, like the TRH current, reverses near -100 mV. In addition, the effects of NE on HMs are occluded by TRH in the perfusing artificial cerebrospinal fluid (ACSF, *Soc. Neurosci. Abstr.*, 19:988, 1993), suggesting that these two neuromodulators share ionic mechanisms of action in HMs.

Since the TRH-mediated increase in R_N is occluded by substitution of barium (Ba^{2+}) for calcium in the ACSF, while the depolarization is not, we tested whether the same held true for the response of HMs to NE. We found that the increase in R_N elicited by NE was reduced from 56% in control to only 3% in Ba^{2+} -ACSF, despite the cells' continued ability to exhibit a depolarizing response (n = 7). After return to Ba^{2+} -free ACSF, HMs again showed increased R_N in response to NE.

To investigate the ionic mechanism responsible for the Ba^{2+} -resistant depolarizing response, we substituted choline chloride for sodium chloride in the ACSF. Within ten minutes of switching into a Ba^{2+} - and choline-substituted ACSF, HMs no longer depolarized in response to NE (n = 4). After longer periods of time the response became a hyperpolarization. In choline-substituted ACSF without Ba^{2+} , a depolarization with increased R_N could still be elicited by NE, but recovery from the depolarization was prolonged, the potential taking longer to return to baseline (n = 3).

We conclude that NE depolarizes HMs by at least two ionic mechanisms: reduction of a Ba^{2+} -sensitive resting K^+ conductance, and activation of a Ba^{2+} -resistant cationic current carried predominantly by sodium ions. (Supported by HL - 49657).

651.4

PRESYNAPTIC INHIBITION BY SEROTONIN OF GLYCINERGIC INHIBITORY POSTSYNAPTIC CURRENTS (IPSCs) IN RAT MOTONEURONS. M. Umekiya* and A.J. Berger. Dept. Physiology and Biophysics, University of Washington, Seattle, WA 98115.

Serotonin (5-HT) plays an important role in the neuronal function of synaptic modulation. Using a thin-slice preparation, we found that 5-HT presynaptically inhibited unitary glycinergic IPSCs evoked by extracellular stimulation of interneurons and recorded in motoneurons of rat brainstem. One possible mechanism for presynaptic inhibition is K^+ channel activation and/or voltage-activated Ca^{2+} channel inhibition at the presynaptic terminal. In this regard, the 5-HT_{1A} receptor activated inwardly rectifying K^+ channels and inhibited voltage-activated Ca^{2+} channels recorded in somata of presynaptic interneurons. However, the 5-HT_{1B} receptor was primarily responsible for inhibition of evoked glycinergic IPSCs, whereas 5-HT_{1A} receptor activation inhibited IPSCs by only 24%. In addition, 5-HT_{1B} receptor activation at the presynaptic terminal reduced the frequency of spontaneous miniature IPSCs (mIPSCs) without changing the mIPSCs amplitude distribution in the presence of TTX. These results indicate that activation of inwardly rectifying K^+ channels and the inhibition of voltage-activated Ca^{2+} channels by 5-HT_{1A} receptor activation is not a main pathway for presynaptic inhibition by 5-HT. Modulation of the transmitter release mechanism through 5-HT_{1B} receptor activation may be a dominant pathway for presynaptic inhibition by 5-HT. (Supported by NS 14857).

EXCITATORY AMINO ACIDS AND GABA ANTAGONISTS POTENTIATE THE EFFECT OF CARBACHOL IN PONTINE RETICULAR FORMATION - CATALEPSY AS THE BEHAVIORAL MEASURE. Z. Elazar* and A. Berchansky. Depart. of Physiology & Pharmacology, Sackler School of Medicine, Tel-Aviv University, Israel.

Microinjections of different amounts of carbachol into the pontine reticular formation (PRF) in rats could induce REM sleep, catalepsy, or epilepsy. The intensity of catalepsy, the object of this study, is high for 5-15 min and decreases to low levels 30 min after the injection. The excitatory amino acids (EAA) L-glutamate, N-methyl-D-aspartate, kainate and quisqualate injected in PRF in picomol doses (0.2 μl) did not by themselves induce catalepsy or induced only mild catalepsy. When injected 15 min before the injection of 1 μg /0.2 μl carbachol in the same PRF site, unilaterally, they greatly potentiated the effect of carbachol: the intensity of catalepsy increased up to more than ten fold and the duration several times. Picrotoxin (30-40 μmol /0.2 μl) injected in the same PRF site 15 min before the carbachol similarly potentiated the intensity and duration of catalepsy. Slightly higher doses of EAA or picrotoxin reduced or prevented the cataleptogenic effect of carbachol. These results suggest the importance of the interactions between the cholinergic mechanisms in PRF and EAA and GABA.

DESCENDING SEROTONERGIC CONTROL OF CROSSED GROUP II INHIBITION IN THE SPINAL CORD OF THE CAT. N.C. Aggelopoulos¹, R.W. Clarke² and S.A. Edgley¹. ¹Department of Anatomy, University of Cambridge and Department of Physiology and ²Environmental Science, University of Nottingham, United Kingdom. SPON: Brain Research Association.

Stimulation of hindlimb group II muscle afferents inhibits many contralateral hindlimb motoneurons. This crossed inhibitory reflex depends on a descending system as it disappears on section of the spinal cord. We have tested the hypothesis that crossed inhibition is dependent on serotonergic transmission.

Experiments were carried out in four cats under chloralose general anesthesia. Intracellular recordings were obtained from hindlimb motoneurons. Electrical stimulation of the contralateral quadriceps nerve at a strength sufficient to activate group II afferents (5T) elicited IPSPs in the majority (44/46 : 96%) of gastrocnemius/soleus and hamstring motoneurons. The incidence of IPSPs was reduced after spinal transection at the thoracic level (9/40 : 22%) and the IPSPs were smaller. After spinalization, intravenous administration of (+/-)-8-hydroxy-2-(di-n-propylamino) tetralin (8-OH-DPAT, Research Biochemicals), a selective agonist of 5HT_{1A} receptors (dose 0.11-1.21 mg/kg), restored the crossed inhibition of many motoneurons (41/48 : 85%) within 5-15 min. The effect of 8-OH-DPAT was antagonized with a latency of 10-20 minutes by the selective 5HT_{1A} antagonist (+)-WAY-100135 (a gift of Wyeth Research UK) injected intravenously at a dose of 0.7-3.7 mg/kg, which markedly reduced the incidence of IPSPs in motoneurons (10/45 : 22%).

The simplest explanation of these results is that a descending pathway acting via 5HT_{1A} receptors permits crossed group II inhibition to operate.

SEROTONIN AND NOREPINEPHRINE MODULATE EXCITATORY AMINO ACID RECEPTOR CURRENTS IN ACUTELY ISOLATED RAT VENTRAL HORN NEURONS. S.C. MacDonald, S. Hochman, and L.M. Jordan*. Dept. of Physiology, University of Manitoba, Winnipeg, MB, R3E 0W3

It has previously been reported that serotonin (5-HT), and norepinephrine (NE) and N-methyl-D-aspartate (NMDA) are involved in locomotor-like activity in the neonatal rat preparation.¹ We hypothesize that neuromodulation of excitatory synaptic transmission by monoamines plays a role in the generation and control of locomotion. Our goal is to examine the mechanisms of this modulation at a single cell level. We examined the effects of two monoamines, 5-HT and NE, on excitatory amino acid (EAA) currents in the ventral horn. Whole-cell voltage clamp recordings were obtained from acutely dissociated neurons from the area of the spinal cord where locomotor-related neurons are found. Local perfusion of NMDA and kainate evoked inward currents. These currents increased or decreased in the presence of either 5-HT or NE. Within single neurons, 5-HT and NE exhibited common actions for a tested EAA receptor subtype, whether facilitatory or inhibitory. Kainate currents were examined in 38 cells and were depressed in 26% of cells and potentiated in 45%. There was a mean current increase of 77.9±64.5% and 66.9±40.3% and decrease of 37.9±17.6% and 21.9±5.2% in the presence of 5-HT and NE respectively. Similarly, out of 28 cells examined with NMDA, 18% of cells were potentiated and 54% were depressed. Mean increases in current were 27.3±22.2% and 33.8±17.2% and decreases 36.6±11% and 16.9±11.4% for 5-HT and NE respectively. Preliminary results indicate that 5-HT_{1A} and α_2 noradrenergic receptors contribute to the observed effects. These results suggest that 5-HT and NE can modulate excitatory synaptic transmission at the level of the post-synaptic receptor. Supported by MRC. S.C.M. is a Network of Centres of Excellence Trainee. ¹(Cazalets, et al., Neuroscience Lett., 1990)

FAILURE OF INTRATHECAL NIMODIPINE TO INCREASE SPINAL CORD BLOOD FLOW. H. Imamura and C.H. Tator*. Division of Neurosurgery and Playfair Neuroscience Unit, Toronto Western Division, The Toronto Hospital, University of Toronto, Toronto, Ontario M5T 2S8, Canada

We have demonstrated that intravenously administered calcium channel antagonist nimodipine produced an increase of spinal cord blood flow (SCBF) in normal and injured rats. However, in the injured rats, due to the hypotension caused by both cord trauma and the vasodilator effects of nimodipine it was necessary to counteract the hypotension and maintain the posttraumatic arterial blood pressure. Nimodipine has high lipid solubility and penetrates well into the central nervous system, so the present study was performed to investigate whether intrathecally infused nimodipine could increase the SCBF in normal rats. Male Wistar rats anesthetized by alpha-chloralose and urethane had a laminectomy from C1 to T1 and a silastic tube was inserted into the subarachnoid space via the atlantooccipital membrane to the C6 level. We administered intrathecal nimodipine (0.05 mg/kg; n=5, 0.2 mg/kg; n=5) and placebo (n=5), and measured SCBF at C7/T1 with the hydrogen clearance method before infusion, during infusion and 30 minutes after infusion of the drug. Neither 0.05 nor 0.2 mg/kg of nimodipine increased SCBF during infusion (df=2,12; F=0.35; P>0.05) or after infusion (df=2,12; F=1.31; P>0.05). Although 0.2 mg/kg nimodipine caused a 26.4% decrease in blood pressure at the end of infusion (p=0.006), it recovered to 85.2% of preinfusion value at the end of the experiment (1 hour after infusion, p=0.001). These results show that intrathecal nimodipine at these doses cannot increase spinal cord blood flow.

NITRIC OXIDE INHIBITION CAUSES STATE-DEPENDENT DEPRESSION OF ACETYLCHOLINE (ACh) RELEASE IN THE MEDIAL PONTINE RETICULAR FORMATION (mPRF). T.O. Leonard*, L. Becker and R. Lydic, Dept. Anesthesia, Penn. State Univ., College of Med., Hershey PA 17033.

NADPH-diaphorase staining is thought to reveal neurons which use nitric oxide as a neuromodulator (J. Comp. Neurology 324:410, 1993). Cholinergic neurons of the pedunculopontine tegmental nucleus (PPT) projecting to the mPRF are NADPH-positive, and electrical stimulation of PPT neurons increases mPRF ACh release (Am. J. Physiol. 264:R544, 1993). Therefore the present study is testing the hypothesis that inhibition of nitric oxide synthase with N^G-nitro-L-arginine (NLA) will result in state-dependent reduction of mPRF ACh release. A cat was chronically implanted with electrodes for monitoring sleep and wakefulness. For each experiment, a microdialysis probe was stereotactically placed in the mPRF for simultaneous recovery of ACh and delivery of either Ringers solution or 10 mM NLA in Ringers. Ten min dialysate samples (n) were collected during waking (n=46), non-rapid eye-movement (NREM) sleep (n=48), and REM sleep (n=16). Samples were analyzed for pmol of ACh using HPLC. ACh levels (mean±SD) during waking with NLA dialysis (0.16±0.11) were significantly less (t=3.27, df=44, p=0.002) than ACh levels with Ringers alone (0.24±0.07). Likewise, during NREM sleep ACh levels with NLA dialysis (0.12±0.11) were less (t=3.29, df=46, p=0.002) than ACh levels with Ringers (0.20±0.05). During REM sleep, however, there was no significant difference (p=0.777) in ACh levels between NLA dialysis (0.34±0.29) and dialysis with Ringers (0.38±0.12). These data suggest nitric oxide may modulate state-dependent cholinergic neurotransmission within the mPRF. Support: Department of Anesthesia, HL-40881 (RL).

SEROTONIN INCREASES HYPOGLOSSAL (XII) REFLEX RESPONSE TO UPPER AIRWAY NEGATIVE PRESSURE. M.A. Douse* and D.P. White, Dept. of Medicine, UCHSC, and Respiratory Care, VAMC, Denver, CO 80220.

Serotonin (5HT) is known to increase XII motoneuron activity levels, yet nothing is known concerning 5HT modulation of XII reflex responses. We determined the effects of 5HT and methysergide (broad 5HT antagonist) microinjection into the XII motor nucleus (200-500 nl; pH=7.2-7.4) on XII whole nerve response to upper airway negative pressures (Paw) in 4 decerebrate, vagotomized, paralyzed and artificially ventilated cats. Results to date indicate control negative Paw tests resulted in graded increases in the reflex response (n=4; Table 1) measured as the inspiratory peak height of XII integrated neural activity (time constant=100ms) in arbitrary units (AU) normalized to pre-test control. Microinjection of 0.5 mM 5HT resulted in an increase in peak inspiratory integrated XII activity at each Paw (cf. to pre-test control), but a decrease in the slope of the response curve from 2.76 to 0.81 AU/cm H₂O (n=2; Table 1). Prior microinjection of 1.0 mM methysergide resulted in a decrease in XII activity at each Paw and a decrease in the response curve slope to 0.88 (n=2; Table 1). Subsequent microinjection of 0.5 mM 5HT had no further effect. These preliminary results indicate exogenous and endogenous 5HT increases the peak XII reflex response to upper airway negative pressures and suggest that state dependent decreases in 5HT may be important in the loss of this reflex during sleep. This may have important implications in the development of obstructive sleep apnea. (NIH HL-48531).

Table 1 - XII Reflex Responses to Paw (Arbitrary Units)

Paw (cm H ₂ O)	0	-5	-10	-15	-20
Control	100	98.1	119.5	136.2	150.0
5HT	175.6	178.9	180.5	181.8	194.5
Methysergide	44.3	30.9	37.1	44.4	59.6

DOPAMINERGIC MODULATION OF THE SWIM NETWORK AND SPINAL NEURONS IN LAMPREY. C.P. Kemnitz, J.T. Buchanan*, W. Merlau, & I.V. Bataeva. Department of Biology, Marquette University, Milwaukee, WI 53233.

We have previously shown that dopamine is present in cell bodies and processes in the lamprey spinal cord and that dopamine modulates fictive swimming (*Neurosci. Lett.* 166:23-26, 1994). To further investigate the actions of dopamine, we examined the effects of dopaminergic agents at several levels: 1) in intact swimming lamprey, 2) on network, cellular, and synaptic properties in the isolated spinal cord, and 3) on ionic currents in isolated spinal neurons. The experiments were done on adult sea lampreys (*Petromyzon marinus*) and adult silver lampreys (*Ichthyomyzon unicuspis*).

Injection of the dopamine agonist apomorphine into intact adult sea lampreys decreased the cycle period of swimming, an effect similar to that of low concentrations (<10 μ M) of dopamine during fictive swimming. The D1 dopamine receptor agonist SKF-38393 decreased cycle period during fictive swimming, while the D2 agonist 3-PPP had no effect. Dopamine reduced the late after-spike hyperpolarization in motoneurons (MN), primary sensory dorsal cells (DC), stretch receptor edge cells (EC), and giant interneurons (GI) and increased the firing frequencies of MNs, ECs, and GIs to current injection. Calcium action potentials in MNs, DCs, and GIs were reduced by dopamine, suggesting that reduced Ca²⁺ influx leads to decreased activation of the Ca²⁺-activated K⁺ current responsible for the late after-spike hyperpolarization. Poly- and monosynaptic inhibitory postsynaptic potentials in motoneurons were also reduced by dopamine. Whole-cell patch clamp studies of isolated dorsal cells indicate that dopamine reduces high-voltage activated calcium currents.

These results suggest that dopamine may modulate fictive swimming in lamprey via a D1 receptor by altering calcium influx, leading to changes in both the firing properties and synaptic strengths of spinal neurons. (Supported by NIH NS-28369, TW00245, and MH-49581)

INTERSEGMENTAL COORDINATION AFTER CHRONIC AND ACUTE LESIONS IN LAMPREY SPINAL CORD ASSESSED DURING FICTIVE SWIMMING. L. Guan, T. Kiemel, D. Liao and A.H. Cohen*. Department of Zoology, University of Maryland, College Park, MD 20742.

Previously, we reported the use of correlational analysis in the isolated lamprey spinal cord to demonstrate that during fictive swimming there is strong intersegmental coupling. We define strong coupling in terms of the speed with which the bursting returns to its regular frequency after external perturbations. In this analysis we compare cross-correlation of periods and auto-correlations of delay between pairs of segments. High cross-correlation of periods and low auto-correlation of delays indicated strong coupling. We compared the results to simple models of coupled non-linear oscillators to illustrate the plausibility of the conclusion.

Here we extend the method to spinal cords previously either acutely or chronically lesioned. Lesions were of either the lateral or the medial fiber tracts or the entire spinal cord. At the time of testing, in partially lesioned animals acute lesions of the formerly spared fibers were often added to the chronic lesion to examine the function of regenerated fibers in the absence of the unlesioned fibers. Chronically lesioned cords were compared to acutely lesioned healthy cords. The analysis in the acutely lesioned spinal cords revealed moderate to strong coupling strength of either medial or lateral tract coordinating fibers. However, there was little evidence that the regenerated fibers were capable of strong or moderate strength coupling even after 10 months of recovery. Only in the presence of spared fibers was any strong coupling found. In only two cases was there even a hint of moderate strength coupling of regenerated fibers with this method of analysis. Thus, the regeneration, at best, seemed to restore only weak or perhaps occasionally moderate strength coupling among the segments. CONTROL OF VENTRAL ROOT BURST PROPERTIES DURING FICTIVE SWIMMING IN THE LAMPREY SPINAL CORD. W. L. Miller and K. A. Sigvardt*. Dept. of Neurology, University of California, Davis, CA, 95616

The main tasks of the lamprey spinal central pattern generator (CPG) for locomotion are to produce bursts of activity in the segmental motor nerves that result in an appropriately sized contraction of the segmental muscles, and to maintain stable, coordinated activity among all segments, over a large range of cycle frequencies. These functions most likely involve both local and long-distance interactions among spinal interneurons, but the details of these interactions are not yet understood. To investigate the relationship between the segmental and coordination functions, we analyzed ventral root burst characteristics from data collected in "split bath" experiments using *in vitro* preparations of the lamprey spinal cord (50 segments) in which the concentration of excitatory amino acid (EAA) bathing the rostral and caudal halves of the cord could be controlled separately. Simultaneous recordings were made from six extracellular electrodes placed at regular intervals along the cord. The analyzed trials comprised a four-fold range of cycle periods, and a three-fold differential range of EAA concentrations in the rostral and caudal bathing solutions. Parameters of interest in the present study include burst duration, burst proportion (burst duration/cycle period), mean amplitude, integrated amplitude, time-to-peak and the variance in these parameters. Several of these values are calculated using both burst recognition and time series approaches. Burst proportion did not change relative to controls over the full range of cycle periods investigated, and rostral burst proportions remained equal to caudal burst proportions when the EAA concentrations were unequal. By contrast, a previous analysis of the same experimental data showed that rostral phase lags decrease relative to controls while caudal phase lags remain unchanged when the EAA concentration is higher in the caudal compartment (Sigvardt et al., *Neurosci. Abst.* 17:122 (1991); Sigvardt and Williams, in preparation).

PHOTO-ABLATION OF COMMISSURAL INTERNEURONS ALTERS FICTIVE SWIMMING IN LAMPREYS. J.T. Buchanan, D.R. McPherson*, & T.R. Strauss. Department of Biology, Marquette University, Milwaukee, WI 53233.

We used photo-ablation to test the involvement of commissural interneurons in fictive swimming in the isolated spinal cord. Spinal interneurons were retrogradely labeled by applying a mixture of fluorescein- and eosin-dextran amines to a transverse hemisection of the midbody spinal cord of adult sea lampreys (*Petromyzon marinus*). After 1 to 5 weeks of survival, fictive swimming was induced in 8-segment lengths of isolated spinal cord with N-methyl-DL-aspartate. An argon laser beam with a diameter of one-half the width of the spinal cord was moved along the spinal cord contralateral to the dye application site, allowing four minutes per location.

A few minutes after laser onset, an asymmetry began to develop in ventral root burst proportions. On the illuminated side (contralateral to dye application site), burst duration as a proportion of cycle period decreased from 0.41 \pm 0.06 (\pm S.D.) to 0.25 \pm 0.06, while on the non-illuminated side it increased to 0.61 \pm 0.09 (n=5). The changes in burst proportion were observed in spinal cord preparations both caudal and rostral to the dye application site. Cycle period increased about 35% with illumination. Phase coupling of left-right burst midpoints was not altered, nor was rostral-caudal coupling. In two cases, all rhythmicity appeared to be lost, leaving continuous firing of ventral roots on the non-illuminated side and weak, irregular spiking on the illuminated side. Control cords without tracer did not show these effects of laser illumination. Intracellular recordings of retrogradely-labeled neurons demonstrated that illumination caused depolarization, action potential broadening, and blockage of axonal propagation.

The results suggest that commissural interneurons play a role in the production of fictive swimming. One interpretation, supported by computer modeling, is that the outputs of crossed inhibitory cells were decreased by the laser, disinhibiting the opposite side. The resulting imbalance in the reciprocal inhibitory network produces an asymmetry in the burst proportions. (Supported by NIH NS-28369 & NS-09111)

ROLE OF RETICULOSPINAL NEURONS IN LOCOMOTOR CONTROL IN THE LAMPREY: INVESTIGATION USING A NEURAL NETWORK MODEL.

R. Jung* and A. H. Cohen, Department of Zoology, University of Maryland, College Park, MD 20742.

Neurons in the spinal cord of the lamprey form the central pattern generator (CPG) for swimming. These CPG neurons and the motoneurons (MN) receive input from reticulospinal neurons (RN). During fictive locomotion induced in *in vitro* spinal cord preparations some of the RN are phasically active. They are believed to be part of a spino-reticulo-spinal loop. We investigated the role of reticular and spinal neuron interaction on locomotor control in a neural network model by examining (a) the change in ascending-descending coupling between the RN and spinal cord neurons (b) the effect of brief perturbing stimuli to an RN during different phases of its cycle. In the model each neuron pool was represented by a single neuron which received tonic input as well as weighted synaptic input from other connecting neurons. In the absence of input from RN the CPG and MN outputs were rhythmic with phase relationships similar to those observed experimentally. (a) With the RN connected the MN cycle period (MN_{pd}) is dependent on the ascending-descending coupling gain ratio (GNratio). For GNRatio < 1, MN_{pd} decreased as descending gain (dscgn) increased ultimately resulting in a tonic output. For GNRatio > 1 and low dscgn, increasing the ascending gain (ascgn) increased MN_{pd} and at very high ascgn the output became unstable. For high dscgn however, the GNRatio must not only be > 1 but also above a threshold level in order to elicit rhythmic output from the CPG and MNs. (b) The effect of perturbing stimuli (20 msec pulse) to the RN on MN output was strength and phase dependent. Stimuli of low strengths had negligible effect on the MN cycle. Stronger stimuli caused obvious phase resetting; stimuli applied early in the cycle increased MN_{pd} (longer burst), while those late in the cycle decreased MN_{pd}. These simulation results are consistent with a role for the RNs both in generating the basic locomotor rhythm and in sensory integration in the intact lamprey. EFFECTS OF APAMIN ON THE FICTIVE GILL AND LUNG VENTILATION IN TADPOLE, *RANA CATESBEIANA*, BRAINSTEM *IN VITRO*. G.-S. Liao, R.J. Galante, A.P. Fishman, L. Kubin and A.I. Pack*. Center for Sleep and Respiratory Neurobiology, University of Pennsylvania, Philadelphia, PA 19104.

Small conductance, Ca²⁺-dependent potassium channels (sK_{Ca}) are involved in regulation of afterhyperpolarization of neurons and affect their repetitive firing properties. This may be particularly important in the generation of rhythmic behaviors. The *in vitro* brainstem of tadpoles generates two respiratory rhythms corresponding to lung and gill rhythms of an intact specimen (Galante et al., *Soc. Neurosci. Abstr.* 18:125, 1992). The neural output changes with the development. Thus, it offers an attractive model with which to study mechanisms underlying rhythmic behaviors and their development. In order to begin to determine the role of sK_{Ca} in the fictive gill and lung ventilation, we recorded neural activities from the facial nerve in brainstems of tadpoles at intermediate developmental stages (VII-XI) while superfusing the preparation with 5 different concentrations of apamin (0.1-2.5 μ M). Apamin increased the amplitude of gill-related activity in a reversible and dose-dependent fashion (at the highest concentration: 290% \pm 86(SD) of the control; n=5). In contrast, changes in the amplitude of lung-related bursts were minor and did not show a dose-dependence. In the time domain, apamin had no effect on the frequency of gill bursts, while it increased the duration of lung bursts in a dose-dependent manner (from 1.5 \pm 0.3 in control, to 2.3 \pm 0.5 at the highest concentration; n=5). Thus, apamin, without disrupting either of the rhythms, had differential effects on gill and lung activities in that only the amplitude of the former and primarily the burst duration of the latter were affected. Because both rhythms are found in most facial motoneurons (Liao et al., *Soc. Neurosci. Abstr.* 19:558, 1993), the effects of apamin must occur at premotoneuronal, including pattern generator, levels. These effects have to be studied in younger and older tadpoles to assess the possible changes in the role of sK_{Ca} with development. (Supported by HL-07713 and HL-49486)

SIMULTANEOUS ACTIVATION OF BOTH MAUTHNER AXONS CAN RESET THE FICTIVE SWIMMING RHYTHM IN GOLDFISH. K.R. Svoboda* and J.B. Fetcho. Dept. Neurobiology and Behavior. SUNY at Stony Brook, NY 11794.

A single action potential elicited in one of the two Mauthner axons (M-axon) while a fish is "fictively" swimming can dramatically reset the swimming rhythm. We are trying to identify cellular elements within the M-cell network that may subserve this resetting phenomenon. Firing both M-axons simultaneously results in cranial motor output, but no spinal motor output because the spinal commissural inhibitory interneurons in the M-cell network block firing of motoneurons and excitatory interneurons. We fired both M-axons simultaneously during bouts of fictive swimming to assess whether the resetting of the swimming rhythm could occur in the absence of spinal motor output from the escape network. Fictive swimming was elicited by stimulation of the midbrain of decerebrate, paralyzed goldfish and the motor pattern was monitored by recording extracellularly from branches of ventral roots. A single intracellularly elicited action potential was initiated in each M-axon simultaneously (within 0.1ms of each other) during bouts of fictive swimming. Simultaneous firing of both M-axons could reset the swimming rhythm as indicated by a shift in the midpoints of swimming bursts post-axon stimulation relative to when they would be expected to occur based upon the pre-stimulation burst pattern. This result indicates that the resetting of the swimming rhythm can occur in the absence of spinal motor output from the Mauthner cells and suggests that the commissural inhibitory interneurons in the M-cell network contribute to the resetting. Support: NIH NS26539 (JRF).

CONFOCAL IMAGING OF RESPONSES IN POPULATIONS OF IDENTIFIED MOTONEURONS DURING ESCAPE BEHAVIORS OF INTACT ZEBRAFISH. J.R. Fetcho* and D.M. O'Malley. Dept. Neurobiology and Behavior and Howard Hughes Medical Institute. SUNY at Stony Brook, NY 11794.

One of the major problems in studies of vertebrate neural networks is the difficulty in simultaneously monitoring the activity in populations of identified neurons. We took advantage of the transparency of larval zebrafish and used confocal microscopy and a calcium indicator to look into intact living fish and observe, with millisecond temporal resolution, activity-related changes in populations of individually identifiable neurons. Pools of primary and secondary motoneurons were backfilled with calcium green dextran and their fluorescence was monitored during escapes elicited by a contralateral tap of the head. Fluorescence increases in motoneurons were well correlated with escapes detected by an electrode grid beneath the fish. In every trial (n=30) from six fish in which 2 or 3 primary motoneurons were monitored, we found that when one of the motoneurons responded, they all did. In addition, whenever segmental groups of primary and secondary motoneurons were monitored (41 trials from 9 fish), all of the secondary motoneurons responded in conjunction with the primary ones. The relative timing of the responses in different motoneurons was examined by rapidly scanning a single line through the cells. These line scans indicated that some motoneurons responded within 6 to 14 milliseconds of one another. Although all motoneurons contralateral to a head tap responded, differential responses of motoneurons were evident in pools ipsilateral to the head tap and in responses to electrical stimulation. The synchronous response of the motoneurons to a contralateral head tap may account for the massive activation of the axial musculature characteristic of the C bend of the escape. This optical approach should allow studies of the functional role of populations of neurons throughout the spinal cord and brain of normal and mutant lines of zebrafish. (Supported by NIH NS26539 (JRF), NS09113 (DMO); a Sloan Foundation Fellowship (JRF) and the Howard Hughes Medical Institute)

652.11

PEPTIDERGIC MODULATION OF THE SPINAL NETWORK FOR LOCOMOTION IN LAMPREY BY NEUROTENSIN AND SOMATOSTATIN. J.-Y. BARTHE and S. GRILLNER*. Department of Neuroscience, the Nobel Institute for Neurophysiology, Karolinska Institute, S-17177 STOCKHOLM - SWEDEN.

Spinal neurones containing the neuropeptides somatostatin (SS) and neurotensin (NT) occur in lamprey. To gain insight into the ionic mechanisms and the functional role of these two peptides the effects of somatostatin and neurotensin were studied both at the cellular and at the network level. Fictive locomotion was elicited by bath application of the glutamatergic agonist NMDA (50-150µM) and monitored by recordings from ventral roots. When bath applied, both NT and SS (10^{-8} - 10^{-6} M) reversibly slowed the NMDA-induced rhythmic activity by 5-25%. Furthermore, SS induced a reduction of the burst proportion (burst duration/cycle period), whereas NT did not alter the burst proportion. In some instances the swimming activity became irregular with higher doses of NT.

NT induced a depolarization (4.4 ± 0.5 mV) of motoneurons and interneurons which remained after blockade of voltage sensitive sodium channels with TTX and after removal of calcium. The fast and slow phases of the afterhyperpolarization were not affected.

SS induced a hyperpolarization of spinal neurons and a decreased their firing frequency in response to depolarizing current pulses. SS also reduced the firing of both interneurons and motoneurons recorded during fictive locomotion. It also induced a slowing of TTX-resistant, NMDA-induced membrane potential rhythmic oscillations.

This study demonstrates that NT and SS modulate spinal neurons by two different mechanisms, which both lead to a slowing of the swimming activity but with a differential control of the burst parameters.

652.8

CONFOCAL IMAGING OF CALCIUM DYNAMICS IN SPINAL NEURONS IN THE INTACT ZEBRAFISH. D.M. O'Malley* and J.R. Fetcho. Dept. Neurobiology & Behavior, Howard Hughes Medical Institute, SUNY at Stony Brook, NY 11794.

Calcium green dextran (CGD) was used to monitor activity in the spinal cord of larval zebrafish. CGD (10k, Molec. Probes) was injected into muscle or spinal cord. After periods ranging from 16 hours to 9 days, the fish were curarized, placed in a glass-bottomed petri dish on the stage of an inverted Zeiss IM 35 microscope, and imaged with a Biorad MRC 600 confocal microscope. The CGD labeling revealed sufficient details of axonal and dendritic morphology to individually identify cells as sensory neurons (Rohon-Beard cells), primary or secondary motoneurons, or spinal interneurons (Cid cells, COPA cells). These cells showed fluorescence increases of up to 150% after electrical stimulation of the body surface or elicitation of an escape reflex. Increasing the duration of electrical stimulation produced a graded fluorescence increase, consistent with an accumulation of intracellular calcium. Fluorescence increases were not observed in surrounding, unlabeled tissue. Spatial resolution was optimized by closing the confocal aperture and fish were stimulated with a head tap during line scans. Fluorescence rose most markedly and rapidly at the rim of the nerve cell; signals in the interior rose more slowly and were attenuated in amplitude, indicating that calcium was diffusing from the plasma membrane to the cell interior. Also, the decay of fluorescence signals paralleled the decay of calcium signals observed in cultured neurons loaded with CGD via patch pipette. These results are consistent with earlier studies performed on isolated chick spinal cord, where neurons were loaded by a similar approach (O'Donovan et al., 1993). Instances of clear nuclear labeling confirmed that much of the CGD was not bound in organelles. This approach permits imaging of subcellular calcium dynamics in the zebrafish CNS. Because mutant lines of zebrafish have been created for genetic and developmental studies, this approach can be used to evaluate the effects of such mutations on neural activity/calcium homeostasis. MECHANISMS CONTRIBUTING TO ROSTROCAUDAL PHASE LAGS IN SPINAL LOCOMOTOR NETWORKS IN LARVAL LAMPREY. A. Hagevik* and A.D. McClellan. Div. of Biol. Sciences, Univ. of Missouri, Columbia, MO 65211

The mechanisms that contribute to rostrocaudal phase lags in larval lamprey (*Petromyzon marinus*) were investigated in partitioned *in vitro* brain/spinal cord preparations and by computer modeling. In *in vitro* preparations, spinal locomotor activity was elicited by chemical microstimulation in brainstem locomotor areas.

Short distance coupling. Strychnine applied to the rostral spinal cord (n=11) converted left-right alternation to synchronous bursting in the rostral cord as well as in the caudal spinal cord (Neurosci. Abst. 19:349, 1993). Strychnine applied to the caudal spinal cord resulted in synchronous activity in the caudal cord (n=7) but had less effect on the left-right phasing of the locomotor activity in the rostral cord. These results suggest that ipsilateral excitatory coupling is stronger in the descending direction. Computer modeling confirmed the biological results and suggested that a dominant descending coupling contributes to rostrocaudal phase lags.

Oscillator frequency gradient and long distance coupling. Cycle times of locomotor activity were examined in sections of the spinal cord when low-calcium Ringer's solution was applied to the rest of the cord. Cycle times of the isolated rostral cord were similar to cycle times in the entire cord (n=7), but did appear to depend on the length of the rostral segment and the intrinsic cycle time. Cycle times of the isolated caudal cord were mostly longer than the overall cycle times (6 of 7). Low-calcium Ringer's solution applied to the middle spinal cord resulted in a reduction in the phase lag between the rostral and caudal cord compared to control.

One interpretation of these results is that a frequency gradient along the cord contributes to rostrocaudal phase lags, and that long-distance coupling is symmetrical or perhaps stronger in the ascending direction which, by itself, would tend to reduce intersegmental phase lags. We are currently conducting experiments and performing computer modeling to investigate the combined effects of short distance coupling, long distance coupling, and oscillator frequency gradient on rostrocaudal phase lags. A CONTINUOUS NETWORK MODEL OF THE LAMPREY SWIMMING RHYTHM GENERATOR - INTERSEGMENTAL COORDINATION.

J. Hellgren^{1,2}, T. Wadden^{2*}, A. Lansner² and S. Grillner¹. ¹Nobel Institute for Neurophysiology, Department of Neuroscience, Karolinska Institute, S-171 77 Stockholm, Sweden. ²Department of Numerical Analysis and Computing Science, Royal Institute of Technology, S-100 44 Stockholm, Sweden.

In the lamprey, a simple eel-like vertebrate, swimming is produced by bursts of activity alternating between the left and right sides, with a frequency from 0.25 to 10 Hz in combination with a constant phase lag between consecutive segments resulting in a wave travelling down the body pushing the animal forward through the water. The swimming rhythm generating network has previously been modelled as a chain of coupled oscillators, due to its ability to produce fictive swimming with only short sections of *in vitro* spinal cord. Here we introduce a continuous network model, using populations of neurons and synaptic connectivity spread rostro-caudally along the spinal cord. Excitatory interneurons and caudally projecting crossed inhibitory interneurons are included in the network. The neurons are modelled according to a Hodgkin-Huxley type formalism. Excitatory synapses extend seven segments both rostrally and caudally with strengths decreasing over distance. The same connection strategy is used for crossed inhibitory synapses with the addition that they extend 20 segments caudally. A network consisting of 2600 neurons and over 700,000 synapses has been simulated using a powerful workstation. This network model produces stable forward swimming over a wide range of frequencies and can exhibit backward swimming by increasing excitability to the caudal segments. In order to further analyze the detailed contribution of different elements in the network we have studied different reduced networks. This has provided a deeper understanding of the different mechanisms underlying intersegmental locomotion in undulatory swimming.

652.13

VISUALIZATION OF SLICES OF THE TURTLE BRAINSTEM BY SECTIONING THROUGH ITS THREE-DIMENSIONAL RECONSTRUCTION. L. He*, R. Sarrafzadeh, E. Mugnaini†, and J. C. Houk. Department of Physiology, Northwestern University Medical School, Chicago, Illinois 60611-3008; †Laboratory of Neuromorphology, University of Connecticut, Storrs, Connecticut 06269-4154.

Three-dimensional reconstruction of the turtle rubro-cerebellar network was recently generated from anatomical data which were obtained from serial sections prepared for *in vitro* neurobiotin and biocytin tracer studies and immunocytochemistry. In the present study, our goal was to visualize slices of the turtle brainstem by sectioning through its three-dimensional reconstruction to identify optimal sectioning schemes of brainstem slices for *in vitro* electrophysiological studies.

Brain slice preparations have been frequently used for investigations of neuronal microcircuits, cellular properties, and synaptic plasticity. One of the difficulties in preparing brain slices is to establish optimal thicknesses and orientations with which the slices are to be cut. During the rendering of our reconstruction, two parallel clipping planes were defined in the object coordinates. Only those graphics primitives that fell in between this pair of clipping planes were rendered. In this way, a virtual brain slice was cut out of the three-dimensional reconstruction. By adjusting the offset of and the distance between the clipping planes and the viewing angles of the reconstruction, the thickness and orientation of the virtual brain slice could be changed to include cell groups and fiber tracts of interest and thus preserve converging inputs for analysis of excitatory and inhibitory synaptic processes. The rendering of the brainstem and ventricular surfaces in such brain slice provides landmarks which guide the preparation of slices for actual experiments.

Several interesting slices of the turtle brainstem obtained with this technique have inspired new potential experimental designs in our turtle premotor network studies. The same technique can be applied to three-dimensional reconstruction of other parts of the central nervous system to facilitate the experimental design of brain slice preparations.

THE ROLE OF GLYCINE- AND GABA_A-MEDIATED INHIBITION IN INTERLIMB COORDINATION IN THE ISOLATED MAMMALIAN SPINAL CORD. E. S. Simon* and A. Lev-Tov, Laboratory of Neural Control, NIH, NINDS, Bethesda MD 20892 and Dept. of Anatomy, The Hebrew University Medical School, Jerusalem, Israel

The effects of the glycine and GABA_A receptor antagonists, strychnine and bicuculline, on neurochemically-induced locomotor rhythms were studied in the isolated spinal cord of the neonatal rat (P2-P6), using wide-band electrotonic recordings from ventral roots (VRs). Bath application of strychnine (1-2 μ M) or bicuculline (2-10 μ M) to otherwise untreated spinal cord preparations induced bilaterally-synchronous paroxysmal bursts in homologous lumbar VRs. These paroxysmal bursts were abolished by addition of the NMDA receptor blocker APV (10-20 μ M) or the non-NMDA antagonist CNQX (1-5 μ M) to the bath. In contrast, bath application of serotonin (5HT, 25-40 μ M) and NMDA (2-5 μ M) induced alternating discharges in homologous VRs, interpreted to be a locomotor rhythm. Addition of the above concentrations of APV or CNQX slowed but did not abolish the alternating rhythm. Alternating VR discharges were abolished and replaced by paroxysmal synchronous VR bursting after addition of the above concentration of strychnine or bicuculline, as might be expected if the alternating rhythm depends on a half-center system with mutual inhibition. However, the alternating rhythm persisted when APV (20 μ M) was added to the bath prior to application of either inhibitory antagonist. Washout of APV returned the activity to bilaterally-synchronous paroxysmal bursting. This result suggests that the neural control of interlimb coordination in the isolated spinal cord may be more complex than a simple half-center model involving only mutual inhibition.

DUAL PATTERNS OF LOCOMOTOR ACTIVITY INDUCED BY 5-HT AND DOPAMINE IN THE *IN VITRO* NEONATAL RAT. Q. Kiehn* and O. Kjaerulff. Sect. of Neurophysiology, Dept. of Medical Physiology, Univ. of Copenhagen, Copenhagen 2200, Denmark.

From invertebrate studies it is known that different transmitters can produce distinct motor output patterns by re-wiring a common network or intermixing adjacent networks (Harris-Warrick and Marder, *Ann. Rev. Neurosci.* 14, 39; 1991). To what an extent the same is true for the spinal locomotor networks in mammals is at present unknown. As a first approach to answer that question we have performed a detailed analysis of dopamine (DA) and 5-HT-induced EMG patterns in the *in vitro* hindlimb-attached spinal cord preparation from neonatal rats aged 0 to 4 days.

5-HT induced a regular fast rhythm while DA evoked a slow irregular rhythm. Furthermore, the two transmitters elicited fundamentally different overall locomotor patterns. Thus, in 5-HT there was a dominant flexor activity in the vastus lateralis/medialis and rectus femoris muscles, while the same muscles shifted to be mainly active in the extensor phase during DA-induced locomotion. Similarly, biceps femoris and semitendinosus activity could shift from extensor activity in 5-HT towards flexor activity in DA. Other hindlimb muscles maintained similar phasing independent on the transmitter. During upstart of rhythmic activity uncoupling and phase-drift of muscle activity was sometimes noted, indicating that the locomotor networks are composed of a mosaic of unit burst generators.

Our results show that the spinal locomotor networks in mammals can have a high degree of flexibility, and we suggest that the networks are reconfigured by extrinsic modulation.

FICTIVE HINDLIMB MOTOR PATTERNS EVOKED BY APPLICATION OF GLUTAMATE AGONISTS TO THE TURTLE SPINAL CORD.

S.N. Currie, Dept. Neuroscience, Univ. of California, Riverside, CA 92521.

In turtles, it has been shown that both NMDA and non-NMDA type glutamate receptors contribute to cutaneous sensory processing in the scratch reflex pathway (Currie and Stein, 1990). In the present study, we tested the ability of NMDA (20-100 μ M) and AMPA (2-10 μ M) to evoke fictive hindlimb motor output when applied exogenously to restricted regions of the turtle spinal cord. Drugs were applied onto the exposed dorsal surface of 2-3 adjacent spinal cord segments near and within the anterior hindlimb enlargement. These segments receive cutaneous afferents from the pocket scratch and flexion reflex receptive fields (Mortin and Stein, 1990) and contain both hindlimb motor neurons and key elements of the scratch motor pattern generator (Ruigrok and Crowe, 1984; Mortin and Stein, 1989). Motor output was recorded unilaterally from 3-5 hindlimb muscle nerves. Both NMDA and AMPA elicited coordinated bursting motor discharge in all recorded hindlimb nerves. These chemically evoked motor patterns exhibit rhythmic alternation between hip flexor (VP-HP) and hip extensor (HR-KF) motor neuron activity; the timing of knee extensor activity within the hip flexor-extensor cycle is similar to that of sensory-evoked pocket scratch motor patterns. These chemically evoked motor patterns interact strongly with cutaneous-evoked reflexes. Stimulation of flexion reflex on the ipsilateral or contralateral side produces phase-dependent resets of the chemically evoked rhythm. Stimulation within a scratch receptive field can reset the rhythm and in some cases, increase burst frequency for several cycles. Supported by NSF Grant IBN-9308804 to S.N.C.

THE EFFECTS OF INHIBITORY AGONISTS AND ANTAGONISTS ON THE OCCURRENCE AND PATTERN OF SPONTANEOUS ACTIVITY IN THE CHICK EMBRYO SPINAL CORD. N. Chub and M. J. O'Donovan*

Lab of Neural Control, NINDS, NIH, Bethesda, MD 20892.

The isolated spinal cord of the chick embryo generates spontaneous episodes of rhythmic motor activity. During each cycle sartorius (SART) motoneurons experience a pause in their firing during peak femorotibialis (FEM) activity. We have investigated the role of inhibitory agonists and antagonists the genesis and phasing of this activity. Bath application of bicuculline (10-100 μ M), picrotoxin (1 μ M), GABA (10-500 μ M), isoguvacine (5 μ M) or strychnine (20-50 μ M) suppressed spontaneously occurring motor activity, although electrically evoked episodes could still be obtained.

The SART pause was blocked following local application of bicuculline (1 mM, 20 sec) or picrotoxin (100 μ M, 20 sec) and was depressed by strychnine (1 mM, 20 sec) over SART motoneurons (see also Sernagor and O'Donovan, 1991 *Soc. Neurosci. Abstr.* 17:120). Paradoxically, however, the pause persisted in the presence of bath applied bicuculline and strychnine (20-50 μ M) and a pause appeared in FEM discharge. Under these conditions local application of the NMDA antagonist AP-5 (500 μ M, 20 s) or the non-NMDA antagonist CNQX (500 μ M, 20 sec) completely abolished inhibition in SART and FEM motoneurons in a reversible manner. Neither AP-5 nor CNQX had this effect in normal Tyrode's solution although CNQX could depress the SART pause. Our results indicate that inhibitory mechanisms may participate in the regulation of spontaneous activity although we cannot exclude the possibility that inhibitory antagonists act non-specifically. They also indicate a clear role for synaptic inhibition in the phasing of motoneuron activity and raise the possibility that, under certain circumstances, glutamate may be functionally inhibitory during development.

The role of NMDA and non-NMDA receptors in locomotor neural networks of embryonic spinal cords. J. Tabak, J. Prime, L. Ritter, A. O'Donovan, M. Murphy, C.R. Danel-Moore, L. and S. Moore, L. E. * S.C.N.R.S. & INSERM U391, Univ. Rennes I, Rennes, Fr., #Lab. of Neural Control, NIH, Bethesda, Md. *Dept. Physiol. & Biophys., UTMB, Galveston, Tx.

Locomotor Neural Networks of Xenopus and chick embryonic spinal cords were compared at different developmental stages. Single cell neuronal models were developed from frequency domain data explicitly incorporating the dendritic structures present in spinal neurons. The neuronal models were based on the biophysical properties of individual neurons measured in both systems. The simulation neural network model of Roberts & Tunstall (Eur. J. Neurosci. 2:11; 1990) was extended to incorporate both NMDA and non-NMDA receptors distributed on dendritic cables, providing a more robust pattern generating system. Locomotor activity, induced by pulses of current applied to the skin, was recorded with extracellular electrodes from ventral roots of curarized, spinalized Xenopus embryos. Locomotor activity was abolished after developmental stage 38 by 100 μ M APV, however at stage 28, there were no or minimal effects. At stage 28, 5 μ M CNQX minimized or abolished locomotor responses and at later stages the duration of activity was shortened. Locomotion was easily evoked at stage 38 in nominally zero Mg, however, 2.5 mM Mg shortened the duration of activity, and 5 mM often led to total blockage. At stage 42, 2.5 mM Mg generally blocked locomotion. At stage 28, 2.5 mM Mg had no clear effect on locomotion. These results support the hypothesis that during the initial stages of embryonic development, locomotion neural networks utilize principally non-NMDA excitatory receptors, however, during development NMDA receptors become more prevalent in conjunction with the appearance of complex dendritic trees. In addition, probes for mapping glutamate receptor distributions on dendritic structures were developed using PCR methods to select highly conserved regions from membrane spanning regions of Xenopus and lamprey. RHYTHMIC OUTPUT OF EMBRYONIC SPINAL NETWORKS IN CULTURE IS INDUCED BY DISINHIBITION BUT NOT BY INCREASED EXCITATION J. Streik*, Institute of Physiology, Bülhplatz 5 3012 Bern, Switzerland

Simple locomotor patterns are based on rhythmic output of local spinal networks. In order to investigate the minimal structure and the formation of such networks, the spontaneous output of cultured slices of the embryonic rat spinal cord was studied. This was done by coculturing the slices with skeletal muscle fibres and recording the patterns of spontaneous muscle contractions using a simple optical device. Neuron-driven muscle contractions were distinguished from autocontractions of the muscle fibres by their typical patterns and by pharmacological tools.

Roughly 20 % of the cocultures showed spontaneous neuron-driven muscle contractions, most of them with random patterns. In all of these cultures rhythmic patterns of muscle contractions were induced by classical pharmacological disinhibition of the spinal networks (strychnine, bicuculline or both). Antagonists at GABA B receptors or substances interfering with cholinergic, catecholaminergic or peptidergic pathways had no effect on rhythmic activity patterns, suggesting that these pathways were not critical for rhythmogenesis.

On the other hand rhythmic activity was not evoked by NMDA, glutamate or the glutamate uptake blocker dihydrokainate. NMDA in the absence of magnesium increased the rate of spontaneous activity without inducing rhythmic activity. Spontaneous activity completely ceased in presence of the glutamate antagonist CNQX.

These findings suggest that rhythmic output patterns arise in glutamatergic spinal networks and that they are induced by reducing inhibitory transmission within these networks but not by increasing excitatory transmission.

NMDA-INDUCED OSCILLATIONS IN SPINAL MOTONEURONS BECOME MASKED BY INHIBITION DURING DEVELOPMENT M.-S. Rioult-Pedotti*, Department of Biology, Yale University, New Haven, CT 06511

Responses were recorded from ventral roots (VR) in isolated hemisectioned frog and tadpole spinal cords (SC). In frog SCs intracellular recordings were simultaneously made from identified lumbar MNs. Tadpole swimming was recorded with a video camera. Application of NMDA (50 μ M) evoked periodic bursting of VR activity in tadpoles but not in frogs (5-200 μ M). However, after strychnine (20-30 μ M) application, synchronized periodic bursts were also initiated in the frog VRs. These persisted after strychnine removal and were coincident with periodic oscillations measured intracellularly in the motoneurons (MN). Thus, this periodic bursting behavior reflects a periodic oscillation of MN membrane potential. In the adult frog this behavior is initiated only after removal of inhibition. The periodic (~1Hz) tadpole VR bursts occur at the same frequency as the tadpole tail moves during swimming. Oscillations in the frog were much slower (>10s/cycle). Oscillations of tadpole and frog MNs have the same properties: they require the presence of physiological Mg^{++} concentration (1mM), they are blocked by APV (100 μ M) but not affected by CNQX (10-15 μ M), and they are resistant to TTX (3 μ M).

These data provide evidence for the existence of a central pattern generator that is active in the tadpole and becomes inhibited during metamorphosis as the locomotor behavior changes from rhythmic to episodic.

ACTIVITIES OF TARSAL AFFERENTS IN FREELY WALKING COCKROACHES. G. S. Larsen, S. F. Frazier and S. N. Zill*. Dept. of Anat., Cell and Neurobiology, Marshall Univ. Sch. Med, Huntington, WV 25755.

Sensory inputs from the distal segments of legs have been shown to modulate walking in many animals. We have recorded activities of sense organs of the distal (tarsal) segments of the cockroach hind leg in restrained and freely walking animals. In restrained preparations, neurographic wires implanted adjacent to sensory nerves in the first tarsal segment recorded afferents responding to the position and movements of the distal tarsal joint. We have morphologically identified a chordotonal organ proximal to the joint and ablation studies strongly suggest that it is the source of these activities. Recordings in freely walking animals show peak activities at the onset and termination of the stance phase. These discharges occur at the time that the claw is engaged and then disengaged when walking or climbing over rough surfaces. We have also shown that electrical stimulation of afferents through the recording electrodes reflexly excites the tibial flexor muscle. We propose that the discharge of the organ signals disengagement of the claw from the substrate, reflexly exciting the flexor muscle at the initiation of swing.

CONTRIBUTIONS OF PERIPHERAL PROPERTIES TO INSECT AND ROBOT LOCOMOTION. R.D. Beer*, W.J. Marx, G.M. Nelson, K.S. Espenschied, R.D. Quinn, J.T. Watson, R.E. Ritzmann, H.J. Chiel. Depts. of Computer Eng. and Science, Biology, Mechanical and Aerospace Eng., and Biomedical Eng., Case Western Reserve University, Cleveland, OH 44106.

In order to better understand the role of peripheral properties in cockroach walking, we have been developing biomechanical models of the insect. We have constructed a passive musculoskeletal model of the femur-tibia (FT) joint of the metathoracic leg. This model suggests that passive properties (i.e. passive muscle tension and damping about the FT joint) play an important role in this joint during the swing phase of walking. Indeed, the initial swing movement can be generated entirely by passive forces. The FT joint model is currently being extended to incorporate active properties. In addition, we have developed a full body dynamic model of the free walking insect with 30 articulated degrees of freedom. This model is being used to estimate joint torques and ground reaction forces from kinematic data.

We have also constructed a 6 legged robot with 18 active degrees of freedom. The purpose of this robot is to investigate the application of biological control principles to robotics. A generalization of leg coordination mechanisms derived from stick insect walking are used to control the robot's locomotion. Muscle-like control of the joints is achieved using a scheme based on the equilibrium point hypothesis. Force feedback permits the robot to comply to uneven surfaces. An implementation of the elevator reflex allows the robot to step over obstacles. The robot can walk in a continuum of gaits, turn and negotiate irregular terrain.

KINEMATIC AND EMG ANALYSIS OF THE FAST AND SLOW RUNNING IN THE COCKROACH. J. T. Watson* and R. E. Ritzmann. Department of Biology, Case Western Reserve University, Cleveland, OH 44106.

As part of a project to implement biological principles into the design of legged robots, we are combining high speed video motion analysis of leg movements with EMG recordings from leg muscles in cockroaches. We have recorded from the depressor and levator coxa and the extensor and flexor tibia muscles in the hind and middle legs at various running speeds.

Slow walking (1-3 Hz) is characterized by long bursts of graded slow motor activity. As expected, the kinematics of joint movement follow the neuromuscular activity closely. During fast running (> 10Hz) distinct changes occur. Slow motor activity increases in frequency and fast motor neurons are recruited. However, muscle potentials associated with fast motor neurons are not recorded on each cycle. They tend to be recruited more regularly at the beginning of runs than in cycles occurring near the end. The principle difference in joint kinematics associated with fast motor activity is a more abrupt transition from stance to swing.

The temporal relationships between various motor activities are consistent within a single animal. These include latency from fast depressor to fast levator of the coxa and latency from fast depressor to fast extensor of the tibia. Although the fast depressor activity occurs at or near the beginning of coxal depression, fast levator activation tends to occur much earlier in the step cycle than expected; i.e. during the stance phase.

We are beginning to make similar observations on the middle legs. Our preliminary findings indicate that although the kinematics of the middle legs are very different from the hind legs, the pattern of electrical activity does not reflect these differences. We believe that this paradox may reflect the influence of passive forces and leg morphology upon leg movements.

CHANGES IN A PROPRIOCEPTIVE PATHWAY DURING MATURATION OF LOCOMOTOR RHYTHMICITY. J.R. Gray* & R.M. Robertson. Dept. Biology, Queen's University, Kingston, Ontario, Canada, K7L-3N6.

The flight system of the locust is a well established model for studying the role of proprioceptive input in motor pattern generation. Gradual hemimetabolous development of this insect makes it ideal for examining maturation of preexisting circuitry as well as potential changes in afferent input.

During maturation of the flight system the wingbeat frequency increases from 13 Hz at 1-2 days after imaginal ecdysis to approximately 23 Hz 14 days later. We examined the morphology of a single cell proprioceptor, the wing hinge stretch receptor, and the response of flight interneurons to stretch receptor activity during maturation.

Preliminary results indicate that during maturation the central arborization of the forewing stretch receptor axon displays heteromorphic growth. Further, within the mesothoracic branch there is an increase in the number of axonal swellings and the branch grows positively allometrically relative to the ganglion. Artificial excitation of the stretch receptor with patterns of stimuli that correspond to increased afferent activity at different stages of maturation produced increased activity of postsynaptic flight interneurons.

These results indicate that changes in the stretch receptor may alter its effect on the operation of the flight motor and suggest that proprioception influences, in part, motor pattern development.

PHASIC MODULATION OF WING HINGE MECHANICS BY THE FIRST BASALAR MUSCLE OF THE BLOW FLY *CALLIPHORA*. M.S. Tu* and M.H. Dickinson. Department of Organismal Biology and Anatomy, University of Chicago, 1025 E. 57th St. Chicago IL 60637.

Among the 17 direct steering muscles in flies, the First Basalar (B1) has been implicated as the muscle most likely to control the timing of ventral wing pronation (the ventral flip). Because of the potentially large aerodynamic forces associated with the ventral flip, rapid and precise modulation of the B1 output may be crucial for flight control. In the blowfly *Calliphora vicina*, the B1 fires an action potential and undergoes a cycle of length oscillation each and every wing beat at 150 Hz. Under conditions simulating flight we previously found that the B1 may function as a spring, with properties of dynamic stiffness and mechanical energy dissipation under neural control. Changes in the dynamic stiffness of the B1 could control the extent of oscillations of the basalar apodeme, which forms the mechanical linkage of the B1 to the wing hinge.

To test the hypothesis that rapid phase changes in B1 activation can phasically modulate oscillations of the basalar apodeme, we measured B1 muscle length changes while making extracellular recordings of B1 action potentials. By measuring the deflection of a laser beam reflected from a small mirror mounted on the external portion of the basalar apodeme, we could non-invasively measure oscillations of the basalar apodeme and the corresponding length changes of the B1 during tethered flight.

We found that changes in the interval between action potentials corresponded to increases in the maximum extent of stretch in the B1 and the extent of posterior deflection of the basalar apodeme. Changes in the amplitude of basalar oscillations occurred within one cycle of changes in action potential timing. This rapid mechanical response suggests that the B1 can modulate wing kinematics on a cycle by cycle basis, even though wing beat frequency stimulation of the B1 under isometric conditions causes nearly complete tetanus.

653.7

THE STRUCTURE OF THE FLUID WAKE GENERATED BY A FLYING FRUIT FLY, *DROSOPHILA MELANOGASTER*. M.H. Dickinson*. Dept. of Organismal Biology & Anatomy, Univ. of Chicago, Chicago, IL 60637.

The flight behavior of insects has been an important model system for the study of rhythm generation, sensory-motor integration, and motor output. However, the net result of these neural processes - the generation of flight forces by the wing - is poorly understood. In an attempt to characterize the aerodynamics of flight behavior in flies, I have visualized the flow structure generated by a tethered flying *Drosophila*. Flow was visualized using *Lycepodium* spores illuminated with laser sheets (670 nm) and imaged using a cooled CCD camera. The capture of images could be synchronized to the wing beat cycle following fixed delay allowing the generation of phase-reconstruction movies showing the change in flow throughout the wing stroke.

The flow visualizations reveal that *Drosophila* generate an inverted single heart-shaped vortex tube during each wing stroke. The dorsal portion of each vortex ring is produced gradually from the shedding of tip vorticity throughout the downstroke. During the ventral flip, the quick supination of the wings at the start of the upstroke, the ventral arms of the vortex ring are rapidly shed, merging distally with the dorsal portion of the ring, and attaching medially to the thorax. It is at this time that the vortex ring detaches completely from the wings and is shed into the wake. In contrast, no vortex structures are generated during the upstroke. The vortex rings generated by successive downstrokes coalesce to form a vortex tube directed posteriorly, roughly normal to the wing stroke plane. The fluid velocity within the central region of the vortex tube is high, instantaneously reaching values nearly ten times that of the free stream velocity.

The rapid shedding of vorticity during the ventral flip correlates with a large transient in the production of lift measured using laser interferometry. The timing and position of the ventral flip shedding may provide an important means for the control of steering forces during flight.

653.9

MOTOR NEURONS INVOLVED IN A REFLEX CIRCUIT EXHIBIT STAGE-SPECIFIC DIFFERENCES IN THEIR PROPERTIES. J.L. Casagrand*, and R.B. Levine. Univ. of Arizona, ARL Div. of Neurobiology, Tucson, AZ 85718.

In *M. sexta* a mechanosensory reflex circuit produces distinct behaviors in larvae and pupae. Many elements in the pupal reflex circuit are retained from the larval stage. However, the activity that is evoked in the motor neurons by sensory nerve stimulation is quite different. We previously reported (Casagrand and Levine, 1993) a difference in the firing properties of motor neurons involved in this reflex at the two stages due to positive current injected into the soma. Pupal neurons exhibited a higher threshold for action potential initiation and a lower level of excitability. These differences were consistent with the changes in physiological responses observed.

We wished to investigate whether these data reflected actual differences in the spike generating regions, or were the result of subtle changes in morphology (Levine and Truman, 1985) that were affecting events recorded at the soma. We thus looked at a number of properties of the neurons in response to injected current. We observed no differences in input resistance, resting potential, or amplitude and rise time of action potentials. We also looked at the threshold for action potentials during responses evoked by synaptic activity (sensory nerve stimulation). As with the injected current experiments, pupal neurons exhibited a higher threshold, contrary to what one would expect if these differences were due to changes in passive properties. These data thus suggest that the differences in action potential threshold and excitability are not due to changes in passive properties of the motor neurons. Thus, it is likely that changes in the active properties of these motor neurons contribute to the altered reflex. Supported by NIH fellowship NS 09249 to J.L.C.

653.6

THE ROLE OF HALTERE AFFERENTS IN THE ACTIVITY OF A STEERING MUSCLE IN THE BLOWFLY, *CALLIPHORA VICINA*. A. Fayyazuddin*, W. P. Chan, C. E. Jordan and M. H. Dickinson. Department of Organismal Biology & Anatomy, Univ. of Chicago, Chicago, IL 60637.

The large direct synchronous basalar muscles in the blowfly are active during turning maneuvers, and are thought to control the steering motions of the wings. One of these muscles, the first basalar (B1), is unique in that it fires one spike each wing beat at a precise phase within the stroke cycle. We have been investigating whether the campaniform fields at the base of the haltere provide the wing beat-synchronous feedback required for this sharp phase tuning of the B1 during flight. Both mechanical oscillation of the haltere and electrical stimulation of the haltere nerve cause the B1 motor neuron (MNB1) to fire a phase-locked action potential. Furthermore, MNB1 can follow stimulation frequencies up to and exceeding the normal wing beat frequency (150 Hz), suggesting that the halteres may be sufficient in establishing the phase-locked firing pattern of B1 during flight. We have begun to characterize the physiology of the connections between MNB1 and haltere afferents by recording intracellularly from the motor neuron while mechanically stimulating identified fields of campaniform sensilla on the base of the haltere. Stimulation of two large dorsal fields, (dF2 and dF3), produce short-latency (<1ms) EPSPs in MNB1. Stimulation of the third dorsal field (dF1) has no effect on MNB1 activity. Campaniform neurons from both dF2 and dF3, visualized with biotinylated dextran, project to the meso-thoracic neuropile near the site of origin of the MNB1 axon. In contrast, neurons originating from dF1 terminate in a different region, consistent with their failure to elicit a short-latency physiological response in MNB1. In other invertebrates, the strength of sensory-motor connections can be modulated by neurotransmitters such as octopamine (OA). In the blowfly, OA also enhances the synaptic efficacy of the connections between the haltere and MNB1.

653.8

THE ROLE OF THE FRONTAL GANGLION IN ADULTS OF THE MOTH *MANDUCA SEXTA*. C.I. Miles* and R. Booker. Section of Neurobiology and Behavior, Cornell Univ., Ithaca, NY 14853.

As part of an ongoing study of metamorphosis of the frontal ganglion (FG) of *Manduca*, we have examined its function in the adult moth. We have found that the FG innervates the muscles of the moth's cibarial pump. These include dilators which expand the pump chamber, as well as compressors which reduce it. The cibarial pump is used during feeding to bring nectar through the proboscis into the foregut. We have recorded the motor program for the cibarial pump muscles during feeding. Its primary component consists of a relatively long burst of dilator activity immediately followed by a brief burst of the pump compressors. The cibarial pump also plays a critical role in the expansion of the moth's wings following its emergence from the pupal cuticle. During wing expansion, the cibarial pump is activated and the animal swallows air, using a motor pattern that is similar to that exhibited during feeding. Air-swallowing is apparently required for expanding both the wings and the abdomen. Animals from which the FG was removed at the onset of metamorphosis develop normally into adults and successfully emerge from the pupal cuticle, but they fail to expand their wings and their abdomens are flattened. Feedback for turning off air-swallowing apparently requires connections between the FG and brain, as animals in which these were bilaterally cut at the end of the larval stage expanded their wings normally but exhibited distended or burst abdomens by 24 hrs after adult emergence.

653.10

DISTRIBUTED MOTOR ACTIVITY IN A SEGMENTALLY RESTRICTED REFLEX. W.C. Lemon* and R.B. Levine. Div. of Neurobiology, University of Arizona, Tucson, AZ 85721.

Stimulation of sensory neurons innervating hairs in the gin traps on the abdomen of pupal *Manduca sexta* evokes a rapid bending of the abdomen that is restricted to three posterior segments. Electrical stimulation of the gin trap sensory nerve in an isolated abdominal nerve cord evokes characteristic motor neuron activity in every abdominal segment. To determine if the segmentally distributed motor activity also occurred in intact animals and how it contributed to the segmentally restricted reflex movement, mechanical stimulation of the sensory hairs in intact animals was used to evoke reflex responses that were recorded as electromyograms synchronized with video recordings of the behavior. Reflex behaviors were compared with the underlying patterns of motor activity to determine if there was activity in many segments when the movement was restricted to one, two, or three segments. Coordinated muscle activity was evoked throughout the abdomen in response to stimulation of any of the three gin traps, even when movement was restricted to one segment. Electromyograms of gin trap muscle activity correlated well with the intracellular and extracellular recordings of motor neuron activity obtained from isolated abdominal nerve cords and semi-intact preparations. These findings show that the neural circuit underlying the bending reflex is distributed throughout the abdominal nerve cord. This network generates a complex yet coordinated motor pattern with muscular activity in every abdominal segment whose concerted action produces a deceptively simple and localized bending reflex. Supported by NIH fellowship NS 07309 to W.C.L.

653.11

MODIFICATIONS OF THORACIC LEG MOTOR ACTIVITY DURING POSTEMBRYONIC DEVELOPMENT IN *MANDUCA SEXTA*. R. M. Johnston* and R. B. Levine. Div. of Neurobiology, University of Arizona, Tucson, AZ 85721

At the end of larval life in *Manduca sexta*, the thoracic legs and muscular system are replaced by new adult legs that differ dramatically in both form and behavior. Kinematic and electromyographic data show that during larval crawling, the left and right prothoracic legs move synchronously. In contrast, during adult walking the prothoracic legs alternate. Many if not all of the thoracic leg motor neurons present in the adult stage are retained from the preceding larval stage (Kent and Levine 1988). To follow the transitions between these coordination patterns, we quantified the overt behavior and electromyograms of the thoracic legs in developing adults.

Leg movements in the proximal segments precede movements in the more distal leg segments during adult development. In the beginning final third of adult development (stage 14), synchronous, phasic muscular activity in femoral levators and depressors is present even though there are no observable movements of the femur. Two days later (stage 16), both synchronous and alternating patterns of leg movement and corresponding muscular activity are seen. At this stage in development, the frequency and temporal patterns of leg motor output are similar to those seen in adult moths. These data will help us determine if the changes in thoracic legs patterns are due to a whole-scale restructuring of the underlying circuit or if the changes reflect modulation of a pre-existing larval circuit. Supported by NIH fellowship NS 09387 to R.M.J. and an NIH grant NS 24822 to R.B.L.

653.13

PERIPHERAL MODULATION OF A CENTRAL SYNAPSE BETWEEN IDENTIFIED MOTONEURONS IN THE METATHORACIC GANGLION OF THE LOCUST. T. Jellema & W.J. Heitler*. Gatty Marine Lab., St. Andrews University, Fife, Scotland KY16 8LB.

The fast extensor tibiae (FETi) motoneuron of the hind leg of locusts, which innervates the muscle providing the propulsive force for the jump and kick, also establishes excitatory, monosynaptic, connections with several flexor tibiae (FITi) motoneurons. These central synaptic connections, which are apparently unique among insect motoneurons, contribute to the co-activation of the FETi and FITi motoneurons during the preparation for a kick or jump. Simultaneous intracellular recordings from the FETi and FITi motoneurons, while evoking ortho- or antidromic FETi spikes, reveal that the amplitude and duration of the central PSPs in the FITi motoneurons are modulated by leg position: during leg flexion the PSPs are larger than during extension. This is in part due to sensory feedback of tension in the extensor muscle summing with the central FETi-FITi synaptic component. However, when extensor tension is abolished by dye-mediated laser photo-axotomy of FETi, the amplitude of the EPSP is still modulated by leg position. The photo-axotomy technique allows specific de-innervation of the extensor muscle, without affecting any of the other structures, and the innervation can swiftly be restored via an electronic "axonal bypass" from the FETi soma to the extensor muscle. In the locust, hind leg position is mainly monitored by the chordotonal organ located in the distal femur. Manipulation (alternately stretching and relaxing) of the tendon of this sense organ, while keeping the leg in fixed position, accounts for most of the PSP amplitude modulation. A relatively enhanced PSP in the FITi with leg flexion makes sense since leg flexion is a prerequisite to go into the co-activation phase. The site and mechanism of the modulation (e.g. pre-synaptic FETi spike amplitude, input resistance of the FITi, presynaptic modulation of the central synapse itself) is currently being investigated.

653.15

DYNAMICS OF A POSTURAL REFLEX IN HERMIT CRAB STUDIED WITH SINUSOID AND NOISE VIBRATION. W.D. Chapple*. Dept. Physiology and Neurobiology, Univ. of Connecticut, Storrs, CT 06269.

A systems model of a phasic stretch reflex, important in the postural support of its shell by the hermit crab, *Pagurus pollicarius*, has recently been developed from experiments using simultaneous recording of muscle force, length, and spike frequencies of pairs of motoneurons during ramp stretch and release of the right fourth segment of the abdominal ventral superficial muscles. (Chapple 1993). A prediction of this model is that the reflex is important primarily in increasing abdominal stiffness in response to sustained rather than transient stimulation. Sinusoidal and bandpass limited noise lasting for 20 seconds was used to vibrate the muscle. Reflex activation of the motoneurons occurred at thresholds of 0.8% of optimum lengths and frequencies above 2.5 Hz. After a transient peak, frequency declined to a steady state level that lasted for the duration of stimulation. This reflex activation of the motoneurons increased muscle stiffness as stimulus amplitude increased, but did not alter its dynamics. The form of the transfer function that best approximated these dynamics was that of a high pass filter with a lower cutoff frequency of 10 Hz, similar to that observed in the isolated, electrically stimulated muscle. The model's prediction that this reflex could increase muscle stiffness during sustained vibration was confirmed. However, in this isolated abdominal preparation, the reflex did not compensate for variations in muscle stiffness with stimulus amplitude, and, thus, did not regulate muscle stiffness.

A SUPERFAST TRAP-JAW REFLEX IN ANTS

W. Gronenberg* Biozentrum der Universität, Am Hubland, D-97074 Würzburg; Germany

Ants of the ponerine genus *Odontomachus* employ a trap-jaw mechanism to instantaneously close their mandibles to catch prey or to defend themselves. When particular mechanosensory trigger hairs, located on the inner edge of the mandibles, are touched by a prey object, the mandible strike is released in less than 0.5 ms (Gronenberg et al. 1993; *Science* 262:561-563). Photoelectric scanning reveals that this reflex may take as little as 4 ms and is thus probably the fastest reflex yet described for any animal. This speed is based on a catapult-like catch mechanism in the mandible joint that keeps the extended mandibles open during contraction of the powerful closer muscle, thus cocking the mandibles. A small specialized trigger muscle unlocks the catch, instantaneously releasing the stored energy to accelerate the mandible. This trigger muscle is activated only a few milliseconds in advance of the strike. It is composed of specialized tubular muscle fibers the central canal of which contains the cell nuclei and mitochondria. The trigger muscle is supplied by two unusually large motor neurons which are enclosed in a glial sheath. Together with the giant afferents originating from the trigger hairs (Gronenberg and Tautz 1994; *J. Comp. Physiol.* 174: 49-60), the entire reflex system is composed of 2 sensory and 2 motor giant neurons on either side. The giant neurons are most likely monosynaptically coupled, which further decreases the latency of the reflex. Supported by DFG (Gr 933/3-2)

NEURAL ELEMENTS OF GRASSHOPPERS SUPPORTING SEXUALLY DIMORPHIC BEHAVIOR. K.J. Thompson* and J.L. Roosevelt. Dept. of Biology, Agnes Scott College, Decatur, GA 30030.

In a continuing study of the neural basis of oviposition behavior in grasshoppers, motor neurons (MNs) and dorsal unpaired median neurons (DUMs) of the terminal ganglia of males have been identified by backfilling lateral nerves with CoCl₂. This information is being compared to information already available for females. Two hypotheses for how the nervous system produces sexual dimorphism in behavior are being tested: 1) *male-deficient hypothesis*, which predicts that the male nervous system is missing female-specific ovipositor elements (males do not lay eggs), and 2) *male-respecified hypothesis*, which predicts that the male contains neurons homologous to ovipositor neurons but involved in other functions. Four clusters of ovipositor MNs have previously been identified in females. Two of these clusters of MNs have axons in different branches of the 8th tergal nerve of the terminal abdominal ganglion. One cluster, the protractors, is a group of 3 MNs with cell bodies contralateral to the filled nerve and the second cluster, the closers, is a group of 3 MNs with cell bodies in the next anterior ganglion. Backfills of the tergal nerve in males produced a similar pattern of MNs, in terms of numbers of cells, cell body positions, and distinctive axonal trajectories. A single DUM neuron, located in the terminal abdominal ganglion, fills from the tergal nerve in both sexes. Thus, for two of the four groups of efferent neurons that have been identified, limited gender differences in MN and DUM complement have been found, despite differences in male and female behavior, and differences in the size and shape of the terminal ganglion. Supported by Whitehall grant #AF93-01.

DEVELOPMENT OF STOMATOGASTRIC MEDIATED MOTOR PROGRAMS IN THE AMERICAN LOBSTER. Kari Lavalli, Joseph Ayers*, Marine Science Center, Northeastern Univ., East Point, Nahant, MA 01908

Feeding and stomatogastric mediated behavior are composed three phases in all larval stages: an ingestion phase a relatively quiescent phase and a periodic grinding phase. We have demonstrated three behavioral stages of development of stomatogastric behavior. The first stage is limited to Stage I and II larvae and consists of: a) a fast peristaltic component which occurs only during ingestion; b) a slow "cardiac sac" rhythm which begins several minutes after the cessation of feeding and continues on until the gut is empty. This rhythm is the only one present for the first hour post-feeding and may serve to mix ingested food with digestive juices. It then alternates with c) the "gastric" rhythm resulting from a constriction of the lateral walls of the cardiac sac and a forceful anterior movement of the entire cardiac sac. No separate pyloric rhythm is noted in either Stage I or II larvae.

The second behavioral stage is observed only in Stage III larvae and adds a medial gastric component due to elaboration and participation of the medial tooth.

The third behavioral stage is first observed in Stage IV postlarvae and demonstrates an excellent replica of the adult patterns with several forms of modulation. Here, separate movements of the cardiac sac, gastric mill and pylorus are present. After Stage IV have been able to identify different modes of operation of the gastric mill, particularly that of "cut and grind" and "squeeze." In addition several modes of modulation of the movements are present in all three stages. Supported by NSF Grant IBN-9121224.

ENHANCEMENT OF NEUROMUSCULAR EFFICACY BY FLRF PEPTIDES IN THE CRAB, *Cancer borealis*. J.C. Jorge-Rivera* and E. Marder. Ctr. for Complex Systems, Brandeis Univ., Waltham, MA 02254

Modulators play a major role in re-shaping the motor rhythms produced by Central Pattern Generators (CPGs). The same modulators can also alter neuromuscular interactions. Recent work has shown that SDRN- and TNRN-FLRFamide produce dramatic changes of the gastric and pyloric motor patterns of the stomatogastric ganglion (STG) of *Cancer borealis* (Weimann et al, 1993). These include: enhancement of the pyloric rhythm frequency, activation of pyloric and gastric rhythms in quiescent preparations, and activation of oscillatory properties in the Dorsal Gastric (DG) neuron. We now use neuromuscular preparations to determine if FLRFamide peptides also modulate neuromuscular junctions (NMJs).

We found that both SDRN- and TNRN-FLRF_{NH2} increase nerve-evoked Excitatory Junctional Potentials (EJP's) on DG-innervated muscles, gastric muscle 4b,c. Nerve-evoked contractions are also enhanced by these peptides in the same muscle: TNRNFLRF_{NH2} produces a 200% increase and SDRNFLRF_{NH2} a 90% increase in contraction. These effects are dose-dependent over the range 10⁻¹⁰ to 10⁻⁶ M. Pyloric (p2, p7), and cardiopyloric valve (CPV4) muscles are also modulated by these peptides.

Our results indicate that in addition to modulating the motor rhythms, FLRFamide peptides increase the efficacy of neuromuscular interactions. Modulation of the NMJ by itself will amplify incoming inputs, or will ensure that changes in the motor rhythms will be translated into changes in motor outputs. This might have different behavioral consequences depending on the physiological context where modulation of the NMJ takes place. Supported by NS17813.

STATIC- AND DYNAMIC-RADULA/ODONTOPHORE KINEMATIC MODELS OF THE BUCCAL MASS OF *APLYSIA CALIFORNICA*. R.E. Drushel,¹ H.J. Chiel,^{1,2} and P.E. Crago.² Departments of Biology,¹ Biomedical Engineering,² and Neuroscience,³ Case Western Reserve University, Cleveland, Ohio 44106 U.S.A.

A computer kinematic model of the buccal mass of *Aplysia californica* (Neustadter, 1992) was revised to more accurately reflect the true shapes and dimensions of buccal mass components *in vivo*. The Neustadter model represents the radula/odontophore as a sphere, the I1/I3 muscles as 6 toruses, and the I2 muscle as a posterior band connecting the dorsal and ventral aspects of the first I1/I3 torus; a ventral hinge attaches the I1/I3 and I2 elements to the odontophore. Protraction/retraction is accomplished by forward/backward rotation of the sphere, and the I1/I3 toruses expand/contract isovolumetrically to conform to the protruding surface of the sphere.

Buccal mass shapes from transilluminated feeding slugs and from models were classified as rest, protraction, or retraction. Actual measurements of the shapes were used to develop plots of eccentricity vs. ellipticity in a "shape space". *In vivo*, shapes classified as rest/protraction/retraction cluster together in distinct regions of the shape space plots. However, the Neustadter model generated shapes only roughly equivalent to those observed *in vivo*, and the shape space plots did not match. To improve the model, two different odontophore shapes (#1 and #2) derived from dissection were substituted for the sphere of the Neustadter model. These shapes were asymmetric in mid-sagittal section, though assumed to be circular in cross section when in contact with the I1/I3 toruses. The model was rewritten to account for arbitrary, asymmetric shapes. Shape #1 gave accurate buccal mass retraction shapes, but poor rest/protraction shapes. Shape #2 gave accurate rest/protraction shapes, but poor retraction shapes. In both cases, the shape space plots, while improved compared to the Neustadter model, did not match those from *in vivo*.

Since no single odontophore shape gives correct buccal mass shapes over the entire range, we hypothesize that the odontophore changes shape dynamically as it moves. We are currently analyzing videotapes of transilluminated feeding slugs to generate a gallery of possible odontophore shapes, and are modifying the model to allow the I1/I3 elements to be fit to arbitrary, non-circular cross sections. NIH PPG HL-25830-11A1.

SEROTONIN FACILITATES NEUROMUSCULAR TRANSMISSION IN PARAPODIA OF *APLYSIA BRASILIANA* BY BROADENING MOTOR NEURON ACTION POTENTIALS J. E. Blankenship* and P. J. Laurienti. Marine Biomedical Inst., Univ. Tx. Med. Br., Galveston, TX 77555-0843

Identified cholinergic motor neurons (MNs) and serotonergic modulatory neurons (POP cells) in the pedal ganglion of *A. brasiliensis* innervate peripheral parapodial muscle and fire rhythmically during swim locomotion. POP-cell firing increases the amplitude of MN-induced excitatory junctional potentials (EJPs) in muscle fibers and increases their contraction amplitude and relaxation rates. This study was designed to determine whether part of the facilitatory effect of serotonin (5-HT) is due to presynaptic actions by measuring its effect on the action potential half-width of MNs using standard intracellular electrophysiological methods. Motor neurons were penetrated with microelectrodes and action potentials were recorded in four experimental conditions: control artificial sea water (ASW), 50mM tetraethylammonium (TEA), 50mM TEA + 5 μ M 5-HT, and after washout with ASW. Spike half-widths were measured as the time taken for the spike to repolarize from its peak back to pre-spike baseline. In 11 experiments, in ASW the average spike half-width was 3.6 ms; the average MN half-width increased significantly ($p < .001$) by 39% to 4.9 ms in TEA. The addition of 5-HT increased the spike half-width to 6.7 ms, a significant ($p < .005$) 35% increase when compared to the TEA spike. Following washout, the average MN spike half-width returned to control values. These results demonstrate that 5-HT, in the presence of TEA, can increase MN action-potential width and can account, at least in part due to increased transmitter release, for the increase in the amplitude of parapodial muscle EJPs and contractions during POP cell firing. Currently, experiments are being performed to identify an effective 5-HT antagonist which is able to block the spike-widening effect of 5-HT.

TEMPERATURE SENSITIVITY OF THE GIANT MOTOR SYNAPSE AND TAILFLIP BEHAVIOR IN CRAYFISH. M.F. Burgess*, F. Issa, D.H. Edwards and W.J. Heitler. Gatty Marine Laboratory, School of Biological and Medical Sciences, University of St. Andrews, Fife, KY16 8LB, Scotland, and Department of Biology, Georgia State University, Atlanta, GA 30302-4010.

The rectifying electrical giant motor synapse (GMS) between the giant fibers (GFs) and motor giant motor neuron (MoG) has previously been shown to have an extreme temperature sensitivity. The large difference between the Q_{10} of the GMS (near 11) and that of the active membrane in the GFs and MoG (presumably near 3) prompted us to examine whether effective transmission would fail at temperatures away from room temperature and so prevent GF-mediated tailflips. We found that transmission was reliable at cold temperatures down to 8°C as both the presynaptic (GF) and postsynaptic (MoG) spikes and the MoG EPSP broadened considerably. Transmission failed at warm temperatures, usually between 25°C and 30°C, as the duration of the presynaptic spike shortened. Compartmental models of the circuit indicate that transmission fails at high temperatures when the GF spike is too brief to inject enough depolarizing current into the MoG to reach threshold. Transmission is maintained in the cold because presynaptic spike broadening compensates for the slowing of the GMS conductance change. GF stimulation in freely behaving animals evokes tailflips that fail between 25°C and 30°C, and are gradually reduced in amplitude between 15°C and 5°C. Recordings in an isolated abdomen indicate that tailflip failure at high temperatures results from transmission failure at the GMS, whereas tailflip reduction in the cold appears to result from slowing of neuromuscular transmission, excitation-contraction coupling, or contraction of the fast flexor muscle that produces the tailflip.

BIOMECHANICS OF APLYSIA I2 MUSCLE. S.-N. Yu, P. E. Crago*, and H. J. Chiel. Dept. of Biomedical Engineering and Dept. of Biology, Case Western Reserve Univ., Cleveland, OH 44106

The buccal muscle I2 is a smooth muscle which plays an important role in the feeding behavior of the sea hare, *Aplysia californica*. In this study, we examined both isometric properties and contractile dynamics of this muscle. The whole I2 muscle was isolated and the activation was applied by electrically stimulating the radula nerve with a suction electrode. The isometric force-frequency relationship had a frequency threshold of about 6 Hz and rose to a saturating force of about 150 mN at 15-20 Hz. The steady state force was approximately linearly related to the firing period.

We studied contractile dynamics by superimposing isovelocity movements on the plateau of isometric contractions during constant stimulation. During isovelocity shortening, the tension always fell below the isometric value and continued to decrease throughout the period of shortening. However, during lengthening, the response showed a quick rise of tension, termed short range stiffness, followed by an abrupt yield, when the force developed more slowly. The higher the velocity, the more the active force gained in lengthening and lost in shortening. The force-velocity relationship also depended on stimulation frequency. However, after normalization to the isometric force value, the responses were very similar. The similarity was more consistent in shortening than in lengthening. The shape of the responses to isovelocity length changes were very similar to those reported for cat soleus.

We modeled the contractile dynamics of this kind of smooth muscle by a 4-state latch bridge model. The model responses to lengthening and shortening were similar to those of the I2 muscle.

A POPULATION OF CEREBRAL INTERNEURONS MEDIATE THE COORDINATION OF VASCULAR RESPONSES INVOLVING FEEDING BEHAVIOR OF *APLYSIA*. Y. Xin, K.R. Weiss and J. Kupfermann*. Center for Neurobiology and Behavior, Columbia University, 722 W. 168 St. New York, NY 10032 and Department of Physiology and Biophysics, Mount Sinai School of Medicine, New York, NY 10029.

A population of neurons (CC neurons) were identified in the cerebral ganglion C cluster. They were found to affect various parts of the body wall as well as cardiovascular system. Each of these CC neurons produces mono or polysynaptic effects on various cerebral, pedal, plural and abdominal ganglion neurons. The CC neurons receive synaptic inputs when the lip is touched with food or during buccal mass movements. They have mutually excitatory or inhibitory interactions with the feeding command-like neuron C-PR. CC5, which excites the ipsilateral pedal artery shortening neuron (PAS), is excited by touch of the ipsilateral lip or during buccal mass retraction. CC7, which monosynaptically excites abdominal vasoconstrictor neurons (LBvc cells), is excited during buccal mass protraction and inhibited by a brief touch of the lip. CC6, which monosynaptically inhibits the ipsilateral pedal artery shortening neuron, could be excited by firing of the C-PR and is inhibited by touch to the ipsilateral lip. CC4, which excites a neuron that shortens the buccal artery, is excited during buccal mass retraction and by a touch to the lip. CC3, which monosynaptically excites abdominal heart excitor neurons (RBmc cells), increases its firing rate when the lip is touched with food. CC2, monosynaptically excites the abdominal L2 neurons, while firing of CC1 contracts the pericardium. Hyperpolarization of specific CC neurons revealed that they mediate all or most of the synaptic effects of buccal mass movements and lip stimulation on cardiovascular motor neurons. Our results indicate that a small population of the cerebral interneurons orchestrates a complex pattern of cardiovascular responses during feeding behavior.

STRETCH-ACTIVATION OF THE ACCESSORY RADULA OPENER MUSCLES OF *APLYSIA*.

C.G. Evans*, E.C. Cropper, S.C. Rosen, I. Kupfermann and K.R. Weiss.
Mt. Sinai Schl. Med., N.Y., N.Y., 10029.

The accessory radula opener musculature of *Aplysia* is comprised of seven strap-like muscles, (three pairs and one single), named 17, 18, 19, and 110, innervated by a common cholinergic buccal motor neuron, B48. The muscles originate from a muscular sheath covering the collostyle at the base of the radula sac and become stretched as the accessory radula closer muscles contract. Even when denervated, the muscles will contract rhythmically if subjected to a constant stretch. Intracellular recordings from muscle fibers of 17 reveal that stretching the muscle induces a depolarization which can cause a slow increase in tension followed by discrete contractions accompanying muscle fiber spikes. The stretch-activated depolarization appears to be sodium-dependent since it is reversibly abolished in sodium-free artificial seawater. Nifedipine, at concentrations of 10^{-6} M and 10^{-5} M, can abolish the spikes but not the stretch-activated depolarization. The stretch-activated depolarization may augment the depolarization of the muscle fibers by the motor neuron elicited excitatory junction potentials to promote a greater contraction. Indeed we found that motor neuron-driven contractions of 17 initiated from a constant length decreased as the load increased, but if the length was permitted to increase, the amplitude of contraction increased. The stretch-activated depolarization may represent a peripheral mechanism to ensure that the muscle is optimally responsive to the mechanical demands of the system.

MAPPING MOTOR NEURON ACTIVITY TO OVERT BEHAVIOUR IN THE LEECH: A BIOMECHANICAL MODEL OF THE LEECH HYDROSKELETON. R.J.A. Wilson¹*, B.A. Skierczynski², J.K. Meyer¹, S. Blackwood¹, R. Skalak², W.B. Kristan, Jr.¹. ¹Dept. of Biology & ²Institute for Biomedical Engineering, UCSD, La Jolla, CA 92093-0357.

The leech has proved a good system in which to determine how neuronal elements generate patterned motor neuron activity. However, little is known as to how these neuronal patterns coordinate the behaviour of the animal as a whole. We have undertaken a study to determine how motor neuron activity interacts with the biomechanical properties of the leech hydroskeleton to produce overt behaviours.

A model was developed to predict the shape of a leech for a given spatial pattern of motor neuron activity. The model was based on the following experimental data: the dimensions of the leech at behavioural extremes, the passive length/tension properties of the muscles in the body wall and the active tension produced by activating single identified motor neurons at different muscle lengths and firing frequencies. We based the model on the assumption that (a) the volume of each segment remains constant and (b) when at a steady-state the shape of the leech is such that the potential energy of the whole body is minimized. The potential energy for the whole body was calculated as the sum of that for each muscle, which in turn was calculated as the integral of the corresponding active and passive tension over the length of the muscle. A key test of the model has been a comparison between predicted and observed pressures recorded in the gut during the extremes of four very different behaviours: crawling, swimming, shortening and feeding.

The model as it stands provides new insight into the biomechanical properties of hydroskeletons and how these properties may be adapted for behaviour. We intend to make the model more realistic by including neuronal, muscle and fluid dynamics. Supported by NSF Research Grant IBN9222039.

THE WHOLE-BODY SHORTENING REFLEX OF THE LEECH: MOTOR PATTERN, SENSORY BASIS, AND INTERNEURONAL PATHWAYS. B.K. Shaw* and W.B. Kristan, Jr. Dept. of Biology, Univ. of California at San Diego, La Jolla, CA 92093-0357.

The leech whole-body shortening reflex consists of a rapid, synchronous contraction of the whole body elicited by a strong mechanical stimulus to the anterior of the animal. We have studied this reflex in semi-intact and isolated nerve cord preparations. The motor pattern consists of an activation of excitatory motor neurons innervating dorsal and ventral longitudinal muscles (DE and VE respectively), as well as the L cell, a motor neuron innervating both dorsal and ventral longitudinal muscles. The motor pattern has phasic and tonic components: the L cell is transiently activated, while cell 3 (a representative DE) shows a more sustained activation.

Stimuli that produce shortening activate the T (touch), P (pressure), and sometimes the N (nociceptive) types of mechanosensory neuron. Stimulating single sensory neurons did not cause the behavior; it appears that a critical number must be activated to yield shortening.

The S cell network, which makes up a 'fast conducting pathway' running through the leech nerve cord, is active during shortening and accounts for the shortest-latency excitation of the L cell. However, the S cell network is not sufficient by itself to account for the reflex: firing the S cells at physiological rates with an intracellular electrode causes just a weak excitation of L cells and little to no behavior. Recordings from the nerve cord connective during shortening reveal fast-conducting spikes besides those of the S cell; these spikes are correlated with motor neuron PSPs. This suggests that the S cell network and other pathways operate in parallel to produce the reflex. Supported by an NSF Predoctoral Fellowship (BKS), NIMH training grant (BKS) and NIMH research grant MH44396 (WBK).

MUSCLE: FIBER TYPES AND ENDPLATES

654.1

THE ROLE OF THYROID HORMONE IN FAST MUSCLE FIBER-TYPE-SPECIFIC EXPRESSION OF A TROPONIN I/LACZ CHIMERIC TRANSGENE. H.L. Bradshaw* and K.E.M. Hastings. Molecular Genetics Laboratory, Montreal Neurological Institute, Montreal, P.Q. H3A 2B1

We are interested in the expression and regulation of fiber-type-specific contractile protein isoforms in developing fast skeletal muscle fibers. This current study focuses on the early post-natal expression of a TnIfast/LacZ chimeric transgene that is driven by an avian TnIfast promoter. Unlike the endogenous TnIfast gene, this chimeric transgene is differentially expressed in the fast muscle fibers of adult mouse, i.e. IIB >> IIA. In the neonatal transgenic mouse, this differential expression is not observed at birth, but emerges during the first week of postnatal life.

These results suggest that transcriptional mechanisms present in IIB fibers may be distinct from those operating in IIA fibers. Because its concentration peaks during the first post-natal week, thyroid hormone may subserve such a mechanism and act to direct the high level TnIfast/LacZ expression seen in IIB fibers. To investigate the role of thyroid hormone in the post-natal emergence of the differential expression pattern, muscle sections from hypothyroid (induced by 5-propyl-2-thiouracil and iodine-deficient chow) and untreated-control neonates will be compared and analyzed using quantitative beta-galactosidase histochemistry.

DISTRIBUTION OF MYOSIN HEAVY CHAIN-BASED INTRAFUSAL FIBER TYPES IN SMALL SPINDLES OF CHICKEN LEG MUSCLES AND THEIR DEVELOPMENTAL SIGNIFICANCE. A. Maier*, Dept of Cell Biology, University of Alabama at Birmingham, Birmingham, AL 35294.

The myosin heavy chain (MHC) composition of intrafusal fibers in postnatal chicken leg muscle spindles containing from 1-4 intrafusal fibers was examined in sections incubated with monoclonal antibodies against slow or fast MHC. In these muscles receptors with fewer than five intrafusal fibers make up a substantial portion of the spindle population. The small receptors are presumably normal spindles, except that they acquired fewer than the average number of seven intrafusal fibers. Oligofibrillar postnatal spindles present an alternate approach for determining the order of appearance of intrafusal fiber types, which in embryonic tissue is difficult to assess. The single fiber in postnatal monofibrillar spindles almost always had a fast MHC profile. In duofibrillar spindles there was a 60:40 fast/slow split. Spindles with three intrafusal fibers typically presented two fast and one slow fiber, while in quadrofibrillar spindles the number of fast and slow intrafusal fibers was nearly equally divided. These data support the earlier finding that the proportion of slow intrafusal fibers increases gradually from the onset of spindle development until the time when 5-6 intrafusal fibers have been formed (Cell Tiss Res, 274:383, 1993). The constant fiber type composition of small postnatal spindles also suggests that the first four fibers in a spindle arise in a fast-slow-fast-slow sequence, provided there is no significant postgenesis MHC transformation.

NEURAL CONTROL OF MYOSIN HEAVY CHAIN EXPRESSION IN REGENERATED RAT MUSCLE SPINDLES. Jun Wang and J.M. Walro, Dept. of Anatomy, NE Ohio Univ. Coll. of Med., Rootstown OH 44272.

Neural regulation of slow-tonic (ST), α -cardiac (α -c), 2A and 2B myosin heavy chains (MHC) was investigated in rat muscle spindles which regenerated in the presence of sensory innervation only (DE), motor innervation only (DA), and in the absence of all innervation (DN group). Either dorsal root ganglia L3-6 were removed (N=9), ventral roots L3-6 were severed (N=10) or sciatic n. was severed (N=5) in young adult female rats. Three days later, a nerve-intact orthotopic graft was performed on the ipsilateral extensor digitorum longus (EDL) muscle. Grafts were excised after 30 days, frozen, cut into 10 μ m sections, reacted with monoclonal antibodies specific for each of the four MHC isoforms or reacted for histochemical demonstration of motor (non-specific esterase) or sensory (NADH-TR) innervation. No fibers in DN grafts expressed ST, α -c, 2A, or 2B MHC. No fibers in DA grafts expressed ST or α -c, although 75% of encapsulated fibers expressed either 2A or 2B uniformly along the length of the fiber. In contrast, 13% of fibers in DE grafts expressed ST. However, only 1% of fibers expressed α -c and no fibers expressed 2A or 2B in DE grafts. Collectively these data suggest that in the absence of sensory innervation, fibers formed within the basal lamina tubes of intrafusal fibers cease to express "spindle-specific" MHCs such as ST and resemble extrafusal fibers in their patterns of MHC expression. Supported by a Research Challenge grant from the O.B.O.R.

NEUROMUSCULAR JUNCTION MORPHOLOGY DURING FAST-TO-SLOW MUSCLE TRANSFORMATION. T.Somasekhar*, R.H. Nordlander and P.J.Reiser, Dept. Oral Biology, Ohio State Univ., Columbus, OH 43210.

Chronic low frequency stimulation results in transformation of muscle from fast- to slow-twitch phenotype. We examined the morphology of neuromuscular junctions (NMJs) in two fast-twitch rabbit muscles, extensor digitorum longus (EDL) and tibialis anterior (TA), after 3 weeks of chronic electrical stimulation at 10Hz. These muscles were stained with rhodamine-alpha-bungarotoxin and their NMJs analyzed with MetaMorph software. Stimulated TA muscles showed significant reductions in mean NMJ area (30%), length (15%) and width (19%) compared to unstimulated contralateral controls (n = 2 rabbits). Changes in NMJ morphology were more profound in TA than in EDL. Mean NMJ area in normal slow soleus muscle was similar to control EDL but was significantly smaller (22%) than control TA. A similar range of NMJ configurations were seen in both controls and stimulated muscles. These observations show that stimulation induces marked changes in NMJ size. Work is underway to determine whether NMJs simply shrink in size or selectively retract branches during fiber transformation. Supported by NIH AR39652 and NS18773.

GROWTH-RELATED ADAPTATIONS OF ENDPLATES ON DIAPHRAGM MUSCLE FIBERS: A 3D STUDY USING CONFOCAL MICROSCOPY. Y.S. Prakash*, K.G. Smithson and G.C. Sieck, Departments of Anesthesiology and Physiology, Mayo Foundation, Rochester, MN 55905.

Previous studies have shown 1) differences in endplate size on slow (type I) & fast (type II) muscle fibers, and 2) a correlation between endplate size and muscle fiber size. The differential growth of type I & II fibers during maturation may account for these differences in endplate size. In the present study, the three-dimensional (3D) surface areas of endplates on type I & II muscle fibers of 21-day old (D21) and adult rat diaphragms were examined using confocal microscopy. Motor endplates were labelled with fluorescein α -bungarotoxin, and muscle fiber type was determined using an anti-fast myosin antibody and indirect immunocytochemistry. Surface areas were calculated from computer-generated reconstructions of confocal optical sections. At D21, in spite of no difference in fiber size, surface areas of type I fiber endplates were greater than those of type II fibers. These differences were enhanced in adults, even though adult type II fibers grew disproportionately to type I fibers. In adults, endplate surface area was positively correlated to muscle fiber size, but only within a fiber type. When normalized for fiber diameter, surface areas of type I fiber endplates were still significantly greater than those of type II fiber endplates, in both age groups. In type I fibers, the increase in endplate surface area was disproportionate to fiber growth, whereas in type II fibers, the increase in endplate surface area was proportionate to fiber growth. We conclude that differences in endplate size on type I & II fibers reflect phenotypic differences unrelated to differential fiber growth. These phenotypic differences in endplate size may impact synaptic efficacy. (Supported by NIH grants HL37680, HL34817 and GM08288).

AGE-RELATED INCREASE IN MUSCLE FIBER "TYPE GROUPING" IN THE HUMAN THYROID TENDON MUSCLE: A DESIGN-BASED STEREOLOGICAL STUDY. L.T. Malmgren*, T. Uno and P.J. Fisher, Dept. Otolaryngology, S.U.N.Y. Health Sci. Ctr., Syracuse, NY 13210.

In many human muscles age-related partial denervation leads to muscle fiber "type grouping", a departure from the normal tendency toward random spatial distribution of muscle fiber types. Techniques for quantifying muscle fiber "type grouping" have generally been based on two-dimensional models that are not applicable to geometrically complex muscles such as the thyroarytenoid. In the present study, a design-based (free of assumption of a geometrical model) second order, stereological technique (Kroustrup et al., J. Microsc. 149:135) has been used to quantify age-related muscle fiber "type grouping" in the human thyroarytenoid muscle.

In humans the thyroarytenoid muscle plays crucial roles in protecting the airway and in vocalization, and age-related changes in this motor system are of concern. Samples were obtained from male and female autopsy cases (49-97 years; n=20). The results indicate a significant ($P=.032$) age-related increase in the tendency for muscle fibers to be nonrandomly grouped in clusters with fibers of the same type (based on expression or lack of expression of fast myosin isoform). Since this phenomenon is the result of reinnervation of denervated fibers by collateral sprouting of a common axon, the muscle fibers in these clusters tend to alter their myosin isoform expression in response to the influence of the new motor neuron. This result therefore indicates an age-related partial denervation followed by reinnervation in the human thyroarytenoid muscle, which is consistent with a hypothesis of age-related motor neuron cell death in this system. (Supported by NIH grant AG0918603)

654.6

IMMUNOREACTIVITY FOR THE NMDA-RECEPTOR, N-ACETYL-ASPARTYLGLUTAMATE AND NAALADASE AT THE RAT NEUROMUSCULAR JUNCTION. U. V. Berger* and J. T. Coyle, Laboratory of Molecular and Developmental Neuroscience, Massachusetts General Hospital, Boston, MA 02129.

The neuropeptide N-acetylaspartylglutamate (NAAG) is co-localized to a number of different neurotransmitter systems in mammalian central nervous system including the ventral horn cholinergic motoneurons. NAAG is released upon depolarization and catabolized by the extracellular enzyme NAALADase to N-acetylaspartate and glutamate. Furthermore, NAAG displays partial agonist activity at NMDA1-type glutamate receptors. The physiological function of NAAG is still uncertain, but may include a role as a neuromodulator or as a glutamate precursor. In the peripheral nervous system, NAAG-like immunoreactivity (LI) is present in axons of sensory and motor nerves while NAALADase is expressed by non-myelinating Schwann cells. The present study investigates the presence of NAAG, NAALADase and NMDA1-receptors at the rat neuromuscular junction. Three days after sciatic nerve ligation, axonal NAAG-LI was increased proximal to the ligation site, indicating that NAAG is transported in sciatic nerve axons. In diaphragm, NAAG-LI was observed in the terminals of phrenic nerve while NAALADase-LI was present in the basal lamina that surrounds neuromuscular junctions and perisynaptic Schwann cells. NMDA1-LI was observed in the endplate region of diaphragm using immunocytochemistry and immunoblotting. The NMDA1-LI was closely associated with alpha-bungarotoxin binding to nicotinic acetylcholine receptors, suggesting that NMDA receptors are present postsynaptically on muscle cells. The presence of NAAG in motor nerve endings corroborates other recent findings of glutamate-like immunoreactivities in rat motor neurons and terminals. These results suggest that NAAG, or glutamate cleaved from NAAG by NAALADase, may be involved in vertebrate neuromuscular transmission.

INFLUENCE OF INACTIVITY ON ENDPLATE SIZE AND NEUROMUSCULAR TRANSMISSION. H.Miyata, W.Z.Zhan, Y.S.Prakash and G.C.Sieck*, Departments of Anesthesiology and Physiology, Mayo Foundation, Rochester, MN 55905.

In the rat diaphragm (DIA), we induced inactivity of the right hemidiaphragm by hemisection of the C2 spinal cord (spinal isolation, SI) or by tetrodotoxin (TTX) blockade of phrenic axonal propagation. After 2 wks of inactivity, we examined adaptations of motor endplates on type I and II muscle fibers, as well as susceptibility to neuromuscular transmission failure (NF). Paralysis of the right hemidiaphragm was confirmed by the absence of EMG. NF was assessed *in vitro* by stimulating the phrenic nerve at 40 or 75 Hz in 330 ms trains repeated each sec for 5 min. Direct muscle stimulation was superimposed every 15 sec, and the forces generated by each stimulus mode were compared to estimate NF. Motor endplates were labeled with fluorescein-conjugated α -bungarotoxin and muscle fiber type was determined immunocytochemically using an anti-fast myosin antibody. Double-labeled samples were analyzed using dual channel laser-scanning confocal microscopy to reconstruct 3D images of motor endplates. In CTL, type II fiber endplates were smaller than type I fiber endplates. Type II fiber endplate surface area increased in the TTX and SI diaphragm but type I fiber endplate size was unchanged. As compared to CTL, NF at both 40 and 75 Hz was less pronounced in the SI group but more pronounced in TTX animals. We conclude that endplate adaptations to inactivity are restricted to type II fibers, but do not necessarily reflect associated alterations in neuromuscular transmission. Supported by NIH grants HL34817 and HL37680.

CIRCADIAN CHANGE OF VIP mRNA EMERGES IN THE SUPRACHIASMATIC NUCLEUS IN CONSTANT DARKNESS FOLLOWING DEPLETION OF SEROTONIN BY PARACHLOROPHENYLALANINE (PCPA). H. Okamura, F. Kawakami, Y. Tamada, T. Nishiwaki, Y. Iwata, S.-I. Inouye. Depts. Anatomy and Psychiatry, Kyoto Pref. Univ. Med., Kyoto 602; Lab. Integrative Brain Function, Mitsubishi Kasei Inst. Life Sci., Tokyo 194, Japan

Neuronal activity of the suprachiasmatic nucleus (SCN) is known to be influenced by two major innervations to the SCN: photic stimulus conveyed by the direct retinohypothalamic tract or indirect geniculohypothalamic tract, and the serotonergic (5-HT) neurotransmission by ascending forebrain 5-HT tract. In the present study, we examined the time-course of VIP mRNA expressions in the SCN of rats in which the two major neuronal transmissions being eliminated, by using the *in situ* hybridization technique combined with computer assisted image analysis. Male Wistar rats were housed in constant darkness, and the 5-HT input to the SCN was blocked by the three days successive intraperitoneal injections of *p*-chlorophenylalanine methylester (300 mg/kg, daily), an inhibitor of tryptophan hydroxylase. After 24 hrs of the last injection, VIP mRNA levels in the SCN were assessed by *in situ* hybridization. In saline treated controls, VIP mRNA levels were almost constant at any time of the day. In contrast, PCPA treatment induced the rhythm of VIP mRNA with the peak at CT 4 and trough at CT 20. These findings suggested that the removal of photic and 5-HT influence induces VIP mRNA rhythm in the SCN, and indicates that VIP mRNA is controlled also by the circadian clock.

ELECTROPHYSIOLOGICAL EFFECTS OF IONOPHORETICALLY APPLIED SUBSTANCE P ON HAMSTER SUPRACHIASMATIC NUCLEUS NEURONS *IN VITRO*. Hugh D. Piggins*, David J. Cutler, and Benjamin Rusak. Depts. of Anatomy & Neurobiology, and Psychology, Dalhousie University, Halifax, N.S., Canada, B3H 4J1.

The suprachiasmatic nuclei (SCN) of the hypothalamus function as the primary circadian pacemaker in mammals. The tachykinin substance P (SP) and tachykinin receptors have been identified in the rat SCN, but little is known about the role of SP in circadian processes of other mammals. In this study, we examined the effects of local applications of SP on the extracellularly recorded discharge rate of Syrian hamster SCN neurons maintained in an *in vitro* brain slice preparation. Brain slices (400-500 μ m thick) were prepared from hamsters housed under a 14:10 light:dark schedule during the light phase of the cycle. SP (1 mM in 165 mM NaCl) or vehicle were ionophoresed as cations (20-400 nA) from a multibarrel pipette located 50-80 μ m from a recording electrode (containing 2 M NaCl) situated in the SCN. When collapsed across all recording sessions (ZT4-20, where ZT0=lights on), SP increased the firing rates of 57 cells, and suppressed the firing rates of 13 cells of 146 cells tested. In contrast, control ejections of vehicle evoked responses from only 3 of 36 cells tested. A larger percentage of cells responded to SP during the middle of the projected day (62.5%) than during the middle of the projected night (25%). These data indicate that local ejections of SP can alter hamster SCN neuronal activity, particularly during the projected day. This study raises the possibility that local release of SP from intrinsic SCN neurons or from afferent projections may play a role in the entrainment of the circadian pacemaker.

Supported by grants from the US AFOSR, and NSERC of Canada, and an MRC postdoctoral fellowship to HDP.

DEVELOPMENT OF GLIA AND VIP-IMMUNOREACTIVE NEURONS IN THE HAMSTER SUPRACHIASMATIC NUCLEUS (SCN). G.I. Botchkina* and L.P. Morin, Dept. Psychiatry, Stony Brook University, NY 11794.

Radial glia are thought to guide neurons to their targets in developing brain and to facilitate their compartmental organization. We have studied the developmental relationships between radial glia, astrocytes and VIP-IR neurons in the SCN, site of the mammalian circadian clock.

Vimentin-IR (VIM) radial glial processes are evident at embryonic day 8 (E8), achieving their highest density in the SCN by E13-14. By postnatal day 5 (P5), VIM-IR radial glia in the SCN have gradually disappeared. VIP-IR identifies a set of ventral SCN neurons as early as E13. A VIP-IR fiber plexus is evident in the SCN by E15. It then progressively increases in density while extending dorsally.

The first GFAP-IR appears in glia of the ventral SCN and optic chiasm by E15. GFAP-IR astrocytes are evident by P0 and they progressively increase in number to adulthood. A few VIM-IR astrocytes are present in the SCN at P21. The embryonic hamster circadian clock may be functional at E15. Thus, it is possible that astrocytes may not appear until after embryonic rhythmicity has begun. Supported by NS22168.

DISTRIBUTION OF NEUROPEPTIDES IN THE HAMSTER SUPRACHIASMATIC NUCLEUS. Kazuo Semba*, Hugh D. Piggins, and Benjamin Rusak. Depts. of Anatomy & Neurobiology, and Psychology, Dalhousie University, Halifax, N.S., Canada, B3H 4H7.

The suprachiasmatic nuclei (SCN) of the hypothalamus are the site of the primary circadian pacemaker in mammals. The distributions of various neuropeptides have been described in the rat SCN but have not been as well documented in other mammals such as the hamster. Using mono- and polyclonal antibodies, we examined the distribution of immunoreactivity for calcitonin gene-related peptide (CGRP), galanin (GAL), gastrin-releasing peptide (GRP), peptide histidine isoleucine (PHI), substance P (SP), vasoactive intestinal polypeptide (VIP), and vasopressin (VP) in the SCN region of both colchicine treated and untreated Syrian hamsters. Intense labelling of cell bodies, fibres and terminals was observed for GRP, PHI, VIP, and VP within the SCN. In contrast, only sparse labelling of GAL and SP immunoreactive fibres and terminals was seen in the SCN, while more intense labelling was present in adjacent hypothalamic areas. A small number of SP-positive cell bodies were observed in the central SCN, whereas GAL-positive cell bodies were found only in hypothalamic areas bordering the SCN region. A few CGRP-positive fibres and terminals were found in the ventral and lateral aspects of SCN, but no cell bodies stained for CGRP.

In summary, various neuropeptides show different patterns of distribution in the hamster SCN. These data suggest different functions for these peptides in circadian processes.

Supported by grants from the MRC of Canada, and a postdoctoral fellowship from the MRC to HDP. KS is an MRC Scholar.

COMPARISON OF NEUROTRANSMITTER PEPTIDE mRNAs: TAU MUTANT HAMSTERS EXHIBITING GIANT PHASE SHIFTS TO LIGHT vs. WILDTYPE HAMSTERS. K. Scarbrough*, F.W. Turek, NSF Center for Biological Timing, Northwestern Univ, Evanston, IL 60208

Tau mutant hamsters respond to saturating white light pulses presented between CT 11 and CT 16 with giant phase shifts (type 0 resetting) under certain circumstances. These include prolonged time in DD, entrainment to a T cycle of 19 h (Shimomura and Menaker, 1992 SRBR abstract #128) and early in the aging process (Zee *et al.* 1994 SRBR). In our study, after 49 circadian cycles in DD, 8 out of 8 tau mutant hamsters responded to a 1 h light pulse at CT15 with phase shifts averaging 10.19 ± 0.35 h. Among wildtype hamsters the mean phase shift was 1.22 ± 0.34 h and the largest observed was 3.67 h. We determined whether neurotransmitter peptide mRNA levels in the SCN differed between wildtype and tau mutant hamsters exhibiting these divergent responses to light. Wildtype and tau mutant hamsters were killed after 66-71 cycles in DD at either CT4 or CT16. Brains were frozen on dry ice and stored at -80°C until cryostat sections (10 μ m) through the suprachiasmatic region were collected. *In situ* hybridization was performed using ³⁵S-labeled oligonucleotide (48mer) probes and clusters of silver grains in the SCN were quantitated under dark field illumination using an image analysis program by Image 1 Inc. Levels of suprachiasmatic somatostatin mRNA tended to be lower among tau mutants compared to wildtypes but this difference did not reach statistical significance ($p = 0.07$). A comparison of VIP and vasopressin gene expression in these same animals is currently underway. Differences in levels of neuropeptide mRNAs correlating with this unusual response to light by the circadian system of tau mutant hamsters may provide insight into the cellular basis of the mutation. MUSCIMOL REDUCES PHASE DELAYS PRODUCED BY COADMINISTRATION OF VASOACTIVE INTESTINAL PEPTIDE (VIP), PEPTIDE HISTIDINE ISOLEUCINE (PHI), AND GASTRIN RELEASING PEPTIDE (GRP) INTO THE SUPRACHIASMATIC NUCLEUS (SCN). C.F. Gillespie*, T.O. Babagbemi, K.L. Huhman, H.E. Albers, Lab of Neuroendocrinol. & Behav., Georgia State Univ., Atlanta, GA 30303.

Coadministration of VIP, PHI, and GRP into the hamster SCN produces large phase delays in activity rhythms. Since GABA has been reported to be found in most neurons of the SCN, the present study examined the phase shifting effects of coadministration of the GABA_A agonist, muscimol, with VIP, PHI, and GRP. Male golden hamsters were implanted with guide cannulae aimed at the SCN region and housed in constant darkness. After a stable free-running rhythm of wheelrunning was established, the hamsters were microinjected at CT 12-14 with a 200nl cocktail consisting of either VIP (50ng in 50nl saline) + PHI (50ng in 50nl saline) + GRP (50ng in 50nl saline) + muscimol (570ng in 50nl saline) and VIP + PHI + GRP + 50nl saline in a counterbalanced order. Microinjection of the cocktail containing muscimol resulted in phase delays (0.23 ± 0.06 hr) that were significantly smaller ($p < 0.001$) than those phase delays induced by microinjection of the cocktail not containing muscimol (0.88 ± 0.13 hr). These data suggest that GABAergic activity within the SCN may be important in regulating the phase-delaying effects of VIP, PHI, and GRP.

MICROINJECTION OF THE GABA_A ANTAGONIST, PHACLOFEN, INTO THE SUPRACHIASMATIC REGION BLOCKS NEUROPEPTIDE Y-INDUCED PHASE ADVANCES. K. L. Huhman*, T. O. Babagbemi, C. F. Gillespie, H. E. Albers, Lab. of Neuroendocrinol. & Behav., Georgia State Univ., Atlanta, GA 30303.

The primary neurotransmitter in the geniculo-hypothalamic tract (GHT) appears to be neuropeptide Y (NPY). There is also evidence that GABA is important in the functioning of this projection. GABA is colocalized with NPY in some GHT neurons, and NPY and GABAergic fibers synapse on some of the same target neurons in the SCN. Recently, we have shown that microinjection of the GABA_A antagonist, bicuculline, into the SCN completely blocks phase advances induced by microinjection of NPY. To determine whether the GABA_A antagonist, phaclofen, could also block NPY-induced phase advances, male golden hamsters were implanted with an indwelling cannula aimed at the SCN and were housed in individual cages with running wheels in constant darkness. Hamsters were microinjected at CT6 with either NPY (100 ng in 100 nl saline)/ vehicle (50 nl saline), NPY/ phaclofen (3.5 µg in 50 nl saline), or phaclofen/ vehicle (100 nl saline) in a counterbalanced order (injections separated by 5 min). NPY/saline injection induced a phase advance of 1.1 ± 0.34 hr, however, when NPY was injected with phaclofen, NPY-induced phase advances were blocked (0.02 ± 0.12 hr). Phaclofen/saline injection caused no phase change (0.07 ± 0.06 hr). The data indicate that GABA_A activity may be important for phase advances induced by NPY.

NEUROPEPTIDES AND BEHAVIOR: OTHER

656.1

ROLE OF SUBSTANCE P IN MEDIAL AMYGDALOID SUPPRESSION OF PREDATORY ATTACK BEHAVIOR IN THE CAT. Y. C. Han*, M. B. Shaikh and A. Siegel, Laboratory of Limbic System & Behavior, Department of Neurosciences, New Jersey Medical School and Graduate School of Biomedical Sciences, UMDNJ, Newark, New Jersey 07103.

The present study tested the hypotheses that: (1) the medial amygdala (ME) suppresses quiet biting "predatory" attack behavior (QBA), and (2) substance P (SP) is utilized as a neurotransmitter in the pathway from ME mediating suppression of QBA. *Phase I:* stimulating electrodes were implanted into the ME and lateral hypothalamic sites (LH) from which QBA could be elicited by electrical stimulation. Response latencies for QBA were significantly ($p < .05$) increased after dual stimulation of the ME and LH relative to single stimulation of the LH alone. *Phase II:* microinjections of the NK₁ antagonist, CP, 96,345, (0.05, 0.5 and 2.5 nm/0.25 µl) were placed into the medial hypothalamus (MH) because it is known to receive inputs from an SP pathway originating in the ME which, in turn, are relayed via a presumed, short inhibitory projection to LH from MH. Significant dose and time dependent blockade of ME-induced suppression was observed. *Phase III:* microinjections of SP into MH (0.5, 1.0 and 2.0 nm/0.25 µl) resulted in significant ($p < .05$) suppression of LH-elicited QBA, thus mimicking the effects of ME stimulation. These results suggest that ME suppresses QBA by acting through an SP mechanism within MH.

HYPOTHALAMIC DYNAMIC INSULIN CHANGES IN WISTAR RATS, IN RELATION TO MEALS AND TO THE MACRONUTRIENT COMPOSITION. A MICRODIALYSIS STUDY. S. Nicolaidis*, K. Gerozissis, M. Orosco, Neurobiologie des Régulations, URA 1860 CNRS, Collège de France, pl M. Berthelot, 75005 Paris, France

The presence of insulin in the brain and its influence on feeding and body weight when centrally infused is now well established. The question of dynamic changes in brain insulin in relation to meals is still unanswered and addressed here.

Immunoreactive insulin was measured by a sensitized radioimmunoassay in microdialysates from the VMH and PVN nuclei during and around scheduled meals in male Wistar rats (Gerozissis et al., Brain Research, 1993, 611, 258).

We indeed observed elevations (+260%) in hypothalamic insulin during the first thirty minutes of one-hour-lasting standard chow meals with a progressive return towards premeal levels. When the rats were accustomed to the scheduled meals, an anticipatory increase in insulin levels (+70% to 125%) was found in the hypothalamus, but not in the plasma, during the thirty minutes preceding the time of the meal. This increase occurred whether the meals were presented or not upon the due time.

When the standard laboratory chow meals were replaced by exclusively fat meals (lard), the rats ingested very large amounts of it but hypothalamic insulin did not rise nor did plasma insulin. This result is not in favor of a role of brain insulin as a signal of satiety per se.

These data show that insulin changes at the hypothalamic level often reflect those in the plasma but with some exceptions that cannot be accounted for by a simple plasma-brain tissue delivery. It can be suggested that the system which delivers insulin to the hypothalamus mainly reflects the beta cells function but it possesses its own way of weighing its potency. Brain insulin might not represent only a satiety signal, as currently proposed.

655.8

PEPTIDE PHENOTYPES OF SUPRACHIASMATIC NUCLEUS (SCN) NEURONS IN THE RAT J.C. Speh*, N. Suhan and R.Y. Moore, Depts. of Psychiatry and the Center for Neuroscience, Univ. of Pittsburgh, PA 15261

The SCN is a circadian pacemaker in the mammalian brain. It has two apparent anatomical subdivisions, a dorsomedial (DM-SCN), containing a population of vasopressin-containing (VP+) cells and a ventrolateral (VL-SCN) with vasoactive intestinal polypeptide (VIP+) cells. Our recent data indicate that most if not all SCN cells are GABA containing and cell counts for VP and VIP are 3176 ± 43 and 2081 ± 59 respectively (Moore and Speh, 1993). Other peptides have been reported localized in SCN neurons, including, gastrin releasing peptide, (GRP), calcitonin (CAR), neurotensin (NT) substance P (SP), and somatostatin (SS). In this study cell counts and colocalization immunocytochemistry were used to analyze the distribution of these neuronal elements. Cell counts from the present study for each of these additional phenotypes is as follows; GRP 1140 ± 30 ; CAR 1370 ± 282 ; NT 283 ± 10 ; SP 168 ± 33 ; SS 302 ± 18 . Total cell counts for the entire SCN have been reported between 8000 (van den Pol, 1980) and 10,000 (Guldner, 1976). The total of the mean cell counts for the phenotypes reported here, including VP and VIP is 8520. The colocalization studies indicate that GRP and SP are each partially colocalized with VIP and that GRP, NT, SP and VIP are found in the VL-SCN; VP, SS and CAR are found in the DM-SCN; CAR cells also occupy a lateral third subdivision of the SCN. Neither VP, VIP nor any of the other cell peptides reported here are found in this area. Van den Pol and Tsujimoto (1985) report that the cells of the DM-SCN and VL-SCN are densely packed with mean cell diameters of $7.8 \mu m^2$ whereas cells in this lateral group are much more loosely arranged with mean cell diameters of $9.6 \mu m^2$. The functional implications of these peptide phenotypes remains to be elucidated. Supported by NS-16304.

656.2

DIFFERENTIAL EFFECTS OF THE NON-PEPTIDE NEUROTENSIN (NT) ANTAGONIST, SR 48692, ON THE NEUROCHEMICAL AND BEHAVIORAL EFFECTS OF NT AGONISTS. T. A. Pugsley*, H. C. Akunne, S. Z. Whetzel, S. DeMattos, A. Corbin, J. N. Wiley, D. J. Wustrow, L. Wise and T. G. Heffner, Neuroscience Pharmacol., Parke-Davis Pharmaceutical Research, Division of Warner-Lambert Co., Ann Arbor, MI 48105.

This study examines the effects of the non-peptide NT receptor antagonist SR 48692 on some neurochemical and behavioral effects of NT agonists. In *in vitro* studies, SR 48692, a non-peptide NT receptor antagonist, inhibited the binding of [³H]NT to membrane preparations from 10-day old post-natal mouse brain and from HT 29 cells with K_d values of 3.9 nM and 8.6 nM, respectively, in agreement with previous findings. SR 48692 also antagonized (IC₅₀ = 159 nM) the NT (50 nM)-induced mobilization of intracellular calcium in HT 29 cells. In rat cerebellar slices, SR 48692 (30-300 nM) blocked in a dose-dependent manner the increase in cyclic GMP levels evoked by NT (100 nM). In *in vivo*, SR 48692 (0.05 and 0.5 mg/kg, i.p.) inhibited the increase in rat brain mesolimbic dopamine turnover (DOPAC/DA ratio) induced by the systemically active NT peptide, EI [(N-Me)Arg-Lys-Pro-Try-*tert*-Leu-Leu] dosed at 2 mg/kg, i.p. 30 min after the SR 48692. No effects on dopamine turnover of either EI or SR 48692 were observed in the striatum. SR 48692 (1, 3 and 10 mg/kg, i.p.) did not antagonize the EI-induced (1 mg/kg, i.p.) decrease in spontaneous locomotor activity (LMA), the decreases in LMA induced by i.c.v. administered NT (0.05 to 0.1 µg/mouse) and did not inhibit the EI (0.1-1.2 mg/kg, s.c.)-induced fall in colonic temperature in mice. SR 48692 alone did not alter LMA or colonic temperature. These findings support the hypothesis that a subtype of the NT receptor mediates the locomotor and hypothermic actions of this peptide and that it is different from the NT receptor that is involved in dopamine turnover.

656.4

OLFACTORY BULBECTOMY ALTERS LEVELS OF GALANIN AND NEUROPEPTIDE Y mRNA IN THE RAT LOCUS COERULEUS

P. V. Holmes*, U. Koprivica, and I. N. Crawley. Section on Behavioral Neuropharmacology, Experimental Therapeutics Branch, NIMH, Bethesda, MD 20892.

The noradrenergic locus coeruleus (LC) contains high levels of galanin (GAL) immunoreactivity and GAL mRNA and moderate levels of neuropeptide Y (NPY) immunoreactivity and NPY mRNA in the rat. LC neurons project to several forebrain areas, including the olfactory bulb. The effects of surgical ablation of the olfactory bulb (OBX) on levels of mRNA for GAL, NPY, and tyrosine hydroxylase (TH) in the LC and other brain regions were examined with quantitative *in situ* hybridization histochemistry. Increases in GAL mRNA levels in the LC were observed two weeks following bilateral OBX. Levels of NPY mRNA were slightly decreased and levels of TH mRNA were unchanged in the LC at this time point. Unilateral OBX increased GAL mRNA levels in the ipsilateral LC, suggesting that the elevation in GAL mRNA was a direct result of axotomy. Behavioral experiments confirmed previous reports of differences in open field activity between rats receiving bilateral OBX and sham-operated controls. Furthermore, alterations in open field activity depended on the aversiveness of the environment. The activity of rats with OBX was increased compared to controls under bright but not dim lighting conditions. Freezing behavior in response to footshock was attenuated in rats with OBX compared to controls. These results suggest that alterations in GAL and NPY mRNA in the LC and other brain regions may underlie the alterations in stress-related behaviors induced by OBX.

656.5

DISTRIBUTION OF NEUROPEPTIDE Y IN THE MALE SYRIAN HAMSTER BRAIN. DB Parfitt and SW Newman. Dept. of Anatomy and Cell Biology, University of Michigan, Ann Arbor, MI 48109-0616

Pharmacological data implicated neuropeptide Y (NPY) in regulation of gonadotropin secretion and mating behavior. While the limbic pathways controlling mating behavior were defined in the male hamster, the pathway's neurotransmitters were not fully characterized. This study examined the distribution of NPY containing cells, fibers, and terminals in the male hamster brain. Brains from colchicine (ICV injection, n=5) and non-colchicine (n=10) treated male hamsters were cut into 40µm coronal sections, and processed for immunocytochemistry using one of two primary antibodies for NPY (Incstar or donation from Dr. Marvin Brown, UCSD). The regional distribution and intensity of neuronal staining was the same in colchicine treated brains using either antibody. However in non-colchicine treated brains, the intensity of neuronal staining was more robust with the Brown antibody than with the Incstar, while the distribution was unchanged. NPY cells were found in the deep layers of cortical structures throughout the telencephalon, including the olfactory bulbs, anterior olfactory nucleus, piriform cortex, and isocortex, as well as in region CA4 of the hippocampal formation. Cells were also distributed throughout the dorsal and ventral striatum. In the extended amygdala, fibers and terminals were prominent in the central amygdaloid nucleus and the bed nucleus of the stria terminalis. Hypothalamic fiber plexuses and terminal fields were found in the medial preoptic area, paraventricular nucleus, supraoptic nucleus and arcuate nucleus. Thus, NPY neurons and fibers distributed in limbic structures that relay chemosensory information to control mating may mediate this essential sensory processing. (Supported by NIH NS-20629, T-32-HD070408).

656.7

DIPSOGENIC DOSES OF ANGIOTENSIN II (AII) DO NOT AFFECT COGNITION, ACETYLCHOLINE (ACh) OR GABA RELEASE IN THE RAT. K. Szczepanski, A. Buxton, S. E. Daniels, P. A. McNeeley, R. M. Johnson, and D. J. Fontana. Department of Neurosciences, Institute of Pharmacology, Syntex Discovery Research, Palo Alto, CA 94303, U.S.A.

We assessed the behavioral and neurochemical action of renin and angiotensin II (AII) in the rat. We studied the behavioral effects of dipsogenic doses of AII and renin on learning and memory in two cognitive tasks: the Morris Water Maze and Passive Avoidance. AII (0.1 and 1 µg, i.c.v.) did not affect latency to find the platform in the water maze. AII (0.01 and 0.1 µg, i.c.v.) and renin (0.1 and 10 µg, i.c.v.) given 30 min before training, and AII (1 µg, i.c.v.) and renin (1 µg, i.c.v.) given 5 min after training, did not affect retention in passive avoidance. These results suggest that while AII and renin are involved in thirst or fluid regulation, they may not be involved in cognition. In neurochemical experiments we used superfusion technology to study the action of AII on K⁺-evoked [³H]-ACh release and [³H]-GABA release in slices of hippocampus and entorhinal cortex. Unlike DuP 996 (10 µM) which increased [³H]-ACh release and [³H]-GABA release in hippocampal and entorhinal cortex slices, AII did not affect release in hippocampal slices (1 µM) or entorhinal cortex slices (0.1 µM). These results suggest that AII does not affect ACh or GABA release. The findings from our behavioral and neurochemical studies suggest that either the brain renin-angiotensin system is not involved in cognition or it mediates cognition through a system other than the cholinergic or GABAergic system.

EXPRESSION OF AMPHIBIAN BRAIN THYROTROPIN-RELEASING HORMONE AND ARGININE VASOTOCIN RECEPTOR GENES IN *Xenopus laevis* OOCYTES. C.L. Mitchell, J.S. Hosler, H.E. Esch and S.K. Boyd. Dept. of Biological Sciences, Univ. of Notre Dame, Notre Dame, IN 46556.

Thyrotropin-releasing hormone (TRH) and arginine vasotocin (AVT) are neuropeptides found throughout the amphibian brain. Although both have numerous CNS effects, brain receptors for TRH and AVT have not been fully characterized in any non-mammalian vertebrate. We expressed amphibian brain TRH and AVT receptors by injecting *Xenopus* oocytes with brain whole mRNA. Expression of receptors was measured by voltage clamping to monitor current flux across the membrane of oocytes in response to ligand. Injected oocytes were responsive to TRH, TRH free acid, cyclo-(his-pro), [3-MeHis]¹TRH and AVT, as indicated by inward membrane currents. The response was specific, since mRNA-injected cells showed no response to the non-endogenous peptide isotocin, and uninjected or water-injected cells showed no change in current when exposed to any neuropeptides. The TRH response was reversible, dose-dependent, and saturable. Time course of response to maximally effective ligand doses was consistent. Latency (from ligand addition to onset of current flux) and response time (from onset of response to saturation) were characteristic of agonist applied. Time course differences suggest that the amphibian brain expresses more than one subtype of TRH receptor. The V₁ vasopressin receptor antagonist d(CH₂)₅[Tyr(Me)²]AVP did not alter response when added to cells already maximally stimulated with AVT. When added alone, however, it produced a gradual current flux which was increased by secondary application of AVT. The mammalian antagonist thus appears to have agonistic effects in this system. We conclude that unique receptors for TRH and AVT are encoded in *Xenopus* brain, and our data represent the first expression of these receptors from any non-mammalian vertebrate.

656.6

EFFECTS OF PARAVENTRICULAR GALANIN AND NEUROPEPTIDE Y ON DOPAMINE AND ACETYLCHOLINE IN THE NUCLEUS ACCUMBENS OF FREELY MOVING RATS. P.V. Rada, G.P. Mark and B.G. Hoebel. Dept. of Psychology, Princeton Univrsity, Princeton, NJ 08544.

Galanin (GAL) and Neuropeptide Y (NPY) injected into the hypothalamus can induce feeding behavior. Moreover, feeding is known to cause changes in extracellular dopamine (DA) and acetylcholine (ACh) in the nucleus accumbens (NAc) of rats. Therefore, the following experiments used microdialysis to study the effects of GAL and NPY injections into the paraventricular nucleus (PVN) on accumbens DA and ACh. Dialysis probes (2 mm tips) aimed at the NAc were implanted 24 hrs before experimentation and DA or ACh was monitored. During dialysis each rat received counterbalanced injections into the PVN of GAL, NPY or saline. Following the dialysis procedure on separate days the effect of GAL, NPY or saline on feeding was tested. The main result was GAL (300 pmoles) significantly increased DA levels to 152 ± 18% (n=8) and decreased ACh to 75 ± 7% (n=7) 60 minutes after the injection. The neurochemical effect was observed exclusively in rats that later showed feeding behavior during testing with GAL. Neither NPY nor saline modified DA or ACh concentrations in the NAc even though NPY induced feeding in 6 of 12 rats. This result demonstrates that hypothalamic GAL activates the mesolimbic dopamine system and suggests that GAL could be involved in the reinforcement of feeding behavior. DISTRIBUTION OF ARGININE VASOTOCIN IN THE EARLY AMPHIBIAN EMBRYO. S.K. Boyd. Dept. of Biological Sciences, Univ. of Notre Dame, Notre Dame, IN 46556.

The neuropeptide arginine vasotocin (AVT) is widespread throughout the brain of adult amphibians. It is unknown, however, when AVT first appears during development. We used immunocytochemistry to map the distribution of AVT in early embryos of the South African Clawed Frog, *Xenopus laevis*. Staining was done in whole albino embryos or in cryostat sections of embryos, at ages from fertilization onward. AVT-immunoreactivity first appeared at the neural tube stage of development (Nieuwkoop and Faber stage 21). Cells (5-10) were located ventro-medially with strong fiber projections extending laterally. These cells were located at the rostral end of the neural tube, within the region which will form the brain. Scattered cells and fibers were also observed throughout the rest of the neural tube, within presumptive spinal cord regions. Around stage 42, primary brain divisions are evident and the majority of AVT-ir was located in the diencephalon. Fibers were also observed in the developing eye. AVT-immunoreactivity thus appears very early in amphibian nervous system development. The homologous peptides in mammals, vasopressin and oxytocin, do not appear until considerably later in embryonic mammalian development. AVT in the early embryo may influence aspects of neural development, including organization of sensory or motor circuits.

V1-RECEPTOR MEDIATED EFFECTS OF VASOTOCIN ON MOTIVATIONAL, MNEMONIC AND AVERSIVE COMPONENTS OF SEXUAL LEARNING IN QUAIL. G. Bernroider and St. Leutgeb. Institute for Zoology, University of Salzburg, A-5020 Salzburg, Austria.

Numerous studies have uncovered "hormonal constraints" imposed on adaptive specializations of sexual learning (Holloway & Domjan, *J Experim Psychol*, 19:47-55, 1993). Studies in rats have revealed a sexually differentiated, steroid dependent and V1-receptor mediated effect of arginine-vasopressin (AVP), facilitating social recognition by olfactory investigation. Because similar peptidergic substrates can be found in birds (e.g. the vasotocinergic innervation within the lateral septal area), it was of interest whether visually dominated sexual learning in birds involves comparable neurochemical mechanisms.

Adult male quail were tested for approach behavior to their own mirror image. Arginine vasotocin (AVT, 100µg/kgBW in 0.1M saline, s.c.) inhibited the response to the mirror between 30 min and 100 min posttreatment and the effect was completely antagonized by a concomitant application of the mammalian V1 specific receptor antagonist dTyr(Me)AVP, 400µg/kgBW. Copulation opportunity following this test did not reveal changes in head grab latency time, indicating undisturbed recognition of females. AVT effects on social proximity to females during five successive days, showed an inhibitory action of AVT to the reinforcing effect of copulatory "award" following visual access. Again this effect could be antagonized by dTyr(Me)AVP.

A dissociation of peptide treatment from copulation experience for up to 6 hours did not change AVT effects on proximity behavior during the following day. Together with a comparison of training effects after positive reinforcement of social proximity by copulation, the experiments provide evidence for AVT action on motivational rather than mnemonic and aversive components of sexual learning. These effects appear to be mediated by receptors homologous to mammalian vasopressor AVP-V1.

RESPONDING FOR REWARDING BRAIN STIMULATION FOLLOWING SYSTEMIC INTERLEUKIN-2 TREATMENT. H. Anisman¹, S. Zalcman², Z. Merali² & L. Kokkinidis^{3*} ¹Dept. Psychology, Carleton Univ., Ottawa, Ont. K1S 5B6, ²Dept. Psychology, Univ. of Ottawa, Ottawa, Ont. K1N 9A9, ³Dept. Psychology, Univ. of Saskatchewan, Saskatoon, Sask. S7N 0W0.

Antigenic challenge influences the turnover and levels of biogenic amines in hypothalamus, as well as in mesolimbic brain regions. In addition to its other functions, the immune system may act in a sensory capacity informing the brain of immunologic challenge, such that immune activation may be interpreted as a stressor. It was suggested that cytokines released from activated immune cells may serve as messengers between the immune and central nervous systems. Indeed, interleukin (IL)-1 and IL-2 both provoke alterations of central neurotransmitters. We report the effects of IL-2 on brain stimulation reward. Using a conditioned discrimination paradigm, rate-current intensity functions were determined for both reward- and nonreward- associated responding for electrical self-stimulation of the medial forebrain bundle at the level of the lateral hypothalamus. Systemic administration of IL-2 (0.5 - 1.0 µg) produced rightward shifts in the rate intensity functions without significantly influencing either maximal rates of operant responding for electrical brain stimulation, or nonreinforced performance levels. Increases in thresholds were evident after both IL-2 doses. It seems that the altered responding for rewarding stimulation could not be ascribed to motoric factors, associative or attentional disturbances, and might reflect anhedonic effects engendered by the cytokine.

CHANGES IN NPY₁ AND LHRH₁ IN COCAINE-, ETHANOL-, OR COCAINE AND ETHANOL-TREATED FEMALE RATS. G.S. Fraley^{*} and C. Ulibarri. Dept. of VCAPP, Washington State Univ., Pullman, WA 99164-6520.

Chronic use of cocaine and ethanol (EtOH) has drastic behavioral and physiological effects. Among them are alterations in reproduction and food intake, however, the mechanisms underlying these changes are unknown. Neuropeptide Y (NPY) is a neuromodulator that functions in the central nervous system's control over both food intake and reproduction. It is hypothesized that cocaine and EtOH alter the NPY release to bring about these physiological changes. To investigate this, female rats were ovariectomized, given steroid replacement therapy, and placed on three binge-type drug treatments of 10 days each to simulate human drug addiction paradigms. Females were randomly assigned to treatment groups of 1) free-fed control (Bio-Serv liquid control diet), 2) EtOH liquid diet (Bio-Serv, EtOH 30% of calories), 3) cocaine (20mg/kg/day), 4) EtOH + cocaine, or 5) nonsteroid lab block fed controls. Rats were weighed and food intake measured daily. All rats were colchicine-treated before being killed by aldehyde perfusion. Brains were collected, sectioned coronally (40 µm) and stained immunocytochemically for NPY or for luteinizing-hormone releasing hormone (LHRH) and c-fos gene product. All drug treatments resulted in significant loss of body weight. However, only EtOH and cocaine treatments significantly reduced food intake. All drug treatments produced a significant increase in NPY₁ in the arcuate nucleus as compared to controls. Cocaine and cocaine + EtOH treatments produced a significant reduction in LHRH₁ in the diagonal band. The number of NPY₁ and LHRH₁ cells were significantly negatively correlated. Since NPY is a common neuromodulator between food intake and reproductive control, these results suggest NPY may be an important factor in pathologies of human drug addiction. MELATONIN ANXIOLYTIC EFFECTS ARE TIME DEPENDENT. Naranjo-Rodríguez, E., Mendoza, V. and C. Reyes-Vázquez^{*}. Sección de Farmacología, Facultad de Química and Departamento de Fisiología. Facultad de Medicina, UNAM.

Anticonvulsive, sedative and hypnotic effects had been described after melatonin (MEL) systemic administration. Furthermore, biochemical and pharmacological studies had linked the effects of MEL with those produced by anxiolytic drugs such as diazepam and chlorodiazepoxide, suggesting a possible anxiolytic action of MEL. Male Wistar rats were deprived of water for 48 hrs prior to a Vogel's conflict procedure, in which the number of electric shocks delivered through a drinkometer was computed. The effects of several MEL doses (0.5 to 2.0 mg/kg) and three classical anxiolytic drugs (Diazepam 2 and 5 mg/Kg), Chlorodiazepoxide (5 and 10 mg/Kg) and Buspirone (5 and 10 mg/Kg), were tested in this experimental model. Flumazenil, a benzodiazepine receptor antagonist, was administered prior MEL and Diazepam application. Different animal groups were tested at 8:00, 12:00, 16:00 and 20:00 hrs. MEL showed higher anxiolytic effects at 20:00 hrs, and no significant effects at 12:00 hrs. Whilst, Diazepam, Chlorodiazepoxide and Buspirone had similar effects at all the tested hours. The application of Flumazenil reverted Diazepam anxiolysis but had not effect on the anxiolytic actions of MEL. The results showed that MEL exert anxiolytic effects in a time dependent manner with effects not related to benzodiazepine receptors. Supported by DGAPA - IN201193.

INTERLEUKIN (IL)-1, IL-2 AND IL-6 INDUCE CYTOKINE-SPECIFIC ALTERATIONS OF EXPLORATORY BEHAVIOR. L. Murray, S. Zalcman^{*}, D. M. Nance, D. G. Dyck and A. H. Greenberg. Manitoba Institute of Cell Biology and Dept. of Pathology, University of Manitoba, Winnipeg, Mb. R3E 0V9.

Immunological challenge induces alterations of behavior that are similar to those induced by uncontrollable stressors. Products of an activated immune system, notably IL-1, have also been shown to induce behavioral changes. We previously reported that IL-1β, IL-2 and IL-6 induced cytokine-specific alterations of central neurotransmitter activity. We presently report that cytokine-specific alterations of exploratory behavior were also evident in male BALB/c mice following peripheral administration of these cytokines. Exploration of a novel environment (i.e., locomotion, rearing, digging, grooming) was markedly decreased 15-50 minutes after IL-1β administration (200 ng, ip). In contrast, IL-2 and IL-6 induced behavioral activating effects. IL-2 (50, 100, 200 or 400 ng, ip) induced dose-dependent increases in time spent in non-ambulatory exploration, number of rears and distance travelled in a novel environment. IL-6 dose-dependently (50, 100, 200 or 400 ng, ip) increased the number of rears, digging episodes and the time spent per episode as well as the number of grooming episodes. Moreover, time-dependent increases in the number of contacts with a novel stimulus and mean-contact time were evident in mice administered IL-2, but not in IL-6-treated animals. Taken together, these data suggest that IL-1, IL-2 and IL-6 induce cytokine-specific behavioral alterations. The data are discussed in terms of the spectrum of behavioral alterations induced by immune-derived products and implications on the characterization of sickness behavior. ACTH-INDUCED GROOMING IN TWO SUBLINES OF SPRAGUE-DAWLEY RATS WITH HIGH-(HY) AND LOW-YAWNING (LY) SPONTANEOUS FREQUENCY. J.R. Eguibar^{*}, A. Moyaho, H. Herrera, B. Holmgren, and R. Urbá-Holmgren. Centro de Investigaciones en Ciencias Fisiológicas, ICUAP. Apdo. Postal 406. Puebla, Pue. México.

The intracerebroventricular (i.c.v.) injection of ACTH in rodents produces a behavioral syndrome characterized by an increase in the frequency of grooming, yawning, stretching, penile erections and wet-dog shakes. In our laboratory we have two sublines of Sprague-Dawley rats which differ in spontaneous yawning and in their sensitivities to cholinergic- and dopaminergic-induced yawning. Additional observations demonstrated that these animals also differ in the structural organization of grooming sequences. In the present study we analyze the effects that i.c.v. injection of ACTH have on grooming and yawning in these two sublines of rats. The animals were maintained in a controlled dark/light cycle, lights on at 7:00 AM, with free access to water and balanced rodent diet (Purina, Mex), and the experiments were carried out when animals were 3 months old. We implanted stainless steel cannula 23 gauge in the right lateral ventricle. One week after surgery we injected ACTH or saline i.c.v. in a random manner using a Hamilton syringe. The observation, with animals placed in individual cages, lasted 70 min and yawning and grooming rates were monitored according to a continuous sampling method. The i.c.v. injection of 1 µg/µl produced a statistically significant increment in the total time spent in grooming and in the mean duration of grooming bouts in comparison to saline injected rats ($p < 0.05$, t test), but not in the number of grooming episodes in both groups of rats. The number of stretches was also significantly increased in both sublines ($p < 0.05$, t test). Quite unexpectedly yawning behavior decreased around 50% in both sublines of rats. These results show that at the ACTH dose used grooming behavior prevails in respect to yawning, which might be inhibited by the former, suggesting that different SNC structures mediate these behaviors. NITRIC OXIDE MODULATES RETENTION IN THE PORSOLT SWIMMING TEST. D. Jefferys^{*} and J.W. Funder. Baker Medical Research Institute, Melbourne, Victoria, Australia 3181

In the Porsolt swim test intact animals become progressively immobile over a 15 min test period and 24h later are immobile for ~70% of the 5 min retest period. Adrenalectomy (ADX) blocks retention of the response, with animals remaining immobile for only ~35% of the retest, an effect reversed by Dexamethasone (6 µg) or Ketocyclazocine (1 mg/kg). When the antigluccorticoid RU38486 is administered to intact rats it is without effect, as is MR2266, a kappa opioid antagonist. In contrast, when RU38486 and MR2266 are simultaneously administered the animals have similar levels of immobility on retest as seen in ADX. Retention of the immobile response thus can be independently mediated by glucocorticoid or kappa opioid pathways.

In the present studies we show that N-nitro-L-arginine (NAME), a nitric oxide inhibitor dose-dependently blocks retention, with animals remaining immobile for 35-42% on retest at a dose of 50 mg/kg. This effect of NAME is blocked by L-arginine (50 mg/kg), with animals immobile for 77% on retest. NAME is effective given immediately pre-test, but was without effect administered 1h post-test. When ADX rats were given L-arginine the effect of adrenalectomy was blocked, with animals remaining immobile for 62% on retest. These findings suggest that both glucocorticoid and kappa opioidergic effects on retention are mediated by a final common pathway involving nitric oxide.

THE CENTRAL ADMINISTRATION OF NITROGLYCERIN INDUCES PENILE ERECTION AND YAWNING IN MALE RATS. M.R. Melis*, R. Stancampiano & A. Argiolas. Bernard B. Brodie Dept. Neurosci., Cagliari Univ., 09124 Cagliari, Italy.

The effect of the central administration of nitroglycerin, a potent organic nitrate vasodilator, on penile erection and yawning was studied in male rats. When given intracerebroventricularly (ICV), nitroglycerin (33 - 99 µg) induced penile erection and yawning in a dose-dependent manner. Nitroglycerin induced penile erection and yawning also when injected in the paraventricular nucleus of the hypothalamus, a brain area that plays a key role in the control of these responses induced by agents such as N-methyl-D-aspartate, dopamine agonists and oxytocin. Nitroglycerin-induced penile erection and yawning were prevented by methylene blue (400 µg), d(CH₂)₅Tyr-(Me)²-Orn²-vasotocin (0.1 µg) but not methemoglobin (100 µg) given ICV. In contrast all these compounds were ineffective when injected in the paraventricular nucleus. Ineffective was also haloperidol (1 mg/kg IP). The results suggest that nitroglycerin induces penile erection and yawning by activating oxytocinergic transmission through the production of NO in the paraventricular nucleus of the hypothalamus.

EFFECTS OF PRENATAL STRESS ON DEFENSIVE WITHDRAWAL IN THE RAT. HE Ward, EA Johnson, DL Birkle, MS Cratty, AJ Azzaro*. Depts. of Behavioral Medicine/Psychiatry, Pharmacology/Toxicology, and Neurology, West Virginia University School of Medicine, Morgantown, WV 26506.

Adult, virgin, female Sprague-Dawley rats were bred with adult males. Between gestational day 14 and 21, pregnant females were exposed to the mild stress of daily handling and saline injection (0.1 ml, s.c.). Control (unstressed) dams were not handled except for normal animal care. Behavioral testing in a defensive withdrawal apparatus was performed on male offspring at 60 days of age. There were no significant behavioral differences noted between control and prenatally stressed animals. However, following 2 hr of restraint stress, prenatally stressed offspring had a longer latency to exit from the defensive withdrawal chamber and spent less time in the open field (n=8, p<0.05). Specific binding of corticotropin-releasing factor (CRF) was increased by 30% in the amygdala of the prenatally stressed animals (n=8, p<0.05). CRF levels and secretion were similarly elevated (Cratty et al, this volume). In the defensive withdrawal paradigm, without an acute stress (restraint), behavioral differences were too subtle to detect. However, it would appear that the animal's ability to adapt to acute stress (restraint) was compromised by prenatal stress and may be a function of prenatal perturbation of developing CRF systems within the amygdala. Supported in part by NIH (2S07RR05433-31 and MH19444) and UHA.

ANXIOLYSIS IN MOUSE LINES BRED FOR DIFFERENTIAL SENSITIVITY TO DIAZEPAM: USE OF A CONFLICT PARADIGM. F.E. Lotrich and E.J. Gallaher*. Departments of Medical Psychology and Pharmacology, Oregon Health Sciences University and VA Medical Research Service, Portland, OR 97201.

The Conditioned Suppression of Drinking conflict paradigm (CSD) permits repeated testing of the same animal and provides the ability to measure both anxiolytic and anxiogenic effects. In the current study, CSD was modified for use with mice and then used to delineate some of the effects of diazepam (DZ) in four lines of mice which were selectively bred for DZ sensitivity (generation 10). These lines of mice have been selected for either high performance (DHP-1 and DHP-2) or low performance (DLP-1 and DLP-2) on an accelerating rotarod. Following 40 mg/kg DZ, rotarod performances were: DHP-1 +0.7±0.7 rpm, DHP-2 +2.0±0.9 rpm, DLP-1 -13.7±1.7 rpm, and DLP-2 -10.6±0.9 rpm. With CSD, dose-dependent sedative-like effects on unpunished responding were observed in all four lines (0.3-100 mg/kg; p<0.0001); both DLP lines were more sensitive than the DHP lines to these sedative-like effects (p<0.01), consistent with the rotarod data. A dose-dependent increase in conflict responding--a measure of anxiolysis--was also found (p<0.01). However, no significant difference was observed between the DLP and DHP lines for these anxiolytic effects of diazepam. DHP mice exhibited anxiolysis at doses below sedative doses while in DLP mice these responses overlap. The results suggest that the effectiveness of BZs as clinical anxiolytics may have a genetic influence. (Supported by VA Medical Research Service and USPHS grant MH10317.)

AN ENDOGENOUS INCREASE IN CYCLIC GMP IS ASSOCIATED WITH INCREASED EXCITABILITY IN IDENTIFIED NEUROSECRETORY CELLS IN *MANDUCA SEXTA*. Stephen C. Gammie, John Ewer, and James W. Truman*. Department of Zoology, University of Washington, Seattle WA 98195.

Ecdysis in insects is triggered by the neuropeptide, eclosion hormone (EH). During the course of EH action in the tobacco hornworm, *Manduca sexta*, a group of neurosecretory cells show a dramatic increase in guanosine 3':5' cyclic monophosphate (cGMP). This increase precedes the onset of the ecdysis behavior and is sustained at high levels in some of the neurons for over 2 hours. Using intracellular recording techniques we have found that this endogenous increase in cGMP is correlated with a significant lowering of the threshold of these neurons. Also, the somata of these cells show a calcium dominated action potential and this is lengthened during the time of cGMP increase. We found, however, no changes in either input resistance, resting potential, or action potential amplitude to be associated with cGMP expression. Currently, we are injecting cGMP into these neurons prior to their endogenous increase in cGMP to directly test the actions of this cyclic nucleotide on cell excitability. These experiments will be followed by whole cell voltage clamp techniques to determine which ionic currents are affected and how.

657.2

COMPARISON OF THE RESPONSE OF 4 HIPPOCAMPAL (H) SITES IN DIAZEPAM (DZ) DEPENDENT RATS TO FLUMAZENIL (F) MICROINJECTIONS. J.W. Sloan*, E.P. Wala and X. Jing, Dept. of Anesthesiology, College of Medicine, Univ. of Ky., Lexington, Ky., 40536.

In order to identify sites in the female Sprague-Dawley central nervous system that contribute to the development of DZ dependence, guide cannulae (GC), also serving as recording electrodes, were implanted into the occipital cortex (OCTX), area 2 (mediomedial [MM]) [AP=3.8; RL=2.4; V=8] or OCTX (area 2, lateral [LAT]) [AP=3.8; RL=4.5; V=8]. Electrodes were implanted into the H (AP=3.7; LL=2; V=6 and AP=4.7; RL=2; V=6.2) and frontal CTX (AP=10.7; LL=1; V=10). After recovery, the rats were implanted subcutaneously with 3 silastic capsules filled with 180 mg DZ/cap/week. After the 3rd implant and the attainment of stable plasma levels of DZ and its metabolites, rats were microinjected weekly with F (25 µg in 1 µl of DMSO) or DMSO into the H via GC. EEGs, behavioral (BEH) and precipitated abstinence scores (PAS) were recorded prior to and for 40 min after microinjection. When F was microinjected via GC into area 2, MM of OCTX with chemotrode (CTR) in CA1 of H, V=7.2, (n=5 rats) neither BEH nor PAS were elevated whereas convulsive signs (twitches and jerks), head and body tremors and respiratory rate were increased. When the CTR was lowered into dentate gyrus, V=6.2 (n=4), F produced no significant signs of PA as was the case when F was microinjected via GC in area 2, LAT of OCTX through CTR into H, V=5.8 (n=5), although 1 rat had a clonic convulsion. In contrast, when F was microinjected via same GC through CTR in CA1 of H, V=6.8 (n=8), BEH and PAS were elevated. Convulsive activity was apparent both by observation and EEG in some but not all rats. These data indicate that DZ given chronically produces dependence in some but not all areas of the H and that the CA1 area of the dorsal H is involved. Supported by NIDA Grant DA02195.

HISTOLOGICAL AND ULTRASTRUCTURAL BRAIN ALTERATIONS OF A MAN CRONICALLY EXPOSED TO HIGH DOSES OF DIAZEPAM. M.C. Márquez-Orozco,* M.E. Pérez-Chavira, M.V. Gazca-Ramírez and A. Márquez-Orozco. Embryology Dept., Medicine School UNAM, México 04510 D.F. and HGZ FPT 2-A, IMSS.

Our purpose was to investigate whether the histological and ultrastructural brain alterations observed in a 55 years-old man, exposed to daily diazepam (DZ) dosis (50/mg) during the last ten years of her life, are similar to those observed in adult mice prenatally treated with DZ. Cerebral and cerebellar cortices and striatum samples were studied with a light and transmission microscopes. The causes of death were not clearly determined. Pathology autopsy showed generalized cortical atrophy, without pre-senil or senil dementia and premature aging. Histological and structural sections showed II y III cortical layers disorganized presence of abundant amyloideus bodies, perinuclear vacuolization. Less number of Purkinje cells than in cerebellum of three healthy men from the similar age. In all neural cells the heterochromatine was seen in dense clumps scattered in its interior, around the nucleolus and mainly located near the nuclear envelope. The euchromatine, was reduced. Golgi complex, mitochondriae, rough endoplasmic reticulum and synaptic vesicles were disorganized. Electrondense bodies were observed. These alterations are similar those showed in adult mice prenatally exposed to DZ and suggest may be due to chronic exposure to high doses of DZ.

657.5

SEXUALLY DIMORPHIC ALTERATIONS IN THE BEHAVIOR OF ADULT RAT PROGENY AFTER PRENATAL EXPOSURE TO LORAZEPAM. G. T. Livezey* and C. V. Smith. Dept. Obstetrics & Gynecology, Univ. of Neb. Coll. of Med., Omaha, NE 68198.

This experiment is part I of a study of the effects of prenatal exposure to the benzodiazepine (BZ), lorazepam (LZ), on the behavior, EEG and brain-specific receptors of the mature offspring. Twenty adult female Sprague-Dawley rats received 1 mg LZ/ kg S.C. or the equivalent volume of vehicle, once daily, for 28 days prior to breeding, during breeding and throughout their 21-day gestation. The behavior of the offspring of both sexes was evaluated at 3-4 months of age. We used a modified radial arm maze test which incorporates measures from the open field test, hyponeophagia model of anxiety test, Olton's original RAM test and other parameters of our own design. Prenatal exposure to lorazepam produces performance deficits indicating a long-lasting state of hyperarousal or "anxiety" in the male offspring. Conversely, the female offspring prenatally exposed to lorazepam show enhanced performance that may indicate a reduction of "anxiety" relative to controls. Thus, prenatal lorazepam exposure has produced an exaggeration of the normal sex-dependent differences in maze performance and spontaneous behaviors. These results could result from an elevation of sex steroid levels or an alteration of the interaction of sex steroids with the benzodiazepine receptor which enhances the efficacy of circulating steroids.

BENZODIAZEPINE LIGANDS MODULATE ETHANOL DRINKING IN ALCOHOL-PREFERRING AA RATS. E.R. Korpi*, K. Wegelius, T. Ovaska and A. Honkanen. Biomedical Research Center, Alko Ltd, POB 350, FIN-00101 Helsinki, and Department of Pharmacy, Division of Pharmacology and Toxicology, University of Helsinki, Finland.

The effects of positive allosteric modulators (agonists) at the benzodiazepine site of the GABA_A receptor (midazolam, abecarnil, ZK 91296, bretazenil, and CGS 9895) and those of negative allosteric modulators (inverse agonists, Ro 15-4513 and Ro 19-4603) were studied on voluntary ethanol consumption in selectively-bred alcohol-preferring AA rat line using limited access paradigm. Each drug was tested after IP injections of three different doses using saline injections as a control treatment. The benzodiazepine agonists had only modest effects on ethanol intake, measured 1 and 4 h after the injections, whereas the inverse agonists strongly decreased ethanol consumption. Food consumption during the 4-h session was decreased by all other benzodiazepine agonists except bretazenil, which also significantly increased the ethanol drinking. The inverse agonists had no significant effect on food intake. Picrotoxin-sensitive [³⁵S]TBPS binding was differently modulated by benzodiazepine ligands between the AA rats and alcohol-avoiding ANA rats. [³H]Ro 15-4513 binding to the benzodiazepine sites did not, however, reveal any drastic differences between the lines. In conclusion, the results suggest that the GABA_A receptor may be involved in the regulation of voluntary ethanol drinking in alcohol-preferring AA rats, but do not indicate that these rats would consume ethanol because of its anxiolytic effects in a way that benzodiazepine agonists (full or partial) could substitute for it.

657.4

DIAZEPAM EFFECTS IN THE ULTRASTRUCTURE OF CEREBRAL CORTEX OF FETAL MICE. A. Márquez-Orozco,* M.V. Gazca-Ramírez, R. Andrade-Martínez and M.C. Márquez-Orozco. Embryology Dept., Medicine School, UNAM, México 04510 D.F.

We investigate whether diazepam (DZ) caused ultrastructural alterations in fetal mice cerebral cortex. Three CD-1 strain gestating mice groups were injected sc between the 6th to 17th gestation day, the first group with single daily DZ doses (2.7 mg/kg/bw), the second with 0.9% saline solution (S) and the third was non treated (NT). All were killed with CO₂ atmosphere the 18th day and the fetus removed. The cerebral cortex was fixed and embedded. Fine sections were observed under transmission microscope. In the DZ fetal mice cerebral cortex was evident delay cellular and neuropile differentiation. The nuclear density per area and the thickness were greater than in the S and NT fetuses (p < 0.05). Heterochromatin was seen in clumps scattered mainly in its interior and near of the nuclear envelope. The rough endoplasmic reticulum showed distended cisternae, the Golgi complex, the mitochondriae and the polyribosomes were more abundant. Such alterations could reveal disruption in cell multiplication and also it could be attributed to DZ inhibition protein synthesis and to the modification of the metabolic pathways mediated by central and peripheral types of benzodiazepine receptors. The results suggest that DZ produce long-lasting ultrastructural alterations in the cerebral cortex.

657.6

LONG-LASTING EFFECTS OF PRENATALLY EXPOSURE TO DIAZEPAM ON SEXUAL BEHAVIOR OF MALE MICE. L.A.I. Hernández-Alvarez,* A. Martínez-Vargas, B. Victoria-Romero, A. Márquez-Orozco and M.C. Márquez-Orozco. Dept. of Embryology, School of Medicine, BUAP and Dept. of Embryology, School of Medicine, UNAM, México 04510 D.F., México.

Effects of prenatal exposure to diazepam (DZ) in adult mice were showed on sexual reproductive behaviors. We assessed the sexual behavior of senile males CD-1 strain mice exposed to DZ during gestation. One group of female mice was s.c. treated with daily DZ doses (2.7 mg/kg/bw) from the 6th to 17th gestation day and a control group received saline sol. On the 27th month of age, the spontaneous male sexual activity to females from the same breeds was tested and videorecorded under red light. Precopulating and copulating activities were evaluated. No difference was found in precopulating behaviors from both groups. During copulating stage, greater sets of mount series with and without penile intromission, as well as falls and interruptions of intravaginal penetration were found in DZ animals. Although ejaculations per animal were unusually in both groups, DZ mice had fewer. Results show a long-lasting effect of prenatal exposure of DZ on sexual behavior.

657.8

THE BENZODIAZEPINE (BDZ) PARTIAL AGONIST RO16-6028 (BRETAZENIL) AUGMENTS THE DEPRESSANT EFFECTS OF ETHANOL (EtOH). A.R. Starosta*, G.G. Blakley, H.L. June, and M.J. Lewis. Neurobehavioral Laboratory, Dept. of Psychology, Temple University, Philadelphia, PA 19122 and IUPUI Dept. of Psychology, Indianapolis, IN 46202.

RO16-6028 (Bretazenil), a partial BDZ agonist with pronounced clinical anxiolytic properties, has been shown to increase EtOH consumption in EtOH preferring and non-preferring rats and recently in randomly bred rat stocks. The present experiment investigated the effects of RO16-6028 on EtOH-induced changes in open field activity. Male Sprague-Dawley rats were tested for basal locomotor activity for one week in a Coulbourn video activity apparatus at 10 min. intervals for 60 min. Animals were then injected IP with saline and vehicle and either EtOH alone (0.25-1.0 g/kg), RO16-6028 (0.5-2.0 mg/kg) alone or RO16-6028 and EtOH (same respective doses) in combination prior to measurement of horizontal and vertical activity. Both EtOH and RO16-6028 generally decreased activity over the period of testing. RO16-6028 did not effect the early effects of EtOH (0-20 min.), but did increase the depressant effects of EtOH 20-60 min. These data suggest a differential role GABA-BDZ mechanisms in early vs late EtOH effects.

COMPARISONS OF [3 H]Ro15-4513 BINDING IN CEREBELLUM FROM ETHANOL-NAIVE WITHDRAWAL SEIZURE PRONE AND WITHDRAWAL SEIZURE RESISTANT MICE. A. Leslie Morrow*, F. Donelson Smith, and Leslie L. Devaud, UNC Sch. of Medicine, Chapel Hill, NC 27599.

Ethanol withdrawal seizure resistant (WSR) and withdrawal seizure prone (WSP) lines of mice have been selectively bred for investigation of the mechanisms involved in alcohol withdrawal. Ethanol-naive WSP mice are more sensitive than WSR mice to GABAergic chemoconvulsants, suggesting differences in GABA_A receptor function or structure are involved. WSR mice exhibit 50-100% higher levels of GABA_A receptor $\alpha 1$, $\alpha 6$ and $\beta 2$ subunit mRNAs in cerebellum, but not cortex. Ro15-4513 is a GABA_A receptor inverse agonist which labels recognition sites on $\alpha 6$ subunits. The present study was undertaken to determine if there are differences in [3 H]Ro15-4513 binding characteristics between WSR and WSP mice. Saturation binding analysis was conducted with [3 H]Ro15-4513 (0.2-20 nM) using individual cerebella from WSR1, WSR2, WSP1 and WSP2 mice. No differences in binding were observed between the WSR1/2 or the WSP1/2 lines, respectively (n=8). Moreover, no differences in [3 H]Ro15-4513 binding were observed in cerebella from ethanol-naive WSR vs. WSP mice. Binding density was 1467 ± 52 fmol/mg protein in the WSR and 1543 ± 41 fmol/mg protein in WSP cerebella. K_D values were 2.90 ± 0.09 nM and 2.82 ± 0.11 nM for WSR vs. WSP mice, respectively. These data indicate a discrepancy between the expression of GABA_A receptor $\alpha 6$ subunit mRNAs and [3 H]Ro15-4513 recognition sites in these mice. (Supported by AA09013, ES07126 and Pharm. Man. Assoc. Found.).

THE BENZODIAZEPINE ANTAGONIST CGS-8216 EXERTS PROLONGED AND SELECTIVE ATTENUATION OF ETHANOL INTAKE IN ALCOHOL-PREFERRING (P) RATS. J. Williams, H.L. June, S. Dejaravu, M.J. Lewis*, and J.M. Murphy. Dept. of Psychology, Inst. of Psychiatric Res. and Program in Medical Neurobiology, Indiana University-Purdue University, Indianapolis, IN 46202 and Dept. of Psychology, Temple Univ., Phila., PA 19123

The present study investigated dose dependence and time course profiles of CGS 8216 (0.0, 0.5, 1.0, 5.0, 10, or 20 mg/kg), a pyrazoloquinoline BDZ antagonist in attenuating EtOH intake in alcohol-preferring P rats (N=13). Animals were provided a 4 hr daily limited access to a two bottle choice between EtOH (10% v/v) and saccharin (0.0125% g/v) solutions. For the remaining 20 hr, rats were provided unlimited access to water, with food available ad libitum. Acute administration of CGS 8216 (1.0 - 20 mg/kg) dose-dependently reduced EtOH intake to 42% - 79% of controls at the initial 15 min interval of the 4 hr access on Day 1. All doses reduced total consumption for the 4 hr period to 15-60% of control levels. On Day 2 (24 hr post-drug administration), the 5.0 and 20 mg/kg doses of CGS 8216 reduced EtOH intake to 41% of controls during the initial 15 min interval, while total consumption was reduced to 20-32% of control levels for all doses except the 10 mg/kg dose. Saccharin drinking generally showed no changes at the initial 15 min interval, however, compensatory increases paralleled the decreased EtOH consumption and the total consumption measure for several of the CGS 8216 doses. These results suggest the BDZ component of the GABA_A receptor complex may play a direct role in the reinforcing actions of EtOH. (Supported in part by grants AA08553 and AA07611).

THE EFFECT OF ANXIOLYTICS ON NOVELTY-INDUCED PLACE PREFERENCE. J.E. Klebaur*, D. Miller, & M.T. Bardo. Department of Psychology, Univ. of KY, Lexington, KY 40506-0044

Previous evidence has shown that rats exposed to one compartment of a place preference apparatus will prefer the novel compartment over the familiar. While this suggests that novelty is rewarding, an alternative interpretation is that rats avoid the familiar compartment because it is associated with stress induced during the inescapable exposure sessions. To test this later possibility, the anxiolytics diazepam (0.1, 0.3, 1.0, 3.0 mg/kg) and gepirone (0.1, 0.3, 1.0 mg/kg) were examined for their ability to alter novelty-induced place preference in rats. As expected, control animals showed a novelty-induced place preference. On test day, this preference was blocked by diazepam, but only at a dose (3 mg/kg) that also decreased locomotor activity. Gepirone failed to alter the preference behavior, even at a dose (1 mg/kg) that decreased locomotor behavior. These experiments indicate that preference for the novel compartment is an indication of the rewarding effects of novelty and not an avoidance of stress associated with the familiar.

DIFFERENTIAL SENSITIVITY OF THE BENZODIAZEPINE INVERSE AGONIST RO19-4603 ON THE LOCOMOTOR DEPRESSANT EFFECTS OF ETHANOL IN ALCOHOL-PREFERRING (P) AND -NONPREFERRING (NP) RATS. H.L. June*, T.L. Greene, M. Lin and J.M. Murphy. Dept. of Psychology, Inst. of Psych. Res. and Prg. in Medical Neurobiology, IUPUI, Indianapolis, IN 46202.

The present study investigated the extent to which possible genetic differences, which are phenotypically expressed as differences in EtOH preference, may influence sensitivity to the BDZ partial inverse agonist, RO19-4603 (R) in modifying low to high doses of EtOH (0.125 - 2.5 g/kg). P (N=20) and NP (N=20) rats of the F2 inbred line were habituated to a photocell apparatus and tested for 10 min sessions during the experimental phase. Animals from each line were randomly assigned to an EtOH only group, or to a R+ EtOH group (n=10/group). Animals in both groups received three daily consecutive EtOH injections. Animals in the R groups, however, were given R (0.15 mg/kg), 5 min prior to the EtOH injection on Day 1 only. EtOH alone caused dose-dependent reduction in motor behaviors on Day 1-3 (50 to 70% of control), with tolerance seen only with the NP rats for the 0.125 g/kg dose on Day 2. R enhanced the suppressant effects of the 0.125 g/kg EtOH dose in the P and NP line on Day 1. R was without effect on Day 1-3 when given before the 1.0 and 1.5 g/kg EtOH dose in the P rats, as well as Day 1 in the NP rats. R antagonized, however, the EtOH suppression on Day 2 and 3 in the NP rats with the 1.0 g/kg dose, as well as Day 1 and 3 with the 1.5 g/kg dose. R was without effect on the 2.5 g/kg dose of EtOH in the P or NP rats or given alone. The results suggest R may induce rapid changes at the GABA_A receptor and mediate the motor-impairing effects of EtOH for 48 hr in the F2 line NP rat, but not P rat. These effects may be related to the low EtOH preference of the NP rat. (Supported in part by grants AA08553 and AA07611)

INTERACTIONS OF ETHANOL AND DIAZEPAM ON HIPPOCAMPAL LONG TERM POTENTIATION. J.L. Polan-Curtain*, M.J. Wayner and D.L. Armstrong. Division of Life Sciences, The University of Texas at San Antonio, San Antonio, TX 78249-0662.

Within a limited range of doses, co-administration of ethanol (EtOH) and diazepam (DZ) produce enhanced anxiolytic effects. These combined effects on long-term potentiation (LTP) in the hippocampus of rats anesthetized with urethane were studied in an attempt to provide an explanation at a more fundamental neuronal level. Male Sprague-Dawley rats received 0.1, 0.5, 0.75 and 1.0 mg/kg DZ i.p. in combination with 0.1, 0.5, 0.75 g and 1.0 g/kg EtOH by gavage, respectively. Drugs were administered 20 min (EtOH) and 15 min (DZ) prior to tetanic stimulation of the medial perforant path which resulted in LTP induction measured in terms of the relative change in slope of the population EPSP as compared to baseline. Effects of both drugs alone and in combination on LTP will be presented. Both drugs depressed LTP induction and significant enhanced interactive effects were observed.

658.1

DIFFERENTIAL ANALGESIA IN ALCOHOL-PREFERRING AA RATS AND ALCOHOL-AVOIDING ANA RATS. A. Honkanen¹, T. Ovaska², L.M.J. Attila¹ and E.R. Korpi². ¹Department of Pharmacy, Division of Pharmacology and Toxicology, POB 15, FIN-00014, University of Helsinki, ²Biomedical Research Center, Alko Ltd. POB 350, FIN-00101 Helsinki, Finland

Brain opioid systems may have a role in the ethanol reward. Our aim was to study possible differences in the sensitivity of the CNS opioid mechanisms of alcohol-preferring (AA) and alcohol-avoiding (ANA) rats by activating the central opioid mechanisms with ethanol, morphine and swimming-induced stress followed by measurement of the analgesia induced by these treatments. Analgesia was measured with the tail-flick (TF) test. The baseline TF-latency was measured 4 times with 5 min intervals before treatments. The mean of the last 3 trials served as baseline (BL). Ethanol (15 %, i.p., 1.0, 1.5 or 2.0 g/kg) or saline was given after the last BL-trial. TF-latency was measured 5, 10, 20 and 30 min after injections. Morphine (MO) was given (s.c) with cumulative dosage (0.5-16 mg/kg) with 20 min intervals. The TF-latency was measured just before each injection. Stress was induced to rats by exposing them to 3-min swimming in 15 °C water. TF-latencies were measured just before and 3, 6 and 9 min after swimming. TF-latencies increased in the AA rats during 4 BL-trials but not in the ANA rats. No difference was found in the MO or stress induced analgesia between rat lines. The smallest ethanol dose (1.0 g/kg) failed to produce analgesia in either rat line, but 1.5 g/kg of ethanol produced slight analgesia in the AA rats but not in the ANA rats. Both rat lines showed similar analgesia after 2.0 g/kg ethanol. These results suggest that the ANA rats may be more resistant to habituate to repeated nociceptive stimuli than the AA rats. The AA rats appear to be slightly more sensitive to analgesic effect of ethanol than the ANA rats. Whether this effect is due to greater release of endogenous opioids in these rats remains to be studied.

LOW-LEVEL HYPERBARIC ANTAGONISM OF DIAZEPAM'S ANTICONVULSANT PROPERTY IN C57BL/6J MICE. D.L. Davies¹, B.L. Jones¹, M.L. Palomares¹ and R.L. Alkana². Molecular Pharmacology and Toxicology, School of Pharmacy, University of Southern California, Los Angeles, CA 90033.

Low-level hyperbaric exposure antagonizes several ethanol-induced behaviors including its locomotor depressing and anticonvulsant effects. Recent work found that pressure also antagonizes diazepam-induced locomotor depression suggesting that ethanol and diazepam may have a common pressure antagonizable site of action. The present study further explored this hypothesis by testing whether this pressure-related link between ethanol and diazepam extends to diazepam's anticonvulsant property. Drug-naive, male C57BL/6J mice were injected intraperitoneally with vehicle, 4.0, 8.0, or 24.0 mg/kg diazepam followed immediately by an intramuscular injection of 300 mg/kg of INH. The mice were then exposed to either 1 atmosphere absolute (1 ATA) air, 1 ATA helium-oxygen gas mixture (heliox) or 12 ATA heliox at temperatures that offset the hypothermic effects of helium. Diazepam increased the latency to onset of myoclonus in a dose dependent manner. Exposure to 12 ATA heliox antagonized diazepam's anticonvulsant effect at 8.0 and 24.0 mg/kg, but not 4.0 mg/kg. Diazepam also increased the latency to onset of clonus in a dose dependent manner beginning at 8.0 mg/kg. Exposure to 12 ATA heliox antagonized this anticonvulsant effect. These findings extend the acute behavioral effects of diazepam known to be antagonized by hyperbaric exposure and support the hypothesis that ethanol and diazepam share a common pressure antagonizable site of action in the GABA_A receptor complex. (Supported by NIAAA grant AA03972).

ALCOHOL AVERSION LEARNING IN RATS SELECTIVELY BRED FOR ALCOHOL SENSITIVITY.

R.L. Elder^{*}, N. Badia-Elder, S.W. Kiefer, and F.A. Martinson. Dept. of Psychology, Kansas State Univ., Manhattan, KS 66506-5302.

Previous work reported that Low Alcohol Sensitive (LAS) rats failed to develop normal saccharin aversions, relative to High Alcohol Sensitive (HAS) rats, when alcohol was used as the illness agent. In the present experiment, HAS and LAS rats were compared with control rats in the acquisition of an alcohol aversion using lithium chloride as the illness agent. Rats were trained to avoid a 6% alcohol solution by pairing it with LiCl intubations (3% body weight of a 0.15 M solution). Rats were tested for taste reactivity to 6% alcohol on the day after training. This test was then followed with extinction trials with 6% alcohol in the drinking situation. No significant differences between groups were found in ingestive or aversive taste reactivity. There were also no significant consumption differences found between groups during aversion extinction. These data indicate that HAS and LAS rat lines are capable of developing normal alcohol aversions when the illness agent is LiCl.

EFFECTS OF LOW LEVEL HYPERBARIC EXPOSURE ON MORPHINE-INDUCED STIMULATION OF LOCOMOTOR ACTIVITY: DOSE-RESPONSE. R.L. Alkana¹, B.L. Jones¹, M.L. Palomares¹, D.L. Davies¹ and J. Merland². Dept. Molec. Pharmacol. & Toxicol., School of Pharmacy, Univ. of Southern California, Los Angeles, CA 90033

Exposure to 12 atmospheres absolute (ATA) helium-oxygen gas mixtures (heliox) antagonizes a broad range of acute and chronic behavioral effects of ethanol. If pressure antagonizes ethanol by blocking or offsetting its initial molecular actions, then the antagonistic effects of pressure should be limited to drugs acting via similar mechanisms. The present study tests this hypothesis by extending preliminary investigations of the effects of hyperbaric exposure versus morphine-induced locomotor activation. Drug-naive C57BL/6J mice were habituated for 60 minutes, injected with saline or morphine (10-32 μ moles/kg) and then exposed to 1 ATA air, 1 ATA heliox or 12 ATA heliox at temperatures which offset helium-induced hypothermia. Morphine induced a dose-dependent stimulation of locomotor activity in air. Exposure to 1 or 12 ATA heliox did not significantly affect morphine induced locomotor stimulation. Helium and pressure did not alter the locomotor activity of saline-injected controls. These results indicate that 12 ATA heliox does not antagonize morphine-induced locomotor activation. This finding supports the hypothesis that low level hyperbaric exposure antagonizes ethanol's behavioral effects in a manner analogous to a specific competitive pharmacodynamic antagonist. Taken with recent findings that exposure to 12 ATA heliox antagonizes the behavioral effects of diazepam, the present results strengthens the evidence linking the allosteric mechanisms mediating diazepam's and ethanol's effects on GABA_A receptor function (Supported by NIAAA, NIH Grants RO1AA03972 and RO1AA05234)

658.4

ALCOHOL PREFERENCE IN RATS SELECTIVELY BRED FOR SACCHARIN CONSUMPTION. N.E. Badia-Elder^{*}, S.W. Kiefer¹, and N.K. Dess². Psychology Dept., Kansas State Univ., Manhattan, KS 66506, Psychology Dept., Occidental College², Los Angeles, CA 90041.

Selectively bred high saccharin consuming (HIS) and low saccharin consuming (LOS) rats, obtained from The Occidental College in Los Angeles, were tested for taste reactivity to 10% alcohol, sucrose, quinine, and a sucrose/quinine mixture. After taste reactivity testing, a two-bottle consumption test with 10% alcohol and distilled water was given for 14 days. At the end of two-bottle testing, rats were tested a second time for taste reactivity to 10% alcohol. In the initial taste reactivity exposure, HIS and LOS rats did not differ in response to 10% alcohol, sucrose, quinine, or the sucrose/quinine mixture. Likewise, there were no significant differences between HIS and LOS rats in their second taste reactivity to 10% alcohol. However, there was an exposure effect in that all rats significantly increased ingestive responding and decreased aversive responding to 10% alcohol on the second test. HIS and LOS rats did not differ in alcohol consumption as measured with two-bottle testing. According to these results, HIS and LOS rats display similar patterns of alcohol preference as measured by taste reactivity and consumption.

658.6

NALTREXONE AND TASTE REACTIVITY TO ALCOHOL IN RATS. K.G. Hill^{*}, N.E. Badia-Elder, and S.W. Kiefer. Dept. of Psychology, Kansas State Univ., Manhattan, KS 66506-5302.

Naltrexone, an opiate antagonist, has been shown to reduce alcohol consumption, particularly in high alcohol consuming rats. In the present study, it was determined whether naltrexone altered the taste reactivity responding of rats when presented with an intraoral infusion of alcohol. Two groups of rats were tested for their taste reactivity response to 10% alcohol 30 min after naltrexone treatment (1 mg/kg ip) and 30 min after saline treatment: High Ingestive Responding (HIR; n=7) rats, which were selectively bred for their taste reactivity to alcohol and which consumed high amounts of 10% alcohol; Sprague-Dawley (n=8) rats that had previous experience with a range of alcohol concentrations. Although naltrexone did not alter alcohol reactivity in the Sprague-Dawley rats, HIR rats did exhibit increased aversive responding and decreased ingestive responding following naltrexone treatment. The results provide preliminary evidence that naltrexone may alter alcohol consumption by altering its palatability.

NALTREXONE ATTENUATES ETHANOL STIMULATED DOPAMINE RELEASE IN THE NUCLEUS ACCUMBENS. R.R. KOHL and W.J. McBRIDE* Depts. of Psychiatry and Medicine, Medical Neurobiology Graduate Program, Indiana University School of Medicine, Indianapolis IN, 46202-4887.

The effect of naltrexone (NAL) on ethanol stimulated-dopamine (DA) release in the nucleus accumbens was studied in adult, female, Wistar rats using *in vivo* microdialysis in conjunction with HPLC with electrochemical detection. Rats were implanted with microdialysis probes 36-48 hours prior to the administration of ethanol alone (2.0 g/kg, i.p.) or ethanol following pretreatment with 20 mg/kg i.p. NAL. Experiments were conducted on awake, freely moving animals. The i.p. administration of 2.0 g/kg ethanol increased extracellular DA concentrations to approximately 160% of baseline (N=6) within 60 minutes and levels remained elevated for at least two hours. The i.p. administration of NAL (N=5) 30 minutes before injection of ethanol reduced ($p<0.001$) the ethanol induced increase in extracellular DA concentrations. There were no effects on extracellular levels of dopamine with i.p. injections of saline. In general, the extracellular levels of DA and serotonin metabolites did not change during any of the treatments. The results suggest a role for endogenous opioids in mediating the actions of alcohol on the mesolimbic DA system. (AA 09090, AA 08553)

658.9

THE EFFECT OF NALTRINDOLE ON EXPRESSION OF ETHANOL-INDUCED CONDITIONED PLACE PREFERENCE. S.D. Dickinson and C.L. Cunningham* Dept. of Medical Psychology, Oregon Health Sciences Univ., Portland, OR 97201.

Recent research has suggested a role of the endogenous opioid system in the reinforcing properties of ethanol. Research in our laboratory has shown that the expression of ethanol-induced conditioned place preference in mice can be attenuated by naloxone (1.5 - 10 mg/kg). However, at these doses, naloxone may act as a nonspecific antagonist, occupying both mu and delta opioid receptors. The current study was designed to determine whether naloxone's actions were delta-receptor mediated. Three groups of male DBA/2J mice underwent a Pavlovian conditioning procedure that paired injection of ethanol (2 g/kg, IP) with a distinctive tactile stimulus and injection of saline with a different stimulus. After four pairings of each type, a preference test was conducted in which mice were exposed to both tactile stimuli. Prior to the preference test, mice were injected with either 0, 3, or 10 mg/kg of naltrindole (NTI), a selective delta opioid receptor antagonist. All groups demonstrated a conditioned preference for the tactile stimulus that had been paired with ethanol. Unlike naloxone, NTI had no effect on the expression of the conditioned preference. This indicates that naloxone's ability to interfere with expression of ethanol place preference is not mediated via delta opioid receptors. Supported by an N. L. Tartar Fellowship.

EFFECT OF CHRONIC ALCOHOL ADMINISTRATION ON DIURNAL ACTH AND CORTICOSTERONE SECRETION IN INTACT AND ADRENALECTOMIZED RATS WITH CORTICOSTERONE REPLACEMENT. T. Chautard, T. Torda, R. Daoud, J.G. Ondo*, and R. Eskay. NIAAA, NIH, Bethesda, MD 20892.

The hypothalamo-pituitary-adrenal (HPA) axis is characterized by a circadian activity with lowest plasma corticosterone (CS) and ACTH levels near lights on and highest hormone levels near lights off. Intact or adrenalectomized (ADX) male rats implanted with CS pellets (plasma CS levels of 3 to 5 μ g/dl) were fed every four hours for up to 10 days via an intragastric cannula with the Leiber-DeCarli liquid control diet (LCD) or ethanol diet (LED). Blood samples were taken via an implanted atrial cannula at the trough and zenith of the diurnal rhythm. In intact alcohol-treated rats, daily plasma CS levels were 2 to 10 fold higher at the nadir, when compared to control rats, whereas daily plasma CS levels at the zenith were elevated less than 50 percent of the time. In ADX rats with CS replacement, plasma ACTH levels were significantly higher only during the trough in LED-treated rats compared with LCD-treated rats. Furthermore, chronic ethanol treatment decreased thymus and spleen weight in both intact and ADX rats with CS replacement. These results indicate that continuous alcohol exposure (150-300 mg/dl) leads to a persistent activation of the HPA axis, particularly during the nadir of the diurnal rhythm.

658.8

NALOXONE FAILS TO BLOCK INHIBITORY EFFECTS OF ETHANOL ON SPONTANEOUS AND AMYGDALA-EVOKED SINGLE UNIT ACTIVITY OF NUCLEUS ACCUMBENS NEURONS. R.-S. Lee*, J.R. Criado, G.I. Berg, and S.J. Henriksen. Alcohol Research Center, Dept. of Neuropharmacology, Scripps Research Institute, La Jolla, CA 92037.

Previous studies from our group have shown diverse effects of ethanol on nucleus accumbens (NAcc) physiology. For example, systemic administration of ethanol reduces the firing rate of spontaneous and glutamate-activated NAcc neurons in both acute anesthetized and unrestrained rats. In contrast, ethanol did not affect the recruitment of fimbria-activated NAcc neurons. Others have demonstrated that naloxone, an opioid antagonist, reduces ethanol preference in rats. The functional significance of these inhibitory effects of ethanol on spontaneous and glutamate-activated NAcc neurons is still unknown. In view of the possible role of the NAcc in mediating the reinforcing properties of ethanol, we studied the effects of naloxone (5 mg/kg, i.p.) on ethanol-dependent inhibition of spontaneous NAcc neurons in acute anesthetized and unrestrained rats. Also, to further characterize the effects of ethanol on limbic-NAcc inputs, we studied the sensitivity of amygdala-activated NAcc neurons to intoxicating doses of ethanol. Systemic administration of ethanol (1.2-1.4 g/kg, i.p.) significantly reduced the firing rate of spontaneous NAcc neurons in both electrophysiological preparations. Similarly, ethanol inhibited the occurrence of amygdala-activated single units in NAcc neurons. Naloxone did not reverse these inhibitory effects. These findings suggest that some of the inhibitory effects of ethanol on NAcc physiology are independent of opioid mechanisms (Supported by ARC AA06420 to SJH).

IBOGAINE ATTENUATES ALCOHOL INTAKE IN ALCOHOL DRINKING RATS. Y.W. Lee, Amir H. Rezvani* and D.H. Overstreet. Skipper Bowles Center for Alcohol Studies, University of North Carolina School of Medicine, Chapel Hill, NC 27599-7175.

Ibogaine, the principal alkaloid of the root bark of *Iboga tabernanthe* grown in West Central Africa, has been claimed to possess anti-addictive properties for cocaine and morphine. This study was designed to determine the effect of Ibogaine on alcohol intake in two strains of alcohol drinking rats. Alcohol preferring (P) and Fawn Hooded (FH) rats were injected IP with either vehicle or one of the doses (10, 30 and 60 mg/kg) of Ibogaine and their alcohol intake was measured 24 hr later. In other experiments the effects of acute and subchronic intragastric as well as acute subcutaneous administrations of Ibogaine in FH rats were determined. Intraperitoneal injections of Ibogaine significantly and dose-dependently attenuated alcohol intake in both strains. However, FH rats were less affected by the drug. Subcutaneous administration of the drug did not exert any effect. Both acute and subchronic intragastric administration of 60 mg/kg Ibogaine significantly reduced alcohol intake without development of tolerance. The fact that Ibogaine reduced alcohol intake when is injected intraperitoneally and intragastrically, but not subcutaneously, suggests the involvement of its metabolite(s) in reducing alcohol intake. Although the true mechanism(s) of action of Ibogaine in reducing voluntarily alcohol intake is not yet clear, the fact that FH rats with genetic serotonin dysfunction were less affected by this drug suggests that, in addition to other neurotransmitters, Ibogaine may interact with serotonergic systems in the brain to reduce alcohol intake.

CENTRAL OXYTOCIN MODULATION OF SPONTANEOUS ETHANOL INGESTION IN RATS. R.E. Blackburn*, W.K. Samson, R.J. Fulton, E.M. Stricker, and J.G. Verbalis. University of Pittsburgh, Pittsburgh, PA 15261 and University of North Dakota, Grand Forks, ND 58202.

Recent studies from our laboratories have implicated central oxytocin (OT) pathways in the inhibitory control of solute ingestion, whether the solute is taken as food or as a concentrated NaCl solution. These data led us to investigate whether central OT may be similarly involved in the control of ethanol (EtOH) ingestion, since EtOH also is a solute. In initial studies rats were pretreated with central injections of ricin A toxin conjugated to OT (rAOT, 5 μ g icv; n=22) to irreversibly destroy brain cells bearing OT receptors, or with control injections of non-conjugated toxin (rA, 5 μ g icv; n=8). When the pretreated rats were given access to standard chow, water, and a range of concentrated EtOH solutions (3%-15%), the rAOT-pretreated rats demonstrated 3-5 fold greater daily EtOH intakes compared to the rA controls at all EtOH concentrations tested ($p<0.01$). This marked EtOH preference in the rAOT-pretreated rats produced significantly greater degrees of tolerance, as measured by latencies to righting reflex after 4 g/kg EtOH ip (90 \pm 15 vs. 2 \pm 1 sec; $p<0.01$). In additional studies, a similarly potentiated EtOH ingestion was achieved when central OT receptors were transiently blocked with a non-peptide OT receptor antagonist (L366,948), which resulted in 5-10 fold greater EtOH intakes than controls at all concentrations tested (3-15%). These data indicate that central OT pathways likely participate in the inhibition of EtOH consumption in rats, and suggest that blockade of central OT receptors may provide a behaviorally relevant model for rapid initiation of spontaneous EtOH consumption in this species.

659.1

DISCRIMINATIVE AND AFFECTIVE STIMULUS PROPERTIES OF THE CALCIUM CHANNEL BLOCKER NIMODIPINE IN RATS.

J. De Vry, M. de Jonge and R. de Beun. Institute for Neurobiology, Troponwerke GmbH & Co. KG, Berliner Strasse 156, 51063 Cologne, FRG

The L-type calcium channel blocker nimodipine, a 1,4-dihydropyridine (DHP) derivative, is effective in reducing alcohol intake and preference in animal models of alcoholism. In order to gain more insight in possible mechanisms underlying the alcohol intake-suppressing effects of this drug, the discriminative and affective (rewarding/aversive) stimulus properties of nimodipine were evaluated in Wistar rats. It was found that racemic nimodipine can function as a cue in a standard two-lever food-reinforced drug discrimination (DD) procedure and, in subsequent generalization tests, inverted U-shaped dose-response curves were obtained with nimodipine and nifedipine, another DHP. The nimodipine cue generalized completely to (+)-nimodipine (again, an inverted U-shaped curve was obtained), but only partially to (-)-nimodipine. Although effective as a discriminative stimulus, the quality of this stimulus appears to be dissimilar to that of ethanol as it was found that rats trained to discriminate ethanol from saline in a similar procedure did not generalize to nimodipine. The latter finding was confirmed in a cross-familiarization conditioned taste aversion (CF-CTA) procedure, an alternative method to reveal stimulus similarities between drugs. In addition to discriminative stimulus effects, nimodipine has also affective stimulus properties, as the compound was found to induce conditioned taste aversion (CTA), as well as, conditioned place preference (CPP). Racemic and (-)-nimodipine were active in CTA and CPP, whereas (+)-nimodipine failed to produce either CTA or CPP, suggesting that, in contrast to the DD effects, the affective stimulus effects are mainly mediated by the activity of (-)-nimodipine. Because the alcohol intake- and preference-reducing effects of nimodipine reside mainly in the (-)-enantiomer, the mechanism involved in these effects may be related to the affective stimulus properties of nimodipine.

EARLY TASTE AVERSION TRAINING IS EFFECTIVE IN PREVENTING THE ONSET OF ALCOHOL DRINKING IN P AND HAD RAT LINES. D.L. McKinzie, R. Eha, J.M. Murphy*, W.J. McBride, L. Lumeng and T.-K. Li. Depts. Psych. & Med., Indiana Univ. Sch. Med. and VA Med. Ctr., and Dept. Psychol., IUPUI, Indianapolis, IN 46202-4887.

The objective of this study was to determine the effects of taste aversion training during adolescence on subsequent alcohol intake of the selectively bred alcohol-preferring P and high-alcohol drinking HAD lines of rats. Beginning at 30 days of age, male and female rat pups were fluid deprived 24 hrs before a 30 min access period to a 10% (v/v) ethanol solution. Following ethanol exposure, rats were given an i.p. injection of either saline or 0.15 M LiCl (10 ml/kg). A total of five training sessions were administered every other day with ad lib access to water on intervening training days. Twenty-four hrs after the last training trial, rats were given continuous free-choice between water and 10% ethanol for four weeks with food available ad lib. There were no obvious gender differences or line differences to the effects of taste aversion training. All LiCl-treated subjects avoided the usually preferred ethanol solution for the entire four week test period (intake in week 4 was 0.6 ± 0.1 g/kg/day; N=6), while saline-treated rats steadily increased their alcohol intake to 8.4 ± 0.7 g/kg/day during week 4 ($p < 0.01$ vs LiCl-treated). Total volume of fluid intake did not differ between groups (39 ± 4 ml/day for saline-treated and 35 ± 5 ml/day for LiCl-treated group). Approximately 60% of the total fluid intake was 10% ethanol for the saline treated group; for the LiCl-treated rats this value was less than 3%. Rats in the saline and LiCl-treated groups gained weight at equivalent rates. These data suggest that early environmental intervention can prevent the onset of alcohol drinking in the selectively bred alcohol-preferring P and high alcohol-drinking HAD lines of rats. CO-MORBID DEPRESSION, DRUG DEPENDENCE, AND ALCOHOLISM

Norman S. Miller, M.D.(1), Norman G. Hoffmann, Ph.D.(2), Mark S. Gold, M.D. (3). University of Illinois at Chicago(1), The University of Minnesota(2) and The University of Florida Brain Institute(3)

We examined the relationship between a lifetime diagnosis of major depression in 6355 patients with drug dependency and/or alcoholism. Evaluations were performed in a personal interview on admission (383 questions) and follow-up data was gathered by a structured telephone interview (110 questions) at 6 and 12 months. The most common diagnosis of a substance use disorder was alcohol (51.3%), followed by cocaine(19.7%) and then marijuana dependence (12.3%). The rate of lifetime diagnosis of major depression was 43.7% and subclinical depression was 9.6%. Over half of the patients had two or more symptoms of depression and 35.9% had five or more symptoms of major depression. The rates of depression were significantly greater for females than males, for alcoholism than other drug dependencies. A lifetime diagnosis of major depression was significantly associated with poly-drug dependence.

THE USE OF A SUCROSE-SUBSTITUTION PROCEDURE TO ESTABLISH ETHANOL AS A POSITIVE REINFORCER IN AN OPERANT RUNWAY. C.L. Czachowski* and A. Ettenberg. Behavioral Pharmacology Lab., Dept. of Psychology, Univ. of California, Santa Barbara, CA 93106.

The reinforcing properties of self-administered ethanol were examined in nondeprived rats trained to traverse a straight-arm runway for the opportunity to drink an ethanol solution in the goalbox. Animals were tested once each day in the runway where each trial culminated in 6 min of access to a drinking bottle containing 5-10% ethanol. In order to ensure reliable and significant levels of ethanol consumption, we employed a modified version of a sucrose-substitution procedure originally described by Samson (1986) in an operant lever-pressing paradigm. In the present study, subjects initially ran the alley for access to high concentrations of sucrose (20% w/v) without ethanol. Over the course of days/trials the concentration of sucrose was gradually reduced while the concentration of ethanol was increased from 0 to 10%. This procedure successfully resulted in a mean ethanol intake of 0.65 g/kg (S.E.M. \pm 0.14) - a dose that rendered several animals ataxic and had clear behavioral/intoxicant effects. These data suggest that the runway/sucrose-substitution procedure may provide a unique model for investigating the reinforcing properties of high doses of ethanol in nondeprived animals.

USE OF ETHANOL INHALATION TO STUDY THE EFFECTS OF ETHANOL AND ETHANOL DEPENDENCE ON NEONATAL DEVELOPMENT IN MICE. N. Pal, B.L. Jones, M.L. Palomares, C. Bowers* and R.L. Alkana. Molecular Pharmacology and Toxicology, School of Pharmacy, University of Southern California, Los Angeles, CA 90033.

The present study explores the use of ethanol inhalation as a model to study the effects of ethanol, ethanol dependence and withdrawal on development in neonatal mice. In these experiments 1-2 day old Swiss Webster mice along with their mother were put in an alcohol inhalation chamber and continuously exposed to alcohol vapors for 6 or 12 days. Pyrazole was not used. At the end of exposure, when the animals were removed from the inhalation chamber they were observed for ethanol dependence, as manifested by withdrawal symptoms. It was found that: (a) the neonates developed substantial blood alcohol levels (180-300mg/dl); whereas the mothers had little (<5mg/dl) or no detectable blood alcohol concentrations; (b) physical dependence to ethanol was produced in the neonates, as evidenced by typical withdrawal symptoms of tremors and convulsions. The severity of withdrawal was related to the length of exposure; (c) exposure to ethanol vapors did not affect the weight gain or physical appearance of the neonates; (d) there was an ethanol exposure dependent effect on the brain weights; (e) exposure to vapors produced changes in behavior and ethanol sensitivity. These results indicate that the ethanol inhalation technique can be used to investigate the effects of ethanol, ethanol dependence and withdrawal on neonatal development in mice as a model for human fetal exposure during third trimester of pregnancy. This technique offers several advantages over other methods commonly used for neonatal alcohol exposure: (1) The pups do not suffer the stress of maternal separation, and can be exposed right after birth; (2) No surgical procedure is necessary; (3) Blood alcohol levels can be easily manipulated by altering the vapor concentration of alcohol; and (4) exposure to vapors does not effect the weight gain of the experimental animals. (Supported in part by NIAAA, NIH Research grants AA03972 and AA05234).

NEURAL EXPRESSION OF C-FOS PROTEIN FOLLOWING AGGRESSIVE BEHAVIOR OR ETHANOL ADMINISTRATION IN MICE. M. Boechler, G. Gunn, J. Maruniak, and F. vom Saal. Division of Biological Sciences, University of Missouri-Columbia, Columbia, MO 65211.

We employed immunocytochemistry to detect the presence of c-fos protein in the brains of male wild mice one hour following i.p. treatment (20ml/kg) with 1) 0.33 g/kg ethanol (EtOH) 2) 1.67 g/kg EtOH 3) .9% saline or 4) .9% saline and an agonistic encounter with an unfamiliar conspecific male in a neutral arena 10 min. following injection. Mice subjected to an aggressive interaction or treated with 1.67 g/kg EtOH exhibited elevated c-fos expression in the accessory olfactory areas, corticomedial amygdala, medial preoptic area and entorhinal cortex relative to mice treated with 0.33 g/kg EtOH or saline. C-fos was also expressed in the piriform cortex of mice that fought and in the hippocampus of mice given the higher dose of EtOH. These results demonstrate c-fos activation in olfactory and limbic structures that have been implicated in the mediation of aggressive and sexual behaviors in other mammals. They also suggest that EtOH may affect mouse social behavior via activation of gene expression in the olfactory-limbic pathway.

TIME-DEPENDENT, QUANTIFIABLE WITHDRAWAL FROM ETHANOL IN THE RAT: EFFECT OF METHOD OF DEPENDENCE INDUCTION. D. Macey, G. Schulteis, S.C. Heinrichs, and G. F. Koob*. Dept. of Neuropharmacology, The Scripps Research Institute, La Jolla, CA 92037.

The importance of temporal factors in the establishment and maintenance of ethanol withdrawal measures in the rat was quantified using a tremor meter, observational rating scale, and acoustic startle test. Ethanol dependence was invoked in naive male Wistar rats either by ethanol liquid diet administration (n=24) or vapor chamber exposure (n=16) for 14-17 days prior to withdrawal in both cases. The rats maintained in the ethanol vapor chambers were divided into 3 groups with target BALs of 120-140, 170-190, and 220-240mg% to determine the effects of BAL concentration on withdrawal measures. Both test groups had appropriate controls (n=8). Repeated-measures trials were conducted at 2, 4, 8, 12, 24, 48, and 72hr postwithdrawal. The tremorogenic activity induced by ethanol withdrawal was quantified using a Plexiglas chamber possessing a piezo-electric film installed in the cage floor. Distortions of the cage floor produced a piezoelectric response which was amplified, filtered, and stored in an IBM computer. Following each tremor trial, subjects were rated for withdrawal signs: ventromedial distal flexion reflex, irritability, tail stiffness, and abnormal body posture/played gait. For acoustic startle, movements were detected by a piezoelectric accelerometer beneath the Plexiglas chamber, digitized and recorded on an IBM computer. Mixed trials with sound pulses of 105 and 120dB were included in each test session. Data analysis revealed that most withdrawal signs reached peak intensities between 8 and 12hr postwithdrawal. Most quantified signs of withdrawal were greater in the vapor chamber subjects than in the liquid diet subjects, probably reflecting higher chronic BAL's in the former case. Results suggest that both liquid diet administration and vapor chamber exposure produce quantifiable, time-dependent measures of ethanol withdrawal.

EXTRACELLULAR CONCENTRATIONS OF ETHANOL IN THE BRAIN FOLLOWING IP, IG OR CONSUMED ETHANOL IN RATS. K. Kianmaa*, M. Nurmi* and J.D. Sinclair. Biomedical Research Center, Alko Ltd., and *Department of Zoology, University of Helsinki, Helsinki, Finland.

The distribution of ethanol in the brain was examined by studying the extracellular levels of ethanol in the nucleus accumbens of the alcohol preferring AA (Alko Alcohol) and alcohol avoiding ANA (Alko Nonalcohol) rats with *in vivo* microdialysis. Samples for the assay of ethanol with head-space GC were collected from freely moving animals at 1 min intervals after administration of ethanol (1 g/kg) IP or IG, as well as during voluntary drinking of 10% (v/v) ethanol solution promoted by limiting the access to ethanol solution to 1 h daily. Tail blood was drawn every 5 min. The results show that there is a steep rise in brain ethanol concentration within minutes after IP injection, but there is no obvious difference between the two rat lines in the distribution of ethanol into the brain. Tail blood ethanol curves from the same animals peaked much later. With IG administration, however, the time courses were similar for brain and tail-blood ethanol. In the drinking study ethanol was found in the brain only a few minutes after the rats started to consume ethanol. The results so far give no indication that the differential ethanol consumption by AA and ANA rats could be explained in terms of differences in the distribution of ethanol to the nucleus accumbens. Nevertheless, the observed level of brain ethanol after voluntary drinking is sufficiently large and rises rapidly enough to provide positive reinforcement. Furthermore, the study shows that microdialysis coupled with head space GC gives detailed information of the brain ethanol curve in individual, freely moving animals after relatively small doses of ethanol.

659.11

LATENCY OF CONDITIONING TRIAL AND EXTENT OF CHRONIC CONDITIONING EFFECT ETOH-INDUCED CONDITIONED PLACE PREFERENCE AND AVERSION. G.G. Blakley*, M.J. Lewis. Neurobehavioral Laboratory, Dept. of Psych., Temple U., Phila. PA 19122

The present experiment was designed to examine the effect of latency of conditioning trials and the extent of chronic conditioning upon a ETOH-induced place preference and aversion. Previous place preference studies suggest that ethanol may gain its reinforcing properties only after prior exposure to the drug. Moreover, research from our lab has suggests that the latency of the conditioning trial to the time of administration is an important factor in ETOH's rewarding properties. Male albino rats were subjected to pairings of a distinctive floor stimulus (CS+) and ip injections of varying doses of ethanol (0.25g/kg-1.0g/kg). Subjects received one trial per day for four consecutive days and were given a free choice test on the fifth day. Each subject received three consecutive recurrences of this venue. Conditioning sessions lasted 15 minutes and began at latencies of 0, 15 or 30 minutes post-injection. Significant interactions between dose, extent of conditioning, and latency with preference and aversion were observed. These data suggest that ETOH has both rewarding and aversive properties depending upon these experimental variables.

REGIONAL CEREBRAL METABOLISM AFTER ETHANOL AS A FUNCTION OF PREFERENCE FOR THE DRUG. J.T. Metz*, H. de Wit, J. Singh, D. Dooley, J. Roemer, M. Jiang, T. Brown, J.-S. Chou, C.-T. Chen, M. Cooper. The University of Chicago, Chicago, IL 60637.

We have continued our studies of the relationship between regional cerebral metabolism of glucose (rCMglu) and subjective responses to drugs of abuse. In order to focus on individual differences in behavioral effects, we have applied PET volumetric and parametric comparison procedures which enable us better to characterize metabolic responses to the drug in different groups of subjects.

Subjects were 22 normal, healthy males aged 21 to 31. Subjects took part in two PET sessions in which they received 0.5 g/kg ethanol and placebo in a double-blind counter-balanced procedure. PET data were collected on a PETT VI using FDG as the metabolic tracer. In each session subjects also completed mood and drug liking questionnaires. On the basis of their self-reported preference for ethanol over placebo, subjects were categorized into two equal groups: high liking (HL, mean difference of liking for ethanol compared to placebo + 44.9, S.D. = 14.8) and low liking (LL, mean difference + 5.4, S.D. = 12.9). PET data sets for each subject were correlated with anatomical MRIs, transformed to standard volumes based on the Talairach atlas, interpolated, and averaged across subjects for HL and LL. For each group the ethanol condition was compared to the placebo condition by repeated measures voxel to voxel t-tests.

Both groups of subjects showed reductions in rCMglu in cerebellar regions. For the HL group these reductions were on the left side only, for the LL group, they were bilateral. Only the LL group, however, showed reduced rCMglu in occipital cortex and only the HL group showed increased rCMglu in left temporal areas. Compared to the LL group, the HL group was significantly lower on behavioral measures of anxiety and depression and significantly higher on friendliness and elation. Thus, we have demonstrated that subjective effects of ethanol are related to differences in rCMglu.

CHRONIC INTRACEREBROVENTRICULAR ETHANOL ADMINISTRATION IMPAIRS NONSPATIAL MEMORY IN RATS. C.L. Weaver, L.M. Copley, R.Z. Couturier, and G.L. Dunbar*. Dept. of Psychology, Central Michigan University, Mt. Pleasant, MI 48858.

Chronic IP injections of ethanol (EtOH) reduces behavioral flexibility in spatial learning tasks (Devenport et al., *Behav. Neurosci.*, 103:1259-1266). We tested the effects of chronic ICV EtOH administration on spatial and nonspatial, working and reference memories on an eight-arm radial water maze (RAWM) task. Male rats were given chronic (28 days) ICV EtOH (20% in saline) or saline via mini-osmotic pumps. Both EtOH- or saline-treated rats could solve the spatial version of the task at unoperated control levels. Rats receiving the EtOH made significantly more reference memory (entries into channels that never had escape platforms) and working memory 'incorrect' (re-entries into channels previously visited within a trial that never had escape platforms) errors than both saline and unoperated controls during nonspatial testing. Our results indicate that chronic ICV EtOH can disrupt some aspects of both reference and working nonspatial memory. Supported by NSF Grant DUE 9352355 and Research Excellence Funds.

ACQUISITION OF A SPATIAL NAVIGATION WORKING MEMORY TASK IN THE MORRIS WATER MAZE: EVALUATION OF SPATIAL WORKING MEMORY IN ADULT RATS EXPOSED NEONATALLY TO ALCOHOL. 1C.R. Goodlett*, 1Stephanie D. Peterson, and 2Kate O'Brien. 1Dept. of Psychology, IUPUI, Indianapolis, IN 46202 & 2Kalamazoo College.

Binge-like exposure to alcohol during the early postnatal brain growth spurt in rats reduces hippocampal CA1 pyramidal neuron density. Behaviorally, severe deficits in Morris water maze place learning are apparent in neonatally exposed rats tested as juveniles, but by adulthood place learning deficits are greatly attenuated. Because hippocampal damage is also linked to impaired spatial working memory processes, a spatial navigation task placing heavy demands on working memory was developed to assess whether neonatal alcohol induced long-lasting spatial working memory deficits. Sprague-Dawley rat pups were randomly assigned within litter to three treatment groups: an ethanol group was exposed to 4.5 g/kg/day of alcohol on postnatal days (PD) 4 through 9 via artificial rearing methods; a calorically matched gastrostomy control group was artificially reared from PD 4 through 9; a suckle control group reared normally throughout the period by lactating dams. This alcohol treatment (10.2% v/v in two consecutive feedings each day) produces mean peak blood alcohol concentrations of approximately 300 mg/dl. At 60 days of age, the rats were assigned either to the working memory trained group (WM) or to a random placement group. The WM groups were given 12 trials each day to find the hidden platform, with the trials divided into four sets of trial triplets in which the platform remained in the same location for each trial (separated by a 10 sec ITI) of the triplet. After completion of a triplet, the platform was moved to a new, random location, and sets were separated by 5-10 min; training continued for 10 days. Thus, the first trial of a set constituted the "information" trial, and the subsequent two trials constituted the "memory" trials. The random groups were given similar training procedures except the platform location was randomly determined for every trial. Neonatal alcohol exposure had no significant effect on performance of female rats; alcohol-treated male rats also learned the task but were less efficient at finding the platform on the "memory" trials at the terminal stages of training. Supported by Grant #AA09596.

MITIGATING EFFECTS OF COMBINED PRENATAL AND POSTNATAL EXPOSURE TO ETHANOL ON HIPPOCAMPALLY-MEDIATED MEMORY-BASED LEARNING IN THE INFANT RAT.

J.L. Diaz-Granados*, M.S. Chuang, & A. Amsel. Department of Psychology & Institute for Neuroscience, University of Texas, Austin, TX, 78712.

We have previously shown that combined prenatal and postnatal exposure to ethanol (EtOH), compared with either pre- or postnatal exposure, has mitigating effects on deficits found in the partial reinforcement extinction effect, a hippocampally-mediated indicator of learned persistence (Diaz-Granados et al., *Behav. Neurosci.*, 107:1059, 1993). Our laboratory has also reported that infant rats, postnatally exposed to EtOH, show a significant deficit in patterned alternation (PA), a hippocampally-mediated memory-based discrimination task (Greene et al., *Behav. Neurosci.*, 106:51, 1992). In the present experiment, we examined the effect of prenatal, postnatal, and combined exposure to EtOH on PA at a 60-s intertrial interval. Pregnant dams were intubated once per day from G12 to G18 with either a 35% EtOH solution (5g/kg) or an isocaloric dextrin solution. In the postnatal condition, pups were artificially reared from postnatal days 4 to 9. Pups in the EtOH condition received 4 consecutive feedings of an EtOH adulterated diet while controls received an isocaloric maltose-adulterated diet. All pups received unadulterated diet for the remaining 20 daily feedings. On days 17-18, pups were tested on PA. The results were that prenatal exposure to EtOH had no effect on memory-based learning, whereas postnatally exposed pups show a deficit. Subjects exposed to ethanol prenatally and postnatally showed better PA learning than subjects in the postnatal EtOH-only condition. This result, along with our previous work, suggests that prenatal exposure to EtOH has an alleviative effect on deficits in hippocampally-mediated learning resulting from postnatal exposure to EtOH. Supported by NIAAA grant AA07052.

INTERACTIONS OF ETHANOL WITH NEURONAL NICOTINIC ACETYLCHOLINE RECEPTORS EXPRESSED IN *XENOPUS* OOCYTES. C.M. de Fiebre* and E.M. Mayer. Dept. of Pharmacology & Therapeutics, Univ. of Florida Col. of Med., Gainesville, FL 32610-0267.

While the correlation between smoking and drinking is very large, little is known about the biological factors which regulate the co-use of nicotine (NIC) and ethanol (EtOH). Previous evidence has suggested that sensitivity to these agents is genetically correlated because EtOH may modulate nicotinic acetylcholine receptor (nAChR) function by stabilizing nAChRs in the nonfunctional, desensitized form. Here we report that ethanol affects neuronal nAChRs in a subtype-selective fashion. Neuronal nAChRs subtypes ($\alpha 2\beta 2$, $\alpha 3\beta 2$ and $\alpha 4\beta 2$) were expressed in *Xenopus* oocytes from cDNA and studied under two-electrode voltage clamp for responsiveness to bath-applied ACh, NIC and EtOH. While EtOH displayed no direct agonist or antagonist effects, it modulated the function of each of these receptor subtypes. At all receptor subtypes, there was a trend for co-application of EtOH to enhance responses to NIC. In oocytes expressing $\alpha 4\beta 2$ and $\alpha 2\beta 2$ receptors, application of NIC 2.5 min after the start of a 5 min application of EtOH attenuated responses to ACh applied 5 min following NIC (2.5 min after the end of the EtOH application). This effect was not seen at $\alpha 3\beta 2$ receptors. Dose-response and time-course analyses are currently being conducted at these as well as at other nAChR subtypes. These results suggest that EtOH may display complex pharmacological properties at specific neuronal nAChR subtypes. Supported in part by training grant AA-07561. The cDNA clones were kindly provided by Dr. Jim Boulter of the Salk Institute.

ACTIONS OF ETHANOL ON SYNAPTIC TRANSMISSION AND MEMBRANE PROPERTIES OF LAYER V CORTICAL NEURONS. W. Liu*, A.E.K. Kosobud, T.N. Felder, R.C.-S. Lin, J.E. Springer and F.M. Sessler. Depts. of Physiology and Biophysics and Neurology, Hahnemann University, Philadelphia, PA 19102.

Ethanol (EtOH) has an extremely complex profile of actions on the CNS, and attention has increasingly focused on factors that create selective vulnerability of specific cell types. The hypothesis tested here was that EtOH effects in the somatosensory cortex may be related to specific neural attributes of membrane function, including electrophysiological signature and morphology. Intracellular recording techniques combined with dye injections were used *in vitro* to investigate the actions of EtOH on synaptic transmission within layer V of the somatosensory cortex. Bath application of EtOH (1-100mM) revealed a large spectrum of effects on membrane parameters and postsynaptic potentials of cortical neurons. In some regular spiking neurons with "bursting" type characteristics, EtOH (10mM) did not change input resistance and rheobase but produced a blockade of accommodation. In this cell type, excitatory postsynaptic potentials (EPSPs) evoked by electrical stimulation of white matter or adjacent layers were monophasic and very sensitive to the depressant action of EtOH. On the other hand, in a population of "doublet" cells, the rheobase and input resistance were altered by EtOH (10mM). In response to stimulation of the white matter, these neurons displayed a characteristic biphasic EPSP, with early and late components. The late component was more strongly affected by EtOH. Neurons of the "intrinsic bursting" type also had biphasic EPSPs whose late components were preferentially depressed by EtOH. Finally, in certain "regular spiking" neurons, EtOH altered input resistance, blocked accommodation, decreased duration and amplitude of the slow afterhyperpolarization potential and had robust inhibitory effects on the late component of the EPSP. These results confirm that EtOH can exert variable effects on different neural elements of layer V neocortical circuits. The influence of EtOH on specific, vulnerable neuronal subtypes within the cerebrocortical circuitry may underlie its effect on specific tasks. (Supported by NIDA DA 08405 to FMS and DA 08349 to AEK).

660.2

ETHANOL MODULATION OF RECOMBINANT ACETYLCHOLINE RECEPTOR CHANNELS EXPRESSED IN HEK-293 CELLS. A. Ravindran*, K. Masood and F. F. Weight. Laboratory of Molecular & Cellular Neurobiology, NIAAA, NIH, Bethesda, MD 20892.

The nicotinic acetylcholine receptor (AChR) is a ligand-gated ion channel located in the postsynaptic membranes of nerve, muscle and electric organ. The AChR from electric organ and muscle consist of four distinct subunits assembled into a $\alpha 2\beta\gamma$ (or ϵ) δ pentamer. The modulation of acetylcholine (ACh) induced current by ethanol was studied in HEK-293 cells transfected with mouse $\alpha\beta\epsilon\delta$ AChR subunit cDNAs. 40-48 hr after transfection whole-cell and out-side out patch clamp techniques were used to record ACh induced inward current from cells expressing AChR. ACh alone and in combination with ethanol (EtOH) were applied to the recorded cell and out-side out patch by a theta-tube rapid perfusion system that enabled complete exchange of solutions in 1-5 ms. ACh activated rapidly desensitizing inward currents with an EC_{50} of 20 μ M. Co-application of EtOH (10-150 mM) potentiated, in a concentration-dependent manner, currents activated by 5 and 10 μ M ACh. The potentiation was between 20-50% of the control response. With higher concentrations of ACh > 25 μ M, EtOH seem to induce significant reduction in peak current amplitude. Further studies are being undertaken to elucidate the mechanism of ethanol modulation of AChR channels.

ALCOHOL ABUSE AND EXPRESSION OF GABA_A NEUROTRANSMITTER RECEPTOR GENES. G. J. Thomas and P. R. Dodd*. John Wilson Memorial Clinical Research Laboratory, Royal Brisbane Hospital Foundation, Bancroft Centre, Herston, Q4029, Australia.

Neuropathological studies in chronic alcoholism and its related diseases (liver cirrhosis) suggest specific brain regions (eg. the superior frontal cortex) are selectively prone to damage(1). However, the mechanism of this damage and the development of dependence and withdrawal are not well understood. Evidence suggests the GABA-mediated neurotransmitter system is involved in the chronic effects of alcohol. Our studies have shown GABA_A receptor properties (affinity and density) are altered in the SFC of human chronic alcoholics *cf* non-alcoholics(2). Also, the receptor binding pattern in alcoholics with cirrhosis is differ *cf* non-cirrhotic alcoholics(2). The GABA_A receptor is a heterooligomeric complex composed of 4 or 5 subunits with atleast 16 candidate genes able to code for the subunits; $\alpha 1-6$, $\beta 1-4$, $\gamma 1-3$, δ and $\rho 1-2$. Recombinant studies have shown that the pharmacological properties of the receptor is determined by its subunit makeup(3). Localized brain damage and alterations in GABA_A receptor properties in alcoholism are possibly due to variation in the receptor's subunit composition. GABA_A mRNA subunit expression was assessed by S1 nuclease protection analysis in post mortem brain tissue (superior frontal and motor cortices) of non-alcoholics (ethanol consumption < 20 g/day), alcoholics (> 80 g/day), alcoholics with cirrhosis and non-alcoholic cirrhotics with human specific cDNA oligonucleotide probes. Regional-specific subunit expression was found to be altered in the alcoholic subgroups *cf* non-alcoholics.

EFFECTS OF CHRONIC ETHANOL EXPOSURE ON GABA_A RECEPTOR $\beta 2$ AND $\gamma 2$ SUBUNIT mRNA LEVELS IN RAT BRAIN. L.L. Devaud¹, D.R. Grayson² and A.L. Morrow¹, ¹UNC Sch. of Med., Chapel Hill, NC 27599 and ²Allegheny-Singer Res. Inst., Pittsburgh, PA 15212.

Chronic ethanol ingestion results in alterations in GABA_A receptor-mediated functions. These effects are associated with decreased GABA_A receptor $\alpha 1$, $\alpha 2$, but not $\alpha 3$, subunit mRNA levels in cortex, while $\alpha 1$ mRNAs are reduced and $\alpha 6$ mRNAs are increased in cerebellum. However, maximal [³H]zolpidem binding, which labels $\alpha 1$ subunit-containing type I BZD GABA_A receptors, is increased in cortex and cerebellum following chronic ethanol exposure. Since type I BZD receptors appear to be comprised of $\alpha 1$, $\beta 2$ and $\gamma 2$ subunits in rat brain, we investigated whether chronic ethanol exposure alters these subunit mRNA levels. Poly A⁺ RNA was prepared from pooled tissue (8 rats/grp) in 3 separate experiments. Northern blot analysis showed no alterations in $\beta 2$ or $\gamma 2$ subunit mRNA levels in cortex or cerebella of ethanol-dependent vs. pair fed control rats. Competitive, quantitative PCR analysis was conducted using subunit specific primers and internal standards to measure $\gamma 2S$ and $\gamma 2L$ mRNA levels. In cortex, $\gamma 2S$ levels were decreased by $23 \pm 4\%$ and $\gamma 2L$ levels increased $14 \pm 4\%$ ($n=3$ exp). These results suggest that chronic ethanol exposure may elicit opposite effects on $\gamma 2$ splice variant mRNA levels. Further studies with total RNA on individual animals are underway to extend the validity of these results. These data are consistent with our hypothesis that chronic ethanol exposure differentially alters GABA_A receptor subunit mRNA levels which results in alterations in the subunit composition of GABA_A receptors. GABAERGIC NEURONS IN THE EXTENDED AMYGDALA MODULATE ALCOHOL REINFORCEMENT. P. Hyvönen* and G.F. Koob. Dept. of Neuropharmacology, The Scripps Research Institute, La Jolla, CA 92037.

The GABA/benzodiazepine receptor complex has been implicated in various behavioral actions of alcohol, including the reinforcing effects, but the specific brain sites where GABA mediates alcohol reward remain to be characterized. The principal components of the extended amygdala (Heimer and Alheid 1991) contain large numbers of GABAergic neurons and may provide potential sites for the modulation of alcohol reinforcement by GABA. The present experiments assessed the role of two of these components, the central nucleus of the amygdala (CeA) and the shell of the nucleus accumbens (AccSh), in the regulation of alcohol-reinforced responding. Wistar rats were trained to orally self-administer alcohol (10% w/v) during daily 30-min sessions using a saccharin fading technique. Once stable alcohol responding was established, the animals were implanted stereotactically with bilateral guide cannulae either above the CeA or the AccSh. After recovery, the rats were tested after intracerebral injections of a competitive GABA_A antagonist SR 95531 (0-16 ng). SR 95531 injections into both sites dose-dependently decreased alcohol-reinforced responding without affecting responses for water. Injections into the CeA significantly reduced responding at doses of 2 and 4 ng, whereas larger doses were required in the AccSh. These findings provide evidence that GABAergic neurons in the extended amygdala, particularly in the CeA, may be involved in the mediation of alcohol reinforcement.

INTRA-STRIATAL ADMINISTRATION OF FLUMAZENIL (FL) TO DIAZEPAM (DZ) DEPENDENT RATS. E.P. Wala*, J.W. Sloan, X. Jing, Dept. of Anesthesiology, College of Medicine, Univ. of Ky., Lexington, KY 40536.

Precipitated abstinence (PA) was characterized in DZ dependent rats following microinjections (MI) of FL into the corpus striatum. Rats ($n=6$) were implanted with a guide cannula, which also served as a recording electrode, in the parietal cortex (AP=8.08, RL=3, V=8). EEGs were recorded from the hippocampus (AP=3.7, LL=2, V=6 and AP=4.7, LL=2, V=6.2), cerebellum (AP=-0.16, LL=3, V=8.4 or AP=-2.6, LL=2, V=5) and frontal cortex (AP=10.7, LL=1, V=10). Stable plasma levels of DZ and its metabolites were maintained by weekly subcutaneous implantations of silastic capsules containing DZ (3×180 mg DZ/cap/week). After the third implantation rats were MI at weekly intervals with 1 μ l of FL (25 μ g in DMSO) or DMSO vehicle into caudate putamen (C-P) (V=6), globus pallidus (G-P) (V=3.8) or either FL (40 mg/kg) or DMSO vehicle was administered systemically as an IV bolus. EEG was recorded and rats were simultaneously observed for signs of PA and behavioral states for 10 min before and 40 min after treatments. EEGs indicated convulsive activity. PA scores (PAS) were significantly different from DMSO when FL was MI into G-P (PAS=5 min) and C-P (PAS avg). Behavioral scores after FL were not different from DMSO. Head and body tremors and clonic convulsions (1 rat) were observed following MI of FL to G-P and C-P. FL tends to evoke more turning, writhing, digging, wet dog shakes and ataxia in G-P and more twitches and jerks, stretching, blinking, chewing and poker tail in C-P. IV injections of FL induced seizures, tachypnea and a variety of signs and symptoms of PA. The data indicate that C-P and G-P make different contributions to the abstinence syndrome which may be related to localization of BZ receptors in corpus striatum. Supported by NIDA Grant DA02195.

AN *IN SITU* HYBRIDIZATION STUDY ON $\alpha 6$ -SUBUNIT mRNA OF GABA_A RECEPTORS OF PENTOBARBITAL (PB) TOLERANT / DEPENDENT RAT BRAINS. T. Ito, T. Suzuki, D.K. Lim and I. K. Ho*, Department of Pharmacol. and Toxicol., Univ. of MS Med. Ctr., Jackson, MS 39216.

Our previous *in situ* hybridization study revealed that contents of $\alpha 1$, $\beta 3$ - or $\gamma 2$ - receptor subunit mRNA were altered in discrete regions of the brain of PB tolerant and dependent rats. As $\alpha 6$ -subunit mRNA is localized in granular layer of the cerebellum, *in situ* hybridization study using $\alpha 6$ -subunit mRNA as a target was performed to elicit cerebellum specific alterations in GABA_A receptor mRNA level. In the PB-tolerant group, rats (male SD rats, body weight 220-250g) were made tolerant to PB by continuous i.c.v. infusion of PB (300 mg/10ml/hour) for 6 days using osmotic minipump (Alzet model 2004). Control group received vehicle infusion for the same duration. In the PB-dependent group, the PB infusion was discontinued on the seventh day and assessed dependence 24 hours after discontinuance. Acute study was also done (dose: 60 mg of PB/kg). Frozen brain sections mounted on gelatin coated slide was used as samples. The content of $\alpha 6$ -subunit mRNA was increased in the PB tolerant rats (149 ± 7 [$p < 0.05$], % of control), whereas no change was observed in PB dependent (120 ± 12) and acutely treated animals (105 ± 1). These results suggest tolerance to PB induced alteration in $\alpha 6$ -subunit mRNA content and this finding might coincide with changes in characteristics of GABA_A receptor bindings in the cerebellum. CHANGES IN GABAERGIC SYNAPSES OF DENTATE GRANULE CELLS DURING CHRONIC ETHANOL TREATMENT. E. Fiková*, H. Eason, K. Buehlmann, P. Schaner. Dept. of Psychology, Univ. of Colorado, Boulder, CO 80309.

Ethanol-sensitive LSIBG and ethanol-insensitive SSIBG mice were exposed to ethanol (23.5% ethanol-derived calories) for 4 months. Half of the animals were sacrificed at this time and the other half was withdrawn from the ethanol diet for 1 month. GABA immunoelectron microscopy was applied to study the impact of the treatments on the density and length of synaptic contacts of the dentate granule cell bodies. The majority of synapses on dentate granule cell bodies is GABAergic (87%). Out of these, 57% are symmetrical synapses with polymorph vesicles and 30% are asymmetrical synapses with round vesicles. These proportions are similar in the LS and SS line. The synaptic density was not affected by the ethanol treatment. However the synaptic length of symmetrical synapses in the LS line was reduced during withdrawal by 20%. No changes either in density or length were seen in the synaptic contacts of the SS mice. This result adds to the numerous other reports in the literature showing differences between the LS and SS line in response of their respective GABAergic systems to ethanol. The observed decreased length of GABAergic synapses on the dentate granule cells complements the loss of GABAergic synapses on dentrites. Both changes indicate reduced inhibition during withdrawal. Since a loss of excitatory synapses in the dentate molecular layer preceded the changes in the GABAergic system, the reduced inhibition during withdrawal could indicate adaptation to the ethanol-induced decreased excitability of the region. Such a reduction of GABAergic parameters is in agreement with the impairment of inhibitory synaptic transmission seen in the hippocampus following chronic ethanol exposure (Durand and Carlen, Science, 224:1359, 1984). Supported by grants AA06196 and AA00130.

ETHANOL INCREASES TAURINE BUT NOT GLUTAMATE NOR GABA IN THE NUCLEUS ACCUMBENS USING MICRODIALYSIS. A. Dahchour, (1) E. Quattermont, (1) Ph. Durbin, (2) and Ph. De Witte* (1). (1) Lab. Psychobiology, Univ. of Louvain - 1 Place Croix du Sud, 1348 Louvain-la-Neuve, Belgium. (2) LIPHA - 115 Av. Lacassagne, 69003 France.

The extracellular concentration of glutamate, taurine and Gaba was simultaneously estimated into the nucleus accumbens following an IP injection of 3g/kg ethanol (15% v/v) using the microdialysis technique *in vivo*. The level of taurine significantly increased for 40 min. after the acute ethanol injection while the other amino acids remained unchanged. Owing to its action on alcohol intake in rats and humans, Acamprosate was chosen to analyse the alterations affecting amino acids within the nucleus accumbens. The IP injection of 1g/kg Acamprosate produced a dramatic increase of taurine reaching 210% of the initial baseline after 300 min, no change was observed in the level of the other amino acids estimated. In rats pre-treated with 400 mg/kg PO Acamprosate for 3 weeks, the acute injection of 3g/kg ethanol induced a higher increase in the extracellular taurine when compared to the effect of ethanol alone.

Our data thus supported the hypothesis of a cross-tolerance between Acamprosate and ethanol on the extracellular taurine as estimated by the microdialysis of the nucleus accumbens.

CHRONIC SHORT-TERM ETHANOL TREATMENT IMPAIRS LTP AND GABAERGIC INHIBITION IN HIPPOCAMPUS. N. Hori¹, K. Yamamoto¹, T. Kosaka¹ and D.O. Carpenter². ¹Faculty of Dentistry & Medicine, Kyushu Univ., Fukuoka 812, Japan, ²Wadsworth Labs, NYS Dept. Health, Albany, NY 12201.

Chronic alcoholism results in functional and morphological changes in the mammalian brain. Many animal models of alcoholism have used rats which were given long-term (greater than 7 months) ethanol treatment. However, the time dependence of physiological and morphological changes occurring at the onset of chronic alcohol ingestion dependency have been studied less. We have focused on physiological and morphological changes in rat brains exposed to alcohol for 2 to 4 months. Rats (200 g starting weight) were given alcohol in drinking water (10% ethanol and 5% sucrose) for 2 to 4 months. (Each rat consumed 25 to 30 mL/day and grew to 300 g during this period). Standard methods of making slices and recording field potentials and intracellular activity were used. A monopolar electrode was placed on both the mossy fibers and the Schaffer collaterals for synaptic activation of CA3 and CA1, respectively. Lucifer yellow was injected into neurons during intracellular recordings to study morphology.

The field potentials in CA3 from animals treated with alcohol for 90 days were of greater amplitudes than controls, and on intracellular recording the discharge rate was not as sensitive to bicuculline (10 μ M). Ionophoretic application of GABA resulted in no response in CA3 and very little response in CA1 as compared to control rats. LTP induced in CA1 of chronic treated rats was significantly less than LTP in control slices. (Ethanol treated rats $114.42 \pm 8.2\%$ n=4; Normal rats $142.41 \pm 10.7\%$ n=4). These observations were in contrast to the effects of acute alcohol perfusion to the slice, in that 5 mM ethanol enhanced LTP in control rats ($163.9 \pm 13.0\%$) while 25% ethanol depressed LTP. Lucifer yellow injections show that some fine processes of the dendrites disappeared when compared to control rats.

THE EFFECT OF PRENATAL ALCOHOL EXPOSURE ON POSTNATAL NMDA1 SUBUNIT EXPRESSION *in vivo* AND *in vitro*. M. Maguire, V. Rema, A. Banerjee, V. Anita, L.M. Smith* & E.E. Ebner. Inst. for Dev. Neuroscience, Kennedy Center, Vanderbilt University, Nashville, TN 37203

NMDA receptors are important during development and later for adjusting synaptic efficacy. Following the ingestion of 6.5% ethyl alcohol in the diet of pregnant rats throughout gestation (Exp), we analyzed the density and location of NMDA receptors in Exp and Con (no alcohol) cultured cortical neurons and in the brains of rat pups after 1 day to 1 month of alcohol-free conditions. Antibodies to NMDA1 subunit were used to assay the effect of alcohol on development of this glutamate receptor subtype subunit. Both Exp cultured neurons and brain sections showed reduction in the NMDA1 immunoreactivity in cortex at postnatal ages up to 3 weeks compared to controls, with a remarkable variation in the intensity of staining from cell to cell. The variability diminishes in cultures after roughly 3 weeks. P-14 is the time of greatest alcohol effect. Exp cultures show intense cell clustering, greater cell survival and some very large neurons. By P-30 the clustered cells show high R1 levels and very short processes. Con cultures at P-30 contain fewer cells with much greater neuropil development. A striking flip-flop effect of alcohol on thalamic cells *in vivo* is present at P-14 when expression of NMDA1 by sensory relay cells is reduced to near background levels and over-expression by cells in the midline/ intralaminar nuclei is intense. These observations suggest that prenatal alcohol exposure produces subtle effects on postnatal NMDA1 expression that change as a function of age during a very dynamic phase of cortical development. The effect of these alterations in NMDA receptor expression is now being assayed using functional/behavioral techniques. (supported by HD-1052-14 and NS-13031)

SENSITIVITY OF MUTANT NMDA RECEPTORS TO INHIBITION BY ETHANOL. Tooraj Mirshahi and John J. Woodward*. Department of Pharmacology and Toxicology, Medical College of Virginia, Virginia Commonwealth University, Richmond, VA 23298.

Ethanol has been shown to inhibit the NMDA subtype of glutamate receptors. Recent cloning of different subunits of the NMDA receptor has made it possible to study their function in expression systems. Three mutant NMDA1 subunits showing decreased sensitivity to Mg^{++} blockade (N616R and N616Q) or decreased Ca^{++} permeability (F609L) were tested for their sensitivity to ethanol inhibition. The mutant receptors were expressed along with the NMDA2A subunit in *Xenopus* oocytes. Membrane currents were measured using conventional two-electrode voltage-clamp methods. Cells were clamped at -80mV and currents were recorded in presence of 100 μ M NMDA and 10 μ M glycine with varying concentrations of ethanol. Ethanol (25-100 mM) inhibited the NMDA-induced current in all receptor combinations tested. The wild-type receptor (NR1/NR2A) was inhibited by 22, 35 and 47% at 25, 50 and 100 mM ethanol respectively. The ethanol sensitivity of the mutant receptor combinations (N616Q, N616R and F609L) was not significantly different from that of the wild-type receptor. These results suggest that mutations which reduce the Mg^{++} sensitivity of the NMDA receptor do not alter the inhibitory effects of ethanol. Supported by NIAAA AA08089 and NIDA07027.

DECREASE OF PAIRED-PULSE INHIBITION IN CA1 AREA OF HIPPOCAMPAL SLICES OF CHRONIC INTERMITTENT ETHANOL TREATED RATS. M.H. Kang¹, I. Spigelman², D.W. Sapp¹, and R.W. Olsen¹. ¹Dept. of Pharmacology, UCLA School of Medicine, ²School of Dentistry, Los Angeles, CA 90024.

Chronic intermittent ethanol (CIE)-treated rats showed severe withdrawal signs including a persistent kindling-like decrease in pentylenetetrazol (PTZ) seizure threshold (Kokka et al., Alcohol Clin. Exp. Res., 525-531, 1993). To understand the cellular mechanism underlying this plasticity, the involvement of GABA_A receptors, the target of ethanol and PTZ pharmacological effects, was studied using biochemical and electrophysiological functional assays. We observed a significant decrease in muscimol (100 μ M)-induced $^{36}Cl^{-}$ efflux in hippocampal slices from CIE rats. Paired-pulse inhibition, which is considered to be predominantly due to GABA_A-mediated recurrent inhibition, was significantly ($p < .005$) decreased in the CA1 area of hippocampal slices from CIE rats measured 2 days post-ethanol. This study suggests that a hypo-function of GABA_A receptors in the hippocampus may play a key role in kindling-like decrease in the seizure threshold in the CIE rat model of alcohol dependence. Supported by AA07680.

FACILITATORY EFFECTS OF ALCOHOL UPON DEFENSIVE RAGE BEHAVIOR IN THE CAT ARE BLOCKED BY AN NMDA RECEPTOR ANTAGONIST. K. Schubert* J. Perez, M.B. Shaikh, L. Pohorecky, D. Benjamin, and A. Siegel. Laboratory of Limbic System and Behavior, Department of Neurosciences, New Jersey Medical School, Graduate School of Biomedical Sciences, UMDNJ, Newark, New Jersey 07103 and Center for Alcohol Studies, Rutgers University, Piscataway, New Jersey 08855.

This study was designed to determine the effects of alcohol upon: (1) defensive rage behavior (DR) elicited from the medial hypothalamus (MH), and (2) MH facilitation of DR elicited from the dorsal midbrain periaqueductal gray (PAG). *Experiment I:* peripheral administration of alcohol (0.02, 0.5 and 1.0 g/kg, I.P.) reduced latency responses in a dose and time dependent manner, the maximal effect occurring at 60 min, postinjection, at the highest dose level. *Experiment II:* peripheral administration of alcohol at the same dose levels markedly enhanced MH-facilitation of DR elicited from the PAG in a dose and time dependent manner. *Experiment III:* microinjections of the NMDA receptor antagonist, AP-7, into PAG-DR sites blocked MH facilitation of DR elicited from the PAG. *Experiment IV:* microinjections of AP-7 into PAG-DR sites blocked the enhancement of alcohol induced MH facilitation of DR elicited from the PAG. These results indicate that: (1) alcohol administration facilitates the occurrence of DR; and (2) the excitatory effects of alcohol upon rage may be manifest through the MH-PAG pathway which involves NMDA receptors. [Supported by NIH Grant NS 07941-24].

EFFECTS OF AN ALCOHOL INJECTION ON AMINO ACIDS AND RELATED COMPOUNDS IN RAT PLASMA, AORTA, HEART, BRONCHI AND PANCREAS. R. Abdel-Nabi, L. Milakofsky, J.M. Hofford, W.H. Vogel, and T.A. Hare*. Thomas Jefferson Univ., Dept. of Pharmacology, Phila., PA 19107 and Penn State Univ., Dept. of Chemistry, Berks Campus, Reading, PA 19610.

An acute injection of ethanol (EtOH) has been shown to affect the levels of plasma amino acids and related compounds in rats (Milakofsky, et al., *Biochem. Pharmacol.* 35:3885, 1986). In order to explore if EtOH would also affect these compounds in certain tissues, rats were injected with 2 g/kg of EtOH, sacrificed 30 min later and plasma, aorta, heart, bronchi and pancreas were obtained. Analysis involved HPLC with fluorometric detection. In plasma, ARG (32%), ASP (29%), SER (18%), GLY (20%), ALA (25%) and B-ALA (26%) were significantly decreased. Ammonia (36%) and TAU (26%) were decreased in the aorta; ASP (50%) and LEU (25%) in the heart; CIT (28%), ASP (49%), TAU (25%), ASN (14%) and ALA (34%) in the pancreas and TAU (31%), ILE (34%), ethanolamine (39%) and HIS (30%) in the bronchi. Increases were found with phosphoserine (44%) in the aorta; ORN (37%), GLU (28%), GABA (41%) and CAR (37%) in the heart; VAL (56%), ILE (73%), LEU (33%) and HIS (30%) in the pancreas. All other compound were unaffected. These results indicate that an acute injection of EtOH can affect certain amino compounds in various tissues of rats. (Supported in part by the Anesthesia Research Foundation, Wilmington, DE).

ROLE OF PROTEIN KINASE C IN ETHANOL INDUCED INHIBITION OF METABOTROPIC - GLUTAMATE RECEPTOR FUNCTION IN PRIMARY CULTURES OF ASTROCYTES. T.L. Smith* and M.S. Bitrick, Research Service (151), Dept. of Veterans Affairs Med. Ctr., Tucson, AZ 85723

Chronic ethanol (E) exposure selectively inhibits metabotropic-glutamate receptor-stimulated polyphosphoinositide hydrolysis in astrocytes (Smith, Alcohol, in press 1994). Because this receptor system is highly sensitive to modulation by protein kinase C (PKC), the aim of the present study was to determine whether the inhibiting effect of E could be reversed in the presence of staurosporine or calphostin C. Astrocytes were cultured in DMEM with 5% FCS in 35 mm dishes in the absence or presence of 100 mM E for 4 days. In some studies, control and E treated cells were co-incubated with 10 nM staurosporine for 3 days or with 2 μ M calphostin C 10 mins prior to addition of agonists. After a 24 hr. preincubation with [3 H]inositol (1 μ Ci/ml), astrocytes were stimulated with 1S, 3R - ACPD and subsequent [3 H]InP determined. Chronic E significantly inhibited the InP response to 1S, 3R - ACPD. Moreover, exposure for 10 min to 10nM phorbol ester (PMA) further inhibited the response in E treated cells, indicating that the effects of E and PKC activation were additive. The results suggest that the inhibitory effect of chronic E is not mediated primarily by PKC. (supported by a research grant from the Dept. of Veterans Affairs, Washington, DC).

660.18

MODULATORY EFFECTS OF ACUTE ETHANOL ON METABOTROPIC GLUTAMATE RESPONSES IN CULTURED PURKINJE NEURONS. J.G. Netzeband* and D.L. Gruol, Dept. Neuropharmacology and the Alcohol Research Center, The Scripps Research Institute, La Jolla, CA 92037.

Of the many actions attributed to ethanol in the brain, little attention has been given to possible interactions with metabotropic glutamate responses that may be involved in synaptic transmission and plasticity. To this end, modified organotypic cultures were prepared from embryonic day 20 rat cerebella and extracellular recordings were made from Purkinje neurons at 21-37 days in culture (37 °C). Metabotropic glutamate responses were induced by pressure ejection of (a) 300 μ M (1S,3R)-1-aminocyclopentane-1,3-dicarboxylic acid [(1S,3R)-ACPD] or (b) 5 μ M quisqualate (50 μ M DNQX was used to block the ionotropic components of quisqualate-mediated responses). Both (1S,3R)-ACPD and quisqualate produced biphasic responses consisting of an initial brief excitatory phase (5-20 s) followed by a prolonged inhibitory phase (10 s to 2.5 min). These agents also induced increases in the appearance of burst-like activity. In the presence of 66 mM ethanol, (1S,3R)-ACPD-mediated responses exhibited a decrease in the magnitude of the excitatory phase and an increase of the total response duration, with no change in the induction of burst activity compared to controls. In comparison, 66 mM ethanol had much different effects on quisqualate-mediated responses. For quisqualate, ethanol decreased the total response duration and the induction of burst activity, but had no effect on the magnitude of excitation. These results indicate that acute ethanol exposure has complex modulatory actions on metabotropic glutamate responses in cultured Purkinje neurons. Supported by ARC 6420 and AA 0756.

DRUGS OF ABUSE: ALCOHOL IV

EMBRYONIC ETHANOL EXPOSURE ALTERS THE DEVELOPMENT OF SEROTONINERGIC NEURONS AND FIBERS IN CHICK SPINAL CORD. B. Mendelson* and A. Driskill, Dept. of Anatomy, University of Arkansas for Med. Sci., Little Rock, AR 72205.

Embryonic exposure to ethanol (ETOH) often produces motor dysfunction consisting of poor balance, altered gait and decreased tendon (stretch) reflexes. To determine if alterations in the development of serotonergic somata and fibers in the spinal cord contribute to these symptoms, chick embryos were exposed to ETOH. Subsequently, the development of serotonergic neurons and fibers was studied with immunohistochemical techniques using a polyclonal antiserum to serotonin (5HT). Groups of chick embryos were treated with 10% ETOH in sterile Tyrode's to produce blood ETOH concentrations of either 0.15-0.2% w/v (medium dose) or 0.275-0.325% w/v (high dose). Control embryos were treated with equivalent volumes of sterile Tyrode's. The ETOH administration began on embryonic day 1 (E1) and continued until the animals were sacrificed. Serotonin immunoreactivity (5HT-IR) was examined in the first 3 lumbosacral spinal cord segments in animals sacrificed on E10, E12 and E14. At all stages analyzed, the density of 5HT-IR fibers was less in both ETOH-treated groups than in control embryos. Camera lucida drawings of 5HT-IR neurons were analyzed for number of primary dendrites (those originating directly from the soma) and secondary dendrites (any dendrite originating from a dendrite). At all stages examined, the number of secondary dendrites was significantly less in both ETOH-treated groups as compared to controls. There were significantly fewer primary dendrites in both ETOH-treated groups at E12 and E14 and in the embryos treated with the high ETOH-dose at E10. These ETOH-induced alterations in the serotonergic system may be involved in the motor dysfunction observed after embryonic ETOH exposure.

661.2

IMPACT OF ETHANOL ON DEVELOPMENT OF ORGANOTYPIC CULTURES FROM NEOCORTEX AND SPINAL CORD.

D.L. Davies* and B. Mendelson, Dept. of Anatomy, Univ. of Arkansas for Medical Sciences, Little Rock, AR 72205.

Development of the CNS is adversely influenced by exposure to ethanol. As part of an endeavor to assess the effects of ethanol on neural development in the absence of confounding systemic variables, organotypic cultures were histologically evaluated following ethanol exposure. Organotypic cultures were prepared from the neocortex of 4-day-old postnatal rats and the spinal cords of embryonic day 10 chicks. Groups of cultures from both sources were incubated in medium containing 0%, 0.2% or 0.5% (w/v) ethanol; cultures were serially harvested for evaluation after 1, 3, 6 and 9 days of *in vitro* ethanol exposure. At these timepoints, both control and ethanol exposed cultures from neocortex and spinal cord retained features of normative cytoarchitecture. Also, these cultures exhibited a dense feltwork of astrocytes identified by immunolocalization of glial fibrillary acidic protein. Throughout the culture interval, serotonergic neurons in the spinal cord were immunocytochemically detected in control and ethanol exposed cultures. The somata and dendritic arbors of motoneurons and particular classes of interneurons were labeled by placement of small crystals of Dil at specific locations on the fixed spinal cord. In the neocortex, ethanol exposed cultures exhibited smaller dimensions than control cultures; this was more evident at the high (0.5%) ethanol concentration and may reflect lower cell viability. These studies suggest the utility of organotypic cultures as alternative models for delineation of the direct effects of ethanol on development and cellular interactions in the CNS.

ALCOHOL SELF-ADMINISTRATION, DOPAMINE AND AGGRESSION IN RATS. A.M.M. van Erp, H.H. Samson* and K.A. Miczek, Department of Psychology, Tufts University, Medford, MA 02155

The objective was to investigate whether ethanol, when self-administered orally, would enhance aggression in residents confronting an intruder. Male Long-Evans rats, housed with a female, attacked a smaller male intruder in their home cage during 5 min tests. Rats which consistently attacked were trained to drink a 10% ethanol solution during 15 min access in their home cage, using a sucrose-fading technique. After ethanol intake stabilized, intruder tests were conducted 2/wk, starting 5 min after the ethanol session. "Control" fights were scheduled before or more than 3 h after the ethanol session (BAC levels 0 mg/kg). Blood samples were taken directly after the fight from the orbital sinus, under isoflurane anesthesia. Under these conditions, rats drank up to 1.0 g/kg, resulting in BAC levels in a range of 10-80 mg/dl, but mostly 20-40 mg/dl. Neither intoxication nor sedation were observed. Aggressive behavior after ethanol self-administration was enhanced in some animals and unchanged in others, similar to previously reported results from tests with experimenter-administered ethanol. The magnitude of the increase in attack and threat responses ranged from 20-50% above control. Individual differences are currently being investigated using microdialysis, to monitor changes in catecholamines in the nucleus accumbens during ethanol drinking and subsequent intruder tests. Preliminary results show that dopamine release is increased during an intruder confrontation; this effect is enhanced and prolonged when the confrontation is preceded by ethanol self-administration. These results suggest that the ethanol-induced increases in aggressive behavior may be modulated by mesocorticolimbic dopamine.

ETHANOL MODIFIES EXTRACELLULAR LEVELS OF DOPAMINE, SEROTONIN, AND CORTICOTROPIN RELEASING FACTOR IN THE LIMBIC FOREBRAIN: STUDIES IN RATS WITH DIFFERENT HISTORIES OF ETHANOL EXPOSURE. A. Smith*, L.H. Parsons, E. Merlo Pich, P. Hyttia, G. Schulteis, M.T. Lorang, M.F. Yackey, G.F. Koob, and E. Weiss, Department of Neuropharmacology, The Scripps Research Institute, La Jolla, CA 92037.

A series of studies was conducted to further examine the neurobiological basis of alcohol preference and reinforcement. The objective of the first experiment was to determine whether Alcohol Preferring (P), Nonpreferring (NP), and Wistar (W) rats can be distinguished on the basis of differences in basal accumbal dopamine (DA) and serotonin (5-HT) function as measured by the "no-net-flux" quantitative microdialysis method. The results suggest a more similar profile of DA and 5-HT release in NP and W as opposed to P rats. Specifically, P rats showed reduced basal extracellular DA and a tendency toward lowered 5-HT levels compared to NP and W rats. A second experiment, designed to identify neurochemical substrates of ethanol dependence, examined the effects of chronic ethanol and subsequent withdrawal in W rats on the efflux of DA and 5-HT in the nucleus accumbens (NAC), and of corticotropin releasing factor (CRF) in the central nucleus of the amygdala (CNA). Ethanol withdrawal produced significant decreases in accumbal DA and 5-HT efflux below pre-withdrawal baselines and a substantial elevation in CNA dialysate CRF concentrations. These data may implicate extracellular DA and 5-HT deficiencies and enhanced CRF release in withdrawal distress and in the maintenance of ethanol dependence. Finally, the neurochemical basis of ethanol-seeking behavior in dependent subjects was explored by monitoring dialysate DA and 5-HT concentrations in the NAC of W rats operantly self-administering ethanol during withdrawal. Ethanol reinstated DA efflux to pre-withdrawal values within 10 minutes. In contrast, 5-HT efflux remained below pre-withdrawal levels, suggesting that DA may play a more prominent role than 5-HT in the motivational effects of ethanol in dependent rats. Supported by NIAAA AA 08164, AA 06420 and NIDA DA 08426 (F.W. and G.F.K.).

661.5

NO REDUCTION OF SPONTANEOUSLY ACTIVE MESOLIMBIC DOPAMINERGIC NEURONS IN ETHANOL-WITHDRAWN RATS.

Marco Diana*, Marco Pistis, Annalisa Muntoni & Gianluigi Gessa. "B.B. Brodie" Dept. of Neuroscience, Univ. of Cagliari, Italy.

It has recently been shown that mesolimbic dopaminergic (DA) neurons are drastically reduced in their spontaneous electrophysiological activity during ethanol withdrawal syndrome. However, the reduction in firing rate, burst firing and spikes/burst is not accompanied by a reduction in the number of spontaneously active DA neurons as evidenced by a cells/track index unchanged between ethanol-withdrawn and saline-treated control rats (Diana et al 1993, PNAS 90, 7966-7969). In spite of this result, a recent report (Shen & Chiodo 1993, Brain Res. 622, 289-293) contends that there is a reduction in the number of spontaneously active dopaminergic neurons recorded from ethanol-withdrawn in chloral hydrate anesthetized rats. Since there is a possibility that the use of anesthetics may be a possible confounding factor, we repeated the experiments in unanesthetized and chloral hydrate anesthetized rats during ethanol withdrawal syndrome. While in unanesthetized rats the cells/track index was found again unchanged (as compared to saline-treated control rats), in chloral hydrate anesthetized rats we found a profound reduction (as compared to saline-treated control rats) of the same index (<62.5%), thereby confirming Shen & Chiodo's report. However, apomorphine administration did not reverse the reduced cells/track index and did not increase firing rate of "silent" DA neurons identified antidromically from the nucleus accumbens. In conclusion, the present results suggest that there is indeed a reduction in the number of spontaneously active mesolimbic DA neurons recorded from chloral hydrate anesthetized rats but 1) this is confined to the anesthetized preparation and 2) this finding does not support the presence of depolarization inactivation of mesolimbic DA neurons in ethanol withdrawn rats.

INVOLVEMENT OF THE DOPAMINE AXIS IN A VERVET MONKEY MODEL OF ALCOHOL ABUSE. B.M. Palmour, D. Mash, F.R. Ervin and S.N. Young*, Dept Psychiatry, McGill Univ. Sch. Med., Montreal QuE CANADA H3A 1A1 & Dept Neurology, U Miami Sch. Med., Miami FLA

Approximately 15% of vervet monkeys voluntarily consume large quantities (>5 g/kg/day) of unsweetened beverage alcohol (Ervin et al., 1990). Several convergent lines of evidence suggest that dopaminergic neurotransmission may differ between Alc preferring (AP) and avoiding (AA) animals. As noted previously (Mash et al., 1993), the density of DA transporters is high in abstinent AP monkeys and reduced in AP animals exposed to chronic Alc. Second, baseline CSF HVA concentrations, determined prior to initial alcohol screening, were lower in AP monkeys (251 ng/ml vs. 202 ng/ml), while other CSF amines and metabolites did not differ between groups. Paradoxically, alcohol consumption was reduced 32% by administration of an amino acid drink devoid of phenylalanine and tyrosine (n = 18). As compared to placebo, this manipulation lowered CSF HVA levels by 40% and 27% at 5 hr and 16 hr after amino acid administration, while CSF MHPG levels fell to 74% and 81% of control values. Reduced consumption of Alc persisted for up to 72 hr.

We also found that mazindol (a non-selective antagonist of catecholamine transport) and GBR12909 (a selective DAT inhibitor) reduced alcohol consumption by 20 to 42% when given repeatedly for 10 days to monkeys drinking in a scheduled access paradigm. These compounds had similar and dose-dependent effects upon alcohol consumption, but Maz significantly reduced water consumption as well. The aggregate data are consistent with an extensive literature implicating the dopamine reward system in ingestive and addictive behaviors, and suggest that further evaluation of DA receptors, as well as molecular and biochemical markers of DA neurotransmission is warranted in AP vervet monkeys.

ALTERED DENSITIES OF DOPAMINE SYNAPTIC MARKERS IN ALCOHOL-PREFERRING VERVET MONKEYS. D. C. Mash, J. Staley, M. Basile*, F. M. Doepel, J. Wagner, F. R. Ervin, and R. P. Palmour, Depts. of Neurology, Pharmacology & Pathology, Univ. of Miami School of Medicine, Miami, FL, 33101 and Dept. Psychiatry and Centre for Human Genetics, McGill University, Montreal H3A1A1, Canada.

The binding characteristics of dopamine synaptic markers were studied in four different treatment groups: alcohol-avoiding, "predrinking" alcohol-preferring, short-term alcohol induction, and long-term alcohol exposure. We have used radioligand binding and autoradiography to quantify and map the status of D1 dopaminergic receptors in alcohol-preferring vervet monkeys. Our analysis demonstrates that the number of D1 receptors labeled with [³H]SCH 23390 are elevated over limbic sectors of the basal forebrain and striatum. Saturation binding analysis demonstrates that elevated number of binding sites seen in autoradiographic studies reflects an increase in the density (B_{max}) with no change in the affinity (K_D values) of the radioligand. Analysis of the autoradiograms taken from alcohol-preferring monkeys allowed unlimited access to ethanol for 5 or 35 days revealed comparable densities to the "predrinking" region-of-interest measurements. These data suggest that D1 receptors do not show tolerance to the effects of ethanol in alcohol-preferring monkeys given voluntary access. In alcohol-preferring vervet monkeys, the D1 receptor antagonist SCH 23390 sharply reduced alcohol consumption. It has been suggested that expression of D1 receptor-mediated behaviors are important for the rewarding effects of drugs of abuse. We have demonstrated a marked elevation in dopamine transporter (DAT) densities with no change in the number of vesicular transporters in alcohol-preferring vervet monkeys. Voluntary consumption of ethanol resulted in a return to "normalized" densities of DAT. The elevated expression of D1 receptor number may reflect a compensatory response to lower dopaminergic tone in alcohol-preferring vervet monkeys. (Alcoholic Beverage Medical Research Foundation & AA09562).

DEFICIENCIES IN DOPAMINE AND SEROTONIN CNS SYSTEMS ASSOCIATED WITH HIGH ALCOHOL PREFERENCE. W.J. McBride, J.K. Chamberlain*, E. Chernet, B. Bodart, L. Lumeng and T.-K. Li. Depts. Psych. & Med., Indiana Univ. Sch. Med. and VA Med. Ctr., Indianapolis, IN 46202-4887.

The hypothesis that high alcohol preference is associated with abnormalities in certain dopamine (DA) and serotonin (5-HT) CNS systems was investigated. In one study, the contents of DA and 5-HT were determined in 4 CNS regions of adult male rats in the F₂ generation obtained by intercrossing the selectively bred alcohol-preferring P and alcohol non-preferring NP lines. Rats with the highest (N=11) and lowest (N=15) alcohol intakes (6.3±0.3 vs 0.4±0.6 g/kg/day; p<0.001) were used for HPLC analysis. Lower contents of DA (46±2 vs 61±3 pmol/mg tissue; p<0.001) and 5-HT (6.3±0.3 vs 7.0±0.2 pmol/mg tissue; p<0.08) were observed in the nucleus accumbens (ACB) of the high compared with the low drinkers. These findings agree with differences previously obtained between the parent P and NP rats. In a second study, the densities of 5-HT_{1A} and 5-HT₂ receptors were determined in alcohol-naïve selectively bred high-alcohol (HAD) and low-alcohol (LAD) drinking lines of rats (N=6/line). In contrast to findings with the P and NP lines, no differences were observed in the densities of 5-HT_{1A} sites in several cerebral cortical areas between HAD and LAD rats. In agreement with differences found between the P and NP rats, the densities of 5-HT₂ sites were lower in layer 4 of the medial prefrontal and frontal cortices and in the lateral (core) ACB of the HAD than LAD group. Overall, the results support the hypothesis that deficiencies in certain DA and 5-HT CNS systems are associated with high alcohol drinking behavior. (AA08553, AA07462, AA07611).

PHARMACOLOGICAL MANIPULATION OF ALCOHOL CONSUMPTION IN VERVET MONKEYS. F.R. Ervin*, R.M. Palmour, M.H. Donglar, Dept Psychiatry, McGill Univ. Sch. Med., Montreal QuE CANADA H3A 1A1

Approximately 15% of vervet monkeys spontaneously consume large quantities (>5 g/kg/day) of unsweetened beverage alcohol (Alc) in the absence of any biological or behavioral coercion (Ervin et al., 1990). Alc consumption during 2 or 4 hour scheduled access is highly correlated with 24hr Alc consumption (r = 0.712 and 0.633, p<0.001), and mean Alc: water preference ratios increase as the duration of availability decreases (24 hr = 1.14, 4 hr = 3.08, 2 hr = 6.70). The data suggest that these animals are drinking to maintain a pharmacological effect, rather than for taste preference.

We have begun to survey the efficacy of pharmacological interventions acting, respectively, on endogenous opiate, serotonin and dopamine systems as possible modulators of Alc selection. Opioids: Naltrexone (5 or 10 mg/day), administered daily for 10 days to monkeys in a chronic scheduled access paradigm, moderately reduced Alc consumption (20-38%) and the Alc:water preference ratio, as compared to placebo. SCH 23354 (an inhibitor of neutral endopeptidases) at 30 mg/day had a similar effect. Serotonin: Buspirone (2 mg), given daily for 5 days to 10 animals under scheduled access, produced a moderate increase in mean ethanol consumption (31%), a significant reduction in the volume of water consumed during the Alc access period (-42%) and a highly significant increase in Alc:Water ratio (2.56-fold over placebo). Dopamine: Long-acting bromocriptine (25 mg depot) transiently decreased Alc consumption (12-20%) in monkeys drinking <5 g/kg/day, but increased consumption (32-36%) in monkeys drinking >5 g/kg/day. D1 antagonists, such as SCH23390, abruptly (within 1 hr) and sharply (32-76%) decreased Alc intake, but increasing doses were required to maintain the effect. These effects, though pharmacologically quite modest, are within the range expected to be useful for treating alcohol abuse and dependence.

661.10

MEDIAL FRONTAL SEROTONERGIC SYSTEMS CORRELATE WITH VOLUNTARY ALCOHOL CONSUMPTION IN RATS A.W. Deckel*, E.

Vavrousek-Jakuba, W.J. Shoemaker, Dept. of Psychiatry, Alcohol Research Center, Univ. of Conn. Sch. of Med., Farmington, CT 06030.

This experiment examines the relationship between dopamine (DA), norepinephrine (NE) and serotonin (5-HT) and their metabolites to voluntary alcohol consumption. Seven Wistar male rats were anesthetized, pretreated with desimipramine and pargyline and then infused bilaterally with 6-OHDA into the frontal region. Thirteen rats had vehicle infusions (sham lesions) and 3 were untreated. All rats were trained to drink ethanol-containing solutions in a modified sucrose fading paradigm. Four weeks after initiation of the sucrose fading protocol, rats drank a solution containing 10% ETOH/5% sucrose for 2 weeks (wk 1 and wk 2), followed by a 10% ETOH/ 3% sucrose solution for two additional days. For each time period, the g ETOH/kg body weight/day was computed. Following sacrifice, monoamine levels in 5 brain regions were analyzed by HPLC/ED. Lesioned animals had significant depletions in DA, HVA and NE, but showed no changes in their 5-HT or HIAA levels, in the FCx. Lesioned animals did not consume significantly different levels of ETOH compared to controls. Regardless of lesion condition, however, animals with low levels of FCx HIAA, as determined by median split, consumed more ETOH than those with high levels of HIAA.

	10% ETOH 5% sucrose (wk 1)	10% ETOH 5% sucrose (wk 2)	10% ETOH 3% sucrose
Low HIAA	1.53/35**	1.51/37**	1.01/34 *
High HIAA	1.00/34	1.00/25	.62/19

(mean intake in g ETOH/kg b.wt. per day / s.d.; ** = p<0.05; * = p<0.1)

These results suggest that medial frontal serotonergic systems are important in regulating alcohol consumption in the rat, and further extend the experimental literature implicating serotonin in the regulation of alcohol-related behaviors.

661.11

CLOMIPRAMINE ALTERS THE RESPONSE OF VENTRAL TEGMENTAL AREA (VTA) NEURONS TO ETHANOL-INDUCED EXCITATION, R.D. Trifunovic and M.S. Brodie, Dept. Physiology and Biophysics, University of Illinois at Chicago, Chicago, IL 60612.

Excitation of dopamine neurons of the ventral tegmental area (VTA) may be a critical factor for the rewarding effect of ethanol (EtOH). EtOH increases the firing rate of VTA neurons *in vivo* and *in vitro*, and the potency of EtOH to excite VTA neurons is increased by serotonin (5-HT). Drugs which block the reuptake of 5-HT, like zimelidine and clomipramine (CLOM), have been used clinically to decrease drinking in alcoholics. Our objective was to test whether clomipramine, at concentrations which block 5-HT reuptake, alters the response of VTA neurons to EtOH, as we have shown for 5-HT.

Coronal brain slices containing the VTA were prepared from young adult F344 rats. Concentrations of EtOH (40 - 120 mM) were tested in the absence and presence of CLOM (125 nM to 2 μ M). All neurons (n=21) studied had electrophysiological characteristics typical of dopamine-containing neurons and were excited by EtOH in a concentration-dependent manner. Clomipramine itself had little or no effect on the firing rate of VTA neurons. In the presence of 500 nM CLOM, EtOH-induced excitations were approximately doubled; with CLOM, the mean excitatory effect of EtOH increased from 10% to 20% for 40 mM EtOH, and increased from 34% to 58% for 120 mM EtOH. This potentiation is consistent with the action of CLOM to block 5-HT reuptake, and with our earlier findings that 5-HT potentiates the excitatory effects of EtOH on VTA neurons. At higher clomipramine concentrations (1 - 2 μ M), there was no significant enhancement of EtOH-induced excitation. These higher concentrations are associated with reuptake blockade of norepinephrine and dopamine, which may obscure the effect of enhanced 5-HT availability. ETHANOL INTERACTIONS WITH GABA AND β -ADRENERGIC MECHANISMS ON CEREBELLAR NEURONS IN LAS AND HAS RATS. Ronald K. Freund, Donatella P. Donatelli, and Michael R. Palmer, Dept. of Pharmacology, Univ. of Colorado Health Sci. Ctr., Denver, CO 80262.

We previously found that ethanol-induced depressions of cerebellar Purkinje neurons in Sprague-Dawley rats are mediated by a GABA_A mechanism, but that ethanol alone only potentiated GABA responses on 20% of these cells unless concomitantly applied with a β -adrenergic agonist. Timolol, a β -adrenergic antagonist, not only blocks these ethanol-induced potentiations of GABA, but also antagonizes ethanol-induced depressions on 20% of these neurons as well. These data may suggest that synaptically-released norepinephrine alters the responsiveness of this subpopulation of Purkinje neurons to ethanol actions under the conditions of our experiments. In the present study, we investigated these ethanol actions in two lines of rats which have been selectively bred for high (HAS) and low (LAS) alcohol sensitivity. We recorded single cerebellar Purkinje neurons from one barrel of a multibarrel micropipette while locally applying drugs from other barrels of the same pipette in urethane-anesthetized rats. Similar to Sprague-Dawley rats, we found that timolol reduced ethanol-induced depressions in 16% of the neurons tested in HAS rats. On 62% of the LAS neurons, however, the ethanol responses were antagonized by timolol application. Based on this observation, we hypothesized that ethanol would more frequently potentiate GABA-induced depressions in LAS than in HAS rats. Indeed, we observed this phenomenon in 69% of LAS neurons studied, but only in 20% of HAS neurons. These data suggest that there is a difference in the interaction of ethanol with GABA mechanisms between HAS and LAS rats which may be regulated by the activity of endogenous β -adrenergic mechanisms.

SUPPRESSIVE EFFECTS OF ALCOHOL UPON PREDATORY ATTACK BEHAVIOR IN THE CAT ARE BLOCKED BY A SUBSTANCE P, NK₁ RECEPTOR ANTAGONIST. M.B. Shaikh*, Y.C. Han, L. Pohorecky, D. Benjamin, and A. Siegel, Laboratory of Limbic System & Behavior, Department of Neurosciences, New Jersey Medical School, Graduate School of Biomedical Sciences, UMDNJ, Newark, New Jersey 07103, and Center for Alcohol Studies, Rutgers University, Piscataway, New Jersey, 08855.

This study was designed to determine the effects of alcohol upon quiet biting "predatory" attack behavior (QBA) elicited from the lateral hypothalamus (LH) and the mechanism within the medial hypothalamus (MH) involved in suppression of this response. *Experiment I*: peripheral administration of alcohol (0.02, 0.5 and 1.0 g/kg, I.P.) resulted in a dose and time dependent suppression of QBA in which the maximal effect (42% suppression) was observed 60 min, postinjection, when tested with 5% alcohol. *Experiment II*: peripheral administration of alcohol at the same dose levels also increased medial amygdaloid (ME)-induced suppression of QBA in a dose and time dependent manner. *Experiment III*: microinfusion of the substance P (SP)-NK₁ antagonist, CP 96,345, into MH blocked alcohol-induced enhancement of the suppressive effects of ME stimulation upon the LH. These results suggest the following conclusions: (1) that alcohol suppresses QBA; and (2) that the underlying mechanism for suppression of this response may involve agonistic-like effects of alcohol upon SP receptors within the MH, which receive direct inputs from an SP pathway originating in the ME.

CHRONIC ETHANOL EXPOSURE ALTERS DOPAMINE D₂ RECEPTOR mRNA EXPRESSION IN NUCLEUS ACCUMBENS IN RATS. B.A. Blanchard* & P.K. Rudeen, Dept. of Pathology & Anatomical Sciences, Univ. of Missouri School of Medicine, Columbia, MO 65212.

Brain dopamine (DA) systems are believed to mediate the reinforcing properties of drugs of abuse, including ethanol (EtOH). Chronic EtOH exposure in rats has been shown to alter DA D₂ receptor populations, with the direction of change possibly dependent on the dose of EtOH and the period of exposure. The present study examined effects of chronic EtOH exposure on expression of the DA D₂ receptor gene in the terminal regions of the mesolimbic and nigrostriatal DA pathways: the nucleus accumbens and striatum. Adult female Long-Evans rats were exposed to EtOH via liquid diet (35% EtOH-derived calories) for periods of either two or six weeks. Following EtOH exposure, DA D₂ receptor mRNA content in the core and shell regions of the nucleus accumbens, and medial and lateral regions of the striatum was examined using *in situ* hybridization histochemistry. After two weeks of EtOH exposure, there were no significant changes in DA D₂ receptor gene expression in any region of either structure. However, six weeks of EtOH exposure produced a significant decrease (approximately 40% below control levels) in DA D₂ receptor mRNA content in the core region of the nucleus accumbens. There were no significant changes in the nucleus accumbens shell, nor in either region of the striatum. The findings suggest that chronic EtOH exposure may alter DA receptor populations by altering gene expression in regions believed to be important in drug reward.

661.14

ENDOGENOUS NORADRENERGIC MECHANISMS REGULATE ETHANOL ACTIONS IN RAT CEREBELLUM. Michael R. Palmer, Ronald K. Freund, Anya M-Y. Lin, and Yun Wang, Dept. of Pharmacology, Univ. of Colorado Health Sci. Ctr., Denver, CO 80262 and National Defense Medical School, Taipei, Taiwan, R.O.C.

We previously found that ethanol-induced depressions of cerebellar Purkinje neurons in Sprague-Dawley rats are mediated by a GABA_A mechanism, but that ethanol alone only potentiated GABA responses on 20% of these cells unless concomitantly applied with a β -adrenergic agonist. In the present study we found that timolol, a β -adrenergic antagonist, not only blocks these ethanol-induced potentiations of GABA, but also antagonizes ethanol-induced depressions on 20% of these neurons as well. These data may suggest that synaptically-released norepinephrine alters the responsiveness of this subpopulation of Purkinje neurons to ethanol actions under the conditions of our experiments. Supporting this conclusion, we find that phencyclidine, a agent that facilitates noradrenergic synaptic function in the cerebellum, reversibly potentiates the depressant effects of locally applied ethanol. Furthermore, we investigated the influence of acute morphine withdrawal on the sensitivity of Purkinje neurons to ethanol-induced depressions, a condition in which there is increased noradrenergic synaptic input from the locus coeruleus. We found that after 7 days of chronic morphine treatment, the systemic injection of naloxone, a morphine antagonist that precipitates withdrawal in chronically morphine-treated animals, enhanced the depressant responses of cerebellar Purkinje neurons to local applications of both ethanol and PCP. These data suggest that endogenous β -adrenergic mechanisms regulate ethanol actions in the cerebellum.

ETHANOL MODULATES MEMBRANE CURRENTS OF NEONATAL RAT PURKINJE NEURONS *IN VITRO*. H.K. Strahlendorf*, Y. Wang and J.C. Strahlendorf, Physiol. & Pharmacol., Texas Tech Univ. Hlth. Sci. Ctr., Lubbock, TX. 79430

Brief exposure to ethanol (ETOH) during critical growth periods causes abnormal development and death of Purkinje neurons (PNs). Mechanisms may relate to ETOH disruption of membrane ionic currents seminal for normal development. Whole-cell patch clamp recordings of PNs in slices of neonatal rat cerebellum (4 to 15 days) revealed multiple actions of low (5 mM) to moderate (50 mM) concentrations of ETOH. Under voltage-clamp at -60 mV, 4 min exposures to 5 mM ETOH most often enhanced the cationic inward rectifier I_h (12-52%, n=6) and consistently elicited periods of brief spontaneous inward currents. During recovery, a transient inward current shift occurred that returned to control levels within 90 sec. ETOH at 50 mM suppressed I_h markedly (15-44%, n=8) and also elicited an inward current shift during recovery that did not return to pre-ETOH levels. At that time all electroresponsiveness was lost. These data reveal effects of ETOH on developing PNs potentially important to its toxicity.

661.17

EFFECTS OF ETHANOL ON MIDDLE LATENCY AUDITORY EVOKED POTENTIALS IN THE RAT. H. Miyazato, R.D. Skinner* and E. Garcia-Rill. Department of Anatomy, University of Arkansas for Medical Sciences, Little Rock, AR 72205

The P1 middle latency auditory evoked potential in the human peaks at a 50-60 msec latency, is present during waking and REM sleep, but absent during slow wave sleep; i.e., it is present during periods of cortical desynchronization. Recently, we described the presence of the P13 potential (peak 11-15 msec) in the rat which correlates with the human P1 potential and wave A in the cat, the feline equivalent of the P1 (Skinner, et al., 1993). The present study was undertaken to determine the effects of ethanol on the behavior of the rat P13 potential.

Under barbiturate anesthesia, cortical leads were implanted at the vertex and over the auditory cortex. An intragastric tube was inserted and routed to exit in the dorsal neck. Auditory stimuli (intensity 103 dB, rate 0.2 Hz) evoked P13 potentials referenced to a frontal sinus screw were recorded and averaged from male rats following intragastric ethanol administration (0.5, 1, 3, or 5 gm/Kg, 40% in water). Following a 0.5 gm/Kg dose of ethanol there was no effect on the P13 potential. However, following a dose of 1 gm/Kg, the P13 potential was reduced to 60% at 5 min and then recovered by 15 min. Larger doses of ethanol (3 and 5 gm/Kg) reduced the P13 potential to 30% and 20%, respectively. The P13 potential recovered after 30 min following the 3 gm/Kg dose, and after 75 min following the 5 gm/Kg dose. Simultaneous recording of the averaged auditory evoked responses (Pa) over the auditory cortex showed only a slight effect on this potential at all ethanol doses tested.

Our results suggest that ethanol reduces the amplitude of the P13 potential and delays its recovery in a dose-dependent manner. Thus, the behavior of this potential indicates that ethanol decreases the ability of the reticular activating system to generate a normal arousal response.

INHIBITION OF CALCIUM ENTRY BY CADMIUM CHANGES ETHANOL INHIBITION INTO EXCITATION IN RAT LOCUS COERULEUS NEURONS.

S.S. Osmanovic* and S.A. Sheffer. Department of Physiology and Biophysics, University of Illinois at Chicago, College of Medicine, Chicago, IL 60612-7342.

We have previously shown that ethanol can inhibit the spontaneous firing of rat locus coeruleus (LC) neurons. In the present study, intracellular recording in completely submerged brain slices from Fisher 344 rats was used to study the involvement of Ca^{2+} entry in the ethanol-induced inhibition of LC neurons. Ethanol was tested before and after application of the calcium channel blocker Cd^{2+} or low Ca^{2+} /high Mg^{2+} media. In 7 LC neurons which showed ethanol-induced inhibition, the mean spontaneous firing rate in control media was 0.72 ± 0.18 Hz (S.E.M.) and 0.28 ± 0.09 Hz after bath application of 100 mM ethanol. The mean ethanol-induced inhibition of firing, calculated with each cell as its own control, was $49.4 \pm 9.1\%$. The ethanol-induced inhibition of spontaneous firing was associated with no change in resting membrane potential ($n=5$) or membrane hyperpolarizations of 2-4 mV ($n=2$). Effects of ethanol were retested after superfusion with media containing Cd^{2+} (100 - 500 μM) for 15 - 25 min. In the presence of Cd^{2+} , ethanol caused membrane depolarization and increased the firing rate in all 7 neurons tested; the mean depolarization and increase in firing rate were 2.7 ± 0.36 mV and $91 \pm 36.8\%$, respectively. The effect of ethanol in Cd^{2+} was significantly different than in control as determined by a paired t-test ($p < 0.05$). Ethanol-induced inhibition was also changed to excitation when the Ca^{2+} concentration in the media was reduced from 2.4 to 0.25 mM and the Mg^{2+} concentration increased from 1.3 to 10 mM ($n=5$). These data indicate that ethanol-induced inhibition of spontaneous firing in LC neurons is dependent on Ca^{2+} entry. Another previously reported action of ethanol on LC neurons is reduction of action potential duration. This action of ethanol was not affected by Cd^{2+} indicating that ethanol effects on spontaneous firing and action potential duration are mediated by separate mechanisms.

INTRAGASTRIC ETHANOL LOWERS THE PEAK FREQUENCY OF TYPE I THETA. S. Morzorati*, T.E. Breen. Indiana Univ. Sch. Med., Inst. Psych. Res., Indianapolis, IN 46202.

Theta is a rhythmic slow wave recorded from the hippocampus during wakefulness and sleep. Type I theta has a frequency between 6-10 Hz and occurs during ambulation; type II theta has a frequency between 4-9 Hz and occurs during alert immobility. Neurons in the medial septum/diagonal band of Broca and entorhinal cortex pace theta activity, sending rhythmic discharges to hippocampal interneurons which, in turn, communicate with hippocampal pyramidal cells, the source of theta activity.

Intravenous administration of ethanol has been shown to disrupt the rhythmic discharges of medial septal cells in freely moving rats (Givens and Breen, JPET 253:95, 1990). Given this fact, experiments were designed to investigate the effect of ethanol on type I theta.

Male Wistar rats ($N=5$) were trained to ambulate steadily on a treadmill and implanted with chronic intragastric cannulae and hippocampal EEG recording electrodes. Water or ethanol (0.5, 1.0, 2.0 g/kg body wt) was infused following an overnight fast. EEG was then recorded while ambulating at 5 min intervals for 120 min. The data were subjected to power spectral analysis and the peak frequency of the power spectra determined.

A preliminary analysis of variance indicated that all doses of ethanol significantly ($p < 0.0001$) decreased the peak frequency of type I theta. The decrease was dose-dependent. Taken together, these and previous data indicate that ethanol decreases theta frequency, perhaps by disrupting the rhythmic activity of medial septal cells.

EFFECT OF ETHANOL ON FORSKOLIN-STIMULATED CYCLIC AMP ACCUMULATION IN CULTURED HUMAN NEUROBLASTOMA CELLS. S. M. Rezazadeh*, H. Lal, and M.W. Martin. Department of Pharmacology, University of North Texas Health Science Center, Ft. Worth, Texas, 76107.

Previous reports indicate that ethanol (ETOH), in some membrane preparations, stimulates adenylate cyclase (AC) activity. Also, acute exposure of some cell types to ETOH increases extracellular adenosine by blocking its reuptake. Thus, adenosine, by stimulating A2 adenosine receptors, may contribute to the enhanced cyclic AMP (cAMP) responses observed in the presence of ETOH. The purpose of this study was to determine whether ETOH directly modifies AC activity independent of endogenous adenosine. Accumulation of cAMP in intact SK-N-SH neuroblastoma cells was measured in the presence of the phosphodiesterase inhibitor Ro 20-1724 and adenosine deaminase. Synthesis of cAMP was stimulated by forskolin (FSK), CGS21680 (CGS), an A2 adenosine agonist, or isoproterenol (ISO). FSK which produces a receptor-independent activation of cAMP synthesis, increased the cAMP levels by 30-40 fold with an EC_{50} of 6 μM . In the presence of 1 mM FSK, stimulation of cAMP synthesis by either CGS or ISO was markedly potentiated. Ethanol (>40 mM) inhibited FSK-stimulated cAMP synthesis in a concentration-dependent manner. Although ETOH (160 mM) produced little or no change in the response of ISO or CGS alone, the response to these agonists in the presence of FSK (1 mM) was significantly inhibited by ETOH. To investigate the effect of long-term ETOH exposure, cells were pre-incubated with 80 or 160 mM ETOH for 2-48 hours. The inhibitory effect of ETOH on FSK response was not attenuated after a previous ETOH exposure. This may indicate that tolerance does not develop to this effect of ETOH. It is concluded that ETOH inhibits FSK-dependent, but not receptor-dependent, AC activity and tolerance does not develop to this pharmacologic effect. These results suggest that ETOH may alter the interaction between Gs, FSK, and the AC catalytic subunit. (Supported by NIAAA-A06890 and UNTHSC Grants).

662.2

POSSIBLE MECHANISM OF ACTION FOR ETHANOL INHIBITION OF INDUCIBLE NITRIC OXIDE SYNTHASE IN C6 GLIOMA CELLS. P. J. Syapin* and J. D. Militante. Dept. of Pharmacology, Texas Tech Univ. Health Sci. Center, Lubbock, TX 79430.

Growth of C6 glioma cells in ethanol for 10 days potentially inhibits inducible nitric oxide synthase (iNOS) activity ($\text{IC}_{50} \approx 30$ mM), measured as nitrite accumulation during 24 h exposure to 400 ng/ml phorbol 12-myristate 13-acetate (PMA) plus 500 ng/ml lipopolysaccharide (LPS). Ethanol for 24 h during stimulation with PMA+LPS was less effective ($\text{IC}_{50} \approx 140$ mM), indicating a change in cell sensitivity after chronic ethanol (Syapin, submitted for publication). Induction of iNOS activity requires both gene expression and interaction of the apoprotein with essential co-factors. Thus, ethanol could inhibit by decreasing gene induction or enzyme activation. The time-course for reversal of inhibition upon withdrawal from chronic ethanol was long (>72 h), suggesting down-regulation of important components of the gene induction pathway. *In vitro* experiments suggest decreased iNOS activity in cytosol from chronic ethanol-exposed cells, consistent with a decrease in gene expression. Using nitrite accumulation to measure iNOS activity, concentration-response curves on cells exposed to 50 mM ethanol showed reduced maximum responses to both PMA (25-400 ng/ml) plus 500 ng LPS/ml and LPS (25-500 ng/ml) plus 400 ng PMA/ml ($p < 0.001$), but potency changed only for LPS (3-4 fold less; $p < 0.05$). In other studies, acute inhibition occurred only when ethanol and LPS were both present. Because the induction of glial iNOS by LPS requires early activation of protein tyrosine kinase, ethanol may act to decrease signal transduction by this pathway. Experiments are investigating this possibility. These data suggest a new mode of action for ethanol effects in the brain.

INFLUENCE OF NITRIC OXIDE SYNTHASE INHIBITOR ON THE DEVELOPMENT OF RAPID TOLERANCE TO ETHANOL. J.M. Khanna*, G.S. Morato, A. Chau and H. Kalant. Department of Pharmacology, University of Toronto, University of Santa Catarina, Brazil and Addiction Research Foundation, Toronto, Canada.

We recently reported that the nitric oxide (NO) synthase inhibitor L-nitro-arginine (L-NA) blocks the development of rapid tolerance to the motor incoordinating effect of ethanol (E) in the tilt-plane test. In the present study, three experiments were carried out using the same test. The first assessed the acquisition of rapid tolerance to E in rats pretreated with L-NA prior to E on both days 1 and 2. In the second, the effect of L-NA given prior to behavioral testing with E on day 1 was compared to the effect of L-NA given after the behavioral testing on day 1. The third investigated the effects of L-NA on the enhancement of rapid tolerance to E by D-cycloserine (CS), an agonist at the N-methyl-D-aspartate (NMDA) receptor. The results demonstrated that L-NA prevents the development of rapid tolerance to E when injected prior to E either on both days or only on day 1. Furthermore, tolerance was blocked only when L-NA was injected before but not after behavioral testing. L-NA also blocked the enhancement of rapid tolerance to ethanol induced by CS. L-NA did not influence brain or arterial blood E concentrations on day 2. These data argue against state-dependent learning and confirm and extend our previous results that NO plays a role in the development of rapid tolerance to E. Moreover, considering that the NMDA receptor and NO participate in the mechanisms underlying learning and memory, our data also support the view that NO is involved in the enhancement of E tolerance by CS.

EXPRESSION OF HEAT SHOCK PROTEINS FOLLOWING EXPOSURE TO CHRONIC ETHANOL. Ellen T. Ott-Reeves, J. Mark Sherman, Clayton M. Pickering and John D. Lane*. Department of Pharmacology, UNTHSC-FW, 3500 Camp Bowie Blvd., Fort Worth, TX 76107 USA.

Heat shock proteins are induced in cultured cells when the culture medium contains 5% ethanol. Patients with a history of chronic ethanol exposure show high levels of heat shock proteins. In this experiment, male Fisher 344 rats were taught to orally self-administer ethanol on an FR4 schedule, using sucrose fading. These rats showed only low response rates for ethanol alone. Rats were fed a liquid diet containing ethanol, then retested over a range of ethanol concentrations. Ethanol intake increased over levels prior to administration of the liquid diet. Rats were again fed the liquid diet for 2 weeks. Tissues from heart, liver, kidney, gastrointestinal tract, skeletal muscle and multiple brain regions were harvested and *in situ* hybridization was performed using oligonucleotide probes specific for either inducible or constitutive 70kd heat shock proteins. Both inducible and constitutive mRNAs were found in control and ethanol rats. In brain, the highest levels of both inducible and constitutive mRNAs were found in the cerebellar granular layer, hippocampus, dentate gyrus and hypothalamic nuclei. In kidney, the inducible probe showed uniform distribution; however, the constitutive form showed a specific pattern with highest levels of mRNA in the medulla. All other organs showed more uniform distribution of both the inducible and constitutive mRNAs. In regions showing a statistically significant difference, levels of inducible mRNAs were greater than constitutive in both ethanol and control rats.

IMMOBILITY IN A SWIM TEST IS NOT ASSOCIATED WITH A GENETIC PREDISPOSITION TO ALCOHOL PREFERENCE. C.D. Godfrey, J.C. Froehlich*, L. Lumeng, T.-K. Li and J.M. Murphy. Dept. Psych., Purdue Sch. Sci.; Inst. Psychiat. Res. and Dept. Medicine, Indiana Univ. Sch. Medicine, IUPUI, Indianapolis, IN 46202.

Alcohol-preferring P rats exhibit less immobility ("behavioral despair") in a forced swim test than nonpreferring NP rats (Godfrey et al., Soc. Neurosci. Abs. 18:541, 1992; Overstreet et al., Alcohol: Clin. Exp. Res. 16:407, 1992). However, the AA alcohol drinking rats exhibit more immobility than nondrinking ANA rats in a similar test (Korpi et al., 1988). The present study compared high alcohol drinking HAD rats with low drinking LAD rats on a swim test and examined the effects of desipramine (10 or 20 mg/kg). Adult male HAD and LAD rats (n=9/line/dose) were placed in a round tub filled with water (21°C). The rats were unable to touch the bottom or escape from the tub. Behavior was videotaped for 10 min on each of two consecutive days and scored for time spent immobile. HAD rats were more immobile ($p < 0.05$) than LAD rats; 124 ± 10 vs. 91 ± 10 sec (mean \pm SEM), respectively. Desipramine attenuated ($p < 0.05$) time spent immobile in LAD but not in HAD rats which contrasts with the attenuation of immobility seen previously in both P and NP rats, with greater attenuation in NPs. Immobility in the swim test is not associated with a genetic predisposition to alcohol preference. Attenuation of immobility by desipramine is seen in both alcohol-nonpreferring (NP and LAD) lines but not in both -preferring lines. (AA07611, AA08553)

THE EFFECT OF REPEATED ETHANOL WITHDRAWAL ON ULTRASONIC VOCALIZATION AND THE INDUCTION OF C-FOS PROTEIN. S.S. Moy*, D.J. Knapp, G.E. Duncan, and G.R. Breeze. Brain and Development Research Center, Univ. of North Carolina Sch. of Med., Chapel Hill, NC 27599-7250.

Repeated withdrawals from chronic ethanol consumption have been linked to an exacerbation of withdrawal symptoms, suggesting that multiple exposures and withdrawals from ethanol lead to a progressive sensitization not apparent with continuous ethanol administration. Previous research has shown that both ultrasonic vocalizations and the expression of fos-like proteins are increased during withdrawal from chronic ethanol administration. In the present experiment, rats given repeated withdrawals from ethanol, rats given the same amount of ethanol continuously, and control animals were compared on the basis of ultrasonic vocalizations in response to air puff and fos-like immunoreactivity (Fos-LI). Behavioral testing occurred seven to eight hours following ethanol withdrawal on the final day of the experiment. The results showed that both withdrawal groups spent more time vocalizing in comparison to the control animals, while the repeated withdrawal group demonstrated increased vocalization in comparison to the continuous ethanol group. Immunohistological analysis of c-fos activity showed a similar trend for specific brain regions. In particular, Fos-LI in the medial prefrontal cortex, ventrolateral orbital cortex, piriform cortex, retrosplenial cortex, locus coeruleus, and tectum was enhanced more by repeated withdrawals than by a single withdrawal. These data support the hypothesis that multiple ethanol exposure/withdrawal cycles result in a more severe withdrawal syndrome than a single ethanol withdrawal. AA-08024, NS26595, & HD07201.

ENHANCED (Na+K)-ATPase EXPRESSION IN MOUSE BRAIN AFTER CHRONIC ETHANOL ADMINISTRATION. Y.M. Chen, P.M. Wixom* and A.Y. Sun. Dept. of Pharmacology, University of Missouri, Columbia MO 65212.

It is the general hypothesis that the primary mode of action of ethanol is the alteration of membrane structure and function including the conformation of receptors and ion channels essential for neurotransmission and signal transduction. (Na+K)-ATPase is of interest because of its major role in Na+ homeostasis and its membrane dependence. In the past we have demonstrated the inhibitory effect of ethanol on (Na+K)-ATPase *in vitro*, and chronic administration of ethanol has led to an increase in the specific activity of this enzyme. However, the issue of whether ethanol affects (Na+K)-ATPase under physiological conditions remains unsettled. In this study, adult mice were treated with a daily dose of 5 g/kg of ethanol for 28 days. The RNA was isolated from brain samples and probed for the (Na+K)-ATPase mRNA using Northern blot analysis. We have found an increased expression of (Na+K)-ATPase in the chronically treated alcohol group as compared with controls. This result was further substantiated by the increased protein phosphorylation of this enzyme after chronic ethanol administration. Thus we have demonstrated that ethanol may directly or indirectly affect (Na+K)-ATPase *in situ*, leading to the increased synthesis of this enzyme through adaptive mechanisms. REPEATED ETHANOL WITHDRAWAL EXPERIENCE DIFFERENTIALLY INFLUENCES WITHDRAWAL-RELATED SEIZURES AND 'ANXIETY' RESPONSES IN MICE. H.C. Becker*, K.G. Fernandes, and R.T. Weathersby. VA Medical Center and Medical University of South Carolina, Charleston, SC 29401

We previously demonstrated an exacerbation of withdrawal seizures in adult C3H mice that experienced multiple cycles of ethanol (EtOH) withdrawal in comparison to mice withdrawn from EtOH a single time, even when total EtOH exposure is equated across groups. This study was designed to examine whether similar results may be obtained in another mouse strain, and with another symptom of withdrawal (anxiety). Adult male NIH Swiss mice were exposed to EtOH vapor prior to withdrawal. A multiple withdrawal (MW) group received 3 cycles of 16 hr EtOH vapor separated by 8 hr periods of abstinence; a continuously exposed (CE) group received the same total amount of EtOH (48 hr) uninterrupted; a single withdrawal (SW) group received a single 16 hr bout of EtOH exposure; and controls received no EtOH exposure. Following the final withdrawal cycle, mice were tested for handling-induced convulsions (HIC) or performance on an elevated plus-maze. Blood EtOH levels upon final withdrawal were similar among EtOH-exposed groups (180-200 mg%). The groups did not differ in % time on or % entries into open arms in the plus-maze at 8 and 24 hrs post-withdrawal. Total arm entries were depressed in the MW and CE groups at 8 hrs, but not at 24 hrs. In contrast, severity of withdrawal seizures was significantly greater in the MW group in comparison to other groups. Mean area under the 24 hr HIC curve was 21.3 ± 2.0 , 10.6 ± 4.7 , 13.3 ± 3.0 , and 1.0 ± 0.3 for MW, SW, CE, and control groups, respectively. These results suggest that in this mouse strain, repeated EtOH withdrawal experience exacerbates the severity of subsequent withdrawal seizures, but does not influence anxiety, as measured in the plus-maze test. Other mouse strains are being used to continue to explore this research question. Supported by VA Medical Research Service and NIAAA.

ULTRASTRUCTURE CHANGES IN THE RAT CEREBRAL CORTEX DUE TO CHRONIC INTAKE OF ETHANOL J. Trujillo Santa-Ana* and G. Espinosa Villanueva. Departamento de Anatomía. Facultad de Medicina, U.N.A.M. México, 04510.

Alcohol has always been the major drug used. Alcohol's abuse is related with a deleterious effect on the organism and the behavior. This, is specifically true for the nervous system. In this study, young Wistar rats of 8 weeks were divided in two groups: control (C, n=9) and experimental (E, n=9). The E group drank ethanol at 15% (v/v) for the last two months up to 5 months of age, and then they were sacrificed and processed for electronic microscopy (EM). Brain of C and E groups were compared. The E group showed mild microencephaly, in most of the individuals. The light microscopy showed a decrease in the thickness of each layer examined. Some alterations, in patches, in subcellular structures: increase in the interlaminar space, altered distribution of both microtubules and neurofilaments, and the myelin sheaths, were shown through EM. These results with 2 months of ethanol intake, show a mild structural damage effects on the cerebral cortex, due to chronic ethanol intake. More studies are needed in order to relate this damage with the behavior in the rat.

662.11

IN UTERO ETHANOL EXPOSURE RETARDS GROWTH & ALTERS MORPHOLOGY OF CORTICAL CULTURES: GM1 REVERSES EFFECTS. H. Laev*, B.L. Hungund, V. Gokhale, & S.E. Karpiak. Divs. of Neuroscience, & Analyt. Psychopharm., NYSP; Dept. Psychiatry, Columbia U. (P&S) NY.

Ethanol, a developmental neurotoxin, affects plasma membrane physico-chemical properties. Its multiple actions in the developing CNS are complex, affecting embryogenesis, cell migration, differentiation & synaptogenesis. In a prior study using a model for the fetal alcohol effects, the neuroprotective lipid GM1 reduced fatty acid ethyl ester accumulations in rat fetuses exposed to ethanol *in utero* (GD7&8 and GD 13&14) (Hungund *et al.*, 1993). This study was initiated to further describe the *in utero* effects of ethanol, and the capacity of GM1 treatment to ameliorate such changes. Sprague-Dawley CWF dams were exposed to ethanol (23.4 g/kg i.g. *supra*). GM1 ganglioside (10mg/kg/i.m.) was given 24hrs & 1hr prior to each ethanol exposure. Cortical cultures were derived from GD15&20 fetuses. Since GM1 is highly localized on the cellular plasma membrane outer surface of CNS cells, we have used it as a marker molecule to assess cell integrity. We used cholera toxin/antitoxin/fluorescence immunohistochemistry to localize GM1. Cultures were stained at 24, 48, 96hrs and 7 & 14 days after plating. Results indicate that the brief *in utero* exposures to ethanol affected cell growth and morphology. We observed a marked retardation in cell development and arborization as early as 24hrs after plating. Also, there was a reduced number of viable cells (24hrs thru 14days). Control cells showed continuous staining for GM1 along outer plasma membranes. Ethanol exposed cells exhibited decreased and discontinuous membrane staining for GM1. This reduced staining is associated with the loss of membrane integrity (Laev *et al.*, 1993). These *in utero* ethanol induced pathologies are remarkably diminished in those cultures derived from fetuses of dams treated with GM1.

SEIZURE SUSCEPTIBILITY DURING WITHDRAWAL FROM ACUTE AND CHRONIC ETHANOL. D.A. Finn*, A.J. Roberts and J.C. Crabbe. Dept. Veterans Affairs & Dept. Med. Psychology, Oregon Health Sci. Univ., Portland, OR 97201.

The present studies were conducted to determine whether Withdrawal Seizure Prone (WSP) and Resistant (WSR) mice, which were selectively bred for differences in handling-induced convulsions following chronic ethanol (EtOH) inhalation, differed in seizure susceptibility to pentylenetetrazol (PTZ) and N-methyl-D-aspartate (NMDA) following chronic EtOH. Male WSP and WSR mice were exposed to EtOH vapor or air for 24 hrs. Once peak withdrawal had been attained, the animals were administered PTZ or NMDA via tail vein infusion. The threshold dose for onset to PTZ-induced tonic hindlimb extension (THE) was decreased in the EtOH vs. air exposed WSP and WSR mice. In contrast, the threshold dose for onset to NMDA-induced THE was unchanged in the EtOH exposed WSPs and increased in the EtOH exposed WSRs vs. their respective air exposed counterparts, suggesting a different time course for adaptation of GABA vs. NMDA receptor systems to chronic EtOH. Additional studies evaluated whether the decreased susceptibility to NMDA-induced seizures during withdrawal was due to an interaction with corticosterone (CORT), since circadian fluctuations in CORT alter seizure susceptibility to kainic acid (KA). WSP and WSR mice were administered EtOH (4 g/kg) or saline and were tail infused with KA during peak acute withdrawal. Separate groups were injected at 4:30 a.m. or 12:30 p.m., so that peak withdrawal would occur at the previously demonstrated minimum (a.m.) or maximum (p.m.) in seizure susceptibility to KA. The threshold dose for onset to KA-induced THE was increased in EtOH vs. saline injected WSP mice in both the a.m. and p.m. The threshold dose in EtOH vs. saline injected WSR mice was unchanged in the a.m. and increased in the p.m. These results suggest that the decreased susceptibility to NMDA receptor specific convulsants during peak withdrawal does not appear to be due to an interaction with CORT. Supported by grants from the VA and AA 08261 (JCC).

ETHANOL PARTIALLY NORMALIZES VESTIBULAR PRONATION OF PONTINE-DAMAGED RATS BUT DISRUPTS THAT OF UNDAAMAGED RATS. Rebecca M. Chesire* & Barbara E. Digman. Coll. Health Sciences & Psychol. Dept., Univ. Hawaii, Honolulu, HI 96822.

Acute or chronic ethanol (ETOH; 5-40%) does not abolish excessive forward locomotion in rats with damage of the nucleus reticularis tegmenti pontis (NRTP). Although ETOH interferes with motor activity in intact rats, it can improve some motor functions of NRTP-damaged rats. Pronation of the head and torso from a supine position in the air using an integrated sequence of movements is an index of neural integrity that is compromised by basal ganglia dysfunction. In NRTP-damaged rats, disruption of pronation is characterized by a change in form from lateral to ventroflexed righting. 11 female and 6 male Long-Evans hooded rats were lesioned electrolytically in the NRTP (1mA anodal current/15s bilaterally; n=8) or were used as controls (n=9). Testing was done over ~ 50 days during availability of tap water (TW), TW+25% sucrose (SU), or 5-30% ETOH in TW+SU in water bottles. A challenge dose (CD) of 30%ETOH was administered i.p. after 8hr withdrawal. Righting was tested by holding the animals in a supine position ~ 35cm above a 7cm thick pillow and releasing them (lateral form=1, ventroflexion=zero; 4 trials/animal/substance&dose). On TW, NRTP-damaged rats showed more ventroflexed than lateral righting (x=.5) and undamaged rats showed lateral righting exclusively (x=1.0). NRTP-damaged rats normalized slightly on SU (x=.6), but unoperated rats began to ventroflex (x=.87). At each level of ETOH, NRTP-damaged rats showed more lateral righting than on TW (x=.68 for 5-30%ETOH & .75 at 30%CD; range=.58-.75 vs. TW=.5), and unoperated rats showed less (x=.76 for 5-30%ETOH and .88 at 30%CD). The results indicate that ETOH can improve vestibular function in NRTP-damaged rats, and further support an appetitive role for ETOH in the presence of pontine damage.

662.12

EFFECT OF ALCOHOL EXPOSURE DURING DEVELOPMENT ON THE AMYGDALA REGION. C.R. Miyazaki and S.J. Kelly. Department of Psychology, University of South Carolina, Columbia SC 29208.

The early postnatal period in the rat is roughly equivalent to the third trimester in humans with respect to birth. Exposure to alcohol during this period has been shown to decrease the DNA concentration in the amygdala region of male rats at both 45 and 90 days of age. Female rats showed no effects. The decrease in DNA concentration suggests that there is an alcohol-induced decrease in cell number in the amygdala region, although the DNA concentration does not differentiate among cell types. In order to continue our investigation of the amygdala region, rats of both sexes were artificially reared and exposed to 5 g/kg/day of ethanol, artificially reared and not exposed to ethanol, or reared normally with dams. Rats were weaned at 21 days of age and housed with a same sex conspecific. At adulthood (130 days), the rats were deeply anesthetized with sodium pentobarbital and perfused intracardially with saline followed by 10% formaldehyde in phosphate buffer. The brains were removed and post-fixed in 10% formaldehyde for at least a week. The brains were cut into 40 um sections, mounted on slides, stained Luxol Fast Blue, and then counterstained with cresyl violet. A section at the level of the stria terminalis was identified and the area of the amygdala region was measured. Among female rats, no differences were found in the areal measurements of the amygdala region. (Supported by NIAAA Grant AA08080 to S.J.K.)

INHIBITORY EFFECT OF THE CALCIUM ANTAGONIST ISRADIPINE ON NICOTINE INTRAVENOUS SELF-ADMINISTRATION IN DRUG-NAIVE MICE. W. Fratta*, M.C. Martellotta, A. Kuzmin¹, E. Zvartau¹. Department of Neuroscience, University of Cagliari, Italy. ¹Department of Pharmacology, Pavlov Medical Institute, St. Petersburg, Russia.

Several reports indicate that nicotine positive reinforcing effect is associated with a selective activation of the mesolimbic dopamine system. Thus, in common with other drugs of abuse, such as morphine and cocaine, nicotine increases dopamine release in rat striatum and nucleus accumbens. We have recently shown that isradipine, an L-type dihydropyridine Ca²⁺ channel antagonist, inhibits the reinforcing properties of cocaine and morphine both in rats and mice. This effect is likely due to an inhibition of cocaine- and morphine-induced dopamine release. Here we show that isradipine dose-dependently and stereospecifically inhibits nicotine intravenous (i.v.) self-administration in drug-naive mice. In fact, nicotine induces a dose dependent i.v. self-administration response in drug-naive mice. Pretreatment with (±) isradipine dose-dependently inhibits nicotine i.v. self-administration in drug-naive mice. Furthermore, testing of both the isomers of isradipine reveals that only pretreatment with (+)isradipine is active in inhibiting nicotine i.v. self-administration in drug naive mice, while pretreatment with the (-)isomer is completely inactive. The possibility that the isradipine inhibitory effect might be related to an inhibition of nicotine-induced dopamine release seems to be very likely. Furthermore, these results might provide an indication for new therapeutic strategies in tobacco addiction.

663.3

AMPHETAMINE WITHDRAWAL-RELATED BEHAVIORS INDUCED BY MEDIAL PREFRONTAL CORTICAL INJECTIONS OF C-FOS ANTISENSE OLIGONUCLEOTIDES IN THE RAT.

A.M. Persico*, C.W. Schindler, S. Davis, E. Ambrosio and G.R. Uhl. Mol. Neurobiol. Branch, ARC/NIDA/NIH, Baltimore, MD 21224; Depts. Neurol. & Neurosci. JHUSM; Dept. NeuroPsychSci., S. Raffaele Hosp., Milan, Italy; Dept. Psicobiol., UNED, Madrid, Spain.

Prefrontal areas display most prominent decreases in immediate-early-gene expression during amphetamine withdrawal. We employed antisense technology *in vivo*, to assess whether prefrontal *c-fos* may play a role in behavioral correlates of rat amphetamine withdrawal.

Phosphorothioated antisense 18-mers aimed at the translation start site of the *c-fos* mRNA display a half-life of about 3 hrs, in contrast to 15-30 min for phosphodiester. Intracerebral medial prefrontal cortical injections of 2nM antisense, but not missense, phosphorothioated oligos, block *c-fos* mRNA translation, while exerting variable and inconsistent effects on *c-fos* mRNA levels. During *c-fos* translational blockade, animals display marked reductions in linear and repetitive locomotor behavior when exposed to a novel environment. No change in locomotor activity is evident in animals accustomed to the activity monitor. These changes closely mimic those recorded during amphetamine withdrawal and suggest that prefrontal *c-fos* may play a role in the chain of neurobiological events responsible for amphetamine withdrawal-induced behavioral alterations.

663.5

TRANSCRIPTION FACTORS INVOLVED IN THE METHAMPHETAMINE-INDUCED INCREASE IN STRIATAL DYNORPHIN EXPRESSION: EFFECTS OF CYCLOHEXIMIDE. D. Bronstein, I. Merchenthaler, K. Pennypacker, L. Perez Olano, P. Hudson, D. Chalmers* & J.-S. Hong. U. Michigan, Ann Arbor, MI & LMIN, NIEHS, Research Triangle Park, NC 27709.

The mechanism by which activation of dopamine receptors in the striatum leads to increased expression of the opioid peptide dynorphin (DYN) has been the subject of recent debate. In this study, the role of newly synthesized immediate early genes (e.g., *c-fos*, *c-jun*) in mediating the increased expression of DYN was addressed by using the protein synthesis inhibitor, cycloheximide (CHX). Adult male rats were pretreated bilaterally with vehicle or CHX (250 µg in 10 µl, i.c.v.), then injected with METH (10 mg/kg, s.c.) and sacrificed 6 hr later. Whereas METH caused only a slight reduction in DYN-ir concentrations in the striata of vehicle-pretreated animals, it caused a significant (35%) reduction in DYN levels in CHX-pretreated animals. This decrease was interpreted to indicate that CHX blocked the biosynthesis of new DYN-ir protein following the METH-induced release/depletion of intraneuronal DYN-ir. However, Northern analyses indicated that METH induced DYN mRNA levels to a comparable degree in CHX and control rats, suggesting that *de novo* biosynthesis of transcription factors (e.g., *c-fos* and *c-jun*) was not necessary to induce DYN mRNA expression. Rather, it supports recent data implicating phosphorylation of pre-existing CREB proteins (and subsequent binding to the CRE site) as a critical step in the regulation of DYN expression. We are presently assessing directly whether CHX affects the expression of transcription factor proteins or the binding activity to AP-1 or CRE DNA elements following METH administration.

663.2

NICOTINE ALLEVIATION OF NICOTINE ABSTINENCE IS NALOXONE-REVERSIBLE. M.C. Payne, O.B. Wilson*, J.R. Lake, V.A. Carter, J.S. Cunningham and D.H. Malin. *Baylor College of Medicine, Houston, TX 77030 and University of Houston-Clear Lake, Houston, TX 77058.

Recently, a rodent model of nicotine abstinence syndrome has been developed based on the frequency of spontaneous behavioral signs following termination of continuous nicotine tartrate infusion in rats. In this model, nicotine abstinence syndrome can be precipitated by naloxone and reversed by morphine as well as nicotine itself. The observed signs closely resemble those typical of rat opiate abstinence syndrome. To test the hypothesis that nicotine alleviation of nicotine abstinence is partly mediated by release of endogenous opioids, 28 rats were infused for 7 days with 9 mg/kg/day nicotine tartrate in saline via Alzet osmotic minipumps. Twenty-one hours following termination of nicotine infusion, 14 rats received 9 mg/kg naloxone s.c. and 14 received saline; 5 minutes later half of each group received 0.35 mg/kg nicotine s.c. and half received saline. Rats were then observed for 15 minutes under "blind" conditions.

Anova revealed a significant interaction effect of naloxone and nicotine injections. Post-hoc comparisons revealed that nicotine significantly reduced nicotine abstinence signs in the absence of naloxone but not in its presence. Conversely, naloxone had a significant effect in the presence of nicotine but not in its absence. The results are consistent with the hypothesis that there is an endogenous opioid peptide component in nicotine dependence and abstinence.

AMPHETAMINE REGULATION OF GENES ENCODING CELLULAR REGULATORS. X.B. Wang*¹, D. Vandenberg², and G.R. Uhl¹. ¹Mol. Neurobiology Br., NIH/NIDA, IRP; ²Depts. Neurol. & Neurosci., JHUSM, Balto., MD 21224.

Psychostimulant drugs such as amphetamine can induce dependence syndromes and presumed corresponding long-term changes in the CNS. Altered expression of genes may provide possible biochemical contributions to these drug induced long-term CNS changes. We have analyzed alterations in gene expression in brains of rats sacrificed 4 hours after injection of d-amphetamine (7.5 mg/kg, i.p.), using differential display PCR followed by differential hybridization. More than 20 bands which were changed after drug administration could be identified after amplification with two primer sets. Some were represented in all brain regions analyzed, and some showed region-specific patterns. Sequence analysis of two differentially-displayed products revealed high homologies with known genes. One product revealed 97% homology with the reported sequence of a calcium activable calmodulin-dependent phosphatase, calcineurin. Northern analysis showed that striatal calcineurin mRNA increased by 40% after d-amphetamine treatment. The second cDNA encoded a transducin-like factor. Hybridizing mRNA showed marked, approximately 10-fold, increases in striatum with changes in cortex and thalamus also notable. Products of genes acutely regulated by d-amphetamine are candidates for participation in drug-induced long-term changes in the CNS.

663.6

BEHAVIORAL SENSITIZATION TO AMPHETAMINE IS CORRELATED WITH A GREATER INCREASE IN C-FOS mRNA LEVELS IN THE STRIATUM OF RATS.

R. Rivest¹, R.A. Wise², T. Di Paolo¹ and S. Rivest³. ¹School of Pharmacy, ²Mol. Endo. Lab., CHUL, Laval university, Quebec and ³CSBN, Dept. of Psychol., Concordia Univ., Montreal.

Most studies exploring the neural basis of behavioral sensitization converge on the mesoaccumbens dopaminergic pathway. The mechanisms underlying this phenomenon may, however, be more complex and recent data suggest the participation of additional neurotransmitters. To better understand the mechanism of behavioral sensitization, we have performed *in situ* hybridization analysis of *c-fos* mRNA in the brain of animals sensitized to amphetamine. Male Long-Evans rats received daily injections of saline or amphetamine (1 mg/kg/ml) for 10 consecutive days. One week later they were given an acute challenge injection of saline or amphetamine (0.5 mg/kg). The animals were sacrificed 45 min or 3 h after the last injection and their brains were collected for further *in situ* hybridization analysis for *c-fos* mRNA. Amphetamine (1mg/kg) increased locomotor activity and the increase was progressively greater as animals received repeated injections. The challenge dose of 0.5 mg/kg in animals previously tested repeatedly with saline produced a slight increase in locomotor activity or *c-fos* mRNA levels in the striatum. The same treatment in animals previously tested with amphetamine resulted in a significantly greater increase in locomotor activity and *c-fos* mRNA levels. Characterization of the neurons in which *c-fos* responses to amphetamine are increased in sensitized animals is presently under investigations. Supported by the MRC.

663.7

PSYCHOSTIMULANT-INDUCED ENHANCEMENT OF FOS-LIKE IMMUNOREACTIVITY IN THE RAT CEREBELLUM. M.A. Klitenick, C.-S. Tham and H.C. Fibiger. Div. of Neurological Sciences, Dept. of Psychiatry, Univ. of British Columbia, Vancouver, B.C. V6T 1Z3

Previous studies have demonstrated increased locomotor activity and immediate-early gene expression in the cerebellum following the administration of various psychostimulants. In the present study, immunohistochemical techniques were used to assess the pattern of Fos-like immunoreactivity (FLI) in the cerebellum following acute, systemic administration of amphetamine and cocaine. Amphetamine (1.5, 6mg/kg) increased locomotor which could be blocked by pretreatment with the D1 dopamine receptor antagonist SCH 23390 (1 mg/kg). Within the cerebellum, amphetamine elicited a dose-dependent increase in FLI that was markedly attenuated by SCH 23390 pretreatment. In contrast, SCH 23390 pretreatment abolished the dose-dependent increase in locomotor activity and FLI following cocaine (10, 20 mg/kg). Psychostimulant-induced FLI was restricted to the granule cell layer within each of the midvermal cerebellar lobules (I-X) and distributed in dense clusters extending from the molecular layer to the Purkinje cell layer. Studies assessing the effects of acute, systemic caffeine administration on FLI in the cerebellum are in progress. Preliminary results indicate that caffeine (15 mg/kg) produces a somewhat different pattern of cerebellar FLI, with greater involvement of the molecular layer than seen following amphetamine and cocaine.

663.9

NBQX INHIBITS LOCOMOTOR ACTIVITY INDUCED BY APOMORPHINE IN DRUG-NAIVE BUT NOT SENSITIZED RATS. P. Laudrup and L.J. Wallace, Ohio State University, College of Pharmacy, Columbus, OH 43210.

The development of sensitization to apomorphine (apo), cocaine, and amphetamine is considered to be mediated by changes in dopamine neurotransmission. Since the acute effects of these agents involve activation of the AMPA receptor subtypes of glutamate receptors, the present study investigates whether the sensitized state is also characterized by a change in glutamate neurotransmission. On day 0, male rats were conditioned to the test cages. At each treatment day they were habituated for one hour, injected (NBQX i.p. and apo s.c.) and distance travelled measured for two hours by automated image analysis. In drug-naïve rats, NBQX (10 mg/kg), an AMPA antagonist, attenuated locomotor activity induced by apo (1 mg/kg) to 45%. However, when pretreated with apo (5 mg/kg) every third day during 13 days, the locomotor activity induced by apo (1 mg/kg) was increased, while NBQX only attenuated to 93%. Preliminary results indicate that sensitization to cocaine and amphetamine also decreases the inhibitory effect of NBQX. These results indicate that sensitization and a change in response to NBQX occurs simultaneously. Additional studies will elucidate if these changes are a part of sensitization and further describe the nature of the alterations. (Supported by a gift of NBQX from Novo Nordisk A/S and grant number DA07722).

EFFECTS OF ACUTE AND REPEATED AMPHETAMINE ADMINISTRATION ON EXTRACELLULAR GLUTAMATE AND ASPARTATE LEVELS IN RAT VENTRAL TEGMENTAL AREA AND NUCLEUS ACCUMBENS. Y. Li, C.-J. Xue and M.E. Wolf. Dept. of Neuroscience, Finch University of Health Sciences/The Chicago Medical School, North Chicago, IL 60064.

Behavioral sensitization refers to the progressive enhancement of the locomotor stimulatory effects of stimulants such as amphetamine (AMP) during their repeated administration. Considerable evidence indicates an important role in sensitization for mesoaccumbens DA neurons, originating in the ventral tegmental area (VTA) and projecting to nucleus accumbens (NAc). Recent work also supports a role for excitatory amino acid (EAA) transmission, since: 1) coadministration of N-methyl-D-aspartate antagonists prevents the development of sensitization, 2) it also prevents functional changes in the mesoaccumbens DA system which accompany sensitization, and 3) EAA receptor sensitivity in VTA and NAc is altered in AMPH-sensitized rats. These findings suggest that AMP administration may be associated with changes in EAA release in the VTA or NAc. However, using *in vivo* microdialysis in behaving rats, we found that AMP (2.5 mg/kg) failed to alter extracellular levels of aspartate or glutamate in the NAc of naïve or AMP-sensitized rats. Preliminary results in VTA are similar. Studies are underway to determine whether the efficiency of the glutamate transporter is masking AMP-induced changes in EAA release. In other studies, the quantitative "no net flux" method was used to determine basal extracellular levels of glutamate in NAc (estimated at 1.9 μ M). This method will be used to examine the effects of repeated AMPH administration on basal EAA levels and *in vivo* turnover rate. Supported by USPHS Grant DA 07735.

NBQX INHIBITS AMPHETAMINE-INDUCED LOCOMOTOR ACTIVITY BUT NOT C-FOS INDUCTION. A. Dalia, N.J. Uretsky, and L.J. Wallace. College of Pharmacy, Ohio State University, Columbus, OH 43210.

Administration of amphetamine activates the dopaminergic and the AMPA subtype of glutamate receptors as well as induces c-fos protein in the nucleus accumbens. A role for basal levels of c-fos in expression of locomotor activity is derived from the observation that administration of c-fos antisense oligonucleotide into the nucleus accumbens 5 hours before amphetamine blocked the locomotor response. Therefore, a possible correlation between activation of glutamatergic receptors, increases in c-fos protein, and stimulation of locomotor activity was explored. A behaviorally relevant dose of amphetamine (1 mg/kg, ip) elicited a small increase in c-fos protein and stimulated locomotor activity. Pretreatment with NBQX (2,3-dihydroxy-6-nitro-7-sulfamoyl-benzo(F)-quinoxalinedione) (30 mg/kg, ip), an AMPA receptor antagonist, had no effect on amphetamine-induced increase in c-fos protein but inhibited locomotor activity. NBQX alone had no effects on c-fos levels or locomotor activity. MK-801 (0.1 mg/kg, sc), an NMDA receptor antagonist, did not increase c-fos but stimulated locomotor activity. These data suggest that induction of c-fos is not correlated with stimulation of locomotor activity. (Supported by DA07722 and DA06776).

COMPETITIVE AND NONCOMPETITIVE NMDA-RECEPTOR ANTAGONISTS BLOCK NICOTINE-INDUCED DOPAMINE OVERFLOW. E. Museo and A. Pert. Biological Psychiatry Branch, National Inst. of Mental Health, Bethesda, MD 20892.

The psychomotor stimulant effects of nicotine are believed to be due, at least in part, to the activation of a dopaminergic substrate; one dopamine (DA)-containing region that appears to be involved is the nucleus accumbens (nAcb). We previously reported that the systemic or intra-nAcb administration of nicotine stereoselectively facilitates DA overflow in this region. The possibility has been raised that nicotine's actions on DA overflow are dependent on the integrity of glutamatergic transmission in the nAcb. The present experiment tested this hypothesis using two NMDA-receptor antagonists: the noncompetitive antagonist MK-801 and the competitive antagonist AP-5. Male, Sprague-Dawley rats were anaesthetized with chloral hydrate and a microdialysis probe was surgically positioned in the nAcb. All pharmacological treatments were administered through the probe and dialysate samples were collected and analyzed for DA content. Nicotine (100 μ M), on its own, increased nAcb DA overflow by approximately 50 percent; the intra-nAcb administration of either the noncompetitive antagonist MK-801 (100 μ M) or the competitive antagonist AP-5 (100 μ M) prior to and during the administration of nicotine (100 μ M) significantly reduced the magnitude of this effect. It appears that the blockade of glutamatergic transmission is sufficient to disrupt the actions of nicotine on DA overflow in the nAcb.

LESIONS OF PREFRONTAL CORTEX OR AMYGDALA, BUT NOT FIMBRIA FORNIX, PREVENT SENSITIZATION OF AMPHETAMINE-STIMULATED HORIZONTAL LOCOMOTOR ACTIVITY. S.L. Dahlin, X.-T. Hu, C.-J. Xue and M.E. Wolf. Dept. of Neuroscience, Finch University of Health Sciences/The Chicago Medical School, North Chicago, IL 60064.

A role for mesolimbic DA neurons in behavioral sensitization to amphetamine (AMPH) is well established. However, the fact that coadministration of N-methyl-D-aspartate antagonists prevents the development of both AMPH sensitization and associated changes in the mesoaccumbens DA system suggests that excitatory amino acid (EAA)-dependent events occur very early in sensitization and are critical to its initiation. This study sought to identify EAA projections required for sensitization, focusing on projections to nucleus accumbens (NAc) or ventral tegmental area (VTA). The major EAA projections to NAc originate in prefrontal cortex (PFC), basolateral amygdala (AMY) and hippocampus (HPC). PFC and AMY also send EAA projections to the VTA. Ibotenic acid lesions of PFC or AMY and electrolytic lesions of fimbria fornix were performed in rats. After 1 week, rats were treated with water or 2.5 mg/kg amphetamine (AMP) for 6 days and challenged with AMP on day 8. Activity was tested in photobeam cages on days 1 and 8. On day 1, control and sham-lesioned rats exhibited an early phase of stereotypy followed by a phase of horizontal locomotor activity; both phases exhibited sensitization on day 8. Lesions of fimbria fornix produced a general disinhibition of locomotor activity, but did not interfere with sensitization. Lesions of AMY or PFC failed to prevent sensitization of stereotypy, but eliminated sensitization of horizontal locomotion. Since both PFC and AMY, but not HPC, send EAA projections to VTA, these data may suggest that EAA projections from PFC and AMY to VTA are critical to the initiation of sensitization. USPHS Grant DA 07735.

BOTH TYPICAL AND ATYPICAL NEUROLEPTICS BLOCK PHENCYCLIDINE (PCP)-INDUCED STRIATAL AND BEHAVIORAL EXCITATION IN FREELY MOVING RATS. I. M. White*, G. S. Flory, J. Speciale, and G. V. Rebec. Program in Neural Science and Dept. of Psychology, Indiana University, Bloomington, IN 47405

The striatum plays a critical role in the behavioral excitation induced by amphetamine and other indirect dopamine agonists. In freely moving rats, amphetamine typically increases the activity of striatal neurons, and this effect is blocked by dopamine antagonists, which also attenuate amphetamine-induced behavioral effects. Phencyclidine (PCP), a non-competitive NMDA antagonist with little or no affinity for dopamine receptors, induces a similar pattern of behavioral excitation, but little information is available on the striatal mechanisms underlying this effect. In the present series of experiments, we assessed the effects of PCP (1.0 - 5.0 mg/kg) on single-unit activity in the striatum of awake, behaving rats. Like amphetamine, PCP routinely increased striatal activity, and this effect was reversed by subsequent injection of either haloperidol (1.0 mg/kg) or clozapine (20.0 mg/kg), typical and atypical neuroleptics, respectively. To the extent that neuroleptics act primarily as dopamine antagonists, our results suggest a striatal dopamine-NMDA interaction in the behavioral effects of PCP.

AMPHETAMINE- AND COCAINE- INDUCED FOS IN THE RAT STRIATUM DEPENDS ON D₂ DOPAMINE RECEPTOR ACTIVATION. D.N. Ruskin* and J.F. Marshall. Department of Psychobiology, University of California, Irvine, CA 92717.

Amphetamine or cocaine injection causes expression of the immediate-early gene *c-fos* in the striatum. Previous studies have shown that dopamine D₁ receptor activation is necessary for this effect, but have not established a consistent role for D₂ receptors. We have investigated the involvement of D₂ receptors in indirect agonist-induced striatal Fos-like immunoreactivity using the selective D₂ antagonist eticlopride. Rats received eticlopride (0.5 mg/kg) or saline 30 min before receiving amphetamine (5 mg/kg), cocaine (40 mg/kg), or saline. All injections were I.P. Two hr after the second injection, the rats were perfused with 4% paraformaldehyde and their brains sectioned at 40 µm through the striatum for immunocytochemistry. Eticlopride treatment caused Fos expression by itself, but also decreased Fos expression in the central striatum due to amphetamine or cocaine by 90% and 85%, respectively. In striatonigral neurons, identified by labeling with the retrograde tracer Fluorogold iontophoresed into the substantia nigra pars reticulata, the blockade of stimulant-induced Fos-like immunofluorescence by eticlopride was nearly complete, with decreases of 98% for amphetamine and 94% for cocaine. In striatonigral neurons, the D₂ antagonist alone induced minimal Fos. We conclude that activation of both D₁ and D₂ receptor classes by dopamine agonists is necessary for induction of Fos in the striatonigral cells of normal rats. These results provide an important parallel to behavioral and electrophysiological work that also demonstrates D₁/D₂ interdependence in the control of normal basal ganglia functions.

STIMULANT-INDUCED FACILITATION OF SELF-STIMULATION IS POSITIVELY CORRELATED WITH MEDIAL DISTANCE OF ELECTRODE FROM SUBSTANTIA NIGRA. S.A. Khan*, S.L. Fledderjohann, V.L. Tsibulsky, S.R. Grocki, R.A. Frank. University of Cincinnati, Cincinnati, OH 45221-0376. We studied the effects of amphetamine and cocaine on self-stimulation train-duration thresholds in rats implanted with bipolar electrodes (0.2 mm) in A9 and A10 dopaminergic regions of the midbrain. Amphetamine (1.0mg/kg, n=29) or cocaine (15mg/kg, n=14) was injected IP 15 min prior to self-stimulation testing. Electrode placements for 43 male rats were independently verified by three researchers and compared with drug effects. The distance between the electrode placement and the brain midline was measured. The correlation of this distance with stimulant-induced facilitation of self-stimulation was $r = -.43$, $p < .004$. Inspection of the data suggested that stimulation sites closest to substantia nigra, pars compacta showed the least stimulant-induced facilitation of self-stimulation. The correlation between drug effect and distance of electrode from the substantia nigra was $r = .44$, $p < .003$. The findings indicate that amphetamine and cocaine may differentially influence self-stimulation obtained from the A9 and A10 regions.

THE ROLE OF DOPAMINE D₃ RECEPTORS IN BEHAVIORAL SENSITIZATION, SENSITIVITY TO APOMORPHINE, AND BASAL DOPAMINE SYNTHESIS. F.M. Robinet*, B.A. Mattingly, J.K. Rowlett & M.T. Bardo. Departments of Psychology, Morehead State Univ., Morehead, KY 40351 and Univ. of Kentucky, Lexington, KY 40506.

Behavioral sensitization to repeated treatments of the mixed D₁/D₂ dopamine (DA) receptor agonist apomorphine (APO) can be blocked by the D₁ antagonist SCH 23390 but not D₂ antagonists. Further, APO increases basal DA synthesis as does the D₂/D₃ agonist quinpirole. This effect is blocked by the D₂ antagonist eticlopride. While behavioral sensitization to APO appears to be D₁ mediated D₂ receptors may be involved in the increased DA synthesis. The current study assessed the role of DA D₃ receptor activation in locomotor activity, sensitivity to APO and basal DA synthesis. In two experiments, the D₃ selective agonist 7-OH-DPAT was administered at 24 hour intervals for 10 consecutive days (0.0, 0.01, 0.1, 1.0 mg/kg). Following each injection locomotor activity was recorded for 20 min. On day 11 in experiment 1, all rats received a challenge injection of APO (1.0 mg/kg) and their locomotor activity was recorded. On day 11 in experiment 2, all rats were injected with the DOPA decarboxylase inhibitor NBD1015 (100 mg/kg). After 30 min the brains were removed and DA synthesis was assessed by measuring DOPA accumulation in the extracted tissue. Locomotor activity was initially inhibited at the higher doses (0.1, 1.0 mg/kg) but increased to control levels by day 10. The low dose (0.01 mg/kg) also inhibited activity initially but in contrast to the higher doses, this inhibition increased with repeated treatment. No increase in sensitivity to APO was found at any dose. Also, chronic treatment did not significantly increase basal DA synthesis. These findings suggest that the development of behavioral sensitization to APO, and the accompanying increase in basal DA synthesis, is not mediated by D₃ receptor activation. (Supported by grants from the Kentucky/NSF EPSCoR committee and Morehead State University).

EFFECT OF INTRAVENOUS SELF-ADMINISTRATION OF *d*- and *l*-AMPHETAMINE ON NUCLEUS ACCUMBENS (NAc) DOPAMINE LEVELS. K. Leeb* and R.A. Wise. Center for Studies in Behavioral Neurobiology, Concordia University, Montreal, Quebec, Canada, H3G 1M8.

Rats given limited access to a variety of stimulant drugs self-administer these drugs with very regular inter-response rates (Pickens and Thompson, 1968; Yokel and Pickens, 1974). To date, the variables responsible for maintaining such a regular pattern of responding for drug have not been fully established. Because amphetamine (AMPH) increases extracellular levels of dopamine (DA) in the NAc we investigated whether fluctuations in dopamine correlate with responding for drug. Male Long-Evans rats with chronic intravenous catheters and intra-accumbens guide cannulae were trained to lever-press for infusions of either 0.25 mg/kg *d*-AMPH or 0.75 mg/kg *l*-AMPH in 4h daily sessions. Once stable self-administration was established animals underwent microdialysis during drug self-administration. Dialysate samples were taken every 5 min and frozen for subsequent determination of DA concentration using HPLC with electrochemical detection. Self-administered AMPH caused rapid elevation of DA levels to 300-500% of baseline, and these elevations were sustained, more or less, for the remainder of the session. However, there were phasic fluctuations in DA, superimposed on the tonic elevations, that were time-locked to lever-presses and the consequent drug injections; DA levels usually increased after each injection and fell prior to the next response. Thus the initiation of a drug-seeking response (e.g., a lever-press) was triggered in the absence of dopamine depletion and, indeed, long before dopamine concentration fell significantly toward basal levels.

RESERPINE ABOLISHES AMPHETAMINE-INDUCED DOPAMINE RELEASE IN VENTRAL MIDBRAIN NEURONAL CULTURE. C. St. Remy, S. Rayport and D. Sulzer*. Depts Psychiatry, Neurology, Anatomy & Cell Biology; Ctr Neurobiology & Behavior, Columbia Univ; Dept Neuropathology, NYS Psychiatric Institute, NY 10032.

Amphetamine-induced (AMPH-induced) dopamine (DA) release has been suggested to occur via actions at plasma membrane uptake transporters or at synaptic vesicles. Since several studies have reported that reserpine, which depletes vesicular DA, does not reduce AMPH-induced DA release, action at the vesicular level has been controversial. However, in these studies reserpine was administered *in vivo* 18 to 24 h prior to AMPH, providing sufficient time for increased DA synthesis or other time-dependent effects. To circumvent these issues, we used postnatal ventral midbrain DA neuron cultures, in which stimulation-dependent, AMPH-induced DA release and total cellular DA content can be reliably and concurrently measured. We found that reserpine (100 nM) reduced stimulation-dependent (40 mM KCl for 3 min) DA release by 60% after 15 min and by 90% after 60 min. At a higher concentration, reserpine (1 µM) reduced stimulation-dependent DA release to undetectable levels and total cellular DA by 95% at 90 min. In control cultures, 10 µM AMPH induced a 250% increase in extracellular DA, while following reserpine (1 µM for 90 min) AMPH induced only a 3% increase. Strikingly, AMPH released over 3-fold more DA from untreated cultures than the total DA content of reserpinized cultures. Together with *in vivo* microdialysis studies (Sabol et al., *Soc Neurosci Abstr*, 1993), this indicates that AMPH releases DA primarily from the vesicular pool, consistent with the weak base model of AMPH action (Sulzer et al., *J Neurochem*, 1993).

AGE-DEPENDENT PERSISTENCE OF FENFLURAMINE EFFECTS ON MONOAMINERGIC NEURONS IN REAGGREGATE TISSUE CULTURE. L. Won*, P.C. Hoffmann and A. Heller, Dept. of Pharmacological & Physiological Sciences, University of Chicago, Chicago, IL 60637.

The three-dimensional reaggregate tissue culture system provides a useful approach to examine the effects of drug exposure on the subsequent development of monoaminergic neurons. Utilizing this system, we have previously demonstrated that exposure of 15 day old reaggregates, containing developing monoaminergic cells (equivalent in development to postnatal day 7 neurons), to 10^{-5} M (\pm) fenfluramine (FEN) for 7 days resulted in significant reductions of reaggregate dopamine (DA) and serotonin (5-HT) levels and this deficit persisted for 3 weeks following cessation of drug exposure. In order to examine the possible age-dependency of such effects, 2 month old reaggregate cultures composed of murine mesencephalon and corpus striatum cells (equivalent in development to adult neurons) were exposed to 10^{-5} M (\pm) FEN for 7 days and then were allowed to recover in drug-free medium for 3 weeks. At the end of the 7 day exposure to FEN, DA and 5-HT levels in reaggregates were significantly depressed to 35% and 69% of control levels, respectively. By the end of the 3 week recovery period, DA levels in FEN-treated reaggregates had attained similar values to those in control cultures whereas 5-HT levels in reaggregates exposed to FEN remained significantly depressed (52% of control). Thus, in reaggregate culture, both DA and 5-HT neurons are susceptible to the persistent effects of FEN during early development. With mature neurons, such longlasting effects are only observed on 5-HT neurons as is seen in the intact adult brain. Supported by MH42134.

ADMINISTRATION OF PERTUSSIS TOXIN IN THE VENTRAL TEGMENTAL AREA DOES NOT ENHANCE THE LOCOMOTOR STIMULATION PRODUCED BY APOMORPHINE. J.J. Byrnes*, D.M. Weinstein, S. Narayanan, N.J. Uretsky, L.J. Wallace, Ohio State University, College of Pharmacy, Division of Pharmacology, Columbus, Ohio 43210

Repeated administration of amphetamine, cocaine, or apomorphine produces a progressively enhanced locomotor response. Recently it has been found that the bilateral administration of pertussis toxin (PTX) into the ventral tegmental area (VTA), the location of the cell bodies of mesolimbic dopaminergic neurons, produces an enhanced locomotor response to amphetamine and cocaine similar to the changes seen in animals sensitized to these agents. This suggests that changes produced by PTX mediate the development of sensitization to drugs that act presynaptically to increase dopaminergic transmission. In the present study we investigated whether administration of PTX into the VTA produces a sensitized locomotor response to apomorphine, which directly activates dopamine receptors. Rats were injected into the VTA with PTX (0.5 μ g/0.5 μ l per side) or vehicle, and 14 to 21 days later, the locomotor responses to amphetamine (0.5 mg/kg, i.p.) or apomorphine (1 and 5 mg/kg, s.c.) were determined. Animals treated previously with PTX showed a markedly enhanced locomotor response to amphetamine compared to vehicle-treated animals. However, the response of PTX-treated animals to either dose of apomorphine was not significantly greater than that of vehicle pretreated controls. Thus, while pretreatment with PTX in the VTA mimics some of the components of sensitization produced by drugs that indirectly stimulate central dopamine systems, it is not sufficient to produce a sensitized response to a directly acting dopamine agonist. (Supported by DA07722 and DA06776)

CORRELATIONS OF NOVELTY AND AMPHETAMINE INDUCED LOCOMOTION IN RATS WITH MICRODIALYSIS MEASUREMENTS OF DA NEURONAL FUNCTION. A. Pap* and C.W. Bradberry, Yale Univ. Sch. Med., Dept. of Psychiatry and the West Haven VA Hospital, West Haven, CT 06516

Using a circular runway locomotor chamber, we have been investigating biochemical correlates of novelty induced locomotion. Previous work by Piazza, et al. indicates this is predictive of amphetamine induced locomotion and of amphetamine self-administration. Novelty and amphetamine induced locomotion were assessed on two separate days, separated by at least two days. Individual locomotor scores from the two sessions were highly correlated. Following amphetamine challenge, animals were implanted with microdialysis guide cannulae overlying the nucleus accumbens, and after at least 48 hours, were implanted with microdialysis probes which were left in place overnight for experiments the following day. The first study examined the correlation of locomotor scores (both novelty and amphetamine) with basal DA (as assessed by *in vitro* probe recovery), and peak DA levels following local infusion (via the microdialysis probe) of 3 μ M amphetamine for one twenty minute collection period. Significant correlations were seen between locomotor scores and basal DA, but not between locomotor scores and peak DA following amphetamine infusion expressed either as an absolute level, or as a percent of basal. Basal levels also did not correlate with peak levels. In a separate study, 3 μ M DA was infused, and the *in vivo* recovery was determined. Justice's group has demonstrated that *in vivo* recovery is primarily a function of DA uptake. In this group, a non-significant trend ($p = 0.10$) toward a correlation was seen between *in vivo* recovery and locomotor-induced novelty, but not with amphetamine induced novelty. Supported by DA 08073, DA 08227, The Yale VA Alcoholism Research Center, and a NARSAD Young Investigator Award to CWB.

THE STIMULATION OF LOCOMOTION BY MK-801 IS MEDIATED BY THE ACTIVATION OF MESO-LIMBIC DOPAMINERGIC NEURONS. S. Narayanan, A. Dalia, L.J. Wallace, N.J. Uretsky*, Ohio State University, College of Pharmacy, Division of Pharmacology, Columbus, Ohio 43210

Low doses of MK-801 (0.05-0.25 mg/kg), a noncompetitive antagonist of NMDA receptors, stimulates coordinated locomotor activity by enhancing dopamine (DA) neurotransmission in the nucleus accumbens (N.Ac). This stimulation may be related to the ability of this drug to increase the firing rate of meso-limbic DA neurons. To test this hypothesis, we have studied the locomotor response to MK-801 in rats after administration of baclofen, a GABA-B agonist that inhibits the firing rate of meso-limbic DA neurons, into the ventral tegmental area (VTA). MK-801 (0.1 mg/kg, i.p.) stimulated locomotor activity, and this effect was inhibited by baclofen (0.15 nmoles per side) injected into the VTA. This inhibitory effect appears to be related to an action on meso-limbic DA neurons, since baclofen did not inhibit the locomotor response to apomorphine (5 mg/kg, s.c.), which is mediated by the activation of DA receptors postsynaptic to the DA terminals. To determine whether the locomotor response to systemic MK-801 is due to its action in the VTA or the N.Ac, MK-801 (1-20 μ g) or vehicle was injected into each of these sites and produced a stimulation of locomotor activity; the potency and maximum response to MK-801 were greater after its injection into the VTA. The locomotor response to MK-801, 10 μ g (30 nmoles) per side into the VTA, was inhibited by the coadministration of baclofen (0.15 nmoles per side). In contrast baclofen did not inhibit the locomotor response to MK-801 (10 μ g per side) injected into the N.Ac. Thus, the locomotor stimulant effect of systemic MK-801 may be mediated by an action of this drug in the VTA, producing an increase in the activity of DA neurons, resulting in an enhancement in DA neurotransmission in the N.Ac. Supported by grant DA07722

REDUCED RESPONSIVENESS OF D1 RECEPTOR DEFICIENT MICE TO THE EFFECTS OF D1 SELECTIVE AGONISTS, ANTAGONISTS AND D-AMPHETAMINE IN TESTS OF LOCOMOTOR ACTIVITY AND CATALEPSY. L.H. Golt*, M. Xu, J. Polis, C. Heyser, S. Tonegawa and G.F. Koob, Dept. of Neuropharmacology, The Scripps Research Institute, La Jolla, CA, 92037 and Center for Cancer Research, Massachusetts Institute of Technology, Cambridge, MA 02139.

Dopamine one (D1)-receptor deficient mice were created through introduction of a deletion in the D1 gene of mouse embryonic stem (ES) cells by homologous recombination. ES cells carrying the D1 deletion were injected into mouse blastocysts to generate chimeric mice which were then bred to obtain homozygous mutant mice. The complete absence of D1 receptors was verified by genomic Southern analysis. In wild-type mice, the D1 agonist SKF81297 (1.2, 4.8, and 7.4 mg/kg, s.c.) produced a dose-dependent increase in locomotor activity compared to saline levels, while SKF81297 had no effect in D1-deficient mice. The D1 antagonist SCH23390 (10, 30 μ g/kg, s.c.) produced a dose dependent reduction in locomotor activity in the wild-type mice, while not altering locomotion in the D1-deficient mice. SCH23390 (0.05, 0.1, 0.2 mg/kg, s.c.) also produced dose-dependent increases in catalepsy in the wild-type mice, measured as percent of time immobile in an elevated ring-procedure, but was ineffective in the D1-deficient mice. Interestingly, the D1-deficient mice exhibited a marked attenuation of the locomotor stimulation produced by d-amphetamine (1, 3 mg/kg, s.c.), an indirect dopamine agonist, compared to wild-type mice. These results demonstrate that D1 receptor ligands are ineffective in D1 receptor deficient mice in behavioral assays of motor activity, and support the further use of these mice to investigate the relationship between D1 and D2 receptors in the behavioral actions of psychostimulant drugs and drug reinforcement.

SELECTIVE INVOLVEMENT OF DOPAMINE D1 RECEPTORS OF THE VTA IN THE BEHAVIORAL SENSITIZATION INDUCED BY INTRA-VTA AMPHETAMINE INJECTIONS. Y. Bijou, L. Stinus, M. Le Moal and M. Cadot*, Unité INSERM U259, rue Camille Saint Saëns 33077 Bordeaux Cedex, France.

In agreement with previous studies, we demonstrated the complete independence of the neurobiological substrates responsible for the induction and the expression of the behavioral sensitization to amphetamine (AMPH). Using a local approach, we showed that AMPH injected at the level of the dopamine (DA) cell bodies (0, 1, 2.5, 5 μ g/0.5 μ l/side) dose-dependently induced a behavioral sensitization to a later challenge with AMPH administered into the nucleus accumbens (1 μ g/ μ l/side) whereas the repeated administration of AMPH into the nucleus accumbens (0, 1, 3, 10 μ g/0.5 μ l/side) did not produce such effect. In order to specify the mechanisms through which AMPH acts in the VTA, we studied the respective involvement of VTA DA-D1 and -D2 receptors in the behavioral sensitization produced by intra-VTA administration of AMPH. In Experiment I, different groups of rats received 4 injections (1 every other day) of different doses of the D1 antagonist SCH-23390 (0, 0.01, 0.1, 1 μ g/0.5 μ l/side) in the VTA followed immediately by intra-VTA administration of AMPH (5 μ g/0.5 μ l/side) or its solvent. Two, 4 and 12 days following the last intra-VTA injection, peripheral challenges were performed with saline (day2) and AMPH (0.5 mg/kg, s.c., day 4 and 12) respectively. Locomotor activity was measured following each injection. In Experiment II, the same protocol as Experiment I was performed but the DA-D2 antagonist sulpiride (10 μ g/0.5 μ l/side) or the serotonin 5-HT2 antagonist ketanserin (1 μ g/0.5 μ l/side) was used for the VTA pretreatment. Results demonstrated that: 1) VTA AMPH pretreatment induced behavioral sensitization as revealed by the potentiation of the response to later peripheral challenges with AMPH. 2) VTA DA-D1 receptor blockade dose-dependently prevented this behavioral sensitization. 3) neither DA-D2 nor 5-HT2 receptor blockade at the doses used had any effect. In conclusion, these results demonstrate clearly the selective involvement of the dopamine D1 receptors of the VTA in the induction of behavioral sensitization to AMPH.

663.25

PRE- AND PERINATAL METHAMPHETAMINE EXPOSURE PRODUCES NEUROCHEMICAL CHANGES IN MATERNAL BUT NOT IN DEVELOPING RAT BRAIN. X.M. Meng, G.D. Newport, M.G. Paule* and S.F. Ali. Neurochemistry Laboratory, Division of Neurotoxicology, NCTR/FDA, Jefferson, AR 72079-9502.

Methamphetamine (METH) is one of the drugs of abuse known to cause neurotoxicity in the adult rodent and nonhuman primate. Little attention has been focused on the evaluation of pre- or perinatal exposure to METH on the developing brain. The present study was designed to evaluate whether pre- or perinatal exposure to METH produces changes in monoamine levels in maternal or developing pup brain. Pregnant CD rats were injected sc with either 0, 2.5 or 5 mg/kg METH daily on gestational days 6 through postnatal day (PND) 21. Pups were sacrificed on PNDs 1, 7, 14 or 21 and dams were sacrificed 24 hours after the last dose (PND 22). Monoamine levels were measured by HPLC/EC. Pre- and perinatal exposure to METH had little effect on monoamine levels in different brain regions at PNDs 1, 7, 14 and 21. However, in maternal brain, dopamine levels were significantly decreased in the caudate nucleus. It is concluded that pre- and perinatal exposure to METH at these doses produces significant alterations in the maternal but not in the developing rat pup brain monoamine levels.

663.27

THE EFFECTS OF RISPERIDONE AND MDL 28,133 ON AMPHETAMINE-INDUCED SELF-STIMULATION THRESHOLDS. S.R. Grocki*, V.L. Tsibulsky, B.A. Dashevsky, R.A. Frank. University of Cincinnati, Cincinnati, OH 45221-0376.

This experiment assessed the ability of D_2 -5HT₂ antagonists to reverse amphetamine-induced facilitation of brain stimulation reward. It has been shown previously that specific 5HT₂ antagonists alone do not reverse amphetamine-induced facilitation of self-stimulation in the VTA. We speculated that the mixed antagonists would have a greater effect than more specific antagonists. Risperidone (.1 & .2 mg/kg) and MDL 28,133 (1.5, 3, 5, 6, & 7.5 mg/kg) were injected 15 min. prior to amphetamine. Both doses of Risperidone and the two highest doses of MDL 28,133 significantly decreased the effects of amphetamine. However, the ability of both drugs to reverse amphetamine's effects could be predicted from the elevation in thresholds produced by the antagonists alone. Therefore, it seems likely that the ability of the mixed antagonists to reverse amphetamine's effects is due to their D_2 component.

This project was supported by NIDA grant # DA 04483 and a grant from Marion Merrell Dow. Acknowledgements to Marion Merrell Dow for supplying MDL 28,133 and Janssen Research Foundation for supplying Risperidone.

SEROTONERGIC RELEASE INDUCED BY MDMA, MDA AND FENFLURAMINE IN CULTURE: EFFECTS OF CHRONIC ADMINISTRATION. C.E. Hyde*, C.E. Hollingsworth, B.A. Bennett. Dept Physiol/Pharmacol, Bowman Gray Sch. Med., Wake Forest Univ., Winston-Salem, NC 27157

Substituted amphetamines such as 3,4-methylenedioxymethamphetamine (MDMA), 3,4-methylenedioxyamphetamine (MDA) and fenfluramine (FEN) are agents that are selective for serotonergic neurons. These compounds are thought to exert their effects by releasing serotonin (5HT) from presynaptic nerve terminals. Here we report on the acute mechanism by which MDMA, MDA and FEN induce 5HT release in primary cultures of fetal rat neurons. Data indicate that release of 5HT by these agents is concentration dependent. Furthermore, these agents promote release in a manner that is not affected by calcium channel blockers (1 μ M conotoxin GVIA, 10 μ M nifedipine) or by the absence of calcium from the media (calcium free media with 100 μ M EGTA). In addition, depletion of the vesicular pool by continuous potassium stimulation (50 mM which eliminates potassium induced 5HT release) had no effect on 5HT release by these agents. However, fluoxetine (50nM), an agent known to inhibit the transporter, attenuated the acute release of 5HT induced by these compounds. This data is consistent with the notion that release by these agents is via a non-vesicular, transporter-mediated event. Studies were initiated to examine adaptive changes in serotonergic function following a chronic (5 day) exposure to MDMA, MDA, and FEN. Data indicate that 5 day exposure to 1 μ M MDMA, MDA, and FEN cause a marked decrease in release capabilities of these neurons following a challenge exposure. These studies agree with recent reports of MDMA- and FEN-induced reductions in 5-HT transporter mRNA. Further studies will determine if these changes in 5HT release are a reflection of decreased transporter number (V_{max}). Supported by NIDA grants 05073, 06634 (BAB), 07246 (CEH).

THE EFFECT OF BODY TEMPERATURE ON THE RAPID DECREASE IN TRYPTOPHAN HYDROXYLASE ACTIVITY INDUCED BY 3,4-METHYLENEDIOXYMETHAMPHETAMINE. S. Che, J.W. Gibb, G.R. Hanson and M. Johnson*. Dept. of Pharmacology and Toxicology, University of Utah, Salt Lake City, UT 84112.

Brain tryptophan hydroxylase (TPH) activity decreases within 2 hours after a single administration of 3,4-methylenedioxy-methamphetamine (MDMA). In this study, the effect of body temperature on this rapid decrease of TPH activity was examined. Male Sprague Dawley rats (180-220 g) were administered a single dose of MDMA (20 mg/kg) or saline, and were maintained at 25°C or 7°C for 2 hours. After this period of time, rectal temperature was measured and the animals were killed. The body temperature of the MDMA-treated rats kept at 25°C was increased by 1.2°C when compared to their control group, whereas the body temperature of MDMA-treated rats kept at 7°C was decreased by 1.1°C. The rectal temperature of control animals maintained in the cold room was not altered. TPH activity measured in the hippocampus, striatum and frontal cortex of hyperthermic rats treated with MDMA was decreased to 60%, 64% and 70% of control, respectively. However, under hypothermic conditions, MDMA administration had no effect on TPH activity in the hippocampus, striatum or frontal cortex. These results suggest that body temperature may affect the rapid decrease of TPH activity induced by MDMA. (Supported by USPHS grants DA 00869 and DA 04222)

THE EFFECTS OF ETICLOPRIDE, MDL 100,907 AND THEIR COMBINATION ON AMPHETAMINE- AND COCAINE-INDUCED FACILITATION OF SELF-STIMULATION. V.L. Tsibulsky*, B.A. Dashevsky, R.A. Frank. Brain Stimulation Lab, University of Cincinnati, Cincinnati, OH 45221-0376.

It was speculated that the combination of D_2 and 5HT₂ antagonists could be more effective against stimulant-induced facilitation of brain stimulation reward in VTA than either compound separately. We used the specific D_2 antagonist eticlopride and specific 5HT₂ antagonist MDL 100,907 to test this hypothesis. ETIC (0.01-0.066 mg/kg) and MDL 100,907 (0.66-2.0 mg/kg) or their combinations were injected 15 min prior to amphetamine (0.33-1.0 mg/kg) or cocaine (7.5-30 mg/kg). ETIC decreased the effects of both stimulants, while MDL 100,907 had no effect either alone or in combination with the D_2 antagonist. These results indicate that 5HT₂ receptors are not involved in mediation of VTA brain stimulation reward or stimulant-induced facilitation of self-stimulation.

This project was supported by NIDA grant # DA 04483. We gratefully acknowledge the gift of MDL 100,907 and a grant from Marion Merrell Dow.

AMPHETAMINE INFUSION INTO THE MEDIAL SEPTAL AREA INCREASES BEHAVIORAL AND EEG INDICES OF AROUSAL: POSSIBLE INVOLVEMENT OF NORADRENERGIC β -RECEPTORS. C.W. Berridge*, S. Bolen, S.L. Foote. Dept. Psychiatry, Univ. Calif., San Diego, CA 92093.

Previous studies indicated that the medial septal/diagonal band region (MS) is a site at which the LC-noradrenergic system, via actions at noradrenergic β -receptors, acts to influence forebrain EEG. Given that stimulants, such as amphetamine, enhance noradrenergic transmission it is hypothesized that stimulants may enhance arousal, in part, through the enhanced release of norepinephrine within MS. As an initial step in the testing of this hypothesis, three series of studies were conducted. First, the EEG effects of small infusions (150 nl) of AMPH (3.75 μ g) or vehicle into MS were examined in the halothane-anesthetized rat. Infusions were made into MS, nucleus accumbens, striatum, or the substantia innominata/ nucleus basalis region. Unilateral MS AMPH (but not vehicle) infusions elicited bilateral forebrain EEG activation. AMPH had no EEG effects in sites other than MS. Second, to assess the degree to which β -receptors contribute to EEG activation following systemic AMPH administration, vehicle or the β -antagonist, timolol (TIM; 75-150 μ g), was administered ICV (2 μ l) 15-30 min prior to an intravenous AMPH injection (0.1 mg/kg) in the halothane-anesthetized rat. Pretreatment with TIM (but not vehicle) blocked the AMPH-induced activation of forebrain EEG. Finally, the effect of AMPH infused into MS on behavior in unanesthetized rats was examined. Unilateral infusions (150 nl) of vehicle or AMPH (3.75 μ g) were made into MS or adjacent brain regions in resting rats in which a 33 ga. needle loaded with drug or vehicle had been inserted via a 26 ga. guide cannulae 90 min prior to infusion. AMPH significantly increased waking behavior (approx. 40 min) in the 60 min following the infusion, compared to vehicle (approx. 5 min). AMPH had no significant effects on waking behavior when infused unilaterally into nucleus accumbens at this dose and volume of infusion. These results suggest that actions at β -receptors within MS may contribute to the arousal-enhancing properties of stimulants.

The Delta-Opioid Receptor Antagonist Naltrindole Attenuates Amphetamine-Induced Increases in Extracellular Dopamine in the Striatum of Rats. C.A. Schadt, J.B. Justice, Jr., and S.G. Holtzman. Departments of Pharmacology and Chemistry¹, Emory University, Atlanta, Georgia, 30322.

The opioid receptor antagonist naltrindole (NTI), a selective delta-opioid receptor antagonist, has been shown to attenuate both the behavioral and neurochemical effects of amphetamine in rats. Furthermore, the amphetamine-induced increase in locomotor activity is attenuated by intracerebrally-administered naltrindole (NTI), a selective delta-opioid receptor antagonist. This suggests a role of central delta-opioid receptors in the mediation of the behavioral effects of amphetamine. Therefore, this research was designed to look at the effects of NTI on the amphetamine-induced increase in extracellular dopamine (DA) in the brain of rats.

Microdialysis was performed on adult male rats (300-350g) that were pretreated with an intracerebral (IC) injection of 3, 10, or 30 µg NTI or vehicle. Pretreatment injections were followed 15 min later by cumulative doses of subcutaneous *d*-amphetamine (0.0, 0.1, 0.4, 1.6, 6.4 mg/kg) at 30 min intervals. The microdialysis probes were perfused at a flow rate of 0.6 µl/min and dialysate samples were collected every 10 min from either the nucleus accumbens (NACC) or striatum (STR).

Amphetamine dose-dependently increased extracellular DA in both the NACC and STR, as reported previously. NTI, 3, 10, and 30 µg IC, significantly reduced the DA response to amphetamine in the STR. In contrast, 30 µg of NTI did not modify the DA response to amphetamine in the NACC. These findings suggest that delta-opioid receptors play an important role in mediating the amphetamine-induced increase in extracellular DA in the STR, but not in the NACC.

GENETICALLY VARIABLE CYTOCHROME P4502D1 IN THE BRAIN

A.J. Tobin* and R.F. Tyndale. Departments of Biology and Pharmacology, UCLA, Los Angeles, California, 90024.

The cytochrome P4502D1 is a hepatic enzyme which is responsible for the metabolism of more than 30 drugs, including many centrally active drugs such as the tricyclic antidepressants, codeine, amphetamines and neuroleptics. There is genetic variability in the P4502D1 gene resulting in some people (7-10% of Caucasians) having no P4502D1 function. Catalytic, pharmacological and molecular studies have identified the genetically variable cytochrome P4502D1 (debrisoquine hydroxylase) in mammalian brain. There is significant overlap between substrates/inhibitors for the dopamine transporter and for the P4502D1 (i.e., (-)-cocaine, MPTP, methylphenidate and d-amphetamine) suggesting that there may be a coordinated function between these two proteins.

RT-PCR were used to detect the presence of P4502D1 mRNA in brain regions and in multiple immortalized cell lines. Variation between rat brain regions in the amount of P4502D1 RNA was observed, as initially suggested by canine CNS activity studies. However differences were found between human and rat brain regional levels of P4502D1 mRNA. Cell lines provide an homogeneous population of cells in which to study the CNS P4502D1. Many of the immortalized cell lines studied contained the P4502D1 mRNA. Treatment of cell lines with forskolin differentiated the cells and altered the levels of the transcript for the enzyme. These preliminary studies suggest 1) that there is regional variation in the levels of CNS P4502D1 mRNA, 2) human and rodent brains may have different regional expression of the P4502D1, and 3) that cell lines may allow us to study the regulation of CNS P4502D1 and further our understanding of the roles for this genetically variable enzyme in the brain. Genetic differences in human brain metabolism of P4502D1 substrates (drugs, toxins, endogenous opiates or neurotransmitters) may effect drug and toxin response, and/or drug addiction. DRUGS OF ABUSE: COCAINE—DOPAMINE

664.1

SPECT Imaging of Dopamine Transporters in Cocaine Dependent and Healthy Control Subjects with [¹²³I]β-CIT. R.T. Malison*, E.A. Wallace, S. Best, M. Gandelman, S.S. Zoghbi, Y. Zea-Ponce, R.M. Baldwin, D.S. Charney, P.B. Hoffer, T.R. Kosten, R.B. Innis. Dept. of Psychiatry, Yale University School of Medicine, New Haven, CT 06519.

Post-mortem studies of cocaine overdose victims have shown elevations in striatal dopamine (DA) transporters relative to healthy control brains. We examined whether acutely abstinent (< 72 hr) cocaine addicts have increased levels of striatal DA transporters compared to drug-naïve controls, and whether posited increases would persist with sustained (2-4 weeks) drug abstinence. Cocaine dependent and healthy control subjects (n = 8 per group; ages 35 ± 10 vs. 33 ± 8 yr, p = NS) were injected with 10 mCi [¹²³I]β-CIT and imaged from 24-30 hr post-injection under sustained equilibrium conditions. The ratio of specific to nonspecific brain uptake (i.e., (striatum - occipital)/occipital), a measure proportional to the binding potential (B_{max}/K_D), was used for all comparisons. Preliminary results suggest a statistical trend (p = 0.09; two-tailed) toward elevations in striatal DA transporters in acutely abstinent cocaine subjects in comparison to healthy controls (10.2 ± 2.7 vs. 8.2 ± 1.6; mean ± SD). Consistent with apparent increases (~25%) in [¹²³I]β-CIT binding relative to controls, were within subject reductions (17 ± 18%; range, 7.8 - 33.3%) in cocaine addicts (n=5) after sustained (2-4 weeks) as compared to acute (< 72 hr) drug abstinence (12.2 ± 2.4 vs. 10.1 ± 1.7; p = 0.05). These results are consistent with preclinical studies which suggest an upregulation of DA transporters in response to chronic cocaine administration, changes which appear plastic and may "normalize" in the continued absence of the cocaine.

Potent and selective probes for the dopamine (DA) transporter. A. K. Dutta, B. K. Madras, P. C. Meltzer* and M. E. A. Reith. Organix, Inc., Woburn, MA 01801. Harvard Medical School, NERPC, Southborough, MA, 01772. University of Illinois, Peoria, IL 61656.

In order to assess the molecular determinants of the activity of the highly potent and selective GBR compounds for the DA transporter, several analogs were synthesized. Binding studies (IC₅₀) were performed on striatal tissue labelled with [³H]CFT. Changing the piperazine ring into piperidine in the GBR molecule did not affect the potency and selectivity for the DA transporter when the nitrogen atom was in the correct position (e.g. 1b-c). Furthermore, the compound 1b had very little (<3%) nonselective piperazine acceptor binding activity compared with the conventional GBR compounds. Compounds 2a-b represent a new class of analogs. These compounds were synthesized in the racemic form and 2a was found to have moderate affinity for the DA transporter. Detailed synthesis and binding studies of these compounds will be discussed.

664.3

IN CONTRAST TO INACTIVE S-COCAINE, A NOVEL SERIES OF S-COCAINE CONGENERS DISPLAY HIGH AFFINITY AND SELECTIVITY FOR THE DOPAMINE TRANSPORTER. B.K. Madras*, A.Y. Liang and P.C. Meltzer. Harvard Medical School, NERPRC, Southborough, MA 01772-9102 and Organix, Inc. Woburn, MA 01801.

A novel series of benztropine analogs of cocaine were synthesized and their affinities for monoamine transporters were determined using [³H]WIN 35,428 to label the dopamine (DA) transporter and [³H]citalopram to label the serotonin (5HT) transporter. In sharp contrast to the active R-forms of cocaine and cocaine congeners (e.g. WIN 35,428), difluoropine* (4β-carbomethoxy-3α-methoxydifluorophenyltropane) and congeners displayed reverse stereoselective effects. The S-form was 200 times more potent (IC₅₀: 10.9 ± 1.2 nM) than the R-form, was highly selective for the DA/5HT transporter (324-fold) and was more potent than the 4β-dihydro analog. Unlike the phenyltropane series, other substituents on the aromatic ring tended to reduce the affinity for the DA transporter. This series of compounds challenges recent views on the binding domain of cocaine/cocaine congeners and offers unique opportunities for probing the binding terrain of the dopamine transporter. 664.4

INVOLVEMENT OF AUTOREGULATION IN THE EFFECT OF COCAINE (COC) ON MONOAMINES MEASURED BY DIALYSIS IN THE RAT VENTRAL TEGMENTAL AREA (VTA). M.E.A. Reith* and N.-H. Chen. Dept. of Basic Sciences, University of Illinois College of Medicine, Peoria, IL 61656.

Dopamine (DA) cell bodies in the VTA have been implicated in the rewarding and stimulatory activity of cocaine. The VTA is innervated by serotonin (5-HT)- and norepinephrine (NE)-containing afferents from the raphe nuclei and locus coeruleus, in addition to reciprocal efferent connections. In the present study, DA, 5-HT, and NE were measured simultaneously in dialysates from the VTA of freely moving rats, and the effect of COC was measured in the presence or absence of monoamine autoreceptor antagonists in the perfusate. Sulpiride (D₂/D₃, 10 µM) increased DA output induced by local (30 µM) or systemic (20 mg/kg i.p.) COC, methiothepin (5-HT₁/5-HT₂, 20 µM) promoted local COC-induced 5-HT output, and idazoxan (α₂, 100 µM) enhanced local COC-induced NE output. This is consonant with activation of autoreceptors in the VTA counteracting the effect of focal COC; possibly, modulation by somatodendritic 5-HT and NE autoreceptors is more important following systemic COC administration. Sulpiride promoted COC-induced NE output without modifying basal 5-HT/NE output, whereas methiothepin and idazoxan increased the basal output of all three amines without modifying COC-induced output of DA/NE or DA/5-HT, implying complex monoamine interactions. Sulpiride stimulated while methiothepin or idazoxan depressed COC (20 mg/kg)-induced motor activity. The analysis of behavioral/neurochemical relationships revealed a positive correlation between dialysate DA output and motor activity in the sulpiride/COC and methiothepin/COC groups, consonant with VTA DA reflecting DA cell firing, and a negative correlation was revealed between dialysate NE output and motor activity in the COC alone and idazoxan/COC groups, consonant with previous DA/NE balance theories. Supported by NIDA 03025.

664.5

FUNCTIONAL AND PHARMACOLOGICAL MODULATION OF SINGLE-UNIT ACTIVITY IN THE VENTRAL TEGMENTAL AREA AND RELATED REGIONS IN THE AWAKE, BEHAVING RAT. Kosobud, A.E., and Chapin, J.K. Hahnemann University, Philadelphia, PA, 19102, USA.

The ventral tegmental area (VTA) is a central element in a system that mediates the reinforcing properties of natural stimuli (such as food), brain stimulation and drugs of abuse. In the present studies, bundles of 4-8 microwire electrodes were chronically implanted in the VTA and target regions, including nucleus accumbens (NA), ventral pallidum (VP), mediodorsal thalamus (MDT) and prefrontal cortex (PFC) of male Wistar rats. Following recovery from surgery, simultaneous recordings from single neurons and unit clusters were obtained in unrestrained rats during pharmacological and behavioral studies. A substantial number of neurons in the VTA and target regions displayed no change in firing rate relative to behavior, or were unaffected by the peripheral administration of cocaine, diazepam, morphine, apomorphine or haloperidol in doses that have been shown to modulate firing rates in anesthetized rats. This suggests that in the awake rat, functional circuits may be more resistant to disruption by drugs. VTA neurons displaying the electrophysiological characteristics of dopaminergic neurons were relatively active in rats at rest, and reduced their firing rates during movement. These neurons were inhibited by apomorphine, and this inhibition coincided with the appearance of behavioral stereotypies (sniffing and head-weaving). This pattern was duplicated in neurons in MD thalamus, suggesting that functional patterns of activation are reflected in multiple sites throughout a neural circuit. A second class of VTA neurons, apparently non-dopaminergic, showed patterns of activity that were exactly the reverse of the VTA DA neurons: i.e. their firing rate was decreased in rats at rest, increased during movement, and excited by peripheral administration of apomorphine. Haloperidol reversed both the behavioral and electrophysiological effects of apomorphine. Supported by NIDA DA 08349 and Hahnemann University RIG 990414.

ACUTE COCAINE ALTERS DOPAMINE SYNTHESIS IN THE NUCLEUS ACCUMBENS OF RATS PRETREATED WITH SALINE, BUT NOT COCAINE OR CPP. D. Johnson*, P. Buckley, M. Kozak, and D. Mokler. University of New England, College of Osteopathic Medicine, Biddeford, Me. 04005

A paradigm to develop rapid sensitization to the locomotor-activating effects of cocaine and the role of competitive NMDA receptor antagonists in rapid sensitization was tested. All rats receiving acute cocaine injections (15 mg/kg) showed higher activity counts ($P < .01$) compared to saline-injected controls. No differences were seen among rats receiving acute cocaine which were pretreated once daily for two days with either cocaine or the competitive NMDA receptor antagonist CPP (2 mg/kg). Neurochemical analysis of norepinephrine (NE), dopamine (DA), DOPAC, HVA, 5-HT, and 5-HIAA in brain homogenates showed decreased ($P < .05$) levels of DA and HVA in the nucleus accumbens (NAC) of cocaine injected rats pretreated with saline, compared to saline injected rats pretreated with saline. Neurochemistry in rats injected with cocaine and pretreated with cocaine, CPP, or both was not different from controls in any brain region examined. These results suggest that this paradigm is inadequate to produce locomotor sensitization to cocaine. However, acute cocaine in this model does produce changes in DA synthesis in the NAC of saline-pretreated rats, but prior exposure to cocaine, CPP, or both negates this effect. Further behavioral paradigms are being tested, using microdialysis to measure neurocorrelates.

664.9

TOLERANCE TO COCAINE INDUCED ELEVATION OF EXTRACELLULAR DOPAMINE IN THE NUCLEUS ACCUMBENS FOLLOWING SEVEN DAYS OF WITHDRAWAL. W.M. Meil*, J.M. Roll and R.E. See. Department of Psychology, Washington State University, Pullman, WA, 99164-4820.

Time-dependent changes in mesolimbic dopamine (DA) function are believed to play a role in behavioral sensitization and drug craving experienced during withdrawal from chronic cocaine administration. The present study utilized intravenous (i.v.) cocaine self-administration coupled with intracranial microdialysis in rats to investigate time dependent changes during withdrawal from chronic cocaine exposure. Following 2 weeks of i.v. cocaine self-administration, rats were allowed contingent access to cocaine at 1 and 7 days of withdrawal while extracellular levels of DA were measured from the nucleus accumbens (NAcc). A second group of animals received yoked, noncontingent cocaine for 2 weeks and were then administered noncontingent cocaine on days 1 and 7 of withdrawal. In addition, a third group of animals received 2 weeks of yoked saline followed by noncontingent cocaine 1 day after withdrawal. There were no significant differences between groups for the overall cocaine dosage or temporal pattern of infusions on days 1 and 7 of withdrawal. Basal extracellular DA concentrations did not differ between any treatment groups at either withdrawal time. Extracellular DA levels were increased throughout the session on both days; however, the increases at day 7 were significantly less than day 1 for both contingent and noncontingent conditions. DA overflow on day 1 did not differ between animals receiving chronic yoked cocaine or saline. These results suggest that tolerance to the DA-elevating effects of cocaine is not apparent early in withdrawal, but does develop by later time points. DA release in the NAcc may not be directly related to cocaine craving, since DA levels were attenuated after 7 days of withdrawal while responding for cocaine was unaltered.

664.6

ELEVATIONS AND PHASIC FLUCTUATIONS IN NUCLEUS ACCUMBENS DOPAMINE DURING IV COCAINE SELF-ADMINISTRATION. R.A. Wise*,¹ P. Newton,² K. Leeb,¹ B. Burnette,² D. Pocock,¹ and J. Justice.² Ctr Stud Behav Neurobiol Concordia Univ., Montréal, PQ, CANADA H3G 1M8¹ and Dept Chem, Emory University, Atlanta GA 30322².

Fluctuations in extracellular nucleus accumbens dopamine and DOPAC levels were monitored in 1-min microdialysis samples from rats engaged in intravenous cocaine self-administration. Dopamine levels were elevated to 200-600% of baseline during cocaine self-administration, fluctuating phasically between responses. Each injection caused a phasic, short-latency increase in dopamine levels, with a decrease prior to the next lever press. This pattern was seen regardless of whether the dose per injection was fixed or varied unpredictably within the sessions. The magnitude of the phasic fluctuations was on the order of 20% of the magnitude of the sustained within-session elevations; dopamine levels never fell close to baseline levels before the animal responded and received another injection. Fluctuations of the same magnitude and with the same time-course were seen when cocaine was injected independent of the behavior of the animals. DOPAC levels increased in the first minutes and stayed elevated during the period of drug availability; there was no significant recovery between injections. These data are consistent with the possibility that falling dopamine levels trigger successive responses in the intravenous cocaine self-administration paradigm, but they offer no support for the hypothesis that extracellular dopamine is depleted at the time of response initiation within a self-administration session.

664.8

PHASIC FIRING PATTERNS OF ACCUMBENS NEURONS ARE RELATED TO CONDITIONED STIMULI ASSOCIATED WITH DRUG REINFORCEMENT DURING COCAINE SELF-ADMINISTRATION IN RATS.

R.M. Carelli*, V.C. King and S.A. Deadwyler. Center for the Neurobiological Investigation of Drug Abuse, Dept. of Phys/Pharm., Bowman Gray School of Medicine, Wake Forest Univ., Winston-Salem, NC 27157.

We have previously reported that a subset of nucleus accumbens (NA) neurons exhibit phasic changes in firing rate during cocaine self-administration and water reinforcement in rats (Brain Res 626:14-22,1993; Neurosci Abst 19:1857,1993). Of 244 NA neurons recorded in 14 self-administering rats, 24% (58 cells) exhibited 4 distinctly different neuronal firing patterns time-locked to the drug reinforced response (0.33 mg cocaine/inf, 5.8 sec) in which drug infusion was paired with a tone-houselight CS complex (20 sec). The purpose of the present study was to investigate the role of the CS in the firing patterns of NA cells. NA phasic activity was not related solely to a pharmacological action of cocaine since it was absent during randomly initiated drug infusions (no CS). Results indicate that NA phasic activity could be triggered by the CS alone since similar patterned discharges occurred independent of drug delivery. However, although the CS was present on all trials, phasic activity time-locked to its occurrence did not emerge until after stable self-administration responding. This onset could be prolonged further within the session by: 1) decreasing the dose of cocaine (0.16, 0.08 mg/inf) and, 2) pretreatment with the dopamine D₁ antagonist SCH23390 (10 µg/kg). This indicates that a crucial level of dopamine in the NA must be achieved before the CS can elicit NA phasic activity. In addition, the timecourse of CS related NA firing to cyclic dopamine levels in the NA during the session suggests that phasic activity triggered by the CS does not reflect changes in dopamine levels.

RESPONSES OF NUCLEUS ACCUMBENS CELLS TO DOPAMINE AND METHYLENEDIOXYMETHAMPHETAMINE (MDMA) ARE ENHANCED FOLLOWING CHRONIC COCAINE SELF-ADMINISTRATION IN RATS. S.R. White*, G.C. Harris, K.M. Imel and M.J. Wheaton. Dept. of Vet. & Comp. Anat., Pharm. and Physiol., Washington State Univ., Pullman, WA 99164.

Cells in the nucleus accumbens are sensitized to the inhibitory effects of dopamine for several weeks following chronic exposure to noncontingent injections of cocaine (Henry & White, J. Pharm. Exp. Ther., 1991, 258:882). The present study examined the effects of cocaine self-administration on responses of nucleus accumbens cells to dopamine and to methylenedioxyamphetamine (MDMA). Rats pressed a lever in an operant chamber to receive cocaine infusions through cannulae implanted in the jugular vein. The average daily cocaine dose obtained by the cocaine self-administering rats was 31.4 ± 1.2 mg/kg, iv. Following 15 daily sessions of cocaine self-administration, access to cocaine was terminated. Electrophysiological experiments were conducted 1-11 days following termination of cocaine self-administration. Dopamine and MDMA produced dose-dependent inhibition of glutamate-evoked firing in the nucleus accumbens of both the cocaine-pretreated group and a saline-control group of animals. However, dopamine and MDMA had significantly greater inhibitory effects in the cocaine self-administration group than in controls. It is concluded that repeated cocaine exposure at doses that are self-administered sensitizes nucleus accumbens cells to the inhibitory effects of dopamine and of other drugs of abuse that elevate extracellular levels of dopamine in the accumbens. (Supported by DA-08116.)

664.11

ACUTE INTRAVENOUS ADMINISTRATION OF COCAINE AND AMPHETAMINE PREFERENTIALLY INCREASES GLUCOSE UTILIZATION IN THE SHELL OF THE NUCLEUS ACCUMBENS OF FREELY MOVING RATS.

F.E. Pontieri*, M. La Rocca, J.V. Faroni, V. Colangelo and F. Orzi. Dept. Neurosciences, University "La Sapienza", Roma (Italy).

The effects of the administration of psychomotor stimulant drugs in experimental animals depend on a series of factors. It has been previously demonstrated that intravenous (i.v.) but not intraperitoneal administration of cocaine in the rat produces increases in glucose utilization in portions of the mesocorticolimbic system, such as the nucleus accumbens (NACC) and the medial prefrontal cortex. Anatomical and biochemical differences have been reported within the NACC, with regard to the density of dopamine nerve terminals and the functional connections. In this study, the 2-[¹⁴C]deoxyglucose method was applied to measure the effects of the acute i.v. administration of cocaine or amphetamine on glucose utilization in the shell and core of the NACC in freely moving rats. After catheterization of the femoral vessels, animals were treated with either cocaine (1 mg/kg), amphetamine (0.5 mg/kg) or saline. Computer-assisted image overlay was performed in order to identify the different portions of the NACC in histological sections. Administration of either cocaine or amphetamine produced increases in glucose metabolism in the shell of the NACC, with respect to control animals. These results provide an useful basis for the understanding of the neural substrates of the effects of reinforcing doses of psychomotor stimulant drugs.

POSSIBLE MECHANISMS OF BIPHASIC FLUCTUATIONS IN MESOLIMBIC DOPAMINE ACCOMPANYING COCAINE SELF-INJECTIONS: A VOLTAMMETRIC STUDY E.A. Kiyatkin¹* and E.A. Stein. Depts. of Psychiatry¹ and Pharmacology, Medical College of Wisconsin, Milwaukee, WI 53226.

Cocaine is known to have a complex action on the mesolimbic dopamine (DA) system enhancing, due to reuptake inhibition, accumulation of pre-released DA and inhibiting, due to depression of DA cells, impulse-dependent DA release. Rapid biphasic fluctuations in nucleus accumbens DA-dependent signal have been reported in our previous electrochemical studies to accompany individual cocaine self-injections (Kiyatkin et al., 1992; Kiyatkin and Stein, 1994). Electrochemical signal gradually increased preceding the lever-press for cocaine, and abruptly (<20 sec) transiently (~2 min) decreased after drug injection. Although inhibiting action of cocaine on reuptake of released DA appears to determine the gradual signal increase preceding self-injections, the mechanisms of post-cocaine signal decreases are unknown. To test the contribution of presynaptic autoreceptor activation and local anesthetic action to the post-cocaine signal decreases, electrochemical signal changes were studied in cocaine-experienced rats during self-injections of the direct DA agonist apomorphine (APO; 25 µg/kg) and the local anesthetic procaine (PRO; 0.8-3.6 mg/kg). Signal decreases were found after APO self-injections, but they occurred with a definite latency (90-100 sec) that is not compatible with the immediate signal decreases seen after cocaine. Gradual signal increases seen preceding cocaine self-injections were absent in this case. Thus, although activation of presynaptic DA autoreceptors may contribute to inhibiting action of cocaine on DA release, this relatively slow and long-term effect seems unlikely to mediate the immediate post-cocaine signal decreases. In contrast, an abrupt (<20 sec) signal decrease found after PRO self-injections implicate cocaine's anesthetic action as a possible contributor to the immediate post-drug signal depression. The combination of local anesthetic and reuptake inhibiting properties may underlie the unique abuse potential of cocaine in contrast to agents with only DA uptake inhibiting properties (mazindol, nomifensine) or local anesthetic properties (lidocaine, procaine).

LOCOMOTOR ACTIVATING AND REWARDING EFFECTS OF DOPAMINERGIC AGONISTS IN VENTRAL PALLIDUM OF RATS. W. Gong*, D. B. Neill and J. B. Justice, Jr. Depts. of Psychology and Chemistry, Emory University, Atlanta, GA 30322

The ventral pallidum (VP) is an output structure of nuc. accumbens. This anatomy suggests that VP may share functions with nuc. accumbens. Our research investigated whether a DA input to VP from ventral tegmental area has a role in locomotor activity and reward. We prepared rats with chronically indwelling cannulae in VP. Drug injections of 0.5 µl were bilateral. Locomotor activity was tested in 1 hr tests in Digiscan activity chambers. Amphetamine SO₄ (10 µg) and dopamine HCL (25 µg) increased activity. Activity was initially suppressed and subsequently elevated by cocaine HCL (12.5-100 µg); the initially suppressed activity was similar to that induced by procaine (50 µg). Place preference conditioning was conducted using a counterbalanced design pairing drug injection in VP with a distinct chamber for two 30 minute sessions. Amphetamine SO₄ (10 µg) produced a strong place preference conditioning. Cocaine HCL (50 µg) also increased time spent on the cocaine-paired side. These data indicate that dopaminergic transmission in VP may be involved in the locomotor and reward effects of psychostimulants, and suggest some effects of intracranially administered cocaine are due to local anesthesia.

ALTERATIONS IN DOPAMINE UPTAKE TRANSPORTER DENSITY IN COCAINE SELF-ADMINISTERING RATS APPEAR TRANSIENT. J. H. Graham*, S. I. Dworkin and L. J. Porrino. Bowman Gray School of Medicine, Wake Forest University, Winston-Salem, NC 27157.

The *in vitro* autoradiographic distribution of dopaminergic uptake transporter sites (DAT) was determined, using [³H]mazindol (MAZ) as a ligand, in brain sections from Fisher 344 rats chronically self-administering (SA) cocaine (COC) (0.33mg/kg/inf) i.v., in daily 3hr sessions. Rats were sacrificed either immediately following a SA session, or after 4 days of withdrawal. Values for DMI insensitive [³H]MAZ binding were compared to those from yoked saline controls similarly sacrificed. Although the distribution of MAZ binding sites in SA rats was decreased in both mesolimbic and nigrostriatal systems, DAT densities returned to levels at or above those found in untreated controls, following 4 days withdrawal. DAT levels in the accumbens (shell and core) and olfactory tubercle of withdrawal rats were elevated above control levels, whereas levels in other areas, e.g. caudate, SNc, rostral pole of accumbens, did not differ from controls. Therefore, adaptations in response to chronic COC SA within both the nigrostriatal and mesocorticolimbic dopaminergic systems may be transient in nature, and only persist as long as COC SA continues. (Supported by NIDA grants P50 DA 06634 and DA 07522).

TRANSLLOCATION OF DOPAMINE AND BINDING OF WIN 35,428 MEASURED UNDER IDENTICAL CONDITIONS IN RAT STRIATAL SYNAPTOSOMES. C. Xu, L.L. Coffey, S.M. Lasley* and M.E.A. Reith. Dept. of Basic Sciences, University of Illinois College of Medicine, Peoria, IL 61656.

One strategy of searching for a cocaine antagonist is to look for a compound that potentially inhibits binding of a cocaine-related radioligand to the dopamine transporter but does not affect dopamine translocation. The conditions commonly used for these assays are not the same, confounding data interpretation. In this study, identical conditions have been adopted for the parallel measurement of the binding of [³H]WIN 35,428 and the translocation of [³H]dopamine in crude synaptosomal preparations from rat striatum: 8-min incubation at 25°C with radioligand and inhibitor in phosphate uptake buffer containing Na⁺, K⁺, Mg²⁺, Ca²⁺, glucose, and nialamide. Binding IC₅₀ values for a series of different uptake blockers (cocaine, WIN 35,428, benztropine, nomifensine, mazindol, methylphenidate, BTCP, Lu 19-005, GBR 12909, GBR 12935 and CGS 12066B) were on the average 1.4-fold higher than the uptake IC₅₀ values. For slowly equilibrating inhibitors, uptake IC₅₀'s decreased by monitoring [³H]dopamine uptake for 1 min only during the last min of the 8-min presence of inhibitor, and under these conditions the average binding over uptake IC₅₀ ratio increased to 2.3. Kinetic calculations, taking into account both radioligand and inhibitor equilibration kinetics, indicated that the latter comparison between binding and uptake measurements was most relevant, and suggested the involvement of complexities beyond simple competitive inhibition of dopamine transport such as different binding domains for substrate and blocker recognition, or spare receptors for blockers. The present results indicate that binding over uptake IC₅₀ ratios should be interpreted with caution depending on the experimental conditions used to measure these ratios. Supported by NIDA 03025.

OSCILLATORY EFFECTS OF COCAINE ON DOPAMINE EFFLUX IN RATS A. R. Caggiula*, S. M. Antelman, D.J. Edwards, S. Kiss, D. Kocan, R. Stiller. Depts. of Psychology, Psychiatry and Pharmacology/Physiology, University of Pittsburgh, Pittsburgh, PA. 15213 and Pittsburgh Cancer Institute

Variability in responsiveness to therapeutic and addictive drugs is a major problem in the replicability of pharmacological research involving both humans and laboratory animals. Recent data from our laboratory (Antelman et al, 1992) suggest that one source of variability may be the tendency of physiological systems to change their response to repeated drug treatment from a unidirectional to an oscillatory pattern. In the present study one injection of cocaine HCl (COC; 15 mg/kg, i.p.), 30 min. before sacrifice, increased *in vitro* amphetamine (AM; 10µM)-induced DA efflux from striatal slices, compared to controls. This increase was prevented when COC treatments were given 4 d and 30 min before sacrifice. This oscillatory pattern continued through 6 COC treatments (4 d apart). As each COC treatment was added, it reversed the effects of the preceding one. Most importantly, the direction of COC's effects was completely reversed over the 6 treatments. COC increased DA efflux by 53% when given only once but decreased it by 32% after 6 treatments. In a subset of rats, this oscillatory pattern also was seen for DA-efflux in the nucleus accumbens in response to 4 COC pretreatments. Supported by MH 24114 and DA 07546.

EFFECTS OF CHRONIC COCAINE ADMINISTRATION ON DOPAMINE TRANSPORTER mRNA LEVELS. S.R. Letchworth*, A. Hedgecock, L.J. Porring. Dept. of Physiology & Pharmacology, Bowman Gray School of Medicine, Winston-Salem, NC 27157 USA.

Repeated administration of cocaine produces sensitization, as seen in increased locomotor behavior. Changes in the density of dopamine transporter protein have been reported in rat striatum after chronic cocaine exposure. The purpose of this study was to investigate possible changes in dopamine transporter mRNA as a result of chronic cocaine treatment. Male Sprague-Dawley rats were treated with 0, 10, 15, or 25 mg/kg cocaine, ip once daily for 8 days, and locomotor activity recorded. The levels of mRNA for the dopamine transporter were determined autoradiographically using *in situ* hybridization with an oligonucleotide probe specific for the transporter. The mean density/area was measured in the substantia nigra and ventral tegmental area. *In vitro* autoradiography using ³H-mazindol to measure the density of the dopamine transporter protein will be carried out on tissue from the same animals. Cocaine treatment resulted in decreased levels of dopamine transporter mRNA by approximately 20% in both midbrain regions as compared to control levels. In contrast to the dose-dependent effects of repeated cocaine treatment on locomotor activity, however, the changes in dopamine transporter mRNA were not dose-dependent in either the substantia nigra compacta or ventral tegmental area. The lack of correlation between these two measures suggests that regulation of the dopamine transporter may not be critical for the expression of cocaine-induced sensitization. Supported by NIDA Grant DA07522.

BEHAVIORAL EFFECTS OF NOVEL 4'- and 4',4"-SUBSTITUTED-3 α -DIPHENYLMETHOXYTROPANE ANALOGS. J.L. Katz*, S. Izenwasser, A.C. Allen, A.H. Newman. Drug Development Group, Psychobiology Section, NIDA Intramural Research Program, NIH, Baltimore, MD 21224, U.S.A.

Cocaine-like behavioral effects of a series of 4'- and 4',4"-substituted-3 α -diphenylmethoxy-1 α H,5 α H-tropane analogs were assessed. These analogs of bupropion share structural features with cocaine and the dopamine uptake inhibitor, GBR 12909; they bind with high affinity to the dopamine transporter and inhibit dopamine uptake. Cocaine and GBR 12909 produce dose-related increases in locomotor activity of Swiss-Webster mice, whereas, of the diphenylmethoxytropane analogs tested, only the 4',4"-difluoro-substituted compound (AHN 1-055) produced increases in this activity that approached those of the reference drugs. In another study, rats were trained to discriminate saline from cocaine (10 mg/kg, ip). After cocaine injections, 20 consecutive responses on one of two levers produced food; after saline, responses on the other lever produced food. Once performances were stable, effects of various doses of cocaine, and of the diphenylmethoxytropane analogs were assessed during test sessions in which 20 consecutive responses on either lever produced food. Cocaine produced a dose-related increase in responding on the cocaine lever, reaching 100% at 10 mg/kg. Only AHN 1-055 (17 mg/kg) and the 4',4"-dimethoxy analog, AHN 1-057 (5.6 mg/kg), produced effects different from saline. These compounds produced maximum percentages of cocaine responding of 65 and 35, respectively. With AHN 1-057, doses higher than 5.6 mg/kg produced less cocaine responding. With AHN 1-055, doses higher than 17 mg/kg could not be tested because they virtually eliminated behavior. These compounds represent the first tropane analogs that have structural and neurochemical similarities to cocaine, but are behaviorally distinct from all other known compounds that share this profile.

LOCOMOTOR STIMULANT ACTION OF THE DOPAMINE UPTAKE INHIBITORS GBR-12935 AND GBR-12909: ADDITIVE AND NON-ADDITIVE INTERACTIONS WITH COCAINE. D. Krug*, M.J. Forster, M. Stokely, and J. Ebe. Department of Pharmacology, University of North Texas Health Science Center at Fort Worth, Fort Worth, TX 76107.

A study was conducted to compare the locomotor stimulant properties of cocaine with the dopamine uptake inhibitors GBR 12909 and GBR-12935. Horizontal locomotor activity of Swiss Webster mice was recorded for 1 h in a Digiscan apparatus following i.p. injection of each drug alone or in combination with 5 to 20 mg/kg cocaine. By themselves, both compounds produced stimulation of locomotor activity with ED₅₀ values of 5.8- and 5.4-mg/kg for GBR-12909 and GBR-12935, respectively. Maximal motor stimulation produced by these drugs was nearly equivalent to that produced by cocaine, and persisted for at least 1 hour following injection. In interaction studies, GBR-12935 produced a dose-related leftward shift in the inverted U-shaped cocaine dose effect curve, whereas, GBR-12909 produced a leftward shift of only the ascending portion. Maximal doses of GBR-12909 failed to influence the response to 20 mg/kg cocaine. These results indicate a non-additive influence of GBR-12909 and cocaine in the modulation of locomotor activity. RATS SELF-ADMINISTER PHENCYCLIDINE (PCP) AND MK-801, BUT NOT NOMIFENSINE, DIRECTLY INTO PREFRONTAL CORTEX. W. A. Carlezon, Jr.* and R. A. Wise. Center For Studies in Behavioral Neurobiology, Concordia Univ., Montréal, Que, CANADA H3G 1M8

We have previously reported that rats will self-administer microinjections of MK-801 (a non-competitive NMDA receptor antagonist), nomifensine (a dopamine [DA] reuptake inhibitor), or PCP (a drug with both of these properties) directly into nucleus accumbens septi (NAS). Because others have reported that the DA reuptake inhibitor cocaine is self-administered into prefrontal cortex (PFC) but not NAS, we explored the possibility that these drugs would also be reinforcing when microinfused into PFC. Rats learned to lever press when given response-contingent microinfusions of PCP or MK-801 directly into PFC at the same concentration of each drug that was effective in NAS (12 nmoles and 1.2 nmoles per 120 nl infusion, respectively). However, when lever-pressing was reinforced with microinfusions of NOM into PFC at a concentration that increased responding when given into NAS (1.7 nmoles/inl), rates of responding were not higher than those of animals that received response-contingent microinfusions of vehicle. Higher concentrations of NOM were not tested due to poor solubility. These findings confirm that drug actions in the PFC can be rewarding but, taken by themselves, suggest that it is the action of PCP at the NMDA receptor rather than PCP-induced blockade of DA reuptake that accounts for its rewarding effects in this brain region. This suggestion—and the fact that NOM was not self-administered into PFC—remains to be reconciled with the previous report that cocaine is self-administered into PFC but not NAS.

664.20

NOVEL 4'- and 4',4"-SUBSTITUTED-3 α -DIPHENYLMETHOXYTROPANE ANALOGS ARE POTENT AND SELECTIVE DOPAMINE UPTAKE INHIBITORS. A.H. Newman*, B.H. Kline, A.C. Allen, S. Izenwasser, J.L. Katz. Drug Development Group, Psychobiology Section, NIDA Intramural Research Program, NIH, Baltimore, MD 21224

A series of 4'- and 4',4"-substituted-3 α -diphenylmethoxy-1 α H,5 α H-tropane analogs have been prepared as probes for the dopamine transporter. Initial studies showed that 4'-chloro-3 α -diphenylmethoxytropane displaced [³H]WIN 35,428 binding (K_i=30 nM) more potently than cocaine, inhibited dopamine uptake (IC₅₀=115 nM) and yet did not display a cocaine-like behavioral profile in locomotor activity or drug discrimination studies. Sensitivity to phenyl ring substitution in this series suggested an additional binding domain that might be exploited for the identification of potential cocaine antagonists. In order to further explore the structure activity relationships in this series of compounds, for binding to the dopamine transporter, inhibiting dopamine uptake and producing cocaine-like behavioral effects, an extended series of analogs, substituted in the *para*-position of one or both phenyl rings was prepared. These compounds were evaluated in radiolabeled binding assays for the dopamine transporter ([³H]WIN 35,428), norepinephrine transporter ([³H]desmethylinipramine), and the serotonin transporter ([³H]citalopram). All of these compounds monophasically displaced [³H]WIN 35,428 binding in rat caudate-putamen with K_i values ranging from 11-2000 nM. None of the compounds displaced >60% of [³H]desmethylinipramine binding (10 μ M) or >66% of [³H]citalopram binding (10 μ M). Therefore, the most potent dopamine uptake inhibitors are highly selective for the dopamine transporter. Furthermore, since the parent drug bupropion is a potent muscarinic antagonist, these compounds were also evaluated for binding to muscarinic-m₁ receptors ([³H]pirenzepine) and muscarinic-m₂ receptors ([³H]AF-DX 384). All of the analogs displayed moderate to high affinity for the muscarinic-m₁ sites (K_i range =1-100 nM) and variable affinities for the muscarinic-m₂ sites (K_i range =2-1500 nM). Structure activity relationship trends are evident and distinct for each of the binding sites and suggest that it will be possible to prepare more selective ligands in the future.

664.22

THE RELATIONSHIP OF COCAINE CONCENTRATION IN BRAIN TO BEHAVIOR: EVIDENCE FOR THE PREFRONTAL CORTEX AS THE INITIATING SITE FOR THE COCAINE LOCOMOTOR STIMULANT EFFECT. Robert J. Carey*, Ernest N. Damjanopoulos and Gail P. De Palma. Psychiatry, SUNY Health Science Center and Research and Development Service -151, VA Medical Center, Syracuse, NY 13210

The behavioral stimulatory effects of cocaine have been linked to cocaine inhibition of dopamine transporter mechanisms in the prefrontal cortex, neostriatum, and limbic areas. In the context of behavioral studies, however, rarely have the cocaine concentrations been measured in these brain structures. Using a recently developed assay procedure, we examined the effects of IP cocaine (10 mg/kg) administration upon locomotor behavior and the concentration of cocaine in the medial prefrontal cortex, neostriatum and limbic-olfactory brain areas. Cocaine concentrations were found to be highest in the cortex followed by the neostriatum and limbic area. Significantly, however, locomotor stimulation effects were reliably correlated only with cocaine concentration in the medial prefrontal cortex. This observation suggests that the medial prefrontal cortex may be the critical initiating site for the mechanisms mediating the cocaine stimulatory effects on locomotor behavior.

COMPARISON OF COCAINE AND COCAETHYLENE IN THE VERVET MONKEY: PLASMA PHARMACOKINETICS AND EFFECTS ON EXTRACELLULAR DA. C.W. Bradberry*, J.B. Nobiletti, R. Iyer, P. Jatlow, Yale Univ. Sch. of Med., Depts. of Psychiatry and Laboratory Medicine, and the West Haven Veterans Administration Hospital, West Haven, CT 06516.

Cocaethylene is a psychoactive metabolite resulting from concurrent cocaine and ethanol consumption, during which a transesterification converts the methyl ester of cocaine to an ethyl ester. It is more selective than cocaine in that it has a lower affinity for the 5-HT and noradrenergic uptake sites than cocaine. This, and the fact that it can be administered to humans in a clinical setting, makes it a unique tool for investigating drug reward mechanisms. Previous work has demonstrated equivalent actions of the two drugs at the dopamine uptake site in the rat both in vivo and in vitro. We have used microdialysis to compare the effect of 1.5 $\mu\text{mol/kg}$ (equivalent to 0.5 mg/kg cocaine-HCl) cocaine and cocaethylene on extracellular DA in the caudate of the anesthetized vervet monkey following i.v. administration. Samples were collected at 5 minute intervals following drug administration. Concurrent plasma samples were collected for pharmacokinetic analysis. Data were fit to an open two compartment model using weighted non-linear fitting (by PC Nonlin ver. 4). Microdialysis results indicated that both drugs caused an identical four-fold increase in extracellular DA following i.v. administration which peaked in the sample collected during the 5-10min post drug period. Pharmacokinetic analysis indicated the terminal elimination half-lives were 31 ± 3 for cocaine, and 53 ± 4 for cocaethylene, $p < 0.01$. However, because of a larger steady state volume of distribution for cocaethylene (3.7 ± 0.2 l/kg vs 2.5 ± 0.4 , $p < 0.03$), the clearances were not different. DRUGS OF ABUSE: COCAINE—DOPAMINE RECEPTORS

665.1

COCAINE SELF-ADMINISTRATION PATTERNS MAINLY REFLECT D_1 , NOT D_2 OR D_3 RECEPTOR ACTIVATION. J.D. Belluzzi*, S. Kossuth, O. Chan, N. Khamamkar, Q. Nguyen and L. Stein, Dept. of Pharmacology, College of Medicine, University of California, Irvine, CA 92717.

Cocaine self-administration (S-A) is characterized by precisely-spaced response patterns and an "inverted-U" dose-response curve. These characteristics may be duplicated in S-A of D_1 agonists (Self & Stein, 1992), but not in D_2 agonist S-A which is characterized by erratically spaced responding and a positively accelerating dose-response curve (Belluzzi *et al.* 1993). Here we report that co-administration of a low dose of a D_1 agonist converts erratic D_2 -agonist S-A into cocaine-like and D_1 -like response rates and patterns. Rats were trained to bar press for i.v. cocaine (750 $\mu\text{g/kg/inj}$) in daily 3-hr sessions. After baseline rates had stabilized, different doses of PHNO were substituted for cocaine. PHNO alone (Fig., \square) was self-administered erratically at high rates, but co-administration of the D_1 agonist SKF 82958 (3 $\mu\text{g/kg/inj}$) with PHNO (\blacksquare) induced low-rate responding similar to that seen with the D_1 agonist alone (Δ). When combined with SKF 82958, other D_2 (quinpirole, N-0923) or D_3 (7-OH-DPAT) agonists gave similar results. Our data indicate (1) that cocaine S-A patterns are reproduced by S-A of D_1 but not D_2 or D_3 agonists, and (2) that D_1 patterns predominate when D_1 and D_2 -like agonists are co-administered. (Supported by NIDA grant DA07747)

665.2

EFFECT OF COCAINE ON cAMP-ADENYLATE CYCLASE SYSTEM IN RAT STRIATUM. S.K. Sahni, J.M. Davis and J.I. Javadi*, Illinois State Psychiatric Institute, University of Illinois at Chicago, Chicago, IL 60612.

Repeated low doses or a single high dose of cocaine administration produces behavioral sensitization in rats. Also, repeated cocaine administration in rats has been reported to increase forskolin-stimulated adenylyl cyclase (AC) activity in nucleus accumbens. In the present study, we examined the effects of cocaine on the formation of cAMP induced by dopamine and a D_1 -selective agonist (through D_1 receptors), NaF (via G protein) and forskolin (acting directly on catalytic unit of AC). Adenylyl cyclase activity in striatal membranes was measured by [^{32}P]-cAMP formation using [^{32}P]-ATP as a substrate. Acute administration of cocaine (10 mg/kg or 40 mg/kg) did not significantly affect cAMP formation 1 hr or 24 hrs post injection. However, when rats were pretreated with a single injection of high dose (40 mg/kg) and then administered a cocaine challenge (10 mg/kg), a significant decrease (about 30%) was observed in the formation of cAMP in the striatum induced by stimulation with D_1 agonist. Similarly, a trend towards decreased formation of cAMP was observed in dopamine-sensitive activity, although it did not reach statistical significance. Since under these conditions of cocaine treatment behavioral sensitization is also manifested in rats, present findings raise the possibility that an inhibition of D_1 -mediated AC activity in the striatum may play a role in cocaine-induced behavioral sensitization.

665.3

SYSTEMIC ADMINISTRATION OF SCH-23390 ATTENUATES LOCOMOTION ELICITED BY INTRA-ACCUMBENS COCAINE. L.E. O'Dell*, R. A. Fuchs, T.V. Khroyan and J.L. Neisewander, Dept. Psychology, Arizona State University, Tempe, AZ 85287-1104.

We have previously demonstrated that intra-accumbens injections of the D_2 -like receptor antagonist sulpiride potently block locomotion induced by systemic administration of cocaine, whereas intra-accumbens injections of the D_1 -like receptor antagonist SCH-23390 only block this effect at a high dose. The present study further assessed the involvement of D_1 -like receptors by examining the effects of systemic SCH-23390 administration on locomotion elicited by intra-accumbens cocaine. Rats received systemic injections of SCH-23390 (0, 0.03, 0.3, 1.0 mg/kg, i.p.) and 10 min later received bilateral injections of either saline or cocaine (100 $\mu\text{g}/0.5$ $\mu\text{l}/\text{side}$) into the NAc. Locomotion and stereotypic behaviors were then measured for 60 min. This procedure was repeated twice at 6-day intervals. The two highest doses of SCH-23390 decreased cocaine-induced locomotion, as well as baseline locomotion. The magnitude of cocaine-induced locomotion did not change across repeated intra-accumbens administrations. Stereotypic behaviors were not observed following acute or repeated intra-accumbens cocaine administration. In summary, although intra-accumbens SCH-23390 does not potently block locomotion produced by systemic cocaine administration, systemic SCH-23390 potently blocks locomotion produced by intra-accumbens cocaine administration. These findings suggest that D_1 -like receptors in brain regions other than the NAc are involved in mediating cocaine-induced locomotion. (Supported by DA07730.)

665.4

EFFECT OF D_2 RECEPTOR ANTISENSE IN THE NUCLEUS ACCUMBENS ON INTRAVENOUS COCAINE SELF-ADMINISTRATION IN THE RAT. A. McGregor and D.C.S. Roberts*, Life Sciences Research Centre, Carleton University, Ottawa, K1S 5B6, Canada.

These experiments examined whether an antisense oligonucleotide directed against D_2 receptor mRNA in the nucleus accumbens of the rat could disrupt intravenous cocaine self-administration behaviour. Rats were trained to self-administer cocaine (1.5 mg/kg/inj IV) under a progressive ratio (PR) schedule of reinforcement and then implanted with intracerebral cannulae above the nucleus accumbens. Following re-establishment of stable self-administration behaviour, three injections of the antisense or randomised antisense sequence were administered at 12 hour intervals. Phosphorothioated at all positions, the antisense and randomised antisense sequences were delivered in a saline vehicle (2.5 nmol/1.0 μl /injection). A large and significant decrease in break point (BP) was produced following antisense treatment, which took five to six days to return to baseline BP. In contrast, treatment with randomised antisense produced a much smaller decrease in BP, which showed a rapid return to pretreatment BP. Furthermore, antisense treatments had no effect on operant responding for food reinforcement under a fixed ratio (FR20) schedule. These results suggest that injection of D_2 antisense into the nucleus accumbens caused large reductions in the reinforcing properties of cocaine as measured under the PR self-administration schedule. The lesser effect of the randomised sequence may be due to nonspecific behavioural deficits following such treatment, and indicates that attention must also be given to the nonspecific effects of such oligonucleotide treatments. Supported by NIDA Contract No. NOIDA-3-7302 and MRC of Canada.

665.5

DIFFERENTIAL EFFECTS OF INTRA-ACCUMBENS SULPIRIDE ON COCAINE-INDUCED LOCOMOTION AND CONDITIONED PLACE PREFERENCE. D.A. Baker*, L.E. O'Dell, T.V. Khroyan, J.L. Neisewander, Department of Psychology, Arizona State University, Box 871104, Tempe, AZ 85287-1104.

The effects of intra-accumbens administration of sulpiride on the stimulant and reinforcing effects of intravenous (IV) cocaine were investigated using the conditioned place preference (CPP) paradigm. Adult male Sprague-Dawley rats received 3 conditioning trials which consisted of 30-min exposures to two distinctive compartments on consecutive days. On one day of the trial, the rats received bilateral injections of saline or sulpiride (0.05 or 0.2 µg/0.5 µl/ side) into the nucleus accumbens (NAc). Fifteen min later, the rats were placed into a compartment and immediately injected with either saline or cocaine (4.2 mg/kg, IV). On the alternate day, rats received sham intra-accumbens injections and 15 min later were placed into the other compartment. Locomotion, stereotypies, and grooming were measured on the first and last trial. Cocaine produced an increase in locomotion which was attenuated by both doses of sulpiride. Cocaine also produced an increase in sniffing and headbobbing, and a decrease in grooming. These behaviors were not affected by either dose of sulpiride. Headbobbing was the only behavior sensitized by repeated administration of cocaine, and this sensitization was blocked by the high dose of sulpiride. Cocaine produced a robust CPP that was not altered by either dose of sulpiride. Conditioned locomotion was evident following saline injections in the drug-paired environment, and acquisition of this response was blocked by the high dose of sulpiride. These findings suggest that D2-like receptors in the NAc mediate cocaine-induced locomotion, but not CPP. This research was supported by DA07730.

665.7

THE EFFECTS OF PARTIAL DOPAMINE D₂ AGONISTS ON SELF-ADMINISTRATION OF COCAINE ON A PROGRESSIVE RATIO SCHEDULE IN RATS. R. Rinaldi*, G. Vickers and D.C.S. Roberts, Life Sciences Research Center, Carleton University, Ottawa, Canada K1S 5B6. There now exists considerable evidence showing that the rewarding effects of cocaine depend on dopamine (DA) neurotransmission. Thus, drugs that interfere with DA function may potentially be beneficial in the treatment of cocaine addiction. Electrophysiological and biochemical studies have demonstrated that the intrinsic efficacy of partial D₂ receptor agonists can be rank-ordered from greatest to least as follows: B-HT 920, SND 919, (-)-3-PPP, SDZ 208-912, SDZ MAR 327. We investigated the effects of these partial D₂ receptor agonists on cocaine self-administration in rats. Subjects were trained to intravenously self-administer each of four unit doses of cocaine (0.075, 0.15, 0.3 and 0.6 mg/injection) on a progressive ratio (PR) schedule and the effects of B-HT 920 (0.25 mg/kg), SND 919 (0.1 mg/kg), (-)-3-PPP (1.25 mg/kg), SDZ 208-912 (0.25 mg/kg) and SDZ MAR 327 (0.25 mg/kg) on the breaking points at each unit dose of cocaine were investigated. The results demonstrated that drugs with the least intrinsic activity (SDZ 208-912 and SDZ MAR 327) decreased breaking points for cocaine. These drugs also disrupted food-rewarded responding on a PR schedule. The drugs with greatest intrinsic activity (B-HT 920 and SND 919) did not affect or increased breaking points for cocaine reward. Thus, the effect of these partial agonists on breaking points for cocaine reward is positively correlated with their intrinsic activity at the D₂ receptor. The data suggest that there may be a point on the continuum where agonists may decrease breaking points for cocaine but not disrupt food-rewarded responding. DOPAMINE D₂ RECEPTOR AGONISTS PARTIALLY REPRODUCE THE DISCRIMINATIVE STIMULUS EFFECTS OF COCAINE. Roger D. Spealman*, Harvard Medical School, New England Regional Primate Research Center, Southborough, MA 01772-9102.

Dopamine agonists with reported selectivity for the D₂ subtype of dopamine receptor were studied for their capacity to reproduce the discriminative stimulus effects of cocaine in squirrel monkeys. Monkeys were trained to discriminate cocaine (0.3 mg/kg) from vehicle using a conventional two-lever choice procedure and subsequently were tested with a range of doses of 7-hydroxy-dipropylaminotetralin (7-OH-DPAT; 0.0001 - 0.1 mg/kg), 2-(N-phenylethyl-N-propyl) amino-5-hydroxytetralin (N-0434; 0.001 - 0.18 mg/kg), quinpirole (0.003 - 0.3 mg/kg) and quinelorane (0.01 - 0.3 mg/kg). Each drug engendered dose-related partial substitution for cocaine, reaching average maximums of 60 - 80% cocaine-appropriate responses after the highest doses tested. The degree of cocaine substitution engendered by the D₂ agonists was comparable to that reported previously for D₁ and D₃ agonists. The results are consistent with the view that D₂ receptors in addition to other dopamine receptor subtypes play a significant role in mediating the discriminative stimulus effects of cocaine in monkeys. Supported by DA00499, DA03774 and RR00168.

EXAMINATION OF THE NOVEL BENZAMIDE ANALOGS IN THE DISCRIMINATIVE STIMULUS EFFECTS OF COCAINE IN RATS. A.K. Singha* and L.L. Hernandez, V.A. Medical Center & University of South Carolina, Columbia, S.C. 29201.

The present study examined the effects of two novel benzamide analogs, MABN and MBP, on the discriminative stimulus effects of cocaine. Both MABN and MBP are D₂ receptor antagonists. Rats were trained to discriminate i.p. injections of cocaine (10 mg/kg) from saline (1 ml/kg) in a two-lever drug discrimination paradigm. When rats (n=5) were given MABN (0.1 mg/kg) in combination with cocaine, responding on the drug lever was attenuated to 65%, while a higher dose of MABN (0.4 mg/kg) produced 73% responding on the cocaine associated lever. Likewise, rats (n=7) given MBP (0.1 mg/kg) displayed a partial blockade (50% drug-lever responding) of the cocaine cue. At the doses tested, animals' rate of response was not significantly reduced. These data support the role of dopamine (D₂ receptors) in mediating the subjective effects of cocaine.

THE EFFECTS OF THE D-3 RECEPTOR AGONIST 7-OHDPAT ON COCAINE SELF-ADMINISTRATION MAY BE MEDIATED POST-SYNAPTICALLY. L.H. Parsons*, S.B. Caine, G.F. Koob and F. Weiss, Department of Neuropharmacology (CVN-15), The Scripps Research Institute, La Jolla, CA 92037.

Recent work from this laboratory has demonstrated that the dopamine (DA) D-3 receptor-selective agonist 7-OHDPAT potently decreases cocaine self-administration in the rat at doses that are not themselves reinforcing (Caine et al., 1993, Science, 260, 1814-1816). In the present experiment, the effects of 7-OHDPAT on extracellular DA in the nucleus accumbens during cocaine self-administration were examined using *in vivo* microdialysis. Rats were trained to self-administer cocaine (0.25 mg/inf) on an FR-5 schedule of reinforcement until stable baseline responding was achieved. On the test day, nucleus accumbens dialysate samples (0.3 µl/min flowrate) were collected during a self-administration session in which rats were allowed to self-administer cocaine (0.25 mg/inf), a combination of cocaine (0.25 mg/inf) and 7-OHDPAT (4.0 µg/inf), 7-OHDPAT alone (4.0 µg/inf), and saline during four consecutive 1.5 hour periods. The baseline dialysate DA concentration was 4.9±0.7 nM (n = 5). During cocaine self-administration, DA levels rose to 373±18% of baseline, with an average of 2.3±0.2 cocaine infusions per ten minutes. When the drug solution was switched to cocaine and 7-OHDPAT, the number of self-administered drug infusions decreased to 1.1±0.3 infusions per ten minutes. During this period dialysate DA concentrations decreased to a stable level of 134±8% of baseline. Almost immediately after switching the drug solution to 7-OHDPAT alone, the number of self-administered infusions increased to an average of 9.1±0.3 infusions per ten minutes. Despite this increased responding for drug, dialysate DA levels decreased to a stable level of 37±6% of baseline. Operant responding extinguished within 90 minutes of switching the drug solution to saline, during which time dialysate DA did not rise above 40% of baseline. The decrease in nucleus accumbens DA efflux coupled with the increased responding during the self-administration of 7-OHDPAT alone suggest that the effects of 7-OHDPAT on cocaine self-administration may be mediated post-synaptically.

665.10

EFFECTS OF DOPAMINE ANTAGONISTS ON CONDITIONED AND UNCONDITIONED RESPONDING DURING A MULTIPLE SCHEDULE OF FOOD AND COCAINE SELF-ADMINISTRATION IN RATS. R. Weissenborn*, G.F. Koob and F. Weiss, Department of Neuropharmacology, The Scripps Research Institute, La Jolla, California 92037.

The present series of experiments sought to examine the effects of selective D1 and D2 dopamine receptor antagonists (SCH 23390 and raclopride) and a D2 partial agonist (SDZ 208-911) on food and cocaine self-administration, as well as on responding for environmental cues associated with the primary reinforcers. Rats were trained on a multiple schedule during which lever-pressing was reinforced with a food pellet and simultaneous presentation of a tone, or with a cocaine infusion and presentation of a stimulus light. Each session was preceded by a 5 min component during which lever presses resulted in presentation of the respective cues only. Non-contingent delivery of food or cocaine prior to this initial component resulted in a significant shift in preference for the tone or light respectively, suggesting that the cues had taken on the role of conditioned reinforcers with incentive-motivational value. Systemic administration of SCH 23390 (10 µg/kg) and raclopride (100 and 200 µg/kg) blocked, while SDZ 208-911 (0.025 - 1.6 mg/kg) enhanced the preference shift induced by non-contingent delivery of cocaine. SCH 23390 and raclopride non-selectively suppressed responding following non-contingent food. During the multiple schedule, SCH 23390, raclopride and SDZ 208-911 decreased the inter-reinforcer intervals for cocaine, and at higher doses increased those for food. These data suggest that low doses of D1 and D2 antagonists and a D2 partial agonist selectively block the reinforcing effects of cocaine but not food under the schedule parameters used here. In addition, selective dopamine antagonists can attenuate cocaine-induced responding for a conditioned reinforcer, implicating both D1 and D2 receptor mechanisms in mediating conditioned stimulus-reward associations. This work was supported by NIDA grants DA 07348, 08467, 04398 (FW and GFK).

665.11

REDUCTION OF THE REINFORCING PROPERTIES OF COCAINE BY A PARTIAL DOPAMINE AGONIST. L. Pulvirenti*, D. Smith and G.F. Koob Dept. of Neuropharmacol., Scripps Res. Inst., La Jolla, CA 92037 and "Mondino-Tor Vergata" Ctr for Exp Neurobiol, Un. of Rome "Tor Vergata", Rome, Italy

Partial dopamine agonists are a recently characterized novel class of compounds acting at the dopamine receptor site with high affinity and low intrinsic activity. These drugs act as functional antagonists in conditions of high dopamine tone, while they show an agonistic profile in conditions of dopamine depletion (e.g. denervation). Since the reinforcing properties of cocaine seem to depend upon activation of forebrain dopamine neurotransmission, the aim of the present study was to evaluate the effects of acute pretreatment with SDZ 208-911, an aminoergoline with partial dopamine agonistic activity, in rats trained to self-administer cocaine IV (0.75 mg/kg/injection). SDZ 208-911 (0.025-1.6 mg/kg IP) dose-dependently reduced the reinforcing properties of cocaine as shown by a reduction of the inter-reinforcement interval in rats self-administering cocaine IV with limited daily access. The pattern of responding was similar to that of animals self-administering a lower dose of cocaine (0.37 mg/kg/injection) and to that of animals pretreated with a dopamine receptor antagonist. Cocaine abuse in humans is characterized by intake of high amount of drug followed by withdrawal. Since partial dopamine agonists also show an agonistic profile in conditions of low dopamine tone (i.e. cocaine abstinence), the potential use of these compounds for effective pharmacological intervention during the various phases of cocaine addiction is a hypothesis worth testing.

SENSITIZATION TO COCAINE SELF-ADMINISTRATION FOLLOWING CHRONIC *cis* (Z)-FLUPENTIXOL. R.L. Peltier* and M.W. Emmett-Oglesby. Dept. of Pharmacology and S.A.I.N.T., UNTHSC, Fort Worth, TX 76107.

Acute pretreatment with the D₂/D₁ antagonist, *cis* (Z)-flupentixol (FLU), results in an increase in the rate of cocaine self-administration (e.g. Ettenberg *et al.*, *Psychopharmacology*, 78: 204, 1982). The present study investigated the effects of acute as well as chronic administration of FLU on the dose-effect curve for cocaine self-administration. Rats were implanted with chronic indwelling jugular catheters. Following implantation, they were allowed to self-administer cocaine (0.25 mg/injection) on a fixed-ratio two (FR2) schedule of reinforcement, 15 reinforcers a day, until baseline responding was stable. Using a multi-dose procedure, a dose-response curve for each rat was then obtained. Rats were then assigned to one of two groups. One group received a 3 hr pretreatment with FLU (0.032, 0.1, or 0.32 mg/kg, i.p.), followed by a multi-dose test. The other group was treated with FLU chronically (0.32 mg/kg/12 hr; s.c.). The chronic regimen lasted for five days, during which rats did not have access to cocaine self-administration. Seventy-two hours after the last chronic injection, cocaine dose-response curves were re-obtained. Acute treatment with FLU produced a dose-dependent shift to the right of the cocaine dose-response curve. In contrast, three days after terminating chronic FLU, a 2-fold shift to the left of the dose-response curve was obtained. The present data suggest that acute dopamine blockade results in a decrease in the reinforcing properties of cocaine as observed by a shift to the right of the cocaine dose-response curve. In contrast, three days after terminating the chronic blockade of dopamine receptors by FLU, there was an increase in the reinforcing properties of cocaine as observed by a shift to the left of the cocaine dose-response curve. COCAINE INDUCED LOCOMOTOR HYPERACTIVITY IN THE RAT IS REDUCED BY QUINACRINE. Kevin H. Souza, Aaron J. Janowsky*, Malcolm S. Reid, S. Paul Berger. UCSF/VAMC, Psychiatry Services 127, 4150 Clement St., San Francisco, CA 94121; + Res Svc 151-PP, VAMC, 3710 SW Veterans Hosp. Rd., Portland, OR 97201

Quinacrine is a phospholipase A2 (PLA2) inhibitor which is clinically used for the treatment of malaria. As a PLA2 inhibitor one of its main effects is the reduction of arachidonic acid levels. The release of arachidonic acid has been suggested to play a role in dopamine D2 receptor signal transduction mechanisms. In the present study we have investigated whether quinacrine has any effects on the acute locomotor and stereotypic behavioral responses to cocaine in Sprague-Dawley rats. Animals were pretreated with quinacrine (16 mg/kg, i.p.) 15 min prior to cocaine (30 mg/kg, i.p.) administration and locomotor activity and stereotypy were scored every 10 min for 1 hr in an Actimex box. Pretreatment with quinacrine reduced the cocaine stimulation of locomotor activity by approximately 30%, but had no effect on the stereotypic behavioral response. Quinacrine alone had no effect on locomotion and stereotypy. The ability of quinacrine to modulate caffeine induced locomotor stimulation was also tested, and it was found that quinacrine had no effect on caffeine. These findings suggest that the ability of quinacrine to reduce drug induced stimulation of locomotion is mediated via the dopamine system. Further studies on the behavioral effects of selective D1 and D2 receptor agonists are underway.

INCREASED SENSITIVITY TO THE LOCOMOTOR DEPRESSANT EFFECTS OF A DOPAMINE ANTAGONIST DURING COCAINE WITHDRAWAL IN THE RAT. B.A. Baldo* and G.F. Koob. Dept. of Neuropharmacology, The Scripps Research Institute, La Jolla, CA 92037.

Clinical studies have identified a behavioral syndrome, occurring in stimulant abusers after prolonged cocaine binges, which is characterized by psychomotor depression and anhedonia. This "cocaine withdrawal syndrome" has been hypothesized to contribute to recidivism in cocaine users; accordingly, much effort has been dedicated to the development of animal models of cocaine withdrawal in order to elucidate its underlying mechanisms. Recent studies in this laboratory have determined that thresholds for rewarding brain stimulation are elevated following prolonged self-administration sessions in the rat. The post-cocaine threshold elevation was reversible by the dopamine receptor agonist bromocriptine, suggesting that impaired dopaminergic function may contribute to cocaine withdrawal. In order to determine additional behavioral correlates of cocaine withdrawal, and to further study the role of the dopamine system in cocaine withdrawal, spontaneous locomotor activity was measured in photocell testing cages 4 h following 12 h cocaine self-administration sessions. Prior to locomotor activity testing, cocaine-exposed and control animals were injected with saline, or 0.05 mg/kg *cis*-flupentixol, a dopamine receptor antagonist. Locomotor activity was found to be significantly depressed in cocaine-exposed animals, but not control animals, treated with *cis*-flupentixol. In a separate experiment, doses of *cis*-flupentixol as high as 0.4 mg/kg failed to produce significant locomotor depression in drug-naïve animals. It is hypothesized that dopamine receptor blockade by a low dose of *cis*-flupentixol may interact with cocaine-induced neurochemical changes to produce locomotor depression during cocaine withdrawal. Supported by DA04398 (GFK) and an NSF Predoctoral Fellowship (BAB).

DOPAMINE RECEPTOR BLOCKADE ALTERS PREPRODYNORPHIN AND ZIF/268 mRNAs IN RATS THAT "BINGE" ON COCAINE. J.B. Daunais*, J.Q. Wang, W.T. Bohler, D.C. Mayer, and J.F. McGinty. Dept. Anat. & Cell Bio., East Carolina University School of Medicine, Greenville, NC 27858-4354

A single injection of cocaine increases *c-fos* and *zif/268* mRNAs whereas repeated cocaine increases dynorphin immunoreactivity (Dyn-ir) and preprodynorphin (PPD), but not preproenkephalin (PPE), mRNA in rat striatum. Cocaine's effects on *c-fos* and *zif/268* mRNAs, and Dyn-ir, are blocked by the dopamine (DA) D₁ receptor antagonist, SCH23390. However, the effects of cocaine "bingeing" on *c-fos* and *zif/268* mRNAs, or of DA D₂ receptor blockade on *c-fos*, *zif/268*, and PPD mRNAs after "bingeing" are unknown. In an effort to answer these questions, thirty adult, male Wistar rats were injected i.p. with SCH23390 (0.5 mg/kg) or the D₂ receptor antagonist, sulpiride (50 mg/kg) 30 min prior to 3 hourly injections of i.p. saline or 20 mg/kg cocaine for 1 day. One hr after the final injection, the rats were anesthetized and decapitated. Sections were collected through the anterior striatum at the level of the nucleus accumbens, and hybridized with 40mer oligonucleotides coding for *c-fos* or *zif/268*, or 48mers coding for PPD or PPE. Quantitative image analysis of autoradiograms revealed that SCH23390 completely blocked the cocaine-induced increase in striatal *zif/268* and PPD mRNAs. Furthermore, SCH23390 alone significantly decreased the basal levels of *zif/268* and PPD mRNAs. Sulpiride completely blocked cocaine-induced PPD mRNA and significantly decreased the induction of *zif/268* mRNA in the striatum. Sulpiride alone decreased basal levels of PPD mRNA but enhanced the expression of *zif/268* mRNA as compared to basal levels in saline-treated rats. *C-fos* mRNA was undetectable and PPE mRNA remained unchanged by the repeated administration of cocaine. These data demonstrate that 1) the D₂ receptor plays a substantial role in modulating the tonic expression of PPD mRNA in the striatum, a role attributed primarily to the D₁ receptor, 2) PPD and *zif/268* gene expression is modulated by both D₁ and D₂ receptors following a cocaine "binge". Supported by DA 03982.

COMBINED SPECT AND QUANTITATIVE EEG STUDIES IN COCAINE ABUSERS. J.W. Crayton*, L.M. Konopka, T. Milo, E. Barnes, and P. Shirazi. Biological Psychiatry Section and Nuclear Medicine Service, Hines VA Hospital, Hines, IL 60141.

To examine the relationship between cerebral blood flow as measured by HMPAO-SPECT and brain electrical activity as assessed by quantitative EEG (qEEG), we studied the pattern of distribution of blood flow and EEG activity in 9 chronic cocaine abusers and compared the results with nine normal controls. HMPAO was injected for SPECT while the subjects were continuously monitored for EEG activity under carefully controlled conditions. Using a novel data-reduction algorithm, SPECT data from the nine subjects could be reduced to a single set of group images for comparison with the normal control group. All of the cocaine abusers had abnormal SPECT scans. Using subtraction topographic maps, cocaine abusers showed areas of both hyperperfusion and hypoperfusion. Hyper-perfusion was particularly notable in frontal regions. This hyperperfusion contrasts with other studies in which only areas of hypoperfusion were noted. In addition, there appear to be small right-left asymmetries in the perfusion pattern.

Quantitative EEG studies of the cocaine abusers showed increased total alpha power compared to the controls. The increase in alpha activity came from two sources: first, a widening of the alpha peak indicating a spreading out of the distribution curve of alpha frequencies within the alpha band; and second, a significant penetration of the normally occipital alpha activity into more frontal regions.

Combining SPECT and qEEG revealed a strong correlation between increased frontal alpha activity and frontal hyperperfusion as assessed by SPECT.

PHYSIOLOGICAL ACTIONS OF COCAINE IN SENSORY CIRCUITS: DRUG INFLUENCES ON SIGNAL TRANSMISSION THROUGH RAT POM AND VPM THALAMIC NUCLEI. J. Bekavac*, J.J. Rutter and B.D. Waterhouse, Dept. of Physiol. and Biophys., MCP/HU, Phila. PA 19102

Previous reports from our laboratory have described a preferential potentiating effect of systemically administered cocaine (0.25-1.0 mg/kg) on long latency excitatory responses (E2) of rat "barrel field" cortical neurons to threshold level stimulation of individual whiskers on the contralateral face. Such long latency responses are relayed to cortex via the POM nucleus of thalamus, whereas short latency responses are relayed to cortex via the VPM thalamus. We postulated that systemic cocaine might produce changes in response properties of neurons in primary somatosensory cortex by exerting differential effects on signal transmission through POM versus VPM thalamus. Thus, the goal of the present study was to characterize the effects of cocaine on somatosensory thalamic neuron responsiveness to peripheral activation of afferent synaptic pathways. Extracellular recordings were obtained from spontaneously active single units in POM and VPM thalamic nuclei of halothane-anesthetized rats. Spontaneous firing rate and cellular responses to mechanical displacement of a single whisker were monitored before and after systemic administration of cocaine (1.0 mg/kg, i.v.). VPM neurons responded to whisker stimulation with a short latency (4-10 msec) burst of action potentials. Responses of POM neurons to whisker stimulation occurred at longer latencies (16-85 msec), and were less robust than those recorded from VPM, appearing as a slightly elevated discharge occurring over a period of 30-100 msec. After cocaine injection, stimulus evoked responses of VPM (n=7) neurons were generally unchanged or within (+/-) 4% of control, whereas, in 5 of 6 cases POM responses were increased 60% above control levels. Cocaine's effects were rapid in onset with peak effects occurring at 6 min post-injection and recovery to control patterns of discharge observed by 20 min. These results provide preliminary support for the idea that cocaine exerts a preferential facilitating effect on POM neuronal responses to whisker displacement. Since the POM confers a qualitative aspect to stimulus discrimination, drug actions at this site may underlie cocaine's influence on sensory perception. (Supported by NIDA DA 05117 to BDW)

GLUCOCORTICOID & DRUG ABUSE (I): INFLUENCES OF CHRONIC INHIBITION OF CORTICOSTERONE SYNTHESIS BY METYRAPONE ON COCAINE-INDUCED LOCOMOTION AND RELAPSE OF COCAINE SELF-ADMINISTRATION. P.V. Piazza*, M. Marinelli, C. Jodogne, V. Deroche, F. Rougé-Pont, S. Maccari, M. Le Moal and H. Simon. Psychobiologie des Comportements Adaptatifs, INSERM U.259, Univ. de Bordeaux II, 33077 Bordeaux Cedex, France.

It has been shown that basal and stress-induced secretion of corticosterone enhances vulnerability to drugs of abuse. In this report, we studied the effects of metyrapone, an inhibitor of corticosterone-synthesis, on cocaine-induced locomotion and intravenous self-administration. Locomotor response to cocaine was studied because psychomotor and reinforcing effects of drugs are related. Self-administration (SA) was studied in the relapse phase because blockade of relapse is central to the therapy of addiction. Before any other test, animals were submitted to 8 days of food-restriction during which they were progressively reduced to 90% of their initial body weight. Food-restricted animals were used in order to test for non-specific effects of metyrapone on motivational behavior. For the SA experiment animals were first trained for cocaine SA for 10 days, they then received a drug-free period of 4 days after which they were treated with either metyrapone or vehicle. After 8 days of this treatment, rats were again allowed to self-administer cocaine, and the metyrapone-treatment was continued. For all other experiments, animals were submitted to an 8-day treatment with either metyrapone (100mg/kg twice a day) or vehicle. Metyrapone-treatment totally blocked stress-induced corticosterone-secretion. Metyrapone-treatment also reduced cocaine-induced locomotor activity and the reinstatement of cocaine SA, without inducing non-specific disruptions of behaviors such as: i) locomotor response to a saline injection; ii) hole exploration in the SA cage, that is the response required during SA; iii) performance in reaching food in a straight alley test. In conclusion on these results confirm the involvement of glucocorticoids in determining vulnerability to drugs, and may open new therapeutic strategies of addiction.

666.2

REGIONAL BRAIN BLOOD FLOW DURING INDUCED COCAINE CRAVING. A.R. Childress, D. Mozley, J. Fitzgerald, M. Reivich, J. Jaggi, and C.P. O'Brien*, Depts. of Psychiatry and Radiology, Univ. of Penn. School of Medicine, and Philadelphia VA Medical Center, Philadelphia, PA 19104

Human cocaine users can experience profound drug desire when they encounter cues (other drug users, drug-buying or drug-using locations, drug paraphernalia, etc.) which remind them of cocaine, but little is known about the brain correlates of this state. Clinically, cue-induced cocaine craving is often accompanied by a number of signs and symptoms similar to the effects of cocaine itself, including generalized arousal, palpitations, light-headedness, ear-ringing, chest-tightness, the 'taste' of cocaine in back of the throat, and even mild euphoria. The drug-like nature of these responses suggests that brain structures activated during cocaine craving may be among those activated by cocaine itself, including particularly the limbic regions implicated in cocaine's pleasurable effects.

We are testing whether limbic regions may be differentially activated during cocaine craving by measuring regional cerebral blood flow (rCBF) with Positron Emission Tomography (PET) and radioactively-labeled water (H_2O^{15}) as the flow tracer. Cocaine patients (n=5 thus far) are imaged during exposure to ambient room stimuli (Baseline), and to videos of Neutral (non-drug) and Cocaine-related scenes. Each subject's functional PET images are co-registered with an MRI for anatomical localization of imaged radioactivity. Change in rCBF from Baseline is calculated for both Neutral and Cocaine cue conditions across selected brain regions. Initial results show the Cocaine video triggered craving, and rCBF during the Cocaine video increased in several limbic regions. Systematic increases in rCBF did not occur in reference areas (eg., whole brain or hemispheres) or in response to the Neutral Video. These preliminary data suggest limbic activation may be one component of drug craving.

COCAINE ACTIONS ON SOMATOSENSORY CORTICAL CIRCUITS: COMPARISON WITH PROCAINE AND AMPHETAMINE. F.M. Sessler*, T.N. Felder, R.D. Mouradian, R.C-S. Lin, J. Lehmann, J.P. Utz and B.D. Waterhouse, Depts. of Physiol. & Biophys., and Neurosurg., Hahnemann U., Philadelphia, PA 19102.

In studies of the action of cocaine on local circuits and intrinsic membrane properties of rat somatosensory cortical neurons, we have observed differential actions of cocaine on identified subpopulations of layer V neurons ("regular spiking" vs "doublet cell"). To distinguish between the local anesthetic vs psychostimulant actions of cocaine, we tested the effects of procaine and amphetamine, respectively, on somatosensory cortical circuits. Experiments were conducted using an *in vitro* brain slice preparation from rat somatosensory cortex. Microelectrodes containing either neurobiotin (2-3%) or lucifer yellow (5%) were used for characterization of individual layer V neurons. Postsynaptic potentials (EPSP and IPSP) were evoked by stimulating the cortical white matter. Drugs were applied at various concentrations (0.3-100μM) to examine the full spectrum of the drug action. Bath application of procaine at high concentrations (10-100μM) produced a dose dependent decrease in EPSP amplitude, area, and duration, as well as spike firing probability in both regular and "doublet" spiking layer V neurons. At lower concentrations (0.3-1μM), procaine did not mimic the cocaine-mediated enhancement of EPSP amplitude and spike firing probability which were routinely observed in "doublet" cells. On the other hand, amphetamine (0.3-10μM) increased both spike firing probability and EPSP amplitude of cortical neurons. These results suggest that cocaine exerts both local anesthetic and complex influences on cells within the cerebral cortical circuitry that can be mimicked by procaine and amphetamine, respectively. Some of these effects may involve monoamine release and may depend on cell type and monoamine terminals reaching these neurons. Thus, to assess the impact of cocaine on signal processing within a sensory cortical network, it may be necessary not only to obtain specific information about the effect of the drug on different cell types but also to describe the type of monoaminergic inputs they receive. (Supported by NIDA DA08405 to FMS and DA05117 to BDW).

GLUCOCORTICOID & DRUG ABUSE (II): INFLUENCES OF ACUTE INHIBITION OF CORTICOSTERONE SYNTHESIS AND ADMINISTRATION OF CORTICOSTEROID RECEPTOR ANTAGONISTS ON COCAINE-INDUCED LOCOMOTION. M. Marinelli, P.V. Piazza, M. Barrot, F. Rougé-Pont, M. Kharouby, M. Le Moal and H. Simon*. Psychobiologie des Comportements Adaptatifs, INSERM U.259, Université de Bordeaux II, 33077 Bordeaux Cedex, France.

Previous results have shown that chronic suppression of corticosterone reduces the behavioral effects of cocaine. In the present experiments we studied the effects of acute pharmacological manipulations of the hypothalamo-pituitary-adrenal (HPA) axis on the locomotor response to cocaine (15 mg/kg i.p.). In a first experiment we investigated the effects of a single injection of the blocker of corticosterone-synthesis metyrapone (50 mg/kg), injected subcutaneously 3h before the cocaine injection. In these conditions, animals pre-treated with metyrapone showed a lower locomotor response to cocaine than control rats. This effect was corticosterone-dependent since it was abolished if metyrapone-treated animals were concomitantly injected with corticosterone (20 mg/kg s.c. in oil). In a second experiment we studied the effects of an acute administration of type I and type II corticosteroid receptors antagonists on the locomotor response to cocaine. These antagonists (100 ng in 3μl) were injected i.c.v. 2h before the cocaine injection. Animals receiving the type I antagonist spironolactone showed an increase in the locomotor response to cocaine, whereas the administration of the type II antagonist RU 38486 had no significant effect. Concomitant administration of both antagonists reduced the locomotor response to the drug. Since administration of corticosteroid antagonists increases corticosterone levels, the increase in the locomotor response to cocaine observed after the administration of the type I antagonist was probably mediated by an over stimulation of type II receptors. Even though, type II antagonist alone had no effects, blockade of both receptors seemed necessary to reduce the locomotor response to cocaine. In conclusion, these results show that behavioral effects of drugs can be modulated by acute pharmacological manipulations of the activity of the HPA axis. These findings may have implications for new therapeutic strategies of addiction.

666.7

GLUCOCORTICOIDS & DRUG ABUSE (III): INFLUENCES OF BASAL CORTICOSTERONE SECRETION ON THE EFFECTS OF COCAINE AND MORPHINE ON ACCUMBENS DOPAMINE. M. Barrot, F. Rouge-Pont, S. Maccari, M. Marinelli, M. Le Moal, H. Simon and P.V. Piazza. Psychobiologie des Comportements Adaptatifs, INSERM U.259, Univ. Bordeaux II, Bordeaux, France.

It has been previously shown that basal corticosterone-secretion facilitates behavioral effects of cocaine and morphine. In these experiments we investigated if changes in the response of mesolimbic dopaminergic (DA) neurons to these drugs may account for the behavioral effects of corticosterone. Morphine- and cocaine-induced changes in extracellular concentration of dopamine were studied in three groups of rats: i) sham operated (Sham); ii) adrenalectomized (ADX); iii) ADX receiving a substitutive treatment which reproduced the corticosterone circadian secretion (ADX+Cort). Dopamine extracellular concentrations were recorded in the nucleus accumbens by means of microdialysis in freely moving animals. We also investigated the functional state of the postsynaptic DA receptors by studying the locomotor response to the direct DA agonist apomorphine (1.5 mg/kg s.c.). Adrenalectomy reduced the locomotor response to both morphine (2mg/kg) and cocaine (15mg/kg) whereas it differentially modified the increase in dopamine concentrations induced by the two drugs. Morphine-induced increase in dopamine levels was reduced by adrenalectomy, in contrast adrenalectomy enhanced the increase in dopamine levels induced by cocaine. For both drugs the effects were corticosterone-dependent since ADX+Cort animals did not differ from the sham group. These results suggest that the ADX-induced decrease in locomotor response to morphine may be mediated by a decrease in the release of dopamine, whereas ADX-effects on locomotor response to cocaine should involve postsynaptic modifications. Indeed, suppression of corticosterone-secretion also reduced DA postsynaptic transmission. ADX animals showed a lower locomotor response to apomorphine and this effect was not present in ADX+cort rats. In conclusion, corticosterone can modulate dopaminergic reactivity to drugs by acting on both the presynaptic and postsynaptic side.

DIFFERENTIAL EFFECTS OF CORTICOSTERONE ON LOCOMOTOR SENSITIZATION TO COCAINE IN FISCHER AND LEWIS RATS: POSSIBLE BIOCHEMICAL MECHANISMS J. Ortiz*, T. A. Kosten, J. DeCaprio and E.J. Nestler. Lab. of Molecular Psychiatry, Dept. of Psychiatry and Pharmacology, Yale University School of Medicine, New Haven, CT 06508.

The Fischer and Lewis inbred rat strains differ in their preferences for opiates, alcohol, and cocaine. They also differ markedly in hypothalamic-pituitary-adrenal axis function, which seems to contribute to cocaine-induced behaviors in other strains. Here we report that corticosterone (CORT) administration by slow-release pellets (giving plasma levels around 150 ng/ml) was necessary for the Fischer rats to initiate locomotor sensitization to cocaine (7.5 mg/kg i.p. for 5 consecutive days). In contrast, Lewis rats developed cocaine sensitization independently of CORT administration. Similarly, CORT administration to Fischer rats, but not to Lewis rats, increased levels of tyrosine hydroxylase (TH) in the ventral tegmental area (VTA) (+75%), abolishing previously described differences between the Fischer and Lewis strains. This supports a possible link between TH levels (and dopamine function) in the VTA and the initiation of locomotor sensitization.

Since TH expression is regulated in cell lines by cAMP and glucocorticoids, we further explored CORT action at the level of glucocorticoid receptor (GR) and cAMP response-element binding protein (CREB) immunoreactivity in the VTA. The drug-naïve Fischer strain had higher levels of CREB (+49%) than the Lewis strain, but comparable levels of GR. Strikingly, CORT down-regulated GR levels in the VTA of Lewis rats (-47%), but not in Fischer rats. These observations could account for the differential responsiveness of the two strains to glucocorticoids: 1) In Lewis rats, GR down-regulation could decrease responsiveness to CORT; 2) In Fischer rats, the lack of GR down-regulation, together with the higher basal CREB levels, could increase the transcriptional actions of glucocorticoids at the TH and other genes.

666.11

AN EFFECT SALIENT TO COCAINE'S REINFORCEMENT IS MODIFIED BY CENTRAL ADMINISTRATION OF DELTA SPECIFIC OPIOIDERGIC AGENTS.

L.D. Reid*, C.L. Hubbell, C.A. Amendola, E.J. Bilsky and F. Porreca.

Lab. for Psychopharm., RPI, Troy, NY 12180 and Dept. of Pharm., U. of Arizona, Tucson, AZ 85724

Some rats were implanted with bilateral, chronically indwelling cannulae for administration of agents to the accumbens n. Others were implanted with a cannula for intraventricular administrations. All rats were implanted with chronically indwelling bipolar electrodes for intracranial stimulation (ICS) of the lateral hypothalamus. Rats were trained to press a lever for ICS and then allowed to press daily for a fixed intensity of ICS. After pressing rates were stable, rats were given IP injections of cocaine at doses producing clear enhancement of pressing. Then, naltrindole and other agents influencing delta opioid receptors were centrally administered in addition to cocaine. Agents blocking delta opioid receptor processes blocked cocaine's effects. These data confirm that effects salient to cocaine's reinforcement are sensitive to delta opioidergic manipulations and extend them by showing that the critical effect is a central neural effect.

666.8

GLUCOCORTICOIDS & DRUG ABUSE (IV): INFLUENCE OF STRESS-INDUCED CORTICOSTERONE SECRETION ON STRESS-INDUCED INCREASE IN COCAINE'S EFFECTS ON ACCUMBENS DOPAMINE. F. Rouge Pont, V. Deroche, M. Marinelli, M. Kharouby, M. Le Moal, H. Simon and P.V. Piazza. (SPONS: Europ. Brain Behav. Soc.) Psychobiologie des Comportements Adaptatifs, INSERM U.259, Univ. de Bordeaux II, 33077 Bordeaux Cedex, France.

Several data indicate that stressful experiences induce a parallel increase in behavioral and dopaminergic responses to psychostimulants. Such may be at the basis of the enhanced vulnerability to psychostimulants induced by stressors, since mesolimbic dopaminergic neurons are one of the principal substrates of the reinforcing effects of drugs. We have previously shown that stress-induced corticosterone-secretion mediates the stress-induced increase in the behavioral effects of psychostimulants. In this experiment we have investigated if stress-induced corticosterone-secretion could also modulate the enhancement of the dopaminergic response to drugs induced by stress. For this purpose, we have studied the effects of the inhibition of corticosterone-synthesis by metyrapone (100 mg/kg s.c., twice a day for 8 days) on the increase in dopaminergic and locomotor response to cocaine (10 mg/kg i.p.) induced by food-restriction. Food-restriction, 8 days during which animals were progressively brought to 90% of their initial body weight, was used as a stressor because it induces a clear-cut increase in corticosterone levels and in the stimulant and reinforcing effects of drugs. Dopamine was studied by means of microdialysis in the nucleus accumbens of freely moving rats. Food-restriction induced a significant enhancement of cocaine-induced increase in both dopamine and locomotion. Metyrapone-treatment, during the food-restriction regimen, blocked the development of these effects. Metyrapone-treatment was also able to reverse the effects of food-restriction once these had established. Locomotor and dopaminergic response to cocaine in metyrapone-treated animals did not differ from *ad libitum*-fed controls also when the treatment was started after 8 days of food-restriction. In conclusion, stress-induced corticosterone-secretion may modify behavioral effects of drugs by acting on dopaminergic neurons.

666.10

EFFECTS OF 17- β ESTRADIOL ON INTRAVENOUS COCAINE SELF-ADMINISTRATION BY CASTRATED FEMALE RATS. J.W. Grimm* and R.E. See. Department of Psychology, Washington State University, Pullman, WA 99164-4820.

Previous studies of female rats self-administering cocaine have indicated differences across the estrous cycle. The present experiments were conducted to further the understanding of the motivation to self-administer cocaine by females and help discern the role of estrogen in cocaine-mediated reinforcement in females. Female Sprague-Dawley rats were castrated, sub-cutaneously implanted with Silastic capsules containing 17- β estradiol or cholesterol, and allowed to self-administer intravenous cocaine (0.78 mg/kg/infusion) on fixed interval and progressive ratio schedules of reinforcement. Animals receiving chronic 17- β estradiol showed increased self-administration of cocaine indicating that estrogen may modulate cocaine craving in female rats. These results may also contribute to an understanding of possible sex-differences in cocaine self-administration. The effects of chronic vs. acute treatment with 17- β estradiol on cocaine self-administration will be discussed. (Supported by the State of Washington Initiative Measure No. 171.)

EFFECTS OF COCAINE AND HEROIN, ALONE AND IN COMBINATION, ON MILK DRINKING IN RATS. J.K. Rowlett* and W.L. Woolverton. Department of Psychiatry and Human Behavior, University of Mississippi Medical Center, Jackson, MS 39216.

The use of drug combinations (e.g., cocaine and heroin "speedball") is common among drug abusers; however, relatively few studies have assessed the pharmacological basis of this phenomenon. In the present experiment, the behavioral effects of combined cocaine and heroin were examined using a milk drinking procedure in rats. Rats (n=8) were given access to a sweetened milk solution for 15 minutes daily until intake had stabilized (3 days with less than 10% variation across days and between subjects). Rats then were administered saline or one of four doses of either cocaine (4.0-32 mg/kg, i.p.) or heroin (0.4-3.2 mg/kg, i.p.) 15 minutes prior to milk access. Both cocaine and heroin produced a dose-dependent decrease in milk drinking, with ED₅₀s (mean mg/kg \pm SEM) of 7.7 \pm 1.1 and 1.9 \pm 0.14, respectively. The dose-response function for cocaine then was redetermined in combination with either 0.8 mg/kg or 1.6 mg/kg heroin. Isobolographic analysis of these dose-response functions revealed that the combination of cocaine and heroin was dose-additive. These results suggest that the combination of cocaine and heroin is additive in disruption of ongoing behavior. (Supported by NIDA grant DA-05951).

666.13

MODULATION OF THE DISCRIMINATIVE STIMULUS EFFECTS OF COCAINE BY MORPHINE IN RATS. K.M. Kantak*, R.D. Spealman, A. Riberdy and P. Clutton. Boston Univ., Boston, MA 02215 and New England Regional Primate Research Center, Southborough, MA 01772.

Modulation of the discriminative stimulus (DS) effects of cocaine by morphine was investigated in rats trained to discriminate a relatively low (3 mg/kg) or a relatively high (10 mg/kg) dose of cocaine from vehicle. When tested alone, cocaine (0.3 - 18 mg/kg) engendered dose-related increases in cocaine-appropriate responding under both training conditions, with ED_{50} values being about 3-fold greater under the high-dose training condition than under the low-dose training condition. Morphine (0.3-5.6 mg/kg) did not engender substantial cocaine-appropriate responding under either training condition. Pretreatment with morphine did, however, enhance the DS effects of cocaine (0.3 - 3.0 mg/kg) under both training conditions, with the degree of enhancement dependent on the dose of morphine (3.0 or 5.6 mg/kg) and the pretreatment time (15 or 30 min). The greatest enhancement was observed when 5.6 mg/kg morphine was administered 30 min before cocaine. At these parameters, morphine produced a leftward shift of the cocaine dose-effect curve under both training conditions and a concomitant reduction in ED_{50} of 8- to 12-fold. The results are consistent with those previously reported in squirrel monkeys and provide relevant information about the boundary conditions under which morphine-cocaine interactions are observed.

666.15

Choline acetyltransferase activity is reduced in rat nucleus accumbens after unlimited access to self-administration of cocaine. J.M. Wilson*, M.E. Carroll, S.T. Lac, L.M. DiStefano and S.J. Kish. Clarke Institute of Psychiatry, Toronto, Ontario and University of Minnesota, Minneapolis.

Activity of choline acetyltransferase (ChAT), the acetylcholine synthesizing enzyme, was measured in discrete areas of rat brain after chronic, unlimited access to self-administration of cocaine. The duration of drug exposure was 6 weeks, during which time the rats self-administered a mean daily dose of approximately 90 mg/kg. Rats were sacrificed either on the last day of cocaine access (n=10) or after three weeks drug withdrawal (n=8). As compared with the controls (n=15), ChAT activity was slightly reduced in striatum (-10%, $P > 0.05$) and moderately reduced in nucleus accumbens (-26%, $P < 0.05$) on the last day of cocaine access. After three weeks withdrawal from cocaine, ChAT activity was still reduced (striatum -18%, $P < 0.05$; nucleus accumbens -32%, $P < 0.05$) relative to controls. These data suggest that self-administration of cocaine is associated with a long-lasting reduction in ChAT activity. Such a reduction in ChAT activity suggests reduced activity of dopamine receptive cholinergic neurones in the basal forebrain, which could underlie some of the behavioral effects of cocaine. (Supported by NIDA grant DA07182).

666.17

PROFOUND EFFECT OF COCAINE ON NEUROPEPTIDE Y (NPY) AND NPY-Y1-RECEPTOR mRNA LEVELS IN THE RAT BRAIN. C. Bjennings* and C. Wahlestedt. Div. Neurobiol., Dept. Neurol. & Neurosci., Cornell Univ. Med. Coll., New York, NY 10021.

Considerable evidence, obtained by studies in man and experimental animals, indicates that NPY plays a role in behavior. For example, NPY appears to be an endogenous anticonflict/antixiolytic agent, whose action depends on activation of NPY-Y1-receptors (Wahlestedt *et al.*, *Science* 259, 528-31, 1993). We have hypothesized that the reduction of forebrain NPY levels (and reduced NPY-Y1-receptor occupancy) resulting from repeated cocaine treatment may be associated with severe anxiety and depression-like states that often follow cocaine withdrawal (Wahlestedt *et al.*, *PNAS*, 88, 2078-82, 1991).

The NPY mRNA and NPY-Y1-receptor mRNA levels in frontal cortex, peripheral cortex, nucleus accumbens, hippocampus and in the hypothalamus were measured with a solution hybridization assay using 300 bp fragments of respective rat cDNA. The hybridization was linear to 500 pg for both NPY and NPY-Y1-receptor sense transcripts.

After 24-hour treatment with cocaine (10mg/kg bw i.p., twice daily), NPY mRNA levels decreased between 20 and 70% in the assayed brain regions. Cocaine treatment for 72 hours, and up to 7 days, further decreased NPY mRNA levels in the sampled regions. NPY-Y1-receptor mRNA levels, on the other hand, peaked (125 to 600% increase in the different regions) after 24 hours and stabilized at 70-185% increase after 72 hours.

Our data thus indicate that treatment with cocaine causes profound alterations in NPY and NPY-Y1-receptor mRNA levels. However, the temporal patterns of these effects are distinct for the two mRNA species. (Supported by DA06805).

U50,488, A KAPPA AGONIST, ATTENUATES COCAINE-INDUCED INCREASES IN EXTRACELLULAR DOPAMINE IN NUCLEUS ACCUMBENS. I.M. Maisonneuve* and S.D. Glick. Dept. PharmTox, Albany Medical College, Albany, NY 12208 and the Capital District Center for Drug Abuse Research and Treatment, Albany, NY 12208.

Recent observations suggest that manipulation of endogenous opioid systems may modify the dopamine-dependent effects of cocaine. The combination of cocaine and a mu opioid agonist produces a mutual enhancement of their reinforcing effects and is commonly referred to as "speed ball" by abusers (Masukawa *et al.*, 1993). In contrast, kappa opioid agonists have been shown to attenuate the discriminative stimulus effects of cocaine (Spealman and Bergman, 1992). Using *in vivo* microdialysis in awake and freely moving female Sprague Dawley rats, we investigated whether U50,488, a selective kappa agonist, would alter cocaine-induced dopamine (DA) increases in the shell of the nucleus accumbens. Cocaine (20 mg/kg, i.p.) produced a ten-fold increase in extracellular DA levels that peaked 20-40 minutes after administration. Pretreatment (20 minutes beforehand) with the selective kappa agonist U50,488 (10 mg/kg, i.p.) produced a 50% decrease in the effect of cocaine on DA levels. This attenuation was completely reversed by administration of nor-binaltorphimine (10 mg/kg, s.c.), a kappa antagonist, 20 minutes before the agonist challenge. These findings indicate that activation of kappa receptors attenuate cocaine's effects and thus kappa agonists may have a potential role in the pharmacological management of cocaine addiction (supported by DA03817 and by the Aaron Diamond Foundation).

AMPEROZIDE REDUCES ORAL CONSUMPTION OF COCAINE AND COCAINE-CONDITIONED PLACE PREFERENCE IN RATS. E.A. Jones*, H.L. Williams, R.D. Myers & B.A. McMillen. Dept. of Pharm., Sch. of Med., East Carolina Univ., Greenville, NC 27858.

Amperozide is a novel serotonin, (5HT₂) receptor antagonist with a low affinity for dopamine receptors. Previously, amperozide (0.5, 1.0 or 2.5 mg/kg b.i.d.) given for 3 days reduced oral consumption of cocaine or alcohol during and after treatment with the drug. In this study, rats were induced to drink a cocaine-saccharin solution, a concentration which produced maximal consumption was used in a two-choice paradigm with 0.03% saccharin solution in a second drinking tube. Amperozide (2.5 mg/kg b.i.d. X 7 days) decreased cocaine consumption by 42% (21.7 to 12.6 mg/kg/day; $p < 0.01$). A decrease in food consumption during the 7 day treatment period was recorded. The 5HT₂ antagonist, trazodone (2.5 mg/kg b.i.d.), but not ritanserin (1.0 mg/kg b.i.d.), reduced the volitional intake of cocaine by 26% ($p < 0.05$). Continuous s.c. infusion by mini-pump of 2.0 mg/kg/day amperozide for 2 weeks decreased intake of cocaine by 42% and 30% during the week after. To test the effect of amperozide on a cocaine-conditioned response, a conditioned place preference (CPP) was induced using 2.5, 5.0 or 10 mg/kg i.p. cocaine. Amperozide (0.1 mg/kg) administered s.c. 60 min. prior to testing did not affect a 5.0 mg/kg cocaine-induced CPP. However, amperozide (0.5, 1.0 or 2.5 mg/kg) reduced the time spent in the cocaine-paired environment. Thus, amperozide potently reduces both the oral consumption of cocaine and cocaine-seeking behavior. (Supported by NIAAA grant AA-04200-11)

REPEATED COCAINE INJECTIONS DECREASE THE FUNCTION OF STRIATAL GABA_A RECEPTORS. J. Peris* & U. Geiss. Dept. Pharmacodynamics, Univ. Florida, Gainesville, FL 32610.

Behavioral sensitization to cocaine is correlated with increased striatal dopamine (DA) neurotransmission which may occur via upregulation of DA receptors or DA release. It is also possible that alterations in other striatal neurotransmitters contribute to these cocaine-induced changes. For example, cocaine decreases ³⁵S-TBPS binding to GABA_A receptors in striatum (Pecins-Thompson & Peris, *Psychopharmacology*, 110: 443-450, 1993). A decrease in GABA-mediated inhibition in striatum might cause a greater increase in striatal DA output caused directly by cocaine. The function of GABA_A receptors was assessed in cortex, substantia nigra and striatum of rats that had received 8 daily injections of cocaine (15 mg/kg, i.p.) or saline. GABA-stimulated ³⁶Cl uptake in microsacs was dose-related in all three regions and was decreased significantly in cocaine-treated rats ($F(1,8) = 9.2$; $p < 0.05$). Since repeated ethanol treatment also affects GABA_A receptor function, we next measured ³⁶Cl uptake in striatal microsacs from rats exposed to 14 daily cocaine (10 mg/kg, i.p.) or ethanol (1.0 g/kg, i.p.) injections given alone or simultaneously. Muscimol stimulation of uptake was dose-related in saline-treated rats and was decreased significantly in all cocaine-treated rats ($F(1,16) = 7.4$; $p < 0.05$) regardless of ethanol treatment. Picrotoxin and bicuculline inhibition of muscimol-stimulated uptake were not affected by drug exposure. Thus, GABA_A receptor function in striatum may be selectively decreased by cocaine treatment which may contribute to changes in DA transmission and behavioral sensitization. Supported by AA00135 and a grant from the Alcohol Beverage Medical Research Foundation.

666.19

Glycine/NMDA antagonist, (+)-HA-966, prevents behavioral sensitization to cocaine and subsequent effects on aversive conditioning.

Bret A. Morrow*, Jane R. Taylor and Robert H. Roth. Depts. of Pharmacology and Psychiatry, Yale University School of Medicine, New Haven, CT 06520

The noncompetitive NMDA receptor antagonist, MK-801, has been shown to prevent locomotor sensitization to repeated cocaine. However, MK-801 has been shown to cause locomotor sensitization to itself. We tested (+)-HA-966, 1-hydroxy-3-aminopyrrolidone-2, an antagonist at the glycine site of the NMDA receptor complex, on locomotor sensitization to repeated cocaine administration. Vehicle or (+)-HA-966, 15 mg/kg i.p., was given 30 min prior to vehicle or cocaine, 15 mg/kg i.p., daily for 5 consecutive days. Seven days later, all rats were challenged with cocaine, 15 mg/kg. (+)-HA-966 prevented sensitization to the cocaine challenge and did not cause a sensitization to itself. Three weeks later, rats were subjected to aversive conditioning: 10 randomly presented tones terminated with 0.5 sec, 400 mA footshocks over 30 min. The following day the rats were returned to the chamber, given 10 tones without footshock, and sacrificed after 30 min. The medial prefrontal cortex (mPFC) and nucleus accumbens (NAS) were harvested and assayed by HPLC-EC for serotonin and dopamine along with their metabolites. As expected, the conditioned rats had significantly greater immobility (freezing) during and after the tone, increased fecal boli and elevated dopamine turnover (DOPAC/DA) in the mPFC and NAS. Prior exposure to cocaine attenuated the increase in behavioral (i.e. freezing and fecal boli) and blocked some of the biochemical (NAS dopamine turnover) correlates of the aversive conditioning. Preexposure to (+)-HA-966 with cocaine prevented these effects. The role of the NMDA receptor with regards to cocaine sensitization and subsequent cross-tolerance to aversive conditioning will be discussed.

EFFECTS OF INTRAVENOUS COCAINE ADMINISTRATION ON GLUTAMATE-INDUCED EXCITATION AND SPONTANEOUS ACTIVITY IN RAT'S CEREBELLAR PURKINJE CELLS. C. A. Jiménez-Rivera*, O. Segarra, S. Matos, V. Algarín, J. Dones and B.D. Waterhouse¹. Depts. of Physiol., UCC, Sch. of Med., Bayamón, P.R. 00956, and Hahnemann¹, Univ. Phil. P.A., 19102.

Cocaine is a well known substance of abuse with central psychostimulant effects and local anesthetic properties. Biochemical studies indicate that cocaine's main action is to increase central synaptic levels of monoamines through blockade of reuptake mechanisms. The present study investigated the effects of intravenous (i.v.) cocaine administration on Purkinje cells response to glutamate, a putative neurotransmitter with clear actions in the cerebellum. Excitatory responses of individual neurons to microiontophoretic pulses (10 sec.) of glutamate (1-45 nA) were examined, before, during and after cocaine injections (0.25 and 1 mg/kg, i.v.). At doses of 0.25 mg/kg cocaine induced a significant reduction in spontaneous activity (spikes/sec \pm SE; 20.49 \pm 4.63 to 5.56 \pm , n = 6) and glutamate-evoked response (37.61 \pm 7.22 to 23.39 \pm 10.97). Similar effects were observed at doses of 1 mg/kg, however, they were lower in magnitude (SA - 24.69 \pm 2.77 to 17.96 \pm 4.20; evoked - 43.7 \pm 4.25 to 29.15 \pm 5.47 n = 12). The major effect was observed within the first 2 min. after cocaine administration. Animals treated with procaine showed no significant changes in either spontaneous or glutamate-evoked excitation. These data suggest that cocaine can modify spontaneous neuronal activity and glutamate-induced excitation in the cerebellum via a mechanism independent of its local anesthetic properties. Studies are underway to elucidate the role of monoamines in this action (Supported by DA 07175 and RCMI RR03035 to C.A.J.R.).

666.23

THE ROLE OF GLUTAMATERGIC ACTIVITY THROUGH NUCLEUS ACCUMBENS AMPA RECEPTORS IN THE EXPRESSION OF BEHAVIORAL SENSITIZATION TO COCAINE. K. B. Bell, P. Duffy* and P. W. Kalivas. Department of Veterinary and Comparative Anatomy, Pharmacology and Physiology, Washington State University, Pullman, WA 99164-6520.

Through two behavioral experiments in the rat, we examined the role of glutamatergic activity through nucleus accumbens (NA) AMPA receptors in the expression of cocaine sensitization. In experiment 1, one group received seven daily IP cocaine treatments, while a control group received an identical treatment schedule with IP saline. For all subjects, open-field locomotor activity was monitored for two hours following first and last treatments to assess the extent of sensitization. On days 20, 21 and 22 of withdrawal from treatment, each subject received bilateral intra-NA microinfusion of 0, .03, or .1 nmol/side of the glutamate agonist AMPA. All subjects received each microinjection dose once, in sequences balanced for order effects. Subjects receiving cocaine and displaying sensitization to criterion (>20% increase in cocaine-induced locomotion, last cocaine versus first cocaine, 15 mg/kg each) showed significantly greater locomotor activity in response to .1 nmol/side intra-NA AMPA than either subjects administered saline or cocaine-administered subjects which failed to sensitize. In experiment 2, all subjects received the chronic cocaine treatment schedule used in experiment 1. On days 14, 17, 20 and 23 of withdrawal from daily treatment, each subject received 0, .01, .1 or 1 nmol/side intra-NA microinfusion of the non-NMDA receptor antagonist CNQX immediately prior to 15 mg/kg IP cocaine. In subjects which met the sensitization criterion, pre-treatment with .1 nmol/side intra-NA CNQX reduced cocaine-induced hypermotility to the level seen in response to the first cocaine administration (p=.06). Taken together, the results of these experiments indicate that the expression of behavioral sensitization to cocaine depends, in part, upon sensitization-specific, AMPA receptor-mediated changes in glutamate transmission within the NA.

666.20

EFFECT OF NMDA RECEPTOR ACTIVATION IN THE VENTRAL TEGMENTAL AREA ON COCAINE-INDUCED LOCOMOTOR ACTIVITY. B. M. Prasad and B. A. Sorg*. Department of VCAPP, Washington State University, Pullman, WA 99164-6520.

Repeated exposure to cocaine causes an enhanced response to subsequent challenges with this drug, a phenomenon called behavioral sensitization. The augmented behavioral response is primarily mediated by enhanced dopamine transmission in neurons projecting from the ventral tegmental area (VTA) to the nucleus accumbens. Glutamatergic input to VTA dopaminergic neurons acting through NMDA receptors has been implicated in the development of the sensitization phenomenon. The present study is an effort to further characterize the role of NMDA receptor activation in behavioral sensitization. Male Sprague Dawley rats were injected with cocaine (15 mg/kg, ip) or saline (1 ml/kg, ip) for 5 consecutive days. After a week of withdrawal, the expression of sensitized behavior was tested with bilateral microinjection of an NMDA agonist, cis-ACDA, into the VTA. Locomotor activity in response to cis-ACDA injection was elevated in rats sensitized to cocaine compared to that of saline injected controls. In a separate experiment, the ability of repeated NMDA receptor activation in the VTA to initiate sensitization was evaluated. Rats were injected with either saline or different doses of cis-ACDA on three days with a 72 hour interval between injections and their locomotor response was monitored. Cis-ACDA injection caused enhanced locomotor activity with a clear dose-response relationship on the first day of administration. On two subsequent cis-ACDA injections, rats appeared to develop tolerance to the locomotor activating effects. A week after the last microinjection, the locomotor response to ip cocaine challenge (15 mg/kg) was measured. Rats that received cis-ACDA injections showed a significantly higher locomotor activity in response to the cocaine challenge, suggesting that repeated NMDA receptor activation may be at least partially responsible for the initiation of behavioral sensitization.

666.22

THE ROLE OF NUCLEUS ACCUMBENS DOPAMINE AND EXCITATORY AMINO ACIDS IN THE EXPRESSION OF COCAINE-INDUCED BEHAVIORAL SENSITIZATION IN RATS. R.C. Pierce*, M. Adams, B. Born, T. Duffy and P.W. Kalivas. Alcoholism and Drug Abuse Program, Washington State University, Pullman, WA 99164 USA

We monitored the behavioral response to intra-accumbally administered dopamine and excitatory amino acid agonists (amphetamine and AMPA, respectively) following 7 daily ip cocaine or saline injections. Our results indicated that both of these drugs dose-dependently enhanced behavioral hyperactivity in cocaine-pretreated rats. In separate animals, we performed *in vivo* microdialysis in order to determine if changes in accumbal dopamine release might underlie these behavioral effects. The neurochemical data revealed that the local administration of both amphetamine and AMPA (through the probe) produced a significant concentration-dependent increase in accumbal dopamine in saline pretreated animals. Among cocaine pretreated rats, however, there was a potentiation of accumbal dopamine release only following amphetamine administration. Taken together, these results suggest at least two distinct mechanisms that contribute to the expression of cocaine-induced behavioral sensitization: 1) a dopamine-mediated mechanism that is expressed through the potentiated ability of psychostimulants to increase accumbal dopamine and 2) an increased ability of non-NMDA excitatory amino acid agonists to induce behavioral hyperactivity that is independent from the accumbal dopamine system.

666.24

ELECTROPHYSIOLOGICAL ANALYSIS OF EXCITATORY AMINO ACID RECEPTOR SUBTYPES INVOLVED IN GLUTAMATE-INDUCED ACTIVATION OF RAT NUCLEUS ACCUMBENS NEURONS *IN VIVO*. X.-T. Hu* and F.J. White. Neuropsychopharmacology Lab., Dept. of Neuroscience, Finch Univ. of Health Sci./The Chicago Medical School, North Chicago, IL 60064.

We have previously demonstrated that repeated administration of psychomotor stimulants (amphetamine and cocaine) leads to reduced responsiveness of nucleus accumbens neurons to glutamate, administered iontophoretically. However, to date, there have been no studies regarding the subtypes of excitatory amino acid (EAA) receptors which mediate the effects of iontophoretically administered glutamate on accumbens neurons *in vivo*. The present study used extracellular single cell recording and microiontophoresis to study the contributions of various EAA receptors to the regulation of accumbens neuronal activity. Pulse-ejected glutamate (1-128 nA) caused a current-dependent increase in the firing of accumbens neurons. A stronger excitatory response to AMPA was observed at much lower ejection currents (0.1-6.4 nA). Compared to AMPA and glutamate, NMDA induced a much less potent excitation in a narrow current range (1-4 nA) usually after accumbens neurons had been "primed" by previous glutamate iontophoresis. Higher ejection currents of all three EAA agonists drove accumbens cells into a state of apparent depolarization block. AMPA-evoked firing was selectively blocked by the AMPA receptor antagonist DNQX whereas NMDA-induced activity was selectively prevented by the NMDA receptor antagonist D-AP5. DNQX, but not D-AP5, significantly attenuated glutamate-evoked activity. The metabotropic glutamate receptor agonist 1S,3R-*t*-ACPD failed to evoke excitatory response of accumbens neurons, but significantly reduced the excitatory effects of the other EAA agonists. These results suggest that the excitatory effects of glutamate on rat accumbens neurons *in vivo* are primarily mediated by AMPA receptors and that metabotropic glutamate receptors may function to dampen excessive transmission through ionotropic EAA receptors. Supported by USPHS grants DA 04093 and DA 00207 (FJW).

EFFECTS OF THE METABOTROPIC GLUTAMATE RECEPTOR BLOCKER AP-3 ON COCAINE-INDUCED DOPAMINE RELEASE AND LOCOMOTOR BEHAVIOR. P.A. Vincent* and E.L. Gardner. Dept. of Psychiatry, Albert Einstein Col. Med., Bronx, NY 10461

Administration of Cocaine (C) has been previously shown to induce dopamine (Da) release in the nucleus accumbens (Nac) using microdialysis-HPLC. To identify the neural substrates that modulate C-induced Da release, we have studied the glutamatergic system because the Nac receives Glu projections from the hippocampus, amygdala and prefrontal cortex, and Glu has been shown to interact with Da functioning. To study this interaction, we administered the Glu metabotropic receptor blocker L(+)-2-Amino-3-phosphonopropionic acid (AP-3) through a microdialysis probe placed in the Nac while monitoring Da release. 0.1mM AP-3 (2 μ l/min) or veh was administered to Sprague-Dawley rats treated with C or veh, ip. Dialysates were collected from animals every 10 min for 10 samples. Animals treated with veh and C had an increase in peak Da release of 484% above baseline. Animals receiving AP-3 and plus showed a 160% increase in Da. Animals receiving AP-3 plus C exhibited a 491% increase in Da, similar to C alone. In a second experiment, 0.1, 0.5, and 1.0 mM AP-3 or veh was infused through bilateral cannulae placed in the Nac 15 min prior to receiving 20 mg/kg C, ip. Locomotor behavior was recorded for the first 2 min of 10 successive 10 min periods. Locomotor activity was not significantly diminished in animals given AP-3 plus C compared to veh plus C. These data suggest that Glu neurons may regulate the same pool of Da that C releases. Further work is needed to determine whether C-induced motor output is modulated by Glu metabotropic receptors. AFFINITY PURIFICATION OF COCAINE RECEPTORS FROM RAT BRAIN. L.P. Raymon*, X.S. He, S. Kim, J. Wright and M.E. Eldefrawi. Pharmacol., Univ. of MD, School of Med., Baltimore, MD 21201.

Dopamine, serotonin and norepinephrine transporters are recognized as the main target for cocaine reinforcement and addiction. 1% digitonin solubilized rat forebrain proteins exhibited cocaine-sensitive [3 H]citalopram (CTL), [3 H]BTCP and [3 H]GBR12935 binding. A BTCP analog, reduced citalopram and an amino-cocaine analog were linked to AffiGel 10 for affinity purification. They all yielded low μ g quantities of proteins that retained cocaine-sensitive binding activity after fast dialysis through ultrafiltration membranes. [3 H]CTL gave the largest binding signal of various transporter ligands tested. Its affinity for the serotonin transporter was not altered by solubilization and it was always recovered in part in the three affinity fractions. The proteins eluted from the aminococaine affinity column exhibited cocaine-sensitive specific binding of [3 H]BTCP, [3 H]GBR12935 and [3 H]CTL. SDS-PAGE electrophoresis of the isolated proteins will also be presented.

IDENTIFICATION OF A NOVEL [125 I]RTI-121 BINDING SITE IN RAT CEREBRAL CORTEX: A POSSIBLE SITE OF ANTIDEPRESSANT ACTION. J.W. Boja*, J.L. Cadet, F.I. Carroll, A.H. Lewin, P. Abraham and M.J. Kuhar. Molecular Pharmacology Section, NIH-NIDA Intramural Research Program, P.O. Box 5180, Baltimore, MD 21224.

Previously we have identified a cocaine analog (RTI-121) that exhibits nanomolar affinity and high selectivity for the dopamine transporter in rat striatum. There was a high correlation ($p < 0.0001$) between the potencies of drugs to inhibit specific [125 I]RTI-121 binding in the striatum (STR) and the potencies of these drugs to inhibit specific [3 H]dopamine uptake. No correlation was found with the potencies of these compounds to inhibit specific [125 I]RTI-121 binding with either [3 H]serotonin or [3 H]norepinephrine uptake.

When [125 I]RTI-121 binding was conducted in the frontal pole (FP) of the rat cerebral cortex several differences were apparent. While [125 I]RTI-121 still bound to a high- and low-affinity site, the number of sites labeled by [125 I]RTI-121 was approximately 1% of that observed in the striatum. However, while the binding of [125 I]RTI-121 observed in the FP was similar to that observed in the STR, several compounds displayed a significantly lower IC_{50} s in the FP than in the STR. These included several of the tricyclic antidepressants (imipramine, chlorimipramine, amtryptiline, nortriptyline and desipramine), trazadone, nisoxetine, tomoxetine, paroxetine and (-)-cocaine. There were no differences in the STR or FP IC_{50} s for either mazindol, WIN 35,428, RTI-121, nomifensine, GBR 12909, talsupram, desipramine, citalopram, or fluoxetine. In addition, these sites showed less sensitivity to the effects of 6-OHDA which unlike striatal binding sites were almost completely eliminated by that toxin. These results suggest that [125 I]RTI-121 may bind to a yet uncharacterized site in the cerebral cortex that may recognize cocaine and many antidepressant drugs with high affinity.

EFFECTS OF DIETARY FAT AND PROTEIN ON COCAINE-INDUCED STEREOTYPY IN RATS. J.S. Shumsky*, P.L. Shultz, J.R. Galler, and J. Tonkiss. Center for Behavioral Development & Mental Retardation, Boston University School of Medicine, 80 E. Concord St., Boston, MA 02118.

Dietary fat and protein produced progressive alterations in cocaine-induced stereotypy that may be associated with changes in drug metabolism. Female Sprague-Dawley rats were fed one of three diets over a three week period: low protein (5%), high fat (15%); high protein (22%), high fat (15%); or high protein (23%), low fat (5%), i.e. rat chow. Following one week of adaptation to the diets, the rats were injected every 3-4 days with either cocaine (30 mg/kg, IP) or saline and total amount of stereotypy was measured. Following each injection, the total amount of cocaine-induced stereotypy increased, peaked within the 90 min observation interval, and then declined for all diet groups. With repeated injections, intensity of stereotypy increased in all diet groups; however, the two high fat diet groups exhibited significantly more stereotypy across injections than the low fat diet group. By the fourth injection, the low protein diet group exhibited the slowest onset and the longest duration of cocaine-induced stereotypy. These data cannot be explained by differences in body weight, and are therefore likely to be related to differences in body composition or alterations in drug metabolism. Supported by NIH grant DA 07934.

PSYCHOTHERAPEUTIC DRUGS: ATYPICAL ANTIPSYCHOTICS

667.1

ANTI-GLUTAMATERGIC INFLUENCES OF CLOZAPINE: EFFECTS AT CLINICALLY RELEVANT CONCENTRATIONS. T.L. Lidsky*, L. Zuck, S.P. Banerjee. Inst. Basic Res., S.I., N.Y.

The bases of clozapine's (Cz) enhanced antipsychotic potency and reduced incidence of motor side effects is unknown. It is conceivable that glutamate, because of its influences on dopamine release and its participation in motor side effects, is a target of Cz's actions. The present work assessed this possibility.

Glutamatergically-mediated field potentials were monitored in striatal slices perfused with Mg^{2+} -free artificial CSF (aCSF). These potentials were suppressed by kynurenic acid or MK-801 and were thus presumed to be mediated, in large part, by NMDA receptors. Cz, added to the aCSF, suppressed these responses in concentrations as low as 10 nM.

Since previous work showed displacement of [3 H]MK-801 at much higher concentrations ($K_D = 17 \mu M$), Cz has at least two sites of action on the NMDA receptor. The Cz concentration that suppressed responses in striatal slices was similar to that in CSF of patients receiving Cz for treatment of psychosis. Thus, activity at one of these sites suggests that anti-glutamatergic effects may enter into this drug's clinical profile.

667.2

TYPICAL AND ATYPICAL NEUROLEPTICS DIFFERENTLY AFFECT FOS PROTEIN EXPRESSION IN THE RAT FOREBRAIN. A. Fink-Jensen* and P. Kristensen. Pharmaceuticals Division and Biopharmaceuticals Division, Novo Nordisk A/S, Novo Nordisk Park, DK-2760 Måløv, Denmark.

The cellular synthesis of the transcription factor protein Fos is regarded as a biochemical marker of neuronal activity and previous studies suggest that the effect of the atypical neuroleptic clozapine on Fos protein expression in the prefrontal cortex (PFC) may be related to its unique effects on negative symptoms in schizophrenia (Neurosci. (1992) 46:315-328). In order to investigate if the Fos protein expression pattern induced by clozapine applies to other compounds with an atypical profile in preclinical or clinical trials, we investigated the acute effect of the atypical neuroleptics clozapine, risperidone, sertindole and NNC 22-0031 (4-(6-fluoro-1,2-benzisoxazol-3-yl)-1-(3-(3,4-methylenedioxyphenylcarboxyloxy)propyl)piperidine) as well as the prototypical neuroleptic haloperidol. The Fos protein expression was assessed by use of immunohistochemistry. The present study shows that atypical and prototypical neuroleptics can be differentiated on the basis of their ability to induce Fos protein since the ratio between Fos protein expression in the limbic PFC and in the non-limbic dorsolateral striatum (DLSi) was higher for the atypical neuroleptics than observed with the prototypical neuroleptic.

667.3

THE ATYPICAL ANTIPSYCHOTIC CLOZAPINE IS A POTENT AGONIST AT HUMAN CHOLINERGIC MUSCARINIC M4 RECEPTORS AND AN ANTAGONIST AT m1, m2, m3, & m5 RECEPTORS. K.M. Ward, D. Liston, S.B. Jones, and S.H. Zom*, Pfizer Inc., Central Research Division, Department of Neuroscience, Groton, CT 06340.

Clozapine is an atypical antipsychotic drug that is more efficacious than conventional neuroleptics and does not produce EPS. Previous reports have shown that clozapine binds with high affinity to all 5 muscarinic receptor subtypes (Eur. J. Pharmacol. 1921:205,1991). Clozapine is an antagonist at some of these subtypes, and has been widely assumed to be an antagonist at all of them. Clinically, one of clozapine's notable side effects is hypersalivation. However, since hypersalivation and clozapine-induced dopamine turnover in rat striatum are blocked by muscarinic antagonists, clozapine may have direct cholinomimetic activity (JPET 268:1452, 1994). In the present study the functional interaction of clozapine with human m1-m5 receptors expressed in CHO cells was characterized. It was discovered that clozapine is a potent ($EC_{50} = 7.5$ nM) and full agonist at only the m4 muscarinic receptor subtype, producing concentration dependent inhibition of forskolin (FSK)-stimulated cAMP accumulation. This effect could be blocked by N-methyl-scopolamine and pertussis toxin. In contrast, clozapine potentially antagonized agonist-induced responses at the other four muscarinic receptors. Thus, clozapine was found to block the inhibitory effect of carbachol on FSK-stimulated cAMP accumulation in m2 expressing cells as well as carbachol-induced PI turnover in cells expressing the m1, m3 & m5 receptor subtypes. Since the m4 receptor is found in salivary glands and is enriched in striatum, the present findings suggest that clozapine-induced hypersalivation as well as its effects on striatal dopamine turnover may be due to direct stimulation of m4 muscarinic receptors in these tissues. This agonist action at the m4 receptor may contribute to clozapine's atypical antipsychotic efficacy.

667.5

EFFECTS OF SUBCHRONIC CLOZAPINE AND HALOPERIDOL ON RATS TRAINED IN A FORELIMB TREMOR TASK.

S.C. Fowler*, J.A. Stanford and S. Das.
University of Mississippi, University, MS 38677.

Rats trained to extend the forelimb through a rectangular hole and exert downward pressure on a force transducer received either the atypical neuroleptic clozapine or the typical neuroleptic haloperidol for 11 consecutive days. Doses were individually titrated daily for each rat in an attempt to achieve a 50% reduction in time on task (TOT). Clozapine treated rats exhibited dramatic tolerance to the drug's suppressive effect on TOT. In contrast, haloperidol rats displayed little tolerance. Despite the accentuated tolerance reflected by TOT in the face of escalating doses of clozapine, no tolerance was seen in clozapine's marked slowing of the dominant frequency of oscillations in forelimb force as measured by Fourier analysis of the force-time recordings. Haloperidol did not produce the oscillation slowing. The dissociation between the tendency to respond (TOT) and the oscillator slowing observed for clozapine may reflect effects at different neurotransmitter receptor sites. Supported by MH43429.

667.7

LIKE CLOZAPINE, OLANZAPINE SLOWS RATS' FORELIMB FREQUENCY OSCILLATIONS IN A PRESS-WHILE-LICKING BEHAVIORAL TASK. J.A. Stanford* and S.C. Fowler. Univ. of Mississippi, University, MS 38677.

Rats were trained to press a force-sensing transducer with one forelimb in a press-while-licking (water fountain) task while initial peak force (PF), hold force (HF), force frequency oscillations (FREQ), and time-on-task (TOT) were measured. Following extensive experience on the task, subjects were administered olanzapine (OL, 0.5, 1.0, 2.0 mg/kg), a candidate atypical neuroleptic. OL significantly decreased TOT dose-dependently and had a significant slowing effect upon FREQ as quantified by Fourier analysis. These results were compared to clozapine's (CL) similar effects on the same measures previously reported in this task and contrasted with haloperidol's (HAL) FREQ acceleration (Fowler, et al., *Psychopharmacology*, in press). Since typical neuroleptics such as HAL tend to induce motor side effects such as tremor, these findings may reflect the antitremor and atypical properties of OL and CL. Supported by MH43429.

667.4

FURTHER EVIDENCE FOR MUSCARINIC ANTAGONISM AS CLOZAPINE'S DISCRIMINATIVE STIMULUS. B.M. Kelley, K.A. Nuti, J.H. Porter*. Psychology, Virginia Commonwealth Univ. Richmond, VA 23284.

Although clozapine (CLZ) has been shown to be superior to conventional neuroleptics in the treatment of schizophrenia, CLZ's mechanism of action has yet to be completely delineated. A two-lever drug discrimination procedure was employed in order to more precisely characterize the effect of drugs interacting with the cholinergic system on the discriminative stimulus properties of clozapine. Evidence for both muscarinic and/or serotonergic mediation of CLZ's cue has been demonstrated in previous studies. Because many of these serotonergic drugs show high binding affinity for cholinergic receptors, two discrimination groups were trained. One group was trained to discriminate CLZ (5.0 mg/kg, i.p.) from vehicle, and another group was trained to discriminate scopolamine (0.125 mg/kg, i.p.) (SCP) from saline. Male Sprague-Dawley rats (85% B.W.) were tested in 15 min. sessions under a FR30 schedule of food reinforcement. After generalization testing with CLZ-trained rats ($ED_{50} = 0.1296$) and SCP-trained rats ($ED_{50} = 0.0136$), promethazine (PRO) and cyproheptadine (CYP) were tested in both groups. Mean percent drug-lever responding (DLR) with PRO peaked at the 10.0 mg/kg dose (99.3%) in the SCP group ($ED_{50} = 0.609$) and peaked at 2.5 mg/kg (97.0%) in the CLZ group ($ED_{50} = 0.751$). Complete substitution with CYP also was observed in both groups. In the SCP group, the 10.0 mg/kg dose produced peak substitution ($ED_{50} = 3.513$). In the CLZ group, the 1.25 mg/kg dose produced maximal DLR (98.2%) ($ED_{50} = 0.114$). Methylscopolamine (MSCP) substitution testing and antagonism of the CLZ-cue with oxotremorine (OXO) also were assessed in the CLZ-group. MSCP did not substitute for CLZ at any dose. MSCP (1.5 mg/kg) was coadministered (i.e., to block the peripheral effects of OXO) with OXO (0.0325, 0.0625, and 0.125 mg/kg), and the highest dose of OXO caused CLZ-DLR to decrease from 96.1% to 61.7%. Results from this study support the notion that CLZ's discriminative stimulus properties in rats are mediated by antagonism at muscarinic receptors.

667.6

ASSESSMENT OF CLOZAPINE'S SUBCHRONIC DOSE EFFECTS ON FORCE, DURATION, AND RHYTHM OF LICKING IN RATS. Shyamal Das* and S.C. Fowler. University of Miss., University, MS 38677.

Three doses (1.5, 3.0, 4.5 mg/kg, ip, 45 min) of the atypical antipsychotic clozapine were studied in a subchronic dosing paradigm (at least 7 consecutive days at each dose with 4 or more vehicle only days separate dosing periods) in order to evaluate potential tolerance or sensitization effects in rats. Thirsty rats (n=20) licked water from a force-sensing disk while force-time waveforms of licking were recorded for a 2-min session. Lick rhythm was quantitated by applying Fourier methods to the force-time records. Other behavioral measures were peak force and duration of individual licks and number of licks. At 3.0 and 4.5 mg/kg, modest, but significant, tolerance effects emerged. 1.5 mg/kg produced sensitization effects, and the lick rhythm was the variable most affected by the drug as measured by omega squared. Clozapine's powerful effects on lick rhythm are unlike those of haloperidol (Fowler & Das, *PBB*, in press) and may reflect effects at serotonin receptors on the hypoglossal nucleus. Supported by MH43429.

667.8

SELF DESTRUCTIVE BEHAVIOR AND CLOZAPINE DISCONTINUATION.

F.G. Moeller¹*, Y.W. Chen,¹ Joel L. Steinberg, M.D.^{2,3} M. Fulton,^{2,3} F. Petty,^{2,3} G.W. Ripper,² D.L. Garver,^{2,3} 1. University of

Texas Houston Health Science Center 1300 Moursund, Houston TX 77030 2. Dallas VAMC 3. Univ. of Texas Southwestern Med. School at Dallas. The atypical antipsychotic clozapine has effects as a serotonin antagonist as well as a dopamine antagonist. There have been reports that clozapine increases depressive symptoms in some patients and it has been speculated that this increase is due to the serotonin antagonist effects of clozapine. In order to determine if patients with preexisting suicidal or self mutilative ideation or behavior were more likely to have a poor outcome with clozapine than patients without this behavior, logistic regression was performed on data obtained from 729 patients treated with clozapine in the VA hospital system. Variables analyzed in the regression included age, sex, race, prior history of treatment failure, presence of suicidal behavior in the past month or ever in the past, and presence of self mutilative behavior in the past month or ever in the past. Of the 729 patients in the study 32 (4.3%) had suicidal ideation or behavior in the month prior to starting clozapine, 337 (46.2%) had suicidal ideation or behavior ever in the past, 32 (4.4%) had self mutilation in the past month, 137 (18.8%) had self mutilation ever in the past. There was no significant effect of suicidality or self mutilatory behavior on clozapine discontinuation in the logistic regression model. There was an effect of race and prior history of treatment failure which have been reported previously. Our study does not support suicidality or self mutilatory behavior as increased risk factors for poor outcome with clozapine.

667.9

D3 AND D4 DOPAMINE RECEPTORS MEDIATE CLOZAPINE-INDUCED C-FOS EXPRESSION IN THE FOREBRAIN. N. Guo* and H.C. Fibiger, Division of Neurological Sciences, Dept. of Psychiatry, Univ. of British Columbia, Vancouver, B.C. Canada V6T 1Z3

The receptor mechanisms underlying clozapine-induced *c-fos* expression in the forebrain are unknown. The regional disparity between clozapine- and haloperidol-induced *c-fos* expression in the brain suggested that D2 receptor antagonism is not sufficient to account for the unique pattern produced by clozapine. In addition, previous studies have demonstrated that neither serotonergic nor noradrenergic mechanisms are involved in this effect of clozapine. To determine whether blockade of D3 and/or D4 dopamine (DA) receptors may contribute to clozapine's effects, the DA receptor agonists quinpirole and 7-hydroxy-N,N-di-n-propyl-2-aminotetralin (7-OHDPAT) were co-administered with clozapine.

Quinpirole, which has approximately equal affinity for D3 and D4 receptors and about 100-fold lower affinity for D2 receptors, completely blocked clozapine-induced *c-fos* expression in the medial prefrontal cortex (mPFC), nucleus accumbens (NAc) and lateral septal nucleus (septum). Co-administration of 7-OHDPAT, which has about 75-fold higher affinity for D3 than D2 receptors, and very low affinity for D4 receptors, reduced the number of clozapine-induced Fos positive neurons by 79% in the NAc and by 52% in the septum but had no effect in the mPFC. These results suggest that D4 receptors are involved in clozapine-induced *c-fos* expression in the mPFC, while blockade of D3 receptors mediates clozapine-induced *c-fos* expression in the NAc and septum. These results are consistent with the view that the contrasting clinical profiles of haloperidol and clozapine are due to the fact that these compounds target different populations of neurons in the forebrain and that the atypical properties of clozapine may be related in part to its antagonist effects at D3 and D4 receptors.

667.11

SELECTIVE ACTIONS OF THE NOVEL ATYPICAL ANTIPSYCHOTIC DRUG AMPEROZIDE IN THE LIMBIC FOREBRAIN. G.G.Nomikos*, M.M.Marcus, C.S.Tham, H.C.Fibiger and T.H.Svensson. Karolinska Institutet, Dept. of Pharmacology, S-17177 Stockholm, Sweden

Amperozide (APZ) exhibits a multireceptor profile with high affinity for 5-HT₂ receptors, relatively low affinity for dopamine (DA) receptors, and a rather marked limbic selectivity of action. Recently, *in vivo* microdialysis studies have revealed that APZ induces a more pronounced increase in DA concentrations in the medial prefrontal cortex (MPC) than in the nucleus accumbens (NAC) or the striatum, analogously with clozapine but not with classical antipsychotics. This effect of APZ may be due to its combined 5-HT₂ and DA-D₂ receptor antagonistic properties. By employing *in vivo* voltammetry and Fos immunohistochemistry, we examined the effects of APZ on DA concentrations in two subsets of the NAC, the shell and core, that are associated with limbic and striatal functions, respectively, and on *c-fos* expression in the limbic forebrain and the basal ganglia. APZ (1.0 and 2.0 mg/kg, iv) almost exclusively increased DA concentrations in the NAC-shell compared to the core. Similar results were obtained with ritanserin but not with raclopride, which instead increased DA equipotently in both parts. The number of Fos-positive neurons was significantly increased by APZ (5.0 and 10 mg/kg, sc) in the MPC and the lateral septum but not in the striatum or the NAC. Thus, APZ shows a somewhat clozapine-like profile as regards also its effects on *c-fos* expression in the forebrain. These results emphasize amperozide's limbic selectivity of action, the importance of 5-HT₂ receptor antagonism for such an effect, and strengthen the hypothesis that the therapeutic profile of atypical antipsychotics may be related to their distinctive effects in the mesolimbocortical dopaminergic system.

667.13

DIFFERENTIAL EFFECTS OF ANTIPSYCHOTIC DRUGS ON EXTRACELLULAR GABA LEVELS IN THE VENTRAL PALLIDUM AND GLOBUS PALLIDUS OF RATS. M.A. Chapman* and R.E. See. Department of Psychology, Washington State University, Pullman, WA 99164-4820. Antipsychotic drugs (APDs) are believed to treat schizophrenia through their effects on mesolimbic dopamine (DA) pathways and produce motor side effects via effects on nigrostriatal DA pathways. In order for these APD-induced changes to affect behavior, neurotransmitter levels must be altered in the output nuclei of these two systems. To test this hypothesis, female, Sprague-Dawley rats were given a subcutaneous injection of haloperidol (1.0 mg/kg), clozapine (30.0 mg/kg), or metoclopramide (10.0 mg/kg). Intracranial microdialysis was used to assess GABA levels simultaneously in the ventral pallidum and globus pallidus, regions which receive major GABAergic projections from the mesolimbic and nigrostriatal dopamine systems, respectively. GABA was analyzed using o-phthalaldehyde derivatization followed by high-performance liquid chromatography with electrochemical detection. Both haloperidol and metoclopramide increased extracellular GABA levels in the globus pallidus, while clozapine decreased GABA in this region. Clozapine also decreased extracellular GABA levels in the ventral pallidum, whereas haloperidol and metoclopramide had no effect. These results suggest that increased extracellular GABA levels in the globus pallidus may be related to the motor side effects of antipsychotic drugs, while decreased GABA levels in the ventral pallidum may be related to the unique clinical profile of clozapine. (Supported by NIH grant MH10644 to M.A.C. and DE09678 to R.E.S.).

667.10

EFFECT OF CHRONIC NEUROLEPTIC ADMINISTRATION ON RAT ORAL DYSKINESIA AND THE mRNA EXPRESSION OF GAD, ENKEPHALIN AND SUBSTANCE P. T. Hashimoto*, X.-M. Gao, O. Shirakawa, T. Kakigi, A.J. Tobin, C.A. Tamminga, M.P.R.C., Department of Psychiatry, U.M.A.B., Baltimore, MD 21228, and Department of Biology, University of California, Los Angeles, CA 90024

Chronic neuroleptic treatment causes tardive dyskinesia in humans. Vacuous chewing movements (VCM) in rats has been used as a model of tardive dyskinesia in humans. We examined VCMs and GAD₆₇, GAD₆₅, enkephalin, and substance P mRNA expression in rats treated chronically with neuroleptics. Rats were treated with different dose levels of haloperidol (1.5 or 3.0 mg/kg/day) and clozapine (10, 20 or 30 mg/kg/day). After 3 months of drug treatment, haloperidol produced significant rates of VCMs: 15.8 ± 2.2 for haloperidol; 1.2 ± 0.5 for water (mean ± S.E./5 min.). Clozapine did induce VCMs (6.4 ± 1.5) but at significantly lower rate than with haloperidol. There was no apparent difference in VCMs between different dose groups. In the basal ganglia of rats treated chronically (6 months) with haloperidol (1.5 mg/kg/day), *in situ* hybridization revealed a significant increase in GAD₆₇ mRNA in striatum of 11% and a decrease in globus pallidus of 15%, with no change in GAD₆₅ mRNA in SNR. GAD₆₅ mRNA did not change in striatum or SNR. Enkephalin mRNA increased 23% in striatum, while substance P mRNA remained unchanged. Changes in GAD₆₇ mRNAs did not correlate with the rates of VCMs. The results indicate that chronic blockade of D₂ receptor might not induce VCMs in dose dependent manner. Moreover, the other neural mechanisms, in addition to the activation of striatopallidal GABA/enkephalin containing neurons with its D₂ receptor blockade, such as D₁ receptor mediated transmission in striatonigral neurons, may be involved in the expression of tardive dyskinesia.

667.12

RITANSERIN POTENTIATES THE STIMULATORY EFFECTS OF RACLOPRIDE ON DOPAMINE ACTIVITY AND RELEASE PREFERENTIALLY IN THE MESOLIMBIC CORTICAL DOPAMINERGIC SYSTEM. J.L. Andersson, G.G.Nomikos, M.M.Marcus and T.H.Svensson*. Karolinska Institutet, Dept. of Pharmacology, S-17177 Stockholm, Sweden

The limbic selectivity of action of some atypical antipsychotic drugs has been attributed to potent 5-HT₂ receptor antagonism and a high ratio of 5-HT₂ to dopamine (DA)-D₂ receptor affinities. By employing *in vivo* single unit electrophysiology, dialysis and voltammetry, we examined the effects of the DA-D₂ receptor antagonist raclopride in combination with the 5-HT₂ receptor antagonist, ritanserin, on DA transmission. Raclopride (10-2560 ug/kg, iv) dose-dependently increased firing rate and burst firing of midbrain DA neurons; this effect was more pronounced in the ventral tegmental area (VTA) than in the substantia nigra-zona compacta (SN-ZC). Ritanserin (1.0 mg/kg, iv) enhanced firing rate and burst firing of midbrain DA neurons. Ritanserin pretreatment (30 min) potentiated the stimulating effects of low doses of raclopride on burst firing, preferentially in VTA DA neurons. Raclopride (50 ug/kg, sc) increased dialysate DA concentrations in the striatum and the medial prefrontal cortex (MPC) to 220 and 175% of baseline, respectively, while ritanserin (1.5 mg/kg, sc) elevated striatal and cortical DA levels by about 30%. Ritanserin pretreatment (40 min) potentiated the raclopride-induced DA increase in the MPC to 255% without affecting the action of raclopride on striatal DA levels. Similar results were obtained in the nucleus accumbens where the raclopride-induced increase in the voltammetric DA signal was enhanced by ritanserin pretreatment. These data indicate that 5-HT₂ receptor antagonism in conjunction with some degree of DA-D₂ receptor antagonism facilitates DA transmission selectively in the mesolimbocortical dopaminergic projection.

667.14

AMPHETAMINE-INDUCED STEREOTYPY AS A RODENT MODEL FOR THE EXTRAPYRAMIDAL SIDE EFFECT (EPS) LIABILITY OF ANTIPSYCHOTIC DRUGS. H. Donovan, C.A. Bankoski, S.H. Lang, L. Rajachandran* and D.C. Hoffman. Behavioral Biology, Neurogen Corp., Branford, CT 06405.

Typical antipsychotics block amphetamine-induced stereotypy in rodents. It is unclear whether this behavioral effect predicts therapeutic efficacy or EPS liability. Because the atypical antipsychotic clozapine is efficacious in treating schizophrenia while producing minimal EPS, we decided to re-evaluate its effects on amphetamine (10 mg/kg)-induced stereotypy, and compare them to the effects of the typical antipsychotic haloperidol and the novel antipsychotics raclopride, risperidone and savoxepine in male Sprague-Dawley rats. With the exception of clozapine, all drugs produced a significant and dose-related antagonism of stereotypy. Clozapine significantly reduced stereotypy at several doses but the inhibition was never greater than 50 percent. For all drugs, the antagonism of amphetamine-induced stereotypy was accompanied by a significant increase in locomotor activity (measured in Omnitech activity monitors) at the intermediate doses. This reflects the emergence of hyperactivity normally seen with lower doses of amphetamine. Thus, according to two measures (stereotypy ratings and activity scores), clozapine is effective in antagonizing amphetamine-induced stereotypy but it is considerably less efficacious than haloperidol and the novel antipsychotics. This latter finding may be related to the few EPS associated with clozapine treatment in humans, and suggests that blockade of amphetamine stereotypy may predict EPS liability more so than therapeutic efficacy.

667.15

CATALEPSY AS A RODENT MODEL FOR DETECTING ANTIPSYCHOTIC DRUGS WITH EXTRAPYRAMIDAL SIDE EFFECTS (EPS) IN HUMANS: A RE-EVALUATION OF SAVOXEPINE. D.C. Hoffman* and H. Donovan. Behavioral Biology, Neurogen Corporation, Branford CT 06405.

The predictive validity of catalepsy as a rodent model for detecting the EPS of antipsychotic drugs was recently questioned when the novel antipsychotic savoxepine produced little catalepsy in rodents while producing significant EPS in schizophrenic patients. Because catalepsy is viewed as an important model for predicting EPS, we decided to re-evaluate the effects of savoxepine. Savoxepine, haloperidol, clozapine, raclopride, risperidone and ORG 5222 were examined in two tests for catalepsy (Grid and Bar Tests) in male Sprague-Dawley rats. The ability to antagonize amphetamine-induced hypermotility was also examined since this measure is believed to predict clinical efficacy. With the exception of clozapine, all drugs produced dose-dependent catalepsy in both tests. For each drug, the MEDs for producing catalepsy were greater than those necessary for antagonizing amphetamine-induced activity. Clozapine demonstrated the widest separation of MEDs in the catalepsy and activity models while haloperidol showed the narrowest separation. This is consistent with the clinical effects of haloperidol (severe EPS) and clozapine (mild EPS). The ratios of MEDs in catalepsy and activity for the remaining novel drugs fell between haloperidol and clozapine; this is consistent with the preliminary clinical findings indicating some EPS with each of these compounds. Thus, catalepsy remains a suitable rodent model for detecting compounds with EPS liability in humans.

ATYPICAL NEUROLEPTICS SHOW REGIONAL SELECTIVITY: ROLE OF OLFACTORY TUBERCLE. A.R. Cools*, E.P.M. Prinssen and B.A. Ellenbroek. Dept. Psychoneuropharmacology, University of Nijmegen, P.O. 9101, 6500 HB Nijmegen, The Netherlands.

In order to validate the hypothesis that atypical neuroleptics are far more potent in the olfactory tubercle (OT) than in the nucleus accumbens (ACC; Behav. Pharmacol. 3, s18, 1992), we investigated to what extent risperidone, sertindole, olanzapine, ORG 5222 and prothipendyl, viz. all compounds claimed to act as atypical neuroleptics, differentially attenuate locomotor activity elicited from the OT and the ACC respectively. First, we used the so-called paw-test to identify the atypical profile of these compounds (Life Sci. 42, 1205, 1988): in all cases, the dose required for enhancing hindlimb retraction time (HRT) was lower than that required for enhancing forelimb retraction time (FRT), underscoring the atypical profile of the tested compounds. Second, the ability of intracerebral administration of the drug (0.5 μ l) to attenuate locomotor activity elicited either by dopamine injections (10 μ g/0.5 μ l) into the OT or by ergometrine injections (1 μ g/0.5 μ l) into the ACC was compared. Following normal habituation procedures to standard locomotor cages, dose-effect curves (1 ng - 10 μ g) were made, using computerized recordings. Using the ratio of the minimum effective doses (OT : ACC), it was found that all compounds were far more potent in the OT than in the ACC. It is concluded that neuroleptics with an atypical profile are far more potent in the olfactory tubercle than the nucleus accumbens; the reverse holds true for classical neuroleptics.

667.16

PRECLINICAL PHARMACOLOGY OF ZD3638: A NOVEL AGENT WITH ATYPICAL ANTIPSYCHOTIC ACTIONS. Jeffrey M. Goldstein* and Michael T. Klimas. Departments of CNS Pharmacology and Medicinal Chemistry, ZENECA Pharmaceuticals Group, Wilmington DE 19897.

ZD3638 is a new putative antipsychotic agent that was evaluated through a series of in vitro and in vivo tests in a variety of species including mice, rats, and monkeys. ZD3638 displays high affinity for dopamine D1, D2 and serotonin 5HT2 receptors (K_i, nM, 13, 42, 39, respectively). ZD3638 also has high affinity for α 1-adrenergic receptors (K_i=63 nM) and is devoid of activity at muscarinic M2 and M3 cholinergic receptors. ZD3638 is active orally in classical tests for antipsychotic activity, eg conditioned avoidance in primates and behavioral or electrophysiological tests involving the reversal of dopamine agonist-induced effects. It possesses considerable selectivity for the limbic system. Both dopamine D1 and D2 functional antagonism, eg reversal of D1 and D2 agonist-induced rotation in rats and blinking in squirrel monkeys, as well as serotonin 5HT2 functional antagonism, eg reversal of quipazine-induced head twitch in rats, can be demonstrated. Additionally, ZD3638, unlike classical antipsychotic agents, has a reduced liability for sensitizing drug-naïve Cebus monkeys after chronic administration. When administered chronically to rats, ZD3638 produces selective depolarization inactivation of mesolimbic (A10) dopamine neurons. These last two properties are like those of clozapine, and are believed predictive of reduced extrapyramidal side effects. On the basis of these overall results, ZD3638 is predicted to have enhanced antipsychotic efficacy with a superior side effect profile as compared to classical antipsychotic agents.

667.18

BEHAVIORAL PHARMACOLOGY OF BW 1205U90, A SATURATED PHthalazinone WITH MIXED DOPAMINE AND SEROTONIN ANTAGONIST ACTIVITY. G.C. Rigidon* and M.H. Norman. Divisions of Pharmacology and Organic Chemistry, Burroughs Wellcome Co, Research Triangle Park, NC 27709.

BW 1205U90 ((+/-)-cis-2-(4-(4-(1,2-benzisothiazol-3-yl)-1-piperazinyl)butyl)-4A, 5, 6, 7, 8, 8A-hexahydro-1(2H)-phthalazinone hydrochloride) was synthesized as part of a program to develop antipsychotics with reduced liability for extrapyramidal side effects (EPS). It bound to 5-HT₂ receptors (IC₅₀ = 0.8 nM) more potently than to dopamine D₂ receptors (IC₅₀ = 1.6 nM) and also bound to 5-HT_{1A} and adrenergic α 1 receptors potently. In mouse, BW 1205U90 antagonized climbing (efficacy) and stereotyped behavior (EPS) induced by apomorphine with ED₅₀s = 16 and 74 mg/kg p.o., and 0.04 and 0.6 mg/kg s.c., respectively. The ED₅₀ for induction of catalepsy (which also predicts EPS) was 58 mg/kg p.o. Head twitches in mice induced by the serotonin agonist 5-methoxydimethyltryptamine were antagonized with ED₅₀s = 2.0 mg/kg p.o. and 0.03 mg/kg s.c.

In rat, BW 1205U90 blocked apomorphine-induced circling in subjects with unilateral 6-hydroxydopamine lesions of the striatum (ED₅₀ = 1.1 mg/kg p.o.) and antagonized apomorphine-induced stereotypy (ED₅₀ = 3.3 mg/kg p.o.). Apomorphine-induced disruption of prepulse inhibition of acoustic startle reflex was antagonized at 0.2 mg/kg s.c. and conditioned avoidance responding was inhibited with an ED₅₀ = 0.05 mg/kg s.c. Shaking behavior induced by the serotonin precursor 5-hydroxytryptophan, was antagonized (ED₅₀ = 0.6 mg/kg p.o.).

BW 1205U90 antagonized 5-HT₂-mediated effects more potently than D₂-mediated effects. It was potent in tests predictive of antipsychotic efficacy, but much less potent in tests for EPS.

EPILEPSY: ANTICONVULSANT DRUGS—OTHER NEUROTRANSMITTER RECEPTORS

668.1

EFFECT OF LAMOTRIGINE ON VOLTAGE DEPENDENT SODIUM CURRENTS AND ON SPONTANEOUS ACTIVITY IN IN VITRO EPILEPTOGENESIS. M. Caeser, K.D. Keegan*, M.L. Evans and C.D. Benham. SmithKline Beecham, Harlow, Essex CM19 5AD UK.

The recently launched anticonvulsant lamotrigine was investigated on TTX-sensitive Na⁺ currents (I_{Na}) and on spontaneous activity in *in vitro* models of epileptogenesis relative to phenytoin, carbamazepine and pentobarbital. All recordings were performed on hippocampal cell cultures using whole cell patch clamp. Sodium currents were activated by membrane depolarizations of 20 ms duration to potentials greater than -60 mV. I_{Na} was reversibly depressed in a voltage dependent manner by bath application of lamotrigine. The block of I_{Na}-evoked by voltage command pulses to -20mV- by lamotrigine (50 μ M) was increased from 12±2% (n=16) to 57±4% (n=20) upon depolarizing the membrane holding potential from -90 mV to -57mV. Similar observations were made when carbamazepine and phenytoin was tested at 50 μ M concentration. Starting from a membrane holding potential of -57mV, lamotrigine (1 and 250 μ M) reduced I_{Na} to 92±2% (n=8) and 18±4% (n=7) of control values, respectively. The EC₅₀ value was 28±5 μ M at a stimulus frequency of 0.1Hz. The depression of sodium currents by lamotrigine (50 μ M) was used dependent, in that raising the stimulus frequency from 0.1 to 5 Hz reduced the peak amplitude of I_{Na} by additional 12±2% (n=7). In current clamp experiments, the shift in resting membrane potential, high spontaneous activity of neurones as well as paroxysmal discharge pattern observed in the presence of high potassium (7.5 mM) or zero Mg²⁺ was significantly reduced by lamotrigine, phenytoin and pentobarbital (all tested at 50 μ M). This study demonstrates, that similar to phenytoin and carbamazepine, lamotrigine acts as a voltage dependent sodium channel blocker at therapeutic concentration, which might contribute to the reported reduction of glutamate release.

668.2

ANTICONVULSANT EFFECTS OF CHRONIC MELANOTIN AT DIFFERENT TIMES OF THE DAY IN MALE GERBILS. TH Champney*, WH Ranneman, ME Legare and JC Champney. Depts Human Anat and Vet Anat, Texas A&M Univ, College Station, TX 77843.

Recently, melatonin's anticonvulsant action has been demonstrated in gerbils (Neuroreport 3:1152-1154, 1992). The present study explored the effects of melatonin (MEL) administration at one of two times of the day on seizure severity after pentylenetetrazol (PTZ) administration. Also, changes in γ -aminobutyric acid (GABA) and amine content from selected brain regions of these animals was determined. Male Mongolian gerbils (*Meriones unguiculatus*) received daily injections of melatonin (MEL, 25 μ g/inj, sc) at 0800 or 1700 h, saline at the same two time points or no treatment for 12 weeks. At the end of the treatment period, the gerbils were challenged with PTZ (60 mg/kg, sc) to produce convulsions and were monitored for convulsive behavior for 50 minutes. Three minutes prior to death, they received 3-mercaptopropionic acid (100 mg/kg, ip) to prevent GABA degradation. The gerbils were anesthetized with metofane and killed by decapitation. Cortex, hippocampus and hypothalamus were collected. These regions were assayed for GABA, dopamine, serotonin and 5-hydroxyindoleacetic acid content (J Chromat Biomed Appl 579:334-339, 1992). MEL injected gerbils were able to survive and respond to seizures better than control animals. Total convulsion scores were reduced in MEL injected gerbils at 0800 or 1700 h compared to saline injected animals. Only one MEL injected gerbil died during seizure-induction (1/12 compared to 5/12 in saline or no treatment animals). Interestingly, the animals receiving no treatment had lower convulsion scores than saline injected gerbils. GABA levels and amine levels were similar in all gerbils with no significant differences between any of the treatment groups. These results suggest that MEL's anticonvulsant activity does not correlate with changes in neurochemicals in the regions studied. The ability of melatonin to prevent convulsions was not time of day dependent as has been observed when examining the reproductive effects of melatonin.

668.3

FURTHER EVIDENCE THAT SEROTONIN PLAYS AN ANTICONVULSANT ROLE IN GENETICALLY EPILEPSY-PRONE RATS (GEPRs). Q-S. Yan*, P. C. Jobe and J. W. Dailey. Department of Basic Sciences, University of Illinois College of Medicine at Peoria, Peoria, Illinois 61656.

Previous reports from this laboratory indicate that fluoxetine, a selective serotonin uptake inhibitor, has anticonvulsant effects in genetically epilepsy-prone rats (GEPRs). Also, the protection against audiogenic seizure following the administration of fluoxetine appears to be selectively correlated with enhanced serotonergic transmission (Dailey et al., 1992; Yan et al., 1994). An important question raised by these findings is whether the anticonvulsant action following the administration of the serotonin uptake inhibitor in GEPRs is peculiar to fluoxetine. This study was designed to evaluate further the role of serotonin in regulating susceptibility and/or severity of audiogenic seizures in GEPRs. For this purpose, sertraline, another highly selective and potent inhibitor of serotonin uptake, was studied. Severe seizure genetically epilepsy-prone rats (GEPR-9s) were used as experimental subjects in the investigation. Sertraline (7.5, 15 and 30 mg/kg, i.p.) produced a dose-dependent reduction in the audiogenic seizure severity. Brain microdialysis studies showed that the same doses of sertraline also caused dose-dependent increases in the extracellular serotonin concentration in the thalamus. Interestingly, the peak anticonvulsant effect correlated temporally with the peak increases in the extracellular serotonin concentration for this drug. These findings provide further support for the concept that serotonin plays an anticonvulsant role in GEPRs.

668.5

THE NOVEL ANTIEPILEPTIC GABAPENTIN ENHANCES PROMOTED RELEASE OF GABA IN HIPPOCAMPUS. O. Honmou*, A. Oyelese, and J. D. Kocsis. Dept. of Neurology, Yale Med. Sch., New Haven, CT, 06510, and Neuroscience Res. Ctr., VAMC, West Haven, CT, 06516.

Gabapentin (GBP), 1-(aminomethyl) cyclohexane-acetic acid, is a new anticonvulsant drug which is used clinically in the United Kingdom and the United States, but its mode of action is unknown. The antiepileptic properties of GBP were initially predicted because it is a structural analogue of the inhibitory amino acid neurotransmitter γ -aminobutyric acid (GABA). However, it lacks agonist and antagonist properties at both GABA_A and GABA_B receptor sites, and does not appear to block GABA uptake. GBP has been shown to increase the apparent rate of synthesis of GABA in several brain regions, and enhanced promoted release of GABA following GBP treatment has been observed in neonatal optic nerve. Here we provide evidence from electrophysiological experiments in the rat hippocampal slice preparation that GBP treatment enhances the reduction in excitatory postsynaptic potentials (EPSPs) elicited by promoted GABA release with nipecotic acid (NPA). NPA both blocks uptake of GABA and promotes release by heteroexchange through the GABA transporter. GBP had no effect on the normal excitability properties of the hippocampus. We suggest a novel mechanism for the antiepileptic properties of GBP whereby there is enhanced nonvesicular release of GABA possibly through reverse operation of the GABA transporter at times of intense electrical activity.

668.7

THE EFFECTS OF D-23129, A NEW EXPERIMENTAL ANTICONVULSANT DRUG, ON NEUROTRANSMITTER AMINO ACIDS (AA) IN THE RAT HIPPOCAMPUS *IN VITRO*. I.M. Kapetanovic*, W.D. Yonekawa and H.J. Kupferberg. Epilepsy Branch, NINDS, Bethesda, MD 20892.

D-23129 (N-[2-amino-4-(4-fluorobenzylamino)-phenyl]carbamate ethyl ester; Asta Medica AG, Germany; ADD230001) is a promising new anticonvulsant compound under investigation in the Antiepileptic Drug Development (ADD) Program. Recently, this compound was also shown to have some unique properties in suppressing *in vitro* epileptiform activity in rat hippocampal slices (W.D. Yonekawa et al., Soc. Neurosci. Abstr. 19:1632, 1993). The balance between the effects of inhibitory (GABA) and excitatory [glutamate (GLU) and aspartate (ASP)] neurotransmitter AA is thought to be important in normal neurological function and also may play a crucial role in the pathogenesis and potential treatment of epilepsy. This study examined the effects of D-23129 and its dihydrochloride (D-20443; ADD172014) on total tissue and newly synthesized (NEW) levels of neurotransmitter AA. NEW AA may be more closely related to the neuronally active pools than their total tissue levels. Isotopic enrichment, after incubation with stable-isotopically labeled precursor (¹⁴C-glucose), was used to measure NEW AA. Total tissue and NEW AA were determined by GC-MS. The primary effect of ADD172014 (5–40 μ M) was a dose-related increase in NEW GABA. ADD172014 was unique in this behavior. Several clinically effective or experimental anticonvulsants either had no effect on total tissue and NEW AA or decreased NEW AA. This effect of ADD172014 was not tetrodotoxin-sensitive and suggests that it is not voltage dependent. While itself increasing NEW GABA, ADD172014 antagonized the TTX-sensitive 4-aminopyridine-induced elevation of NEW GABA, NEW ASP, and NEW GLU. This latter effect was similar to that of phenytoin, carbamazepine, lamotrigine, and U54494A, whose mechanism of action may involve inhibition of use-dependent voltage-sensitive sodium channels (I.M. Kapetanovic et al., Soc. Neurosci. Abstr. 18:379, 1992). Therefore, ADD172014 exhibits two different effects on neurotransmitter amino acids which may contribute to its anticonvulsant action.

668.4

WAY100135 ANTAGONIZES THE SEROTONIN-MEDIATED INHIBITION OF EPILEPTIFORM ACTIVITY IN HIPPOCAMPAL CA1 NEURONS. Delanthi Salgado* and Karim A. Alkadhi. Department of Pharmacological and Pharmaceutical Sciences, University of Houston, Houston, TX 77204-5515 USA.

Previous studies conducted in our laboratory have shown that serotonin inhibits epileptiform activity (Salgado and Alkadhi, Soc. Neurosci. Abstr., 764.4, 1993). In addition, experiments done thus far suggest that the serotonin-mediated inhibition of epileptiform discharge is due to activation of the 5-HT_{1A} receptor subtype. The purpose of this study was to provide more conclusive evidence regarding the involvement of the 5-HT_{1A} receptor in the inhibition of epileptiform activity. Thus we used the new, selective 5-HT_{1A} receptor antagonist, WAY100135. We employed conventional electrophysiological techniques for intracellular recording from CA1 neurons in the rat brain slice preparation. Initial experiments demonstrate that WAY100135 (10 μ M) prevents the serotonin-mediated hyperpolarization, decrease in membrane resistance and current-induced action potential bursts. Furthermore, the serotonin-mediated suppression of bicuculline-induced epileptiform bursts was also antagonized in the presence of WAY100135. The results obtained thus far strongly suggest that activation of 5-HT_{1A} receptors in hippocampal CA1 neurons can suppress epileptiform activity. This study suggests that treatment of epilepsy may be possible with agents selective for serotonin 5-HT_{1A} receptor sites on hippocampal CA1 neurons.

668.6

CHRONIC GAMMA-VINYLGABA REDUCES RAT BRAIN GLUTAMINE SYNTHETASE ACTIVITY. R. A. Waniewski*, K. Rimvall and D. L. Martin. Wadsworth Center for Labs and Research, New York State Department of Health, Albany, NY 12201.

The effect of elevated GABA levels on the glial enzyme glutamine synthetase (GS) was examined in rat brain. Repeated daily s.c. injections of the GABA-transaminase inhibitor, gamma-vinyl GABA (GVG), an anti-epileptic medication, produced a gradual decline in brain GS activity. After 21 days, cortical GS activity was reduced by 36% with 150 mg/kg per day and 9.5% with 30 mg/kg per day compared to saline-injected rats. Cerebellar GS activity was reduced by 22% with 150 mg/kg and unchanged with 30 mg/kg. Skeletal muscle and liver GS activities were unaffected. Cortical GABA levels were increased by 170% after 150 mg/kg for 21 days but were unaffected at 30 mg/kg. Glutamine and glutamate levels were significantly reduced but only at the 150 mg/kg dose. GS activity was inversely correlated with brain GABA levels in the cortex. Shorter dosing periods produced smaller effects on brain GS activity. After 4 days, cortical GS was reduced by 13% and cerebellum was unaffected by 200 mg/kg GVG. GABA levels are maximally elevated even after this short dosing interval. The delay in the effect of GVG on GS may be related to the slow turnover of this enzyme *in vivo*. The glutamine cycle, which provides renewed substrate for neuronal GABA and glutamate synthesis, may be down-regulated by chronically elevated GABA. The reduction in GS activity appears to decrease brain glutamine production and thereby may limit transmitter glutamate synthesis and contribute to the anti-epileptic effect of GVG.

668.8

NOVEL MECHANISM OF ACTION OF ANTICONVULSANT ALKYL-SUBSTITUTED THIOBUTYROLACTONES: REDUCTION OF NEURONAL CA CURRENTS. J.A. Ferrendelli¹, R.A. Gross², D.F. Covey³, & R.W. Subiaga, Jr.² Depts. of Neurology^{1,2} & Pharmacology^{1,3}, ^{1,3}Washington University, St. Louis, MO, ²University of Minnesota, Minneapolis, MN.

Alkyl-substituted thiobutyrolactones (TBLs) produce either convulsant or anticonvulsant effects by modulating the picrotoxin site of the GABA_A receptor. Because of structural similarity to ethosuximide, an antiepileptic drug that blocks T-type Ca currents, we tested the effects of the anticonvulsant α -ethyl, α -methyl-thiobutyrolactone (α -EMTBL) on Ca currents of cultured DRG and neocortical neurons.

Whole cell Ca currents were evoked at +10–20 mV in media which blocked Na and K currents, with 5 mM Ca²⁺ as the charge carrier. Effects on Ca channel subtypes were assessed using nifedipine (L-type) and ω -conotoxin GVIA (N-type) and ω -agatoxin IVA (P-, Q-type). α -EMTBL (500 μ M) had a voltage-dependent effect: high-threshold DRG currents were reduced \leq 10% when evoked from -80 mV, but by 30–50% when evoked from -40 mV. Current inactivation was increased, with a greater effect on currents evoked from more polarized potentials. Neocortical currents were similarly affected. In DRG neurons, 10 μ M ω -conotoxin GVIA reduced currents ~50% and 500 nM ω -agatoxin IVA reduced currents ~15%; 10 μ M nifedipine reduced currents 10–15% at -80 mV and 45% at -40 mV. None of these, used alone, significantly affected the reduction induced by α -EMTBL.

These data suggest that α -EMTBL may have a second mechanism of action, reduction of neuronal Ca currents. This is relatively non-specific for channel subtypes and may occur by open channel block.

Supported in part by NS19613 (RAG) and NS14834 (DFC, JAF).

668.9

INHIBITION OF MAXIMAL ELECTROSHOCK (MES) SEIZURES BY A1 ADENOSINE RECEPTOR AGONISTS. J.B. Wiesner¹ and S. Zimring². Gensia, Inc., San Diego, CA 92121.

Adenosine receptor agonists exert anticonvulsant activity in a variety of animal models, including those involving chemically-induced seizures, audiogenic seizures, and kindled seizures. However, little information exists concerning their efficacy in maximal electroshock (MES) seizures. Since the efficacy profile in such seizure models are often believed to predict efficacy in clinical seizure types, we investigated the effect of adenosine agonists in MES seizures, as well as seizures induced by s.c. pentylenetetrazol (PTZ); we also investigated effects on blood pressure, body temperature, and motor performance. Electrical current (60 Hz, 0.2 sec) was delivered via corneal electrodes at 150 mA in rats and 50 mA in mice at 20 min after i.p. injection of each agonist. The A1 receptor agonists cyclopentyladenosine, R-phenylisopropyladenosine, cyclohexyladenosine, 2-chloroadenosine, and N-ethylcarboxamidoadenosine, dose-dependently inhibited MES seizures in both species. Respective ED₅₀ values (mg/kg) for MES in rats were 2.3, 3.7, 3.6, 5.7 and 10.4. Respective ED₅₀ values for MES in mice were 1.7, 3.6, 13.4, 8.2, and 73.8. The A2 selective agonist CV1808 was ineffective at doses of up to 10-30 mg/kg. The A1 agonists also inhibited PTZ seizures with respective ED₅₀ values of 11.2, 3.1, 4.5, 11.0, and 9.1 (rats) and 1.7, 0.6, 6.7, 3.2, and 0.1 (mice). All of the A1 agonists induced substantial akinetic or ataxic effects at anticonvulsant doses. In addition, the ED₅₀ dose (2.3 mg/kg) of cyclopentyladenosine in conscious rats decreased blood pressure and heart rate by approximately 60% and decreased body temperature by 4-6°C.

These results show that stimulation of A1 adenosine receptors exerts an anticonvulsant effect in the MES seizure model in rats and mice, indicating potential utility of an adenosine receptor approach in generalized tonic-clonic seizures in man. However, the clinical utility of direct A1 agonists will be limited if similar side effects are found in man.

DEGENERATIVE DISEASE: ALZHEIMER'S—BETA AMYLOID XI

669.1

TRANSGENIC MOUSE AND RAT STUDIES OF ALZHEIMER AMYLOID PRECURSOR PROTEIN.

D.S. Howland¹*, M.J. Savage¹, D.M. Lang¹, F.A. Huntress², R.E. Wallace², R. Coffee², L.R. Pinsky¹, A.G. Reaume¹, S.P. Trusko¹, R. Siman¹, B.D. Greenberg¹, M.E. Swanson² and R.W. Scott¹. ¹Cephalon Inc., West Chester, PA, 19380, ²DNX Inc., Princeton, NJ, 08540.

Deposition of the 4 kD A β protein, derived by proteolytic cleavage from the amyloid precursor protein (APP), in brain is a neuropathological hallmark of Alzheimer's disease (AD). Expression of full length human APP in brains of animals should provide a model system for studying proteolytic processing of APP *in vivo*. These animals also serve as a basis to address parameters required for the development of β -amyloid-related neuropathologies in brain. We have generated transgenic mouse and rat lines harboring full length human APP transgenes containing native sequence and genetic mutations linked to familial AD (Δ L717, Δ NL₆₇₀₋₆₇₁) and hereditary cerebral hemorrhage with amyloidosis-Dutch type (Δ Q693). Human APP transgene RNA and protein occurs predominantly in brain. *In situ* hybridization shows human APP RNA enriched in neurons. Evidence for proteolytic cleavage of human APP in mouse brain which is required for A β production has been obtained using antibodies specific for human APP fragments. Recent evidence has implicated apolipoprotein E in the pathogenesis of AD. Apolipoprotein allele E4 cosegregates at high frequency with late-onset and sporadic AD. To study the role of apoE in amyloid deposition we have generated transgenic lines expressing both human apoE4 and APP. Characterization of these lines and results from our ongoing search for amyloid-related neuropathologies in APP transgenic mice and rats will be presented.

669.3

APOLIPOPROTEIN E INDUCES EXPRESSION OF THE AMYLOID β -PROTEIN PRECURSOR IN CULTURED CEREBROVASCULAR SMOOTH MUSCLE CELLS. S.M. Saporito-Irwin^{*}, M. Wessel, W.E. Van Nostrand^{*}. Department of Microbiology and Molecular Genetics, College of Medicine, University of California, Irvine CA 92717-4025.

Recent studies have implicated apolipoprotein E (apoE) in the pathogenesis of Alzheimer's disease (AD). The E4 allele of apoE has been shown to be linked to the occurrence of late onset familial and sporadic AD. In addition, apoE can bind the amyloid β -protein (A β) and has been found tightly associated with amyloid deposits in both senile plaques and cerebral blood vessels. Immunohistochemical studies showed apoE reactivity in the smooth muscle cell medial layer of intracortical and leptomeningeal blood vessels of patients with AD. Furthermore, smooth muscle cells have also been implicated in the cerebrovascular expression of the amyloid β -protein precursor (A β PP) and the production of A β peptide. In view of these findings, we examined the effect of purified apoE from normal pooled plasma on the expression of A β PP in cultured cerebrovascular smooth muscle cells. Cells were incubated with increasing concentrations of purified apoE for 72 hr and then the levels of secreted and cell-associated A β PP were measured by quantitative immunoblotting. Cerebrovascular smooth muscle cells incubated with 1 μ M purified apoE expressed five-fold higher levels of both secreted and cell-associated A β PP compared to untreated cells. The effect of apoE was specific in that purified apoA or apoC had no effect on the levels of secreted nor cell-associated A β PP in the cerebrovascular smooth muscle cells. These findings suggest that in the cerebrovasculature apoE may be involved with increased expression of A β PP and, potentially, the subsequent production of higher amounts of A β peptide. Soluble A β peptide produced by smooth muscle cells may interact with apoE leading to aggregation and deposition in the cerebrovasculature.

668.10

THE PHENYLCARBAMIC ACID ESTER D-23129 IS HIGHLY EFFECTIVE IN EPILEPSY MODELS FOR GENERALIZED AND FOCAL SEIZURES AT NONTXIC DOSES. C. Tober, C. Rundfeldt*, A. Rostock and R. Bartsch. Arzneimittelwerk Dresden GmbH, Department of Pharmacology, Meißner Str. 191, 01445 Radebeul, FRG.

Complex partial seizures comprise the major uncontrolled seizure type in adult patients with epilepsy. New anticonvulsants should not only reduce seizure severity but also suppress focal seizure activity for full seizure protection. The goal of this study was to demonstrate that D-23129 is capable to suppress focal seizure activity at nontoxic doses. The broad effectiveness of D-20443, the hydrochloride of D-23129 (N-[2-Amino-4-(4-fluorbenzylamino)-phenyl]carbamic acid ester), was shown previously (Nickel et al, Epilepsia 34, Suppl. 2, 95, 1993). We could now demonstrate that D-23129 and D-20443 are equipotent in suppressing the tonic extension of hind limb in the maximal electroshock test in mice (ED₅₀ 18.2 and 17.4 mg/kg i.p. respectively); both compounds also nearly doubled the threshold for clonic seizures in the i.v.-metrazole test after administration of 16 mg/kg i.p. and suppressed audiogenic seizures in DBA/2 mice at 3 mg/kg. D-23129 reduced not only kindled seizure parameters after supramaximal stimulation but also increased the threshold for induction of afterdischarges indicating a suppression of focal seizure activity in a dose dependent manner. After oral administration of 10 mg/kg 60 min prior to testing all animals were seizure protected if stimulated with double the individual seizure threshold. The afterdischarge threshold was increased to 408 and 597% of control threshold after 10 and 15 mg/kg respectively. After 15 mg/kg all seizure parameters were significantly reduced after suprathreshold stimulation and no motor impairment was present. First electrophysiological data indicate that part of the effects of D-23129 is mediated through effects on voltage gated Na⁺ and Ca⁺⁺ channels. The results make D-23129 a promising candidate for treatment of generalised and complex partial seizures.

669.2

TRANSCRIPTIONAL REGULATORY ELEMENTS OF THE RAT AMYLOID PRECURSOR PROTEIN (APP) GENE PROMOTER.

P. W. Hoffman* and J. M. Chernak. National Institute on Aging, Lab. of Cellular and Molecular Biology, MPGS, Baltimore, MD 21224

Levels of some amyloid precursor protein (APP) mRNAs are selectively increased in Alzheimer's disease and Down's syndrome (DS) brains relative to age-matched control brains, and overexpression of the APP gene in DS could be related to gene dosage effects. Therefore, transcriptional regulation of the APP gene may play a role in the pathophysiology of several neurodegenerative diseases. In order to study transcriptional regulation of the APP gene, we have begun characterizing the rat APP promoter. The 375 bp directly upstream of the start codon contains all of the transcriptional start sites and drives transcription in rat PC12 cells and human SHSY5Y cells. The promoter activity appears to be dependent upon two small regulatory elements. Deletion of one element at position -260 to -248 reduced activity by 85% in PC12 cells while deletion of a second element at position -223 to -192 reduced activity by 30%. A double mutant which internally deletes both sites reduced transcription to nearly background levels. Additional experiments have suggested that deletion of the element at -260 to -248 may be responsible for uniformly large effects in several rodent and human cell lines, while deletion of the element at -223 to -192 may produce cell line-specific effects. Gel mobility shift assays with nuclear extracts derived from rat brains or rat cell lines suggest that one or more proteins may interact with the element at -223 to -192 but not with the one at -260 to -248. We are currently investigating the role of these regulatory elements using site-specific mutagenesis, further gel shift assays and gel super-shift analysis.

APOLIPOPROTEIN E REGULATES APP LEVELS. Benjamin Wolozin*, Robert Canter, Yongquan Luo, Dale VanderPutten, Trey Sunderland. Lab. of Clinical Science and Lab. of Biochemical Genetics, National Institute of Mental Health, Bethesda, MD 20892.

Recent studies have shown that the apolipoprotein E allele, apo E4, is an important risk factor for Alzheimer's disease. Previous studies showing that Apo E binds to β -amyloid, *in vitro*, and associates with neuritic plaques, *in vivo*, suggest the risk may be due to an association between β -amyloid and apo E (W. J. Strittmatter, et al, 1993 PNAS 90:8098). However, the mechanism for this association is unclear because the affinity of Apo E for β -amyloid is low. We now show that apolipoprotein E is a potent regulator of APP levels in cell culture, being active at levels as low as 30 nM. Addition of apolipoprotein E or HDL to PC12 cells grown in cell culture induces a decrease in the levels of both secreted and cellular amyloid precursor protein (APP) in a dose-dependent manner by up to 63%, with an IC₅₀ of 30 nM. Blockade of protein processing with 1 μ M brifeldin A, 60 μ M chloroquine or 10 μ g/ml leupeptin prevents this, which suggests that internalization and catabolism of APP or Apo E is necessary for this process. These data point to a physiological role for apo E in the regulation of APP and suggest that binding of apo E to APP may be the first step in the association between Apo E and β -amyloid.

669.5

TRANSPORT OF ALZHEIMER'S AMYLOID BETA AND APOLIPOPROTEINS E AND J AT THE BLOOD-BRAIN BARRIER. B.V. Zlokovic,* J.B. Mackic, C.J. Martell, T. Wisniewski, B. Frangione, J. Ghiso. Dept. Neurosurgery, USC School of Medicine, Los Angeles, CA 90033

Two apolipoproteins, apoE and apoJ, have been recently shown to be associated with Alzheimer's amyloid β (A β). It has been proposed that apoE is an A β pathological chaperone protein, acting to modulate and/or stabilize a β -pleated sheet structure in A β . Consistent with this hypothesis, there is a linkage between apoE4 isotype and late onset Alzheimer's disease. On the other hand, apoJ has been shown to be complexed to A β in cerebrospinal fluid. A β , apoE and apoJ are present in senile plaques; however, their origin is not known. We have studied the behavior of these three components at the BBB level. An "in vivo" brain perfusion technique and capillary depletion method were used to determine cerebral capillary binding and BBB transport of [125 I] labeled apoE, apoJ and synthetic A β 1-40 in guinea pigs. A saturable specific binding and transcellular BBB transport were demonstrated for all components although both apolipoproteins exhibit different BBB transport behavior. After 10 min perfusion, the volume of distribution for apoJ was 4-5 times higher than for apoE. Pre-perfusion with a very low dose of cold apoJ completely blocks the transport, indicating a high affinity interaction.

BRAIN CLUSTERIN (APO-J) AND ITS INTERACTION WITH β -AMYLOID (A β). G.M. Pasinetti*, T. Oda, S.A. Johnson, C.E. Finch. Andrus Gerontology Center Neurogerontology Division and Dept. of Biological Sciences, University of Southern California, Los Angeles, CA 90089-0191.

The senile plaque contains aggregations of β -amyloid (A β). In addition to aggregated A β , senile plaque contains other proteins that may be pertinent to neurodegeneration, particularly complement proteins and the putative complement inhibitor, clusterin. We purified clusterin from Alzheimer's disease (AD) cerebral cortex by column chromatography (DEAE, antibody affinity and HPLC size-exclusion). Brain clusterin presented slightly smaller species about 35-40 kDa vs. purified serum clusterin (39-42 kDa), under reducing conditions. In the inhibition of complement-mediated hemolysis, brain and serum clusterin were indistinguishable. Aggregation of A β (1-42) was assayed by centrifugation with [125 I]-A β 1-42 and gave 30% sedimentable A β (48 hrs, 25°C, pH 7.0). Clusterin showed a concentration-dependent inhibition of A β sedimentation. Supported by Alzheimer's Association grant to GMP and by grants to CEF from NIA AG-7909 and Sankyo Co.

669.9

THE ROLE OF APOLIPOPROTEIN E IN AMYLOID FIBRIL FORMATION. F. Prelli, E. M. Castano, M. Pras, S.F. Ferris*, B. Frangione. Dept. of Pathology, NYU Medical Center, New York, NY 10016

Amyloidosis comprises a heterogeneous group of diseases of diverse etiology characterized by the systemic or localized extracellular and intracellular deposition of proteinaceous β -pleated fibrils, which are biochemically and immunohistologically distinguishable. Amyloid P-component, α 1-antichymotrypsin, glycosaminoglycans, vitronectin, apolipoprotein J (apoJ) and apolipoprotein E (apoE) are significant components of these amyloid deposits, although their role in amyloidogenesis is not defined. Recent genetic studies suggest an association of apoE type4 allele with sporadic and familial late onset Alzheimer's Disease (AD). In vitro studies have shown apoE binding to synthetic A β and tau protein, the main constituents of paired helical filaments in neurofibrillary tangles (NFT), an AD hallmark. These data have led to the hypothesis that Apo E plays a pathogenic role in AD. However apoE immunoreactivity is present in all cerebral and systemic amyloidoses tested.

In order to study the role of apoE, we purified amyloid AA and AL fibrils from patients with familial Mediterranean fever and primary amyloidosis, respectively. In each case, apoE fragments, detected by Western immunoblot, copurified with the amyloid fibrils. Following further separation techniques, (HPLC, SDS-PAGE and Western blot) we were able to characterize by microsequencing analysis these apoE fragments as the C-terminus fragment of apoE, similar to the 10 kd fragment produced by thrombin digestion. This is the purported binding region of apoE to A β . We propose that this binding is not specific for A β or tau, but rather that apoE plays a more general role in amyloid formation in acting as a "pathological chaperone" which may modulate the aggregation of amyloidogenic proteins into the β sheets that typically constitute insoluble amyloid fibrils.

669.6

STUDIES OF TRANSCELLULAR TRANSPORT OF A β ACROSS MDCK MONOLAYERS. D. J. Watson and D. J. Selkoe*. Program in Neuroscience, Harvard Medical School and Center for Neurologic Disease, Brigham and Women's Hospital, Boston, MA 02115.

The discovery of soluble amyloid β (A β) protein in CSF and plasma raises the possibility that one source of some amyloid deposits in Alzheimer brain may be the circulation. We have used a cell culture model to test whether A β can be transported across cellular monolayers which form tight physiological barriers. Madin-Darby canine kidney (MDCK) epithelial cells form polarized monolayers with intercellular tight junctions when grown on polycarbonate filters in Transwell chambers. MDCK cells were grown to post-confluence in DMEM/10% FCS. Either 3 H-inulin (a marker for intact tight junctions) or physiological concentrations (0.1 to 1.0 nM) of [125 I]-A β were added to the apical or basal chambers in either serum-free DMEM, fresh DMEM/10% FCS or 16-hour MDCK-conditioned DMEM/10% FCS. After incubation for 3 or 6 hr at 37°C, medium from both chambers was sampled and counted. Under these conditions, transcellular transport of [125 I]-A β was observed to be no greater than the background inulin transport in both the apical-to-basal and basal-to-apical directions. We are therefore examining molecules which are known to be transported across MDCK monolayers by a receptor-mediated mechanism, and asking whether these molecules are able to act as carriers for A β during transcellular transport. The results of such *in vitro* studies can be coupled with intravascular A β injection studies in animals to determine whether A β is able to cross the blood-brain barrier.

669.8

ALZHEIMER'S A β AND APOLIPOPROTEIN J INTERACTION. E. Matsubara, B. Frangione, J. Ghiso*. Dept. of Pathology, NYU Medical Center, New York, NY, 10016.

Peptides with the same amino acid sequence as Alzheimer's amyloid β (A β) exist as a normal soluble protein (sA β) in biological fluids. Hence, a key question is what factors alter sA β in the disease state, promoting conformational changes, aggregation, amyloid fibril formation and cell death. Biochemical and immunohistochemical studies have shown i) apoE and apoJ bind sA β under different conditions in vitro, and ii) sA β is complexed to apoJ in vivo. We have further characterized the interaction ApoJ-A β using purified ApoJ and immobilized A β 1-40 on a solid phase on capture ELISA experiments. The binding ApoJ-A β 1-40 was saturable and specific. When the preformed complex was offered to A β 1-40 complete binding inhibition was achieved, indicating complex stability in physiologic solutions. Solid phase competitive inhibition assay using other plasma/cerebrospinal fluid proteins with demonstrated avidity for A β (ApoE3, ApoE4, α 1-antichymo-trypsin, Transthyretin, Vitronectin) showed that none of these completely displaced apoJ from the complex up to 100 molar excess. Only apoE3 at high molarity (approximately 60 molar excess over apoJ) partially competes with apoJ for A β . The data support the notion that the association ApoJ-A β may play a role in the transport and delivery of sA β .

CHONDROITIN SULFATE PROTEOGLYCAN FORM OF ALZHEIMER'S AMYLOID PRECURSOR PROTEIN IS PRODUCED MOSTLY IN ASTROCYTES BUT NOT IN NEURONS. J. Shioi*, M. N. Pangalos, C. Mytilineou*, N. K. Robakis*. Dept. 'Psychiatry and Fishberg Ctr. Neurobiol., and 'Neurology, Mount Sinai Med. Ctr., New York, NY 10029.

C6 glioma cells and rat and human brain produce the chondroitin sulfate proteoglycan form of Amyloid Precursor Protein (CSPG-APP). In this report we show that CSPG-APP production in Neuro 2A neuroblastoma cells is markedly reduced upon differentiation with cAMP. Using primary cell cultures from rat brain, we examined which cell types in the brain synthesize the CSPG-APP. Neuronal and glial cultures were prepared from cerebral cortices of prenatal and neonatal rats, respectively. Purity of the cell populations in each culture was determined by immunocytochemistry using cell specific markers. Cells were labelled with 35 S-sulfate and both media and cell extracts were immunoprecipitated with various anti-APP antibodies. Immunopurified molecules were further analyzed by SDS/PAGE and fluorography. The PG nature of APP was demonstrated by glycosaminoglycan degradation by chondroitinase. Neuronal cultures produced high levels of APP₆₉₅ but very little CSPG-APP. Astroglial cultures produced mainly APP_{751/770} and high levels of the CSPG form, whereas oligodendrocytes produced only APP but no CSPG-APP. Microglial cultures showed only low levels of APP and CSPG-APP production. Since astrocytes have unique functions such as neuronal guidance, our results suggest that CSPG-APP may play a role in such a cell-specific function, and may contribute to neuronal survival.

669.11

ENDOTHELIAL CELL SURFACE PROTEOGLYCAN BIND TO Beta-AMYLOID PEPTIDE. M.Matic, B. Leveugle, H.M. Fillit*, Department of Geriatrics, Mt. Sinai Medical Center, New York, NY

Proteoglycans (PGs) codeposit with Beta-amyloid peptide (BAP) and are thought to play fundamental role in all form of amyloidosis. Amyloid precursor protein (APP) has at least two distinct processing pathways: a secretory pathway and endosomal-lysosomal pathway which involves internalization of cell surface APP. We have previously demonstrated binding of secreted neuroblastoma and vascular PGs to APP and to BAP. We have also reported binding of cytoplasmic PGs to BAP. In order to examine if PGs might associate with APP at the cell surface, we purified the cell surface pool (trypsin releasable) of metabolically labeled mouse endothelial cells on DEAE-sepharose. Enzymatic digestion with heparitinase II and chondroitinase ABC, as well as nitrous acid degradation of isolated cell surface PGs demonstrated presence of heparan sulfate PGs and indicated presence of chondroitinase ABC sensitive material. Interaction of isolated PGs with BAP (1-28AA) was examined by affinity chromatography. The largest fraction of PGs eluted from the BAP column at 0.65 M NaCl. TNF-alpha treatment of the cells did not alter binding of the cell surface PGs to BAP. Binding of the cell surface PGs to BAP may indicate interaction of PGs and APP at the cell surface and point to the role of PGs in endosomal-lysosomal APP processing and/or APP secretion by APP secretase.

669.13

THE AMYLOID-ASSOCIATED PROTEINS α_1 -ANTICHYMOTRYPSIN AND APOLOPROTEIN E CATALYZE THE ASSEMBLY OF THE ALZHEIMER β -PROTEIN INTO FILAMENTS AND CO-LOCALIZE WITH APP AT THE NEUROMUSCULAR JUNCTION. J. Ma*, A. Yee, & H. Bryan Brewer, U. Kayvali, and H. Potter, Department of Neurobiology, Harvard Medical School, Boston, MA 02115; *National Heart and Blood Institute, National Institutes of Health, Bethesda, MD 20892.

The protease inhibitor α_1 -antichymotrypsin (ACT) and the lipid transport protein apolipoprotein E (apoE) are intimately associated with the 42-amino acid β -peptide (A β) in the filamentous amyloid deposits of Alzheimer's disease. We have found that these two amyloid-associated proteins serve a strong stimulatory function in the polymerization of A β into amyloid filaments. Addition of either ACT or apoE to the A β peptide promoted filament formation 10 to 20-fold. ApoE4, the isoform recently identified as a risk factor for Alzheimer's disease, showed the highest catalytic activity. We are currently testing the effect of ACT and apoE on the neurotoxicity of A β peptide in cell culture. These components of the Alzheimer amyloid deposits—APP, ACT, and apoE—can also be found to be co-localized at the neuromuscular junction together with the acetylcholine receptor. Two proteins are important in the formation of the neuromuscular junction: ARIA, which induces expression of the acetylcholine receptor, and Agrin, which induces its aggregation. Experiments are underway to determine whether, like the acetylcholine receptor, APP, ACT, and apoE mRNAs are up-regulated by ARIA, and whether the proteins are induced to aggregate under the influence of Agrin both at the neuromuscular junction and at neuronal synapses more generally. In sum, our results suggest that Alzheimer amyloid filaments arise when A β and amyloid promoting factors (pathological chaperones) are expressed together in certain brain regions.

669.12

BINDING OF SOLUBLE β -AMYLOID IN VITRO AND IN VIVO. A. Golabek, M. Marques, I. Koji, J. Ghiso, J. Herbert*, B. Frangione, T. Wisniewski. Dept. of Pathology and Neurology, New York Medical Center University, N.Y., 10016.

β -amyloid (A β) is the major constituent of amyloid deposits in the senile plaques and vessels of Alzheimer's Disease (AD). This same peptide exists as a normal component of biological fluids; hence, the A β peptide can have the β -pleated sheet structure of amyloid as well as being a soluble protein. Several proteins are reported to bind sA β including transthyretin, α_1 -antichymotrypsin, apolipoprotein (apo) E and apo J. An allele of one of these proteins, apo E4, has been linked to late onset AD. Using synthetic peptides homologous to A β 1-40 we have done direct binding experiments with the above proteins and found that SDS-stable complexes can be formed with each of them. To evaluate whether such complexes may also exist in vivo immunoprecipitation of these binding proteins was done in CSF and co-precipitation of sA β was determined by Western blotting. In addition an affinity column with 4G8 antibodies (recognizing A β 17-24) was used to extract sA β from pooled normal CSF and associated binding proteins were identified by Western blotting and N-terminal sequencing. These experiments of in vivo binding suggest that in normal CSF the major binding protein is apo J; although, other proteins also bind including apoE. These carrier or chaperone proteins of soluble A β (sA β) may influence its conformational state. Experiments are underway to determine if the carrier proteins differ in AD and normal patients.

669.14

REGULATION OF β -AMYLOID PEPTIDE AGGREGATION BY RECOMBINANT TRANSTHYRETIN AND ITS ANALOGS.

K. Bhattacharya, P. Tonge, A. L. Schwarzman, M. Tsiper, M. Eisenberg, F. Salles, D. Goldgaber and M. P. Vitek*. The Picower Institute for Medical Research, Manhasset, NY 11030 and Dept. of Psychiatry and Pharmacology, SUNY, Stony Brook, NY 11794

Amyloid plaques are found in the brains of patients with Alzheimer's disease and contain fibrillar aggregates of non-covalently linked β AP. *In vitro*, synthetic β AP spontaneously aggregates into morphologically identical fibrillar aggregates which we find are toxic to neurons in culture. The spontaneous transition from soluble β AP to insoluble β -amyloid is inhibited by the presence of μ M levels of transthyretin (TTR, Schwarzman et al., PNAS, 1994, in press). The mechanism whereby TTR inhibits β AP aggregation is unknown, but may be mediated by specific interactions between TTR and β AP (Schwarzman et al., *ibid* and Soc. Neurosci. Abs. 1994). To define the domains of TTR which function to inhibit β AP aggregation, we have produced recombinant human TTR in bacteria using the pET system. Following a multi-step purification protocol, we find that rTTR inhibits β AP aggregation and binds thyroxine in contrast to protein purified from vector controls lacking TTR. Natural TTR purified from cerebral spinal fluid and rTTR inhibited β AP aggregation with equal potencies. Based on our model of β AP-TTR interactions (Schwarzman et al. *ibid.*), we have mutated the residues of TTR which comprise the putative β AP binding site. The potency with which these TTR analogs inhibit β AP aggregation and modulate neurotoxicity will be discussed.

DEGENERATIVE DISEASE: PARKINSON'S—RODENT AND PRIMATE STUDIES

670.1

AN ELISA ASSAY TO DETECT A DOPAMINE RELEASING PROTEIN (DARP) AND POTENTIAL CLINICAL APPLICATIONS. S. Kuhananthan*, and V.D. Ramirez. Dept of Molecular and Integrative Physiology, Univ of Illinois Urbana, IL 61801

A dopamine releasing (DARP) protein was first purified from rat adrenal gland (Chang and Ramirez 1988) and subsequently characterized as a multiunit glycoprotein of 200 Kd. Monoclonal antibodies of IgM isotype were produced against DARP to study this protein further. These antibodies were shown to arrest fetal development and deplete brain dopamine levels when injected into rat fetuses and newborn pups, respectively (Kuhananthan et al 1991).

We developed a direct ELISA assay for DARP utilizing the MAb. A synthetic peptide (DARP 36) consisting of the first 36 N-terminal aminoacids of DARP is specifically detected by the ELISA assay in a dose dependent manner. The presence of DARP in human serum was also specifically demonstrated in ELISA assay. Affinity purified serum DARP releases DA from *in vitro* corpus striatal fragments and is detected in ELISA assay in 1-10 ng protein. Furthermore the crude serum and affinity purified DARP compete for DARP 36 in a competitive ELISA assay, whereas several other proteins did not compete.

The DARP is present in high concentration in the rat brain, liver and adrenal gland. ELISA assay using three different antibodies indicate that the tissue form of DARP is different from circulating DARP.

Interestingly Parkinson disease (PD) patients have higher levels of serum DARP compared to age matched control subjects. The DARP levels in human serum may serve as a biochemical marker and aid in the diagnosis of PD.

670.2

TREATMENT WITH A SYNTHETIC 36aa PEPTIDE FROM THE N-TERMINAL SEQUENCE OF DARP PARTIALLY RESTORED DA LEVELS IN MPP+ LESIONED RATS AND DRASTICALLY REDUCED AMPHETAMINE-INDUCED ROTATION. Ramirez VD*, Phelps S, Kim S. Department of Molecular and Integrative Physiology, Univ. Illinois, Urbana, IL 61801, USA.

Dopamine releasing protein (DARP) is a complex multisubunit protein originally discovered in the adrenal gland. To examine the role of DARP-36 on a rat model of Parkinson's disease, adult male rats were lesioned with MPP⁺ (84 μ g/2 μ l) in the left corpus striatum (L-CS) through a Push-Pull cannulae implanted 5-6 d before the lesion (local infusion group, LIG) or by direct infusion of the neurotoxin on the day of the operation (systemic injection group, SIG). The LIG received 24 h after the lesion a daily infusion of DARP (1 μ g/10 μ l/10min for 10d) or BSA as control. In the 11d they received an amphetamine challenge (2mg/kg,ip) and rotations were recorded for the last 30 min of a 45 min duration test. Rats were sacrificed next day and DA levels in both CS were determined by HPLC-EC. The SIG was divided in 4 subgroups: vehicle-treated and 5, 15 and 30 μ g DARP-treated. All rats received a subcutaneous injection for 10 d. The data indicate a dose response in the SIG with a modest recover of the DA levels in the 30 μ g subgroup to 20% of the contralateral levels but without effect on the AMPH-induced rotations (1.85 \pm .31 vs 3.1 \pm .42, vehicle (n=12) and DARP-treated (n=9) p<.01 L-CS, respectively. The local infusion of DARP in the lesioned side led to a 50% recovery of DA levels compared to the contralateral side (7.91 \pm .34 vs 3.3 \pm .45 DARP, n=9 vs vehicle, n=11, L-CS, respectively) and interestingly to a near complete recovery of the response in the rotation test (vehicle=87 \pm 25 vs DARP=12 \pm 16 rotations/30 min). The data indicate that DARP-36 may be a potential beneficial peptide in the treatment of Parkinsons patients. (Partially supported by Chiron).

670.3

METHYL β -CARBOLINIUM (BC⁺) ANALOGS OF MPP⁺: SUBSTANTIA NIGRA (SN) INJECTIONS IN RATS CAUSE NIGROSTRIATAL TOXICITY. E.J. Neasey*, F. Tamayo, D. Gearhart, R. Albores, and M.A. Collins. Departments of Cell Biology, Neurobiology & Anatomy and Molecular and Cellular Biochemistry, Loyola University Medical Center, Maywood, IL 60153.

Eleven BC⁺s and MPP⁺ were stereotactically injected (40-200 nmoles in 5 μ l of vehicle) unilaterally into the SN of anesthetized adult male Sprague-Dawley rats. The rats were sacrificed after three weeks. The ipsilateral striatum was analyzed for dopamine and DOPAC levels with HPLC. The brainstem injection site was fixed and cut coronally. The largest lesion area in each animal was measured using NIH Image. Three BC⁺s approached MPP⁺'s effectiveness (defined as 100%) in producing lesions at the injection site: 2,9-Me₂-harman (94%), 2-Me-harmol (74%), and 2,9-Me₂-norharman (57%). The other compounds were somewhat less effective: 2-Me-harmaline (34%), 6-MeO-2-Me-harman (29%), and 2-Me-harmine (25%). The remaining compounds were ineffective ($\leq 12\%$): norharman, 2-Me-norharman, 2-Me-harman, harmine, and 2-Me-6-MeO-harmalan. A 40 nmole dose of MPP⁺ reduced ipsilateral dopamine to 0.6% of control. None of the β -carboline analogs approached this, although several did significantly reduce striatal dopamine at doses of either 40 nmoles (2,9-Me₂-harman (37%), 2,9-Me₂-norharman (42%), and 2-Me-harman (63%)) or 200 nmoles (2-Me-harmaline (23%), norharman (63%), and 2-Me-norharman (64%). There was a strong negative correlation between lesion size and dopamine level ($r = -.77$). There were also moderately strong correlations ($r = .55-.74$) between the BC⁺ lesion area or dopamine level potencies and their previously described IC50 values for inhibiting mitochondrial respiration or their toxicity to PC12 cells in culture. Although BC⁺s appear less specific than MPP⁺, their levels in human SN are 8-20 fold higher than in cortex, making their role as relatively selective SN toxins in Parkinson's disease plausible. (NIH grant NS 23891)

670.5

UNILATERAL INTRACAROTID ADMINISTRATION OF MPTP IN NONHUMAN PRIMATES: EFFECT ON DIFFERENTIAL SUBSTANTIA NIGRAL CELL LOSS R. Assietti, K.D. Terry, N.M. Oyesiku*, R.A.E. Bakay. Department of Neurosurgery, Emory University, Atlanta, GA 30322.

Behaviorally, the similarities between the MPTP non human primates model and Parkinson's disease (PD) are quite striking. MPTP's neuropathological effects (specifically, the quantification of cell loss) in the substantia nigra have not been studied in a manner similar to that used to study human PD, and meaningful comparisons have been difficult to obtain. In this study, rhesus (*Macaca mulatta*) monkeys (N=13) with ages ranging from 1 to 20 years were given single or multiple intracarotid left-sided injections of MPTP (0.5mg/kg over a 20 minute period). The monkeys were parkinsonian before sacrifice for a mean period of 1 year (range: 5 months to 2 years). Normal monkeys (N=9) with ages ranging from 1 to 24 years of age were examined in a similar fashion. Serial sections of the midbrains were obtained and immunocytochemically stained for tyrosine hydroxylase (TH). Cell number, cell and nuclear diameters and cell volume were measured in A8, A9 (dorsolateral, dorsomedial, ventrolateral, ventromedial), A10 paraventricular nucleus and A10 total areas using a computerized image analyzer and corrected according to the Abercrombie formula. No difference in cell counts was observed in comparing the left and right sides of the normal monkeys. A trend in cell loss according to age was observed in both normal (dorsolateral A9) and MPTP treated (ventrolateral A9) animals. The most consistent results were obtained at the level of the third cranial nerve. The relative mean TH cell loss in the A9 area (pars compacta) compared to the mean values observed in the normal monkeys was: dorsolateral A9: -82.3%; dorsomedial A9: -73%; ventrolateral A9: -90.1%; ventromedial A9: -81.6%; total A9: -84.2% ($p < 0.005$). Relative cell loss in A8 was -68% and in A10 (ventral tegmental area) total: -74% with a ($p < 0.05$). There was no significant cell loss observed in A10 paraventricular nucleus areas. The analysis of our data demonstrates that the greatest amount of TH cell loss caused by the neurotoxin, MPTP, occurs in A9, and most severely in the ventrolateral area of A9. Importantly, it is this area that has been shown to be most affected in human parkinson's disease. Supported by USPHS Grant RR00165 and NINCDS N2NS4340.

670.7

[³H]FLUNITRAZEPAM BINDING TO GABAA RECEPTORS IN THE EFFERENT PATHWAYS OF THE STRIATUM OF MPTP-MONKEYS TREATED CHRONICALLY WITH A D2 AGONIST (U-91356A) OR L-DOPA: RELATIONSHIP WITH DEVELOPMENT OF DYSKINESIA. F. Calon¹, M. Goulet¹, P. Blanchet², P.J. Bédard^{2*} and T. Di Paolo¹. ¹School of Pharmacy, ²Department of Pharmacology, Laval University, Québec, CANADA, G1K 7P4.

Dyskinesia is one of the main side effects following chronic dopaminergic treatment in Parkinsonians and in MPTP monkeys. Many of the basal ganglia neurons are gabaergic and are probably implicated in the development of dyskinesia. Thus, the GABA_A/benzodiazepine receptor complex was quantified by autoradiography with [³H]flunitrazepam in the brain of MPTP monkeys following continuous or intermittent D2 agonist treatment with U-91356A (Upjohn) or intermittent L-DOPA treatment. Animals treated intermittently with U-91356A or levodopa developed dyskinesia whereas animals treated continuously with U-91356A did not. [³H]flunitrazepam binding in the striatum, internal (GPI) and external segments of globus pallidus, subthalamic nucleus and substantia nigra were investigated. MPTP and dopaminergic treatments affected differently [³H]flunitrazepam binding in these regions suggesting different gabaergic input levels in the various nuclei of the basal ganglia. The most interesting change was an elevation of [³H]flunitrazepam binding in the GPI of animals treated intermittently with U-91356A or levodopa and concomitantly developing dyskinesia (+38% and +36% vs MPTP untreated, respectively; $p < 0.05$). These results suggest supersensitivity of the GPI to gabaergic inputs which may be involved in the triggering of dyskinesia. Supported by the MRC of Canada and the Parkinson Foundation of Canada.

CORRELATION BETWEEN AGE AND DOSE OF MPTP IN HEMIPARKINSONIAN RHESUS MONKEYS

A. Ovadia, Z. Zhang*, M. Smith and D.M. Cash. Department of Anatomy and Neurobiology, University of Kentucky, Lexington, Ky. 40536-0084.

MPTP (1-methyl-4-phenyl-1,2,3,6-tetrahydropyridine) administered to nonhuman primates induces Parkinsonian-like features. However, the vulnerability of these animals to this neurotoxin appears to be age dependent. To test this hypothesis, 27 female Rhesus monkeys, ranging in age from 5 to 23 years old, were given sufficient MPTP via the right carotid artery to induce moderate unilateral Parkinsonian features. Cumulative doses ranged from 0.4 mg/kg to 1.8 mg/kg. In order to produce similar Parkinsonian features in all animals, one or two additional doses of MPTP were needed in most younger monkeys. Horizontal home cage activity was recorded continuously (24 hours) by photocells as well as behavior rated from bimonthly video tapes. After achieving similar scores on the hemiparkinsonian clinical rating scale, most monkeys showed a decrease in home cage activity. However, to achieve similar scores, the younger Rhesus monkeys ($n = 12$, < 10 years old) required a total of 1.0-1.8 mg/kg MPTP, while the older Rhesus monkeys ($n = 15$, > 14 years old) required only 0.4 mg/kg MPTP, with the exception of one which received 0.6 mg/kg. The correlation between age and dose was $r^2 = 0.81$ ($p < 0.01$) with a significant difference ($p < 0.01$) in dose between younger and older monkeys. This data suggests that older Rhesus monkeys are more vulnerable to MPTP toxicity than younger monkeys. Therefore, when producing primate models for Parkinson's disease, age should be a major contributing factor in determining the appropriate MPTP dose to administer. Supported by NIH NS25778

SUBCHRONIC MPTP TREATMENT WITH TETRABENAZINE CHALLENGE: EFFECTS ON NIGROSTRIATAL MARKERS IN THE PRIMATE. J.N. Johannessen*, T.J. Sobotka, S.F. Ališ, A.C. Scallies, M.G. Pauls, and W. Slikk, Jr. § CFSA and §NCTR, FDA, 8301 Muirkirk Rd, Laurel, MD 20708

We hypothesized that MPP⁺, accumulated in dopaminergic synaptic vesicles during repeated treatment with subtoxic doses of MPTP, could be released by tetrabenazine (TBZ), causing nigrostriatal toxicity. Rhesus monkeys were dosed with MPTP i.v. 3 times/wk at 0.1 mg/kg for 8 wks (low dose; total dose 2.4 mg/kg) or at 0.1 mg/kg for 4 wks, followed by 0.2 mg/kg for 4 wks (high dose; total dose 3.6 mg/kg). At the end of dosing, one set of the high dose group was sacrificed. Remaining high and low dose animals were challenged with saline or TBZ (15 mg/kg) and sacrificed 4 wks later. Striatal and adrenal markers were assessed. Controls got 8 wks saline, TBZ, then 4 wks recovery.

The repeated MPTP treatment caused a dose-related decrease in striatal dopamine (DA) 4 wk after dosing. The low dose group sustained a 29% loss of striatal DA. The substantia nigra pars compacta (SNc) remained largely intact, but swollen, degenerating cells were evident. The high dose animals showed >90% reduction in striatal DA and marked SNc cellular pathology (e.g. swollen, distorted or pyknotic neurons with disintegrating processes). Animals in the high dose group sacrificed immediately after the 2 month dosing period showed a modest reduction (38%) in striatal DA and minimal damage to the SNc. Challenge with TBZ following subchronic low dose MPTP caused ptosis, but did not enhance the toxicity of MPTP. These observations suggest that degeneration progressed following the end of MPTP dosing, but was not enhanced by TBZ treatment.

Adrenal MPP⁺ levels were not related to cumulative MPTP dose or survival time. While all treatment groups receiving MPTP had high levels of adrenal MPP⁺, there were no differences between groups, suggesting that 1) accumulation was limited, 2) clearance of accumulated MPP⁺ from adrenal was very slow and 3) TBZ treatment was not sufficient to cause release of MPP⁺ from chromaffin granules, its presumptive storage site.

EFFECT OF DOPAMINERGIC DENERVATION AND LEVODOPA THERAPY ON TYROSINE HYDROXYLASE mRNA EXPRESSION IN THE MONKEY SUBSTANTIA NIGRA

M.-T. Herrero*, Sh. Vyas², R. Levy², N. Faucon¹, J. Guillen¹, M.R. Luquin¹, J. Guridi¹, F. Javoy-Agid², Y. Agid², E.C. Hirsch² and J.A. Obeso¹. (1) Experimental Neurology. University of Navarra. Spain. (2) INSERM U289. Hôpital de la Salpêtrière. Paris. France. (3) Lab. de Neurobiologie Cellulaire et Moléculaire. Gif-sur-Yvette. France.

Loss of midbrain dopaminergic neurons is the pathological characteristic of Parkinson's disease (PD) in human and MPTP neurotoxicity in monkeys. A decrease in tyrosine hydroxylase (TH) protein and mRNA content has been reported *post-mortem* in the surviving neurons in the midbrain from PD patients. Yet, because all patients are treated by levodopa therapy, it is difficult to determine if this decrease is due to dopaminergic denervation or to levodopa therapy.

The present study was aimed to analyze by quantitative *in situ* hybridization the effect of MPTP intoxication and levodopa therapy on the mRNA encoding for TH in four groups of *Macaca fascicularis* monkeys: normal control animals, MPTP-treated animals with moderate or severe parkinsonian symptoms, and levodopa-treated parkinsonian monkeys. Midbrain sections were hybridized with antisense ³⁵S-labelled riboprobes for TH mRNA. Quantification of mRNA expression at the cellular level using computerized image analysis revealed a decrease in TH mRNA expression in dopaminergic neurons from moderate, severe and levodopa-treated parkinsonian monkeys as compared to control monkeys without statistically significant differences between the three groups. Similarly, TH protein content measured in the same animals also decreased.

These results suggest that dopaminergic denervation provokes a decrease in TH mRNA and protein expression which is not reversed by levodopa therapy.

DOGLUTAMATE ANTAGONISTS REVERSE HALOPERIDOL-INDUCED EXTRAPYRAMIDAL SIDE-EFFECTS IN PRIMATES? C.L. Christoffersen* and L.T. Meltzer. Parke-Davis Pharmaceutical Research Division, Warner-Lambert Co., Ann Arbor, MI 48105.

Acute administration of almost all antipsychotic (AP) drugs produces a syndrome of extrapyramidal side-effects (EPS) characterized by dystonia, akathisia and Parkinson-like tremor and rigidity. In both humans and non-human primates, AP-induced EPS is reversed or prevented by treatment with anti-Parkinson drugs. Recent data have suggested that glutamate antagonists may be useful in the treatment of Parkinson's disease (PD). Thus, glutamate antagonists may be effective in reversing AP-induced EPS. We tested, in cebus monkeys, the ability of CPP, a competitive NMDA antagonist, and NBQX, a competitive AMPA (non-NMDA) antagonist, when administered alone or in combination with a sub-threshold dose of apomorphine (APO), to reverse HAL-induced EPS.

Subjects were cebus apella monkeys that were sensitized to acute EPS by once weekly administration of haloperidol (HAL). Individual EPS signs were rated by non-blinded observers on a three point scale, totaled at each time point for each monkey, and group means derived. Test agents were administered 3 hr after administration of HAL, a time at which EPS signs were well established and steady. Ratings were made every 15 min for 1 hr after drug challenge and then at 30-60 min intervals for the next 2 hr. APO, given i.m., produced a dose-related reversal of all EPS signs. No reversal of the HAL-induced EPS was produced by NBQX, CPP or the combination of NBQX and CPP, given s.c. Neither NBQX nor CPP potentiated the ability of a sub-threshold dose of APO to reverse the HAL-induced EPS. These data suggest that glutamate antagonists would not be effective in ameliorating AP-induced EPS and question their role in the treatment of PD. Further experiments are evaluating the effects of treatments designed to increase the brain levels of NBQX on these interactions.

670.11

ALTERATIONS OF PALLIDAL CHOLINERGIC ACTIVITY IN MPTP TREATED MONKEYS: EFFECT OF DIHYDRO- α -ERGOCRYPTINE (DEK). D. Curti*, L. Brambilla E. Izzo and R. Ferrari. Institute of Pharmacology, University of Pavia, 27100 Pavia, Italy.

The neurotoxin MPTP induces Parkinson(PD)-like symptoms in human and non-human primates (Burns et al., PNAS, 80, 1983; Gerlach et al., Eur.J.Pharmac., 208, 1991). The effect of nigrostriatal denervation on cholinergic activity outside the neostriatum is not well understood and it is likely to play a role in PD-associated motor disturbances (Campbell and Dill, Exp.Neurol., 42, 1974). The aim of this investigation was to evaluate in some striatal and extrastriatal brain regions, the short term consequences of MPTP administration on the cholinergic enzymes (choline acetyltransferase, ChAT, and acetylcholinesterase, AChE) and on pyruvate dehydrogenase complex (PDHc) which catalyzes the oxidative decarboxylation of pyruvate to acetylcoenzyme A and links cholinergic and energy metabolism. A treatment with dihydro- α -ergocryptine (DEK), a D₂ receptor agonist was also performed. This ergot derivative improves motor performances PD patients (Martignoni et al., Clin.Neuropharmac., 14, 1991). Monkeys, intravenously administered with MPTP at the dose of 0.3 mg/kg for 5 consecutive days, develop a severe PD-like syndrome. Cholinergic enzyme activities are increased in the internal segment of the globus pallidus (GPi) and into a lesser extent in the external globus pallidus (GPe). Cholinergic activities are not significantly affected in the caudate and putamen nor in the frontal, parietotemporal, occipital cortices and cerebellum. The treatment of the animals twice daily for two weeks with DEK starting 5 days before the first MPTP administration counteracts the neurotoxin-induced alteration in the internal pallidum and ameliorates some motor related parkinsonian symptoms.

670.13

RILUZOLE PREVENTS MPTP-INDUCED PARKINSONISM IN RHESUS MONKEYS: A PILOT STUDY. A.Benazzouz¹, Th.Boraud¹, P.Dubédat², A.Boireau², J.M.Stutzmann²*, and Ch.Gross¹. CNRS URA 1200, ¹ Université de Bordeaux 2, 33076 Bordeaux Cedex France, ² Département Biologie, Rhône Poulenc Rorer, CRVA, Vitry Cedex, France.

MPTP provokes selective destruction of dopaminergic (DA) neurones in the substantia nigra (SN). Previous studies have shown that riluzole (2-amino-6-trifluoromethoxy-benzothiazole), a drug which interferes with glutamate neurotransmission, has a neuroprotective action in rodent models of cerebral ischemia. Experiments were performed on two rhesus monkeys (R1 and R11). Both monkeys received a single injection of MPTP (0.4 mg/kg) in the right internal carotid. R1 was injected with saline one hour before and six hours after the injection of MPTP. From days 2 to 30, it received further administration of saline. From days 31 to 45, it received a single daily injection of riluzole (4 mg/kg i.p.). R11 received riluzole (4 mg/kg) one hour before and 6 hours after the injection of MPTP. From day 2 to 30, this monkey received a single daily injection of riluzole. Both monkeys were examined clinically and muscular rigidity was quantified by electromyography. When riluzole was administered before MPTP, bradykinesia and rigidity were absent. When injected daily in R1, riluzole significantly reduced bradykinesia and rigidity. HVA/DA ratio, currently assimilated to an index of DA use, increase of 81% after MPTP treatment in R1. Interestingly, the pretreatment with riluzole in R11 increased more markedly this ratio (982%). Thus, a neuroprotection coupled to a facilitation of DA release may explain the behavioural effects reported with riluzole treatment. These results show that riluzole would possess both neuroprotective and palliative effects in a primate model of Parkinson's disease.

670.10

DIFFUSION TENSOR BRAIN IMAGING OF MPTP-LESIONED MONKEYS.

I. Linfante*, T. N. Chase, P. J. Basser, and C. Pierpaoli. NINDS, National Institutes of Health, Bethesda, MD 20814.

Magnetic resonance imaging(MRI) have been used to map the scalar diffusivity (D) of water in tissues. In brain ischemia, D is decreased when conventional MRI is still uninformative. It has been recently proposed that the trace of the effective diffusion tensor (Tr(D_{eff})), measured by diffusion tensor imaging, more accurately reflects the mobility of water in tissue (1). We evaluated the utility of Tr(D_{eff}) to detect selective neuronal lesions such as the degeneration of the substantia nigra pars compacta (SNc) neurons and their projections to the neostriatum following MPTP systemic administration. Cynomolgus monkeys were administered with MPTP (0.5 to 1.5 mg/kg i.v. weekly) and scanned with MRI before, immediately after their first MPTP administration and then at 1 week after each MPTP injection. Each scan consisted of the acquisition of 14 diffusion weighted coronal images from which both Tr(D_{eff}) and T2 weighted signal intensity maps were calculated. In the 2 stable parkinsonian animals (cumulative dose of 3-3.5 mg/kg of MPTP) studied so far, Tr(D_{eff}) was decreased by 22% in the dorso-lateral putamen and by 6% in the caudate nucleus. No changes were observed in other brain structures. Tr(D_{eff}) alteration persisted in one animal scanned 44 days after the last MPTP injection. These findings are consistent with previous immunohistochemical studies. The data of this ongoing study suggest that Tr(D_{eff}) could provide "in vivo" information on selective brain damage.

670.12

DRAMATIC DESENSITIZATION OF THE BEHAVIORAL RESPONSE TO A LONG-ACTING D1 BUT NOT D2 AGONIST IN MPTP MONKEYS. R.

Grondin*, P.J. Blanchet, P.J. Bédard, D.R. Britton², K. Shiosaki² and J.W. Keibarian³. Neurobiol. Res. Center., Enfant-Jesus Hosp., Quebec, Canada, ²Neurosci. Res., Pharmaceutical Products Division, Abbott Laboratories, Abbott Park, Ill, USA, ³Res. Biochemicals International, Natick, Mass., USA.

The effects of repeated administration of selective long-acting D1 and D2 dopamine (DA) agonists were examined in monkeys (*Macaca fascicularis*) previously rendered parkinsonian by MPTP. The animals were asked to quantify the antiparkinsonian response and the motor activity was monitored by photocells mounted on each cage. All drugs were administered subcutaneously. In a first experiment, all animals treated once daily with the long-acting D1 DA agonist A-77636 (2 mg/kg), initially showed improvement of their parkinsonian features and a marked increase of their locomotion. However, this effect decreased rapidly in the following days to reach more or less control level in a week. In another group of MPTP monkeys, the long-acting D2 DA agonist cabergoline given every 48 hours at a dose of 0.25mg/kg, also relieved all parkinsonian features and greatly stimulated locomotion. In this group, the locomotion response decreased somewhat, but was thereafter maintained at a high level (more or less 6 times higher than control values). The dramatic desensitization seen with A-77636 was selective for the D1 receptors since, in the same animals, the response to an acute challenge dose of the D1 agonist SKF-82958 (1 mg/kg) was virtually abolished but not the response to the D2 agonists quinpirole (0.1 mg/kg) and (+)-PHNO (6ug/kg).

These results confirm that it is possible to relieve parkinsonian features with either D1 or D2 DA agonists and suggest that the D1 system can be desensitized more completely and independently from the D2 system under a continuous stimulation. The desensitization mechanisms will be explored further. [Supported by Parkinson Foundation and MRC of Canada].

EFFECTS OF THE FULL DOPAMINE D-1 RECEPTOR AGONIST DIHYDREXIDINE ON COGNITIVE FUNCTION AND MOTOR ACTIVITY IN MPTP-TREATED MONKEYS. Z.-Q. Sun*, B.J. Johnson, and J.S. Schneider. Dept. of Neurology, Hahnemann University, Philadelphia, PA 19102.

Dopamine D-2 receptors have been assigned a major role in regulating motor function, based primarily on rodent and human studies with D-2 agonists and the lack of effect of the partial D-1 agonist SKF 38393 on parkinsonian monkeys and humans. However, there are still questions concerning the potential role of D-1 agonists in treating parkinsonism. The discovery of full efficacy D-1 agonists should help to answer questions concerning the therapeutic potential of D-1 receptor stimulation. In the present studies, we used the D-1 agonist dihydrexidine to assess the potential of this drug to induce rotational asymmetry in hemiparkinsonian monkeys and to correct cognitive deficits resulting from chronic low dose MPTP exposure. Dihydrexidine (0.3 to 0.9 mg/kg), administered to 5 hemiparkinsonian monkeys, caused a dose-dependent increase in contralateral rotations that could be blocked by the D-1 antagonist SCH 23390 but not by the D-2 antagonist raclopride. Dihydrexidine also caused a dose dependent reversal of the number of cognitive errors made by 3 chronic low dose MPTP-treated monkeys during delayed response performance. This effect could also be blocked by the D-1 antagonist SCH 23390. These results suggest that D-1 receptor stimulation may be therapeutically effective in treating parkinsonism. Additional studies are needed to further compare the therapeutic and side effect profiles of selective D-1 and D-2 receptor agonists in primate parkinson models. Supported by NIH grant MH-46531.

CHRONIC GM1 GANGLIOSIDE ADMINISTRATION REVERSES COGNITIVE DEFICITS AND DELAYS ONSET OF MOTOR SYMPTOMS IN A SLOWLY PROGRESSING PARKINSON MODEL IN MONKEYS. Anne Coleman*, D.P. Roeltgen and J.S. Schneider. Dept. of Neurology, Hahnemann University, Phila., PA 19102.

We have previously shown that GM1 ganglioside, administered for 6 to 8 weeks after the last of several MPTP injections, can reverse motor deficits and partially restore striatal dopamine levels in monkeys with severe parkinsonism (Science, 256 (1992) 843-846). We suggested that GM1 might be most effective as an anti-Parkinson therapy if administered early after diagnosis, while there is still considerable host dopaminergic function. This study was conducted to assess the potential of long-term GM1 treatment as a means of slowing the progression of parkinsonism. Five macaques were exposed to low doses of MPTP for 24 weeks. These monkeys developed cognitive deficits, followed by mild motor deficits. At this stage, judged to be analogous to early parkinsonism, monkeys were randomly assigned to receive either daily saline or GM1 injections (30 mg/kg) while all monkeys continued to receive the same doses of MPTP. The monkeys receiving GM1 showed significant improvement in cognitive task performance by the end of the first 8 weeks of treatment that has been maintained over time while the saline-treated animals have continued to show increasing task performance deficits. Saline-treated animals are also showing a trend toward a progressive decrease in motor ability not apparent in GM1-treated animals. These results suggest that early intervention with GM1 ganglioside treatment may exert both symptomatic and protective effects in Parkinson's disease patients. Supported by the F.M. Kirby Fdn. and Fidia Pharmaceuticals.

670.17

GM1 GANGLIOSIDE TREATMENT INCREASES DOPAMINE SYNTHESIS IN RESIDUAL NIGROSTRIATAL NEURONS IN MPTP-TREATED MICE. J.S. Schneider* and L. DiStefano. Dept. of Neurology, Hahnemann University, Philadelphia, PA 19102.

GM1 ganglioside has been shown to increase striatal dopamine (DA) levels after various types of lesions to the nigrostriatal DA system. Both *in vivo* and *in vitro* studies have suggested that GM1 ganglioside treatment may have rescue and survival effects on damaged DA neurons and may stimulate a sprouting response in striatal DAergic terminals. The present study was conducted to assess the extent to which GM1 treatment may also cause a biochemical upregulation in residual DAergic neurons after an MPTP-induced lesion. Young (8 week old) C57 BL/6J mice were administered MPTP (20 mg/kg, twice daily for 5 days) and then saline or GM1 ganglioside (30 mg/kg, once daily) for 3 weeks. Some animals received injections of diethylthiocarbamate (DDC, 400 mg/kg) prior to MPTP injections and then received 3 weeks of saline or GM1 ganglioside treatment. Some animals were injected with NSD-1015 (100 mg/kg) 30 min. prior to sacrifice to allow measurement of striatal dopa accumulation consequent to aromatic amino acid decarboxylase activity. MPTP/saline-treated animals had 46% less accumulated dopa than normal animals whereas MPTP/GM1-treated animals had only 17% less dopa than normal. DDC+MPTP-treated animals had more severe dopamine depletions than MPTP-treated animals and striatal dopa levels 41% of normal. GM1 treatment had no effect on DA or dopa levels in these animals. These data suggest that under certain conditions, GM1 treatment can enhance the function of residual DA neurons by increasing dopa synthesis. Supported by NIA grant AG-10280.

670.16

EFFECTS OF GM1 GANGLIOSIDE TREATMENT ON DOPAMINE RELEASE AND REUPTAKE IN MPTP-TREATED MICE. D.S. Rothblat* and J.S. Schneider. Dept. of Neurology, Hahnemann University, Philadelphia, PA 19102.

Both *in vivo* and *in vitro* studies have suggested that GM1 ganglioside treatment may enhance rescue and survival of MPTP/MPP+-damaged dopamine (DA) neurons. Recent data also suggest that GM1 may enhance DA synthesis in residual neurons. This study measured the extent to which GM1 treatment may cause an increase in the releasable pool of striatal DA. Young (8 wk old) C57 BL/6J mice were administered MPTP (20 mg/kg, 2x day for 5 days) and then saline or GM1 (30 mg/kg, 1x day) for 3 weeks. DA release and reuptake were measured electrochemically using Nafion-coated carbon fiber electrodes. DA release was stimulated by pulses of 120mM KCl pressure ejected from a micropipette attached to the recording electrode, at 0.5 mm intervals through the dorsal-ventral and medial-lateral extents of the mid-striatum. Maximal DA release and clearance time were determined at each location. In MPTP/saline-treated mice, the greatest decrease in DA release was in the lateral striatum (39% of normal) and GM1 treatment increased release by almost 25%. The clearance time for released DA increased the most in the dorsolateral striatum in MPTP/saline-treated mice and decreased by almost 30% after GM1 treatment. These changes coincided with a 92% decrease in striatal ³H mazindol binding in MPTP/saline-treated mice vs. a 67% decrease in ³H mazindol binding in MPTP/GM1-treated mice. These results further demonstrate the ability of GM1 ganglioside to enhance dopaminergic neurotransmission after a DA-depleting lesion. Supported by NIA grant AG 10280.

670.18

INTRANIGRAL INFUSION OF CNTF, BUT NOT bFGF, EGF OR TGF- β 1, RESTORES STRIATAL DOPAC BUT NOT DOPAMINE LEVELS IN MPTP-TREATED MICE. T. W. Farris*, L. DiStefano and J. S. Schneider. Dept. of Neurology, Hahnemann University School of Medicine, Philadelphia, PA 19102.

Growth factors (GFs) may rescue or support damaged dopaminergic neurons *in vivo* raising hope for their therapeutic potential in Parkinson's disease. However, the degree of tissue trauma from surgery and CNS delivery of GFs has varied greatly across experiments. Mechanical damage to the CNS can induce considerable release of GFs, complicating the interpretation of results following their administration. In this study, we have minimized non-specific tissue trauma to better isolate GF effects on recovery of DA-ergic markers following an MPTP-induced lesion. 8-week old male C57/BL6J mice were administered MPTP (20 mg/kg, ip.) or saline twice daily for 5 days. Two days later mice were implanted with 30 ga. cannulae connected to low flow rate osmotic pumps (0.2 μ l/h) for delivery of rh-CNTF (20 μ g/14 d), rh-EGF (4 μ g/14 d), rh-bFGF (4 μ g/14 d), rh-TGF- β 1 (2 μ g/14 d) or vehicle to the substantia nigra (SN) or striatum (ST). Infusion of CNTF into SN of MPTP-lesioned mice restored ipsilateral striatal DOPAC levels to 88.5% of vehicle-injected/vehicle-infused controls ($\alpha=.01$, Dunnett's test) while DA levels were unaffected (34% of control). EGF, bFGF and TGF- β 1 had no effects on striatal DA (27.4%, 33.4% and 30.7% of control, respectively) or DOPAC (34.7%, 43.7% and 39.2% of control). Striatal infusions of GFs had no effect. Similar experiments with these GFs in our lab employing more traumatic delivery methods have produced more positive results. We speculate that trophic substances released by trauma may be crucial for some GFs to alter DA-ergic markers. Supported by NIA AG-10280.

DEGENERATIVE DISEASE: OTHER II

671.1

USE OF IN SITU LABELING OF DNA FRAGMENTATION AS AN INDICATOR OF CELL DEATH IN VARIOUS DISEASE PROCESSES IN THE RODENT AND HUMAN CNS. L.B. Thomas*, D.J. Gates and D.A. Steindler. Dept. of Anat. & Neurobiology and Neurosurgery, Univ. of Tenn., Memphis, TN 38163

Cell death occurs by either apoptosis (programmed cell death) or necrosis. Apoptosis occurs during embryogenesis, at the end of the normal life span of differentiated cells, in tumors, and many other physiologic and pathologic conditions. Biochemically, the DNA of apoptotic cells undergoes cleavage via endonuclease into oligonucleosomal-sized fragments. The abundant 3'-OH ends of these fragments can be identified *in situ* by the addition of labeled nucleotides with the enzyme terminal deoxynucleotidyl transferase. Few studies have investigated this technique in the study of cell death in disease processes of the CNS. We describe the application of this technique to various disease processes in human and rodent CNS, including grades 4 of Huntington's disease (HD), human gliomas, and traumatic brain injury. Labeled cells were present in brain areas where degenerated cells would be expected, e.g., associated with the known medial to lateral gradient of cell death in the neostriatum with advancing stages of HD, around necrotic areas in glioblastoma, and in periwound areas following traumatic brain injury. Labeling occurred in control tissues as would be expected, e.g., associated with blood vessels where normal cell turnover occurs. GFAP, OX-42, and PCNA immunohistochemistry was also performed, and these correlative studies demonstrate that death of various types of CNS cells can be detected and distinguished from, e.g., injury-induced cell proliferation. Studies are underway to investigate labeling in ischemic tissue, which is considered to undergo cell death by necrosis. It appears that this method can be used to label dying CNS cells in a variety of disease states. However, it is unclear at this time if it identifies cell death by necrosis, or if it can be used as an early marker of cells at risk of dying. Supported by NIH NS20856 and the Hereditary Disease Foundation.

671.2

OVEREXPRESSION OF THE S-100B GENE IN DOWN'S SYNDROME. A STUDY IN LYMPHOCYTES. H. Riolo*, G. Gaudreault*, J. Cloutier* and M.R.V. Murthy*. ¹Dept. of biochemistry, Fac. of Medicine, Laval University G1K 7P4 and ²Centre hospitalier de Charlevoix, Baie-St-Paul G0A 1B0; Québec, Canada.

The S-100B gene which is localised on chromosome 21 and is mainly expressed in astrocytes, may be implicated in the neurologic abnormalities observed in trisomy 21 which leads to Down's syndrome (DS). However, overexpression of this gene has not been consistently found in DS. S-100B is also expressed in lymphocytes. We have measured the level of S-100B mRNA in lymphocytes of 12 patients with DS (25 to 47 years) and of 16 controls (27 to 53 years), using semi-quantitative reverse transcription combined with polymerase chain reaction (PCR).

The average level of S-100B mRNA was 2.3 fold higher in the DS group as compared to the controls ($p=0.001$). However, two DS subgroups were clearly distinguishable. The first ($n=5$) did not overexpress S-100B mRNA, while the second ($n=7$) overexpressed this mRNA by 2.4 to 5.3 fold ($p=0.001$) when compared to age-matched controls. A negative correlation of the S-100B mRNA level with age was found in normal individuals ($r=-0.600$; $p=0.007$). The DS individuals of the first subgroup showed similar negative correlation with age in their S-100B mRNA expression ($r=-1.000$; $p=0.009$), but in the second subgroup, there was no significant correlation of the S-100B mRNA level with age. Using genomic DNA amplification of the S-100B gene, preliminary results indicated that all the DS patients were in fact trisomic for this gene. Therefore, these data suggest that a proportion of DS patients express S-100B gene as do normal individuals whereas another proportion overexpress this gene in a manner which is higher than the 1.5 fold expected.

The degree of mental deficiency of the DS individuals, based on their learning capabilities, was estimated in a blind study. This was found to be negatively correlated with the S-100B mRNA level ($r=-0.700$; $p=0.001$). These data suggest that S-100B expression may be implicated in controlling the severity of the mental deficiency in adults with DS.

671.3

TAU PATHOLOGY IN NEURODEGENERATIVE DISORDERS: BIOCHEMICAL ANALYSIS. V. Buée-Scherrer, L. Buée, P. Vermersch, P.R. Hof, B. Leveugle, D.P. Perl and A. Delacourte*. INSERM U156, Lille, France; Mount Sinai Medical Center, New York, USA.

Neurofibrillary tangles (NFT) are found in a number of neurodegenerative disorders including Alzheimer's disease (AD), progressive supranuclear palsy (PSP), amyotrophic lateral sclerosis/parkinsonism-dementia of Guam (ALS/PDC), post-encephalitic parkinsonism (PEP), Down syndrome (DS), and in the hippocampal formation of elderly non-demented individuals. NFT result from the aggregation of abnormally phosphorylated tau proteins into paired helical filaments or straight filaments. In this study, we used Western blotting and several immunological probes directed against phosphorylated and non-phosphorylated tau proteins, to investigate whether these neurodegenerative disorders could be distinguished by differences in tau profile. Using specific antibodies to abnormally phosphorylated tau proteins, a triplet of proteins referred to as tau 55, 64 and 69 (or A68), was consistently detected in brain homogenates from AD cases and DS patients older than 30 years. This tau triplet was never found in any brain regions of non-demented elderly individuals, with the exception of the hippocampal formation. In PSP brains, a doublet of abnormally phosphorylated tau proteins (tau 64 and 69) was systematically found in both cortical and subcortical regions. In ALS/PDC cases, the characteristic tau triplet was found in both cortical and subcortical areas. In all PEP cases, a triplet of tau proteins was also found, but their isocortical distribution was quantitatively different among cases. As expected, in Huntington disease (HD) cases younger than 60 years, abnormal tau proteins were not found since no NFT are observed. In all of these neurodegenerative disorders, a very close relationship was observed between the tau pathology in the association cortical areas and intellectual impairment. With this approach, we were able to distinguish at least two types of neurodegenerative disorders: the Alzheimer type (DS, AD, ALS/PDC, PEP) and the PSP type.

671.5

NEURONAL DEGENERATION IN THE PRIMATE DORSAL LATERAL GENICULATE NUCLEUS (LGN) FOLLOWING ELEVATION OF INTRAOCULAR PRESSURE. A.J. Weber¹, P.L. Kaufman², W.C. Hubbard³, and L.R. Stanford². The Waisman Center^{1,4}, Department of Ophthalmology and Visual Sciences^{2,3}, Department of Comparative Biosciences⁴, and Wisconsin Regional Primate Research Center^{1,2}, University of Wisconsin, Madison, WI 53706.

Elevation of intraocular pressure (IOP) is considered to be an important causative factor associated with glaucoma, a leading cause of blindness. Using intracellular staining techniques, we have described previously the degenerative effects that increased IOP has on single ganglion cells in the primate retina (Invest. Ophthalm. and Vis. Sci. suppl. ('94) 35:1573). Here we describe the changes that elevated IOP has on neurons in the LGN, the primary target of retinal ganglion cell axons. IOP was elevated experimentally in one eye of five rhesus monkeys by focal scarification of the trabecular meshwork using an argon laser. Two additional cynomolgus monkeys with similar, but non-laser induced, elevations of IOP also were included in the study. After 1-6 months of elevated IOP (mean IOP: 40-50mm Hg) each animal was deeply anesthetized and perfused transcardially with a 10% formal saline solution. Brains were embedded in low viscosity nitrocellulose, blocked in the frontal plane, sectioned at 25µm, and counter-stained with thionine. Cell area measurements were made for both the magno- and parvocellular layers of the LGN. While as little as 3 weeks of elevated IOP results in neuronal changes in the retina, no differences in soma size are seen for LGN neurons receiving input from either the normal or glaucomatous eye. By contrast, 12 and 24 weeks of elevated IOP produce mean decreases in the soma sizes of LGN neurons receiving input from the damaged eye of 19% and 44%, respectively. Thus, in addition to producing direct degenerative effects in the retina, prolonged elevation of IOP also has a dramatic effect on the target neurons of retinal ganglion cells in both the parvo- and magnocellular layers of the LGN. Supported by NIH-NEI grants EYO2698 (PLK) and EYO4977 (LRS), and National Glaucoma Research/American Health Assistance Foundation (AJW).

APOLIPOPROTEIN E (APOE) ISOFORMS IN PATIENTS WITH LEWY BODIES (LB). M.G. Martinoli¹, J.Q. Trojanowski², V. M-Y Lee², M.L. Schmidt², H.I. Hurtig², J-P. Julien¹ and C. Clark². 1: Centre for Research in Neurosciences, McGill Univ. & Montréal General Hospital, Montréal, Qué., H3G 1A4, Canada, Department of Pathology, Univ. of Pennsylvania Sch. of Med., Philadelphia, PA 19104, USA.

Lewy bodies (LB) are small round eosinophilic inclusions found mainly in brainstem nuclei and cerebral cortex. The presence of (LB) in the pigmented neurons of the substantia nigra is a hallmark of idiopathic Parkinson's disease. The presence of cortical LB and dementia is often called diffuse Lewy body disease (DLBD). When sufficient plaques and tangles are also present the condition may be called Lewy body variant of Alzheimer's disease (LBVAD). Brainstem LB are seen in about 20% of patients with Alzheimer's disease (AD). Apolipoprotein E (APOE) is a lipoprotein expressed in liver and brain as one of 3 isoforms (APOE 2, APOE 3 and APOE 4). Recent findings suggest that the presence of APOE 4 with an increased risk for late onset AD. We examined the frequency of APOE isoforms in a cohort of patients with brainstem LB, some of whom had cortical LB with or without coexisting plaques and tangles. APOE genotype was determined by PCR techniques using DNA isolated from frozen cerebellar cortex. Anonymously donated blood samples were used for the control group genotype. Our preliminary results show that while there is a slight increase in the frequency of APOE 4 in subjects with LB, the correlation is strongest for those patients with co-existing plaques and tangles.

BIOCHEMICAL MAPPING OF NEUROFIBRILLARY PATHOLOGY IN PROGRESSIVE SUPRANUCLEAR PALSY: EVIDENCE FOR A SEVERE CORTICAL INVOLVEMENT.

P. Vermersch*, V. Buée-Scherrer, L. Buée, P.R. Hof, D. Perl, D. Gauvreau, A. Destée, H. Petit, A. Delacourte. INSERM U156 and Depts of Neurology, Lille, France; Fishberg Research Center for Neurobiology and Dept of pathology, Mount Sinai School of Medicine, New York, USA and Projet Image, University of Montréal, Canada.

A study was performed to quantify and map the neurodegenerative process in cortical and subcortical brain areas in 5 cases of progressive supranuclear palsy (PSP). Our approach was based on a western blot analysis of pathological Tau proteins, which are the basic components of neurofibrillary lesions. In two cases, the abnormal Tau proteins were detected in all cortical areas, sometimes in larger amounts than in some subcortical areas. In two cases, posterior cortical areas were spared. In a non demented case, abnormal Tau proteins were not detected in cortical areas while they were present in basal ganglia and thalamus. These abnormal Tau proteins consist of a doublet called Tau 64 and 69, except in the entorhinal cortex where a Tau triplet (Tau 55, 64, 69) similar to that found in Alzheimer's disease, was detected in the older cases. The amounts of abnormal Tau proteins were higher in some neocortical regions, such as area 4, as compared with the hippocampal formation.

Our results show that the neocortical pathology in PSP is more extensive than usually thought, and may play a role in the pathogenesis of the cognitive changes associated with this disease. This biochemical approach clearly distinguishes two types of neurofibrillary pathology, the Alzheimer type with a triplet of abnormal Tau proteins and the PSP type with a characteristic doublet.

EXPRESSION STUDIES OF THE SPINOCEREBELLAR ATAXIA TYPE 1 GENE. A. Servadio, M.-y. Chung, R.P. Elde*, S. Banfi, L. Davick, H.Y. Zoghbi, and H.T. Orr. Baylor College of Medicine, Houston, TX 77030 and University of Minnesota, Minneapolis, MN 55455.

Spinocerebellar ataxia type 1 (SCA1) is an autosomal dominant disorder characterized by progressive degeneration of the cerebellum, spinal cord and brainstem. The mutation causing the disease is an expansion of a trinucleotide repeat (CAG) whose size correlates with the severity and age of onset of the symptoms. Recent cloning and characterization of the SCA1 gene revealed that the transcript is 10,660bp and that the CAG repeat resides within a coding region of 2448bp and codes for a glutamine tract. Sequence analysis did not reveal any homology with known proteins, so that the SCA1 gene appears to code for a novel protein (ataxin-1) of 816aa with an estimated molecular weight of 87kd. To begin to understand the biology of the SCA1 gene, we initiated studies aimed at characterizing the expression patterns of both the transcript and the protein. Northern blot analysis using mRNAs from 16 different human tissues revealed that the SCA1 transcript is expressed in all tissues examined. Analysis of SCA1 expression in adult mouse brain by *in situ* hybridization revealed that this gene is expressed widely throughout the central nervous system. Regions of enhanced SCA1 expression include the cerebellum (Purkinje and granule cells, as well as neurons within the deep cerebellar nuclei) and thalamus. Analysis of RNA expression from normal and SCA1 alleles demonstrated that the allele with the expanded CAG repeat is transcribed. This argues against a pathogenetic mechanism involving loss of function at least at the RNA level. Polyclonal antibodies have been generated using either synthetic peptides or a fusion protein as an immunogen. Western blotting analysis revealed that the protein expression pattern is similar to that of the RNA. Detailed characterization of the antibodies is currently in progress to confirm their specificity.

OXIDATIVE STRESS AND GLUTAMATERGIC HYPOTHESES OF TARDIVE DYSKINESIA. G. Tsai*, D. Goff, J. T. Coyle, Dept. Psychiat., Mass. General Hospital and Harvard Med. School, Boston, MA

The pathophysiologic basis of neuroleptic-induced tardive dyskinesia (TD) remains unclear. The dopamine supersensitivity hypothesis can not account for the time course of the onset of TD nor for the persistence of TD and the associated structural changes after neuroleptics are discontinued. Neuroleptics can induce a vicious cycle by triggering a mutually reinforcing cascade of oxidative stress and glutamatergic activation in animals. Haloperidol increases glutamate (Glu) concentration in the striatum and Glu agonists can enhance the rate of reactive oxygen species generation. The activity of the glutamatergic pathway is increased during long term neuroleptic exposure. The hyperglutamatergic state can have excitotoxic effects on the GABAergic pathways from basal ganglia. On the other hand, neuroleptics increase the turnover of catecholamine which can be metabolized to produce cytotoxic free radicals. Free-radical formation causes release of Glu from rat hippocampal slices. Conventional neuroleptics have recently been shown to inhibit complex I of the mitochondrial electron transport chain. Failure of the electron transport chain causes the formation of free radicals and may make neurons more vulnerable to excitotoxicity. We have studied 13 patients with TD and 13 patients on neuroleptics without TD to determine whether the oxidative stress is related to change in glutamatergic transmission in human TD. Our data support the hypotheses that TD patients have higher indices of oxidative stress and of glutamatergic transmission. TD patients have lower superoxide dismutase (SOD) activities (p<0.05) and higher Glu, Aspartate, and N-acetylaspartylglutamate concentrations (p<0.01) in their CSF compared to non-TD patients. There is a significant correlation between SOD and aspartate, SOD and glycine. It is plausible that the pathophysiology of TD can be better explained by the interaction between oxidative stress and hyperglutamatergic state.

EXPRESSION OF mRNA FOR DRPLA GENE (ATROPHIN-1) AND HD GENE (IT15) IN DEVELOPMENTAL AND ADULT BRAIN. S.H. Li, R.L. Margolis, X.L. Li, C.A. Ross*. Laboratory of Molecular Neurobiology, Johns Hopkins University, School of Medicine, 720 Rutland Ave., Ross 615, Baltimore, MD 21205.

Dentatorubral pallidoluysian atrophy (DRPLA or Smith's disease) is an autosomal dominant neurodegenerative disease. It shares many clinical, genetic and pathological features with Huntington's disease (HD). The molecular basis of DRPLA is an unstable expansion of a CAG repeat in the coding region of a gene originally cloned in our laboratory (CTG-B37, Li et al, Genomics 16: 572-579, 1993, Nagafuchi et al and Koide et al, Nature Genetics, 1994). We are now cloning the full length cDNA for this gene which we have termed atrophin-1 (Margolis et al, see abstract). Since DRPLA and Huntington's disease are similar and little is known about atrophin-1 mRNA expression, we compared the mRNA expression of the DRPLA gene and the HD gene. Northern analysis revealed that atrophin-1, a 5kb transcript, is widely expressed in human tissues, as is IT15. In human brain regions, the greatest atrophin-1 mRNA expression is in the cerebellum, though it is present in a variety of regions within the brain. We also compared the expression of these two genes in embryonic and adult rat brain. Atrophin-1 was predominantly expressed in early rat embryo brain (E16), whereas the greatest expression of the HD gene was in the adult rat brain. These results indicate the differential developmental regulation of IT-15 and atrophin-1.

PREFERENTIAL EXPRESSION OF SUPEROXIDE DISMUTASE BY CHOLINERGIC AND PARVALBUMIN NEURONS IN THE MONKEY STRIATUM. A. Reiner*, G. Figueredo-Cardenas, and L. Medina. Dept. Anat. & Neurobiol., Coll. of Medicine, Univ. of Tennessee, Memphis, TN 38163.

Superoxide radicals may be involved in neurodegenerative processes occurring in aging or in brain ischemia (1). Previous studies showed that global brain ischemia produces a very selective degenerative pattern in the striatum, with loss of projection neurons and sparing of interneurons (2). In the present study, we have investigated the expression of superoxide free radical scavengers by the striatal neurons of the rhesus monkey. We have used antibodies against two enzymes that are involved in the scavenging of superoxide free radicals in cells: copper, zinc superoxide dismutase (SOD1), located in the cytosol; and manganese superoxide dismutase (SOD2), located in mitochondria. Our results indicate that striatal neurons generally express low levels of SOD2 immunoreactivity, except a population of large neurons that were strongly immunoreactive for both SOD1 (SOD1+) and SOD2 (SOD2+), and a small population of medium-sized neurons that were strongly SOD2+. Double label immunofluorescence showed that the large neurons that are strongly SOD1+ or SOD2+ were also labeled for choline acetyltransferase (ChAT). In addition, most of the medium-sized neurons that were strongly SOD2+ were also labeled for parvalbumin (PV). Since monkey striatal neurons expressing low levels of SOD2 were not labeled for either ChAT or PV, we concluded that the majority of them were striatal projection neurons. Our results indicate that the cholinergic and parvalbumin striatal neurons express higher levels of superoxide free radical scavengers than striatal projection neurons, which may help to explain why these interneurons survive striatal degeneration observed following global brain ischemia or in Huntington's disease. FAC1 INTERACTS WITH THE 160 KD NEUROFILAMENT PROTEIN DURING DEVELOPMENT AND IS RE-EXPRESSED IN AMYOTROPHIC LATERAL SCLEROSIS.

R. Bowser*, J.L. Seeburger², J. Springer², and P. Davies. Dept. Pathology, Albert Einstein College of Medicine, Bronx, NY 10461 and ²Dept. Neurology, Hahnemann Univ., Philadelphia, PA 19102.

FAC1 is a developmentally regulated protein that is localized throughout the cell cytoplasm during human brain development but found primarily in neuronal nuclei after birth. We have isolated soluble FAC1 protein from fetal brain by affinity chromatography and report that FAC1 interacts with the 160 kD neurofilament protein (NF-M). Other cytoskeletal elements such as NF-L, tubulin or MAP's do not co-elute with FAC1. Therefore FAC1 represents a novel neurofilament associated protein. Neurofilament abnormalities are present in many neurologic diseases such as Alzheimer's disease (AD) and amyotrophic lateral sclerosis (ALS). FAC1 abnormalities have also been found in these diseases. Within the neocortex of AD brain FAC1 is present in a subset of neuritic plaques. We investigated FAC1 protein expression in fetal, adult and ALS spinal cord by immunocytochemistry. In the developing lumbar cord FAC1 resides in nuclei of multiple cell types, with highest protein levels in anterior horn cells. In adult spinal cord little FAC1 protein is seen. However in ALS lumbar spinal cord FAC1 protein is observed throughout the motoneurons and in axon tracts. We are currently determining if FAC1 re-expression occurs only in cells with NF abnormalities or if FAC1 expression precedes NF changes. Results of *in situ* hybridization studies using probes for FAC1 mRNA will also be presented. Re-expression of FAC1 may be characteristic of cells responding to early cellular abnormalities that occur during AD and ALS.

671.10

PROTECTION OF CELL INJURY AGAINST OXIDATIVE STRESS BY RESVERATROL. S.J. Lee, Y. Cheng and A.Y. Sun*, Dept. of Pharmacology, Univ. of Missouri, Columbia MO 65212.

There is a general consensus that free radical generation leads to alteration of biochemical and biophysical properties of cell membranes and in turn, these changes may lead to pathological manifestations in aging and other degenerative diseases. Recent epidemiological studies have indicated an inverse relationship between moderate consumption of wine and incidence of coronary heart disease. This "French paradox" has drawn considerable attention and analysis has identified the presence of trans-resveratrol (R) in wine. The antioxidant properties of R may contribute greatly to protection of the endothelial cells lining the arteriole walls from oxidative damage. We have investigated the possible protective effect of R in the nervous system after various oxidative insults. PC12 cells were used because of their resemblance to catecholamine neurons. An increase in cell death, as indicated by the extent of intracellular LDH released to the incubation medium, was observed after PC12 cells were exposed to Fe²⁺/DETAPAC (0.1mM) for 36 hrs. R was able to exert a dose-dependent protective effect on the Fe²⁺/DETAPAC-induced cell death. Furthermore, the combined action of R plus Vitamins C and E was far better than the use of each individual antioxidant alone. The result indicated that R may be a potential therapeutic agent for the prevention and treatment of neurodegenerative disease (Supported in part by NIH Grant #AA02054).

ABNORMAL PHOSPHATASE ACTIVITY IN THE PATHOGENESIS OF ALS. R. Wacey*, C. Krieger, and C.A. Shaw, Depts. of Medicine and Ophthalmology, c/o Dept. of Anatomy, Univ. British Columbia, Vancouver, B.C., Canada, V6T 1Z3.

Earlier studies have shown that [³H]MK-801 binding to the NMDA receptor ion channel is decreased in spinal cord tissue from ALS patients compared to controls. This reduction could be completely reversed by the activation of protein kinase C by phorbol ester (PB) (Krieger et al., 1993). These studies suggested that NMDA receptors in ALS spinal cord may be altered by abnormal regulation of enzyme activity. [³H]MK-801 binding was increased after exposure to PB (15 μ M) in both control and ALS spinal cord sections. In the present study, a return to PB-free media resulted in a gradual decrease in specific [³H]MK-801 binding to the original levels with time, where t1/2 = 60 min. for control and 15 min. for ALS. The rate constants for PB-induced effects on [³H]MK-801 in control and ALS were 0.01/min. and 0.05/min., respectively. In control tissue the decay to the original binding level could be blocked by phosphatase blockers, NAV (sodium orthovanadate, a tyrosine-selective inhibitor) and NABD (Sodium B-D-glycerophosphate, a ser/thr inhibitor). For NABD, half maximal block was achieved at the concentration of 10⁻⁷ M for control and 10⁻³ M for ALS. Almost complete block (80%) was achieved at 10⁻³ M for control whereas in ALS a complete block could not be achieved. These differences between ALS and control spinal cord may indicate fundamental alterations in the activity, amount or type of endogenous phosphatase in spinal cord tissue in ALS patients.

OXIDATIVE MARKERS, ELECTRON TRANSPORT CHAIN ACTIVITY, AND SUPEROXIDE DISMUTASE ACTIVITY IN FAMILIAL AND SPORADIC AMYOTROPHIC LATERAL SCLEROSIS. A.C. Bowling*, E.E. Barkowski, J.B. Schulz, U. MacGarvey, R.H. Brown, and M.F. Beal. Neurology Service, Massachusetts General Hospital and Harvard Medical School, Boston, MA 02114.

We investigated superoxide dismutase (SOD) activity, markers of oxidative damage, and electron transport chain activity in patients with familial amyotrophic lateral sclerosis (FALS) and sporadic amyotrophic lateral sclerosis (SALS). Studies were conducted with erythrocytes from 30 controls, 31 SALS patients, and 13 FALS patients with six different SOD1 mutations. In addition, motor cortex (Brodmann area 4) was obtained from postmortem brain samples from 19 controls, 16 SALS patients, and four FALS patients with a codon 4 mutation (ala->val). In the SALS patients, SOD activity in erythrocyte lysates and brain cytosol was not significantly different from that of controls. In the FALS patients, erythrocyte SOD activity was decreased by 49% (p<0.001, range = 25-69%) and brain cytosol SOD activity was decreased by 52% (p<0.001). In brain tissue from the SALS patients, the carbonyl content of cytosolic proteins was increased by 47% (p<0.001) and the 8-hydroxy-2-deoxyguanosine content of nuclear DNA was increased by 32% (p<0.05). Also, complex I activity in brain mitochondrial preparations from the FALS patients was increased by 75% (p<0.001). These findings indicate that oxidative stress may be increased in FALS and SALS patients. Further studies will examine additional brain areas and other markers of oxidative damage.

AMYOTROPHIC LATERAL SCLEROSIS IMMUNOGLOBULINS INCREASE INTRACELLULAR CALCIUM IN A MOTONEURON CELL LINE. L.V. Colom*, M.E. Alexianu, R.G. Smith and S.H. Appel. Department of Neurology, Baylor College of Medicine, Houston, TX 77030.

Amyotrophic Lateral Sclerosis (ALS) is a devastating motoneuron disease of unknown cause. Recent evidence suggests that autoimmune mechanisms are involved in the origin and progression of the disease. We have previously demonstrated the presence of antibodies to voltage-gated calcium channels in ALS patient sera, and shown that ALS IgG induce calcium-dependent cytotoxicity in an hybrid motoneuron cell line, VSC4.1 (Smith *et al.*, PNAS 91:3393-97, 1994). These ALS IgG also increase the amplitude of voltage-dependent calcium currents in VSC4.1 cells (Mosier *et al.*, Soc. Neurosci. Abstr. 19:196, 1993). To determine whether ALS IgG can increase intracellular calcium in VSC4.1 cells, we have employed confocal scanning microscopy and the calcium-sensitive dye Fluo-3. In VSC4.1 cells, basal intracellular calcium levels were 74 ± 32 nM. Increases in intracellular calcium were observed in 29% of cells, following bath addition of IgG from 6 ALS patients. Two types of intracellular calcium changes were observed: 1) an early fast transient (364 ± 233 nM), appearing 15-120 sec after adding ALS IgG to the bath, and 2) a slower, progressive increase appearing 30-120 min later. Of the cells that showed a fast transient, 1/3 developed a slower progressive calcium increase (compared to less than 10% of the cells that lacked a fast transient). Addition of IgG from 4 control patients produced calcium increases in only 1% of cells. ALS IgG failed to produce fluorescence changes in calcium free media. These findings suggest that ALS IgG induces an early calcium influx through the cell membrane which, despite its short duration, may initiate a cascade of events leading to a later progressive increase in calcium and subsequent cell death. This work was supported by M.D.A. and Cephalon, Inc.

POTENTIATION OF CYCAD TOXIN-INDUCED DNA DAMAGE IN BRAIN TISSUE BY DNA-REPAIR INHIBITORS. G.E. Kisby^{1,2}, C. Sweatt, S. McEvoy, P.S. Spencer¹. Center for Res. on Occup. and Environ. Toxicol.; and Depts. ¹Pharmacology and ²Neurol., Oregon Health Sci. Univ., Portland, OR 97201.

Cycasin, the β -D-glucoside of methylazoxymethanol (MAM), is a possible etiological factor for western Pacific amyotrophic lateral sclerosis/Parkinsonism dementia complex. We have hypothesized that these genotoxins act as 'slow toxins' by permanently altering post-mitotic neural tissue DNA. In previous studies, we demonstrated that MAM-induced neurotoxicity *in vitro* is potentiated by O⁶-benzylguanine (O⁶-BG), an inhibitor of the DNA-repair protein methylguanine methyltransferase (MGMT). To further examine the relationship between DNA damage and MAM-induced neurotoxicity, MGMT levels and DNA damage were determined in mature mouse cortical explant tissue, primary rat cortical astrocytes, and primary rat cerebellar granule cell cultures treated for 1-3 days in the presence or absence of 5.0 μ M O⁶-BG with 0.1 mM of the genotoxins MAM, N-methylnitrosourea or procarbazine. Western blots demonstrated MGMT in protein extracts of all three tissue types, with particularly low levels in granule cell cultures. MGMT levels were reduced in explants and astrocytes treated with O⁶-BG. The level of apurinic/apyrimidinic endonuclease, an excision-repair protein, was also reduced in protein extracts from explants treated with O⁶-BG. DNA damage, as determined by immuno-slot-blot using the monoclonal antibody EM-21 to the DNA adduct O⁶-methyldoxyguanosine (O⁶-mdG), was not detected in cultures treated for 24 h with MAM or other genotoxins. However, O⁶-mdG was detected in all cultures treated for 3 days with MAM. O⁶-mdG levels increased ~2x when explants were treated with MAM and 5.0 μ M O⁶-BG. Taken together, the present studies indicate that modulation of DNA repair can increase the susceptibility of nervous tissue DNA to damage by genotoxins that may lead ultimately to cell death. MARIANAS DEMENTIA, A PURELY DEMENTING FORM OF ALS/PARKINSONISM-DEMENTIA COMPLEX OF GUAM. D.P. Perl*, P.R. Hof, J.C. Steele, D.P. Purohit, C. Esteban-Santillan, R. Peterson, L.T. Kurland, Mt. Sinai Med. Ctr., Dept. of Neurobiology, New York, NY 10029; Marianas Health Study, Guam 96923; Mayo Clinic, Rochester, MN 55905.

Among the Chamorro people of Guam, the high incidence and prevalence of ALS has decreased in the past decade, while parkinsonism-dementia complex (PDC) continues to be frequently encountered. We have recently noted the frequent occurrence of cases of dementia who remain free of amyotrophy or parkinsonian signs through the entire course of their illness. Pending further characterization of this disorder, we have referred to such cases as Marianas dementia. We now report neuropathologic findings on 7 pure dementia cases (73 ± 8.5 years old, duration of illness 3.5 ± 1.6 years) among inhabitants of Guam. None of these cases showed evidence of amyotrophy or extrapyramidal features despite careful neurologic surveillance. Five of these cases were of Chamorro extraction and had been life-long inhabitants of Guam. These cases showed evidence of severe cerebral cortical atrophy with widespread neurofibrillary tangles (NFT), in the absence of neuritic plaque formation. The NFT heavily involved limbic structures and predominated in layers II/III (as opposed to layer V) of the neocortex. There was loss of neurons in the substantia nigra with NFT in the upper brainstem. These 5 Chamorro cases were virtually indistinguishable neuropathologically from PDC. The remaining 2 cases were migrants to Guam (82 year old Caucasian, 83 year old Filipino) and both showed typical neuropathologic features of Alzheimer's disease. This study demonstrates that a purely dementing syndrome, in the absence of amyotrophic or parkinsonian manifestations represents an additional form of ALS/PDC among at-risk Chamorro natives of Guam with chronic exposure to unknown environmental factors present on the island.

NEUROTOXICITY: DRUGS

The Organophosphate Insecticide - Chlorpyrifos: Proconvulsant & Behavioral Effects in Adult Rats. John N.D. Wurpel* and Jesse H. Bidanset. Department of Pharmaceutical Sciences, College of Pharmacy, St. John's University, Jamaica, NY 11439

Chlorpyrifos (CPF) has been shown to have proconvulsant effects in immature rats (Wurpel *et al.*, 1993) and elicits behavioral effects when administered pre- or post-natally (Muto *et al.*, 1992). These early studies also demonstrated an interaction of CPF and xylene (XYL). Experiments were performed to determine both the effects of CPF on kindling and behavioral neurotoxicity in adult rats. Xylene was administered alone or in combination with CPF. Rats (Taconic Farms) weighing 175-225 grams received amygdalar electrodes 1 week prior to initiation of kindling paradigms. CPF or XYL, alone or in combination, was administered subcutaneously in 10% peanut oil/saline (vehicle - VEH). Dose range: CPF 0.3-100 mg/kg; XYL 0.2, 0.5 or 1%. In all cases $N \geq 5$. The afterdischarge threshold (ADT) was determined in rats treated with CPF, XYL, CPF+XYL or VEH. No differences were noted between the groups, ADT was not effected by treatments. Kindling was performed (1 stimuli/hour, 400 μ A, 1 sec duration, 60 Hz, square wave pulses) in CPF, XYL, CPF+XYL or VEH treated rats. CPF accelerated kindling in a dose dependent manner. XYL also accelerated kindling within the dose range used. CPF and XYL treatment displayed additivity (kindling rate accelerated). CPF displayed neurotoxicity in adult rats as determined by the rotorod test. XYL appeared to be without effect in this test. The combination of CPF and XYL displayed additivity in this test. Spontaneous Motor Activity (SMA) displayed a biphasic effect of CPF; at 2 hours post-CPF activity increased modestly in a dose-dependent manner. At 36 hours CPF elicited a modest decrease in SMA at the highest doses used. XYL caused an increase in SMA at 2 hours, yet at 36 hours SMA did not differ from VEH-treated controls. CPF +XYL demonstrated additivity at 2 hours post dose. Brain cholinesterase activity was determined by a spectrophotometric method. CPF caused reductions in cholinesterase activity in a dose dependent manner from 2 hours up to 72 hours following CPF administration. Studies supported by St. John's University, Coll. Pharmacy.

HYDROGEN PEROXIDE HYPERPOLARIZES RAT HIPPOCAMPAL PYRAMIDAL NEURONS BY OPENING K⁺ CHANNELS. V. Seutin*, J. Scuvée-Moreau, L. Massotte, A. Dresse. Lab. of Pharmacology, Univ. of Liège (B-4000), Belgium.

Hydrogen peroxide (H₂O₂) may be involved in a number of pathological conditions affecting neural cells, but its electrophysiological effects have not yet been studied in detail in the rat.

Using intracellular recordings of presumed CA1 pyramidal neurons in the slice preparation, we observed that H₂O₂ (0.3-3 mM) induces in these cells a reversible and reproducible hyperpolarization (-12 ± 1 mV, Mean \pm SEM, $N=13$, by 3 mM) from resting potential (-65 ± 2 mV), as well as a decrease in input resistance. This effect persisted in the presence of TTX (0.5 μ M) and was mainly due to a K⁺ channel opening because (1) in 2.5 mM K_e, it had the same reversal potential (-97 ± 3 mV, $N=3$) as the one of baclofen (10 μ M) (-99 ± 1 mV), a known K⁺ channel opener; (2) its reversal potential shifted according to the Nernst equation for K⁺ when [K]_e was changed (from -96 ± 3 mV in 2.5 mM to -63 ± 2 mV in 10.5 mM ($N=3$); (3) it was reduced by a K⁺ channel blocker (100 μ M Ba²⁺, $N=4$).

The precise identity of the channels that are affected, as well as the mechanism by which they are opened, remain to be determined.

672.3

NEUROTOXICITY OF HYDROGEN PEROXIDE. P.A. Boxer*, O. Ben-Yoseph¹, N. Dujovny, B.D. Ross¹. Neuroscience Pharmacology, Parke-Davis Research, Div. of Warner-Lambert Co., Ann Arbor, MI 48105 and ¹Depts. of Radiology and Biological Chemistry, Univ. of Michigan, Ann Arbor, MI 48109.

Free radical induced neuronal injury has been implicated in a number of neurological disorders and has been linked to excitotoxic cell death. The current experiments evaluated the toxicity produced by the direct application of the progenitor of hydroxyl radicals, hydrogen peroxide (H_2O_2). Experiments were performed on 17-day old cerebrotal primary cultures under conditions similar to those employed in excitotoxicity experiments. Cell death was assessed both visually and quantitatively by the measurement of lactate dehydrogenase (LDH) released into the medium. Following a 30 min exposure to H_2O_2 , there was a concentration dependent cell death assessed 24 hr later ($EC_{50}=102 \mu M$). Shorter exposure times to H_2O_2 were less effective. LDH release did not occur until >8 hrs after removal of H_2O_2 indicating a delayed cell death, similar to that seen following exposure to glutamate. Pretreatment with the iron chelator deferoxamine (2 mM) produced a rightward shift in the H_2O_2 -induced toxicity curve ($EC_{50}=458 \mu M$), while inhibition of catalase with aminotriazole (30 mM) enhanced the H_2O_2 induced toxicity ($EC_{50}=54 \mu M$). This neurotoxicity was not mediated by NMDA receptors, since the NMDA antagonist MK-801 did not prevent the cell death. These results are consistent with the assumption that the generation of hydroxyl radicals is necessary for cell death. As with excitotoxicity, a rise in $[Ca^{2+}]_i$ may play a critical role, since there was an abrupt increase in $[Ca^{2+}]_i$ about 40 min following continual exposure to H_2O_2 . Removal of extracellular Ca^{2+} prevented the increase in $[Ca^{2+}]_i$, suggesting that the increase was not the result of the liberation of intracellular stores of calcium. These data demonstrate that H_2O_2 -induced toxicity has many of the same features as excitotoxic cell death, suggesting that there may be a causal link between these forms of neurotoxicity.

672.5

POLYCHLORINATED BIPHENYLS REDUCE TYROSINE HYDROXYLASE ACTIVITY IN RAT BRAIN. R.F. Seegal* and W. Shain. Wadsworth Center, NYSDOH, Albany, NY 12201.

Polychlorinated biphenyls (PCBs) reduce dopamine (DA) concentrations in adult rat and non-human primate brain and in pheochromocytoma (PC12) cells. Using neuroblastoma (N1E-N115) cells that do not express the enzyme dopa decarboxylase (DDC), required for the conversion of *L*-Dopa to DA, we have shown that PCBs reduce media *L*-Dopa concentrations, suggesting that PCBs reduce the ability of tyrosine hydroxylase (TH) to convert tyrosine to *L*-Dopa. To determine if reductions in brain DA concentrations are also due to inhibition of TH we exposed adult Wistar-derived rats to either Aroclor 1254 (1,000 ppm in chow) or control chow for sixty days and sacrificed them thirty minutes after they received intraperitoneal injections of either 100 mg/kg of 3-hydroxybenzylhydrazine (NSD-1015), an inhibitor of DDC or saline. DA, *L*-Dopa, 3,4-dihydroxyphenylacetic acid (DOPAC) and homovanillic acid (HVA) concentrations were determined in the striatum and nucleus accumbens by HPLC. PCBs significantly reduced DA concentrations in the striatum and DOPAC and HVA concentrations in both brain regions. Co-treatment with NSD-1015 resulted in further decreases in DOPAC and HVA as well as reductions in *L*-Dopa concentrations compared to control/NSD-1015 treated animals. These reductions in *L*-Dopa and DA metabolite concentrations strongly suggest that PCBs, *in-vivo*, inhibit production of newly synthesized DA at the level of tyrosine hydroxylase.

CHRONIC EXPOSURE TO IBOGAINE RESULTS IN SEX-DEPENDENT ASTROGLIOSIS IN THE RAT. J.P. O'Callaghan*, L.E. Rodman, T.S. Rogers, J.B. Terrill and J.G. Page. U.S. Environmental Protection Agency, Res. Tri. Pk., NC 27711; Southern Res. Inst., Birmingham, AL 35255; NIDA, Rockville, MD 20857.

Ibogaïne (IBG) is a naturally occurring alkaloid derived from the root of the African shrub, *Tabernaemontana iboga*. Evidence exists showing that IBG interrupts the physiological and psychological aspects of drug addiction, both in experimental animals and in man. Recent reports (e.g. O'Hearn and Molliver, *Neurosci.* 55: 303, 1993) also indicate that IBG has the potential to induce neurotoxicity because, in male rats, it causes degeneration of cerebellar Purkinje cells with an attendant gliosis. Here we evaluated the potential of chronic exposure to IBG to cause neurotoxicity in male and female rats as evidenced by the presence of astrogliosis, a generic response to CNS injury. IBG was administered to male and female Sprague-Dawley rats (0, 25, 75, or 150 mg/kg, p.o.) once daily for 14 days. Rats were sacrificed on day 15 and 31. Brains were dissected into olfactory bulb, hippocampus, striatum, cortex, brain stem and cerebellum. IBG-induced astrogliosis was quantified by assaying the content of the astrocyte intermediate filament protein, GFAP, in each brain region, using a sandwich ELISA. In male rats, GFAP was not elevated as a function of IBG treatment at any dose or in any region on day 15. In female rats, large (as much as 200% of control), dose-, time-, and region-dependent increases in GFAP were observed on day 15. The greatest increases were seen in olfactory bulb and brain stem; notably, the cerebellum was not affected. In both male and female rats GFAP was unaffected on day 31, a finding consistent with the time-dependent nature of chemical-induced astrogliosis. The data indicate that chronic exposure to IBG causes a pronounced sex-dependent astrogliosis, findings suggestive of underlying brain damage. CHARACTERIZATION OF HUMAN SERUM-INDUCED TOXICITY IN RAT PRIMARY HIPPOCAMPAL CULTURES. P.S. Puttfarcken*, A.M. Manelli, and D.E. Frail, Neuroscience Research, Pharmaceutical Discovery Division, Abbott Laboratories, Abbott Park, IL. 60064.

Previous studies have reported the presence of complement proteins in senile plaques of Alzheimer's (AD) brains. Since the hippocampus is a region of the brain severely affected in AD, the effect of complement on primary cultures of rat hippocampal neurons was evaluated. Both morphological and biochemical changes were examined following treatment with either human or rat serum. 3 day old cultures (days in culture, DIC) were not affected by treatment with either serum. In contrast, a significant amount of cell death was observed in 6 DIC treated with 15% human serum for 24 hours. Under these conditions, the magnitude of cell toxicity varied between the lots of serum tested and LDH release did not always correlate with activation of the complement cascade, as measured by iC3b formation. A 24 hour treatment with 15% rat serum had no significant effect on these cultures. To determine if the activation of complement was responsible for the cell death observed following treatment with human serum, cells were treated with serum deficient in C9, the component of the classical complement cascade responsible for completing the assembly of the lytic membrane attack complex. The addition of C9 to 3 DIC treated with C9-deficient serum was not toxic. In contrast, the addition of C9 induced toxicity in 6 DIC treated with C9-deficient serum. These experiments suggest that human serum-induced toxicity in hippocampal neurons is, in part, through the activation of the complement cascade, dependent on the age of the culture, and subject to homologous restriction.

NEUROTOXICITY OF IBOGAINE IN CD MICE. S.F. Ali*, X.M. Meng and J.P. O'Callaghan. Division of Neurotoxicology, National Center for Toxicological Research/FDA, Jefferson, AR 72079, Neurotoxicology Division, US EPA, Research Triangle Park, NC 27710.

Ibogaïne is an indolealkylamine known to have CNS stimulant and hallucinogenic properties in animals. Recently, ibogaïne has been proposed for use as a treatment for drug addiction. The neurochemical basis for such therapy, however, remains unclear. The present study was designed to evaluate the neurotoxic effects of ibogaïne in mice. Ibogaïne was administered to adult female CD-mice (0, 50, 100, or 200 mg/kg, ip) once daily for three days. On day six, animals were sacrificed and brains were removed, and ten different regions were dissected for neurochemical analysis. Dopamine (DA), serotonin (5-HT) and their metabolites were measured by HPLC/EC. Astrogliosis, a common response to neural injury, was quantified by assaying the major intermediate filament protein of astrocytes, GFAP. Ibogaïne produced a dose-related decrease of 5-HT in caudate nucleus (CN), frontal cortex (FC) and brain stem (BS). Ibogaïne caused a significant increase of 5-HT in hippocampus (HIPP). There were no significant change in DA, however, DOPAC was elevated in CN and FC. Ibogaïne increased GFAP in olfactory bulb, HIPP and BS. These data suggest that ibogaïne has a complex neurotoxicity profile in female mice, as assessed by changes in monoamine concentrations and astrogliosis.

A CYTOTOXIC EFFECT OF ESTROGEN ON AMYGDALA NEURONS. S. Kito*, J. Semba, R. Miyoshi, M. Kanazawa, A. Ando, S. Chin and L. Shimada. Division of Health Sciences, The University of the Air, Chiba Japan, *Division of Basic Medical Sciences, Royal Free Hospital School of Medicine, London.

It has been described that estrogen exerts cytotoxic effect on β -endorphin containing neurons in the rat hypothalamus.

In this paper, effects of estrogen on cultured rat amygdala neurons were studied. Primary cultures of rat fetal amygdala neurons were used for the experiment. After adding various concentrations of estradiol, cells were incubated for 24 hours. Then the percent survival of cells was calculated by assaying intracellular LDH activity. Effect of estradiol on intracellular Ca^{2+} concentration in the cultured neurons were also examined by fura-2 fluorometry.

As results, estradiol had a cytoprotective effect on amygdala neurons at concentrations of 10^{-9} ~ 10^{-5} M and cytotoxic effect at higher concentrations. On the other hand, estradiol caused long-lasting Ca^{2+} elevation within cultured amygdala neurons.

Mechanisms of this Ca^{2+} elevation was analyzed by adding dihydropyridine, ω -conotoxin and mRNA inhibitors. Currently, in situ hybridization experiments of hepatocytic growth factor on rat amygdala before and after estrogen administrations are in progress.

NEUROCHEMICAL CHANGES FOLLOWING L-CHLOROPROPIONIC ACID-INDUCED DAMAGE P.S. Widdowson, I. Wyatt, E.P. Christian* and E.A. Lock, Zeneca Central Toxicology Laboratory, Macclesfield, UK and Zeneca Inc, Wilmington, DE 19897, USA.

L-Chloropropionic acid (CPA) when administered systemically to rats produces selective destruction of cerebellar granule cells. We examined the neurochemical changes in rat cerebellum and forebrain during the development of the granule cell necrosis. Groups of rats were administered with CPA (250 mg/kg/day) for 3 days. At various time points groups of rats were killed. Concentrations of amino acids were measured in cerebellum and forebrain using HPLC. Densities of NMDA, kainate, adenosine-A₁ and GABA_A receptors were also measured in brain regions by autoradiography. By day 3, concentrations of the excitatory amino acid transmitters, glutamate and aspartate began to fall and remain low (-55 to 70%). Concentrations of GABA and glutamine increased transiently (+300%) but fell back to control levels by day 5. Concentrations of taurine fell by day 3 (-60% of controls) and remained low. Glycine concentrations increased at day 3 (+200% of control values) and remained elevated. The densities of the glutamate receptors, NMDA and kainate were reduced in cerebellar cortex from CPA treated rats. There was no change in the densities of NMDA or kainate receptors in any other brain region examined. Densities of adenosine A₁ and GABA_A receptors in cerebellar and forebrain regions were not changed following CPA administration. In conclusion, we suggest that reduced glutamate and aspartate levels and NMDA and kainate receptor densities in the cerebellum are related to loss in cerebellar granule cells. Changes in other amino acids may reflect compensatory events in response to the toxic insult.

GLIAL FIBRILLARY ACIDIC PROTEIN IN THE RAT BRAIN RESPONDS BIPHASICALLY TO INHALED TOLUENE. AR Little, ZL Gong, HAN El-Fawal*, HL Evans. Institute of Environmental Medicine, New York University Medical Center, Tuxedo, NY, 10987

GFAP concentration in the hippocampus and cerebellum was evaluated as a biomarker of the neurotoxicity of inhaled toluene. Fisher-344 rats were exposed to toluene at 100ppm or 1000ppm by inhalation for 6 hours/day, 5 days/week. Days 1, 3, 7, 21, and 42 were evaluated. GFAP response in the hippocampus was biphasic at both doses, initially decreasing but later increasing above control by day 21 to day 42. In the cerebellum GFAP levels declined significantly by day 3, increasing thereafter, never quite returning to control levels. These data are consistent with a hypothesis emerging from this laboratory concerning the mechanism by which exposure to low doses of toxic chemicals affect regulation of GFAP. The most familiar finding is an increase in GFAP typical of reactive gliosis. A less frequently observed change may involve decreased GFAP levels, observed with very low level exposures. Our studies also indicate a biphasic response with exposure to Pb (Gong et al., 1994). Relative-ly low level exposures administered chronically may be necessary to observe this early phase of the glial response, a transient decrease followed by an increase if given enough time or a large enough dose. Low level or short term exposure to toluene may induce changes in glial cell function that precede overt toxicity characterized by gliosis. Supported by the American Petroleum Institute and grant ES-04895.

THE PEPTIDIC SUBSTANCE P ANTAGONIST [D-PRO², D-TRP^{7,9}]-SUBSTANCE P BUT NOT THE NONPEPTIDIC ANTAGONIST CP-96,345 INDUCES HIPPOCAMPAL NEURODEGENERATION. D. K. Rush*, S. Aschmies and G. M. Bores, Dept. Biol. Res., Neuroscience Strategic Business Unit, Hoechst-Roussel Pharmaceuticals, Somerville, NJ 08876.

Direct injection (1 µl) of the peptidic Substance P (SP) antagonist [D-Pro², D-Trp^{7,9}]-Substance P (DPDT-SP, 1-3 nmol) induced neurodegeneration in the dorsal hippocampus of rats. Co-injecting SP (30 nmol) reduced the neurotoxicity induced by 3 nmol of DPDT-SP. Another SP antagonist [Arg⁶, D-Trp^{7,9}, MePhe⁸]-SP(6-11) (10 nmol) was also neurotoxic after intrahippocampal injection. Surprisingly, the nonpeptidic SP antagonist CP-96,345 was not neurotoxic at a dose of 10 nmol. The reduced neurotoxicity of the nonpeptide antagonist was apparently not due to a lower affinity for the SP receptor; CP-96,345 displaced the NK-1 agonist [³H][Sar⁹, Met(O₂)¹¹]-SP with higher affinity (IC₅₀=0.34 µM) than DPDT-SP (IC₅₀=8.9 µM) in rat brain membranes. Binding of the peptidic and nonpeptidic antagonists at different receptor subtypes or different epitopes of the same subtype, both of which have been reported for SP receptor ligands, might account for the differential neurotoxicity observed in the present experiments.

HIPPOCAMPUS-HPA-AXIS FUNCTIONS IN RATS INTOXICATED WITH ORGANOTIN COMPOUNDS. H.Imai¹, M.Kabuto*, K.Yan¹, T.Suzuki¹, M.Akaike², and N.Kato³. ¹Natl. Inst. Environ. Studies, 16-2 Onogawa, Tsukuba City, Ibaraki, 305 JAPAN, ²Hoechst Japan Ltd., 1-3-2 Minamidai, Kawagoe City, Saitama, 350 JAPAN, ³Shiga Univ. of Med. Sci., Seta-Tsukinowa, Ohtsu City, Shiga, 520-21 JAPAN.

To investigate whether the hippocampal damage caused by thimethyltin (TMT) involves corticosterone (CORT)-receptors, effects of a single oral dose of TMT-chloride (TMT-c) administration (8, 4 and 0 mg/kg, p.o.) on 1) plasma CORT levels on Day 0, 3, 4 and 5 after the TMT-c and 2) response of the level at 0, 30, 60, 90 and 120 min after corticotropin-releasing-factor (CRF) injection (28 µg/kg, i.v.) on Day 4 were examined using male SD rats aged 6 wks. An apparent hippocampal damage especially in CA3 and CA4 pyramidal cells were observed 4 to 5 days after an administration of TMT-hydroxide of 9 mg/kg (p.o.) in our previous studies. A significant enhancement of the CORT level on Day 3 (mean: 124 ng/ml) and 4 (mean: 187 ng/ml) after the TMT-c of 8 mg/kg compared to the vehicle (distilled water) controls (mean: 24 ng/ml) but no more increase with CRF injection was observed. The enhanced CORT levels on Day 4 were shown to be almost completely suppressed at 90, 180 and 300 min after an administration of dexamethasone of 100 µg/kg (s.c.), indicating that the CORT-receptors both in the hypothalamus and pituitary may not be affected by the TMT-c, whereas alterations of the hippocampal CORT-receptors could not be denied. On the other hand, the animals treated in the same manner with triethyltin-chloride (TET-c) of 4 mg/ml (i.p.) showed significant increases of the CORT level on Day 3 and 4 but no more increase in response to the CRF on Day 4, but those with triphenyltin-chloride (TPT-c) of 4mg/kg (i.p.) did not show significant increase on Day 3 or 4, but their responses of the CORT level to the CRF on Day 4 were exaggerated compared to those among the vehicle (corn oil) controls, suggesting that actions of TPT-c on the hippocampus-HPA axis may be different from those by TMT-c and TET-c.

SEXUAL DIMORPHIC EFFECTS ON BEHAVIOR FOLLOWING IN UTERO EXPOSURE TO PHENOBARBITAL.

W. Pizzi*, S. Baranski, A. Newman, & R. Andrews, Northeastern Illinois Univ. Chicago, IL. 60625

Pregnant rats were administered phenobarbital (PHB, 40 mg/kg, sc) on gestation days 12-18, while controls received equal amounts of saline. PHB-exposed pups showed a hyperexcitability resulting in earlier attainment of a surface righting task (p<0.01). In adult behavioral testing PHB-exposed male rats showed reduced performance on a DRL-20 operant conditioning schedule, & a significant reduction in performance on a FR-10 schedule (p<0.05). Male PHB-exposed rats showed a reduced auditory startle response, but a prepulse inhibition pattern similar to controls. Female PHB-exposed rats showed no significant differences on these tasks. In a two-bottle taste preference for a sweet solution the usual sex dimorphism was seen with females drinking greater amounts than males; however, PHB-exposed males drank more of the sweet solution than control males. In these experiments, prenatal exposure to PHB differentially affected male versus female offspring. These data suggest that PHB-exposure may reduce testosterone levels at a critical period of brain development leading to feminized behavior in male offspring.

DYNORPHIN A INDUCES RELEASE OF LDH IN PC-12 CELLS THROUGH A NON-OPIOID MECHANISM. A.G.Mukhin* and A.I. Faden, Georgetown University Medical Center, Washington, DC 20007.

Dynorphin A (Dyn A) has been implicated in the pathophysiology of both traumatic brain and spinal cord injuries. Both opioid and non-opioid actions of Dyn A seem to be involved. However, the basic mechanisms underlying the damaging effects of Dyn A remain speculative. In order to better address this issue, we have studied the effects of Dyn A and related peptides *in vitro*, using PC-12 cells. PC-12 cells were cultured in minimal essential medium (MEM) supplemented 7.5% fetal bovine serum and 7.5% horse serum. On day 3, cells were washed twice by serum-free MEM, and coincubated with studied drugs in serum-free MEM. LDH release has been used as a marker of cell injury in many *in vitro* studies and has been shown to correlate with subsequent cell death in experiments examining glutamate toxicity. Dyn A, in the micromolar concentration range, induced release of LDH in culture medium, with an ED₅₀ of approximately 20 µM. This effect was maximal by 10 min. Pretreatment with the opioid antagonists naloxone, WIN-44,441-3, or naltrexone in concentrations up to 1 mM failed to significantly attenuate the effect of 10 µM of Dyn A. Moreover, Dyn A-(2-17), which is inactive at opioid receptors, was similar in potency to Dyn A in its ability to induce LDH release. Structure activity studies showed lack of effect of dynorphin-related peptides Dyn A-(1-8) and shorter. This profile of activity is similar to that found with spinal cord injury induced by intrathecal dynorphin administration. Taken together, these studies suggest that PC-12 cells may provide a useful *in vitro* model for studying certain pathophysiological actions of dynorphin, particularly its non-opioid actions.

NEUROPROTECTIVE EFFECTS OF MONOAMINE OXIDASE-B INHIBITORS ON DSP-4 INDUCED DEGENERATION OF NORADRENERGIC AXONS IN THE RAT BRAIN. X. Zhang, P. H. Yu and A. A. Boulton*. Neuropsychiatry Research Unit, University of Saskatchewan, Saskatoon, Canada, S7N 0W0.

DSP-4 [N-(2-chloroethyl)-N-ethyl-2-bromobenzylamine] is a highly selective neurotoxin toward the locus coeruleus noradrenergic (NA) system. Previous biochemical studies have shown that the monoamine oxidase-B (MAO-B) inhibitors, R(-)-deprenyl and 2-HxMP [N-(2-hexyl)-N-methylpropargylamine], are able to prevent DSP-4 induced NA depletion in the mouse hippocampus. It is, however, unknown whether this represents a neuroprotection of NA axons. Employing dopamine- β -hydroxylase immunohistochemical and imaging analysis methods, we have found that 92% and 84% respectively NA nerve fibers in the rat hippocampus are spared from DSP-4 neurotoxicity by a single pretreatment dose of R(-)-deprenyl or 2-HxMP. Similar neuroprotective effects are also observed in the cerebral cortex, thalamus, amygdaloid complex and cerebellum. This is the first morphological evidence demonstrating that deprenyl and 2-HxMP can indeed protect NA axons against DSP-4 neurotoxicity. We are currently also investigating the neuroprotective and neurorescue effects of R(-)-deprenyl and 2-HxMP on DSP-4 induced chronic degeneration of NA neurons in the locus coeruleus.

THE EFFECT OF ACUTE ETHANOL TREATMENT ON CALCIUM HOMEOSTASIS IN CULTURED HIPPOCAMPAL NEURONS BEFORE AND DURING DEPOLARIZATION. B. Webb*, S.S. Suarez, M.B. Heaton, and D.W. Walker. University of Florida, V.A. Medical Center, Gainesville, FL 32610.

The neurotoxic effect of acute ethanol treatment (AET) may lead to an alteration in the regulation of calcium homeostasis in hippocampal neurons. We cultured E18 rat hippocampal neurons for 2 weeks. The cultures were loaded with $2\mu\text{M}$ indo-1/AM for 1 h at room temperature, rinsed with buffer, and incubated for 1/2 h at 37°C . The cultures were divided into 4 groups: control, 100,400,800 mg/dl ethanol. Control readings were taken, and then the buffer was changed for either control buffer or buffer containing 100,400,800 mg/dl ethanol. Fast responses were recorded for the first 6.4 sec and then at 10,30,45,60 min. To determine the effect of AET on calcium homeostasis in cultured hippocampal neurons during depolarization, the buffer was changed after 60 min to either control buffer and 30mM KCL or buffer with ethanol and 30mM KCL. Fast responses were recorded for the first 3.2 sec and then at 5,10 min. In cultures treated with 400 or 800 mg/dl ethanol, $[\text{Ca}^{2+}]_i$ was decreased ($p<0.01$) at later time points before depolarization but increased after depolarization ($p<0.0001$). When AET cultures were compared to control, both 100 and 400 mg/dl ethanol increased resting $[\text{Ca}^{2+}]_i$ at 10 min ($p<0.05$). At later time points, 400 and 800 mg/dl treatment decreased $[\text{Ca}^{2+}]_i$ in a dose-dependent manner. AET inhibited the rise in $[\text{Ca}^{2+}]_i$ after depolarization with 30mM KCL ($p<0.01$) in a dose-dependent manner. The results of this study indicate that AET results in the alteration of calcium homeostasis in cultured hippocampal neurons at resting membrane potentials and during depolarization. These changes in $[\text{Ca}^{2+}]_i$ may disrupt normal cellular function and contribute to cell death. Therefore, the alteration of calcium homeostasis may be an underlying mechanism of ethanol neurotoxicity. Supported by NIAAA grants AA00200, AA09128, and Fellowship #1F31AA05372-01; and Medical Research Service Department of Veterans Affairs.

DELAYED CONSEQUENCES OF PARENTERAL DOMOIC ACID TREATMENT IN RAT BRAIN. Nathan M. Appel*, Stanley I. Rapoport and James P. O'Callaghan. FDA CDER ORR DRT, Laurel, MD 20708; NIH NIA LNS, Bethesda, MD 20852 and USEPA, Research Triangle Park, NC 27711.

Domoic acid (Dom) is a neurotoxic excitatory amino acid (EAA) which appears to act as an agonist at the kainic acid subtype of EAA receptors. Dom has been identified as the contaminant in mussels causing adverse neurological and gastrointestinal effects, and in some cases death, to people who consumed them. Following i.p. Dom, 2.25 mg/kg, some rats displayed seizures and stereotypy (scratching). Seven days later brains from rats manifesting seizures and stereotypy had intense argyrophilia in anterior olfactory nucleus; CA1 hippocampus; lateral septum; and parietal (layer IV), piriform and entorhinal cortices. Brains from rats which did not manifest seizures or stereotypy did not. This pattern of argyrophilia is reminiscent of that seen after kainic acid and of *c-fos* expression shortly after dosing with kainic acid or another convulsant, pentylenetetrazole. Microglia, detected using lectin histochemistry, appeared to be increased in regions having argyrophilia. Glial fibrillary acidic protein expression (GFAP) was more diffuse, however. ^{14}C Arachidonic acid incorporation, which labels mainly *sn-2* positions of brain phosphatidylcholine and phosphatidylinositol was increased in all Dom-treated rats. ^3H Palmitic acid incorporation, which labels the *sn-1* position of brain phosphatidylcholine, appeared unaffected. Local cerebral glucose utilization (^{14}C 2-deoxyglucose incorporation) was also determined. These data suggest that acute activation of discrete brain circuits by Dom and subsequent seizures induce delayed alterations in brain homeostasis which is reflected by gliosis and altered metabolism.

672.18

ETHANOL DECREASES INTRACELLULAR MYO-INOSITOL IN C_6 CELLS. K. E. Isenberg*, S. G. Holstad, B. W. Moore and W. R. Sherman. Department of Psychiatry, Washington University School of Medicine, St. Louis, MO 63110.

Ethanol produces a dose-dependent decrease in the growth of C_6 glioma cells. We hypothesized that the etiology of this phenomena could be similar to effects observed when the cells are grown in hyperosmolar sodium chloride (NaCl). C_6 cells were grown in Dulbecco's Modified Eagles Medium and 10% fetal calf serum (controls) or grown in the same media supplemented with ethanol or NaCl in chronic exposure (7 days) or acute exposure (up to 2 days) experiments. Chronic exposure reveals that ethanol has a more potent inhibitory effect on growth than equiosmolar additional NaCl. Unlike exposure to hyperosmolar NaCl, chronic ethanol exposure does not alter intracellular concentrations of protein. Acute exposure of C_6 cells to ethanol is associated with a 50% decrease in intracellular concentrations of myo-inositol, the opposite of effects observed upon exposure of the cells to hyperosmolar NaCl. The effects of ethanol upon intracellular concentrations of myo-inositol occur in a dose dependent fashion at concentrations of ethanol (8.5 mM to 130 mM) commonly encountered in human intoxication. Growing the cells in media supplemented with myo-inositol then switching the cells to media with added deuterated myo-inositol and ethanol suggests that ethanol alters myo-inositol influx and efflux. The effects of ethanol on influx of myo-inositol appear to be the opposite of the effects of NaCl upon myo-inositol transport. Ethanol induced reductions in the intracellular concentration of myo-inositol may impair the growth of these cells.

NEUROTOXICITY: METALS

673.1

SUBCHRONIC METHYLMERCURY (MeHg) EXPOSURE ALTERS Ca^{2+} RELEASE FROM AN IP_3 -SENSITIVE STORE IN NG108-15 CELLS. J.E. Sirois* and W.D. Atchison Dept. Pharm./Tox., Mich. State Univ., E. Lansing, MI 48824.

MeHg is a neurotoxic organomercurial which exhibits complex effects on intracellular ion homeostasis. Acute exposure to MeHg initially releases Ca^{2+} from an IP_3 -sensitive store, increases the concentration of an endogenous non- Ca^{2+} ion and ultimately leads to influx of Ca^{2+} across the plasma membrane. The present study was undertaken to determine if subchronic exposure to low μM concentrations of MeHg could also alter ion homeostasis and/or affect Ca^{2+} release from IP_3 -sensitive pools. 24 Hour exposure to $1\mu\text{M}$ MeHg did not alter the apparent resting $[\text{Ca}^{2+}]_i$, but did cause an increase in the response to bradykinin (Bk; $1\mu\text{M}$). $2\mu\text{M}$ MeHg for 24 hr also increased the response to Bk in addition to slightly increasing the apparent resting $[\text{Ca}^{2+}]_i$. These results suggest that NG108-15 cells exposed subchronically to MeHg are able to overcome an initial loss of Ca^{2+} from the IP_3 -sensitive pool. The enhanced response to Bk may reflect an ability of MeHg either to facilitate release from the IP_3 -sensitive pool or possibly to inhibit the uptake of Ca^{2+} following its release from this pool. Supported by NIH grant ES03299.

NEUROPSYCHOLOGICAL AND PSYCHIATRIC COMPLICATIONS ASSOCIATED WITH HIGH LEVELS OF SERUM COPPER OF UNKNOWN ETIOLOGY. W.J. Coughlin†, B.D. Fantie†, and J. Joyce- †Human Neuropsychology Laboratory, The American University, Washington, DC 20016, ‡Mt. Vernon Center for Community Mental Health, Alexandria, VA 22309, and ~Psychiatric Associates of Fredericksburg, Fredericksburg, VA 22401. Chronic copper toxicosis is characteristically associated with Wilson's disease, a rare genetic disorder that usually manifests as either a hepatic or neurological syndrome. Wilson's disease is fatal unless treated with chelating agents. Death results from the direct effects of copper toxicity on the brain and liver. Although the subjects in this investigation do not meet diagnostic criteria for Wilson's disease and are without gross hepatic or neurological symptoms, laboratory blood tests have indicated toxic levels of serum copper of unknown etiology that are as high as those typically reported in Wilson's patients. The subjects in the present study suffer from psychiatric disorders and approximately 20% of Wilson's patients initially exhibit psychiatric symptoms prior to the onset of the full clinical entity. Using a comprehensive battery of neuropsychological tests, we assessed two female psychiatric patients with chronic hypercupremia. Preliminary results include deficits in verbal and nonverbal fluency, verbal and nonverbal recall, motor speed, and motor sequencing. The few neuropsychological studies on Wilson's disease in the literature, to date, have found comparable deficits in verbal recall and motor speed. Explanations for the presence of hypercupremia in these subjects are explored including the possible existence of a previously unknown subtype of Wilson's disease. We suggest it is possible, in some rare instances, that patients may present with psychiatric, cognitive, or motor symptoms that may, in fact, be related to undiagnosed hypercupremia.

MOUSE BRAIN UPKEEPS ³H-SPIROPERIDOL RECEPTOR BINDING PATTERN IN AN EARLY STAGE OF MANGANESE POISONING. V. Villalobos, J. Estévez, J.O. Davila, E. Bonilla*. INBIOMED, FUNDACITE-ZULIA, Apartado 376, Maracaibo - Edo. Zulia, Venezuela.

Manganese (Mn) poisoning is an occupational disease whose symptoms resembles the Parkinson's. This study is aimed to assess the effects of Mn in the ³H-Spiroperidol receptor pattern of different regions in mice. Male adult mice received a daily intraperitoneal (i.p.) Mn dose of 5mg/kg for eight weeks. Control mice were injected with saline. At the end of assay, the mice were killed by cervical dislocation, and the brains were removed on ice. Olfactory bulb, striatum and hypothalamus were dissected out and frozen until the assay was performed. After that, samples of each region were taken for Mn determination. ³H-Spiroperidol binding assays were realized according to the method described by Bhargava. Mn concentrations were determined by atomic absorption spectrophotometric. Mn-treated mice showed a significant increase of Mn levels in all regions. The Bmax and Kd values for ³H-Spiroperidol binding were unaltered by the treatment. Our investigation reinforces previous findings which seem to point out that mice submitted to these conditions are in an early stage of Mn poisoning, where cell membranes damage has not occurred.

METHYL MERCURY INDUCED NEUROTOXICITY IS BLOCKED BY ANTI-OXIDANTS. S.T. Park^{1,2}, K.T. Lim¹, Y.T. Chung² and S.U. Kim^{1*}. ¹Div. of Neurology, Dept. of Medicine, Univ. of British Columbia, Vancouver, BC, V6T 2B5, Canada. ²Dept. of Anatomy, Wonkwang Univ. School of Medicine, Iri 570, Korea.

Methyl mercury compounds are known to induce neurotoxic changes in the mammalian central nervous system (CNS). In order to characterize the mechanism of methyl mercury neurotoxicity, neonatal mouse cerebral neuron cultures were exposed to graded concentrations of methyl mercury chloride (0-100 µM) for 2-48 hours. Cell viability was determined using MTT assay and neurofilament ELISA assay.

Methyl mercury was toxic to mouse cerebral neuron cultures (LD50 = 20 µM) after 24 hours of exposure, and neurotoxicity was blocked in a dose-dependent manner by catalase (10-100 µg/ml) and glutathione (0.2-2 mM). Other reagents tested for neuroprotective effects against methyl mercury toxicity such as selenium (1-10 µM), ascorbic acid (20-200 µg/ml), sodium thiosulfate (0.1-1 mM) and cysteine (50-500 µg/ml) were not effective.

These results indicate that anti-oxidants such as catalase and glutathione are effective in blocking methyl mercury neurotoxicity in the CNS.

EFFECTS OF ALUMINUM ON NEURONAL ION CHANNELS. C.H. Wu* and I. Seyama. Dept. of Pharmacology, Northwestern University Medical School, Chicago, IL 60611-3008, and Dept. of Physiology, Hiroshima University School of Medicine, Hiroshima 734, Japan.

Aluminum accumulation in the body during long-term kidney dialysis has been implicated in the pathogenesis of seizure in dialysis encephalopathy. However, the mechanism of seizure induction is unknown. Previously, we have shown that external application of aluminum caused a dose-dependent depolarization of axon membranes, prolongation of the action potential duration, and repetitive firings of action potentials (Wu, FASEB J. 7:A698, 1993). The aim of this study was to elucidate the mechanism of aluminum-induced neuronal hyperexcitability at the ion channel level. Voltage clamp experiments were conducted on giant axons of squid and crayfish. In intact axons, external application of aluminum acetylacetonate (1-2 mM) caused a decrease of the potassium current without significant effects on the sodium current. The reduction of K conductance was dose-dependent, and the effect had a slow onset. In internally perfused axons, aluminum had no effects whether it was applied externally or internally. The results suggest that neuronal hyperexcitability seen in dialysis encephalopathy is due to inhibition of potassium channels by aluminum and the inhibition is probably mediated by cytoplasmic constituents. ALTERED LEVELS OF NERVE GROWTH FACTOR AND ITS LOW-AFFINITY p75 RECEPTOR IN THE DEVELOPING BRAIN FOLLOWING BY PRENATAL EXPOSURE TO MERCURY VAPOUR. Stine Söderström and Ted Ebendal*. Dept. of Developmental Biology, Uppsala University, Box 587, S-751 23 Uppsala, Sweden.

Pregnant rats were exposed to low levels of mercury vapour. The levels of mercury (5-10 ng/g wet weight) found postnatally in the brains of their offspring are comparable with those found in human brains after average mercury exposure. The brains of the pups show an approximately 50% increase of NGF protein in the hippocampus and the cortex at postnatal day 21 with a concomitant decrease to 55% of normal levels in the medial septal area with NGF responsive cholinergic neurons. The levels of mRNA for NGF, p75 LNFR, p140 trk and ChAT were examined by *in situ* hybridization histochemistry. There were no significant changes of NGF mRNA measured at P22 in the dentate gyrus following the prenatal mercury vapour exposure. The mRNA level of the NGF high affinity receptor p140 trk was slightly increased in the diagonal band and the medial septum at P22, while the expression of mRNA for the low affinity receptor p75 was significantly reduced to approximately 30% of normal in both the medial septal area and in the diagonal band nucleus. ChAT mRNA was slightly reduced in the diagonal band and the medial septum and was significantly reduced in the striatum. It is suggested that the retrograde transport of NGF from the target to the basal forebrain was interrupted due to the accumulated mercury. Moreover, NGF produced by the fibroblast cell line 3T3 in the presence of organic mercury (MeHgCl₂) was found to be doubled when methyl mercury was added at concentrations of 0.1 µM-0.5 µM.

METALLOTHIONEIN: ISOFORM PURIFICATION IN HUMAN FRONTAL CORTEX. K. Kinningham, E.J. Kasarskis*. Graduate Center for Toxicology and Department of Neurology, Veterans' Administration Medical Center and University of Kentucky, Lexington, KY 40536.

Metallothioneins (MTs) are a family of ubiquitous cysteine-rich, 6-7 kD proteins which detoxify heavy metals, participate in zinc homeostasis, and may function as an intracellular antioxidant. Six MT isoforms have been sequenced from human liver. Immunocytochemical data suggest multiple isoforms in the central nervous system; however, only one isoform, MT-III, has been sequenced from human brain.

MTs were purified from cortex by homogenizing in 5 mM Tris-HCl, followed by ultracentrifugation. After heat precipitation, the soluble fraction was treated with chymotrypsin. Residual proteins and metals were removed by acid treatment. The MTs were then derivitized with 4-vinylpyridine and the S-pyridylethylated derivatives were separated by reverse phase HPLC.

Sequencing data suggest the presence of multiple isoforms in the cortex in addition to MT-III. Alterations in the proportions of the various isoforms might suggest an increased sensitivity to oxidative stress, metal accumulation and/or aberrant metal homeostasis. Studies in patients with Alzheimer's disease and Amyotrophic Lateral Sclerosis are ongoing to identify the status of the individual MT isoforms. METHYLMERCURY POISONING LEADS TO ENHANCED UPTAKE OF ³⁵S-L-CYSTEINE AND ³H-L-GLUCOSE IN C57BL/6J MOUSE BRAIN. David Park, Simon Yee and Ben. H. Choi*. Neuropathology, University of California, Irvine, College of Medicine, Irvine, CA 92717

Previous studies in our laboratory demonstrated that methylmercury (MeHg) poisoning in mice leads to a significant reduction in glutathione (GSH) contents in both brain and liver. We have also shown that an uptake of ³⁵S-L-cysteine was significantly enhanced in the brains of C57BL/6J mice following MeHg intoxication. To examine whether or not a reduction in GSH may underlie enhanced ³⁵S-L-cysteine uptake in the brain of MeHg-intoxicated animals, a group of C57BL/6J mice were injected with 5 mg/kg of methylmercuric chloride (MMC), and another group with 1.0 mM/kg of buthionine sulfoximine (BSO), γ-glutamyl-cysteine synthetase inhibitor, for 4 consecutive days. The control animals received physiological saline in place of MMC. Four hours after the last injection, ³⁵S-L-cysteine (1.0 µCi/g) and ³H-L-glucose (1.0 µCi/g) were injected intraperitoneally. Forty five minutes thereafter, the brain and liver were obtained following perfusion with saline. Both MMC and BSO groups showed marked GSH reduction in the brain and liver. However, brain uptake of both ³⁵S-L-cysteine and ³H-L-glucose was significantly enhanced only in MMC group and not in BSO group as compared to those in control. These results suggest that the enhanced uptake of ³⁵S-L-cysteine and ³H-L-glucose in the brain of MMC-poisoned animals may be primarily related to a dysfunction of the blood-brain barrier brought about by MeHg intoxication. (Supported in part by NIEHS grant ES 02928)

COMPARISON OF THE TOXICITY OF TRIMETHYLtin FOR FOUR INBRED STRAINS OF MICE. J.E. Ekuta, M. Tharp and J.C. Matthews. Dept. of Pharmacology, University of Mississippi, University, MS 38677.

The central nervous system toxicity of trimethyltin (TMT) is characterized by selective nerve and glial cell destruction, particularly granule cells in the hippocampal fascia dentata, associated with performance deficits in behavioral tasks used to assess learning and memory. In addition to these rather selective effects, TMT also causes systemic toxicity manifested by malaise, cessation of eating and drinking with associated weight loss, convulsions, and death in severe cases. Male mice at 4 months of age from four inbred strains, AKR/J, BALB/cByJ, C57BL/6J and DBA/2J, were compared for their relative sensitivities to the toxicity of TMT following a single intraperitoneal injection. Body weight and mortality were used as indices for assessing systemic toxicity. The average time taken for the mice from each strain to find the submerged platform (swim time) in the Morris water maze was used to assess their learning abilities. Mice of all strains, except BALB/cByJ, died within 36 hours of 3.0 mg/kg TMT administration. At lower doses, the order of sensitivities of the strains based on severity of weight loss was C57BL/6J > AKR/J > DBA/2J > BALB/cByJ. The swim time ranking for the mouse strains was BALB/cByJ > DBA/2J > AKR/J > C57BL/6J. These results demonstrate that different inbred strains of mice exhibit genetically determined differences in their levels of sensitivity to the toxicities of TMT. This finding is an important first step in our quest to understand the role of neurotoxicity in neurodegenerative disease.

673.11

COMPARISON OF INTRACRANIAL AND SYSTEMIC ADMINISTRATION OF TRIMETHYLtin ON HIPPOCAMPAL DAMAGE. V. Luevano, E. Rasmussen and E. Castañeda. Behavioral Neuroscience Laboratory, Department of Psychology, Arizona State University, Tempe, AZ 85287-1104.

It has been suggested that 1) accidental exposure to the organometallic toxin trimethyltin (TMT) produces behavioral deficits that are a result of hippocampal damage, and 2) hyperactivity observed in rats treated systemically with TMT may be useful as a model for attention deficit hyperactive disorder. In order to evaluate further these postulates, the effects of various doses of TMT infused into the hippocampus were examined. Adult male Long Evans rats received four bilateral infusions (2/hemisphere) of either vehicle (phosphate buffered saline) or TMT (total of 50, 100, 200, 500 or 1000 µg) into the hippocampus. Two more groups of rats received 8 mg/kg TMT or vehicle systemically (i.p.). At least two weeks later, animals were decapitated and the left hemispheres underwent histological preparation for Nissl staining. The hippocampi were dissected from the right hemispheres and prepared for assay of dopamine and serotonin using HPLC-EC. It was found that there was a dose-dependent ablation produced by intrahippocampal application of TMT that was not evident in rats treated systemically. In addition, only the two highest intrahippocampal doses produced serotonin depletions relative to systemically treated rats. These results have important implications for understanding the central mechanism of action by which TMT produces behavioral deficits in human and nonhuman animals. Currently, behavioral measures are being examined for changes induced by intrahippocampal infusions of TMT.

INCREASES IN GLIAL FIBRILLARY ACIDIC PROTEIN (GFAP) mRNA PRECEDE INCREASES IN HIPPOCAMPAL GFAP DURING EXPOSURE TO TRIMETHYLtin (TMT) IN DRINKING WATER. J. S. Duffy*, H. A. N. El-Fawal, H. L. Evans, Z. L. Gong, A. R. Little. NYU Medical Center, Inst. of Env. Med., Tuxedo, NY 10987.

Previous work in this lab demonstrated that GFAP levels in hippocampus of rats increased during TMT exposure in drinking water. In order to evaluate whether the increased levels were due to *de novo* synthesis or some other mechanism, we compared the time course of changes in GFAP mRNA with changes in GFAP in the hippocampus, the brain region most sensitive to TMT.

Forty male Long-Evans rats, 45 days of age, were randomly divided into two groups: a dosed group consisting of 30 animals which were exposed to 3 ppm TMT in drinking water, and a control group consisting of 10 animals given plain drinking water. Sacrifices were on days 14, 25, 26, 27, 28, and 42 (5 animals/day) for the exposed group and days 14 and 28 for the control.

Body weight and water consumption were similar in the dosed and control groups. GFAP mRNA levels in dosed animals were significantly elevated compared to pooled control on days 25, 26, 27, 28 and 42. GFAP levels were significantly greater than control on days 26, 27, 28 and 42. Since there was no difference from control in either GFAP mRNA or GFAP on day 14, we conclude that the message increases preceded protein increases by a time range of between 1 and 11 days. These data suggest *de novo* synthesis of GFAP as an important mechanism by which exposure to TMT increased concentrations of GFAP in hippocampus. These are among the earliest changes which precede clinical signs of TMT toxicity and are thus promising both for understanding the brain's early reaction to toxic metals as well as for screening for neurotoxicity. Supported by the Amer. Petroleum Inst. and Grant ES-04895.

TRIMETHYLtin-STIMULATED INOSITOL TRISPHOSPHATE ACCUMULATION IN PC12 CELLS. C.-W. Yang, M. D. Kane, R.P. Maickel* and G. E. Isom. Dept. of Pharmacol. & Toxicol., Sch. of Pharm. & Pharmacol Sci, Purdue Univ., West Lafayette, IN 47907.

Trimethyltin (TMT) is a selective CNS neurotoxicant which produces behavioral, biochemical and histological changes in rodents and man; yet, the primary mechanism(s) underlying its toxicity remain unclear. Since changes in the phosphatidylinositol-mediated second messenger system may play a role in the development of brain injury, it was of interest to determine if TMT could alter phosphatidylinositol turnover. In this study, the effect of TMT on IP₃ formation and the underlying mechanism was studied in rat pheochromocytoma (PC12) cells. As determined by fura-2 microfluorescence, there were no significant changes in cytosolic free calcium in TMT exposed PC12 cells. IP₃ generation was determined by loading cells with [³H] myo-inositol and measuring cellular concentration of [³H] IP₃ following treatment. Glutamate or (trans)-1-amino-cyclopentyl-1,3-dicarboxylate-stimulated IP₃ accumulation was blocked by the selective metabotropic glutamate receptor antagonists, (+)-α-methyl-4-carboxyphenylglycine (+)-MCPG and L-amino-3-phosphonopropionate (L-AP3), indicating PC12 cells express functional metabotropic receptors. IP₃ production was stimulated by TMT in a concentration (1-100 µM) dependent manner and increased levels were detected within 30 sec of exposure. The maximal increase was observed within 2 min following the treatment. Additionally, TMT-stimulated IP₃ production was partially inhibited by atropine and (+)-MCPG. These results indicate that TMT-induced IP₃ accumulation was mediated in part by the cholinergic and metabotropic receptors.

TRIMETHYLtin STIMULATES PROTEIN KINASE C TRANSLOCATION IN DIFFERENTIATED PC12 CELLS. M.D. Kane, G. Pavlaković, and G.E. Isom*. Dept. of Pharmacol. & Toxicol., Purdue Univ., W. Lafayette, IN.

Trimethyltin (TMT) is a potent neurotoxic agent which causes learning and memory perturbations and culminates in necrotic lesions of the limbic system in rodents and man. Differentiated rat pheochromocytoma (PC12) cells were used to determine the effect of TMT on neuronal signal transduction systems. Treatment of cells with TMT did not increase cytosolic free Ca²⁺. However, confocal imaging studies of differentiated PC12 cells showed that 10 µM TMT stimulated mobilization of protein kinase C (PKC) to cellular membranes. To characterize this response in more detail, PC12 cells were treated with TMT (0, 5, and 20 µM) or phorbol 12-myristate 13-acetate (PMA; 100 nM) and the extent of PKC translocation to the membrane was determined at 0.5, 4.0, and 24 hrs of treatment; PKC levels were determined in soluble and membrane cell fractions by western blot analysis using anti-PKC antibodies. The control profile showed greater than 95% PKC in the soluble fraction. Both 5 and 20 µM TMT treatments stimulated a partial translocation of PKC (40%-60%) to the membrane fraction at all time points. PMA treatment stimulated greater than 95% PKC translocation at 0.5 and 4 hrs as well as a complete loss of PKC staining in both fractions at 24 hrs indicating PKC down regulation. TMT stimulated translocation did not result in PKC down regulation at 24 hrs. In separate experiments 100 µM TMT inhibited Ca²⁺/phosphatidylserine stimulated PKC activity to 27% of control activity as determined by the ³²P-histone method. These results show that TMT stimulates a partial and sustained translocation of PKC in PC12 cells and inhibits kinase activity. This event appears to be independent of a rise in cytosolic free Ca²⁺.

673.14

MANGANESE NEUROTOXICITY: GLYCINE RECEPTORS IN MOUSE BRAIN. G. Cano, E. Bonilla, M.E. Alburges*. Fundacite-Zulia and Inst. Invest. Clínicas, Universidad del Zulia, Maracaibo, Venezuela. *Center for Human Toxicology, University of Utah, Salt Lake City.

Glycine (Gly) is an agonist at two neurotransmitter receptor sites, one sensitive to inhibition by Strychnine and linked to an inhibitory Gly-gated chloride channel, and the other a coagonist site on the N-Methyl-D-Aspartate (NMDA) cation channel complex. In previous reports, we have found a reduction of NMDA receptor density in some cerebral areas of manganese intoxicated mice. In the present study, we analyzed the ³H-Gly binding to its receptors by autoradiographic methods. Male albino mice were injected i.p. with manganese chloride (5 mg Mn/kg body weight/day) 5 days per week, during 8 weeks. Control animals were treated with saline. Binding procedures were carried out using 100nM ³H-Gly as a ligand, in the presence or absence of 1mM Strychnine. Non-specific binding was determined using 1 mM Gly.

Twenty brain regions were analyzed. Non-sensitive Strychnine Gly receptors were slightly reduced in all analyzed areas, but this decrease was only significant in Globus Pallidum. Although a reduction similar to that found in NMDA receptor densities was expected, our results suggest that, in manganese intoxication, variations in the expression of NMDA sites are not related with the expression of Strychnine-insensitive Gly sites, or that some Gly sites may not be associated with the NMDA complex. Sensitive Strychnine receptors are markedly absent in brain areas. In the control animals all values were near zero, but treated mice showed a significant increase of these receptors in Globus Pallidum and all areas of Caudate-Putamen. Due to the inhibitory nature of these receptors, these results could be related with motor inhibition detected in late stages of manganese intoxication.

AN *IN VITRO* MODEL TO STUDY THE RELATIONSHIP BETWEEN IRON AND PROTEIN OXIDATIVE MODIFICATION. S.W. Hulet¹, B.S. Snyder¹, S. Powers², W. Van Gelder³, J.R. Connor¹. ¹Depts. of Neuroscience & Anatomy, ²Neurosurgery, Penn State College of Medicine, Hershey PA and ³Dept. of Chemical Pathology, Erasmus University, The Netherlands

A relationship between dysfunction of iron homeostatic mechanisms and oxidative damage has been proposed. The basis of iron's ability to induce oxidative damage is through its role in the generation of free radicals. In this study we present an *in vitro* system in which oxidatively modified proteins can be induced and visualized at the cellular level. With this system we test the hypothesis that increasing iron results in oxidative damage. Two human cell lines are used: SK-N-SH (neuroblastoma) and SW-1088 (astrocytoma). The cells are grown to confluence and then exposed to a free radical generating system (1 mM H₂O₂ and 500 uM vanadyl sulfate). Oxidatively modified proteins were demonstrated immunohistochemically by modifying the 2,4 dinitrophenylhydrazine (DNPH) method for detection of functional carbonyl groups on proteins. Exposure to the free radical generating system resulted in a visible increase in cell staining of carbonyl groups in the neuroblastoma cell line, but not in the astrocytoma cell line. Exposure to 30 uM FeCl₃ for 16 hrs prior to harvesting the cells resulted in a further dramatic increase in the intensity of the immunofluorescence; but again, the increase was specific to the neuroblastoma cells. These results demonstrate that oxidatively modified proteins can be detected *in situ* and that differences exist among cell types with regards to vulnerability to oxidative damage. Future studies are directed at identifying differences in the two cell types which relate to the variation in vulnerability to oxidative damage.

EFFECT OF MESO-2,3 DIMERCAPTOSUCCINIC ACID (DMSA) ON FORCED-SWIM IMMOBILITY IN LEAD-EXPOSED, PAIR-FED AND CONTROL MICE. P. Stewart, R. Burright and P. Donovick¹, S.U.N.Y. at Binghamton.

We investigated the effect of DMSA on forced-swim immobility in lead-exposed and control Binghamton Heterogeneous (HET) Stock mice. Forty-one female and 40 male HETs were divided into three groups: 1) lead (seven weeks of 0.5% lead acetate in drinking fluid), 2) pair-fed and 3) water control. One month after the end of lead exposure, half of each group received 50mg/kg DMSA or vehicle for 5 days. Immobility was measured in a variety of situations including: two forced swim tasks and also during the extinction phase of a water maze place-learning task. Lead reduced immobility in the different testing situations relative to both pair-fed and control groups. DMSA treatment attenuated this effect in male mice. Immobility in lead-exposed female mice, however, was unchanged or even further reduced by treatment with DMSA. Blood-lead and possible dopaminergic involvement were also investigated.

CHRONIC LOW-LEVEL LEAD EXPOSURE IMPAIRS SERIAL REVERSAL LEARNING IN THE RAT. J. Hilson, S. Koger*, & B.J. Strupp. Dept. of Psychology and Division of Nutritional Sciences, Cornell University, Ithaca, NY 14853, and Dept. of Psychology, Willamette University, Salem, OR 97301.

The present study was designed to further define the nature of the cognitive impairment produced by low-level lead (Pb) exposure and to provide a model system for future studies. A serial reversal task was selected in light of suggestive evidence that functions associated with prefrontal cortex may be particularly vulnerable to developmental low-level Pb exposure. The subjects in the present study had been exposed to Pb chronically since the first day of gestation, with resulting median blood Pb (BPb) levels of <5, 22, and 39 µg/dL in the 3 treatment groups, respectively. Each animal was administered a two-choice olfactory discrimination task, followed by five reversals (intradimensional shifts) and an extradimensional shift. All testing was conducted in automated chambers, with a nose-poke as the critical response. Preliminary analysis reveals a dose-related impairment of reversal learning with increasing BPb. These results add to the growing evidence of cognitive impairment at very low BPb levels, and confirm a previous report of impaired reversal learning in nonhuman primates. These findings suggest an impairment in cognitive flexibility, consistent with prefrontal dysfunction.

Supported by grants from NIEHS (ES05950-03) and the March of Dimes Birth Defects Foundation (12-FY93-0730).

IRON-MEDIATED BIOACTIVATION OF 1-METHYL-4-PHENYL-1,2,3,6-TETRAHYDROPYRIDINE (MPTP). D.A. Di Monte*, H.M. Schipper¹, P. Chan and J.W. Langston. The Parkinson's Inst., Sunnyvale, CA 94089, and ¹Dept. of Neurology, McGill Univ., Jewish Gen. Hospital, Montreal, Quebec H3T 1E2, Canada.

A process of metabolic activation is thought to be the first step leading to the neurotoxic effects of 1-methyl-4-phenyl-1,2,3,6-tetrahydropyridine (MPTP). This conversion forms the toxic 1-methyl-4-phenylpyridinium (MPP⁺) metabolite and in the brain is mostly mediated via glial monoamine oxidase (MAO) type B. MAO B inhibition, however, does not completely block MPTP conversion to MPP⁺ since MPP⁺ is still formed in the presence of MAO inhibitors both *in vitro* and *in vivo*. The purpose of this study was to test the hypothesis that iron may act as a catalyst for the MAO-independent bioactivation of MPTP. Primary cultures of mouse astrocytes were treated with both the MAO A inhibitor clorgyline and the MAO B inhibitor deprenyl prior to the addition of MPTP. Production of MPP⁺ was reduced (to approximately 15 %), but not completely blocked by MAO inhibition. This MPP⁺ production appeared to be iron-dependent since it was decreased (30 to 50%) by iron chelators, *i.e.* deferoxamine or phenanthroline, and was enhanced (by more than 50%) in the presence of ADP-Fe³⁺. Data indicate that oxidation via MAO is the primary but not the only pathway of MPTP bioactivation and that transition metals may contribute to the generation of the toxic MPP⁺ metabolite in biological systems.

673.18

CHRONIC POST-WEANING LEAD EXPOSURE IMPAIRS PERFORMANCE IN A DELAYED SPATIAL ALTERNATION TASK. B.J. Strupp* and S. Alber. Dept. of Psychology and Division of Nutritional Sciences, Cornell University, Ithaca, NY 14853.

Despite the increasing evidence that low-level lead (Pb) exposure lowers IQ, the specificity of the impairment is unknown. The present study was designed to further elucidate the nature of the impairment, using a delayed spatial alternation task. This type of task is sensitive to dysfunction in both prefrontal cortex and hippocampus, two structures implicated in Pb-induced cognitive dysfunction. Pb acetate (0, 75, & 300 ppm) was administered chronically after weaning, yielding median BPb levels of 0, 19, & 39 µg/dL, respectively. The performance of both Pb-treated groups was significantly inferior to controls but the impairment was constant across the 4 delays, rendering a memory deficit unlikely. Analyses of the types of errors committed, using logistic regression, revealed that the 300 ppm group exhibited a significantly stronger side bias than the two other groups. The outcome of the previous trial (correct or incorrect), although a significant predictor of performance, did not differentially affect the performance of the treatment groups. The present results demonstrate that low-level Pb exposure alters cognition even after the major period of brain development, questioning the current level of concern for occupational exposure, which is 40 µg/dL.

Supported by grants from NIEHS (ES 05950-03) and the March of Dimes Birth Defects Foundation (12-FY93-0730).

GENETIC SUSCEPTIBILITY TO LEAD INDUCED BLOOD-BRAIN BARRIER DYSFUNCTION. L. Claudio*, J.G. Wemur, P.E. Good, J.G. Eisler, P.M. Woolard, H.M. Elliot. Div. of Environmental and Occupational Medicine, Mount Sinai Med. Ctr., New York, NY 10029

Lead intoxication is one of the most widespread environmentally-induced afflictions in the human population, yet many questions remain regarding the mechanisms of lead-induced neurotoxicity. We hypothesize that one mechanism of lead neurotoxicity involves disruption of the blood-brain barrier (BBB). To explore this hypothesis, we have used two mouse strains which differ in the gene coding for δ-aminolevulinic acid dehydratase (ALAD), an enzyme implicated in susceptibility to lead intoxication in humans. Although the genetic difference we find in these mouse strains appears to be quantitative rather than qualitative, we show that this model parallels observations made in humans. Our findings show that mice with a duplication of the ALAD gene (strain D) accumulate more lead in their blood than mice with a single copy of the gene (strain C) when exposed to the same acute oral doses of lead during adulthood. F1 animals (C x D) show intermediate blood lead levels.

Intracellular localization of lead was assessed by laser microprobe mass analysis (LAMMA) which indicated evidence of lead peaks in perivascular cells. Assessment of BBB function with intravascular tracers and immunocytochemistry for extravasated serum proteins and for basal lamina proteoglycans showed disruption of BBB properties and increased permeability in exposed strain D animals.

The data reported here suggest that lead may cause BBB dysfunction in susceptible animals exposed during adulthood. We hypothesize that a mechanism for these effects of lead may involve a disruption of astrocyte-endothelial cell interactions or of other cellular functions important for maintenance of the BBB.

LEAD REDUCES CALCIUM ENTRY WITHOUT PASSING THE CELL MEMBRANE OF MAMMALIAN NEURONS: FURA 2 MEASUREMENTS. D. Büsselberg*, R. Domann, L. Wunder, and H. L. Haas. Physiology II and BMFZ, Heinrich Heine-University, POB 101007, D-40001 Düsseldorf, Germany.

Lead is an ubiquitous but neurotoxic element. Recently we have demonstrated that its neurotoxicity is partly due to actions on voltage activated calcium channel currents (Büsselberg et al., 1994, *J. Neurophys.*, 71). It reduces calcium channel currents with an IC_{50} of $\sim 0.5 \mu M$. Here we prove our prediction that the rise of the intracellular calcium concentration is prevented by lead. Dorsal root ganglion neurons of rat pups were depolarized by exposure to 50 mM potassium and the rise of internal calcium was measured with Fura 2. Lead reduced this rise in a concentration dependent manner, with a threshold concentration of $0.25 \mu M$ and $\sim 5 \mu M$ lead reduced the calcium entry by $\geq 80\%$. The effect was most likely due to voltage activated channels, since applications of NMDA, an agonist of ligand gated calcium channels did not result in any rise of the internal calcium signal. The effect of lead was partly reversible. While it has been demonstrated that lead itself changes the Fura 2 signal in a typical manner (Tomsig and Suszkiw, 1990, *Am. J. Physiol.* 259), we should have detected low lead concentrations in the cell. But even with no calcium in the extracellular fluid and lead applications over several minutes at relatively high concentrations (up to $5 \mu M$) we have not seen a change in the fura signal. We conclude that lead prevents calcium entry by reducing the voltage activated calcium channel currents but does not pass through the channel itself.

CHRONIC LOW-LEVEL LEAD STIMULATION OF NEURAL CELL SIALYLATION STATE. Fleur D. Hayes & Kieran C. Breen*. Dept. of Pharmacology and Clinical Pharmacology, University of Dundee, Ninewells Hospital Medical School, Dundee DD1 9SY, Scotland, U.K.

Lead is a neurotoxic agent which acts preferentially on the developing nervous system. Although the molecular mechanisms underlying the actions of lead are poorly understood, it has been suggested that it may act to disrupt the process of neurite elaboration and consequent synapse formation. The neural cell sialylation state is precisely regulated at this stage of development and may thus prove a possible target for lead toxicity.

Hippocampally-derived neuronal cell hybrids were cultured in the presence of low-level lead (10^{-14} to $10^{-8} M$) for 72 hours, the cells harvested and the activity of the sialyltransferase enzyme determined. Sialyltransferase activity was stimulated three-fold by very low lead levels in cells derived from both embryonic day 15 and postnatal day 10, the former being more susceptible to lower lead levels. Lectin blot analysis demonstrated an increase in the sialylation state of specific glycoproteins. Although the nerve cell adhesion molecule, NCAM, is a developmentally-regulated sialoglycoprotein, there was no evidence for a lead-induced re-expression of the polysialylated form of the protein.

These results demonstrate that neural cell glycosylation is susceptible to chronic low-level lead exposure, and this may contribute to the upset in synapse formation associated with lead-induced neurotoxicity.

This study was supported by a Wellcome Toxicology Studentship to FDH.

LEAD INDUCES A BIPHASIC GLIAL FIBRILLARY ACIDIC PROTEIN (GFAP) RESPONSE IN RAT BRAIN. Z.L. Gong, A.R. Little, HAN, El-Fawal, H.L. Evans*. Institute of Environmental Medicine, New York University Medical Center, Tuxedo, NY 10987.

GFAP was used to test whether repeated exposure to lead (Pb) produces a different pattern of change in astrocytes at early stages of exposure than at later stages; and whether changes at low doses of Pb were different than at higher doses which produce overt toxicity. Male F344 rats (> 42 days old) received either lead acetate (Pb: 50 or 1000 ppm) or trimethyl lead (TMPb: 8 or 16 ppm as Pb) in their drinking water for 7 or 14 days. Although TMPb was much more toxic, as shown by decrease in body weight, both Pb and TMPb produced a similar biphasic change in brain GFAP. As predicted, decreases in GFAP occurred at lower levels of exposure (50 ppm Pb) or at early stages of exposure (day 7 of 8 ppm TMPb); increases in GFAP occurred at higher levels of exposure (1000 ppm Pb or 16 ppm TMPb) or at later stages of exposure (day 14 of 8 ppm TMPb). Dose-response was observed in hippocampus of rats exposed to TMPb and in cerebral cortex and cerebellum of rats exposed to Pb. The observed biphasic change in GFAP levels during Pb exposure suggests that astrocytes play a role in the brain's earliest response to neurotoxic metals. We propose a two-stage mechanism in the astrocytic response to Pb. In stage 1 astrocytes sequester and accumulate Pb, which may inhibit GFAP synthesis as suggested by other studies and indicated by GFAP decreases in the present study. In stage 2 astrocytic gliosis occurs in response to neuronal damage as indicated by increased GFAP. Supported by the American Petroleum Institute and Grant ES-04895.

EFFECT OF LEAD INTOXICATION ON PYRUVATE DEHYDROGENASE ACTIVITY AND THIAMINE CONTENT IN THE BRAIN OF RAT.

K.H.Ko, J.H.Cheong, H.J.Kim AND J.R.Yu. Department of Pharmacology, College of Pharmacy, Seoul National University, Seoul 151, Korea

Thiamine has been reported to reduce the toxic manifestations of lead and lead level in tissues. Conversely, lead intoxication may affect thiamine status and thiamine-related biochemical reactions and physiological responses. In this study, it was tested if lead intoxication could change thiamine content and the activity of pyruvate dehydrogenase in the brain and administration of excessive thiamine can prevent the toxic manifestation of lead.

Five groups of Wistar rats were prepared: 1) control group, 2) lead treated group, 3) lead plus thiamine treated group, 4) thiamine treated group, 5) pyridoxamine treated group. Each group of animals was divided into three subgroups based on ages: 3, 7 and 16 weeks of age subgroups. Lead was administered through drinking water containing 0.2% lead acetate and thiamine through diet containing thiamine tetrahydrofurfuryl disulfide $2mg/kg$ body weight/day. All animals except pyridoxamine treated ones were received the above treatment from birth. Animals of pyridoxamine treated group received pyridoxamine, $0.5mg/kg/day$, via intraperitoneal injection daily. Lead concentrations, thiamine contents and activities of pyruvate dehydrogenase in brain areas; telencephalon, brain stem and cerebellum were measured in each group as well as the seizure threshold to electroshock. Lead concentrations in all brain regions of lead treated group were significantly higher than those of control group, and those of lead plus thiamine treated group were significantly decreased from those of lead treated group. Thiamine contents in brain regions of lead treated group were significantly lower than those of control group, and those of lead plus thiamine treated group were recovered back to those of control group. Activities of pyruvate dehydrogenase and the seizure threshold to electroshock in lead treated group were significantly lower than those in control group, while those in lead plus thiamine treated group were higher than those in lead treated group.

The results from the present study suggest that neurotoxicity including convulsion following lead intoxication in rats may be mediated at least in part through the changes of thiamine status and thiamine related factors.

EFFECTS OF ACUTE ETHANOL (*IN VITRO*) ON SYNAPTIC PLASTICITY IN HIPPOCAMPUS OF ADULT RATS CHRONICALLY EXPOSED TO LEAD (*IN VIVO*). C.A. Grover* & G.D. Frye, Medical Pharmacology & Toxicology, HSC Texas A&M University, College Station, TX 77843-1114.

Rats chronically exposed to environmentally relevant levels of lead show altered intake and responsiveness to ethanol (Nation et al., *Behav. Neuro.* 100:1986; *Alcohol* 8: 1990). Lead accumulates in the hippocampus, a CNS area known to be affected by ethanol. Acute ethanol treatment (Sinclair & Lo, *Gen. Pharmacol.* 17: 1986), as well as acute (Altman et al., *Neurosci. Lett.* 128:1991) and chronic lead exposure (Lasley et al., *Br. Res.* 614:1993) inhibit long-term potentiation (LTP) in the hippocampus. We examined the effects of acute *in vitro* ethanol treatment on tetanus-induced LTP in the CA1 region of the hippocampus of rats chronically exposed to lead *in vivo*. Adult male Sprague Dawley rats were given 500 ppm lead acetate (Pb) or pair-fed sodium acetate (Na) in the drinking water for 60-70 days prior to *in vitro* electrophysiological experiments. Extracellular recordings of excitatory postsynaptic potentials (EPSPs) were obtained each minute during 15 min bath application of physiological saline, 5 min pre- and 1 min post-tetanus without or with added 60 mM ethanol, an additional 59 min post-tetanus, and again at 90 min post-tetanus. When the same low intensity stimulus was used during tetanus and test pulses, Pb rats showed exaggerated short-term potentiation with LTP comparable to that of Na rats (20-25% $>$ pre-tetanus at 60 & 90 min post-tetanus). Ethanol had no effect on Na slices, but significantly ($p < .05$) blocked LTP in Pb slices (0% $>$ pre-tetanus). When the stimulus intensity during tetanus was increased to produce maximum EPSPs relative to 1/2 maximum EPSPs produced by the test pulse stimulus ethanol had no inhibitory effect on LTP in hippocampal slices from lead exposed rats. The ethanol sensitivity of synaptic plasticity in the hippocampus of chronically exposed lead rats appears to depend on the intensity of the stimulation during tetanus. BICUCULLINE-INDUCED SEIZURE THRESHOLD IN POSTNATALLY LEAD-EXPOSED KITTENS. G.W. Patrick*, J.S. Stewart and A.S. Lloyd. Dept. of Anatomy, Kirksville Coll. of Osteopathic Med. Kirksville, MO 63501.

The purpose of this study was to determine if postnatally lead-treated kittens have a greater susceptibility to bicuculline-induced seizure initiation. Kittens were treated with 20 mg/kg lead acetate solution daily by esophageal intubation for seven days postnatal. Controls were maintained in the same manner but received 20 mg/kg sodium acetate solution. The kittens were allowed to age to one year during which time they were observed for any behavioral abnormalities. No spontaneous seizures were seen in any animals. The kittens were anesthetized with an IM injection of a solution containing 50 mg Ketamine, 5 mg Xylazine and 1 mg Acepromazine and the femoral vein was cannulated for delivery of drugs. Small holes were drilled into the skull and EEG pin electrodes placed over the frontal and parietal cortex. A tracheotomy was performed, a cuffed pediatric ET tube inserted and the kitten respiration with 95% $O_2/5\%$ CO_2 . The animals were paralyzed with 150 $\mu g/kg$ Pavulon. The EEG was recorded during this procedure to determine baseline neural activity. Bicuculline (1.5 mg/ml) was infused via the femoral cannula by a Harvard infusion pump at a rate of 0.20 mg/min. Seizure initiation as measured by EEG occurred with an average of 0.228 mg/kg bicuculline in experimental and 0.369 mg/kg bicuculline in control subjects. The brain of these animals will be processed by the Golgi-Cox method to determine if cerebral cortical neurons are hyperspiny. Hyperspiny neurons in lead-treated kittens have been described previously by our laboratory. It will be of great interest if seizure susceptibility is correlated with the hyperspiny condition. Predilection towards seizure activity may be implicated in neurobehavioral abnormalities seen in lead-exposed humans.

CYTOCHROME OXIDASE AND ACTIVE GLYCOGEN PHOSPHORYLASE HISTOCHEMICAL CHANGES INDUCED BY INTRASTRIATAL INJECTION OF 6-HYDROXYDOPAMINE OR QUINOLINIC ACID. D. Donaldson, M. Levivier, A. Naini*, S. Przedborski. Dept of Neurosurgery, ULB-Hôpital Erasme, Brussels, Belgium; Dept of Neurology, Columbia Univ., New York, NY.

Morphological markers are used to assess the effects of neurotoxins. However, these markers do not reflect the metabolic status of the damaged tissue. We used active glycogen phosphorylase (GP) and cytochrome oxidase (COx) histochemistry to assess metabolic changes following intrastriatal quinolinic acid (QA) or 6-hydroxydopamine (6-OHDA) injection in rats. One week after injection of the neurotoxin, the brain was processed for GP and COx histochemistry as well as for quantitative autoradiography. After 6-OHDA lesion, there were dramatic reductions in striatal binding of [³H]mazindol-labeled dopamine uptake sites while no changes were observed in the binding of [³H]SCH 23390-labeled dopamine D1 receptors or [³H]PK 1119-labeled glial cells. GP and COx staining were not affected by intrastriatal 6-OHDA, except for a weak increase in GP staining along the needle tract and at the injection site. After QA lesion, there was a significant reduction in striatal [³H]SCH 23390 binding and a significant increase in [³H]PK 1119 binding; [³H]mazindol binding was unchanged. Dramatic reduction in COx and increase in GP stainings were observed in the lesioned striatum. Similar but less dramatic changes were observed in the globus pallidus, the subthalamic nucleus and the substantia nigra pars reticulata on the side of the QA intrastriatal injection. Thus, comparison of striatal binding and histochemical findings after 6-OHDA- or QA-induced lesions indicate that both GP and COx reflect the metabolic status of striatal intrinsic elements rather than that of the dopaminergic afferents. The differential striatal changes in these metabolic markers after QA lesion confirm the preferential localization of GP in glia and COx in neurons. Also, QA-induced striatal denervation seems to modify GP and COx staining in its output nuclei.

MPP⁺ AS MARKER OF A PHARMACOLOGICAL HETEROGENEITY BETWEEN DOPAMINERGIC AND OTHER MONOAMINERGIC VESICULAR CARRIERS. S. Ruitu, M.P. Piccardi, A. Bocchetta and M. Del Zompo*. Department of Neurosciences "B.B. Brodie", University of Cagliari, I-09124 Cagliari, Italy.

Metabolism of MPTP to MPP⁺ by the MAO-B and subsequent uptake of this toxic metabolite by dopamine (DA) terminals have been established as critical steps leading to MPTP neurotoxicity. We demonstrated in the mouse DA terminals a vesicular location of a high affinity ³H-MPP⁺ binding site, which may represent a specific marker of striatal DA storage vesicles. Recently we provided evidence for an uptake of MPP⁺ in synaptic vesicles from mouse striatum. To define the characteristics of this uptake we compared the vesicular uptake of DA, norepinephrine (NE) and MPP⁺ in mouse cerebral areas. We found marked differences in the regional distribution of ³H-MPP⁺, ³H-DA and ³H-NE vesicular uptake in striatum, hippocampus and cerebellum. Kinetic analysis of Lineweaver-Burk plots revealed very similar kinetic values between ³H-DA and ³H-NE in each area tested. We detect an uptake of MPP⁺ only in the striatum. This study provides an evidence of a heterogeneity of the monoaminergic vesicular carriers.

LONG-TERM SURVIVAL OF MPTP-TREATED AGING MICE AND THE ROLE OF GLIA. X.L. Chen* and M. Gupta. Department of Anatomical Sciences and Neurobiology, University of Louisville, Louisville, KY 40292.

Previous studies from this laboratory have shown that MPTP treatment in the young adult mice significantly reduces the number of dopaminergic neurons in substantia nigra (SN). Six months after MPTP treatment, there is a significant recovery of the dopaminergic neurons. The present studies were undertaken to examine plasticity of aging dopaminergic neurons in the SN following toxic insult. Aging male C57BL/6 mice (18 month old) received MPTP injections over a two day period (total dose 60-90 mg/kg i.p.) and were examined 3 days, 2 weeks, 2 months and 6 months after MPTP treatment. Control and MPTP-treated mice were anesthetized and perfused intracardially with 4% paraformaldehyde and 1.5% sucrose in 0.1M PO₄ buffer. Frozen 40 µm thick sections were cut through the entire brain. Adjacent sections were stained immunocytochemically tyrosine hydroxylase (TH) and Glial Fibrillary Acidic Protein (GFAP). The number of TH-positive neurons was quantitated in the SN. The results show a significant reduction of TH-positive neurons in SN at 3 days after MPTP compared to the age-matched controls. In addition, there were a reduced recovery even up to 6 months after MPTP treatment compared to the young adult mice. Since glia convert MPTP into its toxic metabolite MPP⁺, and there is increased gliosis in the striatum with age as seen with GFAP immunocytochemistry, it is possible that glia play a role in the reduced ability of aging mice to regenerate following toxic insult. 6-OHDA NEUROTOXICITY IS PREVENTED BY SELEGILINE AND ITS METABOLITES

T. Ahola, A. Haapalinna*, E. Heironen*, J. Suonen and A. Heronen
Univ. of Tampere, Lab. of Gerontology, Tampere Brain Res. Ctr, FIN-33101, Tampere, Finland.
* Orion-Farmos, Department of Neurological Products, Turku, Finland

Selegiline is a selective monoamine B oxidase inhibitor possibly with an antioxidative function. It slows down the progression of Parkinson's disease by rescuing dopaminergic neurons. In animal studies selegiline has significantly increased the life span of rat and protected the dopaminergic neurons from the neurotoxic effect of MPTP, DSP-4 and 6-OHDA. In a previous study we showed that the effect of 6-OHDA on the peripheral sympathetic neurons could be prevented with selegiline. The aim of this study was to investigate which of the metabolites of selegiline (L-amphetamine (L-AMF), L-metamphetamine (L-MAMF) and desmethylselegiline (DMS)) are responsible for the neuroprotection. Two adrenergic histochemical parameters were used: formaldehyde induced fluorescence (FIF) and tyrosine hydroxylase (TH) -immunohistochemistry. In the sympathetic neurons FIF intensity decreased significantly in the saline pretreated 6-OHDA group compared to the control group. In TH staining the saline pretreated 6-OHDA group expressed less positive cells than the control group. In the L-AMF, L-MAMF, DMS or selegiline pretreated groups the number of TH-positive cells was on the same level as in the control group. The submandibular gland (SMG) expressed a dense adrenergic neuronal network, which was significantly reduced after 6-OHDA injection in the saline pretreated group. The pretreatment with L-AMF, DMS or selegiline protected the fibres against the damage, L-MAMF pretreatment showed a less protective effect. All the differences were statistically significant when compared to the saline pretreated 6-OHDA group (p<0.05). In conclusion, the pretreatment with selegiline or its main metabolites protects the peripheral adrenergic nerve cells against 6-OHDA induced neurotoxicity. These results indicate that the metabolites of selegiline, at least in part, contribute to the neuroprotection of selegiline against 6-OHDA toxicity.
